A Single Daily Dose Enhances the Adherence to Immunosuppressive Treatment in Kidney Transplant Recipients Yoshitsugu Obi,[1] Naotsugu Ichimaru,[2] Taigo Kato,[3] Jun-Ya Kaimori,[4] Masayoshi Okumi,[3] Koji Yazawa,[3] Hiromi Rakugi,[1] Norio Nonomura,[3] Yoshitaka Isaka,[1] Shiro Takahara.[4] *[1]Department of Geriatric Medicine & Nephrology, Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [2]Department of Urology, Osaka Central Hospital, Osaka, Japan; [3]Department of Specific Organ Regulation (Urology), Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [4]Department of Advanced Technology for Transplantation, Osaka University Graduate School of Medicine, Suita, Osaka, Japan.*

Background: Nonadherence (NA) to immunosuppressive agents is a major risk factor for allograft failure in kidney transplant recipients (KTRs). The aim of this study was to estimate the relative effect of daily dosing on treatment adherence, not to identify how patients are non-adherent, in long-term KTRs.

Methods: In January 2009, a cross-sectional, anonymous, and voluntary questionnaire survey was given to ambulatory KTRs. A self-reporting questionnaire underestimates NA, but we reasoned that the effect of the dosing regimen should be estimated with relative accuracy by using the generalized ordered logit/partial proportional hazard odds model given that the distribution patterns in the degree of NA have been shown to be similar with other measures.

Results: Of 336 eligible patients, 312 (92.9%) participated in this study. Two hundred seventy-four patients (87.8%) were more than 3 years post-transplant. Univariate analysis revealed that a single daily dose was significantly associated with better adherence. After controlling for age, sex, time since transplantation, and the number of prescribed drugs, the effect of single daily dose still remained significant (odds ratio, 0.40 [95% confidence interval, 0.20–0.83]; p = 0.013). Several sensitivity analyses yielded similar results.

Adjusted Odds Ratios for Single-daily Compared with Twice-daily Dosing

Adjusted covariates	OR	95% CI	p
age and sex	0.46	(0.23-0.91)	0.027
age, sex, and the number of prescribed drugs	0.47	(0.23-0.94)	0.033
age, sex, the number of prescribed drugs, and time since transplantation	0.40	(0.19-0.81)	0.011

Conclusions: A single daily regimen—one of few modifiable factors—might improve treatment adherence and allograft survival in long-term KTRs.

FR-PO934

Graft Loss among Kidney Diseases with a High Risk of Post-Transplant Disease Recurrence: The Size of the Problem in Pediatric Transplantation, Results on Behalf of the ESPN/ERA-EDTA Registry Karlijn J. Van Stralen,[1] Enrico Verrina,[2] Franz S. Schaefer,[3] Kitty J. Jager.[1] *[1]ESPN/ERA-EDTA Registry, Medical Informatics, Netherlands; [2]G Gaslini Hospital, Italy; [3]University of Heidelberg Center for Pediatrics and Adolescent Medicine, Germany.*

Background: Some kidney diseases tend to recur in the renal allograft after transplantation. We studied the risk of graft-loss among primary renal disease (PRDs) known for their high risk of recurrence and compared it to that of patients with hypoplasia or dysplasia.

Methods: Within the ESPN/ERA-EDTA registry, we studied children from 33 countries who received a kidney transplant before the age of 20 between 1990 and 2009. Patients were censored after 5 years of follow-up and cumulative incidence competing risk analysis was used to calculate survival curves.

Results: Patients with focal and segmental glomerulosclerosis (FSGS), haemolytic uremic syndrome (HUS), membranoproliferative glomerulonephritis type I or II (MPGN), primary Hyperoxaluria (oxalosis), IgA nephropathy or Henoch Schönlein (IgA/HS), or Systemic Lupus Erythomatosus (SLE) received significantly less often a pre-emptive transplantation as compared with patients with hypo/dysplasia. The rate of living donation was lower among patients with oxalosis, FSGS and SLE than in patients with hypo/dysplasia. Patients with FSGS had a 5-year risk of graft loss of 25.7%, while it was only 14.4% among hypo/dysplasia patients. The risk of graft loss was more strongly increased among FSGS children who started RRT aged 6-12 (27.7%), or >12 (32.4%) as compared to younger children (17.1%). Patients with MPGN (28.1%, type I; 22.5%, type II; 54.8%), and oxalosis (20.2%) also had significantly increased rates of graft loss, which remained after adjustment for age at start of RRT, time on dialysis, gender, and period of transplantation. No significantly different risks were found for patients with HUS (18.9%), IgA/HS (16.3%) or SLE (20.3%).

Conclusions: The risk of graft loss is increased among PRDs with a high risk of post-transplant recurrence. Physicians seem to anticipate on this higher risk of graft loss by performing less pre-emptive transplantation and providing fewer grafts from living related donors.

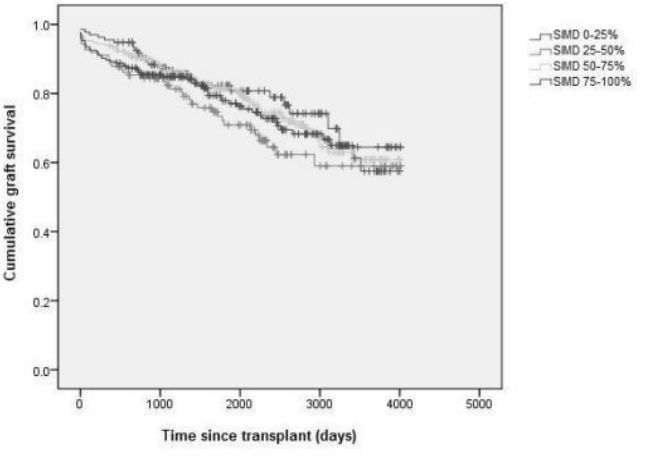
FR-PO935

Social Deprivation Does Not Affect Outcome Following Renal Transplantation Emma L. Aitken, Marc J. Clancy, David Kingsmore. *Department of Renal Surgery, Western Infirmary, Glasgow, United Kingdom.*

Background: Social deprivation is associated with increased mortality for patients on RRT. Similarly patients from lower socioeconomic categories have poorer access to transplantation. However the impact of social deprivation on outcomes following renal transplantation is unknown.

Methods: We undertook a retrospective analysis of all patients undergoing renal transplantation at a single centre serving the West of Scotland over a ten year period 2000-2010 (n=705). Postcode data permitted calculation of a Scottish Index of Multiple Deprivation (SIMD) score which was analysed in quartiles from 0-25% (least deprived) to 75-100% (most deprived). Outcome measures were graft loss, mortality, creatinine at 1 year, DGF and BPAR. Kaplan Meier survival analysis was undertaken ($p<0.05$ is significant). Results are presented as percentages of the total population in SIMD quartiles 0-25%, 25-50%, 50-70% and 75-100% respectively.

Results: Mean follow-up was 5.86+/-0.11 years. There was no difference in overall survival following transplantation depending on SIMD (89.6%, 87%, 88.4%, 90.2%; p=0.928). There was a trend towards improved graft survival in the least socioeconomically deprived however this was not significant (80%, 69.9%, 74.1%, 73.8%; p=0.34) (Figure 1). Similarly, there was a non-significant trend towards lower creatinine at 1 year in the least deprived patients (163.5+/-12.8, 211.7+/-19.5, 170.2+/-9.8, 197.1+/-6.9; p=0.07). There was no difference in rates of DGF (p=0.47) or BPAR (p=0.97) depending on socioeconomic status. The proportion of patients undergoing live donor transplantation was similar across the range of SIMD (23.9%, 27.6%, 25.5%, 21.8%; P=0.76).



Conclusions: Social deprivation does not affect either graft or patient survival after renal transplantation. Additionally it did not influence uptake of live donor transplantation in our patient population.

FR-PO936

Comparison between CKD-EPI and MDRD Equation in the Estimation of Renal Function before and after Kidney Donation in Kidney Donors Jeong Gwan Kim, Hyun Chul Whang, Myung Hyun Lee, Yul Hee Cho, Gun Hee An, Yu Ah Hong, Byung Ha Chung, Cheol Whee Park, Chul Woo Yang, Yong-Soo Kim, Bumsoon Choi. *Department of Internal Medicine, The Catholic University of Korea, Seoul, Korea.*

Background: The aim of this study is to investigate the usefulness of the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) formula to predict renal function in subject in kidney donor before and after kidney transplantation.

Methods: We analyzed the CKD-EPI formula in comparison to Modification of Diet in Renal Disease (MDRD) equation in 207 pontential kidney donors before KT and 71 donors after kidney donation. Correlation, bias, precision and accuracy within 30 % of measured GFR (mGFR) were determined. mGFR was measured by technetium-diethylenetriamine pentaacetic acid (^{99m}Tc-DTPA) clearance.

Results: Before kidney donation, both of the results of MDRD and CKD-EPI equations correlated well with GFR (0.49; 0.52, respectively). eGFR calculated by MDRD underestimated mGFR significantly (100.7 ± 20.4 vs. 110.3 ± 20.7 mL/min/1.73 m^2,P<0.01). In contrast, eGFR calculated by EPI (108.7 ± 18.0 mL/min/ 1.73 m^2) did not showed significant differences to mGFR (P=0.23). Accuracy within 30 % of mGFR was higher for CKD-EPI (91.8 %) compared to MDRD (84.1 %)(P<0.01). After kidney donation, remained kidney showed significantly higher GFR compared to before kidney donation. (58.1 ± 10.3 vs. 78.8 ± 15.7 mL/min/1.73m^2, P<0.01). Both of the results of MDRD and CKD-EPI correlated well with mGFR, the correlation coefficient was lower in EPI (0.48; 0.27, respectively). MDRD equation underestimate mGFR (71.9 ± 14.vs. 78.8 ± 15.7 5 mL/min/1.73 m^2, P<0.01), but eGFR calculated by CKD-EPI (76.9 ± 21.2 mL/min/1.73 m^2, P=0.951 vs. mGFR) did not show significant differences compared to mGFR. However, the accuracy of the CKD-EPI (67.6%) within 30% of mGFR was lower than the accuracy of the MDRD equation (83.3%)(P<0.01).

Conclusions: In potential kidney donor, the healthy population, CKD-EPI equation showed better performance compared to MDRD equation to predict mGFR. However, after kidney donation, in uninephrectomy state, it was inferior to MDRD equation to predict mGFR.

FR-PO937

Effect of Utility-Based Deceased Donor Kidney Allocation on Living Donor Transplantation Rates Philip A. Clayton,[1] Blair S. Grace,[1] Keith McCullough,[2] Robert Merion,[2] Alan B. Leichtman,[2] Scott Campbell,[3] Jenni Wright,[4] Jeremy Chapman,[4] Stephen P. McDonald,[1] Steven J. Chadban.[1] *[1]Australia and New Zealand Dialysis and Transplant (ANZDATA) Registry, Adelaide, SA, Australia; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Princess Alexandra Hospital, Brisbane, QLD, Australia; [4]National Organ Matching System, Sydney, NSW, Australia.*

Background: Allocation of deceased donor (DD) kidneys in order to maximise utility would preferentially allocate DD kidneys to younger, healthier recipients. An unintended consequence of such an allocation system may be to reduce the number of living donor (LD) kidney transplants performed.

Methods: We adapted the US Scientific Registry of Transplant Recipients Kidney-Pancreas Simulated Allocation Model software to simulate allocation of Australian DD kidneys. We constructed two simulations – one replicating the current Australian allocation rules, and a simple utility model that allocated kidneys nationally to the patient with the highest predicted benefit based on donor and recipient age, HLA match and peak PRA. We made a simplifying assumption that wait-listing practice and LD transplant planning were independent of allocation rules.

Results: The simulation included 4146 wait-listed patients and 1882 kidneys from 1043 donors over 06/28/06-12/31/10. Compared with the current rules the utility model allocated kidneys to younger patients (mean 39.7 vs 51.9 years, P<0.001) with fewer co-morbidities and more HLA mismatches. Of the wait-listed patients not allocated a DD kidney, the number of LD grafts fell from 454 to 359 and the LD graft recipients were older (56.5 vs 48.1 years, P<0.001) with more co-morbidities. The total projected life-years following DD transplant increased from 38,130 to 44,687, and projected life-years following LD transplant fell from 10,603 to 7,386. Expected survival of younger patients increased substantially at the expense of smaller reductions in the expected survival of older patients.

Conclusions: The simulated utility model for DD kidney allocation prioritised transplantation of younger patients with fewer co-morbidities, resulting in a fall in LD and thus total transplants in those wait-listed for a DD.

FR-PO938

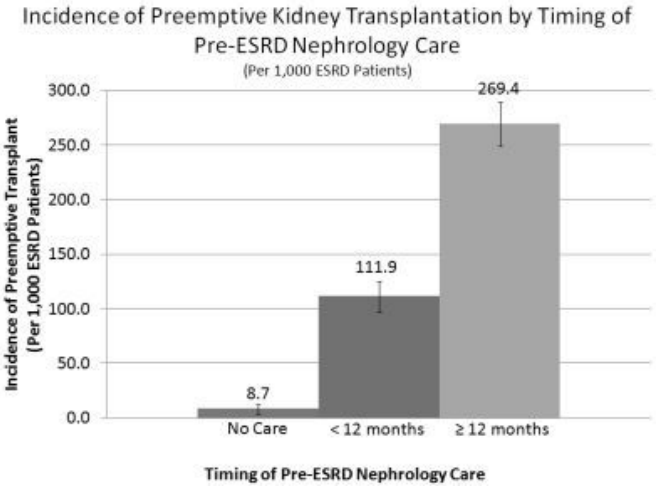
Access to Nephrology Care Prior to End Stage Renal Disease Is Associated with a Higher Incidence of Preemptive Kidney Transplantation among Pediatric Patients Rachel E. Patzer,[1,2] Nancy G. Kutner,[3] William M. McClellan,[2,4] Sandra Amaral.[5] *[1]Emory Transplant Center, Atlanta, GA; [2]Department of Epidemiology, Rollins School of Public Health, Atlanta, GA; [3]USRDS Rehabilitation/QoL Special Studies Center, Emory University, Atlanta, GA; [4]Division of Nephrology, Emory University School of Medicine, Atlanta, GA; [5]Department of Pediatrics, Children's Hospital of Philadelphia, Philadelphia, PA.*

Background: In 2005, the United States Renal Data System (USRDS) began collecting information about whether ESRD patients received care from a nephrologist prior to ESRD. It is unknown how pre-ESRD nephrology care impacts access to preemptive kidney transplant (PKT) in children with ESRD.

Methods: We examined all incident pediatric (< 21 yrs) ESRD patients 2005-2009 in USRDS. Multivariable logistic regression was used to calculate odds ratios (OR) for PKT by timing of pre-ESRD nephrology care.

Results: Among 5,776 pediatric ESRD patients, 741 patients (12.8%) received a preemptive kidney transplant. The incidence of PKT was significantly higher among patients who had more than 12 months of pre-ESRD nephrology care (269.4 transplants per 1,000 ESRD patients; 95% CI: 249.5 - 290.1) compared to those with < 12 months (111.9 per 1,000 ESRD patients; 95% CI: 98.2-126.8) and no (8.7 per 1,000 ESRD patients; 95% CI: 5.1 - 13.9) pre-ESRD nephrology care (p<0.0001). Pediatric ESRD patients with nephrologist care within 12 months prior to ESRD had an adjusted odds of PKT 17 times higher than patients without access to pre-ESRD nephrology care (OR=17.6; 95% CI: 10.3-29.8). Patients with more than 12 months of nephrology care prior to ESRD had an adjusted odds of PKT 24 times that of patients with no access to pre-ESRD nephrology care (OR=23.9; 95% CI: 13.9-41.7).

Conclusions: In the US, access to pre-ESRD nephrology care significantly influences the likelihood of receiving a PKT among pediatric ESRD patients.



FR-PO939

Medication Adherence, Treatment Understanding, and Health Literacy in Kidney Transplant Recipients Rachel E. Patzer,[1] Marina Serper,[2,3] Jennifer King,[3] Kamila Przytula,[3] Titilayo O. Ilori,[1] Audra R. Williams,[1] Daniela Ladner,[2] Michael S. Wolf.[3] *[1]Emory Transplant Center, Emory University School of Medicine, Atlanta, GA; [2]Comprehensive Transplant Center, Northwestern University Feinberg School of Medicine, Chicago, IL; [3]Health Literacy and Learning Program, Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Kidney transplant (KT) recipients must take complex drug regimens and lifelong immunosuppression to maintain graft function. Little is known about health literacy, medication adherence, and treatment understanding in KT recipients.

Methods: Structured interviews were conducted with 28 KT recipients at two transplant centers in Chicago, IL and Atlanta, GA from January to May 2012. Basic demographics, health literacy (as measured by the Rapid Estimate of Adult Literacy in Medicine), cognitive function, medication adherence, treatment understanding, and drug regimen consolidation were assessed.

Results: Table 1 shows demographic and baseline characteristics of the study sample.

Demographics and Baseline Characteristics (N=28)	N (%)
Male	16 (57.1%)
Age, mean (SD)	51.3 (±13.7)
Race/Ethnicity	
White	15 (53.6%)
Black	9 (32.1%)
Hispanic	4 (14.3%)
Income < $50,000	19 (67.9%)
Months from KT, median (IQR)	38 (17.5, 60.5)
Number of daily medications, median (IQR)	9 (7,12)
Inadequate Health Literacy	9 (33.3%)

Patients were taking a median of 9 medications and 19.6% had a medication change within the previous month. A total of 28.6% of patients were non-adherent with at least one medication as measured by self-report. 33.3% of the study sample had limited health literacy. One-fourth of patients demonstrated inefficient dosing and spacing of at least one medication and 21.4% were unable to identify the indication for specific medications. Factors associated with non-adherence included lower health literacy, minority race, female gender, and lower income(p=< 0.05).

Conclusions: This is the first study to deconstruct the knowledge and skills of KT recipients for managing complex medication regimens. Limited health literacy was prevalent and associated with self-reported nonadherence. This is an actively ongoing study with a target enrollment of 100 participants planned by Fall 2012.

FR-PO940

Trends in Kidney Donor and Recipient Risk in the Era Surrounding Initiation of Medicare Conditions of Participation Sarah L. White,[1,2] Dawn Zinsser,[1] Matthew Paul,[1] Gregory Levine,[1] Tempie H. Shearon,[1] Valarie B. Ashby,[1] John C. Magee,[1,3] Alan B. Leichtman.[1,2] *[1]Kidney Epidemiology and Cost Center, University of Michigan, Ann Arbor, MI; [2]Department of Medicine, Division of Nephrology, University of Michigan, Ann Arbor, MI; [3]Department of Surgery, Section of Transplantation, University of Michigan, Ann Arbor, MI.*

Background: In 2007, the US Centers for Medicare and Medicaid Services implemented Conditions of Participation (CoPs) for organ transplant programs, under which programs not attaining specified one-year survival rates are flagged for review. Case-mix is accounted for in the review process, yet anecdotal reports suggest that increased oversight may have prompted some programs to modify their organ and candidate selection criteria.

Methods: Data for the 221 adult kidney transplant programs active in 2007 were collated from CMS ESRD and Medicare claims and the SRTR database. Programs were classified according to whether they were flagged in any of the program-specific reports (PSR) released after the CoPs went into effect. A Cox proportional hazards model of one-year graft survival was constructed based on the July 2007 PSR cohort, and this model used to derive expected hazards for all adult deceased-donor kidney transplants between 2001 and 2010.

Results: Relative to the 2007 case-mix, from 2001 to 2010 the program average risk of one-year graft loss increased 6% (P<0.0001) due to donor characteristics, and 7% (p<0.0001) due to recipient characteristics. No inflection in donor or recipient risk was observed coincident with the introduction of the CoPs.

Conclusions: Trends in average program risk of one-year kidney graft loss do not support the assertion that the introduction of CoPs has reduced overall opportunities for marginal candidates or that there has been a systematic shift away from utilization of higher-risk deceased donor kidneys.

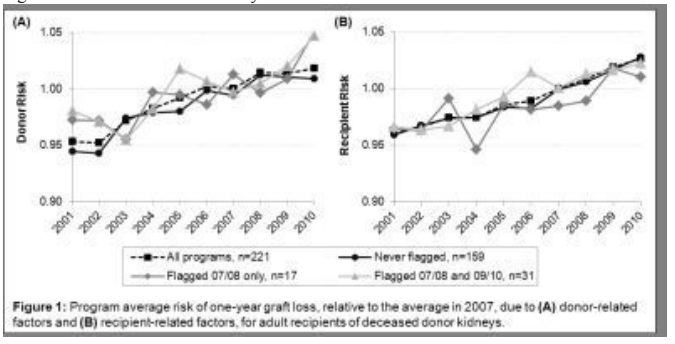

Figure 1: Program average risk of one-year graft loss, relative to the average in 2007, due to **(A)** donor-related factors and **(B)** recipient-related factors, for adult recipients of deceased donor kidneys.

FR-PO941

Pre-Transplant Virtual PRA and Long-Term Outcomes of Kidney Transplant Recipients Lu Y. Huber,[1] Nils Lachmann,[2] Matthias Niemann,[2] Marcel Naik,[1] Danilo Schmidt,[1] Lutz Liefeldt,[1] Hans-Hellmut Neumayer,[1] Constanze Schönemann,[2] Klemens Budde.[1] *[1]Medizinische Klinik m. S. Nephrologie, Charité - Universitätsmedizin Berlin, Berlin, Germany; [2]HLA-Labor, Institut für Transfusionsmedizin, Charité - Universitätsmedizin Berlin, Berlin, Germany.*

Background: Virtual panel reactive antibody(vPRA) is being implemented worldwide to gauge sensitization against HLA antigens. Its impact on longterm outcomes is however largely unknown.

Methods: Data from all 18-65 years(y) kidney-only transplantation(Tx) performed 1.1.1996-31.7.2011 in our centre were collected. vPRA was calculated based on antibody specification by solid phase techniques. Patients(pts) were divided into nonsensitized(NS, <5%), low(LS, 5-50%) or high sensitization(HS, >50%) group based on pre-Tx vPRA.

Results: Total of 896 Tx were performed during this period, 726 cases had vPRA available. There were 617(85%), 44(6%) and 65(9%) cases in NS, LS and HS group, respectively. More females(P=0.002) were in LS(45.5%) and HS(56.9%) than in NS group(34.6%), and more had previous Tx (69.2% in HS, 54.5% in LS, 7.3% in NS, P<0.001). The HS group had longer waiting time(4.6±3 vs. 2.9±3(LS) and 2±2.6y(NS), P< 0.001) and less living donation(9.2% vs. 27.3%(LS), 38.1%(NS), P< 0.001). Sensitized pts had more delayed graft function(38.3% (HS), 31.8%(LS), 17.5%(NS), P<0.001), biopsy proven rejection(12.3%(HS), 18.2%(LS), 7.1%(NS), P=0.017) and shorter followup(4±3.3(HS), 4.2±3.1(LS) and 5.8±3.9y(NS), P<0.001). Post-Tx donor specific antibody was more frequent in HS(35.4% vs. 18.2%(LS), 17.2%(NS), P<0.001). Sensitized group had lower GFR than NS in the first 3y. HS and LS had significantly lower death-censored and non-death censored graft survival(death-censored, 8y: 79%(NS), 57.1%(LS), 62.8%(HS), P< 0.001; non-death-censored: 8y, 78%(NS), 49.6%(LS), 45.9%(HS), P< 0.001), but patient survival rates were not different(8y: 77.0-88.9%, P=0.243), all were significantly better than N=704 waitlisted pts (69%, P< 0.001).

Conclusions: Sensitized pts defined by vPRA show higher graft losses but similar pts survival compared with non-sensitized pts. Level of vPRA does not proportionally correlate to the outcome.

FR-PO942

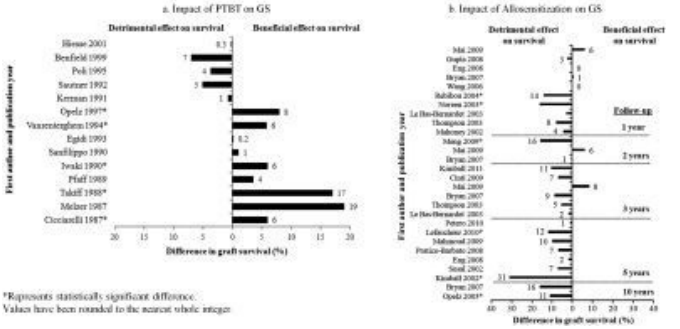
A Systematic Review on the Impact of Pre-Transplant Transfusions and Allosensitization on Allograft Survival Jeffrey Petersen,[1] Juan Scornik,[2] Jonathan Bromberg,[3] Douglas J. Norman,[4] Mayank Bhanderi,[5] Matthew Gitlin.[1] *[1]Amgen Inc.; [2]University of Florida; [3]University of Maryland; [4]Oregon Health & Science University; [5]HERON Health.*

Background: A recent review conducted by the Agency for Healthcare Research and Quality suggested that pre-transplant blood transfusion (PTBT) had a neutral to beneficial effect on graft survival (GS) compared with no transfusion. This review does not address the potential causative pathways of PTBT on outcomes, selection bias, or improvement in graft survival with newer immunosuppressive agents.

Methods: We performed a systematic review to examine the impact of: 1) PTBT on GS; 2) PTBT on allosensitization (the presumed causative pathway) and 3) resulting allosensitization on GS. A search conducted using MEDLINE®, Embase®, and the Cochrane Library for English-language publications identified 7,494 records from which 180 studies met eligibility criteria. Data were summarized descriptively and interpreted clinically.

Results: While many older studies demonstrated a beneficial effect of PTBT on GS, the magnitude of benefit has diminished over time, with most recent evidence suggesting a trend towards a neutral to detrimental effect of PTBT on GS (Figure 1a). PTBT increases the risk of allosensitization (data not shown). Recent data for a 10-year period indicate that allosensitization leads to graft rejection (data not shown) and poor GS (Figure 1b).

Figure 1. Impact of PTBT and Allosensitization on GS



Conclusions: Based on more recent literature, PTBT may be neutral to detrimental when current immunosuppressive regimes are taken into account, thus avoiding PTBT when possible is a sound management option that prevents a number of detrimental effects in patients awaiting a kidney transplant. The design and evaluation of systematic reviews can benefit from clinical judgment.

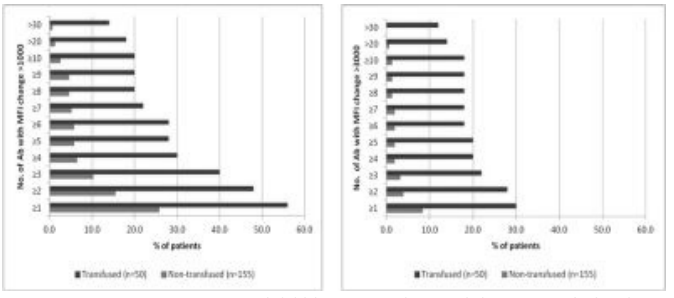
FR-PO943

RBC Transfusions Are Associated with Allosensitization in Patients Awaiting Kidney Transplantation Julie M. Yabu,[1] Matthew W. Anderson,[2] Deborah Kim,[3] Brian D. Bradbury,[3] Calvin D. Lou,[2] Jeffrey Petersen,[3] Jerome A. Rossert,[3] Glenn M. Chertow,[1] Dolly B. Tyan.[2] *[1]Medicine, Stanford Univ, Palo Alto, CA; [2]Pathology, Stanford Univ, Palo Alto, CA; [3]Amgen, Thousand Oaks, CA.*

Background: Human leukocyte antigen (HLA) sensitization is a major barrier to successful kidney transplantation resulting in prolonged wait times and decreased graft survival. This study determined the association of transfusions with the breadth, magnitude and specificity of HLA antibody (Ab) formation using highly sensitive and specific methods.

Methods: We linked demographic, comorbidity and transfusion data from United States Renal Data System (USRDS) with HLA Ab data obtained from Luminex single antigen beads for dialysis patients (pts) awaiting primary kidney transplant. We required pts to have ≥2 HLA Ab measurements. We matched pts who had a transfusion event between 2 Ab measurements (transfused group) with up to 4 non-transfused pts (non-transfused group) by age, sex, race, transfusion history and time on dialysis. We compared changes in mean fluorescence intensity (MFI) and specificities in Ab measurements for transfused and non-transfused pts.

Results: Of 654 pts with ≥2 HLA Ab measurements, there were 50 transfused pts and 155 non-transfused pts. The proportion of pts with change in MFI>1000 and >3000 for ≥1 HLA Ab was significantly higher for transfused compared to non-transfused pts (Fig 1): 20% of transfused vs 3% of non-transfused pts had ≥10 HLA Ab with MFI increase >1000 (p<0.0001); 18% of transfused vs 1% of non-transfused pts had ≥10 HLA Ab with MFI increase >3000 (p<0.0001). The association of transfusion with HLA Ab remained after controlling for other potential sensitizing events.



Conclusions: Among potential kidney transplant recipients, transfusion is an independent risk factor and results in significant increase in HLA Ab strength and breadth.

FR-PO944

Antibody-Mediated Rejection in Pediatric Kidney Allograft Recipients: Risk Factor Analysis Jiwon L. Lee,[1] Yo Han Ahn,[2] Su Jung Park,[1] Hye Jin Chang,[1] Sang Taek Lee,[1] Hye Won Park,[3] IL-Soo Ha,[1] Hae Il Cheong,[1] Hee Gyung Kang.[1] *[1]Department of Pediatrics, Seoul National University Children's Hospital, Seoul, Korea; [2]Center for Pediatric Oncology, National Cancer Center, Goyang-si, Gyeonggi-do, Korea; [3]Health Promotion Center, Seoul National University Bundang Hospital, Bundang, Gyeonggi-do, Korea.*

Background: Antibody-mediated rejection(AMR) is an important cause of graft dysfunction. Non-adherence to drugs and disturbed quality of life are reported to be related to rejection in childhood. The present study compared two groups of kidney rejection, a group with AMR and the other with acute cell mediated rejection(ACR) to investigate risk factors of AMR.

Methods: Retrospective review of allograft recipients(n=138) of the last decade in our hospital was done. Acute rejection was in 49. Excluding protocol biopsies(n=22), there were 7 of AMR, 3 of ACR and 17 of borderline T-cell mediated rejection. Factors including age at transplantation, gender, donor types, HLA mismatches, puberty, socioeconomic status(SES) and compliance were analyzed to compare the AMR group and ACR/borderline group.

Results: While the mean age at rejection were comparable(15.8 years(yrs) vs. 15.5 yrs), AMR group was younger at transplantation(mean age 9.5 vs. 12.6 yrs). One of AMR was diagnosed in ten years after transplant and the rest in 5.6 yrs, after some period of poor compliance, coinciding with family crisis such as divorce or economic collapse. Six (85.7%) AMR patients showed poor compliance while 2(12.5%) of ACR/borderline had the problem. The donor type or HLA mismatch did not show significance. Rejection was treated with methylprednisolone and additional intravenous immunoglobulin, plasmapheresis, and rituximab were given for AMR. At follow-up, 3 of AMRs (43%) were losing their graft (eGFR<15 mL/min/1.73m^2) in 3.5 months after rejection, while 1 ACR lost his graft in 12 months.

Conclusions: Here we found that AMR in pediatric patients developed in those with poor compliance with low SES. While further study is necessary, we suggest that better surveillance and multi-disciplinary support is required to help our patients to keep adherence to their medication, thus may reduce AMR from low compliance.

FR-PO945

Removing HLA Antibodies: What Is the Best Technique? Nicolas Maillard,[1] Manolie Mehdi,[1] Ingrid Masson,[1] Lena Absi,[2] Christopher R. Mariat.[1] *[1]Nephrology, Dialysis, Transplantation, CHU Saint Etienne, Saint Etienne, France; [2]Laboratoire d'Histocompatibilité, Etablissement Français du Sang Auvergne Loire, Saint Etienne, France.*

Background: Antibody mediated rejection represents one of the main cause of graft loss. Several techniques to clear HLA antibodies are available such as plasma exchange methods (PE) and protein A based immunoadsorption (IA). The aim of our study was to compare the performances of PE and IA to lower HLA antibodies concentration.

Methods: Pre-transplant candidates or renal transplant patients presenting an indication of HLA desensitization were non randomly allocated to IA (one single session of 100 mL/kg) or PE (3 consecutive daily PE sessions of 45 mL/kg/session). Single antigen Luminex assays were performed on sera obtained before and immediately after the PE or IA treatment. Concentration of each anti-HLA antibody was estimated by measuring the Mean Intensity of Fluorescence (MFI).

Results: Thirteen patients were allocated to the PE group allowing the analysis of 253 HLA antibodies. In the IA group, 2 patients underwent 9 non-consecutive sessions allowing the analysis of 157 HLA antibodies. MFI were significantly reduced after both types of treatment: from 3518 to 1638 and 5475 to 2330 for the IA group and the PE group, respectively ($p<0.001$) with a similar relative reduction for both treatment (-65,4% and -65,0%, ns). However while class I antibodies were more efficiently removed in the IA group (-72% vs. -69%, p=0.01), the relative MFI reduction for class II antibodies was more pronounced in the PE group (-32% vs -50%, p=0.006). Surprisingly, some of anti- class II antibodies had a higher MFI immediately after treatment. This phenomenon occurred significantly more frequently after IA (20% vs 10% of HLA antibodies, p=0.02) and was abolished by pre-treating sera with DDT.

Conclusions: This study is the first one that compares the efficiency of IA against PE to lower MFI levels of HLA antibodies, using a single antigen Luminex assay. The global efficacy is equivalent between one single high volume IA session and 3 daily consecutive PE sessions. The apparent lack of efficacy of IA on class II antibodies was due to a C1q prozone effect.

FR-PO946

Low Long-Term Antibody Formation and Preserved Kidney Allograft Function with an "Aggressive" Chronic Immunosuppression Protocol Mita M. Shah, Jennifer C. Joliat, Janice Kerr, Robert W. Steiner. *UC San Diego.*

Background: Recent studies suggest that de novo anti-donor antibody (DSA) is a major threat to kidney transplant (KT) survival, and on balance higher CNI exposure may improve outcomes. This study evaluated the rate of DSA formation in a KT recipient (KTR) population that has been maintained on an aggressive immunosuppression (IS) protocol.

Methods: Our long term KT clinic is strictly protocolized, with target trough TAC levels 8-10 ng/ml or CSA 2 hour levels 800-1000 ng/ml, prednisone at 0.1 mg/kg, and MMF 500-750 BID for all patients. IS is not tapered for KTRs who are "doing well". Importantly, empty-stomach CNI dosing is reinforced with all KTRs, improving CNI AUC by 30- 40%, with minimal effect on trough levels. We collected DSA in 61 KTRs perceived to be at higher risk for chronic rejection while maintained on CNIs (11 AA, 27 Hispanic).

Results: At the time of DSA determination, TAC trough levels were 8.3 +/- 2.0 ng/ml and CSA 2 hour levels 811 +/- 217 ng/ml. In the DSA- group who were 3.4 +/- 4.2 yrs post-transplant, serum Cr was 1.5 +/- 0.5 mg/dL with urine protein/creatinine ratio (UP/C) of 0.2 +/- 1.1. Of 61 KTRs, only 4 (7%) had detectable DSA at a mean of 5.6 +/- 2.75 post-transplant yrs, with serum Cr 1.5 +/- 0.3 mg/dL and UP/C of 0.14 +/- 3.7. Three DSA+ KTRs with an acute rejection due to noncompliance were excluded. In the total clinic population of ~400 KTRs, occasional BK viremia occurs with standard IS and is treated with tailored IS reduction. In this population, we documented 2 uneventful cases of CMV viremia and 1 severe CMV infection in a KTR who had TAC exposure above that dictated by protocol. Among all biopsies performed for cause, only 1 suggested CNI toxicity.

Conclusions: The DSA+ rate in KTRs maintained on our "aggressive" IS protocol was 7%; this compares well to the 10-30% prevalence of published DSA positivity in unselected KTRs during long-term follow-up. DSAs were more often surveyed in KTRs felt to be at high risk; thus this rate may represent a worst case outcome. We continue to develop and analyze our database, but such studies of DSA formation under a protocolized IS regimen may help determine optimally effective chronic regimens.

FR-PO947

Does Virtual Cross Matching Affect Outcomes in Renal Transplantation? A 2 Year Experience in Glasgow, UK Matthew Wickham, Emma L. Aitken, Marc J. Clancy. *Renal Transplant Unit, NHS Greater Glasgow and Clyde, Glasgow, United Kingdom.*

Background: Cold Ischaemic Time (CIT) is well established as a key risk factor for Delayed Graft Function (DGF), which is an important predictor of both short and long-term graft outcomes[1]. This study aims to assess the impact of the introduction of virtual cross matching (vXM) in our renal transplant unit.

Methods: vXM was introduced in May 2010. A prospective comparison of all subsequent deceased donor transplants is presented. All live donor transplants were excluded.

Outcome measures were CIT, DGF and creatinine at 6 months. DGF was defined as either dialysis required beyond day 1 or failure of creatinine to fall by 50% in the first week post transplant.

Results are presented as mean +/- SEM. Student's t-test was used to compare continuous variables and x^2 test to compare categorical data ($p<0.05$ is significant).

Results: A total of 140 deceased donor transplants were performed. 74 (52.9%) had a vXM. 6-month follow up data was available for 100 transplants, of which 52 had a vXM. There was no significant difference between the numbers of DCD/DBD transplants with a vXM or full cross matching.

Demographic parameters were otherwise equivalent. CIT was significantly shorter in patients who had a vXM (9.94+/-0.43hr vs. 15.25+/-2.74; p=0.04). DGF was less likely in patients transplanted with a vXM compared to full XM (36.7% vs. 47%; p=0.007).

However, no difference was seen between vXM and full XM in 6-month creatinine (153.73+/-17.2µmol/l vs. 140.52+/-20.2 ; p=0.75) or all cause mortality (0% vs. 2.1%; p=0.48). There was a trend towards improved 6 month graft survival in patients with vXM however this was not statistically significant (98.1% vs 89.6%; p=0.1).

Conclusions: Virtual cross matching significantly reduces the CIT and DGF in deceased donor transplantation, however this does not have an identifiable impact upon graft function at 6 months.

Increased numbers and longer follow up will be required to confirm any beneficial effect on long term graft/patient survival.

FR-PO948

List Paired Exchange Reduces Waiting Times for Kidney Transplantation
Muhammad Saim, Dhiren Kumar, Martha Behnke, Anne L. King. *Department of Transplant Nephrology, Virginia Commonwealth University, Richmond, VA.*

Background: Waiting times on the list have continued to increase over the past decade. Living donor (LD) transplantation can address this long waiting time issue but donor-recipient incompatibility is a major obstacle to (LD) kidney transplantation. In list paired exchange, an incompatible LD provides a kidney to a candidate on the deceased donor (DD) waiting list in return for which the living exchange recipient receives priority on the DD waiting list.

Methods: We retrospectively compared the variance living kidney recipients (VLD) to direct living kidney (LD) recipients and the variance deceased donor (VDD) recipients to the standard criteria deceased donor (SCDD)recipients from October 2004 until August 2011 during which time 19 list paired exchanges were performed at our center.

Results:

Table 1

	VLD	LD	VDD	SCDD
N	19	341	13	389
Race AA	10 (52.6%)	153 (44.9%)	6 (31.6%)	287 (73.8%) *
Age	43.8 +/- 10.1	46.1 +/- 13.4	50.9 +/-12.7	48.6 +/- 12.9
Retransplant	2 (10.5%)	27 (8%)	1 (5.3%)	52 (13.4%)
PRA	13 +/- 18.8	17.3 +/- 26.0	15.9 +/- 24.0	41.1 +/- 38.7 *
Donor Age	42.9 +/- 14.1	40.1 +/- 11.2	25.8 +/- 10.2	34.0 +/- 14.9 *
Wait List (days)	755 +/- 322	305 +/- 368 *	313+/- 252	624 +/- 491 *
CIT	23.3 +/- 6.1	28.3 +/- 23.4	856 +/- 471	1093 +/- 453 *
DGF	2 (10.5%)	15 (4.4%)	3 (15.8%)	174 (44.7%) *
Patient Survival				
1 yr	94.3 +/- 5.6	93.4 +/- 0.4	100	98.4 +/- 0.7
5 yr	94.3 +/- 5.6	89.3 +/- 2.1	100	90.0 +/- 2.1
Death censored graft survival				
1 yr	100	98.8 +/- 0.6	100	95.1 +/- 1.1
5 yr	82.8 +/- 11.1	84.7 +/- 2.4	92.9 +/- 6.9	77.9 +/- 2.9

*p value < 0.05

There was no difference between the VLD and LD groups in any of the parameters. The VDD recipients had a significantly shorter waiting time and lower DGF rate but equivalent graft and patient survivals when compared to the SCDD recipients. The mean time to transplant for the VDD after VLD was 37.5 days.

Conclusions: Variance donation was beneficial to both the VLD and the VDD recipients and produced equivalent patient and graft survivals. This strategy resulted in the availability of high quality living donor kidneys with excellent outcomes for all groups and can be considered as another strategy to address the organ donor shortage.

FR-PO949

Preemptive Plasmapheresis (PP) and CMVIg Improves Survival in Highly Sensitized Renal Transplant Recipients
Anne L. King,[1] Amit Sharma,[2] Qing Ren,[1] Martha Behnke,[2] Pamela Kimball,[2] Todd W. Gehr.[1] *[1]Nephrology, VCU, Richmond, VA; [2]Surgery, VCU, Richmond, VA.*

Background: Kidney transplantation in the highly sensitized recipient carries with it an increased risk of rejection and poor graft survival. We developed a unique scoring system to standardize our approach to the use of preemptive adjuvant PP/CMVIg following deceased donor kidney transplantation in highly sensitized (PRA>50, FCXM>100 channel shifts) but lymphocytotoxic crossmatch negative recipients.

Methods: We retrospectively analyzed all highly sensitized adult deceased donor kidney transplant (KT) recipents at our center from 2006-2009 who were enrolled in this preemptive algorithm and compared them to a historical cohort (2000-2006) who did not receive preemptive adjuvant PP/CMVIg. Standard immunosuppression consisted of 4 doses of rabbit antithymocyte globulin with tacrolimus, mycophenolate mofetil, and steroids. Pateints were scored on a number of parameters at the time of KT including: PRA>50(1point), FCXM>100(1 poimt), FCXM>200(2 points), DGF(1 point). Patients with scores >3 points received preemptive PP/CMVIg(150 mg/kg) thrice weekly for 2 weeks beginning on the first preoperative day.

Results:

Pre- versus Post Protocol PP-CMVIg

	PreProtocol(n=54)	Protocol(n=40)	p-value
Length of Stay(d)	11.1(9.1)	8.2(4.2)	0.06
Delayed Graft Function	36(66.7%)	28(70%)	0.82
rejection 1st year	33(61.1%)	8(20%)	<0.0001
SCr 1 year	2.2(1.9)	1.5(0.5)	0.03
SCr 3 year	1.8(1.0)	1.5(0.6)	0.09
Patient survival 1 yr	92.3(3.6)	97.5(2.5)	<0.005
Patient survival 3 yr	83.3(5.1)	91.7(4.6)	<0.005
Graft survival 1 yr	83.3(5.1)	95.0(3.5)	<0.005
Graft survival 3 yr	68.5(6.3)	89.9(4.8)	<0.005

Mean(SD)

Conclusions: The addition of preemptive PP/CMVIg to a standard immunosuppressive regimen conferred a survival advantage for highly sensitized patients compared to a historical cohort in this single center study. This strategy should be more extensively evaluated in a multicenter trial. This algorithm can be easily applied at the time of kidney transplantation with excellent outcomes in this very high risk patient population.

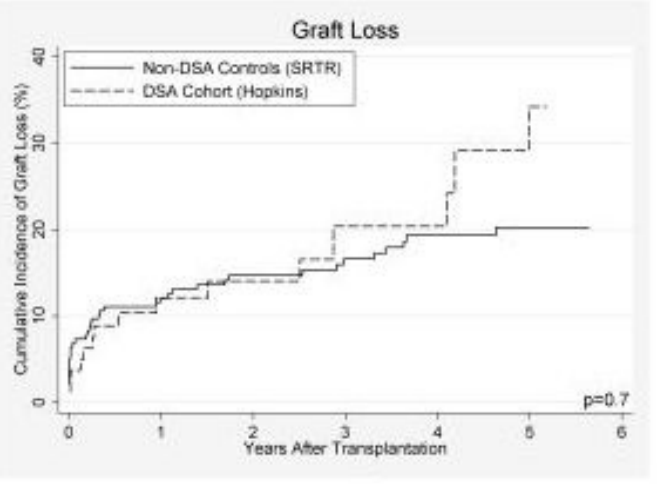
FR-PO950

The Outcome of Deceased-Donor Kidney Transplantation with Preformed Donor Specific Antibodies
John R. Montgomery, Andrew Lawrence Singer, Dorry L. Segev, Niraj Desai, Edward S. Kraus, Gaurav Gupta, Nabil N. Dagher, Robert Avery Montgomery, Hamid Rabb, Nada Alachkar. *Johns Hopkins University.*

Background: Successful live donor kidney transplantation with positive crossmatch has been achieved by utilizing desensitization therapy. Data is limited, however, on the treatment and outcome of deceased donor kidney transplant (DDKT) with preformed donor specific antibody (DSA). We report the outcome of these patients at our institution.

Methods: We identified 80 patients from 2000-2012 who underwent negative cytotoxic-crossmatch DDKT, but found to have DSA (Hopkins-DSA) at time of transplant. These patients were treated preemptively with plasmaphersis and low-dose IVIG ± rituximab immediately after transplantation to prevent DSA escalation and antibody mediated rejection (AMR). We compared this group with matched DDKT controls from the Scientific Registry of Transplant Recipients (SRTR-non-DSA). Subgroup analyses among Hopkins patients, Hopkins-DSA vs. Hopkins-non-DSA (n=1084), were performed to compare allograft function and rejection rate.

Results: When compared with SRTR-non-DSA controls, long-term patient survival of Hopkins-DSA (P=0.2) and graft survival (P=0.7) were comparable.



Comparing with Hopkins-non-DSA, there was a higher incidence of biopsy-proven AMR (31.2 vs. 5.1%, P<0.001) and cellular rejection (50.6 vs. 29.6%, P<0.001) in Hopkins-DSA. Additionally, there was increased chronic glomerular injury manifested on biopsies as chronic transplant glomerulopathy (33.3% vs. 20.0%, P=0.006). Allograft function, was similar after one year in the two groups.

Conclusions: Despite higher rates of acute and chronic rejection in positive DSA group, our data demonstrates equivalent long-term graft and patient survival to DDKT recipients without DSA. This can be achieved by preemptive plasmapheresis and low-dose IVIG ± rituximab along with close DSA monitoring.

FR-PO951

The Clinical Outcome of ESRD Patients Who Return to Peritoneal Dialyssi after Renal Allograft Failure
Keunsuk Yang, Hae Min Lee, Jeong Gwan Kim, Byung Ha Chung, Bumsoon Choi, Cheol Whee Park, Yong-Soo Kim, Chul Woo Yang. *Division of Nephrology, Department of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, Seoul, Korea.*

Background: With the increase of the accumulating numbers of kidney transplantation, the number of patients who return to dialysis after graft loss (DAGL) has increased The aim of this study is to investigate the safety and efficacy of peridoneal dialysis (PD) after graft loss compared to transplant naive PD patients.

Methods: This study is conducted on 714 patients who started PD in Seoul St. Mary's between 1988 and 2009. Out of them 47 patients of them belong to DAGL group while remained 667 patients were transplant-naive PD (TN-PD) group. We compared the overall patient survival rate and the clinical outcome of PD.

Results: The mean age was 40.8±10.7 in DAGL group and it was51.03±14.20 in TN-PD group (P<0.01). In comparison of primary renal disease, the distribution of it showed significantly different pattern (P>0.05). The most common cause of ESRD in DAGL was primanry glomerulonephritis (76.6 %) but it was diabetes mellitus (38.9 %) in TN-PD group. Patient survival rate was not significantly different between two groups. The 1, 5, 10 year patient survival rate was 100%, 86% and 57 % in DAGL group, respectively and they were 92%, 71% and 62% in TN-PD group, respectively. PD survival rate did not show significant differences between two groups as well. The 1, 5 and 10 year PD survival rate were 98%, 95% and 88 % in DAGL group respectively, and they were 95%, 80% and 66 % in TN-PD group, respectively. The most common cause of death in both groups were infection (DAGL :26.7 % TN-PD : 25.8 %) and cardiovascular disease (DAGL : 18.7 %, TN-PD :18.7%), and the distribution of the cause of death did not differ significantly. (P>0.05) The most common cause of PD failure was peritonitis and tunnel infection in both group, and the distribution did not differ between two groups as well. (P>0.05).

Conclusions: In conclusion, the clinical outcome of PD in DAGL group is comparable with that of TN-PD patients. Therefore, PD could be considered for dialysis modality in patients who experienced allograft failure.

FR-PO952

Impact of Nephrologists' Training and Education on Referral for Transplantation Nasrollah Ghahramani. *Medicine (Nephrology), Penn State College of Medicine, Hershey, PA.*

Background: Transplantation (Tx) is the treatment of choice for the majority of patients with ESRD. There is wide variation in the rate of referral for kidney Tx. A key component of the Tx process is the referral by the primary nephrologist. The objective of this study is to evaluate the impact of nephrologists' training and continuing medical education (CME) on referral of patients for Tx.

Methods: Invitations to participate were mailed to 2100 nephrologists practicing in the Mid-Atlantic and Southeastern States. Of these, 822 expressed interest. Two-hundred-fifty nephrologists were randomly selected and invited to complete a survey (online or paper) consisting of questions probing demographics, practice characteristics and perception of suitability for Tx. A total of 206 nephrologists completed the survey. Excluding responses from 19 Tx nephrologists yielded 187 responses. Chi-square and stepwise logistic regression were performed. Variables in the model included: age, race, gender, location, Tx training during fellowship, attendance at major national nephrology meetings and at Tx-related CME sessions.

Results: attendance at > 3 of the national nephrology meetings over the previous 5 yearswas associated with higher likelihood of referral for Tx at an earlier stage (OR:1.56; 95% CI: 1.07 to 2.28; p=0.02). Having received > 4 months of Tx training during fellowship was also associated with earlier referral (OR:2.94; 95% CI: 1.09 to 7.95; p=0.03) and higher likelihood of withholding referral due to the concern about patient's lack of understanding (OR:1.29; 95% CI: 1.05 to 1.59; p=0.01). Nephrologists who regularly attended Tx-related CME activities were more likely to have an established protocol and at least one designated nurse coordinator for workup and referral of the Tx candidate (OR:1.47; 95% CI:1.02 to 2.10; p=0.03).

Conclusions: The training and continuing education that nephrologists receive play a significant role in establishing an infrastructure for patient referral for Tx. Training is associated with earlier and more selective Tx referral with an emphasis on the patient's understanding of the process.

FR-PO953

The Clinical and Molecular Phenotype of Non-Adherence in Kidney Transplant Patients Gunilla Einecke,[1] Jeff Reeve,[2] Joana Sellares,[3] Philip F. Halloran.[2] *[1]Nephrology, Medical School Hannover, Hannover, Germany; [2]Alberta Transplant Applied Genomics Centre, University of Alberta, Edmonton, Canada; [3]Nephrology, Hospital Vall d'Hebron, Barcelona, Spain.*

Background: We assessed the clinical presentation of non-adherence (NA) and the corresponding histologic and molecular features in 403 allograft biopsies (Bx) for clinical indication in 315 kidney transplant patients (pts) 6 days to 32 years post Tx.

Methods: Concerns about NA at or before Bx were recorded by the attending clinicians in 22/280 pts whose charts were available for review.

Results: 82/280 kidneys (29%) progressed to failure. Despite similar GFR at Bx, pts with NA had lower GFR 6 months after Bx (46±33 vs 55±23) and higher rates of graft loss (73% vs 19%). NA was associated with younger age (p<0.001), African American ethnicity (31% vs 8%, p=0.006), and rapid deterioration (45% vs 22%) but not stable impaired function (3% vs 19%). 17/22 Bx (77%) in pts with NA were diagnosed as borderline or rejection, 64% had antibody-mediated rejection (20% in pts without NA). Bx of pts with NA had more interstitial inflammation (1.6±0.9 vs 1.1±0.9, p=0.024), tubulitis (1.4±1.1 vs 0.7±0.9, p=0.001), peritubular capillaritis (1.5±1.2 vs 0.4±0.9, p=0.001), glomerulitis (0.7±0.9 vs 0.3±0.6, p=0.03), and fibrosis (1.7±0.8 vs 1.2±0.9, p=0.008), higher expression of inflammatory and injury gene sets and higher molecular risk scores predictive of graft loss. Based on the molecular changes in the Bx we built a classifier to detect NA and assigned a molecular NA-score to each Bx (Fig 1). 52 Bx had NA-scores > 0.5 (14 from pts with NA, 32 from pts without known NA; sensitivity 64%, specificity 91%, PPV = 0.30, NPV = 0.97). Bx with false-positive NA-scores were diagnosed as TCMR, borderline, or atrophy/fibrosis.

Conclusions: Whether this reflects non-specificity of the molecular classifier or undetected NA cannot be concluded from this data.

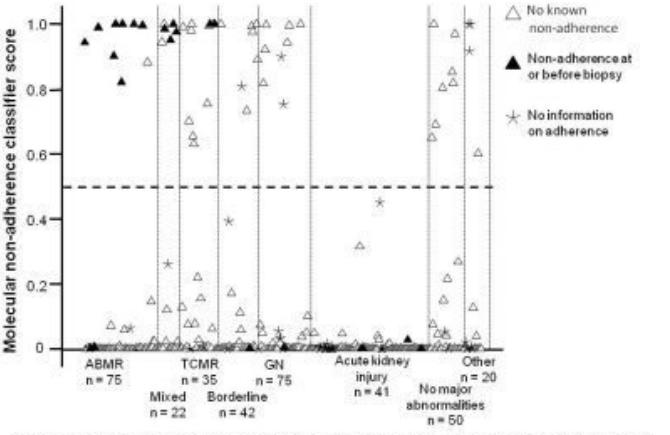

Figure 1. We developed a molecular classifier for non-adherence based on gene expression in the biopsy and calculated a molecular non-adherence score for each biopsy. Biopsies are grouped by their histologic diagnosis. Patients were classified as non-adherent based on physicians notes in their charts.

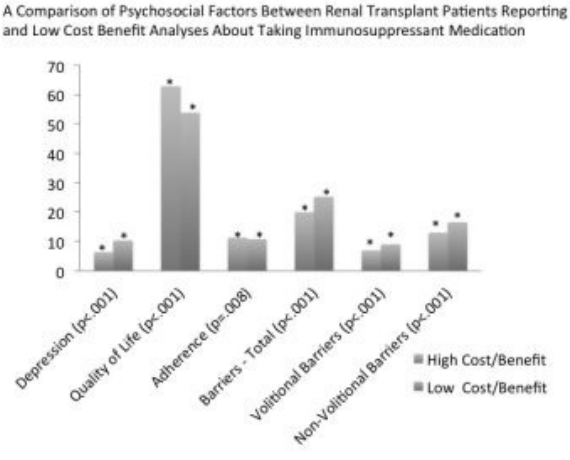
FR-PO954

Kidney Transplant Patient's Beliefs about Immunosuppressant Medication Utility Predict Adherence in a Multi-Ethnic Sample Daniel Cukor,[1] Melissa Constantiner.[2] *[1]Psychiatry, SUNY Downstate Medical Center, Brooklyn, NY; [2]Clinical Health Psychology, Ferkauf Graduate School, Bronx, NY.*

Background: Adherence to immunosuppressant medication is essential for the maintenance and functioning of organ grafts, yet is often below clinical recommendations.

Methods: Subjects completed demographic, medical and psychological questionnaires.

Results: In 312 renal transplant patients from three New York City sites, the average age was 49.63 ± 12.65 years. The sample was 46.9% male, had 13.34 ± 3.68 years of education, and 46.6% were Black, 26.9% Hispanic, and 22.2% White. The Beliefs About Medication-Specific subscale was completed and a single score reflecting the individual cost-benefit analysis for immunosuppressant medications was created. The sample was divided by median split. No significant differences were found when comparing the two groups with regards to gender, age, time since transplantation, income, education, ethnicity, or employment (p> .05). Those endorsing higher cost-benefit ratios endorsed higher immunosuppressant adherence and fewer overall barriers to medication adherence (p< .05) when compared to subjects with a lower cost/benefit ratio.



Conclusions: Subjects who believed more strongly in the utility of their medication had better rates of adherence, a higher quality of life, lower rates of depression, and fewer barriers to adherence, but no significant demographic differences. Even adherence behaviors that are thought of as "non-volitional," such as forgetting a dose or being short of money, were less of a problem for subjects who more strongly believed in the utility of their immunosuppressant medications. Implications for intervention are strong in that increasing transplant patients' beliefs about the utility of taking their medication may have significant positive consequences on adherence behaviors and other measures of psychological health.

FR-PO955

The Effect of a Transition Program on Adherence in Adolescent Kidney Transplant Recipients Moving from a Pediatric to an Adult Care Setting
Rory F. McQuillan,[1] Alene Toulany,[2] Jeffrey Schiff.[1] *[1]Division of Nephrology, University Health Network, Toronto, ON, Canada; [2]Division of Adolescent Medicine, The Hospital for Sick Children, Toronto, ON, Canada.*

Background: Medication non-adherence is prevalent in adolescent kidney transplant recipients and may account for poor long term graft survival. The process of transition from paediatric to adult care is a potentially modifiable factor in influencing adherence. The hypothesis for this study is that adherence can be improved by adult nephrology services engaging with patients in a paediatric setting prior to transfer in a bi-annual transition clinic and by a single nephrologist assuming responsibility for patients upon transfer.

Methods: Thirty-two consecutive patients, transferring from The Hospital for Sick Children to Toronto General Hospital were included. The first 16 transferred prior to the transition clinic; the subsequent 16 attended the clinic. Baseline data included date of end stage kidney disease; date, type and number of transplants; previous rejection; non-adherence and graft function at transfer. After transfer, measures of adherence including attendance at clinic and blood test appointment, drug levels and self reported non-adherence were identified. A patient was considered non-adherent if they directly admitted missing medication doses or exhibited at least 2 of the following 3 characteristics: missing appointments, missing blood tests or undetectable drug levels. The primary outcome was non-adherence during the first year post transfer; the secondary outcome was change in graft function after one year.

Results: There were no significant differences in baseline characteristics. Ten of 16 patients were non-adherent in the group transferred before the transition clinic, compared to 3 of 16 in the group who attended the clinic (p=0.03). The median change in serum creatinine was + 11.5μmol/L (0-16μmol/L) in the pre-transition clinic group compared to - 3.5 μmol/L (-9 - 11μmol/L) in the group who attended the clinic (p=0.03).

Conclusions: This study demonstrates change in the transition process improves adherence in adolescent kidney transplant patients and may lead to better graft function.

FR-PO956

Polycystin-1 Modulates Polycystin-2 Expression
Valeriu Cebotaru,[1] Hangxue Xu,[1] Feng Qian,[1] William B. Guggino.[2] *[1]Department of Medicine, Division of Nephroloty, Johns Hopkins University School of Medicine, Baltimore, MD; [2]Department of Physiology and Pediatrics, Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is a genetic disorder characterized by formation of fluid filled cysts that displace renal parenchyma and lead to end stage renal disease in ~50% of the patients. Mutations in PKD1 or PKD2 genes lead to ADPKD. Polycystin-1 (PC1) and polycystin-2 (PC2) are gene expression products of PKD1 and PKD2 respectively. Knockout of Pkd1 or Pkd2 genes leads to polycystic kidney disease in mice. On the other hand, overexpression of PC1 in Pkd1 transgenic mice or PC2 in TAZ knockout mice also leads to polycystic kidney disease. These data imply that up-regulation or down-regulation of PC1 and/or PC2 protein may play a role in pathogenesis of ADPKD. Here we investigated interrelation between PC1 and PC2.

Methods: MDCK cells were stably transfected with an expression system where expression of full length PC1 or mutant PC1-R4227X can be induced by tetracycline. Next MDCK cells were grown on transwell plates and PC1 expression was induced with tetracycline in the presence or absence of proteasome inhibitors (MG132). Finaly, we studied expression of PC2 in the presence or absence of PC1 and the interaction between PC1 and PC2 by co-immunoprecipitation.

Results: We found that induction of full length PC1 in MDCK cells down-regulates PC2 expression whereas induction of PC1-R4227X has no effect on PC2 protein level. Proteasome inhibitors stabilize PC1 expression leading to up-regulation of PC1 and further down-regulation of PC2 in PC1 induced or un-induced MDCK cells. Up-regulation of PC1 expression in the presence of proteasome inhibitors leads to increased interaction between PC1 and PC2 while total level of PC2 is decreased.

Conclusions: Our results suggest that PC1 may regulate the steady state level of PC2 protein and the extent of their interaction in vivo. C-terminal interaction between PC1 and PC2 may play a role in modulation of PC2 protein expression. Further studies will be conducted to elucidate the mechanism of PC2 regulation by PC1.

FR-PO957

The C-Terminus but Not the Channel Function of PC2 Is Required for Maintaining Normal Expression Levels of PC1 C-Terminal Fragment
Yiqiang Cai,[1] Sorin V. Fedeles,[1] Ke Dong,[1] Hongzhi Quan,[1] Yuehong Wang,[1] Seung H. Lee,[1] Xin Tian,[1] Ming Ma,[1] Ann-hwee Lee,[2] Stefan Somlo.[1,3] *[1]Internal Medicine, Yale University; [2]Immunology and Infectious Diseases, Harvard University, Boston, MA; [3]Genetics, Yale University, New Haven, CT.*

Background: PC1 is a polytopic receptor-like protein that undergoes cleavage at the GPS site to yield the extracellular N-terminal fragment (NTF) and the intra-membranous C-terminal fragment (CTF) that remain non-covalently associated with each other. PC2 is a cation channel in the TRP family. PC1 and PC2 interact via their respective C-termini and it has been proposed that PC1 and PC2 form a gated signaling complex. We have shown that mutations in genes for polycystic liver disease resulted in cyst formation by indirectly affecting PC1 protein levels. Here we sought to define the mechanism of cyst formation following mutation in PC2.

Methods: We generated conditionally immortalized mTAL-derived cell lines from $Pkd2^{fl/fl}$;$Pkd1^{F/H}$-BAC transgenic mice carrying the ImmortoMouse transgene. These cells were made null for Pkd2 ($Pkd2^{-/-}$;$Pkd1^{F/H}$-BAC) by adenoviral-mediated Cre infection. FLAG and HA tagged PC1 expression was examined in $Pkd2^{fl/fl}$ and $Pkd2^{-/-}$ cells and in $Pkd2^{-/-}$ cells in which either myc-tagged PC2, truncated PC2 (L703X) or "channel dead" full-length PC2 (D511V) had been re-expressed.

Results: The steady-state levels of PC1-CTF was dramatically decreased in the absence of PC2; PC1-NTF expression is not altered showing that GPS cleavage was unaffected. Re-expression of wild-type PC2 rescued the expression of PC1-CTF whereas re-expression of L703X, which does not interact with PC1, did not. Re-expression of D511V, which interacts with PC1 but lacks channel activity, also rescued PC1-CTF expression levels.

Conclusions: Interaction with PC2 is required to maintain the stability of PC1–CTF but not for GPS cleavage. Considering that most PKD2 mutations are truncating, the findings define a novel role for PC2 in the PC1-PC2 complex and post the hypothesis that defects in the maintenance of normal levels of PC1-CTF may underlie cyst formation in many cases of ADPKD due to mutations in PKD2.

Filamin-A Stabilizes Polycystin-2 Expression by Preventing Its Degradation
Qian Wang, Zuocheng Wang, Jungwoo Yang, Xing-Zhen Chen. *Physiology, University of Alberta, Edmonton, AB, Canada.*

Background: Polycystin-2 (PC2), encoded by the PKD2 gene, is a Ca-permeable cation channel mainly located on the ER membrane. Mutations in PKD2 account for 10-15% of the autosomal dominant polycystic kidney disease. Filamins are actin-binding protein implicated in scaffolding, membrane stabilization and signal transduction, through interaction with ion channels, receptors and signaling proteins. We recently found that filamin reduces PC2 channel activity through direct binding. Here we studied the effect of filamin on PC2 degradation.

Methods: Cycloheximide treatment, western blotting, shRNA knockdown, ^{35}S pulse labeling, RT-PCR and real-time RT-PCR.

Results: Using synthesis inhibitor cycloheximide we showed that the half life of PC2 protein in filamin-A deficient human melanoma M2 cells is much shorter than that in filamin-A-replete A7 cells. Knockdown of filamin-A by shRNA in A7, Hela and HEK cells significantly shortened the PC2 half life. Furthermore, transient expression of human filamin-A C terminus (aa 2150~2647) prolonged the PC2 half life in M2 cells. Taken together, these data indicate that filamin slows down PC2 degradation, which is consistent with our observation that the steady state level of over-expressed PC2 in A7 is higher than in M2 cells. On the other hand, by use of ^{35}S pulse labeling and synthesis inhibitor cycloheximide we showed that filamin has no effect on the PC2 synthesis rate after normalization by the PC2 mRNA level. We are currently examining whether the effect of filamin on PC2 degradation is through their direct binding, by the use of blocking peptides that disrupt or weaken the PC2-filamin interaction.

Conclusions: Filamin is an important regulator of stabilization and cellular handling of PC2, presumably through direct binding and anchoring to the actin cytoskeleton.

Characterization of Post-Translational Modifications of Native Polycystin-2 (TRPP2)
Alexis Hofherr, Claudius Wagner, Michael Kottgen. *Division of Nephrology and General Medicine, University Medical Centre Freiburg, Freiburg im Breisgau, Baden-Württemberg, Germany.*

Background: Autosomal dominant polycystic kidney disease is the most common lethal monogenetic disorder in humans. Mutations in the PKD2 gene account for approximately 30 % of cases. PKD2 encodes the transient receptor channel polycystin-2 (TRPP2), a non-selective Ca^{2+}-permeable cation channel. The physiological function of ion channels is affected by chemical modification after translation. Nascent peptides are subjected to a battery of specific enzyme-catalyzed modifications on their amino acid side chains. These structural changes and the attachment of biochemical functional groups extend the range of protein functions. So far, several studies have shed light on specific post-translational modifications of TRPP2. However, a comprehensive analysis of posttranslational modifications of TRPP2 is lacking.

Methods: Here we characterize the post-translational modifications of TRPP2 using liquid chromatography tandem mass spectrometry. Endogenous TRPP2 was isolated from canine and mouse cell lines as well as mouse kidneys by immuno-precipitation.

Results: We identified five N-linked glycosylation sites in TRPP2. Mutation of these sites abolished N-linked glycosylation completely and significantly changed the biochemical properties of TRPP2. Furthermore, we mapped known and novel phosphorylation sites in TRPP2. The physiological relevance of these phosphorylation sites is currently under investigation.

Conclusions: These results may be a starting point for a more detailed analysis of the functional implications of post-translational TRPP2 modifications.

Impaired Trafficking of Polycystin-1 May Be a Key Mechanism of Cyst Formation in the Aquaporin-11 Knockout Mouse Yuichi Inoue,[1] Eisei Sohara,[1] Katsuki Kobayashi,[2] Tatemitsu Rai,[1] Kenichi Ishibashi,[3] Sei Sasaki,[1] Shinichi Uchida.[1] *[1]Department of Nephrology, Tokyo Medical and Dental Sciences, Bunkyoku, Tokyo, Japan; [2]Molecular Genetics, Chiba-East National Hospital, Chiba, Japan; [3]Pharmaceutical Department, Meiji Pharmaceutical University, Kiyose, Tokyo, Japan.*

Background: We previously reported that the disruption of aquaporin-11 (AQP11) gene in mice resulted in cyst formation in the kidney. However, the mechanism of cyst formation in the AQP11-/- mouse is still unknown.

Methods: To investigate the mechanism, we analyzed the AQP11-/- mouse and AQP11 BAC transgenic (Tg^{AQP11}) mouse that expresses 3xHA–tagged AQP11, by focusing on the polycystic kidney disease-related gene products such as polycystins.

Results: Cyst formation in the AQP11-/- kidney was rescued by mating AQP11-/- mice with Tg^{AQP11} mice, confirming that 3xHA-tagged AQP11 expressed in the AQP-/- Tg^{AQP11} mouse behaved as a native AQP11 in vivo. Immunofluorescence of the kidney from Tg^{AQP11} mice revealed that 3xHA-AQP11 was localized in the cytoplasm of proximal tubules. Double immunofluorescence with organelle markers revealed that 3xHA-AQP11 was partially co-localized with KDEL, an endoplasmic reticulum (ER) marker. Immunoblots of isolated ER fraction of the kidney of Tg^{AQP11} mice also confirmed the ER localization of AQP11.Since ER is essential for folding, quality control, and translocation of newly synthesized proteins, we hypothesized that the absence of AQP11 in ER might result in defective sorting of the proteins known to be involved in polycystic kidney diseases. Therefore, we performed the immunoblots of those proteins in ER and plasma membrane fractions obtained by a density gradient centrifugation of the AQP11-/- kidney. As a result, polycystin-1 protein expression in the plasma membrane and ER fractions was decreased and increased, respectively, in the AQP11-/- kidney compared to that in wild-type kidney.

Conclusions: In this study, we could clearly demonstrate that the major site of AQP11 expression within the kidney cells was ER. The absence of AQP11 might affect the proper polycystin-1 trafficking from ER to the plasma membrane, thereby causing the cyst formation in the AQP11-/- kidney.

Polycystin-1 Cleavage at GPS Is Essential for Liver Homeostasis Marie Trudel,[1] Almira Kurbegovic,[1] Feng Qian.[2] *[1]Institut de Recherches Cliniques de Montréal; [2]Johns Hopkins University School of Medicine.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is a genetic disease that displays renal and hepatic cysts as well as non-cystic anomalies. The PKD1 gene responsible for most cases of ADPKD encodes polycystin-1 (Pc1). Pc1 is partially regulated by post-transcriptional modifications via cleavage at the GPS domain that generates N- and C-terminal fragments. Functional germline inactivation of Pkd1 in mice results in renal and pancreatic cysts and lethality by birth. Significantly, $Pkd1^{V/V}$ knockin mice without GPS cleavage of Pc1 escape embryonic/neonatal lethality of null mice but developed cystic kidneys and mild liver anomalies postnatally, and die by ~1month of age. Paradoxically, high levels of Pkd1 expression are also pathogenic in mice. Transgenic mice generated with a Pkd1-BAC driven from its native or renal specific promoter developed severe renal cysts leading to renal insufficiency at 4-6 months of age.

Methods: To investigate the role of the GPS cleavage of Pc1 in extra-renal tissues, we questioned whether Pkd1-BAC transgenesis could rescue the renal phenotype of $Pkd1^{V/V}$ mice and examined the hepatic phenotypes.

Results: The Pkd1 kidney or systemic expressors on the $Pkd1^{V/V}$ background rescue at P10 substantially or totally the renal cystic phenotype respectively, as evaluated by kidney to body weight ratio and histomorphometric analysis of cystic area. Lifespan of these $Pkd1^{V/V}$ mice with kidney-specific Pkd1 transgene was extended till ~3-4 months of age. By this age, these binary mice displayed severe liver phenotype with cystic clusters that affected virtually all biliary ducts and network. These results revealed a critical role for the Pc1 cleavage in liver homeostasis. In contrast, mice with the systemic Pkd1 transgene on $Pkd1^{V/V}$ background are healthy and have a lifespan expectancy >1year of age. In these older mice, the livers from each mouse (n=5) developed focal cystic anomalies in periphery of hepatic lobes that were significantly milder than with the kidney Pkd1 transgene expressors.

Conclusions: Together these results support an essential role for Pc1 GPS cleavage in ADPKD kidney but also liver pathogenetic mechanism.

FR-PO962

Physiological Regulation of Polycystin-1 Cleavage and the Creation of the P100 Product Owen M. Woodward, William B. Guggino. *Physiology, The Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: Mutations in PKD1 are responsible for 85% of polycystic kidney disease, but the physiological function of its protein product, PC1 remains unclear. Germ line knockout of PC1 in mice causes severely cystic kidneys before birth, where as the conditional knock out of PC1 later in development results in a much slower development of kidney cysts. This developmental dependent role is reflected in the protein expression of PC1: expression is high in the embryonic kidney but drops to undetectable levels after birth. However, although the full length protein disappears at birth, two c-terminal cleavage products persist after birth, the CTF and P100 cleavage products.

Results: We explored the mechanism regulating this dynamic cleavage of PC1 into the P100 product. Previously, we showed that the P100 product inhibits store operated calcium entry, and does so by inhibiting the translocation of the ER Ca2+ sensor protein STIM1 upon ER store depletion. Here, we demonstrate that extracellular Ca2+, activating a G-protein coupled Ca2+ receptor (CaSR), appears to regulate the creation of the P100 product in our MDCK cell line model system, and does so through a STIM1 dependent manner. And finally we probe the physiological consequence of STIM1 inhibition in kidney development with a kidney specific STIM1 knockout mouse.

Conclusions: Extracellular Ca2+, activating a G-protein coupled Ca2+ receptor (CaSR), appears to regulate the cleavage pf PC-1 and the creation of the P100 product in our MDCK cell line model system, and does so through a STIM1 dependent manner.

Renal Epithelial Disruption of TGFβ/Alk5 Signaling Does Not Affect Cystogenesis and Fibrosis in Pkd1-Mutant Mice: Novel Evidence for a Role of the Activin-A/Alk4 Signaling Pathway in ADPKD Wouter N. Leonhard,[1] Martijn H. Breuning,[1] Peter Dijke,[2] Emile De Heer,[3] Dorien J.M. Peters.[1] *[1]Human Genetics; [2]Molecular Cell Biology; [3]Pathology, Leiden University Medical Center, Netherlands.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD), caused by mutations in *PKD1 / 2*, is characterized by progressive cyst formation and renal fibrosis. Smad2/3 target-genes are highly upregulated at advanced PKD. However, we previously showed that epithelial deletion of *Alk5* (type-I receptor for TGFβ) neither affected fibrosis, nor cyst formation in adult tamoxifen-inducible kidney-specific *Pkd1*-deletion mice. Since the Hippo pathway has previously been described to be activated in PKD, and the YAP/TAZ target activin-A is known to stimulate Smad2/3-phosphorylation by binding to both the activin type-II receptor and its type-I receptor *Alk4*, we investigated whether this pathway may be involved.

Methods: Double inducible *Pkd1;Alk5*-deletion mice were treated with tamoxifen at post-natal day (PN)11 or PN40 in order to disrupt *Pkd1* and *Alk5*. We also generated various primary and immortalized cell-lines to study the effect of stimulation by Activin-A. Immuno-histochemistry, Western blotting and RT-MLPA were used to analyze the activin-A/*Alk4* pathway and Smad2/3 dependent signaling.

Results: *Alk5* disruption had no effect on nuclear translocation of phosphorylated Smad2, cyst formation, or renal survival in mice with fast (PN11) or slowly (PN40) progressing PKD. Activin-A was highly upregulated concordant with increased Hippo signaling and both activin type-I and type-II receptors were found to be highly expressed *in vivo*. In addition, activin-A indeed stimulated Smad2 phosphorylation *in-vitro*.

Conclusions: In two models of PKD, we confirmed that *Alk5* disruption in renal epithelium neither affects cystogenesis, nor fibrosis. However, activin-A was highly upregulated and its receptors abundantly expressed. These data suggest that the activin-A/*Alk4* cascade is likely to contribute to the pathogenesis of ADPKD. We are currently targeting the *Alk4*-gene to further demonstrate its involvement and potential new therapeutic interventions for ADPKD.

Bioactive Sphingolipid Signaling in PKD: New Mechanistic Insights into the Role of Sphingosine Kinase 1 Herve Husson,[1] Thomas A. Natoli,[1] Kelly A. Rogers,[1] Bing H. Wang,[2] Yeva Budman,[2] Katherine W. Klinger,[3] Steven R. Ledbetter,[1] Oxana Beskrovnaya.[1] *[1]Tissue Protection and Repair, Genzyme Corporation a Sanofi Company, Framingham, MA; [2]Analytical Research and Development, Genzyme Corporation a Sanofi Company, Framingham, MA; [3]Genetics and Genomics, Genzyme Corporation a Sanofi Company, Framingham, MA.*

Background: Cyst formation in polycystic kidney disease (PKD) is associated with abnormal rates of epithelial cell proliferation, apoptosis, and mitogenic signaling. Accumulating evidence shows that sphingolipids (SL) and glycosphingolipids (GSL) are important regulator of these cellular processes. Recent data demonstrate that elevated levels of structural GSL promote cystogenesis; however, it is not known whether bioactive SL play a pathogenic role in PKD. To investigate the role of bioactive lipids in PKD, we compared SL levels in normal kidneys to cystic kidneys of jck mice. We found elevated levels of sphingosine-1-phosphate (S1P) in cystic kidneys. Analysis of S1P synthetic enzymes showed that sphingosine kinase 1 (Sphk1) mRNA, but not Sphk2, was highly overexpressed in cystic kidneys compared to normal kidneys. In addition, Serial Analysis of Gene Expression (SAGE) showed upregulation of Sphk1 but not Sphk2 mRNA in human ADPKD kidney epithelial cells relative to normal cells. We set out to test whether genetic loss of the Sphk1 gene could inhibit cystogenesis in jck mice. Surprisingly, loss of the Sphk1 gene aggravated PKD with increased activation of mitogenic signaling, proliferation and apoptosis. These data suggest that S1P produced by Sphk1 is protective. Therefore, we tested this hypothesis by pharmacological inhibition of S1P lyase activity to increase S1P levels. Although S1P lyase inhibition significantly increased kidney S1P levels, there was no effect on cystogenesis or GSL levels. Our data provide new insights into imbalances of sphingolipid homeostasis associated with PKD and help define viable therapeutic targets within this pathway.

Progressive Glomerulotubular Injury and Formation of Atubular Glomeruli in Murine and Human Polycystic Kidney Disease: A Role for Tubular Obstruction Carolina I. Galarreta,[1] Jared J. Grantham,[2] Michael S. Forbes,[1] Robin L. Maser,[2] Darren P. Wallace,[2] Robert L. Chevalier.[1] *[1]Dept of Pediatrics, University of Virginia, Charlottesville, VA; [2]Kidney Institute, University of Kansas, Kansas City, KS.*

Background: Ureteral obstruction in the mouse causes proximal tubular degeneration and formation of atubular glomeruli (ATG) (Forbes MS. AJP-Renal 2011, 2012). We hypothesized that tubular obstruction by cysts leads to progressive nephron damage in polycystic kidney disease (PKD).

Methods: Formation of ATG was examined in kidneys from mice with early (cpk) or late (pcy) development of PKD, and in nephrectomy tissue from an adult autosomal-dominant PKD patient. Cysts form in medullary collecting ducts in each of these examples. Kidneys from cpk mice were studied at 10 and 19 days of age (early maturation), while kidneys from pcy mice were studied at 5 and 9 weeks of age (adulthood). Sections were also stained with *Lotus tetragonolobus* lectin, which binds to functional proximal tubular cells and mature columnar cells of Bowman's capsule in mice with intact glomerulotubular junctions (GTJ).

Results: Serial sections revealed normal GTJ in 100% of 21 glomeruli from 10 day-old cpk mice, whereas in 19 day-old mice, only 74% of 27 glomeruli were normal, with atrophic GTJ in 22% and ATG in 4%. In 9 week-old pcy mice, 74% of 73 GTJ were intact, 8% had atrophic GTJ, and 18% were ATG. In human advanced PKD, 75% of 20 GTJ were atrophic, and the remainder (25%) were ATG. There were fewer *Lotus*-positive glomerular capsules in 10 day-old cpk mice, but some proximal tubules were preserved even at 19 days. *Lotus*-positive proximal tubules were preserved in 5 week-old pcy mice, but there were patches of *Lotus*-negative tubules by 9 weeks: these areas contained ATG. In human PKD, there were few scattered *Lotus*-positive tubules.

Conclusions: In summary, there was progressive injury to the GTJ with the formation of ATG in murine PKD; and similar formation of ATG in advanced human PKD. These findings support the possibility that obstruction of medullary tubules by enlarging cysts contributes to the loss of proximal tubule mass, the formation of ATG, and the decline in GFR characteristic of PKD.

FR-PO966

Role of Ras GTPase Isoforms in Renal Cystic Disease Progression in a *PKD1* Mutant Mouse Model Ayesha Irtiza-Ali,[1] Richard N. Sandford,[2] Dorien J.M. Peters,[3] Claire C. Sharpe,[1] Bruce M. Hendry.[1] *[1]King's College London; [2]Cambridge University; [3]Leiden University Medical Center.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is characterized by abnormal cell proliferative responses that lead to cystogenesis and progressive fibrosis, resulting in loss of renal function. Ras-GTPase signalling has been implicated in these processes. We aim to examine the role of Ras isoforms and their interacting pathways in renal cystic disease progression in an orthologous ADPKD model.

Methods: *PKD1*$^{nl/nl}$hypomorphic mice were bred on a B6xCD1 genetic background. Immunohistochemistry (IHC), PMT stain, qPCR, immunoblotting and serum biochemistry were used to study renal phenotypic and molecular changes at sequential time points.

Results: On this genetic background, renal cystic disease progresses over 7-8 weeks. An initial rise in kidney volume peaking at P35, together with an early phase of increased tubular and cystic epithelial cell proliferation occurs. This is followed by a later stage of volume loss associated with a dramatic decline in epithelial cell proliferation at P35-49, progressive fibrosis and uraemia. Sustained activation of phospho-ERK up to P49 occurs, localizing predominantly to cystic epithelia in 26-37% of cells compared to 5-10% in tubular epithelia on IHC. In parallel, significant upregulation of Kirsten (Ki)-Ras mRNA is seen, with a peak rise at P35 by 3-4 fold compared to wt ($p=<0.001$), and ~2 fold increases at P21 and P49 ($p=<0.05$). Neural (N)-Ras expression is elevated by 2-3 fold through P21-49 ($p=<0.01$). Harvey (Ha)-Ras was not increased. Investigation of Ras-interacting pathways found a significant rise in Raf1 expression between P21 to P49, and late increase in pyk2 at P49. The pattern of Src expression followed that of N-Ras.

Conclusions: A sustained upregulation of Ki- and N-Ras expression together with activation of ERK occurs through both phases of renal disease progression in this model. This suggests Ki- and N-Ras signaling may have dual roles in the early proliferative growth of cysts and the later fibrotic stage associated with renal failure. This is under our further investigation.

FR-PO967

Cyst Fluid from Polycystic Kidney Disease Patients Activates Multiple Chloride Channels in Renal Principal Cells Bonnie L. Blazer-Yost,[1,2] Stephanie Flaig,[1] Vincent H. Gattone,[1,2] Robert L. Bacallao.[3] *[1]Biology, Indiana University Purdue University Indianapolis, Indianapolis, IN; [2]Anatomy and Cell Biology, Indiana University School of Medicine, Indianapolis, IN; [3]Nephrology, Indiana University School of Medicine, Indianapolis, IN.*

Background: In autosomal dominant polycystic kidney disease (ADPKD) renal cysts enlarge slowly during the patient's lifetime. Despite the growing cysts, renal function is not typically compromised until midlife but then the decline is precipitous and progresses to renal failure within a few years. Renal injury, whether traumatic, chemical or hypoxic, exacerbates renal decline. It is our hypothesis that renal injury or natural aging of cysts in ADPKD patients causes cyst rupture thereby releasing factors that accelerate expansion of remaining cysts thus promoting rapid disease progression. The objective of the studies was to characterize the factors and channels involved in cyst growth during late stage ADPKD.

Methods: Electrophysiological techniques were used to characterize the ion transport response of normal renal principal cells (mouse principal cells of the kidney cortical collecting duct; mpkCCD) after exposure to cyst fluid from human ADPKD patients.

Results: We have previously shown that addition of cyst fluid to the basolateral side of principal cells stimulated a Cl^- secretory response that, in vivo, would result in cyst expansion. The active component of the cyst fluid is lysophosphatidic acid (LPA) and cyst fluid contains sufficient LPA to maximally stimulate secretory Cl^- transport. The Cl^- secretory flux involved ion movement through the cystic fibrosis transmembrane conductance regulator (CFTR) and through an alternative channel with an inhibitory profile consistent with TMEM16a. Thus, the secretory activity is mediated by both CFTR and a Ca^{2+}-activated Cl^- channel.

Conclusions: This is the first demonstration of the involvement of Ca^{2+}-activated Cl^- channels in the cellular response to ADPKD cyst fluid. Consideration of alternative chloride channels is important when designing interventions to inhibit cyst expansion.

FR-PO968

Polycystic Kidney Disease 1 Gene in Fibroblast and Cyctic Disease Progression Yunxia Tao, Zonghan Dai, Zijuan Liu, Hongxing Tang. *Internal Medicine, Texas Tech University Health Sciences Center, Amarillo, TX.*

Background: Cyst expansion and loss of renal function in ADPKD kidneys are associated with progressive renal fibrosis, the mechanism of which is not fully understood. Renal interstitial myofibroblast, the active form of fibroblast, are the principal source for the synthesis of ECM components as well as the enzymes that regulate ECM turnover. It is established that the mutation of Pkd1 in renal tubular epithelia cells leads to increased proliferation and cyst development. However, little is known about the function of the Pkd1 in renal interstitial fibroblasts.

Methods: In this study, we show that Pkd1 is expressed in fibroblast cell lines and primary fibroblasts isolated from mouse kidneys. We also show that Pkd1 is expressed in bone marrow and circulating fibroblast precursor cells (FSP-1-positive cells). In order to study the function of Pkd1 in fibroblasts, we knocked down the expression of Pkd1 in NIH 3T3 fibroblasts by shRNA-mediated gene silencing. We tested a panel of lentiviruses expressing various Pkd1 shRNAs and were able to knock down the Pkd1 mRNA expression by up to 80% in fibroblasts.Using BrdU incorporation assay, we found that the knockdown of Pkd1 expression significantly increased fibroblast proliferation.

Results: A significant increase in the aSMA expression, a marker of myofibroblast, was observed in the Pkd1 knockdown fibroblasts compared with parental fiboroblasts, suggesting that the Pkd1 knockdown induces fibroblast activation to myofibroblast. We have previously shown that co-culture of fibroblasts with cystic epithelial cells induces cyst formation and enlargement. Here, we provide evidence that the knockdown of Pkd1 expression in fibroblasts significantly increased their ability to stimulate cyst formation and expansion.

Conclusions: Taken together, our results suggest that Pkd1 plays an important role in fibroblast growth and activation and that Pkd1 mutation in fibroblast in ADPKD kidneys may play a key role in renal fibrosis and cystic disease progression.

FR-PO969

Transforming Growth Factor Beta: A Molecular Target of Polycystin-1 and Nuclear Factor of Activated T-Cell Signaling Tarundeep Kaur,[1] Nidhi Mahajan,[1] Veena Puri,[2] Vivekanand Jha,[3] Surinder Kumar Singla,[1] James P. Calvet,[4] Sanjeev Puri.[5] *[1]Dept of Biochemistry, Panjab Univ, Chandigarh, India; [2]Centre for Systems Biol & Bioinformatics, Panjab Univ, Chandigarh, India; [3]Dept of Nephrology, PGIMER, Chandigarh, India; [4]Kidney Institute, Univ of Kansas Med Ctr, Kansas City, KS; [5]Centre for Stem Cell & Tissue Engineering, and Biotechnology Branch, UIET, Panjab Univ, Chandigarh, India.*

Background: Autosomal dominant polycystic kidney disease is a common hereditary disorder characterized by development of multiple fluid filled cysts in both kidneys. Loss-of-function mutations in the PKD1 gene are the major cause of this slowly progressive, fatal disease. Diminished levels of the PKD1 gene product polycystin-1 (PC1) are thought to result in abnormal cellular signaling. Previously we had shown that PC1 upregulates the NFAT transcription factor (Puri et al J Biol Chem 2004 279:55455). We now demonstrate that TGFβ is a target of this signaling.

Methods: Transient transfection of HEK293T cells using PC1 C-tail constructs with or without augmentation with Gα12; TGFβ RT-PCR expression analysis; NFAT promoter-reporter analysis and NFAT-GFP nuclear localization; antisense and chemical inhibitors of NFAT signaling; cell proliferation by MTT and FACS analysis.

Results: Transient transfection analysis with constructs expressing the PC1 C-tail showed that PC1 upregulates endogenous TGFβ expression in comparison to that seen with a control construct sIg0 that does not contain the PC1 C-tail. PC1-mediated NFAT activation and nuclear localization were augmented by coexpression of the Gα12 subunit of heterotrimeric G-proteins, and this concomitantly augmented expression of TGFβ. This increased TGFβ expression was completely abolished by cyclosporine, an inhibitor of calcineurin/NFAT signaling, and by antisense inhibition of Gα12 and PLCδ. The functional outcome of this signaling crosstalk was a considerable reduction ($p<0.05$) in cell proliferation.

Conclusions: These results demonstrate the importance of PC1/NFAT signaling in understanding PKD1 gene function and suggest a potential pathway through TGFβ crosstalk for the maintenance of normal renal epithelial organization.

Heat-Shock Protein 90 Regulates Cystic Epithelial Cell Proliferation through Histone Methyltransferases Mediated Downstream Pathways

Wei Liu,[1,3] Lucy X. Fan,[1,3] Xia Zhou,[1,3] Xiaogang Li.[1,2,3] *[1]Department of Pediatrics, Medical College of Wisconsin; [2]Physiology, Medical College of Wisconsin; [3]Chrildren's Research Institute, Medical College of Wisconsin, Milwaukee, WI.*

Background: The heat-shock protein 90 (HSP90) is essential for the creation, maintenance, and destruction of proteins. Its normal function is critical for maintaining the health of cells, whereas its dysregulation may contribute to not only carcinogenesis but also cystogenesis in polycystic kidney disease (PKD).HSP90 has been reported to regulate cell cycle progression through p53 and retinoblastoma (RB) mediated signaling pathways. Based on the fact that HSP90 was upregulated in *Pkd1* mutant renal epithelial cells, we hypothesized that HSP90 mediated pathways involved in regulating cyst formation in autosomal dominant PKD (ADPKD).

Methods: We investigated the expression of HSP90 and its relationship with histone methyltransferases (HMTs) in the renal cystic epithelial cells treated with or without HSP90 inhibitor, 17-allylamino-17-demethoxygeldanamycin (17-AAG). We also tested the effect of 17-AAG on cyst development in *Pkd1* knockout mouse embryonic kidneys.

Results: We found that in *Pkd1* mutant cystic epithelial cells: 1) in addition to HSP90, HMTs were also upregulated; 2) HSP90 formed a complex with HMTs; 3) inhibition of HSP90 resulted in the downregulation of HMTs; 4) downregulation of HMTs with siRNAs or HSP90 inhibitor resulted in the upregulation of p21, which might be mediated through the methylation of p53 by HMTs; 5) inhibition of HSP90 decreased the phosphorylation of Rb and the expression of cyclin-dependent kinase 2 (Cdk2) and 4 (Cdk4), which might be through increasing the formation of Rb-E2F1 complex to decrease the cell proliferation. We further found that treatment with 17-AAG delayed cyst formation in *Pkd1* knockout mouse embryonic kidneys.

Conclusions: HSP90 regulated cystic epithelial cell proliferation through histone methyltransferases mediated methylation of p53 and Rb and inhibition of HSP90 delayed cyst formation in *Pkd1* knockout mouse embryonic kidneys. Understanding the role of HSP90 signaling in cystic epithelial cells allows us to develop new therapeutic strategies for ADPKD.

FR-PO971

Aberrant VEGF and sFlt-1 Expression in ADPKD Patients

Wei Wang, M. Chonchol, Robert W. Schrier, Berenice Y. Gitomer. *Department of Medicine, University of Colorado Denver, Aurora, CO.*

Background: Emerging evidence indicates that angiogenesis occurs in human renal cysts in autosomal dominant polycystic kidney disease (ADPKD). We have shown that the serum level of vascular endothelial growth factor (VEGF) correlates with total renal volume in children and young adults with ADPKD. This suggests that VEGF may play a key role in early cystogenesis. VEGF activity is mediated by signaling through its receptors including VEGF receptor -1 (VEGFR-1/Flt-1). Soluble Flt-1 (sFlt-1), a splice variant of the VEGF receptor without transmembrane and cytoplasmic domains, inhibits VEGF signaling and has been shown to contribute to endothelial dysfunction in CKD. We hypothesized that sFlt-1 level may contribute to aberrant VEGF mediated angiogenesis in ADPKD.

Methods: Adult ADPKD patients were divided into two groups for analysis : group A: eGFR > 90ml/min/1.73m^2 and group B: eGFR <40ml/min/1.73m^2. Serum VEGF and sFlt-1 levels were measured by ELISA. Renal VEGF mRNA levels were measured by real-time RT-PCR and expressed as ratio of VEGF/GAPDH.

Results: Serum sFlt-1 levels were significantly lower in group A than in group B (40.9±46.4pg/ml, n=19 vs 71.7±32.3pg/ml, n=18, p<0.05). Group A sFlt-1 levels were similar to that reported for healthy individuals. Serum VEGF level did not differ between the two groups (593.8±500.6 pg/ml, group A, n=19 and 490.6±271.1 pg/ml, group B, n=18, p=NS) but were higher than reported levels in healthy individuals. The ratio of VEGF/sFlt-1 was higher in group A than in group B (16.8±18.1, n=19 vs 8.9±6.3, n=18, p=0.08). VEGF gene expression was significantly lower in ADPKD kidneys compared to normal kidneys (0.11±0.05, n=6 vs 0.25±0.14, n=5, p<0.05) but was higher that levels in kidneys from patients with other renal diseases.

Conclusions: Abnormalities in serum sFlt-1 and VEGF levels, including the increased VEGF/sFlt-1 ratio observed early in ADPKD are indicative of increased bioavailability of VEGF and support a role for angiogenesis in cyst growth. Decreased renal VEGF expression in advanced disease may exacerbate vascular damage in the kidney. Further studies are needed to verify the causal relationship between VEGF/sFlt-1 and cystogenesis in ADPKD.

Over-Expression of the Polycystin-1 (PC1) C-Tail Enhances the Sensitivity of M-1 Cells to the Effects of Ouabain

Kyle Jansson,[1] Brenda S. Magenheimer,[2] James P. Calvet,[2] Gustavo Blanco.[1] *[1]Molecular and Integrative Physiology, Kidney Institute, University of Kansas Medical Center, Kansas City, KS; [2]Biochemistry and Molecular Biology, Kidney Institute, University of Kansas Medical Center, Kansas City, KS.*

Background: We had previously shown that physiological levels of the hormone ouabain enhance proliferation of epithelial cells derived from renal cysts of patients with autosomal dominant polycystic kidney disease (ADPKD cells). This effect is mediated via the Na,K-ATPase signaling complex and activation of the epidermal growth factor receptor (EGFR), Src kinase and the extracellular regulated kinase (ERK) pathway. Here, we have determined whether ouabain had an effect on mouse cortical collecting duct cells stably expressing the C-terminal cytosolic portion of polycystin-1 (M-1 C20), which had been previously shown to cause a PKD phenotype, and compared it with a control cell line which does not express the PC1 C-tail (M-1 C17).

Methods: CellTiter 96 MTT Assays, immunobloting and Na,K-ATPase activity assays were used.

Results: Our results show that while ouabain stimulated proliferation of M-1 C20 cells, it did not modify the growth rate of M-1 C17 cells. Ouabain-enhanced cell proliferation was dose dependent and increased with ouabain amounts between 3 nM to 100 nM, which correspond to the circulating levels of ouabain commonly detected in plasma. Dose response curves for the interaction of ouabain with Na,K-ATPase activity showed that, in contrast to M1-17 cells, in M1-20 cells, approximately 20% of the Na,K-ATPase had higher affinity for ouabain. In addition, M-1 C20 cells, but not M-1 C17 cells, responded to ouabain with an increase in phosphorylation of ERK, which was abrogated by AG1478 and PP2, inhibitors of EGFR and Src, respectively. Altogether, these results show that expression of the C-tail of PC1 makes M1 cells sensitive to physiologic levels of ouabain, stimulating the EGFR-Src-ERK pathway and the proliferation of the cells. This increased response to ouabain resembles that previously found in ADPKD cells.

Conclusions: Over-expression of the C-terminal domain of PC1 transforms M1 cells to the abnormal ouabain sensitive phenotype of ADPKD cells.

The PKD1 Gene Expresses a Second Transcript Using Intron 41 as Its Start Site

Robert L. Bacallao,[1,2] Wei Min Xu,[1] Steven Duane Hatch.[1] *[1]Medicine, Indiana University, Indianapolis, IN; [2]Medicine, Richard Roudebush VAMC, Indianapolis, IN.*

Background: As part of a genome-wide cDNA library construction using a 5' cap approach to identify and capture mRNA, Kimura et al, identified three alternative transcripts in the PKD1 locus (Kimura et al., Genome Research, 16, 55-65, 2006).

Results: We have sequenced one transcript and found that its start site is in intron 40. The cDNA is 1925 bp long and it has a unique splice junction between the 3' end of exon 41 and the 5' end of exon 43 in the PKD1 gene. Northern blot analysis confirms expression of a 1900 bp message found in kidney and placenta. Based on sequence analysis no canonical start site could be found. To evaluate the start site of the cDNA we cloned the gene into pCTAP vectors which permit expression all three reading frames. We left the 5' end of the cDNA intact to provide an unbiased expression profile. Based on the cloning strategy we predicted that one reading frame would result in a full-length protein containing strepavidin and calmodulin binding sites that are encoded by the CTAP vector and can be assayed by immune blot. A unique 42 kDa band was identified in one reading frame by immune blot. The open reading frame (ORF) uses a CAG codon as its putative start site. The ORF predicts that this transcript encodes a 48 kDa protein with a 46 amino acid cleavable signal sequence suggesting that the protein is secreted. Strikingly when this cDNA is transfected into COS-1 cells mesenchymal markers are such as snail and slug are decreased. Furthermore transfected cells increase expression of E-cadherin and occludin.

