Results: 1) Activation of Cx-hemichannels in renal epithelial NRK-E52 cells by lowering the extracellular calcium concentration resulted in a rapid efflux of ATP, which was significantly prevented by hemichannel blocker heptanol and lindane. 2) Inhibition of the hemichannels with various blockers or downregulation of Cx43 using siRNA caused an unexpected activation of AMPK under calcium- or glucose-deprivation. This effect was similarly achieved by degradation of ATP with apyrase or inhibition of P2-purinergic receptor with suramin and PPADS, but abolished by the exogenous ATP. 3) ATP induced a P2-receptor-dependent activation of AKT. Inhibition of PI3K/AKT with specific inhibitors reproduced, whereas transfection of cells with myr-Akt, a constitutively active form of Akt, abrogated the activation of AMPK. 4) Exposure of NRK-E52 cells to hypotonic condition elicited an abrupt release of ATP, which was followed by membrane destabilization. Inhibition of P2-receptor with suramin or activation of AMPK with AICAR significantly prevented the destabilization.

Conclusions: Our results indicate that Cx hemichannel-mediated release of ATP suppresses AMPK activation through P2-purinergic receptor-triggered activation of AKT. Our findings thus provide novel insights into the mechanisms of Cx hemichannels and ATP in the regulation of renal cell functions.

Receptor Activator of NF-kappaB and Its Ligand Is a Novel Receptor-Ligand Complex for Survival Response during Podocyte Injury Shuangxin Liu, Wei Shi, Xinling Liang, Wenjian Wang, Zhiming Ye, Jianchao Ma, Yunfeng Xia, Lixia Xu. *Division of Nephrology, Guangdong General Hospital, Guangzhou, Guangdong, China.*

Background: Glomerulosclerosis correlates with a reduction in podocytes number that occurs through mechanisms that include apoptosis. Podocyte injury or podocyte loss in the renal glomerulus has been proposed as the crucial mechanism in the development of glomerulosclerosis. However, it is poorly understood how podocytes respond to injury. Whether ligand of receptor activator of NF-kappaB (RANKL), a TNF-related molecule that is essential for osteoclast survival and activation through interaction with its receptor activator of NF-kappaB (RANK), is a factor for injured podocytes was investigated.

Methods: In this study, RANKL and RANK was examined in human podocyte diseases and rat model of puromycin aminonucleoside nephrosis (PAN).

Results: Compared with control, RANK was increased in human podocyte diseases and rat PAN model, and double immunofluorescence staining revealed that RANK protein expression was mainly attributed to podocytes. Immunoelectron microscopy showed that RANK was localized predominantly at the top of the foot process membrane and the cytoplasm of podocytes of rat. In addition, RANK was upregulated in mouse podocytes in vitro after injury induced by puromycin aminonucleoside (PA). Knockdown of RANK expression by small interference RNA (siRNA) exacerbated podocytes apoptosis induced by PA. However, RANKL inhibited significantly the apoptosis of podocytes induced by PA.

Conclusions: These findings suggest the increase of RANK expression is a response to podocyte injury, and RANK -RANKL may be a novel receptor-ligand complex for survival response during podocyte injury.

Cyclooxygenase-2 Is Induced by Oxidative Stress in a ROS and MAPK-Dependent Signaling Pathway in Renal Medullary Interstitial Cells
Rikke Norregaard, Martin Østergaard, Line Nilsson, Inge Gram Carlsen, Jorgen Frokiaer. *Institute of Clinical Medicine, Aarhus University, Aarhus, Denmark.*

Background: Oxidative stress resulting from unilateral ureteral obstruction (UUO) may be aggravated by increased production of reactive oxygen species (ROS) from the mitochondria. Our previous studies have documented increased COX-2 expression in renal medullary interstitial cells (RMIC) in response to UUO. We here investigated the role of ROS in the induction of COX-2 in RMIC subjected to oxidative stress.

Methods: Rats were subjected to 3dUUO and treated with inhibitors of the mitochondrial metabolism (complex I inhibitor rotenone (ROT) and NADPH oxidase inhibitor diphenyleneiodonium (DPI)). Furthermore, RMIC were subjected to oxidative stress by administration of H_2O_2 and treated with ROT and DPI in order to study specific cellular pathways involved in the induction of COX-2. Using immunoblot analysis, we examined the regulation of COX-2, nitrotyrosin, ERK1/2 and p38. The fluorescent probe 2',7'-dichloroflourescein deacetate was used to measure intracellular ROS levels. Apoptosis was analyzed using the ratio of Bax/Bcl-2.

Results: The oxidative stress marker nitrotyrosin was induced after UUO in renal medulla. COX-2 was increased in response to UUO in renal medulla and this increase was attenuated by ROT and DPI treatment. Oxidative stress treatment (75 μM H_2O_2) for 6 h induced a 5-fold increase in COX-2 expression and comparable increases in prostaglandin E_2 release in RMIC, both of which were reduced by ROT and DPI. ROS levels were increased following exposure of RMIC to H_2O_2 and this was significantly reduced by DPI administration, but not by ROT. Cell viability and apoptosis were not affected by administration of H_2O_2 or the mitochondrial inhibitors. The increases in phosphorylation of ERK1/2 and p38 were detected 6 h following H_2O_2 treatment and were both prevented by DPI. Blocking the ERK/p38 signaling pathways by pharmacological inhibitors attenuated the H_2O_2 induced COX-2 expression.

Conclusions: Taken together, these results demonstrated that oxidative stress induces COX-2 and this induction might be mediated through NADPH oxidase-derived ROS-dependent ERK/p38 pathways.

Cold Shock Protein YB-1 Triggers Akt and Erk Kinase Signalling via Notch-3 Receptors in Monocytic Cells
Sabine Brandt,[1] Florian Gunnar Scurt,[1] Cheng Zhu,[1] Ute Raffetseder,[2] Sonja Djudjaj,[2] Marion Moeckel,[1] Peter R. Mertens.[1] *[1]Department of Nephrology, Hypertension, Diabetes and Endocrinology, University Hospital Magdeburg, Magdeburg, Germany; [2]Medical Clinic II, University Hospital RWTH-Aachen, Aachen, Germany.*

Background: Y-box (YB) binding protein-1 is the prototypic member of the cold shock protein family with pleiotropic functions relating to transcription and translation, mediating cell proliferation, matrix synthesis and chemotaxis in kidney diseases. Recent findings indicate YB-1 secretion *via* a non-classical pathway and profound extracellular effects mediated by Notch-3 receptors. Here, we determined intracellular signalling following extracellular stimulation with recombinant YB-1 protein (rec.YB-1), abbreviated YB-1 proteins and peptides corresponding to YB-1 protein domains in monocytic (THP-1), mesangial as well as tubular cells.

Methods: Cell lines of different origin were stimulated with purified rec.YB-1 protein. Activation of the PI3K/Akt- and MAPK-signalling pathways was assessed by Western blot analysis.

Results: Extracellular rec.YB-1 (1 μg/ml) resulted in a time- and dose-dependent phosphorylation and activation of Akt as well as MAP (Erk) kinases. Phosphorylation of Akt-S473 was present from 4 to 8h following incubation, phosphorylation at Akt-T308 was not observed at any time point. Erk1/2 activation at T202/Y204 was present from 7' to 8h following protein addition. YB-1 deletion constructs revealed that Akt-S473 phosphorylation is dependent on the ancestral cold shock and adjacent N-terminal domains. Similar results were obtained with synthetic peptides corresponding to YB-1 protein subdomains. Extracellular blockade of Notch-3 receptor signalling in THP-1 cells completely abrogated YB-1 -dependent Akt and Erk1/2 phosphorylation, highlighting the importance of the YB-1:Notch-3 receptor interaction.

Conclusions: Akt as well as MAP (Erk) kinases are involved in apoptosis, cell proliferation, motility and cell growth. Notch-3 receptor signalling activates these two pathways. Thus extracellular YB-1 initiates promitogenic effects in THP-1 cells by Akt and MAP kinase pathways.

FR-PO106

ERK5 Activation in Human Renal Cells under Diabetic Stimuli
Irbaz Isaac Badshah,[1] Deborah L. Baines,[2] Mark Edward Dockrell.[1] *[1]SWT Institute for Renal Research, London, United Kingdom; [2]St George's, University of London, United Kingdom.*

Background: Diabetic nephropathy is the primary factor causing end-stage renal disease worldwide and is particularly characterised by podocytopaenia and tubulointerstital fibrosis. ERK5 is an atypical MAP kinase distinct from its siblings through the possession of a unique C-terminus. Current literature has implicated ERK5 in mediating proliferation and survival pathways in cancer; its effects in podocytes and proximal tubule epithelial cells (PTECs) remain largely unknown. The aim of this study was to explore the expression and role of ERK5 in human podocytes and PTECs.

Methods: Conditionally immortalised human podocytes, terminally differentiated after 14 days at 37°C, and the HKC-8 human PTEC cell line were subjected to growth factor stimulation (10 ng/ml EGF, 2.5 ng/ml TGF-β1), diabetic stimuli (15 mM D-glucose v 5 mM D- + 10 mM L-glucose, 30 mM D- v 5 mM D- + 25 mM L-glucose; 50 μg/ml AGE-BSA v 50 μg/ml control BSA) and inhibition of ERK5 activation with 10 μM of the inhibitor BIX02188 directed to the upstream MEK5. ERK5 protein expression and phosphorylation(p-ERK5), E-cadherin (a marker of PTEC phenotype) were measured by Western blotting.

Results: Podocytes and HKC-8 cells expressed ERK5 and it was phosphorylated in response to EGF and TGF-β1; inhibition of MEK5 attenuated ERK5 phosphorylation. EGF induced distinct morphological changes in podocytes and additional MEK5 inhibition resulted in increased cell death along with de-differentiation as evinced by a loss of synaptopodin. Inhibition of MEK5 in HKC-8 cells rescued E-cadherin expression, following TGF-β1 treatment thereby preventing loss of PTEC phenotype, in contrast to the apparent effect of knock down of total Erk5 expression by siRNA. AGE-BSA treatment of podocytes decreased p-ERK5 whereas glucose appeared to have a biphasic effect; 15mM D-glucose causedan acute reduction whilst 30 mM D-glucose increased p-ERK5.

Conclusions: This work demonstrates that the atypical MAP kinase ERK5 is involved in signalling cascades activated by a number of pathological stimuli involved in renal disease, however its role appears to be complex regulating diverse outcomes.

The Role and Mechanism of T-Brachyury in TGF-β1 Induced EMT of Renal Tubular Epithelial Cells
Huang Chen. *Nephrology, Xijing Hospital, Xi'an, China.*

Background: Epithelial-to-mesenchymal transition (EMT) which is recognized as losing of epithelial characteristics and associated with a mesenchymal phenoptye plays important roles in the progression of fibrosis in the kidney.Recent study have revealed that T-brachyury, an evolutionarily conserved transcription factor, promoted EMT involved in cancer progression and metastasis by repressed E-cadherin transcription, leading to loss of E-cadherin-mediated cell–cell adhesion, activation of EMT regulator which might play important roles in mediating the invasion, migration, and metastatic activity of different carcinoma cell, possibly resulting in renal fibrosis.

Methods: To understand the molecular mechanism in this process, and to identify the critical genes in the initial phase of the TGF-β1–mediated EMT, a high-throughput gene expression microarray analysis was used. To investigate the role and mechanism of T-brachyury in TGF-β1 induced EMT of renal tubular epithelial cells many other biochemical analyses were used.T-brachyury was found to be induced prominently in TGF-β1-treated human proximal tubular epithelial (HK2) cells.

Results: Brachyury overexpression in HK2 cells induced changes characteristic of EMT. Brachyury induction also repressed E-cadherin transcription; an effect partially mediated by Slug, whereas knockdown Brachyury and Slugby short interfering RNA (siRNA) effectively reduced TGF–β1–mediated EMT and partially restored E–cadherin. E-cadherin promoter contains Brachyury -binding sites and increased transcription was showed in Brachyury-overexpressing cells which transfected of reporter constructs using the promoter. Chromatin immunoprecipitation assays identified the presence function of Brachyury -binding sitewithin the E-cadherin gene promoter. In rat model of obstructive nephropathy and IgA nephropathy biopsies, expression of T-brachyury was induced, suggesting that it may play roles in EMT and renal fibrosis *in vivo*.

Conclusions: This studies confirm that T-brachyury play important roles in regulating TGF-β1–mediated EMT and could be an attractive target for progression of renal disease therapies.

Genetic Inactivation and Pharmacological Inhibition of Glycogen-Synthase Kinase 3 beta (GSK-3β) in Madin-Darby Canine Kidney Cells Increase Epithelial Resistance
Francois Jouret, Jingshing Wu, Vanathy Rajendran, Michael J. Caplan. *Cellular and Molecular Physiology, Yale Medical School, New Haven, CT.*

Background: Glycogen-synthase kinase 3-beta (GSK-3β) is a ubiquitous serine-threonine kinase involved in distinct biological processes. Pharmacological inhibition of GSK-3β by lithium or SB216763 compound leads to the assembly of tight junction (TJ) components in epithelial cells, even in the absence of extracellular Ca^{2+} (Ca^{2+}_e).

Methods: First, we stably knocked-down (KD) the expression of GSK-3β in Madin-Darby Canine Kidney (MDCK) epithelial cells using shRNA. Next, we quantified the expression of TJ components in GSK-3β KD versus control cells at steady-state by real-time RT-PCR and immunoblotting. Finally, we investigated the effects of GSK-3β inactivation or pharmacological inhibition on TJ formation and disruption.

Results: In GSK-3β KD cells, the expression of claudin 1, claudin 4, occludin and ZO-1 is significantly increased, with no change in claudin 2 and β-catenin abundance. Steady-state transepithelial electrical resistance (TEER) is significantly higher in GSK-3β KD (763.4 ± 54.5 ohm.cm^2) and SB216763-treated MDCK cells (801.4 ± 32.4 ohm.cm^2) than in untreated cells (332.6 ± 38.6 ohm.cm^2). Following Ca^{2+} switch from low (5μM) to normal (1.8mM) Ca^{2+}_e, the relocation of ZO-1 to cell-cell contacts is significantly faster in GSK-3β KD versus control cells. Conversely, Ca^{2+}_e deprivation in control cells for 2 hours induces an internalization of the GSK-3β substrate, β-catenin, with a loss of measurable TEER. In similar conditions, β-catenin mostly stays at the basolateral membrane in GSK-3β KD cells and in MDCK cells pre-treated with SB216763 [20μM] for 60 minutes, and TEER remains measurable (197.1 ± 23.9 ohm.cm^2).

Conclusions: These results support that GSK-3β activity modulates TJ assembly and disruption in epithelial cells.

The Ubiquitin-Like Protein FAT10 Inhibits Autophagy in Renal Tubular Epithelial Cells Michael J. Ross, Bin Wang, Jeremy S. Leventhal, Pengfei Gong. *Division of Nephrology, Mt Sinai School of Medicine, New York, NY.*

Background: Autophagy is the process by which superfluous or damaged macromolecules or organelles are degraded by the lysosome. Pharmacological and genetic evidence indicate that autophagy plays pleiotropic functions in cellular homeostasis, development, survival and differentiation. FAT10, as a small ubiquitin-like modifier, plays an important role in various cellular processes, including mitosis, immune response, and apoptosis.

Methods: In these studies, we investigated the role of FAT10 in autophagy. We used a lentiviral short hairpin RNA vector directed against FAT10 or control shRNA vector to transduce cells. Tubular cells were grown from kidneys of FAT10$^{-/-}$ and wild type mice according to standard techniques.

Results: We found that over-expression of FAT10 suppressed autophagy in human proximal tubular (HK2) cells as detected by decreased LC3B II/I protein ratio. Knockdown of FAT10 expression in HK2 and 293T cells using FAT10 shRNA increased the LC3B II/I ratio. Moreover, the LC3B II/I ratio was increased in primary renal tubular epithelial cells (RTEC) isolated from FAT10$^{-/-}$ mice was also increased as compared to RTEC from wild type mice. We also detected a marked increased in the abundance of intracellular vesicles staining for acridine orange in FAT10$^{-/-}$ RTECs and in 293T cells expressing FAT10 shRNA and a significant increase in the abundance of fluorescent punctae of 293T cells expressing LC3-mCherry-GFP after transduction with FAT10 shRNA. Finally, increased pAMPK/AMPK was also observed in RTECs from the FAT10 knockout mice and 293T cells expressing FAT10 shRNA.

Conclusions: Together, these data suggest that the ubiquitin-like protein FAT10 inhibits RTEC autophagy and this effect may be mediated via AMPK activation.

Peroxidasin Forms Sulfilimine Bonds in Basement Membranes Using Hypohalous Acids Gautam B. Bhave, Roberto M. Vanacore, Vadim Pedchenko, Billy G. Hudson. *Nephrology and Hypertension, Vanderbilt University Medical Center, Nashville, TN.*

Background: Collagen IV is the predominant protein network of basement membranes, a specialized extracellular matrix, which underlie epithelia and endothelia. These networks assemble through oligomerization and covalent cross-linking to endow mechanical strength and shape cell behavior through interactions with cell surface receptors. A novel sulfilimine (S=N) bond between a methionine sulfur and hydroxylysine nitrogen reinforces the collagen IV network.

Methods: We used a combination of biochemistry, mass spectrometry, and genetics to delineate the mechanism of collagen IV sulfilimine cross-link formation and its role in basement membrane and tissue integrity.

Results: We demonstrate that peroxidasin, an enzyme found in basement membranes, catalyzes formation of the sulfilimine bond. Drosophila peroxidasin mutants exhibit disorganized collagen IV networks and torn visceral muscle basement membranes pointing to a critical role for the enzyme in tissue biogenesis. Peroxidasin generates hypohalous acids as reaction intermediates suggesting a paradoxically anabolic role for these usually destructive oxidants.

Conclusions: This work highlights sulfilimine bond formation as the first known physiologic function for peroxidasin and a role for hypohalous oxidants in tissue biogenesis. Since the sulfilimine cross-link determines autoantibody reactivity in Goodpasture's disease and promotes stability of collagen IV networks, our work implicates a role for peroxidasin in the pathogenesis Goodpasture's disease, glomerular matrix expansion as seen in diabetic nephropathy, and vascular matrix remodeling and atherosclerosis.

Loss of E-Cadherin in Renal Proximal Tubular Cells Promotes Epithelial-Mesenchymal Transition and Kidney Fibrosis through α3 Integrin in Murine Model of Unilateral Ureteral Obstruction Guoping Zheng,[1] So Ra Lee,[1] Jianlin Zhang,[1,2] Hong Zhao,[1,2] Tim Tzu-ting Hsu,[1] Thian Kui Tan,[1] Ye Zhao,[1] David A.F. Loebel,[3] Isabelle Rubera,[4] Michel Tauc,[4] Yiping Wang,[1] Ya Wang,[1] Qi Cao,[1] Changqi Wang,[1] Vincent W.S. Lee,[1] Patrick P.l. Tam,[3] David C. Harris.[1] *[1]CTRR, WMI, University of Sydney, Sydney, New South Wales, Australia; [2]Dept. of Biochem & Mol Biol, Shanxi Medical University, Taiyuan, Shanxi, China; [3]CMRI, University of Sydney, Sydney, New South Wales, Australia; [4]UMR 6097, University of Nice-Sophia, Nice, France.*

Background: Our previous studies in murine models of kidney fibrosis showed that disruption of E-cadherin by MMPs caused EMT whereby E-cadherin passes on extracellular signals to the nucleus through β-catenin and slug. This study examined the role of E-cadherin in renal tubular EMT using a novel conditional knockout of E-cadherin in mouse renal proximal tubular cells.

Methods: Conditional knockout of E-cadherin in renal tubular cells was generated by crossing cdh1flox/flox mice sequentially with CMV Cre, Sglt2Cre mice and then backcrossing to cdh1flox/flox mice. Primary culture of proximal tubular cells from knockout mice was treated with TGF-β1 (3ng/ml) to examine the role of E-cadherin in EMT *in vitro*. Kidney fibrosis was assessed by unilateral ureteral obstruction (UUO) in the E-cadherin -/- and littermate control mice.

Results: Depletion of E-cadherin in proximal tubular cells resulted in a transcriptional upregulation of α3β1 integrin. Forced expression of E-cadherin in E-cadherin-depleted tubular epithelial cells reversed the upregulation of α3β1 integrin. TGF-β1-induced EMT was significantly up-regulated in proximal tubular cells from E-cadherin -/- mice compared to littermate controls. siRNA silencing of α3, but not β1 integrin reduced the upregulation of EMT in proximal tubular E-cadherin -/- cells. Kidney fibrosis after UUO was worse in proximal tubule E-cadherin -/- mice compared to control mice, as demonstrated by Gomori Trichrome and Sirius red staining, and by immunohistological staining of α-SMA.

Conclusions: Conditional depletion of E-cadherin in proximal tubule aggravated kidney fibrosis in UUO through α3 integrin-dependent upregulation of EMT.

Targeting Alternative Splicing of Fibronectin Rescues TGFβ1-Induced Phenotypic Change in Human Tubule Cells Felicia Heidebrecht,[1] Mysore Keshavmurthy Phanish,[1] Susan M. Freier,[2] Mark Edward Dockrell.[1] *[1]SWT Institute for Renal Research, London, United Kingdom; [2]Isis Pharmaceuticals, Carlsbad, CA.*

Background: Fibrosis is characterised by changes in the quantity and quality of extracellular matrix (ECM). Renal fibrosis is associated with a change in the profile of collagen and de novo expression of alternative splice variant of fibronectin EDA+ (FN EDA+). Evidence suggests that these changes may play a critical role in the loss of cell phenotype and function associated with progressive fibrogenesis. This study investigates the role of FN EDA+ in the loss of phenotype of human proximal tubule cells (PTEC) initiated by TGFβ1 and identifies a potential therapeutic intervention to limit progressive fibrosis.

Methods: 20 RNase-H independent antisense oligonucleotides (ASO) targeting the proximal and distal region of the EDA exon were screened in transformed and primary PTEC to identify a sequence that would selectively inhibit splicing of the EDA exon without altering total fibronectin expression or the alternative splicing of the EDB exon. Pro-fibrotic changes were induced by treatment with 2.5 ng/mlTGFβ1; a concentration causing wide ranging alternations of cell phenotype. Subsequently, cells were treated with active and negative control ASO.

Results: TGFβ1 caused pronounced changes in cell phenotype: cadherin expression was altered, α Smooth Muscle Actin (αSMA) and connexin 43 (Cx 43) were induced, less cortical f-actin localisation was observed and MMP2 & 9 secretion was increased. Prevention of EDA inclusion by ASO treatment resulted in significant reduction in αSMA, a reduction in secretion of MMP2 & 9 and an almost complete inhibition of Cx43. There was a moderate increase in f-actin cortical localization and interestingly at this time point the ASO had no discernible effect on TGFβ1-mediated cadherin loss.

Conclusions: These results demonstrate that selective targeting of FN EDA+ with ASO can limit the pro-fibrotic effects of TGFβ1 on PTEC. Importantly, this effect was observed when the ASO was delivered after the initial TGFβ1 challenge. The target sequence on the pre-mRNA would appear to be very specific as striking differences were observed between ASO with a >70% overlap.

FR-PO113

Mechanisms of Extracellular Matrix Modulation in Interstitial Fibrosis: Role for Collagen Crosslinking? Miriam Boersema,[1] Anne-Roos Sophie Frenay,[2] Harry Van Goor,[2] Ruud A. Bank.[1] *[1]Medical Biology, UMCG, Groningen, Netherlands; [2]Pathology, UMCG, Groningen, Netherlands.*

Background: The net accumulation of extracellular matrix (ECM) in renal fibrosis depends, in part, on the delicate balance between the production and degradation of collagens. Crosslinking of collagen fibers by specific enzymes determines the stiffness and degradability of the ECM. We investigated genes involved in production, degradation and cross-linking of extracellular matrix using specific arrays. Furthermore, using *in situ* digestion of collagens with MMP-1 and-2, we measured the degradability of ECM in human and experimental interstitial fibrosis.

Methods: Human interstitial fibrotic tissue (IF/TA) was processed for mRNA using a specific array containing mRNA primers for proteins involved in ECM degradation, production and cross-linking. Cross-linking of collagen may inhibit the capacity of MMPs to degrade collagen. Human (IF/TA) and experimental (AngII infusion) interstitial fibrotic tissue sections were subjected to *in situ* digestion with active MMP-1 and -2 to evaluate the degradability of the ECM, followed by a collagen I immunostaining.

Results: Gene expression of collagen I, III, IV and V was increased (2-10 fold) in fibrotic tissue compared to control kidney tissue. Several members of the lysyl oxidase and lysyl hydroxylase family (collagen crosslink enzymes) were upregulated (2-14 fold), as well as prolyl hydroxylases and other collagen-modifying enzymes. In human IF/TA, MMP-1 digested the smaller fragments of interstitial collagen I, while larger fibrils were unaffected. MMP-2 did not digest collagen I in human IF/TA. In experimental interstitial fibrosis, MMP-1 was able to digest all interstitial collagen I. MMP-2 digested about 80% of all interstitial collagen I.

Conclusions: Gene expression of specific collagen crosslinking enzymes is increased in human IF/TA. Using an *in situ* collagen digestion assay we demonstrated that MMP-1 and -2 did not digest all interstitial collagen I in human IF/TA and experimental interstitial fibrosis. Cross-linking of collagens may inhibit the capacity of MMPs to degrade interstitial collagens and thereby enhance the progression of interstitial fibrosis.

Counting Glomeruli in Mouse Kidneys Using MRI Scott Charles Beeman,[1] John F. Bertram,[2] Min Zhang,[1] Teresa Wu,[1] Jennifer Richardson Charlton,[3] Kevin Bennett.[1] *[1]Arizona State University; [2]Monash University; [3]University of Virginia.*

Background: Glomerular number plays an important role in a wide range of diseases[1-2], though the techniques currently employed to count glomeruli are estimates based on histological sections. A method for counting every glomerulus would be important to research and clinical diagnostics. It has been shown that all glomeruli in the rat kidney can be counted ex vivo using cationized ferritin nanoparticles (CF) and magnetic resonance imaging (MRI)[3-5]. With the huge library of transgenic mouse models employed in kidney research, such a technique, adapted to murine kidneys, would prove vital to basic kidney research. Here, we demonstrate the first steps towards visualizing and counting all glomeruli in the mouse kidney.

Methods: Three male C57BL/6 mice were given a 5.75 mg/100g dose of CF and one remained naive. Mice were perfused with PBS and formalin. Kidneys were imaged ex vivo at 19T using T_2^*-weighted 3D MRI. Glomeruli were counted in the MRI volumes using custom software.

Results: MRI imaging of kidneys resected from mice injected with CF revealed punctate spots of signal darkening (Fig. 1A). Each dark spot represents a single glomerulus. MRI-based counting (Fig. 1B) of kidneys from mice injected with CF yielded 12,084 ± 1,896 glomeruli per kidney (n=3). Histological validation is pending, though our numbers are consistent with those reported in the literature[6].

Conclusions: This result, along with previous in vivo detection of glomeruli and counts made in the rat, suggest the long-term possibility of counting glomeruli in the clinic.

FR-PO115

Dual-Linked Role of Integrin αV Mediates TGF-β Activation and Fibronectin Fibrillogenesis to Regulate Laminin-332-Mediated Repair in MDCK Epithelial Cells Jose V. Moyano,[1] Joshua O. Hendin,[1] Patricia Gonzalez-Greciano,[1] Terhi Piritta Teräväinen,[2] Satu Marja Myllymäki,[2] Aki Manninen,[2] Karl S. Matlin.[1] *[1]University of Chicago, Chicago, IL; [2]University of Oulu, Oulu, Finland.*

Background: TGF-β is secreted by cells in an inactive form (*latent TGF*-β) through its association with Latency-Associated Protein (LAP). Activation is believed to involve binding of LAP by αV integrins, but this has not been clearly demonstrated in kidney epithelial cells. TGF-β has been linked by us and others to epithelial repair, but it also plays a role in fibrosis. Thus, understanding the TGF-β activation machinery in renal epithelial cells is of great importance in epithelial repair after injury.

Methods: Integrin αV expression was suppressed by shRNA. Localization of proteins was assessed by confocal microscopy. Interaction between Integrin αV and LAP was established by cell adhesion assays. TGF-β activation was measured by ELISA, and LM-332 synthesis was assessed by metabolic labeling. Smad signaling was determined by Western blot.

Results: MDCK cells with integrin αV knocked down (αVKD) show a reduction in TGF-β activation, Smad2-mediated laminin-332 production and spreading. Addition of active TGF-β restored normal levels of LM-332 and cell spreading. Control, but not αVKD cells, adhered to LAP, suggesting that LAP is a ligand for integrin αV. In control cells, integrin αVβ3 focally colocalized with LAP in the lamellipodium, but were segregated towards the cell body, suggesting its dissociation. Interestingly, TGF-β accumulated in discrete foci towards the dorsal surface in control cells. However, αVKD resulted in almost perfect colocalization of TGF-β with LAP. This suggests that, in the absence of integrin αV, TGF-β cannot dissociate from LAP, possibly due to lack of mechanical tension. Such mechanical tension might be provided by fibronectin (FN). In fact, αVKD cells were unable to assemble FN. FN assembly is dependent on ROCK, and blocking its activity resulted in reduced TGF-β activation.

Conclusions: Mechanical tension provided by integrin αV-mediated FN assembly during cell migration allows integrin αV to also bind to LAP and activate TGF-β to induce LM-332 expression and epithelial repair.

FR-PO116

Interleukin-1-beta Induces Hyaluronan/CD44-Dependent Cell Protrusions that Facilitate Monocyte-Fibroblast Binding Soma Meran, John Martin, Robert Steadman, Aled O. Phillips. *Institute of Nephrology, Cardiff University, Cardiff, United Kingdom.*

Background: Persistent inflammation is a determinant of progressive tissue fibrosis however the reasons for this remain unclear. In the kidney, fibrosis is the hallmark of progressive disease and is preceded by macrophage infiltration and characterised by matrix deposition and fibroblast expansion. There is evidence indicating the role of the cytokine IL-1b in profibrotic responses; and IL-1b staining has been strongly associated with severity of interstitial lesions, proteinuria and renal impairment. In our previous studies we have shown that fibroblasts stimulated with IL-1b increased their generation of the matrix polysaccharide hyaluronan (HA) and greatly increased their expression of the HA Synthase enzyme (HAS2). Objectives: The aim of this study was to determine the role of IL-1b induced changes in HA and HAS2 in the regulation of fibroblast function.

Methods: HA generation was assessed by radiolabelling and chromatography. HAS2 CD44 ICAM1 TSG6 & CD45 expression was assessed by RT-QPCR. HA, CD44 & ICAM1 cell localisation was identified by immunocytochemistry. siRNA technology was used to inhibit HAS2, CD44 & TSG6 expression.

Results: Stimulation of fibroblasts with IL-1b resulted in relocalisation of HA associated with the cell to the outer cell membrane, where it protruded from the cell in a linear manner. Furthermore IL-1b resulted in the formation of HAS2 and CD44-dependent cell membrane protrusions from which the cell-associated HA projected. CD44 was concentrated within these membrane protrusions where it colocalised with the intracellular adhesion molecule, ICAM1, and enhanced IL-1b-dependent fibroblast-monocyte binding. Whilst previous data has shown the importance of the HA binding protein TSG6 in maintaining the TGF-b1-dependent HA coat; TSG6 was not essential for the formation of the IL-1b-dependent HA protrusions thus identifying it as the key difference between IL-1b and TGF-b1 dependent HA matrices.

Conclusions: IL-1b dependent HA and CD44 play a role in fibroblast immune activation leading to sequestration of monocytes within inflamed tissue and providing a possible mechanism for perpetual inflammation and progressive fibrosis.

FR-PO117

Unilateral Nephrectomy in PEXTKO Mice Leads to the Development of Podocyte Hypertrophy Kevin J. McCarthy,[1] Yingjian Wang,[2] Kaitlin Marie McCarthy,[1] Deborah J. McCarthy.[1] *[1]Pathology, LSU Health Sciences Center, Shreveport, LA; [2]Surgery, LSU Health Sciences Center, Shreveport, LA.*

Background: PEXTKO(podocyte-specific EXT1 knockout)mouse podocytes (podos) cannot assemble heparan sulfate (HS) chains on HS core proteins. Previous reports from our laboratory showed that HS- podos develop significant foot process effacement after birth but PEXTKO mice do not develop significant proteinuria. *In vitro* studies of HS- podos show abnormal cytoskeletal organization, cell-matrix adhesion, and cell migration, due to loss of HS associated with cell surface proteoglycans. Because of the latter *in vitro* functional abnormalities, the *in vivo* performance of PEXTKO podos subjected to a physiologic stressor (hyperfiltration) was evaluated.

Methods: Six month old $Ext1^{+/+}$(control) or PEXTKO mice were either unilaterally nephrectomized (UNX) or subjected to sham surgery(SS). After three months, animals from all groups were sacrificed and the tissues processed for light (LM)and electron microscopy (EM). LM tissue sections were analyzed using morphometric methods to measure differences in glomerular hypertrophy and mesangial expansion. EM was used to to evaluate alterations in the nature of podos-GBM interactions.

Results: Morphometry of PAS stained sections showed that both PEXTKO groups had significant increase in glomerular area compared to EXT1 animals (SS/UNX). UNX-PEXTKO glomeruli had a significant increase in glomerular area compared to SS-PEXTKO glomeruli($1.26x10^5 pixels^2$ vs $1.03\ x10^5 pixels^2$, $p<0.0002$). EM studies showed that the podos morphology from UNX-PEXTKO glomeruli differed significantly from those in the other groups by: 1. Primary attachment by direct processes from the cell body to the GBM rather than the usual 1°→2°→pedicel process attachment seen in control animals; 2. the increase in binucleated podos in tissue sections; 3 the extreme crowding of intercapillary spaces with podos cell bodies/processes.

Conclusions: The added stressor (UNX) on HS- podos results in additive glomerular hypertrophy with concomitant change in podos attachment/organization and podo hypertrophy, a potential compensatory response not seen in the EXT1 SS/UNX or PEXTKO SS.

A New Approach to Targeting the RAS System: Identification of Regulators of AngII-Induced TGFalpha Cleavage, a Novel Risk Factor for CKD Progression Andreas Herrlich. *Renal Division, Brigham and Women's Hospital, Boston, MA.*

Background: Despite dual RAS blockade, residual AngII-AT1R-dependent signals accelerate progression of chronic kidney disease (CKD) and 15-20% of treated patients still reach dialysis. AngII-induced metalloprotease cleavage of TGFalpha in the kdiney is critical in the development of CKD lesions in mice and likely humans. Targeting this pathway downstream of the AT1R would circumvent problems of current therapies. Metalloprotease inhibitors have failed clinically due to their broad-spectrum inhibition of substrate cleavage. Our study identifies novel regulators of AngII-induced TGFalpha release that regulate TGFalpha cleavage independent of affecting protease activity itself, a significant advantage over metalloprotease inhibitors.

Methods: To identify novel genes that regulate ectodomain shedding of substrates downstream of PKC activation, we carried out a lentiviral shRNA gene knockdown screen targeting most human kinases and phosphatases, focusing our attention on phorbol ester-induced cleavage of TGFalpha, a classical ADAM17 substrate. Phorbol ester mimics DAG in the activation of PKC. Cleavage of TGFalpha was measured by FACS (fluorescent-activated cell sorting) (Dang et al., 2011; Herrlich et al., 2008) and western blots. Identified regulators were retested in HEK293T cells expressing the AT1R.

Results: We identify here, for the first time, pathway components that distinguish substrates of ADAM17. Downregulation of protein-kinase-C (PKC) alpha or of the PKC-regulated PP1-inhibitor PPP1R14D block AngII-induced cleavage of TGFalpha, HB-EGF and Amphiregulin, but not of Neuregulin, TNFR-1 or the ADAM10 substrate c-Met. This regulation is conferred by inhibition of PP1alpha. NRG cleavage, in contrast to TGFalpha, is regulated by a PKCdelta-dependent C-terminal serine phosphorylation. Using Proteolytic Activity Matrix Analysis, we show that none of the cleavage regulators affects ADAM17 protease activity.

Conclusions: Our study identifies novel regulators of AngII-induced TGFalpha cleavage and shows that regulation of enzyme activity is clearly separated from substrate selection, an important mechanism that offers itself for application in disease.

Healthy Lifestyle and Risk of Kidney Disease Progression, Cardiovascular Events and Death in the Chronic Renal Insufficiency Cohort (CRIC) Study Ana C. Ricardo,[1,2] Cheryl A. Anderson,[2] Xiaoming Zhang,[2] Michael J. Fischer,[1,2] Martha L. Daviglus,[1] Laura M. Dember,[2] Jeffrey C. Fink,[2] Anne Frydrych,[1,2] Nancy Gail Jensvold,[2] Eva Lustigova,[2] Lisa C. Nessel,[2] Anna C. Porter,[1,2] Mahboob Rahman,[2] Julie A. Wright,[2] Wei (Peter) Yang,[2] James P. Lash.[1,2] *[1]U. Illinois; [2]CRIC Study Group.*

Background: A healthy lifestyle that includes not smoking, regular exercise and low dietary sodium is associated with favorable health outcomes in the general population. The effect of such lifestyle on clinical outcomes in individuals with chronic kidney disease (CKD) is understudied.

Methods: A healthy lifestyle score (HLS) was calculated at baseline for 3,670 CRIC enrollees by allocating 1 point for each of the following 3 factors: not currently smoking; moderate exercise (≥150 min/wk), vigorous (≥75 min/wk) or both (≥150 min/wk); and urinary sodium <100mEq/day. HLS range was 0-3, with 3 indicating the healthiest lifestyle. Cox proportional hazards models were used to evaluate the association of HLS with the following outcomes ascertained over 4 yrs: CKD progression [≥50% eGFR loss or end-stage renal disease], and cardiovascular (CV) events (myocardial infarction, stroke, heart failure or peripheral arterial disease) or death.

Results: Most participants adhered to 1 or 2 healthy lifestyle factors (Table). Women, non-Hispanic Whites and college graduates were more likely to have a HLS of 3 (p<0.01). Adherence to a healthy lifestyle was associated with a significant lower risk of CV events or death. The association of HLS with CKD progression was less definitive (Table).

		CKD Progression		CV Event or Death	
Healthy Lifestyle Score	N (%)	Event Rate*	HR, 95% CI**	Event Rate*	HR, 95% CI**
0	201 (6)	109	Ref	122	Ref
1	1415 (39)	67	0.70, 0.53-0.93	70	0.65, 0.50-0.83
2	1726 (47)	52	0.76, 0.57-1.01	49	0.55, 0.42-0.71
3	328 (9)	41	0.93, 0.62-1.38	39	0.56, 0.38-0.81

*Per 1000 person-year. **Adjusted for baseline demographic and clinical variables

Conclusions: Findings from this cohort suggest that adherence to a healthy lifestyle should be promoted in patients with CKD because it may be associated with more favorable CV and possibly kidney outcomes.

Low Health Related Quality of Life Is Associated with Poor Health Outcomes among Participants in the Chronic Renal Insufficiency Cohort (CRIC) Study Anna C. Porter,[1] James P. Lash,[1] Claudia M. Lora,[1] Ana C. Ricardo,[1] Jennifer Lynn Deluca,[3] Radhika Kanthety,[3] John W. Kusek,[2] Lisa C. Nessel,[3] Qiang Pan,[3] Martin J. Schreiber,[3] Julie A. Wright,[3] Dawei Xie,[3] Michael J. Fischer.[1] *[1]Medicine, U. Illinois/Jesse Brown VA, Chicago, IL; [2]NIH/NIDDK; [3]CRIC Study Group.*

Background: Low health-related quality of life (HRQOL) is associated with higher mortality in end-stage renal disease (ESRD), but the association between HRQOL and outcomes is poorly described in adults with stage II-IV chronic kidney disease (CKD).

Methods: We conducted a prospective analysis of CRIC subjects to assess the association between HRQOL and CKD progression (50% eGFR loss or ESRD), incident cardiovascular disease (myocardial infarction, congestive heart failure, stroke, or peripheral arterial disease), and death. HRQOL was assessed with the Kidney Disease Quality of Life-36 (KDQOL-36), which has 5 subscales: mental component summary (MCS), physical component summary (PCS), burden of kidney disease (burden), effects of kidney disease (effects), and symptoms and problems of kidney disease (symptoms). We examined the association between low baseline HRQOL scores (>1 standard deviation below mean) and outcomes with Cox proportional hazards models.

Results: Among 3939 subjects with a mean of 3.9 years of follow up, lower baseline KDQOL subscale scores were associated with non-white race, income <$20,000/yr, diabetes, and urine albumin/Cr >300 mg/g. Crude rates of these outcomes were significantly higher in those with low PCS, effects, and symptom scores compared to those without the low subscale scores (p<0.05). Regression results adjusted for study site, demographics, comorbidity, eGFR and proteinuria are in Table 1.

KDQOL Subscale	Outcome		
	Hazard Ratio for low HRQOL score		
	CKD progression	Death	Incident CV disease
PCS	1.21*	1.61*	1.64*
MCS	1.06	1.24	1.26*
Burden	1.09	1.22	1.25*
Effects	1.07	1.40*	1.46*
Symptoms	0.99	1.33*	1.45*

*p<0.05

Conclusions: In this cohort, many low baseline KDQOL subscale scores were independently associated with an increased risk for worsening CKD, incident CV disease, and death. PCS, effects, and burden subscales had the largest and most consistent association with the outcomes.

Dietary Patterns and Kidney Disease: A Longitudinal Analysis of the Multi-Ethnic Study of Atherosclerosis (MESA) Julie Lin,[1] Ronit Katz,[2] Jennifer A. Nettleton,[3] Holly J. Kramer,[4] David R. Jacobs,[5] Michael Shlipak,[6] Ian H. de Boer.[2] *[1]Brigham and Women's Hospital, Boston, MA; [2]University of Washington, Seattle, WA; [3]University of Texas Health Science Center, Houston, TX; [4]Loyola Medical Center, Maywood, IL; [5]University of Minnesota School of Public Health, Minneapolis, MN; [6]San Francisco VA, San Francisco, CA.*

Background: Diet may influence kidney disease progression but longitudinal data on this relationship are limited. We examined dietary patterns and change in estimated glomerular filtration rate (eGFR) and urine albumin-creatinine ratio (UACR).

Methods: This is a cohort study of 5,405 MESA participants who had baseline dietary data from a 120-item food frequency questionnaire and at least 2 measures of serum creatinine (sCr), cystatin C (cys C), or UACR. We used principal components analysis to derive 4 dietary patterns (named by highest loading food groups): (1) "fats and processed meats" (similar to a 'Western' pattern); 2) "beans, tomatoes, and refined grains"; 3) "vegetables and fish"; and 4) "whole grains and fruit" (similar to a 'prudent' pattern), previously associated with baseline UACR as well as incident DM and CV disease in MESA. EGFR using sCr or cys C was calculated, and rapid eGFR decline was defined as ≥3 ml/min/1.73 m^2 per year decrease over 5 years of follow up. We also examined change in UACR. We tested associations using logistic regression and linear mixed models.

Results: Mean age was 62 yrs, 52% female, 41% White, 25% Black, 21% Hispanic, 13% Asian, 11% had DM, median baseline eGFR 93 (by cysC) and 78 (by sCr) ml/min/1.73 m^2, and UACR was 5.1 mg/gm. Adherence to each of the 4 dietary patterns varied markedly by race/ethnicity. However, we observed no significant associations between any dietary pattern with either eGFR decline or change in ACR in unadjusted or adjusted models, which included demographics, BMI, HTN, DM, lipids, and physical activity as covariates.

Conclusions: In a large, longitudinal analysis of racially and ethnically diverse adults, we did not observe associations of dietary patterns with change in eGFR or urine ACR over 5 years of follow-up.

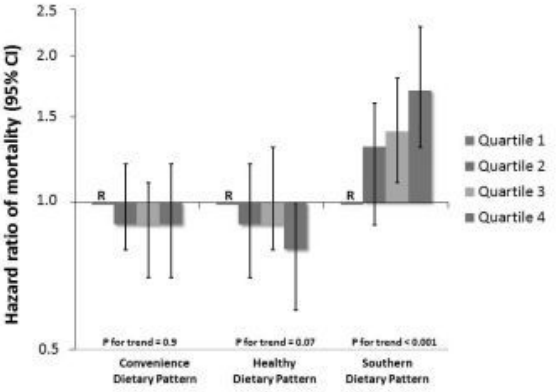
Dietary Patterns and Mortality in Chronic Kidney Disease Orlando M. Gutierrez,[1] Paul Muntner,[1] Dana Rizk,[1] William M. McClellan,[2] David G. Warnock,[1] Suzanne E. Judd.[1] *[1]UAB; [2]Emory.*

Background: Dietary patterns are associated with clinical outcomes in the general population, but few data exist in individuals with chronic kidney disease (CKD).

Methods: We examined the associations of dietary patterns with estimated glomerular filtration rate (eGFR), urinary albumin to creatinine ratio (ACR), c-reactive protein (CRP), and risk of death in 3,971 persons with CKD from the REasons for Geographic and Racial Differences in Stroke (REGARDS) study, a national cohort of black and white adults ≥45 years of age. Principal component analysis was used to empirically derive 5 dietary patterns based on 56 food groups from the Block 98 food frequency questionnaire. We focused on 3 patterns: "convenience," characterized by high intake of Chinese and Mexican foods, pizza, pasta and other mixed dishes; "healthy," by high intake of fruits and vegetables; and "southern," by high intake of fried foods, organ meats, sweetened beverages and by disproportionately high residence in Southern US states.

Results: Convenience pattern scores were not associated with eGFR, ACR, or CRP. In multivariable models adjusted for demographic and clinical factors, higher healthy pattern scores were associated with higher eGFR and lower CRP levels, whereas higher southern pattern scores were associated with lower eGFR, higher ACR, and higher CRP (P for trend<0.05 for all comparisons). There were 611 deaths over a median of 5 years of follow-up. There were no statistically significant associations of convenience or healthy pattern scores with mortality in multivariable-adjusted Cox regression models (figure). In contrast, higher southern pattern scores were associated with higher risk of death in the multivariable model (P for trend<0.001).

Figure: Multivariable-adjusted* hazard ratio (95% CI) of death according to quartiles of convenience, healthy and southern dietary pattern scores



*Adjusted for age, race, gender, geographic region of residence, energy intake, smoking, physical activity, education, income, hypertension, heart disease, urinary ACR, eGFR

Conclusions: A southern dietary pattern rich in fried foods, organ meats and sweetened beverages was independently associated with higher risk of death in persons with CKD.

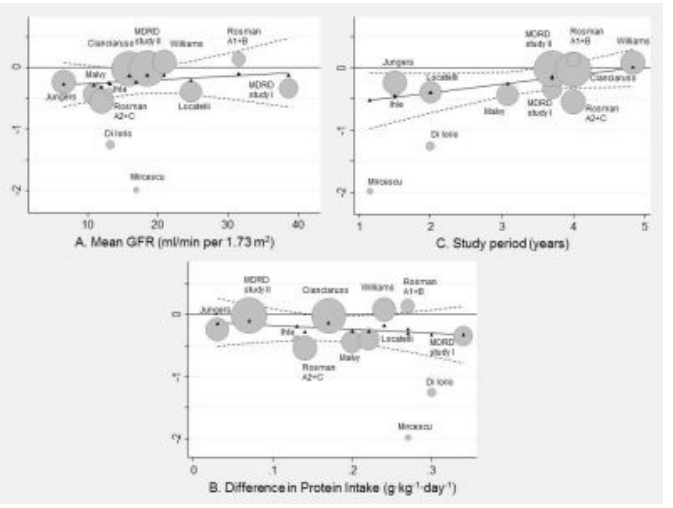
Examining Heterogeneity in the Effect of Protein Restriction for Chronic Kidney Disease: A Meta-Analysis and Meta-Regression of Randomized Controlled Trials Yoshitsugu Obi,[1] Yoshiki Suzuki,[2] Yoshitaka Isaka,[1] Toshiki Moriyama.[3] *[1]Department of Geriatric Medicine & Nephrology, Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [2]Health Administration Center, Niigata University, Niigata, Japan; [3]Health Care Center, Osaka University, Toyonaka, Osaka, Japan.*

Background: Protein restriction offers metabolic benefits to patients with advanced chronic kidney disease (CKD). However, its effect on reducing death or end-stage renal disease (ESRD) remains inconclusive.

Methods: We performed a meta-analysis on the efficacy of protein restriction in reducing the incidence of death or ESRD among adult patients with moderate to severe CKD. We included 10 randomized controlled trials (RCTs) (n = 1,128) comparing 2 protein intake level with ≥1 year of follow-up. To elucidate the heterogeneity in the results of RCTs, we also conducted meta-regressions using the influential characteristics of each trial.

Results: The pooled relative risk (RR) was 0.80 (95% CI, 0.77-0.96), but with obvious "small study effects" favoring protein restriction. Although insignificant due to low statistical power, meta-regressions showed that the lower mean kidney function of the participants and the larger difference of protein intake between study groups tended to be associated with the larger effect. Conversely, the effect was smaller in trials with longer follow-up period, and lost its significance with >3 years of follow-up.



We also found that protein restriction did not show any significant renoprotective effects in RCTs where metabolic acidosis was appropriately corrected in both study groups. Moreover, many RCTs did not even report the serum bicarbonate concentration.

Conclusions: Protein restriction delays the development of ESRD; however, the effecacy under the current standard treatment would be overestimated based on information available from published studies.

FR-PO124

Role of Potential Renal Acid Load (PRAL) in the Relation of Food Insecurity with Kidney Damage Tanushree Banerjee,[1] Deidra C. Crews,[2] Neil R. Powe.[1] *[1]University of California, San Francisco; [2]Johns Hopkins University, Baltimore.*

Background: Food insecurity refers to the inability to afford nutritionally adequate and safe foods, and has been shown to have an association with chronic diseases, including CKD. We hypothesized that food insecurity may influence dietary intake, as can be estimated by calculating dietary Potential Renal Acid Load (PRAL), and thus kidney damage associated with food insecurity could be mediated by PRAL.

Methods: Our analysis included 10,825 participants from the National Health and Nutrition Examination Survey 2001-2006, aged >20 years with a household income ≤400% of the federal poverty level. We considered a participant food insecure if ≥3 items in the 18-item questionnaire were answered affirmatively. We calculated PRAL based on 1-day dietary recall and body surface area, where the highest quintile of PRAL was the least desirable. Kidney damage was defined as microalbuminuria (30-300 mg/g creatinine) or macroalbuminuria (>300 mg/g). Multivariable logistic regression was used to estimate the association between food insecurity, PRAL, and kidney damage, with adjustment for demographics (age, gender, race/ethnicity), income, education, hypertension, diabetes and obesity.

Results: 1,253 (11.6%) participants were food insecure. The median value of PRAL in the food insecure group was greater, -2155.89 mEq/100gm, than in the food secure group, -2461.64 mEq/100gm. Food insecurity showed significant association with the highest quintile of PRAL compared to the lowest quintile both in unadjusted and adjusted analysis (OR [95% CI: 1.69 [1.13, 2.55]). Food insecurity was also associated with macroalbuminuria in unadjusted analyses and after adjustment for demographics (OR [95% CI]: 1.88 [1.16, 3.06]), however inclusion of PRAL to the model fully attenuated the relationship of food insecurity and macroalbuminuria to non-significance (OR [95%CI]: 0.78 [0.38, 1.59]).

Conclusions: Food insecurity is associated with increased dietary acid load which may explain the relationship of food insecurity with macroalbuminuria. Further studies are needed to elucidate the role of high dietary acid load in socioeconomic disparities in CKD.

FR-PO125

Association between Dietary Potential Renal Acid Load (PRAL) and Hyperfiltration Tanushree Banerjee,[1] Deidra C. Crews,[2] Donald E. Wesson,[3] Rajiv Saran,[4] Anca Tilea,[4] Meda E. Pavkov,[5] Nilka Rios Burrows,[5] Neil R. Powe.[1] *[1]University of California, San Francisco; [2]Johns Hopkins University, Baltimore; [3]Texas A&M College of Medicine; [4]University of Michigan, Ann Arbor; [5]Centers for Disease Control and Prevention.*

Background: Hyperfiltration is the result of intraglomerular hypertension, possibly leading to microalbuminuria, and may be influenced by dietary habits. We undertook this study to examine the association of dietary habits, which we quantify as Potential Renal Acid Load (PRAL), with hyperfiltration and with microalbuminuria in the hyperfiltering group.

Methods: We considered 15,903 U.S. adults aged >20 years in NHANES 1999-2004 as our sample. Hyperfiltration was defined as eGFR≥135 ml/min/1.73m^2 which was at least 2 standard deviations above the mean GFR (107 ml/min/1.73m^2) in the reference population with eGFR 80-130 ml/min/1.73m^2. eGFR was calculated using CKD-EPI equation. We calculated PRAL based on 1-day dietary recall and body surface area where the highest quintile of PRAL was the least desirable value. Variables included in logistic regression models were demographics (age, gender, race/ethnicity), poverty status, hypertension, diabetes and obesity.

Results: 6,364 (40%) participants had hyperfiltration. There was a significant linear trend across quintiles of PRAL and hyperfiltration (p=0.003). Fully, 491 (8%) participants with hyperfiltration had microalbuminuria. Significant differences were seen in PRAL values across the normoalbuminuria and microalbuminuria groups (p=0.0002). In unadjusted analyses, a greater PRAL level was associated with greater prevalence of microalbuminuria in the hyperfiltering group. After adjustment, the highest quintile of PRAL was associated with significantly greater odds of microalbuminuria [OR (95% CI) = 3.77 (1.69, 8.43)] compared with the lowest quintile. A significant trend was observed across quintiles of PRAL and microalbuminuria for hypertensives only (p=0.045).

Conclusions: Dietary acid load are associated with microalbuminuria in hyperfiltering individuals. These findings have implications for dietary modification as a potential intervention to reduce high PRAL related albuminuria.

FR-PO126

High Sodium and Low Potassium Dietary Intake May Be Linked to Obesity Risk Nishank Jain,[1,2] Abu T.M. Minhajuddin,[2] Essam F. Elsayed,[1,2] Robert F. Reilly,[1,2] Susan Hedayati.[1,2] *[1]VA North Texas Health Care System; [2]UT Southwestern Medical Center.*

Background: Previous studies that reported an association of dietary sodium (Na) with metabolic syndrome and type 2 diabetes mellitus were limited by use of imperfect measures of Na intake such as dietary recall. To our knowledge, no studies have investigated the association of dietary potassium (K) with obesity. We hypothesized that high dietary Na and low K measured by first void morning urinary Na-to-K ratio ($U_{Na/K}$) is independently associated with markers of obesity in 3,303 participants of the population-based multi-ethnic Dallas Heart Study.

Methods: Robust linear regression was used to explore the association of $U_{Na/K}$ with body mass index (BMI) and total body percent fat (TBPF, measured by dual X-ray absorptiometry scan and expressed in percent), which mitigates the violations of linear regression assumptions when $U_{Na/K}$ distribution is right-skewed. Multivariable models were adjusted for age, race, gender, systolic and diastolic blood pressure and diabetes mellitus.

Results: Of the cohort, 52% were African American, 56% female, 17% Hispanic, 12% diabetic, and 36% hypertensive. Mean (SD) age was 44 (10) years, BMI 30 (7) kg/m^2, TBPF 32 (10) % and $U_{Na/K}$ 4.2 (2.8). In the unadjusted model, for each SD (3 units) increase in $U_{Na/K}$, BMI increased by 0.6 kg/m^2, 95% CI (0.4, 0.9), and TBPF by 0.8% (0.3, 1.3), p <0.0001 and 0.003, respectively. This association remained significant even after adjusting for confounders. TBPF increase was higher in Hispanics and Caucasians than African Americans per 3-unit increase in $U_{Na/K}$, interaction p = 0.02.

Association of Urinary Sodium-to-Potassium Ratio with Body Mass Index (BMI) and Total Body Percent Fat (TBPF)

Univariate Model	Change (95% CI), per 3-unit increase in UNa/K
BMI (kg/m2)	0.63 (0.38, 0.87)
TBPF(%)	0.75 (0.25, 1.25)
Multivariate Model	
BMI (kg/m2)	0.40 (0.17, 0.63)
TBPF(%)	0.45 (0.16, 0.73)

Conclusions: Dietary sodium excess and potassium deficiency may be associated with obesity, independent of other cardiovascular risk factors. Future clinical trials should explore whether modification of dietary Na and K could be used as an interventional strategy to reduce the prevalence of obesity.

Funding: Veterans Administration Support

FR-PO127

Relationships between Osteoprotegerin Level, Vascular Stiffness and Patient Survival in CKD James Ritchie,[1] Lakhvir Assi,[2] Richa Sinha,[1] Darren Green,[1] Philip A. Kalra.[1] *[1]Vascular Research Group, University of Manchester; [2]The Binding Site Group, Birmingham, United Kingdom.*

Background: Osteoprotegerin (OPG), produced by osteoblasts and vascular endothelium, is implicated in the development of vascular calcification in patients with CKD. Elevated levels have been associated with increased mortality in advanced CKD. However, little data exist for earlier CKD stages. This study aims to:

1 Assess the relationship between OPG and mortality in moderate CKD.

2 Explore the relationship between OPG level and vascular stiffness.

Methods: 499 patients with all cause CKD were identified within the Chronic Renal Insufficiency Standards Implementation Study (CRISIS). Vascular stiffness was assessed with pulse wave analysis (augmentation index corrected for heart rate, AIx). OPG levels were measured from stored serum samples, taken on the same day as AIx measurements. Patients were divided by OPG quartile. Survival differences (all cause mortality) between quartiles were assessed using Cox regression. Differences in Aix between quartiles were calculated using a linear regression model. Analyses were adjusted for age, gender, blood pressure, renal function, previous cardiovascular events, smoking, use of angiotensin blockade/statin therapy. The lowest quartile provided the referent group.

Results: Mean age was 65, eGFR 36ml/min/1.73m^2. Hazard ratio (HR) for death significantly increased with each quartile of OPG (quartile 2,3,4 HR for death: 4.0; 5.8; 8.7 respectively, p<0.001 for all). This finding was consistent when the model was adjusted for AIx, but not when also adjusted for other vascular risk factors (quartile 2, 3 and 4 adjusted HR for death: 1.75(p=0.2); 2.65(p=0.03); 2.17(p=0.09)). A significant increase in Aix for higher OPG levels was observed. The increase in Aix peaked in the 3rd quartile of OPG level (23% higher Aix in quartile 3 vs. quartile 1, p=0.002), and was less elevated for the 4th quartile (12% higher Aix in quartile 4 vs. quartile 1, p=0.02).

Conclusions: In moderate CKD, increased OPG levels are associated with increased vascular stiffness. An association is also observed for risk of death, though this becomes less significant when traditional risk factors are taken into account.

FR-PO128

Hypertensive Pregnancy Disorders as a Risk Factor for Future Renal Disease: A Population-Based Study Andrea G. Kattah,[1] Catherine M. Brown,[2] Slavica Katusic,[3] Cynthia L. Leibson,[3] Jeanine Ransom,[3] Amy L. Weaver,[3] Virginia Miller,[4] Veronique L. Roger,[4] Vesna D. Garovic.[1] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Beaumont Hospital, Dublin, Ireland; [3]Health Sciences Research, Mayo Clinic, Rochester, MN; [4]Mayo Clinic, Rochester, MN.*

Background: The long-term effects of hypertensive pregnancy disorders (HPD), including preeclampsia, on kidney function later in life remain unclear. While early reports suggested that there is no increased risk of chronic kidney disease (CKD) after an episode of preeclampsia, more recent case-control and registry-based cohort studies indicate that there is an increased risk of microalbuminuria, need for renal biopsy, and CKD in the affected women later in life. We aimed to confirm the association between HPD and future renal disease in a population-based study.

Methods: Using the unique population-based longitudinal resources of the Rochester Epidemiology Project (REP), we identified all female residents of Olmsted County, MN who delivered between 1976 and 1982. Our exposure definition included any diagnostic code suggestive of HPD and related complications. Outcomes were defined based on codes for renal disease (including albuminuria, renal failure, and CKD) occurring at any time after index pregnancy.

Results: A total of 10,295 births occurred in Olmsted County from 1976-1982, which identified 8100 mothers, of which 7582 had REP records (93%). A total of 1023 mothers had at least one live or stillbirth with codes suggestive of HPD. The median age of women still living in Olmsted County was 52 years. Looking at the entire cohort, 652 (8.6%) mothers had a renal outcome of interest. Women with a history of HPD, compared to those without HPD, had a significantly higher risk for renal disease: 149 of 1023 (15%) versus 503 of 6559 (8%), p<0.0001. The relative risk of having renal disease was 2.05 (CI 1.69-2.50) for women with, versus those without, diagnostic codes suggestive of HPD.

Conclusions: Women with a history of HPD, including preeclampsia, may be at increased risk of renal disease later in life. Our data suggest that the renal function of the affected women should be closely monitored after their pregnancies.

FR-PO129

Kidney Disease Is an Independent Risk Factor for Maternal Mortality in Pregnancy Shailendra Sharma,[1] John R. Holmen,[2] M. Chonchol,[1] Gerard John Smits,[1] Jessica B. Kendrick.[1] *[1]University of Colorado School of Medicine, Aurora, CO; [2]Intermountain Health Care, Salt Lake City, UT.*

Background: Presence of kidney disease is recognized to adversely affect maternal outcomes during pregnancy. The objective of this study is to provide a contemporary assessment of the risk of kidney disease during pregnancy on important maternal outcomes including death.

Methods: We used data from an integrated healthcare system between 2000 and 2011. Of 317,990 pregnancies, 646 pregnancies from women with kidney disease were identified and 62,757 pregnancies from women without kidney disease were randomly selected for comparison. Kidney disease was defined by ICD9 code. Adverse maternal outcomes included pre-term delivery, delivery via cesarean section, length of stay in the hospital and maternal death. Multivariate logistic regression analysis was used to examine the association between kidney disease and adverse maternal outcomes adjusted for important confounders.

Results: In the whole study population there were 4,068 (25%) preterm deliveries, 12,025 (52%) cesarean sections, 113 (1.1%) maternal deaths and the mean (SD) length of stay in the hospital was 2 ± 1.8 days. Women with kidney disease had a mean (SD) age and gestational age at delivery of 28 ± 5 years and 37 ± 3 weeks, respectively. Women with kidney disease were more likely to have comorbid conditions including a history of chronic hypertension (n=177; 27%) and diabetes (n=77; 12%). Compared to women without kidney disease, those with kidney disease had a three-fold increased risk of death after adjusting for age, race, history of diabetes, chronic hypertension, liver disease and connective tissue disorders (OR 3.38, 95% CI 1.40 to 8.12). Furthermore, women with kidney disease had an increased risk of preterm delivery (OR 1.95, 95% CI 1.37 to 2.77), delivery via cesarean section (OR 1.38, 95% CI 1.04 to 1.82) and longer length of stay in the hospital (OR 1.39, 95% CI 1.04 to 1.86).

Conclusions: Pregnant women with kidney disease have an increased risk of adverse maternal outcomes including maternal mortality independent of underlying comorbid conditions that can occur with kidney disease.

Smoking and Risk of End-Stage Kidney Failure in the Singapore Chinese Health Study Tazeen H. Jafar,[1] Jin Ai Zhen,[2] Woon-puay Koh,[3] Khuan Yew Chow.[2] *[1]Duke-NUS Graduate Medical School, Singapore; [2]Health Promotion Board, Singapore; [3]National University of Singapore.*

Background: Studies in European-origin populations suggest potential association between smoking and chronic kidney disease. However, the relationship between smoking and risk of end-stage kidney failure (ESKF) in people of Chinese origin is not clear. We

analyzed data from the Singapore Chinese Health Study to investigate whether smoking increases the risk of ESKF.

Methods: The Singapore Chinese Health Study is a population-based cohort of 63,257 Chinese adults enrolled between 1993 and 1998. Information on smoking status was collected at baseline. Incidence of ESKF was identified via record linkage with the nationwide Singapore Renal Registry until 2008. ESKF was defined by one of the following: 1) serum creatinine ≥5.7 mg/dl, 2) estimated glomerular filtration rate < 15 ml/min/1.73m^2, 3) hemodialysis or peritoneal dialysis, 4) kidney transplantation. Multivariable model was built. Cox proportional hazard regression analysis was performed for the outcome of ESKF after adjusting for age, education, dialect, herbal medications, body mass index, sex, physician-diagnosed hypertension and diabetes.

Results: The mean age of subjects was 55.6 years, 44% were men, and 30.6% were smokers (current or former) at baseline. A total of 674 incident cases of ESKF occurred during a median follow-up of 13.3 years (774,434 person years). Among men, smokers had a significant increase in the risk of ESKF [hazard ratio (HR): 1.29; 95% CI: 1.02-1.64] compared to never smokers. There was a strong dose-dependent association (p for trend=0.011 for duration, and p for trend =0.02 for never, light, and heavy smoker defined by quanity and duration of smoking). The risk of ESKF decreased after prolonged cessation (≥10 years since baseline). Among women, the direction of the relationships between smoking and ESKF were similar however there were too few smokers for conclusive results.

Conclusions: Cigarette smoking is associated with an increased risk of ESKF among Chinese men. The risk appears to be dose and duration dependent, and modifiable after long duration of cessation.

Serum Cholesterol-Ester and Adipose Tissue Fatty Acid Composition as Biomarkers of Habitual Dietary Fat Intake in Older Men with Chronic Kidney Disease Xiaoyan Huang,[1] Per Sjogren,[2] Tommy Cederholm,[2] Johan Arnlov,[2,3] Bengt Lindholm,[1] Ulf Risérus,[2] Juan Jesus Carrero.[1,4] *[1]Renal Medicine and Baxter Novum, Karolinska Institutet, Stockholm, Sweden; [2]Public Health and Caring Sciences, Clinical Nutrition and Metabolism, Uppsala University, Uppsala, Sweden; [3]School of Health and Social Studies, Dalarna University, Falun, Sweden; [4]Center for Molecular Medicine, Karolinska Institutet, Stockholm, Sweden.*

Background: Fatty acid (FA) composition in serum cholesterol esters (CE) and adipose tissue (AT) can provide an accurate measure of long-term FA intake. The objective was to identify which CE and AT fatty acids were suitable biomarkers of habitual FA intake in individuals with chronic kidney disease (CKD).

Methods: Cross-sectional analysis in 506 men of 70 years of age and with serum cystatin C-based glomerular filtration rate (GFR) <60 ml/min per 1.73 m^2 from the Uppsala Longitudinal Study of Adult Men cohort. Dietary habits were evaluated with a 7-day dietary record. FA compositions of CE and AT were analyzed by gas-liquid chromatography in two random subsamples of 248 and 318 individuals, respectively.

Results: Both in CE and AT, linoleic acid, eicosapentaenoic acid (EPA), and docosahexaenoic acid (DHA) were strongly associated with their corresponding intake, after adjustments for non-dietary factors. CE and AT proportions of palmitic and palmitoleic acid moderately correlated with dietary intake, while correlations for other FA were weaker or absent. Proportions of EPA and DHA in CE and AT were positively associated with total energy-adjusted fish intake. Results were confirmed in adequate reporters as identified by the Goldberg cutoff method. These relationships held constant, regardless of GFR above or below 45 ml/min per 1.73 m^2 or the prevalence of microalbuminuria.

Conclusions: Linoleic acid, EPA, and DHA in serum CE and AT are fairly adequate indicators of habitual dietary FA intake in older CKD men. Dietary fish intake may serve as a surrogate marker of intake of n-3 polyunsaturated FA of marine origin.

Provider and Pre-ESRD Care Characteristics Associated with eGFR at Dialysis Initiation Yelena Slinin,[1] Haifeng Guo,[2] Suying Li,[2] Jiannong Liu,[2] David T. Gilbertson,[2] Allan J. Collins,[2] Areef Ishani.[1,2] *[1]Veterans Administration Health Care System, Minneapolis, MN; [2]Chronic Disease Research Group, Minneapolis, MN.*

Background: There is a trend in the United States toward initiation of chronic dialysis at higher levels of estimated glomerular filtration rate (eGFR). Provider and medical care characteristics associated with timing of dialysis initiation as assessed by eGFR are unknown. We aimed to determine whether provider characteristics and pre-ESRD care patterns are independently associated with higher eGFR at dialysis initiation.

Methods: Using United States Renal Data System data for patients who initiated dialysis during 2006 (N=83,621), we defined patient characteristics, eGFR, and identified provider at dialysis initiation. Provider data were obtained from the AMA. Provider/patient ratio (per 100 ESRD patients) in each Health Service Area in 2006 was calculated, expressed as quintiles, and presented by HSA of patients' residence. We determined associations between provider characteristics and eGFR at dialysis initiation (eGFR>10 ml/min – early initiation) using logistic regression.

Results: Of the 83,621 patients included into the cohort, 47.9% initiated dialysis at eGFR > 10 ml/min, 16.2% at eGFR ≥15ml/min.

FR-PO133

Association of Duration of Residence in the Southeastern United States with Chronic Kidney Disease (CKD) Differs by Race: The Reasons for Geographic and Racial Differences in Stroke Study Laura Plantinga,[1] Virginia J. Howard,[2] Suzanne E. Judd,[2] Paul Muntner,[2] Rikki M. Tanner,[2] Dana Rizk,[2] Daniel T. Lackland,[3] David G. Warnock,[2] George Howard,[2] William M. McClellan.[1] *[1]Emory University, Atlanta, GA; [2]University of Alabama at Birmingham, Birmingham, AL; [3]Medical University of South Carolina, Charleston, SC.*

Background: Longer duration of residence in the southeastern United States is associated with higher prevalence of hypertension. We explored whether a similar association exists for CKD within black and white populations.

Methods: In a national population-based cohort study of 30,239 adults (≥45 years; 42% black/58% white) enrolled 2003-2007, lifetime southeastern residence duration was calculated and categorized [none (0%), less than half (>0-<50%), half or more (≥50-<100%), all (100%)]. Prevalent albuminuria (urine albumin:creatinine ratio≥30 mg/g) and reduced kidney function (eGFR<60 ml/min/1.73 m^2) were defined at enrollment. Incident end-stage renal disease (ESRD) was determined through linked United States Renal Data System records.

Results: White and black participants most often reported living their entire lives outside (35.7% and 27.0%) or inside (27.9% and 33.8%, respectively) the southeastern United States. Albuminuria prevalence was not associated with southeastern residence duration, except for half or more vs. none among blacks only (OR=0.74, 95% CI, 0.62-0.89). There was no statistical interaction of race with southeastern residence duration, after adjustment for age, sex, education, income, diabetes, and hypertension ($P_{raceXduration}$=0.27). ESRD incidence was not associated with 100% vs. 0% southeastern residence duration (HR=0.50, 95% CI, 0.22-1.14) among whites but was associated with an increased risk among blacks (HR=1.63, 95% CI, 1.02-2.63; $P_{raceXduration}$=0.011). Reduced kidney function was not associated with southeastern residence duration in whites or blacks.

Conclusions: Estimates suggest that blacks who live in the Southeast their entire lives, relative to never having lived there, are at increased risk of ESRD. These results could help generate further hypotheses regarding the effects of region of residence on the prevalence and incidence of CKD.

FR-PO134

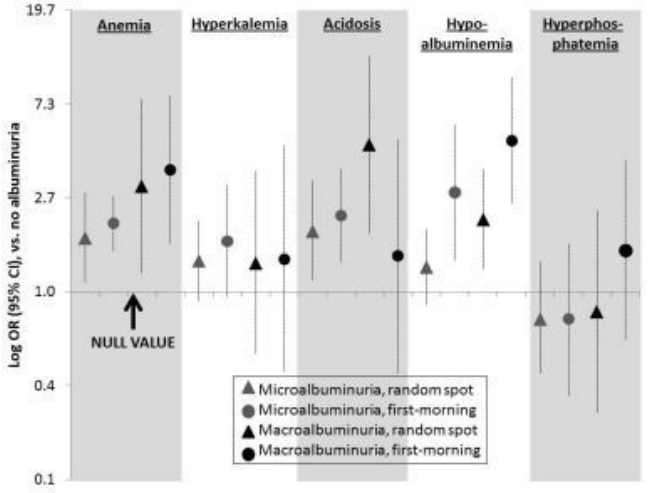
Estimates of Effect of Albuminuria on Common Kidney Complications May Be Underestimated by Random Albuminuria Measurement Laura Plantinga,[1] Vanessa Grubbs,[2] Jerry Yee,[3] William M. McClellan,[1] Nilka Rios Burrows,[4] Mark Eberhardt,[5] Neil R. Powe.[2] *[1]Emory University, Atlanta, GA; [2]University of California, San Francisco, CA; [3]Henry Ford Hospital, Detroit, MI; [4]Centers for Disease Control and Prevention, Atlanta, GA; [5]National Center for Health Statistics, Hyattsville, MD.*

Background: Single urine albumin collection may result in misclassification of albuminuria and bias in risk estimates, which may be reduced by first-morning vs. casual (random) specimen collection. We estimated the associations of albuminuria with common CKD complications using both collection methods and compared the results.

Methods: Using 2009-2010 National Health and Nutrition Examination Survey data, we estimated the urine albumin:creatinine ratio (UACR) of 4,938 non-pregnant adults (≥20 years) with casual urine and first-morning specimens (within 10 days). We used logistic regression to estimate odds ratios (ORs) and 95% CIs by method of urine collection and microalbuminuria (30-299 mg/g) and macroalbuminuria (≥300 mg/g) vs. no albuminuria for anemia (hemoglobin <13/<12 mg/dl for males/females), hyperkalemia (potassium >4.5

mmol/l), acidosis (bicarbonate <23 mmol/l), hypoalbuminemia (albumin <4.0 g/dl), and hyperphosphatemia (phosphate >4.5 mg/dl), adjusting for age, race/ethnicity, sex, eGFR, diabetes, and hypertension.

Results: Generally, ORs were farther from the null when albuminuria was assessed by first-morning vs. casual urine. Precision (width of confidence interval on the log scale) with first-morning vs. casual specimens was better for anemia (64% smaller) but worse for hyperkalemia, acidosis, hypoalbuminemia, and hyperphosphatemia (38% larger, on average).



Conclusions: Assessment of albuminuria obtained casually vs. first-morning produced ORs for the association of albuminuria with CKD complications that were closer to the null.

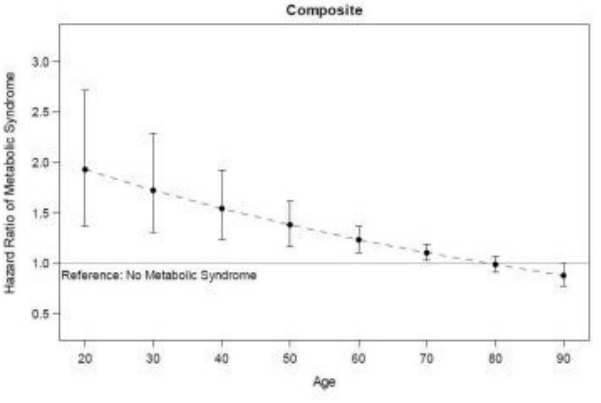
Metabolic Syndrome, Kidney Disease Progression and Death Sankar D. Navaneethan,[1] Jesse D. Schold,[2] Anne S. Tang,[2] George Thomas,[1] Martin J. Schreiber,[1] Emilio D. Poggio,[1] S. Beddhu,[3] Joseph V. Nally.[1] *[1]Nephrology, Cleveland Clinic; [2]Quantitative Health Sciences, Cleveland Clinic; [3]Nephrology, University of Utah.*

Background: Previous studies reported an association between metabolic syndrome (MetS) and incident chronic kidney disease. We examined the associations between MetS and its components with kidney disease progression and death among those with stage 3 and 4 CKD.

Methods: 25,882 patients with stage 3 and stage 4 CKD who had relevant data relating to MetS components after the diagnosis of CKD were included. Cox proportional hazards models were used to assess the associations between MetS, its components and the composite end-point (all-cause mortality and End Stage Renal Disease[ESRD]) while adjusting for relevant confounding variables. Two-way interactions between MetS and age, gender, race and eGFR were examined.

Results: Forty-two percent of the study population (n=10,934) had MetS. During a median follow-up of 2.4 years, 3691 participants died or reached ESRD. In the cox proportional hazards model, presence of MetS was not associated with the composite end-point (HR 1.06; 95% CI 0.99,1.14). However, age modified these associations with younger patients with MetS having a higher risk for reaching the composite end-point (p for interaction <0.001).



Among the individual components of MetS, diabetes (HR 1.32; 95% CI 1.22, 1.43), elevated triglycerides (HR 1.07; 95% CI 1.00, 1.15) and low HDL levels (HR 1.17; 95% CI 1.09, 1.26) were associated with the composite end-point. No significant association between hypertension and obesity with the composite end-point was noted.

Conclusions: Presence of MetS in younger stage 3 and stage 4 CKD patients are associated with all-cause mortality and ESRD. The associations between individual components of MetS and the composite end-point seem to vary with diabetes and dyslipidemia having pronounced associations.

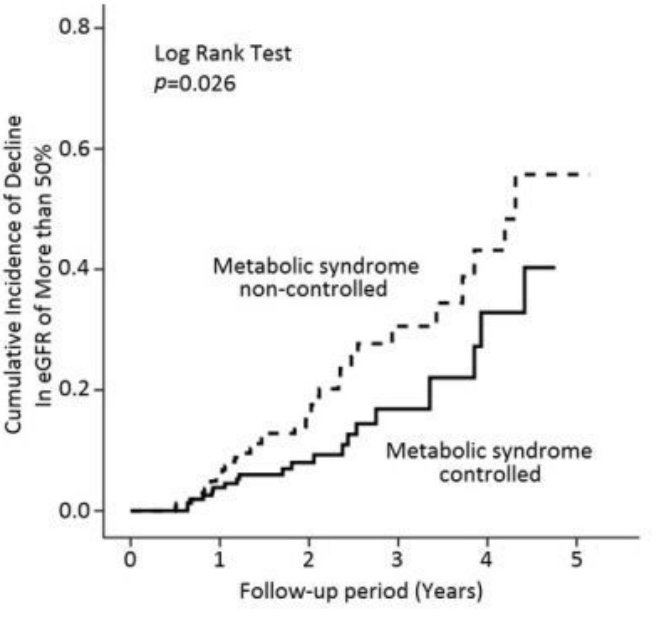
FR-PO136

Treating Metabolic Syndrome Improves Progression of Chronic Kidney Disease Yuan-chun Chiang,[1,2] Chih-Ching Lin,[1,2] Der-Cherng Tarng,[1,2] Yao-ping Lin,[1,2] Jinn-Yang Chen,[1,2] Wu-Chang Yang.[1,2] *[1]Division of Nephrology, Taipei Veterans General Hospital, Taipei, Taiwan; [2]School of Medicine, National Yang-Ming University, Taipei, Taiwan.*

Background: Metabolic syndrome (MetS) is a well-known risk factor for development and progression of chronic kidney disease (CKD). However no data is available to evaluate whether treating MetS components can ameliorate renal function deterioration in such patients with CKD, which prompted this study in a single medical institute.

Methods: A longitudinal retrospective cohort study enrolled 323 patients with incident CKD (eGFR<60ml/min/1.73m2) and MetS who had been followed for ≥12 months. Diagnosis of MetS was defined as modified National Cholesterol Education Program (NCEP), in which the waist circumference>90cm was substituted with body mass index ≥24. After 3 months treatment, patients were divided into 2 groups: MetS controlled (MetS components<3, group 1) and MetS non-controlled (MetS components≥3, group 2). The primary endpoint is defined as reduction in eGFR of > 50%.

Results: The baseline eGFR was comparable between these two groups (27.9±12.1 vs. 28.1±14.1 ml/min/1.73m2, p=0.88), but group 2 had significantly more female, type 2 diabetics and Mets component numbers. During a 4.5 years follow-up group 1 patients had lower cumulative incidence of reduction in eGFR>50%.



Moreover, the more MetS components were controlled, the better preservation of renal function was achieved (p=0.025, figure not shown).

Conclusions: MetS and more MetS components are associated with higher incidence of CKD. This study demonstrated that treating metabolic syndrome and its components has reno-protection effect to delay CKD progression.

Funding: Government Support - Non-U.S.

FR-PO137

Non-Steroidal Anti-Inflammatory Drugs and Chronic Kidney Disease Progression: A Systematic Review and Meta-Analysis Paul Nderitu, Lucy Doos, Peter W. Jones, Simon J. Davies, Umesh Kadam. *Health Service Research Unit, Institute of Science and Technology in Medicine, United Kingdom.*

Background: Non-Steroidal Anti-Inflammatory Drugs (NSAIDs) are widely regarded as one of the risk factors which influence Chronic Kidney Disease (CKD) progression. However, previous literature reviews have not quantified the risk in moderate to severe CKD patients. Our systematic review aims to estimate the strength of association between chronic NSAID use and CKD progression using meta-analysis, by identifying general population studies.

Methods: Searched electronic databases were MEDLINE, EMBASE, Cochrane, AMED, BNI, and CINAHL until September 31st 2011 without date or language restrictions. Searches also included the reference lists of relevant identified studies, WEB of KNOWLEDGE, openSIGLE, specific journals, the British Library and expert networks.

For relevant studies, random effects meta-analysis was used to estimate the association between NSAID use and accelerated CKD progression (defined as a Glomerular Filtration Rate (GFR) decline of ≥15ml/min/1.73m^2).

Results: From a possible 768 articles, after screening and selection, seven studies were identified (5 cohort, 1 case-control and 1 cross-sectional). Using 3 cohort studies (total sample size, n=54,663), regular dose NSAID use did not significantly affect the risk of accelerated CKD progression; pooled Odds Ratio (OR)= 0.96 (95%CI; 0.86 to 1.07), but high dose NSAID use significantly increased the risk of accelerated CKD progression; pooled OR= 1.26 (95%CI; 1.06 to 1.50).

Conclusions: The avoidance of NSAIDs in the medium term is unnecessary in patients with moderate to severe CKD, if not otherwise contraindicated. As the definition of high dose use remains unclear, the lowest effective dose of NSAIDs should be prescribed where indicated.

FR-PO138

Non-Steroidal Anti-Inflammatory Drug Prescription and Significant Chronic Kidney Disease Progression: A Clinical Linkage Study from General Practice

Paul Nderitu,[1] Lucy Doos,[1] Vicky Strauss,[2] Mark Lambie,[1] Simon J. Davies,[1] Umesh Kadam.[1] *[1]Health Service Research Unit, Institute of Science and Technology in Medicine; [2]Institute of Primary Care and Health Sciences, United Kingdom.*

Background: The association between Non-Steroidal Anti-Inflammatory Drugs (NSAIDs) and Chronic Kidney Disease (CKD) progression is unclear. However, NSAIDs are commonly used by patients with inflammatory musculoskeletal conditions. This study aims to quantify the risk of medium term NSAID prescription on CKD progression.

Methods: A historical cohort was constructed from two population-based general practices in England (UK) linking diagnostic, prescribing and routine clinical data. This dataset included all subjects aged 40 years and over with 2 or more estimated Glomerular Filtration Rate (eGFR) measurements spaced at least 90 days apart between January 1st 2009 and December 31st 2010 (n=4,145). Cumulative NSAID prescriptions given before the last eGFR test were standardised using the Defined Daily Dose (DDD) and subjects were categorised into non-user (0 DDDs), normal dose (DDDs <85th percentile) and high dose (DDDs ≥85th percentile) groups. Logistic regression methods were used to explore the associations between NSAID prescription and the outcome of significant CKD progression (defined as eGFR decline rate >5ml/min/1.73m^2 per year) adjusting for age, gender, deprivation, diabetes, cardiovascular disease, Angiotensin Converting Enzyme inhibitor or Angiotensin Receptor Blockers or Renin inhibitor prescription, Aspirin or Paracetamol prescription and baseline CKD stage.

Results: The prevalence of NSAID prescribing was 17.2% (n=711) and 16.1% (n=667) of the study cohort had stage 3-5 CKD. Significant CKD progression occurred in 928/3434 (27.0%) non-users, 149/605 (24.6%) normal dose and 22/106 (20.8%) high dose users. There was no significant association between normal dose NSAID prescribing (odds ratio (OR)= 1.02, 95%CI: 0.83-1.25) or high dose NSAID prescribing (OR= 0.83, 95%CI: 0.51-1.35) and significant CKD progression.

Conclusions: NSAID prescription over two years does not lead to significant CKD progression. However, the effects of long term NSAID prescription on CKD progression remain uncertain.

Funding: Private Foundation Support

FR-PO139

Association of Multidisciplinary Chronic Kidney Disease Care on Patient Outcomes: A Population Based Analysis

Betty K. Chui,[1] Brenda Hemmelgarn,[2] Marcello Tonelli,[1] Scott Klarenbach.[1] *[1]Medicine, University of Alberta, Edmonton, AB, Canada; [2]Medicine, University of Calgary, Calgary, AB, Canada.*

Background: Multidisciplinary chronic kidney disease (MCKD) care may delay and improve transition to renal replacement therapy (RRT), and modify risk factors for both progression of chronic kidney disease (CKD) and cardiovascular disease. The evidence on the effectiveness of MCKD care is based on small studies with limited follow up.

Methods: All incident stable CKD patients with eGFR< 45 between 2002-2007 were identified from a population based cohort in Alberta using laboratory and administrative data. We evaluated the association of MCKD care on outcomes at 5 years using adjusted Cox proportional hazards models with MCKD care as a time-varying exposure. Subgroup analyses were done on patients who did and did not initiate RRT. Sensitivity analyses were done using a 2:1 propensity score matched cohort.

Results: 1,116 patients received MCKD care from a total of 39,102 CKD patients. Overall, MCKD care was associated with lower mortality at 5 years (HR 0.73 95% confidence interval, 0.66-0.81). MCKD care patients were more likely to receive RRT (HR 3.11; 2.75-3.50), transplantation (HR 3.03; 2.24-4.09), and were associated with a lower serious cardiovascular event (acute MI or stroke requiring hospitalization) risk (0.74; 0.61-0.90). In patients who initiated RRT, MCKD care was not associated with mortality benefit (0.82, 0.66-1.01), but was associated with a lower cardiovascular event risk (0.67; 0.49-0.91). Of patients who did not initiate RRT, MCKD care was associated with lower mortality (0.73, 0.64-0.82) and lower cardiovascular event risk (0.62, 0.48-0.81). Propensity score matched analyses show similar results.

Conclusions: Multidisciplinary CKD care is associated with lower mortality, increased transition to renal replacement therapy, and lower risk of serious cardiovascular events. Mortality benefits associated with CKD care may be related to cardiovascular risk factor reduction. While this analysis does not account for unmeasured confounders, results were similar in rigorous propensity score matched analyses.

FR-PO140

Pain Management in a Nephrology Department: Final Results of the PAIN Study

Sarah Zimner-Rapuch,[1] Elisabeth Collin,[2] Nicolas Janus,[1] Sabine Amet,[1] Maud Grimault,[3] Elfie Bruce,[1] Laurence Rouillon,[1] Gilbert Deray,[3] Corinne Isnard-Bagnis,[3] Vincent Launay-vacher.[1] *[1]Nephrology, Pitie Salpetriere Hospital, Paris, France; [2]Pain Treatment and Management, Pitie Salpetriere Hospital, Paris, France; [3]Service ICAR-Nephrology, Pitie Salpetriere Hospital, Paris, France.*

Background: Pain (P) remains underestimated and undertreated. In renal insufficiency (RI) patients, handling drugs is difficult due to drug dosage adjustment (DDA) and especially for analgesics and opioids. The PAIN study (Protocole Analgesia by Service ICAR in Nephrology) aimed at evaluating P, its features, its consequences on the emotional status and its medical management of RI patients admitted in our department of nephrology.

Methods: PAIN is a French prospective monocentric study based on a 4-sections' patient form filled by the patient with the help of medical students from 02-2011 to 07-2011. This form evaluated nociceptive P, neuropathic P, care related P and emotional status. Glomerular filtration rate (GFR) was estimated using abbreviated Modification of Diet in Renal Disease (aMDRD). Pain killers (PK), antidepressant drugs (AD) and anxiolytics (AX) were studied with regard to dosage adjustment.

Results: 76 patients included, 60.5% males; median age, 58 years. 13 patients hemodialyzed and 15 transplanted. Median GFR was 32.5 ml/min/1.73 m^2. 42% and 34% referred at least one pain location for more than 3 months and for less than 3 months respectively. 60.5% received a PK. 19.7% had neuropathic P, 80% were not treated. 69.7% of patients suffered from care related P and 47.2% received a preventive treatment. Anxiety and depression occurred in 40.8% and 22.4 % respectively. 23.5% of depressive patients and 19.4% of anxious patients received an appropriate treatment. Of the 76 PK, AD and AX prescribed, 90.8% required dosage adjustment for RI. Of the 42 patients treated with PK, AD or AX, 59.5% received at least one such drug.

Conclusions: There is a high prevalence of P, anxiety and depression in our RI patients, and DDA is often necessary. P should be better evaluated by a P specialist in coordination with nephrologists for a better handling of those drugs that are used for psychological and physical pain management.

FR-PO141

Association of Mental Illness with Emergency Re-Hospitalization in People with Chronic Kidney Disease

Sterling Mcpherson,[1,2] Celestina Barbosa-Leiker,[1,2] Kenn B. Daratha,[1,3,4] Robert Short,[1,2,3] Katherine R. Tuttle.[1,3,4] *[1]Washington State University College of Nursing and WWAMI, Spokane, WA; [2]Rural Mental Health and Substance Abuse Treatment Program; [3]Providence Sacred Heart Medical Center and Children's Hospital; [4]University of Washington School of Medicine.*

Background: Chronic kidney disease **(**CKD) is associated with high risk for repeated hospitalization. Serious mental illness (SMI) is also associated with increased risk of hospital admission. The primary objective of this study was to determine if SMI further increases risk for re-hospitalization, particularly via the emergency department (ED), among people with CKD.

Methods: People hospitalized in the State of Washington from April 2006 to Dec 2008 were included in the study. Those with index diagnoses of CKD (N=31,166), SMI (defined by schizophrenia and/or mood disorder; N=20,167), and combined CKD and SMI (N=717) were separated into three cohorts for comparisons to the reference group without CKD or SMI (N=548,532). Main outcomes were re-hospitalization for conditions other than mental illness: 1) via ED; 2) any admission; and 3) admission resulting in death. Cox regression was used to analyze time to main outcomes controlling for multiple pre-specified covariates.

Results: Risk of re-hospitalization via the ED was increased for CKD (HR=1.28, 95%CI:1.25-1.31, p<.001) and SMI (HR=1.39, 95%CI:1.34-1.44, p<.001) cohorts, but was significantly greater in the combined cohort (HR=1.65, 95%CI:1.49-1.82, p<.001) relative to any other group. Risk of any re-hospitalization was increased for CKD (HR=1.22, 95%CI:1.19-1.25, p<.001) and SMI (HR=1.15, 95%CI:1.12-1.19, p<.001) cohorts, while significantly greater risk was observed for the combined cohort (HR=1.38, 95%CI:1.26-1.51, p<.001) compared to all other groups. Risk of re-hospitalization resulting in death was increased for CKD (HR=1.47, 95%CI:1.35-1.55, p<.001) and SMI (HR=1.07, 95%CI:1.00-1.15, p=.041) cohorts, but not in the combined group (HR=1.25, 95%CI:0.98-1.59, p=.075).

Conclusions: SMI increased risk of CKD patients experiencing hospitalization; particularly via the ED. Addressing SMI may be an important strategy for reducing emergency admissions in the CKD population.

FR-PO142

Depressive Symptoms and Health Outcomes among Patients with Chronic Kidney Disease: Findings from the Chronic Renal Insufficiency Cohort (CRIC) Study

Michael J. Fischer,[1] Ana C. Ricardo,[1] Neil Jordan,[3] Clarissa Jonas Diamantidis,[3] Dawei Xie,[3] Valerie L. Teal,[3] Amanda Hyre Anderson,[3] Lydia Bazzano,[3] Jing Chen,[3] John W. Kusek,[2] Kristine Yaffe,[3] Neil R. Powe,[3] James P. Lash.[1] *[1]Jesse Brown VAMC/U. Illinois; [2]NIH/NIDDK; [3]CRIC Study Group.*

Background: Depression is associated with increased morbidity and mortality in adults with chronic kidney disease (CKD). However, the impact of depression on a broad range of adverse clinical outcomes in diverse populations with CKD has not been well studied.

Methods: We assessed the relationship between baseline elevated depressive symptoms (DS) in CRIC Study participants and the following outcomes over a 5 year period: CKD progression [50% eGFR loss or end-stage renal disease (ESRD)], incident cardiovascular disease (CVD: myocardial infarction, congestive heart failure, stroke, or peripheral arterial disease), and all-cause death. DS were assessed by the Beck Depression Inventory (BDI) and defined by a BDI score >= 11. Cox proportional hazards models were used to determine the association between baseline DS and outcomes.

Results: Of 3,853 participants at study enrollment, mean age was 58 years, 45% were female, 42% white, 42% black, and 13% Hispanic. Twenty-seven percent had evidence of DS at baseline. During follow-up, rates (per 1000 person-years) of CKD progression (87.2 v. 52.7), incident cardiovascular disease (59.1 v. 39.3), and death (29.7 v. 22.3) were significantly higher in those with DS than in those without DS ($p<0.01$). After adjustment for site, demographics, and clinical factors including eGFR and urine protein, DS were significantly associated with an increased risk of CKD progression (HR 1.21; 95% CI: 1.03-1.43) and incident CVD (HR 1.21; 95% CI: 1.01-1.46) but not all-cause death (HR 1.21; 95% CI: 0.95-1.53).

Conclusions: In a large diverse CKD cohort, DS were independently associated with an increased risk of CKD progression and incident cardiovascular disease but not all-cause death.

Depression Is Associated with Declining Kidney Functioning in Patients with Chronic Kidney Disease Daniel Cukor,[1] Yvette Fruchter,[1] Ankita B. Patel,[2] Subodh J. Saggi.[2] *[1]Psychiatry, SUNY Downstate Medical Center, Brooklyn, NY; [2]Medicine, SUNY Downstate Medical Center, Brooklyn, NY.*

Background: The incidence and prevalence of Chronic Kidney Disease (CKD) is increasing with 17% of the US having CKD. Understanding the factors associated with declining renal function is of clinical significance. Current study surveyed CKD clinic patients with varying stages of GFR. Our main goal was to identify variables that could predict decline in GFR over time.

Methods: Seventy CKD patients completed psychological questionnaires and medical variables were extracted from the medical charts, by an investigator blinded to the patients' questionnaire responses. Follow-up Glomerular Filtration Rate (GFR) was collected 6 months later. CKD patients with elevated depression scores were compared to patients with sub-clinical depression on medical other psychological variables. The impact of depressive affect on variation in GFR scores was examined.

Results: Average Beck Depression Inventory (BDI) score was a 10.0 ± 7.8, placing the mean below the cut-off for clinical elevation. GFR was significantly different for the two groups (w/o depression = 40.0 ±11.3, with elevated depression 29.6 ± 8.9 ($p<.05$)). Similarly, patients with elevated depression scores reported lower quality of life (SF-36, $p<.05$) inferior social support (ISEL, $p<.05$), increased body image sensitivity (BIS, $p<.05$), and worse community integration (CIQ, $p<.05$). There were no between group differences on other medical variables ($p>.05$, all cases). Utilizing a regression, with a model correcting for baseline GFR, the depression explained 10% of the variance in declining GFR score ($t=2.0$, $p<.05$).

Conclusions: Increased levels of pre-existing depression were associated with inferior quality of life, social support and kidney functioning in CKD patients. Depression score explained a significant amount of variance in GFR scores at 6 months even when corrected for baseline variability. Elevated depression scores are prevalent in CKD populations and further research on the impact of depression intervention is warranted, with particular emphasis on improving adherence to both medical appointments and recommendations.

FR-PO144

Depression in People with Chronic Kidney Disease: A Meta-Analysis of Prevalence and Associations with Clinical Outcomes Suetonia Palmer,[1] Mariacristina Vecchio,[2] Valeria Maria Saglimbene,[2] Marinella Ruospo,[3] Fabio Pellegrini,[2] Giovanni F.M. Strippoli.[2,3,4] *[1]University of Otago; [2]Consorzio Mario Negri Sud; [3]Diaverum Medical-Scientific Office.*

Background: Depression is associated with mortality and cardiovascular events in the general population.

Studies evaluating depression in people with chronic kidney disease (CKD) provide variable estimates of prevalence and associations with clinical outcomes. We summarize the evidence on prevalence of and outcomes associated with depression in people with CKD and explore the effects of specific patient and study characteristics on these.

Methods: We conducted a systematic review and meta-analysis of observational studies reporting prevalence of or clinical outcomes related to depression in people with CKD. Studies were identified from systematic searching MEDLINE. Estimates of prevalence and associations with clinical outcomes were summarized using random-effects model. The effects of participant and study characteristics on prevalence and associations with outcomes were explored using meta-regressions.

Results: 201 studies (263 cohorts) including 121 648 people with CKD were analyzed. In 163 cohorts (112 577 participants) the prevalence of depression measured by any tool was 35% (95% confidence interval [CI] 32-39%). Stage of chronic kidney disease was an effect modifier; people on dialysis experienced a higher prevalence of depression (40% [CI 36-44%]), compared to those with earlier stages of CKD (27% [CI 17-40%]) and kidney transplant recipients (23% [CI 16-31%]). People with CKD and depression experienced higher risks of mortality (15 studies, 82,240 participants; risk ratio (RR)1.68 [CI 1.39-2.04]) and hospitalization (6 studies, 16 662 participants; RR 1.17 [CI 1.06-1.30]) compared to people with CKD not depressed. Subgroup analysis incompletely explained differences between studies.

Conclusions: Approximately one-third of people with CKD may be depressed. Prevalence of depression may be higher in people on dialysis and lower in people with earlier stages of CKD. Depression is associated with adverse clinical outcomes in observational analyses.

FR-PO145

Depression Associated with Higher Mortality in the Renal Research Institute Chronic Kidney Disease (CKD) Study Linton Cuff,[1] Anca Tilea,[1] Brenda W. Gillespie,[1] Fredric O. Finkelstein,[3] Margaret A. Kiser,[4] Aleksandar Milovanovic,[1] George Eisele,[5] Peter Kotanko,[2] Rajiv Saran.[1] *[1]Univ. of Michigan; [2]Renal Research Institute; [3]Metabolism Associates; [4]Univ. of North Carolina; [5]Med. College of Albany.*

Background: Depression is common in patients with end stage renal disease (ESRD) and predicts mortality in that setting. However, there is limited information on the prevalence and significance of depression as it relates to health outcomes in patients with CKD .

Methods: This prospective observational study enrolled patients in CKD stages 3-5. Demographic, medical, quality of life (QoL) and medication data were collected at baseline and at follow-up visits. The presence of a diagnosis of clinically documented depression (CDD) was verified by chart review. Patient-reported depressive symptoms (PRD) were inferred from responses to 2 specific questions pertaining to depression in the Kidney Disease QOL SF-36, as previously reported, using the 3 lowest out of 6 ordinal responses. Association between outcomes of death and ESRD with baseline PRD and CDD was assessed by Cox regression.

Results: Of 2,182 enrolled in the study, 1,414 patients completed the KDQoL at enrollment; 192 (14%) with PRD and 158 (7%) with CDD. Mean (±SD) age was 62±15 years, 53% were males and mean eGFR 25±10 ml/min/1.73m^2. In both unadjusted and adjusted models, depression (by either definition) was associated with significantly higher risk of mortality.

		Outcome:Death		Outcome:ESRD	
PRD	*Unadjusted*	1.66	0.06	1.18	0.30
	*Adjusted**	1.69	0.07	1.16	0.36
CDD	*Unadjusted*	1.78	0.03	0.96	0.84
	*Adjusted**	2.43	0.01	1.28	0.19
PRD or CDD	*Unadjusted*	1.65	0.04	1.11	0.44
	*Adjusted**	1.87	0.01	1.21	0.21

* Adjusted for baseline age, gender, race, eGFR, diabetes, and hypertension

Conclusions: A significant proportion (7-14%) of patients in this CKD cohort reported depressive symptoms or had a clinical diagnosis of depression. Depression by either definition was associated with higher risk of mortality. Systematic monitoring and management of depression in this patient population should therefore receive greater attention in the CKD population.

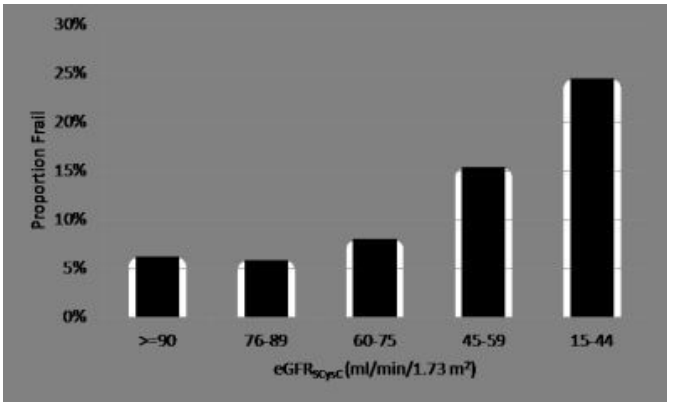
FR-PO146

Kidney Function and Frailty in Older Adults Lorien S. Dalrymple,[1] Ronit Katz,[2] Dena E. Rifkin,[3] Mark J. Sarnak,[4] David Siscovick,[2] Anne B. Newman,[5] Linda F. Fried,[5,6] Michael Shlipak.[7,8] *[1]UC Davis; [2]University of Washington; [3]UC San Diego; [4]Tufts Medical Center; [5]University of Pittsburgh; [6]VA Pittsburgh Healthcare System; [7]VA Medical Center San Francisco; [8]UC San Francisco.*

Background: Frailty is characterized by loss of physiologic reserve and increased vulnerability. The aim of this study was to examine whether lower levels of kidney function, estimated by serum cystatin C ($eGFR_{SCysC}$), were associated with a higher risk of prevalent and incident frailty.

Methods: The Cardiovascular Health Study is a prospective cohort study of adults ≥65. The exposure was $eGFR_{SCysC}$ (ml/min/1.73m^2) and outcomes were prevalent and incident frailty. Frailty was defined by weight loss, exhaustion, and physical limitations using validated criteria.[1] Logistic regression and Cox proportional hazards models estimated the risk of prevalent and incident frailty, respectively. Multivariable models included $eGFR_{SCysC}$, age, sex, race, diabetes, hypertension, heart disease, heart failure, body mass index, and tobacco use.

Results: Analyses of prevalent frailty included 4,150 participants with mean age of 75, 41% male, 17% black, and median $eGFR_{SCysC}$ 73. Prevalence of frailty differed by kidney function.



In multivariable analysis, eGFR$_{SCysC}$ 45-59 and 15-44 were associated with an 80% (OR 1.80;95%CI 1.17-2.75) and 187% (OR 2.87;95%CI 1.72-4.77) higher odds of frailty, respectively, when compared to eGFR$_{SCysC}$≥90. To examine incident frailty, the cohort was restricted to 3,459 participants followed for a median of 4 years. In multivariable analysis, eGFR$_{SCysC}$ was not associated with incident frailty (HR 1.03, 95%CI 0.94-1.13).

Conclusions: Lower level of kidney function is associated with a higher prevalence but not incidence of frailty. Ref: 1. Fried LP et al. Frailty in Older Adults: Evidence for a Phenotype. *J of Gerontology 56(3):M146-156, 2001.*

Cystatin C and Risk of Frailty and Mortality in Older Men Allyson Hart,[1] Areef Ishani,[1] Misti L. Paudel,[1] Brent C. Taylor,[1] Eric Orwoll,[2] Peggy M. Cawthon,[3] Kristine E. Ensrud.[1] *[1]University of Minnesota/Minneapolis VA, Minneapolis, MN; [2]Oregon Health Sciences Center, Portland, OR; [3]California Pacific Medical Center Research Institute, San Francisco, CA.*

Background: Declining kidney function and frailty are common with aging. A prior cross-sectional study reported that higher cystatin C (cysC) was associated with greater prevalent frailty status, but longitudinal associations of cysC with incident frailty and death at follow up are uncertain.

Methods: Serum cysC and creatinine (Cr) were measured at baseline among 1242 non-frail community dwelling men aged ≥65 yrs (mean age 73.8 yrs). Repeat frailty status assessment was performed an average of 4.6 years later. Frailty status (comprised of shrinking, weakness, exhaustion, slowness and low physical activity) was defined as an ordinal outcome of robust, intermediate stage, and frail based on the number of frailty components present (0, 1-2, or ≥ 3 respectively). Vital status was assessed every 4 months. CysC, Cr, and eGFR$_{Cr}$ were expressed in quartiles. Multinomial logistic regression analyses were adjusted for age, race, clinical site, and baseline frailty status (intermediate vs robust).

Results: At follow up, 546 men (44%) were intermediate stage, 113 (9.1%) were frail and 129 (10.4%) died in the interim. Higher cysC was associated in a graded manner with increased odds of intermediate stage (vs robust) and frail (vs robust), and also associated with a higher risk of mortality (vs robust).

Quartile of Baseline Cys.C[a]	Odds Ratio (95% CI)[b]		
	Intermediate (Pre-frail) vs. robust	Frail vs. robust	Dead vs. robust
Q1 (referent)	1.0	1.0	1.0
Q2	1.44 (1.00 – 2.08)	1.38 (0.69 – 2.77)	0.70 (0.33 – 1.51)
Q3	1.55 (1.05 – 2.29)	1.52 (0.75 – 3.09)	1.63 (0.85 – 3.15)
Q4	1.41 (0.93 – 2.15)	1.90 (0.94 – 3.81)	2.67 (1.40 – 5.11)
p for linear trend	0.08	0.05	<0.001

[a] Quartile cutpoints 0.80, 0.90, 1.03
[b] Adjusted for age, race, clinical site and baseline frailty status

In contrast, higher serum Cr and lower eGFR$_{Cr}$ were not related to frailty status and death at follow up.

Conclusions: Among non-frail older men, higher cysC, but not serum Cr or eGFR$_{Cr}$ was associated with a higher odds of greater frailty status and an increased risk of mortality at follow up. These results suggest that cystatin C may be a promising biomarker for identification of older adults at increased risk of adverse health outcomes.

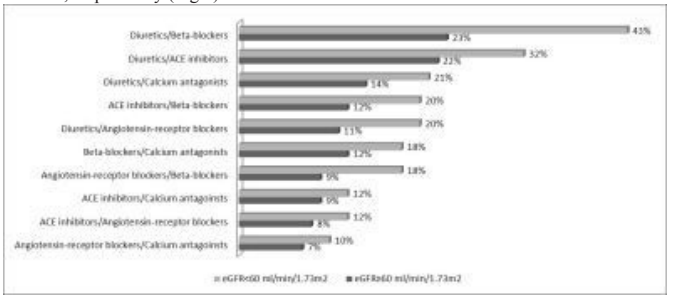
FR-PO148

Antihypertensive Medication and Kidney Function in Individuals at Age ≥70, the Berlin Initiative Study Natalie Ebert,[1] Olga Jakob,[2] Reinhold Kreutz,[3] Peter Martus,[4] Elke Schaeffner.[1] *[1]Nephrology, Charité, Berlin, Germany; [2]Biostatistics, Charité, Berlin, Germany; [3]Clinical Pharmacology, Charité, Berlin, Germany; [4]Biostatistics, Eberhard Karls University, Tübingen, Germany.*

Background: High blood pressure (BP) is one of the most prevalent risk factors for cardiovascular disease, especially at age ≥70. Prevalence data of hypertension in people ≥70 yrs in combination with data on kidney insufficiency are scarce.

Methods: Data are from baseline visit of the Berlin Initiative Study, a population based prospective cohort of 2070 individuals, mean age 80 yrs. A complete list of medication was electronically linked to a German "Rote Liste" reference coding system to identify and classify antihypertensive medication. Office BP was measured twice electronically and eGFR was determined using the CKD-Epi estimating equation.

Results: Overall 61% were hypertensive with 34, 18, and 9% presenting with stage I, II, and III, respectively. Mean BP was 146/81 mmHg. 78% of 2070 participants were on antihypertensive medication. Among those 21, 22, and 19% were receiving 1, 2 and 3 classes of antihypertensives, respectively. Age- and sex-specific means of BP did not significantly differ by eGFR ≥ or <60 ml/min/1.73m^2 (t-test). Participants were prescribed a median of 4 drugs of which 2 were antihypertensives. Most common substances were diuretics (48%), beta-blockers (46%), and ACE inhibitors (27%). Most common combinations were diuretics/beta-blockers and diuretics/ACE inhibitors in individuals with eGFR ≥60 and <60, respectively (Fig 1).



Conclusions: In our elderly cohort we saw a high prevalence of hypertension and antihypertensive treatment. Moreover, mean BP was 146/81 mmHg and thus comparable to target BP of the HYVET trial in octogenarians. No significant differences of BP means were observed when eGFR was ≥ or <60, probably due to effective treatment of participants with decreased GFR.

Octogenarians with Advanced Chronic Kidney Disease (CKD): A Longitudinal Follow-Up Study Ulka M. Desai,[1,2] Nicole Piero,[2] Loretta Simbartl,[2] Christine Edie,[2] Kristen Schmitt,[2] Charuhas V. Thakar.[1,2] *[1]Nephrology and Hypertension, University of Cincinnati, Cincinnati, OH; [2]Renal Section, Cincinnati VA, Cincinnati, OH.*

Background: Octogenarians represent 28% of older US adults and have high prevalence of CKD. Several studies have evaluated outcomes of older dialysis patients. We conducted a longitudinal follow-up of patients older than 80 years (yrs) with advanced CKD and measured parameters of resource utilization and clinical outcomes.

Methods: Between 1/1/06 and 12/31/08 there were 398 patients seen at a Veterans Affairs healthcare system that were > 80 yrs of age and had one outpatient measure of estimated glomerular filtration rate (eGFR) of < 30 ml/min/1.73m2. 78 were excluded (missing data/dialysis at baseline), and 320 were followed until 12/31/2011. Variables included demographics, co-morbidities, resource utilization parameters (renal clinic visits, medical/surgical hospitalizations), and lab parameters (creatinine, eGFR, overt proteinuria). Probability of dialysis and death before dialysis was estimated after accounting for other patient characteristics.

Results: The cohort was 97.5% male (mean age - 84.5 yrs). Median eGFR at the beginning of the study was 26 ml/min/1.73m2 (q1, 22, q3, 28). 44% had diabetes, 94% had hypertension, 86% had heart disease, 57% had proteinuria when assessed. 54% of patients sought nephrology care (renal visits 1-15) during study period. 165 (51%) patients requried hospitalization (15% - primary diagnosis was altered mental status). 18% underwent major/minor surgery. 23% of hospitalizations were associated with falls/trauma. The adjusted probability of dialysis was 7% [95% confidence limit (CI) 4.9% - 11%], and it was 69% (95% CI, 64% - 74%) for death before dialysis. From the beginning of the study period, median time to death and dialysis was 1.4 yrs (q1, 0.5, q3, 2.4) and 1.7 yrs (q1, 1.1, q3, 2.7) respectively. 75% dialysis patients died (median time to death 3.3 months; q1, 1.1, q3, 15.2).

Conclusions: Octogenarians with advanced CKD are 9-times more likely to die than start dialysis; survival after dialysis remains poor. Individualized care may be more appropriate in this age group rather than "guideline" based CKD management.

FR-PO150

Loss of Renal Function in the Elderly: Physiology or Pathology?
Ciro Esposito,[1] Marta Arazzi,[1] Massimo Torreggiani,[1] Nicoletta Serpieri,[2] Maria Lucia Scaramuzzi,[2] Alessandra Manini,[2] Davide Catucci,[1] Edoardo La Porta,[1] Antonino Dal Canton.[2] *[1]Nephrology, Fondazione IRCCS S. Maugeri, University Pavia, Pavia, Italy; [2]Nephrology, Fondazione IRCCS San Matteo, University Pavia, Pavia, Italy.*

Background: In 1950 Davies and Shock showed that GFR decreases at a rate of 1 ml/min/year after the third decade of age. Nowadays it seems that CKD is outbreaking, mostly in the elderly. The aim of our study was to assess the progression of CKD in different ages.

Methods: We conducted a monocentric, retrospective, observational study enrolling 116 patients afferent to our outpatient clinic. Inclusion criteria: age>18 years, follow-up≥5 years, eGFR<60ml/min/1,73m^2 and/or diagnosed renal disease and/or presence of renal damage. We excluded all the patients without at least one control a year and those who presented with acute renal failure at the first visit. Patients were divided into four groups according to their age: 25-55 years (n=27), 56-65 (25), 66-75 (42), 76-87 (22). eGFR was calculated using the MDRD and the CKD-EPI formulas.

Results: Younger patients had a significantly longer follow-up and less comorbidities, evaluated by the CIRS score, compared to the other groups. There was no difference between creatinine at baseline and at the end-of-follow-up period among the groups. Even though renal function significantly decreased in all groups, we noticed a slower progression as the age increased and the difference between basal and end-of-follow-up eGFR was minimal in the group of patients aged 76-87 years. Analyzing the eGFR of every ambulatory control plotted against the year of follow-up, we showed a more rapid loss of filtrate in the younger group. Instead, loss of renal function decreased as the age of patients increased.

Conclusions: Renal function loss progresses more slowly in the elderly than in young patients. Therefore, these patients should not be considered as CKD patients but they should be followed closely by their family physician as they are at greater risk of developing acute renal failure or suffer from cardiovascular complications.

FR-PO151

Rehospitalizations among Elderly Chronic Kidney Disease Patients
Tricia L. Roberts,[1] David T. Gilbertson,[1] Craig Solid,[1] Allan J. Collins.[1,2] *[1]USRDS Coordinating Center, MMRF, Minneapolis, MN; [2]Medicine, University of MN, Minneapolis, MN.*

Background: The reduction of rehospitalizations among Medicare beneficiaries remains a current public policy objective. Previous studies have shown high rehospitalization rates among general Medicare and hemodialysis patients: respectively, nearly one fifth and over one third of hospital discharges were followed by a 30-day rehospitalization. However, current rehospitalization rates among the chronic kidney disease (CKD) population have not been analyzed.

Methods: Rehospitalization rates were calculated among prevalent Medicare CKD patients on January 1, 2010, age 66 and older, using the 5% Medicare sample. During 2009, CKD stage was defined and patients were continuously enrolled in Medicare. ESRD patients were analyzed separately. Live all-cause hospital discharges were included from January 1 to December 1, 2010, and patients with at least one discharge were included. Data excluded rehabilitation claims, transfers, and discharges with a same-day admission to long-term care and critical access hospitals. Events were first rehospitalization and/or mortality. Rates indicated the percent of live discharges with an event within 30 days. Annual adjusted rehospitalization rates were computed using direct adjustment.

Results: Results included 63,031 discharges from 34,862 CKD patients. Rehospitalization rates within 30 days among CKD patients were 24% compared to 18 and 34% for non-CKD and ESRD, respectively, and those for death or rehospitalization were 30% compared to 22 and 39%. Rates increased with CKD severity: rates in CKD stage 4-5 were 26% compared to 23% in stage 1-2 CKD. Among CKD patients, rates were highest among non-white races (27-28%). Adjusted rehospitalization rates among CKD patients decreased only slightly from 27% in 2002 to 24% in 2010.

Conclusions: Nearly one in four hospital discharges among CKD patients were followed by a 30-day rehospitalization, and rates improved minimally in the last decade. Findings support rehospitalization reduction efforts among CKD in addition to ESRD populations. Awareness of high-risk subgroups, including non-white and late-stage patients, could guide reduction efforts.

FR-PO152

A Prospective Study of Serum Uric Acid and Albuminuria in Older Adults: The Rancho Bernardo Study
Simerjot K. Jassal,[1] Caroline K. Kramer,[2] Elizabeth Barrett-connor.[3] *[1]Medicine, VASDHS & UCSD, San Diego, CA; [2]Endocrinology, Hospital de Clínicas de Porto Alegre, Universidade Federal do RioGrande do Sul, Porto Alegre, Rio Grande do Sul, Brazil; [3]Family & Preventive Medicine, UCSD, La Jolla, CA.*

Background: Serum uric acid is associated with albuminuria in those with diabetes, but the association in healthy older adults without diabetes and whether sex differences exist in this association has not been described. We investigated the cross-sectional and longitudinal association between uric acid and albuminuria by urine albumin/creatinine ratio (ACR) in a population of older community-dwelling men and women.

Methods: Uric acid and ACR were measured in 1070 women and 694 men, aged 30-97 (mean 71) years at a baseline visit in 1992-1996 and again in 657 women and 402 men who returned in 1997-99 (mean 3.5 years later). Multivariable linear regression was used to evaluate the association between baseline uric acid and logACR at baseline and follow-up and logistic regression to assess for an association between baseline uric acid and ACR>30mg/g at baseline and follow-up, before and after stratifying by diabetes status and gender.

Results: At baseline, mean uric acid was 4.8mg/dL and median ACR was 12mg/g. In multivariable analyses adjusted for baseline age, sex, body mass index, systolic blood pressure, fasting plasma glucose, estimated glomerular filtration rate and diuretic use, baseline uric acid was not associated with logACR in cross-sectional analyses in any group. In longitudinal analyses, baseline uric acid was associated with follow-up logACR in the entire cohort (β=0.056, p=0.045). In stratified analyses, this association persisted in those without diabetes (β=0.075, p=0.010) but not those with diabetes, and in men (β=0.167, p=0.002) but not in women. In categorical analyses, there was a significant association between baseline uric acid and ACR>30mg/g at the follow-up only in men (OR 1.53, 95%CI 1.13-2.07, p=0.006).

Conclusions: In a cohort of community-dwelling older adults, baseline uric acid was independently associated with future albuminuria among those without diabetes and in men but not women.

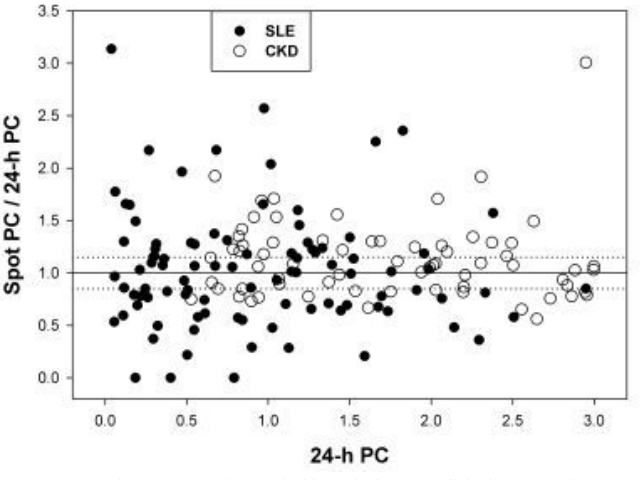
FR-PO153

Inaccuracy of Morning Spot PC Ratio to Estimate 24-h Proteinuria (Pr) Magnitude in Individual Patients with Non-Diabetic Chronic Kidney Disease (CKD) or Lupus Nephritis (LN)
Ganesh B. Shidham,[1] Daniel J. Birmingham,[1] Annalisa Perna,[2] Derek M. Fine,[3] Roger A. Rodby,[4] Giuseppe Remuzzi,[2] Brad H. Rovin,[1] Lee A. Hebert.[1] *[1]Division of Nephrology, The Ohio State University; [2]Instituto de Richerche Farmacologiche, Italy; [3]Johns Hopkins School of Medicine; [4]Rush-Presbyterian Medical Center.*

Background: Spot PC ratio is used clinically to estimate Pr magnitude. However, urine PC ratio shows considerable diurnal variability. Short collections (e.g. spot) reveal this variability. Long collections (e.g.≥ 50% of a complete 24-h collection) conceal this variability. So, the PC ratio of a long collection is a more accurate estimate of the 24-h urine PC ratio than the PC ratio of a short collection. Despite this limitation of short collections, spot PC ratio has performed well in cohort studies where it strongly correlates with 24-h Pr, and predicts CKD progression better than 24-h Pr. However, in cohort studies of spot PC ratio variability is offset by averaging. By contrast, patient management, decisions are often based on a single spot PC ratio. Here, spot PC ratio variability becomes a liability, as we and others have found in LN.



Methods: The present work extends this analysis to non-diabetic CKD patients (REIN trial, 98 pts) and compares it by correlation coefficient and calibration plot to an expanded LN cohort (81pts).

Results: Similar to previous reports, we found a strong statistical association between spot PC ratio and 24 Pr (e.g. P<0.001) however r^2 is weak. (e.g. nephrotic range r^2 =0.164 (CKD) and 0.361 (LN). The figure shows the calibration plot for the subnephrotic range. The dotted lines show the expected limits of agreement if spot PC was an aliquot of the 24hr collection.

Conclusions: Spot PC can be substantially inaccurate in estimating 24hr PC ratio in both CKD and LN. The impact of this inaccuracy on patient management needs further study.

FR-PO154

Influence of Urine Creatinine on the Relation of Albumin to Creatinine Ratio with Cardiovascular Disease Events: The Multi-Ethnic Study of Atherosclerosis Caitlin E. Carter,[1] Ronit Katz,[2] Holly J. Kramer,[3] Ian H. de Boer,[2] Carmen A. Peralta,[4] David Siscovick,[2] Mark J. Sarnak,[5] Andrew S. Levey,[5] Lesley Stevens Inker,[5] Matthew Allison,[1] Michael H. Criqui,[1] Michael Shlipak,[4] Joachim H. Ix.[1] *[1]UC San Diego; [2]University of Washington; [3]Loyola Medical Center; [4]UC San Francisco; [5]Tufts Medical Center.*

Background: Urine creatinine (UCr) correlates with muscle mass and low muscle mass is associated with cardiovascular disease (CVD) events. Whether muscle mass, as reflected by urine creatinine, influences the association between modest elevations in albumin/creatinine ratio (ACR) and CVD events remains poorly explored.

Methods: Among a multi-ethnic cohort of 6,770 without CVD, ACR was measured and participants were followed for median 7.1 years for CVD events (MI, stroke, cardiac arrest, and fatal CVD or stroke). Cox regression evaluated associations of doubling of 1/UCr, urine albumin (UA), and ACR with CVD events in an unadjusted model and models adjusted for demographics and CVD risk factors. Associations of ACR≥10mg/g v. lower with CVD events were evaluated in strata by age (≥ 65 years v younger), sex, race, and weight (tertiles).

Results: Female, older, white or Chinese, and lower weight participants had higher 1/UCr (p<0.001 for all). 1/UCr was not significantly associated with CVD events, whereas higher UA and ACR were. (Table 1)

Table 1. Association of Spot Urinary Indices with CVD Events in MESA.

	HR* (95%CI)
1/UCr	1.04 (0.94, 1.16)
UA	1.21 (1.16, 1.28)†
ACR	1.26(1.20, 1.33)†

*Hazard Ratio (95% CI) per doubling; †p<0.001

Results were similar in adjusted models. ACR≥10mg/g was more strongly associated with CVD in the lowest v. highest weight tertiles (HR 4.34 v. 1.97; p-interaction=0.006). No effect modification was seen by age, gender, or race (p-interactions all > 0.362).

Conclusions: Females, and older, lower weight, and non-black participants have lower UCr. The association of ACR≥10 mg/g with CVD events was stronger in those with low body weight. If confirmed in future studies, the ACR may be biased towards stronger associations with CVD in low weight individuals.

Longitudinal eGFR Trajectories in Patients with Type 2 Diabetes and Nephropathy Hiddo Jan Lambers Heerspink,[1] Liang Li,[4] Paul Smink,[1] Tom Greene,[2] Hans-Henrik Parving,[3] Dick de Zeeuw.[1] *[1]Clinical Pharmacology, University Medical Center Groningen, Groningen, Netherlands; [2]University of Utah, Salt Lake City, UT; [3]Medical Endocrinology, University Hospital of Copenhagen, Copenhagen, Denmark; [4]Cleveland Clinic, Cleveland, OH.*

Background: In contrast to the traditional paradigm of a linear glomerular filtration rate (GFR) decline, a recent study in 846 Afro-Americans with hypertensive nephrosclerosis documented that 42% of patients exhibit a > 90% probability of a nonlinear GFR trajectory or a prolonged period of non-progression. We here describe the estimated GFR (eGFR) trajectories of subjects with type 2 diabetes, nephropathy, and proteinuria.

Methods: Data from the Reduction of Endpoints in NIDDM with the Angiotensin II Antagonist Losartan (RENAAL) trial was used for analysis. RENAAL participants had albuminuria >300 mg/g and serum creatinine values between 1.3 and 3.0 mg/dL. eGFR was calculated every 3 months during an average of 3.4 years follow-up. A total of 1086 subjects (72%) with more than 2 years follow-up and available eGFR measurements were included in order to estimate accurate eGFR trajectories. The probability of a nonlinear trajectory and the probability of a period of non-progression were calculated for each patient from a Bayesian model of individual eGFR trajectories as described earlier.[1]

Results: 101 (9%) patients showed a >90% probability of having a nonlinear trajectory or prolonged period of non-progression; in 419 (39%) the probability was > 0.5. Higher baseline eGFR (β=0.0014; p=0.049) and lower baseline albuminuria (β=0.030; p=0.001) were associated with a higher probability of a nonlinear eGFR decline or period of nonprogression.

Conclusions: The majority of patients with type 2 diabetes, nephropathy and proteinuria have a progressively linear eGFR trajectory in 3 to 4 years follow-up, unlike Afro-Americans with hypertensive nephrosclerosis and minimal proteinuria in ~10 years follow-up. These data support the paradigm that in type 2 diabetes and nephropathy renal function loss progresses linearly over time.

FR-PO156

The Classification Tree Methodology: A New Way to Estimate the Risk and the Predictors of Progression of Chronic Kidney Disease Marcora Mandreoli,[1] Paola Rucci,[2] Dino Gibertoni,[2] Mattia Corradini,[3] Antonio Santoro.[1] *[1]Dept. of Nephrology; Dialysis and Hypertension, Policlinico S. Orsola-Malpighi, Bologna, Italy; [2]Dept. of Public Health and Statistic, University of Bologna, Bologna, Italy; [3]Dept. of Nephrology and Dialysis, Arcispedale S. Maria Nuovo, Reggio Emilia, Italy.*

Background: The measurement of eGFR alone does not give any information as to the rate of CKD progression which is relevant from a clinical point of view. In a large cohort of patients participating in a Regional Program of Prevention of Progressive Renal Insufficiency (PIRP project) we have evaluated the rate of decline of GFR and the factors influencing that decline.

Methods: We analyzed data of 2109 outpatients entering in the PIRP Registry of Emilia Romagna Region, who had at least 4 assessments of GFR to evaluate the annual variation of their GFR using a classification tree analysis (CTA). This methodology was used to define a predictive model of CKD progression using gender, age, BMI, comorbidities, smoke, baseline creatinine and other laboratory variables as independent variables.

Results: The mean age was 70.5± 8.9 years; Female 34.7%. The prevalence of the major comorbid conditions was 32.5% for DM, 55.6% for cardiovascular diseases. The average estimated annual decline in GFR was -1.5 ml/min/1.73 ± 4.3 m^2. The final CTA identified three age-groups with a significantly different decline in GFR: **i) group 1** aged ≤53 years, having the highest annual decline (-3.5 ml/min/1.73 m^2); **ii) Group 2** aged 54-67 years, with moderate decline in GFR (-2.19). In this group diabetic patients and patients with a serum phosphate level more than 3.7 mg/dL, had a faster progression of their CKD. **iii) Group 3** aged >67 years with a slight decline (-1.06). The presence of a proteinuria in this group was an acceleration factor in the GFR decline.

Conclusions: CTA allows for the identification of patients with a different rate of decline in kidney function. Having this information may be important from the clinical point of view because it allows for an intensification in the surveillance and the clinical controls for patients classified as 'fast progressors' and instead reduce it for those who can be considered 'slow progressors.'

FR-PO157

Is Renal Replacement Therapy a Precise Hard Renal Endpoint in Drug Trials? Misghina Tekeste Weldegiorgis,[1] Hiddo Jan Lambers Heerspink,[1] Dick de Zeeuw,[1] Ron T. Gansevoort,[1] Julia Lewis,[2] Hans-Henrik Parving,[3] Vlado Perkovic.[4] *[1]Clinical Pharmacology, University Med Center Groningen, Groningen, Netherlands; [2]Nephrology, Vanderbilt University, Nashville, TN; [3]Med. Endocrinology, University of Copenhagen, Copenhagen, Denmark; [4]George Institute, Sydney, Australia.*

Background: Renoprotective drugs are registered for preventing end-stage-renal-disease. Renal replacement therapy (RRT; chronic dialysis or renal transplantation) is used as a hard clinically relevant endpoint in drug trials, since it reflects the failure of proper kidney function. However, RRT initiation may be based on many factors beyond GFR such as patient wellbeing, doctor habits, and local guidelines. We assessed whether RRT initiation is driven by changes in serum creatinine (eGFR) or whether it is influenced by other factors.

Methods: We performed a post-hoc analysis of the RENAAL and IDNT trials. We used within patient linear regression to estimate the time to reach eGFR 11 ml/min/1.73m^2 and compared this with the actual time to reach RRT as recorded in the trial. Logistic regression was performed to identify factors that were associated with RRT onset before reaching eGFR 11.

Results: In RENAAL 341 patients started RRT. Of these 100 patients started RRT before and 241 after reaching eGFR 11. In univariate regression various characteristics were associated with RRT initiation before eGFR 11 such as male gender, body weight, blood pressure, hemoglobin (Hb), and proteinuria (UP). Independent determinants of RRT initiation before eGFR 11 were male gender [OR 2.4, (95% CI 0.9-6.4)], Hb [OR 0.7, (0.5-0.9)], and UP [OR 2.1, (1.3-3.3)]. A large variability was observed between the time to reach eGFR 11 and RRT: only 34% of subjects reached eGFR 11 within 90 days of the actual RRT decision. Similar results were found in the IDNT trial.

Conclusions: The initiation of RRT may be driven by many parameters beyond serum creatinine alone. These factors may vary among patients and physicians. Interventions could treat a symptom of uremia and delay RRT but not slow the rate of eGFR decline. In this instance using RRT as clinical trial endpoint may be testing drug effects beyond the drug's ability to prevent GFR decline.

FR-PO158

Systematic Analysis of Nephrology Studies in ClinicalTrials.gov Jula K. Inrig,[1,2] Robert M. Califf,[2] Asba Tasneem,[2] Karen Chiswell,[2] Uptal D. Patel.[2] *[1]UT Southwestern, Dallas, TX; [2]Duke Clinical Research Institute, Durham, NC.*

Background: The quality and quantity of clinical trials in nephrology may be lower than other medical specialties, however, the overall profile of recent trials following mandatory registration is not known. Thus, we performed a systematic analysis of nephrology studies using data from ClinicalTrials.gov.

Methods: Between October 2007-September 2010, 40,970 interventional studies were registered with ClinicalTrials.gov. Physician reviewers annotated Medical Subject Heading terms and Conditions by disease areas & studies were individually reviewed to validate classification by clinical specialty. Trial characteristics within and between specialties were compared using chi-square tests.

Results: Of 40,970 trials overall, 1,054 were classified as nephrology (2.6%). The majority of nephrology trials were for treatment (75.4%) or prevention (15.7%) with very few diagnostic, screening, or health services research studies (2.2%, 0.3%, and 1.4%, respectively). Compared to 2,264 cardiology trials (5.5% overall), nephrology trials were more likely to be smaller (64% enrolling <100 patients vs 48% in cardiology), to be phase I-II (29% vs 20%), to have a crossover study design (9.4% vs 5.4%), to have more than 2 study arms (18% vs 13%), and to be unblinded (66% vs 53%; p<0.05 for all). Although not significant during this limited time period, analyses of trends suggest improvements over time in use of more rigorous trial design features in nephrology studies. When compared to cardiology, nephrology trials were also more likely to include a drug intervention (72.4% vs 41.9%), have an endpoint classified as pharmacokinetic, pharmacodynamics or both (9.7% vs 3.3%), and include US sites only (38% vs 32%; p<0.05 for all). Finally there were few registered trials funded by the NIH during this time period (3.3% for nephrology and 4.2% for cardiology).

Conclusions: Critical differences remain between clinical trials in nephrology and other specialties such as cardiology. Improving care for patients with kidney disease will require a concerted effort between the NIH, industry, academia, and key stakeholders to increase the scope, quality, and quantity of clinical trials within nephrology.

Methodological Considerations in the Study of Kidney Function Decline

Michael Sachs,[1] Bryan R. Kestenbaum,[1] Ian H. de Boer,[1] Jonathan Himmelfarb,[1] Michael Shlipak,[2] Mark J. Sarnak,[3] Carmen A. Peralta,[2] Joachim H. Ix,[4] Ronit Katz,[1] David Siscovick,[1] Cassianne Robinson-Cohen.[1] *[1]University of Washington, Seattle, WA; [2]University of California, San Francisco, CA; [3]Tufts Medical Center, Boston, MA; [4]University of California, San Diego, CA.*

Background: Change in kidney function is an important and increasingly common outcome in clinical research studies. The standard approach to modeling change in estimated glomerular filtration rate (eGFR) is to estimate the subject-specific slope between time and eGFR. However, linear slope is often strongly associated with baseline eGFR, creating potential bias and complicating the analysis and interpretation.

Methods: We created a relative change model by estimating the subject-specific slope between time and log-transformed eGFR in 4,436 participants in the Cardiovascular Health Study (CHS), a community-based cohort of older adults, and in 380 participants in the Seattle Kidney Study (SKS), a clinic-based cohort with chronic kidney disease (CKD). We estimated GFR using the CKD-EPI equation.

Results: The number of eGFR measurements range from 2 to 3 in CHS and from 2 to 6 in SKS. Mean relative change (SD) in eGFR was -3.7% (3.9%) in the CHS and -7.4% (20.6%) in SKS. In CHS the Pearson correlation between baseline and change in eGFR was 0.001 in the relative change model compared to -0.22 in the linear change model. In SKS, the correlation between baseline and change in eGFR was 0.06 in the relative change model compared to -0.26 in the linear change model. The relative change model yielded stronger and more precise estimates for associations of known risk factors with kidney function decline.

Conclusions: In two observational cohorts, the use of a relative decline eGFR model dissociates longitudinal change in eGFR with baseline eGFR, more precisely models associations for known kidney disease risk factors, and yields coefficients that are easily interpretable as proportionate decline in eGFR over time. This method should be considered for evaluating changes in eGFR over time in observational studies. Further evaluation is warranted in other study populations and different study designs.

FR-PO160

Evaluating Four Methods of Assessing Protein Excretion and Their Relationship with Chronic Kidney Disease Progression

Boon Wee Teo, Ping Tyug Loh, Titus W. Lau, Evan J.C. Lee. *Medicine, National University Health System, Singapore, Singapore.*

Background: 24-hour urine protein excretion rate (24UPE) is most predictive of chronic kidney disease (CKD) progression or glomerular filtration rate (GFR) decline. Spot urine protein-creatinine ratio (UPCR) and albumin-creatinine ratio (UACR) estimations of 24-hr urine protein excretion (24UPE) and 24-hour urine albumin excretion (24UAE), respectively, are used in clinical practice. But the established accuracy of these ratios for estimating 24-hour urine collections predated the standardization of creatinine assays. Moreover, the reliability of these ratios for predicting GFR decline is unclear. We evaluated 4 methods of assessing urine protein excretion: UPCR, UACR, 24UPE and 24UAE to GFR decline in a multi-ethnic Asian population with a variety of CKD.

Methods: The Asian Kidney Disease Study prospectively collected 24-hour urine followed by early morning spot urine, which were analyzed for protein (pyrogallol-based assay), albumin (turbidimetry), and creatinine (enzymatic assay). 225/232 participants had a follow-up serum creatinine. We estimated GFR using the CKD-EPI equation. To compare the predictive performance of urine protein assessment methods with GFR decline, we developed models using stepwise linear regression. The urine protein assessment method in the best model was substituted in turn for three additional models. Variables with p-values ≤0.05, age, gender, and ethnicity were included in the final models.

Results: All models had good predictive performance, with the best performance in the model that included 24UPE, followed in order by 24UAE, UPCR, and UACR.

Models predicting GFR decline*

Model	R2	Model p-value	Proteinuria assessment	P-value	AIC	BIC
1	0.1224	<0.001	24UPE	<0.001	514	547
2	0.1084	<0.001	24UAE	<0.001	520	550
3	0.1009	0.0032	UPCR	0.0015	522	555
4	0.0758	0.0156	UACR	0.0019	528	558

Includes age, sex, ethnicity

Conclusions: 24-hour urine protein excretion rate is the best predictor of kidney disease progression. However, all the 4 methods correlated well with GFR decline, and any method can be used in routine clinical practice.

The NKFI KidneyMobile: A Mobile Resource for Community Based Screenings of Chronic Kidney Disease and Its Risk Factors

Michael J. Fischer,[1,2] Laurie Ruggiero,[2] Nicole M. Sisen,[3] Nancy Lepain,[3] Kate Grubbs O'Connor,[3] Weihan Zhao,[2] James P. Lash.[2] *[1]Jesse Brown VAMC; [2]U. Illinois; [3]NKFI.*

Background: Early detection and treatment of chronic kidney disease (CKD) and its risk factors improves health outcomes; however, many high-risk individuals do not have access to routine health care or screenings. The National Kidney Foundation of Illinois (NKFI) developed the KidneyMobile (KM) to conduct community based screenings, education, and follow-up for diabetes, hypertension, and CKD in Illinois.

Methods: We conducted a cross-sectional analysis of NKFI KM participants between 2005 and 2011 throughout Illinois. Working with community partners, the NKFI selected KM sites designed to reach high-risk and vulnerable communities. Sociodemographics, medical history, vital signs, anthropometric measures, and laboratory tests were assessed at the screening visit. Consensus definitions based on these data were used to define the presence of hypertension (HTN) or diabetes (DM). CKD was defined by eGFR < 60 ml/min/1.73m^2 or urine albumin/creatinine >= 30mg/g. Telephone interviews were conducted post-screenings with participants with abnormal findings to determine follow-up activities. Descriptive statistics were used to characterize all findings.

Results: Among 23,166 adults, mean age was 54 years, 68% were female, 51% were African-American or Hispanic, 24% primarily spoke Spanish, and over 30% lacked health insurance. At screenings, 65% of adults not reporting HTN and 10% not reporting DM were found to have these conditions, while 24% of participants not reporting kidney disease met criteria for CKD. In adults with known HTN, 42% had blood pressure >= 140/90 mmHg, while in those with known DM, 44% had HbA1c > 8%. Among 4,937 participants with abnormal findings and post-screening interview, 75% had a physician appointment and further evaluation.

Conclusions: A high-risk disadvantaged population with limited resources is being reached by the NKFI KidneyMobile's community based screenings and being connected to appropriate healthcare services. A significant proportion of these individuals were either given a new diagnosis of DM, HTN, and CKD or informed that their DM and HTN were poorly controlled.

The CKD Express©: A New Effective, Efficient and Cost-Saving IT-Based Program to Expedite CKD Care among Large Populations: Results of a Pre-Design CKD Survey

Macaulay A. Onuigbo,[1,2] Nnonyelum T. Onuigbo.[3] *[1]College of Medicine, Mayo Clinic, Rochester, MN; [2]Nephrology, Mayo Clinic Health System, Eau Claire, WI; [3]Information Technology, NTEC Solutions LLC, Eau Claire, WI.*

Background: Over 15% of the US population has CKD. Despite increased calls for referrals of later stage CKD patients to nephrologists, it remains unclear whether this model of care is indeed cost-effective. Also, the natural history of CKD in the general population is uncertain. Furthermore, the escalating cost of the US healthcare system is unsustainable; healthcare costs will increase from $2.5 trillion in 2009 to over $4.6 trillion by 2020. Besides, quality outcomes are suboptimal, and care is fragmented and poorly coordinated. My UW Consortium MBA class developed a new IT-based program to optimize population-based CKD care in a resourceful and yet cost-cutting manner.

Methods: We completed a market survey of CKD patients, with family members/medical staff serving as surrogate patients, to assess the level of satisfaction with current CKD care. We subsequently carried out a market analysis and competitive analysis of the new product.

Results: There were 80 respondents, 49F:31M. 50% ranked cost of care as the most important attribute. Overall, affordability and easy access to care ranked highest. Face-to-face meeting with physician was not as important. We therefore designed a new self-contained IT system with the capability to remotely track and monitor serum creatinine and eGFR of CKD patients, utilizing artificial intelligence and decision support systems tools, and able to prompt the supervising Nurse Practitioner to repeat blood tests, refer to the Emergency Department/nephrologist, and so on. This new system is called The CKD Express © and trial runs have been informally completed in my office.

Conclusions: We must bend the healthcare curve through innovative re-engineering methodologies and the incorporation of economic analysis to healthcare paradigms. The CKD Express © is one such paradigm change waiting to happen. It will make CKD care affordable, more convenient and able to reach large populations all over the US. A patent application for The CKD Express © is in progress.

FR-PO163

A Randomized, Controlled Clinical Effectiveness Trial of Real-Time, Wireless Blood Pressure Monitoring for Older Patients with Kidney Disease and Hypertension Dena E. Rifkin,[1] Joseph A. Abdelmalek,[1] Cynthia Miracle,[1] Chai L. Low,[2] Phil Rios,[1] Carl Stepnowsky,[1] Zia Agha.[1] *[1]UC San Diego; [2]Medicine, VA San Diego.*

Background: Older adults with chronic kidney disease (CKD) have a high rate of uncontrolled hypertension. Home monitoring of blood pressure (BP) is an integral part of management, but requires that patients bring records to clinic visits. Telemonitoring interventions however have not targeted older, less technologically skilled populations.

Methods: Veterans with CKD stage 3 or greater and uncontrolled hypertension were randomized to a novel telemonitoring device pairing a Bluetooth-enabled BP cuff with an Internet-enabled hub which automatically transmitted readings in real time (n=28), or usual care (n=15). Participants did not have to have a computer and no Internet skills were required. Transmitted home recordings were reviewed weekly by the study pharmacist and physician team, and telemonitoring participants were contacted if BP was above goal. Primary endpoints were improved data exchange and device acceptability. Secondary endpoint was BP change.

Results: 43 participants (average age 68, 75% white) completed the 6-month study. Average start-of-study BP was 147/78. Those in the telemonitoring arm transmitted a median of 29 [22,53] BP readings per month, with 78% continuing to use the device regularly, while only 20% of those in the usual care group brought readings to in-person visits. The median number of telephone contacts triggered by telemonitoring was 2[1,4] per patient over the course of the study. Both groups had a significant improvement in systolic BP ($p < 0.05$ for both changes); systolic BP fell a median 13 mmHg in telemonitored participants vs. 8.5 mmHg in usual care participants (p for comparison 0.31). The device was rated as highly acceptable by participants, with 27/28 (96%) stating that they would like to continue using the system.

Conclusions: This low-cost, low-impact telemonitoring solution was rated as highly acceptable by an older population, led to greater sharing of data between patients and clinic, and produced a trend toward improvements in BP control over usual care at 6 months.

FR-PO164

Improving Chronic Kidney Disease Co-Management among Primary Care and Nephrology Practitioners William E. Haley,[1] Amy L. Beckrich,[2] Judy J. Sayre,[3] Rebecca B. Mcneil,[4] Peter Fumo,[5] Vijaykumar M. Rao,[6] Edgar V. Lerma.[6] *[1]Nephrology and Hypertension, Mayo Clinic, Jacksonville, FL; [2]Renal Physicians Association, Rockville, MD; [3]Mayo Clinic, Jacksonville, FL; [4]Biostatistics, Duke University, Durham, NC; [5]Delaware Valley Nephrology, Philadelphia, PA; [6]Associates in Nephrology, Chicago, IL.*

Background: Improving co-management is an important strategy to enhance outcomes in chronic kidney disease (CKD). Objectives were to improve CKD identification, referral, communication and co-management among primary care physicians (PCP) and nephrologists (Neph).

Methods: Six Neph and 9 PCP practices participated over 12-15 months, testing tools provided to improve CKD identification, appropriate referral, communication, and co-management. Practice patterns, perceptions, and tool-use data were obtained from taped interviews of physician leaders and site champions, monthly telephone conferences, questionnaires and surveys. 252 eligible patient charts were audited before and 235 after tool implementation, using instruments pre-specified for PCP and Neph practices; the former focused on CKD identification and the latter on advanced CKD guideline adherence.

Results: Qualitative analysis revealed key themes: 1) Enhanced awareness and identification of CKD 2) Increased and improved communication and co-management 3) Increased awareness of recommended guidelines and changes in CKD referral patterns and care 4) Variation in practice patterns, and barriers to tools use 5) Enhanced satisfaction levels. PCP and Neph patients shared similar demographics. PCP audits revealed significant improvement in CKD identification ($p = 0.0115$); Neph audits demonstrated improved BP control ($p = 0.018$). Improvement in clinical endpoints and guideline adherence rates were denoted in those practices affirming most consistent tool usage.

Conclusions: Engendering co-management and improving processes, facilitated by specific tools, led to enhanced awareness and identification of CKD; increased and enhanced communication among PCPs, Neph, and respective staff; changes in CKD referral patterns; and increased awareness of recommended clinical guidelines. Ameliorating CKD co-management offers promise to improve clinical outcomes.

FR-PO165

The British Columbia Nephrologists' Access Study: Reducing Wait Times for Outpatient Nephrology Consultations Michael Schachter, Alexandra Romann, Ognjenka Djurdjev, Adeera Levin, Monica C. Beaulieu. *BC Provincial Renal Agency, Vancouver, BC, Canada.*

Background: Waiting time (WT) guidelines for outpatient nephrology consultations (ONC) are lacking. Automatic eGFR reporting increased referrals in Canada, and elsewhere. National recommendations suggest development of WT targets (WTT). We sought to describe WT for ONC in British Columbia (BC). Using a modified Delphi process, WTT were developed. WT was then re-measured to determine the impact of target setting.

Methods: Data collection occurred in 2 phases: 1) Baseline description (Jan 18-28, 2010) and b) Post Target-Introduction (Jan 16-27, 2012). WT was defined as the interval from receipt of referral letters to assessment. Nephrologists and Family Physicians developed WTT for commonly referred conditions through meetings and surveys. Targets consider comorbidities, eGFR, BP and albuminuria. Referred conditions were assigned priority scores of 1-4.

Results: In 2010 and 2012, 43/52 (83%) and 46/57 (81%) of BC nephrologists participated. Table 1 describes nephrologists and pts. WT decreased from 98(IQR44,157) to 64(IQR21,120) d from 2010 to 2012 (p=x), despite no change in referral eGFR, demographics, nor number of office hrs/wk. WT improved most in high priority patients (Fig 1).

Nephrologist and Patient Characteristics

Group, characteristic	2010	2012	p value
Nephrologists	n=43	n=46	
Age, yr, number (%)			
<40		17 (37)	
41-50		15(33)	
51-60		6(13)	
>60		8(17)	
Practice Size, number (%)			
<300	4 (10)	16 (37)	
301-500	7 (16)	15 (35)	<0.001
>500	33 (75)	12 (28)	
Office hrs/wk	8.5 (6)	8(6)	
Patients			
Age, yr, number (%)			
<50	78 (15)	63 (16)	
50-64	146 (28)	115 (29)	0.889
65-79	185 (35)	148 (37)	
>80	106 (21)	74 (19)	
sex, female (%)	51	49	0.555
Referral eGFR, ml/min per 1.73m2 (%)			
<30	85 (18)	57 (16)	
30-60	292 (65)	217 (61)	0.044
>60	75 (17)	84 (23)	

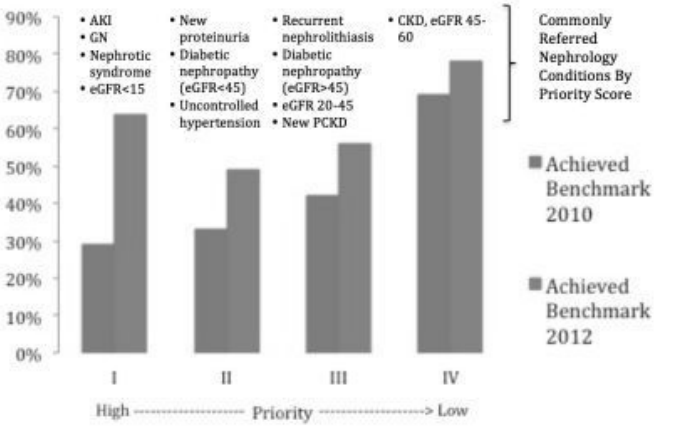

Figure 1| The proportion of patients seen within recommended wait time targets increased the most for high priority patients. Representative commonly referred conditions are shown above bars by priority score.

Conclusions: Development of *WTT* for ONC resulted in marked reductions in WT. Sustainability of the improvement will be monitored.

FR-PO166

Improving Care of Patients with CKD: A Randomized Controlled Trial of a Pharmacist/Registry Based Intervention Paul E. Drawz, Adam T. Perzynski, Yang Liu, Brook Watts, R. Tyler Miller. *Case Western Reserve University.*

Background: The objective of this study was to evaluate whether a pharmacist based intervention utilizing a chronic kidney disease (CKD) registry improves blood pressure (BP) control and quality of care for patients with CKD.

Methods: We conducted a randomized controlled trial at the Louis Stokes Cleveland VAMC. Patients with advanced CKD (estimated glomerular filtration rate < 45 mL/min/1.73m^2) were randomized to the intervention or usual care. The pharmacist based intervention utilized a CKD registry to identify patients not receiving or achieving guideline based recommendations. During the one year study, two pharmacists called intervention subjects within two weeks of a primary care visit and evaluated medication adherence, provided education regarding CKD and hypertension, ordered guideline recommended labs, and communicated with primary providers via the electronic medical record. The primary clinical outcome was the percent of subjects with a baseline BP >130/80mmHg whose last study BP was at goal. The primary process outcome was the percent of patients with at least one PTH measured during the study period.

Results: 1070 subjects were randomized to the intervention and 1129 to usual care. Among those with poorly controlled BP at baseline, there was no difference in the last recorded blood pressure or the percent whose last study BP was at goal (41.7% vs 40.2% in the control arm, *P*=0.7). Subjects in the intervention arm were more likely to have a PTH

measured during the study period (46.9% vs 16.1%, *P* <0.001) and were on more classes of antihypertensive medications at the end of the study (2.7 vs 2.5, *P*=0.05). There was no difference in medication adherence or the rate of ESRD (1.8% vs 2.4% in the control arm, *P*=0.3) but the number of deaths in the intervention arm was slightly lower than the control arm (4.7% vs 6.6%, *P*=0.06).

Conclusions: A pharmacist based intervention utilizing a CKD registry, patient education, and collaboration with primary care physicians did not improve BP control but did improve guideline adherence and increased the number of antihypertensive medications prescribed to subjects with poorly controlled BP.

Budget Impact Model of Medicare Bundled End-Stage Renal Disease Prospective Payment System: A Dialysis Organization Perspective

Haesuk Park,[1] Karen L. Rascati,[1] Michael S. Keith.[2] *[1]University of Texas at Austin; [2]Shire Pharmaceuticals.*

Background: In 2014, oral medications, including phosphate binders (PBs), will be included in the new Medicare bundled reimbursement scheme. We developed a budget impact model (BIM), which is capable of evaluating different scenarios, in order to estimate the incremental budget impact associated with a bundled prospective payment system (PPS) in Medicare beneficiaries on dialysis receiving PBs. The impact on budget was estimated from the perspective of a large dialysis organization in the United States (US).

Methods: The BIM estimated the potential annual budget impact of the new bundled PPS associated with the inclusion of PBs (including calcium-based binders, lanthanum carbonate [LC], sevelamer hydrochloride [SH], and sevelamer carbonate [SC]). Treatment efficacy associated with PBs (in terms of reduced risks of hospital days and mortality rates), market share, costs and any assumptions were based on published literature, market research data, and US Renal Data System reports. Scenario and sensitivity analyses were conducted. Costs were reported in US dollars.

Results: In total, 139,935 patients per year were predicted to be treated by a large dialysis provider and to receive PBs. Current (2012) utilization-weighted Medicare Part D cost per dialysis session for PBs was estimated at $23.52. The predicted base case for the 2014 total bundled rate of $278 per dialysis treatment, included $243 for dialysis-related services and a base case of $35 for oral medications. Future scenarios based on current PB market share utilization estimates may also allow dialysis organizations to remain within the bundled rate. In one such scenario, moving 10% market share from SH and SC to LC remained within the predicted PB bundle reimbursement rate. The BIM also depicts the potential impact of other scenarios and dosing levels in relation to the bundled rate.

Conclusions: This model suggests that PB costs may be manageable with the new PPS bundling rate. However, given the assumptions made and the variety of scenarios, there is uncertainty around the base case forecast. Further research to estimate the budget impact of the new bundled PPS is warranted.

Impact of a Multidisciplinary Low Clearance Clinic on the Management of Predialysis Chronic Kidney Disease Patients

Priscilla P. How,[1,2] Shuli Lim,[1] Jia Jia Lee,[1] Srinivas Subramanian.[2] *[1]Pharmacy, National University of Singapore; [2]Medicine (Nephrology), National University Hospital, Singapore.*

Background: A multidisciplinary low clearance clinic (LCC) run by a renal physician, clinical pharmacist and coordinator was set up in National University Hospital, Singapore. This study aimed to assess LCC's impact on hypertension (HTN), anemia and mineral and bone disorders (MBD) management in predialysis chronic kidney disease (CKD) patients, compared to standard care. Interventions made by the LCC pharmacist and physician acceptance rates were also determined.

Methods: This retrospective cohort study included stage 4-5 predialysis CKD patients referred to LCC or standard care (non-LCC). Blood pressure (BP), hemoglobin (Hgb), serum phosphate (P), calcium (Ca) and intact parathyroid hormone (i-PTH) concentrations, as well as proportion of patients who achieved KDOQI goals for these parameters were compared between both groups at baseline, and approximately 6 and 12 months thereafter. LCC patient charts were reviewed for therapeutic recommendations made by the pharmacist and their acceptance rates calculated.

Results: Fifty-three LCC and 96 non-LCC patients were evaluated. At 6 and 12 months, LCC patients had lower systolic BP (SBP) and higher Hgb than baseline (baseline vs. 12-month SBP and Hgb: 160±24 vs. 149±24 mmHg, and 10.6±1.7 vs. 11.2±1.5 g/dL, respectively; P<0.05). Serum P and Ca were similar over the study period. Non-LCC patients had lower serum Ca at 6 and 12 months (2.30±0.12 and 2.32±0.14 mmol/L, respectively) compared to baseline (2.34±0.11 mmol/L) (P<0.05). The proportion of patients who achieved KDOQI goals for all parameters was similar for both groups. The LCC pharmacist identified 411 drug-related problems during the study period and the overall acceptance rate of therapeutic recommendations was 61.3%.

Conclusions: Compared to standard care, 1-year follow-up at the multidisciplinary LCC was associated with improved HTN control but not anemia and MBD management. The overall acceptance rate of pharmacist recommendations was 61.3%. More studies are needed to confirm the long-term impact of multidisciplinary care on clinical outcomes of predialysis CKD patients.

FR-PO169

Assessing Perceived versus Actual Knowledge and Quality of Life in Predialysis Chronic Kidney Disease Patients

Priscilla P. How,[1,2] Tracy Wanxi Lian,[1] Jia Jia Lee,[1] Hwee-lin Wee,[1] Pallavi Tyagi.[2] *[1]Pharmacy, National University of Singapore; [2]Medicine (Nephrology), National University Hospital, Singapore.*

Background: Educating patients about chronic kidney disease (CKD) and its complications and management is essential as adequate patient knowledge has been linked to improved clinical outcomes. However, little is known about the difference in perceived vs. actual disease knowledge and the impact of such knowledge on health-related quality of life (HRQoL) in CKD patients. This study aimed to assess perceived and actual CKD knowledge, HRQoL, and examine the association between knowledge and HRQoL in our local predialysis CKD patients.

Methods: A survey was developed to assess perceived and actual CKD knowledge in this cross-sectional study involving predialysis CKD patients from the outpatient renal clinic in National University Hospital, Singapore. The Kidney Disease Quality of Life-Short Form (KDQoL-SF™) version 1.3 and EuroQoL-5 dimensions (EQ-5D) questionnaires were administered to assess HRQoL. Knowledge scores were compared using independent t-test. Univariate analyses and multiple linear regression were performed to determine associations between knowledge and HRQoL.

Results: A total of 95 patients were included in the analysis. Patients who perceived they had "At least some knowledge" had higher actual knowledge scores (58.2±21.2%) than those who perceived they had "No knowledge" (52.5±21.0%) (p=0.22). HRQoL of our local predialysis CKD patients is poorer than that of the U.S. general population but was better than patients with other chronic disease states in Singapore. Patients with better disease knowledge reported better HRQoL in only one scale: symptom/problem list (mean±SD scores for moderate vs. poor knowledge: 92.7±9.1 vs. 82.1±16.0 respectively; β-coefficient = -0.331, p=0.030).

Conclusions: This study showed that the self-reported knowledge level and actual knowledge scores of our local predialysis CKD patients were consistent and that CKD knowledge has little impact on actual HRQoL. Further studies need to be done to determine other correlates of HRQoL in predialysis CKD patients.

FR-PO170

Health Literacy and Disease Management Self-Efficacy: The Explanatory Role of Disease Knowledge

Nicole M. Fenton,[1] Kenneth A. Andreoni,[2] Sarah Elizabeth Cohen,[1] Mary Hunter Benton,[1] Karina Javalkar,[1] Kristin K. Kuntz,[2] Julia Whitley,[1] Zion Ko,[1] Maria E. Ferris.[1] *[1]Kidney Center, University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]Ohio State University, Columbus, OH.*

Background: This investigation examined if disease knowledge was mediating the relationship between health literacy and disease management self-efficacy.

Methods: People between the ages of 12 to 29 with chronic kidney disease stages ≥ 4 were eligible to participate. The six IRB-approved measures included: 1) The TR$_x$ANSITION Scale - transition knowledge/ self-activation (Ferris et.al. 2012) 2) A 10-item disease knowledge questionnaire 3) The Newest Vital Sign - health numeracy (Weiss et al., 2005) 4) The REALM (Davis et al., 1993) - health literacy 5) The STAR$_x$ to assess transition self-management and disease management self-efficacy 6) A demographics questionnaire.

Results: To date, 25 participants (12 transplant recipients) have been enrolled. Their demographic characteristics were as follows: 60% female, 44% Caucasian; 32% African-American, 16% Hispanic. The mean age was 21.56 (± 4.7) and the mean age at diagnosis was 9.47 (±8.46). Disease knowledge was a significant positive predictor of self-management (β= .40, p= .08), disease management self-efficacy (β= .45, p= .05), and knowledge/ self-activation (β= .49, p= .03). Additionally, both health literacy (β= .79, p= .00) and health numeracy (β= .72, p= .00) were significant positive predictors of disease knowledge. The Baron and Kenney (1986) procedure was applied to determine that disease knowledge was mediating the relationship between health literacy and disease management self-efficacy (β= .52, p= .01).

Conclusions: Adolescents and young adults with higher disease knowledge have more transition self-management and disease management self-efficacy. This suggests it is important for healthcare providers to provide ongoing patient education. Additionally, results indicate that disease knowledge mediates or is the mechanism through which health literacy contributes to disease management self-efficacy. This suggests the importance of providing patient education at a literacy appropriate level.

FR-PO171

Health Literacy and Numeracy as Predictors of Transition Readiness/Self-Management and Depressive Symptoms among Adolescents and Young Adults with Chronic Kidney Disease

Marley E. Burns,[1] Kristi Bickford,[1] Nicole M. Fenton,[2] Edward Iglesia,[1] Maria E. Ferris.[1] *[1]Kidney Center, UNC Chapel Hill; [2]Department of Psychology, UNC Chapel Hill.*

Background: Adolescents and young adults with chronic kidney disease (CKD) have great survival and must either undergo a transition process from pediatric to adult-focused health care or learn how to self-manage their disease effectively to decrease morbidity. We examined the roles of health literacy and numeracy in predicting transition readiness and/ or self-management and depressive symptoms.

Methods: We recruited English-speaking patients ages 14-29 with CKD stage ≥ 4 from the UNC Kidney Center pediatric and adult nephrology clinics. Participants completed

three provider-administered scales: (1) Rapid Estimates of Adult Literacy in Medicine (REALM) to assess health literacy, (2) Newest Vital Sign, a food label to assess literacy/numeracy, (3) TR$_x$ANSITION Scale to assess transition readiness/self-management, and a self-administered web-based scale: (4) CES-D to assess depressive symptoms.

Results: To date, we have enrolled 25 patients with CKD stage ≥ 4 (including 20 transplant patients) with the following characteristics: 60% Female; 50% White, 34% Black, 13% Hispanic; Mean age 21.6 (±4.7); Mean age at diagnosis 9.5 (±8.5). Nine participants were managed by pediatric nephrology and 16 by adult nephrology. *Health literacy* – The REALM score was a significant negative predictor of depressive symptoms (β= -.38, *p*=.09) and a significant positive predictor for overall transition readiness/self-management (β= .64, *p*=.00). *Health numeracy* – The Newest Vital Sign score was a significant negative predictor of depressive symptoms (β= -.41, *p*= .07) and a significant positive predictor for overall transition readiness/self-management (β= .38, *p*= .02).

Conclusions: Higher health numeracy and literacy independently predict fewer depressive symptoms and higher overall transition readiness/self-management among youth with CKD. Without adequate health literacy and numeracy skills, adolescents and young adults with chronic health conditions are ill-equipped for disease self-management and have poorer mental health. Enrollment continues underway.

OrganJet: Overcoming Geographical Disparities in Access to Deceased Donor Kidneys in the United States Anton I. Skaro. *Feinberg School of Medicine, Comprehensive Transplant Center, Evanston, IL.*

Background: There is a huge imbalance between the supply of and the demand for deceased donor kidneys. Under the current UNOS allocation policy, the vast majority of organs are allocated locally. There are significant disparities in waiting times and access to kidney transplant based on geography. However, there exist substantial ethical and logistical obstacles to the successful reform of organ allocation policy, which limit a more equitable distribution of kidneys. An operational solution (OrganJet) for patients on the transplant list is proposed which facilitates multiple-listing at transplant centers in distant donor service areas (DSA) of their choosing.

Methods: We modeled patient decisions of the location(s) to multiple-list as a selfish routing game in which each patient tries to minimize their "congestion cost" (i.e. maximize their life expectancy). Waiting times in each DSA were modeled through an overloaded fluid model. Using a stylized game-theoretic model, we studied the impact of multiple-listing on patients' accept/reject decisions of organ offers. (Co-authors: B. Ata, S. Tayur).

Results: OrganJet significantly remedies current disparities provided a small fraction (15%) of patients choose to multiple list, resulting in more uniform waiting times for kidney transplant in the US.

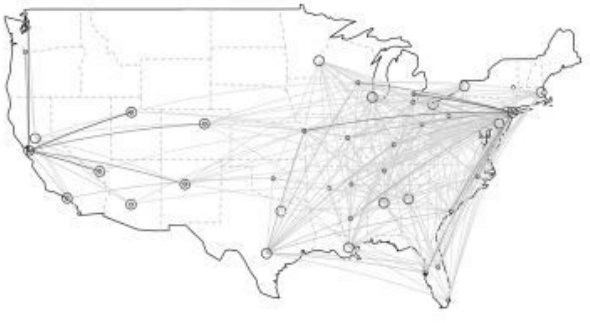

Figure 1: Equilibrium flow rates on a US map for $\pi = 1$. Each line corresponds to a particular flow; and for each flow, the large circle indicates the fly-out DSA whereas the small circle corresponds to the associated fly-in DSA.

The variation in waiting times across DSAs goes down to 13% from 23% as measured by the coefficient of variation. Similarly variation in access to transplant in different DSAs goes down to 21% from 38%. Also, when the time-to-death distribution has an increasing hazard rate, multiple-listing may leads to fewer deaths even if there is no increase in the number of kidneys procured. We also observed that under multiple-listing, organ discard may decrease.

Conclusions: Broader multiple-listing significantly reduced the geographic disparities in access to kidney transplantation in the US.

FR-PO173

Focus Group Evaluation of New CKD Educational Material from the Increasing Kidney Awareness Network (IKAN) Transplant Project Bessie A. Young,[1,2,3] Clarence Spigner,[3] Georgia Galvin.[1] *[1]VA Puget Sound Health Care System, Nephrology, Health Services Research and Development, Seattle, WA; [2]Kidney Research Institute, University of Washington, Seattle, WA; [3]Health Services, School of Public Health, University of Washington, Seattle, WA.*

Background: Although many CKD educational materials are available for kidney replacement therapy (KRT) education, few were developed to be culturally responsive to ethinic minorities.

Methods: We conducted focus groups among subjects with CKD or CKD connections to evaluate familiarity with educational materials and to determine responses to new educational material. Based on prior key informant interviews, a focus group guide was developed after IRB approval. Subjects were recruited from dialysis, transplant recipients, living kidney donors, potential living kidney donors, and pre-dialysis patients. All focus groups were digitally recorded and transcribed verbatim, and then read and re-read for content analysis. Transcripts were coded to develop subject content to develop emerging themes and categories until saturation was acheived.

Results: Two focus groups were held with 12 participants. Of participants 100% were African American, 66% were male, 66% had some college or were single, 22% had a kidney transplant, 33% were pre-dialysis, 22% were on dialysis, and 11% were potential kidney donors. Major themes from the focus groups included: 1) Altruism on the part of the potential recipient; 2) Difficulty with asking a relative for a kidney; 3) Financial Issues; 4) Emotional Issues, and; 5) Lack of Education regarding available therapies. Subjects in mixed focus groups felt they had better support and understanding of issues than they would have in separated focus groups. All groups found the educational material useful and better targeted towards people of color.

Conclusions: Culturally targeted CKD educational increases awareness of specific options for KRT, which may not have been offered previously. Testing of newly developed CKD educational material is needed to determine if interest in and preparation for kidney transplant or home dialysis therapies are increased.

FR-PO174

Evaluation of the Effect of a Health Care Model for CKD Patients on Lifestyle and Renal Function Alberto Barajas,[1] Laura Cortes-sanabria,[2] Guillermo G. Garcia,[1] Marcello Tonelli.[3] *[1]Nephrology, Hospital Civil de Guadalajara, Guadalajara, Jal, Mexico; [2]UIMER, CMNO IMSS, Guadalajara, Jal, Mexico; [3]Medicine, University of Alberta, Edmonton, AL, Canada.*

Background: Negative lifestyle habits are risk factors for progression of kidney disease and a barrier to achiev treatment goals. We evaluated the effect of multidisciplinary care on lifestyle and renal function in patients with stage 3 CKD.

Methods: A prospective cohort of patients received educational intervention guided by a multidisciplinary team (nurse, dietitian, physical) at our CKD Prevention Clinic. A lifestyle questionnaire was applied at baseline and at the end of follow-up (6 months); the questionnaire evaluated diet (maximum value=36), exercise (12), tobacco use (8), alcohol consumption (8), management of emotions (12), knowledge of disease (8) and treatment adherence (16); the higher the score, the healthier the behavior. Relevant clinical, biochemical, and renal function data were recorded. ANOVA, Kruskal-Wallis, and χ^2 were used when appropriate. A p value <0.05 was considered significant.

Results: 61 patients, age 56 ± 17 y, were included; female gender 56%; 57% were diabetics. Results are shown in table 1.

Lyfestyle Questionnaire (max score)	Baseline	3 mo	6 mo
Diet (36)	20 (10-32)	27 (10-36)*	29 (12-36)*
Exercise (12)	6 (0-10)	6 (0-12)	6 (0-12)
Tobacco (8)	8 (0-8)	8 (0-8)	8 (0-8)
Alcohol (8)	8 (0-8)	8 (0-8)	8 (0-8)
Knowledge of Dis (8)	0 (0-6)	0 (0-6)	0 (0-6)
Emotion mgment (12)	6 (0-12)	6 (0-12)	8 (0-12)*≠
Treatment Adherence (16)	12 (2-16)	16 (4-16)*	16 (4-16)*
Total (100)	60 (40-80)	68 (34-92)*	70 (50-92)*≠
Clinical Data			
SystBP mmHg	143±31	137±27	134±23*
DiastBP mmHg	80±15	73±11*	73±11*
BMI	27±5	27±5	26±4
Hgb g/dl	12.4±1.8	12.0±1.7	12.3±1.3
Glucose mg/dl	121±69	117±38	115±40
Urea mg/dl	63±24	74±35*	75±34*
Cholesterol mg/dl	180±59	177±50	171±50*≠
eGFR ml/min/1.73m²†	43(37-40)	41 (31-50)	41(27-47)
Proteinuria mg/day	122(30-500)	146 (30-300)	283 (25-930)

*p=<0.05 vs baseline; ≠ vs 3 months; †MDRD

Conclusions: We conclude that multidisciplinary care provided by a nurse-lead CKD prevention clinic: 1)reduces significantly negative lifestyle behavior, especially diet, emotion management and treatment adherence;2) improves BP and lipid control; and 3) preserves kidney function.

FR-PO175

Barriers to Kidney Transplantation: A Qualitative Study of Perceptions from Dialysis Patients and Transplant Recipients Clarence Spigner,[1] Courtney R. Lyles,[4] Georgia Galvin,[2] Bessie A. Young.[1,2,3] *[1]Health Services, University of Washington, Seattle, WA; [2]VA Puget Sound Health Care, Nephrology, Seattle, WA; [3]Kidney Research Institute, University of Washington, Seattle, WA; [4]GIM, University of California, San Francisco, San Francisco, CA.*

Background: Racial and ethnic disparities in kidney transplantation persist. More research is needed to generate theories and/or explanations as to why these racial/ethnic differences exist, and from the perspective of those most affected by the disease.

Methods: We recruited 58 kidney patients of which 30 were on dialysis and 28 had a kidney transplant. Semi-structure questions were designed to solicit opinions about kidney disease and transplantation. Phone interviews were conducted by a single investigator (GG). Sessions were audio recorded, and transcribed verbatim to hard-copy for content

analysis. Open coding was employed by using each respondent s' exact words from which to form categories. Saturation was reached when no new information was forthcoming. A core phenomenon emerged. Validity was assured by having two team members (CL, BY) independently employ the same coding scheme to systematically assess coding. Where disagreement occurred, discussion ensued until consensus was reached.

Results: The central element to emerge was fear; among both the dialysis respondents facing the transplant procedure and as recalled by the post-transplant respondents. Several propositions directionally led to the concept of fear, which related mainly to overall quality of life. Dialysis respondents were more focused on personal factors that qualified or unqualified them for a transplant, while transplanted respondents indicated more knowledge of institutional and societal requirements for having obtained an organ.

Conclusions: Our findings support studies about apprehension of the unknown surgical outcome. Fear of transplantation stemmed mainly from lack of education about the procedure. This can address in part by post-transplant patients who well understand that fear. What emerged is an aspect of Social Learning Theory where the post-operative patients might be the best teachers of pre-operative patients.

FR-PO176

Cost-Utility Analysis of Sodium Polystyrene Sulfonate versus Potential Alternatives for Chronic Hyperkalemia Dustin J. Little, Robert Nee, Kevin C. Abbott, Christina M. Yuan. *Nephrology, Walter Reed National Military Medical Center, Bethesda, MD.*

Background: Hyperkalemia is common during renin-angiotensin-aldosterone system (RAAS) inhibitor treatment, and may prevent optimum dosing. Limited treatment options include sodium polystyrene sulfonate (SPS) potassium binding resins, but concerns have been raised regarding their efficacy and safety; including associated colonic necrosis (CN), with an incidence of 0.14% (95% CI 0.03– 0.40%) reported recently. Alternative agents have been studied, but their cost-utility has not been estimated.

Methods: A computer-based decision model was developed using TreeAge Pro software (Williamstown, MA) to represent the costs and effectiveness of SPS compared to a theoretical "Drug X" binding resin for treatment of chronic hyperkalemia. Model inputs were obtained from literature review to include a cost of $10.65 per 30gm SPS dose, and baseline quality-adjusted year of life (QALY) utility indices were obtained from the Tufts Medical Center Cost-Effectiveness Analysis Registry. Model life-span was one year. The primary endpoint was the incremental cost-effectiveness ratio in dollars per QALY gained. A willingness-to-pay threshold of $50,000 per additional QALY determined cost effectiveness.

Results: Drug X could cost no more than $10.77 per dose to be cost-effective, and at a cost of $40.00 per dose achieved an incremental cost-effectiveness ratio of $26,088,369.00 per QALY gained. SPS was more cost-effective than Drug X in 100% of model iterations using Monte Carlo probabilistic sensitivity analysis, and the expected value of perfect information (EVPI) was $0.00 at Drug X costs of ≥$21.00 per dose. One-way sensitivity analysis showed SPS to be the cost-effective option for CN incidences of ≤19.9%, over 10-fold greater than the highest estimates of SPS-associated CN.

Conclusions: Our analysis suggests that SPS alternatives may not be cost effective unless priced similarly to SPS. This cost-utility analysis may help to guide decisions regarding adoption of alternative agents for control of chronic hyperkalemia as they enter clinical use, and also suggests that SPS be used as an active control in clinical trials of these agents.

FR-PO177

Cost-Effectiveness of Lowering LDL-Cholesterol in Chronic Kidney Disease: Results from the Study of Heart and Renal Protection (SHARP) Borislava N. Mihaylova,[1] Jingky P. Lozano-kuehne,[1] Iryna Schlackow,[1] William G. Herrington.[2] *[1]On Behalf of the SHARP Collaborative Group, Department of Public Health; [2]Clinical Trial Service Unit, University of Oxford, United Kingdom.*

Background: The SHARP study showed that simvastatin 20mg plus ezetimibe 10mg daily safely reduced the rates of major atherosclerotic events (MAEs: non-fatal myocardial infarction, coronary death, non-haemorrhagic stroke or arterial revascularisation) in patients with advanced chronic kidney disease (CKD). Within-trial cost-effectiveness is reported.

Methods: 9,270 individuals with advanced CKD (3,023 on dialysis) were randomized to ezetimibe/simvastatin or matching placebo for a median follow-up of 4.9 years. Hospital admissions and visits in SHARP were mapped into UK-based Healthcare Resource Groups and hospital costs were derived from NHS costs (2011); ezetimibe/simvastatin cost of £1.19 per day was based on Prescription Cost Data for England (2011). The treatment costs minus the hospital and concomitant lipid lowering drug cost savings per MAE avoided were estimated for all participants (with costs and outcomes discounted at 3.5% per annum). To allow for the different LDL cholesterol (LDL-C) reductions, analyses for participants not on dialysis and on dialysis at baseline are reported using overall study relative effects on MAE and vascular hospitalisation costs per 1mmol/L LDL-C reduction.

Results: Allocation to ezetimibe/simvastatin yielded an average LDL-C difference of 0·85 mmol/L and was associated with a 17% (95% confidence interval 5-28%) proportional reduction in all MAEs (38 MAEs prevented per 1000 treated). The cost of ezetimibe/simvastatin was ca. £1,400 per participant. The reduction in vascular-related hospital cost was 15% (4-25%) (£177 per participant). Costs for hospitalisation for other reasons were not affected. The additional cost per MAE prevented was £34,300. The cost of preventing each MAE per 1mmol/L lower LDL-C was £30,700 for those on dialysis and £37,700 for those not.

Conclusions: The costs of preventing MAEs with ezetimibe/simvastatin in patients with advanced CKD are comparable to those observed for proprietary LDL-C lowering regimens in other patients at high risk of coronary heart disease.

Trends in Predialysis Anemia Care in Older Patients Approaching ESRD in the U.S. (1995-2009) Wolfgang C. Winkelmayer, Aya Alice Mitani, Benjamin A. Goldstein. *Stanford University School of Medicine, Palo Alto, CA.*

Background: Anemia is common in patients with advanced CKD approaching ESRD. Little is known about patterns and trends in the anemia care patients receive prior to initiating chronic renal replacement therapy (RRT) in the U.S.

Methods: From USRDS files, we studied all patients aged 67+ yrs on their ESRD date who had Medicare A+B as their primary payer in >2 yrs prior to start of RRT. From billing claims, we identified the earliest administration of an erythropoiesis-stimulating agent (ESA) as well as the reported hematocrit on this index claim. We tabulated temporal trends of ESA initiation (proportion receiving any ESA prior to start of RRT; timing of ESA initiation relative to first ESRD date; mean hematocrit reported with these ESA initiation claims) and the receipt of any blood transfusions.

Results: We studied 440,924 older patients initiating RRT between 1995 and 2009. The proportion of patients receiving any ESA in the 2 years prior to RRT increased from 3.2% in 1995 to 40.9% in 2007; thereafter ESA use declined to 36.4% in 2009. The median time of ESA initiation relative to the RRT start date increased from 99 days (1995) to 470 days (2009). The mean reported hematocrit at first ESA use was 26.7% in 1995, exceeded 31% in all years from 1999-2007 and then declined to 30.2% in 2009. The proportion of patients receiving any blood transfusions prior to start of RRT increased monotonically from 20.8% in 1995 to 38.6% in 2009.

Conclusions: Between 1995 and 2009, the intensity of anemia care in older adults prior to their start of RRT increased considerably. We observed a slight reversal of this trend in patients initiating RRT after 2007, possibly as a consequence of safety concerns reported in the CHOIR trial in late 2006 and subsequent FDA-mandated boxed warning. Despite ESA treatment being initiated earlier and in more patients over time, the proportion of patients receiving blood transfusions prior to initiation of RRT has almost doubled. While ESAs were first approved for transfusion avoidance, this benefit of increased ESA use prior to RRT is invisible on a population level, likely a consequence of general trends towards more lenient transfusion thresholds in U.S. practice.

FR-PO179

Characterization of the Clinical Context for the Administration of Red Blood Cell (RBC) Transfusions in Patients with Chronic Kidney Disease (CKD) Requiring Chronic Dialysis Jason Jones,[1] Carly J. Paoli,[2] Felicia Bixler,[1] Joseph Cha,[1] Susan V. Yue,[2] Matthew Gitlin,[2] Victoria A. Kumar.[1] *[1]Kaiser Permanente Southern California; [2]Amgen, Inc.*

Background: The objective of this study is to characterize the clinical context surrounding the administration of RBC transfusions among CKD patients requiring dialysis. Understanding the clinical context may suggest ways to improve anemia management and reduce the potential for RBC transfusion events in these patients.

Methods: Two nephrologists reviewed medical records from Kaiser Southern California for CKD on dialysis who received a RBC transfusion in 2009 or 2010; 150 were randomly selected for review; here, we report interim results for 86 patients. Data was collected surrounding the RBC transfusion event and classified into 4 clinical context categories: Hb level/ESA response, anemia symptoms, medical condition, and surgery. The decision to transfuse is likely multifaceted thus patients could have one or more categories supporting the need for a RBC transfusion. The nephrologists then subjectively prioritized the categories for each patient. For patients who had Hb level selected as a clinical context category, the Hb level that supported the order for the RBC transfusion was recorded.

Results: Of the 86 patients identified, the mean age was 67.5 and 52% were female. Table 1 provides the clinical context surrounding the RBC transfusions events. For patients who had Hb level selected as a clinical context category, the median Hb value indicated on the order was 7.8g/dL (95%CI: 7.6 - 8.2); n=71.

Table 1: Clinical Context Categories for RBC Transfusion (n = 86)*

	Clinical Context Categories	Ranked as Priority #1
Hb Level/ESA Response	83% (CI:73-90%); n=71	65% (CI:54-75%); n=56
Lack of ESA Response	8% (CI:3-16%); n=7	-
Medical Diagnosis	64% (CI:53-74%); n=55	20% (CI:12-30%); n=17
Top Diagnosis: Acute Blood Loss (<72 hours)	36% (CI:26-47%); n=31	-
Anemia Symptoms	40% (CI:29-51%); n=34	14% (CI:7-23%); n=12
Top Symptom: Shortness of Breath	15% (CI:8-24%); n=13	-
Surgery	12% (CI:6-20%); n=10	0%; n=0
Top Surgery Type: Elective Surgery	10% (CI:5-19%); n=9	-
No Clinical Context Found in Chart	n=1	n/a

* All percentages are calculated based on total n=86. Descriptive statistics and 95% confidence intervals are provided.

Conclusions: This study is the first in characterizing the clinical context surrounding the need for RBC transfusions in CKD patients on chronic dialysis. We demonstrate that the clinical context for the majority of RBC transfusions is a complex set of conditions including Hb level, medical conditions and anemia symptoms.

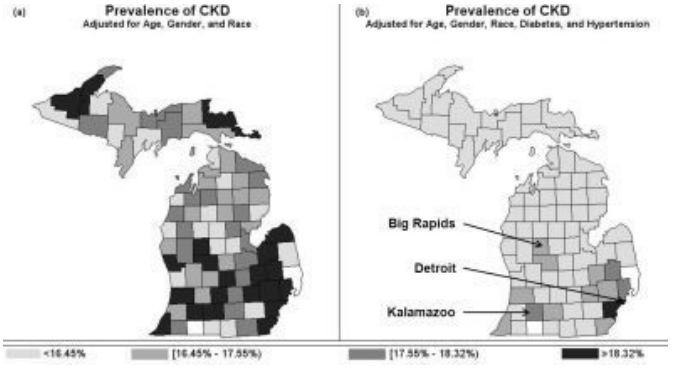
Utility of Administrative Health Data for Chronic Kidney Disease Surveillance at the County Level Elizabeth Hedgeman,[1] Hal Morgenstern,[1] Deidra C. Crews,[2] Meda E. Pavkov,[3] Neil R. Powe,[4] Rajiv Saran.[1] *[1]University of Michigan; [2]Johns Hopkins University; [3]Centers for Disease Control and Prevention; [4]University of California San Francisco.*

Background: Population prevalence of chronic kidney disease (CKD) depends on individual and macro-level factors; identification of CKD depends on healthcare access, awareness, and testing of at-risk individuals. We postulated that healthcare claims could be used for county-level CKD surveillance to identify priority areas for state and county public-health authorities.

Methods: Focusing on Michigan, we examined 2010 Medicare claims 5% sample data. 49,209 adults met the eligibility criteria: age 65+ years, MI resident, continuous enrollment in parts A and B, no part C, no ESRD. County of residence, age, sex and race were identified from the denominator file; CKD, diabetes and hypertension were identified by ICD-9-CM diagnosis claims. County prevalences of diagnosed CKD, standardized to the covariate distribution of the total study sample, were estimated by generalized linear mixed model treating counties as random effects.

Results: The crude prevalence of diagnosed CKD in the sample was 19.3% (95% CI: 18.9-19.6%). County prevalence estimates are displayed in the Figure, adjusting for demographic variables without and with adjustment for diabetes and hypertension. Adjustment for risk factors explained most of the county variation. High CKD prevalence clustered around three areas.



Conclusions: We have shown the feasibility of using claims data to generate county-specific estimates of diagnosed CKD prevalence. This method depends on data completeness and accuracy, and population representativeness. We will expand this approach, incorporating county-level contextual variables (e.g., poverty, rurality) to further explain geographic differences in CKD, thereby informing public policy.

FR-PO181

Hemodialysis Quality-of-Care Indicators and Patient Ability to Work: Data from a Current US Renal Data System Study Nancy G. Kutner,[1] Kirsten L. Johansen,[2] Dana Dacosta,[1] Julie W. Doyle,[2] Rebecca H. Zhang.[1] *[1]USRDS Rehab/QOL SSC, Emory Univ, Atlanta, GA; [2]USRDS Nutrition SSC, UCSF, San Francisco, CA.*

Background: Restoring patients' ability to work was a key rationale for establishing the ESRD Program of Medicare. An association has been shown between incremental achievement of hemodialysis (HD) quality indicator (QI) goals and patient morbidity and quality of life (Lacson et al. 2009), but whether patient-assessed ability to work varies as a function of QI goals is unknown.

Methods: Patients on HD treatment for ≥3 months were enrolled 2009-2011 for a USRDS study ("ACTIVE-ADIPOSE") in 7 San Francisco, CA outpatient clinics and 7 Atlanta, GA outpatient clinics. 509 patients aged 18-64 responded to the interview question "Are you now able to work for pay (full-time or part-time)?" HD QI goals considered were serum albumin ≥ 4.0 g/dl, hemoglobin 10-12 g/dl, kt/V ≥1.2, serum phosphorus 3.5-5.5 mg/dl, and catheter absence. Likelihood of reported ability to work by achievement of QI goals was examined in logistic regression models adjusted for age, sex, race, educational level, diabetes, congestive heart failure, depressive symptomatology (CES-D score), vintage, and facility clustering.

Results: 36% of the cohort (181/509) reported ability to work. Mean (S.D.) number of HD QI goals met was 3.31 (1.07); median = 3.0. The proportion of the cohort meeting a specific goal ranged from 49% for serum phosphorus 3.5-5.5 mg/dl to 91% for kt/V ≥ 1.2. With number of QI goals met (0-5) as a continuous variable, patients' likelihood of reporting ability to work increased with an increasing number of QI goals met (OR 1.28 [95% CI 1.04-1.57]; p = 0.02). Age less than 55 and lower CES-D score were additional independent predictors of reported ability to work.

Conclusions: Meeting more HD QI goals was associated with greater likelihood of reporting ability to work. Ability to work is a concept that cannot be directly measured; self-reported ability to work and employment status both provide only indirect measures (AHRQ Evidence Report 2000). However, the data we summarize suggest an important link between meeting HD QI goals and vocational rehabilitation potential in the HD population.

FR-PO182

Inpatient Healthcare Utilization among US Children with Nephrotic Syndrome Cheryl L. Tran,[1] Debbie S. Gipson,[1] Kassandra L. Messer,[1] Joyce P. Samuel,[2] Emily G. Herreshoff,[1] Susan F. Massengill,[3] David T. Selewski.[1] *[1]Pediatric Nephrology, University of Michigan, Ann Arbor, MI; [2]Pediatric Nephrology, University of Texas-Houston, Houston, TX; [3]Pediatric Nephrology, Levine Children's Hospital, Charlotte, NC.*

Background: There is little data describing the inpatient healthcare utilization in children with nephrotic syndrome (NS) and related complications. Our goals were to define the frequency, charges and length of hospitalizations among children with NS, the frequency of complications and the characteristics associated with inpatient costs.

Methods: Kids' Inpatient Database (HCUP-KID) data was obtained for the 2006 and 2009 cohort years. HCUP-KID is a database of US hospital discharges for children compiled every 3 years with sponsorship from the Agency for Healthcare Research and Quality (AHRQ). We identified patients by searching for NS ICD-9-CM diagnosis codes.

Results: There were 6308 hospitalization discharges in children with a primary or secondary diagnosis of NS reported by 38 and 44 participating states in 2006 and 2009 respectively and representing 9934 discharges nationally. Total charges attributed to NS related hospitalizations summed to nearly $259 million. The mean charge per hospitalization was approximately $26,500 (sd $1,100) and length of stay was 4.9 days (SE 0.1). Sixteen percent of discharges for NS had a diagnosis code for at least one severe complication including thromboembolism (3.6%), septicemia (3.8%), peritonitis (2.6%), pneumonia (5.4%), or diabetes (2.4%). Mulitvariate analysis showed age > 14 years, race, higher socioeconomic status, acute renal failure, thromboembolic disease, hypertension, and infections predicted higher mean hospitalization costs.

Conclusions: We present the first systematic description of inpatient health care utilization in children with NS. NS and associated complications resulted in 9,900 hospitalizations, an estimated 48,700 inpatient days, and $259 million in inpatient charges in children. Furthermore the complications of NS including thromboembolism, infection, and hypertension contribute significantly to these costs.

FR-PO183

Blood Pressure Control among CKD Patients in a Public Health System Delphine S. Tuot,[1] Charles E. McCulloch,[2] Chi-yuan Hsu,[1] Tanushree Banerjee,[1] Margaret Handley,[1,2] Dean Schillinger,[1] Neil R. Powe.[1] *[1]Medicine, UCSF, San Francisco, CA; [2]Biostatistics and Epidemiology, UCSF, San Francisco, CA.*

Background: Blood pressure (BP) control is suboptimal among patients with chronic kidney disease (CKD). Little is known about BP control among ethnically diverse CKD patients who receive care in public health settings, which disproportionately care for patients at higher risk for CKD progression.

Methods: We examined uncontrolled BP (systolic BP >140 or diastolic BP >90) using 18,864 clinical BP measurements from 6618 adults (23% White, 34% Black, 18% Hispanic, 21% Asian) with CKD (defined by 2 values of either eGFR <60 ml/min/1.73m^2 or abnormal dipstick albuminuria) who received primary care in 2010-2012 in the Community Health Network (CHN), the integrated delivery system serving San Francisco's uninsured & publically insured residents. Generalized estimating equations adjusting for age, gender, language, insurance, and primary care clinic were used to estimate the prevalence and odds of uncontrolled BP by race/ethnicity overall, and stratified by CKD stage. Results were compared to weighted and similarly adjusted estimates of uncontrolled BP among 2404 NHANES participants with CKD (defined by single values of eGFR <60 or albuminuria > 30mg/g) who had seen a doctor in the prior year.

Results: Adjusted prevalence of uncontrolled BP in the CHN was 25.3%, with differences across race/ethnic groups overall (p<0.001) and within each CKD stage (p<0.004 for each stage). Compared to Whites, overall odds of uncontrolled BP were higher among Blacks (adjusted odds ratio (AOR)=1.11, 95%CI 1.08-1.13), Hispanics (AOR=1.05, 1.02-1.08) and Asians (AOR=1.04, 1.02-1.08). Adjusted prevalence of uncontrolled BP among NHANES participants was 21.2%; compared to Whites, odds of uncontrolled BP were higher among Blacks (AOR=2.00, 1.62-2.46) but not Hispanics (AOR=1.0, 0.67-1.50).

Conclusions: BP control among patients with CKD in a public health setting is nearly 20% higher than national estimates with smaller, though still significant, disparities between Black and White patients. Continued efforts at improving BP control should target integrated public delivery systems.

FR-PO184

Variation of Pre-ESRD Care and Black-White Difference across Urban-Rural Counties Guofen Yan,[1] Jennie Z. Ma,[1] Alfred K. Cheung,[2] Tom Greene,[2] Mohammed Norman Oliver,[1] Wei Yu.[1] *[1]University of Virginia; [2]University of Utah.*

Background: Access to pre-ESRD care has varied greatly among region, but the variation between urban and rural areas in the U.S. is unknown. Using USRDS, we examined the extent of variation in pre-ESRD care and black-white disparity across urban-rural counties.

Methods: We identified 372,434 black or white patients aged >18 years who initiated first dialysis between 2005 and 2009 across 3081 counties, grouped into large-metropolitan (LM), non-large metropolitan (NLM), suburban (S), and rural (R). Four pre-ESRD care indicators included receipt of nephrologist care at least 12 months prior to ESRD, fistula (AVF) at the first dialysis, receipt of dietitian care, and use of erythropoietin (ESA). Data were analyzed using logistic regression with generalized estimating equation.

Results: LM and NLM counties had the worst and best rates of nephrologist care (24% and 30%), while S and R counties had rates in between (27% and 26%). Among patients who received nephrologist care, those living in metro counties were more likely to receive dietician care (19%) than in S and R (14%). Rates of ESA use were also higher in metro counties (56%) than other areas (50%) while rates of AVF were similar across four areas. Black patients received less care than whites in all areas, especially dietitian care in R (table). The results were largely unchanged after adjusting for various patient factors.

Rates of receiving pre-ESRD care[a]

County category	Neph. Care	AVF	Dietitian	ESA
(#patients/#counties)	black vs. white	black vs. white	black vs. white	black vs. white
LM (193,623/412)	20.9 vs. 26.0**	19.9 vs. 22.3**	20.1 vs. 20.3	53.3 vs. 58.0**
NLM (110,822/676)	29.2 vs. 30.5	20.6 vs. 22.4*	15.8 vs.18.2*	51.5 vs. 56.5**
S (46,409/1,051)	25.6 vs. 27.9*	18.1 vs. 22.7**	10.8 vs. 15.5**	44.5 vs. 51.2**
R (21,580/942)	23.1 vs. 27.0*	21.9 vs. 22.8	7.8 vs. 16.6**	48.8 vs. 51.4

[a] *p < 0.05, **p < 0.001.

Conclusions: Access to nephrologist care appeared to be worst in LM whereas receipt of dietitian care was particularly low in rural counties. Blacks received less care in all areas. Further study to delineate the factors associated with these urban-rural differences will likely improve care for CKD patients.

Funding: NIDDK Support

FR-PO185

Racial/Ethnic Disparities in Mortality among Individuals with Chronic Kidney Disease Rajnish Mehrotra,[2,3] Dulcie Kermah,[1] Keith C. Norris.[1,3] *[1]Research, Charles R. Drew University of Medicine and Science, Lynwood, CA; [2]Research, Harborview Medical Center, University of Washington, Seattle, WA; [3]School of Medicine, David Geffen School of Medicine at UCLA, Los Angeles, CA.*

Background: Black individuals have a significantly higher risk for premature mortality than whites in the general population but have a survival advantage in the ESRD population, particularly among older patients. The association between race/ethnicity and mortality in people with earlier stages of chronic kidney disease (CKD) is less clear.

Methods: We evaluated racial/ethnic differences in mortality among 2185 adult participants (> 20 years) with CKD from the National Health and Nutrition Examination Survey (NHANES 1999-2004), defined as an estimated GFR <60 ml/min per 1.73 m^2 or by the presence of albuminuria (not on dialysis).

Results: Adjusting for age, gender and race in the overall cohort, the hazard ratio (HR) for all-cause mortality in the CKD group compared to No CKD was 2.41 (95% CI - 2.08-2.87; P <0.001). In the cohort with CKD, the HR for all-cause mortality between races after controlling for age, gender, did not differ among those less than 65 years .After further adjustment for cardiovascular risk factors, socioeconomic and CKD stage we found no difference between racial/ethnic groups among those less than 65 years. In the 65-75 year group, blacks had a significantly high risk for mortality with a fully adjusted HR of 1.8 (95% CI - 1.2-2.7; p=0.008) compared to Whites, and in the 75 and older age group, blacks had a trend toward increased mortality risk with an adjusted HR of 1.7 (95% CI - 0.96-2.8; P= 0.06) compared to Whites. Similar findings were noted when we restricted the outcomes to cardiovascular related mortality.

Conclusions: In conclusion, these data demonstrate racial/ethnic disparities in mortality among individuals with CKD. The survival advantages for blacks compared to whites in the ESRD population do not extend fully to the non ESRD CKD population.

FR-PO186

A Mexican Government-Sponsored Chronic Kidney Disease (CKD) Screening Demonstration Project (DP) Based on KEEP (Kidney Early Evaluation Program) Methodology Gregorio T. Obrador,[1] Nadia Olvera,[2] Veronica Gutierrez,[2] Antonio Villa,[1] Patricia D. Lopez Perez,[3] Miguel Angel Mejia,[4] Santiago Lastiri,[5] Juan A. Tamayo-orozco.[5] *[1]Universidad Panamericana School of Medicine; [2]Fundacion Mexicana del Rinon; [3]Secretaria de Salud, Estado de Jalisco; [4]Instituto Nacional de Salud Publica; [5]Sistema de Proteccion Social en Salud.*

Background: KEEP is a CKD screening program aimed at adult individuals with diabetes (DM), hypertension (HTN), and/or family history of DM, HTN, or CKD. KEEP was originally developed by the US-NKF and in 2008 was adapted for use in Mexico by the Mexican Kidney Foundation. The Mexican government planned a CKD screening DP based on KEEP methodology directed to diabetic patients who were already attending primary care clinics in the Jalisco State. The objectives of the study were 1) to adapt the KEEP methodology for rapid and massive CKD screening, and 2) to compare the CKD prevalence between participants in the DP and in KEEP.

Methods: Seven teams comprised of 27 health professionals each were trained. CKD screening was planned to be conducted during 5 working days for 6 consecutive weeks at 6 sites. SCr and urine ACR were measured with the point-of-care testing devices iSTAT and Clinitek, respectively. iSTAT-SCr was aligned to IDMS-SCr with a correction factor obtained in a previous validation study.

Results: A total of 7689 diabetic patients were screened for CKD within a 6-week period. Their mean age was 58±12 years and 72% were women. Forty-five percent of patients had DM and 55% had DM+HTN, with mean disease duration for each of 8 years. The overall CKD prevalence was 44%. Of these, 22% had CKD stage 1, 13% stage 2, 8% stage 3, and 1% stages 4-5. CKD prevalence was 40% for patients with DM and 47% for those with DM+HTN. There were no statistically significant differences in overall CKD prevalence between diabetic participants in the DP and in KEEP (N=1658).

Conclusions: It is possible to successfully conduct rapid and massive CKD screening based on KEEP methodology. CKD prevalence among diabetic patients is high. Most patients have early CKD stages, which allows for implementation of interventions to delay CKD progression.

FR-PO187

Assessing Awareness of Risk Factors for Cardiovascular and Chronic Kidney Disease among Undergraduate Students at a Single Institution Caitlin Thys, Courtland Winborne, Hsiao L. Lai. *IM, ECU, Greenville, NC.*

Background: A preliminary study was conducted from Jun to Oct 2010 to assess cardiovascular (CV) risk among undergraduate students. Of the 525 participants screened 30% had two or more risk factors, 12% had three or more risk factors for CV disease. This group shows a high prevalence of CV risk factors and would be a promising group for targeted risk modification. It is essential to expand this population cohort to further confirm the prevalence of CV risk in this young adult population. It has been well established that CV risk factors such as obesity, hypertension, diabetes, and smoking increase risk for chronic kidney disease (CKD). CKD has a high prevalence in adults, therefore early awareness of CKD risk factors may be an effective prevention strategy.

Methods: From Nov to Dec 2011, 209 undergraduate students participated in cardiovascular screening. Prior to the screening, informed consent was collected. Participants completed a 10-question survey that assessed physical activity, perceived health status, smoking and tobacco use, salt, dairy, and alcohol consumption, and sun exposure. Height, weight, blood pressure, lipid, and glucose measurements were obtained.

Results: The mean age was 19 yo with the youngest being 18 and the oldest being 26. Fifty-one percent are female; 79% are white; 11% are black. Thirty percent of participants were reported to have two or more cardiovascular risk factors, 5.4% had 3 or more risk factors. Predominant risk factors included BMI > 25 (11.5%), hypertension (44.2%), low HDL (52.9%), regular smokers (7.2 %), and sedentary lifestyles (34.6%). Only 5.8% of participants felt their health was worse than other people.

Conclusions: Undergraduate students have a high prevalence of multiple risk factors with a low prevalence of established disease. Risk modification is essential at a young age to decrease the potential for developing chronic disease later in life. This demonstrates that risk factors can be detected early for chronic disease prevention and intervention could be promising. The next phase of the study will focus on risk modification for those with multiple risk factors through an educational intervention.

FR-PO188

Readmission after Hospitalization for Heart Failure among Patients with CKD: A Prediction Model Robert M. Perkins, Ion D. Bucaloiu, Evan Norfolk, William DiFilippo, James E. Hartle, H. Lester Kirchner. *Geisinger Clinic.*

Background: 30-day readmission rates after hospitalization for congestive heart failure (CHF) approach 25% in the general population, and patients with CKD are disproportionately represented.

Methods: We aimed to develop a prediction tool for 30-day readmission after hospitalization for CHF among those with CKD. Geisinger Clinic primary care patients with stage 3-5 CKD (without history of renal replacement therapy) hospitalized with a primary discharge diagnosis of CHF at least once during the period July 1, 2004 through February 28, 2010 were eligible for cohort inclusion, and followed through March 31, 2010 for readmission. Multivariate logistic regression was employed to build models from predictors of 30-day readmission, drawn from demographic, clinical, laboratory, and pharmaceutical variables in the electronic health record. These variables were obtained during the year prior to admission and during the index hospitalization itself. Models were assessed for optimization of the AUC of the ROC curve for readmission within 30-days. Variables were manually removed to achieve satisfactory goodness of fit and parsimony while maximizing AUC. Internal model validation was performed using the bootstrap resampling method with 1000 samples to provide a bias-corrected AUC.

Results: 607 patients with CKD were admitted for CHF during the study period and constituted the study population; 116 (19.1%) were readmitted within 30 days. A model incorporating 22 variables across domains of medical history, active outpatient pharmaceuticals, vital signs, laboratory tests, and recent inpatient and outpatient resource utilization yielded an AUC (95% CI) of 0.792 (0.759-0.848). The bias-corrected AUC was 0.743, suggesting good internal validity. At an estimated readmission probability of 20%, the model correctly classifies readmission status for 73% of the population, with a sensitivity of 69% and a specificity of 73%.

Conclusions: Electronic health records allow for the development of reasonably accurate readmission risk tools which incorporate a large number of predictor variables. Robust IT infrastructure may allow for the clinical application of well-validated prediction tools.

FR-PO189

Establishment of a Method to Detect Microalbuminuria by Measuring the Total Urinary Protein-to-Creatinine Ratio in Patients with Risk Factors for Cardiovascular Disease Kyoko Yamamoto,[1,2] Yasuhiro Komatsu,[2] Hiroyuki Yamamoto,[2] Yutaro Nishi,[3] Koichiro Niwa,[3] Chiyohiko Shindoh.[1] *[1]Laboratory Medicine and Clinical Science, Tohoku University Graduate School of Medicine, Sendai, Japan; [2]Nephrology, St Luke's International Hospital, Tokyo, Japan; [3]Cardiology, St Luke's International Hospital, Tokyo, Japan.*

Background: The latest KDIGO CKD guidelines recommend that CKD is classified based on cause, GFR category and albuminuria category. The American Heart Association recommends combined screening for low eGFR and microalbuminuria in patients with risk factors for cardiovascular disease (CVD). Although albuminuria is preferred marker than total urinary protein, its measurement may be limited in some countries including Japan, due to its higher cost and reimbursement by health insurance system. The aim of the present study is to establish a method that predicts the presence of microalbuminuria by measuring the total urinary protein-to-creatinine ratio (TPCR) among patients with CVD risks.

Methods: Spot urine samples were obtained from 609 adult patients with CVD risks visiting cardiovascular clinics of St. Luke's International Hospital in Tokyo from February 1 to April 30 2012. The TPCR and urinary albumin-to-creatinine ratio (ACR) of spot urine samples were determined.

Results: There was a strong positive correlation between TPCR and ACR (R^2=0.878, p<0.0001). A receive-operating characteristic curve analysis for the TPCR had a sensitivity of 94.8%, specificity of 84.1%, a positive predictive value of 80.5% and a negative predictive value of 95.9%, respectively, for the detection of albuminuria (both micro- and maroalbuminuria) and a cutoff value of 0.084g/g creatinine.

Conclusions: These results suggest that the detection of the TPCR can be used to screen for the presence of microalbuminuria among patients with CVD risks. This simple and inexpensive method can facilitate wider application, which can lead to earlier intervention and public benefit.

FR-PO190

The Role of Body Composition Analysis for Predicting the Presence of Metabolic Syndrome and Renal Dysfunction Jung-ho Shin, Youn-su Park, Min-jee Han, Su Hyun Kim, Suk-hee Yu. *Department of Internal Medicine, Chung-Ang University College of Medicine, Seoul, Korea.*

Background: Metabolic syndrome (MetS) is a complex of metabolic abnormalities that confers increased risk factors regarding renal injury. We investigated if fat contents derived from a bioimpedance analysis (BIA) were associated with MetS and kidney function in a healthy population.

Methods: We retrospectively reviewed 4,841 adults selected from the Health Promotion Center at Chung-Ang University Hospital. The Chronic Kidney Disease Epidemiology Collaboration creatinine equation (CKD-EPI) was used to obtain the estimated glomerular filtration rate (eGFR). The definition of MetS used followed the modified National Cholesterol Education Program Adult Treatment Panel III (NCEP ATP III) criteria. The Inbody 720 Body Composition Analyzer was used for the BIA, and the visceral fat area (VFA) and percentage of body fat (PBF) were derived accordingly.

Results: We recruited 2,604 men (53.8%) and 2,237 women (46.2%). We found a significant relationship between MetS and CKD (p<0.001). VFA and PBF were measured to be 95.5±34.8cm^2 and 26.5±6.7% in men, and 96.1±33.8cm^2 and 26.6±6.6% in women, respectively. In men, eGFR in adults without MetS was significantly higher than those with MetS (p=0.025). However, the VFA and PBF measurements were not different. Also, the VFA and PBF were not correlated with the CKD stage. In women, we could confirm that the presence of MetS was significantly related with eGFR and VFA, but not related to PBF (p<0.001, p=0.032 and 0.077). VFA in women increased according to the progression of the CKD stage; 93.3±33.6cm^2 in CKD stage 1, 98.1±33.7cm^2 in CKD stage 2 and 104.5±35.9cm^2 in CKD stage 3-5 (p=0.002). PBF was also correlated with the CKD stage in women (p=0.024). In a linear regression analysis, eGFR was associated not with PBF but with VFA in women (p=0.575 and 0.015).

Conclusions: We could confirm that metabolic syndrome and chronic kidney disease were significantly related to each other using a bioimpedance analysis. A body composition assessment by the bioimpedance analysis can be simply used to predict the presence of metabolic syndrome and renal dysfunction in healthy women.

FR-PO191

The Effect of Thyroid Hormone Replacement Therapy on Renal Function in Chronic Kidney Disease Patients with Subclinical Hypothyroidism Dong Ho Shin,[1] Dae-Suk Han,[1] Mi Jung Lee,[1] Hye-young Kang,[2] Seong Hun Kim,[2] Shin-Wook Kang.[1,2] *[1]Department of Internal Medicine, College of Medicine, Yonsei University, Seoul, Republic of Korea; [2]Severance Biomedical Science Institute, Brain Korea 21, Yonsei University, Seoul, Republic of Korea.*

Background: Subclinical hypothyroidism (SH) is not a rare condition in female, the elderly, and patients with chronic kidney disease (CKD). Even though previous studies demonstrated that thyroid hormone replacement therapy (THRT) improved cardiac function and dyslipidemia in patients with subclinical hypothyroidism, it has never been explored whether THRT has a beneficial effect on renal function in CKD patients with SH. This study was undertaken to investigate the impact of THRT on the changes in estimated glomerular filtration rate (eGFR) in CKD patients with SH.

Methods: A total of 124 CKD patients with SH, who were treated with L-thyroxine and had available eGFR for at least 24 months both before and after THRT, were enrolled between January 2005 and December 2011. The slopes of the decline in renal function before and after THRT were calculated by linear regression analysis of serial eGFR for each patient; the slope was expressed as the regression coefficient (mL/min/year/1.73m^2). In addition, a linear mixed model was used to compare the changes in eGFR before and after THRT.

Results: The mean age was 60.6 ± 12.4 years, and 62 (50.0%) patients were male. The mean follow-up durations before and after THRT were 28.6±8.5 and 30.6±6.4 months. THRT significantly reduced TSH levels (6.85 ± 1.43 to1.59 ± 1.29 μIU/mL, p<0.001). In contrast, there were no significant changes in T3 and fT4 concentrations by THRT. Serum cholesterol, triglyceride, albumin, calcium, and phosphate levels were also comparable after THRT. The rates of decline in eGFR before and after THRT were -4.64±0.90 and -1.49±0.72 mL/min/year/1.73 m^2, respectively, and a linear mixed model revealed that there was a significant difference in the rates of eGFR decline before and after THRT [coefficient (-0.18, -0.01), P < 0.01].

Conclusions: Thyroid hormone replacement therapy may have a beneficial effect on renal function in CKD patients with SH.

FR-PO192

Dose Dependent Effect of Weight Loss on Hyperfiltration as a Result of Bariatric Surgery Philip D. Evans,[1] Tim J. James,[2] Garry Tan,[1] Chris W. McIntyre.[1,3] *[1]Renal Medicine, Royal Derby Hospital, Derby, United Kingdom; [2]Department of Clinical Biochemistry, Oxford Radcliffe Hospitals, Oxford, United Kingdom; [3]School of Graduate Entry Medicine and Health, University of Nottingham, Derby, United Kingdom.*

Background: Obesity rates and the associated morbidity burden are increasing Worldwide. Obesity is an established risk factor for chronic kidney disease (CKD) but the underlying mechanisms, and impact of weight loss, are yet to be fully defined.

Methods: 14 patients listed for bariatric surgery were recruited from a single secondary care centre. Each participant underwent clinical assessment, including anthropomorphic measurements, iohexol glomerular filtration rate (iGFR) and urine and serum biochemistry tests within the 4 week period preceding their operation. These assessments were then repeated at 3 months post-surgery.

Results: The mean age (SD) was 48 ± 12yrs, 64% were male and 14% had a diagnosis of diabetes. At baseline the mean weight (SD) was 155.9 ± 23.6kg, mean iGFR(SD) 128.79 ± 28.2mL/min and median urinary albumin:creatinine ratio, ACR, [IQR] 0.65 [0.2-2.58] mg/mmol. At 3 months post-surgery there was a significant decrease in mean weight (135.2 ± 20.0kg; p = <0.001) and iGFR (114.3 ± 24.6mL/min; p = 0.009). There was no significant decrease in ACR. Univariable linear regression analysis revealed a significant correlation between the change in iGFR and change in weight (r^2 = 0.488; p = 0.036).

Conclusions: Glomerular hyperfiltration in obese subjects improves significantly within the first 3 months following bariatric surgery. There appears to be a linear relationship between change in iGFR and change in weight. Weight loss may therefore be a significant factor in reducing future renal risk.

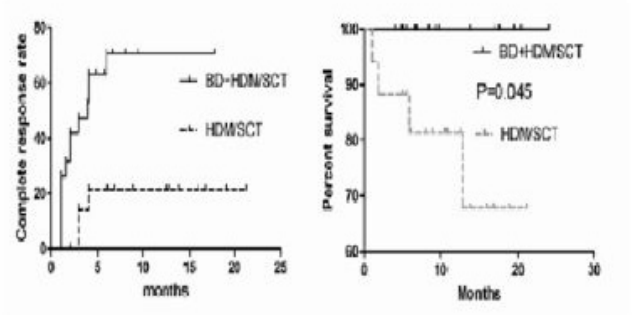
Induction Chemotherapy with Bortezomib and Dexamethasone Followed by Autologous Stem Cell Transplantation for AL Amyloidosis Xiang-hua Huang, Qingwen Wang, Mingjun Shi, Wencui Chen, Cai-hong Zeng, Zhao-hong Chen, Dehua Gong, Zhi-Hong Liu. *Research Institute of Nephrology, Jinling Hospital, Nanjing University School of Medicine, Nanjing, Jiangsu.*

Background: The use of bortezomib alone and in combination with steroids has shown efficacy in primary systemic amyloidosis (AL amyloidosis); however, its role in combination with HDM/SCT is unknown. In this study, we evaluated bortezomib in combination with dexamethasone (BD) for induction chemotherapy prior to HDM/SCT.

Methods: We conducted a prospective study comparing induction therapy consisting of two BD cycles followed by HDM/SCT (Group 1) with HDM/SCT alone (Group 2) in the treatment of patients with naive AL amyloidosis. The efficacy and toxicity of each treatment was evaluated.

Results: Thirty-three patients were enrolled in this study: sixteen in Group 1 and seventeen in Group 2. The patients presented with comparable disease severity and time from diagnosis to transplantation in the two treatment groups. The overall hematological response rates (ORR) were obtained for fifteen (93.8%) group 1 and nine (52.9%) group 2 patients (HR=3.41, *P*=0.004), and the complete hematological response rates were 68.8% (11/15) for group 1 and 17.6% (3/17) for group 2 (HR=4.95, *P*=0.016) (Figure 1A). Group 1 patients also achieved a better renal response (87.5 vs. 35.3%, HR=3.74, *P*=0.008) and a better heart response (40 vs. 20%) without major adverse events related to BD therapy. After a median follow-up of 12 months (range: 4-24 months), overall survival was significantly higher in Group 1 (*P*=0.045).



Conclusions: Our preliminary data suggest that induction chemotherapy with BD can significantly improve both the hematologic and organ response rates in patients with AL amyloidosis who undergo the HDM/SCT procedure; however, confirming the long-term benefits of this treatment will require further observation.

Effects of Atorvastatin on Renal Function in Patients with Dyslipidemia and Chronic Kidney Disease: Design of the ASsessment of Clinical Usefulness in CKD Patients with Atorvastatin (ASUCA) Trial Masato Kasahara,[1] Kenji Ueshima,[1] Daisuke Koya,[2] Tetsuya Babazono,[3] Tosiya Sato,[6] Miyuki Imamoto,[4] Shinji Yasuno,[1] Akira Fujimoto,[1] Genjiro Kimura,[6] Kazuwa Nakao.[1] *[1]EBM Research Center, Kyoto University, Japan; [2]Diabetes and Endocrinology, Kanazawa Medical University, Japan; [3]Nephrology and Hypertension, Diabetes Center, Tokyo Women's Medical University School of Medicine, Japan; [4]Food and Nutritional Science, Kobe Women's Junior College, Japan; [5]Biostatistics, Kyoto University School of Public Health, Japan; [6]Cardio-Renal Medicine and Hypertension, Nagoya City University.*

Background: The ASUCA trial was designed to consider whether the kidney function of Japanese CKD patients with dyslipidemia improves by atorvastatin.

Methods: We have decided to carry out a prospective multi-center, open-labeled, randomized trial to compare the reno-protective effects between diet therapy alone and atorvastatin plus diet therapy in patients with dyslipidemia and CKD (eGFR < 60 mL/min/1.73m^2).The primary endpoint is the change in eGFR after a 2-year treatment.

Results: A total of 334 patients (213 male and 121 female) were randomly assigned to either diet therapy alone or atorvastatin plus diet therapy and included in an intent-to-treatment population. In the atorvastatin and the control groups, mean ages were 63.2 and 63.1 years-old, mean eGFR were 55.9 and 54.0 mL/min/1.73m^2, and median urinary albumin /creatinine ratios were 24.9 and 29.1 mg/g, respectively.

Conclusions: While renal disorder due to metabolic syndrome increases recently, neither ACE inhibitor nor ARB is necessarily effective. The reno-protective effect of statin is suggested in the meta-analyses of large-scale clinical trials of Europeans and Americans. Since Japanese BMI is well known to be low as compared with BMI of Europeans and Americans, our study focusing on mild metabolic patients will lead to a clarification of a direct and/or pleiotropic effect of statin. While CKD patients don't tend to decrease so readily, it's important to establish a kidney disease remedy besides the RAS system restraint medicine; and for that reason alone, we expect that the outcome of our study will be all the more significant.

Cardiac Resynchronization Therapy in Chronic Kidney Disease: A Systematic Review and Meta-Analysis Neha Garg, Sankar D. Navaneethan, George Thomas. *Nephrology and Hypertension, Cleveland Clinic Foundation, Cleveland, OH.*

Background: Congestive heart failure is highly prevalent among chronic kidney disease (CKD) patients. Cardiac resynchronization therapy (CRT) confers mortality benefits to heart failure patients by remodeling of cardiac structure and function. We conducted a meta-analysis to examine the effects of CRT therapy (with or without defibrillator) in CKD population.

Methods: We searched MEDLINE, Web of Science and Scopus (1946 till December 2011) and abstracts from conference proceedings (2005 till 2012) for relevant studies. Studies that compared outcomes of a) CKD patients with CRT to non-CKD patients with CRT and b) CKD patients with CRT to CKD patients without CRT were included. Mortality, eGFR and left ventricular ejection fraction (EF) data reported in individual studies were extracted and pooled when appropriate using random effects model.

Results: Twelve studies (8 observational studies and 4 randomized trials, 8210 patients) were included. In most observational studies the improvement in EF with CRT was found to be similar across CKD and non-CKD populations. However survival outcomes after CRT were inferior in the CKD group as compared to the non-CKD group (3 observational studies, OR 1.89, 95% CI 1.33, 2.69). In contrast, the subgroup-analysis of the RCTs reported no significant mortality difference between the CKD and non-CKD groups after CRT therapy (2 RCTs, HR 0.67, 95% CI 0.50, 0.89). Amongst the CKD population, four studies reported stabilization or improvement in eGFR after CRT compared to those without CRT. One study reported a significantly favorable survival in CKD patients with CRT compared to CKD patients who received other heart failure therapy (HR 2.19%, 95% CI 1.31, 3.65, p= 0.002).

Conclusions: CRT improves EF and eGFR in CKD population with heart failure and whether these improvements translate into a survival benefit remains unclear. Given the increasing number of cardiac device placement in CKD population, further studies examining the effects of CRT in those with CKD on mortality and renal function are warranted.

FR-PO196

Impact of ß-Blocker Therapy on All-Cause Mortality and Initiation of Chronic Dialysis in Patients with Chronic Kidney Disease Not Yet on Dialysis: A Propensity Score Analysis Anna Jeanette Jovanovich,[1] M. Chonchol,[1] Alfred K. Cheung,[2,4] James S. Kaufman,[3] Tom Greene,[2,4] Jessica B. Kendrick.[1] *[1]University of Colorado; [2]VASLCHCS; [3]VA Boston Healthcare System; [4]University of Utah.*

Background: Patients with advanced chronic kidney disease (CKD) not yet on dialysis have an elevated risk of all-cause mortality and kidney disease progression. Sympathetic over-activity is commonly seen in CKD and appears to be an important contributor to increasing the risk of death and kidney disease progression. Little evidence exists on the efficacy of β-blockers for the prevention of death or progression to dialysis initiation in patients with advanced CKD.

Methods: We studied the effects of β-blockers in 1099 patients with advanced CKD not yet on dialysis who participated in the Homocysteine in Kidney and End Stage Renal Disease (HOST) study. Outcome measures were all-cause mortality and initiation of chronic dialysis. Cox proportional hazards models were used to control for important risk factors for cardiovascular disease and kidney disease progression, including propensity analysis for β-blocker use.

Results: Patients had a mean age 69 ± 11 years, 98% were male, 26% were African American, 96% had a history of hypertension, 55% had diabetes, and 82% had a history of cardiovascular disease. The mean estimated Modified Diet Renal Disease-glomerular filtration rate was 18 ± 6 ml/min/1.73m^2, and 653 (59%) were on ß-blocker therapy. Over a mean follow-up of 3 years, 453 (41%) patients died from any cause and 615 (56%) patients initiated chronic dialysis. Baseline β-blocker use was not associated in univariate or multivariate analyses with lower risk of all-cause mortality (adjusted HR of 0.91; 95% CI, 0.75-1.11; p=0.35) or lower risk of initiation of chronic dialysis (adjusted HR of 0.90; 95% CI, 0.76-1.06; p=0.20).

Conclusions: In patients with advanced CKD and a high burden of cardiovascular disease, β-blocker use was not associated with a lower risk of all-cause mortality or initiation of chronic dialysis.

Prevention, Detection, and Management of Early Chronic Kidney Disease: A Systematic Review of Clinical Practice Guidelines Pamela Andrea Lopez-Vargas,[1,2] Allison Tong,[1,2] Premala Sureshkumar,[1,2] David W. Johnson,[3] Jonathan C. Craig.[1,2] *[1]Sydney School of Public Health, University of Sydney, Sydney, NSW, Australia; [2]Centre for Kidney Research, the Children's Hospital at Westmead, Sydney, NSW, Australia; [3]Department of Nephrology, University of Queensland at Princess Alexandra Hospital, Brisbane, Queensland, Australia.*

Background: Chronic kidney disease (CKD) is rapidly increasing worldwide. Clinical practice guidelines have been developed to manage and prevent its progression. This study aims to compare the scope, content and consistency of international guidelines on CKD Stages 1-3.

Methods: Guideline databases, electronic databases, and nephrology societies' websites were searched to November 2011. The Appraisal of Guidelines for Research and Evaluation (AGREE) II instrument and textual synthesis was used to appraise and compare recommendations.

Results: Fifteen guidelines and one consensus statement were included. Guideline methodological rigour was variable.Inconsistencies were evident in a number of recommendations. For detection of CKD, all guidelines recommended eGFR measurement and serum creatinine, but some also recommended dipstick urinalysis and 24 hr urine. The recommended PCR and ACR thresholds varied as did the proteinuria (150-300 mg/day, >300 mg/day and >500 mg/day) values. Blood pressure thresholds varied from 125/75 to 140/90 mmHg. ACEi and ARBs were recommended as first line treatment for hypertension, however recommendations were conflicting regarding separate or combined administration. Dietary protein intake recommendations were inconsistent (no restriction or 0.75g/kg/day -1.0g/kg/day). Salt intake of 6g/day was recommended by most. Psychosocial support and education were recommended but specific strategies were not provided.

Conclusions: CKD guidelines are variable with respect to their methodologic quality, stakeholder involvement, coverage, specific recommendations and applicability. To promote effective primary and secondary prevention of CKD, guideline recommendations that are based on the best available evidence and augmented with healthcare context-specific strategies and action plans for implementation are warranted.

Characteristics and Outcomes of CKD Patients with Implantable Cardioverter Defibrillator Sadaf S. Khan,[1] Jesse D. Schold,[2] Anne S. Tang,[2] Victoria Konig,[2] Jennifer Lyons,[3] Stacey Jolly,[1] Joseph V. Nally,[3] Sankar D. Navaneethan.[3] *[1]Medicine, Cleveland Clinic; [2]Quantitative Health Sciences, Cleveland Clinic; [3]Nephrology, Cleveland Clinic.*

Background: Chronic kidney disease (CKD) is associated with increased cardiovascular morbidity and sudden cardiac death. Implantable cardioverter defibrillator (ICD) placement has been shown to improve mortality rates in certain populations. We examined the characteristics of CKD patients with ICD and its associations with all-cause mortality.

Methods: 43828 patients with non-dialysis dependent CKD (eGFR ≤ 60 ml/min/1.72m^2) in the Cleveland Clinic CKD registry were included. Logistic regression analyses and cox proportional hazards models were used to examine the characteristics of CKD patients with ICD and the associations between ICD and all-cause mortality after adjusting for relevant confounding variables.

Results: Among the 43828 CKD patients, 1939 (4.4%) had ICD. CKD patients with ICD were more likely to be male (OR 2.35, 95% CI 2.08, 2.65), have a diagnosis of heart failure (OR 11.98, 95% CI 10.65, 13.47), coronary artery disease, coronary revascularization procedures, and ventricular arrhythmia. During a median follow-up of 2.3 years, 375 participants died. Among those with CKD and ICD, each 5 ml/min/1.73 m^2 decrease in eGFR was associated with a 2% increased hazard for death (HR 1.02, 95% CI 1.01, 1.03). Compared to stage 3a CKD patients with ICD, stage 4 CKD patients with ICD had a higher hazard for death (HR 2.00, 95% CI 1.47, 2.72). Other independent predictors of mortality in this population included male sex, heart failure, cerebrovascular disease, and ventricular arrhythmia.

Conclusions: Among CKD patients with ICD, advanced kidney disease was associated with an increased mortality. Whether mortality differs among patients with similar comorbid disease burden but without ICD merits further studies to understand the role of ICD in this high-risk population.

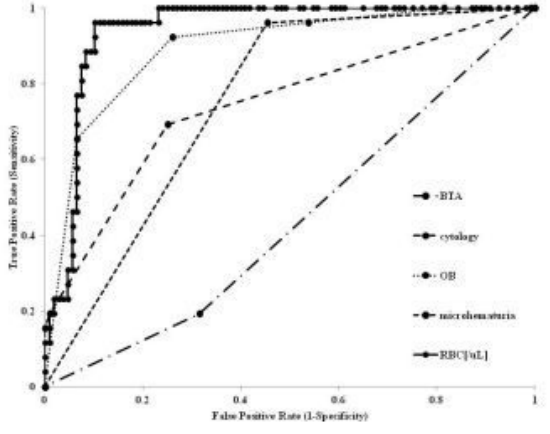
Screening for Bladder Cancer with the Automated Analyzer UF-1000i® Urine Flow Cytometer Satoru Muto, Akiko Nakajima, Akira Horiuchi, Toshiyuki China, Hisamitsu Ide, Shigeo Horie. *Urology, Teikyo University, Tokyo, Japan.*

Background: We evaluated the efficacy of the automated urine analyzer UF 1000i® to diagnose bladder cancer from the morphology of red blood cells (RBC) in urine.

Methods: The Sysmex UF 1000i® data of 264 samples were analyzed. After excluding the patients with other disease that causes of hematuria, we included 134 patients with any one of positive occult blood in urine (OB), microhematuria, positive urine cytology, or positive bladder tumor antigen (BTA) test in this prospective study. We compared the bladder tumor markers such as the morphology of RBC in urine detected by UF 1000i®, urine cytology, BTA test, OB, microhematuria, between bladder cancer group and non-cancer group. RBC in urine were classified into glomerular type (dysmorphic) and non-glomerular type (isomorphic) by using the Sysmex UF 1000i®.

Results: Urine cytology, OB, microhematuria showed the significant differences between cancer group and non-cancer group (cytology; P=0.00, χ^2=28.88, OB; p=0.00, χ^2=56.35, microhematuria; p=0.0000, χ^2=21.86). As the reference for bladder cancer, the area under the curve for UF1000i® RBC counts is 0.94, which is higher than that for BTA (0.44), urine cytology (0.74), OB (0.89), and microhematuria (0.75).



We could detect the isomorphic type of RBC in urine of all 26 patients with bladder cancer without exception (p=0.00, χ^2=91.25). Multiple logistic regression analysis showed the morphology of RBC in urine were significant predictors to detect bladder cancer (P=0.00). Analytic parameters such as sensitivity, specificity, positive predictive value, negative predictive value, and accuracy of isomorphic RBC in urine to detect bladder cancer were 100.0%, 91.7%, 74.3%, 100.0%, 93.3%, respectively.

Conclusions: Our results demonstrated the efficacy of screening for bladder cancer with the automated analyzer UF1000i® Urine Flow Cytometer.

FR-PO200

Serum IgA/C3 Ratio Predicts Progression of IgA Nephropathy Jun Zhang, Cheng Wang, Hui Peng, Zengchun Ye, Tan-qi Lou. *Department of Nephrology, The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou.*

Background: The serum IgA/C3 ratio has been shown to be a good predictor of histological lesions and prognosis for patients with IgA nephropathy (IgAN) in Japanese. But its validity in Chinese population is unclear. We sought to explore the long-term outcomes of IgAN, its clinical and histopathological predictors in Chinese patients. In particular, the role of serum IgA/C3 ratio in course of IgAN was addressed.

Methods: A total of 217 biopsy-diagnosed IgAN patients were recruited into this prospective cohort with a mean follow-up of 36.10±23.51 months. Sociodemographics, serum IgA/C3 level, other clinical examinations, and Lee's histological grade were measured. Receiver operating curve (ROC) of serum IgA/C3 ratio was employed to determine the optimal cut-off in predicting endpoint event. Serum IgA/C3 ratio together with other clinical, pathology parameters, using univariate and multivariate Cox regression analysis, with halving of baseline eGFR or received renal replacement therapy as the endpoint event. Renal survival and the relationships between clinical, pathologyparameters and renal outcomes were assessed.

Results: The optimal cut-off value of serum IgA/C3 ratio was 3.32 in the prediction of renal end point of IgAN. In multivariate analysis, renal end point of IgAN was significantly predicted by Proteinuria ≥1 g/day (RR = 2.65, 95% CI 1.01-7.68), hypertension (RR = 3.15, 95% CI 1.07-9.29), and higher Lee's histological grade (RR = 4.67, 95% CI 1.43-15.25) and serum IgA/C3 ratio≥3.32 (RR = 4.31, 95% CI 1.33-13.96).

Conclusions: A proportion of patients with IgAN developed end stage renal disease in Chinese. In addition to some traditional risk factors, we also confirmed that serum IgA/C3 ratio is a useful predictor of poor outcomes of IgAN in Chinese patients.

FR-PO201

Kidney Damage Markers and Strenuous Labor among Western Nicaraguan Workers in a Region of Epidemic CKD Michael Mcclean,[1] Juan Jose Amador,[1] Oriana Ramirez-rubio,[1] Rebecca L. Laws,[1] James S. Kaufman,[2] Daniel E. Weiner,[3] Marcel Sanchez,[4] Daniel R. Brooks.[1] *[1]Boston University School of Public Health; [2]Boston University School of Medicine; [3]Tufts Medical Center; [4]Ministry of Health, Managua, Nicaragua.*

Background: An epidemic of non-proteinuric CKD is occurring across Central America, with over 20,000 deaths, mainly among younger men. Given the extreme heat in the region, occupational heat stress and recurrent acute kidney injury in the setting of strenuous work is one hypothesized cause of CKD.

Methods: Workers in multiple jobs within the sugarcane industry in Western Nicaragua were tested at the beginning and during the latter part of the 2010-2011 sugar cane harvest to evaluate whether more strenuous jobs, such as cane cutting, were associated with markers of kidney injury, including serum creatinine (to estimate GFR) and urine albumin, NGAL, NAG, and IL-18.

Results: In 284 sugarcane workers, eGFR declined minimally but significantly over the growing season in those engaged in the most strenuous work tasks, while urine ACR remained low in all groups. Significant increases from the start to end of the season were seen in NGAL, NAG, and IL-18 and were most notable among workers engaged in the most intensive tasks. Using factory workers as a reference, the changes from start to end of the season in both NGAL (Table) and IL-18 were significantly greater for cane cutters, while the change in NAG was significantly greater for cane cutters, seed cutters, irrigators and agrichemical appliers.

Conclusions: These results suggest that tubular kidney damage may occur during the working season and may be more common among workers engaged in more strenuous physical labor. If acute kidney damage is on the causal pathway to CKD, heat or other work-related exposures may be contributing to the regional epidemic.

Job	N	Pre-Season NGAL	End-Season NGAL	Mean Change (µg/mg)
Cane Cutters	51	7.6	19	+24
Seed Cutters	26	16	15	-3.2
Irrigators	50	7.2	14	+8.9
Drivers	39	6.8	7.7	0.7
Seeders	28	23	20	-3.2
Chemical Appliers	28	7.0	6.9	+3.0
Factory Workers	59	7.2	7.2	+3.5

Pre- and end-season values are geometric mean urine NGAL levels (µg/mg creatinine)

Assessment of Renal Reserve in Young Adults by Iohexol Plasma Clearance
Dana F. Work, George J. Schwartz. *Pediatric Nephrology, University of Rochester, Rochester, NY.*

Background: Renal reserve (RR) is a concept used to explain the kidney's ability to increase its filtration rate in response to a stimulus. There are no published studies on the use of iohexol for the determination of RR. We sought to find if using plasma iohexol disappearance and a protein load (protein shake or hamburger) to stimulate GFR could be used to measure RR in healthy young adults.

Methods: Serum cystatin C (cysC), a chem. 8, and an iohexol blank were obtained and 10 ml of iohexol was given to adults ages 20-30. CysC, a rapidly responsive renal biomarker, was measured by immunonephelometry and iohexol concentrations by HPLC. Blood samples for iohexol analysis were obtained at 120,180,240,330,390 and 450 min after injection; a second cysC was also obtained 390 min after the meat meal. Subjects drank a 60 gm protein shake or ate a hamburger containing 60 gms of protein 245-260 min after iohexol injection. GFR was calculated from the iohexol dose and slope disappearance and also estimated from cys C (Schwartz,et al,KI in press 2012) before and after the protein load; the difference in GFR was considered the RR.

Results: For 6 subjects who received the protein shake, the mean baseline GFR was 105.8 ± 12.6 ml/min per 1.73 m^2 and the mean change in GFR was -9.0 ± 14.5 (p=0.188 by paired t test). For 6 subjects who ate the hamburger, the mean baseline GFR was 106.3 ± 8.2 and the mean change in GFR was 8.4 ± 7.6 (p=0.044 by paired t test). The average baseline calculated GFR by serum cysC was 102.3 ± 8.6 with a mean change in GFR of 9 ± 4 (p=0.008 by paired t test).

Conclusions: There was no significant increase in GFR with the protein shake but there was with the hamburger. A more significant increase in GFR was computed from cysC changes. The increase in iGFR in response to meat was not consistent between subjects despite a consistent decrease in serum cysC. We speculate that the slope iohexol clearance does not respond quickly enough to the protein load and may underestimate RR. It is likely that repetitive measurement of serum cysC may be adequate to characterize RR in young adults. Further studies on RR utilizing renal clearance methods will help to establish if cysC can serve as a surrogate measurement of RR.

Metabolic Syndrome and Risk of Progression of Chronic Kidney Disease: A Single Center Cohort Study
Kosaku Nitta. *Department of Medicine, Kidney Center, Tokyo Women's Medical University, Shinjuku-ku, Tokyo, Japan.*

Background: Metabolic syndrome (MetS) is a risk factor for the development of diabetes and cardiovascular disease, and recently was linked to incident chronic kidney disease (CKD). The purpose of this study is to examine whether MetS is associated with CKD progression in Japanese at a single center.

Methods: Outcome variables were a decrease in estimated glomerular filtration rate (eGFR) of 50% or 25 ml/min/1.73 m^2, end-stage renal disease (ESRD), death, or a composite outcome of all 3. There were 213 subjects of the analysis, and **40.4% of them met the criteria for MetS.**

Results: The group of subjects with MetS had higher urinary albumin-to-creatinine (UACR) levels. Survival curves stratified by MetS status showed early separation of the curves and a significantly higher survival rate in the group without MetS (P=0.0086). Comparisons with normoalbuminuria and microalbuminuria showed that macroalbuminuria was equally associated with predicted composite outcome (GFR, ESRD, or death) both in the presence and absence of MetS. Multivariate analyses for all covariates showed that eGFR (HR 8.286, 95% CI 2.360-28.044, P=0.0012) and the UACR (HR 2.338, 95% CI 1.442-3.861, P=0.0005) at baseline were independently associated with the composite outcomes.

Conclusions: MetS was associated with albuminuria in a cohort of Japanese CKD patients, and both MetS and albuminuria were independently associated with CKD progression.

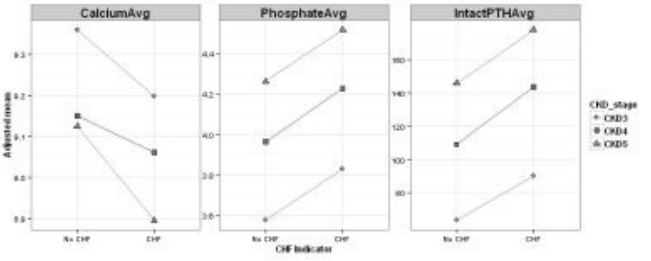
FR-PO204

Management of Metabolic Bone Disease in Patients with Chronic Kidney Disease and Congestive Heart Failure
Claudine T. Jurkovitz,[1] Wei Zhang,[1] Peter A. Burke,[1] James R. Bowen,[1] Rubeen K. Israni.[2] *[1]Christiana Care Health System, Newark, DE; [2]Nephrology Associates, PA, Newark, DE.*

Background: Chronic kidney disease (CKD) is frequent in patients with congestive heart failure (CHF). The prevalence of metabolic bone disease (MBD) increases with advancing CKD. Whether the management of CKD-associated MBD differs between patients with and without CHF is unknown.

Methods: A cohort of patients followed in a Nephrology practice between 2000 and 2010 was evaluated. Adult patients with CKD stage 3 and above were included. Dialysis and Transplant patients were excluded. Average calcium, phosphorus and iPTH were calculated for each patient. Multilinear regressions were used to determine the effect of CKD and CHF on Calcium, Phosphorus and iPTH after controlling for age, race, gender. Because none of the dependent variables were normally distributed, we log-transformed iPTH, and used Box-Cox transformation for Phosphorus and Calcium. The interaction between CHF and baseline CKD stage was explored for each model. The adjusted means were back transformed.

Results: A total of 11,883 patients were included. Mean followup was 4 years; 24.3% had CHF; 75.8% had CKD stage 3, 21.7% CKD stage 4 and 2.5% CKD stage 5 at baseline. Mean age was 68.8 ± 12.5 in patients with CHF versus 65.6 ± 13.7 in those without. As shown in figure 1, the adjusted mean for calcium was lower in patients with CHF at each CKD stage (p<0.0005). The interaction between CKD and CHF was significant (p=0.0053). The adjusted means for phosphorus and iPTH were higher in patients with CHF at each CKD stage (p<0.05) whereas the interactions between CKD and CHF were not significant.



Conclusions: The control of calcium, phophorus and iPTH is poorer in patients with CHF at each CKD stage. Better management of MBD is warranted in these patients and might contribute to lower morbidity and better quality of life.

FR-PO205

The Impact of Chronic Psychological Stress in CKD Progression
Vasiliki Tsarpali,[1] Efharis Panagopoulou,[2] Aikaterini Michalaki,[3] Olga Nikitidou,[3] Dorothea Kapoukranidou,[4] Myrto Kostopoulou,[3] Michail Pazarloglou,[1] Konstantinos Leivaditis,[3] Vassilios Liakopoulos,[3] Nicholas V. Dombros.[3] *[1]Nephrology Department, Agios Pavlos-Panagia Hospital; [2]Department of Biological Sciences and Preventive Medicine, Medical School, Aristotle University of Thessaloniki; [3]Renal Unit, 1st Department of Medicine, AHEPA Hospital, Thessaloniki, Greece; [4]Physiology Department, Medical School, Aristotle University of Thessaloniki, Greece.*

Background: The association of psychological stress with adverse health outcomes like hypertension and cardiovascular disease (CVD) has been well described. Social groups with known psychosocial stressors have an augmented rate of decline of renal function. The direct impact of psychological stress on the progression of CKD has not yet been investigated.

Methods: A retrospective study was conducted in 41 patients with CKD stage 2-4 (age 73±6 years), with controlled levels of blood pressure and plasma glucose receiving optimal therapy. Estimated GFR (MDRD formula) was calculated one year before and at the time of the psychological evaluation. Stress and depression were assessed by Hospital Anxiety Depression Scale (HADS). Salivary cortisol levels were measured after morning awakening and late in the afternoon.

Results: An elevated rate of CKD progression was observed for patients with a high HADS score (decline in eGFR 1.1±1.7 vs. increase 5.4±1.7, p=0.01). Measurement of stress in HADS scale was positively correlated with the rate of CKD progression (r=0.54, p<0.001). After multivariate adjustment for age, sex, CVD, depression, diabetes and hypertension, stress continued to be strongly associated with renal function decline. Morning and afternoon salivary cortisol levels were elevated in all participants and the diurnal rhythm of cortisol secretion was blunted, with higher afternoon values.

Conclusions: The pattern of cortisol secretion resembled the one observed in chronic stress, indicating that CKD itself is an independent stressor that contributes to psychological stress. These results suggest a possible relationship between chronic stress and CKD progression.Further investigation is warranted for factors mediating this relationship and its potential clinical consequences.

FR-PO206

Does Automated Reporting of eGFR Affect Primary Care Practice Patterns?
Micah L. Thorp,[1] David Smith,[1] Nancy A. Perrin,[1] Jessica W. Weiss,[2] Suma Vupputuri,[3] Amanda F. Petrik,[1] Xiuhai Yang.[1] *[1]CHR, Kaiser Permanente Northwest; [2]Oregon Health and Science University; [3]CHR, Kaiser Permanente Georgia.*

Background: Experts have recommended automated calculation and reporting of estimated glomerular filtration (eGFR) rates among all patients who have a serum creatinine measured. Few studies have assessed changes in clinical practice patterns in response to this new initiative. We conducted a time series analysis assessing the rate of nephrology referrals, visits and follow up laboratory testing before and after automated reporting was implemented.

Methods: We conducted a retrospective cohort study of patients who had incident eGFR levels<60 measured before and after implementation of eGFR reporting at an HMO. We compared rates of subsequent evidence of clinical recognition including nephrology referral, repeat serum creatinine and proteinuria testing before and after implementation of eGFR reporting. Logistic models were used to compare change in clinical recognition rates controlling for baseline trends, and determine if the change in rates is related to clinician characteristics.

Results: We found 21,612 adults who had an eGFR<60, and did not have a diagnosis of CKD. The number of referrals increased after the eGFR by 1.3 referrals/month (p=.05). However, the trend in monthly referral slowed after eGFR by .59 per month in comparison to the baseline trend (p = .02). Difference in the change in likelihood of referral after eGFR were found for age (p=.01), amount of FTE (p=.04), and type of practice (p=.01). Slope changes in subsequent orders for other testing (i.e. proteinuria) were not significant.

Conclusions: Following implementation of eGFR reporting, the likelihood of referral to nephrologists increased though the number of nephrology clinic visits did not. Clinicians who were younger, family medicine, and full time were more likely to increase referrals after eGFR.

Highly Efficient Differentiation of Human Embryonic and Induced Pluripotent Stem Cells into Targeted Mesendoderm, Endoderm, and Mesoderm Cell Fates Albert Q. Lam,[1,2] Benjamin S. Freedman,[1] Joseph V. Bonventre.[1,2] *[1]Renal Division, Brigham and Women's Hospital, Boston, MA; [2]Harvard Stem Cell Institute, Cambridge, MA.*

Background: Human pluripotent stem cells (hPSCs) have the potential to generate the wide diversity of human cell types. Here we report a highly efficient system to induce mesendoderm, mesoderm, and endoderm differentiation in human embryonic stem cells (hESCs) and induced pluripotent stem cells (hiPSCs) using simple, chemically defined monolayer culture conditions.

Methods: For all differentiation experiments, hESCs or hiPSCs were plated as single cells onto Geltrex-coated wells in mTeSR1 medium and cultured for 2-3 days until they reached 50% confluence. To induce mesendoderm differentiation, cells were treated with serum-free media supplemented with a small molecule GSK-3β inhibitor (GSK3i). Differentiation into endodermal or mesodermal cell types was achieved by first inducing mesendoderm with GSK3i, then adding specific combinations of growth factors or small molecules at precise time intervals.

Results: Treatment of hPSCs with GSK3i rapidly induced BRACHYURY$^+$MIXL1$^+$ mesendoderm differentiation with nearly 100% efficiency in a manner which recapitulated mesendoderm formation during embryonic development. GSK3i-induced mesendodermal cells could be robustly differentiated into endodermal or mesodermal lineages with the precisely-timed addition of Activin A, BMP, and FGF signals. The combination of GSK3i and Activin A robustly generated SOX17+ definitive endoderm, which could subsequently be differentiated into albumin-expressing hepatocytes, hormone-producing pancreatic endocrine cells, and the precursors to lung, thyroid, and intestinal tissue. Optimization of GSK3i exposure times and the addition of BMP4 and FGF2 resulted in mesoderm differentiation. Importantly, we discovered a novel combination of signals which differentiated hPSCs into PAX2$^+$LHX1$^+$ intermediate mesoderm cells, precursors to human kidney tissue, which have not been previously attainable.

Conclusions: Our findings establish a system whereby hPSCs can be flexibly and robustly differentiated into various endodermal or mesodermal lineages, including kidney progenitors, for regenerative medicine.

Rescue of Chronic Diabetic-Ischemic Nephropathy by Intravenous Renal Cell Transplantation Katherine J. Kelly,[1] Jesus H. Dominguez.[2] *[1]Medicine, IUMC, Indianapolis, IN; [2]Medicine, VAMC, Indianapolis, IN.*

Background: Acute kidney injury (AKI) complicates chronic kidney disease (CKD and it is the most frequent cause of progression to end stage renal disease (ESRD) from diabetic nephropathy (DN). Unfortunately, only a fraction of ESRD patients eventually receive a kidney transplant.

Methods: We developed intravenous renal cell transplantation (IRCT) using primary kidney cells expressing the tubulogenic protein SAA1. We now tested in obese/diabetic female F_1 hybrid Zucker diabetic/SHHF (ZS) rats the hypothesis that unrelenting renal decline in ischemic/diabetic CKD can be abrogated by IRCT.

Results: We studied four groups, diabetic ischemic (subjected to bilateral renal ischemia for 20 min) and transplanted with cells expressing an empty vector (ADI, n = 9), diabetic ischemic transplanted with cells transfected with a SAA expressing vector (BDI, n = 9), sham operated diabetic transplanted with cells transfected with an empty vector (ADS, n = 6), and diabetic sham transplanted with renal cells transfected with a SAA expressing vector (BDS, n = 6). ZS rats were subjected to ischemia or sham surgery at 10 weeks of age, and given two doses of IRCT (1.5 X 10^6 cells per injection) at 15 and 20 weeks of age (after nephropathy was firmly established). The rats were terminated at 34 weeks of age. ADI had severe renal failure with creatinine clearance (CC) of 0.8 ± 0.1ml/min, which improved to 1.5 ±0.2, in BDI (p = 0.009), and unchanged in ADS 1.5 ± 0.2, and BDS 1.3 ± 0.3. These corresponded to a mean serum creatinine of 0.51 ± 0.3 in ADI, 0.37 ± 0.1in BDI (p=0.03), 0.45 ± 0.02 in ADS and 0.35 ± 0.01 in BDS. Kidneys were larger in ADI 3.4 ± 0.2 mg/g body weight, smaller in BDI 2.8 ± 0.06 (p = 0.03), and unchanged in ADS 3.0 ± 0.09, and BDS 2.9 ± 0.08. Fractional interstitial fibrosis (IF) was 25 ± 2 % in ADI, and much lower, 8 ± 1 in BDI (p <0.001). In ADS, IF was 12 ± 1 and reduced to 7 ± 1 in BDS, (p<0.01). IRCT did not affect any of the metabolic syndrome abnormalities.

Conclusions: We conclude IRCT with adult primary cells effectively stops renal decline in ischemic DN, supporting a valuable role for renal regeneration with adult renal cells given by peripheral vein infusions.

In Vitro Branching of Ureteric Bud Tubes Generated by Micropatterned Mold Peter V. Hauser,[1,2] Masaki Nishikawa,[1,2] Hiroshi Kimura,[3] Teruo Fujii,[3] Norimoto Yanagawa.[1,2] *[1]David Geffen School of Medicine, UCLA, Los Angeles, CA; [2]Renal Regeneration Laboratory, VAGLAHS at Sepulveda, North Hills, CA; [3]Institute of Industrial Science, University of Tokyo, Tokyo, Japan.*

Background: Kidney development is initiated by the interaction of the ureteric bud (UB) with the metanephric mesenchyme (MM). Using a micropatterned gel we generated a tubular structure from dispersed UB-derived cells. The aim of this study was to induce budding and branching of the tissue engineered UB tubes *in vitro* using growth factors and aggregation with primary MM cells.

Methods: Tubular structures were formed by seeding dispersed mouse UB (CMUB-1) or collecting duct cells (mIMCD) in collagen I (2.4%) into a micropatterned 3% agarose gel (5.10^5cells/mold) by centrifugation (1200rpm,10min), followed by culture in DMEM (10%FCS+P/S) at 37C, 5% CO_2. Tubes thus formed were harvested after 24h. *In vitro* budding was induced by exposing the generated tubes to growth media with 125ng/ml glial cell-derived neurotropic factor (GDNF) or 125ng/ml fibroblast growth factor 7 (FGF7) for 5 to 7 days, while edogenous Activin A was inhibited by by follistatin-soaked beads (500ng/ml) placed in close proximity to the tubes. To induce branching, the tubes were embedded in aggregates of MM cells harvested from mouse embryos at E11.5 or E13.5. Aggregates were formed by centrifugation of 1 tube with 8.10^4 MM cells (800g, 3min), and cultured in DMEM. To inihibit tubular branching TGF-ß (2ng/ml) was added to the growth media.

Results: Tubular structures generated from dispersed UB cells exhibit budding next to the follistatin soaked beads when cultured in GDNF or FGF7 containing growth media. The generated ureteric tubes further showed strong branching when embedded in primary MM aggregates, which could be inhibited by TGF-ß to the media.

Conclusions: We demonstrate that budding and branching can be induced from the tubular structures generated from dispersed UB-derived cells in micropatterned gels *in vitro*. The branching tubes can be used for tissue engineering attempts to generate renal tissue with functional draining system. Current research is underway to optimize the combination of MM and generated tubes.

Vasculogenesis by Mouse Kidney Progenitor Cells in Three-Dimensional Co-Culture: Role of PDGF-BB Chakradhar Velagapudi,[1] Myung-ja Lee,[2] Hannah Burns,[2] Brent Wagner,[1] Veronique Barnes,[2] Hanna E. Abboud,[1] Jeffrey L. Barnes.[1,2] *[1]Dep of Medicine/ Nephrology, University of Texas Health Science Center, San Antonio, TX; [2]Probetex, Inc, San Antonio, TX.*

Background: PDGF-BB plays an important role in vasculogenesis (VG) during development. We previously showed that mouse kidney metanephric mesenchymal (MM) and ureteric bud (UB) cells undergo reciprocal induction of simple organogenesis when combined in three-dimensional (3-D) matrigel co-culture in SCID mice. We also showed that MM cells proliferate and migrate in response to PDGF-BB chain in 2-D culture. Here we explored contributory roles of metanephric mesenchymal (MM) and uretric bud (UB) cells in PDGF-BB-induced VG in 3-D co-culture.

Methods: Employing a 3-D culture assay using PDGF-BB impregnated agarose beads as surrogates of UB cells to assess MM migration; Interference of a PDGF-BB chemotactic gradient using a neutralizing antibody or excess growth factor; and by interference of PDGFR-ß using the chemical inhibitor, imatinib mesylate (IM), or PDGFR-ß-null MM cells. The effects were examined by bright-field, immunofluorescence, and electron microscopy.

Results: UB cells synthesized PDGF-BB chain, but not its receptor (PDGFR-ß). Conversely, MM cells synthesized PDGFR-ß, but not PDGF-BB chain, indicating that the two cell types have the machinery for directional induction via this growth factor. VG in 3-D co-culture was inhibited using a neutralizing antibody to PDGF-BB or by including PDGF-BB in the matrix presumably disrupting a chemotactic gradient. PDGF-BB impregnated agarose beads in place of UB cells, resulted in the attraction of MM cells and development of rudimentary vasculogenic structures at the bead surface. Inclusion of IM with MM and UB cells inhibited VG. Similarly, PDGFR-ß-null MM cells grown with UB cells in 3-D co-culture failed to undergo VG.

Conclusions: These studies verify that UB cells provide a paracrine source of PDGF-BB that induces MM cell VL in 3-D co-culture that can be inhibited by blocking the growth factor or its receptor. This system provides a new organotypic model to investigate VG under controlled conditions *ex vivo*.

Differentiation of Human Mesenchymal Stem Cells into the Ureteric Bud in Chicken Embryos Akira Fukui, Takashi Yokoo, Nobuo Tsuboi, Yoichi Miyazaki, Yasunori Utsunomiya, Tatsuo Hosoya. *Division of Nephrology and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan.*

Background: We previously demonstrated that human mesenchymal stem cells (hMSCs) transplanted into the metanephric mesenchyme (MM) region of rodent embryos at embryonic day (E) 11.5 resulted in their differentiation into nephrons, derivatives of the MM. However, they were unable to differentiate into collecting duct system, a derivative of the ureteric bud (UB). This suggests that for differentiating hMSCs into collecting duct system, hMSC-derived UB must be generated by their transplantation at earlier stage. So, we focused on using chicken embryos that are easier to be manipulated and cultured than mammals. We already succeeded in having chicken Pax2-expressing hMSCs differentiate into the Wolffian duct (WD) by their transplantation into chicken embryos at E1.5. However, hMSC-derived cells in chimeric WD were few in number and they stopped migrating on their way to elongating WD before reaching the UB. Thus, the aim of this study is to generate hMSC-derived UB in chicken embryos.

Methods: hMSCs were lipofected with chicken Pax2 or Lim1 and they were co-transfected with GFP as a tracer. hMSCs were transplanted *in ovo* into the intermediate mesoderm region adjacent to the most caudal somite at each stage with a mouth pipette. Using a fluorescent dissecting scope, GFP-expressing hMSCs were followed to determine their migration and location at later stage.

Results: We found that chicken Lim1-expressing hMSCs differentiate into the WD more efficiently and that they can differentiate into the WD even by their transplantation at later stage, when the site of transplantation is closer to the UB. As expected, when chicken Lim1-expressing hMSCs were transplanted at E2.5, we found that hMSC-derived cells can migrate into the UB epithelia 3-5 days after transplantation.

Conclusions: We succeeded in having chicken Lim1-expressing hMSCs integrated into the UB epithelia by their transplantation into chicken embryos. We are now examining whether they differentiate properly into the UB and they can differentiate into the ureters and collecting duct after further development.

Proteinuria Impairs Renal Progenitors Differentiation into Podocyte by Sequestering Retinoic Acid Elena Lazzeri,[1] Anna Julie Peired,[1] Maria Lucia Angelotti,[1] Elisa Ronconi,[1] Benedetta Mazzinghi,[1] Alessandro Sisti,[1] Laura Lasagni,[1] Paola Romagnani.[1,2] *[1]Excellence Center DENOTHE, University of Florence, Florence, Italy; [2]Nephrology Unit, Meyer Children's Hospital, Florence, Italy.*

Background: Podocyte loss and proteinuria predict disease progression and renal outcome. Lowering proteinuria retards progression and even induces regression of glomerulosclerosis, which associates with generation of novel podocytes. A population of renal progenitor cells (RPC) localized at Bowman's capsule can differentiate into podocytes and replace lost ones.

Methods: In vitro podocyte differentiation of RPC was performed in VRAD medium and with retinoic acid (RA). RA uptake was performed with [3H]RA and HSA. In vivo experiments were performed in a model of adriamycin nephropathy induced in RA Response Element (RARE)-lacZ transgenic mice treated with injections of RA. RA levels in urine of mice were assessed by mass spectrometry.

Results: Exposure of RPC to HSA impaired their differentiation into podocytes induced by RA. In vitro experiments of RA uptake demonstrated that HSA sequestered RA through specific binding, and blocked its entry within the cell impairing podocyte-specific gene transcription. RA levels were assessed in urine of RARE-lacZ transgenic mice after induction of adriamycin nephropathy. Although RA was not measurable in the urine of healthy mice, it became detectable, following podocyte injury, only in mice with low levels of proteinuria, and disappeared as soon as proteinuria increased. Consistently, activation of RARE-LacZ activity was shown within RPC following the podocyte injury. However, RARE-lacZ signal disappeared as soon as proteinuria increased. Treatment with RA allowed the persistence of RARE-lacZ signal in RPC, which associated with reduction of proteinuria and with an increased generation of novel podocytes, as demonstrated in renal biopsies performed before and after RA treatment.

Conclusions: This study suggests that albumin lost during glomerular disorders sequesters RA in Bowman's space and impairs podocyte regeneration by RPC. These results explain why reducing proteinuria delays progression of chronic kidney disease and can even induces regression of glomerular disorders.

Identifying Genetic Modulators of Cell Senescence in Human Renal Epithelium via Genome-Wide RNA-Interference Sophie Domhan,[1,2] Maoyun Sun,[1] Lili Ma,[1] Orfeas Liangos,[1] Martin G. Zeier,[2] Lynn Hlatky,[1] Amir Abdollahi.[1,2] *[1]Tufts University School of Medicine; [2]University of Heidelberg Medical School.*

Background: Replicative senescence in the aging kidney or stress-induced premature senescence leads to permanent and irreversible cell growth arrest and plays a central role in renal pathophysiology by decreasing the renal regenerative capacity. We aimed to systematically investigate the molecular mechanisms governing replicative senescence in human Renal Proximal Tubule Epithelial Cells (RPTEC) by an *in-vitro* genome-wide loss of function study.

Methods: A library of 200K shRNA constructs against ~47K transcripts was generated using lentiviral vectors. RPTEC were stably transduced with the shRNA library and cultured *in-vitro* (RPTEC-RNAi). Quantitative enrichment of shRNA constructs was determined using a microarray based DNA-barcode readout technology. Telomerase activity, senescence-associated β-galactosidase and expression profile of p16 and ARF were longitudinally detected.

Results: human RPTEC underwent replicative senescence after 11-13 in-vitro passages. In contrast, the life span of RPTEC-RNAi was markedly expanded to 22 passages (p22). The expression levels of p16 and ARF followed a U-shaped curve with max. at p11/12 and a gradual decrease thereafter. Hence, a substantial fraction of gene knock-downs does not surpass the natural p16/ARF senescence barrier in RPTEC. The complexity of the RPTEC-RNAi was significantly reduced in p20 indicating that cell senescence exerted a strong selection pressure. Telomerase activity was not affected in RPTEC-RNAi and p22 cells failed to form tumors in nude mice. Loss of function of ~150 genes delayed the entry of RPTEC into replicative senescence but not immortalized or transformed them providing an attractive therapeutic strategy to improve the regenerative potential of the kidney.

Conclusions: The evolutionary fitness landscape of a fundamental cellular program –senescence- is investigated on a genome-wide scale. Knockdown of the here identified candidate regulators of RPTEC senescence may elicit beneficial effects in modulating aging-related kidney disease.

FR-PO214

A New Mechanism of Chronic Kidney Disease-Induced Muscle Atrophy: Akirin1 Regulates Muscle Progenitor Cells Yanjun Dong, Yanlan Dong, William E. Mitch, Liping Zhang. *Medicine/Nephrology, Baylor College of Medicine, Houston, TX.*

Background: CKD stimulates glucocorticoid (GC) production that is necessary but not sufficient to cause muscle wasting. We have found that CKD impairs muscle progenitor cell (satellite cells or muscle stem cell) functions that contribute to muscle wasting (JASN, 2010). It is not known if GC participates in the CKD-induced impairment of satellite cell function.

Methods: Mice were infused with dexamethasone (Dex,2 μg/100 g/day) for 10 days. Tibialis anterior (TA) muscles were injured by cardiotoxin (CTX) to study satellite cell function *in vivo*.

Results: Dex reduced body and muscle weights ($P<0.05$) vs mice treated with PBS. In gastrocnemius muscles of Dex-treated mice, the expression of myogenic genes (MyoD, myogenin and Myf-5) were low, indicating impaired satellite cell function. There also was an increase in muscle myostatin ($p<0.05$) but a decrease in Akirin-1, a promyogenic factor regulating muscle regeneration. Dex suppressed ($p<0.05$) isolated satellite cells in both their proliferation and differentiation as well as the expression of MyoD, myogenin and Akirin1. To identify the role of Akirin1, we infected satellite cells with an Akirin1 adenovirus and found it blocked Dex-induced defects in satellite cell functions. At 3 days after muscle injury, Dex administration suppressed Brdu incorporation and myogenin expression in muscle of mice (i.e., impairment of proliferation and differentiation). At days 5 or 7 after injury, Dex reduced newly formed myofibers (recognized by central nuclei) in injured muscle. Dex also increased myostatin and decreased Akirin1 in injured muscles. These responses are consistent with the report that myostatin down-regulates Akirin1. To verify that Dex impairs satellite cell function by raising myostatin to decrease Akirin1, we inhibited myostatin with an anti-myostatin peptibody in Dex-infused mice and found improved ($p<0.05$) regeneration and increased levels of Akirin1 and other myogenic genes.

Conclusions: CKD-induced GC production upregulates myostatin which downregulates Akirin1. This new, "feed forward" pathway impairs satellite cell function and ultimately, increases the severity of muscle wasting in CKD.

Adipose-Derived Mesenchymal Stem Cells Regulate miRNA Expression in Renovascular Disease and Decrease Apoptosis and Renal Injury Xiang-Yang Zhu,[1] Behzad Ebrahimi,[1] Alfonso Eirin,[1] Kyra L. Jordan,[1] James Krier,[1] Joseph P. Grande,[3] Amir Lerman,[2] Stephen C. Textor,[1] Lilach O. Lerman.[1] *[1]Nephrology & Hypertension, Mayo Clinic, Rochester, MN; [2]Cardiovascular Diseases, Mayo Clinic, Rochester, MN; [3]Pathology, Mayo Clinic, Rochester, MN.*

Background: Mesenchymal stem cells (MSC) promote tissue repair, but the mechanisms involved are not fully understood. Micro-RNAs (miR) are post-transcriptional regulators, of which miR-26a inhibits cell apoptosis. We hypothesized that MSC-induced

kidney repair in experimental renal artery stenosis (RAS) is partly mediated by increasing miR-26a expression.

Methods: Single-kidney renal blood flow (RBF) and glomerular filtration rate (GFR) were assessed using multi-detector CT, and tubular function (response to IV furosemide) by blood-oxygen-level-dependent (BOLD) MRI in pigs with a 10-wk RAS, RAS 4 wks after intra-renal infusion of autologous adipose-derived MSC ($2.5x10^5$ cells/kg), and controls. Renal expression of miR-26a was measured in kidney tissue using both plate-based and fluorescent in-situ hybridization, and tubular cell apoptosis by TUNEL staining and expressions of apoptosis inducible factor (AIF) and cleaved caspase-3.

Results: The post-stenotic kidney showed decreased miR-26a expression, mainly in tubular cells as compared to normal, which was restored in MSC-treated pigs.

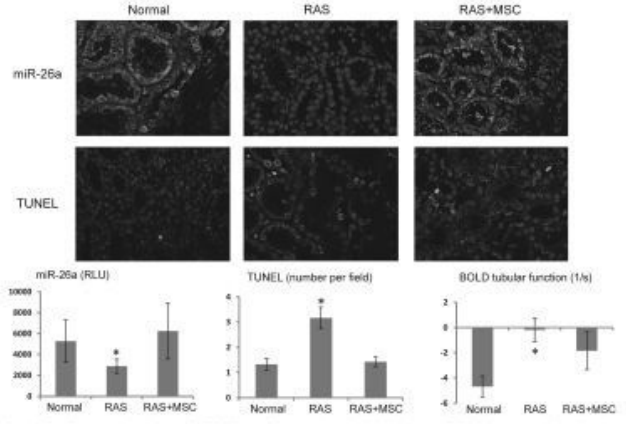

Figure 1. Top: Representative images of miR-26 (green, fluorescent in situ hybridization) and TUNEL (green, nuclei) staining in kidneys of normal, renal artery stenosis (RAS), and RAS treated with mesenchymal stem cells (MSC). Bottom: quantitative results of miR-26a (plate-based hybridization), TUNEL, and kidney tubular function evaluated using MRI BOLD method. *p<0.05 vs. Normal

MSC also attenuated tubular cell apoptosis, downregulated AIF and caspase-3 expressions, and decreased stenotic kidney fibrosis. Furthermore, MSC improved RBF, GFR, and tubular function, which were all reduced in RAS.

Conclusions: Intra renal delivery of autologous MSC restored miR-26a expression, attenuated tubular cell apoptosis, and improved stenotic kidney function. MiR-26a expression might mediate beneficial effects of MSC and represent a novel therapeutic target in renovascular diseases.

Effect of Adipose-Derived Stem Cell Transplantation on Acute Kidney Injury Induced by Cisplatin Weiwei Wang, Wei Wang, Yan Jiang, Jinyuan Zhang. *Division of Nephrology, Jimin Hospital, Shanghai, China.*

Background: Adipose-derived mesenchymal stem cells (ADSCs) have been reported as a new source of stem cells for use in restoring renal tubular structure and improving renal function in acute kidney injury (AKI). We found that ADSCs could promote the cisplatin-induced HK-2 cells in vitro by ameliorating cytoskeletal damage and decreasing the number of apoptotic cells. In this research, we explore the effect of ADSCs transplantation on acute kidney injury induced by cisplatin in animal model.

Methods: ADSCs were labelled by enhanced-green fluorescent protein(EGFP) and the cells expressing EGFP were screened out by FACS. AKI model was established by intraperitoneal injection of cisplatin in mice. Then ADSCs(labelled by EGFP) were administrated by tail vein($1x10^5$). After 3 days, serum creatinine (Scr), blood urea nitrogen (BUN) levels and renal histopathology were examined. Apoptosis of renal cells were tested by TUNEL. The expression of RANTES, TNF-α and IL-10 were detected by immunohistochemical method and ADSCs distribution observed by fluoroscope in renal tissue. Immunofluorescence was performed to detect the expression of cytokeratin-18(phenotype character) in tubular cells. And anti-cytokeratin18 IgG was combined with Cy3(red fluorescence).

Results: After ADSCs intervention, Scr and BUN levels were decreased, and the damage of renal histopathological(such as vacuolar degeneration and disappear of brush border in tubular cells and inflammatory cells infiltration) were lessened. Apoptosis of renal tubular epithelial cells were reduced significantly compared with the model group. And also the expression of inflammatory cytokines(RANTES and TNF-α) in renal tissue were reduced. The immunofluorescence results showed that a small quantity of green fluorescent protein (from ADSCs) were present in renal tissue, but they cannot be observed transformatation to the renal tubular epithelial cells obviously.

Conclusions: ADSCs transplantation can improve the damage of the kidney structure and function in acute kidney injury. The mechanism may not be related to the transformation into tubular epithelial cells and more likely to the effect by the paracrine role in ADSCs.

Therapeutic Effects of Mesenchymal Stem Cell Derived Microparticles in Progressive Chronic Renal Failure Hyeong Cheon Park, Hoon Young Choi, Sung-kuk Kim, Sun Hee Ahn, Sung-Kyu Ha. *Internal Medicine, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Republic of Korea.*

Background: Microparticles (MP) shed from bone marrow mesenchymal stem cells (MSC) conferred protective effects against acute tubular injury via transfer of messenger RNA and microRNA. We recently demonstrated that in vitro expanded kidney derived-MSC (KMSC, Kidney Int 2008; 74:879-889) protected peritubular capillary endothelial cells in acute ischemic reperfusion injury.

Methods: KMSC were cultured in hypoxic chamber in serum deprived MEM with hydrogen peroxide (200 μM) for 24 hours to mimic hypoxic microenvironment. MP were isolated from supernatants by differential ultrafiltration (2,000x g, 10 min, 50,000x g, 2hr, twice) for flowcytometric characteriaztion and MP RNA was extracted using ExoMir kits. Isolated MP were co-cultured with human umbilical vein endothelial cells (HUVEC) to assess their biologic effects on endeothelial cells. Mice subjected to 7 day unilateral ureteral obstruction (UUO) were treated with PKH26 stained MP ($1x10^6$/mice) via tail vein to assess its antifibrotic and peritubular capillary sparing effects. Renal tubulointerstitial damage was examined with Masson's trichrome, F4/80 and alpha-SMA staining and peritubular capillary rarefaction index was determined by CD31 staining.

Results: Flow cytometric analysis of MP demonstrated presence of adhesion molecules shown to be expressed on KMSC membrane such as CD29, CD44, CD73, alpha4- and alpha 6 integrins. Quantitative real time PCR confirmed the presence of 3 splicing variants of VEGF-A (120, 164, 188) and IGF-1 in isolated MP. MP dose dependently improved in vitro HUVEC viability and promoted endothelial tube formation. Indoxyl sulfate (IS: 250ug/mL) or TGF-β (10ng/mL) induced endothelial-mesenchymal transition (EMT) in HUVEC, and pretreatment of HUVEC with MPs ameliorated IS or TGF-β induced EMT. Furthermore, injection of MP significantly improved peritubular capillary rarefaction score and ameliorated tubulointerstital inflammation (F4/80 postive) and fibrosis in UUO mice.

Conclusions: Our results suggest that KMSC-derived MP may confer renoprotective effects via ameliorating tubulointerstitial scarrng.

FR-PO218

KSP-Positive Cells Derived from Mouse Embryonic Stem Cells Serve as Progenitors of Renal Tubule Cells Ryuji Morizane, Toshiaki Monkawa, Shizuka Fujii, Hiroshi Itoh. *Internal Medicine, Keio University School of Medicine, Tokyo, Japan.*

Background: We have previously reported that Activin enhances the expression of kidney specific protein (KSP) of mouse embryonic stem (ES) cells and of induced pluripotent stem (iPS) cells, and that KSP-positive cells derived from mouse ES cells form tubule-like structures resembling renal tubule cells. In this study, we characterized KSP-positive cells derived from mouse ES cells in more depth, and examined effects of Wnt4 on them.

Methods: Mouse ES cells were differentiated with Activin and insulin-like growth factor (IGF) for 18 days, and KSP-positive cells were purified by use of our original mouse monoclonal anti-KSP antibody. To characterize KSP-positive cells derived from ES cells, gene expressions of KSP-positive cells were analyzed by microarray in two independent experiments. After cell selection using anti-KSP antibody, KSP-positive cells were co-cultured with NIH3T3-Wnt4 which ubiquitously expressed Wnt4.

Results: Gene ontology analysis revealed that KSP-positive cells significantly expressed genes related to kidney development and urogenital system development more than KSP-negative cells. Interestingly, mesenchymal genes such as Osr1 were up-regulated in KSP-positive cells compared to KSP-negative cells. These results suggest that KSP-positive cells have relatively immature characteristics rather than mature renal tubule cells. KSP-positive cells derived from ES cells could form tubule-like structures in Matrigel ®, however reproducibility was less than 50%. To promote differentiation and tubular formation, KSP-positive cells were co-cultured with NIH3T3-Wnt4. After one day of co-culture with NIH3T3-Wnt4, abundant tubular formation was observed. PCR showed up-regulation of each segment-specific gene of renal tubule cells such as Megalin, Uromodulin, Slc12A3, AQP1, AQP2, AQP3 and Podocalyxin. Immunohistochemistry also revealed that Megalin, AQP1, AQP2 and Podocalyxin were expressed in tubule-like structures.

Conclusions: In conclusion, KSP-positive cells derived from mouse ES cells serve as progenitors of renal tubule cells, and we could induce renal tubule cells from mouse ES cells with cell selection using anti-KSP antibody and Wnt4.

FR-PO219

A Novel Source of Cultured Podocytes for In Vitro Studies Stefano Da Sacco,[1] Ilenia Zanusso,[1] Sargis Sedrakyan,[1] Astgik Petrosyan,[1] Kevin V. Lemley,[1] Janos Peti-Peterdi,[2] Roger E. De Filippo,[1] Laura Perin.[1] *[1]Children's Hospital Los Angeles, Los Angeles, CA; [2]University of Southern California.*

Background: The podocyte is the pivotal cell maintaining normal structure and function of the glomerulus. Podocytes present a very limited ability to replicate and their loss is associated with progression of kidney disease. Various aspects of podocyte biology have been studied using in vitro systems. The current state-of-the-art cultured podocyte is conditionally immortalized, which replicates only some features of this highly specialized cell. Herein we describe a novel cell population of human amniotic fluid kidney progenitor cells (AKPC) that can be cultured and differentiated toward mature and functional podocytes without immortalization.

Methods: AKPC were differentiated into podocytes and compared to human immortalized podocyte cells (hPOD). Differentiation efficiency was assessed by FACS. Morphology was evaluated by light and electronic microscopy. Microarray, qPCR and Western Blotting analysis were performed to confirm expression of mature podocyte and GBM markers. Contractile ability was assessed by Angiotensin II stimulation and calcium intake assay. AKPC were seeded onto mouse kidney extracellular matrix (ECM) and their structure evaluated by SEM.

Results: AKPC can be fully differentiated into mature podocytes, acquiring an arborized morphology, formation of foot processes and rearrangement of F-actin fibers. Expression of podocyte markers including WT1, nephrin, synaptopodin was confirmed. AKPC showed the ability to vigorously contract upon stimulation. AKPC showed superior traits when compared to hPOD, in particular in the higher expression of podocyte genes confirmed by microarray, in the secretion of collagen IV alpha 3-4-5, the major constituent of the GBM and the ability to attach, replicate, differentiate and develop mature foot processes when seeded onto decellularized ECM.

Conclusions: In conclusion, for the first time we showed in a comprehensive and broad manner that extra-renal cells can be differentiated into fully mature and functional podocytes in vitro and established a culture system that will allow a better understanding of podocyte biology than conventional hPOD lines.

FR-PO220

Microvesicles Derived from CD133$^+$ Human Renal Progenitors Protect from Kidney Injury: A Role for Hypoxia Benedetta Bussolati, Aldo Moggio, Giovanni Camussi. *Dept of Internal Medicine, University of Torino, Torino, Italy.*

Background: Increasing evidences show that stem cells are involved in tissue regeneration through a paracrine release of factors, including exosomes/microvesicles (MVs). MVs released from stem cells, beside proteins and bioactive lipids, may mediate a horizontal transfer of genetic information involved in reprogramming of the target cells. We recently characterized a population of CD133$^+$ epithelial progenitors in the renal papilla and we found that hypoxia promotes their stem/progenitor properties (Bussolati et al., Am J Physiol-Renal Physiol 2012). The aim of the present study was to evaluate the effect of MVs from CD133+ progenitors in renal repair and the possible modulation of hypoxia.

Methods: MVs released from cultured renal CD133$^+$ progenitor cells in normoxia and in hypoxic condition (1% O_2) were isolated by ultracentrifugation and characterized using the NanoSight system and cytofluorimetric analysis using latex beads. The effect of MVs on renal repair was tested in a murine model of glycerol-induced acute kidney injury. MicroRNA content of the normoxic and hypoxic CD133$^+$ MVs was evaluated by the Applied Biosystems TaqMan® MicroRNA Assay and confirmed by deep sequencing.

Results: The CD133$^+$ MVs showed a size of approximately 130 nm and expressed exosome surface markers (CD24, CD63). In vitro, only hypoxic but not normoxic CD133$^+$ MVs stimulated the proliferation of starved epithelial tubular cells. Moreover, RNase treatment reverted this proliferative effect. In vivo, a single injection of hypoxic but not normoxic CD133$^+$ MVs improved renal function evaluated as serum creatinine, nitrogen urea and morphological tissue analysis. Immunofluorescent analysis showed a rapid uptake by tubular cells of labelled MVs. In addition, MV showed the presence of several miRNAs involved in cell proliferation, differentiation and inhibition of fibrotic pathways.

Conclusions: In conclusion, we show the ability of CD133$^+$ renal papillary progenitor cells to induce repair in the injured kidney through the delivery of MVs. This mechanism could be locally involved in cell-to-cell communication in pathological conditions of renal injury and could be exploited for therapeutic purposes.

Kidney-Targeted Gene Delivery Using AAV: Model of Cystinosis Celine Rocca,[1] Frank Harrison,[1] Brian Yeagy,[1] Corinne Antignac,[2] Richard Samulski,[3] Stephanie Cherqui.[1] *[1]Molecular and Experimental Medecine, The Scripps Research Institute, La Jolla, CA; [2]INSERM U983, Hôpital Necker-Enfants Malades, Paris, France; [3]UNC Gene Therapy Center, University of North Carolina, Chapel Hill, NC.*

Background: A wide range of monogenic kidney disorders has been identified and so far no gene therapy has been developed. The main goal of our project is to develop an efficient kidney-targeted gene delivery system using recombinant Adeno-Associated Viruses (rAAV). As a proof of concept, we are using the cystinosis mouse model. Cystinosis is an autosomal recessive metabolic disease characterized by intracellular accumulation of cystine. The defective gene is *CTNS* encoding the lysosomal cystine transporter, cystinosin. Affected individuals typically present with proximal tubulopathy before one year of age and progressive loss of glomerular function and finally progress to end-stage renal failure. The *Ctns*$^{-/-}$ mice develop renal dysfunction similar to the patients. Thus, they represent an excellent model for chronic kidney diseases.

Methods: Our goal is to optimize kidney-targeted gene delivery via retrograde renal vein injection by testing several rAAV serotypes that have the potential of transducing a wide range of renal cells. We performed injections of rAAV5, 6, 8 and 9 coding for either the luciferase or the green fluorescent protein (GFP).

Results: Our preliminary results show that rAAV6 is the most suitable serotype to target specifically the kidney. Indeed, using the IVIS live imaging system, we observed that only rAAV6 leads to a strong luciferase expression specifically localized in the kidney. This has been confirmed by confocal GFP observation and GFP-specific RT-qPCR quantification. We are also testing different promoters that could lead to a more specific and efficient renal cells transduction such as the Parathyroid Hormone Receptor (PTHR) kidney specific promoter. Once the optimal conditions will be defined, we propose to test this approach based on renal vein injection of rAAV-CTNS as a minimally invasive procedure for treating the renal dysfunction in cystinosis.

Conclusions: If successful, this strategy may be used in many monogenic hereditary nephropathies.

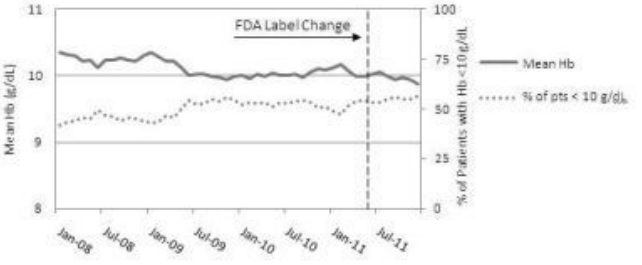
FR-PO222

Hemoglobin Trends in Incident End-Stage Renal Disease Patients from 2008-2011 Joe Weldon,[1] Scott Sibbel,[1] Rhoda Silva Brown,[1] Allen R. Nissenson,[2] Mahesh Krishnan.[1] *[1]DaVita Clinical Research, Minneapolis, MN; [2]DaVita Inc., Denver, CO.*

Background: Major changes to erythropoiesis-stimulating agent (ESA) product labeling in 2011 have impacted anemia management as recently noted in the prevalent end-stage renal disease (ESRD) population (Collins, NKF 2012). However, changes in pre-ESRD care are also affecting incident ESRD hemoglobin (Hb) levels. We sought to describe the mean and distributional changes in Hb among incident ESRD patients (pts).

Methods: In a retrospective analysis, we identified all incident pts at a large dialysis organization from 1/1/08–12/31/11 and used the first Hb measurement on dialysis as a surrogate for pre-ESRD anemia management. Mean values for the first Hb test after starting dialysis (incident pts) were used. Population mean and percent of pts with Hb < 10 g/dL were plotted over time. Hb differences in the ±2 months surrounding the changes in FDA guidelines for ESAs were tested using ANOVA models.

Results: Mean Hb levels at the first test after starting dialysis demonstrated a modest decline over the 4 years analyzed from 10.3 ± 1.4 g/dL (mean ± SD) in Jan 2008 to 9.9 ± 1.3 g/dL in Dec 2011 (Figure). The percent of pts with Hb < 10 g/dL showed a concurrent increase (42.0%–56.6%). Initial Hb levels appeared to plateau after June 2009 and a slight decline was observed after the FDA label change in late June 2011.



Conclusions: Incident pt Hb levels declined from 2008 to 2011, suggesting that ESA treatment prior to initiation of dialysis has become more conservative. Over 50% of patients currently begin dialysis with sub 10 g/dL Hb levels. Pts are starting dialysis with lower Hb, reflecting changes in CKD treatment within the nephrology community. The observed declines in Hb levels corresponded temporally with the implementation of the revised FDA guidelines and label changes for ESAs.

FR-PO223

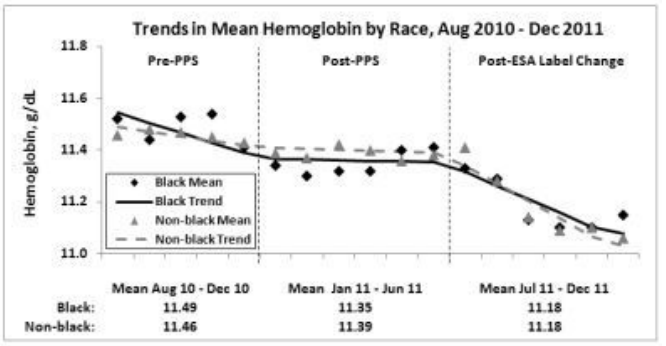
Potential Racial Disparities in Anemia Treatment: Impact of Recent Payment and Regulatory Changes in the US Marc Turenne,[1] Brett Lantz,[1] Douglas S. Fuller,[1] Diane Steffick,[2] Ronald L. Pisoni,[1] Claudia Dahlerus,[1] Jeffrey Pearson,[1] Brian Bieber,[1] Bruce M. Robinson.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]U of Michigan, Ann Arbor, MI.*

Background: Changes to the Medicare ESRD prospective payment system (PPS) in Jan 2011 and dosing guidelines for erythropoiesis-stimulating agents (ESAs) in Jun 2011 removed previous incentives and indications for ESA use in dialysis patients. Given historically higher ESA use among black patients, we studied the potential impact on racial disparities in anemia treatment.

Methods: We defined pre-PPS (Aug-Dec 2010), post-PPS (Jan-Jun 2011), and post-ESA label change (Jul-Dec 2011) periods. Analyses used data from the Dialysis Outcomes and Practice Patterns Study (DOPPS) Practice Monitor, a sample of over 100 facilities. Survey-weighted regressions were used to model mean Hgb and prescribed weekly IV epoetin (EPO) dose using linear splines for time with knots at each policy change and an interaction with race (black/non-black).

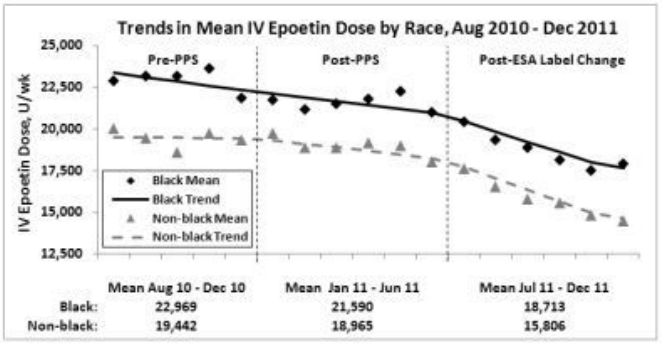
Results: From Aug 2010-Dec 2011, mean Hgb declined from 11.5 to 11.1 g/dL ($p<0.001$), mean EPO dose declined from 20872 to 15578 U/wk ($p<0.001$), and % Hgb<10 g/dL increased (Hgb<9: 3.0 to 5.2%, $p=0.008$; Hgb 9-9.9: 5.7 to 10.5%, $p=0.001$). Declines in mean Hgb and EPO dose and increases in % Hgb<10 also accelerated post label change. Rates of change in Hgb and EPO dose did not differ by race, and mean EPO dose remained higher in blacks (Figure). Overall, % Hgb<10 was more common in blacks, peaking for both races post label change (Hgb<9: 4.7% vs 3.4%, $p=0.03$; Hgb 9-9.9: 9.7% vs 9.2%, $p=0.60$).

Hemoglobin Trend (1 month, continuous)



Mean N (black) = 1097 / month; Mean N (non-black) 2383 / month

Prescribed ESA dose (1 month, continuous)



Mean N (black) = 846 / month; Mean N (non-black) = 1762 / month

Conclusions: Recent US dialysis payment and regulatory changes were associated with similar changes in EPO dosing and Hgb for blacks and non-blacks. Differences by race in prevalence of low Hgb indicate a need to examine possible racial disparities in blood transfusions and other anemia-related clinical outcomes.

Change in Erythropoiesis-Stimulating Agent Dosage in For-Profit versus Non-Profit Dialysis Facilities after a Black Box Warning

Julie H. Ishida,[1] Charles E. McCulloch,[2] R. Adams Dudley,[1] Barbara A. Grimes,[2] Kirsten L. Johansen.[1] *[1]Medicine, UCSF, San Francisco, CA; [2]Epidemiology & Biostatistics, UCSF, San Francisco, CA.*

Background: Erythropoiesis-stimulating agents (ESAs) are a significant component of Medicare's expenditures on dialysis patients, and higher ESA dosing has been observed in for-profit than non-profit dialysis facilities. It is unknown whether ESA use changed to the same extent in for-profit versus non-profit dialysis facilities and if the discrepancy in ESA use persisted after the FDA's black box warning in March 2007 that advised using the minimum necessary ESA dose.

Methods: From the USRDS, we identified 275,291 Medicare-covered adults who were routinely receiving in-center hemodialysis in February 2007, February 2008, or both time periods. Mixed models, accounting for clustering of data by dialysis chain and facility, were used to study the association between year, dialysis facility profit status and mean weekly ESA (epoetin and darbepoetin) dose.

Results: For-profit facilities had a smaller proportional decrease in ESA dose from 2007 to 2008 than non-profit facilities (7.3% vs. 9.8%, p-value 0.001) after adjustment for demographic and clinical characteristics. In 2008, compared with non-profit facilities, for-profit facilities used higher ESA doses in every hematocrit (Hct) category (<30, 30-<33, 33-<36, 36-<39, ≥39%, p-value for all comparisons <0.0001) and had a greater percentage of patients receiving ESA with a Hct ≥39% (13.7% vs. 9.8%), a range far exceeding the upper hemoglobin limit of 12 g/dL (i.e. Hct 36%) recommended by the black box warning. From 2007 to 2008, ESA dose increased by 41.5% in patients who switched from a non-profit to for-profit facility and decreased by 32.6% in patients who switched from a for-profit to non-profit facility.

Conclusions: For-profit facilities decreased their ESA use to a lesser extent after the black box warning and were still prescribing more ESA than non-profit facilities in 2008, even after adjustment for case-mix and regardless of degree of anemia. The persistence of higher ESA usage in for-profit facilities suggests that for-profit facilities may have failed to maximally respond to the FDA's safety directive to use the minimum necessary ESA dose.

Patterns of Anemia and Mineral Bone Disease Management in Hemodialysis Patients in China: Results from the Dialysis Outcomes and Practice Patterns Study (DOPPS)

Xueqing Yu,[1] Mia Wang,[2] Brian Bieber,[2] Shuchi Anand,[3] Mei Wang,[1] Li Zuo,[1] Ronald L. Pisoni,[2] Xiao Yang,[1] Jia Qi Qian,[1] Nan Chen,[1] Yucheng Yan,[1] Bruce M. Robinson,[2] Sylvia Paz B. Ramirez.[2] *[1]China DOPPS Country Investigator; [2]Arbor Research; [3]Stanford U.*

Background: Limited data exist on management of anemia and mineral bone disorder in Chinese hemodialysis (HD) patients (pts). We previously described differences in hemoglobin (Hb) and PTH levels in Chinese pts as compared to other DOPPS countries. This analysis examines whether practices of medical directors for frequency of measurement and target levels contribute to these differences.

Methods: 1379 pts were randomly sampled from a stratified, random sample of 45 HD units in Beijing, Guangzhou and Shanghai in 2011. Medical directors reported data on practice patterns concurrent with the pt data. Results for China are compared to other DOPPS regions from 2009-11.

Results: Hb levels in China (10.5 g/dL) were comparable to Japan (10.4) but lower than EUR/ANZ and North America (NA) (11.5). Nearly all pts were prescribed an erythropoietic stimulating agent (ESA) in China. Hb targets were higher but Hb measurement frequency was lower in China, compared with other DOPPS regions. After a change in ESA dose, Hb level was checked monthly or less often in 66% of Chinese facilities whereas labs were measured more often in other DOPPS regions (>57% of facilities in other regions measured at least every 2 weeks).

Consistent with targets, mean PTH levels in China (386 pg/mL) were higher than Japan (162), but comparable to EUR/ANZ (315) and NA (374). Vit D was less frequently prescribed in China (54%) and cinacalcet was used by <1% of pts. PTH measurement was less frequent in China-75% measured every 3 mos or more often (> 87% in EUR/ANZ and NA); 25% measured bi-annually or less often (similar to Japan).

Conclusions: Despite Hb targets of 11-12 or higher, mean Hb levels in China were lower, potentially due to less frequent Hb monitoring. Mean PTH levels were more consistent with target levels but monitoring was infrequent compared to NA and EUR/ANZ. The long term impact of these practice patterns will be studied prospectively in the current phase of China DOPPS.

FR-PO226

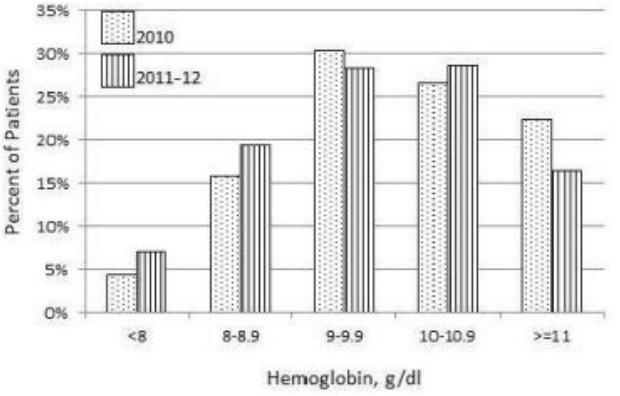
Changing Practice Trends in Erythropoietic Stimulating Agent (ESA) Use Prior to Initiation of Dialysis

John C. Stivelman,[1,2] Kim Benning,[1] Suhail Ahmad.[1,2] *[1]Northwest Kidney Centers, Seattle, WA; [2]University of Washington, Seattle, WA.*

Background: TREAT, CHOIR and recent FDA label changes for ESA have had major impact on their use in the ESRD and CKD population. Introduction of bundling in 2011 has further augmented awareness of ESA exposure risk.

Methods: To assess impact of these developments on physician practice, ESA treatment and hemoglobin (Hb) before initiation of dialysis, we examined data from Form 2728 submissions for new patients initiating ESRD therapy at Northwest Kidney Centers from 1/2010-3/2012, spanning before and after most recent ESA label changes and initiation of the bundle's QIP program (n for 2010, 2011, 2012 = 371,395,103 respectively). Patients returning to dialysis due to transplant failure or other causes were excluded.

Results: Despite comparable percentages of patients seen by nephrologists prior to initiation of dialysis, compared to 2010, a decrease in Hb was seen in 2011 and 2012; average Hb 9.99 g/dL, 9.83 and 9.60 in 2010, 2011 and 2012, respectively (p=0.008, 2010 vs 2012). Similarly, the percent of patients with low Hb (<9.0 gm) increased, and with higher Hb (≥11.0 gm) decreased significantly (p<0.05).



Conclusions: While causality for this finding cannot be identified from these data directly, change in practice pattern is suggested. Possible contributing factors may include later inception of ESA therapy or inception at lower dosages, and/or effects of label changes

and published studies on physician behavior. Such change in delivery of CKD care could predispose new patients to need for transfusion with intercurrent illness, hospitalization, or surgery early in the course of ESRD. Further investigation of the underlying causes of this apparent change in physician practice is needed.

FR-PO227

Treatment of Renal Anemia with Erythropoiesis Stimulating Agents in Predialysis Period Influences Hemoglobin Variability in First Months of Hemodialyis Therapy Michal P. Nowicki, Bartosz Orlowski. *Dept. Nephrology, Hypertension and Kidney Transplantation, Medical University, Lodz, Poland.*

Background: Treatment of CKD-related anemia with ESA may affect variability of hemoglobin (Hb) concentration. Greater hemoglobin variability is associated with increased risk of cardiac events. We tested the hypothesis that introduction of ESA to the treatment of renal anemia before the start of chronic hemodialysis therapy (HD) may allow maintaining more stable Hb levels after start of HD compared to patients who started ESA at beginning of HD.

Methods: Study population comprised 102 patients who were receiving ESA for at least 12 months before HD and continued the therapy after its commencement. The reference group consisted of 70 patients who did not start ESA before HD but were under a care of nephrologists in that period. Analysis of the level of anemia correction and Hb variability was based on monthly blood cell counts performed over a period of first six months of HD. Standard deviation (SD) of Hb values, residual SD and fluctuations across thresholds were calculated.

Results: At start and after six months of HD mean Hb was 8.9 vs. 9.5 ($p<0.05$) and 10.9 vs 10.7 g/dL (ns), respectively in patients untreated and treated with ESA in the pre-HD period. Although mean Hb was maintained within target range of 10 to 12 g/dl from month 3 to 6 of HD in both groups of patients, 17.6% patients in the predialysis ESA treatment group and 48.6% of patients in the reference group showed high amplitude Hb fluctuations ($p<0.01$). Mean residual SD was higher in the group untreated with ESA in predialysis stage than in ESA treated (0.92±0.48 vs 0.73±0.39, respectively, $p<0.05$). Hb fluctuations, SD and residual SD were not different between patients treated with short-acting ESA (epoetin beta, n=43) and long-acting ESA in pre-HD period (darbepoetin alfa and pegylated epoetin beta, n=59) (residual SD 0.69 vs 0,76).

Conclusions: Introduction of anemia therapy with ESA ahead of the start of HD may result in more stable Hb levels after commencement of HD. The choice between short- or long-acting ESA in that period does not have any significant influence on the stability of hemoglobin level after the start of HD.

Funding: Government Support - Non-U.S.

FR-PO228

Predictors of Red Cell Transfusion in Hemodialysis Patients Scott Sibbel,[1] Tracy Jack Mayne,[1] Mahesh Krishnan,[1] David B. Van Wyck.[2] *[1]DaVita Clinical Research, Minneapolis, MN; [2]DaVita, Denver, CO.*

Background: USRDS has recently reported that transfusions increased in 2011 while mean epoetin dose and hemoglobin (Hb) levels declined in US dialysis patients. We undertook the current study to evaluate whether iron status measures predict transfusion in hemodialysis patients.

Methods: We compared maintenance hemodialysis patients receiving transfusion (n=2,252) to patients without transfusion (n=6,646) [1/2/2001-5/31/2011]. We compared demographic variables, dialysis characteristics, and comorbidities to identify a parsimonious risk factor model. After assessment of the largest unadjusted effects for each covariate, we used multivariate logistic models to simultaneously adjust each risk factor and identify the independent effects of covariate on transfusion risk.

Results: The table shows odds ratios (OR) for transfusion for Hb, ferritin, and IV iron dose, unadjusted and adjusted for race, gender, body mass, age, infection, vascular access, osteomyelitis, adequacy, gastrointestinal bleed, and hematologic disease.

Covariate	Unadjusted OR	Adjusted Cumulative Dose Model*
Hemoglobin (g/dL)		
<10	4.457 (3.485-4.718)	3.844 (3.337-4.429)
10-12	REF	REF
> 12	0.786 (0.680-0.909)	0.769 (0.657-0.900)
Ferritin (ng/mL)		
<500	1.102 (0.956-1.271)	1.044 (0.794-1.148)
500-800	REF	REF
800-1,200	1.062 (0.899-1.255)	0.948 (0.784-1.146)
>1,200	2.027 (1.656-2.481)	1.358 (1.071-1.720)
Iron Sucrose (Cumulative 3-month dose)		
0	1.284 (1.084-1.521)	1.145 (0.944-1.391)
0-150	REF	REF
300-500	0.858 (0.768-1.020)	0.993 (0.849-1.161)
500-1,500	1.329 (1.121-1.576)	1.483 (1.229-1.790)
>1,500	2.263 (1.796-2.851)	1.796 (1.378-2.340)

Conclusions: Lower Hb levels, higher serum ferritin levels, and greater IV iron sucrose doses are each independent risk factors for red cell transfusion. These findings call into question the efficacy of high IV iron administration in anemic patients with hyperferritinemia.

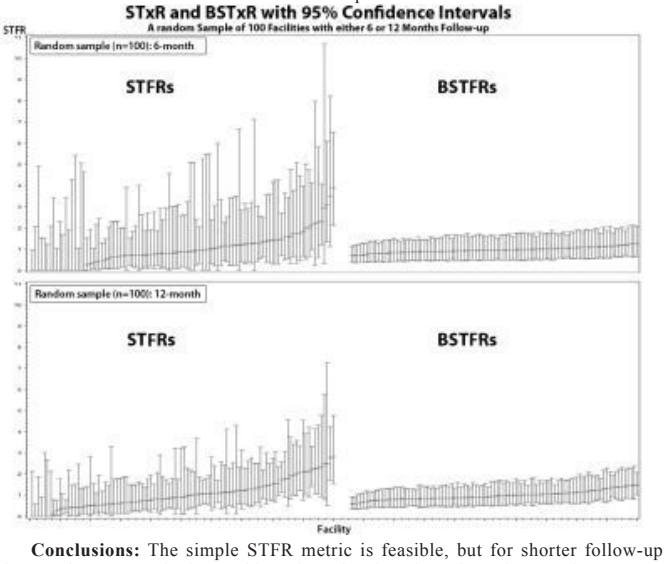
FR-PO229

Development of a Facility-Level Transfusion Quality of Care Metric Jiannong Liu,[1] Suying Li,[1] Keri Monda,[2] Tom Arneson,[1] Brian D. Bradbury,[2] David T. Gilbertson,[1] Allan J. Collins.[1,3] *[1]Chronic Disease Research Group, MMRF, Minneapolis, MN; [2]Amgen, Thousand Oaks, CA; [3]University of Minnesota, Minneapolis, MN.*

Background: Recent evidence has shown hemoglobin levels have declined and transfusions (TF) have increased among dialysis patients (pts) following implementation of the prospective payment system and changes in the FDA label. These changes suggest a quality incentive program metric assessing TF may be warranted.

Methods: Using Medicare data, we constructed a metric to evaluate dialysis facility (DF)-level TF. All US DFs with ≥11 Medicare pts in 2008 were included. Pts were assigned to a DF if they had Medicare as primary payer (MPP) with ≥90 days on dialysis on Jan 1, 2008 and contributed at least 120 days within the DF during the calendar year. Pts were followed from Jan 1 to the earliest of death, transplant, loss of MPP, or 1 year. Inpatient and outpatient TFs were derived from Medicare claims. 6- and 12-month standardized transfusion ratio (STFR, observed divided by expected # of TFs) were estimated for each DF adjusting for pt age, race, sex, ESRD cause, dialysis vintage, and comorbidities. Expected # of TFs was estimated from a Poisson model. The estimate of the STFR may be less stable for small facilities, thus we evaluated estimates from a Bayesian model (BSTFR).

Results: 4,677 DFs and 226,488 pts were included. Mean (SD), range were as follows: 6-month STFR=1.00 (0.83), 0-19.58; 12-month STFR=1.00 (0.60), 0-4.85; 6-month BSTFR=1.00 (0.19), 0.60-4.04; 12-month BSTFR=1.00 (0.23), 0.45-3.52. STFRs/BSTFRs and 95% confidence intervals for a random sample of 100 DFs are shown below.



Conclusions: The simple STFR metric is feasible, but for shorter follow-up times estimates may be less stable and precise than those from the complex BSTFR. Implementation will require balancing timing, precision, and simple vs. more complex methods.

FR-PO230

Outpatient (OP) Red Blood Cell (RBC) Transfusion Payments among Medicare End Stage Renal Disease (ESRD) Patients on Dialysis Andrew Lee,[3] Allyson Kats,[2] Matthew Gitlin,[1] Tom Arneson,[2] Jesse Fishman,[1] Stephan C. Dunning,[2] David T. Gilbertson.[2] *[1]Amgen Inc, Thousand Oaks, CA; [2]Chronic Disease Research Group, Minneapolis, MN; [3]Previously with Amgen.*

Background: Estimate per OP RBC transfusion and associated procedure payments among Medicare ESRD patients.

Methods: Retrospective economic analysis based on 2010 Medicare paid costs per OP RBC transfusion, in dialysis patients, using Medicare Parts A & B data. The study included the US ESRD registry dataset, pts on dialysis, with ≥1 OP RBC transfusion, & ≥ 6 months continuous Medicare primary coverage prior to initial transfusion. Only the first eligible transfusion per patient was used for these analyses. The sum of payments per OP RBC transfusion included pre/post screening/monitoring (+/-3d), blood acquisition/administration (0 to +2d) & associated acute complications (0 to +3d), (eg circulatory overload, acute lung injury, hyperkalemia, hemolytic, non-hemolytic/allergic reactions). Subgroup analyses were run by various patient characteristics.

Results: A total of 5,287 patients with transfusion were included in the analysis, with a mean age of 64.1 (SD 15.4), 54% men, & 64.6% white, 31.5% African American, 3.8% other. Mean OP RBC transfusion payments overall were $662.77 & were highest for those <45 years old, white & with dialysis vintage >5 years; $705.48, $699.27, $758.44, respectively. Acute complications (n=251) were primarily responsible for the variability of the highest transfusion costs which ranged up to $49,486.70 per patient.

OP RBC Tranfusion Payments

	Mean ($)	Median ($)	SD ($)
Per Episode per Patient ($) (N=5287)			
Pre-Transfusion screening/Monitoring	25.03	0	48.45
Post Transfusion Screening/Monitoring	71.01	54.74	71.70
Blood Acquisition/ Administration	390.25	403.52	219.45
Acute Complications	176.47	0	1740.25
Total	662.77	509.72	1756.95

Conclusions: Results show overall mean payments for OP RBC transfusions are driven by blood acquisition/administration (58.9%), followed by acute complications (26.6%). However, acute complications explained some of the variation in payments within subgroups. Although infrequent, transfusion complications have potential to increase costs substantially when they occur.

Funding: Pharmaceutical Company Support - Amgen Inc

FR-PO231

Accuracy of Non-Invasive Hemoglobin Measurements during Hemodialysis Yanna Dou,[1,2] Georges Ouellet,[1,2,3] Stephan Thijssen,[1,2] Nathan W. Levin,[1,2] Peter Kotanko.[1,2] *[1]Renal Research Institute, New York, NY; [2]Beth Israel Medical Center, New York, NY; [3]Maisonneuve-Rosemont Hospital, Quebec, Canada.*

Background: Hemoglobin (Hgb) is one of the most frequently ordered laboratory tests in hemodialysis (HD) patients.Hgb measurements have traditionally required a blood draw. Non-invasive blood volume monitoring devicesare increasingly used to measure relative blood volume (RBV) continuously during HD. The Crit-Line ® device(Hema Metrics), in addition to measuring RBV, also provides a Hgb readout. The objective of this study was to compare the accuracy of Hgb readings obtained with this non-invasive device to routine laboratory Hgb measurements.

Methods: Chronic HD patients from a single U.S. dialysis center were enrolled and studied during one HD treatment each.Crit-Line recordings were performed continuously throughout each treatment,and the Hgb values (Hgb_CL) recorded at the start of HD, at 1h and 2h into the treatment and at the end of HD. At the same time points, blood was drawn for standard laboratory Hgb measurements. These served as the reference values (Hgb_REF).For each time point, correlation analyses between the methods and Bland-Altman analyses were performed.

Results: 19 patients (age 60.7±15.0 years, 7 females) were enrolled in this study.The Hgb values (mean±SD) for each method and time pointwere shown in table 1.

Comparison of Hgb values between Hgb_CL and Hgb_REF during hemodialysis

	start	1 hour	2 hour	end
Hgb_REF[g/dL]	11.18±1.02	10.99±1.02	11.18±1.06	11.76±1.38
Hgb_CL[g/dL]	10.57±0.99	11.06±1.03	11.28±1.08	11.68±1.31
P value	<0.05	NS	NS	NS

At the start of dialysis, Hgb_CL underestimated the reference value by 0.62±0.42 g/dL. At all subsequent time points, however, the bias was consistently less than 0.1 g/dL. Bland-Altman analysis showed no signs of heteroscedasticity or systematic trend in bias.

Conclusions: Aside from the relative blood volume data provided by Crit-Line, the monitor may be used to non-invasively obtain Hgb measurements which could be used in addition to the routinelaboratory measurements when required.

FR-PO232

Red Blood Cell Lifespan Is Associated with Erythropoietin Resistance Index and Its Variability in Hemodialysis Patients Yanna Dou,[1,2] Georges Ouellet,[1,2,3] Stephan Thijssen,[1,2] Nathan W. Levin,[1,2] Peter Kotanko.[1,2] *[1]Renal Research Institute, New York, NY; [2]Beth Israel Medical Center, New York, NY; [3]Maisonneuve-Rosemont Hospital, Canada.*

Background: Increased erythropoietin resistance index (ERI) is correlated with allcause mortality and cardiovascular events. In many patients, inflammation contributes to the hyporesponsiveness to erythropoiesis stimulating agent (ESA) therapy.We aimed to study the association between red blood cell life span (RBCLS) and ERI in hemodialysis (HD) patients.

Methods: Hemoglobin (Hgb), high-sensitivity CRP (hsCRP), serum iron, TSAT and RBCLS were measured at baseline. RBCLS was estimated from alveolar carbon monoxide concentration and Hgb (Strocchi, 1992). Demographics and weekly epoetin alfa (EPO) dose were recorded. ERI was defined as weekly EPO dose per kilogram divided by Hgb. Patients were stratified by RBCLS (<60 and ≥60 days). Following RBCLS measurement, monthly Hgb, EPO dose, and post-HD weight were collected for 6 months. Over these 6 months, mean and standard deviation of ERI (ERImean_6M; ERISD_6M), and slope of ERI (ERIslope_6M) were calculated. Associations between these three variables and RBCLS were assessed by linear correlation analysis.

Results: Forty-five HD patients (31 males, age 58±15 years, dialysis vintage 46±46 months, 21 diabetics) were enrolled. ERImean_6M and ERISD_6M were significantly lower in patients with RBCLS≥60 days, and there was no significant difference in other parameters.

Baseline characteristics of two RBCLS groups

	RBCLS<60 (N=16)	RBCLS≥60 (N=29)
Hgb (g/dL)	11.1±1.4	11.6 ±1.2
hsCRP (mg/L)	8.2 (5.3, 18.6)	4.9 (1.3, 9.7)
Iron (mcg/dL)	71.4±35.2	76.0±26.6
TSAT (%)	31.8±14.9	32.3±9.6
RBCLS(days)	46.4±5.9	82.2±15.5
ERImean_6M(U •dL)/ (week•kg•g) *	20.3 (8.7, 28.1)	8.6 (3.4, 16.1)
ERISD_6M*	8.9 (2.7, 13.5)	2.5 (1.6, 7.5)

Data are presented as mean ± SD or median (quartiles), * means p<0.05

An inverse correlation was found between RBCLS and ERImean_6M (r=-0.38, P<0.05), and RBCLS and ERISD_6M (r=-0.35, P<0.05).

Conclusions: RBCLS is inversely related to mean and SD of ERI over at least 6 months. Considering RBCLS is important when interpreting responsiveness to EPO.

Personalized Anemia Management Improves Hemoglobin Variability in Hemodialysis Patients Adam E. Gaweda,[1] George R. Aronoff,[1] Alfred A. Jacobs,[1] Michael E. Brier.[1,2] *[1]Medicine / Nephrology, University of Louisville, Louisville, KY; [2]Robley Rex VA Medical Center, Louisville, KY.*

Background: Erythropoiesis Stimulating Agents (ESA) are dosed per protocols based on the combination of product label and national guidelines. Recent changes to the label recommend individualization of ESA dose to reduce the need for RBC transfusions. We developed a Clinical Decision Support System for personalized ESA dosing, called "Smart Anemia Manager" (SAM), and performed a double blind randomized controlled trial to test the hypothesis that it improves hemoglobin (Hb) maintenance within 10-12 g/dL over a standard protocol.

Methods: We enrolled 62 subjects receiving hemodialysis at the University of Louisville (KDP) as of April 1, 2011 and used equal allocation to Control (KDP protocol) and Treatment (SAM) arms. Subjects and physicians were blinded to group assignment. Dose recommendations for both groups were generated by computer and validated by physicians, who could override the recommended dose if necessary. Subjects were followed for 12 months. ESA (Epoetin alfa) dose adjustment was performed monthly. The primary endpoint was the percentage of Hb observations within 10-12 g/dL over the follow-up period, calculated using monthly Hb measurements as per standard practice, using last value of the month.

Results: Average Hb achieved was 10.6±1.5 g/dL (Control) vs. 11.0±1.2 g/dL (Treatment). Table 1 presents the percentages of Hb below, within, and above the target range. Absolute difference in primary endpoint between the groups is 11.8%. Hb fell below 10 g/dl in fewer than half as many patients in the Treatment group compared to Controls. Median ESA dose for both groups was 2,000 IU/wk. There were 4 dose overrides in the Control group vs. none in the Treatment group.

Percentage Hb below, within, above target (C-control, T-treatment)

	C	T
% Hb < 10	25.7	11.7*
% 10 < Hb < 12	60.8	72.6*
% Hb > 12	13.5	15.6

* difference significant at p < 0.05

Conclusions: Personalized ESA dosing with SAM resulted in more Hb's within the target range, fewer below 10 g/dl, and not more above 12 g/dl despite a 0.4 g/dL difference in mean Hb. SAM represents a significant step toward satisfying the new ESA label.

Use of the Mayo Clinic Anemia Management System (MCAMS) Decreases Hemoglobin (Hgb) Variation in Chronic Hemodialysis (HD) Patients Receiving Darbepoetin James T. McCarthy,[1] Robert C. Albright,[1] Craig L. Hocum,[1] James Lee Rogers,[3] Edward J. Gallaher,[3] John J. Dillon,[1] LaTonya J. Hickson,[1] Amy W. Williams,[1] David Dingli.[2] *[1]Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Division of Hematology, Mayo Clinic, Rochester, MN; [3]Advance Management Group, LLC, Rochester, MN.*

Background: MCAMS is a proprietary software program that uses Biomedical System Dynamics to simulate erythropoiesis in HD pts receiving an Erythropoietic Stimulating Agent (ESA). It predicts Hgb values in an individual HD pt in response to an ESA. Five physiologic parameters that determine erythropoiesis in the presence of an ESA are included in the model: the average daily rate of production of erythroid blast-forming units (BFU-E); the average survival of erythroid colony forming units (CFU-E), the average daily rate of reticulocyte maturation & survival, the individual response of the erythropoietin receptor (EPOR) to the ESA; & the lifespan of red blood cells (RBC).

Methods: MCAMS was implemented in the HD facilities of the Mayo Clinic Dialysis System in 2009 in place of a protocol-based system that adjusted ESA dose based on the last Hgb value. To determine if MCAMS led to less variation in Hgb values, we analyzed data for all 61 stable HD pts in 2008-2010 meeting these criteria: iron replete; no hospitalization of more than1 day in the time frame of analysis; a minimum of 3 continuous months of Hgb values & darbepoetin doses using our pre-MCAMS protocol; a minimum of 3 continuous months immediately after initiation of MCAMS; administration of at least 90% of darbepoetin doses recommended by MCAMS. The target Hgb value was defined as the midpoint of the desired Hgb range. The mean values for the descriptive statistics pre- and Post MCAMS were compared.

Results:

Table 1

	Pre-MCAMS	Post-MCAMS	P value
Hemoglobin (g/dL)	11.82 ± 0.75	11.36 ± 0.30	< 0.0002
Coefficient of Variation	0.072 ± 0.036	0.053 ± 0.024	< 0.0006
Standard Deviation	0.85 ± 0.42	0.60 ± 0.26	< 0.0001
[Actual - Target]			
Hemoglobin (g/dL)	0.98 ± 0.46	0.67 ± 0.26	< 0.0001

Mean ± SD; Student's t-test with 2 tails and unequal variances

Conclusions: Use of MCAMS was associated with less variation in Hgb values in stable HD pts.

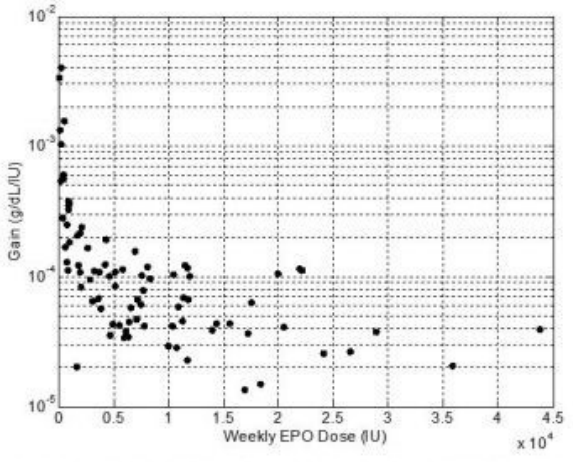
FR-PO235

A Measure of Patient Responsiveness for Effective Anemia Management Protocols Michael J. Germain,[2] Christopher V. Hollot,[1] Joseph Horowitz,[1] Rajiv P. Shrestha,[1] Yossi Chait.[1] *[1]University of Massachusetts; [2]Western New England Renal & Transplant Associates, PC.*

Background: Identifying end-stage renal disease (ESRD) patients' hemoglobin (Hgb) responses to erythropoiesis stimulating agents (ESAs) is central to successful individualization of anemia management. We describe a patient's response using "gain", an important concept in feedback control theory. The main benefit of feedback controllers, of which anemia management protocols (AMPs) are examples, is in dealing with uncertainty. Recent clinical experience indicates that inter-patient gain uncertainty may be too large for a single, fixed AMP to work satisfactorily for all individuals.

Methods: The patient's gain is defined as the ratio of the long-term Hgb response based on a fixed ESA dose to that dose. The gains for 44 ESRD patients were estimated from retrospective Hgb data collected over some 200 weeks. We designed patient-specific AMPs using model-based feedback control and are currently applying them in a small pilot study.

Results: The 44 patients' gains ranged from 1.35×10^{-5} to 4.07×10^{-3} g/dL/IU (a factor of 300) with mean 2.56×10^{-4} and standard deviation 6.05×10^{-4} (see figure). For patients receiving up to 10000 IU/week, the associated factor of gain variation is almost 200. We will report prospective results from the pilot study.



The gains (on log scale) of the 44 ESRD patients are plotted against the weekly EPO doses estimated to produce long-term Hgb level of 11.25 g/dL.

Conclusions: The factor of gain variation 300 is too large to expect a single, fixed AMP to cope with. Moreover, patients receiving up to 10000 IU/week are typically classified as hyper-responsive, which conveys the notion that they are all equally responsive. But the situation is more complicated than that; in fact, the associated factor of gain variation is almost 200. This prompts us to advocate that patients' Hgb responsiveness be classified by their gains rather than by administered ESA doses, and that individualized AMPs be designed in accordance with that classification.

FR-PO236

Persistent Increases in ESA Utilization Following Hospitalization of End-Stage Renal Disease Patients T. Christopher Bond,[1] Steven Wang,[1] Jaime Rubin,[1] Alex Yang.[2] *[1]DaVita Clinical Research, Minneapolis, MN; [2]Affymax Inc, Palo Alto, CA.*

Background: Hemodialysis (HD) patients are frequently hospitalized. The combination of the interruption of normal dialysis and 3x/weekly ESA treatments and the underlying reasons for hospitalization often lead to lowered hemoglobin (Hb) levels and increased utilization of ESAs in the post-hospitalization period.

Methods: In a retrospective database analysis, epoetin alfa utilization before and after hospitalization in 138,762 adult (≥18 yrs old) HD patients receiving in-center dialysis from 01/01/09-12/31/10 was assessed. A total of 181,595 hospitalizations preceded by >30 hospital-free days were included in the analysis. Mean per-session epoetin alfa dose for the time periods 15 and 30 days pre/post-hospitalization, as well as mean monthly epoetin alfa doses for the 2 months before and 6 months after hospitalization were calculated.

Results: Analysis of epoetin alfa use during the pre/post-hospitalization period showed increases in dose which persisted over time. After minimal change in the first immediate post-hospitalization dose (versus last pre-hospitalization dose), a 15-day pre/post analysis showed 53.3% of hospitalizations associated with a rise in mean per-session epoetin alfa dose (13.8% with no change, 32.6% with a drop). In a 30-day pre/post analysis, 60.8% of hospitalizations were followed by an increase in mean per-session epoetin alfa dose (4.9% with no change, 34.3% with a drop). Mean per-session dose increases (for all hospitalizations) were 843 U and 1,322 U (SD; 4,320 and 5,161) for the 15 day and 30 day analyses, respectively. Mean total monthly dose rose starting in the month before hospitalization and continued to increase during the 2 months after hospitalization. Recovery to the mean monthly dose from 2 months before hospitalization did not occur until 4 months after hospitalization.

Conclusions: This analysis suggests that hospitalizations frequently lead to increases in ESA dose, which persist for several months post-hospitalization. Strategies for better management of anemia during hospitalization and in the post-hospitalization period should be assessed.

FR-PO237

Missed Dialysis Sessions Result in Increased Erythropoiesis-Stimulating Agent (ESA) Use T. Christopher Bond,[1] Steven Wang,[1] Jaime Rubin,[1] Alex Yang.[2] *[1]DaVita Clinical Research, Minneapolis, MN; [2]Affymax Inc, Palo Alto, CA.*

Background: Patients who miss dialysis sessions may experience adverse clinical outcomes (Saran et al, 2003). In addition to missing dialysis itself, patients fail to receive medications (such as ESAs) dosed at each session. We characterized missed sessions and ESA utilization to better understand underlying patterns.

Methods: In a retrospective analysis, we assessed 903,179 patient-months of data from 105,519 adult (≥18 yrs old), hemodialysis patients receiving in-center dialysis. Missed sessions for all reasons (including hospitalization) were included. Consecutive missed sessions were considered part of a missed session "episode". Differences in per-session epoetin alfa utilization were calculated for the periods 14, 30 and 31-60 days before and after missed sessions, stratified by length of episode. In a second analysis, total monthly epoetin alfa dose was tracked for all calendar months by number of missed sessions/month.

Results: Per-session ESA use increased following a missed session episode: longer missed session episodes resulted in greater increases in per-session ESA use on return to the clinic. Increases ranged from 134–1,512 U/session, 1,835–4,093 U/session, and 63–2,778 U/session for the 14, 30 and 31-60 day time periods before and after missed session episodes, respectively, with larger increases tied to longer episodes. Total monthly dose was increased in months where patients missed ≤6 sessions, compared to those in which all sessions were attended.

Missed Sessions (per patient-month)	N (patient-months)	Change in Total Monthly ESA Dose (U)
0	613,049	-
1	105,093	+ 8,707
2	53,739	+ 14,130
3	32,358	+ 15,125
4	24,156	+ 9,122
5	16,191	+ 5,651
6	10,279	+ 1,803
7	7,218	- 7,797
8	5,796	- 17,281

Conclusions: The results suggest missed dialysis sessions result in increased epoetin alfa use on a per-session basis in the post-miss period, but also when including missed sessions in calculations of total monthly use. This finding is consistent with the pharmacology and biology of short-acting ESA. Patients missing ≤6 sessions/month use more total ESA than patients attending every session. This may have economic implications for dialysis centers.

Increasing Erythropoiesis Stimulating Agent Dosage in Hospitalized Hemodialysis Patients Increases Risk of Overshooting Target Hemoglobin and Does Not Reduce Transfusion Risk Ben C. Wong,[1] Pietro Ravani,[1] Braden J. Manns,[1] Xin Zhang,[1] Rick Chin,[1] Brenda Hemmelgarn,[1] Marcello Tonelli,[2] Matthew J. Oliver,[3] Robert R. Quinn.[1] *[1]University of Calgary, Calgary, AB, Canada; [2]University of Alberta, Edmonton, AB, Canada; [3]University of Toronto, Toronto, ON, Canada.*

Background: Doses of erythropoiesis stimulating agents (ESA) are often increased in hospitalized hemodialysis (HD) patients in an attempt to restore hemoglobin levels to target. The impact of these changes is not known. We conducted a retrospective cohort study to determine if changes in ESA dose at hospital admission influenced the risk of normalization of hemoglobin, blood transfusions, cardiovascular outcomes, or death.

Methods: Linked administrative, lab, and blood transfusion data were used to identify HD patients hospitalized in the Calgary Health Region between 2004 and 2008. Change in ESA dose was determined by comparing the average weekly dose over the preceding 6 weeks to the dose administered during the first 14 days following admission (expressed as an equivalent darbepoietin alfa dose in micrograms per week). Cox proportional hazards models, adjusted for baseline characteristics, were used to study the impact of change in ESA dose on the risks of normalization of hemoglobin (>130g/L), blood transfusion, cardiovascular outcomes, and death.

Results: A total of 700 hospitalizations in 448 patients (mean hemoglobin 113 g/L) were identified. There was a significant and graded increase in the risk of normalization

of hemoglobin as the ESA dose was increased by more than 40 mcg/week above baseline. However, higher ESA doses were not associated with a reduced need for blood transfusion. Change in ESA dose was not associated with the risk of cardiovascular endpoints or death.

Conclusions: Increasing ESA dose at hospitalization in HD patients is associated with a higher risk of hemoglobin normalization, but does not reduce the need for transfusion. A randomized trial testing different ESA dosing strategies in hospitalized HD patients is needed.

FR-PO239

Impact of Missed Treatments on Epoetin-Alpha to Maintain In-Center Patients in a Target Hemoglobin Range Kirk Finchem. *Clinical Operations, Renal Advantage, Inc, Franklin, TN.*

Background: Clinicians seek to manage ESRD-patient anemia (Hb levels) within a target range (9 to 11 g/dL, for the present study). Individual patients may be hypo-, normal-, or hyper-responsive to epoetin-alpha; the differences may be chronic (due to systemic biological factors), or acute (due to acute conditions).

Methods: Patients (n=5,245) had been on dialysis for more than 90 days, and were treated in-center at one or more of 155 dialysis centers operating in 22 states within the United States, during each month October 2011 thru January 2012.

Table 1: Patient Demographics and Characteristics

	Hyper-responsive	Normal-responsive	Hypo-responsive	Total
Patients	1,314	2,619	1,312	5,245
Men	694	1,285	682	2,661
Women	620	1,334	630	2,584
Age	65.3	63.4	60.2	63.1
Weight (kg)	77.9	79.8	80.5	78.5
Epoetin-alpha Dose (Units)	10,633	31,050	91,734	41,115
Treatments (count)	12.6	12.6	12.4	12.5
Hemoglobin (g/dL)	10.6	10.3	10.0	10.3
Fistula Patients	886	1,635	751	3,272
Graft Patients	289	645	337	1,271
CVC Patients	139	339	224	702

Monthly values for hemoglobin (Hb in g/dL), Albumin (AL in g/dL), treatments, and weight (kg) were averaged. Patient age (as of January 1, 2012), sex, and vascular access type was included. Hyper- and Hypo-Responsive levels were chosen to assign the smallest and largest 20 percent of period-average (monthly) epoetin-alpha doses to each group, respectively; the balance of patients were assigned to the Normal-responsive group.

Results: A linear regression model was developed to estimate the benefit (or penalty) of predictor variables to the dose of epoetin-alpha required to maintain the patient within the target hemoglobin range. The model included hemoglobin, albumin, monthly treatments, weight, access type, responsiveness, and sex. The final model achieved an R^2 of 0.7104, with all predictor variables showing significance at the 95% level.

Conclusions: Higher hemoglobin and albumin values were associated with lower epoetin-alpha doses, as were AV fistulas. The mean penalty (i.e., increased epoetin-alpha dose) for missing a single monthly treatment was 278.2 units per treatment (95%CI: 242.0, 314.3), similar to the penalty of CVCs compared to AV fistulas of 258.7 (95%CI: 114.6, 402.8).

FR-PO240

Reticulocyte-Based Estimation of Red Blood Cell Lifespan Wojciech Krzyzanski,[1] Adam E. Gaweda,[2] Michael E. Brier.[2,3] *[1]University at Buffalo, Buffalo, NY; [2]University of Louisville, Louisville, KY; [3]Robley Rex VA Medical Center, Louisville, KY.*

Background: Decreased red blood cell (RBC) production and increased RBC turnover are the main factors contributing to the anemia of ESRD. To facilitate optimal anemia management, the contribution of both processes should be known.

Methods: We measured the RBC lifespan in 5 hemodialysis dependent end-stage renal disease patients. RBC lifespan is determined by measuring the RBC count using standard techniques and determining the RBC production rate from the reticulocyte residual RNA content. Given these two measures one can simply calculate the RBC production rate. The RNA degradation half-life is determined for each subject on day one over 12 hours using thiazole orange and flow cytometry. Reticulocyte age distribution is then measured weekly for 2 months yielding the RBC production rate time course. The RBC lifespan is estimated by fitting the integrated RBC production rate over a time interval to the RBC count. All calculations were performed using MATLAB.

Results: Results are shown in the following table for RBC Lifespan, RNA half-life, average weekly EPO dose, and mean Hb achieved during 2 month follow up.

Subject	Lifespan (days)	tRNA1/2 (days)	EPO Dose (week)	Hb achieved
1	72	0.71	0	13.67
2	61	0.83	20,000	10.38
3	108	0.74	12,000	10.73
4	74	0.73	4,000	8.75
5	67	0.55	4,000	8.68

We performed an analysis of variance on the data with hemoglobin achieved as the dependent variable. Both EPO (p=0.03) and Lifespan (p=0.05) were statistically significant and positively correlated to hemoglobin.

Conclusions: Despite the small study size, we were able to demonstrate a relationship between EPO dose and RBC lifespan and hemoglobin achieved using a new technique. Subjects with a higher EPO dose and longer RBC lifespan had higher achieved hemoglobin. One subject was EPO naive and despite abnormal RBC lifespan had adequate hemoglobin. We conclude that the achieved hemoglobin is a result of a complex interaction of many variables including EPO dose and RBC lifespan. Determining RBC lifespan using this simple technique can help us better understand the anemia of chronic renal disease and potentially improve patient care and warrants further work.

FR-PO241

Associations among Epoetin Therapy, Inflammation, Nutritional Status and Mortality in Patients on Hemodialysis Hirokazu Honda,[1] Naoki Kimata,[2] Kenji Wakai,[3] Tadao Akizawa.[1] *[1]Division of Nephrology, Department of Medicine, Showa University School of Medicine, Tokyo, Japan; [2]Kidney Center, Division of Blood Purification, Tokyo Women's Medical University, Tokyo, Japan; [3]Department of Preventive Medicine, Nagoya University Graduate School of Medicine, Nagoya, Japan.*

Background: Inflammation is a key factor for increased mortality and associated with abnormal body composition in patients under dialysis. Association among these factors in those patients is quite complex. Inflammation and nutritional status possibly lead to erythropoiesis-stimulating agents (ESA) hyporesponsiveness by close interaction. Thus, the aim of the study was to assess impact of inflammation and nutritional status on mortality considering ESA therapy in hemodialysis (HD) patients.

Methods: We assessed associations among doses of epoetin (EPO), inflammation and nutritional status and estimated the impact of EPO dose on mortality in a cohort of prevalent HD patients (n = 37,003) using data from the Japanese Dialysis Registry (2005–2006). Patients were categorized according to tertiles of ESA responsiveness index (ERI, EPO dose (IU/week)/body weight (kg)/hemoglobin (g/dL). Nutritional index (body mass index (BMI)) and C-reactive protein (CRP) levels were measured and one-year all-cause and cardiovascular mortality were estimated.

Results: CRP levels were lower in the lower ERI tertile than in the other groups. Bimodal peaks indicated associations between CRP and BMI in each group. Hazard ratio (HR) curves of CRP according to BMI in the upper ERI tertile particularly with diabetes mellitus (DM) were U-shaped, whereas the increased HRs were associated with low BMI in the other groups. Survival was worse in the upper ERI tertile, than in the other groups. However, mortality was better in the lower ERI tertile group without DM, than in the EPO-free group. These associations were confirmed by multivariate Cox hazard models in a propensity score-matched population.

Conclusions: The findings indicate that the risk association between CRP and risk of death is changed by nutritional status in patients who require a higher dose of EPO especially those with DM, and a low dose of EPO was effective in patients without DM.

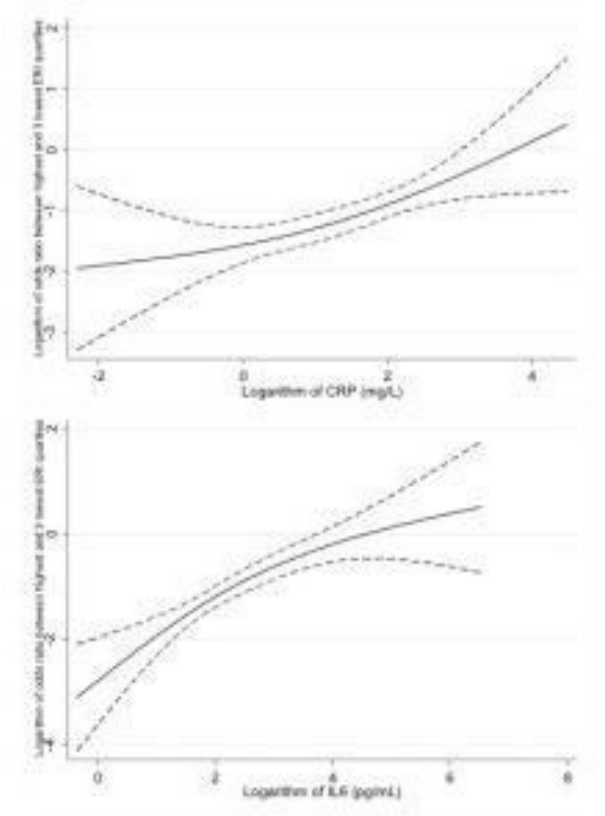
FR-PO242

Association of Malnutrition-Inflammation Complex and Responsiveness to Erythropoiesis Stimulating Agents in Long-Term Hemodialysis Patients Manoch Rattanasompattikul,[1] Miklos Zsolt Molnar,[1,5] Joshua Zaritsky,[2] Parta Hatamizadeh,[1] Jennie Jing,[1] Keith C. Norris,[3] Csaba P. Kovesdy,[4] Kamyar Kalantar-Zadeh.[1,2] *[1]Harold Simmons Center, LABioMed at Harbor-UCLA, Torrance, CA; [2]David Geffen School of Medicine at UCLA, Los Angeles, CA; [3]Charles R. Drew University; [4]Nephrology, University of Tennessee, Memphis, TN; [5]Institute of Pathophysiology, Semmelweis University, Budapest, Hungary.*

Background: Protein-energy wasting, inflammation and refractory anemia are common in long-term hemodialysis patients. A decreased responsiveness to erythropoiesis stimulating agents (ESA) is often the cause of the refractory anemia. We hypothesized that malnutrition-inflammation complex is an independent predictor of decreased responsiveness to ESAs in hemodialysis patients.

Methods: In a 6-year prospective cohort study of 754 hemodialysis patients, we examined for association between inflammatory and nutritional markers including the malnutrition-inflammation score (MIS) and responsiveness to ESA (ERI).

Results: Mean age of patients was 54±15 years, 53% were diabetic and 49% Hispanic. Both C-reactive protein (Log CRP) (β=0.19) and interleukin-6 (Log IL-6) (β=0.32) were strong and independent predictors of ERI using multivariate linear regression. Each 1SD higher MIS, higher CRP and lower albumin were associated with 86%, 44% and 97% higher likelihood of highest vs. 3 lowest ERI quartile in fully adjusted models (odds ratio [95% CI] of 1.86 [1.31-2.85], 1.44 [1.08-1.92], and 1.97 [1.41-2.78]), respectively. Cubic splines illustrated continuous and incremental association of Log CRP and Log IL-6 with ERI.



Conclusions: Malnutrition-inflammation complex is a significant and independent predictor of decreased responsiveness to ESAs in hemodialysis patients.

FR-PO243

Protein Carbamylation, Erythropoietin Resistance, and Mortality in End Stage Kidney Disease Sahir Kalim,[1] Hector Tamez,[1] Elizabeth D. Ankers,[1] Joseph James Deferio,[1] Anders H. Berg,[2] S. Ananth Karumanchi,[3] Ravi I. Thadhani.[1] *[1]Department of Medicine, Division of Nephrology, Massachusetts General Hospital, Boston, MA; [2]Department of Pathology, Division of Clinical Chemistry, Beth Israel Deaconess Medical Center, Boston, MA; [3]Department of Medicine, Division of Nephrology and Center for Vascular Biology Research, Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Resistance to recombinant human erythropoietin (EPO) leads to an increased risk of adverse outcomes but the biological mechanism is not fully understood. Carbamylation is a non-enzymatic reaction which occurs through uremic and inflammatory pathways and can alter the charge, structure, and function of proteins such as erythropoietin.

Methods: In this study, we characterize the relationship between protein carbamylation and EPO resistance index (ERI) in 158 hemodialysis patients using carbamylated albumin levels measured at day 90 of dialysis initiation.

Results: The highest quartile of carbamylated albumin was positively associated with ERI compared to the lowest quartile (P= 0.03; P for trend = 0.002) with similar findings in a multivariate model (highest vs. lowest quartile P= 0.01, P for trend = 0.02). In logistic regression models, ERI was predictive of one year all cause mortality (univariate OR 1.43, [95% confidence interval [CI] 1.02–2.02], P= 0.04; multivariate OR 1.62, [95% CI 1.05–2.50], P=0.03). However, the association between ERI and mortality was mitigated when carbamylation was added to the multivariate analysis (highest vs. lowest quartile carbamylation OR 5.47, [95% CI 1.48–20.21], P=0.01; compared to ERI OR 1.19, [95% CI 0.74–1.93], P=0.47).

Conclusions: Carbamylation burden was associated with ERI in incident dialysis patients and was a better predictor of mortality than ERI.

FR-PO244

Erythropoiesis-Stimulating Agent (ESA) Responsiveness in a European Haemodialysis Cohort: Case-Crossover Study Iain C. Macdougall,[1] Iain A. Gillespie,[2] Marc Froissart,[3] Sharon Richards,[2] Vincent Jones,[2] Kai-Uwe Eckardt.[4] *[1]King's College Hospital, London, United Kingdom; [2]Amgen Ltd, Uxbridge, United Kingdom; [3]Amgen Europe GmbH, Zug, Switzerland; [4]University of Erlangen, Nuremberg, Germany.*

Background: ESA hyporesponsiveness (hR) is associated with increased morbidity and mortality in chronic kidney disease patients. Previous studies, focussing on baseline predictors of hR, may be biased by confounding by indication and may be unable to examine transient exposures. Accordingly, a case-crossover study was performed to examine factors associated with the transition to a hyporesponsive state in a European haemodialysis (HD) cohort. Case-crossover studies are useful for studying the effect of transient exposures on outcomes.

Methods: Patients' follow up time was split into 90 day periods of weight-adjusted weekly ESA exposure. Haemoglobin (Hb) response was evaluated for the last 30 days of one period and the first 30 days of the next. Each period was defined as responsive, hyporesponsive, under-treated or missing based on a median ESA dose (0.404 µg/kg/wk) and a 10g/dL Hb threshold. Where a patient's first hyporesponsive period was preceded by a responsive period, these periods were coded as 'case' and 'control' periods respectively and hospitalisation, HD and laboratory data accompanying the periods were compared using conditional logistic regression.

Results: Patients on ESAs (n=6645) contributed 38,427 ninety-day analysis periods of ESA exposure. Most ESA exposure periods (75.7%) were periods of Hb response. Almost five percent (4.7%) resulted in hR periods. 672 patients experienced hR periods with preceding response periods. Periods of hR were more likely to follow periods of hospitalization or changes in vascular access, and were marked by a preceding increase in ferritin and CRP. The findings were largely insensitive to alternative ESA dose and Hb thresholds.

Conclusions: Transition to ESA hR may be preceded by events requiring hospitalization, vascular access issues and signs of biological inflammation. These events should alert clinicians to the potential occurrence of an ESA hR-related risk.

Influence of Hemoglobin Levels, Hypo-Responsiveness or Hemoglobin Variability on the Survival in Incident Hemodialysis Patients Receiving Erythropoiesis Stimulating Agent Tadao Akizawa.[1] *[1]Department of Nephrology, Showa University School of Medicine, Tokyo, Japan; [2]JET Study Group.*

Background: It has been reported that hypo-responsiveness or large variability in hemoglobin (Hb) levels under erythropoiesis stimulating agent (ESA) therapy are associated with a poor prognosis. In this study, we evaluated the maintained Hb levels and mortality in incident hemodialysis (HD) patients receiving ESA therapy and compared them between patients with hypo-responsiveness (Gr. A) or large Hb variability (Gr. B) and the remaining patients (Gr. C).

Methods: Patients who had newly-initiated HD and received epoetin beta (EPO) therapy in Japan were stratified by their Hb levels at 6 months after the start of EPO therapy to evaluate their mortality during 3 years. Gr. A and Gr. B were defined as those who had a Hb level <10.0 g/dL and also were receiving EPO at a dose ≥9000 IU/week and who had more than one of up/down-excursion of over 1.0 g/dL across 10.0 to 11.0 g/dL of Hb during 6 months, respectively. Analysis was performed using a Cox regression analysis and hazard ratios (HRs) were calculated.

Results: The analysis included 6631 patients. The mean Hb levels were 8.2 g/dL and 10.2 g/dL at baseline and 6 months of EPO therapy, respectively. The patients were stratified by Hb level at 6 months after the start of EPO therapy as follows: 11.4% in Gr. 1(<9.0 g/dL), 28.5% in Gr. 2(≥9.0 and <10.0 g/dL), 35.9% in Gr. 3(≥10.0 and <11.0 g/dL), 19.3% in Gr. 4(≥11.0 and <12.0 g/dL) and 4.9% in Gr. 5(≥12.0 g/dL). The adjusted HR to Gr. 3 was 2.08, 1.17, 0.91 and 1.32 for Gr. 1, 2, 4 and 5, respectively.

Of the 6631 patients, 4.4%, 14.9% and 80.7% were identified as Gr. A, B and C, respectively. Analysis of Gr. C showed the adjusted HR to Gr. 3 was 2.18, 1.23, 0.83 and 1.38 for Gr. 1, 2, 4 and 5, respectively. Gr. A and Gr. B had an adjusted HR of 1.71 and 1.23, respectively, compared with Gr. 3 in Gr. C.

Conclusions: Based on the prognosis during 3 years of EPO therapy, it is associated good survival to maintain the Hb level at 10.0 to 12.0 g/dL in incident HD patients. This study also suggests the presence of ESA hypo-responsiveness or large Hb variability is associated with an increased mortality risk.

Association of Neutrophil-to-Lymphocyte Ratio with Inflammation-Malnutrition Syndrome and EPO Resistance in Dialysis Jerome Pineault, Michel Vallee, Vincent Pichette, Martine Leblanc, Georges Ouellet, Jean-Philippe Lafrance, Robert Zoël Bell. *Nephrology, Maisonneuve-Rosemont Hospital, Montreal, QC, Canada.*

Background: Neutrophil-to-lymphocyte ratio (NLR) has been widely studied in different medical and surgical specialties as a pronostic marker and is yet to be used or validated in nephrology.

Methods: (Single-center retrospective study). We included patients ≥18 y.o. who were on dialysis for ≥3 months and excluded those on chemotherapy, not on EPO or in whom weight was unavailable. We evaluated the relation between NLR and biomarkers of inflammation-malnutrition syndrome: CRP and albumin. We also evaluated the association between EPO resistance and NLR, as it increases in inflammatory states. We made direct correlation analyses between NLR, CRP and albumin. We measured mean values of NLR, CRP and albumin when patients were acutely ill (on antibiotics or hospitalized) and compared them to mean values of the same patients when they are not acutely ill. Among the patients who died during the observation period, we observed the mean NLR monthly during the 6 months preceding death. For the EPO resistance, we calculated EPO resistance index (ERI) monthly for each patient and we calculated a mean NLR corresponding to this value.

Results: A total of 529 patients were analyzed. We found a positive, linear and moderate correlation between NLR and CRP and the exact opposite (as expected) between NLR and albumin that are all statistically significant (SS). Values of NLR with CRP (N=123, r=0.48, B=0.018, P < 0.001) and NLR with albumin (N=123, r=-0.53, B=-0.454, P < 0.001) corresponded well with our reference value that was CRP with albumin (N=123, r=-0.45, B=-0.021, P < 0.001). When comparing values of acutely ill patients vs. not ill, NLR was SS higher among ill patients (5.21 vs. 4.56, P < 0.001). All results mentioned above are still SS among HD patients only and PD patients only. NLR was also rising constantly in the months preceding death. When we divided ERI in quartiles, we also observed that as the ERI rises, NLR is higher.

Conclusions: NLR seems to be a valuable, inexpensive and reproducible marker of the inflammatory state in dialysis. A cut-off of clinically significant inflammation is still needed as well as a normal value of NLR.

FR-PO247

Association between Decrease Rate of Hematocrit due to Renal Anemia and Resistance to Erythropoietin Stimulating Agents Therapy in Hemodialysis Patients Tadashi Kuji,[1,2] Tetsuya Fujikawa,[2] Midori Kakimoto-Shino,[2] Yoshiyuki Toya,[2] Satoshi Umemura.[2] *[1]Yokodai Central Clinic; [2]Cardiorenal Medicine, Yokohama City University, Yokohama, Kanagawa, Japan.*

Background: In treatment of renal anemia of hemodialysis (HD) patients, there is fluctuation of hematocrit (Hct) where Hct basically decreases due to renal anemia by discontinuation of erythropoietin stimulating agents (ESA) and rises by ESA dosing; however, it is unknown how resistance to ESA therapy is associated with the decrease and increase rates of Hct. To help elucidate it, we examined the association of ESA resistance index (ERI) with changes of Hct per week with a simple protocol using fixed-dose ESA in HD patients.

Methods: A total of 120 HD patients, 68.5 ± 11.5 years (mean ± SD), in our units were studied for 26 weeks. Hct was checked weekly. Fixed-dose epoetin beta (EPO) 9000 IU per week were prescribed when Hct level was less than 32%. EPO were discontinued when Hct was 32 % or more. Change rate of Hct (%/week) with EPO administration was defined as the average change rate of Hct per week after restart of EPO therapy. Change rate of Hct (%/week) without EPO administration was defined as the average change rate of Hct per week after discontinuation of EPO therapy. ERI was calculated as weekly weight-adjusted dose of EPO divided by Hct level during the observation.

Results: The mean value of ERI was 2.98 ± 1.50 IU/kg/week/% for 26 weeks. Hct level achieved was 31.8 ± 1.11% during the observation period. The mean change rate of Hct with EPO was 0.738 ± 0.589 %/week, and the mean change rate of Hct without EPO was -0.660 ± 0.750 %/week. The change rate of Hct without EPO administration showed a significant inverse correlation with ERI (r = -0.460, p < 0.001), although the change rate of Hct with EPO administration was not.

Conclusions: The decrease rate of Hct per week after discontinuation of EPO was correlated with ERI, while the increase rate of Hct after restart of EPO was not. Our finding suggested that large decline rate in Hct levels after discontinuation of ESA is a more important factor to deteriorate responsiveness to ESA, compared to increase in Hct with ESA administration. Further study is needed to confirm the association.

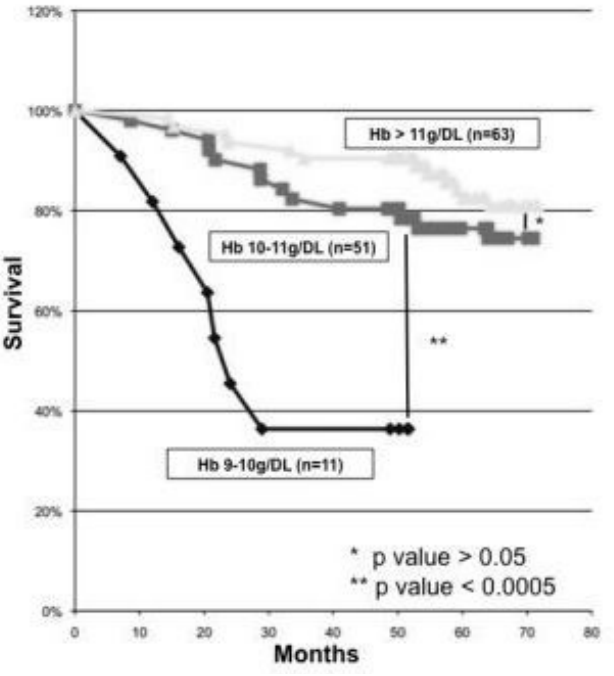
FR-PO248

The Effects of Mean Haemoglobin on the Survival of Patients Requiring Chronic Haemodialysis for End Stage Renal Failure: A 6 Year Retrospective Study Adam Sharp, Subash Somalanka, Maggi Steele, Pinnaduwage Vipula De Silva, David Makanjuola. *St Helier Hospital, Carshalton, United Kingdom.*

Background: Treating & maintaining haemoglobin [Hb] in patients undergoing chronic haemodialysis [HD] is a controversial subject with regard to what the optimal target levels are. We looked at our patient population to investigate the association of mean Hb on the survival of patients requiring chronic HD for ESRF.

Methods: All patients who were started on chronic HD in our renal centre in 2006 & 2007 were eligible for the study. A total of 124 patients were included & followed up over a 6 year period. Their baseline characteristics & comorbidities were recorded. Mean Hb for each patient was calculated from all measurements taken whilst on HD. Patients were grouped according to their mean Hb (9-10g/dl, 10-11g/dl & >11g/dl). A comparison between mean Hb & survival (all cause mortality) was made, correcting for baseline characteristics & co-morbidities.

Results: Of the 124 patients in the study there was no demonstrable difference in their baseline characteristics and comorbidities. Patients with a mean Hb on chronic HD of >11g/dl had no significant survival advantage when compared to those patients with a mean Hb between 10g/dl & 11g/dl (p>0.05) for all cause mortality. However, both groups had a significant survival advantage over patients with a mean Hb between 9 - 10g/dl (p=0.0005) for all cause mortality.



Conclusions: In our patient population there was no survival advantage between chronic HD patients that have mean Hb between 10g/dl & 11g/dl compared to those with mean Hb of >11g/dl. However, both these groups have a significant survival advantage from all cause mortality compared to those patients with Hb between 9 - 10g/dl. Interestingly, our findings lend weight to the current guidelines of the UK renal association, which recommend a target lower limit Hb of 10g/dl.

FR-PO249

Association of All-Cause Mortality with Hemoglobin Variability in Patients Undergoing Peritoneal Dialysis Li Zuo,[1] Li Liu,[1] Nayyar Saleem,[2] Rong Xu.[1] *[1]Institute of Nephrology, Peking University; [2]Shaikh Zayed Hospital Lahore.*

Background: Patients with chronic kidney disease exhibit significant hemoglobin variability, especially with the use of erythropoiesis stimulating agents and iron. Analyses of different dialysis cohorts produced conflicting results regarding association of Hb variability with patient outcomes. Moreover, very few studies were conducted in peritoneal dialysis (PD) patients. Purpose of this study was to assess the association of hemoglobin variability with all-cause mortality in our PD center.

Methods: Totally 219 incident PD patients (59±14 years, males in 41.6%, diabetes in 39.3%)were followed for 12 to 102 months from 2002 Dec to until 2011 Jun. Mean Hb of every three months in the first year after initiation of dialysis were calculated for each patient. Intrapatient hemoglobin variability was defined by two methods, standard deviation (SD) and residual SD, calculated from Hb measured in the first year. The association between Hb variability (represented by SD or residual SD) and mortality were analyzed by univariate logistic regression. Two Cox regression models, including either SD or residual SD, were used to analyze the relation between survival and Hb variability, after age, gender and diabetes were adjusted.

Results: Hb variability SD and residual SD was 10.94 and 7.84 g/L, respectively. There were 90 deaths (41.1% of all patients). In univariate logistic regression analysis, residual SD was associated with mortality (OR=1.076, p=0.013), but SD was not (OR=1.044, p=0.080). By Cox regression analysis with SD, age (older than 65 years, HR=3.019 for SD model, p<0.001; HR=2.934 for residual SD model, p<0.001) and diabetes (HR=1.805 for SD model, p=0.007; HR=1.823 for residual SD model, p=0.006) were associated with mortality, while either SD or residual SD was not (HR=1.010, p=0.565; HR=1.021, p=0.278).

Conclusions: Although hemoglobin variability measured as residual standard deviation was associated with mortality in PD patients, it cannot predict the mortality independently after age and diabetes were adjusted.

FR-PO250

Native Vitamin D Therapy in Hemodialysis Patients Results in Reduced Erythropoietin (EPO) Requirements-A Cluster Randomised Study Tarun Kaushik, Mark Blunden, Martin J. Raftery, Ravindra Rajakariar, Magdi Yaqoob. *Nephrology, The Royal London Hospital, London, United Kingdom.*

Background: Haemodialysis patients have low measured 25-OH Vitamin D levels.Native vitamin D supplementation in dialysis patients has been shown to reduce inflammation by lowering pro inflammatory cytokine.Sterile inflammation in dialysis patients is associated with EPO resistance resulting in higher dosage and increased morbidity and mortality.We therefore hypothesized that Vitamin D2 supplementation leads to reduced EPO requirements.

Methods: We conducted a cluster randomised study where half patients in a satellite unit were given oral ergocalciferol (n = 118) whilst remaining patients did not receive the treatment (n= 117) as per clinical preference of two physicians.In both groups combined,median 25 OH-Vitamin D level at baseline was 33 nmol/L (range 39.7– 48.4). The treated group (n= 118) received supervised 50,000 units weekly for 4 weeks followed by once monthly for 5 months.There was no difference in demographics, dialysis vintage, use of activated vitamin D and Cinacalcet in both groups.

Results: With treatment vitamin D levels rose from median of 32 to 78 nmol/L ($p<0.0001$) which remained unchanged in untreated group.In the treatment group, there was a significant reduction in EPO requirement as assessed by Hb index (weekly EPO dose in units/Hb g/dl) from a mean of 671 to 580 ($p<0.001$) but remained unchanged in the untreated group from mean of 795.0 to 743.1 ($p=0.12$) at 6 months.Furthermore, in the treated group the mean EPO dose per kg body weight per week reduced from 104 to 86 ($p=0.015$) but tended to increase non-significantly in untreated group (120 baseline to 160 at 6 months; $p=0.21$).Serum ferritin, calcium, phosphate, PTH and non hs-CRP were similar in both groups during the six month study period. Ergocalciferol was well tolerated with no adverse effects.

Conclusions: We conclude that native vitamin D2 in physiological doses leads to reduction in EPO requirement by an unknown mechanism.This simple and cheap strategy is both safe and well tolerated.The benefit of this therapeutic approach may potentially translate into significant cost saving and better patient outcomes.

FR-PO251

Effect of Ergocalciferol (D_2) Supplementation on Anemia and Mineral Metabolism Management in Hemodialysis Patients Shweta Bansal,[1] Ruby Naldoza,[2] Jonathan Vidola,[2] Ken Williams,[1] Paolo Fanti.[1] *[1]Division of Nephrology, University of Texas Health Sciences Center at San Antonio, San Antonio, TX; [2]Renal Dialysis Unit, University Health System, San Antonio, TX.*

Background: Vitamin D deficiency is prevalent in chronic kidney disease patients but literature on its supplementation is scarce. The aim of this study was to evaluate the effect of D_2 supplementation on erythropoietin (EPO) requirement and mineral metabolism in hemodialysis (HD) patients.

Methods: Medical records of 53 hemodialysis patients were examined retrospectively for a 6-month period, after initiation of a protocol to assess serum 25(OH)D levels and implement treatment with ergocalciferol if the levels were <35 ng/mL. Fifty patients (94%) had 25(OH)D levels <35 ng/ml and 47 were included for the analysis. Parameters of erythropoiesis, iron, and mineral metabolism and monthly doses of erythropoietin, intravenous iron and paricalcitol were assessed before and after D_2 supplementation.

Results: Mean 25(OH)D level was 17.15 ± 8 ng/ml and increased to 33.66 ± 10.3 ng/ml after 6 months of D_2 supplementation per protocol. Mean EPO use decreased by 15% (from 35,451 ± 26,192 IU/month to 29,960 ± 22,395 IU/month; $p=0.03$), and paricalcitol dose by 16% (from 26.15 ± 17.4 µg/month to 21.85 ± 14.1 µg/month; $p=0.039$) after 6 months of D_2 supplementation without any increase, rather a non significant downtrend in intact parathyroid hormone level. Serum calcium increased from 9 ± 0.5 mg/dl to 9.4 ± 0.7 mg/dl ($p=0.0008$), and bone-specific alkaline phosphatase from 19.4 ± 13.2 IU/ml to 25.6 ± 30.2 IU/ml ($p=0.04$). Monthly hemoglobin, ferritin, iron saturation, albumin, and phosphorus levels were not different before and after D_2 supplementation. No significant change was observed in dosage of phosphate binders and cinacalcet. On multivariate analysis the decrease in EPO dose was partly explained by decrease in paricalcitol dose.

Conclusions: Oral ergocalciferol supplementation in HD patients seems to be a cost-effective therapeutic measure. It allows reduced dosing of erythropoiesis-stimulating agents and active vitamin D analgoue, both of which are associated with their inherited adverse effects.

FR-PO252

Hemodialysis System Using Dissolved Dihydrogen(H2) Produced by Water Electrolysis Reduced the Darbepoetin Dose Noritomo Itami, Kazushi Tsuneyama, Susumu Uemura. *Kidney Center, Nikko Memorial Hospital, Muroran, Japan.*

Background: High levels of pro-inflammatory cytokines and increased oxidative stress are common features contributing to malnutrition, recombinant human erythropoietin(rHuEPO) resistance, and atherosclerosis in ESRD patients. The administration of H2, an inert gas with no known side effects, dissolved in water is reported to suppress oxidative or inflammatory injury. We changed dialysate from standard water to water with high levels of dissolved H2. We report the effect of HD with high levels of dissolved H2 on anemia and darbepoetin alfa(DA).

Methods: Dialysate with high levels of dissolved H2(average of 60 ppb) was produced by mixing dialysate concentrates and reverse osmosis water containing dissolved H2 generated by the HD-24K water electrolysis system(Nihon Trim, Osaka Japan) details are reported in(Nephrol Dial Transplant 25;3026,2010). Thirty-nine stable patients on standard HD(S-HD), (M/F ratio 21:18, Mean Age: 64±10.3yr, Vintage: 11.9±8.5yr, original diseases: 12CGN, 9DM, 4PCK, others 14) were switched to HD with water with high levels of dissolved H2(HD-H2) after obtaining informed consent. DA dose was altered biweekly according to our algorithm considering hemoglobin(Hb) level, Hb change gradient and iron parameters. Other anemia treatment was carried out as usual. Average DA dose and clinical parameters were examined.

Results: Hb was unchanged, S-HD for 12 months the mean Hb was 11.1g±1.0/dL and in HD-H2 for 11 months the mean Hb was 11.0±0.9g/dL. The number of patients taking iron treatment in S-HD was a mean of 15.4±2.8 patients/month and in HD-H2 a mean of 12.9±2.3 patients/month(n.s). Serum ferritin was significantly increased from a mean of 156.3±113.7ng/mL in S-HD to a mean of 184.9±121.2ng/mL in HD-H2. The average TSAT was unchanged, 29.9±11.5% in S-HD VS 28.0±11.2% in HD-H2. Average DA dose was significantly reduced from 15.6±11.0µg/week in S-HD to 14.0±12µg/week in HD-H2($p<0.01$). The average C-reacting Protein was unchanged, 0.20±.34mg/dl in S-HD VS 0.22±0.42mg/dl in HD-H2.

Conclusions: HD-H2 reduced the dose of DA in the same range of Hb although further multicenter studies are needed.

FR-PO253

Comparison between Short Acting Erythropoiesis Stimulating Agents Epotein Alfa, and Long Acting Darbepoietin Alfa, in Hemodialysis Patients: Target Hemoglobin, Variability, Conversion Factor, Outcome and Cost Bassam O. Bernieh,[1] Samra Abouchacra,[1] Yousef Boobes,[1] Mohamed Raafat Al Hakim,[1] Ahmed Chaaban,[1] Faiz Abayechi,[1] Hanan Eljack,[1] Qutaiba Hussain Daoud,[1] Imran Khan,[1] Nicole Gebran,[2] Hanan Al Omary.[1] *[1]Nephrology, Tawam Hospital, Al Ain, United Arab Emirates; [2]Pharmacy, Tawam Hospital, Al Ain, United Arab Emirates.*

Background: Maintaining target hemoglobin (Hb) with minimal hemoglobin variability is a difficult challenge in anemia management of hemodilaysis (HD) patients affecting their outcome. The aim of this study is to compare the long acting ESA Aranesp, and the short acting Eprex,in achieving target Hb, variability, outcome, and cost.

Methods: Randomized,prospective, open labeled study of 24 weeks of 2 phases, titration and evaluation, including stable patients on HD>3 months,age>18 years,and on Eprex for>3 months.Patients randomized in two groups: A-(Aranesp Group):HD patients on Eprex Q TIW or BIW were converted to Aranesp Q weekly,by using the recommended conversion factor of 200:1;and those on Eprex Q weekly to Aranesp Q 2 weeks; B-(Eprex Group):patients continued on Eprex treatment.Hemoglobin target set at (105 – 125 g/l). Primary end points: percentage of patients achieving target Hb,hemoglobin variability, and number of dose changes in each group.

Results: 140 HD patients 72 in the Aranesp,and 68 in the Eprex, Mean (SD) age 54(16.2) year,78(56%) male. 46% were diabetic. Target Hb achieved in 64.8% of the Aranesp, and 59.7% in the Eprex ($p=0.006$). Hb variability was less frequent in the Aranesp at the target Hb (105-125) [$p=0.2$], with significant difference [$p=0.04$] at Hb of (110-130). Mean number of dose changes in the evaluation phase was 1.3 (0.87) in the Aranesp, and 2 (1.2) in the Eprex ($p<0.001$). The average conversion factor was 268 ($p<0.001$). The average weekly cost/kg was 1.4 USD for Aranesp, and 0.7 for Eprex ($p<0.01$).There was 1 vascular access thrombosis in the Aranesp, and 8 in the Eprex ($p<0.001$).There was no difference in hospitalization and death number between the 2 groups.

Conclusions: Aranesp Q weekly or every 2 weeks, is more efficient in achieving target Hb, with less dose changes,Hb variability,and minor vascular access complications.

FR-PO254

Occasional Assist by Epoetin in Addition to Fixed Dosage of Darbepoetin on Anemia Management in Hemodialysis Patients Kazumasa Shimamatsu. *Hemodialysis Unit, Shimamatsu Naika Iin, Chikushino City, Fukuoka, Japan.*

Background: Taking advantage of characteristics of both long- and short-acting drugs (darbepoetin, DA and epoetin, EPO) might be reasonable for anemia management to avoid a possible overshoot in hemoglobin (Hb) rise and to stabilize a Hb cycling. The halves of weekly doses of EPO monotherapy were converted to DA in combination with the remaining half doses of EPO. Thereafter, EPO assisted with on-and-off fashion fixed dosage of DA depending upon Hb levels. The effect of DA therapy assisted by EPO on Hb control was retrospectively evaluated in comparison with that of EPO monotherapy.

Methods: Twenty-six hemodialysis (HD) patients whose annual mean Hb values were available both in EPO monotherapy period and in DA/EPO combination period were selected. The mean age of the patients (15 male, 11 female) was 60.6±13.9 yr (mean±SD). The mean HD duration was 9.1±7.1 years. The DA doses (µg) close to 1/200 of the halves of weekly EPO doses (IU) were given on the second HD day of a week. The remaining half doses of EPO were given dividedly on the first and the third HD day of a week. The target Hb value was 11 g/dl. After introduction of DA therapy when the Hb levels rise over 12 g/dl, EPO was eliminated. When the Hb levels go down under 10 g/dl, EPO was added again. The standard deviation (SD) of annual mean Hb from 26 HD patients in DA/EPO period was compared with that in EPO period. Also, the difference (d-Hb) between the annual mean Hb of 26 patients and the target Hb of 11 g/dl in DA/EPO period was compared with that in EPO period. Paired *t*-test was used for analysis.

Results: The SD of annual mean Hb in DA/EPO period was significantly smaller than that in EPO period (11.2±0.25 vs. 11.0±0.50 g/dl, respectively, $p<0.001$). Also, the d-Hb of annual mean Hb in DA/EPO period was significantly smaller than that in EPO period (0.22±0.21 vs. 0.38±0.31 g/dl, respectively, $p<0.03$). The mean dose of EPO was 3656±2107 IU/week in EPO period and the mean dose of DA was 13.6±7.5 g/week with mean EPO dose of 284±436 IU/week in DA/EPO period.

Conclusions: The occasional assist by EPO in addition to fixed dosage of DA may be useful for controlling Hb levels within narrow range of the target.

FR-PO255

Factors Influencing Hyperviscosity in Maintenance Hemodialysis Patients

Siren Sezer,[1] Mehtap Erkmen Uyar,[1] Selami K. Toprak,[2] Emre Tutal Tutal,[1] Hatice Saglam,[3] Fatma Nurhan Ozdemir Acar.[4] *[1]Nephrology, Baskent University, Ankara, Turkey; [2]Hematology, Baskent University, Ankara, Turkey; [3]Internal Medicine, Baskent University, Ankara, Turkey; [4]Nephrology, Baskent University, Istanbul, Turkey.*

Background: Many factors also could affect plasma viscosity as white blood cell, platelet count, iron deficiency and drugs in maintenance hemodialysis (MHD) patients. Increased risk for thrombosis is the main factor limiting the use of erythropoietin stimulating agents (ESA). In this present study, we investigated the clinical and laboratory factors influencing plasma viscosity in MHD patients.

Methods: 84 MHD patients (30 female, age; 54.7 ± 13.7 years) (TSAT ratio>30; mean ferritin:553,39 ng/ml) were included. Patients with iron deficiency, chronic inflammatory disease and malignancy were excluded. Plasma viscosities of all subjects were measured at 37°C in a Brookfield DV– II + Cone Plate Viscometer (Brookfield, Stoughton, MA, USA). Laboratory data and monthly ESA requirements were retrospectively collected. Patients were grouped according to plasma viscosities as upper and lower halves. Patients were also grouped according to their ESA requirements as no (n: 21), low (n: 31), high (n: 32) ESA requiring patients.

Results: MHD patients had high plasma viscosity compared to healthy subjects (range 1.6-3.9m Pas, 2.52 ± 0.65 mPas vs 1.10-1.30 mPa.s.). Iron parameters, hemoglobin, CRP levels were similar. However we found that subjects in high viscosity group used higher ESA dose in previous year (224.4 ± 237.8 260.4 ± 340.5 U/kg/month, p: 0.038). 68.8% of the high ESA requirement group intersected with higher viscosity group while this was 38.7% in the low ESA group (p: 0.001) despite similar hemoglobin levels. Linear regression analysis revealed that EPO resistance and HD duration were the major determinants of hyperviscosity. HD duration of patients in "no rHuEPO" was the longest; low rHuEPO group had the shortest.

Conclusions: According to our findings, majority of MHD patients have increased plasma viscosity compared to previously reported healthy subjects. We think that high dose ESA usage might increase plasma viscosity despite similar hemoglobin levels achieved when iron deficiency is excluded.

FR-PO256

Darbepoetin-alpha Does Not Increase the Risk for Thrombotic Events in Hemodialysis Patients: Role of TAFI-Dependent Thrombosis and Inflammation

Ali Akcay,[1] Nuket Bavbek,[1] Hakki Yilmaz,[1] Ayse Mukadder Bilgic,[1] Ramazan Yigitoglu.[2] *[1]Nephrology, Fatih University Medical School, Ankara, Turkey; [2]Biochemistry, Fatih University Medical School, Ankara, Turkey.*

Background: Cardiovascular disease is a leading cause of death in hemodialysis (HD) patients. One of the potential side-effects of erythropoietin (EPO) therapy is an increase in thrombotic events. Thrombin activatable fibrinolysis inhibitor (TAFI) is a proenzyme, which potently inhibits fibrinolysis. There are no data about effects of eritropoetic agents on serum TAFI levels in HD patients. Our aim was to assess TAFI levels and its relationship with other parameters in HD patients in which epoetin alfa (EA) was switched to darbopoetin alfa (DA) treatment.

Methods: Thirty-five stable HD patients receiving EA for 6 months were switched to DA. Blood samples were taken at the beginning and 6 months after the start of DA. The control group consisted of HD patients not on EPO treatment.

Results: TAFI and mean platelet volume (MPV) levels were significantly lower after DA treatment than EA treatment and controls. After DA treatment CRP levels were also lower and a positive correlation was detected between TAFI and CRP levels.

Laboratory Parameters in Patients and Controls

	Control (n=35)	EA Group (n=35)	DA Group (n=35)
Hemoglobin (g/dL)	12±0.3	11.06±1.31	10.88±1.5
Platelet count (x109)	251000±123000	248310±100079	267000±154976
MPV (fL)	8.13±0.75(a)	8.62±0.85(b)	7.99±0.68
TAFI antigen (%)	77.12±35.23(c)	79.63±37.44(d)	48.15±18.68
CRP (mg/dl)	2.23±1.87(e)	2.11±2.06(f)	0.80±0.65

a p=0.001 Control versus DA; b p=0.001 EA versus DA; c p=0.001 Control versus DA; d p=0.002 EA versus DA; e p=0.018 Control versus DA; f p=0.011 EA versus DA.

Conclusions: We found that TAFI antigen, CRP and MPV levels were significantly decreased in HD patients on DA therapy. TAFI is expressed as an acute phase protein and causes inflammation and coagulation response. Significant correlation between TAFI level and CRP strenghten this hypothesis. Decreased TAFI levels after DA can be considered as a factor to explain the lower thrombotic tendency in these patients. Lower MPV after DA treatment could be an additional factor for decreased thrombosis as larger platelets can contribute to thrombosis.

FR-PO257

FG-4592, a Novel Oral Hypoxia-Inducible Factor Prolyl Hydroxylase Inhibitor (HIF-PHI), Maintains Hemoglobin Levels and Lowers Cholesterol in Hemodialysis Patients: Phase 2 Comparison with Epoetin Alfa

Robert Provenzano,[1] Anatole Besarab,[2] Sohan L. Dua,[3] Peter V. Nguyen,[4] Steven Howard Wright,[5] Steven Zeig,[6] Robert Leong,[7] James Chou,[7] Wen Shi,[7] Khalil Georges Saikali,[7] Kin-Hung Peony Yu,[7] Thomas B. Neff.[7] *[1]St Clair Specialty Physicians, Detroit, MI; [2]Henry Ford Hosp, Detroit, MI; [3]Valley Renal Medical Group, Northridge, CA; [4]US Renal Care, Ft Worth, TX; [5]US Renal Care, Pine Bluff, AR; [6]Pines Clinical Research, Pembroke Pines, FL; [7]FibroGen, Inc., San Francisco, CA.*

Background: Dyslipidemia is a major factor associated with increased cardiovascular risk in advanced CKD. We evaluated effects of FG-4592 on hemoglobin (Hb) and total cholesterol (TC) in hemodialysis (HD) patients switched from epoetin alfa (rhEPO).

Methods: In an ongoing open-label phase 2 study, 159 HD patients taking rhEPO 3X weekly (TIW) were randomized to FG-4592 TIW or continued rhEPO for 6 or 19 wks. FG-4592 doses were adjusted every 4 wks to maintain Hb 11-13 g/dL. Intravenous (IV) iron supplementation was disallowed. There were no protocol-specified restrictions on lipid medication use or thresholds for medication changes.

Results: Hb data for patients treated 6 wks have been reported (Provenzano 2011). Mean±SD baseline (BL) Hb levels for patients treated 19 wks with FG-4592 (N=54) and rhEPO (N=19) were 11.3±0.7 g/dL and 11.4±0.9 g/dL, respectively. The corresponding mean±SD Hb changes from BL in the last 4 treatment wks were -0.2±1.4 g/dL and -0.6±1.3 g/dL, respectively; changes were not significantly different between the 2 groups.

FG-4592 patients (N=91) had a Week 6 mean±SD 20%±15% TC reduction from BL, and rhEPO patients (N=32) had a mean±SD 4%±16% TC increase from BL ($p<0.0001$); the difference remained significant at Week 19 ($p<0.0001$). A substudy showed lower plasma erythropoietin levels with FG-4592 treatment compared with rhEPO treatment at screening. FG-4592 was well tolerated, with an adverse event profile consistent with the patient population.

Conclusions: Oral FG-4592 TIW for 19 weeks maintained corrected Hb levels in HD patients without IV iron supplementation. The HIF-PHI mechanism of action appeared to reduce TC and plasma erythropoietin in patients given FG-4592 vs rhEPO.

Virdaglin, an Inhibitor of Dipeptidyl Peptidases 4 (DPPI-4), Can Improve Anemia in Diabetic Hemodialysis (HD) Patients

Satoshi Funakoshi,[1] Kenichi Miyazaki,[1] Yoshiaki Lee,[1] Tomoya Nishino,[2] Yoko Obata,[2] Yutaka Mori,[3] Kazunori Utsunomiya,[3] Shigeru Kohno,[2] Takashi Harada,[1] Jyunichiro Hashiguchi.[1] *[1]Division of Blood Purification, Nagasaki Kidney Center, Nagasaki, Japan; [2]Nagasaki University Graduate School of Medicine, Nagasaki, Japan; [3]Jikei University, Tokyo, Japan.*

Background: Several reports demonstrate hematopoietic effects of DPP-4 via CD26pathways for regulating hematopoietic growth factors (Jones B, et al. Blood 2003). We hereby evaluate the effects of DPP-4 on improvement of anemia in HD patients when converted from sulfonyl urea or glinede analogues.

Methods: From September to December 2010, 15 HD outpatients with diabetes were enrolled in this study after appropriate IC, and were monitored by various parameters including fasting plasma glucose (FPG), HbA1c, Hb, albumin or body mass index (BMI). Erythropoietin (EPO) doses had stayed the same.

Results: As shown in Table 1, FPG and HbA1c level had been stabilized after dose adjustment of virdaglin. There was significant increase in Hb level (10.8±1.49 to 11.6±1.08, p=0.018) though EPO doses had been unchanged. Other nutritional parameters stayed the same.

Effects of virdaglin on improving anemia in HD patients (n=15)

	sulfonyl urea / glinede analogues	virdaglin	
FPG (mg/dL)	138±49	119±34	ns
HbA1c (%)	6.8±1.9	7.1±1.1	ns
Albumin (g/dL)	3.2±0.8	3.3±0.4	ns
BMI	24.0±4.3	26.6±3.9	ns
Hb (g/dL)	10.4±1.3	11.8±1.2	p<0.05

Conclusions: Virdaglin can potentially improve anemiain hemodialysis HD patients independently of nutritional status. Whether virdaglin improves the survival of ESRD patients remains to be investigated with further studies.

Novel Sustained Delivery of Erythropoietin in Hemodialysis Patients for Safer Anemia Control Using EPODURE Biopumps: Autologous Dermal Tissue Samples Secreting Erythropoietin

Gil Chernin,[1] Doron Schwartz,[1] Ehud Shoshani,[2] Andrew L. Pearlman,[2] Stephen Bellomo,[2] Veronica Elias Weissmann,[2] Nir Shapir,[2] Anatole Besarab.[3] *[1]Tel Aviv Sourasky Medical Center, Israel; [2]Medgenics, Israel; [3]Henry Ford Hospital.*

Background: EPODURE Biopumps are autologous dermis tissue explants (30mm x 2mm) converted into units producing sustained erythropoietin (EPO) by introducing the EPO gene using a Helper Dependent Adenoviral vector. Increased incidence of cardiovascular

and cerebrovascular complications in hemodialysis patients treated with EPO has been hypothesized to be due to transient supra-physiological serum levels of EPO produced by IV or SC administration. In contrast, EPO levels in patients treated by EPODURE Biopumps remain within physiologic range, as reported in patients with Stage 3-4 CKD (ASN 2011). The current study aims to examine the feasibility of using EPODURE Biopumps in ESRD patients on dialysis, to maintain Hb levels in the target range without the need for exogenous ESA injections.

Methods: Following on the CKD study, where a single implantation of EPODURE Biopumps maintained Hb in the 10-12g/dl range for 3-30 months without any ESA injections and without serum EPO levels exceeding 70 mU/ml, we have commenced a PH2 open label, single center study in up to 20 ESRD hemodialysis patients in Israel. EPODURE Biopumps are implanted to replace ESA injections, with dose based on the patient's weight and historical EPO administered pre-enrollment with baseline Hb levels of 10-12 g/dl.

Results: First ESRD patient received EPODURE Biopumps May 24, 2012, elevating serum EPO to peak of 42 mU/ml, absolute reticulocyte levels above baseline, with Hb maintained in baseline range of 11.0-11.4 g/dl as of abstract submission. Additional patients are being enrolled.

Conclusions: Early results in the first ESRD hemodialysis patient are consistent with prior CKD study results. Enrollment continues and additional results will be obtained to further test the hypothesis that Hb can be maintained within target range by sustained EPO delivery without causing supra-physiologic EPO levels, to potentially improve safety.

FR-PO260

Hemoglobin Control and Dose Alterations with Peginesatide versus Epoetin for Hemodialysis Patients Bruce S. Spinowitz,[1] Steven Zeig,[1] Helen Tang,[2] Sandra Tong,[2] Nina Oestreicher,[2] Alex Yang,[2] Wadi N. Suki.[1] *[1]AFX01-12 and -14 Peginesatide Study Groups; [2]Affymax, Inc., Palo Alto, CA.*

Background: Peginesatide (OMONTYS®) is a PEGylated, peptide-based ESA indicated for treatment of anemia due to CKD in adult patients (pts) on dialysis. Peginesatide demonstrated noninferiority to epoetin in maintaining Hb in hemodialysis pts in two Phase 3 randomized, active-controlled, open-label trials (EMERALD 1, 2; Schiller et al. ASN 2010). This post hoc analysis compared dose adjustments and postponements for peginesatide vs epoetin and achievement of target hemoglobin (Hb).

Methods: Data were pooled from the 2 trials: peginesatide (Q4W; n=1066) vs epoetin (1-3x weekly; n=542). Dose adjustments (defined as change >±20% from last dose) were not to be made more frequently than Q4W to maintain Hb 10-12 g/dL (per guidelines in effect at time of trial). Hb measurements were Q2W, except weekly during evaluation period or dose postponements (defined as >35 d after last dose of peginesatide or >4, 6, or 9 d after last dose epoetin TIW, BIW, or QW, respectively). Frequency of dose alterations was calculated per pt-year of exposure.

Results: Dose adjustments and postponements by study period are below.

Study Period	Peginesatide	Epoetin	Ratio: Peginesatide/ Epoetin
Adjustments/pt-year			
TP	3.80	10.18	0.37
EP	3.84	10.75	0.36
LTSE	3.39	9.81	0.35
Postponements/pt-year			
TP	0.60	4.64	0.13
EP	0.58	4.75	0.12
LTSE	0.66	5.37	0.12

TP, titration period Wks 0-28; EP, evaluation period Wks 29-36; LTSE, long-term safety & efficacy Wks 37-52

Through end of treatment, 22% of patients on peginesatide and 20% on epoetin had confirmed Hb excursions (2 consecutive values above 13 g/dL), with median 22 and 20 days per excursion, respectively. Confirmed Hb excursions below 10 g/dL occurred in 54% of patients on peginesatide and 51% on epoetin; median duration per excursion was 38 and 39 days, respectively.

Conclusions: There was a higher frequency of dose adjustments and postponements for epoetin, compared with peginesatide. Frequency and duration of Hb excursions were also similar between study arms. These results suggest that once monthly peginesatide achieves similar Hb outcomes with fewer dose adjustments and postponements.

FR-PO261

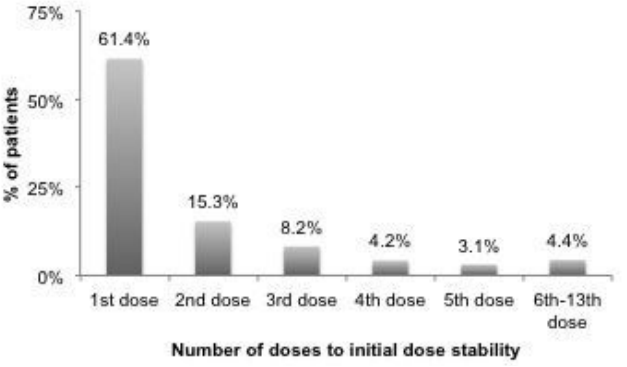
Initial Dose Stability after Conversion to Peginesatide in HD Patients Brigitte Schiller- Moran,[1] Rebecca J. Schmidt,[1] Anjay Rastogi,[1] Whedy Wang,[2] Sandra Tong,[2] Alex Yang,[2] Nina Oestreicher,[2] Mark Kaplan.[1] *[1]AFX01-12 and -14 Peginesatide Study Groups; [2]Affymax, Inc., Palo Alto, CA.*

Background: Peginesatide (OMONTYS®) is a PEGylated, peptide-based ESA indicated for treatment of anemia due to CKD in adult patients (pts) on dialysis. Peginesatide demonstrated noninferiority to epoetin in maintaining hemoglobin (Hb) in hemodialysis (HD) pts in two Phase 3 randomized, active-controlled, open-label trials (EMERALD 1, 2; Schiller et al. ASN 2010). It was previously shown that pts on epoetin had more frequent dose adjustments than peginesatide for maintaining similar Hb (Sharma et al. Renal Nutr Week 2012). This post hoc analysis evaluated the number of doses required to reach initial dose stability following conversion from stable epoetin to peginesatide.

Methods: Data were pooled from the two trials assessing safety and efficacy of peginesatide (Q4W; n=1066) vs epoetin (1-3x weekly; n=542) in HD pts. Dose adjustments were to be made no more frequently than Q4W (unless required for safety purposes) to maintain Hb 10-12 g/dL (per guidelines in effect at time of trial). Hb was measured Q2W (or QW during evaluation period or dose postponements). Initial dose stability was established if (1) the subsequent dose was within 20% of prior dose (21-35d between doses), and (2) at least 1 Hb was within target between doses. The evaluable population included all patients who received ≥2 doses (n=1034).

Results: 61.4% of pts reached initial dose stability after the first dose, 76.7% by the second dose, 85% by the third dose. Only 4.4% required 6 or more doses.

Distribution of Doses to Initial Dose Stability.



Conclusions: Conversion to peginesatide in HD pts was successful, with the majority of peginesatide pts who were previously on stable dose of epoetin reaching initial dose stability within 1-2 doses after conversion to peginesatide.

FR-PO262

Peginesatide Immunogenicity in Clinical Studies of CKD Patients Peter J. Schatz, Sandra Tong, Vandana S. Mathur, Minjia Chen, Karen Leu, Richard B. Mortensen, Rezi Zawadzki, Daniel S. Cooper, Richard B. Stead, Martha Mayo, Krishna R. Polu, Anne-Marie Duliege. *Affymax, Inc, Palo Alto, CA.*

Background: Peginesatide is a synthetic, pegylated, peptide-based erythropoiesis-stimulating agent (ESA) that activates the erythropoietin (EPO) receptor. Peginesatide has no sequence similarity to EPO and is being evaluated in treatment of CKD patients (pts) with anti-EPO antibody (Ab)-mediated pure red cell aplasia (PRCA) (Macdougall, 2009, NEJM). Peginesatide is indicated for the treatment of anemia due to CKD in adult pts on dialysis, with once monthly dosing.

Methods: Peginesatide's immunogenicity was systematically evaluated in Phase 2 & 3 clinical studies in CKD pts receiving peginesatide mostly for up to 2 years, some for up to ~4 years. Serum samples were evaluated by ELISA for peginesatide-specific binding Abs (BAb). Positive samples were tested for in vitro peginesatide-neutralizing Abs (NAb) using a cell-based assay and for Abs cross-reactive with recombinant human (rHu) EPO using a radioimmunoprecipitation assay. Clinical consequences of Abs on safety and efficacy were evaluated.

Results: 29 of 2357 pts tested (1.2%) had detectable BAb levels. NAb were detected in 21 of these pts (0.9%). No pt developed de novo Abs to EPO after exposure to peginesatide, and no new cases of PRCA were reported, suggesting lack of immunological cross-reactivity between peginesatide and EPO. The Abs were specific for the peptide rather than the PEG component of peginesatide. IgG4, which does not fix complement or form immune complexes, was the immunodominant isotype. Allergic, hypersensitivity, or anaphylactic reactions were not observed in BAb^+ pts. In approximately half of the BAb^+ pts, the presence of Abs was temporally (ie, within ±90 days of the Ab detection period) associated with declining hemoglobin levels, increased peginesatide doses, and/or transfusions.

Conclusions: Abs to peginesatide were uncommon (1.2%) and not associated with allergic-type reactions. Although evidence of reduced efficacy was temporally-associated in approximately half of the BAb^+ pts, Abs to peginesatide did not cross-react with rHuEPO, suggesting that peginesatide is unlikely to cause PRCA.

FR-PO263

A Comparative Analysis of Transfusion Trends between Types of Providers of Dialysis Services Using Medicare Claims Data Mahesh Krishnan,[1] Allen R. Nissenson,[1] Rachel Feldman,[2] Mark Desmarais,[2] Lianna Weissblum.[2] *[1]DaVita Inc., Denver, CO; [2]The Moran Company, Arlington, VA.*

Background: The question of practice patterns and impact on transfusions is currently being debated in light of the significant ESA label changes in June of 2011. However, little is known about how these practice patterns varied amongst provider types prior to the label change. We used Medicare data to compare transfusion trends in for-profit (FP) vs non-profit (NP) dialysis facilities in the two years prior to the ESA label change.

Methods: Medicare Standard Analytic File Claims data from 2009 and 2010 were analyzed at the facility level using the Dialysis Facility Compare provider-type data to create comparator groups. Inpatient hospital and dialysis facility blood transfusions were identified using the presence of blood product revenue codes. Outpatient hospital blood transfusions were identified using the presence of blood product revenue codes and transfusion procedure codes.

Results:

Prevalent ESRD Patients with ±1 Type of Product Administrations, %	Inpatient Blood		Outpatient Blood		Blood Product on a Dialysis Claim	
	2009	2010	2009	2010	2009	2010
All Dialysis Facilities	25.8	25.3	6.1	5.9	1.2	1.1
Non-Profit Facilities	25.7	25.3	8.0	7.8	2.8	2.5
For-Profit Facilities	25.9	25.3	5.5	5.4	0.4	0.3
Hospital-based Units	29.3	28.3	12.1	12.0	5.7	5.5
Other Freestanding Facilities	27.2	26.8	6.8	6.8	1.3	1.2

Conclusions: Overall, most transfusions appear to occur in the hospital setting, and there was a slight decrease in use of transfusions in 2010 compared with 2009. Transfusions in the dialysis facility appear to be very rare, but do appear to occur in non-profit and some free-standing facilities. Patients in hospital-based and non-profit facilities had the highest rates of transfusions compared with those in for-profit facilities in 2009 and 2010. As these data reflect anemia management practice patterns prior to June 2011 ESA label changes, they can serve as a baseline to future work reflective of the current treatment paradigms.

FR-PO264

The First Report of the Latin American Register of Anemia Management among Chronic Hemodialysis Patients Raul G. Carlini,[1] Gregorio T. Obrador,[2] Ricardo Correa-Rotter,[3] Liliana Andrade,[4] Alberto Locatelli.[5] *[1]Hospital Universitario de Caracas, Venezuela; [2]Universidad Panamericana School of Medicine, Mexico; [3]Instituto Nacional de la Nutricion, Mexico; [4]Hospital Complejo Medico Policial Churruca-Visca, Argentina; [5]Nefronosa S.A., Argentina.*

Background: Anemia almost invariably occurs in patients with chronic kidney disease (CKD). Limited data are available regarding anemia management in Latin American (LA) hemodialysis (HD) patients. We report the first results of the Anemia Register of the LA Society of Nephrology and Hypertension (SLANH).

Methods: A survey was sent to independent, non-chain owned HD units via the nephrology society members of SLANH to collect cross-sectional anemia management data between 09/2009 and 03/2010. The following parameters were analyzed: age, sex, time on HD, dry weight, etiology of CKD, levels of Hb, ferritin, and transferrin saturation (TSAT), iron, and ESAs doses.

Results: A total of 134 nephrologists from 16 LA countries responded to the survey and provided information on 9,054 patients. Their mean age was 57.4±15.7 years, 58% were men and had been on chronic HD for 5.0±3.7 years. Dry weight was 65.1±14.9 kg. The causes of CKD were hypertension (41%), diabetes mellitus (30%), glomerulonephritis (80%) and others (11%). The mean Hb level was 10.5±1.9 g/dL, ferritin 556±496 mg/dL and TSAT 29.8±15%. In 46.2% of the patients, the Hb level was <10.5g/dL, 32.6% between 10.5 and 12 g/dL and >12.0 g/dL in 23%. Only 32.6% of patients were within the SLANH's recommended anemia guidelines Hb target of 10.5-12.0 g/dL (46.2% were below and 21.3% above). ESAs were given subcutaneously in (SQ) 83.9% of patients. The majority (84.7%) were receiving an ESAs, mostly erythropoietin-α (72.9%) at a median weekly dose of 6,000 IU SQ and 12,000 IU IV. Most patients (69.3%) were receiving IV iron, preferentially iron sucrose (56.3%) at a median monthly dose of 200 mg.

Conclusions: Despite frequent ESAs and IV iron use, nearly half of LA chronic HD patients had Hb levels below the recommended target of 10.5 g/dl. Further studies are needed to determine factors and interventions that can improve the quality of anemia management.

FR-PO265

Intensity of Care at Initiation of Chronic Dialysis and Long-Term Outcomes in Older Adults with End-Stage Renal Disease Susan P.Y. Wong, William Kreuter, Ann M. O'Hare. *University of Washington.*

Background: Prognostication in older adults initiating chronic dialysis can be challenging, particularly when dialysis is begun in the setting of acute illness. We hypothesized that measures of illness severity around the time of dialysis initiation may be useful prognostic markers in this population.

Methods: Using data from the United States Renal Data System, we performed a retrospective study on 585,291 Medicare beneficiaries aged ≥67 years who began chronic dialysis between 1/1/1995 and 12/31/2008. We examined illness severity at dialysis initiation as reflected in the following measures of healthcare intensity: whether dialysis was initiated during a hospitalization for acute illness, the length of hospital stay, and whether an intensive procedure (mechanical ventilation, cardiopulmonary resuscitation, and feeding tube placement) was performed during the index hospitalization. We measured the association between intensity of care experienced at dialysis onset with survival and remaining lifetime spent hospitalized.

Results: One in two older patients (53.9%) initiated chronic dialysis in the inpatient setting. Of these, 36.3% were hospitalized for ≥2 weeks, and 7.4% underwent one or more intensive procedures. Patients who received the highest level of intensity of care at dialysis initiation (hospitalized ≥2 weeks, and received one or more intensive procedures) had a shorter life expectancy (median 0.7 v 2.1 years; HR 1.42, 95% CI 1.39-1.45) and spent a greater percentage of their remaining lifetime in the hospital (median 26.6% v. 1.2%; HR 1.85, 95% CI 1.81-1.89) as compared with those who received the lowest level of intensity of care (initiation as an outpatient). Among patients who received the highest level of intensity of care, median survival was approximately 8 months of which 2 months were spent hospitalized.

Conclusions: The decision to initiate chronic dialysis is often made in the less than ideal circumstance of acute illness. Simple, objective measures of healthcare intensity around this time may have prognostic value to older adults facing the prospect of chronic dialysis.

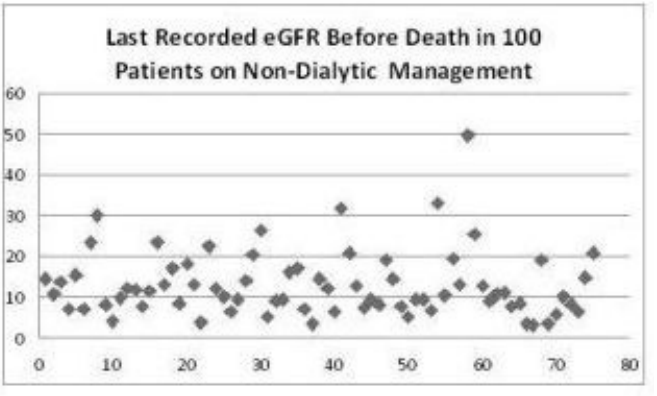
FR-PO266

What Can Elderly Frail Patients with Advanced CKD Expect If They Elect Not to Undergo Dialysis? Thomas D. Hughes, Helen Alston, Aine Burns. *Centre for Nephrology, UCL, London, United Kingdom.*

Background: The growing aged CKD population in first world countries presents many challenges. In the last decade evidence has emerged that hospital free survival amongst elderly patients with multiple co-morbidities who undergo dialysis may not differ substantially from those having non-dialytic or maximum conservative management (MCM).

Methods: We searched the center's database for patients who followed our MCM care pathway and who had died between January 1st 2002 and December 12th 2011 identifying 284 patients. We examined in detail the electronic demographic, medical records, biochemical and haematological data on 100 of these patients selected as they had died most recently. Charlson co-morbidity scores were calculated. Post-codes were used to assess deprivation scores.

Results: The mean age for the population was 82.4 (median 84, range 40 to 98) 55% were male. Amongst the 100 selected for detailed evaluation the Co-morbidity scores were high as expected. Mean last recorded eGFR (MDRD) prior to death was 12.83mls/min (median 10.8, range 2.89 to 49.69).



Mean and median last recorded haemoglobin estimations were 10.5 & 10.3, (range 7 to 14.5). All expected ethnic, religious and social groups were represented in proportion to that found in the local population.

Conclusions: We have described a unique group of elderly patients with CKD who have died having received renal supportive care only. We have determined that a proportion is likely to have died from inter-current illnesses rather than renal failure per se. Many however, survived until eGFRs were well into single figures. This work is important as it enhances understanding of the final journeys of such patients and can be used to help them, their relatives, nephrologists and policy makers to balanced decisions regarding care. It also questions the optimum time to start dialysis in elderly patients with multiple co-morbidities.

FR-PO267

Cognitive Impairement in CKD5D Patients: A Cross-Sectional Study Anne Kathrin Malecki,[1] Sabrina Schneider,[1] Hermann G. Haller,[2] Jan T. Kielstein.[2] *[1]Institute of Psychology, Martin-Luther-University, Halle-Wittenberg, Germany; [2]Department of Nephrology and Hypertension, Medical School Hannover, Hannover, Germany.*

Background: Severel studies could show significant impairement in CKD patients the worsens in parallel with the decline in renal function. Assessment of cognitive function is cumbersome and routine bedside test like the mini mental state exam fail to reflect the changes observed in CKD5D. The current study assesses the congitive function in CKD5D patients using large neuropsychological testbattery and valid test procedures.

Methods: We examined 28 (16 M; 12 F) medically stable CKD5D patients aged 55±11 years. Memory, working memory, attention and concentration, executive functioning, psychomotor speed by using the following tests: Rivermead behavior memory test (RBMT), Rey Cpmplexe Figure Test (RCFT), Trail Making Test A+B (TMT), Wechsler Memory Scale (WMS- R), Behavior Assessment of Dysexecutive Syndrome (BADS), Regensburger Wortflüssigkeits- Test (RWT), Testbatterie zur Aufmerksamkeitsprüfung (TAP).

Results: As compared to matched controls CKD5D patients show a signficant impairment in TMT A / B (CKD5D:47.5s / 110.5s vs 40s / 98s), WMS- R (CKD5D: 5 digits vs cntrols:6 digits), TAP / RWT (CKD5D:25 / 15 words vs controls 30 / 17 words). Moreover there was a trend in deficits of the logical memory span (CKD5D: 7.3 / 6 digits vs. controls:9.5 and 8 digits).

Conclusions: Our data demonstrate cognitive impairement in CKD5D when comparing these patients with their apropriate age group. Like previous studies we could find deficits in executive functioning like visual exploring, cognitive shifting and working memory. Moreover we found deficits in concentration and attention regarding the speed of reaction. In contrast to previous studies we could also find mnestic deficits. These findings should be considered regarding everey day communication as well as in the situation of obtaining consent for procedures or investigating non-adherence to medication.

FR-PO268

Detailed Analysis of Cognitive Function in Patients on Hemodialysis (HD) Anne B. Froment, Virginia M. Newton, Susan L. Hogan, Yichun Hu, Aysenil Belger, Patrick H. Nachman. *University of North Carolina, Chapel Hill, NC.*

Background: Cognitive impairment is common among patients on HD. We aimed to identify risk factors for impairment by performing a longitudinal analysis of change in cognitive function. We report on baseline evaluation and analysis of association with dialysis-related variables.

Methods: Patients underwent tests for each of attention/concentration, visual learning/memory, verbal learning/memory and executive function domains. Each test score was converted to a *t* score adjusted for age ± education according to published norms (the mean ± SD *t* score for a healthy population is 50 ± 10). An average *t* score was calculated for each cognitive function domain. Spearman correlation analysis was performed to explore influences of age, sex, dialysis vintage, ekdrt/v, PTH, blood pressure, and dialytic change in blood pressure and serum Na with each of the 4 domains.

Results: 33 patients (39% males, 65.0 ± 8.4 yo, 61% AA, 63% with diabetes, 40% college educated, median time on dialysis 29.3 months (IQR 12.7-62.5) underwent neurocognitive testing. The mean ± SD (IQR) *t* scores were 41.9±7.5 (35-48) for attention/concentration, 42.7±11.1 (34-48) for verbal learning/memory, 43.6±9.5 (37-49) for visual learning/memory and 40.4±10.1 (32-49) for executive function. 27% of tested patients had impairment in attention, 25% in verbal memory, 22% in visual memory and 45% in executive function. Verbal and visual learning/memory were negatively correlated with dry weight (r= -0.37, p=0.03 and r=-0.37, p=0.04 respectively). Executive function correlated negatively with post dialysis standing systolic pressure (r=-0.55, p=0.005) and correlated positively with time on dialysis among for patients on dialysis > 25 months (n=15) (r=0.82, P <0.0001), but not for those on dialysis ≤ 25 months (n=17) (r=-0.33, P =0.2).

Conclusions: These tests provide a detailed analysis of cognitive function in patients on HD. Decreased executive function is the most commonly detected impairment and is associated with post-dialysis hypertension. The association between decreased executive function and long vintage on HD may reflect a selection bias based on patient survival or willingness to participate in the study.

FR-PO269

Longitudinal Study of Change in Cognitive Function in Patients on Hemodialysis (HD) Anne B. Froment, Virginia M. Newton, Yichun Hu, Aysenil Belger, Susan L. Hogan, Patrick H. Nachman. *University of North Carolina, Chapel Hill, NC.*

Background: Cognitive impairment is common among patients on HD. We aimed to identify dialysis-related risk factors for cognitive impairment in patients (age 50-80 yrs) on HD by performing a longitudinal analysis of change in cognitive function. We describe changes in cognitive function over 1 year of HD.

Methods: Patients underwent tests of attention/concentration, visual learning/memory, verbal learning/memory and executive function at baseline and repeated after 1 year. Test scores were converted to *t* scores, adjusted for age ± education according to published norms (the mean ± SD *t* score for a healthy population is 50 ± 10). p values for change in average *t* score for each cognitive domain were calculated by paired signed rank test. When significant change in a cognitive function domain was detected, Spearman correlation analysis was performed to explore influences of age, sex, dialysis vintage, and baseline ekdrt/v, PTH, blood pressure, and dialytic change in serum Na with change in function.

Results: 22 patients underwent baseline and repeat testing after 1 yr (59% female, 65.86±8.77 y.o.; 63% AA; 59% with diabetes; 36% college educated). No significant change was detected in attention/concentration or executive function. There was a small increase in verbal learning/memory, but a significant decrease in visual learning/memory. The latter was not associated with any of the baseline variables.

	Baseline	Change T2-T1*	P value**
Attention/Concentration	42.1±8.8	-1.0±5.4	0.24
Verbal Learning Memory	47.5±11.1	3.7±6.9	0.016
Visual Learning Memory	36.8±10.1	-5.2±7.8	0.008
Executive Function	42.8±9.1	-2.0±8.0	0.52

*paired difference. **p values were calculated by paired signed rank test.

Conclusions: These tests allow for a detailed analysis of change in cognitive function in patients on HD. The small increase in verbal memory may be attributable to learning from repeated testing. The decline in visual learning/memory was most marked, and was not previously reported. Repeat testing after longer follow up, a larger cohort and additional tests of visual memory are needed to detect the impact – if any- of dialysis-related factors on progressive decline in cognitive function.

Cognitive Performance before and during Hemodialysis: A Randomized Crossover Trial David A. Drew, Hocine Tighiouart, Tammy Scott, Saeed K. Shaffi, Daniel E. Weiner, Mark J. Sarnak. *Tufts Medical Center, Boston, MA.*

Background: Dialysis patients are educated and counseled during the hemodialysis (HD) procedure. There are few data assessing whether cognitive performance varies with testing during dialysis.

Methods: 40 patients from 6 Boston area HD units were randomly assigned using a cross-over design to detailed cognitive testing. Sequences were as follows: Testing 1 hour before dialysis followed by repeat testing during the 1st hour of dialysis (n=21) and testing during the 1st hour of dialysis followed by 1 hour before dialysis (n=19). To limit learning there was a wash-out period of 1 month before crossing over for the second cognitive test. Mixed models were used to evaluate the effect of timing (difference between testing before vs during dialysis) and learning (difference between 1st and 2nd tests).

Results: Mean age was 58.1 years; 60% were female, 23% African American, and 56% had some college education. While a learning effect was detected in 4 of 16 tests (predominantly memory tasks), cognitive assessment before vs during HD had no effect on test performance(Table 1).

Table 1. Effect of Learning and Timing of Testing on Cognitive Performance

Test	Learning Effect β	p	Timing Effect β	p
Mini-Mental State Exam	-0.279	0.43	0.089	0.80
Verbal Intelligence	-0.146	0.79	-0.881	0.23
Delayed Recall	**-0.907**	**0.003**	0.145	0.61
Short Delayed Recall	**-0.813**	**0.005**	-0.234	0.40
Total Recall	**-2.914**	**0.0001**	-0.229	0.74
Recognition	-0.120	0.78	0.406	0.35
Blocks Design	-1.587	0.09	0.026	0.89
Digits Forward	0.287	0.28	-0.239	0.36
Digits Backward	0.032	0.91	0.111	0.71
Digits Total	0.353	0.31	-0.183	0.64
Digit Symbol Substitution	**-3.269**	**0.01**	1.889	0.14
Trails A†	2.385	0.53	-1.194	0.76
Trails B†	1.813	0.84	-8.766	0.29
Mental Alternation	-0.464	0.60	0.787	0.36
COWAT Animal	-0.868	0.30	0.470	0.59
COWAT Supermarket	0.654	0.57	0.917	0.42

Learning effect = Difference in scores for 1st time taking test and 2nd time taking test
Timing effect = Difference in scores for testing before and during dialysis
For all tests except Trails A and B, a negative β coefficient is consistent with learning, while for Trails A and B a positive β coefficient indicates learning
Similarly, for all tests except Trails A and B, a positive timing β coefficient suggests before performance is superior

Conclusions: We found no difference in cognitive performance depending on the time of testing, suggesting that cognitive tests performed during dialysis are a valid assessment of consistent performance.

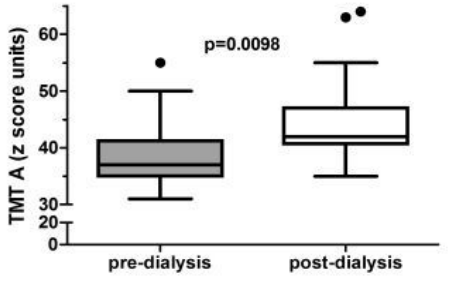
FR-PO271

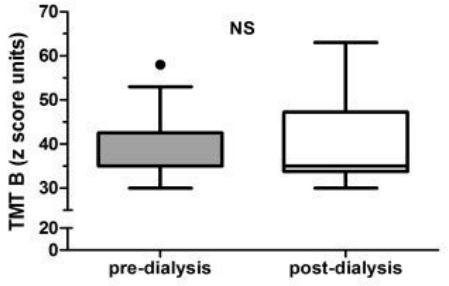
Effect of a Single Dialysis Session on Cognitive Function in CKD5 Patients: A Prospective Clinical Study Sabrina Schneider, Anne Kathrin Malecki, Hermann G. Haller, Olaf Boenisch, Jan T. Kielstein. *Department of Nephrology and Hypertension, Medical School Hannover, Hannover, Germany.*

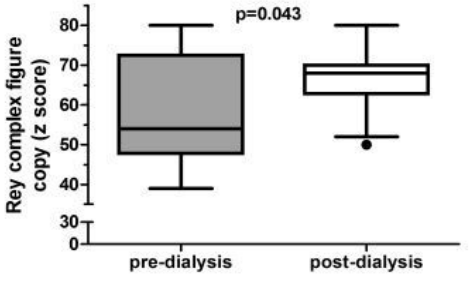
Background: Cognitive function is impaired in CKD5D patients. The potential effect of a single dialysis function on cognitive function reamins still ellusive. im of the study was to assess cognitive function using a wide test battery and avoiding exclusing effects of circadian variations.

Methods: Twentyfive (11 female) CKD5D patients (54 ±12 years, dialysis vintage 4.3±5.7 years) were enrolled. Cognitive testing was performed 1 h prior to dialysis as well as 24 h thereafter including assessment of memory, attention and concentration, executive functioning and psychomotor speed by using the following tests: Rivermead behavior memory test (RBMT), Rey Cpmplexe Figure Test (RCFT), Trail Making Test A+B (TMT), Wechsler Memory Scale (WMS- R), Behavior Assessment of Dysexecutive Syndrome (BADS), Regensburger word fluency test (RWT) and test battery for attention (TAP).

Results: A single dialysis session lead to a significant improvement in logical and visual memory (RBMT [pre: 7.5 and 6 digits/ post: 8.5 and 8 digits] and RCFT [pre:32.5 digits/ post:48 digits]) psychomotor speed and concentration (TMT A), while task switching (TMT B) did not improve.







TESTS	PRE- dialysis (median ± SD)	POST- dialysis (median ± SD)	p
Story RBMT (words)			
recall	7.5 (2.6)	8.5 (3.8)	0.002*
delay	6 (2.5)	8 (3.6)	0.001*
Wechsler Digit Span			
foreward	8 (1.4)	8 (1.9)	0.055
backward	6 (2.0)	6 (1.6)	0.266
Trail Making Test (seconds)			
Trail A	46 (13.7)	40 (12.1)	0.002*
Trail B	108 (38.2)	93 (44.9)	0.726
RWT (words)			
lexical	12 (4.2)	17 (5.8)	0.000*
lexical - change	16 (4.4)	17 (5.9)	0.764
semantic	28 (9.0)	31 (8.4)	0.272

Conclusions: Our data demonstrate improvements in memory functions, executive functions and psychomotor abilities after a single dialysis session, pointing to a reversible component of cognitive impairment in CKD5D.

FR-PO272

Cognitive Impairment Is Common among Malaysian Hemodialysis Patients

Li Ping Tan,[1] Nur Syazwani Jamhuri,[1] Cathie Wu,[1] Soo Kun Lim,[1] Kok Peng Ng,[1] Tee Chau Keng,[1] Yip-Boon Chong,[1] Wai Yew Kong,[1] Chew Ming Wong,[1] Wan Ahmad Hafiz Wan Md Adnan,[1] Mun Hoe Wong,[1] Abdul Hafidz Muhammad Iqbal,[2] Li Han Lim,[1] Maisarah Jalalonmuhali.[1] *[1]Medicine, University of Malaya Medical Center, Kuala Lumpur, Wilayah Persekutuan, Malaysia; [2]Medicine, Universiti Teknologi MARA, Shah Alam, Selangor, Malaysia.*

Background: Cognitive impairment is common among hemodialysis patients with a reported frequency between 16%-37%. Little is known about the factors that contribute to cognitive impairment. Limited asian data exist with most studies being in western populations. The Montreal Cognitive Assessment test (MOCA) is a 30 point cognitive screening test that has been validated for the detection of cognitive impairment, is easy to administer and available in many languages.

Methods: All chronic hemodialysis patients from 5 dialysis centers in the Klang Valley were considered for inclusion. Patients were excluded if they were not able to communicate fluently, had dementia or confusion. All patients were administered the MOCA test by a single trained individual. MOCA scores below 26 were considered as positive for cognitive impairment. Medical charts were reviewed and most recent clinical data was extracted. Data was analyzed with SPSS (version 19.0).

Results: 48 patients were recruited. Mean age was 54.33±10.2 years. 56.3% were male. Ethnicity was mixed with 54.2% Malay, 33.1% Chinese and 10.4% Indian. Etiology of kidney disease was predominantly diabetes (47.9%). 47.9% had only 12 years of schooling. Mean duration of dialysis was 5.4±3.72 years. the MOCA identified 85.4% as having cognitive impairment. Mean scores for the entire cohort was 21.5±4.2. Serum sodium, hemoglobin, calcium, phosphate, iPTH and dialysis duration did not differ amongst those with and without cognitive impairment. Measurement of dialysis adequacy did trend towards significance with kt/v of 1.43±0.45 in those with cognitive impairment while those without had kt/v measurements of 1.92±1.0 (p=0.05).

Conclusions: Cognitive impairment is common amongst hemodialysis patients in Malaysia. Increasing kt/v may result in improved cognitive function. Further studies are needed to confirm this finding.

FR-PO273

Determining Patient Factors Influencing the Switch from Conservative to Dialysis Therapy

Christopher Cheang Han Leo, Tsun Gun Ng. *Renal Medicine, Tan Tock Seng Hospital, Singapore.*

Background: Although not reported in the literature, there appears to be an emerging trend of End Stage Renal Disease (ESRD) patients initially declining dialysis, but subsequently opting for dialysis after referral to Palliative Care Services (PCS). We sought to determine factors that may have contributed to their initial apprehension for renal replacement therapy and to identify aspects of pre-dialysis assessments that may improve the decision making process.

Methods: 273 ESRD patients in a single centre (mean age 73.0±12.0 years, 76% Chinese, 57% Female) who declined dialysis and were referred to PCS from January 2006 to April 2010 were studied. Patients who subsequently underwent dialysis were identified and data extracted from their medical records.

Results: 26 (9.5%) patients on follow-up with PCS subsequently agreed for long-term dialysis (mean age 63.0±7.3 years, 69% Chinese, 58% Male). Most were married (85%) with children (81%) and lived with their families (92%). 80% were ADL independent, 62% were community ambulant without aid and mean Charlson Comorbidity Index score was 5±1, at the time of PCS referral. 35% had consulted a nephrologist <6 months before the PCS referral. All patients were offered dialysis initially but 32% declined formal dialysis counselling. The mean serum creatinine (umol/L)/ eGFR (ml/min/1.73m^2) was 814.4±390.2/5.7±4.1 at the time of PCS referral and 1071.1±352.8/4.5±1.7 at dialysis initiation. 70% of them were initiated on dialysis within 3 months of a PCS consult. Reasons for declining dialysis initially were financial concerns (41%), personal choice (37%) and fear of needling/procedures (15%). Reasons for opting for dialysis subsequently were worsening symptoms (65%) and persuasion by family members (15%). 6-months survival post dialysis initiation was 100%.

Conclusions: Younger ambulant patients with moderate co-morbidities and good family support overcame initial apprehension for dialysis once they became more symptomatic. These unplanned dialysis initiations could be avoided by employing a multidisciplinary approach including early access to a nephrologist, dialysis counsellor, social worker, patient support groups and active family involvement.

FR-PO274

Attitudes and Perceptions of Dialysis Patients to Advance Care Planning

Maria Da Silva-gane,[1] David Wellsted,[2] Ken Farrington.[1] *[1]Renal, Lister Hospital, Stevenage, Hertfordshire, United Kingdom; [2]Centre for Lifespan & Chronic Illness Research, University of Hertfordshire, Hatfield, Hertfordshire, United Kingdom.*

Background: The needs of HD patients who are approaching the end of their life are often unaddressed. We wished to understand the attitudes of patients, perceived as 'failing despite dialysis', to dialysis and to the concept of advance care planning (ACP).

Methods: 20 HD patients previously identified, by use of the "surprise question" were interviewed. Interviews were carried out using a semi-structured schedule and took place in the patient's home. They were audio taped and transcribed, before analysis using Grounded Theory.

Results: Mean age 68years (range 47-88). 12 were male. Dialysis vintage 1-19 years (mean 6). 16 were considered to have severe co-morbidity.

Themes identified.

Complex relationship with dialysis. Despite the negative impact, sense of loss and the limited life experienced on dialysis, the treatment had become such an integral part of their life that it had almost been absorbed into their being. Most had never considered withdrawal from treatment as a future option.

Incongruous perception of prognosis.There a lack of insight into their situation. Most did not perceive themselves as terminally ill. There was an assumption that HD would keep them alive indefinitely, in spite of experiencing increasing physical deterioration. The degree to which patients deployed 'non-engagement' as a coping mechanism was not clear.

Words can be barriers. Many interpreted matters relating to 'end of life' as pertaining to private decisions about wills and funeral arrangements. Having overcome these barriers, many regarded ACP in relation to life goals and future options as being potential beneficial.

Conclusions: Patients approaching end of life have a complex relationship to their treatment. Many professed to have little insight of their prognosis, and few had considered withdrawal. Most articulated the wish for sensitive realistic communication including appropriate and individualised prognostic information. ACP discussions were perceived as being useful if set in the context of current health status, realistic treatment and life goals.

FR-PO275

Withdrawal of Care in Patients Receiving Continuous Renal Replacement Therapy (CRRT) in Intensive Care Units (ICU) Emily S. Kenner,[1] Veronika Glushets,[1] Karen Allard,[1] Anthony Leonard,[1] Charuhas V. Thakar.[1,2] *[1]University of Cincinnati; [2]Cincinnati VA.*

Background: Up to 20% of Americans spend their last days in ICU. In ICU patients receiving CRRT, deliberations regarding prognosis/end of life (EOL) care should occur based on disease severity and evidence of futility of further treatment. No studies have examined patient factors/physician practices associated with withdrawal of care (WOC) in CRRT patients in ICU.

Methods: From a tertiary care academic center, we report data (part of a 5-year project) examining EOL care practices in CRRT patients in ICU. We extracted 64 variables (details of ICU admission, CRRT and events before death/WOC). Characteristics were compared in those who died, by WOC status, using Chi-square and Wilcoxon rank-sum tests.

Results: In 2011, 83/206 (40%) patients receiving CRRT died. 12 were excluded (transplants/missing data), 71 analyzed. 69% were admitted to Medical and 31% to Surgical ICU; infection the diagnosis in 32%. Sample was 62% male, 50% White with mean age 56.8 years [standard deviation (SD) 15]. Co-morbidities included diabetes (45%), end stage renal disease (21%), cirrhosis (17%) and malignancy (13%); 93% required mechanical ventilation. Mean ICU stay - 18.2 days (SD 26), mean dialysis days - 6.7 (SD 6); 28% received both CRRT and intermittent dialysis. Of those who died, futility was documented in 47 (68%), EOL discussion occurred in 59 (83%) and care withdrawn in 52 patients (73%). Of the 19 without WOC, 10 had futility noted and EOL discussions. From the initial documentation of futility, time to death was 2.1 days (SD 5.2). EOL discussions occurred an average of 1.2 days (SD 4.2) before WOC. WOC patients received 87 cumulative days of dialysis after EOL discussion. 28% of patients had a catastrophic event (e.g. cardiac arrest) within 48 hrs of death. Only 18% had palliative care team involved. Patient characteristics were similar when compared by WOC status.

Conclusions: WOC resulting in death was common in CRRT patients and was preceded by a catastrophic event in 28% of subjects. Better predictors of mortality in dialysis subjects and appropriate involvement of palliative care in ICU may avoid unnecessary suffering and impact costs of care.

FR-PO276

Should We Still Focus that Much on Cardiovascular Mortality in End Stage Renal Disease Patients? The CONvective TRAnsport STudy (CONTRAST) Claire H. Den Hoedt,[1,2] Michiel Bots,[3] Muriel Grooteman,[4] Albert H. Mazairac,[2] Erik L. Penne,[4] Neelke C. Van Der Weerd,[4] Pieter M. Ter Wee,[4] Menso Jan Nube,[4] Renee Levesque,[5] Peter J. Blankestijn,[2] Marinus A. Van Den Dorpel.[1] *[1]Maasstad Hospital, Rotterdam; [2]UMCU, Utrecht; [3]UMCU, Utrecht; [4]VU MC, Amsterdam, Netherlands; [5]Centre Hospitalier de l'Université de Montréal, Montréal, Canada.*

Background: We studied the distribution of causes of death in the CONTRAST cohort and compared the proportion of cardiovascular (CV) deaths with other populations to answer the question whether CV mortality is still the principal cause of death in end stage renal disease (ESRD). In addition, we compared patients who died from CVD with those who died from non-CVD. Finally, we aimed to clarify reasons for dialysis withdrawal.

Methods: We used data from CONTRAST, a randomized controlled trial in 714 chronic hemodialysis (HD) patients (age 64 ±14, 62% men, median vintage 2 yrs, 25% DM) on the effects of online hemodiafiltration versus low-flux HD. Causes of death were adjudicated. The distribution of causes of death was compared to that of the Dutch dialysis registry and of the Dutch general population.

Results: In CONTRAST, 231 patients died on treatment. 32% died from CVD, 22% due to infection and 23% because of dialysis withdrawal. These proportions were similar to those in the Dutch dialysis registry and the proportional CV mortality was similar to that of the Dutch general population. CV death was more common in patients <60 years. Patients who withdrew were older, had more co-morbidity and a lower mental quality of life at baseline. Patients usually withdrew from dialysis for a combination of disease conditions. 46% died within 5 days after the last dialysis session.

Conclusions: Although the absolute risk of death is much higher, the proportion of CV deaths in an ESRD population is similar to that of the general population. In older HD patients CV and non-CV death risk are equally important. Withdrawal from dialysis was much more frequent than anticipated. In view of the importance of withdrawal from dialysis in daily practice, well-defined criteria for the registration of dialysis withdrawal are warranted. More insight in the incidence and risk factors for dialysis withdrawal is urgently needed.

FR-PO277

Transplant Professionals' Views on the Participation of Compatible Pairs in Kidney Exchange Programs Marie-chantal Fortin,[1,2] Céline Durand.[2] *[1]Nephrology and Transplant Division, CHUM, Montréal, QC, Canada; [2]Research Center of CHUM, Montréal, QC, Canada.*

Background: Kidney exchange programs (KEPs) facilitate living kidney transplantation for incompatible pairs. While such programs can increase living organ donation, they also pose challenges in terms of distributive justice. Kidney transplant recipients (R) in the O blood group are at a disadvantage when it comes to KEPs, because they can only receive organs from O donors (D) whereas the latter are universal D. A way to remedy this situation is through altruistic unbalanced paired kidney exchange (AUPKE), in which a compatible pair consisting of an O blood group D and a non-O R is invited to participate in a KEP. The aim of this study was to gather empirical data on how transplant professionals view AUPKE.

Methods: 19 transplant professionals working in 4 Canadian transplant programs took part in semi-structured interviews between 11/2011 and 05/2012. The content of these interviews was analyzed using the qualitative data analysis method.

Results: 89% of the transplant professionals were willing to propose AUPKE to compatible pairs. They noted the societal benefits of AUPKE (solution for O blood group R; transplantation of more patients; reduction of costs associated with dialysis), as well as risks for the patient and D (travel of D for procurement; transplantation delayed while waiting for a compatible R, etc.), and disadvantages for medical professionals (more work and logistical issues). All of the transplant professionals (except for two) felt comfortable about discussing the possibility of AUPKE with their patients. However, they also stressed the importance of not pressuring patients and providing compatible pairs with comprehensive information in order to secure their informed consent.

Conclusions: AUPKE appeared to be an acceptable option for the Canadian transplant professionals who participated in this study, since it is a way to increase the number of transplantations and make more organs available for O blood group R. However, the systematic recruitment of compatible pairs did not seem appropriate, since it would not benefit all compatible pairs, and there is also a risk of medical teams pressuring patients to participate.

FR-PO278

The Experiences of Commercial Kidney Donors: Thematic Synthesis of Qualitative Research Allison Tong,[1,2] Jeremy Chapman,[3] Germaine Wong,[3] Nick Cross,[4] Pikli Batabyal,[2] Jonathan C. Craig.[1,2] *[1]Sydney School of Public Health, University of Sydney, Sydney, NSW, Australia; [2]Centre for Kidney Research, The Children's Hospital at Westmead, Sydney, NSW, Australia; [3]Centre for Transplant and Renal Research, Westmead Hospital, Sydney, NSW, Australia; [4]Department of Nephrology, Christchurch Hospital, Christchurch, New Zealand.*

Background: Commercial transplantation has expanded because of the major shortage of kidneys for transplantation, such that waiting times can exceed many suitable patients' life expectancy. This study aims to synthesize qualitative studies on the experiences and perspectives of commercial kidney donors.

Methods: We conducted a comprehensive literature search in electronic databases to April 2011, and consulted experts in the field of commercial transplantation. Thematic synthesis was used to analyse the findings.

Results: Seven studies involving over 676 commercial kidney donors were included. We identified three major themes: desperation, the participants' decision to sell their kidney was forced by poverty or the need to repay a debt or to fulfil a family obligation; despair (destroyed body integrity, shame and secrecy, dehumanised and dispirited, loss of livelihood, heightened sense of vulnerability, disappointment and regret); and debasement (deception by brokers and recipients, victimised by the hospital, stigmatised by community, and rejected by family).

Conclusions: Commercial kidney transplantation can result in severe and often unexpected ramifications on the donors' mental, physical, and social well-being. Donors feel victimised, live in constant fear of their future health, and bear an overwhelming and pervasive sense of emptiness, shame, guilt, regret and depression. Effective implementation of both the WHO guiding principles and legislated regulation in almost all countries is urgently required to deter potential recipients and healthcare providers from pursuing commercial transplantation; to protect the unwitting, vulnerable and impoverished communities which are known sources for commercial transplantation.

Funding: Government Support - Non-U.S.

FR-PO279

Literacy Rates among Hemodialysis and Kidney Transplant Patients Zeeshan Perveze,[1] Amit M. Patel,[1] Hari Garapati,[1] Robert Podolsky,[1] Laura L. Mulloy.[1] *[1]Medicine, Georgia Health Sciences University, Augusta, GA; [2]Medicine, Georgia Health Sciences University, Augusta, GA; [3]Medicine, Georgia Health Sciences University, Augusta, GA.*

Background: ESRD is a life-long health problem commonly treated with hemodialysis (HD) or kidney transplantation (KT). The decision to pursue a KT depends in part on patient (pt) understanding of the causes, treatment and prognosis of both modes of therapy. Pt comprehension and understanding of these issues may influence decisions about the pursuit of KT. Information relevant to this issue is many times dependent on written material provided to pts. Given the necessity to comprehend a high volume of complicated issues

surrounding KT, often presented in writing, we theorized that transplant recipients would exhibit a higher rate of literacy than patients on HD. To address this question we surveyed HD and KT pts and assessed their reading and comprehension skills.

Methods: HD pts in the Augusta area and KT recipients from GHSU were studied. Reading comprehension was assessed using a 66-word recognition test which provides an estimate of reading skills in less than 3 minutes (Rapid Estimate of Adult Literacy in Medicine - REALM).

Results: 50 HD and 50 KT pts completed the study. All HD pts were from 3 HD units in Augusta. There were 27 dialysis units of origin represented in 43/50 KT pts with 22% from Augusta. Seven KT pts were from unknown dialysis units. When compared to KT, HD pts were older (55±13 vs 49±15 mean±SD years for HD vs KT, respectively, $p < 0.05$) and primarily African American (AA) (88% vs 48% for AA vs Caucasian, respectively, $p < 0.05$). There were no differences in the gender distribution between the two groups. KT pts scored significantly higher on the REALM test when compared to HD (96±6% vs 87±14% correct for KT vs HD, respectively, $p < 0.05$). These data indicate that literacy rates are higher among KT pts when compared to HD, and that HD pts tended to be AA.

Conclusions: KT pts have higher literacy rates than HD, and tend to be Caucasian. Socioeconomic, geographic, and/or educational factors may influence these results. Literacy programs focused on HD pts may improve the rate of KT.

FR-PO280

Fertility Preservation in Children Treated for Nephrotic Syndrome or Vasculitis (NS/V) with Cyclophosphamide (CPO) Steven D. Miller,[1] Yimei Li,[2] Kevin E.C. Meyers,[3] Jill P. Ginsberg,[2] Arthur Caplan,[4] Victoria A. Miller,[2] Tuua Ruutiainen,[4] Lindsay M. Griffin.[3] *[1]Pediatrics, Johns Hopkins University, Baltimore, MD; [2]Oncology, Children's Hospital of Philadelphia, Philadelphia, PA; [3]Nephrology, Children's Hospital of Philadelphia, Philadelphia, PA; [4]Penn Center for Bioethics, Perelman School of Medicine at University of Pennsylvania, Philadelphia, PA.*

Background: Fertility preservation for children at risk for infertility from treatment with alkylating agents has become standard practice in pediatric oncology. Within pediatric nephrology, there are no similar standards when CPO is used for NS/V. This study explores current practice patterns among pediatric nephrologists.

Methods: Physicians on the ASPN listserv were sent a survey via email using REDCap. The survey queried participants about demographics, dosing of CPO, counseling, referral, and gamete banking as well as physician attitudes and reported barriers to practice. Descriptive statistics and Chi-squared analyses were employed to analyze the data using SAS.

Results: Of 579 ASPN members invited, N=186 completed the survey (32% response rate). CPO was dosed in mg/kg 23% of the time, g/m^2 40% of the time, and both 37% of the time. 80% agreed that pubertal M should be offered a fertility referral prior to treatment, while 53% report that they actually refer pts >=1% of the time. Those who never refer M pts are less likely to cite infertility as a concern for the doctor (p=0.029), more likely to cite 'lack of training' as a barrier (p=0.045), more likely to cite 'no place to refer' as a barrier (p<0.0001), and more likely to cite 'stays under limit of toxicity' as a barrier (p=0.003). Results were similar for F.

Conclusions: Survey results demonstrate variability in CPO dosing, referral and sperm banking of pts treated with CPO. This points to a divide in the field of pediatric nephrology between those who never preserve the fertility of their pts and those who do. Further research into long-term fertility effects of current dosing regimens of CPO and discussion of standard practice for fertility preservation in pediatric nephrology is needed.

FR-PO281

Severe Cognitive Impairment Is Not a Contraindication to Pediatric Renal Transplantation Ashton Chen, Jen-Jar Lin. *Pediatrics, Wake Forest Baptist Health, Winston-Salem, NC.*

Background: Renal transplantation in patients with mental retardation and cognitive impairment is controversial. There are limited outcomes data in pediatric renal transplant recipients with severe cognitive impairment.

Methods: A retrospective chart review was performed of all children who underwent renal transplantation between January 1, 2002 and May 15, 2012. Patients were divided into two groups, those with severe intellectual or cognitive impairment (CI) prior to transplantation and those without. Demographic characteristics were compared between the two groups using Chi-square test. Patient survival and graft survival were compared between the two groups.

Results: There were N=67 patients who received a renal transplant during the study period. There were n=9 patients who received a renal transplant with CI and n=58 renal transplant recipients without CI. Patient characteristics of the CI group are shown in Table 1.

Table 1 Characteristics of Patients with Cognitive Impairment

Patient #	Etiology of Renal Disease	Etiology of CI
1	Congenital polycystic kidney disease	CVA/Temporal lobectomy
2	Echogenic small kidneys	Joubert Syndrome
3	Sepsis-related ATN	Hypoxic Ischemic Encephalopathy
4	Renal dysplasia	Uncertain
5	HUS	Bacterial meningitis & CVA
6	Renal dysplasia	Periventricular leukomalacia
7	FSGS	CVA
8	PUV	Down syndrome
9	FSGS	Dyskeratosis congenita

The majority of CI patients were non-verbal and required a full-time caregiver. All CI patients were on peritoneal dialysis prior to transplantation and 7 out of 9 patients received a deceased donor transplant. Patient survival at 1 year post-transplant was 100% in both the CI and non-CI groups. Graft survival at 1 year post-transplant was 100% in the CI group and 88% in the non-CI group (P=NS).

Conclusions: There is no contraindication to renal transplantation in pediatric patients with severe CI. These children can be considered as transplant candidates.

FR-PO282

Report of the Hyponatremia Registry, a Multi-Center, International Study of Current Treatment Practices for Hyponatremia Arthur Greenberg,[1] Joseph G. Verbalis,[2] Alpesh Amin,[3] Esteban Poch,[4] Joseph Dasta,[5] Keith Friend,[6] Volker Rolf Burst.[7] *[1]Nephrology, Duke University, Durham, NC; [2]Endocrinology and Metabolism, Georgetown University, Washington, DC; [3]Hospitalist Program, University of CA, Irvine, Orange, CA; [4]Hospital Clinic, Barcelona, Spain; [5]UT College of Pharmacy, Hutto, TX; [6]Otsuka America Pharmaceutical, Inc., Princeton, NJ; [7]Internal Medicine, Renal Division, University of Cologne, Cologne, Germany.*

Background: Hyponatremia (HN) is the most common electrolyte disorder of hospitalized patients (pts) and is an independent predictor of increased mortality. This registry documents currently used HN therapies, characterizes their efficacies, and assesses their impact on hospital resource utilization.

Methods: After informed consent or waiver, records of pts meeting entry criteria, principally adults with euvolemic or hypervolemic HN (serum sodium ([Na]) ≤130 mmol/L), were abstracted. Accrual to date approximates 90% of planned enrollment. Any pt with anomalous data undergoes adjudication to confirm that all inclusion and exclusion criteria were met.

Results: From September 2010 to May 2012, 3,157 pts were enrolled at 149 US and 89 EU sites; 1,838 had sufficient data for analysis. The mean±SD entry and discharge [Na] values were 126.3±7.0 and 131.7±5.1 mmol/L, respectively. The average length of stay was 10.3±9.4 days.

Demographics, Etiologies, Chronicity and Outcomes

Baseline Characteristics	*All Patients with evaluable data (n=1,838)*		*Patients who completed or did not require adjudication (n=482)*
	%		%
Male	46.90		52.70
Age ≥ 65 years	49.13		44.19
Etiology of HN			
SIADH	**40.49**		**33.82**
• Tumor		20.97	18.40
• CNS		8.53	8.59
• Drug Induced		18.67	22.70
• Pulmonary		16.51	15.95
• Other		18.81	21.47
• Unknown or Idiopathic		13.80	14.72
Heart failure	**32.00**		**44.61**
Cirrhosis	**14.81**		**23.44**
Nephrotic syndrome	**3.16**		**1.24**
More than one hypervolemia dx	**2.67**		**3.53**
Onset/Duration of HN			
Chronic HN[1]	41.19		45.85
HN as the admitting dx	24.48		28.42
HN developed during admission	76.82		82.74
HN on a prior admission	25.91		30.08
HN at discharge	41.29		52.28

Single therapy only - all patients (n=1,838)	*Mean rate of [Na] change (mmol/L per day of treatment)*	*Median LOS[2] (days)*	*% of pts whose correction was overly rapid[3]*
			%
No treatment (n= 535, 29%)	0.90	-	2
Any pharmacological agent[4] (n=77, 4%)	2.39	5	2
Vaptan only (n=28, 2%)	3.26	3	4
Any pharmacological agent, excluding vaptans (n=49, 3%)	1.62	5	0
Fluid restriction (n=348, 19%)	1.30	5	1
Normal saline (n=248, 13%)	2.92	4.5	4
Hypertonic saline (n=14, 1%)	9.36	4.5	29

[1]HN of more than 48 hours duration; [2]Length of Stay from the day treatment began; [3]Overly rapid defined as an increase in [Na] exceeding 12 mmol/L/24 h; [4]Conivaptan, tolvaptan, demeclocycline, urea, loop diuretic.

Conclusions: HN pts received no treatment 29% of the time; 19% received fluid restriction only. More than 40% still had HN at discharge. Among pts who received a single therapy, only 4% received a drug targeted at HN. Pts treated with hypertonic saline were most likely to experience overly rapid correction (29%). This registry is the largest study of HN to date, which will allow assessment of multiple aspects of currently employed therapies of hospitalized patients with HN.

Validity of Hospital-Wide Hyponatremia Treatment Protocol: A Quality Improvement Program in a Teaching Hospital Kumiko Shimasaki,[1] Masahiko Nagahama,[1] Fumika Taki,[1] Kenichiro Koitabashi,[1] Keita Hirano,[1] Yuki Heath,[1] Sachiko Ohde,[2] Yasuhiro Komatsu.[1] *[1]Nephrology, St.Luke's International Hospital, Tokyo, Japan; [2]Clinical Epidemiology, St. Luke's Life Science Institute, Tokyo, Japan.*

Background: Hyponatremia is the most common electrolyte disorder and is associated with increases in morbidity, mortality and length of hospital stay. There exits wide variation in clinical practice of hyponatremia management due to lack of specific guidance. Hospital wide systematic approach for the treatment of hyponatremia can be an excellent Quality Improvement (QI) Program, since it will improve patient outcome and lessen unnecessary workload. The aim of the present study is to assess and report our hyponatremia treatment QI program.

Methods: Panel of nephrologists, critical care physicians, and residents developed hyponatremia treatment protocol which specifies timing of nephrology consultation, initial physical and laboratory tests, intravenous fluid prescription (selection and rate), monitoring, and prevention of overcorrection.To evaluate the effectiveness of the QI program, quality indicators were measured, which include nephrology consultation rate, recovery time, and hospital stay, etc. We analyzed clinical and biochemical parameters of all patients admitted to St.Luke's International Hospital in Tokyo in 2012 (QI group). The same medical information in all admitted patients in 2007 was collected as historical comparison (Comparison group).

Results: There were 9,428 patients in Comparison group and 10,233 patients in QI group. Incidence of moderate hyponatremia (120≤serum Na≤135mEq/L) was 13.5% in comparison group and 11.2% in QI group, and incidence of severe hyponatremia (serum Na<120mEq/L) was 0.59% and 0.52%, respectively. Nephrology consultation rate for severe hyponatremia was 25.5% in Comparison group and 37.7% in QI group (P<0.05). Length of hospital stay was 33.9±30.3 (mean+/-S.D.) days in Comparison group and 16.5±15.3 days in QI group (P<0.05).

Conclusions: Our structured program shows safety and feasibility in managing hyponatremia. This underscores the importance of developing QI program, which can improve the quality of practice as well as education in a teaching hospital.

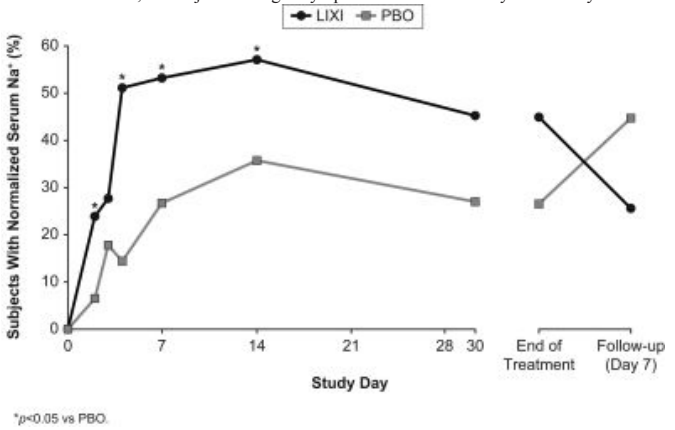
FR-PO284

Effect of Lixivaptan on Serum Sodium Levels in Subjects Initially Hospitalized with Euvolemic Hyponatremia William Abraham,[1] Johannes Hensen,[2] Peter Gross,[3] Daniel G. Bichet,[4] Richard Josiassen,[5] Deodatta Chafekar,[6] Cesare Orlandi.[7] *[1]The Ohio State Univ; [2]Klinikum Hannover-Nordstadt; [3]Uni.Klinikum C.G. Carus; [4]Université de Montréal; Hôpital du Sacré-Coeur; [5]Drexel Univ Col of Med; [6]Shri Samarth Hosp; [7]Cardiokine Biopharma, Inc.*

Background: Lixivaptan (LIXI) was previously shown to increase serum Na^+ levels in subjects with euvolemic hyponatremia (EH) (ASN 2010). We further assessed the rapidity, degree, predictability, and safety of this increase in hospitalized subjects with EH.

Methods: In this multicenter, randomized, double-blind study (LIBRA), subjects received oral LIXI 50mg (n=54) or placebo (PBO; n=52) once daily, with subsequent dose titration (25-100mg) based on serum Na^+ levels. Fluid restriction was implemented at the investigator's discretion. Treatment period: 30 days. Initial titration was in an inpatient setting; subjects were then treated as outpatients.

Results: Mean baseline serum Na^+ was 127.6 (LIXI) and 126.1mmol/L (PBO). Least-squares mean±SE changes from baseline to Day 7 (primary endpoint): 6.7±0.7 and 4.5±0.8mmol/L, resp. (p=0.034). The benefit of LIXI was consistent across gender/age groups; the magnitude of change in serum Na^+ increased with increasing baseline severity of EH. Normalization rates (serum Na^+ levels 135-145mmol/L) were greater with LIXI than PBO (53.2% vs 26.7% on Day 7, p<0.05; Figure). Kaplan-Meier analysis of time to first serum Na^+ level ≥135mmol/L favored LIXI (p=0.004); >50% of subjects achieved this Na^+ level by Day 4 (LIXI) or Day 30 (PBO). Few subjects had serum Na^+ levels >145mmol/L (4.0% LIXI, 2.0% PBO) or a rapid rise during titration (4.0% LIXI, 5.9% PBO). LIXI was well tolerated; no subject had signs/symptoms of osmotic demyelination syndrome.



Conclusions: LIXI normalizes serum Na^+ within 4 days in a majority of subjects with EH, with tolerability similar to PBO.

Hyponatremia Associated Hip Fracture Allen I. Arieff, Juan Carlos Ayus. *[1]Medicine, Univeresity of California, San Francisco, CA; [2]Nephrology, Renal Consultants of Houston, Houston, TX.*

Background: Hyponatremia is often associated with orthopedic injury (JAMA 281; 1999:2299-04). Hip fracture is a worldwide and frequently disabling orthopedic injury. The association with hyponatremia is unclear.

Methods: Hyponatremia as a possible cause of hip fracture was investigated by studying 76 patients who suffered hip fracture and were admitted to two tertiary medical centers. A) This group consisted of 25 acute cases of hip fracture who had hyponatremia (plasma Na < 130 mmol/L) and suffered hip fracture due to impaired balance and falls; B) This group consisted of 51 adult patients who were part of a retrospective analysis of 5 years of adult inpatient surgery. The data in Group B were generated by computer search of the hospital records using the SAS database to evaluate all surgical patients whose preoperative plasma sodium was below 130 mmol/L.

Results: There were 44,225 consecutive adult inpatient surgeries, of whom 7181 had measurement of preoperative plasma Na. Among these were 708 cases of hip fracture (9.9%). Fifty-one patients with hip fracture (7.2% of all hip fractures) had preoperative hyponatremia (plasma Na = 127±7 mmol/L) but this was present in less than 0.1% of all other types of surgery. Seventy - four of 76 hyponatremic hip fracture patients were female (age = 74±12 yrs). Among the 25 Group A patients, the plasma Na was 120±7 mol/L, all had normal renal function, 44% had osteoporosis, 44% had vitamin D deficiency and 31% were taking anti-depressants. The three-month all cause mortality among all 7181 postoperative patients was 1.8%, but among the 76 with hip fracture and hyponatremia, it was 5.8% (p < 0.01).

Conclusions: 1) Hyponatremia can lead to weakness, dizziness and falls with resulting hip fracture; 2) Data from 708 patients with hip fracture suggest that 7.2% of all hip fractures are associated with hyponatremia; 3) The all cause mortality among patients with hip fracture and hyponatremia is triple that of all other postoperative patients.

FR-PO286

The Incidence and Risk Factors for Terlipressin-Induced Hyponatremia in Liver Cirrhosis Patients Dong Jun Park, Yeojin Kang, Se-Ho Chang, Dae-hong Jeon, Hyejung Ha. *Internal Medicine, Nephrology, Gyeongsang National University Hospital, Jinju, Gyeong Sang Province, Korea.*

Background: As a prodrug of vasopressin, terlipressin has agonistic effects on the V1 receptor and partial agonistic effects on renal vasopressin V2 receptors. However, its effects on the serum sodium concentration are controversial.

Methods: This study retrospectively investigated 127 liver cirrhosis patients treated with terlipressin to examine the changes of the serum sodium level.

Results: Terlipressin was prescribed for the purpose of bleeding control (99) and management of hepatorenal syndrome (28). In all of the patients, theserum sodium level decreased from 134.04 ± 6.52 mmol/L to 130.39 ± 6.22 mmol/L during or after the terlipressin treatment (*P < 0.001)*. In 45 patients (35.4%), the serum sodium concentration decreased by more than 5 mmol/L from 137.853.62 mmol/L to 128.49 4.16 mmol/L: in 29 patients (22.8%), by 5 to 10 mmol/L; and in 16 patients (12.6%), by greater than 10 mmol/L. In the latter group, 5 patients showed neurologic manifestations. After the withdrawal of terlipressin, the serum sodium level improved spontaneously to be within the normal range with the restoration of neurologic manifestations. In the univariate analysis it was also found that patients with the normal or near-normal baseline serum sodium level were at high risk of hyponatremia and the initial sodium level and hepatic functions represented with the MELD and Child-Pugh score were significantly associated with the terlipressin-induced reduction of serum sodium. In multivariate analysis, it was found that the initial sodium level was the most powerful predictor of the terlipressin-induced reduction of serum sodium.

Conclusions: An acute reduction of the serum sodium concentration is not uncommon during terlipressin treatment, and the baseline serum sodium level is closely related to the reduction of the serum sodium concentration.

FR-PO287

Use of Serum Albumin (ALB) to Identify Colloid-Related Artifact of Serum Sodium (Na) Measured by the Indirect Ion-Selective Electrode (ISE) Method: A Non-Linear Effect Isabelle Ayoub,[1,2] Reisha T. Browne,[1] Robert H. Barth,[1] Philip Goldwasser.[1] *[1]VA NY Harbor Healthcare System; [2]SUNY Downstate, Bkly, NY.*

Background: When the serum colloid level is lower than normal, the measurement of Na by the usual indirect ISE method (iNa) tends to be artifactually high—compared with direct ISE (dNa) used in gas panels—while above normal serum colloid results in the opposite. One study reported that the iNa artifact can be estimated with a linear regression equation based on ALB, a routinely measured colloid (Story '07), while another found the ALB effect to be nonlinear (Dimeski '05).

Methods: To test this, we (i) paired chemistry and gas panels obtained < 20 minutes apart in a retrospective cohort of all patients (pts) admitted to our critical care units during a 1 year period, (ii) calculated iNa - dNa (NaDIFF) and the inter-panel glucose difference

(GluDiff), and (iii) examined the influence of ALB on NaDIFF, adjusting for GluDiff. Limiting each pt to one pairing and excluding hemolyzed or turbid samples left 190 iNa/dNa pairs.

Results: Significant inter-panel differences were found (NaDIFF [mean±sd]: 1.9±2.0 mM, $p<10^{-28}$; GluDiff: -7.2±25 mg/dL, $p=10^{-4}$) implying calibration bias. NaDIFF correlated weakly with ALB (r=-0.14 p<.06) and GluDiff (r=-0.13 p<.09), and not at all with iNa + dNa (r=0.05). A non-linear effect of ALB was suggested by the trend of NaDIFF means versus ALB grouped into categories (TABLE).

ALB Category	N	ALB, g/dL	NaDiff, mM (t-test)
A (< 2 g/dL)	4	1.7±0.1	4.5±1.3 (p≤01 vs. B & C; P<.001 vs. E)
B (2-2.9 g/dL)	31	2.5±0.2	1.8±1.8
C (3-3.9 g/dL)	71	3.5±0.3	2.0±1.9
D (4-4.5 g/dL)	59	4.2±0.2	2.2±1.9
E (> 4.5 g/dL)	25	4.8±0.2	0.6±2.1 (p≤001 vs. A, C, & D)

ANCOVA testing of ALB category, modeled as a polynomial, revealed significant (p<.001) linear and cubic components, adjusting for GluDiff (slope= -1.2 mM per 100 mg/dL; p<.04).

Conclusions: In summary, three sources of discordance between iNa and dNa were detected: calibration bias; GluDiff; and colloid-related artifact, for which a nonlinear function of ALB may be a useful estimate. When faced extreme values of ALB, confirming iNa with dNa is prudent.

A G2 Cell Cycle Arrest of Proliferating Principal Cells May Explain the Loss of These Cells in Lithium-Induced Nephrogenic Diabetes Insipidus

Theun de Groot,[1] Marcel Jaklofsky,[1] Mohammad Alsady,[1] Ruben Baumgarten,[2] Peter M.T. Deen.[1] *[1]Physiology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [2]SHL-Groep, Ettenleur, Netherlands.*

Background: Vasopressin-induced plasma membrane expression of the Aquaporin-2 (AQP2) water channel is essential for urine concentration. Lithium, the drug of choice for the treatment of bipolar disorders, affects the urine concentrating ability, resulting in ~20% of patients with nephrogenic diabetes insipidus (NDI), a disorder characterized by polyuria and polydipsia. Studies with rats demonstrated that lithium-induced NDI is caused by downregulation of AQP2 on short term (< 5 days) and loss of principal cells on long term (1-4 weeks). Surprisingly, lithium treatment increased the number of principal cells positive for the proliferation marker PCNA. The aim of our study was to identify how lithium-induced principal cell proliferation can lead to its loss.

Methods: To this end mice were treated for 0, 4, 7 and 10 days with lithium and housed in metabolic cages to analyze urinary parameters. Kidneys were analyzed using immunoblotting and immunohistochemistry.

Results: In line with earlier data, lithium treatment resulted in a significantly increased urine volume, decreased urine osmolality, and diminished AQP2 abundance. Analysis of urine, collected during treatment, did not reveal principal cell debris, indicating that principal cells are not shed and lost via the urine. PCNA immunostaining demonstrated that lithium induced proliferation of mainly principal cells in the papilla base starting at 4 days and being most prominent at 7 and 10 days. Additional immunostaining revealed that at 7 days of lithium treatment, around 35% of the proliferating principal cells exhibited a foci-like staining for pHiston-H3, indicative for late G2 phase. As this is significantly higher than the number of pHiston-H3 positive cells during normal proliferation (< 20%), our data indicate that lithium arrests principal cells in the G2 cell cycle phase.

Conclusions: In conclusion, our data indicate that lithium treatment initiates proliferation of renal principal cells, but that these are arrested in the G2 cell cycle phase, thereby halting further proliferation.

FR-PO289

Pseudohyperkalemia with Fist Clenching: A Graded Phenomenon

David Bennett,[1] Maitreyee M. Gupta,[2] Lawrence S. Weisberg.[2] *[1]Medicine, NYPH-Weill Cornell Medical Center; [2]Nephrology, Cooper University Hospital.*

Background: Pseudohyperkalemia is a false elevation of serum potassium concentration (S_K). Unrecognized, it can lead to potentially harmful treatment. Fist clenching with phlebotomy can cause pseudohyperkalemia, but the determinants of its magnitude are unknown. We hypothesized that the increase in S_K is proportional to the force of muscle contraction.

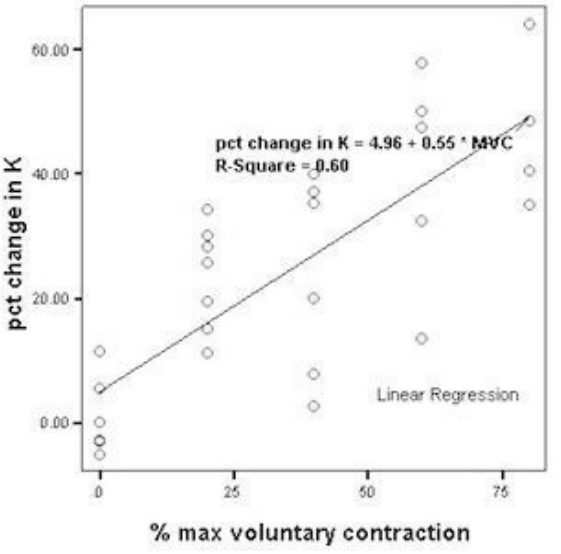
Methods: We studied 8 healthy adult subjects. Maximum voluntary contraction (MVC) was determined by squeezing a dynamometer with maximum force for one minute. We measured antecubital vein S_K at baseline and after one minute, under five conditions: tourniquet only; 20%, 40%, 60%, and 80% of MVC, with a one-minute washout in between. Serum was analyzed for potassium, sodium and bicarbonate using clinical laboratory methods. We analyzed differences with paired t-test; change over MVC, with one-way ANOVA and linear regression.

Results: Results of S_K (mEq/L, mean ± SD) are shown as baseline *vs.* final, by condition.

Serum K (mean±SD) baseline vs final

Condition	Baseline	Final	Difference	p-value
Tourniquet only	3.7 ± .2	3.6 ± .2	0 ± .2	.73
20% MVC	3.7 ± .3	4.5 ± .4	.9 ± .3	<.001
40% MVC	3.8 ± .3	4.6 ± .6	.9 ± .5	<.01
60% MVC	3.6 ± .2	5.1 ± .7	1.5 ± .7	<.01
80% MVC	3.8 ± .2	5.6 ± .6	1.5 ± .8	<.01

There was a linear increase in %-change S_K with increasing force of contraction (R^2 = 0.60; p <.001), which was not seen with serum sodium (R^2 = .01; p = 0.31) or bicarbonate concentration (R^2 = .01; p = 0.45).



Conclusions: We noted a clinically important graded rise in S_K with force of fist clenching. S_K rose ~25% with moderate magnitude of fist clenching (20-40% MVC).

Future studies will estimate the prevalence of significant pseudohyperkalemia, by assessing the strength of fist clenching during routine phlebotomy.

Endemic Severe Hypokalemia (HK) with Chronic Kidney Disease (CKD) in a Rural South Indian Population

Sreejith Parameswaran,[1] Jai Radhakrishnan,[2] Susmitha Chandragiri,[1] Rathinam Swaminathan,[1] Tamilarasu Kadhiravan,[1] K.T. Harichandrakumar,[1] Anca Tilea,[3] Brenda W. Gillespie,[3] Hal Morgenstern,[3] Rajiv Saran.[3] *[1]Nephrology, Medicine & Biometrics, JIPMER, India; [2]Nephrology, Columbia University, New York, NY; [3]University of Michigan.*

Background: Severe hypokalemic paralysis is rare; however we have observed this condition frequently at our hospital's emergency dept & report preliminary findings on a case series from our center in South India.

Methods: We describe the clinical and biochemical features of 90 consecutive patients (pts) from 2010-12. A case report form was used to collect data prospectively with pts followed through their hospital stay.

Results: Mean age (±SD) at presentation was 40±10 yrs (n=90,24 F). Presenting complaints were flaccid quadriparesis in 70, paraparesis in 4, muscle cramps in 15 & myalgia in 1. Nocturia was present in 50 & respiratory paralysis in 8. Mean MDRD eGFR was 79±59 ml/min/1.72m^2; 36 had eGFR <60ml/min/1.72m^2. 44% reported similar attacks in past. 1 pt died. Mean BP was 112±16 mm/Hg. Mean serum K+ at presentation was 2.5±0.05 mEq/L. Mean urinary K+ loss was 15±11 mEq/L. ABG analysis revealed metabolic acidosis in 10; 18 pts had severe metabolic alkalosis & developed carpopedal spasm following K+ correction. Almost half (48%) were agricultural laborers, 34% reported exposure to pesticides, 56% reported excessive sweating at work, and 13% had loose stool; all but 1 pt denied intake of drugs known to produce HK. Our center is located in South India with a tropical climate with average temperatures up to 39^{0}C from March to August. All pts lived in rural settings & were of low socioeconomic status. Rice was their staple diet, consumed thrice daily with low consumption of high K+ foods (meat, vegetables & fruits).

Conclusions: We report, for the first time from rural south India, a high incidence of hypokalemic paralysis possibly related to very low dietary K+ coupled with excessive loss in sweat. We hypothesize that extremely low dietary K+ coupled with excessive loss of K+ in sweat resulted in severe HK±CKD (likely from hypokalemic nephropathy). Further investigation into the epidemiology and etiology of this possible endemic is planned.

Low Dietary Potassium Intake Is Associated with an Increased Risk of Metabolic Syndrome in US Adults

Shailendra Sharma,[1] M. Chonchol,[1] Jessica B. Kendrick.[1,2] *[1]University of Colorado School of Medicine, Aurora, CO; [2]Denver Health Medical Center, Denver, CO.*

Background: High dietary potassium intake decreases blood pressure levels and decreases the risk of cardiovascular disease but the relationship between potassium intake and metabolic syndrome (MetS) has not been examined.

Methods: We performed a cross-sectional study using the National Health and Nutrition Examination Survey (1999-2007). A total of 25,754 US adult participants with dietary data were included in the analysis. Dietary potassium intake was calculated from 24-hour dietary recall obtained by trained interviewers. Potassium intake was examined

in quartiles 1-4 (≤1701, 1702-2415, 2416-3290, >3290 mg/day). The primary outcome was MetS defined according to recent guidelines from the National Cholesterol Education Program. Multivariate logistic regression models were used to examine the association between potassium intake and MetS.

Results: The mean (SE) age of participants was 45 (0.3) years. The mean (SE) potassium intake was 2718 (18) mg/day. Participants in the lowest quartile of potassium intake were more likely to be female, to be black, and to have lower years of education than subjects in the higher quartiles of potassium intake. 6,118 (23.8%) participants met the diagnostic criteria for MetS. Subjects with MetS were older, had higher systolic blood pressure and lower estimated glomerular filtration rate (eGFR) than subjects without MetS. After adjustment for age, sex, race, smoking status, body mass index, eGFR, and serum albumin, subjects in the first quartile of potassium intake had a 35% increased risk of MetS compared to subjects in the fourth quartile (OR 1.35, 95% Confidence Interval [CI] 1.16 to 1.57). Subjects in the second quartile of potassium intake also had an increased risk of MetS compared to subjects in the fourth quartile (OR 1.22, 95% CI 1.06 to 1.40).

Conclusions: Low dietary potassium intake is associated with an increased risk of metabolic syndrome in US adults. Interventional studies are needed to determine if increasing dietary potassium intake reduces the risk of metabolic syndrome.

Funding: NIDDK Support

FR-PO292

Dietary Potassium Intake and Risk of Metabolic Syndrome Hajeong Lee,[1] Jeonghwan Lee,[1] Nam Ju Heo,[2] Jin Suk Han.[1] *[1]Department of Internal Medicine, Seoul National University Hospital, Korea; [2]Department of Internal Medicine, Healthcare System Gangnam Center, Seoul National University Hospital, Korea.*

Background: Higher potassium intake is related to lower blood pressure and subsequent cardiovascular outcomes. Recent studies revealed that lower dietary potassium was associated with new onset diabetes. However, only few studies have investigated the effect of potassium intake on metabolic syndrome (MS).

Methods: To investigate dietary potassium intake in relation to risk of MS, the Korean National Health and Nutritional Examination Survey data from 2008 to 2010 were obtained. Among 29,235 participants, 19,193 adults who performed dietary survey were included. MS was defined as ATP III guideline. To estimate the insulin resistance (IR), homeostasis model assessment indices were calculated and their highest quartile was defined as IR group.

Results: Individuals with higher potassium intake showed lower risk of MS (*P=0.002*) in women, but not in men (*P=0.161*). After multivariate adjustment such as age, body mass index, smoking and alcohol intake, physical activity, education, income, frequencies of vegetables and fruit intake, and carbohydrate energy ratio, highest quartile group of potassium intake was associated with lower risk of MS (odds ratio [OR] 0.739; 95% confidence interval [CI] 0.626-0.873, *P<0.001*) in women. Among the 5 components of MS, this association was maintained only in the hypertriglyceridemia (OR 0.710, 95% CI 0.612-0.823, *P<0.001*). Especially, women without both diabetes and hypertension (OR 0.566, 95% CI 0.439-0.730, *P<0.001*) or with postmenopausal state (OR 0.728, 95% CI 0.597-0.886, *P=0.002*) showed more protective effect of potassium on MS. Furthermore, highest potassium quartile group was an independent protective factor for IR (OR 0.804, 95% CI 0.693-0.933, *P=0.004*). In men, potassium intake was not associated with MS or IR.

Conclusions: Our findings suggest that higher potassium intake is significantly associated with lower risk of MS in women of general population and IR is thought to be participated in the relationship. These results support the recommendations for higher consumption of potassium rich foods to prevent cardiovascular diseases in another aspect.

FR-PO293

Ion Selective Electrode and the Anion Gap (AG): What Should Be the Normal Gap? Rendell E. Manalo, Seyed-Ali Sadjadi, Navin Jaipaul, James I. McMillan. *Nephrology Section, Jerry L Pettis VA Medical Center, Loma Linda, CA.*

Background: For more than 30 years, US labs have used ion selective electrode (ISE) for measurement of serum electrolytes and it is well known that use of ISE is associated with higher serum chloride and lower serum AG. We and others reported on this issue over 20 years ago that the range of the gap is much narrower with ISE than with flame photometery technique. However major journals and textbooks continue to quote the old value of 12±4 meq/L for normal AG.

Methods: We retrospectively reviewed hospital records of 409 patients with eGFR ≥60 mL/min/1.73 m^2 BSA, 68 patients with ESRD, and 299 patients with serum lactate level ≥4 mmol/L in a single medical center. Data were collected and analysed on age, serum electrolytes, BUN, creatinine, albumin, and comorbidites of these patients.

Results: In patients with normal renal function and serum albumin, the mean serum AG was 7.2±2.0 meq/L, with 95% confidence interval (CI) of 3-11 meq/L. Assuming that the negative charge of albumin contributes 75% of the AG, every gram of serum albumin accounted for 1.35 meq/L of the gap. The mean anion gap was 12.4±3.2 meq/L in ESRD patients with mean serum albumin of 3.4 g/dL, and 12.8± 9.5 meq/L in patients with lactic acidosis and a mean serum albumin of 2.4 g/dL. We queried a few hospital labs and found that many of them do not have an established AG reference range of their own and use the manufacturer recommended AG of 10 to 20 meq/L.

AG in patients with normal kidney function, ESRD, and lactic acidosis

Condition	Number of patients	AG± SD, meq/L	Albumin, g/dL	AG albumin corrected, meq/L
Normal function	409	7.2±2.0	≥4.0	
ESRD	68	12.4±3.2	3.4	13.2
Lactic acidosis	299	12.8±9.5	2.4	15.0

Conclusions: 1) Mean serum AG in patients with normal kidney function is 7.2±2 meq/L with 95% CI of 3-11 meq/L. In ESRD and lactic acidosis, it is 12.4±3.2 meq/L and and 12.8±9.5 meq/L, respectively. 2) Every gram of albumin accounts for 1.35 meq/L of the gap, much lower than the current standard of 2.5 meq/L. 3) Many labs do not have an established range for AG. 4) Current levels for AG are too high and need to be lowered to alert clinicians to the presence of acid/base disorders.

Detection of Novel Interstitial Large Deletions in the ATP6V0A4 Gene and Mutations in the ATP6V1B1 Gene in Patients with Distal Renal Tubular Acidosis Ken-ichiro Miura,[1] Takashi Sekine,[1] Yutaka Harita,[1] Junko Takita,[1] Kazuhiro Takahashi,[1] Masayuki Ishihara,[2] Masataka Hisano,[3] Takashi Igarashi.[1] *[1]Pediatrics, University of Tokyo, Tokyo, Japan; [2]Pediatrics, Kochi Medical School, Nankoku, Kochi, Japan; [3]Pediatric Nephrology, Chiba Children's Hospital, Chiba, Japan.*

Background: Mutations in the ATP6V1B1 and the ATP6V0A4 genes, most of which are nonsense or missense mutations, have been reported to cause primary autosomal recessive distal renal tubular acidosis (dRTA). However, interstitial large deletions of either gene in patients with dRTA have not been described thus far.

Methods: A total of 11 Japanese patients with primary dRTA from 9 unrelated kindreds were enrolled in this study. Exon and exon-intron boundaries of the ATP6V1B1 and the ATP6V0A4 genes were analyzed by direct DNA sequencing and quantitative PCR using genomic DNA purified from peripheral blood leukocytes. Clinical features were also analyzed.

Results: Three novel mutations in the ATP6V1B1 gene were identified in 2 kindreds, including frameshift, in-frame insertion, and nonsense mutations. Interstitial large deletions in the ATP6V0A4 gene were identified in 2 kindreds; in one patient, genomic PCR product of exon 15 was not amplified, and PCR covering wide region around exon 15 confirmed compound heterozygous deletions of 3.7 kb and 6.9 kb nucleotides including whole exon 15. In the other patient, only one heterozygous frameshift mutation was identified by direct DNA sequencing. Subsequent quantitative PCR indicated that the region from N-terminus to exon 8 was deleted in the other ATP6V0A4 allele. It should be noted that 4 out of 6 patients whose data were available presented with hyperammonemia at onset.

Conclusions: We described the first cases with interstitial large deletions involving whole one or more exons in the ATP6V0A4 gene in patients with dRTA. Long genomic PCR as well as quantitative genomic PCR analyses should be considered to detect such large deletions. It also should be noted that hyperammonemia is a frequent manifestation in dRTA at onset.

Effects of Dietary Sodium Citrate on Expression of Sodium Transporter and Fibrosis in CRF Rat Kidneys Sejoong Kim,[1] Jinyoung Yang,[1] Shin-young Ahn,[1] Jeonghwan Lee,[2] Nam Ju Heo,[2] Ki Young Na,[1] Jin Suk Han.[2] *[1]Internal Medicine, Seoul National University Bundang Hospital, Seongnam, Korea; [2]Internal Medicine, Seoul National University College of Medicine, Seoul, Korea.*

Background: Metabolic acidosis is associated with the progression of renal disease. Citrates as alkaline agents may affect renal acid-base transporters. However, there are few reports on the role of dietary sodium citrate on expression of those transporters in chronic renal failure rat kidneys.

Methods: Sprague-Dawley rats consumed dietary sodium citrate (NaCitrate) or sodium chloride (NaCl) with 20% casein after a 5/6 nephrectomy, and were sacrificed at week 4 and week 8.

Results: After undergoing the casein diet, the NaCitrate-treated group had higher levels of serum bicarbonate than the control group. At week 4, the glomerular filtration rate in the NaCitrate group was higher than that in the NaCl group. Tubulointerstitial damage at week 4 and in the NaCitrate-treated group were less severe, and the difference became prominent at week 8, compared to controls. Urinary sodium excretion rate in the NaCitrate-treated group was faster than in the control group. Sodium/hydrogen exchanger type 3 (NHE3) expression in the NaCitrate-treated group was significantly decreased at week 4 and week 8. However, H-ATPase and sodium/bicarbonate cotransporter expression was not different between the two groups. Endothelin-1 levels in the kidney were also decreased in the NaCitrate-treated group, compared to the control group.

Conclusions: We found that dietary sodium citrate may correct metabolic acidosis, enhance urinary sodium excretion rate, and reduce the renal expression of endothelin-1, which may be associated with the altered expression of NHE3 in the remaining kidney.

FR-PO296

Clinical Characteristics and Mutational Pattern of Genetically-Proven Gitelman's Syndrome Takeshi Ninchoji,[1] Hiroshi Kaito,[1] Kandai Nozu,[1] Koichi Nakanishi,[2] Norishige Yoshikawa,[2] Kazumoto Iijima.[1] *[1]Pediatrics, Kobe University Hospital, Hyogo, Japan; [2]Pediatrics, Wakayama Medical University, Wakayama, Japan.*

Background: Gitelman's syndrome (GS) is inherited salt-losing tubulopathy (SLT) associated with inactivating mutations in *SLC12A3*. Hypomagnesemia, hypocalciuria and normal growth are common symptoms which allow differentiation between GS and another

SLT. However, clinical characteristics of patients with genetically-proven GS have not been fully-clarified, and pathophysiological processes responsible for these symptoms remain to be completely elucidated.

Methods: We retrospectively investigated clinical data from genetically-proven GS patients, These clinical data were compared with those of age-matched control (pseudo-GS), who is present with symptoms clinically identical to GS but no mutation was found in every disease-causing genes of SLT(*SLC12A1*, *KCNJ1*, *BSND*, *CLCNKA*, *CLCNKB,* and *SLC12A3*).

Results: Thirty-one (13 male and 18 female) patients were enrolled in this study. All the patients showed typical findings of diuretic test. Serum magnesium level (sMg) was 1.6±0.1 mg/dl and 13 (42%) patients presented completely normal value. Male patients showed significantly higher sMg than female (1.69±0.07 vs 1.46±0.07; $p<0.05$). Their height was -1.0±0.2 standard deviation (SD) and 29% of them exhibit medically short stature as below -2SD. Seven (54%) of 13 patients with normal s-Mg have the same mutation as L849H, which is located near the C-terminal tail. In contrast, there are no common genetical features about growth impairment. Pseudo-GS patients have significantly lower BMI (16.0±0.8 vs 20.8±0.7 kg/m^2; $p < 0.05$) and lower eGFR (55.6±12.5 vs 121.0±7.9 ml/min/1.73m^2; $p < 0.05$) than GS.

Conclusions: Our study first revealed that it is not unusual for GS patients to show severe growth impairment. Furthermore, it is of special interest that many patients had no overt hypomagnesemia, despite of the physiological confirmation of failure in the function of the transporter responsible for GS. Gender and mutation site may affect serum magnesium level of GS. Our results also indicated it is of much use to check BMI and renal function for exact differentiation between GS and pseudo-GS.

FR-PO297

Dipeptidyl Peptidase-4 Inhibitor Ameliorates PPARγ Agonist-Induced Body Weight Gain via Reduction in Body Fat Mass, but Not Fluid Volume

Takahiro Masuda, Jan Czogalla, Michael A. Rose, Maria Gerasimova, Volker Vallon. *Division of Nephrology, UC San Diego & VA San Diego Healthcare System, San Diego, CA.*

Background: Peroxisome proliferator-activated receptor γ (PPARγ) agonists, like pioglitazone (PGZ), are anti-diabetic drugs used to treat type 2 diabetes, but they can induce fluid retention and body weight (BW) gain. Dipeptidyl peptidase-4 (DPP-4) inhibitors are new anti-diabetic drugs that can enhance renal fluid and Na^+ excretion. Therefore, we examined whether the DPP-4 inhibitor alogliptin (ALG) ameliorates PGZ-induced BW gain.

Methods: Male SV129 mice were treated with vehicle (VEH; repelleted diet), PGZ (220 mg/kg diet), ALG (400 mg/kg diet) or combination of PGZ and ALG (PGZ+ALG) (n=8-10 per group). After 14 days treatment, BW, plasma DPP-4 activity, hematocrit (Hct) and fluid content of abdominal fat pads were measured. Body fluid distribution [total body water (TBW), extracellular fluid (ECF), intracellular fluid (ICF)] and body fat mass (FM) were measured by bioimpedance spectroscopy. * P<0.05 vs VEH; # P<0.05 vs PGZ alone.

Results: Both ALG and PGZ+ALG decreased plasma DPP-4 activity by about 80% vs VEH (each *) while PGZ alone had no effect. PGZ increased, and ALG lowered BW vs VEH (delta BW: 4.2±0.8*, -0.1±0.5*, and 1.7±0.3 %). ALG+PGZ (0.8±0.8 % #) prevented the increase in BW observed in PGZ alone. ALG+PGZ decreased Hct to a greater degree than PGZ alone (46.9±0.9 # vs 49.9±0.3 %; each *) while ALG alone had no effect vs VEH (50.4±0.3 vs 50.8±0.3 %). PGZ tended to increase and ALG+PGZ significantly increased fluid content of abdominal fat pads vs VEH (9.1±0.9, 9.5±0.6*, 7.4±1.0 %). ALG+PGZ increased TBW, ECF and ICF to a similar degree as PGZ alone (in absolute terms and related to BW; each by 10-20% vs VEH; each *). ALG alone had no effect on FM vs VEH (FM/BW: 22.4±1.4 vs 20.5±1.9 %). However, ALG+PGZ decreased FM to lower levels than PGZ alone (7.6±1.0 # vs 13.7±2.4 %; each *; similar results were obtained for absolute values).

Conclusions: Our data suggest that the DPP-4 inhibitor alogliptin ameliorated the BW gain induced by the PPARγ agonist pioglitazone via a reduction in fat mass, but not in fluid retention.

FR-PO298

Chemical Library Screening for Direct SPAK Inhibitors by a Newly Developed ELISA System

Eriko Kikuchi, Takayasu Mori, Kiyoshi Isobe, Eisei Sohara, Tatemitsu Rai, Sei Sasaki, Shinichi Uchida. *Department of Nephrology, Tokyo Medical and Dental Sciences, Bunkyo, Tokyo-to, Japan.*

Background: Pseudohypoaldosteronism type II (PHAII) is an autosomal dominant disease characterized by hypertension, hyperkalemia, and metabolic acidosis. We found that PHAII caused by a WNK4 mutation was caused by the constitutive activation of WNK-OSR1/SPAK-NaCl cotransporter (NCC) signal cascade. In addition to NCC, OSR1/SPAK kinases phosphorylate and activate other Slc12a transporters such as NKCC1 and NKCC2. In fact, the arteries of SPAK knockout mice showed the reduced response to phenylephrine due to the decreased level of NKCC1 phosphorylation. Thus, the inhibition of SAPK kinase is expected to show anti-hypertensive effect at least by dual actions, i.e., NaCl diuresis and vasodilation. The purpose of this study was to develop an efficient system to screen chemical libraries for direct SPAK inhibitors.

Methods: We sought to develop a new screening system of ELISA for SPAK inhibitors. Indirect ELISA system was used to detect NKCC2 phosphorylation as a substrate of SPAK. The amino terminal portion of NKCC2 fused with GST was first coated on ELISA plate. Then, the kinase reaction was optimized using GST-fused whole SPAK and MO25α. The degree of NKCC2 phosphorylation was determined by anti-phosphorylated NKCC2 antibody.

Results: As a result of initial screening of 18,000 compounds owned by Tokyo Medical and Dental University Chemical Biology Screening Center, we could identify several different primary candidates of SPAK inhibitors with reproducibility.

Conclusions: The ELISA assay we established in this study was easy, efficient, and reproducible. The compounds we identified in this screening could be promising seeds for a new type of antihypertensive drug.

Development of Sandwich Enzyme Linked Immunosorbent Assay for Measurement of Urinary Total and Phosphorylated Na-Cl Cotransporter Protein

Kiyoshi Isobe, Eisei Sohara, Tatemitsu Rai, Sei Sasaki, Shinichi Uchida. *Department of Nephrology, Graduate School of Medicine, Tokyo Medical and Dental Sciences, Tokyo, Japan.*

Background: Thiazide-sensitive sodium chloride cotransporter (NCC) localizes to the apical membrane of the distal convoluted tubule (DCT) in kidney, and was responsible for reabsorbing 5–10% of the filtered load of sodium chloride. Pseudohypoaldosteronism type II (PHAII) is an autosomal-dominant disorder characterized by hyperkalemia and hypertension. By analyzing the pathogenesis of PHAII, we discovered that WNK-OSR1/SPAK kinase cascade is a powerful regulator of NCC. NCC phosphorylated by OSR1/SPAK kinases was shown to be functionally active and increased on the apical plasma membranes of DCT. Since NCC protein is known to be excreted in urine, we hypothesized that NCC excretion in urine could be a biomarker for estimating NCC activity in vivo.

Methods: In order to investigate this hypothesis, sensitive, reproducible, and quantitative methods measuring urinary total NCC (tNCC) and phosphorylated NCC (pNCC) are necessary. In this study, we developed sandwich ELISA methods to measure as low as 1 pmol/ml and 0.1 pmol/ml of tNCC and pNCC in human urine, respectively.

Results: The amount of tNCC and pNCC measured by the sandwich ELISA was well correlated with the data obtained by the immunoblots ($r=0.94$, $p<0.0001$, $r=0.95$, $p<0.0001$, respectively). We also found that pNCC concentration in spot urine samples remained constant within a day when they were corrected by respective creatinine concentration, suggesting that single spot urine can be used to estimate total excretion of pNCC for 24 hours. Urinary tNCC and pNCC from normal healthy volunteer is 241.8±29.2 fmol/mgCr and 50.1±5.3 fmol/mgCr, respectively (n=13, mean±S.E.M). We also confirmed that urine NCC excretion varied according to different salt intake. Finally, we could also detect the increased tNCC and pNCC urinary excretion in the *Wnk4*$^{D561A/+}$ mice, a mouse model of PHAII.

Conclusions: These results suggest the utility of this methods to estimate the in vivo activity of NCC.

Post-Operative Outcomes in Dialysis Patients Undergoing Elective or Emergent Non-Cardiac Surgery

Gurmukteshwar Singh, Arley F. Diaz, Philip Huh, Mihaela Stefan. *Baystate Medical Center/Tufts Univ. School of Med., Springfield, MA.*

Background: Renal failure puts patients at a high risk of complications from noncardiac surgery. Existing literature is scant about post operative risks and mortality in dialysis-dependent patients.

Methods: We used the 2007-08 American College of Surgeons-National Surgical Quality Improvement Program to determine the 30 day mortality and post-operative event rates in chronic dialysis patients who underwent abdominal, major vascular and limb amputation surgery. Low risk and dialysis access surgeries were excluded. We also calculated elective vs. emergent surgical outcomes.

Results: 5178 dialysis patients from 189 hospitals were included. 3872 surgeries were elective and 1306 emergent. 87% of the surgeries used general anesthesia. 30 day mortality was 14.3% (elective: 9.7%; emergent: 27.8%). 30% patients had at least one complication. Respiratory failure, surgical site infection/ wound disruption and sepsis were common complications.

30 day post-operative outcomes

	Abdominal		Major Vascular		Amputation		Overall
	Elective	Emergent	Elective	Emergent	Elective	Emergent	
Patients	1316	830	1431	340	1125	136	5178
30 day mortality	124(9.4)	282(34)	109(7.6)	52(15.3)	143(12.7)	29(21.3)	739(14.3)
Respiratory failure	185(14.1)	320(38.6)	104(7.3)	55(16.2)	89(8)	31(22.8)	784(15.1)
Surgical site complication	146(11.1)	106(12.8)	97(6.8)	26(7.7)	65(5.8)	9(6.6)	449(8.7)
Sepsis/septic shock	102(7.8)	79(9.5)	73(5.1)	33(9.7)	80(7.1)	16(11.8)	383(7.4)
Pneumonia	72(5.5)	107(12.9)	40(2.8)	17(5)	63(5.6)	12(8.8)	311(6)
Venous thromboembolism	23(1.8)	38(4.6)	26(1.8)	7(2.1)	17(1.5)	2(1.5)	113(2.2)
Stroke	7(0.5)	18(2.2)	15(1.1)	4(1.2)	11(1)	0	55(1.1)
Cardiac arrest	42(3.2)	56(6.8)	54(3.8)	10(2.9)	50(4.4)	8(5.9)	220(4.3)
Myocardial infarction	10(0.8)	12(1.5)	13(0.9)	2(0.6)	7(0.6)	0	44(0.9)
Transfusion required	23(1.8)	66(8)	30(2.1)	12(3.5)	8(0.7)	5(3.7)	144(2.8)
Mean length of stay(days)	15.4	21.9	10.7	16.6	17.1	22.6	

Parentheses: Incidence (%) within subgroup

Conclusions: Dialysis patients are at an extremely high risk for morbidity/mortality after intermediate and high risk non-cardiac surgeries; more so in emergent surgeries. Our results should help guide informed decision making about surgery in this patient population.

FR-PO301

Hospital Admissions Following Long and Short Interdialytic Intervals among Hemodialysis Patients Tricia L. Roberts,[1] Robert N. Foley,[1,2] David T. Gilbertson,[1] Allan J. Collins.[1,2] *[1]USRDS Coordinating Center, MMRF, Minneapolis, MN; [2]Medicine, University of Minnesota, Minneapolis, MN.*

Background: An increased risk of cardiovascular (CV) hospital admissions after the long (2-day) interdialytic interval among hemodialysis (HD) patients has recently been reported. We assessed this association among a large, current cohort of Medicare HD patients, with additional analysis of all-cause admissions, infectious admissions, and the short (1-day) interdialytic interval.

Methods: Data included 162,672 U.S. Medicare adult prevalent HD patients on January 1, 2010, alive on January 31, and receiving HD three times weekly on a Monday/Wednesday/Friday or Tuesday/Thursday/Saturday schedule. HD schedule was determined from Medicare claims from January 18 to 31, 2010. Follow-up for hospital admissions began on February 1 and continued until censoring at the latest on December 31, 2010. Patients with a bridge hospitalization spanning follow-up were excluded. Infectious and CV admissions were determined by principal ICD-9-CM diagnosis codes. Admission rates by day of the dialysis week were adjusted for age, gender, race, Hispanic ethnicity, and primary diagnosis using the Poisson model and direct adjustment.

Results: For all-cause, CV, and infectious admissions, the highest adjusted rates occurred on the day after the long interdialytic interval (respectively, 2,101, 682, and 501 admissions per 1,000 patient years). The all-cause admission rate on the day after the long interdialytic interval was 1.5 times the rate on days after the short interdialytic intervals (1,412) and 1.9 times the rate on days without HD (1,093). All-cause, CV, and infectious admissions by day of the HD week produced a sawtooth pattern with higher rates on the days with an HD treatment after the long and short interdialytic intervals than on the preceding and following days.

Conclusions: The days after the long and short interdialytic intervals among HD patients were associated with elevated all-cause and infectious admissions in addition to CV. Results suggest a potential need to further evaluate the U.S. standard frequency of HD treatments.

Funding: NIDDK Support

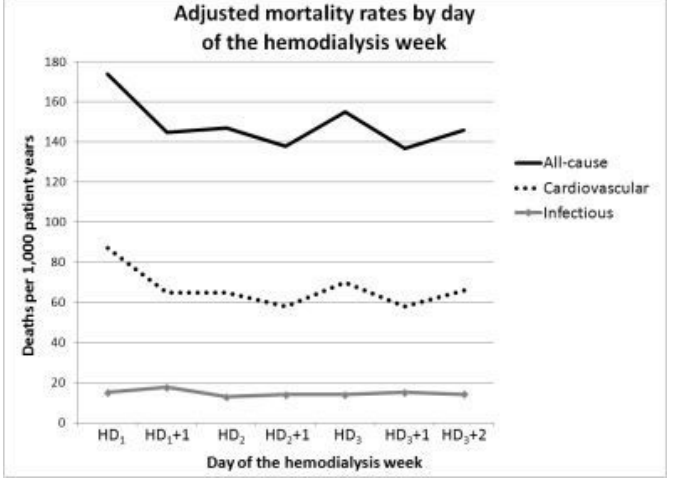
FR-PO302

Mortality Following Long and Short Interdialytic Intervals among Hemodialysis Patients Robert N. Foley,[1,2] Tricia L. Roberts,[1] David T. Gilbertson,[1] Allan J. Collins.[1,2] *[1]USRDS Coordinating Center, MMRF, Minneapolis, MN; [2]Medicine, University of Minnesota, Minneapolis, MN.*

Background: Increased mortality risk following the long (2-day) interdialytic interval has recently been reported among thrice-weekly hemodialysis (HD) participants in the End-Stage Renal Disease Clinical Performance Measures Project. Associations between mortality and long and short (1-day) interdialytic intervals have not yet been assessed in the most recent Medicare cohort.

Methods: We studied 162,679 U.S. Medicare adult prevalent HD patients on January 1, 2010, alive on January 31, and receiving HD three times weekly on Monday/Wednesday/Friday or Tuesday/Thursday/Saturday. Medicare claims from January 18 to 31, 2010, determined the schedule. Follow-up began on February 1, 2010, and was censored at modality change, end of Medicare payer status, recovery of renal function, deviation from HD schedule, loss to follow-up, or December 31, 2010. All-cause, infectious, and CV mortality rates were computed by days of the HD week: HD_1, HD_2, and HD_3 were the first, second, and third HD sessions; HD_1 denoted the day after the long interdialytic interval; and HD_2 and HD_3 were the days after the short intervals. Rates were adjusted for age, gender, race, Hispanic ethnicity, and primary diagnosis with the Poisson model and direct adjustment.

Results: All-cause mortality rates were highest on HD_1 (174 deaths per 1,000 patient years), followed by the days after the short interdialytic intervals (151) and without HD (142). CV mortality also peaked at HD_1 (87), while infectious mortality was highest on the day after the first HD session (18). Patterns of all-cause mortality mirrored CV with generally higher rates on days with HD than days before and after.



Conclusions: The days after the long and short interdialytic intervals were associated with increased all-cause and CV mortality rates.

Funding: NIDDK Support

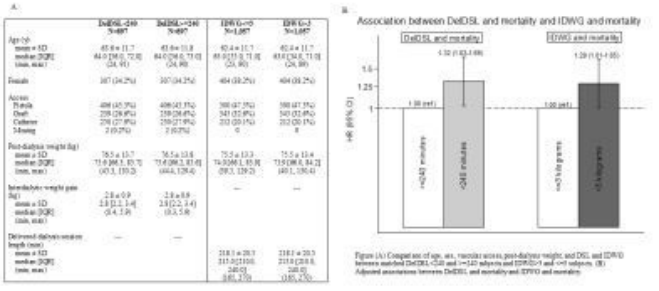
FR-PO303

Disentangling the Ultrafiltration Rate (UFR): Mortality Association: The Roles of Session Length and Weight Gain Jennifer E. Flythe, Steven M. Brunelli. *Brigham and Women's Hospital, Boston, MA.*

Background: Rapid UFRs are associated with increased mortality among hemodialysis (HD) patients. UFR is determined by both interdialytic weight gain (IDWG) and dialysis session length (DSL). Both IDWG and DSL have been linked to mortality, but the relationship of each to mortality, independently of the other, is not defined. This study was designed to evaluate whether shorter DSL independent of IDWG and larger IDWG independent of DSL are associated with mortality.

Methods: Data were taken from a nationally-representative cohort of 11,834 patients undergoing thrice-weekly in-center HD at one large dialysis organization who had adequate urea clearance (URR>=65%). Patients with delivered session length (DelDSL) >=240 and <240 minutes were pair-matched on IDWG (+/- 1.5 kg), and patients with IDWG <=3 and >3 kilograms were pair-matched on DelDSL (+/- 5 minutes), as well as on age, sex, vascular access type, and post-dialysis weight, resulting in near perfect balance (Figure A).

Results: DelDSL<240 was associated with increased mortality: adjusted HR (95% CI) 1.32 (1.03-1.69) when compared to DelDSL >=240 minutes; IDWG >3 was associated with increased mortality: 1.29 (1.01-1.65) compared to IDWG <=3 kilograms (Figure B). All associations were consistent across strata of age, sex, post-dialysis weight; the IDWG--mortality association was similar across DelDSL strata (p-interaction=0.17); the DelDSL--mortality association was similar across IDWG strata (p-interaction=0.56).



Secondary analyses indicated dose-response trends in the associations of DelDSL and IDWG with mortality (not shown).

Conclusions: Among patients with adequate urea clearance, shorter DelDSL and greater IDWG are associated with increased mortality. Both DelDSL and IDWG play important and independent roles in mediating the UFR--mortality relationship.

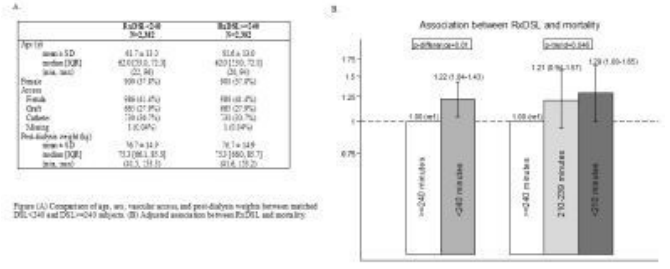
FR-PO304

Shorter Prescribed Dialysis Session Length (RxDSL) Is Associated with Increased Mortality Independent of Body Weight Jennifer E. Flythe, Steven M. Brunelli. *Brigham and Women's Hospital, Boston, MA.*

Background: Prior studies have demonstrated that shorter RxDSL is associated with greater mortality. However, these observations may have been confounded by body size differences among patients with longer and shorter RxDSL. This study was designed to test the hypothesis that shorter RxDSL is associated with greater all-cause mortality independently of body weight.

Methods: Data were taken from a nationally-representative cohort of 10,571 patients undergoing thrice-weekly in-center hemodialysis (HD) at one large dialysis organization who had adequate urea clearance (URR≥65%). Patients with RxDSL ≥240 and <240 minutes were pair-matched on post-dialysis weight (±1 kg), as well as on age, sex, and vascular access type, resulting in near-perfect balance (Figure A).

Results: RxDSL < 240 was associated with greater mortality: adjusted HR (95% CI) 1.22 (1.04-1.43; p=0.01) when compared to RxDSL ≥ 240 minutes (Figure B). A similar trend was observed when RxDSL was considered in categories of < 210, 210-239 and ≥ 240 minutes (p-trend=0.046; Figure B). Restriction subgroup analyses demonstrated that the association between RxDSL and mortality was similar regardless of age (p-interaction=0.53), sex (p-interaction=0.80), race (p-interaction=0.79), and post-dialysis weight (p-interaction=0.89).



Conclusions: RxDSL<240 minutes is associated with increased mortality in chronic HD patients with adequate urea clearance independently of body size. This association follows a dose-response pattern: incrementally shorter sessions are associated with higher hazard.

Left Atrial Volume Is an Independent Predictor of All-Cause Mortality in Chronic Hemodialysis Patients Kosaku Nitta. *Department of Medicine, Kidney Center, Tokyo Women's Medical University, Shinjuku-ku, Tokyo, Japan.*

Background: An enlarged left atrium (LA) has recently been identified as a risk factor for adverse cardiovascular outcomes in various pathologic conditions. However, few studies have valuated its prognostic value in hemodialysis (HD) patients.

Methods: We conducted an observational study to investigate whether an enlarged LA predicted all-cause mortality in 174 HD patients. Patients were stratified into two groups based on the LA volume index (LAVI) value of 32 mL/m^2.

Results: An increased left atrial volume index (LAVI >32 mL/m^2) was present in 28 (16.1%) of the HD patients. During the follow-up period (50.1 ±22.4 months), 77 patients (44.3%) died. A Kaplan–Meier analysis revealed that the 7-year survival rate was significantly lower in the group whose LAVI was >32 mL/m^2 than in the group whose LAVI was ≤32 mL/m^2 (*P =0.0033*). Multivariate analyses adjusted for echocardiographic parameters and clinical and laboratory data showed that increased LAVI was an independent predictor of all-cause mortality (hazard ratio 1.030, 95% confidence interval 1.004–1.056,*P =0.0260*). Moreover, increased LAVI had a higher predictive value for all-cause mortality (area under the receiver operating characteristic curve =0.612, *P = 0.0059*) among the measured echocardiographic parameters.

Conclusions: The results of the present study suggested that measurement of LAVI may be helpful in the risk stratification of HD patients and in providing therapeutic direction for their management.

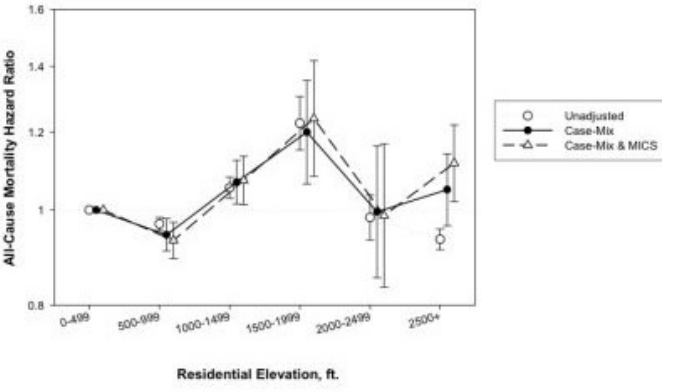
FR-PO306

Association between Altitude and All-Cause Mortality in Maintenance Dialysis Patients Bryan B. Shapiro,[1] Elani Streja,[1] Miklos Zsolt Molnar,[1,2] Joel D. Kopple,[3] Kamyar Kalantar-Zadeh.[1,3] *[1]Harold Simmons Center, LA BioMed at Harbor-UCLA, Torrance, CA; [2]Institute of Pathophysiology, Semmelweis University, Budapest, Hungary; [3]Nephrology, Harbor-UCLA, Torrance, CA.*

Background: Higher residential altitude has previously been reported to be associated with a reduction in all-cause mortality in incident dialysis patients, believed to be attributable to enhanced availability of iron due to hypoxia at high altitudes.

Methods: Using 5-year patient data of a large dialysis organization, we linked all-cause mortality according to patient zip codes to a database containing average residential altitudes for 43,191 zip codes in the United States. We identified 153,334 hemodialysis (HD) patients. Mortality risks were estimated by Cox regression (hazard ratio [HR]).

Results: Patients were 48±14 years old and included 39% women and 35% diabetics. Relative to patients living in low-altitudes (<500 ft), patients residing in the highest altitude sextile were associated with a 12% (HR:1.12[1.02-1.22]) increase in case-mix and malnutrition-information complex (MICS) adjusted mortality risk. However, no clear trend was found between higher altitudes and variation in all-cause mortality at baseline or when adjusted.



Conclusions: No clear association exists between altitude and all-cause mortality in dialysis patients. These data seems to contradict earlier findings indicating that high altitudes are associated with reduced mortality in incident dialysis patients.

Funding: Other NIH Support - R01 DK078106, K24 DK091419

FR-PO307

Increased Mortality Risk of Serum Alkaline Phosphatase: Relation to Changes in Body Composition in Hemodialysis Patients Neal Mittman, Brinda Desiraju, Jyotiprakas Chattopadhyay, Morrell M. Avram. *Avram Division of Nephrology, S.U.N.Y. Downstate Medical Center UHB at Long Island College Hospital, Brooklyn, NY.*

Background: Higher levels of alkaline phosphatase (AlkP) have been associated with increased mortality in hemodialysis (HD) patients (pts). We examined the associations of AlkP with clinical and biochemical status in our HD pts, including body composition.

Methods: Sixty-four HD patients were enrolled in this study beginning in 2000. On enrollment, demographics, clinical data and biochemical data were recorded. Patients were followed up to the end of 2011. Body composition parameters were determined by bioimpedance analysis (BIA).

Results: The mean age was 62 years. Fifty-eight percent were female, and the majority (76%) were of African descent. Forty percent were diabetic. Mean and median AlkP were 122 U/L and 88.5 U/L, respectively, with a very wide range. Thirty-nine percent of patients had elevated levels. Levels of AlkP were not influenced by age, race, gender or diabetic status. Correlations of AlkP with biochemical and body composition variables are shown in Table1.

Correlations of Serum AlkP with Biochemical and Body Composition Parameters

Variable	Correlation coefficient	p-value
Albumin-Corrected Calcium (mg/dL)	0.31	0.02
Intact Parathyroid Hormone (pg/mL)	0.42	0.004
Body Mass Index (Lbs/inch^2)	0.32	0.039
Total Body Fat (Lbs)	0.44	0.004
Extracellular Water (Lbs)	0.39	0.014

Not surprisingly, AlkP correlated directly with serum intact parathyroid hormone and with albumin-corrected calcium. In addition, serum AlkP was directly correlated with extracellular water (ECW), body mass index (BMI), and body fat. In Cox's multivariate analysis, AlkP, above vs. below mean value, was a strong independent predictor of mortality risk (RR: 13.6, p=0.016), imparting a 14-fold greater risk. ECW was also an independent mortality predictor (RR: 1.141, p=0.004), imparting 14% increased risk per lb increase.

Conclusions: Higher AlkP in these HD pts, with increased body fat relative to lean body mass and increased extracellular water, may be partly explained by hepatic congestion related to volume overload or cardiac dysfunction, or both, which may be factors in the associated mortality risk.

Association of Physical Activity with Survival among Ambulatory Patients on Dialysis: The Comprehensive Dialysis Study Kirsten L. Johansen, George A. Kaysen, Lorien S. Dalrymple, Barbara A. Grimes, Glenn M. Chertow. *USRDS Nutrition Special Studies Center, San Francisco, CA.*

Background: Despite high mortality and low levels of physical activity among patients starting dialysis, the link between low physical activity and mortality has not been carefully evaluated in this population.

Methods: The Comprehensive Dialysis Study was a cohort study performed by the United States Renal Data System Nutrition and Rehabiliation/QOL Special Studies Centers. 1678 patients were enrolled from a random sample of 297 dialysis facilities in the US during June, 2005 through June, 2007, of whom 1554 ambulatory patients were included in this analysis. To determine the association between physical activity and mortality, we estimated physical activity using the Human Activity Profile (HAP) and used multivariable

Cox proportional hazards modeling. We followed patients until death or September 30, 2009. Outcome measures were all-cause mortality and death or first hospitalization.

Results: The average age of participants was 59.8 (14.2) years; 55% were male, 28% African American, and 56% had diabetes mellitus. The majority of participants (57.3%) were estimated to have low fitness based on HAP score. The median follow-up was 2.6 (interquartile range 2.2 to 3.1) years. The association between physical activity and mortality was linear across the range of scores (1 to 94). After adjustment for age, sex, race, dialysis modality, and comorbid conditions, lower Adjusted Activity Score on the HAP was associated with higher mortality (HR 1.30, 95% CI 1.23 to 1.39 per 10 points). Patients in the lowest level of fitness experienced a 3.5-fold (95% CI 2.54 to 4.89) increase in risk of death compared to those with average or above fitness. Less active patients were also at significantly increased risk of death or first hospitalization.

Conclusions: Low levels of physical activity are strongly associated with mortality among patients new to dialysis. Interventions aimed to preserve or enhance physical activity should be prospectively tested.

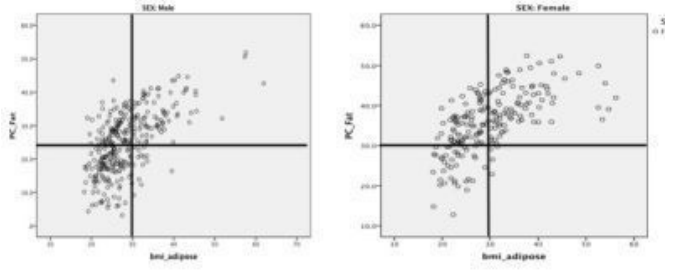
FR-PO309

Comparison of Prevalence of Obesity Based on BMI and Body Fat among HD Patients Kirsten L. Johansen, Glenn M. Chertow, George A. Kaysen, Lorien S. Dalrymple. *USRDS Nutrition Special Studies Center, San Francisco, CA.*

Background: Although the association of obesity with outcomes has been intensely studied among patients on HD, the extent to which the standard BMI-based definition of obesity derived in healthy populations is applicable to dialysis patients has not been addressed.

Methods: The USRDS Analyses Designed to Investigate the Paradox of Obesity in ESRD (ADIPOSE) is a prospective cohort study that enrolled prevalent patients on HD from the San Francisco and Atlanta areas from 6/09 to 8/11. Height, weight, and waist circumference were measured and bioelectrical impedance spectroscopy (BIS) performed before a midweek dialysis session. Designation of obesity by BMI (≥30 kg/m^2) was compared to obesity based on percent body fat by BIS (≥25% for men, 30% for women); waist circumference (>40 in for men, 35 in for women) was also compared to % body fat.

Results: The mean (sd) age was 56 (14) years (n=520), 40% were women, 58% black. Overall, 36.5% were obese by BMI, 62.5% by % fat, and 54.8% by waist circumference; women were more likely to meet all three criteria (45% vs. 31% for BMI; 80% vs. 51% by % fat; 74% vs. 57% by waist). More women were misclassified by BMI (39% vs. 30% of men, p=0.04); both sexes were more likely to be underidentified as obese by BMI (upper left quadrant) than overidentified (lower right quadrant) (Figure).