Conclusions: A second transcript is encoded by the HmPKD1 locus with its start site in intron 40. This transcript codes for a 48 kDa protein which dramatically induces expression of epithelial markers in a mesenchymal cell line.

Inhibition of Ca^{2+}/Calmodulin Activates RAS and Enhances cAMP-Dependent ERK Activation in Human ADPKD Cells

Cibele S. Pinto, Gail Reif, Emily Nivens, Corey White, Darren P. Wallace. *Kidney Institute, University of Kansas Medical Center, Kansas City, KS.*

Background: cAMP plays a central role in the pathogenesis of ADPKD by stimulating cyst epithelial cell proliferation through activation of B-Raf and MEK/ERK signaling. By contrast, in normal renal cells (NHK), cAMP inhibits Raf-1, ERK and cell proliferation. The molecular mechanism for this phenotypic difference in the mitogenic response to cAMP remains unclear. Activated RAS (GTP bound) recruits Raf to the plasma membrane and mediates Raf activation. Ca^{2+} /calmodulin (CaM) can stimulate or inhibit RAS, depending on cell type. Previously, we showed that CaM inhibition with W-7, alone or in the presence of AVP, significantly increased ERK phosphorylation (P-ERK) in ADPKD cells, while having no effect in NHK cells. Here, we determined if Ca^{2+}/CaM differentially regulates RAS activity to account for differences in cAMP-dependent ERK activation between ADPKD and NHK cells.

Methods: ADPKD and NHK cells were treated with W-7 ± AVP and RAS activity was determined by RAS-GTP affinity pull-down assay. NHK cells were treated with a Ca^{2+} chelator BAPTA to restrict intracellular Ca^{2+}, mimicking ADPKD cells.

Results: cAMP stimulated RAS to similar levels in ADPKD and NHK cells; however, it only increased P-ERK and proliferation of ADPKD cells. In ADPKD cells, CaM inhibition with W-7 alone increased RAS activity and P-ERK. cAMP caused a further increase in P-ERK, while having only a modest effect on RAS activation, suggesting cAMP had an effect downstream of RAS. In NHK cells, W-7 increased RAS activity, but did not stimulate ERK. In the presence of W-7, cAMP had no additional effect on RAS and failed to stimulate ERK. Restriction of intracellular Ca^{2+} with BAPTA increased RAS activity 3-fold and stimulated ERK in NHK cells. cAMP had no further effect of RAS but stimulated ERK and cell proliferation, suggesting that the Ca^{2+}-induced phenotypic switch in the cAMP mitogenic response was below the level of RAS.

Conclusions: These data support the hypothesis that the differential effect of cAMP on the ERK signaling pathway between NHK and ADPKD cells is due to regulation of components downstream of RAS, notably the Raf kinases.

N-myc Downstream Regulated Gene 1 Is Engaged in the Regulation of Cyst Growth in PKD2 Transgenic Mice Jong Hoon Park, Bo Hye Kim, Eun Young Park. *Biological Science, Sookmyung Women's University, Seoul, Korea.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is an inheritable and progressive kidney disease featured by formation of fluid-filled cysts. N-myc downstream regulated gene 1 (NDRG1) is involved in cellular proliferation and differentiation. Our research group focused on this gene as a candidate regulator in cyst growth.

Methods: To check expression level of genes, real time RT-PCR and western blot were performed. Protein localization on the specimen was detected by immunohistochemistry. Transient transfection or siRNA treatment was utilized for regulating gene expression level. Also, three dimensional culture (3D culture) of MDCK cells was used for observing *in vitro* cystogenesis.

Results: NDRG1 expression level was higher in the kidney of PKD2 TG mice. Furthermore, NDRG1 protein was highly expressed in the cyst lining epithelial cells. We found that PKD2 gene regulated NDRG1 expression level *in vitro*. Also, NDRG1 knockdown attenuated cyst growth in 3D culture of Madin-Darby canine kidney cells (MDCK). Now, we try to find how PKD2 gene regulates NDRG1 expression level. We investigate transcription factors which bind to NDRG1 promoter as mediators between PKD2 and NDRG1.

Conclusions: In conclusion, overexpression of PKD2 gene upregulates NDRG1 expression level. This could aggravate cyst growth.

Inactivation of Mxi1 Induces Cilia Disassembly through IFT20 Reduction in Polycystic Kidney Jong Hoon Park, Je Yeong Ko, Kyung Hyun Ryu, Eunji Lee. *Department of Biological Science, Sookmyung Women's University, Seoul, Korea.*

Background: Primary cilia are antenna-like projections from the basal body bounded by the cell surface and act as sensory organelles that detect mechanical and chemical signals from extracellular environment. They consist of 9 doublets microtubules but no central microtubules termed 9+0. Intraflagellar transport (IFT) is involved in ciliogenesis so mutation of these genes induces ciliopathies. It is critical that the size control system of cilia be elucidated to enable understanding of ciliary diseases such as autosomal dominant polycystic kidney disease (ADPKD), which involves abnormally short cilia. In previous study, multiple tubular cysts, inflammation and fibrosis were observed in kidneys of Mxi1 KO mice aged six months or more.

Methods: To observe primary cilia phenotype *in vitro* and *in vivo*, SEM and ICC were used. To identify the relationship between Mxi1 and cilia desassembly, Q-PCR, WB and promoter assay are used in this study.

Results: Here, we identify the relationship between inactivation of Mxi1 and cilia disassembly. The length of primary cilia is decreased and p-ERK level induced by cilia defect is increased in kidneys of Mxi1 KO mice. Ciliogenesis of Mxi1 KO MEFs is decreased and this abnormality is restored by Mxi1 transfection to Mxi1 KO MEFs. To elucidate the cilia regulatory mechanism related to Mxi1, IFT genes are validated >*in vitro* and *in vivo* using Q-PCR and IFT20 is selected for candidate gene in this study. Ciliogenesis defects and down-regulation of IFT20 observed in Mxi1-siRNA treated mIMCD-3 compared to controls. Also we identified that Mxi1 regulates IFT20 promoter activity via Ets1 binding to IFT20 promoter.

Conclusions: In conclusion, these results suggest that Mxi1 has an effect on regulation of ciliogenesis through IFT20 expression in polycystic kidneys.

FR-PO977

Development of Renal Cystic Cell Lines of Autosomal Dominant Polycystic Kidney Disease and Characterization through Microarray Ah-Young Kang,[1] Hayne C. Park,[2] Young-Hwan Hwang,[3] Insuk So,[4] Chang-seok Ki,[5] Curie Ahn.[1,2] *[1]Department of Immunology, Seoul National University College of Medicine, Seoul, Korea; [2]Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Korea; [3]Department of Internal Medicine, Eulji General Hospital, Seoul, Korea; [4]Department of Physiology, Seoul National University College of Medicine, Seoul, Korea; [5]Department of Laboratory Medicine & Genetics, Samsung Medical Center, Seoul, Korea.*

Background: Research on the pathogenesis of autosomal dominant polycystic kidney disease (ADPKD) has been hampered by the lack of well-characterized cyst-derived cell lines. Because each cyst from one patients is thought to have a different somatic mutation, tissue in whole is not an adequate tool to study the effect of various second hits. Therefore, developing various ADPKD cell lines with a different cystic origin is necessary to understand heterogenous nature of the disease.

Methods: We established 6 renal cyst epithelial cell lines from 5 ADPKD patients (one cell line each for 4 patients and 2 cell lines from different cyst origin in one patient) using SV40 viral DNA. *PKD 1* and *PKD2* sequencing was conducted in each cell line with its corresponding blood samples, and the cyst origin was confirmed by immunostaining with tubule markers of DBA and LTA. The cDNA microarray was performed to elucidate genetic expression profiles in ADPKD. Further, basal intracellular calcium levels were also measured.

Results: All of these cell lines were found to have *PKD1* gene defects with different germline and somatic mutations. Each cell line was originated from either proximal or distal tubule. The expression of genes associated in calcium-related pathways or calcium entry were altered in ADPKD. Both intracellular and ER storage calcium levels varied among different cell lines.

Conclusions: Our ADPKD cell lines developed from different cyst origins may facilitate the research in unraveling the pathogenesis of ADPKD. Further comprehensive analysis of microarray may provide a potential therapeutic target for ADPKD.

FR-PO978

Hepatocyte Nuclear Factor-1β Regulates Transcription of MicroRNA miR-200 Sachin S. Hajarnis, Massimo Attanasio, Karam S. Aboudehen, Vishal Patel, Peter Igarashi. *Department of Internal Medicine, University of Texas Southwestern Medical Center, Dallas, TX.*

Background: The transcription factor hepatocyte nuclear factor-1β (HNF-1β) regulates tissue-specific gene expression in the kidney and other epithelial organs. HNF-1β is essential for normal kidney development, and mutations of HNF-1β produce kidney cysts by inhibiting the expression of cystic disease genes. We hypothesized that HNF-1β regulates the expression of miRNAs that are important in kidney development and PKD.

Methods: MicroRNA microarray analysis was performed on renal epithelial cells expressing dominant-negative mutant HNF-1β (DN-HNF-1β). Chromatin immunoprecipitation and DNA sequencing (ChIP-seq) were performed on mIMCD3 cells that express wild-type HNF-1β. Combining the results identified miRNAs that are directly regulated by HNF-1β. miRNAs were validated by ChIP, expression analysis, and functional studies. Target Scan and miRanda were used to identify candidate miRNA targets, which were validated by qRT-PCR and luciferase reporter assays.

Results: Microarray analysis and ChIP-seq identified members of the miR-200 family as candidate HNF-1β targets. miR-200 is enriched in the kidney and is down-regulated in cells expressing DN-HNF-1β. HNF-1β and active RNA polII bind to sites located 28 kb upstream to the miR-200 locus and stimulate transcription. mIMCD3 cells express miR-200 and form tubules when grown in collagen gels. Treatment of mIMCD3 cells with antagomirs that specifically target miR-200 disrupts tubulogenesis. Bioinformatic analysis identified two conserved miR-200 binding sites in the 3'UTR of *Pkd1*. Levels of *Pkd1* mRNA are increased in miR-200 antagomir-treated cells. miR-200a/b inhibit the expression of a luciferase reporter gene linked to the 3'UTR of *Pkd1*.

Conclusions: HNF-1β directly regulates the transcription of miR-200, a kidney-enriched miRNA family. miR-200 is required for renal tubulogenesis and post-transcriptionally regulates *Pkd1*. Since deficiency or overexpression of *Pkd1* causes kidney cysts, regulation by miR-200 may be important for maintaining renal tubular structure. These studies reveal a novel pathway by which HNF-1β controls the levels of mRNAs involved in cystogenesis.

ErbB4 Deletion Accelerates Polycystic Kidney Disease Progression in Cys1^{cpk} Mice Fenghua Zeng, Tomoki Miyazawa, Raymond C. Harris. *Medicine, Vanderbilt University, Nashville, TN.*

Background: ErbB4 is a type I transmembrane protein that belongs to the EGF receptor family. There are four isoforms of ErbB4, of which JM-a/CYT-1 and JM-a/CYT-2 are expressed in kidney. In other systems JM-a/CYT-1 has been shown to promote cell differentiation while JM-a/CYT-2 increase cell proliferation. JM-a/CYT-1 is mainly expressed in the renal cortex, while JM-a/CYT-2, the predominant isoform of ErbB4 in kidney, is localized to renal medulla. Our previous studies have shown that JM-a/CYT-2 promotes renal epithelial cell tubulogenesis in vitro, but its function during renal disease is unknown.

Methods: We generated Cys1^{cpk} mice carrying a heart-rescued ErbB4 deletion (ErbB4^{heart}/Cys1^{cpk}) by crossing Cys1^{cpk}, an ARPKD mouse model, with ErbB4^{heart} mice.

Results: ErbB4 is highly expressed in the cyst lining cells of the kidneys of Cys1^{cpk} mice. In ErbB4^{heart}/Cys1^{cpk} mice, accelerated cyst progression and renal function decline were noted as early as 10 days postnatally, as indicated by larger cystic kidney size, higher kidney weight to body weight ratio and elevated BUN level compared to Cys1^{cpk} mice. At this age, no notable renal abnormality can be detected in ErbB4^{heart} mice, although dilated tubes can be seen later in adult ErbB4^{heart} mice. Cell proliferation, assessed by Ki67 immunostaining, showed that Ki67 immunoreactivity was predominately seen in the cortex of the cystic kidneys in both ErbB4^{heart}/Cys1^{cpk} and Cys1^{cpk} mice, with the ratio of Ki67 positive cells to total cyst-lining epithelial cell (TCEC) significantly higher in ErbB4^{heart}/Cys1^{cpk} mice compared to Cys1^{cpk} mice (18.56 ± 2.03 vs. 7.35 ± 0.82, $p < 0.01$). On the other hand, TUNEL staining localized apoptotic cells mainly to the renal medulla. TUNEL positive cell to TCEC ratio was again higher in ErbB4^{heart}/Cys1^{cpk} mice compared to Cys1^{cpk} mice (37.2 ± 4.57 vs. 5.01 ± 1.28, $p < 0.001$).

Conclusions: Our results indicate that ErbB4 deletion in Cys1^{cpk} mice can induce abnormal cell proliferation and increase cell apoptosis, resulting in accelerated cyst formation and earlier renal function deterioration and suggest that ErbB4 may exert cytoprotective and antiproliferative effects in renal epithelia.

Characterisation of a New Mouse Model of Polycystic Kidney Disease Brigitte Lelongt,[1] Zeineb Bakey,[1] Laure Delestre,[2] Marie-thérèse Bihoreau,[3] Pierre M. Ronco,[1] Dominique Gauguier.[2] *[1]INSERM UMR_S 702, Paris, France; [2]INSERM UMR_S 872, Paris, France; [3]Centre National de Génotypage, Evry, France.*

Background: We have demonstrated that a missense mutation in the SAM domain of Anks6 induces renal cysts in the cy/+ rat. Homozygous rats died at 4 weeks. Heterozygous rats displayed a slow progression of the disease leading to death after 1 year. Approximately 75% of the cysts derived from the proximal tubule. Cysts in the liver and pancreas were also observed in about half of old-affected females.

The objective of this study is to further investigate the role of Anks6 in the pathogenesis of PKD by using a mouse model.

Methods: We identified in a library of ENU treated mice a mouse carrying a mutation in the SAM domain of Anks6, six amino acid away from the PKD-causative mutation in the cy/+ rat strain. We rederived the mouse, transferred the mutation on a C3H background by 7 successive backcross breedings and analysed the mutant mouse phenotype.

Results: Anks6 was detected in cilia of normal and cystic tubules. A very slow progression of the disease is observed in homozygous mutant mice which die after 16 months. Mice heterozygous for the mutation do not display any cysts. Cysts are detected in glomeruli and also in different nephron segments in cortex, medullary and papilla. Immunohistochemical markers showed that cysts derive from collecting ducts and thick ascending limb of Henle's loop, whereas only few cysts were observed in proximal tubules. We could not detect cysts in other organs, such as liver and pancreas. No differences in cyst origin, cyst size and cyst number were noticed between males and females.

Conclusions: This new mouse model provides unambiguous evidence of the role of Anks6 mutations in PKD and opportunities to investigate the *in vivo* effects of Anks6 mutation in combination with other PKD-causative mutations in mice. Discrepancies in phenotypes and inheritance mode between the cy/+ rat and the ENU mouse strongly suggest that the mutations in the SAM domain of Anks6, although very close, disrupt sites of interactions to different Anks6 protein partners in the two species and that these different partners are involved in cyst formation.

Roles of N-Terminal Cysteine 38 in the Dimerization and Channel Function of PKD2L1 Wang Zheng, Jungwoo Yang, Xing-Zhen Chen. *Physiology, University of Alberta, Edmonton, AB, Canada.*

Background: Polycystic kidney disease 2-like 1 (PKD2L1) is a homologue of PKD2 but is not related to ADPKD. It is a Ca-activated non-selective cation channels and is present in multiple tissues including retina, tongue, brain and kidney. It acts as part of an acid sensor in the tongue. It was reported that the N-terminal domain D21-S42 is important for the channel activity and that the C-terminus trimerizes in vitro. Here we studied residues that are important for PKD2L1 oligomerization and channel function.

Methods: Mutant and WT PKD2L1 channel function was measured with two-electrode voltage clamp to *Xenopus oocytes*. PKD2L1 Oligomerization was examined with non-reducing SDS-PAGE, and co-IP between GFP- and Flag-tagged PKD2L1.

Results: We examined truncation mutants Δ1-36 (lacking aa M1-R36) and Δ1-38 by electrophysiology in oocytes and found that Δ1-36 exhibits similar function to WT PKD2L1 while Δ1-38 loses channel function. We examined mutants V37A, C38A and T39A, and found that while V37A and T39A have similar function to WT, C38A exhibits very low activity, suggesting the importance of C38 for channel activity. We then examined whether C38 affects PKD2L1 oligomerization. Using PKD2L1 over-expression in oocytes and HeLa cells, and native mouse tissues under non-reducing SDS-PAGE conditions, we observed oligomer bands. Mutation C38A or addition of 2ME (or DTT) substantially reduced oligomerization, suggesting that C38 is part of a disulfide bond critical for PKD2L1 dimerization. Using co-IP between GFP- and Flag-tagged PKD2L1 we found that the WT-C38A interaction is much weaker than the WT-WT interaction. Mutations to the other cysteine residues outside transmembrane spans do not affect channel function. Of note, C38-mediated dimerization is insufficient to account for tetramerization. Interestingly, the N-terminus truncation mutant Δ1-95 did not oligomerize. We are identifying N-terminal residues involved in dimerization via peptide-peptide interaction.

Conclusions: Two PKD2L1 proteins dimerize through a disulfide bond formed by their C38, which is necessary for its channel function. There may exist N-terminal residues involved in dimerization via peptide-peptide interaction.

FR-PO982

Modelling Genetic and Environmental Synergy in Metanephric Cystogenesis Corina Anders,[1] Nick Ashton,[2] Mark R. Dilworth,[1] Adrian S. Woolf.[1] *[1]School of Biomedicine, University of Manchester, Manchester, United Kingdom; [2]Faculty of Life Sciences, University of Manchester, Manchester, United Kingdom.*

Background: Cyclic adenosine monophosphate (cAMP) drives cyst growth in polycystic kidney diseases (PKD) and, in autosomal dominant (AD) and recessive PKD, kidney cystogenesis initiates antenatally. In some PKD families, differences in kidney disease severity exist between affected individuals, and genomic and/or environmental modifying factors have been evoked to explain such observations. We hypothesized that PKD cystogenesis is accentuated by an aberrant fetal milieu, specifically by exposure to glucocorticoids, molecules mediating developmental programming of postnatal diseases.

Methods: Cyst formation was assessed in explanted wild-type mouse embryonic day 13 metanephroi, using 8-Br-cAMP as a chemical model for genetic cystogenesis, and the glucocorticoid dexamethasone as an environmental modulator. On days 3 and 6, cyst areas and numbers were quantified by an observer blinded to culture conditions. Tubules were phenotyped with megalin, aquaporin-1, uromodulin and calbindin-28 antibodies and *Dolichhos biflorus* agglutinin. Glomeruli were counted by stereology.

Results: Dexmethasone, over a physiological to pathological glucocorticoid concentration range, significantly synergized with cAMP increasing cytogenesis. We defined concentrations of each molecule which, on their own, were not cystogenic; when applied together at these same concentrations, however, cysts began to form in embryonic kidneys. Notably, cAMP or dexamethasone alone generated cysts arising in both differentiating proximal tubules and descending limbs of loops of Henle. When these cystogens were applied together, however, a striking glomerulocystic phenotype occurred and we note that glomerular cysts have been reported in histology from fetuses and young children with ADPKD. Glomerular numbers were similar in all culture conditions.

Conclusions: These results provide evidence for concerted cystogenic actions of genetic (i.e. cAMP activity in PKD) and environmental (i.e. glucocorticoid activity in developmental programming) factors. The data support the idea that an adverse antenatal environment exacerbates genetic cystic disease.

FR-PO983

Constitutive Activation of NF-κB Causes Tubule Enlargement and Cyst Formation in Cultured Mammalian Collecting Duct Cells Liping Sun,[1] Xinzhou Zhang,[1] Shixuan Wang,[2] Wanfan Zhang.[1] *[1]Division of Nephrology, Shenzhen People's Hospital, Shenzhen, Guangdong, China; [2]Renal Division, Brigham and Women's Hospital and Harvard Medical School, Boston, MA.*

Background: Polycystic kidney disease (PKD) is characterized by progressive enlargement of renal cysts. We have previously demonstrated an increase in NF-κB in fibrocystin-decreased kidney cells.The aim of the present study was to determine the effect of NF-κB signaling on cyst formation, tubular cell apoptosis and proliferation in the mCCD cells.

Methods: We designed an *in vitro* model of tubulogenesis in mCCD cells.To assess whether the activation of the NF-κB signaling pathway can induce the enlargement of established tubular structures, mCCD cells were treatment with TNF-α. NF-κB activation was determined by measuring IκB degradation and phosphorylation, NF-κB p65 nuclear levels and EMSA.Subsequent addition of caspase-3 inhibitor to test that TNF-α-induced tubule enlargement was mediated through the activation of caspase-3.Lumen diameter was measured using an inverted photomicroscope. PCNAstaining was performedfor proliferation, TUNEL methodand flow cytometry was used to detectapoptotic cells.

Results: Selective activation of NF-κB pathway using TNF-α resulted in progressive dilatation of existing tubules, leading to the formation of cyst-like structures. The caspase-3 inhibitor reduced tubular apoptosis and proliferation and prevented tubule enlargement and cyst formation.

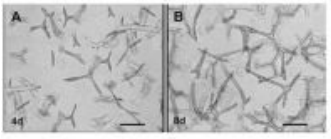

figure1. mCCD cells form well-organized tubular structures

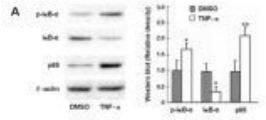

figure2. analysis of NF-κB activity after TNF-α treated

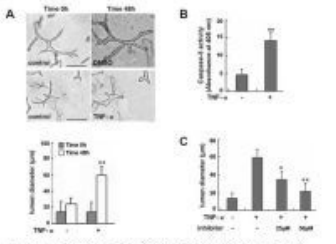

figure3. activation of the NF-κB pathway induces cystic dilatation of existing tubules

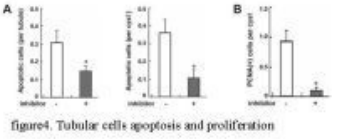

figure4. Tubular cells apoptosis and proliferation

Conclusions: We conclude that NF-κB signaling plays a key role in renal cyst formation, at least in part by inhibiting caspase-3 activity. These observations provide a potential platform for the future treatment of the renal manifestations of PKD.

TRPV4 Participates in Primary Cilia-Mediated Osmosensation of Renal Epithelial Cells Bradley P. Dixon, Brian J. Siroky, John J. Bissler. *Division of Nephrology and Hypertension, Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Primary cilia detect extracellular mechanical and chemical stimuli and are located on the surface of nearly all cells. Defects in primary cilia are associated with cystic kidney diseases and some forms of cancer. Signals transduced by the primary cilium affect cell proliferation, differentiation, migration and apoptosis. The mechanism by which cilia sense changes in osmolality is not well understood. The transient receptor potential vanilloid channel TRPV4 localizes to the primary cilium in hepatic duct cells, and appears to sense changes in osmolality. It is unknown whether TRPV4 participates in the osmosensation of the primary cilium of renal epithelial cells. We assessed the expression and function of TRPV4 in renal epithelial cells. Specifically, we assayed for a role for TRPV4 in sensing osmolality.

Methods: 176-5 renal epithelial cells that contain a floxed *Kif3a* (a kinesin motor required for ciliogenesis) and a tamoxifen-inducible Cre recombinase were cultured with tamoxifen to develop conditionally deleted *Kif3a* (176-5Δ cells). TRPV4 expression was assessed by RT-PCR and immunofluorescence. Both the 176-5 and 176-5Δ cell lines were gradually adapted to 600mOsm/kg with NaCl or urea, or maintained under control conditions, either in the presence or absence of a TRPV4 antagonist, HC-067047 100nM. Cell cycle distribution was assessed by flow cytometry. Cell proliferation was measured by crystal violet viability assay.

Results: 176-5Δ cells continued to proliferate in spite of hyperosmolal adaptation, whereas 176-5 cells arrested cell proliferation upon adaptation to hyperosmolal NaCl or urea. However, blockade of TRPV4 activity with HC-06747 caused an increase in S phase of 176-5 cells in hyperosmolal NaCl, but had no effect on cell cycle distribution in cilia-deficient 176-5Δ cells.

Conclusions: These results indicate that TRPV4 is expressed in renal epithelial cells, and may participate in osmosensation directed by cilia. Further studies are needed to determine the cellular localization of TRPV4 and the mechanism by which TRPV4 influences the response to hyperosmolality.

FR-PO985

Renal Chymase, but Not Angiotensin-Converting Enzyme, Is Upregulated in Polycystic Kidney Disease Mice Michifumi Yamashita,[1,2] Saurabh Chattopadhyay,[2] Ganes C. Sen.[2] *[1]Pathology, University Hospitals Case Medical Center, Cleveland, OH; [2]Molecular Genetics, Lerner Research Institute, Cleveland Clinic, Cleveland, OH.*

Background: Polycystic kidney disease (PKD) is a common genetic disorder, which affects around 6 million worldwide. Renin Angiotensin System (RAS) has been implicated in cyst growth and hypertension in PKD patients. Now a large-scale clinical trial (HALT-PKD) is ongoing to test the effects of RAS blockades on the cyst growth of ADPKD. However, the precise mechanism has not been studied in detail. We have used Juvenile Cystic Kidney (*jck*) mice, a murine model of PKD, to analyze RAS in PKD.

Methods: *Jck* mice (female, 100 days old) and age-matched wild type (WT) mice were used to test blood pressure by non-invasive tail cuff method. Critical components of RAS, Angiotensin Converting Enzyme (ACE), ACE2 and chymase levels were analyzed in the sera and the kidney sections. Serum ACE activity and Angiotensin II (Ang II) level in plasma and kidney were measured by colorimetric assay based on Hip-His-Leu cleavage and radio-immune assay (RIA), respectively. Urine ACE was measured by murine ACE ELISA, and normalized by urinary creatinine level.

Results: *Jck* mice exhibited higher blood pressure as compared to its WT control mice. However, *jck* mice showed reduced serum ACE activity and plasma Ang II level. On the other hand, kidney Ang II was significantly higher in *jck* mice than WT mice. Surprisingly, renal ACE and ACE2 levels as well as urinary ACE in *jck* mice were significantly reduced than WT mice. Furthermore, renal chymase level was significantly increased in the interstitial area and the cystic wall in *jck* mcie than WT mice.

Conclusions: Our study clearly showed that in *jck* mice, systemic RAS is suppressed, and renal RAS is upregulated by chymase, with significant reductions of renal ACE and ACE2. In view of the fact that ARB and/or ACE inhibitor have clinical roles in PKD patients, it will be interesting to test the chymase inhibitors in future clinical studies for controlling the renal RAS activity.

Kidney Injury Molecule-1 (Kim-1) Is Specifically Expressed in Cystically Transformed Proximal Tubules of the PKD/Mhm (cy/+) Rat Model for Polycystic Kidney Disease Nicholas Obermueller,[1] Juergen Engel,[1] Stephanie Schlitt,[1] Sigrid C. Hoffmann,[2] Bettina Kraenzlin,[2] Norbert Gretz,[2] Helmut Geiger,[1] Stefan Gauer.[1] *[1]Division of Nephrology, III. Medical Clinic, University Hospital, University of Frankfurt, Frankfurt, Germany; [2]Medical Research Center, Medical Faculty Mannheim, University of Heidelberg, Mannheim, Germany.*

Background: Kidney injury molecule-1 (Kim-1) is rapidly expressed after acute tubular injury and is considered as a biomarker for kidney damage. We examined the localization of renal Kim-1 in the PKD/Mhm(cy/+) rat, an established model for autosomal dominant polycystic kidney disease.

Methods: Male adult heterozygous (cy/+) rats as well as (+/+) littermates were perfusion-fixed with PFA, after the left kidney had been removed and snap frozen. The right kidney was paraffin embedded and Kim-1 expression was determined by immunohistochemistry (IHC) using a polyclonal antibody, and by western blot analysis.

Results: By IHC Kim-1 was not detectable in wildtyp (+/+) kidneys, whereas a robust de novo expression could be observed solely in cystically transformed proximal tubules of varying size. In detail, Kim-1 was distributed mostly apically in dedifferentiated cystic epithelia, e.g. with an already reduced or even a completely lost brush border. Distal tubules and collecting ducts, as double-labeled with calbindin did not show any expression of Kim-1. In contrast to vimentin and osteopontin (other markers of tubular damage and dedifferentiation) Kim-1 was strictly confined to structures of proximal tubular origin; in cysts, the staining of the three markers did only partially overlap as shown in serial sections. De novo protein expression of Kim-1 in (cy/+) kidneys was corroborated by western blotting.

Conclusions: Our data show upregulation of Kim-1 in the PKD/Mhm(cy/+) model, specifically in the diseased proximal tubular segment, contrasting to other molecules indicating renal injury (e.g. osteopontin), which are also expressed in distal nephron segments in this model. This may indicate, that Kim-1 represents not only a pure marker of tubular injury, but may be causally involved in the events during de-differentiation, cyst formation, and fibrotic remodeling.

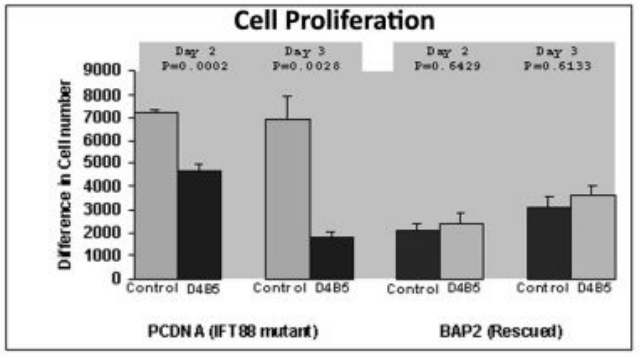
Aberrant Expression of Laminin-332 in ARPKD Contributes to Cystogenesis by Altering Principal Cell Proliferation Soundarapandian Vijayakumar,[1] Tricia M. Nienaber,[1] Matt Peter Marinkovich,[4] Bradley K. Yoder,[2] Vicente E. Torres.[3] *[1]Pediatrics, University of Rochester, Rochester, NY; [2]University of Alabama, Birmingham, AL; [3]Mayo Clinic, Rochester, MN; [4]Stanford University, Stanford, CA.*

Background: A hypomorphic mutation in the mouse laminin α5 gene causes polycystic kidney disease associated with aberrant accumulation of laminin-332 (α3β3γ2) (JASN17:1913, 2006). Laminin-332 promotes proliferation of ADPKD cells and cystogenesis in 3D culture (JBC 281:29181, 2006). Here we examine whether aberrant ECM assembly plays a role in ARPKD cystogenesis (PCK rat and orpk cell lines).

Methods: Real-time PCR using Taqman chemistry was performed on cDNA from Postnatal (PN) day 2, 7, 10, 21, 30 and 40 and 3 month PCK and SD rat kidneys with specific primers to laminin-α3, β3, γ2, integrin β4, collagen XVII and SRY genes. Frozen sections from PCK kidneys were stained with a rabbit polyclonal to laminin-332. Celltiter 96 Aqueous One Solution reagent was used to perform cell proliferation assays for up to three days.

Results: qPCR show significant upregulation of laminin-332 chains and integrin β4 (10 fold increase in laminin-γ2, 8 fold increase in integrin β4) in 3 month PCK compared to SD kidneys. A 3.4 fold increase in laminin-γ2 was observed as early as PN40. Immunohistochemistry shows the presence of ECM laminin-332 not only in the cysts but also in precystic collecting ducts of PCK but not SD rats. A four fold increase in laminin-β3 and a 3-fold increase in integrin β4 were observed in orpk mutant cell lines compared to rescued cell lines. Mutant cells showed increased proliferation (7000 cells vs 3000 cells) which was inhibited by laminin-332 function blocking antibody D4B5. D4B5 had no effect on the proliferation of rescued cells.



Conclusions: Aberrant laminin-332 expression in ARPKD contributes to cystogenesis by inducing abnormal proliferation of collecting duct principal cells.

FR-PO988

Possible Contribution of Fibrocytes to Renal Fibrosis in Cpk Mouse, a Model of ARPKD Taketsugu Hama,[1] Koichi Nakanishi,[1] Hironobu Mukaiyama,[1] Hiroko Togawa,[1] Yuko Shima,[1] Masayasu Miyajima,[2] Hisahide Takahashi,[3] Shizuko Nagao,[3] Kazumoto Iijima,[4] Norishige Yoshikawa.[1] *[1]Pediatrics, Wakayama Medical University, Wakayama, Japan; [2]Laboratory Animal Center, Wakayama Medical University, Wakayama, Japan; [3]Education and Research Center of Animal Model for Human Disease, Fujita Health University, Toyoake, Aichi, Japan; [4]Pediatrics, Kobe University, Kobe, Hyogo, Japan.*

Background: The pathophysiology of cystic epithelia in PKD is characterized by altered proliferative activity, a secretory rather than absorptive function, and an abnormal matrix microenvironment. However, the aspect of extracellular matrix abnormality, especially fibrosis, has not been fully investigated in PKD. Previously, we demonstrated epithelial-to-mesenchymal transition (EMT)-like phenotype in *cpk* mouse, a rapid progressive ARPKD model (JASN 21:520A,2010, 22:576A,2011). Although EMT is thought to be one of key features in PKD fibrosis, it seems to have only a partial role for fibrosis. Recently, circulating fibrocytes expressing both leukocyte (CD45) and mesenchymal (collagen type I) antigens have been clarified to have a key role of progressing fibrosis in any organ and they have the possibility of a new target for therapy. Therefore, we investigate fibrocytes contribution in *cpk* mouse to explore another candidate of fibrosis promoter.

Methods: Kidneys from 5 male *cpk* and control mice (each on day 0, 7, 14, 21) were harvested, and stained with anti-collagen type I antibody and Masson's trichrome stain to evaluate fibrosis. We also performed real-time PCR for collagen type I. We conducted a double-color immunofluorescence analysis using both anti-CD45 and anti-procollagen type I antibodies to identify fibrocytes in the kidney of *cpk* and control mice.

Results: Collagen type I expression area and gene level increased significantly according to age in *cpk* mice (1.4 ± 0.7, 1.8 ± 0.6, 2.9 ± 0.8, 4.3 ± 1.4 [mean ± SD]; relative to each control on day 0, 7, 14, 21), and dual-positive cells were detected predominantly in *cpk* mice.

Conclusions: These findings suggested that fibrocytes were recruited in *cpk* and participated in the progression of fibrosis. Therefore, they may be new targets for a disease-specific intervention.

RNA SEQ Validates the Transcriptional Complexity of *Pkhd1* Ravindra Boddu,[1] Gregory G. Germino,[2] Luiz F. Onuchic,[3] Lisa M. Guay-Woodford.[4] *[1]UAB, Birmingham, AL; [2]NIDDK/NIH, Bethesda, MD; [3]Univ Sao Paulo, Brazil; [4]CNMC, Washington, DC.*

Background: We previously analyzed a kidney-specific plasmid library generated from *Pkhd1* exon 1 and 67-containing amplicons and demonstrated that this mouse ARPKD gene orthologue is transcriptionally complex. Bioinformatic analyses and minigene experiments indicated that exon-splice enhancer (ESE) motifs modulate alternative exon usage. In the current study, we sought to use RNA-Seq strategies to validate the predicted splice variants and evaluate whether human missense variants that disrupt ESE motifs impact *PKHD1* splicing.

Methods: We initially applied standard RNA-Seq to WT kidney total RNA and detected all canonical *Pkhd1* exon junctions, as well as several novel junctions, though the read number for the latter was below the significance threshold. We then developed a novel, targeted strategy to specifically enrich IMCD cell-derived RNA for *Pkhd1* transcripts encoded by approximately 500 kb genomic sequence.

Results: The targeted RNA Seq strategy identified all canonical *Pkhd1* exon junctions, as well as the novel junctions captured in our amplicon catalogue. In addition, this unbiased approach identified novel exon junctions not represented in our catalogue. All novel junctions were expressed at levels at least 100-fold lower than the canonical junctions. These data are consistent with a recent report demonstrating low expression of alternative *Pkhd1* isoforms versus the full-length RNA (Ward *et al*, 2011). Given our evidence for alternative *Pkhd1* splicing, we evaluated 313 publically available missense mutations (http://www.humgen.rwth-aachen.de), as well as those reported to the UAB Hepatorenal Fibrocystic Disease Core Center. Many variants were predicted to disrupt one or more ESE motifs and minigene assays demonstrated that the R760H variant altered *PKHD1* splicing.

Conclusions: We conclude that *Pkhd1/PKHD1* is transcriptionally complex; transcriptional processing is modulated in part by ESEs; and alternative isoforms are expressed at significantly lower levels than the full-length RNA. We propose that mutational disruption of *PKHD1* ESEs may represent an under-appreciated pathogenic mechanism in ARPKD.

FR-PO990

A Singe Mutated Inv Gene Can Modify Murine pcy Nephronophthisis but Not cpk ARPKD Vincent H. Gattone,[1] Alexander J. Carr,[1] Robert L. Bacallao.[2] *[1]Anatomy & Cell Biology, Indiana University School of Medicine, Indianapolis, IN; [2]Nephrology Division, Dept of Medicine, Indiana University School of Medicine, Indianapolis, IN.*

Background: Modifier gene loci for PKD were found at chromosomal locations known to harbor other cystic disease genes. In *cpk, jck, bpk* and *pcy* models, a modifier loci was found on chromosome 4 in the general area known to harbor the *inv* and *mks3* genes. We hypothesized that a single mutant *inv* gene (nphp2) would influence the severity of the cystic pathology caused by the *pcy/nphp3* gene. There are known interactions in cultured cells between nephronophthisis protein products, *inv* with *nphp3* and *nphp9* (Cytoskel. 67:112-119,2010). The *inv* locus is thought to play an important role in ciliogenesis, a central defect in PKD. We tested whether such an interaction between *inv* and *nphp3* would cause an alteration in severity of the cystic phenotype *in vivo*.

Methods: FVB-*inv* mutant mice (*NPHP2*) were crossed with CD1-*pcy* mice (*NPHP3*) and the renal cystic pathology of resulting *pcy/pcy* mice that were *inv/+ or +/+* were compared. Similarly, *inv* mice were crossed with Balb/c-*cpk* mice with ARPKD and renal / biliary pathology assessed. *pcy/pcy* mice were evaluated at 4 weeks of age while *cpk/cpk* mice studied at 10 and 17 days of age.

Results: Non-pcy-cystic *inv/+* and *+/+* were not different suggesting minimal strain background influence on results. However, a single mutant *inv* gene made *pcy/pcy* renal cystic pathology worse at 4 weeks of age. The modifier loci for *cpk* severity on chromosome 4 was described as *kif12* (JASN 16:905-916, 2005). Unlike the *pcy* results, *inv* did not influence the severity of *cpk* ARPKD at either 10 or 17 days of age.

	Body Weight	Kidney Weight	KW%BW	Heart Wgt	Heart % BW
inv/+-pcy/pcy (30)	14.91± 0.42	0.673± 0.046	4.48 ± 0.26	0.098 ± 0.004	0.662 ± 0.026
+/+-pcy/pcy (7)	15.12 ± 0.91	0.460 ± 0.019	2.65 ± 0.11	0.089 ± 0.004	0.511% ± 0.051
	Body Weight	Kidney Weight	KW%BW	Bile Duct Diam.	Bile Duct/BW
inv/+-cpk/ cpk (8)	5.01 ± 0.33	0.333 ± 0.030	6.86 ± 0.70	2.46 ± 0.41	0.51 ± 0.12
+/+-cpk/cpk (3)	5.69 ± 0.47	0.420 ± 0.076	7.39 ± 1.28	2.90 ± 0.42	0.53 ± 0.10

Conclusions: A single mutant nphp gene can act as a modifier gene and alter disease severity, but this may not always be the case.

SDCCAG8 Interacts with RABEP2 and Modulates Sonic Hedgehog Signaling Rannar Airik,[1] Jens S. Andersen,[2] Friedhelm Hildebrandt.[1,3] *[1]Departments of Pediatrics and of Human Genetics, University of Michigan, Ann Arbor, MI; [2]Department of Biochemistry and Molecular Biology, University of Southern Denmark, Odense, Denmark; [3]Departments of Pediatrics and of Human Genetics, Howard Hughes Medical Institute, Ann Arbor, MI.*

Background: *SDCCAG8/NPHP10* is a novel ciliopathy gene, which if mutated, causes nephronophthisis-related ciliopathy (NPHP-RC), characterized by cystic kidneys, retinal degeneration and mild mental retardation in humans (1). We have recently generated a knock-out mouse model of *Sdccag8,* that recapitulates the human ciliopathy phenotypes.

Methods: In order to study the molecular defects in *Sdccag8*-deficient cells we isolated mouse embryonic fibroblasts (MEFs) from wild type and *Sdccag8*$^{-/-}$ embryos. Confluent MEFs were serum starved to induce ciliogenesis and treated with Sonic hedgehog (Shh) pathway agonist SAG to activate the pathway. qRT-PCR was used to analyze the changes in SHH target genes. To identify novel SDCCAG8 protein interaction partners SILAC-assay was performed in collaboration with J.A.

Results: While 80% of wild type cells were ciliated upon serum starvation, only 10% of *Sdccag8*$^{-/-}$ MEFs grew cilia. Moreover, *Sdccag8*$^{-/-}$ MEFs demonstrated very low mRNA levels of Patched1, Gli1 and Gli3 indicating defects in Shh pathway activation. This finding is corroborated by the presence of polydactyly phenotype in 80% *Sdccag8*$^{-/-}$ mice – a common phenotype of dysregulated Shh signalling in the developing limb bud. SILAC-assay identified RABEP2 as a novel interaction partner of SDCCAG8. RABEP2 has been previously implicated in promoting ciliogenesis (2). The protein interaction of SDCCAG8 and RABEP2 was confirmed by immunoprecipitation experiments.

Conclusions: Sdccag8 is required for ciliogenesis and Shh pathway activation. Our data indicate that defects in ciliogenesis and Shh pathway activation may explain some of the ciliopathy phenotypes in *Sdccag8*$^{-/-}$ mice. SDCCAG8 interaction with RABEP2 implicates SDCCAG8 in endosomal trafficking. Further understanding the role of *Sdccag8* in causing NPHP-RC will provide valuable insight into the pathogenetic mechanisms of ciliopathies.

FR-PO992

Loss of Function of Ruvbl1, a Regulator of DNA Damage Response, Causes Pronephric Cysts in Zebrafish Embryos Weibin Zhou,[1] Friedhelm Hildebrandt.[1,2,3] *[1]Pediatrics, University of Michigan, Ann Arbor, MI; [2]Human Genetics, University of Michigan, Ann Arbor, MI; [3]Howard Hughes Medical Institute.*

Background: Genotoxicity and DNA Damage Response (DDR) have been implicated in a variety of human diseases. Recent identification of mutations in proteins (CEP164 and FAN1) involved in DDR as the causes of nephronophthisis (1) and karyomegalic nephritis (2), suggests that defects in DDR may be a cause for renal cystic kidney diseases. ruvbl1 is a protein essential for DNA mismatch repair. It regulates DNA damage- induced histone 2X phosphorylation. We and others (3) found that zebrafish *ruvbl1* mutants displayed pronephric cysts and other ciliopathy-like phenotypes (such as hydrocephalus and retinal degeneration).

Methods: In order to understand the pathogenic mechanism of DDR defects in kidney diseases and test therapeutical compounds, we characterized a zebrafish cystic mutant model for *ruvbl1*.

Results: However,*ruvbl1* mutants had normal cilia in pronephros while the cysts developed. These fish mutant also showed an elevated gH2X and massive neuronal degeneration, indicating DDR defects. Interestingly, rapamycin treatment, which has been shown to protect cells from irradiation-induced DDR, rescued pronephric cysts in ruvbl1 mutants.

Conclusions: Our results confirm that DDR defects are linked to ciliopathy-like phenotypes and suggests that modulators of DDR may also be used to reduce renal cysts. Further study of the connection of DDR and cilium function is warranted to uncover the disease mechanism of "ciliopathy".

FR-PO993

Inactivation of the Epigenetic Factor Reptin Causes Kidney Cyst in Zebrafish Lu Zhao,[1] Shiaulou Yuan,[1] Ying Cao,[2] Zhaoxia Sun.[1] *[1]Yale University, New Haven, CT; [2]Tongji University, Shanghai, China.*

Background: The critical role of the cilium, a cell surface sensory organelle, in polycystic kidney diseases has been well appreciated in recent years. However, how ciliary defects lead to cyst formation remains unclear. In this study, we present evidence that inactivation of the AAA+ ATPase Reptin (also known as RuvbL2/TIP48), a conserved protein component in multiple chromatin-remodeling complexes, causes kidney cysts in zebrafish.

Methods: We show that zebrafish embryos with a proviral insertion in *reptin* (*reptin*^{hi2394} mutants) develop typical cilia associated phenotypes, including kidney cysts and ventrally body curvature. These phenotypes are reproduced in wildtype embryos injected with a morpholino against *reptin*. In addition, both mutants and morphants can be significantly rescued by expressing *reptin* mRNA.We further investigated potential functional interactions between Reptin and cilia. Genetic interaction studies suggest that *reptin* functions in the same genetic pathway as *ift172*, a gene essential for cilia biogenesis. Interestingly, unlike IFT mutants, *reptin*^{hi2394} mutant has no observable defect in cilia generation, maintenance, or size.

Results: Taken together, these results suggest that inactivation of Reptin can lead to kidney cyst formation. However, although *reptin* functions in the same genetic pathway with *ift172*, *reptin*^{hi2394} mutant has no observable ciliary morphologic defects.

Conclusions: In summary, our data suggest that loss of Reptin induces kidney cysts formation through a cilia related mechanism, although not through cilia biogenesis. Since Reptin has a well-defined role in epigenetic control through its interaction with various transcription factors, it will be interesting to investigate how Reptin inactivation leads to kidney cysts formation, and whether epigenetic regulation is involved in the cilia-kidney cysts model.

FR-PO994

The Novel Joubert Gene KIF7 Regulates Microtubular Dynamics and Cellular Polarity Max C. Liebau,[1,2] Claudia Dafinger,[2,3] Thomas Benzing,[2] Hanno Jörn Bolz,[3,4] Bernhard Schermer.[2] *[1]Department of Pediatrics, University Hospital of Cologne, Cologne, Germany; [2]Department of Internal Medicine II, Renal Division, University Hospital of Cologne, Cologne, Germany; [3]Institue of Human Genetics, University Hospital of Cologne, Cologne, Germany; [4]Bioscientia Center for Human Genetics, Ingelheim, Germany.*

Background: Joubert syndrome (JBTS) is characterized by a specific brain malformation with various possible additional pathologies including a nephronophthisis-like renal phenotype. It results from mutations in various different genes. JBTS has been linked to dysfunction of primary cilia since the gene products localize to this ancient organelle.

Methods: We recently identified a novel disease locus, *JBTS12*, with mutations in the *KIF7* gene in a consanguineous JBTS family by linkage analysis. Cellular KIF7 function was now assessed by multiple approaches.

Results: KIF7 regulates the structure of cilia, centrosomes and the Golgi network most likely by control of cytoplasmic tubulin acetylation and microtubular dynamics. Novel studies point to a role of KIF7 in the regulation of cellular polarity and cellular migration. KIF7 can act as a kinesin in intracellular trafficking and interacts with end-binding protein 1 indicating a potential role of KIF7 at microtubular plus ends. Imaging studies are compatible with these findings and confirmative for a function of KIF7 at the cilium and at the ciliary base.

Conclusions: The data suggest a regulation of cytoplasmic cellular microtubules through a mostly ciliary protein.

FR-PO995

RuvBl1 Is a Novel Nephrocystin-1 Interactor and Is Required for Tubular Cell Survival Max C. Liebau,[1,2] Claudia Dafinger,[2] Sandra Habbig,[1,2] Oliver Rinner,[3] Ruedi Aebersold,[3] Thomas Benzing,[2] Bernhard Schermer.[2] *[1]Department of Pediatrics, University Hospital of Cologne, Cologne, Germany; [2]Department of Internal Medicine II, Renal Division, University Hospital of Cologne, Cologne, Germany; [3]Institute of Molecular Systems Biology, Swiss Federal Institute of Technology, Zurich, Switzerland.*

Background: Nephronophthisis is the most common genetic cause of end stage renal failure during childhood and adolescence. Mutations in *NPHP1* encoding the ciliary protein nephrocystin-1 (NPHP1) are a frequent cause of nephronophthisis. However, the cellular NPHP1 protein function is poorly understood.

Methods: In a recently described immunoprecipitation-based gel-free mass spectrometry approach candidates for NPHP1-interacting proteins were identified. Interactions were confirmed with independent methods. For various interactors cellular function was studied in vitro and *in vivo*.

Results: We identified novel candidate proteins and known nephrocystins. One of the confirmed novel interactors was RuvBl1, an AAA ATPase with known roles in the regulation of WNT signalling and DNA damage response signalling. Knockdown of the RuvBl1 homolog in zebrafish leads to cystic kidneys. To further study renal RuvBl1 function *in vivo*, we generated a tubule-specific *Ruvbl1*-knockout mouse. Tubule-specific *Ruvbl1*-deficiency led to neonatal death and tubular cell degradation.

Conclusions: The data support the recently established link between ciliary proteins and members of the DNA-damage response signalling pathway.

Funding: Government Support - Non-U.S.

FR-PO996

Wtip and Vangl2 Are Required for Mitotic Spindle Orientation and Cloaca Morphogenesis Tomoko Obara. *Cell Biology, University of Oklahoma Health Science Center, Oklahoma City, OK.*

Background: Defects in cilia and basal bodies function are linked to ciliopathies, which result in kidney cyst formation. Recently, cell division defects have been observed in cystic kidneys, but the underlying mechanisms of such defects remain unclear. Wtip is an LIM domain protein of the Ajuba/Zyxin family, but its role in ciliogenesis during embryonic development has not been previously described.

Methods: Cloning full length of zebrafish *wtip* and *wtip* gene expression by RT-PCR, *in situ* hybridization, whole-mount immunochemistry, morpholino and mRNA injections, histological analysis, electron microscopy, high-speed video microscopy.

Results: We report Wtip is enriched in the basal body and knockdown of *wtip* leads to pronephric cyst formation, cloaca malformation, hydrocephalus, body curvature, and pericardial edema. We additionally show that *wtip* knockdown embryos display segment-specific defects in the pronephros: mitotic spindle orientation defects are observed only in the anterior and middle pronephros; cloaca malformation is accompanied by a reduced number of ciliated cells; and ciliated cells lack the striated rootlet that originates from basal bodies, which results in a lack of cilia motility. Our data suggest that loss of Wtip function phenocopies Vangl2 loss of function, a core planar cell polarity (PCP) protein located in the basal body protein. Furthermore, we demonstrate that *wtip* and *vangl2* interact genetically.

Conclusions: Taken together, our results indicate that in zebrafish, Wtip is required for mitotic spindle orientation in the anterior and middle of the pronephros, cloaca morphogenesis, and PCP, which may underlie the molecular etiology of ciliopathies.

FR-PO997

Knockdown of *BBS10* in Renal Cells Affects Apical Targeting of AQP2: A Possible Explanation for the Polyuria Associated with Bardet-Biedl Syndrome Giuseppe Procino,[1] Miriam Zacchia,[2] Claudia Barbieri,[1] Monica Carmosino,[1] Giovambattista Capasso,[2] Maria Svelto.[1] *[1]Department of Biosciences, Biotechnologies and Pharmacological Sciences, University of Bari Aldo Moro, Bari, Italy; [2]Department of Internal Medicine, 2nd University of Naples, Naples, Italy.*

Background: Bardet-Biedl syndrome (BBS) is a autosomal-recessive ciliopathy characterized by defects in multiple organ systems causing retinal degeneration, obesity, hypogonadism, polydactyly, mental retardation, and renal dysfunction. In particular, polyuria and polydipsia, with impairment of renal concentration ability, are the earliest signs of renal dysfunction.

Among the 14 identified genes *(BBS1-14),* mutated in BBS patients, *BBS10* and BBS1 contribute approximately 40% of all known mutations. BBS1 partecipates to the formation of the BBSome, a BBS proteins complex having importance in ciliary biogenesis and elongation. BBS10 is not associated with the BBSome and may also be involved in non-ciliary-related microtubule-based transport. Interestingly, patients with BBS10 mutations show a more severe renal phenotype.

Methods: In order to investigate whether the polyuria associated with BBS might be related to a defect in the shuttling of the water channel AQP2 in the kidney collecting duct, we studied the effect of *BBS1* or *BBS10* knockdown in AQP2-expressing renal cells.

Results: Interestingly, apical surface biotinylation indicated that siRNA-mediated silencing of BBS10 but not BBS1 dramatically and specifically prevented the forskolin-induced exocytosis of AQP2 at the apical membrane.

In the same experimental condition, immunofluorescence, followed by confocal analysis, showed that silencing of *BBS10* but not *BBS1* strongly affected the organization of the microtubules cytoskeleton within the cell. As a consequence, we observed that, upon FK treatment, AQP2 mostly redistributed to the basolateral membrane with negligible increase at the apical membrane.

Conclusions: Taken together, these results suggest that lost of proper microtubule-based polarized transport in the collecting duct cells might cause basolateral misrouting of AQP2 and might explain the urine concentration defect of BBS patients carrying mutations of BBS10.

FR-PO998

Role of the Small GTPase Cdc42 in Renal Ciliogenesis Soo Young Choi,[1] Liwei Huang,[1] Xiaofeng Zuo,[1] Sarah Mckenna,[1] Rebecca D. Burdine,[2] Joshua H. Lipschutz.[1] *[1]Renal Electrolyte and Hypertension Division, University of Pennsylvania School of Medicine, Philadelphia, PA; [2]Molecular Biology, Princeton University, Princeton, NJ.*

Background: Primary cilia have been strongly implicated in ADPKD pathogenesis, and disruption results in cysts that destroy the kidney. In renal tubule cells, we showed that the highly conserved eight-protein exocyst complex, which is involved in targeting and docking vesicles carrying membrane proteins, was necessary for ciliogenesis; that *sec10* knockdown phenocopied *pkd2* knockdown in zebrafish; and that the small GTPase Cdc42 interacted with exocyst Sec10 to regulate ciliogenesis in MDCK cells.

Methods: Given the importance of Cdc42 for cell function, to study how *cdc42* affects ciliogenesis and cystogenesis *in vivo*, we used two different animal models and techniques: antisense morpholinos (MOs) to knockdown *cdc42* in zebrafish, and the Cre-Lox system to knockout Cdc42 in a kidney-specific manner in mice. Zebrafish embryos were injected with *cdc42* start-site MOs. Cdc42 renal tubule specific knockout mice were generated by breeding Cdc42 floxed and Ksp-cadherin Cre mice.

Results: *cdc42* morphants developed pericardial edema, short tail, small eyes, abnormal cilia, left-right patterning defects, and glomerular expansion that phenocopied *sec10* and *pkd2* morphants. Co-injection of small amounts of *cdc42* and *sec10* MOs, which individually had no effect, together resulted in an abnormal phenotype, which suggests that *cdc42* and *sec10* act in the same pathway. For Cdc42 kidney-specific knockout, 7 female $Cre^{ksp/+}$-$Cdc42^{fl/+}$ mice were backcrossed against 2 male $Cdc42^{fl/fl}$ mice, and 38 pups evaluated. Of 38 pups, 9 $Cdc42^{fl/+}$, 14 $Cdc42^{fl/fl}$, and 14 $Cre^{ksp/+}$-$Cdc42^{fl/+}$ living mice, and only 1 dead $Cre^{ksp/+}$-$Cdc42^{fl/fl}$ knockout mouse, were identified. The non-Mendelian ratio (1/38) suggests that kidney-specific knockout of Cdc42 leads to early postnatal lethality.

Conclusions: In zebrafish, *cdc42* knockdown results in a ciliary phenotype, and *cdc42* acts synergistically with exocyst *sec10*. Cdc42 kidney-specific knockout in mice leads to an early postnatal death. Taken together, these data suggest that Cdc42 is essential for normal cilia function and nephrogenesis.

FR-PO999

Septin 7b Participates in Ciliogenesis and Regulates Kidney Function in Zebrafish Surjya Narayan Dash,[1] Eero Lehtonen,[1] Pertti Panula,[2] Sanna H. Lehtonen.[1] *[1]Haartman Institute, University of Helsinki, Finland; [2]Neuroscience Center and Institute of Biomedicine/Anatomy, University of Helsinki, Finland.*

Background: The small filament-forming, GTP-binding protein septin 7 is expressed in glomerular epithelial cells but its function in the kidney is unknown.

Methods: To study the role of septin 7 in the kidney, we used morpholino antisense oligonucleotides to knock down septin 7b in zebrafish and analysed the kidney function by using a labelled tracer.

Results: qRT-PCR showed septin 7b mRNA expression already at 2 hours post fertilization and by whole mount in situ hybridization, we found that septin 7b is enriched in the brain, pronephros and cloaca in 1-4 days post fertilization (dpf) larva. Immunostaining of 4 dpf larva revealed that septin 7 concentrates in the apical region of the pronephric tubules and ducts. Suppression of septin 7b with morpholinos caused pericardial and yolk sac edema, pronephric cysts, dorsal body axis curvature and hydrocephalus in 3.5 dpf larva indicating defects in kidney and cilia function. The phenotype of the morphants was rescued by co-injecting in vitro transcribed capped zebrafish septin 7b mRNA along with the morpholinos. Light microscopy indicated that the morphant embryos had distended glomeruli, pronephric tubules and ducts. Electron microscopy revealed podocyte foot process effacement and irregular microvillar-type cell processes extending from the apical surface of podocytes. Pronephric tubules appeared dilated with sparse microvilli that appeared irregular and atrophic. Further, injection of labelled dextran indicated defects in fluid flow in septin 7b morphant zebrafish suggesting dysfunction of pronephric cilia. Staining for acetylated tubulin revealed disorganization and shortening of the cilia in morphants suggesting that septin 7b participates in ciliogenesis. We also found that septin 7 is present at the base of the cilia in cultured mIMCD-3 (mouse inner medullary collecting duct) cells further suggesting that septin 7 may play a role in ciliogenesis.

Conclusions: Ciliary dysfunction and cyst formation in the kidney due to suppression of septin 7b provides new insights into the role of septin 7 in kidney diseases and ciliopathies.

FR-PO1000

The Nephrocystins NPHP9 and NPHP4 Corporately Activate the Hippo Downstream Effector TAZ Sandra Habbig,[1,2] Malte P. Bartram,[2] Roman-ulrich Mueller,[2] Mareike Franke,[2] Thomas Benzing,[2] Bernhard Schermer.[2] *[1]Pediatric Nephrology, University Childrens Hospital, Cologne, Germany; [2]Department II of Internal Medicine, University Hospital, Cologne, Germany.*

Background: Mutations in NPHP genes cause Nephronophthisis (NPH), an inherited cystic kidney disease leading to end stage renal failure in children and adolescents. To date, 12 NPHP genes have been identified. Interestingly, all of them encode for proteins that assemble functional complexes at centrosomes and cilia, linking NPH to a group of oligogenetic disorders called ciliopathies. Despite numerous studies the function of the NPH protein complex in cellular signaling is still not well understood.

Recently, we identified NPHP4 to be an inhibitor of the Hippo signalling pathway implicating that the pathogenesis of NPH and related ciliopathies is linked to dysregulation of the Hippo signaling cascade. De-repressed Hippo signalling and the resulting decrease in the proliferative potential due to the loss of NPHP4 function presents a potential disease mechanism that could explain the rather small, degenerative kidneys, the phenotypic hallmarks in NPH. However this finding had not been extended to other NPH proteins.

Results: Here, we demonstrate that the kinase Nek-8, which is a part of the NPH protein complex and encoded by the NPHP9 gene, also represses hippo signalling and enhances the activity of TAZ/TEAD transcription. Strikingly, all three previously described patient mutations did not affect TAZ/TEAD transcriptional activity. Biochemical analysis revealed that Nek-8 interacts with the hippo effector protein TAZ thereby stabilizing TAZ in its active form in the nucleus. Interestingly, this effect is enhanced in the presence of NPHP4 which promotes the nuclear accumulation of NPHP9.

Conclusions: Our data suggest that NPHP4 acts upstream of NPHP9/ Nek8 and provides further evidence for a role of dysregulated hippo signalling in the pathogenesis of NPH. Both, NPHP4 and NPHP9 antagonize hippo signalling and consecutively stimulate cell proliferation.

FR-PO1001

The Intracelluar Signaling Pathway in Renal Cyst Development of *inv* Mutant Mice Noriyuki Sugiyama, Takahiko Yokoyama. *Anatomy and Developmental Biology, Kyoto Prefecture University of Medicine, Graduate School of Medical Science, Kyoto, Japan.*

Background: Recent studies have identified several genes whose defects cause hereditary renal cystic diseases. Most of these gene products are located in the primary cilia. It has been proposed that primary cilia are involved in signaling pathways. Defects in these signaling pathways are considered to result in abnormal cell proliferation and random oriented cell division in the kidney, which lead to renal cyst formation. The *inv* mutant mouse, a model for human nephronophthisis (NPHP) type 2, develops multiple renal cysts. However, it was not clarified that the intracellular signaling pathway caused renal cyst development in *inv* mutant mice. Then, we searched for the intracellular signaling pathway changed during renal cyst development in *inv* mutant mice.

Methods: We analyzed some intracellular signaling pathways, canonical Wnt/b-catenin, MAPK (ERK, P38 MAPK, and JNK/c-Jun), AKT, STAT, hedgehog intracellular signaling pathway. In *inv* mouse kidneys. Further, we examined the effects of ERK and p38 MAPK inhibition on renal cyst development in *inv* mutant mice.

Results: ERK and p38 MAPK signaling were continued to activate in an early phase in renal cyst development. Activations of STAT3 and JNK/c-Jun signaling were detected in a late phase. Activation of other signals was not detected in *inv* kidneys. Inhibition of ERK signaling reduced renal cyst expansion, abnormal tubular cell proliferation, and fibrosis without affecting p38 MAPK activation. In contrast, inhibition of p38 MAPK decreased the degree of fibrosis. However, the FR167653 did not prevent cyst expansion, abnormal cell proliferation.

Conclusions: These results suggest that the ERK signaling pathway were important in all phenomena of renal cyst development in *inv* mutant mice and the p38 MAPK signaling pathway was related in renal fibrosis but not cyst development. Further, our results suggest that p38 MAPK and ERK signaling pathways independently affect renal fibrosis in *inv* mutant mice.

Defining Uraemic Arterial Functional Abnormalities in HD Patients: Combination of In Vivo and Ex Vivo Arterial Assessment Adil Mohamed Abushufa,[1] Mohamed Tarek Eldehni,[1,2] Aghogho Odudu,[1,2] Philip D. Evans,[1,2] Saoirse O'Sullivan,[1] Chris W. McIntyre.[1,2] *[1]Graduate Entry Medical School, University of Nottingham, Derby, United Kingdom; [2]Department of Renal Medicine, Royal Derby Hospital, Derby, United Kingdom.*

Background: Haemodialysis (HD) patients exhibit significant abnormalities in vascular structure and function, which impact on cardiovascular mortality. The mechanisms underlying these changes are still unclear. We aimed to examine vascular function in isolated subcutaneous arteries of HD patients using myography having first characterised the patients in vivo.

Methods: Abdominal subcutaneous fat biopsies were obtained from 11 HD patients and 26 normal controls. Arteries were dissected, mounted and conducted on a wire myography. Cumulative concentration-response curves were constructed to the following; noradrenalin (NA), endothelin-1 (ET-1), thromboxane A2 (U46619), angiotensin II (AngII), vasopressin,

bradykinin (BK), acetylcholine (Ach) and sodium nitroprusside (SNP). Pulse Wave Velocity (PWV) was measured in HD patients in addition to blood pressure.

Results: Greater contractile responses to U46619, AngII, and vasopressin were observed in all HD arteries compared to controls. The maximum vasorelaxant response to Ach and BK (endothelium-dependent vasodilators) was significantly lower in HD patients than controls; while a similar response to SNP (endothelium-independent response) was obtained in both groups (table1). PWV correlated with the maximum contractile to Vasopressin in large arteries (r=0.829, P=0.042).

Conclusions: Larger vessel responses were correlated to in vivo assessment of arterial function. HD patients are primed to hypertension and end organ demand ischaemia by a markedly elevated pressor response to a wide range of stimuli. The failure of arterial relaxation is mediated by endothelial dysfunction. **Table 1 Maximum responses (R max) to different vasoactive agents in small arteries.**

		HD	Control	P
R Max	NA	5.73 ± 0.16	5.61 ± 0.19	0.6872
	ET-1	11.17 ± 0.27	8.97 ± 0.60	0.0155
	U46619	14.03 ± 0.35	9.31 ± 0.36	< 0.0001
	AngII	7.39 ± 0.22	4.80 ± 0.25	< 0.0001
	Vasopressin	15.13 ± 0.39	7.011 ± 0.42	< 0.0001
% Relaxation	BK	35.67 ± 0.78	40.08 ± 0.62	0.0008
	Ach	36.22 ± 1.29	53.83 ± 1.32	< 0.0001

Gene Expression Analysis of Neointimal Hyperplasia in Arteriovenous Grafts Sun Hyung Kwon,[1] Li Li,[2] Christi M. Terry,[2] Yan-Ting E. Shiu,[2] Huan Li,[2] Ilya S. Zhuplatov,[2] Donald Blumenthal,[1] Alfred K. Cheung.[2,3] *[1]Pharmacology and Toxicology, Univ. of UT, Salt Lake City, UT; [2]Medicine, Univ. of UT, Salt Lake City, UT; [3]Medicine, VASLCHCS, Salt Lake City, UT.*

Background: Failure of arteriovenous grafts (AVG) occurs frequently and predominantly as a consequence of neointimal hyperplasia (NH) formation at the venous anastomosis. Development of effective therapies for NH is impeded by our limited understanding of the molecular genesis of NH.

Methods: A porcine model of AVG stenosis was employed and global gene expression microarray analysis was used to determine the genomic responses of the vein at early time points following AVG placement. We explored genes that were differentially expressed in the NH-prone (venous anastomosis) and NH-resistant (downstream venous segment) regions, compared to the un-operated vein at 5 days and at 14 days post-AVG placement (ANOVA $p<0.05$ with at least 4-fold changes).

Results: Statistical analysis revealed that, compared to the un-operated control vein, the number of significantly altered genes was higher in the NH-prone region than in the NH-resistant region (262 vs. 150 and 224 vs. 108 at 5 days and 14 days, respectively). A substantial number (65%) of such spatially and/or temporally regulated genes in the NH-prone region are associated with gene ontology terms that are consistent with processes occurring during NH development, such as cell proliferation, adhesion and migration, vasculogenesis, extracellular matrix (ECM) organization, and immune response. Notably, genes related to ECM organization and cell motility (e.g., IBSP, SPP1, ADAM7, DCHS2, PHACTR3 and COL11A1) were among the most highly up-regulated in the NH-prone region. The up-regulation of these genes may contribute to the early pathogenesis of NH.

Conclusions: Global gene expression profiling of NH-prone regions at the AVG anastomosis provides clues to the molecular basis underlying the pathophysiology of NH, and may suggest strategies for the development of targeted anti-NH therapies.

FR-PO1004

ANCA-Associated Systemic Vasculitis Is Associated with Impaired Dilatory Capacity of the Conduit Brachial Artery: A Link to Increased Cardiovascular Risk? Peter Clausen, Wladimir M. Szpirt, Bo Feldt-Rasmussen. *Department of Nephrology, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark.*

Background: ANCA-associated systemic vasculitis (AAV) affects small vessels but has also been shown to be associated with subsequent increased macrovascular cardiovascular risk. This study tested the dilatory capacity of the conduit brachial artery and the plasma concentration of the potential vascular marker von Willebrand Factor (vWF) at diagnosis and the effect of immunosuppressive treatment on these parameters in order to examine potential pathophysiological mechanisms behind the association.

Methods: The dilatory responses of the brachial artery (percentage of baseline) to post-ischemic increased blood flow (endothelium-dependent flow-associated dilatation (FAD) and to sublingually administered nitroglycerin (endothelium-independent nitroglycerin-induced dilatation (NID)) were measured by ultrasound in 24 patients with newly diagnosed AAV (female/male: 9/15, age: 55±12 years) and compared to measurements in 24 healthy controls (female/male: 9/15, age: 59±7 years). Plasma concentration of vWF was measured by ELISA. Patients were reexamined after 6 and 12 months of immunosuppression (plasmapheresis, corticosteroids and cyclophosphamide followed by azathioprine). All patients reached remission during follow-up.

Results: NID was impaired in patients with AAV as compared to controls (109±6 vs. 123±5%, $p<10^{-8}$) whereas a tendency to impaired FAD did not reach statistical significance (102±3 vs. 104±4%, p=0.17). Plasma vWF concentration was increased in patients (2.0 (1.0-3.8) kIU/L vs. 1.1 (0.4-1.8), $p<10^{-6}$). One year of immunosuppressive treatment did not affect neither NID, FAD nor vWF in patients.

Conclusions: The dilatory capacity of the brachial artery is impaired and the plasma concentration of von Willebrand Factor, a potential marker of vascular function, is increased in ANCA-associated systemic vasculitis. These disturbances are not reversed by 1 year of immunosuppression. This may indicate a sustained damage also to major vessels which could be a potential mechanism underlying the demonstrated association between ANCA-associated systemic vasculitis and increased cardiovascular risk.

FR-PO1005

Sildenafil Reduces Arterial Stiffness in ESRD Patients Treated with Hemodialysis William D. Paulson,[1,2] Allison Dubner,[2] John White,[2] David M. Pollock,[2] Jennifer S. Pollock,[2] Gaston K. Kapuku.[2] *[1]Charlie Norwood VAMC, Augusta, GA; [2]Georgia Health Sciences University, Augusta, GA.*

Background: ESRD is characterized by increased arterial stiffness, which contributes to high cardiovascular morbidity and mortality. Measures that reduce arterial stiffness may potentially improve cardiovascular outcomes, but there are currently no established treatments for this problem. In this study, we tested the hypothesis that sildenafil, which enhances and prolongs the effects of nitric oxide, decreases pulse wave velocity (PWV) and increases small artery elasticity index (SAE) in hemodialysis patients.

Methods: Chronic hemodialysis patients (mean age = 47 years, range 19-78) were randomly assigned to ingest a placebo (N = 20) or 50 mg sildenafil capsule (N = 20). Just before, and 60 and 120 min post ingestion, patients underwent measurement of arterial blood pressure, carotid-femoral PWV (SphygmoCor System), and SAE (HDI/PulseWave System).

Results: Mean values in the 40 patients were consistent with increased arterial stiffness: high systolic (144.0 ± 3.5 mmHg [±SE]) and pulse pressures (61.9 ± 1.9 mmHg), high PWV (9.36 ± 0.47 m/sec), and low SAE (5.37 ± 0.40 ml/mmHg·100). After ingesting the capsule, PWV in the control group increased by 0.56 ± 0.29 m/sec and decreased in the sildenafil group by 0.39 ± 0.32 m/sec (P = 0.037) during the next 120 min. Similarly, SAE decreased in the control group by 0.65 ± 0.52 ml/mmHg·100 and increased in the sildenafil group by 0.80 ± 0.63 ml/mmHg·100 (P = 0.08). Patients with the highest baseline PWV had the largest decrease in PWV at 120 min after sildenafil ($R^2 = 0.247$, P = 0.05), and patients with the lowest baseline SAE had the largest increase in SAE ($R^2 = 0.205$, P = 0.045).

Conclusions: ESRD patients treated with hemodialysis have increased arterial stiffness, manifested by high PWV and low SAE. In this randomized study, a single 50 mg dose of sildenafil significantly improved PWV and SAE when compared with a control group. These results suggest that treatments that enhance and prolong the effects of nitric oxide could potentially improve cardiovascular outcomes in ESRD.

Matrix Metalloproteinase 10 and Coronary Artery Calcification in Chronic Kidney Disease Patients without Cardiovascular Disease Joaquin Manrique,[1] Alvarez Virginia,[3] Carolina Purroy,[1] Fernanda Slon,[1] Josune Orbe,[2] José A. Paramo,[2] Jesus Arteaga,[1] Jose A. Rodriguez.[2] *[1]Nephrology, Complejo Hospital Navarra, Pamplona, Spain; [2]Atherosclerosis Research Lab, Division of Cardiovascular Sciences, CIMA, Universidad de Navarra, Pamplona, Spain; [3]Cardiology, Complejo Hospital Navarra, Pamplona, Spain.*

Background: Cardiovascular disease is the main cause of mortality among chronic kidney disease (CKD) patients and atherosclerosis is the common pathophysiological substrate for ischemic vascular diseases and their thrombotic complications. Accelerated vascular dysfunction and calcification is also highly prevalent in patients with CKD. The imbalance between matrix metalloproteinases (MMP) and their inhibitors has been proposed to play a main role in atherosclerosis progresion and plaque rupture. We hypothesized that MMP-10 can be associated with atherosclerosis burden in CKD patients, measured by coronary artery calcification.

Methods: a cross-sectional, observational study including 75 CKD patients stages III–V, without previous cardiovascular disease (stroke, cardiac or peripheral), and 30 healthy control subjects. Serum MMP10 levels were measured by enzyme-linked immunosorbent assay and coronary artery calcification (CAC) was determined by multi-detector computed tomography (Agatston score).

Results: CKD patients exhibited significantly augmented serum MMP-10 levels as compared with control subjects ($p<0.001$), and also higher incidence of coronary calcification ($p<0.01$). Patients on dialysis showed increased MMP-10 and vascular calcification, in comparison with earlier stages of CKD ($p<0.05$ both). However, no relationship could be found between MMP-10 and vascular calcification in CKD patients, that was mainly associated with age. MMP10 was associated with PTH levels ($p<0.05$) and, among patients with stages III&IV, correlated inversely with GFR ($p<0.01$).

Conclusions: increased serum MMP10 levels in CKD are closely related with renal function but not with coronary calcification in CKD patients without previous cardiovascular disease.

FR-PO1007

The Protein Acyl Transferase ZDHHC21 Is a Novel Regulator of α1 Adrenergic Receptor Signaling, Vascular Tone, and Blood Pressure
Ethan P. Marin,[1] Kara Held,[2] Annarita Di Lorenzo,[2] Heino Velazquez,[1] William C. Sessa.[2] *[1]Nephrology, Yale School of Medicine, New Haven, CT; [2]Pharmacology, Yale School of Medicine, New Haven, CT.*

Background: Multiple proteins involved in α1 adrenergic signal transduction require palmitoylation, the reversible post-translational attachment of a lipid (typically palmitate) to specific cysteine residues. Protein palmitoylation is generally catalyzed by members of the newly-described ZDHHC family of protein acyl transferases, The role of ZDHHC enzymes in vascular function is unknown.

Methods: We have characterized cardiovascular function in a mutant mouse strain that expresses a nonfunctional mutant of ZDHHC21, an isoform widely expressed in vascular and other tissues. Experiments have included (1) ex vivo myograph studies of isolated aortic rings and mesenteric arteries, (2) in vivo studies using ambulatory blood pressure measurements and echocardiography, and (3) in vitro studies of signaling in cultured cells derived from ZDHHC21 mutant mice.

Results: Aortic rings and mesenteric arteries isolated from ZDHHC21 mutant mice both displayed specific defects in response to phenylephrine, an α1 adrenergic receptor agonist. In vivo, the mutant mice displayed significant tachycardia and nocturnal hypotension. Stroke volume and fractional shortening were normal. There was also significant blunting of circadian cycles of heart rate and blood pressure. Cultured vascular smooth muscle cells from mutant mice mobilized calcium normally in response to phenylephrine.

Conclusions: Together the data support the presence of hypotension and tachycardia due to diminished peripheral vascular resistance in ZDHHC21 mutant mice. The underlying mechanism likely involves reduced vascular responsiveness to α1 adrenergic agonists. The molecular defect in adrenergic signaling may lie in pathways that modulate the sensitivity of smooth muscle contraction to calcium concentration rather than calcium mobilization itself. In sum, these data identify ZDHHC21 as a novel regulator of vascular α1 adrenergic receptor signaling and may reveal new targets to modulate vascular tone and blood pressure.

Glyoxalase I Ameliorates Age-Related Endothelial Dysfunction
Airi Jo,[1] Takamoto Ohse,[1] Reiko Inagi,[1] Yoichiro Ikeda,[1] Toshio Miyata,[2] Yasunobu Hirata,[3] Masaomi Nangaku.[1] *[1]Division of Nephrology and Endocrinology, University of Tokyo, Tokyo, Japan; [2]Tohoku University, Miyagi, Japan; [3]Department of Cardiovascular Medicine, University of Tokyo, Tokyo, Japan.*

Background: Endothelial dysfunction is a major culprit of chronic kidney disease (CKD) and cardiovascular diseases (CVD), especially in elder people. Extracellular advanced glycation end-products (AGEs) are associated with age-related endothelial dysfunction, however, the role of intracellular glycation affecting endothelial function is not elucidated. We investigated effect of glycation in thoracic aorta of rats systemically overexpressing glyoxalase I (GLO-1), which detoxifies methylglyoxal (MG), a typical reactive intermediate carbonyl formed in early glycation process.

Methods: Four groups of rats: young (13-week)/ old (48-week) and wild type (WT)/ glyoxalase I-overexpressing (Tg) Wistar rats, were examined. GLO-1 activity was measured for all groups. Glycated protein level and senescence markers of thoracic aorta were evaluated by immunohistochemistry. Finally, we examined endothelium -dependent and -independent vasorelaxation by tension studies of aortic ring treated with acetylcholine or sodium nitroprusside.

Results: There was no significant difference in blood pressure and glucose tolerance among 4 groups. Plasma lipid levels of old WT and Tg were comparable. GLO-1 activity was twice as high in young and old Tg as WT rats of the same age. MG-modified protein (argpyrimidine) was increased in aortic intima of old WT rats compared with young, while age-related accumulation of argpyrimidine was significantly reduced in Tg rats. Expression of senescence markers p53, p21, and p16 was decreased in aortic intima of old Tg compared with WT of the same age. Tension studies showed attenuation of age-related endothelial dysfunction in Tg compared with WT, while there was no difference in endothelium-independent vasorelaxation between WT and Tg rats.

Conclusions: The present study revealed that glycation was accelerated in intima of thoracic aorta with aging, and that age-related endothelial dysfunction was attenuated by GLO-1 overexpression. GLO-1 appears to be a potent target for prevention and treatment of CKD and age-related CVD.

FR-PO1009

Defective EphrinB2 Reverse Signaling Promotes Capillary Rarefaction and Fibrosis after Kidney Injury
Yujiro Kida,[1] Amparo Acker-Palmer,[2] Jeremy Stuart Duffield.[1] *[1]Nephrology and Center for Lung Biology, University of Washington, Seattle, WA; [2]Institute of Cell Biology and Neuroscience, Goethe University Frankfurt, Frankfurt am Main, Germany.*

Background: Microvascular disease is a characteristic of acute and chronic kidney diseases, which leads to rarefaction of peritubular capillaries (PTCs) and promotes secondary injury due to ischemia, a process that may be central to kidney disease progression. We recently showed that pericytes detach themselves from PTCs in response to injury and this detachment is an important step both for PTC rarefaction and fibrosis, but our understanding of the molecular signals in this process is limited. Bidirectional signaling by EphB4 receptor and ephrinB2 ligand has been identified as a critical angiogenesis cue during embryogenesis and fetal development. Therefore, we investigated the role of ephrinB2 reverse signaling in injury-induced angiogenesis, and subsequent PTC rarefaction and fibrosis in the kidney.

Results: EphrinB2 reverse signaling was activated in the kidney only after injury induced by unilateral ureteral obstruction (UUO). Mice lacking the PDZ intracellular signaling domain of ephrinB2 (ephrinB2 dV) experienced impaired angiogenesis followed by increased PTC rarefaction and increased fibrosis after kidney injury. EphrinB2 dV primary kidney pericytes were more migratory than wild type (WT) pericytes, had impaired capacity to stabilize capillaries generated in 3D culture, and impaired capacity to stimulate capillary basement membrane synthesis. EphrinB2 dV primary kidney microvascular endothelial cells (MVECs) migrated and proliferated less than WT MVECs in response to vascular endothelial growth factor A (VEGFA) and showed impaired internalization and activation of VEGF receptor-2 (VEGFR2).

Conclusions: Defective PDZ binding motif dependent ephrinB2 reverse signaling promotes PTC rarefaction via impaired angiogenesis and impaired vascular stability during kidney injury. Additionally, defective PDZ binding motif dependent ephrinB2 reverse signaling in kidney pericytes promotes pericyte to myofibroblast transition and myofibroblast activation, leading to enhanced fibrosis.

FR-PO1010

Cyclosporine Attenuates Arginine Transport, in Human Endothelial Cells, through Modulation of Cationic Amino Acid Transporter-1
Gil Chernin,[1] Tamara Chernichovski,[1] Doron Schwartz,[1] Idit F. Schwartz.[1] *[1]Nephrology, Tel-Aviv Medical Center, Tel Aviv, Israel; [2]Tel Aviv University, Tel Aviv, Israel.*

Background: The spectrum of cardiovascular toxicity by cyclosporine (CSA) includes hypertension, accelerated atherosclerosis, and thrombotic microangiopathy, all of which are the result of endothelial cell dysfunction (ECD). ECD is characterized by decreased endothelial nitric oxide synthase (eNOS) activity. Cationic amino acid transporter-1 (CAT-1) is the specific arginine transporter for eNOS. Cyclosporine has been shown to attenuate nitric oxide generation. However, the mechanism remains elusive.

Methods: We studied the effect of cyclosporine on arginine uptake by human umbilical vein endothelial cell cultures (HUVEC) in the absence and presence of L-arginine.

Results: Cyclosporine (0.1-0.5 mmole/L) significantly attenuated arginine transport in a dose and time dependent manner, a phenomenon which was prevented by co-incubation with L-arginine (1 mM). The aforementioned findings were accompanied by increased protein nitration, a measure of peroxynitrite accumulation. Protein abundance of CAT-1, PKCα, and phsphorylated PKCα (CAT-1 inhibitors) were not affected by cyclosporine. Co-incubation of cells exposed to CSA with a JNK inhibitor abolished CSA effect on arginine transport.

Conclusions: Cyclosporine inhibits arginine transport in HUVEC through post translational modulation of CAT-1, possibly through activation of the MAP kinase JNK pathway.

FR-PO1011

Loss of the Endothelial Glucocorticoid Receptor Prevents Rescue by Dexamethasone in a Mouse Model of Sepsis
Julie Goodwin,[1] Yan Feng,[1] William C. Sessa.[2] *[1]Pediatrics, Yale University School of Medicine, New Haven, CT; [2]Pharmacology, Yale University School of Medicine, New Haven, CT.*

Background: The glucocorticoid receptor (GR) is ubiquitously expressed in most cell types and previous studies suggest that elimination of GR in specific tissues may have profound effects. The synthetic steroid dexamethasone (DEX), which acts through GR, is often given systemically in sepsis, sometimes with questionable benefit.

Methods: In vivo, mice with a tissue specific deletion of endothelial GR (eGR) and their littermate controls were pre-treated with DEX 2 mg/kg and then sepsis was induced by injecting LPS 12.5 mg/kg. Survival was monitored over a period of 4 days. Corticosterone, IL-6 and nitric oxide levels were measured at baseline and 8 hours after LPS injection. Continuous blood pressure and heart rate monitoring were also performed in anesthetized mice at baseline and after DEX pre-treatment and acute LPS injection.

Results: Survival in control animals after DEX+LPS treatment was 100% (n=8 animals) while survival in similarly treated eGR knockout mice was only 66% after 1 day and 22% after 2 days (n=9 animals, p=0.0031). eGR knockout animals demonstrated statistically significant increases in IL-6 (116.4 ± 37.1 vs. 5.4 ± 1.4 ng/ml, p=0.04) and nitric oxide (43.5 ± 9.3 μM vs. 12.0 ± 0.9 μM, p=0.01) after DEX+LPS treatment compared to similarly treated controls. Corticosterone levels were similar between the two groups. Mean BP in control animals that had been pretreated with DEX was 71.7 ± 2.1 mm Hg (n=5) 4 hours after LPS while BP was only 42.9 ± 6.2 mm Hg in similar treated eGR knockout animals (n=5, p <0.01).

Conclusions: In conclusion these data suggest that:

(1) eGR knockout mice have more hemodynamic instability and inflammation than control mice after DEX+LPS treatment

(2) DEX confers no protective benefit in eGR knockout mice and actually appears to worsen outcomes

(3) the presence of eGR is necessary for the beneficial actions of DEX in this model.

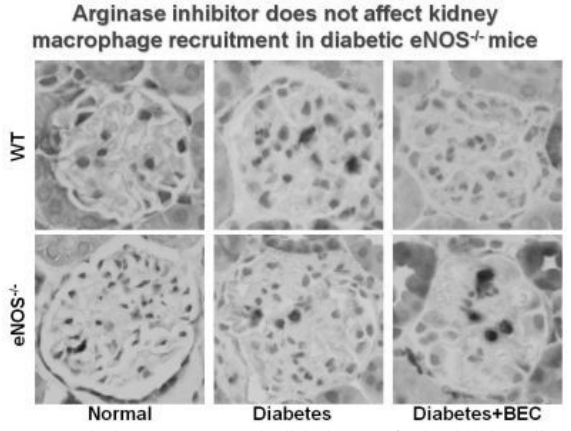
Arginase Inhibition Mediates Renal Tissue Protection in Diabetic Nephropathy via a Nitric Oxide Synthase 3-Dependent Mechanism

Alaa S. Awad,[1] Hanning You,[1] Ting Gao,[1] Timothy K. Cooper,[2] Sidney M. Morris.[3] *[1]Medicine, Penn State University College of Medicine; [2]Comparative Medicine, Penn State University College of Medicine, Hershey, PA; [3]Microbiology and Molecular Genetics, University of Pittsburgh, Pittsburgh, PA.*

Background: Our recent publication (Diabetes 60:3015-22; 2011) shows increased kidney arginase activity in diabetic mice that was associated with a reduction in renal medullary blood flow. Furthermore, pharmacological blockade or genetic deficiency of arginase-2 confers kidney protection in diabetic mouse models. However, the mechanism by which arginase inhibition mediates renal tissue protection is not clear. Here we hypothesize that the protective effect of arginase inhibition is nitric oxide synthase 3 (eNOS) dependent in diabetic nephropathy.

Methods: Experiments were conducted in eNOS knockout ($eNOS^{-/-}$) and their wild type littermate ($eNOS^{+/+}$) mice using multiple low doses of vehicle or streptozotocin (STZ; 50 mg/kg ip for 5 days) treated with continuous subcutaneous infusion of vehicle or the arginase inhibitor S-(2-Boronoethyl)-L-cysteine (BEC; 2.3 mg/kg/day) via osmotic pump for 6 weeks.

Results: Using immunohistochemistry, we confirmed the localization of arginase-2 but not arginase-1 in human and murine kidneys, mainly in the endothelial cells. Blocking arginases using BEC for 6 weeks in diabetic $eNOS^{+/+}$ mice significantly attenuated albuminuria ($p<0.05$), the increase in plasma creatinine ($p<0.01$), histopathological changes and kidney macrophage recruitment compared to vehicle-treated diabetic $eNOS^{+/+}$ mice.



Interestingly, BEC treatment in diabetic $eNOS^{-/-}$ mice failed to affect any of these parameters and was not significantly different from vehicle-treated diabetic $eNOS^{-/-}$ mice.

Conclusions: These findings indicate that arginase inhibition mediates renal tissue protection in diabetic nephropathy via eNOS-dependent mechanism.

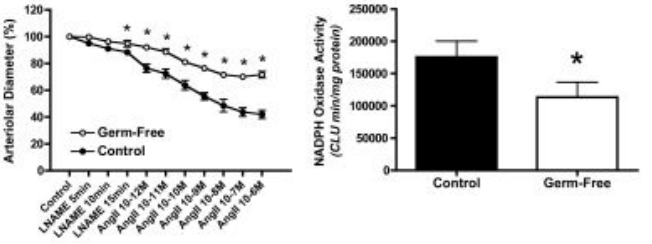
Regulation of Renal NADPH Oxidase Activity and Vascular Function by Gut Microbiota

Ting Yang,[1] Xiang Gao,[2] Eddie Weitzberg,[1] Jon Lundberg,[1] Erik G. Persson,[2] Mattias Carlstrom.[1] *[1]Physiology & Pharmacology, Karolinska Institutet, Sweden; [2]Medical Cell Biology, Uppsala University, Sweden.*

Background: Angiotensin II mediated contraction of the vasculature involves activation of NADPH oxidases. Angiotensin II induced oxidative stress is associated with vascular remodeling and increased preglomerular resistance that are both implicated in the pathogenesis of renal and cardiovascular disease. Recent studies have demonstrated that changes in gut microbiota may influence obesity and diabetes, conditions associated with oxidative stress and inflammation. We used germ-free mice to investigate the hypothesis that host microorganisms regulate NADPH oxidase activity and vascular responses to Angiotensin II in the kidney.

Methods: Isolated and perfused afferent arterioles were used to investigate the arteriolar responses to Angiotensin II (10^{-12} to 10^{-6} mol/L, each dose 2 min), after inhibition of nitric oxide synthase with L-NAME (10^{-4} mol/L). NADPH oxidase activity was measured as Lucigenin-dependent chemiluminescence of superoxide.

Results: Arterioles from conventional mice displayed greater L-NAME induced contraction (-12±2%) and maximal Angiotensin II responses (58±3%) compared with that of germ-free mice (-5±3% and -30±6%, respectively). Basal NADPH oxidase activity in the kidney, measured as Lucigenin-dependent chemiluminescence of superoxide, was markedly reduced in germ-free mice (113±21x10^3 CLU min/mg protein) compared with conventional mice (176±25x10^3 CLU min/mg protein).



Conclusions: The gut microbiota modulate renal NADPH oxidase activity and Angiotensin II mediated contraction of preglomerular vessels. The mechanisms are currently being investigated.

Impact of Renal Denervation on Inflammation

Xing Gao,[1] Sebastian Alexander Potthoff,[1] Johannes Stegbauer,[1] Felix Mahfoud,[2] Lars C. Rump,[1] Oliver Vonend.[1] *[1]Department of Internal Medicine / Nephrology, Heinrich-Heine University - Medical Faculty, Düsseldorf, Germany; [2]Department of Medicine III, University Saarland, Germany.*

Background: Renal Denervation (RDN) is a new tool in resistant hypertension. First clinical trials (HTN1/HTN2-Trial) could demonstrate a significant reduction in blood pressure in these cardiovascular high risk patients. The kidney with its sensory nerves plays an important role in blood pressure regulation. Animal data and observations on patients after nephrectomy support this hypothesis. However, the underlying mechanisms on blood pressure reduction are not fully understood. In addition, it is unclear, why it is taking weeks to months before the effect can be observed. There is new evidence that inflammatory cells are regulated by the autonomic nervous system. Furthermore, direct correlation of C-reactive-Protein (CRP) and cardiovascular risk has already been shown.

The aim of this prospective analysis was to find the influence of RND on the inflammation markers CRP and TNFalpha.

Methods: Patients with refractory hypertension were prospectively evaluated for blood pressure and high-sensitive CRP and TNFalpha at baseline and after 6 months. In n=55 patients RDN and in n=38 optimal medical therapy (OMT) was applied.

Results: Systolic blood pressure dropped significantly in both groups to -23mmHg (RDN) and -7mmHg (OMT), respectively. Only in the RDN group CRP was reduced significantly (4265ng/ml to 2900ng/ml). No significant reduction was observed in OMT group (3184ng/ml to 3020ng/ml). TNFalpha declined from 2,97pg/ml to 2,45pg/ml in RDN patients.

Conclusions: For the first time it could be shown, that RND has an impact on systemic inflammation. The reduction of inflammation might be one explanation for the time-shifted response in blood pressure. Ongoing analyses on isolated leucocytes will elucidate underlying mechanisms.

FR-PO1015

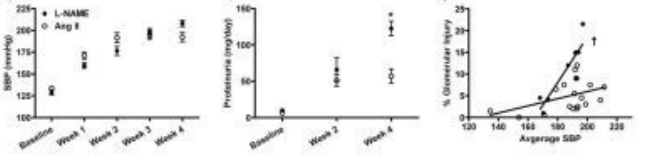
Nitric Oxide Inhibition Enhances the Susceptibility to Glomerular Injury as Compared to Angiotensin II Infusion Despite Similar Levels of Blood Pressure in Rats

Aaron Polichnowski,[1,2] Maria M. Picken,[3] Karen A. Griffin,[1,2] Anil K. Bidani.[1,2] *[1]Edward Hines Jr. VA Hospital, Hines, IL; [2]Medicine, Loyola University, Maywood, IL; [3]Pathology, Loyola University, Maywood, IL.*

Background: Experimental models of hypertension induced by elevated Ang II or reduced nitric oxide (NO) are commonly used to investigate the pathogenesis of renal injury. Recent studies have suggested that Ang II attenuates, while reduced NO potentiates, RBF autoregulation, predicting differences in the relationship between BP and glomerular injury. However, the quantitative relationships between BP and renal injury have not been examined in these models of renal vasoconstriction-associated hypertension.

Methods: Male SD rats (Harlan) were prepared for BP radiotelemetry and 1 wk later administered either Ang II (n=18, 300-500 ng/kg/min SQ via Alzet minipump) or the NO synthase inhibitor, L-NAME (n=9, 50 mg/kg/day via drinking water), for 4 wks. BP was measured every 10 minutes/24 hr. day, 24-hr. proteinuria was assessed at 2 and 4 wks, and the kidneys were perfused fixed at 4 wks.

Results: Ang II and L-NAME led to significant and similar patterns of hypertension (Fig. 1a). Proteinuira was greater in L-NAME vs. Ang II rats at 4 wks (* $p<0.05$ vs. Ang II, Fig. 1b). Glomerular injury was greater in L-NAME (10.8 ± 2.2%) vs. Ang II (4.9 ± 0.8%) rats ($p<0.05$). Furthermore, the slope of the relationship between BP and glomerular injury was > 5-fold higher in L-NAME vs. Ang II rats († $p<0.05$ slope vs. Ang II, Fig. 1c). Results are mean±SE.



Conclusions: These data suggest that BP transmission to the glomerular capillaries is attenuated in Ang II- vs. L-NAME-induced hypertension. Thus, the consequences of impaired RBF autoregulation on glomerular injury are different in experimental models of hypertension associated with renal vasoconstriction (Ang II) vs. vasodilation (renal mass reduction).

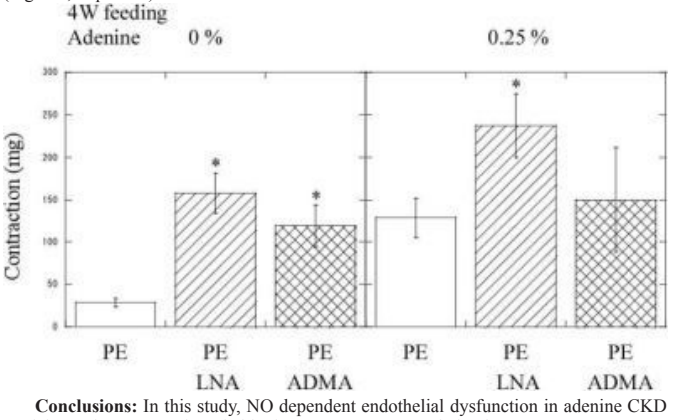
Role of ADMA in Endothelial Dysfunction in Adenine CKD Mice

Yoshinari Yasuda,[1] Mayumi Kawabe,[2] Miyuki Ito,[1] Motomitsu Goto,[1] Sawako Kato,[1] Mutsuharu Hayashi,[1] Shoichi Maruyama,[1] Enyu Imai,[1] Seiichi Matsuo.[1] *[1]CKD Initiatives/Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Japan; [2]Pharmacology, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan.*

Background: Chronic kidney disease (CKD) is a serious risk factor for cardiovascular diseases (CVD). Asymmetric dimethylarginine (ADMA) is an endogenous nitric oxide synthase (NOS) inhibitor which plays a key role both in renal deterioration and arteriosclerosis in CKD through endothelial dysfunction, however its pathophysiological mechanisms in CKD have not been fully clarified. In this study, we analyzed vascular function in adenine CKD mice in association with ADMA.

Methods: C57BL/6 mice (10 weeks old) were randomized to chow with or without 0.25% adenine. Thoracic aortas were analyzed ex-vivo by wire myography at 4 weeks.

Results: Plasma creatinine levels were elevated in adenine treated group (A) compared to control (C) (A: 0.21+-0.09, C: 0.013 +- 0.006 mg/dL). After phenylephrine (PE) pretreatment, concentration-dependent curves for acetylcholine -induced relaxation was decreased in A compared to C, and sodium nitroprusside, NO donor, induced relaxation was not different between A and C, suggesting NO dependent endothelial dysfunction. PE induced contraction after NOS inhibitor treatment was significantly increased by N-nitro-L-arginine (NLA) both in A and C, however it was only increased in C by ADMA (Figure1, *: p<0.05).



Conclusions: In this study, NO dependent endothelial dysfunction in adenine CKD model was demonstrated, probably due to ADMA accumulation in CKD.

Acute Antihypertensive and Renal Hemodynamic Effects of Tempol and PEG-Catalase in CKD

Diana A. Papazova, Arianne van Koppen, Maarten P. Koeners, Marianne Christina Verhaar, Jaap A. Joles. *Nephrology & Hypertension, UMC Utrecht, Utrecht, Netherlands.*

Background: Excess reactive oxygen species (ROS) increase blood pressure (BP) and renal vascular resistance (RVR). Administration of superoxide dismutase mimetic Tempol normalizes BP and RVR in various models of hypertension. There are fewer reports on H_2O_2 reduction by catalase. No such data are available in chronic kidney disease (CKD). We assessed acute antihypertensive and renal vasodilatory effects of Tempol or polyethylene glycol (PEG)-catalase in CKD and control (CON) rats.