Misclassification was less using waist circumference (women 26%, men 24%). Misclassification by BMI differed by age and was greater among older (>65) compared with younger (47% vs. 29%, p<0.0001) but did not differ statistically by race.

Conclusions: BMI identified considerably fewer patients as obese than criteria based on estimation of body fat, particularly among women and older patients, 80% and 74% of whom were obese based on body fat, respectively. Waist circumference performed slightly better than BMI.

FR-PO310

Differences in Mortality between Hispanic and Non-Hispanic Whites Initiating Dialysis in the United States Maria Cristina Arce,[1] Benjamin A. Goldstein,[2] Aya Alice Mitani,[2] Wolfgang C. Winkelmayer.[1] *[1]Division of Nephrology, Stanford University School of Medicine, Palo Alto, CA; [2]Division of General Medical Disciplines, Stanford University School of Medicine, Palo Alto, CA.*

Background: Hispanic patients undergoing chronic dialysis experience better survival compared with non-Hispanics. It is unknown, however, whether this association differs by age, has changed over time, or is due to differential access to kidney transplantation.

Methods: Using the U.S Renal Data System, we identified 615,618 Caucasians who initiated dialysis between 1/1/1995 and 12/31/2007 and investigated the temporal trends in relative mortality, stratified by age, between Hispanics and non-Hispanic whites initiating dialysis. All-cause mortality was analyzed using proportional hazards regression and estimating unadjusted and adjusted cause-specific hazard ratios (HR_{CS}) and subdistribution (competing risk analysis) hazard ratios (HR_{SD}) with corresponding 95% confidence intervals (CI).

Results: We found that Hispanics initiating dialysis experienced a lower mortality but age modified this association (P<0.001). Compared with non-Hispanics, mortality among Hispanics was 35% lower at ages 18-39 (HR_{CS}=0.65; 95%CI, 0.62-0.69) and 40-59 (HR_{CS}=0.65; 95%CI, 0.64-0.67), and 20% lower at ages 60-79 (HR_{CS}=0.80; 95%CI, 0.79-0.81), and 7% lower at age ≥80 years (HR_{CS}=0.93; 95%CI, 0.91-0.96). When accounting for the differential rates of transplantation, the associations were markedly attenuated in the younger age strata—the survival benefit for Hispanics was reduced from 35% to 14% at ages 18 to 39 years (HR_{SD}=0.86; 95% CI, 0.82-0.91) and from 35% to 21% among those aged 40 to 59 years (HR_{SD}=0.79; 95% CI, 0.77-0.80).

Conclusions: Overall, Hispanics experienced a lower mortality but the association decreased with older age. Interestingly, competing risk analyses attenuated these findings suggesting that differential access to kidney transplantation was responsible for much of the apparent survival benefit among Hispanics.

Weakness of Propensity Score Matching in the Comparison of Mortality on Hemodialysis versus Peritoneal Dialysis from Registry Data Maurizio Nordio, Gianpaolo Amici, Mariano Feriani, Barbara Rossi, Nicola Tessitore. *Veneto Dialysis and Transplantation Registry, Padua, Italy.*

Background: The only RCT comparing hemodialysis (HD) and peritoneal dialysis (PD) survival was inconsistent for unsuccessful recruitment. Recently many observational studies using propensity score as causal inference methodology were performed. Their results were heterogeneous. The aim of the study was to investigate this heterogeneity.

Methods: We considered the cohort of incident dialysis patients from 1/1/1998 to 31/12/2010 in Veneto Region with demographic characteristics, prevalent dialysis modality, primary renal disease and comorbidities. A propensity score matching was performed using nearest neighborg. Since 32% of PD patients and 13% of HD patients were transplanted, a competing risk (death and transplantation) survival analysis was performed to avoid informative censoring. The treatment effect was compared by Gray's test and competing risks regression. The Rosenbaum approach was used to perform sensitivity analysis.

Results: 6962 patients were recruited in the considered period, 77.5% were on HD and 22.5% on PD. 1070 subjects on PD and 1998 on HD were matched. The common support covered patients achieving a probability from 2.4% to 51.3% to be offered PD. The cumulative incidence of death was significantly different with a mortality of 68% on HD and 48% on PD at 10 years, but the effect became non significant (SHR = 0.92, CI 95% : 0.78 -1.03) after adjustment. The patients out of the common support showed fewer comorbid conditions and a female excess. Sensitivity analysis showed that the study was sensitive to a hidden bias increasing only by 20% the odds.

Conclusions: Dialysis modality does not affect survival. Sensitivity analysis shows that the propensity score is not robust to hidden bias. The effect may significantly change simply considering different populations or other factors. This behavior may be due to the presence of important unknown confounders not included in propensity score as well as to a weak treatment effect. The heterogeneity of patients out of common support undermine the external validity of this approach, underlining the necessity of a RCT.

FR-PO312

Predictors of Mortality in the First 90 Days of Dialysis in an Asian Dialysis Cohort Sabrina Haroon,[1] Horng Ruey Chua,[1] Nan Luo,[2] Boon Wee Teo,[1] Evan J.C. Lee,[1] Titus W. Lau.[1] *[1]Division of Nephrology, National University Health System, Singapore; [2]School of Public Health, National University of Singapore, Singapore.*

Background: Dialysis served as life saving therapy for end stage renal failure (ESRF) patients. However, it is resource intense and appropriate counseling with regards to prognosis is essential and ethical. Knowing the various predictors of early mortality will help guide risk counseling in starting dialysis.

Methods: This is a retrospective study of all incident ESRF patients that were started on dialysis from Jan 1, 2005 to Dec 31, 2010. SAS was used for all statistical analyses. All plausible mortality risk factors were included in the final model to determine predictors of early mortality (90-day mortality) using logistic regression analysis.

Results: A total of 870 patients were included in this study. There were a total of 92 deaths (10.6%) within 90 days of starting dialysis. The predictors of interest included were age (< 45 years being the reference; 45-<65; >=65); diabetic status; gender; presence of various co-morbiodities - ischemic heart disease, stroke, periphery vascular disease with and without amputation; hemoglobin level; serum albumin level; serum phosphate level and if patient was initiated on dialysis with a ready access (AV fistula/graft or Tenkhoff catheter). Results of our analysis showed that older age (> 65 years) (OR 6.68 95% CI 1.93-23.16, p = 0.0027) and periphery vascular disease with amputation (OR 3.12 95% CI 1.41-6.93, p = 0.0051) were independently associated with higher risk of first 90 days mortality after initiating dialysis. Co-morbidities such as diabetes, history of ischemic heart disease, stroke or periphery vascular disease without amputation did not independently predict early mortality. Starting dialysis with a planned access reduces the risk of early mortality significantly (OR 0.27 95% CI 0.13-0.55, p = 0.0003).

Conclusions: Any patient above age 65 years with amputation due to periphery vascular disease has a high risk of early mortality on dialysis and should take this into consideration when deciding for maintenance dialysis. This risk is mitigated by planning an access early and initiating dialysis with a planned access.

FR-PO313

Characteristics and Mortality among Young Adults with Incident End-Stage Renal Disease (ESRD) in the United States Brett W. Plattner, Debbie S. Gipson, Hal Morgenstern, Rajiv Saran, Yi Li, Ying Qian, Valarie B. Ashby. *University of Michigan.*

Background: Despite evidence for heterogeneity of the US ESRD population by age, young adult patients (ages 19-35) have received little attention by researchers. Our aims were to describe this population, compare it with patients diagnosed at other ages, and identify risk factors for mortality.

Methods: 85,839 young adult ESRD patients diagnosed from 1995 to 2011 were identified from the CMS national data. Cox regression was used to examine associations between demographic and clinical characteristics and all-cause mortality between diagnosis and 12/31/11.

Results: 42% of the patients were black, compared with 28% of patients diagnosed before age 19 and 28% diagnosed after age 35. Glomerulonephritis (26%), diabetes (25%), and HTN (20%) were the leading causes of ESRD. The majority (87%) utilized hemodialysis (HD), compared to 56% of patients diagnosed before age 19 and 92% diagnosed after age 35. The adjusted hazard ratio (HR) was greatest for blacks, a diabetes etiology, HD patients, and those with cardiovascular or drug-dependency comorbidities.

Demographics and Adjusted HR for ESRD Pts Ages 19-35

Predictor	N	%	Adjusted HR* (95%CI)
Race			
White	42344	49	1 (ref)
Black	36179	42	1.14(1.11,1.18)
Asian	3982	5	0.48(0.44,0.56)
Native American	1186	1	0.81(0.72,0.89)
Sex			
Male	48284	56	1 (ref)
Female	37555	44	1.11(1.08,1.14)
Etiology of ESRD			
Diabetes	21303	25	1(ref)
HTN	17451	20	0.4(0.39,0.42)
Lupus	6307	7	0.57(0.54,0.61)
GN(except Lupus)	22582	26	0.51(0.49,0.53)
Modality			
HD	74825	87	1(ref)
PD	10724	12	0.86(0.82,0.90)
CHF	2629	10	1.27(1.23,1.32)
Atherosclerotic Heart Disease	2015	2	1.19(1.11,1.28)
Other Cardiac	26292	3	1.27(1.19,1.36)
PVD	2240	3	1.22(1.14,1.29)
Drug Abuse	2580	3	1.49(1.40,1.58)

*HR adjusted for age,BMI, Hispanic ethnicity, access type, comorbidities, incidence year and the predictors above. p<.0001 for each predictor

Conclusions: This analysis focuses on young adult dialysis patients. Unexpected findings include low PD utilization, a high prevalence of congestive heart failure, and a higher mortality rate among blacks. Future research should further explore distinct features of young adult ESRD cases to improve the healthcare of this understudied population.

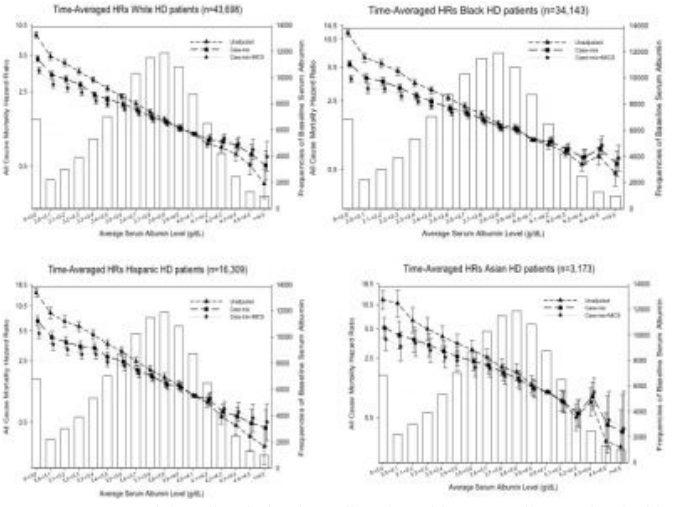
FR-PO314

Association of Serum Albumin and Mortality in Four Races in Hemodialysis Patients Alla Victoroff,[1] Miklos Zsolt Molnar,[1,2] Jennie Jing,[1] Elani Streja,[1] Vanessa A. Ravel,[1] Csaba P. Kovesdy,[3] Joel D. Kopple,[4] Kamyar Kalantar-Zadeh.[1,4] *[1]Harold Simmons Center for Chronic Disease Research & Epidemiology, LABioMed at Harbor-UCLA, Torrance, CA; [2]Institute of Pathophysiology, Semmelweis University, Budapest, Hungary; [3]Nephrology, University of Tennessee, Memphis, TN; [4]David Geffen School of Medicine at UCLA, Los Angeles, CA.*

Background: Low serum albumin level is the strongest mortality-predictor in maintenance hemodialysis (MHD) patients. It is not entirely known whether this association is consistent across all races.

Methods: We examined the association of time-averaged serum albumin and all-cause mortality in 105,523 MHD patients across different race groups using time-dependent Cox models to estimate death hazard ratios for time-averaged serum albumin increments controlled for case-mix, comorbidity, dialysis dose, and available markers of malnutrition-inflammation-complex syndrome (MICS) in all race groups.

Results: The study population consisted of 105,523 patients with mean age of 60±16 years old and included 45% women, 33% African Americans and 59% diabetic patients. Compared to white patients with time-averaged serum albumin 4.0-<4.1 g/dL, white patients with serum albumin ≥4.5, 3.4-<3.5, and <3.0 g/dL had 39% (HR: 0.61, 95% CI: 0.45-0.85) lower; 90% (HR: 1.90, 95% CI: 1.78-2.03), and 292% (HR: 3.92, 95% CI: 3.65-4.21) higher all-cause mortality in fully adjusted models, respectively (see Figure). Similar trend was seen in African-Americans, Hispanic and Asian patients.



Conclusions: Higher albumin levels are linearly and incrementally associated with greater survival in all major racial and ethnic groups of MHD patients.

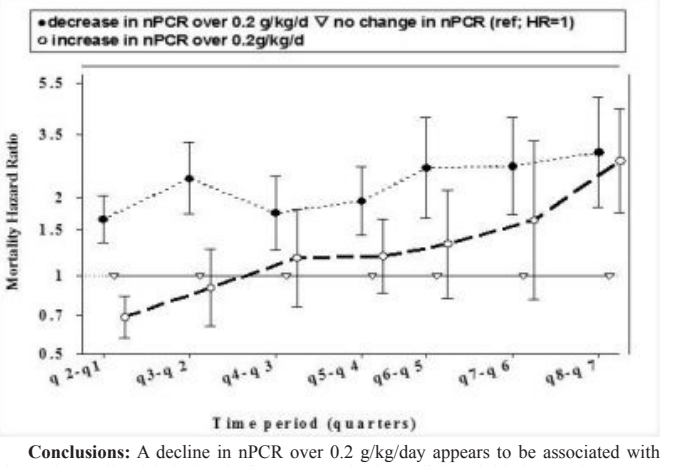
FR-PO315

Associations between Changes in Protein Catabolic Rate and Mortality in Incident Hemodialysis Patients during First Two Years after Hemodialysis Initiation Lilia R. Lukowsky,[1,3] Leeka I. Kheifets,[3] Onyebuchi A. Arah,[3] Allen R. Nissenson,[4] Kamyar Kalantar-Zadeh.[1,2,3] *[1]Harold Simmons Center, LABioMed at Harbor UCLA; [2]Harbor-UCLA; [3]UCLA Fielding School of Public Health; [4]DaVita, Inc.*

Background: Urea dynamic calculated protein catabolic rate (nPCR) is assumed to represent dietary protein intake normalized for body weight. It is recommended that maintenance hemodialysis (MHD) patients have a high daily protein intake of 1.2g/kg/day. Some studies suggest that nPCR >1g/kg/day is associated with better survival in dialysis patients. However, the role of nPCR in early dialysis mortality is not clear.

Methods: Over a five-year period, we identified 17,445 incident hemodialysis patients from a large dialysis organization. We examined the mortality impact on change in serum levels of nPCR across the first 8 consecutive calendar quarters following the hemodialysis therapy initiation. MHD patients with no change in nPCR (an increase or a decrease within ±0.2 g/kg/day) served as the reference category. Change in nPCR was defined as change above ±0.2g/kg/day from a previous quarter.

Results: Patients were 64±15 years old (mean±SD) and included 45% women, 24% African Americans, and 58% diabetics. A decline in nPCR over time was associated with elevated all-cause mortality. An increase in nPCR was associated with better survival during the first several months of dialysis treatment. However, further increase in nPCR during subsequent calendar quarters was associated with a paradoxical increase in the risk of death by more than two folds, especially towards the end of 2nd year.



Conclusions: A decline in nPCR over 0.2 g/kg/day appears to be associated with elevated mortality risk during the first 2 years after hemodialysis initiation. An increase in nPCR has varying associations with mortality, from lower mortality in the first 3 months to higher mortality in Year 2.

Funding: Other NIH Support - R01 DK078106, K24 DK091419

FR-PO316

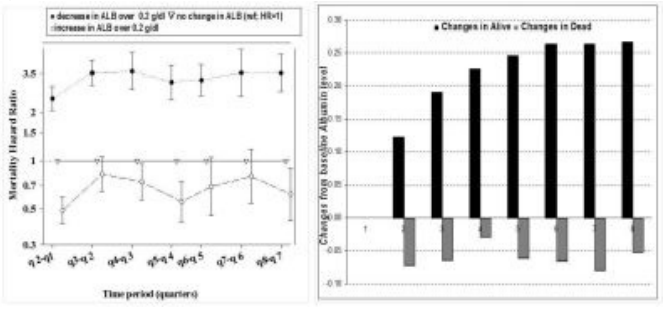
Associations between Quarterly Changes in Serum Albumin and Mortality in the First 24 Months after Initiation of Hemodialysis

Lilia R. Lukowsky,[1,3] Leeka I. Kheifets,[3] Onyebuchi A. Arah,[3,4] Allen R. Nissenson,[2,5] Kamyar Kalantar-Zadeh.[1,2,3] *[1]Harold Simmons Center for Chronic Disease Research & Epidemiology, LA BioMed at Harbor UCLA, Torrance, CA; [2]David Geffen School of Medicine at UCLA, Los Angeles, CA; [3]Department of Epidemiology, UCLA Fielding School of Public Health, Los Angeles, CA; [4]Department of Public Health, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands; [5]DaVita, Inc., Denver, CO.*

Background: Low serum albumin level is associated with lower survival. The role of change in serum levels from one quarter to the next is less clear in clinical outcomes of the first several months of hemodialysis therapy.

Methods: Over a five-year period (7/2001-6/2006), we examined the association between mortality and changes in serum levels of albumin from the prior quarter for the first eight quarters after dialysis initiation in 17,445 incident hemodialysis patients. We used a group with no change (an increase or a decrease no higher than ±0.2 g/dl) as a reference category and compared them to those who had changes greater than ±0.2g/dl.

Results: Patients were 64±15 years old (mean±SD) and included 45% women, 24% African Americans, and 58% diabetics. We observed a negative change in the mean serum levels of albumin from the prior quarter among patients who died but an increase or no change from the previous quarter in mean serum levels of albumin among the survivors. A decrease in serum level of albumin was associated with elevated all-cause mortality by over 3 fold.



Conclusions: Decrease in quarterly serum levels of albumin over 0.2 g/dl was associated with elevated mortality risk during all eight calendar quarters of the first 2 years after dialysis initiation in incident hemodialysis patients.

Funding: Other NIH Support - R01 DK078106, K24 DK091419

FR-PO317

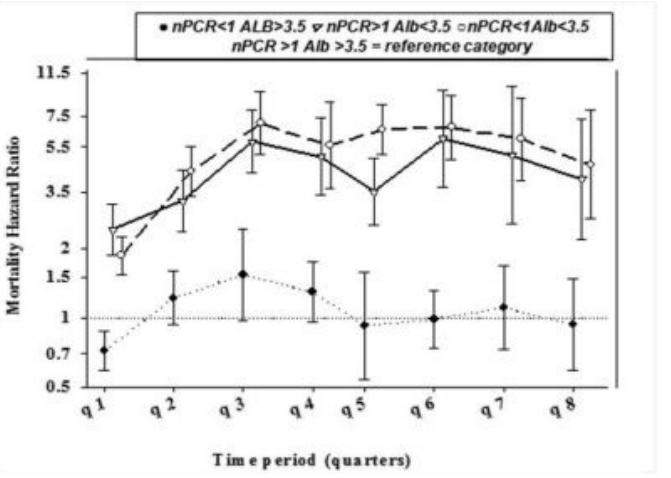
Associations of Serum Albumin Level and Dietary Protein Intake Estimate with Patient Mortality in the First 24-Months of Incident Hemodialysis

Lilia R. Lukowsky,[1,2] Leeka I. Kheifets,[2] Onyebuchi A. Arah,[2] Allen R. Nissenson,[3] Kamyar Kalantar-Zadeh.[1,2] *[1]Harold Simmons Center, LABioMed at Harbor UCLA; [2]UCLA Fielding School of Public Health; [3]DaVita, Inc.*

Background: Low serum albumin and low dietary protein intake are known to correlate with higher mortality in maintenance hemodialysis (HD) patients. The role of these nutritional markers is less clear in clinical outcomes of the first several months of hemodialysis therapy, when mortality is exceptionally high.

Methods: Over a five-year period, we identified 17,445 incident HD patients whose first week of dialysis treatment started in an outpatient dialysis clinic or a large dialysis organization. We examined the association between mortality and combined categories (alb<3.5 g/dl vs. higher, and nPCR <1d/kg/day vs. higher; leading to 2x2=4 groups) of quarterly averaged values for albumin and normalized protein catabolic rate (nPCR) for the first eight calendar quarters after hemodialysis initiation.

Results: Patients were 64±15 years old and included 45% women, 24% African Americans, and 58% diabetics. Correlation coefficients between albumin and nPCR varied from +0.18 to +0.25. Compared to the concordant group of alb ≥3.5g/dl & nPCR ≥1g/kg/day, both categories with low alb <3.5g/dl were persistently associated with higher mortality for all quarters regardless of nPCR levels (increase in death hazard ratio over 3-folds after the 3rd quarter). Contrasting the original hypothesis, nPCR of<1g/kg/day was significantly associated with greater survival during the first 3 months although this association reversed thereafter.



Conclusions: Whereas low albumin <3.5g/dl is a robust and persistent predictor of high mortality in new HD patients, the nPCR-death association varies over the first 24 months. The paradoxical association of lower nPCR <1g/kg/day with greater survival in the first 3 months warrants additional studies.

FR-PO318

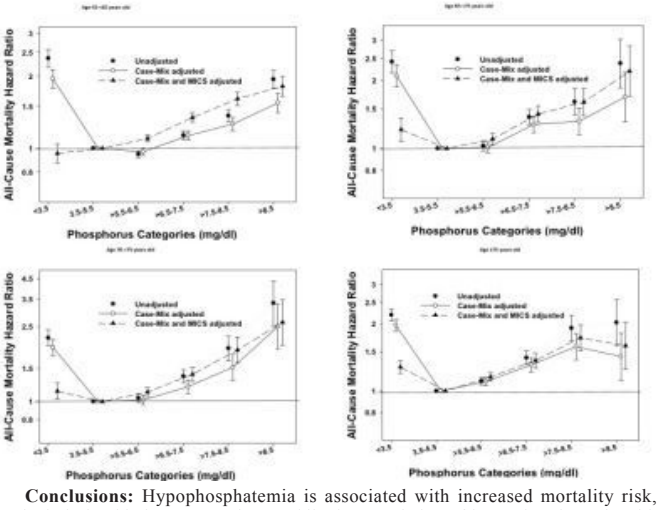
The Association of Serum Phosphorus Levels with Mortality in Elderly and Non-Elderly Hemodialysis Patients

Paungpaga Lertdumrongluk,[1] Miklos Zsolt Molnar,[1,2] Wei Ling Lau,[3] Joshua Zaritsky,[4] John J. Sim,[5] Csaba P. Kovesdy,[6] Kamyar Kalantar-Zadeh.[1,4] *[1]Harold Simmons Center for Chronic Disease Research & Epidemiology, LABioMed at Harbor UCLA, Torrance, CA; [2]Institute of Pathophysiology, Semmelweis University, Budapest, Hungary; [3]University of Washington; [4]David Geffen School of Medicine at UCLA, Los Angeles, CA; [5]Kaiser Permanente; [6]Nephrology, University of Tennessee, Memphis, TN.*

Background: Hypo- and hyperphosphatemia are associated with increased mortality in maintenance hemodialysis (MHD) patients. The correlations between serum phosphorus levels and mortality risks have not been investigated across different age groups of MHD patients.

Methods: We divided 88,635 MHD patients (aged ≥ 45 years old) treated in a large dialysis organization into 4 age groups (45-<65, 65-<70, 70-<75 and ≥75 years old). We examined the relationships of serum phosphorus levels with mortality risk in 4 incremental age categories using Cox proportional hazards models with adjustment for case-mix and surrogates of malnutrition and inflammation complex syndrome (MICS).

Results: Patients were 66±11 years old and included 46% women, 32% Blacks and 63% diabetics. The median follow-up time for the cohort was 761 days (408-1274 days). In the fully adjusted model hypophosphatemia (P<3.5 mg/dL) was significantly associated with increased death risks only in the older age groups (aged ≥65 years old), but not in the younger group (aged 45-<65 years old). Hyperphosphatemia was associated with increased mortality risk in all age categories.



Conclusions: Hypophosphatemia is associated with increased mortality risk, particularly in elderly MHD patients, while the association of hyperphosphatemia with increased death risk is similar across different ages.

FR-PO319

Physical Activity and Its Association with Mortality and Quality of Life in a Large Cohort of Hemodialysis (HD) Patients in the DOPPS

Antonio Alberto Lopes,[3] Brett Lantz,[1] Hal Morgenstern,[1,2] Brenda W. Gillespie,[1,2] Yun Li,[1,2] Patricia Lynn Painter,[4] Stefan H. Jacobson,[5] Hugh C. Rayner,[6] Donna L. Mapes,[1] Raymond C. Vanholder,[7] Takeshi Hasegawa,[8] Bruce M. Robinson,[1] Ronald L. Pisoni.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]U of Michigan; [3]U Federal da Bahia Facudade de Medicina; [4]U of Utah; [5]Danderyd Hospital; [6]Birmingham Heartlands Hospital; [7]U Ziekenhuis; [8]Showa U Fujigaoka Hospital.*

Background: Physical activity is associated with better outcomes in the general population. We examined associations of types and levels of activity with outcomes in 5677 ambulatory chronic HD patients (pts) from 12 countries in the Dialysis Outcomes and Practice Patterns Study (DOPPS 4 2009-2011).

Methods: Self-reported activities (aerobic, muscle strength and flexibility) were assessed with the Rapid Assessment of Physical Activity instrument. The KDQOL and CES-D were used to assess quality of life (QOL) and depression, respectively. Adjusted associations were estimated by using Cox models for mortality, linear models for continuous outcomes, and ordinal logistic models for categories of HD recovery time.

Results: The distribution of aerobic activity was 29% sedentary, 10% infrequent, 17% light, 24% moderate, and 20% active. Frequencies of muscle activities were 4% strength, 9% flexibility, 7% both, and 80% neither. Pts at the 43% of facilities offering exercise programs reported higher levels of aerobic activity ($p<0.001$). Aerobic activity was inversely associated with mortality, recovery time, and depression, and positively associated with QOL (Table 1). Results for strength and flexibility were inconsistent (Table 2).

Table 1: Aerobic Activity

Adjusted Association* (95% CI)	Sedentary (N=1,654)	Infrequent (N=590)	Light (N=958)	Moderate (N=1,363)	Active (N=1,167)

*Adjusted for sociodemographics, vintage, BMI, 14 comorbidities, lab variables, Kt/V, catheter use, geographic region and accounting for facility-level clustering. **Bold** values indicate $p<0.05$. Sample excludes non-ambulatory patients and those with missing RAPA data. For published RAPA scoring methods, the highest self reported activity level activity was used to classify patients. Infrequent and moderate refer to "under-active" and "under-active regular" in RAPA.

Conclusions: Our findings support the possibility that aerobic activity improves survival and QOL in ambulatory HD pts. Clinical trials to investigate the effectiveness of physical activity interventions are indicated.

FR-PO320

Independent and Joint Associations of Handgrip Strength and Malnutrition-Inflammation Score with Mortality Risk in Men and Women on Hemodialysis in the PROHEMO

Antonio Alberto Lopes,[1] Luciana Ferreira Silva,[2] Larissa Moura Silva,[1] Cacia Mendes Matos,[3] Gildete Barreto Lopes.[1] *[1]Universidade Federal da Bahia; [2]Universidade do Estado da Bahia; [3]INED, Salvador, Brazil.*

Background: Higher malnutrition-inflammation score (MIS) is associated with higher risk of death in maintenance hemodialysis (MHD) patients. We have shown that lower handgrip strength (HGS) correlates with higher MIS in MHD patients. We investigated independent and joint associations of HGS and MIS with mortality risk, separately for men and women on MHD.

Methods: The data were from 863 adult patients (340 women, 523 men, mean age 48.6±14.3 yr) from the first phase of the Prospective Study of the Prognosis of Chronic Hemodialysis Patients (PROHEMO), a prospective cohort developed at four dialysis clinics in Salvador, Brazil (2005-2011). Collection of HGS was initiated in 2007 using a dynamometer. Data on MIS, HGS and both MIS and HGS were available for 813, 493 and 443 patients, respectively. Cox regression was used to estimate hazard ratio (HR) of death adjusted for sociodemographics, vintage, Kt/V and comorbid conditions. Interaction between MIS and HGS was evaluated under the additive risk model.

Results: The observed death rates for the combination MIS≥6 and HGS≤median (Table) were higher than the expected under additivity by 6% in men (observed 14.1, expected 13.3) and 44% in women (observed 11.7, expected 6.6). The reduction in the adjusted hazard of death per 5-point increase in HGS was 31% (HR= 0.69, 95% confidence interval (CI)= 0.50-0.94, P=0.020) in women and 27% (HR=0.73, 95% CI=0.62-0.85, P<0.001) in men. The increase in the adjusted hazard of death per 5-point increase in MIS was 33% (HR=1.33, 95% CI=1.01-1.73, P=0.039) in women and 47% (HR=1.47, 95% CI=1.18-1.83, P=0.001) in men.

Death Rate by 100 Person-Years in Men and Women

MEN			
	HGS>Median	**HGS≤Median**	**Rate Difference**
MIS<6	1.4	9.3	7.9
MIS≥6	5.4	14.1	8.7
WOMEN			
MIS<6	3.7	4.3	0.6
MIS≥6	6.0	11.7	5.7

HGS=Handgrip Strength, MIS=Malnutrion-Inflammation Score, Median HGS was 18.5 kg for women and 28.8 kg for men

Conclusions: The results support the evaluation of MHD patients with both HGS and MIS to identify those who may need special care to improve survival.

FR-PO321

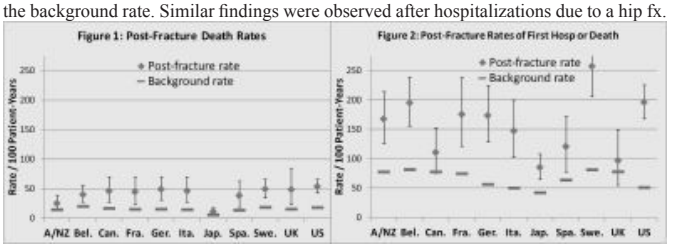
Higher Rates of Death and Hospitalization Following a Fracture among Participants in the Dialysis Outcomes and Practice Patterns Study (DOPPS)

Francesca Tentori,[1,2] Keith McCullough,[1] Ryan D. Kilpatrick,[3] Peter G. Kerr,[4] Brian D. Bradbury,[3] Bruce M. Robinson,[1,5] Ronald L. Pisoni.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]Vanderbilt University Medical Center; [3]Center for Observational Research, Amgen, Inc.; [4]Monash Medical Center; [5]University of Michigan.*

Background: Altered bone structure increases the risk of fracture (fx) in patients with end-stage renal disease. Though it is likely that major fx events adversely affect overall health, this has not been tested in a multi-national study. We estimated death and hospitalization (hosp) rates following a fx-related hosp in the international DOPPS cohort.

Methods: Rates of first hosp due to fx (length of stay ≥1 day) were collected from 34,083 hemodialysis (HD) patients from 12 DOPPS countries (2002-11). Within each country, death rates were estimated (1) over a 1-yr follow-up period among participants who had experienced any fx (n=1,183) and a hip fracture (n=509) ("post-fx") and (2) among all participants ("background"). Country-specific rates of the composite event of death or first hosp were also calculated.

Results: Fx incidence after DOPPS enrollment varied across countries (range: 1.2 [Japan] - 4.4 per 100 patient-years [Sweden]). Post-fx mortality rates were higher than background rates across the countries (Figures 1,2). Rates of the composite hosp/death events after a bone fx also varied across countries and ranged from 1.2-3.8 times higher than the background rate. Similar findings were observed after hospitalizations due to a hip fx.



Conclusions: Fx events can have serious implications for HD patients. After a fx, the morbidity and mortality burden is substantially elevated compared to the risk in the general dialysis population. Thus prevention of fxs is of great importance. Future studies should investigate post-fx healthcare resource utilization to more fully quantify their burden.

FR-PO322

Performance of Health Literacy Assessment Methods in Chronic Hemodialysis

Kerri L. Cavanaugh, Kenneth A. Wallston, Natalia E. Plotnikova, Francesca Tentori, T. Alp Ikizler. *Vanderbilt University.*

Background: Limited health literacy (HL) is a risk for poor outcomes, including mortality, in patients receiving hemodialysis therapy. Current methods commonly used to evaluate health literacy are not practical for clinical applications. We examined the performance of three brief health literacy screening questions in a sample of prevalent maintenance hemodialysis (MHD) patients.

Methods: In a cross sectional study, we enrolled adults receiving MHD therapy. We administered previously validated HL measures, REALM and TOFHLA, and 3 brief HL screening questions: 1). How confident are you filling out forms; 2). How often do you have problems learning about your medical condition; and 3). How often do you have someone help you read hospital materials. Adequate and inadequate HL was defined for each survey and the C-index and test characteristics were compared. In addition, associations between the brief HL items and patient outcomes was analyzed using Chi-squared or Student's t-tests.

Results: In 150 patients, mean (SD) age 52 (14) years, 50% male, 75% non-white, vintage 4.7 (5.4) years the prevalence of limited HL was 27%, 15%, 14% by REALM, TOFHLA, and brief questions, respectively. Overall, 30% reported being confident with forms "somewhat" or less. These questions showed similar performance for detecting limited HL when compared to the REALM (C-index=0.64, (0.52-0.75)) or the TOFHLA (C-index=0.64, (0.48-0.81)). Limited HL by brief items was associated with older age, non-white race, and years education. Limited HL was also associated with lower dialysis knowledge (53% vs. 69%, p=0.003) and less optimal phosphorus control (76% vs. 54%, p=0.06).

Conclusions: Limited health literacy is common among patients receiving hemodialysis. The brief 3 HL items discriminated between those with inadequate and adequate literacy compared to other measures and were related to important patient outcomes. HL may be a factor to consider in risk stratification and as an intervention target to improve outcomes in hemodialysis for both researchers and clinicians.

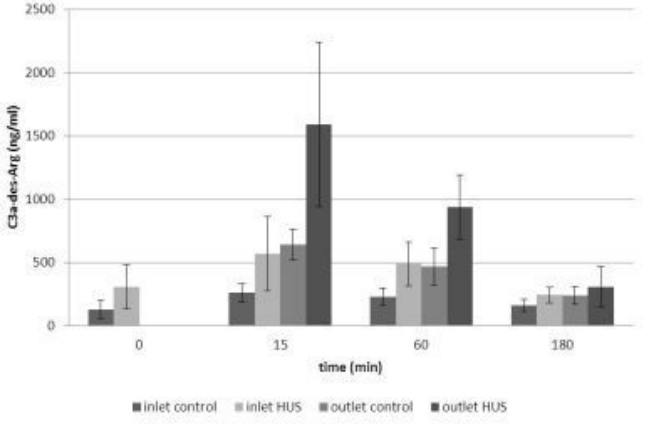
FR-PO323

Complement Activation during Hemodialysis in Patients with Atypical Hemolytic Uremic Syndrome Rogier Caluwé,[1] Annemieke Dhondt,[2] Eric Goffin,[3] Steven Van Laecke,[2] Ignace M. Becaus,[1] Bruno Van Vlem,[1] Raymond C. Vanholder.[2] *[1]Nephrology, OLV Hospital, Aalst, Belgium; [2]Nephrology, University Hospital, Gent, Belgium; [3]Nephrology, UCL Hospital, Brussels, Belgium.*

Background: Atypical hemolytic uremic syndrome (aHUS) is often caused by a defect in one of the regulatory proteins of the alternative complement system pathway. This case-control study evaluates whether aHUS patients have more intense complement system activation during hemodialysis.

Methods: During 2 hemodialysis sessions complement system activation was evaluated in 4 patients with aHUS (proven factor H mutation) and 14 controls. C3a-des-Arg was measured at the start of dialysis and after 15, 60 and 180 minutes at both the helixone dialyzer inlet and outlet. Factor B, factor Bb and the soluble terminal complement complex (sTCC) were measured at the start of dialysis and after 180 minutes at the dialyzer inlet. The Mann-Whitney-U test was used for statistical analysis.

Results: C3a-des-Arg levels were significantly higher in aHUS patients at baseline (109±66 vs. 267±317, p=0.015) and at every measured timepoint at the dialyzer inlet as visualized in the figure. After passing the dialyzer membrane C3a-des-Arg levels increased at every timepoint. This increase was significantly higher in aHUS patients at 15 (353±143 vs. 916±684, p=0.003) and 60 (207±118 vs. 434±151, p=0.015) minutes. Factor B levels did not differ between groups. The increase in Factor Bb levels was higher in aHUS patients (1561±821 vs. 2269±1194, p=0.026). sTCC levels increased but did not differ between groups.



Conclusions: aHUS patients have a more pronounced activation of the alternative complement pathway during hemodialysis when compared to controls. In view of the poor prognosis of aHUS patients on hemodialysis these findings are of importance as they might play a role in sustaining a deleterious pro-inflammatory tendency.

FR-PO324

Body Composition Is Associated with Quality of Life in Hemodialysis Patients Nestor E. Almeida,[1] T. Alp Ikizler,[3] Y. Zhang,[1] R. Filipowicz,[1] Mary B. Sundell,[3] G. Morrell,[1] G. Wei,[1] J. Abraham,[1] A. N. Habib,[1] T. S. Bjordahl,[1] Tom Greene,[1] Alfred K. Cheung,[1,2] S. Beddhu.[1,2] *[1]Univ of Utah, Salt Lake City, UT; [2]VA, Salt Lake City, UT; [3]Vanderbilt Univ, Nashville, TN.*

Background: Even though, higher body size has been linked to increase survival in hemodialysis (HD) pts, it is not clear whether muscle mass or fat mass or both are associated with better quality of life (QOL). Therefore we examined the associations of physical composite score (PCS) and mental composite score (MCS) of SF-12, a validated survey for QOL with body size, body mass index (BMI) and body composition, MRI measurement of mid-thigh muscle area (MTMA) and intra-abdominal fat area (IAFA).

Methods: 110 pts in the Protein Intake, Cardiovascular disease and Nutrition in CKD stage V (PICNIC) study who underwent SF-12 survey and MRI were included. Generalized estimating equations (GEE) were used to relate the associations of the PCS and MCS with MTMA and IAFA areas, and BMI.

Results: Mean age was 51 ± 17 years, 57% were men, 78% were Caucasians and 42% had diabetes. Follow-up MRI data were available in 82 and 46 pts at 6 and 18 months visits, respectively. Mean MTMA and standard deviation (SD) at baseline, 6 and 18 months were 108 ± 29, 107 ± 27, and 102 ± 26 cm^2, respectively, and IAFA were 128 ± 73, 132 ± 80, and 141 ± 81 cm^2, respectively. The associations of BMI and body composition with QOL are summaryzed in Table 1.

Table 1. Associations of mid-thigh muscle, intra-abdominal fat areas, and BMI with PCS and MCS scores of the SF-12 survey

	PCS β, (95% CI), p value	MCS β, (95% CI), p value
Each SD ↑ in MTMA (cm^2)	2.0 (-0.03 to 4.0), 0.054	1.0 (-1.1 to 3.1), 0.37
Each SD ↑ in IAFA (cm^2)	-1.5 (-3 to -0.02), 0.05	0.2 (-1.4 to 1.8), 0.82
Each SD ↑ in BMI (kg/m^2)	-0.05 (-1.5 to 1.4), 0.94	0.2 (-1.2 to 1.6), 0.74

Adjusted for age, gender, race, ESRD duration, vascular access type and study site

Conclusions: Higher muscle area and lower fat area are associated with better PCS. Body composition is not associated with MCS. Interventions that increase muscle mass and decrease fat mass may improve physical well being of patients undergoing HD.

Pregnancy in Patients on Dialysis: Experience over 40 Years in Australia and New Zealand Shilpa Jesudason,[1] Blair S. Grace.[2] *[1]Central Northern Adelaide Renal and Transplantation Service, Royal Adelaide Hospital, Adelaide, Australia; [2]ANZDATA Registry, RAH, Adelaide, Australia.*

Background: The management of the pregnant woman requiring dialysis is a rare but challenging scenario. Recent case series from single centres suggest outcomes in these high-risk pregnancies are improving. This study reports for the first time outcomes regarding women receiving dialysis in pregnancy across Australia and New Zealand over 40 years.

Methods: The ANZDATA Registry records annual incident data from all Renal units in Australia and New Zealand. Prior to 2001, pregnancy was recorded only when reported; after 2001 detailed pregnancy-related data including conception date was collected. We reviewed all reported data for pregnancies in women who recieved intra-pregnancy dialysis from 1963 – 2010 (n=104).

Results: From 1963-2000, 33 women had dialysis during 38 pregnancies - 35 were conceived on dialysis, 3 conceived with a transplant then required dialysis. Almost all were managed with haemodialysis. There were 9 live births, 9 surgical terminations, 14 spontaneous abortions < 20 weeks gestation and 2 stillbirths > 20 weeks. From 2001-2010, there were 64 pregnancies in 61 women. 45 of these pregnancies were conceived on dialysis and 19 conceived before dialysis started. 56 were managed with haemodialysis, and 8 with peritoneal dialysis. There were 41 live births, 11 surgical terminations, 6 spontaneous abortions < 20 weeks and 6 stillbirths > 20 weeks. In those who did not terminate the pregnancy, the live birth rate was 77 %. Live births had median gestational age 33.6 weeks (IQR 30.4 – 38.6) and median birth weight 1780 g (IQR 1186 – 2675). The 28 day neonatal survival for live births was 98%. There were no maternal deaths.

Conclusions: This is one of the largest series reported and the only nation-wide, multi-centre report. Pregnancy in this cohort resulted in a high live birth rate, advanced gestational age and excellent neonatal survival, which is important to report given the high risk nature of these pregnancies and previous pessimism regarding outcomes. Further analyses will address the relevance of timing of conception, rate of complications and aspects of dialysis delivery.

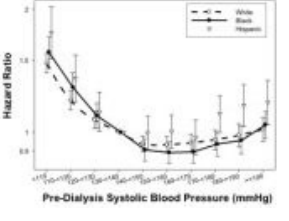
FR-PO326

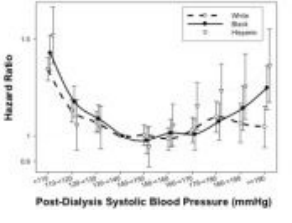
Racial-Ethnic Differences in the Impact of Systolic Blood Pressure on Mortality in Hemodialysis Patients Joni L. Ricks,[1] John J. Sim,[2] Miklos Zsolt Molnar,[1] Csaba P. Kovesdy,[3] Kamyar Kalantar-Zadeh.[1,4] *[1]Harold Simmons Center for Chronic Disease Research & Epidemiology, LABioMed at Harbor-UCLA, Torrance, CA; [2]Kaiser Permanente; [3]Nephrology, University of Tennessee, Memphis, TN; [4]Nephrology, Harbor-UCLA, Torrance, CA.*

Background: Previous research has demonstrated that low systolic blood pressure (SBP) is associated with decreased survival among maintenance hemodialysis patients (MHD). Empirical research examining this link by race has indicated that black patients demonstrate a survival advantage compared to whites across all SBP groups. However, additional racial-ethnic groups have not been examined.

Methods: We examined the survival impact of baseline SBP in a 5-year (7/2001-6/2006) cohort of 47,813 white, 35,874 black, and 16,180 Hispanic outpatients in DaVita dialysis clinics using Cox models adjusted for case-mix and surrogates of Malnutrition-Inflammation Complex.

Results: Among whites, blacks and Hispanics, the mean age (mean±SD) was 65±15, 57±15, and 58±15, yrs old and included 42%, 48% and 45% women; and 54%, 56% and 69% diabetics, respectively. Across 10 a priori selected SBP groups from <110 to ≥190, both low Pre-Dialysis and Post-Dialysis SBP were associated with higher mortality in whites, blacks and Hispanics. Moreover, the two highest Pre-Dialysis SBP groups were not associated with higher mortality among blacks and whites; whereas the two highest Pre-dialysis SBP groups were associated with higher mortality in Hispanics.





Conclusions: Our findings evaluate the differential impact of SBP among racial-ethnic groups. Among MHD patients, all races show worsened survival in the lowest SBP groups; however, only Hispanics demonstrated an increased mortality with high pre and post-dialysis SBP.

FR-PO327

Secular Trends and Outcomes in Lower Extremity Amputations in End Stage Renal Disease Patients

Ashte K. Collins,[1] Paul L. Kimmel,[2] Paul W. Eggers.[2] *[1]Department of Medicine, George Washington University, Washington, DC; [2]Division of Kidney, Urologic, and Hematologic Diseases, NIDDK, NIH, Bethesda, MD.*

Background: The nontraumatic lower extremity amputation (LEA) rate attributable to diabetes mellitus and peripheral vascular disease has been high in ESRD patients. LEA rates increased during the 1990s, but ESRD patient survival has since improved. We present trends in LEA in Medicare ESRD patients between 1985 and 2007, to identify risk factors for and rates and levels of LEA, and associations between LEA and survival.

Methods: Using the United States Renal Data System (USRDS), rates for LEA among ESRD patients were calculated from 1985-2007, stratified by demographic factors, diabetes, and amputation level. Kaplan-Meier analysis was used to estimate patient survival after first LEA, stratified by amputation level. Cox regression analysis identified associations between patient characteristics and mortality.

Results: From 1985-2007, 173,612 (9.4%) of the 1,851,652 patients in the ESRD program had a LEA. ESRD amputees were more likely to be older, male, black, Native American, and have diabetes than nonamputees. The LEA rate among diabetic ESRD patients fell from 13/100 person years in 1996 to 7.9/100 in 2008, with a similar trend among nondiabetic ESRD patients. 1-year mortality among ESRD patients undergoing amputation was 47.2%. Above the knee amputees had a 69.8% 1-year mortality compared to 34.9% among toe amputees. ESRD amputees experienced poorer survival than nonamputees. In multivariate analysis, increasing age, female gender, white race, absence of diabetes, and proximal sites of amputation were all associated with a higher mortality after LEA.

Conclusions: LEA rates in both diabetic and nondiabetic ESRD patients are very high, but have dramatically decreased from 1996-2008, perhaps related to advances in vascular, radiologic, microbiologic, and multidisciplinary diagnosis and care in patients at risk for lower limb ischemia. Level of amputation was associated with differential 1-year mortality in univariate and multivariate analysis. Programs to improve care for lower extremities in ESRD patients may improve survival.

Funding: NIDDK Support

FR-PO328

Post-Fracture Outcomes among U.S. Medicare Hemodialysis Patients from 2000-2008

Anne C. Beaubrun,[1] Ryan D. Kilpatrick,[2] Janet K. Freburger,[1] Brian D. Bradbury,[2] Lily Wang,[1] M. Alan Brookhart.[1] *[1]University of North Carolina at Chapel Hill; [2]Center for Observational Research, Amgen, Inc.*

Background: Dialysis patients (pts) are at increased risk of fracture (Fx), a contributor to morbidity and mortality. Data on post-Fx consequences in this population are limited.

Methods: A retrospective study was conducted using U.S. Medicare claims of adult hemodialysis pts from Jan. 1, 2000-Dec. 31, 2008. Index hospitalizations (hosp) for 7 Fx categories [vertebral, pelvis/hip, femur, lower leg, ribs/sternum, shoulder/upper arm, forearm/wrist] were identified. Median hosp length of stay (LOS), mortality, and discharge destination were determined. Age, sex, and race adjusted mortality, hosp and skilled nursing facility (SNF) admissions, hosp and SNF days were calculated over 1-year of follow-up.

Results: Primary hosp LOS was shortest for forearm/wrist Fxs (5 days, 95% CI 3-9) and longest for femur Fxs (8 days, CI 5-13). 28% (ribs/sternum) to 56% (pelvis/hip) of patients were discharged to a SNF or other post-acute care facility. Re-hosp rates ranged from 3.3-4.4/PY and pts spent a median of 16-28 days in the hosp and/or 0-25 days in a SNF. Death rates ranged from 0.4 to 0.6/PY; highest for vertebral, pelvis/hip and femur Fxs.

Post-Fx Consequences by Fx Type, 2000-2008

	Primary Hosp		Post-Discharge (1yr)				
Fx Type (N)	LOS§	Discharged to SNF(%)	Re-hosp Rate†	Re-hosp Days§	SNF Admission Rate†	SNF Days§	Death Rate†
Pelvis/Hip (15,423)	7 (5-12)	56	3.7 (3.6-3.7)	25 (6-70)	1.0 (1.0-1.0)	25 (0-99)	0.5 (0.5-0.5)
Vertebral (6536)	7 (4-13)	33	4.4 (4.3-4.5)	28 (6-74)	0.9 (0.9-1.0)	0 (0-79)	0.6 (0.6-0.6)
Lower leg (4747)	6 (4-10)	48	3.5 (3.4-3.6)	20 (4-57)	0.9 (0.9-0.9)	11 (0-83)	0.4 (0.4-0.4)
Shoulder/ Upper arm (3223)	6 (3-10)	41	4.0 (3.9-4.1)	22 (4-61)	0.8 (0.8-0.9)	9 (0-89)	0.5 (0.5-0.6)
Femur (2627)	8 (5-13)	53	3.9 (3.8-4.0)	27 (6-77)	1.1 (1.1-1.2)	22 (0-99)	0.6 (0.5-0.6)
Ribs/ Sternum (2308)	6 (3-10)	28	4.1 (4.0-4.2)	20 (4-55)	0.7 (0.7-0.8)	0 (0-45)	0.5 (0.5-0.5)
Forearm/ Wrist (1693)	5 (3-9)	38	3.3 (3.2-3.4)	16 (3-47)	0.7 (0.6-0.7)	0 (0-66)	0.4 (0.4-0.4)

*With follow-up,†per person-year(CI),§median(Q1-Q3)

Conclusions: The burden of Fxs in the dialysis population continues well beyond the inpatient admission. Efforts to prevent Fxs in dialysis pts are warranted.

FR-PO329

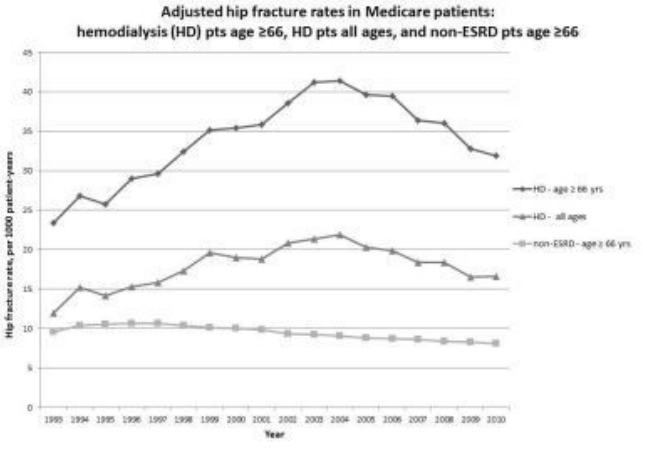
Hip Fracture Trends in US Medicare Hemodialysis Population, 1993:2010

Tom Arneson,[1] Shuling Li,[1] Jiannong Liu,[1] Ryan D. Kilpatrick,[2] Britt B. Newsome,[3] Wendy L. St. Peter.[1,4] *[1]Chronic Disease Research Group, MMRF, Minneapolis, MN; [2]Amgen, Inc, Thousand Oaks, CA; [3]Denver Nephrologists, PC, Denver, CO; [4]University of Minnesota, Minneapolis, MN.*

Background: Hip fracture (Fx) is the most common fracture type resulting in hospitalization among hemodialysis (HD) patients (pts), causing significant morbidity and increased mortality. We aimed to estimate current hip Fx rate and characterize historical rates to describe changes which may have resulted from medication management strategies or changing HD population characteristics.

Methods: We studied annual cohorts of point prevalent Medicare (MC) HD pts from 1993-2010 for first hip Fx, defined by hospitalization with a diagnosis code for hip Fx. Pts were followed to earliest of Dec. 31 of index yr, hip Fx, kidney transplant, change of MC Parts A/B enrollment or death. Rates were adjusted for age, race, gender, dialysis vintage, ESRD cause, number of hospitalized days and comorbidities in prior year. To distinguish trends specific to dialysis pts, hip Fx rates in the subset of pts ≥66 yrs old (50-53%) were compared to annual cohorts of non-ESRD pts, in MC 5% sample, adjusting for age, gender and race.

Results: Both unadjusted and adjusted hip Fx rates in MC HD pts increased from 1993 to 2004 and decreased from 2004 to 2010. Linear spline with node at 2004 showed a significant change in the trend before and after 2004 (p<.0001). The trend for the ≥66 HD subset was similar to the trend for the full HD cohort, but differed markedly in magnitude and pattern for ≥66 non-ESRD MC pts, which was always substantially lower with a slowly decreasing rate since 1996.



Conclusions: Hip fracture rates among MC HD pts increased from 1993-2004 and since 2004 have been decreasing, in contrast to non-ESRD MC pts where hip fracture rate has steadily declined since 1996. Further research is needed to define factors associated with observed trends.

Administration of IL-1ra Improves Adiponectin (ADPN) Levels in Chronic Hemodialysis (CHD) Patients

Chutatip Limkunakul,[2] Edward D. Siew,[1,2] Cindy Booker,[1,2] Charles D. Ellis,[2] Ayumi Shintani,[3] T. Alp Ikizler,[1,2] Adriana Hung.[1,2] *[1]CSR&D, Veterans Administration TVHS, Nashville, TN; [2]Nephrology, Vanderbilt University, Nashville, TN; [3]Biostatistics, Vanderbilt University, Nashville, TN.*

Background: Adiponectin (ADPN), an adipose tissue-derived hormone, is known to be insulin sensitizing, anti-inflammatory, and anti-atherogenic in the general population. However ADPN secretion is suppressed by inflammation. Interleukin 1 receptor antagonist (IL-1ra) administration is an effective anti-inflammatory intervention in CHD patients. In this study, we evaluated the effects of IL-1ra administration on adipokines (ADPN and Leptin) in 14 stable CHD patients. We also examined the association between adipokines and insulin sensitivity at baseline.

Methods: Data was derived from a pilot RCT of the administration of IL-1ra in CHD patients with hsCRP > 5 mg/dL for 3 consecutive months. Patients were randomized to Anakinra 100 mg subcutaneous injection or placebo at each dialysis session for 4 weeks. Analysis of covariance was used to compare percent change from baseline to 4 weeks.

Results: Twenty CHD patients were randomized and 14 completed the trial (mean age 49 ± 13 years, 71% African American, 71% males and 21% had diabetes). At baseline, the median values for ADPN, Leptin, Leptin-Adiponectin ratio (LAR) and HOMA were 11.5 µg/mL (IQR 9, 28.5), 17.8 ng/mL (3.9, 50.0), 2.20 (0.13, 3.98) and 2.8 (2.0, 3.6), respectively. HOMA was associated with ADPN (p=0.004), Leptin (p=0.01) and LAR (p=0.0006). IL-6 was associated with HOMA (p=0.03) and borderline with LAR (p=0.06), but not with ADPN or leptin alone. Patients in the intervention arm had a mean percent

increase in serum ADPN of 22% vs. 14% decrease in the placebo arm (p=0.003). Leptin, LAR or HOMA did not change with intervention.

Conclusions: Administration of IL-1ra significantly increased adiponectin (ADPN) levels while concomitantly reducing inflammation among CHD patients. There were no obvious improvements in insulin sensitivity with the intervention. This study demonstrates that anti-inflammatory interventions significantly impact adiponectin physiology in ESRD population.

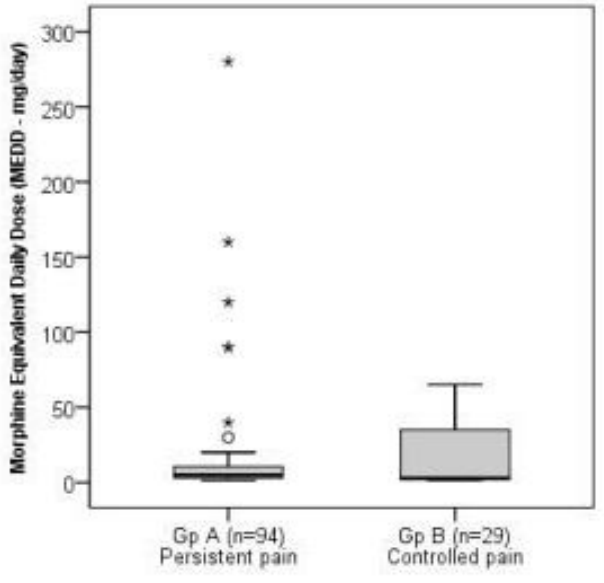
Factors Associated with Persistent Pain in Hemodialysis Patients

Ahraaz Wyne, Jessica M. Sontrop, Sharon L. Baker, William F. Clark, Rita Suri. *Western University, London, Canada.*

Background: Persistent pain is highly prevalent in hemodialysis (HD) patients. We hypothesized that inadequate pain control in HD patients is associated with psychiatric illness and analgesic under-prescription.

Methods: We surveyed a random sample of 189 HD patients from 4 Canadian academic HD units for pain, comorbidities, medications, preferences, anxiety (Spielberger State Trait Anxiety Inventory), depression (Beck Depression Inventory) and sleep (MOS Sleep Scale). To eliminate indication bias, we excluded 65 patients not taking analgesics (41 no pain, 25 with pain). Of the remaining 123, we compared 94 (76%) subjects with persistent pain despite analgesic use (GpA), to 29 (24%) controls whose pain was completely controlled on analgesics (GpB).

Results: Demographics and comorbidities were similar between groups, except for trend to more males in GpA (59 vs 35%, p=0.06). Compared to GpB, GpA had less anxiety (STAI=21 vs 24, p=0.02), but similar depression and sleep. There was no difference in type of analgesics used (GpA, GpB: opioids 44, 48%; NSAIDs 12, 7%; acetaminophen 72, 69%; all p=NS). Opioid doses were similar (median morphine equivalent daily dose: GpA 5mg/d, GpB 3mg/d, p=0.4), but GpA had a narrower interquartile range. Interestingly, most in GpA (76%) felt their physicians were addressing their pain, but only 31% would accept more analgesics if offered. Reasons for declining more analgesics included fears of: too many medications (38%), side effects (15%) and addiction (10%).



Conclusions: We found that inadequate pain control was not associated with depression, insomnia, more anxiety, or physician inattention. Rather, most HD patients with persistent pain did not want more analgesics due to fear of polypharmacy and addiction. There is a need to educate patients about acceptability regarding analgesics and explore non-pharmacologic pain control strategies in HD patients.

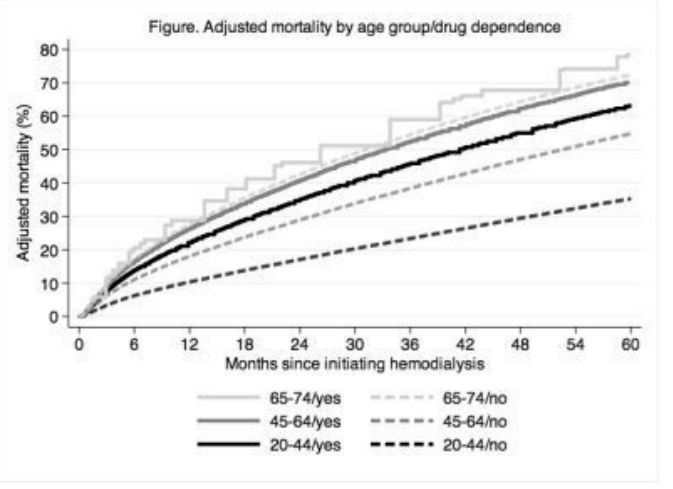
The Burden of Drug Dependence among Hemodialysis Patients

Vanessa Grubbs,[1] Eric Vittinghoff,[2] Barbara A. Grimes,[2] Kirsten L. Johansen.[3] *[1]Nephrology, UCSF, San Francisco, CA; [2]Epidemiology and Biostatistics, UCSF; [3]Nephrology, UCSF-VAMC, San Francisco, CA.*

Background: Illicit drug use is known to cause and exacerbate a wide spectrum of kidney disease. We examined the prevalence and associated mortality of illicit drug dependence among the hemodialysis population.

Methods: From the U.S. Renal Data System 2000-2009, we examined the prevalence of illicit drug dependence (current or within the last 10 years) checked off as a comorbidity on the Medical Evidence Form 2728 among 931,280 incident hemodialysis patients aged 20-90 years. Among the 95,750 patients initiating hemodialysis in 2005, we used Cox proportional hazard models to estimate the probability of death by age group and drug dependence adjusted for gender, race, and primary cause of end-stage renal disease.

Results: The prevalence of drug dependence was 1.3% overall, but increased over time from 1.0% to 1.6% (p<0.001 by chi-square test for linear trend) and was 4.1% among 20-44 year olds and 2.0% among 45-64 year olds. Nearly all (95.9%) drug dependence was among patients under age 65 years. Adjusted mortality varied by drug dependence and age group (Figure, $p_{interaction}$ <0.001). Dependent 20-44 year olds had higher likelihood of mortality than their non-dependent counterparts (HR 2.30, 95% CI 2.03-2.60) and non-dependent 45-64 year olds (HR 1.26, 95% CI 1.12-1.42). Likelihood of mortality among dependent 45-64 year olds was higher than their non-dependent counterparts (HR 1.54, 95% CI 1.39-1.69) and similar to that of non-dependent 65-74 year olds (HR 0.94, 95% CI 0.86-1.04). Likelihood of mortality was similar among 65-74 and 75-90 year olds regardless of drug dependence (p>0.1).



Conclusions: Illicit drug dependence among the youngest adult hemodialysis patients is common and is associated with a higher likelihood of death than non-dependent middle-aged patients.

Clinical Parameters in Dialysis Patients Show Different Circannual Patterns in Different Regions of the World

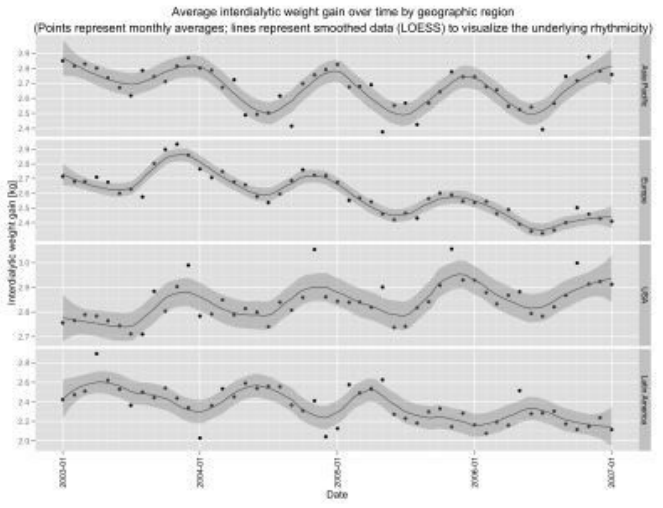
Stephan Thijssen,[1] Len A. Usvyat,[1] Inga Bayh,[4] Michael Etter,[3] Aileen Grassmann,[4] Adrian Marcos Guinsburg,[5] Jeroen Kooman,[6] Nathan W. Levin,[1] Eric Liu,[3] Daniele Marcelli,[4] Cristina Marelli,[5] Frank van der Sande,[6] Laura Scatizzi,[4] Adam Tashman,[1] Edwin B. Toffelmire,[7] Yuedong Wang,[2] Peter Kotanko.[1] *[1]Renal Research Institute, New York, NY; [2]University of California, Santa Barbara, CA; [3]Fresenius Medical Care, Hong Kong, Hong Kong; [4]Fresenius Medical Care, Bad Homburg, Germany; [5]Fresenius Medical Care, Buenos Aires, Argentina; [6]University Hospital Maastricht, Maastricht, Netherlands; [7]Fresenius Medical Care, Toronto, Canada.*

Background: Seasonal variability in clinical parameters has been described in hemodialysis (HD) patients. No systematic comparison of these patterns has been performed between different regions of the world.

Methods: The MONitoring Dialysis Outcomes (MONDO) consortium consists of HD databases from Renal Research Institute clinics (US), Fresenius Medical Care clinics in Europe, Asia, Latin America and Canada, Maastricht University (Netherlands), and KfH clinics in Germany (latter three not used here). Monthly data (up to 20,000 pat. records) on serum albumin, pre-HD systolic BP (SBP), pre-HD weight and interdialytic weight gain (IDWG) were analyzed between 01/2003 and 01/2007 for the US, Asia Pacific (5 countries excl. Australia), Latin America (Argentina), and Europe (16 countries).

Results: IDWG, SBP, and body weight showed a circannual rhythm with highest values in winter and lowest values in summer. With Argentina being in the southern hemisphere, the pattern was shifted by about 6 months compared to the other regions (see Fig. 1 for IDWG; shaded area shows 95% conf. band). There was no clear seasonal pattern for albumin in any region.

Conclusions: SBP, weight and IDWG show clear circannual patterns, and our data suggest the primacy of climatic factors in determining these patterns.



FR-PO334

Prediction of Serum Bicarbonate Levels in Chronic Hemodialysis Patients: Results from a Retrospective Cohort Study Jochen G. Raimann, Len A. Usvyat, Stephan Thijssen, Peter Kotanko. *Renal Research Institute.*

Background: Chronic hemodialysis (HD) patients have varying levels of acid generation which mainly derive from dietary proteins. Dialysate bicarbonate (DBic) counteracts the resulting metabolic acidosis. This analysis aims to investigate the feasibility to predict post-HD serum bicarbonate levels (post-HD SBic).

Methods: We studied chronic HD patients treated between 7/2005 and 11/2011 in Renal Research Institute HD clinics in whom pre- and post-HD SBic were available. Pre-HD DBic to SBic gradient (GBic) was defined as DBicminus pre-HD SBic. Linear regression analysis was employed to predict post-HD SBic.

Results: Three-hundred ninety-five HD patients were included (pre-HD SBic24.4±3.2 mEq/L; post-HD SBic30.1±3.1 mEq/L; pre-HD GBic 12.3±3.4 mEq/L; treatment time 209±29 minutes; blood flow rate 407±57 mL/min; dialysate flow rate 648±87 mL/min). Pre-HD SBic and GBic were significant predictors of post-HD SBic (R^2=0.24; P<0.01).

Conclusions: In multiple regression analysis post-HD SBic is significantly correlated with pre-HD SBic and GBic. The low predictive power of the developed model suggests that a mathematical model including inter– and intradialytic acid-base balance, intradialytic bicarbonate mass transfer as being necessary to individualize DBic prescription.

FR-PO335

Prediction of Monthly Serum Bicarbonate Levels in Chronic Hemodialysis Patients Jochen G. Raimann, Len A. Usvyat, Stephan Thijssen, Peter Kotanko. *Renal Research Institute.*

Background: In chronic hemodialysis (HD) patients both high (>28 mmol/L) and low (< 20 mmol/L) pre-HD serum bicarbonate levels (SBic) have been associated with mortality. We aimed to identify predictors of monthly SBic.

Methods: We studied chronic HD patients treated between 11/2011 and 3/2012 in Renal Research Institute HD clinics. Multiple linear regression models with backward elimination were constructed with SBic in 3/2012 as the dependent variable and laboratory and clinical predictors assessed in the 4 preceding months. Models were developed in a randomly selected derivation cohort and tested in an independent validation cohort.

Results: We enrolled 994 chronic HD patients (age 62±15 years, 49% Blacks, 50% diabetes; SBic 24.6±3.0 mmol/L). In the derivation cohort (N=364) SBic was predicted by SBic levels of the 3 preceding months, dialysate concentrations of acetate and chloride, enPCR, and serum sodium concentration (all P<0.001); serum levels of albumin, creatinine, and chloride were marginally significant predictors (P-values between 0.02 and 0.05). Current and historical dialysate bicarbonate concentrations were excluded from all models (all P>0.1). Model evaluation in the validation cohort (N=630) showed a high correlation between predicted and observed Sbic (adjusted R^2 0.393; P<0.001); the mean difference between predicted and observed Sbic was 0.41 mmol/L (95%CI 0.19 to 0.63).

Conclusions: Next month's SBic can be predicted with clinically acceptable accuracy with SBic levels of the preceding 3 months, protein intake (enPCR), acetate and chloride levels in the dialysate and serum sodium as the key determinants.

FR-PO336

Quality of Life among Hemodialysis Patients in China: Results from the China Dialysis Outcomes and Practice Patterns Study (DOPPS) Jia Qi Qian,[2] Brian Bieber,[1] Mia Wang,[1] Mei Wang,[3] Li Zuo,[3] Xueqing Yu,[3] Xiao Yang,[3] Nan Chen,[3] Yucheng Yan,[3] Ronald L. Pisoni,[1] Sylvia Paz B. Ramirez.[2] *[1]Arbor Research; [2]Co-First Author, China DOPPS Country Investigator; [3]China DOPPS Country Investigators.*

Background: Differences in Quality of Life (QoL) for Asian vs non-Asian pts with chronic medical conditions have been reported. However, published literature among Chinese hemodialysis (HD) pts compared to other racial/ethnic groups is limited. To understand practice patterns of HD care and pt QoL in China, an initial cross-sectional study using the DOPPS protocol was conducted in Beijing, Guangzhou and Shanghai.

Methods: We present analyses of self-reported QoL and depression (self-reported and physician diagnosed) for 1090 pts in China from 2011 compared to pts in the other DOPPS 4 countries (2009-11). QoL was captured via pt responses to the SF-12. Self-reported depression was defined by a CES-D (Center for Epidemiological Studies Depression Screening Index) score of ≥ 10.

Results: The mean MCS score in China (44) was, similar to other DOPPS countries (range, 41-48). Mean PCS score in China (36) was lower than Japan (42) but slightly higher than other DOPPS countries (range, 34-36). A relatively high percentage (51%) of self-reported depression was seen in China as compared to other countries (range, 34-64). Only 6% of Chinese pts had a history of physician-diagnosed depression in their medical record, similar to Japan(5%) but less frequently diagnosed than in other DOPPS countries (range, 11%-22%).

Conclusions: The SF-12 has previously been utilized in the Chinese non-ESRD population. Assuming that the SF-12 is valid for Chinese HD pts, similar MCS and PCS scores were observed as pts in other DOPPS countries. Mean MCS scores were similar in Japanese and Chinese pts, but mean PCS scores were higher among Japanese HD pts. The discrepancy observed between self-reported and physician-diagnosed depression in China, suggests that depression is potentially under-diagnosed. Determinants of these pt-reported outcomes, as well as their relationship with clinical outcomes, will further be explored in an ongoing longitudinal DOPPS study in China.

FR-PO337

Associations of Epworth Sleepiness Scale and Cognitive Function in Hemodialysis Population Neelakania A. Dadi,[1,2] G. Wei,[1] G. Chelune,[1] R. Filipowicz,[1] S. Boddeda,[1] Y. Zhang,[1] Nestor E. Almeida,[1] Manjula Kurella Tamura,[3] Mark L. Unruh,[4] Tom Greene,[1] T. Alp Ikizler,[5] S. Beddhu.[1,2] *[1]Univ of Utah, Salt Lake City, UT; [2]VHASLC, Salt Lake City, UT; [3]Stanford Univ, Palo Alto, CA; [4]Univ of Pittsburgh, Pittsburgh, PA; [5]Vanderbilt Univ, Nashville, TN.*

Background: Hypoxic episodes associated with sleep disordered breathing might result in ↑ sleepiness and ↓ cognition. Therefore, we examined the associations of ↑ sleepiness on Epworth Sleepiness Scale (ESS) with cognitive function assessed by Montreal Cognitive Assessment (MOCA) in 121 hemodialysis (HD) patients (pts).

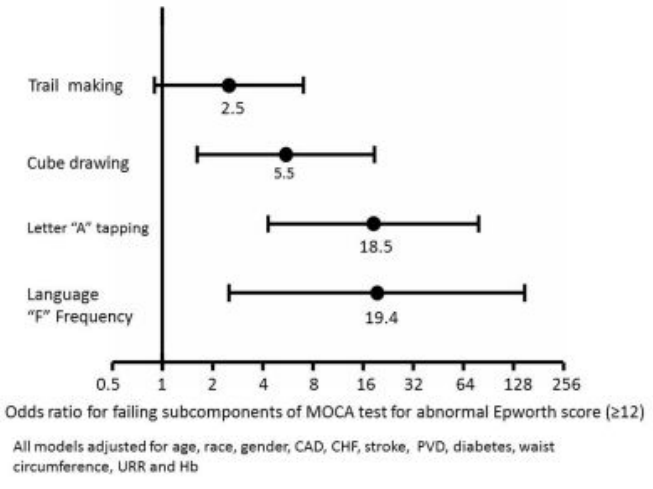
Methods: Separate multiple linear regression and logistic regression models were used to relate the total MOCA score and each of the 30 MOCA sub-components to an abnormal ESS (score≥12) controlling for comorbidity and demographics.

Results: Clinical characteristics in those with low and high ESS scores are summarized in Table 1.

Clinical characteristics by low and high ESS scores

	Low (0-12)	High (12-24)	P value
Age (yrs)	61 ± 17	62 ± 15	0.58
Male (%)	58	65	0.44
White (%)	90	83	0.25
CAD (%)	32	54	0.01
CHF (%)	23	44	0.02
Stroke (%)	23	19	0.55
PVD (%)	26	31	0.53
Diabetes (%)	56	48	0.37
Waist circumference(cm)	112 ± 18	105 ± 17	0.04
Hemoglobin (g/dl)	11.5 ± 1.5	12.8 ± 9.4	0.24
URR	0.7 ± 0.1	0.7 ± 0.04	0.86
Serum Albumin(mg/dl)	3.8 ± 0.6	3.8 ± 0.4	0.96
MOCA score	20 ± 6	19 ± 5	0.66

In the linear regression model, compared to the low ESS group, the high ESS group did not have significantly different MOCA scores (beta -1.4, p=0.18). However, subject to multiple comparisons, the odds of failing some of the subcomponents of MOCA appeared to differ between the 2 groups as shown in Figure 1.



Conclusions: Prevalence of moderate to severe cognitive impairment is common in HD pts. The overall cognitive scores were not different between those with low and high ESS scores. The association of ESS with executive function, attention and language fluency warrants further investigation.

Funding: NIDDK Support

FR-PO338

Depression as a Risk Factor for Mortality in Dialysis Patients: A Systematic Review and Meta-Analysis Farhat Farrokhi,[1] Neda Abedi,[2] Joseph Beyene,[3] Sarbjit Vanita Jassal.[1,4] *[1]Institute of Health Policy, Management & Evaluation, University of Toronto, Toronto, ON, Canada; [2]Department of Psychiatry, University of Saskatchewan, Saskatoon, SK, Canada; [3]Department of Clinical Epidemiology & Biostatistics, McMaster University, Hamilton, ON, Canada; [4]Division of Nephrology, Department of Medicine, University Health Network, University of Toronto, Toronto, ON, Canada.*

Background: We aimed to systematically review and analyze the association of depression with survival of patients on chronic maintenance dialysis.

Methods: Searching MEDLINE, EMBASE, PsychINFO, we identified studies examining the association of depression, measured as depressive symptoms or clinical diagnosis. Data extraction were carried out by two reviewers. Appraisal of the studies was done using the Newcastle-Ottawa Scale. The inverse variance method and random effects model were used to summarize the effect sizes, and the trim-and-fill method to adjust for potential publication bias.

Results: Fifteen of 31 included studies showed a significant link between depression and mortality, including 5 of 6 studies with >6000 participants. A significant link was established between presence of depressive symptoms and mortality (HR=1.51; 95%CI=1.35-1.69; I^2=40%), based on 12 studies reporting depressive symptoms using depression scales (n=21055). After adjusting for publication bias, depressive symptoms remained a significant predictor of mortality (HR=1.45; 95%CI=1.27-1.65). Combining across 6 studies reporting depression scores (n=7857) resulted in a similarly significant effect (HR=1.04 per score; 95%CI=1.01-1.06; I^2=74%). Based on 3 retrospective studies reporting odds ratios, the association of depression (diagnosis in medical charts) with mortality was non-significant.

Conclusions: There is considerable between-study heterogeneity in the reports of depressive symptoms among dialysis patients, especially because of utilization of variable measurement methods of depression. However, the overall significant independent effect of depressive affect on survival of dialysis patients warrants studying the underlying mechanisms of this relationship and the potential benefits of interventions to improve depression on the outcomes.

FR-PO339

Statin Use, and Calciphylaxis: A Case Control Study Sagar U. Nigwekar, Ishir Bhan, Ravi I. Thadhani. *Massachusetts General Hospital.*

Background: Calciphylaxis, described as cutaneous analogue of myocardial infarction, is a highly fatal condition seen in hemodialysis (HD) patients. Key features of calciphylaxis include cutaneous vascular calcification and intense inflammation. Statins have anti-inflammatory and anti-calcification properties; however, association between statin use and calciphylaxis has not been investigated.

Methods: Cases (n=62) comprised HD subjects with skin-biopsy confirmed calciphylaxis diagnosed between 2000 and 2011. Controls (n=124) were HD subjects without calciphylaxis matched to cases by gender and calendar year. Covariates were compared between cases and controls and between statin users and non-users. Odds ratios (OR) and 95% confidence intervals (CI) were calculated using unadjusted and adjusted logistic regression models.

Results: Comparison between cases and controls is summarized below-

Comparison of calciphylaxis cases and controls

Characteristic	Cases (n=62)	Controls (n=124)	P
Age, yr	58.3	58.1	0.94
Females, %	67.7	67.7	NA
Caucasian, %	58.9	63.8	0.62
HD vintage, days	312	365	0.71
Diabetes, %	43.5	41.9	0.88
Obesity, %	37.1	34.7	0.75
Macrovascular disease, %	38.3	40.1	0.99
Calcium, mg/dL	8.6	8.4	0.52
Phosphorous, mg/dL	5.4	4.9	0.07
Alkaline phosphatase, U/L	123	120	0.11
PTH,pg/mL	297	285	0.60
Albumin, g/dL	2.9	3.6	<0.001
LDL, mg/dL	89	90	0.29
Statin, %	12.9	25.8	0.04
Active vitamin D therapy, %	50.0	40.3	0.22
Calcium based phosphate binders, %	32.3	33.1	0.91
Warfarin, %	43.6	18.5	<0.001

Statin use was significantly lower in calciphylaxis cases compared to controls (p=0.04). Statin users had lower LDL (p= 0.04), higher prevalence of diabetes (p=0.02) and obesity (p<0.001) compared to non-users. In unadjusted analyses, statin use was associated with reduced odds of calciphylaxis (OR 0.43, 95% CI 0.18-0.99) whereas elevated alkaline phosphatase, hypoalbuminemia, and warfarin use were associated with increased odds. In adjusted analyses, statin use continued to be associated with reduced odds of calciphylaxis (OR 0.23, 95% CI 0.07-0.77).

Conclusions: Statin use might confer protection against calciphylaxis development. Larger prospective studies are needed to confirm this association.

FR-PO340

Renal Recovery Function Trends and Dispositions Shu-cheng Chen,[1] James P. Ebben,[1] Robert N. Foley,[1,2] Allan J. Collins.[1,2] *[1]USRDS Coordinating Center, MMRF, Mpls, MN; [2]Medicine, University of MN, Mpls, MN.*

Background: Generally, a very small percent of ESRD patients are expected to recover renal function after ESRD initiation. The recent increase of recovered renal function (RRF) noted by CMS and the renal research community, however, has raised concerns regarding the ESRD certification process and the accuracy of RRF ascertainment at dialysis facilities. We proposed to analyze trends of RRF, post-RRF dispositions, and the RRF coding system.

Methods: Data were derived from the USRDS database and CMS's Standard Information Management System (SIMS) with 98,761 total patients in the study population as of 9/30/2011. CMS and ESRD Networks identify RRF with an event code in the SIMS Patient Event File. In order to strengthen the definition, USRDS applies additional RRF criteria: < 180 days of first ESRD service date, >= 90 days before the next event, and must not be contradicted by other USRDS data sources.

Results: Using CMS/ESRD Networks definition, nearly 73% of the RRF events occurred in the first 6 months of ESRD. Many of the events seemed implausible: RRFs followed by death and RRFs occurring a year or more after initiation. In examining post-RRF events within a 90-day window, 72% were restart dialysis and another 25% death. These findings give evidence for a more robust RRF definition. Using this enhanced definition, we found a steady escalation of RRF rates among incident dialysis patients, from 1.6% in 1990 to 5.2% in 2010, a 3.25 times increase in the last 20 years. Regionally, similar rising trends were observed across Networks with Network 3 having the lowest RRF rate of 2.0% and Network 7 the highest at 8.1% in 2010. Among these USRDS defined renal recovered patients, 11% restarted dialysis and 25% died within a year. This one-year death rate is almost 1/3 higher than the 1-year crude death rate of dialysis patients of 19%.

Conclusions: Increases in RRF in recent years suggest that the criteria for ESRD certification have changed. The renal community should adopt a consistent and more accurate definition of ESRD for certification. More studies are needed to assess factors associated with rising RRF rates and evaluate the reasons behind post-RRF death and return to ESRD rates.

FR-PO341

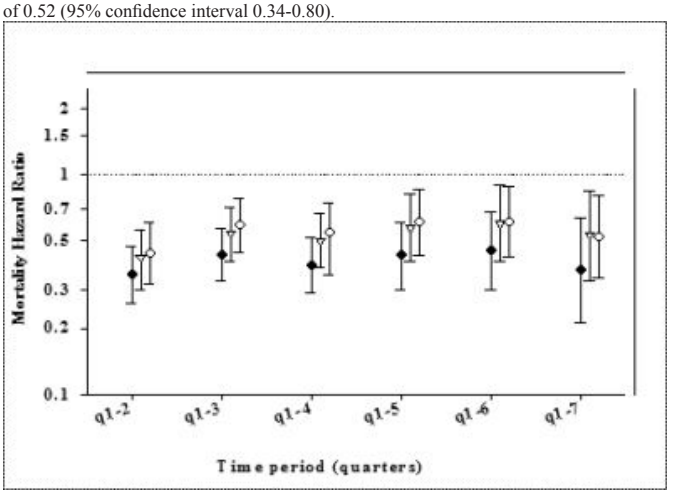
Marginal Structural Modeling of Dialysis Modality and Survival in Incident Dialysis Patients during the First Two Years Lilia R. Lukowsky,[1,3] Leeka I. Kheifets,[3] Onyebuchi A. Arah,[3] Allen R. Nissenson,[2,4] Kamyar Kalantar-Zadeh.[1,2,3] *[1]Harold Simmons Center for Chronic Disease Research & Epidemiology, LA BioMed at Harbor-UCLA, Torrance, CA; [2]David Geffen School of Medicine at UCLA; [3]UCLA Fielding School of Public Health; [4]DaVita, Inc.*

Background: Previous research indicated survival differences between hemodialysis (HD) and peritoneal dialysis (PD) modalities. Given the challenges of conducting randomized trials, differential rates of modality switch and transplantation, and time-varying confounding in cohort data during early dialysis treatment, use of novel analytical techniques in contemporary observational cohorts can help examine the PD versus HD survival discrepancy.

Methods: Over a three-year period (7/2001-6/2004), we identified 22,360 incident hemodialysis (HD) and 1,358 peritoneal dialysis (PD) patients from a large contemporary cohort. We used casual models known as marginal structural models (MSM) fitted using

inverse probability weights (IPW) to examine survival differences between PD and HD over the first 24 months. Our methods accounted for modality change, differential transplantation rates, and detailed time-varying laboratory measurements in incident dialysis patients.

Results: Incident PD patients were younger, had less co-morbidity and were 9-times more likely to switch dialysis modality and 3-times more likely to receive kidney transplantation over the 2 year period, compared to HD patients. In MSM analyses, PD offered persistently greater survival independent of the known confounders including dialysis modality switch or transplant censorship with a PD-versus-HD death hazard ratio of 0.52 (95% confidence interval 0.34-0.80).



Conclusions: PD was associated with 48% lower mortality over the first 2 years of therapy.

FR-PO342

Brain Swelling during Dialysis: A Comparison of Low Flux Hemodialysis with Pre-Dilution Hemodiafiltration Niels Johansen,[1 3] Krista Dybtved Kjaergaard,[1 3] Christian D. Peters,[1 3] Michael Pedersen,[2 3] Jens Dam Jensen.[1 3]
[1]Department of Renal Medicine, Aarhus University Hospital, Aarhus, Denmark; [2]MR Research Centre, Aarhus University Hospital, Aarhus, Denmark; [3]Institute of Clinical Medicine, Aarhus University, Aarhus, Denmark.

Background: Previous studies have shown that hemodialysis (HD) is associated with subsequent brain swelling. No studies have compared low flux HD and pre-dilution hemodiafiltration (pre-HDF) with respect to brain swelling. Our aim was to measure the effect of HD and pre-HDF on brain swelling after dialysis, and their impact on ventricular, grey and white matter volumes.

Methods: 12 patients (9 males/3 females), dialysis vintage (47 months), age (58 years) were treated with HD and pre-HDF on separate days in a randomized controlled crossover study. Session length (4 hours), ultrafiltration (2.7±1.3 L), blood flow (300 mL/min), and dialysate flow (500 mL/min) was equal in both sessions. Pre-HDF substitution fluid flow was 65 L/session. Dialysate sodium concentration was matched to the spontaneous sodium concentration in plasma. Brain volumetric MRI was performed before and after HD/pre-HDF. MRI data was processed in the neuroanalysis software SIENA v2.6, allowing for accurate automatic segmentation of the brain and estimation of volume changes. 5 healthy controls underwent a 4-hour resting period instead of dialysis in order to test measurement precision.

Results: The mean increase in brain volume was 1.8±1.7% (18.7 mL) during HD and 2.0±0.9% (22.3 mL) during pre-HDF. It was significantly higher ($p = 0.001$) than the control group, -0.1±0.3%. The difference between HD and pre-HDF was -0.2±1.4% (NS). The differences in mean ventricular (HD -3.8 mL, pre-HDF -3.6 mL), grey (HD 19.3 mL, pre-HDF 21.2 mL) and white matter volumes (HD 7.4 mL, pre-HDF 5.7 mL) were NS when comparing HD and pre-HDF. Urea reduction ratio was 68±2% in HD and 69.7±2% in pre-HDF (NS).β2-microglobulin reduction ratio was -14±4% in HD and 67±3% in pre-HDF ($P < 0.001$).

Conclusions: Both HD and pre-HDF caused brain swelling. No significant differences were observed between mean HD and pre-HDF brain volumes. Results from the control group indicate that changes in brain volume can be accurately assessed using MRI.

FR-PO343

Oral Hygiene Habits in People on Hemodialysis: A Multinational Prospective Cohort Study (Oral-D) Suetonia Palmer,[1] Marinella Ruospo,[2] Patrizia Natale,[2] Letizia Gargano,[2] Mariacristina Vecchio,[3] Valeria Maria Saglimbene,[3] Fabio Pellegrini,[3] Jonathan C. Craig,[4] Paul Stroumza,[2] Eduardo Jorge Celia,[2] Michela Sciancalepore,[2] Jorgen B.A. Hegbrant,[2] Giovanni F.M. Strippoli.[2,3,4]
[1]University of Otago; [2]Diaverum Medical Scientific Office; [3]Mario Negri Sud Consortium; [4]University of Sydney.

Background: Data describing oral hygiene habits in people with end end-stage kidney disease on hemodialysis as sparse. We prospectively surveyed global oral hygiene habits in a large outpatient hemodialysis population.

Methods: ORAL-D is an ongoing multinational prospective cohort study of oral diseases in people on hemodialysis. We consecutively enrolled adults on hemodialysis in 75 outpatient clinics selected randomly from a collaborative dialysis network in Europe and South America. We assessed oral hygiene habits using standard self-administered patient questionnaires. We summarized data using descriptive statistics.

Results: 4720 hemodialysis patients in the participating clinics from Italy, Hungary, Poland, Argentina, Portugal, France and Spain responded to the questionnaire. Of these, 2388 (52%) did not remember when they had last visited a dentist or reported they did not have a regular dental practitioner. 1264 (27%) reported their first dental visit at 30 years or older, 533 (12%) never brushed their teeth, 1722 (37%) used mouthwash and only 327 (7%) used dental floss. 1510 (33%) participants changed their toothbrush as needed, and only 1492 (35%) spent more than 2 minutes on daily oral hygiene cares.

Conclusions: Using validated instruments to evaluate oral hygiene, nearly half of adults on hemodialysis do not regularly visit a dental practitioner and many have poor oral hygiene habits. Additional study of the effectiveness of dental intervention and education on dental and clinical outcomes may be warranted.

Plasma Gelsolin and Survival in Chronic Hemodialysis Patients Laura Rosales,[1] Georges Ouellet,[3] Len A. Usvyat,[1] Rebecca H. Apruzzese,[1] Mary Carter,[1] Stephan Thijssen,[1,2] Nathan W. Levin,[1] Peter Kotanko.[1,2]
[1]Renal Research Institute, New York, NY; [2]Beth Israel Medical Center, New York, NY; [3]Nephrology, Maisonneuve-Rosemont Hospital, Montreal, QC, Canada.

Background: Low levels of circulating plasma gelsolin (pGSN) which is an actin-binding protein, have been associated with poor outcomes in critically ill and in hemodialysis (HD) patients [Lee JASN 2009; Jin Y Crit Care 2012]. In a prospective study we investigated the relationship between pGSN levels and all-cause mortality in chronic HD patients.

Methods: We determined pGSN levels (normal range between 3600 and 9750 mU/mL) on one occasion with the 2C4 pGSN ELISA kit (Critical Biologics, Cambridge, MA) in maintenance HD patients from 3 inner-city HD centers; demographics (age, vintage, race, gender, body mass index (BMI), vascular access) and co-morbidities (diabetes, cardiovascular disease, HIV status, hepatitis) were recorded. Patients were stratified into two groups by the median pGSN levels. Survival was assessed by Kaplan-Meier analysis and Cox proportional hazards models with adjustment for age, race, gender, albumin, body mass index, diabetes, vintage, and access type.

Results: We studied 153 patients (age 61±15 years; vintage 3.9±3.7 (range 0.2-20.0) years; 52% male; 42% Blacks, 52% diabetes). Median follow-up time was 390 days (interquartile range: 388 to 415). Median pGSN level was 6353 mU/mL (interquartile range 5244 to 7640). Kaplan-Meier analysis revealed no significant difference in group survival ($P=0.570$). Cox proportional hazards analysis indicated that pGSN was not a significant predictor of all-cause mortality ($P=0.181$).

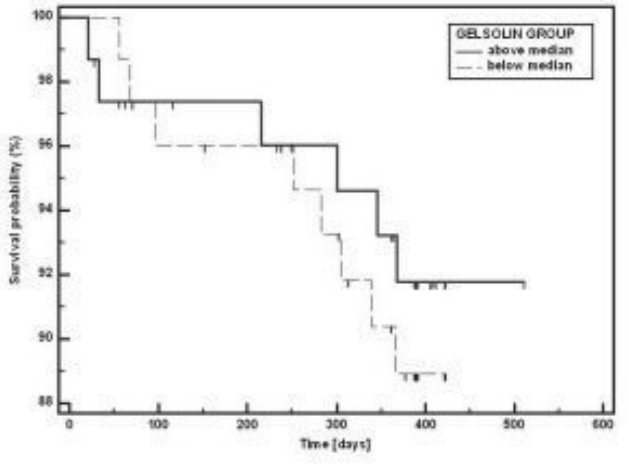

Fig 1. Kaplan-Meier curves showing survival stratified by above groups of high and low levels of pGSN.

Conclusions: This study in chronic HD patients indicates that pGSN is not related to all-cause mortality.

FR-PO345

Dialysis Adequacy and Solute Removal: Effect of Intradialytic Exercise Danielle Kirkman,[1,2] Mahdi Jibani,[2] Jamie Hugo Macdonald.[1] *[1]College of Health and Behavioural Sciences, Bangor University, Wales, United Kingdom; [2]Betsi Cadwaladr University Health Board, Wales, United Kingdom.*

Background: Dialysis adequacy is a significant predictor of hospitalization and mortality in maintenance hemodialysis (HD) patients. Whether intradialytic exercise training can enhance dialysis adequacy is unclear.

Methods: In a single blind, controlled, randomized crossover study, 11 HD patients (mean (SD) age: 58(13) years) completed three trial arms: normal routine care (CONT); increased HD time of 30 minutes (TIME); and intradialytic exercise (EXER), consisting of 60 minutes of cycling exercise at 95% of the lactate threshold in the last 90 minutes of HD. Each trial was completed twice, with all treatment parameters standardized between trials. The primary outcome was equilibrated Kt/V_{urea}. Secondary outcomes included reduction and rebound ratios of urea, creatinine, phosphate and $beta_2$-microglobulin. Data were analyzed by repeated measures analysis of variance.

Results: Increased HD time, but not exercise, significantly increased equilibrated Kt/V_{urea} compared to the control trial (TIME:1.48(0.28); EXER:1.36(0.24); CONT:1.33(0.27); p=0.02). Increased time also improved reduction ratios of urea (TIME:77(5)%; EXER:73(5)%; CONT:73(4)%; p<0.01) and creatinine (TIME:69(6)%; EXER:68(6)%; CONT:66(5)%; p=0.02), and tended to improve reduction ratio of $beta_2$-microglobulin (TIME:58(12)%; EXER:53(7)%; CONT:50(11)%; p=0.09). In contrast, phosphate reduction ratio was enhanced with exercise compared to both extra time and control trials (TIME:55(11)%; EXER:59(10)%; CONT:50(18)%; p=0.03).

Conclusions: This is the first study to compare intradialytic exercise and longer HD session time for dialysis adequacy. As expected, an extra 30 minutes of HD time significantly enhanced small and middle molecule clearance. Although exercise enhanced phosphate clearance, exercise did not enhance dialysis adequacy, as determined by the primary outcome of equilibrated Kt/V_{urea}. Thus intradialytic exercise cannot replace the traditional prescription of increased HD time, but may be a useful adjunctive therapy for serum phosphate control. *Registered clinical trial NCT01481688. Funding:* Unrestricted grant from B Braun Avitum AG.

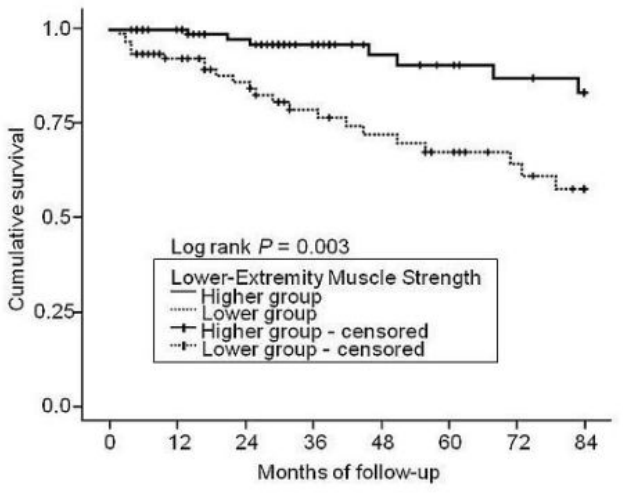
FR-PO346

Lower-Extremity Muscle Strength and Survival in Hemodialysis Patients: A Prospective Cohort Study Ryota Matsuzawa,[1] Atsuhiko Matsunaga,[1] Akira Ishii,[1] Yoshifumi Abe,[1] Toshiya Minowa,[1] Kei Yoneki,[1] Yutaka Takagi,[2] Atsushi Yoshida,[2] Kouju Kamata,[1] Naonobu Takahira.[1] *[1]Kitasato University; [2]Sagami Junkanki Clinic.*

Background: Decreased muscle strength is closely associated with physical inactivity and adverse health-related events such as fall-related injuries or walking disabilities in both the general population and those with chronic diseases. In this study, we investigated the prognostic significance of lower-extremity muscle strength on 7-year survival in a cohort of clinically stable hemodialysis (HD) patients.

Methods: A total of 190 outpatients (age 65±10, 46.8% male) who were undergoing maintenance HD therapy 3 times a week at a HD center were monitored for 7 years. Clinical characteristics including age, sex, body mass index, time on HD, comorbid conditions and serum albumin and C-reactive protein levels were obtained at baseline. In addition, maximum voluntary isokinetic knee extensor strength (leg strength), which reflects lower-extremity muscle strength, was measured using a handheld dynamometer (μTas MT-1; Anima, Japan). The median value of leg strength was used to divide patients into higher and lower groups. A Kaplan-Meier estimate of survival and a Cox proportional hazard regression were used to assess the contribution of leg strength to all-cause mortality.

Results: During the follow-up period (median 45±30 months), 30 patients died. The 7-year cumulative survival rate was 92.6% in the higher group and 75.8% in the lower group.



After adjusting for the effects of clinical characteristics, leg strength was a significant predictor of all-cause mortality. The hazard ratio of the lower group to the higher was 3.96 (95% confidence interval, 1.50-10.42; p=0.005).

Conclusions: Decreased lower-extremity muscle strength was strongly associated with survival in clinically stable HD patients.

FR-PO347

Determinants of Decreased Walking Speed among Patients Undergoing Ambulatory Hemodialysis Yoshifumi Abe, Atsuhiko Matsunaga, Ryota Matsuzawa, Akira Ishii, Toshiya Minowa, Kei Yoneki, Toshiki Kutsuna, Kyo Shigeta, Kouju Kamata. *Kitasato University, Sagmihara-shi, Kanagawa-ken, Japan.*

Background: Walking speed among patients undergoing hemodialysis (HD) reportedly decreases by 60% compared to healthy people, suggesting that patients undergoing HD may be at risk for adverse health-related events such as physical inactivity, limited mobility, and hospitalization. However, factors that decrease walking speed among these patients remain unclear. The purpose of this study was to identify factors associated with decreased walking speed based on clinical data of patients undergoing ambulatory HD.

Methods: A total of 118 Japanese outpatients undergoing maintenance HD three times per week at a HD center, who did not require assistance for walking and did not have dementia, low vision, or paralysis due to stroke, were eligible for inclusion in the study. We measured clinical characteristics (age, sex, HD duration, serum albumin and hematocrit, and history of fall-induced injury), walking speed, motor function (leg strength, lower extremity flexibility, and standing balance), and comorbid conditions (peripheral neuropathy and vascular diseases). HD patients were divided into two groups based on maximum walking speed: the slow speed group (women, ≤1.35 m/s; men, ≤1.50 m/s for men) and the fast speed group. Multivariable logistic regression analysis was performed to identify factors that predict slow and fast speed.

Results: Mean (SD) age, HD duration, and maximum walking speed were 68 (9) years, 8.6 (8.6) years, and 1.51 (0.36) m/s, respectively; 48% of subjects were women and 41% belonged to the slow speed group. The slow speed group was significantly associated with leg strength (odds ratio [OR] = 0.94, 95% confidence interval [CI] = 0.89 - 0.99, P = 0.014), standing balance (OR = 0.97, 95% CI = 0.95 - 1.00, P = 0.02), age (OR = 1.07, 95% CI = 1.01 - 1.14, P = 0.03), and a history of fall-induced injury (OR = 6.23, 95% CI = 1.31 - 29.52, P=0.02).

Conclusions: These results suggest that periodic evaluation and management of both motor function and falls are necessary to implement effective measures to prevent decreases in walking speed among clinically stable patients undergoing HD.

FR-PO348

Effect of Electron Beam Radiation Sterilized Polyethersulfone Dialyzers on Platelets during Hemodialysis Detlef H. Krieter,[1] Horst-Dieter Lemke,[2,3] Karin Merget,[2] Christoph Wanner.[1] *[1]Div. of Nephrology, University Hospital, Würzburg, Germany; [2]eXcorLab GmbH, Obernburg, Germany; [3]R & D, Membrana GmbH, Wuppertal, Germany.*

Background: In a substantial number of maintenance dialysis patients, e-beam sterilized polysulfone (ePSu) dialyzers are associated with significant thrombocytopenia following HD. The present study investigated if e-beam sterilized polyethersulfone (ePES) dialyzers induce a similar effect.

Methods: The platelet count (PC) of 63 patients subjected to maintenance HD with ePES dialyzers (PUREMA® H, 1.9 m^2) was measured pre- and postdialysis. Those patients with a significant PC drop (≥25% decrease) were enrolled in a prospective randomized controlled trial (RCT) comparing platelet activation (PC and P-selectin (CD62P)) at 0, 10, 60, and 240 min during HD with ePES, ePSu (Optiflux® Advanced Fresenius Polysulfone®, 1.8 m^2), and g-sterilized PES (gPES; PUREMA® H, 1.8 m^2).

Results: In 3 of 63 patients on ePES, a significant, but non-hazardous PC reduction to 65% (Patient #1; 181 vs. 118 x 10^3/μl), 45% (#2; 239 vs. 107 x 10^3/μl), and 54% (#3; 320 vs. 174 x 10^3/μl) of baseline was identified. In the RCT, the postdialysis PC with ePES was 67, 89, and 95% of baseline for #1, #2, and #3, resp. (mean±SD 225±70/195±85 x 10^3/μl pre/post). HD with gPES resulted in a PC decrease to 54, 89, and 96% (231±78/196±107 x 10^3/μl pre/post). With ePSu, the PC at 240 min was 64, 77, and 97% of baseline for #1, #2, and #3, resp. (246±794/205±119 x 10^3/μl pre/post). The PC with ePES and gPES was lowest at 240 min. With ePSu, a steep and early nadir at 10 min was observed in all patients. CD62P increased to between 132 % (ePES #3) and 210 % (ePSu #1) after 10 min and declined to baseline levels at 240 min. Interestingly, patient #2, differing in a clopidogrel comedication, had 2 to 3 times higher baseline CD62P and reached its maxima at 60 min.

Conclusions: Like with other sterilization modes, also with ePES, we found a minority of patients with reduced postdialysis PC. Comedications (e.g. GP IIb/IIIa antagonists) may impact on platelet activation. Screening for postdialysis PC drop should become a standard in maintenance HD.

FR-PO349

U Shaped Cost Curve in an ESRD Value-Based Integrated Care System
Robert C. Albright, Jeffrey Sigrist, John J. Dillon, James T. McCarthy, Stephen F. Gudgell, Kathryn Zavaleta, Paul Klugherz, Michelle C. Hedin, Bradley D. Wick, Amy W. Williams. *Division of Neph/HTN, Mayo Clinic, Rochester, MN.*

Background: Provision of value-based, patient-centric care to patients with ESRD demands maximizing meaningful longevity, patient satisfaction and transplantation rates, while minimizing hospitalizations, preventable complications and cost. The aim of this study was to determine the actual costs in the 6-month initiation phase of ESRD, the intervening months and the last 6 months of receiving ESRD care.

Methods: We conducted a prospective query of a decision support system of an integrated care system, which captures all costs for patients who initiated and/or received chronic ESRD care from 2006 through 2010. All patients whose care was delivered entirely at this center's hospital, outpatient multispecialty clinics and dialysis units were included. All costs were captured for this cohort, comparing the initial 6 months, the interval months and the last 6 months of ESRD care. Care was captured as dialysis days, which were defined as days in the system's care.

Results: 781 unique patients with 29,615 encounters, and 283,812 dialysis days were included. Cost data was normalized to the middle period, and then segregated into the 3 groups specified: initial 6 months of ESRD care, last 6 months of ESRD care, interval middle time. Despite only 12.8 avg days spent in the hospital/year on dialysis, ~50% of all costs were due to hospital care.

Costs

COSTS	Initial 6 months	Middle HD career	Last 6 months
GLOBAL*	1.17 ± 0.11	1.0 ± 0.15	1.55 ± 0.15
N	718	789	253
Hospital**	1.93 ± 0.23	1.0± 0.16	2.41 ± 0.12
N	220	414	196
[Mean + SD] costs of middle time = 1.00			
*p=0.06 Initial vs Middle; p=0.002 Middle vs Last			
**p=0.002 First vs Middle; p<0.0001 Middle vs Last			

Conclusions: A U shaped cost curve illustrates an increase in costs during the first and last 6 months of ESRD care. A major contribution was the higher hospital costs during these two phases of ESRD care. Emphasizing integrated care processes that avoid initiation of ESRD care in the hospital, and fostering compassionate care team engagement for end of life issues should lead to enhanced value of care for ESRD patients.

FR-PO350

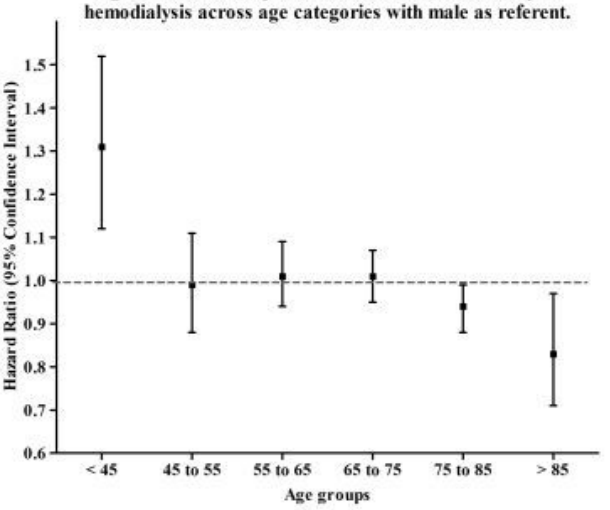
Mortality Risk for Women on Hemodialysis Differs by Age
Manish M. Sood,[1] Brenda Hemmelgarn,[2] Claudio Rigatto,[1] Navdeep Tangri,[1] Paul Komenda.[1] *[1]Medicine, Section of Nephrology, University of Manitoba, Winnipeg, MB, Canada; [2]Medicine, Section of Nephrology, University of Calgary, Calgary, AB, Canada.*

Background: Previous reports have demonstrated similar survival for men and women on hemodialysis, despite women's increased survival in the general population. To examine this paradox, we investigated the effect of age on mortality in women undergoing hemodialysis.

Methods: We identified 28,971 (Women 11,792 (40.7%), Men 17,179 (59.3%)) adult patients who initiated hemodialysis between Jan. 2000 and Dec. 2009 from the Canadian Organ Replacement Registry (CORR) and survived > 90 days. Multiple imputation was used for missing data. Crude and Adjusted rates were calculated for men and women. Cox proportional hazards and competing risks models were employed to determine the independent association between gender, age and likelihood of mortality or renal transplantation.

Results: Overall there was no mortality difference between the gender however, the age X gender interaction was highly significant (p<0.0001). Younger women experienced a considerable increase in mortality (Age < 45: aHR 1.31(1.12-1.52), p<0.0001) whereas elderly women experience improved mortality (Age 75-85: aHR 0.94 95%CI 0.88-0.99, Age > 85: aHR 0.83 95%CI 0.71-0.97).

Figure 1: Female adjusted hazard ratio for mortality on hemodialysis across age categories with male as referent.



Adjusted for demographics, co-morbidities, BMI, cause of ESRD, region, pre-dialysis care, distance, serum albumin and hemoglobin, vascular access and transition to PD by 90 days.

This relationship persisted after accounting for the competing risk of transplantation. Predictors of mortality in women < 45 included increasing age, co-morbidity (cardiac disease, pulmonary edema, diabetes, any serious illness), lower albumin and lack of an AVF.

Conclusions: Female survival on chronic hemodialysis varies by age compared to men with a significant increase in mortality in women < 45. AVF creation in this age group may represent a modifiable risk factor for mortality.

FR-PO351

Aboriginal Mortality Differs Based on Dialysis Modality: A Canadian National Study
Manish M. Sood,[1] Claudio Rigatto,[1] Paul Komenda,[1] Karen E. Yeates,[2] Brenda Hemmelgarn,[3] Julie Mojica,[1] Navdeep Tangri.[1] *[1]Medicine, Section of Nephrology, University of Manitoba, Winnipeg, MB, Canada; [2]Medicine, Section of Nephrology, Queen's University, Kingston, ON, Canada; [3]Medicine, Section of Nephrology, University of Calgary, Calgary, AB, Canada.*

Background: Previous studies have shown that Aboriginals and Caucasians experience similar outcome on dialysis in Canada. Utilizing the Canadian Organ Replacement Registry (CORR), we examined whether dialysis modality (peritoneal or hemodialysis) impacted mortality in Aboriginal patients.

Methods: We identified 30,601 adult patients (Hemodialysis: Aboriginal 1,897, Caucasian 22,116, Peritoneal dialysis: Aboriginal 463, Caucasian 6125) who initiated dialysis between Jan. 2000 and Dec. 2010. Aboriginal status was identified by self report. Dialysis modality was determined 90 days after dialysis initiation. Multivariate Cox proportional hazards and competing risk models were constructed to determine the association between race and mortality by dialysis modality.

Results: During the study period, 962 (50.7%) of Aboriginals and 12,193 (55.1%) of Caucasians initiating hemodialysis died while, 140 (30.2%) and 1,842 (30.1%) respectively initiating peritoneal dialysis died. In comparison to Caucasians, Aboriginals on hemodialysis had a comparable risk of mortality (adjusted HR 1.04 95% CI 0.96-1.11, p=0.4). However on peritoneal dialysis, Aboriginals experienced a higher risk of mortality (aHR 1.29 95% CI 1.06-1.57, p<0.0001) and technique failure (aHR 1.29 95%CI 1.03-1.60, p=0.03) than Caucasians. The risk of technique failure varied by patient age, with younger Aboriginals (<50 years old) more likely to develop technique failure than Caucasians (aHR 1.76 95% CI 1.23-2.52, p=0.002).

Conclusions: Aboriginals on peritoneal dialysis experience higher mortality and technique failure relative to Caucasians. Reasons for this race disparity in peritoneal dialysis outcomes are unclear.

FR-PO352

Impact of a Multidisciplinary Intensive Management Clinic on Asian Incident Hemodialysis Patients
Priscilla P. How,[1,2] Wan Chi Wong,[2] Jia Jia Lee,[1] Pallavi Tyagi.[2] *[1]Pharmacy, National University of Singapore; [2]Medicine (Nephrology), National University Hospital, Singapore.*

Background: Morbidity/mortality rates are high in the early months after hemodialysis (HD) initiation. The Hemodialysis Initiation and Transition (HIT) Clinic run by a renal physician, clinical pharmacist and coordinator was set up to provide multidisciplinary, intensive and consistent care to patients in the first 3-4 months after HD initiation. This longitudinal study aimed to compare lab, clinical (morbidity/mortality) and economic outcomes between patients of HIT clinic vs. conventional management.

Methods: Adult incident HD patients referred to HIT clinic or outpatient renal clinic prior to set up of HIT clinic (control group) were included. Patient demographics, medical/medication histories, lab data [hemoglobin (Hgb), transferrin saturation (TSAT), ferritin,

serum calcium (Ca), phosphorus (P), intact-parathyroid hormone (i-PTH), albumin (alb), and hemoglobin A1c (HbA1c)], hospitalizations, 90/120-day mortality and medication costs were compared between HIT and control groups at the patients' first (baseline) and third clinic visits.

Results: Eighty-five HIT and 78 control patients were included. Mean lab values of both groups at baseline and third visit were similar. More HIT patients met KDOQI goals for Hgb (61.2% vs. 33.8%; P<0.05) at the third visit compared to control group, and achieved KDOQI targets for TSAT, ferritin, CaxP, alb and HbA1c at third visit compared to baseline. Conversely, fewer control patients achieved KDOQI targets for P and i-PTH at third visit. More HIT patients had reduction in monthly medication costs (77.1% vs. 62.8%) at the third visit, received influenza (72.9% vs. 15.4%) and pneumococcal (72.9% vs. 17.9%) vaccines and had permanent access created within 6 months of HD initiation (92.9% vs. 80.8%) (P<0.05). Hospitalization and mortality rates between groups were similar.

Conclusions: A multidisciplinary intensive management clinic helps incident HD patients achieve goal therapeutic targets, create permanent vascular access and may result in costs savings for patients. Further studies are needed to determine if such interventions help reduce morbidity and mortality in these patients.

FR-PO353

Comparison between Interferon Gamma Release Assay and Tuberculin Skin Tests for the Diagnosis of Latent Tuberculosis in Patients on Hemodialysis in India, a Tuberculosis Endemic Area Sanjay K. Agarwal,[1] Sabahat Husain Zaidi,[3] Urvashi B. Singh,[2] Sanjay Gupta.[1] *[1]Department of Nephrology, AllMS, New Delhi, India; [2]Department of Microbiology, AllMS, New Delhi, India; [3]Department of Biochemistry, JN Medical College & Hospital, Aligarh, UP, India.*

Background: Tuberculosis (TB) is common in maintenance hemodialysis (MHD). Majority have reactivation of past infection. Diagnosis of latent tuberculosis (LTB) is important. Interferon Gamma Release Assay (IGRA) is reported to be better than tuberculin skin test (TST) in this setting. However, there is no data from an endemic area of TB like India.

Methods: Patients on MHD were included. Active TB patient excluded. Patients were subjected to TST using 0.1 ml solution (5 tuberculin units). After 72 hours, an induration of ≥10 mm was taken as positive. All patients were subjected to IGRA, using QuantiFERRON gold tube test (Cellestis Limited, Australia), which included purified protein derivative from *M. tuberculosis,* ESAT-6 & CFP-10 and avian sensitin. Positivity criteria for IGRA were as per CDC recommendation. TST and IGRA were compared for diagnosis of LTB. Study was funded by Indian Council of Medical Research.

Results: Of 185 patients, 69.7% were males; mean age 36.7 ± 12.3 years. History of TB was in 9.9% and 72.4% had BCG vaccination scar. IGRA was positive in 66 (35.6%), TST in 32 (17.2%) and both in 13 (7%) patients. Of the 66 patients positive with IGRA, 13 (19.6%) were TST positive. Of the 32 TST positive, 13 (40.6%) were IGRA positive. 100 (54%) were negative for both and 85 (45.9%) were positive for either of two tests. Of the 153 TST negative, IGRA was positive in 53 (34.6%). Agreement between two tests was 61.08% (kappa = 0.0421, St. Error = 0.0656). In Logistic regression, Odds of positive IGRA with BCG vaccination was 1.23 and with history of TB 0.99, (insignificant). Odds of positive TST in patients with BCG vaccination was 1.04 and with history of TB 0.99(Insignificant).

Conclusions: In conclusion, in India, on MHD, more patients (35.6%) were positive for IGRA than with tuberculin skin test (17.2%). There is agreement of 61.08% between the two tests for diagnosis of LTB. There is no effect of BCG vaccination and history of TB on both tests.

FR-PO354

Successful Elimination of Hemodialysis Related Bacteremia and Vascular Access Infection Jafar Al-Said, Aimee Pagaduan, Soni Murdeshwar. *Nephrology and Internal Medicine, Bahrain Specialist Hospital.*

Background: Hemodialysis related Bacteremia and dialysis induced infection are one of the major mortality and morbidity factors for patients with end stage renal disease.

Methods: Since the start of our hemodialysis service, 8 years ago, we have been following tight infection control steps to monitor, control and prevent infection. In this retrospective study we wanted to identify the results of our tight infection control protocol on the prevalence of hemodialysis related Bacteremia and vascular access infection. All the hemodialysis sessions performed from Jan. 2004 till the end of Dec 2011 were reviewed. Patients demographics were collected. Vascular access type, the presence of DM and HTN were recorded too. Hemodialysis related Bacteremia was confirmed by the combined presence of any of the clinical signs such as: fever, chills, generalized weakness or hypotension with a positive blood or dialysis catheter culture.

Results: Over 108 months we had 6161 hemodialysis sessions performed on 118 patients. over 8 years we had only 15 episodes of dialysis related Bacteremia in 9 patients. Three of them required admission for hemodialysis related bacteremia. The blood culture in one patient was MRSE and the other 14 patients had Sphingomonas paucilomobilis. The source of Sphingomonas organism was found to be the main dialysis water tank and machines stagnant tubing water. Infection protocol adjustments were implemented and this had successfully eliminated all infections since then. All the 9 patients recovered from the infection with Antibiotic course.

Hemodialysis Related Bactermia Outcome Results

Prevalence of HD related Bacteremia /100 patients month	0.0198
Average rate of HD Bacteremia per monthly HD sessions	0.001
Prevalence of admission for HD related Bactermia/1000 patient year	0.79
Mortality rate secondary to HD related Bacteremia	Zero

Conclusions: As compared to published figures, our infection control protocol have successfully reduced hemodialysis related Bacteremia, vascular access infection and related admissions. We would like to discuss and share our successful infection control experience with nephrologist from different parts of the world. We believe it would make a difference.

FR-PO355

Potassium Binders: "Old & Tried"… but Are They Useful in Hemodialysis Patients? Samra Abouchacra,[1] Ahmed Chaaban,[1] Nicole Gebran,[2] Faiz Abayechi,[1] Qutaiba Hussain Daoud,[1] Noura Saif Al Nuaimi.[1] *[1]Medicine, Tawam Hospital, Al-Ain, United Arab Emirates; [2]Pharmacy, Tawam Hospital, Al-Ain, United Arab Emirates.*

Background: There is insufficient evidence for the utility of potassium binding resins in dialysis patients especially given their poor tolerability. Our objective was to assess the efficacy and tolerability of the binder calcium resonium (CaR) and investigate the impact of patient education (Ed) on adherence and treatment response.

Methods: Adult hemodialysis (HD) patients receiving CaR were enrolled with control group not on this agent. Adherence and adverse effects were recorded in adherent (A), non-adherent (NA), and control (C) groups. An educational intervention was undertaken and serum potassium levels (SK) were evaluated for 3 months before and after. Inter-and intra group results were analyzed by ANOVA and paired student t- test respectively.

Results: SK levels were much lower in controls (p<0.001) and there was a significant difference in baseline SK between A and NA (p<0.003) but not post Ed (p 0.71). This was due to worsening control in the former, because of GI- related noncompliance, and not due to an improvement in NA. Dietary indiscretions and lack of cathartics use may have contributed but no difference in dialysis adequacy was noted among groups, although the impact of residual renal function was not assessed. Of note, no within group effect was observed for patient counseling.

Table 1

	NA (n= 42)	A (n=28)	Control (n=30)
Age (yrs)	61.8 ± 16.8	54.5 ± 17.9	48.9 ± 18.7

Conclusions: These findings raise concern regarding the cost-efficacy of CaR and support investing in traditional antihyperkalemic measures; namely dietary compliance and adequate dialysis. Long-term trials are awaited to better define the role of CaR in the dialysis setting.

FR-PO356

Ramadan Fasting in Hemodialysis Patients Wan Ahmad Hafiz Wan Md Adnan, Mun Hoe Wong, Abdul Hafidz Muhammad Iqbal, Yip-Boon Chong, Tee Chau Keng, Kok Peng Ng, Li Ping Tan, Soo Kun Lim. *Nephrology Unit, Department of Medicine, University Malaya Medical Centre, Kuala Lumpur, Malaysia.*

Background: Muslims are required to fast during the month of Ramadan except for those who are sick. Despite the uncertainty of the risks involved in patients undergoing haemodialysis, many Muslim patients voluntarily fast during Ramadan. The purpose of the study was to determine the effect of voluntary Ramadan fasting in patients undergoing haemodialysis.

Methods: This prospective cohort study was performed in 3 haemodialysis centres in Kuala Lumpur from 15th July 2011 to 29th August 2011. All patients who managed to fast for any number of days were included in this study (n=35, 54% female, mean age 54 ± 11 years). 89% of patients fasted for more than 15 days, 89% have hypertension and 49% have diabetes. 43% of patients have diabetes as the primary cause of end-stage kidney disease. Blood tests were taken in the last week prior to Ramadan and the last week of Ramadan for comparison. Paired t-test was used to examine the differences in dialysis parameters and biochemical values pre and post Ramadan using SPSS 19 statistical software.

Results: Both pre and post dialysis weight were significantly decreased during Ramadan fasting by 0.8±1.0 kg and 0.7±0.9 kg, respectively (p=<0.001), compared to the month prior. There was a significant decrease in the amount of ultrafitration by 0.3±0.5 litre (p=0.002). Mean urea reduction ratio (URR) pre- and during Ramadan were 67.2% and 66.5%, respectively (p=0.53). There were no significant differences in dry weight, inter-dialytic weight gain or blood pressure measurement at the end of Ramadan compared to the month prior. Biochemically, there was a significant increase in serum albumin level (1.0±2.0 g/L, p=0.006) and a significant decrease in serum phosphate level (0.2±0.4 mmol/L, p=0.02) at the end of Ramadan. There were also trends towards significant decreases in serum urea (1.2±3.4 mmol/L, p=0.051) and serum haemoglobin (0.3±0.9 g/dL, p=0.066) as well as an increase in serum calcium (0.06±0.16 mmol/L, p=0.053).

Conclusions: Ramadan fasting is associated with reduced weight, improved serum albumin and phosphate level in haemodialysis patients.

Patients with Diabetic Kidney Disease Have a Worse Survival than Patients with Diabetes as Co-Morbidity in Chronic Hemodialysis Patients

Chiu-Ching Huang,[1,2] Che-yi Chou,[1,2] Chih-chia Liang,[1] Huey-Liang Kuo,[1,2] Chiz-tzung Chang,[1,2] Jiung-hsiun Liu,[1,2] Hsin Hung Lin,[1,2] I-kuan Wang,[1,2] Yafei Yang,[1,2] Yi-Tzone Shiao,[3] Kuang Fu Cheng.[3] *[1]Kidney Institute and Division of Nephrology, Department of Internal Medicine, China Medical University Hospital, Taichung, Taiwan; [2]College of Medicine, China Medical University, Taichung, Taiwan; [3]Biostatistics Center, China Medical University, Taichung, Taiwan.*

Background: Diabetic kidney disease is a major cause of end-stage renal disease (ESRD). It is not clear if the survival of patients with diabetic kidney disease (DKD) associated ESRD is different from patients with diabetes as a co-morbidity. The aim of this study is comparing the survival of DKD patients and patients with diabetes as co-morbidity in chronic hemodialysis (HD) patients.

Methods: An observational cohort analysis based on database of Taiwan Renal Registry. Patients: Adult patients (n=46596) on chronic HD for at least 90 days at 450 facilities in Taiwan from 1995 to 2005. Survival status was observed until Dec 31, 2008. All patients have complete observation of study factors - age, gender, primary renal disease, co-morbidity, blood glucose, hematocrit and serum levels of albumin, calcium, phosphate and i-PTH. Statistics: Patients' survival and hazard ratio for death were determined using Kaplan-Meier analysis and Cox proportional-hazard models.

Results: A total of 20,489 (44%) patients were identified from 46,596 hemodialysis patients. Among them, 15430 patients had DKD and 5059 patients had DM as co-morbidity. They were followed for an average of 4.9 ±2.5 years. The mortality rate was 68.9% for patients with DKD and 39.7% for patients with diabetes as co-morbidity ($p<0.001$). The survivals for patients with DKD associated ESRD was significantly worse than patients with DM as co-morbidity ($p<0.001$, log-rank test). The hazard ratio for death of DKD associated ESRD patients was 1.95 (95% CI: 1.849 to 2.056) in Cox proportional regression with case-mix-and multiple covariant adjustment.

Conclusions: In chronic hemodialysis patients, those with diabetic kidney disease as primary renal disease are linked to a much higher mortality risk than patients with diabetes as co-morbidity.

The Risks of Long-Term Hospitalization at the Initiation of Hemodialysis

Toshifumi Sakaguchi,[1] Takashi Shigematsu,[2] Ryoichi Ando,[2] Daijo Inaguma,[2] Masato Ikeda,[2] Nobuhiko Joki,[2] Fumihiko Koiwa,[2] Yasuhiro Komatsu,[2] Toshio Shinoda.[2] *[1]Nephrology, Rinku General Medical Center, Izumisano, Japan; [2]The Japan Study Group of Assesing Initiation of Renal Replacement Therapy (JSTART).*

Background: Long-term hospitalization at the initiation of hemodialysis(HD) increases the cost of hospitalization and reduces the patients' quality of life. In order to prevent those, we have to elucidate the positive and negative.

Methods: In our study group, there were 2,120 HD initiations from 2006 to 2010. We selected the patients with whom the necessary data were available. Those items were age, sex, early referral to a nephrologist (ER), the incidence of diabetes mellitus, the modality of vascular access at the initiation of HD (AVF), average blood pressure (ABP), hemoglobin (Hb), Albumin (Alb), C-reactive protein (CRP), estimated glomerular filtration rate (eGFR), and blood urea nitrogen (BUN), and the medication before the initiation such as recombinant erythropoietin (EPO), angiotensin receptor blocker (ARB), angiotensin converting enzyme inhibitor (ACEI), calcium channel blocker (CCB), and loop diuretics. We defined a long hospital stay as longer than three weeks in a hospital and an early referral to a nephrologist as longer than three months. We applied binominal logistic regression. The dependant variable was a long hospital stay and the independent variables were those items mentioned above.

Results: The number of subjects was 1.351. Average age was 66.9±13.5. Male and female ratio was 895/456. The duration from the first referral to nephrologist to the initiation of HD, 25% 59 days, median 407 days, 75% 1,123 days. Significant ($P<0.05$) independent variable were age, EPO, ARB, CCB, AVF, ABP, BUN, Alb, CRP. The values of their odds ratio were 1.013, 0.673, 0.653, 0.730, 0.160, 0.986, 1.006, 0.551, 1.101 respectively.

Conclusions: The factors that increase the risk of a long hospital stay were age, BUN, CRP. The factors that contribute to a shorter hospital stay were EPO, ARB, AVF, ABP, Alb. Except age all factors are controllable to some extent by nephrologists. Therefore a referral to a nephrologist contributes directly and indirectly to a shorter hospital stay at the initiation of HD.

FR-PO359

Differences in Predicting Mental Health among Taiwanese and American Dialysis Patients

Krister Cromm,[1,2] Len A. Usvyat,[3] Jochen G. Raimann,[3] Peter Kotanko.[3] *[1]City University, Hong Kong; [2]Fresenius Medical Care, Hong Kong; [3]Renal Research Institute, NY, NY.*

Background: Explore differences in predicting mental health by comparing QOL data from dialysis patients in Taiwan and the US.

Methods: KDQOL surveys collected from patients treated in Renal Research Institute (US, 4349) and NephroCare clinics (Taiwan, 294). US surveys collected routinely; only first survey per patient was used. Taiwanese data was collected for academic research on QOL predictors across cultures. Predictor variables: disease burden, symptoms, effects subscales. Control variables: gender; age; relationship, vocational, socio-economic status; ethnicity; cause of renal failure; dialysis vintage. Outcome measure: mental composite score (MCS).

Results: Incomplete questionnaires were excluded. Refer to Fig.1 for significant associations (r) with MCS.

	US (n=4103)			Taiwan (n=258)		
	α	β	r	α	β	r
Burden	0.83	0.31**	0.52**	0.86	0.20**	0.45**
Symptoms	0.58	n/a	n/a	0.88	n.s.	0.41**
Factor 1	0.78	0.17**	0.46**	n/a	n/a	n/a
Factor 2	0.76	0.07**	0.38**	n/a	n/a	n/a
Effects	0.84	0.19**	0.50**	0.83	0.48**	0.60**
Employment	n/a	0.02	0.02	n/a	0.14**	0.25**
SES	n/a	0.01	0.01	n/a	0.09*	0.30**

**: p<0.01; *: p<0.1; n.s.: not significant; n/a: not applicable; SES: socio-economic status

For Taiwan, hierarchical multiple regression model explained 44% of adjusted variance in MCS ($F(5,252) = 41.10$, $p<0.01$). Demographic variables explained 11% (block 1, $\Delta R^2=0.11$, $F(2,255)=15.43$, $p<0.01$), disease variables 34% (block 2, $\Delta R^2=0.34$, $F(3,252) = 52.04$, $p<0.01$). Disease effects were most significant independent predictor (β). For US, internal consistency (α) of symptoms scale could only be improved to acceptable standards by separating into two factors. Regression model explained 36% of adj. variance ($F(4,4201)=587.93$, $p<0.01$).

Conclusions: Mental health in Taiwanese patients appears less affected by burden and symptoms of dialysis than by its effects on daily life that cannot be mitigated through internal mental processing. Future research should analyze why internal consistency in symptoms scale was low in the US, and contribution of disease symptoms not significant in Taiwan, e.g. because of different disease perception. New tools may need to be developed to measure mental health for dialysis patients across cultures.

FR-PO360

Generalized Anxiety Disorder in Prevalent Patients on Hemodialysis

Bilal El Hayek,[1] Eduardo Baamonde,[1] Elvira Bosch,[1] German Perez Suarez,[1] Ignacio Ramirez,[1] Cesar Garcia-canton,[2] Maria Dolores Checa.[2] *[1]Nephrology, AVERICUM, Las Palmas, Spain; [2]Nephrology, Hospital Universitario Insular de Gran Canaria, Las Palmas, Spain.*

Background: The prevalence of the Generalized Anxiety Disorder (GAD) in Spain is up to 13.7%. GAD is characterized by excessive anxiety symptoms, worrying, nervous feeling, irritability, concentration difficulties, sleep disturbances and fatigue syndrome. Generalized Anxiety Disorder questionnaire (GAD-7) is a validated tool to identify potential patients suffering from GAD. Aims: To describe the prevalence of GAD in patients on hemodialysis (HD) and its impact on several clinical and laboratory parameters.

Methods: We studied 156 patients on HD between January and March in 2011, the mean age was 62.0 ± 12.9 years, 67.9% were male, on HD for a median time of 29.5 months (IQR: 16-53 months), and 47.4% were diabetic. It was used the following scoring scale of the GAD-7: a) grade 1 (0 to 4 points). b) grade 2 (5 to 9 points). c) grade 3 (10 to 14 points). d) grade 4 (15 to 21 points). We divided the population into 2 groups considering that a cut-off value > 9 points defines moderate-severe GAD. We compared clinical and laboratory parameters between both groups.

Results: 20.5% out of the studied patients exhibited a clinically relevant anxiety disorder. Compared with patients not suffering from anxiety disorder, we observed an increased use of psychiatric drugs (62.5% vs 41.9%, $p = 0.037$) and the prevalence in women was higher (34% vs 14%, $p = 0.004$). Furthermore, we observed a negative correlation between the GAD-7 score and the age (OR: -0.24, $p <0.001$) as well as with the time on dialysis (OR: -0.18, $p = 0.016$). We either found no correlation GAD-7 score with the related- bone-mineral metabolism, and biochemical parameters, weight gained between dialysis sessions and the absolute number of drugs taken by these patients.

Conclusions: The GAD-7 is a simple and easy to use tool for the screening of GAD in patients on HD. GAD was associated with increased use of psychiatric drugs and was more common in women. The prevalence of GAD was higher in younger patients and in those with less time on HD, which was possibly related to their adaptation to a chronic treatment.

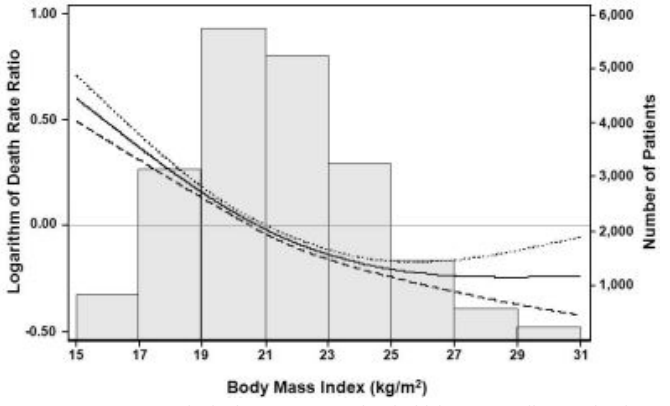
FR-PO361

Mortality Prediction of Body Mass Index in South Korean Hemodialysis Patients Jongha Park,[1,2] Dong Chan Jin,[3] Jong Soo Lee,[2] Hyun Chul Chung,[2] Jennie Jing,[1] Miklos Zsolt Molnar,[1] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center for Chronic Disease Research & Epidemiology, LA BioMed at Harbor-UCLA, Torrance, CA; [2]Ulsan University Hospital, Ulsan, Republic of Korea; [3]St. Vincent Hospital, the Catholic University of Korea, Suwon, Republic of Korea.*

Background: In hemodialysis (HD) patients, lower body mass index (BMI) has been show to correlate with higher mortality rates, a phenomenon referred to as the obesity paradox or reverse epidemiology. However, this association has not been firmly proven in East Asian dialysis populations who tend to have smaller average body size than non-Asian dialysis patients.

Methods: The association of baseline BMI with all-cause mortality was evaluated in 20,818 HD patients registered on ESRD Registry Program of Korean Society of Nephrology from February 2001 to June 2009 (with follow up to February 2012). Survival analyses included Cox proportional hazard and spline models with adjusting for case-mix and other surrogates of nutritional status.

Results: The patients were 54±14 (mean±SD) years old and included 43% women and 39% diabetics. Median BMI was 21.2 kg/m^2 (1st to 99th percentiles: 15.6-30.5). Patients were divided into BMI quartiles: 1st; <19.4, 2nd; 19.5-21.2, 3rd; 21.3-23.2 and 4th; >23.2 kg/m^2. With 2nd quartile as the reference, patients in 1st quartile reported 26% (HR: 1.26, 95%CI: 1.18-1.36) higher risk of death; while patients in 3rd and 4th quartiles reported 9% (HR: 0.91, 95%CI: 0.85-0.99) and 21% (HR: 0.79, 95%CI: 0.73-0.86) lower risk of death, respectively. The spline models confirmed that higher BMI exhibited a monotonic association with lower mortality rates.



Conclusions: Larger body size appears associated with lower mortality rates in a large cohort of Korean HD patients, suggesting that the obesity paradox previously reported for the US and European HD populations also hold in East Asian HD patients.

FR-PO362

Iron Deficiency without the Presence of Anemia Is Associated with Intradialytic Hypotension: Role of Iron beyond Erythropoiesis Kenichiro Koitabashi,[1] Masahiko Nagahama,[1] Kumiko Shimasaki,[1] Keita Hirano,[1] Yuki Heath,[1] Fumika Taki,[1] Sachiko Ohde,[2] Yasuhiro Komatsu.[1] *[1]Nephrology, St Luke's International Hospital, Tokyo, Japan; [2]Clinical Epidemiology, St Luke's International Hospital, Tokyo, Japan.*

Background: Intradialytic hypotension (IDH) is a relatively common problem, being related to high morbidity and mortality as well as increased patients care in hemodialysis (HD) unit. Several potential risk factors for IDH have been addressed, such as old age, female sex, presence of diabetes, low cardiac ejection fraction (EF) and hypoalbuminemia. Although several studies suggested that iron deficiency is related to hemodynamic instability through reduced vascular tone, the relation of iron deficiency and IDH has not been elucidated. The aim of the present study is to clarify the association of body iron store and IDH.

Methods: We analyzed clinical and biochemical parameters of 99 patients on maintenance HD at St Luke's International Hospital in 2012. IDH was diagnosed with a decrease in systolic BP≥30mmHg associated with clinical events and need for nursing interventions. Risk factors for IDH were sought using multivariate logistic regression.

Results: Among 99 patients, 44 (44.4%) patients were diagnosed with IDH. The mean age of the patients was 66±13 (mean+/-S.D.) yr, the male/female ratio was 26/18, duration of HD was 8.9±6.6 years and the Kt/V was 1.4±0.2. The mean Hb level was 10.7±1.2 g/dl, blood ferritin level (FRN) was 39.8±36.9 ng/ml and transferrin saturation (TSAT) was 18.1±11.8%. On univariate analysis, patients with IDH had more interdialytic weight gain (P=0.004), more likely to be iron deficient, TSAT <20% (P<0.01) and FRN<100 ng/ml (P=0.02). Multivariate logistic regression analysis identified TSAT<20% (odds ratio = 3.00, P=0.034) and higher Hb (odds ratio = 1.80, P=0.034) as independent risk factors for IDH.

Conclusions: The present study shows that iron deficiency without presence of anemia is related to IDH. This implies importance of iron role beyond erythropoiesis, being involved in oxidative metabolism and cellular energetics. Given the effects of IDH on HD patients, our study underscores the importance of treating iron deficiency even without the presence of anemia.

FR-PO363

The Survival of Elderly Hemodialysis Patients Misaki Moriishi,[1] Hideki Kawanishi.[2] *[1]Internal Medicine, Tsuchiya General Hospital, Hiroshima, Japan; [2]Surgery, Tsuchiya General Hospital, Hiroshima, Japan.*

Background: Recently, the numbers of elderly dialysis patients are increasing, but they are poorly prognosis on dialysis therapy. We studied risk factors of death in dialysis patients aged over 80 years.

Methods: In this single center, 146 dialysis patients aged over 80 years who started hemodialysis from 2005 through 2010, were investigated age, gender, primary ESRD cause, e-GFR, serum albumin, hemoglobin, comorbidity disease, planned dialysis, and non-planned dialysis, associated with survival. Date a was analyzed using multivariable stepwise Cox analysis, Kaplan- Meier analysis, and Student's t-test.

Results: For 6 years, 87 patients out of all patients were died. 1 year survival rate was 70%, 2 years survival rate was 57%. In multivariable stepwise Cox analysis, independent predictors of death were non-planned dialysis and >1.8mg/dL CRP. HR was 2.1 (95%CI, 1.51-4.02) for non-planned dialysis, and 2.3 (95%CI, 1.76 -4.64) for >1.8mg/dL CRP, respectively. For 19 patients who died < 90 dialysis days, their serum albumin value was significantly lower compared to surviving patients. (3±0.6 mg/dL vs. 3.3±0.5 mg/dL, p<0.001). Based on their serum albumin value of the 146 patents, the three groups can be formed, which is 1) < 3 mg/dL, 2) 3-3.4 mg/dL and 3) >3.5 mg/dL. Applying the Kaplan- Meier analysis, the survival rate of the group 1) was significantly lower than the other groups. The 40% of the group 1) died within 180 dialysis days.

Conclusions: The expected benefit of RRT should be considered and discussed for the elderly patients with low serum albumin and high CRP, at the time of the application of the hemodialysis.

FR-PO364

Outcomes Associated with Years of Hemodialysis Therapy in the HEMO Study Chi-Ting Su,[1,2] Jonathan Yabes,[1] Mark L. Unruh.[3] *[1]GSPH, University of Pittsburgh; [2]Nephrology, National Taiwan University Hospital, Yun-Lin; [3]Renal-Electrolyte Division, University of Pittsburgh Medical Center.*

Background: The factors associated with long-term survivorship on maintenance thrice weekly hemodialysis (HD)are unclear.This study examines the extent to which comorbid conditions, nutrition,life quality,and HD parameters are associated with long-term survivorship.

Methods: This report takes advantage of the HEMO Study,which provides a well-characterized cohort of prevalent HD patients.HD years, Index of coexistent diseases score, baseline demographics, fluid removal, membrane flux, dialysis dose, vascular access and anthropometric parameters were selected as covariates.Adjusted Cox-regression model was used to examine patient survival predictors.We characterized patients on dialysis >3.7 years as long-term survivors.

Results: Compared to patients on HD for <1 year and >3.7 years, the history of peripheral vascular diseases (PVD), congestive heart failure (CHF) admission, vascular access, sleep quality, and midarm circumference(MAC) were different predictors.Among those on HD >3.7 years, patients with a history of CHF admission(HR1.7, p=.003) had worse all-cause mortality and those with better sleep quality(HR0.96)and higher MAC(HR0.93) tended to have better survival.Diagnosis of PVD(HR1.6,p=.014) and vascular access(AVG *vs* AVF:HR1.8,p=.008) were factors for higher mortality in patients on dialysis <1 year but not in those who survived longer on HD(p=.231).

Conclusions: There were a number of modifiable factors associated with long-term survivorship including avoiding overhydrated, sleep quality, nutrition status, and vascular access. Among long-term survivors, history of CHF admission, poor quality of sleep and less MAC was associated higher mortality in the subgroup of patients with >3.7 HD years but not in those with<1 year.

Comparison Predictors for all-cause mortality

Predictors	<1 year(n=403)	>3.7 years(n=933)
PVD	79.2% HR1.6	80.9% N/A
CHF	44.2% HR1.6	36.7% HR1.32

FR-PO365

Blood Pressure Control without Antihypertensive Medications Is a Good Predictor of Dry Weight in Dialysis Pre Transplant Patients Sonia C. Rivera Gonzalez, Nadia Saavedra, Magdalena Madero. *National Heart Institute, Mexico City.*

Background: Hypertension in renal replacement therapy (RRT) is usually related to volume expansion. Adequate blood pressure (BP) control in RRT suggests an appropriate dry weight. There are limited data regarding the utility of pre transplant RRR weight comparing the use of antihypertensive medications (HTNM) as a marker of dry weight. The aim of this study was to compare pre transplant RRT weight with and without HTNM with post transplant weight.

Methods: This was a retrospective study that included patients undergoing living kidney transplant (LKT) between 2008-2012. Weight and mean blood pressure (MBP) were analyzed at the time they started RRT (B), 1 week before undergoing LKT (PRE) and 1 week after the LKT (W1). W1 was considered the dry weight. Other variables included number of pre LKT HTNM, ecocardiographic parameters (left ventricular septum and

posterior wall thickness) and urine output (UO) in the first 24 hrs post LKT. We calculated the percent change in body weight PRE and W1.

Results: The study included 100 patients that were divided according to the use of HTNM. Mean age was 28±9 and 67% were male. Patients in the HTNM group had an average of 1.7±1 BP meds. Compared to the group with HTNM, patients in the group without HTNM did not have a significant difference in weight when PRE and W1 were compared. In addition MBP, urine output and left ventricular hypertrophy parameters were lower in the no HTNN group.

Patient characteristics according to the use of HTNM

	B , PRE, W1 (weight/kg)	p value W1/B, pW1/PRE	Delta W1/ PRE (%)	MBP mmHg	UO 24 h post LKT (L)	LV septum (mm)	Posterior wall thickness (mm)
BP with HTNM (n=60)	60±13, 62±14, 58±14	0.01, 0.01	0.4±6	105±15	5.5±2	11.4±2	11.4±2
BPcontrol no HTNM(n=40)	60±14, 57±15,56±14	0.01, NS	-6.5±7	88.9±13*	3.7±1.7*	10.4±2*	10.7±2*

p<0.05

Conclusions: BP control without HTNM is a precise method of assessing dry weight.

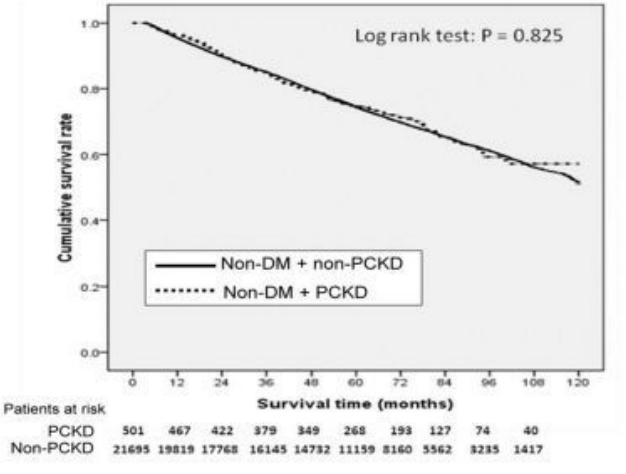
FR-PO366

Epidemiology and Mortality among Dialysis Patients with and without Polycystic Kidney Disease: A National Cohort Study in Taiwan Chih-Ching Lin.[1,2] *[1]Division of Nephrology, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan; [2]School of Medicine, National Yang-Ming University, Taipei, Taiwan.*

Background: Polycystic kidney disease (PCKD) is one of the most common inherited disorders in end-stage renal disease (ESRD) patients. It is generally thought that survival of PCKD patients on dialysis surpasses that of general dialysis patients, but the cause of better survival is not well defined.

Methods: Using Taiwan's National Health Insurance claim data, we performed a longitudinal cohort study to investigate the survival and impact of comorbidities on mortality in dialysis patients with and without PCKD. Further analysis among non-diabetic mellitus (DM) patients were performed after excluding DM patients. A Cox proportional hazards model was used to identify the risk factors for all-cause mortality. Overall patient survival was described using the Kaplan-Meier method.

Results: Of 22298 non-diabetic incident dialysis patients, 501 patients (2.25%) had PCKD. There was no significant difference in survival rates between the two groups. Male gender, age ≥ 65 years old, congestive heart failure, and cerebrovascular accident were independent predictors of mortality among PCKD dialysis patients.



Conclusions: The proportion of PCKD as the underlying cause of ESRD in Taiwan is lower than those in Western countries. The long-term survival outcome was similar between non-diabetic dialysis patients with and without PCKD in Taiwan.

Funding: Government Support - Non-U.S.

FR-PO367

Descriptive Analysis of a Single-Center 40-Year Home Hemodialysis (HHD) Experience Eric Goffin,[1] Tony Goovaerts,[1] Krystel Carlier,[2] Veronique Chapalain,[3] Michel Y. Jadoul.[1] *[1]Nephrology, Université Catholique de Louvain, Brussels, Belgium; [2]Keyrus Biopharma, Lasnes, Belgium; [3]Keyrus Biopharma, Paris, France.*

Background: There is worldwide renewed interest in HHD, a dialysis modality chosen by a significant proportion of our ESRD patients over the last four decades.

Methods: We here present the patients' and dialysis modality characteristics, trends over time and outcomes of the HD patients from our institution who started HHD as their first RRT modality over the last 40 years.

Results: Between 1970 and 12/2011, 246 [169 males; 181 (73.6 %) being professionally active] patients started HHD as first RRT. Median follow-up time on HHD was 2.4 (IC 95%: 2.1-3.0) years.The trends over those 4 decades are presented in the table.

	<1980	1980-89	1990-99	2000-11	Overall	p
N (patients)	49	65	38	94	246	
Age at first HHD (range)	46 (19-67)	44 (21-69)	42 (16-71)	42 (15-79)	43 (15-79)	NS
Solo-HHD : N (%)	0 (0)	2 (3.1)	5 (13.2)	48 (51.1)	55 (23.4)	<0.001
Charlson comorbidity*	2 (2-8)	2 (2-7)	2 (2-7)	2 (2-10)	2 (2-10)	NS
AV Fistula (%)	100	96.9	100	81.9	92.2	<0.001
Catheter ** (%)	2.1	1.5	2.6	23.4	10.2	<0.001
Training time (days)*	81 (21-250)	73 (17-205)	56 (7-120)	36 (10-149)	60 (7-250)	<0.001
Dialysis modality *** (%)						<0.001
Conventional (3x4 hrs)	73.4	92.3	84.2	41.5	67.9	
Daily	0	3.1	10.5	7.4	5.3	
Nocturnal	4.1	1.5	0	11.7	5.7	
Other	22.4	3.1	5.3	39.4	21.1	

* median (range), ** transient or permanent, *** at last follow-up. Hospitalization incidence (all causes) averaged 3.21 (3.15-3.27) cases/100 patients-months. At last follow-up, 123, 49, 33 and 41 patients have been transplanted, changed their mode of dialysis, died (one only in relation to a HHD technical problem) or are still on HHD, respectively.

Conclusions: HHD is a safe and convenient modality for ESRD patients. Over time, there has been i. a significant increase in the proportion of patients doing solo-HD, ii. with a transient or tunnelled catheter and iii. doing more intense (daily or nocturnal) HHD while iv. training time significantly decreased.

FR-PO368

Improvement in Left Ventricular Hypertrophy after Nocturnal Home Hemodialysis with an Alternate Night Schedule Hon-lok Tang,[1] Ho Sing Joseph Wong,[3] Clara Poon,[1] Culen Lau,[2] William Lee,[1] Au Cheuk,[1] Ka Fai Yim,[1] Ka-foon Chau,[3] Samuel K.S. Fung,[1] Matthew K.L. Tong.[1] *[1]Division of Nephrology, Department of Medicine and Geriatrics, Princess Margaret Hospital, Hong Kong, China; [2]Cardiology Unit, Department of Medicine and Geriatrics, Princess Margaret Hospital, Hong Kong, China; [3]Renal Unit, Department of Medicine, Queen Elizabeth Hospital, Hong Kong, China.*

Background: Left ventricular hypertrophy (LVH) is an independent risk factor for mortality in dialysis patients. LVH in end-stage renal disease (ESRD) patients has been attributed to factors including hypertension, anemia and uremia. In Hong Kong, nocturnal home hemodialysis (NHHD) is performed with alternate night schedule. This study aims to investigate the effect of alternate night NHHD on LVH and its contributing factors.

Methods: Sixty-two consecutive patients were started on NHHD in 2 dialysis centers between 8/2006 and 12/2011 with an alternate night schedule (3.5x/week) for 6-9 hours. Left ventricular mass index (LVMI) measured by echocardiogram, systolic and diastolic blood pressure (BP), number of anti-hypertensive medications, hemoglobin (Hb), erythropoietin (EPO) dosage and weekly spKt/V at baseline before NHHD and at 24 months were retrospectively reviewed.

Results: Twenty-three patients had completed NHHD for 24 months. After 2 years of NHHD, LVMI decreased from 214.4±72.5 at baseline to 191.7±82.2 g/m^2 (P<0.05). Systolic BP decreased from 146±18 to 135±15 (P<0.05) and diastolic BP decreased from 90±9 to 84±9 (P<0.05). The number of anti-hypertensive medications also significantly reduced from 2.6±1.2 to 1.3±1.5 (P<0.01) with 10 patients (43%) able to stop all anti-hypertensives. Hb increased from 9.4±1.4 g/dL to 11.3±2.4 g/dL (P<0.01) despite a reduction in EPO dose requirement from 113.3±44.5 to 51.8±50.7 U/kg/week (P<0.01). Weekly spKt/V during conventional HD was 3.67±0.98 while that during NHHD was 2.7 times higher at 9.85±4.04 (P<0.001).

Conclusions: NHHD with an alternate night schedule improves left ventricular hypertrophy in patients with ESRD. It alleviates the contributing factors: reduces BP and the need for anti-hypertensive medications, improves anemia control, and enhances uremia clearance.

FR-PO369

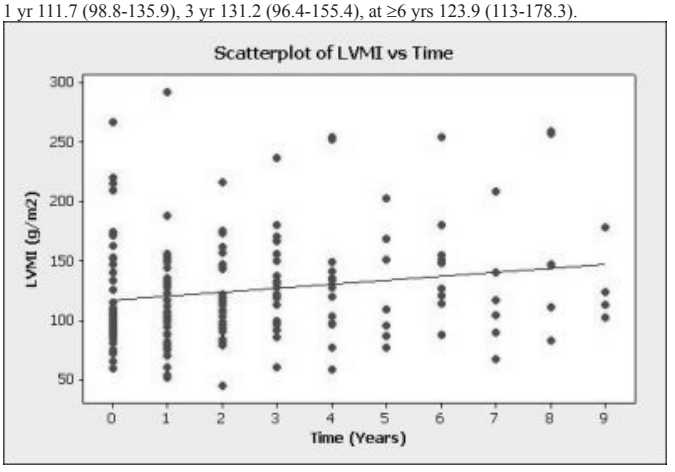
Long Term Effects of Nocturnal Home Hemodialysis on Left Ventricular Mass Index Holly L. Hutton,[1] Yu Zhang,[2] John W.M. Agar,[1] Christine A. Somerville,[1] Anthony D. Perkins.[1] *[1]Nephrology, Barwon Health, Geelong, Victoria, Australia; [2]Medicine, University of Melbourne, Melbourne, Victoria.*

Background: Trials have shown decreases in left ventricular mass index (LVMI) in pts treated with Nocturnal Hemodialysis (NHD) compared to conventional HD. However there is a paucity of data about the long term effects of NHD on LVMI. We studied changes in LVMI in a cohort of NHD pts, focusing on a subgroup on NHD ≥6 years.

Methods: Yearly transthoracic echocardiograms (TTE), comorbidities, cardiac events, duration of previous RRT, BP and laboratory parameters were obtained by retrospective analysis of records. Correlation was done using regression analysis. A sign test was used to calculate average LVMI, expressed as median and interquartile range(g/m^2).

Results: 39/44 pts had at least a baseline and 1 yr TTE. Median baseline LVMI was 108.05 (92.63-146.72); 1 yr 106.81(88.18-132.1). 11 pts with data at 1, 3 and ≥6 years were

studied with most recent TTE as the final reading(mean 7.8 yrs). At ≥6 yrs, 4 patients had a reduction and 7 had an increase in LVMI. Median LVMI at baseline was 115 (75.5-152.7), 1 yr 111.7 (98.8-135.9), 3 yr 131.2 (96.4-155.4), at ≥6 yrs 123.9 (113-178.3).



Changes in LVMI did not correlate with Hb, CRP, PTH, Ca/PO4 product, homocysteine, BP, or cardiac events on regression analysis. At 3 yrs, longer duration of previous conventional HD was associated with less of an increment in LVMI (0.62 g/m^2 per mth, p=0.001).

Conclusions: Decreases in LVMI seen in the first year of NHD were not sustained after 3 yrs, and changes during the first year were not indicative of long term trends. A previous study in conventional HD showed decrements in LVMI over 5 yrs; whilst this was not shown in our small cohort, baseline and final LVMI were comparatively lower. The lack of correlation between changes in LVMI and the studied parameters may be attributed to relative stability of these parameters.

FR-PO370

Dialysate Recirculation Significantly Reduces Dialysate Volume James G. Heaf,[1] Mette K.M. Axelsen,[2] Robert Smith Pedersen.[3] *[1]Nephrology B, Herlev Hospital, University of Copenhagen, Herlev, Denmark; [2]Institute of Public Health, Aarhus University, Aaarhus, Denmark; [3]Flexdialysis A/S, Rungsted Kyst, Denmark.*

Background: The use of single pass (SP) hæmodialysis treatment requires the production of large volumes of dialysate. An in vitro investigation has shown that dialysate recirculation leads to a better utilization of dialysate. We tested a new dialysis principle in vivo, using minimal dialysate volumes, continuously recycled during treatment (multipass hemodialysis, MPHD). Theoretical calculations suggest that MPHD performed 6 times weekly for 8 hours/night, using a dialysate bath containing 50% of the calculated body water, will achieve urea clearances equivalent to conventional HD 4 hours thrice weekly, and a substantially higher middle molecule clearance.

Methods: Ten stable HD patients were dialyzed for 4 hours using standard SPHD (dialysate flow 500 ml/min). Used dialysate was collected. One week later an 8-hour MPHD was performed. The dialysate volume was 50% of the calculated water volume. The dialysate inflow was 500 ml/min – 0.5 x ultrafiltration/minute and the outflow 500 ml/min + 0.5 x ultrafiltration/minute. Elimination rates of urea and β2-microglobulin (B2M) determined hourly.In addition to calculation the water volume (TBW) was measured directly using bioimpedance.

Results: Eight hours of MPHD removed 63% of the amount of urea removed by 4 hours of SPHD. The corresponding figure for B2M was 111%. The dialyate volume was 22.9 ± 4.8 liter. If TBW determined by bioimpedance had been used, only 19.9 liters on average would have been required.

Conclusions: The clearance of both small and (even more so) middle molecules using MPHD will exceed traditional HD. The limited dialysate requirement permits the delivery of centrally produced dialysate delivered to the patient's home or any other destination. This modality will increase patients' freedom of movement compared to traditional home HD. The principle can also be used in the intensive care unit and for automated peritoneal dialysis (APD).

FR-PO371

Sufficient Phosphate Elimination Can Be Achieved Using a Multipass Batch System James G. Heaf,[1] Mette K.M. Axelsen,[2] Robert Smith Pedersen.[3] *[1]Nephrology B, Copenhagen University Hospital at Herlev, Herlev, Denmark; [2]Institute of Public Health, Aarhus University, Aarhus, Denmark; [3]Flexdialysis A/S, Rungsted Kyst, Denmark.*

Background: The phosphate content of protein is 12-16 mg/gram. A dialysis patient, weighing 70 kg, and eating 1.2 gram protein/day consumes therefore approx. 1 g phosphate/day, of which 60% is absorbed. The absorbed phosphate is thus 4.2 g/week. Only about 1 g/treatment is removed using conventional single pass dialysis (SPHD) for 4 hours x3/week. Most HD patients therefore require phosphate binders. We investigated phosphate removal using a minimized dialysate volume, continually recirculated during dialysis, multipass hemodialysis (MPHD). Theoretical calculations suggest that MPHD performed 6 times weekly for 8 hours/night, using a dialysate bath containing 50% of the calculated body water, will achieve substantially higher phosphate clearance than SPHD.

Methods: Ten stable HD patients were dialyzed for four hours using standard SPHD (dialysate flow 500 ml/min). Used dialysate was collected. One week later an 8-hour MPHD was performed. The dialysate volume was 50% of the calculated body water. The dialysate inflow was 500 ml/min – 0.5 x ultrafiltration/min and the outflow 500 ml/min + 0.5 x ultrafiltration/min. Elimination rates of phosphate and dialysate saturation were determined hourly.

Results: Three hours of MPHD removed 51% (~ 496 mg) of the amount of phosphate removed by 4 hours of SPHD (~ 972 mg), and eight hours removed 77% (~ 753 mg). 34% of the total phosphate removal occurred during the last 5 hours of dialysis. Substantial compartment effects were observed, with mobilization of phosphate from the deep compartments after 3 hours. SPHD was calculated to remove 2.9 g/week and MPHD 4.5 g/week.

Conclusions: The amount of phosphate removed using MPHD will be sufficient to maintain a normal serum phosphate without the need for phosphate binders, even in anuric patients.

FR-PO372

Dialysate Volume Requirements for High Dose Hemodialysis Based on Urea and Phosphorus Kinetics J. Ken Leypoldt,[1] Alp Akonur,[1] Angelito A. Bernardo,[1] Hieronymus Henricus Vincent,[2] Bruce F. Culleton.[1] *[1]Medical Products R&D (Renal), Baxter Healthcare Corporation, Deerfield, IL; [2]Internal Medicine, St. Antonius Ziekenhuis, Nieuwegen, Netherlands.*

Background: The Frequent Hemodialysis Network Daily Trial showed that daily hemodialysis (HD) improves patient outcomes; approximately 90% of the patients treated in this trial by daily HD had urea stdKt/V > 3.0. Serum phosphorus (P) levels were reduced by daily HD in this trial; however, the levels achieved were not generally in the normal range.

Methods: We used kinetic modeling for urea and P using conventional 2-compartment and pseudo 1-compartment models, respectively, to assess the effect of a frequent HD prescription on urea stdKt/V and serum P levels. Patient differences in P kinetics were characterized by the rate of P mobilization (K_M). Frequent HD (4, 5 or 6 treatments or Tx per week) included: short daily HD (SDHD) for Tx times of 2, 3 and 4 hours and nocturnal HD (NHD) for a Tx time of 8 hours. Using dialysate volumes per Tx of 30, 45, 60, 90, and 120 L, we determined whether such therapies could achieve high dose HD targets, defined as urea stdKt/V > 3.0 and serum P < 7.0 mg/dL without oral phosphate binders. Patients of normal and large body size and with normal and high P dietary intake were considered.

Results: 1) For NHD with 5 & 6 Tx per week, 45 L of dialysate achieved high dose HD targets, except for patients with low K_M and high P intake who required 60 L when treated 5 times per week. 2) For NHD with all HD prescriptions, 90 L of dialysate achieved urea stdKt/V > 3.0 in all patients but at least 5 Tx per week were needed to achieve serum P < 7.0 mg/dL for patients with low K_M and high P intake. 3) For SDHD, 90 L of dialysate achieved urea stdKt/V > 3.0 in all patients, but 6 Tx per week for 3 and 4 hours are generally necessary to achieve serum P < 7.0 mg/dL for patients with normal and high P intake, respectively.

Conclusions: Achievement of high dose HD targets during frequent HD requires individualized prescriptions. NHD requires less dialysate volume than SDHD. To achieve high dose HD targets during both NHD and SDHD in a large fraction of patients, a dialysate volume of at least 90 L is necessary.

Intradialytic Hypotension in 6x Weekly In-Center Hemodialysis: Results from the Randomized Frequent Hemodialysis Network Daily Trial Peter Kotanko,[1] John B. Stokes,[2] Amit X. Garg,[3] Thomas A. Depner,[4] Andreas Pierratos,[5] Christopher T. Chan,[6] Nathan W. Levin,[1] Tom Greene,[7] Brett Larive,[7] Gerald J. Beck,[7] Jennifer J. Gassman,[7] Alan S. Kliger,[8] The FHN Trial Group.[9] *[1]Renal Research Institute, NY; [2]Univ of Iowa, IA; [3]Western Univ, ON, Canada; [4]Univ of California Davis; [5]Univ of Toronto, ON, Canada; [6]Univ Health Network, ON, Canada; [7]Cleveland Clinic Foundation, OH; [8]Yale Univ School of Medicine, CT; [9]NIDDK.*

Background: Intradialytic hypotensive episodes (IDHE) are common complications during hemodialysis (HD) and an independent risk factor for mortality. It is unknown if 6x weekly in-center HD affects the frequency of IDHE.

Methods: The Frequent Hemodialysis Network (FHN) Daily Trial randomized 245 patients to receive 12 months of 6x vs. 3x weekly in-center HD. We sampled HD sessions during one week periods for each month of follow-up. We defined IDHE as those HD sessions (IDHE sessions) during which hypotensive symptoms led to either solely lowering the ultrafiltration rate or to saline administration. We analyzed relative rates as well as the absolute counts of IDHE sessions. Treatment-based differences were tested using generalized estimating equations.

Results: As a percentage of the total number of HD sessions sampled, the trend was for a lower rate of IDHE sessions among the 6x weekly group (10.9%) compared to the 3x weekly group (13.6%, P=0.056). However, as there were more HD sessions in the 6x weekly group, the absolute number of IDHE sessions involving saline administration was significantly greater among the 6x weekly subjects (Table 1).

Conclusions: Frequent in-center HD is associated with an increased relative risk for number of IDHE sessions with saline administration. The clinical significance of this finding is unclear.

Table 1

Event	Count of Sampled Dialysis Sessions		Relative Risk (95% CI)	P-value
	3x weekly Group	6x weekly Group		
No IDHE	2973	5945		
IDHE sessions without saline administration	218	293	1.26 (0.89, 1.77)	0.18
IDHE sessions with saline administration	249	429	1.53 (1.11, 2.09)	0.0086

Interdialytic Weight Gain in Hemodialysis Patients Is Influenced by Dialysis Time and Frequency, Pre-Dialysis Serum and Dialysate Sodium Concentrations Plus Sex and Serum Albumin Benjamin Ka Thomson,[1] Shih-Han S. Huang,[1] Christopher T. Chan,[2] Rita Suri,[1] Robert M. Lindsay.[1] *[1]Medicine/Nephrology, Western University, London, ON, Canada; [2]Medicine/Nephrology, University of Toronto, Toronto, ON, Canada.*

Background: Increased interdialytic weight gain (IDWG) is associated with hypertension, left ventricular hypertrophy and may influence cardiac morbidity and mortality. Reductions in dialysate sodium have been shown to reduce IDWG and improve morbidity and perhaps mortality. The dialysis time and frequency will influence patient sodium gain where a diffusive sodium gradient exists but this has previously been overlooked as an influence on IDWG.

Methods: We performed a retrospective Cox multivariate regression analysis of 86 patients in the Southwestern Ontario home hemodialysis program where patients are treated by frequent nocturnal, short hours daily, or intermittent conventional hemodialysis, to determine the factors involved in predicting IDWG. Age, diabetic status and residual renal function did not correlate to IDWG.

Results: Using factors that significantly correlate to IDWG, we created an equation that predicted IDWG on the basis of serum albumin, patient sex, patient minus dialysate sodium gradient, and dialysis time and frequency ($R2 = 0.275$, $p<0.001$). **IDWG (Liters)** = 5.0244 – 0.0963 (dialysis frequency) – 0.19014 (if female) – 0.03439 (albumin in g/L) + 0.00014153 (Dialysate – predialysis serum Na+)(dialysis time in minutes).

Conclusions: This equation identifies factors that may be modified to reduce IDWG. This equation will be validated in a prospective study involving the same patient cohort.

FR-PO375

Treatment Effect of Frequent Hemodialysis (HD) on Interdialytic Weight Gain (IDWG) and Extracellular Volume (ECV) and Their Relation to Changes (Δ) in Left Ventricular Mass (LVM): Frequent Hemodialysis Network (FHN) Daily Trial Jochen G. Raimann,[1] John T. Daugirdas,[2] Frank A. Gotch,[1] Tom Greene,[3] George A. Kaysen,[4] Alan S. Kliger,[5] Robert M. Lindsay,[6] Nathan W. Levin,[1] The FHN Trial Group.[7] *[1]Renal Research Institute; [2]University of Illinois College of Medicine; [3]University of Utah; [4]UC Davis; [5]Hospital of Saint Raphael; [6]London Health Sciences Centre; [7]NIDDK.*

Background: Frequent dialysis reduces LVM particularly in patients (pts) with low daily urine volume (UV; Chan 2012). Effects on ECV have been reported previously (Kaysen 2012). We analyzed treatment effects on IDWG and bioimpedance-measured ECV and the relation to ΔLVM.

Methods: Treatment effects on IDWG and ECV were analyzed in subgroups (UV≤ and >100 mL/day) of subjects randomized to daily (6x/wk) or conventional (3x/wk) HD, using mixed models. Predictors of ΔLVM from baseline to month 12, focusing on ΔIDWG and ΔECV were analyzed using linear regression (LR). Data reported as mean (95% CI).

Results: Frequent dialysis reduced IDWG by -0.98 (-1.16 to -0.81) kg in 234 pts with available data. The effect in pts with UV≤100 mL/day was -1.00 (-1.22 to -0.79) kg and in those with UV >100 mL/day -0.90 (-1.21 to -0.60) kg, interaction P=0.16. Frequent dialysis also lowered ECV, but the treatment effect did not differ significantly {UV≤100 mL/day [-0.6 (-1.5 to +0.3) L; UV > 100 mL/day [-2.1 (-3.4 to -0.9) L], interaction P=0.33}. ΔECV was a significant independent predictor of ΔLVM in pts with UV≤100mL/day only (Table 1).

ΔLVM [g] as a function of ΔIDWG [L] and ΔECV [L].

	All Pts	All Pts	Pts with UV≤100 mL/day	Pts with UV≤100 mL/day
Parameter	Reg. Coeff. (SE)	P	Reg. Coeff. (SE)	P
ΔIDWG [L]	3.3 (4.0)	0.42	8.1 (5.3)	0.13
ΔECV [L]	2.0 (1.2)	0.09	3.3 (1.5)	0.03

LR Model with ΔLVM as dependent variable, controlling for baseline ECV/Total body water, baseline IDWG, age, diabetes, and randomized treatment assignment. Regression coefficients (Reg. Coeff.) show the magnitude of the association.

Conclusions: In addition to previously described associations between ΔLVM and Δblood pressure, ΔECV is involved in pts with low UV. A similar but non-significant association was found in pts with higher UV.

The Impact of Frequent Hemodialysis on Sleep Quality: Frequent Hemodialysis Network (FHN) Trials Jocelyn Kim, Mark L. Unruh, Brett Larive, Paul W. Eggers, Amit X. Garg, Jennifer J. Gassman, Fredric O. Finkelstein, Paul L. Kimmel, Glenn M. Chertow. *FHN Trials Group, NIDDK.*

Background: Patients undergoing maintenance HD have an impaired quality of sleep. Previous studies suggest frequent HD improves sleep quality, which is a strong motivation for some patients to undertake the treatment. We studied the effects of frequent in-center and nocturnal HD on self-reported sleep quality in the FHN randomized trials.

Methods: A total of 332 patients were randomly allocated to frequent (six times per week) or conventional (three times per week) HD in the Frequent Hemodialysis Network Daily (n=245) and Nocturnal (n=87) Trials. We used the Medical Outcomes Study Sleep Problems Index (SPI), a validated and reliable instrument in the ESRD population, to measure self-reported sleep quality. The SPI is scored from a value of 0 to 100 with a lower value indicating better sleep quality. The primary sleep outcome was the change over 12 months on the SPI score.

Results: The results for the SPI in the FHN Trials are show in the Table. In the Daily Trial, after adjustment for baseline SPI, subjects randomized to frequent as compared with conventional in-center hemodialysis experienced a 4.2 (95% CI 0.4 to 8.0) greater adjusted mean decline in SPI at 4 months, and a 2.6 (-2.3 to 7.5) greater decline at 12 months. In the Nocturnal Trial, subjects randomized to frequent as compared with conventional home hemodialysis experienced 2.9 (-3.4 to 9.3) and 4.5 (-3.2 to 12.2) greater declines at months 4 and 12, respectively. None of the treatment differences approached statistical significance with the exception of the Daily Trial Month 4 comparison ($p < 0.05$).

FHN: Comparison of changes for frequent (6x-per-week) vs. conventional (3x-per-week) hemodialysis

Trial	**Trt.**	**Sleep Symptoms & Problems Index (Mean ± SD)**		
		Baseline	**F4**	**F12**
Daily	3X	35.5 ± 21.0	35.7 ± 19.3	34.8 ± 22.8
	6X	36.2 ± 21.2	31.7 ± 19.4	31.2 ± 22.3
Noct.	3X	32.3 ± 17.9	33.8 ± 18.7	33.0 ± 23.1
	6X	32.3 ± 18.3	31.5 ± 18.1	29.1 ± 18.6

Conclusions: Although a trend suggesting a possible benefit of daily in-center HD was observed at 4 months, the FHN Trials were unable to demonstrate significant improvements in sleep quality at 12 months.

Funding: NIDDK Support, Other NIH Support - T35 Training Grant

FR-PO377

Effect of Daily Hemodialysis (DHD) on Anemia Parameters: Interim Results from the FREEDOM Study Bertrand L. Jaber,[1] George R. Aronoff,[2] Lori Lyn Price,[1] Amy W. Williams,[3] Janice P. Lea,[4] Isaac Teitelbaum,[5] Michael S. Gersch,[6] Troy J. Plumb,[7] James E. Novak.[8] *[1]Tufts, MA; [2]U Louisville, Louisville, KY; [3]Mayo, MN; [4]Emory, GA; [5]U Colorado, CO; [6]ANRA, AR; [7]U Nebraska, NE; [8]HFHS, MI.*

Background: The FREEDOM Study, an ongoing prospective cohort study investigating the benefits of DHD, has demonstrated improvements in several health-related quality of life measures.

Methods: This interim analysis presents the trends in anemia parameters during the first year of DHD (for patients enrolled by June 30, 2010), including changes in levels of hemoglobin (Hgb), hematocrit (Hct), ferritin, and transferrin saturation (TSat), as well as trends in prescribed erythropoietin-stimulating agents (ESAs) and oral/intravenous iron preparations.

Results: Of 336 enrolled pts, 171 completed 1 year follow-up, constituting the as-treated cohort. Mean age was 53 yrs, 65% male, 70% white, 59% used a fistula, 46% had diabetes, and 26% had heart failure. Mean (SD) estimates of the as-treated cohort are shown below:

Anemia Parameters of the As-Treated Cohort

Anemia Parameter	Baseline	Month-4	Month-12	Global P value[1]
Hgb (g/dL)	11.8 (2.3)	11.3 (1.6)	11.2 (1.7)	0.008[1]
Hct (%)	35.4 (3.9)	34.5 (5.1)	33.8 (5.1)	0.004[1]
Ferritin (ng/mL)	538 (344)	506 (342)	470 (353)	0.02[1]
TSat (%)	29 (12)	27 (13)	26 (11)	0.03[1]
% Prescribed ESAs	66	80	77	0.003[2]
% Prescribed Iron	36	46	50	0.01[2]
% in-range Hgb (11-12 g/dL)[3]	36	35	36	0.93[2]
% in-range Hgb (10-11 g/dL)[4]	22	18	26	0.23[2]

[1]by repeated measures ANOVA; [2]by GEE model; [3]In accordance with 2007 KDOQI update on anemia management in CKD; [4]In accordance with clinical practice following 2011 FDA Drug Safety Communication on ESA use

Conclusions: In summary, at 1 year, pts initiating DHD had a significant decrease in mean Hgb, Hct and TSat, accompanied by a significant increase in the proportion of pts prescribed ESAs and iron. However, these trends did not result in a significant shift in the proportion of pts maintaining in-range Hgb levels during the same period. Factors that may confound these results include changes in Hgb target ranges and ESA prescribing guidance, reliance on prescribed vs. self-administered ESA data, variability of timing and dosing of iron, and center therapy practices.

FR-PO378

Catheter-Related Bacteremia in Nocturnal Home versus In-Center Hemodialysis Patients Hui Xue,[1] Eduardo K. Lacson,[2] Nien-chen Li,[2] Steven M. Brunelli,[1] Franklin W. Maddux,[2] Robert S. Lockridge.[3] *[1]Brigham and Womens Hospital, Boston, MA; [2]Fresenius Medical Care North America, Waltham, MA; [3]Lynchburg Nephrology Physicians, Lynchburg, VA.*

Background: The CDC reported catheter-related bacteremia (CRB) rate of 3.2/100 pt-months for hemodialysis patients. We hypothesized that patients with central venous catheters (CVC) on nocturnal home hemodialysis (NHHD) will have lower CRB rates than conventional in-center hemodialysis patients (IHD).

Methods: 63 of 64 NHHD patients with CVC from Lynchburg Nephrology Dialysis (VA) were matched at a ratio of ~1:2 by age, gender, race, vintage, and diabetes to 121 IHD patients, from a pool of 6,285 admitted to Fresenius Medical Care North America facilities using a CVC in Virginia and surrounding states, from January 1, 2007 to December 31, 2010. CRB events (positive blood cultures or hospitalization for sepsis) were followed for up to 20 months or until censoring (e.g. death, removal of the catheter, etc.). Cox models were used to compare time to CRB.

Results: Both NHHD and IHD study cohorts were younger and had less DM than the general IHD population, but were similar to each other in terms of age (52.8 vs. 53.8 years), vintage (38.5 vs. 37.1 months), sex (57.1% vs. 57.9% males), race (57.1% vs. 57.0% white), and DM (20.6% vs. 21.5%), respectively. Mean duration for the first CVC was longer for NHHD than IHD (16.3 vs. 6.4 months). CRB-rates were similar when only the first catheters (1.77/100 vs. 1.95/100 pt-months, p=ns) were considered and with inclusion of subsequent catheters (1.51/100 vs. 2.01/100 pt-months, p=ns). The corresponding hazard ratios for NHHD were 1.01 (unadjusted) and 1.03 (adjusted) for first catheters; and 0.80 (unadjusted) and 0.91 (adjusted) including subsequent catheters, all p=ns.

Conclusions: CRB rates were not significantly different between matched NHHD and IHD patients. However, CRB rates were lower in both cohorts than published data. Patient selection (e.g. healthier subjects), small sample size, and failure to capture all CRB events (like hospital drawn cultures for IHD) may help explain these findings.

FR-PO379

Racial Differences in Initial Dialysis Access and Hospitalizations among Home Hemodialysis Patients Luis A. Bent-Shaw,[1,2] Margaret K. Yu,[1,2] Bessie A. Young.[1,2,3] *[1]Nephrology, University of Washington, Seattle, WA; [2]Kidney Research Institute, University of Washington, Seattle, WA; [3]Veterans Affairs Puget Sound Health Care System, Seattle Epidemiology Research and Information Center, Seattle, WA.*

Background: Home hemodialysis (HH) is a rapidly growing modality, however, less is known regarding differences in initial access among patient initiating home hemodialysis in a large urban program.

Methods: Data from all HH patients treated in the Northwest Kidney Center's HH unit were abstracted from 2001-2010. Patients received 3Xweek HD, 2.5-4 hours SD on the NxStage machine, or ND defined as greater than 6-8 hours of dialysis at night. Categorical and continuous data were analyzed using student t-test and chi squared. Logistic regression models were used to analyze odds of tunneled catheter or graft compared to arterial-venous fistula (AVF).

Results: Of the 174 patients who were scheduled to initiate training in the HH unit, 42 (24.1%) initiated CHD, 108 (62.1%) SD, 11 (6.3%) ND, and 13 (7.5%) did not complete training. The majority of patients were white (59.9%), while blacks (21.3%), Asians (14.4%), and others (7.4%)) made up the remainder of patients. Diabetes was the main cause of kidney failure for 42.8% of patients. The majority of patients had arterial venous fistulas (69.5%), while 1.7% had grafts and 28% had catheters. African American patients were 2.6-fold (95% CI 1.01-6.6) more likely to start without a fistula compared to whites after adjusting for age, diabetes, smoking, sex, modality, and hospitalizations. There was no difference in the number of hospitalizations between African American and Asian American patients compared to whites.

Conclusions: African Americans are more likely to start an outpatient home hemodialysis program without a fistula compared to whites; however, no racial difference in hospitalizations was found. Efforts should be continued for fistula first in all patients.

FR-PO380

Distress Screening for Dialysis Patients: The Distress Assessment Response Tool (DART) Marta Novak,[1,2] Joanne M. Dell,[1] Christopher T. Chan,[3] Joanne M. Bargman,[3] Sarbjit Vanita Jassal,[3] Madeline Li.[1] *[1]Dept. of Psychiatry, University Health Network, Toronto, ON, Canada; [2]Inst. of Behavioral Sciences, Semmelweis University, Budapest, Hungary; [3]Division of Nephrology, University Health Network, Toronto, ON, Canada.*

Background: DART is a tool currently used to assess distress and the needs of patients living with cancer. We aimed to test the utility and feasibility of integrating the DART system in the clinical care of patients receiving home dialysis therapy.

Methods: Fourty patients on home dialysis therapy were approached to complete the self-report questionnaires of the DART: the Edmonton Symptom Assessment System (ESAS), the Patient Health Questionnaire (PHQ-9), the General Anxiety Disorder-7 (GAD-7) and the Social Difficulties Inventory (SDI-21). The DART protocol was used to examine the proportion of patients that would be referred for further assessment.

Results: 39/40 patients (22 women, 17 men; mean [+/-SD] age 58 [17] yrs) completed the DART. Among them, 20 received PD (12 male and 8 female, average age 65.0, SD = 16.9) and 19 received HHD (10 male and 9 female, average age 50.5, SD = 15.0). Gender and dialysis vintage did not differ between the PD and HHD groups, but HHD patients were significantly younger.

26 patients were flagged for further assessment: 8 (20%) for depression, 5 (13%) for anxiety, and 17 (44%) for social difficulties. Nineteen participants (49%) received at least one flag for further assessment, while 7 (19%) were flagged in two or more areas. HHD patients experienced significantly greater levels of symptoms than the PD group on the GAD-7, PHQ-9, and SDI-21, as well as on the pain, depression, and drowsiness subscales of the ESAS and this remained significant when controlling for age. Significantly more HHD vs PD patients (68 vs 30%, p=0.016) were flagged for further assessment or referral.

Conclusions: The DART tool identified a significant proportion of patients on home dialysis who would likely benefit from further assessment and intervention. The DART tool, after further validation of the protocol, could be an important clinical instrument to identify patients at risk to improve their quality of life and their coping with the burden of dialysis.

Predictors of Patient Selection to Home Dialysis Patrik Finne,[1] Eero Honkanen,[2] Carola Gronhagen-Riska.[2] *[1]Finnish Registry for Kidney Diseases, Helsinki, Finland; [2]Department of Nephrology, Helsinki University Central Hospital, Helsinki, Finland.*

Background: The use of home dialysis, i.e. peritoneal dialysis and home hemodialysis, varies greatly internationally from less than 10% in the United States to more than 50% of all dialysis patients in New Zealand. The very large variability indicates that there is a potential for increasing home dialysis in many places. Our aim was to explore which factors predict selection of patients to home dialysis.

Methods: The Finnish Registry for Kidney Diseases provided information on all patients who had entered RRT aged 20 years or older in 2000 to 2010 in Finland and who were still on dialysis at 91 days after dialysis start (n=4984). The registry contains information on patients' basic characteristics, kidney disease diagnosis, comorbidities, and laboratory variables. Using forward stepwise selection of these explanatory variables, we established a multivariable logistic regression model with the binary outcome variable home dialysis or centre hemodialysis at 91 days from start of dialysis treatment. Based on this model, probability of home dialysis could be calculated for each patient.

Results: At 91 days from dialysis start 1463 (29%) patients were on home dialysis, and of these 92% were on peritoneal dialysis. The final multivariate model included twelve variables of which the most significant predictors of home dialysis were a body mass index lower than 35 kg/m^2, high concentration of hemoglobin, and high diastolic blood pressure. Age decreased probability of home dialysis. Of kidney disease diagnoses, polycystic kidney degeneration and amyloidosis were connected to the lowest, and type 1 diabetes to the highest probability of home dialysis.

Conclusions: Multiple factors predict home dialysis. Our multivariable model produced individual probabilities of home dialysis, and thus it was possible to identify centre hemodialysis patients with high calculated probability of home dialysis (indicating typical characteristics of home dialysis patients). In the next step of this research project we will examine this group of patients closer, in order to estimate whether there is a potential to increase the proportion of patients on home dialysis.

Determinants of Home Hemodialysis Training Outcomes Michael Schachter, Karthik K. Tennankore, Christopher T. Chan. *University of Toronto, Canada.*

Background: Home hemodialysis (HHD) has clinical and economic advantages over in-center therapy. Many health systems wish to broaden the population to which HHD can be successfully offered. The purpose of this study was to examine HHD training outcomes.

Methods: Characteristics of patients (pts) initiating HHD in our center were collected from 2003-2011. We compared those who received HHD for at least 365 days, or received a renal transplant ("HHD/Tx>365"), to those who failed training or experienced technique failure (TF) before 1 year ("HHD<365").

Results: 177 pts trained for HHD. In HHD<365 pts (n=38), 24 did not finish training, 8 had TF, and 6 died. Table 1 shows demographic, comorbidity, social and dialysis factors. The most common reasons for modality end <365 days (n=38) were death (16%), medical deterioration (16%), inability to cope with HHD (13%), inadequate family support (8%) and non-compliant pt (8%). Reasons for not finishing training are shown in Table 2. In HHD/Tx>365 pts, the most common outcomes were: remain on NHD (47%), renal transplant (35%), or expire (11%). Median modality survival was 3.3 (2.0,5.2) yrs.

Table 1| Characteristics of Patients who initiated home hemodialysis training during the era 2003-2010

Characteristic	HHD <365 (n=32)	HHD > 365 or transplant (N=139)	P-value
Demographics			
Age	49 (16)	45 (13.5)	0.13
Percent male	56	63	0.46
Race (%)			
Caucasian	49	57	0.367
Non-Caucasian	51	43	
Education (%):			
High school or below	32	39	0.452
College/University or higher	68	61	
Comorbidities			
Charlson comorbidity Index	4.6 (2.1)	3.5 (1.8)	0.003
Prior renal transplant (%)	19	27	0.38
Social Factors			
Owns Home (%)	62	75	0.152
Living alone (%)	28	18	0.221
Distance from HHD training unit (km)	18 (8,29)	22 (11,44)	0.48
Nephrology management before start of HHD (%)	82	98	0.001
Dialysis Factors			
RRT Vintage (years)	0.83 (0,10.5)	6.8 (0.61,14.8)	0.013
Initiating HHD with CVC (%)	72	47	0.007

Table 2| Reasons for Failure to Graduate from HHD Training (n=24)

Rank	Reason	Proportion of Patients (%)
1	Home Inappropriate	16.7
2	Can't cope with burden of HHD	12.5
2	Pt unable to work constructively with team	12.5
2	Failed Training Tests	12.5
3	Insurmountable language barrier	8.3
3	Inadequate Family support	8.3
3	Imminent renal transplant, decided to forego training	8.3
3	Financial burden	8.3
4	Anxiety/nervousnes about HHD	4.2
4	Care-giver anxiety about HHD (dependent pt)	4.2
4	Manual dexterity	4.2
4	Visual impairement	3.1

Conclusions: Pts who failed training had greater co-morbidity and were more likely to be unprepared for renal replacement therapy. Given these challenges, enhanced supports or a customized education strategy could be considered to further promote adoption of HHD in vulnerable pts.

Present Status of Home Haemodialysis in Japan: from the Japanese Home Haemodialysis Registry Ikuto Masakane,[1] Norio Hanafusa,[2] Shigeru Nakai,[3] Kanenori Maeda,[4] Hiromichi Suzuki.[5] *[1]Yabuki Shima Clinic, Yamagata, Japan; [2]University of Tokyo Hospital, Tokyo, Japan; [3]Fujita Health University School of Health Scieneces, Toyoake, Japan; [4]Maeda Clinic, Shimabara, Japan; [5]Saitama Medical University, Iruma, Japan.*

Background: In recent two decades home haemodialysis (HHD) has been promoted throughout the world because it has dramatically improved the prognosis and the QOL of choric dialysis patients. HHD started in 1968 in Japan but the number of HHD patients has been still very small, 327 at the end of 2011 as 0.1% of all dialysis patients. The Japanese Society for Home Haemodialysis (JSHHD) established a patient registry system (JHHDR) on 2011 to grasp the present status of HHD and promote more utilization of HHD throughout Japan.

Methods: Clinical parameters about HHD patients as of 31st Dec 2011 were collected using questionnaire. The parameters were patient's basal characters, results of blood chemistry, therapeutic options for renal anaemia and CKD-MBD, dialysis prescriptions and outcome parameters.The questionnaires have been still collected, and 142 patients' data from 22 dialysis facilities were collected by the end of April 2012. Some of data were compared with the past data of the Patient Registration of the Japanese Society for Dialysis Therapy (JSDT).

Results: The interim analysis showed that the mean age of the patients was 51.7 years old and 15 years younger than JSDT, and male was dominant (76.1%). The mean dialysis vintage was longer than JSDT (10.8 yrs. vs. 7.05 yrs.) The mean frequency of dialysis session in HHD was 4.45 per week and haemodialysis products (HDP) were greater than 72 in 60 % of the patients. The mean systolic blood pressure was significantly lower than JSDT (141.2 mmHg vs. 153.5mmHg) and the percentage of the patients who didn't need antihypertensive agents was greater than JSDT (47.9% vs. 37.3%).

Conclusions: It is a very interesting issue how much impact HHD has on the survival rate of chronic dialysis patients in Japan, which has been still one of the best results in the world. The findings from JHHDR could give us much useful information about better dialysis prescriptions for HHD.

FR-PO384

An Overview of a 8-Year-Old Provincially Coordinated Independent Hemodialysis Program in British Columbia Canada Lee Er,[1] Donna Murphy-burke,[1] Ognjenka Djurdjev,[1] Adeera Levin.[1,2] *[1]BC Provincial Renal Agency, Vancouver, BC, Canada; [2]Division of Nephrology, University of British Columbia, Vancouver, BC, Canada.*

Background: BC has the only coordinated provincial program for independent hemodialysis (IHD) in Canada. Established in 2004, the program has been actively involved in enhancing and fostering excellence in the delivery of IHD throughout BC. The objectives are to describe the program growth experience over 8 years, and to identify trends and the potential implications for further program growth.

Methods: Observational cohort study of all patients who started IHD between 2004 and 2011, using data obtained from the provincial centralized patient registry known as PROMIS. Outcomes of interest include technique survival, pt survival, and annual program growth.

Results: A total of 390 pts received IHD training of which 364 (93%) pts started IHD. Fig 1 indicates a fast growth in the first 4 yrs but on a gradual decline since settling at 5% prevalent rate. The IHD technique survival at 1yr is 80% and median survival time is 33 mos (Fig 2). The in-take is declining over time after the peak at 2nd yr (Fig 3); the attrition rate is increasing over time (Fig 4). Transplantation, deceased and medical reasons (e.g. hospitalization, inadequate dialysis etc) are the top 3 attrition reasons. The potential barriers for expansion identified are: 1) high turn-over rate on supporting staff like trainers, 2) lack of pt education during pre-dialysis, and 3) lack of respite-care and home support.

Conclusions: Despite provincial funding and support of IHD growth appears to have plateaued. Systematic evaluation of causes, and development of strategies to a) look at barriers to the uptake of new patients, and b) look at ways to minimize attrition rate within a provincial framework is important to ensure sustainability of this modality.

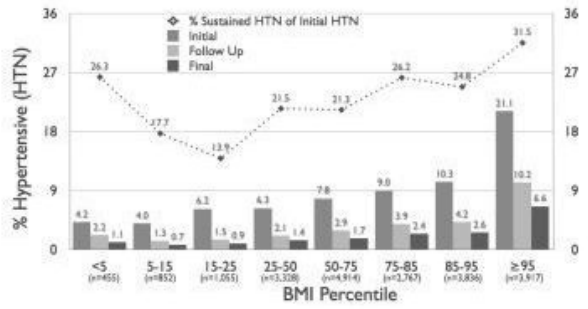
Blood Pressure and BMI in School Aged Children Joshua A. Samuels,[1] Karen Mcniece Redwine,[2] Tim Poffenbarger,[1] Joyce P. Samuel,[1] Cynthia S. Bell.[1] *[1]Pediatric Nephrology & Hypertension, UT Houston Medical School, Houston, TX; [2]Pediatric Nephrology & Hypertension, UAMS/Arkansas Children's Hospital, Little Rock, AR.*

Background: Obesity is the leading risk factor for essential hypertension in adolescents. We hypothesize that overweight and obese children have a higher prevalence of hypertension at initial and follow-up BP measurement screenings.

Methods: We performed school-based BP screening in Houston area children from 2000 to 2012. At each screening visit, height and weight were measured to determine BMI and BP was obtained up to 4 times with the average used to determine final BP status. Children whose BP was initially elevated underwent confirmation visits on 2 subsequent occasions to diagnose sustained hypertension according to Working Group criteria.

Results: Over 21,000 children aged 10-19 years (mean 13.3±1.7) have been screened. Although 13% of all children are hypertensive at the initial screening, the final prevalence of sustained hypertension is 2.7%. Hypertension rates are markedly increased in children with higher BMI percentiles at all screenings (Figure). Among children who are hypertensive at the initial screening, those with a high BMI percentile are more likely to have sustained HTN after 3 screenings (OR=1.09 for each additional 10 BMI percentiles, p<.001).



Conclusions: Though initial screening identifies significantly more abnormal blood pressure than final diagnosis, elevated BMI is an important factor associated with higher rates of initial and sustained hypertension in school aged children. Additionally, hypertensive children with a normal BMI are more likely to normalize their BP at follow-up screenings.

FR-PO386

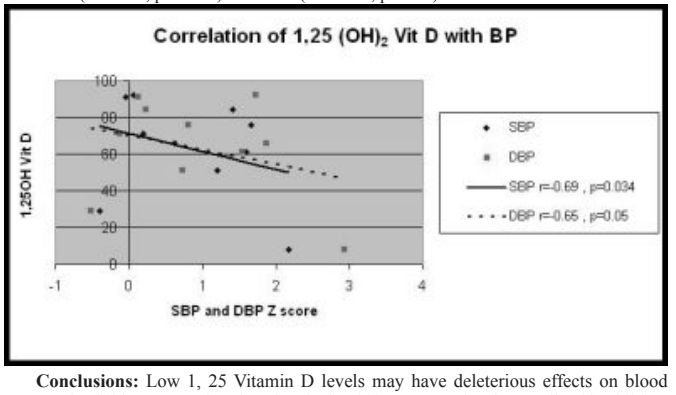
High Blood Pressure in Children with Chronic Kidney Disease (CKD) Correlates with 1,25(OH)2 Vitamin D and Not 25(OH) Vitamin D

Bandana Paudyal,[1] Gail Prado,[1] Morris J. Schoeneman,[1] Hanan K. Tawadrous,[1] Nataliya Chorny,[1] Vaishali Bansilal,[1] Valeriya M. Feygina,[1] Amrit Bhangoo,[2] Anil K. Mongia.[1] *[1]Department of Pediatrics, Div. of Pediatric Nephrology, SUNY Downstate, Brooklyn, NY; [2]Department of Pediatrics, Div. of Pediatric Endocrinology, SUNY Downstate, Brooklyn, NY.*

Background: Vitamin D deficiency is well known for its musculoskeletal complications in children and adults. In vitro studies have suggested 1, 25(OH)2Vit D (1,25 Vit D) as a vascular protective agent by its effect on the endothelium. However, limited studies are available looking at the effect of Vitamin D on blood pressure in children.

Methods: We enrolled 46 patients (25 patients with CKD, 9 primary hypertension (PH), and 12 Control (C). We collected data on age, sex, race, cause of kidney disease, eGFR, Ht, Wt, BMI, BP percentiles and z scores, phosphorus, calcium, 25 vit D, 1,25 vit D, PTH. Spearman coefficient was used to determine the correlation between Vitamin D, SBP/DBP z score, GFR, and PTH using SPSS version 2.0.

Results: SBP %'ile was significantly higher in PH (87.7 ± 17.6) and CKD (75.4 ± 27.6) than C (43.5 ± 26.9) and DBP%'ile significantly higher in PH (90 ± 10.6) and CKD (77 ± 24.6) than C (46.4 ± 18.9).eGFR (ml/min/1.73m2) was significantly lower in patients with CKD (70.2 ± 37.6) than C (106 ± 27.7). 86% patients had Vitamin D level <30 ng/ml. Mean 25 Vit D level was 14 ± 5.8 ng/dl. There was no correlation of 25 Vit D with SBP(r=+ 0.041, p=0.42) and DBP(r= - 0.16, p= 0.23)z-score. 25 Vit D did not correlate with eGFR (r= + 0.290, P=0.134) or PTH (r= - 0.260, P=0.370). 1,25 Vit D level correlated negatively with SBP (r= -0.69, p=0.034) and DBP (r= - 0.65, p=0.05) z scores.



Conclusions: Low 1, 25 Vitamin D levels may have deleterious effects on blood pressure in children. 1,25 Vitamin D levels should be measured and normalized in children with hypertension.

FR-PO387

Implementation of a Home Blood Pressure Telemonitoring System in Children with Hypertension

Cozumel S. Pruette,[1] Jeffrey J. Fadrowski,[1] Joseph Finkelstein.[2] *[1]Pediatrics, Johns Hopkins University, Baltimore, MD; [2]Medicine, Johns Hopkins University, Baltimore, MD.*

Background: Successful chronic disease management requires a coordinated effort including adherence to clinical practice guidelines and treatment plans and comprehensive patient-provider communication.Major barriers to successful hypertension (HTN) management include medication non-adherence and failure to monitor/communicate BP readings.Development of successful HTN monitoring and treatment programs in children,such as the home telemonitoring system (HTMS) in our study,is vitally important given the high prevalence of pediatric HTN and concern for associated HTN-related morbidity/mortality in adults.

Methods: A study member provided training on the HTMS to children ≤21 years of age with essential HTN.The HTMS was used to complete a symptom diary,assess medication side effects,obtain BP and complete HTN education modules.Acceptance of the HTMS was assessed by attitudinal survey and semi-structured qualitative interview.

Results: 8 children participated:62.5% male,75% Caucasian,mean age 12 yrs,average time with HTN 2.3 yrs. 63% reported their BP as stable and BP symptoms as none;50% reported their HTN knowledge to be good; 63% reported daily home computer use. Attitudinal survey results: 88% reported that working with the computer was not difficult;100% reported that self-testing procedures,BP monitor,symptom diary and medication side effect questions were not complicated;75% felt the self-testing procedure took little time and did not interfere with their usual activities;63% felt slightly to significantly safer while monitored by the HTMS;63% felt it was important to know that the self-testing results can be immediately reviewed in the medical center after the test;88% would like to use the HTMS in the future.Qualitative interview results showed consistently positive comments for content,interface and process components and provided suggestions for improvements.

Conclusions: The HTMS was positively accepted, reported as easy to use and participants found the components to be helpful.This system demonstrates a new method to monitor BP,BP symptoms,and provide HTN education in the home setting to children with HTN.

FR-PO388

Association of Blood Pressure and Sleep Complaints in Children Evaluated for Hypertension by Ambulatory Blood Pressure Monitoring (ABPM)

Neena R. Gupta,[1] Ted M. Kremer,[1] Ann Salerno,[1] Seema Adhami,[1] Jennifer Kremer,[1] Rakesh Gupta.[2] *[1]Pediatric Nephrology/Pediatric Sleep Medicine, UMass Memorial Medical Center, Worcester, MA; [2]Pulmonary and Sleep Medicine, Roger Williams Medical Center, Providence, RI.*

Background: Understanding the risk factors for hypertension (HTN) in childhood is a key to preventing serious long term outcomes such as cardiovascular and end stage renal disease as HTN has its antecedents in childhood. Sleep problems are associated with development of HTN in adults but there is very little information about this association in children. Our aim was to study the association between sleep complaints and blood pressure (BP) in a pediatric population.

Methods: Consecutive patients between age 13-19 yrs referred to pediatric nephrology between 2009-2012 who had ABPM for evaluation of HTN and who completed a sleep questionnaire were included. Of the 66 patients undergoing ABPM, 39 were included in final data analysis. Medical records were reviewed to obtain demographics and BMI. Data are presented as mean ± SD. Student t-test was used to compare continuous data.

Results: Characteristics for the 39 children were : M:F ratio 2:1, Age 15.9 ± 1.6 years, BMI 29.4 ± 6.6 kg/m^2, week day sleep 516.3 ± 111.7 minutes, week end sleep 592.2 ± 86.5 minutes. Prevalence of sleep related complaints were: ever snore 41%, habitual snoring (>50% of time) 15%, wake up not refreshed 30%, daytime sleepiness 36%, morning headache 24%. Stages of hypertension were: prehypertension 6 (15%), stage I - 22 (56%), stage II - 11 (28%). Habitual snorers had significantly higher average daytime diastolic BP (89.2 ± 16.6 vs. 79.2 ± 8.0 mmHg, p =.026) and a trend towards higher average daytime systolic BP (145.5 ± 11.3 vs. 139.6 ± 6.6 mmHg, p =.082). Children reporting daytime sleepiness had higher average night diastolic BP (69.6 ± 10.8 vs. 64.0 ± 5.7 mmHg, p =.040). As expected, children with weekday sleep duration ≤ 8 hours reported more daytime sleepiness (67% vs. 18%).

Conclusions: There is a high prevalence of sleep related complaints in pediatric patients referred for evaluation of HTN. Habitual snoring and daytime sleepiness are associated with higher BP parameters on ABPM.

FR-PO389

Etiology of Hypertension and Prevalence of Target Organ Damage in a Referral Sample of Icelandic Children

Sigridur Birna Eliasdottir,[1] Sandra Dis Steinthorsdottir,[1] Olafur S. Indridason,[2] Runolfur Palsson,[1,2] Vidar O. Edvardsson.[1,2] *[1]University of Iceland, Reykjavik, Iceland; [2]Landspitali – the National University Hospital of Iceland, Reykjavik, Iceland.*

Background: Limited information exists on the prevalence and extent of target organ damage (TOD) in children with hypertension. The aim of the study was to investigate the causes of hypertension and prevalence of TOD in a group of hypertensive Icelandic children.

Methods: This was a retrospective study of all patients below 18 years of age who received care at the Pediatric Hypertension Clinic of Landspitali - The National University Hospital of Iceland during the years 2003-2008. This institution is a referral center for the whole nation. Medical records of all identified pediatric subjects were retrospectively reviewed for the etiology of hypertension, echocardiographic changes consistent with hypertensive heart disease and microalbuminuria.

Results: Of 93 children identified with hypertension during the study period, 50 (54%) were male and the median age was 12 (0-17) years. Twenty-three children (25%) had sustained essential hypertension, 66 (71%) had secondary hypertension and 4 (4%) were considered to have white coat hypertension. Causes of secondary hypertension included renal parenchymal disease in 23 children (25%), congenital anomalies of the kidney and the urinary tract in 20 (22%), medications known to elevate blood pressure in 7 (8%), coarctation of the aorta in 2 (2%) and miscellaneous etiology in 10 (11%). Echocardiography was carried out in 59 children (63%) and showed left ventricular hypertrophy in 11 (19%) and decreased ejection fraction or dilated left ventricle in 2 (3%). Microalbuminuria was noted

in 18 children, 6 of whom had no evidence for underlying renal parenchymal disease. Of those, 3 had secondary hypertension and 3 essential hypertension. Thus, TOD was noted in 16 (17%) study subjects.

Conclusions: Two-thirds of this referral cohort of hypertensive children had secondary hypertension. Evidence for TOD was present in a significant proportion of study subjects.

FR-PO390

Increased Provider Recognition of Elevated Blood Pressure in Children Tammy M. Brady, Alicia M. Neu, George Siberry, Barry Solomon. *Pediatrics, Johns Hopkins University, Baltimore, MD.*

Background: High blood pressure (BP) in children is often unrecognized by providers. We evaluated the effect of a real-time electronic medical record (EMR) alert on recognition of high BP in a pediatric clinic.

Methods: Cross-sectional review of well and acute care visits from 1/1/09-6/30/09 of children 3-21 yrs with a high BP in triage and no history of hypertension (HTN). All high BPs (≥90th%ile or ≥120/80) generated an EMR alert. High BP was "recognized" by providers if the clinic note documented: high BP or HTN; provider repeated BP; plan to repeat BP or evaluate high BP. Prevalence of recognition was compared pre- and post-EMR alert implementation. Continuous and categorical variables were compared with t-tests and chi-squared analyses. Prevalence ratios of recognition were obtained by univariate log-binomial regression.

Results: Post-EMR alert, 42% (568/1368) of high BP were recognized (vs. 13% pre-alert; p<0.001). Children with recognized BP were more likely older, non-African American (non-AA), male, overweight/obese, with a family history of cardiovascular disease (CVD), a systolic BP≥120 and seen for well care.

Characteristics of 1368 Children with Elevated Blood Pressure and Prevalence Ratios of Recognition

Characteristic (Mean (SD) or % (N))	Overall	BP Recognized	BP Unrecognized	p-value		Prevalence Ratio (95% Confidence Interval)	p-value
Age (yrs)	12.4 (5.8)	12.9 (5.7)	12.1 (5.8)	0.02		1.01 (1.00, 1.02)	0.02
AA (vs. non-AA)	93% (1275)	92% (520)	94% (755)	0.049		0.8 (0.64, 0.97)	0.03
Male	42% (568)	46% (259)	39% (309)	0.01		1.2 (1.04, 1.34)	0.009
Overweight/obese*	61% (530/870)	65% (270/416)	57% (260/454)	0.02		1.19 (1.02, 1.38)	0.02
Acute visit (vs. well visit)	54% (439/808)	40% (132/334)	65% (307/474)	<0.001		0.55 (0.46, 0.65)	<0.001
Family history CVD	11% (146)	15% (86)	8% (60)	<0.001		1.49 (1.28, 1.74)	<0.001
SBP >=120 mmHg	64% (872)	70% (398)	59% (474)	<0.001		1.3 (1.16, 1.53)	<0.001
DBP >=80 mmHg	8% (105)	9% (50)	7% (55)	0.9		1.16 (0.94, 1.43)	0.2

*Body Mass Index >=85%ile

Conclusions: EMR alerts increase recognition of high BP in a pediatric clinic setting; however, younger, female and AA children, and those without obvious CV risk factors are less likely to be recognized. Increased provider awareness is needed to improve recognition.

Vitamin D Deficiency and Cardiovascular and Renal Risk Factors among Children from Various Ethnic Groups in the United States Gangadarshni Chandramohan,[1] Sheena Cecille Marie T. Go,[1] Keith C. Norris,[2] Kamyar Kalantar-Zadeh.[1] *[1]Pediatric Nephrology, LA Bio-Medical Research Institute at Harbor-UCLA Medical Center, Torrance, CA; [2]Charles R. Drew University, Lynwood.*

Background: According to recent studies vitamin D (VitD) deficiency has become highly prevalent among children of every ethnicity, particularly, among the African American (AA) population. Over 80% of AA children has either vitamin D insufficiency (vitDinsuf) or vitamin D deficiency (vitDdef) in the United States. Vitamin D deficiency is known to be associated with cardiovascular/renal risk factors. There are only a few studies that have looked at the association between vitDdef and CV/renal risk factors in children of different ethnicities. Thus, in this study we determined the prevalence of vitDinsuf and vitDdef in children from different ethnicities and assessed the OR for CV risks among those who had vitDdef, utilizing the National Health and Nutrition Survey 2001-2004.

Methods: CV/renal risk factors were defined according to standard guidelines. VitDdef defined as <15ug/ml and vitDinsuf <30ug/ml.

Results: We identified 4849 children between the ages of 6 – 17 years, Whites 28%, AAs 36% and Hispanics 36%, males 50%. African American children had a significantly higher prevalence of vitDdef compared to Whites (31% vs. 2%, p=<.001). Similarly, Hispanicv children had a higher prevalence of vitDdef compared to Whites (7% vs 2%, p=<.001). Association between vitDdef and high BP and fasting blood sugar (FBS) were observed among Hispanic children. However the odds ratio for vitDdef and obesity, high BP, abnormal lipid profile and abnormal FBS were not significant in White and Hispanic children. Female gender carried a higher risk of vitDdef across all ethnic groups. When obesity and high BP were clustered, there was a strong association observed with vitDdef in AA and Hispanic children.

Conclusions: Vitamin D deficiency is highly prevalent among minority children compared to White children. The association between vitDdef and high BP and obesity combined, and abnormal FBS raises a concern regarding long term CV/renal outcome in this population. A longitudinal study is warranted to confirm this findings.

The Significance of Combined Biomarkers Test for Renal Injury in Preeclampsia Yong Gu,[1,2] Jing Xiao,[1] Jianying Niu,[1] Qianqian Yu,[1] Xianwu Ye,[1] Chuan-Ming Hao.[2] *[1]Nephrology, The Fifth People's Hospital of Shanghai, Fudan University, Shanghai, China; [2]Nephrology, Huashan Hospital, Fudan University, Shanghai, China.*

Background: Preeclampsia is a pregnancy-specific disorder, It is characterized by hypertension and proteinuria. Rapid diagnosis and early treatment are vital to preserve kidney function and slow down renal injury, while traditional markers for diagnosing the injury are insensitive. The aim of our study was to determine whether combined biomarkers detecting renal injury in preeclampsia was more sensitive.

Methods: Three groups were included in our study, they are preeclampsia, gestational hypertension and normal pregnant women and each group included 25 people. ELISA kits were used to measure the level of serum(s)Cystatin C, retinol-binding protein(RBP), neutrophil gelatinase-associated lipocalin(NGAL)and Interleukin-18 (IL-18), urinary (u) kidney injury molecule-1(KIM-1), NGAL, RBP, and IL-18 were also tested.

Results: Compared with the normal pregnancy group, the level of sCystatin C, uRBP, uNGAL, and uKIM-1 were significantly higher in preeclampsia group (P <0.05). The area under the ROC curve of above-mentioned biomarkers is 0.769,0.831,0.830 and 0.875. When biomarkers combined, the sensitivity and specificity was increased. The sensitivity and specificity of sCystatin C combined with uRBP, sCystatin C with uNGAL, sCystatin C with uKIM-1, uRBP with uNGAL, uRBP with uKIM-1, uNGAL with uKIM1 were 96%/51.2%, 96% /49.9%, 94%/57.6%, 94%/70.2%, 96%/62.4% and 94%/72% respectively.When three biomarkers combined, the sensitivity and specificity was as follows:sCystatin C,uRBP anduKIM-1 was 92%/88%; sCystatin C,uNGAL anduKIM-1 was 94%/80%; sCystatin C,uRBP and uNGAL was 90%/72%; uRBP,uNGAL and uKIM-1 was 94% /94%;when sCystatin C,uNGAL,uRBP and uKIM-1 combined, thesensitivity and specificity was 100%/98.20% .

Conclusions: The level of sCystatin C,uRBP, uNGAL and uKIM-1 were significantly increased in patients with preeclampsia. uKIM-1,with the highest sensitivity and specificity, was the most potential one and may serve as a useful early biomarker for renal injury in preeclampsia. We also showed that the more biomarkers combined, the better sensitivity and specificity.

FR-PO393

Circulating Endothelial Cell Number and Markers of Endothelium in Previously Preeclamptic Women Zeyneb Tuzcu, Ebru Asicioglu, Mehmet Koc. *Division of Nephrology, Marmara University, Istanbul, Turkey.*

Background: Patients with preeclampsia (PE) have an increased risk of mortality. Recent studies suggest that the endothelium plays a key role in the development of atherosclerosis. Circulating endothelial cells (CEC) may reflect the state of the endothelium since CEC number is markedly increased in conditions associated with a high degree of endothelial cell activation/injury. We hypothesized that the number of CEC is increased in previously PE women reflecting ongoing endothelial cell activation/injury.

Methods: We studied 21 healthy women with ongoing normal pregnancy, 24 healthy currently non-pregnant women with a history of normal pregnancy, 17 women with currently active PE and 16 currently non-pregnant women with a history of PE.

Results: Blood samples from women with active PE (mean age 29 ± 6 years) had higher CEC (9.9 ± 7.9 per ml) compared to healthy pregnant women (3.0 ± 4.1 per ml, p<0.001) or healthy non-pregnant women (3.4 ± 4.0 per ml, p<0.001) and women with a history of PE (2.4 ± 2.0 per ml, p<0.001). The number of CECs were similar between women with a history of PE and healthy non-pregnant women with a history of normal pregnancy. Patients with active PE had significantly higher sVCAM-1, sE-selectin and soluble vascular endothelial receptor-1 (sVEGFR1) and urinary albumin/creatinine ratio than healthy pregnant women. sVCAM-1, sE-selectin, urinary albumin/creatinine ratio were similar in women with a history of PE and healthy non-pregnant women with a history of normal pregnancy. However, women with a history of PE had higher sVEGFR1 levels than women with a history of normal pregnancy (p<0.05).

Conclusions: Our results suggest that the endothelium is activated in PE but after the term its activation status is similar to the age matched non pregnant women with a a history of normal pregnancy. In addition, sVEGFR-1 levels remains higher in women with a history of PE compared to women without a history of PE. Further studies are needed to evaluate the significance of higher sVEGFR-1 levels in women with a history of PE.

FR-PO394

Postpartum Evaluation of Blood Pressure and Kidney Function in Preeclamptic Women Antoinette Pechere-Bertschi,[1] Michel Burnier.[2] *[1]Hypertension Unit, University Hospital, Geneva, Switzerland; [2]Nephrology and Hypertension Unit, CHUV, Lausanne, Switzerland.*

Background: It has been shown that preeclampsia is not just a disease of the pregnancy that resolves with the delivery. Preeclampsia may be considered a risk marker for later-life diseases, including cardiovascular and renal diseases.

Methods: In a longitudinal prospective cohort study, we examined women having suffered from a preeclampsia defined as de novo hypertension (BP ≥140/90mmHg) and proteinuria (≥0.3g/d or ++ urine dipstick) >20we of gestation. Office BP and 24hABPM, plasma creatinine, electrolytes, CRP, hormonal profile and genetics data bank were obtained. Urine spot and 24h collect were obtained in order to establish renal sodium handling.

Results: We evaluated 127 women, mean age 32.1±5.8, 69% were Caucasian, 14% Hispanic, 12% Black and 5% from Asia. Mean BMI was 29.4 ±5.7. Mean duration of pregnancy was 36 weeks. Thirty % suffered from severe preeclampsia or HELLP, 21% were previously hypertensive, 10% were active smokers, and 10% suffered from gestational diabetes. At 6 weeks postpartum the prevalence of office hypertension defined by BP≥140/90 mmHg or ongoing antihypertensive treatment was 36%, and the prevalence of 24hambulatory hypertension was 39%. Mean day time ambulatory BP was 122/86 ±16/11mmHg, and nigh time 111/75 ±20/11mmHg. We observed a renal hyperfiltration when measured by Gault et Cokroft formula,and a high prevalence of microalbuminuria. eGFR measured with MDRD formula was lower, especially for black people.

Us CRP (mg/ml)	Normal <2	6.9 ± 9.7
GFR ml/min/1.73m2	GaultCokroft	160 ± 23
eGFRml/min/1.73m2	MDRD	106± 12
MAU/creat. ratio (mg/ml/ mmol/ml)	Normal < 3.5	13.0±6.5
24h Urine albumin mmol/d	Normal <20/d	225±52
Urine 24h Na excretion (mmol/ day)	Normal<100mmol/d	204±48
% ≥ 135/85 mmHg mean ABPM		39%
% nocturnal hypertension (non-dippers)		10%

Conclusions: Preeclamptic women do not normalize their BP and renal fucntion in the post-partum. We have to better identify women in whom early prevention may reduce their risk and need scientific data in order to establish an efficient prevention and to impact throughout the postpartum course.

FR-PO395

Preeclampsia and Prevalence of Microalbuminuria 10 Years Later Bjorn Egil Vikse,[1,2] Miriam Kristine Sandvik,[2] Stein I. Hallan,[3,4] Einar Svarstad.[1,2] *[1]Department of Medicine, Haukeland University Hospital, Bergen, Norway; [2]Renal Research Group, Institute of Medicine, University of Bergen, Bergen, Norway; [3]Department of Medicine, St.Olav University Hospital, Trondheim, Norway; [4]Department of Cancer Research and Molecular Biology, Norwegian University of Science and Technology, Trondheim, Norway.*

Background: Previous studies indicate increased risk of microalbuminuria after a preeclamptic pregnancy. These studies have however been small, and more data is needed.

Methods: We used data from the Medical Birth Registry in Norway and identified women who had preeclampsia in their first pregnancy 9 to 11 years previously, excluding women with diabetes, rheumatic disease, essential hypertension or renal disease before first pregnancy, and/or preeclampsia in later pregnancies. 180 women with preeclampsia and 180 women without preeclampsia were invited (matched on age, year of first birth and municipality). We measured blood pressure, body mass index (BMI), serum creatinine and albumin/creatinine ratio (ACR) in three morning urine samples.

Results: A total of 89 women with preeclampsia and 69 women without preeclampsia participated. Only one woman had urinary albumin/creatinine ratio above 2.5 mg/mmol in two of three urine samples, she belonged to the preeclampsia group. Median ACR was 0.53 mg/mmol and 0.50 mg/mmol in women with and without preeclampsia, respectively. There was also no difference in mean estimated glomerular filtration rate (107.9 vs. 104.9 ml/min/1.73m^2, p=0.1) or BMI (26.7 vs 26.0 kg/m^2, p=0.4). Preeclampsia, low birth weight offspring, preterm birth, higher blood pressure and body mass index was not associated with higher risk of having a urinary ACR above the 75th percentile (0.70 mg/mmol).

Conclusions: No increased risk of microalbuminuria was observed 10 years after pregnancy complicated with preeclampsia.

Funding: Government Support - Non-U.S.

FR-PO396

Pre-Partum Proteinuria Is a Risk Factor for Short-Term High Blood Pressure Persistence after Delivery Ciro Esposito,[1] Maria Lucia Scaramuzzi,[2] Alessandra Manini,[2] Massimo Torreggiani,[1] Fausta Beneventi,[3] Andrea Spinillo,[3] Fabrizio Grosjean,[1] Gianluca Fasoli,[2] Antonino Dal Canton.[2] *[1]Nephrology, Fondazione S. Maugeri, University of Pavia, Pavia, Italy; [2]Nephrology, Policlinico San Matteo, Pavia, Italy; [3]Gynecology, Policlinico San Matteo, Pavia, Italy.*

Background: Gestational hypertension complicates 10-15% of pregnancies, being of new onset in 70% of cases. A small percentage of women maintains chronic elevated blood pressure even after delivery. Several evidences suggest that gestational hypertension is associated with a greater risk of future cardiovascular disease. We aimed to identify risk factors predisposing to the persistence of high blood pressure after delivery in patients who developed gestational hypertension.

Methods: We conducted a prospective observational study enrolling 38 patients with gestational hypertension or preeclampsia. We recorded anthropometric, clinical and biohumoral parameters before and every 15 days after delivery. We divided patients into two groups: women whose blood pressure normalized in 15 days after delivery (group 1) and women who still had high blood pressure values 15 days after delivery (group 2). We defined hypertension as the need to assume medications to maintain blood pressure below 130/80 mmHg.

Results: Patients were comparable for age, BMI, primiparity and comorbidities. We did not notice significant differences in the intragravidic weight gain or in the newborn's weight. Hypertension was diagnosed earlier in group 2 (17 days) than group 1. Pre-partum proteinuria greater than 300mg/24hours was observed more frequently in group 2 (84% vs. 32%). Pre-partum proteinuria was associated with an 11 fold greater risk of maintaining elevated blood pressure 15 days after delivery (OR=11.56, p<0.01). Moreover, both systolic and diastolic blood pressure were higher in group 2 than 1 and not completely controlled by the therapy (132 vs. 122 mmHg, p<0.05; 88 vs 77 mmHg, p<0.001).

Conclusions: This study demonstrates a strong association between the presence of pre-partum proteinuria and the risk of maintaining hypertension after delivery. Thus, it is mandatory to follow proteinuric patients closely even after delivery.

FR-PO397

Etiology and Outcome of Neonatal Hypertension Shefali Vyas, Isabel Roberti. *Pediatric Nephrology and Transplantation, Saint Barnabas Medical Center, Livingston, NJ.*

Background: Hypertension (HTN) in the NICU setting is often multifactorial. Its follow-up data has been rarely reported. Overall, HTN is rare in the normal neonate with a reported incidence of 0.2-3%.

Methods: We reviewed NICU consults for the past 5 yrs for HTN. We identified 70 babies with HTN among a total of 138 NICU consults. HTN definition: SBP and/or DBP>95 centile for age/gender, confirmed in multiple evaluations when child asleep. Chart review included: Pre-natal history, birth weight, gestational data, apgar, canulation of umbilical vessels, renal sonogram with doppler, echocardiogram, blood chemistries, UA, thyroid panel, PRA and aldosterone. Co-morbidities and medications were noted. Clinical data was compared between neonates with "early HTN" (< 2 mos of age) vs "late HTN" (>2 mos).

Results: We found complete records in 47 of the 70 NICU consults for HTN. Overall 29 (62%) were males, 33 (70%) AA; age at presentation: 1 to 245 days (median 56); Birth wt: 400 to 3820g (median=1190); gestational age: 24 to 40 weeks (median=30); Catheterization of umbilical vessels in 27 (57%). Seven were symptomatic: 1CHF, 3 ALTE, 1 seizures, 2 irritability. Thirteen had **LVH** (28%). **Etiology**:2 arterial thrombosis, 5 persistent pulmonary hypertension (PPH) (3 ECMO), 31 BPD, 2 drug induced, 2 renal infarcts, 1 ARPKD, 1 renal dysplasia, 1 thyrotoxicosis. **Outcome**: **Anti-HTN meds:** 38 (81%). 39 (81%) resolved (median time:4 weeks), 1 ESRD, 1 deaths, 6 lost f/u. **Comparison between "early HTN" (n=23) vs "late HTN" (N=24):** the "late HTN" group had significantly lower gestational age and birth weight, more umbilical lines (p=0.01). At the time of first consultation 54% were on diuretics (p<0.01 vs "early HTN") and 21 (91%) had BPD/PPH (p<0.01). However there were no differences regarding need for medications, time to resolution or outcome.

Conclusions: Neonatal hypertension has been reported as uncommon but represented 50% of the renal consults in the NICU in our institution. Most required treatment for the HTN which typically resolved in 4 weeks. Its diagnosis was done at a later age in prematures and often associated with BPD. **The prognosis was excellent despite high rate of LVH and serious symptoms.**

FR-PO398

Renal Histology in Preeclampsia, Normal Pregnancy and in Young Women with Chronic Hypertension: A Nationwide Autopsy Study Maria Elisabeth Penning,[1] Kitty Bloemenkamp,[2] Jan A. Bruijn,[1] Ingeborg M. Bajema,[1] Hans J. Baelde.[1] *[1]Pathology, Leiden University Medical Center, Leiden, Netherlands; [2]Obstetrics, Leiden University Medical Center, Leiden, Netherlands.*

Background: Knowledge on the histopathological changes in the kidney during preeclampsia (PE) is mostly derived from biopsy studies and small group autopsy studies. Endotheliosis and vascular changes due to anti-angiogenic factors seem to be salient features of PE, but it is unknown to what extent these changes also occur in normal pregnancies and/or chronic hypertension. Renal autopsy materials of these groups were compared in this study.

Methods: A search for tissue specimens derived from autopsies was performed using a nationwide computerized database (PALGA). Renal tissue samples were studied from 9 women who died during pregnancy with PE; from 16 women who died during pregnancy due to non-hypertensive causes and from 8 non-pregnant women with chronic hypertension.

Results: Women with PE had MPGN-like lesions with varying amounts of tram tracking, endotheliosis and podocyte damage. Women with normal pregnancies only had minor lesions in the kidneys: glomeruli were normal although 2 cases had endotheliosis and only 2 cases showed hyalinosis of arterioles. Young women with chronic hypertension had severe ischaemic glomerular lesions, 2 had hyalinosis of arterioles, and 2 had FSGS. In this group all women had intimal thickening of arteries, in 1 case with onion shapes. Positive intraglomerular staining for Ki-67 was occasionally found in all groups, and was regarded non-specific. Mean glomerular size measurements showed no significant differences between all groups.

Conclusions: In this study, all women with PE had MPGN-like lesions in their kidneys, which were absent in the other groups and therefore regarded characteristic for PE. Endotheliosis was, although not exclusively, most prominent in PE. Major large vessel lesions were only found in women with chronic hypertension, and were not an important feature of PE. As VEGF downregulation leads to glomerular endotheliosis in animal studies, we hypothesize inhibition of VEGF by sFlt-1 might play a crucial role in the pathogenesis of renal lesions in PE.

FR-PO399

Angiotensin Converting Enzyme 2 Plasma Activity Is Lower in Female Hemodialysis Patients and Associations Differ between Males and Females

Matthew A. Roberts,[1,2] Elena Velkoska,[2] Francesco L. Ierino,[1,2] Louise Burrell.[2] *[1]Nephrology, Austin Health, Melbourne, Victoria, Australia; [2]Medicine, University of Melbourne, Melbourne, Victoria, Australia.*

Background: Angiotensin converting enzyme 2 (ACE2) is a novel regulator of the renin-angiotensin system that counteracts the adverse effects of angiotensin II. The gene for ACE2 is located on the X chromosome. Plasma ACE2 is an independent predictor of adverse events and elevated levels are associated with greater severity of myocardial dysfunction in patients with heart failure. To date there have been no studies examining plasma ACE2 activity in patients with kidney disease, who have a substantial risk of cardiovascular disease (CVD).

Methods: Patients groups included (a) chronic kidney disease Stage III/IV (CKD), (b) patients treated with hemodialysis (HD), and (c) kidney transplant recipients (KTR). Plasma ACE2 enzyme activity was measured (serum stored at -80ºC) using a fluorescent substrate assay. Linear regression was performed in males and females separately to determine covariates associated with log-transformed ACE2.

Results: The median (inter-quartile range) plasma ACE2 activity in pmol/minute/mL was 15.9 (8.4-24.2) in CKD (n=57), 9.2 (3.9-18.2) in HD (n=100) and 13.1 (5.7-21.9) in KTR (n=80; p<0.01). Males on HD had levels of 12.1 (6.8-19.6) compared to 4.4 (2.5-10.3) in females undergoing HD (p<0.01). Log-transformed ACE2 plasma activity was associated with the post-HD systolic blood pressure (SBP) in females (β-coefficient 0.04, 95% confidence interval 0.01-0.06, p=0.006), but not log-transformed B-type Natriuretic Peptide (BNP). In males, log-transformed ACE2 plasma activity was associated with BNP (0.39, 0.19-0.60, p<0.001), and inversely associated with diabetes (-1.01, -1.73 to -0.28, p=0.007) and log-transformed time (years) on dialysis (-0.29, -0.53 to -0.05, p=0.018). No independent association with SBP was demonstrated in males.

Conclusions: Plasma ACE2 activity is reduced in HD patients compared to CKD patients, and in female HD patients compared to male. In HD patients, the association of plasma ACE2 activity with BNP in males and SBP in females indicates that the role of ACE2 in CVD may differ by gender.

UMOD Gene in Salt Sensitivity: A New Pathogenetic Mechanism

Guido Gatti,[1] Chiara Lanzani,[1] Luca Rampoldi,[1] Agnese Binaggia,[1] Simona Delli Carpini,[1] Matteo Trudu,[1] Marco Simonini,[1] Giacomo Dell'Antonio,[1] Mara Ferrandi,[2] Lorena Citterio,[1] Laura Zagato Villa,[1] Paolo Manunta.[1] *[1]San Raffaele Scientific Institute, Milan, Italy; [2]Sigma-Tau Institute, Milan, Italy.*

Background: Uromodulin, codified by UMOD gene, is the most abundant urinary protein and is produced only by epithelial cells of the thick ascending limb of Henle's loop (TAL). Even if its function is not completely known, two recent studies showed that its co-expression with ROMK e NKCC2 induces an increment of the activity of these two carriers of the apical membrane, which are involved in the renal reabsorption of sodium and chloride in the TAL. This suggests a role for uromodulin in the saline homeostasis in the kidney. Genome wide scan identified polymorphisms in UMOD gene associated to chronic kidney disease and hypertension.

Methods: To verify the associated functional aspect we colleced AMBP and tested the response to oral furosemide 25 mg in a group of 233 essential hypertensive patients.

Results: The results show that carriers of risk variants of UMOD have an increase of diastolic blood pressure in basal condition (day-time DBP at ABPM: TT n=163, 96.6±0.7 mmHg vs CT+CC n=70, 94.0±1.0 mmHg; p = 0.036). A greater reduction of blood pressure, increased excretion of sodium and water after administration of furosemide (TT n=118 ΔSBP: -4.32 ± 0.95 mmHg vs CT+CC n=47 -0.88 ± 1.61 mmHg with p = 0.006; ΔDBP: TT -2.03 ± 0.64 vs CT+CC 0.47 ± 1.00 mmHg with p = 0.037; UNa: TT 532.2 ± 18.6 µEq/min vs CT+CC 454.76 ± 28.50 µEq/min with p = 0.030; urinary volume: TT 1746.5 ± 46 ml vs CT+CC 1529.0 ± 71 ml with p = 0.013) was observed.

Conclusions: These data suggest a new mechanism of hypertension dependent by the modulation of sodium homeostasis in TAL caused by overexpression of uromodulin.

FR-PO401

Hyponatremia in Malignant Hypertension: Predictor of Long-Term Renal Outcome

Fouad Amraoui,[1] Liffert Vogt,[2] Bert-jan Van den Born.[1] *[1]Vascular Medicine, Academic Medical Centre, Amsterdam, Netherlands; [2]Nephrology, Academic Medical Centre, Amsterdam, Netherlands.*

Background: Hyponatremia is associated with malignant hypertension (MHT) and might reflect the vicious cycle of severe hypertension, pressure natriuresis and renal ischemia. We assessed whether hyponatremia predicts renal outcome in these patients.

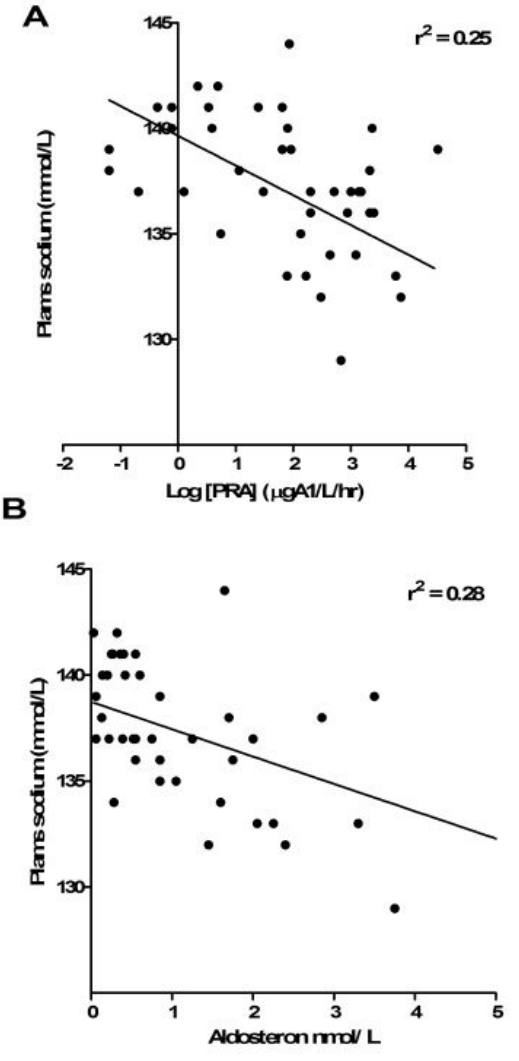
Methods: Retrospective analysis.

Results: 120 patients with MHT were included. Thirty-five (29%) patients had a plasma sodium < 136 mmol/L and were classified as having hyponatremic-hypertensive syndrome (HHS). Patient characteristics are listed in Table 1. Median serum creatinine was higher in patients with HHS ($P < 0.01$) and these patients more often had macroalbuminuria ($P < 0.05$) and Thrombotic microangiopathy ($P < 0.01$). Plamsa renin activity and plasma aldosterone were correlated with plasma sodium ($P < 0.01$ for both), Figure 1.

After 67 months, 14 (40%) patients with and 15 (18%) patients without HHS developed end-stage renal disease (ESRD), $P = 0.02$. The likelihood ratio for ESRD in patients with MHT and hyponatremia was 4.8 ($P = 0.03$).

Conclusions: Hyponatremia is common in MHT and is associated with more severe renal insufficiency. Plasma sodium is inversely correlated with RAAS activation suggesting that pressure natriuresis and subsequent volume depletion further activate RAAS. After 5 years, patients with hyponatremia have a higher risk of developing ESRD.

Clinical characteristics	Plasma sodium < 136 mmol/L	Plasma sodium >=136 mmol/L	P-value
Patients, n (%)	35 (25%)	90 (75%)	
Age, years (mean ± SD)	40 ± 9	45 ± 13	< 0.05
Male, n (%)	22 (73%)	61 (68%)	0.57
Black, n (%)	21 (70%)	36 (40%)	< 0.01
Systolic BP, mmHg (mean ± SD)	233 ± 25	229 ± 22	0.47
Diastolic BP, mmHg (mean ± SD)	148 ± 15	144 ± 16	0.28
Serum creatinine, µmol/L (median, [IQR])	402 [176-664]	155 [96-264]	< 0.01
Macroalbuminuria, n (%)	27 (75%)	39 (46%)	< 0.05
Trombotic microangiopathy, n (%)	22 (61%)	14 (17%)	< 0.01



FR-PO402

Chlorthalidone Alters the Serum Potassium Set-Point in African Americans

Anubha Mutneja,[1] Mark S. Segal,[2] Xuerong Wen.[2] *[1]Internal Medicine, University of Florida, Gainesville, FL; [2]Nephrology, University of Florida, Gainesville, FL.*

Background: In the African American population, hypertension occurs at a younger age and can lead to more severe target organ damage. Chlorthalidone is a thiazide diuretic that has been shown to have beneficial effects in lowering blood pressure and to reduce cardiovascular events in African Americans, however, its use may be limited by hypokalemia.

Methods: We used the data from the Uric Acid in Hypertension in African Americans Trial to investigate the level of potassium losses in individuals on chlorthalidone to provide guidelines for supplementation. 121 African-American men or women between the ages of

18 and 50 years with stage I hypertension were started on chlorthalidone (25 mg/day) and potassium chloride (20 mEq/day) for 4 weeks. At 4 weeks, if blood work demonstrated hypokalemia they were given oral potassium supplementation 25-100 mEq up to three times a day for 3 days and their potassium chloride supplementation was increased to 40 mEq/day. Due to persistent hypokalemia, the protocol was changed to potassium chloride at 40mEq/day and at 4 weeks if hypokalemia was detected, we increased the potassium supplementation to 50 mEq/day. The levels of serum potassium was determined at weeks 5 and 13 and at week 5, 24 hr urinary potassium excretion was determined.

Results: Multivariate mixed effects linear model with repeated measurements showed that the serum potassium was significantly different between baseline and week 4 (p-value 0.0007) independent of the level of initial potassium supplementation. Unexpectedly, there was no significant change in serum potassium noted between week 4 and week 5 (p-value 0.7603), and week 4 and week 13 (p-value 0.6823). Interestingly the only significant difference in those subjects initiated on 20 mEq or 40 mEq potassium chloride a day was the urinary potassium excretion (p-value 0.0037).

Conclusions: This study suggests that in African Americans increasing potassium chloride supplementation in patients on chlorthalidone who are hypokalemic does not improve serum potassium, suggesting that there is a set-point for serum potassium that cannot be overcome with further potassium supplementation.

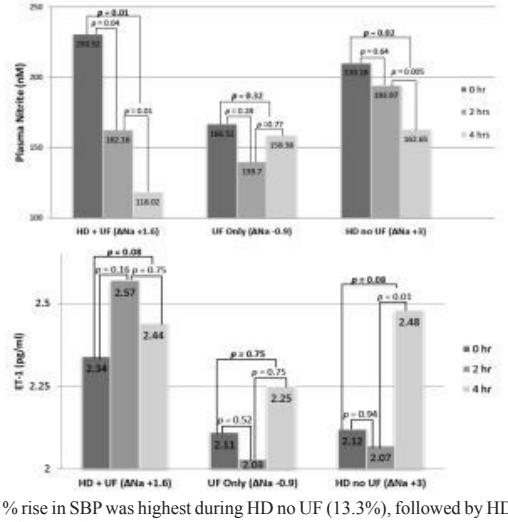
FR-PO403

Dialysate Sodium Promotes Endothelial Cell Dysfunction in Patients with Intradialytic Hypertension Bohyun C. Kim, Peter N. Van Buren, Natasha Klimas, Robert D. Toto, Jula K. Inrig. *University of Texas at Southwestern.*

Background: Intradialytic hypertension (HTN) is associated with endothelial cell (EC) dysfunction, but the cause is unknown. In EC culture, exposure to high sodium (Na^+) concentration promotes EC stiffness and imbalances in vasoconstrictors (endothelin-1 [ET-1]) and vasodilators (nitric oxide [NO]). We hypothesized that, among patients with intradialytic HTN, exposure to standard dialysate Na^+ (140 mEq/L) would lead to decreases in NO, increases in ET-1, and increases in systolic blood pressure (SBP) during hemodialysis (HD).

Methods: In a 6-week crossover study of 13 HD patients with intradialytic HTN, changes in nitrite, ET-1, and SBP were measured during 3 different midweek HD treatments consisting of: 1) regular HD with standard dialysate (Na^+ 140) and ultrafiltration (HD+UF); 2) UF only without dialysate exposure (UF only); and 3) HD (Na^+ 140) without UF (HD no UF). Changes between treatments were analyzed using mixed linear models.

Results: Among 13 subjects, the average age was 60.4 years, 85% were male, 46% AA, 46% Hispanic, 54% diabetic. The average pre-HD serum Na^+ was 137.4 mEq/L. Serum Na^+ levels rose during HD+UF (+1.6) and HD no UF (+3), but fell during UF only treatments (-0.9). Plasma nitrite levels fell with all treatments, but significant changes were seen only in treatments with dialysate exposure (HD+UF and HD no UF, Figure). There was a trend toward greater increases in ET-1 with dialysate exposure (HD+UF and HD no UF, Figure)



The % rise in SBP was highest during HD no UF (13.3%), followed by HD+UF (6.9%) and UF only (5.7%).

Conclusions: Among patients with intradialytic HTN, there was an association between dialysate Na^+ exposure and decreases in NO, increases in ET-1, and increases in SBP during HD. We propose that high dialysate-to-plasma Na^+ gradient may promote EC dysfunction and contribute to intradialytic HTN.

Effects of Dietary Potassium on Blood Pressure in Stage 3 Chronic Kidney Disease: A Randomized, Controlled, Feeding Trial Sharon Turban, Edgar R. Miller, Cheryl A. Anderson, Carol B. Thompson, Lawrence J. Appel. *Johns Hopkins University, Baltimore, MD.*

Background: In the general population, potassium (K) lowers blood pressure (BP) and may help prevent cardiovascular disease. K has renoprotective effects in animals. Patients with chronic kidney disease (CKD) may therefore benefit from higher K intake, but due to concerns of hyperkalemia, the currently recommended K intake in stage 3 CKD is 51-102 mEq K/d, lower than for the general population.

Methods: Randomized, controlled feeding trial with 2-period crossover to test the effects of a diet containing 100 vs 40 mEq K/d on BP in adults with stage 3 CKD and prehypertension or stage 1 hypertension. A 3-4 week washout separated the 4-week periods. Generalized linear models with generalized estimating equations were used.

Results: Of the 29 randomized participants, 2 were withdrawn because repeated serum K > 5.5 mEq/L. The 24 participants who finished both periods (38% male and 29% White) had a mean screening: estimated glomerular filtration rate 52 ml/min/1.73 m^2, age 69 yrs, SBP 126 mmHg, and DBP 71 mmHg. Effects of dietary K depended on K order; P value for interaction of K intake and K order: 0.03 (SBP) and 0.001 (DBP). In participants who received the lower K diet first, the higher K diet significantly lowered SBP and DBP (see table). In those who received the higher K diet first, there was no significant BP difference, suggesting a possible carryover effect.

Mean SBP, DBP (mmHg), urinary K (UrK; mEq/d), & serum K (SK; mEq/L) ± SD, adjusted Δ *, & P values by K level and K order

K order	Outcome	Lower K	Higher K	Adj Δ* (lower K - higher K)	P value
L to H (N=12)	SBP	123±12	116±13	7	< 0.001
	DBP	65±11	62±8	2	0.003
	UrK	36±12	80±35	-44	<0.001
	SK	4.2±0.4	4.5±0.3	-0.3	0.002
H to L (N=12)	SBP	121±6	120±11	2	0.3
	DBP	67±6	68±5	-1	0.1
	UrK	41±18	83±34	-41	<0.001
	SK	4.1±0.4	4.3±0.4	-0.1	0.2

*Model includes K level, K order, & their interaction and is adjusted for age, race, sex, & outcome at baseline.

Conclusions: These results highlight the potential benefit of a higher K diet in lowering BP in stage 3 CKD, but also the need for monitoring serum K given the risk of hyperkalemia. Longer-term trials evaluating the effects of K intake on BP and other clinical outcomes are warranted.

Long WNK1 Correlates with Blood Pressure Increase in Response to Low Dietary Potassium Susan Hedayati,[1,2] Masoud Afshar,[2] Beverley Adams-huet,[2] Jian Xie,[2] Orson W. Moe,[2] Chou-Long Huang.[2] *[1]Dallas VA; [2]Univ of TX Southwestern, Dallas, TX.*

Background: Mechanisms mediating salt-sensitive hypertension are poorly understood. Diet K^+ restriction in rats increased whole-kidney WNK1 mRNA. Upregulation of WNK1 in humans causes hypertension in type 2 pseudohypoaldosteronism. We investigated whether low dietary potassium (K) correlates with increased long WNK1 mRNA (using white blood cells as surrogate tissue) and higher BP, and if this BP increase is mediated by renal sodium (Na) retention.

Methods: In a cross-over double-blind study, 10 healthy subjects were randomized to 70 mEq of oral KCl or placebo for 4 weeks and consumed a diet with 150 mEq/d of Na and 30 mEq/d of K. After a 21-day washout of random diets, subjects crossed over to the other drug for 4 weeks. WNK1 mRNA, 24h urine Na and K, and BP response to 2 L IV saline were measured after each 4 weeks and compared as a paired t-test or Wilcoxon Signed Rank for each subject. WNK1 was log-transformed.

Results: Baseline mean (SD) systolic and diastolic BP were 106 (21) and 74 (8) mmHg. Mean urinary K was 33 (4) mEq/24h during the placebo and 92 (15) mEq/24h during the KCl phase, p <.0001, indicating adequate adherence. Urinary Na excretion was not statistically different between the 2 phases at 141 (48) and 147 (59) mEq/24h. WNK1 mRNA was lower during the KCl vs. placebo phase, geometric means (95% CI) 0.78 (0.61, 1.10) and 1.19 (0.92, 1.53) respectively, p =.03. Both systolic and diastolic BP were lower following the saline load during the KCl as compared to the placebo phase (p =.003 for systolic and .03 for diastolic; Figure 1). Urinary Na excretion rate following saline increased during the KCl as compared to the placebo phase, suggesting impaired natriuresis during placebo (AUC =33, p =.03, Figure 2).

Conclusions: Dietary K may exert a BP-lowering effect by increasing renal Na excretion mediated by WNK1.

Utility of Renin/Aldosterone Profiling in Complex Hypertension Debbie L. Cohen, Danny Haddad. *Medicine, University of Pennsylvania, Philadelphia, PA.*

Background: Despite multiple pharmacotherapies BP remains poorly controlled. Renin/aldosterone (R/A) profiling helps identify categories of hypertension (HTN). Purpose of this study was to determine if R/A profiling would aid in control of HTN with tailored therapy.

Methods: Retrospective study was performed of all new patients (pts) seen at the UPenn HTN clinic by one HTN specialist from 2005-2010. Pts were screened with renin and aldosterone levels. Pts with known secondary causes of HTN such as pheo were excluded. Data was reviewed at initial and subsequent visits for 1 year. The pts were categorized as: normal, salt sensitive (SS) (renin <1, aldo <15), hyperaldo (renin <1, aldo ≥ 15) and high renin (renin ≥ 10). Meds were then tailored to the individual profile.

Results: 158 patients with a mean age of 52.9 ± 1.25 years were included, 47% males, 53% females, 75% white, 21% black, and 4% other. Mean SBP/DBP at baseline for the entire cohort was 149/87 ± 2/1 mm Hg and was decreased by mean of 20/9 ± 2/1 mm Hg at 1 year (p=0.000). No change in the overall number of meds at baseline and 1 year despite improved BP control (p = 0.770).

	Normal	SS	Hyperaldo	High Renin
Patients n (%)	56 (36)	43 (27)	40 (25)	19 (12)
Renin (ng/ml)	4.0 ± 0.37	0.4 ± 0.04	0.4 ± 0.05	33.3 ± 4.2
Aldosterone (ng/dl)	12.8 ± 1.5	7.3 ± 0.59	38.5 ± 7.3	33.3 ± 3.5
SBP/DBP baseline (mmHg)	150±3/88±2	154±4/87±2	149±4/90±4	**138±4/76±3***
SBP/DBP at 1 year (mmHg)	131±3/79±2	130±3/78±2	123±3/77±2	132±5/77±4
Average Change in SBP/DBP (mmHg)	**19±3/8±2 ****	**25±4/9±3****	25±4/13±2 **	5±5/-2 ± 3
# of Meds Time 1 - Time 2	-0.14 ± 0.2 (ns)	**-0.46 ± 0.2 *****	**0.55 ± 0.2 ******	0.52 ± 0.2 (ns)

Values expressed as mean ± SEM. Values considered significant if p < 0.005. *SBP only significantly lower when compared to SS group, DBP significantly lower than all other groups, ** p≤ 0.001; ***p=0.003; **** p=0.026 ; ns: non-significant

Conclusions: R/A profiling in pts with severe HTN helps tailor therapy resulting in significantly improved BP control without an overall increase in number of meds. Most patients required at least 3 meds to achieve BP control. R/A profiling is a helpful tool to improve BP control in a referred population with severe HTN.

FR-PO407

Marinobufagenin and Dietary Sodium Restriction: Influences on Blood Pressure and Large Elastic Artery Stiffness Kristen L. Jablonski,[1] Olga Fedorova,[2] M. Chonchol,[1] Matthew Racine,[3] Candace Geolfos,[3] Bradley S. Fleenor,[3] Edward G. Lakatta,[2] Alexei Bagrov,[2] Douglas R. Seals.[3] *[1]Medicine/ Renal, University of Colorado Denver, Aurora, CO; [2]Intramural Research Program, NIA, NIH, Baltimore, MD; [3]Integrative Physiology, University of Colorado Boulder, Boulder, CO.*

Background: Systolic blood pressure [SBP] and large elastic artery stiffness both increase with age, and dietary sodium restriction reduces SBP and large elastic artery stiffness, as measured by aortic pulse-wave velocity [aPWV]. Production of the natriuretic hormone marinobufagenin (MBG), an endogenous α1 Na+,K+-ATPase inhibitor, is increased in salt-sensitive hypertension (i.e. contributes to the rise in SBP following high sodium load).

Methods: We hypothesized that dietary sodium restriction would reduce SBP and aPWV in middle-aged and older adults with moderately elevated SBP (139±2/83±2 mmHg, mean±S.E.) in part by reducing MBG production.

Results: SBP and aPWV were reduced (-10±3 mmHg and -143±25 cm/sec) following a 4 week low sodium (LS; 77±9 mmol/day) vs. normal sodium (NS; 144±7 mmol/day) diet (p<0.05; randomized, cross-over design; 8M/3F; 62±1 yrs). Urinary MBG excretion was lower during the LS vs. NS condition (range for weekly measurements: 24.0±4.2–28.3±4.6 [LS] vs. 27.8±5.7-32.4±3.7 [NS] pmol/kg/day, p<0.05) and was positively correlated with both SBP (r= 0.39, p<0.001) and urinary sodium excretion (r= 0.46, p<0.001). When each sodium condition was analyzed separately, these relations were evident during the NS (SBP: r= 0.49, p<0.001; sodium excretion: r=0.44, p<0.005) but not the LS condition (SBP: r=0.16, p=0.24, sodium excretion: r=0.20, p=0.14). As measured following each 4 week condition, MBG excretion was also positively correlated with aPWV (r=0.51, p<0.05), and plasma MBG levels were inversely related to endothelial cell protein expression of the antioxidant enzyme manganese superoxide dismutase (r=-0.51, p<0.05).