Methods: In male Lewis rats 2/3 of each kidney was ablated (CKD). CON were sham-operated. 24h proteinuria, lipid peroxide (TBARS), 8-isoprostane and H_2O_2 urine excretions were determined. Hemodynamics were studied when proteinuria exceeded 100mg/24h. Under isoflurane we measured mean arterial pressure (MAP) and renal blood flow (RBF, Transonic flow probe on left renal artery), allowing calculation of RVR (MAP/RBF) during continuous infusion of Tempol (CKD n=6, CON n=5), PEG-catalase (CKD n=8, CON n=5) or vehicle (CKD n=4, CON n=4). GFR (inulin), glomerulosclerosis (GS) and tubulo-interstitial injury (TI) were measured.

Results: CKD rats had low GFR (P<0.0001) and high GS and TI (both P<0.05) compared to CON. 24h TBARS (P<0.05), 8-isoprostane (P<0.001) and H_2O_2 excretions (P<0.1) were elevated. Baseline MAP (123±13 vs. 99±8 mmHg, P<0.0001) and RVR (21±11 vs. 7±1 units, P<0.0001) were consistently increased in all CKD groups. Versus baseline Tempol caused marked reduction in MAP in CON (81±10 vs. 99±11 mmHg, P<0.05) but not in CKD (127±16 vs. 130±13 mmHg), without much change in RVR in CON or CKD. PEG-catalase had effect on MAP in both CON (94±8 vs. 102±4 mmHg, P<0.05) and CKD (110±12 vs. 118±12 mmHg, P<0.05), but the difference in MAP between CON and CKD was unchanged. PEG-catalase slightly decreased RVR in CON and CKD (-0.8±0.3 and -2.7±2.0 units, both P<0.05). Vehicle did not change MAP or RVR.

Conclusions: In CKD ROS were increased but, contrary to our hypothesis, BP and RVR did not depend more on ROS than in CON. Limited reduction of RVR by Tempol and PEG-catalase in both CON and CKD suggests that in general ROS-mediated vasoconstriction is mainly extrarenal.

The Endothelial Progenitor Cell (EPC) Migration Inhibitor FTY720 Augments Malignant Nephrosclerosis in Deoxycorticosterone Acetate (DOCA)/Salt Hypertensive Rats

Yoshitaka Iwazu, Shigeaki Muto, Yuko Watanabe, Kana Iwazu, Takashi Ioka, Eiji Kusano. *Division of Nephrology, Department of Medicine, Jichi Medical University, Shimotsuke, Tochigi, Japan.*

Background: The novel immunosuppressant FTY720 induces lymphocyte migration and homing in secondary lymphatic organs by regulating egress from lymph nodes. FTY720 also supports bone marrow homing of circulating EPCs, which are incorporated into foci of neovascularization. We explored how FTY720 affects the renal vascular damage in DOCA/salt hypertensive rats, a model of human malignant nephrosclerosis.

Methods: Uninephrectomized rats were divided into control, control plus FTY720, DOCA alone, and DOCA plus FTY720 groups, which were given vehicle, vehicle plus FTY720 (0.5 mg/kg/day), DOCA alone, and DOCA plus FTY720 (0.5 mg/kg/day) for 4 wks, respectively. All rats were given 0.9% NaCl/0.3% KCl to drink. We compared systolic blood pressure (SBP), the number of circulating EPCs, and renal tissues stained with picro-Sirius red among the groups of rats.

Results: SBP was higher in rats given DOCA plus FTY720 than in rats given DOCA alone, although it was higher in the two groups than in controls. In rats given DOCA plus FTY720 and rats given DOCA alone, the onion-skin lesion was prominently observed in their renal arterioles, with the number being greater in rats given DOCA plus FTY720. The number of circulating EPCs was less in rats given DOCA plus FTY720 than in controls and in rats given DOCA alone. Control rats given FTY720 exhibited less circulating EPCs than control rats given vehicle alone, but had no onion-skin lesions in their renal arterioles.

Conclusions: We conclude that FTY720 administration augments malignant nephrosclerosis in the DOCA/salt hypertensive rats. These findings suggest that in the DOCA/salt hypertensive rats, FTY720 may reduce circulating EPCs from the blood, inhibit their infiltration into the diseased kidney, and thus suppress repair processes of the renal arteriole damage.

FR-PO1019

Association of Uric Acid with Vascular Stiffness in the Framingham Heart Study

Diana I. Jalal,[1] Kim Mcfann,[1] Magdalena Madero,[2] Mark J. Sarnak.[3] *[1]Medicine/Renal, University of Colorado, Aurora, CO; [2]Medicine/Nephrology, Instituto Nacional de Cardiologia Ignacio Chavez, Mexico; [3]Medicine/Nephrology, Tufts Medical Center, Boston, MA.*

Background: Uric is associated with increased risk of cardiovascular disease as well as with arterial stiffness in patients with hypertension or stroke. It remains unknown if uric acid is associated with arterial stiffness in the general population.

Methods: Cross sectional study evaluating the relationship between serum uric acid levels and carotid femoral pulse wave velocity (CF- PWV) using multivariable linear regression in 3914 participants from the Generation 3 Framingham cohort.

Results: Mean (SD) age, MDRD estimated GFR (eGFR) and uric acid were 40.0 (8.8) years, 101.4 (22.1) mL/min/1.73 m^2 and 5.3 (1.5) mg/dL, respectively. Mean (SD) CF- PWV was 7.0 (1.4) m/s. Individuals in the highest quartile of uric acid (>6.3 mg/dl) were more likely to be male, have a higher prevalence of hypertension, higher BMI, fasting glucose and insulin, and lower estimated GFR. Multivariate adjusted means of CF-PWV by uric acid quartiles are show in Table 1. In unadjusted analysis each 1 mg/dL higher serum uric acid was associated with a 0.27 ± 0.01 higher CF-PWV (R^2= 0.09, p < 0.0001). This was attenuated but remained significant after adjusting for age, sex, smoking, hypertension, BMI, fasting glucose, insulin, and eGFR (β= 0.07 ± 0.02, Model R^2= 0.45, p < 0.0001).

Conclusions: Serum uric acid levels are significantly associated with CF-PWV in a younger Caucasian population. It remains to be determined however whether this is of clinical importance as the variation in CF-PWV explained by uric acid is relatively small.

Table 1: Association between uric acid quartiles and carotid-femoral pulse wave velocity:

Uric acid quartile (mg/dL)	Carotid-Femoral PWV LS MEAN* ± SE	P -value
< 4.2	6.90 ± 0.04	0.002
4.2-5.1	6.94 ± 0.04	0.005
5.2-6.3	7.06 ± 0.04	0.339
> 6.3	7.15 ± 0.04	--

*: Adjusted for age, sex, estimated GFR, smoking, hypertension, fasting glucose, insulin, and body mass index. P-value for the comparison with the 4th quartile

Calcimimetic R-568 Impacts Arterial Structure and Function but Does Not Lower Blood Pressure via the Renin Angiotensin System Navid Shobeiri, Kimberly J. Laverty, Michael A. Adams, Rachel M. Holden. *Queen's University.*

Background: Calcimimetics modulate calcium sensing receptors (CaRs) of the parathyroid gland, thus decreasing parathyroid hormone release. Lowering of PTH levels with calcimimetics (R-568) has been linked to a decrease in vascular calcification and a short-term lowering of blood pressure in animal models. CaRs have also been identified in the renin-angiotensin system (RAS) as well as within the arterial wall, however the direct effect of R-568 on these receptors has not been studied. We investigated the impact of R-568 in RAS mediated blood pressure control as well as its direct impact on vascular calcification and function.

Methods: Spontaneously hypertensive rats (SHR) were given a low salt diet to enhance the RAS and were put on two doses (20 and 50 mg/kg/day, gavage) of the calcimimetic, R-568 for 5 days. Furthermore, rats were also treated with enalapril at a later time point to assess the integrity of their RAS. Blood pressure was recorded every 4 minutes by radio-telemetry for 60 days. Calcification was induced by incubating aortic rings in 3.8mM phosphate in DMEM for four days. Contractility of aortic rings was assessed by wire myography.

Results: Both doses of R-568 significantly reduced serum PTH (52±17% and 65±17% reduction) and serum calcium (34±8% and 34±5% reduction) four hours after dosing. There was no impact of either R-568 dose on blood pressure either short-term (minutes to hours) or long-term (days); however enalapril lowered blood pressure in the same SHR rats on low salt diet (150.8±15.4 to 93.7±14.0 mmHg, $p<0.0001$). R-568 dilated phenylephrine pre-contracted vessels in myographs. Incubation of aortic ring in 3.8mM phosphate in DMEM for four days increased calcification (180±87 nmol/mg); however, addition of R-568 (30μM) decreased calcification (79.9±54.3nmol/mg, $p<0.005$).

Conclusions: R-568 appears to directly affect vascular function and vascular calcification independent of its effect on PTH. The blood pressure lowering effect of R-568 is most likely not RAS mediated.

AMPK Plays a Significant Role in Modulation of Myogenic Constriction of the Renal Artery Mahdi Hamidi Shishavan, Sjoerd W. Landheer, Hendrik Buikema, Leo E. Deelman, Robert H. Henning. *Clinical Pharmacology, University Medical Center Groningen, University of Groningen, Groningen, Netherlands.*

Background: Adenosine Monophosphate Protein Kinase (AMPK) is involved in cellular energy homeostasis. In diabetes, activation of AMPK improves vascular function, resulting in attenuation of diabetic vascular complications. Myogenic tone, the contractile response of vascular smooth muscle cells to increased intralumal pressure, is important in the autoregulation of renal blood flow and pressure.

In the present study we investigated the effects of AMPK activation on myogenic constriction of the renal artery of lean and Zucker Diabetic Fatty rats (ZDF).

Methods: ZDF (n=8) and Lean (n=8) rats, age 17 weeks, rats were sacrificed and intrarenal vessels were mounted in a vascular perfusion setup. Vessels were denuded by phenylephrine (1mM). After equilibration of arteries for 30 min, the first myogenic pressure response curve was assessed by stepwise increasing the pressure in the range of 20-140mmHg. Subsequently, vessels were incubated with AICAR(0.2mM) for 30 min before assessment of a second myogenic pressure response curve. Time controls were included and passive properties of vessels were obtained in Krebs without calcium.

Results: Myogenic responses did not differ between Lean (2427±889) and ZDF (2496±656) but incubation with AICAR resulted in a reduction of myogenic responses in both groups (1511±541, 1236±621, respectively). Although the reduction was most pronounced in ZDF, it did not reach significance($p=0.4$) compared to Lean rats. Time controls did not show a significant reduction in myogenic response. The inhibitory effect of AICAR was significantly correlated with the primary myogenic response in the Lean group ($p=0.03$) but not in ZDF ($p=0.6$).

Conclusions: Findings indicate that AMPK activation inhibits renal artery myogenic constriction. The effect of AICAR was similar in Lean and ZDF, indicating that the effects of AICAR were independent of metabolic status. Results suggest that AMPK activation could contribute to impaired renal autoregulation resulting in increased glomerular pressure. Future studies on the effects of AMPK activation on myogenic response in-vivo are therefore warranted.

FR-PO1022

Higher Potassium Intake Is Associated with Reduced Large Elastic Artery Stiffness, Oxidative Stress, and Inflammation in Healthy Middle-Aged and Older Adults Kristen L. Jablonski,[1] M. Chonchol,[1] Matthew Racine,[2] Candace Geolfos,[2] Bradley S. Fleenor,[2] Douglas R. Seals.[2] *[1]Internal Medicine/Renal, University of Colorado Denver, Aurora, CO; [2]Integrative Physiology, University of Colorado Boulder, Boulder, CO.*

Background: Large elastic artery stiffness increases with age and is a strong independent predictor of incident cardiovascular diseases (CVD) in healthy middle-aged and older (MA/O) adults. Dietary potassium may attenuate this age-associated stiffening, but the relation and associated physiological mechanisms are unclear. We hypothesized that greater potassium intake (measured by 24-hr urinary excretion) would be associated with reduced large elastic artery stiffness (as indicated by aortic pulse-wave velocity [aPWV]) and reduced circulating and/or endothelial cell markers of oxidative stress and inflammation.

Methods: Potassium excretion, aPWV and markers of oxidative stress/inflammation were measured at 2 time-points in 14 MA/O adults (62±2 years, mean±S.E.) with moderately elevated systolic blood pressure [SBP] (138±2 mmHg).

Results: Linear regression analysis of these pooled timepoints demonstrated that potassium excretion (72±4 mmol/d) was inversely related to aPWV (817±33 cm/sec; $r=-0.38$, $p<0.05$). This relation persisted when models were adjusted for age, SBP, serum creatinine, sodium excretion, body-mass index and cholesterol ($\beta= -0.38\pm0.15$, $p<0.05$). Potassium excretion was then divided into tertitles. Compared to the lowest tertile (n=10; 29-65 mmol/d), the highest tertile (n=9; 83-106 mmol/d) demonstrated increased antioxidant activity (glutathione peroxidase, 8570±919 vs. 6297±438 U/L; total antioxidant status, 1.48±0.02 vs. 1.40±0.02 mmol/L; endothelial cell manganese superoxide dismutase, 0.61±0.03 vs. 0.43±0.04 A.U.), reduced inflammation (log C-reactive protein, -0.22±0.18 vs. 0.33±0.13 mg/L), as well as increased endothelial cell nitric oxide synthase (eNOS) protein expression (0.42±0.03 vs. 0.24±0.03 A.U.; all $p<0.05$).

Conclusions: These results support the hypothesis that greater dietary potassium intake is associated with reduced large elastic artery stiffness, oxidative stress and inflammation in MA/O with moderately elevated SBP.

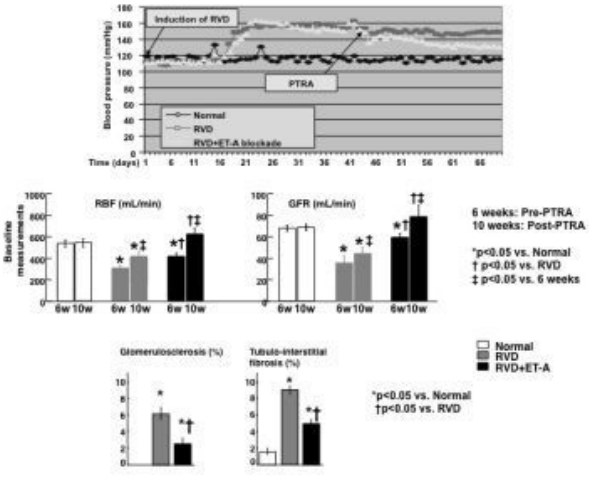
FR-PO1023

Chronic Endothelin-A Receptor Blockade Improved the Responses to Renal Revascularization in Experimental Renovascular Disease Alejandro Chade. *Physiology and Biophysics, and Medicine, University of Mississippi, Jackson, MS.*

Background: Renal angioplasty (PTRA) is the most frequent therapeutic approach to treat renal artery stenosis. However, PTRA improves renal function and/or resolves hypertension in only 1/3 of the patients due to still unknown causes. We have shown that chronic blockade of the ET-A receptor attenuates functional and structural damage in the stenotic kidney during progression of renovascular disease (RVD). However, whether ET-A receptor blockade could improve renal function and hypertension in response to PTRA in RVD is unknown.

Methods: Unilateral RVD was induced in 8 pigs and randomized into untreated (RVD) or chronically treated with ET-A blocker (RVD+ET-A, 0.75 mg/kg/day, oral, n=4 each). After 6 weeks, single-kidney blood flow (RBF) and glomerular filtration rate (GFR) was quantified in the stenotic kidney using multi-detector CT (MDCT). Then, PTRA was performed in all RVD and RVD+ET-A pigs and observed for 4 additional weeks. At 10 weeks, in vivo MDCT studies were repeated. Pigs were then euthanized, stenotic kidneys were removed, and ex vivo studies performed.

Results: Renal stenosis and hypertension were similar in RVD and RVD+ET-A. On the other hand, the blunted RBF and GFR in RVD pigs were largely preserved by ET-A blockade. PTRA resolved RVD in all pigs. However, improvements in blood pressure and renal function were greater in RVD+ET-A+PTRA than in RVD+PTRA, accompanied by a substantial decrease in renal fibrosis.



Conclusions: Chronic ET-A blockade slowed the progression of renal functional and structural injury in RVD and significantly improved the responses to PTRA. These data suggests ET-A blockade as a potential therapeutic co-adjuvant intervention to improve the outcomes of renal revascularization in RVD.

FR-PO1024

Sustained Renal Vein NGAL Elevation in Human Atherosclerotic Renal Artery Stenosis Despite Reversal of Tissue Hypoxia and Improved Blood Flow after Renal Artery Stenting Ahmed Saad,[1] Sandra Herrmann,[1] Behzad Ebrahimi,[1] John A. Crane,[1] James Glockner,[2] Michael A. Mckusick,[2] Sanjay Misra,[2] Lilach O. Lerman,[1] Stephen C. Textor.[1] *[1]Nephrology and Hypertension, Mayo Clinic; [2]Radiology, Mayo Clinic, Rochester, MN.*

Background: Atherosclerotic renal artery stenosis (ARAS) is known to reduce renal blood flow (RBF) and amplify kidney hypoxia, The relationship between post-stenotic kidney tubulo-interstitial injury and these factors is poorly understood. We hypothesized that renal injury reflected by renal vein levels of acute phase reactant, neutrophil gelatinase associated lipocalin (NGAL), would correlate with RBF, tissue perfusion and hypoxia in subjects with ARAS.

Methods: Inpatient studies performed in ARAS patients (n=18 kidneys, 71±5.5% occlusion) before and 3 months after stent revascularization, or with essential hypertension (EH) (n=42 kidneys), during fixed Na+ intake and ACE/ARB Rx. Single-kidney (SK) cortical,medullary perfusion and RBF measured using multidetector CT, and glomerular filtration rate (GFR) by iothalamate clearance. Tissue deoxyhemoglobin levels (R2*) measured by Blood Oxygen Level Dependent (BOLD) MRI at 3T, as was fractional kidney hypoxia (% of axial area with R2*>30/s).

Results: SK-RBF, perfusion, and GFR were reduced in the post-stenotic kidney. Renal vein NGAL and fractional hypoxia were higher in untreated ARAS than EH. NGAL levels and fractional hypoxia at baseline correlated inversely with RBF and tissue perfusion (r= -0.6, p<.03).GFR correlated inversely with NGAL (r=-0.5, p<.003). After stenting, fractional hypoxia fell with modest increase in RBF, while GFR and NGAL remained unchanged.

Single-kidney	RAS N=18 Before stenting	RAS N=18 After stenting	EH N=42
NGAL (ng/ml)	131±54	123±34	65.8 ± 36**
RBF(ml/min)	269±127	305.6±179*	377±164**
Fractional hypoxia(R2*>30/s)	19.4±14	10.7±9.2*	12.9±9.3**
GFR(ml/min)	27±14	31±17	43.2±13**

Mean ± SD, *P<.05 VS RAS Before. ** P<.02 VS RAS

Conclusions: These data demonstrate that despite reversal of hypoxia and partial restoration of RBF after revascularization, renal vein NGAL remains elevated and GFR fails to recover in ARAS, consistent with ongoing tubulo-interstitial injury in post-stenotic kidneys.

Funding: Other NIH Support - NHLBI

FR-PO1025

Endothelin-Converting Enzyme-1 Is Regulated by Calcitriol in Human Endothelial Cells Patricia Martinez-miguel,[2] Diana Medrano,[2] Vanesa Lopes-martin,[2] Alicia Luengo,[1] Sergio De Frutos Garcia,[1] Ignacio Arribas,[2] Diego Rodriguez-Puyol,[2] Susana Lopez-ongil.[2] *[1]Department of Physiology, Universidad de Alcalá, Alcalá de Henares, Madrid, Spain; [2]Research Unit, Hospital Universitario Principe de Asturias, Alcalá de Henares, Madrid, Spain.*

Background: Secondary hyperparathyroidism is a cardiovascular risk factor. Active analogues of vitamin D such as 1a-25 di-hidroxi-vitamin D3 (Calcitriol) are successfully used in its treatment but with several disadvantages, as its possible effects on the endothelium. Since chronic kidney disease patients present endothelial dysfunction, the present study was designed to assess the intrinsic effects of Calcitriol over endothelial cells, which express vitamin D receptors, where we evaluated endothelin (ET1)-converting enzyme 1 (ECE-1) regulation.

Methods: Human endothelial cells (EA) were incubated at different times and doses of Calcitriol, to evaluate ECE-1 regulation. Expression levels of mRNA and proteins were analysed by Western and Northern blot and its promoter activity by using luciferase reporter plasmids. The ET-1 levels and ECE-1 activity was determined by ELISA.

Results: Calcitriol induced in a dose and time-dependent manner the increase in the ECE-1 transcriptional activity and protein expression, with a slight increase on ET-1 production. The use of ECE-1 promoter serial deletions reversed the transcriptional activity when AP-1 binding sites where depleted. AP-1 activity was confirmed by EMSA analysis and the use of the specific Erk1/2 inhibitor PD98059 or the JNK inhibitor SP-600125: both AP-1 activity inhibitors were able to block Calcitriol-dependent ECE-1 activation, suggesting this effect as AP-1-dependent.

Conclusions: Calcitriol increased ECE-1 expression through activation of AP-1 transcription factor. These results suggest Calcitriol as a potential endothelial function regulator, at least in our in vitro model. However, animal studies will be necessary to go into its physiological consequences.

FR-PO1026

Blood Pressure Independent Effects of ACE Inhibition on Myogenic Tone in Chronic Kidney Disease Sjoerd W. Landheer, Peter Vavrinec, Hendrik Buikema, Leo E. Deelman, Robert H. Henning. *Clinical Pharmacology, University Medical Center Groningen, Groningen, Netherlands.*

Background: In patients with chronic kidney disease (CKD), angiotensin converting enzyme (ACE) inhibition results in better renal protection than treatment with other antihypertensive drugs. It is suggested that this is caused by additional intrarenal effects of ACE inhibition, beside its systemic antihypertensive effects. Myogenic tone (MT): the ability of arteries to constrict in response to increased intraluminal pressure, protects the kidney from fluctuations in systemic blood pressure. We hypothesized that the additional protective effects of ACE inhibitors include improvement of intrarenal MT.

Methods: We compared the effect of ACE inhibition by lisinopril with an antihypertensive triple therapy that only effects blood pressure on MT in 5/6 nephrectomized rats. Male wistar rats (n=21) underwent a 5/6 nephrectomy or were sham operated (n=7). Six weeks after 5/6 nephrectomy, rats were stratified based on proteinuria into 3 groups and treated for 6 weeks with: vehicle (control, n=7), Lisinopril (n=7) and a triple therapy of reserpine, hydrochlorothiazide and hydralazine (n=7). After sacrification, mesenteric and intralobular arteries with a diameter of 100-200µm were mounted in a vessel perfusion setup for assessment of MT.

Results: After 5/6 nephrectomy, rats became hypertensive and progressively proteinuric. Both lisinopril and triple therapy reduced blood pressure to the level of sham rats, while proteinuria was only reduced by lisinopril. 5/6 nephrectomized rats showed impaired myogenic constriction in both systemic mesenteric and local intralobular arteries. Lisinopril and triple therapy both improved myogenic tone in mesenteric arteries, while myogenic tone in intralobular arteries was only improved by lisinopril.

Conclusions: The protective effect of ACE inhibition on MT in systemic mesenteric arteries is due to its antihypertensive properties, while in intrarenal arteries MT was improved by its additional protective effects. Improved intrarenal MT could be a possible explanation for the finding that ACE inhibitors outperform other antihypertensive drugs in renoprotection in CKD.

FR-PO1027

Augmentation of GFR in Critically Ill Traumatic Brain Injured (TBI) Patients Is Dependent on Acuity of Critical Illness and Severity of Trauma Krunal M. Patel, George N. Coritsidis, Parth Rali, Win Naing, Marie France R. DeLeon, Nechama Diamond. *Elmhurst Hospital Center, New York, NY.*

Background: Recent studies have shed light on the augmentation of GFR in the critically ill and primarily in young patients. This may play an important role in pharmacodynamics and especially proper antibiotic dosage.

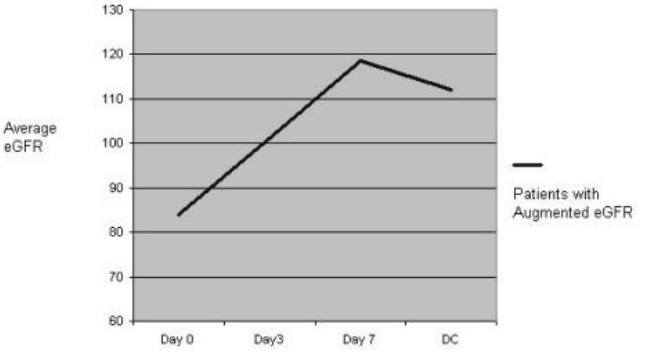
Methods: 135 TBI patient's record were reviewed who admitted to the surgical/trauma ICU between 2008 and 2011 at Elmhurst Hospital, a level 1 trauma center in New York. Patients with CKD-EPI GFR (eGFR) <60cc/min on admission and those that developed AKI were excluded leaving 110 patients. APACHE II, injury severity scores (ISS), eGFR,hospital length of stay (hLOS) were calculated. Patients with increased eGFR by >25% (Augmented GFR) were compare to those that failed to reach >25%(Not Augmented GFR), and first week vancomycin levels were also recorded (n=27 a vs n=24, respectively). Data presented as average ± SEM.

Results: Age, and hLOS of the total 110 patients were 48±1.8 years and 30±2 days respectively, eGFR increased by 18% from admission baseline (98.6± to 116.3±, p<.0001) and declined after 7 days. eGFR increased by 41% in augmented GFR group compare to 8% in non augmented. There were no differences in age, degree of proteinuria, incidence of sepsis,vasopressor use, hLOS between groups. ISS and APACHE were greater in augmented GFR group.

Table 1

Group (N=110)	Augmented(n=43)	Not Augmented (n=67)	p
Δ eGFR	34.5 (41%)	8.9(8%)	NA
Age (years)	47±3	48±2	NS
APACHE II	11.6± 0.9	9.5± 0.7	0.0648
ISS	21.9±2.6	15.8±1.01	0.0161
hLOS (days)	32±3	28±6	NS
Vanco Level(mcg/ml)	8.27	9.05	NS

hLOS= hospital length of stay



Conclusions: In our neuro critically ill patients, eGFR increased significantly by 18%. This rise persisted for at least a week before returning to baseline. When correcting for age, patients achieving higher eGFR had increased trauma and acuity scores.

Mitochondrial Protection with Pre- and Postconditioning during Renal Ischemia-Reperfusion Sandrine Lemoine,[1,2] Nicolas Rognant,[1,2] Fitsum Guebre-egziabher,[1,2] Lionel Augeul,[2] Maurice Laville,[1,2] Michel Ovize,[2,3] Laurent Juillard.[1,2] *[1]Néphrologie, Hospices Civils de Lyon, France; [2]CARMEN 1060, Université Lyon 1, France; [3]Cardiologie, Hospices Civils de Lyon, France.*

Background: Ischemia-reperfusion (IR) injuries often cause kidney dysfunction after renal transplantation or aortic clamping. A study on cardiac IR injuries showed that the mitochondrial permeability transition pore (mPTP) plays a key role in activating cell death. The aim of our study is to see whether PreCsA and PostCI help prevent early mPTP opening and electron transport chain dysfunction in kidney mitochondria.

Methods: We conducted a right unilateral nephrectomy with 30-minute contralateral clamping of the left renal artery on C57BL6 mice. The animals were divided into 4 groups: a control group (C), an ischemic group (IR), a preconditioning group with 3mg/kg cyclosporine IV injections 10 minutes before clamping (preCsA), and an ischemic postconditioning group with 3 cycles of 5 minutes each (postCI). We measured calcium retention capacity (CRC) to study mPTP opening, and mitochondrial respiration (expressed in RCR ratio: stage 3/stage 4) 24 hours after reperfusion. Means were compared using Fisher's exact test, with a significant difference $p<0.05$.

Results: In the C group, 404 ± 56 nmol ca^{2+}/mg-proteins were needed for opening the mPTP, while 97±54 nmol ca^{2+}/mg in the IR group, 214±62 nmol ca^{2+}/mg in the preCsA group and 246±68 nmol ca^{2+}/mg in the postCI group. CRC was increased either by preCsA and postCI vs IR ($p=0.006$ and $p=0.002$, respectively); RCR (stage 3/stage 4) for complex I in the electron transport chain was at 5.4 ± 0.49 for group C, 3.5 ± 0.98 for group IR, 4.9 ± 1.2 for group preCsA and 5.4 ± 0.67 for group postCI. Mitochondrial respiration was also improved significantly between preCsA group ($p=0.02$) and postCI group ($p=0.009$) vs IR.

Conclusions: Both preCsA and postCI help prevent IR by delaying the early opening of mPTP that leads to cell death, and by protecting mitochondria from sustained dysfunction of electron transport in the mitochondrial chain.

Humans with IgA Nephropathy Have Increased Systemic RAS Activity but Decreased Arterial Sensitivity to Angiotensin II Compared to Healthy Controls Ahmed Abdi Ali, Michelle C. Mann, Brenda Hemmelgarn, Jennifer M. MacRae, Tanvir Chowdhury Turin, Darlene Y. Sola, Sofia B. Ahmed. *Deparment of Medicine, University of Calgary, Calgary, AB, Canada.*

Background: IgA nephropathy (IgAN) is associated with increased cardiovascular (CV) risk. Arterial response to angiotensin II (AngII), a measure of endothelial health and local intrinsic RAS tone, is an intermediate measure of CV risk. We sought to compare arterial stiffness, both at baseline and in response to angiotensin (Ang) II challenge, in humans with mild IgAN (eGFR>60, proteinuria < 1g/d) to that of healthy individuals.

Methods: Eight (age 45±5, 88% men) normotensive, non-diabetic, non-obese subjects with IgAN were compared to 37 healthy controls (age 37±2, 35% men). Subjects were studied in high salt balance and women were studied in the same phase of their menstrual cycle. Brachial blood pressure and arterial stiffness, expressed as pulse wave velocity (PWV) and aortic augmentation index (AIx) were measured manually and by tonometry respectively, at baseline and in response to AngII infusion (3ng/kg/min x 30 min then 6ng/kg/min x 30 min). The primary outcome was the impact of mild IgAN on arterial response to AngII challenge at 60min. Baseline variables were adjusted as appropriate for gender, age and BMI using ANCOVA.

Results: At baseline, IgAN subjects demonstrated greater MAP (94±3 vs. 84±2 mmHg, $p=0.009$), PWV (9.2±0.8 vs. 7.6±0.2 m/s, $p=0.07$) and circulating RAS components (plasma renin activity: 0.56±0.2 vs. 0.22±0.03 ng/l/hr, $p=0.006$; AngII: 26±6 vs. 18±1 ng/l, $p=0.03$; aldosterone: 164±34 vs. 131±11 pmol/l, $p=0.3$). The baseline AIx values were similar between the groups(13±4 vs. 12±2.7 %, $p=0.6$). IgAN was associated with a blunted BP response (ΔMAP: 19±3 vs. 30±1 mmHg, $p=0.04$) and arterial stiffness response (ΔPWV: 0.5±0.8 vs. 1.7±0.2 m/s, $p=0.01$; ΔAIx: 12±2 vs. 13±2%, $p=0.9$) to AngII challenge.

Conclusions: IgAN, even in the setting of normal kidney function, is associated with increased blood pressure, arterial stiffness and systemic RAS activity but decreased arterial sensitivity to AngII compared to healthy controls. Increased CVD risk in the setting of IgAN may be mediated, in part, by changes in vascular RAS activity.

FR-PO1030

Increased 25- and 1,25-Hydroxy Vitamin D Levels Are Associated with Enhanced Blood Pressure Responsiveness to Angiotensin II in Healthy Humans David Donald McTavish Nicholl, Ahmed Abdi Ali, Darlene Y. Sola, Sofia B. Ahmed. *University of Calgary, Calgary, AB, Canada.*

Background: Reduced 25- and 1,25 Hydroxy Vitamin D (25VD and 1,25VD) levels are risk factors for kidney and cardiovascular disease. Limited studies suggest a role for VD in the modulation of the renin angiotensin system (RAS), though in humans the mechanism remains unclear. We sought to determine the relationship between 25VD and 1,25VD levels and the blood pressure response to Angiotensin II (AngII) challenge, a well-accepted measure of RAS activity, in healthy humans.

Methods: Thirty-five normotensive, non-obese, healthy subjects (11 men, 24 women; 35±2y; 25VD, 68±4 nmol/L; 1,25VD, 100±5 pmol/L) were studied fasted in high salt balance, a state of maximal RAS suppression. Female subjects were studied in the follicular phase of their menstrual cycle. 25VD and 1,25VD were measured at baseline. Blood pressure (BP) was measured every 15 min at baseline, in response to a graded AngII infusion (3ng/kg/min x 30min followed by 6ng/kg/min x 30min), and after a 30 min recovery period. The primary outcome was the relationship between 25VD and 1,25VD levels and greatest BP response to AngII.

Results: 25VD levels were associated with an enhanced mean arterial pressure (MAP), systolic BP (SBP), and diastolic BP (DBP) responses to AngII infusion at 45 min (MAP: $R=0.503$, $p=0.002$; SBP: $R=0.382$, $p=0.02$; DBP: $R=0.482$, $p=0.003$). These relationships remained even after adjustment for covariates (MAP, $\beta=0.16$, $p=0.001$; SBP, $\beta=0.17$, $p=0.007$; DBP, $\beta=0.15$, $p=0.003$). 1,25VD levels were associated with an enhanced SBP response to AngII infusion at 45 min ($R=0.4$, $p=0.02$) and non-significant trends with the MAP ($R=0.339$, $p=0.054$) and DBP ($R=0.2$, $p=0.17$) responses. However, these relationships remained after adjustment for covariates (MAP, $\beta=0.1$, $p=0.023$; SBP, $\beta=0.13$, $p=0.017$; DBP, $\beta=0.08$, $p=0.061$).

Conclusions: Higher levels of both 25VD and 1,25VD are associated with an enhanced hemodynamic response to AngII challenge in healthy humans. Larger, prospective studies are needed to further examine the relationship between VD and the RAS in humans.

FR-PO1031

Obstructive Sleep Apnea Treatment Improves Arterial Stiffness and Alters Vascular Sensitivity to Angiotensin II in Humans David Donald McTavish Nicholl, Patrick Hanly, Jennifer M. MacRae, George Handley, Brenda Hemmelgarn, Marc Poulin, Darlene Y. Sola, Sofia B. Ahmed. *University of Calgary, Calgary, AB, Canada.*

Background: Obstructive sleep apnea (OSA) is a recognized risk factor for the development of vascular disease, particularly hypertension. Limited studies suggest a prominent role for the renin angiotensin system (RAS), activation of which is deleterious to kidney and cardiovascular function. We sought to determine the effect of continuous positive airway pressure (CPAP) therapy on arterial stiffness and the RAS at baseline and in response to Angiotensin II (AngII), in humans with OSA.

Methods: Ten newly diagnosed (8 men, 2 post-menopausal women; 50±4y) OSA subjects (respiratory disturbance index [RDI]>15) with nocturnal hypoxia [oxyhemoglobin saturation {SaO_2} <90% for >12% of night]) who were otherwise healthy were studied pre- and post-CPAP therapy (1 month of adequate therapy [>4h/night]). Subjects were studied in high salt balance, a state of maximal RAS suppression. Arterial stiffness (aortic augmentation index [Aix] and carotid femoral pulse wave velocity [PWV]) was measured by applanation tonometry at baseline and in response to a graded AngII infusion (3ng/kg/minx30min followed by 6ng/kg/minx30min, and a 30min recovery). The primary outcome was the effect of CPAP treatment on the Aix and PWV responses to AngII at 60 min and the recovery period.

Results: CPAP corrected OSA (RDI: 52±6 vs 5±1hr^{-1}, $p=0.005$; duration SaO_2<90%: 33±5 vs 5±3% of night, $p=0.005$) and reduced baseline AIx (23.2±3.6 vs 17.2±4.7%, $p=0.025$), but did not affect baseline PWV (7.93±0.33 vs 8.15±0.31m/s, $p=0.8$). There was a non-significant increase in AIx (9.2±1.9 vs 12.3±2.9%, $p=0.2$) and a non-significant decrease in PWV (1.41±0.43 vs 0.99±0.66m/s, $p=0.4$) sensitivity to AngII (all values pre- vs post-CPAP). There was no change in how quickly AIx returned to baseline after AngII challenge (3.1±1.8 vs 1.7±3.1%, $p=0.8$), but a more rapid recovery was observed with PWV post-AngII challenge (1.69±0.42 vs 0.43±0.26m/s, $p=0.017$).

Conclusions: Our preliminary observations suggest OSA treatment with CPAP may improve arterial stiffness through changes in vascular sensitivity to AngII.

Obstructive Sleep Apnea Treatment Improves Renin Angiotensin System Activity in Humans David Donald McTavish Nicholl, Patrick Hanly, George Handley, Brenda Hemmelgarn, Marc Poulin, Darlene Y. Sola, Sofia B. Ahmed. *University of Calgary, Calgary, AB, Canada.*

Background: Obstructive sleep apnea (OSA) is strongly associated with kidney and cardiovascular disease. Limited studies suggest a prominent role for the renin angiotensin system (RAS), activation of which is deleterious to cardiorenal function. We sought to determine the effect of continuous positive airway pressure (CPAP) therapy in patients with OSA on mean arterial pressure (MAP) and RAS components at baseline and in response to Angiotensin II (AngII).

Methods: Ten newly diagnosed (8 men, 2 post-menopausal women; 50±4y) OSA subjects (respiratory disturbance index [RDI]>15) with nocturnal hypoxia [oxyhemoglobin saturation {SaO_2} <90% for >12% of night]) who were otherwise healthy were studied pre- and post-CPAP therapy (1 month of adequate therapy [>4h/night]). Subjects were studied in high salt balance, a state of maximal RAS suppression. MAP, plasma renin activity (PRA), and aldosterone were measured during each study period at baseline and in response to a graded AngII infusion (3ng/kg/minx30min, 6ng/kg/minx30min, 30min recovery). MAP was measured every 15min. The primary outcome was the effect of CPAP therapy on MAP and RAS components at baseline and in response to AngII.

Results: CPAP corrected OSA (RDI: 52±6 vs 5±1hr^{-1}, $p=0.005$; duration SaO_2<90%: 33±5 vs 5±3% of night, $p=0.005$) and reduced baseline MAP (97±1 vs 89±2mmHg, $p=0.007$), PRA (0.27±0.02 vs 0.19±0.03ng/L/s, $p=0.02$), and aldosterone (195±30 vs 122±16pmol/L, $p=0.009$), but did not affect AngII (20±4 vs 20±4ng/L, $p=0.7$). CPAP increased MAP sensitivity to 3ng/kg/min AngII (15min: 10±2 vs 16±2mmHg, $p=0.01$; 30min: 12±3 vs 15±3mmHg, $p=0.1$), but did not affect the MAP response to 6ng/kg/min AngII or recovery. There was a blunted PRA response post-CPAP (3ng/kg/min: -0.10±0.02 vs -0.07±0.02ng/L/s, $p=0.097$; 6ng/kg/min: -0.17±0.02 vs -0.12±0.03ng/L/s, $p=0.05$), but improved recovery (-0.14±0.02 vs -0.09±0.03ng/L/s, $p=0.038$).There were no changes in the aldosterone response to AngII.

Conclusions: CPAP treatment for OSA results in decreased RAS activity and increased hemodynamic sensitivity to AngII. Our results support a role for the RAS in mediating OSA-induced hypertension.

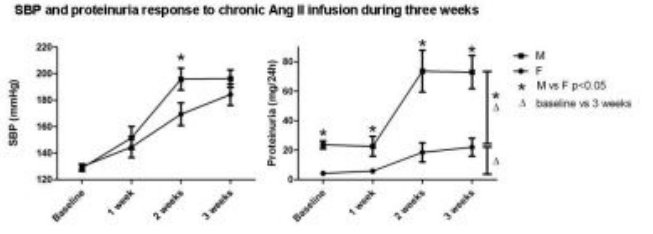
Gender Differences in Vascular and Renal Response to Chronic Angiotensin II in Rats Tsjitske Toering,[1] Anne Marijn van der Graaf,[2] Mienke van der Wiel,[3] Robert H. Henning,[4] Hendrik Buikema,[4] Marijke M. Faas,[2] Gerjan Navis,[1] Titia Lely.[3] *[1]Nephrology; [2]Medical Biology; [3]Obstetrics&Gynaecology; [4]Clinical Pharmacology UMCG, Groningen, Netherlands.*

Background: Epidemiological data show gender differences in susceptibility to cardiovascular and renal disease, possibly due to differences in AngII sensitivity. We studied gender differences in vascular and renal response to chronic infusion of AngII in rats.

Methods: Nineteen weeks old female (F) and male (M) Wistar rats were treated with AngII for three weeks (200ng/kg/min, i.p; F/M:n=11/10) or sham treated (F/M:n=13/10). Systolic blood pressure (SBP) and proteinuria were measured at baseline and weekly. Aortic rings of sham treated rats were mounted for isotonic measurement of vasotonus. AngII sensitivity was studied using response curves in the presence of vehicle, AT2-R blocker PD123319 or AT1-R blocker losartan. Endothelium mediated relaxation was studied after vehicle, nitric oxide (NO) synthase inhibitor L-NMMA or cyclooxygenase (COX) inhibitor indomethacin incubation.

Results: M show a more rapid increase in SBP and proteinuria reaching a plateau after two weeks of AngII (figure). No M-F differences were seen in in-vitro AT1-R-mediated contraction. AT2-R-mediated relaxation was found in F, but not in M ($p=0.03$). Endothelium mediated relaxation was more pronounced in F compared to M ($p<0.01$). L-NMMA reduced relaxation more in M (78±19%) than in F (50±22%;$p<0.01$), while indomethacin increased relaxation in M ($p<0.01$), but not in F. Relaxation in M depends to a larger extent on NO, and is counteracted by constrictive COX products.

Conclusions: These data show gender differences in vascular and renal response to chronic AngII. Differences in AT2-R function and mediators of endothelial relaxation might be involved. Gender should be taken into account in regimens for cardiovascular and renal protection.



FR-PO1034

Long-Term Hemodynamic and Molecular Effects after Renin Angiotensin System Blockade in Humans with Type 1 Diabetes Mellitus David Cherney,[1] Bernard Zinman,[2] Rahim Moineddin,[3] Vesta S. Lai,[1] Judith A. Miller,[1] James W. Scholey,[1] Heather N. Reich.[1] *[1]Division of Nephrology, Toronto General Hospital, University of Toronto; [2]Samuel Lunenfeld Research Institute, Mount Sinai Hospital, Department of Medicine, University of Toronto; [3]Department of Family and Community Medicine, University of Toronto.*

Background: Early intensive glycemic control is associated with long term clinical benefits in type 1 diabetes mellitus [T1DM], an effect referred to as "metabolic memory". Animal studies have similarly suggested that blockade of the renin angiotensin system (RAS) can lead to a "memory" effect on vascular tissue and long term benefit. In this context we evaluated the effect of prior RAS blockade on subsequent renal and systemic vascular function and inflammatory cytokine excretion in patients with T1DM.

Methods: We recruited 27 subjects who had completed the 5-year RAS Study [Renin Angiotensin System Study] in Toronto (9 placebo-treated, 18 RAS blockade-treated [enalapril or losartan]). Four years after completing the RASS and off study medication for the same period, we measured renal hemodynamic function, arterial stiffness, flow-mediated vasodilatation (FMD/flow), nitroglycerin responsiveness and urine cytokines/chemokines during clamped euglycemia and hyperglycemia.

Results: Placebo and RAS-blockade treated subjects had similar baseline characteristics. The renal hemodynamic response to clamped hyperglycemia was greater in the RAS blockade group (106±15 to 120±16 ml/min/1.73 m^2) compared with the placebo group (109±11 to 110±16 ml/min/1.73 m^2, repeated measures ANOVA $p=0.025$). In the systemic circulation, FMD/flow during clamped euglycemia was higher in RAS-treated vs. placebo-treated subjects (repeated measures ANOVA $p=0.021$), while arterial stiffness and nitroglycerin responses were the same. Urinary cytokine/chemokine excretion in response to clamped hyperglycemia was exaggerated in placebo vs. RAS-blockade subjects.

Conclusions: A 5 year period of RAS blockade confers long-term protective renal and systemic vascular changes and alters the response to hyperglycemia. Our data suggest RAS-related memory effects on vascular function and inflammatory responses can occur in humans.

FR-PO1035

Filtered Angiotensinogen, Not Renal Renin, Determines the Renal Angiotensin II Synthesis when Podocytes Lose Their Molecular Barrier Function Iekuni Ichikawa,[1,3] Fumio Niimura,[1] Akira Nishiyama,[2] Taiji Matsusaka.[1] *[1]Tokai University, Japan; [2]Kagawa University, Japan; [3]Vanderbilt University.*

Background: Urinary tract obstruction activates the renal renin-angiotensin (A) system (RAS) through enhancement of renin release. In view of the well-established detrimental effect of AII on the glomerular structure, ureteral obstruction in glomerular disease is expected to exacerbate destruction of glomerular architecture. It was, therefore, truly surprising to find in our recent study with the NEP25 transgenic model of inducible podocyte-selective injury that unilateral ureteral obstruction (UUO) near completely prevented progression of podocyte injury and subsequent glomerulosclerosis in obstructed kidneys (Am J Physiol 2011;300:F792). The results led us to test the possibility that podocyte injury causes derangement in renal RAS regulation.

Methods: Thus, the above UUO protocol was duplicated in NEP25 mice (n=7) by inducing unilateral ureteral obstruction (UUO) for 7 days following induction of podocyte injury.

Results: The level of renal renin activity measured at the completion of study was comparable in obstructed kidneys and kidneys of control sham-operated mice (6.1±0.7 vs. 6.4±0.7 µg AI/H/mg protein). In contrast, the renal tissue AII content was significantly downregulated in the obstructed kidneys when compared to contralateral kidneys (121±31 fmol/g tissue vs. 210±42, $P<0.05$) along with marked suppression of renal angiotensinogen (Agt) protein. These were not observed in sham operated NEP25 mice (n=7) (AII, 308±74 and 316±66).

Conclusions: In conjunction with our recent findings from tissue-specific Agt knockouts that renal AII is derived primarily from the Agt of liver origin (JASN, In press), the results indicate that the protective effect of ureteral obstruction on the glomerulus is, at least in part, attributed to diminution of filtered Agt. Moreover, the study demonstrated that podocyte injury causes shift of the primary regulatory step for the renal RAS from renin activity to filtration of circulating angiotensinogen.

FR-PO1036

Inorganic Nitrite Attenuates Angiotensin II Mediated Contraction of the Renal Microcirculation by Reducing NADPH Oxidase and Increasing Nitric Oxide Xiang Gao,[1] Ting Yang,[2] Jon Lundberg,[2] Erik G. Persson,[1] Mattias Carlstrom.[2] *[1]Medical Cell Biology, Uppsala University, Sweden; [2]Physiology & Pharmacology, Karolinska Institutet, Sweden.*

Background: Oxidative stress and nitric oxide (NO) deficiency are associated with renal and cardiovascular disease. Stimulation of a nitrate-nitrite-NO pathway has shown therapeutic effects, however, the mechanisms are not clear. We investigated the hypothesis that nitrite may moderate renal oxidative stress and influence microvascular function.

Methods: Mouse afferent arterioles were used to investigate effects of nitrite on luminal diameter and NO production (DAF-FM). Contractions to angiotensin II (AngII; 10^{-12} to 10^{-6}M) and L-NAME (10^{-4}M) were studied with nitrite (10^{-5}M) acutely and after nitrate supplementation (10^{-2}M, 7 days). NADPH oxidase activity was measured as Lucigenin-chemiluminescence of superoxide.

Results: Nitrite increased arteriolar diameter and enhanced NO bioavailability (7±1%). Contraction to AngII alone (31±3%), and during NOS inhibition (56±4%), was attenuated with simultaneous nitrite treatment (17±4% & 25±2%, respectively). Dietary nitrate increased circulating nitrite and attenuated the L-NAME+AngII response (32±2%).

Attenuation of the AngII+L-NAME response with nitrite was abolished with NO scavenger (cPTIO; 66±2%) and guanylyl cyclase inhibitor (ODQ; 58±4%). NADPH oxidase activity in isolated/cultured preglomerular VSMC (50±8 x10^3 CLU/min/cells) was reduced with nitrite (33±5 x10^3 CLU/min/cells). In whole kidney, nitrite reduced NADPH oxidase activity and abolished AngII induced stimulation of the NADPH oxidase.

Effects with nitrite were investigated in a mouse model with oxidative stress (SOD1 knockouts). SOD1-deficient arterioles had abnormally strong AngII contraction (89±5%), which was normalized by simultaneous nitrite (48±6%).

Conclusions: Stimulation of a novel nitrate-nitrite-NO pathway attenuates AngII-mediated contraction in the renal microcirculation. Mechanistically, this is associated with reduced NADPH oxidase activity and increased NO. Dietary approaches with nitrate/nitrite may have therapeutic implications in renal and cardiovascular disease.

FR-PO1037

Angiotensin Converting Enzyme and Glomerular Arteriole Reactivity in Normal and Diabetic Mice Nadine Bouby,[1] Catherine Chollet,[1] Nathalie Caron,[2] Annette Hus-citharel,[3] Lise Bankir.[1] *[1]INSERM U872, Paris, France; [2]FUNDP, Namur, Belgium; [3]INSERM U1050, Paris, France.*

Background: Angiotensin 1 converting enzyme (ACE=kininaseII) insertion/deletion polymorphism is associated with renal prognosis. We previously demonstrated in mice a causal link between the constitutive level of ACE and the renal complications of diabetes mellitus (DM). The present work examined whether this susceptibility to DM nephropathy is related to changes in renal hemodynamic and vascular reactivity induced by ACE level.

Methods: Mice with 2 or 3 copies of the ACE gene (ACE2+, ACE3+, respectively) exhibiting normal or high concentration of plasma and tissue ACE were studied 3 weeks after type 1 DM induction by low doses of streptozotocin. Control ACE2+ and ACE3+ mice received vehicle. Contractile response to AngiotensinII (AngII) or bradykinin (BK) of

microdissected juxtamedullary afferent (AA), and muscular (mEA) or thin efferent (tEA) arterioles was evaluated by intracellular calcium $[Ca^{2+}]_i$ mobilization. Endothelial nitric oxide synthase (eNOS) expression was quantified by RT-qPCR.

Results: Genotype or DM did not alter the dose-response curves to AngII in AA and tEA. In contrast, the maximal response of mEA to 10^{-8} mol/L AngII was decreased by DM ($p<0.01$) in both genotypes. Application of 10^{-6} mol/L BK during the plateau phase of the response to AngII induced a $[Ca^{2+}]_i$ decrease by 10% in tEA and 25% in mEA and AA, with no effect of genotype or DM. eNOS mRNA expression was found only in mEA of ACE3+ mice, and inhibition of NOS with L-Name (2.10^{-5} mol/L) blunted the vasodilatory response to BK or acetylcholine only in mEA of ACE3+ mice, in both control or DM conditions. Prostanoid inhibition with indomethacin (2.10^{-5} mol/L) had no effect on BK response.

Conclusions: An increase in constitutive ACE level induced specific change in signalling pathway of BK in mEA in normal or diabetic conditions. The emergence of the NO pathway might prevent marked vasoconstriction in mEA, that supply medullary blood flow, in situation of high Ang II level and might partially blunt alterations in glomerular filtration rate and medullary blood flow during the early phase of DM.

FR-PO1038

Acetazolamide Reduces Glomerular Hyperfiltration and Renal Plasma Flow in Obese Subjects: A Randomized Controlled Trial Boris Zingerman,[1] Arie Erman,[1,2] Sarit Bar Sheshet Itach,[1] Yaacov Ori,[1,2] Michal Herman-Edelstein,[1,2] Uzi Gafter,[1,2] Avry Chagnac.[1,2] *[1]Nephrology, Rabin Medical Center, Israel; [2]Sackler School of Medicine, Tel Aviv University, Israel.*

Background: Glomerular hyperfiltration is one of the factors involved in the pathogenesis of obesity-associated glomerulopathy. Treatment with acetazolamide (Aceta), a diuretic acting on the proximal tubule, increases delivery of sodium chloride to the macula densa and thus has the potential of decreasing hyperfiltration by blunting tubulo-glomerular feedback. The aim of the present randomized controlled study with cross-over design is to examine whether administration of Aceta may reduce obesity-associated increase in glomerular filtration rate (GFR) and renal plasma flow (RPF). Furosemide (Fur) was used as control using an equipotent natriuretic dose.

Methods: Eight male obese subjects (BMI 36.5 [34-53]), with no diabetes mellitus and no hypertension, aged 40±8 yrs participated in the study. Serum creatinine was 0.79±0.08 mg/dl. In Phase 1, following baseline measurement of GFR (inulin clearance) and RPF (aminohippurate clearance), they received by random assignment either intravenous Aceta (5 mg/kg BW) or Fur (2 mg). GFR and RPF were measured during one hour after administration of Aceta or Fur (two 30 min periods). Phase 2 was performed 2 weeks later using the same protocol, where the diuretic not injected at Phase 1 was injected. Volemia was maintained constant throughout the 2 phases.

Results: Natriuresis increased from 1.7± 0.6 to 4.0± 1.1 ($P<0.0005$) and from 1.9± 0.7 to 4.5± 1.5 ($P<0.0005$) mEq/min following Aceta and Fur administration respectively.

		Baseline	Change (%)	
			Post 0-30 min vs Baseline	Post 31-60 min vs Baseline
Aceta	GFR (ml/min)	154±25	-21% ($P<0.0005$)	-24% ($P<0.0002$)
Aceta	RPF (ml/min)	675±64	NS	-17% ($P<0.01$)
Fur	GFR (ml/min)	155±17	NS	NS
Fur	RPF (ml/min)	771±168	NS	NS

vs: versus

Conclusions: Acute treatment of obese subjects with Aceta, a proximally acting diuretic, results in a decrease in glomerular hyperfiltration. This effect may have therapeutic implications for alleviation of obesity-associated hyperfiltration.

Trial registration: NCT01146288.

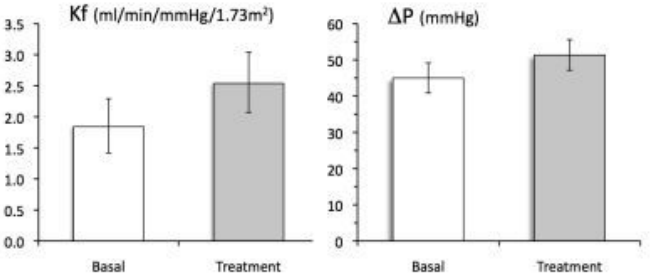
FR-PO1039

Effect of Bardoxolone Methyl on the Determinants of Glomerular Ultrafiltration Andrea Remuzzi,[1,2] Fabio Sangalli,[2] Giuseppe Remuzzi.[2,3] *[1]University of Bergamo, Italy; [2]Mario Negri Institute, Bergamo, Italy; [3]Ospedali Riuniti, Bergamo, Italy.*

Background: It has been recently reported (Pergola et al. NEJM 2011) that a 24 week treatment with bardoxolone methyl was associated with improvement in estimated GFR in patients with advanced CKD and type 2 diabetes, suggesting that this treatment may have promise for amelioration of CKD. We used theoretical analysis of the determinants of GFR to estimate potential changes associated with bardoxolone methyl treatment.

Methods: We used the theoretical model of glomerular ultrafiltration of WM Deen (AJP 1972) to calculate expected values of whole kidney glomerular ultrafiltration coefficient (Kf) before and after 24 week treatment with bardoxolone (150 mg). We initially assumed constant glomerular transmembrane pressure difference (ΔP) to calculate changes in Kf associated with treatment. Subsequently, we assumed constant values of Kf and calculated expected changes in ΔP. Assumed values of eGFR were 32.3 and 42.7 ml/min/1.73m^2 for basal and after treatment evaluation, respectively. We assumed that drug treatment did not affect afferent arteriolar plasma flow and protein concentration.

Results: As shown in the Figure, assuming a constant value of ΔP=45 mmHg, we estimated that the basal value of Kf = 1.84 must increase to 2.54 ml/min/mmHg/1.73m^2 to justify the increase in eGFR associated with treatment, with an average increase of 37.4%. Assuming that Kf remained constant with treatment, we calculated a corresponding increase in ΔP from 45 to 51.3 mmHg, with an average increase of 14.1%.



Conclusions: The results of our theoretical analysis show that the elevation in eGFR observed in type 2 diabetic patients treated with Bardoxolone is more likely the result of an elevation in glomerular capillary pressure (of 6.3 mmHg in average) rather than of a change in Kf that should imply an unattainable increase in glomerular filtering surface area.

FR-PO1040

Renal TGF-β in Transjugular Biopsies Is Associated with Reduced Blood Flow Rather than Hypoxia in Human Atherosclerotic Renal Artery Stenosis (ARAS) Sandra Herrmann,[1] Monika L. Gloviczki,[1] Ahmed Saad,[1] Alfonso Eirin,[1] Michael A. Mckusick,[2] Lilach O. Lerman,[1] Stephen C. Textor.[1] *[1]Nephrology, Mayo Clinic; [2]Radiology, Mayo Clinic, Rochester, MN.*

Background: ARAS reduces renal blood flow (RBF) and amplifies regional kidney hypoxia, leading to inflammatory injury. Transforming growth factor-beta (TGF-β) is an inflammatory cytokine and our previous studies demonstrate higher tissue expression of TGF-β in ARAS as compared to normal kidney donors. The relationships of TGF-β to RBF and tissue oxygenation in ARAS are unknown.

Methods: Single kidney measurements were obtained in the stenotic kidney (STK,n=23) before and 3 months after stent revascularization and compared to non-stenotic kidneys (NSTK,n=11) from the same subjects. Single Kidney GFR and RBF were measured using multi-detector CT. Tissue deoxyhemoglobin levels (R2*) were determined by Blood Oxygen Level Dependent MRI at 3T in the cortical region as was the fractional tissue hypoxia (% of entire axial kidney area with R2*>30s^{-1}). Kidney biopsies obtained from a subset of patients (n=10) before revascularization, stained for TGF-β, were graded on a scale 0=0%, 1<25%, 2=25-50%, 3>50%.

Results: Single kidney RBF and GFR were reduced in the STK. TGF-β tissue score correlated inversely with RBF ($r=-0.67$; $p=0.03$) but not with renal levels of deoxyhemoglobin. Fractional hypoxia was elevated in the STK compared to NSTK and fell to similar levels after revascularization.

Single Kidney Parameter	STK N=23 Before Revascularization	STK After Revascularization	NSTK N=11 Baseline
% R2*>30s^{-1}	20.1±13.4	9.7±8.2†	11.5±5.7*
RBF(mL/mn)	216.2±106.7	272.4±156.9	257.6±164*
GFR(mL/mn)	28.1±13.5	28.9±14.4	50.5±17.4*

†STK before vs STK after Revasc $\rho<0.05$;*NSTK vs STK before Revasc $\rho<0.05$

Conclusions: These data demonstrate reduced RBF in human ARAS is associated with progressively higher tissue TGF-β expression. Our results suggest pre-stent TGF-β expression is not dependent on renal hypoxia. Persistently reduced GFR despite increased RBF and reduction in hypoxic signal to NSTK levels suggest sustained tissue injury. Revascularization may require additional measures, such as those targeted to counter TGF-β, for effective repair.

Evaluation of Renal Blood Flow in High-Fat Diet-Induced Kidney Disease Using Contrast Ultrasound Imaging Anne-Emilie Decleves,[1] Joshua J. Rychak,[2] Dan J. Smith,[2] Kumar Sharma.[1] *[1]University of California, San Diego; [2]Targeson, Inc.*

Background: Obesity is a major contributor of progressive renal disease which occurs as a result of complex interactions between metabolic and hemodynamic, and is characterized by alterations in renal blood flow (RBF). However, the changes of RBF are difficult to assess, emostly in small animal models of disease. In this study, we tested the use of microbubble contrast agents for ultrasound (US) to quantitate changes in the RBF.

Methods: C57BL/6J mice were randomized to a standard diet (STD) or a high-fat diet (HFD). To better evaluate the changes in RBF, at 30 week on diet, mice were treated either with Losartan (an Angiotensin II receptor 1 antagonist) or the placebo (normal saline) for 6 weeks. A perfusion contrast agent was administered i.v. to anesthetized mice, and real-time imaging data was acquired at 14 MHz using a clinical ultrasound scanner. The kidney was imaged in the long axis, and cortical blood flow was assessed at low mechanical index (non-destructive imaging). Renal functional and structural studies were also performed.

Results: Ultrasound perfusion imaging provided an excellent method of analyzing blood flow in the mouse kidney. A cortico-medullary flow gradient was readily visualized in all mice. We observed that the time required for the contrast agent to perfuse the cortex, quantified by time-to-peak analysis, was significantly longer in HFD mice relative to STD mice (10.49±1.64 vs 2.71±0.63 sec, $P<0.05$). The treatment with losartan alleviated this change (5.89±0.84 sec, $P<0.05$). These data were concurrent with an increased glomerular filtration rate in HFD mice compared to STD (270.48±30.41 vs 178.5±10.6μl/min,

P<0.05) or HFD+losartan-treated mice (270.48±30.41 vs 183.4±21.51µl/min, P<0.05). Immunostaining of CD31, a marker of endothelial cells, significantly decreased in the HFD suggesting a rarefaction of peritubular capillaries in the tissues.

Conclusions: These data showed for the first time that ultrasound contrast imaging represents a non-invasive method for the evaluation of changes in RBF in a mouse model of obesity. This technique may be useful both in a research setting and in the clinic.

FR-PO1042

A Novel Vascular Morphology in Perfusion Fixed Human Glomeruli
Chris R. Neal. *Microvascular Research Labs, Physiology and Pharmacology, University of Bristol, Bristol, United Kingdom.*

Background: Human glomeruli have perfused volumes which are large compared to their input arterioles compared to mice or rats. In this study, the human glomerular vascular tree has been reconstructed from perfusion fixed human kidneys, to search for structural changes that may compensate for these large perfusion volumes.

Methods: Unusable human transplant kidneys (4) were perfused with Marshall's solution and transported on ice. Renal arteries were cannulated and the vasculature flushed at 100mmHg hydrostatic pressure with mammalian HEPES Ringer containing Ficoll 400 (25mmHg colloid osmotic pressure). This was followed by a glutaraldehyde fixative solution at the same colloid osmotic and hydrostatic pressures. Tissues were dehydrated, embedded in resin and serial section reconstructions made of glomeruli. Vascular diameters (d) and branching intervals were measured using Image J software from reconstructed images of vascular poles.

Results: In human glomeruli (n=12) both afferent arterioles (d=21±2µm) and efferent arterioles (d=15±2µm) lead into ellipsoidal vascular chambers (VCs). Afferent VCs (mean d=29x50x42 µm) are twice the volume of efferent VCs (mean d=24x36x41 µm) and lead into an average of 6 high capacity unbranching conduits (Capcon vessel; d=14±1µm) that convey blood to peripheral glomerular sectors. The smaller efferent VCs have on average 11 narrower highly branched vessels (d=9±0.5µm) with an occasional wider efferent vessel draining into them.

Conclusions: VCs and Capcon vessels are not apparent in the collapsed vasculature of human renal biopsy. Perfusion fixation at the correct pressures reinflates the glomerular vascular tree to *in vivo* diameters, allowing these vessels to be observed and measured in an *in vivo* state for the first time. Human glomerular VCs and Capcon vessels are unique structures that may effectively distribute pressure and flow among a large population of filtration capillaries in human glomeruli. There are huge implications in glomerular disease where complications can originate at the vascular poles and glomerular periphery at the location of VCs and peripheral Capcon vessels.

FR-PO1043

Vascular Endothelial Growth Factor A and C Modify Glycosaminoglycans in Human Glomerular Endothelial Cells
Rebecca R. Foster,[1] Sian Louise Baker,[1] Robert H. Jenkins,[2] Robert Steadman,[2] Gavin Iain Welsh,[1] Peter W. Mathieson,[1] Simon C. Satchell,[1] Raina D. Ramnath.[1] *[1]School of Clinical Sciences, University of Bristol, Bristol, United Kingdom; [2]Institute of Nephrology, Cardiff University, Cardiff, United Kingdom.*

Background: Glomerular endothelial cells (GEnC) in culture express a surface glycocalyx, consisting of proteoglycan core proteins and glycosaminoglycan side chains (GAG), which contribute to the permeability barrier to macromolecules [1, 2]. Given that vascular endothelial growth factor (VEGF)A and C are both produced by podocytes and affect a wide range of endothelial behaviour including permeability, our aim was to investigate whether they could modify components of the glycoclayx.

Methods: GEnC were treated with vehicle, 1nM VEGFA or 10nM VEGFC in serum containing media in the presence of 20µci/ml [6-^{3}H] glucosamine for 48h to label newly synthesised GAG. Cell media and cell lysate (ammonium hydroxide) were separated and injected onto a DEAE ion exchange column. A salt gradient was used to elute GAG depending on charge (sulphation). Fractions were read on a scintillation counter, then ethanol precipitated, digested with hyaluronidase or left undigested and injected onto a size exclusion column and fractions were read again. Cells were also treated as above in serum free media without radiolabel for 48h and charged GAG were quantified in the media using a colourimetric Alcian blue assay.

Results: Both VEGFA (p<0.05) and VEGFC (p<0.01) increased the synthesis of non-sulphated GAG (0.3M NaCl elution) in the media of cells, confirmed to be hyaluronic acid using size exclusion analysis. VEGFC was shown to increase the degree of charge overall (>0.6M NaCl elution), mostly in the cell media. In contrast, under conditions of stress, VEGFA induced a significant increase in charged GAG release (p<0.05).

Conclusions: In conclusion, we demonstrate for the first time that VEGFs differentially regulate GAG in GEnC in terms of synthesis, charge and release, which may have implications in glomerular filtration barrier regulation.

FR-PO1044

Renal Tubular Creatinine Secretion Changes in Thyroid Disease
Jubi Den Haan, Marinus A. Van Den Dorpel, Arie Berghout. *Internal Medicine, Maasstadziekenhuis, Rotterdam, Netherlands.*

Background: Serum creatinine levels are decreased in hyperthyroidism and increased in hypothyroidism. Usually creatinine levels return to baseline after treatment, resulting from alterations in renal hemodynamics or an direct effect of thyroid hormone on tubular transporters as studied in animals. We hypothesize that thyroid hormone enhances renal tubular creatinine secretion (RTCS).

Methods: Patients with hyperthyroidism (TSH<0.05mU/L) or hypothyroidism (TSH>12mU/L) were subjected to clearance studies before and 3 months after treatment. Clearance of inuline (Cin) and creatinine (Ccr) were determined. Cin was determined using the continuous infusion method(Inutest®, Fresenius Kabi, Austria) and concomitant Ccr using timed urine collection. RTCS was denominated as the ratio between Ccr and Cin (Ccr/Cin).

Results: Seven patients with hyperthyroidism due to Graves' disease and three patients with autoimmune hypothyroidism were included; two hyperthyroidism patients withdrew and were excluded. In the remaining five hyperthyroid subjects TSH (0.02±0.01 and 1.15±1.00mU/l), FT4 (57.0±25 and 12.2±2.4pmol/l), total T3 (6.8±3.0 and 1.7±0.37pmol/l) were changed (all p<0.05) before and after treatment respectively. Serum creatinine (37±6 and 53±8umol/l) increased and GFR (169±21 and 147±17ml/min/1.73m2) decreased (NS). In the hypothyroid patients TSH (51±17 and 3.63±3.41mU/l), FT4 (5.9±3.5 and 14.3±3.6pmol/l), total T3(1.5±0.26 and 1.7±0.2pmol/l) changed before and after treatment. Serum creatinine (85 ±28 and 75±20umol/l) decreased and GFR (155±24 and 186±39ml/min/1.73m2) increased(NS). The fractional excretion of sodium, chloride, phosphate, calcium and uric acid remainde stable. After treatment of hyperthyroidism Ccr/Cin ratio fell from 2.1±1.80 to 0.91±0.27 (p=0.06), but after correction of hypothyroidism Ccr/Cin remained stable (0.88±0.16 vs 0.92±0.31. Pooled analysis of the change in Ccr/Cin ratio in both groups was near significant (1.65±1.5 vs 0.88±0.28;p=0.07) compared to euthyroidism.

Conclusions: We demonstrated a near significant change in RTCS in a small group of hyperthyroid and hypothyroid patients, supporting our rationale that renal tubular function might be influenced by thyroid hormone.

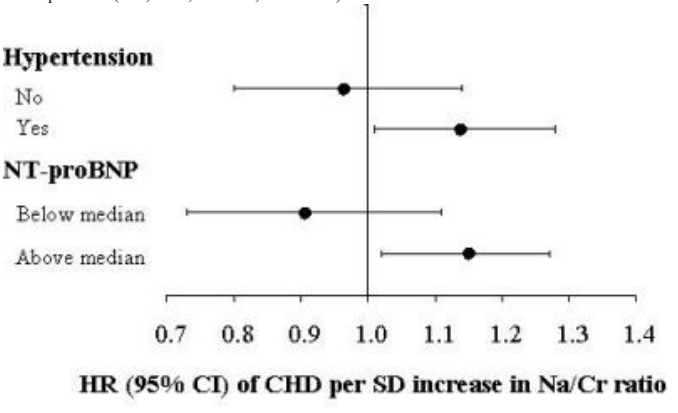
Sodium Intake and Risk of Coronary Heart Disease in the Overall Population and Specific Sub-Populations
Michel M. Joosten,[1,2,3] Ron T. Gansevoort,[2] Kenneth J. Mukamal,[3] Hiddo Jan Lambers Heerspink,[2] Johanna M. Geleijnse,[1,4] Gerjan Navis,[2] Stephan J.L. Bakker.[1,2] *[1]TI Food & Nutrition; [2]University Medical Center Groningen; [3]BIDMC; [4]Wageningen University.*

Background: Whether sodium intake is a risk factor for coronary heart disease (CHD) has recently been challenged, despite effects on blood pressure and extracellular volume. We hypothesized that the association between sodium intake and CHD risk would be more pronounced in subjects potentially more susceptible to the adverse effects of high sodium intake.

Methods: We followed 7779 adults without prior CHD at baseline (1997-8) from the observational, community-based PREVEND study. Sodium intake was measured in two 24h urine collections and normalized to creatinine excretion. Hypertension (n=2453 of which 42% used antihypertensive drugs) and N-Terminal pro-B-type Natriuretic Peptide (NTproBNP) levels > the sex-specific median (n=3796) were defined as predisposing factors.

Results: Mean (SD) sodium intake was 144 mmol/24h (51 mmol/24h). During a median follow-up of 10.5 y we documented 464 events. Sodium intake was not clearly associated with risk of CHD in the entire cohort after adjustment for age, traditional CHD risk factors and potassium/creatinine ratio [multivariable hazard ratio (HR), 1.06; 95% confidence interval (CI), 0.97-1.17 per SD increase], but was associated with higher risk in subjects with hypertension (HR, 1.14; 95% CI, 1.01-1.29) and also in subjects with higher levels of NTproBNP (HR, 1.14; 95% CI, 1.02-1.28).



Conclusions: Sodium intake was associated with increased risk of CHD in subjects with hypertension and in subjects with relatively high levels of NTproBNP. These findings warrant emphasis on sodium reduction, particularly in these risk groups. Differences between cohorts in vulnerability to the adverse effects of sodium may partially explain the inconsistencies on this topic.

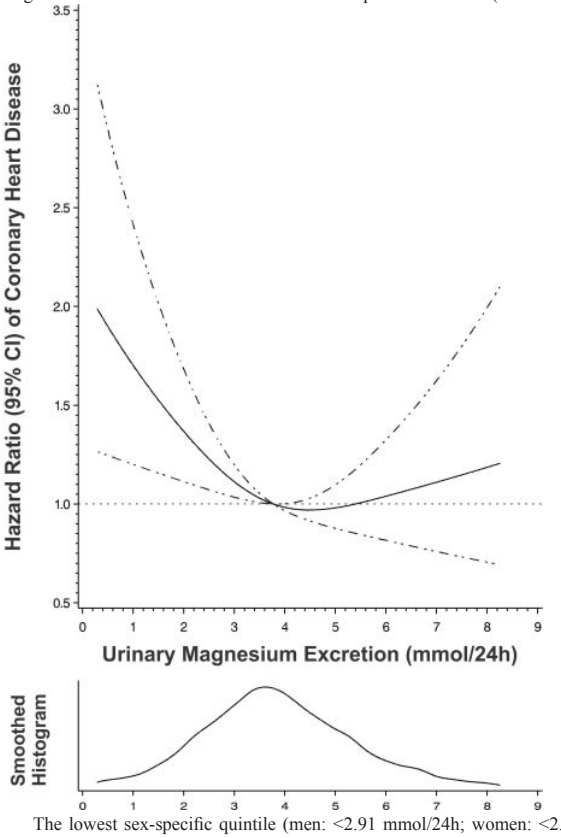
FR-PO1048

Urinary Magnesium Excretion and Risk of Coronary Heart Disease Michel M. Joosten,[1,2,3] Ron T. Gansevoort,[2] Kenneth J. Mukamal,[3] Gerjan Navis,[2] Stephan J.L. Bakker.[1,2] *[1]Top Institute Food and Nutrition, Wageningen, Netherlands; [2]University Medical Center Groningen, Groningen, Netherlands; [3]Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Previous studies on dietary magnesium and risk of coronary heart disease (CHD) have yielded inconsistent results, possibly due to the use of dietary questionnaires, which reflect food magnesium content, but not intestinal magnesium uptake. We investigated whether urinary magnesium excretion, a direct reflection of dietary magnesium uptake, is associated with CHD risk.

Methods: We prospectively followed 7780 adults free of diagnosed CHD at baseline (1997-98) from the community-based, observational PREVEND Study. Urinary magnesium excretion was measured in two 24-h urine collections at baseline.

Results: During a median follow-up of 10.5 year, 465 CHD events occurred. After adjustment for age, traditional CHD risk factors, excretion of creatinine and other cations, magnesium excretion had a threshold relationship with CHD risk (P for curvature=0.02).



The lowest sex-specific quintile (men: <2.91 mmol/24h; women: <2.47mmol/24h) had an increased risk of fatal and non-fatal CHD [multivariable hazard ratio (HR), 1.66; 95% confidence interval (CI), 1.33-2.07) compared with the upper four quintiles. A similar increase in risk for the lowest quintile was observed for mortality related to CHD (HR, 1.57; 95% CI, 1.01-2.46), but not for mortality related to cancer (HR, 0.92; 95% CI, 0.65-1.29) or all-cause mortality (HR, 1.10; 95% CI, 0.88-1.38).

Conclusions: Low urinary magnesium excretion was associated with a higher risk of CHD incidence and mortality. These results suggest that increasing dietary magnesium intake or intestinal uptake, particularly among those with the lowest urinary magnesium excretion, could reduce the risk of CHD. These findings also emphasize the value of 24h-urine collections to assess dietary exposure.

Identification of Proteins that Interact with NFAT5, Using Peptide Affinity Chromatography and Mass Spectrometry Yuichiro Izumi, Jinxi Li, Maurice B. Burg, Joan D. Ferraris. *NHLBI/SBC, National Institutes of Health, Bethesda, MD.*

Background: Nuclear Factor of Activated T-Cells 5 (NFAT5) induces transcription of osmoprotective genes in response to hypertonicity. NFAT5 is associated with many other proteins, only a few of which have been identified. In order to identify additional proteins that regulate NFAT5 by interacting with it, we performed peptide affinity chromatography. Interactions with transcription factors often involve intrinsically disordered regions, so we concentrated on regions of NFAT5 predicted to be intrinsically disordered.

Methods: Biotin-tagged peptides were synthesized, each containing 20 amino acids from a region in the N-terminus of NFAT5 predicted to be intrinsically disordered (UniProtKB/Swiss-Prot: O94916.1). HEK293 cells were grown in light, medium, or heavy SILAC medium for several passages, then incubated at 200, 300, or 500 mOsm (NaCl varied), respectively, for 30 min. Cytoplasmic or nuclear extracts from the different osmolalities were combined and incubated with peptides and streptavidin-coated magnetic beads to isolate proteins associated with the peptides. Proteins eluted from the beads were digested with trypsin and the resultant peptides analyzed on an Eksigent nanoLC Ultra coupled with a Thermo LTQ-Orbitrap Velos mass spectrometer. LC-MS/MS files were searched via Proteome Discoverer (PD) against Sprot human database for peptide and protein identification.

Results: Coomassie staining of SDS gels showed protein enrichment associated with peptides corresponding to NFAT5 amino acids 191 – 210 and 206 – 225 in cytoplasmic fractions and 161 – 180, 191 – 210, and 206 – 225 in nuclear fractions. Numerous proteins were reproducibly identified in biological replicates associated with peptide baits 161 – 180, 191 – 210 and 206 – 225 in nuclear and/or cytoplasmic fractions. PSPC1, SFPQ and NONO are notable among the proteins identified. We are currently investigating their importance for regulation of NFAT5 by hypertonicity.

Conclusions: Peptide-based affinity chromatography revealed proteins that are associated with NFAT5 and that presumably regulate it in response to hypertonicity.

FR-PO1050

Focal Adhesion Kinase Regulates NFAT5 Activity Wolfgang Neuhofer,[1,2] Christoph Küper,[2] Julia Lichtnekert,[1] Maria-luisa Fraek,[2] Franz Beck.[2] *[1]Dept. of Nephrology, Medical Clinic and Policlinc IV, University of Munich, Munich, Germany; [2]Dept. of Cellular Physiology, University of Munich, Munich, Germany.*

Background: NFAT5 is a major regulator of the urinary concentrating process and is essential for the osmoadaptation of renal medullary cells. Focal adhesion kinase (FAK) is a mechanosensitive non-receptor tyrosine kinase that is expressed abundantly in medullary nephron segments. The present study thus addressed the question of whether FAK is involved in NFAT5 activation by hypertonicity.

Methods: FAK activation was monitored by phospho-specific antibodies. FAK inhibition was performed by PF-228 and siRNA-mediated knockdown of FAK. Expression of NFAT5 and appropriate target genes was assessed by qRT-PCR and Western blot analysis. Transcription of the NFAT5 gene was determined using a reporter construct containg 1.0 kb of the human NFAT5 promoter. Transcriptional activity of NFAT5 was monitored by reporter constructs under control of NFAT5, and NFAT5 transactivating activity was analyzed using the binary GAL4 assay. The contribution of the NFAT5 mRNA 3'-UTR on mRNA stability, a luciferase construct containing the full-length NFAT5 3'-UTR was used.

Results: Osmotic stress induced time-dependent activation of FAK as evidenced by phosphorylation at Tyr-397. Both pharmacological inhibition of FAK with PF-228 and siRNA-mediated knockdown of FAK drastically reduced NFAT5 transcriptional activity and target gene expression in HEK293 cells. This effect was not mediated by impaired nuclear translocation or by reduced transactivating activity of NFAT5. However, NFAT5 abundance under isotonic and hypertonic conditions was diminished by 50% by FAK inhibition or siRNA knockdown of FAK. This effect was not caused by reduced transcription of the NFAT5 gene as assessed in reporter gene assays using a 1.0-kb fragment from the human NFAT5 promoter. Rather, NFAT5 mRNA stability was diminished significantly by FAK inhibition, which correlated with reduced activity in a reporter construct containing the NFAT5 mRNA 3'-UTR.

Conclusions: In conclusion, FAK is a major regulator of NFAT5 activity by increasing its abundance via stabilization of the mRNA. This in turn, depends on the presence of the NFAT5 3'-UTR.

FR-PO1051

Hypertonicity Increased Intracellular Glutathione (GSH) Content with Reduced GSH Efflux from Cells Masaru Horio. *Functional Diagnostic Science, Osaka University Graduate School of Medicine, Suita, Osaka, Japan.*

Background: Oxidative stress in renal tubular cell is a possible factor inducing cell damage. Hypertonicity is one of the main causes of the oxidative stress. Glutathione (GSH) is an important antioxidant. It is synthesized in the cell and exported to the extracellular space. Intracellular GSH content depends on the rates of the synthesis and the efflux. In the present study, intracellular GSH content and GSH efflux from cells were evaluated in hypertonic MDCK cells.

Methods: Hypertonicity was made by addition of NaCl. GSH efflux was evaluated by GSH content in culture medium.Multiple drug resistance protein (MRP) has been implicated in the GSH efflux. Transport activity of MRP was measured by efflux of carboxyfluorescein, a substrate of MRP. Effects of MK571, a specific inhibitor of MRP, on efflux of GSH and carboxyfluorescein were studied.

Results: Hypertonicity of 400 and 450 mOsm significantly increased intracellular GSH content up to 1.5 fold the value of isotonic cells after 8h. Content of GSH in culture medium was significantly lower in 450mOsm cells compared with 300mOsm cells after 8h (8.8±2.0 and 25±2.2 nmoles/mg protein, respectively). Hypertonicity made by addition of mannitol showed similar results. MRP transport activity measured by efflux of carboxyfluorescein was significantly increased after hypertonic exposure. The efflux of carboxyfluorescein was partially inhibited by 2.5μM MK-571 in both isotonic and hypertonic conditions. On the contrary, the efflux of GSH was stimulated by 2.5μM MK-571 in both isotonic and hypertonic conditions. Addition of MK571 significantly decreased intracellular content of GSH in 450mOsm cell.

Conclusions: Hypertonicity decreased GSH efflux and increase intracellular content of GSH. Low GSH efflux in hypertonic condition might be one of the mechanisms of increasing intracellular GFR content. Effect of MK571 on GSH efflux suggested the participation of MRP in GSH transport, although the effect of MK571 was opposite direction compared with the effect on carboxyfluorescein efflux. The mechanism of GSH transport has remained elusive. Further study is needed.

Cell Cycle Checkpoint Activation and DNA Damage Response under Hyperosmolal Conditions Are Tissue-Specific Bradley P. Dixon, Brian J. Siroky, John J. Bissler. *Division of Nephrology and Hypertension, Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Children with complex urogenital anomalies frequently require bladder augmentation, and the gastrointestinal tissues utilized for these surgeries are at increased risk for malignancy. We previously demonstrated aberrant cell cycle distribution in colon epithelial cells under hyperosmolal conditions, whereas bladder cells have normal cell cycle distribution under the same conditions. We sought to characterize the cell cycle checkpoint activation and DNA damage response of gastrointestinal and bladder epithelial cells adapted to a hyperosmolal microenvironment.

Methods: Conditionally immortalized colon (YAMC), small intestine (MSIE), gastric (ImSt), and bladder (ULTI) epithelial cell lines were gradually adapted to hyperosmolal conditions with either NaCl or urea, or maintained under isoosmolal conditions, and exposed to etoposide. Cell cycle analysis was performed by propidium iodide staining and flow cytometry. Activation of the DNA damage response was assessed in cell lysates by western blot analysis.

Results: Bladder epithelial cells were able to activate a G1/S phase cell cycle checkpoint under both isoosmolal and hyperosmolal conditions. In contrast, the gastric and small intestine epithelial cells were only able to activate this checkpoint under isoosmolal conditions. Colon, small intestine, and gastric epithelial cells demonstrated an attenuated DNA damage response under hyperosmolal conditions, whereas bladder epithelial cells had a more robust activation of the DNA damage response under such conditions.

Conclusions: The failure of gastrointestinal cells to activate cell cycle checkpoints and the DNA damage response following induction of DNA damage under hyperosmolal conditions may explain the susceptibility to carcinogenesis experienced by gastrointestinal tissues in the augmented bladder.

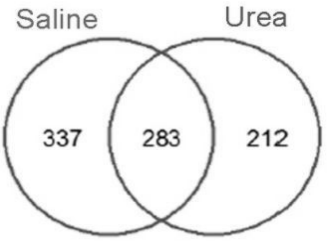
Correction of Hyponatremia with Saline versus Urea Induces Deferential Gene Expression Changes in the Brain Fabrice Gankam Kengne, Bruno Couturier, Alain Georges Soupart, Guy Decaux. *Medicine, ULB - Hopital Erasme, Brussels, Belgium.*

Background: Osmotic demyelination syndrome (ODS) occurs after rapid correction of chronic hyponatremia (HypoNa) which can be prevented with urea. The gene expression profile of the brain during ODS and after urea treatment could provide some insight into the pathophysiology and treatment of ODS.

Methods: We performed gene expression analysis in 3 groups of rats: Hyponatremic rats(I), and after its correction with hypertonic saline (II) or urea (III). hypoNa was induced by DDAVP and liquid diet for 4 days. 24 hrs after the correction, the brain RNA was collected and microarray analysis performed (Illimuna platform) and results analysed with genomestudio software. Significant gene changes (fold change >1.5) were uploaded into Metacore software to identify the major differentially affected pathways in the two treatments.

Results: All animals (urea = 5, hypertonic saline =5 and chronic hypoNa =4) had severe hypoNa (Na<120mEq/L) and its correction in group II and III induced an significant increase in serum Na at 24 hrs (30mEq/L). 620 genes were differentially regulated in group II vs 495 in III and only 283 genes were common to both treatments.



Pathway analysis revealed that apoptosis/survival trough endoplasmic stress response and protein folding were the highest differentially affected networks between group II and III.

Top Deferentially affected networks after correction of hypoNa with urea vs saline

Pathways	pValue
apoptosis-ER stress	8.7e-6
Protein folding ER and cytoplasm	1e-4
Reproduction-Gonadotropin regulation	3.9e4
Cytoskeleton Actin filament	4e-4
DNA dammage checkpoint	9e-4

Conclusions: There is a different response of the brain to correction of hyponatremia with urea and hypertonic saline including gene affecting the ER stress response-protein folding. These results could illuminate the pathophysiologic mechanisms involved in ODS.

Funding: Private Foundation Support, Government Support - Non-U.S.

FR-PO1054

Analysis of Gene Expression Changes in Rat Brain after Acute and Chronic Hyponatremia Fabrice Gankam Kengne, Bruno Couturier, Alain Georges Soupart, Guy Decaux. *Internal Medicine, Universite Libre de Bruxelles, Brussels, Belgium.*

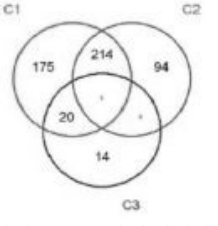
Background: Acute hyponatremia (hypoNa) in contrast to chronic hypoNa produces several CNS symptoms including potentially fatal brain edema. Little is known about the genetic changes underlying that differential effect. Analysis of the gene expression profile in acute vs chronic hypoNa could provide a basis for the understanding of the pathophysiology of the brain adaptation to hypoNa and its treatment.

Methods: We performed gene expression analysis in 3 groups of rats: Normonatremic rats(I), acutely hyponatremic rats (12 hrs of hypoNa) and chronic hyponatremic rats (4 days). hypoNa was induced by DDAVP and liquid diet. We collected brain mRNA and performed miccroarray analysis (Illimuna platform and genome studio software) to identify differentially affected genes in the 2 conditions.

Results: Acute (group I n =5) and chronic hyponatremic rats (II, n=4) had severe hypoNa (Na<120mEq/L) vs normonatremic rats (III, n=5)(Na =140mEq/L). Compared to controls, acute hypoNa induced significant changes (fold change >1.5) in 417 genes and chronic hypoNa induced changes in expression of only 51 genes. When comparing group I and II, we found that 326 genes were differentially regulated.

Comparison	UP-regulated	DN-regulated
c1 – Acute vs. Cont.	225	192
c2 – Acute vs. Chronic	192	133
c3 – Chronic vs. Cont.	32	19

(cutoff: FDR < 5%, FC > 1.5)



Top regulated genes in acute hyponatremia vs chronic hyponatremia included transcription factor arc and hmgn1 which is a downstream target of the osmotic regulator p38MAPK.

Top 5 of upregulated genes in acute vs chfonic hyponatremia

Gene Name	Fold change Acute vs Chronic
Hmgn1	7.39
Gatad2b	6.78
Arc	5.88
Abcg2	4.56
osteoprotegerin	4.09

Conclusions: Chronic hyponatremia induces fewer gene changes in the brain when compared to acute hyponatremia. This could explain the paucity of symptoms seen in chronic hyponatremia. Careful analysis of the differentially affected genes could provide better understanding of the brain adapatation to various forms of anisosmolarity.

FR-PO1055

Functional Expression of P0 (Adenine) Receptor in the Collecting Duct Intercalated Cells in Rat and Mouse Janos Peti-Peterdi,[1] Yue Zhang,[2] Anush Gevorgyan,[1] Donald E. Kohan,[2] Christa E. Müller,[3] Bellamkonda K. Kishore.[2] *[1]Physiology, Univ of Southern California, Los Angeles, CA; [2]Medicine, VAMC & Univ of Utah, Salt Lake City, UT; [3]Pharmaceutical Chemistry, Univ of Bonn, Bonn, Germany.*

Background: The P0 is a Gi-coupled receptor (R), which binds adenine with high affinity as compared to adenosine, AMP/ADP/ATP, and reduces cellular cAMP levels. Blood levels of adenine are markedly increased in chronic kidney disease (CKD) and positively correlate with the duration or severity of CKD. We previously reported that rat kidneys express P0-R mRNA and protein. Hence, intrarenal expression and distribution of P0-R may have a potential role in the pathogenesis of CKD.

Methods: We generated and characterized a peptide-derived polyclonal antibody specific for an 18-amino acid C-terminal sequence of rat P0-R. This antibody detects both rat and mouse P0-R. Using this antibody in confocal immunofluorescence (IF) microscopy we localized P0-R protein in the medulla of rat and mouse and compared to the distribution of AQP2 protein. The inhibitory effect of adenine (10 μM) on the dDAVP (desmopressin; 10 nM)-stimulated cAMP production was determined in freshly isolated inner medullary collecting duct (IMCD) fractions.

Results: In both rat and mouse medulla IF showed P0-R labeling on the apical aspect of the collecting duct. The P0-R protein was predominantly localized to non-AQP2 expressing collecting duct cells, although a few AQP2-positive cells also had sparse PO-R labeling. In IMCD fractions from the rats, adenine significantly reduced dDAVP-stimulated cAMP production (by 43%). Surprisingly, adenine did not affect dDAVP-stimulated cAMP production in mouse IMCD.

Conclusions: P0-R is predominantly expressed in the intercalated cells of the rodent kidney, with minor expression in principal cells. The functional data suggest that significant levels of P0-R may be present in the principal cells of rat, but not in the mouse, to reduce dDAVP-stimulated cAMP production. Conversely, a signal transduction from intercalated cells to principal cells may also be possible. Thus, the markedly increased blood adenine levels in CKD may perturb urinary concentration/medullary function in the kidney.

Aldosterone Reduces Uptake of Interstitial Albumin into Renal Type A Intercalated Cells Thomas Buus Jensen, M. Umar Cheema, Jeppe Praetorius. *Department of Biomedicine, Aarhus University, Health, Aarhus, Denmark.*

Background: Albumin has been identified in preparations of distal renal tubules or collecting ducts by mass spectrometry. This study aimed to establish whether albumin was a contaminant in those studies or actually present in the tubular cells, and if so, determine the origin of the albumin.

Methods: Immunohistochemistry and immuno-gold electron microscopy were applied to localize albumin in distal tubules. Albumin mRNA expression was assessed by RT-PCR and cellular albumin-fluorescein uptake into MDCK cells on permeable support was determined by fluorescence microscopy. The effect of 24-hour aldosterone administrationon distal tubular albumin uptake was studied in c57/bl6 mice.

Results: Albumin was localized to mouse renal intercalated cells by three different anti-albumin antibodies. In addition to the expected proximal tubular albumin immunoreactivity, double fluorescence labeling with various tubule and cell markers identified type A intercalated cells as the site of albumin in the distal renal tubules and collecting ducts. Albumin did not colocalize with markers for early endosomes (EEA1), late endosomes/lysosomes (Cathepsin D) or recycling endosomes (Rab11). Ultrastructural analysis confirmed the presence of albumin-containing large membrane associated bodies in the basal parts of the intercalated cells. Albumin mRNA was detected in mouse renal cortex but was absent from isolated connecting tubules and cortical collecting ducts. This suggests that type A cells are taking up albumin rather than producing it. Wild type type I MDCK cells showed robust uptake of fluorescein-albumin from the basolateral side but not from the apical side when grown on permeable support. Albumin-aldosterone conjugates were internalized from the basolateral side as well by MDCK cells. Aldosterone administration for 24 and 48 hours decreased albumin abundance in connecting tubules and cortical collecting ducts from mouse kidneys.

Conclusions: We conclude that albumin is taken up from the basolateral side by type A intercalated cells and speculate that the protein might acts as a carrier of less water-soluble substances from the blood to the tubular cells.

Effect of Isotonic and Hypertonic Sodium Chloride and Glucose on Excretion of Urinary Aquaporin2 in Healthy Subjects Janni Majgaard Jensen, Frank H. Mose, Jesper N. Bech, Erling B. Pedersen. *Department of Medical Research, Holstebro Hospital and Aarhus University, Holstebro, Denmark.*

Background: Urinary excretion of aquaporin2 (u-AQP2) is currently used to evaluate the water transport in AQP2 water channels in the principal cells in the nephron. The effect of different types of volume expansion on u-AQP2 has never been studied in a randomized controlled trial in healthy humans. The aim of this study was to measure u-AQP2 after isotonic saline, hypertonic saline and glucose infusion in healthy subjects.

Methods: We studied the effect of isotonic saline 0.9% (23 ml/kg), hypertonic saline 3.0 % (7 ml/ kg) and isotonic glucose 5 % (23 ml /kg) at the end of three periods each of 5 days duration with wash out periods of two weeks between interventions, in a randomized, placebo-controlled crossover study. The study comprised of 23 healthy subjects, who consumed a standardized diet regarding calories, sodium and fluid for 4 days before each examination day. GFR was measured as ^{51}Cr-EDTA renal clearance using continuous infusion technique. We measured blood pressure (BP), free water clearance (CH2O), fractional excretion of sodium (FE_{Na}), plasma concentrations of renin (PRC) and aldosterone (p-Aldo) and urinary concentrations of AQP2 at baseline and after infusion.

Results: After isotonic saline infusion, u-AQP2 and CH2O were unchanged, whereas FE_{Na} increased (167%). After hypertonic saline infusion there was an increase in u-AQP2 (344%) and FE_{Na} (144%), whereas CH2O decreased (-186%). After isotonic glucose infusion there was a decrease in u-AQP2 (-64%) and FE_{Na} (-31%) whereas CH2O increased (230%). Systolic BP, pulse rate and GFR increased slightly and to the same extend during all three infusions. PRC and p-Aldo decreased after isotonic and hypertonic saline infusion, but not after glucose infusion.

Conclusions: The study documented that u-AQP2 reflects changes in water channel activity in the kidney tubule during isotonic and hypertonic saline and isotonic glucose infusion in healthy subjects. The study underlines the value of u-AQP2 to estimate water transport in the distal tubule during changes in extracellular volume.

Effects of Oral Tolvaptan in Patients with Heart Failure, Chronic Kidney Disease and Hyponatremia Mari Katsumata,[1] Nobuhito Hirawa,[1] Keisuke Yatsu,[1] Sanae Saka,[1] Gen Yasuda,[1] Satoshi Umemura.[2] *[1]Nephrology, Yokohama City University Medical Center, Yokohama, Kanagawa, Japan; [2]Medical Science and Cardiorenal Medicine, Yokohama City University Graduate School of Medicine, Yokohama, Kanagawa, Japan.*

Background: Tolvaptan, a vasopressin V2 receptor blocker, has a diuretic effect for patients with heart failure. Tolvaptan has been applied to the excessive body fluid state, regardless of using the clinical doses of diuretics. However, there were few data concerning the effects of tolvaptan in patients with chronic kidney disease (CKD).

Methods: We compared the urinary volume and laboratory findings of 10 patients with CKD stage 3-5. Tolvaptan (15mg/day) was administered every day with other diuretics in use. In order to clarify the factors, which relate to the response to tolvaptan, we compared the difference between the responder and the non-responder. Furthermore, we examined the correlations between baseline data and the alterations of urinary volume.

Results: The urinary volume increased from 798 ml/day to 951 ml/day by use of tolvaptan. Concurrently, creatinine increased slightly (from 3.64 mg/dl to 4.16 mg/dl, p=0.02) and urine osmolarities decreased significantly (from 256.0 to 220.7 mOsm/kg, p=0.01). When the patients were divided to the responder (n=5) group and the non-responder group, the urinary volume was significantly higher in the responder group (from 675 ml/day to 1058 ml/day, p=0.017). The responder exhibited a higher serum creatinine levels than that of the non-responder group (4.25 mg/dl vs 2.12 mg/dl, p=0.05). However, the reason was not clear. Hyponatremia was improved dramatically to the normal value, and the augmentations of the sodium concentration were negatively associated with the basal sodium levels (r=-0.91,p<0.001).

Conclusions: Add on treatment with tolvaptan is partly useful to increase diuresis, even in patients with CKD stage 3-5. Furthermore, tolvaptan improve the hyponatremia seen in CKD patients. Thus, tolvaptan might be a good alternative drug for patients with chronic heart failure, renal failure and hyponatremia.

FR-PO1059

Renal Escape from Antidiuresis: Involvement of Key Intrarenal Factors Saad Hussain, Joseph G. Verbalis. *Endocrinology & Metabolism, Georgetown University, Washington, DC.*

Background: Downregulation of renal arginine vasopressin (AVP) V2 receptors (V2R) and subsequent removal of aquaporin-2 (AQP2) water channels play a critical role in escape from AVP-induced antidiuresis. Previous studies have implicated endothelial and neuronal nitric oxide synthetase (eNOS & nNOS) and prostaglandins (PG) in the decrease in renal AQP2 levels that leads to escape, while angiotensin II (Ang II) signaling appears to antagonize escape.