Conclusions: These results demonstrate that dietary sodium restriction reduces urinary MBG excretion and suggest that changes in MBG may contribute to reductions in SBP and large elastic artery stiffness, possibly via a reduction in oxidative stress.

FR-PO408

Impact of Fructose and Sodium Restriction on Mitochondrial Content and Oxidative Stress in Hypertensive and Overweight Subjects Magdalena Madero,[1] David Cruz-robles,[1] Sergio Hernández-Estrada,[1] Silvia Hernández-Lobato,[1] Maria Villalobos-Martín,[1] Richard J. Johnson,[2] Roman Hernandez,[1] Francisco E. Rodríguez Castellanos,[1] L. Gabriela Sanchez-Lozada.[1] *[1]INCIC; [2]U of Colorado.*

Background: Fructose and sodium intake have been associated with hypertension and metabolic syndrome (MS). This association may be mediated in part by mitochondrial dysfunction and systemic oxidative stress (SOS).There are no data regarding whether fructose and sodium restriction have an effect on SOS and mitochondrial DNA (mtDNA) content in overweight and hypertensive subjects. The objective of this study was to compare the effect of two isocaloric diets, Na restricted and Na-fructose restricted, on SOS and mtDNA.

Methods: This study is an exploratory analysis of a randomized controlled trial aiming to determine the impact of the low Na, low Na-fructose isocaloric diets (with respect to baseline diets), on blood pressure (BP) over 8 weeks. The present study included 36 overweight subjects with prehypertension or stage 1 hypertension selected randomly from the trial. 24hr ambulatory BP, anthropometric measures, laboratory data, mtDNA by Real-time PCR, malondialdehyde(MDA) and 2,4-dinitrophenylhydrazine(DNPH) as markers of SOS were determined at baseline, weeks 4 and 8.Markers of SOS were measured in plasma and mtDNA was determined from peripheral white cells.

Results: Weight loss was not achieved in any group. Both diets resulted in a significant decrease in DNPH and an increase in mtDNA, effect that was more marked at week 8. At week 8 MtDNA levels were higher in the low Na-Fructose group compared to the low Na group although this was not significant.

Table

Diet	Low Na n=21	Low Na-Fructose n=15	Low Na	Low Na-Fructose	Low Na	Low Na-Fructose
	Baseline		Week 4		Week 8	
BMI (kg/m²)	32±4	34±4	32±4	32±4	32±4	32±4
SBP (mmHg)	136±10	134±12	134±14	132±14	131±11	128±10
MDA (nmol)	2.2±2.3	1.9±2	1.8±1.7	1.1±1.3	1.4±1.8	2±2.6
DNPH (nmol)	4.6±2.2	5.8±2.2	3.4±1.7α	4.8±3.1	2.6±0.8β	2.2±1.9β
mtDNA (copies X10³)	2±6	1±4	3±6α	1±0	13±25β	140±420β

α p<.05 within group week 4 vs baseline, β within group p<.05 week 8 vs 4

Conclusions: Both diets had a beneficial effect on SOS and mtDNA content.These effects were independent of weight loss.

Promoter Polymorphism of the IL-6 (C-174G) Gene and the Estimation of Metabolic Syndrome Occurrence among a Cohort of Patients with Hypertension Andrei Alkmim Teixeira,[1] Maria Dalboni,[1] Beata Marie Redublo Quinto,[1] MArcelo Costa Batista.[1,2] *[1]Medicine/ Nephrology Division, UNIFESP; [2]Hospital Israelita Albert Einstein.*

Background: Visceral obesity, the central core of Metabolic Syndrome (MS) is conceived as the pathogenic basis of increasing cardiovascular burden of syndrome and is related with higher cytokines levels. In observance of the modern concept of MS as an inflammatory disease we investigated whether IL-6 (C-174G) gene polymorphism is associated with MS prevalence in a cohort of hypertensive patients.

Methods: It was included 664 patients currently followed in Hypertension and Diabetes Clinic where we concomitantly analyzed lipid profile apolipoprotein A and B, CRP and albumin. Patients were stratified by the presence of MS according to International Diabetes Federation criteria for MS. Framingham risk score was used to evaluate the CV risk. The IL-6 –174 (C/G) genotyping was performed by polymerase chain reaction with sequence-specific priming using the SSP DNA Typing kit.

Results: MS prevalence was 52,6 % (n= 349) and 34% were men. Smoking habit was observed in 11,1% of patients. Cardiovascular disease (CVD) was present in 10,1% n=62) of the cohort and 27,4% of patients (n=168) had positive familiar history for CVD. It was identified 45 % of "C" carriers genotype among MS patients. Characteristics of "C" carriers and non-carriers patients were respectively: BMI(30.1±5.4 *vs* 28.9±5.1;p<0.05 waist(97.1±12.2 *vs* 95.0±12.3,p<0.04), CRP(0.67±0.73 *vs* 0.5±0.6,p<0.005), VLDL-C(30.5±13.4 *vs* 27.1±13.1,p<0.0002); HDL-C (55.4±15.3 *vs* 58.7±15.4;p<0.01) and apoA (137±25.4 *vs* 143±25.4;p<0.008). On binary logistic regression it was observed that the presence of IL-6 single nucleotide polymorphism 174 C/Gwas independently

associated with MS occurrence. This association remained significant after adjusting for covariates**:** sex, age, race, CVD, LDL-C and Framingham score covariates (variation of HR 1.47 – 1.68, 95% CI).

Conclusions: The C-allele at the -174 locus of human IL-6 gene is independently associated with occurrence of MS pinpointing the importance of inflammatory genetic background as the basis of visceral obesity and related cardiovascular burden.

FR-PO410

Influence of Blood Pressure Levels on Urinary Albumin Excretion in Patients with Chronic Renin-Angiotensin System Suppression Julian Segura, Cesar Cerezo, Jose A. Garcia-donaire, Diego Marquez, Manuel Praga, Luis M. Ruilope. *Hypertension Unit. Department of Nephrology, Hospital 12 de Octubre, Madrid, Spain.*

Background: An adequate blood pressure (BP) control and renin-angiotensin system (RAS) suppression are both useful tools to prevent or delay the development of micro or macroalbuminuria. However, there are evidences that renal and cardiovascular damage may still develop under chronic RAS suppresion.

Methods: We analyzed the effect of BP control on urinary albumin excretion in hypertensive patients treated with an angiotensin-converting enzyme inhibitor (ACEi) or angiotensin receptor blocker (ARB), alone or in combination with other antihypertensive drugs. We included 1141 patients (mean age 59.7±12.5 years, male 48.7%), all presenting normoalbuminuria at baseline. New-onset microalbuminuria was defined as albumin-to-creatinine ratio between 20–200 mg/g in men or 30–300 mg/g in women confirmed in at least a second occasion among the 6-monthly determinations performed in three samples of early morning urine. Patients received during the follow-up the highest available dose of an ACEi or an ARB, accompanied by a diuretic or a calcium channel blocker, or both, if needed.

Results: Percentage of patients developing microalbuminuria increased progressively during the follow-up: 13.0%, 16.4% and 17.1 % after 1, 2 and 3 years of follow-up, respectively. When patients were classified according BP level at each visit, the development of albuminuria took place at any level of systolic BP maintained, starting in values below 130mmHg and ending above 160mmHg.

	UAE	Baseline	Year 1	Year 2	Year 3
SBP<130	Normo	376 (100)	333 (88.6)	321 (88.2)	322 (85.6)
	Micro	0	43 (11.4)	43 (11.8)	54 (14.4)
SBP 130-139	Normo	338 (100)	298 (88.2)	280 (84.8)	287 (84.9)
	Micro	0	40 (11.8)	50 (15.1)	51 (15.1)
SBP 140-159	Normo	343 (100)	294 (85.7)	268 (80.0)	274 (79.9)
	Micro	0	49 (14.3)	67 (20.0)	69 (20.1)
SBP ≥160	Normo	84 (100)	67 (79.8)	60 (73.2)	63 (75.0)
	Micro	0	17 (20.2)	23 (26.8)	21 (25.0)

n (%)

Conclusions: A long-term office BP control does not exclude the development of de-novo microalbuminuria in patients chronically RAS suppressed. This finding is observed at category of BP, from normal to grade 3 hypertension.

FR-PO411

Long Term Evolution of Blood Pressure Control in Resistant Hypertension Julian Segura, Jose A. Garcia-donaire, Cesar Cerezo, Diego Marquez, Manuel Praga, Luis M. Ruilope. *Hypertension Unit. Department of Nephrology, Hospital 12 de Octubre, Madrid, Spain.*

Background: Therapeutic recommendations for resistant hypertensive patients have been proposed by short-term studies, but information about long term evolution of blood pressure control in these patients is scarce.

Methods: We analyzed the evolution of 106 patients presenting resistant hypertension (RH) after 12 months of follow-up. At baseline, patients were classified as white coat RH (n=50), RH with adequate response to spironolactone (n=43) and RH non responders to spironolactone receiving a combination of aliskiren 300mg+amlodipine 10mg+chlortalidone 25 mg (n=13).

Results: After 12 months of follow-up, those patients presenting RH with adequate response to spironolactone maintain significant reduction both in clinic (mean average reduction -21.7±23.1 and -7.4±10.2 mmHg for systolic [SBP] and diastolic blood pressure [DBP], respectively), ambulatory (-17.7±16.8 and -6.2±8.8 mmHg for 24h SBP and DBP, respectively) and central BP (-17.7±20.1 and -7.4±11.9 mmHg, respectively). These patients showed a significant increase in body weight, body mass index, serum creatinine, potassium and uric acid, and a diminished estimated GFR. Those patients receiving a combination of aliskiren+amlodipine+chlortalidone on top of previous antihypertensive drugs (ACEi, ARB, alpha or betablockers) maintain significant reduction both in clinic (mean average reduction -28.7±23.5 and -13.7±10.9 mmHg for SBP and DBP, respectively), ambulatory (-18.7±20.2 and -8.5±8.5 mmHg for 24h SBP and DBP, respectively) and central BP (-22.9±24.9 and -11.6±12.0 mmHg, respectively). These patients showed non significant changes in body weight, body mass index, serum creatinine, potassium, uric acid and estimated GFR.

Conclusions: In conclusion, after 12 months of follow-up, spironolactone add-on therapy is effective for BP control in true RH, with slight but significant increase in serum creatinine and potassium. In non-responders to spironolactone, the combination of aliskiren+amlodipine+chlortalidone on top of concomitant antihypertensive therapy is effective for BP control, without significant increase in renal parameters.

FR-PO412

Discrepancies between Office and 24-Hour Blood Pressure Control in Hypertensive Patients with Chronic Kidney Disease Julian Segura,[1] Pantelis Sarafidis,[1,2] Manuel Gorostidi,[3] Alejandro De la Sierra,[4] Juan J. De la Cruz,[5] Jose R. Banegas,[5] Luis M. Ruilope.[1] *[1]Hypertension Unit. Department of Nephrology, Hospital 12 de Octubre, Madrid, Spain; [2]Section of Nephrology and Hypertension, 1st Department of Medicine, AHEPA University Hospital, Thessaloniki, Greece; [3]Department of Nephrology, Hospital Central de Asturias, Oviedo, Spain; [4]Department of Internal Medicine, Hospital Mutua Terrasa, Barcelona, Spain; [5]Department of Preventive Medicine and Public Health, Universidad Autonoma, Madrid, Spain.*

Background: Recent evidence suggests major discrepancies between office and 24-hour BP levels in hypertensive populations. We examined control of ambulatory BP in a large cohort of CKD patients.

Methods: A total of 5,624 hypertensive individuals with CKD Stage 1-5 from the Spanish ambulatory BP monitoring (ABPM) Registry were included in this analysis. Office-based BP was calculated as the average of 2 readings, and 24-hour ABPM was performed using a SpaceLabs 90207 device, according to recommendations. Control rates of hypertension were calculated at the <140/90 and <130/80 mmHg office thresholds, and the <130/80 and <120/75 mmHg ABPM thresholds.

Results: Only 21.7% and 7.9% of the total population had office BP <140/90 and <130/80 mmHg, respectively; at both these office thresholds, the rates of control were increasing with advancing CKD stages (*P<0.01*). In contrast, control of ambulatory BP was much higher, with 44.8% of subjects having average 24-hour BP <130/80 and 20.5% 24-hour BP <120/75 mmHg. Furthermore, 52.2% of the population had average daytime BP <135/85 mmHg and 36.6% night-time BP <120/70 mmHg. In multi-variate analysis, age ≥60 years and favourable dipping status were associated with successful 24-hour BP control, whereas male gender, smoking, diabetes, target-organ-damage, and hypertension duration were adversely related to control.

Conclusions: In hypertensive patients with CKD, ambulatory-based control rates were far better than office-based rates. These findings call for wider use of ABPM to evaluate success of hypertension treatment in CKD patients both in clinical practice and randomized trials.

FR-PO413

A Comparative Analysis of Two Methods of Blood Pressure Measurement in an Adult Diabetic Population Pierce Geoghegan, Eadaoin Ni Sheaghdha, Donal John Sexton, Donal N. Reddan, David Lappin. *Medicine, University College Hospital Galway, Galway, Co. Galway, Ireland.*

Background: Blood pressure (BP) control predicts morbidity and mortality in diabetes. However, the optimal approach to monitoring BP in the diabetic population is unclear. Ambulatory blood pressure monitoring reliably predicts prognosis but can be inconvenient. The automated 'BpTRU' device, which provides up to six successive in-office BP measurements, has been shown to correlate more strongly with ambulatory measurements than traditional "once-off" measurements of BP. We investigated whether there was a difference between measurement of BP using traditional methods versus the "BpTRU" device in an outpatient diabetic population.

Methods: Patients were enrolled from an outpatient diabetes day clinic. We recorded the BP of 52 diabetics by traditional measurement and with the BpTRU device. We established whether there was a statistically significant disagreement between the values measured by the two methods and whether these differences had an impact on the assessment of BP control.

Results: Mean systolic BP was significantly lower by BpTRU measurement than by standard assessment, by 7.25 ± 2.94mmHg (95% CI 13.1 to 1.04mmHg, p=0.0154). Significantly more patients achieved their systolic BP target of ≤ 130mmHg by BpTRU measurement than by traditional techniques (69% vs 46%, P=0.0285). No significant disagreement in the measurement of diastolic BP was detected between the two methods and there was no significant difference in the proportion of patients deemed to reach their diastolic BP target when comparing the methods. Overall, significantly more patients simultaneously achieved both their systolic (≤ 130mmHg) and diastolic (≤ 80mmHg) blood pressure targets by BpTRU measurement than by traditional techniques (56% vs 35%, P= 0.0483).

Conclusions: Our study suggests that the BpTRU device can reduce the effect of "white coat" hypertension in a diabetic population. The use of this device in routine practice could improve the overall accuracy of in-office blood pressure assessment in these "hard to treat" patients. This in turn could potentially reduce the cost and morbidity associated with overtreatment of hypertension in diabetes.

FR-PO414

Extreme Blood Pressure Elevations and Risk for Death in CKD Francesco Rainone, James Ritchie, Philip A. Kalra. *Vascular Research Group, Salford Royal Hospital, UK.*

Background: Hypertension exists in over 80% of CKD patients with both cause and effect relationships. In the general population, uncontrolled blood pressure (BP) associates with increased mortality in an exponential fashion. Here we consider the association between extreme BP elevations and risk for death in an all cause CKD-population.

Methods: 1808 patients from the Chronic Renal Insufficiency Standards Implementation Study (CRISIS) were divided by baseline BP: Normal (NBP) - SBP 120-140mmHg;

DBP<80mmHg; Resistant hypertension (RH) - *SBP>160mmHg±DBP>90mmHg; Extreme hypertension (EH) - SBP>190mmHg±DBP>100mmHg; **despite three different classes of antihypertensive medications*. Cox regression (adjusted for age, eGFR, sex, baseline BP, body mass index and number of antihypertensive medications) was used to compare all cause mortality at 1 year and entire follow-up period (censored at death, dialysis, last follow-up or 1/1/2011).

Results: Mean age was 54.5 years, eGFR 36ml/min/1.73m^2, BP 135/75mmHg. Patients with EH (n=65) had significantly increased risk for death at 1 year (HR 5.08, p=0.009) but not over the full follow-up period. For EH, risk for 1 year death was significantly elevated vs NBP (HR 7.8, p=0.008) with a trend to increase vs RH (HR 7.66, p=0.06). Of 52 surviving EH patients with 1 year follow-up data, 10 had persistent EH and 15 NBP. Mean ΔSBP/DBP was -33/-16mmHg. Mean number of antihypertensives increased from 2.6 to 3.0 (no significant difference in types of agents used). Patients with persistent EH, had an increased risk for death vs the remainder of the population (HR 6.97, p=0.008) and vs those who previously had EH (HR 16, p=0.17). The 42 patients with BP no longer defined as EH did not have an ongoing increase in risk for death (HR 1.18, p=0.51).

Conclusions: BP elevations above those defined as RH further increase risk for death in CKD. Most patients with baseline EH can be successfully treated with dose adjustment of medications, reducing risk for death. Patients with persistent EH have significant increases in risk for death and should be considered for intensified therapy including new techniques such as renal sympathetic nerve ablation.

FR-PO415

The Standardized Blood Pressure Lowering Effect of Renal Denervation Eva Vink,[1] Willemien Verloop,[2] Evert-jan Vonken,[4] Michiel Voskuil,[2] Wilko Spiering,[3] Peter J. Blankestijn.[1] *[1]Nephrology, UMC Utrecht, Utrecht, Netherlands; [2]Cardiology, UMC Utrecht, Utrecht, Netherlands; [3]Vascular Medicine, UMC Utrecht, Utrecht, Netherlands; [4]Radiology, UMC Utrecht, Utrecht, Netherlands.*

Background: The first studies on renal denervation(RDN) suggest a clear BP-lowering effect. An important limitation of these studies is that BP was measured while patients used antihypertensives which makes it difficult to quantify the net effect of RDN. The aim of our study is to determine the standardized effect of RDN. This abstracts presents an interim analysis of an ongoing study.

Methods: We evaluated the BP-lowering effect of RDN in 2 types of patients who were treated with RDN: patients with resistant hypertension or with intolerance for antihypertensives (office SBP of ≥160mmHg). Secondary causes of hypertension were excluded. At baseline, 6 and 12 months after RDN, office BP is determined. At baseline and 12 months after RDN 24-h ambulatory BP monitoring(ABPM) is done in a standardized fashion: after cessation of all antihypertensives when this is considered to be safe or under the same treatment. For the available within-group paired data, a paired *t* test is used with a 2-sided alpha level of 0.05.

Results: At the moment of submission, 43 patients are treated with RDN. Currently 6 months follow -up data are available of 27 patients, 12 months follow-up data are available of 12 patients. BP decreased significantly during follow-up, but a broad range in effect is observed. The number of antihypertensives did not change significantly during follow-up. Currently 12 months follow-up on 24-h ABPM is available of 8 patients. Mean daytime BP decreased from 161/97mmHg to 147/91mmHg (P=0.103).

Figure 1: Significant decrease in BP after 6 months of follow-up. (N=27)

	Baseline (n=27)	6 months (n=27)
SBP	201 mm Hg	173 mm Hg
DBP	109 mm Hg	97 mm Hg

Conclusions: RDN is a promising treatment for patients with resistant hypertension or intolerance for antihypertensives. It is worth to put more effort in further exploration on this treatment and its options.

FR-PO416

A Clinicopathologic Study of 52 Patients with Essential Malignant Hypertension Confirmed by Renal Biopsy Peng Xia, Xiaoxiao Shi, Lanping Jiang, Yubing Wen, Xuemei Li, Xuewang Li, Limeng Chen. *Nephrology Department, Peking Union Medical College Hospital, Beijing, China.*

Background: This study aimed at evaluating the associations between pathological findings and prognosis in essential malignant hypertension (MHT) patients, with emphasis on the value of peritubular capillary (PTC) loss.

Methods: We retrospectively reviewed the clinical records of 52 patients with essential MHT confirmed by renal biopsy in our hospital from January 2003 to March 2012. The tubular atrophy / interstitial fibrosis (TA/IF), proliferative endarteritis and mucoid changes were evaluated semi-quantitatively. The PTC was evaluated by immunohistochemical staining of CD34, a specific marker of arteriolar endothelium.

Results: The enrolled patients were mostly male (M:F 12:1) and relatively young (age 34.0±8.2y). The Scr was 5.51±4.25mg/dL and the 24h urine protein (24hUpro) was 1.87±1.50g/24h. 21.1% (11/52) of the patients required dialysis. The mean percentage of TA / IF were 56±20%. Lumen occlusion(24.3%), mucoid changes(22.4%) and intimal hyperplasia (22.1%)were commonly seen in 580 observed arterioles. The PTC proportion was 2.27±0.74%, which was significantly less than that of glomerular minimal lesion patients (3.75±0.79%, *P*<0.001). TA/IF correlated positively with Scr, 24Upro and the need for dialysis. PTC proportion correlated negatively with TA/IF, Scr and the need for dialysis. After adequate anti-hypertension therapy, the control rate of BP improved significantly from 5.8% to 76.9% (*P*<0.001), Scr and 24Upro levels also decreased. The mean follow-up time were 29.1±30.1 months and the renal survival rate at 1, 3 and 5 year was 65%,55% and 50%, respectively. The prognostic factors for renal survival identified by COX regression were CKD stage (RR=4.38, 95%CI (1.46, 13.15), P=0.008) and PTC loss (RR=13.21, 95%CI (1.50, 116.69), P=0.020).

Conclusions: Renal involvement in essential MHT patients is severe. PTC loss correlates with renal function well and may predict the long time renal survival.

Single Center Experience of Renal Denervation Procedure besides Clinical Studies: Renal Artery Supply Indicates Treatment Success Wolfgang Weiss, Markus Tolle, Markus van der Giet. *Med. Klinik mit SP Nephrologie, Charite - Campus Benjamin Franklin, Berlin, Germany.*

Background: Renal Denervation (RDN) gradually moves mainstream as supplementary interventional procedure for treatment of therapy resistant hypertension. 40 patients with therapy resistant hypertension have been identified and treated with RDN procedure. Due to missing predictors and indicators for treatment efficacy we examined which patients benefit most of RDN treatment procedure.

Methods: 40 patients were treated with RDN procedure. Office blood pressure and ambulatory blood pressure monitoring data (ABDM) were collected every third month after intervention for at least 1 year per patient. In practice renal artery anatomy of patients varied over the known limitation of double sided single renal artery supply. Thus only multiple renal artery supply for both kidneys was an exclusion criterion for treatment with RDN procedure. Patients with reduction in systolic pressure ≥ 10 mmHg in office and ABDM measurements were defined as responder.

Results: After RDN treatment the extent of systolic blood pressure reduction within responders did not differ statistically significant between office and ambulatory blood pressure measurements at any time point of observation. 11 of 19 patients (58%) with multiple renal artery supply failed to show a blood pressure reduction and derogated responder rates within treated patients. In contrast effective blood pressure reduction was achieved in 15 of 21 patients (71%) with bilateral single renal artery supply (n=21). One year after RDN responder showed a mean systolic blood pressure reduction of approx. 20 mmHg in office as well as in ABDM measurements.

Conclusions: One year after treatment with RDN procedure a mean systolic blood pressure reduction of approx. 20 mmHg can be estimated. Renal artery supply might be a key point for RDN treatment success and should be judged more critically, although RDN seems to be the last therapeutic option for treatment of therapy resistant hypertension. Hence well-known RDN responder rates of about 70-80% of treated patients could only be achieved if renal artery supply is as highly selected as done for simplicity HTN trial population.

FR-PO418

Renal 123I-MIBG Scintigraphy, a Novel Technique to Assess Efficacy of Renal Sympathetic Denervation: A First Impression Daan W. Eeftinck Schattenkerk,[1] Hein Jan Verberne,[2] Liffert Vogt,[3] Bert-jan Van den Born.[1] *[1]Vascular Medicine, Academic Medical Center, Amsterdam, Netherlands; [2]Nuclear Medicine, Academic Medical Center, Amsterdam, Netherlands; [3]Nephrology, Academic Medical Center, Amsterdam, Netherlands.*

Background: Radiofrequency ablation of the renal sympathetic nerves (RSD) has emerged as a minimally invasive technique to improve blood pressure (BP) control in patients with therapy resistant hypertension. Despite the general effectiveness of RSD, the magnitude of the individual BP lowering response is variable. This variation may partly be due to inconsistency in efficacy of renal ablation, indicated by renal nor-adrenaline spillover studies in human showing an average reduction of 47% (95% CI 28-65%) after RSD. Furthermore, the relative contribution of the kidneys in determining central sympathetic drive may vary and is incompletely understood. Here, in analogy to cardiac

^{123}I-metaiodobenzylguanidine (MIBG) imaging as measure for cardiac sympathetic activity, we introduce renal ^{123}I-MIBG scintigraphy, aiming to give insight into the variable BP effect of RSD.

Methods: Renal, cardiac ^{123}I-MIBG scintigraphy and 24h ambulatory BP monitoring (ABPM) were performed in patients eligible for RSD prior to and 6 weeks after RSD. Subjects received 185 MBq of ^{123}I-MIBG intravenously. At 15 min and 4 hrs post injection scintigrams were made. A low dose CT-scan of the abdomen was made to relate tracer uptake to anatomical structures.

Results: Data of 6 patients (4 male), age 59±11 years, was analyzed. ABPM tended to go down after RSD from 171/106 mmHg (±17/14) to 151/95 mmHg (±29/17) (p=ns). Renal MIBG washout decreased by 21% (from 0.40 to 0.32, p=0.027). Cardiac MIBG washout did not change significantly (from 0.60 to 0.57, p=0.441). However the cardiac / renal MIBG washout ratio decreased by 16% (from 0.67 to 0.56, p=0.026). A correlation between MIBG and ABPM could not be found.

Conclusions: Our preliminary data show that renal ^{123}I-MIBG scintigraphy may prove to be a suitable noninvasive technique to assess the effectiveness of RSD. Furthermore, our data suggest that RSD mainly exerts a renal efferent rather then afferent effect.

FR-PO419

Diastolic Blood Pressure Profile when Targeting Intensive Systolic BP Control B. Peter Sawaya,[1] Hwasoon Kim,[2] Jonathan D. Wilkerson,[1] Leslie Mcclure,[2] Pablo E. Pergola.[3] *[1]Division of Nephrology, Bone and Mineral Metabolism, University of KY, Lexington, KY; [2]Biostatistics, University of Alabama, Birmingham, AL; [3]Renal Associates PA, San Antonio, TX.*

Background: Conflicting reports exist in regard to whether there is a J curve in diastolic blood pressure (DBP) in which cardiovascular events actually increase after lowering DBP below 60-70 mmHg. We hypothesized that DBP is lower in patients undergoing intensive systolic blood pressure (SBP) reduction. We further tested whether factors such as: age, diabetes, isolated systolic hypertension and number of antihypertensive medications contribute to the frequency of observing low DBP.

Methods: The SPS3 study is an international randomized controlled trial that assessed the impact of antiplatelet therapy and optimal level of SBP control in the secondary prevention of subcortical strokes. Patients were assigned to two groups of SBP target (mmHg): Usual Group (UG: SBP 130-149) and Intensive Group (IG: SBP<130), irrespective of DBP.

Results: A total of 3021 patients were enrolled in the study. Mean age (yrs ± SD): UG 63.4 ± 10.8; IG 63.3 ± 10.7. The proportion of visits at which DBP (mmHg) <70 and <60 (measured at 3-month intervals for up to 72 months) were: UG 27.2% and 5.3%; IG 46.9%* and 13.8%*, respectively (* = p <0.0001, UG vs. IG). The mean DBP reached 70 within 12 months in the IG and remained <70 throughout the study period. At no time was the mean DBP <70 in the UG.

DBP Profile

Group	Baseline	12-Month	36-Month	72-Month
UG	80.0 ± 0.3 *(N=1520)*	76.3 ± 0.3 *(N=1356)*	75.6 ± 0.4 *(N=875)*	74.4 ± 0.8 *(N=232)*
IG	78.3 ± 0.3* *(N=1501)*	70.0 ± 0.3* *(N=1354)*	68.1 ± 0.4* *(N=886)*	67.6 ± 0.7* *(N=253)*

**= p <0.0001; Mean ± SD*

Linear regression analysis identified only the following factors as independently associated with increasing percentage of DBP <60 mmHg: targeting SBP <130*, older age* and presence of DM* (* = p <0.0001).

Conclusions: The SPS3 study demonstrates that targeting SBP <130 is more than twice as likely to result in a DBP <60. Older age and DM were the strongest predictors of lower DBP. This study potentially may clarify whether lowering DBP can independently increase cardiovascular events in this high risk population.

FR-PO420

The Association between Annual Change in Systolic Blood Pressure and Mortality in an All-Cause CKD Population James Ritchie,[1] Francesco Rainone,[2] Philip A. Kalra.[1] *[1]Vascular Research Group, Salford Royal Hospital; [2]San Raffaele University, Milan.*

Background: There is a recognized association between increased blood pressure and risk for mortality in both the general and CKD populations. The effects of annual rates of change in blood pressure are less well described.

Methods: 2141 patients from the Chronic Renal Insufficiency Standards Implementation Study (CRISIS) were included. Cox proportional hazards were used to calculate the effect of baseline blood pressure (divided by quartile) on hazard ratio (HR) for all-cause mortality. Time averaged rates of change in systolic blood pressure were calculated and a second Cox model generated to assess differences in HR for death for different rates of blood pressure change. All models were adjusted for age, gender, baseline blood pressure, number of antihypertensive medications and eGFR (CKD-EPI).

Results: Mean baseline age was 54.5 years, eGFR 35.5ml/min/1.73m^2, blood pressure 138/74mmHg on 2.4 different anti-hypertensive medications. No association was observed between quartile of baseline blood pressure and HR for death. However, patients in the highest quartile of time averaged blood pressure change (>4mmHg/year **increase**) had a significantly increased HR for death (HR = 2.04) and patients in the lowest quartile (>4mmHg/year **reduction**) a significantly reduced HR for death (HR=0.33).

Using patients with no annual blood pressure increase as a referent group, significant incremental increases in HR for death were observed for all time-averaged increases in blood pressure over 4mmHg/year. Patients with <4mmHg/year blood pressure increase did not have an increased HR for death.

Baseline blood pressure (mmHg)	HR death	Annual increase in systolic blood pressure (mmHg/year)	HR death
<122	Referent	<1	Referent
122-137	1.08	4	2.04*
137-150	1.05	5	2.17*
>150	1.08	6	2.94*
		7	4.44*
		8	4.90*

* p<0.05

Conclusions: This study demonstrates that in an all-cause CKD population, and independent of baseline blood pressure and eGFR, rate of change in systolic blood pressure may be a predictor of mortality.

FR-PO421

Assessment of Blood Pressure Control and Target Organ Damage in Patients with Chronic Kidney Disease and Hypertension Ran-hui Cha,[1] Hajeong Lee,[2] Yun Jung Oh,[2] Yon Su Kim.[2] *[1]Internal Medicine, National Medical Center, Seoul, Republic of Korea; [2]Internal Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: Blood pressure shows diurnal variation, 'dipping'. And the loss of dipping and higher pressure load seems to be related with more target organ damages (TODs).

Methods: APrODiTe is a nationwide multicenter cross sectional study for Korean CKD stage 2, 3, and 4 patients with hypertension. The primary aim is to find out the achievement pattern of BP control and the secondary aim is to identify the relationship between TODs and BP pattern. Clinic BP was measured with OMRON IA-2 automatic BP device and 24 hour ABPM was performed with the A&D Co., Ltd, TM-2430. We used ABP definitions proposed by Fagard et al (daytime BP between 10AM and 8PM and nighttime BP between 12AM and 6AM).

Results: We analyzed data from 1,317 participants. Mean age was 57 year, 62.9% of participants were males and diabetic nephropathy was 24.9%. Mean level of serum creatinine and estimated GFR were 1.64 mg/dl and 48.86 ml/min/1.73m^2, respectively. The proportion of each BP pattern was as below: sustained uncontrolled, 42.3%; masked, 33.9%; white coat, 4.3%; true controlled, 19.4%; Dipper, 33.3%; non-dipper, 34.5%; reverse- dipper, 17.3%; extreme-dipper, 14.9%. Younger age, female gender, less proteinuria, and use of ACEi/ ARB were independently related with true controlled hypertension. Older age, male gender, higher BMI, diabetic nephropathy, and more proteinuria were independently related with sustained uncontrolled hypertension. History of stable angina and heart failure was more prevalent in non-/ reverse-dippers. Diabetic nephropathy was significantly related with reverse-dippers. And higher BP burden (sustained uncontrolled hypertension, non-/ reverse-dippers) was associated with advanced renal dysfunction (CKD stage 3 and 4).

Conclusions: Significant proportion of CKD patients with hypertension were treated inappropriately in Korea. And higher pressure load and loss of dipping were related with more profound TODs. More appropriate BP control in CKD patients is needed and precise BP monitoring has a significant role to improve physicians' practices.

Funding: Pharmaceutical Company Support - sanofi-aventis Korea Co., Ltd.

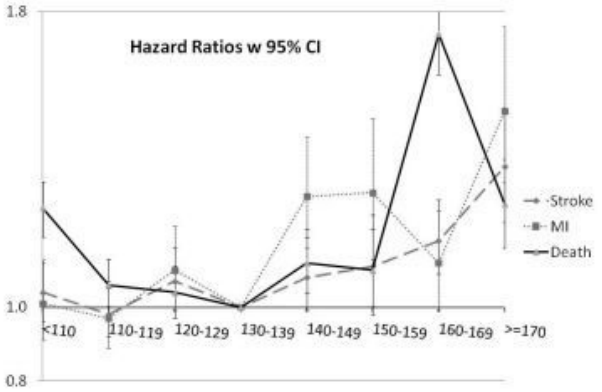
FR-PO422

Exploring a J Curve for Blood Pressure (BP) and Outcomes in a Large Ethnically Diverse Population: Where Is the Ideal BP? John J. Sim,[1] Simran K. Bhandari,[1] Jiaxiao Shi,[1] Joni L. Ricks,[2] Miklos Zsolt Molnar,[2] Kamyar Kalantar-Zadeh.[2] *[1]Nephrology & Hypertension, Kaiser Permanente Los Angeles Medical Center, Los Angeles, CA; [2]Nephrology & Hypertension, Harbor UCLA Medical Center, Torrance, CA.*

Background: Aggressive lowering of BP has not led to superior health outcomes and may even be detrimental based on clinical observations. We sought to determine the relationship of BP with mortality and cardiovascular outcomes in subjects with hypertension (HTN).

Methods: 470,988 HTN subjects from Kaiser Permanente So Cal age ≥ 18 yrs during 1/1/2006 – 12/31/2009 evaluated. Systolic (SBP) and diastolic (DBP), demographics, medications, comorbidities, and outcomes data retrieved from electronic medical records. Cox regressions analyses used to calculate adjusted hazard ratios (HR) comparing different BP's (increments of 10mmHg w SBP 130-139 & DBP 80-89 as reference) for myocardial infarction (MI), stroke, and mortality as independent and competing risk models. Adjustments made for the covariates of age, gender, race, and comorbidities (DM, CKD, cardiovascular disease).

Results: The mean cohort follow up was 3.1 yrs. The lowest crude events rates occurred in SBP 130-139 and DBP 90-99 ranges. Adjusted HR comparing SBP <110, 110-119, 120-129, 140-149, 150-159, 160-169, and >/= 170 vs 130-139 for outcomes were: for MI (1.04, 0.98, 1.07, 1.08,1.11, 1.18, 1.38), stroke (1.01, 0.97, 1.10, 1.30, 1.12, 1.53) and mortality (1.27, 1.06, 1.04, 1.12, 1.10, 1.73, 1.28) respectively. (See figure with 95% CI added). Similar HR was demonstrated for DBP with the nadir however at 90-99 instead of the reference of 80-90.



Conclusions: In a large diverse HTN population, BP relationship to MI and stroke was linear starting at >140 while mortality demonstrated a J shaped relationship across differing BP. Our findings beg the question of where the optimal treatment BP targets should be.

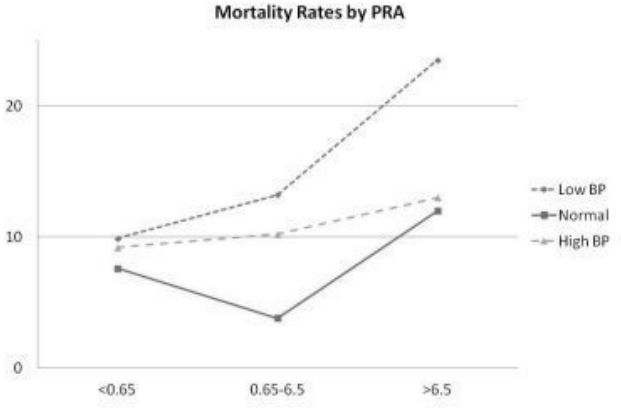
FR-PO423

Plasma Renin Activity (PRA) as a Biomarker for Mortality in Those with Extremes of Blood Pressure (BP) John J. Sim,[1] Jiaxiao Shi,[1] In-lu Amy Liu,[1] Scott A. Rasgon,[1] Kamyar Kalantar-Zadeh.[2] *[1]Nephrology & Hypertension, Kaiser Permanente Los Angeles Med Ctr, Los Angeles, CA; [2]Nephrology & Hypertension, Harbor UCLA Med Ctr, Torrance, CA.*

Background: PRA is reflective of renin angiotensin system activity and works to maintain hemodynamic function. Its values may reflect whether this mechanism is appropriately functioning. We sought to evaluate PRA levels in those with low BP and high BP subjects. We hypothesize that in those with extremes in BP, PRA is a biomarker that can prognosticate poor outcomes as a surrogate for hemodynamic stress and/or a mechanism for it.

Methods: HTN subjects with measured BP and PRA during (1/1/2006 – 12/31/2009). Medication usage, demographics, comorbidities, and outcomes extracted from electronic medical records. Subjects categorized as low (SBP<120), normotensive (120-140), & high (>140). Effective PRA determined based on ACEI/ARB use and classified into <0.65, 0.65-6.5, and >6.5 ng/ml/hr. Crude cardiovascular and mortality event rates and adjusted cox proportional hazards modeling were used to compare outcomes based on the 3 PRA categories.

Results: 1,629 HTN subjects (260 low, 627 normotension, 742 high) were evaluated. Greatest mortality occurred in low (11.9%) and high (9.6%) BP groups compared to normotensives (6.5%). Higher PRA was associated with higher mortality rates within low and high BP groups. Mortality (%) per PRA <0.65, 0.65-6.5, and >6.5 were; 9.9, 13.2, 23.5 in low BP subjects; 9.2, 10.2, 13.0 in high BP subjects whereas it was unrelated in normotensive BP subjects (7.6, 3.8, 12%).



Conclusions: With SBP 120-140 mmHg as the reference range, in subjects with both high (>140) and low BP (<120), higher PRA values>6.5 appear associated with significantly greater mortality risks. Whether PRA serves as a biomarker for worsened outcomes and/or as a mechanism of vascular injury outcomes remains to be determined.

FR-PO424

Progression of Renal Injury after Normotensive Renal Mass Reduction (RMR): Relationship to BP Parameters over 6 Months Karen A. Griffin,[1] Aaron Polichnowski,[1] Hector Licea-vargas,[1] Maria M. Picken,[1**] Rongpei Lan,[3] Christian Rosenberger,[2] Manjeri A. Venkatachalam,[3] Anil K. Bidani.[1] *[1]Medicine (Pathology**), Loyola University Chicago and Hines VA Hospital, Maywood, IL; [2]Medicine, Charite Campus Mitte, Berlin, Germany; [3]Pathology, Univ. of Texas Health Sci Ctr, San Antonio, TX.*

Background: BP is fundamentally labile even in normotensive states and renal autoregulatory mechanisms provide the primary protection against glomerular transmission of BP fluctuations. With impaired autoregulation (RMR), pathogenic glomerular BP transmission may occur despite systemic normotension.

Methods: Male SD rats (Charles River) were prepared for BP radiotelemetry and underwent normotensive 3/4 RMR by surgical excision (SBP during the 2nd wk 128±2 mmHg, n=25). After 6 months, perfusion-fixed kidneys were harvested for correlation of individual BP patterns with a blinded assessment of % glomerulosclerosis (GS) and tubulointerstitial (TI) fibrosis. HIF-1α expression was additionally examined in other rats with 3/4 RMR by either surgical excision (normotensive) or infarction (hypertensive) at 10, 20 and 30 days after RMR (n = ~5/group/time point). Results: Mean ± SE.

Results: Significant heterogeneity was seen for BP courses, with several rats developing progressive BP increases over the last ~ 2 months. Similar variability was observed for proteinuria 151±18 (mg/24h) and % GS (36±5) with a strong correlation ($r^2 = 0.61$). The correlation of GS with BP parameters is shown in the table.

	Average BP (mmHg)		% reading > 150 mmHg		% reading > 175 mmHg	
	Awake	Sleep	Awake	Sleep	Awake	Sleep
BP Parameters	142±2.4	137±2.4*	28.6±4.2	19.5±3.5*	5.9±2.3	4.6±2.1*
Correlation with GS (r^2)	0.52 †	0.54 †	0.57 †	0.67 †	0.45 †	0.49 †

* p < 0.001 vs. respective awake BP parameters; †P < 0.0001

HIF-1α positivity was seen focally, appeared restricted to individual nephrons, was far more abundant in hypertensive vs. normotensive rats, and increased between 10 to 30 days.

Conclusions: These data indicate that in states of impaired autoregulation, glomerular transmission of BP fluctuations, particularly during the sleep periods, remains a major initiating mechanism for CKD progression despite normotension.

Funding: NIDDK Support, Veterans Administration Support

FR-PO425

Normotensive Pheochromocytoma: Clinical, Biochemical, and Radiological Features Anca C. Rafiroiu, Emmanuel L. Bravo. *Nephrology and Hypertension, Cleveland Clinic Foundation, Cleveland, OH.*

Background: Pheochromocytomas are rare catecholamine-producing tumors with varied clinical manifestations. About 8% are asymptomatic and about 13% are normotensive.

Methods: We report the demographics, clinical and biochemical profile and pathologic findings in seventeen normotensive pheochromocytomas managed in our institution in the last two decades.

Results: Mean age was 48 years (range 32-70 years); 56% were females. None had the cluster of signs and symptoms suggestive of catecholamine (CA) excess. Blood pressure ranged from 95/75 to 130/80 mm Hg. Plasma norepinephrine (NE) was increased in all patients (range 312 to 4548 pg/ml, mean 2237). Plasma epinephrine (E) was increased only in 4 patients (range 52 to 14720 pg/ml, mean 1424), plasma dopamine was slightly increased in 4 patients (range 24 to 173 pg/ml, mean 60). Plasma fractionated metanephrines (n=14) ranged from 0.5 to 32 nmol/L (mean 8) and 24 hr fractionated urinary metanephrines (n=9) ranged form 531 to 31887 ug (mean 6356). At surgery, all tumors had histopathological findings consistent with pheochromocytoma. The tumors ranged in size from 11 to 424 grams. There was no correlation between tumor size and NE levels in the plasma, but there was a strong positive correlation (r = 0.9) between urine NM and tumor size. Postsurgery, CA and MN returned to normal in all.

Conclusions: These studies illustrate the difficulty in detecting pheochromocytomas in some patients. A significant number are normotensive and asymptomatic and are detected only during evaluation for unrelated problems. Since there is no relationship between plasma free CA and the level of blood pressure, it is suggested that NE released from axon terminals of sympathetic postganglionic neurons is biologically more significant than circulating CA. The strong positive correlation between tumor size and urine MN indicate that these tumors metabolize most of the secreted CA resulting in lower circulating levels of plasma free CA and fewer signs and symptoms.

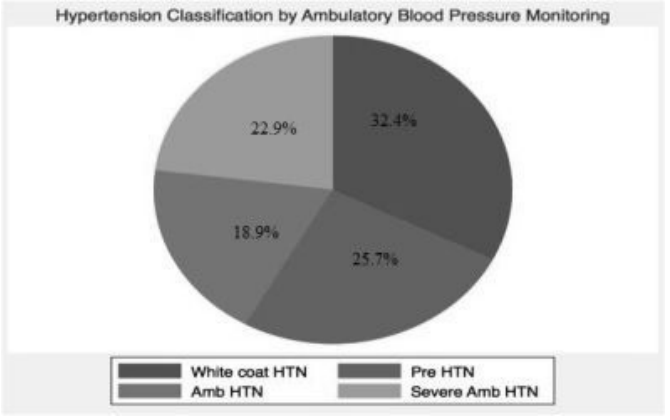
FR-PO426

Association between Kidney Length Adjusted for Body Surface Area and Ambulatory Blood Pressure Parameters Hridya Suman,[1] Oleh M. Akchurin,[1] Frederick J. Kaskel,[1] Robert Woroniecki.[2] *[1]Childrens's Hospital at Montefiore/ Albert Einstein COM, New York, NY; [2]New York-Presbyterian Hospital/Columbia Univ., New York, NY.*

Background: Blood pressure(BP) patterns such as loss of nocturnal dipping,elevated systolic BP (SBP) load & pulse pressure(PP) obtained by 24-hour ambulatory BP(ABP) monitoring can be used to identify children at increased risk of end organ damage.We examined the relationship between kidney size obtained by renal ultrasound & ABP to identify risk groups.

Methods: We conducted a single-center,cross sectional,retrospective analysis of subjects <20 years of age referred for primary hypertension(HTN) from 1/2009 to 12/2011.Exclusion criteria were secondary HTN,hydronephrosis,kidney disease,transplants,congenital heart disease.

Results: 74 subjects with newly diagnosed primary HTN were identified; the distribution is shown in the figure.



Mean age was 16.8(14-17.9) years.15% self-identified as White,44% as Black,39% as mixed race & rest as Asian.There was no significant difference in age,sex distribution,BMI z-score,birthweight,prematurity,eGFR or comorbidities(diabetes, sleep apnea) between subjects based on severity of ABP.Averaged kidney length adjusted for body surface area (K/S) was strongly correlated with mean SBP,PP & SBP variability.Multivariable linear regression of mean SBP showed that K/S was a statistically significant predictor($p=0.006$) after adjusting for age,sex,BMI z-score,family history of HTN & prematurity.This model accounted for 36% of variability in mean SBP.K/S was associated with mean PP by bivariate association($p=0.0001$) & remained an independent predictor of PP on adjustment for age,sex,BMI z-score,family history of HTN & prematurity.

Conclusions: K/S was a statistically significant independent predictor of mean SBP & mean PP.If validated by future studies,K/S may be of use as a non-invasive biomarker to allow identification & management of targeted risk groups.

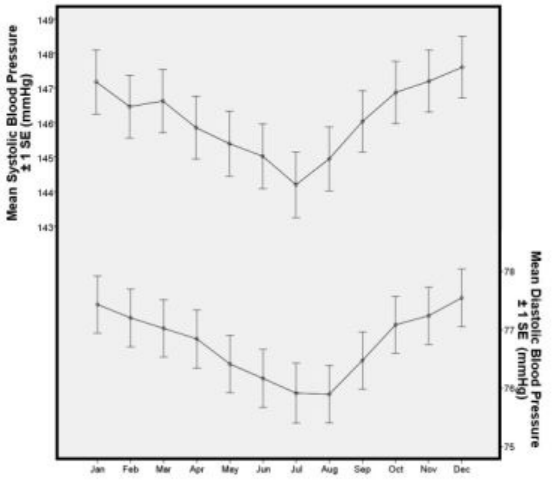
FR-PO427

Seasonal Variation of Blood Pressure and Volume Status in Chronic Hemodialysis Patients: A 10-Year Cohort Study Gretchen Norine De Graav,[1] Charlotte van Noord,[2] Marinus A. Van Den Dorpel.[2] *[1]Internal Medicine, Erasmus MC, Rotterdam, Zuid-Holland, Netherlands; [2]Internal Medicine, Maasstad Hospital, Rotterdam, Zuid-Holland, Netherlands.*

Background: Cardiovascular morbidity and mortality show a seasonal variation in patients on hemodialysis. This variation could be related to higher blood pressure during the winter period. We studied which parameters of volume status and climate have an influence on seasonal variation of blood pressure in patients on maintenance hemodialysis.

Methods: We compared blood pressure and interdialytic body weight gain between summer and winter. Parameters of possible influence on systolic blood pressure were determined with a multivariate regression analysis.

Results: Both systolic and diastolic blood pressure showed a seasonal variation with the lowest average value in summer (144±18 and 76±10 mmHg respectively) and the highest average value in winter (147±18 and 77±10 mmHg). The mean summer-winter difference in SBP and DBP is -2.4 mmHg (95% CI -3.3 to -1.4 mmHg), r=-0.08, and -1.4 mmHg (95% CI -1.8 to -0.9 mmHg), $p<10^{-9}$, r=-0.05, respectively.



Mean Systolic and Diastolic Blood Pressure (plus standard error) of haemodialysis patients from January 2000 to December 2010 (*n*=417)

Volume status had a significant correlation with level of blood pressure, but not with seasonal variation of blood pressure and was not an independent predictor after conducting a multivariate regression analysis. Of all climaticological factors that were studied, only sunshine duration was a significant independent predictor for a lower blood pressure.

Conclusions: In patients on maintenance hemodialysis systolic and diastolic blood pressure are significantly lower in summer. This seasonal variation in blood pressure was not related to differences in interdialytic bodyweight gain between seasons. The underlying mechanism of the relationship between direct sunshine exposure and a lower blood pressure needs further study.

FR-PO428

Plasma Bicarbonate and Risk of Incident Hypertension Ernest I. Mandel,[1,2] John P. Forman,[1,2] Gary C. Curhan,[1,2] Eric N. Taylor.[2,3] *[1]Renal Division, Brigham and Women's Hospital, Boston, MA; [2]Channing Division of Network Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, MA; [3]Division of Nephrology and Transplantation, Maine Medical Center, Portland, ME.*

Background: Several biomarkers of metabolic acidosis, including lower plasma bicarbonate, lower urinary citrate excretion, and higher anion gap, have been associated cross-sectionally with prevalent hypertension. However, it is unknown whether lower plasma bicarbonate is an independent risk factor for the development of hypertension among originally non-hypertensive individuals.

Methods: We conducted a prospective, nested case-control study within the Nurses' Health Study II of 695 individuals without hypertension who provided a blood sample between 1997 and 1999 and who subsequently developed hypertension by 2005. Controls were matched according to age, race, time and day of blood draw, and day of menstrual cycle. We used logistic regression to generate odds ratios (OR) for development of hypertension over 6 years of follow-up by quartile of baseline plasma bicarbonate.

Results: Estimated GFR was similar (mean 92 ml/min/1.73m^2; SD 13) among cases and controls. After adjusting for matching factors, BMI, family history of hypertension, plasma creatinine, smoking, physical activity, and dietary intakes of animal protein, potassium, carbohydrate, total fat, calcium, magnesium, dietary fiber, folate, sodium, and caffeine, those in the highest compared with the lowest quartile of plasma bicarbonate had 33% lower odds (OR 0.67; 95% CI 0.48-0.95) of developing hypertension.

Conclusions: Higher plasma bicarbonate was independently associated with a reduced risk of developing hypertension. Further studies are needed to elucidate the mechanism for this relation and to examine the role for alkali therapy in the prevention of hypertension.

Exercise Training and Post Exercise Hypotension in Kidney Patients Sam A. Headley,[1] Michael J. Germain,[2] Richard J. Wood,[1] Jyovani W. Joubert,[1] Charles M. Milch,[1] Beth Parker,[3] Elizabeth E. Evans,[1] Allen Cornelius,[4] Britton W. Brewer,[1] Linda S. Pescatello.[5] *[1]Springfield College; [2]WNERTA; [3]Springfield College; [4]Hartford Hospital; [5]University of Colorado; [6]Springfield College; [7]Springfield College; [8]University of Connecticut; [9]Springfield College.*

Background: The purpose of the current study was to examine the effect of 16 weeks of aerobic training of moderate intensity on post exercise hypotension (PEH) in stage 3 CKD patients.

Methods: Thirty two CKD patients between the ages of 35-70 attended 4 preliminary sessions before being randomized to either the treatment (TG n=16) or control group (CG n=16). At the first visit, resting blood pressures (BP) were measured using an automated system. At least 3 days later at session 2, a graded exercise test was performed using the Modified Bruce protocol with direct measurement of oxgyen uptake (VO2peak). During sessions 3 & 4, baseline (BL) resting BPs were taken in duplicate after a 5-min rest period. Then subjects either walked for 40 minutes on a treadmill at 50-60% of their VO2peak, or they sat quietly for the same period. Then BPs were measured for 60 min at 10-min intervals as subjects sat in the laboratory. Subjects randomized to the TG received personal training for 16 weeks while those in the CG continued with their usual daily activities. Sessions 2,3,& 4 were repeated after 16 weeks.

Results: There were no differences between the groups for PEH at BL or after the intervention. At BL prior to the 16 weeks of training, SBP (mm Hg) was reduced by 6.8 ± 2.1 while after 16 weeks, this value was 6.3 ± 1.9, p = 0.87. DBP (mm Hg) was reduced at BL by 3.4 ± 1.1 and by 1.7 ± 1.0 after the training program, p = 0.31. The training program did not affect either resting SBP or DBP.

Table 1

Variable	Pre	Post	p =
SBP (mm Hg, TG)	127±17.7	124.6±15.1	p=0.9
SBP(mm Hg, CG)	136.7±19.5	130.9±27.1	
DBP(mm Hg, TG)	78.0±9.8	75.8±9.9	p=0.8
DBP(mm Hg,CG)	79.6±11.3	76.1±15.9	

Conclusions: In conclusion, the magnitude of PEH is not altered by short-term exercise training in stage 3 CKD patients.

FR-PO430

Alphacalcidol May Lower Systolic Blood Pressure in Systemic Lupus Erythematosus: 8 Year Follow-Up Study Takeshi Nakatsue,[1] Hiroe Sato,[1] Yoko Wada,[1] Shuichi Murakami,[1] Takeshi Kuroda,[2] Masaaki Nakano,[3] Ichiei Narita.[1] *[1]Division of Clinical Nephrology and Rheumatology, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan; [2]Health Administration Center, Niigata University, Niigata, Japan; [3]School of Health Sciences, Faculty of Medicine, Niigata University, Niigata, Japan.*

Background: Vitamin D3 analogues, such as alphacalcidol (1α-hydoroxycholecalciferol), are often used for glucocorticoid-induced osteoporosis in systemic lupus erythematosus (SLE). It has been reported that 1, 25-dihydoroxycholecalciferol negatively regulate renin-angiotensin system (Li YC et al., J Clin Invest, 2002), and that paricalcitol (1, 25-dihydoroxyergocalciferol) can decrease systolic blood pressure (SBP) and albuminuria in patients with type 2 diabetes mellitus (de Zeeuw D et al., Lancet, 2010). We tested the hypotheses that alphacalcidol reduce proteinuria, maintain estimated glomerular filtration rate (eGFR), lower blood pressure, and thus prevent cardiovascular events in SLE.

Methods: Patients with SLE who were followed-up for 8 years in Niigata University Medical and Dental Hospital were recruited (n=70). They were randomly divided into two groups, alphacalcidol group (n=29) and non-alphacalcidol group (n=41). Their proteinuria, eGFR, SBP, diastolic blood pressure (DBP), and the incidence of cardiovascular events were analyzed. Patients who have received antihypertensive medication after the initiation of alphacalcidol were excluded.

Results: No significant differences were observed in proteinuria, eGFR, the incidence of cardiovascular events in two groups. SBP before the initiation of alphacalcidol were 122±21.5 mmHg in alphacalcidol group and 113±15.5 mmHg in non-alphacalcidol group. SBP after 8 years were 116±11.4 mmHg and 120±14.7 mmHg. The changes of SBP were -6.10±20.7 and 7.00±12.7 mmHg, respectively (p=0.04). DBP before the initiation of alphacalcidol were 72.4±13.4 mmHg in alphacalcidol group and 66.7±11.1 mmHg in non-alphacalcidol group, and at the end of follow-up, 70.2±10.5 mmHg and 72.6±11.1 mmHg, respectively. The changes of DBP were -2.20±12.8 mmHg and 5.90±12.5 mmHg (p=0.11).

Conclusions: Alphacalcidol can lower SBP in SLE.

FR-PO431

Paricalcitol Reduced Left Atrial Volume in Patients with Chronic Kidney Disease Hector Tamez. *Department of Medicine / DIvision of Nephrology, Massachusetts General Hospital. On Behalf of the PRIMO Steering Committee, Boston, MA.*

Background: Left atrial enlargement, a sensitive integrator of left ventricular diastolic dysfunction, is associated with increase risk of cardiovascular related hospitalizations, arrhythmias and mortality. Vitamin D is linked to lower cardiovascular morbidity, possibly modifying cardiac structure and function, however firm evidence is lacking. We assessed the effect of an activated vitamin D analog with changes in left atrial volume index (LAVi) in a post-hoc analysis of the Paricalcitol capsules benefits in Renal failure Induced cardiac MOrbidity randomized trial (PRIMO, clinicaltrials.gov: NCT00497146).

Methods: A total of 196 patients with chronic kidney disease, mild to moderate left ventricular hypertrophy and preserved ejection fraction were randomly assigned to 2 µg of oral paricalcitol or matching placebo for 48 weeks. Two-dimensional echocardiographic measures were obtained at baseline, 24 and 48 weeks after initiation of therapy. We compared change in LAVi (volume changes indexed to body surface area) over the 48 weeks of therapy.

Results: During the study period, there was significant decrease in LAVi of -2.79 mL/m2 (95% confidence interval [CI]: -4.00 to -1.59 mL/m2) in the paricalcitol group compared to the placebo group (-0.70 mL/m2 [95% CI: -1.93 to 0.53 mL/m2]; P=0.002). Paricalcitol attenuated the increase of brain natriuretic peptide (9% in paricalcitol vs. 21% in placebo; P=0.02). Change in brain natriuretic peptide was correlated with change in LAVi (r=0.17; P=0.03). LAVi decreased by 3.04 ml/m2 when comparing the lowest to the highest quartiles of BNP change (P=0.02).

Conclusions: Forty-eight week therapy with paricalcitol significantly reduced LAVi and attenuated the rise of brain natriuretic peptide. This post-hoc result is hypothesis-generating and warrants further confirmation.

FR-PO432

Utility of Spectroscopic Bioimpedance (BIA) in the Management of Refractory Hypertension in Patients with Chronic Kidney Disease (CKD) Ursula Verdalles, Soledad Garcia de Vinuesa, Marian Goicoechea, Borja Quiroga, Javier Reque, David Arroyo, Nayara Panizo, Jose Luno. *Nephrology, HGUGM, Madrid, Spain.*

Background: Expansion of extracellular volume (ECV) is frequent cause of resistant hypertension (RHT) in patients with CKD. Aim of this study was identify patients with RHT, CKD and ECV expansion, trying to control BP by intensification diuretic treatment.

Methods: We included 50 patients with RTH and CKD in whom BIA was conducted. For control of BP, diuretic treatment was increased in patients with ECV expansion and in rest, another antihypertensive drug was added.

Results: Mean age of patients was 68.2±10.4 years, 68% male, 58% diabetic and the mean estimated glomerular filtration rate(eGFR) 50.7±22.4ml/min/1.72m². Baseline SBP 167.2±8.6 mmHg and DBP 84.8±9.5mmHg, and mean number of antihypertensive drugs was 3.7±0.9. ECV expansion was found in 60% of the patients (1.9±0.9L). We could not found significant relation between degree of overhydration and stage of CKD. ECV expansion was found more frequently in diabetics (69%.vs.31%,p<0.01) and in patients with more albuminuria (UACR 745±901 vs 328±450mg/g,p<0.01). At 6 months of follow-up, a decline of 21.4±7.1 mmHg of SBP was observed in group of patients with ECV expansion, versus a decrease of 9.4±3.4 mmHg in normal ECV group(p<0.01). DBP decreased 4.3±3.7 mmHg in both groups. At 6 months of follow-up, 9(30%) of the patients with ECV expansion who increased diuretic therapy reached the target BP,<140/90mmHg, as compared with only 2(10%) of those patients without ECV expansion who added other antihypertensive drug. Total body water decrease 1.9±1.1 L, in group of patients with ECV expansion who intensified diuretic treatment, at expense of a decline of ECV 1.1±1 L. eGFR remained stable in both groups(47,1±21,1 vs 54,1±25,2ml/min/1.73 m²,p=0.37).

Conclusions: ECV expansion is frequent cause of RHT in patients with CKD, independently of stage of CKD. Diabetic and severe proteinuric patients are more exposed to ECV expansion. BIA is a useful method for identifying these patients with CKD, RHT and ECV expansion. Intensification diuretic treatment, in these patients, permits better control BP, without changing eGFR.

FR-PO433

Risk of Coronary Heart Disease in Individuals with History of Kidney Stones: Results from Three Large Prospective Cohort Studies Pietro Manuel Ferraro,[1,2] Eric N. Taylor,[2] Giovanni Gambaro,[1] Eric B. Rimm,[2] Gary C. Curhan.[2] *[1]Division of Nephrology - Renal Program, Department of Internal Medicine and Medical Specialties, Catholic University of the Sacred Heart, Rome, Italy; [2]Channing Division of Network Medicine, Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

Background: Previous studies analyzed the association between kidney stones (KS) and coronary heart disease (CHD). However, they often failed to control for important risk factors and results were inconsistent. We analyzed the risk of developing CHD for individuals with a history of KS in three large prospective cohort studies.

Methods: We used data from three large ongoing cohort studies: the Health Professionals Follow-Up Study (HPFS) and Nurses' Health Study (NHS) I and II. Information on KS and CHD was collected by biennial questionnaires and confirmed through further validated questionnaires (KS) or review of hospital records (fatal and non-fatal myocardial infarction [FMI, NFMI]). The risk of developing CHD (defined as FMI or NFMI or coronary revascularization [CR]) in participants with and without history of KS was assessed with a Cox model adjusted for race, family history of heart disease, smoking status, BMI, physical activity, diabetes, hypertension, gout, elevated cholesterol, use of medications and daily intake of calcium, protein, fat, caffeine and alcohol.

Results: The analysis included 189,339 participants. After up to 22 years of follow-up in men and 16 years in women, 6,937 incident cases of CHD were confirmed. Among women, those with a history of KS compared to those without had an increased risk of CHD in NHS I (HR 1.27, 95% CI 1.03 to 1.56) and NHS II (HR 1.70, 95% CI 1.13 to 2.55); there was no association in the male HPFS cohort (HR 1.01, 95% CI 0.91 to 1.13). Similar results were found when analyzing the individual end-points (FMI, NFMI, CR).

Conclusions: We found a significant independent increased risk of CHD among women with a history of KS but no association was found in men. Mechanisms for such an association remain to be elucidated.

FR-PO434

Soda and Other Beverages and the Risk of Kidney Stones: Results from Three Large Prospective Cohorts Pietro Manuel Ferraro,[1,2] Eric N. Taylor,[2] Giovanni Gambaro,[1] Gary C. Curhan.[2] *[1]Division of Nephrology - Renal Program, Department of Internal Medicine and Medical Specialties, Catholic University of the Sacred Heart, Rome, Italy; [2]Channing Division of Network Medicine, Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

Background: Increasing fluid intake is a well accepted method for reducing the recurrence of kidney stones (KS), but not all types of fluids may be equally beneficial. In particular, it is not clear whether consuming sugar- (SS) and artificially-sweetened (AS) carbonated beverages (CB) increases the risk of developing KS. We analyzed the association between intake of several types of beverages and incidence of KS in three large prospective cohort studies.

Methods: We used data from three large ongoing cohort studies: the Health Professionals Follow-Up Study (HPFS) and Nurses' Health Study (NHS) I and II. Information on frequency of consumption of beverages and development of KS was collected by validated questionnaires every four and two years, respectively. The risk of developing KS associated with each beverage was assessed using a Cox model adjusted for covariates including age, race, physical activity, BMI, diabetes, high blood pressure, gout, use of diuretics and intake of calcium, potassium, animal protein, phytate and vitamin C. Pooled results are reported.

Results: During a follow-up of up to 20 years in HPFS, 22 years in NHS I and 16 years in NHS II, 4,462 of the 194,095 participants developed an incident symptomatic KS. We found a significantly higher risk of developing KS across categories of increased consumption of SS cola (p for trend=0.02) and non-cola CB (p=0.003), whereas the trend was border-line for AS cola (p=0.08) and non-cola CB (p=0.05). We found an increased risk of KS for increasing consumption of punch (p=0.04) and a decreased risk for increasing consumption of caffeinated coffee (p<0.001), decaffeinated coffee (p=0.01), tea (p=0.02), wine (p<0.004), beer (p<0.001) and orange juice (p=0.004).

Conclusions: Our analysis confirmed that some beverages (coffee, tea, wine, beer and orange juice) are inversely associated with KS formation while others (SS CBs and punch) are associated with an increased risk.

FR-PO435

Non-Dairy Calcium Intake and Kidney Stone Risk Eric N. Taylor,[1,2] Gary C. Curhan.[2] *[1]Division of Nephrology, Maine Medical Center, Portland, ME; [2]Channing Laboratory, Brigham and Women's Hospital, Boston, MA.*

Background: Higher dietary calcium is associated with lower kidney stone risk. However, high correlations between dietary calcium and dairy intake suggest the possibility that milk, rather than calcium per se, reduces risk of nephrolithiasis.

Methods: We prospectively examined independent associations between non-dairy calcium intake and incident kidney stones in the Health Professionals Follow-up Study (N=30,762 men), the Nurses' Health Study I (N=94,167 older women), and the Nurses' Health Study II (N=101,701 younger women). We excluded men ≥ 60 years old because we previously reported inverse associations between calcium intake and stone risk only in men < 60. Validated food frequency questionnaires were used to assess non-dairy calcium intake every four years. Medical record review confirmed ≥ 95% of self-reported kidney stones in each cohort, and the majority of stones (≥ 77%) were predominantly calcium oxalate. Cox regression was used to adjust for age, BMI, thiazide use, family history of kidney stones, hypertension, diabetes, fluid intake, dairy calcium intake, supplemental calcium, and a wide variety of other dietary and non-dietary factors.

Results: We documented 4,987 incident kidney stones over a combined 50 years of follow-up. Mean energy-adjusted non-supplemental total calcium and non-dairy calcium intakes were 796 and 326 mg/d in men, 720 and 334 mg/d in older women, and 886 and 338 mg/day in younger women. For men, older women, and younger women, the correlation coefficients between energy-adjusted non-supplemental total calcium and dairy calcium intakes were ≥ 0.96. In contrast, the correlation coefficients between energy-adjusted non-supplemental total calcium and non-dairy calcium intakes ranged between 0.13 and 0.22. For participants in the highest compared to lowest quintile of non-dairy calcium, the multivariate relative risks of kidney stones were 0.72 (95% CI 0.56-0.93; P trend 0.01) for men, 0.81 (95% CI 0.67-0.97; P trend 0.11) for older women, and 0.73 (95% CI 0.62-0.87; P trend 0.001).

Conclusions: Both non-dairy and dairy calcium intake are independently associated with a lower risk of kidney stones.

Funding: NIDDK Support

FR-PO436

Association of Prevalent Kidney Stone Disease with All-Cause & Cardiovascular Death among US Adults Jie Tang, Pamela Mettler, M. Chonchol. *Medicine, University of Colorado, Aurora, CO.*

Background: Nephrolithiasis is considered a systemic disorder associated with bone loss, chronic kidney disease and multiple cardiovascular disease (CVD) risk factors. However, its association with all-cause and CVD death is unknown.

Methods: We assessed the relationship between kidney stone disease and risk of mortality among a nationally representative sample of US adults (age ≥18 years), using the Third National Health and Nutrition Examination Survey and its Linked Mortality File (through 2006). Kidney stone disease was defined as self-report of any previous episode of kidney stone. Cox proportional hazard regression analyses were used to estimate the risks of all-cause and CVD death.

Results: Among 15,141 participants, 701 reported a history of kidney stone. Stone formers tended to be male, white and older, had a higher BMI, and more likely to have hypertension, diabetes and CVD. There were a total of 3739 all-cause deaths and 1684 CVD deaths with a median follow up of 15 years. Unadjusted analysis showed that stone formers had a higher risk for death (HR=1.98, 95% CI 1.66-2.36, p<0.0001), and CVD death (HR=2.06, 95% CI 1.61-2.64, p<0.0001) [Table 1]. However, after multivariate adjustment for age, race and sex, stone formers no longer had increased risk for death (HR=1.07, 95% CI 0.92-1.25, p=0.4) or CVD death (HR=1.05, 95% CI 0.83-1.34, p=0.7). After further adjustment for other CVD risk factors, independent associations of prevalent kidney stone disease with all-cause and CVD death remained non-significant.

Table 1. Hazard ratios for all-cause and CVD mortalities in stone formers

	Regression Model	HR (95% CI)	P value
All-cause mortality	Unadjusted	1.98 (1.66-2.36)	<0.0001
	Model 1	1.07 (0.92-1.25)	0.4
	Model 2	0.99 (0.85-1.16)	0.9
	Model 3	0.99 (0.85-1.16)	0.9
CVD mortality	Unadjusted	2.06 (1.61-2.64)	<0.0001
	Model 1	1.05 (0.83-1.34)	0.7
	Model 2	0.94 (0.74-1.20)	0.6
	Model 3	0.94 (0.75-1.19)	0.6

Model 1: adjusted for age, race, sex. Model 2: adjusted for BMI, histories of hypertension, diabetes and CVD, in addition to model 1. Model 3: adjusted for serum CRP, serum 25(OH)D, and MDRD-eGFR, in addition to model 2

Conclusions: Prevalent kidney stone disease is not independently associated with all-cause and CVD death.

Funding: Clinical Revenue Support

FR-PO437

Trend of Incident Kidney Stone Disease in Utah and Idaho Jie Tang,[1] John R. Holmen,[2] Angela Keniston,[1] M. Chonchol.[1] *[1]Nephrology, University of Colorado, Aurora, CO; [2]Intermountain Healthcare, Murray, UT.*

Background: Recent trends of incident kidney stone disease are unclear. Our primary objective was to determine the kidney stone incidence trend through time in an integrated healthcare system serving a defined geographical region.

Methods: Incident kidney stone rates were obtained using Intermountain Healthcare (IHC) Data Warehouse. IHC is a healthcare organization that serves 2.4 million Utah and Idaho residents. Incident stone formers were defined as patients having first ever diagnosis of kidney stone disease and were identified by ICD9 code 592.0 assigned from 1994 to 2010. Negative binomial regression analyses were used to examine the incidence trend.

Results: A total of 176,499 incident stone formers were identified. Adjusted for age, gender and race, kidney stone incidence rates were 0.60% in 1994 and 1.29% in 2010. This represented a significant increase from 1994 to 2010 (p<0.0001 for trend). Age and race adjusted incidence rates for men were 0.81% and 1.51% in 1994 and 2010, respectively. On average, it increased by 2.2% per year during 1994-1999 (p=0.98 for trend) and 4.7% per year during 2000-2010 (p=0.001 for trend). For women, the age and race adjusted rates were 0.44% and 1.12% in 1994 and 2010, respectively. It increased by 2.2% per year during 1994-1999 (p=0.22 for trend) and 5.3% per year during 2000-2010 (p<0.0001 for trend). Age and gender adjusted incidence rates for non-hispanic white (NHW) were 0.59% and 1.26% in 1994 and 2010, respectively. For non-hispanic blacks (NHB), the corresponding rates were 0.55% and 0.61%, respectively, and for Mexican Americans (MA), the corresponding rates were 0.37% and 0.62%, respectively. Rates for NHW increased by about 4.2% per year (p<0.0001 for trend), whereas rates for NHB increased by 0.4% per year (p=0.57 for trend), and the rates for MA increased by 1.6% per year (p<0.0001 for trend). The incidence rate increase in NHW occurred primarily during 2000-2010 (p=0.008 for trend).

Conclusions: Kidney stone incidence rates progressively increased from 1994 to 2010. The increase primarily occurred during 2000-2010 and the causes of these findings remain to be determined.

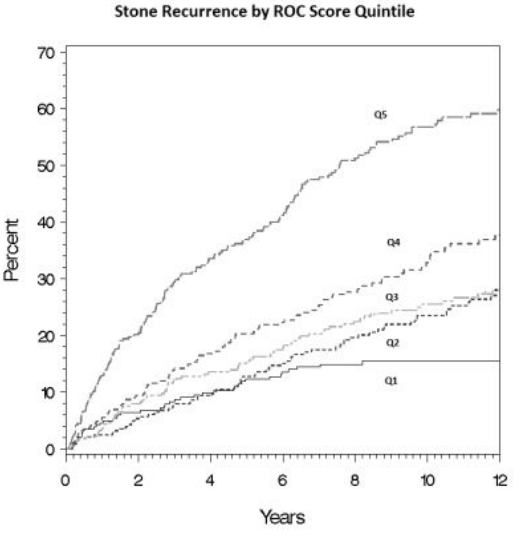
FR-PO438

The Recurrence of Calculus (ROC) Score for Predicting a Second Symptomatic Episode among Stone Formers in the General Population Eric J. Bergstralh, John C. Lieske, Xujian Li, Amy E. Krambeck, Andrew D. Rule. *Mayo Clinic, Rochester, MN.*

Background: A prediction tool for kidney stone recurrence is needed to optimize prevention and treatment strategies. This study was conducted to estimate recurrence rates, evaluate predictors, and develop a risk score for recurrence among incident stone formers.

Methods: We identified first time kidney stone episodes among residents of Olmsted County, MN. Charts were reviewed to validate episodes based on evidence of a passed or obstructing stone with supportive symptoms. Recurrence was defined as having a second validated stone episode >30 days later. Life table methods were used to estimate recurrence rates and predictors of recurrence. Candidate predictors included gender, age, race, family history of stones, body size, signs and symptoms, stone characteristics at the time of the first episode (number, location, size, composition), and prior asymptomatic stones. A recurrence of calculus (ROC) score was developed using the Cox model.

Results: There were 1586 validated stone formers (median age 42 years, 62% male, 87% white) with a median follow-up of 11.2 years. Recurrence rates at 2, 5, and 10 years were 10%, 20%, and 31%, respectively. The full model C-statistic with 18 predictors was 0.657. A more parsimonious multivariable model with 10 predictors had C=0.652. Significant (p<0.05) risk factors in this model included younger age, male gender, family history, prior asymptomatic stone, current pregnancy, multiple stones on imaging, renal pelvic location, and presence of any uric acid in the stone. Ten-year recurrence rates varied greatly (from 16% to 57%) by ROC score quintile.



Conclusions: A scoring system (ROC) was developed that identifies incident symptomatic kidney stone formers at greatest risk for recurrence. Such individuals may benefit from medical intervention and be good candidates for prevention trials.

Presenting Characteristics of Dent Disease Patients John C. Lieske,[1] Steven J. Scheinman,[2] Lawrence A. Copelovitch,[3] Hae Il Cheong,[4] Eric J. Bergstralh,[1] Ramila A. Mehta,[1] Lada Beara Lasic.[5] *[1]Mayo Clinic, Rochester, MN; [2]SUNY, Syracuse, NY; [3]CHOP, Philadelphia, PA; [4]Seoul National University Children's Hospital, Seoul, Korea; [5]NYU School of Medicine, New York, NY.*

Background: Dent disease is an X-linked disorder characterized by low molecular weight proteinuria, hypercalciuria, kidney stones, and chronic kidney disease. Two causative genes have been identified. The most common presenting phenotype remains poorly defined.

Methods: The Rare Kidney Stone Consortium maintains a voluntary registry for Dent disease. Presenting characteristics of enrolled patients were queried. Data are presented as mean (SD) or % affected.

Results: 71 patients are currently enrolled including 43 from North America, 9 from Europe, 9 from Asia, and 10 unknown/other locations. Disease type was confirmed Dent 1 (*CLCN5* mutation, n=44), Dent 2 (*OCRL1* mutation, n=1), neither Dent 1 nor Dent 2 (n=4), or unknown (n=22). Age at diagnosis was 13.6 (11.7) yrs (range 0-44; 9 patients (13%) diagnosed after age 30). Mean followup was 3.8 yrs. 14 patients had kidney stones at an age of 17.2 (10.2) years, most as the presenting symptom but 3 substantially (6.8 yrs) later. For those with data, low molecular weight proteinuria (95%), hypercalciuria (87%), and hematuria (44%) were common, while kidney stones (27%) and bone disease (11%) were less common. Total protein excretion was 1.8 (1.6) g/24-hr. Random urinary calcium:creatinine ratio was 0.61 (0.60) mg/mg. Among those with normal kidney function and >16 yrs old (n=8), 24-hr urine calcium was 361 (174) mg. First available serum creatinine was 1.1 (1.9) mg/dl at an age of 14.1 (11.6) yrs. 6 patients progressed to ESRD at a mean age of 30.5 (13.2) yrs; 4 currently have functioning renal allografts.

Conclusions: Patients with Dent disease are most often diagnosed in their early teens and only a minority ever experience clinical kidney stones. Moderate proteinuria, hypercalciuria, and hematuria are more commonly present. Clinicians should maintain a high index of suspicion for Dent disease in younger males with unexplained proteinuria and CKD.

Determinants and Outcome of Renal Calcification in Primary Hyperoxaluria John C. Lieske,[1] Eric J. Bergstralh,[1] Ramila A. Mehta,[1] Craig B. Langman,[2] Dawn S. Milliner.[1] *[1]Mayo Clinic, Rochester, MN; [2]Northwestern University, Chicago, IL.*

Background: Stone formation and nephrocalcinosis are both very common features of Primary Hyperoxaluria (PH), yet the numbers and extent vary markedly between patients. We investigated whether kidney damage from stones, nephrocalcinosis and/or urologic procedures contributed to chronic kidney disease.

Methods: Clinical information collated from 293 of 336 patients enrolled in the Rare Kidney Stone Consortium PH registry with at least one renal image was analyzed including number of stones by imaging; stones passed; urological procedures; urine chemistries; serum creatinine; and measured or estimated GFR. Correlations were assessed by Spearman correlation coefficient.

Results: Mean patient age at last f/u was 25.8yr (25^{th}, 75^{th} = 9.0, 39.8y) and kidney imaging was documented in 293 (87%). Overall, 79% passed a stone, with a mean number of 0.32 passed/yr. One or more urologic procedures were required by 83% of patients ever, with a mean number of 0.16 procedures/yr. Number of stones or procedures was not associated with ESRD risk. Nephrocalcinosis was documented in 36% of all patients. Further, the presence of NC at time of first image or later (time dependent covariate) was associated with a significantly (p=0.0037) increased risk of subsequent ESRD (HR 2.38, 95% CI: 1.30, 4.33). Of urine factors, only low urine citrate was a weak risk factor for stone events. Urinary oxalate, citrate and volume were all associated with risk for nephrocalcinosis, which was more common in PH type 1 compared to other PH types.

Conclusions: Stone events are a hallmark of PH, averaging about 1 every 3 years. Urinary oxalate level does not clearly correlate with stone number, but together with citrate and volume does influence risk of nephrocalcinosis. Stone and nephrocalcinosis appear to be pathophysiologically distinct entities, and the presence of nephrocalcinosis implies a modest risk for ESRD.

FR-PO441

Severity of Renal Tubular Plugging but Not Randall's Plaque Associated with Clinical and Laboratory Characteristics of 78 Stone Formers Undergoing Endoscoping Mapping John C. Lieske, Michael P. Linnes, Eric J. Bergstralh, Xujian Li, Terri J. Vrtiska, Andrew D. Rule, Amy E. Krambeck. *Mayo Clinic, Rochester, MN.*

Background: Two forms of renal papillary micro-calcifications that are thought to be the antecedent of kidney stones have been described, interstitial Randall's plaques and duct of Bellini plugs. We hypothesized that severity of these two forms of micro-calcification reflect stone composition as well as important differences in clinical and laboratory characteristics of stone formers (SF).

Methods: Patients were prospectively enrolled during a percutaneous nephrolithotomy for kidney stone disease. Composition of removed stones was determined by both IR-spectroscopy and micro-CT. Each accessible calyx was endoscopically mapped using a flexible digital nephroscope and representative papillary tip biopsies were acquired. Images of each papillum were digitally analyzed to quantify the area covered with plaque or plug. 24-hr urine samples were analyzed for determinants of supersaturation (SS) and crystal growth inhibition (CGI).

Results: On average 4.5 calyces were mapped in each of 78 patients (39 idiopathic CaOx; 8 CaOx with malabsorption; 12 CaP; 7 struvite; 4 uric acid and 8 others). Randall's plaque was present in 98.7% of kidneys covering an average of 3.0 ±3.3% of the papillary surface, and did not associate with stone type, urinary chemistries, or number of stones. Tubular plugging was less common with moderate amounts (<1%) in 17 SF, and severe amounts (>1%) in 16 others. Severe tubular-plugging associated with higher urinary pH (p=0.03), lower citrate (p=0.02), higher CaP SS (p<0.007), brushite stones, and reduced CGI (27% vs 37%, p=0.003). Those with severe tubular plugging also had more kidney stones (mean 9.2 vs. 2.6, p=0.0002).

Conclusions: Tubular plugs but not Randall's plaques associate with urinary factors and stone severity. The pathogenesis of Randall's plaques may be more complex and involve factors not commonly measured in standard urine panels. Endoscopic papillary mapping documents patterns of microcalcification and improves characterization of stone patients for clinical studies.

FR-PO442

Heritability of Urinary Traits that Contribute to Nephrolithiasis John C. Lieske,[1] Stephen T. Turner,[1] Samuel Edeh,[1] Tracy Fuller,[2] Jennifer Smith,[2] Sharon R. Kardia.[2] *[1]Mayo Clinic, Rochester, MN; [2]University of Michigan, Ann Arbor, MI.*

Background: Kidney stones tend to aggregate in families. Of known risk factors for stones, evidence is strongest for heritability of hypercalciuria.

Methods: Measures of urinary supersaturation were determined from 24 hr urine samples collected from families in the Rochester, MN cohort of the Genetic Epidemiology Network of Arteriopathy. Diet was assessed using the Viocare Food Frequency Questionnaire. Heritability was estimated by using variance components analysis.

Results: Samples were available from 811 individuals (344 men, 467 women, mean (SD) age 66(9) yrs). Age, gender, and weight significantly influenced the vast majority of urinary parameters. Many urine and diet parameters as shown in the Table had strong evidence for heritability (P<0.001), in raw and adjusted models. Overall, 12-36% of the variance in urinary traits could be attributed to heritable factors, while 20-54% of dietary intakes could be.

Heritabilities of 24-Hour Urine and Dietary Measures

Trait	h2 unadjusted	Proportion of variance of measure explained by covariates	h2 adjusted for age, gender, height, weight
Urinary measures			
Calcium	0.41	0.16	0.25
Magnesium	0.34	0.14	0.25
pH	0.35	0.08	0.27
OSM	0.26	0.21	0.20
Citrate	0.39	0.08	0.36
Oxalate	0.11	0.17	0.12
Diet measures			
Animal Protein	0.32	0.12	0.26
Calcium	0.60	0.03	0.54
Fructose	0.25	0.03	0.20
Oxalate	0.28	0.02	0.25
Protein	0.46	0.11	0.38
Sucrose	0.37	0.02	0.37

Conclusions: Evidence from this large cohort suggests a strong genetic component to many nephrolithiasis risk factors, including dietary intake, often considered an environmental influence. Continued efforts to understand genetic influence of kidney stone risk is warranted.

FR-PO443

American and Brazilian Children with Urolithiasis: Similarities and Disparities Maria Goretti Penido,[1] Marcelo S. Tavares,[1] Uri S. Alon.[2] *[1]Pediatric Nephrology Unit, Federal University of Minas Gerais, Belo Horizonte, Minas Gerais, Brazil; [2]Pediatric Nephrology, Children's Mercy Hospital, University of Missouri, Kansas City, MO.*

Background: Considering the different racial, socioeconomic backgrounds and geographic locations the aim of this study was to identify the demographic and biochemical differences between American and Brazilian children with urolithiasis.

Methods: We evaluated the data of 222 American and 190 Brazilian children seen between January 1999 and December 2010. Data included age at diagnosis, gender, BMI, imaging technique used and serum chemistries. 24-h urines were analyzed, at least 1 month after stone expulsion while the patients were on their usual diet, for volume, creatinine, calcium, uric acid, citrate, oxalate, cystine. Unpaired T-test was used for statistical analysis.

Results: No abnormalities were noted in serum chemistries in either group. Despite some differences between the populations, like younger age and leaner body mass among Brazilian children, and some differences in the frequencies of various etiologies, the leading

causes of urolithiasis among both groups were "oliguria", hypercalciuria and high Ca/citrate ratio. In neither country was obesity *per se* more frequent in stone patients compared with the general population. US was the most preferred imaging technique excluding more frequent use of CT as the reason for the increased incidence of pediatric urolithiasis.

Clinical, demographic and biochemical data of American and Brazilian children

	American children (n=222)	Brazilian children (n=190)	p
Gender (%)	Male 48%	Male 51%	
Age at diagnosis (years)	11.8±3.8	8.2±3.2	0.001
BMI Z-score	0.36	0.01	0.00001
Overweight (Z-score>2)	15%	2%	
Imaging technique US/CT	73%/27%	98%/2%	
Urine flow <1.0ml/kg/day	63%	49%	
Hypercalciuria (>4.0 mg/kg/day)	47%	69%	
Calcium/citrate ratio (>0.33)	54%	41%	
Hypocitraturia (<180mg/g creatinine)	10%	9.5%	
Hyperuricosuria (factored for GFR)	6.4%	9.5%	
Idiopathic absorptive hyperoxaluria	1.4%	1.6%	
Cystinuria	0.5%	1.0%	
No abnormality	9.0%	13.0%	

Conclusions: Although we observed some differences between the 2 populations, overall etiologies were quite similar justifying combining efforts in addressing the problem.

FR-PO444

A Case-Control Study of Comorbid Disorders Patients in with Kidney Stone Disease Vaka Kristin Sigurjonsdottir,[1,3] Olafur S. Indridason,[2] Runolfur Palsson,[1,2] Vidar O. Edvardsson.[1,3] *[1]Fauculty of Medicine, University of Iceland; [2]Division of Nephrology; [3]Hringurinn, Children´s Hospital, the National University Hospital of Iceland, Reykjavík, Iceland.*

Background: Hypertension and obesity have been associated with an increased risk of nephrolithiasis. The aim of this study was to compare patients with kidney stone disease to control subjects with respect to selected comorbid factors.

Methods: This was a cross-sectional case-control study in which 121 individuals with a history of kidney stone disease were selected from the Icelandic Kidney Stone Registry. Patients with recurrent stone events or a history of a single stone event and elevated serum creatinine (SCr) >100 mmol/l were invited to participate. All study subjects underwent an evaluation of height, weight and blood pressure, and their last SCr value was obtained from medical records. For each patient we randomly selected 2 control subjects without history of kidney stones and matched for age and sex, from participants in a population-based study of bone and mineral health. Wilcoxon-Mann-Whitney and chi-square tests were used to compare the groups.

Results: The 121 subjects with kidney stone disease had a median (range) age of 58 (19-70) years and included 72 (60%) men. Fifty-eight patients had experienced 1-4 stone episodes, 16 had experienced 5-10 episodes and 46 more than 10 stone episodes. The median BMI was 27.9 (19.9-48) kg/m^2 among the cases compared to 26.6 (13.8-46.6) in the controls (p=0.01). The prevalence of hypertension was 55% among the cases and 47% in the controls (P=0.14) and there was no difference between the two groups in measured systolic blood pressure (BP). The diastolic BP was, however, significantly lower among the cases, 78 (38-120) mmHg compared to 81 (54-120), (p=0.01.) Excluding the 6 patients who were selected based on a single stone episode and elevated SCr, the median SCr was 74 (47-363) mmol/l in the patients compared to 66 (27-168), (p<0.001).

Conclusions: Our study suggests an association between obesity and recurrent kidney stone disease but the results do not indicate an association with hypertension. Kidney stone disease appears to have a deleterious effect on kidney function.

FR-PO445

A Twin Study of Genetic Influences on Nephrolithiasis in Women and Men David S. Goldfarb,[1] Carolyn Noonan,[3] Jack Goldberg.[2] *[1]Nephrology Division, NY Harbor VA Medical Center, New York, NY; [2]Medicine, University of Washington, Seattle, WA; [3]Epidemiology, University of Washington, Seattle, WA.*

Background: Nephrolithiasis is a complex phenotype influenced by both genetic and environmental factors. Previously we found a genetic component to stone disease using a middle-aged sample of male twin pairs. We now report on the genetic contribution to stones in a younger sample of female and male twin pairs.

Methods: We conducted a classical twin study of kidney stones using the University of Washington Twin Registry. Data were collected by questionnaire to obtain the self-reported history of kidney stones. Proband concordance rates were estimated for kidney stones in monozygotic (MZ) and dizygotic (DZ) pairs; univariate structural equation modeling was used to determine the relative contributions of additive genetics, common environment and unique environment.

Results: There were 4,988 same-sex pairs with kidney stone data. The mean age of the sample was 37 years (range 18-90) and was similar in women and men. The prevalence of kidney stones was 4.7% of women and 4.8% of men. Kidney stone proband concordance rates were higher in MZ than DZ pairs for both women and men.

Kidney Stones in Women and Men in the UW Twin Registry

	MZ Women	DZ Women	MZ Men	DZ Men
Concordant for stones, N pairs	21	5	20	5
Discordant for Stones, N pairs	159	188	75	51
Proband Concordance	0.21	0.10	0.35	0.16

We found significant contributions from genetics and the unique environment ($p < 0.05$ for both) to the liability to stone disease in women and men. There was no significant contribution from the common environment. The heritability was 45% (0.32-0.57) in women and 66% (0.53-0.77) in men; these heritabilities were not significantly different (p=0.27).

Conclusions: Nephrolithiasis in women, as in men, has a substantial heritable component. The size of the genetic contribution in this twin study is similar to our previous study of older male twins. More stone formers are men than women; our data do not support differences in hereditability as the basis for that difference. The genetic basis for stone disease in the general population has not been established.

Funding: Private Foundation Support

FR-PO446

Randomized Controlled Trial (RCT) of Febuxostat (FBX) versus Allopurinol (ALLO) and Placebo (PBO) in Subjects with Hyperuricosuria and Calcium Oxalate (CaOx) Stones David S. Goldfarb,[1] P. MacDonald,[2] L. Gunawardhana,[2] S. Chefo,[2] L. McLean.[2] *[1]NYU Langone Medical Center, New York, NY; [2]Takeda, Deerfield, IL.*

Background: About 1/3 of patients with recurrent CaOx stones have hyperuricosuria as a urinary risk factor. ALLO treatment can reduce the incidence of recurrent CaOx stones in hyperuricosuric stone formers (SF). FBX, a newer xanthine oxidase inhibitor (XOI), may be superior to ALLO in stone prevention. We studied whether FBX would reduce 24h urinary uric acid (uUA) excretion and prevent stone formation and pre-existing stone growth.

Methods: In this 6-mos, double-blind, multicenter RCT, hyperuricosuric (>700 mg/d) patients with a history of CaOx stones and ≥1 3-mm stone seen by multidetector computed tomography (MDCT) were randomized to receive daily FBX 80mg, ALLO 200 or 300mg (based on Ccr), or PBO. Primary end-point was % change from baseline (CFB) to mo 6 in 24h uUA; secondary end-points were % CFB in size of index stone, CFB in no. of stones and in 24h creatinine clearance (Ccr).

Results: 99 patients enrolled, 86 completed the study. Key baseline characteristics were balanced. 86% were men with a mean lifetime history of 10.9 stone episodes, mean largest stone diameter 9.9 mm and a mean of 5.7 stones on MDCT. Mean baseline Ccr was 147mL/min/1.73m^2, serum urate (sUA) 6.3 mg/dL, urine calcium excretion 272.2 mg/d, and uUA 952.7 mg/d. FBX led to significantly greater reduction from baseline in uUA than either PBO or ALLO.

	PBO (n=33)	FBX 80mg (n=33)	ALLO 300mg (n=33)
Baseline uUA (mg/d)	909.4±166.4	1000.6±224.0	948.1±231.2
Treated 6M uUA (mg/d)	783.5±288.0	411.4±288.4	580.0±301.8
CFB in uUA (%)	-12.7±28.8	-58.6±28.6[a,b]	-36.4±37.0
CFB in sUA (%)	-1.04±13.3	-47.3±16.7[b,c]	-26.2±15.0

mean±SD; [a]P=0.003 vs ALLO; [b,c]P<0.001 vs PBO and ALLO, respectively.

Reductions in stone size and number with FBX were not statistically greater than ALLO or PBO. There was no change in serum creatinine.

Conclusions: FBX 80mg lowered 24h uUA significantly more than ALLO 300mg in SF with hyperuricosuria. Neither XOI was associated with reduced stone number compared with PBO in only 6 mos of treatment. Extended duration of FBX treatment leading to greater 24h uUA reductions may demonstrate improved prevention of CaOx stone recurrence.

FR-PO447

Thiazide Reduces Stone Risk by Increasing Proximal Tubule Calcium Reabsorption and Lowering Urine pH Kristin J. Bergsland, Elaine M. Worcester, Fredric L. Coe. *Department of Medicine, Nephrology Section, University of Chicago, Chicago, IL.*

Background: Calcium (Ca) stone formers with idiopathic hypercalciuria (IH) have decreased reabsorption of Ca in the proximal tubule (rCa_{PT}), as judged by endogenous lithium clearance. Thiazide (TZ) diuretics reduce Ca excretion and prevent stone recurrence. In mice, evidence suggests that TZ acts by increasing fractional rCa_{PT}, thereby reducing urine Ca excretion, but the mechanism in humans is unknown.

Methods: In the General Clinical Research Center, we studied the effect of TZ on renal mineral handling in 4 male IH patients (2 had Ca stones). We collected 15 urines and 20 blood samples over a 15 hour day, both fasting and with 3 meals of known composition. Each subject was studied twice: once before treatment and once after 4-6 months of the TZ chlorthalidone, 25 mg daily.

Results: As expected, urine Ca fell after TZ treatment; the same was true for the fraction of filtered Ca excreted (FECa). Fraction of filtered lithium excreted (FELi) fell sharply with TZ as did calculated distal delivery of Ca out of the PT (DDelCa). This effect was slightly more marked during fasting compared to the fed period. An unexpected effect of TZ was to reduce urine pH; this combined with reduced urine Ca led to a marked fall in CaP SS, but not CaOx SS.

	UCa (mM/hr)	FECa (%)	FELi (%)	DDelCa (mM/hr)	UpH	CaOx SS	CaP SS
PreTx	0.45 ± 0.02	4.7 ± 0.2	28.1 ± 1.2	2.79 ± 0.13	6.43 ± 0.07	7.4 ± 0.5	2.5 ± 0.2
TZ	0.38 ± 0.02*	4.0 ± 0.2*	15.8 ± 1.2#	1.59 ± 0.13#	5.97 ± 0.07#	6.5 ± 0.5	1.2 ± 0.2#

Daily mean ± SEM adjusted for age and weight. *, differs from preTx, p<0.05; #, differs from preTx , p<0.0001.

Conclusions: This may impact stone prevention because CaOx stones begin with an initial CaP overlay on Randall's plaque (RP). In IH, high Ca delivery to the thick ascending limb (TAL) may raise the absolute rate of TAL Ca absorption and increase interstitial Ca concentration. Vasa recta blood, running downward inside the medulla, will be enriched

in Ca, favoring apatite nucleation and RP formation. TZ, by decreasing distal nephron Ca delivery and lowering urine pH, might reduce stone risk by lowering CaP SS as well as slowing progression of RP, providing a new rationale for treatment with TZ.

Funding: NIDDK Support

FR-PO448

The Contribution of Hydroxyproline Metabolism to Urinary Oxalate and Glycolate Excretion in Normal Subjects Ross P. Holmes,[1] Dean G. Assimos,[1] W. Todd Lowther,[2] John Knight.[1] *[1]Urology, Wake Forest University School of Medicine, Winston-Salem, NC; [2]Biochemistry, Wake Forest University School of Medicine, Winston-Salem, NC.*

Background: The metabolism of hydroxyproline (Hyp) produces an equimolar amount of glyoxylate which may be converted to glycolate, glycine or oxalate. Experiments with mouse models of Primary Hyperoxaluria (PH) suggest that this metabolism will make a significant contribution to urinary oxalate excretion in humans with the disease.

Methods: To determine how Hyp is metabolized in humans, 4 normal subjects were infused with 750 nmoles of ($^{13}C_5{}^{15}N$)-Hyp/kg/hr for 6 hrs in the fasted state after a priming dose equivalent to the amount to be infused in 2 hrs that was delivered over a 5 min period. ($^{13}C_5{}^{15}N$)-Hyp was measured in plasma by GC/MS, ^{13}C-glycolate in plasma by IC/MS, and $^{13}C_2$-oxalate and $^{13}C_2$-glycolate in urine by IC/MS.

Results: Enrichment of plasma with ($^{13}C_5{}^{15}N$)-Hyp was constant from 4 – 6 hrs when it reached 19.0 ± 4.3%. Urinary oxalate was enriched by 2.4 ± 1.2% and glycolate by 11.9 ± 1.6%, indicating that the mean contribution of Hyp metabolism to total urinary oxalate excretion was 13.0 ± 5.5% and to urinary glycolate excretion was 63.4 ± 3.7%. There was an 18.5 ± 6.8% increase in the enrichment of urinary glycolate compared to the enrichment in plasma glycolate suggesting that renal metabolism of ^{13}C-Hyp contributed directly to the urinary glycolate pool.

Conclusions: These results suggest that Hyp metabolism is a major source of urinary glycolate and a minor source of urinary oxalate in normal subjects. As much as half of the urinary oxalate may have been obtained from the diet, Hyp metabolism may contribute at least 25% to the urinary oxalate derived from endogenous synthesis. This contribution would increase with the consumption of dietary Hyp. The inability of subjects with PH to efficiently metabolize glyoxylate produced from Hyp breakdown may be a major source of endogenous oxalate production in this disease.

FR-PO449

Purinergic Signaling Inhibits Oxalate Transport by Human Intestinal Cells Hatim A. Hassan, Sapna Sharma, Sireesha Ratakonda, Ruhul Amin. *Medicine, University of Chicago, Chicago, IL.*

Background: The majority of kidney stones are composed of calcium oxalate, and minor changes in urine oxalate affect stone risk. Intestinal oxalate secretion mediated by anion exchanger SLC26A6 plays a crucial role in limiting net absorption of ingested oxalate, thereby preventing hyperoxaluria and calcium oxalate nephrolithiasis. We previously reported that PKC activation negatively regulates Slc26a6 activity in mouse duodenal tissue. To identify physiologic agonists upstream of PKC, we used the human intestinal Caco2-BBE (C2) cells. We measured ^{14}C-oxalate uptake in the presence of an outward Cl gradient as an assay of Cl-oxalate exchange activity, ≥ 50% of which is mediated by SLC26A6. Purinergic signaling is known to modulate intestinal ion transport through pathways including PKC. We therefore examined whether purinergic stimulation with ATP affects Cl-oxalate exchange activity in C2 cells. We found that ATP significantly inhibited oxalate transport by C2 cells, an effect blocked by the PKC inhibitor Gö6983. Since the response to ATP could be partially mediated by its degradation into adenosine and the activation of the adenosine receptors, we evaluated the effects of UTP and observed significant inhibition of oxalate transport by UTP in C2 cells through a Gö6983-sensitive pathway. We next examined the effect of the selective P2Y2 agonist (2-ThioUTP TSS) since UTP is known to mediate its effects by mainly activating the P2Y2 and/or P2Y4 purinergic receptors. 2-ThioUTP TSS significantly inhibited oxalate transport by C2 cells. Using selective pharmacological inhibitors, we found that ERK1/2, p38, PI3K, and Src kinases are not involved in the observed regulation. Preliminary experiments utilizing immunocytochemistry and surface biotinylation showed that ATP led to reduced surface expression of SLC26A6. These findings are of potential importance because intestinal cells are known to be exposed to extracellular nucleotides (ATP and UTP) under physiological conditions. We conclude that purinergic signaling inhibits oxalate transport by C2 cells, by reducing SLC26A6 surface expression, through signaling pathways that likely include the P2Y2 receptor and PKC.

FR-PO450

Inhibition of Bone Resorption Suppresses $1,25(OH)_2D_3$-Induced Hypercalciuria in Genetic Hypercalciuric Stone-Forming Rats Kevin K. Frick,[1] John R. Asplin,[2] Ignacio Granja,[2] Nancy Krieger,[1] Christopher D. Culbertson,[1] Kelly Kyker-snowman,[1] David A. Bushinsky.[1] *[1]Univ. of Rochester, Rochester, NY; [2]Litholink Corporation, Chicago, IL.*

Background: Genetic hypercalciuric stone-forming (GHS) rats, inbred from Sprague-Dawley (SD) rats to maximize urine (U) calcium (Ca) excretion, all form kidney stones. GHS rats have increased intestinal Ca absorption, increased bone resorption and reduced renal tubular Ca reabsorption; these sites all have an increased number of vitamin D receptors (VDR). The hypercalciuria in GHS rats is increased further by injection of $1,25(OH)_2D_3$ (1,25D) indicating that VDR are active. The 1,25D-induced increased UCa persists on a low Ca diet (LCD, 0.02% Ca) suggesting enhanced bone resorption. To test this hypothesis, we used the bone resorption blocker alendronate (Aln) in rats fed LCD.

Methods: SD (n=16) and GHS rats (n=16) were fed 13 g/d LCD (2.6 mg/d Ca) and half of each group was injected daily with 1,25D (25ng/100gBW/d). After 8d all rats were also injected daily with Aln (5µg/100gBW/d) until sacrifice at d16.

Results: At 8d, 1,25D increased UCa in SD (from 2.4±0.8 to 13.1±1.0 mg/d, $p<0.01$) and to a greater extent in GHS (from 4.3±0.4 to 23.7±1.7 mg/d, $p<0.01$) indicating that 1,25D induced bone resorption in both groups as UCa exceeded diet Ca. At 16d, Aln eliminated the 1,25D-induced increase in UCa in SD (2.2±0.3 vs 2.1±0.2) but in GHS Aln lessened, but did not eliminate, the 1,25D-induced increase in UCa (2.8±0.3 vs 7.9±1.3, $p<0.01$). Renal mRNA expression of mediators of active transepithelial Ca reabsorption TRPV5, calbindin D28k and PMCA were not altered by 1,25D in either group given Aln, while NCX1 levels were suppressed by 1,25D in both SD and GHS. TRPV6 was stimulated by 1,25D in SD but not GHS. Mediators of paracellular Ca reabsorption CLDN16 and NKCC2 were not altered by 1,25D.

Conclusions: With LCD, the 1,25D-induced hypercalciuria indicates increased bone resorption in SD and GHS. Aln eliminates the increase in UCa in SD; however, in GHS the increased UCa is lessened, but not eliminated, suggesting incomplete inhibition of bone resorption coupled to ongoing decreased renal tubule Ca reabsorption, perhaps due to reduced NCX1 expression.

FR-PO451

Characteristics of Incident Symptomatic Kidney Stones by Composition in the General Population Andrew D. Rule,[1] Amy E. Krambeck,[1] Eric J. Bergstralh,[1] Xujian Li,[1] John C. Lieske,[1] James Williams.[2] *[1]Mayo Clinic; [2]Indiana University.*

Background: Stone composition analysis is useful for guiding therapy. Little is known about the relationship between stone composition and the clinical and laboratory characteristics of the incident episode.

Methods: Charts were manually reviewed for Olmsted County, Minnesota residents who received their first diagnostic code for kidney stones between 1984 and 2003. Symptomatic stone formers were validated by the presence of symptoms (pain or hematuria) with either a voided stone or an obstructing or infected stone seen on radiographic imaging. Validated stone formers were grouped by their first available stone composition analysis.

Results: There were 4,262 coded stone formers of which 2,059 were validated. Except for 15 with infected stones, all had stone passage or obstruction symptoms. Stone composition analysis was available in 1,281 (62%), but we excluded 7 with drug stones (triamterene, guaifenesin, or ephedrine) and 2 with cystine stones. Stone formers were divided into the following mutually exclusive groups: any brushite (1.1%), any struvite (0.9%), any uric acid (5.3%), and of the remaining with calcium stones, mostly oxalate (76%) or mostly apatite (17%). The table shows presenting characteristics varied by composition.

Characteristics that differ by composition

Characteristic (mean or %)	Missing (n=777)	Oxalate (n=960)	Apatite (n=219)	Brushite (n=14)	Struvite (n=12)	Uric acid (n=67)	p-value
Age, y	43	44	37	46	49	55	<.001
Men, %	59	72	33	50	25	76	<.001
Family history of stones, %	20	30	32	21	25	18	<.001
Body mass index, kg/m2	28	29	27	29	26	32	<.001
Diarrhea, %	9	9	15	14	0	18	.008
Renal colic, %	90	91	86	86	58	90	.004
Gross hematuria, %	20	21	22	21	50	34	.02
Active UTI, %	5	3	11	14	58	6	<.001
Urine pH	6.2	6.2	6.4	6.5	6.8	5.0	.04
Radiographic stone, %	89	78	85	64	83	67	<.001
-Multiple stones, %	28	31	47	58	58	30	<.001
-Stone diameter, mm	2.4	2.1	2.8	6.4	4.6	1.6	<.001
-Staghorn, %	1	1	1	8	42	2	<.001
-UVJ location, %	37	28	32	42	0	19	<.001

Conclusions: Calcium stones are more common among incident stone formers in the general population (94%) than has been reported in referral-based studies (70-80%). Presenting characteristics may help predict stone composition to guide therapy.

FR-PO452

Endogenous Thiosulfate Excretion Is Related to Protein Intake Andreas Pasch,[1] Felix J. Frey,[1] Harry Van Goor,[3] Brigitte Frey,[1,2] Stefan Farese.[1] *[1]Department of Nephrology & Hypertension, University Hospital Bern, Inselspital, Bern, Switzerland; [2]Department of Clinical Research, University Hospital Bern, Inselspital, Bern, Switzerland; [3]Department of Pathology and Medical Biology, University Medical Center Groningen, University of Groningen, Groningen, Netherlands.*

Background: Thiosulfate (TS, $S_2O_3^{2-}$) is an endogenous intermediate of sulfur metabolism. The sodium salt of TS, sodium thiosulfate (STS, $Na_2S_2O_3$) has been used as a drug for the treatment of cyanide poisoning, cisplatin toxicity, vascular calcifications and nephrolithiasis. Thus, endogenous TS excretion is of potential clinical utility. The determinants of urinary TS excretion are unknown.

Methods: Measurement of 24-hour urinary TS excretion in renal calcium stone formers (n = 40) and age and sex matched healthy controls (n = 40). Determination of volume, creatinine, sodium, calcium, phosphate, urate, oxalate, citrate, sulfate and urea in 24-hour urine. Sequencing of single nucleotide polymorphisms in the genes coding for sulfide:quinone oxidoreductase (SQR, Ile264Thr) and rhodanase (TST, Pro285Ala).

Results: Urinary TS was not different in stone formers and healthy controls (10 ± 8 µmol/day vs. 14 ± 12 µmol/day, p = 0.10) and did not correlate with urine volume or the excretion of creatinine, sodium, calcium, phosphate, urate, oxalate or citrate in 24-hour urine samples from stone formers or healthy controls. TS excretion did also not correlate with the genotype of SQR SNP Ile264Thr or TST SNP Pro285Ala. TS excretion did however correlate with urinary sulfate (p = 0.04) and urea excretion (p = 0.002), two established markers of protein intake. The estimated protein intake, derived from urinary urea excretion, was different in stone formers (1.08 ± 0.31 g/kg bw) and healthy volunteers (1.28 ± 0.33 g/kg bw, p=0.01) in our cohort. The TS-to-sulfate ratios, which might reveal differences in mitochondrial sulfur metabolism showed no differences between stone formers and healthy controls (p = 0.58).

Conclusions: Endogenous TS excretion correlated with markers of protein intake and was not different between stone formers and healthy controls in our cohort. The physiologic role of endogenous TS awaits further clarification.

FR-PO453

Hepatic and Renal sat1 and CFEX Expression in Ethylene Glycol-Induced Oxalate Nephrolithiasis in Rats Birgitta C. Burckhardt,[1] Hrvoje Brzica,[2] Davorka Breljak,[2] Ivana Vrhovac,[2] Vedran Mivek,[2] Mila Lovric,[3] Nina Schnedler,[1] Maja Henjakovic,[1] Waja Wegner,[1] Ivan Sabolic,[2] Gerhard Burckhardt.[1] *[1]Physiology and Pathophysiology, University of Göttingen, Göttingen, Germany; [2]Institute for Medical Research and Occupational Health, Zagreb, Croatia; [3]Laboratory Diagnosis, University Hospital Centre, Zagreb, Croatia.*

Background: The epidemiological incidence of oxalate nephrolithiasis is higher in men than in women. Oxalate is predominantly produced in the liver and then released into the systemic circulation by sat1, a sulfate anion transporter, which is localized in the sinusoidal membrane of hepatocytes, where it mediates exit of oxalate in exchange for sulfate. In renal proximal tubules, sat1 is responsible for basolateral uptake of oxalate into the cell and release of sulfate into the systemic circulation. Finally, oxalate is extruded into the urine by the luminal chloride-formate exchanger, CFEX, which also accepts oxalate as a substrate.

Methods: The model of ethylene glycol (EG)-induced oxalate nephrolithiasis in adult male and female rats was used to monitor changes in sat1, CFEX, and the rate-limiting enzymes of oxalate synthesis, alcohol dehydrogenase (Adh1) and hydroxy acid oxidase (Hao1). Protein and mRNA expression was studied by immunochemistry and real time RT-PCR.

Results: As compared to controls, EG-treated animals exhibited higher concentrations of oxalate in plasma and urine, and a higher abundance of oxalate crystals in urine with male dominance. Sat1 protein in liver and kidneys was male-dominant in controls, increased only in EG-treated females, while sat1 mRNA stayed unchanged. CFEX mRNA in both organs was sex-independent and unaffected by EG treatment. Adh1 and Hao1 mRNA in both organs exhibited distinct sex dependency which remained unchanged upon EG treatment. A general male-dominant Hao1 expression in kidneys of untreated rats was also shown by microarray analysis.

Conclusions: In conclusion, despite hyperoxaluria in EG-treated animals, the expression of sat1 in males and of CFEX in both sexes was sufficient to handle the EG-induced production and secretion of oxalate.

FR-PO454

Insufficient Adjustment of Water Intake Associated with Western-Rich Diet Increases the Risk of Urine Crystallization Inmaculada Buendia,[1] Oriane Dohein,[1] Marion Vallet,[3] Ivan A. Tack,[3] Michel Daudon.[2] *[1]Danone Research RD128, Palaiseau, France; [2]Dpt of Clinical Physiology, Tenon Hospital, APHP, Paris, France; [3]Dpt of Clinical Physiology, CHU Toulouse, Toulouse, France.*

Background: Calcium oxalate (CaOx) nephrolithiasis is often related to dietary habits and low diuresis. Indeed, dilution of urine is efficient for CaOx kidney stone prevention. High energy intake based on Western diet results in high consumption of salted animal proteins leading to increased protein catabolism responsible for the majority of daily urine waste. Surprisingly, only little attention has been paid to spontaneous adjustment of fluid intake according to the diet.

Methods: We have examined the relationship between Body mass index (BMI), considered to reflect global energy intake, and daily osmotic load, waste excretion (24 hours urine osmolality, oxalate, calcium, citrate, urea and sodium) and the Tiselius crystallization risk index (Tcri) in a population of 312 (F/M: 128/184) recurrent stone formers (RSF). Results were compared to those of 48 healthy control volunteers (F/M: 21/27) from a previous study.

Results: In RSF: 1) BMI positively and significantly correlated with osmotic load, 24h urine urea, sodium, uric acid, oxalate and citrate but not with calcium and magnesium urine excretion; 2) BMI was positively correlated with 24h urine osmolality and Tcri but not with urine volume; as a result, BMI was negatively correlated with free water clearance, a confounding factor of the relationship between BMI and Tcri.

In control subjects: BMI positively and significantly correlated with 24h excretion of most urine waste but also with urine volume. As a consequence BMI was neither correlated with urine osmolality nor with free water clearance or Tcri.

Conclusions: In conclusion, in renal stone formers, by contrast to healthy subjects, high energy and protein intake is not associated with a significantly higher urine volume, leading to more concentrated urine and an increased risk of CaOx crystallization. This observation stresses the interest to screen urine osmolality in RSF exhibiting a western high energy diet and, if necessary, to educate them to adjust water intake in order to prevent CaOx kidney stones.

FR-PO455

Standard Dose Hydrochlorothiazide Is Associated with Less Urinary Calcium Reduction Compared to Chlorthalidone Dawn F. Wolfgram,[1] Brad C. Astor,[1] Amarinder Singh Garcha,[2] Vinod K. Gundu,[2] Stephen J. Knohl,[2] Roy A. Jhagroo.[1] *[1]Medicine, University of Wisconsin, Madison, WI; [2]Medicine, Upstate Medical Center, Syracuse, NY.*

Background: Medical treatment of calcium nephrolithiasis is centered on thiazide diuretics to reduce urinary calcium (UCa) levels; with increased reduction in UCa correlating with decreased risk of stone recurrence. Recent data demonstrate effective BP lowering at low doses of thiazides, prompting use of lower doses in stone prevention, as well. In addition there has been a switch from chlorthalidone (CTL) to less potent hydrochlorothiazide (HCTZ) due to concerns over hypokalemia with CTL. It is unknown whether low doses of HCTZ are effective in lowering UCa levels to target levels. We hypothesize that UCa reduction will be greater with CTL than HCTZ when comparing currently used doses.

Methods: Observational study of stone-forming individuals seen in a metabolic stone clinic over a two year period. Data included patient demographics, co-morbidities, and 24h urine electrolyte composition. Primary outcome was the change in 24 hour UCa comparing HCTZ and CTL.

Results: 322 patients were identified with 112 meeting criteria and used in analysis. The majority were placed on HCTZ (n=42) or CTL (n=47) 25mg QD. Patients on CTL 25mg had a greater reduction in UCa (164 mg; 41%) than those on HCTZ (85mg; 21%), p = 0.006. When comparing a higher dose of HCTZ (50mg) with a lower dose of CTL (25mg) there was no significant differences in 24h UCa reduction at 144mg va 164mg, respectively p = 0.712. Neither CTL nor HCTZ at 12.5mg QD significantly lowered UCa. There was a decrease in serum [K] of 0.5Meq/L (p = 0.001) in patients on CTL 25mg daily, but no serum [K] recorded below 3.3, or cardiac arrhythmia recorded.

Conclusions: In our study there was greater reduction of UCa levels with CTL compared to HCTZ. Although patients on CTL 25mg had a decrease in serum [K] there was no severe hypokalemia or adverse effects documented at that dose. Our data shows that UCa reduction is greater on CTL compared to similarly dosed HCTZ without increased risk of severe hypokalemia.

FR-PO456

Urinary Macromolecular Net Charge: A Promising New Test for Kidney Stone Risk Jeffrey Wesson,[1,2] Ann M. Kolbach,[2] Kevin P. Tucker,[2] Vishal N. Ratkalkar,[2] Jack G. Kleinman.[2] *[1]Medicine, VA Medical Center, Milwaukee, WI; [2]Medicine, Medical College of Wisconsin, Milwaukee, WI.*

Background: There are hundreds of urinary macromolecules (UM) in normal urine, many thought to inhibit stone formation, including strongly anionic proteins like osteopontin and Tamm-Horsfall protein. Though some cationic proteins are found in urine, the overall Net Charge (NC) is anionic. Model polymer studies have shown that polymers or mixtures with very low NC aggregate, which then induces calcium oxalate crystal aggregation. We have tested the hypothesis that stone formers have lower UM NC (weaker inhibitor function) than normals in two independent patient panels, as reported below.

Methods: Freshly voided mid-morning urine samples were obtained from stone formers (SFU) and normals (NU - matched for age, gender, and race) and protease inhibitors were added. UM were isolated immediately by ultradiafiltration through a 10kD cutoff membrane, using a 100mM NaCl buffer for the first panel and 10mM NaCl buffer for the second panel (to prevent loss of UM through precipitation). NC was determined by mixing varied amounts of UM with known quantities of polyarginine (pR) and measuring the absorbance at 400nm. NC was defined as the mass ratio (pR/UM) of the mixture showing maximum absorbance.

Results: The NC results (see Table) show that NC for SFU was about 20% lower than the NC in NU in both panels. The difference in absolute values for NC between the two panels for both SFU and NU was a consequence of differences in pR lots.

Urine Macromolecular Net Charge Results:

+/-,pR/UM	Urine Panel 1		Urine Panel 2	
NU	0.74±0.14	n=22	0.55±0.10	n=13
SFU	0.60±0.09	n=22	0.44±0.14	n=23
p-Values	p=0.0008		p=0.04	

Conclusions: The reduction of NC in SFU is consistent with reduced crystallization inhibition (particularly aggregation) for UM from SFU compared to NU. While the distributions of NC values in the two populations were overlapping, low UM NC appears to be predictive of stone formation and this simple urine test may be useful in identifying patients from a random population at risk for stone disease,and thus allowing for pre-emptive treatment.

FR-PO457

Can Highly Precise Microanalytical Methods Be Helpful for Understanding the Detail Insight and Growth Behavior of Primary Hyperoxaluria (PH) and Non-PH Stones? Michaela Gessner,[1] Dorrit E. Jacob,[2] Bernd Grohe,[3] Bodo B. Beck,[4] Bernd Hoppe.[1] *[1]Department of Child and Adolescent Medicine, Pediatric Nephrology, University Hospital, Cologne, Germany; [2]Earth System Science Research Centre and Institute for Geosciences, Johannes Gutenberg University, Mainz, Germany; [3]Schulich School of Medicine & Dentistry, Western University, London, ON, Canada; [4]Institute of Human Genetics, University Hospital, Cologne, Germany.*

Background: There are currently 3 types of primary hyperoxaluria (PH) known. All are rare autosomal-recessive inherited disorders of the glyoxylate metabolism. They manifest with varying degrees of nephrolithiasis and/or nephrocalcinosis and also early progression to ESRD in PH1. The diagnosis is frequently delayed and often only made in ESRD. Until now urine excretion parameters and mutation analysis led to the diagnosis. Our study was to determine on whether more specific stone analysis using methods of geosciences allow a faster diagnosis and a deeper insight in stone pathology and growth, so that this data can later be used to develop new therapeutic approaches.

Methods: Kidney stones from PH and non PH-patients were compared. Fragments of stones were embedded in epoxy resin, polished with diamond paste and analyzed by reflected light microscopy and by Raman spectroscopy. Native stone fragments were analyzed by scanning electron microscopy and X-ray microanalysis.

Results: PH1 stones and stones of patients with idiopathic hyperoxaluria consists mainly of calcium-oxalate monohydrate (COM), while the white-yellowish porous PH 3 stones mainly consists of calcium-oxalate dihydrate (COD) and smaller COM inclusions. But PH stones and non-PH stones differ clearly in crystal morphology. The PH stone has a looser and disordered crystal morphology, while the non-PH stone seems to be well ordered. Also, mineral components in the stones such as magnesium, phosphate and sodium were present in different amounts.

Conclusions: The more differentiated breakdown and understanding of the structure and composition of kidney stones can possibly help to understand the differences in clinical expression and may help to open new possibilities for therapeutic approaches.

FR-PO458

Acid and Protein Enhance Calcium Oxalate Deposition in Experimental Nephrolithiasis Jack G. Kleinman,[1,2] Laura J. Alatalo,[1] Ann M. Kolbach,[1] Jeffrey Wesson.[1,2] *[1]Medicine, Medical College of Wisconsin, Milwaukee, WI; [2]Medicine, Veterans Affairs Medical Center, Milwaukee, WI.*

Background: Acid-ash high protein diets (HP) are recognized as a risk factor for kidney stones. We reported that the mean net charge (NC) of urinary macromolecules (UM) in stone formers is less negative than in non-stone formers. These UM inhibit processes involved in stone formation but are less effective when their NC is less negative. We also reported that enhancing UM NC by infusing a highly anionic macromolecule poly(acrylic acid) inhibits Ca oxalate (CaOx) deposition in ethylene glycol (EG)-fed rats. The studies reported here were designed to ascertain whether HP is associated with a less negative mean NC of UM and also renders rats more susceptible to CaOx deposition when they are fed EG.

Methods: Male SD rats were either fed standard purified diet (NP) with 1% NH_4Cl (acid) or a 40% protein (HP) casein-based diet with acid. 24-h urines were obtained at intervals to ascertain UM NC. Other rats were either fed NP or a 40% HP diet with acid. 24-h urines for chemistries were obtained on the day prior to & on the 8th day of being fed 0.2, 0.4, & 0.8% EG in the drinking water and then kidneys were obtained to determine CaOx deposition.

Results: The NC of UM had declined by 40% at 1 week in the rats on the acid-HP diet & the effect of acid and HP appeared to be additive. Rats on NP did not have significant CaOx deposition until they were fed 0.8% EG; the rats fed the acid-HP had significant CaOx crystal deposition when fed 0.4% EG. The decrease in the threshold for CaOx deposition with acid-HP could not be attributed to a difference urinary oxalate. Calcium excretion & the relative supersaturation (RSS) of the rat urine with respect to CaOx were significantly higher in the acid-HP group; however in the groups that did not receive EG, there were no significant differences in Ca excretion & RSS. This suggests that the RSS change in EG-treated rats was the result rather than the cause of the increased CaOx deposition.

Conclusions: These data are consistent with the hypothesis that a HP diet contributes to the risk of developing Ca nephrolithiasis and that it does so by rendering the NC of UM less negative.

FR-PO459

Effect of pH on Cystine Binding Capacity of Thiol Drugs John R. Asplin, Daniel M. Asplin. *Litholink Corporation, Chicago, IL.*

Background: Pharmacologic therapy for cystinuria consists of alkali salts to raise urine pH and thiol drugs to form cysteine-drug complexes. The large number of pills required for these two therapies affects compliance, leading some clinicians to discontinue alkali when thiol drugs are used. However, the effect of alkalinizing urine on the cystine binding capacity of thiol drugs has not been studied.

Methods: Urine samples were obtained from 4 healthy subjects and 5 aliquots of each urine had pH adjusted from 6.0 to 8.0. Urine samples were incubated with cystine crystals at 37C for 5 minutes and 48 hours. Standard measurements of supersaturation are 48 hours, but shorter incubation times are more germane to in vivo conditions for cystine-thiol drug interaction. Comparisons were made between urine with and without the thiol drugs Tiopronin (TIO) or d-Penicillamine (dPCN), each added at a concentration of 2 mM. The primary endpoint was the amount of cystine that could dissolved in the urine samples, known as cystine capacity (CysCap), measured using a nitroprusside assay (Kidney Int 69:1041, 2006).

Results: In urine without thiol drug, CysCap increased from 230 ± 19 to 286 ±25 mg/l as urine pH was increased from 6.0 to 8.0 at 48 hrs. In the 48 hr incubations CysCap increased dramatically when either of the thiol drugs were added to urine and was not significantly influenced by pH. However, when incubation time was shortened to 5 minutes, representative of the dwell time of urine in the renal pelvis, the effect of thiol drugs to solubilize cystine was greatly dependent on urine pH.

Table 1. Effect of pH and thiols on CysCap (mg/l) at 5 minute incubation

pH	Control	TIO	dPCN
6.0	158 ± 5	207 ± 34	180 ± 26
6.5	163 ± 9	272 ± 58	221 ± 31
7.0	165 ± 14	390 ± 57	298 ± 39
7.5	191 ± 11	460 ± 40	385 ± 35
8.0	226 ± 14	492 ± 33	432 ± 28

Conclusions: Increasing urine pH greatly increased the efficacy of thiol drugs to complex and solubilize cystine. In order to maximize benefit from thiol drugs, alkali therapy should be used in conjunction with thiol drugs with the goal of keeping urine pH at 7.5 or above. Clinical trials are needed to confirm these in vitro findings.

FR-PO460

Heritability of the Coefficient of Variation in a Sample of Stone-Former Probands and First-Degree Relatives Guy M.L. Perry,[1] Steven J. Scheinman,[1] John R. Asplin.[2] *[1]Medicine, SUNY Upstate Medical University, Syracuse, NY; [2]Medicine, SUNY Upstate Medical University, Syracuse, NY; [3]Litholink Inc., Chicago, IL.*

Background: Classical genetics usually consists of the estimation of the heritability of single observations as indicative of genetic means. However, our work indicates genetic variance for *residuals* in renal solutes, including heritability, gender effects and quantitative trait loci (QTL) for the coefficient of variation (*CV*) in urinary calcium in a rodent model of hypercalciuria and kidney stone formation. We hypothesized that urinary solute *CV*s were also heritable in humans.

Methods: We investigated the heritability of the *CV*s in urinary solutes in 949 kidney stone probands from 249 families with relationship structures ranging from proband-sib pairs to full-sib families with multiple offspring measured on two consecutive days.

Results: Narrow-sense (additive) heritability was non-zero for *CV*s for urinary calcium, citrate and sulfate. There was also dominant genetic variance for citrate, sodium, phosphorus and uric acid (Table 1). Sex-by-family interaction effects on *CV* were significant for citrate and uric acid ($P<0.001$).

Table 1. Narrow- (additive, h^2_a) and broad-sense (dominant, h^2_d) estimates of heritability for 2-day coefficients of variation (CV) in urinary calcium (Ca), citrate (Cit), sodium (Na), ammonium (NH_4), phosphorus (P), sulfate (SO_4) and uric acid (UA) in 949 stone-former probands and first-degree relatives.

CV	h^2_a	h^2_d
Ca	0.076 (0.071)	0.041 (0.055)
Cit	0.234 (0.063)	0.079 (0.043)
Na	0.0 (0.051)	0.124 (0.049)
NH_4	0.088 (0.047)	0.0 (0.0)
P	0.0 (0.0)	0.083 (0.035)
SO_4	0.049 (0.048)	0.0 (0.0)
UA	0.0 (0.0)	0.047 (0.030)

Conclusions: Genetic and sex-by-genotype effects on *CV*s in renal solutes corresponds to previous findings for this phenomenon. Genetic variance for urinary solute *CV*s might affect baseline renal phenotyping, produce heritable uncertainty in stone precursors (phosphorus, calcium) or protective solutes such as citrate, or affect the outcome of conventional genetic mapping and/or candidate analysis in renal solute phenotype. Other work of ours suggests that even small (~2%) alterations in residual error are sufficient to affect genetic analysis of solute traits.

Netrin-1 Regulates Inflammatory Response of Neutrophils by Suppressing COX-2 Mediated PGE2 Production and Suppresses Ischemic Acute Kidney Injury Punithavathi Vilapakkam Ranganathan, Riyaz Mohamed, Calpurnia Jayakumar, Ganesan Ramesh. *Medicine, Vascular Biology Center, Georgia Health Sciences University, Augusta, GA.*

Background: Inflammation is a major causative factor for acute and chronic diseases. The molecule netrin-1 has been shown to regulate inflammation but the mechanism by which this occurs are unknown. We show here the unexpected role of netrin-1 in the regulation of the production of prostanoid metabolite PGE2 from neutrophils in in vitro and in vivo disease models.

Methods: Ischemia reperfusion injury of the kidney was induced by clamping renal pedicle clamping for a period of 26 minutes followed by reperfusion in wild type and RAG-1 knockout mice. Some of these mice received recombinant netrin-1 or vehicle 1hr before renal pedicle clamping. Kidney function, inflammation and immune cell infiltration were quantified by immunostaining, RT-PCR, ELISA, measuring serum creatinine and Western blot analysis.

Results: Ischemia reperfusion in wild-type and RAG-1 knockout mice induced severe kidney injury that was associated with a large increase in neutrophil infiltration and COX-2 expression in the infiltrating leukocytes and proximal tubular epithelial cells. Administration

of netrin-1 suppressed COX-2 expression, PGE2 production, and neutrophil infiltration into the kidney and was associated with reduced apoptosis, inflammatory cytokine and chemokine expression, and improved kidney function. Moreover, administration of PGE2 receptor EP4 agonist enhanced neutrophil infiltration and renal injury which was not inhibited by netrin-1. Consistent with in vivo data, addition of IL-17 increased COX-2 expression and IFNγ production, which was inhibited by addition of netrin-1. Netrin-1-mediated suppression of IFNγ production was abolished by addition of PGE2.

Conclusions: Our results suggest that netrin-1 regulates inflammation and infiltration of neutrophils through COX-2-mediated PGE2 production in neutrophils and renal tubular epithelial cells, and could be a potential drug for treating many inflammatory immune disorders.

FR-PO462

Obesity Magnifies Kidney and Peri-Renal Fat Inflammation and Fibrosis in Experimental Renal Artery Stenosis Xin Zhang,[1] Zilun Li,[1] Alfonso Eirin,[1] Kyra L. Jordan,[1] Amir Lerman,[2] Stephen C. Textor,[1] Lilach O. Lerman.[1,2] *[1]Division of Nephrology and Hypertension, Mayo Clinic; [2]Division of Cardiovascular Diseases, Mayo Clinic, MN.*

Background: Obesity has been increasing in prevalence and is an independent risk factor for chronic kidney disease. Obesity often coexists with ischemic nephropathy due to renal artery stenosis (RAS), yet its impact on the stenotic kidneys (STK) and the underlying mechanisms remain unexplored.

Methods: Obesity-prone Ossabaw pigs were randomized as Lean, Obese, Lean RAS, and Obese RAS (n=6 each group) fed an atherogenic (Obese) or standard (Lean) diet for 16 wks. Unilateral RAS was induced after 12 wks of diet, and 4 wks later single-kidney glomerular filtration rate (GFR) assessed by CT. Oxidative stress was measured in plasma by 8-isoprostane and in the STK by p47phox expression. Inflammation was assessed in both STK and peri-renal fat tissue by the ratio of pro-inflammatory (M1, CD163+/iNOS+) vs. reparative (M2, CD163+/Arginase+) macrophages (MØ), and fibrosis by trichrome staining.

Results: Obese pigs had higher body weight and cholesterol levels than Lean. Both RAS groups achieved comparable stenosis and hypertension. Obesity in RAS increased 8-isoprostane and STK p47 expression (Figure, B), suggesting systemic and local oxidative stress (Figure, B). Obesity increased M1 MØ abundance in both STK and peri-renal fat (Figure, C). Obesity in RAS tended to increase STK fibrosis (P=0.08 vs. Lean STK; P<0.05 vs. Lean) and significantly increased peri-renal fat fibrosis (P<0.05 vs. Lean STK).

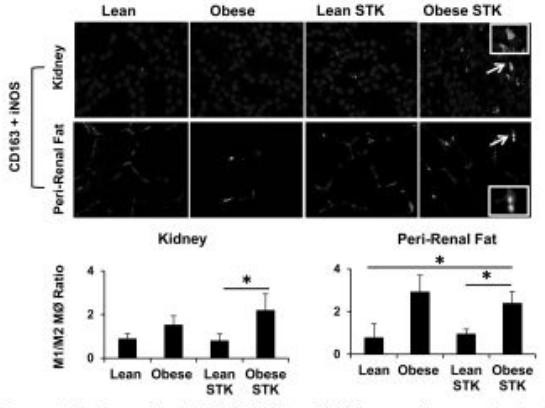
C



Representative images for M1 MØ (CD163+ red /iNOS+ green, 40x, merged yellow) staining in kidney and peri-renal fat, and quantifications for M1/M2 MØ ratio for both. * P<0.05

Conclusions: Obesity aggravates STK oxidative stress, inflammation, and fibrosis. These deleterious effects may be amplified by pathological remodeling of peri-renal fat in RAS, and establish obesity a significant risk factor for kidney disease progression.

Metabolic Syndrome Exacerbates Contralateral Kidney Hyperfiltration and Fat Deposition in Renovascular Hypertension Xin Zhang,[1] Zilun Li,[1] Alfonso Eirin,[1] Aditya S. Pawar,[1] Hui Tang,[1] Kyra L. Jordan,[1] John R. Woollard,[1] Amir Lerman,[2] Stephen C. Textor,[1] Lilach O. Lerman.[1,2] *[1]Division of Nephrology and Hypertension, Mayo Clinic; [2]Division of Cardiovascular Diseases, Mayo Clinic, MN.*

Background: The prevalence of metabolic syndrome (MetS) is increasing and accelerating the progression of many chronic kidney diseases. We hypothesized that MetS aggravates contralateral kidney (CLK) dysfunction in renovascular hypertension (RVH).

Methods: Ossabaw pigs in Lean, MetS, Lean RVH and MetS RVH groups (n=6 each) were fed with atherogenic or standard diet for 16 wks, Unilateral renal artery stenosis was induced after 12 wks of diet, and 4 wks later single-kidney glomerular filtration rate (GFR) assessed by CT. Systemic oxidative stress was assessed by oxidized (ox)-LDL levels and inflammation by TNF-alpha. Kidney fat deposition was assessed by Oil Red O staining and triglyceride (TG) content, inflammation by the ratio of inflammatory (M1, iNOS+) vs. reparative (M2, Arginase+) macrophages (MØ, CD163+), and fibrosis by trichrome staining.

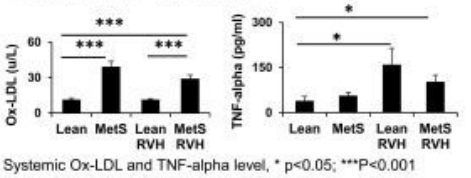
Results: MetS increased insulin resistance, body weight, and cholesterol levels, but did not affect blood pressure in RVH (Figure, A). MetS did not affect stenotic kidney GFR, but increased CLK GFR (P<0.05 vs. Lean), suggesting hyperfiltration. Systemic ox-LDL was increased in both MetS and MetS RVH and TNF-alpha level increased in both RVH groups (Figure, B). MetS increased in the RVH CLK fat deposition, M1/M2 MØ ratio (Figure, C), and fibrosis (P<0.01 vs. Lean; P<0.05 vs. Lean RVH CLK).

A

	Lean	MetS	Lean RVH	MetS RVH
Body weight (kg)	31.4±4.3	45.0±5.7*	35.7±2.1	45.3±1.1*#
HOMA-IR (U/ml×mg/dl)	3.6±0.3	6.7±2.4*	2.6±0.5	10.5±2.9*#
Total Cholesterol (mg/dl)	97.0±2.9	388.0±48.1*	85.4±5.0	346.7±40.6*#
MAP (mmHg)	104.7±6.9	105.1±11.5	122.3±4.4*	130.1±5.9*
Single-kidney (CLK) GFR (ml/min)	50.1±6.9	55.8±2.4	60.8±3.6	75.0±6.8*#

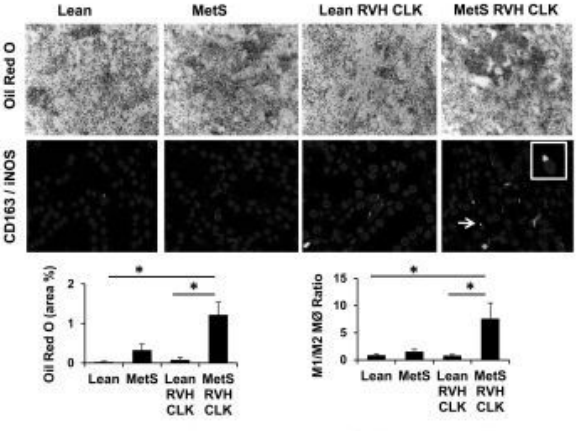
HOMA-IR: homeostasis model assessment insulin resistance; MAP: mean arterial pressure. * P<0.05 vs. Lean; # P<0.05 vs. Lean RVH

B



Systemic Ox-LDL and TNF-alpha level, * p<0.05; ***P<0.001

C



Representative images for Oil red O (10x) and M1 MØ (CD163+ red /iNOS+ green, 40x, merged yellow), and quantifications for oil red o and M1/M2 MØ ratio . * P<0.05

Conclusions: MetS amplifies renal hyperfiltration in the contralateral kidney in RVH, associated with increased fat deposition, recruitment of activated M1 MØ, and fibrosis, indicating adverse tissue remodeling. Thus, MetS is a significant risk factor for kidney injury associated with RVH. Strategies are needed to attenuate its impact on the kidney.

The Role of Macrophage Stimulating Protein and Its Receptor Recepteur d'Origine Nantais in Renal Ischemia Reperfusion Injury Koeun Lee, Chang Seong Kim, Joon Seok Choi, Eun Hui Bae, Seong Kwon Ma, Soo Wan Kim. *Internal Medicine, Chonnam National University Medical School, Gwangju, Korea.*

Background: Macrophage stimulating protein (MSP) and its receptor RON, recepteur d'Origine nantais, play an important role in the cell proliferation and migration. We have investigated the role of MSP/RON pathway in tubule regeneration in ischemia-reperfusion (IR) injury.

Methods: We induced bilateral renal IR injury in C57BL/6 mice by clamping both renal pedicles for 30min and sacrificed on 1 or 5 days after IR injury. The expression of MSP, RON, COX-2, Bcl-2, Bax and caspase-3 was determined by immunoblotting. The mRNA level of IL-1β and TNF-α was measured by real-time PCR. Using an in vitro model, human renal proximal tubular (HK-2) cells were incubated with hydrogen peroxide (H_2O_2) for 24h at different concentrations of MSP, and cell viability was measured by MTT assay. The protein expression of mitogen-activated protein kinases (MAPKs), and nuclear factor-kappa B (NF-κB) was detected by immunoblotting. Apoptosis was determined by flow cytometry analysis after HK-2 cells were stained by fluorescein isothiocyanate conjugated annexin V protein and propidium iodine.

Results: Plasma creatinine was markedly increased on day 1 after IR injury compared with controls, which was attenuated on day 5. Accordingly, protein level of Bax/Bcl-2 ratio, COX-2 expression and mRNA level of IL-1β and TNF-α in the kidney were increased on day 1, which were attenuated on day 5. The expression of MSP was upregulated on day 1 and 5, but RON was markedly decreased only on day 5. H_2O_2 treatment decreased cell viability, which was counteracted by MSP. Flow cytometry analysis revealed MSP can prevent H_2O_2-induced apoptosis. Additionally, MSP attenuated phosphorylation of P38 and NF-κB expression.

Conclusions: In conclusion, the protein level of MSP was increased during the regeneration of I/R injured tubular cells, and MSP attenuated H_2O_2-induced apoptosis in HK-2 cells through the modulation of P38 and NF-κB pathways, suggesting a beneficial potential role of MSP/RON in renal tubule cell regenaration.

FR-PO465

Delayed Inhibition of PAR-1 Signaling Ameliorates Renal Ischemia Reperfusion Injury: Potential Role of Sphingosine-1-Phosphate Signaling

Jonathan H. Erlich,[1] Anthony Chuang,[1] Sean E. Kennedy.[2] *[1]Nephrology, UNSW/ Prince of Wales Hospital, Randwick, NSW, Australia; [2]Nephrology, UNSW/ Sydney Childrens Hospital, Randwick, NSW, Australia.*

Background: To determine if delayed treatment with a PAR-1 inhibitor SCH79797 could reduce renal injury following renal ischaemia reperfusion injury (IRI). Background: Thrombin may signal via PAR-1 to contribute to renal injury following renal IRI. PAR-1 may signal via Sphingosine -1-phospahe (S1P) generation and receptor signalling. S1P signalling by the S1Pr1 receptor has been suggested to be protective and SIPr3 signalling injurious. Pre-treatment of mice with SCH79797 a PAR-1 inhibitor reduces renal injury following renal IRI. We tested whether delayed treatment with SCH79797 could ameliorate renal injury following reperfusion.

Methods: Using a mouse model of renal IRI we examined the effect of administration of SCH79797 30 min after reperfusion. We also examined the effects of PAR-1 inhibition on SPHK 1 and 2 and SIPr1 and 3 mRNA and protein expression.

Results: SPHK 1 and 2 and S1Pr1 and 3 mRNA and protein expression were induced at 24 h reperfusion in C57BL/6 mice compared to sham operated mice. Mice administered SCH79797 2 h pre ischemia had reduced renal injury as measured by serum creatinine and reduced expression of SPHK 1 and 2 and S1Pr1 and 3 mRNA and protein. To further assess the potential importance and timing of PAR-1 signalling we administered SCH7979 30 min after IRI at time at which time injurious signalling pathways have been shown to be activated.

SCH79797 administered 30 min post reperfusion reduced renal injury as assessed by serum creatinine relative to control mice (133±5 micromol/l vs 163±6 micromol/l p <0.005). Thus suggesting a potential therapeutic role for delayed PAR-1 inhibition.

Conclusions: Taken together our data suggests that PAR-1 inhibition by SCH7979 may be protective when administered both pre and post reperfusion suggesting a potential therapeutic benefit. This protection may at least in partoperate by reducing S1Pr3 signalling and inflammation.

FR-PO466

RGS4 Protects against Vascular Smooth Muscle Cell-Mediated Reperfusion Injury in the Kidney

Paul Pang,[1] Nilay Roy,[2] Joseph V. Bonventre,[1] Andrew M. Siedlecki.[1] *[1]Medicine, Brigham and Women's Hospital, Boston, MA; [2]Computer Science, Partners Healthcare, Boston, MA.*

Background: Regulator of G protein Signaling 4 (RGS4) is a modulator of smooth muscle vasoconstriction in the kidney while the known systemic anti-inflammatory effects of RGS4 in the same cell type have not been investigated in the microvasculature of the kidney.

Methods: LacZ knock-in RGS4 reporter mouse; transgenic RGS4-eGFP reporter mouse; An $rgs4^{flox/flox}$ mouse was generated and crossed to a smooth muscle myosin heavy chain (SMMHC)-Cre mouse. Animals were used in ischemia-reperfusion injury experiments.

Results: LacZ RGS4 reporter mice demonstrated an increase in RGS4 expression localized to smooth muscle cell-specific myosin-expressing cells in the corticomedullary junction acutely 4 hours after moderate ischemic injury. RGS4-eGFP mice that demonstrate a 5-fold overexpression of RGS4 in the kidney at baseline were found to be resistant to moderate ischemic injury (serum creatinine [Cr], tubular injury score). To isolate the in vivo role of RGS4 in microvascular injury, separate from tubular injury, animals underwent ultra-mild ischemia reperfusion injury (UMIRI), that is, 10 minute unilateral ischemia. Only endothelial injury could be identified 18 hours after injury by morphology, immunostaining, and quantitative analysis. Calponin-1 was not elevated in vasculature of any cohort above baseline indicating a non-vasoconstrcited state. VCAM expression was enriched in congenic controls compared to RGS4-eGFP. To investigate the functional anti-inflammatory role of RGS4 expression in vascular smooth muscle cells of the kidney SMMHC-Cre-$Rgs4^{flox/flox}$ and SMMHC-Cre underwent UMIRI followed by intravenous injection of magnetic iron oxide nanoparticle-47 (MION-47) to detect regional macrophage infiltration. MION-47 sequestration in the corticomedullary junction was elevated in SMMHC-Cre-$Rgs4^{flox/flox}$ compared to SMMHC-Cre as evaluated by high resolution T2-weighted magnetic resonance imaging.

Conclusions: RGS4 expressed in renal vascular smooth muscle cells has an important role in dampening ischemia-induced endothelial dysfunction that results in leukocyte localization and reperfusion injury.

Adenosine 2A (Adora2a) Agonists Block Pro-Inflammatory Role of Type I IFNs in Kidney Ischemia-Reperfusion Injury (IRI)

Li Li,[1] Liping Huang,[1] Hong Ye,[1] Peter I. Lobo,[1] Diane L. Rosin,[2] Mark D. Okusa.[1] *[1]Division of Nephrology, Center for Immunity, Inflammation and Regenerative Medicine, Department of Medicine, University of Virginia, Charlottesville, VA; [2]Center for Immunity, Inflammation and Regenerative Medicine, Department of Pharmacology, University of Virginia, Charlottesville, VA.*

Background: The interplay of innate and adaptive immunity contributes to the pathogenesis of kidney IRI. Type I interferons (IFN-a and b) produced from plasmacytoid dendritic cells (pDC) and known for their role in viral immunity. In this study, we investigated the function of type I IFNs and pDC in kidney ischemia-reperfusion injury (IRI).

Methods: Real-time PCR, FACS and HE staining were used in this study.

Results: IFN-b mRNA increased in kidney as early as 2 hrs during the 24 hr reperfusion period and peaked at 6 hrs (20 fold, P<0.01 compared to sham). Neutralization antibodies for IFN-a or IFN-b (50 μg/mouse) given 18 hrs prior to IRI reduced plasma creatinine compared with isotype control antibody treated mice [37% or 29% % of control](P all <0.05). Gating on the $CD45^{+}7AAD^{-}$ live kidney leukocytes, a significant increase in the number of $CD11c^{+}B220^{+}$ pDC measured by FACS in kidney after IRI compared with sham (P<0.05). To test the role of pDC in kidney IRI inflammation, monoclonal anti-PDCA-1 (Miltenyi Biotec) or anti-pDC/IPC (120G8.04, IMGENEX) antibodies (50 μg) were used to deplete pDC prior to kidney IRI. pDC-depleting antibodies prevented the rise in plasma creatinine following IRI that was observed with isotype control antibody (15% or 27% of control; P all <0.05). To further elucidate the role of type I IFNs in kidney IRI inflammation, $IFNaR^{-/-}$ mice were subjected to kidney IRI. Plasma creatinine in $IFNaR^{-/-}$ mice after IRI was 44% of WT mice (P<0.05) and kidney morphology was preserved. The adenosine A2a receptor (adora2a) agonist, ATL313, administered 18 hrs prior to kidney IRI led to marked kidney protection and reduction of kidney IFN-b mRNA.

Conclusions: We conclude that pDC and/or type I IFN contribute importantly to the pathogenesis of kidney IRI and that targeting this pathway with adora2a agonists may offer a unique and potent strategy to attenuate kidney IRI.

Identification of a Novel Hypoxia-Inducible Factor 1 (HIF-1) Regulator, CCAAT/Enhancer-Binding Protein Delta (CEBPD) in Kidney Disease

Junna Yamaguchi,[1] Tetsuhiro Tanaka,[2] Nobuaki Eto,[1] Takamoto Ohse,[1] Takehiko Wada,[1] Reiko Inagi,[1] Masaomi Nangaku.[1] *[1]Division of Nephrology and Endocrinology, University of Tokyo; [2]Division for Health Service Promotion, University of Tokyo.*

Background: HIF-1 plays a critical role in tubular cells of both acute and chronic ischemic kidney. Given an important role of HIF in kidney diseases, we aimed to identify a novel gene involved in regulation of HIF-1.

Methods: Microarray analysis of the renal cortex of rat renal artery stenosis (RAS) model (day3 and day7) was used as in vivo screening for potential HIF-1 regulating genes. HeLa cells transfected with shRNA plasmids against continuously regulated genes in RAS kidney compared with sham kidney were evaluated for potency of HIF-1 regulation. Acute and chronic rat ischemic models were analysed for this gene's expression to localize and identify its role in kidney. To confirm its HIF-1 regulation in cultured human renal tubular cells, we performed knockdown and overexpression experiments in HK-2 cells.

Results: 150 genes were extracted from microarray analysis. shRNA library screening revealed CEBPD as the most promising HIF-1 upregulator. CEBPD is a transcription factor involved in regulation of inflammatory responses. In vivo, CEBPD's mRNA was upregulated in the cortex of RAS, 5/6 nephrectomy, ischemia reperfusion injury, and cisplatin nephrotoxicity. Immunohistochemistry clarified its prominent expression in the nuclei of tubular cells of S3 segment, the most hypoxic portion in ischemic renal injury. In HK-2 cells, hypoxia augmented CEBPD protein expression via HIF-1 independent pathway, and siRNA-mediated knockdown of CEBPD resulted in downregulation of HIF-1α protein expression, target genes of HIF-1, and hypoxia- response element (HRE) reporter activity. HIF-1 was regulated at transcription level.

Conclusions: These results altogether demonstrate that CEBPD is a novel HIF-1 upregulator in kidney. We also identified CEBPD's expression profile in various kidney disease models. CEBPD is likely to contribute to protection of tubular cells from its injury through HIF-1, which can be a therapeutic approach for kidney diseases, especially under co-existing condition of ischemia and inflammation.

HIF-1 in Myeloid Cells Is Protective in Acute and Chronic Kidney Injury
Alexander Weidemann,[1] Joanna Kalucka,[1] Gunnar Schley,[1] Bernd Klanke,[1] Jonathan Jantsch,[2] Susanne Olbrich,[1] Jasmin Baumgartl,[1] Kerstin U. Amann,[3] Kai-Uwe Eckardt.[1] *[1]Nephrology and Hypertension, University of Erlangen-Nuremberg, Erlangen, Germany; [2]Microbiology, University of Erlangen-Nuremberg, Erlangen, Germany; [3]Nephropathology, University of Erlangen-Nuremberg, Erlangen, Germany.*

Background: Apart from tubular damage, acute (AKI) and chronic kidney injury (CKI) triggers an inflammatory cell response. HIF-1 is central for the adaptation to low oxygen conditions and also critical for inflammatory macrophage responses. Stabilization of HIF-1 is protective in models of AKI and CKI, however the contribution of HIF-1 in inflammatory cells is still unclear. To assess the specific role of myeloid HIF, we used a genetic model of HIF-1 deletion in myeloid cells in models of both, AKI and CKI. Moreover, in a model of CKI, wt and HIF-1ko mice were treated with a PHD-inhibitor to assess whether HIF in inflammatory cells is necessary to confer protection.

Methods: LysM-Cre mice were used to specifically delete HIF-1 in myeloid cells. AKI was induced by bilateral clamping for 30min. CKI was induced by feeding an adenine- rich diet for 3 wks. PHD-inhibitor was administered daily during the adenine diet.

Results: Deletion of HIF-1 in myeloid cells significantly impares recovery after AKI. Acute tubular necrosis is increased, influx of inflammatory cells is accelerated and tubular regeneration reduced. HIF-1 ko mice also exhibit a significantly impared renal function in CKI. Inflammatory and fibrotic genes are upregulated, however with no difference between genotypes. Adenine induced renal failure is ameliorated by concomittant administration of a PHD-inhibitor with significant reduction of creatinine levels. Surprisingly, renal function is not different between PHD-I treated wt and HIF-1ko mice, and inflammation is similarily reduced in both genotypes.

Conclusions: Loss of myeloid HIF-1 is detrimental in AKI and CKI in mice, suggesting a protective role for HIF in these models. Treatment of CKI with HIF-stabilizers is beneficial, however protection is independent of myeloid HIF-1. These data suggest that PHD-inhibition exerts its protective effects in cells other than myeloid cells, or might act HIF-independetly.

FR-PO470

Glomerular Expression of Chemokines and Proinflammatory Cytokines in an Experimental Model of Anti-Neutrophil Cytoplasmic Autoantibody Associated Glomerulonephritis
Go Kanzaki, Akira Shimizu, Shinya Nagasaka, Seiichiro Higo, Takatsugu Iwashita, Yukinari Masuda. *Department of Analytic Human Pathology, Nippon Medical School, Bunkyo-ku, Tokyo, Japan.*

Background: Myeloperoxidase (MPO)-anti-neutrophil cytoplasmic autoantibody (ANCA) associated glomerulonephritis (GN) is characterized by necrotizing and crescentic glomerular lesions with leucocyte infiltration. Chemokines and their receptors participate in leukocyte infiltration, which play an important role in the pathogenesis of glomerular injury. However, their expression pattern and function in the early phase of MPO-ANCA necrotizing and crescentic glomerulonephritis remain to be fully elucidated. In the present study, we analyzed gene expression of chemokines and proinflammatory cytokines (namely CCL2, CCL3, CCL20, CXCR1, CXCR2, CXCR8, TNFα, IFNγ, IL-1β, IL-6, IL-17, IL-21, and IL-23) in MPO-ANCA associated GN using an experimental rat model by generation of an immune response to exogenously administered human MPO in adjuvant.

Methods: Necrotizing and crescentic GN was induced in WKY rat by immunization with human MPO (1600 μg/kg or 800μg/kg prime/boost combination). Blood and urine samples were obtained at every week. Quantitative RT-PCR was used to determine gene expression of chemokines and proinflammatory cytokines were analysed in isolated glomeruli in 8 weeks after NCGN induction.

Results: Hematuria (3+) and proteinuria (1000mg/dl) were noted at 4 weeks. hMPO-immunized rats had anti hMPO titers of 1:800 by ELISA. Renal pathology showed GN with elastase+ neutrophil and CD68+ macrophage infiltration in glomeruli. Necrotizing glomerular lesions were mainly constituted with fibrin exudation, infiltration of neutrophils and macrophages, and extracapillary cellular crescents. Several chemokines and proinflammatory cytokines, which are mainly involved in neutrophils and macrophages infiltration, were induced or up-regulated.

Conclusions: This study revealed that expression levels of various chemokines and proinflammatory cytokines were increased in the early phase of MPO-ANCA associated GN. These chemokines provide new insights into the epigenetic factors responsible for crescent formation.

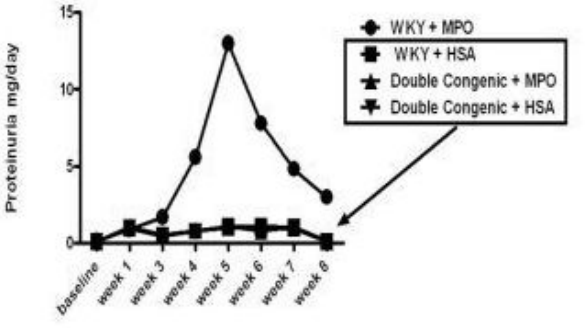
FR-PO471

Genetic Susceptibility in Experimental Autoimmune Vasculitis
John P. McDaid,[1] Anisha Tanna,[1] Gurjeet Bhangal,[1] Mark A. Little,[2] Jacques Behmoaras,[1] H. Terence Cook,[1] Charles D. Pusey,[1] Frederick W.K. Tam,[1] Alan D. Salama.[3] *[1]Renal and Transplant Institute, Imperial College, London, United Kingdom; [2]Centre for Nephrology, Trinity College Dublin, Ireland; [3]Centre for Nephrology, University College London, United Kingdom.*

Background: We have developed an experimental model of ANCA associated vasculitis (EAV), in the Wistar Kyoto (WKY) rat that recapitulates human disease. We have previously shown, using a nephrotoxic nephritis model (NTN) in the genetically susceptible WKY rat and compared it with the resistant Lewis strain, that a number of quantitative trait loci (QTL) are important in the pathogenesis of Glomerulonephritis (GN). Congenic strains, using these QTL, were subsequently generated and these animals used to examine their role in EAV. **Aim: To investigate whether EAV susceptibility in WKY rats is determined by QTLs Crgn1/2.**

Methods: Groups of wildtype WKY and double congenic (DC) WKY animals (WKY with QTLs from the Lewis strain) were immunised with myeloperoxidase (MPO) or human serum albumin in Freund's complete adjuvant. Rats were given pertussis toxin on day(s) 0, 2. Weekly urine collections were taken and disease assessed by quantifyng haematuria, proteinuria and by histology.

Results: MPO treated wildtype WKY rats strongly positive (+++) or (++) for haematuria (dipstick) through weeks 3-8. Haematuria was not detectible in either the control group or in any (DC) WKY animals. Proteinuria was also apparent in the MPO treated wildtype WKY group by week 3, this increased to a peak at week 5 before (Fig 1) before decreasing through weeks 6-8. Proteinuria was not detected in control groups or (DC) WKY animals. Abnormal glomeruli were found only in MPO treated WKY animals. Also, all MPO treated groups produced equivalent ANCA autoantibody titres.



Conclusions: These novel findings demonstate that genes located in these QTLs are important in the pathogenesis of EAV.

FR-PO472

Leukocyte and Serum Calprotectin Expression Reflect Disease Activity in ANCA Associated Vasculitis
Ruth J. Pepper,[1] Sally Hamour,[2] Hsu-han Wang,[1] Niels Rasmussen,[3] Charles D. Pusey,[2] H. Terence Cook,[2] Alan D. Salama.[1] *[1]Centre for Nephrology, UCL, United Kingdom; [2]Imperial College London, United Kingdom; [3]Autoimmune Serology, Statens Seruminstitut, Denmark.*

Background: Calprotectin (MRP8/14), a TLR4 agonist, expressed in neutrophils, monocytes and infiltrating macrophages, is pro-inflammatory. We have previously shown patients with active renal ANCA associated vasculitis (AAV) have elevated serum levels, and calprotectin deficient (Cal-/-) mice are protected from nephrotoxic nephritis (NTN). We now correlate renal biopsy calprotectin expression with the Berden classification of AAV (therefore outcome), we correlate serum calprotectin expression and relapse in patients with early systemic AAV, and demonstrate abnormalities in neutrophil and monocyte calprotectin surface expression. Finally we explore the interaction of calprotectin with isolated kidney endothelial cells (EC).

Methods: We performed immunohistochemistry on renal biopsies. Serum calprotectin levels were measured by ELISA, and correlated with disease parameters, cell surface expression was assessed by flow cytometry. Accelerated NTN was performed on wild-type (WT) and Cal-/- mice with LPS given during induction. EC were isolated by positive magnetic bead selection from kidneys.

Results: Patients with focal and crescentic glomerular lesions demonstrated the most calprotectin, sclerotic the least ($p<0.05$), linking calprotectin expression with disease activity. In limited systemic disease, calprotectin levels assessed at 1 and 6 months following treatment predict relapse, as shown by ROC (>626 ng/ml at 1 month [sensitivity 78.6%, specificity 92.3%], at 6 months >454 ng/ml [sensitivity 78.6%, specificity 92.3%]. Patients had higher monocyte and neutrophil cell surface calprotectin expression than healthy controls during active and convalescent disease. When given LPS, Cal-/- mice had similar renal disease to WT. Stimulation of primed TLR4-expressing EC with calprotectin increased IL-8 production.

Conclusions: Serum calprotectin is a potential biomarker in patients with AAV predicting future relapse, with glomerular calprotectin representing acute lesions. Calprotectin contributes to inflammation and glomerulonephritis.

FR-PO473

ADAM17 Is Increased in Granulomatosis with Polyangiitis and Contributes to Endothelial Inflammation
Torsten Kirsch,[1] Anna Bertram,[1] Svjetlana Lovric,[1] Joon-Keun Park,[1] Jan U. Becker,[2] Marion Haubitz,[3] Hermann G. Haller.[1] *[1]Nephrology, Hannover Medical School, Hannover, Germany; [2]Pathology, Hannover Medical School, Hannover, Germany; [3]Nephrology, Klinikum Fulda, Fulda, Germany.*

Background: Shedding of membrane proteins like L-selectin (L-Sel), IL-6 receptor or VE-cadherin (VEC) by ADAM proteases is a hallmark of vascular inflammation. ADAM17 is described as the prototype of ADAMs and aggravates vascular inflammation by modulating both innate and acquired immune responses. Granulomatosis with polyangiitis

(GPA) is characterized by increased serum level of ADAM17 substrates like TNF-alpha, sIL-6R or sL-Sel. Therefore, this study aimed to analyze ADAM17 expression in GPA.

Methods: We established an ADAM17-specific ELISA and determined serum ADAM17 levels of active GPA patients and patients with IgA nephropathy or membranous glomerulonephritis (disease controls). ADAM17 whole blood transcript amounts as well as protein distribution in serum samples and kidney biopsy sections were determined by real-time qPCR, immunoblotting and immunohistochemistry. In vitro, endothelial cells (ECs) were exposed to rhADAM17 and alterations in paracellular permeability, junction architecture and release of sVE-Cadherin were analyzed.

Results: Serum ADAM17 levels were highly increased in GPA patients compared to disease controls or healthy individuals. Concordantly, ADAM17 mRNA amounts were significantly upregulated in GPA whole blood samples. Immunoblotting demonstrated that serum-derived ADAM17 exhibited the same molecular size than ADAM17 extracted from tissue lysates. In kidney sections from GPA patients ADAM17 could be localized to matrix deposits whereas in disease controls ADAM17 showed an endothelial staining pattern. In vitro, exposure to rhADAM17 induced enhanced paracellular permeability and shedding of sVE-Cadherin as well as disassembly of intercellular junctions in ECs.

Conclusions: ADAM17 could be detected in serum samples and was highly increased in GPA compared to renal diseases without endothelial involvement. In vitro studies suggest that sADAM17 aggravates the inflammatory response. These data warrant further studies to examine the benefit of ADAM17 inhibition in vascular disorders.

FR-PO474

Subtle Changes in the Glomerular Endothelial Glycocalyx Do Not Lead to Albuminuria but Decrease the Glomerular Leukocyte Influx during Experimental Glomerulonephritis Angelique Rops,[1] Markus Alexander Loeven,[1] Jo H.M. Berden,[1] Ton J. Rabelink,[2] Jeffrey D. Esko,[3] Johan Van der Vlag.[1] *[1]Dept. of Nephrology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [2]Dept. of Nephrology, Leiden University Medical Centre, Leiden, Netherlands; [3]Dept. of Cellular & Molecular Medicine, University of California, San Diego, CA.*

Background: Proteinuria is manifested in a range of glomerular diseases. Proliferative glomerulonephritis is characterized by glomerular leukocyte influx. The glycocalyx is an endothelial layer consisting of complex polysaccharides, of which HS is the major constituent. HS consists of repeating GlcNAc-GlcA disaccharide units and is extensively modified by a multitude of enzymes of which N-deacetylase-N-sulfotransferase-1 (NDST-1) facilitates the initial modification. The function and structure of the glomerular endothelial glycocalyx is largely unknown. Here, we evaluated the effects of a modified glycocalyx on albuminuria and glomerular leukocyte influx using mice deficient in endothelial and leukocyte NDST-1.

Methods: Albuminuria, plasma creatinine, glomerular leukocyte influx, histology and glomerular HS expression were determined before and after anti-GBM nephritis induction. Leukocyte adhesion was evaluated i*n vitro* using mouse glomerular endothelial cells (mGEnC) with reduced NDST-1 expression and HS-deficient granulocytes.

Results: Glomerular expression of the specific HS domain GlcNS6S-IdoA2S-GlcNS6S was significantly decreased in NDST-1-/- mice corresponding to an altered glomerular mRNA expression of HS. The NDST-1-/- mice showed no albuminuria. However, glomerular leukocyte influx was significantly reduced in NDST-1-/- mice during anti-GBM nephritis, which was accompanied by a decreased glomerular expression of inflammatory HS domains. The NDST-1-/- mice showed lower plasma creatinine levels and less glomerular injury during anti-GBM nephritis. Finally, the *in vitro* leukocyte adhesion assay showed a decreased adhesion of granulocytes upon NDST-1 silencing in mGEnC.

Conclusions: A subtle modulation of the endothelial glycocalyx does not lead to albuminuria but significantly ameliorates anti-GBM nephritis by reduced glomerular leukocyte influx.

FR-PO475

Effect of Aliskiren on Renal Inflammation and (Pro)renin Receptor in Crescentic Glomerulonephritis Maki Urushihara,[1] Yukiko Kinoshita,[1] Shuji Kondo,[1] Ariunbold Jamba,[1] Takashi Nagai,[1] Toshiaki Tamaki,[2] Shoji Kagami.[1] *[1]Department of Pediatrics, Tokushima University, Tokushima, Japan; [2]Department of Pharmacology, Tokushima University, Tokushima, Japan.*

Background: Crescentic glomerulonephritis (GN) is characterized by severe infiltration of massive inflammatory cells into glomeruli and crescent formation. Although renin angiotensin system (RAS) is the key player in renal injury, the impact of aliskiren on glomerular crescent formation is not elucidated yet.

Methods: To examine whether aliskiren ameliorate renal injury in crescentic GN, we investigated renal injury induced by anti-glomerular basement membrane (GBM) antibodies in Wistar Kyoto rats treated with aliskiren. In addition, using cultured glomerular mesangial cell (MCs) and parietal epithelial cell (PECs), we examined whether recombinant renin could induce monocyte chemoattractant protein-1 (MCP-1) and cell proliferation, respectively.

Results: An anti-GBM nephritis model developed progressive proteinuria and glomerular crescent formation, accompanied by increased MCP-1 and (pro)renin receptor. Interestingly, (pro)renin receptor expressed strongly in the crescent formation area in diseased glomeruli. Proteinuria was significantly reduced by the treatment of aliskiren. Then, aliskiren markedly ameliorated renal injury (% glomerular crescent: 26.0 +/- 1.7 %) compared to vehicle treatment (59.6 +/- 3.6 %). Excretion of urinary protein in a group of rats treated with aliskiren (37.8 +/- 9.5 mg/day) were significantly reduced compared to vehicle-treated rats (128.0 +/- 16.3 mg/day). Aliskiren treatment markedly decreased MCP-1 and (pro)renin receptor mRNA levels in the diseased kidney, measured by quantitative real-time PCR analysis. Next, primary cultured MCs stimulated by recombinant renin showed significant increases of MCP-1 mRNA expression. Furthermore, primary cultured PECs showed an increase in recombinant renin-induced cell proliferation.

Conclusions: These data suggest that therapeutic strategy of aliskiren may prove beneficial for crescentic GN by the suppression of the RAS activation and the decrease of inflammation and cell proliferation in glomerular crescent via (pro)renin receptor.

FR-PO476

Toll Like Receptor (TLR) Signaling Is Required for Induction of Experimental Autoimmune Glomerulonephritis (EAG) in CD1 Mice Jitendra K. Gautam, Anjana Gevaria, Kline Bolton. *Department of Medicine, Division of Nephrology and Center for Immunity, Inflammation and Regenerative Medicine, Universtity of Virginia Health System, Charlottesville, VA.*

Results: A single immunization of CD1 mice with recombinant col4α3(IV)NC1 emulsified in complete Freund's adjuvant (CFA-H37Ra) results in the development of EAG. Disease is characterized by heavy albuminuria starting at 4-6 weeks that progresses during the course of the experiment. At sacrifice, mice have abdominal inflammation, fluid accumulation and enlarged spleen and lymph nodes. Most mice show grossly visible kidney damage at 12 weeks. Kidney H&E analysis shows glomeruloneohritis and glomerular sclerosis with infiltration of lymphocytes. By immunofluorescence there is linear IgG deposition on the glomerular basement membrane (GBM). Subclasses IgG1, IgG2a and IgG2b are equally distributed. Kidneys have higher MHC class II expression and infiltration of CD4 T cells, macrophages and dendritic cells.

We hypothesized that EAG in CD1 mice could be induced by synthetic TLR ligands acting as infection mimetics. We tested four TLR agonists with specific signaling pathways: PAM_3CSK_4 (TLR1/2) as a Gram positive infection mimetic, poly IC(TLR3) as a viral infection mimetic, bacterial *lipopolysaccharide* (LPS)(TLR4) as a Gram negative infection mimetic and CpG oligos(TLR9) as unmethylated bacterial DNA. We found that EAG in CD1 mice could be induced with individual TLR agonists. Each TLR agonist's ability to induce EAG differed. PAM_3CSK_4 induced severe EAG followed by poly IC and CpG oligos. EAG in these animals had a comparable course to CFA induced EAG, albeit with a lower overall intensity. LPS did not induce significant EAG but mice still developed linear deposition of IgG on the GBM. Control mice immunized with recombinant col4α3(IV) NC1 in saline did not develop albuminuria or cellular infiltration in the kidney but had linear IgG deposition on the GBM.

Conclusions: These results demonstrate a differential role of TLR stimulation in the development of EAG in CD1 mice. Experiments are underway to understand these differences and what role individual TLR signaling pathways may play in this model.

Kidney Endothelium-Specific Knockdown of Stanniocalcin-1 Aggravates Anti-GBM Glomerulonephritis Luping Huang,[1] Jie Du,[1] Pumin Zhang,[2] David Sheikh-Hamad,[1] Tatiana Belousova.[1] *[1]Medicine, Baylor College of Medicine, Houston, TX; [2]Molecular Physiology and Biophysics, Baylor College of Medicine, Houston, TX.*

Background: Inflammatory cells (macrophages, T-cells and neutrophils) play critical roles in anti-GBM GN. Stanniocalcin-1 (STC1) inhibits macrophages (leukocyte Biology, 2009); stabilizes endothelial barrier function (ATVB, 2008), and diminishes trans-endothelial migration of leukocytes (AJP-Renal, 2007). Transgenic overexpression of STC1 protects from anti-GBM GN in mice (Am. J. Pathol., 2009). In the following experiments, we sough to determine the contribution of endothelium-mediated effects by STC1 – to protection from anti-GBM GN.

Methods: We employed two powerful and innovative approaches to address the above question: 1) we generated STC1 shRNA Tg mice that express STC1 siRNA conditionally upon removal of floxed reporter stuffer (PGK-driven EGFP), bringing the H1 promoter ahead of the siRNA cassette; 2) using ultrasound microbubble-mediated delivery of Tie2-Cre to the kidney we were able to knockdown the expression of STC1 in kidney endothelial cells in STC1 shRNA Tg mice (within 3-5 days), but not in scrambled shRNA Tg mice.

Results: Applying anti-GBM GN to STC1 shRNA and scrambled shRNA Tg mice 3 days after the delivery of Tie2-Cre to the kidney using ultrasound microbubble-mediated gene delivery confirmed endothelium-specific knockdown of STC1 in STC1 shRNA Tg mice, and revealed worse anti-GBM GN [vacuolization and epithelial cell sloughing, tubular dilatation and cast formation, greater number of crescents, higher creatinine].

Conclusions: These observations suggest that endothelium-mediated effects of STC1 play an important role in preventing anti-GBM disease and suggest that systemic delivery of STC1 may be a viable therapeutic option for kidney inflammation.

Role for CD4-Lymphocyte Specific NEMO or IKKbeta Deletion in an Experimental Model of Rapid Progressive Glomerulonephritis

Eveline Piella,[1] Linlin Guo,[1] Anna Hermann,[1] Hans-Joachim Paust,[1] Sebastian Braehler,[2] Paul T. Brinkkoetter,[2] Gunther Zahner,[1] Friedrich Thaiss.[1] *[1]Univ. Hospital UKE, III. Medical Department, Hamburg, Germany; [2]Univ. Hospital Cologne, II. Medical Department, Cologne, Germany.*

Background: Nephrotoxic serum nephritis (NTN), a T-cell mediated disease induced in mice serves as a model of human rapid progressive glomerulonephritis. Engagement of the T-cell receptor (TCR) by antigen leads to intracellular signaling events causing activation of transcription factors, such as NF-kappa B. We now examined ablation of IKK2 or NEMO specifically in T-cells in NTN.

Methods: T-cell specific ablation of IKK2 or NEMO was achieved through deletion of $IKK2^{fl/fl}$ or $NEMO^{fl/fl}$ alleles by Cre -recombinase expression under control of the $CD4^{cre}$ transgene. NTN-antiserum was injected and functional and histopathologic parameters were determined during a 10 observation period. T cells infiltrating into the kidney were quantitated by immuno-histochemistry and FACS-analysis and kidney chemokine expression was determined by RT-PCR.

Results: Nephritic $CD4^{Cre}IKK2^{fl/fl}$ and $CD4^{Cre}NEMO^{fl/fl}$ mice had an increase in albumin/creatinine-ratio and glomerular crescents ($p<0.01$) at day 10 although the total number of CD4 lymphocytes was reduced in the kidneys. Further analysis showed significantly reduced Tregs in $CD4^{Cre}IKK2^{fl/fl}$ and $CD4^{Cre}NEMO^{fl/fl}$ animals. $CD4^{Cre}IKK2^{fl/fl}$ furthermore showed a higher infiltration of IFN-γ producing Th1-cells when compared with control nephritic mice. Renal expression of cytokines and chemokines was not changed in $CD4^{Cre}IKK2^{fl/fl}$ mice when compared with NTN-controls, however, significantly increased ($p<0.05$) in $CD4^{Cre}NEMO^{fl/fl}$ mice while CCL5 expression was selectively and significantly reduced when compared with NTN-nephritic controls.

Conclusions: Our data demonstrate that ablation of IKK2 or NEMO specifically in $CD4^{+}$T-cells significantly reduced the number of Tregs in kidneys after NTN-induction. Differential regulation of cytokine expression in $CD4^{Cre}IKK2^{fl/fl}$ when compared with $CD4^{Cre}NEMO^{fl/fl}$ mice might reflect further differences in T-cells infiltrating the kidney and point out differential regulation of $CD4^{+}$T-cells via IKK2 and NEMO.

Pirfenidone Inhibits Macrophage Infiltration in 5/6 Nephrectomized Rats

Junfeng Chen, Haifeng Ni, Bi-Cheng Liu. *Institute of Nephrology, Zhong Da Hospital, Southeast University School of Medicine, Nanjing, Jiangsu, China.*

Background: Macrophage infiltration is involved in the progression of chronic kidney disease(CKD). Pirfenidon as an anti-fibrotic drug is impliacted in the treatment of CKD. This study was to investigate the effects of pirfenidone on M1/M2 Macrophage infiltration in nephrectomized rats.

Methods: Male SD rats underwent a five-sixths nephrectomy. Nephrectomized rats were treated with pirfenidone by gavage for 12 weeks. 24-h urinary protein, NAG activity, Systemic blood pressure(SBP) and CRP were determined. Paraffin-embeded sections were immunohistologically stained for CD68(macrophages)-, CCR7(M1 macrophages)- and CD163(M2 macrophages)-positive cells. MCP-1 and *macrophage inflammatory protein-1α(* MIP-1α) as well as M1 and M2 macrophages secretory proteins were evaluated by Western blotting analysis.

Results: pirfenidone significantly improved the elevated proteinuria and *NAG activity* from 2 to 12th week after surgery(*$p<0.05$).* SNx rats presented with a significant increase of SBP from the 6th week onward, while there was no significant change for SBP in pirfenidone treatment group compared to the control. Pirfenidone attenuated interstitial fibrosis in the cortex and decreased the infiltrating macrophages significantly($p<0.05$). The number of M1 and M2 macrophages were significantly lower after pirfenidone treatment($p<0.05$). the protein expressions of MCP-1 and MIP-1α were increased in rats of control group. Pirfenidone treatment significantly decreased their expressions ($p<0.05$). TNF-α, IL-6 and Nitric oxide synthases 2(iNOS) expressed by M1 macrophages were increased in nephrecomized rats, and Pirfenidone reduced their expressions significantly($p<0.05$). Pirfenidone treatment also significantly decreased Dectin-1 and arginase-1 expressed by M2 macrophages ($p<0.05$).

Conclusions: Pirfenidone attenuates inflammation and inhibits M1 and M2 macrophage infiltration in 5/6 nephrectomized rats, which offers a new insight into the role of pirfenidone in treatment of CKD.

Murine Double Minute (MDM)-2 Mediates Podocyte Loss, Proteinuria, and Subsequent Tubular Injury and Interstitial Fibrosis in Progressive Focal-Segmental Glomerulosclerosis

Shrikant R. Mulay, Dana Thomasova, Mi Ryu, Onkar Kulkarni, Regina Groebmayr, Hans J. Anders. *Klinische Biochemie, Ludwig Maximillians University, Munich, Germany.*

Background: Murine double minute (MDM)-2 is a cytoplasmic molecule with p53-dependent mitogenic effects during development and tumor cell growth. We recently described that this mitogenic effect also contributes to tubular repair after acute tubular necrosis. In addition we found that MDM-2 has p53-independent nuclear factor-κB agonistic effect that promotes tubulointerstitial inflammation. Since we noticed prominent MDM-2 expression also in podocytes and parietal epithelial cells, we hypothesized that MDM-2's mitogenic and pro-inflammatory effects also contribute to glomerular pathology, e.g. to adriamycin-induced glomerulosclerosis in Balb/c mice.

Methods: Balb/c mice were procured from Charles River, Germany. All experimental procedures were approved by the local government authorities. Adriamycin (13mg/kg) and Nutlin 3a (20mg/kg) were injected *i.p.* Immunostainings were used for analysing kidney pathology.

Results: After onset of the early glomerular injury phase MDM-2 blockade with nutlin 3a significantly reduced intrarenal cytokine and chemokine expression, glomerular macrophage and T cell recruitment, segmental and global glomerular lesions as well plasma creatinine which correlated with higher podocyte numbers in affected glomeruli. Early MDM-2 blockade had no effect on proliferating parietal epithelial cells. In other mice MDM-2 blockade was initiated only after 2 weeks for 14 days to cover the phase of disease progression, tubular atrophy, interstitial inflammation and fibrosis. MDM-2 blockade significantly improved all these parameters together with a significant reduction in plasma creatinine but without affecting glomerular lesions, proteinuria or tubular cell proliferation.

Conclusions: Together, MDM-2 mediates podocyte loss, proteinuria, and subsequent tubular injury and interstitial fibrosis in progressive glomerulosclerosis, hence, MDM-2 blockade might be suitable therapeutic strategy to prevent the progression of glomerulosclerosis and other disorders that involve nuclear factor-κB-dependent renal inflammation.

CD36 Knockout Mice Are Protected from Chronic Kidney Disease Progression after 5/6 Nephrectomy with Angiotensin II Infusion

Ana Carolina Souza, Yuning George Huang, Xuzhen Hu, Alexander V. Bocharov, Alejandro Alvarez-Prats, Shokhi Goel, Thomas L. Eggerman, Robert A. Star, Peter S.T. Yuen. *NIH, Bethesda, MD.*

Background: The class B scavenger receptor CD36 is important in lipid metabolism, inflammation and atherosclerosis. We recently discovered that CD36 knockout (KO) mice are protected from sepsis-induced acute kidney injury and systemic inflammation. Bacteria can also enter cells via CD36. The role of CD36 in chronic kidney disease (CKD) is unknown, but CD36 expression is up-regulated in blood monocytes of dialysis patients, and soluble plasma CD36 is increased in advanced CKD patients. We aimed to study the role of CD36 on CKD progression.

Methods: We compared CKD progression in CD36 KO vs. WT mice (C57BL6 background) using a 5/6 nephrectomy (Nx) model with angiotensin II (AngII, osmotic mini pump 0.75 μg/Kg/min) for 4 weeks. WT 5/6 Nx mice without AngII infusion did not progress to CKD and were used as controls. BUN was measured colorimetrically, Scr by HPLC. Albumin, HMGB1 and IL-6 were measured by ELISA. We used Masson's trichrome and PAS staining to detect interstitial fibrosis and glomerulosclerosis, respectively. Spleen apoptosis was measured by immunohistochemical staining with anti-active caspase-3 antibody. Mean Arterial Pressure (MAP) was measured by radiotelemetry. ANOVA/post hoc was used for statistical analysis.

Results: Kidney function was protected in KO mice (BUN control 95±9, WT 187±36 and KO 119±16 mg/dl; Scr control 0.33±0.32, WT 0.64±0.13 and KO 0.38±0.04 mg/dl, $p<0.05$). KO had less albuminuria than WT mice ($p<0.0001$), glomerulosclerosis score (control 1.8±0.2, WT 3.6±0.3 and KO 2.3±0.2, $p<0.0001$), interstitial fibrosis score (control 1.2±0.2, WT 3.0±0.5, KO 1.8±0.3, $p<0.01$) and weight loss (control -2.9±0.6, WT -8.5±1.8, KO -3.8±0.8 g, $p<0.01$). IL-6 and HMGB1 levels and baseline blood pressure were not different between KO and WT. Spleen apoptosis was not different between the groups.

Conclusions: CKD progression is impaired in CD36 KO mice in a 5/6 nephrectomy + AngII infusion model. The mechanism of protection does not appear to be a global reduction of inflammation as the acute inflammatory cytokines tested were not different in CD36KO.

Prevention of Chronic Kidney Disease Progression after 5/6 Nephrectomy in TLR4 Mutant Mice C3H/HeJ

Ana Carolina Souza,[1] Takayuki Tsuji,[1,2] Xuzhen Hu,[1] Alejandro Alvarez-Prats,[1] Shokhi Goel,[1] Robert A. Star,[1] Peter S.T. Yuen.[1] *[1]NIDDK, NIH, Bethesda, MD; [2]1st Department of Medicine, Hamamatsu University School of Medicine, Japan.*

Background: Chronic inflammation is closely linked to several complications of chronic kidney disease (CKD) and predicts CKD progression and mortality. The impact of innate immunity on CKD are largely unknown. Toll-like receptors (TLRs) recognize pathogen associated molecular patterns; TLR4 is the major signaling receptor for endotoxin (lipopolysaccharide) and recognizes host-derived DAMP ligands such as HMGB1.

Methods: We used 5/6 nephrectomy (Nx) to test the role of TLR4 on CKD progression in C3H/HeOuJ (TLR4+) vs C3H/HeJ (TLR4-) mice. As TLR4+ mice did not fully develop CKD by 8 weeks, we infused a low dose (0.0625 μg/Kg/min) of angiotensin II (AngII) by osmotic mini-pump for 4 weeks after 5/6 Nx. BUN was measured colorimetrically; Scr by HPLC; albumin, HMGB1 and IL-6 by ELISA. We stained kidney sections with Masson's trichrome and PAS. Spleen apoptosis was measured by anti-active caspase-3 immunohistochemistry. Student's t-test or ANOVA were used for statistics and log-rank test for survival analysis.

Results: 4 weeks after 5/6 Nx with AngII infusion, TLR4+ mice developed severe kidney dysfunction. Kidney function was protected in TLR4- vs TLR4+ mice (BUN 310.3±34.1 vs 70.1±5.34 mg/dl, $p<0.0001$ and HPLC Scr 0.74±0.12 vs 0.24±0.01 mg/dl, $p<0.001$). TLR4- mice had less albuminuria ($p<0.0001$), glomerulosclerosis score (3.15±0.3 vs 1.65±0.15, $p<0.01$), interstitial fibrosis score (2.29±0.24 vs 1.3±0.09, $p<0.01$), and weight loss (Δ body weight -12.4±1.5 vs +0.09±0.33 g, $p<0.0001$) than TLR4+ mice. Mortality was higher for TLR4+ mice ($p<0.05$) and TLR4+ mice had higher heart weight/100g body

weight ratios than TLR4- (0.61±0.08 vs 0.43±0.02, p<0.05). Serum IL-6 and HMGB1 levels were not significantly different between TLR4+ and TLR4- mice. Spleen apoptosis was higher in TLR4+ mice (18.17±1.53 vs 2.17±0.29 + cells/HPF, p<0.0001).

Conclusions: We found that TLR4 plays a role in AngII-mediated amplification/progression of CKD. AngII is known to up-regulate TLR4 in kidney, but the upstream ligand and the effects on downstream signaling are unkown.

Funding: NIDDK Support

FR-PO483

High suPAR Levels in FSGS Patients Is Associated with Decreased Treg Cells Chang Yien Chan,[1] Wee Song Yeo,[1] Changli Wei,[2] Subhra K. Biswas,[3] Hui Kim Yap.[1] *[1]Pediatrics, National University of Singapore, Singapore; [2]University of Miami; [3]SIgN, A-Star, Singapore.*

Background: Immune-mediated focal segmental glomerulosclerosis (FSGS) is a common cause of end-stage kidney disease in children worldwide. Recent studies have suggested that urokinase receptor (uPAR) signaling is involved in the pathogenesis of FSGS, and that soluble uPAR (suPAR) is increased in sera of FSGS patients. This study aimed to investigate the relationship between elevated suPAR in nephrotic patients and the immune system.

Methods: Plasma suPAR was analyzed in 51 primary nephrotic patients (26 MCNS, 25 FSGS) and 24 healthy controls, using Quantikine Human uPAR Immunoassay (R&D Systems). Patients were stratified into groups I and II, according to whether they had high or low suPAR levels respectively. Peripheral blood mononuclear cells were isolated and MACS-magnetic beads (Miltenyi Biotec) were used to isolate CD4, CD8. CD19 and monocyte fractions. suPAR levels were measured in supernatents following 4-hour cell cultures. Lymphocyte subsets were analyzed by flow cytometry. Results were expressed as mean±SEM. Statistical analysis was done using Mann-Whitney test.

Results: Plasma suPAR levels in patients with FSGS (3216.8±295.2 pg/ml) were significantly higher than controls (2330.8±207.2 pg/ml) and MCNS patients in relapse (2178.9±196.7 pg/ml) and remission (2389.2±225.6 pg/ml)(p<0.02). Following cell culture, suPAR was detected in monocyte supernatants (137.3±11.8 pg/ml) but not in lymphocyte supernatants. Group I patients had significantly higher monocyte supernatant suPAR levels than Group II (166.7±29.4 pg/ml *vs* 78.4±17.4 pg/ml)(p=0.02). Additionally, Group I patients showed a significant decrease in percentage of ICOS on both $CD8^+CD3^+$ (0.61±0.09% *vs* 2.25±0.65%) and $CD4^+CD3^+$ cells (3.95±0.49% *vs* 7.45±1.40%)(p<0.05). The percentage of CD45RA on $CD25^+CD4^+CD3^+$ cells was also significantly lower in Group I patients (4.11±0.63% *vs* 8.13±1.34%)(p<0.001).

Conclusions: Monocytes appear to be the source of suPAR in patients with active FSGS and high suPAR levels was associated with decrease in Treg cells, suggesting a possible regulatory role.

FR-PO484

Monocyte Cell Death Correlates with Disease Severity in Shiga Toxin Induced Hemolytic Uremic Syndrome in Adult Patients Shuwang Ge, Barbara Hertel, Sang Hi Karen Emden, Jan Beneke, Jan Menne, Hermann G. Haller, Sibylle Von Vietinghoff. *Nephrology and Hypertension, Hannover Medical School, Hannover, Germany.*

Background: E. coli shiga toxin can induce a hemolytic uremic syndrome (STEC-HUS) that is characterized by hemolysis, intravascular micro- and macrothrombi, renal failure and various degrees of central nervous system involvement. The pathophysiology of STEC-HUS is poorly understood. Data from animal models on the role of leukocytes are controversial. We therefore investigated leukocyte cell death in vivo in adult STEC-HUS patients during acute disease and recovery and studied its association with disease severity.

Methods: Leukocyte cell death in a group of 30 adult patients treated at a tertiary care centre during the STEC-HUS outbreak in Germany in 2011 was assessed by staining for apoptotic and dead cells and multi-color flow cytometry analysis during acute disease and recovery.

Results: A significant leukocytosis was observed in STEC-HUS patients. In addition, concentrations of apoptotic and necrotic monocytes and granulocytes were significantly increased in the circulation of patients compared to healthy controls. This phenotype reverted during recovery. Monocyte apoptosis on admission was significantly higher in patients subsequently assigned to plasma exchange or admitted to the intensive care unit.

Conclusions: In STEC-HUS, elevated numbers of dead leukocytes were detected. Monocyte and granulocyte death are novel markers of acute STEC-HUS that may actively contribute to tissue destruction by liberation of pro-inflammatory enzymes and cytokines.

FR-PO485

Complement Proteins in Neutrophils: A Functional Role in Neutrophil Extracellular Trap Mediated Bacteria Clearance Joshua Yuen,[1,3] Fred G. Pluthero,[1] Walter H. Kahr,[1,2] Nades Palaniyar,[1,3] Christoph Licht.[1,2,3] *[1]Sick Kids Research Institute, The Hospital for Sick Children, Toronto, ON, Canada; [2]Paediatrics, University of Toronto, Toronto, ON, Canada; [3]Laboratory Medicine and Pathobiology, University of Toronto, Toronto, ON, Canada.*

Background: Atypical Hemolytic Uremic Syndrome (aHUS) is a severe renal disorder that is associated with mutations in genes encoding regulatory proteins of the complement alternative pathway (AP). However, clinical insight illustrates that not all carriers precipitate the disease. While cases are often preceded with an infectious episode, the role neutrophils (PMN), key effectors of innate immune and inflammatory responses, play in aHUS is not well established. We set out to characterize the interactions between the complement system and PMN to elucidate their potential pathogenic roles in aHUS.

Methods: PMN purified from human peripheral whole blood by density gradient were subjected to immunoblot analysis and confocal microscopy to identify protein constituents of the complement system. *P. aeruginosa* (mPAO1) was used for bacterial assays.

Results: We identified complement: properdin (CFP), complement factor H (CFH), complement component 3 (C3), and complement factor B (CFB) in resting PMN. Activation of PMN with Phorbal 12-myristate 13-acetate (PMA) induces the formation of neutrophil extracellular traps (NETs), a recently discovered response of PMN to trap bacteria. Activation with PMA leads to a gradual process of intracellular compartmentalized distribution of complement proteins. As the nuclear envelope disintegrates and nuclear chromatin decondenses, C3 mixes with genomic material, while CFP, CFB, and CFH remain at the periphery. When NETs are released, the complement AP proteins are found on their surface and deposited on bacteria.

Conclusions: This suggests complement AP activation on the surface of bacteria ensnared by NETs. We propose that PMN, via this mechanism, create a targeted immune response to microbes through localized activation of AP. Without proper regulation, as found in patients with mutations in the regulatory proteins of AP, this mechanism may precipitate a complement driven disease process.

Factor H and Properdin Recognize Different Epitopes on Renal Tubular Epithelial Heparan Sulfate Azadeh Zaferani,[1] Romain Vives,[2] Pieter van der Pol,[3] Gerjan Navis,[1] Mohamed R. Daha,[1,3] Cees van Kooten,[3] Hugues Lortat-jacob,[2] Marc Seelen,[1] Jacob van den Born.[1] *[1]Nephrology, UMCG, Groningen, Netherlands; [2]Institut de Biologie Structurale, Grenoble, France; [3]Nephrology, LUMC, Leiden, Netherlands.*

Background: During proteinuria, renal tubular epithelial cells become exposed to ultrafiltrate-derived serum proteins, including complement factors. Recently, we showed that properdin binds to tubular heparan sulfates (HS). We now document that factor H also binds to tubular HS, although to a different epitope than properdin.

Methods: Binding properties of HS for factor H were evaluated by using competition ELISA and Surface Plasmone resonance experiments. Factor H binding and complement activation on proximal tubular epithelial cells (PTEC) were investigated by FACS analysis.

Results: Factor H was present on the urinary side of renal tubular cells in proteinuric, but not in normal renal tissues and co-localized with properdin in proteinuric kidneys. Factor H dose-dependently bound to PTEC in vitro. Pre-incubation of factor H with exogenous heparin and pretreatment of PTECs with heparitinase abolished the binding to PTECs. Surface Plasmon resonance experiments showed high affinity of factor H for heparin and HS (KD values of 32 and 93 nM respectively). Using a library of HS-like polysaccharides, we showed that chain length and high sulfation density are the most important determinants for glycosaminoglycan-factor H interaction, and clearly differ from properdin-heparinoid interaction. Co-incubation of properdin and factor H did not hamper HS/heparin binding of one another, indicating recognition of different non-overlapping epitopes on HS/heparin by factor H and properdin. Finally we showed that certain low-anticoagulant heparinoids can inhibit properdin binding to tubular HS, with minor effect on factor H binding to tubular HS. As a result, these heparinoids can control the alternative complement pathway.

Conclusions: In conclusion, factor H and properdin interact with different HS epitopes of PTECs. These interactions can be manipulated with some low-anticoagulant heparinoids which can be important for preventing complement-derived tubular injury in proteinuric renal diseases.

FR-PO487

Anti-Aging Gene Klotho Is Essential in the Maintenance of Normal Kidney Structure and Function Zhongjie Sun. *Physiology, University of Oklahoma HSC, Oklahoma City, OK.*

Background: Klotho is a recently discovered anti-aging gene. Genetic mutation of klotho expedites the aging process and shortens the lifespan while overexpression of klotho slows down the aging process and extends the lifespan by 20%. Klotho is predominately expressed in renal distal convoluted tubule cells. The purpose of this experiment is to test our hypothesis that klotho deficiency causes glomerular and tubular damage and impairs kidney function *via* inflammation.

Methods: *In vivo* expression of klotho and IL-10 were achieved by AAV2 delivery of klotho and IL-10 genes.

Results: We found that klotho gene deficiency resulted in leukocyte infiltration in kidneys (T cells, macrophages), glomerular collapse, and tubule atrophy and dilation in KL (+/-) mice. The kidney function was impaired as evidenced by the increased creatinine in the blood. In another experiment, we silenced klotho gene in rats using KL-shRNA. In vivo silencing of klotho gene resulted in macrophage infiltration, upregulation of superoxide production, downregulation of Mn-SOD, and oxidative stress damage in kidneys. Glomerular atrophy and collapse were found in rats treated with KL-shRNA, indicating kidney damage. Interestingly, these devastating effects may be mediated by increased inflammation because they can be abolished by simultaneous over-expression of anti-inflammatory cytokine IL-10 gene. On the other hand, the klotho level was decreased while inflammation was increased in aging-related and hypertension-related kidney damages. Notably, in vivo klotho gene delivery increased the IL-10 level, suppressed superoxide levels, abolished kidney damages (glomerular collapse, tubule atrophy, protein deposition), and improved kidney function in spontaneously hypertensive rats (SHRs).

Conclusions: Therefore, klotho is essential in the maintenance of normal kidney structure and function. In vivo expression of klotho may be a novel approach to the protection of kidneys.

Klotho Attenuates Inflammation of Adipose Tissue and Development of Insulin Resistance in High-Fat Induced Obese Mice Minoru Satoh, Kengo Kidokoro, Hajime Nagasu, Chieko Ihoriya, Yuko Nishi, Hiroyuki Kadoya, Tamaki Sasaki, Naoki Kashihara. *Department of Nephrology and Hypertension, Kawasaki Medical School, Kurashiki, Okayama, Japan.*

Background: Chronic inflammation in adipocyte tissues plays a crucial role in the development of obesity-related insulin resistance, which contributes to an increased risk of hypertension, atherosclerosis, and diabetes. The enlargement of adipocytes due to impaired adipocyte differentiation leads to a chronic state of inflammation in the adipocytes. The secretion of proinflammatory cytokines mainly from macrophages enhances local inflammation. In recent years, the Wnt5a/JNK signaling pathway in adipocytes and macrophages has emerged as an important mediator of adipose tissue inflammation that affects systemic metabolism. Secreted klotho protein has been reported to inhibit Wnt signaling. Klotho, an anti-aging gene, is mainly expressed in the kidney tubules, and chronic kidney disease (CKD) patients exhibit low serum levels of klotho. Therefore, we hypothesized that CKD patients show chronic inflammation in adipose tissue due to low levels of klotho. In the present study, we examined whether the klotho protein attenuates high-fat diet–induced chronic inflammation in adipose tissue.

Methods: To determine the in vivo effects of klotho in dietary fat-induced obesity, we investigated klotho-transgenic (KLTG) mice fed with high-fat diet (HFD). Ten-week-old male C57BL/6 wild type (WT) mice and KLTG mice were fed normal fat diet or HFD for 12 weeks.

Results: HFD resulted in insulin resistance, hyperglycemia, and impaired glucose tolerance in WT mice. KLTG mice were resistant to the development of insulin resistance. This lean phenotype was associated with lower leptin and retinol binding protein 4 levels and higher glucose sensitivity than WT mice which consumed similar amounts of HFD. KLTG mice showed reduced macrophage content and an improved inflammatory profile of the adipose tissue.

Conclusions: The klotho protein controls adipose tissue inflammation and systemic insulin resistance in HFD-fed mice. Inhibition of CKD progression may be beneficial to suppress the development of insulin resistance due to obesity.

Neuroinflammation Status Plays a Role in Nephrectomy-Induced Cognitive Impairment in Rats Sabrina Degaspari,[1] Carmen B. Tzanno-martins,[2] Clarice K. Fujihara,[3] Roberto Zatz,[3] Tania Araujo Viel,[4] Carolina D. Munhoz,[1] Ana Elisa Bohmer,[1] Larissa De Sá Lima,[1] Cristoforo Scavone,[1] Elisa M. Kawamoto.[1,5] *[1]Institute of Biomedical Science, USP, SP, Brazil; [2]CINE, São Paulo, Brazil; [3]Renal Division-Departament of Clinical Medicine, USP, SP, Brazil; [4]School of Arts, Sciences and Humanities, USP, SP, Brazil; [5]Laboratory of Neurosciences, NIH, Baltimore, MD.*

Background: Renal insufficiency could impair cognitive function; chronic kidney disease (CKD) is associated with increases of the inflammatory process that might play a role in cognitive impairment (CI). The aim of this study is to evaluate if serum and cerebral spinal fluid (CSF) cytokines and corticosterone (CORT) levels correlate with cognitive deficits in 5/6 nephrectomized rats (Nx).

Methods: Wistar rats underwent 5/6 nephrectomy (Sham-operated rats as controls). After 30 days, animals were tested once a month for their cognitive status. Nx with scores 75% less than sham were included in a CI group (Nx-CI, n=12), the remaining rats constituted the Nx group. After 4 months, serum and CSF levels of interleukin-10 (IL-10), tumor necrosis factor (TNF), and CORT were measured.

Results: All Nx showed higher levels of creatinine (1.13±0.05) compared to Sham (0.65±0.05). Nx-CI showed impaired memory retention. Serum TNF (Sham=14.4±3 pg/ml*) and IL-10 (Sham=2904±602 pg/ml*) levels were lower in Nx (TNF=4.0±2 pg/ml; IL-10=321.3±54 pg/ml) and Nx-CI (TNF=4.0±2 pg/ml; IL-10=176.6±657 pg/ml), in the CSF the Nx-CI showed higher levels of TNF (17.4±3 pg/ml*) and lower levels of IL-10 (97.8±7 pg/ml*) compared with Sham (TNF=5.1±0.1 pg/ml; IL-10=888.7±298 pg/ml) and Nx (TNF=3.9±1.4 pg/ml; IL-10=48.1±29). Serum CORT levels (Sham=2680±280 ng/ml) were higher in Nx (8112±106 ng/ml*) and Nx-CI (8130±175 ng/ml*). However, CSF CORT levels were elevated only in the Nx (13052±262 ng/ml*)(*p<0.05).

Conclusions: High serum CORT levels in Nx and Nx-CI rats associated with low levels of proinflammatory cytokines, but CSF measurements indicated a specific central nervous proinflammatory response in Nx-CI rats. These results suggest that neuroinflammation may play a role in the Nx-induced cognitive impairment in CKD rats. **FINANCIAL SUPPORT**: FAPESP; CNPq; USP.

Renal Impairment Increases Aortic Antigen Presenting Cell and Lymphocyte Accumulation during Atherosclerosis Development Sibylle Von Vietinghoff,[1,2] Shuwang Ge,[1] Barbara Hertel,[1] Ekaterina Koltsova,[2] Jan T. Kielstein,[1] Klaus Ley,[2] Hermann G. Haller.[1] *[1]Nephrology and Hypertension, Hannover Medical School, Hannover, Germany; [2]Inflammation Biology, La Jolla Institute for Allergy and Immunology, La Jolla, CA.*

Background: Atherosclerosis is a major cause of death in patients with chronic kidney disease. Chronic inflammation of the arterial wall including invasion, proliferation and differentiation of leukocytes is important in atherosclerotic lesion development. While hemodynamics and mineral metabolism have been investigated in detail, how atherosclerotic inflammation is altered in renal impairment is incompletely understood. This study tested whether moderate renal impairment alters leukocyte composition in the aorta of atherosclerotic mice.

Methods: Apolipoprotein E and LDL-receptor deficient mice underwent unilateral nephrectomy or sham surgery and were maintained on high-fat diet for three, six and twelve weeks. Aortic leukocyte infiltration was determined by immunofluorescence staining and confocal microscopy and by flow cytometry of aortic single cell suspensions. Aortic leukocyte interactions were investigated by life cell multiphoton imaging of atherosclerotic aortas.

Results: A 50% reduction in renal function increased atherosclerotic lesion size and aortic leukocyte numbers in both models. The number of aortic leukocytes, among them antigen presenting cells, mostly of myeloid origin, increased significantly. Intravascular interaction of antigen presenting cells with T cells as determined by vascular wall life cell imaging and in vivo aortic T cell proliferation were significantly enhanced in renal impairment.

Conclusions: Mild renal impairment significantly increases aortic inflammatory leukocyte accumulation and antigen presentation in atherosclerosis.

FR-PO491

Kidney-Brain Crosstalk during Sepsis Misako Asada, Motoko Yanagita. *Department of Nephrology, Kyoto University Graduate School of Medicine, Kyoto, Japan.*

Background: Patients with chronic kidney disease (CKD) have a higher prevalence, severity, and mortality of sepsis. However, the mechanism that CKD influences the outcome of sepsis remains unclear. The main cause of death in septic patients is multi-organ failure, and increasing evidences support the presence of crosstalk between kidney and other distant organs via soluble and cellular inflammatory mediators. Here we investigated the influences of CKD on kidney-brain crosstalk in the context of systemic inflammation.

Methods: We divided C57BL/6J male mice (8~9week) into 4 groups: sham-operated mice injected with vehicle (sham/vehicle mice), sham mice injected with lipopolysaccharides (LPS, 2.5mg/kg BW)(sham/LPS mice), mice operated with unilateral ureter obstruction (UUO) and injected with vehicle (UUO/vehicle mice), and mice operated with UUO and injected with LPS (UUO/LPS mice). Mice were sacrificed 5 days after the operation, and organs were subjected to histological analysis and quantitative reverse transcription polymerase chain reaction (qPCR) to evaluate the expression of injury markers and inflammatory mediators.

Results: The expression of IL-6, TNF-a and MCP1 was significantly up-regulated both contralateral and diseased kidneys of UUO/LPS mice compared to the expression of UUO/vehicle mice and sham/LPS mice. Next we evaluated the damages in the brain and demonstrated that the expression of IL-6, IL-6 receptor and glial fibrillary acidic protein (GFAP), a marker for activated glial cells during brain inflammation, was significantly up-regulated in UUO/LPS mice compared to other 3 groups. Induction of GFAP was further confirmed by immunostaining. To analyze the molecular mechanism for kidney-brain crosstalk, we evaluated the expression of neuroprotective factors in the kidneys, and found that the expression of EGF and VEGF was significantly decreased in both contralateral and diseased kidneys in UUO/LPS mice compared to other 3 groups.

Conclusions: Existence of fibrotic kidneys during sepsis aggravates brain injury, possibly due to the reduced expression of neuroprotective factors in the kidneys. Further analysis of the inter-organ crosstalk will provide better insights into the link between sepsis and CKD.

FR-PO492

Stat3 Is Involved in Indoxyl Sulfate-Induced Inflammatory and Fibrotic Gene Expression and Cellular Senescence in Proximal Tubular Cells Toshimitsu Niwa,[1] Fuyuhiko Nishijima,[2] Hidehisa Shimizu.[1] *[1]Department of Advanced Medicine for Uremia, Nagoya University Graduate School of Medicine, Nagoya, Japan; [2]Biomedical Research Laboratories, Kureha Co., Tokyo, Japan.*

Background: Increased phosphorylation (activation) of signal transducer and activator of transcription 3 (Stat3) on tyrosine 705 leads to renal fibrosis. Indoxyl sulfate, a uremic toxin, induces renal fibrosis through expression of transforming growth factor-β1 (TGF-β1) in proximal tubular cells.The present study aimed to determine whether Stat3 is involved in indoxyl sulfate-induced dysfunction of proximal tubular cells.

Methods: Localization of phosphorylated Stat3 in the kidneys of normal, subtotally nephrectomized, and AST-120-treated subtotally nephrectomized rats was examined by immunohistochemistry. The effect of indoxyl sulfate on phosphorylation of Stat3, and the role of Stat3 on indoxyl sulfate-induced cellular effects were examined using human proximal tubular cells (HK-2 cells).

Results: Subtotally nephrectomized rats showed increased immunostaining of phosphorylated Stat3 in the renal tubules compared with normal rats. Administration of AST-120, which reduces serum level of indoxyl sulfate, to subtotally nephrectomized rats reduced the immunostaining of phosphorylated Stat3 in the renal tubules. Indoxyl sulfate induced phosphorylation of Stat3 in HK-2 cells. Stat3 small interfering RNA (siRNA) suppressed indoxyl sulfate-induced expression of an inflammation maker gene (monocyte chemotactic protein-1), fibrosis maker genes (TGF-β1, α-smooth muscle actin) and a subunit of nuclear factor-κB (p65), and attenuated a cellular senescence maker, senescence-associated β-galactosidase activity.

Conclusions: Stat3 is involved in indoxyl sulfate-induced inflammatory and fibrotic gene expression and cellular senescence in proximal tubular cells.

FR-PO493

Indoxyl Sulfate, a Uremic Toxin, Downregulates Renal Expression of Nrf2 through Activation of NF-κB Toshimitsu Niwa,[1] Dilinaer Bolati,[1] Maimaiti Yisireyili,[1] Fuyuhiko Nishijima,[2] Hidehisa Shimizu.[1] *[1]Department of Advanced Medicine for Uremia, Nagoya University Graduate School of Medicine, Nagoya, Japan; [2]Biomedical Research Laboratories, Kureha Co., Tokyo, Japan.*

Background: Indoxyl sulfate is accumulated in the serum of uremic patients, thereby accelerating the progression of kidney failure. Nuclear factor (erythroid-derived 2)-like 2 (Nrf2) is a transcription factor that regulates induction of numerous antioxidant and phase II detoxifying enzymes. In uremic rat kidney, the expression of Nrf2 and its related genes is downregulated. The present study aimed to determine whether indoxyl sulfate affects Nrf2 expression in the kidney.

Methods: AST-120, an oral sorbent which reduces serum level of indoxyl sulfate, was administered to subtotally nephrectomized rats. The effects of indoxyl sulfate on Nrf2 functions in the kidney were determined using following animals: (1) Dahl salt-resistant normotensive rats (DN), (2) Dahl salt-resistant normotensive indoxyl sulfate-administered rats (DN+IS), (3) Dahl salt-sensitive hypertensive rats (DH), and (4) Dahl salt-sensitive hypertensive indoxyl sulfate-administered rats (DH+IS). To determine whether indoxyl sulfate directly downregulates expression of Nrf2, human proximal tubular cells (HK-2 cells) were used.

Results: AST-120 upregulated the expression of Nrf2 and heme oxygenase-1 (HO-1), an antioxidant gene and a target of Nrf2, and suppressed expression of 8-hydroxydeoxyguanosine (8-OHdG), a marker of reactive oxygen species, in the kidney. Expression of Nrf2 and HO-1 was decreased, whereas expression of 8-OHdG was increased in the kidneys of DN+IS, DH, DH+IS compared with DN. Indoxyl sulfate downregulated Nrf2 expression in HK-2 cells. Furthermore, the indoxyl sulfate-induced downregulation of Nrf2 expression was alleviated by pyrrolidine dithiocarbamate, an inhibitor of nuclear factor-κB (NF-κB), and small interfering RNA (siRNA) specific to NF-κB p65.

Conclusions: Indoxyl sulfate downregulates renal expression of Nrf2 through activation of NF-κB. More notably, AST-120 is a novel inducer of renal Nrf2 expression.

AST-120 Attenuates Chronic Kidney Disease-Related Monocyte Inflammation through Reduction of Indoxyl Sulfate Shunsuke Ito,[1,2] Sumie Goto,[2] Hideyuki Yamato,[2] Mizuko Osaka,[1] Masayuki Yoshida.[1] *[1]Life Schiences and Bioethics, Tokyo Medical and Dental University, Tokyo, Japan; [2]Biomedical Research Laboratories, Kureha Corporation, Tokyo, Japan.*

Background: Management of cardiovascular disease development is critical in patients with chronic kidney disease (CKD). An oral adsorbent AST-120 retards deterioration in renal function by reducing indoxyl sulfate, a major compartment of uremic toxins, in CKD patients. In the present study, we examined the anti-inflammatory potential of AST-120 in a mouse model of CKD.

Methods: Renal failure was induced by subtotal nephrectomy in ten weeks old male C57BL/6 mice. After four weeks, AST-120 was administered for four weeks. Flow cytometry was performed on the peripheral blood leukocytes stained for monocyte activation marker Mac-1 and dihydroethidium to detect reactive oxygen species (ROS). THP-1 monocytic cells were stimulated with indoxyl sulfate and subjected to flow cytometric analysis and adhesion assay to human umbilical vein endothelial cells (HUVEC) under flow conditions in vitro.

Results: A significant elevation of Mac-1 expression and ROS production were observed in peripheral blood monocyte in nephrectomized mice. These monocytes activation were suppressed by AST-120. Administration with indoxyl sulfate enhanced both Mac-1 expression and ROS production. Treatment with indoxyl sulfate dose-dependently enhanced Mac-1 expression and increased THP-1 adhesion to IL-1β-activated HUVEC. Indoxyl sulfate induced phosphorylation of p38MAPK. SB203580, an inhibitor of p38MAPK, reduced Mac-1 expression and indoxyl sulfate-induced THP-1 adhesion to HUVEC, but not that of JNK and ERK1/2 inhibitors. Indoxyl sulfate enhanced ROS production, and induced membrane translocation of NAD(P)H oxidase subunit p47phox in THP-1 cells. Apocynin, an inhibitor of NAD(P)H oxidase, inhibited Mac-1 expression, ROS production and THP-1 adhesion.

Conclusions: Indoxyl sulfate induced up-regulation of Mac-1 through NAD(P)H oxidase- and p38MAPK-dependent pathways. AST-120 inhibited monocytes activation via reducing indoxyl sulfate in vivo. These observations provide a novel therapeutic approach using AST-120 in CKD-associated cardiovascular disease.

PPARα Activation Improves Glomerular Injury Caused by Anti-Thy1 Nephritis through Suppression of NF-κB Signaling Koji Hashimoto, Makoto Harada, Taro Kanno, Yasufumi Takahashi, Makoto Higuchi, Yuji Kamijo. *Department of Nephrology, Shinshu University, Matsumoto, Japan.*

Background: The vast increase of chronic kidney disease (CKD) has attracted considerable attention worldwide, and the development of a novel therapeutic option against a representative kidney disease that leads to CKD, mesangial proliferative glomerulonephritis (MsPGN), would be significant. Peroxisome proliferator-activated receptor α (PPARα), a member of the steroid/nuclear receptor superfamily, is known to perform various physiological functions. Recently, we reported that PPARα in activated mesangial cells exerted anti-inflammatory effects and that the deficiency of PPARα resulted in high susceptibility to glomerulonephritis. To investigate whether PPARα activation improves the disease activity of MsPGN, we examined the protective effects of a PPARα agonist, clofibrate, in a well-established model of human MsPGN, anti-Thy1 nephritis, for the first time.

Methods: Anti-Thy1 nephritis was induced by a single intravenous injection of a mouse anti-Thy1 monoclonal antibody. The clofibrate-treated rats were fed a 0.02 or 0.1% clofibrate containing diet beginning 5 days before the injection. We examined urine protein excretion and kidney function, and carried out histopathological analysis, transcription factor assay (PPARα and NF-κB), and analysis of mRNA of target molecules of these transcriptional factors.

Results: Pretreatment with clofibrate exerted anti-proteinuric effects and ameliorated the active glomerular pathologic inflammatory changes in rat anti-Thy1 nephritis. The clofibrate treatment continuously activated the glomerular PPARα. The PPARα activation appeared to suppress the NF-κB signaling pathway in glomeruli by the induction of IκBα, resulting in the reduction of proteinuria and the improvement of pathologic glomerular changes.

Conclusions: The current study suggest the anti-nephritic potential of PPARα agonist, clofibrate, against MsPGN. PPARα-related medicines might be useful as a treatment option for CKD.

FR-PO496

Curcumin Ameliorates CKD by Decreasing Paracellular Permeability of LPS Siddhartha S. Ghosh, Richard Krieg, Dominic A. Sica, Todd W. Gehr. *Nephrology, VCU, Richmond, VA.*

Background: Recent studies suggest that the paracellular permeability of uremic toxins such as lipopolysaccharide (LPS) from the intestine plays a proinflammatory role in CKD patients. Our earlier studies show that curcumin is as effective as enalapril in controlling inflammation in our CKD animals. In this study we investigated if paracellular permeability is increased in animal model of CKD and if curcumin can also act locally in the gut to prevent paracellular permeability of LPS and reduce inflammation.

Methods: CKD was induced in CD1 mice by 5/6 nephrectomy (Nx). A group of Nx (n=5) was treated with 100 mg/kg curcumin (CUR) for 12-weeks and results were compared with Nx and sham-operated animals (SH). Proteinuria, BUN and creatinine were used as measures of renal function. To check if curcumin has any effect on paracellular permeability we added LPS to intestinal epithelial cells (Caco2) and monitored permeability of ^{3}H mannitol in presence and absence of curcumin from 0-4 hrs.

Results: Curcumin significantly decreased progressive proteinuria in Nx animals. BUN and creatinine levels of Nx group (62±10 mg/dl and 1.5±0.3) were reduced by 32% ($p<0.05$) and 36% ($p<0.01$) respectively in CUR group. Serum LPS levels of Nx animals vs CUR was 3.2±1.6 and 1.6±0.5 EU/ml respectively, p= 0.0242. LPS is known to stimulate inflammatory biomolecules such as TNFα and IL6 in macrophages. Compared to CUR macrophages from Nx cohort had a 3.6 and 2.8 fold higher TNF ($p<0.01$), and IL-6 ($p<0.05$) mRNA respectively. Intestinal tight junction proteins claudin1 and ZO1 responsible for maintaining the integrity of intestinal smooth muscle measured by immunoblot was significantly lower in Nx vs CUR ($p<0.05$).Paracellular permeability of ^{3}H mannitol in LPS treated Caco2 cells gradually increased with time and was 1.7 ($p<0.01$) and 2.4 fold higher ($p<0.001$) than the CUR+LPS treated cells at 2 and 4 hours respectively.

Conclusions: Our experiments suggest that intestinal permeability is abnormal in animals with renal failure and this leads to leakage of LPS and subsequent inflammation. Curcumin by maintaining the intestinal integrity prevents LPS absorption which ameliorates inflammation and renal failure.

Protective Effects of Rosiglitazone on the Rat Kidney under Chronic Ischemia Jinlei Lv,[1] Hong-bo Xiao,[1] Qinkai Chen,[1] Guohua Ding.[2] *[1]Nephrology, The First Affilliated Hospital of NanChang University, NanChang, JInagXi, China; [2]Nephrology, Renmin Hospital of Wuhan University, WuHan, HuBei, China.*

Background: To investigate the expression of PPARγ,$TGFβ_1$ in the rat kidney under chronic ischemia and mechanisms by which rosiglitazone protects the ischemic kidney.

Methods: Sprague-Dawley rats were randomly assigned to four groups:sham-operated (sham), ischemic nephropathy(IN), IN treated early with rosiglitazone(RGE), IN treated late with rosiglitazone(RGL). Biochemical indicators were measured at the end of 12W. Morphological changes of renal tissue were observedby HE,PASM,Masson stain. RealTime-PCR were performed to investigate the mRNA expression of PPARγ,α-SMA,$TGFβ_1$. Immunohistochemistry method was used to observe the protein expression

of PPARγ,α-SMA. The correlations between the mRNA expression of PPARγ,α-SMA, $TGF\beta_1$ and renal pathology counting scores were also conducted.

Results: Compared with sham group, biochemical indicators were significantly increased in IN group($P<0.01$), pathological lesions were observed. Early treated with rosiglitazone significantly decreased biochemical indicators and pathological lesions,The protein expressions of PPARγ,α-SMA were increased significantly in IN group($P<0.01$),meanwhile the protein expressions were decreased in both RGE and RGL group. There were significant increased expressions of PPARγ,αSMA and $TGF\beta_1$ mRNA in IN and RGL group versus sham group;Compared with sham group,the mRNA expressions of αSMA and $TGF\beta_1$ in RGE group increased($P<0.01$).There were positive correlations between mRNA expressions of PPARγ,α-SMA,$TGF\beta_1$ and renal pathology counting scores($P<0.01$).

Conclusions: Rosiglitazone may exert protective effects on chronic ischemic kidney by, at least partially, regulating PPARγ transcription,down-regulating the espression of $TGF\beta_1$, suppressing the activation of renal myofibroblast.

FR-PO498

Chronic Renal Failure Increases Monocyte Cell Surface Expression of Galectin-3, a Pro-Inflammatory, Pro-Fibrotic Galectin Andrew Duncan Stewart Findlay, Julius Edward Kieswich, Magdi Yaqoob. *Translational Medicine and Theraputics, William Harvey Research Institute, Queen Mary's School of Medicine and Dentistry, London, United Kingdom.*

Background: Galectin-3 is a pro-inflammatory galactoside binding protein expressed on leucocytes with diverse roles in cardiac fibrosis, inflammation and cell-cell interactions. Whilst both human and animal plasma Galectin-3 is elevated in heart failure and chronic renal failure, the source of the plasma Galectin-3 and implications for elevated Galectin-3 are unknown.

Methods: Murine plasma Galectin -1, -9 and -3 were measured by Elisa over 4 weeks on 0.25% adenine diet (a model of chronic renal failure) vs sham diet. After 2 weeks 0.25% adenine diet vs sham diet Flow Cytometry was performed measuring Galectin-3 cell surface staining of monocytes (Ly6c+ve cells), neutrophils (Ly6g+ve cells) and resting peritoneal macrophages (identified by morphological characteristics).

Results: Plasma Galectin-3 but not 1 and 9 was significantly elevated from 1 week adenine diet and continued to rise over 4 weeks. At 2 weeks diet the chronic renal failure group (0.25% adenine n=8) had a significantly greater proportion of monocytes with cell surface expression of Galectin-3 than sham group (n=8) (Median % of Ly6c +ve cells staining +ve for Galectin-3 = 55.57% vs 30.62% P=0.0079). The median flourescence intensity(MFI) of Galectin-3 positive monocytes was also significantly stronger in the adenine group vs sham ($p<0.05$). There were no significant differences between the 2 groups in neutrophil or peritoneal macrophage expression of Galectin-3 at 2 weeks of diet.

Conclusions: Plasma Galectin-3, derived from leucocytes, is raised in chronic renal failure. Increased cell surface expression of Galectin-3 in the chronic renal failure model was specific to monocytes and not elevated above the sham group in neutrophils or resting peritoneal macrophages. There is an acknowledged correlation between elevated Galectin-3 and heart failure particularly cardiac fibrosis. This is via a proposed monocyte/macrophage derived Galectin-3 activation of cardiac fibroblasts. Galectin-3 may therefore be implicated in uraemic cardiovascular disease.

Funding: Government Support - Non-U.S.

FR-PO499

Effect of a Serine Protease Inhibitor on the Progression of Chronic Renal Failure Manabu Hayata,[1] Yutaka Kakizoe,[1] Kohei Uchimura,[1] Jun Morinaga,[1] Rika Yamazoe,[1] Teruhiko Mizumoto,[1] Tomoaki Onoue,[1] Miki Ueda,[1] Sakai Yoshiki,[2] Kimio Tomita,[1] Kenichiro Kitamura.[1] *[1]Department of Nephrology, Kumamoto University Graduate School of Medical Sciences, Kumamoto, Japan; [2]Research Headquarters, Ono Pharmaceutical Co., Ltd., Osaka, Japan.*

Background: The number of the chronic renal failure (CRF) patients is increasing explosively. Hypertension, proteinuria, inflammation, fibrosis, and oxidative stress are intertwined in a complicated manner that leads to the progression of CRF. However, the therapeutic strategies to delay its progression are limited. Since serine proteases are involved in many aspects of these risk factors, we investigated the effects of a synthetic serine protease inhibitor camostat mesilate (CM) on the progression of CRF in 5/6 nephrectomized (Nx) rats.

Methods: Eighteen male Sprague-Dawley rats were divided into three groups, a sham-operated group (Sham: n=6), a vehicle-treated Nx group (Nx: n=6) and a CM-treated Nx group (Nx+CM: n=6). Following the 9-weeks study period, all rats were sacrificed and blood samples and the remnant kidney were collected for the assessment of the renal injury.

Results: At the end of the experiment, both proteinuria (Sham: 19±1 mg/day, Nx: 158±38 mg/day; $P<0.01$) and serum creatinine levels (Sham: 0.31±0.01 mg/dL, Nx: 0.87±0.07 mg/dL; $P<0.001$) were substantially increased in the vehicle-treated Nx group and treatment with CM significantly reduced proteinuria (Nx+CM: 54±9 mg/day; $P<0.05$ vs. Nx) and serum creatinine levels (Nx+CM: 0.68±0.02 mg/dL; $P<0.05$ vs. Nx). Podocyte-associated proteins such as nephrin and synaptopodin were markedly decreased by 5/6 nephrectomy, and was significantly ameliorated by CM. CM also suppressed the mRNA levels of inflammatory and fibrotic markers including TGFβ1, TNFα, collagen type I, III, and IV, and reduced glomerulosclerosis and interstitial fibrosis in histologic studies. Furthermore, CM decreased the mRNA expression of NADPH oxidase components as well as reactive oxygen species generation and advanced oxidative protein products.

Conclusions: Our current results strongly suggest the possibility that CM might be useful therapeutic strategy against the progression of CRF.

FR-PO500

HIV-Induced Kidney Cell Injury: Role of ROS-Induced Downregulated Vitamin D Receptor Divya Salhan, Nirupama Chandel, Ashaan Subrati, Partab Rai, Tejinder Singh, Mohammad Husain, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY.*

Background: Reactive oxygen species (ROS) have been demonstrated to contribute to HIV-induced tubular cell injury. We hypothesized that HIV-induced ROS generation may be causing tubular cell injury through downregulation of vitamin D receptor (VDR) and associated down stream effects.

Methods: Immunoblots of empty vector and HIV (NL4-3) transduced human proximal tubular cells (HPTC) were probed for VDR and actin. To determine the role of ROS, immunoblots of HIV/HPTC-pretreated with catalase or HPTCs directly treated with H_2O_2 were probed for VDR and actin. EV/HPTC and HIV/HPTCs were assayed for the activation of renin-angiotensin system (RAS), ROS generation. EV/PTCs' and HIV/HPTCs' DNA damage and repair in the presence or absence of a VDR agonist (EB1089, 30 nM) and an Ang II blocker (losartan, 10^{-7}M) were assyed by immunofluorescnece studies under confocal microscopy.

Results: HIV not only downregulated tubular cell VDR expression but also inflicted DNA injury. On the other hand, EB1089 inhibited both down regulation of VDR and tubular cell DNA injury in HIV milieu. H_20_2 directlydown regulated tubular cell VDR; whereas, catalase, a free radical scavenger, inhibited HIV-induced down regulation of tubular cell VDR expression HIV also stimulated tubular RAS. Both E1089 and losartan partially inhibited HIV-induced tubular cell ROS generation. HIV/HPTCs exhibited enhanced expression of phospho-p53 and associated downstream signaling. Both EB1089 and losartan not only preserved expression of tubular cell DNA repair proteins but also inhibited induction of double strand breaks. In *in vivo* studies, renal cortical sections of Tg26 mice displayed attenuated expression of VDR both in podocytes and tubular cells. In addition, renal cortical sections of Tg26 mice displayed enhanced oxidative stress-induced kidney cell DNA damage.

Conclusions: These findings indicated that HIV-induced tubular cell downregulation of VDR contributed to the RAS activation and associated tubular cell DNA damage. However, both VDRupregulation and RAS blockade provided protection against these effects of HIV.

FR-PO501

Loss of Syndecan-1 Induces Endothelial Damage and Albuminuria in Zebrafish and Mice Hermann G. Haller,[1,2] Torsten Kirsch,[1] Joon-Keun Park,[1] Mario Schiffer.[1,2] *[1]Clinic of Hypertension and Nephrology, Hannover Medical School, Hannover, Germany; [2]Mount Desert Biological Laboratory MDIBL, Bar Harbor, ME.*

Background: Syndecans are a family of cell surface heparan sulfate proteoglycans that act as cell surface receptors and are part of the glycocalyx. Recently, syndecan-4 was associated with podocyte function and proteinuria. Since alterations of the enothelial cell glycocalyx seem to be important for the pathogenesis of proteinuria and circulating syndecan-1 is increased in diabetic patients we hypothesized that syndecan-1 plays a role in endothelial cell dysfunction and albuminuria in diabetes.

Methods: Albuminuria was assessed using (1) a novel model albuminuria in embryonic zebrafish and (2) in streptozotocin-induced hyperglycemia in the mouse using immunohistochemistry, immunoblotting real-time PCR and electron microscopy. Syndecan inhibition was achieved by (1) antisense morpholinos and (2) generation of syndecan-1-/- mice. Mice were made hyperglycemic by streptozotocin treatment.

Results: Functional knockdown of syndecan-1 in zebrafish led to endothelial and podocytic cell damage with distorted glomerular capillaries. In addition, vascular development was impaired. Hyperglycemia in a mouse model led to an increased albuminuria after 8 weeks associated with a loss of syndecan-1 and other glycocalyx molecules. The diabetes-induced albuminuria was significantly enhanced in syndecan-/- mice. In addition, the decrease in other gylcocalyx molecules was observed earlier.

Conclusions: Syndecan-1 is important for endothelial function in the glomerulus and rapidly down-regulated by hyperglycemia. Lack of syndecan -1 leads to endothelial dysfunction and albuminuria. Our results support an important role of syndecan-1 in the maintenance of the glomerular barrier.

FR-PO502

Endothelial Cell Responses to Circulating Immune Complexes In Vivo Scott E. Wenderfer, Adisak Suwanichkul. *Pediatrics, Renal Section, Baylor College of Medicine, Houston, TX.*

Background: Antibodies or antibody-antigen immune complexes (IC) are present in the glomeruli in >50% of glomerulopathies. Fixed IC deposits form in distinct regions of the glomeruli of the kidney, and often predominate in the subendothelial space. The response of endothelial cells during deposition and clearance of IC from the subendothelial space is unknown.

Methods: To assess the functional responses of renal endothelial cells to either antibodies or IC in health and in disease, a mouse model of acute circulating IC deposition was adapted for fluorescence microscopic and biological assessment.

Results: The introduction of monoclonal or polyclonal, homologous or heterologous immune complexes resulted in transient glomerular IgG staining, whereas introduction of antibodies alone did not. The accumulation of IC in this model is independent of antigenic specificity. Significant inflammation is not detected in this model, allowing for parenchymal responses to IC accumulation to be studied. The pattern of responses seen in

vivo corresponds to that detected in vitro using cultured renal endothelial cells, and includes induction of pro-inflammatory, pro-angiogenic, and pro-apoptotic factors. In addition, markers of endothelial precursor cell involvement are detected along with wound-healing responses in the resolving phase of the model.

Conclusions: Renal endothelial cells play a primary role in the initial response to circulating IC in the kidney and endothelial precursor cells may play a role in resolving IC kidney diseases. This acute circulating IC model can help to unravel the complexities of kidney disease in autoimmune mouse models and patients with IC diseases, such as lupus nephritis.

Funding: NIDDK Support

FR-PO503

Heme Oxygenase-1 (HO-1) Derived Iron and Ferritin Regulate Macrophage Polarization Subhashini Bolisetty,[1] Abolfazl Zarjou,[1] Reny Joseph,[1] Amie Traylor,[1] Viktória Jeney,[2] James George,[1] Jozsef Balla,[2] Anupam Agarwal.[1] *[1]Medicine/Division of Nephrology, University of Alabama at Birmingham, Birmingham, AL; [2]Medicine, University of Debrecen, Hungary.*

Background: HO-1 is a microsomal enzyme that breaks down heme to generate iron, carbon monoxide and biliverdin. Iron released is sequestered by H-ferritin, which is co-induced with HO-1 as a protective response. The purpose of this study was to determine the role of HO-1 and H-ferritin in macrophage activation and polarization.

Results: HO-1$^{-/-}$ mice display increased renal macrophage infiltration and fibrosis following unilateral ureteral obstruction (UUO) compared to HO-1$^{+/+}$ mice. Proximal tubule (PT)-specific H-ferritin deletion led to a significant increase in macrophage infiltration while PT-specific HO-1 overexpression decreased infiltration. M1 (iNOS, TNF-α) and M2 (Arginase-1, mannose receptor) markers were evaluated in CD11b+ macrophages isolated from UUO kidneys from HO-1$^{-/-}$ and HO-1$^{+/+}$ mice. HO-1 deficiency was associated with marked dysregulation of macrophage polarization with significantly higher expression of M2 markers. In vitro studies demonstrated that HO-1$^{-/-}$ macrophages are more prone to activation and polarization towards both M1 and M2 pathways, a process that was significantly blunted by HO reaction products (biliverdin and carbon monoxide). Iron chelation by deferoxamine and the consequent decrease in H-ferritin provided similar inhibitory effects. On the contrary, addition of iron, apoferritin or recombinant H-ferritin (both devoid of iron) to HO-1$^{+/+}$ cells mimicked the HO-1 deficient state and increased macrophage polarization towards M1 and M2 phenotype. The clinical relevance of these findings was further corroborated in peripheral blood monocytes isolated from patients on chronic hemodialysis with serum ferritin levels above 900ng/ml. Hemodialysis patients (n=9) revealed significantly higher levels of H-ferritin, iNOS and arginase-1 in monocytes compared to healthy volunteers (n=8).

Conclusions: Our findings elucidate the key role of HO-1/ferritin system in macrophage polarization and suggest that modulation of this system in inflammatory disorders may serve as a novel therapeutic strategy.

Epigenetic Histone Methylation Primes Uremic Macrophage Inflammatory Responses Neal B. Blatt,[1] Patricia L. Christopherson,[1] Timothy Cornell,[2] Thomas P. Shanley.[2] *[1]Pediatrics-Nephrology, University of Michigan, Ann Arbor, MI; [2]Pediatrics-Critical Care, University of Michigan, Ann Arbor, MI.*

Background: Monocytes from ESRD patients demonstrate increased cellular activation including increased pro-inflammatory cytokine production, and are implicated in the development of an ESRD-mediated chronic inflammatory state leading to excess cardiovascular disease. The mechanism behind these altered cellular responses is currently unknown. We hypothesized that uremia induces changes in histone methylation patterns (epigenetic signatures) that would favor pro-inflammatory gene expression.

Methods: 129SvJ mice underwent subtotal nephrectomy (SNx) or a sham procedure. Bone marrow-derived macrophages (BMDM) were isolated from sham and SNx mice. Chromatin immunoprecipitation (ChIP) was performed using antibodies recognizing trimethylated lysine-4 within histone H3 (H3K4) followed by qPCR for the promoter regions of TNF-α, IL-12, and IL-10.

Results: SNx mice developed increased BUN values (SNx: 38±5 vs Sham: 18±4 mg/dL, P<0.001) indicating the development of uremia. Following stimulation with LPS, BMDM from SNx mice show increased TNF-α production in tissue culture supernatants (SNx: 661±74 vs sham: 394±42 pg/mL, P<0.05) indicating that the BMDM's model human monocyte responses. Analysis of histone methylation patterns showed that SNx BMDM have increased H3K4 methylation at TNF-α and IL-12, but decreased methylation at the IL-10 promoter (see Table).

	TNF-α	IL-12p35	IL-12p40	IL-10 (a)	IL-10 (b)	IL-10 (c)
SNx	2.0 ± 1.2*	1.3 ± 0.4*	2.3 ± 1.7*	0.7 ± 0.3*	0.6 ± 0.4*	0.7 ± 0.4*
Sham	1.0 ± 0.3	1.0 ± 0.1	1.0 ± 0.1	1.0 ± 0.1	1.0 ± 0.1	1.0 ± 0.1

H3K4 methylation at the indicated promoters. Three different regions of the IL10 promoter are indicated by (a-c). For each IP, %input DNA from the qPCR was normalized to sham %input DNA. Data is presented as mean ± SD. * = P<0.05

Conclusions: Using a well-established mouse model of chronic renal failure, we demonstrate that macrophages from uremic mice are primed to respond to TLR ligands. These findings suggest that uremia is able to reprogram the bone marrow to foster the development of a chronic inflammatory state via epigenetic alterations to histone methylation.

Statin Directly Inhibit Macrophage Differentiation and Activation, and Provide Anti-Inflammatory Function Shinya Nagasaka, Akira Shimizu, Seiichiro Higo, Go Kanzaki, Takatsugu Iwashita, Toru Iwahori, Yukinari Masuda. *The Department of Analytic Human Pathology, Nippon Medical School, Bunkyo-ku, Tokyo, Japan.*

Background: We have reported the anti-inflammatory effects of statin in experimental anti-glomerular basement membrane glomerulonephritis (anti-GBM GN) through modulation of infiltrating macrophages (Mφ). In this study, we assessed the direct effects of statin on Mφdifferentiation and functions, and possibilities of therapeutic approaches with statin-pretreated Mφ on anti-GBM GN.

Methods: We examined the influences of atorvastatin on the differentiation and activation of bone marrow-derived Mφ (BMDMs). BMDMs were differentiated in the presence of several concentrations of atorvastatin. BMDMs were also pretreated with 2.5 μM of atorvastatin for 24 hr followed by stimulation with IFN-γ, and phenotype of Mφ, the expression of Mφ function related molecules including cytokine and chemokine were analyzed. In addition, we administered intravenously statin-pretreated BMDMs (1x10^7 cells) in the anti-GBM GN rats at 3, 4, and 6 days after disease induction, and examined the effects of these cells in anti-GBM GN.

Results: Statin inhibited Mφ development from rat bone marrow progenitor cells with decreased adhesion molecule LFA-1α expression on Mφ. Cox-2 expression and prostaglandin E2 (PGE2) production were significantly increased in Mφ in the presence of statin compared to absence. Statin-pretreated Mφ were enhanced IL-33 expression and down-regulated MCP-1 expression upon IFN-γ stimulation. Furthermore, injection of statin-pretreated Mφ to anti-GBM GN rat resulted in reduced Mφ infiltration and inhibited the formation of crescentic glomerular lesions.

Conclusions: Statin directly inhibits the differentiation and activation of Mφ, and might provide the anti-inflammatory function in Mφ through enhanced PGE2 production by the increased Cox-2 expression. Furthermore, treatment using statin-pretreated Mφ may be usefulfor the inhibition of active and severe GN.

FR-PO506

Active Macrophage Migration Inhibitory Factor (Active MIF) Is a Previously Unrecognized Isoform of MIF and a Potential New Biomarker for Lupus Nephritis Randolf J. Kerschbaumer,[1] Josef H. Kovarik,[2] Dirk Voelkel,[1] Michael Thiele,[1] Patrice Douillard,[1] Frederick W.K. Tam,[3] Mahmoud Loghman-Adham,[4] Hartmut Ehrlich,[1] Hans Peter Schwarz,[1] Friedrich Scheiflinger.[1] *[1]Baxter Innovations GmbH, Vienna, Austria; [2]Department of Nephrology, Wilhelminenspital, Vienna, Austria; [3]Imperial College Kidney and Transplant Institute, London, United Kingdom; [4]Baxter Healthcare Corporation, Westlake Village, CA.*

Background: MIF plays a central role in inflammatory responses and elevated MIF levels have been detected in patients with inflammatory kidney diseases. Some features of MIF are markedly different from those of other pro-inflammatory cytokines. MIF is constitutively expressed, stored in the cytoplasm and constantly present in the circulation of healthy subjects. We have discovered a novel, previously unrecognized conformational isoform of MIF (designated 'active MIF') that is produced in diseases and cannot be detected in healthy subjects. Active MIF is specifically recognized by human monoclonal anti-MIF antibodies showing beneficial effects in animal models of glomerulonephritis.

Methods: New ELISA methods were established that allow for the determination of active MIF as well as non-active MIF. Urine and plasma samples collected from lupus nephritis (LN) patients and healthy subjects were analyzed. MIF concentration in urine was corrected for creatinine (Cr) concentration.

Results: Active MIF could not be detected in the urine and plasma of healthy controls. In LN patients there was a clear correlation between the severity of the disease and the active MIF/Cr ratio in the urine (acute renal flare: median 1780 pg/mg, n=23; healthy controls: median 0 pg/mg, n=38; p<0.01). Concentrations of active MIF in plasma were not increased during acute renal flare, but were elevated during systemic exacerbations of SLE without renal involvement (median 8340 pg/ml, n=9; healthy controls: median 0 pg/ml, n=20; p<0.0001).

Conclusions: Active MIF in urine and plasma of LN patients may be a suitable marker of disease activity or disease progression. Determination of active MIF levels could furthermore be suitable to predict susceptibility for anti-MIF antibody treatment.

FR-PO507

Monodisperse SynBiosys Microspheres for Sustained Intrarenal Drug Delivery Jurjen Zandstra,[1] Christine Hiemstra,[2] Arjen H. Petersen,[1] Johan Zuidema,[2] Audrey Lathuile,[3] Gert Veldhuis,[3] Rob Steendam,[2] Eliane R. Popa.[1] *[1]Medical Biology, University Medical Centre Groningen, Groningen, Netherlands; [2]InnoCore Pharmaceuticals, Groningen, Netherlands; [3]Nanomi B.V., Oldenzaal, Netherlands.*

Background: The alarmingly increasing prevalence and treatment costs of chronic kidney disease call for novel therapeutic strategies that prevent disease progression at an early stage. We propose biodegradable polymeric microspheres (MSP) with physical and chemical properties tailored to sustained intrarenal drug delivery as a tool to modulate processes responsible for chronic kidney disease, such as inflammation and fibrosis. In this study we generated monodisperse microspheres (MonospheresÔ) composed of hydrophilic

phase separated multi-block copolymers (SynBiosys©) and investigated their intrarenal biocompatibility and thus adequacy for future therapeutic application.

Methods: Polymer-only MSP spheres of 30 μm diameter were injected under the capsule of healthy F344 rat kidneys. Kidneys were retrieved 3, 7, 14 and 28 days after MSP implantation. General histology was evaluated by PAS staining. Renal interstitial presence of macrophages (ED-1) and myofibroblasts (αSMA) as a result of MSP implantation was studied by immunohistochemistry.

Results: MSP demonstrated excellent subcapsular injectability. MSP were detected in the subcapsular space at all time points and showed little degradation in time. MSP implantation did not affect tubular integrity at any time point. Low numbers of macrophages were strictly present around MSP. Macrophages and myofibroblasts were virtually absent in the renal interstitium at all time points.

Conclusions: We report for the first time the intrarenal biocompatibility of SynBiosys Monospheres designed for intrarenal drug delivery. Based on their slow degradation rate and the lack of adverse effects of their subcapsular implantation on the renal tissue, we conclude that SynBiosys Monospheres provide a promising tool for sustained intrarenal drug delivery.

Renal Afferent Innervation Exhibits an Impaired Excitability in an In Vitro Model of Inflammation Wolfgang Freisinger, Tilmann Ditting, Annalena Karl, Sonja Heinlein, Karl F. Hilgers, Roland E. Schmieder, Roland Veelken. *Department of Nephrology and Hypertension, Friedrich-Alexander Universität Erlangen-Nürnberg, Erlangen, Germany.*

Background: Renal denervation may be beneficial in inflammatory renal disease. Recently, we found that afferent renal neurons showed a characteristic excitability, exhibiting predominantly a sustained firing upon current injection. So far, excitability of these neurons under pathological conditions such as renal inflammation is unclear. Hence, in an in vitro model we wanted to test the hypothesis that a proinflammatory mediator like CXCL1 could alter the firing pattern of renal afferent neurons and thus decrease their excitability.

Methods: Dorsal root ganglion (DRG) neurons (Th11-L2) were incubated with the chemokine CXCL1 (1,5nmol/ml) for 12 hours before patch clamp recordings. Labelling (DiI) allowed the identification of renal afferent neurons. Current clamp was used to characterize neurons as "tonic", i.e. sustained action potential (AP) firing or "phasic", i.e. <5 APs according to their firing response to current injections. AP properties were determined in renal and non-renal neurons incubated with CXCL1 and compared to controls.

Results: Renal afferent DRG neurons exhibited in 57% a tonic firing pattern vs.11,7%* in non-renal neurons. However, exposed to the chemokine, renal DRG neurons exhibited significantly less tonic firing (35,6% vs. 57%, *p<0,05) but instead an increased occurrence of phasic firing. Renal DRG neurons with phasic firing pattern showed a significantly lower threshold for AP-firing (600pA [320-1000] vs.1000pA [400-3200]) and a significantly shorter AP-duration at threshold-level (2,095ms [1,75-4,25] vs. 5,15ms [4,3- 8,7]) after exposure to CXCL1.

Conclusions: We could show that after exposure to a proinflammatory mediator like CXCL1, renal afferent DRG neurons exhibited a significantly higher proportion of neurons with a phasic pattern (<5 APs) and decreased excitability as compared to control conditions. Significant changes in action potential properties of phasic neurons point to an altered sodium channel expression likely inducing a faster inactivation of these channels with decreased firing activity.

FR-PO509

Characteristics of T-Cell Migration at the Single Cell Level Using Microfluidics Modeling Namrata G. Jain,[1,2,3] Ian Y. Wong,[2,3] Elisabeth A. Wong,[2,3] Leo Boneschansker,[1,3] A.J. Aranyosi,[2,3] David M. Briscoe,[1,3] Daniel Irimia.[2,3] *[1]Division of Pediatric Nephrology, Children's Hospital Boston, Boston, MA; [2]Massachusetts General Hospital, Boston, MA; [3]Harvard Medical School, Boston, MA.*

Background: Understanding patterns of T cell migration have significant implications for the development of anti-inflammatory therapeutics. However, prior studies evaluating T cell chemotaxis are limited by use of static migration assays (i.e. Boyden and transwell assays). Microfluidics allows for live-time imaging of T cells migrating towards a gradient; characteristics of migration patterns, velocity, stop-start motility events, and footprinting can be evaluated. We developed microfluidics devices to analyze T cell migration at the single cell level.

Methods: Human CD3+ T cells were isolated by negative selection from PBMC, and used either unstimulated or following 24hrs of activation with anti-CD3/anti-CD28 (1mcg/ml). T cells were injected into the main channel of devices, where they have potential to migrate in 15 hrs into a maze of 10um channels towards a chemokine gradient, either 100nM RANTES or 100nM IP-10. The velocity of T cell movement within the maze was evaluated in two dimensions (Vx or Vy), and directional persistence (Px) towards the chemokine gradient was tracked using Image J software.

Results: We found that mitogen-activated T cells displayed greater exploration within the maze (movement in x and y), vs. unstimulated cells ($p<0.001$). However, unstimulated T cells migrated at higher velocities towards IP-10 (Vx=147.2 um/hr, n=96) vs. RANTES (Vx=101.8 um/hr, n=201,$P<0.001$). Mitogen-activated T cells migrated at a greater velocity towards RANTES (Vx=157.4 um/hr, n=227) vs. IP-10 (Vx=119.3 um/hr, n=203, $p<0.001$), and migrated at a slower velocity towards IP-10 vs unstimulated cells ($p<0.001$). Ultimately, both unstimulated and activated T cells persist towards each chemokine, albeit with different migratory patterns.

Conclusions: Our newly developed microfluidic devices allow for the analysis of T cell migration at the single cell level. Understanding the complexity of migratory patterns has potential to support the development of novel anti-rejection therapeutics.

FR-PO510

Pathogenesis of Hypercholesterolemia in *IL13* Overexpression Rat Model of Minimal Change Nephrotic Syndrome (MCNS) Lauretta Danwei Low,[1] Chang Yien Chan,[1] Tarun K. Maheshwari,[1] Jinmiao Chen,[2] Henry He Yang,[1] Caroline G.L. Lee,[1] Hanry Yu,[1] Hui Kim Yap.[1] *[1]Pediatrics, Biochemistry, Physiology & Cancer Science Institute, National University of Singapore, Singapore; [2]SIgN, A-Star, Singapore.*

Background: Hypercholesterolemia in experimental rat models of NS is thought to be due to abnormalities in hepatic cholesterol metabolism secondary to the marked proteinuria. This study aimed to investigate the pathogenesis of hypercholesterolemia in an *IL13* overexpression rat model of MCNS.

Methods: Plasmid containing rat *IL13* gene was electroporated into rat quadriceps every 10 days. Plasma IL13, cholesterol, albumin and urine albumin levels were assayed weekly. Liver RNA from rats sacrificed at Week 10 was used for microarray analysis. The direct effect of IL13 (25ng/ml) on primary rat hepatocyte and HepG2 cell cultures were studied after 24-hour incubation.

Results: Weekly biochemistry showed significant increase in plasma cholesterol in *IL13* transfected rats (n=58) compared to controls (n=24) from Week 1 (2.08±0.09 vs 1.66±0.05 mmol/l, $p=0.001$), with hypercholesterolemia preceding development of proteinuria by Week 10. Microarray analysis on Week 10 *IL13* transfected rat liver showed >1.9-fold increase in *IL13Ra2* and *CYP7A1*, and 11.3-fold downregulation in *ABCG5*, validated by RT-PCR. Additionally, RT-PCR detected significant increase in *HMGCR* in *IL13* transfected rats (0.056±0.0054 vs 0.039±0.0054, $p=0.034$). Early studies in *IL13* transfected rats with hypercholesterolemia prior to onset of proteinuria at Week 10, showed similar upregulation of *IL13Ra2* (0.15±0.047 vs 0.016±0.0032, $p<0.001$), with downregulation of *ABCG5* (0.019±0.011 vs 0.12±0.016, $p<0.001$) and *LXRa* (0.23±0.021 vs 0.31±0.024, $p=0.043$). IL13 stimulation resulted in upregulation of *IL13Ra2* and downregulation of *LXRa* gene expression in both rat hepatocyte ($p<0.002$) and HepG2 cells ($p<0.05$).