Methods: We studied the role of intrarenal pathways by creating a mouse model of escape and comparing single gene knockout (KO) mice to C57BL/6 wild type (WT) mice. For each experiment, 15 mice were divided into three groups of n=5: 1) KO mice (eNOS, nNOS, or Ang II receptor 1a [$AT_{1a}R$]) fed a gel diet and infused with desmopressin (dDAVP); 2) WT mice fed a gel diet and infused with dDAVP; 3) WT mice fed a solid diet and infused with dDAVP. All experiments were repeated to yield a final n=10 for each group. Urine volume and osmolality, plasma [Na^+] and [K^+], ad libitum water and food intake, and body weight were measured daily. Escape from dDAVP-induced antidiuresis was observed over the course of 5 days.

Results: eNOS KO mice escaped to the same level as gel diet controls without delay in escape (WT Uosm=626 & KO Uosm=633 mOsm/kg H_2O on day 5), but produced significantly lower urine volumes on days 3 & 4. nNOS KO mice showed delayed escape, but eventually reached the same level of diuresis by day 5 (WT Uosm=696 & KO Uosm=639 mOsm/kg H_2O). Escape in $AT_{1a}R$ KO mice was also significantly delayed, but these mice similarly escaped to the same level by day 5 (WT Uosm=637 & KO Uosm=603 mOsm/kg H_2O).

Conclusions: Our data demonstrate that each of these intrarenal signaling pathways likely plays a role in escape from antidiuresis, because no KO strain exhibited the same pattern of escape as the WT mice. However, each of the KO strains did eventually escape from dDAVP-induced antidiuresis. Thus, our data suggest that renal escape in chronically hyponatremic patients is due to a complex signaling system that involves intrarenal eNOS, nNOS, and Ang II, but is not solely attributable to changes in any one of these signaling pathways alone.

FR-PO1060

A Vasopressin-Induced Change in Prostaglandin Receptor Subtype Expression Provides an Explanation for the Paradoxical Effect of Prostaglandin E_2 on Urine Concentration Marleen L.A. Kortenoeven,[1,3] Michelle Boone,[1] Horst Schweer,[2] Robert A. Fenton,[3] Jack F. Wetzels,[4] Peter M.T. Deen.[1] *[1]Department of Physiology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [2]Department of Pediatrics, Philipps-University Marburg, Marburg, Germany; [3]Department of Biomedicine, Aarhus University, Aarhus, Denmark; [4]Department of Nephrology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.*

Background: Urine concentration involves vasopressin (AVP), which via a Gs-cAMP cascade increases transcription of aquaporin-2 (AQP2) water channels and AQP2 redistribution to the apical membrane in renal collecting duct principal cells. Besides AVP, prostaglandins are also involved in water balance regulation. Intriguingly, without AVP, prostaglandin E_2 (PGE_2) increases water reabsorption in the collecting duct, while in the presence of AVP, PGE_2 and $F_{2\alpha}$ ($PGF_{2\alpha}$) decrease water reabsorption.

Methods: To delineate how prostaglandins can exert their diverse effects on water reabsorption, we utilized mouse cortical collecting duct ($mpkCCD_{cl4}$) cells, which endogenously express AQP2 in response to AVP.

Results: In the absence of dDAVP, AQP2 abundance was increased by PGE_2. In the presence of dDAVP, blocking prostaglandin production by indomethacin application increased AQP2 levels, while both PGE_2 and $PGF_{2\alpha}$ application reduced AQP2. dDAVP significantly increased PGD_2 and PGE_2 production, while $PGF_{2\alpha}$ was decreased. RT-PCR showed that, without dDAVP, the prostaglandin receptors EP1, EP4 and FP were expressed. dDAVP application increased the expression of the Gi/q-coupled EP1 and FP receptors, while expression of the Gs-coupled EP4 receptor was decreased.

Conclusions: In agreement with in vivo effects on water permeability, our study showed that PGE_2 increased AQP2 abundance without dDAVP, but PGE_2, as well as $PGF_{2\alpha}$, decreased it in the presence of dDAVP. dDAVP increased $PGD_2$and PGE_2 release, and reduced that of $PGF_{2\alpha}$. As AQP2 abundance is cAMP/Gs-dependent, which is counteracted by activity of Gi/Gq-coupled receptors, the dDAVP-induced increase in Gq-coupled EP1 expression and the decrease in Gs-coupled EP4 expression may explain the paradoxical PGE_2-mediated effects on water permeability.

Impaired Vasopressin Escape in Transgenic Mice Over-Expressing Human CD39: Role of Prostaglandins Bellamkonda K. Kishore,[1] Yue Zhang,[1] Kaiya L. Morris,[1] Karen M. Dwyer,[2] Simon C. Robson.[3] *[1]Medicine, VAMC & Univ of Utah, Salt Lake City, UT; [2]Medicine, Univ of Melbourne, Victoria, Australia; [3]Medicine, BIDMC & Haravard Univ, Boston, MA.*

Background: CD39, an ectonucleotidase (NTPDase1) that hydrolyzes ATP/ADP to AMP, is expressed at several sites within the kidney, and thus may impact the availability of ligands for P2 receptors. Recently we reported that transgenic mice (Tg) over expressing hCD39 have impaired ability to concentrate urine under basal conditions. Hence, we hypothesized that the Tg mice may have enhanced ability to escape from vasopressin-induced anti-diuresis.

Methods: WT and Tg mice (N = 5/genotype) were infused with dDAVP (desmopressin; 2 ng/h) via subcutaneous osmotic mini pumps, with free access to chow and drinking water. After 4 days of dDAVP infusion, the mice were switched to a high water-containing gelled diet as the sole ration (water-loading). Urine output, osmolality and PGE2 excretion were monitored. After 11 days of infusion, the mice were euthanized and renal medullary AQP2 protein abundance was determined by immunoblotting.

Results: Both WT and Tg mice responded equally to dDAVP infusion with no significant difference in urine output and osmolality by day 4. However, water loading caused the onset of AVP escape in WT mice as assessed by increase urine output, and prostaglandin excretion, associated with decreased urine osmolality, which were clear by days 10 and 11. These responses in Tg mice on day 10 and 11 were significantly different ($P < 0.05$) from the WT mice showing a lack of AVP-response. No significant differences in AQP2 protein in WT and Tg mice kidney medullas were found.

Conclusions: The above observations in Tg mice are in line with the previous report of synergistic effects of nitric oxide and prostaglandins in renal escape from AVP-induced antidiuresis (Am J Physiol 284:R354, 2003) and our observations that P2Y2 receptor knockout mice have delayed onset of AVP-escape (JASN 18:114A, 2007). Thus, increased scavenging of extracellular nucleotides in Tg mice might have alter the ability of the kidney to recover from AVP-escape by impaired production of PGE2 and/or impaired P2 receptor signaling.

FR-PO1062

Forskolin Stimulation Induces Cell Membrane UT-A1 Mono-Ubiquitination and Lysosomal Degradation Hua Su, Conner Carter, Jeff M. Sands, Guangping Chen. *Renal Division, Department of Medicine, Emory University, Atlanta, GA.*

Background: Urea transporter UT-A1 plays an important role in the urinary concentrating mechanism. We previously reported that forskolin stimulation promotes UT-A1 ubiquitination, endocytosis and degradation.

Methods: The cell plasma membrane was isolated by sucrose gradient ultracentrifugation. The type of ubiquitination was judged by immunoblotting with specific ubiquitin antibodies to different linkages of ubiquitin chains. We used ubiquitin activating E1 enzyme inhibitor PYR-41 and deubiquitylase inhibitor PR-619 to block ubiquitination and deubiquitination. The endocytosis and recycling of UT-A1 were measured by cell surface biotinylation and MesNa treatment.

Results: UT-A1-MDCK cells were treated with forskolin for 1 h and the cell plasma membrane was isolated. Forskolin stimulation mainly induced UT-A1 ubiquitination on the plasma membrane. Interestingly, the forskolin-induced UT-A1 ubiquitination is mono-ubiquitination. Inhibition of ubiquitination by ubiquitin activating E1 enzyme inhibitor PYR-41 significantly reduced forskolin-induced UT-A1 endocytosis and degradation. We further found that forskolin stimulated UT-A1 degradation is blocked by lysosome inhibitors chloroquine and NH4Cl. Deubiquitylase inhibitor PR-619 promotes cell surface UT-A1 degradation by reducing protein recycling back to the membrane.

Conclusions: Our study reveals that forskolin stimulation induces UT-A1 mono-ubiquitination on the cell plasma membrane and subsequent protein degradation in the lysosome.

Altered Renal Expression of AQP2 and UT-B in α-Galactosidase A Deficient Mice Ji-eun Kim,[1] Su-Youn Lee,[1] Sae Jin Lee,[1] Sung-chul Jung,[2] Ki-Hwan Han.[1] *[1]Department of Anatomy, Ewha Womans University School of Medicine, Seoul, Republic of Korea; [2]Department of Biochemistry, Ewha Womans University School of Medicine, Seoul, Republic of Korea.*

Background: Fabry disease is an inherited disorder caused by deficiency of α-galactosidase A (α-Gal A) resulting in lysosomal accumulation of globotriaosylceramide (Gb3). The purpose of this study was to investigate the mechanism of the decreased urinary concentration, one of the earliest renal manifestation of Fabry disease, in α-Gal A deficient mice.

Methods: Kidney tissues were processed for α-Gal A enzyme activity assay, Gb3 level quantification, immunocytochemistry, and immunoblot analysis.

Results: α-Gal A deficiency caused typical histopathology and significant polyuria that was associated with increased renal Gb3 level. Fabry kidneys showed a significantly increased expression of ER stress proteins, Bip and CHOP. Immunocytochemistry revealed that the expression of CHOP was induced mainly in glomeruli, outer medullary vascular bundles, and medullary collecting duct. CHOP immunoreactivity was also detected in the descending thin limb (DTL) of the loop of Henle. UT-B, AQP2, and AQP1 are key transport proteins involved in urine concentration in vascular bundles, collecting duct, and DTL, respectively. Expression of UT-B and AQP2 proteins significantly decreased in Fabry kidneys, but the abundance of AQP1 protein remained unchanged. Confocal microscopy demonstrated that AQP2 was abnormally localized in the cytoplasm in CHOP-expressing medullary collecting ducts.

Conclusions: These findings suggest that altered expression of AQP2 and UT-B may play an important role in the urinary concentration defect in Fabry disease.

FR-PO1064

Resveratrol Increases NO Bioavailability in the Rat Thick Ascending Limb via a NOS-Dependent Mechanism Agustin Gonzalez-Vicente, Jeffrey L. Garvin. *Hypertension and Vascular Research Division, Henry Ford Hospital, Detroit, MI.*

Background: About 30% of the NaCl filtered through the glomerulus is reabsorbed in the thick ascending limb (TAL). Nitric oxide (NO) produced by nitric oxide synthase 3 (NOS3) inhibits salt absorption in this segment. The phytoalexin resveratrol has been reported to increase NOS3 expression and activity in vascular endothelium cells. It also inhibits NADPH oxidase, a source of superoxide anion (O_2^-) which can scavenge NO. We hypothesized that in the TAL resveratrol increases NO bioavailability via NOS activation.

Methods: To test this TAL suspensions were prepared from collagenase-perfused rat kidneys, and NO bioavailability measure using 4-amino-5-methylamino-2',7'-difluorofluorescein diacetate.

Results: In the presence of 100μM L-arginine, resveratrol acutely increased NO bioavailability in a dose dependent manner, reaching a maximum at 100μM (2.5 ± 0.3 *vs* 1.6 ± 0.2 AFU/mg/min in vehicle, $p<0.05$, $n=4$). This rise in NO bioavailability was blunted by 80% in the presence of 5mM N_ω-Nitro-L-arginine methyl ester (L-NAME), a NOS competitor inhibitor (1.0 ± 0.3 *vs* 0.2 ± 0.2 AFU/mg/min, $p<0.05$, $n=4$). When 100μM TEMPOL, a O_2^- scavenger, was added to the media, resveratrol was able to significantly increase NO bioavailability to the same extent as in its absence (1.6 ± 0.4 *vs* 1.1 ± 0.3 AFU/mg/min in vehicle, $n=6$).

Conclusions: We conclude that: 1) resveratrol increases NO bioavailability in the TAL; and 2) this is due to activation of NOS rather than a reduction in O_2^-.

Funding: Other NIH Support - NHLBI

FR-PO1065

Individual Roles of the Homologous STE20-Like Kinases SPAK and OSR1 in Vasopressin Signaling along the Distal Nephron Sebastian C. Bachmann,[1] Turgay Saritas,[1] Eric J. Delpire,[2] James A. McCormick,[3] David H. Ellison,[3] Kerim Mutig.[1] *[1]Department of Anatomy, Charité Universitätsmedizin, Berlin, Germany; [2]Department of Anesthesiology, Vanderbilt University, Nashville, TN; [3]Division of Nephrology and Hypertension, Oregon Health & Science University, Portland, OR.*

Background: The Na^+-K^+-2Cl^--cotransporter (NKCC2) of the thick ascending limb (TAL) and the Na^+-Cl^--cotransporter (NCC) of the distal convoluted tubule (DCT) are critical for renal salt handling. Activation of these transporters by vasopressin (AVP) includes their phosphorylation at defined, conserved N-terminal threonine and serine residues. Little is currently known, however, about the kinase pathways mediating this action of AVP. Two homologous Ste20-like kinases, SPAK and OSR1, have been recognized as key enzymes within a signaling cascade providing phosphorylation of the cotransporters. Interactions between the catalytically active, full-length variant (FL-SPAK), the dominant-inhibitory, short variant (KS-SPAK) and OSR1 determine this process. Our study aimed at dissecting the individual functions of SPAK and OSR1 in substrate activation along the nephron at baseline and after AVP stimulation.

Methods: To this end, acute and chronic effects of V2 receptor-specific desmopressin (dDAVP) on the kinases and transporters were evaluated in SPAK-deficient mice and AVP-deficient Brattleboro rats.

Results: SPAK variants displayed prominent regulatory changes along TAL and DCT along with an activation of the cotransporters, whereas OSR1 was less involved. The KS- and FL-SPAK variants were modulated by AVP for their selective interaction with NKCC2 in control of its activation, whereas the phosphorylation of NCC was essentially governed by FL-SPAK alone.

Conclusions: In sum, our data specify how SPAK may serve as a hallmark kinase in modulating Na+ reabsorption along the distal nephron under the endocrine control of AVP.

FR-PO1066

Heat Shock Protein 70-kDa Plays a Role in AQP2 Trafficking in Kidney Collecting Duct Cells Euijung Park, Jung-suk Lim, Hyun Jun Jung, Tae-Hwan Kwon. *Department of Biochemistry and Cell Biology, School of Medicine, Kyungpook National University, Daegu, Korea.*

Background: The AQP2 is a vasopressin-regulated water channel protein in the kidney collecting duct. Several proteins (Heat shock protein 70-kDa (Hsp70 and Hsc70), annexin II, tropomyosin 5b and heat shock protein 70-5 (BiP)) were identified as interating proteins with C-terminus of AQP2, where phosphorylation of AQP2 (Ser256) occurs. However, it remains unknown whether these proteins play a role in AQP2 trafficking.

Methods: The changes in protein expression were examined by semiquantitative immunoblotting. The effects of siRNA-mediated knockdown of Hsp70 on the AQP2 phosphorylation (Ser^{256}) and trafficking were examined by semiquantitative immunoblotting and cell surface biotinylation; and the effects of dDAVP on the regulation of Hsp70 transcription were examined by in silico analysis and luciferase reporter assay.

Results: Renal abundance of AQP2, Hsp70 and annexin II was significantly decreased in rats with hypokalemia-induced NDI. Immunohistochemistry demonstrated decreased immunolabeling intensity of AQP2, Hsp70, and annexin II and apical targeting of AQP2 in the inner medulla (IM). In contrast, AQP2 and Hsp70 were significantly increased in the IM of dDAVP-infused rats for 5 days. In silico analysis of 5'-flanking regions of AQP2, Hsp70-1 and Hsp70-2 genes revealed that transcriptional regulator binding elements associated with cAMP response were identified at both the Hsp70-1 and Hsp70-2 promoter regions, in addition to AQP2. Luciferase reporter assay demonstrated the increase of luminescence after dDAVP stimulation (10^{-8}M, 6 h) in LLC-PK1 cells transfected with 1 kb of 5'-flanking region in Hsp70-2 construct, but unchanged luminescence in cells transfected with Hsp70-1 construct. Cell surface biotinylation analysis demonstrated that forskolin (10^{-5}M, 15 min)-induced AQP2 trafficking to the apical plasma membrane was significantly attenuated in the mpkCCDc14 cells with siRNA-mediated knockdown of Hsp70-2, which was associated with markedly decreased phosphorylation of AQP2 (Ser256).

Conclusions: Taken together, Hsp70-2 is likely to play a role in AQP2 trafficking, possibly by affecting phosphorylation of AQP2 at Ser 256.

Funding: Government Support - Non-U.S.

FR-PO1067

Dynamics of Aquaporin 2 Phosphorylation at Serine 256 and Serine 261 upon Co-Expression of Constitutively Active Variants of the Calcium-Sensing Receptor (CaSR) in Renal Cells Marianna Ranieri,[1] Grazia Tamma,[1] Annarita Di Mise,[1] Peter M.T. Deen,[2] Maria Svelto,[1] Giovanna Valenti.[1] *[1]Dept of Biosciences, Biotechnologies and Pharmacological Sciences, University of Bari, Bari, Italy; [2]Dept of Physiology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.*

Background: We have recently shown that in MCD4 renal cells, cell surface AQP2 expression in cells exposed to CaSR agonists was higher than in control cells and did not increase significantly in response to short term exposure to forskolin. Those findings were in line with data obtained in hypercalciuric subjects displaying at baseline significantly higher AQP2 excretion and no significant increase in AQP2 excretion and urinary osmolarity after acute DDAVP administration compared to normocalciurics (Procino et al Plos One 2012). This indicates that CaSR-AQP2 interplay represents an internal renal defense to mitigate the effects of rising of calcium during antidiuresis on the risk of calcium precipitation.

Methods: Human wild-type CaSR (hCaSR-wt) and its constitutively active variants (hCaSR-R990G; hCaSR-N124K) were functionally expressed in renal HEK cells stably expressing hAQP2. The N124K mutation is one of eight naturally occurring activating mutations in subjects with autosomal dominant hypocalcemia, whereas R990G is a gain-of-function of the CASR gene polymorphism. Western blotting analysis of a crude membrane fraction was performed using phospho-specific antibodies.

Results: Compared to mock cells, pS256-AQP2 abundance was significantly increased in cells expressing either the wt-CaSR or its activating variants. Of note, we also found a significant increase in pS261-AQP2 in hCaSR-wt expressing cells compared to mock. Interestingly, the expression of pS261-AQP2 was significantly higher in cells expressing the constitutively active CaSR variants with respect to wt-CaSR expressing cells. No change in the pS269 was observed.

Conclusions: Since previous data demonstrated that the amount of pS261 significantly decreases in response to short-term vasopressin exposure, it can be speculated that the increase in pS261 observed in cells expressing constitutively active CaSR variants might counteract the vasopressin response.

Funding: Government Support - Non-U.S.

FR-PO1068

Sildenafil (Sil) Treatment Increases AQP2 Production and Insertion in Lithium (Li)-Induced Nephrogenic Diabetes Insipidus via cGMP-Mediated PKA Activation Talita R. Sanches, Leticia U. De Castro, Antonio C. Seguro, Lucia Andrade. *Nephrology, University of Sao Paulo School of Medicine, SP, Sao Paulo, Brazil.*

Background: Plasma membrane accumulation of AQP2 results from arginine vasopressin type 2 receptor stimulation of adenylyl cyclase, cAMP-mediated activation of PKA, and AQP2 phosphorylation, as well as PKA-induced phosphorylation of the cAMP responsive element binding protein (CREB), which stimulates transcription of the AQP2 promoter. Sil, a type-5 cGMP phosphodiesterase inhibitor, elevates intracellular cGMP and might induce AQP2 membrane insertion, independently of vasopressin receptor activation, by activating a parallel, cGMP-mediated signal transduction pathway. In experimental Li-induced NDI, Sil is known to decrease urinary volume by upregulating renal AQP2.

Methods: Wistar rats received 4 weeks of Li (40 mmol/kg food) or not (control), some also receiving Sil (200 mg/kg food) in weeks 2-4, with or without Li (Li+Sil or Sil). We immunoblotted renal tissue to evaluate expression of AQP2, GSK3β, CREB and phosphorylated CREB (pCREB). In suspensions of medullary collecting duct cells from the papillae of Li-group kidneys—Li+susp (n = 6); Li+Sil+iPKA+susp (n=6, incubated with 5μM Sil and 5 nM PKA inhibitor); and Li+Sil+iPKG+susp (n=6, incubated with 5μM Sil and 100μM Protein Kinase G Inhibitor)—we immunoblotted for AQP2 expression. Data are mean±SEM.

Results: In renal tissue, AQP2 expression in Li+Sil rats was higher than in Li rats but lower than in controls and Sil rats. GSK3β expression was slightly lower in the Li group than in the other groups. Although CREB abundance was similar across groups, pCREB was higher in the Li+Sil group than in the control, Li and Sil groups (355±60.1 vs. 100±0.7, 162±13.4 and169±9.4; $p<0.01$). AQP2 expression was higher in Li+Sil+iPKG+susp than in Li+susp and Li+Sil+iPKA+susp (57.37±4.33 vs. 37.7±5.31 and 36.13±1.73; $p<0.01$).

Conclusions: cGMP mediates activation of PKA-induced AQP2 phosphorylation, which is necessary for membrane accumulation of AQP2. PKA also induced pCREB phosphorylation, which stimulates transcription of the AQP2 promoter. Sil might provide significant clinical benefits to patients suffering from Li-induced NDI.

Chlorpromazine Inhibits Clathrin-Mediated Endocytosis of AQP2 from the Basolateral Membrane by Selective Basolateral F-Actin Depolymerization Naofumi Yui,[1,2] Hua Ann Jenny Lu,[1] Ying Chen,[1] Richard Bouley,[1] Dennis Brown.[1] *[1]Center for Systems Biology, Program in Membrane Biology, Nephrology Division, Massachusetts General Hospital, Harvard Medical School, Boston, MA; [2]Department of Nephrology, Tokyo Medical and Dental University, Tokyo, Japan.*

Background: Recently, we found that AQP2 is continuously targeting to the basolateral plasma membrane in polarized MDCK cells, from which it is rapidly retrieved by clathrin-mediated endocytosis. It then undertakes microtubule-dependent transcytosis. We also found that treatment with chlorpromazine (an inhibitor of clathrin-mediated endocytosis) results in AQP2 accumulation in the basolateral, but not the apical, membrane of epithelial cells.

Results: In this study, we investigated how the chlorpromazine effect on AQP2 might occur. In MDCK cells, both AQP2 and clathrin were concentrated in the basolateral membrane after chlorpromazine treatment (100 μM, 15 min). Interestingly, we found that basolateral, but not apical, cortical F-actin was selectively depolymerized by chlorpromazine. Next, we applied chlorpromazine to rat kidney slices in vitro. After incubation with chlorpromazine, basolateral accumulation of AQP2 and clathrin were significantly increased in collecting duct principal cells, which showed a significant decrease of their basolateral F-actin. As for the MDCK cells, the drug-induced reduction in F-actin was also restricted to the basolateral domain of rat kidney collecting duct cells.

Conclusions: These results further support our new trafficking model of AQP2, which demonstrates continuous basolateral targeting and subsequent apical transcytosis. We show that chlorpromazine selectively depolymerizes basolateral F-actin, and this results in an inhibition of clathrin-mediated endocytosis of AQP2 from the basolateral membrane.

Importantly, the regulation of cortical F-actin organization seems to be different between apical and basolateral domains. We previously showed that vasopressin mediated F-actin depolymerization requires the presence of AQP2. Whether this "catalytic" effect of AQP2 on actin depolymerization is enhanced by chlorpromazine, even in the absence of vasopressin, will be examined in future studies.

Cationic Uremic Toxins Interact with the Organic Cation Transporter, OCT2, in Human Kidney Proximal Tubule Cells Carolien M.S. Schophuizen,[1] Martijn J. Wilmer,[2] Jitske Jansen,[3] Joost G. Hoenderop,[3] Lambertus V. Heuvel,[1] Rosalinde Masereeuw.[2] *[1]Department of Pediatric Nephrology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [2]Department of Pharmacology & Toxicology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [3]Department of Physiology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.*

Background: Several organic cations, such as guanidines and polyamines, have been found to accumulate in the plasma of uremic patients due to inadequate renal clearance. Here, we studied the interaction of these cationic uremic toxins with the organic cation transporter, OCT2, in a conditionally immortalized human proximal tubule epithelial cell line (ciPTEC).

Methods: Transporter activity was measured in cell suspensions by studying the uptake of the fluorescent substrate, 4-(4-(dimethylamino)styryl)-N-methylpyridinium iodide (ASP^+). IC_{50} values were determined for cationic uremic toxins, cadaverine, putrescine, spermine and spermidine (polyamines), acrolein (polyamine breakdown product) and guanidine and methylguanidine (guanidines).

Results: Concentration-dependent inhibition of ASP^+ uptake by TPA, cimetidine, quinidine and metformin confirmed functional, endogenous OCT2 expression in ciPTEC. All cationic uremic toxins tested inhibited ASP^+ uptake by OCT2, of which acrolein was the most potent (IC_{50} = 116 ± 30 μM). A Dixon plot was constructed for acrolein using three independent inhibition curves (10, 20 or 30μM ASP^+), demonstrating a competitive type of interaction (Ki = 93 ±16 μM). This suggests that acrolein is a substrate for the OCT2 transporter. Exposing the cells to a uremic toxin mixture resulted in a more potent and biphasic inhibitory response curve, indicating complex interaction between the toxins and OCT2. Plotting the inhibitory potencies against logP values revealed a correlation of -0.67 ($P < 0.05$), illustrating that hydrophobicity plays a significant role in OCT2 interaction.

Conclusions: OCT2 interactions can be elucidated using ciPTEC. Here, the interaction of cationic uremic toxins, and especially acrolein, was demonstrated, indicating their involvement in the accumulation of uremic toxins in renal disease.

ER-Stress and Endosomal Abnormalities in the Kidney of AQP11 Null Mice Shintaro Kondo,[1] Tadashi Yamamoto,[2] Yasuko Tanaka,[1] Kenichi Ishibashi.[1] *[1]Meiji Pharmceutical University, Japan; [2]Niigata University School of Medicine, Japan.*

Background: AQP11 null mice suffer from fatal kidney failure a month or so after birth due to polycystic kidneys following the huge intracellular vacuole formation in the proximal tubule formed a week or so after birth.

Methods: To obtain the insights into the mechanisms for the vacuole and cyst formations, we compared the gene and the protein expression profiles between the kidney of AQP11 null and wild mice.

Results: At the very beginning of the vacuole formation (postnatal day 3: p3), nine genes were expressed less than half and five genes were expressed more than twice than wild mice including proapoptotic Chac1 and Trib3. As our previous microarray analysis at p7 with full vacuoles documented up-regulation of ER-stress genes, Der13 was compared by real-time PCR to reveal the fifteen fold increase even at p3. At the polycystic stage (p30), 821 genes were expressed less than half and 1172 genes were expressed more than twice including genes related inflammation (Lcn2, Serpina3n, Lyz2, C3, Egr2, Havcr1) and apoptosis (Casp12). As active LC3-II protein was not induced at p3, the vacuole seemed not to be due to autophagy but more likely due to endosomal abnormality as the staining of both EEA1 (early endosome antigen 1) and M6PR, a late endosome marker, were decreased at p1 and the staining of M6PR recovered at p3 with still decreased EEA1 staining. Two-dimensional gel electrophoresis was employed to compare the protein profile of the kidney at the beginning of the cyst formation (p17). Three increased spots were found in AQP11 null mice and the two of them were identified by LC-MS/MS as ER-stress related 78kDa glucose regulated protein (Hspa5) and Major urinary protein 3 (MUP3). Interestingly, MUP3 has also been reported to be increased in the cysts of another PKD model mouse (jck).

Conclusions: In the kidney of AQP11 null mice endosomal abnormalities appeared at the early vacuole formation, when ER-stress was initiated to continue to the stage of the polycysts with epithelial vacuoles.

Impaired Aquaporin2 Trafficking in Medullary Collecting Ducts of Sodium Chloride Co-Transporter (NCC)/Pendrin Double Knockout Mice Kamyar A. Zahedi,[1] Hassane Amlal,[1] Jie Xu,[1] Sharon Barone,[1] Manoocher Soleimani.[1,2] *[1]Medicine, University of Cincinnati, Cincinnati, OH; [2]Veterans Administration Research Services, Veterans Administration Hospital, Cincinnati, OH.*

Background: Mice with combined deficiency of the sodium chloride co-transporter and Cl^-/HCO_3^- exchanger pendrin (NCC/pendrin-dko) are polyuric and have increased levels of salt excretion compared to wild type (WT) animals. As a result these animals are severely volume depleted and develop pre-renal kidney failure. The adverse hemodynamic effects of combined NCC/pendrin deficiency can be corrected by salt replacement. Furthermore, despite appropriately elevated vaspressin levels, the volume depleted NCC/pendrin-dko mice have impaired urine concentrating ability.

Methods: Western blotting and immunofluorescent studies were performed using aquaporin2 (AQP2) antibodies.

Results: The effect of NCC/pendrin deficiency on the expression and distribution of AQP2 was examined in order to determine the cause of urine concentrating defect and polyuria. Immunofluorescent studies indicated that AQP2 is diffusely distributed in the apical, sub-apical and cytoplasmic regions of principal cells in kidneys of NCC/pendrin-dKO mice. Thus, we hypothesized that the trafficking of AQP2 is altered in NCC/pendrin-dko mice. Phosphorylation of AQP2 on serine residues 256, 264 and 269 is important in its cell surface expression while its phosphorylation on serine 261 is important in its internalization and recycling. In order to test our hypothesis we compared the phosphorylation of AQP2 on serine 261 in wt and NCC/pendrin double ko mice by western blot analysis. Our results indicate that the abundance of serine 261-phosphorylated AQP2 is elevated in the protein extracts from NCC/pendrin-dko mice compared to their WT counter parts. Immunofluorescent examination of kidneys from both genotypes using anti-phosphoserine 261AQP2 confirmed its increased subapical and intracellular localization in NCC/pendrin-dko compared to WT mice.

Conclusions: These studies suggest that altered cellular trafficking and localization of AQP2 is in part responsible for the impaired urine-concentrating ability and polyuria in NCC/pendrin-dko animals.

The Activation of Renal Unfolded Protein Response Reduces Urinary Exosomal Aquaporin-1 Excretion Kanako Shigemura, Hiroko Sonoda, Saki Takahashi, Yoshiki Higashijima, Masahiro Ikeda. *Veterinary Pharmacology, University of Miyazaki, Miyazaki, Japan.*

Background: The unfolded protein response (UPR) is an intracellular signaling pathway in response to the accumulation of misfolded proteins in the endoplasmic reticulum. Renal ischemia-reperfusion (I/R) injury is an important cause of acute kidney injury and several studies have indicated that the UPR is activated after renal I/R mainly in the outer medulla. Also, it has been reported that the UPR activation has a protective role against I/R-induced cell injury. Recently, our group found that urinary exosomal aquaporin-1 (AQP1) excretion was reduced in response to renal I/R, leading to discovery of a novel biomarker. However, the mechanism of the reduction is largely unknown.

Methods: In this study, we asked whether the induction of the UPR affects the urinary exosomal excretion of AQP1, using chemical UPR inducers, including tunicamycin and thapsigargin. Tunicamycin (0.3 mg/kg) was administered to rats by sub renal capsule injection to minimize any indirect action under in vivo conditions. Urine samples were collected at 18-24 h after the administration. Urinary exosomes were isolated from the urine samples by differential ultracentrifugation.

Results: Real-time PCR analyses showed that the treatment with tunicamycin dramatically increased GRP78 and CHOP mRNAs (known to be markers for activation of the UPR), and decreased AQP1 mRNA in the outer medulla. These responses were accompanied with the decreased abundance of urinary exosomal AQP1 protein, but not with that of AQP2 protein. When tunicamycin (3 mg/ml) or thapsigargin (1 mM) was added to cultured proximal tubule cells (NRK-52E cells), up-regulation of GRP78 and CHOP mRNAs, and down-regulation of AQP1 mRNA were also observed.

Conclusions: These findings suggest a possible mechanism by which the UPR pathway mediates the reduction of urinary exosomal AQP1 protein excretion following renal I/R.

Compartmental Discrepancies in Uremic Toxin Composition and Implications on Solute Removal by Dialysis Leonard Ebah, Milind Nikam, Anuradha Jayanti, Angela M. Summers, Paul E. Brenchley, Sandip Mitra. *Manchester Institute of Nephrology and Transplantation, Manchester Royal Infirmary, United Kingdom.*

Background: Uremic toxin (UT) removal is a key objective of dialysis, its efficacy often measured by plasma solute clearance. Little is known about extraplasmatic UT composition and the effect of dialysis on extravascular compartments such as interstitial fluid (IF). We compared IF and plasma UT composition.

Methods: Microdialysis was used to sample subcutaneous IF and measure its composition in a range of UTs (urea-MW 60, creatinine-MW 113, phosphate-MW 95, urate, MW 168) both off and during haemodialysis(HD). A novel minimally invasive

microneedle array was developed and used to directly sample subcutaneous IF. GCMS and LCMS-MS were applied to paired plasma and IF samples of CKD patients to compare their metabolomic and proteomic profiles.

Results: Off dialysis, IF small toxin levels correlated closely to that of plasma (r=0.98, 0.94, 0.74 and 0.82 for plasma vs. IF urea, creatinine, phosphate and urate respectively). However, paired analysis of the whole group revealed subtle but significant differences between plasma and IF urea (15.4±7 vs. 14.4±7mmol/L; p=0.01), creatinine (397.4 ±286 vs. 344.7±255 μmol/L; p=0.02) and urate (0.4±0.2 vs. 0.3±0.2 mmol/L; p=0.03). During HD, a significant lag of IF toxin decay curves occurred in ~30% of cases. Metabolomics revealed over 5000 metabolites of <1000Da within IF; 40 of these corresponded to known small and protein-bound UTs. Thousands of other metabolite peaks were detected (some possibly yet unidentified UTs), with marked discrepancies between plasma and IF levels, indicating that the two fluid types exhibit different metabolite profiles in CKD. Proteomics of IF and plasma revealed markedly different profiles, with middle molecules such as beta-2 microglobulin, cystatin C, IgG kappa light chain, IgG lambda light chain and complement factor D consistently found in significantly higher quantities in IF than in plasma.

Conclusions: IF is a toxin-rich environment and certain toxins may be unevenly distributed within extracellular fluid with a possible sequestration in IF, potentially rendering them harder to clear by dialysis.

FR-PO1075

Copeptin as a Novel Serum Marker of Upper and Lower Urinary Tract Infections Anna Masajtis-zagajewska, Ilona Kurnatowska, Malgorzata Jadwiga Wajdlich, Michal P. Nowicki. *Department of Nephrology, Hypertension and Kidney Transplantation, Medical University, Lodz, Poland.*

Background: A differentiation between lower and upper urinary tract infection (UTI) depends mainly on clinical presentation with atypical and variable symptoms posing a diagnostic challenge.

Vasopressin has recently attracted scientific interest as a diagnostic and prognostic biomarker, e.g. in sepsis and pneumonia. Copeptin is a stable C-terminal pro-vasopressin Thus, it could become an important biomarker in infections, including UTI. In this pilot study we compared the discriminatory usefulness of serum copeptin with conventional inflammation markers such as C-reactive protein (CRP), procalcitonin (PCT) and IL-6 in patients with upper and lower UTI.

Methods: The study comprised 24 patients; 11 with lower (9F,2M) and 13 with upper UTI (10F,3M). Serum markers and urine cultures were assessed immediately before commencing an antibiotic treatment and 24, 48 hours and 7 days thereafter.

Results: Before an antibiotic therapy serum levels of all biomarkers and copeptin were increased in both groups. In upper UTI group only serum CRP (93.1±71.2 mg/dl) and PCT (1.6±3.1 ng/ml) were significantly higher than in patients with lower UTI (14.5±38 mg/dl and 0.05±0.001 ng/ml, respectively). On day 7 of the antibiotic treatment all inflammatory markers and copeptin levels decreased significantly Serum copeptin levels were decreased to the similar extend in both groups of patients. In contrast, a decrease of serum CRP and IL-6 levels was significantly greater in patients with upper than lower UTI. A decrease of PCT level was much lower in both groups.

Conclusions: Serum Copeptin seems to be a useful inflammation marker in UTI. However, serum levels of CRP and IL-6 may be more suitable for the discrimination between lower and upper UTI and for the assessment of the effect of antibiotic therapy.

FR-PO1076

Drinking Effect on Aquaporins 1 and 2 and eNOS Expression, in Renal Medulla of Acute Sodium Overload Rats Silvana L. Della Penna,[1] Maria Ines Rosón,[1] Gabriel Cao,[2] Elsa Zotta,[3] Marcela Pandolfo,[1] Andrea Fellet,[1] Ana Balaszczuk,[1] Lorena Sarati,[1] Jorge E. Toblli,[2] Belisario Fernandez.[1] *[1]Pathophysiology Department, Facultad de Farmacia y Bioquimica, Universidad de Buenos Aires, Buenos Aires, Argentina; [2]Experimental Medicine Laboratory, Hospital Aleman, Buenos Aires, Argentina; [3]Physiology Department, Facultad de Medicina, Universidad de Buenos Aires, Buenos Aires, Argentina.*

Background: The objective was to investigate the effects of water drinking on aquaporin 1 and 2 expressions (AQP1 and AQP2 respectively) in renal medulla of rats subjected to an acute sodium overload and to explore its association with eNOS expression.

Methods: Male Sprague-Dawley rats were intraperitoneally injected with 2ml/100g of body weight with the following solutions: Controls: C group (saline: 0.15 mol/L NaCl) and experimental Na group (hyperosmolar: 0.80 mol/L NaCl). Then the animals rested in the animal care room for 2 h with free (+W) or restricted (-W) access to drinking water. Then, plasma levels of Na^+, Cl^-, K^+ and proteins were measured and eNOS, AQP1 and AQP2 expressions were detected in renal medulla by Western-blot and immunohystochemical stain.

Results: Plasma Na^+ and proteins were significantly higher in Na–W group than in C-W group ($P<0.05$). AQP2 expression increased in Na+W group compared with C+W group: AU (arbitrary units); C+W: 1.20 ±0.07, Na+W: 1.84±0.08, $P<0.05$. AQP2, AQP1 and eNOS expression decreased in Na-W group compared with Na+W group (AU, AQP2: Na-W: 1.47±0.10, Na+W: 1.84±0.08, AQP-1, Na-W: 0.77±0.11, Na+W: 1.27±0.19, $P<0.05$; eNOS, Na-W: 0.77±0.03, Na+W: 1.49±0.09, $P<0.05$).

Conclusions: Urinary sodium concentration may be favored in animals subjected to an acute saline overload, by increased AQP2 levels in renal medulla, when they have free access to drinking water. However, drinking restriction to these rats could facilitate urinary sodium excretion, by decreasing AQP1, AQP2 and eNOS expression in renal medulla.

FR-PO1077

Aqp5 Is a New Dot1a Transcriptional Target and Links Aldosterone to Polyuria Wenzheng Zhang,[1] Hongyu Wu,[1] Lihe Chen,[1] Qiaoling Zhou,[2] Oleh Pochynyuk,[1] Xi Zhang.[1] *[1]UTHSC, Houston, TX; [2]Central South Univ, Houston, TX.*

Background: Histone methyltransferase Dot1a represses ENaC in aldosterone (aldo) signaling network. High [aldo] induces polyuria. We developed $Dot1l^{AC}$ mice that lack Dot1l and thus H3 dimethylation (H3m2K79) in $Aqp2^+$ cells. $Dot1l^{AC}$ vs. $Dot1l^{f/f}$ mice increased intercalated cells (IC) by 20% in the expense of principal cells (PC) (Wu et al, 2011 ASN abstract # 21278).

Methods: Mice on the normal Na+ pellet were used for urine analysis, patch clamping, RT-qPCR, IB, IF and ChIP. Urine analysis was also done with mice on a normal Na+ gel diet, after 24-h H2O deprivation or aldo infusion. RNAi knockdown and luciferase assays were done in IMCD3 and MLE15 cells.

Results: $Dot1l^{AC}$ vs. $Dot1l^{f/f}$had normal ENaC mRNA levels, but significantly reduced ENaC Po and effective ENaC activity; 2) $Dot1l^{AC}$ vs. $Dot1l^{f/f}$ elevated the urine volume by 83 ± 29% and decreased urine osmolarity by 34 ± 9.1% with normal Aqp2 mRNA and protein expression. $Dot1l^{f/f}$and $Dot1l^{+/+}$ Aqp2Cre had similar urine volume and osmolarity. $Dot1l^{AC}$ also had polyuria on the gel diet or after water deprivation; 3) Aqp5 mRNA is >100-fold and 12-fold higher in $Dot1l^{AC}$ and $Dot1l^{+/+}$ Aqp2Cre than in $Dot1l^{f/f}$,respectively. Aqp5 immunostaining was robustly detected in most of PC in $Dot1l^{AC}$, but barely detectable or very faintly in controls; 4) ChIP showed strong binding of Dot1l and H3m2K79 in 4 out of 12 regions covering the 6.5 kb between Aqp2 and Aqp5 in $Dot1l^{f/f}$. The binding was significantly impaired in each of these 4 regions in $Dot1l^{AC}$; 5) Dot1a depletion significantly increased Aqp5 mRNA by >10-fold in IMCD3 cells; 6) Dot1a overexpression significantly decreased expression of Aqp5 and Aqp5-promoter luciferase reporters in MLE15 cells. 7) Aldo-infused mice significantly increased Aqp5 mRNA and urine volume.

Conclusions: ENaC mRNA level in $Dot1l^{AC}$ may be counterbalanced by loss of Dot1a-mediated repression and a decreased PC population. The PC towards IC shifting may lead to the impaired ENaC function. Aqp5 is likely a new aldo and thus Dot1a transcriptional target. Dot1a and Aqp5 seem to be the missing components linking aldo to polyuria.

Funding: NIDDK Support

FR-PO1078

Aqp5 Interacts with Aqp2 and Impairs Its Membrane Localization Wenzheng Zhang,[1] Lihe Chen,[1] Hongyu Wu,[1] Qiaoling Zhou,[2] Xi Zhang.[1] *[1]UTHSC, Houston, TX; [2]Central South Univ, Changsha, China.*

Background: While Aqp5 is the closest homolog of Aqp2 and shares 66% sequence identity with it, Aqp5 expression is undetectable in normal mouse kidney. $Dot1l^{AC}$ mice lack H3 K79 dimethylation (H3m2K79) in $Aqp2^+$ cells, express substantial Aqp5 mRNA and protein, and display polyuria (Wu et al, 2012 ASN abstract # 1439). We hypothesize that Aqp5 contributes to polyuria, partially by impairing Aqp2 membrane expression.

Methods: IF, Co-IP, and confocal microscopy were used to examine if AQP2 and AQP5 interact in vivo in mouse kidney and in kidney biopsies from patients with minimal change disease (MCD) and patients with diabetic nephropathy (DN), and in vitro in transfected IMCD3 cells. Cell surface biotinylation was done to determine the effect of AQP5 overexpression on AQP2 membrane localization in IMCD3 cells.

Results: Aqp5 and Aqp2 colocalized in most of Aqp2+ cells in $Dot1l^{AC}$, with barely detectable Aqp5 in $Dot1l^{f/f}$. $Dot1l^{AC}$ vs. $Dot1l^{f/f}$ had apparently reduced apical distribution of Aqp2, with diffuse Aqp2 at both apical and basolateral sides; 2) All of the 15 MCDs had undetectable AQP5, with AQP2 primarily seen at the apical side. All 17 DN samples contained $AQP2^+AQP5^-$, $AQP2^+AQP5^+$, $AQP2^-AQP5^+$ and $AQP2^-AQP5^-$ tubules. In the $AQP2^+AQP5^+$ tubules, these two proteins were typically colocalized as large discrete foci near the perinuclear region. 3) All MCDs had strong H3m2K79 expression. Significant reduction of H3m2K79 was seen in all of the DN samples. Such reduction occurred throughout the whole biopsies in some cases or focally in others, to various degrees. Most of AQP5+ cells had weak or no H3m2K79 at all in the nuclei; 4) RFP-AQP5 and GFP-AQP2 colocalized as large discrete foci in the perinuclear region in IMCD3 cells; 5) GFP-AQP2 was specifically coimmunoprecipitated with FLAG-AQP5 in IMCD3 cells; 6) Myc-AQP5 significantly decreased plasma membrane-associated FLAG-AQP2 to about 21% of Myc vec in IMCD3 cells.

Conclusions: Aqp5 interacts with Aqp2 and apparently impaired Aqp2 membrane localization in vivo in kidneys of Dot1lAC mice and in kidney biopsies of patients with DN, and in vitro in transfected IMCD3 cells.

Remission of Crescentic Glomerulonephritis due to Henoch Schonlein Purpura in an Elderly Adult Achieved with Rituximab and Glucocorticoid Therapy Panupong Lisawat, Varun Agrawal, Pamela C. Gibson. *Fletcher Allen Healthcare.*

Background: Henoch-Schonlein Purpura (HSP) is an uncommon systemic vasculitic disease in adults due to immunoglobulin A (IgA) deposits predominantly in the skin, joints and glomeruli. Eleven percent of the patients with HSP are reported to progress to end stage kidney disease. We present an interesting case of crescentic HSP nephritis in an elderly adult that was successfully treated with rituximab and glucocorticoids.

Methods: A 78-year-old woman was hospitalized for lower extremity palpable rash for 3 weeks. She had acute kidney injury (serum creatinine [Cr] 1.5 mg/dl, with baseline Cr 0.9 mg/dl six months ago). She complained of swelling involving her face and both feet.

She had hypertension and temporal arteritis that was treated with prednisone 15 months ago. Biopsy of skin rash revealed leukocytoclastic vasculitis that stained with anti-IgA conjugate. Urine studies were notable for 3+ blood, protein: creatinine ratio of 20 g/g and dysmorphic RBCs. Her Cr continued to increase to 1.8 mg/dl. Kidney biopsy was significant for diffuse necrotizing glomerulonephritis with cellular crescents (involving 53% and 9% glomeruli respectively). Promient subendothelial, mesangial and paramesangial staining with IgA (3+) was seen. Crescentic HSP was diagnosed. Cyclophosphamide therapy was considered, but was not favored for concerns of toxicity in the elderly. We initiated induction therapy with rituximab and pulse methylprednisolone, followed by maintenance therapy with prednisone (1mg/kg/day) tapered over 6 months. At 6 months, her Cr was 1.6 mg/dl with hematuria but no proteinuria (urine protein: creatinine ratio of 0.1g/g).

Conclusions: Crescentic glomerulonephritis in HSP is an uncommon cause of RPGN with a paucity of randomized clinical trials to guide therapy. We speculate that Rituximab, by its anti CD-20 activity, may have altered IgA production by B lymphocytes resulting in remission in our patient. Our case highlights rituximab with glucocorticoids as a therapeutic option for treating crescentic GN associated with HSP in an elderly adult while avoiding cyclophosphamide toxicity.

FR-PO1080

Successful Stenting of Acute Renal Artery Dissection in a Patient with Vascular Ehlers Danlos Syndrome Panupong Lisawat, Richard J. Solomon. *Division of Nephrology, University of Vermont, Burlington, VT.*

Background: Endovascular procedures have increased in treating many vascular complications in Vascular Ehlers Danlos Syndrome (VEDS). However, the experience in treating renal artery complications is limited. We describe a case of VEDS that had bilateral renal artery dissections and renal infarction that was successfully treated with endovascular stenting.

Methods: A 41-year-old female with a history of Vascular Ehlers-Danlos syndrome (VEDS) presented with right-sided back pain that resembled the pain that led to left nephrectomy 14 years previously. On examination, she was not in distress but her blood pressure was >200 mmHg systolic during episodes of uncontrolled pain. She had mild right upper abdominal tenderness with right costovertebral angle tenderness. Her serum creatinine was 1.2 (baseline of 0.8.). She underwent renal angiography which revealed a dissection with decreased flow in the posterior division of right renal artery and focal dissection with focal stenosis of the anterior division right renal artery. Another emergent interventional angiogram was performed a few day later as she had abrupt back pain associated with an increase in creatinine. She was found to have a new occlusion of posterior division of right renal artery. Stenting was successfully performed. Her serum creatinine peaked at 2.46 on the day of procedure and then began to trend downward. Two weeks after stenting, her creatinine was 1.4.

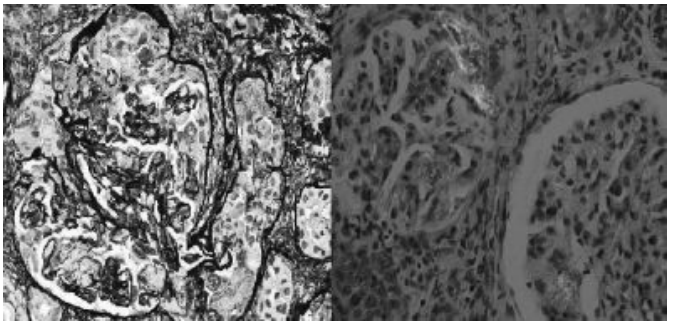
Conclusions: There have been successful endovascular procedures attempted to control the control vascular complications in VEDS patients (Lum et al). However, due to the collagen defect and tissue fragility, invasive procedure mortality can exceed 40% (Pepin et al). No renal stenting procedures have been reported for management of dissection in these patients. Our patient is the first case of VEDS that has a second symptomatic renal artery dissection after prior contralateral nephrectomy for renal artery dissection. It is also the first case in a VEDS patient with renal artery dissection successfully treated with an interventional stent placement.

FR-PO1081

Crescentic Glomerulonephritis with AA Amyloidosis in a Patient with Sarcoidosis Katherine Duello,[1] Xochiquetzal J. Geiger,[2] Walter Hellinger,[1] Nabeel Aslam.[1] *[1]Medicine, Mayo Clinic Florida, Jacksonville, FL; [2]Pathology, Mayo Clinic Florida, Jacksonville, FL.*

Background: Sarcoidosis is a granulomatous disease which rarely causes Crescentic Necrotizing Glomerulonephritis (CNG). AA amyloidosis (AA) has been reported with sarcoidosis. However, co-existent CNG with AA in sarcoidosis has not been previously described. Here we report a case of CNG with AA amyloidosis in a pt with sarcoidosis.

Methods: A 66 yr old female presented with wt loss, anorexia, and liver lesions of 8 months duration. Prior workup showed splenic lesions concerning for abscesses prompting splenectomy, pathology showed granulomatous inflammation without infection. Liver biopsy showed non-necrotizing epitheloid granulomas with negative stains for AFB, fungi and negative cultures. Chest CT showed lymphadenopathy and pleural effusion. ACE level was elevated. Based upon these findings, sarcoidosis was diagnosed. She developed hematuria, rise in creatinine (Scr) to 3.2 mg/dL and nephrotic range proteinuria. Lupus and vasculitis serology were negative. Renal biopsy showed CNG, Congo red was positive for amyloid in the glomeruli and vessels.



EM confirmed amyloid fibrils and typing via liquid chromatography mass spectrometry showed amyloid AA. She was treated with steroids with improvement in her renal function (Scr 1.3) and reduction in proteinuria.

Conclusions: AA amyloidosis has been associated with chronic inflammatory states, but rarely with sarcoidosis. However, previously reported cases did not show CNG. In our case, renal biopsy showed CNG with AA amyloidosis. We speculate that AA amyloid deposits lead to glomerular basement membrane injury leading to crescentic necrotizing lesions in our patient similar to cases reported with with rheumatoid arthritis. This correlation should be considered in patients with sarcoidosis who develop RPGN or nephrotic range proteinuria.

FR-PO1082

Dilated Cardiomyopathy: An Unusual Presentation of Cryoglobulinemic Glomerulonephritis Successfully Treated with Rituximab Allyson Hart, Marc L. Weber, Milind Y. Junghare. *Renal Diseases and Hypertension, University of Minnesota, Minneapolis, MN.*

Background: Hepatitis C virus (HCV) infection is the main cause of mixed cryoglobulinemia vasculitis and may affect any organ system. We describe a patient with HCV-associated cryoglobulinemia with new-onset dilated cardiomyopathy and glomerulonephritis (GN) who dramatically improved with plasmapheresis and rituximab.

Methods: A 49 woman with a history of HCV presented with new onset non-ischemic cardiomyopathy, rash on her lower extremities and acute kidney injury (AKI). She was found to have an ejection fraction (EF) of 35% and no significant valvular disease. She had microscopic hematuria, a rise in HCV RNA, hypocomplementemia and type II cryoglobulnemia. Kidney biopsy showed cryoglobulin-associated membranoproliferative GN.She was treated with plasmapheresis and rituximab with subsequent resolution of cryoglobulinemia, rash, and AKI. Repeat echocardiogram showed normalization of her left ventricular EF.

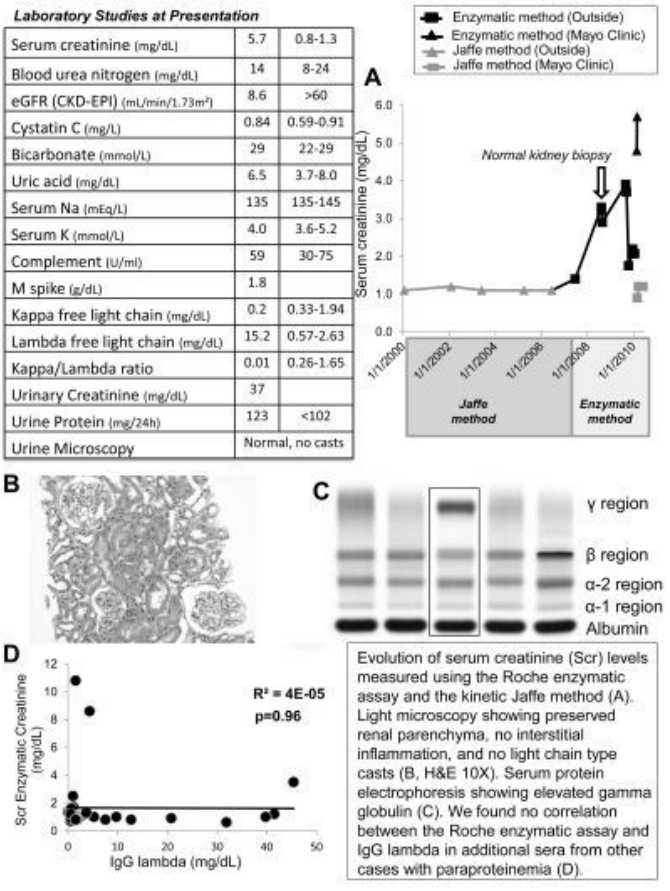
Conclusions: Heart involvement in HCV-associated cryoglobulinemic GN is rarely reported in the literature, while up to up to 21% of deaths in this disease have been attributed to acute myocardial infarction or heart failure. Maestroni and Gorevic et al. reported small and medium sized coronary vasculitis in 22% and 55% of patients with cryoglobulinemia and heart disease at autopsy, respectively, suggesting that alterations in immune function amendable to therapy may frequently go unrecognized. Antiviral and immunosuppressive therapies remain the mainstay of treatment for HCV-associated cryoglobulinemic GN; however, reduced kidney function often precludes ribavirin therapy. Rituximab has been reported to be effective in treating HCV-associated cryoglobulinemic GN in conjunction with plasmapheresis, thus allowing subsequent treatment of underlying HCV. This case demonstrates that rituximab is well tolerated, does not necessarily lead to increased HCV viral levels and may be effective in treating HCV-associated cyroglobulinemic GN. Furthermore, rituximab proved successful in treating "idiopathic" dilated cardiomyopathy in the setting of HCV and cryoglobulinemia.

FR-PO1083

Falsely Elevated Serum Creatinine in a Patient with a Monoclonal Gammopathy Alfonso Eirin,[1] John C. Lieske,[1] Francis Buadi,[2] Timothy S. Larson,[1] Marie C. Hogan.[1] *[1]Div of Nephrology; [2]Hematology, Mayo Clinic, MN.*

Background: Estimation of glomerular filtration rate (eGFR) using serum creatinine (Scr) is widely employed to assess renal function. In recent years, Scr assays have been standardized. Many labs have changed from the kinetic Jaffe to enzymatic methods, in part due to concerns regarding potential interfering substances such as ketoacids.

Methods: An 80yo man was evaluated for a 10 year history of "progressive chronic renal insufficiency", during which time Scr had progressively increased from 1.1 to 3.3mg/dL (fig 1A). At presentation, Scr was 5.7mg/dL, measured on a Roche C-501 Modular analyzer using a Roche enzymatic assay (IDMS-traceable). BUN, potassium, and cystatin C levels were normal (Table). Further evaluation identified elevated lambda immunoglobulin free light chain and a corresponding IgG lambda paraprotein on serum protein electrophoresis(fig 1C). A renal biopsy revealed normal cortex (fig 1B) with no evidence of light chain deposition, amyloid, or cast nephropathy. Subsequently, a Scr measured using a Roche kinetic Jaffe assay was normal at 0.9mg/dL. Analysis of 34 additional sera from other cases with paraproteinemia did not interfere with the Roche enzymatic assay (Fig 1D).



Evolution of serum creatinine (Scr) levels measured using the Roche enzymatic assay and the kinetic Jaffe method (A). Light microscopy showing preserved renal parenchyma, no interstitial inflammation, and no light chain type casts (B, H&E 10X). Serum protein electrophoresis showing elevated gamma globulin (C). We found no correlation between the Roche enzymatic assay and IgG lambda in additional sera from other cases with paraproteinemia (D).

Conclusions: Although the enzymatic Scr assay is thought to have less interference than the Jaffe assay, this study suggests that they can still occur. Previous studies have identified dopamine and/or related metabolites as potential substances that interfere with the enzymatic Scr assay, and this case suggests that paraproteins can also rarely interfere with the test. Thus, regardless of assay, nephrologists should suspect interfering analytes when discrepancies are found between the Scr levels, clinical presentation, and other measures of renal function (e.g., cystatin C). Most labs can measure SCr by an alternative assay when an interfering substance is suspected.

FR-PO1084

Reversible Renal Failure and Minimal Change Disease (MCD) Induced by Vascular Endothelial Growth Factor (VEGF) Blockade with Sunitinib
Tarun Chugh, Savneek S. Chugh, Rajan Kapoor, Sreedhar R. Adapa, Dominick F. Reda, Praveen N. Chander. *New York Medical College, Valhalla, NY.*

Background: VEGF produced by podocytes helps maintain the integrity of glomerular endothelium and podocytes. Blockade of VEGF by specific antibodies such as Bevacizumab can cause acute kidney injury (AKI) and proteinuria mostly with thrombotic microangiopathy (TMA) i.e. endothelial injury. Recently, nephrotic syndrome and/or irreversible AKI have been reported with VEGF blockade by tyrosine kinase receptor inhibitors (TKI) like Sunitinib. The pathology, however, is not well characterized. We report the first case of Sunitinib induced reversible AKI with acute interstitial nephritis (AIN) and marked proteinuria (38g/day) with MCD.

Methods: An 82 year old male with history of renal cancer, on Sunitinib for 2 years, was admitted with 4 weeks of lower extremity edema and progressive renal failure, requiring dialysis. He was on Insulin, Furosemide, Simvastatin and denied taking herbal or OTC products. Physical examination was remarkable for pedal edema; BP 138/78 mmHg. Relevant labs: BUN 70mg/dl, creatinine (Cr) 5.3mg/dl, total protein 5.2g/dl, S.albumin 1.8g/dl. Urinalysis 3+ protein, 3+ blood, urine protein 38g/day. Immunofixation and serological work-up was negative. Renal imaging was normal. Renal biopsy showed primarily MCD and severe AIN. Sunitinib was discontinued and he was started on tapering doses of Prednisone followed by marked improvement. Dialysis was discontinued in a week; Cr stabilized at 1.8mg/dl and proteinuria decreased to <1g/day.

Conclusions: VEGF blockade is known to cause renal disease with variegated pathology. Most cases are reported with Bevacizumab and show TMA. Rare case reports of TMA, FSGS with TMA and acute tubular necrosis (ATN) alone or with MCD (one case) have been reported with TKIs, the latter suggesting podocyte injury. Only three cases of AIN have been described so far; none were associated with MCD. In conclusion, our case shows: 1) TKIs can result in a constellation of AKI with AIN and MCD, 2) TKIs can result in podocytic damage in addition to endothelial injury, and 3) the pathology can be reversed with appropriate therapy.

FR-PO1085

Lupus Nephritis with Severe Renal Failure: Successful Induction with Mycophenolate Mofetil
Tarun Chugh, Rajan Kapoor, Savneek S. Chugh, Sreedhar R. Adapa, Karim B. Solangi. *Department of Nephrology, New York Medical College, Valhalla, NY.*

Background: Mycophenolate mofetil (MMF) has been shown to be noninferior to cyclophosphamide (CYC) as an inducing agent in patients with active lupus nephritis (LN) class III, IV or V. The role of MMF in severe renal failure (CrCl < 30ml/min) has not yet been defined. We present a case of LN (class IV/ V) in severe renal failure (CrCl 8ml/min) who had successful induction with MMF.

Methods: A 25 year old African American (AA) male with history of SLE for past 4 years, was admitted with progressive bilateral lower extremity swelling of 6 weeks duration. He denied similar complaints in the past and was currently not on any medications. His vitals were stable with BP 146/92 mmHg. Physical exam was unremarkable except for anasarca. Relevant labs: Hemoglobin 10.1 g/dl, serum K^+ 5.8 meq/L, BUN 60 mg/dl, creatinine 5.9 mg/dl which trended up to 6.8mg/dl on day 5, albumin 1.7g/dl. Urinalysis 3+ protein, 3+ blood. Urine protein 4.5gm/day. Renal US/Doppler: normal. C3, C4 were extremely low and ANA, anti dsDNA titers were high. Rest of the serological work up including HIV was negative. Renal biopsy showed Class IV-G and V active LN. He was then treated with pulse steroids and MMF. About 16 weeks later his creatinine decreased to 1.1mg/dl, proteinuria decreased and complements normalized. He never required dialysis.

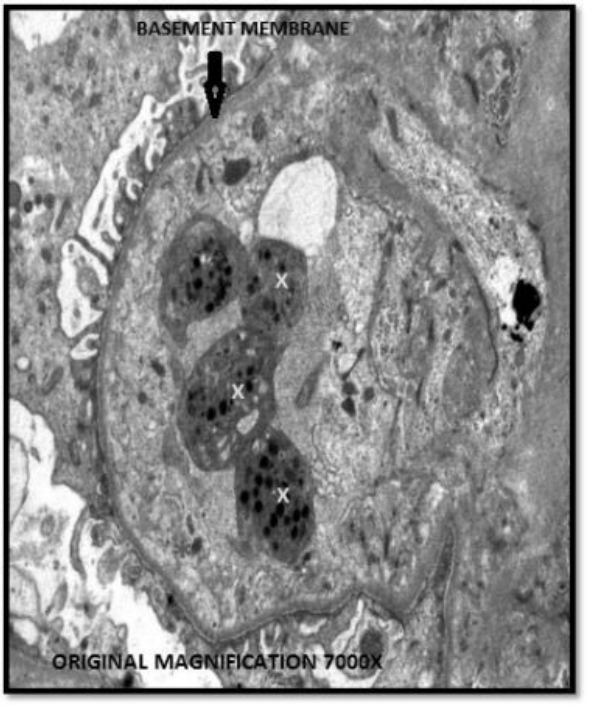
Conclusions: Majority of the trials comparing MMF vs CYC as inducing agent excluded patients with CrCl < 30ml/min and/or creatinine > 1.5 mg/dl. However, in ALMS trial, 11% of the patients in MMF arm had CrCl < 30ml/min and mean creatinine was 1.2 ± 1.1 mg/dl, in contrast to our patient with creatinine of 6.8mg/dl. Post-hoc analysis of this trial also suggested better outcomes with MMF in AA population. After discussion regarding treatment options (CYC vs MMF) and the side effects of each therapy, MMF was chosen per patient preference. Successful outcome with MMF as inducing agent in a LN patient with such severity of renal involvement is encouraging. In view of this, MMF may be used as an alternate inducing agent in LN even with severe renal failure, especially in young AA patients where CYC toxicity is of concern.

FR-PO1086

Renal-Limited Thrombotic Microangiopathy Associated with Clopidogrel
Jehanzeb Bilal, Antoine J. Harb, Neil Lachant, I. Bruce Elfenbein, William D. Sirover. *Internal Medicine, Division of Nephrology, Division of Hematology-Oncology, Department of Pathology, Cooper University Hospital, Camden, NJ.*

Background: Thrombotic microangiopathy (TMA) in the form of TTP-HUS with renal manifestations has been well described. TMA limited to the kidneys is rare. We describe the first case of clopidogrel-associated renal-limited TMA without thrombocytopenia.

Methods: An 82 year old Caucasian female was referred to the Renal clinic for sub-acute kidney injury. Her serum creatinine (SCr) had increased from 1.03 to 2.23 mg/dl over 22 months. Her medical history was significant for hypertension, hyperlipidemia and peripheral vascular disease. She had been on clopidogrel for 5 years. Labs showed hemoglobin 10.7 gm/dl with platelet count 237,000/ul. Urine microscopy, serological evaluation and Renal ultrasound were unremarkable. A renal biopsy was performed. Biopsy findings were notable for electron microscopy that showed platelet clumps(X) within capillaries, endothelial cell swelling(*) and subendothelial space expansion.



These were consistent with acute TMA. Clopidogrel was stopped. Serologic testing for ADAMTS13 was within normal limits. The patient's SCr had acutely increased to 2.95mg/dl and was admitted to the hospital. Admission labs showed normal platelet count and Serum LDH level. Schistocytes were absent on peripheral blood smear. She received daily plasma exchange(PE) for 10 days along with dexamethasone. SCr was 1.87 on day 10, 1.40 in one month and was 1.83mg/dl six months later.

Conclusions: Our patient presented with sub-acute kidney Injury and a *normal* platelet count while on clopidogrel. Renal biopsy revealed findings consistent with TMA. Patient had no systemic symptoms. With drug withdrawal, PE, and glucocorticoid therapy, her renal function improved to baseline. We report the first case of renal-limited TMA associated with clopidogrel.

FR-PO1088

Complication of Nephrotic Syndrome: It Can Be a Headache

Kathryn Treit, Raimund H. Pichler. *Division of Nephrology, University of Washington, Seattle, WA.*

Background: Venous thromboembolism is a recognized complication of patients with nephrotic syndrome. The nephrotic syndrome, defined by proteinuria (>3.5grams/24 hours), edema, hyperlipidemia, hypoalbuminemia and lipiduria, has a significant impact on the regulation of clotting factors. This increases patients' risk for life threatening thrombotic complications. In this case report we present the rare complication of a cerebral venous sinus thrombosis in a young woman with nephrotic syndrome.

Methods: A 20 year old woman with a relapse of minimal change disease presented to the hospital with a two day history of frontal headaches. Her headache was accompanied by photophobia, nausea, decreased appetite and emesis. Physical exam was notable for pretibial and periorbital edema, photophobia and an otherwise normal neurologic exam. Laboratory values were notable for: WBC 22,000, Hb 18.2g/dL, Platelets 286,000, Creatinine 0.7mg/dL, INR 1.0, Albumin 1.4g/dL and a Protein/Creatinine 19.7. A lumbar puncture was without evidence of infection or intracranial bleed. An MRI venogram was completed and revealed a cerebral venous sinus thrombosis. The patient was initiated on anticoagulation using unfractionated heparin and her steroid dose changed to intravenous methylprednisolone. The patient's neurological symptoms completely resolved.

Conclusions: Nephrotic syndrome is associated with a 7-8 fold increase in the rate of venous thromboembolism compared to the general population. This is secondary to both urinary loss of anticoagulants such as Antithrombin and Protein S as well as hepatic upregulation of procoagulants. Patients at greatest risk for venous thromboembolism are those with a serum albumin less than 2.9g/dl and those within the first six months of their diagnosis [Barbour,S. KI, 81, 190-195]. The duration of treatment as well as primary prophylaxis remains uncertain for this patient population. Given the significant morbidity and mortality associated with cerebral venous sinus thrombosis early recognition and initiation of anticoagulation is necessary for optimal clinical outcomes. At this time, thrombolysis is considered only in patients who are not responsive to anticoagulation with heparin.

FR-PO1089

Belimumab for ANCA-Associated Vasculitis

Elizabeth J. Brant, Ronald J. Falk, Mary Anne Dooley. *UNC Kidney Center, University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: A 55-year-old woman with a 28-year history of refractory antinuetrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) is effectively treated with belimumab, a B cell modulator that does not deplete B regulatory cells.

Methods: This patient presented in 1984 with subglottic stenosis. Laryngeal biopsy revealed acute and chronic inflammation. Immunfluorescence for myeloperoxidase (MPO) ANCA was positive. Diagnosis was organ limited AAV. Despite treatment with oral methotrexate, azathioprine, corticosteroids, inhaled and intralesional steroids, and topical mytomycin C, repeat biopsies were unchanged. In 2005, she presented with fever, malaise, weight loss, episcleritis, otitis, cough, arthralgias, myalgias, and rash. With negative infectious workup but newly positive enzyme-linked immunosorbent assay for MPO ANCA, symptoms were attributed to systemic AAV. She was treated with mycophenolate and subcutaneous methotrexate but continued to have smoldering disease and recurrent infections. Kidney biopsy in 2006, prompted by active urine sediment, noted pauci-immune glomerular sclerosis and fibrocellular crescents. She was prescribed 6 courses of rituximab over 5 years, and methotrexate and mycophenolate for maintenance. She continued to have frequent disease flares and recurrent infections. In December 2011, belimumab was prescribed every 2 weeks for 3 infusions, then monthly at a dose of 10mg/kg. The patient had rapid improvement of subglottic stenosis, glomerulonephritis, and fatigue, and resolution of episcleritis.

Conclusions: Belimumab, a monoclonal antibody approved for treatment of systemic lupus erythematosus in 2011, prevents binding of soluble human B lymphocyte stimulator protein (BLyS) to B lymphocyte receptors, thereby suppressing B-cell mediated immunity. This is a case of a patient with AAV effectively treated with belimumab. AAV is known to be mediated by B-cell activity, but not all B cells are equal. Research now shows B regulatory cells may be important in preventing relapse in AAV. Belimumab may be an option for refractory AAV by modifying B cell response without obliterating B regulatory cells.

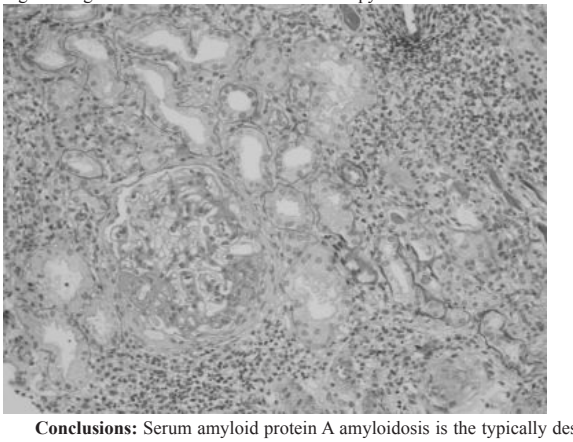
FR-PO1090

Proteinuria and Hematuria in a Patient with Familial Mediterranean Fever

Shuchi Anand, Neeraja Kambham, Neiha Arora. *Stanford University, Palo Alto, CA.*

Background: Familial Mediterranean fever (FMF) is a rare serositis, so named due to its classic presentation of fever and autosomal recessive inheritance among Mediterranean individuals. Patients present with periodic fever, abdominal pain, pleurisy, joint pain, or rash. Since the cloning of the FMF gene (MEFV), mutations in pyrin, leading to an inability to downregulate neutrophil activation, are considered causative. Colchicine is the mainstay of therapy.

Results: Our patient is a 22 year-old Indian female who was referred for microhematuria and proteinuria. She had been diagnosed with FMF after presenting at age 21 with episodic fevers. Lab work up revealed elevated inflammatory markers, with unremarkable serologies. Gene testing for FMF was heterozygous for a known mutation. Colchicine therapy was initiated 10 mo prior to renal evaluation, with resolution of fevers. A urinalysis at that time showed microhematuria and proteinuria, with subsequent urine protein/creatinine ratios of 1.5-2.8g/g. Serum creatinine rose from 0.9 to 1.2 mg/dL over the next 9 months. On exam, she was normotensive without edema. A renal biopsy was performed, demonstrating patchy chronic active interstitial nephritis, segmental membranous nephropathy and secondary segmental glomerulosclerosis. Prednisone therapy was recommended.



Conclusions: Serum amyloid protein A amyloidosis is the typically described renal manifestation of FMF, thought to occur in patients with prolonged untreated disease. Our patient received prompt treatment, making AA amyloidosis less likely. Whether the observed pathology in our case is idiopathic vs. secondary to FMF is unclear, given that her systemic disease was quiescent at the time of renal biopsy. Management will focus on treatment of interstitial nephritis, as we feel that her impaired kidney function and sclerotic changes were out of proportion to mild membranous changes seen.

Funding: NIDDK Support

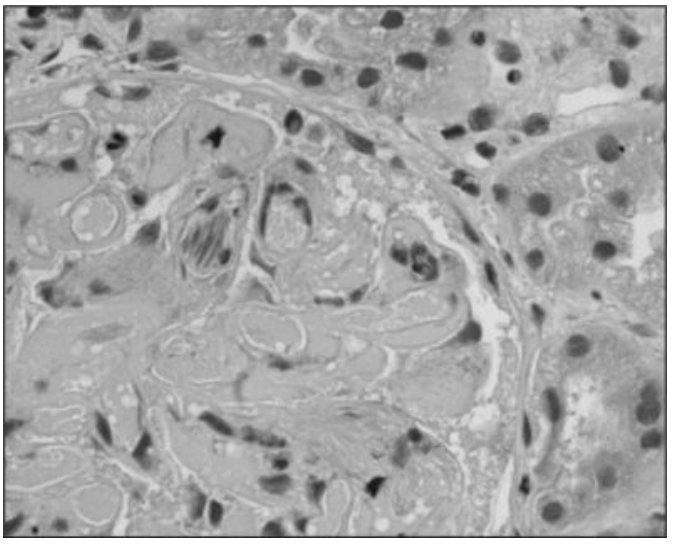
FR-PO1091

An Unusual Histologic Presentation of Lambda Light-Chain Deposition Disease Concomitant with De Novo Thrombotic Microangiopathy in a Renal Allograft Recipient

Wanwarat Ananthapanyasut,[1] Davis Massey,[2] Todd W. Gehr,[1] Anne L. King.[1] *[1]Nephrology, Virginia Commonwealth University, Richmond, VA; [2]Pathology, Virginia Commonwealth University, Richmond, VA.*

Background: Light chain deposit disease (LCDD) is an uncommon monoclonal gammopathy characterized by deposition of monoclonal kappa or lambda-immunoglobulin (Ig) light chains in various organs. Invariably, LCDD recurs after renal transplantation leading to early graft loss.

Methods: We report a patient with no known history of plasma cell dyscrasia, who presented with renal allograft dysfunction shortly after transplantation. A 44-year-old female presented with acute kidney injury (AKI) 4 weeks following living related donor kidney transplantation. Plasmapheresis (PP) was initiated with presumption of acute humoral rejection. Renal biopsy demonstrated intracapillary fibrin thrombi with focal collections of eosinophilic rhomboid-shaped crystalline material in glomeruli without evidence of rejection.



Immunofluorescence stained positive for lambda light chains in the glomeruli. Subsequent workup for plasma cell dyscrasia demonstrated IgG lambda in serum and bone marrow biopsy contained 10% plasma cells. Pretransplant banked sera revealed a monoclonal IgG lambda spike. After treatment with 3 cycles of bortezomib, the patient again developed AKI. Renal biopsy revealed changes identical to the initial biopsy with new thrombotic microangiopathic (TMA) changes. PP was reinstituted with improvement in renal function. A diagnosis of atypical hemolytic uremic syndrome was entertained and eculizumab was initiated with discontinuation of PP and stabilization of renal function.

Conclusions: We hypothesize that the unusual histologic glomerular changes with crystalline deposition represent precipitation of light chains which in turn may have triggered the development of TMA in this patient.

FR-PO1092

Rapid Renal Recovery in a Case of Crescentic Glomerulonephritis Secondary to Infective Endocarditis Kunal Malhotra, Vibhu Dhawan, Venkatesh Kumar Ariyamuthu, Preethi Yerram. *Department of Nephrology, University of Missouri, Columbia, MO.*

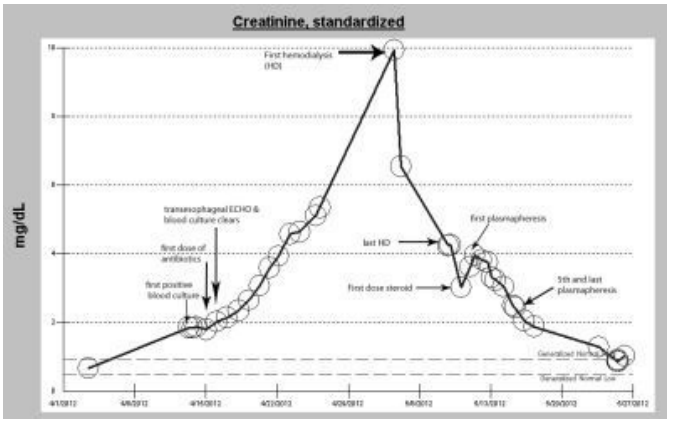
Background: Post infectious immune-complex related glomerulonephritis (GN) usually resolves with treatment of IE. We present a patient who became dialysis dependent despite being on appropriate antibiotic therapy and resolution of bacteremia.

Methods: 59-year-old female with history of congenital Ventricular Septal Defect and baseline creatinine of 0.7 mg/dl presented with rash on her legs, night sweats, and weight loss for 3 weeks. Cardiac exam revealed a new diastolic murmur. Mobile vegetations on aortic and mitral valves were seen on Trans-esophageal echocardiogram. Her blood cultures grew gamma-hemolytic streptococcus, which subsequently cleared on appropriate antibiotic therapy.

Relevant labs

WBC /mcL	6000
Hb g/dL	9.3
Platelets	105000
BUN mg/dL	12-38
Creatinine mg/dL	0.7- 9.9
CRP mg/dl	7.6
C3 mg/dl	28
C4 mg/dl	<9
ANA	1:320
ANCA	negative
UA	>30 RBC
Hepatitis B & C	negative

Her creatinine progressively worsened with a peak value of 10 mg/dl, and required hemodialysis. Kidney biopsy showed immune–complex mediated necrotizing and crescentic GN with disruption of Bowman's capsule and minimal interstitial fibrosis. She was started on plasmapheresis (PE) and high dose steroids with rapid taper, with subsequent improvement in her creatinine to 0.8 mg/dl. She subsequently had aortic valve replacement and VSD closure.



Conclusions: Our patient with IE-related GN did not improve as expected with antibiotic therapy, but turned around dramatically with steroids and PE. In literature, there is limited evidence supporting this therapy, while antibiotics alone have been successful in many cases. Our case supports the possible beneficial role of PE and steroids in IE-related crescentic GN worsening despite appropriate antibiotic therapy, although the risk of immunosuppression and aggravating endocarditis needs to be considered.

FR-PO1093

Factitious Antistreptolysin-O Activity in a Case of Multiple Myeloma with Combined Light Chain Cast Nephropathy and Light Chain Deposition Disease Ekamol Tantisattamo, Chuong Dinh. *Medicine, University of Hawaii, Honolulu, HI.*

Background: Antistreptolysin-O (ASO) is well-known to be elevated in poststreptococcal glomerulonephritis (PSGN). However, falsely elevated ASO can occur in paraproteinemia like multiple myeloma (MM) and leads to delay in diagnosis and treatment. We report a case of a woman presented with acute kidney injury (AKI) secondary to combined light chain cast nephropathy (LCCN) and light chain deposition disease (LCDD) from MM with high ASO level.

Methods: A 42-year-old Caucasian woman presented with nausea and vomiting for 2 months. She had low-grade fever but no sore throat. Three days prior to admission, her serum creatinine was elevated to 5.4 mg/dl from normal baseline. Repeated creatinine elevated up to 11.2 mg/dl. Workup for AKI revealed markedly elevated ASO of 3,036 IU/ml and streptozyme of > 800 STZ Units. Complements and anti-DNase-B Ab were normal. Urine microscopy did not reveal dysmorphic RBC or red cell casts. ANA, ANCA, and anti-GBM were negative. Renal ultrasound was normal. Initially, she was supportively treated as PSGN; however, serum creatinine was still high. Kidney biopsy revealed κ type LCCN and κ LCDD. Given high UPCR of 5 mg/g of creatinine, workup for paraproteinemia was performed. She had unexplained anemia with Hb of 8.9 g/dl. Serum calcium was 9.4 mg/dl. SPEP showed 2 monoclonal proteins. Serum IFE revealed 2 free κ light chain monoclonal proteins. There were high free κ chain and normal free λ chains. β-2 microglobulin was elevated to 26.3 mg/l. Bone survey was negative. Bone marrow biopsy revealed plasma cells > 90% of all cells consistent with MM. Intermittent hemodialysis and plasmapheresis were initiated with bortezomib-based chemotherapy.

Conclusions: Many chemical laboratory measurements can interfere with paraproteins. Falsely elevated ASO is one of those conditions due to coating of the ASO antigen-laden latex particles by the paraprotein. If we relied only on the serologic diagnosis of PSGN, then the diagnosis of myeloma kidney would have been missed. Our patient presented with AKI with highly elevated ASO. Therefore, paraproteinemia should be considered in a patient with a high ASO but with atypical features of PSGN.

FR-PO1094

Type 1 Cryoglubulinemia Presenting as Acute Kidney Injury (AKI) from Thrombotic Microangiopathy Gaurav Agarwal,[1] Olatokunbo O. Shobande,[1] Maria Alejandra Alfonso-Jaume,[1] Micah R. Chan,[1] Jose R. Torrealba,[2] Weixiong Zhong.[2] *[1]Department of Medicine and Division of Nephrology, University of Wisconsin School of Medicine and Public Health, Madison, WI; [2]Department of Pathology, University of Wisconsin School of Medicine and Public Health, Madison, WI.*

Background: The main renal presentation of cryoglobulinemia is Membrano-proliferative glomerulonephritis (MPGN) type 1 from immune complex mediated injury. Cryoglobulinemia causing TMA is not described in literature. Here we describe a rare presentation of type 1 cryoglobulinemia as TMA causing AKI.

Methods: A 53-year old male presented with fever and generalized rash, digital gangrene. His baseline creatinine was 1.1mg/dl. The next day his creatinine increased to 4mg/dl and he became oliguric. On urinalysis there was 2+ proteinuria and 2+ hematuria and no active sediments. He was also noted to have a low platelet count of 20K/uL. Serology including complement, ANCA, anti-GBM, Hep panel, ASO, ANA, and HIV were negative.
Intervention: We treated the patient as an unknown RPGN with pulsed high dose steroids and plasmapharesis.

Results: Renal biopsy showed severe thrombotic microangiopathy and 70% acute cortical necrosis. A skin biopsy showed thombotic occlusion of small size arteries with cryoglobulins without any vasculitis. Days later, labs confirmed type 1 cryoglobulinemia with monoclonal band. Bone marrow examination was also done which confirmed B cell lympho- proliferative disorder. He was then started on Rituximab. He remained dependent upon dialysis.

Conclusions: In conclusion, this patient had B cell lymphoproliferative disorder causing type 1 cryoglobulinemia. The cryoglobulin burden caused acute TMA and presented as AKI. **Review of literature:** Type 2 and type 3 cryoglobulinemia (mixed cryoglobulinemia) usually present as type 1 MPGN and mechanism are immune complex mediated injury causing vasculitis. Type 1 cryoglobulinemia usually presents as thrombotic occlusion of small size vessels without any vasculitis. Renal biopsy should be promptly done in type 1 cryoglobulinemia to look for TMA and early institution of plasmapharesis can potentially make a difference in outcome.

FR-PO1095

Beware Maslow's Hammer: A Case of Sirolimus Induced Pneumonitis

Mukesh Sharma, Adrian P. Sequeira. *Nephrology, Louisiana State University Health Sciences Center, Shreveport, LA.*

Background: A 54 year old male received a second cadaveric renal transplant from a 40 year old diabetic. Both donor and recipient were cytomegalovirus (CMV) IgG positive. Maintenance immunosupression included mycophenolate mofetil (MMF), tacrolimus and prednisone. His post-operative period was complicated by delayed graft function and one month later by biopsy proven CMV esophagitis. Valganciclovir was started; tacrolimus levels were maintained around 10ng/ml, while MMF dosage was reduced. A kidney biopsy was performed two months later because of acute renal failure. Tacrolimus was switched to sirolimus after the biopsy revealed isometric tubular vacuolization with acute thrombotic microangiopathy. His creatinine stabilized between 2.5-3 mg/dl after the switch. Sirolimus levels were maintained at 10 ng/ml. Two weeks later, he presented with fever, generalized malaise and dry cough. His oxygen saturation on room air was 89%. His laboratory data included platelet count 62 x10^3 cells/ul, WBC 5.2 x 10^3 cells/ul (86% neutrophils and 13% bands), BUN 56 mg/dl and creatinine 3.4 mg/dl. The chest X-Ray (CXR) showed diffuse bilateral infiltrates. MMF was discontinued and empiric antibiotics started. Blood cultures were negative for bacterial and fungal etiologies. Serologies remained negative for atypical organisms and CMV. 2-D echocardiogram showed preserved systolic function. While his CXR worsened inspite of antibiotics, he was peculiarly not dyspneic and his chest was normal to auscultation. Sirolimus induced pneumonitis (SIP) was suspected. Sirolimus was discontinued and 60mg IV solumedrol initiated. Within the next few days there was complete resolution of fever, CXR findings, and thrombocytopenia. Pt was eventually discharged on everolimus. SIP is an idiosyncratic reaction and is a diagnosis of exclusion. It commonly occurs in patients with limited kidney function, especially those who are switched to sirolimus later because of CNI toxicity. Respiratory distress is very rare. Pulmonary infiltrates on CXR maybe the lone finding. Treatment involves either dose reduction or a switch to everolimus and high dose steroids. This case highlights the diagnostic dilemma of SIP.

FR-PO1096

Acute Kidney Injury of a Transplanted Kidney Secondary to Donor Rhabdomyolysis

Liwei Huang,[1] Zhanyong Bing,[2] Simin Goral.[1] *[1]Division of Nephrology, University of Pennsylvania, Philadelphia, PA; [2]Department of Pathology, University of Pennsylvania, Philadelphia, PA.*

Background: Donor rhabdomyolysis after live donor laparoscopic nephrectomy has been reported in the past but in general the recipients were reported to have uneventful courses after transplantation. We report the first case of acute kidney injury requiring dialysis treatment secondary to donor rhabdomyolysis.

Methods: A 64-yo-male, with medical history of End Stage Kidney Disease on hemodialysis received a living related kidney transplant. He developed decreased urine output after surgery and his serum creatinine and BUN started rising. Kidney biopsy on post transplant day 8 showed "degenerative and regenerative changes in tubules compatible with acute tubular necrosis (ATN)". Patient was on hemodialysis for a week (totally four treatments), then his urine output started to pickup and his creatinine and BUN started to come down. His serum creatinine was 0.96 mg/dl six months after transplantation. The donor was a 34 years old healthy male with a BMI of 32. Although he tolerated the open nephrectomy procedure well and had good urine output post operatively, his serum creatinine was elevated at 2.64 mg/dl with a CPK of 14214 Units/L on postop day three, consistent with rhabdomyolysis. Given the donor was diagnosed with rhabdomyolysis after the nephrectomy, an immunohistochemical staining for myoglobin was performed on the transplanted kidney, which showed focal staining in the apical cytoplasm of the renal tubular cells, as well as in the interluminal granular cast material. The recipient had ATN and slow graft function due to his donor's rhabdomyolysis.

Conclusions: Acute kidney injury in a recipient due to rhabdomyolysis/myoglobinuria after living donor nephrectomy is quite rare. Prolonged surgery as well as long lateral decubitus positioning, increased body mass index of the donor, and volume depletion may be predisposing factors. Since rhabdomyolysis after kidney transplantation can be associated with allograft loss and death, increased surveillance for rhabdomyolysis is warranted in donors as well as in recipients who are at increased risk.

FR-PO1097

Acremonium Skin and Soft Tissue Infection in a Kidney Transplant Recipient

Ezra Israel,[1] David Hirschwerk,[2] Kenar D. Jhaveri.[1] *[1]Nephrology, Hofstra North Shore-LIJ School of Medicine, Great Neck, NY; [2]Infectious Disease, Hofstra North Shore-LIJ School of Medicine, Great Neck, NY.*

Background: Acremonium species are ubiquitous fungal organisms found in soil and air that can lead to superficial infections after traumatic inoculation. Not much is reported regarding this organism in patients with kidney transplantation.

Methods: A 66 year old male with LURT (2 years prior) and DM type 2 presented with a soft mass that had been growing over his left lateral malleolus for two months. The patient was a 5/6 HLA mismatch, induced with thymoglobulin and corticosteroids. Donor and recipient were CMV positive and the patient had received a CMV prophylaxis post-transplant. The patient had an episode of acute cellular rejection secondary to medication noncompliance for which he was treated with pulse corticosteroids 2 months prior to presentation. The patient's immunosuppression included MMF, tacrolimus, and prednisone. The physical exam was remarkable at the left ankle, there was a 2X4 cm soft mass palpable superior to the lateral malleolus. The lesion was tender to palpation with mild erythema. His laboratory results were unrevealing. He had a normal baseline creatinine of 1.2mg/dl. Initially, the patient was managed with intravenous antibacterials including vancomycin for a presumed bacterial abscess. After one week of therapy and no improvement, the mass was biopsied and found on culture to grow an Acremonium species susceptible to posaconazole. The patient improved while on oral posacanozole but there was recurrence once the medication was discontinued. Subsequently he underwent surgical debridement and treatment with voriconazole. He has had resolution to date.

Conclusions: To the best of our knowledge, there are only five reported cases of Acremonium species documented in kidney transplant recipients and only one previously documented case that resulted in a subcutaneous abscess. There are no standard therapy guidelines for the treatment but in several case reports excision and long-term therapy with a susceptible antifungal. This is the second reported case of successfully treated subcutaneous Acremonium infection in a kidney transplant patient.

FR-PO1098

Third Time's a Charm: A Case of Recurrent Transplant FSGS

Nashila AbdulRahim, Angelina Edwards, Horacio E. Adrogue, Aleksandra De Golovine. *Renal Diseases and Hypertension, University of Texas at Houston, Houston, TX.*

Background: Circulating permeability factors have been implicated in recurrence of focal segmental glomerulosclerosis (FSGS) in as many as 30% of renal transplant patients. Therapies are targeted towards decreasing levels and blocking their effects. We describe here a case of recurrent transplant FSGS treated with a combination of therapies thereby leading to graft salvage.

Methods: A 39 year old Vietnamese male with end-stage renal disease; living-unrelated kidney transplant in 2002, complicated by recurrent FSGS leading to transplant nephrectomy in 2007; received a cadaveric kidney transplant on February 16, 2012. The donor kidney belonged to a 41 year old Caucasian woman who died of cerebral brain death; prior to procurement, her serum creatinine (sCr) was 0.4 mg/dl. Our patient had an uncomplicated intraoperative course. Thymoglobulin and methylprednisolone were used as induction agents. He was started on tacrolimus, mycophenolate mofetil (MMF) and prednisone as maintenance agents. The patient's sCr remained elevated at 8.3 mg/dl; hemodialysis was initiated on post-operative day 3 secondary to a rise in blood urea nitrogen and fall of serum bicarbonate. A transplant kidney biopsy was done on February 24, which showed diffuse podocyte foot process effacement, suspicious for early recurrent FSGS, with no evidence of acute rejection. His immunosuppression was changed from tacrolimus to cyclosporine (CsA), and MMF and high dose prednisone were continued. The patient continued to receive hemodialysis until April 4 as well as consecutive plasmapheresis, followed by a dose of rituximab. He was also started on galactose 12 grams twice daily. Galactose has been shown in vitro to block the activity of a permeability factor implicated in FSGS. A repeat transplant kidney biopsy on April 5 showed no evidence of acute rejection; the diffuse pattern of foot process effacement was no longer observed. His sCr improved to 1.7 mg/dl on May 24. The circulating factor was sent and results are pending at this time.

Conclusions: Our case illustrates a successful therapeutic approach in a patient at a 50-80% risk for a second graft loss due to recurrent FSGS.

FR-PO1099

Acute Necrotizing Gingivitis Following Kidney Transplantation

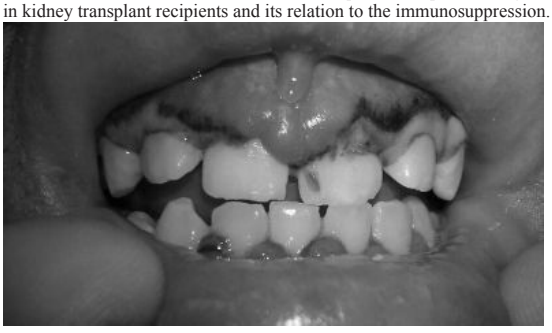
Oleh M. Akchurin,[1,2] Marcela Del Rio.[1,2] *[1]Pediatrics, Division of Pediatric Nephrology, The Children's Hospital at Montefiore, Bronx, NY; [2]Albert Einstein College of Medicine, Bronx, NY.*

Background: Acute necrotizing ulcerative gingivitis (ANUG) is a rare complication after transplantation. It is important to recognize this condition as it can be confused with other gingival lesions, e.g. herpetic infections, drug-induced gingival hyperplasia from cyclosporine or calcium channel blockers and PTLD.

Methods: An 18 year old male with ESRD secondary to FSGS in a solitary kidney received a deceased donor renal transplant from an EBV and CMV positive donor. Patient's serology was EBV and CMV negative. Induction immunosuppression consisted of basiliximab, tacrolimus and glucocorticoids, maintenance with tacrolimus, MMF and prednisone. No episodes of acute rejection. The hypertension was treated with amlodipine. Four months post transplant, patient developed gingival swelling, and amlodipine was discontinued. He then presented with oral pain, fever, severe gingival hyperplasia with

areas of necrosis, and cervical adenopathy. No systemic lymphadenopathy or visceromegaly was present. Laboratory results: WBC 3,600 cells/mcL with 0% granulocytes, 23% lymphocytes, and 76% monocytes. EBV PCR, CMV PCR and HSV culture were negative. Gram stain of a gingival lesion showed 1-2+ polys, bacterial culture revealed normal oral flora, and blood cultures were negative. Based on the clinical presentation and negative laboratory findings, the patient was diagnosed with ANUG due to poor dental hygiene. After debridement, the patient was treated with piperacillin/tazobactam and MMF was held until the infection resolved. Patient was advised to use a soft bristle toothbrush. Two weeks later, the patient fully recovered.

Conclusions: Further observations are required to explore the significance of ANUG in kidney transplant recipients and its relation to the immunosuppression.



FR-PO1100

A Case of Squamous Cell Carcinoma Arising from Long-Term Indwelling Urinary Catheter in Patient with Chronic Kidney Disease Eleni Chelioti,[1] Evdokia Efthimiou,[1] Maria Sotiraki,[1] Kassiani Manoloudaki,[2] Maria Tsilivigou,[1] Gabriel Papadakis.[1] *[1]Dept of Nephrology, General Hospital of Piraeus, Athens, Greece; [2]Dept of Pathology, General Hospital of Piraeus, Athens, Greece.*

Background: Patients with chronic indwelling urinary catheter are known to have an increased risk of urinary malignancy. This condition has been attributed to chronic inflammation and mechanical stimulus from the catheter. However, squamous cell carcinoma (SCC) around the inguinal area is relative rare. We report a case of lower abdominal SCC arising from the long-term indwelling urinary catheter.

Methods: A 72 years-old male with chronic kidney disease due to chronic obstructive uropathy presented in a uremic state that necessitated the urgent initiation of dialysis treatment. After a 5 sessions of hemodialysis his renal function was improve. The patients also had a history of long – term indwelling urinary catheter-less than 5 years- due to prostatic hypertrophy and chronic urinary infections. Physical examination revealed an abdominal mass around the left inguinal area. Abdominal enhanced computed tomography (CT) showed a 6-cm mass at the left inguinal area, an osteolitic lesion at the left pubosciatic adhesion and a small hepatic mass. Histopathology examination of percutaneous biopsy specimens revealed SCC with moderate differentiation. The cystoscopy suggested ulcerative infiltration of the left ureterobladder conjuction and the lateral bladder wall. Histology at biopsy specimens was consistent with SCC grade II. CT of lungs was negative. Four months after his admission he died with multiple visceral metastization.

Conclusions: In the western world SCC represent <5% of all bladder tumors and 10% in patients with a catheter indwelling for ≥10years. Predisposing factors: patients with spinal cord injury with prolonged indwelling catheter and chronic irritation to bladder wall either by chronic urinary infections, calculi, long-term indwelling catheter or bladder diverticula. Although distant metastasis is infrequent (8-10%) the prognosis is poor and most patients die. Our patients had many predisposing factors for the development of SCC and in the literature there have been only four reported cases.