Conclusions: Hypercholesterolemia preceded development of proteinuria in the *IL13* transfected rats. IL13-induced downregulation of LXRa-ABCG5-pathway of hepatic cholesterol elimination through bile appeared to be important early in the genesis of hypercholesterolemia. This was perpetuated by upregulation of *HMGCR* later in the course of the disease.

FR-PO511

The SNARE Protein VAMP2 Binds the Carboxy-Terminus of NKCC2 and Mediates cAMP-Stimulated Exocytic Insertion in Thick Ascending Limbs Paulo S. Caceres,[1,2] Pablo A. Ortiz.[1,2] *[1]Int. Med.- Hypert. & Vasc.Res, Henry Ford Hospital; [2]Physiology, Wayne State Univ, Detroit, MI.*

Background: AVP and β-adrenergic receptors enhance NKCC2 activity and NaCl absorption by the Thick Ascending Limb (TAL) *via* cAMP. cAMP increases apical surface NKCC2 by enhancing its exocytic delivery. Inactivation of vesicle associated membrane protein (VAMP) 2 and 3 blocks cAMP-stimulated NKCC2 activity and surface levels. However the molecular mechanism and the specific VAMP that mediates cAMP-stimulated NKCC2 trafficking are not known. We hypothesize that VAMP2 binds NKCC2 and mediates cAMP-stimulated exocytic delivery in TALs.

Methods: We isolated rat TALs and immunoprecipitated (IP) NKCC2 and VAMP isoforms. To map the interacting motif in NKCC2, we generated GST-fusion proteins coding for the amino (N)-terminus of NKCC2 or the carboxy (C)-terminal region containing the apical targeting signal.

Results: We found that NKCC2 co-IP with VAMP2 but not with VAMP7 or VAMP8. VAMP2 bound the C-terminus of NKCC2 but not the N-terminus. We next studied whether VAMP2 co-localized with NKCC2 at the apical surface. To selectively label VAMP2 at the apical surface we expressed VAMP2 tagged with GFP facing the extracellular space in primary cultures of TALs. Endogenous surface NKCC2 was labeled with an antibody against an extracellular epitope. We found that NKCC2 localization at the apical surface was heterogeneous, with most of the NKCC2 present in discrete domains (nanoclusters) with an area of 0.14±0.04 μm^2. After stimulation of cAMP, 45±7% of NKCC2 surface clusters also contained VAMP2. Finally we tested whether VAMP2 mediates cAMP-stimulated exocytic delivery. *In vivo* transduction of the outer medulla with VAMP2-shRNA adenoviruses decreased VAMP2 expression in TALs by 69±7% and completely blocked cAMP-stimulated NKCC2 exocytic delivery without affecting baseline "constitutive" delivery (baseline: 100%, cAMP: 91±12%, n=5). In control TALs (scrambled shRNA), cAMP enhanced NKCC2 exocytic delivery by 88±17% ($p<0.05$).

Conclusions: We conclude that VAMP2 is a novel interacting partner of NKCC2 that mediates cAMP-stimulated NKCC2 exocytic delivery. In addition, NKCC2 and VAMP2 co-localize in clusters at the apical surface of TALs.

FR-PO512

Wnk4 Deficient Mice Manifest Gitelman's Syndrome-Like Phenotype
Sung-Sen Yang,[1] Shinichi Uchida,[2] Sei Sasaki,[2] Shih-Hua P. Lin.[1] *[1]Division of Nephrology, Department of Medicine, Tri-Service General Hospital and National Defense Medical Center, Taipei, Taiwan; [2]Department of Nephrology, Tokyo Medical and Dental University, Tokyo, Japan.*

Background: By the *in vitro* studies, With-No-Lysine [K] (WNK) kinase 4 exerts dual effects on Na^+-Cl^- cotransporter (NCC) by inhibiting NCC membrane expression directly or activating NCC through WNK4-SPAK/OSR1-NCC phosphorylation signaling. Activation of Spak/Osr1-Ncc phosphorylation signaling had been observed in pseudohypoaldosteronism type II (PHAII)-mutant Wnk4 D561A knock-in mice presenting with typical phenotype of PHAII characterized by salt-sensitive hypertension and hyperkalemic metabolic acidosis.

Methods: The phenotype, mRNA and relevant protein expression and localization in the kidneys were examined.

Results: Unlike the embryonic lethality in global $Wnk1^{-/-}$, global $Wnk4^{-/-}$ mice grew normally and were indistinguishable from wild-type (WT) controls in appearance and behavior. $Wnk4^{-/-}$ mice presented Gitelman-like phenotype with mild hypokalemia and decreased urine calcium excretion. $Wnk4^{-/-}$ mice also revealed a blunted and exaggerated response to thiazide (NCC inhibitor) and furosemide [Na^+-K^+-$2Cl^-$ cotransporter 2 (NKCC2) inhibitor], respectively, in urine Na^+, K^+ and Cl^- excretion. In kidney tissues of $Wnk4^{-/-}$ mice, decreased phosphor (p-)Spak, total Ncc and p-Ncc as well as increased p-Osr1 and p-Nkcc2 mimicking Spak knockout mice were observed. NHE3 was increased but ROMK1 and ENaC(β) expression were decreased.

Conclusions: These phenomena suggested WNK4 dominantly exerts an activation effect on NCC through SPAK-NCC cascade *in vivo*. Blocking WNK4 activity may be a promising strategy for anti-hypertensive drugs development.

Funding: Government Support - Non-U.S.

FR-PO513

Blunted Hypertensive Response to Angiotensin II (AngII) Infusion in CD8 Deficient Mice Is Not Associated with Blunted Stimulation of Na-Cl Cotransporter (NCC)
Nikhil Kamat,[1] Salim Thabet,[2] Nicholas K. Fletcher,[1] David G. Harrison,[2] Alicia A. McDonough.[1] *[1]Cell and Neurobiology, Keck School of Medicine of USC, Los Angeles, CA; [2]Vanderbilt Vascular Biology Center, Vanderbilt University Medical Center, Nashville, TN.*

Background: Previous work has shown that T cells play a critical role in hypertension. Recently we found that the hypertension caused by AngII infusion (490 ng/kg/min for 14 days) is blunted in mice lacking CD8 cells ($CD8^{-/-}$) but not in mice lacking CD4 cells ($CD4^{-/-}$). AngII increased systolic BP (telemetry) to 169±3, 166±4 and 142± 4 mmHg in the WT, $CD4^{-/-}$ and $CD8^{-/-}$ mice respectively ($p < 0.001$). Moreover, we find that hypertension is associated with a striking polarization of renal $CD8^+$ cells to production of IFN-gand IL-17. We sought to determine the role of T cell subtypes on renal sodium transport.

Methods: The abundance of the NCC and its phosphorylated active form (NCC-p) were measured in whole kidney homogenates by immunoblotting. Density values were normalized to baseline values in sham-infused mice, defined as 1.00; * = $p < 0.05$.

Results: Baseline levels of NCC were significantly lower in both $CD4^{-/-}$ (0.71 ± 0.03*) and $CD8^{-/-}$ mice (0.75 ± 0.02*) vs. WT (= 1). Additionally, baseline NCC phosphorylation in mice lacking either $CD4^+$ or $CD8^+$ cells was only 2-3% of that observed in WT mice. AngII infusion increased NCC total levels in all three groups: 1.31 + 0.13* fold in WT, 1.66 + 0.05* fold in CD4-/- and 1.65 + 0.08* fold in CD8-/-; NCC-p levels were increased in WT (3.56 ± 1.04* fold), and brought back to WT levels in CD4-/- (31.6 ± 2.6* fold) and CD8-/- (60.3 ± 11.6* fold).

Conclusions: 1. At baseline, CD4-/- and CD8-/- mice had very low levels of NCCp (and NKCCp levels, not shown) vs. WT.

2. With AngII infusion, CD4-/- vs CD8-/- mice did not demonstrate blunting of the AngII response to NCC or NCCp.

3. The study demonstrates that T cells of both the $CD4^+$ and $CD8^+$ subtype have a major effect on renal sodium transport, and provide a heretofore unrecognized role of these immune cells in modulation of electrolyte homeostasis.

WNK3 Inhibits the Nedd4-2 Mediated Inhibition of the NaCl Cotransporter
Dagmara Lagnaz,[1] Juan Pablo Arroyo,[2] Norma Hilda Vázquez,[2] Anne Debonneville,[1] Norma Bobadilla,[2] Olivier Staub,[1] Gerardo Gamba.[2] *[1]Pharmacology and Toxicology, University of Lausanne, Lausanne, Switzerland; [2]Nephrology, INNSZ and IIB, UNAM, Mexico City, Mexico.*

Background: The With No Lysine (K) (WNK) kinases are known regulators of the activity of the renal NaCl cotransporter NCC, which plays a key role in the regulation of blood pressure and the development of arterial hypertension. We have recently shown that NCC, is modulated by the ubiquitin-protein ligase Nedd4-2 and this effect can be prevented by the serum glucocorticoid kinase 1, Sgk1, which interferes with the Nedd4-2/NCC interaction (Arroyo et al. JASN, 2011).

Methods: In the present study we used *Xenopus laevis* oocytes and HEK293 cells.

Results: Searching for novel regulatory proteins, we observed that WNK3, but not WNK4, interacts with Nedd4-2. In HEK293 cells co-transfected with WNK3 and Nedd4-2 cDNA, there is no variation in WNK3 ubiquitylation, suggesting that WNK3 is not a target of Nedd4-2. On the other hand, in *Xenopus* oocytes, WNK3 is capable of recovering the Nedd4-2 mediated inhibition of NCC, without interfering with the Nedd4-2/NCC interaction, suggesting that WNK3 acts differently than Sgk1 on Nedd4-2 action. In support we found that, in contrast to Sgk1, WNK3 does not phosphorylate mNedd4-2 on S222 or S328 and is able to fully prevent the mutant Nedd4-2 S222/328A provoked inhibition of NCC. *In vitro* phosphorylation demonstrates that WNK3 does phosphorylate Nedd4-2 on another yet to be defined serine residue. Co-expression of the WNK3-F242A mutant, which lacks the ability to bind STE20 kinase, SPAK, and thus cannot activate NCC, is able to completely prevent the Nedd4-2 mediated inhibition of NCC, which points to dissimilar mechanisms between NCC activation by WNK3 (SPAK dependent) and WNK3 mediated inhibition of Nedd4-2 (SPAK independent).

Conclusions: WNK3 prevents the Nedd4-2-induced inhibition of NCC, likely by interfering with Nedd4-2 enzymatic activity, representing a novel mechanism for regulation of NCC activity. The effect of WNK3 on Nedd4-2 is different to the Sgk1 because the serine residues 222 and 328 are not implicated, suggesting the possibility for differential regulation of NCC by WNK3-Sgk1.

FR-PO515

Nitric Oxide-Induced Inhibition of NKCC2 Activity Is Blunted in Thick Ascending Limbs from Angiotensin II-Hypertensive Rats: Role of Phosphodiesterase 5
Vanesa D. Ramseyer,[1,2] Pablo A. Ortiz,[1,2] Jeffrey L. Garvin.[1,2] *[1]Hypertension and Vascular Research, Henry Ford Health Systems; [2]Physiology, School of Medicine, Wayne State University, Detroit, MI.*

Background: Thick ascending limbs (THALs) reabsorb 25% of the filtered NaCl load primarily *via* the Na/K/2Cl cotransporter (NKCC2). NO inhibits NKCC2 activity and NaCl absorption *via* cGMP. In angiotensin (Ang) II-induced hypertension, NaCl reabsorption is increased in THALs; however, whether this is due to impaired NO/cGMP signaling is not known. Intracellular cGMP levels are reduced by cGMP-specific phosphodiesterase 5 (PDE5). Ang II elevates PDE5 and reduces cGMP levels in smooth muscle cells, but whether this occurs in THALs in Ang II-induced hypertension is unknown. We hypothesized that inhibition of NKCC2 by NO is blunted in Ang II-induced hypertension due to increased PDE5 activity.

Methods: Male Sprague Dawley rats were infused with vehicle or 200 ng/kg/min Ang II. On day 5 we measured blood pressure in anesthetized rats and NKCC2 activity in perfused THALs by fluorescence microscopy.

Results: Ang II infusion increased blood pressure from 96 ± 4 to 120 ± 8 mmHg ($p<0.02$). In THALs from vehicle-treated rats, 100 μM of the NO donor spermine NONOate reduced NKCC2 activity by 33% from 1.67 ± 0.31 to 1.11 ± 0.21 AU/s ($p<0.01$) but not in Ang II-hypertensive rats (control: 1.13 ± 0.17 vs NO: 1.32 ± 0.23 AU/s). Addition of 100 μM dibutyryl cGMP reduced NKCC2 activity in control rats from 0.97 ± 0.19 to 0.73 ± 0.15 AU/s ($p<0.01$) but not in THALs from Ang II-hypertensive rats (1.00 ± 0.09 to 1.02 ± 0.30). However, 500 μM dibutyryl cGMP reduced NKCC2 activity in THALs from both controls (1.20 ± 0.32 to 0.76 ± 0.27 AU/s; $p<0.03$) and Ang II-hypertensive rats (1.15 ± 0.07 to 0.68 ± 0.10 AU/s; $p<0.03$). Inhibiting PDE5 with 25 nM vardenafil restored the ability of NO to reduce NKCC2 activity in THALs from Ang II-hypertensive rats (vardenafil: 1.17 ± 0.23 vs vardenafil + NO: 0.44 ± 0.08 AU/s, $p<0.02$).

Conclusions: Inhibition of NKCC2 activity by NO and cGMP is blunted in Ang II-induced hypertension due to elevated PDE5. Increased PDE5 activity in the THAL could contribute to the enhanced THAL NaCl reabsorption seen in this model of hypertension.

Dietary Salt Intake and Angiotensin II Regulates WNK-SPAK-NKCC1 Phosphorylation Cascade in Mouse Aorta
Moko Zeniya, Eisei Sohara, Katsuyuki Oi, Motoko Chiga, Koichiro Susa, Takayasu Mori, Tatemitsu Rai, Sei Sasaki, Shinichi Uchida. *Department of Nephrology, Tokyo Medical and Dental Sciences, Bunkyo-ku, Tokyo-to, Japan.*

Background: NKCC1 is localized in vascular smooth muscle cells and regulates vascular contractility. Recently, we have reported WNK-OSR1/SPAK-NCC/NKCC1/NKCC2 phosphorylation cascade in the kidney and blood vessels. In this study, we investigated how this cascade in mouse aorta was regulated by dietary salt intake and angiotensin II.

Methods: The phosphorylations of SPAK at Thr383 (a phosphorylation site by WNK kinase) and NKCC1 at Thr206 (a phosphorylation site by SPAK) were examined in the aorta of C57BL/6J mice fed high-salt, normal or low-salt diet for a week. Acute (125ng/kg) and chronic (1.4ug/kg/min for a week) angiotensin II (AngII) infusion was also performed to investigate AngII effect on this signal cascade in aorta.

Results: SPAK and NKCC1 phosphorylations in the mouse aortic tissue was increased by low-salt diet and decreased by high-salt diet, respectively. Both acute and chronic AngII infusion also increased SPAK and NKCC1 phosphorylations. Interestingly, this low-salt diet-induced phosphorylation of SPAK and NKCC1 in aorta was impaired in the WNK3 knockout mice, suggesting that WNK3 may be one of the major WNK kinases in mouse aorta.

Conclusions: In this study, we demonstrated that dietary salt intake and AngII regulated WNK-SPAK-NKCC1 phosphorylation cascade in mouse aorta. This could be an important mechanism of blood pressure regulation by WNK kinases in extrarenal tissues.

Nedd4-2 Ablation in Mice Leads to Upregulation of NCC Compensated by Decreased αENaC and Increased ROMK Caroline Ronzaud,[1] Dominique Loffing-Cueni,[2] Sumedha Malsure,[1] Baoli Yang,[3] John B. Stokes,[4] Robert Koesters,[5] Marc P. Maillard,[6] Edith Hummler,[1] Johannes Loffing,[2] Olivier Staub.[1] *[1]Department of Pharmacology and Toxicology, Lausanne University, Lausanne, Switzerland; [2]Institute of Anatomy, Zurich University, Zurich, Switzerland; [3]Obstetrics and Gynecology, Iowa University, Iowa City, IA; [4]Department of Internal Medicine, Iowa University, Iowa City, IA; [5]INSERM UMRS 702, Tenon Hospital, Paris, France; [6]Nephrology, CHUV, Lausanne, Switzerland.*

Background: Control of renal Na^+ and K^+ transport by aldosterone is crucial for maintaining Na^+/K^+ balance and blood pressure (BP). Aldosterone acts in part by preventing ENaC degradation by the ubiquitin ligase Nedd4-2 (N4-2).

Methods: To determine the role of renal N4-2 in mediating salt-sensitive hypertension observed in N4-2 total knockout (KO) mice (Shi *et al*, 2008), inducible renal tubule-specific N4-2 KO mice were generated using the TetOn/CreLoxP systems to delete exons 5-6 of the N4-2 gene. Pax8/LC1 mice, allowing tetracycline-inducible Cre-mediated recombination in renal tubules, were bred with $N4\text{-}2^{fl/fl}$ mice to obtain mutants ($N4\text{-}2^{fl/fl}$/Pax8/LC1) and controls ($N4\text{-}2^{fl/fl}$/Pax8 or $N4\text{-}2^{fl/fl}$/LC1), all treated with doxycyclin.

Results: N4-2 was completely lost in all renal tubular segments in dox-treated mutants. Under both standard and high-Na^+ diets, mutants were able to maintain normal Na^+/K^+ balance, whereas plasma aldosterone and urine volume were increased. Interestingly, mutants displayed hypertension and elevated urine Ca^{2+} excretion under high-Na^+ diet that could be treated with thiazides, suggesting increased NCC activity. Consistently, mutants showed increased NCC protein abundance and phosphorylation. βENaC, γENaC, and ROMK protein expression was increased as well. Unexpectedly, αENaC protein and mRNA were decreased, likely related to the lowered plasma aldosterone levels and compensating the increased NCC activity.

Conclusions: These *in vivo* data show : 1) N4-2 effects on β/γENaC, but not αENaC; 2) importance of N4-2 for controlling BP and Ca^{2+} absorption via regulating NCC; 3) αENaC downregulation and ROMK upregulation that may help preventing hypertension and hyperkalemia, respectively.

FR-PO518

The Drosophila NKCC Ncc69 Is Required for Normal Renal Tubule Function Aylin R. Rodan, Michel Baum, Chou-Long Huang. *Depts. of Medicine and Pediatrics, UTSW Medical Center, Dallas, TX.*

Background: NKCCs play a key role in renal epithelial ion transport. We are using *Drosophila melanogaster*, which has sophisticated genetics, a rapid life cycle, and easily accessible tubules, to better understand NKCC function and regulation. In the fly tubule, cation flux occurs through the principal cells, which express an apical H^+-ATPase that generates a lumen-positive transepithelial potential difference and drives K^+ secretion by K^+/H^+ exchange. Basolateral K^+ uptake may occur through NKCC, Na^+/K^+-ATPase, and other mechanisms.

Methods: Here, we examine the role of the NKCC Ncc69 in *Drosophila* tubule function by measuring fluid secretion (nl/min/tubule) and K^+ flux (pmol/min/tubule) in isolated tubules from wild-type and *Ncc69* mutant flies.

Results: *Ncc69* mutant tubules have decreased rates of fluid secretion (0.43 +/- 0.03 nl/min vs. 0.55 +/- 0.02 nl/min in wild-type) and K^+ flux (62 +/- 4 pmol/min vs. 93 +/- 4 pmol/min in wild-type), and these phenotypes were rescued by expression of wild-type Ncc69 in the principal cells of the tubule. Ouabain decreased K^+ flux in wild-type tubules, from 92 +/- 6 pmol/min to 64 +/- 6 pmol/min, but had no effect in *Ncc69* mutant tubules, indicating that *Ncc69* is the sole Na^+/K^+-ATPase-dependent transporter in unstimulated tubules. However, in the presence of cAMP, which stimulates diuresis, additional Na^+/K^+-ATPase-dependent K^+ transport pathways are recruited, as ouabain abolished non-Ncc69-mediated, cAMP-stimulated K^+ flux. Na^+ flux was unaltered in *Ncc69* mutants, suggesting Na^+ recycling through the Na^+/K^+-ATPase. This enables the fly, which consumes a K^+-rich, Na^+-poor diet, to secrete K^+ and conserve Na^+. Inhibition of fluid secretion and K^+ flux by the regulatory hormone capa-1, which signals through a NO/cGMPpathway, was abolished in *Ncc69* mutant tubules, indicating that Ncc69 is a target for the inhibitory action of this hormone. This is reminiscent of the inhibition of NKCC2 in thick ascending limb by NO/cGMP signaling.

Conclusions: Thus, the fly renal tubule provides a model in which to study NKCC regulation by pathways conserved in the mammalian tubule. Future studies will examine regulation of Ncc69 by the *Drosophila* homologs of WNK and SPAK/OSR1 kinases.

Characterization of the Endocytotic Pathways Involved in Internalization of Renal Na^+-K^+-2Cl^--Cotransporter Anna Daigeler,[1] Christin Dathe,[1] Bridget S. Wilson,[2] Nicholas R. Ferreri,[3] Sebastian C. Bachmann,[1] Kerim Mutig.[1] *[1]Institute of Vegetative Anatomy, Charité Universitätsmedizin Berlin, Berlin, Germany; [2]Department of Pathology and Cancer Research and Treatment Center, University of New Mexico, Albuquerque, NM; [3]Department of Pharmacology, New York Medical College, Valhalla, NY.*

Background: The Na-K-2Cl cotransporter (NKCC2) mediates NaCl absorption in the thick ascending limb of Henle's loop (TAL). Vasopressin (AVP) activates NKCC2 by increasing its surface expression to promote urinary concentration. While NKCC2 exocytosis was intensively studied in the last years, little is known about the endocytotic pathways modulating its surface expression. This study was aimed to characterize the pathways involved in the internalization of NKCC2 at steady state and upon AVP.

Methods: To this end we have tested the involvement of NKCC2 in clathrin-, caveolae-, and multiligand type-1receptor sortilin (Sort1)-dependent endocytotic pathways in rat, mice, and cultured TAL and macula densa (MD) cells using immunohistochemistry, electron microscopy, immunoblotting, and co-immunoprecipitation (co-IP). Effects of AVP were evaluated in AVP-deficient Brattleboro rats after short term desmopressin (dDAVP) administration.

Results: In rat and mouse kidneys, NKCC2 was strongly co-localized with clathrin and moderately co-localized with Sort1, whereas no significant expression of caveolins was detected in TAL. These results were confirmed by electron microscopic evaluation of cultured cells and co-IP from rat kidney extracts. Blockade of the clathrin-mediated endocytosis by potassium depletion or chlorpromazine (30 min each) induced significant accumulation of endogenous NKCC2 (+143%) at the apical membrane in cultured cells. By contrast, genetic deletion of Sort1 in mice did not affect the surface expression or phosphorylation of the transporter. Stimulation of TAL in Brattleboro rats by dDAVP markedly increased NKCC2 surface expression, reduced its association with clathrin (-29%), but did not alter its association with Sort1.

Conclusions: We conclude that NKCC2 internalization is chiefly governed by clathrin-mediated endocytosis and can be modulated by AVP.

FR-PO520

WNK4 Modulates WNK3/SPAK-Mediated NCC Phosphorylation and Activation Maria Castañeda-Bueno,[1] Chao-Ling Yang,[2] Lorena Leonor Rojas,[1] Norma Hilda Vázquez,[1] Shaunessy L. Rogers,[2] James A. McCormick,[2] Gerardo Gamba,[1] David H. Ellison.[2] *[1]Molecular Physiology Unit, INNSZ-IIB, UNAM, Mexico City, Mexico; [2]Nephrology & Hypertension, Oregon Health & Science University and VA Medical Center, Portland, OR.*

Background: WNK3 is a positive activator of NCC through a SPAK-dependent phosphorylation of its N-terminal. In contrast, WNK4 exerts a moderate inhibitory effect upon NCC activity. Additionally, wild type WNK4, but not mutant WNK4-PHAII, decreases WNK3-mediated activation of NCC in oocytes. WNK isoforms interact each other and this is prevented by the elimination of two conserved residues (His and Gln) in the C-terminal domain (WNK4/3-HQ).

Methods: Modulation of NCC phosphorylation and activity by wild type and mutant combinations of WNK3, WNK4, and SPAK was assessed in HEK293 cells and in *Xenopus laevis* oocytes.

Results: Cotransfection of WNK3 with NCC in HEK293 cells increased NCC-T53 phosphorylation. This effect was blocked by knocking down endogenous SPAK with siRNA or by co-expressing the kinase-inactive SPAK T243A. Cotransfection of full-length or a C terminal fragment of WNK4 blocked WNK3-mediated NCC phosphorylation. Full length WNK4 also inhibited NCC activation by WNK3 in oocytes. While WNK4-DA (kinase inactive) was also inhibitory, mutants WNK4-PHAII and WNK4-HQ (which does not interact with WNK3) were not. In concordance with this, WNK3 increased the phosphorylation and abundance of glycosylated NCC, and WNK4 or WNK4-DA reduced them; again, WNK4-PHAII and WNK4-HQ were without effect. WNK4 inhibition of WNK3-induced activation of NCC was not associated with changes in WNK3-T-loop phosphorylation. Finally, WNK3-HQ lost the ability to activate NCC, while WNK4-HQ and WNK3-DA-HQ lost the ability to inhibit NCC, suggesting that the basal effects of these kinases depend on interactions between monomers or with endogenous WNKs.

Conclusions: WNK3 promotes NCC phosphorylation in a SPAK dependent manner. WNK4 inhibits WNK3 mediated activation and phosphorylation of NCC. This WNK4 effect is lost when interaction is prevented by the HQ mutations and is also lost with PHAII-WNK4; the results suggest that PHAII mutations may alter WNK interactions.

FR-PO521

Phosphorylation of Na-Cl Cotransporter by OSR1 and SPAK Kinases Regulates Its Ubiquitination Muhammad Zakir Hossain Khan, Eisei Sohara, Tatemitsu Rai, Sei Sasaki, Shinichi Uchida. *Department of Nephrology, Tokyo Medical and Dental University, Tokyo, Japan.*

Background: Na-Cl cotransporter (NCC) is phosphorylated in its amino terminus based on salt intake under the regulation of the WNK-OSR1/SPAK kinase cascade. Phosphorylation has been shown to be important for its transport activity and plasma membrane expression. We have observed that NCC protein abundance varies in the kidney based on phosphorylation status.

Methods: To clarify the mechanism, we examined NCC ubiquitination status in mice fed low, normal and high salt diets, as well as in a model mouse of pseudohypoaldosteronism type II (PHAII) where NCC phosphorylation by OSR1/SPAK is constitutively elevated.

Results: Low-salt diet decreased NCC ubiquitination, while high-salt diet increased NCC ubiquitination in the kidney, and this was inversely correlated with total and phosphorylated NCC abundance. In the PHAII model, the ubiquitination of NCC in kidney was also lower when compared to that in wild-type littermates. To evaluate the relationship between phosphorylation and ubiquitination of NCC, we expressed wild-type, phospho-deficient and -mimicking NCC in COS7 cells, and the ubiquitination of immunoprecipitated total and biotinylated surface NCC was evaluated. NCC ubiquitination was increased in the phospho-deficient NCC and decreased in phospho-mimicking NCC in both total and surface NCC.

Conclusions: We demonstrated that NCC phosphorylation by the WNK-SPAK/OSR1 signaling cascade decreased NCC ubiquitination, which may contribute to the increase of NCC abundance in plasma membranes.

Generation and Analysis of WT-WNK4 Transgenic Mice Reveal the Physiological Role of WNK4 Takayasu Mori, Eisei Sohara, Tatemitsu Rai, Sei Sasaki, Shinichi Uchida. *Department of Nephrology, Tokyo Medical and Dental Sciences, Bunkyo-ku, Tokyo-to, Japan.*

Background: WNK kinases were identified as the causative genes of pseudohypoaldosteronism type II (PHA II), a hereditary hypertensive disease with hyperkalemia and acidosis. We identified that WNKs form a signal cascade with OSR1/SPAK kinases and SLC12A transporter families. On the other hand, the physiological role of wild-type (WT) WNK4 is still controversial. The purpose of this study is to elucidate this issue by generating and analyzing the transgenic mouse over-expressing WT-WNK4.

Methods: We generated WT-Wnk4 BAC transgenic mice. Purified BAC DNA containing the Wnk4 gene was digested with SwaI, and the desired 36.8-kb fragment was isolated, as reported previously (Lalioti et al.). The purified fragment was injected into one-cell embryos of C57BL/6J mice. We analyzed representative two transgenic lines; one had a low copy number of the transgene (2 copies), and the other had a high copy (30 copies). Blood pressures were measured by telemetry.

Results: WNK4 protein levels in the kidneys of low and high copy (LC and HC) number transgenic mice [Tg($Wnk4^{WT}$)] were increased 1.7±0.1 and 9.1±0.2 fold, respectively, compared with that of wild-type mice. Systolic blood pressure of Tg($Wnk4^{WT}$) mice was increased at night when the WNK4 protein level was increased by the transgene. LC and HC-Tg($Wnk4^{WT}$) mice showed metabolic acidosis, the magnitude of which was larger in HC-Tg than in LC-Tg. The phosphorylations of OSR1, SPAK and NCC in the kidney were clearly increased as the WNN4 protein levels increased in the TG mice.

Conclusions: The increased WT-WNK4 protein level could activate the WNK-OSR1/SPAK-NCC cascade in the in vivo kidney and induce PHAII-like phenotypes.

Sorting Protein-Related Receptor SORLA Modulates Renal Na^+-K^+-2Cl^- Cotransporter through Interaction with the β Isoform of Calcineurin Phosphatase Kerim Mutig,[1] Aljona Borschewski,[1] Christin Dathe,[1] Alexander Paliege,[1] Nicholas R. Ferreri,[2] Sebastian C. Bachmann.[1] *[1]Institute of Anatomy, Charité-Universitätsmedizin Berlin, Berlin, Germany; [2]Department of Pharmacology, New York Medical College, Valhalla.*

Background: Activity of the Na^+-K^+-2Cl^- cotransporter (NKCC2) of the thick ascending limb (TAL) is dependent on its N-terminal phosphorylation. Sorting protein-related receptor SORLA was shown to facilitate this process, but the underlying mechanisms are not fully understood. We hypothesized that SORLA may interfere with kinases or phosphatases relevant for NKCC2 phosphorylation.

Methods: We have studied the regulation of the proline/alanine-rich kinase (SPAK), oxidative stress responsive kinase 1 (OSR1), and calcineurin phosphatase (CnA) in wildtype (WT) and SORLA-deficient (SORLA-/-) kidneys using immunoblotting and confocal microscopy. Protein-protein interactions were studied by co-immunoprecipitation. Functional analyses included SPAK/OSR1-knockdown in cultured cells and application of the calcineurin inhibitor, cyclosporin A (CsA), in vivo and in cell culture.

Results: SPAK, OSR1 and the calcineurin isoform CnAβ were co-localized with NKCC2 in mouse and rat TAL. Their interactions with the transporter were established by co-IPs from rat kidney tissue. Knockdown of SPAK/OSR1 in cultured rat TAL cells led to a diminished phosphorylation of NKCC2. Application of CsA increased the phosphorylation of the transporter, confirming the functional relevance of these kinases and the phosphatase for NKCC2. SORLA-deficiency was associated with near-absence of NKCC2 phosphorylation (-84%), unchanged abundance and distribution of SPAK and OSR1 kinases, but increased renal abundance of CnAß (+201%) and accumulation of the phosphatase in the apical compartment of TAL. Short term administration of CsA to SORLA-/- mice restored their decreased NKCC2 phosphorylation levels, suggesting that CnAß was responsible for the impaired phosphorylation of the transporter upon SORLA-disruption.

Conclusions: Our results thus suggest that SORLA mediates degradation of CnAß in TAL and thus facilitates NKCC2 phosphorylation.

FR-PO524

A Primary Culture of Distal Convoluted Tubules Expressing Functional Thiazide-Sensitive NaCl Transport René J. Bindels, Nicolas Markadieu, Pedro San-Cristobal, Joost G. Hoenderop. *Physiology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.*

Background: Studying the molecular regulation of the thiazide-sensitive Na^+-Cl^- cotransporter (NCC) is important to understand how the kidney contributes to blood pressure regulation. Until now, a native mammalian cell model to investigate the molecular function of this sodium transporter remained elusive. Our aim was to establish, for the first time, a primary distal convoluted tubule (DCT) cell culture exhibiting transcellular thiazide-sensitive Na^+ transport.

Methods: The Complex Object Parametric Analyzer and Sorter (COPAS) was used to sort fluorescent PV-positive tubules from these kidneys, which were then seeded onto permeable supports. To this end, kidneys from mice expressing enhanced green-fluorescent protein (eGFP) under the PV gene promotor (PV-eGFP-mice) were employed. Parvalbumin (PV) is primarily expressed in the DCT, where it colocalizes with NCC.

Results: Kidneys from PV-eGFP-mice were digested by collagenase and subsequently ~5000 fluorescent tubules per micewere isolated. The purity of the sorted tubules was evaluated by RT-PCR with primers of different tubule-segment specific genes. NCC, TRPM6, ROMK and PV were abundantly detected in the sorted tubules, while NKCC2, TRPV5 and ENaC were less abundant. The isolated DCT fragments were seeded on permeable support and after 6 days of culturing, DCT cell monolayers developed transepithelial resistance values of 630 ± 33 Ω.cm^2. The monolayers also established opposing transcellular concentration gradients of Na^+ and K^+. Radioactive $^{22}Na^+$ flux experiments showed a net apical to basolateral thiazide-sensitive Na^+ transport across the monolayers. Both hypotonic low-chloride medium and 1 mM angiotensinII increased this $^{22}Na^+$ transport significantly by four times, which could be totally blocked by 100 µM hydrochlorothiazide. Angiotensin II-stimulated $^{22}Na^+$ transport was also inhibited by 1 µM losartan. Furthermore, NCC present in the DCT monolayers was detected by immunoblot and immunocytochemistry studies.

Conclusions: A murine primary DCT culture was established which expresses functional thiazide-sensitive Na^+-Cl^- transport.

Funding: Government Support - Non-U.S.

FR-PO525

Phosphorylation of an Alternative Splice Variant of the Thiazide-Sensitive NaCl Cotransporter Markedly Augments Its Transport Activity Pedro San-Cristobal, Henrik Dimke, Jacob (Jaap) Deinum, Jacques W.M. Lenders, Joost G. Hoenderop, René J. Bindels. *Department of Physiology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.*

Background: Despite the importance of the thiazide-sensitive NaCl cotransporter (NCC) in renal electrolyte transport and blood pressure regulation, several aspects related to the control of NCC activity remain unexplained. Recently, a novel splice variant in the carboxyl (C)-terminal domain of NCC (NCC-Sv) was identified, containing a phosphorylation site at residue serine 811. The aim of the present study was to establish the functional role of the newly discovered NCC-Sv.

Methods: NCC-Sv and corresponding phospho mutant's activity were evaluated by $^{22}Na^+$ influx measurements using the *X. laevis* expression system. Moreover, NCC-Sv expression and plasma membrane localization was investigated using fluorescence confocal laser scanning microscopy.

Results: Thiazide-sensitive $^{22}Na^+$ transport rates for NCC-Sv (4250 ± 325 pmol/oocyte/hr) were statistically higher than the wild-type transporter (NCC-wt) (3025 ± 336 pmol/oocyte/hr). Furthermore, the mutant mimicking a constitutively active phosphorylation site (S811D) presents a robust transport (5104 ± 313 pmol/oocyte/hr). In line with this result, elimination of this serine residue in NCC-Sv (S811A) (inactive mutant) prevented the enhanced response (2832 ± 239 pmol/oocyte/hr). All phosphomutants showed similar behavior in transport rates when co-expressed with the With No Lysine "K" Kinases WNK4 (63% inhibition) or WNK3 (250% activation), suggesting that NCC splicing and phosphorylation modulates NCC activity indepedently from the WNK pathway. Confocal microscopy of green fluorescent-tagged protein showed no changes in any of all constructs at plasma membrane abundance. Finally, metolazone affinity appeared unaltered between the different variants.

Conclusions: The present study suggest that phosphorylation of NCC-Sv stimulates the intrinsic activity of the transporter, in addition to the currently described molecular mechanisms. Thus, regulation of the phospho site present in NCC-Sv is a novel pathway whereby NCC activity and hence blood pressure can be regulated.

Defective Processing and Trafficking of NKCC2 Proteins in Bartter Syndrome: Role of OS9 Yingying Zhu, Nadia Defontaine, Sylvie Demaretz, Kamel Laghmani. *Universités Paris V, Paris VI, Paris, France.*

Background: Mutations in the renal specific Na-K-2Cl co-transporter, NKCC2, lead to type I Bartter syndrome (BS1). Yet very little is known about the molecular mechanisms underlying the trafficking of NKCC2 mutants in mammalian cells. We have previously shown that wild-type (WT) and NKCC2 mutants are subject to regulation by the endoplasmic reticulum-associated degradation (ERAD). Here, we studied the implication of the ER-resident protein OS9, in the ERAD of BS1-causing mutants.

Methods: The expression of WT and three NKCC2 mutants was monitored in transiently transfected OKP and HEK cells, using immunoblot (IB) and confocal imaging. Protein-protein interactions were investigated by co-immunoprecipitation (Co-IP).

Results: As expected, WT NKCC2 was detected mainly as a complex-glycosylated form, expressed at the cell surface. In contrast, the three BS1-causing mutants exhibited reduced expression levels and were detected mainly intracellularly. Mutant Y477N displayed partial loss of complex glycosylation at the cell surface, and E368G and A628D mutants showed only immature forms and were trapped in the ER. To identify the molecular components of the ERAD of NKCC2 mutants, we focused on OS9, a binding partner of NKCC2 that we identified by the yeast two-hybrid system. Co-IP assay showed that endogenously expressed OS9 interacts with immature forms of WT and NKCC2 mutants. Overexpression of OS9 led to a decrease in the expression and maturation of WT NKCC2, an effect reversed by the proteasome inhibitor MG132. Conversely, knockdown of OS9 by small interfering RNA improved the maturation of WT NKCC2. Importantly, knockdown of OS9 increased the abundance of mutants E368G and Y477N and partially restored the expression of their complex-glycosylated and functional forms. In contrast, knockdown of OS9 had no effect the expression of mutant A628D failing therefore to improve its maturation.

Conclusions: We conclude that OS9 is involved in the ERAD of WT NKCC2 and only some forms of BS1-causing mutants. Moreover, our results suggest that physiological or pathological changes in OS9 expression levels may affect NKCC2 function by modulating its maturation and surface expression.

FR-PO527

Tamm-Horsfall Protein-Deficient Mice Have Increased Sodium Excretion during Acute Sodium Loading Hajamohideen S. Raffi, James M. Bates, Satish Kumar. *Medicine/Nephrology, University of Oklahoma Health Sciences Center, Oklahoma City, OK.*

Background: Tamm-Horsfall Protein (THP) is urine's most abundant protein. THP is synthesized in the thick ascending limb of the loop of Henle where it is postulated to play a role in the regulation of sodium transport. Recent studies have shown increased abundance but reduced activity of the Na+,K+,2Cl- cotransporter (NKCC2) in the kidney, in the absence of THP, suggesting that THP increases the activity of NKCC2. In this study, we determined the effect of acute sodium loading in mice in the presence and absence of THP.

Methods: $THP^{-/-}$ mice were created by homologous recombination and backcrossed for eight generations in order to create similar genetic background in $THP^{+/+}$ and $THP^{-/-}$ mice. Six age matched $THP^{+/+}$ and $THP^{-/-}$ mice were selected. Base line urine samples were collected for 4 hours. The mice were gavaged with 1.8 % sodium chloride solution (10 ml/kg body weight). Urine samples were collected for 4 hours. Urine volume and sodium were measured and compared using Student's t test.

Results: At baseline urine volume was higher in $THP^{-/-}$ mice ($THP^{-/-}$, 0.48ml ± 0.21 vs. $THP^{+/+}$, 0.34ml ± 0.09, p = 0.022) but sodium excretion (mEq/4h) was not different between the two groups. After the salt load, urine volume remained higher in $THP^{-/-}$ mice ($THP^{-/-}$, 0.485ml ± 0.04 vs. $THP^{+/+}$, 0.385ml ± 0.04, p = 0.041) and urinary excretion of sodium (mEq/4h) was higher in $THP^{-/-}$ mice compared to $THP^{+/+}$ mice ($THP^{-/-}$, 0.093 ± 0.009vs. $THP^{+/+}$, 0.072 ± 0.007, p = 0.032).

Conclusions: THP-deficient mice have reduced renal sodium absorption and a secondary defect in urinary concentration. THP plays a role in renal handling of sodium.

FR-PO528

WNK4-OSR1/SPAK-NCC Signal Cascade Has Circadian Rhythm Dependent on Aldosterone Koichiro Susa, Eisei Sohara, Kiyoshi Isobe, Motoko Chiga, Tatemitsu Rai, Sei Sasaki, Shinichi Uchida. *Nephrology, Tokyo Medical and Dental University, Tokyo, Japan.*

Background: Blood pressure and renal salt excretion show circadian rhythms. Recently, it has been clarified that clock genes regulate circadian rhythms of renal transporter expression in the kidney. We found that the activity of WNK-OSR1/SPAK-NaCl cotransporter (NCC) signal cascade is important for regulating salt balance and blood pressure in the body. Although WNK4 and NCC mRNA levels reportedly showed circadian change in the mouse kidney, it remained to be determined whether the activity of this signal cascade also showed circadian change. In this study, we sought to determine whether the protein levels and the phosphorylations of WNK4, OSR1, SPAK, and NCC showed circadian changes in the mouse kidneys.

Methods: Male C57BL/6J mice were sacrificed every 4 h (at 20:00, 0:00, 4:00, 8:00, 12:00, and 16:00), and the expression and phosphorylation of WNK4, OSR1, SPAK, and NCC were determined by immunoblots. (Lights were turned on at 8:00, which was the start of the rest period, and turned off at 20:00, which was the start of the active period, since mice are nocturnal).

Results: Although the protein level of each component of this cascade did not show circadian change, the phosphorylation levels of OSR1, SPAK, and NCC were increased around the start of the active period and decreased around the start of the rest period. Oral administration of eplerenone (10 mg/day) attenuated the overall phosphorylation levels of these proteins and also diminished the circadian change of NCC phosphorylation.

Conclusions: The activity of WNK4-OSR1/SPAK-NCC cascade was shown to have a circadian change in the kidney that may be governed by aldosterone. WNK-OSR1/SPAK-NCC signal cascade may start to be suppressed upon awakening to prepare for adequate sodium excretion during the day. After adequate sodium excretion, this cascade may start to accelerate at bedtime to decrease sodium excretion during the night.

FR-PO529

Aldosterone Increases Surface NCC Protein Expression via Inhibiting ERK1/2 Phosphorylation-Induced NCC Ubiquitination Xiuyan Feng,[1,2] Matthew Lee,[1] Hui Cai.[1,2] *[1]Renal Division, Department of Medicine, Emory University School of Medicine, Atlanta, GA; [2]Renal Section, Atlanta VA Medical Center, Atlanta, GA.*

Background: The thiazide-sensitive Na^+-Cl^- cotransporter (NCC) localizes to the distal convoluted tubule (DCT) and is one of key regulators of sodium balance. The MAPK-ERK1/2 signaling pathway was reported to be mediated in NCC ubiquitination. We have previously shown that knockdown of ERK 1/2 expression increased the surface protein expression of NCC. We also found that aldosteone downregulated the phosphorylation of ERK 1/2. We, therefore, hypothesized that aldosterone up-regulate the NCC surface protein expression via blocking ERK 1/2 phosphorylation-induced NCC ubiquitination.

Methods: We used western blot analysis in mDCT cells and HEK 293 cells.

Results: To further confirm the hypothesis, we treated the mDCT cells with aldosterone 1 μM for 3 hours and found that NCC surface expression was increased whereas ERK 1/2 phosphorylation and NCC ubiquitination were decreased. The NCC ubiquitination was partially increased when we pretreated the mDCT cells with BCI, a specific inhibitor of ERK1/2 phosphatase, suggesting that increase in ERK1/2 phosphorylation enhanced NCC ubiquitination. In addition, when aldosterone treated the HEK 293 cells transiently expressed HA-NCC we found the similar result as that in mDCT cells.

Conclusions: These results suggest aldosterone induced the NCC surface protein expression via inhibiting ERK1/2 phosphorylation-induced NCC ubiquitination.

mTORC2 Critically Regulates Distal Tubular Sodium and Potassium Homeostasis Florian Grahammer, Tobias B. Huber. *Renal Division, Department of Medicine, University Hospital Freiburg, Freiburg, Germany.*

Background: The mTOR pathway plays a pivotal role in orchestrating cellular homeostasis. Yet most data relate to the rapamycin sensitive mTOR complex 1 while the organ specific *in vivo* function of mTOR complex 2 has remained more or less elusive.

Methods: Distal tubular cell specific mTORC 2 (*Rictor*) knock-out mice were generated by crossing *Rictor fl/fl* animals with *Ksp*Cre mice. After crossing, these mice were analyzed using functional assays, light and immunofluorescence microscopy, western blotting and primary culture of CCDs.

Results: *Rictor fl/fl*Ksp*Cre mice were viable and did not show any obvious macroscopic, microscopic nor renal functional phenotype under control conditions up to one year of age. Compared to wild-type mice on a low salt diet, *Rictor fl/fl*Ksp*Cre mice were able to adequately reduce Na+ excretion, whereas a high K+ diet led to moderate hyperkalemia. Under a low salt and high K^+ diet *Rictor fl/fl*Ksp*Cre mice rapidly developed weight loss, hyperkalemia and acute renal failure within 4 days. The same phenotype was seen when *Rictor fl/fl*Ksp*Cre mice were treated with the ENaC blocker triamterene indicating a vital salt conserving role of mTORC2 under salt loosing/potassium sparing conditions.

Biochemically we observed a strikingly reduced phosphorylation of sgk1 at Ser422 which seems to be critical to allow K^+ secretion under reduced Na^+ uptake. Experiments with primary cells from *Rictor fl/fl*Ksp*Cre mice could further substantiate the decisive role of mTORC2 for aldosterone mediated distal tubular signalling.

Conclusions: mTORC2 is a vital kinase for the aldosterone mediated renal tubular stress response under clinically relevant conditions and seems decisive for K+ excretion under low salt or salt loosing conditions.

High-Throughput NKCC Functional Assay in Adherent Epithelial Cells Monica Carmosino, Federica Rizzo, Giuseppe Procino, Silvia Torretta, Maria Svelto. *Biosciences, Biotechnologies and Pharmaceutical Sciences, University of Bari, Bari, Italy.*

Background: The kidney-specific isoform of the Na-K-2Cl cotransporter NKCC2 is involved in the Na+ reabsorption in the TAL cells and in the regulation of body fluid volume. In contrast, the isoform NKCC1 represents the major pathway for Cl- entry in endothelial cells, playing a crucial role in cell volume regulation and vascular tone. Indeed both NKCC isoforms are involved in the regulation of blood pressure and represent important potential drug targets for hypertension treatment. Accordingly a high-throughput screening for NKCC inhibitors is extremely useful in the development and characterization of new anti-hypertensive drugs. So far the high-throughput screening of NKCC transporters activity has been done by 86Rb+ influx assays.

Methods: We developed a Tallium (Tl+) based fluorescent influx assay that can accurately and rapidly measure NKCC transport activity in adherent epithelial cells in the high-throughput Flex station device (FLEXA). We assessed the feasibility of this assay in the renal epithelial LLC-PK1 cells stably transfected with a previously characterized chimeric NKCC2 construct (c-NKCC2).

Results: In the absence of Cl- in the assay buffer, Tl+ addition did not induce any increase in fluorescence. However a robust Tl+ influx was observed after Cl-addition in c-NKCC2 transfected cells but not in mock-transfected or in parental LLC-PK1 cells suggesting that the Tl+ influx is actually mediated by the c-NKCC2 cotransporter. The c-NKCC2-driven FLEXA signal displays a rapid linear increased phase within the first 20 s after Cl- addition followed by a slower increase and a plateau phase. The initial rate of

Tl+-dependent Cl- influx observed in c-NKCC2 transfected cells is about 3-fold over the background signal in mock-transfected LLC-PK1 cells. The preincubation with furosemide prevented the Cl-dependent Tl+ influx confirming the specificity of the NKCC-mediated Tl+ influx.

Conclusions: We demonstrated that this assay is highly reproducible, offers high temporal resolution of NKCC-mediated ion flux profiles and, importantly, as a continuous assay, it offers improved sensitivity over endpoint NKCC functional assay.

The Expression of ClC-Kb, NCC and Calbindin-D_{28k} in Patients with Chronic Hypokalemia Min-hua Tseng,[1,3] Sung-Sen Yang,[2,3] Pei-yi Chu,[3] Shih-Hua P. Lin.[2,3] *[1]Division of Pediatric Nephrology, Department of Pediatrics, Chang Gung Memorial Hospital, Taoyuan, Taiwan; [2]Division of Nephrology, Department of Medicine, Tri-Service General Hospital, Taipei, Taiwan; [3]Graduate Institute of Medical Sciences, National Defense Medical Center, Taipei, Taiwan.*

Background: The actual expression of basolateral membrane chloride channel Kb (ClC-Kb) and apical membrane sodium-chloride cotransporter (NCC) (ClC-Kb) in distal tubules in patients with genetically-confirmed Gitelman's syndrome (GS), classic Bartter's syndrome (cBS), and other causes of chronic hypokalemia has not been well studied.

Methods: Eleven GS patients with different *SLC12A3* mutations (8 missense, 1 nonsense, 1 small deletion, 2 deep intronic), 4 cBS (4 missense, 1 large deletion), and 6 non-GS and non-cBS (3 anorexia nervosa, 2 diuretic abusers, 1 distal renal tubular acidosis) were included. Immunofluoresence (IF) staining for NCC, ClC-Kb and calbindin-D_{28k} of the renal biopsy specimens from these patients and of normal renal tissues obtained from patients receiving total nephrectomy were performed. Urine NCC expression was also measured. All patients underwent renal biopsy have mild proteinuria.

Results: Compared with normal renal tissue, all GS patients showed virtually or markedly attenuated NCC, increased calbidin-D_{28K} but normal ClC-Kb expression. cBS patients had deceased CLC-Kb, but normal NCC and calbidin-D_{28K} expression. Patients with non-GS and non-cBS had normal CLC-Kb, but increased NCC and calbidin-D_{28K} expression. The expression pattern of NCC and CLC-Kb found in the respective GS and cBS was not corrected with the nature and pattern of the corresponding mutations. In contrast to patients with cBS or non-GS and non-cBS, Urinary NCC excretion was markedly decreased in GS patients.

Conclusions: In addition to urinary electrolytes and NCC excretion, the detection of NCC and CLC-kb expression from the renal tissue of patients with chronic hypokalemia may help diagnose the underling causes, especially in patients without *SLC12A3* and *CLCNKB mutations.*

Novel Genetic Variant rs623011 Associates with Non-Familial Thyrotoxic and Sporadic Hypokalemic Paralysis Min-hua Tseng,[1,2] Sung-Sen Yang,[3] Pei-yi Chu,[1] Chih-Jen Cheng,[3] Shih-Hua P. Lin.[1,3] *[1]Graduate Institute of Medical Sciences, National Defense Medical Center, Taipei, Taiwan; [2]Department of Pediatric, Chang Gung Memorial Hospital at Linkou, Taoyuan, Taiwan; [3]Division of Nephrology, Department of Medicine, Tri-Service General Hospital, Taipei, Taiwan.*

Background: Non-familial hypokalemic periodic paralysis (hypoPP) is mainly composed of thyrotoxic (TPP) and sporadic periodic paralysis (SPP) and features with ictal hypokalemia and muscle paralysis. We have previously suggested that reduced K^+ efflux in skeletal muscle originated from mutations or inhibition of Kir channels may lead to acute hypokalemia and paralysis in these patients (Cheng CJ et al. JBC 2011 and Lin SH et al. JASN 2012). A recent genome-wide association study of Thai TPP patients identified a novel genetic variant rs623011, which may potentially reduce the transcription of Kir2.1 and total Kir current (J Hum Genet 2012). The aim of this study was to evaluate if this genetic variant is present in our patients with TPP and SPP without hyperthyroidism, the second leading cause of non-familial hypoPP in Asia.

Methods: A case-control association study that examines the relationship between rs623011 genetic variant and non-familial hypoPP patients in Taiwanese population sequence rs623011 in 87 patients with TPP, 57 SPP, and 100 healthy subjects. All patients with TPP and SPP did not have mutations in the skeletal muscle voltage-gated Ca^{2+} or Na^+ channels, Kir2.1 and Kir2.6 channels. A chi-square test and SPSS 17.0 software were used to analyze the sequencing results.

Results: Compared with normal control, the frequency of the risk allele A of rs623011 was significantly higher in TPP and SPP patients (73.6% versus 53.2%, p=0.004; 81.5% versus 53.2%, p=2.36E-005, respectively) with the Odds Ratios (95% confidence interval) 2.426 (1.329-4.426) and 4.493(2.194-9.201), respectively. However, the frequency of the A allele of rs623011 was not significantly different between TPP and SPP.

Conclusions: We confirm that rs623011 is the susceptible locus not only in TPP but also in SPP. TPP and SPP may share the pathogenic mechanism of reduced Kir current in skeletal muscle independent of thyroid hormone.

FR-PO535

Role of Nedd4-2 and ß$_1$Pix in the Regulation of ENaC by AMPK in Kidney Epithelial Cells Hui Li,[1] Tengis S. Pavlov,[2] Jeffrey Lee,[1] Roland D. Tuerk,[3] Dietbert Neumann,[3] Alexander Staruschenko,[2] Kenneth R. Hallows.[1] *[1]Medicine, Univ. of Pittsburgh, Pittsburgh, PA; [2]Physiology, Medical College of Wisconsin, Milwaukee, WI; [3]Molecular Genetics, Maastricht Univ., Maastricht, Netherlands.*

Background: Renal collecting duct epithelial Na^+ channels (ENaCs) play a key role in total body volume and blood pressure control. The metabolic sensor AMP-activated kinase (AMPK) inhibits ENaC by enhancing ENaC binding to the ubiquitin ligase Nedd4-2, but the mechanisms involved are unclear. The guanine nucleotide exchange factor β_1Pix inhibits ENaC by impairing 14-3-3 protein binding to and sequestration of Nedd4-2, thereby promoting Nedd4-2 targeting to ENaC. We thus hypothesized that β_1Pix participates in ENaC regulation by AMPK.

Methods: Mass spectrometry and in vitro phosphorylation assays were used to detect and define AMPK phosphorylation sites in Nedd4-2 and β_1Pix. Co-immunoprecipitation (co-IP) assays were used to examine modulation of β_1Pix/14-3-3/Nedd4-2 interactions by AMPK in renal epithelial cells. Whole-cell patch-clamp studies were performed in CHO cells co-expressing ENaC and various β_1Pix and AMPK constructs.

Results: AMPK phosphorylates Nedd4-2 at Ser-444, a site previously shown to enhance Nedd4-2 cellular stability. AMPK also directly phosphorylates β_1Pix in vitro. In preliminary co-IP studies the AMPK activator metformin enhanced 14-3-3-β_1Pix binding and inhibited 14-3-3-Nedd4-2 binding in MDCK cells, consistent with our earlier finding of enhanced ENaC-Nedd4-2 association with AMPK activation in cells. Whole-cell ENaC currents were inhibited by the AMPK activator AICAR or by β_1Pix over-expression, but these effects were not additive. Moreover, ENaC current inhibition by AICAR or by over-expression of a constitutively active AMPK mutant (γ1-R70Q) was fully overridden in cells co-expressing a β_1Pix mutant (Δ602-611) that is unable to bind 14-3-3 proteins.

Conclusions: ENaC regulation by AMPK requires both functional Nedd4-2 and β_1Pix. We propose that AMPK inhibits ENaC by phosphorylating Nedd4-2, which enhances Nedd4-2 stability, and by regulating the function of β_1Pix, which then competes with Nedd4-2 for 14-3-3 binding and thereby enhances Nedd4-2 binding to ENaC.

Scaffold Protein CNK3 Coordinates Assembly of a Multiprotein ENaC-Regulatory Complex Rama Soundararajan,[1] Tim Ziera,[1] Eric Koo,[1] Karen Ling,[1] Jian Wang,[1] Steffen Borden,[2] David Pearce.[1] *[1]Division of Nephrology, Department of Medicine, University of California San Francisco, San Francisco, CA; [2]Strategic Planning, Bayer Healthcare Pharmaceuticals, Berlin, Germany.*

Background: Hormone-regulation of ion transport in the kidney tubules is essential for fluid and electrolyte homeostasis in vertebrates. A large body of evidence has suggested that transporters and channels exist in multiprotein regulatory complexes, however, relatively little is known about the composition of these complexes or their assembly. The epithelial sodium channel (ENaC), in particular, is tightly controlled by the salt-regulatory hormone aldosterone, which acts, at least in part, by increasing expression of the serine-threonine kinase SGK1.

Methods: We used biotinylation assays in transiently transfected HEK293T kidney epithelial cells to study the effect of CNK3 on ENaC surface expression. We also used these cells to test protein-protein interactions in co-immunoprecipitation assays. We used polarized mpkCCD$_{cl4}$ kidney epithelial cells grown on Transwell filters to study effects on ENaC activity. We used GST pull-down assays to analyze direct protein-protein interactions *in vitro*.

Results: We show that aldosterone induces the formation of a native 1.0-1.2 MDa plasma membrane complex, which includes ENaC, SGK1, and the ENaC inhibitor, Nedd4-2, a key target of SGK1. We further show that this complex contains the PDZ domain-containing protein Connector-Enhancer-of-Kinase-Suppressor-of-Ras isoform-3 (CNK3). CNK3 physically interacts with ENaC, Nedd4-2 and SGK1, enhances the interactions among them, and stimulates ENaC surface expression and function in an aldosterone-induced PDZ domain-dependent manner.

Conclusions: These results strongly suggest that CNK3 is a molecular scaffold, which coordinates the assembly of a multiprotein ENaC-regulatory complex at the plasma membrane, and hence plays a central role in Na^+ homeostasis.(NIH Grants DK078679, DK056695 and DK085101).

FR-PO537

P2X$_4$ Regulates ENaC-Mediated Na Reabsorption and Salt-Sensitivity of BP Eilidh Craigie, David G. Shirley, Scott S.P. Wildman, Robert J. Unwin. *Centre for Nephrology, UCL, London, United Kingdom.*

Background: Nucleotides act via P2 receptors to modify ENaC-mediated Na reabsorption in the ASDN (Bailey & Shirley 2009, Purin Sig). An inhibitory role for P2Y$_2$ receptors upon ENaC activity has been proposed as an intrinsic control system that assists the ASDN to respond appropriately to a high Na load (Toney *et al 2012, Curr Opin Neph Hypert*). An *in vitro* investigation showed that activation of apical P2X$_4$ receptors can potentiate ENaC activity at a normal ASDN Na concentration, highlighting the possibility that P2X$_4$ may also act as a regulator of ENaC (Wildman *et al* 2008, JASN).

Methods: We investigated the role of the $P2X_4$ receptor in the regulation of ENaC activity in $P2X_4$ null mice ($P2X_4^{-/-}$) and littermate controls ($P2X_4^{+/+}$). Mice were maintained on either a standard (SD;0.3%) or a low (LD;0.03%) Na diet for 2 weeks. They were anaesthetised (Inactin, 100mg/kg IP) and surgically prepared for renal clearance studies. After control collections of urine and plasma, mice were given benzamil (1 mg/kg bolus, IV) and further collections were made. Mean arterial (MA) BP was also measured. Data are presented as mean±SEM; statistical comparisons were made using ANOVA and post-hoc Bonferonni.

Results: MABP was significantly elevated in $P2X_4^{-/-}$ compared with $P2X_4^{+/+}$ mice on SD (95±2 vs 85.2±2mmHg; P=<0.01; n=8); LD significantly reduced MABP in $P2X_4^{-/-}$ mice (P=<0.01) while the reduction in dietary Na had no effect in $P2X_4^{+/+}$ mice (87.4±3.2 vs 86.7±2.6mmHg; n=6). On SD ENaC-mediated Na reabsorption (presented as Δ fractional Na excretion [FE_{Na}]) was similar for $P2X_4^{-/-}$ and $P2X_4^{+/+}$ mice (1.9±0.2 vs 1.7±0.2%). On LD $P2X_4^{-/-}$ mice had a significantly lower ΔFE_{Na} than $P2X_4^{+/+}$ mice (1.5±0.2 vs 3.2±0.5%; P<0.01) reflecting an inability to increase ENaC-mediated Na reabsorption on LD.

Conclusions: The BP response to LD in the $P2X_4^{-/-}$ mice suggests that they have a salt-sensitive BP. Moreover, the inability of the $P2X_4^{-/-}$ mice to increase their ENaC-mediated Na reabsorption after LD feeding is compatible with the *in vitro* finding that $P2X_4$ activation potentiates ENaC activity; these observations suggest that $P2X_4$ may act as an intrinsic regulator of ENaC activity in the ASDN in response to normal and/or low Na loads.

FR-PO538

Epigenetic Repression of the Epithelial Sodium Channel α-Subunit Gene Involves Promoter Methylation and a Loss of Sp1 Binding Zhiyuan Yu, Qun Kong, Bruce C. Kone. *Medicine, University of Texas Medical School at Houston, Houston, TX.*

Background: ENaC in the distal nephron constitutes the rate-limiting step for renal sodium and fluid reabsorption. Aldosterone increases tubular sodium absorption in large part by increasing α-ENaC transcription in collecting duct principal cells. We previously demonstrated that epigenetic changes in chromatin repress basal α-ENaC transcription. Here, we investigated the role of promoter methylation in epigenetic control of the gene.

Methods: mIMCD3 collecting duct cells, and stable mIMCD3 cell lines harboring an α-ENaC promoter-reporter construct, were analyzed after vehicle or aldosterone treatment. The effects of DNA methyltransferase (DNMT) inhibitor 5-aza-2'-deoxycytidine (5-Aza-dC) or DNMT isoform gene silencing on α-ENaC mRNA levels and promoter activity were measured by qRT-PCR and luciferase assays, respectively. Bisulfite treatment and sequencing analysis were used to identify methylation of cytosines in the α-ENaC promoter. In vitro methylation and gel shift analysis were used to assay the effects of promoter methylation on α-ENaC promoter activity and Sp1 binding to it.

Results: 5-Aza-dC treatment of IMCD3 cells augmented basal and aldosterone-induced α-ENaC mRNA levels and promoter activity by ~50%. In a corresponding manner, in vitro methylation of the α-ENaC promoter was sufficient to silence its activity in transfected IMCD3 cells. In contrast, siRNA-mediated knockdown of DNMT-3b dramatically increased α-ENaC mRNA levels and promoter activity. Bisulfite treatment and sequencing analysis of the α-ENaC promoter identified methylation of cytosines framing an Sp1 enhancer element. In vitro methylation inhibited binding of Sp1 to this element.

Conclusions: DNMT3b-dependent methylation of α-ENaC promoter sequences framing an Sp1 enhancer element limits α-ENaC transcriptional activity under basal conditions and in response to aldosterone. These results disclose a novel epigenetic mechanism for control of basal and aldosterone-induced α-ENaC transcription.

FR-PO539

Disruption of Bradykinin Signaling Impairs ENaC Adaptation to Dietary Salt Intake Mykola Mamenko, Oleg L. Zaika, Oleh Pochynyuk. *Integrative Biology and Pharmacology, University of Texas Health Science Center at Houston, Houston, TX.*

Background: Activation of the renal kinin-kallikrein system promotes natriuresis and diuresis via generation of its principal signaling peptide bradykinin (BK). We have recently identified that BK inhibits activity of the Epithelial Na^+ Channel (ENaC) in the aldosterone sensitive distal nephrons (ASDN) via B2R-PLC pathway.

Methods: The current study combines single channel patch-clamp recordings, fluorescent imaging in split-opened ASDNs of B1R, B2R -/- and wild-type (WT) mice with systemic assessment of urinary Na+ excretion to probe the physiological relevance of BK regulation of ENaC.

Results: We found that in contrast to WT mice BK (500 nM) has no effect on ENaC activity in B1R, B2R knock-outs. ENaC open probability (P_o) is greatly elevated in B1R, B2R -/- mice compared to WT animals during high salt intake (2% Na^+). This difference is less apparent under regular salt intake (0.32% Na^+) and blunted upon salt restriction (<0.01% Na^+). ENaC activity is comparably increased in both mouse strains by saturation of systemic mineralocorticoid status with deoxycorticosterone acetate (DOCA) suggesting that the effect of BK on ENaC is independent of aldosterone. It is accepted that angiotensin converting enzyme (ACE) represents the major pathway of BK degradation. Systemic inhibition of ACE with captopril (30 mg/kgBW for 7 days) significantly decreases ENaC activity and increases urinary Na^+ excretion in WT mice, but this effect is diminished in B1R, B2R -/- mice. At the cellular level, captopril (100 μM) greatly potentiates the inhibitory action of 100 nM BK on ENaC and augments BK-induced elevations of $[Ca^{2+}]_i$ in ASDN cells.

Conclusions: BK reduces ENaC activity especially during elevated sodium intake via a distinct pathway. Moreover, antihypertensive action of ACE inhibitors can be augmented by elevated BK levels, decreasing ENaC-dependent sodium reabsorption in ASDN.

FR-PO540

PKC and PKA Differentially Regulate TRPV4 Activity and Trafficking in Distal Nephron Mykola Mamenko, Oleg L. Zaika, Oleh Pochynyuk. *Integrative Biology and Pharmacology, University of Texas Health Science Center at Houston, Houston, TX.*

Background: Distal nephron (DN) is responsible for final regulation of water and electrolyte balance. The ability of DN cells to reabsorb/secrete numerous ions and water is regulated by mechanical stimuli, such as changes in tubular flow and fluid composition. DN cells respond to increased flow by elevations in $[Ca^{2+}]_i$. It was recently shown that Ca^{2+}-permeable TRPV4 channel is abundantly expressed in DN and functions as a sensor/transducer of flow-induced stimuli. The mechanisms involved in regulation of TRPV4 activity in DN, though potentially important, remain poorly understood.

Methods: The current research combined Fura-2 Ca^{2+} imaging with IHC on split-opened distal nephrons of C57BL/6 mice to study subcellular distribution and functional activity of TRPV4 channels in distal nephron.

Results: We found that activation of PKA pathway with forskolin does not affect TRPV4-mediated Ca^{2+} responses to flow, while markedly shifting subcellular distribution of the channel to the apical membrane. These actions are blocked with a specific PKA inhibitor H-89. On the other hand application of phorbol-12-myristate-13-acetate (PMA), to activate PKC, significantly increases TRPV4-mediated Ca^{2+} responses to flow, without affecting the subcellular distribution of the channel. Inhibition of PKC with BIH-1 diminishes cellular responses to elevated flow.

Conclusions: Functional status of TRPV4 channel in the DN is regulated by two distinct signaling pathways. While PKA cascade is responsible for TRPV4 trafficking and translocation to the apical membrane, PKC-dependent pathway increases the activity of the channel on the membrane.

FR-PO541

Uncleaved αENaC Is the Predominant form at the Cell Surface of Renal Tubules In Vivo Søren Olesen,[1] Birgitte M. Christensen,[1] Johannes Loffing,[2] Jeppe Praetorius.[1] [1]*Department of Biomedicine, Aarhus University, Health, Aarhus, Denmark;* [2]*Department of Anatomy, University of Zurich, Zurich, Switzerland.*

Background: The principal cells in the renal connecting tubules and collecting ducts reabsorb Na^+ from the preurine by apical entry through the ENaC complex and basolateral extrusion by the Na,K-ATPase. In this process, ENaC is the rate-limiting step. Both α- and γENaC subunits are modulated by proteolytic cleavage. Cleavage of αENaC is believed to occur by furin during transit trough the Golgi apparatus. The cleavage state of ENaC subunits has profound impact on channel activity as well as the resident time in the plasma membrane. The aim of the study was to test the current hypothesis that αENaC subunits are predominantly found in the cleaved form in the cell surface of connecting tubules and collecting ducts.

Methods: Surface-biotinylation of renal tubules was performed after enzymatic treatment of the renal cortex from normal mice.The surface biotinylation of CNT and CD was validated by co-labelling tubules with fluorescent Alexa488-conjugated streptavidin and endogenous green fluorescent tubules in a TRPv5 promoter driven eGFP expressing mouse line. Biotinylated and total protein fractions were immunoblotted with anti-n-terminal αENaC antibodies to determine various processed forms by molecular weight of the protein.

Results: The majority of αENaC in the biotinylated fraction is in full length forms (approximately 100 kDa and 85 kDa). Only a minor fraction (23±4 %) corresponds to the cleaved n-terminal of 30 kDa. In the total homogenate, the 30 kDa band was slightly more pronounced (34±3%) compared to the higher molecular weight forms. Approximately 10% of total αENaC was found in the biotinylated (surface) fraction. These fractions were not altered by aldosterone in preliminary experiments with 6hrs to 7 days aldosterone treatment. Compared to the total homogenate, the biotinylated fraction virtually excluded the intracellular protein α-tubulin.

Conclusions: In conclusion, αENaC at the surface of connecting tubules and collecting ducts exists primarily in a cleavable form accessible to regulation by exo-proteases.

Mechanistic Insights into ENaC Na^+ Self-Inhibition Ossama B. Kashlan, Brandon M. Blobner, Thomas R. Kleyman. *Medicine, University of Pittsburgh, Pittsburgh, PA.*

Background: The epithelial Na^+ channel (ENaC) is key to the regulation of extracellular fluid volume and blood pressure through its action in the aldosterone-sensitive nephron. Inhibition of ENaC by extracellular Na^+, referred to as Na^+ self-inhibition, likely occurs through an allosteric mechanism of Na^+ binding to low affinity sites in the large extracellular regions of ENaC subunits. Na^+ self-inhibition reflects Na^+ or Li^+ specific inhibition of ENaC currents. The effector binding sites and transduction pathways remain unidentified. A recent comparative model of the ENaC α subunit revealed an acidic cleft, analogous to the acidic region observed in the resolved structure of acid sensing ion channel 1 (ASIC1).

Methods: We hypothesized that this cleft and analogous clefts in the β and γ subunits host Na^+ effector sites. Mutations of acidic residues in the α subunit acidic cleft led us to identify one site in the peripheral finger domain that has a role in Na^+ self-inhibition. Mutations of analogous sites in the β and γ subunits produced similar results. We examined the effects of mutations of nearby sites on Na^+ self-inhibition, which implicated a loop that connects the central palm and β-ball domains of the α subunit in Na^+ self-inhibition.

To determine whether these sites were involved in effector coordination, we measured the ability of mutants to change the effector specificity of Na^+ self-inhibition, which is $Na^+ > Li^+ >> K^+$ for wild type mouse ENaC.

Results: Several mutations in the palm/β-ball loop of the α subunit induced greater inhibition by Li^+ than by Na^+. Some of these also induced increased K^+ inhibition, compared to wild type. To identify steps in the transduction pathway, we attempted to trap ENaC in a specific conformation by crosslinking sites within the acidic cleft. Introducing Cys to both sites on the finger domain and the nearby loop led to channels that were strongly stimulated by dithiothreitol.

Conclusions: Our results suggest that sites in the acidic cleft influence the effector selectivity of Na^+ self-inhibition, and that conformational changes between nearby structures are associated with channel gating. These data suggest that the acidic cleft may host an inhibitory Na^+ binding site.

FR-PO543

Colon Specific αENaC Gene Inactivation Fully Inhibits Electrogenic Amiloride Sensitive Sodium Transport, Leading to Sodium Loss in Faeces without Compromising Overall Sodium and Potassium Balance

Sumedha Malsure,[1] Romain Perrier,[1] Marc P. Maillard,[2] Bernard C. Rossier,[1] Edith Hummler.[1] *[1]Department of Pharmacology and Toxicology, UNIL, Lausanne, Vaud, Switzerland; [2]Service of Nephrology, CHUV, Lausanne, Vaud, Switzerland.*

Background: The epithelial sodium channel (ENaC) composed of three sub-units α, β and γ plays an important role in sodium balance, blood volume and blood pressure. Although the role of ENaC on sodium reabsorption in kidney and lung is well established, less is known in colon. The aim of this project is to investigate the importance of αENaC expression in the distal colon for maintaining sodium and potassium balance.

Methods: It was assessed by generating a double-transgenic mouse in which αENaC expression is deleted in the colonic crypt cells by using the *villin* promoter ("KO" mice). Quantitative RT-PCR and protein expression of αENaC was distal colon specific and near-complete (>98%) in "KO" mice.

Results: Following a standard or sodium-deficient diet, the "KO" mice did not show any difference in body weight compared to WT. By contrast, the "KO" mice exhibited a highly significant decrease in amiloride-sensitive rectal potential difference that was maintained under standard (ko, n=7: -6±1 mV versus wt, n=6: -16 ±5 mV; P< 0.005) and salt-deficient (ko, n=6: -6 ±4 mV versus wt, n=5: -29 ± 3 mV; P< 0.0005) diets indicating that in colon, electrogenic sodium transport is mediated by ENaC. Sodium loss through faeces was significantly increased in "KO" mice, confirming reduced sodium reabsorption via ENaC in colon. Under standard and salt restriction, plasma sodium and potassium electrolytes were normal in "KO" and WT mice. Under standard diet, urine electrolytes were similar in both groups. Under salt restriction, however, sodium retention was significantly increased in KO mice suggesting activation of RAAS.

Conclusions: We conclude that i) upon standard diet, ENaC-mediated sodium reabsorption in colon is not crucial for sodium or potassium balance. ii) under sodium restriction, sodium reabsorption through the colon becomes limiting and it may lead to activation of RAAS to compensate for salt loss through the colon.

Neural Precursor Cell Expressed, Developmental Down-Regulated 4 like Protein, Serum- and Glucocorticoid-Induced Protein Kinase 1, and 14-3-3 Proteins Differentially Regulate the Cleaved and Uncleaved Forms of the Epithelial Sodium Channel

Mariana Labarca, Donald Goens, Wuxing Dong, Vivek Bhalla. *Nephrology Division, School of Medicine, Stanford University, Stanford, CA.*

Background: The epithelial sodium channel (ENaC) enhances sodium retention via the principal cells of the distal nephron which is a crucial determinant of hypertension. Nedd4-2 ubiquitin ligase is a major regulator of ENaC activity *in vivo*. ENaC channels require proteolysis of the extracellular domain for full maturation and activation. Aldosterone stimulates ENaC-mediated sodium transport by activating serum and glucocorticoid kinase 1 (SGK1) which phosphorylates Nedd4-2 and promotes its interaction with 14-3-3 proteins, thus avoiding Nedd4-2-mediated inhibition of ENaC. Whether Nedd4-2, SGK1, and 14-3-3 differentially regulate cleaved and uncleaved forms of ENaC is not well known.

Methods: Cell-based assays to analyze exogenously or endogenously expressed proteins by co-immunoprecipitation, biotinylation and subcellular fractionation assays.

Results: Nedd4-2 preferentially binds to cleaved ENaC in transfected HEK293T cells (10.9:1 +/- 0.009, p < 0.05). The majority of Nedd4-2 co-fractionates with cleaved but not uncleaved ENaC in subcellular fractionation assays performed on transfected 293T and mpkCCDc14 cells. SGK1 increases cell surface cleaved and uncleaved ENaC (1.55 +/- 0.17, 2.38+/-1.59, respectively, p<0.05) but increases only cleaved ENaC in the total cell lysate (4.96 +/- 0.22, p<0.05). SGK1 also shifts the preference of Nedd4-2 interaction from cleaved to uncleaved ENaC. R18 is a peptide that interferes with interaction of 14-3-3 and Nedd4-2. R18 reverses the SGK1-mediated increase in cell surface ENaC and total cleaved ENaC.

Conclusions: Aldosterone-induced SGK1 and 14-3-3 proteins coordinately regulate Nedd4-2 and thereby ENaC activity via several mechanisms, and each effect is dependent on the cleavage status of ENaC. The interplay between intracellular regulators of ENaC activity is more complex than currently understood and warrant further investigation.

Regulation of Sodium Homeostasis by the Deubiquitylating Enzyme Usp2 In Vivo

Daniel Pouly,[1] Anne Debonneville,[1] Marc P. Maillard,[2] Olivier Staub.[1] *[1]Department of Pharmacology and Toxicology, University of Lausanne, Lausanne, Switzerland; [2]Service of Nephrology, Lausanne University Hospital, Lausanne, Switzerland.*

Background: Na^+ homeostasis maintenance is a key process for renal blood pressure regulation in mammals. Na^+ reabsorption occurs all along the renal tubule and about 15% is under the hormonal control of the Renin-Angiotensin-Aldosterone-System in the Aldosterone-sensitive Distal Nephron (ASDN) through the thiazide-sensitive Na^+-Cl^- Cotransporter (NCC) and the amiloride-sensitive Epithelial Na^+ Channel (ENaC). Both have been shown by our lab and collaborators to be regulated by ubiquitin mediated regulation via the SGK1-NEDD4-2 pathway. The deubiquitylating enzyme Usp2-45 was identified as an aldosterone-induced gene and *in vitro* studies showed that it enhances ENaC cell surface expression and activity. Moreover, USP2-45 interacts with the ubiquitin ligase NEDD4-2 and ENaC. Altogether, these data make USP2-45 a putative regulator of ENaC and NCC by counteracting their down-regulation by NEDD4-2.

Methods: We address here the implication of Usp2 in Na^+ homeostasis *in vivo* by taking advantage of a total and constitutive Usp2-knockout mouse model. We subjected these animals to dietary switch from Normal Sodium (0.17% Na^+; NSD) to either Low Sodium (>0.01% Na^+; LSD) or High Sodium (3.2% Na^+; HSD) diets. Their renal phenotype was addressed in metabolic cages, blood pressure measurements by telemetry and Western blot analyses using antibodies against various proteins involved in renal Na^+ reabsorption.

Results: We report here that the Usp2-KO mice have normal Glomerular Filtration Rate and adapt perfectly to Na^+ dietary changes. They display normal plasma Na^+, K^+ and aldosterone levels, comparable expression levels of αENaC, NCC, SGK1 and NEDD4-2 and show no variation in blood pressure under either LSD or HSD.

Conclusions: These unexpected results indicate that Usp2-KO mice are perfectly able to maintain Na^+ and K^+ homeostasis which may suggest that compensatory mechanisms have taken place in these animals.

Role of the Renal Mineralocorticoid Receptor for Potassium Homeostasis

Marian Andreas Roesinger,[1] Dominique Loffing-Cueni,[1] Caroline Ronzaud,[2] Jérémie Canonica,[2] Anne Debonneville,[2] Olivier Staub,[2] Edith Hummler,[2] Johannes Loffing.[1] *[1]Institute of Anatomy, University of Zurich; [2]Department of Pharmacology and Toxicology, University of Lausanne.*

Background: The mineralocorticoid hormone aldosterone (aldo) is released from the adrenal glands upon a dietary K^+ load. Aldo enhances renal K^+ excretion via ROMK channels and stimulates apical epithelial Na^+ channels (ENaC) to provide the electrochemical gradient for K^+ secretion.

Methods: Here we studied knockout mice ($MR^{flox}/AQP2^{cre}$) with targeted inactivation of the mineralocorticoid receptor (MR) in the renal collecting system (CS).

Results: $MR^{flox}/AQP2^{cre}$ mice show mild hyperaldosteronism, but are otherwise healthy. The mice tolerate K^+ loading (5% K^+, 2d) without major illness, but show slightly reduced food intake indicating K^+ avoidance. Immunoblotting (IB) and immunohistochemistry (IHC) reveal a K^+ diet-induced increase in ROMK protein abundance and apical localization that is similar for the CS of control and $MR^{flox}/AQP2^{cre}$ mice. However, $MR^{flox}/AQP2^{cre}$ mice show less K^+ diet-induced α- and γENaC proteolytic activation (assessed by IB) and the apical translocation of ENaC is restricted to the remaining MR-positive late DCT (assessed by IHC). ENaC apical translocation is not seen in the MR-negative CS. Interestingly, $MR^{flox}/AQP2^{cre}$ have a reduced abundance and phosphorylation of the NaCl-cotransporter (NCC) in the DCT. This NCC down-regulation is observed already under basal conditions, but becomes even more pronounced on 5% K^+ diet.

Conclusions: Thus, the K^+ diet-induced activation of ENaC, but not of ROMK, appears to depend on MR. In $MR^{flox}/AQP2^{cre}$ mice, the loss of the MR-dependent activation of ENaC in the CS might be compensated, at least in part, by down-regulation of NCC, which increases Na^+ delivery to cells with remaining ENaC activity, and hence improves the electrochemical gradient for K^+ secretion.

FR-PO547

The Aldosterone Paradox: How the Kidney Combines Sodium Retention and Potassium Secretion

Nils van der Lubbe, Alexander H. Danser, Robert Zietse, Ewout J. Hoorn. *Internal Medicine - Nephrology, Erasmus Medical Center, Rotterdam, Netherlands.*

Background: The aldosterone paradox refers to the question how aldosterone can promote renal Na^+ retention during hypovolemia and K^+ secretion during hyperkalemia. The main Na^+ transporters in the aldosterone-sensitive distal nephron are the Na^+ Cl^- cotransporter (NCC), which is regulated by WNK and SPAK kinases, and the epithelial Na^+ channel (ENaC), which is regulated by NEDD4-2. Here, we challenged rats not only with low Na^+ (LS) and high K^+ diets (HK) but also with a combined diet (LSHK).

Methods: Normal rats (n=6/group) were fed control diet (0.5% Na^+, 0.8% K^+), LS (0.001% Na^+), HK (5% K^+), or LSHK (0.001% Na^+, 5% K^+) for 8 days. Plasma assays and immunoblotting of kidney homogenates were conducted using standard methods.

Results: Compared to control diet, LS increased plasma renin activity, angiotensin I and II, and aldosterone (429±149 pg/mL), while HK increased aldosterone only (420±183 pg/mL). LSHK caused mild hyperkalemia (5.9±0.2 mmol/L) and increased aldosterone

to a greater extent (1355±228 pg/mL). LSHK increased renin activity similar to LS but failed to increase angiotensin I and II. In the kidney, LS increased NCC 1.4-fold, whereas both HK and LSHK decreased NCC 1.4-fold ($p<0.05$ for all). Both LS and HK increased ENaC (average for all subunits 1.5-fold), while this effect was greater with LSHK (3.0-fold). Only LS increased SPAK (2.4-fold), while both HK and LSHK decreased NEDD4-2 (1.7-fold, $p<0.05$ for all). In a follow-up experiment, LS was still able to increase NCC in the presence of losartan.

Conclusions: LS favors Na^+ reabsorption through NCC, whereas HK favors Na^+ reabsorption through ENaC to indirectly promote K^+ secretion. LS may activate NCC through angiotensin II and SPAK, although this effect was not reversed by losartan. The inhibition of NEDD4-2 by HK and LSHK may contribute to ENaC stimulation. LSHK resulted in maximal aldosterone secretion, but still inhibited NCC, possibly to deliver sufficient Na^+ to ENaC for potassium secretion. The inhibition of NCC during LSHK may be explained by low angiotensin II levels, which, in turn, may be due to an effect of LSHK on the conversion of angiotensinogen to angiotensin I.

FR-PO548

MicroRNA-194 (miR-194) Regulates ROMK Channel Activity by Targeting Intersectin 1(ITSN1) WenHui Wang. *Pharmacology, New York Medical College, Valhalla, NY.*

Background: The aim of the present study is to explore the role of miR-194 in mediating the effect of high K (HK) intake on ROMK channel activities.

Results: Northern blot analysis showed that MiR-194 was expressed in renal cortex and out medulla and that the expression of miR-194 was upregulated by increasing dietary K intake. Moreover, real-time PCR analysis further demonstrated that a HK intake increased the miR-194 expression in the cortical collecting duct. Inserting 3'UTR of ITSN1 which has the seed-sequence for miR-194 into luciferase report gene vector decreased luciferase activity in the cells transfected with human miR-194. Moreover, expression of human miR-194 decreased while application of miR-194 antagomer increased the protein level of endogenous ITSN1 in HEK293T cells. Since a HK intake decreased the expression of ITSN1 which enhanced With-No-Lysine Kinase (WNK)-induced endocytosis of ROMK, we explored whether miR-194 suppressed the expression of ITSN1 thereby increasing ROMK channels in HEK293T cells transfected with GFP-tagged ROMK1. The biotin labeling technique showed that expression of miR-194 increased the ROMK expression in the plasma membrane. The whole-cell recording demonstrated that expression of miR-194 increased ROMK current from 1170pA/25pF to 1750pA/25pF and also abolished the inhibitory effect of WNK4 on ROMK channels. Coexpression of ITSN1 reversed the stimulatory effect of miR-194 on ROMK channels and reduced K currents to 1150pA/25pF, suggesting the role of ITSN1 in mediating the effect of miR-194 on ROMK channels.

Conclusions: We conclude that miR-194 regulates ROMK channel activity by modulating ITSN1 expression and that HK induced increase in miR-194 may be involved in mediating the effect of a HK intake on ROMK channel activity.

Src-Family Tyrosine Kinase (SFK) Phosphorylates With-No-Lysine Kinase4 (WNK4) and Modulates the Inhibitory Effect of WNK4 on ROMK Channels WenHui Wang. *Pharmacology, New York Medical College, Valhalla, NY.*

Background: Previous studies have demonstrated that SFK modulates the effect of SGK1-WNK4 interaction on ROMK channels (PNAS, 106:15061-6, 2009). The aim of the present study is to examine whether SFK phosphorylates WNK4 using HEK293T cells transfected with flag-tagged WNK4 and c-Src.

Results: Western blots with anti-phosphotyrosine antibodies demonstrated that c-Src increased WNK4 phosphorylation. The mutation of tyrosine residue 1092 (Tyr^{1092}), Tyr^{1094} and Tyr^{1143} to phenylalanine ($WNK4^{Y1092F}$, $WNK4^{Y1094F}$ and $WNK4^{S1143F}$) decreased the SFK-induced phosphorylation of WNK4, suggesting that they are possibly SFK phosphorylation sites. Mass spectrometry further confirmed that $tyr^{1143}$of WNK4 was phosphorylated by c-Src. Coimmunoprecipitation experiments identified protein tyrosine phosphatase type 1D (PTP1D) in complex with WNK4 and this association was diminished in the cells transfected with $WNK4^{Y1143F}$, suggesting that Tyr^{1143} was a binding site of PTP1D to WNK4. Coexpression of $WNK4^{Y1143F}$ inhibited ROMK channels as potently as those of wt WNK4. However, expression of SGK1 reversed the inhibitory effect of WNK4 on ROMK channels but did not change the inhibitory effect of $WNK4^{Y1143F}$. Moreover, expression of SGK1 failed to stimulate serine phosphorylation of WNK4 at Ser^{1196} in the cells transfected with $WNK4^{Y1143F}$. In contrast, SGK1 increased wt WNK4 phosphorylation at Ser^{1196}. The notion that expression of $WNK4^{Y1143F}$ impairs the association of PTP1D to WNK4 thereby enhancing the effect of SFK was suggested by the finding that SGK1 reversed WNK4's inhibition of ROMK channel in the cells treated with SFK inhibitors.

Conclusions: We conclude that WNK4 is the substrate of SFK and that Tyr^{1143} is one of tyrosine phosphorylation site. The significance of the present study is to illustrate a novel mechanism by which SFK modulates WNK4-dependent regulation of ROMK.

The Role of Renal SGK1 in the Control of Potassium Homeostasis in Inducible Nephron-Specific Sgk1-KO Mice Lama Al-qusairi,[1] Anne Debonneville,[1] Nourdine Faresse,[1] Johannes Loffing,[2] Olivier Staub.[1] *[1]Dpt. of Pharmacology and Toxicology, University of Lausanne, Lausanne, Switzerland; [2]Institut of Anatomy, University of Zurich, Zurich, Switzerland.*

Background: Dietary K+ load results in an increased kalemia, leading to aldosterone release in order to stimulate K+ secretion in the ASDN. However, the regulatory mechanisms involved in this process remain unclear. Here, we aim to identify new pathways involved in the regulation of K+ secretion. More specifically, we have investigated the role of the aldosterone inducible SGK1 kinase.

Methods: Inducible nephron specific SGK1-KO mice (SGK1fl/fl/Pax8/LC1 model), recently generated in our group (Faresse et al., AJP, 2012), are employed to avoid the compensatory mechanisms which may mask the role of SGK1. Thanks to the previously described TetOn/CreLoxP system, in which rtTA is expressed under the control of the Pax8 promotor (Traykova-Brauch M et al., Nat Med. 2008), inducible inactivation of the floxed SGK1 allele occurs specifically in the renal tubules. Normal and nephron-specific SGK1-KO animals are challenged by different potassium diets. The metabolic parameters are analyzed, together with the protein and the mRNA levels of the key players in K+ regulation.

Results: Our results indicate that K+ secretion is altered in nephron-specific SGK1-KO mice. Indeed, mutant animals exhibit 35% decrease in urine K+ level after 2 days under high K+ diet (5%). Interestingly, urine Na+ level are also decreased in these conditions.

Conclusions: Our results indicate that SGK1 plays an important role in the long-term regulation of K^+ secretion. We are currently investigating accompanied changes in plasma aldosterone and electrolyte levels. Moreover, blood pressure measurements will be undertaken.

FR-PO551

Role of Big-Conductance K Channels in Principal Cells for K Homeostasis Timo M. Rieg,[1,2] Jessica A. Dominguez Rieg,[2] Volker Vallon.[1,2,3] *[1]Medicine, University of Califonia San Diego, CA; [2]VA San Diego Healthcare System, CA; [3]Pharmacology, University of Califonia San Diego, CA.*

Background: Big-conductance K (BK) channels are expressed in principal cells and intercalated cells of the kidney and contribute to K homeostasis and flow-induced K secretion.

Methods: To define the role of BK channels in principal cells we generated mice with conditionally inactivated BK channels in principal cells of the connecting tubule/collecting duct (AQP2:Cre; $BK^{loxloxCre}$). Cre negative BK^{loxlox} mice served as controls (Con). Mice were placed for 7 days on a low (<0.03%) and subsequently on high (5%) K intake. Spontaneous voided urine was collected daily and K and creatinine determined. Systolic blood pressure (SBP) was measured by tail cuff daily. At the end of each diet regimen blood samples were analyzed for K, pH and aldosterone. ROMK membrane protein expression was determined in renal cortex lysates.

Results: During low K intake (all values are averages over 7 days, Con vs. $BK^{loxloxCre}$, n=12/group), fluid intake (4.4±0.3 vs. 4.7±0.3 ml/day), food intake (3.0±0.2 vs. 2.9±0.1 g/day), urinary K/creatinine (3.7±0.4 vs. 4.2±0.5 mmol/mmol) and SBP (111±5 vs. 112±5 mmHg) were not different between groups. Plasma K (3.9±0.1 vs. 3.9±0.1 mmol/l), aldosterone (445±68 vs. 370±63 pg/ml) and pH (7.38±0.01 vs. 7.4±0.01) were also comparable. After switching to high K diet, fluid intake (9.8±0.8 vs. 9.0±0.4 ml/day) and urinary K/creatinine increased (139±14 vs. 134±17 mmol/mmol), whereas food intake (3.4±0.7 vs. 3.4±0.5 g/day) and SBP were unchanged (110±4 vs. 108±4 mmHg). Increased plasma K (4.8±0.1 vs. 4.6±0.1 mmol/l) triggered higher aldosterone (1589±281 vs. 1262±209 pg/ml) and induced acidosis (7.34±0.02 vs. 7.34±0.01); however, values were not different between groups. After 7 days of high K intake ROMK protein expression in renal cortex was not significantly different between groups (100±8 vs. 104±11%).

Conclusions: Our data indicate that K homeostasis was maintained in mice with conditional inactivation of BK channels in principal cells when mice were challenged with high K intake. ROMK channels in principal cells as well as BK channels in intercalated cells may primarily maintain K balance under these conditions.

FR-PO552

Mechanoregulation of BK Channel Activity in the Distal Nephron: Role of the MAP-Kinase (MAPK) Pathway Rajeev Rohatgi,[1,2,3] Cindy Else,[3] Daniel Armando Flores,[2] Beth Zavilowitz,[3] Wen Liu,[3] Lisa M. Satlin.[2,3] *[1]Medicine, James J. Peters VAMC, Bronx, NY; [2]Medicine, Mount Sinai School of Medicine, New York, NY; [3]Pediatrics, Mount Sinai School of Medicine, New York, NY.*

Background: An increase in tubular flow rate, associated with an increase in fluid shear stress (FSS), stimulates BK channel-mediated net K secretion (BK-JK) in the cortical collecting duct (CCD), a segment comprised of intercalated (ICs) and principal cells (PCs). Patch clamp studies in rodent CCD (Li et al, 2006) reveal that inhibitors of ERK and p38 augment BK channel activity in PCs, suggesting that (i) the channel therein is tonically suppressed by MAPK and (ii) MAPK inhibition should stimulate BK-JK in CCDs perfused at a slow flow rate. As FSS stimulates the MAPK pathway in endothelial cells, we hypothesized that FSS regulates MAPK signaling in PCs, which, in turn, modulates BK-JK.

Methods: Immortalized murine CCD cells (mpkCCD) of PC origin were grown to confluence on glass slides and subjected to 0 or 0.4 (physiological) dynes/cm^2 FSS. Western Blot analysis was performed on cell lysates to quantitate phosphorylated p38 and ERK. The effects of MAPK inhibition on net Na (JNa) absorption and K (JK; pmol/min. mm) secretion were measured in microperfused rabbit CCDs in the absence and presence of SB203580, a p38 inhibitor.

Results: mpkCCD cells exposed to FSS for 3, 5, 10, 30 and 60 min expressed greater abundance of phospho-ERK and phospho-p38 than non-sheared cells. SB203580 had no effect on JK (-8.6±1.3 vs. -8.7±2.1) or JNa (14.1±1.5 vs. 14.8±3.7) in CCDs perfused at a slow (1 nl/min.mm) flow rate approximating the "static" conditions used in patch clamp studies.

Conclusions: FSS induces phosphorylation of p38 and ERK in mpkCCD cells (model of PCs), a response expected to inhibit BK channel mediated JK. Our failure to detect an increase in JK in CCDs treated with a MAPK inhibitor, in light of the patch clamp studies by Li et al, lead us to conclude that either 1) MAPK regulates other cellular processes (e.g. the basolateral Na-K-ATPase, NKCC1) which indirectly modulate BK-JK or 2) the BK channel in PCs does not mediate BK-JK.

FR-PO553

Kv1.1/Kv1.3 Potassium Channel Upregulation by Metabolic Acidosis in the Rat Kidney Rolando Carrisoza-Gaytan, Laura I. Escobar. *Department of Physiology, Facultad de Medicina, Universidad Nacional Autónoma de México, México City, Distrito Federal, Mexico.*

Background: Potassium (K) deficiency is a common electrolyte disorder. Prevalence and severity of different etiologic groups reveals the importance of the mechanisms involved in the maintenance of the external potassium balance. Renal losses represent the most frequent cause of K depletion, which results from a pathologic amplification of several kaliuretic mechanisms, activated simultaneously with additive effects on the kaliuresis. Metabolic acidosis (MA) is one of the conditions where hypokalemia is observed as a secondary abnormality due to an increased renal K secretion. Previously we identified that the voltage gated K channel Kv1.3, in the intercalated cells of the cortical collecting ducts, participates in K secretion in during a high potassium diet (HK) (Carrisoza-Gaytán et al; 2011).

The aim of this wok was to demonstrate the heteromeric expression of Kv1.1/Kv1.3 potassium channel and its regulation by metabolic acidosis.

Methods: From renal cortical and medullary plasma membranes we performed coimmunoprecipitation and immuno blot assays for Kv1.1 and Kv1.3 proteins. Western blot and Immunohistochemistry assays were done for Kv1.1 and Kv1.3 proteins from mebranes of renal cortex and medulla from rats under metabolic acidosis (MA), acute (24h) and chronicle (5 days).

Results: Kv1.1 coimmunoprecipitates with Kv1.3 from the rat kidney plasma membranes. Both, Kv1.1 and Kv1.3 subunits were upregulated to the plasma membranes in MA. Immunohstochemistry assays showed an increased immunoreactivity of the Kv1.1 and Kv1.3 to the apical membranes in collecting ducts in chronic MA.

Conclusions: Upregulation of Kv1.1/Kv1.3 channel under MA suggest its contribution to the increased potassium secretion in collecting ducts. Microperfusion studies of isolated cortical and medullary collecting ducts will allow to support this finding.

Protein Carbonylation in Regulation of Renal Proximal Tubular Na/K-ATPase Signaling and Sodium Transport Yanling Yan,[1,3] Anna P. Shapiro,[1] Steven T. Haller,[1] Vinai Kumar Katragadda,[1] Chiamaka Mbaso,[1] Deepak K. Malhotra,[1] Zi-jian Xie,[2,1] Joseph I. Shapiro,[1,2,3] Jiang Liu.[1,3] *[1]Medicine, University of Toledo College of Medicine, Toledo, OH; [2]Physiology and Pharmacology, University of Toledo College of Medicine, Toledo, OH; [3]Pharmacology and Physiology, Marshall University JCE School of Medicine, Huntington, WV.*

Background: We have shown that cardiotonic steroids signaling through the Na/K-ATPase regulate sodium reabsorption in renal proximal tubule (RPT). Here we report that reactive oxygen species (ROS) are critical in Na/K-ATPase signaling and RPT ion transport.

Methods: c-Src phosphorylation, protein carbonylation, sodium transport.

Results: In RPT LLC-PK1 cells, ouabain (100nM) induced ROS production and c-Src activation, enhanced interaction between the α1 subunit and c-Src, stimulated accumulation of Na/K-ATPase α1 and NHE3 in early endosome (EE) fractions, and inhibited transepithelial $^{22}Na^+$ flux. Pretreatment with N-Acetyl-L-Cysteine (NAC) can prevent these effects in a dose-dependent manner. NAC alone had no effect. Both ouabain and glucose oxidase (GO, 1 and 3mU/ml) stimulated protein carbonylation in whole cell lysates and EE fractions. GO alone inhibited the transepithelial $^{22}Na^+$ flux when it was applied on both basolateral and apical aspects. Immunoprecipitation studies indicated that both ouabain and GO caused protein carbonylation of Na/K-ATPase α1 subunit, NHE3 and c-Src. Disruption of the Na/K-ATPase/c-Src signaling complex (α1 subunit knock-down, caveolin-1 knock-out, or Src kinases-null SYF cell) and c-Src inhibitor PP2 abolished ouabain-induced ROS generation and protein carbonylation, but also attenuated GO induced protein carbonylation. Moreover, carbonylation reversed after removal of ouabain from the culture medium, even when evaluated in the presence of protein biosynthesis inhibitor cycloheximide, proteasome inhibitor MG132, and lysosomotropic weak base agent chloroquine.

Conclusions: Protein carbonylation, stimulated by ouabain and glucose oxidase, may regulate Na/K-ATPase/c-Src signaling and related $^{22}Na^+$ flux. The data suggest that the Na/K-ATPase/c-Src signaling complex is a functional receptor of ROS.

FR-PO555

Regulation of Glomerulotubular Balance III: Implication of Cytosolic Calcium in Flow-Dependent Transport Zhaopeng Du,[1] Laxiang Wan,[1] Sheldon Weinbaum,[2] Alan Mark Weinstein,[3] Tong Wang.[1] *[1]C. & M. Physiology, Yale University, School of Medicine, New Haven, CT; [2]Biomedical Engineering, City College of New York, New York, NY; [3]Physiology and Biophysics, Weill Medical College of Cornell University, New York, NY.*

Background: Underlying glomerulotubular balance (GTB) is the impact of axial flow to stimulate Na^+ and HCO_3^- reabsorption by modulating both NHE3 and H-ATPase activity; the flow effect is proportional to estimated microvillous torque (bending moment). Angiotensin receptor blockade decreases these fluxes, but preserves the relative impact of flow on transport; dopamine leaves baseline fluxes intact, but abrogates the flow-effect. In the present work, we provide evidence implicating cytosolic calcium signals in flow-dependent transport.

Methods: Mouse proximal tubules were microperfused *in vitro* at perfusion rates of 5 and 20 nl/min, and reabsorption of fluid (J_v) and HCO_3^- (J_{HCO3}) were measured. We examined the effect of luminal high Ca^{2+} (5 mM), 0 mM Ca^{2+}, Ca^{2+} chelator BAPTA-AM (10^{-7}M), the IP3 receptor antagonist 2-APB (10^{-7}M), and the CaATPase inhibitor thapsigargin (10^{-5} M).

Results: As previously observed, an increase in perfusion rate from 5 to 20 nl/min increased J_v by 62% and J_{HCO3} by 104% in control tubules. With respect to Na^+ reabsorption, high luminal Ca^{2+} decreased transport at low flow, but preserved the flow-induced increase; low lumen Ca^{2+} had little impact; both BAPTA and 2-APB had no effect on baseline flux, but abrogated the flow effect; thapsigargin decreased baseline flow, leaving the flow effect intact. With respect to HCO_3^- reabsorption, high luminal Ca^{2+} decreased transport at low flow, and mildly diminished the flow-induced increase; low lumen Ca^{2+} had little impact; both BAPTA and 2-APB had no effect on baseline flux, but abrogated the flow effect; thapsigargin decreased baseline flow, and mildly diminished the flow effect.

Conclusions: These data suggest that the IP3 receptor-mediated intracellular Ca^{2+} signaling plays a critical role in transduction of microvillous torque to increases in proximal Na^+ and HCO_3^- transport.

Sex Differences in Renal Adaptation to High-NaCl Diet Plus Aldosterone Infusion Lijun Li, Lamia Alamri, Carolyn M. Ecelbarger. *Medicine, Georgetown University, Washington, DC.*

Background: Numerous sex and sex hormone differences exist in the regulation of sodium balance; however, the mechanisms are not well defined. High-NaCl diet reduces the abundance of several major sodium transporters. Some, although not all, of these effects can be attributed to the fall in endogenous Aldo. In this study, we test whether sex differences exist in these Aldo-independent responses to changes in dietary NaCl.

Methods: Young male and female mice (n = 12/sex) were placed on a LS diet (0.02% Na+) and implanted with osmotic minipumps to infuse Aldo (1 ug/g body weight/day). Four days later, ½ of the mice were switched to a HS diet (5% NaCl). Urine was collected daily on 1/2 of the mice, and the other 1/2 were used for blood pressure recording by radiotelemetry. Mice were euthanized after 3 more days and kidneys harvested.

Results: Despite clamping Aldo, mice fed HS diet had a 10-fold increase in urine Na+ and Cl- by day 3, with no change in urine K+, as compared to LS-fed littermates. Natriuresis due to HS was slightly diminished in females, but not significantly different from males. BP was not affected by Aldo infusion alone; however addition of HS diet led to a rise in BP in both sexes by day 2: (4.3 and 9.5 mm Hg, for males and females, respectively). HS led to a substantial decrease in cortical levels of the bumetanide-sensitive Na-K-2Cl cotransporter (NKCC2), the thiazide-sensitive Na-Cl cotransporter (NCC), and the gamma subunit of the epithelial sodium channle ENaC (70 kDa band), with a rise in the sodium hydrogen exchanger (NHE3), and gamma-ENaC (85 kDa band). The change for NCC and NKCC2 was greater in males. In addition, females had significantly greater levels (over 2-fold) of beta- and gamma-ENaC (both bands) under LS + Aldo, as compared to males.

Conclusions: In summary, young mice of both sexes are able to adapt to HS + Aldo infusion with a robust natriuresis, due to down-regulation several major apical sodium transporter pathways. This likely protects against excessive BP rises. However, the mechanisms whereby this adaptation is achieved may be different, with females showing higher expression of many sodium transporters under LS conditions, and less change overall in response to HS diet.

Impaired Aldosterone Escape in Transgenic Mice Over-Expressing Human CD39: Role of Altered Sodium Transporter Regulation Yue Zhang,[1] Simon C. Robson,[2] Kaiya L. Morris,[1] Karen M. Dwyer,[3] Bellamkonda K. Kishore,[1] Carolyn M. Ecelbarger.[4] *[1]Medicine, VAMC & Univ of Utah, Salt Lake City, UT; [2]Medicine, BIDMC, Harvard Univ, Boston, MA; [3]Medicine, Univ of Melbourne, Victoria, Australia; [4]Medicine, Georgetown Univ, Washington, DC.*

Background: CD39, an ectonucleotidase (NTPDase1), hydrolyzes extracellular ATP or ADP to AMP. We showed that CD39 is expressed at several sites within the kidney, and thus may impact the availability of ligands for P2 receptors. Recently we reported that transgenic mice (Tg) over expressing hCD39 exhibit defective renal water handling.

Methods: Since P2 receptors regulate both water and sodium transport in the kidney, we examined the effect of low- or high-salt diet (LSD or HSD) feeding for 4 days while clamping the blood aldosterone (Aldo) levels (20 μg/day infusion) in Tg mice vs. wild

type (WT) mice (N = 6). Kidneys were harvested after euthanasia and cortex and medulla were processed separately for Western blotting.

Results: After 2 days of HSD, urine Na started decreasing in Tg mice with a significant difference on day 4 ($P < 0.005$). There were no significant differences in terminal serum osmolality or Na between the genotypes. Two-way ANOVA revealed that mean band density of thiazide-sensitive cotransporter (NCC) was significantly higher in the Tg mice (~14-18%), but was similarly reduced by HSD (15-18%), thus showing no significant interaction. In contrast, the bumetanide-sensitive Na-K-2Cl cotransporter (NKCC2) was reduced by HSD in WT mice, but increased in the Tg in both cortex and medulla, resulting in a significant interactive term for both regions. Other proteins, including the subunits of the epithelial sodium channel (ENaC), were also differentially regulated between the genotypes. e.g., major band (85 kDa) associated with γ-ENaC in the cortex significantly increased in HSD fed Tg vs. WT mice.

Conclusions: In summary, hCD39-Tg mice had impaired natriuretic ability in the model of Aldo escape as compared to the WT mice, supporting a role for ATP in facilitating natriuresis. Impaired down-regulation of Na transporters in both medulla and cortex under the conditions of HSD+Aldo may have contributed to this deficiency.

Activation of NAD(P)H Oxidase Contributes to Impaired Aldosterone Escape in mPGES-1 Deficient Mice Zhanjun Jia,[1,2] Sunhapas Soodvilai,[1] Ying Sun,[1,2] Tianxin Yang.[1,2] *[1]Nephrology Division, University of Utah; [2]VA Medical Center, Salt Lake City.*

Background: We previously reported mPGES-1 deletion impaired aldosterone (Aldo) escape and potentiated Na retention (Jia et al, AJP-Renal, 2009). The present study examined the role of NADPH oxidase-derived ROS in this phenomenon.

Methods: The Aldo escape was generated by a 2-wk Aldo infusion at 0.35mg/kg/day via mini-pump with a normal Na diet.

Results: After Aldo infusion, urinary TBARS and 8-isoprostane in mPGES-1 KO but not WT mice were increased by 2-fold and 1.9-fold, respectively, contrasting the unaltered levels in WT. By qRT-PCR, Aldo infusion selectively induced a 2-fold increase in renal mRNA expression of $gp91^{phox}$ in KO but not WT mice. The expression of $p47^{phox}$, NOX4, SOD1, SOD2 and SOD3 was unaffected in either genotype. To test the functional role of NADPH oxidase, a specific NADPH oxidase inhibitor apocynin (APC, 10 mg/kg/day by mini-pump), was administered to the KO mice together with Aldo. Interestingly, Aldo alone in KO mice resulted in an Hct reduction by 7.3% on day 4 and 7.8% on day 14, which was completely reversed by APC. Meanwhile, Aldo caused hypernatremia (KO Cont: 141.7±2.8 mmol/L vs. KO Aldo: 155.9±1.2 mmol/L, $P<0.01$) was markedly diminished by APC (145.9±2.5mmol/L vs. KO Cont, $p>0.05$). In parallel, APC entirely blocked Aldo-induced increases in urinary 8-isoprostane, as well as the kidney hypertrophy; the later was confirmed by the kidney to body weight ratio (KO Aldo: 0.96±0.04% vs. KO Aldo+APC: 0.77±0.05%, $p<0.05$) and PAS staining. The impaired Aldo escape in KO mice was associated with upregulations of NCC (+37%) and ENaC-α (+31%) and downregulations of ENaC-γ (-32%) and NKCC2 (-42%), all of which were significantly corrected by APC. Lastly, we examined the effect of APC on Aldo-induced ENaC activity in primary IMCD cells using Ussing chamber. ENaC activity, as reflected by amiloride-sensitive Isc, was increased after 24-h exposure to Aldo (Aldo: 1.57±0.07 vs. Cont: 1.0±0.07, $p<0.01$) and this increase was abolished by APC (Aldo+APC: 1.14±0.08, $p=0.01$ vs. Aldo).

Conclusions: These findings indicated mPGES-1-derived PGE2 attenuates Aldo-induced Na and fluid retention via inhibiting NADPH oxidase.

FR-PO559

Renal Compensatory Response to TZD-Induced Plasma Volume Expansion: Role of mPGES-1 Zhanjun Jia,[1,2] Ying Sun,[1,2] Tianxin Yang.[1,2] *[1]Nephrology Division, University of Utah; [2]VA Medical Center, Salt Lake City.*

Background: PGE2, a product of prostaglandin E synthase, is considered to participate in renal response to plasma volume expansion owing to its natriuretic/diuretic property. The present study examined the role of mPGES-1 in the renal response to rosiglitazone (Rosi)-induced fluid retention.

Methods: mPGES-1 WT and KO mice were fed with a diet incorporated with or without Rosi (320 mg/kg diet).

Results: A 2-wk Rosi treatment induced a 1.8-fold increase of urinary PGE2 excretion which was completely blocked in KO mice. At day 14, Rosi treated WT mice exhibited increased urinary Na excretion (Rosi:1.23±0.08 mmol/24h vs. Cont: 0.81±0.05 mmol/24h, $p<0.05$) and reduced net Na accumulation (intake-excretion: Rosi 0.25 ± 0.03 mmol/24h vs. Cont 0.47±0.08mmol/24h, $p<0.05$), both of which were completely blocked in KO mice (Na excretion: Rosi: 1.16±0.1 mmol/24h vs. Cont 1.06 ± 0.11 mmol/24h, $p>0.05$; Na^+ intake – excretion: 0.4±0.09mmol/24h vs. 0.44 ± 0.04 mmol/24h, $p>0.05$). The changes in 24-h urine volume and water balance followed the same pattern as Na. Rosi treatment in WT significantly increased plasma volume (PV) as determined by using Evan's blue (Rosi: 29.6 ± 0.56 vs. Cont: 25.6 ± 0.95 ul/gBW, $p<0.05$) and decreased Hct (Rosi: 45.1±0.9% vs. Cont 50.9±0.78%, $p<0.05$) and these changes were greater in KO (PV: 33.7±0.7 ul/g BW, $p<0.05$ vs. WT Rosi; Hct: 41.4±1.0%, $p<0.05$ vs. WT Rosi), indicating accelerated PV expansion. qRT-PCR demonstrated 2-wk but not 2-day Rosi treatment led to widespread downregulation of all Na transporters and aquaporins, including NHE3, NKCC2, NCC, α-Na-K-ATPase, α- and γ-ENaC and AQP2 in WT. In contrast, these compensatory changes did not occur in KO. Rosi treatment in WT mice markedly elevated the urinary output of nitrate/nitrite (Rosi: 338.2 ± 45.2 nmol/24h vs. Cont: 120.0±18.6 nmol/24h, $p<0.01$) and cGMP (Rosi: 11478.8 ± 3496.1 pmol/24h vs. Cont: 2505.8±311.9 nmol/24h, $p<0.05$), both of which were significantly blocked in KO(nitrate/nitrite:197.2 ± 43.1 nmol/24h, $p<0.05$ vs. WT Rosi; cGMP: 3862.6±295.5 pmol/24h, $p<0.05$ vs. WT Rosi).

Conclusions: Renal mPGES-1-derived PGE2 plays an important role in mitigating Rosi-induced plasma volume expansion via NO/cGMP.

FR-PO560

With-No-Lysine Kinases in Aldosterone Escape Phenomenon Jeonghwan Lee, Jin Suk Han, Kwon Wook Joo. *Internal Medicine, Seoul National University Hospital, Seoul, Korea.*

Background: Escape from aldosterone-induced sodium retention (aldosterone escape) was reported to occur primarily by decreased abundance of the Na-Cl cotransporter (NCC) in distal convoluted tubules. However, underlying mechanisms of decreased expression of NCC is still uncertain. With-no-lysine kinases (WNKs) play an important role in regulating NCC abundances and activity. We investigated the changes of WNKs expression in aldosterone escape rat model.

Methods: Male Sprague-Dawley rats were used. Aldosterone (200 μg/day) was infused for the entire experimental period using osmotic minipump. The control group was kept on a low sodium diet (0.02 mEq/day), and theexperimentalgroup was fed with a higher sodium diet (2.0 mEq/day). Thekidneys were taken on day 4. The protein expression of sodium transporters,WNK1 and WNK4 was determined bysemiquantitative immunoblotting.

Results: Aldosterone escape developed in the experimental group. Aldosterone levels were not different in both groups (11.2 ± 3.2 nM/L in control group and 13.5 ± 3.7 nM/L in experimental group). Sodium excretion rose to the level of the intake in the experimental group (2.0 ± 0.19 mEq/day in experimental group). There was no change in creatinine clearance. The expression of NCC significantly decreased (55 ± 13.4 % of the control group) in the experimental group. The protein abundance of WNK4 was not changed and the expression of WNK1 was decreased (51 ± 11.1 % of the control group) in the experimental group without change of aldosterone level. KS-WNK1 mRNA expression was significantly decreased in the experiment group (58.3 ±24.5 % of the controls).

Conclusions: Decreased expression of NCC in aldosterone escape phenomenon is influenced by WNK1, which is independent of aldosterone level.

Characterization of NaCl Transport in Mouse Medullary Thick Ascending Limb from P2Y2 Wild-Type and Knock-Out Mice Jens G. Leipziger, Helle A. Praetorius, Rita D. Marques. *Dept. of Biomedicine, Aarhus University, Aarhus, Denmark.*

Background: Local purinergic signals modulate renal tubular transport. Acute activation of renal epithelial P2 receptors causes transport inhibition and thus triggers a diuretic effect. The effects of extracellular nucleotides on ion transport in the thick ascending limb are so far poorly studied. In the medullary thick ascending limb (mTAL) we recently described a basolateral P2X receptor that mediates a marked inhibition (25%) of NaCl absorption. In addition, mTALs also express apical and basolateral P2Y2 receptors. We showed that short term activation of basolateral P2Y2 receptors had no effect on transport in mouse mTAL. Objective: Here we studied, if the absence of the P2Y2 receptor leads to chronic alterations in mTAL NaCl absorption by comparing basal and AVP-stimulated transport rates in tubules isolated from P2Y2 receptor WT and KO mice.

Methods: We used isolated, perfused mouse mTALs to electrically measure NaCl absorption. By electrodes we determined the transepithelial voltage (V_{te}) and the transepithelial resistance (R_{te}) and thus transepithelial NaCl absorption (equivalent short circuit current, I'_{sc}).

Results: No apparent differences of NaCl absorption were observed between WT and KO mTALs (WT: 2064±144 μA/cm², n=53; KO: 1880±174 μA/cm²; n=32). An extended analysis, however, revealed that tubules from male KO mice transported less NaCl as compared to female KO tubules which showed higher rates of NaCl absorption. Both WT and KO tubule showed similar transport inhibition by luminal furosemide and could similarly be activated by basolateral AVP.

Conclusions: Absence of the P2Y2 receptors apparently has no major effects on NaCl absorption in mouse TAL. Intriguingly, however P2Y2 receptor KO mice display a gender-dependent difference in NaCl absorption. These data support a functional role of the P2Y2 receptor in NaCl handling of the thick ascending limb.

Different Classes of Purinoreceptors in the Apical and Basolateral Membranes of Renal Cells Hui-fang Bao, He-ping Ma, Douglas C. Eaton. *Physiology, Emory University School of Medicine, Atlanta, GA.*

Background: Extracellular ATP alters renal sodium transport via P2 purinoceptors, but the receptors in the apical and basolateral membranes are different: the apical membrane contains $P2Y_2$ receptors that inhibit ENaC and the basolateral membrane contains $P2X_4$ receptors that stimulate ENaC.

Methods: Renal cells (A6) were used for single channel patch clamp studies. Cell attached patches on the apical membrane were formed directly. To access the basolateral membrane, a sharp glass needle was used to make a triangular tear in the monolayer and the needle was used to lift up the wedge of cells to provide access to the basolateral surface.

Results: Confocal imaging was used to show that the cellular location of $P2Y_2$ receptors was near or in the apical membrane while $P2X_4$ receptors were near or in the basolateral

membrane. Addition of 100 μM ATP to the apical surface produced a reversible inhibition of ENaC activity (P_0 untreated 0.38±0.16 vs 100 μM ATP 0.06±0.03, n=11, p<0.05). This effect was mimicked by 100 μM UTP, but blocked by 100 μM XMAR ($P2Y_2$ receptor antagonist). Application of either ATP or 2-methylthio-ATP (2-meSATP, a selective P2X receptor agonist) at a final concentration of 50 μM to the basolateral bath significantly elevated ENaC activity. In contrast, no such effect was observed when 2-meSATP was applied to the apical bath. Chelation of extracellular Ca^{2+} with 2 mM EGTA abolished the stimulatory effect of basolateral 2-meSATP, indicating that local Ca^{2+} influx through $P2X_4$ receptors accounts for the stimulation. The stimulation was inhibited when aldosterone was removed from the culture medium for 72 h. Western blots showed that removal of aldosterone strongly reduced $P2X_4$ receptor expression and confocal imaging showed that the $P2X_4$ receptor density in the basolateral region of aldosterone-deprived cells was reduced.

Conclusions: These results suggest a regulatory role for purinoceptors in renal salt and water transport. But the effects of purines on the apical surface produce inhibition while basolateral purines stimulate ENaC. This implies that the same ligand can produce different effects depending upon whether it is present in the tubular fluid or in the blood.

A Novel Sodium Pathway in the Proximal Tubule and Its Regulation by Potassium Diets Zinaeli Lopez-Gonzalez, Rolando Carrisoza-Gaytan, Laura I. Escobar. *Fisiología, Facultad de Medicina, Universidad Nacional Autonoma de Mexico, Mexico, D.F., Mexico.*

Background: The Na^+/H^+ (NHE3) and NaPi2 transporters have been recognized as the major pathways for Na^+ reabsorption by the proximal tubule (PT). We identified HCN hyperpolarized-activated sodium channels in the apical membrane of the PT from the rat kidney. Na^+ transport through the renal epithelium is coupled to the distal K^+ secretion. A high K^+ diet inhibits Na+ reabsorption in the PT to increase the flow and loading of Na^+ to the distal nephron and then, K^+ secretion. In contrast, K^+ depletion increases Na^+ reabsorption in the PT and reduces the flow toward the distal nephron, decreasing K^+ secretion. The objective of this work is to determine the regulation of HCN3 channel expression by a high and a deficient K^+ diet in the rat kidney.

Methods: Male Wistar rats of 200 g were fed with a control (1.2%), high (10%) and deficient (0%) K^+ diet for 15 days. Protein expression was quantified in plasma membrane from renal cortex and outer medulla by Western blot assays.

Results: We detected a protein band of ~65 kDa corresponding to the HCN3 channel in the renal tissue. A high K^+ diet caused a decrease of HCN3 of both cortex (44%) and outer medulla (75%). Depletion of K^+ increased the expression of HCN3 only in the outer medulla (60%). These changes were statistically significant ($p < 0.05$) compared to the control diet.

Conclusions: The apical localization of the channel HCN3 and its regulation by high and deficient K^+ diets, support the hypothesis that this channel participates in the reabsorption of Na^+ in the PT. Functional studies in isolated tubules are necessary to confirm this finding.

FR-PO564

NO/sGC/cGMP/ERK Pathway Mediates a Unique Dose-Dependent Stimulation of Human Proximal Transport by Angiotensin II Ayumi Shirai,[1] Osamu Yamazaki,[1] Motonobu Nakamura,[1] Hideomi Yamada,[1] Masashi Suzuki,[1] Shoko Horita,[1] Yukio Homma,[2] George Seki.[1] *[1]Internal Medicine, Tokyo University, Tokyo, Japan; [2]Urology, Tokyo University, Tokyo, Japan.*

Background: Although angiotensin II (Ang II) is known to regulate renal proximal tubule (PT) transport in a biphasic manner via AT1 receptor in mouse, rat, and rabbit, little is known about its effect on human PT transport.

Methods: Normal human kidney cortex tissues were obtained during the nephrectomy for renal carcinoma. The Na-HCO_3 cotransporter (NBCe1) activity was determined by cell pH measurement in isolated human PT.

Results: Ang II does-dependently stimulated the NBCe1 activity in human PT (+38%, +60%, and +103% stimulation by 10^{-10} M, 10^{-8} M, and 10^{-6} M Ang II, respectively). Ang II also induced a similar dose-dependent stimulation of the transtubular HCO_3 absorption determined by microfluorometric stop-flow method. AT1 blocker valsartan, MEK inhibitor PD98059, nitric oxide synthetase (NO) inhibitor L-NAME, soluble guanylyl cyclase (sGC) inhibitor ODQ, but not protein kinase G (PKG) inhibitor KT5823 suppressed this stimulation. NO donor sodium nitroprusside (SNP) stimulated NBCe1, which was suppressed by PD98059. 8Br-cGMP also mimicked the stimulation by Ang II. In human renal cortex, Ang II, SNP, and 8Br-cGMP stimulated ERK phosphorylation without enhancing PKG-dependent GSK3b phosphorylation. In mouse kidney, by contrast, 10^{-6} M Ang II, SNP, and 8Br-cGMP inhibited the NBCe1 activity, and stimulated GSK3b phosphorylation without enhancing ERK phosphorylation. Furthermore, L-NAME, ODQ, and KT5823 converted the inhibitory effect of 10^{-6} M Ang II on NBCe1 to stimulation.

Conclusions: These results, for the first time to our knowledge, revealed that Ang II has a dose-dependent stimulatory effect on human PT transport. This stimulation is dependent on the downstream NO/sGC/cGMP pathway, which works inhibitory via PKG in other species but works stimulatory via ERK in human. In view of much higher concentrations of Ang II in kidney than in plasma, the lack of inhibitory effect of high concentration of Ang II on human PT transport may be relevant to the pathogenesis of hypertension.

FR-PO565

Regulation of Rat Proximal Tubule Fluid Reabsorption by Nitric Oxide Synthase and Dimethylarginine Dimethylaminohydrolase 1 (DDAH-1): Role of Nitric Oxide and Asymmetric Dimethylarginine (ADMA) Tracy Bell,[1] James Alexander Tomlinson,[2] Christopher S. Wilcox,[1] William J. Welch.[1] *[1]Medicine, Georgetown University, Washington, DC; [2]Medicine, Imperial College London, United Kingdom.*

Background: Nitric oxide (NO) stimulates proximal tubule (PT) Na^+ and fluid reabsorption. ADMA is an endogenous inhibitor of NOS but its effects on tubular function are unknown. ADMA is metabolized by DDAH whose type 1 isoform is predominant in the PT. SNIPs of DDAH-1 predicted the rate of decline of renal function in patients with chronic kidney disease (CKD). Therefore, we tested the hypothesis that DDAH-1 metabolizes ADMA in the proximal tubule and thereby enhances PT fluid reabsorption (J*v*).

Methods: J*v* was measured in anesthetized rats by direct in vivo microperfusion and recollection of artificial tubular fluid (ATF) in S2 segments of the PT.

Results: Addition of a selective inhibitor of DDAH-1, L-257 (10^{-4}M) to ATF did not effect J*v* when compared to addition of vehicle (3.4±0.6 vs 3.1±0.3 nl/min/mm). However, L-257 administered as a bolus i.v. injection (60mg/kg) 2hrs before microperfusion of the PT with L-257 significantly reduced J*v* to 1.8±0.2 nl/min/mm, (P<0.05)and significantly enhanced urine flow rate (2.1±-0.3 vs 9.0±1.8 μl/min; P<0.05). Microperfusion of ADMA (10^{-4} M) or L-NAME (10^{-4} M) into the PT both reduced J*v* significantly to 2.0±0.2 and 1.8±0.2 nl/min/mm, respectively (P<0.05). Rats pretreated with a rapid intravenous injection of siRNA targeted to DDAH-1 that reduced its renal mRNA expression significantly also had reduced J*v* (3.1±0.2 vs 2.2±6.2 nl/min/mm; P<0.05) and had a further reduction in J*v* with 10^{-4}M ADMA added to ATF to 1.4±0.1 nl/min/mm; (P<0.005).

Conclusions: In conclusion, PT fluid reabsorption is regulated by ADMA and its tubular metabolism by DDAH-1. The two hour delay in the effects of a bolus injection of L-257 to diminish J*v* indicated the time required after inhibition of DDAH-1 for accumulation of sufficient tubular ADMA to impair PT reabsorption. Thus, L-257 is a novel regulator of PT function and is a proximal tubule diuretic. PT fluid reabsorption is increased by NOS-dependent NO but decreased by DDAH-1-dependent ADMA.

FR-PO566

The Alpha-Ketoglutarate Receptor OXGR1 Is Involved in Renal Sodium Handling and Creatinine Excretion Joris Hubertus Robben,[1] Ana Carolina Ariza,[1] Olivier Devuyst,[2,3] Peter M.T. Deen.[1] *[1]Physiology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [2]Physiology, University Zurich, Zurich, Switzerland; [3]UCL Medical School, Brussels, Belgium.*

Background: The alpha-ketoglutarate receptor OXGR1 is almost exclusively expressed in the kidney, where its mRNA was found to be expressed in the distal convoluted tubules. Currently its role in renal (patho)physiology is completely unknown. Here, using a knockout mouse strain, we present the first characterization of the function of this receptor in renal physiology.

Methods: Wild-type (WT) and OXGR1-/- mice were housed in metabolic cages to monitor food and water intake and urine output. Subsequently, mice were sacrificed and blood, urine and kidneys were collected for analysis. Urine and plasma were analyzed for levels of individual osmolytes and hormones of the renin-angiotensin system. Kidneys were histologically stained and analyzed for overall morphology. Renal homogenates were prepared for Q-PCR analysis and western blotting.

Results: OXGR1-/- mice showed significant polyuria in comparison to WT littermates (1.74 ± 0.1 vs. 1.27 ± 0.21 mL/24 h, respectively). This may be due to the increased osmolyte secretion observed in the OXGR1-/- animals compared to WT (3700 ± 209 vs 2988 ± 334 mOsm/24 h), including increased sodium excretion (1.82 ± 0.15 vs 1.33 ± 1.33 mmol/24 h). Interestingly, creatinine excretion was significantly increased in the OXGR1-/- mice (56.58 ± 3.89 vs 39.04 ± 3.37 mg/24 h), indicating that OXGR1 may be involved in either creatinine transport, or alternatively in regulating the glomerular filtration rate.

Conclusions: OXGR1 is a novel regulator of renal sodium handling, and potentially regulates the glomerular filtration rate. The sodium transporters involved and whether creatinine secretion or GFR is changed is currently under investigation.

FR-PO567

Loss of the Succinate Receptor SUCNR1 Yields Increased Glomeruli and Affected Renal Sodium and Potassium Transport Joris Hubertus Robben,[1] Ana Carolina Ariza,[1] Olivier Devuyst,[2,3] Peter M.T. Deen.[1] *[1]Physiology, Nijmegen Centre for Molecular Life Sciences, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [2]Physiology, University of Zurich, Zurich, Switzerland; [3]UCL Medical School, Brussels, Belgium.*

Background: The succinate receptor SUCNR1 (also known as GPR91) is expressed in the afferent arteriole and glomerular vasculature, cortical thick ascending limb (including the macular densa) and collecting duct. This receptor recently emerged as a novel regulator of the renin-angiotensin system in diabetes mellitus, while it may also play a role in promoting renal fibrosis in this disorder. However, its role in renal physiology and electrolyte handling remains unknown.

Methods: Wild-type and SUCNR1 knockout mice were housed in metabolic cages to monitor food and water intake and urine output. Subsequently, mice were sacrificed and blood, urine and kidneys were collected for analysis. Urine and plasma were analyzed for levels of osmolytes and hormones of the renin-angiotensin system. Kidneys were histologically stained and analyzed for overall morphology. Renal homogenates were prepared for Q-PCR analysis and western blotting.

Results: The weight of the kidneys of SUCNR1-/- mice was significantly higher than their wild-type littermates, which was accompanied with an increased glomerular size. Serum Na+ levels of SUCNR1-/- mice were slightly but significantly elevated compared to wild-type, while serum potassium, urea, chloride and creatinine values were similar Moreover, SUCNR1-/- mice showed a trend to be polyuric, coinciding with significantly increased osmolyte losses ofmainly sodium, urea and potassium. These osmolyte losses were accompanied by decreased protein levels of the sodium-chloride co-transporter NCC and the epithelial sodium channel ENaC.

Conclusions: SUCNR1 plays a role in the regulation of renal and glomerular morphology, but its mechanism of action in this respect remains to be determined. Moreover, under physiological conditions, SUCNR1 contributes to maintaining a proper sodium and osmolyte balance. Whether SUCNR1 regulates this directly or via the renin-angiotensin system is currently under investigation.

Evidence for an Absorptive Paracellular Pathway for Fluid Transport in the Proximal Tubule: Micropuncture Studies in Claudin2-Deficient Mice

Jurgen B. Schnermann, Yuning George Huang, Diane Mizel. *NIDDK, National Institutes of Health, Bethesda, MD.*

Background: Claudin2 (cldn2), a tight protein expressed in renal proximal tubules, has been shown to create a water conducting pathway in MDCK cell culture and to contribute to net fluid efflux in isolated proximal tubules (Rosenthal R et al J Cell Sci 123, 2010; Muto S et al PNAS 107, 2010). The present studies were performed to confirm these important findings in vivo in a different strain of cldn2-deficient mice (MMRRC, University of Davis, CA).

Methods: Fluid samples obtained by free micropuncture in end-proximal segments of inactin/ketamine anesthetized mice were analyzed for volume, I^{125}-iothalamate (125-io) concentration, and osmolarity.

Results: End-proximal $TF/P_{125\text{-}io}$ ratio used as fluid flux marker showed a marked reduction from 1.95 ± 0.05 (34 tubules/9 mice) in $cldn2^{+/+}$ (WT) to 1.56 ± 0.2 (34 tubules/8 mice) in $cldn2^{y/-}$ (KO) equivalent to a reduction of fractional reabsorption from 47.7 ± 1.4% to 34.6 ± 1.5% ($p < 0.0001$). TF/Posm ratio was slightly below unity in both WT and KO (0.977 and 0.983) demonstrating near isotonicity of claudin2-dependent water absorption. SNGFR was significantly lower in KO than WT (11 ± 0.7 vs. 16.3 ± 1.1 nl/min; $p<0.0001$). Arterial blood pressure during micropuncture was comparable between genotypes (110 ± 2.6 mm Hg in KO, 104 ± 1.9 in WT). Plasma renin concentration and arterial hematocrit were significantly higher in KO than WT. Saline infusion (7% BW/hr) reduced $TF/P_{125\text{-}io}$ to 1.48 ± 0.03 (n=17) in WT, but had no effect in KO (1.5 ± 0.05; n=22).

Conclusions: Our data show that a fraction of 27.5% of proximal fluid reabsorption is claudin2-dependent and is therefore presumably absorbed along the paracellular pathway. Inhibition of fluid reabsorption by ECV expansion is cldn2-dependent suggesting that a reduced paracellular fluid reabsorption is the cause for this inhibition. The force driving paracellular water flux remains to be determined.

Salt Excretion and Renin Secretion in Mice with a Knock-In Mutation of the AMP-Activated Protein Kinase (AMPK) Site in Acetyl CoA Carboxylase 1

Suet-Wan Choy,[1,2] Scott Andrew Fraser,[1] Marina Katerelos,[1] Kurt Gleich,[1] Peter F. Mount,[1,2] Nuria M. Pastor-Soler,[3] Kenneth R. Hallows,[3] David A. Power.[1,2] *[1]Nephrology, Austin Health, Heidelberg, Victoria, Australia; [2]Medicine, Austin Health, University of Melbourne, Heidelberg, Victoria, Australia; [3]Renal-Electrolyte Division, University of Pittsburgh School of Medicine, Pittsburgh, PA.*

Background: The master metabolic controller AMPK plays a pivotal role in regulating cellular energy supply and demand. Acetyl CoA carboxylase (ACC) is a major controller of fatty acid metabolism and a well-known substrate for AMPK. We have previously shown that ACC1 was strongly phosphorylated in WT mice in response to salt restriction. In this study, we attempted to determine the role of AMPK and its substrate ACC1 in urinary sodium excretion and renin secretion.

Methods: Mice bearing a knock-in mutation of the AMPK phosphosite in ACC1 ($ACC1^{S79A}$ mice) were placed on a normal salt (0.3%) or salt deficient (0%) diet for 7 days and responses compared with those of wild type (WT) mice.

Results: $ACC1^{S79A}$ mice had no change in urinary sodium excretion when on a normal or salt deficient diet compared with WT mice. There was also no difference in plasma renin concentration (PRC) when receiving a normal salt diet, but $ACC1^{S79A}$ mice receiving a salt deficient diet had a 180% increase in PRC ($p<0.05$), a 170% increase in preprorenin mRNA ($p<0.05$) and a 73% increase in Cox-2 mRNA ($p<0.05$) compared to WT mice. Expression of distal tubule salt transporters was similar in both WT and $ACC1^{S79A}$ mice, apart from a significant increase in expression of NCC in $ACC1^{S79A}$ mice receiving a salt deficient diet and significantly less βENaC in $ACC1^{S79A}$ mice ($p<0.05$) in mice receiving a normal salt diet. Phosphorylation of NCC on T58 and NKCC2 on T100/105 was similar in WT and $ACC1^{S79A}$ mice, with a significant increase in mice receiving a salt deficient diet. Expression of βENaC was significantly reduced in WT mice receiving a salt deficient diet compared with those on a normal salt diet ($p<0.01$), and this also occurred in the $ACC1^{S79A}$ mice ($p<0.01$).

Conclusions: This data suggests that phosphorylation of ACC1 by AMPK within the kidney contributes to control of renin secretion.

Involvement of ACCN1 Channel in Sodium Retention in the Nephrotic Syndrome

Marc Fila,[1,2] Luciana Morla,[2] Lydie Cheval,[2] Georges Deschenes,[1,2] Alain Doucet.[2] *[1]Pediatric Nephrology, CHU Robert Debre, Paris, France; [2]Renal Physiology, CRC UMRS 872, Paris, France.*

Background: Nephrotic syndrome features proteinuria and Na^+retention leading to ascites and edema formation. Previous studies in a corticosteroid-clamped rat model of nephrotic syndrome (CC-PAN) showed that increased Na^+absorption in cortical collecting duct (CCD) is associated with increased Na/K ATPase activity, is independent of aldosterone, does not require activation of ENaC and is sensitive to amiloride.We therefore searched for alternate amiloride-sensitive Na^+channel in CCDs from CC-PAN rats.

Methods: Transcriptomes of CCDs from corticosteroid-clamped (CC) and CC-PAN rats were analyzed. Changes in gene expression were confirmed by RT-qPCR. Protein expression was evaluated by western blot and immunohistochemistry. Sodium transport was evaluated *in vivo* in metabolic cages, and *in vitro* microperfused CCDs.

Results: Metabolic study showed that Na^+excretion and ascites reached a nadir at day 6 after PAN injection and were similar in CC-PAN and PAN rats. Comparison of Na^+absorption in CCDs from CC-PAN and Na^+depleted rats (LN),a model of increased ENaC expression, revealed that Na^+flux was higher in LN than in CC-PAN rats but was fully inhibited by 10µM amiloride in both groups. Na^+flux was inhibited by 0.3M zinc in LN but not CC-PAN rats and it was inhibited by acid pH (pH=6.0) in LN but not CC-PAN rats. These findings confirm that ENaC is not involved in Na^+reabsorption in CC-PAN rats. Transcriptomes and RT- qPCR revealed over-expression of ACCN1 in CC-PAN rats and down-expression of Hsc70, a chaperone that sequesters ACCN in intracellular compartments. Western blot revealed increased expression of ACCN1 in CCDs from CC-PAN rats (arbitrary units±SE; CC-PAN:0.72±0.12; CC:0.31±0.03; $p<0.05$) and immunohistochemistry highlighted an apical labeling in CCDs from CC-PAN but not CC rats.

Conclusions: We found that a channel of the ACCN family (ACCN1) is expressed in CCDs of nephrotic rats where it carry Na^+ reabsorption in low aldosterone nephrotic syndromes. To our knowledge, it is the first demonstration of ACCN channel expression in kidney. Full molecular and functional characterization of this channel will require additional investigations.

The Circadian Clock in the Renin-Secreting Granular Cells of the Juxtaglomerular Apparatus Is Involved in the Control of Blood Pressure

Natsuko Tokonami,[1] Gabriel Centeno,[1] Marc P. Maillard,[2] Roberto Ariel Gomez,[3] Maria Luisa S. Sequeira Lopez,[3] Dmitri Firsov.[1] *[1]Department of Pharmacology and Toxicology, University of Lausanne, Lausanne, Switzerland; [2]Service of Nephrology, Department of Medicine, CHUV, Lausanne, Switzerland; [3]University of Virginia, Charlottesville, VA.*

Background: Recent evidence suggest that the circadian timing system controls renal function and blood pressure. Here, we analysed the role of the circadian clock in the renin-secreting granular cells of the juxtaglomerular apparatus.

Methods: The activity of the circadian clock was suppressed by crossing mice expressing Cre recombinase under the control of endogenous $ren1^d$ promoter and mice carrying a floxed allele of Bmal1 gene, an essential component of the molecular clock.

Results: The suppression of the clock activity in the granular cells was validated by qPCR analysis of several clock-dependent genes, including Bmal1, Dbp and Npas2. Urine chemistry parameters were measured in the urine collected hourly from freely moving mice housed individually in the metabolic cages. This analysis has shown that $ren1^d$-Cre/$Bmal1^{lox/lox}$ mice exhibit a significant increase in the urine output and a significant change in the circadian pattern of urinary sodium excretion. Blood chemistry examination revealed that $ren1^d$-Cre/$Bmal1^{lox/lox}$ mice exhibit a significant reduction in plasma aldosterone levels during the light phase of the circadian cycle. In parallel, the expression of aENaC mRNA in the kidney was significantly reduced. Arterial blood pressure, heart rate and general motion activity were measured in conscious unrestrained animals using telemetry. The two latter parameters were not different between wild-type and knockout mice. However, the systolic blood pressure was significantly reduced in $ren1^d$-Cre/$Bmal1^{lox/lox}$ mice during the activity phase.

Conclusions: Collectively, these results indicate that the intrinsic circadian clock in the granular cells is involved in the generation/maintaining circadian rhythms of urinary sodium excretion and blood pressure. This control mechanism potentially involves the circadian control over renin production/secretion in the granular cells.

FR-PO572

Notch Signaling Is Required for the Specification of Mesangial Cells from a Stromal Progenitor during Kidney Development

Scott C. Boyle, Raphael Kopan. *Developmental Biology, Washington University, St. Louis, MO.*

Background: Mesangial cells are a specialized type of smooth muscle cell that surround the vascular network within the glomerulous. During development, these cells are derived from mesenchymal stromal progenitors that also give rise to vascular smooth muscle cells (VSMC) and interstitial fibroblasts. VEGF and PDGF govern the migration and assembly

of the mesangial tree during glomerular development, however little is known about how mesangial cells are specified from the stromal progenitor pool.

Methods: To investigate the role of Notch signaling in stromal derived cell types we used Notch activation-dependent fate mapping methods and conditional gene inactivation of Notch pathway components in the stromal progenitor compartment.

Results: Here we show that Notch signaling is active in the stromal mesenchyme and is essential for mesangial cell fate specification. Stromal-specific deletion of RbpJ, the common, obligate DNA binding partner of all active Notch receptors, results in loss of mesangial cells, glomerular hemorrhage and perinatal death due to kidney failure. The defect is evident by the absence of desmin-positive cells within the proximity of the developing glomerulus and in the failure of any stromal-derived cell to invade the vascular cleft of the S-Shaped body. This is in contrast to other mutants lacking a mesangium which specify Desmin-positive mesangial cells that fail to migrate into the cleft. These defects are specific to the mesangial lineage as VSMC and interstitial fibroblasts form normally in the absence of RBPj. Notch1 and Notch2 act redundantly in specifying mesangial cells during development, though Notch2 mutants develop glomerular dysfunction and cysts within the first 4 weeks of life.

Conclusions: These data demonstrate a novel function for Notch signaling during kidney development and provide the first evidence of a pathway required for mesangial cell specification. It also raises questions regarding the proper direction of Notch pathway manipulation in renal diseases.

Growth Arrest Specific 1, a Novel and Direct Target of the Wilms Tumor Suppressor, Is Required for Maintenance of Nephrogenesis and Nephron Progenitor Cells

Martin Kann,[1] Baotran Tranguyen,[1] Chen-ming Fan,[2] Jordan A. Kreidberg.[1] *[1]Nephrology, Boston Children's Hospital and Harvard Medical School, Harvard Stem Cell Institute, Boston, MA; [2]Embryology, Carnegie Institution for Science, Baltimore, MD.*

Background: We recently defined a set of WT1 target genes in the developing kidney, that included Gas1, a GPI-anchored protein expressed in NPCs. In embryonic kidney organ cultures, morpholino knockdown experiments demonstrated that WT1 is required to maintain Gas1 expression, and Gas1 is required to maintain viability of nephron progenitor cells (NPC).

Methods: Luciferase reporter assays in a WT1 expressing immortalized cell line were coupled to siRNA-mediated knock-down of Wt1 expression to delimit the WT1 regulatory region. Mutagenesis and chromatin immunoprecipitation was used to confirm direct interaction of WT1 the Gas1 5' upstream region. Gas1 -/- kidneys were analyzed by immunostaining, and in-situ hybridization.

Results: Luciferase reporter constructs, mutagenesis and siRNA mediated knockdown of Wt1 expression delimited the WT1-dependent regulatory sequence of Gas1 to a 250bp upstream sequence. Kidney development in Gas1-/- kidneys appears to progress normally until E15.5. Thereafter, Gas1 -/- kidneys become hypoplastic, with a 75 percent reduction in nephron mass, and a near complete loss of NPC at birth. At stage E17.5, BrdU incorporation demonstrates decreased proliferation in NPC. Wnt4 expression, marking pretubular aggregates, is lost while NPC marked by Six2 expression are still present, and the inducing signal Wnt9b continues to be expressed in the ureteic bud. A decreased number of S-shaped bodies and renal vesicles supports this finding and accounts for the decreased nephron mass.

Conclusions: Gas1 is a direct target gene of WT1 required to maintain NPC. While Gas1 expression is restricted to NPC, it has a role in the formation of the pretubular aggregate. Unlike other genes that are required to maintain NPC at the earliest stages of kidney development, the Gas1 phenotype demonstrates a novel and distinct requirement for additional signals to maintain NPC during later stages of kidney development.

P53 Regulates Progenitor Cell Renewal in the Nephrogenic Niche of the Developing Kidney

Zubaida R. Saifudeen,[1,2] Jiao Liu,[1,2] Thomas J. Carroll,[3] Samir S. El-Dahr.[1,2] *[1]Pediatrics, Tulane University; [2]Tulane Hypertension and Renal Centers of Excellence, Tulane University, New Orleans, LA; [3]Internal Medicine, UT Southwestern Medical Center, Dallas, TX.*

Background: Low nephron number is a predisposing factor for hypertension and associated cardiovascular disease. The self-renewing capability of the Cited1^{+}sub-population of the Six2+ cap mesenchyme (CM) ensures availability of nephron progenitors cells (NPC) for nephrogenesis. p53 plays a key role in cell-fate regulation by transcriptionally regulating genes that control cell cycle arrest, apoptosis and differentiation. Recent studies link p53 with regulating the self-renewal potential of embryonic stem cells. This study examined the role of p53 in NPC renewal.

Methods: Cytometric and molecular marker analyses were performed on embryonic mouse kidneys with conditional deletion of p53 from the Six2+ CM (Six2$^{p53-/-}$).

Results: Six2$^{p53-/-}$ mice have hypoplastic kidneys from E13.5. FACS isolation of genetically labeled GFP^{+}/Six2$^{p53-/-}$ and GFP+/WT CM gave 30% fewer cap cells from mutant than wild-type kidneys (n=6 kidneys, p<0.05). Mutant caps are loosely organized with greatly diminished Cited1 immunoreactivity at E14.5, but maintained Six2 expression. By P1 Cited1 is completely lost and the Six2 domain is reduced. QPCR analysis of CM markers at E15.5 showed significant reduction in expression of Cited1 (80%, p<0.001), Osr1 (40%, p<0.05), Meox1 (45%, p<0.005), tafa5 (75%, p<0.05), Fgf9 (25%, p<0.05) and Pax2 (30%, p<0.005), but Six2 and GDNF expression were maintained. At E13.5 proliferation measured by H3-P-S10 immunostaining showed a 30% decrease in Pax2+ cap cells of mutant kidneys (n=6 kidneys, p<0.05), whereas apoptosis measured by TUNEL was significantly higher (n=6 kidneys, p<0.05). Furthermore, Six2$^{p53-/-}$ kidneys have fewer generations of Lhx1+ nascent nephrons indicative of defective progression of nephrogenesis, supported by decreased Pax8 and Fgf8 expression. Renal vesicles in mutant kidneys have markedly weaker Laminin and Lhx1 immunostaining.

Conclusions: We propose a model wherein p53 promotes the self-renewal of the multipotent NPCs (Cited1^{+}) while promoting the differentiation of the induced Six2^{+} sub-population of NPC to nascent nephrons.

Linking Developmental Control Genes to Histone Acetylation

Sanjeevkumar R. Patel, Raghavendra S. Paknikar, Saji Abraham. *Internal Medicine, University of Michigan Medical School, Ann Arbor, MI.*

Background: Specification of cell lineages begins during the time of gastrulation in the mammalian embryo and continues in a sequential fashion as the germ layers become more specialized. Comparmentalization of the mesoderm into paraxial, intermediate and lateral plate is controlled by extrinsic signaling molecules and intrinsic transcription factors. One such factor is the paired domain protein Pax2. Pax2 and the related protein Pax8 are amongst the first markers expressed in the intermediate mesoderm. Mutations in Pax2 result in renal agenesis as intermediate mesoderm cells are unable to generate the epithelial cells of the urogenital system.

Methods: To understand how Pax2 helps specify tissues of the intermediate mesoderm, we have identified and characterized the protein PTIP, which interacts with the Pax2 transactivation domain. PTIP is a ubiquitous protein with six BRCT domains, the most carboxy-terminal of which bind specifically to phosphor-serine peptides. Prior biochemical purification and mass spectrometry revealed multiple histone methyl transferases are part of the PTIP complex.

Results: Here we show that PTIP interacts with proteins that are part of a Histone Acetyltransferase Complex. Immunoprecipitation of PTIP also demonstrates associated histone lysine acetyltransferase activity. At an integrated Pax2 responsive gene as well as an endogenous Pax2 target gene, both histone lysine methylation and histone lysine acetylation are required for gene expression in a PTIP dependent manner.

Conclusions: Thus, PTIP could serve as an adaptor protein that links tissue and cell lineage specific DNA binding proteins to the epigenetic modification complexes that include both histone lysine methylation and histone lysine acetylation. Our data suggests that Pax2 may mark specific regions of chromatin by modification of histones. These epigenetic marks can delineate both active and inactive regions of the genomes in a stable and heritable manner through potential interactions with nucleosome remodeling complexes and other chromatin effectors.

Histone Deacetylases 1 and 2 Target p53 and Lhx1 to Regulate Nephron Progenitor Cell Renewal and Differentiation

Shaowei Chen, Xiao Yao, Samir S. El-Dahr. *Pediatrics, Tulane University School of Medicine, New Orleans, LA.*

Background: Histone deacetylases (HDACs) are a large family of evolutionarily conserved epigenetic regulators, which catalyze the removal of acetyl groups from histones as well as non-histone proteins. We previously demonstrated that HDAC activity mediated by class I HDACs is required for nephrogenesis by regulating a number of key transcriptional regulators, including Pax2, Eya1, WT1, and Lhx1 (JBC, 2011). However, the specific role of individual HDAC members in nephrogenesis remains to be identified. Here, we examined the functions of HDAC1 and HDAC2 in nephron progenitor cell renewal and fate.

Methods: Mice bearing conditional null alleles for HDAC1 and HDAC2 were crossed to Six2-creEGFP mice to delete HDAC1 and HDAC2, singly or in combination, in cap mesenchyme (CM) cells.

Results: Our data show that 1 allele of either HDAC1 or HDAC2 in the CM is sufficient to support normal nephrogenesis, whereas concurrent deletion of all 4 alleles of HDAC1 and HDAC2 causes deficient nephron formation, leading to bilateral renal cystic dysplasia at birth. Immunofluorescence staining of CM$^{HDAC1,2-/-}$ and wild-type kidney sections at E14.5 and P0 revealed that HDAC1/2 are essential for Six2^{+} cell proliferation but have no obvious effect on their survival. CM$^{HDAC1,2-/-}$ cells exhibit hyperacetylated histones and ectopic hyperacetylated p53, but express lower levels of Six2 and Pax2 compared to wild type CM cells. Remarkably, CM$^{HDAC1,2-/-}$ cells can form pre-tubular aggregates and renal vesicles at a slower rate, but fail to progress to comma- and S-shaped bodies. It is known that, in Lhx1$^{-/-}$ mice, tubulogenesis is blocked at the renal vesicle stage. In line with our phenotypic observations, Lhx1 mRNA and protein expression is lacking in renal vesicles of mutant kidneys. By contrast, Wnt4 and Pax8 are still expressed at a lower level in mutant kidneys.

Conclusions: We conclude that HDAC1 and HDAC2 perform redundant yet essential functions during nephrogenesis. HDAC1 and HDAC2 mediate nephron progenitor cell renewal and renal vesicle differentiation via histone and non-histone dependent mechanisms.

FR-PO577

Defining Nephron Progenitor Gene Regulatory Networks Lori L. O'Brien,[1,3] Joo-seop Park,[2] Andrew P. McMahon.[1,3] *[1]Stem Cell and Regenerative Biology, Harvard University, Cambridge, MA; [2]Pediatric Urology and Developmental Biology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [3]Broad CIRM Center, University of Southern California, Los Angeles, CA.*

Background: In the mammalian kidney, nephrons are derived from the cap mesenchyme which surrounds the ureteric bud tips. Maintenance of the cap mesenchyme, the nephron progenitors, is essential to ensure that a sufficient number of nephrons are formed. The progenitors express the transcription factor Six2 which prevents ectopic nephrogenesis and promotes their self-renewal.

Methods: In addition to Six2, the transcriptional regulatory factors Pax2, Hox11, Osr1, Sall1 and Eya1 are expressed within the progenitor population, and they are all required for kidney development. Despite their integral roles, little is known about their transcriptional targets. Identifying regulatory networks will enhance our understanding of nephrogenic programming and facilitate efforts to generate, manipulate and propagate this critical cell population. To this end, we have developed a transgenic strategy to identify targets of any transcriptional regulator-of-interest from nephron progenitors in the developing mouse kidney. The system utilizes a *Six2* enhancer element to drive expression of FLAG-tagged factors specifically within the progenitor population and allows subsequent ChIP-seq to identify targets.

Results: FLAG-Six2, -Hoxd11 and -Osr1 lines have been generated, and their expression recapitulates endogenous Six2 expression. Initial results show significant enrichment of binding for these transcription factors near genes associated with kidney development. Comparison of the Six2 and Hoxd11 datasets reveals that ~ 50% of Hoxd11 bound regions overlap with Six2 bound regions.

Conclusions: Taken together, these data suggest that Six2 and Hoxd11 regulate the expression of progenitor targets through shared networks. Continued investigation and validation of targets and their cis-regulatory input will help shed new light onto the gene regulatory networks operating within the nephron progenitors and lead the way to the discovery of new therapeutic targets and strategies to treat kidney disease.

FR-PO578

Maintenance of Mesenchymal Progenitor Cells in Culture by Aggregation Shunsuke Yuri,[1,2] Naomi Yanagawa,[1] Oak Dong Jo,[1] Masaki Nishikawa,[1,2] Norimoto Yanagawa.[1,2] *[1]Medical and Research Services, GLAVAHS at Sepulveda, North Hills, CA; [2]Dept. of Medicine, UCLA School of Medicine, Los Angeles, CA.*

Background: In the metanephros during kidney development, the metanephric mesenchymal (MM) cells that localize around the ureteric bud (UB) tips, known as cap mesenchyme (CM), are considered to be the progenitor cells capable of self-renewal and differentiation. The potential of this CM for regenerative applications, however, is limited by the lack of culture system whereby its progenitor status can be maintained *in vitro.* In this study, we have tested a wide variety of factors and culture conditions for this purpose.

Methods: UB were separated from E11.5 mouse metanephroi and the remaining cells were dissociated and cultured *in vitro* over 5 days. The ability of various factors and culture conditions to maintain CM was tested by monitoring the expression of marker genes with real time RT-PCR and by the previously described colony-forming assay with Wnt4-3T3 cells (Osafune, Development, 2006).

Results: We found that the use of low calcium KSFM medium (Loo, Method Cell Biol, 2008) in the presence of ROCK inhibitor (Y27632) was effective to sustain the cell proliferation for up to 60 days. While different factors and extra-cellular matrices were effective to prevent the decrease in the expression of marker genes to various extents, they were not able to sustain the colony formation. In contrast, we found that reaggregation with dispersed UB cells enabled colony formation even after 5 days, although at a lower number than the fresh cells. By using metanephroi isolated from Hoxb7-GFP mice, we confirmed the formation of colonies from non-UB cells. This notion was further supported by the expression in the colonies of genes characteristic of podocyte, proximal tubule and loop of Henle. The effect of UB cells in maintaing CM cells appears to require the direct cellular contact because conditioned media derived from UB cells were not effective.

Conclusions: In conclusion, we found that reaggregation with UB cells were effective in maintaining CM cells in culture *in vitro*. On going studies are being conducted to further characterize the underlying mechanism.

FR-PO579

Impact of Kidney Progenitor Cell Differentiation Status in Wilms Tumorigenesis Le Huang, Sharada Mokkapati, Qianghua Hu, Weihua Tian, Vicki Huff. *Genetics, MD Anderson Cancer Center, Houston, TX.*

Background: Wilms Tumor (WT) is a pediatric cancer of the kidney and is thought to arise from the undifferentiated renal mesenchyme. However, it is unknown from which renal mesenchymal cell types WT can arise. We hypothesize that WT can arise from fetal kidney cells at different differentiation stages and that different progenitor populations at risk will result in tumors with differing histologies and gene expression profiles.

Methods: We used kidney progenitor-specific Cre^{ER} to somatically and mosaically ablate *Wt1* in the context of *Igf2* up-regulation and are determining whether these alterations are tumorigenic. Moreover, we ablated *Wt1* in a high proportion of progenitor cells to study the effects of *Wt1* ablation on kidney development and how *Wt1* ablation predisposes progenitor cell to malignant transformation.

Results: We have generated cohorts of mutant mice and littermate controls and are assessing them for tumor development. Additionally, we found that *Wt1* ablation in stromal progenitors has no obvious effect on nephrogenesis. However, when *Wt1* is ablated in nephrogenic progenitors, nephrogenesis is blocked. The mutant kidneys at E19.5 contain fewer mature nephron structures and an increased number of stromal cells. Furthermore, the nephrogenic zone (NZ), where the progenitor cells reside, is expanded. Cells in the expanded NZ express the progenitor markers and are proliferative. This suggests that *Wt1* ablation in the nephron progenitors prevents the cells from epithelial differentiation and the cells maintain their proliferation and self-renewal property in the NZ.

Conclusions: These results will help us to understand the functions of *Wt1* in the nephron and stroma progenitors and provide significant insights into the mechanisms of Wilms Tumor initiation and progression.

Distinct Temporally and Spatially-Restricted Roles for Tcf21/Pod1 in Kidney Development Yoshiro Maezawa,[1] Tuncer Onay,[1] Lindsay S. Keir,[2] Henrik Dimke,[1] Chengjin Li,[1] Vera Eremina,[1] Susan E. Quaggin.[1,3] *[1]The Samuel Lunenfeld Research Institute, Mount Sinai Hospital, Toronto, Canada; [2]Academic Renal Unit, University of Bristol, Bristol, United Kingdom; [3]St. Michael's Hospital and University Health Network, Toronto, Canada.*

Background: Tcf21/Pod1 is a basic helix loop helix transcription factor that is required for development of various organs. Conventional Tcf21/Pod1 KO mice die in the perinatal period due to profound cardiac and lung defects. Kidneys of Tcf21 KO mice are hypodysplastic and exhibit defects in branching of the ureteric bud, failure of medullary formation and an arrest in nephrogenesis. Within the metanephros, Tcf21 is expressed in a dynamic pattern in the Six2+cap and Foxd1+stromal mesenchyme, peri-ureteric bud mesenchyme and in developing and mature podocytes, interstitial fibroblasts and pericytes.

Methods: To further dissect the role of Tcf21 in renal development, we generated a conditional allele and bred it to a variety of kidney Cre-driver strains: podocin-Cre; Six2-Cre, Wnt4-Cre and Foxd1-Cre.

Results: Loss of Tcf21 from podocytes results in an FSGS lesion starting at 3 weeks of age, characterized by occasional glomeruli with crescentic transformation and podocyte injury. In situ analysis, immunostaining, microarray analysis and knockdown in podocyte cells in culture identify a variety of downstream targets. Loss of Tcf21 at an earlier stage of nephrogenesis from the cap mesenchyme (Six2-Cre/$Tcf21^{flox/flox}$) leads to glomerular developmental defects characterized by dramatic alterations in glomerular capillary loop formation and abnormal mesangial cell influx. However, in contrast to the conventional KO, ureteric branching, renal medullary formation and renal growth are preserved suggesting distinct roles for Tcf21 at different time-points and in different cell compartments. Analysis of Foxd1-Cre/$Tcf21^{flox/flox}$ and Wnt4-Cre/$Tcf21^{flox/flox}$ mice are currently underway.

Conclusions: Taken together, our results demonstrate multiple roles for Tcf21 during renal development that vary over time and space. Furthermore, these mice provide valuable tool to investigate the transcriptional targets of Tcf21 in cap, stromal mesenchyme and podocyte cell lineage.

Podocyte-Specific Expression of the Podocin Gene Is Combinatorially Regulated by Lmx1b and FoxC Protein Bing He,[1] Lwaki Ebarasi,[2] Sarah De Val,[3] Christer Betsholtz,[2] Karl Tryggvason.[1] *[1]Division of Matrix Biology, Department of Medical Biochemistry and Biophysics, Karolinska Institute, Stockholm, Sweden; [2]Division of Vascular Biology, Department of Medical Biochemistry, Karolinska Institute, Stockholm, Sweden; [3]Ludwig Institute for Cancer Research, Oxford University, United Kingdom.*

Background: Podocin is a key structural protein of the kidney podocyte slit diaphragm. Mutations in the podocin gene cause familial or sporadic forms of renal diseases owing to disruption of the filtration barrier integrity. The fact that podocin is exclusively expressed in podocytes reflects its unique function, but its regulatory mechanism remains incompletely understood.

Methods: Transgenic zebrafish was used to identify the podocyte-specific enhancer. To characterize the potential DNA binding motif, mutagenesis, EMSA, morpholino-mediated knockdown and in vitro luciferase assay were performed.

Results: Our previous study has localized a potential enhancer in the 2.5-kb zebrafish podocin promoter (JASN 2011;22:1019). Here we define this 5´element and identify a 49-bp enhancer that sufficiently directs expression in zebrafish podocytes. This enhancer contains two adjacent DNA-binding sites (FLAT-E and forkhead) that are synergistically bound by Lmx1b and foxc1a. Importantly, these two transcription factors strongly induce endogenous podocin expression in zebrafish. The cis-acting motif conserved in the human counterpart is bound and activated by LMX1B and FoxC2 and is also present in COL4A4.

Conclusions: We demonstrate a combinatorial control of podocyte expression by the Lmx1b-FoxC enhancer. Our finding provides insights into transcriptional mechanisms required for normal podocyte functions and critical for kidney diseases.

Wnt/β-Catenin Signaling by Exogenous Embryonic CD24(+) Renal Progenitor Cells during Integration into Glycerol-Damaged Renal Tubules

Paul R. Goodyer, Diana Iglesias. *Pediatrics, McGill University, Montreal, QC, Canada.*

Background: During nephrogenesis, CD24(+) cells in metanephric mesenchyme are induced to differentiate into renal epithelia and form nephrons by Wnt/βcatenin signals from the ureteric bud (UB). Following acute glycerol-induced proximal tubular damage, exogenous embryonic renal progenitor cells (RPC) are integrated into renal tubules, but the mechanisms involved are poorly understood.

Methods: CD24(+) RPC were isolated by FACS from embryonic day E15 kidneys of mice from heterozygous parents bearing the βCatenin/TCF reporter transgene. Proximal renal tubular injury was induced with i.m. injection of 50% glycerol (8ml/kg) in normal adult mice. Experimental mice were twice infused (via tail vein) with 0.5 million CD24(+) RPC (vs control) three and four days respectively after glycerol injection.

Results: In normal E15-E18 kidney, CD24 (+) cells are seen in the cap mesenchyme, comma- and S-shaped bodies and scattered within the UB trunk of mice bearing a HoxB7/GFP transgene. When isolated by FACS, E15 CD24 (+) RPC express transcripts marking metanephric mesenchyme (Wt1, Osr1, Six2) and UB trunk (Wnt7b), but not the UB tip (Wnt9b, Ret and Wnt11). E15 CD24(+) cells from mice bearing a β-Catenin/TCF reporter (RPC^{TCF}) activate the canonical WNT pathway in response to co-culture with L-cells expressing WNT3a. We infused 0.5 million RPC^{TCF} into adult mice 3 and 4 days after glycerol injection. On day 6, the exogenous RPC^{TCF} were seen widely integrated into the damaged proximal tubules and showed robust re-activation of the canonical WNT signaling pathway. In similar studies, we isolated embryonic CD24(+) cells and stained them with $PKH26^{Red}$ prior to infusion into glycerol mice.The Red-stained RPC were widely integrated into proximal tubules, showing epithelial polarization and staining for LTA, a marker of differentiated proximal tubular cells. The exogenous RPC expressed WNT4 and the proliferation marker, PCNA.

Conclusions: Embryonic CD24(+) renal progenitor cells express WNT4 and re-activate the WNT/β-Catenin signalling pathway during integration into the damaged proximal tubule.

β-Catenin Controls Branching Morphogenesis via the Gdnf-Ret Signaling Axis during Renal Development

Sanjay Sarin,[1] Norman D. Rosenblum,[2] Darren Bridgewater.[1] *[1]Pathology and Molecular Medicine, McMaster University; [2]Developmental and Stem Cell Biology, The Hospital for Sick Children; [3]Pathology and Molecular Medicine, McMaster University.*

Background: Renal malformation is the major cause of human childhood renal failure. ß-catenin has established roles in the ureteric epithelium by regulating branching and in the mesenchyme by regulating nephrogenesis. We demonstrate that ß-catenin is elevated in human dysplastic renal tissue most notably in the renal mesenchyme. The purpose of this study is to determine the mechanisms by which ß-catenin overexpression in the mesenchyme leads to renal dysplasia.

Methods: We overexpressed or deleted ß-catenin in the metanephric mesenchyme (MM) using Rarß2Cre and floxed ß-catenin mice (*Rarβ2Cre;β-cat$^{GOF\text{-}MM}$* or *Rarβ2Cre;β-cat$^{LOF\text{-}MM}$*). Kidneys were analyzed by histology, immuno-labeling, in situ hybridization, and ChIP analysis.

Results: Rarß2Cre;ß-cat$^{GOF\text{-}MM}$ kidneys were characterized by cystic tubules, dysplastic stroma, and patchy ectopic nephrogenesis. PAX2, CITED1 and SIX2 staining revealed no noteworthy alterations in nephrogenesis. Analysis of branching morphogenesis revealed ectopic ureteric budding off the nephric duct and ureteric bud stalk, and a disorganization of branch patterning. Interestingly, Rarß2Cre;ß-cat$^{GOF\text{-}MM}$ mice exhibited 6 ectopic kidneys consisting of Cytokeratin/PAX2 positive tubules, and WT1 and Nephrin positive glomeruli. Surprisingly, the Cytokeratin/PAX2 positive tubules were not connected to the kidney proper or the nephric duct. In situ hybridization of E11.5 kidneys revealed increased Gdnf, Cret, and Wnt11 expression. Analysis of Rarß2Cre;ß-cat$^{LOF\text{-}MM}$ mice demonstrated renal hypoplasia, reduced ureteric branching and markedly reduced Gdnf expression. No changes in Ret or Wnt11 expression were observed. We further demonstrate that ß-catenin binds to a Tcf consensus site located 4.9kb upstream of the Gdnf transcriptional start site. Molecular cloning of the 4.9kb fragment into pCDNA/LacZ reporter construct was sufficient to regulate LacZ expression.

Conclusions: These data establish that β-catenin is essential in the MM to guide appropriate ureteric budding and branching through the regulation of the Gdnf signaling axis.

β-Catenin Expression in the Renal Stroma Is Essential for Branching Morphogenesis and Nephrogenesis

Felix Julien Boivin, Darren Bridgewater. *Pathology and Molecular Medicine, McMaster University, Hamilton, ON, Canada.*

Background: Congenital Anomalies of the Kidney and Urinary Tract (CAKUT) are among the most common of all birth defects, with an incidence rate of 1 in 250 live births. Included in these defects is renal dysplasia, the major cause of childhood renal failure. We recently demonstrated that β-catenin, a protein essential for normal kidney development, is expressed in the renal stroma in the developing and mature kidney. Further we demonstrated that β-catenin is overexpressed in the stromal compartment in dysplastic renal tissue. The functional significance of β-catenin expression and misexpression in renal dysplasia in the renal stroma is not known. *The purpose of this study is to determine the specific functions of β-catenin in the renal stroma during murine kidney development.*

Methods: We generated mice with ß-catenin deficiency or overexpression in the renal stroma using the Foxd1Cre and ß-catenin mice with LoxP sites flanking exon 2-6 (Foxd1Cre;ß-cat$^{LOF\text{-}MM}$) or flanking exon3 (Foxd1Cre;ß-cat$^{GOF\text{-}MM}$) respectively. Embryonic kidneys were analyzed by histology, immunohistochemistry, immunofluoresence, and in situ hybridization.

Results: Analysis of Foxd1-Cre;β-cat$^{LOF\text{-}S}$ kidneys revealed renal hypodysplasia, pancake-like kidneys, an irregular renal capsule, and ill-defined nephrogenic zone. Ureteric branching analysis by cytokeratin immunostaining at E12.5 revealed disorganized and elongated ureteric branches. Remarkably, PAX2, CITED1 and SIX2 immunostaining revealed a marked reduction in condensed mesenchyme around the ureteric tips suggesting impairment in the initial stages of nephrogenesis. Foxd1-Cre;β-cat$^{GOF\text{-}S}$ kidneys demonstrated bilateral renal aplasia or severe hypodysplasia, absence of nephrogenic structures, and increased renal stroma. Analysis of ureteric branching revealed a marked reduction in the number of ureteric branches. Interestingly, PAX2, CITED1, and SIX2 immunostaining revealed a marked increase in condensed mesenchyme around the ureteric tips and essentially no uninduced mesenchyme.

Conclusions: Taken together these studies indicate that β-catenin plays an essential role in the formation of the renal stroma and in regulating ureteric branching and nephrogenesis.

FR-PO585

A Novel Mechanism Mediating Canonical β-Catenin Signaling during Kidney Development

Diana Iglesias,[1] Thomas M. Kitzler,[1] Thomas J. Carroll,[2] Rachel Corsini,[1] Paul R. Goodyer.[1] *[1]Pediatrics, McGill University, Montreal, QC, Canada; [2]Medical Center, University of Texas Southwestern, Dallas, TX.*

Background: Nephrogenesis is driven by signals from the ureteric bud which initiate differentiation of adjacent renal progenitor cells in the metanephric mesenchyme. Our previous studies of mice bearing a β-catenin/TCF reporter demonstrate robust activation of the canonical WNT signaling pathway in the ureteric bud (UB) and the immediately adjacent cap mesenchyme. To explain how the UB signal is so exquisitely targeted to adjacent progenitors, we examined the hypothesis that transfer of membrane-bound proteins from the ureteric bud is required for the progenitor cell response to WNT9b.

Methods: CD24(+) renal progenitor cells(RPC) were isolated by FACS from E15 kidneys of mice bearing a β-catenin/TCF reporter and co-cultured with mouse L-cells transfected with various WNTs and FRZ receptors or with UB cells isolated by FACS from E15 kidneys of mice bearing a HoxB7/GFP(+) transgene. Similar studies were performed by co-culturing WNT9b/L-cells as above with HEK293 cells c0-transfected with TOPFLASH reporter and various FRZs.

Results: E15 CD24/TCF RPC exhibited robust canonical signaling activity when co-cultured with HoxB7 UB cells, but showed no response to co-culture with L-cells expressing WNT9b or WNT11. A screen for expression pattern of various FRZs showed that FRZ4 and FRZ8 are expressed in embryonic ureteric bud but not in cap mesenchyme. Like RPC, HEK293 cells transfected with TOPFLASH were unresponsive to co-cultured L-cells expressing WNT9b, but showed striking responsiveness when they were transfected with FRZ4 or FRZ8. Furthermore, CD24/TCF RPC were responsive to co-cultured L cells co-expressing either WNT9b or WNT11 and FRZ4 or FRZ8. Interestingly, transfected L-cells were shown to shed microvesicles containing FRZ4 or FRZ8 into the culture medium.

Conclusions: These results suggest that renal progenitor cells are unresponsive to WNT9b and WNT11 secreted by neighboring cells. We hypothesize that microvesicle-mediated transfer of FRZ4 or FRZ8 may confer WNT9b- and WNT11 responsiveness to progenitors in the cap mesenchyme.

FR-PO586

GLI3 Repressor Controls Urinary Tract Development in a Lineage Specific Manner

Josh Blake,[1,2] Norman D. Rosenblum.[1,2,3] *[1]Dept. Physiology, Univ. Toronto, Toronto, ON, Canada; [2]Dev. & Stem Cell Bio., SickKids, Toronto, ON, Canada; [3]Dept. Nephrology, SickKids, Toronto, ON, Canada.*

Background: The transcription factor GLI3 is proteolytically cleaved to a transcriptional repressor (GLI3R) in states of reduced Hedgehog (HH) signaling. Sonic HH deficiency causes renal agenesis or a single ectopic hypodysplastic kidney. Homozygous loss of both GLI3 and SHH rescues kidney development, implicating GLI3R as a negative regulator of urinary tract (UT) formation. Yet specific events controlled by GLI3R remain undefined.

Methods: GLI3R-dependent control of UT development was analyzed in mouse embryos with constitutive (*Gli3$^{\Delta 699/\Delta 699}$*, Bose et al 2002) or conditional (*Gli3^{TFlag}*, Vokes et al 2008) GLI3R expression.

Results: HH activity in E11.5 WT mice, defined using *Ptc1^{lacZ}*, was strongest in the intermediate mesoderm (IM), common nephric duct (CND) and tail-bud mesenchyme (TM) with moderate activity in the metanephric mesenchyme (MM) but not the Wolffian duct (WD) or ureteric bud (UB). Analysis of *Gli3$^{\Delta 699/\Delta 699}$* mice demonstrated severe renal hypoplasia (100%) and a double collecting system (~47%) at E15.5 (n=12) with hydronephrosis at E18.5 (100%, n=16). Mutants at E11.5 had a marked reduction in HH activity in the MM, CND and TM. UBs were hypoplastic at E10.5 and E11.5 with reduced UB branching at E12.5 (51%, n=16). Induced GLI3R expression at E12.5 in *Esr1-cre;Gli3TFlag* mice caused hypoplasia at E15.5. A double collecting system arose from two primary UBs (67%, n=6) in E11.5 *Hoxb7-cre;Rosa$^{lacZ/+}$;Gli3$^{\Delta 699/\Delta 699}$* mice. The length from cranial WD to bud site(s) indicated normal positioning of one UB with cranial ectopic positioning of the second (p=0.0026). All UBs failed to maintain position caudally with

the CND at E11.5 (p=0.004) and were associated with blind-ended ureters at E16.5 (100%, n=6). UB specific expression of GLI3R in E15.5 *Hoxb7-cre;Gli3^{TFlag}* embryos caused renal hypoplasia (100%, n=14) without a duplex collecting system. IM specific expression of GLI3R using E15.5 *Pax3-cre;Gli3^{TFlag}* embryos caused renal agenesis.

Conclusions: Our data reveal multiple temporal and lineage-specific roles for GLI3R in early UT development by controlling ureteric budding, branching, and ureteric insertion into the bladder.

FR-PO587

Deletion of miR-143/145 Leads to Hydronephrosis Silvia Medrano, Maria Luisa S. Sequeira Lopez, Roberto Ariel Gomez. *Pediatrics, University of Virginia.*

Background: Obstructive nephropathy, the leading cause of kidney failure in children, can be anatomical or functional. The underlying causes of functional hydronephrosis are not well understood. microRNAs are small, non-coding RNAs that negatively regulate the expression of target genes at the post-transcriptional level. We recently found that miR-145, a member of the miR143/145 cluster highly expressed in smooth muscle (SM) cells of renal arterioles, is also present in the pelvicalyceal system and the ureter. The present study was conducted to evaluate whether the miR143/145 cluster is involved in urinary tract function.

Methods: Morphological, functional, and gene expression studies were performed in mice carrying a whole body deletion (KO) of miR-143/145.

Results: miR-143/145 KO mice did not exhibit overt morphological changes in the kidney vasculature. However, these mice developed hydronephrosis (100% penetrance), characterized by severe papillary atrophy and dilatation of the pelvicalyceal system without obvious anatomical obstruction.To determine whether ureteral peristalsis is affected in these mice, we recorded the frequency of contractions in exposed ureters of anesthetized animals. The number of contractions was significantly higher in KO mice compared to WT controls. Moreover, in mutant mice, peristaltic waves were replaced by incomplete, short and rapid contractions that failed to propagate in a proximal-distal direction. Microarray analysis of ureters from WT and KO mice showed that of a total of 35,512 genes screened, 109 were upregulated and 216 were downregulated in the KO mice, with at least a 2-fold difference in expression levels, including genes with potential regulatory roles in frequency, intensity and propagation of SM contraction.

Conclusions: Our data suggest that miR-143/145 are important for the normal contractility of the ureter and therefore for the normal transport of urine from the kidney to the bladder. These studies will help understand how ureteric peristalsis is regulated and may provide insights into the etiology and treatment of hydronephrosis in children.

FR-PO588

DLG1 and CASK Affect Kidney Development through an ERK-Dependent Pathway Sun-Young Ahn,[1] Yeawon Kim,[1] Sung Tae Kim,[2] Jeffrey H. Miner.[2] *[1]Pediatric Nephrology, Washington University in St. Louis, St. Louis, MO; [2]Renal Division, Washington University in St. Louis, St. Louis, MO.*

Background: Dlg1 (discs-large homolog 1) null mice exhibit hydronephrosis, hydroureter, and occasionally hypoplastic kidneys. CASK (calcium/calmodulin-dependent serine protein kinase), which interacts with DLG1 at some membrane-cytoskeleton interfaces, functions as a scaffolding protein that links signaling molecules, receptors and other scaffolding proteins at tight and synaptic junctions. Furthermore, CASK regulates neuronal and epithelial cell polarity. Our aim is to investigate whether DLG1 and CASK cooperate in the developing kidney and to identify the signaling pathways involved.

Methods: We generated mice deficient in both DLG1 and CASK, either globally using null alleles, or specifically in nephron progenitors using Six2Cre/GFP and floxed Dlg1 and Cask alleles. Immunostaining and in situ hybridization were performed on frozen kidney sections. Western blotting was performed using lysates from embryonic kidneys.

Results: Cask-/-;Dlg1-/- (DKO) kidneys were severely hypoplastic and dysplastic and demonstrated a striking premature depletion of nephron progenitors. Importantly, we also observed that Cask-/-;Dlg1+/- (null/het) kidneys were small, though not as small as the DKO kidneys. Nephron-specific null/het mice survived with small kidneys but developed glomerulocystic kidney disease and renal failure. We discovered several cellular and molecular defects in the double mutants. These include reduced proliferation and increased apoptosis of cells in the nephrogenic zone, and a decrease in the number of cells expressing Six2, a transcription factor critical for maintaining the nephron progenitor population. Because CASK binds to syndecan, a co-receptor that modulates FGF receptor (FGFR) activity, we investigated the potential involvement of DLG1 and CASK in the FGF signaling pathway, and found a reduced level of ERK, a mediator of FGF signaling.

Conclusions: Taken together, these results show that DLG1 and CASK play an important role in maintaining the nephron progenitor population, potentially through an ERK-dependent pathway.

FR-PO589

Deletion of Fgfr2 in Tailbud-Derived Stroma Is Associated with Vesicoureteral Reflux, Dysfunctional Voiding and Chronic Kidney Disease Kenneth A. Walker,[1] Irina Zabbarova,[2] Youko Ikeda,[2] Caitlin M. Schaefer,[1] William Chet De Groat,[2,3] Anthony Kanai,[2,3] Carlton M. Bates.[1,4] *[1]Children's Hospital of Pittsburgh, Pittsburgh, PA; [2]Medicine, University of Pittsburgh, Pittsburgh, PA; [3]Pharmacology, University of Pittsburgh, Pittsburgh, PA; [4]Nephrology, University of Pittsburgh School of Medicine, Pittsburgh, PA.*

Background: During development, tailbud-derived stroma (ST) acts on the Wolffian duct to regulate ureteric bud induction and later forms the smooth muscle of the ureter and bladder. Previous data shows deletion of Fgfr2 in ST with Tbx18cre mice (Fgfr2$^{ST-/-}$) results in vesicoureteral reflux (VUR) likely due to induction defects. We aim to use Fgfr2$^{ST-/-}$ mice to investigate the natural history of: 1)VUR 2)the role of Fgfr2 in bladder muscle function, and 3)how bladder defects affect renal morphology and function.

Methods: Bladder function was studied by in vivo cystometry and in vitro bladder sheet assays. Tissue morphology were shown by histology. Renal function was investigated by analyzing urine and serum.

Results: At 1 month, Fgfr2$^{ST-/-}$ mice have high rates of VUR. While bladders from all mice had similar morphology, Fgfr2$^{ST-/-}$ mice had dysfunctional voiding (DV) shown by more frequent and smaller voids. Fgfr2$^{ST-/-}$ mice had higher baseline and threshold bladder pressures and shortened intercontractile intervals than controls. Fgfr2$^{ST-/-}$ mice also have poor compliance, decreased muscle relaxation and decreased muscle contractility. At 6 months, Fgfr2$^{ST-/-}$ mice had high rates of VUR similar to 1 month old mice, often with hydronephrosis. Aged Fgfr2$^{ST-/-}$ mice continued to have DV and develop polyuria. 6 month Fgfr2$^{ST-/-}$ bladders often appear distended with thin, irregular muscle layers. Aged Fgfr2$^{ST-/-}$ mice also have signs of chronic kidney disease (CKD) with fibrosis, elevated blood urea nitrogen and other biomarkers of injury.

Conclusions: Fgfr2$^{ST-/-}$ mice are a novel genetic model linking VUR and DV with impaired bladder function that together pose a significant risk for CKD. This model may ultimately change the way clinicians assess and follow patients with VUR and/or DV and could lead to novel therapeutic approaches to prevent CKD.

Integrin-Linked Kinase (ILK) Controls Ureteric Bud (UB) Gene Expression via p38MAPK-Dependent and -Independent Mechanisms Joanna Smeeton,[1,2] Norman D. Rosenblum.[1,2,3] *[1]Laboratory Medicine and Pathobiology, U of Toronto, Toronto, ON, Canada; [2]Program in Developmental and Stem Cell Biology, Hospital for Sick Children, Toronto, ON, Canada; [3]Division of Nephrology, Hospital for Sick Children, Toronto, ON, Canada.*

Background: In mammals, the renal collecting system is derived via growth, branching and remodeling of the UB, a process termed renal branching morphogenesis (RBM). The intracellular molecular mechanisms that control RBM are largely undefined. Previously, we demonstrated that ILK is required for RBM *in vivo* and controls UB branching via p38MAPK *in vitro* (Smeeton et al, Development, 2010; Leung-Hagestejn et al, Mol Cell Biol, 2005).

Methods: To identify genes that act downstream of ILK during RBM, whole transcriptome microarray analysis was performed using E12.5 kidneys from mutant mice with *Ilk* deficiency targeted to the UB and from controls. p38MAPK signaling was inhibited in kidney explants to investigate whether its activation is required for the expression of candidate genes identified by the microarray analysis.

Results: Microarray analysis identified 227 differentially expressed mRNA transcripts ($p<0.003$). Correlation with the GenitoUrinary Development Molecular Anatomy Project database (gudmap.org) identified 14 UB-enriched genes whose expression was downregulated in mutant kidneys. Quantitative RT-PCR confirmed decreased expression of Ilk, critical gene targets in the Ret/GDNF signaling pathway (Wnt11, Sox8, Myb, CXCR4), and 3 less well-characterized UB-specific genes (SCF, Krt23, Slco4c1). Phospho-p38MAPK protein levels were decreased by 70% in mutant embryonic kidneys ($p=0.004$). The functional requirement for p38MAPK in ILK-mediated gene expression was investigated in kidney explants cultured for 48hr with a p38MAPK inhibitor. While no effect on Sox8, Myb or CXCR4 mRNA expression was observed, p38MAPK inhibition significantly decreased expression of Wnt11 (50%), SCF (45%), Krt23 (85%), and Slco4c1 (58%) ($p<0.05$).

Conclusions: We conclude that (i) ILK regulates downstream gene targets through both p38MAPK-dependent and -independent pathways to control UB branching and (ii) ILK regulates key components of the Ret/GDNF signaling pathway in the developing UB.

FR-PO591

The Transcription Factor Sry-Related HMG Box-4 (Sox4) Is Required for Normal Renal Development *In Vivo* Sunny Hartwig,[1] Junzhuo Huang,[1] Michel G. Arsenault,[1] Martin Kann,[2] Monique C. Saleh,[1] Carlos Lopez,[1] Jonathan Spears,[1] Jacqueline Ho,[2] Glenda M. Wright.[1] *[1]Biomedical Sciences, Atlantic Veterinary College, Charlottetown, PE, Canada; [2]Division of Nephrology, Children's Hospital Boston, Boston, MA; [3]Division of Nephrology, Children's Hospital Pittsburgh of UPMC, Pittsburgh, PA.*

Background: The DNA-binding nuclear transcription factor Wilms' Tumor Suppressor-1 (WT1) plays an essential role in nephron progenitor cell (NPC) differentiation during renal development in humans and mice; however, the gene targets that mediate WT1 function *in vivo* are largely undefined. Genome-wide location analysis using chromatin immunoprecipitation coupled to microarray (ChIP-chip) in embryonic mouse kidney tissues

identified all three members of the *Sry-related HMG box (Sox)-C* subfamily - *Sox4, Sox11* and *Sox12* – as gene targets bound by WT1 *in vivo*. *Sox* genes play master roles in fate determination of specific cell types in a multitude of developmental processes, however, SoxC function during renal development has not been investigated.

Results: We confirmed that Wt1 physically binds the promoter regions of all three *SoxC* genes by direct ChIP. Next, we demonstrate that Wt1 knock-down in embryonic kidney explants results in reduced *SoxC* expression *ex vivo.* Together, these data strongly suggest that *SoxC* genes are transcriptional Wt1 targets *in vivo.* While all three *SoxC* genes are expressed in NPCs, *Sox4* exhibits strongest and most specific expression in NPCs throughout renal development. We therefore investigated the role of *Sox4* in NPC fate by conditionally ablating *Sox4* function in NPCs (*Sox4 NPC*$^{-/-}$ mice). Six2Cre-mediated removal of *Sox4* activity from NPCs leads to reduced nephron number and premature termination of nephrogenesis at birth. Postnatally, *Sox4 NPC*$^{-/-}$ kidneys exhibit multifocal, tubular degeneration and proteinosis, interstititial nephritis and severe segmental to global glomerulopathy by 3 weeks, progressing to renal failure within 5 months.

Conclusions: *SoxC* genes are novel transcriptional Wt1 targets in the developing kidney. Preliminary data demonstrates that at least one SoxC member, Sox4, plays an essential role in controlling renal development *in vivo*.

FR-PO592

Suppression of Nephrogenesis in Response to Hypoxia Is Mediated via Disruption to Wnt Signaling Melissa H. Little, Calida Neal, Bree Rumballe, Lorine J. Wilkinson. *Institute for Molecular Bioscience, University of Queensland, Brisbane, Queensland, Australia.*

Background: Kidney development and final nephron number are affected by environmental stressors resulting in long term effects on renal function. We investigated the affect of hypoxia, a common insult to the fetus during pregnancy, on the developing kidney.

Methods: E12.5 kidney explants were cultured in CoCl2, or 1%, 5%, 12% oxygen, and normoxia for 30-40 hours. WISH, RTPCR, electron microscopy (EM), and immunofluorescence were performed to quantitate tip and nephron numbers, and investigate changes in gene expression, and ultrastructure.

Results: The culture of explants in CoCl2 and 1% oxygen resulted in reduced branching and a disproportionate reduction in nephrogenesis. Development was optimal at 5% with increases in nephron number and nephron/tip ratio at this oxygen concentration. Optimal branching was seen at 12% while nephron/tip ratio was equivalent to that of normoxia. Explants cultured in CoCl2 and 1% oxygen retained a progenitor population and nephrogenesis could be rescued by returning the explants to normoxia, suggesting that the progenitors remain competent but do not receive the appropriate signals to undergo MET. Gene expression studies showed that a reduction in the expression of Wnt9b targets occurred in CoCl2 and 1% oxygen cultures.[1] EM revealed accumulation of glycogen granules and a reduction in cell-cell adhesion within the ureteric compartment, supporting the presence of hypoxia and a reduction of b-catenin.[2,3] Indeed, the culture of explants with IWR-1-an inhibitor of canonical Wnt signaling resulted in a similar suppression of differentiation without the loss of cap mesenchyme coupled with altered ureteric morphology. Conversely, suppression of Wnt secretion with the inhibitor IWP-2 resulted in cap mesenchyme loss.

Conclusions: Our data implies an oxygen concentration of 5% is optimal for nephrogenesis but that there is a dissociation between the response of the ureteric epithelium and the cap mesenchyme to oxygen concentration. Our data also highlights an association between hypoxia and suppression of canonical Wnt signaling.

FR-PO593

Cell Junction Protein TM4SF10 Organizes Actin Filaments at the Adherens Junction Complex in Renal Epithelial Cells Jeffrey S. Simske, Leslie A. Bruggeman. *MetroHealth Medical Center, Case Western Reserve University, Cleveland, OH.*

Background: Regulation of morphogenesis and cell polarity requires the coordinated interaction between the actomyosin contractile apparatus and cellular junctions. We have shown the claudin-like protein TM4SF10 is expressed during glomerular development and is re-expressed in adult podocytes during injury repair following foot process effacement. We propose that TM4SF10 has important regulatory functions in the formation of the podocyte foot process and slit diaphragm.

Methods: We used *C. elegans* and MDCK cells to explore the role of TM4SF10 in epithelial cell junction formation. In vitro, new cell junction formation (newly plated) and re-forming junctions (calcium switch) were used to monitor protein co-localizations. In vivo studies in worms used mutants and re-expression studies with tagged proteins to monitor protein co-localizations and functional rescue.

Results: In MDCK cells, TM4SF10 localized with cadherin at nascent cell junctions and co-immunoprecipitated with adherens junction proteins. In addition, in cells that do not express cadherin, TM4SF10 failed to stably localize to cell-cell contacts. Overexpression of TM4SF10 delayed reformation of cell junctions following calcium switch, reduced apical surface area, and altered cell polarity, with disorganized cell junctions and altered F-actin organization. Knockdown of TM4SF10 resulted in opposite phenotypes. TM4SF10 rescued the phenotype of worms defective in VAB-9, the worm TM4SF10 ortholog. VAB-9, myosin phosphatase, and activated myosin light chain proteins all co-localized at the cell junctions of enclosing worm epidermal cells. In VAB-9 defective worms, myosin phosphatase failed to migrate to cell junctions and had lower levels of activated myosin light chain.

Conclusions: During cell junction formation, TM4SF10 localization at the plasma membrane is dependent on the placement of cadherin. In the absence of TM4SF10, myosin phosphatase is not recruited to the cell junction. Our studies suggest that TM4SF10 plays an important but transient role in stabilizing cell junctions by mediating actomyosin activity through the recruitment of myosin regulatory proteins to points of cell-cell contact.

FR-PO594

FGF9 Supports Survival, Proliferation and GDNF-Receptor Expression of Wolffian Duct Cells Kohei Johkura,[1] Hiroyuki Sakurai,[2] Kevin T. Bush,[3] Sanjay K. Nigam.[3] *[1]Department of Histology and Embryology, Shinshu University School of Medicine, Matsumoto, Nagano, Japan; [2]Department of Pharmacology and Toxicology, Kyorin University School of Medicine, Mitaka, Tokyo, Japan; [3]Departments of Medicine, Pediatrics, and Cellular and Molecular Medicine, University of California, San Diego, La Jolla, CA.*

Background: Fibroblast growth factor (FGF) signaling plays a key role in ureteric bud development in renal organogenesis, while its significance in maintaining Wolffian duct (WD) competence is largely unknown. In isolated WD culture in vitro, GDNF alone did not maintain WD integrity or induce ureteric bud formation. Analogous to isolated ureteric bud culture in vitro, where addition of certain FGFs supported branching morphogenesis, we hypothesized that some FGF(s) may act on WD cells to maintain its integrity and GDNF responsiveness.

Methods: WD and its surrounding mesenchyme were isolated from SD rats at embryonic day 12 and 13. Isolated WDs were cultured in Matrigel in the presence/absence of FGFs. Some cultured WDs were recombined with freshly isolated metanephric mesenchyme (MM) to assess their competence to form ureteric buds. Expression of FGF ligands (all 15 canonical FGFs) and receptors (FGFRs) in mesonephric tissue were examined in rats with real-time PCR and immunohistochemistry.

Results: Several canonical FGFs were expressed in WD and the mesenchyme at meaningful levels, among which only FGF9 successfully supported survival and growth of isolated WD in culture for more than 7 days. Recombination of such WD with MM resulted in ureteric bud formation and nephron tubule induction. FGFRs that can be stimulated by FGF9 were expressed in WD, and the effects of FGF9 on WD were blocked in the presence of FGFR, MAPK, or PI3K inhibitor. The expression levels of GDNF receptors (Ret and Gfrα1) and CyclinD1 were significantly higher in WDs cultured with FGF9 than those of control (10% FBS) while apoptosis marker Bax/Bcl2 ratio was reduced. FGF9 treated WDs formed multiple ureteric bud like structures in response to GDNF.

Conclusions: These results suggest that FGF9 is likely to act on the maintenance of WD cell proliferation, survival and responsiveness to GDNF.

FR-PO595

MicroRNAs in the Metanephric Mesenchyme Are Critical for Early Kidney Development Jacqueline Ho,[1,2] Sunder Sims-Lucas,[1,2] Jessica Chu,[1,2] Andrew J. Bodnar,[1,2] Jordan A. Kreidberg.[3,4] *[1]Pediatrics, Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA; [2]Pediatrics, University of Pittsburgh School of Medicine, Pittsburgh, PA; [3]Pediatrics, Harvard Medical School, Boston, MA; [4]Medicine, Children's Hospital of Boston, Boston, MA.*

Background: MicroRNAs (miRNAs) are endogenous, small, non-coding RNAs that act as novel regulators of gene expression through the post-transcriptional repression of their target mRNAs. The production of mature miRNAs requires processing by the enzyme, Dicer. Recent studies using a conditionally floxed Dicer allele have demonstrated a critical role for miRNAs in modulating nephron progenitor survival in Six2-expressing cells and their derivatives during kidney development. However, the role of miRNAs in the early metanephric mesenchyme (which gives rise to nephron progenitors and renal stroma) is yet to be defined.

Methods: To elucidate whether miRNAs are necessary in the early metanephric mesenchyme, we utilized the Pax3CreTg allele and the conditionally floxed Dicer allele to generate embryos that lack functional miRNAs in the early metanephric mesenchyme and its derivatives.

Results: The loss of miRNAs in the metanephric mesenchyme results in severe renal dysgenesis. However, the earliest stages of kidney formation is relatively conserved. Ureteric bud outgrowth from the Wolffian duct and the initial specification of the ureteric and metanephric mesenchymal lineages transpires normally, as evidenced by appropriate expression of Six2, Sall1, NCAM, Pax2, and calbindin in the mutant kidneys. Marked apoptosis is observed in the mutant mesenchyme, as measured by TUNEL staining, by E11.5. The ureteric bud fails to branch, and the metanephric mesenchyme involutes, resulting in absence of kidneys by E14.5.

Conclusions: The phenotype observed in this early loss of miRNAs is temporally distinct from that observed when miRNAs are deleted in nephron progenitors, which may reflect differing developmental roles for miRNAs due to the timing and/or cell lineages in which miRNAs are expressed. Taken together, these results demonstrate a previously undetermined requirement for miRNAs during early kidney development.

FR-PO596

Wnt5a and Planar Cell Polarity in Kidney Development and Renal Cyst Formation Liwei Huang,[1] Soo Young Choi,[1] Sarah Mckenna,[1] Xiaofeng Zuo,[1] Yun Kyoung Ryu,[2] Rejji Kuruvilla,[2] Rebecca D. Burdine,[3] Joshua H. Lipschutz.[1] *[1]Division of Nephrology, University of Pennsylvania, Philadelphia, PA; [2]Department of Biology, Johns Hopkins University, Baltimore, MD; [3]Department of Molecular Biology, Princeton University, Princeton, NJ.*

Background: Congenital anomalies of the kidney and urinary tract encompass a large group of disorders that result from abnormal renal developmental processes, and include disorders of terminal differentiation, such as autosomal dominant polycystic kidney disease. Planar cell polarity (PCP) is the coordinated orientation of cells and cellular structures along an axis within the plane of an epithelial surface. Patients with nephronophthisis type II have mutations in the gene INVS/NPHP2, and *Nphp2* knockout mice developed cystic kidney disease via affects on PCP signaling. We previously showed that Wnt5a, a noncanonical Wnt, plays a important role during prostate development, with lumen formation and planar cell polarity being abnormal in the Wnt5a null mouse prostate (Huang et al, *Dev Biol, 2009*). Wnt5a is expressed in metanephroi of mouse embryos. **We hypothesize that Wnt5a acts through planar cell polarity pathway to regulate kidney growth and altered Wnt5a signaling will lead to renal cyst formation.**

Methods: We microinjected zebrafish embryos with antisense *wnt5a* morpholinos at the 1-cell stage and allowed them to grow for 72 hrs to determine the effect of Wnt5a knockdown on pronephric kidney development and PCP pathway. Kidneys/urinary tracts were dissected from wildtype and Wnt5a null mouse before birth.

Results: In zebrafish, Wnt5a morphants had a curly tail down phenotype, which was consistent with a ciliary defect. Wnt5a null mice have either absent or markedly abnormal kidneys. H&E staining showed dilated renal tubules. Since Wnt5a null mice die at birth, kidney cyst formation could occur before or after birth; we plan to generate kidney-specific knockout mice. Floxed Wnt5a mice will be mated with FoxD1-Cre mice.

Conclusions: Knocking out Wnt5a specifically in Wnt5a-expressing kidney cells will directly test our hypothesis that Wnt5a disruption interferes with kidney development, specifically planar cell polarity, and results in developmental defects.

FR-PO597

Differential Requirement of Gfrα1 in Early and Later Kidney Development Thomas K. Davis,[1] Masato Hoshi,[2] Sanjay Jain.[2] *[1]Division of Pediatrics (Nephrology), Washington University School of Medicine, St. Louis, MO; [2]Division of Internal Medicine (Renal), Washington University School of Medicine, St. Louis, MO.*

Background: Glial cell line-derived neurotrophic factor (GDNF) coreceptor α1 (GFRα1) is essential for early ureteric bud induction and kidney development as global Gfrα1-knockout mice die at birth from renal agenesis/aplasia due to absence in Ret tyrosine kinase signaling. A number of studies suggest that GFRα1/GDNF/RET tyrosine kinase signaling remains important after ureteric bud induction however, evidence in vivo for this conclusion is lacking. We have created a mouse model which allows inducible deletion of Gfrα1 in a temporal manner using the tamoxifen inducible Cre-ERT2.

Methods: Animals: Gfrα1 reporter, HoxB7Cre and tamoxifen inducible conditional deletion of Gfrα1 in mice in vivo or in explants cultures using timelapse microscopy.

Immunohistological analysis of tissue sections and wholemounts. Antibodies: E-cadherin, GFP, Gfrα1, phospho-histone H3, phospho-Erk 1/2.

Quantitative real-time polymerase chain reaction (qRT-PCR) using Applied Biosystems 7900 HT Sequence Detection System.

Results: We show Gfrα1 is expressed before UB induction in both epithelial and mesenchymal compartments and remains present during branching. Conditional deletion of Gfrα1 before UB branching in WD epithelia results in renal agenesis. Deletion of Gfra1 after initial UB budding using a tamoxifen inducible Cre strain results in mild renal hypoplasia. The mechanism of hypoplasia is decreased epithelial cell proliferation. Furthermore, this elegant system allows direct visualization and characterization of Gfrα1 negative cells through an EGFP reporter.

Conclusions: Gfrα1 has a broader expression in the urinary tract than either Ret or Gdnf. Gfrα1 is required for metanephric kidney induction but becomes less critical as development progresses. Our results provide further support for redundant pathways other than Gdnf-Gfrα1-Ret signaling to ensure on-going branching morphogenesis.

Cytogenomic Aberrations in Children with Isolated Multicystic Dysplastic Kidney (MCDK) Dominique Monlezun, Renfang Song, Tianjian Chen, Graeme James Preston, Adam T. Janssen, Ihor V. Yosypiv. *Pediatrics, Tulane University School of Medicine, New Orleans, LA.*

Background: Cytogenomic microarray has been demonstrated to be a powerful tool to reveal pathogenic mechanisms for multiple congenital anomalies. However, the pathogenic roles of cytogenomic aberrations for isolated MCDK has not been well investigated yet.

Methods: Patients (six females and four males) were diagnosed with MCDK by renal ultrasonography. The mean age of patients was 8.5±1.1 years. Comparative genomic hybridization (CGH) microarray was performed on Agilent 105K array. Data were analyzed using Cytogenomic software package from Agilent.

Results: All patients had normal renal function at the time of collection of the blood specimen. Three pathogenic aberrations were detected in 3 patients. The first aberration was a deletion at 7p14.3 with size of 2.07 Mb. At least 12 genes are located within this deletion region, including *BBS9* and *BMPER*. Mutations in *BBS9* are responsible for Bardet-Biedl syndrome (BBS). Cystic kidney dysplasia is one of the clinical features of BBS. Defects in *BMPER* result in diaphanospondylodysostosis. Nephroblastomatosis with cystic kidneys is the most commonly described extraskeletal finding in patients with diaphanospondylodysostosis. The second aberration was a duplication on 16p13 and 11p12.3 with size of 3.28 Mb. There are more than 20 genes located within this duplicated region. This duplication has not been reported as a benign copy number variant in general population. The third aberration is a monosomy X for female patient. Kidney anomalies are reported in 30% of patients with Turner syndrome. In addition to the 3 aberrations, five of ten patients were detected to carry a duplication at 15q11.2 with size range from 1.2 to 1.9 Mb. This duplication is a common copy number variant and is outside of the epigenetic imprinting region of Prader-Willi/Angelman syndromes.

Conclusions: In summary, our results showed that 30% of patients with MCDK possess cytogenomic aberrations. Exploring the pathogenic changes in MCDK patient genome will reveal new etiology and molecular mechanisms of this disease.

FR-PO599

Sall1 and NuRD Regulate Renal Progenitor Cell Fate Jeannine M. Basta,[1,2] Darcy R. Denner,[1] Lynn R. Robbins,[1] Susan M. Kiefer,[1,2] Michael I. Rauchman.[1,2] *[1]St. Louis University; [2]St. Louis VA Medical Center.*

Background: Renal progenitor cell self-renewal and differentiation must be balanced in order to produce the full complement of nephrons, as reduced self-renewal or accelerated differentiation results in depletion of progenitor cells and renal hypoplasia. The molecular mechanism that regulates this critical cell fate decision in nephrogenesis is not understood.

Methods: We used *Sall1*^{GFP} mice to isolate progenitor cells by FACS from E11.5 and E12.5 kidneys and performed transcriptional profiling. We analyzed informative Sall1 and NuRD mutants.

Results: Genome wide data revealed reduced expression of progenitor genes (*Osr1*, *Cited1*, *Six2*, *Bmp7*, *Eya1*) and ectopic expression of many renal vesicle genes in *Sall1* mutants. There was an increase in the number of Lef1, Lhx1 positive renal vesicles in the mutant, with some in ectopic locations. Cell cycle profiles revealed no difference in proliferation or apoptosis at E12.5 when ectopic vesicles are present indicating that depletion of renal progenitors in *Sall1* deficient kidneys is due to accelerated differentiation. Sall1 associates with the Mi2-NuRD chromatin remodeling complex to regulate gene expression. We thus tested the requirement of the Mi2-NuRD complex and its association with Sall1 in vivo for kidney development. We used *Six2*-Cre to delete NuRD specific components *Mi2* and *Mta2*. Both conditional mutants displayed significant renal hypoplasia with depletion of renal progenitor cells. Moreover, *Sall1* and *Mi2* exhibit a strong genetic interaction in the kidney, supporting a functional link between Sall1 and NuRD. To test if Sall1-NuRD interaction is required in vivo, we prepared mice in which three residues in the N- terminus of Sall1 required for NuRD binding are mutated. These mice die peri-natally due to severe renal hypoplasia and at E13.5 have reduced renal progenitor cells.

Conclusions: We conclude that Sall1 and NuRD coordinately regulate the balance between self-renewal and differentiation of renal progenitor cells. Ongoing studies are aimed at identifying common direct target genes and epigenetic mechanisms of gene regulation by Sall1-NuRD.

FR-PO600

Drosophila as a New Model to Identify and Study Renal Disease Genes Zhe Han. *Internal Medicine, University of Michigan, Ann Arbor, MI.*

Background: Genetic mutations affecting renal function are major cause of renal disease. About 20 genes have been identified to be directly linked to renal disease over the past decade, but the majority of genes required for renal function and involved in renal disease remain unknown. The Drosophila nephrocyte shares striking similarities with mammalian podocytes, making Drosophila a potent model to study genes involved in renal function and renal disease.

Methods: We have developed a novel functional readout for Drosophila nephrocytes. By combining this functional readout and nephrocyte-specific gene knockdown technique, we performed a large-scale genetic screen for genes required for ultra-filtration and protein reabsorption in Drosophila. Our system makes it possible for the first time to examine thousands of genes efficiently for their requirement in renal functions. Using this system, we also developed the Drosophila models for human renal disease caused by specific gene mutations and tested drug treatments.

Results: From our genetic screen, we identified ~150 genes required for ultra-filtration and protein reabsorption in *Drosophila*. Most of these genes are conserved from Drosophila to humans, and encode slit diaphragm components, membrane receptors, glomerular basement membrane components, actin cytoskeletons, TRP channels, vesicle trafficking molecules, myosin and dynein motors, transcription factors and the Coenzyme Q (CoQ) biosynthesis pathways, etc. Many of these genes have been directly linked to renal diseases. Here, we summarize the known renal disease genes that we identified from our screen, and provide a list of genes that are likely to be involved in genetic kidney disease. We also describe the development of the *Drosophila* renal disease models that recapitulate the exact genetic mutations causing renal disease and the use of these fly renal disease models for drug treatment.

Conclusions: Our study demonstrated that the genes involved in ultra-filtration and protein reabsorption are highly conserved from Drosophila to humans, and that Drosophila can be used as a new renal disease model for pathogenic study and drug discovery.

Identification of Kidney Development Pathways Using Zebrafish Forward Genetics Rebecca A. Wingert, Jennifer Cihlar, Rachel Bounds, Michael Mckernan, Annemarie Fox, Gary F. Gerlach. *Department of Biological Sciences, University of Notre Dame, Notre Dame, IN.*

Background: The genetic pathways that pattern nephron segments along the proximo-distal axis remain poorly understood. Zebrafish are a useful genetic model for nephron developmental studies as their nephron segment composition is conserved with humans.

Methods: We have performed a novel haploid screen to identify nephrogenesis genes using zebrafish. Adult wildtype males were mutagenized with ethylnitrosurea and used to make F1 fish, then kidney development was assessed in F1 haploid embryos by whole mount *in situ* hybridization to assay multiple nephron cell types in each sample. We screened 685 females and identified 42 prospective alleles associated with defects in podocytes (17), proximal segments (16), distal segments (7), or axial patterning (2). F1 founders were outcrossed, and lines are now being recovered in the diploid state.

Results: Axial pattern mutant ND154 had reduced proximal and expanded distal segments, hallmarks of a defect in *aldehyde dehydrogenase1a2* (*aldh1a2*), required for retinoic acid (RA) synthesis. We found that ND154 fails to complement $aldh1a2^{m15}$, suggesting it is a new *aldh1a2* allele and providing proof of principle that our strategy will yield nephron patterning mutants. To date we have recovered a total of 10 other lines that represent a unique cohort of kidney mutants. Of these, 5 lines have podocyte formation defects. For example, lines ND172 and ND233 have absent and reduced podocytes, respectively, and display normal development until 3-4 days, when they exhibit renal failure. These data suggest that ND172 and ND233 play specific roles in podocyte formation, while the other podocyte mutants have widespread defects suggesting a disruption in genes with pleiotropic functions. We have also recovered 5 lines with tubule patterning defects that exhibit alterations in proximal or distal segment formation that have not been previously reported.

Conclusions: Taken together, our collection will provide a useful resource to delineate the genes that direct nephrogenesis pathways, and may provide new models to study human congenital kidney defects.

FR-PO602

The Transcription Factor *Evi1* Is Essential for Proximo-Distal Patterning and Differentiation of the Zebrafish Pronephros Rebecca A. Wingert,[1] Valerie Verdun,[1] Alan J. Davidson,[2] Yue Li.[1] *[1]Department of Biological Sciences, University of Notre Dame, Notre Dame, IN; [2]Department of Molecular Medicine & Pathology, University of Auckland, Auckland, New Zealand.*

Background: Nephron segmentation remains poorly understood. The zebrafish pronephros is a good model to study segmentation, as it is composed of two nephrons that have conserved segments of transporting epithelia: proximal convoluted and straight tubule (PCT, PST), distal early and late (DE, DL) and pronephric duct (PD). Interspersed among the transporting epithelia cells are multiciliated epithelial cells (MCC).

Methods: The transcription factor *MDS1 and EVI1 complex locus* (*evi1*) is broadly expressed in nephron progenitors. To study the role of *evi1*, we performed morpholino knockdowns.

Results: *evi1* morphants had an expanded PST and reduced DL, indicating that *evi1* is necessary for DL formation and may restrict PST fates. In addition, MCC number increased in *evi1* morphants, with a caudally expanded domain. Interestingly, *evi1* morphants had expanded proximal nephron progenitors at early timepoints, suggesting that *evi1* regulates nephron patterning. Retinoic acid (RA) signaling directs proximodistal segmentation early, being essential to form the proximal progenitor domain, while Notch signaling triggers epithelial cell type choice much later. To assess the epistatic relationship between *evi1* and RA, *evi1* morphants were treated with exogenous RA and showed a more severe phenotype than *evi1* knockdown, with a further expanded PST and highly truncated DL. These data indicate that *evi1* acts in parallel to RA or is a downstream RA target. Embryos treated with the Notch inhibitor DAPT exhibited increased MCC numbers in the PST and DE similar to *evi1* morphants, but not the PST domain expansion seen in *evi1* morphants.

Conclusions: Taken together, these studies suggest a model in which *evi1* and RA function early to mediate proximo-distal patterning, and that *evi1* acts later to mediate MCC/transporting-epithelium fate choice, possibly in collaboration with Notch activity. This study has revealed novel developmental roles of *evi1*. Future work will further delineate the relationships between *evi1*, RA, and Notch in nephron formation.

Formation of a Novel N-Glycosylation Motif in Integrin α3 due to a Rare *ITGA3* Gene Polymorphism Causes Congenital Nephrotic Syndrome and Interstitial Lung Disease Nayia Nicolaou,[1] Coert Margadant,[2] Sietske H. Kevelam,[1] Marc Lilien,[3] Michiel J.S. Oosterveld,[3] Maaike Kreft,[2] Albertien M. Van Eerde,[1] Rolph Pfundt,[4] Paulien A. Terhal,[1] Bert Van der Zwaag,[1] Norman Sachs,[2] Roel Goldschmeding,[5] Nine V. Knoers,[1] Arnoud Sonnenberg,[2] Kirsten Y. Renkema.[1] *[1]Medical Genetics, University Medical Center Utrecht, Utrecht, Netherlands; [2]Cell Biology, Netherlands Cancer Institute, Amsterdam, Netherlands; [3]Pediatric Nephrology, Wilhelmina Pediatric Hospital, University Medical Center Utrecht, Utrecht, Netherlands; [4]Human Genetics, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands; [5]Pathology, University Medical Center Utrecht, Utrecht, Netherlands.*

Background: Congenital nephrotic syndrome and interstitial lung disease is a rare disorder, characterized by disrupted basement membrane structures. Causal *ITGA3* gene mutations were recently identified, but the underlying disease mechanism remained poorly understood.

Methods: We describe a patient who presented with glomerulosclerosis, proteinuria and neonatal respiratory distress, who died 7 months after birth due to respiratory insufficiency. A genome-wide screening for structural variations revealed a homozygous region of 19.2 Mb on chromosome 17 that included *ITGA3*. Sequencing of *ITGA3* revealed a homozygous mutation A349S, which was functionally characterized.

Results: Immunostaining in a cell model showed appropriate cell surface localization for the wild type but no surface localization for mutant integrin α3, consistent with the lack of integrin α3 in the kidneys of our patient. The mutation resulted in a *de novo* formation of an N-glycosylation motif. Normally integrin α3 forms heterodimers with integrin β1, though hyperglycosylation disrupted its conformation, preventing it from associating with β1 integrin. Increased ubiquitination indicated that the mutant integrin α3 gets targeted for degradation.

Conclusions: Our findings underscore the role of integrin α3β1 as the main regulator of basement membrane integrity in kidney. We suggest hyperglycosylation of integrin α3 finally resulting in complete lack of expression of α3β1 on the basement membrane, is a new pathogenic mechanism for this severe multiorgan disorder.

FR-PO604

Urinary Metabolomic Profiling in Preterm Neonates Mina H. Hanna, Patrick D. Brophy. *Pediatrics, University of Iowa, Iowa City, IA.*

Background: Metabolomics is an emerging field, increasingly being recognized as functionally, the most relevant discipline in personalized health care. Literature regarding the etiology and impact of acute kidney injury (AKI) in the neonatal population is scare. Given the rapid advancement of genomics and proteomics in the identification of renal disease markers, the next logical step is to evaluate the role metabolomics plays as a diagnostic and experimental paradigm in the setting of neonatal AKI. The objective of this metabolomic based strategy pilot project is to define a normative renal metabolomics data set for preterm infants.

Methods: We have prospectively enrolled 3 groups of preterm newborns admitted to the NICU. The 3 groups have been determined by birth weight (BW): 500-1000 grams, 1000-1500 grams, and 1500-2000 grams. Urine samples were collected on days of life 1, 3, 7, 14 and 30. Metabolites present in the urine are evaluated using LC-MS (liquid chromatography mass spectrometry) and GC-MS (gas chromatography mass spectrometry).

Results: 30 preterm infants were enrolled, 10 in each BW group, with mean BWs of: 860 grams, 1275 grams and 1649 grams and mean gestational ages of: 27.0, 29.7 and 31.2 weeks respectively. Infants in the lowest BW group had a significantly longer duration of antibiotics exposure compared to infants in the highest BW group (10.9 ± 7.4 vs 5.2 ± 3.6 days $p<0.05$). Altered excretion of aminoacids suggested an increased aminoaciduria that was more significant in the lower birth weight groups at later time.

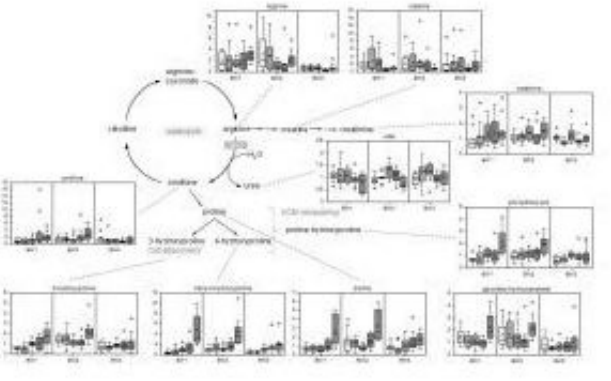

Figure 1: Differences in metabolites associated with Arginine metabolism pathway may indicate decreased renal function in BW1 - and BW2- at the 30 days collection time

Conclusions: Urinary metabolomic profiling provides a robust and readily available approach for defining a normative neonatal data set. We speculate that further metabolite identification and data analysis of our data set is likely to allow delineation of early AKI identification and therefore prompt earlier and possibly preventive intervention.

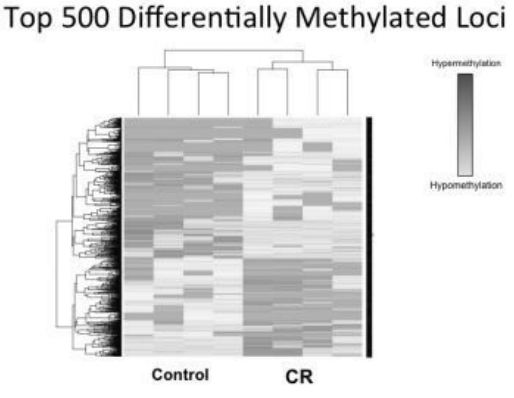
FR-PO605

The Epigenetics of Kidneys Is Altered in Offspring of Maternal Caloric Restriction Howard Slomko,[1] Hye J. Heo,[2] Fabien Delahaye,[2] Yongmei Zhao,[2] Zhongfang Du,[1] Kimberly J. Reidy,[1] Francine Einstein.[2] *[1]Nephrology, Children's Hospital at Montefiore, Bronx, NY; [2]OB/GYN, Montefiore Medical Center, Bronx, NY.*

Background: The epigenome serves as the interface between the genome and the environmental exposure. We hypothesize that exposure to a suboptimal intrauterine environment (via maternal calorie restriction) will induce phenotypic and epigenetic renal dysregulation in male offspring that will predispose them to the development of hypertension (HTN) and chronic kidney disease (CKD) later on in life.

Methods: Rat dams were fed 1)standard chow(Con) or 2)50% calorie restricted from gestational day 11 through lactation(CR). Litters were culled(8/lit) and fed standard chow post weaning. Non-invasive tail BP and urine albumin(alb) measured from 2 month(mon) and 6 mon old male pups. Kidneys at 2 mon of age were utilized for glomerular(glom) counts and DNA extraction. Massively parallel sequencing-based HELP assay was used to examine cytosine methylation levels in 2 mon old kidneys.

Results: At 2 mon, while CR and Con have similar bp(145±3/94±3 v 149±2/97±2mmHg,p=NS) and alb/creatinine ratio(0.37±0.07 v 0.34±0.09mg/mg,p=NS), CR already has decreased glom number(20,177±933 v 31,680±1126 /kidney,p<0.01) compared to con. By 6 mon CR developed HTN(161±5/109±4 v 140±5/94±5mmHg,p<0.05) and increased alb/cr ratio(0.69±0.06 v 0.42±0.13mg/mg,p=0.06) compared to con. HELP tagging revealed a trend towards hypomethyation in CR(p<0.0001). A heat map of the top 500 differentially methylated loci in the kidney demonstrate global regional differences.



Conclusions: In utero exposure to CR lead to phenotypic and epigenetic renal dysregulation in young male rats and suggests that the underlying pathophysiology for development of overt CKD and HTN later in life may originate from developmental programming. Validation of loci are ongoing.

FR-PO606

Maternal Undernutrition Alters DNA Methylation Profiles in Rat Embryonic Kidney Mariko Hida, Midori Awazu. *Department of Pediatrics, School of Medicine, Keio University, Tokyo, Japan.*

Background: Maternal undernutrition leads to low nephron number. We found that ureteric bud branching, a crucial factor in determining nephron number, is reduced by maternal undernutrition in rats. Reduced nephron number by a nutritional insult is transmitted to the second generation in rats. Furthermore, maternal nutrient restriction alters global methylation in the baboon kidney. We therefore investigated the effect of maternal undernutrition on genome-wide DNA methylation in the rat embryonic kidney.

Methods: The embryonic day 18 kidneys of dams given food ad libitum (CON) and those subjected to 50% food restriction throughout pregnancy (NR) were examined. The DNA methylation landscape around promoter CpG islands was analyzed using methylated DNA immunopreciitation (MeDIP) coupled with microarray (NimbleGen Rat ChIP-chip 385K Promoter array) comparing methylated fractions of CON and NR. MeDIP probe significances were generated using the Kolmogorov–Smirnov test as implemented by NimbleScan. These values were transformed (-log10) to give peak scores, which reflect the probability of methylation at a p-value of less than 0.01. Glomerular number was determined by acid maceration at 3 weeks.

Results: Glomerular number of NR was significantly reduced by 20%. Of 15911 promoter regions included in the array, 7330 regions were hypomethylated and 6310 regions were hypermethylated in NR compared with CON. In NR, nearest genes to methylated regions were categorized as, in descending order of freuency, G-protein coupled receptor signaling pathway, detection of chemical stimulus involved in sensory perception of smell, transcription, transport, apoptosis, development, and others. Hypermethylated genes in NR important in kidney development are, in descending order of peak score, β catenin, heparin-binding EGF-like growth factor,activin A receptor, integrin β4, HGF, BMP4/Smad5, TGF-ß1/Smad4, MMP9, cAMP dependent kinase, integrin linked kinase, PKCδ, and kinases in MAP kinase cascades. Most of these are critical for ureteric branching.

Conclusions: Maternal nutrient restricition changes DNA methylation of genes involved in ureteric branching, which may contribute to reduced nephron number and transgenerational transmission.

FR-PO607

A Canadian Study Evaluating Long-Term Impact of a Multifaceted Educational Program on Chronic Kidney Disease Management by Primary Care Physicians Daniel Garceau,[1] Serge Normand,[2] Carl Fournier.[3] *[1]Nephrology, IUCPQ, Quebec, QC, Canada; [2]Office of Evaluation, Faculty of Medicine, University of Montreal, Montreal, QC, Canada; [3]CME Office, Faculty of Medicine, University of Montreal, Montreal, QC, Canada.*

Background: Management of CKD represents a major burden for medical organizations. International societies suggested involvement from PCPs and implementation of large scale teaching programs. However, the long term benefits of such initiatives are unknown. The PREVENIR PROGRAM measured the impact of a large scale educational program intended for 1000 PCPs, from Quebec province, on their clinical behavior, over 33 months.

Methods: Four workshops and a software program on CKD management were developed and updated. From 2009 to 2011, group 1 (500 PCPs) attended 4 workshops and could use the software. Group 2 (500 PCPs) attended 1 to 3 workshops from 2009 to 2010 and did not use the software. Sample of 50 PCPs from both groups and a control group were evaluated before (T0), during (T1) and after (T2) this program using 5 instruments: knowledge questionnaire, interest chart, practice and PCPs profile and structured clinical vignettes. These vignettes measured PCPs skills and reasoning with simulated cases of different complexity. Containing 6-9 items each, they were administered by pairs at T0, T1 and T2.

Results: Group 1 and 2 significant gains in knowledge and clinical skills occurred at T1, and then stabilized without any significant change between T1 and T2. No significant change was observed in CONTROL group.

GLOBAL SCORE FOR KNOWLEDGE AND CLINICAL BEHAVIOR

KNOWLEDGE %				**BEHAVIOR %**		
	EVALUATION PERIOD					
	T0	T1	T2	T0	T1	T2
GROUP	JAN-FEB 2009	APR-SEP 2010	JUL-DEC 2011	JAN-FEB 2009	APR-SEP 2010	JUL-DEC 2011
1	28.4	60.9*	65.2*	34.1	46.1*	47.7*
2	25.6	41.2*	47.7*	32.3	39.8*	42.4*
CONTROL	29.0	32.9	38.0	33.6	33.7	37.9

*p <0.05 vs T0

Conclusions: Our study showed long term benefits on knowledge and clinical behavior of PCPs for CKD management. Of the 8000 PCPs serving a population of 8 million, 1000 were exposed to our program (12.5%). The cost was $250 cad per workshop/physician and $250 cad/physician for the software program. Funding to replicate this program could be provided by governmental or corporate partners.

Eleven Key Areas of Renal Nurse Responsibility: The Foundations of Quality Patient Dialysis Outcomes Ali Mohammed Allehbi,[1] Donavilla Paguia,[2] Archie Dumdum Bunani.[3] *[1]Medicine - Nephrology, DaVita Lehbi Care - Saudi Arabia, Riyadh, Central Province, Saudi Arabia; [2]Nursing, DaVita Lehbi Care - Saudi Arabia, Riyadh, Central Province, Saudi Arabia; [3]Clinical Services, DaVita Lehbi Care, Riyadh, Central Province, Saudi Arabia.*

Background: Renal nurses develop their expertise over time and in the exercise of their professional skills deliver the essence of safe, competent, and compassionate care. The knowledge, attitude and skills of a nurse develop progressively where complexities of clinical procedures and experiences are intertwined. This study identifies whether Quality Patient Dialysis Outcomes (QPDO) were directly affected by eleven key areas of nurse responsibility used when evaluating renal staff competency (SC).

Methods: 59 Staff Nurses were appraised evaluating SC while 525 hemodialysis patients were evaluated using the QPDO parameters. Univariate linear regression and Pearson rho moment correlation were used to build relationships.

Results: Data indicated both increase and decrease trends in relation to staff competency. Competencies related to Health Education (↑172.6), Communication (↑147.5), Records Management (↑141.6), Safe and Quality Nursing Care (↑135.0), and Management of Resources (↑133.5) demonstrated increase trends. Competencies related to Research (↑-35.2), Quality Improvement (↑-12.3), and Legal Responsibility (↑-6.68) were relatively decreased as the period of competency evaluation progressed. It was notable that QPDO related to Kt/V, Albumin, Hemoglobin, and Hematocrit Levels were directly proportional to increasing extent of SC ρ=(+0.61) while calcium and phosphorus levels were directly associated to areas where staff were demonstrated an decreasing trend ρ=(+0.66).

Conclusions: The eleven key areas of responsibility used to measure SC in a periodic evaluation demonstrated a strong correlation to the increasing extent of QPDO. Additionally, as the nurses progressed to becoming expert a direct correlation to the QPDO was notable. The study became the foundation for staff training and developing a competency appraisal framework in renal nursing practice thereby promoting quality assurance procedures while attaining QPDO.

FR-PO609

Variation in the Confidence and Knowledge of General Physicians Managing Acute Kidney Injury: A Need for Better Education Gang Xu,[1] Christopher Thompson,[1] James Trew,[1] Joanne H. Kirtley,[1] Richard J. Baines,[1] Rachel Westacott,[1] Nicholas M. Selby,[2] Sue Carr.[1] *[1]John Walls Renal Unit, Leicester General Hospital, Leicester, Leicestershire, United Kingdom; [2]Renal Medicine, Royal Derby Hospital, Leicester, Leicestershire, United Kingdom.*

Background: Acute Kidney Injury(AKI) presents a global challenge which remains significantly under recognized and yet has a significant effect on mortality and morbidity within the population. In the UK the majority of patients with AKI are looked after by non-nephrologists. Therefore educational initiatives, targeted at general internists are a potential tool to help improve the management and outcomes of patients with AKI. The aim fo the study was to establish the baseline knowledge and confidence of physicians admitting patients with AKI, at University Hospitals of Leicester and Royal Derby Hospital (serving a population of 2 million).

Methods: Physicians and trainees working in the hospitals were surveyed in November 2011. The survey included 15 Multiple Choice Questions designed to test knowledge on AKI.

Results: 342 doctors were surveyed; 39% Interns (pre registration), 42% Residents (post registration), 15% Fellows (Specialised trainee), 4% Consultants. Consultants answered 55% of MCQs correctly, Fellows 53%, Residents 46%, Interns 38%. Fellows felt most confident about diagnosing AKI (92%); however Consultants and Residents scored better on MCQs designed to test knowledge on diagnosis despite being less confident. Only 37% of Interns were confident at starting treatment for AKI despite having knowledge on the subject. 56% had used books/journals to learn about AKI, 56% had attended courses or attended lectures, 69% had received clinical teaching, 37% had used Internet resources, and 18% had used eLearning resources (multiple answers allowed).

Conclusions: Despite being a common presentation many physicians seem to lack both confidence and knowledge on AKI. Perceived confidence levels were higher in all grades of hospital doctor than demonstrated knowledge. This reaffirms the need for educational intervention if patient care and outcomes from AKI are to be improved; electronic learning resources appear underused compared to traditional teaching resources.

Initial Responses to Antihypertensive Therapy in Essential Pediatric Hypertension Stephen D. Cha, Hiren P. Patel, John D. Mahan. *Pediatric Nephrology, Nationwide Children's Hospital, Columbus, OH.*

Background: Essential hypertension (HTN) is becoming increasingly prevalent in pediatrics. To develop an educational program for primary care practitioners (PCP) regarding management of pediatric hypertension, we sought to define the pattern of treatments initiated by PCP and the short-term effectiveness of such interventions.

Objective: To assess the choice of initial medication class to treat pediatric HTN and its short term efficacy at 6 months.

Methods: We used our electronic medical records system to look at all referrals to outpatient pediatric nephrology for hypertension/elevated blood pressure (BP) from 1/1/11 through 12/31/11.

Results: Of the 434 patients who were referred for HTN or elevated BP, 35 were started or continued on a hypertensive medication (Rx) by PCP and 82 by pediatric nephrology.

Table 1

	Primary Care Practitioners	Pediatric Nephrology	Total
ACEi/ARB	23	42	65
CCB	4	38	42
Other	8	2	10
Total Started	35	82	117

The majority of patients started on an ACE inhibitor/angiotensin receptor blocker (ACEi/ARB) or diuretics by PCP were continued on it by pediatric nephrology (84%). Of the 117, 98 were followed in nephrology clinic. Only 19 (20%) were at the desired BP goal by 6 months. Of the 65 on an ACEi/ARB, 13 (20%) reached goal BP. Of the 42 on a calcium channel blocker (CCB), 6 (14%) were at goal BP. Ten patients started on other agents (diuretics, beta blockers or clonidine) without improvement. Of the 35 patients with Rx initiated by PCP, none had Rx changes due to side effects.

Conclusions: 1. Only a minority of patients had BP control with an ACEi/ARB or CCB by 6 months. 2. There are opportunities to address gaps in care for these patients by both PCP and pediatric nephrologists reflected by the suboptimal BP control in the short-term period. 3. Effective pediatric HTN education for PCP should address methods to initiate antihypertensive therapy and empower PCP to help such children reach desired BP goals.

FR-PO611

Pediatric Hypertension: Defining the Educational Needs of Primary Care Pediatricians Stephen D. Cha,[1] Deena J. Chisolm,[2] Hiren P. Patel,[1] John D. Mahan.[1] *[1]Pediatric Nephrology, Nationwide Children's Hospital, Columbus, OH; [2]Research Institute, Nationwide Children's Hospital, Columbus, OH.*

Background: Essential hypertension (HTN) is becoming increasingly prevalent in pediatrics, affecting 3-5% of the general pediatric population. Suspected pediatric HTN is evaluated with varying degrees of accuracy by primary care pediatricians (PCP). In an effort to improve recognition, evaluation and treatment of HTN among PCP, the comfort level and educational gaps for PCP need to be understood and addressed.

Objective: To identify the educational needs and to develop effective teaching methods to educate and influence practice behaviors of PCP regarding appropriate recognition, diagnostic evaluation, and therapeutic intervention in pediatric essential HTN.

Methods: We conducted 4 separate focus group (FG) discussions with pediatric residents, Adolescent Medicine physicians and 2 outpatient pediatric groups associated with Nationwide Children's Hospital in Columbus, OH. Six to 9 participants in each group discussed approaches to 3 common pediatric HTN scenarios. Sessions were recorded and transcribed for review. Themes were elucidated amongst the focus groups by 4 reviewers.

Results: Five major themes emerged from the focus group sessions (utilization of resources to obtain BP, BP measurement method, co-morbidities, barriers to care, and experience level of training) and 6 minor themes also emerged (differences in BP measurement, accuracy of BP, recognition, practice pattern, education, and differences in level of training). Most participants in each FG wanted further education on pediatric HTN but different groups defined varied needs and identified multiple preferences for how to learn this material.

Conclusions: These results support the need to develop programs to increase PCP knowledge of specific aspects of pediatric HTN. Based on the varied stated preferences of these PCP, education modules and methods will need to employ multiple presentation methods (e-learning, small group sessions, self-study, large group presentations) to be useful and ultimately improve outcomes in pediatric HTN.

FR-PO612

Great Job! Is Not Enough: Faculty Development to Improve Quality of Comments on Evaluations of Fellows Mireille El Ters, Suzanne M. Norby. *Nephrology & Hypertension, Mayo Clinic, Rochester, MN.*

Background: With the upcoming implementation of the ACGME Next Accreditation System, it will be essential for faculty members (FM) to provide meaningful information about trainee performance in order to determine whether milestones are met. Behavior-specific comments (BSC), rather than nonspecific comments (NSC) such as "great job" and "excellent", will be necessary. To improve quality of comments on evaluations of fellows, a live faculty development activity was presented during divisional Grand Rounds, consisting of an interactive didactic presentation along with distribution of copies of FM's own written comments about fellows for critical review during the session.

Methods: To determine whether FM who attended increased % BSC, written summative electronic evaluations of fellows were retrospectively reviewed, and comments were categorized as BSC or NSC. FM not attending the session served as controls. Median % BSC during the 6 months before and 6 months after the presentation were compared using the Wilcoxon rank sums test.

Results: 10 FM attending the session and 9 FM controls completed evaluations of fellows during both pre- and post- time periods. 3 FM (2 attendees, 1 control) with 100% BSC at baseline were excluded, leaving 8 FM in each group. During the pre-activity time period, median % BSC was 0.57 (range 0.10–0.88) for attendees and 0.59 (range 0.07–0.92) for controls (p=0.96). During the post-activity period, median % BSC for attendees was 0.71 (range 0.12–1.0) and for controls was 0.61 (range 0–1.0; p=0.46). Using a paired analysis, attendees demonstrated a 12.1% mean increase in BSC whereas BSC by controls fell by 2.4%. While numerical differences were seen, these changes were not statistically significant.

Conclusions: This faculty development activity was associated with an absolute increase in % BSC written by FM on summative electronic evaluations of nephrology fellows in a single training program. While sample size was small and the improvement did not achieve statistical significance, the findings suggest that a simple targeted faculty development activity may effect behavior change and improve the quality of comments written by FM on summative evaluations.

FR-PO613

Palliative Care Experience of US Adult Nephrology Fellows Hitesh H. Shah, Divya Monga, April Caperna, Lourdes G. Bahamonde, Tanveer Mir, Kenar D. Jhaveri. *Internal Medicine, North Shore LIJ Health System, Hofstra NSLIJ School of Medicine, Great Neck, NY.*

Background: Palliative care (PC) experience and knowledge of current US adult nephrology fellows is not known. It is also unknown if nephrology fellows undergo formal training in PC medicine during fellowship.

Methods: An anonymous online survey was created and subsequently distributed to nephrology fellows via nephrology training program directors.

Results: 65% of the respondents were international medical graduates (IMGs). 74% of fellows had no PC rotation during their medical school. 50% of the respondents had a formal PC elective during residency. Although 91% of the fellows have a PC division in their institution, only 49% had formal didactic PC experience. 85% of the respondent's fellowship program did not offer formal clinical training in PC during their fellowship.

While over 90% of fellows felt most comfortable with either writing dialysis orders or seeing an ICU consult, only 36% felt most comfortable not offering dialysis to a patient in the ICU with multi-organ failure. On a 5-point scale where 1 being least comfortable and 5 being most comfortable, majority of the fellows felt less comfortable in the following areas: not offering renal replacement therapy (RRT), withdrawing RRT, managing pain, treating depression and having end of life discussions. Nearly one out of five fellows surveyed felt obligated to offer RRT to every patient regardless of benefit. Female fellows felt less comfortable not offering or withdrawing RRT as compared to male fellows. US medical graduates felt more comfortable compared to IMGs when not offering or withdrawing RRT and having end of life discussions. 69% felt that a PC rotation during the course of fellowship would be helpful. Majority of the respondents felt that they would benefit from learning "how not to offer aggressive medical management" and "how to discuss withdrawal of life supporting measures".

Conclusions: Education and clinical training in PC medicine is not well experienced by US adult nephrology fellows. To enhance knowledge and clinical experience in PC medicine, a formal rotation during fellowship should be highly considered by nephrology training community.

FR-PO614

Palliative Care Experience of US Internal Medicine Subspecialty Fellows: A Comparative Study Divya Monga, April Caperna, Hitesh H. Shah, Tanveer Mir, Lourdes G. Bahamonde, Kenar D. Jhaveri. *Internal Medicine, Hofstra North Shore-LIJ School of Medicine, Great Neck, NY.*

Background: Palliative care (PC) experience of current US Internal Medicine (IM) subspecialty fellows is unknown. It is unknown if IM subspecialty fellowship programs in US offer formal training in PC medicine during fellowship.

Methods: An anonymous online survey was created and subsequently distributed to IM subspecialty fellows via fellowship training program directors. We compared the PC experience of nephrology fellows to pulmonary/critical care (PCC), hematology/oncology, cardiology and gastroenterology (GI) fellows in training.

Results: Preliminary results showed 26% respondents were from nephrology, 12% from cardiology, 14% from hematology/oncology, 31% from PCC and 17% from GI. 69% of nephrology fellows felt that a formal rotation in PC during fellowship would be very useful compared to 47% of PCC, 32% of cardiology, and 31% of GI fellows. While most IM fellows felt that a PC rotation would help in how not to offer aggressive medical management, majority of PCC fellows felt it would help in learning how to run family meetings. The table below compares the PC experience of IM fellows.

Palliative Care Experience	Nephrology (%)	Cardiology(%)	Hematology/ Oncology (%)	PCC(%)	GI(%)
During medical school	26	19	19	14	25
During medical residency	50	53	56	46	49
Didactics sessions during fellowship	49	32	90	60	20
Formal clinical training during fellowship	14	3	53	24	5
>10 end of life discussions during fellowship	33	32	81	61	46

Comparative Palliative Care Experience of IM fellows

Conclusions: Significant higher percentage of nephrology fellowship programs does not offer a formal clinical training in PC as compared to hematology/oncology and pulmonary/critical fellowships. Majority of the nephrology fellows felt the need of having a formal PC rotation during their fellowship as compared to other IM fellows. More efforts are needed by training community to improve the PC experience of IM fellows.

FR-PO615

Nephrology-Rheumatology Debate Session, an Innovative Educational Experience Kenar D. Jhaveri, Hitesh H. Shah, Divya Monga, Ashish Kataria, Joseph Mattana. *Nephrology, Hofstra North Shore-LIJ School of Medicine, Great Neck, NY.*

Background: Innovative teaching methods can create an environment that might promote interest and motivation to pursue careers in nephrology. However, such teaching methods might also be useful in maintaining and enhancing both satisfaction and enthusiasm for nephrology amongst fellows during training. Conducting debates created around clinical questions is a learner-centered approach that might be able to accomplish this.

Methods: For the past two years, we have conducted annual combined nephrology-rheumatology debate sessions. Topics were treatment for ANCA vasculitis(AAV) and lupus nephritis. A month prior, questions for the topic to be debated were sent out to all nephrology and rheumatology fellows via e-mail. Fellows were equally divided into two groups mixed from both divisions. On the day of the debate, only fellows were allowed to speak and present their side of the debate (50 minutes). The final 10 minutes was devoted to comments from faculty members in the audience. To assess the value of this tool, an anonymous on-line survey was conducted. Using a 5 point Likert scale, the fellows were asked to assess the impact of these sessions on self study, looking into primary data, usefulness in day to day practice.

Results: 46.2% were first year fellows, 38.5% were second year fellows and 7.7% were third year fellows. The fellows chose on average a score of 4 out of 5 (5 being extremely helpful) when asked about the debate session facilitating their personally looking up primary data on the topic debated, and helping them to better care for their patients with lupus nephritis and AAV. A lower score of 2 out of 5 was reported for the value of having a faculty member assign each member of the team to do a specific topic and allowing for more faculty participation during the debate. Other variables received scores of 3 and above. All fellows reported enjoying the sessions and would want to do it every year.

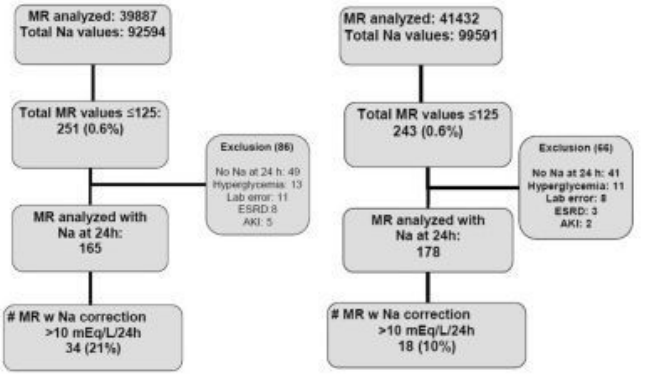
Conclusions: Novel ways of providing nephrology education using methods such as learner-centered debates described above may allow our fellows to learn more effectively and help keep them satisfied and engaged during training.

FR-PO616

Severe Hyponatremia Is Frequently Corrected Too Quickly: A Quality Improvement Project Marie A. Sosa,[1] Jennifer Russo,[2] Francis M. Wanjau,[2] Jeffrey S. Stoff.[1] *[1]Department of Medicine, Division of Nephrology, University of Massachusetts Medical School, Worcester, MA; [2]Department of Medicine, University of Massachusetts Medical School, Worcester, MA.*

Background: Hyponatremia (Na <135 mEq/L) is the most common electrolyte disorder encounter in clinical practice, is considered severe when the Na is below 125 mEq/L. Community-acquired hyponatremia has been described in 38% of hospitalizations and hospital-acquired in 38%. Osmotic demyelination syndrome (ODS) are the neurologic manifestations associated with rapid correction of hyponatremia. ODS can be prevented with Na correction rate of <10mEq/l in 24 h. The incidence of rapid Na correction of hyponatremia and ODS are not known. A quality improvement (QI) project was conducted with the goal of reducing the incidence of rapid Na correction.

Methods: Retrospective review of records of hospitalized patients with Na ≤125 over 4 months in 2011. The rate of correction of serum Na during the first 24h was determined. A second retrospective review of same data was obtained post intervention in 2012.



A root cause analysis identified lack of knowledge of practitioners as one of the causes for rapid correction. QI Intervention: 1)Residents Lecture 2) Review article on hyponatremia 3) Education maintained by small group sessions and the "Na Question of the week". Other data: 47% of the cases were managed by PCP/hospitalist and 24% by ICU staff. Renal was consulted in <1% of the cases. The average time to re-check the initial low Na was 10 h.

Results: In 2011, 21% of the cases of severe hyponatremia were corrected >10mEq/l 24h; the number was decreased to 10% in 2012 after conducting a QI project. Chi-square test 7.33, p value <0.007.

Conclusions: Severe hyponatremia is frequently corrected too quickly. A QI Intervention can be effective in decreasing the number of cases of rapid Na correction.

FR-PO617

Does Lack of Nephrology Fellow Involvement in Patient Education Affect Utilization of Peritoneal Dialysis in the United States? Nand K. Wadhwa,[1] Catherine Messina,[2] Nasser M. Hebah.[3] *[1]Division of Nephrology, Stony Brook School of Medicine, Stony Brook, NY; [2]Preventive Medicine, Stony Brook School of Medicine, Stony Brook, NY; [3]Corporate Home Dialysis, Dialysis Clinics Inc., NY.*

Background: Peritoneal dialysis (PD) use has declined to 7.2% of ESRD patients from a 1984 peak of 15%. The most common barrier to PD is patient preference. However, PD underuse may also reflect a lack of patient education about PD. We examined whether education of nephrology fellows and their involvement in patient education about PD contributed to its' underuse in the US.

Methods: Self-report surveys were administered electronically to directors of US nephrology fellowship programs and medical directors of Dialysis Clinics, Inc (DCI) dialysis units, Oct 2010-Mar 2011. Program directors were identified from the American Society of Nephrology list-serve; medical directors' were identified from the DCI list-serve.

Results: 55% (n=78) of program directors and 21% (n=38) of medical directors responded. Most nephrology programs provide fellow training in PD and HD; PD training was only 20% of total training vs. 80% for HD. Most program and medical directors provided pre-ESRD patient education (80% and 76%) with 98% providing education on treatment options. However, half of medical directors reported that ≤50% of patients attended. 89% of program directors vs. 56% of medical directors reported that ≥65% of patients choose HD (vs. PD) after education on treatment options. Only 33% of program directors reported that nephrology fellows participate in pre-ESRD patient education. 78% of program directors believe that lack of patient education on PD limits utilization, while <50% of medical directors believe this. 88% of program directors believe that limited physician training in PD limits PD use vs. 24% of medical directors.

Conclusions: Inadequate nephrology fellows' PD training and limited involvement in ESRD patient education may contribute to PD underuse in the US. Low patient participation in education programs and differing beliefs among program and medical directors regarding patient and physician education suggest that barriers to PD use may differ by dialysis setting.

FR-PO618

Central Venous Line Placement Competency among Incoming Nephrology Fellows Eric L. Wallace, Kelli R. King-Morris, Jamie P. Dwyer, Julia Lewis. *Nephrology, Vanderbilt University, Nashville, TN.*

Background: In July 2009, the ACGME removed the technical proficiency requirement for Internal Medicine residents to perform central venous line (CVL) placement. Nephrology fellows starting in 2012 are the first who at no time during residency have been required to place CVL to graduate. Little is known about the effect of this policy change on the experience of incoming fellows to place CVL, or how these changes will affect procedural training in Nephrology fellowships.

Methods: Nephrology Fellowship Program Directors and/or Coordinators were sent a survey on CVL placement to distribute to the 2012 Fellows. Fellows answered questions pertaining to their experience with CVL placement, comfort level on the procedure, and ultrasound (US) skills obtained during residency. The survey, data collection, and analysis were performed using REDCap (Research Electronic Data Capture) a secure, web-based application designed to support data capture for research studies.

Results: Of 360 incoming fellows surveyed, 120 (33%) responded. Of respondents, 27% at PGY3 or PGY4 level placed less than 10 CVL. 48% of PGY3 have never placed a large-bore CVL, and 75% of PGY3 have never placed an unsupervised large-bore CVL. 11% of PGY3 have never placed a femoral CVL, and 66% of PGY3 placed <25% of CVL as femoral. 14% of PGY3, 36% of PGY4, and 50% of PGY5 self-identify as novice in US usage. Despite overall low numbers of CVL placed, 90% of respondents reported being somewhat or very comfortable placing CVL.

Conclusions: Faculty supervision of large-bore catheters placement is still required given that 75% of PGY3 fellows have not placed unsupervised large-bore CVL. The femoral CVL may be where most attention is needed as this necessary nephrology procedure is not being done by residents. Decreasing US skill as PGY level increases is likely due to changes in standard of care in placement of CVL. Despite the policy change, residents still place CVL, and perceived comfort level is high, despite low numbers of CVL placed. Perceived comfort level may not correlate with technical proficiency given the low numbers of CVL placed, however; further study is warranted.

FR-PO619

Insertion of Temporary Hemodialysis Catheters by Nephrology Fellows in Canada: A Survey of Training and Current Practice Edward G. Clark,[1] Michael Schachter,[2] Cedric A.W. Edwards.[3] *[1]Kidney Research Centre, Ottawa Hospital Research Institute, Ottawa, ON, Canada; [2]The British Columbia Renal Agency, Vancouver, BC, Canada; [3]Division of Nephrology, Faculty of Medicine, University of Ottawa, Ottawa, ON, Canada.*

Background: Little is known about the extent to which evidence-based practices regarding central venous catheter insertion have been taught to, and adopted by, nephrology trainees.

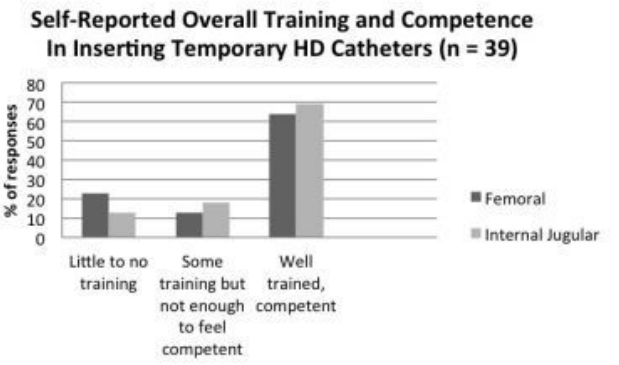
Methods: A web-based survey of fellows enrolled in the 12 English-language adult-nephrology training-programs in Canada assessed the estimated number of temporary hemodialysis (HD) catheters inserted in the prior 6 months of training, adherence to infection control procedures, use of real-time ultrasound, prior training and self-perceived competency in inserting temporary HD catheters.

Results: Completed surveys were received from 68% (39 of 57) of fellowship trainees in the target sample. Eighty-two percent (32 of 39) reported having inserted a temporary HD catheter in the prior 6 months of training.

Self-Reported Adherence To Infection Control Procedures and the Use of Real-Time Ultrasound (n=34)

	RESPONSES, % (n)			
USE OF:	**Always**	**Most of the time**	**Occasionally**	**Never**
Sterile gloves & gown	100 (34)	0	0	0
Facemask	88 (30)	12 (4)	0	0
Cap/hair-covering	62 (21)	18 (6)	21 (7)	0
Head-to-toe sterile drape	38 (13)	27 (9)	15 (5)	21 (7)
Ultrasound at femoral site*	60 (18)	23 (7)	10 (3)	7 (2)
Ultrasound at IJ site§	82 (27)	12 (4)	3 (1)	3 (1)

*n=30, §n=33



Conclusions: Within a representative sample of nephrology fellows in Canada, a majority report having adopted most of the evidence-based practices for temporary HD catheter insertion that were inquired about. Nonetheless, our results highlight many areas for improvement. It is concerning that a significant number of respondents indicated less than adequate training to feel competent in placing temporary HD lines. This finding merits further study.

Funding: Clinical Revenue Support

FR-PO620

Nephrology Journals of the Future: A Quantitative Study Vinay Nair,[1] Shahab Khan,[2] Kenar D. Jhaveri.[3] *[1]Internal Medicine, Mount Sinai Medical Center, New York, NY; [2]American University of Antigua Medical School, Coolidge, Antigua and Barbuda; [3]Nephrology, Hofstra North Shore LIJ School of Medicine, Great Neck, NY.*

Background: Journals are becoming more interactive creating websites that allow public commentary, blogs and sharing features with use of social media. This interaction can encourage all trainees and physicians to discuss important publications in a non-threatening manner.

Methods: We reviewed all journals with an impact factor ≥ 4 using the 2010 Journal Citation Reports Science Edition accessed March 20th 2012. All internal medicine(IM) and subspecialty journals were selected. Each journals website was accessed and reviewed for a blog, Twitter ®, Facebook® or email sharing, and a comment section. If a link to a blog was not found we then performed a google search with the title of the journal and the word blog. Comment section was defined as the ability for readers to publish comments on an article directly on the journals website. We compared the use of blogs, comment section, and social media for sharing between nephrology journals and other internal medicine journals.

Results: 199 journals with an impact factor ≥ 4 were Internal medicine or subspecialty journals. The number of journals in each field of IM with the use of blogs, public commentary and sharing features are seen in table 1.

Journals breakdown by Subspecialty

Specialty	# Journals >=impact factor 4.0	Blogs(%)	Commenting(%)	Sharing(%)
Int Medicine	30	43.3	30	96.7
Hem/Onc	47	2	4.2	91.4
Cards	28	3.5	21.4	96.4
Rheum	26	3.8	7.6	96
Endo	20	0	0	100
ID	18	11.1	11.1	94.4
GI	14	14.2	0	85.7
Pulm	9	0	11	100
Renal	7	14	0	100

No nephrology journal permitted public commentary. One (14%) nephrology journal had a blog, compared to 43.3% of general internal medicine journals. All nephrology journals supported sharing with social media or email.

Conclusions: Adopting social media is a slow process in nephrology academia. Compared to other subspecialties in medicine and general medicine, top nephrology journals had a 100% sharing feature but were slower in adopting blogs and commentary sections. We need our medical journals to be more interactive and allow more features to integrate the current generation of readers.

FR-PO621

Kidney Disease Screening and Awareness Program as a Potential Workforce Model: An Experience from Toronto Cheryl Hao Cui,[1] Li-Li Hsiao.[2] *[1]University of Toronto, Toronto, ON, Canada; [2]Renal Division, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

Background: Kidney Disease Screening and Awareness Program (KDSAP) provides free kidney disease screenings and health education for local communities with a specific focus on low-income and ethic minority populations. Such health screenings are run by undergraduate student volunteers, and hence offer students an unparalleled hands-on clinical experience and exposure to nephrology whilecultivating student leadership. With the success of the original KDSAP chapter at Harvard College, we propose that current KDSAP infrastructure can serve as a student organization model and magnify its impact in the community and student education.

Methods: The establishment of the new KDSAP chapters is lead by previous student volunteers who found the KDSAP experience to be rewarding and recognized the impact of the KDSAP in the community. These student leaders took the initiatives to apply for student organization sponsorships and to recruit student volunteers. Because of the well-recognized value of KDSAP in student development, KDSAP received enormous support and initial seeding funds from the school faculty.

Results: We established the first Canadian KDSAP chapter at the University of Toronto, which has demonstrated the scalability of the model. KDSAP Toronto Chapter launched its first community health screening at February 2012. We have successfully recruited 46 student volunteers from various departments. All student volunteers received formal training and participated in the Universal Precaution and Professionalism training session hosted by medical professionals. We have screened 100 participants in one day at the Chinatown Center and received overwhelmingly positive feedback from the participants and volunteers.

Conclusions: Overall, we showed that KDSAP is a reproducible program strategically targeting the undergraduate students and we have successfully validated the scalability of the KDSAP model across the country and internationally. The rapid and organic growth of the KDSAP is driven by the educational benefits it provides for the student volunteers and the remarkable impact it has on the communities.

Factors in Career Choice among Contemporary US Nephrologists

Gearoid M. McMahon, Lynette E. Thomas, J. Kevin Tucker, Julie Lin. *Nephrology, Brigham and Women's Hospital, Boston, MA.*

Background: There is a projected future shortage of kidney specialists, and retention of trainees in academic and non-academic nephrology is important. Determining factors that result in choosing a nephrology career could inform future strategies to attract nephrology fellows.

Methods: An anonymous, internet-based survey was sent to members of the American Society of Nephrology (ASN) in June 2009. Respondents answered questions about demographics, training background, and career choices.

Results: Of the 3399 members, 913 (23%) returned the survey. Mean age was 51.1±10.5 years, and 46.1% were academic nephrologists. Interest in nephrology began early in training for most with the intellectual aspects of nephrology, early mentoring and participation in nephrology electives named as the most common reasons in choosing nephrology. Academic nephrologists were more likely to have participated in research in medical school, have a Master's Degree or PhD and successfully obtained research funding during training. Academic debt was higher among non-academic nephrologists. Respondents were generally happy with their career choices. Research opportunities and intellectual stimulation were the main factors for academic nephrologists when choosing their first post-fellowship positions, while geographic location and work-life balance were foremost for non-academic nephrologists. One important limitation is that senior academic nephrologists were disproportionately represented among respondents.

Conclusions: These findings highlight the importance of exposing medical students and residents to nephrology early in their careers through involvement in research, electives, and positive mentoring. Further work is needed to develop and implement effective strategies, including increased early exposure to pre-clinical, clinical, and research medical education, in order to attract future nephrology trainees.

Funding: Private Foundation Support

FR-PO623

Kidney Disease Screening and Awareness Program: Health Education and the Facilitation of Student Career Development

Rena Mei,[1] Li-Li Hsiao.[1,2] *[1]Harvard College, Cambridge, MA; [2]Rena Division, Brigham and Women's Hospital, Harvard Medical School, MA.*

Background: Although Chronic kdiney disease (CKD) is one of the leading causes of death nationwide, there is low patient awareness of CKD along with decreasing interest in the field of nephrology. Initiatives involving renal health education may lead to earlier detection and lower rates of CKD. Health education also exposes students to nephrology and helps raise interest in this field.

Methods: Kidney Disease Screening and Awareness Program (KDSAP) is a kidney health initiative that holds monthly health screenings in underserved communities. KDSAP includes a Health Education component that targets both students and the community. A nephrologist gives a health talk at a partner site prior to a screening; patients then receive individualized advice during the screening. KDSAP also encourages career development of its members, which consists of high school, college and medical students. All new volunteers are trained to act professionally and safely in a clinical setting through the Universal Precaution and Professionalism Session. Blood Pressure Workshops train and certify students to measure blood pressure, a skill that they can then apply at screenings. The "Meet the Patient" and "Meet the Professor" series are campus events that give students insight into the life of a patient and a professional in the medical field specifically in Nephrology practice.

Results: Since its establishment in 2008, KDSAP has successfully trained 109 students for UPP and 99 students for measuring blood pressure. Health talks have been given in 22 communities, educating a total of 5000 patients. Of the 29 KDSAP alumni who were followed, 1 decided to become a nephrologist, 10 enrolled in medical school, 7 joined research groups focused on kidney disease, 4 work at hospitals/medical centers, and 1 works in global health.

Conclusions: KDSAP's Health Education program raises awareness about kidney health in high-risk communities and facilitates student career development by giving students direct exposure to clinical settings and patient interaction. KDSAP hopes to expand this component by training students to lead talks in schools and communities.

FR-PO624

Effectiveness of Multidisciplinary Group Patient Education Programs for CKD Patients: 5 Years Practices and Outcomes

Fumika Taki, Keita Hirano, Kenichiro Koitabashi, Kumiko Shimasaki, Masahiko Nagahama, Yasuhiro Komatsu. *Department of Internal Medicine, Division of Nephroloy, St Lukes' International Hospital, Tokyo, Japan.*

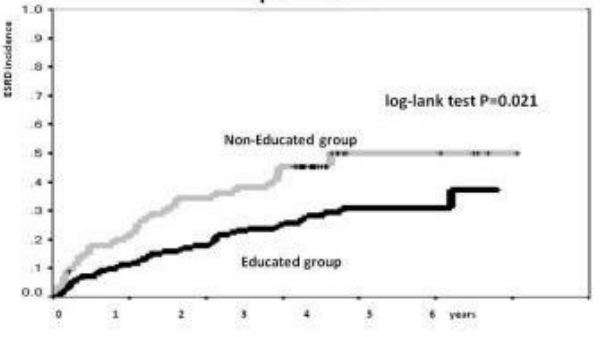
Background: Patients' education is an integral part of managing chronic diseases. However there are a few reports for CKD patients, especially for specific practices and evaluations. We already reported our pilot study on ASN 2007, which our group multidisciplinary education is effective for preserving renal functions in short term. We continued these programs for 5 years, and assessed long term outcomes.

Methods: We organized CKD education class which was designed under specific adult educational methods. This education program is focused on the importance of controlling blood pressure. Classes were held on total 3 hours and instructed by multidisciplinary educators. To evaluate effectiveness of the program we assessed knowledge, behavior and clinical parameters. Incidence of ESRD, which determined by initiation of dialysis, was evaluated for primary end point.

Results: Total 765 individual CKD patients were followed up in our clinic, and 265 patients were (34.6%) participated in this education program. On educated group, mean age 62.4 y.o., 54.5% (N=128) were male, their baseline GFR were 36.2±12.3 mg/dl/min. Their average score of knowledge about CKD or importance of blood pressure was 60% before class, this score significantly improved to 82% after class. After 1 or 5 years later, this score still maintained 75 or 73%. Also, the number of patients who monitored blood pressure themselves, who achieved below 130/80 mmHg were larger than non educated group. On the primary end point, incidence of ESRD patients was significantly lower on educated group than non-educated group. (Figure 1).

Conclusions: Multidisciplinary educational interventions for the CKD patients are effective in long term, and contribute to decrease ESRD patients.

Figure 1. Cumulative incidence rate of ESRD
Kaplan-Meier



FR-PO625

Dietary Sodium Knowledge in Patients with Chronic Kidney Disease

Julie A. Wright,[1] Cheryl A. Anderson,[2] T. Alp Ikizler,[3] Kerri L. Cavanaugh.[3] *[1]Internal Medicine, University of Michigan, Ann Arbor, MI; [2]School of Public Health, Johns Hopkins University, Baltimore, MD; [3]Internal Medicine, Vanderbilt University, Nashville, TN.*

Background: Adherence to sodium restriction is important for patients with chronic kidney disease (CKD). Little is known about patient knowledge necessary to support adherence.

Methods: One hundred fifty-five adult patients with CKD Stages 1-5, seen in nephrology clinic, were enrolled from April-October 2010. Patients were asked if they received counseling to decrease dietary sodium and if they knew their recommended daily sodium intake limit. They also answered three questions: Which food item has the most sodium? (1 apple, 2 ounces of lunchmeat, 1 banana, 1 baked potato), What is the best way to cut back on sodium? (trim visible fat from meats, eat more fresh vegetables instead of canned, substitute skim milk for whole milk, drink more fresh orange juice instead of canned), and Where does most of the sodium that people eat come from? (salt added at the table, processed/packaged foods, soda pop, plain frozen vegetables). We generated mean (SD) and percentages to describe data. Associations between patient characteristics and sodium knowledge were analyzed using logistic regression.

Results: The mean (SD) age was 56.6 (15.0) years, 46% were female, 77% white, and 79% had stages CKD 3-5. 86% received counseling to limit sodium, and 97% reported making changes as a result. 84% identified the highest sodium food, 83% identified fresh vegetables as a way to cut down on sodium, and 19% believed most sodium comes from table salt. 53% of patients said they did not have a daily sodium intake limit. In analysis adjusted for age, sex, race, health literacy, education, stage of CKD, and kidney education,

women and those of non-white race had a lower odds (OR 0.43 [CI 0.02,0.93; p=0.03] vs. men, and OR 0.35 [0.15,0.81; p=0.01] vs. white, respectively) of answering all sodium knowledge questions correctly.

Conclusions: Opportunity exists to support patient adherence by developing education interventions. Research is needed to determine why sodium knowledge is lower in women and patients of non-white race.

Transtheoretical Model of Behavior Change: Application of a Nutrition Education Program to Control Hyperphosphatemia in Hemodialysis Patients Carmen B. Tzanno-martins,[1] Bárbara Margareth Menardi Biavo,[2] Jacqueline Santos,[2] Camila Machado de Barros,[2] Elzo R. Junior,[1] Paul Clesca Troconis.[3] *[1]CINE-HDC-RENALCLASS Group, São Paulo, Brazil; [2]CINE-HDC-RENALCLASS Group, Sao Paulo, Brazil; [3]CINE-HDC-RENALCLASS Group, Sao Paulo, Brazil.*

Background: In patients with chronic kidney disease, it is crucial to begin treatment as early as possible to prevent and decrease the occurrence of complications. Motivating this population of patients to adhere to a treatment plan is a major challenge for health care professionals. In this study, we assessed the impact of a nutritional education program using the transtheoretical model of eating behavior change to control hyperphosphatemia in these patients.

Methods: This prospective observational study performed in satellite dialysis centers included 189 patients out of a total of 378 who exhibited phosphorus concentrations ≥ 5.5 mg/dL. The nutritional intervention consisted of lectures and group dynamics sessions performed during dialysis sessions. The didactic materials used included an illustrated album, photographs of food and brochures. The following data were analyzed pre- and post-intervention: anthropometric, clinical, demographic and laboratory data (serum phosphorus concentration and intact parathyroid hormone (iPTH)) as well as application of the transtheoretical model to eating behavior.

Results: After the nutrition intervention, we found a statistically significant reduction of the serum phosphorus concentration, and most patients exhibited positive changes in their eating behaviors. Reduction of phosphatemia is a measure of compliance with treatment, and it is associated with decreased mortality in patients with chronic kidney disease undergoing hemodialysis.

Conclusions: Thus, we conclude that nutritional intervention through an education program is an effective tool to reduce hyperphosphatemia in this population.

An Oral Adsorbent AST-120 Adsorbed the Precursors of Uremic Toxins in the Intestines Ryoko Tateoka, Yoshiharu Itoh, Atsuko Ezawa, Hideyuki Yamato. *Kureha Corporation, Tokyo, Japan.*

Background: An oral sorbent AST-120 is clinically used in Japan for the treatment of chronic kidney disease (CKD) patients to slow the progression of CKD. We found some metabolites such as indoxyl sulfate (IS), p-cresyl sulfate (PCS), phenyl sulfate (PhS), 4-ethylphenyl sulfate (4EtPhS) and hippuric acid (HA) were accumulated in the serum of CKD rats, and their serum levels were reduced by administration of AST-120. In this research, we investigated the toxic effect of these metabolites on proliferation of a pig kidney-derived cultured renal epithelial cell line (LLC-PK_1). In addition, we analyzed their precursors which were adsorbed on AST-120 recovered from the feces of CKD rats to elucidate the role of AST-120 in the intestines.

Methods: Cell proliferation assay: The LLC-PK_1 cells were incubated with metabolites for 4 days. Then, the cell number in each well was estimated using a cell counting kit. Analysis of adsorbates on AST-120 recovered from the feces of CKD rats: AST-120 was administered to CKD rats by oral gavage at a dose of 1.0 g/kg, 4.0 g/kg. Twenty four-hour feces were collected and separated into AST-120 and residue, and then extracts were obtained from each by liquid extraction. By using gas chromatography/mass spectrometry (GC/MS), we analyzed indole (ID), p-cresol (PC), phenol (Ph), 4-ethylphenol (4EtPh) and phenylpropionic acid (PPA) in the extracts from AST-120 which are considered precursors of IS, PCS, PhS, 4EtPhS and HA, respectively.

Results: Cell proliferation assay: IS, PCS, PhS, 4EtPhS and HA inhibited significantly the cell proliferation relative to control medium, and their inhibitions were dose-dependent. Analysis of adsorbates on AST-120 recovered from the feces of CKD rats: ID, PC, Ph, 4EtPh and PPA were detected in the extracts from AST-120. The amounts of them were dose-dependently increased by administration of AST-120.

Conclusions: We showed that IS, PCS, PhS, 4EtPhS and HA induced an inhibition of renal epithelial cell proliferation in a dose-dependent manner. We detected ID, PC, Ph, 4EtPh and PPA as adsorbates on AST-120. These results indicate that AST-120 reduce the serum level of uremic toxins by adsorbing their precursors in the intestines.

FR-PO628

Central Role of Urea in Disruption of Intestinal Tight Junction and Barrier Dysfunction in CKD Nosratola D. Vaziri, Gaytri Gandotra, Hamid Moradi, Jun Yuan. *Medicine, Division of Nephrology and Hypertension, University of California, Irvine, CA.*

Background: CKD causes intestinal barrier dysfunction which contributes to systemic inflammation. Recently we found depletion of key trans-cellular [claudin-1 and occludin) and intracellular [ZO1] protein constituents of epithelial tight junction (TJ) in the colon of CKD animals [Vaziri et al NDT, 2012]. These findings elucidated the mechanism by which uremia impairs intestinal barrier function. Present study explored the effect of simulated uremia on intestinal epithelial barrier function/structure and possible causal role of urea whose influx into the gut and conversion to ammonia by bacterial urease is well known.

Methods: TJ-forming T84 cells were seeded on the apical compartment of Transwell plates to achieve polarization and utilized when trans-epithelial electrical resistance (TER) approached 1,000 $\Omega.cm^2$ to ensure full polarization and TJ formation. The cells were then incubated for 24 hr in media containing 10% plasma from ESRD or healthy individuals or in media containing zero, 70, or 120 uM urea with or without urease to recapitulate the effect of microbial flora.TER was then measured (Millicell ERS-2 meter) and cells harvested for Western blot and immunohistology.

Results: TER fell by 48% in presence of uremic plasma and by 28-30% in presence of clinically-relevant urea levels reflecting barrier dysfunction. Incubation in media containing ESRD patients' plasma and urea respectively reduced cluadin-1 (by 85% & 90%), occludin (15% & 80%), and ZO1 (by 70% & 75%). The effect of urea was dramatically amplified by urease.

Conclusions: Exposure to uremic milieu impairs intestinal barrier function and structure which by enabling influx of endotoxin and other noxious products can contribute to inflammation and accumulation of gut-derived uremic toxins. This is partly mediated by urea which is generally known as a nontoxic metabolite.

FR-PO629

Myocardial Infarction Accelerates Renal and Cardiac Impairment Post Subtotal Nephrectomy: Implications for Cardiorenal Syndrome Shan Liu,[1] Andrew Kompa,[1] Darren J. Kelly,[2] Henry Krum,[1] Bing Hui Wang.[1] *[1]Department of Epidemiology & Preventive Medicine, Monash University, Melbourne, Australia; [2]Department of Medicine, University of Melbourne, St. Vincent's Hospital, Melbourne, Australia.*

Background: Renal failure with co-morbid cardiac dysfunction is associated with significant worsening of mortality requiring further investigation into the pathophysiology and related mechanisms. We investigated the renal and cardiac pathophysiological changes that occur when myocardial infarction (MI) follows chronic kidney injury (induced by 5/6 nephrectomy – STNx).

Methods: Male Sprague Dawley rats (n=36) were randomized into four groups: Sham-operated STNx + Sham-operated MI (Sham+Sham), Sham-operated STNx + MI (Sham+MI), STNx+Sham-operated MI (STNx+Sham) and STNx+MI. STNx/Sham surgery was first induced followed by MI/Sham surgery 4 weeks later. Renal function was assessed prior to the 2nd surgery and 8 weeks later. Thereafter, tissues were collected for analysis.

Results: Survival rate was 100%, 77.8%, 60.9% and 39.8% in Sham+Sham, Sham+MI, STNx+Sham and STNx+MI rats, respectively. All rats that underwent STNx had significantly reduced glomerular filtration rate (Sham+Sham: 8.6±0.5, Sham+MI: 8.1±0.5, STNx+Sham: 0.7±0.4, STNx+MI: 0.2±0.4 ml/min/kg) and creatinine clearance (Sham+Sham: 242.6±26.6, Sham+MI: 255.5±39.7, STNx+Sham: 32.2±8.7, STNx+MI: 33.9±12.4 ml/min), and significantly increased urine total protein (Sham+Sham: 23.1±2.0, Sham+MI: 16.2±1.6, STNx+Sham: 344.4±48.9, STNx+MI: 380.0±89.1 mg/day) compared to rats that did not undergo STNx. Increases in renal interstitial fibrosis ($p<0.05$) and kidney injury molecule-1 ($p<0.001$) in the non-infarct zone were observed in STNx+MI compared to STNx+Sham rats, despite no difference in blood pressure (BP) ($p=0.27$). Heart weight ($p<0.05$), cardiomyocyte cross-sectional area ($p<0.01$) and cardiac interstitial fibrosis ($p<0.05$) was greater in STNx+MI compared to STNx+Sham rats.

Conclusions: Combined STNx and MI accelerated renal fibrosis, and cardiac hypertrophy and fibrosis; all of these alterations were BP independent. This study demonstrates the potential of this model in assessing the pathophysiology and mechanisms of cardiorenal syndrome.

FR-PO630

Immunomediated Mechanism of Organs Damage in Cardiorenal Syndrome Type1 Grazia Maria Virzì,[1,2] Massimo de Cal,[1,2] Dinna N. Cruz,[1,2] Elisa Scalzotto,[1,2] Claudio Ronco.[1,2] *[1]Nephrology Dep, St Bortolo Hosp, Vicenza; [2]International Renal Research Institute Vicenza, IRRIV, Italy.*

Background: Cardiorenal syndrome Type1 (CRS1) is characterized by acute cardiac events leading to acute kidney injury (AKI). CRS1 pathophysiology is very complex. Given circulating nature of many inflammatory mediators, it is tempting to examine the immunomediated mechanism as mediator of organs crosstalk in CRS1. The main objective was to examine *in vitro* that CRS1 plasma was able to trigger a response in monocytes and renal tubular cells (RTC), resulting in apoptosis and in cytokine-release.

Methods: We enrolled 12 patients with Heart Failure (HF)(age 73.5±12.9yrs, sCr 0.87mg/dl (IQR 0.82-0.96), 7 patients with CRS1 (75.8±10.8yrs, sCr 0.93mg/dl (IQR 0.89-0.99) and 5 healthy controls (CTR)(63±8yrs). Plasma from different groups were

incubated with monocytes and RTCs for 24h and, subsequently, cell apoptosis was evaluated by different methods and quantitative levels of TNF-α and IL-6 in supernatants was performed by ELISA.

Results: Both cell lines treated with CRS1 plasma showed higher DNA ladder formations, suggesting presence of apoptotic events. In fact, a quantitative analysis of apoptosis showed significantly higher apoptosis rates in CRS1(30.5%, IQR 24-39.9) compare to HF (8%, IQR 6.7-9.5) and CTR (5%, IQR 4.5-7.5)(p<.005). Moreover, Caspase-3 levels in cells incubaed with the plasma from CRS1 patients demonstrated a significantly higher concentration (1.2ng/ml, IQR 1.1-2 vs HF 0.78, IQR 0.6-0.9 and CTR 0.1, IQR 0.1-0.2).When compared with CTR (2.4, IQR:1.5-4.1), TNF-α levels in supernatant were significantly elevated both in HF (28.2pg/ml, IQR:20.7-32.8) and in CRS1 group (28.45, IQR 22.4-29.6)(both p<.005). Furthermore, in CRS1 patients IL-6 was significantly higher compared with HF patients and CTR (46.1pg/ml, IQR 24.4-70 vs HF 21.25, IQR 18.4-36.5 and CTR 2.4, IQR 1.8-3.4)(p<.005).

Conclusions: This pilot study suggests the presence of defective regulation of apoptosis in monocytes and RTCs in CRS1, and the presence of an immunomediated mechanism. Furthermore, these preliminary results imply that inflammatory pathways may have a central role in pathogenesis of CRS1 and may be fundamental to damage distant organs.

FR-PO631

Nicotine and the Progression of Chronic Kidney Disease: Role of COX-2 Derived Prostaglandins Gabriel Rezonzew,[1] Phillip H. Chumley,[1] Gene P. Siegal,[2] Wenguang Feng,[1] Ping Hua,[1] Edgar A. Jaimes.[1,3] *[1]Medicine/Nephrology, University of Alabama at Birmingham; [2]Pathology, University of Alabama at Birmingham; [3]Nephrology, VA Medical Center, Birmingham, AL.*

Background: Cigarette smoking is a risk factor in the progression of CKD. Nicotine (NIC), a major component of tobacco, worsens renal injury in 5/6 nephrectomy rats (Nx), a well validated model of CKD (AJP'12). COX-2 derived prostaglandins (PGs) have been postulated to participate in the pathogenesis of renal injury. Herein we determined the role of COX-2 on the adverse effects of NIC in the severity of injury in Nx rats.

Methods: Male SD rats were divided in five groups: Sham, Nx, Nx+NIC (0.1 gm/L, DW), Nx+NIC+COX-2 innhibitor (NS, 1.5 mg/Kg/day, SQ), Nx+NS. Urine was collected for proteinuria and PGs (PGI_2 and PGE_2) and blood pressure (BP) measured by tail cuff. Rats were euthanized after 12 weeks and kidneys saved for western blot (WB) and histology.

Results: Nx did not affect COX-2 expression (WB) and had a small effect on the urinary excretion of PGI_2 and no effect on PGE_2 (Table). NIC did not modify COX-2 expression in Nx rats but increased the urinary excretion of PGI_2. NS increased COX-2 (WB) and reduced urinary excretion of PGI_2 but not of PGE_2 (Table). COX-2 inhibition significantly reduced BP in Nx and Nx+NIC rats and improved glomerular injury score (GIS), proteinuria and fibronectin in Nx+NIC rats but not in Nx rats.

	Sham (n=8)	5/6Nx (n=9)	5/6Nx+NIC (n=7)	5/6Nx+NIC+NS (n=8)	5/6Nx+NS (n=8)
COX-2 (A.U.)	1.1±0.01	1.02±0.11	1.04±0.03	1.30±0.1*,#,**	1.47±0.1*,#,**
PGI2 (ng/mg creat)	7.7±0.4	13.3±6.7	37.4±7.2 *,#	3.2±0.9#,**	2.4±0.5#,**
PGE2 (ng/mg creat)	2.6±0.3	1.6±0.4	2.6±1.2	2.8±1.0	2.5±0.5
SBP(mmHg)	128±5.1	162±8.4*	159±7.8*	135±7.7**	140±6.6#
GIS	0.27±0.03	0.85±0.2*	1.6±0.26 *,#	0.26±0.05 #,**	0.86±0.28*
Proteinuria(mg/mg creat)	1.97±0.45	8.4±1.3 *	13.24±1.7 *,#	4.35±0.72**	20.1±3.8 *,#
Fibronectin(fold increase)	1±0.09	1.64±0.34*	2.56±0.28 *,#	1.78±0.06**	1.7±0.03 *

* p<0.05 vs Sham, # p<0.05 vs 5/6Nx, ** p <0.05 vs 5/6Nx+NIC

Conclusions: We have demonstrated that COX-2 plays an important role as mediator of the deleterious effects of nicotine in CKD making it a potential target for the prevention of accelerated progression of CKD in smokers.

Nicotine Receptors Are Widely Expressed in the Human, Rat and Mouse Kidney: A Potential Role in Tobacco Induced Renal Injury? Phillip H. Chumley,[1] Gabriel Rezonzew,[1] Ping Hua,[1] Wenguang Feng,[1] Edgar A. Jaimes.[1,2] *[1]Medicine/Nephrology, University of Alabama at Birmingham; [2]Nephrology, VA Medical Center, Birmingham, AL.*

Background: Nicotine acetylcholine receptors (nAChRs) are formed by the combination of five subunits to form pentameric receptors that function as agonist-regulated Ca^+ channels. Their activation by nicotine in the central nervous system is responsible for the addictive properties of tobacco smoking. Recently several nAChR subunits have been identified in other tissues including the systemic vasculature, lung, and skin. Nicotine contributes to the progression of chronic kidney disease (CKD) via the promotion of mesangial cell proliferation, extracellular matrix production and reactive oxygen species generation. We previously showed the presence of nAChR subunits in human mesangial cells (AJP '07) and recently demonstrated that blockade of the α7-nAChR subunit reduces renal injury associated with the administration of nicotine in 5/6 nephrectomy rats, a validated model of CKD (AJP '12). To shed further insight into the importance of the different nAChR subunits it is critical to characterize their presence and primary distribution in the renal parenchyma.

Methods: Western blot analysis and immunofluorescent methods were used to determine the expression and localization of several subunits (α1-7, ß1-4) in the normal kidney from human, rat (Sprague-Dawley) and mouse (C57BL/6) origin.

Results: As shown in table 1 we observed the presence of several nAChR subunits in the normal kidney of three different species.

Table 1

subunit	Human IF	Mouse IF	Rat IF	Mouse western	Rat western	Primary location
α1	++	-	-	-	-	Human - glomeruli and tubules
α2	-	-	-	-	+	n/a
α3	+	-	-	-	-	Human - tubules
α4	+	++	++	++	++	glomeruli and tubules
α5	+	++	++	++	+++	tubules
α6	++	++	++	++	+++	glomeruli, tubules, interstitial and vascular
α7	+++	+++	+++	++	+++	tubules, glomeruli in human
β1	-	-	-	-	-	n/a
β2	+	+	+	++	-	tubules
β3	++	++	-	+++	-	glomeruli and tubules
β4	+++	+++	+++	+++	+++	glomeruli and tubules

Conclusions: We conclude that several nAChR subunits are present in the normal kidney, that when activated by nicotine may play a role in the pathogenesis of accelerated CKD in smokers.

FR-PO633

Induced Overexpression of VEGF Ameliorates Glomerulosclerosis Progression in Mice Anne P. Wilson,[1] Haichun Yang,[1] Ji Ma,[2] Agnes B. Fogo.[1] *[1]Pathology, Microbiology and Immunology, Vanderbilt University, Nashville, TN; [2]Pediatric Medicine, Vanderbilt University, Nashville, TN.*

Background: Vascular endothelial growth factor (VEGF) is a pro-angiogenic factor produced by the podocyte in glomeruli. In healthy mice, overexpression of VEGF leads to proteinuria. However, in the setting of chronic renal disease, podocyte loss reduces VEGF in glomeruli, which may contribute to glomerulosclerosis progression. We investigated whether induced overexpression of VEGF after glomerulosclerosis could decrease progression.

Methods: VEGF loxp (V) mice were mated with TetO-podocin-Cre (R) mice to create double transgenic mice (RV) that permit inducible overexpression of VEGF, or single transgenic mice (R), which will not induce VEGF. All mice underwent 5/6 nephrectomy (Nx). At 8 weeks after 5/6 Nx, overexpression of VEGF was induced by administration of 2 mg/mL doxycycline in the drinking water. Mice were sacrificed at week 12, or earlier in severely ill mice. Systolic blood pressure and proteinuria were measured at week 0, week 8, and the time of sacrifice, and glomerulosclerosis assessed.

Results: RV mice did not have proteinuria at baseline (ACR 72.2 ± 8.2 mg/mg). At week 8, both RV and R mice had developed proteinuria (*RV:* 8835.6 ± 2996 mg/mg; *R:* 7760.6 ± 1791 mg/mg). Systolic BP increased significantly in both groups from week 0 to week 8 (*RV:* 116.4 ± 4.96 week 0 to 140.9 ± 9.1 mmHg at week 8; *R:* 117.7 ± 2.4 week 0 to 139 ± 5.7 mmHg at week 8, p<0.05). After administering doxycycline at week 8, RV mice survived longer than R mice (17.3 days vs. 15.2 days). Systolic BP did not change significantly from week 8 to sacrifice in RV or R mice.In R mice, there was a 3.5 fold increase in proteinuria (measured by ACR) on average from week 8 to sacrifice, while in RV mice, ACR remained steady over this time period. However, despite longer survival times, there was less glomerulosclerosis in RV mice (sclerosis index 1.05 ± 0.18, 0-4 scale) than in R mice (1.31 ± 0.16).

Conclusions: Our data indicate induced overexpression of VEGF slows the progression of existing glomerulosclerosis and prevents increased proteinuria by local mechanisms, not through systemic blood pressure effects.

FR-PO634

Establishing a Biomarker for the Vasculopathy of Fabry Disease Liming Shu, Anuradha Vivekanandan-Giri, Subramaniam Pennathur, James A. Shayman. *Internal Medicine, University of Michigan, Ann Arbor, MI.*

Background: Vascular endothelial dysfunction of Fabry disease, resulting from a deficiency of α-galactosidase A (α-Gal A), is a consequence of the accumulation of globotriaosylceramide (Gb3). We have previously established models of vasculopathy in the α-Gal A null mouse including oxidant induced thrombosis, accelerated atherogenesis, and impaired arterial reactivity to better delineate the mechanistic basis for the vasculopathy. These studies have demonstrated that excess Gb3 deposition in both lysosomes and caveolae of plasma membranes cause decreased nitric oxide bioavailability as a result of both reduced eNOS activity and uncoupling.

Methods: To better understand the pathogenesis of Fabry disease in humans, we generated a human cell model of Fabry disease by using RNA interference. EA.hy926 cells, a hybridized human endothelial cell line, were transiently transfected with either control or siRNA specifically directed against α-Gal A.

Results: α-Gal A knockdown was greater than 85% and was confirmed by immunoblotting and Gb3 accumulation. Enzyme expression and Gb3 levels were proportionate to the level of transfection. eNOS activity was correspondingly decreased and the reduction was greater than 60%. The oxidized amino acids were then quantified by tandem mass spectrometry. 3-Nitrotyrosine, a specific marker for reactive nitrogen species (RNS) was markedly increased (40 to 120 fold) without corresponding changes in other oxidized tyrosines, including chlorotyrosine, dityrosine, and orthotyrosine, consistent with eNOS as the source of the RNS.

Conclusions: These data confirm the previously observed association between Gb3 accumulation, decreased NO bioavailability, and RNS resulting from eNOS uncoupling. These findings raise the possibility that 3-nitrotyrosine may serve as a biomarker for the vascular involvement in Fabry disease.

Role of SDF-1/CXCR4/eNOS Signaling in Maintaining Endothelial Integrity and Renal Function in Chronic Kidney Disease Li-Hao Chen,[1] Suzanne Advani,[1] Darren A. Yuen,[1] Kim Connelly,[1] Ian W. Gibson,[2] Manish M. Sood,[2] Philip A. Marsden,[1] Richard E. Gilbert,[1] Andrew Advani.[1] *[1]Dept. of Medicine, St. Michael's Hospital, Toronto, ON, Canada; [2]Health Sciences Centre, University of Manitoba, Winnipeg, MB, Canada.*

Background: Therapeutic strategies antagonizing the angiogenic chemokine stromal cell-derived factor-1 (SDF-1), or its cognate receptor CXCR4, are being keenly investigated for the treatment of malignancies and other chronic diseases. In the present study, we explored the role of the SDF-1/CXCR4 system in chronic kidney disease (CKD), where decreased angiogenic factor activity and capillary loss are pathophysiologically linked to renal decline.

Methods: Gene expression was determined in both rat and human kidney tissue. CXCR4 antagonism was achieved by treating subtotally nephrectomized (SNx) rats with the bicyclam, AMD3100. SDF-1 signaling was induced by infusing recombinant SDF-1 into the kidneys of normal rats prior to glomerular isolation. In vitro studies were performed in wildtype and eNOS$^{-/-}$ glomerular endothelial cells (GECs).

Results: CXCR4 protein was noted in endothelial cells of both glomerular and peritubular capillaries in normal adult human kidney tissue, while renal expression of the receptor was increased in the kidneys of SNx rats and in biopsies of patients with secondary focal segmental glomerulosclerosis. In contrast, while SDF-1 mRNA was reduced in SNx kidneys, it was increased following treatment with the ACE inhibitor, perindopril. Chronic CXCR4 antagonism accelerated renal decline and capillary loss in SNx rats, while acute infusion of SDF-1 induced CXCR4-dependent glomerular endothelial signaling through endothelial nitric oxide synthase (eNOS) activation. Exposure of cultured GECs to recombinant SDF-1 resulted in tube formation, proliferation and migration, each of which was impaired in eNOS deficient GECs.

Conclusions: These observations indicate that local SDF-1/CXCR4/eNOS signaling functions to preserve endothelial integrity in CKD. While caution should be applied with the chronic systemic use of anti-SDF-1/CXCR4 agents in the renally impaired population, augmentation of this pathway, by conventional or novel agents, may attenuate declining function in CKD.

The Sphingosine-1-Phosphate Receptor Agonist FTY720 Improved Expression of eNOS in Kidneys from Subtotal Nephrectomized Rats Haifeng Ni, Junfeng Chen, Bi-Cheng Liu. *Institute of Nephrology, Zhong Da Hospital, Southeast University School of Medicine, Nanjing, Jiangsu, China.*

Background: Previous study suggested that decreased bioavailability of endothelial nitric oxide (NO) produced from endothelial NO synthase (eNOS) plays a crucial role in the progression of kidney damage. Sphingosine 1-phosphate (S1P) has been highlighted as an endothelial barrier-stabilizing mediator. FTY720 is a S1P analog originally developed as a novel immunosuppressant. In this study, we investigated the effects of FTY720 on the levels of nitric oxide (NO) and the expression of eNOS in the renal tissue from subtotal nephrectomized rats.

Methods: Seven days after surgery, SD rats were allocated to the following groups: Sham, subtotal nephrectomy (SNX), and SNX +FTY720. Rats were killed on week 12 after surgery and blood, urine and kidneys were collected for analyses. The renal histological changes were investigated by light and transmission electron microscopy. The expression of eNOS were detected by immunohistochemical staining, RT-PCR and Western blot.

Results: FTY720 attenuated the increase of BP, proteinuria, SCr and NAG in SNX($P<0.01$). FTY720 treatment prevented the downregulation of nitric oxide(NO) in kidney in SNX. SNX rats had severer glomerular sclerosis and vascular lesions than sham rats ($P<0.01$). FTY720 treatment ameliorated these effects ($P<0.01$). There was endotheliosis in glomerulus and widening of subendothelial spaces in SNX by Electron microscopy, these abnormalities were attenuated by FTY720. Immunohistochemistry showed the tissue localization of eNOS protein in the sham rat kidneys was in endothelial cells in glomeruli and vasculature. Semiquantitative analyses showed that eNOS expression in the glomeruli and vessles was lower in SNX rats compared with the sham ($P<0.01$), whereas FTY720 abrogated this change($P<0.01$). FTY720 treatment improved eNOS mRNA expression ($P<0.01$) and protein expression ($P<0.01$) compared with the untreated SNX.

Conclusions: FTY720 ameliorates endothelial injury in glomeruli and vasculature in kidneys from SNX. Alterations of eNOS may be an explanation for the underlying mechanism of FTY720 renoprotection.

Sirtuin 1 (SIRT1) Deficiency in Endothelial Cells Leads to Microvascular Rarefaction, Premature Senescence, and Cardiomyopathy Julien Maizel,[1,2] Sandhya Xavier,[2] Jun Chen,[2] Radovan Vasko,[2] Michael S. Goligorsky.[2] *[1]INSERM 1088, Jules Verne University of Picardie and University Medical Center, Amiens, France; [2]New York Medical College, Valhalla, NY.*

Background: Cardiovascular diseases are the leading cause of death in CKD. Recently several studies demonstrated the role of impaired angiogenesis in the development of cardiomyopathies. SIRT1 regulates angiogenesis. Therefore we analyzed the cardiac functions of mice deficient in SIRT1 in endothelial cells.

Methods: The left ventricular diastolic function of Sirtuin1$^{f/f}$;Tie2-Cre (KO), Sirtuin1$^{f/+}$Tie2-Cre (Het), Tie2-Cre, Sirtuin1$^{f/f}$ (all controls) mice was examined echocardiographically: isovolumic relaxation time (IVRT) and myocardial performance index (Tei index). Hearts were examined by Masson's trichrome staining, CD31 immunostaining and analyzed for RNA abundance for Collagen 1 and 3, short and long endoglin, MMP14, TIMP2 and VEGF.

Results: The KO mice compared to control groups of animals exhibited diastolic dysfunction with increased IVRT and Teï index (Table 1). The percentage of fibrosis in the left ventricle of KO mice was increased. The number of CD31+ structures in the left ventricle was significantly lower in the KO compared to controls animals. The RNA expression of collagen 1 and collagen 3 and the ratio of short-to-long endoglin, a marker of senescence were all higher in the KO group. The RNA expression of VEGF, MMP14 and TIMP2 were all lower in the KO group.

Table 1. Echocardiographic parameters of heart function and markers of remodeling

	Het Cont	Het	KO Cont	KO

Sirt3 Is a Target for Acetyl-L-Carnitine Protection against Angiotensin II-Induced Insulin Resistance Daniela Macconi,[1] Luca Perico,[1] Simona Buelli,[1] Marina Morigi,[1] Paola Cassis,[1] Lorena Longaretti,[1] Federica Casiraghi,[1] Giuseppe Remuzzi,[1,2] Ariela Benigni.[1] *[1]Mario Negri Institute for Pharmacological Research, Bergamo, Italy; [2]Unit of Nephrology and Dialysis, Azienda Ospedaliera Ospedali Riuniti di Bergamo, Italy.*

Background: Sirt3 deficiency is causally linked to IR and metabolic syndrome and data are available that angiotensin II (Ang II) down-regulates Sirt3 gene expression in cultured cells. Since acetyl-L-carnitine (ALCAR) has been found to ameliorate hypertension and insulin resistance (IR) in subjects at increased cardiovascular risk, here, we explored whether ALCAR ameliorates Ang II-induced IR through Sirt3 modulation.

Methods: Rat skeletal muscle cells, L6 myotubes, were incubated in the absence or presence of 100 nM Ang II for 24 h before and during 30-min stimulation with 100 nM insulin. IR was evaluated as inhibition of insulin-induced glucose uptake and GLUT4 translocation to the plasma membrane. Surface GLUT4 was assessed in L6 GLUT4-myc. Mitochondrial ROS were measured by MitoSOX. Sirt3, phospho/total AMPK, acetylated proteins were analyzed by western blot. NAMPT mRNA was measured by real time PCR. Silencing of Sirt3 was induced by siRNA Sirt3 transfection in L6 GLUT4-myc myotubes.

Results: ALCAR prevented Ang II-induced IR by improving insulin-stimulated GLUT4 transport and glucose uptake in L6 myotubes. These effects were associated with reduced mitochondrial oxidative stress and upregulation of manganese superoxide dismutase (MnSOD). Similarly to ALCAR, MnTBAP, a mitochondria SOD mimetic, enhanced cell surface GLUT4-myc in Ang II-treated cells suggesting that control of mitochondrial superoxide is a crucial step for improving insulin sensitivity. ALCAR reversed the inhibitory effect of Ang II on Sirt3 activity/expression. Reduced mitochondrial protein acetylation by ALCAR was associated with activation of AMPK and up-regulation of NAMPT. Silencing of Sirt3 in L6 GLUT4-myc myotubes induced IR in unstimulated cells mimicking the effect of Ang II and completely abrogated the beneficial effect of ALCAR on Ang II-induced IR.

Conclusions: Sirt3 mediates the protective effect of ALCAR in Ang II-induced IR.

Epigenetic Alterations at Laminin Genes in Aging Kidneys Karol Bomsztyk, Daniel S. Mar, Oleg N. Denisenko. *UW Medicine SLU, University of Washington, Seattle, WA.*

Background: Aging is associated with a gradual decline of kidney function. Glomerular filtration rates decrease due to changes in structure and composition of basement membrane. We hypothesized that in a rat model aging induces changes in renal expression of laminin genes that encode key components of basement membrane.

Methods: To control for the effect of genetic background we used two rat lines, i) Fisher 344 (F344), and ii) F344xBN hybrid (FBN-F1) with median life spans 24 and 33 months respectively RT-PCR and multiplex Matrix chromatin immunoprecipitations were used to assess levels of mRNA and transcription/chromatin changes in kidneys from young (4 mo) and old animals (F344 - 24/28 mo, FBN-F1 - 32 mo).

Results: In both animal lines, aging was associated with increased transcript levels of laminin chains a3, b3 and c2, with little or no changes in other laminin mRNAs. These changes were more pronounced in old F344 animals that have shorter life span. Aging-induced laminin genes showed increased density of RNA polymerase II at these loci, suggesting altered transcription. There was a correlation between increases in laminin transcript levels and loss of the repressive epigenetic mark H3K27m3 at these genes during aging. These observations suggested a causal link between the loss of this silencing mark and

upregulation of laminin genes. *In vitro* experiments supported this suggestion, as inhibition of activity of cognate methyltransferase, Ezh2, in kidney cell line HEK293 decreased H3K27m3 levels and upregulated Lama3/b3/c2 expression. However, Ezh2 levels were not reduced in old kidneys, indicating that a decrease in the histone methyltransferase cannot account for the loss of H3K27m3 density and aberrant laminin gene expression during aging. Instead we found that levels of H3K27m3 demethylase KDM6A were increased along Lamc2 gene in old compared to young kidneys.

Conclusions: These data suggest that upregulation of Lama3/b3/c2 expression in aging kidneys is caused by increased activity of KDM6A histone demethylase at these genes. Thus, deregulation of epigenetic enzymes could be a major contributor to altered composition of basement membranes and the decline in kidney function associated with aging.

FAT10-Knockout Mice Are Protected from HIV-Associated Nephropathy

Michael J. Ross, Bin Wang, Pengfei Gong. *Division of Nephrology, Mt Sinai School of Medicine, New York, NY.*

Background: HIV-associated nephropathy (HIVAN) is a rapidly progressive form of focal segmental glomerulosclerosis that is accompanied by tubular dilation and tubulointerstitial inflammation and fibrosis. We have previously shown that the ubiquitin-like protein FAT10 is upregulated in renal tubular cells of HIVAN and that FAT10 mediates NF-kB activation and HIV-induced apoptosis in renal tubular cells in vitro.

Methods: To determine whether FAT10 expression is necessary for HIVAN pathogenesis in vivo, we studied whether FAT10 $^{-/-}$ HIV transgenic mice are protected the HIVAN phenotype that occurs in the Tg26 HIV-transgenic model of HIVAN. After fully backcrossing FAT10$^{-/-}$ mice onto the FVB/N genetic background (same as Tg26), we bred them with Tg26 mice and compared the renal phenotype of FAT10 $^{-/-}$ HIV mice with FAT10 $^{+/+}$ HIV mice (Tg26) at 3 months of age.

Results: We found that 76% (19 of 25 mice) developed typical HIVAN pathologic abnormalities including glomerulosclerosis, microcystic tubular dilatation and inflammatory cells infiltration while these abnormalities occurred in only 24% (8 of 33 mice) of FAT10 $^{-/-}$ HIV mice. FAT10 $^{-/-}$ HIV mice developed less severe proteinuria (albumin/creatinine ratio 1.29±0.31 vs 2.19 ± 0.31, $p<0.05$), but there was no significant difference in serum levels of BUN, creatinine, or TNFα. FAT10 $^{-/-}$ HIV mice also had markedly lower expression of renal chemokines and cytokines (*CCL2, CCL20, CXCL1, CXCL2, CXCL5, IL-6* and *VCAM*) as compared to Tg26 mice however, there was no difference in renal expression of HIV RNA (*tat-rev, nef, vpr*).

Conclusions: Together, the results suggest that FAT10 has an important role in the pathogenesis of HIVAN and that FAT10 may mediate these effects via enhanced expression of NF-kB dependent pro-inflammatory mediators.

FR-PO641

Increased Mortality in the Tg26 Mouse Model of Human Immunodeficiency Virus Associated Nephropathy when Podocan Expression Is Decreased

Wei Zou, Alexander Thomas Batista, Jae Choi, Maricela Ortiz Ramirez, Deborah P. Hyink, Paul E. Klotman. *Internal Medicine, Baylor College of Medicine, Houston, TX.*

Background: Podocan was originally identified as an upregulated gene in mouse podocytes expressing HIV-1 viral genes. Tg26 mice, a murine model of HIVAN, also have an increased expression of podocan in sclerotic glomeruli. To test the hypothesis that decrease in podocan expression would improve renal function in Tg26 mice, we crossed Tg26 mice with podocan deficient mice.

Methods: Body weight, blood urea nitrogen (BUN), and proteinuria from at least 10 mice per group of wild type, podocan deficient, Tg 26, and Tg 26/podocan deficient mice (Tg 26/podn$^{+/-}$) were monitored from 3 to 24 weeks of age. Kidneys from above groups at 12 weeks of age were analyzed by PAS staining.

Results: Podocan deficient mice showed normal development, life span, and renal function. Similar to Tg26 mice, Tg 26/podn$^{+/-}$ mice had onset of proteinuria at three weeks postnatally, and the severity of proteinuria was comparable between these two groups ($p>0.05$). BUN levels of Tg 26/podn$^{+/-}$ mice were normal. Although both Tg 26 and Tg 26/ podn$^{+/-}$ mice had histopathological changes characteristic of HIVAN including diffuse collapsing glomerulosclerosis, microcystic tubular changes, and proteinaceous casts, these changes were less severe in Tg 26/podn$^{+/-}$ mice. Notably, in the kidneys of Tg 26/podn $^{+/-}$ mice, there was increased monocytic interstitial infiltration. However, there was increased mortality of Tg 26/podn $^{+/-}$ mice (n=15) compared to age-matched Tg 26 mice (n=25) ($p<0.0001$): more than half of Tg 26/podn $^{+/-}$ mice were dead by 12 weeks of age and by 20 weeks of age only 13% of Tg 26/podn $^{+/-}$ mice were still alive, while the survival rates of Tg26 mice at the age of 12 and 20 weeks were 84% and 68%, respectively.

Conclusions: Our results indicate that podocan deficiency alleviates clinical and histological manifestations in experimental HIVAN, suggesting that increased expression of podocan contributes to HIVAN pathogenesis. Our results also suggest that podocan has certain functions that are essential for the survival of these HIV transgenic animals, and these functions are currently under investigation.

Kidney Proximal Tubular Epithelial Cell-Specific Overexpression of Netrin-1 Suppresses Inflammation and Albuminuria through Suppression of COX-2-Mediated PGE2 Production in Streptozotocin-Induced Diabetic Mice

Riyaz Mohamed, Calpurnia Jayakumar, Punithavathi Vilapakkam Ranganathan, Ganesan Ramesh. *Medicine/Vascular Biology Center, Georgia Health Sciences University, Augusta, GA.*

Background: Inflammation plays a key role in development and progression of diabetic kidney disease. However the role of the anti-inflammatory molecule netrin-1 in diabetic kidney disease is unknown. Here we examined the role of netrin-1 in diabetes-induced kidney inflammation and injury using tubule-specific netrin-1 transgenic mice.

Methods: Diabetes was induced using streptozotocin in wild type and netrin-1 transgenic animals. Kidney function, fibrosis, albuminuria and inflammation were determined by measuring serum creatinine, Western blot analysis, immunostaining, ELISA and RT-PCR. The mechanism of netrin-1-induced suppression of inflammation was studied in vitro using a proximal tubular epithelial cell line.

Results: Diabetes was associated with increased infiltration of neutrophil and macrophage, chemokine expression, tubular epithelial cell apoptosis and interstitial fibrosis in the kidneys. These changes were minimal in the kidney of netrin-1 transgenic mice. In addition, diabetes induced a large increase in the excretion of prostaglandin E2 (PGE2) in urine, which was suppressed in netrin-1 transgenic mice. Netrin-1 induced suppression of PGE2 production was mediated through suppression of NFkB mediated cyclooxygenase-2 (COX-2) in renal tubular epithelial cells. In addition, netrin-1 also increased albumin uptake by proximal tubular epithelial cells through the PI3K and ERK pathways but does not alter glucose excretion and uptake by tubular epithelial cells.

Conclusions: Our results suggest that netrin-1 is a major regulator of inflammation and apoptosis in diabetic nephropathy and may be a useful therapeutic molecule for treating chronic kidney diseases such as diabetic nephropathy.

Manipulation of Hif2a to Treat Anemia of CKD: A Viable Option?

Dong-Ryeol Ryu,[1,2] Nasir Shah,[2] Hoon-ki Sung,[2] Hibret Adissu,[3] Yoshiro Maezawa,[2] Susan E. Quaggin.[2,4] *[1]Ewha Womans University, Seoul, Korea; [2]The Samuel Lunenfeld Res. Inst., Toronto, Canada; [3]Hospital for Sick Children, Canada; [4]St. Michael's Hospital, Canada.*

Background: Anemia management is a major component of caring for CKD patients. EPO and ESAs are a mainstay of therapy. However, there is interest to develop new agents that stimulate endogenous EPO production in a more physiologic manner. Prolyl hydroxylase inhibitors stabilize HIF2a, thus increasing EPO production and are currently under investigation for the treatment of anemia. Here we sought to understand how HIF2a stabilization affects erythropoiesis *in vivo*.

Methods: We generated an inducible gain-of-function tetO-HIF2a transgenic mouse and bred it to Pax8-rtTA and Rosa-rtTA driver strains. We also generated a stress model of anemia (30% reduction in hematocrit following blood-letting) in wildtype mice.

Results: Pax8 is expressed in renal tubular epithelial cells and some hepatocytes; induction results in Hif2a mRNA upregulation in these cells (4,500-fold and 7,800-fold, respectively). Within 2 weeks, hematocrits doubled, resulting in thrombosis, cardiovascular events and death. Upon removal of induction (- dox), hematocrits promptly returned to baseline. In Pax8-rtTA-tetO-HIF2a mice, most Epo is produced by hepatocytes (550-fold increase), not renal cells. In contrast, stress anemia (decrease in Hct 30% after blood-letting) in wildtype mice results in increased Epo production from renal interstitial cells (2,500-fold) but not liver. Using a Rosa-rtTA-driver strain bred to tetO-Hif2a mice, results in more modest Hif2a upregulation (600~2,400-fold; all cells), resulting in massive expansion of erythroblasts in bone marrow, liver and spleen. Interestingly, these mice are anemic due to failure of RBC maturation. Switching off HIf2a (-dox) permits rapid differentiation of erythroblasts. Epo levels were modestly increased (70~100-fold; kidney and liver).

Conclusions: Our data demonstrate multiple roles for Hif2a in control of erythropoiesis through Epo production and effects on RBC differentiation. Pharmacologic manipulation of Hif2a (e.g. prolyl hydroxylase inhibitors) will require careful dosing and monitoring to avoid serious complications.

FR-PO644

Assessment of Erythropoietin Effects in the Progression of Experimental Chronic Kidney Disease

Fernando Felippe Carvalho, Vicente de Paulo Castro Teixeira, Waldemar S. Almeida, Nestor Schor. *Nephrology Division, UNIFESP, Sao Paulo, Brazil.*

Background: Erythropoietin (EPO) has been used primarily to treat anemia caused by chronic kidney disease. Recent studies have shown a renoprotective EPO effect in ischemic kidney diseases. The mechanisms of renoprotection include antiapoptotic effects and stimulation of endothelial progenitor cells. Thus, the aim of this study is to evaluate the influence of EPO on progression of kidney disease in experimental chronic kidney disease.

Methods: Male Wistar rats weighing 280-300g underwent 5/6 nephrectomy and were divided into two groups: (NX) only nephrectomized(n=6) and (NX-EPO) nephrectomized(n=6) and treated with a weekly dose of erythropoietin (250UI/kg/ip). All animals were sacrificed 8 weeks after surgery. Hematocrit, serum creatinine, proteinuria, indirect blood pressure measurement, immunohistochemical analysis, glomerular score and tubular lesion were assessed.

Results: The NX-EPO group showed significant improvement in serum creatinine (NX 1.6 ± 0.4 versus NX-EPO 0.8 ± 0.1, P ≤ 0.001) and protein/urine creatinine ratio (NX 11.2 ± 6.0 versus NX-EPO 4.1 ± 2.2, P = 0.021). Histopathological results demonstrate a lower rate of glomerular sclerosis (NX =33% versus NX-EPO=17%) and tubulointerstitial fibrosis (grade III NX versus grade I NX-EPO) according to Banff classification. Preliminary results of immunohistochemistry reveal an increased expression of desmin in NX group.There were no significant differences in hematocrit and blood pressure between the two groups.

Conclusions: Our study suggests a beneficial effect of EPO in the model of progression of experimental chronic renal disease reflected by improvement of serum creatinine, proteinuria and attenuation of glomerular lesion score and a lower expression of desmin in podocytes, regardless of its effect on hematocrit and blood pressure.

FR-PO645

Effects of H.P. Acthar Gel® in the NZB/W Mouse Model of Spontaneous Lupus Nephritis Shaun Jordan, Dima Decker, David Young. *Research & Development, Questcor Pharmaceuticals Inc., Ellicott City, MD.*

Background: H.P. Acthar Gel® (Acthar) is a long-acting porcine-derived highly purified preparation of ACTH1-39 that may include other proopiomelanocortin (POMC) peptides and is FDA approved "to induce a diuresis or a remission of proteinuria in the nephrotic syndrome without uremia due to lupus erythematosus." We investigated whether Acthar can reduce proteinuria and other renal measures of disease severity and progression in the spontaneous lupus nephritis NZB/W mouse model.

Methods: Eligible female NZB/W F1 mice (spot urine protein test strip score < 3 between 20 to 26 weeks of age) were randomly assigned into 3 treatment groups at 28 weeks. Treatments were administered by s.c. injection once every other day (160 IU/kg Acthar or 0.4 ml/kg Acthar Placebo Gel, APG) or once daily (5 g/kg prednisolone, PRED) for 18 weeks. Animals were terminated if they developed either severe proteinuria, lost ≥ 20% body weight, or exhibited prostration. Proteinuria, survival, and body weight were monitored weekly, and serum creatinine and renal histopathology and IgG deposition were conducted on terminal serum and kidney samples.

Results: Proteinuria and weight loss occurred after two weeks of APG and PRED treatment, albeit to a lesser extent in PRED treated mice. In contrast, proteinuria was not observed in any Acthar treated mice, and this effect persisted beyond 10 weeks of treatment. Furthermore, body weight remained stable, and in some cases slightly elevated, in Acthar treated mice. These effects of Acthar were consistent with improvements in serum and renal measures of disease severity and progression.

Conclusions: Acthar produced beneficial effects on renal measures of disease severity and progression, as well as survival, in a mouse model of spontaneous lupus nephritis, which were superior to those produced by PRED, a standard of care that extends survival in NZB/W mice. These are the first preclinical evidence supporting the on-label indication of Acthar as a treatment for lupus nephritis. Preclinical research is ongoing to determine whether these effects represent potential immunomodulatory and anti-inflammatory effects of Acthar mediated through melanocortin receptors.

FR-PO646

Active Involvements of Glucagon-Like Peptide-1 (GLP-1)/Dipeptidyl Peptidase IV (DPP4) System in the Development of Renal Injury in a Rat Model of Chronic Kidney Disease (CKD) Ryotaro Ando,[1] Seiji Ueda,[1] Nana Obara,[1] Yusuke Kaida,[1] Kei Fukami,[1] Sho-ichi Yamagishi,[2] Seiya Okuda.[1] *[1]Division of Nephrology, Department of Medicine, Kurume University School of Medicine, Kurume, Fukuoka, Japan; [2]Department of Pathophysiology and Therapeutics of Diabetic Vascular Complications, Kurume University School of Medicine, Kurume, Fukuoka, Japan.*

Background: GLP-1 not only increases the postprandial insulin secretion, but also has various extra-pancreatic actions. GLP-1 receptor is presented in the kidney and DPP4 is abundantly expressed in renal tubular cells. However, the precise roles of GLP-1/ DPP4 in the pathogenesis of CKD remain unclear. Here we examined whether manipulation of GLP-1 or DPP4 could affect the development of renal injury in a rat model of CKD.

Methods: Sprague-Dawley (SD) rats and F344/DuCrlCrlj (F344) rats, genetically DPP4-deficit rats, were divided into sham-operated rats (sham) and 5/6 nephrectomized rats (5/6Nx), respectively (SD-sham; n=10, SD-5/6Nx; n=69, F344-sham; n=12, F344-5/6Nx; n=15). SD-5/6Nx rats were subdivided into 1) hydralazine, 2) exendin-4, an agonist of GLP-1 receptor, and 3) exendin(9-39), an antagonist of GLP-1 receptor -treated groups. Four weeks after the operation, the rats were killed to evaluate their urinary protein excretion, metabolic data, histology, and morphometry.

Results: In SD-5/6Nx rats, progressive increases in blood pressure, proteinuria and BUN levels were observed, all of which were significantly attenuated in F344-5/6Nx rats. Similarly, administration of exendin-4 into SD-5/6Nx rats decreased these deteriorated effects, whereas these were aggravated by exendin(9-39). Further, immunohistochemistry revealed that progressive capillary and podocyte loss observed in the SD-5/6Nx rats were also attenuated in both genetically and pharmacologically GLP-1-activated models.

Conclusions: These results indicate that GLP-1 may exert renoprotective effects, at least in part by preventing endothelial and podocyte injury in 5/6Nx rats and therefore, could be a novel therapeutic tool for CKD.

FR-PO647

Development and Treatment of HUS in Nonhuman Primates Induced by Toxins from Enterohemorrhagic *E.coli* Deborah Stearns-Kurosawa, Shinichiro Kurosawa. *Pathology, Boston University School of Medicine, Boston, MA.*

Background: Hemolytic uremic syndrome (HUS) is a potentially lethal complication of infection with enterohemorrhagic *E.coli* O157:H7 bacteria (EHEC), a food-borne pathogen. Bacterial Shiga-like toxins (Stx1,Stx2) induce HUS, characterized by thrombocytopenia, hemolytic anemia and thrombotic microangiopathy, with acute renal injury. Nonhuman primates (Papio baboons, 4-6kg) were evaluated for response to toxins, development of HUS, response to therapeutics and discovery of damage associated molecular pattern (DAMPs) biomarkers reporting cell injury.

Methods: Animals were challenged i.v. with Stx1 (10-100ng/kg), Stx2 (10-50ng/kg), or Stx1+Stx2 (25ng/kg each). Physiology was monitored; blood and urine were collected over 7-28 days for analysis of: kidney & liver chemistries (IDEXX labs), cytokines by multiplex immunoassays (Luminex, Millipore), HMGB1(ELISA), plasma mitochondrial DNA (qPCR). Therapeutic interventions were Rescue Protocols beginning up to 24 hours after toxin with synthetic anti-toxin peptide (TVP) or activated protein C anticoagulant (APC; drotrecogin alfa, activated; Eli Lilly). Primary outcomes were survival and measures of kidney function.

Results: Animals challenged with Stx1 or Stx2 developed HUS and dose-dependent acute kidney injury. Mixed Stx1+2 toxin was synergistic, with reduced survival ($p<0.001$), reduced platelets ($p<0.05$), and more rapid loss of kidney function relative to similar single toxin load. Stx1 elicited a more pro-inflammatory cytokine profile and high DAMPs (HMGB1, mtDNA). Treatment with cell permeable TVP peptide or APC resulted in surviving otherwise lethal Stx2.

Conclusions: Up to 25% of EHEC patients who develop HUS have life-long kidney problems. Outbreaks are sporadic, so animal models are vital. This project describes the only animal model that develops HUS in response to the EHEC toxins. We demonstrate disease similar to patients, and reduced disease severity with a synthetic peptide that regulates toxin cytotoxicity and a natural enzyme that reduces coagulopathy to protect organ function. Availability of this animal model provides the opportunity to evaluate novel therapeutics and to identify biomarkers that report HUS risk.

Nlrp3 Is a Key Modulator of Metabolic Syndrome-Induced Nephropathy Pieter J. Bakker,[1] Loes Butter,[1] Lotte Kors,[1] Gwendoline J.D. Teske,[1] Fayyaz Sutterwala,[2] Sandrine Florquin,[1] Jaklien Leemans.[1] *[1]Pathology, Academic Medical Center, Amsterdam, Netherlands; [2]Inflammation Program, University of Iowa, Iowa City, IA.*

Background: Metabolic syndrome (MetSyn) is defined as a cluster of five risk factors such as obesity and insulin resistance. MetSyn-driven nephropathy is characterized by microalbuminuria, fibrosis and inflammation which ultimately leads to end-stage renal disease. The innate immune receptor Nlrp3 has been implicated in obesity and type 2 diabetes. We hypothesized that the MetSyn-driven nephropathy is mediated by Nlrp3.

Methods: Nlrp3 -/- (Nlrp3KO) and wild-type C57BL/6J mice (n=8 per group) were fed a control diet (CD) or Western diet (WD) for 16 weeks. Blood was collected and kidneys were harvested, formalin-fixed or snap frozen. Snap frozen kidneys were used to determine cytokine, lipid and mRNA levels by respectively ELISA, enzymatic reaction and quantitative PCR. Paraffin-embedded kidneys were used for immunohistochemistry. Statistics were done by Mann-Whitney U test.

Results: A Western diet induced renal Nlrp3 expression. Nlrp3 deficiency protected against kidney function decline in WD-fed mice as seen by increased plasma urea and micro-albuminuria. Renal pathology in WD-fed wild-type mice was characterized by lipid accumulation, fibrosis and inflammation. Nlrp3 deficiency prevented WD-induced renal cholesterol accumulation. Furthermore, proximal tubules showed extensive Nlrp3-dependent vacuolization in WD-fed mice. Vacuoles contained phospholipids as indicated by Nile Red staining. Moreover, WD-induced fibrosis consisted of an increase in Collagen1$^+$ glomeruli in wild-type mice. Fibrosis was absent in Nlrp3KO mice. Renal inflammation in WD-fed wild-type mice was enhanced as seen by a profound accumulation of F4/80$^+$ macrophages and an increase in MCP-1. No macrophage influx was observed in Nlrp3ko mice despite increased MCP-1 levels. We established that Nlrp3 mediates WD-induced renal ICAM-1 suggesting a role for Nlrp3 in regulating macrophage influx through ICAM-1.

Conclusions: Here we demonstrate that Nlrp3 is a key modulator of renal lipid accumulation, inflammation and fibrosis leading to decreased renal function in a model for MetSyn-induced nephropathy.

Serum miR-148b as a Novel Non-Invasive Biomarker of IgA Nephropathy (IgAN) Grazia Serino,[1,2] Fabio Sallustio,[1,2] Francesco Pesce,[1] Sharon N. Cox,[1] Giuseppe De Palma,[2] Francesco Paolo Schena.[1,2] *[1]Department of Emergency and Organ Transplantation, University of Bari, Bari, Italy; [2]C.A.R.S.O. Consortium, Valenzano, Bari, Italy.*

Background: IgA nephropathy (IgAN) is the most common form of primary glomerulonephritis worldwide characterized by aberrant O-glycosylation in the hinge region of IgA1. Our recent work demonstrates that miR-148b regulates the enzyme core 1, β1,3-galactosyltransferase 1 (C1GALT1) explaining the abnormal glycosylation process in

IgAN (JASN, 23:814-824; 2012). miR-148b was reported to be overexpressed in PBMCs of IgAN patients, but its levels in serum have never been investigated. The aim of our study was to evaluate if serum levels of miR-148b may be considered as a novel non-invasive biomarker for the diagnosis of IgAN.

Methods: Serum miRNA was extracted from patients and controls using QIAzol Lysis Reagent and miRNeasy Mini Kit (Qiagen) according to the manufacturer's protocol. Using quantitative real-time PCR, we detected the expression of circulating miR-148b in 60 patients with IgAN and 60 healthy blood donors (HBD) with negative urine analysis. IgA1 O-glycosylation serum levels using helix aspersa agglutinin (HAA) lectin binding assay were also measured in each sample.

Results: We found that miR-148b serum levels were higher in IgAN patients compared to HBD (IgAN 0.49±0.03; HBD 0.39±0.01; p<0.01). Similarly, deglycosylated IgA1 serum levels were significantly higher in IgAN patients (p<0.01). Logistic regression analysis showed that both miR-148b (p=0.01) and deglycosylated IgA1 (p=0.02) levels were significantly able to predict the IgAN affection status. Moreover, subjects with higher miR-148b serum levels (≥75th percentile) were at high risk for IgAN (OR 2.9, 95% CI: 1.3-6.9).

Conclusions: These results suggest that miR-148b may be a novel non-invasive biomarker for the diagnosis of IgAN which, also combined with deglycosylated IgA1 serum levels, could better define the disease state.

Funding: Government Support - Non-U.S.

FR-PO650

IgA Nephropathy: A Murine Model that Displays Typical IgAN Pathology after Passive Administration of Immune Complexes Zina Moldoveanu,[1] Hitoshi Suzuki,[2] Kenji Satake,[2] Yusuke Suzuki,[2] Lea Novak,[1] Zhi Qiang Huang,[1] Colleen J. Winstead,[1] Darrell B. O'Quinn,[1] Bruce A. Julian,[1] Casey T. Weaver,[1] Jiri F. Mestecky,[1] Yasuhiko Tomino,[2] Jan Novak.[1] *[1]University of Alabama at Birmingham, Birmingham, AL; [2]Juntendo University, Faculty of Medicine, Tokyo, Japan.*

Background: IgA nephropathy (IgAN) is an autoimmune glomerulonephritis wherein immune complexes (IC) composed of galactose-deficient IgA1 (Gd-IgA1; autoantigen) and anti-glycan IgG autoantibodies deposit in the glomeruli. Here we developed an animal model by using *in vitro*-formed IC from human Gd-IgA1 and anti-glycan IgG for induction of IgAN-like disease in mice.

Methods: Gd-IgA1 and anti-glycan IgG, either recombinant or isolated from sera of IgAN patients, were used to form IC to be injected *i.v.* into SCID or nude mice. Samples of blood and urine were collected to determine serum IgA1 and IgG, urinary protein and creatinine and hematuria. The excised kidneys were evaluated by light-, immunofluorescence- and electron-microscopy (EM).

Results: Gd-IgA1 and anti-glycan IgG formed IC that deposited in the mesangium with murine C3, and induced hematuria and proteinuria. Albuminuria increased by ~50% at 24 h after injection of IC. EM confirmed electron-dense mesangial deposits and showed podocyte injury and erythrocytes in Bowman's space. In control mice injected with only Gd-IgA1, IgA1 deposited only transiently and did not cause renal injury. Morphometric analysis of glomeruli in PAS-stained renal tissue sections showed mesangial hypercellularity and matrix expansion. Mean number of nuclei per unit area was the same in naïve mice and mice injected with Gd-IgA1 (38.5 ± 4.8 *vs.* 39.4 ± 6.5), but was higher in mice injected with IC (51.6 ± 8.0). Matrix expansion and enhanced mesangial expression of alpha-smooth muscle actin were observed in the mesangium of mice injected with IC.

Conclusions: We confirmed the role of Gd-IgA1-IgG IC in IgAN. This new animal model provides a useful tool for elucidation of pathogenesis of IgAN and for testing and development of future therapeutic strategies.

Role of *N*-Acetylgalactosaminyl Transferases in the Synthesis of Aberrant IgA1 *O*-Glycans in IgA Nephropathy Milan Raska,[1,2] Koshi Yamada,[2] Tyler J. Stewart,[2] Milada Stuchlova-Horynova,[1,2] Zhi Qiang Huang,[2] Hitoshi Suzuki,[3] Zina Moldoveanu,[2] Bruce A. Julian,[2] Robert J. Wyatt,[4] Jiri F. Mestecky,[2] Matthew B. Renfrow,[2] Ali G. Gharavi,[5] Jan Novak.[2] *[1]Palacky University, Olomouc, Czech Republic; [2]University of Alabama at Birmingham, Birmingham, AL; [3]Juntendo University, Tokyo, Japan; [4]University of Tennessee, Memphis, TN; [5]Columbia University, New York, NY.*

Background: IgA nephropathy (IgAN) is associated with the presence of IgA1 with galactose (Gal)-deficient *O*-glycans in the hinge region (HR) which are recognized as an autoantigen by specific antibodies. The mechanisms leading to the aberrant glycosylation are related to changes in the expression, activity, and/or localization of specific glycosyltransferases. The initiation step in *O*-glycan formation is attachment of *N*-acetylgalactosamine (GalNAc) to the IgA1 HR, catalyzed by GalNAc-transferases (GalNAc-Ts). Among the 17 known human GalNAc-Ts, only GalNAc-T14 is differentially expressed in IgAN patients and healthy controls. Here, we determined the effect of down-regulation of GalNAc-T14 expression on IgA1 glycosylation in IgA1-producing cells.

Methods: EBV-immortalized IgA1-secreting cellsderived from circulatory B cells of IgAN patients (n=3)and healthy controls (HC, n=3) were subjected to GalNAc-T14 siRNA knock-down. RealTime PCR was used for determination of GalNAc-T14 expression and lectin ELISA for determination of Gal deficiency of HR *O*-glycans.

Results: We confirmed that all tested IgAN cell lines overexpressed GalNAc-T14 in comparison to HC cell lines. The efficacy of GalNAc-T14 siRNA knock-down was >80% for all tested cell lines. Lectin ELISA confirmed that decrease in GalNAc-T14 expression leads to less Gal deficiency, especially in IgAN cell lines. This observation indicates that overexpression of GalNAc-T14 observed in IgAN cell lines could contribute to Gal deficiency of IgA1 molecules in IgAN.

Conclusions: GalNAc-T14 is the only overexpressed GalNAc-T in IgAN cell lines. As knock-down of its expression resulted in decrease of Gal deficiency on IgA1, we conclude that disregulation of GalNAc-T14 expression represents a new mechanism contributing to etiology of IgAN.

Enalapril Treatment in Early Life Causes Lifelong Progressive Renal Injury in the Kidneys of Adult Male Rats Hyung Eun Yim, Kee Hwan Yoo, In Sun Bae, Young Sook Hong. *Department of Pediatrics, Korea University Medical Center, Seoul, Republic of Korea.*

Background: Interruption of the renin angiotensin system (RAS) during the period of ongoing nephrogenesis produces renal histological abnormalities and functional defect. We have previously shown that the RAS block even after the completion of nephrogenesis induces renal injury in young male rats. However, at present there is a lack of studies as to long-term renal effects exposed to blockade of the RAS after the achievement of nephrogenesis. The aim of the present study was therefore to determine the longstanding renal consequences of early postnatal RAS inhibition after the completion of nephrogenesis in adult male rats.

Methods: Newborn Sprague-Dawley male pups were given enalapril (30 mg/kg/day) or vehicle by orogastric tube between the ages of 2 and 4 weeks postnatally. Body weight, blood pressure (BP) and renal alterations were determined at 6 and 12 months, respectively.

Results: Pups in the neonatally enalapril-treated rats weighed less than rats in the control group between 16 days and 5 weeks of age and more than those between 14 weeks and 12 months ($P < 0.05$). Mean BP levels in the enalapril-treated rats were not different from the controls at 6 months; however, they were higher than the LC group at 12 months ($P < 0.05$). At 12 months, apoptotic renal cortical cells were increased in the enalapril-treated rats, compared to the controls ($P < 0.05$). The enalapril-treated group showed increased glomerulosclerosis and tubulointerstitial fibrosis at 6 and 12 months ($P < 0.05$). In the immunoblotting and immunohistochemistry, neonatally enalapril-treated ratsshowed increased intra-renal expression of matrix metalloproteinase (MMP)-9 and decreased angiotensin II receptor type (AT) 1 at 6 months ($P < 0.05$). At 12 months, the expressions of tissue inhibitor of MMP-1 and plasminogen activator inhibitor-1 were increased and AT2 expression was decreased in the kidneys of neonatally enalapril-treated rats ($P < 0.05$).

Conclusions: Our findings suggest that angiotensin II inhibition even after the completion of nephrogenesis can induce deferred systemic hypertension and progressive renal damage in adult male rats.

FR-PO653

Early Treatment with Enalapril Is Not Renoprotective in 'Programmed' Obese 3 Month-Old Rats Hyung Eun Yim, Kee Hwan Yoo, In Sun Bae, Young Sook Hong. *Department of Pediatrics, Korea University Medical Center, Seoul, Republic of Korea.*

Background: Countering the renin angiotensin system (RAS) has been reported to be beneficial in obese patients with chronic kidney disease.We have shown that early postnatal overnutrition leads to the development of renal injury in adult rats. This study was aimed to investigate that the RAS block in early life can ameliorate renal injury induced by early postnatal overnutrition.

Methods: Three or 10 male pups per mother were assigned to either the small litter (Obese group) or normal litter (Lean group) rats during the first 21 days of life. With this, all pups were randomized into 4 groups, and treated with enalapril (Obese enalapril, OE; Lean enalapril, LE) or vehicle (Obese control, OC; Lean control, LC) between the ages of 2 and 4 weeks postnatally. Body weight, blood pressure (BP) and renal alterations were determined at 3 months.

Results: Pups in the OC group weighed more than rats in the LC group between 7 days and 3 months of age ($P < 0.05$). Enalapril decreased body weights in the Lean group at weaning (22 days) and at 3 months ($P < 0.05$); however, body weights in the OE group were not different from the OC group at 3 months. Mean BP levels in the LE, OC and OE groups were higher than the LC group at 3 months ($P < 0.05$) while there was no difference between the OC and OE groups. At 3 months, the LE group showed increased renal cell apoptosis, glomerulosclerosis, and tubulointerstitial fibrosis and decreased renal cell proliferation, compared to the LC group ($P < 0.05$). The index scores of glomerulosclerosis and tubulointerstitial fibrosis were higher in the OE group than the OC group ($P < 0.05$). In immunoblotting and immunohistochemistry, the LE group showed increased intra-renal angiotensin II receptor type (AT) 2 and matrix metalloproteinase (MMP)-9 and decreased renin and tissue inhibitor of MMP (TIMP)-1 expression, compared to the LC group ($P < 0.05$). The OE group also demonstrated increased intra-renal AT2 and decreased AT1 and TIMP-1 expression, compared to the OC group (< 0.05).

Conclusions: The RAS block in early life can induce the detrimental renal impact and may be not renoprotective in 'programmed' obese adult rats.

Lack of Renoprotective Effect of Angiotensin 1-7 and Angiotensin 2-10 in a Rat Model of Hypertension and Focal Segmental Glomerulosclerosis

Juan Carlos Q. Velez,[1] Megan Hicks,[1] Sally Self,[2] Wayne R. Fitzgibbon.[1] *[1]Dept. of Medicine, Division of Nephrology, Medical University of South Carolina, Charleston, SC; [2]Dept. of Pathology, Medical University of South Carolina, Charleston, SC.*

Background: Angiotensin (Ang) II mediates progressive glomerulosclerosis (GS). We previously showed that Ang I is largely converted to Ang 1-7 and Ang 2-10 by glomeruli, and observed that Ang 2-10 binds to the AT_2 receptor (R) with more affinity than to the AT_1 R. Ang 1-7 may be antifibrotic. We hypothesized that Ang 1-7 and Ang 2-10 could be renoprotective in a model of focal segmental GS, the Fawn-Hooded Hypertensive (FHH) rats.

Methods: Rats (n=9/group) underwent uninephrectomy at week (wk) 6 to accelerate GS and implantation of osmotic minipumps at wk 18 for intravenous (IV) delivery of saline (S), Ang 1-7 or Ang 2-10 (100 or 400 ng/kg/min) until wk 30. Two other groups received oral captopril (CAP, 100 mg/kg/d) or losartan (LOS, 20 mg/kg/d).

Results: S-treated rats were hypertensive at wks 24 (179 ± 2 mmHg) and 30 (185 ± 3 mmHg). CAP and LOS decreased systolic blood pressure (SBP) (156 ± 7 and 155 ± 5 mmHg at wk 24, 145 ± 5 and 146 ± 5 mmHg at wk 30; for CAP and LOS, respectively; p<0.0001 vs. S). In contrast, low-dose Ang 1-7 had no effect on SBP, low-dose Ang 2-10 raised it by wk 30 (194 ± 3 mmHg; p<0.001 vs. S), and high-dose Ang 1-7 and Ang 2-10 raised SBP (188 ± 3 and 187 ± 3 mmHg at wk 24, 197 ± 3 and 196 ± 4 mmHg at wk 30; for high-dose Ang 1-7 and Ang 2-10, respectively; p<0.001 vs. S). Proteinuria in S-treated rats was 2 (1–5), 537 (184–862), 978 (433–2839) and 738 (622–2032) mg/d, at wk 6, 18, 24 and 30, respectively. The course of proteinuria between wks 18 and 24 was significantly regressed by CAP (+ 342 ± 289 vs. - 225 ± 453 mg/d, S vs. CAP, respectively; p<0.01), but was otherwise not modified by any of the other treatments. CAP significantly reduced global GS (34 ± 9 vs. 9 ± 4%, p=0.03) and tubular injury score (2.6 ± 0.4 vs. 1.3 ± 0.4, p=0.04) compared to S, whereas structural damage was not halted by Ang 1-7 or Ang 2-10 treatment.

Conclusions: In summary, chronic IV administration of Ang 1-7 and Ang 2-10 failed to ameliorate kidney damage in uninephrectomized FHH rats.

Inhibition of Renin Activity Slows down the Progression of HIV-Associated Nephropathy (HIVAN)

Partab Rai, Andrei Plagov, Dileep Kumar, Ashwani Malhotra, Guohua Ding, Pravin C. Singhal. *Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY.*

Background: Renin-angiotensin system has been reported to play an important role in the development of HIVAN. In the present study, we evaluated the effect of aliskiren, an inhibitor of renin activity (aliskiren) on the progression of renal lesions in two different mouse models (Vpr and Tg26) of HIV-associated nephropathy (HIVAN).

Methods: In protocol A, Vpr mice were fed either water (C-VprA) or doxycycline (D-VprA) in their drinking water for six weeks. In protocols B and C, Vpr mice received either saline (C-VprB/C), Doxy (D-VprB/C) + normal saline, or Doxy + aliskiren (AD-VprB/C) for 6 weeks (protocol B) or 12 weeks (protocol C). In protocols D and E, Vpr mice were fed Doxy for 6 weeks followed by kidney biopsy. Subsequently, half of the mice were administered either saline (D-VprD/D) or aliskiren e(AD-VprD/D) for 4 weeks (protocol D) or 8 (protocol E) weeks. In protocol F, Tg26 mice were administered vehicle, aliskiren, or hydralazine for 4 weeks. Subsequently, renal biomarkers were determined and severity of renal lesions were scored.

Results: All D-VprA showed renal lesions in the form of focal segmental glomerular sclerosis and dilatation of tubules. In protocol B and C, aliskiren diminished both progression of renal lesions and proteinuria. In protocol C, aliskiren also diminished (P<0.01) rise in BUN. In all groups, Doxy-treated mice displayed increased serum Ang I levels (the product of plasma renin activity, PRA); on the other hand, all aliskiren-treated mice displayed diminished serum Ang I levels. Renal tissues of D-VprC displayed increased Ang II content; however, aliskiren attenuated renal tissue Ang II production in AD-VprC. In protocol D, AD-VprD showed 24% increase in number of sclerosed glomeruli when compared to 139% increase in sclerosed glomeruli in D-VprD (P<0.01) from their baseline. The attenuating effect of aliskiren on the progression of renal lesions continued in AD-VprE. Aliskiren also diminished blood pressure, proteinuria and progression of renal lesions in Tg26 mice.

Conclusions: These findings indicate that renin activity inhibition retards the progression of HIVAN.

Functional Role of Aquaporin-1 in Renin Angiotensin System-Induced Hypertension and Kidney Injury

Shiao-ying Chang,[1] Chao-Sheng Lo,[1] Xin-ping Zhao,[1] Yessoufou Aliou,[1] Isabelle Chenier,[1] Julie R. Ingelfinger,[2] Shao-Ling Zhang.[1] *[1]Research Center, CRCHUM, Montreal, QC, Canada; [2]Pediatr Nephrol Unit, Mass. Gen. Hosp, Boston, MA.*

Background: Aquaporin-1 (AQP1), a major water channel in proximal tubules is responsible for reabsorbing 80% of glomerular filtrate fluid. Angiotensin II (Ang II) increases AQP1 gene expression in cultured rat immortalized renal proximal tubular cells (IRPTCs) and in rat kidneys *in vivo*. Little is known about AQP1 regulation in animal models of renin angiotensin system (RAS) -induced hypertension and kidney injury. We reported that RAS blockade prevents intrarenal RAS activation, hypertension, and nephropathy progression in angiotensinogen (Agt)-transgenic (Tg) mice specifically overexpressing Agt in their RPTCs. The present studies explored the role of AQP1 in RAS-induced hypertension and kidney injury, focusing on underlying molecular mechanisms.

Methods: Male Agt-Tg mice (and non-Tg littermates served as control) ± RAS blockade (losartan and perindopril treatment from 13 to 20 weeks). Systolic blood pressure (SBP), renal reactive oxygen species (ROS) generation, glomerular filtration rate (GFR), urinary albumin/creatinine ratio and Ang II levels, as well as renal morphology were measured. Renal proximal tubular Agt, AQP1 and HO-1 (heme oxygenase-1) gene expression was assessed by real time-qPCR, western blot and immunohistochemistry.

Results: Untreated, Agt-Tg mice developed hypertension, renal hypertrophy and tubulointerstitial fibrosis with upregulation of AQP1 and downregulation of HO-1expression in their RPTCs as compared with non-Tg littermates. RAS blockade prevented these abnormalities. Furthermore, *in vitro* studies showed that AQP1 gene expression is significantly upregulated in an Agt-RPTCs stable clone (stably transfected with rat Agt cDNA), and this augmented AQP1 gene expression was normalized by losartan via the activation of HO-1 gene.

Conclusions: Our data suggest that the counter balance of AQP1 and HO-1 gene expression plays a key role in RAS -induced hypertension and kidney injury, both *in vivo* and *in vitro.*

Angiotensin II Blockade and Calorie Restriction Prevent Progression by Different but Complementary Mechanisms

Ryuzoh Nishizono,[1] Madhusudan M. Venkatareddy,[1] Mahboob A. Chowdhury,[1] Su Qing Wang,[1] Akihiro Fukuda,[3] Larysa T. Wickman,[2] Yan Yang,[2] Roger C. Wiggins.[1] *[1]Internal Medicine, University of Michigan; [2]Pediatrics and Communicable Diseases, University of Michigan, Ann Arbor, MI; [3]Internal Medicine, University of Miyazaki, Miyazaki, Japan.*

Background: Podocyte depletion drives progression in glomerular diseases. Angiotensin II drives progression through promoting podocyte loss from destabilized glomeruli (Fukuda et al, Kidney Int 2011). Progressive podocyte loss leading to progression and ESKD can also be triggered by growth-dependent glomerular enlargement, as demonstrated using the podocin promoter-driven AA4EBP1 transgenic rat model. In this model proteinuria, glomerulosclerosis and progression to ESKD is triggered by body growth alone and can be completely prevented by calorie restriction to prevent weight gain and glomerular enlargement (Fukuda, JASN, 2012, in press).

Methods: To compare mechanisms by which calorie restriction and angiotensin II blockade prevent progression we used the uninephrectomized podocin-AA4EBP1 transgenic rat model on an ad lib or 40% calorie restricted diet, with and without enalapril/losartan delivered in the drinking water. Morphometry was used to measure glomerular tuft volume, podocyte number per tuft, podocyte density and glomerulosclerosis.

Results: Both angiotensin II blockade on an ad lib diet and calorie restriction prevented progression (prevented proteinuria, reduction in podocyte density and glomerulosclerosis), but by different mechanisms. Calorie restriction maintained normal podocyte density by preventing glomerular tuft enlargement. In contrast angiotensin II blockade on an ad lib diet did not prevent glomerular tuft enlargement, but reduced the rate of podocyte loss so that podocyte number per tuft increased to maintain normal podocyte density.

Conclusions: Reduced podocyte density as the trigger and driver of podocyte depletion-dependent progression can be prevented by two different mechanisms (calorie restriction and angiotensin II blockade), which should be complementary in the clinic.

Aldosterone Induces Proteasome Aggregation in Distal Renal Tubules

M. Umar Cheema,[1] Ebbe Toftgaard Poulsen,[2] Jan J. Enghild,[3] Robert A. Fenton,[1] Jeppe Praetorius.[1] *[1]Department of Biomedicine, Health, Aarhus University, Aarhus C, Denmark; [2]Inano School, Aarhus University, Aarhus C, Denmark; [3]Department of Molecular Biology and Genetics, Aarhus University, Aarhus C, Denmark.*

Background: Aldosterone is the main mineralocorticoid and thereby responsible for body Na^+ conservation. Prolonged plasma aldosterone elevation induces gene transcription and protein synthesis. We hypothesized that in renal tubules, the aldosterone induced increase in protein synthesis and turnover would challenge the cellular protein degradation by proteasomes.

Methods: Male Wistar Rats (Taconic) were given 50µg/kg body wt· day^{-1} aldosterone or vehicle for 7 days through subcutaneous osmotic minipumps. Kidney samples were prepared for immunoblotting and immunohistochemistry. Electron microscopy was also used to resolve the structure of protein aggregates. The kidney homogenate was labelled with aggresome dye and sorted by using Fluorescence activated particle sorting. The resulting samples were vaccum dried and processed for mass spectrometry.

Results: The cellular accumulation of specific proteins and the development of aggresomes were compared in kidney samples from rats receiving 50 µg aldosterone/ kg body weight/ 24 hrs and vehicle in osmotic minipumps for 7 days by immunohistochemistry and electron microscopy. Aldosterone induced a 1.5-fold increase in proteasome 20s abundance in distal renal tubules with a concomitant increase in aggresome-like structures. An alternative antibody revealed a much stronger induction of the aggresome-like punctate labeling, with 80% co-localization with proteasome 20s labeling, but negligible

co-localization with endosomal and lysosomal markers. Fluorescence activated particle sorting and subsequent mass spectrometry identified several proteins in the aggresomes including rat keratins specific to simple epithelia. The accumulation of aggresomes was specific to the aldosterone sensitive renal tubules, especially the distal convoluted tubules.

Conclusions: We conclude that high physiological concentrations of a key hormone in the regulation of renal function challenges the protein degradation system to such a degree that certain proteins accumulate in aggresomes.

FR-PO659

Inhibition of Angiotensin II (AngII) Induced Increases in Glomerular Permeability by Scavengers of Reactive Oxygen Species (ROS), Inhibitors of Small GTPases and by Calcineurin Blockade Josefin Axelsson, Anna Rippe, Kristinn Sverrisson, Bengt Rippe. *Department of Nephrology, Lund University, Lund, Sweden.*

Background: AngII can induce acute increases in the permeability of the glomerular filtration barrier (GFB). After binding of AngII to its receptor (AT1R) there is Ca^{2+} influx into the cell, which activates signaling cascades, involving e.g. calcineurin, kinases, and, further downstream, small GTPases, such as Rac1 and RhoA. In the present study we sought to interact with elements of this signaling cascade in order to test new antiproteinuric agents during AngII activation.

Methods: In anaesthetized Wistar rats the left urether was cannulated for urine collection and blood access was achieved. Rats were infused with AngII (16 ng/kg/min) alone, or together with the ROS scavengers, 4-Hydroxy-TEMPO (TEMPOL) or dimethylthiourea (DMTU), or the RhoA-kinase inhibitor, Y-27632, the Rac-1 inhibitor, NSC23766, or the calcineurin inhibitor, tacrolimus (Prograf®). Polydisperse FITC-Ficoll-70/400 (mol.radius 13-80Å) and ^{51}Cr-EDTA were infused throughout the experiment. Plasma and urine samples were taken during baseline and at 5 and 15 min after the start of the infusions and analyzed by high performance size exclusion chromatography (HPSEC) for determination of glomerular sieving coefficients for $Ficoll_{13\text{-}80Å}$. GFR was analyzed from the plasma to urine clearance of ^{51}Cr-EDTA.

Results: AngII infusion into rats caused rapid, partly reversible increases in glomerular permeability to large Ficoll molecules ($Ficoll_{50\text{-}80Å}$), peaking at 5-15 min. The increases in glomerular permeability were totally abrogated by TEMPOL and partly by DMTU. RhoA and Rac-1 inhibition were also effective in reducing the permeability actions of AngII, as was tacrolimus (max effect at 15 min).

Conclusions: AngII markedly increased the permeability of the GFB. This effect cannot not only be blocked by AngII receptor inhibition, but also by interactions with several elements of the AT1R downstream signaling cascade. Scavengers of ROS are also able to reduce the permeability response to AngII, pointing to new avenues for the treatment of proteinuria in states of AngII activation.

Epigenetic Role of WHSC1L1 in Nephrin Gene Expression Yugo Ito, Zentaro Kiuchi, Yukino Nishibori, Kunimasa Yan. *Pediatrics, Kyorin University, Tokyo, Japan.*

Background: The epigenetic regulation of nephrin gene expression is poorly understood. Unbiased transcriptome profiling identified WHSC1L1 (Wolf-Hirschhorn syndrome candidate 1-like 1) to be one of the highly glomerulus-specific transcripts (EMBO J, 25:1160, 2006). WHSC1L1 is a histone methyltransferase known to be involved in epigenetic control in cancers. Thus, the present study aimed to investigate whether WHSC1L1 plays a regulatory role in nephrin gene expression.

Methods: HEK-293 cell line stably expressing human full-length WHSC1L1 (WHSC1L1-293) and anti-human WHSC1L1 antibody were generated. The localization and the expression pattern of protein and mRNA of WHSC1L1 in the adult and fetal mouse kidney were determined by immunohistochemistry, western blot study and RT-PCR. Identification of methylated lysine on histone H3 interacting with WHSC1L1 was studied by siRNA experiment with WHSC1L1 using wild-293 cells. The interaction of WHSC1L1 with nephrin promoter was studied by the chromatin immunoprecipitation assay using anti-WHSC1L1 antibody in WHSC1L1-293 cells. Finally, the expression of nephrin and WT1 mRNA in the samples from wild-293 and WHSC1L1-293 cells was compared by RT-PCR.

Results: WHSC1L1 of the kidney consisted of 2 isoforms: long-form 200-kDa and short-form 100-kDa proteins. Glomerulus expressed both forms of WHSC1L1 whereas tubulus expressed only short-form. The glomerular WHSC1L1 in the adult kidney predominantly located at the podocyte nucleus, which was also apparent at the pre-capillary stage. Inhibition of WHSC1L1 gene expression in wild-293 cells revealed the exclusive reduction of methylated histone H3K36. Nephrin promoter was precipitated by chromatin-WHSC1L1 complex. Finally the expression of nephrin mRNA was accelerated by the WHSC1L1 induction.

Conclusions: WHSC1L1 is a novel podocyte molecule that up-regulates nephrin by epigenetic regulation.

The Lipid-Modifying Enzyme PON2 as a New Slit Diaphragm Protein Henning Hagmann,[1] Dontscho Kerjaschki,[2] Bernhard Schermer,[1] Thomas Benzing,[1] Paul T. Brinkkoetter.[1] *[1]Nephrology, University Hospital Cologne, Cologne, Germany; [2]Clinical Pathology, University of Vienna, Vienna, Austria.*

Background: Signalling at the mammalian slit diaphragm (SD) via the non-selective cation channel TRPC6 plays an important role in podocyte disease. It has been shown that TRPC6 protein expression as well as TRPC6 channel activity are increased in glomerular diseases such as focal segmental glomerulosclerosis, minimal change disease and membranous nephropathy.

Previous studies suggest that the activity of the TRPC6 channel depends largely on the lipid environment directly surrounding the channel protein. The mammalian Podocin-TRPC6 complex shows remarkable homology to the neuronal touch sensor complex of C.elegans where the Podocin homologue MEC-2 orchestrates the lipid environment necessary for proper touch sensation via the degenerin cation channel MEC-4/-10. In addition the lipid modifying enzyme MEC-6 interacts with and enhances the channel activity of MEC-4/-10.

Results: Here, we identify the mammalian homologue of MEC-6, the paraoxonase family protein PON2, as a novel slit diaphragm protein. PON2 not only associates with cholesterol-rich detergent resistant membrane domains but also co-precipitates directly with SD-proteins in pull-down experiments. In addition, we provide first-time evidence that PON2 is an integral transmembrane protein that localizes to the plasma membrane with its enzymatically active domain facing extracellular.

To understand the implication of PON2 on cellular lipid metabolism we generated a stable PON2-deficient mouse podocyte cell line by lentiviral gene transfer. Functional studies on cellular lipid-profiles revealed that total cholesterol levels are increased whereas DAG levels appeared to be decreased in PON2-deficient cells.

Conclusions: In conclusion we identified PON2 as a novel transmembrane protein at the slit-diaphragm. It not only interacts directly with known SD proteins but also modifies the lipid surrounding at the plasma membrane. It could be easily envisioned that PON2 represents an important regulator of TRPC6 channel activity similar to its homologue MEC-6 in the nematode C.elegans.

Shp2 a Non-Receptor Tyrosine Phosphatase Regulates Nephrin Phosphorylation and Podocyte Mobility Rakesh Verma, Madhusudan M. Venkatareddy, Puneet Garg. *Internal Medicine/ Nephrology, University of Michigan, Ann Arbor, MI.*

Background: Recent studies suggest that podocyte injury or foot process effacement is a form of podocyte mobility, a result of increased lamellipodia formation. Nephrin's ability to regulate podocyte actin dynamics, lamellipodia formation and focal adhesion dynamics in a phosphorylation dependent manner suggests its role in foot process mobility or effacement. Furthermore, increase in Nephrin tyrosine phosphorylation has been observed following podocyte injury and during podocyte development. Src kinase Fyn has been shown to be responsible for Nephrin phosphorylation. Though the consequences of Nephrin phosphorylation are better understood, the upstream molecular events responsible for Src kinase activation and Nephrin phosphorylation are not known.

Methods: We used biochemical and cell biology studies to demonstrate association between Nephrin and Shp2. Mice with podocyte specific deletion of shp2 were generated by breeding Shp2 floxed mice with Podocin-Cre mice.

Results: In a biased screen we found association between purified recombinant Nephrin and non-receptor phosphatase Shp2. Shp2 has been shown to dephosphorylate a regulatory tyrosine (Y416) on Src kinases, resulting in increased kinase activity. Using the CD16 clustering approach we observed recruitment of shp2 to CD16-Nephrin clusters at the membrane. We observed increase in Nephrin phosphorylation in the presence of shp2 in transfected cells. As anticipated, immunostaining of newborn mouse kidneys as well as kidneys perfused with protamine sulfate showed increased Shp2 activity. Furthermore, mouse kidneys perfused with Shp2 small molecule inhibitor prior to protamine sulfate abrogated both Nephrin phosphorylation and foot process spreading. Similarly, mice with podocyte specific deletion of Shp2 are resistant to foot process spreading following injury.

Conclusions: Our results suggest that, Nephrin phosphorylation is necessary for foot process spreading observed in glomerular diseases that present with proteinuria. Furthermore, inhibition of signaling events that increase podocyte mobility or lamellipodia formation prevent podocyte foot process spreading following injury.

The Novel Nephrotic Syndrome-Causing Gene Products, ARHGDIA and KANK2 Interact with and Regulate Rho Family Small GTPases in Podocytes Heon Yung Gee,[1] Shazia Ashraf,[1] Pawaree Saisawat,[1] Toby W. Hurd,[1] Virginia Vega-Warner,[1] Humphrey Fang,[1] Lutz T. Weber,[2] Julia Hoefele,[3] Bodo B. Beck,[4] Corinne Antignac,[5] Friedhelm Hildebrandt.[1,6] *[1]Departments of Pediatrics and of Communicable Diseases, University of Michigan, Ann Arbor, MI; [2]Pediatric Nephrology, Ludwig-Maximilian's University, Munich, Germany; [3]Center for Human Genetics and Laboratory Medicine Dr. Klein and Dr. Rost, Martinsried, Germany; [4]Institute of Human Genetics, Institute of Human Genetics, Cologne, Germany; [5]Inserm U983, Necker Hospital, Paris, France; [6]Howard Hughes Medical Institute.*

Background: Nephrotic syndrome (NS) is a heterogeneous group of disorders characterized by gross proteinuria with hypoalbuminemia and edema. We performed homozygosity mapping (HM) and whole exome resequencing (WER) in 63 sibling cases of childhood onset NS from 28 different families. This resulted in the identification of ARHGDIA and KANK2 as novel recessive single-gene causes of NS.

Methods: The function of ARHGDIA and KANK2, and their relation to Rho family GTPases, were examined in podocytes and rat kidney tissues using cell biological and molecular approaches.

Results: We found two ARHGDIA mutations in 2 patients with steroid-resistant NS, a nonsense (p.R120X) and a missense (p.G173V) mutation. We demonstrated by co-immunoprecipitation that ARHGDIA, KANK2, and Rho family GTPases physically interacted in cultured human podocytes and rat glomeruli, which was also confirmed by GST pulldown assay. Interestingly, both mutations in ARHGDIA abrogated interaction with RHOA, RAC1 and CDC42. In addition, the mutations increased the active GTP-bound RAC1 and CDC42 which result in a more migratory phenotype of podocytes. We found a homozygous missense mutation in KANK2 (p.S181G) in two siblings with steroid-sensitive NS. This missense mutation enhances its interaction with ARHGDIA and Rho GTPases and decreased the active states of RHOA, RAC1 and CDC42.

Conclusions: By our combined gene strategy we found two novel NS-causing genes ARHGDIA and KANK2, which interact within a protein complex of glomerular podocytes. Our data suggest that imbalances between RHOA and RAC1/CDC42 signaling in podocytes can cause NS.

Like Crk1/2, Podocyte-Specific CrkL Deletion Prevents Foot Process Spreading Following Mouse Podocyte Injury Britta George,[1,2] Abdul A. Soofi,[3] Jidong Zhang,[1] Rakesh Verma,[3] Lawrence B. Holzman.[1] *[1]Renal-Electrolyte and Hypertension, University of Pennsylvania, Philadelphia, PA; [2]Renal, University of Münster, Münster, Germany; [3]Renal, University of Michigan, Ann Arbor, MI.*

Background: Activation of Nephrin induces actin cytoskeletal remodeling resulting in lamellipodia formation in podocyte culture in a PI-3 kinase, FAK, p130Cas, and Crk1/2-dependent fashion that is distinct from the previously described nephrin-Nck1/2 pathway necessary for assembly and polymerization of actin filaments (J Clin Invest. 2012;122(2):674-92). In mice, podocyte-specific deletion of Crk1/2 prevented foot process effacement in one model of podocyte injury and attenuated foot process effacement and associated proteinuria in a second model. These observations suggested that cellular mechanisms governing lamellipodial protrusion in culture are similar to those used in vivo during foot process effacement. Because Crk1/2 null mice were normal at birth and survived to 20 months without developing glomerulopathy, we hypothesized that the Crk1/2 paralog, CrkL, functionally complements Crk1/2 in a podocyte-specific context.

Methods: Podocyte-specific CrkL null mice or podocyte-specific Crk1/2;CrkL double knockout mice were derived and characterized by light microscopy, scanning and transmission electron microscopy, and by examining urine albumin/creatinine ratio over time.

Results: Podocyte-specific CrkL null mice had a phenotype identical to that observed in Crk1/2 null mice: CrkL null mice developed and aged normally but were protected from protamine sulfate-induced foot process effacement. Further, simultaneous podocyte-specific deletion of Crk1/2 and CrkL resulted in proteinuria that was first detected by six weeks post-gestation and that was associated with unusual foot process elongation detected by scanning electron microscopy.

Conclusions: These results are consistent with the conclusions that Crk1/2 and CrkL functionally complement each other in the podocyte, and that Crk1/2 and CrkL are required for developing typical foot process architecture. These results also emphasize that Crk1/2 or CrkL or their associated protein complex might serve as therapeutic targets for glomerular disease.

The Calcium Channel TRPC6, Known to Cause FSGS when Chronically Hyperactive, Protects Podocytes from Acute Complement-Mediated Injury Andreas D. Kistler,[1] Jeffrey W. Pippin,[2] Geetika Singh,[3] Katherina Walz,[1] Amit K. Dinda,[3] Christian Faul,[1] Stuart J. Shankland,[2] Jochen Reiser.[1] *[1]University of Miami; [2]University of Washington, Seattle, WA; [3]All India Institute of Medicine, New Delhi, India.*

Background: Gain-of-function mutations in the calcium channel TRPC6 lead to autosomal dominant FSGS and podocyte expression of normal TRPC6 is increased in acquired human glomerular diseases, particularly in membranous nephropathy (MN). We therefore speculated that overexpression of TRPC6 in cultured podocytes may lead to loss of actin stress fibers through calcineurin-mediated dephosphorylation of synaptopodin and subsequent cleavage by cathepsin L.

Methods: We used standard methods, including podocyte culture, lentiviral gene transfer, Ca-imaging and cell surface biotinylation.

Results: Overexpression of TRPC6 in differentiated podocytes did not affect synaptopodin levels or actin stress fibers despite correct membrane localization and activity of the channel. Unexpectedly, overexpression of TRPC6 protected podocytes from complement-induced injury, an in vitro model of MN. In contrast, overexpression of dominant-negative TRPC6, knock down of TRPC6 and the administration of a TRPC antagonist increased podocyte sensitivity to complement. This effect was mediated by CaMKII: complement attack activated CaMKII in podocytes and the degree of activation correlated with TRPC6 levels. Pretreatment of podocytes with a CaMKII inhibitor phenocopied the effect of TRPC6 inhibition. Human MN biopsy samples, where induced TRPC6 expression has been previously shown, displayed increased activity of CaMKII. In the nephrotoxic serum (NTS) nephritis model, where complement contributes to glomerular injury, podocyte-specific TRPC6 transgenic mice showed stronger CaMKII activation, reduced podocyte FP effacement and reduced levels of proteinuria. In contrast, TRPC6 knock out mice exhibited reduced CaMKII activation and higher levels of proteinuria after NTS injection compared to WT littermates.

Conclusions: These data suggest a dual role of TRPC6 in podocytes: whereas chronic hyperactivity leads to FSGS, acute activation protects from complement-mediated damage in the short term.

Matrix Metalloproteinase-7 Promotes Podocyte Injury and Proteinuria by Proteolytic Shedding of Nephrin Ying Li, Dong Zhou, Youhua Liu. *Department of Pathology, University of Pittsburgh, Pittsburgh, PA.*

Background: Recent studies implicate Wnt/β-catenin signaling in the pathogenesis of podocyte dysfunction and proteinuria. However, the underlying mechanism remains poorly understood. As a transcriptional target of the Wnt/β-catenin signaling, matrix metalloproteinase-7 (MMP-7) is demonstrated as a surrogate biomarker for Wnt/β-catenin signaling in the kidney. Here, we tested the hypothesis that MMP-7 may mediate the pathogenic action of Wnt/β-catenin in the development and progression of podocyte injury and proteinuria.

Methods: We assessed the potential role of MMP-7 in the proteolytic shedding of slit diaphragm proteins. Using MMP-7 null mice, we investigated its effect on podocyte dysfunction and proteinuria after injury in vivo.

Results: In podocytes, MMP-7 expression was transcriptionally controlled by Wnt/β-catenin signaling. In ex vivo glomerular culture system, MMP-7 induced nephrin degradation in a time- and dose-dependent manner. Furthermore, this MMP-7–mediated nephrin cleavage was prevented by MMP inhibitor II. MMP-7 treatment leaded to flattening and fusion of the podocyte foot processes and increased glomerular permeability to albumin in ex vivo glomerular culture. The proteolytic shedding of nephrin mediated by MMP-7 was also confirmed in vitro using recombinant nephrin protein. Interestingly, onlyMMP-7, but not MMP-2 or MMP-9, mediated cleavage of nephrin. To delineate the role of MMP-7 in vivo in causing proteinuria, we utilized genetic MMP-7 knockout mice. Comparing with wild-type controls, MMP-7 null mice were protected from developing albuminuria after adriamycin injection. Conversely, intravenous injection of recombinant MMP-7 protein or ectopic expression exogenous MMP-7 plasmid in vivo caused podocyte dysfunction and de novo albuminuria in normal healthy mice. Inhibition of Wnt/β-catenin by Paricalcitol, a synthetic vitamin D analogue, repressed MMP-7 expression and prevented proteinuria after adriamycin injection.

Conclusions: These results identify podocyte slit diaphragm protein nephrin as a novel substrate of MMP-7. Our data also suggest that MMP-7 plays a critical role in mediating Wnt/β-catenin-induced podocyte injury and proteinuria.

FR-PO667

Endothelium-Derived tPA Promotes Podocyte Injury and Proteinuria by Activating LRP-1/β1 Integrin Signaling Ying Li, Youhua Liu. *Department of Pathology, University of Pittsburgh, Pittsburgh, PA.*

Background: Endothelium and podocytes are essential, integral constituents of the glomerular filtration barrier. However, whether or how endothelial dysfunction/activation induces podocyte injury and proteinuria is elusive.

Methods: We studied this issue by investigating the role of endothelium-derived tissue-type plasminogen activator (tPA) in mediating podocyte injury and proteinuria.

Results: We showed that tPA was specifically upregulated in the glomerular endothelium in human biopsies of patients with proteinuric kidney diseases such as focal segmental glomerulosclerosis (FSGS) and diabetic nephropathy. tPA was also rapidly induced in mouse glomeruli in adriamycin (ADR) nephropathy, prior to the onset of proteinuria in this model. To delineate the role of tPA in proteinuria, we utilized genetic tPA knockout mice. Comparing with wild-type controls, tPA null mice were almost completely protected from developing albuminuria after ADR injection. Similarly, tPA ablation also preserved podocyte integrity, nephrin, podocin and WT1 expression in ADR nephropathy. Interestingly, LDL receptor-related protein 1 (LRP1), known as tPA functional receptor, was activated in glomerular podocytes in proteinuric nephropathies. In vitro, tPA induced tyrosine phosphorylation of LRP1 in cultured mouse podocytes, which triggered focal adhesion kinase (FAK) phosphorylation, ERK1/2 activation, p90RSK and GSK-3β phosphorylation, leading to Snail1 induction. In ex vivo glomerular culture system,tPA suppressed nephrin expression and increased glomerular permeability to albumin. Intravenous infusion of recombinant tPA protein caused podocyte dysfunction and de novo albuminuria in normal healthy mice. Conversely, podocyte-specific ablation of LRP1 in conditional knockout mice ameliorated ADR-mediated proteinuria and podocyte injury.

Conclusions: These results suggest that endothelium-derived tPA promotes podocyte injury and proteinuria by activating a novel signaling cascade of LRP-1/β1 integrin/GSK-3β/Snail1.

FR-PO668

NF-kB-Dependent Chemokine Production in Podocytes Contributes to Glomerular Damage and Prolonged Proteinuria

Sebastian Braehler,[1] Christina Ising,[1] Henning Hagmann,[1] Friedrich Thaiss,[2] Stuart J. Shankland,[3] Bernhard Schermer,[1] Thomas Benzing,[1] Paul T. Brinkkoetter.[1] *[1]Department II of Internal Medicine, University Hospital of Cologne, Cologne, Germany; [2]Division of Nephrology, University Hospital Hamburg-Eppendorf, Hamburg, Germany; [3]Division of Nephrology, University of Washington, Seattle, WA.*

Background: Inflammation is a major mechanism in the development of glomerular injury and is an important cause of progressive kidney disease. NF-kB controls the expression of pro-inflammatory signaling molecules such as chemokines. The role of this pathway in podocytes is poorly understood.

Results: Here, we disrupted NF-kB signaling in podocytes by specific knockout of the NF-kB essential modulator (NEMO). Podocyte-specific NEMO-deficient mice ($NEMO^{pko}$) were healthy and did not show proteinuria or morphological kidney changes. After induction of glomerulonephritis both $NEMO^{pko}$ and control mice developed severe proteinuria. However, $NEMO^{pko}$ mice showed a rapid recovery, with remission of proteinuria and restoration of podocyte morphology. Moreover, we observed a strongly activated endothelial cell layer at day 7 following NTN-injection in control mice which was absent in the NEMO-deficient mice. At day 7 of disease, expression of proinflammatory chemokines including MCP1, MCP3, RANTES was strongly reduced in glomeruli of $NEMO^{pko}$ mice. However, the altered chemokine expression did not result in differences in the amount of infiltrating macrophages, T-lymphocytes and granulocytes. In line with these findings, cell culture experiments in NEMO-knockdown mouse podocytes showed a reduced secretion of chemokines after stimulation with IL-1 and TNFa.

Conclusions: Collectively, we hypothesize that endothelial or mesangial cells are one of the primary targets of the podocyte-dependent pro-inflammatory chemokine secretion and that the proinflammatory activity of NF-kB in podocytes aggravates proteinuria in experimental glomerulonephritis in mice. Based on these data it can be speculated that immunosuppressive drugs may not only target professional immune cells but also podocytes directly to convey their beneficial effects in various types of glomerulonephritis.

FR-PO669

Complete Regression of Existing Podocyte Injury by Mineralocorticoid Receptor Blockade in Podocyte-Specific Arhgdia Knockout Mice

Miki Nagase,[1] Kohei Ueda,[1] Kenichi Ishizawa,[1] Nobuhiro Ayuzawa,[1] Shigetaka Yoshida,[1] Takayuki Shindo,[3] Takayuki Sakurai,[3] Taiji Matsusaka,[2] Masaomi Nangaku,[1] Toshiro Fujita.[1] *[1]University of Tokyo, Tokyo, Japan; [2]Tokai University, Kanagawa, Japan; [3]Shinshu University, Nagano, Japan.*

Background: We previously reported that systemic depletion of Arhgdia (also designated as RhoGDIα) causes podocyte damage, possibly via 'Arhgdia-Rac1-mineralocorticoid receptor (MR)' cascade. In the present study, we established podocyte-specific Arhgdia knockout mice ($Arhgdia^{pod-/-}$), and analyzed morphological and functional alterations of podocytes and their underlying mechanisms.

Methods: $Arhgdia^{pod-/-}$ were established by mating $Arhgdia^{flox/flox}$ with Nephrin-Cre mice. Primary culture of podocytes was performed by cultivation of glomeruli isolated using Dynabeads method.

Results: Arhgdia was predominantly expressed in glomerular podocytes and tubular cells in control mice. In $Arhgdia^{pod-/-}$ mice, Cre recombinase was highly and exclusively expressed in WT1-positive podocytes. Podocyte-specific deletion of Arhgdia was confirmed by immunostaining of Arhgdia in the kidney and reduced expression in primary cultured podocytes from $Arhgdia^{pod-/-}$ mice. $Arhgdia^{pod-/-}$ mice spontaneously developed massive albuminuria, podocyte injury, and FSGS. At 5 weeks of age, $Arhgdia^{pod-/-}$ mice already exhibited podocyte damage (albuminuria 6730 ± 1065 μg/d vs 26± 4 μg/d in control mice), when administration of MR blocker eplerenone was initiated. Albuminuria was gradually reduced, and after 8 weeks of treatment, podocyte injury was totally regressed with disappearance of albuminuria (30 ± 8 μg/d) and normalization of nephrin staining. In cultured podocytes, Arhgdia knockdown resulted in increased active Rac1. In addition, MR expression was enhanced in the glomeruli of $Arhgdia^{pod-/-}$ mice.

Conclusions: Our results suggest a role for the 'Arhgdia-Rac1-MR' cascade within podocytes in the pathogenesis of podocyte damage in $Arhgdia^{pod-/-}$ mice. Recently, Arhgdia and Rac1 regulator Arhgap24 were identified as causative genes for some patients with nephrotic syndrome and FSGS. Our experimental data, together with these clinical findings, would provide mechanistic insights into podocyte pathobiology.

Activation of Podocyte NMDA Receptors Leads to Generation of Reactive Oxygen Species, Mobilization of TRPC6 Channels, NFAT Activation, and Apoptotis

Stuart E. Dryer, Eunyoung Kim. *Biology and Biochemistry, University of Houston, Houston, TX.*

Background: NMDA receptors mediate several forms of synaptic plasticity. However, excessive activation of neuronal NMDA receptors evokes neurodegeneration, owing to calcium overload and oxidative stress. Podocytes express an atypical population of NMDA receptors that are preferentially activated by metabolites such as L-homocysteic acid. Here we analyze if similar effects occur in podocytes.

Methods: Experiments were performed on the MPC-5 mouse podocyte cell line, and in 21-week *db/db* mice and lean litter-mate controls. ROS generation was assayed using fluorometric assays. TRPC6 mobilization was assayed by cell-surface biotinylation and whole-cell recordings. Localization of NFAT was analyzed by confocal microscopy and cell fractionation/immunoblot. Expression of podocyte markers and NMDA receptors was by confocal microscopy. Apoptosis was assessed by TUNEL and caspases assays.

Results: A 24-hr application of NMDA to cultured podocytes increased production of ROS. NMDA-evoked ROS generation drove an increase in surface expression of TRPC6 channels, which was blocked by the NMDA antagonist MK-801 and by MnTBAP, a scavenger of ROS. Increases in TRPC6-like cationic currents were also observed in NMDA-treated podocytes. NMDA increased nuclear localization of NFAT, which was blocked by MK-801, MnTBAP, cyclosporine, and by the TRPC inhibitor SKF-96365. NMDA treatment for 24 hr reduced expression of nephrin and podocin but there was no loss of cells. With 72 hr NMDA exposure we observed cell death, increased expression of caspases and nuclear fragmentation. In obese *db/db* mice, we observed markedly increased glomerular expression of NMDA receptor NR1 subunits compared to lean litter-mate controls.

Conclusions: Excessive activation of NMDA receptors may contribute to podocyte dysfunction and degeneration owing to oxidative stress and calcium overload, mediated in part through mobilization of TRPC6 channels and their associated pathways. Sustained increases in NMDA receptor activation could occur as a result of hyperhomocysteinemia, or in conditions such as type II diabetes in which expression of these receptors appears to be increased.

FR-PO671

Synergistic Effect of Mesangial Cells Induced CXCL1 and TGF-β1 in Promoting Podocyte Loss in IgA Nephropathy

Qingxian Zhang, Li Zhu, Sufang Shi, Lijun Liu, Jicheng Lv, Hong Zhang. *Renal Division, Department of Medicine, Peking University First Hospital.*

Background: Podocyte loss was reported to reflect disease severity and progression in IgA nephropathy (IgAN). But the mechanisms of podocyte loss are still unclear. Recent evidence showed that IgA1 complexes from IgAN patients could directly activate mesangial cells, and further induce podocyte injury through indirect mesangial cell-podocyte cross-talk. In the present study, we explored the mechanism of mesangial cells induced podocyte apoptosis and adhesion dysfunction in IgAN.

Methods: IgA1 complexes (cIgA1) were purified from serum of 28 IgAN patients and 20 health controls (HC). Cultured human mesangial cells were then treated with 100μg/ml cIgA1. Multiple cytokines produced by mesangial cells were detected using Human Cytokine Array and confirmed by ELISA. Then the diluted mesangial conditional medium or recombinant human (rh) cytokines up-regulated in mesangial cells (2ng/ml CXCL1 and/or 2ng/ml TGF-β1) were used to treat cultured human podocyte. Podocyte apoptosis was detected by TUNEL and adhesion capability was detected by counting the adhesive cells.

Results: cIgA1 from IgAN significantly up-regulated the expression of CXCL1 and TGF-β1 in mesangial cells compared with HC (CXCL1: 718.4±532.1pg/ml vs. 311.6±191.8pg/ml, P=0.002; TGF-β1: 1535.5±255.5pg/ml vs. 1304.9±363.8pg/ml, P=0.031). The podocyte over-expression of CXCR2 (the receptor of CXCL1) was induced by mesangial cell conditional medium from IgAN (IgAN-MsCM) and rhTGF-β1, but not rhCXCL1. Increased podocyte apoptosis (19.48%±1.9% vs 4.5%±1.7%, P<0.05) and reduced podocyte adhesion (5790±377 vs 9272±736, P=0.002) were induced by IgAN-MsCM, as well as rhCXCL1 together with rhTGF-β1. Moreover, both the effect of increased podocyte apoptosis and reduced podocyte adhesion recovered partially by the blocking antibody of CXCR2.

Conclusions: Our present study implied that the cIgA1 from IgAN patients could up-regulate the secretion of CXCL1 and TGF-β1 in mesangial cells; and then the synergistic effect of CXCL1 and TGF-β1 further induced the apoptosis and adhesion dysfunction in podocyte via CXCR2. It might be a potential mechanism of podocyte loss in IgA nephropathy.

FR-PO672

Protein 4.1O Is a Novel Linker between Nephrin and the Actin-Cytoskeleton and Protects from High Glucose Mediated Nephrin Endocytosis
Eva Koenigshausen,[1] Sinja Ohlsson,[1] Magdalena Woznowski,[1] Ivo Quack,[1] Marcus G. Pezzolesi,[2] Andrzej S. Krolewski,[2] Lars C. Rump,[1] Lorenz Sellin.[1] *[1]Nephrology, Heinrich Heine University, Duesseldorf, Germany; [2]Genetics, Joslin Diabetes Center, Boston, MA.*

Background: Microalbuminuria is an early marker for diabetic nephropathy. A GWAS for diabetic nephropathy revealed FRMD3 as a candidate gene in type 1 diabetics. FRMD3 encodes for 4.1O which belongs to the family of band 4.1 proteins. These proteins are adaptors of plasma membrane receptors to the actin cytoskeleton. In zebrafish, moe, the 4.1 orthologue is expressed in podocytes and is required for slit diaphragm formation. The function of 4.1O in human podocytes is unkown so far. Interaction of nephrin with β-arrestin2 preceeds nephrin endocytosis which is perceived to promote proteinuria.

Methods: RNA was isolated from human podocytes and subjected to rt-PCR for 4.1 family members. Cells expressed 4.1O, nephrin, podocin, Glepp1, Neph1, FAK and IQGAP1. After cell lysis coimmunoprecipitation was performed.

Results: Protein 4.1 family members 4.1O, 4.1G, 4.1B and 4.1N are expressed in human podocytes. 4.1O interacts with nephrin, podocin, Glepp1 but not with Neph1. 4.1O binding to nephrin maps to nephrin 1158-1190, whereas nephrin binds to the c-terminal domain of 4.1O. GLEPP1 interacts with 4.1O within its phosphatase domain. 4.1O binds to GLEPP1 by its FERM domain. 4.1O shows a strong interaction with FAK and IQGAP1. The FERM-domain of 4.1O is required for IQGAP1 binding. Nephrin endocytosis is ameliorated in the presence of 4.1O. 4.1O reduces the interaction of nephrin with β-arrestin2 in high glucose media while 4.1O does not influence the nephrin-β-arrestin2 interaction under low glucose condition.

Conclusions: Protein 4.1O is a candidate gene for diabetic nephropathy in type 1 diabetics. The deletion of its orthologue in zebrafish causes proteinuria. Due to the interaction with nephrin and actin 4.1O is a promising adaptor for slit diaphragm proteins connecting to the actin cytoskeleton. Its interaction with IQGAP1 and FAK may influences the migration of podocytes. We therefore postulate that 4.1O plays an important role in the development and progression of proteinuric kidney diseases.

FR-PO673

A Molecular Mechanism for Angiotensin II Induced Proteinuria
Eva Koenigshausen, Ulf Zierhut, Martin Rütze, Johannes Stegbauer, Magdalena Woznowski, Ivo Quack, Sebastian Alexander Potthoff, Lars C. Rump, Lorenz Sellin. *Nephrology, Heinrich Heine University, Duesseldorf, Germany.*

Background: Microalbuminuria is as an early marker for glomerular permeability in hypertensive patients. Inhibitors of the RAAS but not calcium channel blockers reduce albuminuria in these patients. Albuminuria results from a defect in the glomerular filter that is composed of endothelium, basal membrane and podocytes with slit diaphragms. Nephrin is a major component of the glomerular slit diaphragm which is endocytosed upon binding to the adaptor protein β-arrestin2.

Methods: Cells expressing the AT1-receptor (AT1R) or its mutant D125AR126L, nephrin and β-arrestin2 were stimulated with Angiotensin II (Ang2). Co-immunoprecipitation with subsequent westernblot analysis was performed. Cells were pretreated with the inhibitor before stimulation with Ang2. For siRNA experiments cells were transfected with Gaq siRNA. The effect of Ang2 on the β-arrestin2 binding was studied with two nephrin mutants. For the endocytosis assay, cells were stimulated with Ang2. Glomeruli were isolated from mice, lysed and β-arrestin2 was precipitated.

Results: Ang2 stimulation increases the interaction between nephrin and β-arrestin2. This Ang2 effect is dependent on the AT1R and is inhibited by AT1R blockers. The G-protein signalling is essential for the Ang2 effect, as the AT1R mutant D125AR126L abolishes all G-protein signalling and inhibits the Ang2 mediated increase of the nephrin β-arrestin2 interaction. Gaq siRNA as well as a phospholipase C (PLC) inhibitor block the Ang2 effect. The phosphorylation status of nephrin Y1217 is crucial for the Ang2 effect. Stimulation with Ang2 increases endocytosis of nephrin, which can be inhibited by AT1R- and PLC-blockers. In podocytes, nephrin endocytosis is enhanced after Ang2 treatment. The Ang2 effect on nephrin-β-arrestin2 binding can be reproduced in isolated glomeruli.

Conclusions: Ang2 weakens the integrity of the slit diaphragm thru increased nephrin endocytosis and is perceived to promote proteinuria. This previously unknown molecular effect of Ang2 could help to understand the molecular mechanisms of Ang2 induced proteinuria beyond hemodynamic effects.

FR-PO674

Targeted Deletion, but Not Systemic Inhibition of NF-kappa-B Essential Modulator Preserves Podocyte Morphology and Function *In Vivo* and *In Vitro*
Luigi Villa, Claudia R.C. van Roeyen, Gerald S. Braun, Bart Smeets, Veronika Kraaz, Peter Boor, Jürgen Floege, Tammo Ostendorf. *Division of Nephrology, University Clinic of Aachen, Aachen, Germany.*

Background: NF-kappa-B (NFkB) essential modulator (NEMO) is necessary for the activation of the NFkB signaling cascade, which plays a pivotal role in proteinuric glomerular disease. As systemic, unspecific inhibition of NFkB impairs both protective and damaging mechanisms we investigated NEMO-inhibition by selectively targeting podocytes *in vivo* and *in vitro*.

Methods: First, consequences of systemic inhibition of NFkB with pyrrolidine dithiocarbamate (PDTC) were studied in mice with nephrotoxic nephritis (NTN). Secondly, by crossbreeding mice expressing Cre-recombinase behind the podocin-promoter with floxed NEMO-mice, we generated podocyte specific NEMO -/- mice. Course and renal outcome of NTN at days 7 and 14 following disease induction were studied in these mice (n=14) and compared to wildtype littermates (n=16). Third, the consequences of NEMO-inhibition were studied in podocytes transfected with NEMO-siRNA.

Results: Systemic inhibition of the NFkB pathway with PDTC in NTN improved neither proteinuria, renal function nor podocyte morphology and function. In contrast, podocyte specific NEMO deletion significantly ameliorated proteinuria, albuminuria and creatinine clearance on d7, which was mirrored by improved glomerular morphology (reduced GBM thickness and podocyte effacement) on d14. Immunohistochemical analysis on d14 showed a significant preservation of glomerular podocin expression in NEMO -/- mice compared to controls. *In vitro*, podocytic NEMO-silencing increased the gene and protein expression of podocin and improved F-actin organisation in comparison to control.

Conclusions: In conclusion, targeted deletion of podocytic NEMO, but not systemic NF-kB inhibition, ameliorated podocyte damage and preserved expression of podocin, a key component of the slit diaphragm, and improved cell morphology and function *in vivo* and *in vitro*. Thereby NEMO represents a new modulator of glomerular damage.

FR-PO675

Podocyte-Specific Deletion of Prohibitin 2: A Novel Protein at the Slit Diaphragm: Leads to Progressive Proteinuria and Glomerular Sclerosis
Christina Ising, Bernhard Schermer, Thomas Benzing, Christine E. Kurschat, Paul T. Brinkkoetter. *Renal Division, Department II of Internal Medicine, University Hospital of Cologne, Cologne, Germany.*

Background: Prohibitins as well as Podocin belong to the PHB domain protein family. Loss or SNPs of Podocin are known to cause steroid-resistant forms of nephrotic syndrome. So far, very little is known about the function of other PHB-domain proteins in podocytes. Prohibitin 1 and Prohibitin 2 (Phb1/Phb2) are two closely related proteins that reside within the inner mitochondrial membrane where they are essential for membrane stability and cristae structure without affecting mitochondrial membrane potentials or activity of the respiratory chain.

Results: Here, we report on a podocyte-specific Phb2 knockout mouse. At postnatal day 14 Phb2 knockout mice showed no signs of glomerular dysfunction. However, starting postnatal day 18 the absence of Phb2 led to significant proteinuria and massive loss of body weight resulting in premature death. Kidney histology revealed proliferation of parietal epithelial cells with partial vacuolization and collapsing glomerular capillaries as well as highly disorganized mitochondrial cristae. Floxed Phb2;Cre negative mice served as control mice and showed normal kidney morphology and function. As a Phb2-knockout does not affect mitochondrial function we further addressed its subcellular localization in podocytes. Immunogold labeling localized Phb2 not only to mitochondria but also to the slit diaphragm. Coimmunoprecipitation experiments identified Phb2 as a novel interactor of Podocin. On a molecular level, the formation of multimeric Podocin complexes was found to be reduced in Phb2 knockdown cells as analyzed by sucrose gradient ultracentrifugation.

Conclusions: In conclusion, loss of Phb2 leads to massively impaired glomerular filtration in mice. Not only the localization of Phb2 to the slit diaphragm but also the interaction with Podocin point to an important extra-mitochondrial role of Phb2. As loss of Phb2 affects the formation of multimeric Podocin complexes we hypothesize a role of Phb2 as a stabilisator of the podocyte slit diaphragm complex. Phb2 – a novel player at the slit diaphragm?

FR-PO676

Podocyte-Derived VEGF Regulates Glomerular Tuft Development through the Suppression of PDGF Receptor β Phosphorylation
Masahiro Suyama,[1] Yoichi Miyazaki,[1] Yasunori Utsunomiya,[1] Tetsuya Kawamura,[1] Taiji Matsusaka,[2] Iekuni Ichikawa,[2] Tatsuo Hosoya.[1] *[1]The Jikei University School of Medicine, Japan; [2]Tokai University School of Medicine, Japan.*

Background: Glomerular podocyte-derived VEGF is indispensable for migration and proliferation of endothelial cells, as evidenced by the findings from podocyte-specific *Vegf* knockouts. In contrast, whereas podocyte-specific *Vegf* overexpression, that can mimic diabetic nephropathy or POEMS syndrome, led to the collapse of glomerular tufts and thickening of GBM, the details of phenotype have not been reported earlier. The aim of this study is to clarify further the function of VEGF on the glomerular cells.

Methods: Since the podocyte-specific *Vegf* transgenic mice die within a few weeks after birth, we have established dual transgenic mice (Tg), which can express *Vegf* only in podocytes under the control of "Tet-On system" (*Pod-rtTA; TetO-Vegf*). *Vegf* was induced only by administration of Doxycycline, as confirmed by the positivity of podocyte-*lacZ* driven by bi-directional *TetO* promoter.

Results: Macroscopic and microscopic inspections found that prominent cortical hemorrhages were present, and Bowman's capsules and tubules were occupied with red blood cells in Tg. In addition, endothelial cells increased in number with subendothelial spaces enlarged. Endothelial fenestration was impaired and PV-1 remained to be expressed in mature glomeruli. In contrast, mesangial cells lacked or decreased in number, resulting in the defect of intussusceptive splitting of the glomerular tufts. We analyzed the effect of VEGF on the PDGF-PDGF receptor β axis. In Tg, the expression of PDGF per se in endothelial cells were lower, when compared to the wild type. Moreover, in cultured mesangial cells, VEGF inhibits ligand-induced PDGF receptor β phosphorylation.

Conclusions: Taken together, podocyte-derived VEGF positively and negatively acts on endothelial and mesangial cells, respectively, thereby regulating the development of glomerular capillary tufts.

FR-PO677

A Novel Mouse Model of Podocyte Depletion Liming Wang,[1] Phillip Ruiz,[2] Robert F. Spurney.[1] *[1]Medicine, Duke University Medical Center, Durham, NC; [2]Pathology, University of Miami, Miami, FL.*

Background: A decrease in the number of glomerular podocytes is observed in both animal and human kidney diseases. Because podocytes are terminally differentiated cells with a limited capacity for replication, it has been suggested that podocytes which are lost may not be effectively replaced, causing instability of the glomerular tuft and glomerulosclerosis. As a result, some investigators contend that a reduction in glomerular podocytes may be a final common pathway causing progressive renal injury in glomerular diseases. The goal of these studies was to examine the capacity for glomerular repair after a podocyte depleting injury.

Methods: We created transgenic (TG) mice expressing the yeast enzyme cytosine deaminase specifically in glomerular podocytes. In these TG animals, the prodrug 5-flucytosine (5-FC) is converted to 5-fluorouracil (5-FU) and promotes podocyte death.

Results: Treatment with increasing dosages of 5-FC caused graded increases in proteinuria 1-2 weeks after treatment, which returned to control levels by the 10-week time point. Light microscopic examination revealed minimal pathology at the 2-week time point, but electron microscopy revealed found foot process effacement as well as focal areas of glomerular basement membrane duplication, and immunohistochemical studies detected podocyte apoptosis and a decrease in the number of Wilms tumor protein 1 (WT-1) positive cells. By the 10-week time point, however, the number of WT-1 positive cells was similar to controls and a few mice had developed focal areas of glomerulosclerosis. Consistent with the effects of 5-FC on podocyte number, expression of the podocyte proteins nephrin, podocin, synaptopodin and podocalyxin were altered in a similar temporal fashion.

Conclusions: The glomerulus has a significant capacity for repair after a podocyte depleting injury.

Differential Role of Notch1 and Noth2 in Podocytes Ae Seo Deok Park, Bhaskar Vadla, Katalin Susztak. *Renal Electrolyte and Hypertension Division, University of Pennsylvania, Perelman School of Medicine, Philadelphia, PA.*

Background: Our lab has recently demonstrated that ectopic activation of Notch signaling in podocytes resulted in proteinuria and glomerulosclerosis. There are four Notch isoforms: Notch1-4, however, the relative contribution of each of these isoforms and the cognate ligand are largely unknown. The aim of this study is to understand the mechanism of activation and the role of Notch1 and Notch2 in podocytes and their contribution to diabetic kidney disease development.

Methods: Animals with podocyte specific deletion of Notch1 or Notch2 were generated by crossing podocin-cre ($NPHS2^{Cre}$) driver mice with Notch1 or Notch2 flox/flox mice. Mice were injected streptozotocin intraperitoneally and were sacrificed at 20 weeks of age. The urinary albumin/creatinine ratio measurements were performed and histology was analyzed by PAS staining. For *in vitro* studies we used conditionally immortalized mouse podocyte cell lines.

Results: Mice with podocyte-specific deletion of Notch1 or Notch2 had no baseline phenotype, consistent with the findings that Notch1 and Notch2 are silenced in differentiated podocytes. Mice with podocyte specific deletion of Notch1 but not Notch2, had significantly reduced albuminuria, when we made them diabetic. We also observed improved renal histology in diabetic Notch1 null mice. We found significant decrease in podocyte number in wild-type diabetic animals, while the podocyte loss was much less in diabetic Notch1 knock-out animals. These data indicate that Notch1, but not Notch2, is critical for diabetes-induced podocyte damage. *In vitro* results indicate that upon TGF-beta treatment, there is an increase in endogenous Jagged1 expression in the podocytes, suggesting a cell-autonomous activation of Notch1 pathway (via Jagged1). The activation of Notch pathway is reflected in the expression of Notch downstream genes and an increase in Notch1 protein activity. Notch2 activity is relatively unchanged under these circumstances.

Conclusions: Thus we conclude that the Notch isoforms are differentially activated by the different Notch ligands. The Jagged1 induced Notch1 activation seems to play a critical role in podocyte damage.

mTORC1 Signaling in Focal Segmental Glomerulosclerosis Stefan Zschiedrich, Tobias B. Huber. *Renal Division - Department of Medicine, University Hospital Freiburg, Freiburg, Germany.*

Background: Mammalian target of rapamycin (mTOR) represents an evolutionary conserved protein kinase regulating a variety of essential cellular processes including growth, proliferation and survival. mTOR forms two distinct functional complexes, termed mTOR complex 1 (mTORC1) and mTOR complex 2 (mTORC2), whereby mTORC1 is sensitive to rapamycin and consists of multiple components including Raptor. We could recently decipher the role of mTOR complexes in podocyte homeostasis and diabetic nephropathy. However, the role of mTORC1 in the course of focal-segmental glomerulosclerosis (FSGS) remained elusive.

Methods: For a detailed analysis of mTOR function in the course of FSGS we combined gene expression analysis of human biopsies, transgenic mice targeting mTORC1 as well as pharmacological mTOR inhibitor studies of the adriamycin FSGS mouse model.

Results: Both mTORC1 target genes and mTOR mRNA itself were induced in human FSGS and the FSGS mouse model, indicating that induction of mTORC1 activity is a general characteristic of FSGS. Strikingly, curtailing mTORC1 signaling by genetically reducing mTORC1 copy number in podocytes prevented glomerulosclerosis and significantly ameliorated the progression of glomerular disease in FSGS, evidencing that mTORC1 is centrally involved in the progression of FSGS. However, podocyte-specific abrogating of mTORC1 activity resulted in massive proteinuria, stressing the importance of an initial mTORC1 response to glomerular disease. In addition, pharmacological inhibition of mTOR by rapamycin could ameliorate proteinuria and podocyte loss in the FSGS mouse model. Interestingly, these rapamycin effects were dose dependent with lower doses of rapamycin being most efficient in preventing glomerular disease progression.

Conclusions: Genetical or pharmacological reduction - but not abolition - of mTORC1 activity can prevent the consequences of mTOR hyper-activation in podocytes in FSGS mouse model, suggesting that a carefully titrated inhibition of mTORC1 may prevent podocyte injury and ameliorate the progression of human FSGS.

PodNet: A Protein-Protein Interaction Network of the Podocyte Gregor Warsow,[1,2,3] Nicole Endlich,[1] Eric Schordan,[1] Sandra Schordan,[1] Ravi Kumar Chilukoti,[4] Georg Homuth,[4] Marcus J. Moeller,[5] Georg Fuellen,[2] Karlhans Endlich.[1] *[1]Anatomy and Cell Biology, University Medicine Greifswald, Greifswald, Germany; [2]Biostatistics and Informatics in Medicine and Ageing Research, University of Rostock, Rostock, Germany; [3]Mathematics and Informatics, University of Greifswald, Greifswald, Germany; [4]Functional Genomics, University of Greifswald, Greifswald, Germany; [5]Division of Nephrology and Immunology, University Hospital of the Aachen University of Technology (RWTH), Aachen, Germany.*

Background: Interactions between proteins crucially determine cellular structure and function. Thus, differential analysis of the interactome in protein-protein interaction (PPI) networks may considerably help to elucidate cellular mechanisms and transitions. Though podocytes play a central role in kidney function and pathology, podocyte specific PPI networks do not exist.

Methods: We screened the literature for podocyte genes and PPIs, and built PodNet, a mouse podocyte PPI network in Cytoscape format. Using database PPIs, we expanded PodNet to XPodNet. Interactome analysis was done with the Cytoscape plugin ExprEssence, based on the law of mass action.

Results: Mapping podocyte transcriptomes on XPodNet, the most abundant PPIs were observed between slit diaphragm proteins, actin-associated proteins and the apical membrane/adapter proteins podocalyxin/Nherf2 (Podxl/Slc9a3r2) and claudin 5/ZO-1 (Cldn5/Tjp1). To demonstrate the performance of XPodNet in differential interactome analysis, we examined developmental differentiation and the effect of cell culture, using transcriptomes of podocytes in 10 different states. PPIs between slit diaphragm proteins are most significantly upregulated during podocyte development and most significantly downregulated in culture. On the other hand, our analysis revealed that PPIs, which are lost during podocyte differentiation, are not regained in culture, suggesting rather a loss than a reversal of differentiation for podocytes in culture.

Conclusions: In summary, we have developed PodNet as a valuable tool for differential interactome analysis in podocytes, identifying potential key regulated interactions in developing and cultured podocytes.

FR-PO681

A Combined Proteomic and Transcriptomic Ex Vivo Fingerprint of the Mouse Podocyte Florian Grahammer, Tobias B. Huber. *Renal Division Department of Medicine, University Hospital Freiburg, Freiburg, Germany.*

Background: Application of high-throughput methods to the endogenous podocyte have been hampered by low yields of current isolation procedures preventing reliable and reproducible determination of its transcriptome and proteome.

Methods: A *hNPHS2* Promoter driven Cre recombinase in a dual color membrane tagged GFP/Tomato reporter mouse was used. First, a modified and optimized bead perfusion protocol was applied to establish a highly enriched glomerular fraction of kidney lysates. Further single cell dissociation based on collagenase digest and vigorous mechanic disruption of the glomerular architecture led to a more than 100 fold increase in podocyte yield as compared to previous reports, which greatly facilitates downstream applications such as gene arrays and proteomics.

Results: On average 500.000 cells could be obtained per mouse. Gene ontology analysis of gene arrays comparing podocytes with non-podocyte glomerular cells revealed an enrichment of processes related to cytoskeleton, cell differentiation, receptor and synapse activity as well as endosomal transport. qPCR confirmed selected targets from differentially expressed sets of genes. Both label-free and SILAC proteomics with spiked "heavy" glomerula were performed. A total of 1448 proteins could be detected by MS with 161 being differentially expressed. Again, proteins from cytoskeleton, plasma membrane, cell junction, synapse and membrane rafts were found to be enriched in podocytes. Several differentially expressed proteins were confirmed by Western Blot.

Conclusions: We have established a method for large-scale isolation of podocytes allowing efficient use in downstream screening applications. For the first time we were able to analyze a proteome of the podocyte and hence correlate mRNA and protein expression. Analysis of splice variants, miRNA and transcription factor networks yielded interesting and novel insights into podocyte biology.

FR-PO682

The Slit Revisited: Analyzing the Role of Nephrin and the Whole Neph Family Using an In Vivo Comparative Approach Christoph Schell, Florian Grahammer, Tobias B. Huber. *Renal Division, Department of Medicine, University Hospital Freiburg, Freiburg, Germany.*

Background: The slit diaphragm constitutes the final component of the glomerular filtration barrier. NEPHRIN and NEPH1 are essential components of the SD, while the role of other members of the NEPH family (NEPH2 and 3) is unclear. By using conditional alleles we try to decipher the precise function of these genes.

Methods: We crossed conditional Nephrin and Neph1 alleles to the *hNPHS2-cre* line. Furthermore constitutive knockout mice were generated. Generation of Neph2 and Neph3 mice was performed in a similar way. By employing *Nphs2rtTA*TetOCre* models timed deletion in adulthood could be induced. Detailed analysis was performed with functional, phenotypic assays, light microscopy, IF, WB, SEM and TEM.

Results: As expected podocyte specific *Nephrin* knock-out mice show congenital proteinuria, growth retardation and die within ten days. Interestingly, Neph2 and Neph3, constitutive KO mice did not show any obvious phenotype over a 12 week period. Surprisingly the analysis of *Neph1* conditional and constitutive knock-out mice displayed totally differing results. While constitutive *Neph1* mice present with almost 100% lethality during 24h after birth, conditional *Neph1* mice show a proteinuric, non lethal phenotype resembling a FSGS like glomerulopathy. NEPH1 plays a fundamental role in the enteric nervous system being responsible for the early lethality of constitutive NEPH1 KO mice. Ultrastructural analysis revealed that both, NEPH1 and Nephrin molecules, are required for a fine tuned targeting of podocyte foot processes. Interestingly, the slit diaphragm can still be formed in the absence of NEPH1, but not in the absence of Nephrin.

Conclusions: This unique comparative approach revealed for the first time distinct functions for the slit diaphragm molecules NEPHRIN, NEPH1, NEPH2 and NEPH3 *in vivo*. While NEPHRIN seems to be essential for the formation of the slit diaphragm, NEPH1 rather appears to have a guidance function for podocyte foot processes; on the contrary NEPH2 and NEPH3 appear to be dispensable In addition, our data point to an unexpected fundamental role of NEPH1 for the innervation of the intestine.

FR-PO683

Role of Microtubule Associated Protein 1b (Map1b) in Glomerular Podocytes Stefan Kohl,[1,4] Markus Gödel,[1] Friedrich Propst,[2] Beat M. Riederer,[3] Tobias B. Huber.[1] *[1]Renal Division, University Hospital Freiburg, Freiburg, Germany; [2]Max F. Perutz Laboratories, Department of Biochemistry and Cell Biology, University of Vienna, Vienna, Austria; [3]Center for Psychiatric Neurosciences, Proteomics Unit, Psychiatric Hospital, CHUV, Prilly-Lausanne, Switzerland; [4]Department of Pediatrics, University of Michigan, Ann Arbor, MI.*

Background: Glomerular podocytes are process-bearing, octopus-like specialized epithelial cells. The cytoskeleton of podocyte main processes and processes of neurons have a similar basic architecture: Both are supported by prominent bundles of microtubules (MT). Furthermore, they share a common set of proteins (e.g. Map Tau) which are needed to assemble, maintain, and utilize their complex MT cytoskeleton but are absent in simple shaped cells.

Methods: We used immunofluorescence microscopy of human and rat kidney sections, as well as human cell culture podocytes. Common molecular cloning methods were employed to generate lentiviral constructs of GFP/mCherry labeled Map1b. A newly created transgenic podocyte cell line was used for live cell imaging (Nikon Biostation). Kidneys of total Map1b KO mice were examined by light and electron microscopy.

Results: We studied the microtubule cytoskeleton of podocytes and identified the neuronal microtubule associated protein 1b (Map1b) as a new protein to be highly enriched in podocyte main processes. Expression of Map1b in differentiating glomerular podocytes of newborn rats was detected in very early stages of glomerulogenesis (comma shaped bodies). Live cell imaging of GFP/mCherry-tagged Map1b in cell culture podocytes revealed the highly dynamic organization of the microtubule cytoskeleton and its close association with Map1b. Surprisingly, mice being constitutively depleted of Map1b did not show structural podocyte defects.

Conclusions: We identified the "neuronal" Map1b as a new "podocytic" protein. It is associated with a highly dynamic MT skeleton of podocyte main processes. However, Map1b is not essential for glomerulogenesis and podocyte differentiation in mice.

FR-PO684

Dynamin Ring Stabilizer Protect the Actin Cytoskeleton in Proteinuric Kidney Disease Changkyu Gu, Sanja Sever. *Nephrology, Massachusetts General Hospital, Charlestown, MA.*

Background: Dynamin oligomerization into rings has been linked to stimulation of F-actin elongation and protection of damaged kidney podocytes from dynamin proteolysis. Therefore, development of dynamin ring stabilizer compounds as novel therapeutics is important for the treatment of actin-based diseases such as proteinuric kidney disease.

Methods: Dynamin ring stabilizer compound was characterized and tested for the effects on dynamin activity using the various approaches including GTPase assay, electron microscopy, endocytosis assay and protein binding assay. Cell staining assay and PAN or LPS-induced transient proteinuric animal models were used to reveal the effects of dynamin ring stabilizer compound on actin cytoskeleton in podocytes and proteinuria respectively.

Results: 1. Dynamin ring stabilizer compound induces formation of long-lived dynamin rings.

2. Dynamin ring Stabilizer compound regulates formation of focal adhesions and stress fibers.

3. Dynamin ring Stabilizer compound does not inhibit clathrin-mediated endocytosis, unless it is actin-dependent clathrin-mediated endocytosis.

4. Effects dynamin ring Stabilizer compound on actin dynamics are independent of RhoA signaling.

5. Dyamin ring Stabilizer compound reduces proteinuria.

Conclusions: Dynamin oligomerization regulates actin dynamics independent of the endocytosis and the well-known actin cytoskeleton regulator, Rho GTPase family. Our data showed that dynamin ring stabilizer compound promotes formation of stress fibers and focal adhesion in podocytes. Furthermore, its actin stabilizing action could be harnessed to reduce the symptoms of an actin-based disorder in two rodent models of proteinuric kidney disease. The dynamin ring stabilizer compound has therefore provided key new insights into dynamin oligomerization, actin dynamics and introduces a possible new candidate therapeutic.

FR-PO685

A VEGFR2-Gαi3-GIV Molecular Complex Regulates Actin Remodeling, Cell Survival and Cell Migration in Podocytes Honghui Wang,[1] Taro Misaki,[1] Akiko Eguchi,[2] Pradipta Ghosh,[2] Marilyn G. Farquhar.[1] *[1]Department of Cellular and Molecular Medicine, University of California San Diego, La Jolla, CA; [2]Department of Medicine, University of California San Diego, La Jolla, CA.*

Background: We previously demonstrated that after acute injury in Puromycin Aminonucleoside Nephrotic (PAN) rats expression of GIV increases as the nephrin level decreases. GIV is phosphorylated and phospho-GIV binds VEGFR2 and Gαi3, and Akt signaling is increased. These results suggest that GIV takes over the task of enhancing Akt survival signaling in response to VEGF. The objective here was to investigate the mechanistic role of GIV in actin remodeling, cell survival and cell migration of cultured podocytes.

Methods: To mimic early PAN injury, in vitro differentiated mouse podocytes were treated with PA (30 μg/mL) for 24-72 h. Expression and phosphorylation of GIV and VEGFR2 and Akt were assessed by quantitative immunoblotting, endogenous interaction between VEGFR2 and GIV in podocytes by co-immunoprecipitation, and in vitro interaction between GIV and Gαi3 by GST-pulldown assay. To study the function of GIV, GIV was depleted by siRNA, actin remodeling was assessed by rhodamine-phalloidin staining, cell migration by wound healing assay, and apoptosis by caspase 3 cleavage and Annexin V assays.

Results: In PA treated podocytes, phosphorylation of GIV is increased, phosphorylation of VEGFR2 is elevated, and the interaction between GIV, VEGFR2 and Gαi3 is enhanced. In addition, interaction between inactive but not active GST-Gαi3 and GIV is increased in PA treated podocytes. These results are consistent with previous findings in PAN rats and validate that PA injury of podocytes is a suitable in vitro model for investigating early podocyte injury. In GIV depleted podocytes, Akt activation is attenuated, the actin cytoskeleton reorganizes, and cell migration is impaired. Upon PA injury, Akt activation in response to VEGF stimulation is abolished, and cell apoptosis is dramatically increased.

Conclusions: We conclude that upon PAN injury GIV interacts with VEGFR2, assembles a VEGFR2-Gαi3-GIV signaling complex that stimulates Akt activation, actin remodeling and cell survival in podocytes.

FR-PO686

INF2 Preserves Lamellipodial Actin Dynamics and Slit-Diaphragm Trafficking by Modulating Rho/mDia Signaling Hua Sun, Johannes S. Schlondorff, Martin R. Pollak. *Division of Nephrology, Department of Medicine, Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA.*

Background: Mutations in INF2 are a common cause of familial focal segmental glomerulosclerosis (FSGS). We have previously established that INF2 antagonize Rho-mediated activation of diaphanous related formins (mDia). Here we investigated the role of INF2 in regulating actin dynamics and trafficking of slit diaphragm (SD) proteins in podocytes.

Methods: Cultured podocytes were treated with INF2-targeting siRNA. The effect of INF2 knockdown on actin dynamics, actin-dependent lamellipodial morphology and trafficking of SD proteins were examined by immunofluorescence microscopy. Wild-type and mutant INF2 were transfected to ascertain their ability to rescue the observed phenotypes.

Results: Knockdown of INF2 in podocytes led to a loss of lamellipodia and the associated actin meshwork, accompanied by disruption of nephrin and podocin trafficking. Both the changed phenotypes were reversed by overexpression of dominant negative Rho or mDia. Overexpression of wild-type INF2 restored lamellipodia and SD trafficking disrupted by active Rho or mDia, while overexpression of INF2 mutants that are unable to bind and inhibit mDia, led to SD protein mislocalization. The ability of INF2 to direct SD trafficking is mediated by its interaction with podocin and caveolin-1.

Conclusions: INF2 plays an essential role in preserving lamellipodial actin dynamics by antagonizing the Rho/mDia pathway. INF2 directs lipid-raft mediated trafficking of SD proteins to lamellipodia via an interaction with podocin. FSGS-causing mutations disrupt the ability of INF2 to inhibit mDia, thereby impairing actin dynamics critical for podocyte morphology and trafficking of SD proteins. These results suggest that excess mDia activation play a central role in the development of INF2-related FSGS.

FR-PO687

Loss of Apoptosis Antagonizing Transcription Factor (AATF) in Podocytes Leads to FSGS Katja Hoepker,[1] Safiya Khurshid,[1] Heike Goebel,[2] Linus A. Völker,[1] Heiko Schweizer,[3] Bernhard Schermer,[1] Thomas Benzing.[1] *[1]Internal Medicine II and Center of Molecular Medicine Cologne, University of Cologne, Cologne, Germany; [2]Institute of Pathology, University of Cologne, Cologne, Germany; [3]Internal Medicine IV, University of Freiburg, Freiburg, Germany.*

Results: AATF is expressed in developing podocytes. Because AATF´s conventional knockout is early embryonically lethal we generated a mouse containing a floxed AATF allele and crossed it with the Podocin-Cre line. This created an embryonic podocyte knockout (pod ko) at approx. E12.5. Surprisingly the pod ko shows a considerably late phenotype. The mice are born in a normal mendelian ratio and are not to be distuingished from their littermates until the age of 12 weeks when they become proteinuric. At varying age, between 4-7 months the pod ko animals loose weight and show ESRD. Histologically, their kidneys present with the classical criteria of focal segmental glomerulosclerosis (FSGS). The genomic integrity of podocytes is being challenged by ROS, ionizing irradiation or chemotherapeutic agents. Their specific features of the DNA damage response (DDR) as postmitotical cells are largely being uninvestigated. We and other groups have identified AATF as a key protein involved in DDR pathways. The DDR signaling cascade ultimately activates p53, which then eventually determines the fate of the cell: DNA repair or elimination by apoptosis. We show that in resting cells AATF resides in the cytoplasm where it interacts with MRLC3. On encountering DNA damage MAPKAP Kinase 2 gets activated and migrates out of the nucleus into the cytoplasm where it phosphorylates AATF, abrogating its interaction with MRLC3 and thus allowing AATF to translocate into the nucleus. In the nucleus AATF localizes on to the promoters of the p53 dependent pro-apoptotic target genes like PUMA, Bak and BAX and hence negatively regulates p53 dependent apoptosis.

Conclusions: We therefore bring forth a DNA damage player, which on a systems level, acts in a switch-like manner to control the quality of the p53 response to DNA damage and plays a central role in podocyte maintanance.

FR-PO688

PTEN Deletion in Podocytes: A Potential General Mechanism Causing Foot Processes Effacement and Proteinuria Jamie Lin,[1] Jing Xu,[2] William E. Mitch,[1] Zhaoyong Hu.[1] *[1]Internal Medicine, Nephrology Division, Baylor College of Medicine, Houston, TX; [2]Internal Medicine, Changhai Hospital, Shanghai, China.*

Background: Proteinuria is a serious complication of chronic kidney disease (CKD), including diabetic nephropathy (DN). Podoycytes play a prominent role in maintaining the integrity of the glomerular filtration barrier but they can undergo cytoskeletal remodeling resulting in foot processes effacement and increasing albuminuria. We studied PTEN (phosphatase and tensin homolog) because it is known to be down-regulated in glomeruli of type 1 (T1DM) or type 2 (db/db) mice and PTEN regulates cytoskeletal remodeling(e.g., fibroblast).

Methods: In kidneys of DN patients or db/db mice, we assessed PTEN expression in podocytes. In cultured podocytes, we examined whether down-regulation of PTEN stimulates Rac1 to disrupt the cytoskeleton. We also created mice with podocyte-specific PTEN KO (PPKO) to examine structural changes in podocytes and albuminuria.

Results: In glomeruli of DN patients or db/db mice, PTEN protein levels were decreased as was the level of Nephrin. In cultured podocytes, we inhibited PTEN with BpV(Hopic), a specific PTEN inhibitor, and found disorganization of F-actin in the cytoskeleton plus an increase in albumin permeability. In contrast, forced expression of PTEN in cultured podocytes blocked RAC1/Cdc42 activation and the disorganization of the cytoskeleton stimulated by PDGF. We hypothesize that reduced PTEN in podocytes is responsible for a cytoskeletal disorganization leading to effacement and proteinuria. To test our hypothesis, we examined PPKO mice and found about a 2-fold increase in albuminuria over control, lox/lox mice. PAS staining of kidney sections from PPKO mice revealed early glomerulosclerosis. Nephrin immunostaining exhibited interrupted, granularity vs smooth pattern in podocytes of normal lox/lox mice. By electron microscopy, there was extensive foot process effacement in podocytes of PPKO mice.

Conclusions: PTEN down-regulation in podocytes causes effacement and albuminuria. Because PTEN is reduced in kidneys of DN patients, targeting glomerular PTEN could become a therapeutic strategy for suppressing proteinuria.

FR-PO689

Vitamin D Reduces the Enhanced TRPC6 Expression in Injured Podocytes and Glomerular Disease Tom Nijenhuis,[1] Ramon Sonneveld,[1] Silvia Ferrè,[2] Joost G. Hoenderop,[2] Henry Dijkman,[3] Jo H.M. Berden,[1] René J. Bindels,[2] Jack F. Wetzels,[1] Johan Van der Vlag.[1] *[1]Nephrology, Radboud University Nijmegen Medical Centre, Netherlands; [2]Physiology, Radboud University Nijmegen Medical Centre, Netherlands; [3]Pathology, Radboud University Nijmegen Medical Centre, Netherlands.*

Background: Transient Receptor Potential channel C6 (TRPC6) is a slit diaphragm protein expressed by the podocyte. TRPC6 gain-of-function mutations cause hereditary focal segmental glomerulosclerosis (FSGS). Glomerular TRPC6 expression is increased in acquired proteinuric disease. We demonstrated that acquired increased TRPC6 expression is ameliorated by anti-proteinuric angiotensin receptor blockers and angiotensin converting enzyme inhibitors. Because vitamin D also has an anti-proteinuric effect, we hypothesized that it may affect podocyte TRPC6 expression.

Methods: Podocyte injury was induced by adriamycin exposure in cultured mouse podocytes. TRPC6 promoter activity was studied in a TRPC6 promoter-luciferase assay. Adriamycin-induced Nephropathy (AN) in rats was used as a model for FSGS and 1α-hydroxylase (1α-OHase) knockout mice as model for 1,25-D_3 deficiency.

Results: Adriamycin-induced podocyte injury increased TRPC6 expression, which was dose-dependently reduced by 1,25-D_3 treatment. Accordingly, 1,25-D_3 reduced TRPC6 promoter activity. AN rats showed increased TRPC6 mRNA and glomerular TRPC6 protein expression and proteinuria. 1,25-D_3 treatment normalized TRPC6 expression and reduced proteinuria. In 1,25-D_3-deficient 1α-OHase KO mice, TRPC6 mRNA and glomerular TRPC6 protein expression were increased, accompanied by podocyte foot process effacement and proteinuria. 1,25-D_3 supplementation normalized TRPC6 expression, podocyte morphology and proteinuria in these mice.

Conclusions: Our results demonstrate that 1,25-D_3 reduces TRPC6 expression in injured podocytes, possibly by inhibiting TRPC6 promoter activity. *In vivo*, 1,25-D_3 reduced glomerular TRPC6 expression in FSGS, whereas 1,25-D_3 deficiency was associated with enhanced TRPC6 expression, which correlated with signs of podocyte injury and proteinuria. Thus, this TRPC6 expressional regulation could be relevant in the anti-proteinuric effect of vitamin D.

FR-PO690

Motor Protein Myo1c Is Critical in Organizing the Slit Diaphragm Protein Neph1 at the Podocyte Cell Membrane Ehtesham Arif,[1] Leena Mallik,[2] Yogendra Singh Rathore,[2] Babita Kumari,[1] Lawrence B. Holzman,[1] E. Michael Ostap,[3] Fnu Ashish,[2] Deepak Nihalani.[1] *[1]Department of Medicine, Renal Electrolyte and Hypertension Division, University of Pennsylvania, Philadelphia, PA; [2]Protein Engineering, CSIR Institute of Microbial Technology, Chandigarh, Punjab, India; [3]Pennsylvania Muscle Institute, University of Pennsylvania, Philadelphia, PA.*

Background: Podocytes are the key components of the glomerular filtration system and their dysfunction is often associated with massive proteinuria and loss of kidney function. Our previous studies have demonstrated that the slit diaphragm components Nephrin and Neph1 fail to localize to the podocyte cell membrane in the absence of motor protein Myo1c that is critical for podocyte functioning.

Methods: We performed Immuno-precipitaiton, peptide walking and small/wide angle X-ray scattering (SWAXS) approaches to characterize the interaction between Myo1c and Neph1.

Results: In this study, we provide molecular details of this interaction and identify critical residues in Myo1c and Neph1 that mediate this binding. We identified mutations in the C-terminal domain of Myo1c and the cytoplasmic domain of Neph1 that nearly abolished this interaction. Further, the Neph1 binding mutants demonstrated their inability to localize at the membrane suggesting an active role for Myo1c in Neph1 localization. Similar results were obtained when Myo1c mutants including the dominant negative and the Neph1 binding mutant, were substituted in this assay. To further understand the structural details of this interaction, we determined the solution structures of full length Myo1c and its truncated mutants individually and in complex with the cytoplasmic domain of Neph1 using SWAXS.

Conclusions: The preliminary analysis of this data shows that this association is mediated via multiple binding regions in Neph1 and Myo1c and the binding of Neph1 induces a shape change in the C-terminus of Myo1c. Collectively, these results highlight the mechanism through which Myo1c serves as a major transporter of Neph1 to its physiological location in podocytes and therefore, contributes to the maintenance of the glomerular filtration assembly.

FR-PO691

Def-6 Expression and Localization in Atypical PKCλ/ι Deficient Mice and Podocytes Kirstin Worthmann,[1] Michael Leitges,[2] Beina Teng,[1] Irini Schaefer,[1] Hermann G. Haller,[1] Tobias B. Huber,[3] Mario Schiffer.[1] *[1]Division of Nephrology, Medical School Hannover, Hannover, Germany; [2]Biotechnology Centre of Oslo, University of Oslo, Oslo, Norway; [3]Renal Division, University Hospital Freiburg, Freiburg, Germany.*

Background: Podocyte specific deficiency of the atypical PKC isoform λ/ι in mice leads to a severe glomerular phenotype. In vitro studies of PKCλ/ι knockout podocytes revealed the guanine nucleotide exchange factor (GEF) Def-6 as a possible target gene of PKCλ/ι.

Methods: Monoclonal cell lines were isolated from control and deficient mice and their phenotype observed under the microscope. Cells were stained with phalloidin to visualize the actin cytoskeleton and vinculin to mark the focal adhesions. Furthermore, the cells were tested for the activity of small GTPases. Microarrays of the PKCλ/ι deficient and wildtype cells revealed several genes that are differentially regulated. For rescue experiments in deficient podocytes we generated adenoviral constructs of PKCλ/ι-GFP. Moreover, we analyzed the Def-6 expression and localization in PKCλ/ι deficient and wildtype kidney sections.

Results: When we compared PKCλ/ι deficient and wildtype cells we observed strong differences regarding cell shape and cell size. Furthermore, we observed increased cytoskeletal rearrangements in the deficient cells and less focal adhesions. Small GTPases assays revealed an increased activation of Rac1 and decreased amounts of total Cdc42. In

microarrays we detected Def-6 as one of the strongest upregulated genes in the deficient cells. Stainings of fixed podocytes and fractionizations revealed a strong membranous Def-6 localization in vitro. The actin cytoskeletal phenotype and the mRNA expression of Def-6 in the deficient cells could be rescued in overexpression experiments. Furthermore, we detected a strong glomerular expression of Def-6 in PKCλ/ι deficient and wildtype mice while the expression pattern of Def-6 changes obviously in glomeruli of deficient mice.

Conclusions: In summary, we can show that the actin cytoskeleton of podocytes is negatively influenced by increased Def-6 levels and that the expression and localization of this regulator is highly affected in PKCλ/ι deficient podocytes and glomeruli.

Funding: Government Support - Non-U.S.

Protective Effects of Everolimus on Puromycin-Induced Cytoskeletal Alterations in Human Podocytes Are Mediated by RhoA Signaling Stefanie Weber,[1] Stefanie Jeruschke,[1] Anja K. Büscher,[1] Jun Oh,[2] Perihan Nalbant.[3] *[1]Pediatrics II, University Duisburg-Essen, Essen, Germany; [2]University Children's Hospital Hamburg, Hamburg, Germany; [3]Center for Medical Biotechnology, Molecular Cell Biology, University Duisburg-Essen, Essen, Germany.*

Background: Podocytes are highly differentiated cells playing an important role in maintaining the glomerular filtration barrier. Damage of the podocyte actin cytoskeleton is a major cause of proteinuria associated with foot process effacement and loss of slit diaphragms. Recently, antiproteinuric actions of immunosuppressants have been attributed to the recovery of the actin cytoskeleton in podocytes.

Methods: In this study, actin-related effects of treatment with the mTOR inhibitor everolimus (EV) were investigated in a puromycin aminonucleoside (PAN) in vitro model of proteinuric disease.

Results: EV substantially recovered PAN-induced defects in human cultured podocytes as increased apoptosis, decreased adhesion and enhanced migration. These protective effects were associated with restored cell morphology and recovery of actin stress fibers. Biochemical studies revealed that activities of the Rho GTPase RhoA and myosin light chain (MLC), both regulators of actin stress fiber formation, were substantially increased by EV. Y-27632, an inhibitor of the RhoA effector ROCK *(Rho*-associated protein kinase), abolished phosphorylation of MLC and stress fiber recurrence, substantiating that the RhoA-ROCK-MLC pathway is the mediator of EV induced stress fiber reorganization. In addition, live-cell imaging of RhoA activity in untreated podocytes using a FRET-based biosensor revealed elevated activation in dynamic protrusions and contractile regions indicating tight spatial and temporal regulation of the GTPase.

Conclusions: Together, our results indicate stabilizing effects of EV on podocyte viability and structure, in particular regarding the actin cytoskeleton involving the RhoA-ROCK-MLC pathway in an experimental setting of proteinuria. These observations might prompt further studies focusing on mTOR inhibitors in proteinuric disease.

Na^+/H^+ Exchanger-1 Reduces Injury of Podocytes due to Endoplasmic Reticulum Stress via Activation of Autophagy Zhe Feng, Shaoyuan Cui, Quan Hong, Guangyan Cai, Xiang-Mei Chen. *Department of Nephrology, Nephrology Development of the State Key Laboratory, Chinese PLA General Hospital, Beijing, China.*

Background: Injury of podocytes plays a critical role in glomerular proteinuria. Induction of endoplasmic reticulum (ER) stress in podocytes is thought to lead to loss of the cytoskeleton and subsequent injury of podocytes, but the clearance mechanism of unfolding or misfolding of protein due to ER stress is not well understood.

Methods: A passive Heymann nephritis model of membranous nephropathy and conditionally immortalized mouse podocyte cells (MPCs) were used with these experiments. pcDNA-NHE-1 plasmid was constructed and siRNA-NHE-1 was designed.Activation of autophagy was evaluated by GFP-LC3 detection, measurement of autophagic vacuoles by AO and LC3 conversion (LC3-I to LC3-II).

Results: We found that induction of ER stress and activation of autophagy in podocytes were related to cytoskeleton injury and an increase in proteinuria in a passive Heymann nephritis model of membranous nephropathy. In vitro experiments showed that ER stress induced the loss and recombination of the cytoskeleton in MPCs. The efficiency of autophagy could be a pivotal degradation system for unfolding or misfolding of protein due to ER stress in podocytes. Disturbance of autophagy resulted in cells being vulnerable under ER stress, and it aggravated the loss of the cytoskeleton. Furthermore, Na^+/H^+ exchanger-1 (NHE-1) may exert a protective effect by reducing the loss of synaptopodin in MPCs exposed to ER stress, which were recognized using overexpression of a full NHE-1 clone plasmid and NHE-1 siRNA deficiency methods.

Conclusions: This protective mechanism is due to NHE-1 activated autophagy of podocytes via PI3K/Akt phosphorylation, which reduces ER stress, and this may provide a pathway to prevent podocyte injury and decrease proteinuriaduring the course of glomerular disease.

Increased Mesangial Cell Number and Podocyte Effacement in Calponin h-2 Knockout Mice Shane Joychan,[1] Haiping Chen,[1] Jian-ping Jin,[1] Moazzem Hossain,[1] Noreen F. Rossi.[1,2] *[1]Physiology and Internal Medicine, Wayne State University School of Medicine, Detroit, MI; [2]John D. Dingell VA Medical Center, Detroit, MI.*

Background: Calponin, an actin filament-associated protein, is found in smooth muscle and non-smooth muscle cells. H-2 calponin is highly expressed in mature kidney and has been implicated in regulating the actin cytoskeleton in other tissues especially during mechanical stress. We hypothesized that h-2 calponin knockout mice would display changes in mesangial cell number and abnormal podocyte morphology compared with wild type mice.

Methods: Expression of calponin h-2 in knockout mice, heterozygous and wild type C57B/L6 mice was performed by western blot using anti-h-2 calponin polyclonal antibodies RAH1 and mAB CP21. Kidneys from each group were perfusion fixed with glutaraldehyde, then evaluated by an investigator blinded to the genetic background of the mice. Mesangial cell number was quantitated on 60 independent sections per kidney (~ 4 glomeruli per section) on periodic acid-schiff stained sections. The extent of podocyte effacement was assessed on electron microscopic images by counting the number of slit diaphragms per millimeter of glomerular basement membrane (GBM) length.

Results: Calponin h-2 knockout mice exhibited significant mesangial proliferation compared with wild type mice ($P < 0.01$). The number slit diaphragms per length were significantly fewer 863 ± 52 per mm GBM in the h-2 calponin knockout mice compared with 1033 ± 24 per mm GBM in the wild type mice. Segments of podocyte effacement were evident along the GBM in the h-2 calponin knockout mice but none in the wild type mice. Heterozygotes more closely resembled the calponin h-2 knockout mice.

Conclusions: These findings suggest that calponin h-2 influences mesangial cell number and is involved in podocyte morphology in basal conditions. Calponin h-2 may be involved in the cytoskeletal changes observed during mechanical stress that occurs in glomeruli under pathological conditions.

Sphingomyelin Phoshodiesterase-Like 3b (SMPDL3b) Affects β3 Integrin Signaling in Podocytes Tae-hyun Yoo,[1,3] Changli Wei,[1] Rodrigo Villarreal,[1] Christopher E. Pedigo,[1] Johanna Guzman,[1] Christian Faul,[1] Jochen Reiser,[1] George William Burke,[2] Sandra M. Merscher-Gomez,[1] Alessia Fornoni.[1] *[1]Department of Medicine, University of Miami; [2]Department of Surgery, University of Miami, Miami; [3]Yonsei University College of Medicine, Seoul.*

Background: Deficiency of SMPDL3b renders podocytes susceptible to injury in focal segmental glomerulosclerosis (FSGS), and down-regulation of SMPDL3b in FSGS can be prevented by rituximab. However, little is known about the mechanisms by which SMPDL3b deficiency may cause podocyte injury. The aim of this study is to investigate if and how SMPDL3b and rituximab affect β3 integrin activation and signaling induced by either urokinase-type plasminogen activator receptor (uPAR) or by its soluble form (suPAR).

Methods: Co-immunoprecipitations (Co-IP) and competitive Co-IPs were performed to detect interactions between SMPDL3b, uPAR or suPAR and β3 integrin. Wildtype (WT), SMPDL3b knockdown (KD), and overexpressing (OE) human podocytes were cultured with or without lipopolysaccharide (LPS) or recombinant human uPAR (rhuPAR). in the presence or absence of rituximab. Total (AP3) and activated (AP5) β3 integrin, as well as Src and focal adhesion kinase (FAK), were analyzed by Western blot (WB) as downstream effectors of uPAR signaling. Activation of β3 integrin was also analyzed by immunofluorescence (IF) staining for AP3 and AP5.

Results: Co-IPs showed interactions between SMPDL3b and uPAR/suPAR. Competitive Co-IPs indicated that SMPDL3b competes with the ability of uPAR/suPAR to immunoprecipitate β3 integrin. The degree of β3 integrin activation, phospho-Src and -FAK protein expression was increased in LPS- and rhuPAR- stimulated cells, and was prevented in OE and rituximab pretreated podocytes. KO podocytes were characterized by constitutive activation of β3 integrin, Src and FAK and increased susceptibility to LPS- and rhuPAR. IF staining confirmed the findings obtained by WB.

Conclusions: In summary, we demonstrated that down-regulation of SMPDL3b renders podocytes susceptible to LPS and uPAR induced activation of β3 integrin in podocytes. These findings, suggests a possible mechanism by which SMPDL3b affects podocyte function in FSGS.

GIV Binds VEGFR and Assembles a GIV-Gαi3 Signaling Complex during Puromycin Aminonucleoside Nephrosis (PAN) Taro Misaki,[1,3] Honghui Wang,[1] Hirotaka Fukasawa,[1] Vanessa Taupin,[1] Pradipta Ghosh,[2] Marilyn G. Farquhar.[1] *[1]Department of Cellular and Molecular Medicine, University of California San Diego, La Jolla, CA; [2]Department of Medicine, University of California San Diego, La Jolla, CA; [3]Division of Nephrology, Seirei Hamamatsu General Hospital, Hamamatsu, Shizuoka, Japan.*

Background: Podocyte injury is a common determining factor in glomerular disease progression. Nephrin dependent signaling has been proposed to maintain podocyte survival via Akt activation. However, in PAN at early time points (7d) Akt phosphorylation is increased when nephrin expression is decreased and no apoptosis is detected, suggesting that

there is an alternative survival signaling pathway. GIV is a novel GEF that binds receptor tyrosine kinases and activates Gαi3 which leads to Akt activation, rearrangement of the actin cytoskeleton and cell migration. Here we investigated the role of GIV in PAN rats.

Methods: Glomeruli were isolated from normal and 7d PAN rats. Expression and phosphorylation of GIV, VEGFR2 and Akt, and expression of VEGF were assessed by quantitative immunoblotting; localization of GIV was determined by immunofluorescence; interaction between endogenous VEGFR2 and GIV by co-immunoprecipitation; and in vitro interaction between GIV and Gαi3 by GST-pulldown assay.

Results: Both the expression and phosphorylation of GIV are significantly increased in PAN glomeruli, and the increased GIV is localized in podocytes. Expression of both VEGF and VEGFR2 is elevated and activation (phosphorylation) of VEGFR2 and Akt are greatly enhanced in PAN. Moreover, VEGFR2 binds phospho-GIV from PAN glomeruli but not GIV from normal glomeruli. Finally, GIV from PAN glomeruli binds inactive but not active GST-Gαi3 whereas GIV from normal glomeruli does not bind either active or inactive GST-Gαi3, indicating that GIV binds and presumably activates Gαi3 and Akt only in PAN rats.

Conclusions: Our results show that GIV is induced after PAN injury, and enhanced GIV expression coincides with decreased nephrin expression and activation of VEGFR2 and Akt. Thus GIV interacts with VEGFR2 and activates Gαi3 in PAN which most likely enhances podocyte survival via activation of Akt.

Percutaneous Renal Biopsy of Native Kidneys: A Single Center Experience of over 1000 Biopsies Stephen M. Korbet, William Whittier. *Nephrology, Rush University Medical Center, Chicago, IL.*

Background: Percutaneous renal biopsy (PRB) of native kidneys is an invaluable tool in the diagnosis and management of renal disease. We report a single academic center's experience.

Methods: PRB of native kidneys was performed in 1055 stable adult patients by an attending nephrologist (15%) or supervised fellow (85%) from 6/1983 to 3/2012 using real-time ultrasound guidance and 14-gauge biopsy needles. All patients were observed for 23-24 hours post-biopsy. From 1991 forward data was prospectively obtained and an automated needle was used.

Results: The primary indications for PRB were proteinuira (49%), SLE/vasculitis (26%), ARF (12%) and hematuiria (8%). Pts were 46±17 yo with 23% ≥60 yo, 38% were male, 40% white, 43% AA, 12% Hispanic and 4% Asian/other. The pre-PRB BT was 7±2 min with only 6% >9 min and the PTT was normal in 95% of pts. The SCr was 2.3±2.3 with 47% >1.5 mg/dl and the pre-Hgb was 12±2 g/dl with 21% ≤10 g/dl. The post-Hgb was 10.8±2 with a 1.0±0.9 delta Hgb (P <0.0001) overall. By light microscopy glomeruli were obtained in 99.6% of cases with 90% having ≥10 glomeruli and the average number of glomeruli per biopsy was 23±12. Glomeruli for immunofluorescence and EM were present in 98% of cases. Biopsies done with the automated 14-gauge needle obtained more glomeruli than with the manual needle (21±13 vs. 23±12, P 0.0001). Adequate tissue for diagnosis was obtained in 99% of biopsies and 88% of lesions were glomerular (SLE/Vasc 28%, FSGS 14%, IgAN/TBM 10%, MGN 8%, MCD 8% and MPGN 8%), 7% had tubulointerstitial lesions and 4% had nondiagnostic changes. There was no difference over time in the proportion of pts with FSGS, MGN or IgAN. Minor complications (no intervention) occurred in 8% of biopsies (mainly gross hematuria 4.5%). Major complications (required intervention) occurred in 6.6% of biopsies and resulted in death in 2 (0.18%: 1 due to bleeding and 1 sudden and unexplained), cystoscopy in 2 (0.18%), embolization in 9 (0.85%), transfusion in 48 (4.6%) and other/readmission 9 (0.8%). There was no difference in major complication rates between fellows or attendings or over the period of study.

Conclusions: PRB of native kidneys remains a highly successful and safe procedure.

FR-PO698

Safety and Outcomes According to Practitioners and Techniques in Percutaneous Native Renal Biopsy Eun Sil Koh, Sungjin Chung, Hyun Chul Whang, Yu Ah Hong, Seok Joon Shin, Cheol Whee Park, Yong-Soo Kim, Yoon-Sik Chang. *Department of Internal Medicine, The Catholic University of Korea College of Medicine, Seoul, Korea.*

Background: The purpose of this study is to compare the safety and the adequacy of tissue yield in percutaneous renal biopsy according to practitioners and techniques based on ultrasound.

Methods: This study included 658 native renal biopsies performed from 2005 to 2010 at a single center. The biopsies were performed by the nephrologists or the ultrasound (US) expert radiologists, and performed by the US-marked blind or the real-time US-guided technique.

Results: During the study period, 271 US-marked blind biopsies were performed by nephrologists, 170 real-time US-guided biopsies by nephrologists, and 217 real-time US-guided biopsies by US expert radiologists. There were no differences in post-biopsy complications such as hematoma, need for intervention, gross hematuria, pain or infection among groups. In the results of the adequacy of tissue yield, there was no significant difference in glomerular yield according to renal biopsy technique based on US. However, glomerular yield from renal biopsy performed by nephrologist was superior to that performed by US expert radiologist ($p<0.001$).

Conclusions: Percutaneous renal biopsy performed by nephrologist is equivalent to biopsy performed by US expert radiologist in post biopsy complications, and is even superior in glomerular yield.

FR-PO699

Timing of Complications of the Percutaneous Native Kidney Biopsy Kaelin C. Volpini, Stephen M. Korbet, William Whittier. *Nephrology, Rush University Medical Center, Chicago, IL.*

Background: Percutaneous kidney biopsy (PKB) of native kidneys is a safe procedure; however, in the modern era, the timing or rate of complications may have changed.

Methods: PKB of native kidneys was performed in 1055 adult pts by a nephrologist or supervised fellow from 6/1983-3/2012 using real-time US guidance and 14-gauge biopsy needles. Baseline demographic and laboratory data at the time of PKB was recorded. All pts were observed for at least 23-24 hours (h) post-PKB for the presence, severity, and timing of complications. From 1991 forward data prospective and an automated needle was used. Data was divided into Era 1 (1983-1990), Era 2 (1991-2000) and Era 3 (2001-2012) and complications were divided into major (requiring intervention) and minor (no intervention required).

Results: On avg at the time of PKB pts were 46 ± 17 years old, 38% male and had a systolic BP (SBP) of 133±18 mmHg. The avg baseline bleeding time (BT) was 7±2 min, Hgb was 12±2 g/dl, and SCr was 2.3±2.3 mg/dl. Overall, the avg post-PKB Hgb was 10.8±2 with a change of 1.0±0.9 g/dl (P < 0.0001). PKB related complications occurred in 14.6% of pts; minor complications in 8% of pts and major ones in 6.6% of pts. Two pts died (0.18%: 1 PKB related). Baseline characteristics with increased risk for complication included female gender (69% vs. 61%, p= 0.0493), elevated SCr (2.8±2.8 vs. 2.2±2.2 mg/dl, p=0.0019), increased BT (7.2±2.0 vs. 6.7±1.9 min, p= 0.0026), anemia (Hgb 11.4±2.2 vs. 11.9±2.0 g/dl, p=0.0101) and HTN (SBP 137±20 vs. 133±18 mmHg, p=0.0145) compared to none. There was no change in complication rate over time (overall for Era 1, 13.4%; Era 2, 13.6%; Era 3, 16.5%, P=NS). Complications post-PKB were discovered in 58% of pts at ≤ 4h, 75% ≤ 8h, 88% ≤ 12h, 91% ≤ 24h. Major complications were noted in 56% of pts at ≤ 4h, 74% ≤ 8h, 89% ≤ 12h, 91% ≤ 24h. Complications post-PKB were discovered sooner in Era 3 than in Era 2 (overall complications ≤ 8h in Era 3 87% vs. Era 2 56%, p=0.0022; major complications ≤ 8h in Era 3 83% vs. Era 2 56%, p=0.033).

Conclusions: PKB of native kidneys remains a safe procedure. The rate of complications has not changed over time, but they are discovered sooner post-PKB in the modern era.

FR-PO700

Validation of the Oxford Classification in IgA Nephropathy, a Systematic Review and Meta-Analysis Sufang Shi,[1] Jicheng Lv,[1] Damin Xu,[1] Hong Zhang,[1] Stephan Troyanov,[2] Daniel C. Cattran,[3] Haiyan Wang.[1] *[1]Renal Division, Department of Medicine, Peking University First Hospital; Peking University Institute of Nephrology, Beijing, China; [2]Department of Nephrology, Ho´pital du Sacre´-Coeur de Montre´al, University of Montreal, QC, Canada; [3]Division of Nephrology, Toronto General Hospital, University of Toronto, Otaria, Canada.*

Background: Oxford Classification of IgA nephropathy, recently developed in 2009, has been validated in different populations. However the results remained inconsistent. We undertook a systematic review and meta-analysis to synthesize all available data and evaluate Oxford Classification utilization in IgA nephropathy.

Methods: We systematically searched Medline, Embase, and the Cochrane Library for trials published between 2009 and December, 2011. Studies assessing Oxford Classification in IgA nephropathy were included. Summary estimates of relative risk reductions were calculated with a random effects model. Renal outcome was defined as the composite of doubling of serum creatinine concentration or 50% decline of eGFR or end-stage kidney disease.

Results: Twelve identified studies provided data for 3449 patients among whom 501 kidney failure events were recorded. Overall, Oxford Classification including mesangial hypercellularity (M), segmental glomerulosclerosis (S), and tubular atrophy /interstitial fibrosis (T), showed a good correlation with kidney progression. In the multivariate model, the hazard ratio (HR) was 0.65 (95% CI 0.53 to 0.81, p<0.001), 1.63(95% CI 1.24 to 2.13, p<0.001) and 4.78(95%CI 2.37, 9.66, p<0.001) in M0,S1 and T1-2 lesions respectively without evidence of heterogeneity. Although the pooled results showed endocapillary hypercellularity (E) lesions were associated with kidney failure (HR 1.60, 95%CI 1.05 to 2.46, p=0.030) with evidence of heterogeneity (I^2=60.5%, p=0.007), subgroup analysis showed that E lesions were only reported risk factor in small studies with few end points (p=0.023) while not in large studies (p= 0.46).

Conclusions: This study validated Oxford Classification MST but not E lesions in IgA nephropathy.

FR-PO701

Is the Oxford System Associated with Changing Therapy in Canadian Pediatric IgAN/HSPN? Maury N. Pinsk,[1] Chantal Bernard,[2] Ian W. Gibson,[3] Aicha Merouani,[4] Christoph Licht,[5] Aviva M. Goldberg,[3] Pavel Geier,[6] Keith K. Lau,[7] Andrew W. Wade,[8] Tom D. Blydt-Hansen.[3] *[1]U Alberta, Canada; [2]McGill U, Canada; [3]U Manitoba, Canada; [4]U Montreal, Canada; [5]U Toronto, Canada; [6]U Ottawa, Canada; [7]McMaster U, Canada; [8]U Calgary, Canada.*

Background: IgA and HSP nephropathies are common glomerulonephritites affecting children. We examined the degree to which the Oxford Scoring System was associated with a change in therapy from pre- to post- biopsy in a cohort of 46 biopsy- proven IgAN and HSPN Canadian children.

Methods: Canadian children undergoing kidney biopsy for initial diagnosis of IgAN or HSPN were consented and enrolled in the REDDCAPP registry at four centres across Canada

once the histological diagnosis was confirmed. Clinicians independently managed the care of these patients with the available local interpretation of the histopathology. Pre-biopsy and post-biopsy therapies were recorded. Tissue histology was scored centrally according to the Oxford Criteria using the M (0,1), E(0,1), S(0,1) and T(0,1,2) scoring rubric by a single pathologist. Statistical methods used the $\chi 2$ analysis of differences in categorical variables.

Results: Statistical analysis indicated that a biopsy alone was significantly associated with change of therapy ($\chi^2 = 24.2$, $p<0.05$). Specifically, performing a biopsy was most associated with a change in therapy with respect to ACEi ($\chi^2 = 25.1$, $p<0.05$), daily prednisone use ($\chi^2 = 15.5$, $p<0.05$), and azathioprine use ($\chi^2 = 19.6$, $p<0.05$), but not ARB, alternate day prednisone, mycophenolate, cyclosporine, tacrolimus or fish oil use. Assessment of the components of the Oxford Scoring System showed that no individual component of the scoring rubric was associated with change of therapy with ACEi, daily prednisone or azathioprine use.

Conclusions: Performing a biopsy is strongly associated with changing therapy for pediatric IgAN/HSP, but there is no component of the Oxford Scoring System that showed an association with changing therapy. This suggests that in clinical practice the Oxford criteria do not reflect subjective clinical or histological characteristics of disease severity that clinicians identify as triggers to alter management.

Validity of Oxford Classification of IgA Nephropathy in Arabs

Abdulkareem Alsuwaida,[1] Hala M. KFoury,[2] Khaled Alsaad,[3] Fayez F. Alhejaili,[3] Mohammed A. Al-Ghonaim,[1] Jamal S. Alwakeel,[1] Sufia Husain,[2] Noura Aloudah.[3] *[1]Medicine Department, King Saud University, Riyadh, Saudi Arabia; [2]Pathology Department, King Saud University, Riyadh, Saudi Arabia; [3]Medicine Department, King Abdulaziz Medical City, Riyadh, Saudi Arabia.*

Background: Several classification systems has been developed trying to predict renal outcome. The aim of this study is to assess the validity of this classification in a cohort of adult Saudi patients with biopsy proven IgAN.

Methods: A retrospective review of clinical and histological data of patients with biopsy proven IgA nephropathy seen from May 1998 to May 2011 was undertaken. The study was conducted at the King Khalid University Hospital and at the King AbdulAziz Medical City, Riyadh, Saudi Arabia. A total of 70 patients with primary IgA nephropathy were included in the analysis. The primary endpoint was a worse renal outcome which was defined as decrease of estimated glomerular filtration rate by 25% of their baseline value at last follow up.

Results: The study included 70 patients with the mean age of 32.2 ± 12.9 years and a median of 3.5 years of follow up. Higher stages of mesangial score and segmental glomerulosclerosis were associated with a trend for higher degree of proteinuria and lower estimated GFR at presentation and higher rate of worsening of renal function, but did not reach statistical significance. In multivariate logistic regression worsening of renal function was not predicted by any histologic class (Table 1).

Table 1. The odd ratios for worsening of renal function and Oxford Histological classifications of kidney biopsies.

Oxford Class	25% decrease in eGFR
M1 (M0 Control)	0.36 (0.07-1.75)
S1 (S0 Control)	1.35 (0.26-6.97)
E1 (E0 Control)	1.85 (0.35-9.83)
T1 (T0 Control)	1.55 (0.23-10.49)
T2 (T0 Control)	1.67 (0.18-15.31)

Mesangial hypercellularity in > or <50% of glomeruli (M0/1); Segmental sclerosis/adhesions–(S0/1); Endocapillary hypercellularity–(E0/1); Tubular atrophy/interstitial fibrosis–0-25%, 26-50%, >50% (T0/1/2).

Conclusions: The Oxford classification system is a useful tool that reflects the severity of the initial clinical presentation in Arabs with IgA nephropathy. However, it did not predict long term renal outcomes.

FR-PO703

Characteristics of Periglomerular Angiogenic Small Vessels in IgA Nephropathy

Chisako Kamano,[2] Akira Shimizu,[1] Seiichiro Higo,[2] Go Kanzaki,[1] Yukinari Masuda.[1] *[1]Pathology, Nippon Medical School, Tokyo, Japan; [2]Nephrology, Nippon Medical School, Tokyo, Japan.*

Background: In diabetic nephropathy, several angiogenic small vessels are frequently observed as polar vasculosis at the glomerular vascular pole. In IgA nephropathy (IgA GN), angiogenic small vessels at the periglomerular areas are also detected sometimes.

Methods: Periglomerular angiogenic small vessels are defined as small vessels with pericytes or monolayered smooth muscle cells around Bowman's capsule, except for afferent and efferent arterioles. We examined 114 cases of IgA GN. Clinical and histopathological characteristics of IgA GN with angiogenic small vessels were clarified.

Results: In the 114 cases of IgA GN, 46 cases (40.4%) had the glomeruli with periglomerular angiogenic small vessels, and showed higher incidence of glomerular (global and segmental) sclerosis, crescentic lesions than the rest ($P<0.001$). Interestingly, no periglomerular angiogenic small vessels could be detected in the cases with only active glomerular lesions. Angiogenic small vessels were present at glomerular hilus (42 glomeruli in 28 cases), glomerular adherence lesions (47 glomeruli in 28 cases), and the other regions (24 glomeruli in 19 cases). Serial sections revealed that periglomerular angiogenic small vessels were connected between glomerular capillaries and peritubular capillaries, sometimes with red blood cells, indicating functional vessels. We also found angiogenic small vessels, located in neither glomerular hilus nor glomerular adherence lesions, would be glomerular hilus or adherence lesions in consecutive slices. In clinical findings, IgA GN patients who had glomeruli with angiogenic small vessels showed past-history of macrophematuria, however, renal function and daily proteinuria at the biopsy were not significantly differences between the cases with and without periglomerular angiogenic small vessels ($P=0.02$).

Conclusions: Periglomerular angiogenic small vessels might result from the historical active glomerular lesions, but would demonstrate resolution of these activity and development of glomerular repair.

FR-PO704

Endothelial Cell Injury in Acute Active and Chronic Glomerular Lesions in IgA Nephropathy

Taiko Yoshida,[1,2] Hideki Takano,[1,2] Yukinari Masuda,[1] Akira Shimizu.[1] *[1]Department of Pathology, Nippon Medical School, Tokyo, Japan; [2]Division of Nephrology, Tokyo Teishin Hospital, Tokyo, Japan.*

Background: Glomerular capillary injuries may contribute to the progression of various glomerular diseases. We examined glomerular capillary injuries in active and chronic glomerular lesions in IgA nephropathy. We selected renal biopsy samples of IgA nephropathy (n = 149).

Methods: Glomerular endothelial cell injuries were assessed by immunohistochemistry for CD34 and electron microscopy, and the correlation between these lesions and renal functions was examined. The characterization of endothelial cells injury were examined in various glomerular lesions that were difined by Oxford classification. Acute active and chronic glomerular lesions were defined using ISN/RPS 2003 classification of lupus nephritis.

Results: Injured glomerular capillaries in active glomerular lesions (endocapillary hypercellularity, fibrinoid necrosis, karyorrhexis, rupture of glomerular basement membrane (GBM), and cellular and fibrocellular crescents) were characterized by separation of endothelial cells from GBM, and loss of glomerular capillaries, together with inflammatory cell infiltration, fibrin exudation, rupture of GBM, and/or cellular and fibrocellular crescent formation. Injured capillaries in chronic glomerular lesions were characterized by loss of capillaries and segmental or global glomerular sclerosis with or without fibrous crescents.

In acute active glomerular lesions, necrosis and crescents correlated significantly with hematuria (necrotic lesion, $p<0.05$; crescents, $p<0.01$) and daily proteinuria (necrotic lesion, $p< 0.01$; crescents, $p<0.01$). In chronic glomerular lesions, segmental or global sclerosis correlated significantly with daily proteinuria (segmental sclerosis, $p< 0.01$; global sclerosis, $p<0.01$) and renal dysfunction (segmental sclerosis, $p< 0.01$; global sclerosis, $p<0.01$).

Conclusions: In conclusion, glomerular endothelial cell injuries involved in the formation of severe and progressive glomerular injuries, and contributed to disease activity and the progression of chronic lesions in IgA nephropathy.

FR-PO705

The Correlation between Histological Parameters and Renal Prognosis with or without Steroid Therapy in IgA Nephropathy

Sayuri Shirai, Daisuke Ichikawa, Naohiko Imai, Yugo Shibagaki, Takashi Yasuda, Kenjiro Kimura. *Nephrology and Hypertension, St.Marianna University School of Medicine, Kawasaki, Kanagawa, Japan.*

Background: The Japanese guideline for IgA nephropathy by Ministry of Health, Labour and Welfare is widely used in Japan but the prognostic factor is different from oxford classification. These guidelines were produced using relationship between renal prognosis and pathology. The renal prognosis may have been affected by various treatments including steroid therapy.

Methods: We retrospectively analyzed 56 patients who could be pursued over five years after renal biopsy out of 220 patients diagnosed with IgA nephropathy between 1991 and 2000. Renal prognosis was evaluated using alteration rate of estimated glomerular filtration rate (eGFR). Correlation between histological parameters and eGFR decline rate was evaluated in all patients (ALL), moreover evaluated separating two groups; steroid using (S) group (N=18) and steroid non-using (N) group (N=38).

Results: On the histological analysis using each parameter, the % of total crescent, adhesion, collapsing, segmental sclerosis (SS), global sclerosis (GS), tubular atrophy/interstitial fibrosis (TI) had significant positive correlation with eGFR decline rate in ALL($P<0.001$on TI, others $P<0.01$). Those parameters didn't show correlation with eGFR decline rate in group S, but showed significant positive correlation with eGFR decline rate in group N ($P<0.001$on TI, others $P<0.01$).

Using the Japanese guideline for IgA nephropathy, the % of chronic lesion (SS, GS, and fibrous crescent) didn't correlate with eGFR decline rate in group S, but showed significant positive correlation with eGFR decline rate in ALL and group N ($P=0.002$, 0.012). Meanwhile the % of active lesion (cellular crescent and fibrocellular crescent) didn't correlate with eGFR decline rate in any group.

Conclusions: The correlation between histological parameters and renal prognosis in IgA nephropathy was different whether steroid therapy was given or not. Steroid therapy might influence histological parametersconcerning renal prognosis. Further analysis of the retrospective study is needed to clarify the relationship not using steroid therapy.

FR-PO706

Membranoproliferative-Like Henoch-Schönlein Purpura Nephritis in Children: Clinico-Pathological Features and Outcome Yanjie Huang,[1] Xiaoqing Yang,[1] Tatsuo Yamamoto.[2] *[1]Pediatrics, The First Affiliated Hospital of Henan University of Traditional Chinese Medicine, China; [2]Second Department of Medicine, Numazu City Hospital, Japan.*

Background: The prognostic value of renal clinical symptoms and histological lesion in children with membranoproliferative-like Henoch-Schönlein purpura nephritis (HSPN), which belongs to International Study of Kidney Disease in Children (ISKDC) grade VI, remains to be clarified.

Methods: We analyzed retrospectively the clinico-pathological features and outcome of 9 cases of membranoproliferative-like HSPN, which were all hospitalized patients in our hospital between 2008 and 2010. The morbidity of The ISKDC grade VI was 3.67% in 245 cases of HSPN with renal biopsy at the same period. Among the 9 patients, 7 (77.78%) cases presented with hematuria and nephrotic syndrome, and received steroids (oral prednisone or venous methylprednisolone pulse therapy) and immunosuppressive drugs (oral tripterygium glycosides or venous cyclophosphamidepulse therapy); 1 (11.11%) with hematuria and heavy proteinuria (>50mg/kg/24h) received oral prednisone and tripterygium glycosides; 1 (11.11%) with hematuria and moderate proteinuria (25~50mg/kg/24h) were only treated with oral tripterygium glycosides.

Results: Light microscopic examination showed that the diffuse membranoproliferative-like lesions, including glomerular mesangial and endothelial cell proliferation, mesangial interposition, and double contours formation in all cases. The predominant deposition of IgA and fibrinogen in mesangium and segmentally in capillary walls were observed in all cases. Nine patients were followed up for 1 to 3 years, and all had recovered.

Conclusions: In this study, the clinical manifestation of Membranoproliferative-like HSPN in children was serious, but the outcome was well. It may reason from all specimens with very mild glomerulosclerosis and tubulointerstitial fibrosis, and without severe destruction of the glomerular basement membrane.

FR-PO707

Low Proximal Tubular Expression of Megalin and Cubilin in Highly Albuminuric Patients with IgA Nephropathy Jia Sun,[1] Kjell R. Hultenby,[2] Annika Wernerson,[1] Jonas Axelsson,[3] Karin Elisabet Lindström.[1] *[1]CLINTEC, Karolinska Institutet, Stockholm, Sweden; [2]Laboratory Medicine, Karolinska Institutet, Stockholm, Sweden; [3]Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden.*

Background: Reabsorption of polypeptides from the glomerular filtrate occurs via receptor-mediated endocytosis in the proximal tubule (PXT), primarily mediated by the receptors, megalin and cubilin. While previous studies in dogs have indicated altered PXT lysosome formation in proteinuria, megalin and cubilin expression was not investigated and there are few human data. The aim is to investigate human PXT expression of megalin and cubilin in nephritis with high and low levels of albuminuria.

Methods: Using immunogold electron microscopy (iEM), we studied renal biopsy samples from subjects with clinical and immunohistochemically verified IgA nephropathy. From each biopsy, 10 PXT were randomly selected, and from each three images of the epithelium were obtained using a random procedure. PXT epithelial and intracellular expression of megalin, cubilin and albumin were tested using polyclonal antibodies.

Results: We assayed 6 patients with low (LA; n=2, GFR: 98-114ml/min, U-alb: 58-150mg/24h), medium (MA; n=2, GFR: 65-68ml/min, U-alb: 1499-1925mg/24h) and high (HA; GFR: 61-132ml/min, U-alb: 6938-9767mg/24h). Compared to LA, both MA and HA patients had significantly higher intra cellular but not membrane-bound albumin. Meanwhile, expression of cubilin and megalin in both locations decreased as albuminuria increased (Fig 1).

Conclusions: Highly albuminuric IgA nephropathy is characterized by decreased expression of megalin and cubilin, while intracellular albumin is increased.

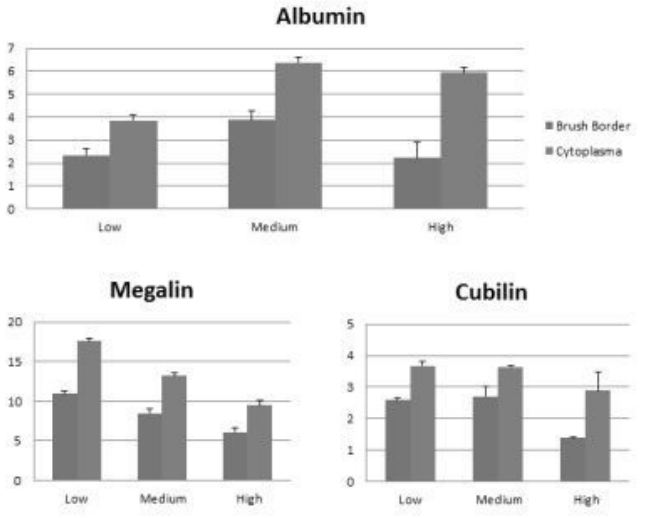

Figure 1. Expression of megalin, cubilin and albumin in LA, MA and HA patients.

FR-PO708

Thrombotic Microangiopathy in IgA Nephropathy Is Strongly Associated with Hypertension and Chronic Lesions Jamie S. Chua,[1] Johan W. De Fijter,[2] Jan A. Bruijn,[1] Ingeborg M. Bajema.[1] *[1]Pathology, Leiden University Medical Center, Leiden, Netherlands; [2]Nephrology, Leiden University Medical Center, Leiden, Netherlands.*

Background: In a recent publication from Karoui et al, 53% of 128 cases with IgA nephropathy (IgAN) had lesions consistent with thrombotic microangiopathy (TMA). The aim of our study was to validate these findings.

Methods: In this study, 69 consecutive biopsies from the period 2005-2012 were incorporated, of which 56 were previously diagnosed with IgAN and 13 with Henoch-Schonlein nephritis (HSN). Biopsies were re-evaluated according to the Oxford Classification. TMA, arterial intimal sclerosis and arteriolar hyalinosis were scored according to the guidelines of Cattran et al. Clinical data comprising age, sex and blood pressure were collected.

Results: TMA occurred in 20.3% (n=14) of all biopsies and in 23.2% (n=13) of all IgAN patients. Only 1 patient with HSN had TMA. TMA lesions were chronic in 78.6% (n=11) and acute in 21.4% (n=3). Mesangial hypercellularity, IFTA and arterial intimal fibrosis were found more frequently in patients with TMA than in those without TMA (X-square test, respective p-values 0.02; <0.001 and <0.001). Also hypertension was present more frequently in patients with TMA than in those without TMA (82% versus 41%, p=0.02). All reported associations remained statistically significant when omitting patients with HSN.

Conclusions: It was hypothesized by Karoui et al. that in their study, the high frequency of TMA in IgAN could be explained by the selection of patients from a hypertension-clinic. Our results confirm this hypothesis. Moreover, we also find TMA in IgAN to be associated with chronic damage. Although in our study, TMA was found less frequently in patients with IgAN than recently reported, it seems clear that IgAN-associated TMA is an underappreciated phenomenon.

FR-PO709

An Overview of Idiopathic Renal Thrombotic Microangiopathy Saeed Iftikhar Khilji, Catherine M. Brown, Anthony Dorman, Patrick O'Kelly, John J. Walshe. *Nephrology Department, Beaumont Hospital, Dublin, Ireland.*

Background: RenalThrombotic Microangiopathy is a well-recognized complication of numerous established medical conditions. We have observed a number of cases where no known cause was found; Idiopathic Renal Thrombotic Microangiopathy (IRTMA). However, reports on IRTMA are limited. The aim of this study was to give an overview and outcomes of IRTMA in our centre.

Methods: We conducted a retrospective review of all renal biopsies performed in our institution from 1996 to 2009 inclusive. The pts presenting with a known cause for TMA were excluded. Indications for renal biopsy, clinical course and outcomes were studied.

Results: A total of 5338 renal histopathology reports were reviewed and 436 pts were identified with a diagnosis of TMA. Follow up in our centre was available for 282 patients, with 80 patients confirmed as cases of IRTMA. Characteristics of IRTMA included a higher male to female ratio (n=46/34) and average age at the time of biopsy was 47 years (SD 13.52) ranging from 25 to 81 years. Indications for biopsy in patients with IRTMA were impaired renal function and hypertension(gp A),ARF(gp B),isolated proteinuria(gp C) and hypertension and proteinuria(gp D).Outcomes for the 4 groups are shown in Table 1.

Table 1: Indications and outcomes for patients with IRTMA

Outcomes	Group A- Impaired renal function and HTN 41%(n=33)	Group B- ARF 25%(n=20)	Group C- isolated proteinuria 23%(n=18)	Group D- HTN and proteinuria 11%(n=9)
Normal renal function	0	3	13	9
Impaired renal function	22	3	1	0
Haemodialysis or peritoneal dialysis	8	6	4	0
Renal Transplantation	3	8	0	0

Overall patient survival was 90%. Age at the time of biopsy and female sex were associated with better renal function and survival but were not statistically significant. A multivariate analysis revealed no independent risk factor for recovery to normal renal function or survival.

Conclusions: We believe that IRTMA is an under reported condition which requires further study. It presents most commonly with impaired renal function and hypertension followed by ARF. Our data suggests that the outcome is variable but patients with isolated proteinuria have the best clinical course.

FR-PO710

The New Histopathologic Classification for ANCA-Associated Glomerulonephritis Predicts Renal Relapse Arda Goceroglu,[1] Chinar Rahmattulla,[1] Robert A. De Lind van Wijngaarden,[2] Annelies Evaline Berden,[1] Kerstin W. Westman,[3] Oliver Flossmann,[4] Herbert Hauer,[5] David R.W. Jayne,[6] Niels Rasmussen,[7] Laure-Helene Noel,[8] Franco Ferrario,[9] Ruediger Waldherr,[10] Charles D. Pusey,[11] Ron Wolterbeek,[1] Ernst C. Hagen,[12] Jan A. Bruijn,[1] Ingeborg M. Bajema.[1] *[1]Leiden University Medical Center; [2]Erasmus Medical Center Rotterdam; [3]Skane University Hospital Malmö; [4]Royal Berkshire Hospital; [5]Medical Center Leeuwarden; [6]Addenbrooke's Hospital, Cambridge; [7]Statens Seruminstitut; [8]Necker Hospital; [9]San Gerardo Hospital; [10]University of Heidelberg; [11]Imperial College London; [12]Meander Medical Center.*

Background: This study investigates whether the new histopathologic classification of ANCA-associated glomerulonephritis (AAGN) [Berden, JASN 2010] predicts renal relapse during long term follow-up.

Methods: Diagnostic renal biopsies with minimally 10 glomeruli and clinical data of 109 patients with mild to severe AAGN from 2 multi-center European randomized clinical trials were available. Cox regression analysis was performed with the histopathologic classification, age and baseline eGFR (eGFR0) as candidate predictors. Diagnosis of renal relapse was based on clinical manifestations attributable to active AAGN. Data were censored for end-stage renal failure and last visit.

Results: The median follow-up was 91 months (range 0.2–136 months). During follow-up 16 (15%) patients had a renal relapse. The AAGN classification was, corrected for age and eGFR0, independently related to renal relapse (p=0.027). Patients with a focal class (HR=0.095, 95% CI 0.013-0.671, p=0.018) or crescentic class (HR=0.191, 95% CI 0.054-0.675, p=0.010) had a lower risk for renal relapse than patients with a sclerotic class biopsy. Patients with a mixed class did not show a lower risk than patients with a sclerotic class (HR=0.230, 95% CI 0.042-1.263, p=0.091).

Conclusions: In this long term follow-up study, the new histopathologic classification for AAGN proved to be an important predictor for renal relapse. Regarding the focal, crescentic and sclerotic class, the risk for renal relapse increased with ascending class.

FR-PO711

Dutch TRAnsplantation in VAScultis (DUTRAVAS)-Study: A Multi-Center Study on Renal Transplantation in ANCA-Associated Vasculitis (AAV) Arda Goceroglu,[1] Chinar Rahmattulla,[1] Annelies Evaline Berden,[1] Marlies E.J. Reinders,[1] Marcory van Dijk,[2] Carine Peutz-Kootstra,[3] Maarten H.L. Christiaans,[3] Iris Noorlander,[4] Roel Goldschmeding,[5] Arjan D. Van Zuilen,[5] Eric Steenbergen,[6] Luuk Hilbrands,[6] Lorraine Harper,[7] Mark A. Little,[8] Ernst C. Hagen,[9] Jan A. Bruijn,[1] Ingeborg M. Bajema.[1] *[1]Leiden University Medical Center; [2]University Medical Center Groningen; [3]Maastricht University Medical Center; [4]Erasmus Medical Center Rotterdam; [5]University Medical Center Utrecht; [6]Radboud University Nijmegen Medical Center; [7]University of Birmingham; [8]Trinity College Dublin; [9]Meander Medical Center.*

Background: It is practically unknown how a disease recurrence of AAV in a renal allograft defines graft outcome. We investigated the outcome of renal transplantation in Dutch patients with AAV with special focus on disease recurrence and graft survival within 5 years after transplantation.

Methods: Patients with AAV and a renal transplant were retrospectively recruited through the Dutch national pathology database PALGA. Transplant biopsies and clinical data were available for an analysis on 83 patients. Biopsies were scored according to Banff '09. Renal disease recurrence was scored according to the new histopathologic classification of ANCA-associated glomerulonephritis.

Results: Five years after transplantation, 16 grafts were lost: 4 due to recurrence (1 focal, 1 crescentic, 2 mixed class), 4 due to infarction, 3 due to acute rejection, 3 due to interstitial fibrosis and tubular atrophy, 2 due to sepsis and 1 due to PTLD. Ten patients had a relapse: 6 intra- and extrarenal, 3 intrarenal (3 focal, 1 crescentic, 4 mixed class and 1 unknown) and 1 extrarenal. There were 19 histologically proven acute rejections in 17 patients.

Conclusions: This is one of the largest studies to date investigating long-term outcome of renal allografts in AAV patients. The relapse rate in this cohort was 3.3% per patient year within 5 years follow-up. Five years graft-survival was 78.3%. In a substantial proportion of patients with disease recurrence in the kidney (4 out of 9) the recurrence led to graft loss within 5 years after transplantation.

FR-PO712

CCL-18 Is a Potential Target in Renal Tissues of Patients with ANCA Associated Rapidly Progressive Glomerulonephritis Gesa Stege,[1] Silke R. Brix,[1] Thorsten Wiech,[2] Elion Hoxha,[1] Benjamin Otto,[3] Kristin Klaetschke,[3] Ulf Panzer,[1] Gunter B. Wolf,[4] Wolfram J. Jabs,[4] Fedai Özcan,[4] Frieder Keller,[4] Dirk Bokemeyer,[4] Peter J. Heering,[4] Karl Wagner,[4] Saskia Schröder,[1] Ursula Kneissler,[2] Udo Helmchen,[2] Rolf A. Stahl.[1] *[1]III. Medizinische Klinik, Universitätsklinikum Hamburg-Eppendorf, Germany; [2]Nierenregister Hamburg, Universitätsklinikum Hamburg-Eppendorf, Germany; [3]Klinische Chemie, Universitätsklinikum Hamburg-Eppendorf, Germany; [4]RPGN Study Group, Germany.*

Background: In order to characterize potential new molecular targets in the pathogenesis of ANCA associated rapidly progressive glomerulonephritis (RPGN) we prospectively analyzed 62 patients with necrotizing glomerulonephritis.

Methods: RNA from 27 renal biopsies of these patients and from 17 control kidneys was used for microarray analysis. CCL-18 mRNA levels referred to 18S RNA were determined by real-time RT-PCR (TaqMan). CCL-18 protein was detected in serum by ELISA (R&D Systems) and by staining of renal biopsies with anti-CCL-18-antibody (PeproTech).

Results: Among 1,300 differentially regulated transcripts 935 were up-regulated. One of the most up-regulated transcripts in patients with ANCA associated RPGN was the chemokine C-C-type motif ligand 18 (CCL-18).

CCL-18 is a chemokine which plays a role in macrophage maturation and is a chemoattractant of T-cells. Compared with controls CCL-18 expression was 94 times higher in renal biopsies from patients with RPGN when measured by RT-PCR. Immunohistologic analysis of renal biopsies from patients with RPGN showed expression of CCL-18 protein in a subpopulation of tubulointerstitial cells, which belong to the monocytic or dendritic cell lineage. CCL-18 serum levels were significantly higher in patients with ANCA associated RPGN (AR) compared to those with non-ANCA associated RPGN (NR) (32 AR: median 95.1 ng/mL; IQR: 62 - 163.7 ng/mL vs 12 NR: median 37.1 ng/mL; IQR:20.3 - 67.4 ng/mL; p=0.0013).

Conclusions: Our findings suggest, that CCL-18 may play a pathophysiologic role in ANCA associated RPGN but needs further prospective clinical evaluations.

FR-PO713

Need of Interstitial Fibrosis Parameter on the Newly Proposed Simplified Glomerular Histological Classification to Predict the Longterm Outcome in Japanese Cohort of MPO-ANCA Associated RPGN Eri Muso,[1] Tomomi Endo,[1] Wako Yumura,[2,3] Kensuke Joh.[4] *[1]Division of Nephrology and Dialysis, Kitano Hospital the Tazuke Kofukai Medical Research Institute, Osaka, Japan; [2]4th Dept Internal Medicine, Tokyo Women Medical College, Tokyo, Japan; [3]Department of Nephrology, Jichi University School of Medicine, Jichi University School of Medicine, Tochigi, Japan; [4]Sendai Shaho Hospital, Sendai, Japan.*

Background: The newly proposed classification categorized into focal(F), crescentic(C), mixed(M), and sclerotic(S) showed prognostic value for 1- and 5-year renal outcomes (Berden et al :JASN 21: 2010). The predictive potency of this newly proposed categorization was performed in Japanese cohort with dominant MPO-ANCA positive MPA patients.

Methods: 87 patients,median age 63 years, male: female:37:50 Renal biopsy was performed in all before treatment. At least 5 year prognosis was observed and eGFR and renal survival at onset and 6months, one year and 5 years after renal biopsy period were analyzed. The histological categories based on glomerular lesion was performed as Berden et al (JASN 2010) In addition, the severity of interstitial fibrosis(IF) were categorized into three grade from .<50%, 50-75%, >75% and eGFR change of various classes adding these parameters on the 4 glomerular classes were compared.

Results: In 87 Japan cases, all were MPA patients. 41were F, 6:C, 26:M and 14:S, respectively. Higher frequency of F and rarer in C were noted. Median number of glomeruli per biopsy, renal survival data available for 5-years and life survival in one year were higher in Japan than JASN cases (25.9vs 14.8, 60/87 vs 47/100 and 76/87 vs 75/100, respectively) Survival rate of S was significantly poor. EGFR outcomes at 5years independently favorable in F and poor in S were consistent with JASN cases, however, no significant difference between C and M in Japan. After adding interstitial parameter, M with >75% IF showed significantly lower eGFR than F, C with same IF and M with less IF and higher than S with same IF.

Conclusions: In Japan, only in S group, the prediction was potent by glomerular classification. For other glomerular classes, the evaluation adding interstitial fibrosis parameter was necessary.

FR-PO714

Necrotizing Vasculitis of Small Renal Arteries in Patients with Anti-Neutrophil Cytoplasmic Antibody Associated Nephritis Akiko Endo,[1,2] Yoshifumi Ubara,[1] Keiichi Sumida,[1] Noriko Hayami,[1] Tatsuya Suwabe,[1] Junichi Hoshino,[1] Kenmei Takaichi,[1] Yoshihiro Arimura,[2] Akira Yamada.[2] *[1]First Department of Internal Medicine, Kyorin University School of Medicine, Tokyo, Japan; [2]Nephrology Center, Toranomon Hospital, Tokyo, Japan.*

Background: Anti-neutrophil cytoplasmic antibody (ANCA)-associated nephritis is considered to be a vasculitis of small vessels, including the glomerular capillaries, arterioles, and interlobular to arcuate arteries. Although crescent formation affecting glomerular capillaries had been reported as representative of this disease, the significance of coexisting vasculitis of small arteries (such as the arterioles, interlobular arteries, and arcuate arteries) has not been investigated.

Methods: The subjects were 50 patients with rapidly progressive nephritis and ANCA positivity whose renal biopsy specimens contained arterioles and interlobular arteries. They were retrospectively evaluated. Cellular crescents and/or necrotizing glomerulonephritis were noted in all 50 patients. Patients were classified as having necrotizing vasculitis with inflammatory cells and fibrinoid necrosis affecting their arterioles and interlobular arteries (Group A, n=10) or as being without necrotizing vasculitis (Group B, n=40), and were compared clinically.

Results: Granulomatosis with polyangiitis (GPA) was diagnosed in 40% of Group A versus only 2.5% of Group B ($p<0.05$). C-reactive protein (CRP) was significantly higher in Group A compared with Group B (11.58±6.19 versus 2.7±3.55 mg/dl, $p<0.05$). Pulmonary involvement was significantly more frequent in Group A compared with Group B (80% versus 37.5%, $p<0.05$), and the relapse rate was significantly higher in Group A than Group B ($p<0.05$).

Conclusions: Necrotizing vasculitis of small renal arteries may be closely related to elevation of CRP and pulmonary involvement.

FR-PO715

Intrarenal Plasma Cells in ANCA Associated Rapidly Progressive Glomerulonephritis Might Be a Marker of Disease Activity and Predict Clinical Outcome Silke R. Brix,[1] Thorsten Wiech,[2] Gesa Stege,[1] Ulf Panzer,[1] Gunter B. Wolf,[3] Wolfram J. Jabs,[3] Fedai Özcan,[3] Frieder Keller,[3] Dirk Bokemeyer,[3] Peter J. Heering,[3] Karl Wagner,[3] Udo Helmchen,[2] Rolf A. Stahl.[1] *[1]III. Medizinische Klinik, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; [2]Nierenregister, Institut für Pathologie, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; [3]RPGN Study Group, Germany.*

Background: The potential pathogenic role of B cells in the development of ANCA associated rapidly progressive glomerulonephritis (RPGN) becomes increasingly evident and is supported by the successful treatment of these patients with Rituximab. The significance of antibody producing plasma cells in these inflamed kidneys is, however, unclear.

Methods: We therefore studied the appearance and localisation of plasma cells in 10 renal biopsies of patients with ANCA associated RPGN (MPO-ANCA, n=5; PR3-ANCA, n=5). Glomeruli were categorised for the presence of necrosis, crescents, sclerosis and capsular rupture. Plasma cells of 94 periglomerular and 50 interstitial fields were counted using immunohistochemical stains (Immunoglobulins A, G and M).

Results: Plasma cells were seen in all stages even in the early stages of glomerular damage. The number of periglomerular plasma cells increased significantly when glomeruli had a capsular rupture (64 vs. 30; $p=0.04$). According to the classification of Berden et al., these 10 biopsies contained 1 focal case, 3 crescentic and 5 mixed cases as well as 1 sclerotic case. Initiation of immunosuppressive treatment before biopsy did not alter the density of plasma cells. In our cohort a high number of plasma cells correlated with a poor renal function at the time of biopsy ($p=0.03$). Patients with plasma cell rich biopsies showed greater improvement in renal function after six months compared to those with few plasma cell infiltrates ($p=0.03$).

Conclusions: A high number of intrarenal plasma cells might be a marker of disease activity. Furthermore the presence of plasma cells may predict a better response to treatment and could influence the decision towards a therapy of B cell depletion.

FR-PO716

Clinico-Pathological Characteristics of Rapidly Progressive Glomerulonephritis (RPGN) of Post-Infectious Glomerulonephritis (PIGN), Compared with RPGN of Anti-Neutrophil Antibody-Associated Glomerulonephritis (ANCA-GN) Yu Tateishi,[1] Toshiyuki Komiya,[2] Tatsuo Tsukamoto,[2] Eiji Ishimura,[1] Masaaki Inaba,[1] Eri Muso.[2] *[1]Osaka City University Graduate School of Medicine, Japan; [2]Kitano Hospital, Japan.*

Background: PIGN, a relatively rare type of RPGN, has been reported to recently increase in the elderly. The aim of the present study is to reveal the clinico-pathological characteristics of RPGN of PIGN to make a rapid differential diagnosis from RPGN of ANCA-GN.

Methods: Fifty five cases of RPGN, which consisted of 8 PIGN (7 males and 1 female, 69.3±8.4 years) and 47 ANCA-GN (29 males and 18 females, 69.2±12.1 years) who were admitted from 2001 to 2010, were retrospectively examined. Clinical data at renal biopsy were compared between the two types of RPGN. Pathological findings of renal biopsy, evaluated according to the pathological classification of ANCA-GN (Clin Exp Nephrol 2008, 12: 277), were compared between the two.

Results: All 8 PRGN of PIGN had bacterial infection with negative titer of ANCA, and was treated by antibiotics after the diagnosis. All 47 RPGN of ANCA-GN were treated by corticosteroid after the diagnosis. Urinary protein levels of PIGN group were significantly higher than those of ANCA-GN group (8.9±5.7 v.s. 1.1±0.3 g/day, $p<0.05$). Serum IgA and compliment C3 levels of PIGN were significantly higher than those of ANCA-GN group (631±256 v.s. 332±41 mg/dL, $p<0.05$; 86.1±15.5 v.s. 110.1±8.3 mg/dL, $p<0.05$; respectively). Regarding pathological findings, mesangial cell proliferation (46.9±14.0% v.s. 22.9±21.2% of all glomeruli, $p<0.01$), and endocapillary proliferation (24.9±15.1% v.s.10.3±15.9%, $p<0.05$) were significantly more frequently observed in PIGN group than in ANCA-GN group, but cellular and fibrocellular crescents were significantly less in the former ($p<0.05$). Immunopathologically, positive staining of IgA was significant in PIGN, while negative staining in all ANCA-GN.

Conclusions: RPGN of PIGN was characterized by nephrotic range of proteinuria, higher serum IgA and complement 3 levels, and pathological findings of mesangial and endocapillary proliferation. These clinico-pathological features are helpful to differentiate RPGN of PIGN from RPGN of ANCA-GN.

FR-PO717

Laser Microdissection and Proteomic Analysis of Amyloidosis, Fibrillary and Immunotactoid Glomerulonephritis Sanjeev Sethi,[1] Julie A. Vrana,[1] Jason David Theis,[1] Anjali Sethi,[3] Samih H. Nasr,[1] Lynn D. Cornell,[1] Nelson Leung,[2] Fernando C. Fervenza.[2] *[1]Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN; [2]Internal Medicine, Mayo Clinic, Rochester, MN; [3]Drexel University College of Medicine, Philadelphia, PA.*

Background: Organized deposits are present in amyloidosis, fibrillary and immunotactoid glomerulopathy. The deposits are fibrillar in amyloidosis and fibrillary glomerulonephritis and microtubular in immunotactoid glomerulopathy. We performed these studies to determine the composition of the deposits to better characterize these conditions.

Methods: We performed laser microdissection of glomeruli in 5 cases of amyloidosis and 3 cases each of fibrillary and immunotactoid glomerulopathy. This was followed by tandem mass spectrometry based proteomics analysis.

Results: We divide the results into 3 major groups: structural proteins, complement proteins, and immunoglobulin/others.

Structural Proteins: Large spectra of vimentin, collagen alpha-3, basement membrane heparin sulfate, vinculin and fibrillin are noted in immunotactoid glomerulopathy compared to fibrillary glomerulonephritis. On the other hand, large spectra of apolipoprotein E, vitronectin, and clusterin are noted in fibrillary glomerulonephritis compared to immunotactoid glomerulopathy. Other than apolipoprotein E, vitronectin and serum amyloid P component, amyloid deposits do not contain large spectra of any other structural proteins compared to fibrillary and immunotactoid glomerulopathy. Surprisingly, small spectra of SAP are also noted in fibrillary and immunotactoid glomerulopathy.

Complement Proteins: Fibrillary and immunotactoid glomerulopathy contain large spectra of complement factors of the classical pathway compared to amyloidosis.

Immunoglobulins and other: The cases tested for fibrillary and immunotactoid glomerulopathy contain spectra for Ig gamma-1C region while amyloidosis contain spectra for light chains, serum amyloid A protein or leukocyte derived chemotaxin-2 (depending on the type).

Conclusions: There is a distinct pattern of deposition of structural, complement and fibrillar/amyloidogenic proteins in amyloidosis, fibrillary and immunotactoid glomerulopathy.

FR-PO718

Distinguishing Features of κ Light Chain AL Amyloidosis in Clinical Manifestation and Renal Biopsy Ying Yao, Youkang Zhang, Su-xia Wang. *Renal Division, Department of Medicion, Peking University First Hospital, Beijing, China.*

Background: The aim of this study was to compare the clinical and pathological features among patients with renal AL amyloidosis derived from κ light chain (AL-κ) and λ light chain (AL-λ).

Methods: We collected 190 patients with biopsy-proven renal AL amyloidosis in our institute between 1990 and 2011. AL was diagnosed by the demonstration of selective λ or κ staining of the amyloid by immunohistochemistry. Among them, 25 cases were confirmed as AL-κ, and 165 cases were AL-λ. The clinical and laboratory data at renal biopsy was recorded and used for analysis. We reassessed the kidney biopsies of all patients, and the extent of amyloid deposition in glomeruli (GA), blood vessels (VA) and interstitium (IA) were evaluated semiquantitatively. The renal amyloid load (TA) was defined by the sum of GA, VA, and IA.

Results: Monoclonal proteins were detected by serum immunofixation electrophoresis(IFE) in 39.1% of AL-κ and 59.7% of AL-λ patients ($P=0.06$). The most common monoclonal immunoglobulin type was IgM (21.7%) in AL-κ, whereas IgG (27.1%) in AL-λ, $P<0.001$. AL-κ patients presented with higher incidence of extrarenal organ involvement than AL-λ (hepatic involvement 75% versus 24.4%, $P<0.001$; cardiac involvement 72.7% versus 34.2%, $P=0.020$). Renal function and proteinuria were similar between the two groups. In renal biopsy, the extent of vascular deposition and the renal amyloid load were more severe in AL-κ than AL-λ.

Comparison of main clinical and pathological characteristics between patients with AL-κ and AL-λ

	AL-κ	AL-λ	P value
Male, n (%)	13(52)	107(64.8)	0.215
Age, years	53.9±11.2	57.6±10.6	0.115
Positive in serum IFE, n (%)	9(39.1)	80(59.7)	0.06
Positive in urine IFE, n(%)	7(53.8)	56(75.7)	0.104
Proteinuria, g/day	6.38±4.1	6.39±3.9	0.989
Nephrotic syndrome, n(%)	19(76.0)	115(76.2)	0.986
Renal insufficiency, n(%)	4(17.4)	27(18.2)	1
Heart involvement, n(%)	8(72.7)	32(34.2)	0.020
Liver involvement, n (%)	12(75)	21(24.4)	<0.001
VA, median(IQR)	3.5(3-4)	2(1-3)	0.002
TA, median(IQR)	8(5.75-9.25)	6(4-7)	0.004

IQR, interquartile range

Conclusions: Patients with AL-κ were more likely to presenting with hepatic and cardiac involvement and had severe vascular amyloid deposition in renal biopsy.

FR-PO719

The Modern Spectrum of Renal Biopsy Findings in Diabetics Shree G. Sharma,[1] Andrew S. Bomback,[2] Jai Radhakrishnan,[2] Leal C. Herlitz,[1] Michael B. Stokes,[1] Glen S. Markowitz,[1] Vivette D. D'Agati.[1] *[1]Pathology, Columbia University Medical Center (CUMC); [2]Nephrology, Columbia University Medical Center (CUMC); [3]Nephrology, CUMC; [4]Pathology, CUMC; [5]Pathology, CUMC; [6]Nephrology, CUMC; [7]Pathology, CUMC.*

Background: With the epidemic of diabetes mellitus (DM), renal biopsies performed in diabetics are increasing in number and complexity.

Methods: To assess modern trends, we performed a single-center study of clinical-pathologic findings in all diabetics biopsied over the past year. Among 2642 native kidney biopsies, 620 (23.5%) were from diabetics.

Results: The cohort included 376 (60.7%) males with mean age 60.1 ± 12.3 y and mean duration of DM 11.4 ± 8.8 y. Mean creatinine was 3.39 mg/dL, including 22% with stage 1 or 2, 27% stage 3, 25% stage 4 and 27% stage 5 CKD. On renal biopsy, 36% had nondiabetic renal disease (NDRD) alone; 37% had diabetic nephropathy (DN) alone; and 26% had DN plus NDRD as shown.

Table 1

	DN	DN + NDRD	NDRD	p-value*
Number (%)	227 (37)	164 (26)	220 (36)	
Age (y)	57	62.7	61.4	<0.001
Duration of DM (y)	13.8	13.7	7.2	<0.001
Creatinine (mg/dL)	2.9	3.9	3.4	0.004
eGFR	42.2	33.0	45.8	0.003
Nephrotic proteinuria	123 (54.2%)	77 (47%)	69 (31.4%)	<0.001
Active urine sediment	63 (27.8%)	62 (37.8%)	74 (33.6%)	0.3
AKI (no baseline CKD)	101 (44.5%)	85 (51.8%)	110 (50.0%)	0.4
AKI on CKD	37 (16.3%)	43 (26.2%)	37 (16.8%)	0.04
All AKI	138 (60.8%)	128 (78.1%)	147 (66.8%)	0.001
Low C3/C4	2 (0.9%)	16 (9.8%)	12 (5.5%)	<0.001
M-spike	16 (7.1%)	13 (7.9%)	30 (13.6%)	0.04

* One way ANOVA

In NDRD alone, FSGS (27%), ATN (17%), hypertensive nephrosclerosis (12%), IgA nephropathy (10%), MGN (8%) and pauci-immune GN (7%) comprised 80% of diagnoses, compared to ATN (43%), hypertensive nephrosclerosis (24%), FSGS (7%) and IgA nephropathy (7%) for NDRD plus DN. Among serologies, ANCA, M spike and low C3/C4 were more likely than HCV to identify a related NDRD. In multivariate analyses, nephrotic range proteinuria (p=0.02) and longer duration of DM (p<0.001) were associated with increased odds of any DN. DM duration ≥12 y was the best predictor (57% sensitivity, 73% specificity) of DN alone.

Conclusions: Judicious use of renal biopsy has uncovered NDRD alone or superimposed on DN in the majority (62%) of biopsies.

FR-PO720

Collapsing Glomerulopathy in Advanced Diabetic Nephropathy Steven P. Salvatore,[1] Chandra B. Chandran,[2] Chike N. Okechukwu,[3] James M. Chevalier,[1] Surya V. Seshan.[1] *[1]Weill Cornell Med Coll, NY, NY; [2]St. Joseph's Med Center, Paterson, NJ; [3]Crozer-Chester Med Center, Chester, PA.*

Background: Collapsing glomerulopathy (CG) is a pattern of podocyte injury presenting with massive proteinuria, rapid progression, and relative resistance to therapy. Etiologies include viral infections, drugs, and autoimmune conditions in native kidneys, and obliterative arteriopathy in transplants, previously proposed due to ischemic podocyte injury. Glomerular ischemia also occurs in diabetic nephropathy (DN) with severe vascular hyalinosis.

Methods: DN was seen in 12.5% of native kidney biopsies (2003-2011) of which 4.8% had at least 1 glomerulus with CG. Immunostaining for vascular endothelial growth factor (VEGF), cytokeratin (CK) and podocyte markers WT-1, synaptopodin, podocin, and beta-dystroglycan were analyzed. A DN control group without CG was used for comparison.

Results: The 26 patients were 26-80 years old and mostly type 2 diabetics (78%) with long-standing disease (mean (M) 14 years), insulin dependence (67%), and hypertension (83%). Serum creatinine (Cr) levels were elevated, M 3.8 mg/dL (1.1-10.4). Most had nephrotic range proteinuria, M 9.8 g/d (2-29). No patients had HIV. Renal biopsy showed segmental or global glomerulosclerosis (GS) in 2% (0-23) and 33% (0-80), respectively. DN classification was Class IV (12), III (8), IIb (4), and IIa (2). CG was present in 2-30% (M 16%) of glomeruli. Vascular disease was prominent, moderate in 44% and severe in 56%. Extensive arteriolar hyalinosis with >50% luminal stenosis was seen in 85.2% of cases. Markers of podocyte differentiation were lost in the glomeruli with CG for 100% synaptopodin and podocin, 75% beta-dystroglycan, and 70% WT-1. CK was positive in 70% and VEGF overexpressed in 43%. Follow-up on 17 patients: 13 developed chronic renal failure M 7 months from the biopsy (0-36), significantly more than controls (P=.005). The 4 remaining, 5-24 months follow-up, had increasing Cr with stable proteinuria.

Conclusions: CG contributes to an increased level or new onset of proteinuria in DN. Identification of CG in advanced DN with significant vascular hyalinosis is presumably due to podocyte ischemia and is of prognostic significance.

FR-PO721

IgG Subclass Distribution in Different Stages of Membranous Glomerulonephritis Tibor Nadasdy,[1] Sergey V. Brodsky,[1] Anjali A. Satoskar,[1] Gyongyi Nadasdy,[1] Brad H. Rovin,[2] Lee A. Hebert.[2] *[1]Pathology, The Ohio State University, Columbus, OH; [2]Medicine, The Ohio State University, Columbus, OH.*

Background: Recent breakthrough findings revealed that most patients with idiopathic (primary) membranous glomerulonephritis (MGN) have IgG4 antibodies to the phospholipase A2 receptor (PLA2R). These IgG4 antibodies can be detected in the glomerular immune complexes and they colocalize with PLA2R. In secondary forms of MGN, such IgG4 antibodies are absent or less prevalent. There are no studies addressing the IgG subclass distribution across different stages of MGN.

Methods: During a 25 month period, we identified 157 consecutive biopsies with MGN with adequate tissue for light, immunofluorescence and electron microscopy. Of the 157 MGN cases, 114 were primary MGN; 43 were secondary MGN. The glomerular stage distribution was the following: stage 1 n=22; stage 2 n=50; stage 3 n=25, Stages 3 to 4 (overlap between stages 3 and 4) n=17. We compared the Intensity of IgG subclass staining (on a semiquantitative scale of 0 to 3+) and the IgG subclass dominance between primary and secondary MGN and between the different stages of MGN.

Results: In primary MGN most (76% of cases) were IgG4 dominant. In contrast, in secondary MGN IgG1 was dominant in 60% of biopsies (p=0.0018). Interestingly, in early stage (stage 1) primary MGN, IgG1 was the dominant IgG subclass (64% of cases); in all later stages IgG4 dominated (82%, 80% and 76% in stages 2, 3 and 3 to 4, respectively) (p=0.0493). The staining intensity for IgG1 in stage 1 MGN was 2.1 +/- 0.8 versus a 1.6 +/- 1.3 intensity for IgG4. In all later stages, IgG4 showed the strongest staining. In secondary forms of MGN, we did not find such correlations (heterogeneous group with low case numbers).

Conclusions: In early stage MGN, antibody response is different from later stages, with IgG1 dominant deposits. It is possible that early on, antigens other than PLA2R play an important role, Alternately, there may be a subclass switch in the antibody response with IgG4 taking over later as the dominant immunoglobulin.

Nonmuscle Myosin Heavy Chain IIA (NMMHC-IIA) as a Dominant Target Antigen in Human Idiopathic Membranous Nephropathy Chang Ying Xing,[1] Suyan Duan,[1] Peter W. Mathieson,[2] Moin Saleem,[2] Gang Liu,[3] Haiyan Wang.[3] *[1]Dept. of Nephrology, The First Affiliated Hospital of Nanjing Medical University, Nanjing, China; [2]Academic Renal Unit and Children's Renal Unit, University of Bristol, Bristol, United Kingdom; [3]Renal Division, Peking University First Hospital, Beijing, China.*

Background: Idiopathic membranous nephropathy (IMN) is the main pathological type in adult nephrotic syndrome. Although the NEP and PLA2R, etc. as target antigens have been identified in the pathophysiology of IMN, there are still lots of unanswered questions to be resolved. Our preliminary study generated a new rat model induced by rabbit anti-human podocyte protein antibody, whose clinical and pathological changes resembled the human MN, and the target antigen of this model was sequentially identified to be NMMHC-IIA expressed on podocytes.

Methods: Cell lysates were prepared from human podocytes. Western blotting(WB) and co-immunoprecipitation(Co-IP) were performed with the total cell lysates using serum from patients with IMN or other glomerular diseases or normal individuals. Mass spectrometry was used to analyze the reactive protein bands and confirm the identity of the target antigen with specific antibodies. ELISA was used to compare the antibody concentration in different patients.

Results: In Co-IP, serum from 29 of 35 patients (82.9%) with biopsy-proven IMN specifically identified a 227-kD protein, which was sequentially identified to be the NMMHC-IIA confirmed by mass spectrometry. By WB under reducing and nonreducing conditions respectively, 14 of other 15 IMN(93.3%) had circulating antibodies reacting to the NMMHC-IIA protein, while 13 of them(80.0%) had detectable anti-PLA2R antibodies. There were 11(73.3%) patients had both antibodies. Furthermore, ELISA showed much higher concentrations of the antibodies in IMN than other proteinuric diseases and normal controls(p<0.05). The follow-up results in 10 patients indicated that the concentration of autoantibodies against NMMHC-IIA was significantly positively correlated with 24-hour urinary protein.

Conclusions: Antibody against NMMHC-IIA, a podocyte protein, can be detected in a majority of patients with INM, indicating that is a major autoantigen in this disease.

FR-PO723

Autoantibody Epitope Mapping of the Phospholipase A2 Receptor as Autoantigen in Membranous Nephropathy Astrid Behnert,[1] Beina Teng,[1] Meifeng Zhang,[2] Andrej Skoberne,[1] Marvin J. Fritzler,[2] Hermann G. Haller,[1] Mario Schiffer.[1] *[1]Hannover Medical School, Hannover, Germany; [2]University of Calgary, Calgary, AB, Canada.*

Background: In idiopathic membranous nephropathy (IMN) PLA_2R was discovered as autoantigen and thus far, the published evidence suggested a conformation dependent antigen. An indirect immunofluorescence assay on cells overexpressing the receptor is the standard to detect and quantify PLA_2R autoantibodies. We examined antibody-antigen interactions in order to identify specific epitopes and reactive domains of PLA_2R that could be used to improve testing by using small peptides in various diagnostic platforms. We also tested recombinant overexpressed receptor as target antigen on ELISA and Luminex beads.

Methods: Epitope mapping was done using SPOT technology. Immunoblotting was then performed with patient serum as primary antibody (ab) and anti-human IgG_4 as a secondary ab. ELISA plates were coated with PLA_2R peptides and analyzed with patient sample as primary ab and HRP conjugated anti-human IgG_4 as detection ab. A capture immunoassay was performed by coupling anti-GFP ab to Luminex beads followed by capture of GFP-tagged PLA_2R from transfected HEK293 cell lysates. The beads were incubated with patient sample and diluted PE conjugated anti-human IgG and reactivity determined on a Luminex 100.

Results: Seven reactive antigen determinants were identified using epitope mapping and when these putative epitope regions were analyzed by testing synthetic peptides in ELISA, the absorbance of positive samples was higher than of negative and control samples but the difference was not significant ($p>0.05$). However, in the Luminex based capture assay, the median fluorescence units of positive samples was significantly higher than that of negative and healthy control samples.

Conclusions: In summary, we developed a novel observer independent assay for detecting PLA_2R autoantibodies. We could confirm that antibody binding to PLA_2R seems to depend to a large extent, on a conformational epitope. However, in our SPOT technology assay we identified multiple different epitopes that PLA_2R antibodies of patients with IMN were reacting to, confirming that epitope spreading occurs in IMN.

FR-PO724

Rebiopsy in Idiopathic Membranous Nephropathy (IMN) on Long Term Tacrolimus Marie Condon, H. Terence Cook, Megan Griffith. *Imperial College Kidney and Transplant Centre, London, United Kingdom.*

Background: Remission of nephrotic syndrome due to IMN can be achieved with tacrolimus (Tac). Relapse rates are high on withdrawal of therapy and many pts require long term treatment. Although stable renal function is maintained in most pts, little is known about the underlying histology. This study reports histology in repeat biopsies (RBs).

Methods: 23 pts on Tac for > 12 mths have had RBs at a median time of 3.39 yrs (range 1.69 – 8.79). 11/23 in complete remission (CR) for consideration of Tac withdrawal (WD); 3/23 for rising creat in partial remission (RCPR); 9/23 for nephrotic relapse (NPR) (6/9 on Tac; 3/9 during/after withdrawal).

Results:

	Biopsy 1 - Pre Tac			Biopsy 2 > 12months on Tac			
n=23	M(R) Creat umol/L	M(R) % Segmental Sclerosis (SS)	M(R) % Tubular Atrophy (TA)	M(R) Creat umol/L	M(R) % SS	M(R) % TA	No. (%) with Arteriolar Hyaline
WD=11	97(83-203)	0(0-67)	10(0-40)	132(54-188)	8(0-20)	20(5-50)	4(36)
RCPR=3	68(61-71)	0(0-9)	5(5-10)	130(123-265)	11(10-50)	30(20-30)	2(67)
NPR=9	117(74-172)	0(0-29)	10(0-15)	122(71-239)	9(0-55)	30(10-50)	2(22)
All	96.5(61-203)	0(0-67)	10(0-40)	131(54-265)	9(0-55)	20(5-50)	8(35)

M(R) = Median(Range). Change in % SS: WD (p=0.31), RCPR (p=0.14), NPR (P=0.08). Change in % TA: WD (p=0.18), RCPR (p=0.02), NPR (p=0.001).

2/11 WD pts had stage I&II deposits on RB, despite being in CR for > 12 mths. Tac withdrawal was commenced on the other 9; 3/9 relapsed at 5, 5, & 7 mths after Tac was stopped (On RB at withdrawal 1/3 had no deposits; 2/3 had stage IV deposits). 2/3 biopsied for RCPR had a TIN (1/2 with stage I&II deposits); 1/3 had stage I&II in addition to III&IV deposits, arteriolar hyaline was also present.

Conclusions: Pts who do not achieve/sustain a CR, appear to have more progression of scarring on RB. However, even in pts with stable GFR and in CR (the WD group), an increase in SS and TA may occur. It is not clear whether these histological changes are part of the natural history of IMN or as a result of Tac; it will be important to follow the GFR in these pts. In our pre withdrawal biopsies, the absence of new immune deposits did not predict sustained remission and no specific histological features predicted relapse. More work is required to identify pts at risk of relapse.

FR-PO725

Increased Risk of Treatment Failure and End-Stage Renal Disease in Familial FSGS Xu Hao, Jingyuan Xie, Jun Ma, Qiongxiu Zhou, Wen Xue, Hong Ren, Nan Chen. *Nephrology, Nephrology Department, Ruijin Hospital Affiliated to Shanghai Jiaotong University School of Medicine, Shanghai, China.*

Background: Few studies comparedsporadicand familial focal segmental glomerular sclerosis (FSGS). The aim of this study is to study the clinical features and prognosis of FSGS patients with or without family history.