FR-PO1101

Tumor Induced Osteomalacia (TIO): Associated with Elevated Circulating Plasma Fibroblast Growth Factor (FGF)-7 along with FGF-23 Khaled Khazim,[1] Christine L. Gear,[1] Rajeev Suri,[2] Paolo Fanti,[1] Shweta Bansal.[1] *[1]Division of Nephrology, University of Texas HSC at San Antonio, TX; [2]Dept of Radiology, UTHSC at San Antonio, TX.*

Background: FGF-23 is regarded as the prominent phosphatonin causing TIO. Other phosphaturic hormones including FGF-7, secreted frizzled related protein-4, and matrix extracellular phosphoglycoprotein have been identified by in vitro studies of tumors resected from patients with TIO, but limited information is available about their circulating levels. In many cases identification of tumor is a challenge in itself.

Methods: 64 year male was seen for fatigue, weakness and hypophosphatemia for 10 years. During 4-year follow-up, serum phosphorus was as low as <1.0mg/dL, calcium 9.3mg/dL, 25(OH)VitD 22ng/mL, 1,25$(OH)_2$VitD 37pg/ml, iPTH 63pg/mL, urine phosphorus 3.6gm/24hr with fractional excretion of 90%, and CrCl 95ml/min. Plasma FGF-23 mildly elevated at presentation increased gradually over next 3 years. The presence of hypophosphatemia, renal phosphate wasting, and osteomalacia, and absence of primary hyperparathyroidism, Fanconi's syndrome or familial rickets, raised the suspicion of TIO. However, a tumor could not be identified using CT scans, MRI scan, bone scan, octreotide scintigraphy and FDG-PET/CT. Simultaneous regional blood sampling revealed high levels of both FGF-23 and FGF-7 and lateralization in the left femoral as compared to the contralateral vessels, with more pronounced imbalance for FGF-7 than FGF-23; e.g., FGF-7 concentration was 15.77 vs. 1.66 pg/ml in the left vs. right femoral veins, while FGF-23 concentration was 170 vs. 152 RU/ml, respectively, confirming initial suspicion of likely source in left lower extremity. The focused MRI showed only degenerative joint disease. In absence of identifiable tumor patients was started on cinacalcet with significant improvement in serum phosphorus and decrease in fractional excretion of phosphorus to 29% over next 3 months.

Conclusions: We are first to demonstrate that FGF-7 can be analyzed in the circulation and assist in the diagnosis and localization of TIO-inducing tumors. Clinicians should be aware of association between TIO and phosphatonins other than FGF-23.

Funding: Veterans Administration Support

FR-PO1102

Acute Kidney Injury in a Patient with Metastatic Urothelial Cancer Silvi Shah, Neha Nainani, Pradeep Arora. *Department of Nephrology, University at Buffalo, Buffalo, NY.*

Background: Acute kidney injury (AKI) occurring secondary to renal metastasis from solid tumors is rare. We report a case of 71-year-old white male with history of urothelial cancer that presented to the hospital with acute kidney injury.

Methods: A 71-year-old male was admitted to the hospital with one-month history of nausea and was found to have elevated serum creatinine of 2.2 mg/dl (estimated glomerular filtration rate [eGFR] 30 ml/min/1.73m^2). Baseline serum creatinine was 1.1 mg/dl (eGFR 72 ml/min/1.73m^2). Past medical history was significant for stage II transitional cell carcinoma of bladder diagnosed 5 years ago and was in remission following treatment. The physical examination revealed blood pressure of 160/77 mmHg and mild lower extremity edema. He was non-oliguric; and was not dehydrated or volume overloaded. Urine analysis showed 0-1 RBC/hpf, 30mg/dl proteins and was negative for leukocyte esterase and nitrite. No casts were seen and 24-hour urinary protein excretion was 0.7 grams. Renal ultrasound revealed bilaterally enlarged unobstructed kidneys. His renal function continued to deteriorate and he became lethargic and confused. Hemodialysis was initiated. CT scan showed bilateral kidney enlargement, pulmonary consolidation, multifocal lytic lesions and retroperitoneal nodules. Renal biopsy was consistent with diffuse metastatic infiltration by poorly differentiated urothelial cancer cells. Due to poor prognosis, he was not considered a candidate for chemotherapy and died.

Conclusions: AKI due to renal parenchymal invasion from solid tumors is distinctly unusual. This case illustrates the rare potential of solid tumors to metastasize to kidneys and cause irreversible acute kidney injury. Early recognition with renal biopsy and treatment of solid tumor with chemotherapy or radiation may prevent progression to end stage renal disease.

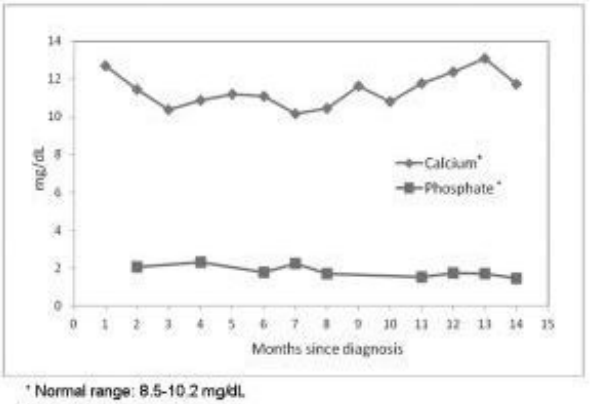
FR-PO1103

Non PTH-rP Related Hypercalcemia in a Patient with Neuroendocrine Tumor of the Pancreas: First Case Report Ioan-andrei Iliuta, Felix Couture, Fabrice Mac-Way. *Medicine, L'Hotel-Dieu de Quebec, Quebec, QC, Canada.*

Background: Neuro-endocrine tumours (NET) of the pancreas complicated by hypercalcemia are rare entities that have rarely been described in the literature. All case-reports have shown that hypercalcemia was related to the production of PTHrP by the tumour. We describe for the first time the case of a non PTH-rP related hypercalcemia in a patient with pancreas NET.

Methods: We report the case of a 48 year-old man diagnosed with a NET of the pancreas associated with liver metastasis. Octreotide was rapidly started but he was seen in nephrology for multiple episodes of severe hypercalcemia that was treated with i.v Bisphosphonates and hydration. Evolution of blood calcium and phosphorus are shown in Figure 1.

Figure 1. Evolution of serum calcium and phosphate since diagnosis



* Normal range: 8.5-10.2 mg/dL
* Normal range: 2.4-4.1 mg/dL

Biochemistry anomalies included hypophosphatemia, slightly decreased blood 25(OH) vitamin D level, high 1.25 (OH)vitamin D, low PTH and increased urinary phosphate secretion.

Table 1. Bone and mineral parameters at first visit

	First visit	+ 3 months
PTH (pg/mL)	0	0
PTHrP (pg/mL)*	5.5	6.0
25(OH) vit D (ng/mL)+	-	20.8
1,25 (OH) vit D (pg/mL)**	-	102.7
24 hour urinary calcium (2.5-7.5 mmol)	7.06	-
24 hour urinary phosphate (10-32 mmol)	35.3	-
Creatinine (mg/dL)	0.73	0.84
TSH (mU/L)	normal	-

*Normal < 15; + Normal range 32-100 ng/mL ** Normal range 15-51 pg/mL

Surprisingly, blood PTHrP level measured twice was also in the lower range. As serum calcium was consistently elevated, monthly i.v Bisphosphonate was recently introduced. Despite Octreotide treatment, liver metastasis progressed and blood calcium remained elevated.

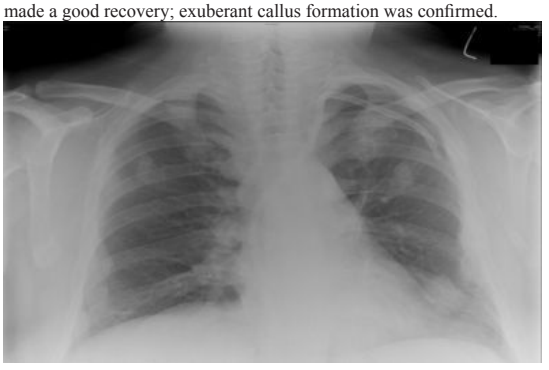
Conclusions: This is the first case describing hypercalcemia in a patient with a NET of the pancreas without elevation of PTHrP. We hypothesized that hypercalcemia and hypophosphatemia were respectively caused by 1.25 (OH)vitamin D and FGF-23 tumour production. The production of a PTH-like fragment molecule that has yet to be identified is also possible.

FR-PO1104

Skin and Bone: Skeletal Demineralisation Following Treatment of Calciphylaxis Miriam R. Berry, Calum Neil Ross. *Department of Renal Medicine, Norfolk and Norwich University Hospital, Norwich, Norfolk, United Kingdom.*

Background: Calcific uraemic arteriolopathy (CUA) - calciphylaxis - is a feared complication of end stage renal failure (ESRF) characterised by medial calcification of subcutaneous arterioles and tissue necrosis. Management should optimise components of the calcium-phosphate-parathyroid axis. Sodium thiosulphate (STS) is an emerging adjuvant therapy which enhances solubility and subsequent excretion of chelated extraskeletal calcium. We report a unique complication of this life-saving therapy.

Methods: A 35-year-old female haemodialysis patient, with ESRF due to ANCA-positive vasculitis, developed severe proximal CUA on her trunk, breasts and limbs three months after total parathyroidectomy; she was not expected to survive. Treatment was escalated to include STS three times weekly, increased dialysis dose with low calcium dialysate, bisphosphonate therapy and correction of hyperphosphataemia. The extensive skin lesions resolved by secondary intention over 18 months. Six months after discontinuing STS therapy, our patient complained of skeletal pain; imaging confirmed insufficiency fractures of multiple ribs and pubic rami. Bisphosphonate therapy was discontinued and our patient made a good recovery; exuberant callus formation was confirmed.



Conclusions: Our patient demonstrates a hitherto unreported complication of CUA treatment. Skeletal demineralisation may be a predictable complication of STS therapy which reduces total body calcium. The high mortality of CUA means that most patients will not survive to develop this iatrogenic complication. The enhanced bone mineralisation mediated by bisphosphonates is outweighed by the decalcifying action of STS leading to multiple insufficiency fractures. Withdrawal of bisphosphonate therapy may reverse the potential for adynamic bone disease and permit osteoblastic activity to resume.

FR-PO1105

Sildenafil as Adjunct to Therapy in Lithium Induced Nephrogenic Diabetes Insipidus Humberto C. Sasieta-Tello,[1,2] Thomas P. Monson,[1,2] Robert L. Safirstein.[1,2] *[1]Department of Medicine, Central Arkansas Veterans Healthcare System, Little Rock, AR; [2]Department of Medicine, University of Arkansas for Medical Sciences, Little Rock, AR.*

Background: The pathogenesis of lithium-induced diabetes insipidus (LiDI) is not fully elucidated. It is uncommon, chronic and difficult to treat. Its treatment is based on four principles: Low-sodium diet, hydrochlorothiazide, amiloride and NSAIDs. This agents decrease polyurea, allowing the patient to maintain euvolemia and normonatremia relying on oral intake. Hypovolemic hypernatremia is a common complication.

Methods: 61 year old male with proven LiDI was admitted with the following diagnosis: LiDI, Acute Renal Failure, Hypernatremia and Hyperkalemia. His prior medical history included Bipolar Disorder, managed with Lithium Carbonate. LiDi was managed as outpatient with HCTZ-Amiloride and NSAID. After initial evaluation and stabilization, amiloride and NSAIDs were suspended to prevent further nephrotoxicity and he received intravenous fluids trying to maintain water balance and achieve normonatremia. HCTZ was maintained throughout all hospital stay. Normonatremia and return to baseline creatinine was achieved after 4 days, with a urine output of 10 liters. On his 6th hospital day he was started on Sildenafil 20mg PO TID, due to prior AKI and hyperkalemia. Within 48 hrs, his urine output decreased to 5.5 liters, he was able to match his free water requirements by the oral route and was safely discharged. After 90 days, he remains on sildenafil and HCTZ, and maintains normonatremia.

Conclusions: The decrease in the AQP2 density in the luminal aspect of the collecting duct is the end-step in the development of LiDI. cAMP is the mediator of the main pathway of AQP2 luminal positioning. Recently, cGMP was found to be a mediator in a minor luminal expression pathway. Inhibition of cGMPase leading to increased expression of AQPs has been found, in both a molecular and animal model setting. Sildenafil has been extensively in this patient's demographic group; side effects and pharmacological interactions are known and predictable. Sildenafil could be an effective drug to treat LiDI. Further testing is required.

Funding: Veterans Administration Support

FR-PO1106

Recurrent Uric Acid Renal Stones: Novel Phenotype for a Known Mutation Badreldin M. Bedri, Davoud Mohtat, Alda Tufro. *Pediatric Nephrology, Yale University, New Haven, CT.*

Background: The incidence of renal stones has increased significantly in United States and industrialized countries in the past decades. Uric acid renal stones constitute 5-10% of renal stones in children in United States. Hyperuricemia is observed in most children with uric acid renal stones and is mostly due to a genetic cause. The most common genetic mutations that lead to hyperuricemia are in hypoxanthine phosphoribosyltransferase 1(HPRT1) gene with a wide spectrum of clinical phenotypes. The most severe mutations in HPRT1 gene are associated with Lysch-Nyhan syndrome, characterized by hyperuricemia, hyperuricosuria, severe developmental delay with self-mutilation behavior and severe neurological abnormalities.

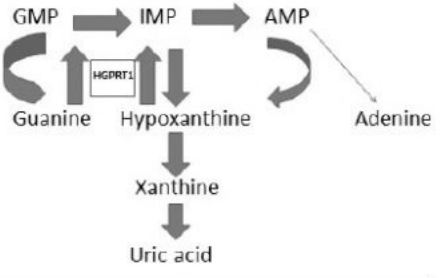


Fig 1: Purine metabolism. AMP: adenosine monophosphate, GMP: guanine monophosphate, HGPR1: hypoxanthine guanine phosphoribosyltransferase, IMP: inosine monophosphate.

Methods: 11 years old boy who had mild developmental delay, recurrent uric acid stones, hyperuricemia and hyperuricosuria. He initially presented with gross hematuria and then developed left renal Staghorn stone associated with left hydronephrosis and underwent laparoscopic percutaneous nephrolithotomy. Stone analysis revealed a composition of 100% calcium, sodium and magnesium urate. His work up showed normal renal function and excluded secondary causes of hyperuricemia. Genetic testing identified a hemizygous single nucleotide substitution, c.527C>T(p.P176L), in exon 7 of the HPRT1gene which is associated with an incomplete Lesch-Nyhan syndrome.

Conclusions: More than 400 mutations in HPRT1 gene have been reported, with a wide spectrum clinical phenotype. The identified mutation in our patient has been reported in the literature as associated with partial HPRT1 deficiency and incomplete lysch-Nyhan syndrome but no clinical phenotype information was reported. To our knowledge, our patient is the first in the literature to have this mutation along with a clinical phenotype.

FR-PO1107

Severe and Advanced Form of Acquired Perforating Dermatosis in a Patient with End Stage Renal Disease Sasan Raeissi,[1] Antoine L. Samaha,[2] Maryam Pourpaki.[1] *[1]Internal Medicine, Good Samaritan Hospital, Cincinnati, OH; [2]Nephrology, Good Samaritan Hospital, Cincinnati, OH.*

Background: Acquired Perforating Dermatosis (APD) is usually seen in adults with end stage renal disease (ESRD) and/or diabetes mellitus (insulin dependent > non-insulin dependent). The lesions of APD are usually dome-shaped papules or nodules, 1 to 10 mm in diameter, with a central crust-filled crater. They occur predominantly on the trunk and extensor limb surfaces and are severely pruritic.

Methods: A 34-year-old African American Female with a 23 years history of uncontrolled diabetes mellitus type 1 and diabetic nephropathy that progressed to ESRD at age 28 years. She was initially on automated peritoneal dialysis and later switched to hemodialysis at age 31 years due to non adherence to therapy. She had multiple hospitalizations for diabetic ketoacidosis and uremic symptoms. She also had uncontrolled

bone and mineral disease. She developed pruritic and papular skin lesions (initially <5mm in diameter) over lower extremities within few months of initiating dialysis and was referred to a dermatologist who made the diagnosis APD. This was confirmed with a skin biopsy showing epidermal invagination with a keratotic plug containing basophilic cellular debris. She had erratic visits with dermatology and non adherence with therapy (retinoids, phototherapy, etc.). Her APD progressed to diffuse 4 to 32mm hyperpigmented papulo-nodular skin lesions, covered with keratotic film. Some of the lesions were umbilicated and some coalesced and formed large vegetating lesions.

Conclusions: This case represents APD in extremis and at late stage due to non adherence to therapy. The precise pathogenesis of APD is unknown. Topical retinoids, topical and intradermal steroid and phototherapy have variable effects. In some instances, APD has remitted completely after renal transplantation.

FR-PO1108

Cognitive Function at a Creatinine of 28.8 mg/dL Sabrina Schneider,[1] Anne Kathrin Malecki,[2] Olaf Boenisch,[1] Hermann G. Haller,[1] Jan T. Kielstein.[1] *[1]Department of Nephrology and Hypertension, Medical School Hannover, Hannover, Germany; [2]Institute of Psychology, Martin-Luther University, Halle-Wittenberg, Germany.*

Background: We report one of the rare cases of severe uremia and describe the day to day improvement in neuro-cognitive function by dialysis starting at a serum creatinine of 27.8 mg/dl.

Methods: A 27-year-old male with s/p kidney transplantation presented with graft failure due to non-adherence to immunosuppressive medication. Performance in memory, attention and executive function was regularly assessed by: (digit span, Rivermead Behavioral Memory Test, Trail Making Test (TMT) A and B, test battery for attentional performance, word fluency test and Rey Complex Fgures).

Results: In parallel to the correction of uremia we saw a general improvement of cognitive function. While memory and attention improved over time yielding average performance, executive function (assessed by TMT), despite improvement remained below average.

Raw scores and percentile of neuropsychological test battery

				RAW SCORES (PERCENTILE)

FR-PO1109

Anaphylaxis due to Ethylene Oxide Used to Sterilize the Dialysis Needle Tubing Set Iqbal Masood, Paul Robbins. *Nephrology, Lankenau Medical Center & Lankenau Institute for Medical Research, Wynnewood, PA.*

Background: Dialyzer reactions both type A and type B have declined with less use of ethylene oxide for dialyzer sterilization and an increase in the use of bio-compatible membranes .Ethylene oxide is still used for sterilizing the needle set and blood tubing of the dialysis circuit. We are presenting a case of anaphylaxis due to the use of ethylene oxide for sterilization in dialysis needle tubing set, noted when a reaction occured even before connecting to the dialysis circuit.

Methods: 62 year black female with a history of failed kidney transplant necessitating reinitiation of hemodialysis .After starting hemodialysis with Polysulfone dialyzer she was noted to have intermittent pruritis, treated with benadryl.Patient had an episode of facial swelling, prompting change of the dialyzer to cellulosynthetic membrane(ASAHI 100) but 10 minutes into the first session ,she was noted to have stridor, chest pain and required intubation, inspite of pre-treatment rinsing of the dialysis circuit. The dialyzer was again changed to cellulose tri-acetate(Exeltra 150) but yet nother episode of facial swelling occurred within a minute of cannulation and flushing of the needle set tubing prior to connecting to the dialysis circuit, indicating allergy to ethylene oxide used to sterilize the needle tubing set.We found that at our facility needle set tubing and dialysis circuit blood tubing are sterilized with ethylene oxide .Patient did well with pre-treatment rinsing of the entire circuit before cannulation, in additon to dexamethasone,famotidine and benadryl and has not had any more episodes, since she is receiving the same pre-treatment for almost one year before every dialysis treatment.

Conclusions: Dialyzer reactions with anaphylaxis (type A)are mostly due to allergy to ethylene oxide, dialyzer membrane, heparin or bacterial contamination.Ethylene oxide is still used to sterilize the tubing of needle set and dialysis circuit and patients may still face the same reaction. This case illustrates that in addition to the dialyzer, sensitivity to ethylene oxide used in tubings of dialysis circuit and needle set can cause life threatening anaphylaxis.

FR-PO1110

Acute Kidney Injury due to Alvimopan (Entereg) Iqbal Masood, Alejandro Diez. *Nephrology, Lankenau Medical Center & Lankenau Institute for Medical Research, Wynnewood, PA.*

Background: Medications can frequently cause acute kidney injury (AKI). We encountered a case of post renal AKI due to Alvimopan (Entereg). A review of the literature failed to show other documented cases.

Methods: 51 year old black female with normal renal function (serum creatinine: 0.9 mg/dl) underwent an uneventful reversal of a Hartman's procedure. On post operative day 2 her indwelling urinary catheter was removed. On post operative day 4 she was noted to have an elevated creatinine at 3.8mg/dl. Bladder revealed approximately 900mL of urine prompting re-insertion of an indwelling urinary catheter. Serum creatinine improved to 1.0 mg/dl on postoperative day 5.Repeat imaging showed no abnormalities. Indwelling catheter was removed with minimal residual volumes. Review of the medications administered during the hospitalization revealed the patient was started on Entereg on post op day 1. Discontinuation of the medication improved the urinary retention. Unfortunately the medication was restarted during the same hospitalization with concomitant urinary retention and rise in creatinine. The agent was discontinued resulting in resolution of urinary retention and creatinine improvement to 1.0mg/dl.

Conclusions: Entereg is a peripherally acting μ-opioid receptor antagonist which achieves selective gastrointestinal opioid antagonism without reversing the central analgesic effects of μ-opioid agonists. Entereg is used to speed recovery of intestinal motility after gastrointestinal surgery, and prevent adverse effects caused by narcotics. Most common adverse effects of Entereg undergoing bowel resection are anemia, dyspepsia, hypokalemia, back pain, and urinary retention. Entereg is a new medication associated with urinary retention leading to post renal AKI. Prompt discontinuation of the medication may reverse this process.

FR-PO1111

Is Buttonhole Cannulation Associated Bacteremia Under-Reported?

Sabyasachi Roy,[1] Sarabjit S. Bhalla,[2] Priya Radhakrishnan,[1] Rajiv Poduval.[2] *[1]Internal Medicine, St Joseph Hospital & Medical Center, Phoenix, AZ; [2]Nephrology, Southwest Kidney Institute, Phoenix, AZ.*

Background: AV fistulas (AVF) remain the access of choice for hemodialysis (HD) patients. In recent years, the buttonhole (BH) technique for AVF cannulation has been gaining popularity. However BH cannulation (BHC) associated infection remains under-reported. We report 2 cases of bloodstream infection in patients who underwent BHC.

Methods: Case 1. 69-year-old diabetic HD patient, cannulated using BH technique was evaluated for persistent Staphylococcus lugdunensis bacteremia. Inpatient workup with Chest X ray, urine & sputum cultures, & echocardiogram failed to identify any source of infection. Patient was treated with IV Vancomycin for 4 weeks but surveillance cultures showed recurrence of bacteremia. Patient was treated with 2 more weeks of Vancomycin and switched from BH to sharp cannulation. Subsequent surveillance cultures were negative.

Case 2. 53-year-old diabetic HD patient, also cannulated by the BH technique, developed Methicillin Sensitive Staphylococcus Aureus (MSSA) bacteremia. Workup with sputum and urine cultures, Chest X ray and Echocardiogram was negative. Patient was treated with 2 weeks of IV Vancomycin, with resolution of bacteremia. Patient continues HD using BHC, but with improved technique and stringent sterile precautions. Surveillance cultures remain negative.

Conclusions: While the incidence of bacteremia is fairly common in patients undergoing HD, the actual incidence with BHC is unknown. Staphylococcus lugdunensis and MSSA are natural skin commensals. As BHC involves blunt needle introduction through the same fistula site repeatedly, non-healed infected skin and scab overlying the BH can potentially lead to introduction of skin flora into the bloodstream causing bacteremia, sepsis, increased morbidity and healthcare expenditures. Recognising BH associated infections, careful patient selection for this technique, training HD staff adequately regarding aseptic scab removal and proper angulation techniques for needle insertion can help minimize such infections. Further prospective studies will be required to examine the association of infections with BHC.

FR-PO1112

Treatment of Thyroid Storm Using Charcoal Hemoperfusion

Asish Thakkar, Rose Marie Shim, Christopher Valentine, Samir Parikh. *Department of Nephrology, Wexner Medical Center at the Ohio State University, Columbus, OH.*

Background: Untreated hyperthyroidism can be a devastating condition that may lead to thyrotoxicosis. Complications can be severe and include development of congestive heart failure, arrhythmias, psychosis, stupor, coma, and hepatic failure. Traditional treatments include beta-blockers, propylthiouracil, glucocorticoids, and iodine. In refractory cases, thyroidectomy is treatment of choice, however in unstable patients surgery may not be possible and non-traditional therapies must be considered. We report a case of thyrotoxicosis treated with charcoal hemoperfusion at our institution.

Methods: 27 year old female with history of untreated hyperthyroidism presented at 21 weeks gestation with new onset atrial fibrillation and stupor. She was found to be in severe thyroid storm and cardiogenic shock (EF-20%). On initial labs her TSH was <0.008uIU/mL and free T4 was 4.43ng/dl. She was started on hydrocortisone, PTU, propanolol, and SSKI. Unfortunately, her fetus did not survive. Despite five days of aggressive treatment her thyroid hormone levels continued to rise with Total T4>30ug/dl, free T4 >6ng/dl, total T3 >8.0ng/ml. She remained hemodynamically unstable and a poor surgical candidate. Given her refractory course, we attempted charcoal hemoperfusion for thyroid hormone removal. Results are shown in table.

Thyroid Function

Hemoperfusion Tx#	Total T4(ug/Dl)	Free T4(ng/dl)	Total T3(ng/ml)
One	>30.0	>6.00	>8.00
Two	27.9	>6.00	5.67
Three	24.1	>6.00	3.79
Four	19.7	>6.00	3.49
Five	16.4	>6.00	2.98

Conclusions: Hemoperfusion is an uncommon therapy for thyrotoxicosis but has been reported to be successful, particularly after L-thyroxine overdose. The absorbent particle in hemoperfusion can vary from charcoal to other resins which are effective in removing substances that are highly lipid soluble or protein bound. In our patient, hemoperfusion successfully removed thyroid hormone, improved clinical parameters and allowed for successful thyroidectomy. Charcoal hemoperfusion is an effective therapeutic tool for severe thyrotoxicosis and should be considered in patients' refractory to traditional therapies.

FR-PO1113

Persistent Left Superior Vena Cava

Niama Huda, Jian Li, Lalathaksha Murthy Kumbar. *Nephrology and Hypertension, Henry Ford Hospital, Detroit, MI.*

Background: A significant proportion of patients start dialysis with a temporary or tunneled cuffed catheter (TCC) inserted by anatomical landmarks or ultrasound (U/S) guidance. U/S guidance reduces the complications of dialysis catheter insertions.

Methods: A 76-year-old man with a history of end stage renal disease (ESRD) on hemodialysis through a right TCC presented with chest pain and respiratory distress requiring intubation. A contrast enhanced computed tomography (CT) scan of chest revealed septic emboli. The TCC was removed. A left internal jugular vein (IJV) CVC was inserted under U/S guidance at bedside after failed femoral vein catheterization. Post placement chest X ray showed the catheter along the left para-mediastinal region. The CT scan showed a persistent left superior vena cava (PLSVC).

Conclusions: CVC placement is a common procedure. Awareness and recognition of anatomic anomalies of the great vessels of the neck and chest is important. Differential diagnoses for a catheter following a left-sided course include subclavian or carotid artery, pericardium, mediastinum, superior intercostal vein, the left internal mammary vein or PLSVC placement. Arterial insertion can be ruled out through blood gas analysis and waveform transduction, while nonvascular site placement may fail to yield blood upon aspiration. Embryologically, the cardinal veins are the main venous drainage system. The superior vena cava (SVC) is formed by the right common and the right anterior cardinal vein. Left-sided SVC (PLSVC) is the most common thoracic venous anomaly (0.3– 0.5% of the population). PLSVC is caused by the persistence of the left anterior cardinal vein and obliteration of the common cardinal and proximal part of the anterior cardinal veins. Two types of PLSVC reported: 1.PLSVC connecting to the right atrium via coronary sinus-90%. 2. PLSVC connects to the left atrium-10%. Right-sided SVC often coexists with a PLSVC, and CVCs are more commonly placed in the right IJV, hence PLSVCs often go unnoticed. The presence of a PLSVC should be considered when CVC placement is difficult, as it may result in serious complications. Catheter tip manipulation in the coronary sinus may cause angina, arrhythmias or cardiac arrest.

FR-PO1114

Hemodialysis for Treatment of Severe Accidental Hypothermia

Tripti Singh, Kenneth R. Hallows. *Renal Electrolyte Division, University of Pittsburgh School of Medicine, Pittsburgh, PA.*

Background: Severe hypothermia is defined as a core body temperature <28°C. Delays in rewarming and slower rates of rewarming are the most important prognostic factors associated with increased mortality. Consensus exists about the use of cardiopulmonary bypass as a treatment of choice for active internal rewarming of patients. We describe a case where hemodialysis was used to treat severe accidental hypothermia.

Methods: A 49-year old male was found down unresponsive in his garage. On presentation to a regional hospital at 6pm his core temperature was measured at 23.5°C. He was promptly intubated and given warm air along with warm crystalloids intravenously. On arrival at our center, his core temperature was 25.9°C, heart rate 58 bpm, BP 160/90 mm Hg and respiratory rate of 19 on the ventilator. Admission laboratory results included: hemoglobin 4.4g/dl, white blood cell count $2.2\times10^3/\mu l$, serum BUN 44 mg/dl, creatinine of 2.5 mg/dl, Na^+ 138 mmol/L, K^+ 4.4 mmol/L and lactate 10 mmol/L. Arterial blood gas on admission showed a pH <6.8, PaCO2 38mmHg, PaO2 90mmHg and HCO_3^- 5mmol/L which improved to pH 7.01, $PaCO_2$ 33, PaO_2 193, HCO_3^-8 after initial resuscitation. Serum and urine toxicology screens were negative. His core temperature increased to 28.5°C at 11.30pm when hemodialysis was initiated through a right femoral catheter. A large surface area Rexeed 18 dialyzer was used with dialysate flow rate of 800ml/min and a blood flow rate of 400ml/min. The dialysate composition was Na^+ 139mmol/L, K^+ 4mmol/L, Ca^{2+} 2.5mmol/L and HCO_3^- 40mmol/L. No heparin was used. The initial dialysate temperature was 36°C and increased to 38°C after 3 hours. Hemodialysis was continued for a total of 4hours until the core temperature of the patient had increased to 33.4°C. The average rate of rewarming achieved during hemodialysis was 1.25°C/hr.

Conclusions: Hemodialysis can be used as an effective method for active internal rewarming for patients with accidental hypothermia and hemodynamic stability. It is more widely available, less invasive and less expensive than cardiopulmonary bypass and can correct associated acidosis and electrolyte disturbances commonly seen in patients with severe hypothermia.

FR-PO1115

Bilateral Superior Vena Cava: An Interesting Anatomic Variation

Don N. Chang, Jamie L. Ross. *Division of Nephrology, Univerisity of California Davis, Sacramento, CA.*

Background: Chest x-rays are often used for confirmation of successful central venous catheter placement in the internal jugular or subclavian vein. Clinicians should be aware of normal variations in venous anatomy that will change the position of dialysis catheters when viewed on confirmatory x-rays.

Methods: A 59 year old male with a history of diffuse large cell lymphoma was seen in the interventional nephrology suite for placement of an apheresis catheter. He was diagnosed with lymphoma in 1999 and completed a course of chemotherapy with complete remission until November 2011, when he developed back pain and was found to have recurrent disease. He had a port-a-cath placed via his right internal jugular vein 3 months prior to presentation to initiate salvage therapy with R-ICE, with the plan to proceed with autologous stem cell transplant using apheresis to collect the cells. Under flouroscopy, cannulation of his left internal jugular vein resulted in the guidewire persistently staying straight down

and to the left. There was initial concern that the guidewire was in the hemiazygous vein. Contrast was injected through the left internal jugular demonstrated drainage to the heart through a large, left sided venous structure, diagnostic of a left-sided superior vena cava. The catheter was placed with good blood flow through both ports.

Conclusions: Persistent left superior vena cava has an incidence of 0.3% in the general population and 4.3% in those with congenital heart disease. It is the most common anomaly of venous circulation resulting from a failure of the left anterior cardinal vein to obliterate with drainage normally to the coronary sinus. After ruling out placement in the hemiazygous vein, practitioners without the benefit of fluoroscopy should be aware of this anomaly and include it in the differential when a left-sided central venous catheter does not travel along its usual course.

FR-PO1116

Role of Hemodialysis after Disruption of Blood Brain Barrier Following Intra-Arterial Contrast Jingyin Yan, Medha Airy, Venkataraman Ramanathan. *Nephrology, Baylor College of Medicine, Houston, TX.*

Background: Osmotic disruption of blood brain barrier (BBB) and subsequent subarachnoid contrast extravasation and cerebral edema have been rarely reported after intra-arterial contrast use. We report an end stage renal disease (ESRD) patient who developed such a complication following intra-arterial contrast and who also had brisk clinical improvement and complete resolution of intraventricular contrast enhancement after emergent hemodialysis (HD). We propose a potential role for HD in those patients.

Methods: A 63 year old man, with history of left orbital apex syndrome and ESRD on HD, was admitted with massive epistaxis. Pseudo aneurysm in left internal carotid artery (ICA) was diagnosed and cerebral arteriogram was performed with subsequent embolization. 910 mL of intra-arterial contrast (iodixanol) was used during the procedure. Following the procedure, the patient developed severe altered mental status and was intubated. CT was done immediately and it showed new bilateral subarachnoid hyperattenuation and diffuse cerebral edema. The patient was emergently dialyzed, within 4 hours after contrast exposure, with high-flux dialyzer, followed by another HD session in 24 hours. His mental status improved remarkably following contrast removal with HD and was extubated the next day with no residual neurologic deficits. Repeat CT done in 24 and 72 hours showed partial and complete resolution of both subarachnoid hyperattenuation and brain edema, respectively.

Conclusions: Iodinated contrast can be removed with HD and blood concentration can be quickly reduced. This is partly due to its size, water solubility and low protein binding properties. Even though ~80% of contrast is removed with a 4 hr HD session, the utility of immediate post-contrast HD in ESRD patients is always questioned. But this case represents a unique situation. Large volume of intra-arterial contrast used in neurologic interventional procedures is associated with disruption of BBB and severe cerebral edema. Prompt removal of contrast with HD lead to significant clinical recovery. To our knowledge, this is the first case to describe a potential therapeutic role for prompt HD in such patients.

FR-PO1117

Congenital Arteriovenous Fistula of Left Brachial Vessels Used for Hemodialysis after Superficialization Mariusz Kusztal,[1] Krzysztof Letachowicz,[1] Tomasz Golebiowski,[1] Ewa Watorek,[1] Przemyslaw Szyber,[2] Maciej Guzinski,[3] Katarzyna Madziarska,[1] Magdalena Krajewska,[1] Jerzy Garcarek,[3] Waclaw Weyde,[1] Marian Klinger.[1] *[1]Nephrology and Transplantation Medicine, Wroclaw Medical University, Wroclaw, Poland; [2]General and Vascular Surgery, Wroclaw Medical University; [3]Radiology, Wroclaw Medical University.*

Background: Vascular abnormalities (more often in ADPKD) may produce difficulties in vascular access creation.

Methods: We report on a 20-year-old men with a history of ADPKD and currently failing 5-year kidney transplant that presented with congenital arteriovenous fistula (AVF) in the left arm. At the age of 14y due to the lack of suitable veins on both upper extremities for AVF creation and asymptomatic "vascular anomaly" on the left arm he started peritoneal dialysis. Currently, following physical examination, Doppler ultrasonography, venogram, CT-angiography (figure) the diagnosis of a brachial artery-to-brachial vein AVF was made. The oblique communicating channel between the brachial artery and brachial vein mapped near cubital fossa, 5cm before bifurcation of brachial artery.

Results: The patient underwent surgical superficialization of concomitant vein as described by Weyde et.al (Kidney Int. 2002;61:1170, J Vasc Access. 2006;7:74), used for deeply located arterialized vein. Four weeks after the procedure the AVF was successfully cannulated for hemodialysis. Doppler ultrasonography showed AVF blood flow of 1292ml/min, brachial artery diameter of 6.1 and 4mm at pre and post communicating channel section respectively. The vein transposed underneath the skin had 7mm in diameter. Plethysmography (PVL, Biomedix, MN) performed pre and post operatively showed no ischemia up to fingers level on both extremities.

Conclusions: To our knowledge, this is the first reported case of congenital AVF converted to vascular access for hemodialysis.

FR-PO1118

Acute Kidney Injury as the Initial Manifestation of Non-Hodgkin Lymphoma Mana Dissadee, Andres Serrano. *Department of Medicine Mount Sinai Hospital, RFUMS/CMS, Chicago, IL.*

Background: Bilateral infiltration of the kidneys from lymphoma is a rare entity. We report a case of diffuse large B-cell lymphoma presenting as acute kidney injury (AKI).

Methods: An 18-year-old man with no significant past medical history, presented with two months history of right-sided headache. He was taking 20 tablets of Ibuprofen per day for pain control. The review of systems was positive for generalized weakness, anorexia and 15 kg weight loss in 3 months. Physical exam showed right temporal scalp swelling and mild bilateral costovertebral tenderness. Laboratory data revealed a BUN of 64 mg/dl and a creatinine of 9.18 mg/dl. Urinalysis showed protein of 30 mg/dl, negative glucose, RBC of 1/HPF, WBC 1/HPF and no casts. Patient was admitted with diagnosis of AKI secondary to NSAIDs abuse. Ibuprofen was discontinued and he was started on IV fluids. Two days later, his renal function failed to improve. Renal ultrasound revealed bilateral enlarged kidneys with hydronephrosis. Urology was consulted and bilateral ureteral stents were placed, but his renal function did not change. Renal biopsy showed diffuse infiltration by intermediate-to-large mononuclear cells with prominent nucleoli. Immunophenotype studies were CD20+, Bcl-6+, MUM-1+, CD10-, TdT-. This is consistent with diffuse large B-cell lymphoma. Subsequent staging work-up was initiated. Bone marrow aspiration and biopsy were negative for malignancy. MRI of the brain showed thickening of the dura with lesion within the calvarium. Bone scintigraphy showed lytic lesion in the right ilium. Patient was treated with hemodialysis and chemotherapy. A dramatic improvement of renal function was observed after 2 weeks with complete recovery in 4 weeks.

Conclusions: This is an unusual presentation of extranodal lymphoma. Overall understanding of this disease is limited to 20 case reports in the literature. Prognosis is poor with 1-year mortality rate of 75%. Chemotherapy with CHOP plus Rituximab can increase complete response rates and prolong disease-free survival.

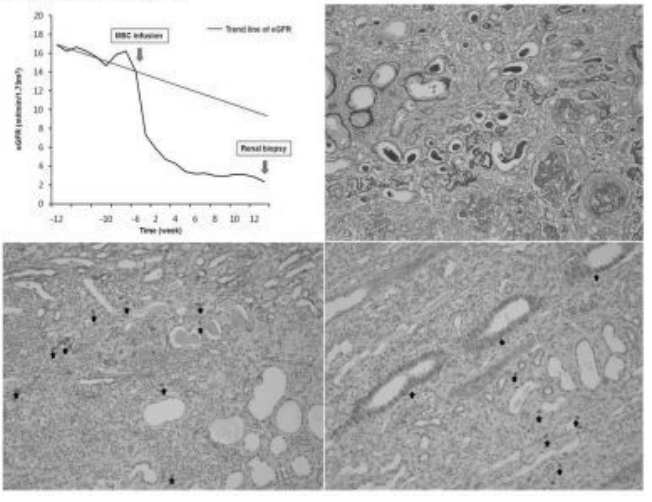
FR-PO1119

Rapid Deterioration of Preexisting Renal Insufficiency after Autologous Mesenchymal Stem Cells Therapy Jun-Seop Kim,[1,2] Owen Kwon,[1,2] Ji-Young Choi,[1,2] Jang-Hee Cho,[1,2] Sun-Hee Park,[1,2] Chan-Duck Kim,[1,2] Yong-Jin Kim,[3] Yong-Lim Kim.[1,2] *[1]Department of Internal Medicine, Kyungpook National University School of Medicine, Daegu, Republic of Korea; [2]Clinical Research Center for ESRD in Korea, Republic of Korea; [3]Department of Pathology, Yeungnam University College of Medicine, Daegu, Republic of Korea.*

Background: Autologous mesenchymal stem cell (MSC) administration has shown to improve renal function and histologic finding in acute kidney injury (AKI) models. However, whether MSC can contribute to the regression of renal fibrosis and regeneration of nephron in chronic kidney disease (CKD) is unclear, especially in clinical setting. Moreover, efficacy of homing mechanism and safety of transdifferentiation are not established in late CKD patient. Here, we report a case of CKD patient with focal segmental glomerular sclerosis treated by intravenous infusion of autologous MSC derived from adipose tissue in a foreign country.

Methods: The renal function of patient had been stable for several years before MSC administration. One week after the autologous MSC infusion, the preexisting renal insufficiency was rapidly aggravated without any evidences of AKI. Two months later, eGFR was markedly reduced from 16 to 7.3 ml/min/1.73m^2. Hemodialysis was started at 3 months after MSC administration. The renal biopsy findings at the time of dialysis showed severe interstitial fibrosis and inflammatory cell infiltration with a few cells expressing CD34 and CD117, surface markers of stem cell.

Figure 1. Clinical course and renal biopsy findings of patient with MSC therapy. (a) Clinical course. (b) Histologic finding with PAS staining. (c) Immunohistochemical staining with CD34. (d) Immunohistochemical staining with CD117.



Conclusions: This case emphasizes the potential nephrotoxicity of autologous MSC therapy in CKD patients although positive reports about the efficacy of MSC therapy in experimental CKD model are increasing.

Funding: Government Support - Non-U.S.

FR-PO1120

A Case of Lymphocytic Hypophysitis with Normal Imaging Adeel A. Siddiqui,[1] Aqeel A. Siddiqui,[1] Anshul Kumar.[2] *[1]Nephrology, Lankenau Medical Center, Wynnewood, PA; [2]Internal Medicine, Lankenau Medical Center, Wynnewood, PA.*

Background: There have been over 350 cases of Lymphocytic Hypophysitis identified so far. Among these, several had positive MRI findings. We report a case of Lymphocytic hypophysitis with normal MRI.

Methods: The patient is a 31-year-old female 5 months postpartum with no significant PMH presented with 1 day history of confusion.She was brought to the ER and intubated for airway protection. For the last 2 weeks, she noticed decrease lactation. BP 130/78, HR 71, temp 98.9 F.Lab data revealed Na 121 mEq/L, BUN < 5mg/dl, Creatinine 0.6 mg/dl ,Uric acid 1.4mg/dl, S. Osmolality 280 mOsm/kg, Urine Osmolality 106 mOsm/kg, Urine Na 69 mEq/L/day. Initially, she was treated with NSS and her Na increased to 137 in a span of 16 hours, then she was given DDAvP and her Na dropped to 131. In the mean time, she developed hypotension and was started on Nor Epinephrine drip. CT of the brain and LP was unremarkable.Euvolemic hyponatremia due to SIADH, glucocorticoid deficiency, or hypothyroidism was considered. MRI of the brain was performed to R/O destructive pituitary lesion that showed a normal pituitary gland.TSH and Free T4 were normal,ACTH was low at <5 pg/ml with low cortisol level 2.5 mcg/dl .Prolactin level was normal at 58.3 ng/ml.With hypotension and low ACTH, she was started on IV hydrocortisone. After glucocorticoid replacement, the patient's symptoms were dramatically resolved. However, 2 days after glucocorticoid replacement, her Na level increased to 139 meq/L with urine osmolality of 54. Patient was started on DDAvP which later tapered off as an outpatient. She was continued on hydrocortisone with stable Na.

Conclusions: Among the reported cases of lymphocytic hypophysitis,our patient had a very unique presentation.The pathophysiological process was well shown in our patient who developed water diuresis and hypernatremia after glucocorticoid therapy.Characteristics of lymphocytic hypophysitis seen on brain MRI include stalk thickening, diffuse enlargement of the pituitary gland and homogeneous enhancement of gadolinium contrast medium.Our patient had a normal MRI.

FR-PO1121

Healthy Young Male with Left-Lower Quadrant (LLQ) Abdominal Pain Huma S. Hasnain, Susanne B. Nicholas. *David Geffen School of Medicine at UCLA, Los Angeles, CA.*

Background: Renal artery dissection (RAD) is a rare condition that can lead to renovascular hypertension and renal mass loss. The following is a rare presentation of acute isolated spontaneous bilateral RAD.

Methods: A 52-year-old gentleman presented to the Emergency Department for evaluation of the sudden onset of sharp, LLQ abdominal pain lasting 2 hours, associated with nausea and emesis. His past medical history was significant for a similar episode of right-lower quadrant pain two years prior that prompted an appendectomy for presumed appendicitis. The pathology report showed a normal appendix, but renal angiogram done 2 weeks later noted vascular occlusion of the right renal artery with renal infarctions and focal cortical loss. His occupation as an air-traffic controller involved unusual physical exertion and stress with rapid twisting of the abdomen and periods of "bearing down." He had no known history of hypertension, and was normotensive on the recent presentation. Laboratory findings noted a serum creatinine level of 1.4mg/dl, urea nitrogen level of 14mg/dL; and an unremarkable urinalysis. CT scan noted a new, left renal infarct with decreased perfusion to the lateral aspect of the left kidney. Extensive evaluation for an underlying cause was negative: skin biopsy revealed no collagen abnormalities, echocardiogram was normal and genetic testing revealed no prothrombotic mutations. Management of this patient's bilateral RAD was non-operative, without anticoagulation. CT scan obtained 1 year later showed normal renal arteries without evidence of dissection; cortical loss was seen in 2-3 areas of the right kidney and 2 areas of the left kidney. Iothalamate renal clearance studies showed an improvement in GFR from 57ml/min to 73ml/min.

Conclusions: This is a rare presentation of isolated spontaneous RAD. These types of dissections can occur as a result of unusual physical exertion and are temporally related to the activity. Mechanisms may include the sudden increase in intra-abdominal pressure or blood pressure via the Valsalva maneuver. Management is mostly non-operative, with improvement within 6-12 months of anticoagulation and blood pressure control.

FR-PO1122

Dabigatran Induced Acute Kidney Injury Deepak Kadiyala,[1] Ursula C. Brewster,[1] Gilbert W. Moeckel.[2] *[1]Nephrology, Yale University, New Haven, CT; [2]Pathology, Yale University, New Haven, CT.*

Background: Dabigatran is a newly approved oral direct thrombin inhibitor that does not require frequent blood monitoring of levels. We describe a patient who developed AKI in the setting of its initiation and a renal biopsy that revealed the mechanism.

Methods: A 67 year-old caucasian male presented with AKI and 1 week of gross hematuria. He denied flank pain or respiratory tract symptoms. Past medical history included coronary artery disease, paroxysmal atrial fibrillation, and benign prostatic hypertrophy. He had no prior renal disease. Medications included aspirin, sotalol, omperazole, lisinopril and dabigatran. Coumadin was changed to dabigatran 1 week prior to presentation. BP was 140/76mmHg. Physical examination was unremarkable; no rashes or edema. Laboratory data: normal CBC, BUN 57 mg/dl, creatinine 5.5 mg/dl, autoimmune and viral serologies were negative, complements were normal. Renal biopsy showed extensive tubular injury with cytoplasmic reabsorption droplets containing eosinophilic proteinaceous material and RBC casts in the areas of tubular injury. Immunohistochemistry showed strong, diffuse positivity for CD163 in proximal tubular cells. Light microscopy, IF and EM of the glomeruli were consistent with mild underlying IgA nephropathy with no hypercelluarlity. His serum creatinine stabilized at 6.0 mg/dl without need for dialysis and slowly declined over a 2-month period to 2.7 mg/dl. Final diagnosis was subclinical IgA Nephropathy that led to glomerular bleeding with Dabigatran.

Conclusions: AKI in IgA-nephropathy can be due glomerular bleeding leading to tubular injury, Heme molecule is tubulo-toxic by causing lysosomal overload, inflammation, apoptosis, oxygen radical formation and endothelin-1 induction causing ischemic injury. Dabigatran should be used cautiously in patients with known kidney disease or with evidence of hematuria. Monitoring for hematuria might be prudent for an early diagnosis of subclinical nephropathy as in our patient.

Kveder, R AKI in IgA nephropathy: potential role of macroscopic hematuria and acute tubulointerstitial injury. Ther Apher Dial, 13: 273-277, 2009.

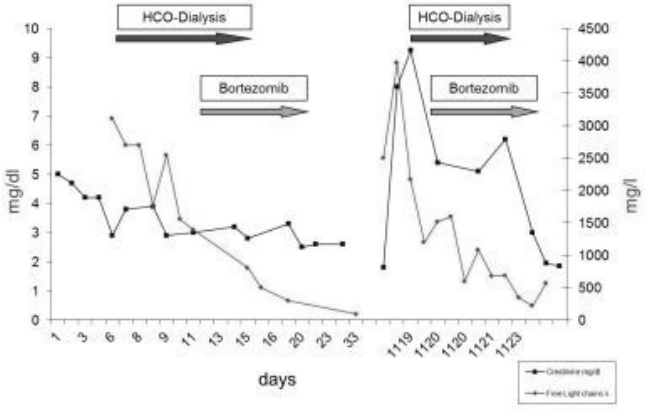
FR-PO1123

Twice Successful Treatment of Multiple Myeloma-Induced Acute Renal Failure with High-Cutoff Dialysis Daniel Zickler, Achim Joerres, Ralf Schindler. *Nephrology and Intensive Care, Charite University Medicine.*

Background: Multiple Myeloma with excessive free light chain production can lead to Cast-nephropathy with impairment of renal function. In cast nephropathy kidney damage is induced via the toxic effects of the free light chains. Early removal of FLC correlates with chances of renal recovery. The High-cutoff-filter HCO 1100 is a new dialysis-membrane which allows the elimination of molecules with a size of up to 60-70 kd. We report a 63

year-old female patient diagnosed with Multiple Myeloma Type Lambda developing Cast-nephropathy with consecutive acute renal failure. The treatment of the first episode, as well as the relapse was treated with HCO-Dialysis in addition to Chemotherapy.

Methods: Case Description Initially the 63 year-old female patient presented to the ER with back pain. Laboratory values revealed acute renal failure and 120-fold-increased lambda FLC. Kidney biopsy showed Cast nephropathy. Thus, chemotherapy with Bortezomib, Dexamethasone and Cyclophosphamide was started. Acute renal failure required hemodialysis therapy. To enhance FLC removal, six dialysis sessions with the High-cutoff-filter HCO 1100 were performed. Lambda FLC have a molecular size of 45 kd. Kidney function improved to a non-dialysis dependent level. Three years later, after high-dose melphalan and preceding stemmcell apheresis a relapse with excessive FLC production occurred, again causing dialysis dependent acute renal failure. Once more, dialysis with High-cutoff-filters was started, again causing significant reduction of FLC, as well as improvement of renal function.



Conclusions: High cutoff dialysis may provide a therapy option not only for newly diagnosed cast nephropathy but may also be of interest in therapy of relapsing multiple myeloma with high levels of free light chains.

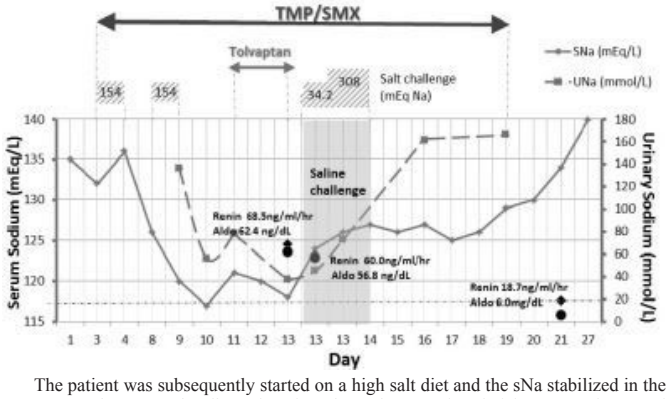
FR-PO1124

Trimethoprim/Sulfamethoxazole Associated Renal Salt Wasting

Revekka Babayev, Sofia Fayngold, Subani Chandra, Jai Radhakrishnan, Sumit Mohan. *Department of Medicine, Columbia University Medical Center, New York, NY.*

Background: Renal salt wasting (RSW) is rare and difficult to differentiate from SIADH clinically. Here we report a case of a 28 year old man with HIV and Pneumocystis pneumonia (PCP) who developed hyponatremia while receiving 16mg/kg/d trimethoprim-sulfamethoxazole (TMP/SMX).

Methods: Serum Na (sNa) on admission was 135mEq/L (with no prior history of hyponatremia) and dropped gradually to 117mEq/L by day 7 of TMP/SMX. In a setting of unclear volume status and PCP, he was initially treated for SIADH with fluid restriction and tolvaptan without improvement in sNa. A diagnosis of renal salt wasting secondary to TMP was subsequently confirmed with clinical hypovolemia and high renin 68.5ng/mL/hr (normal 0.2-4ng/mL/hr), aldosterone 62.4ng/dL (normal ≤31ng/dL), urinary Na 45mmol/L, FEphosphate 76% (normal <20%) and FEurate 13.6% (normal ≤10%). Tolvaptan was discontinued and a challenge of 2L 0.9%NaCl was given with improvement in sNa to 126mEq/L, and reductions in renin and aldosterone to 18.7ng/mL/hr and 6ng/dL respectively confirming the diagnosis of RSW.



The patient was subsequently started on a high salt diet and the sNa stabilized in the 126-129mEq/L range. After discontinuation of TMP/SMX on hospital day 19, sNa improved further into the normal range and was 140mEq/L on last follow up.

Conclusions: TMP/SMX related RSW is probably underdiagnosed and often mistaken for SIADH since both have low serum uric acid levels. RSW should be considered for patients on high dose TMP/SMX and can be differentiated from SIADH by the presence of high FEurate and FEphosphate and clinical hypovolemia (confirmed by high renin and aldosterone levels) (Maesaka et al, Kid Intl, 71, 2007). RSW from TMP can be treated with Na supplementation to offset ongoing urinary losses if the TMP/SMX cannot be stopped.

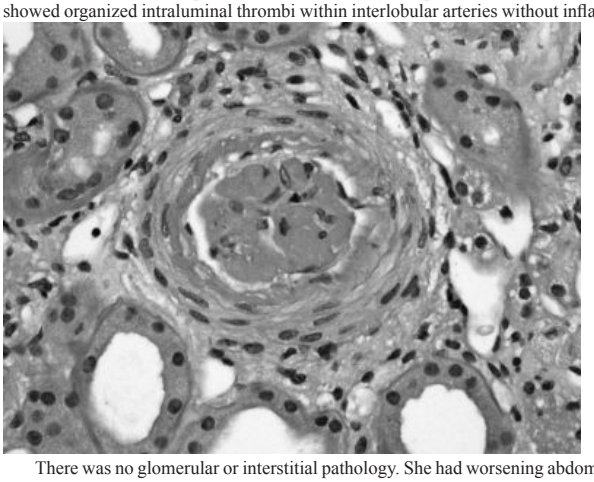
FR-PO1125

Bilateral Renal Artery Thrombosis Associated with Acute Necrotizing Pancreatitis

Bijin Thajudeen, Pooja Budhiraja. *Nephrology, University of Arizona College of Medicine, Tucson, AZ.*

Background: Renal artery thrombosis is a rare, but serious and often under diagnosed, condition. Prevalence is 0.002% based on case series of emergency department patients.

Methods: A 66-year old Caucasian female presented with abdominal pain and oliguria. She was diagnosed with acute renal failure 2 weeks ago due to acute pancreatitis which resolved with hydration. The only significant finding on physical examination was epigastric tenderness. Serum chemistry revealed elevated BUN, Creatinine and LDH. Urine analysis showed hematuria and 1+ proteinuria without any dysmorphic RBCs or casts. Renal biopsy showed organized intraluminal thrombi within interlobular arteries without inflammation.



There was no glomerular or interstitial pathology. She had worsening abdominal pain, hypotension and CT of the abdomen with contrast was done which showed renal infarction and bilateral renal artery thrombosis in addition to possible bowel perforation. Emergent laprotomy showed necrosed pancreas. Hemodialysis and anticoagulation were initiated. Doppler studies showed deep vein thrombosis of bilateral lower extremity and internal jugular vein thrombosis. Workup for hypercoagulability and vasculitis were unremarkable. There was no past medical or family history of hypercoagulable state. Final impression was acute kidney injury secondary to bilateral renal artery thrombosis and eitiology of renal artery thrombosis thought to be due to hypercoagulability of acute necrotizing pancreatitis.

Conclusions: Renal infarction from bilateral renal artery thrombosis secondary to hypercoagulable state of necrotizing pancreatitis has never been reported before. Possible etiologies increase in factor VIII, fibrinogen ,factor V activity,DIC. A high degree of suspicion is thus needed when symptoms arise acutely in the setting of a predisposing condition.

FR-PO1126

Gitelman's Syndrome in Pregnancy: Challenges in Management

Rajan Kapoor, Tarun Chugh, Savneek S. Chugh, Sreedhar R. Adapa, Maureen E. Brogan. *Department of Nephrology, New York Medical College, Valhalla, NY.*

Background: Gitelman's syndrome (GS) is a rare autosomal recessive disorder, caused by inactivating mutation of NaCl cotransporter in DCT, leading to hypokalemia and hypomagnesemia. GS in pregnancy is associated with further worsening of serum electrolyte making management of GS in pregnancy a challenge.

Methods: We present a case of 23 yo female with GS, diagnosed 2 yrs ago, when we worked her up for persistent hypokalemia and hypomagnesemia following a seizure episode with no apparent neurological cause. She was started on spironolactone, potassium chloride (KCl) and magnesium oxide (MgO). Since then her K^+ stayed 3 -3.5meq/L and Mg^{2+} 1.5 – 2.4mg/dl with no seizures. Now, she presents during her second pregnancy at 6 weeks gestation. Her first pregnancy was in Peru (records not available). She was on prenatal vitamins and above supplements except spironolactone (stopped 4 weeks back). Vitals were stable, BP 90-96/ 46-50 mm Hg. LABS: K^+ 2.7meq/L, Mg^{2+} 1.2mg/dl, HCo_3 26meq/L. She was started on Eplerenone and KCl and MgO doses were increased. Despite increasing medication doses (max doses- KCl 80meq Q4hr, MgO 800mg Q4hr, eplerenone 25mg BID), her K^+ remained 2.5 – 3.0 meq/L and Mg^{2+} 0.8 – 1.5 mg/dl and hence, she required three hospitalizations by 24th week for intravenous (IV) supplements. To minimize hospitalizations, she initially got intramuscular (IM) Mg^{2+} twice weekly and later K^+ and Mg^{2+} through PICC line/IV(thrice weekly) along with oral supplements. At 37th week, she delivered a 2420 g child vaginally with no complications. Post delivery, her serum K^+ and Mg^{2+} levels improved and oral supplement doses were decreased.

Conclusions: Obstetric literature supports the association of GS with development of oligohydramnios and IUGR in pregnancy. Given our patient's history of seizures and risk of developing above complications, she required a very close weekly follow up. Literature shows good outcomes in these patients, with aggressive electrolyte repletion (even multiple hospitalizations for IV supplements), as reciprocated in our case too. We propose an outpatient management approach with IV or IM supplements in such high risk patients.

FR-PO1127

Electrolyte Abnormalities of the Ectopic ACTH Syndrome Rebecca Kurnik Seshasai, John S. Barbieri, Amos J. Shemesh, Mina Sedrak, Brenda B. Hoffman. *Univ of Pennsylvania, Philadelphia, PA.*

Background: We describe a patient who presented with severe hypertension, hypokalemia and metabolic alkalosis with a rare diagnosis of ectopic ACTH syndrome secondary to thymic carcinoid tumor.

Methods: A 61 year old man with history of stable hypertension presented with lower extremity edema, dyspnea, 16kg weight loss, new onset diabetes, and worsening hypertension. He denied vomiting and diarrhea. Home medications were ramipril 10mg, furosemide 20mg, valsartan/hctz 320/25mg, amlodipine 10mg and metformin. Exam was notable for BP 184/120 and 3+ lower extremity edema. Labs were notable for Na 140 mmol/L, K 1.7 mmol/L, Cl 95 mmol/L, HCO_3 40 mmol/L, BUN 26 mg/dL, creat 1.3 mg/dL, Mg 1.6 mg/dL, and arterial pH 7.63. CTA showed patent renal arteries and bilateral pulmonary emboli. Lower extremity doppler showed an acute DVT. Renin activity and aldosterone levels were low: renin 0.2ng/ml/hr and aldosterone <1.6ng/dL. Cortisol was 47.9 µg/dL (normal 6-23 µg/dL) and 24 hr urine cortisol was 2960 µg/day (normal <60 µg/day). After 1mg dexamethasone suppression, cortisol was elevated at 91.6 µg/dL. ACTH was 185 pg/ml (normal 7-69 pg/ml). These findings were consistent with ACTH dependent Cushing syndrome. PET-CT showed a 3.7 x 5.5cm mass in the anterior mediastinum and bilateral adrenal hyperplasia. The patient received carvedilol 25mg bid, hydralazine 10mg tid, valsartan 320mg daily, spironolactone 100mg daily, ramipril 10mg daily, amiloride 5mg bid and >200mEq KCl daily, yet he remained hypokalemic. His TTKG was 17.84 demonstrating significant urinary potassium wasting, and his BP remained elevated. The tumor was removed and pathology showed a typical carcinoid tumor of the thymus which stained positively for ACTH, confirming ectopic ACTH syndrome. His cortisol, ACTH, glucose and potassium all normalized post-operatively.

Conclusions: Most patients with the ectopic ACTH syndrome have severe hypokalemic metabolic alkalosis due to cortisol binding the mineralocorticoid receptor. This syndrome is rarely seen in Cushing disease with pituitary secretion of ACTH. Thymic carcinoid tumors are rare and aggressive with a poor prognosis, and those patients with Cushing syndrome have the lowest survival rates.

FR-PO1128

IgA Nephropathy Following TNF-alpha Antagonists for Ankylosing Spondylitis and Crohns Disease Muhammad Omer, Cybele Ghossein. *Nephrology/Internal Medicine, Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: We report an unusual case of IgA nephropathy in a patient treated with Tumor Necrosis Factor (TNF) alpha antagonists for Ankalosing Spondilitis (AS) and Crohns Disease (CD).

Methods: A 22 year old man with AS diagnosed in 2006 presented for nephrology consultation for an elevated creatinine obtained on routine screening. His AS was initially treated with non steroidals and Etanercept until 2008 when he was diagnosed with CD and etanercept was switched to Adalimumab. Both AS and CD remained in remission with improvement in back pain, joint stiffness, diarrhea and functional status. Laboratory data on presentationrevealed a serum creatinine was 1.73 mg/dl. His urinalysis showed 3+ protein and > 100 RBCs/HPF and his urine spot protein / creatinine ratio was 2.6. Serological work up including ANA and ANCAwas negative on presentation. A Kidney biopsy was consistent with IgAN HAAS grade III.

Conclusions: Both AS and CD have been associated with IgAN (1, 2). Frequent flares usually secondary to respiratory and gastrointestinal infections, leading to antibody production by the hyperactive mucosal immune system is considered to be the underlying etiology in these patients (3). Our case is unique in that our patient was in remission, with no recent flares. The most likely etiology of his IgAN, is the use of Adalimumab. This effect by Adalimumab, a human monoclonal antibody against TNF, is the result of cytokine imbalance, caused by a switch of the cytokine response from T-helper type 1 to T-helper type 2. This switch can result in the production of antibodies by activated B cells which can potentially cross-react with relatively elevated circulating IgA1 in patients with AS and Crohns disease producing IgA1 immune complexes and leading to IgAN. Frequent and close monitor of renal function and urinalyses in patients on TNF alpha antagonists may lead to the detection of the glomerular disease process in its earliest form.

FR-PO1129

A Case Report of Noncirrhotic Portal Fibrosis in a Renal Transplantation Recipient Hae Min Lee, Keunsuk Yang, Jeong Gwan Kim, Myung Hyun Lee, Byung Ha Chung, Cheol Whee Park, Chul Woo Yang, Yong-Soo Kim, Bum Soon Choi. *Division of Nephrology, Department of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, the Catholic University of Korea, Seoul, Korea.*

Background: Noncirrhotic portal fibrosis (NCPF) can be a cause of portal hypertension in non-cirrhotic patients, and it can lead to serious complications such as a variceal bleeding. Although bacterial infection and immune abnormalities have been proposed as possible etiologies of NCPF, there is a limited understanding of the disease process. We describe a rare case report of NCPF in renal transplantation recipient which first manifested as a variceal bleeding then treated successfully.

Methods: A 40-year-old man who underwent living donor kidney transplantation 7 months ago visited our emergency room because of syncope. He had diabetes and history of CMV DNAemia. He had a tachycardia at the time of visiting. His hemoglobin level declined to 5.1 g/dL from 9.8 g/dL within 2 weeks. He was performed emergency esophagogastroduodenoscopy (EGD). We found active bleeding on gastric cardiac varices then stopped bleeding by endoscopic variceal ligation (EVL). We reviewed his past EGD before transplantation, but there was no evidence of variceal change. On his abdominal imaging, we could find intra-hepatic arteriovenous shunt without liver cirrhosis nor splenic thrombosis, then performed embolization successfully. He had a liver biopsy that shows he has mild portal fibrosis. 6 months later, we performed transjugular intrahepatic portosystemic shunt (TIPS), because cardiac varices had been growing on follow up EGD despite additional EVLs and adequate dose of beta blocker. 7 months later, he had no additional bleeding and the patency of TIPS stent is intact.

Conclusions: NCPF can occur in renal transplantation recipients because they use immunosuppressant and are vulnerable to infection. The most important point of managing NCPF is to prevent life-threatening variceal bleeding. EVL and beta blockers are common therapy for the primary prophylaxis. But if variceal bleeding recurred frequently in patients with NCPF despite adequate primary prophylaxis, TIPS can be considered to reduce the portal flow.

FR-PO1130

Improvement of Aplastic Anemia after Kidney Transplantation and Immunosuppressive Therapy Jeong Gwan Kim, Hae Min Lee, Myung Hyun Lee, Keunsuk Yang, Byung Ha Chung, Bumsoon Choi, Cheol Whee Park, Yong-Soo Kim, Chul Woo Yang. *Department of Internal Medicine, Seoul Saint Mary's Hospital, the Catholic University of Korea, Seoul, Korea.*

Background: Usually treatment of aplastic anemia (AA) is bone marrow transplantation (BMT) or immunosuppressive (IS) therapy. And common IS agents are anti-thymocyte globuline (ATG) plus cyclosporine A (CsA). Several investigators tried to deliver an intensified IS by adding a third IS agent. However, this strategy did not show results in a substantial benefit.

Methods: A 35-years-old female patient was diagnosed with stage V chronic kidney disease (CKD) and severe AA. And she had been treated chronic kidney disease by continuous ambulatory peritoneal dialysis. For the treatment of AA, we used ATG in five days, but there was no response. So we planed kidney transplantation (KT) and BMT. At first KT and IS therapy were begun. That IS agents were tacrolimus, MMF and prednisolone. Laboratory finding was improved gradually after KT. Recently laboratory findings show that her AA status is not indication of BMT. So we will decide a need for BMT after further IS therapy.

Conclusions: On the basis of our clinical experience, we suggest that kidney transplantation in AA patients may be success, and tacrolimus may be an effective IS agent used to treat AA.

FR-PO1131

An Exploration of Falsely Elevated Tacrolims Concentrations in a Kidney Transplant Patient: A Case Report Sahoko Yamamura, Yudo Tanno, Hiroshi Hayakawa, Hiroyasu Yamamoto, Keitaro Yokoyama, Tatsuo Hosoya. *Division of Kidney and Hypertension, Department of Internal Medicine, Jikei University School of Medicine, Tokyo, Japan.*

Background: Affinity column mediated immunoassay (ACMIA) is a more simple and rapid way of measuring tacrolimus (TAC) levels compared to previous methods such as chemiluminescence immunoassay (CLIA). Although a good correlation in the results has been reported, there have been some reported cases with a discrepancy between the two sets of results.

Methods: We report a case of a 61 year old woman who underwent renal transplantation 3 years ago. After transplantation, her baseline serum creatinine level remained around 1.3mg/dl with a stable trough TAC level of around 5ng/ml measured using CLIA. However, when her TAC level was measured using ACMIA, it showed a sudden rise to 58.1ng/ml. Thereafter, it continued to yield consistently high levels when using ACMIA with no correlation with the results obtained from CLIA. Furthermore, levels of TAC in the serum, which should have been undetectable also demonstrated abnormally high readings using ACMIA. Thereby, instead of using whole blood samples, samples containing only washed erythrocytes (without serum) were used to assess if factors in the serum were playing a role. In this test, same results were obtained using the two methods (ACMI and CLIA). This suggested that factors in the serum were somewhat responsible for giving falsely high TAC levels in ACMIA. Furthermore, in samples tested after removal of human IgG, IgA, IgM, correct levels of TAC were only obtained in those containing no IgG. This indicated that false readings were due toIgG antibodies in the serum. Effects of human anti-mouse antibody and anti-β-galactosidase antibody on TAC levels, which had been reported to give high readings were also assessed. However, this yielded negative results.

Conclusions: In our case, IgG subclass was found to be responsible for the falsely high TAC levels. In such cases, whole blood samples should be re-tested if available, using other methods such as CLIA. Otherwise, in order to avoid false results it is sufficient to use ACMIA, provided washed erythrocytes without serum are used for testing.

FR-PO1132

Reactivation of Whipple's Disease in a Prosthetic Aortic Valve after Kidney Transplant Jiwan K. Thapa, Neha Garg, Titte Srinivas. *Nephrology and Hypertension, Cleveland Clinic, Cleveland, OH.*

Background: Whipple's disease (WD) is a bacterial infection with multi-system manifestations caused by gram positive bacterium Trophyrema Whipplei. Here, we describe a rare presentation of reactivation of WD as prosthetic valve endocarditis (PVE) after initiating immunosuppression for renal transplant.

Methods: We present a case of 72 yr old male diagnosed with WD 14 years prior when he had presented with polyarthritis involving large joints for past 7 years unresponsive to treatment. Diagnosis was made after Lt Hip arthroplasty when PCR (in blood and synovial tissue) and PAS positive staining (in synovial tissue) showed T. Whipplei. Duodenal tissue PCR was negative for T.Whipplei. His symptoms resolved with IV Ceftriaxone followed by oral Bactrim for 1 year. Rt hip arthroplasty done 2 years later was negative for T. Whipplei by PCR.

2 yrs ago, he underwent Aortic Valve Replacement (AVR) with Carpentier Edwards # 23 valve for Aortic Regurgitation. 1 year ago, he received deceased donor kidney transplantation (CMV D/R-, EBV D-/R-) for hypertensive nephrosclerosis. He had Simulect induction and was maintained on Tacrolimus/ Cellcept/Prednisone with stable allograft function (S.Cr 1.5 mg/dl).

Over last 1 year, he developed progressive fatigue & weight loss. Evaluation showed 3-4 + Aortic Insufficiency & he underwent redo- AVR with Trifecta prosthesis # 25. A large tear in Left Cusp and small perforation in Right cusp of unclear etiology was found. Pathology of ex-planted valve showed no gross vegetation but granular deposits on the ventricular side of leaflet and no inflammatory infiltrate on microscopy. PCR on the ex-planted valve was positive for T.Whipplei. Treatment for PVE was initiated with IV Ceftriaxone followed by lifelong bactrim therapy.

Conclusions: Tissue invasion by T.Whipplei is characterized by lack of immunologic response and inflammatory infiltrates. Although host immune deficiency has been implicated in the past, WD has not been demonstrated to reactivate in transplant patients on mmunosuppressants. Our case demonstrates that immunosuppression used for solid organ transplant might pose a risk for reactivation and atypical presentation of this elusive infection.

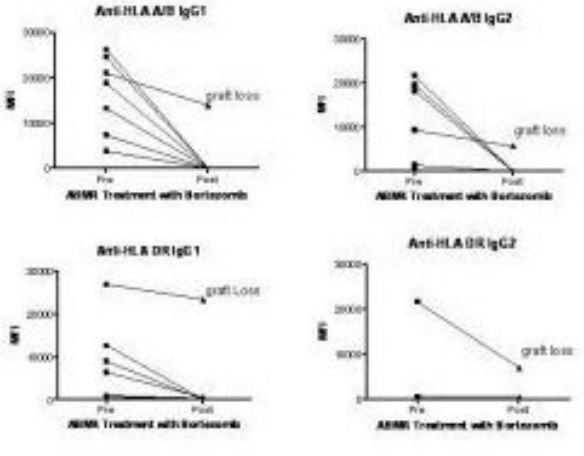
FR-PO1133

Donor Specific Antibody IgG Subtypes AND Responsiveness to Bortezomib Based Therapy for Acute Antibody Mediated Rejection (ABMR) Dinesh Kannabhiran,[1] Matthew J. Everly,[2] Blanca Mae Ponce,[1] Vijay K. Sharma,[1] Manikkam Suthanthiran,[1] Darshana Dadhania.[1] *[1]Nephrology, Cornell Med. Center, NY, NY; [2]Terasaki Foundation.*

Background: Donor Specific Antibodies (DSA) are routinely measured at the time of ABMR. Class I DSAs are more likely to decline following treatment for ABMR compared to Class II and the presence of Class II DSAs correlates with poor allograft survival. We investigated the reduction in IgG subtypes for Class I & Class II DSAs following Bortezomib based therapy for ABMR.

Methods: We analyzed serum obtained at the time of biopsy (pre-Bortezomib therapy) and 2-6months following treatment of ABMR with Bortezomib (post-Bortezomib therapy) from 7 kidney recipients with biopsy confirmed ABMR (2-Class I, 3-Class II, 2-ClassI&II DSAs) had both Class I and II DSA). Sera were diluted 1:3 and tested for anti-HLA IgG using LABScreen single antigen beads (SAB). Importantly, sera were tested for IgG subclass (1, 2, 3, and 4) using SAB with an IgG subclass specific secondary antibody. The cutoff for single antigen positivity was 1000 mean fluorescence intensity (MFI).

Results: DSAs against HLA- class I A, B (N=7) and DSAs against HLA- class II DR (N=7) were studied. The predominant IgG subtypes of the DSAs directed at HLA-A and/ or B were IgG1 & IgG2 (1 patients had Class I-IgG3) and for HLA-DR, the predominant subtype was IgG1 (1 had IgG2). Bortezomib therapy reduced both IgG1 & IgG2 DSA directed at HLA A, B & DR except in the two patients who lost their grafts.



Conclusions: Our data suggest that successful reversal of ABMR with Bortezomib is associated with reduction in both IgG1 & IgG2 DSA whereas failure to reduce IgG1 DSA is associated with graft loss. Mechanistic basis for persistently elevated levels of both IgG1 & IgG2 remains to be resolved and may represent a significantly larger and/or resistant plasma cell clone.

FR-PO1134

Very Early Onset De Novo Crescentic Nephropathy with IgA Predominance in a Kidney Transplant Recipient Karthik Karanam, Muhammad Ahmad Mujtaba. *Indiana University Hospital, Indianapolis, IN.*

Background: It is reported that 20% patients of IgA nephropathy have some degree of crescents. Further de novo IgA with crescents is very rare. Recurrent or denovo IgA with crescents has been seen as early as 5 months after transplant. We report a case of de novo IgA with crescents diagnosed very early at 3 weeks post transplant.

Methods: A 23 year old white male with ESRD due to congenital dysplasia of kidneys underwent living related kidney transplant in 1987; the kidney lasted for less than a week for technical reasons. He was on CAPD; in 1990 had a deceased donor transplant that worked till year 2000, biopsy revealed chronic transplant glomerulopathy. He was on intermittent HD and then underwent a deceased donor 3 antigen mismatch kidney transplant from a 18 year old female Caucasian in 2009. He was highly sensitized & was given IVIG. He was on thymoglobulin, steroids, mycophenolate and tacrolimus. He was discharged with a downward trending creatinine in low 2's. Post op day 14 creatinine increased to 3.4mg/dl with worsening proteinuria of 7 grams & RBC's. Transplant kidney biopsy showed acute glomerulonephrritis (GN) and acute cellular rejection; BANFF 2A. Immunological work up for complements, anti-GBM antibodies, ANA, anti-dS DNA, RF, hepatitis C, ANCA's were negative. Pulse steroids were given and creatinine improved but proteinuria persisted. A repeat biopsy was done on 34th Post op day for acute renal failure, proteinuria 13 grams and dysmorphic RBC. It showed Immune complex GN with crescents (2/11) and tubular necrosis, IgA predominant. The mate kidney from the same donor was followed but the other recipient of the paired kidney was doing fine. Patient underwent plasmapheresis, received Rituximab but his renal function deteriorated. Post op day 84 another biopsy showed DPGN with 1 crescent and segmental sclerosis. His renal function continued to worsen with fluid overload. He was initiated on intermittent HD.

Conclusions: Patient's history of congenital kidney, lack of IgA in previous transplant and no features of IgA in the potential donor with a normal mate kidney makes the possibility of de novo disease. We suggest that de novo IgA can arise in post transplant kidneys very early.

FR-PO1135

A Case of Posterior Reversible Encephalopathy Syndrome during Eculizumab Therapy Sajan Thomas. *Nephrology, Goldcoast Hospital, Gold Coast, Queensland, Australia.*

Background: This is a case of Eculizumab related complication in a patient treated for hemolytic uremic syndrome.

Methods: This is a 24 year old male who presented with five day history of diarhoea to the Emergency department.On examination he was found to be dehydrated but hemodynamically stable.His investigation revealed acute renal failure with a creatinine of 1430umol/L,hemolytic anemia with Hb of 94g/L,thrombocytopenia with platelet count of 89*10^{9}L,raised LDH 1130U/L,low haptoglobin 0.03g/L and fragmented red cells on peripheral smear.A diagnosis of Hemolytic uremic syndrome was made later confirmed by a renal biopsy. He was initiated on Plasma exchange and haemodialysis. He had five sessions of daily plasma exchange and on day six of his hospital admission he was started on eculizumab. He was dialysis dependent for further three weeks. His renal functions has progressively improved. His main complication during eculizumab therapy was hypertension related PRES. He is currently on three antihypertensive agents with well controlled blood pressure and stable renal functions. He continues to be on fortnightly doses of eculizumab.

FR-PO1136

Olanzapine Induced Hypercalcemia Deep Adhikari, Eric Iida. *Nephrology, University of Massachusetts Medical Center, Worcester, MA.*

Background: Olanzapine is an atypical antipsychotic used to treat schizophrenia and bi-polar disorder. We describe a case of olanzapine induced hypercalcemia in a patient with CKD.

Methods: A 67 y.o. female developed new hypercalcemia with a total calcium of 13.3 mg/dL and an ionized calcium of 6.8 mg/dL. Lithium had been discontinued ten years previously due to CKD with Cr 2.5 mg/dL and nDI. She was not on thiazides, vitamin D or calcium supplements. iPTH was 8 pg/mL and 25 vitamin D was 19 ng/mL. CXR, SPEP, UPEP, TSH and PTH-rp were all normal. The only new medication was olanzapine, started 20 days earlier. She was treated with IVF, furosemide and pamidronate. She had a similar presentation 9 weeks later. Shortly after, olanzapine was discontinued for psychiatric reasons. Calcium remained normal for 15 months until olanzapine was restarted. Hypercalcemia ensued fifteen days later. Again, iPTH and 25 vitamin D were unremarkable. A 1, 25 vitamin D was 105 pg/mL but was normal 3 days later. CXR, CT chest, CBC, Vitamin A level and total body bone scan were unrevealing. Hypercalcemia resolved with IVF, furosemide, calcitonin and a weekly bisphosphonate. She remained on olanzapine. She presented 4 months later with hypercalcemia. In the interim, she had been on cholecalciferol and had self-discontinued the bisphosphonate. Repeat CT chest showed lung

nodules suggestive of metastatic calcium deposits. CBC, PFTs, and 1, 25 Vitamin D were normal. She was treated as previously. Discontinuation of olanzapine is being considered.

Conclusions: Olanzapine is an atypical antipsychotic classified as a thienobenzodiazepine. Although hypocalcemia has been reported in the setting of pancreatitis, our patient developed hypercalcemia with a temporal association to olanzapine. Lithium may cause hypercalcemia even after discontinuation, but not with a suppressed PTH. The single elevated 1, 25 Vitamin D level was not reproducible.

A mechanism for olanzapine causing hypercalcemia is obscure. Its effects are mediated through serotonin, dopamine, and other receptors, none of which explain hypercalcemia. To our knowledge, this is the first report of olanzapine induced hypercalcemia.

FR-PO1137

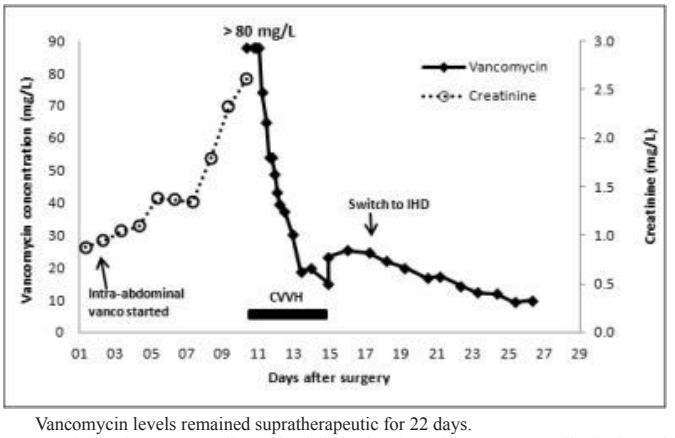
Vancomycin-Associated Nephrotoxicity Joelle Mardini,[1] Karine Mardini,[3] Marc Ghannoum,[3] Josee Bouchard,[2] Valery Lavergne.[2] *[1]Mcgill University, Montreal, QC, Canada; [2]Sacre-Coeur Hospital, Montreal, QC, Canada; [3]Verdun Hospital, Montreal, QC, Canada.*

Background: Vancomycin-induced AKI remains a controversial entity. Current literature suggest that etiology of AKI is often clouded by other comorbidities. We present a patient who developped AKI when vancomycin overdosage was the only risk factor.

Methods: A 73 year-old man, known with type 2 diabetes and normal kidney function, was admitted following abdominal surgery for ampulloma.

Cultures from the Jackson-Pratt grew MRSA. High dose intraabdominal vancomycin (2g q 12h) was purposely started on day 2 following surgery to counter possible exudation of the antibiotic. Acute kidney injury progressively ensued although no etiology was identified. Vancomycin level was not monitored until day 11 post-surgery, when it was found to be > 80mg/L. No other associated vancomycin-related complication were evident, namely ototoxicity, hemodynamic instability or cardiac conduction defects. Vancomycin was discontinued immediately.

In order to remove vancomycin, high-dose CVVH (4L/h) was started on day 11 and continued until day 15. Intermittent HD was began on day 17 and continued for 2 more weeks.



Vancomycin levels remained supratherapeutic for 22 days.

Hospitalization was complicated by delirium but the patient was eventually discharged 2 weeks later with some degree of renal impairment (eGFR = 40 mL/min/1.73 m^2), which persisted on follow-up 2 months later.

Conclusions: AKI can occur in the setting of isolated severe vancomycin toxicity.

Vancomycin T1/2 under CVVH was 148h, which is considerably longer than what is reported by DelDot et al, 2004 (15.6h). This suggests ongoing absorption from the abdominal cavity.

Disposition of intra-abdominal vancomycin shortly after surgery is erratic and requires closer monitoring.

FR-PO1138

All that Is Natural Is Not Innocuous Connie Rhee, Li-Li Hsiao. *Renal Division, Brigham and Women's Hospital, Boston, MA.*

Background: Aristolochic Acid (AA) is a known cause of tubulointerstitial disease and urothelial cancer. In the absence of herbal medicine regulation, US consumers are at increased risk of exposure.

Methods: A 54 year-old white male was referred to the clinic for stage 3 chronic kidney disease. 3 years prior, he presented to an outside nephrologist with an elevated creatinine (1.6 mg/dl) and microalbumin/creatinine ratio (54 mcg/mg) in the context of heavy herbal use (16 pills/day). Two renal biopsies showed interstitial fibrosis/tubular atrophy (IFTA) and a renal papillary neoplasm fragment for which he was referred to urology. Serial imaging studies were negative for malignancy. His creatinine rose to 2.0 mg/dl, and he was referred to a second nephrologist.

By this time, he had stopped all supplements and was on lisinopril 10 mg daily for hypertension. Examination demonstrated a fit male with normal blood pressure. His creatinine was 1.9 mg/dl and urine sediment was bland. Review of prior biopsies revealed a gradient pattern of IFTA (outer cortex>inner cortex>medulla). Ingredient labels from his supplements did not list any nephrotoxins, but evaluation at an outside laboratory revealed low amounts of AA (240-279 ppm) in 2 bottles, pointing to AA as the cause of his nephropathy and neoplasm.

Conclusions: Herbal medicine use is highly prevalent in the US (17.7% in a 2007 survey), with sales estimated at $4.8 billion annually. Although some herbals confer health benefits, AA is a nephrotoxin and carcinogen characterized by proximal tubular defects, rapid renal function decline, and urothelial malignancy. AA nephropathy is recognized by its gradient pattern of hypocellular IFTA and glomerular sparing.

The 1994 Dietary Supplement Health and Education Act exempts supplement manufacturers from the safety, efficacy, and quality regulations that apply to prescription and over the counter drugs. Consumers may be subject to toxin exposure due to 1) inaccurate labeling, 2) contamination, 3) substitutions, and 4) herb-drug interactions. The 2007 Good Manufacturing Practices aim to improve standards, but criteria remain lenient. It is imperative that physicians routinely ask patients about herbal use and that rigorous regulation of supplements be implemented.

FR-PO1139

Methotrexate-Induced Nephrotoxicity Abdur R. Baig,[1] Gustavo Westin-figueiredo,[2] Ahmed A. Waheed,[1] Dollie F. Green,[1] Oliver Lenz.[1] *[1]Nephrology and Hypertension, University of Miami, Miller School of Medicine, Miami, FL; [2]Medicine, University of Miami, Miller School of Medicine, Miami, FL.*

Background: Methotrexate (MTX) is one of the most widely used anticancer medications. Despite aggressive hydration, urinary alkalinization and LV rescue therapy, nephrotoxicity remains a major concern.

Methods: A 51-Year-old male with Mantle Cell Lymphoma and hyper IgE syndrome received high dose intravenous (IV) MTX therapy (3000 mg/m^2) as part of his R-MACLO (IV rituximab, doxorubicin, vincristine, cyclophosphamide, methotrexate with LV rescue therapy) chemotherapy regimen. He had previously received methotrexate 1200 mg/m^2 without adverse reactions. On admission his serum creatinine was 1 mg/dl. He developed acute renal failure, initially non-oliguric and later oliguric, within less than 12 hours of MTX infusion. Renal function continued to worsen, and his serum creatinine peaked at 5 mg/dl. Maximum blood MTX level was 26 mcmol, and he was given bicarbonate infusions and was started on LV rescue as per his initial chemotherapy protocol. On the following day, MTX level was 10.55 mcmol. After administration of glucarpidase, MTX level improved to 0.69 mcmol. There was no indication for dialysis, and his renal function slowly improved.

Conclusions: High-dose MTX (≥ 1000 mg/m^2) is used for the treatment of variety of malignancies, including lymphoma. Nephrotoxicity has been observed since the 1970s and is caused by tubular precipitation. Although leucovorin rescue, volume expansion, and urinary alkalinization, have decreased complication rates significantly, nephrotoxicity remains a major concern. Carboxypeptidase-G_2 (glucarpidase) metabolizes circulating MTX to the inactive metabolite diamino methylpteroic acid, providing an alternate route for elimination. Glucarpidase administration in combination with thymidine and LV is highly effective. Within 15 minutes of administration plasma MTX concentration decrease by 95%–99%. Rebounds <10% in plasma MTX concentrations were reported in only 60% of patients. Both charcoal hemoperfusion in combination with hemodialysis or high-flux hemodialysis have been shown to effectively remove MTX.

FR-PO1140

Acute Interstitial Nephritis and Cocaine: An Unusual Presentation for Acute Kidney Injury Narender Goel,[1] James M. Pullman,[2] Maria Coco.[1] *[1]Nephrology, Albert Einstein College of Medicine, Bronx, NY; [2]Pathology, Albert Einstein College of Medicine, Bronx, NY.*

Background: Acute interstitial nephritis (AIN) is a well-recognized cause of acute kidney injury (AKI). Most AIN cases are caused by medication. However, possible relationship of AIN with Cocaine is unusual and seldom reported.

Methods: A 49 years old male with history of Diabetes Mellitus, Hypertension, chronic Hepatitis C and prior substance abuse, presented with nausea, vomiting and decreased oral intake for 1 week. He stated to have taken ibuprofen for last 2 weeks and later admitted to recent intravenous cocaine use. Initial physical examination was unremarkable.

Initial labs were serum Sodium 131 meq/L, Potassium 6.1 meq/L, Blood Urea Nitrogen/ Creatinine (BUN/Cr) 110/12 mg/dl, WBC count 12500/mm^3 with 3% eosinophil, Creatinine Phosphokinase (CPK) 45 U/L. Urinalysis showed specific gravity 1.014, large blood but no protein, with large hematuria, leukocyturia and eosinophils but no casts. Urine toxicology was positive for Cocaine. Renal sonogram showed 14 cm size kidneys and mildly increased echogenicity. Hemodialysis was initiated. Antineutrophilic cytoplasmic antibody, Anti-GBM antibody, rheumatoid factor, serum/urine protein electrophoresis and HIV were negative. Serum complements were normal. Kidney biopsy showed AIN. Patient was started on Prednisone 60 mg daily with gradual renal recovery. He was discharged home with serum Cr 3.2 mg/dL but presented 1 week later with anuria for 1 day after recurrent cocaine use. Chemistries at that time showed serum Potassium 7 meq/L, BUN/Cr 230/12 mg/dL and CPK 34 U/L. Hemodialysis was resumed. Course was further complicated by acute bacterial endocarditis requiring aortic valve replacement.

Conclusions: Literature reports 3 cases of cocaine induced AIN. Rhabdomyolysis, glomerular microcirculation vasoconstriction, malignant HTN and renal infarcts are primarily defined mechanisms of cocaine induced AKI. Diagnosis of AIN may be difficult due to lack of classical allergic symptoms such as rash, fever and eosinophilia. In our case ibuprofen may have been contributory, but his 2nd presentation with recurrent AKI following another cocaine exposure suggests cocaine as etiology of AIN.

FR-PO1141

Plasmacytoma Masquerading as Acute Kidney Injury with Hematuria Jagannath H. Saikumar,[1] Mazen El Atrache,[2] Mona Vekaria,[2] Pablo Buitron de la Vega,[2] Kausik Umanath.[1] *[1]Nephrology, Henry Ford Hospital, Detroit, MI; [2]Internal Medicine, Henry Ford Hospital, Detroit, MI.*

Background: Acute kidney injury (AKI) and hematuria have many etiologies ranging from pre-renal to glomerulonephritides and nephrolithiasis with obstruction.Plasma cell dyscrasias can affect the kidneys in many ways. We present a unique case of plasmacytoma causing mechanical obstruction and hematuria.

Methods: A 65 y.o. Hispanic woman presented to the emergency room (ER) with left sided flank pain and gross hematuria.She had a history of IgG Kappa multiple myeloma (MM) diagnosed one year prior that was treated with 4 cycles of bortezomib, dexamethasone and autologous stem cell transplant with good response.In the ER,she was found to have AKI with a serum creatinine (SCr) of 2.9 mg/dL.Renal ultrasound showed left sided hydronephrosis.A subsequent noncontrast CT scan of the abdomen/pelvis showed a large left retroperitoneal hemorrhage surrounding the left kidney extending into the renal pelvis and presacral region, compressing the left external iliac vessels.A left nephrostomy tube was placed after failure to position stents via cystoscopy.This was inadvertently removed and her kidney function declined prompting placement of a right nephrostomy tube. Worsening serum immunoglobulins led to repeat bone marrow biopsy that showed MM relapse. Transurethral bladder biopsy revealed a plasmocytoma infiltrating the bladder mucosa.The patient was treated again with chemotherapy as well as 10 sessions of palliative radiation targeting the bladder without response. An MRI of the retroperitoneal hemorrhage showed infiltrative tissue surrounding the left kidney.Biopsy of this mass was also consistent with plasmacytoma. She was then started on daunorubicin, vincristine and dexamethasone therapy which was complicated by tumor lysis syndrome and AKI requiring dialysis.Her renal function eventually recovered with a SCr of 1.4.

Conclusions: Most extramedullary plasmacytomas are in the lung but can rarely occur in the abdomen. They present with end-organ damage leading to anemia, AKI, hypercalcemia or lytic bone lesions. This case highlights the complexity and range of renal involvement of MM.

FR-PO1142

A Case Report: Severe Neurotoxicity Induced by Isoniazid and Ethambutol in a Peritoneal Dialysis Patient Hui Peng, Meirong Zhong, Yan-ru Chen, Yuanqing Li, Sujay Dutta Paudel, Tan-qi Lou. *Division of Nephrology, Department of Medicine, The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, Guangdong, China.*

Background: Patients with end stage kidney disease are vulnerable to toxic effects of anti-tuberculous drugs. However, concurrence of severe peripheral neuropathy, retrobulbar neuritis and recurrent laryngeal nerve injury induced by isoniazid and ethambutol was rarely reported in peritoneal dialysis patient with active tuberculosis. Here, we present a patient of such case.

Methods: A 36-year-old man was diagnosed with CKD (stage 5) as well as infiltrative pulmonary tuberculosis on admission in April 2011. CAPD was initiated soon. And anti-tuberculosis treatment was begun with isoniazid 200 mg/day, ethambutol 750mg every other day, rifapentine 600 mg/week and VitB6 30mg/d. After four months, the patient gradually experienced numbness and weakness of lower extremities and finally he became unable to stand on his own. Electromyogram indicated peripheral nerve injury. Simultaneously, he noticed numbness of the fingertips and declined vision. Given the suspicion of side effect of anti-tuberculosis drugs, isoniazid and ethambutol were discontinued. Levofloxacin, Pyrazinamide combined with rifapentine were then used to anti-tuberculosis. Large dose of vitamin B6 and vitamin B12 were administered. However, there was no improvement in one month. Subsequently he displayed blurred vision, hoarseness and drink water to cough. Ophthalmological examination revealed blurred borders of both optic disks. Visual acuities were finger counting at 0.5 meter both eyes. Laryngoscopy found glottic dysraphism, therefore, recurrent laryngeal nerve injury associated with isoniazid was considered.

Three months after withdrawal, weakness and numbness of both extremities as well as hoarseness disappeared. Four months later, he was able to walk with a crutch, and his eyesight restored to near normal as well.

Conclusions: Severe neurological toxic effects associated with isoniazid and ethambutol may occur in patients undergoing chronic dialysis. Early discontinuation of anti-tubercolosis drugs and intensified neurotrophic therapy may be effective in dealing with neurological complications.

Severe Rhabdomyolysis Caused by Red Yeast Rice with Concomitant Use of Diltiazem and Warfarin Dhwanil Vyas, Anuja Vyas, Mamta Shah. *University of Connecticut.*

Background: Red Yeast Rice (RYR) is cooked rice fermented with Monascus purpureus (Red Yeast). It is widely used in China as a coloring agent as well as a dietary supplement. In recent years, it has been shown to successfully reduce LDL, total Cholesterol and triglyceride levels. Monacolin K, amongst other constituents of RYR, is thought to be primarily responsible for this effect. Its molecular structure resembles Lovastatin. The mechanism of action is similar, hepatic 3-methylglutaryl coenzyme A reductase (HMG-CoA) inhibition. Despite its increasing use, RYR is not regulated by FDA. Also, the safety profile and drug interactions are not well studied. We describe a case of rhabdomyolysis caused by RYR and possibly its interaction with Warfarin and Diltiazem.

Methods: A 77 year-old man with a history of Simvastatin-induced-myopathy and atrial fibrillation on stable doses of Diltiazem and Warfarin, presented with 4 weeks' history of generalized muscle aches predominantly in bilateral thighs and shoulders. He was found to have rhabdomyolysis and acute kidney injury with creatinine kinase level of 42,705 U/L and creatinine of 1.6 mg/dl. His complete medication list that was later obtained from the pharmacy included supplemental Red Yeast Rice 1200mg/day. Evidently, it was started 4 weeks prior to the beginning of his symptoms. No other potential causes of Rhabdomyolysis could be identified in this patient. He improved clinically with supportive care and avoidance of RYR.

Conclusions: Literature search yielded 5 reports of Rhabdomyolysis caused by RYR. Studies suggest that there is a higher incidence of milder forms of myopathy with RYR. Also, since many constituents of RYR are metabolized by cytochrome P450 isoenzyme 3A4 (CYP450 3A4) in the liver, there is a risk for drug interactions. We hypothesize that CYP450 3A4 inhibition by Diltiazem and Warfarin led to high levels of monacolin K in our patient, predisposing him for getting rhabdomyolysis. Basic science research to delineate drug interactions and large clinical studies to assess incidence of adverse effects of RYR as compared to statins are warranted.

FR-PO1144

A Rare Case of Voriconazole Induced Acute Kidney Injury Alin A. John, Gautham Viswanathan, Ronald D. Perrone. *Division of Nephrology, Tufts Medical Center, Boston, MA.*

Background: Acute Kidney Injury (AKI) in kidney transplant recipients is common. Voriconazole is a potent anti-fungal for which there is limited data regarding nephrotoxicity. A case of Voriconazole associated AKI is reported below.

Methods: A 52 year old male underwent living unrelated kidney transplantation for ESRD secondary to diabetic nephropathy, receiving Tacrolimus, Mycophenolate Mofetil and Prednisone for immunosuppression. His post-transplant course was complicated by acute allograft glomerulopathy at 3 months treated with high dose steroids with excellent response. Serum creatinine had decreased to 1.25 mg/dL from a nadir creatinine of 2.5 mg/dL. 6 months post transplant, a draining ulcer on the patient's left ear lobe was noted which grew Fusarium. He was initially started on Posaconazole, and then switched to Voriconazole 300 mg twice daily once sensitivities returned; tacrolimus level at this time was 20.7. One week later he presented with lower extremity edema, dyspnea, weight gain, and a peak creatinine of 4.46 mg/dL with a protein/creatinine ratio of 2g/g, tacrolimus level was 5.4. A repeat biopsy showed no evidence of rejection, but revealed severe tubular injury. Voriconazole levels returned elevated at 5.3 mcg/mL (nl < 2.1 mcg/mL). The AKI was thought to be secondary to voriconazole which was discontinued. Off Voriconazole, creatinine steadily improved over 2 weeks to 1.19 mg/dLwith significantly reduced proteinuria.