Methods: We enrolled 124 family FSGS patients from 83 families (FFSGS group) and 124 age and sex matched sporadic FSGS patients (SFSGS) in this study. FSGS patients were proven by renal biopsy. The mean follow up time was 26.5±19.5 month in SFSGS group and 28.3±12.5 month in FFSGS group ($p>0.05$). Baseline clinical characteristics of allparticipants were recorded. Primary outcomes of this study were ESRD and remission of proteinuria (defined as 50% reduction from baseline proteinuria).

Results: There were no difference in age and gender between the two groups. Patients in SFSGS group had higher urine protein secretion (2.0±1.8 vs 1.4±1.4g/24h) and lower serum albumin (3.0±1.1 vs 3.6±6.2g/dL) than FFSGS group ($p<0.01$). Accordingly, more patients had NS in SFSGS group than FFSGS group (22.6% vs 13.3%, $p=0.003$). The baseline serum creatinine and eGFR between the two groups were similar. In addition, 35.16% of sporadic and 43.75% of familial patients had high blood pressure when biopsy was performed ($p=0.08$). During follow-up period, remission of proteinuria was observed in 48.39% sporadic patients while only in 23.08% familial patients ($p=0.006$).The median ESRD-free survival times for SFSGS and FFSGS group were 96 and 72 months respectively (Log rank $p=0.04$).

Conclusions: Familial FSGS patients had increased risk to proteinuriatreatment failure and progression to ESRD compare to sporadic FSGS patients.

FR-PO726

Low Glomerular Density with Glomerulomegaly in Primary Focal Segmental Glomerulosclerosis Kentaro Koike, Nobuo Tsuboi, Yasunori Utsunomiya, Tetsuya Kawamura, Tatsuo Hosoya. *Division of Kidney and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan.*

Background: Studies have shown that glomerular size in patients with focal segmental glomerular sclerosis (FSGS) is large. Also, it is known that FSGS lesions are more frequently observed in juxtamedullary cortex in which the hemodynamic stress is more prominent. Observations of FSGS in very low birth weight infants suggest a link between FSGS and low nephron number. These findings indicate that increased glomerular capillary pressure associated with low number of glomeruli may be one of the important mechanisms implicated in the development of FSGS. We have recently reported that a low glomerular density (GD, number of glomeruli per renal cortical area) in the renal biopsy is associated with an enlarged glomerular size as well as a lesser response to corticosteroid therapy in patients with minimal change disease (MCD) (AJN, 2011). The present study aimed to prove our hypothesis that GD represents the disease status of primary FSGS.

Methods: The GD and the glomerular volume (GV) of the primary FSGS patients (n=23) were measured using a computed imaging analyzer. Biopsies of kidney transplant donor (KTD) (n=20) and those of MCD (n=50) were used as comparison.

Results: As compared to KTD and MCD, the GD of the FSGS patients was low (3.1±1.0 vs. 3.6±1.1 vs. 2.1±1.0/mm^2, $p<0.001$). In contrast, the GV in the FSGS patients was significantly larger than those of the KTD and MCD (2.4±0.6 vs. 2.5±0.8 vs. 5.0±0.3×$10^6$$\mu m^3$, $p<0.001$). Interestingly, the GD showed significant inverse correlations to the rate of FSGS lesions ($r=-0.427$) as well as the GV values ($r=-0.420$). A comparison of FSGS patients with nephrotic syndrome (NS) (n=10) and those without NS (n=13) showed different patterns of GD/GV distribution. In the FSGS patients with NS, the GD showed a relatively extensive distribution like those observed in the KTD and the MCD patients. In the FSGS patients without NS, the GD was extremely low and the GV tended to show further enlargement.

Conclusions: These results suggest that a low GD, together with glomerulomegaly, is a histological characteristic in renal biopsies of primary FSGS patients.

FR-PO727

Upper Limit of Normal for Number of Globally Sclerotic Glomeruli on a Sectioned Core-Needle Biopsy of the Renal Cortex Walter K. Kremers,[1] Hisham Elsherbiny,[1] Mariam P. Alexander,[1] Emilio D. Poggio,[2] Hatem Amer,[1] John C. Lieske,[1] Andrew D. Rule.[1] *[1]Mayo Clinic, Rochester, MN; [2]Nephrology, Cleveland Clinic, Cleveland, OH.*

Background: Global glomerulosclerosis is characteristic of chronic kidney disease but also occurs with normal aging. The objective of this study was to determine the upper limit of normal (ULN) for number of globally sclerotic glomeruli.

Methods: Living kidney donors had a core-needle biopsy of the donated kidney cortex during the transplant surgery at the Mayo Clinic from 1999 to 2009. One paraffin-embedded section (3 um thickness) stained with periodic acid-Schiff was scanned into a high resolution image file and the number of non-sclerosed glomeruli (NSG) and globally sclerosed glomeruli (GSG) were counted. Linear regression was used to predict mean number of GSG based on demographics and biopsy characteristics and quantile regression estimated the 95^{th}%ile for number of GSG.

Results: After excluding 4 donors with >25% interstitial fibrosis on renal biopsy, there were 952 donors (mean age 44 years, 43% were male, 6.3% had hypertension). Predictors of the number of GSG on renal biopsy were age, number of NSG, area of cortex, presence

of corticomedullary junction, presence of capsule, and hypertension (p<.05 for all). In the multivariable model only age, cortical area and hypertension were independent predictors (p<.05 for all). For ease of use in clinical practice, the quantile regression model was fit with age and number of NSG as predictors with only a slight decrease in the model goodness-of-fit. The 95th percentile for number of GSG is shown in the Table.

Upper limit of normal for the number of GSG on a renal biopsy section

Age	0-4	5-8	9-16	17-32	33-64
18-30	0	0	0	1	1
31-35	0	1	1	1	2
36-40	1	1	1	1	2
41-45	1	1	1	2	3
46-50	1	1	2	3	4
51-55	2	2	2	3	5
56-60	2	2	3	4	6
61-65	2	3	3	5	7
66-70	3	3	4	5	8
71-75	3	4	4	6	9

Conclusions: The ULN for number of GSG varies by age and the number of NSG on the renal biopsy. These thresholds may help identify chronic pathological injury in patients who do not have significant interstitial fibrosis.

Funding: NIDDK Support

FR-PO728

Distribution of Glomerular Density in Different Cortical Zones of the Human Kidney Go Kanzaki,[1] Nobuo Tsuboi,[1] Yasunori Utsunomiya,[1] Akira Shimizu,[2] Tetsuya Kawamura,[1] Tatsuo Hosoya.[1] *[1]Division of Kidney and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Minato-ku, Tokyo, Japan; [2]Department of Analytic Human Pathology, Nippon Medical School, Bunkyo-ku, Tokyo, Japan.*

Background: Recent studies have suggested that low nephron number associated with low birth weight is a risk factor for progression to ESRD and cardiovascular events in later life. We have recently reported that glomerular number per renal cortical area in biopsies (glomerular density: GD) differs significantly between individuals, and that a low GD predicts a worse renal outcome in patients with IgA nephropathy and idiopathic membranous nephropathy (CJASN2010, NDT2011). These results suggest that GD represents each nephron number and is useful in the prediction of CKD progression. However, variations of GD in anatomically different cortical zones remain undetermined in human kidney.

Methods: A total of 100 autopsies without CKD were included in this study. The GD and the glomerular volume (GV) in both of the superficial and juxtamedullary cortexes were measured using a computed imaging analyzer. The measured values were analyzed in relation to the clinicopathological features of these autopsies.

Results: As a whole, the GD and the GV had approximately 3.5-fold and 4.9-fold differences between the individuals, respectively. In addition, a close inverse correlation was observed between the GD and the GV (r=-0.494, p<0.001). The GD in juxtamedullary cortex was lower than that in the superficial cortex (2.2±0.6 vs. 3.0±0.7/mm^2, p<0.001). In contrast, the GV in juxtamedullary cortex was higher than that in the superficial cortex (3.1±0.8 vs. 2.7±1.0 x10^{6}μm^3, p<0.001). The GD of the juxtamedullary cortex was associated with the kidney weight. On the other hand, the GD of the superficial cortex was associated with the rate of global glomerulosclerosis and the presence of atherosclerosis lesions. Age, BMI, kidney function, heart weight and history of hypertension did not show significant relationships with the GD levels of each cortex.

Conclusions: Independent of potential variations observed between individuals, there are significant zonal differences in the distribution of GD in human kidney.

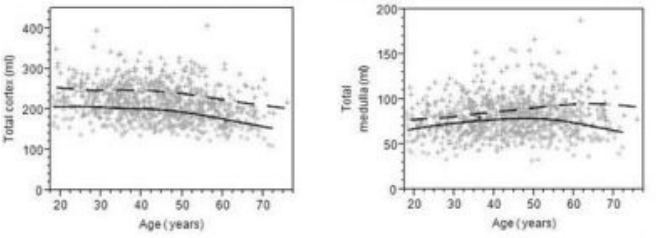
FR-PO729

Kidney Cortical Volume, but Not Medullary Volume, Decreases with Age and Partially Accounts for the Age-Related Decline in Glomerular Filtration Rate Xiangling Wang, Ramesh Avula, Hatem Amer, Leah Walters, Terri J. Vrtiska, Lilach O. Lerman, Andrew D. Rule. *Mayo Clinic.*

Background: Age-related changes in kidney morphology are poorly understood, particularly in relationship to kidney function. We investigated age trends in kidney cortical and medullary volume and assessed the relationship between the decline in GFR with normal aging and age-related changes in kidney volume.

Methods: Kidney cortical and medullary volume was measured on contrast-enhanced abdominal CT images of healthy subjects (n=878) evaluated as potential kidney donors between 2001 and 2008 at the Mayo Clinic. ITK-Snap Version 2.2.0 was used to segment kidneys and calculate three-dimensional (3D) cortical and medullary volume. Total kidney volume was sum of cortical and medullary volume; volumes of both kidneys were compiled. GFR was measured by iothalamate clearance. Kidney volumes were regressed on age and compared between genders. Multivariable regression was used to determine whether the decline in GFR with age occurred independent of age differences in kidney volumes.

Results: Among the 878 donors (59% female, ages range 18 to 75 years), kidney cortical volume decreased with age (p<.001 for both genders), and medullary volume increased with age in men (p<.001), while no linear change was evident in women (p=0.77) (Figure).



GFR declined (all per age-decade) by 7.1 (95% CI 6.1 to 8.0) ml/min/1.73 m^2 unadjusted, by 5.4 (95% CI 4.5 to 6.4) ml/min/1.73 m^2 after adjusting for cortical volume, by 7.7 (95% CI 6.7 to 8.7) ml/min/1.73 m^2 after adjusting for medullary volume, and by 6.0 (95% CI 5.0 to 6.8) ml/min/1.73 m^2 after adjusting for total kidney volume.

Conclusions: Kidney cortical (but not medullary) volume decreased with age in healthy adults, but only partially accounted for age related decline in GFR. Further work needed to identify the primary mechanism of GFR decline with aging.

Glomerular Number and Individual Glomerular Volume in Female Americans Victor G. Puelles,[1] Rebecca N. Douglas-Denton,[1] Wendy E. Hoy,[2] John F. Bertram.[1] *[1]Department of Anatomy and Developmental Biology, Monash University, Melbourne, Victoria, Australia; [2]Center of Chronic Disease, University of Queensland, Brisbane, Queensland, Australia.*

Background: The study of individual glomerular volume (IGV) in male Americans has provided new insights into the relationship between glomerular size and glomerular number (N_{glom}). IGV mean and heterogeneity per subject are significantly higher in Caucasian American men with low N_{glom}, compared to those with high N_{glom}. The aim of this study is to determine for the first time if this trend is also present in female Americans.

Methods: We included renal autopsy tissue from 24 females, 12 African (AA) and 12 Caucasian (CA) Americans (sampled from 129 available adult females - 77 AA and 52 CA), based on extremes of N_{glom} (low or high) for a total of 6 age-matched pairs between N_{glom} categories per race. Age and body surface area (BSA) were obtained from the autopsy report and medical records. N_{glom} was estimated by the disector/fractionator principles and IGV by the Cavalieri estimator (a total of 30 glomeruli per subject; 10 superficial, 10 middle and 10 juxtamedullary glomeruli). Analysis was performed using non-parametric tests within N_{glom} categories.

Results: In AA with high N_{glom}, N_{glom} was >1.06 million (mean: 1.2 million) and in those with low N_{glom}, N_{glom} was <0.65 million, (mean: 0.58 million). AA with high N_{glom} had a 3-fold range in IGV, with a median of 3.9; while those with low N_{glom} had a 7.6-fold range of IGV, median 4.7 (P=0.24 for mean, P=0.26 for variance). In CA with high N_{glom}, N_{glom} was >0.99 million glomeruli (mean: 1.1 million) and in those with low N_{glom}, N_{glom} was <0.65 million glomeruli, (mean: 0.45 million). CA with high N_{glom} had a 4.2-fold range in IGV, with a median of 3.5; while those with low N_{glom} had a 4.8-fold range of IGV, median 3.9 (P=0.59 for mean, P=0.13 for variance). It is noteworthy that BSA was greater in AA compared to CA females (P=0.01).

Conclusions: AA females with lower N_{glom} tended towards a higher mean IGV and IGV variability than those with high N_{glom}. Such a trend was not apparent in CA. The higher BSA in the AA females might be exacerbating the glomerular hypertrophy in the setting of modestly lower N_{glom}.

Calcineurin Inhibitors (CNI) Cause Glomerulosclerosis in Children in the Absence of Arteriolar Hyalinosis: An In Vivo Model for CNI Nephrotoxicity in Non-Renal Conditions Matthew Tabinor,[1] Martin T. Christian,[1] Thomas A. Mcculloch.[2] *[1]Children's Renal and Urology Unit, QMC Campus, Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom; [2]Department of Histopathology, City Campus, Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom.*

Background: The calcineurin inhibitors (CNI) ciclosporin (CsA) and tacrolimus (Tac) cause chronic nephrotoxicity which is demonstrated on renal biopsy by arteriolar hyalinosis (AH). We have observed glomerulosclerosis (GS) in the absence of AH during chronic CNI therapy. We hypothesise GS can occur without AH, making GS an independent marker of CNI nephrotoxicity.

Methods: Retrospective analysis of biopsies from a histopathology database between 1/1/1997 and 1/3/2012 in patients ≤ 18y with nephrotic syndrome caused by minimal change nephropathy (MCN). Other histological lesions, which could confound for GS, were excluded.

Results: 109 biopsies were grouped into preCNI therapy (n=83), postCNI therapy without AH (n=22) and postCNI with AH (n=4). The difference in mean %GS between preCNI (1.1%) and postCNI without AH (10.6%) was significant (p=0.001). %GS was significantly associated with duration of CNI therapy (n=26, R=0.28, p<0.001) but not disease duration (n=60, R=0.009, p=0.81). Analysis of serial biopsies revealed a significant change in the mean %GS between the 1st (preCNI therapy) and 2nd biopsy (n=13; 9 treated with CsA; 4 treated with Tac; Δ%GS=+11.9%; p=0.006), representing significant

progression of GS on CNI therapy. There was a positive association between average CNI plasma trough level and %GS, but this was non-significant for both CsA (n=14, R=0.37, p=0.29) and Tac (n=5, R=0.13, p=0.55).

Conclusions: GS occurs without AH in children with MCN treated with CNI and correlates with the duration of CNI therapy. Progressive GS does not occur in MCN, indicating the development of GS during CNI therapy represents an *in vivo* model of nephrotoxicity caused by CNI when used for non-renal indications. Our data suggest a need for periodic assessment of nephrotoxicity in these children.

FR-PO732

Development of Steroid-Resistant Pediatric Nephrotic Syndrome Following Prolonged Steroid Therapy Is Associated with Alternative Macrophage Activation Yohei Ikezumi,[1] Toshiaki Suzuki,[1] Takeshi Yamada,[1] Hiroya Hasegawa,[1] David J. Nikolic-Paterson,[2] Akihiko Saitoh.[1] *[1]Department of Pediatrics, Niigata University Medical and Dental Hospital, Niigata, Japan; [2]Monash University Department of Medicine, Monash Medical Centre, Clayton, Victoria, Australia.*

Background: Most cases of pediatric nephrotic syndrome (NS) are steroid-sensitive; however, some patients become steroid-resistant during treatment. We have previously shown that chronic lesions, including matrix expansion and fibrosis, seen during steroid therapy are associated with alternatively activated (M2) macrophages (MΦ). This study examined M2-type MΦin pediatric steroid resistant NS (SRNS).

Methods: Renal biopsies from a group of 12 children with NS were examined. Of these 9/12 were steroid sensitive (SSNS), but 5/9 of those initially responding became steroid resistant (SRNS) with worsening proteinuria and were re-biopsied.CD68+ MΦand M2 markers (CD36, CD163, CD204) were assessed by immunofluorescence. Dexamethasone (Dex) and oxidized LDL (oxLDL) stimulation of cultured human monocyte-derived MΦwas also analysed.

Results: Analysis of all 17 biopsies showed a 3-fold increase in glomerular CD68+ MΦ in SRNS vs SSNS ($p<0.001$), with increased numbers of glomerular $CD36^+$, $CD163^+$ and $CD204^+$ cells ($P<0.05$ vs SSNS). Analysis of the 5 patients who developed steroid resistance showed significantly increased glomerular infiltrates of $CD68^+$, $CD36^+$, $CD163^+$ and $CD204^+$ cells in the second biopsy compared to the first (all $P<0.05$). Double immunostaining showed that close to 100% of glomerular $CD68^+$ MΦexpressed the oxLDL scavenger receptor, CD36. In vitro studies showed up-regulation of CD36 by human MΦ in response to M2 (Dex, oxLDL, IL-4, IL-13) but not M1 (IFNγ, LPS) stimuli. Dex augmented oxLDL induced up-regulation of CD36 expression. Also, Dex plus oxLDL had an additive effect on up-regulating expression of TGFβ, ACE, and LR11; a smooth muscle cell migration factor.

Conclusions: A substantial increase in glomerular M2-type MΦwas seen in pediatric SRNS. In vitro studies support a role for glucocorticoids and oxLDL in promoting this M2-type response. Further studies are warranted to determine whether M2-type MΦare involved in the pathogenesis of SRNS.

Significance of Foot Process Effacement in Minimal Change Disease with Acute Kidney Injury in Humans and Animal Models Akihiro Tojo, Kensuke Asaba. *Division of Nephrology and Endocrinology, University of Tokyo, Tokyo, Japan.*

Background: Some patients with minimal change disease develop acute kidney injury (AKI) associated with severe proteinuria. Recently, we have reported that albumin was selectively transported across the podocyte cell body in minimal change nephrotic syndrome (KI 2011; 80: 1328), in which effaced foot processes with tight-junction like connections cover the glomerular capillary and may reduce the glomerular filtration rate. We examined the mechanism of AKI related to foot process effacement in minimal change disease.

Methods: We evaluated retrospectively the clinical and pathological characteristics of 38 patients with biopsy-proven minimal change disease, and also investigated the pathogenesis of AKI compared to the puromycin aminonucleoside nephrotic rat model with a single injection (10mg/100g BW), or two injections with a 2 week interval.

Results: Of 38 patients with minimal change disease, 13 patients (34%) developed AKI. Patients with AKI were older (41±6 years vs. 31±3 years, $P<0.05$) and had lower levels of serum albumin (1.8±0.1 vs. 2.2±0.2 g/dL, $P<0.05$) compared to patients without AKI. Although baseline serum creatinine (0.86±0.05 vs. 0.79±0.04 mg/dL) was not significantly different between these two groups, serum creatinine levels were elevated in patients with AKI (1.74±0.37 mg/dL). There were no differences in renal histological lesions including glomerulosclerosis, arteriolosclerosis and interstitial fibrosis. The extent of foot process effacement and urinary protein were correlated significantly ($R=0.48$, $P<0.001$). In puromycin nephrotic rats, the extent of foot process effacement became severer in rats with two injections of puromycin than in the single injection model (90.4±2.0 vs. 69.6±4.9% of capillary wall length, $p<0.001$), urinary protein was increased (79.1±3.4 vs 27.2±1.2 mg/mgCr), and serum creatinine increased in the twice injection model suggesting the onset of AKI (sCr 1.22 vs.0.49 mg/dL).

Conclusions: In minimal change disease, the extent of foot process effacement is correlated with the amount of urinary protein, whereas severe foot process effacement may impede water and creatinine filtration, resulting in AKI.

Leukocyte Infiltration and Glomerular Capillary Injury in Endocapillary Proliferative Lesions in Various Glomerulonephritis Akiko Mii, Yukinari Masuda, Akira Shimizu. *Nippon Medical School, Tokyo, Japan.*

Background: Leukocyte infiltration and glomerular capillary injury may involve in the progression of various glomerular diseases. In this study, we assessed the association between infiltrating cell phenotype and glomerular capillary injury in post-streptococcal acute GN (PSAGN), lupus nephritis (LN), and Henoch-Schonlein purpura nephritis (HSPN).

Methods: The renal biopsy samples presenting endocapillary proliferative lesions of PSAGN (n=18), LN (n=23) and HSPN (n=23) were selected. To assess the character of infiltrating cells, we performed immunostaining against esterase, MPO, CD3, CD68, CD163 (a marker of M2 Mφ), CD169 (a marker of M1 Mφ), MPO+CD68 Mφ. To identify the alteration of glomerular capillaries, we examined electron microscopic findings, and performed immunostaining against CD34.

Results: In mild endocapillary lesions of PSAGN, inflammatory cells existed in glomerular capillaries, and CD34+ glomerular capillary lumina were retained in periphery of glomeruli. In the severe lesions, leukocytes migrated into subendothelial space, and CD34+ glomerular capillaries separated from glomerular basement membrane (GBM), however, many capillaries remained in glomerular lobes. In contrast, in LN and HSPN, endocapillary proliferative lesions were characterized by the loss of CD34+ endothelial cells with leukocyte infiltration, necrotizing lesion, and GBM rupture. Glomerular infiltrating cell phenotype was distinct between PSAGN and LN/HSPN. In PSAGN, esterase+ neutrophils were remarkable, and MPO+ cells showed similar distribution. Many CD68+ Mφ and a few CD3+ T cells were noted, and most of CD68+ Mφ were CD163+ M2 Mφ. However, in LN and HSPN, some MPO+ cells were MPO+/CD68+ Mφ. A large number of CD169+ M1 Mφ and a small number of CD163+ M2 Mφ were evident.

Conclusions: Glomerular capillary injury develops in endocapillary proliferative lesions. Glomerular capillary network is remained in PSAGN. However, in LN and HSPN, capillary destruction and endothelial injury is prominent and contributes to the formation of active necrotizing lesions. M1 Mφ, MPO+ Mφ, and a small number of M2 Mφ may mediate active inflammation as well as glomerular capillary injury in LN and HSPN.

Changing Trends of Primary GN in Chulalongkorn University Talerngsak Kanjanabuch, Kearkiat Praditpornsilpa, Somchai Eiam-Ong, Kriang Tungsanga. *Medicine, Chulalongkorn University, Bangkok, Thailand.*

Background: The nationwide renal registry has not yet been organized in Thailand, thus the aim of the present study was to examine the prevalence and changing trends of primary glomerular diseases in the King Chulalongkorn Memorial Hospital (KCMH) in the last 3 decades (1980-2010).

Methods: the patient profiles and renal biopsy specimens of KCMH were reviewed. Final diagnosis was made for each patient based on clinicopathologic correlations. The comparison among individual decade and with literature report from Asian countries according to the demographics and patient outcome were studied.

Results: A total of 1,493 primary glomerular diseases in 2,099 native renal biopsies were retrieved. 69.8% were female and 30.2% were male. Their age average was 37±14 (13-80) years. The most common indication for renal biopsy was nephrotic syndrome (NS: 36.5 %). IgAN (19.5%) and FSGS (19%) are the most 2 common causes, followed by minimal change disease (16.9%) and membranous nephropathy (MN: 13.3%). In recent decades, the prevalence of IgMN has tended to decline, but high rates persist in IgAN and increasing rates are found in FSGS and MN, although the indication of renal biopsy is not change from the last 2 decades. Compared to other reports from Asian population, our IgAN population had worse prognostic factors and higher Oxford score. 30% had hypertension (HT), 34% had Scr ≥ 1.5 mg/dL and urine protein values of > 3 gm/dL, and one fourth had moderate-severe tubulo-interstitial fibrotic score. However, the annual change in eGFR was -0.82 mL/min/m^2. FSGS, the second contributor, most of them presented with NS with HT. Average Scr and serum albumin were 1.5 (0.4-8.2) mg/dL and 2.8 (0.9-4.5) g/dL, respectively. NOS and tip were the leading pathologic variants of the FSGS (84%). Majority of them were steroid responder (70%), only 1 case had spontaneous remission. This responsiveness to steroid was not changed during the 3 decades.

Conclusions: IgMN trended to decline their prevalence during the last 3 decades. On the contrary, the prevalence of IgA nephropathy remained unchanged while the rate of FSGS was increase.

FR-PO736

Histiocytic Glomerulopathy Associated with Macrophage Activating Syndrome Alfonso Eirin, Maria V. Irazabal, Fernando C. Fervenza, Sanjeev Sethi. *Mayo Clinic, Rochester, MN.*

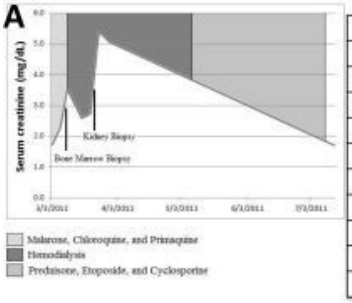
Background: Macrophage-activating syndrome (MAS) is a severe condition due to a hyperinflammatory response resulting from exaggerated activation and proliferation of non-malignant macrophages. MAS falls under the umbrella group of diseases known as of hemophagocytic lymphohistiocytosis (HLH) or hemophagocytic syndrome (HPS). Acute tubular necrosis is the most common renal manifestation in HLH/MAS, but little has been reported about glomerular involvement in acute renal failure.

Methods: A 37-year old man presented with acute renal failure following a febrile illness. His serum creatinine was 1.69 mg/dL, with an estimated glomerular filtration rate of 57.9 mL/min/1.73m^2. Initially, malarial infection was suspected and the patient was treated with malarone, chloroquine, and primaquine for 7 days without any improvement.

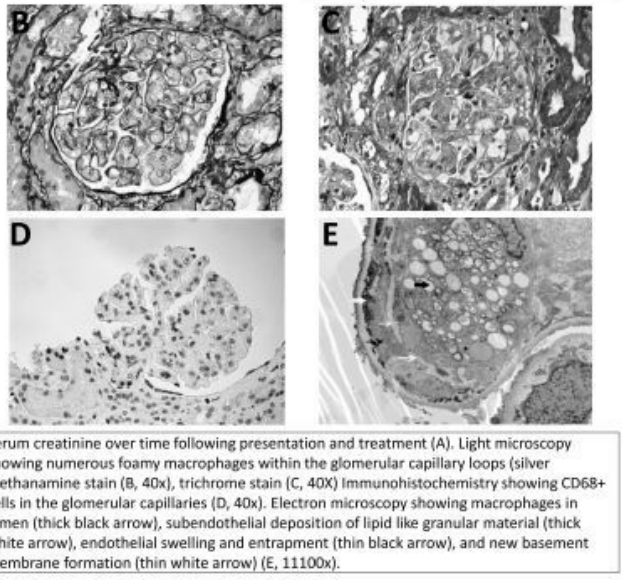
Laboratory results showed features of macrophage activating syndrome with anemia, thrombocytopenia, hypofibrinogenemia, and elevated ferritin levels (Table). Bone marrow aspirate showed granulocytic and megakaryocytic hyperplasia, slightly left-shifted erythropoiesis and polyclonal plasmacytosis. At that time, the patient developed a progressive renal dysfunction requiring dialysis.

Results: Renal biopsy was then done to determine the cause of renal failure and showed unique glomerular findings with massive histiocytic infiltration ("Histiocytic Glomerulopathy") with numerous endocapillary macrophages and features of endothelial injury (Figure). The patient was referred to our institution to initiate therapies to target activated macrophages/histiocytes (prednisone 60mg/day, etoposide, and cyclosporine 75mg/day) and responded well.

Conclusions: Recognizing that the histiocytic infiltrate and endothelial injury is a part of the macrophage activating syndrome is important since early recognition and treatment is of utmost importance since the disease can be fatal.



Serum creatinine (mg/dL)	1.72	0.8-1.3
BUN (mg/dL)	15	8-24
eGFR (mL/min/1.73m²)	57.9	>60
Hemoglobin (g/L)	7.3	13.5-17.5
Hematocrit (%)	20.5	38.8-50.0
White blood cells (x 10³/μL)	22.3	4.5-11.0
Platelet count (x 10³/μL)	342	130-400
Fibrinogen (g/L)	6.76	1.5-2.77
Ferritin (μg/L)	1727	24-336
CRP (mg/L)	296	<6
Urinalysis	unremarkable	



Serum creatinine over time following presentation and treatment (A). Light microscopy showing numerous foamy macrophages within the glomerular capillary loops (silver methanamine stain (B, 40x), trichrome stain (C, 40X) Immunohistochemistry showing CD68+ cells in the glomerular capillaries (D, 40x). Electron microscopy showing macrophages in lumen (thick black arrow), subendothelial deposition of lipid like granular material (thick white arrow), endothelial swelling and entrapment (thin black arrow), and new basement membrane formation (thin white arrow) (E, 11100x).

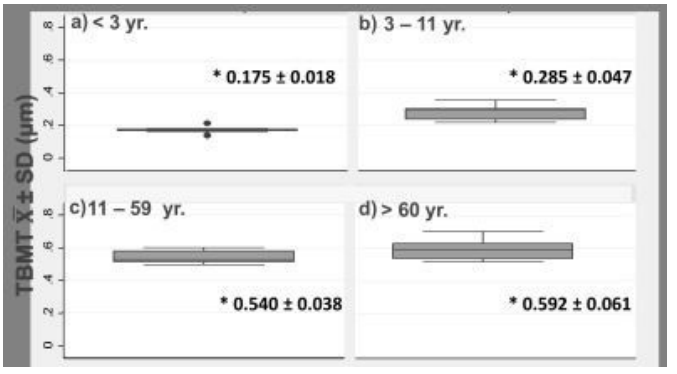
FR-PO737

Tubular Basement Membrane Thickness Increases over the Life Span in an Age Specific Manner Randa Razzouk,[1] Ellen Brooks,[1] Anthony Chang,[2] Michael Z. David,[3] Craig B. Langman.[1] *[1]Kidney Diseases, Children's Memorial Hospital, Chicago, IL; [2]Pathology, University of Chicago, Chicago, IL; [3]Medicine, University of Chicago, Chicago, IL.*

Background: Kidney basement membranes of glomerular (G) and tubular (T) origin serve critical functions including permselectivity, filtration, transport, & cell anchoring. Measurement of G basement membrane thickness (GBMT) in human biopsies is a practical method to diagnose several kidney diseases, including thin GBM & diabetic nephropathies (DN). GBMT can be divided into 4 sub-groups based on developmental stage: infancy(<3yrs);childhood(3-11yrs);adulthood(11-59 yrs) & older age (>60 yrs) while no gender effect is seen. T basement membrane (TBM) ultrastructure demonstrates two distinct layers, the lamina densa & the lamina lucida. Evaluation of TBM thickness (TBMT) has been rarely studied & only in adults with DN where TBMT is thicker, compared to controls.Thus, TBMT measurement may provide relevant information in the development of renal pathology.

Methods: We measured TBMT from proximal tubules (PT) of archived kidney biopsies obtained over the last decade: across all ages, both genders, & excluding cases of DN,IgA Nephropathy, Membranous Nephropathy, Thin GBM & moderate to severe tubular atrophy. Using electron microscopy, we examined N =40 biopsies (10 per age category: <3 yrs, 3-11 yrs, 11-59 yrs & >60 yrs). We performed 39± 4(x ¯± SD) measurements/patient/PT at 5800x. For each age stratum, we determined the x ¯± S.D.TBMT. Results were compared by ANOVA & Spearman's Rank test.

Results: Figure a-d. Mean TBMT Differ by Age,*$p<10^{-3}$. There was a strong positive relationship between Proximal TBMT across age ($r=0.93$, $p<10^{-3}$).



Conclusions: We demonstrated an age-related increase in TBMT from <3yrs to >60 yrs. We are now expanding our research to compare GBM & TBM thicknesses in thin GBM disease.

FR-PO738

Immunopathology of Omeprazole-Induced Acute Interstitial Nephritis Linda Berney-meyer,[1] Noelyn Hung,[1] Tania L. Slatter,[1] A. Richard Kitching,[2] Robert J. Walker.[1] *[1]Medicine and Pathology, University of Otago, Dunedin, New Zealand; [2]Nephrology, Monash Medical Centre, Melbourne, Australia.*

Background: Omeprazole is now a common cause of drug-induced acute interstitial nephritis (AIN). How omeprazole-induced AIN is mediated is unknown. It is not the classical allergic AIN, rather the histological appearances are more characteristic of an acute tubulitis as seen in vasculitis or cellular rejection.

Methods: Data from 25 biopsy-proven cases of omeprazole-induced AIN were reviewed. The H&E stained biopsies were scored using the Banff criteria for tubulitis. The interstitial infiltrate was then analysed using immunohistochemical and fluroscopic chromogenic insitu hybridization techniques to identify and semi-quantitate the cellular infitrate, using CD20 for B-cells, CD4, CD8, IL17A, IL17F and Foxp3 staining to identify and characterise T-cells.

Results: All patients presented with evidence of AKI. Urinalysis demonstrated a sterile pyuria with varying amounts of proteinuria. There were no urinary eosinophils. There were no systemic symptoms to suggest a vasculitis and ANCA (PR3 & MPO titres) were negative in all cases. Histologically, all cases had evidence of inflammatory cells crossing the tubular basement membrane and attacking the tubular epithelial cells. 56% had evidence of mild tubulitis (t1), 24% moderate tubulitis (t2) and 20% severe tubulitis, and 78% of all cases were a mononuclear cell infiltrate,. There was no glomerular involvement. There was no significant eosinophilic infiltrate seen. Immunohistochemical staining confirmed the predominant inflammatory cells to be CD4 positive cells, present in clusters, in 77% of cases and combined CD4 IL17A/F staining in 44 - 48% of cases, suggesting a predominantly Th1 - Th17 mediated inflammatory process.

Conclusions: This is the largest reported biopsy series of omeprazole-induced AIN. The tubulitis evident with the intense interstitial infiltrate appears to be mediated by a Th1 - TH17 process analagous to vasculitis. How omeprazole induced this Th1 - Th17 inflammatory response is unclear. Once better defined, more appropriate therapy can be introduced.

FR-PO739

Frequency and Associations of C4d Deposits in Explanted Kidney Allografts Jolanta Kowalewska,[1] Beata Naumnik,[2] Gabriela Korakiewicz,[1] Jerzy Glowinski,[3] Lech Chyczewski.[1] *[1]Pathology, Medical University of Bialystok, Bialystok, Poland; [2]Nephrology and Transplantation with Dialysis Unit, Medical University of Bialystok, Bialystok, Poland; [3]Vascular Surgery and Transplantology, Medical University of Bialystok, Bialystok, Poland.*

Background: The presence of C4d deposits in peritubular capillaries (PTC) in kidney allograft is one of the histological markers of antibody-mediated rejection (AMR). There is emerging evidence that AMR may contribute to late kidney allograft function deterioration. It has been shown that significant proportion (in some studies 39%) of kidney allografts have significant PTC C4d deposits and this finding is associated with an increased risk of subsequent graft failure.

Methods: We searched the Department of Pathology database for kidney allograft nephrectomy specimens. The time after the transplantation (tx) and the cause of graft loss were recorded. All identified cases were reviewed for histological findings and retrospectively stained for C4d using immunohistochemical method.

Results: We identified 31 kidney allograft nephrectomies. Among the recipients were 17 (55%) females and 14 (45%) males, ages 16 to 70 (average 41 years old at the time of tx). The average time post tx was 8 years (range 1 month to 19 years). The causes of allograft failure were: chronic allograft nephropathy (24 cases), infection (2 cases), CNI toxicity (2 cases), acute rejection (2 cases), and renal artery stenosis (1 case). Twenty two (22/31, 71%) grafts showed strong diffuse staining for C4d in PTC. Additionally, in 7 cases there was focal weak staining for C4d. Two cases were negative. Strong C4d deposition was associated with transplant glomerulopathy (TG; 20/22, 90%) and chronic active transplant arteriopathy (19/22, 86%). In the groups of focal or negative C4d, TG and arteriopathy were seen in two cases.

Conclusions: The majority of removed kidney allografts show strong PTC C4d staining (in our study 71% grafts), pointing to humoral rejection process as a significant contributor to the allograft failure.

C4d deposits in explanted grafts are associated with transplant glomerulopathy and chronic active transplant arteriopathy.

FR-PO740

IgG4-Positive Plasma Cells in Renal Allograft Biopsies Thomas Paulraj Thamboo,[1] Vathsala Anantharaman,[2] Ming Teh.[1] *[1]Pathology, National University Health System, Singapore, Singapore; [2]Medicine, National University of Singapore, Singapore, Singapore.*

Background: IgG4 is thought to play an anti-inflammatory role or be a response to inflammation, with attention focussed recently on its role in the newly-recognised IgG4-related disease. This retrospective study investigated the presence of IgG4-positive plasma cells (IgG4PC) in renal allograft biopsies.

Methods: Archival formalin-fixed and paraffin-embedded tissue from consecutive renal allograft biopsies over a 3 year period was studied. Immunostaining for CD138 and IgG4 was performed and the number of IgG4PC and total plasma cells present in each biopsy was assessed.

Results: 146 cases that met the entry criteria had residual tissue for study. Overall, IgG4PC were identified in 65 cases (44.5%). In cases with acute T-cell mediated rejection, the mean number of IgG4PC per biopsy was significantly higher than in cases with no rejection (65.46 versus 5.47; p=0.049) (t-test; 1 tail) as was the mean number of IgG4PC per HPF (5.18 versus 0.79; p=0.046). The mean total number of all plasma cells per biopsy was also significantly higher in the former group (765.08 versus 80.53; p=0.019). When cases of acute antibody-mediated rejection were compared to cases with no rejection, the mean total number of all plasma cells per biopsy was significantly higher (p=0.011). However, there was no significant difference in the mean number of IgG4PC per biopsy and the mean number of IgG4PC per HPF between the two groups. In cases with "Borderline rejection" (Banff Category 3), the mean number of IgG4PC per biopsy, the mean number of IgG4PC per HPF and the total number of all plasma cells per biopsy were less than those of cases with acute rejection and more than those of cases with no rejection, but these differences were not statistically significant. When all cases were considered, there was no significant difference in the number of IgG4PC or in the number of all plasma cells between cases with mild and severe interstitial fibrosis and tubular atrophy.

Conclusions: IgG4PC are present in a significant number of renal allograft biopsies. Significantly more IgG4PC are present in cases with acute T-cell-mediated rejection compared to cases with no rejection.

FR-PO741

Distributions of eGFR in Patients Examined by Contrast-Enhanced Computed Tomography before and after eGFR Self-Report Yoshinari Yasuda,[1] Kanako Shibata,[1,2] Sawako Kato,[1] Motomitsu Goto,[1] Mutsuharu Hayashi,[1] Shoichi Maruyama,[1] Enyu Imai,[1] Seiichi Matsuo.[1] *[1]CKD Initiatives/Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Japan; [2]Pharmacy, Kinjyo Gakuin University School of Pharmacy, Nagoya, Japan.*

Background: Renal insufficiency is the most important risk factor for contrast induced nephropathy (CIN), however it is difficult to assess renal function only by serum creatinine (sCr). Estimated glomerular filtration rate (eGFR) is globally recommended for evaluation of renal function, and eGFR self-report may affect clinical decision making to prevent CIN. Since Nagoya University Hospital (NUH) started eGFR self-report in December 2009, we analyzed distributions of eGFR in patients who were examined by contrast-enhanced computed tomography (CE) in NUH before and after eGFR self-report.

Methods: Study subjects were 1,123 and 967 patients who were examined by CE in NUH in April 2008 and 2011. Patients under 18 years of age were excluded. Age, gender and sCr before CE (until 4 months before) were collected from medical record and eGFR was calculated by Japanese eGFR equation. Distributions of age, gender and eGFR categories (G1: 90 and above, G2: 60-89, G3a: 45-59,G3b: 30-44 ,G4: 15-29 and G5: less than 15 mL/min/1.73m^2) were compared before and after eGFR self-report.

Results: Age and gender distributions were not different in 2008 and in 2011. Although most of hospitalized patients were examined sCr before CE, 20% of outpatients were not examined sCr in NUH before CE both in 2008 and in 2011. In remaining patients, proportions of eGFR category G1, G2, G3a, G3b, G4 and G5 were 26.2%, 55.5%, 12.7%, 5.3%, 0.3% and 0.1% in 2008, and 21.8%, 56.8%, 16.9%, 3.2%, 0.5% and 0.9% in 20011, respectively. Proportion of G3b was significantly decreased, while that of G4 and G5 was increased in 2011. In most of G4 and G5 patients in 2011, referral to nephrologists had been completed previous to CE.

Conclusions: Distributions of eGFR categories among patients examined by CE were different before and after eGFR self-report in NUH, suggesting its preferable effect to prevent CIN.

Renal Safety Evaluation after Gd-DOTA-Enhanced-MRI Compared with Non-Enhanced-MRI in Patients at High Risk of Developing Contrast Medium Induced Nephropathy Jean Marie Gustave Billiouw,[1] Luis Martibonmati,[3] Olivier Rouviere,[4] Lorenzo Bacigalupo,[10] Bart Dirk Maes,[5] Thierry P. Hannedouche,[6] Francois Vrtovsnik,[7] Claire Rigothier,[8] Paolo Campioni,[9] Gilbert Deray.[2] *[1]Nephrology, Ziekenhuis, Aalst, Belgium; [2]Nephrology, Salpétrière Hospital, Paris, France; [3]Radiology, Valencia Hospital, Valencia, Spain; [4]Department of Urinary and Vascular Imaging, Hospices Civils de Lyon, Department of Urinary and Vascular Imaging, Hôpital E. Herriot, Lyon, France; [5]Nephrology, Heilig Hartziekenhuis, Roeselare, Belgium; [6]Nephrology, Strasbourg Hospital, Strasbourg, France; [7]Nephrology, Bichat Hospital, Paris, France; [8]Nephrology, Pellegrin Hospital, Bordeaux, France; [9]Radiology, Sant'Anna Hospital, Ferrara, Italy; [10]Radiology, Ospedali Galliera, Genova, Italy.*

Background: To assess the safety profile of Gd-DOTA in patients with chronic renal failure.

Methods: Phase IV, non-randomized, comparative, multinational trial (RESCUE study) including 135 adult patients with a known stable stage III/IV renal insufficiency (15<estimated glomerular filtration rate (eGFR) <60 ml/min/1.73m²) scheduled to undergo a MRI with Gd-DOTA (Dotarem®) or unenhanced-MRI. The primary endpoint was the percentage of patients with a nephrotoxicity, defined as a serum creatinine level increase at 72±24h of at least 25% or 0.5mg/dl compared to baseline, using a non-inferiority analysis. Main secondary criteria were serum creatinine and eGFR variations, clinical safety.

Results: The difference (unenhanced-MRI–Gd-DOTA-MRI) in nephrotoxicity incidence was -1.4% and significantly (p=0.001) superior to the clinical non-inferiority limit, demonstrating the non-inferiority. The serum creatinine variation from baseline was -1.4±10.4% for Gd-DOTA-MRI and -3.5±9.9% for unenhanced-MRI (p=0.291). No relevant differences for the other secondary endpoints were noted. The good general safety profile of Gd-DOTA was also confirmed.

Conclusions: The non-inferiority of Gd-DOTA-MRI over unenhanced-MRI in terms of nephrotoxicity was demonstrated. Among the few contrast medium-induced-nephropathy studies with gadolinium products, this prospective study included a control group emphasizing the very good renal tolerance of Gd-DOTA in at-risk patients.

FR-PO743

Incidence of Infectious Complications after Rituximab in Glomerular Disease Claire Trivin,[1] Alexandre Karras,[1] Gabriel Choukroun,[2] Cecile M. Vigneau,[3] Gatault Philippe,[4] Cécile Courivaud,[5] Jean Francois Augusto,[6] Maxence Ficheux,[7] Bruno Moulin,[8] Eric Thervet.[1] *[1]Hôpital Européen Georges Pompidou, Paris; [2]CHU Amiens; [3]Hôpital Pontchaillou, Rennes; [4]Hôpital Bretonneau, Tours; [5]Hôpital St Jacques, Besançon, France; [6]CHU Angers; [7]CHU Caen; [8]Hopitaux Universitaires de Strasbourg, France.*

Background: Rituximab (RTX) is largely used in many renal diseases but the related risk is still debated. The aims of this study were to describe infectious complications after RTX treatment, to consider potential risk factors and the outcome of these patients.

Methods: In 7 French renal units, we retrospectively analyzed RTX treated patients for renal disease, excluding renal transplant recipients and patients with hematological indications. We retrospectively determined the incidence and the characteristics of infectious complications and retrieved clinical and biological data.

Results: Between 2005 and 2011, we individualized 92 patients who had received RTX for glomerular disease. The mean duration of follow-up was 25.9±19.9 months. Patient survival was 94.5%. Overall, a total of 38 infectious episodes were observed in 28 (30.4%) patients. Pneumonia (n=11), Septicemia (n=7) and cellulitis (n=6) were the most frequent infections. Compared to patients without infection, patients who presented any infectious complication were significantly older (55.1±18.9 vs 45.7±19.2; p=0.03), exhibited more frequent diabetes mellitus and had cryoglobulinemia as initial nephropathy (p=0.008 and p=0.001 respectively). The total RTX dose was positively correlated with the risk of infection. Serum creatinine before RTX was significantly higher, and gammaglobulin concentration during the follow-up was significantly lower in patients with infection (p=0.01 and 0.04 respectively).

Conclusions: Infectious risk after RTX therapy in nephrology is high, especially in elderly patients and when higher dose of treatment are used. Cryoglobulinemia, renal failure and diabetes mellitus are independent risk factors. Patient should be monitored for gammaglobulin levels to evaluate the infectious risk leading to the question of systematic intravenous gammaglobulin treatment in this population.

Potential Medication Risk for Restless Legs Syndrome in Dialysis Patients: Part D Data in the United States Renal Data System Donald L. Bliwise, Rebecca H. Zhang, Nancy G. Kutner. *USRDS Rehab/QOL SSC, Emory University, Atlanta, GA.*

Background: ESRD is a significant risk factor for restless legs syndrome (RLS). The presence of RLS in dialysis patients is associated with poorer quality of life, and in several studies, higher rates of mortality. Because RLS is commonly associated in the general population with medications with central nervous system effects, we examined USRDS data to investigate whether use of these drugs might be associated with RLS Dx.

Methods: Cases were identified by the unique ICD-9 code for RLS (333.94) that became effective October 1, 2006. The RLS code was present for 1,508 patients who initiated regular dialysis therapy October 1, 2006 through December 31, 2008. Four controls who started dialysis in the same time period, matched by age, race, and sex, were selected for each case (n=6,032). Part D medication data were searched for October 1, 2006 through December 31, 2008. Prevalence of prescribed drugs was investigated in four classes: (I) tricyclic antidepressants, selective serotonin uptake inhibitors, serotonin–norepinephrine reuptake inhibitors, and buspirone; (II) first generation anti-histamines; (III) anti-psychotics with partial dopamine blockade; and (IV) metoclopramide. The study hypothesis was that usage prevalence for these classes would be higher in patients with RLS than in those without an RLS Dx.

Results: Even after matching for age, race and sex (all known risk factors for RLS), usage of each of the 4 medication classes was strongly associated with RLS Dx: Class I (OR = 2.18; 95% CI 1.92-2.48); Class II (OR = 1.75; 95% CI 1.23-2.48); Class III (OR = 1.19; 95% CI 1.10-1.30); Class IV (OR = 2.07; 95% CI 1.77-2.43).

Conclusions: These data raise the possibility that some medications that see widespread usage in dialysis patients may actually increase risk for a comorbidity that commonly distresses many patients. Clearly, for any individual patient, the risk/benefit ratio for these medication classes may warrant such usage. On the other hand, these data also imply that a careful review of concurrent medications should be undertaken when a dialysis patient expresses troubling RLS symptoms.

FR-PO745

The Osmolality of Nonionic, Iodinated Contrast Agents as an Important Factor for Renal Safety Diana C. Lenhard,[1] Hubertus Pietsch,[1] Philipp D. Lengsfeld,[2] Gregor Jost.[1] *[1]CT and MR Contrast Media Research, Bayer Pharma AG, Berlin, Germany; [2]Radiology & Interventional Global Medical Affairs, Bayer Pharma AG, Berlin, Germany.*

Background: Non-ionic contrast agents (CA) can be classified into low-osmolar and iso-osmolar CA. Targeting the differences in the CA's osmolalities, we analyzed and compared renal iodine retention and potentially occurring kidney injury.

Methods: Rats were injected with low-osmolar iopromide 300, iso-osmolar iodixanol 320 and with an iodixanol/mannitol mixture containing an osmolality of 610 mOsm/kg H2O, equal to iopromide 300. Iodine retention was determined 2h post injection (p.i.) on the basis of CT measurements. Potential injury of kidneys was analysed by qRT-PCR of acute kidney injury (AKI) markers.

Results: CT analysis exhibited twice as much residual iodine in the kidneys 2h after iodixanol administration compared to iopromide injection. Interestingly, iodine retention after iodixanol/mannitol administration was reduced down to iopromide level. 2h p.i. Iodixanol caused a significantly upregulated expression of the AKI marker PAI-1 occurring to a much lesser degree in iopromide treated rats. Additionally, 2h and 24h after Iodixanol administration KIM-1 and NGAL transcripts were significantly increased compared to iopromide and NaCl application. However, the iodixanol enhanced AKI marker induction was reversed by iodixanol/mannitol down to almost Iopromide transcript levels in all cases.

Conclusions: Increased renal iodine concentrations and elevated AKI marker expression seem to be mainly caused by the explicitly higher viscosity of Iodixanol and appear to be reversed by raising Iodixanol's osmolality, demonstrating a positive osmodiuretic effect and a higher renal tolerance of low-osmolar CAs.

FR-PO746

The Activity Report of Dialysis Service Continuity and the Staging Base Function for Wide Area Medical Transportation on the Great East Japan Earthquake Mariko Miyazaki,[1,2] Yaeko Murata,[1] Tae Yamamoto,[1] Toshinobu Sato,[3] Hiroshi Sekino,[4] Sadayoshi Ito.[2] *[1]Blood Purification, Tohoku University Hospital, Sendai, Japan; [2]Nephrology, Endocrinology, and Vascular Medicine, Tohoku University Graduate School of Medicine, Sendai, Japan; [3]Nephrology, Sendai Shakaihoken Hospital, Sendai, Japan; [4]Urology, Kojinkai Hospital, Sendai, Japan.*

Background: Twenty thousands of people fell victim to the Great East Japan Earthquake. The half of them had lived at the coast of Miyagi prefecture. In this area, electrical power service and water supply were interrupted widely after earthquake. It was the great difficulty for the people who need renal replacement therapy.

Methods: We examined the activity record of disaster response in Tohoku University hospital.

Results: Over 2,000 patients needed the dialysis in Sendai city area. They were treated in their area by full working of Sendai Shakaihoken Hospital and Kojinkai Hospital and one after the other recovered facilities supplied by water truck. After 3.11, Kesennuma city hospital worked using emergency generators and water tank, however, couldn't recover the electrical power supply after more than 72 hours. Furthermore, the prolonged harsh conditions threatened the patients staying at devastated area. We coordinated the wide-area medical transportation for 80 patients using Japanese Self Defense Force Aircraft to Hokkaido, 400 miles north of Miyagi. The function of staging base by Tohoku University Hospital enabled the long-distance transportation safely in medical check and stabilizing the condition for the suffered dialysis patients. That was the first systematical and largest operation planned by Japanese government associating prefectural governments, Japanese Associations of Dialysis Physicians, and many dialysis facilities containing outside of Miyagi.

Conclusions: The scheme for large number of dialysis patients' staging base was different from injured victims' transportation. Network centric information management enabled the co-operation of many organization.

Acknowledgment: Dr. Seiji Ueno, Dr. Kazuhiko Orikasa, and Dr. Hiroshi Ohtomo in Dialysis center of Kesennuma city hospital.

FR-PO747

A Novel Assessment of Fall Risk in Hemodialyis Patients: Preliminary Findings Emaad M. Abdel-Rahman,[1] Rahul Soangra,[3] Thurmon E. Lockhart,[3] John Lach,[2] Rasheed A. Balogun.[1] *[1]Nephrology, UVA, Charlottesville, VA; [2]Engineering, UVA, Charlottesville, VA; [3]Engineering, Virginia Polytechnic University, Blacksburg, VA.*

Background: Falls among the hemodialysis (HD) patients are more common after HD than before (Cook et al, 2006) with resulting high morbidity and mortality. The functional and mobility mechanisms that contribute to falls need to be studied. The timed up and go (TUG) test is a reliable and valid clinical test for quantifying functional mobility and fall risk (Mathias et al, 1986). Sit-to-walk (STW) component of TUG is a complex sequential postural locomotor task (Magnan, 1996). Impaired timing of STW events and sequencing may place patients at higher risk of falling. Aim: Assess the effects of hemodialysis therapy on fall risk in ESRD patients using a validated novel instrument.

Methods: Measurement of locomotor performance using time to complete the phases of STW tasks as a marker of dynamic stability (fall risk) immediately before and after 22 HD sessions in 6 ESRD patients (54±4 years; 4 females and 2 males). Each HD session lasted four hours with no intradialytic complications. Instrumentation: A novel inertial measurement unit (IMU) - TEMPO (Technology-Enabled Medical Precision Observation (Barth et al, 2009).

Results: After HD, significant increases in time to complete all phases of STW tasks were found.

Time interval from initiation to reach peak flexion (PF) and extension (PE) events and the time taken to complete all phases of STW (C) task.

Time between events	Pre HD(seconds)	Post HD (seconds)	P
STW PF	0.471±0.037	0.799±0.073	0.030*
STW PE	1.533±0.196	1.907±0.205	0.026*
STW C	2.462±0.566	2.900±0.893	0.041*

Conclusions: There is a demonstrable decrease in locomotor performance and dynamic stability immediately after HD. This increases fall risk. This study has high potential to shift current clinical practice paradigms with an immediate impact because this type of assessments can be easily implemented in most clinical settings. Furthermore, this study has the potential to elucidate the mechanism underlying increased fall risk in this population outlining the specific deficiencies potentially leading to novel approaches to intervention in the future.

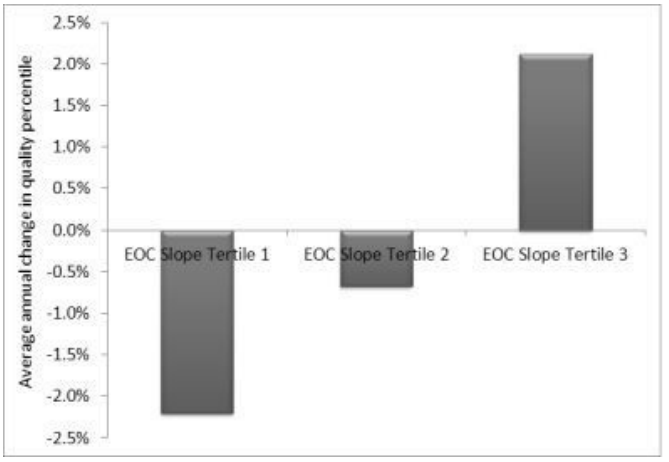
FR-PO748

Improvements in Clinical Quality Are Associated with "Environment of Care" Rounds Penny Faith Sheppard, Seth Johnson, Robert Levin, Nancy Ginsberg, Len A. Usvyat, Mary T. Sullivan, Paul Balter, Peter Kotanko, Paul M. Zabetakis. *Renal Research Institute, NY, NY.*

Background: "Environment of Care" (EOC) rounds are a monthly process in the RRI clinics. It was introduced in 2008 and involves a detailed inspection of each clinic based on 28 operational and clinical criteria that involve Infection Control/Patient Care/Housekeeping & Medication preparation, handling, storage and administration. Scores on a scale from 0% to 100% (best) are assigned to each clinic. We aimed to understand whether these scores are aligned with quality outcomes in the clinics.

Methods: All RRI clinics are ranked monthly based upon their quality outcomes. These rankings cover patient parameters, such as anemia, phosphorus control, nutrition, vascular access, dialysis adequacy, as well as mortality and hospitalization rates. The best clinics are assigned the highest percentile (on a scale from 1 to 100%). We studied all clinics bn Jan 2009 and April 2012.

Results: We studied 19 RRI clinics; mean EOC score was 89.2% (SD 3.4%). We found a positive and significant correlation between EOC scores and clinical quality percentile ($r=0.36$, $p<0.05$). We also found that clinics with improvements in EOC scores experienced an improvement in the clinical quality ranking during the study period ($r=0.22$, $p<0.05$). Dividing clinics into tertiles of EOC slopes [tertile1: below -0.9%/year; tertile 2: -0.9 to +0.5%/year; tertile 3: greater +2.5%/year] over the 40 month study period, we found a gradient relationship with clinics with highest increases in EOC scores having the highest ranking improvements.



Conclusions: Environment of care rounds aimed at monthly checks of 28 clinic operation issues covered in CMS's Conditions of Coverage are associated with not only improved operational procedures in the dialysis clinics but are also with improved clinical quality and patient outcomes.

FR-PO749

User Profiles of a Smartphone Application to Support Drug Adherence: Experiences from the iNephro Project Stefan Becker,[1] Anna Mitchell,[1] Andreas Kribben.[2] *[1]Medizinische Klinik I, Marienhospital Herne, Klinikum der Ruhr-Universität Bochum, Herne, Germany; [2]Klinik für Nephrologie, Universitätsklinikum Essen, Essen, Germany.*

Background: One of the key problems in the drug therapy of patients with chronic renal failure is drug adherence. In 2010 the initiative iNephro was launched (www.inephro.de). A "context sensitive" software to support regular and correct drug intake was developed for a smartphone platform (iOS). The present study investigates, whether and how such an application is deployed by smartphone users.

Methods: Together with cooperating partners the mobile application "medication plan" was developed. Users are able to keep and alter a list of their regular medication. A memory function supports regular intake. The application can be downloaded free of charge from the iTunes App Store. After individual consent of users from 21/10/2010 to 04/02/2012 2,042,338 actions were recorded and analyzed from the downloaded applications. In 2,279 cases, demographic data were collected by a questionnaire.

Results: Overall the application was used by 11,688 smartphone users, in 3,406/11,688 (29.1%) cases at least once a week for at least 28 days. 3,209/11,688 (29.5%) used the application at least 84 days. 1,554/2,279 (68.2%) of users surveyed were male, the stated age of all users was between 6-87 years (mean 44). 1,697/2,279 individuals (74.5%) declared to be suffering from cardio-vascular disease, 292/2,279 (12.8%) had a previous history of transplantation and 161/2279 (7.1%) suffered from diabetes mellitus. 1,568/2,279 (68.8%) of users were on <6 different medications, 201/2,279 (8.8%) 6 – 10 and 26/2,279 (1.1%) on more than 10.

Conclusions: A smartphone application that supports drug adherence is already regularly used by chronically ill users with a wide range of diseases over a longer period of time.

FR-PO750

Is Frequency of Renal Tumors Increased in Lithium-Treated Patients? Mohamad Zaidan,[1] Fabien Stucker,[2] Benedicte Stengel,[3] Aurelie Hummel,[1] Paul Landais,[1] Viorel Vasiliu,[1] Jean-Jacques Boffa,[1] Pierre M. Ronco,[2] Jean-pierre Grünfeld,[1] Aude Servais.[1] *[1]Necker Hospital, Paris, France; [2]Tenon Hospital, Paris, France; [3]Inserm U1018, Villejuif, France.*

Background: Prevalence of renal cancers (RC) is increased in some toxic interstitial nephropathies. Our aim was to determine whether the frequency of renal tumors in lithium-treated (Li2+) patients was increased.

Methods: 170 Li2+-patients with renal imaging were included. The diagnosis of renal tumor was confirmed by pathological analysis. Two sex-, age- and eGFR-matched CKD patients with renal imaging but no Li2+ exposure were randomly selected for each Li2+-patient.

Results: 108 females and 62 males were included (mean age 65±12 years) with a mean follow-up of 6±6 years and eGFR of 40±17 ml/min/1.73m². 14 patients (8F/6M, mean age 64±9 years) had renal tumor including 7(4%) cancers and 7(4%) benign tumors. Pathological analysis was performed for all cases but 2 with typical angiomyolipomas. RC included 3 clear cell renal cell carcinoma (RCC), 2 papillary RCC, 1 hybrid tumor characterized by the association of chromophobe RCC and oncocytoma, and 1 clear cell carcinoma with leiomyomatous stroma. Benign tumors included 4 oncocytomas, one of which was associated with numerous papillary adenomas, 1 mixed epithelial and stromal tumor and 2 angiomyolipomas. The mean duration of Li2+ exposure at diagnosis was 23±10 years.

Standardized Mortality Ratio of RC in Li2+-patients compared to the French population were: 7.5 (95%CI [1.51-21.95]) and 13.7 (95%CI [3.68-35.06]) in men and women, respectively, suggesting the incidence of RC was significantly increased. The prevalence of RC cancer was also increased in Li2+-patients compared to 340 sex-, age- and eGFR-matched CKD patients without Li2+ exposure (4% *vs* 0%, p <0.001), indicating that the higher frequency in Li2+-patients does not result from detection bias.

Conclusions: Our study demonstrates that the frequency of renal tumors, particularly RC, is increased in Li2+-patients and underscores the importance of a screening by renal imaging. The high frequency of other benign tumors, including oncocytomas, also suggests a potential role of Li2+ exposure in the development of these tumors.

FR-PO751

Risk Factors and Timing of Native Kidney Biopsy Complications Marie-christine Simard-meilleur,[1] Louise Roy,[1] Stephan Troyanov,[2] Soumeya Brachemi.[1] *[1]Nephrology, CHUM Saint-Luc, Montreal, QC, Canada; [2]Nephrology, Hopital Sacre-Coeur, Montreal, QC, Canada.*

Background: The optimal observation period after percutaneous renal biopsy is uncertain. Identifying risk factors and timing of complications is essential to patient care.

Methods: We retrospectively studied all native kidney biopsies performed between January 2007 and July 2011.

Results: The cohort consisted of 287 patients and a total of 313 biopsies, 147 of which were done as an outpatient procedure; 98 patients were kept under observation for 8 hours (h) and 49 for 24h. Fourteen had an abnormal bleeding time, 3 had an INR ≥ 1.5, 33% received dDAVP, 3% platelets and 4% FFP. Outpatients had fewer comorbidities. Eighteen percent of inpatients developed minor complications, a symptomatic hematoma or hematuria not requiring intervention, (12% in outpatients); 17% had major complications, bleeding requiring transfusion or angiographic intervention, (2% in outpatients). Fifteen percent experienced a symptomatic hematoma (12% in outpatients), 8% had macroscopic hematuria (4% in outpatients), 17% received a red blood cell transfusion (2% in outpatients) and 3 inpatients required angiographic intervention. Overall, 79% of complications manifested within the first 8h, 83% at 12h and 91% at 24h. In outpatients, >95% of complications manifested within the first 8h. The risk of symptomatic hematoma correlated with the level of platelets. It increased from 10, 15, 29 to 40% in individuals with >200, 140-200, 100-140 and <100 x 10^9/L platelets who did not receive transfusions, respectively (p =0.03). By contrast, in those with <100 x 10^9/L platelets who did receive a platelet transfusion, a hematoma was observed in only 17%. A needle gauge ≤ 15 tended to predispose to hematomas. Associations between comorbidities, hemostasis (INR, bleeding time), preventive therapy (dDAVP, FFP) and complications were not statistically significant.

Conclusions: Outpatients presented with fewer comorbidities and experienced fewer complications than inpatients. Complications also manifested earlier in outpatients with >95% observable at ≤8 hours. The platelet count was the most predictive risk factor of bleeding. Same-day discharge in selected patients is safe.

FR-PO752

Safety of Native and Transplant Kidney Biopsy Jason M. Kidd, Eddie R. Fuller, Vimal K. Derebail. *Division of Nephrology and Hypertension, University of North Carolina Kidney Center, Chapel Hill, NC.*

Background: Renal biopsy is an important tool for the diagnosis and treatment of patients with kidney disease. The benefits of biopsy must be weighed against potential risks. The purpose of this study was to identify predictors and frequency of complications in native and transplant kidney biopsies.

Methods: We retrospectively examined 301 consecutive percutaneous renal biopsies performed from December 2010 through December 2011. Biopsies were performed with a 16-gauge spring-loaded biopsy needle under real-time ultrasound guidance. The primary outcome measured was any bleeding associated with biopsy. Major complications were defined as significant bleeding requiring blood transfusion, interventional radiology procedure or hospital admission. Minor complications were defined as active bleeding seen radiologically without resultant hematoma formation, arteriovenous fistula (AVF) formation or hematoma without need for intervention.

Results: 301 total biopsies were performed (129 native and 172 transplant). The frequency of complications varied significantly between native and transplant biopsies (Table 1). The risk of significant bleeding requiring transfusion was 5.4% in native kidneys and 0.6% in transplant kidney biopsies. No significant risk factors were identified between patients with and without complications. 37 patients had multiple transplant biopsies performed in the period studied with no major complications.

Type of Complication by Kidney Biopsy

	Native (N=129)	Transplant (N=172)	
	N (%)	N (%)	p-value
Bleeding (incl hematoma/ retroperitoneal bleed)	68 (52.7)	44 (25.6)	<0.001
Major Complication	12 (9.3)	1 (0.6)	<0.001
Transfused blood	7 (5.4)	1 (0.6)	0.02
Bleeding seen radiologically without hematoma formation	6 (4.7)	25 (15)	0.02
AVF	4 (3.1)	16 (9.3)	0.04
Hematoma	61 (47.3)	19 (11.1)	<0.001

Conclusions: Transplant kidney biopsies have a significantly lower risk of major complications compared with native kidney biopsies despite an increased risk of AVF formation. Native kidney biopsies had more bleeding complications. Multiple biopsies of renal allografts did not increase the risk of major complications.

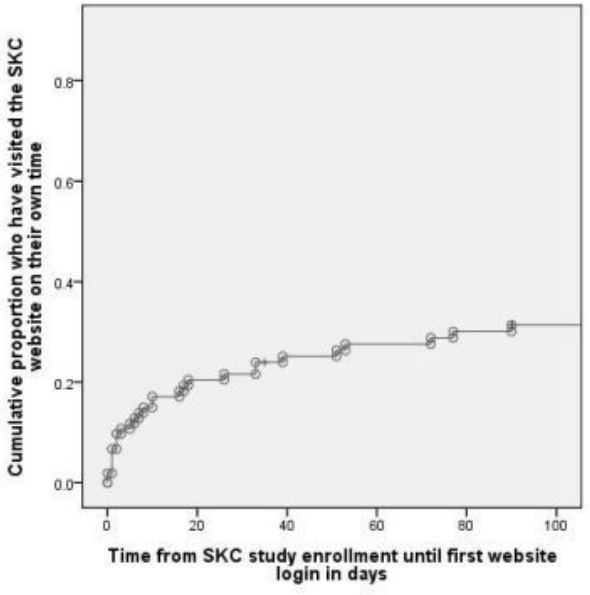
FR-PO753

If You Build It, Will They Come? Use of an Educational Patient Safety Web Site by Patients with Chronic Kidney Disease (CKD): Results from Safe Kidney Care Clarissa Jonas Diamantidis,[1] Marni Zuckerman,[1] Wanda Fink,[1] Peter F. Hu,[2] Shiming Yang,[3] Jeffrey C. Fink.[1] *[1]Medicine, University of Maryland School of Medicine, Baltimore, MD; [2]Anesthesiology, University of Maryland R. Adams Cowley Shock Trauma Center, Baltimore, MD; [3]Computer Science, University of Maryland Baltimore County, Baltimore, MD.*

Background: Use of health information technology (health IT) has become increasingly common in the delivery of care to patients with chronic diseases. We evaluated how frequently patients with pre-dialysis CKD visited an informational Web site aimed at providing disease-specific safety information.

Methods: As part of the Safe Kidney Care (SKC) study, an educational Web site was designed to provide information on specific safety concerns for patients with CKD. Participants in Phase 1 of the study were provided a medical alert bracelet with a unique ID which can be entered into the SKC Web site to track participant entry into the Web site by participants after an in-person tutorial. Participants' visits and dwell times on specific safety modules were tracked.

Results: Of 108 participants, 27% (n = 30) visited the Web site a median of 1 time (range 1-7) from study enrollment after 3 month of follow-up.



Median access time was 7 minutes (range <1-44 minutes). The three most frequently visited pages were "Renal function calculator," "Pills to avoid," and "Foods to avoid." In multivariate adjustment, more than high school education and annual household income >$50,000 were associated with Web site entry. Pertinent factors not found to be predictive were age, race, gender, or GFR.

Conclusions: Preliminary results show general interest in a Web-based platform designed to improve patient safety in CKD.

Funding: NIDDK Support, Pharmaceutical Company Support - American Medical ID

Outcomes of Renal Dosing of Tenofovir in HIV Infected Individuals Alfredo B. Tiu, William Christopher Mathews. *Medicine, Owen Clinic UCSD and Veteran's Admnistration Oceanside Clinic, Oceanside, CA.*

Background: Tenofovir disoproxil fumarate (TDF), a nucleotide reverse transcriptase inhibitor, has been reported to cause proximal renal tubular dysfunction and acute kidney injury. This study evaluates safety and efficacy of extended-interval TDF dose.

Methods: Retrospective, case-control, study of HIV-positive patients prescribed extended-interval dose of TDF between October 2001 to March 2010. Data were collected from Owen Clinic at University of California, San Diego. The primary endpoints were viral load (VL) rebound and CD4 count. Secondary endpoints were serum creatinines (SCr) and estimated glomerular filtration rates (eGFR), proteinuria and glycosuria on random urinalysis, serum phosphate and bicarbonate levels. eGFR was calculated based on MDRD and CKD-EPI equations.

Results: 65 patients met inclusion and exclusion criteria. Average VL prior at start of daily TDF was 89045 copies/mL. 63 patients acheved VL suppression in 6 months. CD4 counts of the 65 patients increased from average of 343 to 406 cells/µl. After dose adjustment of TDF, CD4 counts were stable. 11 patients had TDF discontinued. 13 patients had TDF dose adjusted back to daily dose. 41 patients remained on extended-interval dosing of TDF. 6 on extended-interval dose of TDF had viral rebound. The average SCr was 1 mg/dL, corresponded to an eGFR of 87 mL/min by MDRD at the start of TDF. The average SCr and eGFR when TDF dose was changed to extended-interval were 1.5 mg/dL and 55 mL/min. eGFR by both MDRD and CKD-EPI were stable or improved when TDF dose was adjusted. Proteinuria and glycosuria were higher on extended-interval TDF dose. Hypophosphatemia and metabolic acidosis were not significant.

Conclusions: In HIV positive adult patients on dose-adjusted TDF for renal impairment, viral rebound appears unlikely and CD4 counts are likely to remain stable. Renal function stabilize or slighly improve after dose adjustment. Proteinuria and glycosuria were better markers for renal injury compared to low serum phosphate or bicarbonate. This study provides insight and clinical confidence in continuation of TDF at renally adjusted dose, which allows preserving alternative HAART regimens for the future.

FR-PO755

Cross Reacting Antibodies to Fab 2 Fragments Causing Liver Toxicity after Rituximab and Adalimumab Therapy Joerg Latus,[1] Peter Fritz,[2] Martin Kimmel,[1] Mark Dominik Alscher,[1] Niko Braun.[1] *[1]Nephrology, Robert- Bosch Hospital, Stuttgart, Germany; [2]Division of Pathology, Diagnostic Medicine, Stuttgart, Germany.*

Background: We present a case ofacute liver toxicity in a patient with refractory ANCA-associated GPA, first after treatment with Rituximab and secondly after Adalimumab therapy. We hypothesized the presence of cross reactive antibodies to the two different therapeutic monoclonal antibodies (Tmab) and performed a detailed scientific work-up.

Methods: Three sera from the patient were analyzed for antibodies to rituximab and adalimumab by ELISA. As controls, the microtiter plates were coated with the Fab fragment of an unrelated humanized monoclonal antibody, with human Fc proteins as well as a mouse IgG globulin. Additionally, lymphocyte transformation test (LTT) using rituximab and adalimumab as antigens was performed.

Results: Viral serology for hepatitis A, B, C and autoantibodies specific for autoimmune liver disorders were negative. Transjugular liver bopsy showed histopathological findings compatible with drug-induced liver toxicity. In all three sera from the patient antibodies to rituximab could be detected by ELISA. Two samples had also antibodies to adalimumab, although the patient had not received adalimumab at that time, indicating cross reactivity between both substances. Testing against an unrelated human Fab fragment also revealed positive results, indicating that the patient had developed antibodies against human Fab fragments in general. The Fc proteins were negative, and patients' sera did also not react with mouse IgG globulins. LTT revealed negative results.

Conclusions: This is the first study demonstrating liver toxicity induced by two different Tmabs. Cross reacting antibodies to Fab2 fragments are probably involved. Whether drug toxicity or treatment failure of Tmab therapy are associated with the presence of antibodies to Fab2 fragments has to be evaluated in further studies.

FR-PO756

Disparity in the Treatment of Pediatric Nephrotic Syndrome with Rituximab: Survey of Pediatric Nephrology Centers in the United States Teri L. Crumb, Alejandro Quiroga. *Pediatric Nephrology, Helen DeVos Children's Hospital, Grand Rapids, MI.*

Background: Off-label use of rituximab has been increasingly reported in recent literature for treatment of refractory nephrotic syndrome (NS). An assessment of center practices would ascertain areas of variability and establish the foundation for future research that promotes the safe utilization of this therapy.

Methods: A survey was designed to assess pediatric nephrology centers use of rituximab across the U.S. We assessed for standard practices and experiences by examining: indications, dosing, treatment intervals, clinical side effects, clinical markers used, concomitant therapies and weaning parameters.

Results: 46 pediatric centers were contacted and 25 responses were received with a rate of response of 54%. 4 centers (16%) reported no use of rituximab for NS and 2 (8%) had not used it in the last year. 19 (76%) reported treatment utilization and those results follow. Indication for treatment identified 84% use rituximab as a last resort option and 90% reported dosing at 375mg/m^2. Markers commonly followed were CD 19 and urine Pr/Cr ratio (both 84%). Concomitant medications used were steroids (84%), calcineurin inhibitors (47%) and mycophenolate mofetil (42%). Centers identified the 1st therapy to be weaned post infusion was steroids (74%). The areas of great variability were intervals of dosing, indications for weaning concomitant therapy and the weaning period. The following intervals were reported: single dose (21%), 4 doses/1wk interval (26%), 2 doses/2wk interval (32%), initial/1yr (11%) and variable (26%). When to start weaning therapies was reported as time interval (11%), clinical exam (11%), markers (37%) and variable (47%). Weaning periods were 2 wk (5%), 4 wk (11%), 8 wk (26%), >12wk (11%) and variable (42%).

Conclusions: Rituximab is widely used in the U.S. for NS (76% of survey centers). However, the lack of current guidelines and standardization given the widespread use of rituximab could affect patient safety. We have identified variability in three major areas. This great disparity among centers in the dosing intervals and weaning parameters should prompt us towards the establishment of consensus group guidelines.

FR-PO757

Managing Peritoneal Dialysis-Related Peritonitis Using a Cloud-Based Web App Dimas Yusuf, Daniel Schwartz. *Faculty of Medicine, University of British Columbia, Vancouver, BC, Canada.*

Background: Peritonitis is a common and serious complication of peritoneal dialysis. Most cases of uncomplicated peritonitis may be safely treated on an outpatient basis, however this requires timely patient care and rigorous follow-up involving a multidisciplinary team approach.

Methods: We sought to improve our management of peritonitis with the goal of improving care and reducing the frequency of subsequent infections. We created a secure web-based app to optimize day-to-day management and ensure adherence to our evidence-based care pathway. This app allows us to monitor our cases and ensure that we: (1) obtain samples for culture and sensitivity; (2) start empiric antimicrobial therapy; (3) adjust the treatment based on culture results; (4) obtain a follow-up culture to ensure resolution of infection; and (5) complete a home visit to provide additional patient support. Any divergence or delay from this protocol is detected by the app, which generates a visual alert that prompts corrective action. The app also assists with drug dosing and provides reminders for fluconazole prophylaxis. Lastly, it provides a platform for data collection and analysis to aid in CQI activities.

Results: Since our app was launched in November of 2010, our peritonitis rate decreased from 1 in 24.4 months in the 6 months prior to launch, to 1 in 29.2 in the 6 months prior to June 2012 (NS). Pre-and-post launch staff surveys revealed increased confidence in quality of care—the proportion of staff who "strongly agree" that all cases of peritonitis are thoroughly managed and followed-up increased from 6.3% to 45.8% ($p < 0.001$).

Conclusions: A web-based app to manage and track infectious peritonitis can be used to encourage adherence to a clinical care path. While we demonstrated improvement in team confidence in quality of care, further study is required to determine if patient outcomes can be improved.

FR-PO758

Peritoneal Dialysis Patients in Thailand's Worst Flood Piyatida Chuengsaman. *CAPD Service and Training Center, Banphaeo Hospital, Bangkok, Thailand.*

Background: Last year, from late September till early December, Thailand's worst flood occurred in the central region of Thailand. This affected everyone included PD patients. We provide special services to make sure the patient's safety.

Methods: There are three options which we provide for our patients.

First: move to other provinces.

Our staff will inform the patient destination's PD center. In case of emergency, or shortage of any supplies, our patients can contact them. Our patients should bring all the supplies and the medicines they needed along with them. They will check for the quality of water supply and area for exchange procedure. If they would like to have any suggestions, they can phone or MMS to our staff.

Second: move to our own shelter "Banphaeo shelter for PD patients".

We set Banphaeo shelter in Samutsakorn province near Bangkok. This shelter contains all the basic need for normal daily living. And the most important things are to provide PD solution, water supply, space to make the exchange procedure and medical care.

Third: decide to"not move".

We provide a specific guideline for our patients. The guideline contains suggestion for hand hygiene in case of shortage of water supply or water treatment in case of suspect the quality of tap water. Additionally, it contains how to prepare the space for exchange procedure in case of any limitation. We also keep contact with them to provide any help.

Results: We analyze for the patient's safety in this time period compare to the three months before the disaster. The number of peritonitis episodes from June till December 2011 are as followed; 29, 23, 23, 24, 19, 18 and 22 respectively. In the first group, which is about 50 patients, one patient expired due to acute myocardial infarction, one got peritonitis and one got exit site infection. In the second group, which are about 40 patients, one patient expired due to sudden death and one got peritonitis. In the third group, which are about 550 patients, who decide to "not move", the number of dead cases, peritonitis did not change compare to normal situation.

Conclusions: Peritoneal dialysis patients are at risk when disaster occurred. But if PD center helps our patients to manage, we can ensure our patient safety in this special situation.

FR-PO759

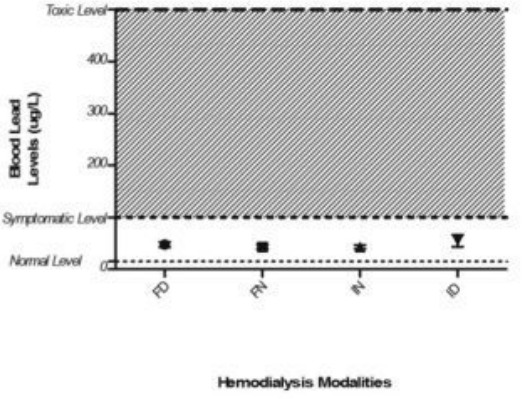
Elevated Blood Lead Levels in Home Hemodialysis Patients: Are They Toxic or Acceptable? Shih-Han S. Huang,[1] Guido Filler,[2] Benjamin Ka Thomson,[1] Peter G. Blake,[1] Robert M. Lindsay.[1] *[1]Medicine, Division of Nephrology, London Health Sciences Centre, London, ON, Canada; [2]Paediatric, London Health Sciences Centre, London, ON, Canada.*

Background: Hemodialysis patients with minimal or no residual renal function may be liable to trace metals (example: lead) exposure (dialysate and phosphate binders) and accumulation. In this study, we reported the blood lead levels in our home hemodialysis patients and assessed variables that may influence the levels.

Methods: Blood lead levels were taken from 46 home hemodialysis patients during their clinic visits. These were compared with those found in the general population and with known toxic levels. The blood lead concentrations of patients on different treatment modalities (conventional vs. quotidian) were compared. The relationship between the blood lead levels and other continuous variables was examined.

Results: The median (Shapiro-Wilk test indicated non-normal distribution) blood lead level was 44.4 ug/L (inter quartile range: 32.2, 55.9), which was significantly different (Wilcoxon Signed Rank test, $p<0.001$) than normal (15 ug/L) and toxic (>100-500 ug/L) levels.

Figure 1. The blood lead levels (ug/L) of patients on different treatment modalities: frequent daily (FD), frequent nocturnal (FN), intermittent nocturnal (IN) and intermittent daily/conventional (ID) hemodialysis.



There were no significant differences in median blood lead levels between patients who were on different hemodialysis modalities (Kruskal-Wallis test, P=0.81). There were no significant correlations between blood lead levels and any of the variables we assessed (Spearman's test, P=0.09-0.66).

Conclusions: The blood lead levels were elevated but not related to age, dialysis vintage or modalities, residual renal function nor parathyroid hormone levels. Thus potentially iatrogenic contribution of dialysis to lead accumulation was excluded. These elevated blood lead levels may represent the "acceptable" levels in this population. Further prospective studies are indicated to establish the acceptable levels for other trace metals with various dialysis modalities.

FR-PO760

Epoetin Zeta for Treatment of Anemia in Chronic Kidney Disease: 4-Year Post-Marketing Surveillance Helen Phillips, Andrew Buckley. *Hospira UK Ltd, Royal Leamington Spa, United Kingdom.*

Background: Epoetin zeta (Retacrit®, Hospira UK) is a biosimilar erythropoiesis-stimulating agent (ESA) indicated for treatment of anemia associated with chronic renal failure in adult and pediatric patients on hemodialysis, adult patients on peritoneal dialysis, and for treatment of severe anemia of renal origin accompanied by clinical symptoms in adult patients with renal insufficiency not yet undergoing dialysis. Approval of biosimilar ESAs in the EU requires extensive scientific evaluation and stringent regulatory procedures, ranging from preclinical/clinical studies to tightly controlled manufacturing processes. Post-marketing pharmacovigilance is an integral part of regulatory requirements. This post-marketing surveillance study was undertaken as part of periodic safety update reports submitted to the regulatory authorities. **Aim:** To assess the continuing safety of epoetin zeta in treating renal anemia.

Methods: Data were obtained from 18 December 2007 – 31 December 2011. Adult patients with symptomatic anemia received subcutaneous epoetin zeta as per the EU summary of product characteristics (50 IU/kg 3 times/week for 4 weeks). Depending on response, subsequent dosage varied from 75–300 IU/kg/week. A 3-month dosing period was used as average exposure time and total cumulative post-marketing exposure estimate was based on sales of finished product.

Results: Patients received approximately 45,000 IU during the initial course of treatment and 112,500 IU during maintenance therapy. The average total dose per patient was 157,500 IU. During the surveillance period, 8,522,817,000 IU or 54,113 patient-courses were used according to the epoetin zeta nephrology indication. The total cumulative post-marketing and clinical exposure estimate (oncology and nephrology data) was approximately 25,770,847,000 IU or 86,159 patient-courses. No reports of neutralizing antibodies or cases of pure red cell aplasia have been received to date.

Conclusions: The total epoetin zeta patient exposure now exceeds 86,000 patient-courses, of which over 54,000 patient-courses were in the nephrology indication. In these patients, no new safety issues have been identified which impact on the established safety profile of the product.

FR-PO761

Antibiotic Spacers in the Treatment of Infected Prostheses: A Systematic Review and Risk-Benefit Clinical Decision Analysis Andrew Luu, Madhumathi Rao. *Nephrology, Tufts Medical Center, Boston, MA.*

Background: Two-stage arthroplasty is currently the treatment of choice for infected joint prostheses. There is limited data regarding safety or risk benefit ratio. In a systematic review of the literature we examined the rate of acute kidney injury (AKI) and infection recurrence as a measure of efficacy, and assessed the risk-benefit ratio of antibiotic spacer use to aid clinical decision making.

Methods: We applied screening filters to searches from Ovid. Using data inputs from systematic review, primary analyses and expert opinion we computed probabilities for AKI and infection recurrence for different therapeutic approaches - medical therapy, two stage arthroplasty without antibiotic spacers, low dose or high dose aminoglycoside spacers or other antibiotic spacers. Risk benefit analysis was run with TreeAge Pro 2012 modeled for age and baseline CKD to find the best utility and quality-adjusted life expectancy by the DEALE method.

Results: We found 10 studies addressing AKI and 31 studies addressing infection recurrence in patients undergoing 2-stage arthroplasty. The incidence of AKI in 544 patients ranged from 1.8 to 17% depending on definition of AKI. Reported risk factors were aminoglycoside dose, age, baseline chronic kidney disease (CKD), vascular comorbidity and hypotension. Infection recurrence occurred in 6.6% of 1019 patients and was associated with knee rather than hip prostheses (56% vs 44%), but not with type of antibiotic in the spacer or organism including MRSA. Limitations of the literature included inadequate and heterogenous data precluding metaanalysis.

The best utility and quality-adjusted life expectancy calculated by the DEALE method was seen in the younger patient without comorbidity.

Conclusions: Antibiotic spacers are associated with significant nephrotoxicity and systemic complications. Judicious patient selection with treatment tailored to patient comorbidities guided by robust data and application of decision analyses models would support the best outcomes.

Renal and Cardiovascular Outcomes in Patients with Fabry Disease under Long Term Enzyme Replacement Therapy Ricardo M. Heguilen,[1] Amelia Rita Bernasconi,[1] Juan Politei,[1] Gustavo H. Cabrera,[1] Roland C. Blantz.[2] *[1]Medicine & Neprhology, Hospital Fernandez, Universidad de Bs As., Bs As, Caba, Argentina; [2]Medicine, University of California San Diego and VASDHS, San Diego, CA.*

Background: Variable degree of proteinuria and progressive renal failure, along with CV and CNS involvement are major features in adult patients with Fabry disease (FD). Enzyme replacement therapy (ERT) must be initiated as early as possible to prevent terminal organ damage; ERT has been proved to reverse substrate storage in lysosomes. We report the renal and CV outcomes of a cohort of FD pts, most of them on ERT.

Methods: 29 pts (18 F) aged 17-56 years (35.2 ± 2.1y) with a history of FD based upon typical manifestations and a reduced activity of leukocyte a-gal were prospectively studied for up to 9.5 y (median 5y). 22 pts were on ERT with IV agalsidase α or agalsidase β; administered according to manufacturer´s directions. Glomerular and tubular, as well as cardiac functions were evaluated clinically and through standard laboratory methods and echocardiographically.

Results: 25 individuals displayed renal involvement (mild proteinuria and/or excretory dysfunction). Baseline Cr clearance was 89.0 ± 5.3 mL/min and 8 individuals exhibited baseline urine protein excretion > 0.5 g/d. Hypercalciuria, was present in 8 patients. Proteinuria as well as excretory function remained. The average CrC at the end of follow up was 80.0 ± 6.0 mL/min (p: NS vs. baseline). $TRPO_4$ decreased slightly although significantly from 86.2 ± 1.1 to 80.3 ± 2.0% ($p<0.05$). Similarly, $TmPO_4$/GFR decreased from 3.3 ± 0.2 to 2.7 ± 0.1 mg/dL ($p< 0.05$). There was a trend for this reduction be more pronounced in males than in females. 7 patients displayed non progressive concentric myocardial hypertrophy with prolonged isovolumetric ventricular relaxation time (IVRT).

Conclusions: Renal and cardiac involvement are frequent in individuals suffering from FD but may be stabilized by ERT. The long term subtle reduction in $TRPO_4$ may be an early marker of proximal tubular dysfunction due to the disease or as a consequence of drug - induced toxicity.Enzyme replacement therapy is safe and effective in preserving renal and CV function in patients with Fabry.

FR-PO763

Static and Dynamic Balance Function in Dialysis Patients Yafei Yang,[1] Hsiu-chen Lin,[2] Shuya Chen,[2] Chiu-Ching Huang.[1] *[1]Nephrology, China Medical University Hospital, Taichung, Taiwan; [2]Physical Therapy, China Medical University, Taichung, Taiwan.*

Background: Falls in dialysis patients are common and cause significant morbidity and mortality. Multiple risk factors of falls have been identified, such as age, falling history, lower extremities weakness, balance problems, arthritis, orthostatic hypotension, and anemia. Computerized dynamic posturography (CDP) system, which can perform sensory organization test (SOT), limits of stability (LOS) and rhythmic weight shifting (RWS) tests, is widely used for evaluating static and dynamic balance problems in the elderly and various patient groups. However, limited literature addressed the issue of balance function in dialysis patients. The aim of this study was to fill this gap.

Methods: Twenty-six patients (19 peritoneal dialysis, 7 hemodialysis) receiving dialysis more than 3 months were enrolled. Twenty-eight age-matched healthy volunteers were also recruited as control group. Each participant received anthropometric measurements, physical fitness (5-repetition sit-to-stand (STS), grip strength test, sit-bend test and 6-minute walk test) and static and dynamic balance function tests on the CDP system.

Results: There were no differences in height, weight, body fat and body mass index between groups. All the physical fitness parameters, except for sit-bend test, were significantly worse in the dialysis group. They also demonstrated worse performance in the balance tests, i.e. lower composite equilibrium score in SOT, lower composite score of reaction time, movement velocity, endpoint excursions in LOS test, and directional control in LOS and RWS tests. The composite equilibrium score, the average score of four SOT conditions, was moderate correlated with 5-rep STS time (-0.41, *P=0.04)*, grip strength (0.43, *P=0.03)*, 6-min walk distance (0.55, *P=0.004)*, and sit bend length (0.50, *P=0.01)*.

Conclusions: Balance functions of dialysis patients are significantly impaired compared to age-matched controls. The composite equilibrium score was the best balance variable that related to all the physical fitness variables.

Funding: Government Support - Non-U.S.

FR-PO764

Percutaneous Insertion of Peritoneal Dialysis Catheters by Nephrologists: The Learning Curve Matthew R. Todd, Gerry Endall, Mark Dominic Uniacke, Paul Gibbs. *Wessex Renal & Transplant Service, Queen Alexandra Hospital, Portsmouth, Hampshire, United Kingdom.*

Background: The Wessex Renal & Transplant Service has been using a combination of percutaneous and open surgical techniques for peritoneal dialysis catheter insertion since 2006. Around 1/3 of catheters are inserted percutaneously under conscious sedation by nephrologists. We have recently instituted a formalized training program for nephrologists-in-training learning catheter insertion.

Methods: We retrospectively analyzed catheter survival (censored for non-patency-related change of modality and death) and compliance with ISPD audit standards for technical success (<1% bowel perforation/hemorrhage, <5% exit site infection/peritonitis within 2 weeks of insertion, <20% need for manipulation/replacement or technique failure). Catheters were grouped by the experience of the operator at the time of insertion (number of catheters previously inserted). Catheter survival was plotted using the Kaplan-Meier method.

Results: 133 catheters were inserted percutaneously by nephrologists over the 6-year period by 15 different operators (range 1-31 catheters per operator). Overall all ISPD audit standards were met. The technical failure rate (catheter not usable at day 14 post-insertion) was higher with inexperienced operators: 1st catheters 13% (2/15), 2nd-10th catheters 10% (7/67), >10th catheters 5% (2/44). There were no technical failures in 28 catheters inserted by operators with experience of 13 or more prior catheter insertions.

Conclusions: Our data show a distinct learning curve for percutaneous peritoneal dialysis catheter placement by nephrologists in training. This has implications for training programs for interventional nephrologists. In the UK, the Renal Association recommend that all nephrology trainees have the opportunity to learn peritoneal dialysis catheter placement; however, the needs of trainees needs to be balanced with the outcomes for patients. Our data would suggest that, with our current rate of around 25 percutaneous insertions per year, it may not be possible to give all trainees adequate experience in peritoneal dialysis catheter insertion whilst giving patients the highest likelihood of technical success.

FR-PO765

Safety and Long Term Outcomes of Percutaneous Peritoneal Dialysis Catheter Insertion under Local Anaesthesia Jonathan Dick, Kate Bramham, Elaine Bowes, Ravi Kumar, Sean Main, Elaine Ruth Sylvester, Claire C. Sharpe, Hugh Cairns, Satish Jayawardene. *Renal Unit, King's College Hospital, London, United Kingdom.*

Background: Percutaneous peritoneal dialysis (PD) catheter placement under local anaesthesia (LA) allows PD to be offered as the initial mode of renal replacement therapy. However, theoretical concerns over safety and outcomes may influence the choice of this access approach amongst clinicians.

Methods: Records of 543 catheter insertions performed from 2002-2011 were retrospectively reviewed. LA catheters were inserted using the Seldinger technique by nephrologists or a specialist nurse. Surgical insertion took place under general anaesthetic (GA). Procedure failure was defined as failure to insert a catheter or it was not functioning at day 0 or 1. Failures were not included in analysis of other complications. Patients who died, received a renal transplant, or transferred to another unit during the period assessed were excluded from analysis.

Results: Patient baseline characteristics were not significantly different between access approaches.

Outcomes of LA/GA Catheter insertions

	LA	GA	P Value
Total Catheter Insertions (No. Patients)	324 (254)	219 (112)	-
1st Catheter Insertion	251 (78%)	99 (45%)	<0.0001
Procedure Failure	32 (10%)	9 (4%)	0.013
Received Haemodialysis before 1st Catheter Insertion	49 (19%)	37 (38%)	<0.0001
Catheter Functioning at 6 Months / 1 Year	138 (51%) /102(36%)	109 (57%)/76 (41%)	NS
Exit Site Infection <30 Days	32 (11%)	28 (13%)	NS
Peritonitis <30 Days	16 (5%)	15 (7%)	NS
Inpatient Stay Days Median (IQR)	0 (0-5)	4 (3-6)	<0.0001

Conclusions: To our knowledge this is the largest series of LA PD catheter insertions. Patients who have LA PD catheter insertion have significantly shorter inpatient stays and are less likely to require haemodialysis prior to the procedure. LA PD catheter insertion is associated with a higher immediate procedure failure, however rates of infective complications and catheter patency at one year are similar to insertions under GA.

FR-PO766

The Development and Success of an Outpatient Peritoneal Dialysis Catheter Placement Program Randall L. Rasmussen,[1] Rajeev Narayan,[2] Aris Q. Urbanes,[1] Gerald A. Beathard,[1] Terry Litchfield.[1] *[1]Lifeline Vascular Access, Vernon Hills, IL; [2]San Antonio Kidney Disease Access Center, San Antonio, TX.*

Background: Peritoneal dialysis (PD) success depends upon timely and skilled placement of a PD catheter (PDC). Most PDCs are placed by surgeons, but advances in percutaneous or laparoscopic placement have resulted in non-surgeons placing more PD catheters. In this study, a large outpatient vascular access system developed a national program to provide this service to patients.

Methods: Ten (10) centers were trained in percutaneous and peritoneoscopic placement of PD catheters by an expert physician. Training including a didactic training; followed by simulation training and performance of procedures with the training physician present. During the training period, the local dialysis provider and PD nurses were engaged in the program. Data was collected in an electronic health record and analyzed using SPSS software.

Results: One hundred and forty seven (147) PD catheters were placed during the one year period following training and program launch. The program has been a clinical success with a 95.9% success rate and a 1.4% complication rate including a .7% major complication rate. The mean age of the patients were 55 years old; 54% diabetic. More than 70% of the patients have come from one large dialysis organization (LDO), reflecting their active engagement in patient PD starts.The most common reasons for PD catheters were to either start dialysis (43.5%) or modality change (44.2%). Average case times were 74.39 minutes. The early failures are small (n=3) and 2 of the 3 successfully got another PD catheter.

Conclusions: A dedicated outpatient program for the placement of PD catheters can be very successful when training is formal along with focus on quality outcomes. In addition, the support of LDOs is critical to program development and success.

FR-PO767

Emergent and Urgent Peritoneal Dialysis Instead of Hemodialysis with a Central Venous Catheter Mukesh Sharma, Kenneth D. Abreo, Bharat Sachdeva. *Nephrology, Louisiana State University Health Sciences Center, Shreveport, LA.*

Background: In the US, 60-80% of ESRD patients start HD with a central venous catheter (CVC), resulting in an unacceptably high morbidity and mortality from infections. Selecting PD as the initial dialysis modality is an excellent CVC avoidance strategy.

Methods: Emergent PD (EPD) is defined as starting PD immediately (24-48 h) after PD catheter (PDC) placement whereas urgent PD (UPD) is defined as starting PD within 2 weeks of PDC placement. 5 new ESRD patients were educated by their nephrologist on the merits of each dialysis modality and chose PD over HD. Of these 5 patients only 1 had a vascular access in place. 3 patients did EPD and 2 UPD. Indications for EPD and UPD were uremia, volume overload, and hyperkalemia. Two EPD and 1 UPD patients received 1-3 HD treatments through a CVC and AVF respectively prior to PDC placement. Interventional nephrologists placed PDCs with fluoroscopy guidance under moderate sedation and local anesthesia. A purse string suture was intentionally placed in the anterior rectus sheath encircling the catheter to prevent PD fluid leak. Low volume (1 liter) exchanges were used with the patient in the supine position.

Results: There were no PDC infections, leaks, malfunction, or any procedure related complications in any of the patients immediately after placement. Demographics and laboratory results for EPD and UPD were as follows:

#	PD Type	Gender/Age/ Race	Indication	eGFR	Pre-PD Crt	Post PD Crt	Pre-PD BUN	Post PD BUN	Pre-PD K	Post PD K	Pre-PD HCO3	Post PD HCO3
1	EPD	M/30/AA	Uremia	4	19.5	16.5	139	92	5.1	3.8	18	27
2	EPD	M/62/AA*	Hyperkalemia	11	8.6	6.8	93	51	6.3	4.9	25	25
3	EPD	F/57/AA*	Hyperkalemia	8	4.7	5.2	63	60	5.5	4.8	17	23
4	UPD	F/21/AA	Uremia	10	8.7	5.7	123	64	4.4	4.3	25	25
5	UPD	F/62/W†	Volume	11	3.5	3.2	38	44	5.8	5.4	33	24
			Mean	8.8	8.2	7.5	87.2	62.2	5.0	4.6	23.6	24.8
			Std. Dev.	2.9	6.5	5.2	40.5	18.4	1.3	0.6	6.3	1.5

AA=African-American, W=White, Pre-PD=before start of PD, Post PD for EPD=hospital discharge day, Post PD for UPD=after ~ 7 d of PD
*Patient had one HD treatment for Hyperkalemia, †Patient had HD for 3 days for volume overload using AVF

Conclusions: ESRD patients are often amenable to PDC placement, especially if the physician can provide modality options and the pros and cons of PDC versus CVC. Insertion of PDC at short notice is a sine qua non for starting EPD or UPD. PD can be started immediately with no complications and continued in the outpatient setting thus avoiding the perils of a CVC in patients without a vascular access.

FR-PO768

A Comparison of Swan-Neck and Conventional Straight Catheters with Upper Abdominal Exit-Site Locations Masahiro Eriguchi,[1] Hisako Yoshida,[2] Kazuhiko Tsuruya,[2] Takanari Kitazono.[1] *[1]Department of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; [2]Department of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan.*

Background: Catheter related infections are crucial problem among peritoneal dialysis patients. Compared to a conventional method with a lower abdominal exit-site location, clinical studies of extended catheters with an upper abdominal exit-site (UAE) location tended toward lower incidences of exit-site infection (ESI) and catheter infection-related peritonitis. Also, several studies have been reported with the use of swan neck (SN) catheters compared with conventional straight (CS) catheters. But a beneficial effect on clinical outcomes by a SN catheter with an UAE location is not critically investigated.

Methods: This is a non-randomized comparison of 56 consecutive patients who were applied CS catheter with an UAE location (CS group) and 21 consecutive patients who were applied SN catheter with an UAE location (SN group). Prospective data collection included patient demographics, infectious complications and catheter survival. To evaluate infectious complications, we use Kaplan-Meier survival curves for first episode of infectious complications and recurrence data analyses for recurrent episodes of infections.

Results: Less exit-site infections (1/15.6 vs 1/10.3 patient-month) and peritonitis (1/41.6 vs 1/28.9 patient-month) were observed in the SN group than in the CS group. Survival rate for first episode of ESI of the SN group tended better than that of the SN group (p=0.062). But survival rate for first episode of peritonitis and catheter survival were not different. By recurrence data analyses, mean cumulative episodes of ESI tended less in the SN group than the CS group, but this was not statistically different.

Conclusions: For an upper abdominal exit-site location, the extended swan-neck shaped catheter may contribute to reduce exit-site infections.

FR-PO769

Acute Peritoneal Dialysis in the Pediatric Population of New Zealand: A Review of the Introduction of a New Catheter Insertion Technique Maria P. Stack, Hemal Kodikara, Tonya Kara. *Pediatric Nephrology, Starship Children's Hospital, Auckland, New Zealand.*

Background: Starship Hospital is the only national referral centre providing acute dialysis for pediatric patients in New Zealand. The advantages of using peritoneal dialysis (PD) in these children include the ability to perform continuous renal replacement therapy, with optimized nutrition, avoiding central venous access. The disadvantages include the potential for early leaks, delayed use and restricted volumes with an open insertion. To allow early use the surgeons at this centre have been using a laparoscopic technique since 2005. We specifically examined the introduction of laparoscopic assisted PD catheter insertion compared with open insertion technique.

Methods: We performed a 10 year review of acute peritoneal dialysis in Starship Hospital from 2001 to 2011. We excluded peritoneal dialysis carried out post cardiac surgery and catheters placed for chronic use. We analyzed data based on insertion technique, either open or laparoscopic assisted.

Results: Data on 99 children who had acute kidney injury (AKI) and received PD was analyzed. The mean age of the group was 3.9 years (SD 3.3years). Predominant diagnosis was HUS, accounting for 69/99 cases, followed by sepsis related AKI and acute glomerulonephritis. There were no cases of peritonitis in the 18 children who had laparoscopic approach, and 5/81 (6%) cases in the standard open approach. In the lapraoscopic group 2/18 (11%) required further manipulation of catheter after initial insertion, compared to 14/81 (17%) in the open group. Conversion to HD due to catheter related complications was seen in 2/18 (11%) laparoscopic cases and 9/81 (11%) of open cases.

Conclusions: Overall we have had success with acute peritoneal dialysis in New Zealand and the introduction of the new technique has not resulted in an increased rate of catheter related complications when compared to standard approach. The infection rates are lower with the laparoscopic approach, acknowledging the low number of cases in our group.

Peritoneal Dialysis Solutions Containing Low Polydispersity Glucose Polymers as Osmotic Agents: Theoretical Predictions from the Three-Pore Model J. Ken Leypoldt, Alp Akonur, Clifford J. Holmes. *Medical Products R&D (Renal), Baxter Healthcare Corporation, Deerfield, IL.*

Background: Icodextrin is an osmotic agent for peritoneal dialysis (PD) solutions containing glucose polymers with a weight-average molecular weight (Mw) between 12 and 20 kilodaltons (kD) and a number-average molecular weight (Mn) between 5 and 6.5 kD; the polydispersity (Mw/Mn) for icodextrin has been reported to be 2.6 (Vonesh et al, Perit Dial Int 2006). We used mathematical modeling based on the three-pore model to determine combinations of Mw (1-24 kD), polydispersity (1.6-2.4) and glucose polymer concentration (4.0-15.0%) that achieved higher ultrafiltration (UF) without an increase in carbohydrate absorption compared with icodextrin.

Methods: Mathematical modeling of UF as a function of time during a long dwell of 12 hours was performed based on PD Adequest 2.0 for high, high-average and low-average transport patients, according to their UF profile. All glucose polymer, including icodextrin, distributions were assumed to be log-normal, and carbohydrate absorption was calculated as the mass of glucose polymer infused minus that remaining after 12 hours. Glucose polymers were defined as having improved UF performance if they achieved higher UF after 12 hours than that using icodextrin at any concentration between 7.5 and 15% without additional carbohydrate absorption for all patient transport types (with a tolerance of 3 g).

Results: Computed results demonstrated that 1) no glucose polymer with Mw between 1 and 7 kD had improved UF performance at any polydispersity or concentration; 2) glucose polymers with Mw between 8 and 14 kD at a concentration of 7.5% achieved modestly improved UF performance (up to 20% higher UF, depending on polydispersity); 3) glucose polymers with Mw between 8 and 24 kD at concentrations greater than 7.5% achieved more substantial improvements in UF performance at specific low polydispersity-concentration combinations.

Conclusions: As osmotic agents for PD solutions, glucose polymers can achieve higher UF than icodextrin without additional carbohydrate absorption by decreasing their polydispersity and increasing the glucose polymer concentration.

FR-PO771

Peritoneal Dialysis Solutions Containing Low Polydispersity Glucose Polymers as Osmotic Agents Achieve Higher Ultrafiltration than 7.5% Icodextrin without an Increase in Carbohydrate Absorption: Validation in a Rabbit Model J. Ken Leypoldt, Catherine M. Hoff, Clifford J. Holmes. *Medical Products R&D (Renal), Baxter Healthcare Corporation, Deerfield, IL.*

Background: Peritoneal dialysis (PD) solutions containing icodextrin as the osmotic agent have advantages during long dwells. The glucose polymers comprising icodextrin have been reported to have a polydispersity (ratio of weight-average to number-average molecular weight or Mw/Mn) of 2.6 (Vonesh et al, Perit Dial Int 2006). We hypothesized that a PD solution containing glucose polymers with low polydispersity at high concentration could achieve higher ultrafiltration (UF) without an increase in carbohydrate absorption (CA) compared with 7.5% icodextrin solutions.

Methods: Experimental studies were performed during 8-hour dwells in New Zealand White rabbits (2.35-2.90 kg body weight). Study 1 compared solutions containing 7.5% icodextrin (N = 9) with 11% 19K glucose polymer (Mw = 18.8 kilodalton & Mw/Mn = 2.06, N = 9). Study 2 compared solutions containing 7.5% icodextrin (N = 12) with 11% 18K glucose polymer (Mw = 18.0 kilodalton & Mw/Mn = 1.98, N = 12). A control study compared solutions containing 11% icodextrin (N = 9) with 11% 19K glucose polymer (N = 9). Net UF was measured by complete fluid collection, and CA was measured by subtracting the total carbohydrate in the collected fluid from that initially infused.

Results: In Study 1, UF for the 11% 19K glucose polymer was higher than that for 7.5% icodextrin (89±31 ml [mean±SD] vs. 49±15 ml, P = 0.004) without an increase in CA (5.2±0.9 g vs. 5.0±0.9 g, P = 0.7). In Study 2, UF for the 11% 18K glucose polymer was higher than that for 7.5% icodextrin (96±18 ml vs. 66±17 ml, P < 0.001) without an increase in CA (4.8±0.7 g vs. 5.2±0.6 g, P = 0.2). In the control study, UF for 11% 19K glucose polymer and 11% icodextrin were similar (68±20 ml vs. 57±15 ml, P = 0.2), but CA was lower for the 19K glucose polymer solution (5.3±0.8 g vs. 6.4±1.1 g, P = 0.03).

Conclusions: These findings suggest that long dwell PD solutions containing 11% 18-19K glucose polymers with low polydispersity can provide higher UF than 7.5% icodextrin solutions without an increase in CA.

FR-PO772

4-Hour Dwell Period Ultrafiltration Volume with Icodextrin Solution Is Better than 4.25% Glucose Solution to Predict Peritoneal Equilibrium Test (PET) Results Sara Mohrbacher, Erica A. Guimaraes, Rosilene M. Elias, Benedito J. Pereira, Manuel C. Castro, Hugo Abensur. *Division of Nephrology, University of São Paulo School of Medicine, Sao Paulo, Brazil.*

Background: The PET is a well-defined, yet cumbersome, method to classify patients on peritoneal dialysis (PD) by transport pattern. The ultrafiltration (UF) volume for a 4-hour dwell period with 4.25% glucose is then employed to estimate peritoneal membrane capacity. With icodextrin (ICO), UF is mainly through the small pores of the peritoneal membrane. ICO was not yet tested to evaluate membrane capacity. Here, we compared UF with 4-hour dwell period with ICO and 4.25% glucose solutions, correlating to PET.

Methods: We included 11 patients on chronic PD (mean age, 44 ± 19 years; male, 50%). The median time on PD was 14.5 months. Each patient underwent three assessments: standard PET, UF with 4-hour dwell period with 4.25% glucose and UF with 4-hour dwell period with ICO.

Results: Table 1 shows the UF volume, as well as the PET classification by glucose at 4h/0h (G4/G0) and by dialysate/plasma creatinine (D/P Cr). Patients were divided into two groups: low (L) + low average (LA) or high (H) + high average (HA). The UF with ICO correlated with G4/G0 (r=-0.758, p=0.007) and with D/P Cr (r=0.674, p=0.023). ROC determined that the best cut-off point to predict transport pattern with ICO was 181 ml based on PET classification by G4/G0 (area under the receiver operating curve, 1.0; p=0.006) and 152 ml for PET classification by D/P Cr (area under curve 1.0, p=0.008). The sensitivity and specificity were 100% for both cut-off points.

	L-LA	HA-H	L-LA	HA-H
	G4/G0 (n=5)	G4/G0 (n=6)	D/P Cr (n=4)	D/P Cr (n=7)
Dialysate	UF volume, ml			
4.25% glucose	749±179	588±157	719±166	645±207
ICO	48±103	344±131*	17±88	319±136*

*p<0.05 vs. L-LA

Conclusions: UF volume with 4-hour dwell period with ICO can predict peritoneal membrane transport pattern better than 4-hour dwell period with 4.25% glucose. High transporters have more small pores than low transporters. ICO acts through small pores, and is less absorbed than is glucose, which explains the high UF volume in HA-H patients. Further studies are needed to confirm these results in a larger sample.

FR-PO773

Fluorescent Albumin to Assess Water Transport in a Mouse Model of Peritoneal Dialysis Johann Morelle,[1] Sara Terryn,[1] Yvette Cnops,[1] Anna Rippe,[2] Eric Goffin,[1] Bengt Rippe,[2] Olivier Devuyst.[1,3] *[1]Nephrology, Saint-Luc UCL, Brussels, Belgium; [2]Nephrology, University Hospital, Lund, Sweden; [3]Institute of Physiology, University of Zurich, Zurich, Switzerland.*

Background: Intraperitoneal volume (IPV) tracers are warranted to accurately assess fluid transport during peritoneal dialysis (PD), but their current use is limited by stringent biosafety regulations and tracer kinetics requiring correcting equations. Here we demonstrate that albumin labelled with Alexafluor, a particularly bright, photostable and pH-insensitive dye, is an easy-to-use and highly reliable IPV tracer for investigation of water transport in mouse models of PD.

Methods: Transport across the mouse peritoneum was investigated during a 2-h exchange in 41 SV129 mice, with a PD solution in which 100 µg of fluorescent albumin was added. Dialysate microsamples were taken at 0-10-30-60-90-120min to measure fluorescence, assess tracer kinetics and determine IPV changes; volumetric measure of IPV was considered as the gold standard. The technique was further applied to test the influence of various concentrations of glucose (G) and to assess the role of the ultrasmall pore aquaporin-1 (AQP1) in *Aqp1* mice.

Results: The intra-peritoneal mass of fluorescent albumin remained constant during the whole duration of the dwell performed with G3.86%, indicating no disappearance of the tracer (relative albumin mass at 120min 98±2%, p>0.05). Calculated IPV closely correlated with the volumetrically assessed IPV at each time point (p=0.31 between IPV curves) and calculated and measured net ultrafiltration (UF) were not different (41.0±2.4 vs 39.6±2.4 µl/g, p=0.34). Fluorescent albumin had no effect on albumin concentration in the dialysate, dialysate osmolality, or net UF. G1.36% reduced by 68% and G7% increased by 56% the net UF, as compared to G3.86% (p<0.001 between IPV curves). Aqp1 wildtype and knockout mice had an initial UF rate of 25.1±1.4 µl/min and 7.2±1.7 with G3.86%, respectively, while the net UF in the latter was decreased by 40% (p<0.001).

Conclusions: Alexafluor labelled-albumin is an accurate IPV tracer and a promising tool to unravel the molecular mechanisms and test new strategies to improve water removal during PD.

Aquaporin-1 Mice Provide Novel Insights into the Physiology of Crystalloid and Colloid Osmosis across the Peritoneal Membrane Johann Morelle,[1] Sara Terryn,[1] Yvette Cnops,[1] Eric Goffin,[1] Olivier Devuyst.[1,2] *[1]Nephrology, Saint-Luc UCL Academic Hospital, Brussels, Belgium; [2]Institute of Physiology, University of Zurich, Zurich, Switzerland.*

Background: The principle of osmosis has now been applied for more than 50 years to generate ultrafiltration (UF) across the peritoneum of peritoneal dialysis (PD) patients. The use of transgenic mouse models of PD has contributed to the understanding of crystalloid osmosis, by demonstrating that the water channel aquaporin-1 (AQP1) is the molecular counterpart of the ultrasmall pore. We tested the hypothesis that colloid osmotic agents induce UF independently of AQP1 and that combinations of crystalloid and colloid osmotic agents have a synergistic effect on water and sodium removal through the so-called small pore system.

Methods: Peritoneal transport was investigated during 2-h exchanges in transgenic *Aqp1* mice (knockout, in which water transport occurs exclusively through the small pores, vs. wild-type littermates) with PD solutions including glucose (G) 1.36% and 3.86%, icodextrin (I) 7.5% and combinations of G/I (CIG 1.36% and CIG 3.86%).

Results: Water removal was not affected by the absence of AQP1 when using the colloid agent icodextrin, as indicated by the same net UF in *Aqp1* knockout and wild-type mice. CIG 3.86% and CIG 1.36% resulted in a 9.4 and 5.4-fold increase in net UF, and in a 4.8 and 2.8-fold increase in sodium removal, respectively, as compared to icodextrin 7.5% alone. Net UF and sodium removal obtained with glucose and icodextrin were superior to the sum of the results generated by each osmotic agents used separately. The estimated amount of water generated through small pores increased from 11.6±1.2 µl/g to 31.1±1.4 µl/g (p<0.001) when icodextrin 7.5% was added to glucose 3.86%, while the contribution of AQP1 remained unchanged.

Conclusions: Using various osmotic agents alone or in combination in the *Aqp1* mice unequivocally demonstrates that (1) colloid osmosis occurs independently of the ultrasmall pore AQP1; (2) bimodal solutions synergistically enhance UF and sodium removal; (3) these synergistic effects result from an increased contribution of small pores to water removal.

Peritoneal Fluid Flow Can Be Detected and Quantified with Dynamic Electrical Impedance Tomography Using an In Vivo Peritoneal Dialysis Model Edward A. Ross,[1] Aaron S. Tucker,[2] Jennifer Paugh-Miller,[1] Rosalind J. Sadleir.[2] *[1]Division of Nephrology, Univ of Florida; [2]Dep't of Biomedical Engineering, Univ of Florida, Gainesville, FL.*

Background: Bioimpedance technology has many applications including body-content analyses during ultrafiltration. We previously showed how noninvasive multi-sensor arrays and reconstruction algorithms could monitor abdominal fluid flow and accumulation using Electrical Impedance Tomography (EIT), and reported proof of principle during PD exchanges. We now studied refined algorithms and an 8-electrode sensor array to image and quantify PD fluid flow.

Methods: PD subjects underwent a manual exchange during continuous EIT monitoring: 8, 5x10 cm electrodes attached to the anterior abdomen near the umbilicus level. Our EIT device (EPack 2 system) measured impedances between pairs of electrodes in multiple configurations during 2000 ml fluid infusion. Data were reconstructed into color-coded images, and then post-processed to calculate a measure (Quantity Index or QI) of the total impedance variation. QI data were used to calculate fluid accumulation rate and total volume, which was compared to that measured by weighing the PD bag during instillation.

Results: We studied 9 PD exchanges in 3 subjects. We found it possible to detect fluid accumulations of >60 g with 98% sensitivity and 95% specificity. The color-coded tomography-like reconstructed images visually demonstrated the pattern of fluid flowing

into the abdomen. Since this technology may be extended to emergent detection of intra-abdominal bleeding, we calculated that our frame acquisition rate of 1 Hz could show 60 ml of hemorrhage within 60 seconds, which is less than half the imaging time required using rapid ultrasound methodologies.

Conclusions: This study clearly demonstrates the feasibility of EIT to monitor fluid flow and accumulation in the abdomen. This dynamic technology has merit for noninvasively studying PD fluid flow patterns and may extend to the rapid and potentially automated detection of other abdominal fluid collections, such as that in traumatic hemorrhage. Thus optimizing the imaging algorithms, as well as the number and placement of electrodes, warrants further investigation.

FR-PO776

Long Term Follow Up of Volume Status in Peritoneal Dialysis Patients
Young Sun Kang,[1] Jung Eun Kim,[1] Mihwa Lee,[1] Hye Kyung Song,[1] Mi Jin Lee,[1] Jin Joo Cha,[1] Young Youl Hyun,[2] Nam Ho Kim,[3] Dae R. Cha.[1] *[1]Nephrology, Korea Univ., Korea; [2]Kangbuk Samsung Hospital; [3]Chonnam Univ.*

Background: Volume overload is prevalent in ESRD patients and is an independent risk factor of morbidity and mortality in dialysis patients. We evaluated the long term effects of volume status in peritoneal dialysis patients.

Methods: 98 patients were enrolled in a single center and were followed up for 36 months. Body composition was measured using body composition monitor (BCM, FMC): overhydration(OH), lean tissue mass index(LTI), fat tissue mass index(ATI). Overhydration was defined as OH value over 1.1L. Geriatric nutritional risk index (GNRI=[14.89x albumin(g/dl)]+[41.7x body weight/ideal body weight]) were used as a nutritional marker. Aortic calcification score (0-24) was assessed using lumbar spine x-ray.

Results: Total seventy eight patients completed the study with mean follow up period of 30months. Patients with volume overload increased up to 82.1% from 74.5% of total study patients during follow up without any intervention. Those who were overhydrated remained constantly overhydrated after 36months. The patients with excess fluid showed poorer nutritional parameters (lower GNRI, lower LTI, lower lipid profile) and the results remained similar after the completion of the study. Aortic calcification score was significantly increased overall after 2.5year(3.2±4.8 to 5.3±5.6, p=0.001). However, the score was not significantly different from patients with or without overhydration. During mean follow-up of 30months, 12(15%) died. All-cause mortality was increased in fluid overload state (unadjusted HR 1.26(95% CI 1.009-1.563), adjusted HR 1.31(95% CI 1.01-1.713). Those with higher protein, albumin and LDL cholesterol level showed decreased risk of all cause mortality.

Conclusions: Volume overload is associated with malnutrition and seems to be an independent predictor of mortality in PD patients. Further study should evaluate the effects of intervention of volume control in PD patients.

	Harzard Ratio	95% HR Confidential Interval		p value
Age	1.066	1	1.136	0.049

Should PD Patients Be Kept 'Wet' to Preserve Residual Renal Function?
Kieran Kieran Mccafferty,[1,2] Stanley Fan,[1] Andrew Davenport.[2] *[1]Department of Nephrology, Barts and the London NHS Trust, London, United Kingdom; [2]Department of Nephrology, The Royal Free Hospital NHS Trust, London, United Kingdom.*

Background: Preservation of residual renal function (RRF) is a cornerstone in the management of PD patients, with loss of RRF associated with technique failure, LVH and death. Objective: to clarify whether long-term alterations in volume status measured using bioimpedance are associated with preservation of RRF.

Methods: Patients undergoing peritoneal dialysis between March 2003 and January 2011 at 2 tertiary university hospitals, who had a set of paired bioimpedance measurements and dialysis adequacy measurements 12 months apart were considered (n=427). RRF as measured by urine Kt/V (uKt/V), was correlated with baseline demographic, biochemical and physiological parameters. Additionally to investigate whether a relative change in hydration status affected RRF, the cohort was divided into tertiles both by baseline ECW/TBW and 12-month follow up ECW/TBW. We examined whether a change from baseline hydration tertile to follow up hydration status tertile was associated with alterations in loss of RRF over the 12 month follow-up.

Results: loss in RRF as measured by change in uKt/V at 1 year compared to baseline was not correlated with dialysis vintage, PD modality (CAPD v APD), ethnicity, sex, BMI, presence of diabetes, HbA1c, PTH, albumin, CRP, number of antihypertensive medications, hemoglobin, serum sodium or change in hydration status as measured by change in ECW/TBW between baseline and year 1. However there was a correlation between loss of RRF and baseline mean arterial pressure (r=0.13, p<0.02), a younger age(r=0.15, p<0.0005), greater daily UF volume (r=0.12, p=0.03) and a higher baseline RRF as measured by daily UO (r=0.4, p<0.0001). In addition changes in volume status (overhydrated v neutral v underhydrated) over a 12-month follow up did not alter loss in RRF (1-way ANOVA p=0.21: Dunn's multiple comparison test no demonstrated significant difference between any group).

Conclusions: Both relative and absolute changes in volume status over a 12-month period do not appear to significantly alter loss in RRF. Clinicians should not 'chase' hydration status to ensure preservation of RRF.

Comparative Study of Enalapril versus Losartan on Residual Renal Function Preservation in Automated Peritoneal Dialysis: A Randomized Controlled Study
Arturo R. Marin. *Nephrology, Hospital ISSEMYM, Satelite, Estado de Mexico, Mexico.*

Background: Residual renal function (RRF) is an important determinant of mortality and morbidity in patients receiving peritoneal dialysis (PD). Recent studies have shown a positive effect of angiotensin converting enzyme inhibitors (ACEi) and angiotensin II receptor blockers (ARBs) on RRF in PD patients**.** Treatment with ACEi and ARBs has been shown to be associated with decreased risk of residual renal function (RRF) decline in PD patients and was independently associated with a 32% decrease in the development of anuria in patients with chronic kidney disease (CKD) irrespective of the dialysis modality. A 70% decrease in mortality of PD patients treated with either ACEi or ARBs therapy has been shown. The objective was comparing enalapril and losartan for RRF preservation in automated peritoneal dialysis (APD) patients.

Methods: An open label randomized controlled trial (RCT) with a 12 month follow-up period was conducted to compare the effect of enalapril versus losartan on RRF preservation in 60 APD patients. Measurements were done at the start of the study (baseline), 6 and 12 months. The primary outcome measures were the longitudinal change in RRF and the time to anuria. Secondary outcome measures included peritonitis, duration of hospitalization for any cause, drug effects, cardiovascular events and cerebrovascular events with permanent neurologic deficit.

Results: RRF was similar at baseline in both groups, 3.65±1.6 in the enalapril group and 4.1±2.01 ml/min/1.73 m^2 in the losartan group (ns). At 6 months, RRF was 3.0±0.5 in the enalapril group and 3.14±1.6 ml/min/1.73 m^2 in the losartan group (ns) and at 12 months RRF was 2.36±0.38 in the enalapril group and 2.54±0.47 ml/min/1.73 m^2 in the losartan group (ns). RRF declined by 1.29±1.21 in the enalapril group compared with 1.56±1.54 ml/min/1.73 m^2 in the losartan group (ns). The average decline in RRF in patients receiving losartan was 0.27 ml/min/1.73 m^2 less than that in enalapril group (ns).

Conclusions: There was not significant difference on RRF preservation between enalapril and losartan groups. The treatment with any of the drugs is useful in preserving RRF in APD patients.

FR-PO779

Incremental Peritoneal Dialysis Prescriptions Including Icodextrin for Patients Having Residual Kidney Function
Alp Akonur, Steven Guest. *Renal, Baxter Healthcare Corporation, Deerfield, IL.*

Background: Incremental peritoneal dialysis (PD) has been proposed as a gradual way to introduce dialysis and is based on the concept that patients may have significant residual kidney function (RKF) at the initiation of dialysis and therefore do not require full-dose therapy at initiation. We have performed kinetic modeling of glucose and icodextrin-based regimens to better understand the RKF requirements that would allow incremental PD to be a viable option.

Methods: Prescriptions of 1-3 exchanges per day were modeled using a modified 3-pore model. Average patient characteristics (e.g. BSA=1.86 m^2, 4-hr D/P creatinine=0.65), 2.27% glucose (G) during 5-hour, and icodextrin (I) during 8-hour exchanges with 2L fill volume were considered. The minimum glomerular filtration rate (GFR) and residual urine volume required to achieve a total weekly urea Kt/V of 1.7 and total daily fluid removal of 1L were calculated.

Results: Three levels of incremental prescriptions consisting of only glucose, only icodextrin or combinations of the two resulted in three levels of minimum required residual GFR and urine volume as shown in the Figure. At each level, prescriptions including icodextrin provided improved ultrafiltration requiring approximately 150 mL less residual urine volume compared with 2.27% glucose.

Conclusions: Incremental PD allows for gradual introduction of dialysis in certain patients. We demonstrated that incremental prescriptions including icodextrin meet current adequacy targets in patients with residual GFR and residual urine volume as low as 3.7 mL/min/1.73 m^2 and 215 mL. By providing improved UF, icodextrin may especially benefit patients with lower residual urine volume and help avoid excess glucose exposure.

		Model Predictions		Required RKF	
		UF (mL/day)	Kt/V (per week)	Urine Volume (mL/day)	GFR (mL/min/1.73 m^2)
Level I	Glu	209	0.35	791	>7.7
	Ico	356	0.39	644	
Level II	2xGlu	429	0.70	571	5.7–7.7
	Glu+Ico	565	0.74	435

Periostin and Peritoneal Inflammation Aditi Nayak, Ying Wang, Tiane Dai, Cynthia C. Nast, Lan Quang, Janine A. La Page, Ali Andalibi, Sharon G. Adler. *Nephrology, LA Bio Medical Research, Torrance, CA.*

Background: Periostin(Postn) is implicated in inflammation, scarring, and angiogenesis, characterizing peritoneal membrane(PMemb) failure. Postn's promoter has binding sites for STATs. We did studies to show associations between inflammation, JAK/STAT activation and Postn.

Methods: Met5A mesothelial cells were incubated in 1) filter-sterilized peritoneal dialysate (1.5% dextrose; fPDF); 2) fPDF at pH7.3 (7.3mPDF); 3) heat-sterilized PDF (hPDF); 4) low concentration glucose degradation products (lGDP) in fPDF; and 5) high concentration GDP in fPDF (hGDP). Media Postn was measured by immunoblotting. PD effluent (PDE) was collected from patients on PD ≤ 2wks (New (N), n=8) and ≥6 mos (Long-term (LT), n=8), centrifuged, and Postn measured. CA125 and JAK/STAT activators were measured in PDE in N and LT patients by electrochemiluminescence (Meso Scale Discovery, Gaithersburg, MD). Results are expressed as [analyte], [analyte]/[CA125] ratio, and analyte appearance rate (AR) ([analyte]xPDE volume/dwell time,mins). PMembs were stained for Postn in pts with encapsulating peritoneal sclerosis (EPS) and in PD (13mos).

Results: GDPs, and less so PDF glucose, induced Postn secretion by Met5A($p<0.01$). Postn in PDE was significantly higher in LT PD pts vs N. Table shows values for CA125 and JAK/STAT activating cytokines.

	[Analyte]		[Analyte]/[CA125]		AR	
Marker,pg/ml	N,(n=8);LT,(n=7)	p	N,(n=8);LT,(n=7)	p	N,(n=5);LT,(n=3)	p
IL 4	0.43;0.14	**0.03**	10.96;4.77	0.08	5.14;0.07	**0.03**
IL 13	0.89;0.17	**0.04**	20.37;6.80	0.12	8.36;2.43	0.18
IL 6	32.54;41.44	0.49	649.19;10968.04	**0.04**	147.18;179.67	0.18
GM-CSF	0.40;0.59	0.2	10.31;46.87	**0.03**	4.04;3.59	0.88
IFNγ	0.50;0.81	0.11	14.71;64.91	**0.05**	5.92;7.19	0.46
CA 125	46.55;20.33	**0.04**			527.80,183.16	**0.03**

Postn in PMemb was in peritoneal vascular smooth muscle cells, pericytes, fibroblasts, macrophages and basement membrane; in EPS also co-localizing with collagen in matrix.

Conclusions: Postn is induced in GDP/glucose containing media and LT PDE; and in LT and EPS PMemb. IL6, GM-CSF and IFNγ are candidate stimulators of JAK/STAT-mediated Postn transcription. Decrements in IL 4 and 13 may represent attenuation of macrophage repair in LT pts. These identify potential therapeutic targets.

Clinical Investigation of Relationship between Peritoneal Monocyte/Macrophage and Peritoneal Solute Transport Rate Xiao-jun Chen,[1] Xing Chen,[1] Yan Ge,[1] You-ming Peng,[1] Lin Sun,[2] Fu-You Liu.[1] *[1]Department of Nephrology, Second Xiangya Hospital, Center of Kidney Disease and Dialysis in Hunan Province, Central South University, Changsha, Hunan Province, China; [2]Departments of Pathology and Medicine, Northwestern University, Chicago, IL.*

Background: Recent studies have shown that macrophage may involved in the angiogenesis on peritoneum which results in increased effective surface area, and thus in a decrease in the glucose-driven osmotic pressure of the PDE leading to UF loss.

Methods: We investigated Overnight (8-10-hour) PDE (with glucose 2.5%) collected from 40 incident PD patients (duration<3 months)and 23 long-term PD patients (duration>12 months). The population of peritoneal cells was studied by flow cytometry analysis, especially the percentage of monocyte/macrophages. Overnight dialysate level of VEGF, TNF-α, IL-10 were measued by ELISA. Baseline dialysate-to-plasma ratio for creatinine (D/P Cr) was determined within 3 months of PD induction.

Results: Baseline D/P Cr was correlated with percentage of monocyte/ macrophages ($R=0.683$, $P<0.001$), dialysate appearance rate of VEGF ($R=0.561$, $P<0.001$), and low serum albumin($R=0.440$, $P=0.005$). However, baseline peritoneal permeability was not associated with serum C-reactive protein, TNF-α or other clinical factors. The ratio of monocyte/macrophages in incident patient was correlated with dialysate appearance rate of VEGF ($R=0.586$, $P<0.001$). On multiple linear regression analysis, the ratio of monocyte/macrophages in overnight dialysate was an independent factor influencing baseline peritoneal permeability ($P<0.001$). D/P Cr of Long-term patients was correlated with dialysate appearance rate of VEGF ($P < 0.05$), but correlation with other clinical or laboratory parameters were not found.

Conclusions: These data suggested that the number of peritoneal monocyte/macrophage in peritoneal dialysate is correlated with peritoneal transport characteristic and is a possible determinant of baseline peritoneal transport rate. Macrophage infiltration probablely changes peritoneal solute transport rate via expressing VEGF.

Effect of Wnt/β-Catenin Signaling on Human Peritoneal Mesothelial Cells Epithelial-Mesenchymal Transition Yuanyuan Guo,[1] Li Xiao,[1] Xun Zhou,[1] You-ming Peng,[1] Yashpal S. Kanwar,[2] Lin Sun,[1,2] Fu-You Liu.[1] *[1]Department of Nephrology, Second Xiangya Hospital, Center of Kidney Disease and Dialysis in Hunan Province, Central South University; [2]Departments of Pathology and Medicine, Northwestern University.*

Background: Recently, the role of Wnt/β-catenin signaling in regulating epithelial-mesenchymal transition (EMT) during organ fibrosis has been estabilised. In the present study, we determine the hypothesis that Wnt/β-catenin signaling may involve in the process of peritoneal dialysis induced peritoneal mesothlial cells EMT.

Methods: Here, we analyzed the expression of Wnts, β-catenin, E-cadherin and α-SMA in peritoneal mesothelial cells isolated from peritoneal dialysis effluents of patients (Real time PCR and/or Western Blot).

Results: Compared with new patients, the levels of Wnt1, Wnt5a, Wnt7b, Wnt8a and β-catenin in patients undergoing peritoneal dialysis over one year were higher, along with higher α-SMA and lower E-cadherin, indicating reactivation of the Wnt/β-catenin signaling. In vitro, human peritoneal mesothelial cell line (HMrSV5) was exposed to different concentrations of high glucose (30, 60, 90mM D-glucose) for 24 hours, and the expressions of Wnt1, Wnt5a, β-catenin, E-cadherin and α-SMA were examined (Western Blot, Real time PCR and Immunofluorescence). HMrSV5 cells treated with 90mM mannitol served as control. Results showed that high glucose upregulated the expression of Wnt1, Wnt5a and β-catenin in concentration-dependent manner, along with increased α-SMA and decreased E-cadherin. Futhermore, delivery of the Wnt antagonist Dickkopf-1 (DKK1) gene significantly reduced the levels of β-catenin, along with the upregulation of E-cadherin and downregulation of α-SMA, compared to high glucose group. Additionally, TGF-β1 could also elevated the levels of Wnt1, Wnt5a and β-catenin in HMrSV5 cells.

Conclusions: Taken together, these results establish a role for Wnt/β-catenin signaling in the process of peritoneal mesothelial cell EMT and identify this pathway as a potential therapeutic target.

FR-PO783

The Size and Viability of Mesothelial Cells Affect Peritoneal Membrane Function Masanobu Akazawa,[1] Eiichiro Kanda,[1] Tomomi Uno,[2] Yoshitaka Maeda,[2] Sei Sasaki.[3] *[1]Tokyo Kyosai Hospital, Japan; [2]JA Toride Medical Center; [3]Tokyo Medical and Dental University.*

Background: Various tests including the peritoneal equilibrium test (PET) and measurement of the surface area of peritoneal mesothelial cells are used for the evaluation of the deterioration of peritoneal membrane in peritoneal dialysis (PD) patients. By flow cytometry (FCM), we can evaluate all cells including mesothelial cells in dialysate. We aimed to evaluate the relationship between peritoneal membrane function and the characteristics of mesothelial cells in dialysate.

Methods: A cross-sectional analysis of 40 patients (29 males and 11 females) on PD was performed. Overnight dialysates were collected for PET. By FCM, we analyzed the cell populations in the overnight dialysate to evaluate the characteristics of mesothelial cells: size and viability. Cell size was measured by forward scatter levels. By using 7-Amino-Actinomycin D, the viability of mesothelial cells was measured. A multivariable regression analysis was adjusted for age, gender, diabetic nephropathy and peritonitis.

Results: The average age was 64.6 years and the average PD duration was 42.0 months. D/P creatinine correlated with the size of peritoneal mesothelial cells (Spearman's rank correlation coefficient $\rho=0.545$, $p=0.0003$) and the viability of peritoneal mesothelial cells ($\rho=0.4494$, $p=0.0036$). A positive correlation between the size of peritoneal mesothelial cells and the viability of mesothelial cells was observed ($\rho=0.6050$, $p<0.0001$). An adjusted multivariable regression analysis showed that D/P creatinine was significantly associated with the size of peritoneal mesothelial cells ($p=0.0034$). Another adjusted multivariable analysis showed that the size of peritoneal mesothelial cells associated with the viability of peritoneal mesothelial cells ($p<0.0001$).

Conclusions: Our findings showed that the size of peritoneal mesothelial cells in dialysate was associated with D/P creatinine and the viability of peritoneal mesothelial cells. It was suggested that enlarged mesothelial cells may become easily detached from peritoneal membrane in viable condition and lead to increase the membrane permeability.

FR-PO784

Inadequate Cellular Stress Response in Peritoneal Dialysis: A Novel Pathomechanism and Its Therapy Klaus Kratochwill,[1,2] Rebecca Herzog,[1] Anton Lichtenauer,[1,2] Lilian Kuster,[1,2] Andreas Vychytil,[3] Christoph Aufricht.[1,2] *[1]Department of Pediatrics and Adolescent Medicine, Medical University of Vienna, Austria; [2]Zytoprotec GmbH, Austria; [3]Universitätsklinik of Medicine III, Medical University of Vienna, Austria.*

Background: PD-fluid (PDF) has cytotoxic effects on mesothelial cells (MC), which form an essential part of the peritoneal dialysis membrane. Recent results indicated an inadequate cellular stress response (ICSR) upon PDF exposure as a novel mode of cytotoxic action, leading to further increased vulnerability of cells. Our aim was to elucidate molecular mechanisms involved in ICSR and to test novel cytoprotective strategies.

Methods: In experimental PD and samples from patients of the PD-protec phase I trial (ClinicalTrials.gov; NCT01353638), gel-based fluorescent detection of protein abundance and MALDI-MS together with systems biology was applied to yield protein interaction networks of enriched biological processes following PD with and without therapeutic cytoprotective interventions.

Results: Combined proteomics and bioinformatics identified an ICSR associated with sterile inflammation via interleukin-1 receptor (IL-1R) associated pathways. Addition of an IL-1R antagonist led to significant cytoprotection of MC, blockade of cytokine levels and altered expression of the stress proteome. Addition of alanyl-glutamine (Ala-Gln) ameliorated "dampening" of the MC stress proteome, associated with increased survival of MC. Exposure to PDF with and without Ala-Gln also revealed different patterns of post-translational modification of proteins with N-acetyl-glucosamine (O-GlcNAc) potentially explaining the cytoprotective effects of Ala-Gln during in-vitro PD. Early data from the PD-protec trial also suggest cytoprotective cellular responses induced by Ala-Gln in clinical PD.

Conclusions: This work describes the ICSR of MC following PDF exposure as a novel pathomechanism. Depressed cytoprotective responses increased the susceptibility of MC during experimental PD. Supplementation of PDF restored the cytoprotective stress proteome, resulting in improved cellular resistance. The implication of Ala-Gln addition to PDF on outcome during clinical PD is currently under investigation.

Transcription Factor SRF Enhances Fibrosis of Human Peritoneal Mesothelial Cells via Modulating miRNA-199a/214 Cluster Dependent Epithelial-Mesenchymal Transition

Lijie He,[1] Shiren Sun,[2] Hanmin Wang.[3] *[1]Department of Nephrology, Xijing Hospital, FMMU; [2]Department of Nephrology, Xijing Hospital, FMMU; [3]Department of Nephrology, Xijing Hospital, FMMU.*

Background: High glucose (HG) induced epithelial-mesenchymal transition (EMT) of primary human peritoneal mesothelial cells (HPMCs) is characterized by markers, as E-cadherin and claudins. Our previous study showed that Serum response factor (SRF), a transcription factor that binds to CArG boxes, is a major regulator of HPMCs EMT and fibrosis. However, the target and pathway of SRF in PD process hasn't to be elucidated.

Methods: All these immortal HPMCs were characterized by phenotype markers and tested the expression of SRF and miRNA-199a/214 cluster by real time PCR and Western blot.

Results: Our study showed that a series of miRNAs, such as miR-214/miR-199a-5p cluster from selected primary HPMCs miRNA array and have CArG element in the promotor, were found to be regulated by SRF. ChIP and luciferase reporter assays revealed that nuclear translocation of SRF directly promotes the transcription of miR-214 and miR-199a-5p, which are examined to be highly expressed in HG-induced HPMCs. Depletion of miR-214/miR-199a cluster in HPMCs reduces EMT marking by upregulating E-cadherin, claudins and downregulating α-SMA in vitro. Mechanistically, miR-199a-5p and miR-214 were characterized to target the E-cadherin and claudin-2 messenger RNA CDH1 and CLDN2 to contribute to the epithelial-mesenchymal transition (EMT).

Conclusions: Together, this study reveals a novel function of SRF in HPMCs EMT and fibrosis and identified a new SRF-miR-199a/miR-214 cluster-CDH1/CLDN2 EMT axis which highlights the potential association between TFs and miRNA-mediated EMT and fibrosis in PD.

FR-PO786

Peritoneal Membrane Vessels in CKD Stage 5 Patients Starting PD and Its Relationship with Cardiovascular Status, Dialysis Adequacy and Peritoneal Membrane Characteristics after 12months of Dialysis Treatment

Rafal Donderski,[1] Pawel Strozecki,[1] Ilona Miskowiec-wisniewska,[1] Magdalena Grajewska,[1] Roman Stankiewicz,[2] Ryszard Trafny,[3] Jacek Manitius,[1] Andrzej Marszalek.[4] *[1]Dept of Nephrology, Hypertension and Internal Diseases, Nicolaus Copernicus University, Poland; [2]Dept of Pediatric Nephrology, Nicolaus Copernicus University, Poland; [3]Braun Dialysis Unit, Braun Dialysis Unit, Golub-Dobrzyn, Poland; [4]Dept of Clinical Pathology, Nicolaus Copernicus University, Poland.*

Background: Peritoneal dialysis (PD) causes alterations in peritoneal membrane (PM)-vasculopathy with vessels obliteration, also reported before PD initiation. Cardiovascular system (CV) damage, changes in dialysis adequacy and PM transport are reported during PD. We wanted to evaluate PM vessels before starting PD and to establish their relationship with CV, lab, adequacy and PM transport data during 12months of PD.

Methods: 23 pts,CKD aetiology were: diabetic nephropathy–10pts, non-diabetic nephropathies-13pts. PM specimen was taken during PD catheter insertion. Histological analysis-using-NIS ELEMENTS AR. Peritoneal vessels thickness, ratio of luminal diameter to vessel diameter (L/V) were calculated. CV evaluation was: EF, LVMI, IMT performed before PD start. PET test and kt/v calculation - after 12months of PD. Albumin, CRP, Hb, cholesterol, PTH at the onset and at 6 months intervals.

Results: CV assessment, PM vessels data are shown in table 1. There were no statistically significant correlation between peritoneal vessels indices, CV data, lab data, clinical variables and kt/v. There were no differences between HA and LA transporters.

Results expressed as mean + SD in diabetic and non-diabetic pts.

Variables	non-diabetic	diabetic	P
Age	48,4±20,4	55,0±11,47	0,37
EF (%)	64,05±5,67	60,73±9,27	0,30
LVMI (g/m2)	119,51±38,25	118,58±21,19	0,94
PWV(m/s	10,12±2,94	14,83±3,57	0,002946
IMT (mm)	0,65±0,16	0,78±0,21	0,11
PV Wall Thickness (μm	9,89±3,34	10,01±2,00	0,92
L/V ratio	0,60±0,92	0,60±0,95	0,94
kt/v (after 12months)	2,43	2,19	0,0401

Conclusions: Initial peritoneal vessels status and CV system status in diabetic and non-diabetic pats who enter PD therapy has no influence on dialysis adequacy and PM transport after one year of PD.

FR-PO787

The Effect of Celecoxib on Peritoneal Lymphangiogenesis in Uremic Peritoneal Dialysis Rats

Zhao Zhanzheng,[1] Guo Jia.[1] *[1]Department of Nephrology, The First Affiliated Hospital, Zhengzhou University.*

Background: To investigate the effect of COX-2 inhibitor(Celecoxib)on the expression of (lymphatic vessel endothelial hyaluronan receptor-1,LYVE-1) in uremic peritoneal dialysis rats.

Methods: 48 male SD rats (180-200g) were randomly divided into 5 groups: normal control (A,n=6), rats with sham operation (B,n=6), uremic rats without PD (C,n=6), uremic rats dialyzed with 4.25% PD solution (D,n=24), uremic rats dialyzed with 4.25% PD solution and treated with celecoxib (20 mg/kg BW) via oral gavage(E ,n=6).The rats from D groups were given regular peritoneal dialysis (3ml/100g BW) and divided into 4 groups(0w/2w/3w/4w,each group=6). The rats from E groups were treated by celecoxib (20 mg/kg BW) via oral gavage. A 2-hour peritoneal equilibration test (PET) was performed before rats were killed. Immunohistochemistry or RT-PCR was applied to detect the expression of LYVE-1,VEGF-C,COX-2 in rats'peritoneal tissues,and record the net ultrafiltration quantity of group D and E. Statistical analysis was performed.Significance was defined as a=0.05.

Results: There was no significant difference of LYVE-1 VEGF-C,COX-2 expression between group A and group B. And compared with group A or B, the expression of these proteins were significantly increased in group C, D or E($P<0.05$). There was a positive correlation between COX-2 and VEGF-C, VEGF-C and LYVE-1. Compared with group D(0w), the peritoneal thickness was significantly increased in the submesthelial compact zone and the net ultrafiltration quantity was significantly decreased in group D(2W/3W/4W, $P<0.05$). Compared with roup D, the peritoneum thickness was significantly decreased, the net ultrafiltration quantity was significantly decreased in group E.

Conclusions: The expression of LYVE-1 might be up-regulated by peritoneal dialysis. Celecoxib may decrease lymphangiogenesis by inhibiting VEGF-C pathway and increase the net ultrafiltration quantity.

Daikenchuto, a Herbal Medicine, Suppresses the Progression of Peritoneal Fibrosis in Mice

Mineaki Kitamura,[1] Tomoya Nishino,[1] Yoko Obata,[1] Kumiko Io,[1] Takehiko Koji,[2] Shigeru Kohno.[1] *[1]Second Department of Internal Medicine, Nagasaki University Hospital, Nagasaki, Japan; [2]Depertment of Histology and Cell Biology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan.*

Background: Long-term peritoneal dialysis (PD) leads to histological changes in the peritoneal membrane and results in peritoneal fibrosis. One of the mechanisms of these structural changes is considered to depend on inflammation. Daikenchuto (DKT) is a herbal medicine, and widely used to treat postoperative ileus in Japan. Although DKT has been reported to ameliorate intestinal inflammation, its effect on peritoneal fibrosis remains unknown. Here we investigated the effect of DKT on peritoneal fibrosis in animal model.

Methods: Male ICR mice were divided into three groups, the chlorhexidine gluconate (CG) group, the CG + DKT group, and the control group. 15% ethanol in saline with or without CG was injected intraperitoneally three times per week and DKT was dissolved drinking water and administrered for 3 weeks, approximate dose 3000 mg/kg/day. The CG group and the control group were receiving drinking water. For histological examination, 4-μm-thick paraffin-embedded tissues were stained using the Masson-trichrome method. The expression of collagen type III, heat shock protein (HSP)-47, α-smooth muscle actin (α-SMA), transforming growth factor (TGF)-β, monocyte chemotactic protein-1 (MCP-1), and F4/80 were examined by immunohistochemistry.

Results: In the CG group, peritoneal tissues showed marked thickening of the submesothelial zone, and the numbers of HSP-47, α-SMA, TGF-β, MCP-1 positive cells and F4/80 positive macrophages were significantly increased compared to those in the control group. On the contrary, these changes were significantly suppressed in the CG + DKT group.

Conclusions: These results suggested that DKT could prevent peritoneal fibrosis through the suppression of inflammation. We conclude that DKT might be one of the candidates for a novel therapeutic agent in preventing peritoneal fibrosis.

FR-PO789

Espironolactone to Prevent Peritoneal Fibrosis in Peritoneal Dialysis Patients: A Randomized Controlled Trial

Armando Vazquez-Rangel, Virgilia Soto, Rafael G. Toledo, Edgar A. Castillo, Nasser Abdel Polanco Flores, Ilse Falcon-Chavez, Magdalena Madero. *INCICH.*

Background: Progressive loss of peritoneal function is prevalent in peritoneal dialysis (PD) patients and in part related to infections and hypertonic solutions. These latter factors are responsible for the inflammatory cascade which stimulate peritoneal fibrosis (PF). In animal studies the renin angiotensin system (RAA) is implicated in PF. There are no human data regarding the impact of RAA blockade on PF. The objective of this study was to evaluate the role of espironolactone on PF.

Methods: This was a randomized double blind controlled trial that included PD patients recruited from 2008 to 2011 at our institution. Patients were elegible if they were 18 years

or older, were not assigned to RAA blockade meds and had signed informed consent. Exclusion criteria included pregnancy or hiperkalemia (>5.5 meq/l). The primary endpoint was PF and thickness in peritoneal biopsies. Patients were randomly assigned to receive either spironolactone 25 mg or placebo for 6 months. Peritoneal biopsies were performed at the time the PD catheter was placed and at the end of follow up.Clinical and laboratory data were assesed monthly by the nephrologist. Peritoneal biopsies were evaluated for peritoneal fibrosis, thickness and inflammation.

Results: A total of 20 patients were included in the study. Median age was 41 (26-59) years, 60% were male and 35% were diabetic.There was no difference between groups in the percentage of diabetics, glucose exposure in PD bags or peritoneal membrane transport chacarteristics. Compared to baseline, at the end of follow up there was a significant increase in peritoneal fibrosis, thickness and inflammation (median % increase 19, 75 and 39, respectively) ($p<0.01$ for all). Spironolactone did not prevent fibrosis, peritoneal thickness or inflammation. There was a trend towards higher peritonitis rates($p=0.09$) and hiperkalemia (K>5.5 meq/l) ($p=0.07$) in the espironolactone group.

Conclusions: We found a significant increase in PF, peritoneal thickness and inflammation at the end of follow up, effects which were not attenuated by use of spironolactone.

FR-PO790

PDF-Induces Peritoneal Membrane Damages via Hypoxic Pathway Talerngsak Kanjanabuch,[1,2] Wasin Manuprasert,[1,2] Kearkiat Praditpornsilpa,[1] Somchai Eiam-Ong,[1] Kriang Tungsanga.[1] *[1]Medicine, Chulalongkorn University, Bangkok, Thailand; [2]Kidney and Metabolic Disorders Research Center, Chulalongkorn Univeristy, Bangkok, Thailand.*

Background: To investigated the role of hypoxia as a pathogenic factor in peritoneal membrane damages after exposed to peritoneal dialysis fluids (PDFs).

Methods: Twenty Sprague-Dawley rats were subjected to intraperitoneal injection with normal saline and 3.86%G PDFs as well as hypoxic conditions. After 4 weeks, the peritoneum hypoxia was assessed by hypoxyprobe (pimonidazol) and HIF-1α expression. The hypoxia-responsive protein and mRNA levels were quantitated by western blot and RT-PCR. Human peritoneal mesothelial cells (HPMCs) were incubated with 0.1%FCS, various concentrations of PDF, and 100μM cobalt chloride (chemical-induced hypoxic milieu) in normoxia (95%room air, 5% CO2) and hypoxic (94%N2, 5%CO2, 1%O2) conditions. Cell injuries were determined by LDH assay and number of apoptotic HPMC was counted by TUNEL-labeling flow cytometry. The intra-cellular hypoxia and its response to hypoxia were demonstrated similarly to the *in vivo*.

Results: Pimonidazol (an exogenous hypoxic marker) and the expression of HIF-1α (an endogenous hypoxic marker) were significant detected both in animal treated with PDF and hypoxic conditions. The hypoxia-responsive proteins and genes, including TGF-β and VEGF, were up-regulated both in the PDF and hypoxia-treated groups. All findings above were correlated well with histo-morphologic changes of peritoneal membrane (submesothelial thickening and neoangiogenesis). Of interest, up-taken of pimonidazol as well as expressions of HIF-1α and hypoxia-responsive genes correlated well with the degree of HPMC injuries and the number of cellular apoptosis and the concentration of glucose in the PDF. The exposures of the cells to hypoxic conditions by both chemical and physical inducers caused cell injury and death at similar degree of severity to the PDF exposure.

Conclusions: The hypoxic milieu in peritoneum was induced by exposure to the PDF and may play a pathogenic role in the peritoneal membrane changes.

Funding: Government Support - Non-U.S.

FR-PO791

Overexpression of the Klotho Protein Attenuates Peritoneal Fibrosis by Suppressing Wnt-Signaling Yuko Nishi, Minoru Satoh, Tamaki Sasaki, Naoki Kashihara. *Nephrology and Hypertension, Kawasaki Medical School, Kurashiki, Japan.*

Background: For peritoneal dialysis (PD) patients, one of the obstacles of successful long-term PD is peritoneal fibrosis in the peritoneal membrane after exposure to nonphysiological dialysis solutions. Several studies have demonstrated that peritoneal mesothelial cells undergo epithelial-to-mesenchymal transition (EMT) after expose to injury. Furthermore, the induction of EMT is associated with activation of Wnt-dependent beta-catenin signaling.Klotho, secreted from the kidneys and characterized as an anti-aging gene, has been shown to function as a Wnt antagonist. Therefore, we explored the possibility that the klotho protein could reduce peritoneal fibrosis by inhibiting Wnt signaling.

Methods: Transgenic mice that overexpress the alpha-klotho gene under the control of the human elongation factor 1 alpha promoter (KLTG; C57BL/6 background) and C57BL/6 (wild type) mice underwent scratched peritoneal injury and were examined after 7 and 14 days. The activation of beta-catenin signaling was examined by crossing the transgenic mice with BAT-LacZ mice that overexpress the beta-galactosidase gene under the control of 7 repeats of the T cell factor/lymphoid enhancer-binding factor 1 promoter.

Results: At 7 days after peritoneal injury, Wnt/beta-catenin signaling was activated in the regenerated endothelium in wild type mice and to a lesser extent in KLTG mice. The expression of α-smooth muscle actin, as a marker of EMT, also increased during peritoneal mesothelial regeneration in wild type mice and to a lesser extent in KLTG mice. At 14 days after peritoneal injury, wild type mice showed progression of peritoneal fibrosis and adhesion of the peritoneum was demonstrated by Masson's trichrome stain. In addition, enhanced mRNA expression of connective tissue growth factor and fibronectin in peritoneal tissue was also observed. On the other hand, KLTG mice showed attenuated progression of peritoneal fibrosis associated with a reduction of EMT.

Conclusions: Overexpression of the klotho protein protects the peritoneal membrane by attenuating Wnt signaling. Present results give us deeper insight into clinical benefit of preserving residual renal function in PD patients.

FR-PO792

Analyses of microRNAs Targeting CTGF in Peritoneal Fibrosis Mouse Model Kenichi Koga, Masashi Mukoyama, Hideki Yokoi, Kiyoshi Mori, Masato Kasahara, Takashige Kuwabara, Hirotaka Imamaki, Tomoko Kawanishi, Akira Ishii, Keita P. Mori, Yukiko Kato, Shoko Ohno, Naohiro Toda, Akira Sugawara, Kazuwa Nakao. *Department of Medicine and Clinical Science, Kyoto University Graduate School of Medicine, Kyoto, Japan.*

Background: MicroRNAs (miRNAs) are small non-coding RNAs that regulate gene expression by blocking protein translation. Peritoneal fibrosis is a major complication upon continuous ambulatory peritoneal dialysis (CAPD), leading to a loss of peritoneal function. Some cytokines or growth factors are reported to be involved in the pathogenesis of peritoneal fibrosis. Connective tissue growth factor (CTGF) is one of the growth factors that can potentially induce peritoneal fibrosis; PDGF is also reported to be associated with peritoneal induction of angiogenesis, fibrosis and mesenchymal transition, but little is known about miRNAs that regulate gene expressions including CTGF gene in the course of peritoneal fibrosis.

Methods: We searched miRNAs that target the CTGF gene by database. We analyzed miRNA expressions in a human mesothelial cell line, MeT-5A cells, under the treatment with PDGF-BB, AngII or TGF-β. Total RNA was extracted at 24 hours after the stimulation and miRNA expressions were assayed by TaqMan PCR. We also assessed the miRNA expressions in peritoneal membrane of chlorhexidine gluconate (CG)-treated mice at days 7, 14, 21 and 28.

Results: We identified miR-26a and miR-30c that were expressed in Met-5A cells, targeting the CTGF gene. miR-30c expression in MeT-5A cells was not changed with PDGF-BB, AngII or TGF-β1 stimulation. In contrast, PDGF-BB tended to increase miR-26a expression by 1.5-fold in Met-5A cells. In the peritoneal tissue of CG-treated mice, miR-26a expression was gradually increased after CG treatment, and showed significant increase at 14 days after the treatment by 2.3-fold compared with control mice.

Conclusions: These results indicate that miR-26a is upregulated in the mouse peritoneum during a course of peritoneal fibrosis, suggesting that miR-26a may regulate CTGF expression in PDGF-BB-induced peritoneal injury.

FR-PO793

Decorin Regulates Cell Activation and Fibrotic Processes in Human Peritoneal Mesothelial Cells through Inhibition of ERK Phosphorylation Susan Yung, Mel Chau, Qing Zhang, Andy Yim, Jiang Na, Daniel Tak Mao Chan. *Department of Medicine, University of Hong Kong, Hong Kong.*

Background: Mesothelial cell dysfunction contributes to peritoneal fibrosis during long-term peritoneal dialysis (PD). We previously demonstrated that mesothelial cells synthesize abundant decorin, a dermatan sulfate proteoglycan with anti-fibrotic properties. In this study, we investigated the mechanisms through which decorin regulates fibrogenesis and epithelial-to-mesenchymal transition (EMT) in human peritoneal mesothelial cells (HPMC) in the setting of PD.

Methods: Growth arrested HPMC were stimulated with spent non-infected or infected PD fluid in the presence or absence of exogenous decorin (0-1000 ng/ml) for 24h. Cell morphology, expression of fibronectin and fibroblast specific protein-1, and ERK activation were assessed. The effect of decorin gene silencing on cell activation and fibrotic processes in HPMC was also investigated.

Results: Non-infected PDF induced EMT and cell detachment in HPMC. These changes were more marked in cells exposed to infected PD fluid. Pre-incubation of HPMC with decorin preserved HPMC morphology and inhibited PD fluid-induced EMT, accompanied by decreased fibronectin synthesis and increased E-cadherin expression. The effect of decorin was mediated through the suppression of ERK phosphorylation. Knockdown of decorin expression in HPMC resulted in increased expression of fibroblast specific protein-1, fibronectin and TGF-β1 in both control and PD fluid stimulated HPMC ($P<0.01$, for all), accompanied by decreased E-cadherin expression ($P<0.01$, for all).

Conclusions: The data demonstrate that decorin regulates cell activation and fibrotic processes in HPMC during PD through modulation of the ERK signaling pathway.

FR-PO794

Therapeutic Use of Murine Peritoneal Macrophages Changqi Wang,[1] Qi Cao,[1] Ya Wang,[1] Guoping Zheng,[1] Ye Zhao,[1] Hong Zhao,[2] Thian Kui Tan,[1] Yiping Wang,[1] David C. Harris.[1] *[1]Centre for Transplant and Renal Research, Westmead Millennium Institute, Westmead, NSW, Australia; [2]Biochemistry Faculty, Shanxi Medical University, Taiyuan, Shanxi, China.*

Background: Each day patients treated with chronic peritoneal dialysis discard dialysate which contains a large number of mononuclear phagocytes (MP, predominantly comprising macrophages, MΦ and dendritic cells, DCs). As a rich source of MP, peritoneal dialysate may be useful to better understand the biology of these cells and to explore their therapeutic potential.

Methods: MP were isolated from peritoneal dialysate and differentiated in vitro into MΦ with M-CSF or into DCs with IL-4 and GM-CSF. The MΦ and DCs were modulated

into effector and regulatory phenotypes. Murine peritoneal MΦ were modulated into M2 MΦ with IL-4/IL-13 and transfused into mice with adrimycin nephropathy (AN).

Results: Dialysate of PD patients contains a large number of MP (4.4 ± 2.8 x10^6 Mφ and 0.93 ± 0.55 x 10^6 DCs per 2 L). Peritoneal Mφ; expressed a higher percentage of CD163, a marker for alternatively activated macrophages, than did those from blood (26.6±3.8% vs 8.3±1.6%). These MP could be differentiated *in vitro* into Mφ or DCs with high purity (Mφ 90% and DCs 85%).Human MP were modulated into M1 or M2 Mφ and immunogenic or tolerogenic DCs, that showed a similar cytokine expression pattern to those of mice.Adaptive transfer of M2 Mφ derived from mouse peritoneum provided a level of protection against AN injury that was similar to those derived from spleen, whereas M2 derived from bone marrow were not protective.

Conclusions: MP from dialysate could be differentiated into Mφ and DCs, and further modulated to an effector or regulatory phenotype. M2 derived from mouse peritoneum reduced renal injury. These data indicate the possibility of using human peritoneal MP to treat kidney disease.

FR-PO795

Effect of Thalidomide in Experimental Peritoneal Fibrosis Developed in Uremic Rats Dayana G. Viloslada, Filipe M. Silva, Irene L. Noronha. *Nephrology, University of Sao Paulo, SP, Brazil.*

Background: Peritoneal fibrosis (PF) is considered the most serious complication of long-term peritoneal dialysis, responsible for ultrafiltration failure. The use of drugs with anti-inflammatory and anti-fibrotic properties, such as thalidomide, represent an alternative strategy of treatment. The aim of this study was to analyze the effect of thalidomide in experimental model of PF developed in uremic rats.

Methods: Chronic kidney disease (CKD) was induced in male Wistar rats by adenine in the diet (0.75%), for 30 days. At day 15, rats with CKD, characterized by hypertension (170±8 mm/Hg) and high serum levels of BUN (78±8 mg/dL) and creatinine (0.7±0.4 mg/dL), were subjected to intraperitoneal injections of 0.1% chlorhexidine gluconate (CG) daily for 15 days, to induce PF. Animals (n=30) were divided into 3 groups: **CKD,** CKD rats receiving only vehicle; **CKD+PF**, PF induced in CKD rats; **CKD+PF+Thalid**, CKD rats+PF treated with thalidomide (100mg/Kg/d daily by gavage) for 15 days. At day 30, animals were sacrificed and the following parameters were analyzed: thickness of peritoneal membrane (masson thrichrome staining), number of macrophages (MØ), T-cells and α-smooth muscle actin (α-SMA) (immunohistochemistry), and collagen III, TGF-β, TNF-α and IL-1β expression (real time PCR).

Results: At day 30, CKD with uremia was confirmed by increased serum BUN and creatinine levels (134 ±17 and 1.81±0.21 mg/dL, respectively). PF was also successfully induced. Thalidomide significantly reduced the peritoneal membrane thickness, α-SMA and the number of MØ and T-cells. Reduction of TGF-β, collagen III, TNF-α and IL-1β mRNA levels was also observed.

Table 1

	CKD	CKD+PF	CKD+PF+Thalid
Peritoneal Membrane thickness (μm)	30±10	123±32*	42±9#
MØ (cells/mm²)	379±120	958±204*	233±108#
T-cells (cells/mm²)	208±161	806±217*	101±83#
α-SMA (%)	2.1±1.4	6.4±2*	0.5±0.2#
Collagen III (mRNA level)	1.0±0.8	18.9±2.4*	10.8±0.7#
TNFα (mRNA level)	1.0±0.8	8.0±0.3*	0.3±0.3#
IL-1β (mRNA level)	1.0±1.0	7.1±1.8*	0.5±0.8#
TGFβ (mRNA level)	1.0±0.4	2.1±0.1*	1.0±0.2#

*p<0.05 vs CKD, #p<0.05 vs CKD+PF

Conclusions: Thalidomide was effective in reducing the thickness of peritoneal membrane in this experimental model, possibly due to its anti-inflammatory and anti-fibrotic properties.

Not Only the Selected Peritoneal Cell Therapy but Also the Secreted Factor from the Implanted Cells Is Important to Ameliorate Peritoneal Fibrosis Shinji Kitamura, Kenji Tsuji, Hitoshi Sugiyama, Hirofumi Makino. *Department of Medicine and Clinical Science, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan.*

Background: Long-term peritoneal dialysis (PD) causes chronic peritoneal damage. Peritoneal mesothelial cells (PMCs) play an important role to peritoneal function. We investigated the possibility of cell therapy using the PMCs to prevent peritoneal damage in PD patients.

Methods: We harvested human PMCs from the peritoneal dialysis effluent of PD patients. The PMCs were separated based on morphological characteristics into epithelial-like (Epi) cells and fibroblast-like (Fib) cells by the limiting dilution method. We transplanted these cells into nude mice whose parietal and visceral peritoneum were scratched by mechanical scraping. After 14days transplantation, we sacrificed the mice and evaluated peritoneal thicknesses, intra-abdominal adhesion number.

Results: The transplanted cells were detected at the parietal and visceral peritoneum. Compared with the positive control, the Epi cell therapy group showed very few adhesions and exhibited no thickening of the parietal and visceral peritoneum (parietal peritoneal thicknesses: positive control group 46.5±8.1μm vs. Epi cell therapy group 18.2±6.8μm, P<0.05). However, the group with Fib cell therapy could not inhibit peritoneal adhesion and thickening (parietal peritoneal thickness: Fib cell therapy group: 59.1±13.1μm). In addition, HGF was expressed by the grafted Epi cells but not Fib cells. Fib cells expressed VEGF stronger than Epi cells. These findings suggest that selected PMCs cell therapy contribute to the regeneration of damaged peritoneum by both direct cellular interactions and cytokine secretion from the grafted cells. Moreover, when we injected the culture medium that included the secreted factor from Epi cells into the peritoneal injured mice, the peritoneal adhesion and thickening in the mice were inhibited as same as the Epi cell therapy.

Conclusions: We suggested that not only the effect of selected transplanted Epi cell attachment but also the secreted factor from implanted Epi cells contribute the regeneration process for peritoneum.

FR-PO797

Stimulation of Cyclooxygenase 2 Protein Expression in Cultured Peritoneal Mesothelial Cells Michael E. Ullian, Linda Walker, Megan Hicks, Thomas Morinelli. *Medicine/Nephrology, Medical University of South Carolina, Charleston, SC.*

Background: Peritoneal fibrosis decreases peritoneal dialysis (PD) efficacy. Angiotensin II (AngII) and glucose (PD fluid osmotic agent) each causes inflammation/fibrosis. We investigated whether AngII or glucose activates cyclooxygenase 2 (Cox2, profibrotic) in cultured peritoneal mesothelial cells (MC).

Methods: From rat peritoneum we harvested MC, which were cobblestone in appearance in culture passages 0-1, for experiments [N 4-9 (N of 1=cells from 1 rat)]. Techniques included: equilibrium receptor binding (125I-AngII, 90 min, 4°C); intracellular free calcium (Calcium-3 probe, fluorescent plate reader); immunoblotting of Cox2 protein normalized for ß-actin protein, expressed as fold-increase over control; inhibitor concentrations 10 μM.

Results: AngII binding was 95% inhibited by unlabeled AngII or losartan (AT1 receptor antagonist) and 36% inhibited by PD123319 (AT2 receptor antagonist), suggesting that most receptors are AT1. AngII stimulated concentration-dependent, losartan-inhibitable increases in intracellular free calcium, confirming surface receptor coupling to intracellular signals. Increase in Cox2 expression by 100 nM AngII and 4.25% (240 mM) glucose was maximal at 6 and 24 hr, respectively. AngII (1–100 nM) and glucose (1.5%-4.25%) elicited concentration-dependent increases in Cox2 expression at optimal exposure times; maximal responses were 6-fold with 100 nM AngII and 30-fold with 4.25% glucose. Mannitol (4.25%, non-metabolizable osmotic control) stimulated Cox2 expression at 24 hr but only by 6-fold. Maximal AngII stimulation of Cox2 expression was completely inhibited by losartan and only 35% inhibited by PD123319. Maximal glucose stimulation of Cox2 expression was not significantly inhibited by losartan, 45% inhibited by resveratrol (antioxidant), and 95% inhibited by RO1069920 (NFκB inhibitor).

Conclusions: In primary rat peritoneal MC, glucose activates Cox2 through oxidants and NFκB but not AT1 receptors. Glucose is more potent than mannitol, suggesting that glucose stimulates Cox2 via both osmotic and metabolic mechanisms. Inhibitors (oxidants, Cox2, NFκB) may slow peritoneal membrane fibrosis in PD patients.

Effect of miRNA-302c on Epithelial Mesenchymal Transition of Peritoneal Mesothelial Cells and the Mechanism Xiejia Li,[1] Li Xiao,[1] Xun Zhou,[1] Lin Sun,[1,2] Fuyou Liu.[1] *[1]Department of Nephrology, Second Xiangya Hospital, Center of Kidney Disease and Dialysis in Hunan Province, Central South University, Changsha, Hunan Province, China; [2]Departments of Pathology and Medicine, Northwestern University, Chicago, IL.*

Background: Epithelial mesenchymal transition (EMT) is the initiate and reversible process of TGF-β-induced peritoneal fibrosis. Connective tissue growth factor (CTGF) acts as an effector in the downstream cascade of TGF-β-induced fibrosis, and it also can facilitate EMT in the process of fibrosis. MicroRNAs are important regulators in the process of TGF-β induced EMT such as microRNA-200 family and microRNA-205. In our pilot study, we found that the expression of miRNA-302c was downregulated in TGF-β1-treated human peritoneal mesothelial cells (HPMCs) and we also found that CTGF is a target gene of miRNA-302c. So our object is to investigate whether miRNA-302c plays a role in TGF-β1-induced EMT by regulating the expression of CTGF.

Methods: We constructed a lentiviral vector to stably express has-miRNA-302c. Then we treated HPMCs with 5ng/ml TGF-β1 for 48 hours in the presence or absence of LV-hsa-miR-302c. The expression of miRNA-302c was analysed using TaqMan quantitative fluorescence probe real time PCR, the expression of E-cadherin,α-SMA,collagenIand CTGF were analysed using real time PCR and western blot.

Results: Compared with control group, the expression of miRNA-302c was downregulated with the stimulation of TGF-β1, but the expression of miRNA-302c was rised in the presence of LV-hsa-miR-302c. The presence of LV-hsa-miR-302c can ameliorate the morphology change induced by TGF-β1. The expression of E-cadherin in TGF-β1-treated HPMCs was decreasing and the expression of α-SMA and collagenIwas increasing, but the presence of LV-hsa-miR-302c can ameliorate the changes. Meanwhile, compared with the control group, the expression of CTGF was rising with the stimulation of TGF-β1, but the presence of LV-hsa-miR-302c can ameliorate the increase of CTGF.

Conclusions: The infection of LV-hsa-miR-302c can upregulate the expression of miR-302c in HPMCs; miR-302c can ameliorate the TGF-β1-induced EMT through suppressing the expression of CTGF.

Downregulation of miRNA-29c Inhibits High Glucose Induced Epithelial-Mesenchymal Transition in Human Peritoneal Mesothelial Cells Yan Ge,[1] Li Xiao,[1] Xiao-jun Chen,[1] Yuanyuan Guo,[1] Xiejia Li,[1] Xun Zhou,[1] Lin Sun,[1,2] Fuyou Liu.[1] *[1]Department of Nephrology, Second Xiangya Hospital, Center of Kidney Disease and Dialysis in Hunan Province, Central South University, Changsha, Hunan Province, China; [2]Departments of Pathology and Medicine, Northwestern University, Chicago, IL.*

Background: It is believed that epithelial-mesenchymal transition (EMT) of peritoneal mesothelial cells plays a pivotal role in the pathogenesis of peritoneal fibrosis in peritoneal dialysis patients. Recent studies demonstrated that miRNA could regulate EMT in different kind of cells and inhibit organ fibrosis. However, the role of miRNA in EMT of peritoneal mesothelial cells and peritoneal fibrosis is largely unknown.

Methods: We identified that miR-29c upregulated in peritoneal mesothelial cells derived form dialysis effluent in long term PD patients compared to newly starters using miRNA array analysis and we validated that the expression of miR-29c also increased both in derived peritoneal mesothelial cells from 24 PD patients and human peritoneal mesothelial cell line (HMrSV5) treated with high glucose in vitro by real-time PCR.

Results: And the upregution of miR-29c was correlated with the expression of EMT markers (E-cadherin, α-SMA, Collagen-Iand finbronectin) both ex vivo and in vitro examined by RT-PCR, western-blot and immunofluorescence cell staining. We hypotheses that miR-29c may regulate the EMT of peritoneal mesothelial cells, thus the miR-29c inhibitor was transferred into peritoneal mesothelial cells treated with high glucose and the expression of Sprouty homolog 1 (Spry1), a confirmed target of miR-29c was also measured. Knockdown of miR-29c unregulated the expression of E-cadherin, but downregulated the expression of α-SMA, Col-Iand FN in peritoneal mesothelial cell induced by high glucose. And the expression of Spry1 in peritoneal meosthelial cell was decreased while inhibition of miR-29c upregulate the expression of spry1 in vitro.

Conclusions: These findings demonstrated that miR-29c could regulate EMT of peritoneal mesothelial cell and the effect of miR-29c on the regulation of EMT in peritoneal mesothelial cells may be mediated by Spry1.

Long-Term Effect of Low Glucose Degradation Product Dialysis Solution on Ex Vivo Phenotype of Human Peritoneal Mesothelial Cells in Continuous Ambulatory Peritoneal Dialysis Patients Kyu-hyang Cho,[1] Jun-Young Do,[1] Seokhui Kang,[1] Jong-Won Park,[1] Kyung Woo Yoon,[1] Sun Young Jung.[2] *[1]Department of Internal Medicine, Yeungnam University Hospital, Daegu, Republic of Korea; [2]Department of Internal Medicine, Soonchunhyang University Gumi Hospital, Gumi, Republic of Korea.*

Background: The purpose of this study was to analyze the long-term effect of low GDP dialysis solution on the changes of ex vivo phenotype of human peritoneal mesothelial cells (HPMCs) and epithelial to mesenchymal transition (EMT) of HPMCs in CAPD patients.

Methods: Among new CAPD patients from May 2001 to January 2009 in our hospital, 74 patients (DM: 27, mean age: 48 years) finished a 60 month protocol.Patients were assigned to one of four groups, group D (n=21, high GDP, Dianeal®), group P (n=24, low GDP, Physioneal®), group S (n =10, high GDP, Stay-safe®), group B (n=19, low GDP, Balance®).HPMCs were also cultured from overnight dwell effluent at months 1, 6, 12, 24, 36, 48 and 60. We scored HPMCs (1: cobble stone appearance mesothelial cell, 2: mixed, 3: fibroblast) as morphologic characteristics by the same researcher and measured CA125 levels.

Results: There were significant decreases in CA125 level and increases in cell score in effluent over time on peritoneal dialysis. There were no significant differences in cell score in effluent between the high GDP group and the low GDP group during the first 5 years. However, the group B showed lower cell score than the group S during the first 5 years as a result of subgroup analysis. The group B showed significant higher CA125 level in effluent than the group S at months 1, 6 and 12. There were no differences in cell score between the group D and the group P during the first 5 years. Factors associated with higher cell score was old age and the high GDP solution.

Conclusions: There were significant decreases in CA125 level and increases in cell score of HPMCs in effluent over time on peritoneal dialysis. The group B showed significant lower cell score of HPMCs in effluent than the group S during the first 5 years in incident CAPD patients. Further study is needed to explain the differences in long-term effects of two kinds of low GDP solutions on EMT of HPMCs.

The Effect of Icodextrin on Long-Term Patient Survival in Continuous Ambulatory Peritoneal Dialysis Patients Kyu-hyang Cho,[1] Jun-Young Do,[1] Seokhui Kang,[1] Jong-Won Park,[1] Kyung Woo Yoon,[1] Sun Young Jung.[2] *[1]Department of Internal Medicine, Yeungnam University Hospital, Daegu, Republic of Korea; [2]Department of Internal Medicine, Soonchunhyang University Gumi Hospital, Gumi, Republic of Korea.*

Background: We conducted this study to analyze the effect of icodextrin dialysis solution on long-term patient survival and the factors associated with patient survival in CAPD patients.

Methods: 183 incident patients were enrolled from May 2001 to October 2004 in our hospital and 75 (DM:28, icodextrin:36, follow-up range:1-132 months) patients finished a complete a 36 month protocol among 183 patients. We defined icodextrin group as once daily use of icodextrin more than 6 months.Serum leptin and adiponectin were measured at months 1 (baseline), 6, 12, 24, and 36. Degree of comorbidity was assessed on the basis of the Davies comorbidity score. For the analysis of patient survival, we included all 183 (DM:92, icodextrin:57, follow-up range:38-132 months) patients who entered into the study (intention-to-treat analysis). We also conducted analysis of patient survival, by including only 75 patients who fulfilled a 36 month protocol (per-protocol analysis).

Results: Icodextrin group showed higher serum adiponectin than non-icodextrin group. Icodextrin group showed lower serum leptin/adiponectin ratio than non-icodextrin group. As a result of intention-to–treat analysis, icodextrin group had a better patient survival rate compared to non-icodextrin group (89.5% vs. 59.1% in 3 years and 82.3% vs. 45.2% in 5 years). As a result of per-protocol analysis, icodextrin group also showed a better patient survival rate compared with non-icodextrin group (97.1% vs. 78.8% in 5 years and 75.0% vs. 53.2% in 10 years). The factors associated with patient survival were young age, non-DM, low Davies comorbidity score, use of icodextrin.

Conclusions: This study suggests that the application of icodextrin solution may be a better option to improve leptin/adiponectin ratio in CAPD patients. The icodextrin group showed a better long-term patient survival in CAPD patients compared to the non-icodextrin group. We need further studies to clarify the factors associated with patient survival.

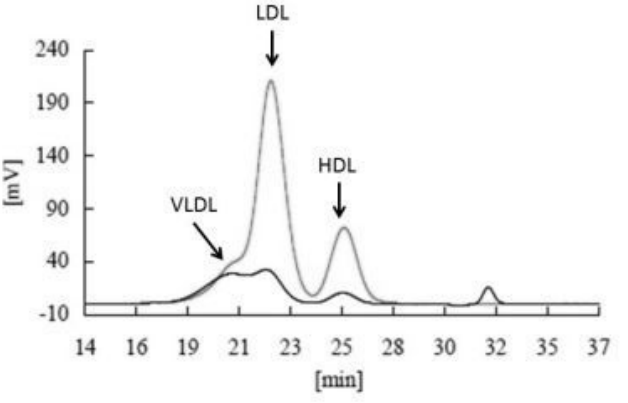
A New High-Performance Liquid Chromatography Showed that Icodextrin Dialysate Favorably Improved Lipid Profiles in Peritoneal Dialysis Patients Eiichiro Kanda,[1] Masumi Ai,[2] Yoshitaka Maeda,[3] Mitsuyo Okazaki,[2] Sei Sasaki,[2] Masayuki Yoshida.[2] *[1]Tokyo Kyosai Hospital; [2]Tokyo Medical and dental University; [3]Toride Medical Center.*

Background: Peritoneal dialysis (PD) patients show an atherogenic lipid profile. Lipoprotein profile consists of a continuous spectrum of particles of different sizes and densities. We investigated lipoprotein subclasses in PD patient, and evaluated the effects of icodextrin on lipid metabolism.

Methods: 49 patients were enrolled in this cross-sectional study in Japan. Cholesterol levels of 20 lipoprotein subclasses were measured using an improved method of high performance liquid chromatography: CM, fraction (F) 1-2; Large VLDL, F3-5; Medium VLDL, F6; Small VLDL, F7; Large LDL, F8; Medium LDL, F9; Small LDL, F10; Very small LDL, F11-13; Very large HDL, F14-15; Large HDL, F16; Medium HDL, F17; Small HDL, F18; Very small HDL, F19-20.



Lipoprotein Profile of A Diabetic

Results: 26 patients used icodextrin: average age, 64.1 years; male, 77.6%; diabetics, 42.8%; duration of PD, 39.9 months; statin use, 32.6%; total cholesterol level, 183.1 mg/dl; total triglyceride level, 139.3 mg/dl. Although no significant difference was observed in age, gender, diabetics, or statin use between patients using icodextrin (icodextrin group) and those not using (control group), the icodextrin group showed significantly lower cholesterol levels of F10 (t-test p=0.05) and F11 (p=0.019), and significantly higher cholesterol levels of F15 than the control group (p=0.037). Adjusted multivariate regression analysis showed that icodextrin use was associated negatively with cholesterol levels of F10 (p=0.031) and F11 (p=0.023), and positively with those of F15 (p=0.037).

Conclusions: Icodextrin dialysate improved lipid profiles with regard to the prevention of atherosclerosis. It can be recommended to PD patients to reduce the risks of atherosclerosis.

FR-PO803

Low GDP Peritoneal Dalysis Regimen Lowers Plasma Levels of Proinflammatory Ligands of Receptor for Advanced Glycation End Products Sylvie Opatrna,[1] Anna Popperlova,[1] Marta Kalousova,[2] Zima Tomás.[2] *[1]Medicine I, Charles University Medical School and Teaching Hospital, Pilsen, Czech Republic; [2]Institute of Medical Biochemistry and Laboratory Medicine, 1st Faculty of Medicine, Charles University and General Hospital, Prague, Czech Republic.*

Background: Intraperitoneal glucose degradation products (GDP) load from instilled peritoneal dialysis (PD) solutions has recently been shown to directly influence systemic advanced glycation end products (AGEs) levels. AGEs exert part of their effects after engagement with the receptor for AGEs (RAGE). We studied the effect of three PD regimen that differ in GDP load on plasma and effluent levels of s-RAGE and its proinflammatory ligands: extracellular newly identified RAGE (EN-RAGE) and high mobility group box-1 protein (HMGB-1).

Methods: PD regimen with high GDP load (glucose-lactate PD fluid, D; n=8) was compared with a low GDP load (glucose-bicarbonate/lactate with icodextrin exchange for overnight dwell, E; n=9) and a very low GDP load (glucose-bicarbonate/lactate, P; n=16).

Results: D group demonstrated higher plasma EN-RAGE levels, 77.8 ng/mL, vs. both E, 11.2, p<0.001 and P, 27.0, p<0.001 as well as higher plasma HMGB1 levels, 2.2 ng/mLvs. both E, 1.1, p<0.01 and P, 1.5, p<0.01. Plasma s-RAGE did not differ between the three PD regimen used. Peritoneal clearance of s-RAGE and EN-RAGE was higher with E compared to both D and P (p<0.001 resp. p<0.01). In the whole PD patients´ group, those with dialysate-to-plasma creatinine ratio (D/Pcr) > 0,65 tended to have higher s-RAGE plasma levels (p= 0.056); and those with CRP level above median demonstrated higher HMGB-1 and EN-RAGE (p<0.05 for both).

Conclusions: Lower intraperitoneal GDP load is associated with decreased plasma levels of EN-RAGE and HMGB-1 thus possibly reflecting reduced systemic AGEs generation. Peritoneal transport characteristics, microinflammation as well as the capability of icodextrin to increase removal of middle molecular weight substances might also exert an effect on plasma RAGE ligands levels.

Funding: Government Support - Non-U.S.

FR-PO804

The Effect of Biocompatibility of PD Solutions on Pro-Inflammatory Cytokine Secretion by Peripheral Blood Mononulclear Cells Gyu Tae Shin, Inwhee Park, Heungsoo Kim. *Department of Nephrology, Ajou University School of Medicine, Suwon, Kyunggi, Republic of Korea.*

Background: Previous studies showed that in vitro exposure to biocompatible amino acid solution or bicarbonate-buffered solutions resulted in more pronounced secretion of pro-inflammatory cytokines by PBMC compared to conventional glucose based lactate-buffered solutions, and this observation was interpreted as improved host defense status by biocompatible solutions and conversely immune suppressive effect of conventional solutions. In this study, we investigated whether such in vitro results are reproduced in PD patients.

Methods: We enrolled 32 patients on PD as well as 10 healthy controls. Sixteen patients (P-E-N group) were using amino acid solutions (Nutrineal), bicarbonate/lactate-buffered glucose solutions (Physioneal) and icodextrin solutions (Extraneal), and the other 16 (D-E group) were on lactate-buffered glucose solutions (Dianeal) and icodextrin solutions. PD patients' PBMC were incubated with lipopolysaccharide (LPS). Additionally, control PBMC were exposed to dialysis solutions and then incubated with LPS.

Results: Serum CRP, serum TNF-alpha and IL-6 levels as well as unstimulated TNF-alpha and IL-6 production by PBMC were comparable between the the P-E-N group and the D-E group. LPS stimulated TNF-alpha production was significantly higher in the D-E group (2969.07±1835.08pg/ml) compared to the P-E-N group (1743.43±828.79pg/ml, p=0.021) and healthy controls (1609.02±822.48pg/ml, p=0.038). Similarly, LPS stimulated IL-6 production was higher in the D-E group (65807.27±30090.67pg/ml) compared to the P-E-N group (48385.19±18111.04pg/ml, p=0.056) and healthy controls (37588.63±10814.56pg/ml, p=0.009). In vitro exposure of PBMC to PD solutions showed that TNF-alpha levels were comparable between Dianeal1.36% and Physioneal1.36%, whereas Nutrineal showed higher TNF-alpha levels compared to both solutions. IL-6 levels were highest in Nutrineal followed by Dianeal1.36% and then Physioneal1.36%.

Conclusions: PD patients on biocompatible solutions showed normal ex vivo pro-inflammatory cytokine secretion by PBMC, whereas patients on lactate-buffered solutions showed hyper-responsive secretion of pro-inflammatory cytokines.

FR-PO805

The Effect of HMG-CoA Reductase Inhibitor on Insulin Resistance in Patients Undergoing Peritoneal Dialysis Seung Hyeok Han,[1] Dae-Suk Han,[1] Mi Jung Lee,[1] Shin-Wook Kang,[1,2] Hye-young Kang,[2] Seong Hun Kim,[2] Dong Ho Shin.[1] *[1]Department of Internal Medicine, College of Medicine, Yonsei University, Seoul, Republic of Korea; [2]Severance Biomedical Science Institute, Brain Korea 21, Yonsei University, Seoul, Republic of Korea.*

Background: Insulin resistance is associated with the progression of atherosclerosis and is reported to predict cardiovascular mortality in patients with end-stage renal disease (ESRD). Although statin exerts pleiotropic effects, it is uncertain whether statin therapy may improve insulin resistance in these patients.

Methods: We conducted a prospective open randomized trial to investigate the effects of statin on insulin resistance in 70 patients undergoing peritoneal dialysis (PD). After a 4-week run-in period, patients were randomized into a statin group (n=35) or a control group (n=35). The statin group received 10 mg/day of rosuvastatin for 6 months. Insulin resistance was determined using homeostatic model assessment-IR (HOMA-IR). We also measured serum concentrations of adipokines and inflammatory markers.

Results: Compared to baseline values, statin treatment significantly decreased HOMA-IR index (2.37±1.08 to 2.05±0.82, P=0.014). In addition, there was a concordant decrease in high sensitivity C-reactive protein (hsCRP) levels in the statin group (2.05±1.57 to 1.21±0.84 mg/L, P<0.001). Such improvements were not observed in the control group. When between-group differences in the changes of these parameters were compared, hsCRP levels were more decreased in the statin group than in the control group (P=0.021 for between-group difference), but the changes in HOMA-IR index were comparable between the two groups (P=0.189 for between-group difference). During this period, altered adipokine profiles did not improve in both groups.

Conclusions: Statin failed to improve insulin resistance in PD patients despite a significant decrease in hsCRP levels by statin treatment, suggesting that reducing inflammation by statin is of limited help to fully attenuate insulin resistance in these patients.

FR-PO806

Oxidative Stress Assessed by Modified Assay of Advanced Oxidation Protein Products (AOPP) in Peritoneal Dialysis Patients Hong Xu, Abdul Rashid Tony Qureshi, Olof Heimburger, Peter F. Barany, Björn Anderstam, Ann-christin Bragfors Helin, Bengt Lindholm, Peter Stenvinkel. *Renal Medicine and Baxter Novum, Karolinska Institutet, Stockholm, Sweden.*

Background: End-stage renal disease (ESRD) patients (pts) have increased circulating levels of markers of inflammation and oxidative stress (OS). The relations between these markers, how they should be assessed, and if they are linked to antioxidants such as vitamin E, α-tocopherol (α-T) are unclear in peritoneal dialysis (PD) pts.

Methods: In 83 prevalent PD pts (57 men, median age 64 years) we analyzed circulating markers of inflammation (interleukin-6 (IL-6), tumor necrosis factor (TNF), and high-sensitivity C-reactive protein (hs-CRP)) and two markers of OS: 8-hydroxy 2'-deoxy-guanosine (8-OH-dG) which reflects oxidative damage to DNA, and a modified assay of AOPP (mAOPP), which takes into account the impact of raised levels of s-triglycerides on AOPP. We also analyzed serum lipids, and other biochemical parameters including α-T at baseline, and after 1, 2, and 3 months. The variation of the studied variables was calculated as the intra-class correlation (ICC) from estimates of between-pts and within-pts variance (Mixed model).A high ICC indicates that most variability is between pts and less within pts.

Results: mAOPP levels correlated with 8-OH-dG (rho=0.29, p<0.01) and TNF (rho=0.27; p<0.05), while correlations with IL-6, hs-CRP, α-T and cholesterol were not significant. 8-OH-dG correlated with IL-6 (rho=0.35; p<0.001) and hs-CRP (rho=0.32; p<0.003). In women, median mAOPP was higher in diabetic than in non-diabetic pts (134 (106-168) vs 116 (97-161) umol/L; p=0.06). In men, median mAOPP was higher in malnourished than in well-nourished pts (150 (118-224) vs 135 (104-172) umol/L; p=0.05). ICC (95% CI) for mAOPP was 0.80 (0.73-0.86), TNF 0.72 (0.64-0.80), IL-6 0.33 (0.22-0.46) and α-T 0.70 (0.60-0.79), respectively. Within-pts variation of mAOPP was lower than that of IL-6, TNFand α-T.

Conclusions: In PD, pts, AOPP is associated to inflammation, but less so than 8-OH-dG. AOPP levels vary less than inflammation markers. AOPP should be considered when designing studies targeting increased OS and inflammation in ESRD pts.

Funding: Pharmaceutical Company Support - Baxter Healthcare Corporation, Government Support - Non-U.S.

FR-PO807

Serum 8-Hydroxy 2'-Deoxy-Guanosine (8-OH-dG) as a Marker of Oxidative Stress in Peritoneal Dialysis (PD) and Hemodialysis (HD) Patients Hong Xu, Abdul Rashid Tony Qureshi, Olof Heimburger, Peter F. Barany, Björn Anderstam, Monica Irene Eriksson, Bengt Lindholm, Peter Stenvinkel. *Renal Medicine and Baxter Novum, Karolinska Institutet, Stockholm, Sweden.*

Background: 8-OH-dG reflects oxidative damage of DNA and is considered to be a suitable marker of oxidative stress. Here we analyzed 8-OH-dG and its relationship with inflammatory biomarkers in a cohort of prevalent PD patients (pts) and compared the results to those obtained in a group of prevalent hemodialysis (HD) pts .

Methods: In a cross-sectional study, serum 8-OH-dG and interleukin-6 (IL-6) and high sensitivity C-reactive protein (hs-CRP) were measured in 83 prevalent PD (27 men, median age 64 years) and in 224 prevalent HD (100 men, median age 63 years) pts along withbiochemical markers, assessments of Davies comorbidity score and presence of wasting (subjective global assessment, SGA). 8-OH-dG was analyzed by ELISA (Japan Institute for Control of Aging, Shizuoka, Japan). Overall mortality was assessed after 31 months (1-52) of follow up.

Results: The median levels of 8-OH-dG level (1.34 vs 0.51 ng/ml; P<0.001), serum IL-6 (8.6 vs 6.5 pg/ml; P<0.001), hs-CRP (6.5 vs 4.4 mg/L; P=0.031), and the mean albumin level (34.6±4.5 vs 31.3±4.6 g/L; P<0.001) were greater in HD than in PD pts while age, gender, Davies comorbidity score, and SGA score did not differ between PD and HD pts. 8-OH-dG and IL-6 (rho=0.347; p<0.001) and hs-CRP (rho=0.322; p<0.003) were correlated in PD pts but did not attain statistical significance in HD pts. During a mean follow up of 34 months (3-52) in HD pts, 102 (46%) died, higher 8-OH-dG level was associated with a greater hazard ratio for death, 1.72; 95% confidence interval 1.15-2.56). During a mean follow up of 22 months (1-48) in PD pts, 18 (22%) died, 8-OH-dG level was not significantly associated with mortality.

Conclusions: Serum 8-OH-dG levels differed between HD and PD pts, along with differences in inflammatory biomarkers, suggesting that factors related to dialysis modality may modify oxidative stress in pts with end-stage renal disease. Oxidative stress assessed by using 8-OH-dG level is a strong predictor of mortality in HD pts.

FR-PO808

Serum Interleukin-18 Levels Predict 3-Year Mortality in Peritoneal Dialysis Patients Yao-Lung Liu,[1,2] Jiung-hsiun Liu,[1,2] Che-yi Chou,[1,2] Huey-Liang Kuo,[1,2] Chiu-Ching Huang.[1,2] *[1]Division of Nephrology and Kidney Institute, China Medical University, Taichung, Taiwan; [2]School of Medicine, China Medical University, Taichung, Taiwan.*

Background: Interleukin-18 (IL-18), a pro-inflammation cytokine, is up-regulated and associated with high hospitalization in maintenance dialysis patients. However, it has not been determined whether serum IL-18 levels may predict mortality in dialysis patients. The aim of this study was to evaluate the association between serum IL-18 levels and all-cause mortality in peritoneal dialysis patients.

Methods: A total of 63 patients (27 male and 36 female) with median age of 53 (45-65) yr with end-stage renal disease underwent incident peritoneal dialysis were included in this prospective cohort study. Serum IL-18 levels were measured at one month after the start of peritoneal dialysis therapy. The follow-up period was 36 months.

Results: Ten patients (15.9%) expired, three patients (4.7%) received kidney transplantation and two patients (3.2%) transferred to hemodialysis therapy during the 36-month follow-up period. The death group showed significantly higher serum IL-18 levels than the survival group [903.8 (843.0-1173.1) pg/ml vs. 784.6 (633.1-959.9) pg/ml, p =0.022]. On the basis of the receiver-operator curve, the most appropriate cut-off point for serum IL-18 levels to predict all-cause mortality was 857.2 pg/ml (sensitivity 80.0%; specificity 64.2%; area under the curve = 0.730). The Kaplan-Meier survival analysis showed significantly higher mortality rate in the high serum IL-18 group (IL-18>857.2 pg/ml) compared with the low group (IL-18<857.2 pg/ml) (p=0.049).

Conclusions: High serum IL-18 levels predicted a high all-cause mortality rate in incident peritoneal dialysis patients.

FR-PO809

Impact of Prior Hemodialysis on First Year Peritoneal Dialysis Outcomes Eduardo K. Lacson, Nien-chen Li, Franklin W. Maddux, Joseph P. Pulliam. *Fresenius Medical Care, North America, Waltham, MA.*

Background: Patients initiating maintenance peritoneal dialysis (PD) are known to have good outcomes in their 1st year. We investigated whether prior history of HD influences 1st year PD outcomes.

Methods: Incident patients who started PD in Fresenius Medical Care North America facilities within their first year of dialysis were stratified into 3 groups: (A) direct to PD, (B) ≤90 days of HD prior to PD, or (C) >90 days of HD prior to PD. Mortality, hospitalization, and peritonitis incidence in the first PD year was recorded. Kaplan-Meier survival curves were created and log-rank tests were performed. Cox's proportional hazards models with stepwise selection were constructed with initial covariates: age, vintage, BMI, gender, race, comorbidities (diabetes, amputation, CHF, and PVD and baseline albumin, hemoglobin, and phosphorus levels. For stepwise selection, alpha for model entry and deletion were both set at 0.05.

Results: Group A (N=1,309) patients were older (58 vs. 55 vs. 56 years) compared to B (N=492) and C (N=403), respectively. They also had higher weight (85 vs. 83 vs. 82 kg.) but with similar BMI at 32 kg/m^2. Residual CrCl was 10 vs. 9.0 vs. 8.6 ml/min with A>B>C. Other trends showed fewer comorbidities, lower phosphorus and lower creatinine at baseline for Group A, with Groups B and C being similar to each other. Crude mortality rates were 9% vs. 11 % vs. 14%, respectively, with A<B<C (p=0.009). Hospitalization rates were also A<B<C at 56% vs. 63% vs. 65% (p<0.0001). Peritonitis rates were not different at 29% vs. 32% vs. 27% (p=0.26). Adjusted hazard ratio (HR) of death for B vs. A was 1.64 (1.17, 2.31); and that of C vs. A was 1.92 (1.36, 2.69); HR of hospitalization for B vs. A was 1.27 (1.11, 1.45); and that of C vs. A was 1.35 (1.17, 1.56); and HR of peritonitis for B vs. A was 1.36 (1.09, 1.70); and that of C vs. A was 1.67 (1.03, 2.69).

Conclusions: Among incident patients in this national cohort, prior HD before starting PD was associated with higher risk for mortality, hospitalization and peritonitis within the first year. Predialysis care, early modality selection, and/or self-care ability may explain these findings.

FR-PO810

Vascular Access at Transfer from Peritoneal Dialysis to Hemodialysis Predicts Survival Patrick Lan,[1] Philip A. Clayton,[1,2] John Saunders,[1] Kevan Polkinghorne,[3] Paul Snelling.[1] *[1]Royal Prince Alfred Hospital, Sydney, Australia; [2]Australia and New Zealand Dialysis and Transplant (ANZDATA) Registry, Adelaide, Australia; [3]Monash Medical Centre, Melbourne, Australia.*

Background: Peritoneal dialysis (PD) patients commonly transfer to hemodialysis (HD), however the literature describing the outcomes of such transfers is limited. The aim of our study was to describe the predictors and outcomes of these transfers.

Methods: Data were obtained from the Australia and New Zealand Dialysis and Transplant (ANZDATA) Registry on adult patients commencing PD as their initial renal replacement therapy in Australia or New Zealand between 2004-2010. Follow-up was until 31 December 2010. Logistic regression models were constructed to determine predictors of transfer within 6 and 12 months of PD commencement. Cox analysis and competing risks regression were used to determine the predictors of survival and transplantation post-transfer.

Results: The analysis included 4781 incident PD patients, of whom 1699 transferred to HD during the study period. The main reasons for transfer were: peritonitis (42%); inadequate dialysis (15%); dialysate leak (7%); or an inability to manage self-care (7%). 51% of transfers occurred within 12 months of commencing PD. Logistic models did not identify any clinically useful predictors of transfer within 6 or 12 months (c-statistics 0.54 and 0.55 respectively). 67% of patients commenced HD with a central venous catheter (CVC). CVC use at transfer was associated with increased mortality (hazard ratio 1.38, 95%CI 1.12-1.70, p=0.002) and a reduced incidence of transplantation (subhazard ratio 0.76, 95% CI 0.58-1.00, p=0.05). A sensitivity analysis restricted to patients who remained on HD for 30 or more days, confirmed that transfer with a CVC was associated with increased mortality.

Conclusions: It is difficult to predict when incident PD patients will require transfer to HD. Post-transfer survival and access to transplantation are lower in those who commence HD via a CVC. PD patients require adequate vascular access at the time of transfer, but the optimal time of vascular access creation is not known and requires further research.

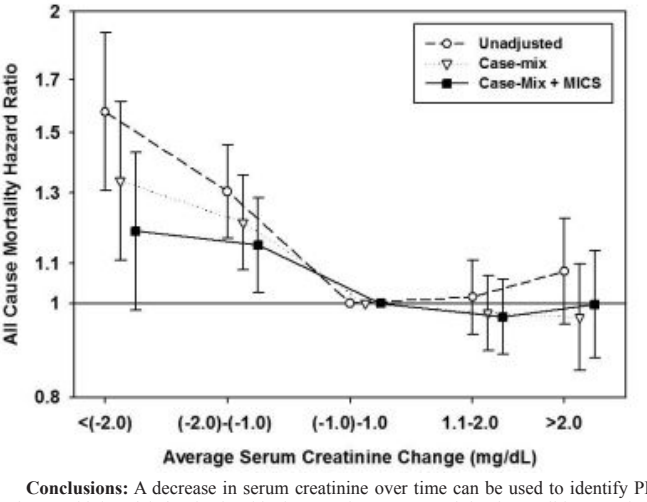
FR-PO811

Decrement of Serum Creatinine Level over Time and Increased Death Risk in Peritoneal Dialysis Patients Lilia R. Lukowsky,[1,2] Rajnish Mehrotra,[3] Jongha Park,[1,4] Miklos Zsolt Molnar,[1] Sapna Singh Patel,[3] Joel D. Kopple,[2,3] Csaba P. Kovesdy,[5] Kamyar Kalantar-Zadeh.[1,2,3] *[1]Harold Simmons Center for Chronic Disease Research & Epidemiology, LA BioMed at Harbor-UCLA, Torrance, CA; [2]David Geffen School of Medicine and Fielding School of Public Health at UCLA, Los Angeles, CA; [3]Harbor-UCLA Medical Center, Torrance, CA; [4]Ulsan University Hospital, Ulsan, Republic of Korea; [5]University of Tennessee, Memphis, TN.*

Background: Protein-energy wasting includes sarcopenia and is associated with increased mortality in end-stage renal disease. There are little data concerning whether muscle wasting is associated with mortality in peritoneal dialysis (PD) patients.

Methods: Change in serum creatinine (Cr) levels over 3 months, as a dynamic surrogate of muscle mass change, was evaluated for its association with all-cause mortality in 8,981 PD patients treated in 580 US dialysis units from July 2001 to June 2006. Survival models were adjusted by baseline serum Cr, case-mix and malnutrition-inflammation cachexia syndrome.

Results: The patients were 55±16 (mean±SD) years old and included 47% women, 25% blacks and 48% diabetics. Compared to patients for whom serum Cr level did not change (-1.0 to 1.0 mg/dl), patients with decrements of >2.0 and 2.0-1.1 mg/dl had a 19% (HR 1.19, 95%CI: 0.98-1.43) and 15% (HR: 1.15, 95%CI: 1.03-1.28) higher risk of death, respectively; however, there was no association of increments of +1.1-2.0 and >2.0 mg/dl with survival (adjusted HR: 0.97, 95%CI: 0.89-1.06 and HR: 1.00, 95%CI: 0.88-1.13).



Conclusions: A decrease in serum creatinine over time can be used to identify PD patients at higher risk for death. This decrease in serum creatinine is possibly a result of muscle wasting, although it may also reflect anorexia with reduced meat intake. The risk may, in some cases, be modifiable with nutritional intervention.

Suberoylanilide Hydroxamic Acid Attenuates Peritoneal Fibrosis Induced by Chlorhexidine Gluconate in Mice Kumiko Io,[1] Tomoya Nishino,[1] Mineaki Kitamura,[1] Yoko Obata,[1] Takehiko Koji,[2] Shigeru Kohno.[1] *[1]Second Department of Internal Medicine, Nagasaki University School of Medicine, Nagasaki City, Nagasaki Prefecture, Japan; [2]Department of Histology and Cell Biology, Nagasaki University School of Medicine, Nagasaki City, Nagasaki Prefecture, Japan.*

Background: Long-term peritoneal dialysis causes peritoneal fibrosis in submesothelial areas. However, the mechanism of peritoneal fibrosis is unclear. Epigenetics is defined as a heritable change that occurs outside the modification of DNA coding sequence. Among epigenetic modifications, histone acetylation leads to the transcriptional activation of genes. Recent studies indicate that histone acetylation involves the progression of fibrosis. Therefore, we examined the effect of suberoylanilide hydroxamic acid (SAHA), one of HDAC inhibitors, on the progression of peritoneal fibrosis in mice.

Methods: 10 week-old male ICR mice were divided into three groups, chlorhexidine gluconate (CG), CG + SAHA, and control group. Peritoneal fibrosis was induced by the injection of CG into peritoneal cavity in mice every other day for 3 weeks. SAHA or vehicle was administered subcutaneously every day from the start of CG injection for 3 weeks. The mice were sacrificed 3 weeks after the first CG injection and peritoneal tissues were dissected out. Morphologic peritoneal changes were assessed by Masson's Trichrome staining and fibrosis-associated factors were assessed immunohistochemically.

Results: In CG-injected mice, the marked thickening of the submesothelial compact zone was shown. In contrast, the administration of SAHA suppressed the progression of submesothelial thickening and typeIII collagen accumulation in CG-injected mice. The numbers of fibroblast-specific protein-1-positive cells and phosphorylated-Smad 2/3-positive cells were decreased to a significantly greater extent in CG + SAHA group than CG group. Histone acetylation was reduced in the peritoneum of CG group, whereas it was increased in CG + SAHA group.

Conclusions: Our results indicate that SAHA can suppress peritoneal thickening and fibrosis in mice. These results suggest that SAHA may have therapeutic potential for peritoneal fibrosis.

FR-PO813

Ambulatory Arterial Stifness Index as a Determinant of Mortality in Continuous Ambulatory Peritoneal Dialysis Patients Ayse Mukadder Bilgic,[1] Ali Akcay,[1] Siren Sezer.[2] *[1]Nephrology, Fatih University Medical School, Ankara, Turkey; [2]Nephrology, Baskent University Medical School, Ankara, Turkey.*

Background: Cardiovascular disease is the most important cause of mortality and morbidity in patients with end stage renal disease(ESRD). "Ambulatory Arterial Stiffness Index(AASI)" has been proposed recently as an indicator of arterial stiffness and shown to provide prognostic information on cardiovascular mortality. We aimed to determine the relation between AASI and clinical-laboratory parameters and survival in peritoneal dialysis(PD) patients.

Methods: Fifty patients (M/F:17/33; mean age, 41.9±11.8 years, mean PD duration, 60.0±27.6 months) receiving PD at least 6 months were enrolled. Demographic, clinical and laboratory data and left ventricle mass index(LVMI) were recorded. AASI were obtained from 24-hour ambulatory blood pressure monitoring records. The patients have been followed for 18 months.

Results: Mean AASI values were 0.41±0.17 and positively correlated with duration of ESRD, comorbidity index, serum calcium, calciumxphosphorus value, parathyroid hormone, LVMI, and dipper/nondipper status. Calciumxphosphorus value (b=0.277, p=0.03), parathyroid hormone (b=0.290, p=.02), dipper/nondipper status (b=-0.388, p=.009), and daytime systolic blood pressure load (b=0.870, p=.009) were independent predictors of AASI. During 18 months following period, four patients disappeared. The shows Kaplan-Meier survival curves for all-cause mortality according to AASI above and below the mean (0.41). All-cause mortality was significantly elevated in PD patients with AASI > 0.41.

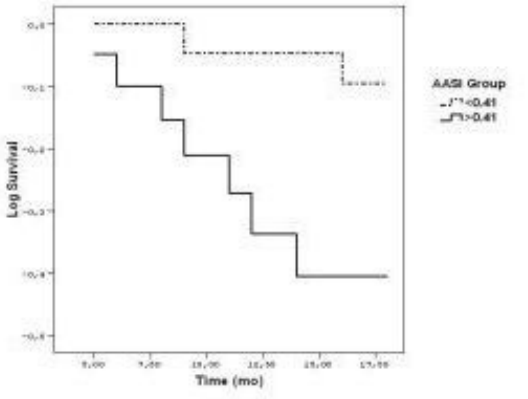

Figure 1: Kaplan-Meier survival curves for all-cause mortality according to AASI above and below the mean (0.41) in Peritoneal dialysis patients.

Conclusions: This is the first study which evaluated AASI in patients with ESRD. We obtained the results similar to previous studies about arterial stiffness measures. Also, we showed that AASI has significant value as a marker of all-cause-mortality in PD patients.

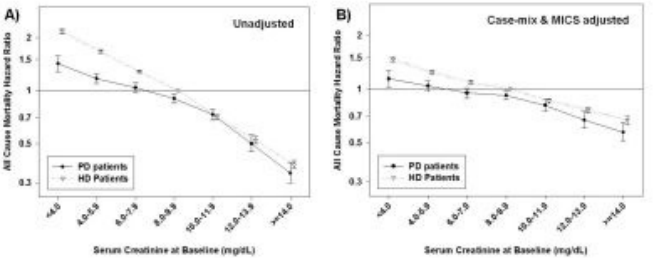
FR-PO814

Comparing Association of Serum Creatinine and Mortality between Peritoneal Dialysis and Hemodialysis Patients Jongha Park,[1,2] Rajnish Mehrotra,[3] Miklos Zsolt Molnar,[1] Lilia R. Lukowsky,[1,4] Sapna Singh Patel,[3] Joel D. Kopple,[3,4] Csaba P. Kovesdy,[5] Kamyar Kalantar-Zadeh.[1,3,4] *[1]Harold Simmons Center for Chronic Disease Research & Epidemiology, LA BioMed at Harbor-UCLA, Torrance, CA; [2]Ulsan University Hospital, Ulsan, Republic of Korea; [3]Harbor-UCLA Medical Center, Torrance, CA; [4]David Geffen School of Medicine and Fielding School of Public Health at UCLA, Los Angeles, CA; [5]University of Tennessee, Memphis, TN.*

Background: Peritoneal dialysis (PD) and hemodialysis (HD) patients appear to have similar mortality patterns despite protein losses via peritoneal dialysate and lower serum albumin levels in the former. We hypothesized that the muscle-death association is similar between HD and PD patients.

Methods: Association of baseline serum creatinine (Cr) level, which is affected by muscle mass, with all-cause mortality was compared between 10,922 PD and 113,617 HD patients treated in 580 outpatient dialysis clinics in the US from July 2001 to June 2006. Stabilized serum Cr in PD was compared to pre-dialysis serum Cr in HD patients.

Results: PD patients were 55±15 yrs old and included 52% women, 24% blacks and 48% diabetics; while HD patients 59±14 yrs, 41%, 38% and 52%. With HD patients with serum Cr 8.0-9.9 mg/dl as reference group for estimating HR, PD patients showed lower adjusted HRs for death than HD patients with serum Cr ≤9.9 mg/dl; mortality risk with <4.0, 4.0-5.9, 6.0-7.9, and 8.0-9.9 mg/dl were lower with PD vs. HD by 33%, 20%, 14%, and 8%, respectively. However, there were no significant differences with PD vs. HD for higher serum Cr categories ≥10.0 mg/dl.



Conclusions: At lower ranges of serum Cr levels, reflecting lower muscle mass, PD patients had lower risk of death than HD patients, but this observation should be qualified for potential role of residual renal function and meat intake in PD and HD patients.

FR-PO815

Automated Peritoneal Dialysis in Hong Kong: There Are Two Distinct Groups of Patients Cheuk-Chun Szeto, Bonnie Kwan, Kai Ming Chow, Chi-bon Leung, Philip K.T. Li. *Department of Medicine & Therapeutics, The Chinese University of Hong Kong, Shatin, Hong Kong.*

Background: Although 80% of the dialysis patients in Hong Kong are treated with peritoneal dialysis (PD), most received continuous ambulatory PD (CAPD), while automated PD (APD) accounts for 5% of the patients. Recent evidence suggests that clinical outcomes are different for CAPD and APD in specific subgroups of patients.

Methods: We reviewed the clinical outcome of 90 consecutive incident APD patients and 180 CAPD patients (control group) in our center.

Results: The average follow up was 56.6 ± 47.5 months. The APD group was younger and had a lower Charlson's score than the control group. Furthermore, the APD group had a highly skewed, bimodal distribution of the Charlson's score, indicating the presence of two different groups of patients. Multivariate analysis showed that in addition to the treatment mode (APD versus control) and Charlson's score, there was a significant interaction between the two ($p = 0.002$) on patient survival. For patients with Charlson's score ≤6, the APD group had a significantly better patient survival than the control group (85.4% vs 66.6% at 5-year, $p = 0.0002$), while for patients with Charlson's score ≥7, the patient survival was similar. Similarly, Charlson's score and its interaction with treatment mode, but not the treatment group *per se*, were independent predictors of technique survival ($p = 0.013$). For patients with Charlson's score ≥7, the APD group had a significantly lower technique survival than the control group (8.8% vs 34.3%, $p = 0.001$), while for patients with Charlson's score ≤6, the technique survival was similar (44.4% vs 42.5%, $p = 0.15$). Peritonitis-free survival was 35.2% and 32.2% for APD and control groups, respectively ($p = 0.021$), and the difference was not affected by Charlson's score.

Conclusions: Comorbid diseases had a significant interaction with the mode of PD on patient and technique survival of incident PD patients. Our result suggests that APD is associated with a survival advantage in, and only in, young patients with minimal comorbid diseases.

FR-PO816

Peritoneal Dialysis in the Elderly: Comparison of Outcomes Jeffrey Laut, Ann Starinovich, Helen Brickel. *Nephrology/Home Dialysis, Fresenius Medical Care, East Hartford, CT.*

Background: The dialysis population is aging. Finding age appropriate dialysis modalities for the elderly continues to be a challenge to the dialysis community. Peritoneal dialysis (PD) appears to be a gentler, less traumatic modality for this aging population, allowing for an easier transition, and ultimately a more normal lifestyle once on dialysis. Existing literature supports the view that functional status and quality of life are better on PD then HD. However, literature is lacking in regards to measurable outcomes of elderly patients on PD when compared to their younger cohorts.

Methods: We reviewed our single center experience with an elderly (>75 years) population of PD patients over 5 years (2006 to 2011) and compared outcomes to that of a younger (<75 years) PD population.

Results: During the study period 152 patients participated in our PD program, 115 patients in the younger group (group A), mean age 54.1 yrs. (range 20-74), and 37 patients in the elderly group (group B), mean age 81.2 yrs. (range 75-89). The mean duration time on PD was not different between the groups; group A, 18.7 months v group B, 17.1 months. 35 patients (30.4%) from group A are still active in the program compared with 11 patients (29.7%) from group B ($p=0.94$). As expected the mortality rate over the observation period was higher (35%) in the elderly (group B) as compared to 22% in group A, though the difference was not statistically significant ($p=0.11$). A similar pattern was seen in regards to withdrawl from dialysis, with 16% (n=6) of group B and only 3% (n=4) of group A withdrawing entirely from dialysis; this did reach statistical significance ($p=< 0.01$). Of interest, only 10.8% (n=4) of the elderly failed PD due to peritonitis, as compared with 20% (n=23) of the younger group ($p=0.2$).

Conclusions: Our data demonstrate that PD as a dialysis modality for the elderly, has acceptable outcomes when compared to their younger cohorts, in regards to 1) longevity of PD, 2) expected mortality, and 3) failure of PD due to peritonitis. Currently an equal percentage of patients from both groups are still active in our program. PD should be considered a viable option for the elderly.

FR-PO817

The Association between Body Mass Index and Mortality in Patients with Peritoneal Dialysis Yong Kyun Kim,[1] Su Hyun Kim,[2] Young Ok Kim,[1] Ho Cheol Song,[1] Euy Jin Choi,[1] Yong-Lim Kim,[3] Yon Su Kim,[4] Shin-Wook Kang,[5] Nam Ho Kim,[6] Chul Woo Yang.[1] *[1]Department of Internal Medicine, College of Medicine the Catholic University of Korea; [2]Department of Internal Medicine, College of Medicine Chung-Ang University; [3]Department of Internal Medicine, School of Medicine Kyungpook National University; [4]Department of Internal Medicine, College of Medicine Seoul National University; [5]Department of Internal Medicine, College of Medicine Yonsei University; [6]Department of Internal Medicine, Chonnam National University Medical School.*

Background: Previous studies have demonstrated that increasing body mass index is associated with decreased mortality in hemodialysis (HD) patients. In patients with peritoneal dialysis (PD), the association between body mass index (BMI) and survival has not been well established. The aim of study was to determine the association between BMI and mortality in the PD population in the Clinical Research Center (CRC) for End Stage Renal Disease (ESRD) cohort in Korea.

Methods: Prevalent patients with PD were selected from CRC for ESRD, a prospective cohort study in dialysis patients in Korea. Patients were categorized into four groups by quartile of BMI. Cox regression analysis was used to calculate adjusted hazard ratio (HR) of mortality with a BMI of quartile 2 (21.35 - 23.48 kg/m^2) as the reference.

Results: In total, 900 patients with PD were included. The median follow-up period was 24 months.The multivariate Cox proportional hazard models showed that the lowest quartile of BMI was associated with increased mortality (HR 3.14, 95% CI, 1.39-7.08, $p=0.006$). But highest quartile of BMI was not associated with improved survival (HR 1.55, 95% CI, 0.65-3.67, $p=0.320$).

Conclusions: In PD patients, lower BMI was a significant risk factor for death. But increasing BMI was not associated with decreased mortality in PD patients, which are inconsistent with the results from studies in HD patients.

FR-PO818

Socioeconomic Status & Barriers to Peritoneal Dialysis: A Mixed Methods Study Suma Prakash,[1] Adam T. Perzynski,[1] Peter Austin,[3] Fangyun Wu,[2] Mary Ellen Lawless,[1] Michael Paterson,[2] Robert R. Quinn,[4] Ashwini R. Sehgal,[1] Matthew J. Oliver.[3] *[1]Case Western Reserve University; [2]Institute for Clinical Evaluative Sciences; [3]University of Toronto; [4]University of Calgary.*

Background: Lower socioeconomic status (SES) has been associated with lower use of peritoneal dialysis. This study aimed to determine 1) the effects of SES (income & education) on eligibility for peritoneal dialysis (PD) and starting dialysis on PD and 2) the effects of SES on barriers to PD eligibility and initiation.

Methods: This was a mixed-methods study of incident end stage renal disease (ESRD) patients of age ≥ 18 years from eight dialysis programs in Ontario, Canada. Patients were assessed for PD candidacy, educated and made a modality choice. Income and education were estimated as mean values for the dissemination area (DA) of residence (400-700 people per DA) using Canadian census data. PD initiation was analyzed in patients eligible for both PD and hemodialysis (HD). Multivariable logistic regression models estimated using generalized estimating equations were used to describe the relationship between SES and the likelihood of PD eligibility and of PD initiation. Frequencies of reasons for PD non-eligibility & not initiating PD were coded using a thematic, constant comparative approach and compared across SES categories.

Results: There were 1314 and 857 patients in the eligibility and initiation analyses respectively. SES was not a significant independent predictor for PD eligibility or initiation. Reasons for PD non-eligibility were consistent across SES categories. However, SES did influence barriers to initiating PD. In lower income DAs, space issues ($p=0.02$) and social support ($p=0.03$) were more frequently cited as barriers to PD. Space issues ($p=0.049$) and support issues ($p=0.0003$) were more common in lower education DAs while schedule barriers were more common in higher education DAs ($p=0.049$).

Conclusions: In a universal health care system, SES did not affect PD eligibility or initiation. However, specific barriers to starting PD differed significantly by SES. Further examining ways to incorporate information on various barriers during education may impact patient receptiveness to PD.

FR-PO819

Mannose-Binding Lectin Gene Polymorphism May Predict Response to Leflunomide in Patients with Progressive IgA Nephropathy Beili Shi, Zhaohui Ni, Liou Cao, Shan Mou, Min Zhang, Qin Wang, Renhua Lu, Minjie Zhou, Jia Qi Qian. *Renal Division, Renji Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China.*

Background: The optimal treatment or progressive IgA nephropathy remains undefined. The aim of this study was to investigate risk factors which may predict response to Leflunomide (LEF) in a prospective, randomized, controlled trial.

Methods: Patients (renal biopsy proven, Lee SMK grade II-IV, with urinary protein > 1.0g/d, and/or baseline eGFR 29-60ml/min/1.73m^2) were randomly enrolled. LEF group was given oral LEF (40mg/d for 3 days followed by 20mg/d) plus oral prednisone (0.8mg/kg/d tapered to10mg/d), and steroid group prednisone alone (1mg/kg/d tapered to 10mg/d), both for 12 months. The efficacy and safety was evaluated after 6, 12 and 24 months. Integrated capillary electrophoresis was used to detect MBL gene polymorphism in peripheral blood DNA. The clinical and pathological factors which could predict patients' response to LEF was investigated by Logistic regression analysis.

Results: 85 patients (38 in LEF group and 47 in steroid group) were enrolled. There was no difference in baseline data. All patients received an ACEI or ARB. At 6, 12, 24 months of treatment, decrease of proteinuria ($p<0.05$), improvement of serum albumin ($p<0.05$) were observed in both groups and renal function maintained stable. Total effective rate in LEF group were 68.42% and 68.09% in steroid group, respectively ($p=0.26$). The adverse events prevalence was low and slight in both groups. Compared with those who response to LEF therapy, NR (no response) patients had higher baseline serum creatinine ($P=0.035$), uric acid level ($P=0.027$), severer histological tubular-interstitial damage ($P=0.028$), accompanied with a higher mutation prevalence in MBL gene exon 1 (+54) ($P<0.001$). Logistic regression analysis found that MBL gene exon 1 (+54) polymorphism may predict renal response to leflunomide ($\beta=-0.469$, $P=0.04$) in IgAN patients.

Conclusions: LEF combination with low dose of predinisone appears to be a safe and effective treatment in progressive IgAN, while those with MBL gene variation may predict lower response probability.

Transcriptome Sequencing Identifies Potential Steroid Resistance Biomarkers in Childhood Nephrotic Syndrome William E. Smoyer,[1,2] Audrey Carol Papp,[3] Amy Webb,[3] Milan Popovic,[3] Rainer Benndorf,[1,2] Shipra Agrawal,[1] Richard F. Ransom.[1,2] *[1]Center for Clinical and Translational Research, The Research Institute at Nationwide Children's Hospital, Columbus, OH; [2]Program in Pharmacogenomics, Department of Pharmacology, The Ohio State University, Columbus, OH.*

Background: Glucocorticoids (GC) induce remission of nephrotic syndrome (NS) in most children, though ~20% present with or develop GC resistance. The molecular basis for differences in GC efficacy between steroid-sensitive (SSNS) and steroid resistant (SRNS) children remain largely unknown. This study seeks to determine the mechanisms responsible for differential responses to GC in children with SSNS and SRNS.

Methods: Total mRNA from leukocytes, collected at presentation (S1) and after the first course of GC therapy (S2) from children with SSNS and SRNS, was used to produce cDNA libraries for deep sequencing using the SOLiD™ Series 4 sequencer. Each sample produced ~100 million sequence reads of ~50 bases/read, sufficient to obtain whole transcriptome sequences over a wide range of transcript expression.

Results: Transcriptome-wide deep sequencing identified numerous GC-regulated genes and splice variants, as well as structural and regulatory SNPs. As expected, expression of genes known to be induced by GC in many cell types, including leukocytes (*TSC22D3, DUSP1, RNF130*), was greater in S2 than S1 in both SRNS and SSNS patients. In contrast, the most striking difference in gene expression between SRNS and SSNS patients was the inability of GC to down-regulate expression of several genes in SRNS (but not SSNS) patients, including those encoding specific cytokines (*IL8, TNF, TNFSF10*), transcription factors (IRF1), and enzymes (PTGS2) with known or suspected relevance to NS.

Conclusions: In this preliminary, small-scale analysis from our large available patient cohort, we can already conclude that transcriptome-wide deep sequencing of leukocyte mRNA from children with SSNS and SRNS holds the potential to identify novel molecular mechanisms underlying both the development of, and effective therapy for, NS in children, and may also improve our understanding of the many other diseases treated with GC.

Novel Sets of Genes Correlated with Progressive Tubular Damage and Tubulointerstitial Fibrosis in Patients with Chronic Kidney Disease Shunsaku Nakagawa,[1] Haruka Shinke,[1] Kumiko Nishihara,[1] Tomoko Sato,[1] Hitomi Miyata,[2] Takeshi Matsubara,[2] Noriyuki Iehara,[2] Yoshinobu Igarashi,[3] Hiroshi Yamada,[3] Atsushi Fukatsu,[2] Motoko Yanagita,[2] Kazuo Matsubara,[1] Satohiro Masuda.[1] *[1]Department of Pharmacy, Kyoto University Hospital, Kyoto, Japan; [2]Department of Nephrology, Graduate School of Medicine, Kyoto University, Kyoto, Japan; [3]Toxicogenomics Project, National Institute of Biomedical Innovation, Osaka, Japan.*

Background: In chronic kidney disease (CKD), the irreversible loss of nephron causes not only glomerular sclerosis but also progressive tubular atrophy and tubulointerstitial fibrosis. In this study, we aimed to identify the molecular characteristics that reflect the histopathological changes seen in the kidneys of CKD patients.

Methods: A total of 47 patients with histopathologically confirmed renal disease were enrolled in the study after obtaining written informed consent. The gene expression profiles of renal biopsy specimens of CKD patients were determined using microarray analysis (Whole Human Genome Microarrays, Agilent Technologies) and assessed with respect to the severity of pathological lesions related to tubular cell damage and tubulointerstitial fibrosis.

Results: Analysis involving 43,376 probes indicated that 23 and 105 genes showed significantly increased expression with the progression of tubular cell injury and tubulointerstitial fibrosis, respectively. Eight genes, including neutrophil gelatinase-associated lipocalin (NGAL) and kidney injury molecule-1 (KIM-1), were common between these 2 sets. We determined the tubular damage score on the basis of the expression levels of these 8 genes in the biopsy specimens. Composite area under the receiver operating characteristics curve (AUC-ROC) analysis showed that the score had high sensitivity for diagnosing severe tubular cell damage (AUC = 0.952, $P < 0.01$) and tubulointerstitial fibrosis (AUC = 0.894, $P < 0.05$). In addition, we found that the tubular damage score was inversely correlated with the estimated glomerular filtration rate ($r = -0.594$, $P < 0.01$).

Conclusions: Novel sets of genes correlated with progressive tubular damage and tubulointerstitial fibrosis were identified in patients with CKD.

Metabolomic Approach for Clarifying the Effect of AST-120 in 5/6 Nephrectomized Rats by Capillary Electrophoresis Mass Spectrometry Yasutoshi Akiyama,[1,2] Yoichi Takeuchi,[2,5] Eikan Mishima,[2] Takehiro Suzuki,[2] Sadayoshi Ito,[2] Tomoyoshi Soga,[3] Takaaki Abe.[2,4,5] *[1]Department of Community Health Promotion, Tohoku University Graduate School of Medicine, Sendai, Japan; [2]Division of Nephrology, Endocrinology and Vascular Medicine, Tohoku University Hospital, Sendai, Japan; [3]Institute for Advanced Biosciences, Keio University, Tsuruoka, Japan; [4]Division of Medical Science, Ohoku University Graduate School of Biomedical Engineering, Sendai, Japan; [5]Department of Clinical Biology and Hormonal Regulation, Tohoku University Graduate School of Medicine, Sendai, Japan.*

Background: An oral adsorbent AST-120 consists of spherical carbon particles and prevents the progression of chronic kidney disease (CKD) by adsorbing uremic toxins or their precursors in the intestine. The best-known uremic toxin whose plasma level is decreased by AST-120 treatment is indoxyl sulfate. Other than indoxyl sulfate, some compounds have been reported whose plasma levels are decreased by AST-120 treatment. However, the target compounds of AST-120 have not been fully elucidated.

Methods: Plasma concentrations of 147 compounds (62 anions and 85 cations) in 5/6 nephrectomized rats with or without 4 weeks of AST-120 treatment were comprehensively evaluated by capillary electrophoresis mass spectrometry (CE-MS).

Results: We identified 7 anions and 17 cations that were significantly decreased by AST-120 treatment. In contrast, we also identified 2 cations that were significantly increased by AST-120. Among them, 5 anions and 19 cations except for 3-indoxyl sulfate and hippurate were newly identified in this study. Plasma levels of 10 compounds (N-acetyl-neuraminate, 4-pyridoxate, 4-oxopentanoate, glycine, γ-guanidinobutyrate, N-γ-ethylglutamine, allantoin, cytosine, 5-methylcytosine and imidazole-4-acetate) were significantly increased by 5/6 nephrectomy and significantly decreased by AST-120 treatment.

Conclusions: These 10 compounds newly identified in this study could be added as the uremic compounds that indicate the effect of AST-120 treatment in CKD rats. This study provides the useful information not only for identifying the indicators of AST-120, but also for clarifying the change of metabolic profile by AST-120 treatment.

FR-PO823

Efficacy of a Human Anti-Macrophage Migration Inhibitory Factor Antibody in a Rat Model of Proliferative Nephritis Bernhard Baumgartner,[1] Jeff McKee,[1] Randolf J. Kerschbaumer,[2] Frances A. Clemo,[1] Audrey M. Hutchcraft,[1] Martin Wolfsegger,[2] Alfred Weber,[2] Gerald Hoebarth,[2] Frederick W.K. Tam,[3] Friedrich Scheiflinger,[2] Hans Peter Schwarz,[2] Eva-Maria Muchitsch,[2] Werner Hoellriegl.[2] *[1]Baxter Healthcare Corporation, Round Lake; [2]Baxter BioScience, Vienna, Austria; [3]Imperial College Kidney and Transplant Institute, Imperial College, London, United Kingdom.*

Background: Baxter developed a fully human monoclonal antibody (BAX B01) against the macrophage migration inhibitory factor (MIF). BAX B01 exerts anti-inflammatory properties by neutralizing MIF and is currently in a phase I clinical trial for the treatment of lupus nephritis. The pharmacodynamic evaluation of BAX B01 in a model for proliferative nephritis was required for filing IND.

Methods: Proliferative glomerulonephritis in Wistar Kyoto rats was induced by intravenous (i.v.) injection of nephrotoxic serum (NTS), an anti-rat glomerular basement membrane serum raised in rabbits. BAX B01 was injected i.v. at 5 different dose levels (1, 5, 10, 20, and 40 mg/kg) 4 and 11 days after NTS administration. Urine total protein, albumin, and TNF-α as well as histological kidney changes (glomeruli crescent formation and ED-1 positive cells) were measured and compared to 40 mg/kg isotype control antibody and buffer solution-treated animals.

Results: The lowest BAX B01 dose showing a therapeutic effect was a single 10 mg/kg application that significantly reduced urine total protein compared to the isotype control antibody- and buffer-treated animals (25% and 33% respectively). Administration of 20 or 40 mg/kg BAX B01 (either single dose on day 4 or two doses on days 4 and 11) led to further significant reduction in glomerulonephritis severity (up to 63% reduction in proteinuria, 61% reduction in albuminuria, and 38% reduction in crescent formation). Evaluation of pharmacokinetic parameters of i.v. administered BAX B01 in healthy Wistar rats gave a terminal half-life of approximately 12 days. No BAX B01 related signs of toxicity were observed during the efficacy and PK studies.

Conclusions: The results of our studies show that BAX B01 is efficacious in a rat model of proliferative nephritis, even after a single administration.

Impact of Cyclin-Dependent Kinase Inhibition with Roscovitine on Actin Cytoskeleton and Intracellular Calcium Signaling in Renal Cells: Dual Effect of the S and R Enantiomer Grazia Tamma, Marianna Ranieri, Annarita Di Mise, Alessia Spirlì, Maria Svelto, Giovanna Valenti. *Dept. Biosciences Biotechnologies and Pharmacological Sciences, University of Bari, Bari, Italy.*

Background: Cyclin-dependent kinases (CDK) inhibitors represent interesting therapeutic candidates due to their ability to target cell cycle proteins. Of these, roscovitine is currently entering phase II clinical trials against cancers and phase I clinical tests against glomerulonephritis because reduces the abnormal cell proliferation. The two roscovitine

enantiomers (R and S) are both very promising therapeutic tools due to their ability to regulate cell proliferation, however they might exert distinct actions at tissue levels. Here we evaluated roscovitine effect on actin cytoskeleton and intracellular calcium signaling in MDCK cells.

Methods: Intracellular calcium was evaluated by Fura-2AM microfluorimetry. Actin filaments were visualized by phalloidin-TRITC.

Results: The two enantiomers had opposite effects on actin organization as R-roscovitine caused actin depolymerization whereas S-roscovitine stabilized actin filaments. *Long term* R-roscovitine treatment significantly reduced basal cytosolic calcium compared to control cells. In contrast, S-roscovitine treated cells showed a significant increase in basal intracellular calcium. S*hort term* exposure to S-roscovitine induced a cytosolic calcium peak, which was abolished after store depletion with cyclopiazonic acid (CPA). Instead R-roscovitine caused cytosolic calcium oscillations followed by a small calcium plateau. Calcium oscillations were prevented after store depletion with CPA or treatment with the PLC inhibitor U73122. Bafilomycin, a selective vacuolar H+-ATPase inhibitor abolished the small calcium plateau.

Conclusions: To our knowledge this is the first study revealing the differential effect of S- and R-roscovitine on cytoskeleton and intracellular calcium signaling in renal cells. Since calcium and CDKs are pleiotropic cellular regulators and both exert powerful effects on cell proliferation and regulation of membrane transporter trafficking through actin dynamics, the use of S- and R-roscovitine as therapeutic tools has to be carefully evaluated.

FR-PO825

Renal Damage Induced by Iron Sucrose Similars in a Rat Model

Jorge E. Toblli, Gabriel F. Cao, Margarita Angerosa. *Lab Exp. Medicine Hospital Aleman, University of Buenos Aires, Argentina.*

Background: IV iron preparations are non-biological complex drugs (NBCD) based on a polynuclear iron(III)-oxyhydroxide core stabilized by various carbohydrates (sucrose, dextran, gluconate or carboxymaltose). This study assessed kidney function after IV administration of either the original iron sucrose (IS, Venofer) or iron sucrose similar (ISS) preparations.

Methods: SD rats received IV iron preparations (40mg iron/kg bw weekly for 4 weeks, blinded samples) with: J1 (Ferri, India); K1 (Encifer, India); L1 (Ijzehydroxide Saccharose Complex, Netherlands);M1 (Likefer, Russia);N1 (Venofer, Switzerland); controls with normal saline. Proteinuria, cr.cl, NGAL in urine and kidney tissues, oxidative/nitrosative stress and iron parameters were comparatively evaluated. Iron disposition, hepcidin and apoptosis were also assessed.

Results: Differences in iron disposition in the kidney were observed between IS and ISS groups in tubular and glomerular cells. Markers for functional kidney parameters from animals treated with N1 (originator) and J1-M1 (ISS preparations) differed significantly ($p<0.01$).

Mean ± SD	J1	K1	L1	M1	N1 (originator)	Control
Proteinuria (mg/day)1	79.1± 9.0	83.2± 10.3	39.9 ± 4.4†	28.9 ± 4.0†	7.5 ± 3.4**	4.1 ± 2.3*
Urine NGAL (ng/ml)1	1871.0±247.1	2662.2±398.7*	1428.1±263.2†	974.8±118.5†	441.5±47.9**	366.5 ± 63.0**
Iron (Prussian Blue positive staining /area)	6.6 ± 0.4	6.5 ± 0.5	4.4 ± 0.6†	4.5 ± 0.7†	1.5 ± 0.3**	0.4 ± 0.2 *
L Ferritin (positive staining /area)	2.6 ± 0.4	2.7 ± 0.3	3.9 ± 0.4†	4.2 ± 0.3†	9.1 ± 0.3**	0.8 ± 0.3*
Nitrotyrosine (positive staining /area)	14.8 ± 1.2	14.5 ± 1.3	9.7 ± 1.0†	9.5 ± 0.9†	3.4 ± 0.8**	3.0 ± 0.5**
Caspase 3 (number of positive cells /area)	8.1 ± 1.5	8.7 ± 1.2	7.5± 1.6	7.2 ± 1.4	1.0 ± 0.5**	0.2 ± 0.2*
Hepcidin (positive staining /area)	12.5 ±2,4	11.1±1,8	8,5±1,5†	7,8±1,6†	3.3±0,8**	2.1± 0.9*

1 Values a day 29.* $p<0.01$ vs. all. † $p<0.01$ vs. J1 and K1. ** $p<0.01$ vs. J1, K1, L1, and M1 $p<0.01$

Conclusions: ISS preparations showed a different pattern of iron disposition in the kidneys, a higher level of oxidative/nitrosative stress and kidney injury versus the original IS. These results may be due to subtle and not always predictable structural differences of these non-biological complex drugs.

Citrate Pharmacokinetics in Severe Acute Kidney Injury Patients

Yin Zheng,[1] Zheng Jiao,[2] Zhongye Xu,[1] Chuan-Ming Hao,[1] Feng Ding.[1] *[1]Nephrology, Huashan Hospital, Fudan University, Shanghai, China; [2]Clinical Pharmacy Laboratory, Huashan Hospital, Fudan University, Shanghai, China.*

Background: Regional citrate anticoagulation (RCA) has been increasingly used in severe acute kidney injury (AKI) patients at high risk for bleeding. However, citrate metabolism has never been evaluated in this patients group. This study systematically evaluated the pharmacokinetics of citrate in severe AKI patients and applied the kinetic parameters to the prediction of systemic citrate concentrations during continuous veno-venous hemofiltration (CVVH) using citrate anticoagulation.

Methods: Critically ill patients with AKI (n=12) and healthy volunteers (n=10) were infused 4% sodium citrate and substituted calcium for 2 hours. Serial blood samples were taken before, during and up to 120 min after citrate infusion. Systemic citrate concentrations were measured. Subgroup analyses of severe AKI patients according to RIFLE class, SOFA scores and the necessity for vasopressors were performed. The kinetic parameters were applied to a citrate kinetic equation to predict the systemic citrate concentrations during 10 patients' CVVH using citrate anticoagulation.

Results: Total body clearance of citrate was similar in patients with AKI and healthy volunteers (648.04 ± 347.00 L/min versus 686.64 ± 353.60 L/min ; P = 0.624). There were no significant differences in citrate basal and peak concentrations between groups (p=0.423 and 0.247, respectively). Subgroup analyses showed there were tendencies of increasing AUC and reducing clearance in patients with higher SOFA scores or using vasopressor agents, though no statistical differences were found. Measured citrate concentrations fitted well with the predicted citrate curve. No patient developed citrate accumulation and citrate-related metabolic complications during CVVH using citrate anticoagulation.

Conclusions: Citrate clearance in critically ill patients with AKI is not impaired. Patients with higher SOFA scores or using vasopressor agents are suggested to be under careful monitoring during long-term CRRT procedures. With the help of citrate kinetic equation, citrate pharmacokinetic data could provide a basis to predict the risk of citrate accumulation.

Dialyzability and Pharmacokinetics of Sitafloxacin Following Multiple Oral Dosing in Infected Hemodialysis Patients: Comparison with Levofloxacin

Shuichi Tsuruoka, Kunihiro Yamagata. *Nephrology, University of Tsukuba, Tsukuba, Ibaraki, Japan.*

Background: The pharmacokinetics and dialyzability of oral sitafloxacin, a newly available quinolone, in hemodialysis patients have not been reported previously.

Methods: Fourteen maintenance hemodialysis patients with acute pyelonephritis were randomly assigned either oral sitafloxacin (50 mg daily for three days, N=7) or levofloxacin (500 mg on the first day and 250mg on the third day, N=7) after obtaining their informed consent. On the 3rd day, pharmacokinetic parameters and dialyzability of the drugs were evaluated in these patients by arterio-venous difference method.

Results: All patients exhibited improved symptoms without major problems. Drug concentrations in all arterial samples were compatible with that of healthy subjects orally receiving 100 mg daily and above their MIC of targeted bacteria. Dialyzer clearance of sitafloxacin was slightly but significantly higher than that of levofloxacn (57.8 ± 3.9 and 49.9 ± 0.9 ml/min/m^2, sitafloxacin and levofloxacin, respectively). Apparent half-lives of both drugs during dialysis session were almost same and they were significantly increased after the dialysis; however the increment after the session was significantly prominent in sitafloxacin (4.0 ± 0.4 and 46.5±3.8 hours for sitafloxacin, 4.6±0.5 and 27 .1 ±3.6 hours for levofloxacin, during and after the session, respectively). Dialyzer clearances were positively correlated with urea reduction ratio and negatively correlated with serum albumin concentration in both drugs. Rebound of the drug concentrations after the dialysis were not seen.

Conclusions: Oral dosing of sitafloxacin at 50 mg daily in maintenance hemodialysis patients provides a safe drug concentration compatible with that of healthy subjects orally receiving 100 mg daily. Because significant amount of both drugs were removed, administration might be undertaken after the dialysis session. Comparing with levofloxacin, higher dialyzer clearance and reduction of half-life during the HD session of sitafloxacin may be due to smaller protein-binding rate of the drug.

FR-PO828

Validation Pharmacokinetic Study for Minimum Dose Oseltamivir Using LC/MS/MS in Peritoneally Dialyzed Patients

Kook-Hwan Oh,[1] Yon Su Kim,[1] Kwon Wook Joo,[1] Dong Ki Kim,[1] Mira Kim,[1] Kwang-hee Shin,[2] Joo-youn Cho,[2] Kyung-sang Yu,[2] Curie Ahn.[1] *[1]Nephrology, Seoul National Univeristy Hospital, Seoul, Korea; [2]Clinical Pharmacology and Therapeutics, Seoul National University College of Medicine and Hospital, Seoul, Korea.*

Background: The present study was undertaken for developing and validating a pharmacokinetic(PK) study using minimum dose oseltamivir for patients receiving peritoneal dialysis (PD) using high-performance LC-MS/MS.

Methods: The study was performed in three steps. First, we developed a highly sensitive and specific assay for oseltamivir and its active metabolite, oseltamivir carboxylate. Second, dose-finding pilot PK study was performed for PD patients (n=4) in order to verify the linearity and concordance of PK profiles among 2.5mg, 5mg and 10mg oseltamivir, for which the regular dose is 75mg b.i.d. Third, two separate PK studies in CAPD patients (n=10) with a minimum and regular therapeutic doses of oseltamivir were conducted and the two PK parameters were compared.

Results: Validation for the determination of oseltamivir in plasma and dialysate by LC-MS/MS was carried out with LLOQ of 0.5 ng/mL and linear range between 0.5 and 500 ng/mL. In the dose-finding study, the three oseltamivir doses (2.5mg, 5mg and 10mg) exhibited linear pharmacokinetics. Therefore, PK study with 2.5mg oseltamivir was performed in CAPD patients (n=10) in order to validate the accuracy of minimum dose, compared with regular therapeutic dose (35mg). There were high concordance rates between 2.5mg and 35mg PK studies both for oseltamivir and oseltamivir carboxylate - i.e., AUC_{last} / Dose, CL/F, and drug excreted by dialysis (%). No significant differences between the two doses were observed in the dose adjusted parameters such as C_{max} / Dose (0.64+/-0.24 vs 0.65+/-0.27 ng/mL/mg, p:NS), and AUC_{last} / Dose (1.15+/-0.76 vs 1.48+/-0.68 ng·h/mL/mg, p:NS) for oseltamivir. No differences were observed in the C_{max} / Dose, and AUC_{last} / Dose for oseltamivir carboxylate, either.

Conclusions: The present study could be a model of minimum dose PK study predicting the PK parameters at a therapeutic dose and can be extended to other drugs in such vulnerable patients with end stage renal disease.

FR-PO829

Population Pharmacokinetics and Dose Adjustment Strategy of Cyclosporine in Steroid-Resistant Nephrotic Patients Satoru Ogahara, Takao Saito, Yasuhiro Abe, Yoshie Sasatomi, Katsuhisa Miyake, Hitoshi Nakashima. *Nephrology and Rheumatology, Internal Medicine, Fukuoka University Hospital, Fukuoka, Japan.*

Background: Cyclosporine A (CsA) is widely used in the treatment for steroid-resistant nephrotic patients. Therapeutic drug monitoring is essential to avoid adverse effects while maximizing immunosuppressive efficacy. The aims of this study were 1) to determine the population pharmacokinetic parameters of CsA in these populations; and 2) to propose a simplified strategy to predict AUC_{0-4}, a parameter that has recently been recommended as an index for the dose adjustment of CsA.

Methods: A total of 300 CsA concentration data were collected from 22 patients, who had received CsA once daily in the morning, either before or after breakfast. Population pharmacokinetic analysis was performed using the NONMEM program. A one-compartment pharmacokinetic model with first-order absorption and elimination were used to fit the data. The CsA concentrations predicted using the individually adjusted pharmacokinetic parameters by Bayesian method were compared with the observed CsA concentrations. Then, the AUC_{0-4} predicted by the 1-point sampling strategy using C_1 were compared with the AUC_{0-4}.

Results: The estimated mean population pharmacokinetic parameters (interindividual variability) for oral clearance (CL/F) and apparent volume of distribution for the central compartment (Vd/F) were 19.6 L/hr (34.5%) and 40.5 L (39.5%), respectively. The CsA concentrations predicted using the individually adjusted pharmacokinetic parameters shown an excellent correlation with observed CsA concentrations. The AUC_{0-4} predicted by the 1-point sampling strategy using C_1 exhibited an excellent correlation with the AUC_{0-4} calculated by the trapezoidal method ($R^2 = 0.668$). The final regression model was: $AUC_{0-4} = 1.5(C_1) + 633$(dosing time) + 8.27(dose) where dose timing = 0 for before breakfast, dose timing = 1 for after breakfast.

Conclusions: The present findings suggest that 1-point sampling strategy using C_1 based on population pharmacokinetics can accurately predict AUC_{0-4}, providing an excellent method for the daily dose adjustment of CsA.

FR-PO830

Novel Model for Prediction of Pharmacokinetics at a Therapeutic Dose with a Low-Dose Pharmacokinetics in End-Stage Renal Disease on Hemodialysis: Low-Dose Oseltamivir Pharmacokinetics Yun Jung Oh,[1] Dong Ki Kim,[1] Kwang-hee Shin,[2] Jeonghwan Lee,[1] Kook-Hwan Oh,[1] Kyung-sang Yu,[2] Yon Su Kim,[1] Kwon Wook Joo.[1] *[1]Internal Medicine, Seoul National University Hospital, Seoul, Republic of Korea; [2]Clinical Pharmacology and Therapeutics, Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: Adverse drug reaction due to drug overdosing may give rise to safety issues in pharmacokinetic (PK) study in patients with end-stage renal disease (ESRD). To reduce the risk, we aimed to develop a model for prediction of PK at a therapeutic dose (TD) with a low-dose (LD) PK study in ESRD patients using oseltamivir as a model drug.

Methods: Two-step PK studies using LC-MS/MS were performed in 14 anuric ESRD patients undergoing hemodialysis. First, the dose-finding pilot step (n=4) was designed as dose-escalation study by dose-doubling from 2.5mg of single oral oseltamivir to find the LD that shows linear PK with two higher doses. Once the LD was determined, PK predictability assessment study (n=10) was performed using the LD defined in the pilot study and TD (35mg) with a 3-week washout period. The PK profiles of oseltamivir and its active metabolite oseltamivir carboxylate (OC) at a TD simulated from the LD data were compared with observed PK.

Results: In the dose-finding pilot study, a 2.5mg of oseltamivir was defined as the LD that shows dose-proportionality with two higher doses (5 and 10mg). Therefore, PK study with 2.5mg oseltamivir was performed to validate its predictability of the PK profiles at a TD. Despite the 14-fold difference in dose, the plots of the plasma oseltamivir and OC concentration-time profiles for the LD and TD have a similar shape. The population PK analysis demonstrated that the simulated PK parameters of oseltamivir and OC were well correlated with observed values, and that the simulated OC concentration-time profiles were well corresponded to the measured values.

Conclusions: The close agreement between the observed and the model-simulated concentrations indicated the rational to use the LD PK study for predicting the PK profiles of drugs at a TD in ESRD patients undergoing hemodialysis.

FR-PO831

Safety and Pharmacokinetics of Single and Multiple Doses of a First in Class Dual NADPH Oxidase 1 and 4 Inhibitor Administered Orally in Healthy Subjects Philippe Wiesel,[1] Lionel Hovsepian,[2] Peter J. Mutch,[3] Jacques Herve,[1] Freddy Heitz,[1] Patrick Page.[1] *[1]Genkyotex S.A., Plan-les-Ouates, Switzerland; [2]SGS-Aster, Paris, France; [3]Aptiv Solutions, Stevenage, United Kingdom.*

Background: NADPH oxidases (NOX) are important sources of reactive oxygen species (ROS), and excessive NOX-mediated ROS production has been implicated in a broad range of human diseases, including respiratory, cardiovascular, renal, and metabolic disorders and other conditions where oxidative stress, inflammation and fibrosis play a role. The NOX1 and NOX4 isoforms seem to be centrally implicated in the development of diabetic complications. We report the single and multiple dose safety and pharmacokinetics (PK) of the first in class dual NOX1/4 inhibitor, GKT137831.

Methods: A first, open label single ascending dose study assessed increasing doses of oral GKT137831 (10, 30, 100, 300, 900, 1500, and 1800mg) in 36 healthy adult male subjects. A second, randomized, double-blind, placebo controlled, multiple ascending dose study assessed 10 consecutive (daily or twice daily) doses of oral GKT137831 in 4 sequential cohorts of 12 subjects each (9 active and 3 placebo). GKT137831 was administered at doses of 100mg OD, 300mg OD, 400mg BID, and 900mg OD.

Results: Single-dose and multiple-dose GKT137831 was safe and well tolerated, and dose limiting toxicities were not identified at the doses tested. The incidence of adverse events (AEs) was low and comparable across the placebo and all presumed biologically active doses, and there were no serious AEs. Following a single oral dose, GKT137831 was rapidly absorbed ($T_{max} \sim 1$ hour) and had dose-proportional PK (AUC_{0-24} and C_{max}) up to 900mg. The terminal half-life was approximately 12 hours at the anticipated therapeutic dose. There was no change in PK characteristics following 10 consecutive daily or twice daily administrations, and no accumulation occurred.

Conclusions: The excellent safety and pharmacokinetic profiles of single-dose and multiple-dose GKT137831 in healthy subjects warrant further investigations in patients. Phase 2 clinical studies in patients with diabetic nephropathy and other disorders are planned.

FR-PO832

Pharmacokinetics (PK) of Single Dose Oral Ranolazine in Subjects Receiving Maintenance Hemodialysis (HD) Bruce A. Mueller,[1] Bridget Scoville,[1] Rachel F. Eyler,[3] Michael Heung,[2] Jonathan H. Segal.[2] *[1]College of Pharmacy, U Michigan; [2]Division of Nephrology, U Michigan School of Medicine; [3]College of Pharmacy, U Connecticut.*

Background: Ranolazine is an anti-anginal medication that requires dose adjustment for renal insufficiency but does not have manufacturer's dosing recommendations for patients receiving HD in the product label. The objective of this study was to characterize the PK of ranolazine in subjects with CKD-5 receiving HD.

Methods: This adaptive design study was a prospective, open-label, single dose PK study of ranolazine in non-fasting subjects with CKD-5 receiving HD. A single Ranexa ER 500mg tablet was administered. Plasma samples were collected at t=1, 2, 4, 8, 12, 15, 18, 20, 22, 23, 30 and 65 hours post dose. A 4 hour HD session began 18 hours post-dose. Pre/post dialyzer plasma samples were obtained at 20, 22 hours post dose. Samples were analyzed by LC-API/MS/MS with a lower limit of detection of 50 ng/mL.

Results: Three subjects (mean±SD age 38±12 years, weight 56.6±10.2 kg) completed the study. The Cmax ranged from 372 to 906 ng/mL and the Tmax ranged from 4 to 12 hours. Ranolazine AUC0-24 was 8281.0 ng*hr/mL, 9550.0 ng*hr/mL, and 2818.9 ng*hr/mL for subjects 1, 2, and 3, respectively. Subject 3 had undetectable concentrations starting at 18 hours post dose. The t1/2 of 3.6±1.7 hours was calculated from samples t=23 and 30 for subject 1 and 2 and t=12 and 15 for subject 3. Post dialyzer plasma ranolazine concentrations were 10.2%±7.6% lower than pre dialyzer plasma ranolazine concentrations. Post-HD rebound 1 hr after HD ranged from 3.6%-7.6%.

Conclusions: The Tmax varied widely in subjects receiving HD and was longer than the 2-5 hours reported in subjects with normal renal function. The t½ of 3.6 hours was shorter than the 7 hour t½ reported in subjects with normal renal function. The ~10% difference between pre and post dialyzer samples, ranolazine's large Vd, and significant plasma protein binding suggests that ranolazine is not very dialyzable. Our ranolazine PK findings are in-line with published data from subjects with renal insufficiency. Further evaluation in this population is necessary for proper PK characterization.

Continuous versus Intermittent Infusion of Loop Diuretics in Hospitalized Patients: A Meta-Analysis of Randomized Controlled Trials Fahad S. Alqahtani,[1] Ioannis Koulouridis,[1,2] Khagendra Dahal,[1] Bertrand L. Jaber.[1,2] *[1]Department of Medicine, St. Elizabeth's Medical Center, Boston, MA; [2]Department of Medicine, Tufts University, Boston, MA.*

Background: Several studies have examined the potential benefits of continuous vs. intermittent intravenous loop diuretic administration in hospitalized patients with conflicting results. We conducted a meta-analysis to compare the efficacy of continuous vs. intermittent infusion of loop diuretics in hospitalized patients with fluid overload of various causes.

Methods: We searched MEDLINE (through December 2011) and prior meta-analyses for randomized controlled trials comparing the efficacy of continuous vs. intermittent infusion of loop diuretics. We extracted data on dosing algorithm, mean diuretic dose, daily urine output, and weight change. Random-effects model meta-analyses were used to examine net change in daily urine output and body weight.

Results: We identified 7 cross-over and 11 parallel-arm randomized controlled trials (936 patients) of adults and children. Continuous infusion of loop diuretics resulted in a non-significant net increase in daily urine output of 334 mL (95% confidence interval [CI] CI -74, 742; P = 0.109; I^2 = 84%), but a significant net increase in urine output (normalized to furosemide-equivalent dose) of 147 ml/100mg (95% CI 8, 285; P = 0.038; I^2 = 83%). Studies that used a loading dose prior to the continuous diuretic infusion had a significant net increase in daily urine output of 294 mL (95% CI 31, 557; P = 0.028) compared to studies that did not use a loading dose (340 ml; 95% CI -417, 1096; P = 0.379). Body weight loss was significantly greater in the continuous vs. intermittent infusion group (-0.8 kg; 95% CI -1.5, -0.1; P = 0.041; I^2 = 0%). There was significant heterogeneity in effect sizes among individual studies based on an I^2 index value of greater than 50%.

Conclusions: Continuous infusion of loop diuretics preceded by a loading dose results in greater diuresis in hospitalized patients with fluid overload compared to intermittent dosing regimens. Studies are required to examine whether these benefits translate into improved clinical outcomes.

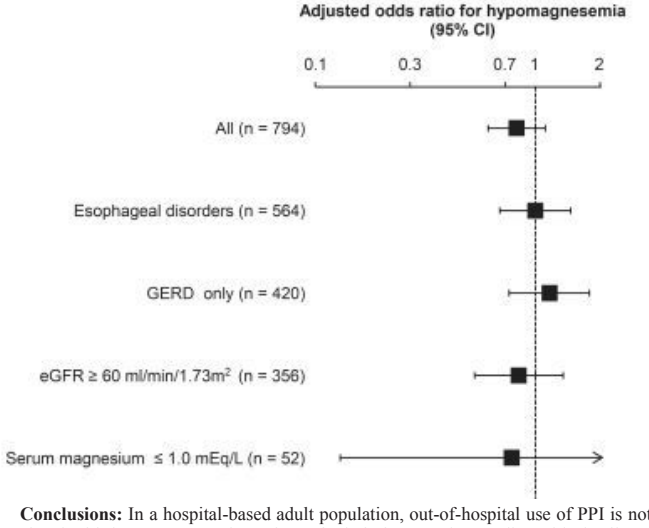
FR-PO834

Out-of-Hospital Use of Proton Pump Inhibitors and Hypomagnesemia at Hospital Admission: A Nested Case-Control Study Ioannis Koulouridis,[1,2] Mansour Alfayez,[1] Hocine Tighiouart,[3] Nicolaos E. Madias,[1,2] David M. Kent,[2,3] Jessica K. Paulus,[2,4] Bertrand L. Jaber.[1,2] *[1]Department of Medicine, St. Elizabeth's Medical Center, Boston, MA; [2]Department of Medicine, Tufts University School of Medicine, Boston, MA; [3]Biostatistics Center, Tufts University Clinical Research, Boston, MA; [4]Epidemiology, Harvard School of Public Health, Boston, MA.*

Background: Case series suggest that chronic use of proton pump inhibitors (PPIs) is associated with hypomagnesemia. Current literature lacks systematically collected data. We examined whether the presence of hypomagnesemia at time of hospital admission is associated with PPI use.

Methods: Nested, age- and sex-matched case-control study of 402 adult cases of hypomagnesemia (<1.4 mEq/L) and 402 controls (1.4-2.0 mEq/L). All magnesium levels were measured at time of hospital admission. Out-of-hospiral PPI use was ascertained from medical records. We included the first hospitalization documenting an ICD-9-CM diagnosis code for disorders of the esophagus, stomach or duodenum. Omeprazole equivalent daily dose was calculated whenever possible. Conditional logistic regression was performed to examine the association of PPI use with hypomagnesemia. Adjustment variables included the Charlson-Deyo comorbidity index, diabetes, diuretic use, eGFR, and gastro-esophageal reflux disease (GERD).

Results: PPI use was not associated with hypomagnesemia (adjusted odds ratio [OR] 0.82; 95% CI 0.61, 1.11). Neither PPI type nor omeprazole equivalent daily dose was associated with hypomagnesemia (data not shown). Several sensitivity analyses were unrevealing (Figure).



Conclusions: In a hospital-based adult population, out-of-hospital use of PPI is not associated with hypomagnesemia at time of admission. Further studies with details on exposure and duration of PPI use are needed to address this potential medication-related issue.

FR-PO835

Influence of Kidney Disease on Drug Pharmacokinetics: An Assessment of Industry Studies Submitted to Food Drug Administration for New Molecular Entities 1999-2010 Gary R. Matzke,[1] Samantha A. Marks,[1] Thomas C. Dowling,[2] John E. Murphy,[3] Gilbert J. Burckart.[4] *[1]School of Pharmacy, Virginia Commonwealth University, Richmond, VA; [2]School of Pharmacy, University of Maryland, Baltimore, MD; [3]Colleges of Pharmacy and Medicine, University of Arizona, Tucson, AZ; [4]Center for Drug Evaluation and Research, Food and Drug Administration, Silver Spring, MD.*

Methods: The quality of renal studies reported in the Food and Drug Administration approved prescribing information (FDA-API) and the clinical pharmacology section of the FDA review (FDA-CPR) of each new molecular entity (NME) approved from 1999 to 2010 were reviewed. The relationship between NME characteristics and the type of renal study and labeling language as established in the 1998 FDA Guidance for Industry were evaluated.

Results: 194 small molecules intended for oral or parenteral use were approved by FDA during 1999-2010. Renal studies were conducted for 89.6% of the 48 NMEs that had > 30% of the drug eliminated renally unchanged (fe); in contrast 65.8% of the 146 NMEs with fe < 30% had a renal study conducted ($p<0.01$) Hemodialysis studies were conducted in just 39.5% and 17.1% of the high and low fe NMEs ($p<0.01$) and CRRT studies were done for less than 1% of NMEs. The study design evaluation revealed that: single dose were more common than multiple dose studies; studies in 3 or more renal function groups were more common than studies conducted in only 2 groups for high (65% vs 18.6%) and low (43.8% vs 35.4%) fe NMEs. Dosage regimen reduction was recommended for 75% ± 9.7 of high fe NMEs and 21.2% ± 5.4 of low fe NMEs ($p<0.0001$). The specificity of the drug dosage adjustment recommendations was better for high (85% ± 13.3) than low fe NMEs (73.4% ± 4.8).($p< 0.0001$) FDA-API language improved over time for high but not low fe NMEs.

Conclusions: Renal function study methodologies, especially dialysis studies, are rarely well described in FDA-API. Dosing recommendations often lack specificity sufficient for individualizing patients' drug therapy. Modifications of FDA guidance to improve the quality of renal studies and FDA-API content appear warranted.

FR-PO836

Pharmacokinetics, Efficacy and Safety of Lesinurad, a Novel URAT1 Inhibitor, in Individuals with Mild to Moderate Renal Impairment Jeffrey N. Miner, Bradley Kerr, Zancong Shen, Li-tain Yeh, David T. Hagerty, Vijay Hingorani, Matthew Cravets, Kimberly J. Manhard, Barry D. Quart. *Ardea Biosciences, San Diego, CA.*

Background: Lesinurad is novel URAT1 inhibitor that blocks reabsorption of uric acid in the proximal tubule of the kidney. Serum urate (sUA) lowering effect, pharmacokinetics (PK), safety, and tolerability of lesinurad were examined in subjects with normal and impaired renal function in 3 clinical trials.

Methods: In 2 double-blind, placebo-controlled, Phase 2b studies, 331 gout patients were randomized to receive a 28-day once-daily course of placebo or lesinurad from 200 to 600 mg as monotherapy or in combination with allopurinol (ALLO). In a phase 1 study, 24 subjects with varying degrees of renal function were given a single oral dose of lesinurad 200 mg. Full PK profiles were obtained in the phase 1 study and in a sub-study of the Phase 2b ALLO-combination study and predose concentrations were measured weekly in both phase 2b studies. Urinary lesinurad concentrations and sUA levels were also evaluated.

Results: Lesinurad C_{max} increased ≤30% in the various renal impairment categories compared to subjects with normal renal function. Lesinurad AUC increased ~33% in subjects with mild renal impairment and approximately doubled in subjects with moderate renal impairment. Renal clearance of lesinurad was similar between subjects with normal renal function and with mild renal impairment, but appeared to decrease as the creatinine clearance declined below around 40 ml/min. Median sUA reduction with the 400 mg dose in patients with normal, and mild to moderate renal impairment was 32%and 28% for monotherapy and 21%and 25% for combination with ALLO, respectively. Across the 3 studies, the tolerability and safety of lesinurad was similar in patients with normal and impaired renal function.

Conclusions: In Phase 2B clinical trials, there were no meaningful differences in lesinurad exposure in patients with mild-to-moderate renal impairment. Similar serum urate reductions were observed in these patients compared to patients with normal renal function. The efficacy and safety profile of lesinurad was similar in patients with normal and impaired renal function.

FR-PO837

Pharmacokinetics (PK): Pharmacodynamics (PD) of Peginesatide in Patients with Chronic Kidney Disease on Dialysis Richard Czerniak, Michael J. Kukulka, Himanshu Naik, Ping Qiu, Max Tsai, Eric Schmidt, Majid Vakilynejad. *Takeda Global Research and Development Center, Inc., Deerfield, IL.*

Background: Peginesatide (OMONTYS®) is an erythropoiesis-stimulating agent indicated for treatment of anemia due to chronic kidney disease (CKD) in adult patients on dialysis. Peginesatide cyclically increased reticulocyte count and maintained hemoglobin (Hb) levels within ±1 g/dL of baseline following intravenous (IV) or subcutaneous (SC) doses in dialysis patients switched from epoetin treatment. A phase 3 randomized, open-label, active-controlled study in dialysis patients showed that similar Hb levels were achieved with similar doses by IV or SC routes.

Methods: A population PK-PD model was developed using NONMEM VI and data from 4 phase 2 studies and 1 phase 3 study in CKD patients on and not on dialysis. Non-compartmental methods used WinNonlin v5.2.

Results: Volume of distribution (Vd) after IV dose was 35 mL/kg, terminal elimination half-life ($t_{1/2}$)was 48 hr, and plasma clearance (CL) was 0.5 mL/h•kg. After SC dose, time to C_{max} was 2 days. Absolute bioavailability (BA) was ~ 40%. The Vd/F after SC dose was 74 mL/kg, $t_{1/2}$ ranged from 33 to 77 hours, and CL/F was 1.5 mL/h•kg. No accumulation was observed following IV or SC doses every 4 weeks (Q4W).

A 2-compartment model with first order absorption and Michaelis-Menton elimination well described the PK. The relationship between peginesatide plasma concentrations and Hb levels in dialysis patients was well characterized by a modified precursor-dependent indirect PD response model. The exposure and BA estimated were similar to those obtained following noncompartmental analysis. The estimates for EC_{50} and E_{max} were 0.4 µg/mL and 0.54, respectively. None of the identified covariates including concomitant medications were considered clinically relevant, based on their impact on simulated peginesatide exposure (<±30%) and Hb levels (<±0.2 g/dL). Based on simulations, following 10 mg IV and SC injection, plasma concentrations were sustained above the estimated EC_{50} for similar durations with 4QW dosing interval.

Conclusions: Peginesatide produced similar PD response with IV or SC administration, despite the differences in PK.

PK/PD-Guided Development of a Novel Hepcidin Antagonist for the Treatment of Functional Iron Deficiency in CKD Andreas M. Hohlbaum,[1] Andrea Allersdorfer,[1] Nicole Andersen,[1] Jürgen Christian,[1] Hendrik Gille,[1] Martin Huelsmeyer,[1] Galina Katzmann,[1] Max Mayr,[1] Bernd Meibohm,[2] Stefan Trentmann,[1] Laurent P. Audoly.[1] *[1]R&D, Pieris AG, Freising, Germany; [2]Pharmaceutical Sciences, Univ. of Tennessee, Memphis, TN.*

Background: Many CKD hemodialysis patients exhibit functional iron deficiency and will become anemic despite treatment with IV iron and ESA's. Blockade of hepcidin offers a novel pharmacological point of intervention for addressing functional iron deficiency in CKD by modulating iron availability and/or the response to ESA's. We recently presented the discovery of a highly specific and potent hepcidin-specific Anticalin (PRS-080) that can effectively increase serum iron levels in a non-human primate model (ASH#687). We are now trying to identify an appropriate half-life for our drug candidate to match hepcidin production rates and consequently optimize pharmacodynamic responses.

Methods: Different versions of PRS-080 were rationally engineered using PEGylation to modify the half-life of the drug. PK properties of PRS-080 bearing either a PEG 12, 20, 30, or 40kDa moiety were measured in mice, rats and cyno's.

Results: Human volumes of distribution and clearance were extrapolated by allometric scaling and half-lives were then calculated to be 6, 17, 50 and 298 hours depending on the PEG moiety. The different versions of PRS-080 also caused a significant increase in total plasma iron in cyno's. A PK/PD model for the interaction between PRS-080 and hepcidin was developed to predict format, dose and time-dependent suppression of hepcidin in a chronic setting. The model accurately described the observed concentration-time profiles of total and hepcidin-free Anticalin in cyno's after single IV administration while the predicted profiles of free hepcidin correlated well with observed iron responses. The model also revealed that therapeutics with antibody like half-lives result in the accumulation of hepcidin-drug complexes, but do not prolong hepcidin suppression.

Conclusions: These results have provided a rationale for identifying the most appropriate serum half-life for our drug candidate while maximizing efficacy. Clinical development of PRS-080 in CKD is planned.

FR-PO839

Comparison of PR3-ANCA and MPO-ANCA Epitope Specificity upon Disease Relapse Aleeza J. Roth,[1] Witold M. Winnik,[2] JulieAnne G. McGregor,[1] Caroline Jennette Poulton,[1] Elisabeth Berg,[1] Susan L. Hogan,[1] Yichun Hu,[1] Gloria A. Preston,[1] J. Charles Jennette,[1] Ronald J. Falk.[1] *[1]Kidney Center, University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]National Health and Environmental Effects Research Laboratory, Environmental Protection Agency, Research Triangle Park, NC.*

Background: Relapse is a major clinical problem in ANCA vasculitis that causes increased morbidity and mortality. Compared to MPO-ANCA patients, patients with PR3-ANCA run a significantly increased risk of experiencing relapses. We hypothesized that a relapsing patient is producing autoantibodies with epitope specificities differing from those at disease onset or previous active disease.

Methods: Epitope mapping entailed immobilizing ANCA to native PR3 or MPO, which protects epitopes from enzymatic digestion. Epitopes were eluted and identified by matrix-assisted laser desorption mass spectrometry (MALDI-MS). ^{16}O-to-^{18}O exchange was used to detect peptide targets of low level autoantibodies from healthy individuals. Autoantibody specificity was determined for 25 patients (active vs. relapse) and 15 healthy individuals.

Results: A total of 14 PR3 epitopes or 25 MPO epitopes were detected from patients with active disease. Upon reactivation of disease PR3-ANCA patients developed additional unique anti-PR3 autoantibodies whereas MPO-ANCA patients did not. MPO-ANCA target the same MPO epitopes upon reactivation of disease. In contrast, PR3-ANCA patients develop anti-PR3 that do not target the same epitopes. Natural PR3-ANCA (3/14) and MPO-ANCA (12/25) from patients in remission and healthy controls reacted at very low levels with unique epitopes.

Conclusions: ANCA titers in clinical assays reflect a combination of both pathogenic and nonpathogenic ANCA. Relapse of disease in patients with PR3-ANCA, un-like MPO-ANCA, develop a different repertoire of B cell clones which target previously unrecognized epitopes. This abstract does not necessarily reflect EPA policy.

FR-PO840

Regulatory B Cells in Patients with ANCA Vasculitis Lydia Aybar,[1] Susan L. Hogan,[2] Yichun Hu,[2] Elisabeth Berg,[2] Caroline Jennette Poulton,[2] Ronald J. Falk,[2] Donna O. Bunch.[2] *[1]Microbiology and Immunology, UNC, Chapel Hill, NC; [2]UNC Kidney Center, UNC, Chapel Hill, NC.*

Background: ANCA disease is a relapsing and remitting autoimmune disease where pathogenesis is B cell dependent; yet, how particular B cell subsets contribute to immunopathogenesis remains unknown. Regulatory B cells (Bregs) are phenotypically characterized as CD19^{+}CD24^{hi}CD38^{hi} and play a role in immunological tolerance by suppression of TH1 cells' inflammatory cytokine production via IL-10 secretion. We hypothesize that a decrease in functional, IL-10 producing B cells is a component of B cell dysregulation that accompanies active disease.

Methods: We examined 140 samples from 94 ANCA patients and 19 healthy individuals by flow cytometry. To identify Bregs, PBMCs were stained with antibodies against CD19, CD24, CD38, and CD5. A smaller cohort of 15 ANCA patients and 3 healthy controls was examined for IL-10 producing B cells. To determine the competency of B cell subsets to produce IL-10 in patients with ANCA disease during active and remittent disease states, PBMCs were stimulated with CD40 ligand and CpG DNA, a TLR9 agonist, for 72-96h and processed for intracellular staining of IL-10.

Results: ANCA patients, regardless of disease activity, and healthy individuals had similar percentages of B cells with a regulatory phenotype: 14±2% vs 10±1% respectively (p=0.2). Patients in remission are similar to healthy individuals with regard to IL-10 producing B cells (mean=29±3%) and 29±3% (p=0.9) respectively. In contrast, B cells from patients with active disease produced significantly less IL-10 (13+4%) than ANCA patients in remission (p=0.003).

Conclusions: ANCA patients and healthy individuals had similar percentages of Bregs; yet, active ANCA patient B cells produced significantly less IL-10. These data suggest that Bregs are present in ANCA patients but functionally impaired. These findings emphasize the importance of functional IL-10 producing Bregs in maintaining disease remission and support the hypothesis that a loss of functional Bregs may permit the immunopathogenesis of active ANCA disease. Assessing Breg ability to secrete IL-10 may be an important biomarker of ANCA remission.

Abstract Withdrawn

FR-PO842

AIRE Is Necessary for Myeloperoxidase Tolerance in Autoimmune Anti-Myeloperoxidase Glomerulonephritis Poh-Yi Gan, Diana S. Tan, Shaun A. Summers, A. Richard Kitching, Stephen R. Holdsworth. *Medicine, Monash Medical Centre, Monash University, Melbourne, Victoria, Australia.*

Background: The autoimmune regulator (AIRE) transcription factor is important in the maintenance of central tolerance. AIRE has been found to regulate the promiscuous presentation and expression of tissue-restricted antigens in medullary thymic epithelial cells. The role of central tolerance mechanisms in the maintenance of tolerance to the potential auto-antigen, MPO is unknown. This study aims to define the role of AIRE in nephritogenic autoimmunity to myeloperoxidase (MPO).

Methods: We compared AIRE and MPO mRNA expression in isolated thymic cell subpopulations in AIRE-/- and AIRE+/+ littermate control C57Bl/6 mice. We then assessed the development of induced MPO autoimmunity and renal injury among AIRE-/- and AIRE+/+ mice in a model of autoimmune anti-MPO GN.

Results: AIRE and MPO mRNA were predominately expressed in thymic medullary epithelial cells. MPO mRNA was not detectable in AIRE-/- thymii. Compared with AIRE+/+ littermates, AIRE-/- mice immunized with MPO and developed significantly greater MPO autoimmunity with increased ANCA titres (0.59±0.05 vs 0.37±0.04 OD450nm), greater frequency of IFNγ-producing CD4+ cells (234±33 vs 130±16 ELISPOT) and delayed type hypersensitivity responses to MPO (0.1±0.01 vs 0.03±0.001 mm). Associated with increased autoimmunity, GN in AIRE-/- mice was significantly enhanced (glomerular CD4+ cells: 0.6±0.1 vs 0.3±0.1 cells/glomerular cross section [c/gcs]; macrophages: 1.1±0.2 vs 0.5±0.04 c/gcs) and proteinuria (1.6±0.3 vs 0.2±0.1 relative score), all $p<0.05$.

Conclusions: This study highlights the importance of AIRE in controlling the maintenance of central tolerance to MPO and deficiency in AIRE resulting in enhanced autoimmunity to MPO and increased severity of GN in a model of autoimmune anti-MPO focal necrotizing GN.

FR-PO843

Defective Treg Function Exacerbated by Expansion of a Suppression-Resistant Effector Population in Human ANCA Disease Meghan E. Free,[1] Donna O. Bunch,[2] Elisabeth Berg,[2] Madelyn Burkart,[2] Susan L. Hogan,[2] Yichun Hu,[2] Gloria A. Preston,[2] J. Charles Jennette,[1,2] Ronald J. Falk,[2] Maureen Su.[3] *[1]Pathology and Laboratory Medicine, UNC Chapel Hill, Chapel Hill, NC; [2]UNC Kidney Center, UNC Chapel Hill, Chapel Hill, NC; [3]Pediatrics, UNC Chapel Hill, Chapel Hill, NC.*

Background: The development of pathogenic anti-neutrophil cytoplasmic autoantibodies (ANCAs) can result in systemic small vessel vasculitis. However, the breakdown in immune tolerance that results in the induction and persistence of ANCAs is not well-understood. We hypothesized that abnormal T cell regulation is central to disease pathogenesis and demonstrate here two separate abnormalities in T cell regulation in patients.

Methods: Analyses were performed using flow cytometry on lymphocytes stained with appropriate antibodies. Functional studies were completed using a standard suppression assay.

Results: First, we show that the Treg frequency in the peripheral blood of active disease patients is increased, but have decreased suppressive function. Tregs from active disease patients disproportionately utilize a FOXP3 isoform lacking exon 2, which may alter Treg function. Second, we identify a markedly expanded CD4+ T cell population that is resistant to Treg suppression, produces pro-inflammatory cytokines, and is antigen-experienced.

Conclusions: Thus, not only is the suppressive network of Tregs disrupted, but a distinct pro-inflammatory effector T cell subset comprises the majority of peripheral CD4+ T cells in ANCA disease patients.

Detection of Newly Synthesized MPO and PR3 Protein in Peripheral Neutrophils from Patients with ANCA Vasculitis Elizabeth A. Alderman, Anshul K. Badhwar, Jia Jin Yang, Olivier Lardinois, J. Charles Jennette, Ronald J. Falk, Gloria A. Preston. *UNC Kidney Center, UNC-CH.*

Background: Generally, mature neutrophils are considered pre-apoptotic cells minimally synthesizing RNA and protein. Studies of ANCA vasculitis revealed neutrophils are environmentally-responsive cells whose normal biology can be disrupted in disease. Peripheral neutrophils from patients in active disease were transcribing genes normally silenced during granulopoesis including autoantigens PR3 and MPO. We determine whether disease-associated transcripts of PR3 and MPO are translated.

Methods: Neutrophils were separated from blood of patients with ANCA disease (BVAS range 2-22), and control subjects. Cells were incubated (20hrs) in methionine free medium supplemented with methionine analogue, L-azidohomoalanine with or without anisomycin. PR3/MPO were immunopurified and the proteins that incorporated AHA were biotinylated using a Click chemistry approach. Biotin-labeled PR3/MPO was purified using an anti-biotin Ab and detected by western blot probed with streptavidin conjugated to alkaline phosphatase and validated using anti-PR3 and anti-MPO Abs. Gel purified product was analyzed by mass spectrometry. Transcript levels were monitored by QPCR.

Results: Neutrophils produce a plethora of newly translated proteins, absent when cultured with the protein synthesis inhibitor anisomycin. Seven patients were analyzed for translation of PR3 and MPO: PR3 ANCA (n=3) and MPO ANCA (n=4). QPCR values for PR3 ranged from 0.76 to 86.73 and MPO ranged from 46.37 to 384.99 fold above normal. Seven patients were positive for biotinylated PR3,and five positive for biotinylated MPO. Remission samples were negative. Mass spetrometry analysis confirmed de novo synthesize of PR3 and MPO. A patient with chronic neutropenia injected daily with GM-CSF served as a control**.** Although the patient had ample protein synthesis in cultured neutrophils, the patient was negative for PR3 and MPO message by TaqMan and negative for PR3 and MPO by western blot.

Conclusions: Neutrophils from patients are actively synthesizing proteins, including PR3 and MPO. These newly synthesized proteins may play a role in disease by increasing antigen availability.

FR-PO845

Toll Like Receptor 9 Enhances Glomerular Injury in Anti-Neutrophil Cytoplasmic Antibody Vasculitis Shaun A. Summers, Sharon Lee Ford, Poh-Yi Gan, Stephen R. Holdsworth, A. Richard Kitching. *Department of Medicine and Nephrology, Monash Medical Centre and Monash University, Melbourne, Victoria, Australia.*

Background: Neutrophils are early effector cells in ANCA vasculitis. Clinical studies suggest infections promote vasculitis, with Toll Like Receptors (TLRs) a link between infection and glomerulonephritis. We sought to define the role of TLR9 in ANCA vasculitis.

Methods: We used myeloperoxidase (MPO) deficient mice to generate MPO-ANCA. TLR9 was assessed in human and murine MPO-ANCA glomerulonephritis by immunofluorescence. C57BL/6 wild type (WT) mice were injected with: 1) TLR9 ligand (CpG-ODN) alone, 2) MPO-ANCA alone or 3) CpG-ODN+MPO-ANCA. Neutrophil recruitment was assessed after 5 hours. TLR9$^{-/-}$ mice were injected with CpG-ODN+MPO-ANCA. WT and TLR9$^{-/-}$ mice were irradiated and reconstituted with WT or TLR9$^{-/-}$ bone marrow cells (BM) to generate bone marrow chimeras. WT BM→ WT mice (BM+ Tissue Cell[TC]+), TLR9$^{-/-}$BM→WT mice (BM-TC+) and WT BM→TLR9$^{-/-}$mice (BM+TC-) all received CpG-ODN+MPO-ANCA.

Results: TLR9 immunostaining is increased in murine and human biopsies with active MPO-ANCA glomerulonephritis. TLR9 ligation enhances MPO-ANCA induced glomerular neutrophil recruitment. Compared to WT mice receiving CpG-ODN or MPO-ANCA alone, neutrophil recruitment synergistically increased after CpG-ODN+MPO-ANCA (CpG-ODN alone 0.3±0.1, MPO-ANCA alone 0.9±0.1, CpG-ODN+MPO-ANCA 1.5±0.1 neutrophils/ glomerular cross section (n/gcs), P<0.01). Enhanced neutrophil recruitment corresponded with increased kidney mRNA CXCL1, CXCL2 and TNF expression. Control oligonucleotides (GpC-DNA) did not affect recruitment. In TLR9$^{-/-}$ mice receiving CpG-ODN+MPO-ANCA, neutrophil recruitment (WT 1.4±0.1 vs. TLR9$^{-/-}$ 0.6±0.1n/gcs, P<0.001) and kidney mRNA expression (CXCL1, CXCL2, TNF) decreased. In chimeric mice, neutrophil recruitment was similarly decreased in BM-TC+ and BM+TC- mice (BM+TC+1.7±0.2, BM-TC+0.8±0.1, BM+TC-1.0±0.1n/gcs, P<0.001). In further experiments functional and histological renal injury was increased in WT mice 6 days after receiving CpG-ODN+MPO-ANCA, compared to mice receiving either CpG-ODN or MPO-ANCA alone.

Conclusions: TLR9 ligation enhances glomerulonephritis in ANCA vasculitis.

Histone H3K9 Methylation Contributes to the Epigenetic Silencing of Proteinase 3 (PR3) and Myeloperoxidase (MPO) Genes in Patients with ANCA Disease Jia Jin Yang,[1] Kerry R. Colby,[1] Chao Guo,[1] Caroline Jennette Poulton,[1] Elisabeth Berg,[1] Madelyn Burkart,[1] J. Charles Jennette,[2,1] Gloria A. Preston,[1,2] Ronald J. Falk,[1,2] Dominic J. Ciavatta.[3,1] *[1]Medicine, UNC-CH, Chapel Hill, NC; [2]Pathology, UNC-CH, Chapel Hill, NC; [3]Genetics, UNC-CH, Chapel Hill, NC.*

Background: We described a role for histone H3K27 methylation in the epigenetic silencing of PR3 and MPO autoantigen genes, and a defect in this mechanism in patients with ANCA disease (J Clin Invest 120: 3209). In this study, we investigated whether histone H3K9 methylation, a repressive histone modification, might also be disrupted in ANCA patients.

Methods: Expression levels of H3K9 methyltransferase genes, EHMT1 and EHMT2 (G9a), were determined by Affymetrix microarray (Array) and quantitative PCR (Q-PCR), and H3K9 trimethylation (H3K9me3) level was measured by chromatin immunoprecipitation (ChIP).

Results: Array analysis revealed that expression of EHMT1 (ANCA: 51±32 vs HC: 72±24, p=0.03) and EHMT2 (ANCA: 42±27 vs HC:60±11, p=0.005) were significantly depleted in leukocytes from ANCA patients (n=25) compared to healthy controls (n=16). The expression levels of EHMT1 and EHMT2 negatively correlated with PR3 and MPO mRNA level, which were markedly elevated in ANCA patients. Expression of EHMT1 was significantly lower in MPO-ANCA (n=12) than PR3-ANCA patients (n=13). Q-PCR confirmed the reduced expression of EHMT1 and EHMT2 in ANCA patients (n=80) compared to controls (n=20), and the negative correlations for EHMT1 and EHMT2 compared to PR3 and MPO genes. EHMT1 and EHMT2 mRNA levels were significantly lower in patients with active disease (n=40) than patients in remission (n=40). ChIP showed that levels of H3K9me3 were statistically depleted at the PR3 and MPO promoter regions in MPO-ANCA patients (n=7, PR3: 3.0±4.1% of input, p=0.01; MPO: 3.0±5.1, p=0.01) compared to controls (n=23, PR3: 21.2±28.6; MPO: 20.0±26.0), but not in PR3-ANCA patients (n=8, PR3: 20.7±28.2; MPO: 18.7±23.9).

Conclusions: These results further implicate epigenetic mechanisms in the regulation of ANCA autoantigen genes, and suggest that transcriptional control of autoantigen genes may differ in MPO-ANCA versus PR3-ANCA patients.

Combination Treatment of Beraprost and Telmisartan Remarkably Ameliorates Renal Dysfunction in Anti-Glomerular Basement Membrane Nephritis Rats Mitsuko Miyamoto, Fuko Matsuda, Shigeo Fujii, Hidenori Mochizuki, Hajimu Kurumatani. *Pharmaceutical Research Laboratories, Toray Industries, Inc, Kanagawa, Japan.*

Background: A prostacyclin analogue beraprost sodium or an angiotensin II type I receptor antagonist telmisartan has separately been reported to have renoprotective effects in rats. We examined the effect of the combination treatment of beraprost and telmisartan on chronic renal failure in progressed glomerulonephritis (GN) rats by concomitantly administering both drugs at the doses not showing clear effects.

Methods: GN was induced to rats by injecting anti-glomerular basement membrane antibody. Fourteen days after the induction, serum creatinine levels of GN rats were significantly elevated compared with those of normal rats. Then, we divided GN rats into four groups and started the administration of vehicle, beraprost (0.1 mg/kg, twice a day), telmisartan (3 mg/kg, once a day), or their combination.

Results: At day 35 after GN induction, systolic blood pressure was significantly reduced in the beraprost/telmisartan combination group compared with that of control group. At day 42 after GN induction, serum creatinine level significantly decreased in the beraprost/telmisartan group compared with that of control group, while beraprost or telmisaltan alone tended to improve serum creatinine levels, but it is not statistically-significant. In addition, the oxidative stress-related factors in the renal cortex, Nox2 and p47-phox subunits of NADPH oxidase, were decreased significantly in the beraprost/telmisartan group; inflammation-related factors monocytes/macrophages infiltration in the kidney and plasma level of MCP-1 were also decreased in the beraprost/telmisartan group. Furthermore, endothelial cell damage rather than podocyte damage in the kidney was found to be markedly ameliorated in the combination treatment of beraprost and telmisartan.

Conclusions: The combination treatment of beraprost and telmisartan is likely to ameliorate chronic renal failure in progressed GN more effectively than mono-treatment of each drug through both the endothelial protection and glomerular podocyte protection which have been reported in beraprost and telmisartan, respectively.

FR-PO848

The Immunodominant T Cell Goodpasture Epitope Induces Anti-Glomerular Basement Membrane Glomerulonephritis in Susceptible HLA-DR Transgenic Mice A. Richard Kitching,[1] Joshua D. Ooi,[1] Janet Chang,[1] Vadim Pedchenko,[2] Billy G. Hudson,[2] Stephen R. Holdsworth.[1] *[1]Medicine, Monash University, Clayton, VIC, Australia; [2]Medicine, Vanderbilt University Medical Center, Nashville, TN.*

Background: Anti-glomerular basement membrane (GBM) glomerulonephritis (GN) is strongly HLA-DRB1*15:01 associated. The autoantigen is the non-collagenous domain of the α3 chain of Type IV collagen (α3(IV)NC1), but the pathogenic T cell epitope in humans is not known.

Methods: These studies aimed to define the immunodominant and pathogenic T cell Goodpasture epitope using humanized mice deficient in all elements of mouse MHCII but transgenic for susceptible (HLA-DRB1*15:01; 1501tg) or non-susceptible (HLA-DRB1*01:01; 0101tg) human MHCII.

Results: Immunizing 1501tg or 0101tg mice with overlapping α3(IV)NC1 20-mers defined an HLA-DRB1*15:01 restricted T cell epitope ($\alpha3_{133-152}$). This epitope was immunoreactive in *ex vivo* recall responses by T cell proliferation and IFN-γ/IL-17A ELISPOT, but was non-reactive in 0101tg or C57BL/6 mice. Mouse $\alpha3_{133-152}$ and human $\alpha3_{132-151}$ were cross-reactive. Further studies refined the epitope to an 11-mer ($\alpha3_{136-146}$), including 4 critical residues. 1501tg mice immunized with human α3(IV)NC1 or C6 (an α1/α3 chimeric molecule with $\alpha3_{127-141}$ in the non-immunogenic α1 backbone) responded to $\alpha3_{136-146}$ but not $\alpha3_{9-28}$ (containing another putative epitope). However, α1(IV)NC1 or C2 (containing $\alpha3_{17-31}$)-immunized mice responded to neither peptide. Transferring $1x10^7$ $\alpha3_{136-146}$-specific CD4+ Th1 clones generated from 1501tg mice into naive 1501tg mice with LPS (0.5μg/g) induced crescentic GN (day 35: glomerular necrosis 59±6%, crescents 33±5%; control cells 0%), albuminuria (control cells 0.01±0.01, $\alpha3_{136-146}$ clones 0.44±0.03 mg/μmol creatinine, P<0.001) and glomerular CD4+ T cell and macrophage infiltrates. Active immunization with $\alpha3_{136-146}$ (100μgx3) induced GN in 1501tg.FcγRIIB-/- mice (Fcγ receptors are implicated in disease susceptibility) but not in 0101tg.FcγRIIB-/- mice (day 42). Similarly, α3(IV)NC1 immunization induced anti-GBM GN only in 1501tg. FcγRIIB-/- mice.

Conclusions: T cell autoimmunity and injury in anti-GBM GN are defined by the HLA-DRB1*15:01 restricted epitope $\alpha3_{136-146}$.

B7x Deficiency Exacerbates Renal Injury in Antibody Mediated Nephritis in Mice

Rahul Pawar,[1,3] Beatrice Goilav,[2] Yumin Xia,[1,3] Leal C. Herlitz,[4] Kaya Ghosh,[3] Xingxing Zang,[3] Chaim Putterman.[1,3] *[1]Department of Medicine (Rheumatology), Albert Einstein College of Medicine, Bronx, NY; [2]Department of Pediatrics (Nephrology), Albert Einstein College of Medicine, Bronx, NY; [3]Department of Microbiology and Immunology, Albert Einstein College of Medicine, Bronx, NY; [4]Department of Pathology, Columbia University Medical Center, New York, NY.*

Background: B7x (B7-H4, B7S1) is an important member of the B7/CD28 superfamily of T cell costimulatory proteins. B7x is a negative regulator of $CD4^+$ and $CD8^+$ T cell activation and proliferation, and is primarily expressed in peripheral, non-lymphoid tissues.

Methods: We hypothesized that B7x may modulate the pathogenesis of antibody mediated nephritis through its effects on T cells. We induced nephritis in B7x-deficient (B7x-/-) (n=10) and B7x-WT B6 mice (n=10) by intravenous injection of nephrotoxic sera (rabbit anti-mouse glomerular antibodies).

Results: Following nephritis induction, we observed a significant increase in the levels of serum IgG (p=0.023), particularly of the IgG2b and IgG1 isotype, in B7x-/- mice as compared to WT mice. At the mRNA level, IL-23 (p=0.046), CCL2 (p=0.061) and CCR5 (p=0.045) was found to be upregulated in B7x-/- kidney tissue. Immunohistochemistry revealed increased glomerular infiltration of $CD3^+$ T lymphocytes (p=0.034) and $CD68^+$ macrophages (p=0.003) in B7x-/- mice kidneys. Furthermore, kidney histopathology was more severe in B7x-/- mice, in terms of infiltrating polymorphonuclear cells in glomeruli (p<0.0001) and interstitium (p=0.004), crescent formation, and tubular atrophy/dilatation. Finally, serum creatinine and BUN were elevated in the B7x-/- group receiving nephrotoxic sera, as compared to WT mice.

Conclusions: In conclusion, B7x plays a protective role in the pathogenesis of antibody mediated nephritis, likely through exerting an inhibitory effect on T cell activation. Our results provide the first demonstration of a potential role for modulation of the B7x signaling pathway as a new approach for the treatment of immune mediated nephritis.

Lipocalin-2 Is an Endogenous Inhibitor of Inflammation in Murine Nephrotoxic Serum Nephritis

Kathrin Eller,[1] Miriam C. Banas,[2] Alexander H. Kirsch,[1] Alexander R. Rosenkranz.[1] *[1]Clinical Division of Nephrology, Medical University of Graz, Graz, Austria; [2]Department of Nephrology, University Hospital Regensburg, Regensburg, Germany.*

Background: Lipocalin-2 (Lcn-2) is involved in divergent processes such as acute kidney injury or bacterial host defence. Our study was designed to evaluate the functional role of Lcn-2 in nephrotoxic serum nephritis (NTS).

Methods: NTS was induced in wild-type (WT) and Lcn-2 knock-out mice as well as Lcn-2 chimeras.

Results: Mice lacking Lcn-2 exhibited more glomerular damage with increased proteinuria and interstitial leukocyte accumulation compared to WT mice. Since Lcn-2 is expressed in tubular epithelial cells as well as cells of innate immunity such as macrophages and polymorphonuclear neutrophils (PMN), we induced NTS in Lcn-2 chimeras. Chimeras with Lcn-2 expressed in macrophages and PMN were found to develop NTS comparable to wild-type controls. In contrast, chimeras with Lcn-2 expressed in tubular epithelial cells developed increased NTS due to decreased concerted apoptosis but increased necrosis and formation of damage-associated molecular patterns (DAMPs) such as high-mobility group box 1 (HMGB-1) in the kidney. *In vivo* blockade of HMGB-1, a toll-like receptor (TLR)-2 agonist, significantly reduced inflammation and NTS in Lcn-2 knock-out mice. *In vitro*, we found IL-6 to be significantly upregulated in immortalized tubular epithelial cells and macrophages by TLR-2 stimulation. In parallel, Lcn-2 was found to be increasingly transcribed by TLR-2 signalling *in vitro*.

Conclusions: Taken together, Lcn-2 expressed in innate immune cells is protective in NTS by inducing concerted apoptosis and inhibiting the formation of HMGB-1 thereby limiting cytokine production via TLR-2 signalling. In parallel, TLR-2 dependent transcription of Lcn-2 is an endogenous inhibitor of inflammation in NTS.

IL-6 Mediates Crescentic Glomerulonephritis via Differential Effects on Th17 Responses and Macrophage Activation

Michael Mülleneisen,[1] Malte A. Kluger,[1] Boeren Goerke,[1] Stefan Rose-john,[3] Hans-willi Mittrücker,[2] Rolf A. Stahl,[1] Ulf Panzer,[1] Oliver M. Steinmetz.[1] *[1]III. Med Klinik (Nephrology), University Hospital Hamburg Eppendorf, Germany; [2]Immunology, University Hospital Hamburg Eppendorf, Germany; [3]Biochemistry, University of Kiel, Germany.*

Background: IL-6 is central for generation of pro inflammatory Th17 responses but also mediates anti inflammatory effects by dampening macrophage activation. Aim of the current study is to clarify the controversial role of IL-6 in crescentic glomerulonephritis, especially in the light of newly developed IL-6 directed therapies.

Methods: The Th17 and macrophage dependent model of nephrotoxic nephritis (NTN) was induced in wildtype and IL-6-/- mice. Antibodies for differential blockade of IL-6 signalling pathways were used.

Results: NTN induction in IL-6-/- mice resulted in abscence of nephritogenic Th17 responses and amelioration of disease. To dissect opposing effects of IL-6 on Th17 responses and macrophage activation, neutralization studies were performed. An IL-6 antibody was applied at a dose insufficient to block Th17 responses which in contrast to the results in IL6-/- mice aggravated NTN. Aggravation was most likely due to increased macrophage activation with augmented renal infiltration and TNFa production. To verify this hypothesis, aIL-6 treatment was started late in the macrophage dependent effector phase of NTN after Th17 responses had already developed. Again, IL-6 blockade aggravated nephritis and increased macrophage infiltration. Worsening of nephritis was not observed after treatment with sgp130Fc fusion protein which specifically blocks alternative but not classical IL-6 signalling.

Conclusions: In summary our data show that partial IL-6 blockade is not sufficient to suppress nephritogenic Th17 responses and aggravates nephritis via increased macrophage activation. This pro inflammatory effect is mediated by classical but not alternative IL-6 signalling. Complete lack of IL-6, however, prevents development of Th17 responses which overrules macrophage activation and ameliorates disease. Our studies identify IL-6 as differential mediator of crescentic GN and underline the central role of Th17 cells for disease pathogenesis.

Regulatory T Cell-Derived Interleukin-10 Protects Mice against Crescent Glomerulonephritis

Annett Ostmann,[1] Hans-Joachim Paust,[2] Ulf Panzer,[2] Annette Erhardt,[1] Gisa Tiegs.[1] *[1]Experimental Immunology & Hepatology; [2]Nephrology, University Medical Center Hamburg-Eppendorf, Hamburg.*

Background: Regulatory T cells (Tregs) exert their immunosuppressive activity through different immune-regulatory mechanisms including the production of anti-inflammatory cytokines such as IL-10. The suppressive mechanisms of Tregs in renal autoimmune disease, however, remains to be elucidated. In the present study we investigate the role of Treg cell-derived IL-10 in the T cell-dependent murine glomerulonephritis (GN) model of nephrotoxic nephritis (NTN).

Methods: NTN was induced by intraperitoneal injection of nephrotoxic sheep serum in mice. To identify renal IL-10-producing $Foxp3^+$ Tregs we used transgenic reporter (FIR x *tiger*) mice, which enable simultaneous detection of IL-10 and Foxp3 via flow cytometry. To analyze the role of $IL\text{-}10^+$ Tregs we first adoptively transferred $CD4^+CD25^+$ Tregs from either naïve wt C57BL/6 mice or $IL\text{-}10^{-/-}$ mice in nephritic mice. Furthermore, we performed analyses in nephritic $Foxp3^{Cre}$ x $Il10^{flox/flox}$ mice carrying a specific deletion of *Il10* in $Foxp3^+$ Tregs.

Results: By using the FIR x *tiger* mice we identified a significant frequency of IL-10-producing Tregs in the kidney, which was increased upon NTN induction. Adoptive cell transfer experiments revealed a protective effect by wt but not $IL\text{-}10^{-/-}$ Tregs in NTN mice since wt Tregs dampened glomerular crescent formation and albumin/creatinine ratio, whereas $IL\text{-}10^{-/-}$ Tregs did not. Moreover, nephritic mice deficient of endogenous $IL\text{-}10^+$ Tregs exhibit an increased renal and systemic Th1 and most notably Th17 immune response, as determined by flow cytometry, qRT-PCR and ELISA. This was associated with an aggravated course of glomerulonephritis as measured by glomerular crescent formation and albumin/creatinine ratio.

Conclusions: In conclusion, our results contribute to the understanding of the suppressive mechanisms of Tregs in crescentic glomerulonephritis by highlighting the indispensability of Treg-derived IL-10 in reduction of disease severity and regulation of the Th17 immune response. Hence, the immunosuppressive cytokine IL-10 has to be kept in mind with respect to therapeutic approaches in GN.

FR-PO853

Serum Starved Adipose-Derived Stromal Cells Ameliorate Rat Crescentic Glomerulonephritis by Promoting the Generation of M2 Immunoregulatory Macrophages Kazuhiro Furuhashi, Naotake Tsuboi, Hangsoo Kim, Takayuki Katsuno, Waichi Sato, Enyu Imai, Seiichi Matsuo, Shoichi Maruyama. *Nephrology, Nagoya University, Nagoya, Aichi, Japan.*

Background: We have reported that adipose tissue-derived stem cells (ASC) promoted regeneration in a rat model of acute kidney injury and more recently that ASC more strongly modulate T-cell immune reaction than bone marrow derived mesenchymal stem cells (BM-MSC). In the present study, we examined the renal protective effects of ASC focusing on their immunomodulatory properties in anti-GBM GN.

Methods: Necrotizing crescentic glomerulonephritis was induced in WKY rats by intraperitoneal injection of anti -GBM mAb. Renal function and histology were assessed in animals treated with ASC or BM-MSC.To evaluate ASC-driven functional M2 polarization in macrophage(MΦ), we cultured peritoneal MΦ with ASCs or BM-MSC.

Results: Intravenous injection of ASC significantly prevented renal dysfunction and proteinuria in diseased animals. Crescent formation was significantly decreased in ASC group compared to control group. Interestingly, infiltration of M2 MΦ in glomeruli was increased only in ASC group despite comparable number of infiltrated MΦ to control group. In vitro co-culture system clearly demonstrated that ASC, but not BM-MSC, directly turned MΦ into M2 phenotype. Moreover, these effects of ASC were more prominent in low serum cultured ASC (LASC) than high serum cultured ASC (HASC). The number of ASC in glomeruli was 1.5/glomerulus/cross section without any difference between HASC and LASC, but this would be efficient since individual LASC could polarize around 200 MΦ to M2 phenotype in vitro. These results collectively suggest that LASC recruited into diseased glomerulus make stronger effect on MΦ for protection of glomerular injury than HASC. Moreover we found PGE2 derived from LASC induced MΦ into M2 phenotype.

Conclusions: ASC exerted profound immunoregulatory properties especially on MΦ by PGE2 and ameliorated glomerular injury in rat anti-GBM GN model. In human immunosuppressive therapy is often restricted for their adverse effect. Therefore, LASC administration would be desirable therapeutic approach to improve prognosis of anti-GBM GN patients.

FR-PO854

Th17/IL-17 Immune Response Drives CXCL5 Dependent Neutrophil Infiltration and Renal Damage during Crescentic Glomerulonephritis Erik M. Disteldorf,[1] Geraldine Nouailles,[3] Hans-Joachim Paust,[1] Anett Peters,[1] Sabrina Bianca Bennstein,[1] Hans-willi Mittrücker,[2] Rolf A. Stahl,[1] Ulf Panzer.[1] *[1]Universitätsklinikum Hamburg Eppendorf, Nephrology, Hamburg, Germany; [2]Universitätsklinikum Hamburg Eppendorf, Immunology, Hamburg, Germany; [3]Max-Planck-Institut, Department for Infectious Biology, Berlin, Germany.*

Background: The Th17/IL-17 immune response plays a pivotal role in the pathogenesis of autoimmune diseases including human and experimental crescentic glomerulonephritis. The mechanism of Th17/IL-17-induced tissue injury, however, remains to be fully elucidated.

Methods: We used a murine model of crescentic glomerulonephritis (nephrotoxic nephritis).

Results: Here we show that the Th17/IL-17 immune response is paralleled by the expression of the chemokine CXCL5 in tubular cells and consecutive tubulointerstial infiltration of pathogenic $CXCR2^+$ neutrophils. In line with this, IL-17A strongly induced CXCL5 expression in tubular cells, and renal CXCL5 levels and neutrophil recruitment were markedly reduced in nephritic $IL\text{-}17^{-/-}$ mice and in $RAG1^{-/-}$ mice transferred with $IL\text{-}17^{-/-}$ lymphocytes. To test whether CXCL5 plays a functional role in renal inflammation, we generated CXCL5-deficient mice and induced nephritis in $CXCL5^{-/-}$ and wild-type mice. CXCL5-deficient mice developed less severe nephritis in terms of reduced renal neutrophil infiltration, less renal tissue injury and better preserved renal function. Finally we show that CXCL5 expression is highly up-regulated in the kidneys of patients with crescentic glomerulonephritis.

Conclusions: Our data therefore identify a unique role of CXCL5 in Th17-mediated glomerulonephritis and suggest that CXCL5 may be an intriguing therapeutic target.

FR-PO855

Deficiency of Limp-2, an Integral Lysosomal Membrane Protein, Attenuates Renal Injury in Experimental Crescentic Glomerulonephritis Darren H.K. Lee,[1,2] Poh-Yi Gan,[3] Marina Katerelos,[4] Scott Andrew Fraser,[4] Kurt Gleich,[4] Stephen R. Holdsworth,[3] David A. Power.[1,2,4] *[1]Department of Nephrology, Austin Health, Melbourne, Victoria, Australia; [2]Department of Medicine, Austin Health, University of Melbourne, Melbourne, Victoria, Australia; [3]Centre of Inflammatory Diseases, Department of Medicine, Monash University, Monash Medical Centre, Melbourne, Victoria, Australia; [4]The Institute of Breathing and Sleep, Austin Health, Melbourne, Victoria, Australia.*

Background: Deficiency of lysosomal membrane protein SCARB2 (Limp-2 as murine homologue) causes FSGS in humans, and tubular proteinuria in humans and mice. Limp-2 deficiency in mice, however, leads to failure of fusion of phagosomes with lysosomes, defective macrophage activation and innate immunity in response to *Listeria infection.*

Methods: To define the role of Limp-2 in experimental crescentic glomerulonephritis (GN), wild-type (WT) and $Limp\text{-}2^{-/-}$ littermates received i.p. injections of 2 mg of nephrotoxic sheep serum per gram of body weight. Renal injury and immune response were assessed at day 14.

Results: Compared with WT, $Limp\text{-}2^{-/-}$ mice had significantly reduced crescent formation (15.6±10.2% vs 40.2±22.5%, $P<0.005$), interstitial inflammation ($P<0.05$) and a trend for reduced tubulointerstitial injury. On day 1, urinary albumin/creatinine ratio was significantly increased in WT (4921±5180 vs 18±11 mg/mmol, $P<0.05$) but not $Limp\text{-}2^{-/-}$ mice (1655±1842 vs 315±173 mg/mmol) compared to baseline. At day 14, albuminuria and renal function were similar. There was, however, a significant reduction in the influx of glomerular macrophages (0.6±0.2 vs 1.2±0.4 cells per glomerular cross section (c/gcs), $P<0.05$) and $CD4^+$ T cells (0.2±0.1 vs 0.6±0.2 c/gcs, $P<0.05$) in $Limp\text{-}2^{-/-}$ vs WT mice. Renal MCP-1 mRNA expression was also reduced ($P<0.05$). Systemic humoral immune response, determined by glomerular mouse IgG deposition and mouse anti-sheep IgG subclass production, was similar in both groups.

Conclusions: The data suggest that Limp-2 is essential in mediating the local immune response in experimental crescentic GN. The likely reason is a failure of macrophage activation and cytokine release. This study identifies a novel role for a lysosomal protein in autoimmunity.

FR-PO856

Lipoxin A4 and Resolvin E1 Reduce the CD16+ Pro-Inflammatory Subsets of Monocytes Eileen Nolan,[1,2] Debra F. Higgins,[1] Yvonne M. O'Meara,[2,3] Catherine Godson.[1,2] *[1]UCD Conway Institute of Biomolecular and Biomedical Research, University College Dublin, Dublin 4, Ireland; [2]UCD School of Medicine and Medical Science, University College Dublin, Dublin 4, Ireland; [3]Mater Misericordiae University Hospital, Dublin 7, Ireland.*

Background: Monocytes are a structurally and functionally heterogeneous cell population, with three subsets defined on the basis of their surface expression of CD14 and CD16. The classical subset is CD16- and produces anti-inflammatory IL-10, whereas the intermediate and non-classical subsets are CD16+ and produce the inflammatory cytokines TNF-α and IL-6. Expansion of CD16+ monocyte populations occurs in CKD and is associated with chronic inflammation and increased cardiovascular mortality. Lipoxins and resolvins are endogenously-produced eicosanoids with established anti-inflammatory and pro-resolution properties. The purpose of this study was to determine whether lipoxin A_4 (LXA_4) and resolvin E1 (RvE1) would prove effective in modulating monocyte responses to inflammatory stimuli.

Methods: The human cell line THP-1 was used as a model of monocytes. Cells were treated with LXA_4 (10 nM), RvE1 (1 pM), or vehicle (0.1% EtOH) for 30 minutes, before exposure to pro-inflammatory stimuli (IFN-γ 200 ng/ml and LPS 0.1 ng/ml). Cells were stained with monoclonal antibody to CD16 and analysed by flow cytometry. Cytokine content of cell supernatants was assayed by ELISA.

Results: Stimulation of THP-1 monocytes with IFN-γ and LPS resulted in increased expression of CD16 and increased production of both TNF-α and IL-6. A reduction in CD16 expression was observed following exposure to LXA_4 ($p<0.01$) or RvE1, suggesting that these pro-resolution mediators reduce inflammatory monocyte subsets. Treatment of monocytes with RvE1 or LXA_4 also resulted in reduced production of TNF-α ($p<0.01$) and IL-6 ($p<0.05$), as compared with IFN-γ and LPS-stimulated cells, suggesting that these agents attenuate pro-inflammatory monocyte behaviour.

Conclusions: Our results suggest that both lipoxin A_4 and resolvin E1 may have therapeutic potential in reprogramming pro-inflammatory monocytes, thereby reducing their detrimental influence in kidney disease.

FR-PO857

Characterization of the Renal CD4+ T-Cell Response in Experimental Autoimmune Glomerulonephritis Hans-willi Mittrücker,[1] Stefanie Hünemörder,[1] Julia Holzer,[1] Hans-Joachim Paust,[2] Ulf Panzer,[2] Helmut Hopfer.[3] *[1]Institute for Immunology, University Medical Center Hamburg-Eppendorf, Germany; [2]Department of Internal Medicine III, University Medical Center Hamburg Eppendorf, Germany; [3]Institute for Pathology, University Hospital Basel, Switzerland.*

Background: Anti-glomerular basement membrane (GBM) glomerulonephritis results from an autoimmune reaction against the Goodpasture antigen, the non-collagenous domain of the alpha3 chain of type 4 collagen (alpha3IV-NC1). The production of autoantibodies and their deposition along the basement membrane of glomeruli and pulmonary alveoli are central to pathogenesis of disease. However, there is also increasing evidence from clinical and experimental data for a contribution of T cells to disease development.

Methods: We use the mouse model of experimental autoimmune glomerulonephritis (EAG) to analyze the role of T cells in renal destruction.

Results: Following immunization with recombinant alpha3IV-NC1, DBA/1 mice display a pathogenesis that reflects all hallmarks of human anti-GBM glomerulonephritis. We observe an initial alpha3IV-NC1-specific IgG response with deposition of autoantibodies along the GBM and progressive proteinuria. In this stage, the kidney shows only marginal signs of inflammation. After 9-13 weeks, mice develop severe signs of glomerulonephritis including crescent formation as well as massive tubulointerstitial damage with accumulation of T cells and macrophages. Renal inflammation eventually results in a severe loss of kidney function accompanied by massive edema formation. CD4+ T lymphocytes isolated from the kidneys of end stage EAG mice display a highly activated phenotype and produce

TNFalpha, IFNgamma and IL-17A upon polyclonal in vitro stimulation. Using highly sensitive FACS-based techniques, we can also detect renal CD4+ T cells that produced cytokines in response to stimulation with alpha3IVNC1.

Conclusions: From our data, we conclude that renal accumulation of autoreactive T cells might play a role in the progression from mild renal inflammation to severe glomerulonephritis with cell-mediated destruction of glomerular structures and severe tubulointerstitial inflammation.

Funding: Government Support - Non-U.S.

Experimental Study of Application of Anti-Glomerular Basement Membrane Antibodies Neutralizing Monoclonal Antibody on Anti-Glomerular Basement Membrane Nephritis Rats

Jing Xiao, Liu Zhangsuo. *Department of Nephrology, Zhengzhou University, Zhengzhou, Henan, China.*

Background: The development of anti-GBM disease is often sudden onset,extremely dangerous,and the prognosis is poor. On the anti-GBM nephritis rats, we try to use the neutralizing monoclonal antibodies to the anti-GBM antibody to improve the progression of the disease,aim to observe the effect of the neutralizing monoclonal antibodies to the anti-GBM antibody on anti-GBM nephritis rats.

Methods: Wistar rats were randomly divided into five groups:(1)Anti-GBM nephritis group was injected with human anti-GBM antibody via the caudal vein, meanwhile the same dose of Freund's complete adjuvant(FCA) was injected.(2)Control group I was injected with healthy human IgG via the caudal vein.(3)Control group II was injected with neutralizing monoclonal antibodies to anti-GBM antibody via the caudal vein, also the same dose of FCA.(4)Intervention group I was injected with human anti-GBM antibody, the same dose of FCA via the caudal vein and then neutralizing monoclonal antibodies to anti-GBM antibody at day 7.(5)Intervention group II was injected with human anti-GBM antibody, the same dose of FCA via the caudal vein and then neutralizing monoclonal antibodies to anti-GBM antibody at day 14.At day 7, 14 and 21, serum ,urine and renal specimen were collected for analysis.

Results: At day 21, there were significant decreases in intervention group I compared with anti-GBM nephritis group in 24-hours proteinuria[(16.62±5.53)g], BUN[(11.53±2.26) mmol/L] and Scr[(102.46±16.86)umol/L](P<0.05), and also in intervention group II as compared to anti-GBM nephritis group,but no significant difference was found(P>0.05). There was obvious decrease of renal cell proliferation,crescent formation and deposition of immune complexes in intervention group I and intervention group II compared with anti-GBM nephritis group, while such improvement in intervention group I was more significant. There was no significant change in control group I and control group II.

Conclusions: Early application of neutralizing monoclonal antibodies to anti-GBM antibodies can effectively improve the kidney lesion of anti-GBM nephritis rats.

Funding: Government Support - Non-U.S.

FR-PO859

Beraprost Sodium Improves Survival Rates in Anti-Glomerular Basement Membrane Glomerulonephritis and 5/6 Nephrectomized CKD Rats

Shinichi Yamaguchi, Chifumi Inada, Mitsutaka Tamura, Masateru Yamada, Shoichi Itaba, Seiji Okazaki, Shigeo Fujii, Fuko Matsuda, Yasufumi Goto, Hidenori Mochizuki, Hajimu Kurumatani, Mitsuko Miyamoto. *Toray Industries, Inc., Kamakura, Kanagawa, Japan.*

Background: In order to clarify whether beraprost sodium inhibits the progress to end-stage renal disease, the effects of beraprost sodium on survival rates in two rat chronic kidney disease (CKD) models were evaluated.

Methods: (A) 5/6 nephrectomized CKD rats

Beraprost sodium was administrated at a dose of 0.6 mg/kg/day from Day 29 after 5/6 nephrectomized (Nx) operation. Death or serum creatinine doubling time of each rat was evaluated, and the slope of plots of reciprocal serum creatinine was also calculated as the renal function.

(B) Glomerulonephritis (GN) rats induced by anti-glomerular basement membrane serum

Beraprost sodium was administrated at a dose of 0.2 or 0.6 mg/kg/day from Day 5 after GN induction when serum creatinine increased significantly.

Results: In 5/6 Nx CKD rats, 190 days after operation, survival rates of vehicle and beraprost sodium groups were 4 and 32%, respectively. In GN rats, 70 days after nephritis induction, survival rates of vehicle, beraprost sodium 0.2 and 0.6 mg/kg/day groups were 17, 50 and 83%, respectively. In both models, beraprost sodium improved survival rates statistically significantly. In 5/6 Nx rats, the slopes of reciprocal of serum creatinine of beraprost sodium groups were sweeper than those of vehicle group, suggesting that beraprost sodium suppressed the reduction of renal function.

Conclusions: In this study it was confirmed that beraprost sodium improved the survival rates in both anti-GBM GN and 5/6 Nx rats; therefore, beraprost sodium is likely to suppress the progression of CKD to ESRD.

The mTOR-Inhibitor Rapamycin Mediates Proteinuria in Nephrotoxic Serum Nephritis by Activating the Innate Immune Response

Alexander H. Kirsch,[1] Michael Rudnicki,[2] Alexander R. Rosenkranz,[1] Kathrin Eller.[1] *[1]Internal Medicine, Nephrology, Medical University of Graz, Graz, Austria; [2]Internal Medicine, Nephrology & Hypertension, Innsbruck Medical University, Innsbruck, Austria.*

Background: The mTOR inhibitor Rapamycin (Rapa) is currently used in the prevention of allograft rejection in renal transplantation. Proteinuria is a limiting factor in the clinical use of Rapa. We have previously shown that Rapa deteriorates murine nephrotoxic serum nephritis (NTS), when application is started 14 days after disease induction. This study was designed to study the glomerular effects of Rapa in NTS in order to improve the understanding of Rapa-induced proteinuria.

Methods: Glomeruli of nephritic Rapa- or vehicle-treated mice were laser-microdissected and qRT-PCR was performed to study the expression of glomerular cell markers, inflammatory chemokines and cytokines. Immunohistochemistry was performed to assess glomerular infiltration by inflammatory cells and to assess viability of podocytes and glomerular endothelial cells.

Results: The increase in urinary albumin/creatinine ratio in Rapa-treated compared to control animals went along with a more prominent glomerular infiltration by $CD4^+$ T cells and macrophages. Glomeruli from animals treated with Rapa showed increased mRNA levels of the proinflammatory cytokines IL-6 and TNFα, as well as the chemokines MCP-1 and MIP-1β and their cognate receptors CCR2 and CCR5, both of which are expressed on monocytes. Also, we detected a higher transcription level of the regulatory T cell transcription factor Foxp3 in the Rapa-group, while the expression levels of the Th1 marker t-bet and the Th17 marker RORγt were unchanged.

To assess the effect on resident glomerular cell types, we studied the expression of the podocyte marker nephrin, the endothelial-cell marker CD31 as well as the growth factor VEGF-A and did not find any differences in their glomerular expression on mRNA or protein level.

Conclusions: In conclusion, these data suggest that the Rapa-mediated increase in proteinuria in the setting of murine NTS is a result of the activation of the innate immune system rather than a direct cytotoxicity to prodocytes or glomerular endothelial cells.

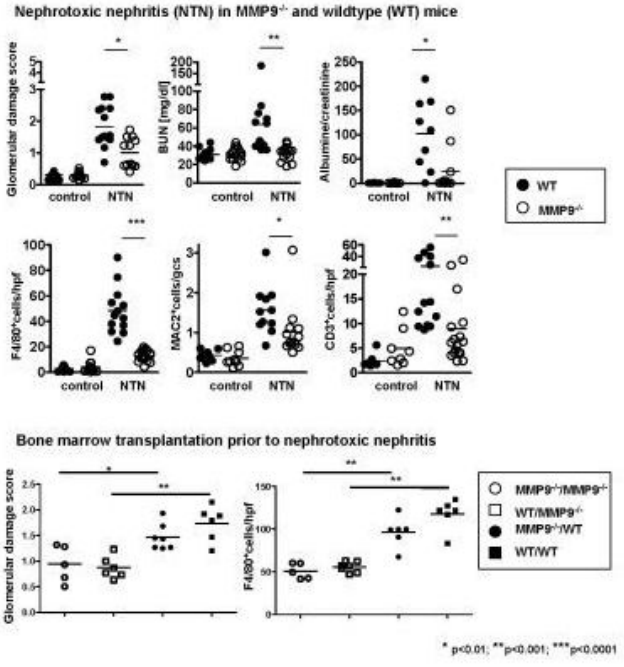
Leukocyte-Derived Matrix Metalloproteinase 9 Is Crucial for the Recruitment of Monocytes/Macrophages in Experimental Glomerulonephritis

Malte A. Kluger, Gunther Zahner, Hans-Joachim Paust, Ulf Panzer, Rolf A. Stahl. *Universitätsklinikum Hamburg-Eppendorf, Germany.*

Background: Matrix Metalloproteinase 9 (MMP9) is a conditionally expressed collagenase and upregulated in glomerulonephritides. Its ultimate function in these diseases is, however, still unclear. In this study, we investigated the leukocyte-specific role of MMP9 in crescentic nephrotoxic nephritis (NTN) in mice.

Methods: Nephrotoxic nephritis (NTN) was induced in 10 wk-old male $MMP9^{-/-}$ and $MMP9^{+/+}$ mice by injection of nephrotoxic sheep serum (C57BL/6 background, microsatellite analysis). Albuminuria and BUN were determined at day 10. Kidneys were harvested for immunohistochemistry, RT-PCR or flow cytometry. Migratory capacity of peritonitis-elicited macrophages was assessed in chemotactic-assays. The specific function of leukocyte-derived MMP9 was investigated performing bone marrow transplantation prior to the induction of NTN.

Results: NTN in wildtype mice resulted in upregulation of MMP9 followed by profound leukocyte infiltration, albuminuria, glomerular crescents and renal failure. MMP9-deficiency ameliorated the course of NTN and significantly reduced histological injury. The absence of MMP9 attenuated the infiltration of $F4/80^+CD11b^+$ macrophages as determined by flow cytometry and immunohistochemical analyzes. Migration of MMP9-deficient macrophages was impaired in chemotactic assays. Bone marrow transplantation was able to restore renal tissue injury and macrophage recruitment when wildtype-derived donor cells were transplanted onto MMP9-deficient mice prior to the induction of NTN.



Conclusions: MMP9-deficiency ameliorates renal impairment during nephrotoxic nephritis in C57BL/6 mice by attenuating migration and renal infiltration of monocytes/macrophages. As bone marrow transplantation studies show, this effect is mediated by leukocyte-derived MMP9 and not by resident kidney cells.

FR-PO862

Comprehensive Re-Classification of Resident Renal Mononuclear Phagocytes Identifies 5 Subpopulations, One of Which Is an IL-10 Producing Reno-Protective Subpopulation Takahisa Kawakami, Prasanthi Karna, Peter J. Nelson, Jeremy Stuart Duffield. *Division of Nephrology, Institute for Stem Cell & Regenerative Medicine, University of Washington, Seattle, WA.*

Background: Monocytes, Macrophages and Dendritic Cells (DCs), although lineally linked, have been thought to be separate cell types. However, there are no definitive discriminatory markers, & their functions & origins are increasingly recognized to be overlapping. Recently, we proposed that they be unified & re-classified as Renal Mononuclear Phagocytes (MPCs) (Nelson et al JASN 2012 23:194). The function, ontogeny & fate of resident MPCs is poorly understood but they play critical roles not only in inflammatory diseases but also in nephrogenesis, angiogenesis, & the maintenance of homeostasis and tolerance in tissues, including kidney.

Methods: We developed a 7-color flow cytometry assay to comprehensively analyze MPCs in kidney using an unbiased approach, in which granulocytes, B cells, T cells, and NK cells are excluded.

Results: Analysis of MPCs simultaneously by CD11b and CD11c expression identified 5 subpopulations: CD11b^{hi} CD11c^{hi} (H-H), CD11b^{hi} CD11c^{lo} (H-L), CD11b^{int} CD11c^{int} (I-I), CD11b^{int} CD11c^{hi} (I-H), CD11b^{lo} CD11c^{int}, and a small CD11b- CD11c- population of undefined cells. Each subpopulation demonstrated marked differences in other surface markers: e.g. I-I MPCs are F4/80^{hi} while H-H and H-L are F4/80^{int}. H-H, I-I, and I-H are MHC-II^{high}. Further, I-H cells exclusively express CD103, an integrin associated with cells thought to function as DCs in non-lymphoid tissues. Transcriptional analysis of sorted populations identified other marked differences: e.g. H-H cells expressed high levels of CCR7 (p=0.017), found on cells that migrate to lymph nodes. Using a novel mouse model that reports IL-10 producing cells, in normal kidney, IL-10 expressing cells reside almost exclusively in the I-I population. For each of these populations we will additionally report ontogeny, relative capacity to induce tolerance or activate T cell responses, phagocytose, & follow their cell fate in response to injury.

Conclusions: The renal MPCs comprise 5 phenotypically and functionally distinct subpopulations which share macrophage and DC properties.

Glomerular IgM Exacerbates Glomerular Disease Progression Sarah E. Panzer,[1] Matthew C. Pickering,[2] Joshua M. Thurman.[1] *[1]Renal Diseases and Hypertension, University of Colorado Denver, Denver, CO; [2]Imperial College, London, United Kingdom.*

Background: Glomerular deposits of IgM and the complement protein C3 are observed in a variety of proteinuric renal diseases. The clinical significance of IgM in the glomerulus is a source of debate. We hypothesized IgM binds to neoepitopes in the diseased glomerulus and tested whether IgM plays a role in the progression of glomerular disease.

Methods: Mice with a targeted genetic deletion of factor H (fH$^{-/-}$) were used as a model of non-immune complex mediated glomerular disease. We crossed these mice onto μMT mice, which lack B cells and therefore have no ability to produce IgM, generating fH/μMT double knockout mice. Urine, blood, and renal tissue were harvested at 9 months of age. Urine albumin was determined by ELISA and BUN and Cr were measured. Glomerular IgM and C3 were assessed by immunofluorescence on frozen kidney sections. In addition, a murine mesangial cell line was used to test whether IgM in normal mouse serum binds to epitopes on mesangial cells by flow cytometry.

Results: Glomerular IgM deposition progressively accumulated in fH$^{-/-}$ mice, expanding throughout the glomerular tufts as the mice aged. Albuminuria in fH/μMT mice was attenuated at 9 months compared to fH$^{-/-}$ mice (1596 ng/mg Cr, N=10 vs 2847 ng/mg Cr, N=13, P = 0.065). Glomerular C3 deposits were similar among fH$^{-/-}$ and fH/μMT mice (mean fluorescence intensity 55.3 vs 56.5, P=NS). Also, flow cytometry of cultured murine mesangial cells exposed to serum demonstrated binding of IgM to the cells, but no binding of IgG.

Conclusions: In the fH$^{-/-}$ model we demonstrate IgM binds within the injured mesangium as disease progresses. Mice deficient in B cells develop milder disease. We also demonstrate that, *in vitro*, IgM binds cultured murine mesangial cells. Our data suggest glomerular IgM deposition occurs after injury, which may expose mesangial epitopes. IgM specific for these epitopes appears to contribute to disease progression. Glomerular IgM may provide an important new therapeutic target for slowing progression of glomerular disease.

Immune Tolerance toward NC1 Hexamers of α3α4α5(IV) Collagen Is Selectively Breached by Proteolysis: A Mechanism Eliciting Non-Nephritogenic Anti-GBM Autoantibodies Florina Olaru,[1] Xu-Ping Wang,[1] Wentian Luo,[1] Linna Ge,[1] Jeffrey H. Miner,[3] Andrew Wasiluk,[2] Xochiquetzal J. Geiger,[2] Dorin-Bogdan Borza.[1] *[1]Vanderbilt University School of Medicine, Nashville, TN; [2]Mayo Clinic Hospital, Jacksonville, FL; [3]Washington University, St. Louis, MO.*

Background: Goodpasture/anti-GBM disease usually presents as rapidly progressive glomerulonephritis (GN) associated with autoAbs against the NC1 domain of α3(IV) collagen. Rare atypical presentations can provide new insights into the disease pathomechanisms.

Methods: We characterized novel anti-GBM autoAbs associated with atypically mild, non-progressive GN. The mechanisms breaching self-tolerance to α3α4α5(IV) collagen and eliciting non-nephritogenic anti-GBM autoAbs were determined using mouse models.

Results: We identified a novel type of anti-GBM autoAbs that specifically bound to α3α4α5NC1 hexamers but not monomeric NC1 subunits, were restricted to human IgG4 subclass, and did not mediate rapid progressive GN. In both wild type and FcγRIIB-/- mice, non-nephritogenic anti-GBM autoAbs selectively targeting α3α4α5NC1 hexamers and restricted to mouse IgG1 subclass were induced by immunization with NC1 hexamers solubilized from murine GBM. Although mIgG1 autoAbs bound to the GBM of immunized mice, glomerular inflammation and C3 deposition were absent, while kidney function and histology remained normal. Unlike its NC1 hexamer fragment, intact α3α4α5(IV) collagen from murine GBM was not immunogenic in wild type mice, yet elicited robust IgG antibody responses in Alport mice lacking α3α4α5(IV) collagen.

Conclusions: These results reveal that self-tolerance toward NC1 hexamers of α3α4α5(IV) collagen is established in wild type but not Alport mice. Self-tolerance is selectively breached by limited proteolytic cleavage of the autoantigen, eliciting atypical anti-GBM autoAbs against NC1 hexamer epitopes accessible in the native GBM. This autoimmune response is associated with an extreme polarization of the anti-GBM autoAbs toward Th2-associated IgG subclasses (hIgG4, mIgG1), which likely accounts for their lack of nephritogenicity. Hence, complement-fixing subclasses of anti-GBM autoAbs are likely required for the development of rapid progressive GN.

FR-PO865

Development of Novel In Vivo Model for Rapid Characterization of Allelic Variants in Systemic Lupus Erythematosus William Franklin Pendergraft,[1-3] Amit Prasad,[3] Terry K. Means,[1,3] Nir Hacohen.[1,3] *[1]Broad Institute, Cambridge, MA; [2]Joint Fellowship Program in Nephrology, Brigham and Women's Hospital and Massachusetts General Hospital (MGH), Boston, MA; [3]Center for Immunology and Inflammatory Diseases, Division of Rheumatology, Department of Medicine, MGH, Charlestown, MA.*

Background: With the advent of genome-wide association studies (GWAS) came tantalizing allelic variants in patients with systemic lupus erythematosus (SLE); however, a critical barrier to understanding their role, especially pertaining to lupus nephritis, is that their characterization has been limited in vivo. We address this critical barrier by creation of a temporally-controlled in vivo system of lupus nephritis-prone mice harboring an immune system reconstituted with hematopoietic bone marrow progenitor cells (HPCs) that either overexpress allelic variants or their respective short hairpin RNA (shRNA).

Methods: To validate this system, HPCs from mice constitutively overexpressing actin were infected with IPTG-inducible actin short hairpin RNA (shRNA) and injected into irradiated wild-type B6 mice after which reconstitution occurred followed by dietary IPTG administration. An identical method was then applied to HPCs from lupus-prone NZB/W F1 female mice using either myd88 shRNA or the doxycycline-inducible human allelic variant recently implicated in SLE, TREX1^{R114H} followed by disease activity monitoring.

Results: GFP expression was abolished after IPTG administration in wild-type B6 mice harboring an immune system reconstituted with hematopoietic cells overexpressing GFP and GFP shRNA. Anti-nuclear and anti-nucleosome autoantibodies did not develop in NZB/W F1 mice exposed to IPTG whose hematopoietic cells overexpressed myd88 shRNA, and autoantibody development occurred faster in those mice exposed to doxycycline whose hematopoietic cells overexpressed TREX1.

Conclusions: This model provides a new mechanism to characterize the role of proteins implicated in the pathogenesis of not only SLE, but also immune-mediated diseases in general and has broad applicability to other fields of science.

FR-PO866

Spontaneous Development of Lupus in Mice Deficient in SCARF1 William Franklin Pendergraft,[1,2,3] Zaida G. Ramirez-ortiz,[3] Amit Prasad,[3] Nir Hacohen,[1,3] Terry K. Means.[1,3] *[1]Broad Institute, Cambridge, MA; [2]Joint Fellowship Program in Nephrology, Brigham and Women's Hospital and Massachusetts General Hospital (MGH), Boston, MA; [3]Center for Immunology and Inflammatory Diseases, Division of Rheumatology, Department of Medicine, MGH, Charlestown, MA.*

Background: Defects in mechanisms governing apoptotic cell detection and clearance in vivo can lead to accumulation of apoptotic cells, which has been associated with systemic lupus erythematosus (SLE); however, the phagocyte-specific receptor responsible for apoptotic cell clearance has yet to be identified. Interestingly, ced-1 is required for apoptotic cell engulfment in the worm, and it encodes a transmembrane protein homologous to the human scavenger receptor expressed by endothelial cells-1 (SREC1 also known as SCARF1).

Methods: In order to analyze the role of the scavenger receptor SCARF1 in apoptotic cell clearance and autoimmunity, we generated Scarf1-deficient mice and analyzed their ability to capture and clear apoptotic cells as well as their propensity for developing autoimmunity.

Results: Scarf1$^{-/-}$ mice, as compared to their wild-type counterparts, have a roughly 3-fold increase in the percentage of endogenous circulating apoptotic cells and CD11c^{+}CD8^{+} dendritic cells (DCs) isolated from Scarf1$^{-/-}$ mice capture ~50% less apoptotic cells when compared to wild-type DCs in vitro. Using an in vivo phagocytic assay in which apoptotic B cells were labeled with CFSE and injected intravenously, we found that splenic DCs from Scarf1$^{-/-}$ mice captured significantly less apoptotic cells than wild-type DCs. In addition, six-month old Scarf1$^{-/-}$ mice spontaneously develop autoantibodies to nuclear antigens and concomitant dipstick hematuria and proteinuria, all of which appear to be more severe in females.

Conclusions: The scavenger receptor, SCARF1, functions in the recognition and phagocytosis of apoptotic cells to maintain tissue homeostasis and prevent lupus-like autoimmune disease. This also represents a new spontaneous model of SLE, which yearns to be explored further.

Anti-Annexin II Level in Serum Correlates with Disease Manifestations in Lupus Nephritis Daniel Tak Mao Chan, Kwok Fan Cheung, Andy Yim, Desmond Y.H. Yap, Susan Yung. *Department of Medicine, University of Hong Kong, Hong Kong.*

Background: We have reported that anti-dsDNA antibodies from patients with lupus nephritis could bind to annexin II on the surface of human mesangial cells and mediate downstream inflammatory processes. In this study we investigated the relationship between serum anti-annexin II activity, measured with ELISA, and clinical parameters.

Methods: Serial serum samples from 23 patients with biopsy-proven severe proliferative lupus nephritis were included. Sera from patients with non-lupus renal diseases and healthy subjects were used as controls.

Results: A total of 487 serum samples were from patients with lupus nephritis, including 97 during active disease and 390 samples during remission. IgG anti-annexin II activity was significantly higher in patients with lupus nephritis compared with controls (P<0.001). Sero-positivity rate for anti-annexin II IgG was 20.3%, 5.3%, and 3.1% in patients with lupus nephritis, non-lupus glomerular diseases, and healthy controls respectively (P<0.001 for both). Anti-annexin II titre (IgG) correlated with the level of anti-dsDNA antibodies (r=0.26, P<0.001), total IgG (r=0.45, P<0.0001), and serum creatinine (r=0.45, P<0.001), while there was an inverse correlation with C3 level (r=-0.31, P<0.001). In 15 of 23 patients investigated, the levels of anti-annexin II and anti-dsDNA were both higher during active disease than during remission.

Conclusions: The data show that IgG anti-annexin II titre correlates with serological and clinical markers indicating disease activity in lupus nephritis.

The Role of IL-17-Producing Invariant NKT Cells in the Autoimmune Lupus Nephritis Seung Hee Yang,[1] Su Mi Lee,[2] Yun Jung Oh,[2] Jung Pyo Lee,[3] Yon Su Kim.[2] *[1]Internal Medical Research Center, Seoul National University, Seoul, Republic of Korea; [2]Internal Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea; [3]Internal Medicine, Seoul National University Boramae Medical Center, Seoul, Republic of Korea.*

Background: CD1d-restrictive invariant NKT cells modulate various autoimmune diseases through secreting multiple cytokines, but the major determinant cytokines in these autoimmune diseases and the functional relationship between these cytokines are still poorly understood. The purpose of this study was to examine the role of the NKT cells as IL-17 producer in the development of glomerulonephritis (GN) using a murine autoimmune lupus nephritis (ALN) model.

Methods: ALN was induced by administering pristane either to C57BL/6 (B6), NKT cell-deficient B6 (B6.CD1d$^{-/-}$), Balb/C, or IL-17A deficient Balb/C (Balb/C.IL-17A$^{-/-}$) mice.

Results: Compared with wild-type mice, B6.CD1d$^{-/-}$ andBalb/C.IL-17A$^{-/-}$ mice showed attenuation of GN in terms of mesangial proliferation and the deterioration of renal function. With the induction of ALN, renalNKT cell infiltration increased, which suggests that NKT cells might actively participate in the renal injury produced by ALN. Expressions of STAT3, IFN-γ, TGFβ, CXCL16, IL-23 and IL-17 mRNA were up-regulated in the ALN mice kidneys, whereas the levels of those mRNA were suppressed by the deletion of NKT cells. In *in-vitro* mesangial cell-T cell interaction system, we found that IL-17 producing NK1.1^{-}NKT cells enhanced the secretion of pro-inflammatory cytokines. αGalCer-primed NK1.1^{-}NKT cells produced IL-17 and the activation of IL-17 by NK1.1^{-}NKT cells increased proliferation of mesangial cells. In addition, treatment of anti-CXCL16 antibody reduced the IL-17 mediated proinflammatory reaction in this system.

Conclusions: These results suggest that NKT cells play an important pro-inflammatory role in pristane-induced lupus nephritis by promoting the secretion of IL-17 and proinflammatory cytokines, and lead to renal injury in this model.

FR-PO869

Lack of Basigin Exacerbates Lupus Nephritis in Experimental Lupus Model Kayaho Maeda, Tomoki Kosugi, Waichi Sato, Hiroshi Kojima, Yuka Sato, Hiroshi Nagaya, Mayuko Maeda, Tomohiro Masuda, Shoichi Maruyama, Seiichi Matsuo. *Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Japan.*

Background: Basigin (Bsg/CD147), a glycosylated transmembrane protein, plays important roles of cell survival, invasion and metastasis. Recently, we demonstrated deleterious effects of Bsg in renal inflammation caused by ischemia and renal fibrosis. As Bsg identifies activated regulatory T cell (Treg), the attention has become extended to the autoimmune diseases, including rheumatoid arthritis and systemic lupus erythematosus (SLE). Particularly, IL-17/IL-23 axis and Treg also serve important roles in the pathogenesis of SLE. However, the molecular mechanism involving Bsg remains unknown yet. We therefore investigated the role of Bsg in lupus nephritis.

Methods: Lupus nephritis was induced in Bsg deficient mice (Bsg$^{-/-}$) or wild-type mice (Bsg$^{+/+}$) with an intraperitoneal injection of pristane (0.5ml/each mice). They were sacrificed at 6 months after an injection for histological and immunohistochemical analyses. Kidney, spleen and thymus were analyzed.

Results: There was no difference between Bsg$^{+/+}$ and Bsg$^{-/-}$ in serum anti-nuclear antibody and anti-dsDNA antibody during the experimental period, whereas serum C3 decreased in Bsg$^{-/-}$. Albuminuria in Bsg$^{-/-}$ was more than Bsg$^{+/+}$. Mesangial and endothelial cells proliferations, macrophage and T lymphocyte infiltration, and wire loop lesion were prominent in Bsg$^{-/-}$ mice. Consistent with these data, IgG, C3, and C1q depositions in Bsg$^{-/-}$glomeruli were predominantly observed. By flow cytometry analysis, IL-17A producing CD3^{+} and CD4^{+} T cells were higher in Bsg$^{-/-}$ spleen than Bsg$^{+/+}$. Interestingly, no obvious difference in the number of Treg is found in both genotypes, whereas IL-10 production and CTLA4 expression strikingly decreased in Bsg$^{-/-}$ Treg than Bsg$^{+/+}$ Treg. Suppression assay also demonstrated the effect of Bsg$^{+/+}$ Treg in the proliferation of CD4^{+}CD25^{-}T cell compared with Bsg$^{-/-}$Treg. These data suggest that Bsg deficiency causes Treg dysfunction, eventually leading to the development of lupus nephritis.

Conclusions: This study identifies Basigin/CD147 as a key molecule in lupus nephritis.

FR-PO870

Switch from Proteasome to Immunoproteasome in Children with Idiopathic Nephrotic Syndrome Roberta Camilla, Elisa Loiacono, Maria Elena Donadio, Licia Peruzzi, Rachele Gallo, Laura Morando, Alessandro Amore, Rosanna Coppo. *Nephrology, Dialysis, Transplantation, R. Margherita Hospital, Turin, Italy.*

Background: The etiology and pathogenesis of idiopathic nephrotic syndrome (NS) in children is still unknown, but signs of involvement of innate immunity through viral infections and activation of the interferon pathway have been reported. The proteasome (PS) is converted into immunoproteasome (iPS) by interferons (INF γ and α) by replacing β1, β2 and β5 PS subunits with LMP2, MECL-1 and LMP7 iPS subunits. The switch to iPS improves the catalytic proteasomal activities and leads to production of optimal MHC-I ligands, shaping T cell response. We investigated in peripheral mononuclear cells (PBMC) of children with NS the innate immunity activation focusing on Toll-like receptor (TLR) expression and the switch from PS to iPS.

Methods: PBMC from 28 children (2-18 y.o.) with NS and 30 healthy controls were tested with real time PRC (Taqman) to measure mRNA expression of TLR3, TLR4, TLR9 and of PS (ß1, ß2, ß5) and iPS (LMP2, MECL-1, LMP7) subunits. The iPS/PS switch was expressed as ratio between iPS and corresponding PS mRNA fold changes.

Results: iPS/PS mRNA subunits ratio of MECL-1/β2 was significantly increased in PBMC from NS patients in comparison to healthy controls (1.26 ± 0.61 versus 1.02 ± 29, P= 0.04) while LMP2/β1 and LMP7/β5 in NS patients were not different from controls (respectively 1.00±0.51 vs 0.91±0.42 and 0.91±0.5 vs 1.07±0.33; p ns). The switch MECL-1/β2 was significantly correlated with TLR3 mRNA (P= 0.02). This switch remained unchanged in different phases of clinical activity, however, in 3 patients treated with a protease inhibitor provided with anti-PS activity, saquinavir, a reversal to normal values of the MECL-1/β2 mRNA ratio was observed (2.02 before treatment vs 0.86 after treatment). No significant changes were detected in mean levels of TLR3-4-9 between patients and healthy controls.

Conclusions: We reportfor the first time an abnormal switch from proteasome to immunoproteasome in children with NS which was found to be correlated with TLR3 activation. These results suggest an involvement of the interferon pathway of innate immunity in this disease.

FR-PO871

Efficacy of CD40 DNA Vaccine in Preventing Heymann Nephritis Is Enhanced by Dendritic Cell Targeting Yuan Min Wang,[1] Ya Wang,[2] Yiping Wang,[2] Guoping Zheng,[2] Geoff Yu Zhang,[1] Jimmy Jianheng Zhou,[1] Thian Kui Tan,[2] Qi Cao,[2] Min Hu,[2] Debbie Watson,[1,3] Huiling Wu,[4] Dong Zheng,[2] David C. Harris,[2] Stephen Alexander.[1] *[1]Centre for Kidney Research, Children's Hospital at Westmead, Westmead, NSW, Australia; [2]Centre for Transplant and Renal Research, Westmead Millennium Institute, Westmead, NSW, Australia; [3]Centre for Medical Bioscience, University of Wollongong, Wollongong, NSW, Australia; [4]Collaborative Transplant Research Group, Royal Prince Alfred Hospital, Camperdown, NSW, Australia.*

Background: Heymann Nephritis (HN) is an experimental rat model of human membranous nephropathy (MN), a common cause of chronic kidney disease (CKD) in adults. CD40 and its ligand CD154 are critical costimulatory molecules required for T cell activation and B cell differentiation, which make them important therapeutic targets for treating CKD. Studies have shown the benefits of targeting antigen to DC using single-chain Fv antibody directed at DEC205. Here we utilized this approach in generating the DNA vaccine targeting CD40 to DC and compared the efficacy of CD40 DNA vaccine enhanced by DC targeting (DEC-CD40) to that without DC targeting (con-CD40).

Methods: Lewis rats were immunized twice with either DEC-CD40 or con-CD40 (3 weeks apart with 300mg/rat/injection) via intramuscular injection with electroporation two weeks before the induction of HN via immunization of crude renal tubular antigen (Fx1A). Twelve weeks after HN induction, renal function and histology were assessed.

Results: DEC-CD40 induced a stronger immune response with higher levels of serum anti-CD40 autoantibody as compared to con-CD40. DEC-CD40 completely prevented proteinuria throughout the 12 week period. con-CD40 delayed the onset of proteinuria, demonstrating an effect though less potent than DEC-CD40. Renal structural injury was ameliorated by CD40 DNA vaccines with DEC-CD40-HN showing much less injury than con-CD40-HN. Immune cell infiltrations ($CD4^+$, $CD8^+$ and macrophage) and glomerular IgG deposition were reduced by DEC-CD40. The protective effects of CD40 vaccine were not associated with B cell depletion.

Conclusions: By targeting antigens to DCs, the efficacy of DNA vaccines can be greatly improved.

FR-PO872

EGFR and Src Are Essential for TLR3-Mediated Podocyte Injury Michifumi Yamashita, Saurabh Chattopadhyay, Volker Fensterl, Ganes C. Sen. *Molecular Genetics, Lerner Research Institute, Cleveland Clinic, Cleveland, OH.*

Background: Podocyte injury is a leading factor of many glomerular diseases, and leading to renal failure. We reported viral innate immunity, especially Toll-like receptor 3 (TLR3), disturbs podocyte cell function. TLR3 is a sensor for double-stranded (ds) RNA, a common byproduct of viral replication. Recently, we reported that TLR3 has five tyrosine (Tyr) residues in the cytoplasmic domain, and that Tyr759 and Tyr858, and those phosphorylations are essential for the signaling (Nat Struct Mol Biol. 2004). However, the detailed mechanisms: who phosphorylates Tyr residues and how it does, are not understood at all.

Methods: To identify the candidate protein kinases for TLR3 Tyr residues, various Tyr kinase inhibotors, shRNA knock-down cells, and knock-out cells were used. Co-immunoprecipitation was used to test the interactions between EGFR, Src, TRIF, and wild type- or various mutant TLR3. To test TLR3 phosphorylation, *in vitro* kinase assay and immunoprecipitation-based phospholylation assay were employed.

Results: Using various Tyr kinase inhibitors, knock-down cells, and knock-out cells, we identify Epidermal Growth Factor Receptor (EGFR/ErbB1) and Src as candidate kinases for TLR3 Tyr residues. EGFR and Src were physically interacted with TLR3 upon dsRNA stimulation. This interaction was independent of TLR3 Tyr residues, suggesting this event precedes TLR3 phosphorylation. Interestingly, TLR3-EGFR interaction did not require Src, while TLR3-Src interaction needed EGFR. Finally EGFR directly phosphorylated Tyr858, whereas Src phosphorylated Tyr759 in *in vitro* kinase assay. Furthermore, the phosphorylation of the two Tyr residues were essential for the recruitment of TRIF, the obligatory adaptor molecule, leading to the downstream signalings.

Conclusions: EGFR/ErbB1 and Src, bind sequentially to dsRNA-activated TLR3 and phosphorylated the two Tyr residues: EGFR phosphorylates Tyr858, Src phosphorylates Tyr759, a step essential for the recruitment of the obligatory adaptor protein, TRIF. EGFR and Src are essential for TLR3-mediated podocyte injury.

FR-PO873

The Calcineurin-NFAT Pathway Allows for Urokinase Receptor Mediated beta3 Integrin Signaling to Cause Podocyte Injury Wei Shi, Juan Ma, Bin Zhang. *Department of Nephrology, Guangdong General Hospital, Guangdong Academy of Medical Sciences, Guangzhou, Guangdong, China.*

Background: Clinically, calcineurin inhibitors (e.g., cyclosporine A, CsA) have been used to reduce proteinuria in focal segmental glomerulosclerosis (FSGS) or other proteinuric kidney diseases. A novel role for CsA has been reported in inhibiting the dephosphorylation of podocyte synaptopodin by calcineurin. It is possible, however, that the suppression of calcineurin-NFAT signaling in podocytes also plays a role in the antiproteinuric effect of CsA. *In vivo* conditional NFATc1 activation in podocytes can lead to podocyte injury and proteinuria in mice. Podocyte urokinase receptor (uPAR)-β3 integrin signaling axis is involved in podocyte injury, proteinuria and FSGS.

Methods: we used the 5/6 nephrectomy and LPS animal models in vivo and cultured podocytes in vitro.

Results: Here we show that calcineurin inhibition by CsA reduced podocyte uPAR expression and with that it suppressed β3 integrin activation in podocytes. This finding raises the possibility of a potential molecular link between calcineurin and uPAR-β3 integrin signaling in podocytes. Our results further show that, in LPS- or inomycin-induced NFAT activation podocyte model, podocyte uPAR expression and activated β3 integrin increased, but β3 integrin expression remained unchanged. In contrast, NFAT-siRNA reduced uPAR expression and inhibited β3 integrin activation but not its expression. Meanwhile, we show that CsA inhibited podocyte motility in a NFATc1-dependent manner. We also showed that NFAT inhibition using a cell-permeable NFAT inhibitor (11R-VIVIT) can reduce proteinuria and suppress podocyte uPAR expression and β3 integrin activation in LPS-induced proteinuric SCID mice that are devoid of T and B cells.

Conclusions: These findings suggest the involvement of uPAR-β3 integrin signaling in calcineurin/NFAT activation-induced podocyte injury.

The Generation of Inducible Podocyte Specific Human Phospholipase A_2-Receptor-1 Transgenic Mice Gunther Zahner,[1] Elion Hoxha,[1] Udo Helmchen,[2] Rolf A. Stahl.[1] *[1]III. Medizinische Klinik, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; [2]Nierenregister, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany.*

Background: The Phospholipase A_2 Receptor-1 (PLA_2R), which is in human kidneys exclusively expressed on glomerular podocytes, is the major antigen in 70% of patients with primary membranous nephropathy. In order to get more insight in the pathogenetic role of the PLA_2R and to be able to create a murine model of membranous nephropathy (MN), we generated transgenic mice which exclusively express the human PLA_2R on glomerular podocytes.

Methods: To achieve this goal the full length coding region of the human PLA_2 R was cloned into an expression vector carrying a tetracycline responsible promotor (pWTT1). After successfull expression in HEK 293 cells cotransfected with a Tet-Off vector (Clontech), mice expressing the human PLA_2R were generated by microinjection of the PLA_2R construct in pronuclei of single cell mouse embryos (PLA_2Rtg mice). These mice were cross bred with mice which express a tetracycline activator under the control of the podocin promotor (Podo-TA mice). The litters, PodoTA/PLA_2Rtg mice, were used for further studies.

Results: Feeding these mice with 2 mg/ml doxycycline in the drinking water for 14 days markedly induced the mRNA expression of the human PLA_2R in isolated glomeruli. When PLA_2R positive antisera from patients with primary MN were used as developing antibodies PLA_2R protein was detected by Western blotting only in isolated glomeruli from PodoTA/PLA_2Rtg mice following doxycycline.

Conclusions: Thus, doxycycline-inducible PodoTA/PLA_2Rtg mice may serve as a murine model of human membranous nephropathy and will eventually allow to get a better understanding of the role of PLA_2R in membranous nephropathy.

Membranous Nephropathy and Anti-PLA2R Antbody Induced by an Epitope in Nonmuscular Myosin Heavy Chain IIA (NMMHC-IIA) in Rabbits Suyan Duan,[1] Chang Ying Xing,[1] Peter W. Mathieson,[2] Moin Saleem.[2] *[1]Dept. of Nephrology, The First Affiliated Hospital of Nanjing Medical University, Nanjing, China; [2]Academic Renal Unit and Children's Renal Unit, University of Bristol, Bristol, United Kingdom.*

Background: Our previous study found the antibody against NMMHC-IIA, a podocyte protein, could be detected in a majority of patients with INM, indicating that is a major autoantigen in this disease. To study the immune activity of a synthetic epitope-peptide in NMMHC-IIA and its pathogenicity in rabbits.

Methods: This epitope-peptide were synthesized and coupled with keyhole limpet hemocyanin(KLH), which were used to immune male New Zealand rabbits to prepare epitope-specific antibody. Western blotting(WB) and co-immunoprecipitation(Co-IP) were performed with the total cell lysates and anti-peptide rabbit serum. The kidneys of rabbits were performed renal pathological examination by LM, IF and EM.

Results: Compared with the normal control group (saline-injected group), the epitope-peptide immunized rabbits could produce specific anti-peptide antibodies. The serum from the epitope-peptide immunized rabbits had antibody combined with a 227-kD protein by Co-IP, which was sequentially identified to be NMMHC-IIA by mass spectrometry. The same distribution of special protein in cultured human podocyte was visualized by rabbit serum and commercial anti-NMMHC-IIA antibody. The epitope-specific antibodies were reactive to the commercial NMMHC-IIA protein (Tagged-His Tag) by WB. At 8 week, the rabbit produced another antibody against PLA2R by WB under nonreducing condition. Furthermore, the immunostaining study of rabbit kidney tissues showed that the rabbit IgG was granular deposits along the GBM, while the renal pathological changes under the electron microscope were foot process fusion, irregular thickness of GBM and mesangial widening. The rabbits had proteinuria either.

Conclusions: The synthesized epitope-peptides in NMMHC-IIA as an antigen can induce rabbit to produce epitope-specific antibody against NMMHC-IIA, and another antibody against PLA2R, both podocyte proteins, and it can lead rabbit to resemble pathological change of human MN. It may be a good animal model of MN.

FR-PO876

Retinoic Acid-Inducible Gene-I and Melanoma Differentiation-Associated Protein 5 Are Induced by Polyinosinic-Polycytidylic Acid in Human Podocytes in Culture Michiko Shimada,[1] Yoshiko Shutto,[1] Ikuyo Narita,[1] Tadaatsu Imaizumi,[1] Moin Saleem,[2] Peter W. Mathieson,[2] Richard J. Johnson,[3] Hideaki Yamabe,[1] Ken Okumura.[1] *[1]Nephrology, Hirosaki University, Hirosaki, Japan; [2]University of Bristol; [3]University of Colorado.*

Background: Immunologic factors are implicated as a cause of proteinuira, since it sometimes occurs after or is exacerbated by virus or bacterial infection. In innate immunity, pathogens are recognized by various pattern recognition receptors (PRR). Among them, several toll-like receptors are proved to be expressed in podocytes and their activation induces phenotype changes of podocytes causing proteinuria. However, expression of other PRR such as retinoic acid-inducible gene-I (RIG-I) and melanoma differentiation-associated protein 5 (MDA5) have not been proved in podocytes. In this study, we examined the expressions of RIG-I and MDA5 in human podocytes stimulated with double stranded RNA, polyinosinic-polycytidylic acid (Poly-IC), mimicking viral infection.

Methods: Conditionally immortalized human podocytes were grown at 33°C then converted to differentiated cells by incubating at 37°C for 10 days. The differentiated cells were stimulated with poly-IC (2-500 ng/ml) for 6-30 hours. Total RNA was harvested and mRNA expression of RIG-I and MDA-5 were analyzed by quantitative RT-PCR. The cell lysates were analyzed by Western blotting.

Results: In the differentiated human podocytes, poly-IC dose-dependently increased the relative mRNA expressions of RIG-I and MDA5. 6-hour incubation of Poly-IC (500ng/ml) increased mRNA expressions of RIG-I (7.3±0.7 fold: $p<0.0001$) and MDA5 (16.5±0.7 fold: $p<0.0001$). Besides, mRNA expressions of RIG-I and MDA5 increased over time: 30 hours incubation with Poly-IC (500ng/ml) increased mRNA expression of RIG-I (13.1±1.5 fold, $p<0.001$) and MDA5 (20.3±1.4 fold, $p<0.001$). Similarly, Western blotting showed that expression of both RIG-I and MDA-5 were dramatically increased by poly-IC in a dose- and time-dependent fashion.

Conclusions: RIG-I and MDA5 are expressed in human podocytes and their expression was increased by poly-IC. Induction of these viral receptors may also contribute to podocyte changes in viral infections.

Calcium-Oxalate Crystals Induce Renal Inflammation and Acute Kidney Injury by Activating NLRP3 Inflammasome-Mediated Interleukin-1β Secretion in Renal Dendritic Cells Shrikant R. Mulay,[1] Onkar Kulkarni,[1] Khader Valli Rupanagudi,[1] A. Migliorini,[1] Murthy Darisipudi,[1] Helen Liapis,[2] Hans J. Anders.[1] *[1]Ludwig Maximillians University, Munich, Germany; [2]Washington University School of Medicine, MO.*

Background: Calcium oxalate (CaOx) crystal nephropathy cause intrarenal inflammation & tissue damage but the molecular mechanisms remain elusive. The aim of the study was to investigate whether CaOx crystals have the potential to activate IL-1β-dependent innate immunity via the NLRP3-ASC-caspase-1 axis in kidney, and how?

Methods: All mice were procured from Jackson Laboratories (Bar Habour, MA). All experimental procedures were approved by the local government authorities. Immunostaining and electron microscopy were used for analysing kidney pathology. Bone marrow derived dendritic cells (DC) & renal DC was generated by established protocols.

Results: We show that CaOx crystals activate renal DC to secrete IL-1β via NLRP3-ASC-caspase-1 axis. CaOx crystal phagocytosis and potassium efflux were essential for this. CaOx crystals killed tubular cells (TEC) in culture to release a NLRP3 agonist ATP; however ATP-degradation with apyrase did not abrogate IL-1β release by DC upon exposure to supernatants of TEC killed by CaOx crystals. In experimental oxalate nephropathy, CaOx localized to tubular lumen as well as inside tubular and interstitial cells as detected by Pizzolato staining, TEM, SEM, FFEM. Intrarenal crystal desposition induced severe tubular damage, cytokine expression, neutrophil recruitment, and renal dysfunction. These effects were abrogated upon DC-depletion or in mice deficient in MyD88, IL1-r1, NLRP3, ASC or caspase-1 despite a similar extent of CaOx crystal deposition. In addition, ATP depletion or therapeutic IL-1 antagonism had same effect.

Conclusions: CaOx crystals directly damage tubular epithelial cells. Inside renal DC they activate the NLRP3-ASC-caspase-1 axis to trigger IL-1β release. Subsequent IL-1R signaling sets off MyD88-dependent renal inflammation, neutrophil recruitment and accelerates tubular damage & renal dysfunction. Therapeutic blockade of IL-1 is protective in murine model and might potentially be protective in human crystal nephropathies.

FR-PO878

Indoleamine 2,3-Dioxygenase Inhibition and Kidney Gene Expression Following Ischemia-Reperfusion Injury Todd D. Merchen,[1] Erika I. Boesen,[1] Eiko Kitamura,[1] Rachel Harbarger,[1] Andrew L. Mellor,[1] James J. Wynn,[1] Robert Podolsky,[1] N. Stanley Nahman,[1,2] David M. Pollock.[1] *[1]Georgia Health Sciences University, Augusta, GA; [2]Charlie Norwood VAMC, Augusta, GA.*

Background: In kidney transplantation (KTx) ischemia reperfusion injury (IRI) is associated with delayed function and chronic injury. In rats with IRI, recovery was improved by inhibiting indoleamine 1, 2-dioxygenase (IDO) (JASN 22:817A). IDO also reduces rejection in rat renal allografts (J Gene Med 13:373). We have hypothesized that IDO-induction of pro-tolerant pathways in KTx may carry the paradoxical risk of slowing recovery from IRI. To define changes in genes modulated by IDO in IRI, we inhibited IDO in the face of IRI and assessed renal gene expression.

Methods: Male SD rats underwent IRI (30 mins of bilateral renal pedicle clamping, followed by 1 hr of recovery (N=4)) or sham surgery (N=4). IDO was blocked with 140 mg/kg of oral 1-methyl-D-tryptophan (1MT). 1MT treated were subjected to IRI (N=4) or sham surgery (N=4). Following IRI recovery, the kidneys were taken, the cortex isolated, and total RNA hybridized to the GeneChip®Rat Gene 1.0 ST Array (Affymetrix).

Results: IRI vs sham: significant changes in 102 transcripts (2.00 – 45.51 (range of fold change)), dominated by genes coding for cell death and proliferation. 1MT without IRI vs sham: significant changes ($p<0.002$) in 32 transcripts (1.04 – 1.4) with immune cell trafficking molecules predominating. Pretreating with 1MT followed by IRI: significant change ($p<0.001$) in 54 genes (1.07 – 2.63), with cell death and proliferation predominating, without evident change in immune cell trafficking molecules. These data indicate substantial alterations in gene expression following IRI or 1MT therapy. IDO inhibition with 1MT prior to IRI induced changes in cell death and proliferation genes.

Conclusions: Inhibition of IDO with 1MT alters immune cell trafficking molecules in the absence of IRI. In the face of IRI, IDO inhibition results in predominant changes in cell death, growth and proliferation transcripts. We would theorize that IDO inhibition with 1MT improves renal recovery from IRI by altering expression of genes associated with death and/or cellular proliferation.

FR-PO879

Renal Tubular Cells (RTCs) from Hibernating Squirrels Are Protected against Apoptosis Swati Jain, Charles L. Edelstein, Alkesh Jani. *Univ of CO Denver, CO.*

Background: Donor kidney cold (4°C) ischemia (CI) of >24 hrs is an important cause of DGF. The 13-lined ground squirrel (GS) is a hibernating mammal that undergoes winter hibernation, when its core body temperature falls to 4°C for 6-18 days. Since hibernation is a normal part of the GS life-cycle, we hypothesized that RTCs from hibernating GS are protected from apoptosis due to CI.

Methods: Kidneys of C57BL6 mice and hibernating GSs were exposed to CI in UW solution for 72 hrs. Apoptotic RTCs were scored by a pathologist. Immunoblots were performed for caspase-3, XIAP (an inhibitor of caspase-3 and apoptosis) and phosphoAKT (pAKT) which converts BAD to pro-survival factor phosphoBAD (pBAD).

Results: RTC apoptosis and caspase-3 activity were significantly increased in mouse vs. GS kidneys. XIAP, pAKT and pBAD were significantly increased in hibernating GS kidneys, but were undetectable in mouse kidneys.

Table 1

Stage	Caspase-3 activity (nmol/min/mg)	Apoptosis (cells/hpf)	pAkt protein	pBAD protein	XIAP protein
GS (0 hr CI)	6.5	0.1	+++	+++	+++
GS (72 hr CI)	13.6	0	+++	+++	+++
Mouse (0 hr CI)	0	0	ND	ND	ND
Mouse (72 hr CI)	800*	1*	ND	ND	ND

n = 3; * $p<0.05$ vs mouse and 0 hr ; ND = not detected

To determine the mechanism of resistance of GS RTC to apoptosis, GS and mouse RTCs were treated with cisplatin (50uM), an agent known to cause apoptosis. Cisplatin treated GS RTC had significantly less apoptosis, no active caspase-3, increased XIAP, pAkt and pBAD vs. mouse RTC. (Table 2)

	Mouse RTE	Mouse RTE + 50uM cisplatin	Squirrel RTE	Squirrel RTE + 50uM cisplatin
Apoptosis (TUNEL + cells/hpf)	3.4%±0.88	24.6%±2.5*	0.5%±0.28	1.32 %±0.32**
Caspase-3 protein	+	+++	ND	ND
XIAP protein	+++	+	++	++++
pAkt protein	+++	+	++	+++
pBAD protein	++	+	++	++++

n = 3; * p <0.05 vs mouse RTE. ** p < 0.0001 vs mouse RTE + 50uM cisplatin; ND = not detected

Wortmannin inhibition of pAKT reduced pBAD, and increased caspase-3 in GS RTC demonstrating the importance of Akt signaling in GS RTC survival.

Conclusions: We have shown for the first time that GS RTCs are protected against apoptosis induced by CI and cisplatin, associated with upregulation of pro-survival factors XIAP, pAKT and pBAD. Inhibition of pAKT in GS RTC results in reduced anti-apoptotic pBAD and increased pro-apoptotic caspase-3 expression.

Increased Autophagic Flux, Caspase-3 and Apoptosis in Renal Tubular Epithelial Cells Undergoing Warm Reperfusion (WR) after Cold Ischemia (CI)

Swati Jain, Charles L. Edelstein, Alkesh Jani. *Univ of CO Denver, CO.*

Background: Delayed graft function (DGF) is primarily caused by cold ischemia (CI) and warm reperfusion (WR). The mechanism by which CI/WR cause cell renal tubular epithelial (RTE) cell death is not known. Autophagy is a cell-survival strategy employed by cells during stresses such as ischemia and reperfusion. The relationship between apoptosis and autophagy during CI/WR of donor kidneys is not known. We hypothesized of increased autophagic flux and apoptosis during CI/WR of RTE cells.

Methods: Renal tubular epithelial cells (LLC-PK1 cells) were subjected to CI in University of Wisconsin (UW) solution at 4°C for 24h. To simulate rewarming UW solution was replaced with DMEM containing bovine serum at 37°C for 24h. LLCPK cells incubated at 37°C served as controls. Immunoblot and densitometry were used to assess active caspase-3 (17kDa), caspase-1 (45kDa) and LC3–II (14kDa) (autopahgic flux). Autophagic flux is measured by comparing the amount of LC3-II with and without Bafilomycin, a lysosomal inhibitor. Cells were treated with Bafilomycin (150nM) one hour before CI.

Results: During CI, Caspase-1 is not increased but apoptosis and active caspase 3 were significantly increased vs. controls.

table1

	Control	CI	CI + Baf	WR	WR + Baf
TUNEL	2.4%±0.83	24.6%±4.7*	36%±2.1	7.4%±1.4	42.9%±5.4**
Caspase-3	++	+++	++++	+	+++++
Caspase-1	+	+	+	++++	++++
LC3-II	+	+	+	+++	++++

n = 3; * p <0.05 vs control, **p<0.001vs control and WR

Treatment with Bafilomycin did not change LC-3 II protein during CI vs. controls, indicating that CI did not increase autophagic flux. In contrast, during WR, apoptosis and caspase-3 did not increase whereas caspase-1 was increased vs. controls. Treatment with Bafilomycin resulted in significantly more apoptosis and LC-3II expression indicating an increase in autophagic flux during WR.

Conclusions: Caspase-3 and apoptosis are increased during CI. Autophagic flux is increased during WR. Caspase-1 (a proinflammatory marker) is increased in WR vs. CI. Lysosomal inhibition with Bafilomycin, increases caspase-3 and apoptosis during both CI and WR. Further study of relationship between apoptosis and autophagy during CI and WR is merited.

Funding: NIDDK Support

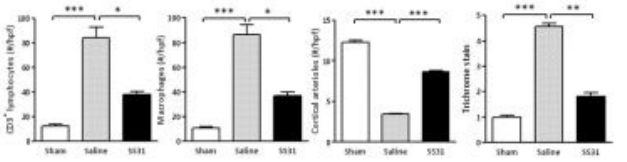
Mitochondria-Targeting Peptide (SS-31, Bendavia®) Prevents Microvascular Rarefaction, Inflammation, and Fibrosis Caused by Ischemia-Reperfusion Injury

Hazel H. Szeto,[1] Shaoyi Liu,[1] Yi Soong,[1] Surya V. Seshan.[1] *[1]Pharmacology, Weill Cornell Medical College, New York, NY; [2]Pathology, Weill Cornell Medical College, New York, NY.*

Background: Interstitial fibrosis and tubular atrophy is the primary cause of chronic graft dysfunction resulting in end-stage renal disease. Ischemia-reperfusion (IR) injury during renal transplantation leads to acute kidney injury, oxidative stress, inflammation, microvascular rarefaction, and interstitial fibrosis. SS-31 is a mitochondria-targeting tetrapeptide that has been shown to accelerate ATP recovery, reduce oxidative stress, and minimize ischemic kidney injury (Szeto et al., JASN 22:1041-1052, 2011). Here we examined the effects of SS-31 on microvascular rarefaction, inflammation, and fibrosis after acute IR injury.

Methods: Sprague-Dawley ratswere assigned to sham, IR+saline and IR+SS-31 (n=4-6). Rats were subjected to bilateral renal ischemia for 45 min followed by 4 weeks reperfusion. SS-31 (2.0 mg/kg, sc) was administered 30 min before ischemia and immediately before reperfusion. Renal function was determined on day 28, and kidneys were harvested for histopathology. Results are expressed as mean ± SEM.

Results: 45 min ischemia resulted in apoptosis and necrosis of proximal tubular epithelial cells, and damage to the microvasculature. This was followed by significant interstitial fibrosis (trichrome, aSMA, FSP), inflammation (CD3, CD68), and loss of microvasculature (aSMA, CD31) observed after 28 days reperfusion. Treatment with SS-31 significantly reduced inflammation, microvascular rarefaction, and interstitial fibrosis.



Conclusions: These results indicate that protection of mitochondrial function during IR injury prevents long-term changes in renal microvasculature and prevents inflammation and fibrosis. SS-31 (Bendavia®) is a promising drug candidate for renal transplantation.

Angiopoietin-1 Administration in a Brain Death Rat Model

Welmoet H. Westendorp,[1] Susanne Veldhuis,[1] Harry Van Goor,[2] Rutger J. Ploeg,[3] Henri G.D. Leuvenink.[1] *[1]Surgery, University Medical Center Groningen, Groningen, Netherlands; [2]Pathology, University Medical Center Groningen, Groningen, Netherlands; [3]Nuffield Department of Surgical Sciences, University of Oxford, Oxford, United Kingdom.*

Background: Kidneys derived from deceased brain dead (DBD) donors have inferior outcomes after transplantation compared to kidneys from living donors. Also, DBD donors suffer from bacterial translocation and endotoxemia. A link between Angiopoietin 1 (Ang1), Angiopoietin 2 (Ang2) and endotoxemia has been established. Ang1 and Ang2 are antagonictic ligands that bind to the Tie2 receptor. We aimed to modify the Ang1 levels in our brain death rat model to clarify whether exogenous administration of Ang1 has a protective role and may be of therapeutical value to improve outcome after DBD transplantation.

Methods: We administrated 0,1µg/kg Ang1 or 0,9% saline 30 min before brain death (BD) induction. BD was induced by inflating a subdurally placed balloon catheter in rats. Two groups of sham operated animals were injected with either Ang1 or 0,9% saline (n = 7 for all groups). The animals were monitored for 4 hrs. Just before sacrificing the animals blood was collected and kidneys were harvested for histology and PCR.

Results: Plasma levels of ALT, AST, creatinine, LDH and urea increased in the BD groups compared to sham operated groups ($p<0.05$). The 2fold induction of E-selectin, P-selectin, VCAM-1, ICAM-1, IL-6, KIM-1 and HO-1 in the kidney is elevated in the BD groups compared to the sham operated groups ($p<0.05$). The renal TNF-α fold induction of the BD+Ang1 group is increased compared to both sham groups ($p<0.05$). Tie2 fold induction in the kidney is not influenced by Ang1 administration and decreased significantly in the BD groups (mean fold induction 0.45 BD+saline and 0.38 BD+Ang1) compared to the sham groups (mean fold induction 2.5 sham+saline and 2.6 sham+Ang1).

Conclusions: Functional and inflammatory markers were increased in the BD groups and not affected by this dosage of Ang1. These results show a remarkable effect of brain death on Tie2 fold induction. This reduction suggests a functional role for Tie2 in BD which could not be compensated by administrating Ang1.

FR-PO883

Identification of MicroRNAs Associated with Delayed Graft Function(DGF) in Deceased Donor Kidney Allografts

Mita M. Shah,[1] Kristin Mekeel,[1] James B. Tee.[2] *[1]UC San Diego; [2]University of Calgary.*

Background: DGF following kidney transplantation impacts immediate and long-term graft function. The molecular mechanisms that contribute to DGF remain poorly uncerstood. MicroRNAs (miRNAs) act to reduce the expression of their target genes, and their expression has been implicated in a variety of processes that affect allograft function. The role of miRNAs in controlling the genetic processes that predispose to DGF in kidney allografts is unknown.

Methods: Kidney tissue from 10 individual allografts were obtained prior to implantation. Total RNA from each specimen was concurrently evaluated by microarray for whole-transcript mRNA and miRNA expression. Samples from transplants were compared based on the presence (n=5) or absence of DGF (n=5) post-transplant. Differentially expressed genes and miRNAs were narrowed down to those satisfying 1-way ANOVA and a >=2-fold (for mRNA) or >= 1.5-fold (for miRNA) change in expression. Hierarchical clustering of both significantly expressed genes and miRNAs was observed for DGF and matching donors. Predicted target mRNAs were generated for each miRNA using two algorithms (MicroCosm and TargetScan) and correlated with this subset of differentially expressed genes.

Results: Nine upregulated miRNAs paired with 8 target genes and 12 downregulated miRNAs matching 29 target genes were identified in the presence of DGF.

Differentially regulated miRNA

miRNA	Target Gene	r value*
Upregulated miRNA		
miR-885-3p	PPP1R16B	-0.89
miR-663b	RHOBTB1	-0.74
miR-885-5p	RHOBTB1	-0.74
miR-498	COL1A1	-0.59
miR-122	SLC25A34	-0.46
Downregulated miRNA		
miR-509-3-5p	DCLK1	-0.77
miR-146b-5p	SLC2A14	-0.73
miR-510	IRF1	-0.71
miR-509-3p	EGR1	-0.71
miR-506	BTG2	-0.51

*pearson correlation coefficient

Many of the top correlated miRNA-target gene pairings are implicated in cell-cycle regulation, an important process during recovery from ischemia-reperfusion injury.

Conclusions: This report identifies a number of dynamically regulated miRNAs in kidney allografts that suffer DGF. Further investigation will help to elucidate the molecular mechanisms that underlie DGF as well as potentially identify novel biomarkers to predict allografts at risk for DGF and therapeutic targets to ameliorate the risk of DGF.

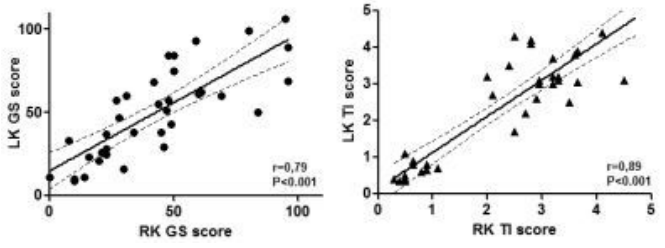
FR-PO884

Systemic Predictors of Single Kidney Function and Injury in a Bilateral Ablation Model of CKD in the Rat Diana A. Papazova, Marianne Christina Verhaar, Arianne van Koppen, Maarten P. Koeners, Jaap A. Joles. *Nephrology & Hypertension, UMC Utrecht, Utrecht, Netherlands.*

Background: Renal transplantation from expanded–criteria donors (ECD) increases mortality and graft failure [Molnar. AJKD 2012]. Organ shortage demands fundamental research on ECD including accurate predictors of function and injury prior to experimental transplantation. However, traditional models of chronic kidney disease always include uninephrectomy. Avoiding uninephrectomy in ablation models would allow prediction of function and injury at the time-point of experimental transplantation. To establish an ECD model we examined systemic predictors of single kidney function and injury as well as symmetry of injury in a novel bilateral ablation (BA) model in the rat.

Methods: Male Lewis rats underwent 2/3 ablation of each kidney in a one-step procedure (BA, n=20), controls underwent bilateral sham surgery (CON, n=16) and systolic BP, urea and proteinuria were measured regularly. A terminal measurement, performed when proteinuria exceeded 100mg/24h in BA rats, included split-urine collection for single kidney function (GFR: inulin and ERPF: PAH) in left and right kidney (LK and RK). Glomerulosclerosis (GS) and tubulo-interstitial injury (TI) were scored. CON rats were age-matched.

Results: Proteinuria, in comparison to BP and urea, was the best predictor for GFR, RPF, TI and GS(r=-0.72; r=-0.63, r=0.81 and r=0.82 respectively, all P<0.001). Symmetry: LK-GS and LK-TI correlated strongly with RK-GS and RK-TI (r=0.79, P<0.001, r=0.89, P<0.001) respectively.



Conclusions: In this model of BA, the best systemic predictor for function and injury was proteinuria. Injury (GS and TI) was symmetrical. These findings firmly position this new bilateral ablation model in the field of ECD transplantation.

FR-PO885

Epithelial (EMT) and Endothelial (EndMT) to Mesenchymal Transition in Renal Transplant Recipients with Antibody-Mediated Allograft Rejection (R) G. Castellano,[1] Antonia Loverre,[1] C. Divella,[1] Claudia Curci,[1] Alessandra Stasi,[1] Anna Zito,[1] Loreto Gesualdo,[1] Giuseppe Grandaliano.[2] *[1]Nephrology Unit, DETO, University of Bari, Italy; [2]Nephrology Unit, Dept of Medical and Surgical Sciences, University of Foggia, Italy.*

Background: Antibody-mediated graft R is one of the main causes leading to chronic kidney graft damage and loss. EMT and EndMT processes contribute to the progression of chronic allograft damage.The aim of our study was to investigate the role of IL-17 and Complement (C) in the induction of EMT and EndMT in acute (AHR) and chronic (CHR) humoral R.

Methods: IL-17, E-cadherin, CD31 and FSP1 protein expression were investigated by confocal microscopy in graft biopsies with acute T-cell-mediated rejection (ATMR, n=10), chronic T-cell-mediated rejection (CTMR, n=10), AHR (n=10), CHR (n=10) and in cultured tubular and endothelial cells.

Results: Both CHR and AHR were characterized by a significant increase in tubular IL-17 protein expression (CHR .12±.04, AHR 11.6±4.9 IL-17$^+$pixel/total area) compared to CTMR (.03±.008; p=.004 vs CHR) and ATMR (1.0±.3; p<.0001 vs AHR). Interestingly, CHR and AHR were characterized by a significant increase of tubular E-cadherin$^+$/FSP1$^+$ cells (CHR 15.3±1.5, ABMR 5.9±2.1) compared to CTMR (5.2±1.2, p=.001 vs CHR) and ATMR (2.0±.4, p=.02 vs AHR), suggesting the presence of EMT. Moreover, CHR and AHR showed a significant increase of CD31$^+$/FSP1$^+$cells (CHR 53.4±7.5, AHR 77.6±16.2) compared to CTMR (26.8±6, p=.004 vs CHR) and ATMR (14.7±5.2, p=.004 vs AHR) in peritubular capillaries, suggesting the occurrence of EndMT. Interestingly, the number of FSP1$^+$cells correlated with IL17 expression in both AHR and CHR (R^2 =.41, p<.05).

Finally, we observed a significant increase of FSP1$^+$ cells both in EpC (basal 2.34±.6; IL-17+C3a 7.5±2.4, p<.04) and in EndC (basal:3.06±.2; C3a:3.50±.23; IL-17 4.45±1.15; IL-17+C3a: 6.03±2.5)(p<.05 IL-17+C3a vs basal)stimulated for 24 hours.

Conclusions: In conclusion, our data suggest a synergistic role of IL-17 and Complement in the induction of EMT and EndMT in CHR and AHR. The ttherapeutic inhibition of these systems may be essential to prevent the progression of renal fibrosis in transplanted kidney.

FR-PO886

Endothelial Cell Proliferation Augments Endothelial-to-Mesenchymal Transition in the Presence of Inflammation and Hypoxia Craig Bryan Woda,[1,2] Sarah Bruneau,[1,2] David M. Briscoe.[1,2] *[1]Division of Nephrology, Children's Hospital Boston, Boston, MA; [2]Department of Pediatrics, Harvard Medical School, Boston, MA.*

Background: Cellular and humoral allograft rejection is associated with microvascular endothelial cell (EC) proliferation (identified by Ki67 staining) within renal biopsies. EC proliferation has also been reported to precede chronic allograft rejection. We hypothesize that proliferating EC de-differentiate into fibroblasts in the presence of local cytokines and/or hypoxia, and thus endothelial-to-mesenchymal transition (EndMT) drives chronic allograft fibrosis.

Methods: We treated human umbilical vein endothelial cells (HUVEC), that had undergone <20, 40-60, 80-100 or >120 cellular divisions, with TGFβ1 (10 ng/ml) or TGFβ2 (2.5 ng/ml) for 7-10 days. EndMT was evaluated by FACS (CD31 and N-cadherin co-expression) and confirmed by qPCR (N-cadherin, αSMA, and Snail).

Results: Contrary to publications using commercial EC lines, neither TGFβ1 nor TGFβ2 alone induced significant EndMT in primary cultures of HUVEC, and overall, we found EndMT to be a rare event (<5% cells, P=NS vs. untreated cells, n=3-6 per group). However, EndMT by both FACS and qPCR increased significantly in EC that had undergone >80 cellular divisions when treated with TNFα (100U/ml), in combination with TGFβ1 or TGFβ2. Interestingly, 70% of EC that underwent >120 divisions developed EndMT following treatment with TGFβ2 + TNFα (P<0.01, n=4) as compared to ~25% of EC treated with TGFβ1 + TNFα (p<0.05, n=5). Finally, to evaluate the role of hypoxia on inflammatory EndMT, EC were exposed to 10% pO2 for 7-10 days. We found that hypoxia alone induced EndMT in only 10% of cells as compared to ~3% of EC in normoxia (p<0.03, n=6), but again EndMT was significantly induced in proliferating EC with >120 doublings (~35%, P<0.02, n=6) following activation with TGFβ1 + TNFα.

Conclusions: Collectively, these findings indicate that intragraft inflammatory conditions known to be associated with rejection induce EndMT selectively in proliferating EC. Monitoring EC proliferation/doubling within grafts may identify risk for the development of chronic rejection.

FGF-23: A Novel Role in Transplant Vasculopathy and Chronic Antibody Mediated Rejection Eileen W. Tsai,[1] Yiping Jin,[2] Isidro B. Salusky,[1] Katherine Wesseling-Perry,[1] Robert B. Ettenger,[1] Elaine F. Reed.[2] *[1]Pediatric Nephrology, UCLA, Los Angeles, CA; [2]Pathology and Laboratory Medicine, UCLA, Los Angeles, CA.*

Background: Fibroblast growth factor 23 (FGF-23) has been associated with allograft rejection, CKD progression, and poor graft survival in pediatric and adult renal transplant recipients. FGF-23 binds to the FGF receptor, which is also up-regulated by HLA class I antibodies (Abs) in the endothelium. Therefore, we aimed to determine whether FGF-23 induced endothelial cell (EC) signal transduction and proliferation, contributing to transplant vasculopathy.

Methods: Primary human aortic EC, passages 2-8, were treated with varying concentrations of FGF-23 (1-100 ng/ml) and basic fibroblast growth factor (bFGF, 1-10ng/ml). Phosphorylation of mTOR Ser2448, S6 kinase Thr389, S6 Ribosomal Protein (S6RP) Ser235/236, Akt Ser473, 4E-BP1 Thr37/46 and ERK Thr202/Tyr204 was measured by Western blot. EC were stimulated with either FGF-23 or bFGF alone or in combination with the murine anti-Class I HLA mAb W6/32 (1ug/ml) directed against a monomorphic epitope on all HLA class I molecules. EC proliferation was assessed by flow cytometry using CSFE labeling.

Results: FGF-23, similar to bFGF, stimulated a 60% increase in mTOR phosphorylation when compared to untreated EC (p<0.05). FGF-23 induced a 70% and 20% increase in S6 kinase and S6RP phosphorylation, which are downstream targets of mTOR responsible for EC proliferation (p<0.05). FGF-23 stimulated a 60% increase in Akt Ser473 phosphorylation, an essential regulator of survival proteins Bcl-2 and Bcl-xL (p<0.05) and a 35% increase in ERK phosphorylation, a known mediator of cell proliferation (p<0.05). Additionally FGF-23 induced a 30% increase in EC proliferation compared to untreated EC (p<0.05) which was significantly augmented to 80% by the addition of HLA class I Ab (p<0.05).

Conclusions: FGF-23 induction of PI3K/Akt, mTOR and MAPK/ERK pathways may play an important and novel role in EC proliferation, which is augmented by HLA class I Ab. Thus, together they can be synergistic in promoting antibody-mediated rejection and development of transplant vasculopathy, leading to poor transplant outcomes.

FR-PO888

Non-Anticoagulant Heparinoid Reduces Inflammation in Experimental Renal Transplant Dysfunction Saritha Adepu,[1] Kirankumar Katta,[1] Ditmer Talsma,[1] Pramod Kumar Agarwal,[1] Saleh Yazdani,[1] Annamaria Naggi,[3] Giangiacomo Torri,[3] Jan-luuk Hillebrands,[2] Jacob van den Born.[1] *[1]Nephrology, UMCG, University of Groningen, Netherlands; [2]Pathology & Med. Biology, UMCG; [3]G. Ronzoni" Institute for Chemical and Biochemical Research.*

Background: Renal chronic transplant dysfunction (CTD) is a major cause of long-term renal allograft failure. The pathogenesis of CTD is multifactorial but essentially involves tissue remodeling partly related to inflammation. To date, immunosuppressive therapies are ineffective in attenuating renal CTD. Endogenous heparan sulfate proteoglycans maintain tissue homeostasis by modulation of inflammation by their heparan sulfate polysaccharide side chains. We hypothesized that intervention with heparan sulfate-like glycomimetics limits CTD, knowing their involvement in inflammation.

Methods: To test this hypothesis a rat model of renal CTD was used. Rats were treated subcutaneously daily with 2 mg/kg of unfractionated heparin (n=4) or with the non-anticoagulant heparinoids N-acetyl heparin (n=5) or periodate-oxidized, borohydrate-reduced heparin (RO-heparin; n=7) for 9 weeks. Saline-treated rats served as control (vehicle group; n=7). Immunostaining was performed to quantify inflammation. Neointima formation was quantified on Verhoeff stained sections. Blood pressure was measured and biochemical analyses were done in 24h-urine and in plasma.

Results: Compared to the vehicle group, RO-heparin-treated rats had >2-fold lower cortical tubulo-interstitial accumulation of CD45+ leukocytes ($p<0.02$) and >2-fold reduced proteinuria 9 weeks after transplantation (NS). Regular heparin increased neointima formation in arteries <200 µm (week 9: heparin vs vehicle group; $p=0.006$), whereas both non-anticoagulant heparinoids did not enhance neointima formation. Heparin(oid) treatment did not affect body weight, graft survival, blood pressure, and renal function, neither reduced glomerular and interstitial tissue remodeling.

Conclusions: These data demonstrate beneficial effects of non-anticoagulant heparinoids in experimental CTD. We suggest to investigate selected non-anticoagulant glycomimetics as potential adjunct therapy to attenuate CTD.

FR-PO889

Systematic Histological Analysis of Thrombotic Microangiopathy in a Porcine Xeno-Kidney Transplant-Model Jan U. Becker,[1] Wolf Ramackers,[2] Juliane Wittig,[1] Putri Andina Agustian,[1,3] Maximilian Ernst Daemmrich,[1] Clemens L. Bockmeyer.[1] *[1]Institute of Pathology, Hannover Medical School, Hannover, Germany; [2]Clinic for General, Visceral- and Transplant Surgery, Hannover Medical School, Hannover, Germany; [3]Clinic for Nephrology and Hypertension, Hannover Medical School, Hannover, Germany.*

Background: Despite a variety of pharmacologic and transgenic interventions thrombotic microangiopathy (TMA) is still a big challenge in porcine to human xenotransplantion. A detailed molecular analysis of histological patterns in xenokidneytransplant-models is necessary for a targeted anticoagulant therapy.

Methods: Porcine kidneys were perfused with human and porcine (control) whole blood (each n=4). The histological alterations as well as the function of these kidneys were analysed in different intervention groups (each n=4). Microthrombi positive for fibrin (Fib+MT) and platelets (CD61+MT) were defined as lumen occlusion of more than 50% with fibrin and platelets. 100 glomeruli per sample were analyzed for thrombi count as well as PAI-1, tPA, KLF4 mRNA and miRNA-143 expression.

Results: In total CD61+MT were more frequently observed than Fib+MT. Glomerular CD61+MT were increased in xenotransplants with and without intervention compared to controls. Only aPC was able to significantly diminish glomerular CD61+MT in xenotransplants. There was a significant positive correlation of glomerular and preglomerular CD61+MT as well as of glomerular PAI-1 and tPA mRNA expression. There were no differences in glomerular PAI-1, tPA, KLF4 mRNA expression between xenotransplants and controls and no correlation of these mRNA transcripts with thrombus deposition. However there was an elevated expression of miRNA-143 in xenotransplants with and without intervention.

Conclusions: Microthrombi in xenotransplants seem to be composed predominantly of platelets. aPC seems to be the most effective antithrombotic intervention. There seems to be a sufficient mRNA expression of the protective KLF4 and fibrinolytic tPA in contrast to our recent human data. miRNA-143 seems to have no effect on mRNA expression of KLF4 in this model. Therefore this xenotransplant model seems to be different from human acute humoral rejection associated TMA.

FR-PO890

Glomerular microRNA Expression Profiles in Transplant Associated Thrombotic Microangiopathy Jan U. Becker,[1] Juliane Wittig,[1] Maximilian Ernst Daemmrich,[1] Putri Andina Agustian,[1,2] Clemens L. Bockmeyer.[1] *[1]Institute of Pathology, Hannover Medical School, Hannover, Germany; [2]Clinic for Nephrology and Hypertension, Hannover Medical School, Hannover, Germany.*

Background: Thrombotic microangiopathy (TMA) in renal transplants occurs in CNI-toxicity (CNI-TMA) and acute humoral rejection (AHR-TMA). microRNAs regulate the expression and transcription of mRNA transcripts. So far nothing is known about the compartment-specific microRNA dysregulation in the glomerular capillary bed in CNI-TMA and AHR-TMA. We hypothesized (i) that transplant biopsies with CNI-TMA, AHR-TMA and without TMA (each n=5) display different microRNA profiles and (ii) that there is an association of differentially expressed microRNAs with pro- and antithrombotic mRNA transcripts that could explain microthrombosis.

Methods: The expression of 675 microRNAs and selected pro- and antithrombotic mRNA transcripts was assessed in microdissected glomeruli from transplant biopsies by real time PCR.

Results: From 88 microRNAs expressed in all samples only miR-195, miR-222 and miR-532-3p were differentially expressed. miR-195 was significantly up-regulated in CNI-TMA compared to AHR-TMA. miR-222 and miR-532-3p were up-regulated in all TMA samples as well as in CNI-TMA compared to controls. miR-532-3p was also up-regulated in AHR-TMA compared to controls. miR-532-3p was correlated positively with CD59, CD73 and PAI-1 and negatively with fibrinogen, tPA and ADAMTS13. miR-222 correlated positively with PAI-1 and negatively with KLF-2.

Conclusions: microRNAs may play a role in the regulation of the altered expression levels of pro- and antithrombotic mRNA transcripts in CNI-TMA and AHR-TMA. In particular miR-222 and miR-532-3p could lead to impaired fibrinolytic activity in the glomerular capillary bed, directly via up-regulation of PAI-1 and/or down-regulation of tPA as well as indirectly via the transcription factor KLF2. This potentially novel pathomechanism should be studied in vitro and in vivo.

FR-PO891

The Metabolic Reprogramming in a Kidney as a Consequence of CypD Ablation Jelena Klawitter, Alexander T. Pennington, Jacek Klepacki, Jost Klawitter, Joshua M. Thurman, Uwe Christians. *University of Colorado Denver, Aurora, CO.*

Background: Cyclophilin D (CypD, encoded by *Ppif*) modulates the opening of the MPTP. The immunosuppressant CsA inhibits CypD, leading to desensitization of MPTP opening, Ca^{2+} overload and ROS stimulation. In this study we aimed to investigate (A) the role CypD ablation has on the kidney metabolism and (B) the role CypD plays in CsA-induced nephrotoxicity.

Methods: *Ppif-/-* and *Ppif* +/+ wild type (WT) male mice were treated with either CsA (25 mg/kg/day) or vehicle (skim milk) from 8-12 weeks of age. Following perchloric acid extraction, water-soluble kidney tissue fractions (n=5-7) were used for mass spectrometry-based measurement of mitochondrial nucleotide loads and Krebs cycle intermediates.

Results: (A) The concentrations of Krebs cycle intermediates citrate and succinate were significantly higher in kidneys and urine of *Ppif-/-* as compared to WT mice. The consequence of this metabolic reprogramming towards mitochondrial energy production was a significantly higher energy charge in *Ppif-/-* as compared to WT mice kidneys.

(B) After treatment with CsA, no significant changes in the Krebs cycle metabolites within the kidney of either knockout or WT mice were observed. Their urinary concentration was however significantly reduced in *Ppif-/-* mice. This suggested that *Ppif-/-* mice try to retain the Krebs cycle intermediates inside the kidney in order to cope with the declining ATP production. And while the kidney energy charge significantly decreased and plasma creatinine significantly increased in *Ppif-/-* mice, both remained stable in WT mice. It is interesting to note that the described metabolic changes occurred before any histological changes in the kidney became detectable.

Conclusions: Our data suggest that CypD knockout and dysfunction in the MPTP opening, as a coping mechanism, increases the energy demand of the kidney. This in turn activates kidney's mitochondrial energy production pathways. The observation that this metabolic reprogramming makes the kidney more vulnerable to the negative effects of CsA suggests that there is an alternative pathway, independent of CypD, by which CsA causes mitochondrial dysfunction.

FR-PO892

An Investigation of Calcineurin Inhibitor Toxicity and Cadherin Expression in Human Kidney Nileshkumar Shah,[1] Seema Jain,[1] Roel Goldschmeding,[2] Iain Macphee,[3] Mysore Keshavmurthy Phanish,[1] Mark Edward Dockrell.[1] *[1]SWT Institute for Renal Research, London, United Kingdom; [2]UMC, Utrecht, Netherlands; [3]St George's, University of London, United Kingdom.*

Background: Calcineurin inhibitors (CNI) are the mainstay of transplant immunosuppressive regimes although long term graft life remains limited due to their nephrotoxicity, the mechanism of which remains unclear. We investigated the effects of CNIs on human primary proximal tubule cells (PTEC) with respect to their effects on native cadherins, K & N. We also investigated the role of Cytochrome P450 (CYP) enzyme activity on calcineurin mediated nephrotoxicity.

Methods: Biopsy samples demonstrating Chronic Allograft Nephropathy (CAN) and controls, were probed for K & N cadherins. In experiments carried out on human PTEC,

cells were treated with vehicle, Cyclosporine, CsA 1μg/ml,Tacrolimus, FK 0.1μg/ml, TGFβ1 5ng/ml for 72hr. An ALK5 inhibitor was used to assess the role of TGFβ1 in CNI mediated effects. Secreted TGFβ1 was measured by BioPlex. Cells were treated with CYP enzyme inhibitor, Ketoconazole 10μM with or without CNI. Expression of cadherins and profibrotic proteins were measured.

Results: Biopsy tissue from patients with CAN revealed loss of K & N cadherin compared to healthy controls. Treatment with FK caused loss of K cadherin in human PTEC similar to treatment with TGFβ1. CsA and FK induced significant 4 and 3 fold increases in TGFβ1 secretion. CNI caused activation of Smads and P38 at 48 h. CNI caused a significant rise in pro-fibrotic proteins (Fn, MMP2 & CTGF). These effects were abrogated by inhibition of Alk5. There was no increase in N cadherin expression with CNI treatment. CYP3A expression and inhibition of its activity by Ketoconazole was observed in PTEC. Combination of Ketoconazole and CNI augmented loss of K cadherin. Ketoconazole alone caused loss of K cadherin without significant cell death.

Conclusions: Our results suggest that CNI induced nephrotoxicity is mediated by increased TGFβ1 production rather than activation of the latent form; lack of N cadherin rise suggests differential activation of TGFβ-mediated outcomes. In addition, ketoconazole augmented the effects of CNI but also directly damaged human PTEC.

The Effect of Calcineurin-Inhibition on the Renal Renin-Angiotensin System: New Place for Renin Excretion Agnes Prokai,[1] Nora Himer,[1] Katalin Kis-petik,[1] Janos Peti-Peterdi,[2] Attila Szabo.[1] *[1]Semmelweis University and Research Laboratory of Hungarian Academy of Sciences, Hungary; [2]University of Southern California.*

Background: Tacrolimus (Tac) and Cyclosporin A (CyA) are two potent immunosuppressants being essential therapeutic solutions for the prevention of allograft rejection, at the same time possessing nephrotoxic side effects. However, the underlying patomechanism how these drugs act as nephrotoxic agents are still not fully understood. In this study we investigated *in vivo* the effect of calcineurin-inhibitors (CNI) on the renal renin-angiotensin system (RAS).

Methods: Three week old, male C57B6 mice (n=15) were divided into three groups: controls (C) and mice treated with 0.075 mg/kg/day of Tac twice a day (Tac) or 2mg/kg/day of CyA (CyA). Following three weeks of administration serum creatinine was measured. The renin content in the collecting duct (CD) and juxtaglomerular apparatus (JGA) were evaluated applying FACS and multi-photon microscopy. The extent of vessel contraction was assessed and the consequent fibrosis was determined by Masson staining.

Results: The trough level of CNI was comparable to that used in clinical practice. Serum creatinine was significantly elevated in both Tac and CyA groups. Applying FACS analysis we demonstrated that both the JGA and CD renin content increased 4-fold following the administration of CNI. These data were further supported by *in vivo* multi-photon microscopy; renin granulation increased remarkably in both locations. As a result of local RAS activation vasoconstriction was present in both treated groups and as early as the third week of immunosuppression fibrotic islands developed.

Conclusions: In summary, our studies visually revealed that CNI possess nephrotoxic effect on the kidney parenchyma due to enhanced renin activity not only in the JGA but in the CD segment as well. Therefore, RAS inhibition could be beneficial by preventing the nephrotoxic effect of the CNI. However, further studies are needed to reveal what kind of inhibitors provide the most efficient treatment.

The Effect of Korean Red Ginseng on Chronic Cyclosporine-Induced Renal and Pancreatic Injury Kyoung Chan Doh,[1,2] Sun Woo Lim,[1,2] Shang Guo Piao,[1,2] Ohk Bun Jung,[4] Soo Kyung Bae,[4] Gyu Hyun Hwang,[5] Gyeong Il Min,[5] Byung Ha Chung,[1,2,3] Chul Woo Yang.[1,2,3] *[1]Convergent Research Consortium for Immunologic Disease, Catholic University of Korea, Seoul, Republic of Korea; [2]Transplant Research Center, The Catholic University of Korea, Seoul, Republic of Korea; [3]Division of Nephrology, Catholic University of Korea, Seoul, Republic of Korea; [4]College of Pharmacy, The Catholic University of Korea, Bucheon-si, Republic of Korea; [5]School of Medicine, Catholic University of Korea, Seoul, Republic of Korea.*

Background: The study was performed to investigate whether the Korean red ginseng (KRG) has protective effect in an experimental model of chronic CsA toxicity.

Methods: Mice were treated with CsA (30 mg/kg/day, s.c.) and KRG (0.5g or 1 g/kg/day, P.O.) under 0.01% salt diet for 4 weeks. Body weight, urine volume, and blood glucose level were measured before sacrifice. Blood level of CsA was evaluated using LC/MS/MS. Induction of renal fibrosis and islet mass were analyzed in tissue sections. Immunohistochemistry using F4/80 antibody was performed to detect macrophage infiltration. Oxidative stress was measured with urinary excretion and serum level of 8-hydroxy-2'-deoxyguanosine (8-OHdG).

Results: After 4 weeks, there were no differences in Δ body weight and urine volume. Blood glucose level of CsA treated mice was normalized concurrent with KRG 0.5 but not in KRG 1. Blood level of CsA does not differ with concurrent with KRG 0.5 but was significantly increased compared with CsA+KRG 1 group. KRG 0.5 treatment significantly decreased both of CsA-induced renal fibrosis and islet mass but not in KRG 1. Consistently, increased macrophage infiltration in kidney and islet in CsA group was markedly decreased in only CsA+KRG 0.5. 8-OHdG level detecting oxidative stress in urine and serum was also significantly decreased concurrent with KRG 0.5+CsA group compared with CsA, however, there was no difference in CsA+KRG 1.

Conclusions: From our results, we suggest that KRG have protective effect against CsA-induced renal and pancreatic injury through decreasing oxidative stress. However, high dose of KRG on CsA toxicity may aggravate CsA level in blood, and there is possibility synergistic organ toxicity.

Funding: Government Support - Non-U.S.

Gene Therapy with Indoleamine 2,3-Dioxygenase Inhibits Development of Chronic Transplant Dysfunction in Rat Diana Vavrincova-Yaghi,[1] Leo E. Deelman,[1] Marc Seelen,[2] Harry Van Goor,[3] Robert H. Henning,[1] Maria Sandovici.[1] *[1]Department of Clinical Pharmacology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands; [2]Department of Internal Medicine, University of Groningen, University Medical Center Groningen, Groningen, Netherlands; [3]Department of Pathology and Medical Biology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands.*

Background: Chronic transplant dysfunction (CTD) is the primary reason for late allograft loss in kidney transplantation. Indoleamine 2, 3-dioxygenase (IDO) is involved in foeto-maternal tolerance, and prevents allograft rejection. In our previous experiment, we showed gene therapy with IDO inhibits acute rejection of renal allograft. The aim of current study is to show whether IDO is also able to improve CTD.

Methods: Transplantation was performed in Dark-Agouti to Wistar-Furth CTD model. Adenovirus carrying IDO gene (AdTIDO, n=7) and gene for GFP (AdTL, n=5) and saline were injected into renal artery of donor kidney. Recipients were immunosuppressed with cyclosporine for 10 days. After, the contra lateral kidney was removed. Body weight, serum creatinine and blood pressure (BP) were measured and 24 hour urine was collected every two weeks. Rats were sacrificed after 12 weeks.

Results: IDO treatment significantly improved body weight during whole experiment compared to AdTL and saline groups. Although there was no significant change in plasma creatinine or creatinine clearance, treatment with IDO decreased significantly elevated proteinuria (20.3±5 mg/24 h, vs 56.8±19 mg/24 h and±32.8 mg/24 h). Additionally, IDO therapy decreased BP significantly (137±2 mmHg vs 154±10 mmHg and 163±8 mmHg). Moreover, it decreased the incidence of focal glomerulosclerosis (2.57±0.74 %) compared to AdTL and saline (7.92±4.19 %; 9.60±5.47 %). Furthermore, IDO gene therapy decreased significantly the number of graft-infiltrating macrophages and expression of α-smooth muscle actin. The level of foxp3 mRNA, the marker of tolerogenic T cells, was elevated in the IDO treated group.

Conclusions: Here we show for first time the beneficial effect of local IDO gene therapy in a model of CTD.

FR-PO896

Antithymocytes Globulines and Immune Senescence in Renal Transplant Patients Jamal Bamoulid,[1,2,3] Caroline Roubiou,[1,2,3] Thomas Crépin,[1,2,3] Béatrice Gaugler,[2,3] Jean Marc Chalopin,[1,2,3] Philippe Saas,[2,3] Didier Ducloux.[1,2,3] *[1]Nephrology, CHU Besançon, Besançon, France; [2]INSERM 1098, IFR 133, Besançon, France; [3]Faculté de Médecine et de Pharmacie, Université de Franche-Comté, Besançon, France.*

Background: CD4 T cell reconstitution after antithymocyte globulins (ATG) is dependent on pre-transplant thymic function and persistent ATG-induced CD4 T cell lymphopenia is associated with abnormalities close to those observed in immune senescence. We hypothesized that ATG could be responsible of accelerated immune senescence in renal transplant recipients (RTR).

Methods: We analyzed a prospective cohort of 66 incident RTR. Thymic output of recent thymic emigrants (RTE), regulatory T cells (Treg), $CD8^+$ T cell subsets were studied by flow cytometry at transplant and one year after transplantation. Twenty out of 66 patients were also studied for T lymphocyte relative telomere length and telomerase activity at both times. Age, gender, induction therapy (ATG or anti-CD25 monoclonal antibody [mAb]), immunosuppressive regimen, and CMV status were analyzed as potential confounding factors.

Results: 46 patients received ATG whereas 20 received monoclonal anti-CD25 mAb. Pre-transplant RTE cell count predicted $CD4^+$ T cell count 1 year after transplantation. RTE cell count significantly decreased and were lower in ATG than in anti-CD25 mAb-treated recipients. Proportion of $CD8^+CD28^-$T cells increased after transplant in ATG patients. This increase was more pronounced in RTR with an inverted CD4/CD8 T-cell ratio and in CMV-positive RTR. Treg were more frequent after transplant in ATG than in anti-CD25 mAb recipients. In ATG recipients, Treg peripheral expansion was related to poor thymic function one year post-transplant. The relative telomere length of T lymphocyte increased in anti-CD25 mAb but not in ATG recipients after transplantation. No statistical differences were observed in relative telomerase activity after transplantation.

Conclusions: ATG is associated with reduced thymic output of naive T cells, increased Treg, lymphocyte phenotype and relative telomere length evocative of immune senescence. Mechanisms underlying this thymic alteration and clinical consequences remain to be studied.

FR-PO897

Treatment with a Spleen Tyrosine Kinase (SYK) Inhibitor Reduced the Severity of Experimental Renal Allograft Rejection Jennifer Smith,[1] Gurjeet Bhangal,[1] Asim Syed,[1] Esteban S. Masuda,[2] H. Terence Cook,[1] Nadey S. Hakim,[1] Charles D. Pusey,[1] Frederick W.K. Tam.[1] *[1]Imperial College Kidney and Transplant Institute, Hammersmith Hospital, Imperial College London, London, United Kingdom; [2]Rigel Pharmaceuticals Inc, South San Francisco, CA.*

Background: Spleen tyrosine kinase (SYK) is important in downstream signalling of immune receptors, including B cell receptors and Fc receptors in lymphocytes, monocytes/ macrophages and intrinsic renal cells. Fostamatinib, a SYK inhibitor, was effective in prevention and treatment of antibody mediated experimental glomerulonephritis (Smith J et al. J Am Soc Nephrol. 21:231-6, 2010). However, it is not known whether inhibition of SYK will be effective in prevention of renal allograft rejection.

Methods: We investigated the effect of fostamatinib (provided by Rigel Pharmaceuticals and AstraZeneca) in a rat model of severe rapidly progressive renal allograft rejection. In each operation, the left kidney of a Lewis rat was removed and replaced by a left kidney from a Brown Norway rat. The native right kidneys of the Lewis rats were kept in situ. Fostamatinib treatment or vehicle was given by oral gavage twice daily. The extent of renal allograft rejection was analysed in renal tissue collected 7 days after transplantation. The severity of cortical infarction was assessed with a scale from 0 to 5.

Results: In the vehicle treated rats (n=12), there was extensive infarction of the renal allograft, grades 5 (4-5), median (quartiles). In the fostamatinib treated rats, there was complete prevention of allograft infarction 0 (0-0) and 0 (0-0) in rats treated with 20 mg/kg (n=7) and 30 mg/kg (n=7) respectively twice daily ($p<0.001$). There was dose dependent reduction of the interstitial infiltrates in the fostamatinib treated rats. Interstitial macrophages were reduced by 93 %, $p<0.01$; CD8+ cells reduced by 96 %, $p<0.05$ and endothelial expression of C4d reduced by 78% ($p<0.05$) in the rats treated with 30 mg/kg fostamatinib in comparison to the vehicle treated rats.

Conclusions: To our knowledge, this is the first report showing that treatment with a SYK inhibitor is effective in reducing the severity of experimental renal allograft rejection.

FR-PO898

Thrombin Modulate T Cells Response Induced by Dendritic Cells (DC) in Kidney Transplant Recipients with Delayed Graft Function (DGF) Paola Pontrelli,[1] M. Cariello,[1] Raffaella Verrienti,[1] T. Tataranni,[1] Giovanni Stallone,[2] Francesco Paolo Schena,[1] Loreto Gesualdo,[1] Giuseppe Grandaliano.[2] *[1]DETO-Nephrology Unit, Univ. of Bari, Italy; [2]Dept. of Medical and Surgical Sciences, Univ. of Foggia, Italy.*

Background: Coagulation and complement (C) activation represent key pathogenic events in ischemia-reperfusion-induced renal injury leading to DGF. Aim of our study was to evaluate if thrombin (thr) may induce renal C production and influence the ability of DCs to modulate Th1/Th2 bias.

Methods: PAR-1, BDCA1 (myeloid DC), BDCA4 (plasmacytoid DC), fibrin and C3c protein expression were evaluated by confocal microscopy in pre-transplant and DGF graft biopsies (n=10). Cultured DCs were obtained incubating monocytes with IL-4 and GM-CSF. DC maturation was achieved using a cytokine cocktail. PAR1 protein expression on cultured DC was evaluated by flow cytometry. C receptors, C3, IL12p40 and IL10 gene expression were evaluated by real time PCR.T cell phenotype was analyzed by ELISPOT, after a 2 weeks-exposure to thr-treated DC.

Results: PAR1, the main thr receptor, was expressed by myeloid, but not plasmacytoid, infiltrating DCs in DGF patients. BDCA1+ DCs localized in interstitial areas characterized by fibrin and C3c deposits and expressed C3. To investigate the link between thr and C activation, we evaluated the ability of thr to modulate C3 expression in cultured DC. PAR-1 protein abundance increased in cultured immature and mature DC compared to Ms (73.8±14.4; 73.5±10.4; 32.1±12.4 MFI, respectively p=.03). Thr stimulation induced an increase in C receptors 1, 2 and 3 expression, with a peak at 6 hours ($p<.05$). PAR-1 activation caused a time-dependent increase in C3 (6 fold at 6 hours) and IL-12 p40 gene expression (2.7 fold at 6 hours), while strikingly reducing IL-10 mRNA abundance (2.4 fold at 6 hours). ELISPOT confirmed the ability of thr-treated DC to increase IFNg production by T cells (1.6 fold), suggesting the activation of the Th1 bias.

Conclusions: Our data suggest that thr-activated PAR-1 may induce renal C production and modulate Th-1 response by DC. This observation may suggest a potential pathogenic link between DGF and acquired alloresponse leading to progressive graft damage.

Macrophage Transcripts ADAMDEC1, CXCL13 and CCL18 Are a Hallmark of T Cell-Mediated Rejection in Humans Dina F. Badr,[1] Luis G. Hidalgo,[2] Konrad S. Famulski,[2] Philip F. Halloran.[1] *[1]Medicine, University of Alberta, Edmonton, AB, Canada; [2]Laboratory Medicine and Pathology, University of Alberta, Edmonton, AB, Canada.*

Background: The two types of rejection recognized in the Banff classification are T cell-mediated rejection(TCMR) and antibody-mediated rejection(ABMR). Macrophages and T cells are the dominant cells infiltrating acutely rejecting renal allografts.

Methods: Four hundred and three kidney transplant biopsies for cause (BFC) were classified using a modified Banff classification. Using microarray analysis, we compared the gene expression in biopsies with TCMR (n=35) vs ABMR (n=75) and defined transcripts that are preferentially expressed in TCMR. We studied their relationship to Banff lesions and macrophage/T cell burden.

Results: CXCL13, ADAMDEC1 and CCL18 were the top three transcripts with higher expression in TCMR over ABMR (FDR<0.0001). All 3 transcripts were significantly higher in TCMR than in BFC with no major abnormalities, acute kidney injury,borderline rejection and interstitial fibrosis and tubular atrophy. All 3 transcripts correlated particularly well with Banff interstitial inflammation (i-score), tubulitis (t-score) and intimal arteritis (v-score) in all 403 BFC (table 1). Higher expression of ADAMDEC1, CXCL13 and CCL18 was associated with increased T cell/macrophage burden in all 403 BFC and in TCMR biopsies. In a primary human cell panel, only macrophages expressed higher levels of all 3 transcripts compared to nephrectomies (figure 1).

Conclusions: Macrophage transcripts ADAMDEC1, CXCL13 and CCL18 expression distinguish TCMR from other Banff categories. Their correlations to Banff lesions for TCMR and to T cell/macrophage burden suggest a role for macrophages in alloimmune mechanisms implicated in TCMR. Better understanding of the role of macrophages in rejecting kidneys may offer helpful diagnostic tools as well as possible future therapeutic targets.

Table 1. Correlations of ADAMDEC1, CXCL13 and CCL18 to Banff scores and burdens of macrophages and T cells in 403 BFC†

Probe set ID	Gene	Banff lesion score			T cell burden	Macrophage burden
		i-score	t-score	v-score		
206134_at	ADAMDEC1	0.44	0.40	0.27	0.72	0.78
205242_at	CXCL13	0.37	0.39	0.21	0.74	0.53
32128_at	CCL18	0.30	0.28	0.22	0.48	0.58

† Spearman correlation coefficient, p values <0.0001

The Role of TIM-4 on Antigen Presenting Cell Function in Alloimmunity Martina M. McGrath, Melissa Y. Yeung, Nader Najafian. *Brigham and Women's Hospital, Harvard Medical School.*

Background: TIM4, expressed on DCs and macrophages, functions both as a costimulatory molecule and a phosphotidylserine receptor, mediating phagocytosis of apoptotic cells. Costimulatory blockade of TIM4 in vivo is associated with increased allograft survival. However, this is associated with splenic accumulation of apoptotic cells. The impact of this effect on allograft outcome is unclear. We have sought to specifically examine the effect of TIM4 blockade on phagocytosis.

Methods: Apoptotic cells were generated by incubating CFSE-labeled Balb/c thymocytes for 6 hours in 10mM Dexamethasone, where >75% of cells become apoptotic. In vitro phagocytosis assays were carried out using apoptotic cells incubated with B6 splenocytes for 2 hours. Phagocytosis was assessed using flow cytometry, analysing cells positive for CFSE and either CD11c or F4-80. For in vivo phagocytosis assays, $20x10^6$ apoptotic cells were injected IV into B6 recipients. At 2 hours, spleens were harvested for flow analysis as outlined.

Results: TIM4+ and TIM4neg DCs have a similar capacity for in vitro phagocytosis (67.7% vs 68.2% p=NS). TIM4+ macrophages show greater phagocytosis than TIM4neg (32.9%vs 15.9% $p<0.01$). In vitro treatment with RMT 4-53 has no effect on uptake of apoptotic cells by DCs but leads to marked decrease in phagocytosis by peritoneal macrophages (PMs) (48.78% to 27.68% $p<0.01$).

DC phagocytosis in vivo is increased after treatment with RMT4-53 (18% to 27.5% p=0.049). This appears to be due to a shift in uptake to DCs, as phagocytosis by F4-80+ splenic macrophages is not blocked. After exposure to apoptotic cells in vivo, DCs downregulate MHC Class II expression (from 94% to 80% by 6hrs).

Conclusions: TIM-4 plays a non-crucial role in phagocytosis of apoptotic cells by splenic DCs. It is highly expressed on PMs, and blockade impairs their ability to phagocytose. Despite widespread expression on macrophages, it remains unclear which subset is most affected in vivo, leading to observed splenic accumulation of apoptotic cells. We hypothesise that the shift in phagocytosis of apoptotic cells to DCs after blockade of TIM4 may promote a more tolerogenic DC phenotype and may contribute to allograft survival.

FR-PO901

Role of T Regulatory Cells (CD4+CD25+FOXPS3+) in Renal Transplant Patients with Chronic Allograft Dysfunction Raj K. Sharma, Sharad K. Mittal, Amit Gupta, Sita Naik. *Nephrology, Sanjay Gandhi Post Graduate Institute of Medical Scineces, Lucknow, UP, India.*

Background: We studied the role of CD4+CD25+FOXP3 T regulatory cells (Tregs) in renal transplant patients with chronic allograft dysfunction.

Methods: Patients with chronic allograft dysfunction (n=20, Serum Creatinine; range 2.0 to 4.23), patients with normal graft function (n=20, Serum Creatinine; 0.8 to 1.5) surviving for >2.5 years, and healthy volunteers (n=10) were enrolled. Of these 20 patients with chronic allograft dysfunction (CAD), 10 patients had history of acute rejection in past and or evidence of chronic immune mediated rejection on graft biopsy and 10 patients had non immunological graft dysfunction but had interstitial fibrosis and tubular atrophy. CD4+CD25+FOXP3+ Tregs were enumerated by flow cytometry. CD4+CD25+ T cells (Tregs) and CD4+CD25- T effector cells (Teff) from PBMC of renal patients were isolated. Teff cells were stimulated with anti CD3 for 3 days and cocultured in the presense and absence of Tregs at ratios (Tregs:Teff) of 1:1 and 2:1. Proliferation was measured using the thymidine (H3) uptake.

Results: The median suppressive capacity of CD4+CD25+ Tregs of patients with chronic allograft dysfunction (n=20) was 20.4% (range 0 to 51.29) at 1:1 ratio and 8.95% (0 to 28.5) at 2:1 ratio. This was significantly less than the patients with normal graft function (median 66.38%; range 30.1 to 95.35; $p<0.05$ at 1:1 ratio and 23.3%; 0 to 59; $p<0.05$ at 2:1 ratio) and healthy control (72.56; 19.8 to 92.5 at 1:1 ratio and 30.65; 7.22 to 46.05 at 2:1 ratio) at both ratios. Frequency of Tregs in patients with chronic allograft dysfunction (median 7.54%; range 2.61 to 15.45) and patients with normal graft function (8.21%; 3.25 to 19.1) was higher than healthy control (5.53%; 3.79 to 10.79; $P<0.05$). However, it was comparable between the patients with normal graft function and with chronic allograft dysfunction.

Conclusions: We conclude that Tregs in patients with chronic allograft dysfunction though expanded were less suppressive as compared to patients with normal graft dysfunction. Suppressive functionality of expanded Tregs may be important for the maintenance of good graft function in transplant recipients.

FR-PO902

Immune Response Indictors in Kidney Transplant Recipients within the First Year after Transplantation Magdalena Krajewska,[1] Katarzyna Koscielska-Kasprzak,[1] Marcelina Zabinska,[1] Katarzyna Madziarska,[1] Waclaw Weyde,[1] Dariusz Janczak,[3] Agnieszka Gomulkiewicz,[2] Piotr Dziegiel,[2] Marian Klinger.[1] *[1]Dept. of Nephrology and Transplantation Medicine, Wroclaw Medical University, Wroclaw, Dolnoslaskie, Poland; [2]Dept. of Histology and Embryology, Wroclaw Medical University, Wroclaw, Dolnoslaskie, Poland; [3]Dept. of Vascular and General Surgery, Wroclaw Military Hospital, Wroclaw, Dolnoslaskie, Poland.*

Background: In previously examined 170 pts (7y after KTx) we observed expansion of $CD8^+CD28^-$ cells.

The goal of this research was to investigate regulatory and cytotoxic gene expression in a group of Ktx pts during the 1 year post-KTx. The phenotype analysis of T cell subpopulations was also performed.

Methods: 36 KTx pts and 20 volunteers have been included. The research involved PBMC gene expression analysis on Taqman LDAs of FOXp3, ILR2A, GZMB, PRF1, GAPDH genes. The cells were flow cytometry phenotyped and the $CD3^+CD8^+CD28^-$, $CD3^+CD4^+CD25^+CD127^{low}$ populations were assessed. GZMB expression by $CD3^+CD4^+$ and $CD3^+CD8^+$ cells has been determined.

Results: The number of $CD3^+CD8^+CD28^-$ cells increases after KTx and is correlated with GZMB and PRF1 gene expression. However, this subpopulation does not predict the transplant outcome.

The level of nTregs observed 1 m after KTx is similar to controls and is decreasing over time reaching significance 6 m after KTx p=0.011. The nTreg number observed 3 m after KTx is a predictor of 1 y transplant outcome rs=-0.43, p=0.015. The nTreg population is correlated with FOXp3 and ILR2A expression in PBMC.

The FOXp3 and ILR2A expression in KTx pts is lower than in controls and remains unchanged over the first y post-transplant. The higher regulatory gene expression is related to better transplant outcome FOXp3 expression 3 m post-KTx and 1 y sCr correlation rs=-0.66, $p<0.0001$. The GZMB expression is also developed post-KTx in $CD3^+CD4^+$ cells and is related to CD28 negativity. Additionally initial study shows that $CD3^+CD4^+CD28^-$ population may be negatively correlated with graft function >1 year post-KTx, SCr, rs=0.44, p=0.039.

Conclusions: The immune state in KtX is characterized by nTreg fall and $CD8^+CD28^-$ T cells induction. The latter seems to have cytotoxic properties.

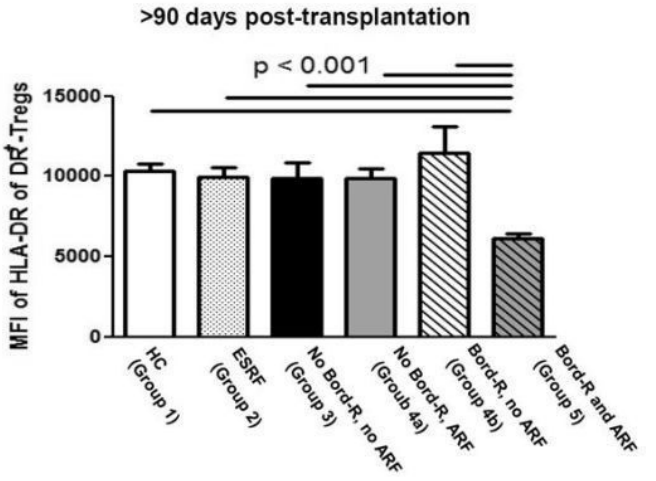
FR-PO903

The Extent of HLA-DR Expression of DR^+-Tregs Is Significantly Reduced in Transplanted Patients with Clinically Relevant Borderline Rejection Matthias Schaier,[1] Nicole Seissler,[1] Luis Eduardo Becker,[1] Claudia Sommerer,[1] Sebastian Schäfer,[1] Ruediger Waldherr,[3] Andrea Steinborn,[2] Martin G. Zeier.[1] *[1]Department of Nephrology, Univeristy of Heidelberg, Heidelberg, Germany; [2]Department of Gynecology, Univeristy of Heidelberg, Heidelberg, Germany; [3]Department of Pathology, Univeristy of Heidelberg, Heidelberg, Germany.*

Background: Regulatory T cells (Tregs) were shown to be involved into the pathogenesis of acute rejection after transplantation. The suppressive activity of the total regulatory T cell pool depends on its percentage of highly suppressive $HLA\text{-}DR^+$-Treg cells.

Methods: Therefore, both the suppressive activity of the total Treg pool and the extent of HLA-DR expression of DR^+-Tregs (MFI HLA-DR) were estimated in non transplanted volunteers, patients with end-stage renal failure (ESRF), healthy renal transplant patients with suspicion on rejection, due to sole histologic Bord-R or sole acute renal failure (ARF), and patients with clinically relevant borderline rejection (Bord-R and ARF).

Results: Transplanted patients with clinically relevant borderline rejection show significantly reduced suppressive activity of their $CD4^+CD127^{low+/-}CD25^+$-Tregs. Our data propose that the HLA-DR MFI strongly depends on its composition with DR^{high+} and DR^{low+} Tregs. Patients with clinically relevant borderline rejection have significant lower HLA-DR MFI´s and significantly reduced proportions of DR^{high+}-Tregs, which have the highest suppressive capacity within the total Treg pool.



Conclusions: Our findings clearly demonstrate that the determination of the HLA-DR MFI of the $HLA\text{-}DR^+$-Treg subset allows a highly sensitive, specific and non-invasive discrimination between patients with clinically relevant Bord-R (Bord and ARF) and patients with subclinical rejection or other causes of transplant failure.

FR-PO904

The Pathological Characteristics of Kidney in Acute Graft-Versus-Host Disease after DA-to-Lewis Rat Bone Marrow Transplantation Seiichiro Higo,[1,2] Akira Shimizu,[1] Shinya Nagasaka,[1] Go Kanzaki,[1] Yukinari Masuda,[1] Akiko Mii.[2] *[1]Department of Analytic Human Pathology, Nippon Medical School, Tokyo, Japan; [2]Department of Internal Medicine, Divisions of Neurology, Nephrology and Rheumatorogy, Nippon Medical School, Tokyo, Japan.*

Background: It is known that allogeneic bone marrow transplantation (allo-BMT) causes acute or chronic graft-versus-host-disease (GVHD). Liver, gut, and skin are known to primary target sites of acute and chronic GVHD. However, kidney is still uncertain to be influenced by GVHD. In the present study, we examined the pathology of kidney in acute GVHD in DA-to-Lweis rat allo-BMT.

Methods: Acute GVHD was induced in Lewis rats (RT1l) by transplantation of DA rat (RT1a) bone marrow cells ($6.0x10^7$ cells) after lethal irradiation (10Gy). We examined the clinical and pathological characteristics of acute GVHD in various organs, after BMT without immunosuppression.

Results: Almost all white blood cells in peripheral blood were constituted with DA phenotype. Between 21 and 40 days after allo-BMT, acute GVHD was developed with decreased body weight (>20%), skin rush with alopecia, and diarrhea. Liver and kidney dysfunction was detected: asparate aminotransferase (AST:143±103U/L), alanine aminotransferase (ALT:105.5±6.5U/L), and blood urea nitrogen (BUN:30.6±7.0mg/dL). The pathology of liver, skin, and gut showed acute GVHD that was characterized by very similar findings of severe acute T-cell mediated rejection in transplanted liver, skin, and small intestine grafts. In kidney, many $CD3^+$ T cells and $CD68^+$ macrophages infiltrated that mediated the interstitial inflammation around small arteries that expanded into peritubular interstitium with severe peritubular capillaritis. Acute glomerulitis and endarteritis in small arterioles were evident. Acute tubulitis with $CD3^+$ T cells was also noted. No obvious IgG, IgM, and C3 deposition was detected in the kidney.

Conclusions: Kidney was one of the target organs of acute GVHD. The pathology of acute GVHD in the kidney was characterized by the T cell-mediated injury for the microvascular endothelium and renal tubules, and these findings were very similar of acute T-cell mediated rejection in transplanted kidney grafts.

FR-PO905

Impact of Immunosuppressive Treatment on Digestive Tract Colonization of Pyelonephritis Strain Escherichia Coli 536 Jerome Tourret,[1] Ben P. Willing,[2] Gilbert Deray,[1] Corinne Isnard-Bagnis,[1] Brett B. Finlay.[2] *[1]Dpt of Urology, Nephrology and Transplantation, AP-HP, Pierre and Marie Curie University, Paris, France; [2]Michael Smith Laboratories, University of British Columbia, Vancouver, BC, Canada.*

Background: Uropathogenic *E. coli* (UPEC) strains cause urinary tract infections (UTIs) which are a major concern in kidney transplant recipients (KTRs). Acute graft pyelonephritis is responsible for long term kidney graft function deterioration. The determinants of *E. coli*'s establishment in the host's digestive tract before it reaches the urinary tract and the impact of immunosuppressive (IS) drugs on intestinal colonization have not been studied.

Methods: C3H mice were orally challenged with UPEC strain 536. Digestive tract colonization was assessed by plating of fecal samples. Mice were sacrificed at various time points and cytokine expression was measured in different segments of the digestive tract. Strain-specific anti-*E. coli* antibodies were measured in blood. The experiment was repeated after 2 weeks of treatment with prednisolone, mycophenolate mofetyl and tacrolimus.

Results: Pyelonephritis *E. coli* strain 536 efficiently colonized the mouse digestive tract, with fecal counts as high as 10^8 CFU/g after a single oral challenge. Intestinal colonization remained stable for at least 2 weeks. The incoming *E. coli* strain was specifically detected in the distal intestine through a peak of the inflammatory cytokines IL6 and TNF 48 hrs after bacterial oral challenge. Yet, no inflammatory infiltrate was observed in intestinal sections. Even though specific anti-*E. coli* IgG could be detected in blood 2 weeks after intestinal colonization, an inflammatory response was observed 48 hrs after a second oral challenge in pre-colonized mice. When mice were treated for 2 weeks with IS drugs before oral challenge, host's digestive inflammatory response was abrogated and *E. coli*'s digestive tract colonization increased 1000 fold.

Conclusions: Innate and adaptive immunity cooperate to control UPEC intestinal colonization. IS drugs might favor UTIs in kidney transplant recipients through enhanced digestive colonization. Trying to block digestive colonization by UPEC could be a new strategy to prevent UTIs in KTRs.

United Kingdom Study of Living-Kidney Donor Relationships: Gender and Ethnic Variations Rishi Pruthi,[1] Rommel Ravanan,[2] Anna Casula,[1] Paul J. Roderick.[3] *[1]UK Renal Registry, Bristol, England, United Kingdom; [2]Renal Unit, Southmead Hospital, Bristol, England, United Kingdom; [3]Public Health, University of Southampton, Southampton, England, United Kingdom.*

Background: Ethnic minorities constitute a disproportionate number on the waiting list, and are subject to longer waiting times. By analysing the relationships between live donors and their recipients, we aim to gain a better understanding of how different communities/ populations view living donation.

Methods: Using data from NHS Blood & Transplant we reviewed the demographic characteristics of all living donor renal transplant recipients and their respective donors between 2001-2010 in the UK. The relationship between recipients and their donors was analysed together with their ethnicity and gender.

Results: 6580 patients and their respective donors were analysed. Women contributed 54.2% to the donor group, and 40.1% to the recipient group. Ethnic minorities received fewer transplants; Asian 7.2% (n=471) and Black 3.7% (n=244) than their proportional representation on the waiting list 26.2% (n=1760). Spousal donation was similar in both white 23.8% (n=1360) and Asian 21.7% (n=102) populations, but significantly reduced in the Black population 13.5% (n=33) p=0.0001 which had significantly higher sibling donation (43.6%) p<0.0001. Whilst spousal gender disparity (female preponderance) was universal in all groups this was significantly greater in the Asian population where women donated 79.4% compared to black 60.6% and white 61.4% p=0.003. Gender disparity was not seen amongst offspring donating. The proportion of parental donations has reduced over time, with a rise in kidney donation from offspring and from 'other' relationships p<0.001.

Conclusions: Living kidney donation is subject to significant unexplained relationship differences amongst ethnic minorities. Spousal donation is significantly lower in the Black population which has higher sibling donation. Gender disparity is greatest in the Asian spousal population, and donation from 'other' relationships has risen over time. There is a need to understand these differences, and develop a strategy to increase donation rates in ethnic minorities especially from male spouses.

FR-PO907

Quality of Life after Living Renal Donation Claudia Sommerer,[1] Ralf A. Dikow,[2] Matthias Schaier,[1] Christian Morath,[1] Vedat Schwenger,[1] Martin G. Zeier.[1] *[1]Nephrology, University Hospital Heidelberg, Heidelberg, Germany; [2]Dialysis Center, Bruchsal, Germany.*

Background: Living renal transplantation represents a favourable alternative to deceased renal transplantation with excellent recipient and allograft survival results. Until now, only limited data about short- and longterm quality of life and psycho-social consequences for the living donor are available.

Methods: In an open, prospective observational study renal allograft donors were evaluated concerning quality of life and psycho-social results of living donation. Standardized questionnaires as well as additional questions related to living donation were used (Zerssen Symptome Score, SF-12).

Results: Altogether, 125 renal allograft donors were evaluated (43 male, median age 52.7±11.4, mean time after transplantation 3.7±3.8). None of the donors had any serious post-transplant complications and the renal function was stable. Most of the donors were satisfied with their organ donation (n=119); 3 patients denied and 3 patients were uncertain about the question if they would be willing to donate again. In addition, 18 donors were unsatisfied with their present living situation, 6 donors complaint about negative familial consequences. In 17 donors quality of life was worse after donation and 13 patients stated that their discomforts were caused by renal donation. Mean Zerssen Symptom score of the donors was 10.0±4.9 (min 0, max 56) compared to 14.3±10.8 in a healthy population. In 8 patients (6.4%) the Zerssen score was above the cut-off of 27 (5 female), and in another 6 patients the Zerssen Score was between 22 and 27. Mean age of the eight patients with a Zerrsen Score above 27 was 49.2±9.1 years, mean time after donation was 3.5±2.1.years, 6/8 patients were married, 80% were employed, and 3/8 donors reported a migration background. Medical problems of the recipients were indicated by 3 of these 8 donors. Most complaints were about back pains and sleeplessness.

Conclusions: Concerning no less than 10% of living donors complaining impaired QoL directly related to living renal donation there is a need to improve pre and post-transplant psycho-social donor supervision.

FR-PO908

Blood Pressure Characteristics Measured by Three Different Modalities in Living Kidney Donors Yasushi Ohashi, George Thomas, Martin J. Schreiber, Emilio D. Poggio. *Nephrology and Hypertension, Glickman Urological and Kidney Institute, Cleveland Clinic, Cleveland, OH.*

Background: Most kidney transplant centers exclude prospective living kidney donors with hypertension from donation because of concerns that nephrectomy may increase medical risks associated with hypertension after donation. It is unclear, however, how various approaches to measure blood pressure (BP) correlate with each other to provide accurate measurements. Our objective was to assess BP in donors using 3 different modalities.

Methods: 93 living kidney donors seen between 2009 to 2011 had BP measured by the following modalities before donation: in-office BP (single BP using aneroid sphygmomanometer in clinic), BpTRU BP (average of 5 automated readings in clinic using BpTRU device), and 24 hour ambulatory blood pressure monitoring.

Results: Hypertension (defined as average 24-h BP ≥ 130/80 mmHg) was present in 20 donors. Masked hypertension (normal BP in clinic but elevated 24-h BP) was noted in 13 donors when BP was measured in-office, and in 14 donors with BpTRU. White coat hypertension (BP ≥ 140/90 mmHg in clinic but normal 24-h BP) was seen in 2 donors when BP was measured in-office.

	In-office BP, mmHg			BpTRU BP, mmHg		
BP Classification	<120/80	120–139/80–89	≥140/90	<120/80	120–139/80–89	≥140/90
Normal 24-h BP, n (%)	41 (44.1)	30 (32.3)	2 (2.2)	52 (55.9)	21 (22.6)	0 (0.0)
24-h BP ≥ 130/80 mmHg, n (%)	2 (2.2)	11 (11.8)	7 (7.5)	9 (9.7)	5 (5.4)	6 (6.5)

A higher 24-h systolic BP (SBP) was significantly associated with higher serum creatinine, lower HDL, higher LDL, higher hemoglobin, higher kidney volume, pre-diabetes, and smoking. Smoking was significantly associated with nocturnal non-dipping. BP was significantly lower on BpTRU than on in-office measurement ($p<0.05$). Sensitivity and specificity for elevated 24-h BP are 77.8% and 84.5% by in-office BP, and 100% and 83.9% by BpTRU BP.

Conclusions: While BpTRU BP has higher sensitivity for elevated 24-h BP than in-office BP, average 24-h BP has the highest correlation with risk factors among the 3 modalities and is also useful to detect masked hypertension.

FR-PO909

Changes in Serum Biomarkers 6 Months after Living Kidney Donation Shiv Kapoor,[1] Megan E. Donato,[1] Stephanie DeLoach,[3] Raymond R. Townsend,[1] Peter P. Reese,[1] Kevin E.C. Meyers.[2] *[1]Univeristy of Pennsylvania, Philadelphia, PA; [2]Pediatrics, CHOP, Philadelphia, PA; [3]Thomas Jefferson University, Philadelphia, PA.*

Background: Living kidney donation is an important means to improve health in patients with advanced chronic kidney disease or who are receiving dialysis therapy. Kidney donation is considered to be of low risk when donors are carefully selected, but some concern exists especially in young donors who are anticipated to have only one kidney for the rest of their life. Although we showed recently that blood pressures by ABPM do not change substantially 6 months after donation, we were concerned that more subtle changes, such as in the levels of important serum biomarkers, would change adversely after living kidney donation. Thus, we studied markers of endothelial function (ARG, homoARG, ADMA, SDMA), bone metabolism (FGF23) & inflammation (TNF,hsCRP,IL-6) pre-, and 6 months post-nephrectomy in living kidney donors.

Methods: We obtained blood samples on 14 subjects (6 men/8 women; mean(S.D.) age of 41(10) years) who donated a kidney at the University of Pennsylvania or the Children's Hospital of Philadelphia. Their eGFR by CKD-EPI decreased, from 86(11) to 60(12) mL/min/1.73m2. *We measured FGF-23, TNF, and IL-6 by ELISA, ARG, H_ARG, ADMA, SDMA by HPLC and hsCRP by the Roche Analyzer.*

Results: These data indicate a small but definite adverse change in several biomarkers that are important surrogates for inflammation (TNF), endothelial function (ADMA) and bone metabolism (FGF23) and suggest potential targets for monitoring and potentially intervention in living kidney donors.

Marker	ARG	ADMA	SDMA	FGF-23	TNF1-α	IL-6	hsCRP
Units	μM	μM	μM	RU/ml	pg/ml	pg/ml	mg/l
Pre	66.5+26.2	0.40+.05	0.56+.07	57.8+40.7	1.62+.37	1.33+.82	3.89+6.38
Post	82.0+22.6	0.44+.05	0.77+.09	74.1+48.1	2.07+.55	1.61+1.04	2.05+2.52
p-value	0.06	0.006	<0.001	<0.001	0.006	0.44	0.34

Conclusions: Current follow-up of living kidney donors is often minimal, perhaps related to the perception of low CV risk as reflected in our subject's young age and normal BP, which may overlook modest but important changes in metabolism occurring after nephrectomy that could influence future health outcomes.

FR-PO910

Racial and Ethnic Differences in Determinants of Live Donor Kidney Transplantation in the United States Tanjala S. Purnell,[1] Ping Xu,[2] Yoshio N. Hall.[2] *[1]Johns Hopkins University; [2]University of Washington.*

Background: Few studies have comprehensively examined multi-level determinants of live-donor kidney transplantation (LDKT) across all major US racial/ethnic groups.

Methods: We performed a retrospective cohort study to examine racial/ethnic differences in determinants of LDKT among 162,308 non-elderly patients who initiated dialysis in 2005-2008. We linked patient-level data from the USRDS and UNOS registries and area-level socioeconomic data from the 2000 US Census. The primary outcome was time from dialysis initiation to receipt of LDKT through Sept. 30, 2008. We analyzed associations of race/ethnicity and time to LDKT using Cox proportional hazards models, and we estimated racial/ethnic differences in the degree of delayed LDKT attributable to demographic, socioeconomic and clinical factors in bootstrap analyses.

Results: Overall, 6126 subjects received a first LDKT during 221,185 person-years. Mean crude rates of LDKT were lowest among blacks (1.05 per 100 person-years [95% CI: 0.1-1.1]), American Indians/Alaska Natives-AIANs (1.22 [0.9-1.7]) and Pacific Islanders (1.47 [1.1-2.0]), intermediate among Hispanics (2.23 [2.1-2.4]) and Asians (3.20 [2.8-3.6]), and highest among whites (4.77 [4.6-4.9]). Disparities in LDKT attenuated but remained clinically and statistically significant after adjustment for demographic, socioeconomic and clinical factors. The largest fraction (34%, 21% and 33%, respectively) of the disparity among blacks, Hispanics and AIANs compared with whites was attributed to adjustment for health insurance and zip code poverty. Measures of pre-dialysis care accounted for 6%, 7%, 4% and 3% of the disparity among blacks, Hispanics, AIANs and Pacific Islanders but none of the disparity among Asians. Among Asians, Hispanics and Pacific Islanders, notable fractions were attributable to household linguistic isolation (4%, 5% and 5%, respectively).

Conclusions: In the US, rates of LDKT remain significantly lower among nonwhites relative to whites, but determinants of these disparities appear to vary according to race/ethnicity. Targeted efforts to address race/ethnicity-specific determinants of delays in LDKT may help mitigate these disparities.

FR-PO911

Subclinical Abnormalities in Post-Perfusion Biopsies of Living Donor Kidneys Elizabeth A. Kendrick,[1] Kelly D. Smith,[2] Connie L. Davis.[1] *[1]Division of Nephrology, University of Washington, Seattle, WA; [2]Department of Pathology, University of Washington, Seattle, WA.*

Background: To identify preexisting abnormal findings in the donor kidneys, we performed post-perfusion (T0) intraoperative biopsies(bx) of kidney transplants performed at our center.

Methods: We retrospectively reviewed results of T0 bx in live donor kidneys performed from 10/1/2008 to 4/1/2012. 116 LD txs were performed of which 73 T0 bxs were available for review. Bx reports were reviewed for glomerulosclerosis (GS), interstitial fibrosis and tubular atrophy (IFTA), acute tubular injury(ATN), vascular abnormalities(VAB), and positive immunoflorescence (IFAB). None of the LDs had any urinalysis abnormalities, microalbuminuria, hypertension, or abnormal glucose tolerance.

Results: ATN was seen in 44 T0 biopsies(60.3%) consistent with reperfusion injury; 5 also had focal glomerular capillary thromboses. GS was seen in 35 (47.9%) of biopsies; <5% in 19(26.0% of all bxs); 5-10% in 9 (12.3%); >10-15% in 7 (9.6%). Three of 7 bx with >10% GS were kidneys from donors younger than 50 years, all male. Focal IFTA was seen in 17 (23.3%); more mild diffuse IFTA in 6(8.2%). Focal or greater VAB(arteriosclerosis or hyalinosis) were seen in 29(39.7%); moderate VAB in 5(6.8%). IFAB was seen in 12(16.4%); 6 had weak staining in various patterns, felt due to non-specific binding of doubtful clinical significance. Six biopsies showed more significant IFAB, most often mesangial IgA deposition. Electron microscopy (EM) demonstrated mesangial immune deposits in 4 of 6 cases, and one case also had subepithelial deposits. One biopsy showed IFAB in areas of GS but EM was negative for deposits. IFAB was generally seen in the absence of any significant glomerular abnormalities on light microscopy, and not generally seen with GS, IFTA or VAB.

Conclusions: Bx abnormalities are frequent in kidneys from healthy living donors. If unknown they can potentially confound interpretation of post tx kidney bxs. Importantly, these abnormalities could have implications for future health risk of LDs and counseling them.

FR-PO912

Pregnancies amongst Australasian Living Kidney Donors Andrew J. Mallett,[1] Nicole M. Isbel,[1] George T. John,[2] Helen G. Healy,[2] Philip A. Clayton.[3] *[1]Department of Nephrology, PAH, Brisbane, Queensland, Australia; [2]Department of Renal Medicine, RBWH, Brisbane, Queensland, Australia; [3]Australia and New Zealand Dialysis and Transplant (ANZDATA) Registry, RAH, Adelaide, South Australia, Australia.*

Background: Living kidney donors consistently account for >33% of Australasian renal transplant procedures. Females represent >50% of this population; their obstetric outcomes are unreported. This study aims to describe pregnancies amongst living kidney donors reported to the ANZDATA living kidney donor registry (LKDR).

Methods: The ANZDATA LKDR was interrogated for reported pregnancies from its commencement (January 2004) to 31 December 2010. The size of the potentially fertile population (female living kidney donors ≤50years) was also assessed. This registry currently has a ~60% loss to follow up rate by 1year post donation.

Results: The population of potentially fertile living kidney donors was 1197, representing 57.5% of all living kidney donors ≤50years. 12 pregnancies amongst 12 donors were identified, resulting in 5 livebirths, 3 spontaneous abortions (<20weeks), 1 surgical termination, and no stillbirths (>20weeks). The outcome of 3 pregnancies is unknown. No information is known about other obstetric complications or outcomes. Mean donor age at time of kidney donation was 32.67yrs (24-46yrs) and mean time to first report of pregnancy after donation was 18.17months (2-50months). Mean blood pressure at donation was 120.96/74 mmHg (106-134/60-89mmHg), with a mean GFR of 123.89ml/min/1.73m² (108-138ml/min/1.73m²). 83.3% were related to their recipient. None have been reported to be deceased, receive dialysis or undergo transplantation, with a mean follow up time of 33.42months (12-57months).

Conclusions: Whilst little meaningful information is known about Australasian living kidney donor obstetric outcomes, this report of 12 pregnancies amongst 12 donors in a potentially fertile population of 1197 donors may be interpreted with optimism. Vigilance to maximise and improve living kidney donor follow up to similar levels as organ recipients is required. An appreciation of obstetric outcomes in Australasian living kidney donors may help inform the choices of potential female living kidney donors.

FR-PO913

Living Kidney Donation Appears Safe in African-American Donors Based on Short-Term Follow-Up of Renal Function at 6 Months Post Nephrectomy Lavanya Kodali, Jyothishree R. Pinnaka, Sanjaya Satapathy, Oleksandra Dryn, Melissa Moore, James D. Eason, Luis Campos, Kasturi Vinay Ranga. *Methodist Hospital Transplant Institute, University of Tennessee Health Sciences Center, Memphis, TN.*

Background: Living donation has been the most promising solution to the shortage in organ availability for renal transplantation worldwide. While short-and long-term safety have been reported, studies have been largely limited to Caucasian donors.Given the mix of both African-Americans (AA) and non-African-Americans (Non AA) in our donor population, we aimed to compare short term outcomes of renal function post-donation.

Methods: Retrospective, cohort study of all living kidney donors at a single center from 2007 to 2011. Statistical calculations were performed using SPSS software.

Results: There were a total of 100 donors, M: F= 31:69, in this time period. Of them,only 67 donors had follow-up labs at 6 months (group 1 non- AA, n =45 ; group 2-AA, n = 22). Mean age (yrs) was 41.76 vs. 37.0 (NS),mean BMI in kg/m2, 24.98 vs 29.08 (S). baseline MDRD GFR (ml/min) was significantly higher in group 2 compared to group 1 at baseline (96.49 vs 108.89) and at 6 months post-donation (61.5 vs 73.0),

Factors significantly predicting a higher 6 month GFR on univariate analysis were younger age, race, and BMI. Upon multivariate analysis, only baseline MDRD GFR achieved statistical significance.

As noted above, 33 / 100 donors did not return for their 6 month follow-up, which is a cause for worry, reflecting a national trend.

Conclusions: We conclude that living kidney donation is safe, at least in the short-term post donation, whether African-American or not, in a well selected population based

on age and BMI. Larger multicenter studies and the donor registry should validate our findings.These observations are encouraging in a population consisting of large numbers of African –Americans as a majority of patients on the waiting list and have historically had low rates of living transplantation. Given the higher prevalence of hypertension and kidney disease in the African -American population, careful screening prior to donation is of utmost importance.

FR-PO914

Impact of Simultaneous Liver Kidney Transplant Policy on Patients with End-Stage Renal Disease Anton I. Skaro,[1] Yaojen Chang,[2] Daniela Ladner,[1] John J. Friedewald,[1] Lorenzo G. Gallon.[1] *[1]Comprehensive Transplant Center, Northwestern University; [2]Oncology, Georgetown University.*

Background: Simultaneous liver kidney (SLK) transplant provides better survival to end-stage liver disease (ESLD) patients with renal impairment than liver transplant alone (LTA). During the era of the Model for End-Stage Liver Disease (MELD) allocation system, the number of SLK transplants has increased. However, this could prolong the waiting period for kidney transplants for ESRD. Consequently, the most equitable and efficacious use of deceased donor kidneys remains controversial.

Methods: A discrete time state transition Markov model was constructed to simulate ESLD patients following the proposed UNOS SLK guidelines to receive SLK transplant or LTA. The simulation included the transition between MELD quintiles, change in dialysis status, re-transplantation for chronic/acute graft failure, and the probability of native renal recovery based on the dialysis duration and transplant strategy. The model output, measured in life years, was estimated from the results of one million micro-simulations for each scenario. Validity of the model output was examined by comparing projected survival rates of each transplant strategy in the model with data from UNOS.

Results: In the base case model the UNOS SLK guidelines led to 273 kidneys released at the expense of 777 life years lost from ESLD patients. When the 10-year difference in life expectancy between KTA and dialysis patients was 2.48 years, the 677 life years gained from 273 KTA is less than the 777 life years lost from ESLD patients. According to the 2009 Annual Report of the USRDS, KTA recipients survived longer than dialysis patients by 3.5 years over a 10-year period. Under these circumstances, the 956 life years gained from 273 kidneys exceeded 777 life years lost from ESLD patients.

Conclusions: An unintended consequence of MELD-based liver allocation has been an increase in SLK transplant in the US. The development of SLK transplant listing criteria would restore access to kidney transplant for patients with ESRD. The SLK guidelines underscore the dichotomy of life years lost for ESLD patients and life years gained for ESRD patients on the kidney waitlist.

FR-PO915

Re-Examining the Impact of Pre-Donation Renal Function Criteria for Living Kidney Donor Selection on Long-Term Graft Survival Ann Young,[1] Joseph Kim,[1,2] Amit X. Garg,[3] Charmaine E. Lok.[1,2] *[1]Department of Medicine, University of Toronto, Toronto, ON, Canada; [2]Division of Nephrology, University Health Network, Toronto, ON, Canada; [3]Division of Nephrology, Western University, London, ON, Canada.*

Background: Individuals with reduced kidney function are being accepted as living kidney donors. The impact of liberalizing this criterion in the most recent era of transplantation on long-term outcomes needs to be revisited.

Methods: This retrospective, population-based cohort study followed kidney allograft recipients from Ontario, Canada from July/1992 to March/2010. Recipients and donors were identified through the provincial transplant database, and linked to large electronic healthcare databases. Baseline donor GFR was estimated using the CKD-EPI equation. Outcomes were defined using reliable codes compared to chart review. Multivariable survival analysis was performed with the primary outcome of graft loss with death as a competing event.

Results: In total, 2,087 living donor kidney transplants were studied. Baseline eGFR of donors (in mL/min) were: ≥ 110 (n = 508, 24%), 100-109 (n = 480, 23%), 90-99 (n= 471, 23%), 80-89 (n = 337, 16%), and < 80 (n = 291, 13%; reference group). The majority of transplants (74%) occurred after the year 2000. Recipients of the lowest eGFR kidneys were older than those receiving highest eGFR kidneys (46 vs. 42 years). Mean follow-up time for the cohort was 7.6 years after transplant. There was no significant difference in the HR for graft loss when comparing recipients in each eGFR category to the reference group (adjusted HRs (95%CI) from highest (≥ 110 mL/min) to lowest (80- 89 mL/min): 0.79 (0.52-1.19), 0.97 (0.66-1.42), 0.97 (0.67-1.41), and 1.13 (0.77-1.65), respectively).

Conclusions: The risk of graft loss with death as a competing event was not significantly higher for recipients of living donor kidneys with eGFR < 80 mL/min. Transplant centres utilizing explicit eGFR cut-off criteria for living kidney donor selection may consider cautious liberalization, especially for potential donors who are otherwise deemed suitable.

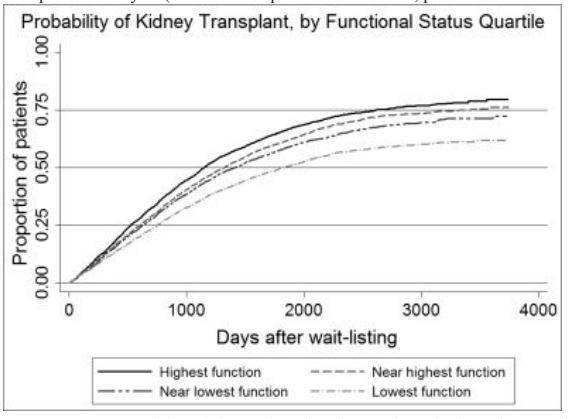
FR-PO916

The Influence of Functional Status on Outcomes for Patients Awaiting Kidney Transplant Peter P. Reese,[1] Roy D. Bloom,[1] Justine Shults,[1] Adam S. Mussell,[1] Sylvia E. Rosas,[1] Kirsten L. Johansen,[2] Peter Abt,[1] Matthew H. Levine,[1] Arthur Caplan,[3] Jason Karlawish,[1] Harold I. Feldman.[1] *[1]University of Pennsylvania; [2]UCSF; [3]NYU.*

Background: Functional status is a summary measure of global health that might help nephrologists counsel patients about the value of kidney transplant. We hypothesized that patients with the lowest functional status would (1) be less likely to receive a transplant, and (2) not derive a survival benefit from kidney transplant.

Methods: Using Organ Procurement and Transplantation Network data linked to data on functional status (physical function [PF] scale of the Medical Outcomes Study Short Form-36) assessed by a dialysis provider, we performed a cohort study of 19,640 adults who were wait-listed from 6/1/2000 – 5/31/2006. First, we fit a MV Cox regression model to examine the association of PF with the receipt of a kidney transplant. Second, we used Cox regression, with transplant status as a time-dependent covariate, to evaluate the survival benefit associated with transplant vs dialysis, stratified by quartile of PF score.

Results: Median age 50 years; 36% were black and 60% male. As in the figure, better PF had a "dose-dependent" association with the probability of receiving a kidney transplant (adjusted hazard ratio [aHR] 1.43 for highest vs lowest PF quartile, p<0.001). Within 9 months post-transplant, patients in every PF quartile derived a survival benefit from transplant vs dialysis (For each PF quartile: aHR <0.60, p<0.001 at 9 months).



Conclusions: Although lower functional status is an independent predictor of lower likelihood of kidney transplant, patients at every level of function can derive a survival benefit from kidney transplant by 9 months beyond transplant. Future studies should examine whether low functional status patients should accept extended criteria donor kidneys in order to be transplanted sooner.

FR-PO917

Evaluation for Kidney Transplantation in the Elderly Nicole Beauvais,[1] Ashley E. Davis,[2] Anton I. Skaro,[2] Bing Ho,[2] Daniela Ladner.[2] *[1]Northwestern Memorial Hospital; [2]Comprehensive Transplant Center, Northwestern University.*

Background: Elderly patients (pts) >65 years comprise 44.6% of the ESRD population but make up only 19.6% of the kidney transplant (KT) waitlist. Little is known about how transplant centers evaluate elderly pts. Recipient age is a significant negative risk factor for post transplant outcomes, and KT recipient selection varies widely across the U.S., especially with regard to age. We describe how listing and transplanting the elderly at a large transplant center compares to the non-elderly and examine reasons for rule-out. A comparative analysis using national data are presented.

Methods: A single-center (NMH) retrospective chart review of all pts evaluated for KT between 2/2007-5/2012 was performed. Demographics and characteristics were obtained from the EMR. Statistical analyses using Fisher and chi-square tests were performed.

Results: 3,993 pts were evaluated for KT. 645 (16.2%) were elderly. The rate of KT eval for the elderly increased by 176% from 2007 to 2011. 57% of the pts <65 yrs were listed compared to 38% of elderly. 83% of all elderly at NMH who had a KT received a living donor (LD) which is statistically significantly higher than nationally (p<0.001).

	≥65 yr (n=645)	<65 yr (n=3348)
Currently listed	144	1096
Transplanted (p=0.06 Fisher's)	101	783
Living donor	84	582
Deceased donor	17	201
Ruled out (p<0.0001 Fisher's)	279	905
Medical	63	181
Financial	3	53
Non-adherence	28	78
Did not complete testing	50	187
Pt choice	38	190
Pre-emptive	7	7
Other/Unknown	90	209
Expired in evaluation or listed	46	149
In evaluation	58	222
Tx elsewhere	17	124

χ^2 $p < 0.001$ for table

Mortality on KT waitlist

	NMH	National	p-value
>65 yr (%)	21	44	<0.001
<65 yr (%)	12	28	<0.001

Conclusions: As ESRD in elderly is rising, pts >65 yrs are increasingly being evaluated for KT. Interestingly, medical rule out is only slightly higher in elderly (23%) than in younger pts (19%). At NMH, an elderly pt is as likely to receive a LD KT as is a younger pt. Compared to national rates, waitlist mortality in the elderly is two times lower at NMH and LD KT in both the elderly and younger pts is significantly higher. Identifying barriers that the elderly face in completing KT testing and determining why they remove themselves from evaluation may offer opportunities to increase LD KT.

FR-PO918

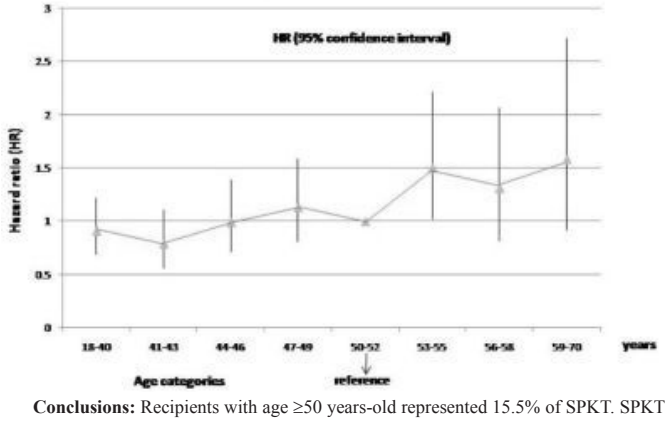
Simultaneous Pancreas-Kidney Transplantation Outcomes in Recipients Older than 50 Years Naowanit Nata, Mandana Kamgar, Edmund Huang, Marcelo Santos Sampaio, Suphamai Bunnapradist. *UCLA, Los Angeles, CA.*

Background: Simultaneous pancreas kidney transplantation (SPKT) is the treatment of choice for type 1 diabetics (T1D) with end-stage renal disease. Many institutions do not accept older patients as SPKT candidates, and therefore SPKT outcome data on recipients older than 50 year-old is limited.

Methods: Using UNOS/OPTN database as of March 2011, we selected all T1DM adult recipients who received a SPKT between 2000 and 2009, and categorized by age at the time of transplant as ≥50 and <50 years old. Five-year kidney, pancreas and patient survival were examined. Multivariate analysis was used to define hazard ratios (HR) of graft loss and death in ≥50 years, with <50 as reference.

Results: We found 6387 and 1172 recipients with <50 and ≥50 year-old, respectively. The mean age of SPKT≥50 was 53.7±3.4 and SPKT<50 was 38.2±6.4 years. Five-year patient survival was 85 and 88% (p<0.001); death-censored kidney (DCK) survival was 87 and 86% (p-value=0.32) and death-censored pancreas (DCP) survival was 83 and 78% (p=0.001) for ≥50 and <50, respectively. Risk of death (HR=1.32; 95% CI 1.10-1.59) and kidney loss (HR=1.19; 95% CI 1.02-1.38) were increased in SPKT≥50. Hazard-ratios of pancreas failure, DCK failure and DCP failure in SPKT ≥50 recipients were 0.95 (95% CI 0.83-1.10), 0.97 (95% CI 0.79-1.20) and 0.75 (95% CI 0.64-0.90), respectively. Adjusted risk of death for age categories of 18-40, 41-43, 44-46, 47-49, 53-55, 56-58 and ≥59 compared with 50-52 year-old is showed in figure1.

Figure 1. Risk of death



Conclusions: Recipients with age ≥50 years-old represented 15.5% of SPKT. SPKT recipients ≥50 year-old had an increased risk of death, decreased risk of death-censored pancreas failure, but a similar risk of death-censored kidney failure when compared to SPKT recipients<50 year of age.

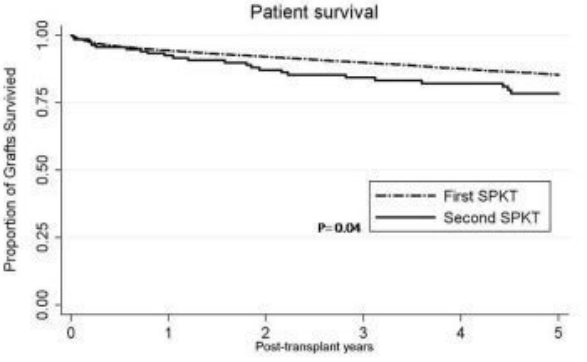
FR-PO919

Outcomes of Simultaneous Pancreas-Kidney Re-Transplantation after a First Simultaneous Pancreas-Kidney Transplantation Naowanit Nata, Edmund Huang, Mandana Kamgar, Marcelo Santos Sampaio, Suphamai Bunnapradist. *UCLA, Los Angeles, CA.*

Background: Simultaneous pancreas-kidney transplantation (SPKT) is the treatment of choice for end stage renal disease diabetic patients. Data on outcome of a SPK re-transplant after a first SPKT is limited.

Methods: Using OPTN/UNOS database as of March-2011, we found 16788 adult first SPKT (f-SPKT) between years 1987 and 2011. Of those, 5440 (32.4%) failed both grafts, and only 140 (2.6%) were subsequently re-transplanted with a SPKT (SPK-rT). Kidney graft, pancreas graft, and patient survival were compared between f-SPKT and SPK-rT. Adjusted hazard ratios (HR) of kidney and pancreas failure, and death were examined in SPK-rT recipients, with f-SPKT as the reference group.

Results: Mean age was 39.5±8.2 and 39.7±8.2 years; median (25^{th}-75^{th} p) PRA was 0 (0-5.0) and 29 (2.0-79.5); and median follow-up were 1949 (771-3370) and 1457 (432-2449) days, for f-SPKT and SPK-rT, respectively. Five-year patient survival was 78 and 85% (p=0.04) (Figure 1); death-censored kidney (DCK) survival were 74 and 84% (p=0.01) and death-censored pancreas (DCP) survival were 73 and 77% (p=0.32) for SPK-rT and f-SPKT, respectively.



First SPKT	16788	14452	12911	11597	10192	8869
Second SPKT	140	115	96	84	70	55

Risk of kidney failure (HR=1.39; 95% CI 1.01-1.91) and DCK failure (HR=1.52; 95%CI 1.02-2.25) were increased in SPK-rT recipients. Risk of death (HR=1.25, 95% CI 0.83-1.89), pancreas failure (HR=1.14; 95% CI 0.84-1.56), and DCP failure (HR=1.13; 95%CI 0.79-1.62) were not significant increased in SPK-rT recipients.

Conclusions: Only 2.6% of a first failed SPKT received a second SPKT. A second SPKT after a first failed SPKT was associated with inferior overall and death censored kidney survival when compared to a first SPKT.

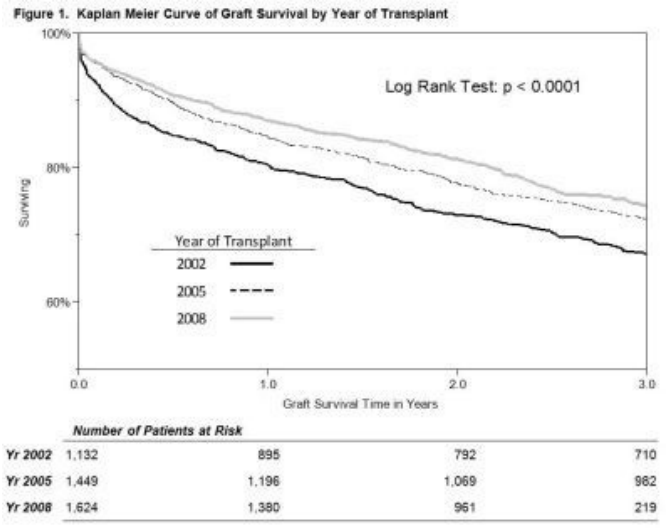
FR-PO920

Trend in Graft Survival for Expanded Criteria Donor Kidney Transplants in the United States: Is There a Learning Curve? Anthony W. Castleberry,[1] Kadiyala V. Ravindra,[1] Deepak Vikraman,[1] Mathias Worni,[1] Andrew S. Barbas,[1] Matthew Jay Ellis,[1] William Irish,[2] Debra Sudan.[1] *[1]Duke University Medical Center; [2]Clinical Trial and Consulting Services.*

Background: The trend in graft survival nationwide in United States (US) expanded criteria donor (ECD) kidney transplants remains poorly understood. Our objective was to perform a trend analysis of transplant characteristics and graft survival for all US ECD kidney transplants performed over the past decade.

Methods: We performed a longitudinal cohort study of all US ECD transplants performed between 01/2002 and 12/2010 recorded by the United Network for Organ Sharing. Exclusion criteria included pediatric recipients, living donors, non heart beating donors, repeat or multiorgan transplants, and pre-dialysis recipients. Kaplan-Meier method was used to assess graft survival while trends in transplant characteristics and survival were analyzed by ordinary least squares regression and the Cochran–Armitage trend test.

Results: 12,731 ECD transplants were available for analysis (mean age 60 years, 32% Black and 64% male). Use of ECD kidneys increased from 16.9% in 2002 to 20.9% in 2010 (p<0.001) during which time graft survival significantly improved (Figure 1). The rate of delayed graft function declined from 35.2% in 2002 to 27.8% in 2010 (p<0.001), the mean donor kidney risk index increased from 1.88 to 1.97 (p<0.001), the percent of ECD kidneys pumped increased from 26.5% to 62.7% (p<0.001) as did the percent of pre-transplant kidney biopsies (79.9% in 2002 versus 94.4% in 2010; p<0.001).



Number of Patients at Risk				
Yr 2002	1,132	895	792	710
Yr 2005	1,449	1,196	1,069	982
Yr 2008	1,624	1,380	961	219

Conclusions: Despite an increasing mean donor kidney risk index over time among ECD kidneys, graft survival has improved, suggesting a learning curve. Contributory factors may include an increased use of pumping and biopsies to improve selection of ECD kidneys.

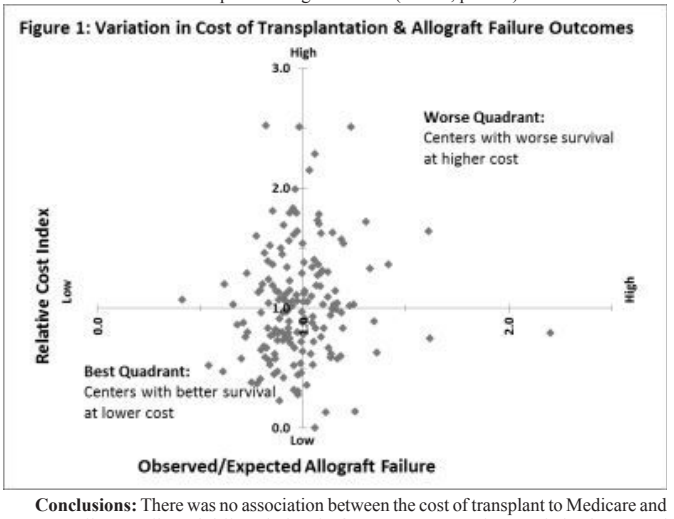
FR-PO921

Is Medicare Getting What It Pays for in Kidney Transplant Outcomes? Suying Li,[1] Nicholas Salkowski,[2] Craig Solid,[1] Mark Schnitzler,[3] Jon J. Snyder,[1] Joseph Kim,[4] Bertram L. Kasiske,[1,2] Ajay K. Israni.[2] *[1]USRDS Coordinating Center, MMRF, MN; [2]Hennepin County Medical Center, University of Minnesota - Medicine, MN; [3]University of St. Louis, MO; [4]University of Toronto, School of Medicine, Canada.*

Background: The relationship between cost and kidney allograft failure has not been investigated in the US.

Methods: Using Medicare claims from the United States Renal Data System, we determined Part A and B costs for all adult Medicare kidney recipients transplanted between 1/1/2007 and 6/30/2009. We compared the relative cost (observed/expected cost) for the first year posttransplant for all transplant centers, adjusting for recipient, donor and transplant characteristics, region, and the local wage index. Using program-specific reports (PSRs) created by the Scientific Registry of Transplant Recipients, we correlated relative cost with observed/expected allograft failure between centers. We excluded small transplant centers with less than 3.69 expected allograft failures.

Results: Among 20,757 transplants at 165 centers, the mean observed cost was $65,366 (IQR=55,094-71,624) and the relative cost was 0.99 (IQR=0.88-1.08). The mean observed/expected allograft failure was 1.03 (IQR=0.61-1.37). There was no correlation between relative cost and observed/expected allograft failure (r=0.10, p=0.20).



Conclusions: There was no association between the cost of transplant to Medicare and a center's all cause allograft failure during the first year posttransplant. Variation in cost and outcomes suggests a need to determine the most cost- effective practices to reduce costs.

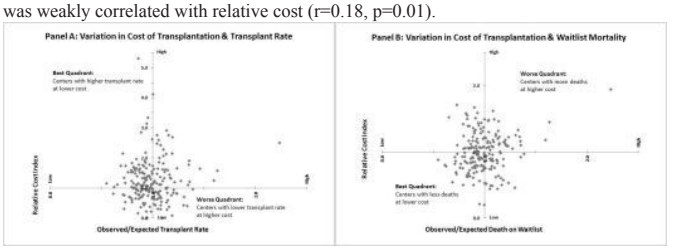
FR-PO922

Does an "Aggressive" Transplant Center Lead to Higher Medicare Costs? Suying Li,[1] Nicholas Salkowski,[2] Craig Solid,[1] Mark Schnitzler,[3] Jon J. Snyder,[1] Joseph Kim,[4] Bertram L. Kasiske,[1,2] Ajay K. Israni.[2] *[1]USRDS Coordinating Center, MMRF, MN; [2]Hennepin County Medical Center, University of Minnesota - Medicine, MN; [3]University of St. Louis, MO; [4]University of Toronto School of Medicine, MN, Canada.*

Background: Higher wait-list mortality for a center could suggest that the center accepts high-risk candidates for transplant. A higher transplant rate suggests that the center accepts higher-risk donors. We hypothesized that cost of kidney transplant at such centers may be higher.

Methods: Using Medicare claims data, we determined Part A and B costs for all adult Medicare kidney recipients transplanted between 1/1/2007-6/30/2009. We then developed a relative cost (observed/expected cost) for the first year posttransplant for all transplant centers, adjusting for transplant characteristics, geographic region, and local wage index. Using program-specific reports (PSRs) created by the Scientific Registry of Transplant Recipients, we correlated relative cost with adjusted wait-list mortality and adjusted transplant rate between centers. We excluded small centers with expected wait-list mortality or expected transplant rate less than 3.69 in 2009.

Results: The study included 20,726 transplants at 203 centers for transplant rate. The mean observed cost was $64,903 (IQR=54,741-71,624) and the relative cost was 0.99 (IQR=0.88-1.08). The mean observed/expected wait-list mortality of 0.99 (IQR=0.78-1.18) was weakly correlated with relative cost (r=0.18, p=0.01).



The mean observed/expected transplant rate on the waiting list of 1.24 (IQR=0.82-1.59) was not correlated with the relative cost (r=0.08, p=0.26).

Conclusions: There was no association between being an "aggressive center" and the cost of transplant to Medicare.

Funding: NIDDK Support

FR-PO923

Development and Validation of a New Statistical Model for Prognosis of Long-Term Graft Function after Pediatric Kidney Transplantation Lars Pape,[1] Thurid Ahlenstiel,[1] Antonia Zapf.[2] *[1]Pediatric Nephrology, Hannover Medical School, Hannover, Germany; [2]Biostatistics, Hannover Medical School, Hannover, Germany.*

Background: No adequate statistical model has been established to estimate future glomerular filtration rate (GFR) in children after kidney transplantation (KTX). In adults, equations based on simple linear regression analysis are used, but it is questionable if this approach is also suitable for children.

Methods: To address this issue, an optimal prognostic model of GFR was generated for 63 children at 3-7 years after KTX. The main regression model for prediction of the log-transformed GFR (logGFR) included the mean monthly change of GFR in the period 3-24 months after KTX (ΔGFR), the baseline GFR at 3 months after KTX (bGFR), and an intercept. Additionally it was investigated if the inclusion of cofactors leads to more precise predictions. The model was validated by leave-one-out-cross-validation for years 3-7 after KTX. Prognostic quality was determined with the mean squared error (MSE) and mean absolute error (MAE). Results were compared with the simple linear regression model used in adults.

Results: Compared to the simple linear model for adults, lower MSE and MAE values, this means more precise predictions, were observed with the new pediatric model. The benefit of inclusion of cofactors was not relevant.

Conclusions: To our knowledge, this is the first statistical model to predict long-term graft function in children with a very high precision. The next step would be to validate the results in an independent cohort.

FR-PO924

Predictors of Early and Late Graft Loss in Recipients with Kidneys from the Same Donor: Analysis of the UNOS Database Joyce P. Samuel, Cynthia S. Bell, John S. Bynon, Joshua A. Samuels, Rita Swinford. *UT-Houston Medical School, Houston, TX.*

Background: When a deceased donor provides kidneys to 2 different recipients, a unique opportunity to study recipient-specific risk factors for graft loss is created. The UNOS database from 1987-2010 was queried to identify matched pairs of transplant recipients who had received their kidney allograft from the same donor. We sought to identify recipient factors that predicted early vs late allograft loss independent of donor factors.

Methods: This analysis included only donor-matched recipient pairs with divergent graft survival determined if one of the allograft kidneys failed within 2 ys, and the other

survived at least 7.5 ys. These time points were chosen as they represented the 25th and 75th percentile for kidney allograft loss among donor-matched pairs in the database.

Results: We identified 2315 donors with 4630 recipients who had divergent graft survival. Median graft survival time was 5 mo in the early graft loss (EGL) group vs 122 mo in the late graft loss group. Those with early graft loss were older (median age at transplantation of 47 yr [interquartile range 35,57] vs. 45 [IQR 35, 54]), and had a higher proportion of Blacks (33% vs. 22%). Multivariate mixed effects logistic regression analysis for early vs late graft loss showed a 68% increase in odds of EGL if the recipient was Black (odds ratio 1.68, 95%CI 1.47, 1.92), had a higher BMI (OR 1.01, 95%CI 1.002, 1.02), or was older (1.01, 95%CI 1.004, 1.012). Other significant covariates were whether the recipient had been transplanted previously (OR 1.63, 95%CI 1.26, 2.11), increasing cold ischemia time (OR 1.63, 95%CI 1.25, 2.11), and high peak PRA (greater than 80%) (OR 1.60, 95%CI 1.24, 2.06). Recipient gender, dialysis prior to transplant, and time on transplant waiting list were not associated with an increased risk for EGL in this analysis.

Conclusions: By reporting the outcomes of both kidneys from 2315 individual donors, we confirmed previously identified risk factors for EGL while controlling for donor factors. Black race, higher BMI, older age, previous transplant, increasing cold ischemia time, and higher antibody sensitization predicted EGL in this cohort.

FR-PO925

Long-Term Results of Renal Transplantation from Donors with Acute Renal Failure Jacqueline Apaza, Esther Gonzalez Monte, Natalia I. Polanco Fernandez, Laura Garcia-puente Suarez, Ignacio Bengoa, Enrique Morales, Amado Andres, J. Morales. *Nephrology, Hospital Universitario 12 de Octubre, Madrid, Spain.*

Background: In order to reduce the waiting time for renal transplantation the selection criteria for kidney grafts have been extended in recent years. The aim of our study was to evaluate the initial and long-term evolution of patients transplanted from a donor with acute renal failure (ARF).

Methods: Between 1990 and 2009 were analyzed 40 patients who received a kidney transplant from a donor with Serum Creatinine ≥ 2 mg / dl at the time of extraction, and compared the evolution with their respective transplant patient with donor serum creatinine < 2 mg/dl, transplanted in the same period of time and similar ages and sex.

Results: The table 1 analyzes the characteristics and evolution of the group of patients with ARF and controls. In the donor group with SCr ≥ 2 mg / dl there was a higher proportion of males (p = 0.01). The mean SCr at the time of removal from donors with ARF was 2.8mg/dl compared to 0.9mg/dl in the control group (p <0.001). Cold ischemia time was higher in donors with ARF (21.8 min vs 17.8 min, P <0.01). There was no difference in the rate of primary graft non-function, in the mean time to recover renal function or the rate of acute rejection. SCr at 3, 6 and 12 months of evolution was similar in both groups. In the analysis of survival at 5 years there were no differences when comparing both groups (90% in the group with ARF and 95% in controls).

Characteristics of transplant patients from donors with ARF compared with controls

Donors	SCr≥ 2 mg/dl	SCr <2mg/dl	P
Age (years)	42,2±17	39,9±16	NS
Gender (M/F) %	80/20	60/20	0,02
SCr (mg/dl)	2,8±0,7	0,9±0,28	<0,001
Recipients			
Age (years)	49±12	45,2±11	NS
Gender (M/F) %	60/40	57,5/42,5	NS
PRA>50%	5 %	12,5 %	NS
Transplantation			
Cold ischaemia time (min)	21,8±4	17,8±6,3	0,01
acute tubular necrosis(days)	14±12	10±9	NS
Primary non-functioning grafts (%)	2,5	0	NS
Acute rejections (%)	15	15	NS
SCr 3 months	1,4±0,46	1,6±1,1	NS
SCr 6 months	1,4±0,7	1,4±0,38	NS
SCr 12 months	1,3±0,46	1,4±0,7	NS

Conclusions: Donors with ARF secondary to acute tubular necrosis may be good donors with excellent graft outcome and long survival.

FR-PO926

KDPI Scores: Observed Outcomes Exceed Expectations at Three Years Cynthia Leaphart, Martin L. Mai, Sherry Sonnenwald, Stephanie Koonce, Mary B. Prendergast, Hani Wadei, Thomas A. Gonwa, Burcin Taner. *Department of Transplant, Mayo Clinic Florida, Jacksonville, FL.*

Background: The Kidney Donor Profile Index(KDPI) proposes allocation of donor kidneys to decrease waitlist times. To understand the KDPI system and outcomes, we performed a retrospective analysis to determine a) KDPI scores of organs transplanted at our institution and b) correlation of actual recipient outcomes with KDPI scores.

Methods: Retrospective chart review of transplanted kidneys(1/1/2000-12/31/2008) extracted donor characteristics(age, height, weight, race, history of hypertension or diabetes, cause of death, serum creatinine(highest,lowest,&final), Hepatitis C Viral status, donation after cardiac death(DCD) status) to calculate KDPI. KDPI highest(**KH**), lowest(**KL**), and final(**KF**) percentages were calculated from donors' highest, lowest, and final creatinine. Recipient demographics including age at transplant, graft and recipient survival, & length of follow up were collected. Recipients of dual transplant, living kidney, & multi-organ transplants were excluded from analysis. Donor and recipient matching was categorized by ascending KDPI.

Results: Of 330 complete records, mean±s.d., median, and range of KDPI(%) are:**KH:**41.37±24.2,40,(1-93), **KL:**33.4±24.6,30,(1-88), **KF:**37.3±24.6,37,(1-93), suggesting that acceptable donors span the extent of KDPI scores. Recipient graft survival at 1-,2-, and 3-years analyzed by **KH** are shown in Table 1. Strikingly, allograft survival at 3-years post-transplant exceeded predicted outcomes from the KDPI allocation model, excluding 3-year survival for KDPI=80-89%.

Actual Graft Survival

KDPI(%)	1-Yr(%)	2-Yr(%)	3-Yr(%)	3-Yr Predicted
1-4	100	100	93.3	87.8
5-9	100	100	100	86.8
10-19	97	93.6	85.1	85.9
20-29	95.7	91.5	91.5	84.5
30-39	95.2	92.9	88.1	83.1
40-49	97.5	95	90	81.5
50-59	97.3	94.6	86.5	79.7
60-69	83.9	77.4	74.2	77.9
70-79	91.9	83.8	83.8	75.7
80-89	100	86.7	66.7	73.1
90-94	80	80	80	69.2

Conclusions: Previously accepted kidneys used for transplant ranged broadly across KDPI percentage. Graft survival exceeded predictions of the KDPI range for this single transplant center. Matching strategies using the KDPI may improve outcomes and shorten waitlist times.

FR-PO927

Dual Kidney Transplant Outcomes in the US: The UNOS Database Analysis Sowmini Medavaram, Zouhair M. Kabbara, Sumit Mohan, Mark A. Hardy, Lloyd Ratner, David J. Cohen, Bekir Tanriover. *Columbia University Medical Center.*

Background: Dual kidney transplant (DKT) is not a consideration in the current allocation algorithm in the US for waitlisted transplant candidates. Many kidneys used for DKT would otherwise have been discarded because of their high-risk characteristics (donor age>60yrs, terminal creatinine>2.5mg/dL, eGFR<65mL/min, donor diabetes and/or hypertension, and moderate glomerulosclerosis 15-50%). We report the rate of complication and outcomes of DKT compared to expanded criteria kidney (ECD) transplants to assess their potential utilization as a form ECD allocation.

Methods: From 1994 to 2001, a total of 1,601 DKT and 23,457 ECD transplants from donors aged ≥50years are identified in the UNOS STAR file. Donor quality (Kidney Donor Risk Index, KDRI), allograft survival, renal function at last follow-up and rate of surgical complications are primary outcomes.

Results: DKT comprised 3.7% of kidney transplants form donors aged ≥50years. The comparative results are summarized on below table:

		Dual donor age>50	ECD	p value
N		1,601	23,457	
±Donor age (years)		64.1±7.5	59.8±6.1	< 0.001
Donor gender (female %)		55.7	55.1	<0.001
Terminal Creatinine (mg/dL)		1.3±1.3	1.2±1.4	0.202
Diabetic donors (%)		16.8	11.7	<0.001
KDRI - Rao		1.8±0.5	1.8±0.4	0.884
Recipient age (yrs)		59±10.8	56.4±12.2	<0.001
Recipient gender (female %)		37.9	37.2	0.612
Cold ischemia time (hrs)		23.9±12.6	19.7±9.3	<0.001
Delayed allograft fucntion (%)		27.8	33.6	<0.001
Follow up years		3.8±3.2	3.9±3.4	0.0334
eGFR (MDRD) at last follow up (mL/min/1.73m2)		47.7±22.9	41.2±18.4	<0.001
Cause of kidney failure				0.861
	Acute rejection(%)	14.8	13.4	
	Chronic rejection (%)	35	38.4	
	Primary nonfunction(%)	12.2	11.3	
	Graft thrombosis (%)	6.5	5.1	
	Urological complication (%)	0.7	0.6	
	Other (%)	20.7	22	
Death functioning kidney (%)		6.7	4.3	0.077
Posttransplant 90 day mortality (%)		3.9	3.1	0.057
5 yr death censored graft survival(%)		51.1	51	0.22

Conclusions: Outcomes with DKTs are comparable to those with ECD transplants but are performed relatively infrequently. DKT utilization needs to be optimized by offering them as a part of ECD algorithm to and should be considered prior to discard of available kidneys.

FR-PO928

Renal Transplantation in the over 70s Is Safe and Successful Miriam R. Berry,[1] Anil Chalisey,[2] Andrew K. Coutinho,[3] Kate S. Wiles,[4] Sourjya Kar,[5] Nicholas Torpey.[1] *[1]Addenbrooke's Hospital, Cambridge, United Kingdom; [2]Norfolk and Norwich University Hospital; [3]Broomfield Hospital, Chelmsford; [4]Ipswich Hospital; [5]Lister Hospital, Stevenage.*

Background: Improving survival of patients with end stage renal failure in the context of an aging population demands that the safety and efficacy of renal transplantation in the elderly is evaluated.

Methods: We performed a retrospective analysis of every renal transplant performed in a patient in their 70s at our institution since January 1st 2000. A control group was identified comprising the recipient of the paired kidney where possible (n=10), or the subsequent cadaveric transplant recipient at our institution.

Results: Since 2000, 26 patients have received a renal transplant after their 70th birthday; 14 from cadaveric non heart-beating donors, 9 cadaveric heart-beating donors and 3 living donors. Demographic and outcome data were collected for the 23 recipients of cadaveric grafts and compared to a control group comprising 21 patients. The median age was 72 (range 70-74) vs 57 (range 41-68) yrs ($p<0.001$). There were no significant differences in duration of renal replacement therapy nor time spent on the transplant waiting list. There was a trend towards older patients receiving kidneys from older donors: 63 (57-71.5) vs 58 (52-63) yrs ($p=0.051$). Neither graft nor patient survival were significantly different between study and control groups: 1 year graft and patient survival 84 vs 95% ($p=0.60$) and 100 vs 95% ($p=1.00$) respectively, and to date: 87 vs 90% ($p=1.00$) and 96 vs 90% ($p=0.60$) with a median follow up period of 34 (range 5-117) months. Current level of graft function was similar: median creatinine 151 vs 170 µmol/l ($p=0.42$). Surprisingly, delayed graft function was significantly more common in the control group: 90 vs 48% ($p=0.003$) despite comparable cold ischemic times. Neither length of stay (10 vs 10 days, $p=0.13$) nor re-admission rate at 3 months (22 vs 14, $p=0.20$) were different. There was no difference in the frequency of acute and late complications between groups.

Conclusions: Renal transplantation in patients in their 70s is safe and successful. Longer term follow up will show if this is an effective use of donor organs.

FR-PO929

Long-Term Outcome of En Bloc Paediatric-Kidney Transplantation in Adult Recipients Hildegard Hafner-Giessauf,[1] Astrid Mauric,[1] Helmut Mueller,[2] Philipp Eller,[3] Florian Iberer,[2] Alexander R. Rosenkranz,[1] Kathrin Eller.[1] *[1]Clinical Division of Nephrology, Medical University Graz, Austria; [2]Clinical Division of Transplant Surgery, Medical University Graz, Austria; [3]Clinical Division of Angiology, Medical University Graz, Austria.*

Background: Renal transplantation has been shown to be the best therapeutic option in end stage renal disease (ESRD) patients. Nowadays, non-heartbeating as well as old and very young donor kidneys are accepted for transplantation. En bloc transplantation of paediatric-kidneys into adult recipients (EBKT) is one strategy to increase the donor pool.

Methods: We here report on 10 to 22 years of follow-up of patients receiving EBKT in a single centre retrospective cohort study approach.

Results: The mean donor age and donor body weight was 14±12 months and 8±3 kilograms, respectively. Thirteen recipients (6 females, 7 males) were followed for 10 to 22 years. The mean recipient age was 44±13 years at the time of transplantation. Two of 13 patients lost their grafts in the first week after EBKT because of haemorrhagic infarction of the kidney transplants or sepsis. The latter patient died due to septic shock. Only one patient had an acute cellular rejection that was successfully treated with steroids and anti-CD3-antibody. Eleven out of 13 patients after EBKT survived and have a functioning graft 10 to 22 years after successful EBKT. The serum creatinine was 1.34±0.6 mg/dl 5 years (n=11), 1.37±0.7 mg/dl 10 years (n=11), 1.40±0.6 mg/dl 15 years (n=4), 1.08 mg/dl 20 years after EBKT (n=2). The eGFR evaluated by using MDRD-2 was 66.5±22 ml/min/m^2 5 years (n=11), 62±28 ml/min/m^2 10 years (n=11), 56±23 ml/min/m^2 15 years (n=4), 61 ml/min/m^2 20 years after EBKT (n=2).

Conclusions: In summary, EBKT in our hands has a brilliant long-term graft and patient survival when the acute post-operative phase is uncomplicated.

FR-PO930

Year of the Transplantation and/or Early Renal Graft Function: Influence on Long-Term Outcomes in Renal Trasplantation Maria Luisa Agüera, Alberto Rodriguez-benot, Maria Dolores Navarro, Raquel Ojeda, Sagrario Soriano, Alejandro Martin-Malo, Pedro Aljama-Garcia. *Renal Unit, H.U.Reina Sofia, Cordoba, Spain.*

Background: There is not any consensus if the year of the transplantation and/or the early renal graft function has any influence on long-term outcomes of kidney transplantation recipients.

Methods: We included all transplant recipients of a renal graft alone in our centre from 1979 to 2005. Demographic, clinical, analytical and therapeutic variables have been recorded for each patient pre, peri and post-transplantation. Time of transplantation was defined by quartiles. Early renal graft function was defined by glomerular filtration rate (GFR) estimated from different equations (Cockroft-Gault, MDRD, Nankivell) and by stratification on End Stage Renal Disease Staging. It was performed survival test of cumulative survival (uni and multivariate), actuarial survival and projected half mean live calculated using the most adjusted mathematics' equation to 156 or 130 observed real survival data (weekly data).

Results: 778 kidney graft's recipients were included and divided in four quartiles depending on the moment of the transplantation. The most adjusted mathematics equation was potential equation for Q1-Q4 and second grade polynomial equation for Q2-Q3 at the 156-observed-data analysis. Using these equations, the kidney graft survival initially improved (Q1-Q2) and lastly was stabilized (Q3-Q4). Classical methods of survival and real half mean life confirmed these results. GFR at 12 months post-transplant could have influenced on renal graft survival censored by death of the patient after adjusted by the rest of the covariables.

Conclusions: Patient and kidney graft's survival improved until the introduction of the calcineurin inhibitor and after that it has been stabilized, regardless of the survival test used. Projected half mean life based on a high number of observed data after the six months post-transplantation is an adequate method to compeer renal graft outcomes of recent times. Early renal graft function, defined on GFR estimated at 12 months post-transplantation, has some influence in long-term renal graft outcomes (censored by death of the patient).

FR-PO931

Five Year Graft Survival and Delayed Graft Function Predicted by Pre-Existent Renal Damage Welmoet H. Westendorp,[1] Hilde Tent,[3] Hendrik Sijbrand Hofker,[1] Rutger J. Ploeg,[4] Henri G.D. Leuvenink,[1] Marcory van Dijk,[2] Harry Van Goor.[2] *[1]Surgery, UMCG, Groningen, Netherlands; [2]Pathology, UMCG, Groningen, Netherlands; [3]Nephrology, UMCG, Groningen, Netherlands; [4]Nuffield Dept. of Surgical Sciences, University of Oxford, Oxford, United Kingdom.*

Background: Organs derived from deceased brain dead (DBD) donors show worse function and more acute rejection episodes than those from living donors (LD). Brain death induces a progressive inflammatory response in potential donor organs. Minor renal damage is present in healthy donors. We hypothesize that pre-existent renal damage is more prominent in kidneys from DBD donors compared to LD and might predict graft failure after transplantation.

Methods: We used renal biopsies of 125 living and 73 DBD donors. Associations with donor characteristics and recipient outcome were determined. The degree of FGS, interstitial fibrosis (IF), intima thickness and vascular hyalinosis were scored. Sections were scored for macrophages, granulocytes and pre-fibrosis (α-SMA).

Results: Vascular hyalinosis, FGS, macrophages and granulocytes are markedly increased in DBD compared to LD ($p<0.05$). Intima thickness and IF are not significantly different between the donor types. The degree of FGS and IF are associated with donor age ($\rho = 0.265$, $\rho = 0.315$ resp; both $p<0.01$). IF correlates with diastolic blood pressure and effective renal plasma flow prior to donation ($\rho = 0.144$, $\rho = -0.197$ resp; both $p<0.05$). Macrophages and intima thickness correlated univariate with delayed graft function (DGF) (Exp(B)=261.1, Exp(B)=1.021 resp; both $p<0.05$). In multivariate analysis, 5 year graft survival was best predicted by granulocytes ($p<0.05$). Separately analyzed, 1 year graft survival in DBD donor is best predicted by IF ($p<0.05$) and in LD by the degree of intima thickness. Five year graft survival in DBD donor is best predicted by IF and in LD by the degree of vascular hyalinosis.

Conclusions: Pre-existent renal damage is more prominent in kidneys of DBD donors than in kidneys from LD. Therefore, therapeutic interventions in the DBD donor could be a tool to reduce inflammatory damage of the graft-to-be and thereby improve organ quality and graft survival.

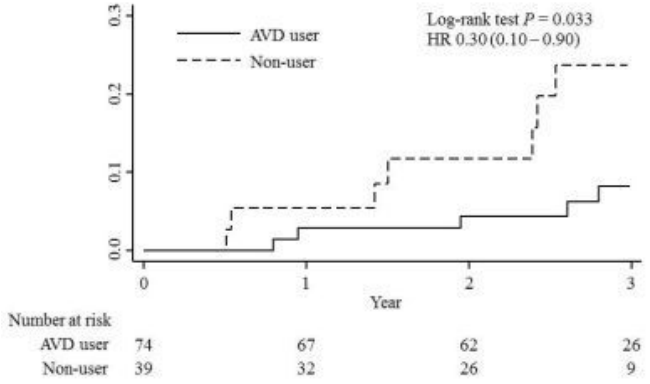
FR-PO932

Oral Active Vitamin D Therapy for Potential Chemoprevention of Post-Transplant Malignancy Yoshitsugu Obi,[1] Naotsugu Ichimaru,[2] Takayuki Hamano,[3] Isao Matsui,[1] Masayoshi Okumi,[4] Jun-Ya Kaimori,[5] Koji Yazawa,[4] Yoshiharu Tsubakihara,[3] Hiromi Rakugi,[1] Shiro Takahara,[5] Yoshitaka Isaka.[1] *[1]Geriatric Medicine & Nephrology, Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [2]Urology, Osaka Central Hospital, Osaka, Japan; [3]Comprehensive Kidney Disease Research, Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [4]Specific Organ Regulation (Urology), Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [5]Advanced Technology for Transplantation, Osaka University Graduate School of Medicine, Suita, Osaka, Japan.*

Background: Post-transplant malignancy (PTM) is a limiting factor for survival in kidney transplant recipients (KTRs). We hypothesized that active vitamin D compounds (AVDs) could reduce PTM development in KTRs.

Methods: Ambulatory KTRs were prospectively followed from 2007 to 2010. A propensity score (PS) of having received AVDs was estimated using 26 clinically relevant factors. We used Cox models to estimate the effect of AVDs on newly diagnosed PTM.

Results: Among 218 participants, median age was 50 (IQR, 40–59) years, 63.3% were male, median time since transplantation was 11.2 (IQR, 5.2–17.1) years, and mean estimated GFR was 41.3 (SD, 15.6) ml/min/1.73 m^2. At baseline, 42.2% had been treated with AVDs mainly for glucocorticoid-induced osteoporosis. AVDs used were calcitriol (58.7%) and alfacalcidol (41.3%). During follow-up, PTM developed in 5.4% of 92 AVD users and 8.7% of 126 non-users. Poor vitamin D status was common in the participants, but serum 25-hydroxyvitamin D levels did not predict PTM. After stratifying patients by PS tertiles, we found that AVDs were significantly associated with a lower risk of PTM (HR 0.25 [0.07–0.82]). Sensitivity analyses using PS matching yielded similar results.



Also, HR was 0.30 (0.10-0.90) by IPW method.

Conclusions: AVDs are potential chemopreventive agents against PTM in KTRs.

FR-PO933