Conclusions: This patient had biopsy proven severe tubular injury in the setting of a supratherapeutic voriconazole level, suggesting this medication as the causative agent. The data regarding acute kidney injury secondary to Voriconazole is limited. Voriconazole is a potent anti-fungal agent which is commonly used in immunosuppressed patients, including those with kidney transplants. This case indicates that closer monitoring of renal function may be indicated.

FR-PO1145

Warfarin Related Nephropathy in a Patient with Normal Renal Function Banshi M. Rathi, Praveen N. Chander, Stephen Adler. *New York Medical College, Valhalla, NY.*

Background: Warfarin was introduced as an oral anticoagulant in 1950 and has been the most often prescribed anticoagulant ever since. Warfarin related nephropathy (WRN) is a recently described complication of warfarin anticoagulation associated with significant morbidity and possible mortality. The risk factors associated with WRN are chronic kidney disease (CKD), diabetes, diabetic nephropathy, hypertension and heart failure. We report an interesting case of WRN in a patient without risk factors and with normal baseline renal function.

Methods: A 66 year old female with history of multiple myeloma and peripheral stem cell transplant was consulted for 4 weeks of hematuria, bilateral flank pain and acute kidney injury. She did not have a history of CKD, proteinuria, diabetes mellitus, heart failure, nephrolithiasis, trauma or hypertension. There was no history of non-steroidal anti-inflammatory drug intake or intravenous contrast exposure. Outpatient work-up with non-contrast computed tomography scan and cystoscopy were unrevealing. The patient had been on warfarin for deep venous thrombosis for one year, with therapeutic prothrombin time and international normalized ratio (INR). Urinalysis revealed hematuria (3+, 30-50 red blood cells, dysmorphic) without proteinuria. A kidney biopsy was performed and revealed tubules blocked with fresh or hemolyzing erythrocyte consistent with WRN. The patient did not recover renal function with conservative management and was initiated on hemodialysis for worsening renal function and uremia.

Conclusions: WRN has been associated with supra-therapeutic INR, nephrotic syndrome, and drugs causing glomerular hypertension. Our patient did not have CKD by clinical, laboratory or radiologic criteria, and did not meet the above mentioned risk factors. WRN frequently leads to a progressive decline in renal function terminating in end stage renal disease. The clinical course of our patient is consistent with the currently opined natural history of this condition. Our report emphasizes that WRN can also occur in patients considered at low risk for this disorder. Prospective multicenter studies are needed to better define the clinical features and natural history of this entity.

FR-PO1146

Beta HCG Producing Poorly Differentiated Carcinoma Causing Acute Kidney Injury

Ahmed A. Waheed,[1] Prodipito Pal,[2] Yehia S. Abdelwahed,[1] Abdur R. Baig,[1] Monica T. Garcia-buitrago,[2] Gabriel Contreras.[1] *[1]Nephrology and Hypertension, University of Miami, Miami, FL; [2]Pathology, University of Miami, Miami, FL.*

Background: A case of beta HCG producing poorly differentiated carcinoma infiltrating the kidney causing acute kidney injury requiring dialysis.

Results: A 63 year old white male with systemic hypertension and transient ischemic attack presented to the hospital with nausea, vomiting, and upper abdominal pain. He was found to have microscopic hematuria, proteinuria of 500 mg/g of creatinine and an elevated serum creatinine of 2.8 mg/dL, and bilateral exudative pleural effusions. Thoracentesis yielded an exudative effusion with negative cytology. Serum complement levels and screening for ANA, double-stranded DNA, ANCA, anti-GBM, hepatitis B and C, and HIV were unremarkable. A cystoscopy revealed a WHO grade 2 of 3 non-invasive papillary urothelial carcinoma of the urinary bladder. The renal failure progressed, requiring renal replacement therapy, and he underwent a kidney biopsy, which revealed a poorly differentiated carcinoma in all cores with a negative p63 stain. It was histologically different from the papillary urothelial carcinoma of the bladder. Multiple tumor markers were normal except for Ca19-9 of 50 unit/ml and beta-HCG level of 777 mlU/ml. Further tissue diagnosis was sought with a CT guided biopsy of a pancreatic lesion which revealed poorly differentiated carcinoma similar to that seen on the kidney biopsy. CT scan of the chest revealed pleural effusion with pleural thickening, septal thickening, mediastinal lymphadenopathy and partial collapse of right middle lobe. A scrotal ultrasound did not show any mass. A diagnosis of beta HCG producing poorly differentiated carcinoma was made.

Conclusions: The frequency of metastases to the kidney in cancer patients is 7% - 13 % in large autopsy series. The most common primary malignancy to involve the kidney is bronchogenic carcinoma, then breast and gastrointestinal cancers. A literature search for beta HCG producing poorly differentiated carcinoma metastases to the kidney was performed. No such cases were readily found with the search.

SA-PO001

Long Term Impact of Preventing AKI with Off-Pump Coronary Artery Bypass Surgery: A Risk-Adjusted Propensity-Matched Cohort Study
Alejandro Ferreiro,[1] Raul Lombardi.[2] *[1]Instituto Nacional de Cirugía Cardíaca, Montevideo, Uruguay; [2]SMI, Montevideo, Uruguay.*

Background: Off-pump (OPCAB) surgery should protect kidneys from On-Pump (ONCAB) CABG related AKI. The long-term impact of OPCAB AKI prevention on hard outcomes needs to be established.

Methods: All adult patients submitted to CABG surgery in INCC-IMPASA between 1/1/2000 and 12/31/2008 were enrolled (n=4384; 1747 OPCAB (39.8%), 2637 ONCAB (60.2%)). Patients were propensity-matched if included into a mean ± 2 SD logistic regression probability of receiving OPCAB (logistic EuroSCORE (ESC), bypass number and diabetes). ESRD patient were excluded. Demographics, comorbidities, intraoperative and postoperative (PO) variables were prospectively-collected. AKI was defined according to R+I+F criteria. Long-time survival (up to 10 year) was obtained by a systematic telephone survey, minimum 2-year follow-up, and ESRD status from the Uruguayan Dialysis Registry. eGFR was assessed by Cockroft-Gault formula. ***Statistical analysis***. t test, Mann-Whitney test, ANOVA, $\chi 2$, Kaplan-Meier curves, long-rank test and Cox regression for survival analysis. $p<0.05$ (*).

Results: 785 OPCAB and 1377 ONCAB patients included into analysis: age 64.7±9.4 yrs (31-91). No differences between groups in: diabetes, ESC, previous stroke, hemodinamic instability, LVEF, AMI, sex, bypass number, age, preoperative (PreO) SCr and eGFR. In PO (OPCAB vs ONCAB): SCr: 1,27 mgrs/dl vs.1,47 mgrs/dl*, AKI: 25,6% vs 38,5%*; RRT: 0.1% vs 1,5%*. PreO eGFR-stratified RRT (stages: I, II, IIIa, IIIb, IV, V): 0%; 0%; 0%, 0%, 11,1% vs 0%; 0,4%, 1.1%; 2,9%, 10,4%, 50%*; 33% higher mortality in ONCAB due to mortality in AKI patients (6,7% vs 1,5%*), mainly in eGFR stages IIIb, IV and V*. The long-term 5-year composite end point (ESRD and mortality) survival was higher in OPCAB (0.89 vs 0,84*) due to less events in non-AKI patients (0.89 vs 0,81*). In Cox model, age, AKI, eGFR, ESC and ONCAB were associated with long-term mortality and ESRD*.

Conclusions: Lower incidence of AKI and a 10-fold reduction of PO RRT were observed in OPCAB, resulting in a higher 5-year event free survival. Few other preventive strategies described in the literature demonstrated such impact on long-term PO AKI related events.

SA-PO002

In-Hospital and Long Term Management and Outcomes of Acute Kidney Injury
Brittany E. Yee, Emmett D. Ratigan, Katherine Yang, Sam Kuo, Ravindra L. Mehta. *Nephrology, University of California San Diego, San Diego, CA.*

Background: Recent studies have shown that management of patients with AKI is variable and subject to significant gaps in diagnosis, investigations and follow up contributing to sub-optimal care. We conducted a retrospective case-control study to evaluate the quality of inpatient management and assess short and long-term outcomes of patients with and without AKI at an academic medical center. We hypothesized that AKI patients would have worse outcomes and their care would be associated with gaps in recognition, diagnosis, management and follow-up.

Methods: We reviewed charts of 100 patients discharged with ICD-9 diagnosis codes 584.4-9 for AKI (ICD-9+) and 190 matched controls (ICD-9-). AKI was confirmed by a modification of the AKIN criteria (Standard: increase in serum creatinine (sCR) or Modified: decrease in sCR of > 0.3 mg/dl over 48 hrs. We evaluated the in-hospital management and post-discharge events within one year to determine the follow up care and outcomes including repeat AKI, re-hospitalizations, ESRD, and mortality.

Results: All ICD-9+ patients were confirmed to have AKI but only 38% met the standard criteria, while 25.8% of the ICD-9- group had AKI (8.9% by standard criteria). AKI patients experienced more complicated hospital stays and had worse outcomes than non-AKI with volume overload (49% vs. 8.4%, p<0.001), sepsis (32% vs. 5.3%, p<0.001), need for dialysis (15% vs. 0%, p<0.001), and mortality (18% versus 1.1%, p<0.001). Within the first year, ICD-9+ patients had a greater frequency of subsequent AKI (59.4% versus 22.3% in ICD-9-, p=0.005), had a significantly increased rate of progression to ESRD (7.8% versus 0.6%, p=0.007), while rates of readmission and mortality were not different. Only 23.4% of ICD-9+ patients followed up with a nephrologist post-discharge.

Conclusions: Our results are consistent with prior studies highlighting the need for continued improvement in the recognition and management of AKI patients both during and following hospitalization. Focused attention is required to improve outcomes from this disease.

Funding: NIDDK Support

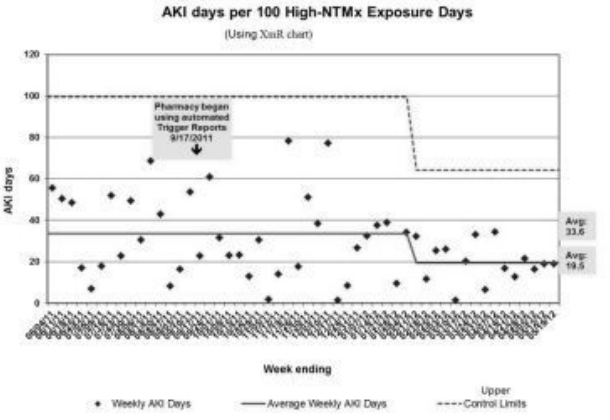
SA-PO003

Electronic Health Record (EHR) Identification of Nephrotoxic Medication (NTMx) Exposure Can Guide Systematic Kidney Function Assessment, Detect Acute Kidney Injury (AKI) Reliably, and Lead to Decreased AKI Rates and Intensity
Stuart Goldstein, Eric S. Kirkendall, Hovi Nguyen, Joshua K. Schaffzin, Stephen E. Muething. *Center for Acute Care Nephrology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Nephrotoxic medications are a common cause of AKI (NTMx-AKI) in hospitalized children. A portion of NTMx-AKI goes unnoticed from lack of reliable kidney function surveillance in exposed patients. We developed an HER screening process to quantify NTMx-exposure and AKI rates in non-critically ill patients over a ten month period.

Methods: High NTMx exposure was defined as ≥3 NTMx exposure at once OR an IV aminoglycoside for ≥3 days. AKI was defined by pRIFLE criteria, based on serum creatinine (SCr) values. We recommended daily SCr in high NTMx-exposed pts. Outcome metrics were 1) High NTMx admissions (adm) per 1000 hospitalized patient days (pt-days) 2) AKI rates per High NTMx adm (%) and 3) Days in AKI per 100 high NTMx days.

Results: 71,794 pt-days resulted from 24,913 adm (19,942 unique patients). Of these, 663 unique pts comprised 773 adm (5,857 pt-days) with high NTMx exposure (11 High NTMx adm per 1000 pt-days). Daily SCr monitoring occurred in >99% high NTMx days. Pts with high NTMx exposure had 1,746 AKI-days (1,135, 482, 129 days in pRIFLE R, I and F). AKI rates per high NTMx adm decreased from 35% to 28.8% in the last 4 months of study. Days in AKI per 100 days of high NTMx exposure decreased by 42%, potentially avoiding 880 annual AKI days.



Conclusions: We successfully implemented an EHR-based daily NTMx-AKI screening program. We found a 1) high rate of AKI in non-critically ill children with high NTMx-exposure and 2) decrease in AKI rates and duration with only recommendations for daily SCr monitoring. We suggest improvements resulted from increased awareness and earlier identification of AKI with daily SCr screening.

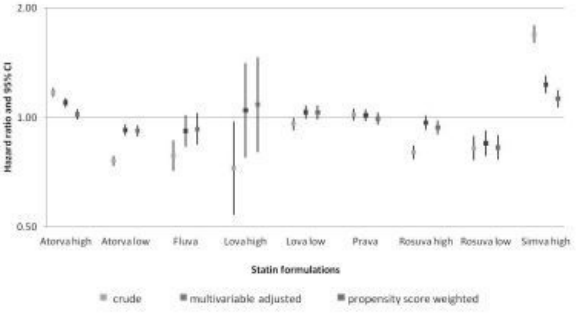
SA-PO004

Comparative Renal Safety of Statin Formulations by Dose and Potency
J. Bradley Layton,[1,2] M. Alan Brookhart,[1] Michele Jonsson Funk,[1] Ross J. Simpson,[2] Virginia Pate,[1] Til Stürmer,[1] Abhijit V. Kshirsagar.[2] *[1]Epidemiology, University of North Carolina, Chapel Hill, NC; [2]Medicine, University of North Carolina, Chapel Hill, NC.*

Background: Higher-potency statins effectively lower lipoprotein cholesterol, but may also have greater risk of adverse events. Limited information is available on the effect of these agents on acute kidney injury (AKI). We examined the association of higher-potency formulations and doses with AKI in a large US insurance claims database, years 2000-2010.

Methods: We identified statin initiators following a six-month washout period, and categorized them into potencies by formulation and dosage. Diagnosis codes during a one-year follow-up were searched for AKI. We estimated hazard ratios (HR) and 95% confidence intervals (CI) for the risk of AKI in all higher-potency vs. lower-potency users. Individual formulations were also compared to lower-dosage simvastatin. Covariates included cardiovascular and renal risk factors, medications, and other claims and diagnoses. Analyses were repeated with propensity score methods.

Results: We identified 4,146,507 eligible statin initiators (73.8% lower-dosage formulations). As a class, higher-dosage statins showed no increased risk of AKI over lower-dosage statins: HR=1.09 (95% CI: 1.07-1.12). Some individual formulations conveyed a higher risk of AKI: higher-dosage atorvastatin, HR=1.09 (1.07-1.13); and high-dosage simvastatin, HR=1.23 (1.17-1.30). Formulations with lower AKI risk were: lower-dosage atorvastatin, HR=0.92 (0.89-0.96); lower-dosage rosuvastatin, HR=0.85 (0.79-0.92).



Conclusions: While the risk of AKI in most statin formulations is comparable to lower-dose simvastatin, some higher-intensity formulations are associated with higher risk of AKI. Residual confounding by disease severity may partially explain the observed effects, but modern adjustment techniques reduce this possibility.

SA-PO005

The Incidence, Risk Factors, and Prognosis of Warfarin-Related Nephropathy in a Tertiary Hospital in Korea

Jung Nam An,[1] Jiwon Ryu,[2] Shin-young Ahn,[2] Sejoong Kim,[2] Ho Jun Chin,[2] Ki Young Na,[2] Dong Wan Chae.[2] *[1]Department of Internal Medicine, Seoul National University Hospital, Seoul, Korea; [2]Department of Internal Medicine, Bundang Seoul National University Hospital, Seongnam-si, Korea.*

Background: Warfarin-related nephropathy(WRN) is a recently described disease entity, where excessive warfarinization(international normalized ratio(INR)>3.0) causes acute kidney injury. Hence we analyzed the incidence, risk factors, and prognosis of WRN by the retrospective analysis in a single tertiary hospital in Korea.

Methods: During the period March 2003 to December 2011, a total of 1297 warfarin-treated patients who had at least one event of INR>3.0 and also had serum creatinine(sCr) levels measured within 1week after INR>3.0 and within 6months before INR>3.0 were identified. WRN was defined as more than 50% or more than 0.3mg/dL elevation of sCr level measured within 1week after INR>3.0 over sCr level measured within 6months before INR>3.0. Chronic kidney disease(CKD) was defined as eGFR<60ml/min/1.73m^2.

Results: WRN developed in 19.3% of entire patients. The incidence was higher in CKD group(24.0%) than non-CKD group(17.4%). The majority cases of WRN(82.2%) occurred within 1year after the initiation of warfarin therapy. In laboratory findings after INR>3.0, patients with WRN had higher INR and lower hemoglobin and hematocrit level than those without WRN. In multivariate analysis, the risk of WRN increased as basal serum albumin level decreased and was strongly associated with coronary artery disease and congestive heart failure. The presence of CKD or basal eGFR were not independent risk factors for WRN. Despite of no significant difference in basal sCr level, sCr level was higher in patients with WRN than those without WRN after follow-up. The mortality rates at 1,2,and 5years were also higher in patients with WRN than those without WRN(33.0% vs 15.6%; 41.7% vs 23.3%; 56.8% vs 45.1%).

Conclusions: WRN developed in 19.3% of patients having excessive warfarinization. Lower basal serum albumin level and comorbidities such as coronary artery disease and congestive heart failure were associated with the occurrence of WRN. The development of WRN adversely affected the renal and patient outcomes.

SA-PO006

Incidence and Outcomes of Acute Kidney Injury in a Large NHS Hospital

Mark A.J. Devonald,[1,2] Christine Porter,[1] Irene Juurlink.[1] *[1]Nottingham University Hospitals NHS Trust, United Kingdom; [2]School of Clinical Sciences, University of Nottingham, United Kingdom.*

Background: There are few published data on incidence and outcome of acute kidney injury (AKI) in the United Kingdom since the widespread use of RIFLE and AKIN criteria. We constructed and analyzed a four year retrospective database of AKI for Nottingham University Hospitals NHS Trust (NUH), one of the largest acute NHS hospitals in the U.K.

Methods: For every patient >16 years admitted to hospital and requiring an overnight stay between 31 March 2007 and 31 March 2011, we scrutinized all serum creatinine results during the admission using algorithms operating within the hospital computer systems. Primary analyses used AKIN criteria to detect and stage AKI, taking baseline creatinine to be the lowest serum creatinine from 7-365 days prior to admission. Where no baseline creatinine existed, a theoretical value was applied (based on GFR 75mL/min). Only the highest stage of AKI episode during an admission was counted. For secondary analyses we applied RIFLE and KDIGO criteria; we also compared the use of different baselines, including average creatinine from 7-365 days prior to admission. Main outcome measures were in-hospital mortality, length of stay and fall in GFR from baseline with follow-up of >1 year post-discharge. We are undertaking subset analyses for different specialties and demographic groups.

Results: Mean number of qualifying admissions per year was 99,571 (95,475-103,913). Using AKIN criteria, incidence of AKI was 5.20% stage 1, 1.45% stage 2, 0.95% any stage 3; 0.15% required acute renal replacement therapy (RRT). Percentage of each AKIN stage detected from admission creatinine (i.e. 'community acquired') was 69.8% of stage 1, 87.8% of stage 2, 79.9% of stage 3. Average length of stay: 14 days (stage 1), 15 days (stage 2), 16 days (all stage 3), 30 days (stage 3 with RRT). In-hospital mortality for AKIN stage 1,2,3 was 16.3%, 29.5% and 36.1% respectively.

Conclusions: We have compiled and analyzed one of the largest single centre datasets of AKI in the U.K. In-hospital mortality and length of stay increase with AKIN stage. Most AKI was 'community acquired' but 30% of stage 1 AKI developed after admission.

Funding: Private Foundation Support

SA-PO007

Low Preoperative Hepcidin Concentrations in Urine and Plasma as Risk Factors for Mortality after Cardiac Surgery: A Pilot Study

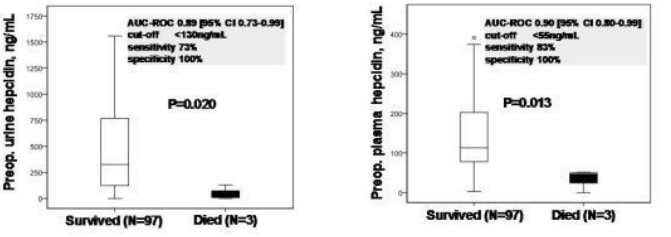
Anja Haase-Fielitz,[1] Michael Plass,[2] John R. Prowle,[3] Peter R. Mertens,[1] Mark E. Westerman,[4] Rinaldo Bellomo,[3] Michael Haase.[1] *[1]Nephrology, Otto-von-Guericke University, Magdeburg, Germany; [2]Anesthesiology, German Heart Center, Berlin, Germany; [3]Intensive Care, Austin Hospital, Melbourne, Australia; [4]Intrinsic LifeSciences, La Jolla.*

Background: Hepcidin regulates iron absorption and recycling and is central to host defence, protection from reactive iron species, and is a biomarker of iron-related pathophysiology. Here, we assess the value of hepcidin measured preoperatively for the prediction of in-hospital mortality and renal outcomes.

Methods: We studied 100 adult patients undergoing cardiac surgery in the control arm of a randomized controlled trial. Plasma and urine were sampled before induction of anesthesia and hepcidin-25 was quantified by cELISA. Renal outcomes were acute kidney injury (AKI, defined by RIFLE) and acute dialysis. Variables potentially influencing hepcidin expression were investigated.

Results: Low preoperative hepcidin concentration in urine (15.3 [0-129.1] ng/mL) and in plasma (49.2 [0-52.2] ng/mL) were observed in patients who died in the hospital (Figure 1). Preoperative urine and plasma hepcidin predicted in-hospital mortality (Figure 1 - Box). However, preoperative serum creatinine did not predict mortality (AUC-ROC 0.50 [0.10-0.94]). Further, at this time point, urine and plasma hepcidin as well as serum creatinine did not distinguish patients with acute dialysis from those without (urine: AUC-ROC 0.62 [0.38-0.86], plasma: AUC-ROC 0.63 [0.34-0.91], creatinine: AUC-ROC 0.61 [0.22-0.99]). Preoperative renal function and hemoglobin did not correlate with hepcidin indices whereas plasma markers of inflammation did (plasma IL-6, CRP).

Conclusions: Low preoperative hepcidin may be a risk factor for in-hospital mortality. Findings should be validated in larger patient cohorts with greater number of events.



Funding: Pharmaceutical Company Support - Intrinsic LifeSciences

Non-Steroidal Anti-Inflammatory Drugs Associated with Pediatric Acute Kidney Injury

Mark D. Poirier, Kevin C. Abbott. *Nephrology, Walter Reed National Military Medical Center, Bethesda, MD.*

Background: Non-steroidal anti-inflammatory (NSAID) medications can induce two (2) different forms of acute kidney injury: hemodynamically mediated and acute interstitial nephritis. It has been shown previously in adults that volume depletion, in the setting of taking NSAIDs can lead to acute kidney injury. The studies done to date involve adults and to the best of our knowledge there has not been any description of NSAIDs in the pediatric population to date. We hypothesized that NSAIDs are associated with pediatric acute kidney injury.

Methods: We conducted a retrospective study of the entire Department of Defense (DoD) database in which we identified patients less than 18 years of age receiving a prescription for an NSAID between the dates of September 1, 2001 through December 31, 2009 in an outpatient setting. A separate search for pediatric acute kidney injury (pAKI), defined as a 50% increase in the serum creatinine above the baseline, in a cohort of patients less than 18 years of age was also conducted n the same DoD database between the dates January 1, 2011 through January 1, 2011. We excluded patients with no serum creatinine measurements, evidence of AKI without a known baseline, neonates or history of prescriptions written for NSAIDs.

Results: A total of 10,065 outpatient prescriptions for NAIDs were identified in the pediatric cohort. There were also a total of 5,540 (55%) cases of AKI associated with pediatric acute kidney injury with all of these receiving the NSAID prescription within 90 days of the pAKI. The odds ratio for developing pAKI was 3.373 (95% CI 1.74-6.55) and a p value < 0.0001. In a separate sub-population analysis, African Americans and males prescribed NSIADs had odds ratios of 2.22 (95% CI 1.23-3.91, p value <0.0001) and 2.33 (95% CI 1.32-4.11) respectively.

Conclusions: In a pediatric cohort identified from a DoD database, NSAIDs were associated with acute kidney injury and the association was ore pronounced in African American males. Our results suggest that NSAIDs, currently known to be nephrotoxic for certain adult populations, may also have similar toxic effects in children and therefore may need to be prescribed with more caution.

SA-PO009

Fluid Balance during Renal Replacement Therapy Affects Mortality in Critically Ill Patients Marzena Wojewodzka,[1,2] Jie Teng,[1,3] Dehua Gong,[1,4] Claudio Ronco,[1] Dinna N. Cruz.[1] *[1]IRRIV, St Bortolo Hospital, Italy; [2]Medical University, Poland; [3]Fudan University, China; [4]Jinling Hospital, China.*

Background: Among critically ill patients with severe AKI, fluid overload (FO) of >10-20% of body weight at RRT initiation is associated with poor outcomes in many studies. However, fluid balance during RRT itself may be equally important, and few studies have addressed this aspect. Our aim was to evaluate the impact of the sum of fluid balance before and during RRT on hospital mortality.

Methods: We studied 99 patients (mean age 64 yrs; 78%M) with severe AKI treated with continuous RRT in the ICU. We recorded cumulative fluid balance (CFB) from ICU admission to RRT initiation (A), and during the entire duration of RRT (B). Total FO was calculated as (A+B)/weight x 100%. Patients were divided into 2 groups: total FO<20% and FO≥20%. Hospital mortality was compared using survival curve analysis. Multivariable analysis was performed using Cox regression adjusting for sepsis and CKD.

Results: There were 63 patients in the FO≥20% group, and 36 in FO<20%. The FO≥20% group had a higher proportion of sepsis (27% vs 8%, p=0.04) and CKD (70% vs 50%, p=0.06). This group had significantly higher CFB both before and during RRT (Fig. 1). Notably, the FO<20% group had negative CFB during RRT. The total FO≥20% group had significantly higher 28-day hospital mortality (p=0.046, Fig. 2). This remained significant after adjusting for sepsis and CKD (adjusted HR 2.23, 95%CI 1.08-4.60). Similarly, FO≥20% during RRT was associated with higher mortality (adjusted HR 2.89, 95%CI 1.11-4.32).

Fig.1. Cumulative fluid balance: total, pre- and during RRT

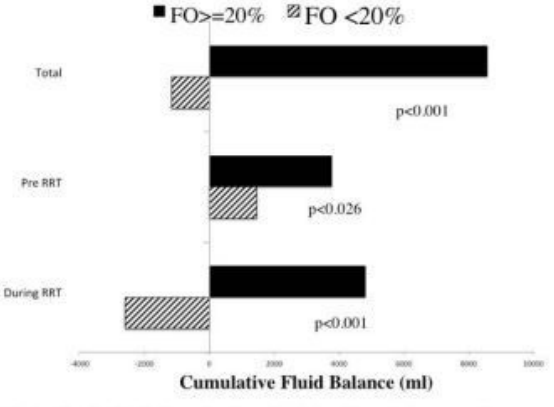

Fig.2. Total Fluid Overload and 28 day hospital mortality

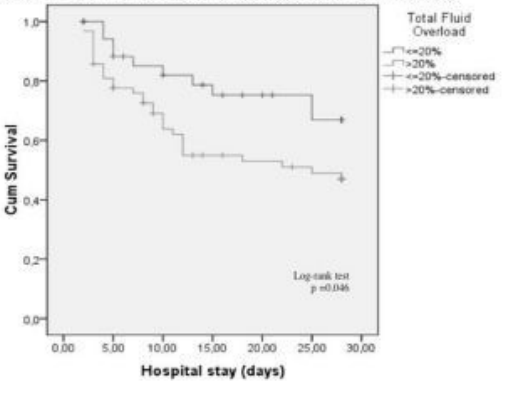

Conclusions: This is the first study examining the effect of fluid overload both before and during RRT. More fluid overload, both in total and during RRT, is associated with increased hospital mortality. This highlights the importance of adequate fluid removal during RRT, in addition to timely RRT initiation.

SA-PO010

AKI Biomarkers Remain Elevated 5-8 Years Following AKI due to Cardiac Surgery in Children Donna J. Claes, David S. Cooper, Michael R. Bennett, Qing Ma, Catherine D. Krawczeski, Stuart Goldstein. *Center for Acute Care Nephrology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Novel biomarkers can predict AKI after cardiac surgery (CPB-AKI). Emerging evidence shows AKI increases risk for future CKD, yet no studies assess novel urinary biomarkers long-term after CPB-AKI.

Methods: We assessed for CKD and urinary NGAL, IL-18, KIM-1 & L-FABP in 14 pts (mean age 8.6±1.6yr) who had pRIFLE-I (n= 10) or –F (n=4) (SCr-based) within 24 h post-CPB from 2004-2007 (mean follow-up 6.5 +/-0.8 yr) and compared baseline characteristics to pts with pRIFLE-I or –F from the same AKI study who were not readily available for follow-up.

Results: Study pts who had history of pRIFLE-I were older (median age 1.3 vs 0.5 yrs, p=0.037), had higher peak SCr (median 0.75 vs 0.6 mg/dl, p=0.0004), and longer CPB time (164 vs 100 min, p=0.04) than non-study pRIFLE-I pts. At follow-up, study pts had normal urine microalbumin to creatinine ratios (median 10.53 mcg/mg, IQR 4.92-17.03), Schwartz eGFR (median 114 ml/min/1.73m2, IQR 95-137) & were normotensive (mean SBP 100, SD 6.67; mean DBP 59, SD 10). 4 pts were on anti-hypertensive meds for afterload reduction. We compared follow-up biomarkers to pre-CPB & 24 hour urinary biomarker values of an independent cohort previously reported in the literature (median and IQR are provided unless noted):

	NGAL (ng/ml)	IL-18 (pg/ml)	KIM-1 (pg/ml)	LFABP (ng/ml)
Baseline, no AKI (n=160)	8.5 (4, 12.5)	1.2 (0, 8)	193.9 (83.9, 301.4)	7.3 (2.3, 27.4)
Baseline, AKI (n=54)	16 (8, 23)	0.9 (0, 12)	250 (84, 399)	8.8 (3.7, 31)
24 h, no AKI (n=160)	12 (5, 30)	10 (0, 29.3)	373.42 (150.5, 753.7)	77.1 (16, 234.4) n=150
24 h, AKI (n=54)	99 (35, 206)	50 (27, 100)	1010 (668, 1589)	244.1 (132.7, 590.6) n=50
5-8 yrs later, AKI (n=14)	9.13 (5.37, 20.73)	56.9 (41.1, 77.3)**	473.43 (256.6, 686.6)***	8.87* (3.68)

*mean, SD,** p< 0.0001, ***p = 0.0192 as compared to Baseline AKI (Wilcoxon Rank Sum)

Conclusions: In this follow-up of a small cohort of children with post-CPB AKI, we observed 1) persistent urinary IL-18 & KIM-1 elevation and 2) minimal evidence of classic CKD signs. We suggest novel urinary biomarkers could serve as a more sensitive marker of chronic kidney injury.

SA-PO011

Urinary Biomarkers and Association with Recovery from Severe AKI Rahul Agarwal, Divakar Jammalamadaka, Bita Fakhri, Chirag R. Parikh, Steven G. Coca. *Yale School of Medicine, New Haven, CT.*

Background: Few studies have examined the ability of urinary biomarkers to associate with recovery from AKI. We hypothesized that urinary biomarkers of kidney injury (NGAL, IL-18) or repair (YKL-40) would be associated with renal recovery in patients with severe AKI.

Methods: We prospectively enrolled 48 patients admitted at Yale New Haven Hospital with severe AKI (AKIN Stage 3). Daily morning urine samples were collected (until recovery up to max of 9 days). Levels of urinary YKL-40, NGAL, and IL-18 were measured. The primary exposures were the concentrations of the biomarkers on the first, last, and average daily values of the biomarker during enrollment. The primary outcome was renal recovery at discharge and was classified as "complete" if SCr ≤1.4 mg/dL, "partial" if 1.4 < SCr < 4 mg/dL and "non-recovery" if SCr ≥ 4mg/dL or death.

Results: Sixteen patients recovered completely, 18 recovered partially, and 14 did not recover. Mean time to partial recovery from the first sample collection was 6.7 ± 10 days and mean time to complete recovery was 10 ± 9 days. Median values of only the last and average YKL-40 (p=0.01 and 0.02) and NGAL (p=0.02 and 0.007) were significantly higher in patients that did not recover from AKI, compared to those that experienced partial or complete recovery (Figure 1). The upper tertiles of the last (RR 8, 95% CI 1.1-56.8) and average (RR 9, 95% CI 1.3-63.0) YKL-40 values were associated with a greater risk of non-recovery, as were the upper tertiles of the last (RR 9, 9% CI 1.3-63.0) and average (RR 8, 95% CI 1.1-56.8) NGAL values. The AUCs for first, last and average YKL-40 for non-recovery were 0.61, 0.77, and 0.77 respectively, 0.76, 0.78, and 0.79 for NGAL, and 0.62, 0.66, and 0.67 for IL-18.

Conclusions: High values of YKL-40 and NGAL appear to be associated with non-recovery from severe AKI. Larger studies will need to confirm these findings.

Outcomes of Dialysis after Continuous Flow Left Ventricular Assist Device (LVAD) Implantation John J. Dillon,[1] Salil V. Deo,[2] Lyle Joyce,[2] Amy W. Williams,[1] Robert C. Albright,[1] Margaret M. D'Uscio,[1] Richard C. Daly,[2] Tal Hasin,[3] Michelle M. O'Shaughnessy,[1] Sudhir S. Kushwaha,[3] John Stulak,[2] Barry A. Boilson,[2] Soon J. Park.[2] *[1]Division of Nephrology & Hypertension, Mayo Clinic; [2]Division of Cardiovascular Surgery, Mayo Clinic; [3]Division of Cardiology, Mayo Clinic, Rochester, MN.*

Background: Continuous flow LVADs, such as the HeartMate II, are now an established treatment option for patients with severe heart failure. The FDA approved the continuous-flow HeartMate II LVAD as a bridge to transplantation in 2008 and as destination therapy in 2010. Acute or chronic renal failure, requiring dialysis, may occur after LVAD implantation.

Methods: One hundred twenty-eight patients underwent HeartMate II implantation at our institution between February 2007 and June 2011. We report the outcomes of those who required dialysis. Follow up was through December 2011.

Results: Twenty-one patients (16%) required dialysis after LVAD implantation. Three of these had received CVVH for a median of 2 (range 2-7) days prior to LVAD implantation. The initial post-LVAD dialysis was CVVH for 19 patients, hemodialysis for 2. Although continuous flow LVAD patients have little or no pulse, this was not a barrier to dialysis. The median time from LVAD implantation to dialysis was 3 (range 0-1048) days. Among 10 patients (48%) who recovered renal function, 8 (80%) survived to last follow up with a median survival > 536 (range 39-1184) days. Among 11 who did not recover renal function, 2 (18%) survived to last follow with a median survival of 36 (range 1-915) days (P<0.01 vs those who recovered renal function.) Among those who recovered, the median time to renal recovery was 17.5 (range 1-220) days. Only one patient recovered renal function after 45 days. Five patients required outpatient dialysis and 4 developed ESRD.

Conclusions: Renal failure, requiring dialysis, is not uncommon after LVAD implantation. We demonstrate that this can be done successfully despite the continuous flow nature of current devices. Almost half of our patients recovered renal function, most with good outcomes. When renal recovery occurred, it usually happened within 45 days. Nineteen % of those requiring dialysis developed ESRD.

SA-PO013

Delayed AKI Referral and Mortality: A Single Centre UK Post NCEPOD-AKI Audit Azharuddin Mohammed, Simon Fletcher, Sunil Daga. *Nephrology, University Hospital Coventry and Warwickshire, Coventry, United Kingdom.*

Background: 2009 UK NCEPOD AKI National Clinical Enquiry into Patient Outcome and Death-Acute Kidney Injury) report identified delayed referral (LR) as an area of concern and early renal referral (ER) recommended (NICE CG 50).We looked into change in practice pattern of AKI referral post NCEPOD-AKI and mortality outcome.

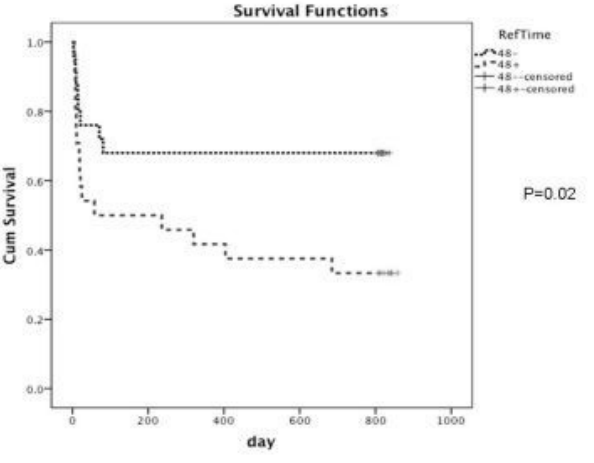
Methods: All inpatient AKI nephrology referrals at a single UK university hospital over 6 weeks studied. Data collected using 1) referrer interview, clinical assessment 2) CRRS(IT)-lab results and clinic letters. Only new referrals with raised creatinine (Cr) and not under renal team included. We excluded all CKD patients under nephrologists, referrals for electrolyte/acid base disorders, dialysis and kidney transplantation patients. Referrals grouped into ER<48 hours and LR >48 hours. Mortality analysed.

Results: 49(n=) referrals included, M:F at 63.3 Vs 36.7%. Median age 65.5 years (16-95). 52% had baseline CKD, 44% HTN, 24% DM, 18% proteinuria >500mg/d, 68% septic and hypovolemic. Mean referral Cr was 362 (umol/L). Fisher exact test used for categorical and t-test for continuous data. Overall 30 day mortality was 34.6% with ER: LR at 24 Vs 46 % (RR=1.9). Mortality groups showed significant differences in length of hospital stay, referral time and mean referral Cr, despite equal RF scores.

Demographics of AKI mortality group

	< 48 hours	> 48 hours	p=
Median Age	68.3	75.1	NS
Mean AKI risk score	3.8	4.4	NS
Mean length of hospital stay	1	9.4	<0.01
Mean days for AKI referral	0.6	6.3	0.01
Mean referral Cr	305	380	0.02
Overall mortality%(n) 30-day	24(6)	46(11)	0.13
2 years	66(14)	66(14)	0.02

30-day mortality was high in LR but not statistically significant (small n=). Long term survival in LR is significantly poor at 2 years (p=0.02).



Conclusions: LR has significant long term mortality. ER may allow treatment optimization, reduce complications and risk of death. Electronic prompt system may improve AKI care.

SA-PO014

A Collaborative Approach to Kidney Biomarker Qualification Joe Keenan,[1] Patrick T. Murray,[2] Frank Dieterle,[3] Ralf Schindler,[4] Scott H. Adler.[5] *[1]SAFE-T Consortium, Argutus, Dublin, Ireland; [2]SAFE-T Consortium, UCD Mater Hospital, Dublin, Ireland; [3]SAFE-T Consortium, Novartis AG, Basel, Switzerland; [4]SAFE-T Consortium, Charite Hospital, Berlin, Germany; [5]SAFE-T Consortium, Astrazeneca, Wilmington, DE.*

Background: A European consortium (SAFE-T) was established in 2009 consisting of 12 pharmaceutical companies, 3 SMEs and a number of hospitals with the objective of providing a data submission package to the Health Authorities to allow for the qualification of biomarkers to monitor drug induced kidney injury. The working plan of the consortium is to perform a first phase exploratory study of a larger list of candidate biomarkers through a number of healthy volunteer and drug induced kidney injury (DIKI) clinical cohorts. Following statistical assessment of these exploratory studies SAFE-T will dismiss certain candidates that do not meet performance criteria and then perform a larger confirmatory DIKI study, the results of which are intended to serve as a convincing submission package for the qualification of a number of key kidney markers with the health authorities.

Methods: SAFE-T have established a candidate list of 22 most promising kidney biomarkers assembled from an extensive literature search and graded accordingly. Assays have been validated at 4 sites for all of the 22 markers (some markers using dual technology i.e. both microtitre ELISA and Luminex). A healthy volunteer cohort of samples has already been assessed. Clinical samples from four studies are being collected. 1. Cisplatin Nephrotoxicity 2. Acute Glomerulonephritis (GN) 3. Contrast Media 4. Transplantation study.

Results: Healthy volunteer data will be presented. Normative ranges of the markers will be presented. Performance of all 22 markers in an interim analysis of the key Cisplatin, acute GN and Contrast Media study cohorts will be assessed, presented and discussed. SAFE-T will discuss critical aspects of this biomarker qualification, such as using an adjudication committee to compensate for imperfect gold standards to diagnose kidney injury. Furthermore, the decision process for advancing successful biomarkers as well as failing unsuccesful ones will be discussed.

SA-PO015

A Need for New Acute Kidney Injury Classification in Patients with Pre-Existing Chronic Kidney Disease Nitin V. Kolhe, Richard J. Fluck, Chris W. McIntyre, Nigel Lawson, Nicholas M. Selby. *Department of Renal Medicine, Royal Derby Hospital, Derby, Derbyshire, United Kingdom.*

Background: Current AKIN classification for diagnosing AKI performs less well in patients with pre-existing chronic kidney disease (CKD). Using a subset of patients with background CKD from a large group of prospectively identified patients with AKI we aimed to test different creatinine thresholds for AKI staging and correlate these with mortality, to help guide future strategies for AKI classification.

Methods: All episodes of AKI occurring in the period September 2010 - October 2011 in Royal Derby Hospital were identified by a hospital wide, real-time electronic reporting system. We extracted cases of AKI who had abnormal baseline creatinine values along with demographic, outcome and hospital coding data. AKI was then reclassified using several different methods, testing both absolute increase and percentage increase over baseline. The different AKI models were then compared with current AKIN criteria with respect to the strength of the associations between increasing AKI stage and mortality.

Results: During the study period we identified 999 patients with AKI who had pre-existing CKD (1123 episodes of AKI in total). 198 died during their index admission (17.6% mortality). The mean age at onset of AKI was 78yrs and the mean baseline creatinine was 168μmol/L. AKIN classification resulted in very few patients in AKI stage 2 and proportionally more in stage 3; the higher AKI stages were not differentiated by higher mortality rates. A model using absolute rises in creatinine over baseline (table 1) produced improved associations between increasing AKI stage and increasing mortality rates.

Creat. rise from baseline	No. of patients	In hospital mortality	30 day mortality
27-44μmol/L (stage 1)	301 (26.8%)	24 (8%)	29 (9.6%)
45-88μmol/L (stage 2)	405 (36.1%)	56 (13.8%)	64 (15.8%)
≥89μmol/L (stage 3)	417 (37.1%)	118 (28.3%)	122 (29.3%)

Table 1

Conclusions: The optimal method to classify AKI in patients with background CKD remains uncertain although it appears that the current AKIN staging may need to be adapted. Methods that employ an absolute rise in creatinine rise over baseline may be more predictive of outcomes in this group.

SA-PO016

Validation of KDIGO AKI Definition in AKI Population with Various Renal Parenchymal Injuries Rong Chu, Gang Liu, Cui Li, Li Yang. *Renal Division, Peking University First Hospital, Beijing, China.*

Background: The current definition for acute kidney injury (AKI) mainly comes from the ICU patients and reflects the course of acute tubular necrosis (ATN). This study aimed to investigate whether the KDIGO AKI definition is applicable for the AKI population with various acute renal parenchymal injuries.

Methods: Patients who were pathologically defined as diffuse renal parenchymal acute injuries throughout 2011 were enrolled in the study. The pathological changes include cellular crescentic glomerulonephritis (CCGN), ATN, acute interstitial nephritis (AIN), and acute thrombotic microangiopathy (TMA). Changing profile of serum creatinine (Scr) and urine volume throughout the disease course was analyzed in each individual case. 2012 KDIGO AKI definition was applied to recognize patients with AKI, acute kidney disease (AKD), and non-AKD.

Results: One hundred and thirty-nine patients, 77 men and 62 women, aged 45±16y, met the enrollment criteria, with CCGN in 44, ATN in 33, AIN in 53, and TMA in 9 cases. One hundred and twenty-six patients (91%) conformed to AKD, among which 82 (59%) were defined as AKI, with 20 cases at stage 1 (24%), 4 at stage 2 (5%), and 58 at stage 3 (71%). There was no difference of gender or age among cases with AKI, non-AKI-AKD and non-AKD. AKI patients had the highest level of Scr at biopsy ($p<0.001$) and the longest hospitalization time (33±19, 18±9 and 17±8 days, $p<0.001$) among the three groups. AKD definition recognized 91% of CCGN, 94% of ATN, 94% of AIN, and 56% of TMA. AKI was diagnosed in 66% of CCGN, 70% of ATN, 52% of AIN and 22% of TMA. Non-AKI-AKD took more part in AIN and TMA than the other two groups. For those who did not meet the AKI definition, 63% had less rapid Scr increase than the proposed criteria, 37% already reached the peak of renal dysfunction while the first Scr information was collected.

Conclusions: KDIGO AKD definition detects most of the patients that have diffuse acute renal parenchymal histological injuries, while the AKI definition recognizes patients who have more severe renal dysfunction and need longer time for hospitalization treatment. The applicable capacity of AKI definition varies with different pattern of histological injuries.

Funding: Government Support - Non-U.S.

SA-PO017

The Use of Urine Dipstick and Lab Urinalysis within 24 Hours of Admission in the Emergency Department in Three Irish Teaching Hospitals Limy Wong,[1] Frank J. O'Brien,[2] Sean F. Leavey,[2] Marie Patricia Boyle.[2,3] *[1]Department of Nephrology, Beaumont Hospital, Dublin 9, Ireland; [2]Department of Nephrology, Waterford Regional Hospital, Waterford, Ireland; [3]Department of Emergency Medicine, Mater Misericordiae University Hospital, Dublin, Ireland.*

Background: The UK Renal Association, KDOQI and KDIGO guidelines recommend AKI risk assessment (serum biochemistry, urine dipstick and lab urinalysis). We audited guideline adherence in three large Irish teaching hospitals.

Methods: Serum creatinine, recent creatinine trends and performance of urine dipstick and lab urinalysis within 24 hours of admission was collected prospectively for 94 randomly selected medical patients in all three hospitals.

Results: Hospital 1

Mean age was 63.5 years (17-93). Mean plasma creatinine 107 μmol/l (28-929). Sixty-nine had normal renal function, 20 had AKI and acute on chronic kidney disease (CKD) and 5 had stable CKD. Urine dipstick was performed in 1 patient, lab urinalysis in 39 patients.

Hospital 2

Mean age was 64.5 years (19-96). Mean plasma creatinine 121 μmol/l (42-769). Sixty-nine had normal renal function, 17 had AKI and acute on chronic kidney disease (CKD) and 8 had stable CKD. Urine dipstick was performed in 24 patients, lab urinalysis in 43 patients.

Hospital 3

Mean age was 66.3 years (27-98). Mean plasma creatinine 96 μmol/l (36-693). Seventy-five patients had normal renal function, 4 had AKI and acute on chronic kidney disease (CKD) and 14 had stable CKD. Urine dipstick was performed in 2 patients, lab urinalysis in 65 patients.

Conclusions: Both urine dipstick and lab urinalysis were underutilised: urine dipstick–mean 5.6% (range 0–11.7%) and lab urinalysis–mean 38.4% (range 35.3–40.0%). Our results demonstrate suboptimal guideline adherence. A pilot clinical pathway was introduced in hospital 2 whereby the medical admission proforma was altered to formally document abnormal renal function and the performance of urine dipstick and lab urinalysis. Following clinical pathway introduction, 87 patients (93%) had urine dipsticks (25% initially) and 66 patients (70%) had lab urinalysis (46% initially). Our study suggests structured documentation proformas may facilitate adherence to good standards of clinical practice.

SA-PO018

Do Urine Eosinophils Have a Role in the Diagnosis of Acute Interstitial Nephritis? Angela K. Muriithi,[1] Samih H. Nasr,[2] Nelson Leung.[1] *[1]Division of Nephrology, Mayo Clinic; [2]Division of Anatomic Pathology, Mayo Clinic, Rochester, MN.*

Background: Urine eosinophils (UE) were shown to correlate with acute interstitial nephritis (AIN) but the three largest series that investigated the test characteristics did not use kidney biopsy as the gold standard. This study was undertaken to determine the ability of UE to diagnose AIN in patients with a renal biopsy.

Methods: We conducted a retrospective study of adult patients with biopsy-proven diagnoses from 1994 to 2011 and who had UE as part of their work-up. UE were tested using Hansel's stain. Results were compared using the 1% and 5% eosinophils of all urinary white blood cells cutoffs.

Results: Of the 566 patients, 322 were male. Median age was 61 years (range 18-91). Pyuria was defined as one or more white cell/HPF and was detected in 467 of 566 patients. AIN was diagnosed in 91 patients of whom 73 had drug-induced. UE were found in a variety of kidney diseases (Figure 1). Moving the cutoff from 1% UE to 5% UE decreased the sensitivity but increased the specificity (Table 1). Presence of pyuria did not affect the diagnostic characteristics. UE was no better at distinguishing AIN from acute tubular necrosis (ATN) as compared to other kidney diseases (Table 1).

Figure 1: Eosinophiluria in Kidney Disease

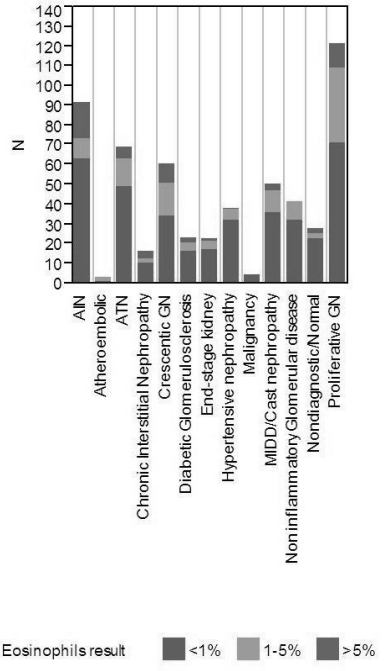

Table 1: AIN compared to all other diagnoses and to ATN alone

	Cutoff of UE	Sensitivity	Specificity	PPV	NPV
AIN compared to all other diagnoses					
All patients (566)	>1%	30.8%	68.2%	15.6%	83.7%
	>5%	19.8%	91.2%	30.0%	85.6%
Patients with Pyuria only (467)	>1%	38.4%	61.7%	15.6%	84.4%
	>5%	24.7%	89.3%	30.0%	86.5%
AIN compared to ATN					
All patients (160)	>1%	30.8%	71.0%	58.3%	43.8%
	>5%	19.8%	91.3%	75.0%	46.3%
Patients with Pyuria only (128)	>1%	38.4%	63.6%	58.3%	43.8%
	>5%	24.7%	89.1%	75.0%	47.1%

Conclusions: UE were found in a variety of kidney diseases besides AIN. Even at a cutoff of 5%, UE had poor sensitivity, specificity, PPV and NPV distinguishing AIN from ATN or other kidney diseases.

SA-PO019

Acute Interstitial Nephritis: A Current Perspective Angela K. Muriithi,[1] Nelson Leung,[1] Lynn D. Cornell,[2] Mary E. Fidler,[2] Sanjeev Sethi,[2] Samih H. Nasr.[2] *[1]Division of Nephrology, Mayo Clinic; [2]Division of Anatomic Pathology, Mayo Clinic, Rochester, MN.*

Background: Acute Interstitial Nephritis (AIN) is an important cause of Acute Kidney injury (AKI), especially in hospitalized patients. We conducted this study to provide a current perspective on its causes, outcome, and predictors of response to steroids.

Methods: We retrospectively studied 136 patients with biopsy-proven AIN seen at our institution between 1994-2011.

Results: The median age was 58 years with M:F ratio of 1. In 54% of patients, AIN occurred during hospitalization. AIN was suspected in 46% prior to biopsy. 28% had leukocytosis and 18% had eosinophilia. Only 6% had the "classical triad" of fever, rash and eosinophilia, all with drug-induced AIN. 47% of patients had pyuria, 33% eosinophiluria, 87% some proteinuria, 30% hematuria and 14% oliguria. Peak serum creatinine was 5.4 mg/dL and 20% required dialysis. 86% of patients were treated with steroids. Causes of AIN were drugs in 70%, autoimmune diseases in 20% (Sarcoidosis, Sjögren's, TINU and IgG4 disease), infections in 3%, other conditions in 3%, and unknown in 4%. Drug-induced AIN was due to antibiotics in 47% (most commonly penicillins and fluoroquinolones), proton pump inhibitors (PPIs), particularly Omeprazole, in 13%, NSAIDs in 10%, and other drugs in the rest. Of the 118 patients with available follow up, 39% had complete recovery, 42% partial recovery, and 19% no recovery by 3 months from renal biopsy. The mean time to recovery was 7.7 weeks. Of the 82 patients with drug-induced AIN treated with steroids, 38% achieved complete recovery, 41% partial recovery and 21% did not recover by 3 months. Drug-induced AIN was less likely to recover at 3 months compared to other types of AIN. For patients with drug-induced AIN treated with steroids, predictors of complete recovery were a shorter exposure to the culprit drug and a shorter interval between the development of AKI and start of steroid therapy.

Conclusions: The etiology of AIN is shifting: PPIs are emerging as an important contributor to this disease as are autoimmune diseases. Prompt discontinuation of the culprit drug and initiation of steroid therapy are essential in the management of drug-induced AIN.

SA-PO020

Long-Term Prognosis and Affecting Factors of Acute Interstitial Nephritis Cui Li, Tao Su, Rong Chu, Xiaomei Li, Li Yang. *Renal Devision, Peking University First Hospital, Beijing, China.*

Background: Acute interstitial nephritis (AIN) has abrupt response to prednisone treatment and is thought to have optimal prognosis in most cases. This study aimed to disclose the long-term outcomes of AIN and investigate the potential affecting factors.

Methods: Seventy-two patients, 17 men and 55 women, aged 47±13y, clinical-pathologically diagnosed as AIN from 2001 to 2011, were enrolled in this study. These patients were regularly followed up for 3 (1~11) years after renal biopsy and the etiology of AIN was re-evaluated and confirmed. Detailed clinical data was collected. Semi-quantitative scores for interstitial inflammation, fibrosis, tubulitis, and tubule atrophy were developed. The outcome of AKI was determined at 3m, 6m and 12m post biopsy by the assessment of eGFR, and the affecting factors were analyzed.

Results: Fifty patients had drug-induced AIN (DAIN), 22 developed Tubulointerstitial Nephritis and Uveitis syndrome (TINU), among which 13 (59.1%) were diagnosed as DAIN at the time of biopsy, but developed uveitis within one year after. Prednisone was prescribed to all the cases and cyclophosphamide was administered in 29% of the patients. Scr decreased acutely within one month after prednisone initiation, and reached relatively stable levels in 82% of patients by three months. One year after biopsy, 12.1% of the cases were with normal kidney function, 36.2% at CKD stage 2, 48.3% at stage 3, and 3.4% at stage 4. Correlation analysis showed that eGFR at 12m was correlated with age (r=-0.572, p=0.000), levels of peak Scr (r=-0.409, p=0.001), accompanied thyroid diseases (r=-0.289, p=0.028), and tubule atrophy (r=0.281, p=0.038). Patients with TINU tended to have worse outcome, with 19/22 (86.4%) developed CKD stage 3 and 4 [OR=7.4 (1.614-34.291), p=0.01].

Conclusions: AIN leads to CKD in 87.9% of the patients, which urges re-evaluation of the treatment strategy, and reinforces the importance of long-term follow up of the patients. Patients with TINU tend to have worse outcome and are easy to be miss-diagnosed since half of them develop uveitis months after AIN. Age, Scr peak, accompanied thyroid diseases, and tubule atrophy are related to the worse outcome of AIN.

SA-PO021

Long Term Outcomes in Biopsy Proven Acute Interstitial Nephritis Treated with Steroids Maria Prendecki, Anisha Tanna, Alan D. Salama, Frederick W.K. Tam, Tom Cairns, David Taube, H. Terence Cook, Neill D. Duncan, Charles D. Pusey. *Imperial College, London, United Kingdom.*

Background: There are no prospective randomised control trials describing the outcome of Acute Interstitial Nephritis (AIN) treated with steroids and retrospective studies are limited. AIN is a common pathology found in 9.5% of native renal biopsies at our centre in 2000-2010.

Methods: All patients with an acute interstitial inflammatory infiltrate on native renal biopsy were identified. Patients on maintenance steroids were excluded. Treated patients received oral prednisolone or IV methylprednisolone then oral prednisolone; dose and duration of treatment depended on clinician choice. Data were collected retrospectively and outcomes analysed according to treatment.

Results: 164 patients were steroid treated, 89 male, age 51.5 (range 16.4-85.3) years, follow up 41.8 (0.2-164) months. 31 were not treated, 20 male, age 55.2(19.2-87.8) years, follow up 31.3 (0.2-138) months. There was no difference in median eGFR at time of biopsy, 22.5(2-110) ml/min in the steroid group, 24.0(4-59) ml/min in untreated group (p=0.423 Mann-Whitney U test). 12.1% of steroid treated and 19.3% of untreated patients required renal replacement therapy (RRT) at the time of biopsy (p=0.32, χ^2).

Steroid treated patients showed greater improvement in eGFR.

Median Change in eGFR (ml/min)from biopsy to	Steroid treated	Untreated	p (Mann-Whitney U test)
4-6 months	+9(n=133)	+0.5(n=24)	0.0002
10-14 months	+9(n=124)	+3(n=22)	0.002
30-36 months	+11(n=77)	+2(n=11)	0.02
Last follow up	+11(n=164)	+1(n=31)	0.0001

Fewer patients were dependent on RRT at last follow up in the steroid group, 11.56% vs 38.71% (p=0.0004, χ^2).

46/56 patients with drug induced AIN were steroid treated, proportionately more than those with non-drug induced. The median change in eGFR at 6 months was +21 ml/min in the steroid group and -1ml/min in the untreated group (p=0.002 Mann-Whitney U test) and at 12 months, +24 ml/min in the steroid group and -4 ml/min in the untreated group (p=0.009 Mann-Whitney U test).

Conclusions: This retrospective study suggests a benefit of steroids in the treatment of AIN with improvement in eGFR and fewer patients progressing to end stage renal disease.

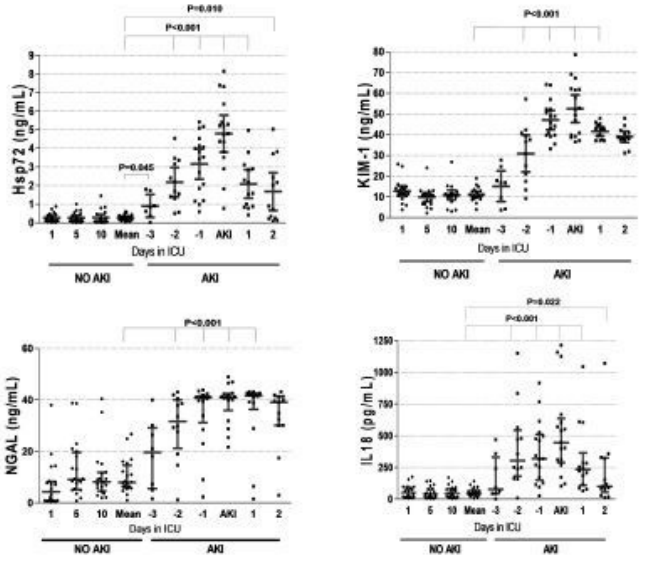
SA-PO022

Heat Shock Protein 72 Is a Novel Biomarker to Predict Acute Kidney Injury in Critical Care Patients Omar Israel Salas-Nolasco,[1] Jonatan Barrera-Chimal,[1,2] Gustavo Alejandro Casas-Aparicio,[1] Irizar S. Sergio Saul,[1] Ricardo Correa-Rotter,[1] Norma Bobadilla,[1,2] Luis E. Morales-Buenrostro.[1] *[1]Nephrology & Mineral Metabolism, Instituto Nacional de Ciencias Médicas y Nutrición S.Z., D.F., Mexico; [2]Molecular Physiology, Instituto de Investigaciones Biomédicas, UNAM, D.F., Mexico.*

Background: Several biomarkers have been proposed for early diagnosis of AKI in specific and predictable situations; however their performance in the intensive care unit (ICU) setting is unknown. Previously, we showed that Heat Shock Protein 72 (Hsp72) is an early and sensitive biomarker of AKI. This study was designed to evaluate the performance of urinary Hsp72 compared to NGAL, KIM-1, and IL-18 to predict AKI in ICU patients.

Methods: We recruited 37 critically ill patients with eGFR >60 ml/min/1.73 m2. Urine samples were collected every day during ICU hospitalization. AKIN criteria were used to define AKI. Urinary Hsp72, KIM-1, NGAL, and IL-18 were measured by ELISA in 17 patients with AKI since 3 days before and until two days after AKI development and 20 patients without AKI (urine from days 1, 5 and 10 after admission). Using ROC curve, we analyzed the biomarkers sensitivity and specificity at 2 and 1 days before AKI development.

Results: The Figure depicted the biomarkers behavior in ICU patients. The Table shows the biomarkers sensitivity and specificity.



Biomarker	48 hrs before (-2) AKI			24 hrs before (-1) AKI		
	Cut-off Value	AUC	Sensitivity/ Specificity(%)	Cut-off Value	AUC	Sensitivity/ Specificity(%)
Hsp72 (ng/mL)	0.5	0.98	100/90	1	0.99	94/100
KIM-1 (ng/mL)	16	0.91	83/95	26	1	100/100
NGAL (ng/mL)	20	0.89	83/90	20	0.91	88/90
IL-18 (pg/mL)	150	0.92	92/100	120	0.93	88/95

AUC= Area Under Curve

Conclusions: The earliest urinary biomarker was Hsp72 (48-h before AKI) and it was similar to KIM-1 (24-h before AKI). Moreover, Hsp72 and KIM-1 exhibited a better performance than NGAL and IL-18 to predict AKI development in ICU patients.

SA-PO023

Urinary Glutathione S-Transferase Does Not Predict Acute Kidney Injury in Patients Undergoing Cardiac Surgery Shay Mcguinness,[1] Rachael L. Parke,[1] Rinaldo Bellomo,[2] Frank Van Haren,[3] Michael J. Bailey,[4] Anja Haase-Fielitz,[5] Michael Haase.[5] *[1]ICU, Auckland City Hospital, New Zealand; [2]Intensive Care, Austin Health, Melbourne, Australia; [3]ICU, Canberra Hospital, Australia; [4]ANZIC Research Center, Monash University, Melbourne, Australia; [5]Nephrology, Otto-von-Guericke University, Magdeburg, Germany.*

Background: Previously, it was shown that alpha-GST (Glutathione S-transferase) - a proximal tubular damage marker - and pi-GST, a potential marker of distal tubule damage, may be useful in the prediction of acute kidney injury (AKI) progression. However, best predictive values were reported at the time of AKI diagnosis.

Methods: Here, we assessed the predictive value of early postoperatively measured alpha- and pi-GST concentrations in urine for the prediction of RIFLE-AKI, acute dialysis and in-hospital mortality in 474 adult patients undergoing cardiac surgery (NCT 00878956). Urine and plasma samples were collected at the time of ICU admission at three Australian and New Zealand hospitals between July 2009 and June 2011. Urinary alpha-GST and pi-GST levels were measured with commercially available enzyme-linked immunosorbent assay (ELISA) kits.

Results: 161 (34%) subjects developed AKI. Patients developing AKI required more dialysis (10% vs 1%, P<0.001) and had a higher in-hospital mortality rate (6% vs 2%, P=0.031) compared to patients without AKI. At ICU arrival, urinary alpha-GST and pi-GST were not able to predict subsequent development of AKI, the need for acute dialysis or mortality (Table 1). Also, serum creatinine measured at the same time had no value in the prediction of these clinical outcomes.

At 24 hours postoperatively, findings remained essentially unchanged for all assessed endpoints except for creatinine (AUC for dialysis: 0.78).

Conclusions: Urinary GST seems not to be useful for prediction of renal outcomes or mortality after cardiac surgery in adults.

	At ICU admission	24 hrs postoperatively
	AUC-ROC (95% CI)	AUC-ROC (95% CI)
RIFLE-AKI		
Alpha-GST	0.56 (0.51-0.62)	0.44 (0.38-0.49)
Pi-GST	0.57 (0.52-0.63)	0.54 (0.48-0.60)
Serum creatinine	0.57 (0.51-0.63)	0.68 (0.62-0.73)
Acute Dialysis		
Alpha-GST	0.62 (0.48-0.77)	0.45 (0.34-0.57)
Pi-GST	0.69 (0.54-0.84)	0.66 (0.53-0.79)
Serum creatinine	0.65 (0.52-0.78)	0.78 (0.64-0.91)
In-hospital mortality		
Alpha-GST	0.58 (0.45-0.72)	0.55 (0.40-0.71)
Pi-GST	0.55 (0.39-0.72)	0.64 (0.48-0.79)
Serum creatinine	0.49 (0.34-0.64)	0.60 (0.43-0.78)

Maximum Dose of N-Acetylcysteine and Prevention of Renal Dysfunction in Patients with Chronic Kidney Disease Undergone Surgical Coronary Intervention: A Prospective, Randomized, Double-Blind, Controlled Trial Eduesley Santana Santos,[1] Luiz Antonio Machado Cesar,[1] Ludhmila Abrahão Hajjar,[1] Jose Jayme Galvão De Lima,[1] Valéria A. Costa-hong,[1] Maria Heloisa M. Shimizu.[2] *[1]Hypertension Unit/Intensive Unit Care Cardiovascular Surgery, Heart Institute - School of Medicine University of Sao Paulo, Sao Paulo, Brazil; [2]LIM-12, School of Medicine University of Sao Paulo, Sao Paulo, Brazil.*

Background: The role of N-acetylcysteine (NAC) for the prevention of renal damage in experimental models as well as in diverse clinical settings is controversial. Disparate results may be caused by differences in dosing and route administration.

Methods: We test the safety and efficacy of maximum IV dose of NAC, as recommended for the management of acetaminophen overdose, on the incidence of renal dysfunction, in 50 patients with GFR <60/≥15 ml/min, undergone elective surgical coronary intervention (CI). Patients were randomized to receive either IV saline (n=26) or NAC (n= 24) in equal volume of saline (150 mg/Kg followed by 50 mg/kg) during surgery. End-points: renal dysfunction (AKIN criteria) during the first 72-h post-operation; serum NGAL and TBARS, need of dialysis and death (30-days post-operation).

Results: NAC was not associated with significant side-effects. There was one death in the NAC group (cardiac arrest, 48-h after operation) and none among controls and no patient needed dialysis. Baseline age, gender, race, diabetes, dyslipidemia, smoking, comorbidities, GFR, Euroscore, and number of grafts, on-pump surgery, transfusions, vasoactive drugs and diuresis (during and after operation) did not differ between groups. Renal dysfunction was observed in 64% (controls) and 27% (NAC) patients (p= 0.02) and no use of NAC was the only independent predictor of renal dysfunction (OR= 4.86, p=0.02). NGAL and TBARS were higher in patients not receiving NAC (=< 0.05).

Conclusions: Maximum IV dosing of NAC was well tolerated and was associated with reduction on the incidence of renal dysfunction in patients with CKD undergone surgical coronary intervention. More work is needed to determine the optimal dosing of NAC in this setting.

Factors Predicting Acute Renal Failure after Heart Surgery Bernhard M.W. Schmidt,[1] Katharina A. Foerster,[1] Jan T. Kielstein,[1] Tobias Schilling,[2] Axel Haverich,[2] Hermann G. Haller,[1] Tim Kaufeld.[2] *[1]Nephrology and Hypertension, Hannover Medical School, Hannover, Germany; [2]Heart, Thoracic, Transplant and Vascular Surgery, Hannover Medical School, Hannover, Germany.*

Background: Acute kidney injury (AKI) following cardiac surgery is a frequent complication and several risk factors increasing its incidence have already been characterized. The aim of this study was to compare the relative importance of patient factors and surgery associated factors to predict AKI after cardiac surgery.

Methods: 247 consecutive patients who underwent elective coronary artery bypass grafting, valve replacement/ repair or combined bypass and valve surgery were prospectively analyzed. Primary endpoint was the incidence of AKI as defined by the AKIN criteria.

Results: 30 (12.1%) of the 247 patients developed postoperative AKI. In univariate analysis BMI >30 kg/m² (OR 3.220, p=0.004) and CABG (OR 0.418, p=0.049), preoperative serum creatinine (OR 4.509, p<0.001), preoperative uric acid (OR 4.680, p=0.001), chronic kidney disease (OR 3.938, p=0.001) and diabetes (OR 2.609, p=0.017) were significantly associated with the incidence of AKI. Intraoperative parameters as operation time >300 minutes (OR 4.466, p=0.002), cardiopulmonary bypass (CPB) time >90 minutes (OR 4.360, p=0.001), aortic cross clamp (ACC) time above the median (OR 2.502, p=0.036) and the number of intraoperative transfused fresh frozen plasma (FFP) (OR 2.776, p=0.012) go along with a higher risk for postoperative AKI.

In the multivariate analysis uric acid levels above the median (OR 5.497, CI 95% 1.772; 17.054, p=0.003), cardiopulmonary bypass (CPB) time >90 minutes (OR 4.595, CI 95% 1.587; 13.305, p=0.005), body mass index (BMI) >30 kg/m² (OR 3.208, CI 95% 1.202; 8.562; p=0.02), and preoperative elevated serum-creatinine levels (OR 1.015, CI 95% 1.001; 1.029, p=0.04) were independently associated with postoperative AKI.

Conclusions: Serum uric acid is the most important risk marker for AKI after cardiac surgery. Notably, elevated uric acid levels are associated with a higher odds ratio than creatinine levels.

SA-PO026

Acute Kidney Injury Following Cardiac Surgery: A Prospective Observational Study to Assess Incidence, Severity, Risk Factors, and Mortality at a Single Center in India

Reetesh Sharma,[1] Salil Jain,[1] Vijay K. Kher,[1] Udgeath Dhir,[2] Naresh Trehan.[2] *[1]Division of Nephrology and Renal Transplant Medicine; [2]Medanta Heart Institute, Medanta the Medicity, Gurgaon, India.*

Background: Acute kidney injury (AKI) occurs in up to 30% of patients undergoing cardiac surgeries and is associated with increased morbidity and mortality. There is paucity of such data in our country. Hence this study was performed to assess the incidence of AKI following cardiac surgery and its associated risk factors, in the Indian context.

Methods: All patients age>18yrs undergoing cardiac surgeries were enrolled prospectively from July to October 2011. Patients on dialysis, renal transplants or with pre-existing AKI were excluded. Incidence and severity of AKI was defined by AKIN criteria. NKF/KDOQI definition was used to define CKD. Prevalence of risk factors such as age, sex, BMI, DM, HTN, dyslipidemia, CKD, past CVA, PVD, prior MI, periop AMI, use of cardiopulmonary bypass (CPB) and prolonged ventilation were assessed.

Results: 1,040 patients were enrolled with these baseline characteristics: 83.5% were males, mean age 58.2±10. 4yrs, mean BMI 25.6±4.3, DM 48.2%, HTN 57.5%, dyslipidemia 70%, CVA 36%, CKD 6.3%, PVD 0.9%, peri-op AMI 0.6% and use of CPB 24%. Overall incidence of AKI was 23.3% and 71.2% in patients with CKD. AKI was more severe in patients with higher CKD stages. Stage 3 AKI occured only in those with CKD3 or 4. Overall need for dialysis was 1.1% and 4.9% in AKI group. 8.5% of patients with CKD needed dialysis as compared to 4.1% without CKD. In multivariate risk factor analysis HTN (p=0.01), peri-op AMI (p=0.03), prolonged ventilation (p=0.01), CVA (p=0.01) and CKD (p<0.001) were found to be significantly associated with AKI whereas DM (p =0.12), PVD (p=0.13), use of CPB (p=0.4), prior AMI (p=0.07) were not significant. Overall mortality was 0.67% and 2.9% in AKI group. All mortalities were associated with AKI.

Conclusions: Incidence of AKI (23.3%) and mortality (0.67%) in cardiac surgery patients at our center in India is similar to other reported studies.We found that underlying CKD is the most significant risk factor for AKI in these patients in addition to HTN, past CVA, prolonged ventilation and pre-op AMI. Use of CPB did not increase the incidence of AKI.

SA-PO027

Risk Models of Acute Kidney Injury (AKI) in Cardiac Surgery

Marco Simonini, Elena Bignami, Chiara Lanzani, Elena Frati, Nunzia Casamassima, Elisabetta Messaggio, Paolo Manunta. *San Raffaele Scientific Institute, Milan, Italy.*

Background: AKI is a frequent complication of cardiac surgery. A large number of novel postoperative biomarkers have been proposed to assess the risk of AKI. However, there are neither preoperative biomarkers nor robust validated risk models that predict AKI. Endogenous Ouabain (EO) is an adrenal stress hormone with hemodynamic and renal effects. Our group have already reported that higher pre-operative EO levels are associated with a worse renal outcome after cardiac surgery. Our aim is to develop a new risk model of AKI using both clinical aspects and levels of EO as biomarker.

Methods: The primary outcome was AKI according to AKIN stage II. We built predictive risk model (CLIN-AKI) considering clinical variables (age, sex, preoperative ejection fraction, basal eGFR, surgery type, hypertension, diabetes, redo-intervention). A further risk score (CLIN-EO-AKI) was developed including preoperative EO values in CLIN-AKI score. These models were tested on 407 patients admitted for elective cardiac surgery and in a validation population of 219 patients.

Results: In both populations EO levels were confirmed strongly associated with incidence of AKI and clinical complication (total ICU stay and in-hospital mortality). AKI incidence according to EO tertiles were 2.8%, 8.3%, 20.3% and 0%, 5.9%, 8.2% in the two populations(p<0.001). To calculate CLIN-AKI risk score we considered β coefficients of logistic regression analysis for AKI. CLIN-AKI model has a good predicting power for AKI per se (AUC 0.81 – CI 95% 0.75-0.88). Adding the preoperative EO level to the clinical model AUC increased to 0.85 (CI 95% 0.79-0.91). We confirmed all these results in the validation cohort. Cumulative AUC were 0.79 (CLIN-AKI) and 0.85 (CLIN-EO-AKI). Inclusion of EO provided improved risk prediction over the clinical models alone (AUC difference 0,065, CI 95% -0.011 to 0.015, p <0.01).

Conclusions: Preoperative EO level is a powerful biomarker of AKI. Since elevated plasma EO levels are related to target organ damage (heart and kidney), incorporation of preoperative values in clinical model significantly improves predictive risk score.

SA-PO028

Mortality and Causes of Death in Patients with Acute Kidney Injury

Nicholas M. Selby, Richard J. Fluck, Chris W. McIntyre, Nigel Lawson, Nitin V. Kolhe. *Department of Renal Medicine, Royal Derby Hospital, Derby, Derbyshire, United Kingdom.*

Background: High mortality rates are well recognised in acute kidney injury (AKI). The exact mode of death in AKI remains under-studied, particularly in general hospitalised populations who represent the majority of those affected. We aimed to report causes of death in a large group of prospectively identified patients with AKI that may guide future strategies to improve patient outcomes.

Methods: A hospital wide, real-time electronic reporting system for AKI has been in place at Royal Derby Hospital since 2010. This system has good diagnostic accuracy (false positive rate 1.7%, false negative rate 0.2%). It generated a prospective database of all cases of AKI collecting demographic, outcome and hospital coding data automatically. Between Sept 2010 - Oct 2011 we extracted causes of death as recorded on the death certificate for those who died during hospital admission.

Results: During the study period there were 4949 episodes of AKI in 3930 patients. 861 died during their index admission (21.9% mortality). Median age was 80 (IQR 16) and 51% were male. Median Charlson co-morbidity score was 2 (IQR 2). Distribution across the AKIN stages were: 62% stage 1 AKI, 20.8% stage 2, 17.4% stage 3. 65% of AKI was acquired in the community. 7.5% were elective admissions.

Cause of death could be identified in 802 cases (93.4%). Three causes of death accounted for three quarters of mortality; sepsis (41%), cardiovascular disease (19.2%) and malignancy (12.9%). AKI was the primary cause of death in only 3% of cases. The median creatinine value prior to death was 168mmol/l (IQR 116). 76.2% of patients had not recovered renal function by the time of death (defined as serum creatinine less than 26μmol/l above baseline value). 88.1% of death certificates did not mention AKI in any part.

Conclusions: Mortality associated with AKI remains high, although this occurs due to concurrent acute illness. By identifying the major causes of death, it may be possible to target specific interventions to improve outcomes aimed not just at treating AKI but also the co-existing conditions. Examples would include care bundles for pneumonia with AKI and focussing on cardiac patients with AKI.

COMT Gene Variants in Patients with Severe Sepsis or Septic Shock: Results from the VISEP Trial#

Michael Haase,[1] Michael Oppert,[2] Anja Haase-Fielitz,[1] Melanie Naether,[3] Duska Dragun,[2] Wolf-hagen Schunck,[4] Michael Kiehntopf,[5] Frank Martin Brunkhorst.[6] *[1]Nephrology, OvG University, Magdeburg, Germany; [2]Nephrology and Intensive Care Medicine, Charite Campus Virchow, Berlin, Germany; [3]Knauer GbmH, Berlin, Germany; [4]Max Delbrück Center for Molecular Medicine, Berlin, Germany; [5]Clinical Chemistry and Laboratory Medicine, Friedrich-Schiller-University Jena, Germany; [6]Anesthesiology and Intensive Care Medicine, Friedrich-Schiller University Jena, Germany.*

Background: Adrenergic gene variants contributing to catecholamine-refractory septic shock and acute kidney injury (AKI) have not been investigated, yet. Catecholamin-O-methyltransferase (COMT) is a ubiquitous enzyme with co-dominant inheritance which is involved in systemic and renal catecholamine degradation. Recently, COMT LL carriers, coding for thermolabile COMT variant Val158Met with low enzyme activity, were identified to be at increased risk for vasodilatory shock and AKI in two independent cardiac surgery cohorts.

Methods: We hypothesized that in septic shock patients, COMT LL genotype occurs more frequently and affects outcomes. Data from patients with septic shock enrolled in the VISEP trial [1] (n=430) were analyzed. COMT genotyping was performed using PCR-based RFLP-assay.

Results: Distribution of COMT genotypes in septic shock patients (LL 30.0%, HL 47.2%, HH 22.8%) was different from that expected basing on pooled data from two independent cardiac surgery cohorts (LL 23.9%, HL 51.2%, HH 24.9%), P<0.05. However, LL carriers were not different from HL or HH carriers with regard to demographics, cause/severity of septic shock, dose and type of vasopressors, renal outcomes and 90day mortality, all P>0.2.

Conclusions: LL genotype seems to predispose to septic shock, however not to affect outcomes within a septic cohort.

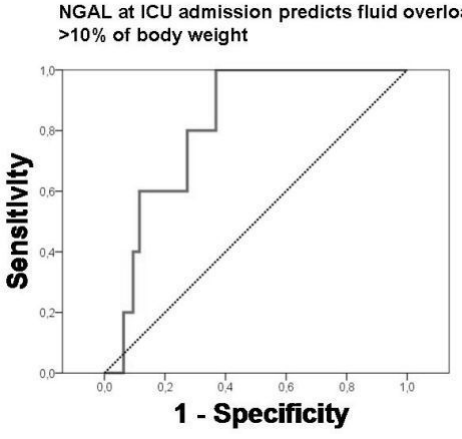
NGAL Predicts Postoperative Fluid Overload after Cardiac Surgery

Michael Haase,[1] Prasad Devarajan,[2] Michael Plass,[3] Rinaldo Bellomo,[4] Anja Haase-Fielitz.[1] *[1]Nephrology, Otto von-Guericke-University, Magdeburg, Germany; [2]Pediatrics and Develop. Biology, Cincinnati Childrens Hospital; [3]Anesthesiology, German Heart Center, Berlin, Germany; [4]Intensive Care, Austin Health, Melbourne, Australia.*

Background: Neutrophil gelatinase-associated lipocalin (NGAL), early measured after cardiac surgery, has been demonstrated to predict postoperative acute kidney injury (AKI). Fluid overload is a typical postoperative complication associated with increased mortality. Fluid overload potentially masks a subsequent acute renal function loss through dilution of creatinine and maintenance of urine output just above AKI-defining criteria.

Methods: We investigated the early postoperative value of NGAL - a marker of tubular damage - versus that of simultaneously measured serum creatinine to predict subsequent fluid overload. We studied 100 adult cardiac surgery patients in the control arm of a RCT. Severe postoperative fluid overload was defined as positive fluid balance>10% of preoperative body weight within 48hrs after surgery. Urine NGAL (ARCHITECT) and creatinine were sampled immediately after ICU admission.

Results: Severe postoperative fluid overload was present in 5% of patients with a mean positive fluid balance of 15.8±9.5L. Body weight-adjusted fluid balance predicted mortality (N=3) with AUC 0.91 (95%CI 0.76-0.99). Fluid overload correlated with length of stay in ICU (corr. coeff. 0.43; P<0.001). At ICU admission, urine NGAL predicted severe fluid overload (AUC-ROC 0.82 [95%CI 0.70-0.94]) and mortality (AUC-ROC 0.88 [95%CI 0.78-0.97]). Serum creatinine measured at the same time did not predict severe fluid overload (AUC-ROC 0.52 [95%CI 0.26-0.79] or mortality (AUC-ROC 0.61 [95%CI 0.16-0.99]).



Conclusions: Early NGAL-guided adjustments to fluid management may reduce organ edema after cardiac surgery. Our findings should be validated in larger patient cohorts.

Cystatin C at Admission in the ICU Predict Mortality among Elderly Patients

Maria Dalboni,[1] Beata Marie Redublo Quinto,[1] Julio Martin Monte,[1,2] Marcelino Durao,[1,2] Marcelo Costa Batista.[1,2,3] *[1]Nephrology, Universidade Federal de São Paulo, Sao Paulo, Brazil; [2]ICU - Nephrology, Hospital Israelita Albert Einstein, Sao Paulo, Brazil; [3]Nephrology, Tufts-New England Medical Center, Boston, MA.*

Background: Cystatin C has been used in the critical care setting in the evaluation of renal function. It has also been found to correlate with mortality. It is not clear whether this association is due to the occurrence of Acute Kidney Injury (AKI) or to some other mechanism. To evaluate whether serum cystatin C at intensive care unit (ICU) entry predicts AKI occurrence and mortality in critically ill elderly patients.

Methods: This was a prospective cohort study of critically illelderly patients (> 60 years old) without AKI at admission in the ICU (initially normalserum creatinine levels)**.** We evaluated 400 consecutive ICU patients, of whom 234 (58%) were selected, 45 (19%) developed AKI during the ICU stay according to AKIN criteria. We also evaluated the demographic and clinical characteristics of patients according to normality for serum cystatin C at ICU admission (≤ 0.96 and > 0.96 mg/dL).

Results: We observed that those patients on mechanical ventilation at admission were more prone to develop AKI (35.5%). Higher serum levels of cystatin C were more prevalent in patients longer ICU stay (6±16 vs. 4±6; p = 0.04). Interestingly, higher levels of cystatin C did not discriminate AKI occurrence (1.05±0.48 vs 0.94±0.36; p = 0.1). However, in logistic regression analysis, we observed that a higher cystatin C level was an independent predictor of mortality H.R. = 6.16; (95% CI 1.46 – 26.00; p = 0.01). In contrast, AKI was not associated with death. Additionally, in the ROC curves, cystatin C also provided a moderate and significant area (0.67; p = 0.03) compared to AKI (0.47; p = 0.6) to detect death.

Conclusions: We demonstrated that a higher cystatin C level is an independent predictor of mortality in critically ill elderly patients in the ICU, indicating that it could be used as a marker of poor prognosis in this population.

SA-PO032

TNF-α Plus IL-10 Low Producer Gene Predicted AKI and Death in Acute Kidney Injury (AKI)

Maria Dalboni,[1] Beata Marie Redublo Quinto,[1] Caren Cristina Grabulosa,[1] Edgar Ferreira Cruz,[1] Marcelo Costa Batista.[1,2,3] *[1]Nephrology, Universidade Federal de São Paulo, Sao Paulo, Brazil; [2]ICU - Nephrology, Hospital Israelita Albert Einstein, Sao Paulo, Brazil; [3]Nephrology, Tufts-New England Medical Center, Boston, MA.*

Background: Patients in ICU with SIRS have a high risk to development acute renal failure (AKI) and death.

Aim: To investigate whether genetic polymorphism of –308 TNF-α, -174 G>C IL-6 and 1082 G>A IL-10 gene may to predispose ICU patients with SIRS to development AKI and death.

Methods: In a prospective nested case-control study, we enrolled 672 ICU patients. Of them, 220 (33%) developed AKI (n = 220/ 33%) and 452 (67%) had not AKI, according to AKIN criteria. We measured serum creatinine, CRP, albumin and accessed genetic polymorphism to TNF-α, IL-6 e IL-10 in leukocytes.

Results: Patients who developed AKI had a higher APACHE score (p=0.0001), CRP levels (p=0.02) lower albumin (p=0.001) and were on mechanical ventilation (MV) (p=0.001). In the regression analysis, only APACHE (O.R. 1.07 C.I. 1.04 – 1.10; p=0.0001) and MV (O.R. 0.53 C.I. 0.31 – 0.90; p=0.02) remained as markers of risk for AKI. Patients who had higher APACHE and lower albumin had significantly death rates. We did no observe significant differences in the frequency of genotypes of TNF-α, IL-6 and IL-10 in respect to AKI or no AKI or death. To phenotypes, we observed 54% to low of TNF-α, 59% to intermediate of IL-10 and 75% to high producer of IL-6 gene in both groups. When we stratified by genotype combinations to the TNF-α and IL-10, we observed that TNF-α plus IL-10 low producer gene was more prevalent in patients whose occurred AKI and/ or death (54.3% vs. 33.3%; p=0.02). In regression analysis, adjusted by overall variables, TNF-α plus IL-10 low producer gene remain as risk factor for these outcome (O.R. 3.03, C.I. 1.34 – 6.86; p=0.008).

Conclusions: Although the phenotype of low of TNF-α and high producer of IL-6 in overall patients may lead to poor outcome and a pro-inflammatory state, these isolated polymorphisms did not predict AKI or death in our population. However, the combination of TNF-α plus IL-10 low producer gene predicted AKI and/or death in our population.

Hypoxia-Inducible Factor-1 alpha (HIF-1α) Haplotypes and Acute Kidney Injury (AKI) Following Cardiopulmonary Bypass (CPB)

Mary Celine R. Perianayagam,[1] Manjula Mahata,[2] Kuixing Zhang,[2] José Pablo Miramontes-González,[2] Fangwen Rao,[2] Hocine Tighiouart,[3] Orfeas Liangos,[4] Diana Kouznetsov,[5] Ron Wald,[6] Daniel T. O'Connor,[2] Bertrand L. Jaber.[1] *[1]Medicine, St. Elizabeth's Medical Center, Boston, MA; [2]Medicine, Center for Human Genetics and Genomics, La Jolla, CA; [3]Biostatistics Research Center, Tufts Medical Center, Boston, MA; [4]III. Medizinische Klinik, Klinikum Coburg, Coburg, Germany; [5]University of Massachusetts Memorial Medical Center, Worcester, MA; [6]St. Michael's Hospital, Toronto, Canada.*

Background: HIF-1α is a transcription factor regulating several genes in response to ischemia-reperfusion injury, a common cause of AKI. We examined whether 3 polymorphisms in the HIF-1α gene and their respective haplotypes predict development of severe AKI (>2-fold ↑ sCr or dialysis) or in-hospital death in patients undergoing CPB.

Methods: We tested this hypothesis in a prospective cohort study of 283 adults undergoing CPB at 4 acute care facilities. Genomic DNA was extracted from leukocytes. Using the HapMap genome browser for European populations, 3 SNPs (rs12435848, rs4899056 and rs2057482) were selected and genotyped with the TaqMan system. Haplotypes were imputed using the PLINK software.

Results: Tests for Hardy-Weinberg equilibrium showed no deviation from expected frequencies. Baseline characteristics did not significantly differ across genotypes, with a few exceptions. Of the 5 haplotypes identified, A-C-T, the second most frequent (12%) haplotype, was associated with development of severe AKI (>2-fold ↑ sCr or dialysis).

	>2-fold ↑ sCr or dialysis		>2-fold ↑ sCr, dialysis, or in-hospital death	
	Odds ratio (95% CI)	P value	Odds ratio (95% CI)	P value
HIF-1α A-C-T haplotype (per 1-copy increase)				
- Unadjusted	2.23 (0.87, 5.72)	0.095	1.75 (0.78, 3.93)	0.173
- Adjusted for age, sex and race	3.74 (1.39, 10.01)	0.009	2.47 (1.09, 5.63)	0.031
- Adjusted for age, sex, race, heart failure, surgery status, and CPB time	3.30 (1.23, 8.81)	0.017	2.29 (0.97, 5.39)	0.058

Conclusions: This study identifies a common HIF-1α A-C-T haplotype derived from 3 SNPs as a risk marker for post-CPB severe AKI. Additional studies are needed to confirm these findings.

SA-PO034

Perioperative Risk Factors and Clinical Predictive Score for Acute Kidney Injury Associated with Cardiac Surgery Nan Ye, Yan Zhang, Hong Cheng, Yi-Pu Chen. *Division of Nephrology, Beijing Anzhen Hospital, Capital Medical University, Beijing, China.*

Background: To develop a clinical score to predict the acute kidney injury (AKI) after cardiac surgery by incorporating the effects of all of its major risk factors.

Methods: a total of 3500 patients receiving cardiac surgery were divided into two groups, AKI and non-AKI group, based on AKI due to AKIN definition. The univariable analysis and logistic regression model were used to establish the predictive score.

Results: The derivation cohort consisted of 2385 patients and the validation consisted of 1115 patients. In derivation cohort, the rate of AKI was 40.5%, while rate of ARF requiring dialysis was 2.5%. In the validation cohort, the rate of AKI was 39.6%, while rate of ARF requiring dialysis was 1.4%. In the derivation cohort, the mortality rate was 5.6% for AKI patients, while 45.8% for ARF requiring dialysis. In the validation cohort, the mortality rate was 4.3% for AKI patients, while 68.8% for ARF requiring dialysis. Variables selected for the logistic regression model and then predictive score were the following: male (2 points), older age (increased 1 point with every 5 years increment from 60), diabetes mellitus (2 points), preoperative use of ACEI/ARB (1 point), eGFR (increased 1 point with every 10 decrements from 90 ml/(min•1.73m^2)), NYHA class 4 (3 points), CPB time>120min (2 points), intraoperative hypotension time>60min (2 points), postoperative hypotension time>60min (3 points), postoperative use of loop diuretics 60-100mg per day (2 points), postoperative use of loop diuretics>100mg per day (3 points), postoperative mechanical ventilation time>24h (2 points). The stratification of risk factors is as follows:low-risk (within 0-5 point), intermediate-risk (6-11 point), and high-risk (≥12 point). The frequencies of AKI were 20.7%, 44.3%, and 83.6% respectively. The score showed adequate discrimination for the derivation dataset and the validation sample as well as adequate calibration (P=0.305).

Conclusions: we developed a clinical predictive score for AKI after cardiac surgery. This predictive score presented good discrimination and calibration. It would help the clinicians to make decision for preventive intervention.

SA-PO035

Decreased Baseline GFR Is a Predictor of AKI after Off-Pump Cardiac Surgery Rachita Sethi Reddy, Michael F. Michelis, Nirav C. Patel, Maria V. DeVita. *Lenox Hill Hospital, New York, NY.*

Background: Acute kidney injury (AKI) is a serious complication of cardiothoracic surgery (CTS), with a 7-28% incidence increasing hospital length of stay, infections, dialysis and mortality. We previously reported on AKI in off-pump CTS patients, showing greater incidence in those with diabetes and postoperative complications. Since prior studies lacked a standard definition of AKI, we reanalyzed our data using the AKI Network definition. Our study is the first to specifically investigate risk factors for AKI in patients undergoing off-pump CTS, and the association between preoperative GFR and AKI as defined by established guidelines.

Methods: Using database entry points for The Society of Thoracic Surgeons Adult Cardiac Surgery Database, we performed a single-center, retrospective analysis on all off-pump CTS patients at Lenox Hill Hospital from June 2009 to January 2011. Extracted data included: age, sex, race, preoperative serum creatinine (SCr), postoperative peak SCr, comorbidities (diabetes, dyslipidemia, hypertension, peripheral arterial disease, cerebrovascular disease), urgent versus elective surgery, complications during postoperative period, use of ACEI/ARBs, mortality.

Results: Of the 441 patients in the database, 22% had AKI. Patients were grouped by baseline GFR ranges similar to CKD stages. Groups 1-4 had AKI rates of 21%, 15%, 31%, 53%, respectively. There were no CKD5 patients. Chi-squared analyses compared risk factors between patients with and without AKI. Patients with AKI were older ($p<0.01$), more likely to be diabetic ($p<0.01$), undergo urgent vs. elective surgery ($p<0.05$) and have postoperative complications ($p<0.02$), mainly atrial fibrillation and prolonged ventilation. The presence of multiple risk factors compounded a patient's risk of AKI ($p<0.01$). All other data points had no significant difference in predicting risk of kidney injury.

Conclusions: Incidence of AKI was linearly related to baseline GFR. Patients with AKI after off-pump CTS were older, had urgent surgery and other postoperative complications. Diabetics were twice as likely to have AKI. Finally, multiple risk factors compounded the risk of AKI.

SA-PO036

Risk Factors of Acute Kidney Injury after Coronary Artery Bypass Grafting and Mortality Nara Shin,[1] Sejoong Kim,[2] Ho Jun Chin,[2] Dong Wan Chae,[2] Ki Young Na.[2] *[1]Internal Medicine, Seoul National University Hospital, Seoul, Republic of Korea; [2]Internal Medicine, Seoul National University Bundang Hospital, Republic of Korea.*

Background: Acute kidney injury (AKI) after coronary artery bypass grafting (CABG) has been proved as an important and independent predictor of morbidity and mortality. The purpose of our study was to investigate the risk factors of AKI and the mortality associated with AKI in the patients who received CABG.

Methods: We conducted the retrospective observational study with electronic medical records. Patients undergoing elective CABG from 2004 to 2010 in Seoul National University Bundang Hospital were studied. The outcomes were the risk factors of AKI after CABG, and mortality.

Results: AKI by the definition of AKIN classification occurred in 304 patients among a total of 819 patients. After multivariate regression, male sex (OR 1.866, 95% CI 1.188-2.933, p=0.007), use of IABP (OR 2.278, 95% CI 1.285-4.039, p=0.005), combined valve operation (OR 1.831, 95% CI 1.056-3.175, p=0.031) and on-pump operation (OR 3.281, 95% CI 2.210-4.870, p<0.001) were the risk factors. In-hospital mortality (non-AKI group vs. AKI group=1.4% vs. 12.5%, p<0.001) and long-term mortality (10.1% vs. 28.6%, p<0.001) were high in the AKI group. There were differences between the survival group and deceased group in valve operation, emergency, use of IABP, except on-pump operation. After multivariate Cox proportional hazard model analysis, older age (OR 1.056, 95% CI 1.029-1.084, p<0.001), male sex (OR 1.920, 95% CI 1.181-3.121, p=0.008), high CRP (OR 1.081, 95% CI 1.024-1.142, p=0.005), and AKI (OR 1.928, 95% CI 1.249-2.976, p=0.003) affected the long term mortality. There were no meaningful relationship between albuminuria, CKD and long-term mortality.

Conclusions: Our study showed the independent risk factors of AKI and high mortality were as above. In-hospital mortality and long-term mortality were high in AKI group. After multivariate regression analysis, older age, male, high CRP and postoperative AKI affected the long term mortality. AKI is the important risk factor in long-term mortality in patients undergoing CABG after adjustment with CKD, albuminuria and other variables.

SA-PO037

The Additive EuroSCORE Predicts the Risk of Acute Kidney Injury Post Cardiac Surgery David A. Ferenbach,[1] Sharleen Hill,[2] David C. Kluth,[1] Jeremy Hughes.[1] *[1]Centre for Inflammation Research, University of Edinburgh, Edinburgh, United Kingdom; [2]Cardiothoracic Surgery, Royal Infirmary of Edinburgh, Edinburgh, United Kingdom.*

Background: The aetiology of Acute Kidney Injury (AKI) following surgery is complex. This study sought to identify the incidence and factors predicting post-operative AKI in cardiac surgery patients.

Methods: Demographic data, surgical procedure, medical co-morbidities and clinical course of 4651 cardiac surgery patients at the Royal Infirmary of Edinburgh between April 2006 and March 2011 was analysed. Pre-op and peak post-op creatinine levels were used to determine the presence and severity of AKI using the Acute Kidney Injury Network (AKIN) scoring system. The additive EuroSCORE was available for all patients as a validated scoring system for predicted operative mortality risk.

Results: Incidence & effect of AKI: 1862 of 4651 had a pre-op eGFR<60ml/min. The incidence of AKI stage I-III was 9.3% with dialysis required in 1.5% of cases. Any post-op AKI was associated with increased mortality (2%Þ18.9%, RR 9.4, p<0.0001) & hospital stay (9.6±0.3Þ18.6±1.3 days, p<0.0001)

Factors associated with AKI on univariate analysis were:Increasing Age, Diabetes, NYHA IV dyspnoea, Baseline eGFR<60ml/min, Hypertension, Female sex, Extra-cardiac atherosclerosis, LVEF<30%, Urgent surgery and procedures other than CABG alone. Of these Age (RR 1.022/additional year), Diabetes (RR 1.6), NYHA IV dyspnoea (RR 1.9) & Urgent surgery (RR 2.7) were all significant after multivariate analysis.

Additive EuroSCORE: Patients with AKI had higher pre-op EuroSCOREs (Additive EuroSCORE 4.9±3.2 vs 6.8±3.6, no AKI vs AKI, p<0.05). The additive EuroSCORE outperformed any single demographic factor in predicting AKI, with each additional point resulting in a 15% increase in the rate of AKI on multivariate analysis (p<0.0001).

Conclusions: Post-op AKI in cardiac surgery patients is associated with both increased mortality and use of health resources. The additive EuroSCORE may usefully highlight patients at high risk of AKI and thus assist in both clinical management (fluid, drugs etc) and future trial design aimed at improving outcomes.

SA-PO038

Development of a Risk Score for Prediction of Contrast Induced Nephropathy after Coronary Angiography and Intervention in China Yu-mei Gao, Di Li, Hong Cheng, Yi-Pu Chen. *Division of Nephrology, Beijing Anzhen Hospital, Capital Medical University, Beijing, China.*

Background: This study is to develop and validate a score to contrast induced nephropathy (CIN) baseed on cumulative effect of multi-risk factors.

Methods: A total of 3,957 patients undergoing coronary angiography and percutaneous coronary intervention were randomly assigned to a development and a validation dataset. Several baseline clinical and procedural characteristics of 2,773 patients in the development dataset were considered as candidate univariate predictors of CIN (increase ≥ 0.5 mg/dL in serum creatinine levelwithin 72 hours following the procedure vs. baseline). Multivariate logistic regression was then used to identify independent predictors of contrast induced nephropathy. Based on the odds ratio and clinical characteristic, the independent predictors were assigned a weighted integer and a risk score system was derived. The risk score was validated in a second cohort of 1,184 patients.

Results: CIN occurred in 4.4% of patients (176/3957). In the development dataset, the following factors were independent predictors of CIN: age ≥65years(OR=1.98), acute myocardial infarction(OR=2.30), 103μmol/L < baseline serum creatinine≤177μmol/L(OR=1.52), baseline serum creatinine >177μmol/L(OR=3.39), Periprocedural heart failure(OR=2.11), Periprocedural intra-aortic balloon pump(OR=3.86), pre-procedural ACEI or ARB therapy(OR=1.69), 200mL<contrast media≤300mL(OR=1.49), contrast media >300mL(OR=3.02). The risk score system based on these variables, the patients in development cohort were further categorized into three groups: low risk (0~3 points), the incidence of CIN was 2.3%; moderate risk (4~6 points), 8.0%; high risk (>6 points), 21.6% *P<0.001).* The incidence of CIN in the validation cohort was close to those in the development cohort inside each of the three risk groups. In the validation dataset, the risk score system demonstrated good discriminative power (ROC 0.73, 95% CI 0.66-0.8).

Conclusions: We developed and validated a clinical prediction tool based on to determine which patients are at high risk for CIN. Use of this risk score system may help physicians perform targeted intervention to reduce this risk.

An Audit on the Preventative Measures against Contrast-Induced Nephropathy in Patients Undergoing Contrast-Enhancing Imaging Studies

John Y. Li,[1] Lindsey Moira Macleod,[1] Anthony Chan.[2] *[1]Medicine, Bart's and the London School of Medicine and Dentistry, London, United Kingdom; [2]Renal Medicine, Broomfield Hospital, Chelmsford, Essex, United Kingdom.*

Background: Contrast induced nephropathy (CIN) is a common form of hospital acquired acute kidney injury with a mortality rate of up to 64% in high-risk individuals. It is an easily preventable condition. Royal College of Radiologists guidelines recommend that if IV contrast studies are unavoidable, sufficient hydration needs to be given with stoppage of any nephrotoxic drugs. The aim of this audit is to benchmark CIN preventative measures at Broomfield Hospital, Chelmsford, England.

Methods: It was a retrospective review of patients who had IV contrast-enhanced imaging over a 2-week period (10/10/11 – 24/10/11). We determined how many of these patients had assessment of their renal function pre- and post-contrast study. Using an eGFR of <60 ml/min, we reviewed the case notes of patients who fell into this category and audited the CIN preventative measures that were instituted.

Results: 243 patients were eligible for analysis; 64 inpatients, 141 outpatients, and 38 cardiac angiography patients. 19 inpatients (30%) did not have a post-contrast eGFR. 8 of 45 patients (18%) who had a pre- and post-contrast eGFR, showed a significant decrease in eGFR in keeping with the definition of CIN. Of the outpatient studies, 75/141(53%) did not have a pre- or post-contrast renal function test. Only 7 patients (5%) had a post-contrast renal function test. 32/38 (84%) angiography patients did not have a post-angio eGFR. 4/7 patients (57%) with a pre-contrast eGFR of <60 did not have a post-contrast eGFR. Of the 14 case notes reviewed, 6 (43%) did not have sufficient hydration and in 11 patients (79%) nephrotoxic drugs were not stopped prior to the study.

Conclusions: A significant number of patients undergoing contrast-enhanced studies did not have their renal function assessed peri-procedure and were not identified as at risk of developing CIN, and therefore not given the necessary preventative measures. Even amongst the group of patients who had reduced eGFR (<60ml/min), a large majority did not receive preventative measures as recommended by current guidelines.

SA-PO040

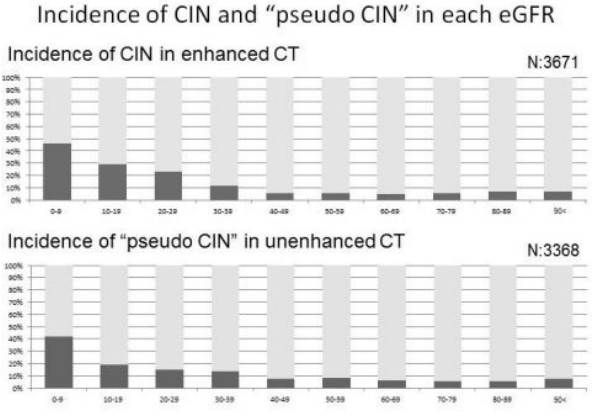
"Pseudo Contrast Induced Nephropathy": Creatinine Elevation after CT without Iodinated Contrast Use

Masahiko Nagahama,[1] Goki Eriguchi,[2] Fumika Taki,[1] Kenichiro Koitabashi,[1] Kumiko Shimasaki,[1] Keita Hirano,[1] Yuki Heath,[1] Yasuhiro Komatsu.[1] *[1]Nephrology, St. Luke's International Hospital, Tokyo, Japan; [2]Biostatistics, Kurume University Graduate School of Medicine, Kurume-City, Fukuoka, Japan.*

Background: Most studies in contrast induced nephropathy (CIN) lack controls to distinguish it from nephropathy from other causes. The purpose of this study was a retrospective comparison of the incidence of CIN in patients undergoing enhanced CT and the incidence of AKI in patients undergoing unenhanced CT (a condition we have termed "pseudo CIN").

Methods: Serum creatinine (sCr) was evaluated for 7039 patients who had had, either enhanced CT (Exposure, n=3671) or unenhanced CT (Comparison, n=3368), at St. Luke's international hospital in Tokyo between 2003 and 2010. Rates of CIN in exposure group and "pseudo CIN" in control group, defined as a 0.5 mg/dL increase in sCr or a 25% or greater decrease in eGFR within 7 days after CT, were compared among groups stratified according to baseline sCr and eGFR.

Results: 7.2% of patients in exposure group developed CIN and 9.5% of patients in comparison group developed "pseudo CIN". In both groups, the incidence of sCr elevation was increased with worsening baseline sCr.



The incidence of "pseudo CIN" is higher than that of CIN for all baseline sCr values and all stages of CKD (P<0.05 by Wilcoxon test).

Conclusions: We identified a high incidence of " pseudo CIN" among control group undergoing unenhanced CT. These findings suggest that the additional risk of AKI accompanying administration of contrast medium may be overstated and that much of the sCr elevation in patients developing CIN is attributable to underlying disease, condition or treatment. A more accurate assessment of the risk of CIN could lead to wider contrast use, more accurate diagnoses, and better clinical treatment.

SA-PO041

Development and Validation of a Prognostic Risk Score for Acute Renal Injury in Patients Hospitalized for Acute Decompensated Heart Failure

Yin-na Wang, Hong Cheng, Yi-Pu Chen. *Division of Nephrology, Beijing Anzhen Hosptial, Capital Medical University, Beijing, China.*

Background: This study is to develop and validate a score of acute renal injury(AKI) in patients hospitalized for acute decompensated heart failure(AHDF).

Methods: A total of 1709 hospital medical records of AHDF cases were reviewed. AKI was defined as a increase of SCr(≥26.4 μmol/l or 50%) in 48 hours**.** A multivariate logistic regression analysis was undertaken to develop a prediction score. The area under the ROC curve and the H-L goodness-of-fit statistic were calculated to assess the discrimination and calibration of the score.

Results: A risk scoring system was developed based on the β coefficients of each identified risk factors retained in prediction model as follows:2 points were assigned to worsen heart functional class on admission, admission serum Na <130mmol/L and positive urinary protein on admission; 3 points were assigned to age≥70 years, history of heart failure more than 3 times and intravenous furosemide dose 80~159 mg/d; 4 points were assigned to admission systolic blood pressure <90 mmHg; 5 points were assigned to serum creatinine on admission 104~176umol/L; 7 points were assigned to serum creatinine on admission 177~264umol/L; 8 points were assigned to intravenous furosemide dose ≥160mg/d; and 10 points were assigned to serum creatinine on admission ≥265umol/L. The rate of AKI increased gradually with increasing risk score. A risk score of 8 points was identified as the optimal diagnostic cut-off point, with sensitivity of 70.0 %, specificity of 70.6 %, positive-predictive value of 55.1% and negative-predictive value of 82.0 %, respectively. Patients with a score of ≥8 would be considered at high risk for developing AKI(55.1% compared to 18% in those <8 patients, P<0.001). The score showed adequate discrimination for both the derivation dataset and the validation sample (ROC curve 0.760 and 0.761, respectively) as well as adequate calibration (H-L statistic 0.985 and *P*=0.133, respectively).

Conclusions: Newly developed and validated clinical prediction scores may allowsearly identification of patients at high risk of AKI, and may support decision making for early protective kidney treatment.

Funding: Government Support - Non-U.S.

SA-PO042

Transient Acute Kidney Injury and Acute Kidney Injury on Admission Are Associated with Increased Readmission and Mortality in Acute Decompensated Heart Failure

Benjamin J. Freda,[1] Alexander B. Knee,[2] Paul F. Visintainer,[2] Ngina Muigai,[1] Gregory Lee Braden,[1] Charuhas V. Thakar.[3] *[1]Medicine, Baystate Medical Center, Springfield, MA; [2]Epidemiology and Biostatistics, Baystate Medical Center, Springfield, MA; [3]Internal Medicine, University of Cincinnati, Cincinnati, OH.*

Background: Acute Kidney Injury (AKI) influences therapy and outcomes in Acute Decompensated Heart Failure (ADHF). Little is known regarding the impact of timing [admission (AKI-A) vs hospital-acquired (AKI-HA)] or duration [transient AKI (TA) vs sustained AKI (SA)] on outcomes.

Methods: We studied 15,296 patients from a 70-hospital cohort with a primary discharge diagnosis of ADHF and use of a diuretic during an index hospitalization (2008-10). Exclusions were age < 18, ESRD, length of stay < 1 day or < 3 serum creatinines (Scr). AKI-HA, defined as a 0.3 mg/dl or 1.5 times increase in Scr from admission, was categorized as TA (Scr returned to < 10% of admission value within 72 hrs) or SA (>72 hours). AKI-A had a 0.3 mg/dl or 1.5 times decline in Scr from admission. Using regression models, AKI groups were compared to no AKI for hospital mortality (including hospice), length of stay (LOS) (log-transformed) and 30-day readmission rate (censored for death/hospice).

Results: The sample was 51% female, 75% Caucasian, with a mean age 73.8 years. 35% had diabetes mellitus, and 62% received an ACE inhibitor/Angiotensin receptor antagonist. Crude (not shown) and adjusted estimates predict poor outcomes across most AKI groups. Of patients with TA and AKI-A, 31% and 67% respectively, reached a nadir Scr <1.3 mg/dL.

Multivariable Adjusted Outcomes

Group	N (%)	Mortality %, RR (95% CI)	30-Day Readmission %, RR (95%CI)	LOS Mean Days
No AKI	6,630(46)	3.7%, referent	17.6%, referent	4.5
AKI-A	2,608(18)	5.5%, 1.48(1.21-1.81)	19.0%, 1.08(0.97-1.19)	6.8
TA	1,310(9)	6.7%, 1.80(1.43-2.27)	21.2%, 1.21(1.07-1.36)	7.5
SA	3,935(27)	8.2%, 2.21(1.87-2.61)	21.3%, 1.21(1.11-1.32)	6.1

Conclusions: AKI-A, TA and SA are associated with increased risk of hospital mortality in ADHF; TA and SA increase the risk of readmission. Regardless of improvement in Scr, AKI in ADHF predicts poor outcomes.

SA-PO043

Antihypertensive Medication Use before and after Acute Kidney Injury in General Medicare Patients Areef Ishani,[1,2] Ghaziuddin Qadri,[3] Craig Solid.[1] *[1]USRDS Coordinating Center, MMRF, Minneapolis, MN; [2]Minneapolis VAMC, Minneapolis, MN; [3]HealthPartners.*

Background: Acute kidney injury (AKI) is a common antecedent to ESRD. Many patients have their reno-protective medications stopped during the AKI episode. We aimed to determine if these medications, specifically antihypertensive medications, are then restarted within the next year.

Methods: We used the Medicare 5% Random Sample to identify patients aged 65+ who had an Acute Kidney Injury (AKI) during 2008. Medicare Part D enrollment and medication information was used to identify prescription medications that were filled before and after the AKI. Followup periods included the first 2 months immediately following the AKI event, as well as the period of time 10 to 12 months after the AKI.

Results: We identified a total of 10,294 patients with AKI in 2008. Of these, the percent with Part D claims for medications prior to the AKI were as follows: Beta Blocker: 44%; Calcium Channel Blocker: 21%; Loop diuretic: 38%; ACE Inhibitor: 36%; ARB 18%. During followup, of patients who received the medication prior to their AKI, the percent of patients who had another claim for a Beta Blocker were 78% (0-2 months after AKI) and 73% (10-12 months after), for another Calcium Channel Blocker were 69% and 59%, and for another ACE/ARB were 61% and 51%.

Conclusions: Many antihypertensive medications are stopped during an AKI episode and are not restarted up to one year after the AKI episode. It is unclear if medication discontinuation may account for some of the poor outcomes after an AKI episode.

SA-PO044

Recognition, Diagnosis and Management of Acute Kidney Injury Remains Poor Despie Recent Initiatives Christopher Lawrence, Peter Hill. *Department of Renal Medicine, The Hillingdon Hospital NHS Trust, Uxbridge, Middlesex, United Kingdom.*

Background: Acute Kidney Injury (AKI) is a common feature of patients presenting to hospital as medical emergencies. AKI is associated with increased morbidity and mortality (3-5 fold), longer length of stay and higher healthcare costs. The aim of this study was to assess our practice in light of the National Confidential Enquiry into Patient Outcomes and Deaths (NCEPOD) report 'Acute Kidney Injury: Adding Insult to Injury' (2009) and assess the knowledge of clinicans caring for acutely unwell patients with respect to these guidelines.

Methods: KDIGO AKI stage (delta creatinine) was assessed for all patients admitted to hospital during a one week period. Care was assesed against a standard taken from national guidelines. At the end of the week an electronic survey was sent to clinicians.

Results: 22/201 (11%) patients admitted as a medical emergency had AKI (Stage 1 n=16, Stage 2 n=5, Stage 3 n=1). All patients had electrolytes (UEs) checked on admission but only 12 (55%) had UEs rechecked within 24 hours. Although case review identified 7 patients who required imaging of the renal tract because of severity of AKI or failure of AKI to resolve, no patient had been imaged before 24hrs. 26 physicians (all grades) answered a web based survey. The majority of clinicians correctly identified, or over estimated, the incidence of AKI (21/26, 81%) and the associated mortality rates (22/26, 85%) but clinicians were either unaware of the KDIGO classification for AKI (19/26, 73%) or were not confident in its application (7/26, 27%). Only 11/26 (42%) clinicans correctly identified the target of obtaining renal tract imaging within 6 hours for patients suspected of having an obstructed and infected kidney. Clinicians felt that automated reporting of AKI stage with serum creatinine (19/26, 73%), and electronic ordering of diagnostic imaging (20/26, 76%) would improve management of patients with AKI.

Conclusions: AKI is a common feature of acutely unwell medical patients but depsite recent national initiatives (NCEPOD 2009) remains under recognised and poorly managed. Clinicans need further education and superior informatics to facilitate improved care for patients with AKI.

SA-PO045

Acute Kidney Injury in Reykjavik, Iceland 1993-2011 Þórir E. Long,[1] Martin I. Sigurdsson,[2] Gisli H. Sigurdsson,[1,2] Olafur S. Indridason.[3] *[1]Faculty of Medicine, University of Iceland; [2]Department of Anesthesia and Intensive Care; [3]Division of Nephrology, Landspitali - National University Hospital of Iceland, Reykjavik, Iceland.*

Background: The epidemilogy of acute kidney injury (AKI) has not been extensively studied. The aim of this study was to determine the incidence of AKI in Landspitali-The National University Hospital of Iceland (LUH), and examine renal recovery following AKI.

Methods: The laboratory at LUH serves the hospital and primary care facilities in the Reykjavik area. We searched its database for every serum creatinine (SCr) value measured from May 1993 to end of 2011. We identified the highest SCr value for each person, searched for a baseline value within the 6 preceding months and used it to categorize patients into risk (R), injury (I) and failure (F) groups using the RIFLE criteria. Subsequent SCr measurements for up to 12 months were used to examine renal recovery. The population of the Reykjavik area aged above 18 years was used for incidence calculations and time trends examined using regression analysis.

Results: A total of 1,642,295 SCr values were found for 215,000 subjects, of whom 54,814 had a baseline SCr available. AKI occurred in 12,561 (22.9%), with 12.5%, 5.4% and 5.1% in the R, I and F groups, respectively. AKI incidence increased with age and those in the older age-groups were more likely to have I or F than the younger ones (p<0.001). There were more females in the R and I groups, and more males in the F group (p< 0,001). The total AKI incidence increased steadily over time, from 414 to 662 per 100,000 per year (p<0.001) from the first to the last year. The rise in incidence was 55.3% in the R group (p<0.001), 55.1% in the I group (p=0.001) and 80.9% in the F group (p=0.01). Of those surviving AKI with creatinine available at 12 months, 8.9% of the R group, 26.1% of the I group and 26.2% of the F group had average SCr above 1.5x the baseline SCr.

Conclusions: The incidence of AKI seems to be rising in Reykjavik during the last two decades. The reasons are probably multifactorial, including higher age and more use of medications with effect on renal blood flow. A considerable proportion of survivors remain with impaired kidney function long term.

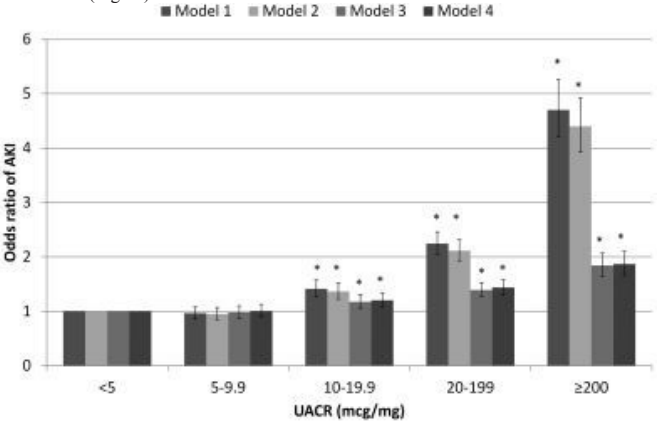
SA-PO046

Independent Association of Proteinuria with Acute Kidney Injury in a Large National Cohort of US Veterans Csaba P. Kovesdy,[1,2] Miklos Zsolt Molnar,[3] Jun Ling Lu,[4] Jennie Z. Ma,[5] Leigh Darryl Quarles,[2] Kamyar Kalantar-Zadeh.[3] *[1]Memphis VA Medical Center, Memphis, TN; [2]University of Tennessee Health Science Center, Memphis, TN; [3]Harold Simmons Center at Harbor-UCLA, Torrance, CA; [4]Salem Research Institute, Salem, VA; [5]University of Virginia, Charlottesville, VA.*

Background: Lower GFR predicts an increased risk of acute kidney injury (AKI), but it is unknown if the severity of proteinuria is also associated with AKI independent of kidney function.

Methods: We examined the association between the amount of urine microalbumin/creatinine ratio (UACR) and AKI (based on ICD-9 codes) during 2005-2006 in a national cohort of 299,180 US veterans, using crude (Model 1) and multivariable adjusted random effects logistic regression. Multivariable models were adjusted sequentially for age, gender, race (Model 2), plus comorbidities (Model 3), plus blood pressure, use of ACE-inhibitors, and estimated GFR (Model 4). UACR was examined both as a continuous variable and as a categorical variable with pre-defined cutoffs.

Results: 4,140 patients (1.4%) developed AKI, with 357 patients (0.1%) having experienced more than one episode during a median follow-up period of 1.0 year. Higher levels of UACR were associated with increased incidence of AKI, independent of confounders (Figure). A one-unit higher UACR in log-scale was associated with odds ratios (95% confidence interval [CI]) of AKI of 1.41 (1.38-1.43) in unadjusted and 1.15 (1.12-1.17) in fully adjusted models. Patients with UACR <10 mcg/mg were at the lowest risk for AKI (Figure).



Conclusions: Severity of UACR is associated with the incidence of AKI independent of the level of kidney function. Assessment of proteinuria should be considered along with measurement of kidney function when risk-stratifying patients for AKI.

SA-PO047

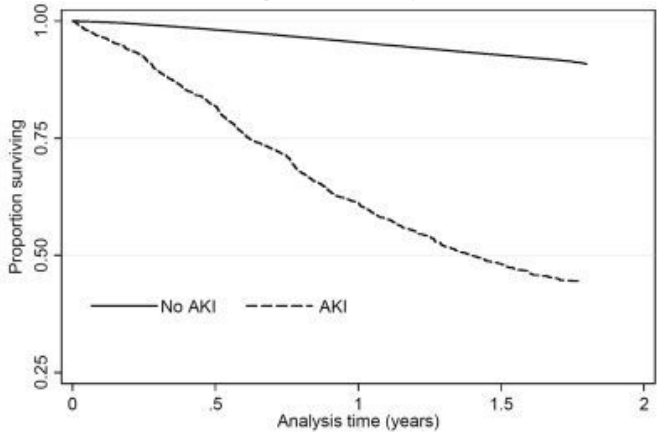
Predictors of Acute Kidney Injury and Its Association with Mortality in a Nationally Representative Cohort of US Veterans Csaba P. Kovesdy,[1,2] Miklos Zsolt Molnar,[3] Jun Ling Lu,[4] Jennie Z. Ma,[5] Leigh Darryl Quarles,[2] Kamyar Kalantar-Zadeh.[3] *[1]Memphis VA Medical Center, Memphis, TN; [2]University of Tennessee Health Science Center, Memphis, TN; [3]Harold Simmons Center at Harbor-UCLA, Torrance, CA; [4]Salem Research Institute, Salem, VA; [5]University of Virginia, Charlottesville, VA.*

Background: The incidence of acute kidney injury (AKI), its predictors, and its association with mortality in the wider population of CKD is unclear.

Methods: We examined the incidence of AKI, its predictors, and its association with all-cause mortality in a national cohort of 615,591 US veterans with CKD stages 1-5. Predictors of AKI were determined from logistic regression. The association of AKI with mortality was examined in time-dependent Cox models with adjustment for age, gender, race, hospitalizations, BP, ACE-inhibitor use, comorbidities, and laboratory variables.

Results: The incidence of AKI was 18.7/1000 patient-years (95%CI: 18.4-19.1), with a linear increase with more advanced stages of CKD. Older age, black race, higher comorbidity burden, lower SBP, eGFR, albumin, bicarbonate and hemoglobin, and higher

WBC were associated with increased risk of AKI. During a median follow-up of 1.0 year 30,572 patients died. AKI was associated with significantly higher crude mortality rate (HR, 95% CI: 9.8, 9.2-10.4, Figure), which remained significant but was attenuated substantially after multivariable adjustment (adjusted HR, 95% CI: 1.33, 1.24-1.43). The mortality risk associated with AKI was similar in patients with all stages of CKD.



Conclusions: AKI is common in CKD, especially in those with advanced stages. AKI is associated with a 10-fold higher risk of death, but most of this is due to characteristics that predispose to AKI. The risk of mortality associated with AKI is similar in all stages of CKD.

SA-PO048

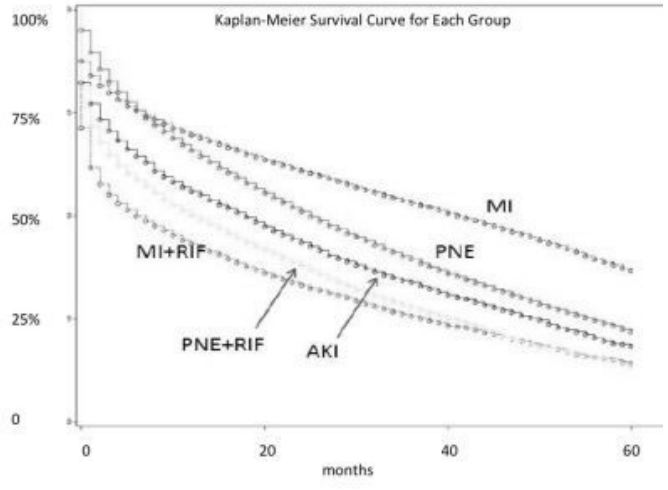
Incidence of Major Acute Kidney Events (MAKE) and Major Acute Renal-Cardiovascular Events (MARCE) after an Episode of Acute Kidney Injury: A Study of US Veterans

Lakhmir S. Chawla,[1] Richard Amdur,[1,2] Carlos E. Palant,[2] Paul L. Kimmel.[1,3] *[1]George Washington University; [2]Washington VA; [3]NIDDK, NIH.*

Background: NIH & AKI Consensus groups have proposed MAKE as a composite endpoint in clinical trials of AKI. The incidence of MAKE & MARCE are not well characterized.

Methods: We assessed patients admitted with a primary diagnosis indicating AKI (ARF ICD9- 584.xx), myocardial infarction(MI; codes 410.xx), and pneumonia(PNE; codes- 486. xx). PNE and MI patients who developed AKI during their hospitalization (defined by RIFLE) were designated PNE-RIF and MI-RIF, respectively. Patients with a pre-existing eGFR < 60 ml/min were excluded. From this dataset we generated 5 exclusive groups: AKI, MI, PNE, PNE-RIF, MI-RIF. Our endpoints were MAKE, defined as the composite of death, need for dialysis, or permanent loss of GFR (a persistent decrement of 25% from baseline eGFR). Our other endpoint was MARCE, defined as MAKE, plus a diagnosis of MI, CHF, or stroke after the index hospitalization.

Results: 67,878 subjects were assessed: AKI (5,352), MI (16,671), PNE (29,940), MI-AKI (6,362), and PNE-AKI (9,552). The likelihood of reaching the composite endpoint of MARCE was higher in patients with AKI (MI+RIF 75.9%, PNE+RIF 72.7%, AKI 62.6%), compared with patients admitted for PNE or MI without AKI (61.3% and 48.0%, respectively). Patients with MI and PNE were significantly less likely to reach the composite endpoint than all other groups, and the three groups with AKI were the most likely to reach this endpoint throughout the next 5 years (log-rank < 0.001 for all groups).



Conclusions: The occurrence of AKI magnifies adverse outcomes in hospitalized patients. AKI survivors are at risk for both renal and cardiovascular complications after their index hospitalization. Future clinical trials AKI should capture the composite outcomes of MAKE and MARCE; this will enhance power of AKI trials.

SA-PO049

Long-Term Outcomes of Community-Acquired (CA-AKI) versus Hospital-Acquired Acute Kidney Injury (HA-AKI)

Paul J. Der Mesropian,[1] John Kalamaras,[2] Roy Mathew.[3] *[1]Internal Medicine, Albany Medical Center, Albany, NY; [2]Department of Epidemiology & Biostatistics, University at Albany, Albany, NY; [3]Nephrology, Stratton VA Medical Center, Albany, NY.*

Background: Medical literature on CA-AKI is limited compared to HA-AKI, especially in relation to clinically relevant outcomes. Our hypothesis: renal survival and mortality would be better for patients suffering CA-AKI vs HA-AKI.

Methods: Retrospective cohort of 718 cases of AKI and 2320 cases without AKI (NA) among hospitalized U.S. veterans from 2004-5. AKI defined by RIFLE creatinine criteria. Outcomes were assessed 3y after discharge from index hospitalization. Primary: doubling of the serum creatinine, end-stage renal disease (ESRD), death, and composite of the three. Secondary: de novo chronic kidney disease (CKD), recovery of renal function, and re-admission rate.

Results: CA-AKI (>50% rise from baseline creatinine on admission) was identified in 78% of patients with AKI. CA-AKI had better baseline renal function (mean estimated glomerular filtration rate 71.3 vs. 61.1 mL/min/1.73 m^2, P<0.05), and a lower percentage of chronic kidney disease (42.3 vs. 51.9%, P=0.03) than HA-AKI. No other significant differences in demographics and clinical characteristics. More patients with CA-AKI than HA-AKI met failure RIFLE criteria (43.8 vs. 29.1%, P<0.001). In contrast, patients with HA-AKI had an average length of stay twice as long (22.6 vs. 11.4 days, P<0.001), were more than twice as likely to require ICU stay or mechanical ventilation (45.6 vs 20.5%, P<0.001), and had a higher in-hospital mortality rate (26.6 vs. 19.6%, P=0.06). Need for inpatient dialysis was similar (19.6 vs. 26.6%, P>0.05). By 3y, the composite end point occurred in 74.3% patients with CA-AKI vs 74.1% patients with HA-AKI (P=0.66). Similarly, no differences were found for the other primary and secondary outcomes tested (all P>0.05).

Conclusions: CA-AKI was found to be considerably more common than HA-AKI. In contrast to our hypothesis, we found that long-term consequences in CA-AKI were similar to HA-AKI. Prospective analyses will be needed to identify measures to prevent AKI from developing in the outpatient setting.

SA-PO050

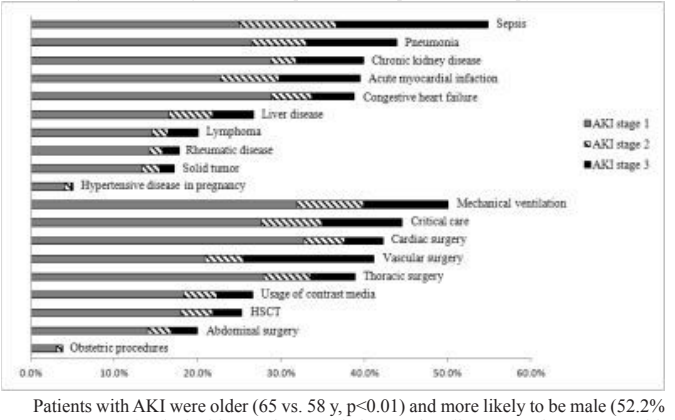
The Epidemiology of Acute Kidney Injury According to the KDIGO Criteria

Xiaoxi Zeng, Sushrut S. Waikar. *Renal Division, Brigham and Women's Hospital, Harvard Medical School.*

Background: Acute kidney injury (AKI) is a common complication in hospitalized individuals. We undertook this study to update the epidemiologic profile of AKI in hospitalized patients using the newly released KDIGO consensus definition and staging system.

Methods: Adult patients hospitalized at Brigham and Women's Hospital in 2010 with at least one inpatient serum creatinine (SCr) value were included. We excluded patients with end-stage renal disease and those who received kidney transplantation. We defined and staged AKI according to SCr-based KDIGO criteria (increase in SCr ≥ 0.3 mg/dl in 48 hours or to ≥ 1.5 times baseline in 7 days). Baseline was defined as mean outpatient SCr within 7 to 365 days prior to admission. We estimated the association between AKI and mortality, length of stay (LOS), and costs using logistic or linear regression analyses, adjusting for demographic and clinical confounders.

Results: Among 18,814 patients, the incidence of AKI was 16.9% (75.5% stage 1, 13.3% stage 2, 14.2% stage 3; 4.7% required renal replacement therapy).



Patients with AKI were older (65 vs. 58 y, p<0.01) and more likely to be male (52.2% vs. 40.3%, p<0.01). The incidence of AKI varied across baseline eGFR, from 15.3% with baseline eGFR ≥ 90 to 45.8% with baseline eGFR < 30. In-hospital mortality was higher in patients with AKI (11.3% vs. 0.9%, p<0.01) and increased with the severity of AKI (stage 1: 6.3%, stage 2: 13.4%, stage 3: 34.4%). Increasing severity of AKI was associated with adjusted increased odds of mortality: stage 1, 3.4 (95%CI 2.6 to 4.4); stage 2, 5.3 (95%CI

3.6 to 7.7); stage 3, 17.9 (95%CI 12.8 to 25.1). AKI was associated with 38.7% increase LOS (p<0.01) and 34.4% increase in cost (p<0.01).

Conclusions: Approximately 1 in 6 hospitalized patients developed AKI as defined by the KDIGO definition. AKI is strongly associated with in-hospital mortality, increased LOS and increased costs.

SA-PO051

Comparison of Creatinine-Based Definitions of Acute Kidney Injury
Xiaoxi Zeng, Joseph V. Bonventre, Sushrut S. Waikar. *Renal Division, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

Background: A number of definitions have been proposed to standardize the diagnosis and staging of acute kidney injury (AKI). We compared the incidence, mortality, and predictive values of AKI according to 4 distinct definitions: KDIGO, AKIN, RIFLE, and a definition we previously proposed which others have termed the Waikar-Bonventre (WB) definition.

Methods: Adult patients hospitalized at Brigham and Women's Hospital in 2010 with at least one inpatient serum creatinine (SCr) measurement were included. We excluded patients with end-stage renal disease and those who received kidney transplantation. We defined AKI using inpatient SCr values according to KDIGO (increase in SCr ≥0.3 mg/dl in 48 hours or to ≥ 1.5 times baseline in 7 days), AKIN (increase in SCr ≥0.3 mg/dl or ≥ 50% in 48 hours), RIFLE (increase in SCr to ≥ 1.5 times baseline in 7 days), and WB (increase in SCr ≥ 0.3 mg/dl in 24 hours or ≥ 0.5 mg/dl in 48 hours) definitions, and calculated incidence and in-hospital mortality. Using standard metrics of diagnostic accuracy, we then tested the ability of the 4 definitions to identify the eventual need for renal replacement therapy (RRT).

Results: Among 18,814 patients, AKI incidence was 15.0% as defined by KDIGO, 12.4% by AKIN, 10.8% by RIFLE and 8.8% by WB. Mortality was highest in patients with AKI defined by WB (19.0%), followed by RIFLE-AKI (16.0%), AKIN-AKI (15.0%) and KDIGO-AKI (13.2%). Prior to the initiation of RRT (n = 150), the diagnosis of AKI was made in 79.3% by RIFLE, and 92.0% by KDIGO, AKIN and WB. Among those meeting criteria for AKI, RRT was eventually required in 4.9% for KDIGO, 5.9% for AKIN and RIFLE, and 8.4% for WB.

Diagnostic performance characteristics of AKI definitions for the identification of RRT

	Sensitivity	Specificity	Positive predictive value	Negative predictive value
KDIGO	92.0%	85.7%	4.9%	99.9%
AKIN	92.0%	88.3%	5.9%	99.9%
RIFLE	79.3%	89.8%	5.9%	99.8%
WB	92.0%	91.9%	8.4%	99.9%

Conclusions: The estimated incidence and mortality of AKI varies according to the definition used. The highest incidence was observed with the KDIGO definition. The Waikar-Bonventre definition had the highest positive predictive value for the eventual need for RRT.

SA-PO052

Prognostic Value of Kidney Biopsy in Myeloma Cast Nephropathy: A Retrospective Study of 69 Patients from a Single Institution
Laure Ecotiere,[1] Céline Debiais-delpech,[2] Sebastien Delbès,[1] Estelle Desport,[1] M. Guy Touchard,[1] Frank Bridoux.[1] *[1]Nephrology, Dialysis and Renal Transplantation, CHU Poitiers, Poitiers, France, Metropolitan; [2]Pathology, CHU Poitiers, Poitiers, France, Metropolitan.*

Background: Myeloma cast nephropathy (MCN) is the major cause of severe renal failure in multiple myeloma (MM), which significantly impacts survival.

Methods: The prognostic value of renal pathological findings on renal and vital outcomes was retrospectively evaluated in 69 patients with biopsy-proven MCN and MM. Patients were categorized in 2 groups according to the achievement (RR group) or not (NRR group) of renal response (RR), defined by estimated glomerular filtration rate (eGFR) value ≥ 30 ml/min/1.73m^2 and/or dialysis independence at 3 months.

Results: Compared with the NRR group, the RR group had lower baseline median serum creatinine (605 vs 328 µmol/l, P=0.024) and higher median eGFR value (7 vs 15 ml/min/1.73m^2, respectively, P=0.009). Hematological response (HR) rate (30% vs 91%, P<0.0001) and median percentage of light chain (LC) reduction at day 21 (13% vs 92%, P=0.025) were higher in the RR group. The extent of interstitial fibrosis (evaluated semi-quantitatively and by automated analysis), tubular atrophy and interstitial inflammation were not significantly associated with RR. By multivariate analysis, the median number of casts per 10 fields (13.5 vs 25, P=0.005) were significantly lower in the RR group among patients who achieved HR.

Conclusions: The achievement of RR is closely associated with the baseline eGFR and the HR. The presence of numerous casts (>20) is associated with poor renal and vital prognosis.

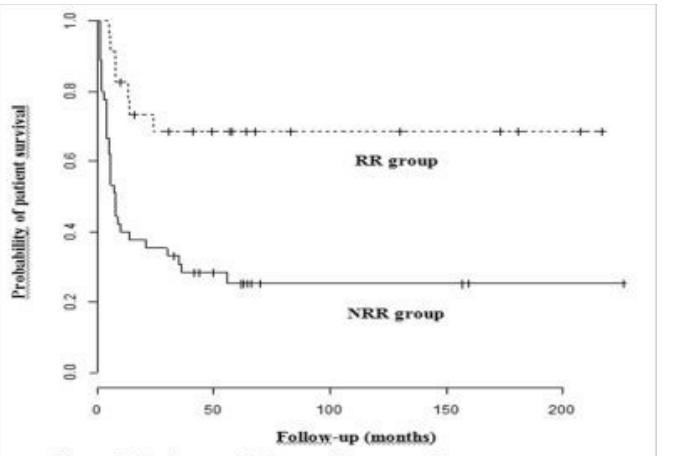


Figure 1: Patient survival according to renal response

Moreover, it is an independant predictor of RR in patients who achieved HR, in whom rapid removal of circulating LC through high cut-off dialysis or plasma exchanges should be considered in addition to efficient chemotherapy to improve outcomes.

SA-PO053

Acute Kidney Injury Is Associated with Increased Morbidity after the Arterial Switch Operation and Underestimated by Failure to Correct for Fluid Balance
Rajit K. Basu, Catherine D. Krawczeski, Derek Wheeler, Stuart Goldstein. *Center for Acute Care Nephrology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Acute kidney injury (AKI) is common and carries significant morbidity after cardiopulmonary bypass (CPB) in children. Few studies examine the impact of AKI in lesion specific – surgery specific populations.

Methods: We examined the impact of AKI in 92 consecutive patients (pts) after arterial switch operation (ASO).

Results: The AKI rate by KDIGO criteria (Kidney Disease - Improving Global Outcomes) was 18/92 (20%). Patient age, weight and CPB time did not correlate with AKI development. AKI was associated with: higher post-operative day 1 (POD_1) net fluid balance, higher inotrope scores (POD_1 and POD_2), and longer: post-operative intensive care unit (ICU) length of stay (LOS), overall ICU length of stay, and post-operative hospital LOS. Time to peak creatinine for AKI pts was between POD_1 and POD_2. Correction of creatinine for fluid balance increased the population defined as severe AKI (KDIGO Stage II-III) and strengthened the association of AKI with post-operative morbidity.

	UNCORRECTED			CORRECTED		
VARIABLE	No AKI or Stage I	Stage II-III	p value	No AKI or Stage I	Stage II-III	p value
Post-op ventilation (hours)	58 (36,114)	99 (44,129)	0.19	56 (34.5, 113.3)	99 (62, 161)	0.033
POD 1 Inotrope Score	13.5 (10,16)	13 (10,16)	0.87	13.5 (10,16.2)	15 (12, 18.6)	0.06
POD 2 Inotrope Score	10 (7.5,14)	10.6 (7.6,14)	0.58	10 (7.5, 13.9)	13 (8, 16.3)	0.05
Post-op ICU LOS (days)	5 (4,7.3)	7 (5,12.3)	0.056	5 (4,7)	8 (6, 14)	0.005
ICU LOS (days)	9 (8,12.3)	14 (7,19)	0.12	9 (8,12)	13 (10,16)	0.05
Post-op hospital LOS (days)	8 (7,13)	11 (8.5,16.8)	0.07	8 (7,12)	13 (9,20)	0.006

Impact of AKI after ASO and the effect of correction of creatinine for fluid overload.
AKI = acute kidney injury, POD = post operative day, LOS = length of stay

Conclusions: We conclude AKI following the ASO is associated with increased morbidity. In this single center, single population, and homogenous cohort of patients, the development of AKI was associated with prolonged duration of ventilation and hospitalization. Notably, failure to correct serum creatinine for fluid balance underestimates the prevalence and impact of AKI. Finally, even with corrected creatinine, the delayed time to diagnosis of AKI underscores the need to utilize more time-sensitive biomarkers of kidney injury.

SA-PO054

Acute Kidney Injury Diagnosis Delayed by Intravenous Fluids

John W. Pickering,[1] Zoltan H. Endre.[1,2] *[1]Christchurch Kidney Research Group, Department of Medicine, University of Otago, Christchurch, New Zealand; [2]Department of Nephrology, Prince of Wales Hospital, Sydney, New South Wales, Australia.*

Background: A positive fluid balance produced by fluid resuscitation may dilute creatinine concentration and delay acute kidney injury (AKI) diagnosis or result in the underestimation of its severity. The extent of dilution will depend on fluid type and timing of sampling following infusion.

Methods: The study combined a two-compartment creatinine kinetic model with a two-compartment volume kinetic model to quantify dilution during AKI taking into account fluid type, and the rate of fluid input and urine output. Creatinine kinetics incorporated dynamic changes in the volume of distribution of each compartment and changes in glomerular filtration rate (GFR). Volume kinetics simulated the distribution and elimination of infused fluids. A simulated patient received 1000 ml/h for 6 hours of crystalloids or colloids under four GFR scenarios corresponding to RIFLE criteria AKI severity stages: no-change, 33.3%, 50%, and 66.7% loss. The model was applied to four critically ill patients to estimate GFR change.

Results: During fluid infusion, creatinine concentration decreased irrespective of fluid type or extent of GFR change. AKI diagnosis was delayed by about 8 hours. Colloids produced a greater reduction in creatinine concentration. The model provided a more accurate estimate of the loss of GFR in a patient with sustained AKI, and accounted well for the changes in creatinine in two of three others. In the fourth patient, the fall in creatinine concentration was greater than predicted; hyperfiltration could explain this outcome.

Conclusions: Combining creatinine and volume kinetics allowed quantitation of dynamic changes in GFR in the critically ill, facilitated earlier diagnosis, provided insight into progression and more accurate estimates of AKI severity.

Funding: Government Support - Non-U.S.

SA-PO055

Soluble CD25 Is Increased in Patients with Septic Acute Kidney Injury

Eunjung Cho,[1] Jae-Won Lee,[1] Won-Yong Cho,[1] Sang-Kyung Jo,[1] So-young Lee.[2] *[1]Korea University Hospital, Seoul, Korea; [2]Eulji University Hospital, Seoul, Korea.*

Background: Sepsis has been shown to induce the expansion of suppressive CD25+CD4+ regulatory T cells (Tregs) and this paradoxical immune suppression has also been suggested to be closely associated with the development of sepsis induced organ dysfunction. The purpose of this study was to investigate the possible link between immune suppression and the development of septic AKI.

Methods: We prospectively enrolled patients older than 18 years with the diagnosis of sepsis with or without AKI and also patients with non-septic AKI from Jan 2010 to Dec 2011. AKI was diagnosed according to RIFLE criteria, and serum and urine were collected to measure NGAL, cytokines, and soluble CD25 (sCD25).

Results: Of 82 patients enrolled, 44, 18 and 20 patients were classified into septic AKI, sepsis-no AKI and non-septic AKI. There was no difference in baseline characteristics including age, sex, and the prevalence of chronic kidney disease among these groups. The severity of AKI was also not different between septic and non-septic AKI. Patients with septic or non-septic AKI had significantly higher APACHE II score and FeNa compared to patients with sepsis-no AKI. Serum levels of proinflammatory cytokine IL-6, IL-1β, and serum and urine NGAL levels were significantly elevated in patients with septic AKI compared to those with sepsis-no AKI or non-septic AKI. Finally, the level of serum sCD25, the marker of suppressive Tregs, was significantly increased in patients with septic AKI (18.8±14.4 vs. 11.2±10.1 vs. 8.3±6.1 ng/ml, septic AKI vs. non-septic AKI vs. sepsis-no AKI, $p<0.05$), suggesting the possible association of paradoxical immune suppression and the development of septic AKI.

Conclusions: These results might suggest that immune suppression in sepsis is closely linked to the development of AKI and can also propose that sCD25 might be useful for a novel biomarker of septic AKI.

SA-PO056

Fluid Overload and Mortality: A Problem beyond Acute Kidney Injury

Catarina Teixeira,[1] Francesco Garzotto,[1] Nicola Brienza,[2] Claudio Ronco,[1] Pasquale Piccinni,[1] Dinna N. Cruz.[1] *[1]St Bortolo Hosp; [2]Univ of Bari.*

Background: Fluid overload (FO) has been associated with poor clinical outcomes in selected critically ill populations, particularly AKI and acute respiratory distress syndrome. Few studies have addressed the impact of FO in a general intensive care unit (ICU) population. Our aim was to evaluate the effect of mean fluid balance (MFB) on ICU mortality, and compare its effect in patients with and without AKI.

Methods: We performed a secondary analysis of data from a prospective multicenter ICU cohort (NEFROINT study). AKI was defined by renal SOFA score (sCr>3.5mg/dL or urine output (UO)<500mL/d). Oliguria was defined as a UO<500mL/d. MFB and mean urine output (MUO) were the mean of all daily values in ICU. Diuretic use was noted daily. Multivariable analysis was performed by Cox regression; variables included MFB, MUO, age, sex, co-morbidities, sepsis, SOFA and diuretic use.

Results: Of 573 patients (63 yrs; 60%M), 132 had AKI. In AKI vs non-AKI group, MFB was higher (0.75 vs 0.45 L/d; P=0.008) and MUO was lower (1.81 vs 2.26 L/d; P<0.001). Oliguric AKI patients had higher MFB (P<0.001) and had higher mortality (P<0.001). Overall, non-survivors had higher MFB; this was seen in both AKI and non-AKI groups (Fig 1). MUO was lower in non-survivors as a whole and in AKI group, but not in non-AKI. On multivariable analysis, MFB and MUO were independent predictors of mortality in all patients and in AKI (Tab 1). In non-AKI, MUO was no longer a predictor. Of interest, diuretic use was associated with lower mortality in all groups.

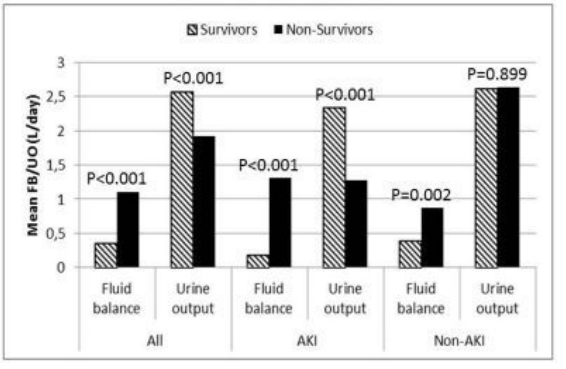
Conclusions: Fluid balance was an independent predictor of ICU mortality in AKI and non-AKI patients while UO was significant only in AKI. These results suggest that despite preserved UO in non-AKI patients, attention to fluid intake and prevention of FO are also fundamental in these patients.

Table 1: Independent predictors of mortality

	All	AKI	Non-AKI
	Adjusted Hazard Ratio		
Mean fluid balance	1.48 (1.29-1.70)**	1.67 (1.33-2.09)**	1.38 (1.10-1.72)*
Mean urine output	0.66 (0.52-0.86)*	0.47 (0.33-0.67)**	1.08 (0.72-1.61)
Diuretic use	0.31 (0.20-0.48)**	0.25 (0.12-0.52)**	0.25 (0.13-0.47)**
Non-renal SOFA	1.11 (1.04-1.18)*	1.04 (0.96-1.14)	1.15 (1.05-1.26)*

*P<0.01; **P<0.001

Figure 1: Mean fluid balance and mean urine output in survivors and non-survivors



SA-PO057

Adverse Mortality Effect of Fluid Overload Can Be Applicable to All Critically Ill Patients with Acute Kidney Injury Receiving Continuous Renal Replacement Therapy?

Il Young Kim, Soo Bong Lee, Dong Won Lee, Harin Rhee, Byeong Yun Yang, Eun Young Seong, Ihm Soo Kwak. *Pusan National University School of Medicine, Busan, Republic of Korea.*

Background: Fluid overload (FO) has known to be associated with increased mortality in critically ill patients with acute kidney injury (AKI). In this study, we investigated whether adverse mortality effect of FO could be applicable to all patients with AKI receiving continuous renal replacement therapy (CRRT).

Methods: We analyzed 171 AKI patients who received CRRT in intensive care units of our university hospital from 2007 to 2009. The presence of FO was defined as ≥10% increase in body weight over the baseline. Demographics, comorbid diseases, clinical data, severity of illness (the sequential organ failure assessment (SOFA) score, number of vasopressors, diagnosis of sepsis, use of ventilator) at ICU admission, FO status were reviewed from medical records.

Results: Of total subjects (n=171), patients with FO≥10% (n=59) from 3 days before CRRT initiation to 3 days after it showed significant higher mortality compared to patients with FO<10% (n=112) (30-day mortality: 71.2% vs. 43.7%, Log rank p<0.001). The adjusted hazard ratio for mortality associated with FO≥10% was 1.70 (95% CI: 1.09-2.66). We classified all patients into sepsis group (n=101) and non-sepsis group (n=70). The sepsis group showed the patients with FO≥10% had the higher mortality over 30 days compared to those with FO<10% (30-day mortality: 72.5% vs 40.9%, Log rank p<0.001). However, the non-sepsis group did not. Next, we divided all patients into high SOFA score group (≥13, n=87) and low SOFA score group (<13, n=84) according to severity of illness. In high SOFA score group, there was statistically significant difference of survival between patients with FO≥10% and FO<10% (30-day mortality: 86.5% vs 66.0%, Log rank p=0.002), but not in low SOFA score group.

Conclusions: The result of this study shows FO is independently associated with mortality in AKI patients receiving CRRT. However, our study demonstrates adverse mortality effect of FO could not be applicable to some subgroups of AKI patients receiving CRRT such as non-sepsis group or low SOFA score group.

SA-PO058

Bioelectrical Impedance Analysis: An Useful Tool as Prognosis in Acute Kidney Injury Francisco Javier Lavilla, Nuria Garcia-Fernandez. *Nephrology, Clinica Universidad de Navarra, Pamplona, Navarra, Spain.*

Background: Bioelectrical impedance analysis (BIA) is a simple, cheap and non-invasive tool for monitoring nutritional and hydration status in several diseases. The aim of this prospective study was to evaluate BIA in the prognosis of Acute Kidney Injury (AKI).

Methods: In a cohort of 96 patients (mean age: 64 years-old, SD: 1.57, 76 males) with a diagnosis of AKI, a bioimpedance analysis was made. Bioelectrical parameters: Phase angle (PA), Total Body Water, Extracellular/Intracellular water ratio (EC/IC), Na/K exchange rate (Na/K); acute clinical index: individual severity (ISI), multiorgan failure index (MOFI); chronic clinical index: Charlson and Karnofsky; biochemical parameters: C-reactive protein, prealbumin, albumin and peak creatinine; and mortality were evaluated. The mortality rate was 14%.

Results: In Table 1 correlation results are shown among different variables. According to mortality, the PA provided the highest prognostic information with an Area Under the curve (AUC) of 0.78 (95%CI: 0.65-0.91) and the cutoff was 3.2º (Sensitivity: 78%, Specificity: 67%). Respect to survival, the Na/K exchange showed an AUC of 0.81 (IC95%CI: 0.61-1.00), the cutoff was 1.39 (Sensitivity: 83%, Specificity:67%). Using a stepwise multivariate logistic regression analysis including all the bioelectrical parameters, an independent relationship was found between Na/K exchange and mortality (OR 15.38; 95% CI: 1.61-146.4).

Table 1. Correlations among different studied variables.

	Phase angle (º)	Phase angle (º)	EC/IC	EC/IC	Na/K exchange rate	Na/K exchange rate
	r	p	r	p	r	p
ISI	- 0.22	0.035	0.23	0.03	ns	ns
MOFI	- 0.25	0.035	- 0.32	0.002	0.34	0.014
C-reactive protein (mg/dL)	- 0.42	0.005	0.40	0.001	ns	ns
Prealbumin (mg/dL)	0.38	0.025	- 0.48	0.004	- 0.43	0.049
Albumin (mg/dL)	0.32	0.011	- 0.39	0.002	ns	ns
Karnosfky	0.44	0.005	- 0.54	0.005	- 0.32	0.025
Charlson	ns	ns	ns	ns	ns	ns

ISI: individual severity index, MOFI: multi organ failure index EC/IC: Extracellular/Intracellular water ratio

Conclusions: Bioelectrical impedance analysis can be used as a parameter in the prognosis of AKI. High Extracellular water volume, and moreover decreased phase angle and elevated Na/K are related to a worst prognosis in the patient with AKI.

SA-PO059

Biomarkers and Renal Ultrasound in the Diagnosis of Cirrhosis' Acute Kidney Injury (AKI) Belen Ponte, Laurent Spahr, Grégory Berra, Pierre-Yves F. Martin. *University Hospitals of Geneva.*

Background: AKI is frequent in patients with cirrhosis. Pre-renal, acute tubular necrosis (ATN) or hepatorenal syndrome (HRS) have different prognosis but are difficult to differentiate. As plasmatic creatinin is not helpful we aimed to study new biomarkers as well as renal artery resistive indexes (RI) to distinguish AKI etiologies.

Methods: We included in a prospective study adults presenting with cirrhosis and ascitis. Exclusions' criteria were: multifocal hepatocellular carcinoma, acute hemorrhage, severe chronic kidney disease (eGFR<15ml/min/1.73m2 or dialysis) and renal or hepatic transplant. AKI diagnosis was made according to AKIN criteria. Urine and blood were taken as soon as possible from the admission to analyze cystatin c, NGAL and KIM1. Renal doppler ecography was performed within the next days. The follow-up period was 1 month.

Results: In an intermediate analysis 77 patients were included, mostly men (66.2%) aged 58.3±10.2 years old. AKI occured in 50.6% cases: 76.9% pre-renal, 15.4% ATN and 7.7% HRS. Seven patients were admitted to intensive care unit (ICU) and 6 died. RI, age, sex, infection, ICU admission or death were similar in the 3 etiological groups. New biomarkers were significantly useful to differenciate ATN from pre-renal not from HRS.

Table 1: Comparison beween AKI causes

Variables	Pre-renal (n=30)	ATN (n=6)	HRS (n=3)	p
Chronic kidney disease (%)	2(5)	3(7.7)	0	0.012
Creatinin mimol/l	72 (64.8-141)	224.5 (128.3-300.3)	189 (121-200)	0.07
Plasmatic NGAL ng/ml	90.8 (67.8-229-2)	216.4(167.6-672.3)	261.3(207.5-371.3)	0.023
Urinary NGAL ng/ml	70.5(25.5-101)	134(114.8-171.7)	82.5(72.3-344.5)	0.002
Urinary/Plasmatic NGAL	6.2(3.9-9.1)	12.5(9.9-50.8)	7.5(7.1-15.9)	0.02
Urinary KIM-1 ng/ml	0.12 (0.05-0.23)	0.38(0.31-0.69)	0.55(0.53-0.73)	0.04
Serum Cystatin C	1.5(1.2-2.0)	2.4(2.0-2.7)	2.1(1.8-2.5)	0.028
Renal artery resistive index	0.78(0.63-0.9)	0.83(0.77-0.87)	0.79(0.75-0.87)	0.162

Variables are expressed as median and 25th-75th percentiles

In the ROC analysis, AUC for ATN was 0.93 (0.78-100) using urinary NGAL.

Conclusions: Novel biomarkers can help to differentiate ATN from pre-renal AKI but not from HRS. Renal artery RI are not useful to distinguish AKI etiology. Urinary NGAL seems to be the better predictor to diagnose ATN.

SA-PO060

Factors Impacting the Development of Acute Kidney Injury (AKI) after a Liver Transplantation (OLT) Hugues Bouchard, Veronique Lapointe, Louise Roy, Marie-Noelle Pepin. *Nephrology, Centre Hospitalier de l'Université de Montréal, Montreal, QC, Canada.*

Background: The aim of this retrospective study was to compare the characteristics of patients developing AKI (RIFLE stages 1, 2, 3) within the first week post liver transplantation and patients not developing AKI.

Methods: From 2004 to 2008, 125 patients with cirrhosis and receiving a first OLT were included in the study. Among them, 48 patients developed no AKI during the first week post transplant (controls (C)), 28 patients developed an AKI stage 1, 18 patients AKI stage 2 and 31 patients AKI stage 3. Factors studied were baseline demographics factors, complications of cirrhosis, baseline renal function and biochemical values; factors occurring during surgery and after transplantation.

Results: All four groups had similar baseline clinical and biochemical characteristics (including renal function) except for MELD score, hyponatremia and hospitalization awaiting OLT. Other factors were also significantly different between controls and AKI patients Results are Mean ± SEM; *p≤0.05 vs AKI; # p≤0.01 vs AKI (proportional odds ratio).

	Controls	AKI 1	AKI 2	AKI 3
MELD score	11.5±6.0 #	13.4±5.1	16.6±5.9	14.6±7.2
% pts with Na <130	10% #	7,7%	27,8%	35,5%
Hosp before OLT	35.4% *	46.4%	61.1%	56.7%
Blood loss during OLT (ml)	546±446 *	1352±972	1193±900	1095±752
BP drop during OLT	60.7%#	78.6%	88.9%	87.1%
INR post OLT	1.07±0.09 #	1.13±0.14	1.25±0.17	1.28±0.36
Bilirubin post OLT(mm/l)	52.8±50.2 #	53.3±50.9	89.9±115.6	129.7±126.0
Hb (g/l) 1 week post OLT	89±21 #	85±19	78±15	78±20
Total tacolimus dose during 1st week (mg)	57±19 *	62±27	53±39	38±26
Serum creatinine (umol/L) at 1 month	87.6 ± 26.2 #	95.8 ± 32.3	107.5 ± 31.8	136.3 ± 81.2

Results are Mean ± SEM; *p≤0.05 vs AKI; # p≤0.01 vs AKI

More patients were on dialysis at 1 month, although it did not reach statistical significance (C: no patient, AKI-1: no patient, AKI-2: 5.6%, AKI-3: 16.1%).

Conclusions: Other factors than baseline renal function affect the risk of developing AKI post-OLT such as liver function and hemoglobin. The outcome of AKI is not as good as shown by higher creatinine levels at one month. This study could be the basis for a randomized control trial evaluating new renal-sparing protocols.

SA-PO061

Use of the Acute Kidney Injury Criteria Facilitates Earlier Detection of Renal Dysfunction in Hospitalized Cirrhotics David A. Foxwell,[1] Andrew D. Yeoman,[1] Gareth Roberts,[2] Marek A. Czajkowski.[1] *[1]Hepatology, Royal Gwent Hospital, Newport, United Kingdom; [2]Nephrology, University Hospital of Wales, Cardiff, United Kingdom.*

Background: Acute Kidney Injury (AKI) is common in hospitalized cirrhotics and portends a poor prognosis. Anecdotal data suggest that AKI is poorly recognised and under treated, and is frequently mislabelled as hepatorenal syndrome (HRS). The AKI network (AKIN) criteria is sensitive for the detection of early renal dysfunction. The aims of this study were to determine if use of AKIN criteria would be a more sensitive and rapid indicator of acute renal dysfunction in cirrhotics and determine how occurrence and severity of AKI relate to in-patient mortality.

Methods: A prospectively collated cohort of 120 hospitalized cirrhotic patients was retrospectively analysed. The AKIN criteria and HRS creatinine criteria (>133 µmol/l / 1.5 mg/dl) were utilised.

Results: Mean baseline creatinine was 61 µmol/l (0.69mg/dl) in females and 65 µmol/l (0.74mg/dl) in males. At admission, 38% met AKI whilst 17% met HRS criteria and cumulative incidences were 54% and 35% respectively. Inpatient mortality was 35% for those meeting AKI criteria versus 7% in those without AKI (p=<0.0001). Mortality was not significantly higher in patients who met AKI criteria during their admission than at presentation (53% versus 28% p=0.06). Amongst patients with AKI, 51% were stage 1, 14% stage 2 and 35% stage 3. Corresponding mortality was 12%, 44% & 65% respectively. 20 patients who met AKI stage 1 but did not progress had similar mortality (12%) to patients with no AKI (7%) (p=0.9). Of 26 patients who met criteria for AKI but not HRS at admission, 14 later met HRS criteria at a mean interval of 4.3 days with an in-patient mortality of 50%.

Conclusions: AKI is extremely common in hospitalized cirrhotics and has a high mortality dependent on stage. Most AKI (70%) is present at time of admission. The use of AKIN criteria rather than HRS criteria doubles the detection rate of renal dysfunction. Of greater significance, AKIN criteria ensures earlier detection of renal failure, so that basic therapeutic interventions can be delivered, potentially limiting progression and improving outcomes.

SA-PO062

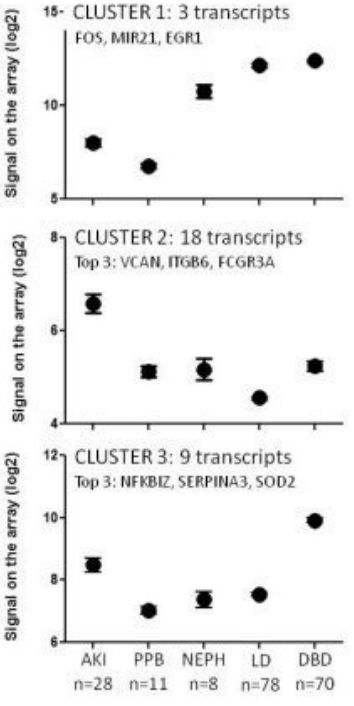
The Injury-Repair Response Reflects General Stress, Acute Kidney Injury and the Effect of Brain Death at the Time of Implantation Konrad S. Famulski,[1] Chatchai Kreepala,[2] Jessica Chang,[2] Philip F. Halloran.[2] *[1]Laboratory Medicine and Pathology, University of Alberta; [2]Medicine, University of Alberta.*

Background: We previously reported that human kidney transplants with early acute injury express transcripts indicating injury repair process (IRRATs). Expression of IRRATs correlated with delayed graft function and future recovery. The present study investigated expression of IRRATs at the time of implantation. Our hypothesis was that IRRATs will reflect various injuries of implanted kidneys.

Methods: Expression of IRRATs was measured by microarrays in biopsies from grafts with early AKI, early stable grafts (PPB), nephrectomies (NEPH), living donors (LD) and donation after brain death (DBD). K-means clustering identified expression patterns across conditions.

Results: We found that cluster 1 had highest expression of IRRATs in both LD and DBD biopsies, whereas in cluster 2 highest expression was in grafts with AKI. Cluster 3 had highest expression of IRRATs in DBD biopsies. Clusters 2 and 3 had the best predictive value for early delayed graft function of DBD kidneys.

Figure 1. Transcriptional profiling



Prediction of delayed graft function (AUC)		
Cluster 1	**Cluster 2**	**Cluster 3**
0.72	**0.81**	**0.81**

We identified other transcripts with highly similar profiles to clusters 1-3.

Genes highly similar to clusters 1-3

Similar to cluster	Gene Ontology p<0.001	Transcription factor / regulator* IPA
Cluster 1 (n=573)	DNA binding (n=140)	n=127
Cluster 2 (n=419)	Cell adhesion (n=55)	n=104
Cluster 3 (n=170)	none (p>0.05)	n=13

*significant difference between clusters 1-2 and 3

Cluster 1 and 2-like genes represented different transcriptional regulation, while cluster3-like genes had no prevailing function.

Conclusions: Thus in the implant biopsies expression of IRRATs reflects general stress, acute injury and the effect of brain death. Each of these processes has different functional and transcriptional programs. Prediction of early delayed graft function at the implantation by molecular test will aid management post-transplant.

SA-PO063

Molecular Signal of Reversible Acute Kidney Injury Predicts Failure of Scarred and Inflamed Grafts Konrad S. Famulski,[1] Chatchai Kreepala,[2] Philip F. Halloran.[2] *[1]Laboratory Medicine and Pathology, University of Alberta, Edmonton, AB, Canada; [2]Medicine, University of Alberta, Edmonton, AB, Canada.*

Background: We previously reported that human kidney transplants with early acute injury express transcripts indicating injury repair process – the acute kidney injury (AKI) signal. The AKI signal correlated with depression of function and future recovery. The present study investigated significance of this signal in transplants with progressive diseases, late post transplant. Our hypothesis was that kidneys have one fundamental response to injury or diseases, the injury-repair response.

Methods: Expression of 30 transcripts constituting the AKI signal was measured by microarrays. For each biopsy, we summarized their expression as the AKI signal.

Results: High injury signal correlated with increased frequency of graft failure, particularly in fibrotic and inflamed grafts, but not with fibrosis alone.

Distribution of failures in non-rejecting grafts according to their histology status and the strength of AKI signal

	Strength of AKI signal		
	Low signal	Moderate signal	High signal
No fibrosis and inflammation*	2	1	1
Fibrosis only	0	0	1
Fibrosis and inflammation*	2	4	20

* indicates significant difference in the distribution among AKI tertiles (Chi-square test)

In late biopsies (>1 year) the AKI signal predicted future graft loss, similar to a published molecular Risk Score previously derived in late kidneys (Figure 1) and shared many individual transcripts with the Risk Score e.g. ITGB6, VCAN, NNMT.

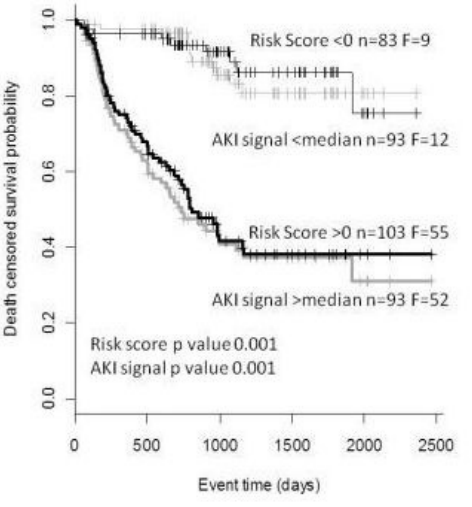

Figure 1. Survival curves of kidney grafts based on the AKI signal and the molecular Risk score.

F - failed, n – number of transplants.

In late transplants, the AKI signal was a better predictor of future graft loss than fibrosis, inflammation, or expression of collagen genes.

Conclusions: Thus the AKI signal is present in progressive diseases and reflects parenchymal distress. Progression in chronic diseases is not due to fibrosis but to parenchymal injury from diseases, with secondary inflammation and fibrosis (wound healing).

Funding: Government Support - Non-U.S.

SA-PO064

Central Venous Oxygen Saturation as Predictor of Azotemia and Adverse Clinical Outcomes in Cardiovascular Surgical Patients Jonathan Chavez,[1] Jaime Briseño,[2] Yajaziel Azpeitia,[3] Guillermo G. Garcia.[1] *[1]Nephrology, Hospital Civil de Guadalajara, Guadalajara, Jal, Mexico; [2]Internal Medicine, Hospital Civil de Guadalajara, Guadalajara, Jal, Mexico; [3]Cardiology, Hospital Civil de Guadalajara, Guadalajara, Jal, Mexico.*

Background: Close to 30% of patients undergoing cardiac surgery develop transient elevation of serum creatinine that does not meet AKIN definition (< 0.3 mg/dl). However, this elevation has been associated to adverse clinical outcomes. Predictive models of acute kidney injury after cardiovascular surgery don't consider central venous oxigen saturation (CVO_2S) as a risk factor for the development of AKI or azotemia

We determined the association between CVO_2S and the development of azotemia and adverse clinical outcomes in CV surgical patients.

Methods: We measured perioperative CVO_2S and other adverse prognostic variables and outcomes in 42 consecutive patients undergoing cardiovascular surgery at our center. A $CVO_2S < 68\%$ prior, during, or 12 h after surgery was considered low. Azotemia was defined by the presence or absence of any rise in serum creatinine < 0.3 mg/dl postoperatively. t test, ANOVA, and multivariate regression analysis where used when appropriate. A p value < 0.05 was considered significant.

Results: Patients' age was 57 ± 11.6 years (range 24-76 years); 52% were diabetics. Mean CVO_2S was lower in patients with azotemia (75.5 ± 8.86) than those without it (82.0 ± 7.51), p < 0.01. The most common surgical procedure was coronary revascularization (25%). 73% had a low CVO_2S that was associated with the development of azotemia, use of vasopressors, and death (table 1).

HR (95% CI) of azotemia and adverse outcomes associated with low CVO2S

		RR (95% CI)	p value
Azotemia (%)	22 (52.4)	2.66 (1.4-6.18)	0,02
AKI (%)	6 (14.2)	1.18 (0.92-1.50)	0.24
S Lactate >2.5 mmol/l (%)	8 (19.0)	1.6 (0.89-2.8)	0.12
Vasopressors (%)	21 (50.0)	4.0 (2.10-7.59)	0.01
Death (%)	9 (21.4)	1.36 (1.02-1.83)	0.05

AKI, acute kidney injury

Conclusions: We conclude that a low perioperative CVO_2S in patients undergoing CV surgery is associated with the development of azotemia and adverse clinical outcomes.

SA-PO065

Mild Elevation of Urinary Biomakers in Pre-Renal Acute Kidney Injury: Distinct Responses of Urinay L-FABP and NGAL Kent Doi,[1,2] Daisuke Katagiri,[1] Kousuke Negishi,[1] Yoshifumi Hamasaki,[1] Masaomi Nangaku,[1] Takehiro Matsubara,[2] Naoki Yahagi,[2] Eisei Noiri.[1] *[1]Nephrology and Endocrinology, University of Tokyo, Tokyo, Japan; [2]Emergency and Critical Care Medicine, University of Tokyo, Tokyo, Japan.*

Background: Pre-renal acute kidney injury (AKI) has been regarded as reversible renal function loss without structural damage. Although pre-renal and renal AKI frequently co-exist in clinical situations, serum creatinine and urine output provide no information to support their differentiation. Because recently developed biomarkers reflect tubular epithelial injury sensitively, we evaluated urinary biomarker levels in patients who had been clinically evaluated as pre-renal AKI and animals that showed transient BUN elevations by volume depletion.

Methods: Urinary biomarkers of L-FABP, NGAL, IL-18, NAG, and albumin at ICU admission were evaluated with an adult mixed ICU cohort consisted of 337 patients. Pre-renal AKI was defined as showing recovery within 48 hr and FENa <1%. We further conducted a proof-of-concept animal experiment to examine urinary L-FABP and NGAL excretion in pre-renal AKI induced by volume depletion.

Results: Modest but significant increases of urinary L-FABP, NGAL, IL-18, NAG, and albumin were observed in AKI patients who had been clinically defined as pre-renal AKI. Animal experiment revealed that volume depletion caused modest secretion of L-FABP and NGAL into urine compared with cisplatinum and ischemia reperfusion models. Of note, urinary L-FABP responded more sensitively than NGAL did. Although no histological evidence of structural damage was observed using light microscopy, partial hypoxia in the kidney was demonstrated by pimonidazole incorporation in the volume depletion model.

Conclusions: Mild increases of urinary AKI biomarkers were detected in AKI patients who were regarded clinically as pre-renal. Animal experiments indicated that renal hypoxia is associated with urinary secretion of L-FABP in pre-renal AKI. These data suggest that new AKI biomarkers, especially L-FABP, can detect mild but significant renal tubular injury that occurs in pre-renal AKI.

SA-PO066

Bedside Tool for Predicting the Risk of Acute Kidney Injury after Cardiac Surgery in Chinese Elderly Patients Penghua Hu, Xinling Liang, Wei Shi, Zhilian Li, Fen Jiang. *Division of Nephrology, Guangdong General Hospital, Guangdong Academy of Medical Sciences, Guangzhou, Guangdong, China.*

Background: The purpose of this study was to provide a risk score for predicting acute kidney injury (AKI) after cardiac surgery in Chinese elderly patients.

Methods: A total of consecutive 848 elderly patients (age≥60 years old) undergoing cardiac surgery with cardiopulmonary bypass between January, 2005 and July, 2010 was evaluated. The clinical outcome was AKI according to the serum creatinine criteria of the RIFLE clssification during the first 7 days postoperatively. Patients were excluded if they had an end stage renal disease, or experienced renal replacement therapy. Those who had missing data were also excluded. In randomly selected 682 patients of the total cohorts, multivariate logistic regression analysis was used to develop a new prediction score based on clinical characteristics and perioperative variables of patients. The new score was validated in the remaining patients.

Results: The incidence of AKI in the derivation cohort was 62.3% (425/682), while in the test cohort was 59.6% (99/166). Eight variables were included in the predictive index and each was assigned a number of points based on its standardized regression coefficients. Variables and points of each variable in score were an estimated glomerular filtration rate ≤ 60 ml/min (2 points), male (2 points), hypertension (2 points), New York Heart Association above stage 2 (2 points), total red blood cell transfusions above 625 ml (2 points), cardiopulmonary bypass time above 113 minutes (3 points), duration of ventilator-assisted respiration during postoperative above 24 hours (3 points), previous cardiac surgery (1 points). The area under the receiver operating characteristic curve, judging the discrimination of the score, was 0.798 (95%CI 0.764 to 0.832) in the derivation, which in the validation set was 0.804 (95%CI 0.739 to 0.870). The calibration of the score assessed using the Hosmer-Lemeshow statistic in derivation and validation set were 0.362, 0.221, respectively.

Conclusions: We provide a new and simple score, based on data from Chinese elderly subjects, to predict AKI after cardiac surgery.

Funding: Government Support - Non-U.S.

SA-PO067

Biomarkers of Acute Kidney Injury in Children Treated with Cisplatin, Carboplatin, and Ifosfamide Maya Harel-Sterling,[1] Julie Ho,[3] Ang Gao,[3] Melissa Piccioni,[1] Michael Pizzi,[1] Zubaida Al-Ismaili,[1] Michael R. Bennett,[2] Prasad Devarajan,[2] Michael Zappitelli.[1] *[1]McGill Univ Health Cent, Montreal, Canada; [2]Cincinnati Children's Hosp Med Cent; [3]Section of Nephrology, Univ of Manitoba, Canada.*

Background: Cisplatin (Cis), Carboplatin (Carb) and Ifosfamide (Ifos) are commonly used nephrotoxic chemotherapies. Biomarkers (BioM) of tubular injury may allow for early acute kidney injury (AKI) diagnosis, treatment (Rx) and chronic injury prevention.

Methods: We prospectively measured serum creatinine (SCr), urine alpha-glutathione S-transferase (a-GST, µg/L, proximal tubule) and pi-GST (µg/L, distal tubule), from children receiving Cis/Carb and Ifos Rx. AKI definition: ≥50% rise from pre-Rx. We compared peak AKI *vs.* non-AKI BioM levels (Mann-Whitney) and characterized BioM changes over consecutive Rx days (ANOVA) in patients with and without AKI. In a pilot study, we measured hepcidin-25 (HEP-25, ng/ml) and liver-type fatty acid-binding protein (L-FABP, ng/ml) in a subset of patients.

Results: We studied 42 children (24 Ifos;18 Cis/Carb), mean[SD] age was: 9.9[4.0] yrs; 41% boys; 33% Cis/Carb-AKI; 54% Ifos-AKI. a-GST rose significantly on Ifos Rx (Day 1: mean[SD] 4.3[9.1]; Day 5: 9.5[20.5], p=0.0035); pi-GST rose on Cis/Carb (Day 1: 3.7[6.5]; Day 5: 21.5[30.3], p=0.0034) and Ifos Rx (Day 1: 3.5[2.9]; Day 5: 9.2[10.8], p=0.03). a-GST and pi-GST on Cis/Carb Rx only rose significantly in AKI patients (both p=0.002); with Ifos, pi-GST only rose in AKI (p<0.01) but a-GST rose with and without AKI (both p<0.05). Peak Rx alpha-GST and pi-GST levels were not significantly different for the AKI *vs.*non-AKI patients for both drugs. Peak HEP-25 was higher (p=0.0108) in *non*-AKI patients on Ifos (as per previous research). Peak L-FABP was higher in AKI vs.non-AKI with Ifos Rx, but without statistical significance (p=0.08).

Conclusions: This is the first evaluation of these BioM in pediatric Cis/Carb and Ifos-AKI. The a-GST and pi-GST excretion pattern is consistent with tubular damage from these drugs. As in other study populations, HEP-25 is higher in non-AKI patients. These BioM show promise for early AKI diagnosis and possibly for predicting renal tubular damage severity.

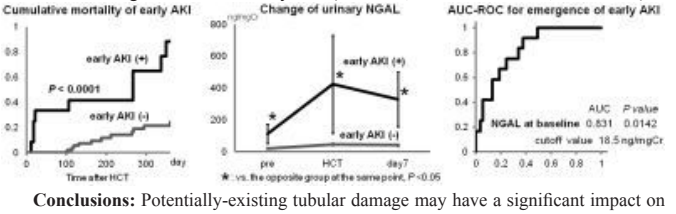
SA-PO068

Potentially-Existing Tubular Damage Is Associated with Early Emergence of Acute Kidney Injury Following Hematopoietic Stem Cell Transplantation Taku Morito,[1,2] Minoru Ando,[1] Ken Tsuchiya,[2] Kosaku Nitta.[2] *[1]Department of Nephrology, Tokyo Metropolitan Komagome Hospital, Bunkyo-ku, Tokyo, Japan; [2]Department IV of Internal Medicine, Tokyo Women's Medical Hospital, Shinjuku-ku, Tokyo, Japan.*

Background: Acute kidney injury (AKI) in the early stage of hematopoietic stem cell transplantation (HCT) is often fatal. Prediction of such AKI may contribute to the improvement of prognosis.

Methods: A 1-year prospective study was conducted in 67 patients receiving allogeneic myeloablative HCT. Urinary neutrophil gelatinase associated lipocalin (NGAL) levels were consecutively measured as a marker of tubular damage before conditioning therapy (baseline), and at days 0 (the morning of HCT) and 7. "Early AKI" defined as AKI developing before stem cells are engrafted in the bone marrow. Cumulative mortality was analyzed by the Kaplan–Meier method. Discriminative ability of NGAL for emergence of early AKI was evaluated using area under the receiver operating characteristic curve (AUC-ROC). Multivariate Cox hazards regression analysis was performed to evaluate the association of NGAL level and the emergence of early AKI, adjusting for known risk factors.

Results: Incidence of early AKI was 18% (Risk: 1.5%, Injury: 6.0%, and Failure: 10%). The Kaplan-Meier estimate of the group with early AKI was significantly higher. While serum Cr remained statistically constant, in early AKI group, urinary NGAL level manifested the peak at HCT and the transient decrease at day 7. Notably, the AKI group already had significantly higher NGAL level at baseline, which had good discriminative ability of AKI and was a significant risk of early AKI (HR: 4.14, 95%CI: 1.31-13.2, P = 0.0164).



Conclusions: Potentially-existing tubular damage may have a significant impact on the development of early AKI, leading to poor prognosis.

SA-PO069

Outcomes of Acute Kidney Injury Patients with and without Cancer: A Single Center Study Yeon Soon Jung, Ye Na Kim, Ho Sik Shin, Hark Rim. *Internal Medicine, Kosin University College of Medicine, Busan, Republic of Korea.*

Background: The risk of AKI was 18% during the 1st year after cancer diagnosis. Up to 50% of cancer patients experience AKI while in the ICU. Few studies have examined the outcomes of AKI in patients with and without cancer (esp. solid cancers). Therefore, we evaluated these outcomes. The purposes of this study were to evaluate and compare the characteristics and outcomes of cancer and non-cancer patients, to determine the impact of cancer diagnosis on hospital mortality; and to compare outcome predictors between the two groups of patients.

Methods: We conducted a retrospective cohort study in Kosin University Gospel Hospital during 12 years. The patients were divided into two major groups:1,360 AKI patients without cancerand 851 AKI patients with cancer. Predictors of all-cause death were examined using Kaplan-Meier and Cox proportional hazards analyses in both groups.

Results: The main contributing factors of AKI were sepsis (31.1%) and ischemia (52.7%). AKI was multifactorial in 78% of patients with cancer and in 71% of patients without cancer. Hospital mortality rates were higher in patients with cancer (42.8%) than in patients without cancer (22.5%) (P = 0.014). In multivariate analyses, diabetes mellitus (DM) and cancer diagnosis were associated with hospital mortality. Cancer diagnosis was independently associated with mortality [odds ratio = 3.010 (95% confidence interval, 2.340-3.873), P = 0.001]. Kaplan-Meier analysis revealed that subjects with DM and cancer (n = 146) had lower survival rates than subjects with DM and without cancer (n = 687) (log rank test, P = 0.001).

Table 1. Main patient characteristics and outcomes

Variables	All patients (n = 2211)	Non-cancer patients (n = 1360, 61.5%)	Cancer patients (n = 851, 38.5%)	P-value
Age (years)	61.1 ± 14.1	61.4 ± 15.3	60.7 ± 12.1	0.221
Male gender	1356 (61.3%)	789 (58%)	567 (66.6%)	0.001
DM	833 (37.7%)	687 (50.5%)	146 (17.1%)	0.001
Sepsis	687 (31.1%)	442 (32.5%)	245 (28.7%)	0.001
Hospital mortality	671 (30.3%)	306 (22.5%)	365 (42.8%)	0.001
ICU admission	523 (23.7%)	385 (28.3%)	138 (16.2%)	0.001
ICU mortality	340 (66.0%)	230 (59.7%)	110 (79.9%)	0.001
Inotropics	607 (27.4%)	441 (30.2%)	166 (19.5%)	0.001
Mechanical ventilator	480 (21.7%)	385 (28.3%)	95 (11.2%)	0.001
Chronic hepatitis B	211 (9.5%)	93 (6.8%)	118 (13.8%)	0.001
Chronic hepatitis C	185 (8.4%)	114 (8.4%)	71 (8.3%)	0.512
Cause of death				
cancer	234 (34.9%)	NA	234 (64.2%)	
cerebrovascular disease	58 (8.6%)	51 (16.7%)	7 (1.9%)	0.001
heart disease	49 (7.3%)	45 (14.7%)	4 (1.0%)	0.001
DM	1 (0.2%)	1 (0.3%)	0	0.001
infection	273 (40.8%)	160 (52.3%)	113 (31.0%)	0.001
liver diease	53 (7.7%)	46 (15.0%)	7 (1.9%)	0.001
hypertensive disease	3 (0.5%)	3 (1.0%)	0	0.001
Type of cancer				
Locoregional solid tumor	189 (8.5%)		189 (22.2%)	NA
Metastatic solid tumor	604 (27.4%)		604 (71.0%)	
Hematological malignancy	58 (2.6%)		58 (6.8%)	
Cancer status				
controlled	143 (6.4%)	NA	143 (16.8%)	
uncontrolled/newly diagnosed	81 (3.6%)	NA	81 (9.5%)	
uncontrolled/recurrence progression	627 (28.3%)	NA	627 (73.8%)	

Conclusions: Hospital mortality rates were higher in cancer patients than in non-cancer patients. DM and cancer were associated with hospital mortality, and cancer diagnosis was independently associated with mortality.

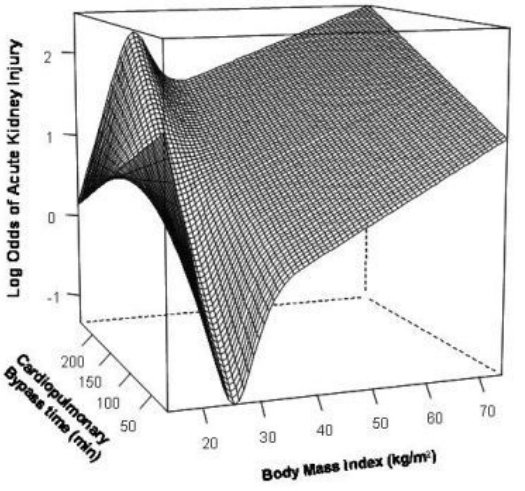
SA-PO070

Body Mass Index Is an Independent Risk Factor for Acute Kidney Injury Following Cardiac Surgery Sevag Demirjian,[1] Sankar D. Navaneethan,[1] Jean-pierre Yared,[2] Allen Bashour.[2] *[1]Nephrology & Hypertension, Cleveland Clinic; [2]Cardiothoracic Anesthesiology, Cleveland Clinic.*

Background: Obesity is a risk factor for diabetes, hypertension and other illnesses, however mortality following cardiac surgery is lower in overweight and obese patients compared to normal (obesity paradox). We examined the effect of body mass index (BMI) on the incidence of acute kidney injury (AKI) following cardiac surgery.

Methods: 21,502 subjects who underwent valve and/or coronary artery bypass graft surgery at Cleveland Clinic between April 2000 and January 2008 were included. AKI was defined as doubling of serum creatinine or need for dialysis. The multivariable logistic regression model adjusted for demographics, comorbidities, baseline renal function, surgery type, and cardiopulmonary bypass (CPB) time.

Results: Median age was 66 years; 68% were male, and 89% white. The median height, weight, and BMI were 172 cm, 81 kg, and 27 kg/m^2, respectively. There were 8188 valve only, and 4923 combined surgeries; the median CPB time was 94 minutes (see Table). There were 258 (1.2%) subjects with BMI< 18.5, 6144 (29%) with BMI between 18.5 – 24.99, 8362 (39%) with BMI between 25 – 29.99, and 6731(31%) with BMI ≥ 30. BMI had an independent and nonlinear association (p<.0001) with AKI in the multivariable model; the latter association was modified by the length of CPB time (p=.005).



Conclusions: BMI has nonlinear and independent association with AKI following cardiac surgery. Obesity was associated with higher incidence of AKI compared to subjects in normal and overweight categories when CPB time was less than 150 minutes. With longer CPB times, the incidence of AKI was comparable in normal, overweight and obese groups.

SA-PO071

Long-Term Survival among Acute Kidney Injury Patients Was the Worse in Group of Patients Experiensed Sepsis Mai Ots-Rosenberg, Jana Uhlinova. *Internal Medicine, University of Tartu, Tartu, Estonia.*

Background: Acute kidney injury (AKI) is a serious risk factor which impairs patients (pts) outcomes. In pts with pre-existing chronic kidney disease (CKD), renal recovery after AKI is less likely and end-stage kidney disease frequently develops. The aim of our study was to investigate etiology and long-term outcome of only dialysis requiring AKI at university clinic as well as to determine the quantity of acute-on-chronic started dialysis.

Methods: The report is based on retrospective data from patients' records in 3 year period starting from January 1, 2009. A Kaplan-Meier analysis was used to determine 3-year survival and separately in septic and diabetic pts groups.

Results: The study was comprised of 318 dialysis requiring AKI pts. In 86 pts pre-existing CKD was known and dialysis was started acutely. During the hospitalization period 106 pts died. Among those 33% were septic and 31% diabetic pts and all together 212 survived. Renal function was completely recovered in a half of the survivors. CKD developed or progressed in 110 pts (52%) from the survival group and after the hospital discharge 30% of CKD pts remained dialysis dependent. Long-term analysis revealed that the overall 3-year survival in the study population was 45% and 3-year survival among discharged pts was 67%. The Kaplan-Meier curve showed significant overall survival difference between sepsis and patients' group without sepsis (P=0.039). There was not a statistically significant difference in long-term survival between diabetics and non-diabetics.

Conclusions: Our study demonstrated that almost one third of AKI survivors stayed dialysis dependent. Acute-on-chronic start dialysis pts formed only 8% of all the AKI population. But, among chronic dialysis incidence pts at our centre acute-on-chronic pts formed 33%. AKI in septic and diabetic pts formed the biggest part of all the AKI population at our hospital and these conditions were associated with high in-hospital mortality. Long-term survival was worse especially in patients with sepsis.

SA-PO072

Cerebral Blood Flow during Hemodialysis in Acute Kidney Injury and Liver Cirrhosis Giuseppe Regolisti,[1] Carola Cademartiri,[1] Umberto Maggiore,[1] Aderville Cabassi,[1] Riccardo Antoniotti,[1] Santo Morabito,[2] Alberto Caiazza,[3] Enrico Fiaccadori.[1] *[1]Department of Internal Medicine and Nephrology, University of Parma, Parma, Italy; [2]Division of Nephrology, Policlinico Umberto I, Rome, Italy; [3]Department of Medicine and Diagnostics, AUSL, Parma, Italy.*

Background: Hemodialysis (HD) can decrease cerebral blood flow (CBF) in patients with acute kidney injury (AKI). Moreover, since regulation of cerebral hemodynamics may be impaired in liver cirrhosis (LC), patients with AKI and LC may be at increased risk of cerebral hypoperfusion during HD.

We studied CBF during the first HD session in patients admitted for oliguric AKI, with or without LC.

Methods: CBF was examined by measuring middle cerebral artery mean flow velocity (MCAmfv) with transcranial Doppler (posterior temporal window, duplicate measurements) at baseline, at midtime and at the end of the first 4-h HD session *(Qb 200 ml/min, Qd 300 ml/min, parallel flows)* in 11 patients with both AKI and LC (median age 69 yrs, range 40-87, 7 males). Eleven patients with AKI without LC (median age 77 yrs, range 69-92, 6 males) served as controls. Data were analyzed using mixed models for repeated measurements.

Results: At the start of the HD session there was a trend, albeit not statistically significant, toward a higher MCAmfv in patients with LC compared to controls (mean MCAmfv 33.8 cm/sec [SEM 4.9] vs 25.4 cm/sec [SEM 2.4], P=0.14). Also, we observed

a marginally smaller relative blood volume (RBV) decrease (hemoglobinometry) during the HD session in the patients with LC than in the controls (-0.6% [SEM 1.2] vs -5.5% [SEM 2.6], P=0.05). The change in mean arterial pressure at end HD was similar between the 2 groups (P=0.70). MCAmfv decreased significantly during the HD session in both groups (P=0.01). However, after adjusting for baseline MCAmfv values and the difference in RBV decrease, the change in MCAmfv during the HD session did not differ between the patients with LC and the controls (time-averaged difference between groups: P=0.99; group-by-time interaction: P=0.07).

Conclusions: HD induces a decrease of CBF in patients with AKI. Patients with LC do not show a more pronounced fall of CBF during the course of the HD session.

SA-PO073

Urine Output on Continuous Renal Replacement Therapy Predicts Survival in Pediatric Acute Kidney Injury Heather A. Lesage-Horton,[1] Rebecca M. Lombel,[1] Theresa Mottes,[1] Kassandra L. Messer,[3] Michael Heung,[2] Neal B. Blatt.[1] *[1]Pediatrics-Nephrology, University of Michigan, Ann Arbor, MI; [2]Internal Medicine-Nephrology, University of Michigan, Ann Arbor, MI; [3]Biostatistics, University of Michigan, Ann Arbor, MI.*

Background: Acute kidney injury (AKI) remains a common and serious medical condition in intensive care unit patients with mortality rates approaching 50%. Currently, the indications for starting Continuous Renal Replacement Therapy (CRRT) and the timing of when to initiate and discontinue CRRT are clinician- and hospital-dependent.

Methods: Retrospective chart review of pediatric patients who received CRRT in the C.S. Mott Children's Hospital from July 1, 2006, through September 30, 2010. Statistical comparisons were made via unpaired t-tests for continuous variables and chi-square or Fisher's exact test for categorical variables. Logistic regression was used to look for associations with survival for the whole cohort and for renal recovery or dialysis for survivors.

Results: 84 patients with AKI had 107 sessions of CRRT during the study period. Looking only at the last circuit of the first CRRT session, 43% (n=36) had renal recovery, 30% (n=25) required intermittent hemodialysis or peritoneal dialysis, and 27% (n=23) died. Significant differences between survivors and non-survivors were found for initial fluid overload (FO, 15 vs. 25%, p=0.02), final FO (6 vs. 19%, p<0.01), and urine output (UO, mean 0.8 vs. 0.1 mL/kg/hr, p <0.01). Each 1 mL/kg/hr increase in UO increased the odd ratio for survival by 14.9-fold. Survivors with renal recovery had increased use of diuretics (43 vs. 16%, p=0.03) compared to those with dialysis dependence.

Conclusions: Pediatric survivors of severe AKI requiring CRRT show increased UO at CRRT discontinuation. Survivors have less FO at both CRRT initiation and discontinuation compared to non-survivors. These findings suggest that readily available clinical characteristics may help predict long-term outcomes for children on CRRT. We are analyzing additional patient characteristics with the hope of developing a model that may be used to predict which patients can be successfully discontinued from CRRT.

SA-PO074

Pulmonary Artery Pressure Is a Strong Predictor of Acute Kidney Injury after Lung Transplantation Jiwan K. Thapa, Edgard I. Wehbe, Marie M. Budev, Andra E. Duncan, Brian R. Stephany. *Nephrology and Hypertension, Cleveland Clinic Foundation, Cleveland, OH.*

Background: Pulmonary hypertension (PH) is common in patients awaiting lung transplantation. The impact of pulmonary artery pressure on the risk of perioperative AKI remains unknown.

Methods: Using the Cleveland Clinic lung transplant registry, we identified 354 patients who underwent lung transplantation between 1997 and 2009 and who had pre-operative assessment of pulmonary artery pressure. PH was defined as mean pulmonary artery pressure (mPAP) >25 mmHg. We further categorized the severity of PH as - mild: mPAP 25-34 mmHg (n=133), moderate: mPAP 35-44 mmHg (n=39), severe: mPAP ≥ 45 mmHg (n=20). AKI was defined by absolute rise in creatinine by >= 0.3 mg/dl according to the AKIN classification.

Results: We identified 192(54%) patients with pre-operative PH. Of those, 136(70%) developed AKI compared to 84(52%) who developed AKI in the non PH cohort (P=0.0002). The rate of AKI increased as the severity of PH increased (mild 66%, moderate 74%, severe 95%, P=0.001). In multivariate logistic regression, controlling for known risk factors for AKI, PH was significantly associated with post-operative AKI (OR 1.76, 95% CI 1.08-2.9, OR 2.41, 95% CI 1.08-5.7 and OR 13, 95% CI 2.5-23) for mild, moderate and severe PH respectively). When mPAP was examined as a continuous measure, every 10-mmHg increase in pulmonary pressure was associated with 67% increase in risk for AKI (OR 1.67, 95% CI (1.28,2.24).

Conclusions: In patients undergoing lung transplantation, pre-operative pulmonary hypertension is a strong risk factor for perioperatve acute kidney injury.

SA-PO075

Acute Kidney Injury Is Under-Recognized in Pediatric Presentations of Sepsis Marie-Carmelle Elie-Turenne, Azra Bihorac, Tezcan Ozrazgat Baslanti, Mohammad G. Abu-farsakh, Mark S. Segal. *University of Florida, Gainesville, FL.*

Background: The incidence of acute kidney injury in severe sepsis (sAKI) ranges from 23-67% in adults. Since the incidence is not clearly defined, the objective was to characterize sAKI in pediatric patients.

Methods: This is a 10 year retrospective study from a single academic hospital of sepsis patients ≤19 years admitted from 2001 to 2011. Patients with a history of chronic kidney disease or long-term dialysis were excluded. Demographics, laboratory, and outcome data were collected.

Results: 405 subjects were identified of whom 45% met criteria for AKI. 2.5% (10/405) of subjects had a documented diagnosis of AKI by their physician. Using pRIFLE criteria, 137/405 (33%) were R, 18/405 (4%) I, and 26/405 (6%) F. When height data was available (157/405), the Schwartz equation estimated a higher creatinine clearance 141 (130, 153) compared to the Shull equation 102 (98, 107) p <.0001. However, among all patients with sAKI, there was no difference between the calculations rendered by the equations 57.9 (51, 64) 62.8 (53.1, 72.5) p=0.163. Of subjects under 1 year of age, 84% (133/158) had AKI.

Characteristics of Patients with and Without Sepsis Related AKI

	No AKI (n=224)	AKI (n=181)	p-value
Median (Q1, Q3)	17.5 (15.5, 21.2)	16.4 (14.4, 18)	0.016
BMI	17.5 (15.5, 21.2)	16.4 (14.4, 18)	<0.0001
Age (months)	92 (30, 173)	2 (1, 14)	0.2241
Anion Gap	16 (14, 18)	16 (14, 19)	0.2165
C Reactive protein	32 (8.7, 68.9)	34.7 (13.1, 108.6)	0.3708
Sedimentation rate	32 (17, 56)	30 (7, 52)	0.0974
Hemoglobin	11.6 (10.2, 12.7)	11 (9.7, 12.5)	0.0009
BAND	9.5 (5, 19)	5.5 (2, 12)	0.9585
WBC	12 (7.1, 16.1)	11.5 (7.9, 15.9)	0.0299
Day1 Lactate	2.1 (1, 2.7)	2.6 (1.8, 4.8)	0.8829
Day 1 Cr	0.4 (0.3, 0.6)	0.3 (0.3, 0.5)	<0.0001
Day 1 Cr Clearance	117.2 (98.4, 135.2)	78.7 (61.7, 78.7)	0.045
Day2 Lactate	1.2 (0.9, 1.7)	1.9 (1.1, 3.1)	0.3931
Day 2 Cr	0.5 (0.3, 0.7)	0.4 (0.3, 0.9)	0.0587
LOS	2 (1, 4)	2 (2, 6)	0.0055
ICU_LOS	0 (0, 0)	0 (0, 0)	0.1588
Female Gender, n(%)	92 (41%)	87 (48%)	0.0137
ICU, n(%)	31 (14%)	43 (24%)	0.0137
In-hospital mortality, n(%)	0 (0%)	5 (3%)	0.0173

Conclusions: AKI is highly prevalent among septic pediatric children. Increased recognition is needed early in the course of presentation.

SA-PO076

Acute Kidney Injury in Pregnancy: Experience from a Large Tertiary Care Referral Centre Alexandra Mihalache, Oier Ateka, Inês Palma Reis, Kate Harding, Catherine Nelson-piercy, Anita Banerjee. *Women's Services, St Thomas' Hospital, London, United Kingdom.*

Background: Acute Kidney Injury (AKI) in pregnant women can be due to several causes such as preeclampsia, sepsis and volume depletion. The causes and outcomes of AKI in pregnancy have not been explored in detail. This study investigated the clinical features, aetiology, and perinatal outcomes of de novo AKI and AKI in patients with CKD.

Methods: Data on clinical features and outcome were collected on 39 patients with AKI. AKI was defined as a serum creatinine (sCr) >90 µmol/L during any time of hospital admission. Data on previous CKD before pregnancy were also collected.

Results: The clinical features of the patients were as follows: age 32±5 (mean±SD) years and BMI 27±5 kg/m^2. Peak sCr was 121±35 µmol/L (range 90-263), peak potassium was 4.9±0.6 mmol/L (range 4.1-7.1). AKI in pregnancy was commonest in the third trimester (73%). Preeclampsia was the cause in 65% of cases and 20% of cases were due to postpartum haemorrhage. AKI in pregnancy was not recognised in 43.5% of cases. There was no significant difference in peak creatinine between patients in whom the AKI was and was not recognised. Birth weight was also similar in both groups. 72% of cases required either high-dependency unit or intensive care unit support. Five patients had peak sCr >150 µmol/L and these women had similar maternal age and birth weight to the rest of the cohort. There was no association between peak sCr and birth weight. Prior known CKD was present in 9/39 (25%) of the cases. Those with CKD had similar age, birth weight but higher peak sCr than those without (162±41 µmol/L vs. 109±21 µmol/L; p<0.005). Causes of CKD included focal segmental glomerulosclerosis, reflux nephropathy, previous nephrectomy, Sjogrens Syndrome and tubulointerstitial nephritis. 60% of women with AKI required an emergency Caesarean section.

Conclusions: AKI in pregnancy is worse in women with prior CKD and 43% cases were not recognised. A large proportion of patients were managed in high-dependency and intensive care and required emergency Caesarean section.

SA-PO077

Acute Kidney Injury in Pediatric Idiopathic Nephrotic Syndrome without Hypovolemia Yoshinobu Nagaoka,[1] Kenji Ishikura,[1] Riku Hamada,[1] Tomoyuki Sakai,[1] Yuko Hamasaki,[2] Hiroshi Hataya,[1] Masataka Honda.[1] *[1]Nephrology, Tokyo Metropolitan Children's Medical Center, Fuchu, Tokyo, Japan; [2]Pediatric Nephrology, Toho University Omori Medical Center, Ota-Ku, Tokyo, Japan.*

Background: Acute kidney injury (AKI) is an occasional complication in idiopathic nephrotic syndrome (NS). Hypovolemia accompanied with hypoalbuminemia had previously been considered the major cause of AKI in NS. On the contrary, several recent reports documented AKI in NS without hypovolemia. However, these studies contained small number of patients and no mention of frequency.

Methods: We analyzed retrospectively 156 children (102 boys, 54 girls) with idiopathic NS managed in our hospital from 2000 to 2011. AKI was defined as prerenal and renal states having more than the twice the baseline serum creatinine value, with prerenal AKI as having more than +5% of the baseline hematocrit level.

Results: AKI was observed 42 times in 29 (18.6%) of 156 patients. Among them, 9 times in 6 patients (boy/girl ratio 1.3) were prerenal AKI, and 33 times in 27 patients (boy/girl ratio 3.1) were renal AKI. Comparisons of mean value (prerenal vs renal) were as follows: age at AKI, 4.1+/-1.4 years vs 5.4+/-0.7 years [p=0.37, t-test]; difference from the 50th percentile systolic blood pressure (by age and height), 17.7+/-4.0 mmHg vs 20.4+/-2.1 mmHg [p=0.60]; cardiothoracic ratio, 44.6+/-2.5% vs 48.9+/-1.2% [p=0.26]; fractional excretion of sodium (FENa), 0.03+/-0.06% vs 0.11+/-0.03% [p=0.045]; urea nitrogen, 32.1+/-8.7 mg/dl vs 47.9+/-4.6 mg/dl [p=0.11]; and uric acid, 6.0+/-1.1 mg/dl vs 9.5+/-0.5 mg/dl [p=0.004].

Conclusions: In pediatric idiopathic NS cases, about 20% were complicated with AKI, and most of them (approximately 80% of AKI) were renal AKI. In renal AKI, decrease of FENa and increase of urea nitrogen or uric acid were observed, which appeared similar to hypovolemia and different from acute tubular necrosis. Hypertension or enlargement of cardiothoracic ratio were observed, which seemed likely to cause increase in circulating plasma volume. It is important that clinicians are alert to the possibility of hypervolemia, and should perform infusion of crystalloid or albumin preparations with care.

SA-PO078

Acute Kidney Injury after Antibiotic Spacer Implantation for Infected Joint Prostheses

Renu Bansal, Andrew Luu, Madhumathi Rao. *Nephrology, Tufts Medical Center, Boston, MA.*

Background: Acute kidney injury (AKI) is an under-recognized complication after antibiotic spacer placement for two-stage arthroplasty for infected joint prostheses, progressing to dialysis in 2-6% patients. Antibiotic impregnated spacers produce high and sustained joint antibiotic levels exceeding the MIC of many potential organisms. Two stage arthroplasty is standard of care and performed at an increasing rate in older and higher risk patients. Between August 2007 and July 2011 this procedure comprised 4% of joint surgeries at this center (national average 1%).

Methods: We performed a retrospective study of 42 patients undergoing 2-stage arthroplasty who received antibiotic spacers containing tobramycin (3.6 g to 10.8 g) and vancomycin, and examined the incidence and risk factors of AKI. AKI was defined as doubling of serum creatinine from baseline, anytime between implant and explant of spacer.

Results: The mean age was 61 years, a third each had diabetes or vascular disease and 20% had CKD. AKI developed in 50% of patients in three clinical patterns – early rise in serum creatinine followed by recovery (50% of AKI), delayed rise in serum creatinine (20% of AKI) and AKI without recovery (30% of AKI). Three patients needed dialysis and one patient died. Patients who developed AKI were found to be older, with poorer kidney function and vascular disease.

Table 1

Variable	HR	95% CI	p value
Age (10 years)	1.4	1.03-1.91	0.03
CVD	4.84	1.9-12.5	0.002
CKD 1 (reference)			0.16
CKD 2 (eGFR 60-90 ml/min)	3.2	1.10-9.0	0.032
CKD 3-4 (eGFR <60 ml/min)	4.6	1.5-13.8	0.006

For every 0.1 mg increase in serum creatinine the risk of AKI increased by 9 % (95% CI 4 to 14%), p=0.001 and for every 10 ml increase in baseline eGFR the risk of AKI decreased by about 30% (95%CI 14-34%), p=0.001.

Conclusions: In summary, at a referral center, after 2-stage arthroplasty with antibiotic spacers, the incidence of AKI was 50%, cumulative toxicity appeared to occur and specific risk factors were identified including even minor declines in baseline eGFR. We therefore recommend careful selection of patients, close monitoring and long term follow up.

SA-PO079

Electronic Results Reporting of Acute Kidney Injury in Cirrhotics

Robert A.D. Scott, Nitin V. Kolhe, Nicholas M. Selby. *Department of Renal Medicine, Royal Derby Hospital, Derby, Derbyshire, United Kingdom.*

Background: Current Acute Kidney Injury Network (AKIN) criteria for defining AKI perform well in general hospitalised patients but have not been validated in certain subgroups. Liver disease is increasing, disproportionately affecting younger patients with reduced body mass. We aimed to apply AKIN definitions of AKI to a population of cirrhotic patients and correlate this with outcomes in a 1000-bedded acute teaching hospital with a Tier 2 hepatology centre.

Methods: A hospital wide, real-time electronic reporting system based on the AKIN diagnostic criteria for AKI has been in place at Royal Derby Hospital since 2010. We prospectively identified all hepatology patients with AKI over an 18 month period. They were screened for radiological or histological evidence of cirrhosis and compared to a control group with evidence of cirrhosis and no evidence of AKI identified from the same time period and clinical setting.

Results: 162 cirrhotic patients were identified. They were predominantly young (56.8 +/- 13.6), male (65.4%) and had alcoholic liver disease (78.4%). 110 cirrhotics had AKI: 44 stage 1, 32 stage 2 and 34 stage 3. They were well matched in terms of age, sex and liver severity with 52 cirrhotics without AKI. There were important differences in diabetes and baseline creatinine between those with and without AKI. AKI was significantly associated with increased mortality in cirrhotics (31.8% vs 3.8%, p<0.000). Mortality increased with increasing AKI stage; 3.8% in cirrhotics without AKI, 13.5% in stage 1, 37.8% in stage 2 and 43.2% in stage 3. Increasing severity of liver disease (Child-Pugh class) correlates with increased mortality (p=0.006 for trend). AKI was associated with an increased length of stay (p<0.000). Multivariable analysis was performed for independent factors in predicting mortality (table 1).

Factor	Significance	Hazard Ratio	95% Confidence Intervals
AKI	0.02	10.6	2.4 - 47.0
Child Pugh B	0.04	8.1	1.0 - 65.4
Child Pugh C	0.016	13.1	1.6 - 106.0

Table 1

Conclusions: AKIN diagnostic criteria does correlate and associate with increased mortality in patients with cirrhosis. Severe liver disease and AKI appear to be independent variables in predicting death in cirrhotic patients.

SA-PO080

Urinary Angiotensinogen Predicts Outcomes of AKI Patients in the ICU

Joseph Alge,[1,2] Nithin Karakala,[1,2] Michael G. Janech,[1,2] John M. Arthur.[1,2] *[1]Medical University of South Carolina; [2]Ralph H. Johnson VAMC.*

Background: We have identified urinary angiotensinogen as a prognostic biomarker of acute kidney injury (AKI) after cardiac surgery. However, AKI can be the result of many other etiologies, and it is necessary to qualify angiotensinogen in other settings.

Methods: Urinary angiotensinogen was measured by ELISA in urine samples from ICU patients with AKI of diverse causes including both ischemic and non-ischemic etiologies (n=40; Table 1). The ability of the ratio of angiotensinogen-to-urine creatinine (uAnCR) to predict the following outcomes was evaluated using the area under the ROC curve (AUC): worsening of AKI, AKIN stage 3, need for renal replacement therapy (RRT), AKIN stage 3 or death, and RRT or death.

Results: Median uAnCR was markedly elevated in patients who met the primary outcome of RRT or death compared to those who did not (133.3 ng/mg versus 11.4 ng/mg), and uAnCR was a strong predictor of this outcome (AUC=0.79). It was also a modest predictor of the composite outcome AKIN stage 3 or death (AUC=0.71). Finally, patients with high concentrations of uAnCR (*i.e.* ≥median value) had increased median length of stay in the hospital compared to those with low uAnCR (22 days versus 7 days; p=0.03), and uAnCR was a strong inverse predictor of hospital discharge ≤7 days from sample collection (AUC=0.79).

Conclusions: These data confirm the potential of angiotensinogen as a prognostic AKI biomarker, and this is the first report to demonstrate that it is predictive of outcomes in the setting of AKI secondary to causes other than cardiac surgery.

Table 1. Characteristics of ICU Patients with AKI

	No RRT/Survived	RRT/Death	p

SA-PO081

Serum and Urine NGAL after Partial Nephrectomy: No Greater Renal Injury in Warm Robotic versus Cold Open Techniques

Edward A. Ross,[1] Neil S. Harris,[2] Xuerong Wen,[1] Chris D. Nelsen,[3] Li-Ming Su.[3] *[1]Division of Nephrology, Univ of Florida; [2]Dept of Pathology, Univ FL; [3]Urology, Univ FL, Gainesville, FL.*

Background: There is concern that advantages of minimally invasive robotic partial nephrectomy (RPNTX) could be outweighed by arterial cross clamping causing renal injury: "warm" ischemia, compared to "cold" ischemia used during open partial nephrectomy (OPNTX).

Methods: We measured the serum and urine renal ischemia biomarker neutrophil gelatinase-associated lipocalin (NGAL, at time 0, 4, 8, 12, 24 and 48 hrs post-op) to test the hypothesis that renal injury is avoided in RPNTX by virtue of brief renal hilar arterial clamp times. 32 pts underwent RPNTX for tumors, excluding pts with solitary kidneys: 61.3 ± 10.9 years old, 55% male, BMI 29.8 ± 5.4 kg/m^2, eGFR 79.4 ± 25.7 ml/min, tumor size 2.7 ± 1.0 cm, warm ischemia time 25.4 ± 5.2 min, and blood loss 96.1 ± 57.5 ml. A contemporaneous group of 12 pts underwent OPNTX: some of higher BMI (34.7 ± 12.4, p=ns); trend for larger tumor size (3.4 ± 1.3, p=0.06); longer (cold) ischemia time (38.2 ± 9.6, p=0.0007); and more blood loss (206 ± 103 ml, p=0.004).

Results: With RPNTX mean peak serum NGAL was 213 ng/ml (range 77 to 934). Mean peak urine NGAL was 101 ng/ml (range <25 to 1462), with 28% of pts having values <25 ng/ml at all time points. OPNTX peak serum NGAL was 194 ng/ml (65 to 437) and urine NGAL was 111 ng/ml (<25 to 666), with 17% of pts remaining <25 ng/ml at all times. Neither serum or urine peak NGAL correlated with ischemia time, tumor size, blood loss, BMI or age: for RPNTX, OPNTX or across all pts. There were no significant differences in NGAL or changes in eGFR between groups. While most of the maximal NGAL levels occurred between 2-12 hrs, for many pts the serum and urine values had a second (or delayed) peak at 24 or 48 hrs: occurring in 45.5% and 47.3% of all pts, respectively.

Conclusions: In conclusion, RPNTX with warm ischemia time of no more than approx 30 minutes has risk for renal injury that appears relatively low and comparable to that of the more invasive OPNTX performed with cold ischemia. Delayed or second peaks of serum and urine NGAL are worrisome for reperfusion injury, and warrant further study.

SA-PO082

Incidence and Outcomes of Acute Kidney Injury Complicating Hospitalization with Acute Nonvariceal Upper Gastrointestinal Bleeding in the U.S. (1999-2008) Juyeh Yang,[1,2] Tsung-chun Lee,[3] Maria E. Montez-Rath,[2] Glenn M. Chertow,[2] Wolfgang C. Winkelmayer.[2] *[1]Far Eastern Memorial Hospital, New Taipei City, Taiwan; [2]Stanford University School of Medicine, Palo Alto, CA; [3]National Taiwan University Hospital, Taipei, Taiwan.*

Background: Kidney failure is an established risk factor for mortality after upper gastrointestinal bleeding (UGIB). However, little is known about the incidence and outcome of acute kidney injury (AKI) among patients hospitalized with UGIB.

Methods: From the U.S. Nationwide Inpatient Sample, we identified patients admitted with acute nonvariceal UGIB (ANVUGIB) between 1999 and 2008. We analyzed trends in the incidence of diagnosed AKI and AKI requiring dialysis (AKI-D) and assessed their associations with in-hospital mortality using survey methods to obtain national estimates. Analyses were conducted using multivariable log-Poisson regression models to estimate adjusted relative risks (RR).

Results: We identified 3,814,416 hospitalizations with a diagnosis of ANVUGIB of which 321,878 (8.4%) were complicated by AKI (AKI-D: 34,797; 0.9%). Adjusted percents of AKI (AKI-D) among ANVUGIB patients increased from 4.3% (0.7%) in 1999 to 15% (1.2%) in 2008. The overall in-hospital mortality of ANVUGIB with AKI (AKI-D) was 18.8% (31.1%) and declined from 27.9% (39.0%) in 1999 to 14.7% (25.1%) in 2008 after adjustments. Compared with ANVUGIB patients without diagnosed AKI, the adjusted mortality risk ratios for AKI and AKI-D were 1.88 (95% CI: 1.84-1.93) and 1.45 (95% CI: 1.39-1.52), respectively. Between 1999 and 2008, adjusted mortality decreased among ANVUGIB episodes without or with AKI or AKI-D, but the decrease was significantly more pronounced for patients with AKI (RR=0.53) compared with ANVUGIB patients without AKI (0.62; p-interaction=0.008. For AKI-D: RR=0.64; p-interaction=N.S.).

Conclusions: In summary, the incidences of AKI and AKI-D among patients with ANVUGIB increased, while the in-hospital mortality declined between 1999 and 2008. Overall, AKI and AKI-D were associated with higher mortality in patients with ANVUGIB. Reductions in mortality over the past decade were more pronounced among patients whose ANVUGIB episode was complicated by AKI than in those without it.

SA-PO083

Fluid Overload Is an Independent Risk Factor for Worse Outcome in ICU Patients Pedro Fidalgo,[1] Silvia Coelho,[1] Bruno Rodrigues,[1] Luis Inchaustegui,[1] Ana Luisa Papoila,[2] Fernando Liano,[3] Karina Soto.[1] *[1]Nephrology, Hospital Fernando Fonseca, Lisbon, Portugal; [2]Biostatistic, Faculty of Medical Sciences, Lisbon, Portugal; [3]Nephrology, Hospital Universitario Ramon y Cajal, Madrid, Spain.*

Background: The beneficial effect of Early Goal-Directed Therapy approach was a hallmark in the standard of care of critically ill patients. However, there is a growing concern about the threshold beyond which fluid therapy determines adverse outcomes. The aim of the present study was to determine whether the fluid balance influences worse outcomes in critically ill patients.

Methods: A prospective study of 128 consecutive ICU patients over 6 months was developed. AKI was defined as >Risk, according to RIFLE criteria. Daily intake and output fluids were recorded and fluid balance (FB) was calculated. Cumulative fluid balance (CFB) was calculated by the sum of daily fluid balance. The Percentage of CFB (PCFB) was calculated according to formula:PCFB= [$\sum$ daily FB/admission body weight (kg)]*100. Mann-Whitney test was used for continuous variables. Odds Ratios were calculated by logistic regression.p value <0.05 was considered significant.

Results: Patients were median age 66y, 61.7% male, 85.2% non-black and 35.2 % of them developed AKI. Median SAPS II and APACHE II scores were 57 (CI 50-58) and 24 (CI 22-26), respectively. Crude mortality was 31.3% and 70% of deaths were AKI patients. Median CFB was 7.6 L (P_{25}3.7-P_{75}14.2), median PCFB was 10.1% of body weight (P_{25}4.8-P_{75}18.3), and both were significantly higher in patients who died than in survivors (p=0.04 in ICU, p=0.02 in-hospital mortality). Higher fluid overload was significantly associated with the length of ICU stay (p<0.001) and with mechanical ventilation (p<0.001). In a multivariable analysis, septic shock, MOF, APACHE II and PCFB were determinants of ICU and in-hospital mortality. For each 5% increase in the PCFB, there was an increase of 24.6% and 19.7% in the odds of in-hospital and ICU dead, respectively.

Conclusions: There is a strong association between fluid overload and mortality in ICU patients. Even after adjustment for known risk factors, it remains an independent risk factor for mortality.

SA-PO084

Dietary Intake of Creatinine Can Mimic Acute Kidney Injury Sha Liu, Cory Iverson, David L. Hyndman, David T. Hagerty, Kimberly J. Manhard, Jeffrey N. Miner, Barry D. Quart. *Ardea Biosciences, San Diego, CA.*

Background: During the conduct of a phase 1 clinical trial, significant elevations in serum creatinine (sCr) were observed during the pre-dose and post-dosing periods in both placebo and compound treated subjects at one of two clinical research units (CRU). The elevations were very large (often >0.5 mg/dL), transient, not associated with urinalysis or renal function changes, and were temporally associated with meals. Heat is known to convert the creatine found in meat into creatinine and prolonged exposure to heat results in a significant rise in creatinine concentration in the meat and meat juices. Cases of elevated sCr due to meat consumption have been reported sporadically, but this issue is not widely appreciated and was not highlighted in published recommendations.

Methods: Careful evaluation of the two CRUs revealed that the CRU where elevations were observed served meat that had been cooked for extended periods (longer than 45 minutes) and sometimes included the resulting meat juice as well. To confirm that the elevations were not due to a problem with the serum enzymatic creatinine assay, additional samples were assayed by both the Jaffe and LC-MS/MS methods, and the same intra-day creatinine elevations were observed.

Results: Serial measurements of plasma cystatin C confirmed no change in renal function. Ingestion of long cooked meat resulted in the largest sCr elevations. Simultaneous determination of both plasma creatine and creatinine revealed a strong association between meal time and creatine/creatinine peaks. Meals with shorter meat cooking times were associated with larger creatine peaks but smaller creatinine peaks, while meals with longer cooking times were associated with equal size creatine and creatinine peaks. First morning blood samples collected under fasting conditions were the most stable and provide an easy means of eliminating the effect of dietary creatinine.

Conclusions: We conclude that meat cooked for prolonged periods may cause very large and transient increases in sCr. We recommend that for patients with non-fasting, unexpectedly large increases in sCr, the potential effect of diet should be considered.

SA-PO085

Colistin (Colistimethate Sodium) Induced Nephrotoxicity: A Single Center Experience Mamdouh N. Albaqumi, Lutfi Alkorbi. *Medicine, KFSHRC.*

Background: The emergence of multidrug-resistant, gram negative bacteria has resulted in significant increase in the use of colistin, which had previously fallen out of favour because of reports of nephrotoxicity. Rates of nephrotoxicity have ranged from around 50% in older studies to almost no toxicity in recent reports. Our objective in this study is to determine the incidence of colistin-associated nephrotoxicity at our center and to assess possible associated risk factors.

Methods: This retrospective study was designed to identify predictors of acute kidney injury (AKI) associated with intravenous (i.v.)colistin treatment. From July 2004 to Jan 2010, 327 adult patients receiving colistin for at least 72 h were enrolled. AKI was defined using Acute Kidney Injury Network (AKIN) criteria. We excluded all patients who have estimated glomerular filtration rate (eGFR) of 15 ml/min or less on the first day of using colistin.

Results: A total of 327 patients were included in the study. AKI developed in 144 patients (44.04%).In the AKI group, AKIN stage I developed in 74 patients (51.39%), stage II in 43 patients (29.86%), and stage III in 27 patients (18.75%).

Patients with AKI secondary to colistin were older (mean of 50 y in AKI group vs. 42.5 y in those without AKI), received higher cumulative dose, and longer duration of colistin therapy. Aminoglycosides and Diuretics use were more common in those who developed AKI while use of ACEI/ARBS, Amphotericine, NSAIDs, and Vancomycin was comparable in both groups.

Patients who didn't develop colistin-induced AKI had a better 1 year survival in comparison to those who had AKI (33.9% vs. 20.4%, respectively).

Conclusions: AKI was a common complication of colistin treatment. Age, cumulative dose, duration of treatment, and use of Aminoglycosides and diuretics were associated with higher risk of colistin-induced AKI.

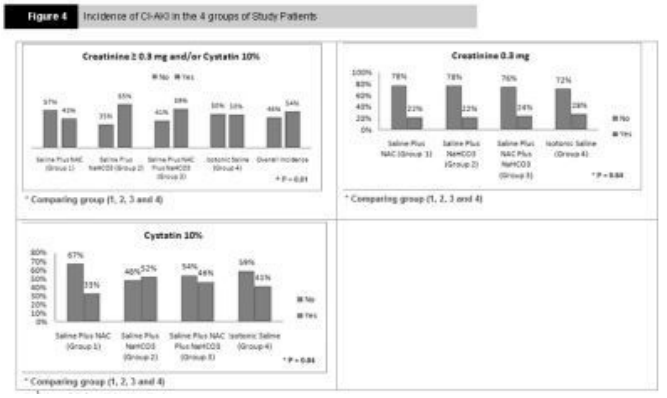
SA-PO086

Intravenous High Dose of N-Acetylcysteine and Sodium Bicarbonate for the Prevention of Contrast-Induced Acute Kidney Injury: A Randomized Controlled Trial Antonio Jose Inda-Filho,[1] Adriano Caixeta,[2] Marcia Manggini,[4] Fabio Santos,[3] Nestor Schor.[1] *[1]Nephrology, Federal University of Sao Paulo, Sao Paulo, Brazil; [2]Cardiology, Hospital Israelita Albert Einstein, Sao Paulo, Brazil; [3]Internal Medicine, Hospital das Forças Armadas, Brasilia, Distrito Federal, Brazil; [4]Cardiology, Instituto de Cardiologia de Brasilia, Brasilia, Distrito Federal, Brazil.*

Background: Contrast-induced nephropathy (CI-AKI) has become an important cause of iatrogenic acute renal impairment. Prior studies using N-acetylcysteine (NAC) or sodium bicarbonate ($NaHCO_3$) in the prevention of CI-AKI have found conflicting results.

Methods: Randomized, controlled study enrolling 500 patients undergoing coronary angiography at a single center using high-osmolar contrast media. The patients were allocated: IV NAC+saline(group 1), IV $NaHCO_3$+saline (group 2), IV NAC+$NaHCO_3$+saline (group 3), IV saline (group 4). All solutions were given 1h before contrast in doses: NAC 150 mg/kg, $NaHCO_3$ 3.5 ml/Kg/h, saline 1ml/Kg/h. During and 6h after procedure doses were: NAC 50 mg/kg, $NaHCO_3$ 1.18 ml/Kg/h, saline 1 ml/Kg/h. Cr and CyC were measured before procedure and at days 1, 2, 3. The end point was CI-AKI based on the Cr (≥0.3 mg/dL) and/or CyC (≥10%) increase between day 0 and 72h after contrast administration.

Results: 75 (15%) patients were excluded. Median patient age was 59.8 ± 11.6 years. The end point was met in 20.0% of the NAC group, 30.4% of the $NaHCO_3$ group, 26.5% of the NAC plus $NaHCO_3$ group, and 23.0% of the saline group (P = 0.01).



Multiple logistic regression model (dependent variable: nephropathy; independent variables: group, diabetes, medications, total volume infused) did not show a significant relationship with nephropathy.

Conclusions: This study suggests that high dose IV NAC was effective to prevent CI-AKI.

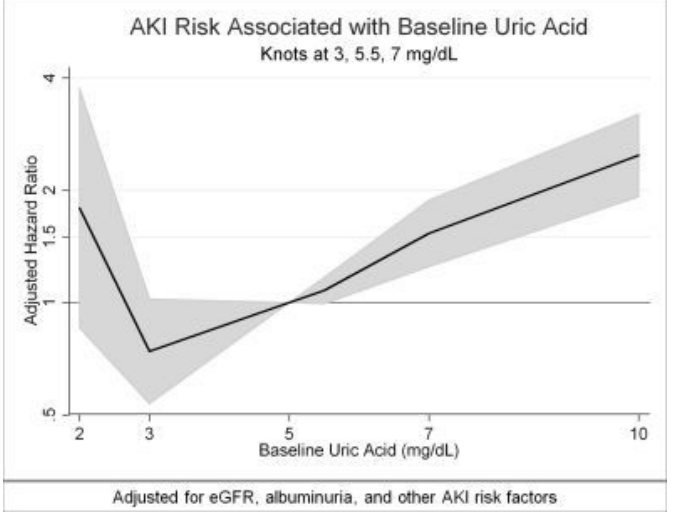
Uric Acid, Gout, and the Risk of Acute Kidney Injury: The ARIC Study

M. Grams, Mara Mcadams, Janet W. Maynard, Michelle M. Estrella, Rugmini P. Warrier, Wen Hong Linda Kao, Josef Coresh. *JHU.*

Background: Urate levels above 5.5 mg/dL associate with AKI after cardiac surgery. Whether this association extends to all AKI over the full range of serum urate is unknown.

Methods: Visit 4 (when urate and gout were assessed) ARIC participants were included (N= 11,487). Participants with previous AKI or eGFR<15 were excluded (N=50). Urate levels were modeled as splines (knots at 3, 5.5, and 7 mg/dL). Cox regression estimated associations with hospitalized AKI, adjusting for race, sex, age, hypertension, diabetes, coronary heart disease, log-albuminuria, and eGFR splines. Additional adjustment in European-Americans included the genetic urate score, or the difference in expected urate level for a given individual compared with an individual homozygous for the major alleles at 8 susceptibility loci and expressed per 100 µmol/L (1.68 mg/dL).

Results: Mean urate was 5.6 mg/dL (SD: 1.5 mg/dL); mean follow-up was 12 years. At levels > 3 mg/dL, urate displayed a nearly linear relationship with AKI in adjusted analysis.



An increase in 1 mg/dL of urate above levels of 3 mg/dL was associated with a 20% increase in AKI risk (adjusted hazard ratio [aHR] 1.20, 95% CI: 1.14-1.25, p<0.001). A history of gout was significantly associated with AKI (aHR 1.29, 95% CI: 1.02-1.64, p=0.03); however, this association was no longer significant with adjustment for urate (aHR 1.10, 95% CI: 0.87-1.41, p=0.4), while the coefficients for urate were unchanged. In European-Americans, genetic urate score was not associated with AKI in crude or adjusted analysis (aHR 0.99, 95% CI: 0.94-1.04, p=0.6).

Conclusions: Higher urate levels above 3 mg/dL were independently and continuously associated with increased risk of AKI in a population-based cohort. A genetic urate score was not associated with AKI: perhaps the relationship between urate and AKI represents latent confounding rather than causality.

Annualized Change in Estimated GFR Associates with Acute Kidney Injury

M. Grams,[1] Kunihiro Matsushita,[1] Brad C. Astor,[2] Josef Coresh.[1] *[1]JHU; [2]U Wisconsin.*

Background: Reduced eGFR is a potent risk factor for acute kidney injury (AKI). It is unknown, however, whether antecedent rates of kidney function decline provide additional AKI risk information.

Methods: Data from 11,432 participants in the Atherosclerosis Risk in Communities (ARIC) Study were used to evaluate the relative hazard of hospitalized AKI associated with antecedent 9-year annualized changes in eGFR, as calculated using the CKD-Epi equation. Participants with CKD stage 5, a history of AKI, or missing eGFR measures at ARIC enrollment or year 9 were excluded. Cox proportional hazards analyses were adjusted for race, sex, age, hypertension, diabetes, coronary heart disease, log-albuminuria, and eGFR at the last time point (year 9, or ARIC visit 4).

Results: Median follow-up was 12 years after visit 4. There were 763 incident AKI hospitalizations (1.5 events per million person-years). Median eGFR change was -1.0 ml/min/ 1.73m^2/year (IQR: -2.0 to +0.4 ml/min/year) over the antecedent 9 years. The relationship between annualized change in eGFR and AKI appeared U-shaped, although the association of increasing eGFR and AKI was not statistically significant. In categorical analysis, annual eGFR loss more than 3 ml/min/1.73m^2 was significantly associated with AKI, independent of either first or last eGFR.

Longitudinal changes in kidney function and their association with AKI

9-year annualized change in eGFR	N (%)	Crude HR	Adjusted HR (+ first eGFR)	Adjusted HR (+ last eGFR)
≥ 3 ml/min/1.73m2 yearly decline	1,195 (10.5%)	2.8 (95% CI: 2.3-3.5)	2.3 (95% CI: 1.8-2.8)	1.5 (95% CI: 1.2-2.0)
1-3 ml/min/1.73m2 yearly decline	4,374 (38.3%)	1.2 (95% CI: 1.0-1.4)	1.1 (95% CI: 0.9-1.4)	1.0 (95% CI: 0.9-1.3)
0-1 ml/min/1.73m2 yearly decline	3,861 (33.8%)	Reference	Reference	Reference
Increase in eGFR over time	2,002 (17.5%)	1.1 (95% CI: 0.9-1.4)	0.9 (95% CI: 0.7-1.2)	1.1 (95% CI: 0.9-1.4)

Coronary heart disease, older age, diabetes, hypertension, male sex, black race, and first or last eGFR were also significantly associated with AKI in fully adjusted analysis (p<0.02 for all).

Conclusions: Long-term antecedent changes in eGFR provide additional risk information over traditional AKI risk factors.

Funding: NIDDK Support, Private Foundation Support

SA-PO089

Determinants of Renal Function at Hospital Discharge of Patients Treated with Renal Replacement Therapy in the Intensive Care Unit

Gijs Fortrie,[1] Susanne Stads,[2] Hilde R. De Geus,[2] Johan Groeneveld,[2] Robert Zietse,[1] Michiel G.H. Betjes.[1] *[1]Nephrology, Erasmus Medical Center, Rotterdam, Netherlands; [2]Intensive Care, Erasmus Medical Center, Rotterdam, Netherlands.*

Background: Acute kidney injury (AKI) requiring renal replacement therapy (RRT), is a frequently seen complication in the critically ill and constitutes a risk factor for chronic kidney disease (CKD) and increased mortality after hospital discharge. Identification of patients at risk for poor recovery of renal function is important for the development of renal protective strategies.

Methods: We conducted a retrospective cohort study in a large academic hospital, evaluating all patients admitted to the intensive care unit (ICU) suffering from AKI requiring RRT in the period January 1994 to April 2010. Clinical characteristics and potential risk factors for poor renal recovery, were documented in the patients that survived their hospital stay. The outcome variables were estimated glomerular filtration rate (eGFR-MDRD) and dialysis dependency at hospital discharge.

Results: Of the 423 patients in our cohort, 75 (18%) patients had documented CKD before admission to the ICU. Only 18.4 % of the patients were discharged from the hospital with an eGFR > 90 ml/min/1.73m^2. An eGFR ≤ 60 ml/min/1.73m^2 at hospital discharge occurred in 64.8% of cases and 12.1% of the cases left the hospital dialysis dependent. Multivariate logistic regression showed that age (OR = 1.04, p < 0.001), a medical history of CKD (OR = 29.77, p = 0.001), serum creatinine concentration at start of RRT (OR = 1.003, p < 0.001) and administrations of iodine-containing contrast (OR =0.82, p = 0.007) were significantly associated with an eGFR ≤ 60 ml/min/1.73m^2 at hospital discharge. In contrast, potential risk factors such as diabetes mellitus and hypertension lost their significance within a multivariate analysis. Only a medical history of CKD (OR = 9.20 p < 0.001) was associated with dialysis dependency.

Conclusions: The majority of critically ill patients surviving an episode of AKI requiring RRT have an impaired renal function at hospital discharge. The elderly and in particular the patients with pre-existent CKD, have a high risk of reaching end-stage renal disease.

SA-PO090

Long-Term Outcome of Patients Followed by Nephrologist after an Acute Tubular Necrosis Episode Daniela Ponce, Germana Alves Brito, Juliana Abrao, Pasqual Barretti, André Balbi. *Internal Medicine, Botucatu School of Medicine - University Sao Paulo State, Botucatu, Sao Paulo, Brazil.*

Background: Acute Kidney Injury is associated with high mortality in-hospital. However, data from long-term survival and recovery of renal function are controversial. The aims of our study were to analyze the long-term survival and recovery of RF in patients surviving an acute tubular necrosis (ATN) episode followed by the same nephrologist and determines factors associated with long-term mortality.

Methods: We performed a prospective cohort study from October 2004 to May 2011 that evaluated the long term outcome of patients surviving an ATN episode. Variables were analyzed at the time of the acute episode and during follow-up.

Results: We followed 212 patients, of whom 34.4% were diabetics, 39.1% had previous CKD, 38.6% had cardiovascular disease, and age was 59.2 years (48-71) Mortality at the end of follow-up was 24.5% and 19.3% lost the follow-up. Fifty percent of the patients had a follow-up of 24.4 months (9-39). The probability of these patients being alive 5 years after discharge was 55%. During the follow-up, 4.7% of patients needed for chronic dialysis. Only patients with glomerular filtration rate < 60mL/min at the first assessment progressed to dialysis after 12 months. Univariate analysis showed that previous CKD (*log rank* = 9.14, p = 0.0079), cardiovascular disease *(log rank* = 8.18, p = 0.019), older than 60 years (*log rank* = 1.05, p <0.0001) and higher SCr baseline (*log rank* = 2.18, p = 0.001) after 12 months (*log rank* = 1.43, p = 0.0015) and 36 months of follow-up (*log rank* = 1.58, p = 0.004) were predictors of long-term mortality. In multivariate analysis, older age (HR = 6.4, CI 95% = 1.2-34.5, p = 0.02) and higher SCr after 12 months of follow-up (HR = 2.1, 95% CI 95%= 1.14- 4.1, p = 0.017) were identified as risk factors associated with long-term mortality.

Conclusions: Fifty five percent of patients surviving an ATN episode were still alive and less than 5% required chronic dialysis 60 months later and age and increased Scr after 12 months of follow-up were identified as risk factors associated with late death. Finally, the survivors of AKI deserve a careful and long-term medical follow-up.

SA-PO091

A Randomized Clinical Trial of High Volume Peritoneal Dialysis versus Extended Daily Hemodialysis for Acute Kidney Injury Patients Daniela Ponce, Germana Alves Brito, Juliana Abrao, Bianca Albino Balarin, Pasqual Barretti, André Balbi. *Internal Medicine, Botucatu School of Medicine - University Sao Paulo State, Botucatu, Sao Paulo, Brazil.*

Background: Acute kidney injury (AKI) requiring dialysis in critically ill patients is associated with an in-hospital mortality rate of 50 to 80%. Extended daily hemodialysis (EHD) and high volume peritoneal dialysis (HVPD) have recently emerged as alternative modalities.

Methods: A double center, randomized, controlled trial was conducted comparing EHD vs. HVPD for the treatment of AKI in the intensive care unit (ICU). One hundred forty three patients were randomized and analyzed. Principal outcome measures were hospital mortality, recovery of renal function and metabolic and fluid control.

Results: There was no difference between the two groups in relation to median ICU stay (11 (5,7-20) vs. 9 (5,7-19)), recovery of kidney function (26.9 vs 29.6%, p= 0.11), need for chronic dialysis (9.7 vs 6.5%, p=0.23) and hospital mortalitiy (63.4 vs. 63.9%, p=0.94). The groups were different in metabolic and fluid control. Blood urea nitrogen (BUN), creatinine and bicarbonate levels were stabilized faster in EHD group than in HVPD group. Delivered Kt/ V and ultra filtration were higher in EHD group. Despite randomization, there were significant differences between the groups in some covariates, including age, pre dialysis BUN and creatinine levels, biased in favor of the EHD. Using logistic regression to adjust for the imbalances in group assignment, the odds of death associated with HVPD was 1.4 (95% CI, 0.7 to 2.4, p=0.19). A detailed investigation of the randomization process failed to explain the marked differences in patient assignment.

Conclusions: Despite faster metabolic control and higher dialysis dose and ultra filtration with EHD, this study provides no evidence of a survival benefit of EHD compared with HVPD. This study did not control for other supportive management strategies as nutrition support and timing of initiation that might influence outcomes in AKI.

SA-PO092

A Risk Prediction Tool to Predict Death or Dialysis after Admission with Severe Rhabdomyolysis Gearoid M. McMahon, Sushrut S. Waikar. *Nephrology, Brigham and Women's Hospital, Boston, MA.*

Background: Rhabdomyolysis occurs due to damage to muscle and can cause severe acute kidney injury (AKI). The epidemiology of rhabdomyolysis is not well characterized, and risk stratification of patients is not commonly performed. We aimed to develop a simple risk prediction tool to identify patients at risk for poor clinical outcomes.

Methods: We obtained laboratory and clinical data from the medical records of all patients at two teaching hospitals in Boston, MA with CPK levels >5000 U/L within 3 d of admission between 2000 and 2011. We excluded patients <18 years old or with end stage renal disease on admission. We determined the etiology of rhabdomyolysis by review of discharge summaries. Using multivariable logistic regression modeling, we developed a prediction model for the composite outcome of AKI requiring dialysis or in-hospital death. We used data from Massachusetts General Hospital (MGH) as the derivation cohort and data from Brigham and Women's Hospital (BWH) as the validation cohort.

Results: The final dataset included 2,910 patients (1,713 MGH, 1,197 BWH). Mean age was 52±18 yrs and 74.6% were male. 55.2% were surgical patients. 44% developed AKI as defined by the Acute Kidney Injury Network criteria while death or dialysis occurred in 19.3%. The commonest clinical settings were cardiac disease (26.5%) followed by trauma (21.4%) and immobilization (14.7%). The lowest risks of death or dialysis were noted in patients presenting following exercise (3.3%), myopathies (5.3%) or seizures/ syncope (6%). The final prediction model included age, sex, etiology and quintiles of initial calcium, phosphate, creatinine and bicarbonate. The C-statistic for the model was 0.82 in the MGH cohort and 0.86 in the BWH cohort. The model was well calibrated according to the Hosmer-Lemeshow test (p=0.17 and p=0.12 respectively). Based on the model, a score was generated for each patient. A score of <1 identified patients with a risk of <1.5% compared to 68% for a score >4.

Conclusions: We developed and validated a simple risk calculator using commonly available clinical and laboratory variables to accurately predict the risk of death or dialysis in patients admitted with severe rhabdomyolysis.

SA-PO093

The Effect of Renin-Angiotensin-Aldosterone System Blockade on Contrast-Induced Nephropathy in Patients with Chronic Kidney Disease Jisuk Han, Jwa-kyung Kim, Myung Jin Choi, Min-Gang Kim, Young Rim Song, Sung Gyun Kim. *Internal Medicine, Hallym University Sacred Heart Hospital, Kidney Research Institute, Republic of Korea.*

Background: The aim of the present study was to assess the influence of renin-angiotensin-aldosterone system (RAAS) blockade on the development of contrast-induced nephropathy (CIN) in patients with chronic kidney disease (CKD).

Methods: A retrospective analysis was conducted on a total of 239 patients with CKD stage 3 and 4 who underwent contrast-enhanced computed tomography from May 2011 to May 2012. Patients were stratified according to pre-contrast ACEI or ARB therapy. CIN was defined as an increase in serum creatinine (SCr) of at least 25% or 0.5mg/dL from baseline value within 72 hours of radio-contrast exposure.

Results: Of the total patients, 101 (43.0%) were treated with RAAS blockade: 17 with ACEI (7.1%), 83 with ARB (34.7%) and 1 with both (0.4%). There were no significant differences in age (p=0.068), creatinine (p=0.309), gender (p=0.174), diabetes mellitus (p=0.093), use of prophylactic N-acetylcysteine (p=0.857) between patients with or without RAAS blockade. However, patients with RAAS blockade had higher prevalence of statin use (p=0.048) and previous history of coronary artery disease (CAD, p=0.026) and hypertension (p<0.001). CIN occurred in 16 patients (6.7%) and the incidence was significantly higher in patients with RAAS blockade than without (10.7% vs. 1.3%, p=0.020). Post contrast SCr of patients with RAAS blockade were higher than patients without (1.49±0.09 vs. 1.28±0.06, p=0.069). Patients treated with RAAS blockade had 9.3-fold increased risk for CIN and the risk was higher for patients at CKD stage 4 than those at stage 3. Multivariate analysis showed that history of CAD [odds ratio (OR) 3.37, 95% confidence interval (CI) 1.14-9.94], left ventricular systolic dysfunction (ejection fraction<50 %) (OR 2.62, 95% CI 2.10-5.22), nonuse of N-acetylcysteine (OR 10.55, 95% CI 6.18-33.12), and pre-contrast RAAS treatment (OR 6.36, 95% CI 1.09-70.45) were significant risk factors for the development of CIN.

Conclusions: The use of RAAS blockade before contrast exposure was associated with the development of CIN in patients with CKD.

SA-PO094

KDIGO Acute Kidney Injury Classification and Outcomes Ligia Costa Battaini, Liliany P. Repizo, Janaina De Almeida Mota Ramalho, Lilian P.F. Carmo, Etienne Macedo. *Nephrology, University of São Paulo, São Paulo, SP, Brazil.*

Background: The two current criteria for diagnosing and staging AKI, RIFLE and AKIN, are widely used and validated; however, they are not uniformly applied across studies. Discrepancy in the determination of baseline and reference SCr and different time frames to detect changes in SCr cause inconsistency in the classification. A new consensus definition has emerged from KDIGO. This definition will help to identify the largest number of AKI patients and provide early intervention. The aim of our study is to diagnose and classify patients according to the new consensus staging and to assess its prognostic value.

Methods: We performed a retrospective study of patients with AKI who were followed by nephrologists in a tertiary center. They were categorized by the SCr criterion of the KDIGO AKI staging at the moment of nephrologist consultation and later at peak SCr or dialysis initiation. Reference SCr was defined as recorded SCr in the period of 6 months before admission or the lowest during hospitalization.

Results: Baseline characteristics and patients outcomes according to maximum KDIGO are shown in table 1. We identified progressive AKI in 63 (39%) patients and observed a higher mortality in this group (63%x41% p0.006). DeltaCr, percentage of elevation of creatinine or maximum creatinine was no different between survivors and non-survivors. MaxKDIGO was associated with increased mortality across stages.

Conclusions: MaxKDIGO category was associated with hospital mortality which was not observed with changes in creatinine.

Table 1

	Maximum KDIGO			
	1(n=28)	2(n=30)	3(n=108)	p
Age, yrs	68.5 (55-72)	69 (51– 78)	56 (46 -71)	
Baseline creatinine	1.55 (0.98-1.85)	1.14 (0.78-1.62)	0.9 (0.66-1.30)	
Gender, male n (%)	14 (50)	19 (63)	66 (61)	0.621
Mechanical ventilation, n (%)	8 (28.6)	8(26.7)	73 (67.6)	<0.001
RRT*, n (%)	0	0	73 (67.1)	<0.001
In-hospital mortality, n (%)	11 (40.7)	9 (31)	59 (56.7)	0.031
Initial KDIGO 1 mortality , n (%)	11 (36)	5 (16)	15 (48)	< 0.001
Initial KDIGO 2 mortality, n(%)	0	4 (17)	20 (83)	< 0.001
Initial KDIGO 3 mortality, n (%)	0	0	24 (44.5)	< 0.001
Maximium Creatinine	2.35 (1.30-3.30)	2.23 (1.75-3.65)	3.56 (2.67-4.68)	

SA-PO095

Acute Kidney Injury Associated with Spice Use: A New Clinical Entity Denyse Thornley-Brown, Gautam K. Bhanushali, Gaurav Jain. *Division of Nephrology, Department of Medicine, Univeristy of Alabama at Birmingham, Birmingham, AL.*

Background: Spice or K2 encompasses preparations of synthetic cannabinoids marketed as incense products, bath additives and air fresheners and used for recreational purposes. These preparations are usually smoked for their cannabis-like effects. They are of increasing popularity as drugs of abuse since they do not appear on routine urine toxicology screens. Geographic clusters of acute kidney injury (AKI) have been reported in the lay press; however, little is known about the clinical features of the disorder.

Methods: This was a retrospective review of patients presenting to University of Alabama Hospital with AKI and a history of spice ingestion over the 12 week period from March 1 to May 31, 2012.

Results: All patients were male, and all were from the same community in Northeast Alabama. Clinical features are summarized in Table 1.

table1 Clinical findings of spice users with AKI

Case	Age (yrs)	Clinical features	Admission creatinine	Peak creatinine	Discharge creatinine	biopsy findings	Urine drug screen
1	20	nausea, vomiting	11.3	13.7	2.9	ATN	negative
2	23	nausea, vomiting	8.2	15.2	11.5	ATN	negative
3	26	nausea, vomiting, diarrhea	11.1	13.3	8.6	ATN	negative
4	30	nausea, vomiting, diarrhea	2.9	2.9	2.4	N/A	negative

Serum creatinine, in mg/dL; ATN, acute tubular necrosis

Initially, all were suspected of having pre-renal azotemia; however their kidney function did not improve with the administration of intravenous fluids. Three of the patients had renal biopsies; all of which showed acute tubular necrosis. Two of the biopsies had the additional finding of calcium oxalate crystals.

Conclusions: Synthetic cannabinoids are associated with AKI, as indicated in this report. Given the widespread use of these agents and the geographic clustering of these cases, it is likely that a nephrotoxin was present in the preparation. Further studies are needed to identify the nephrotoxin(s). Spice nephropathy should be included in the differential diagnosis of unexplained AKI.

Funding: Clinical Revenue Support

SA-PO096

Acute Kidney Injury in Patients with Acute Liver Failure: A Cohort Analysis Maria Joao Melo,[1] Jose Lopes,[1] Marta Pereira,[1] Paula Alexandrino,[2] Jose Velosa,[2] Antonio Gomes da Costa.[1] *[1]Department of Nephrology and Renal Transplantation, HSM; [2]Department of Gastrenterology, HSM.*

Background: The epidemiology of acute kidney injury (AKI) in patients with acute liver failure (AFL) has not been extensively studied.

Methods: The objective of this study was to analyze the incidence, risk factors and prognosis of AKI in a cohort of patients with ALF hospitalized in the Gastrenterology and Hepatology Intensive Care Unit (ICU) of the Hospital de Santa Maria (Lisbon, Portugal) between January 1992 and December 2011. Exclusion criteria were chronic kidney disease on renal replacement therapy, requirement for renal replacement therapy prior to and/or in the first 48 hours after ICU admission, less than 48 hours of ICU stay and/or less than two determinations of serum creatinine (SCr). AKI was defined by an increase in baseline serum creatinine (SCr) ³50% and/or an increase in SCr ³0.3 mg/dl within 48h during ICU stay. Comparisons between patients with and without AKI were performed using the Student's t-test or the χ2-test. Multivariate logistic regression method was used to determine predictors of AKI and in-hospital mortality. A two-tailed P value <0.05 was considered significant.

Results: A total of 73 patients were analyzed. Forty-six patients (63%) had AKI. Patients with AKI were more likely to be Caucasian (P=0.018) and had higher bilirubin levels (P=0.002) at ICU admission. Sepsis was more frequent among patients with AKI (P=0.045) and these patients were more likely to receive vasopressor support (P=0.012) and mechanical ventilation (P=0.019). Bilirubin (adjusted odds ratio (OR) 1.1; 95% confidence interval (CI) 1.03-1.21; P=0.006) and vasopressor support (adjusted OR 4.7; 95% CI 1.03-20.9; P=0.045) were associated with increased risk for AKI. Overall mortality was 47.9% (N=35). Twelve patients (16.4%) underwent hepatic transplantation and none died. Patients with AKI had higher in-hospital mortality than those patients without AKI (82.9% versus 44.7%, P=0.001). AKI was independently associated with in-hospital mortality (adjusted OR 3.9, 95% CI 1.2-13.7, P=0.028).

Conclusions: AKI is a common complication in patients with ALF and it is associated with increased mortality.

SA-PO097

Outcomes of Obstetric Acute Kidney Injury at a University Medical Center of a Developing Country Syed Rizwan Bokhari,[1] Hafiz I. Ahmad,[1] Sara Saeed,[1] Amtullah Zarreen,[1] Sabin Nasir,[1] Ayesha Mahmood Malik,[1] Arif Asif.[2] *[1]Department of Nephrology, Allama Iqbal Medical College, Lahore, Punjab; [2]Division of Nephrology, University of Miami School of Medicine, Miami, FL.*

Background: Acute kidney injury (AKI) continues to be a cause of increased morbidity and mortality in pregnant women. While there have been studies on the incidence and etiology of this complication the current study focused on the outcomes of obstetric AKI.

Methods: Fifty six patients admitted with obstetric AKI (May 2011 to April, 2012) were included in this prospective study. Patients were followed for a period of three months postpartum. Fifteen patients were lost to follow-up and as such were excluded from study. The diagnosis of AKI was based on the classification of the Acute Kidney Injury Network group.

Results: The mean age of the patients was 26±6 years. Twenty-two (53%) patients were multipara and 19(46%) were primigravida. Twenty (48%) patients did not receive any antenatal care, 13(31%) were visited by a traditional birth attendant and only 8(19%) had adequate antenatal care by a physician/gynecologist. Of the 41 patients with AKI, seven presented before 28-weeks and 34 patients after were seen after 28-weeks of gestation. Four patients were found to be in stage I, 4 in stage II and 33 in stage III AKI during hospitalization. The cause of AKI included sepsis in 32 (78%), intrauterine death (IUD) in 24(60%), postpartum hemorrhage in 17(41%), preeclampsia/eclampsia in 7(17%), shock in 15(36%) and coagulopathy in 3(7%) patients. Twenty-eight (68%) patients received hemodialysis therapy during their hospital stay. Three-month follow-up showed complete resolution of AKI in 14 (34%) patients, partial resolution in 7 (17%), ESRD in 10 (24%) and death in 10 (24%) patients.

Conclusions: The current study indicates that a great majority of patients with obstetric AKI require dialysis. Residual renal dysfunction and ESRD are common at a 3-month follow-up. Incidentally, sepsis and IUD were the most common causes. Increased awareness and appropriate antenatal/obstetrical care can have a major positive impact on minimizing morbidity and mortality.

SA-PO098

Regional Citrate Anticoagulation (RCA) for Continuous Venovenous Hemodialysis (CVVHD) in Acute Kidney Injury (AKI) Cancer Patients in the Intensive Care Unit (ICU) Veronica T. Costa e Silva,[1] Juliana Silva Bezerra,[1] James Hung,[1] Henrique Palomba,[1] Elerson Costalonga,[1] Ludhmila Abrahão Hajjar,[2] Ana Paula Leandro Oliveira,[1] Luciane Oikawa,[1] Cilene Muniz Soares,[1] Luis Yu,[1] Emmanuel A. Burdmann.[1] *[1]Nephrology Division, Sao Paulo State Cancer Institute - University of Sao Paulo School of Medicine, Sao Paulo, Brazil; [2]Intensive Care Department, Sao Paulo State Cancer Institute - University of Sao Paulo School of Medicine, Sao Paulo, Brazil.*

Background: The safety and efficacy of RCA have not been studied in AKI cancer ICU pcts.

Methods: We prospectively analyzed all CVVHD performed in AKI adult cancer pcts in the Sao Paulo State Cancer Institute ICU from January 2010 to December 2011. RCA for CVVHD was utilized according to an adapted protocol published by Mehta et al. CVVHD was performed with a Diapact machine (BBraun) with polysulphone hemofilter.

Results: A total of 9303 hours of CVVHD therapy (319 filters) were performed in 152 AKI pcts. Pcts' characteristics were age 60 +/- 15 y, 60% male, 71.5% on vasopressors and 45% on mechanical ventilation. Most (76.3%) patients had solid cancer, 35.7% with metastatic disease (MD) and 29.6% with previous chemotherapy (CT). Sepsis was the most important AKI etiology factor (71.1%). Hospital mortality was 80%. Venous access was temporary triple lumen catheter (11 Fr) in 97% (70% femoral and 27% internal jugular veins). Blood flow was 180 (150 -180) ml/min and citrate dose was 20.4 mmol/hr. Dialysis dose was 29 (21 – 31) ml/Kg/hr. Systemic ionized calcium (SCai) was 4.35 (4.10 – 4.70) mg/dL and hypocalcemia (SCai < 4.0 mg/dL) was observed in 19% of procedures. There was a satisfactory metabolic control: Na 142 (138 – 147) mEq/L; K 4.00 (3.70 – 4.50) mEq/L; Bic 25.2 (21.9 – 29.3) mEq/L. Median Total systemic calcium (CaT)/SCai ratio was 1.88 (1.75 – 2.04). Median filter patency was 24.0 (11.0 – 43.00) hr despite of post-filter ionized calcium level of 1.63 (1.40 – 190). There were no differences in CaT/SCai (P: 0.846) or Bic (P:0.915) between pcts with international normalized ratio above or under 2.0.

Conclusions: RCA is a safe method for CVVHD therapy in AKI ICU cancer pcts. Short filter patency needs to be better evaluated.

SA-PO099

Early Initiation and Optimal Indications of Continuous Renal Replacement Therapy in Acute Kidney Injury Patients with Early Renal Recovery and Early Death Hiroo Kawarazaki. *Department of Nephrology and Hypertension, St. Marianna University School of Medicine, Kawasaki, Kanagawa, Japan.*

Background: The role and/or necessity of short term continuous renal replacement therapy (CRRT) in acute kidney injury (AKI) patients with early renal recovery and early death is equivocal. The objective of this study was to characterize the following AKI patients; (1) those who had recovered renal function within 48 hours of CRRT and (2) those who died within 48 hours of CRRT.

Methods: The study was a multicenter retrospective study of AKI patients hospitalized in 12 different Japanese intensive care units (ICU) who were initiated on CRRT from January, 2010 to December, 2010. Patients under 18 years of age, on chronic dialysis and those who had RRT before ICU admission were excluded. (1) Patients who recovered from AKI after CRRT for less than 48 hours (Early Recovery group; ER) were compared to the rest of the cohort, and (2) patients who died within 48 hours of CRRT (Early Death group; ED) were compared to the rest of the cohort.

Results: Total of 343 AKI patients (65.9% male) were included. Median age was 69 (59-77) years, sequential organ failure assessment (SOFA) score was 11 (8-13) and simplified acute physiology score II was 53 (40-68). There were 52 ER patients and 52 ED patients. Multivariate stepwise regression analysis of parameters at the time of CRRT initiation showed that; (1) early initiation of CRRT (p=0.01), low serum lactate (p=0.002) and high urinary output (p<0.001) were independently associated with early renal recovery and, (2) high SOFA score (p=0.04), low urinary output (p=0.03), low serum albumin (p=0.01) and high serum lactate (p<0.001) were independently associated with early death.

Conclusions: AKI patients with high urinary output and low serum lactate may not necessitate early initiation of CRRT. Furthermore, AKI patients with high SOFA scores, low urinary output, low serum albumin and high serum lactate may have extremely high mortality in spite of CRRT. Appropriate timing and indication for such AKI patients need reassessment.

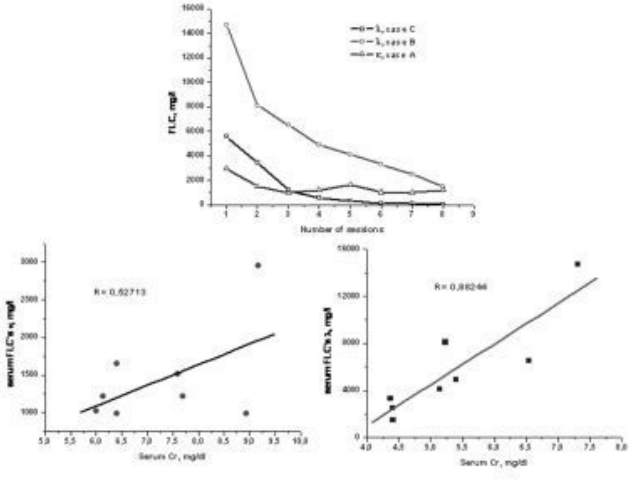
SA-PO100

The Combination of Extracorporeal Free Light Chains Removal and Chemotherapy in Myeloma Acute Kidney Injury: New Therapeutic Options and Old Prognostic Factors Sonia Pasquali,[1] Mattia Corradini,[1] Silvia Mattei,[1] Achiropita Bovino,[1] Francesco Iannuzzella,[1] Danio Somenzi,[1] Alfredo Stefani,[1] Marialuisa Caiazzo,[2] Giuseppe Palladino.[3] *[1]ASMN-IRCCS, Reggio Emilia, Italy; [2]UNIMORE, Italy; [3]Bellco, Italy.*

Background: The combination of high cut-off membranes extracorporeal treatments (ET) and chemotherapy allows sustained reductions in circulating free light chains (FLC) and a high rate of renal function (RF) recovery in patients affected by Acute Renal Failure (ARF) due to Myeloma (M). These ET are well tolerated, but require albumin replacement in about 80% of the cases. We studied a new therapeutic approach with adsorbent resins in order to evaluate its efficacy.

Methods: We treated 3 patients, affected by dialysis-dependent ARF due to biopsy proven FLC M cast nephropathy (λ in 2 cases and k in the remaining case). The M was newly diagnosed in all patients. Within 7 days after the onset of ARF, each patient underwent Bortezomib chemotherapy associated to ET with SUPRA HFR technique, that utilizes separated convection by a high cut-off membrane, diffusion and adsorption with a styrenic resin. The ET, lasting 4 hours each, were repeated for 8 consecutive days and followed every other day.

Results: All the patients showed a significant reduction of serum FCL and a complete recovery of RF after 21, 30 and 44 days from the beginning of the therapy. Serum FLC and creatinine correlations are shown in Figure 1.



The albumin values maintained stable in all the patients.

Conclusions: We confirm the close association between FLC reduction and RF recovery. ET with adsorbent resins represent an effective therapeutic strategy that does not require albumin replacement. In agreement with the literature, timely initiation of the therapy, newly diagnosed M and histological picture of M cast nephropathy represent good prognostic factors, correlated with the reversibility of RF.

SA-PO101

Recurrent Acute Kidney Injury and the Risk of ESRD or Death Bipin R. Bista,[1] Craig Solid,[2] Eric D. Weinhandl,[2] Areef Ishani.[2,3] *[1]University of MN, Minneapolis, MN; [2]USRDS Coordinating Center, MMRF, Minneapolis, MN; [3]Minneapolis VAMC, Minneapolis, MN.*

Background: In patients with acute kidney injury (AKI), the risk of AKI recurrence and long-term implications in terms of ESRD and mortality has not been studied in a large patient population. In this study, we aimed to determine the risk of recurrences of acute kidney injury and the subsequent risk of ESRD and mortality in that patient population.

Methods: We identified 70,710 Medicare beneficiary patients with 85,902 AKI claims in 2005-2006. A cohort of 41,002 eligible elderly patients aged >66 years, discharged with a diagnosis of AKI and without ESRD, were followed for one year.

Results: In this cohort, 22.31% had recurrent AKI within 1 year following the hospital discharge. The risk of development of ESKD within one year of AKI was significantly higher (3.63%) in patients with recurrent AKI as compared to those without (2.44%), with RR 1.50[CI 95%(1.32-1.70); P<0.0001]. The patients with recurrent AKI were also found more likely to die within one year (total incidence of death of 49.5% as compared with 37.0% in patients without recurrence) with RR 1.33[CI 95%(1.32-1.70); P<0.0001]. There were no significant differences in the rate of recurrence among different age groups in this study. However, the risk of recurrence was found to be higher in patients with diabetes [RR 1.35(95% CI 1.30-1.39)], hypertension [RR 1.31(95% CI 1.25-1.37)] and more in CKD patients [RR 1.62 (95% CI1.56-1.68)].

Conclusions: In summary, there was a significant risk of recurrence of acute kidney injury and was associated with worse outcome in terms of ESRD and mortality in a one-year period.

Funding: NIDDK Support

SA-PO102

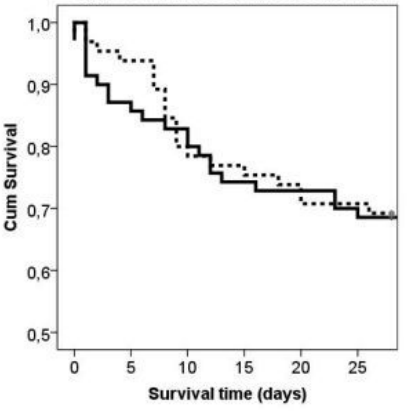
Citrate Anticoagulation versus Systemic Heparinisation in Continuous Venovenous Hemofiltration in Critically Ill Patients with Acute Kidney Injury: A Multicentered Randomized Clinical Trial Louise Schilder, Shaikh Azam Nurmohamed, Marc G. Vervloet, Albertus Beishuizen, Pieter M. Ter Wee, Johan Groeneveld. *VU Medical Center.*

Background: During continuous venovenous hemofiltration (CVVH) in critically ill patients with acute kidney injury, anticoagulation is often administered. The aim was to compare mortality and renal function recovery between systemically administered unfractionated heparin and regional anticoagulation with citrate buffered replacement solution in CVVH. Secondary endpoints were safety and efficacy.

Methods: Adults without a high bleeding risk admitted to the ICU requiring CVVH, were randomly assigned to heparin-CVVH or citrate-CVVH in a predilution fashion. Primary endpoints were patient mortality after 28 days and renal function recovery defined as independence from dialysis after 28 days. Safety was defined as the absence of adverse events necessitating discontinuation of the study anticoagulant. For efficacy, among other variables, survival times of the first hemofilter were studied.

Results: Of the 139 patients, 73 were randomized to heparin-CVVH and 68 to citrate-CVVH. Mortality rates were similar; 35% for heparin-CVVH versus 33% for citrate-CVVH (P=0.92).

Figure 1. Survival times. Dotted line represents citrate.



Renal function recovery did not differ; 66% in heparin-CVVH versus 68% in citrate-CVVH (P=0.85). Heparin was discontinued in 15 patients whereas citrate was discontinued in 4 patients (P=0.001). Manifest bleeding occurred more in the heparin group (P=0.06). Circuit survival times were superior for citrate-CVVH (46 hrs vs 32 hrs, P=0.001), as were the number of filters used (P=0.002) and the offtime within 72 hours (P=0.002).

Conclusions: Patient mortality and renal function recovery did not differ between heparin and citrate anticoagulation in CVVH in the critically ill patient with acute kidney injury. However, citrate-CVVH appeared superior in terms of safety and efficacy.

SA-PO103

Pattern of Acute Kidney Injury(AKI) in a Tertiary Hospital in Sri Lanka Dinith Prasanna Galabada, Abdul Latiff Nazar. *Nephrology, National Hospital of Sri Lanka, Colombo, Western, Sri Lanka.*

Background: Observational studies of acute kidney injury (AKI) and acute-on-chronic renal failure are surprisingly sparse and confounded by differences in definition. There is limited data on the pattern of acute kidney injury in Sri Lanka. It is crucial to know the etiology, prognostic factors and outcome of AKI to promote preventive strategies and to provide adequate resources for the management of AKI.

Methods: Prospective observational study of 201 patients with AKI presented between June to November 2011.

Data was collected using an interviewer administered questionnaire and through a review of medical records.AKI was defined according to RIFLE criteria.

Results: Mean age was 52.8± 21 (range 13 to 91) years, 70% were males. 25% of patients were managed in intensive care units.15% had hospital acquired AKI. Acute on chronic renal failure was present in 18.4%. Sepsis was the most common cause of AKI (37%), followed by leptospirosis (26%). Urosepsis(38%) was the commonest aetiology for sepsis. Commonest co-morbidities were hypertension (32.8%),diabetes (25.9%). 10% of acute kidney injuries were related to post surgical reasons. Hypotension was present in 34%. 69% required renal replacement therapy.

Hospital mortality was 29.5%. 66.5% of patients were dialysis independent on discharge.ICU mortality was significantly higher than the ward mortality.(53.1% vs 18.5%, P <0.0001).ICU deaths were most frequently associated with sepsis(77%).

According to the RIFLE criteria, 83.8 % was in the Failure category. There was nearly linear increase in mortality from Risk to Failure (Risk, 11.1%; Injury, 21.7%; and Failure, 28.3%).

Age, maximum RIFLE category, and hypotension were independent predictive factors of mortality.

Age, hypotension, acute heart failure, disseminated intravascular coagulation and hypertension were independent predictive factors of need for intensive care.

Conclusions: Sepsis and leptospirosis were the leading causes for AKI. Hospital mortality was 29.5%. Majority of patients were in Failure category according to RIFLE criteria. Increasing age, maximum RIFLE category, and presence of hypotension were independent predictors of poor outcome.

Variation of *NEDD4L* Is Associated with Hypertension in Chronic Kidney Disease Patients Jun Zhang, Cheng Wang, Hui Peng, Zengchun Ye, Tan-qi Lou. *Department of Nephrology, The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou.*

Background: Neural precursor cell expressed developmentally down-regulated 4-like(NEDD4L), a regulator of the epithelial sodium channel (ENaC), is suggested a candidate gene for essential hypertension. Carriers of an NEDD4L rs4149601 (G/A) AA genotype which result a frameshift mutation of *NEDD4L*, has been shown to be associated with ambulatory BP. However, there is no study to investigate whether polymorphism of NEDD4L rs4149601 contributes to hypertension in patients with chronic kidney disease. The purpose of the current study was to investigatethe relationship between the variation of NEDD4L rs4149601 and hypertension in Chronic Kidney Disease (CKD) patients.

Methods: A total of 307 CKD patients were eligible (aged 18–70 years) and enrolled in our study. The rs4149601 polymorphism was genotyped using real-time PCR based techniques. All patients underwent ambulatory BP monitoring. Clinical data were also collected and eGFR were assessed by simplified MDRD equation. Multivariate logistic regression analysis was used to identify the relationship between polymorphisms and hypertension.

Results: 277 patients carried GG/GA genotype and 30 carried AA genotype. Chi-squared test revealed that rs4149601 AA genotype carriers had significantly higher rate of hypertension than GG/GA genotype carriers(73.3% vs 42.2%, P = 0.02). AA genotype carriers also had a higher day (142±15 vs 133±18, P=0.029) and night (135±21 vs 125±21, P=0.037) mean systolic blood pressure when compared with GG/GA genotype carriers. Multivariate logistic regression models revealed that AA genotype [OR= 3.28, 95% CI (1.09–9.85)], eGFR decline [OR=0.98, 95% CI (0.97–0.99)], old age [OR=1.02, 95% CI (1.01–1.04)] were independently associated with hypertension in CKD patients.

Conclusions: Polymorphism of NEDD4L may be associated with hypertension in CKD patients.

SA-PO105

Renal Denervation Using Standard Irrigated Cardiac Ablation Catheter Is Effective in the Management of Refractory Hypertension in Chronic Kidney Disease Patients Jocemir R. Lugon,[1] Maria A. Carreira,[1] George M. Maia,[2] Tetsuaki Kiuchi,[2] Miguel Luis Graciano,[1] Marcio Galindo Kiuchi.[1] *[1]Medicine, Universidade Federal Fluminense, Niteroi, Rio de Janeiro, Brazil; [2]Surgery, Hospital Regional Darcy Vargas, Rio Bonito, Rio de Janeiro, Brazil.*

Background: Target blood pressure (BP) levels may not be achieved in severe forms of hypertension. Recently, the transcatheter renal sympathetic denervation procedure (TRD) has proved effective in lowering BP in refractory cases. We evaluated the safety and efficacy of TRD using standard irrigated cardiac ablation catheter (SICAC) and its impact on estimated glomerular filtration rate (eGFR) and albuminuria in chronic kidney disease (CKD) patients with refractory hypertension.

Methods: Twelve patients with CKD (NKF stages 2, 3 and 4) and refractory hypertension underwent bilateral TRD with SICAC (Biotronik, Germany). Duplex ultrasound of renal arteries was performed before the procedure. Office BP measurements, eGFR (simplified MDRD equation), plasma renin activity (PRA), serum levels of catecholamines and microalbuminuria were obtained at baseline. The first 30 days of follow-up are reported.

Results: Baseline data (Mean±SEM) were: BP 181.6±4.4 / 108.4±3.4 mmHg; eGFR 58.0±6.4 ml/min/1.73m^2. BP values at 7 and 30 days after the procedure fell to 131.5±2.8 / 84.7±1.6 mmHg and 131.9±2.6 / 85.3±2.3 mmHg, respectively (P<0.0001 for every comparison). There was a mean reduction of 2.9±0.3 (P=0.0028) in the number of BP drugs per patient. Except for bleeding at the site puncture requiring blood transfusion in one patient, no other complication was observed with the procedure. eGFR increased significantly from baseline (58.0±6.4 ml/min/1.73m2) to 30 days (87.3±11.0 ml/min/1.73m2), P=0.0014. No significant change was found in PRA, serum levels of catecholamines, or in microalbuminuria along the evaluation period.

Conclusions: TRD may be performed safely in CKD patients with refractory hypertension using SICAC resulting in better control of blood pressure, reduction in the number of antihypertensive drugs, and a short term improvement in eGFR. Although encouraging, data are preliminary and need to be confirmed in the long term.

SA-PO106

The Effect of the Amorphous SDD Formulation of Bardoxolone Methyl on Blood Pressure George L. Bakris,[1] Pablo E. Pergola,[2] Melanie Chin,[3] Susan Potts,[3] Sudarshan Hebbar,[3] Colin John Meyer,[3] Paul Audhya.[3] *[1]ASH Comprehensive Hypertension Center, University of Chicago Medicine, Chicago, IL; [2]Renal Associates PA, San Antonio, TX; [3]Reata Pharmaceuticals, Irving, TX.*

Background: Bardoxolone methyl (BARD) is a synthetic triterpenoid that induces Nrf2 and suppresses NF-κB and has been shown to increase GFR in patients with diabetes and stages 3b/4 CKD. A multicenter, randomized, open-label, adaptive dose-ranging study was conducted to investigate the effects of the amorphous spray-dried dispersion (SDD) formulation of BARD in type 2 diabetic patients with stages 3b/4 CKD. Additional analyses were conducted to assess the effect on systolic and diastolic blood pressures (SBP and DBP).

Methods: Patients (n = 131) were assigned to receive 2.5, 5, 10, 15, or 30 mg of BARD once daily for 12 weeks. Antihypertensives were adjusted by investigators per their standard of care. SBP and DBP values over time were analyzed in the combined and individual dose groups.

Results: Baseline mean (SD) SBP and DBP in the combined dose group was 130.0 (12.1) mmHg and 69.2 (8.9) mmHg respectively; these were similar across individual dose groups. After 12 weeks of treatment, mean SBP and DBP were unchanged from baseline for the combined and each individual dose group.

Change in SBP and DBP (Mean ± SD)

	2.5 mg	5 mg	10 mg	15 mg	30 mg	All Doses
	N = 14	N = 25	N = 28	N = 50	N = 14	N =131
Week 12 SBP Change (mmHg)	0.1 ± 15.59	-1.5 ± 11.46	-2.4 ± 15.31	1.1 ± 15.59	7.1 ± 21.64	0.4 ±15.48
p -value*	0.99	0.54	0.45	0.63	0.28	0.78
Week 12 DBP Change (mmHg)	0.2 ± 6.72	-1.4 ± 7.58	0.3 ± 6.46	-1.0 ± 8.37	3.2 ±7.60	-0.3 ± 7.61
p-value*	0.91	0.38	0.80	0.42	0.18	0.71

* p-value calculated from two-sided t-test comparing Week 12 change to zero.

Conclusions: In this study, treatment with BARD at doses between 2.5 and 30 mg per day had no measurable effect on SBP or DBP in any dose group or timepoint during the study. Further assessments of the effects of BARD on blood pressure will be conducted in the BEACON trial (using 20 mg per day of BARD;NCT01351675), including an ambulatory blood pressure monitoring substudy.

SA-PO107

Bardoxolone Methyl and Albuminuria in Type 2 Diabetes Patients with CKD Peter Rossing,[1,2] Melanie Chin,[3] William M. Deen,[4] Sudarshan Hebbar,[3] Susan Potts,[3] Paul Audhya,[3] Colin John Meyer,[3] Hans-Henrik Parving.[2,5] *[1]Steno Diabetes Center, Gentofte, Denmark; [2]HEALTH, Aarhus University, Aarhus, Denmark; [3]Reata Pharmaceuticals, Irving, TX; [4]Department of Chemical Engineering, Massachusetts Institute of Technology, Cambridge, MA; [5]Department of Endocrinology, University Hospital, Copenhagen, Denmark.*

Background: Bardoxolone methyl (BARD) is a synthetic triterpenoid that promotes the resolution of inflammation by inducing Nrf2 and suppressing NF-κB. A phase 2 trial (BEAM) of BARD in patients with type 2 diabetes and CKD (eGFR of 20-45 mL/min/1.73m^2), reported an increase in eGFR and urinary albumin creatinine ratio (UACR). In this post-hoc analysis, ratios of UACR/eGFR were analyzed to further characterize the relationship between changes in eGFR and urinary albumin excretion.

Methods: Patients (n=227) were randomized to placebo or BARD at a target dose of 25, 75 or 150 mg for 52 weeks. UACR and eGFR (by MDRD) were measured every 4 weeks. ANCOVA analysis was used to compare UACR and UACR/eGFR changes throughout the active treatment period in the combined (all 3 BARD groups) ITT population versus the placebo group.

Results: The mean (SD) eGFR at baseline was 31.2 (0.8) and 32.7 (0.5) ml/min/1.73 m^2 and UACR geometric mean was 62.4 and 77.4 mg/g in the placebo and BARD groups respectively. At week 52, the mean (SD) change from baseline in eGFR was -1.0 (1.0) and +7.5 (1.0) ml/min/1.73 m^2 and the change in UACR (ratio of week 52/baseline (95%CI)) was 1.3 (1.0 to 1.8) and 1.9 (1.6 to 2.3) for placebo and BARD groups, respectively. Adjusting for baseline values, ANCOVA analysis noted a 44% (11 to 87) increase in UACR for treatment with BARD relative to placebo (p<0.01). In contrast, change in UACR/eGFR with BARD was not significantly different from placebo: 15% (-12 to 49) (p=0.30).

Conclusions: Treatment with BARD increases eGFR and UACR. UACR/eGFR ratios were not statistically different between BARD-treated and placebo patients. This suggests that the increase in UACR is potentially due to increased filtration (eGFR).

SA-PO108

Current Status of Anti-Hypertensive Treatment in Hospitalized Chinese Patients with Chronic Kidney Disease: A Multicenter Analysis Shuwen Liu, Guangyan Cai, Xiang-Mei Chen, Ying Zheng. *Department of Nephrology, State Key Laboratory of Kidney Diseases, Chinese PLA General Hospital, Beijing, China.*

Background: Hypertension is the most common comorbidity in patients with chronic kidney disease (CKD), which associate with progression of CKD and the risk of cardiovascular diseases. Currently, there is no nation-wide investigation on the therapy status of hypertension in Chinese CKD patients.

Methods: From November 2009 to January 2010, we performed a multi-center cross-sectional study on hospitalized patients with CKD in 61 hospitals among 31 provinces in Mainland China. The demographic, socioeconomic and clinical data were collected. Blood pressure level, classifications and numbers of antihypertensive agents were recorded. Blood pressure goal was set as less than 130/80mmHg. Multivariable logistic regression analysis was used to explore risk factors associated with uncontrolled and resistant hypertension.

Results: Overall, 6826 eligible patients were analyzed, including 57.4% male. The mean age was 51.0±17.1 years. Calcium channel blockers (CCBs) were the most common used antihypertensive agents in Chinese CKD patients, which account for 78%. The second type was angiotensin II receptor blockers (ARB), which account for 42.2%. Only 16.6% patients took diuretics. 34.7%, 33.3%, 21.1% and 10.9% of patients took one, two, three or more than four kinds of antihypertensive agents, respectively. The prevalence of resistant hypertension was 15.3%. After multivariable adjusted, CKD3 stage (OR 1.3; 95%CI 1.1-1.7), CKD4 stage (OR1.9; 95%CI 1.4-2.4), CKD5 stage (OR 2.7; 95%CI 2.2-3.4), obesity (OR1.4; 95%CI 1.1-1.8), high-salt diet (OR1.2; 95%CI 1.1-1.4), current smoking (OR1.2 95%CI 1.0-1.8), diabetes (OR1.4; 95%CI 1.2-1.7), cardiovascular disease (OR1.5 95%CI 1.3-1.9), cerebrovascular disease(OR1.4; 95%CI 1.0-1.8), and proteinuria (OR1.2; 95%CI 1.0-1.5) were independently associated with resistant hypertension.

Conclusions: In China, blood pressure control rate in CKD patients was suboptimal. Antihypertensive agents with diuretics or combination therapy were low. Adequate antihypertensive treatment and life-style change will improve the control of hypertension in CKD patients.

ApoAI Modifications of HDL in Patients with End-Stage Renal Disease Results in a Reduction of Cholesterol Efflux Capacity Mirjam Schuchardt, Tao Huang, Vera Jankowski, Markus Tolle, Markus van der Giet. *Med. Klinik mit SP Nephrologie, Charite - Campus Benjamin Franklin, Berlin, Germany.*

Background: The endogenous high density lipoprotein (HDL) particle has pleiotropic protective properties. In patients compositional changes of HDL could be detected and are related to reduced protective function of HDL. The aim of this study was to investigate the apolipoprotein composition and cholesterol efflux capacity of HDL from patients with end-stage renal disease (ESRD) in comparison to healthy subjects.

Methods: HDL was isolated from serum using ultracentrifugation. Apolipoprotein content were measured via Luminex™ technology. HDL protein and lipids were separated using isopropanol/hexane. The protein fraction were separated using high pressure liquid chromatography and the apoAI fraction was analyzed via mass spectrometry.

Results: The apolipoprotein concentration of HDL is different in ESRD patients compared to healthy controls. The patients have an increased level of apoCII and apoCIII. The apoAI content is not significantly different in both investigated groups. The apoB content were measured as control and could not be detected in all investigated HDL samples. A main function of HDL is the cholesterol efflux capacity. Compared to healthy subjects, the patients had a significantly reduced cholesterol efflux capacity. Furthermore, the enzyme activity of lecithine-cholesterol-acyltransferase (LCAT) is significantly reduced in patients with ESRD. ApoAI is the main apolipoprotein of HDL and has a major function in cholesterol efflux and as cofactor for LCAT. Mass spectrometric analysis of the apoAI protein fraction shows oxidative modifications on three amino acids in the apoAI sequence in patients with ESRD. These oxidative modifications could be induced in HDL from healthy controls using hypochloric acid. The modifications are associated with a reduced cholesterol efflux capacity.

Conclusions: ApoAI from ESRD patients has oxidative-modified amino acids. These may be associated with a reduced functionality of HDL, e.g. as seen in this study for cholesterol efflux capacity. The molecular mechanisms has to be further investigated.

SA-PO110

Biologically Active Osteopontin Is an Accurate Biomarker of Type 2 Diabetic Nephropathy in Mexican Americans Susanne B. Nicholas,[1,2] Satyesh K. Sinha,[2] Keith C. Norris,[1,2] Kamyar Kalantar-Zadeh,[3] Dulcie Kermah.[2] *[1]Medicine, David Geffen School of Medicine at UCLA, Los Angeles, CA; [2]Research, Charles R. Drew University of Medicine and Science, Lynwood, CA; [3]Medicine, Harbor- UCLA LA Biomed, Carson, CA; [4]Family Investigation of Nephropathy and Diabetes (FIND) Investigators, UCLA.*

Background: Ethnic minorities have ~2-4-fold higher incidence of type 2 diabetic nephropathy (T2DN), more rapid progression to end stage renal disease, and significantly higher rates of premature cardiovascular mortality compared to non-Hispanic whites. Several factors contribute to disparities in the diagnosis and management of T2DN. Identification of a highly sensitive biomarker that accurately reflects the mechanisms of intrinsic glomerular disease in T2DN could be an important tool to reduce these disparities. We have shown that full-length osteopontin (flOPN) is critical in the development of T2DN in OPN-null mice. Here, we investigate the mechanisms of a biologically active, thrombin-cleaved N-terminal fragment of OPN (ntOPN) in primary mesangial cells (MC), and as a clinical biomarker of T2DN in a subset of Mexican Americans (Mex Am) from the FIND study.

Methods: MC were grown in normal (4mM) and high glucose (25mM) and treated with thrombin (0-7.5U/ml), and an arginine-glycine-aspartate (RGD) peptide, which blocks the RGD-motif of ntOPN and activates signal transduction through integrin-binding, for Western blot analyses. We quantified ntOPN and flOPN levels in plasma and urine of Mex Am subjects (N=101).

Results: Expression of ntOPN is increased with thrombin in high glucose, RGD peptide (100μg/ml) down-regulated TGF-β, ERK/MAPK, AKT, STAT3, fibronectin, collagen I and collagen IV. Plasma ntOPN did not change, but ntOPN-to-creatinine ratio (ntOCR) was 3-fold higher in T2DN compared to diabetics or healthy controls (p<0.001). The area under the receiver operating characteristic curve for ntOCR was 0.9. The true positive and false positive rates were 0.75 and 0.02, respectively. Urine flOPN did not indicate the presence of T2DN in diabetics. ntOCR may accurately diagnose T2DN in Mex Am.

Conclusions: Thus, ntOCR may accurately diagnose T2DN in Mex Am.

MicroRNA-21 Modulates Renal Fibrogenesis by Regulating the Expression of Smad7 Phillip Kantharidis,[1] Radko Komers,[2] Mark E. Cooper,[1] Aaron D. McClelland,[1] Karin Jandeleit-Dahm.[1] *[1]Diabetic Complications, Baker IDI Heart and Diabetes Institute, Melbourne, Victoria, Australia; [2]Division of Nephrology and Hypertension, Oregon Health and Science University, Portland, OR.*

Background: Diabetic nephropathy (DN) is characterised by the accumulation of extracellular matrix (ECM) proteins in the kidney. TGF-β1 is the main pro-fibrotic driver of this process. A number of microRNAs modulated by TGF-b1 have been shown to be important in renal fibrogenesis. Here we demonstrating a role for miR-21 in promoting fibrosis by regulating the TGF-β1 signalling.

Methods: Proximal tubular epithelial cells were analyzed for changes in ECM gene and miRNA expression following exposure to TGF-β1. miR-21 levels were modulated to determine the effect of this miRNA on fibrogenesis. The effect of miR-21 on ECM gene expression, SMAD signalling and in particular SMAD7 was also assessed. The relationship between diabetic nephropathy and miR-21 was also examined in the kidney from streptozotocin-induced diabetic SD rats.

Results: TGF-β1 treatment of PTCs resulted in the typical EMT-like changes. Significanlty increased expression was observed for collagen I and IV, fibronectin and PAI-1.

Realtive Gene Expression in NRK52E Cells

	Collagen I	Fibronectin	PAI-1
Control	1	1	1
TGF-β1	2	3	7
miR-21	1.6	2	1.8
miR-21+TGF β1	4	7	13

TGF-β1 also increased miR-21 expression 4 fold. Ectopic expression of miR-21 also elevated expression of these genes but to a lesser extent than TGF-β1. Interestingly, miR-21 further enhanced the fibrotic effects of TGF-β1. miR-21 also induced SMAD7 mRNA expression, a negative regulator of TGF-β1 signalling. In contrast SMAD7 protein levels

were reduced, consistent with the SMAD7 3'UTR data demonstrating that miR-21 targets SMAD7. Furthermore, miR-21 also increased SMAD3 activity by 50%. Inhibition of miR-21 attenuated the fibrotic action of TGF-β1. miR-21 was also elevated in the kidney of diabetic rats in association with increased ECM gene expression, a finding that is consistent with the in vitro observations.

Conclusions: These data demonstrate an important mechanism by which miR-21 regulates the TGF-β1 signalling pathway and therefore fibrosis, by targeting SMAD7.

SA-PO112

A New Mechanism of Insulin Resistance in Chronic Kidney Disease: Actions of SIRP-α, an Unexplored Phosphatase Sandhya S. Thomas, Liping Zhang, Yanjun Dong, John Kent Lin, William E. Mitch. *Nephrology, Baylor College of Medicine, Houston, TX.*

Background: Insulin resistance in CKD begins at a creatinine ≤2.4 mg/dL blunting anabolic responses to insulin which is identified by a low p-Akt activating proteases and leading to muscle protein breakdown. Although inflammation is an inciting factor, the mechanism leading to impaired insulin signaling is unknown.

Methods: In muscles of CKD mice (BUN>80 mg/dL) vs pair-fed control mice and in myotube studies, defects in insulin function were based on microarray, RT-PCR, immunofluorescence, and western blot.

Results: Microarray analysis revealed upregulation of inflammatory cytokines($P<0.05$), and signal regulatory protein (SIRP) (5.2-fold increase; $P<0.05$ vs. control mice). We hypothesized that this membrane-bound tyrosine phosphatase impairs insulin signaling. 1. SIRP-α in myofibers membranes from CKD mice was substantially greater vs that in muscles of pair-fed control mice. 2. The SIRP-α promoter contains NF-kB binding sites, and a combination of IL-6, TNF-α, INF-γ and LPS increased NF-kB activity in muscle cells. This led to increased SIRP-α mRNA and protein ($P<0.05$) levels. 3. p-Akt was reduced 3-fold($P<0.05$), leading to increased proteolysis via upregulation of E3 ubiquitin ligases (Atrogin-1 & MuRF-1, initiators of proteolysis in the ubiquitin-proteasome system). 4. SIRP-α in myotubes was suppressed($P<0.05$) by transfection of a silencing RNA(SiRNA) vs responses to scrambled siRNA, which increased p-Akt, reducing the expression of E3 ligases($P<0.01$), despite cytokine exposure. 5. SIRP-α overexpression in myotubes lowered p-Akt($P<0.001$) and enhanced proteolysis($P<0.05$). 6. SIRP-α upregulation was also found in db/db mice, another model of muscle atrophy and insulin resistance.

Conclusions: Thus, CKD activates SIRP-α in muscle and impairs insulin signaling. SIRP-α blockade not only improves insulin signaling but also suppresses cytokine-induced muscle protein losses. This novel mechanism may be the pathway linking CKD, inflammation and insulin resistance to muscle wasting. Targeting SIRP-α could prevent muscle wasting in CKD and improve insulin action in other catabolic conditions with impaired insulin signaling.

Diabetic Nephropathy in Meprin Deficient Mice Elimelda Moige Ongeri. *Biology, North Carolina A&T State University, Greensboro, NC.*

Background: Diabetic nephropathy (DN) is the single most common cause of end stage renal disease (ESRD), and is associated with an increased risk for cardiovascular disease and mortality. Pathological changes seen in DN are a direct consequence of accumulation of extracellular matrix (ECM) proteins, suggesting that the rate of ECM production exceeds removal. Meprins are metalloproteinases that are abundantly expressed in the brush border membrane (BBM) of proximal kidney tubules. Expression of meprins has also been documented in podocytes and leukocytes such as monocytes and macrophages. Meprins are capable of degrading several ECM proteins, and could play a role in reversing the ECM imbalance observed in DN. Meprin β gene polymorphism is also associated with human DN in the Pima Indians, a United States group with an extremely high incidence of type 2 diabetes and subsequent ESRD. Meprin levels in human kidneys are much lower compared to those in mouse models commonly used to study DN. Compared to humans, common mouse models for DN such as the db/db mouse,and STZ models develop modest elevations in albuminuria, serum creatinine, and kidney histological lesions. The objective of this study was to determine if meprin deficiency makes mice more susceptible to DN.

Methods: STZ was used to induce type 1 diabetes in 8-week old male WT and meprin KO mice on a C57BL/6 background. Blood and urine samples were collected at 7, 10, and 18-weeks post STZ-injection. Samples were analyzed for BUN, and the albumin to creatinine ratio determined by ELISA.

Results: Diabetic meprin αβ KO mice had a significantly higher mortality rate compared to WT and meprin α KO counterparts. An important finding was a significantly higher albumin/creatinine ratio in diabetic meprin αβ KO mice when compared to diabetic WT mice. Diabetic meprin αβ KO mice also had higher BUN levels at 7 and 10 weeks post STZ injection, compared to non-diabetic controls. This trend was not observed in WT diabetic mice.

Conclusions: Our data imply that meprin αβ double KO mice have more severe diabetic kidney damage compared to WT mice with normal meprin expression levels. High meprin levels may thus confer partial resistance to diabetic kidney damage in mice.

SA-PO114

Indoxyl Sulfate Exacerbates Renal Anemia by Induction of Hemolysis Following Methemoglobin Formation in Rats Junya Hirata, Hirobumi Asai, Sayaka Mizukami, Misaki Miyamoto, Kazuya Hirai, Mie Watanabe-akanuma. *Kureha Corporation, Tokyo, Japan.*

Background: Renal anemia is common among patients with chronic kidney disease (CKD). Recently, uremic toxins are known to be involved in hypoxia and erythropoietin (EPO) production. In the present study, we investigated the effect of indoxyl sulfate (IS), a representative uremic toxin, on the progression of renal anemia.

Methods: First, male Wistar rats were fed a diet containing 0.3% adenine (w/w) for 4 weeks to establish CKD model. Rats were then given IS in drinking water at 0.025%, 0.05% and 0.1% (w/v) for 4 weeks. Red blood cell (RBC) parameters and serum EPO level were examined periodically. Second, IS was given at 0.1% and 0.25% for non adenine-treated rats as well to clarify the mechanism of IS-induced anemia. The previous parameters, reticulocyte ratio and methemoglobin (Met-Hb) were examined periodically and histopathology of the spleen was performed.

Results: S-Cr and BUN levels significantly increased and the RBC parameters and serum EPO level significantly decreased in adenine-induced CKD model rats. Under CKD condition, RBC parameters decreased further by IS administration, which highly correlated with the serum IS level. These hematological effects of IS were observed in non adenine-treated rats as well. Further investigations revealed that IS increased Met-Hb level in the RBCs. Other than this, congestion and deposition of brown pigments in the spleen were observed in IS-treated rats, indicating an increase of hemolysis. On the other hand, increases in reticulocyte ratio and serum EPO level in IS-treated rats indicated enhanced erythropoiesis.

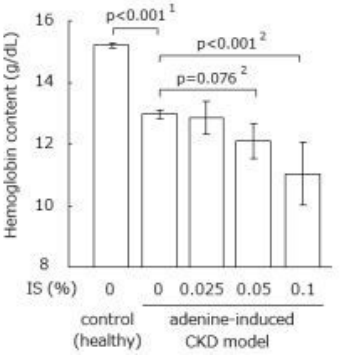

Figure 1.
Hemoglobin content at 1 week after IS administration in adenine-induced CKD model rats.
Values are mean±SD (n=6).
[1], t-test; [2], Dunnett's test.

Conclusions: IS exacerbates renal anemia by induction of hemolysis in the spleen following Met-Hb formation in the RBCs. Therefore, IS could contribute to progression of renal anemia in CKD patients whose serum IS level is increased by the renal dysfunction.

SA-PO115

Urinary Angiotensinogen Is a Significant Predictor of the Need for Erythropoiesis-Stimulating Agent Therapy in Patients with Chronic Kidney Disease Keiichi Takiue,[1] Hitoshi Sugiyama,[1] Hiroshi Morinaga,[1] Masashi Kitagawa,[1] Ayu Ogawa,[1] Toshio Yamanari,[1] Yoko Kikumoto,[1] Tatsuyuki Inoue,[1] Shinji Kitamura,[1] Shigeru Akagi,[1] Yohei Maeshima,[1] Akira Nishiyama,[2] Hirofumi Makino.[1] *[1]Medicine and Clinical Science, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan; [2]Pharmacology, Kagawa Medical University, Kita-gun, Kagawa, Japan.*

Background: Patients with chronic kidney disease (CKD) exhibit anemia and the progression of renal dysfunction as a consequence of reduced production of erythropoietin in the kidneys. However, little is known about the associations between urinary biomarkers that predict the progression of anemia and the need for treatment with erythropoiesis-stimulating agents (ESAs) in CKD patients. Therefore, we investigated the relationship between urinary angiotensinogen (AGT) levels and the use of ESA therapy in patients with CKD.

Methods: Using sandwich ELISA analyses specific for human angiotensinogen, we determined the levels of urinary AGT in spot urine samples of patients with CKD (n=90). The associations between the levels of urinary AGT, levels of hemoglobin, estimated glomerular filtration rate (eGFR) and the use of ESA therapy were analyzed during an observation period of two years.

Results: Urinary AGT to creatinine ratios (AGT/Crs) at baseline were significantly higher in patients who received ESA therapy during the two-year period than in those who did not receive ESA therapy ($P = 0.0156$). Urinary AGT/Crs at baseline showed a significant correlation with subsequent decreases in hemoglobin levels, but not with changes in eGFR. Higher levels of urinary AGT at enrollment significantly predicted the need for ESA therapy during the follow-up period ($P = 0.0234$). In a multivariate analysis, urinary AGT/Crs were found to be significant predictors of monthly decreases in hemoglobin levels, even after adjusting the initial levels of hemoglobin and proteinuria ($P = 0.0004$).

Conclusions: These data suggest that urinary AGT levels are significantly associated with the progression of anemia in CKD patients. AGT levels may become a novel biomarker for predicting the need for ESA therapy in patients with CKD.

Intravenous Ferric Carboxymaltose versus Standard Medical Care in the Treatment of Iron Deficiency Anemia in Patients with Chronic Kidney Disease: A Randomized, Active-Controlled, Multi-Center Study
Chaim Charytan,[1] Marializa Bernardo,[2] Todd Koch,[3] Angelia Butcher,[3] David D. Morris,[4] David B. Bregman.[3] *[1]New York Hospital Medical Center, NY; [2]Southwest Houston Research, TX; [3]Luitpold Pharmaceutticals, PA; [4]WebbWrites, LLC, NC.*

Background: Ferric carboxymaltose (FCM) is a stable, non-dextran iron formulation developed for rapid intravenous (IV) administration in high doses with controlled delivery of iron into target tissues. The objective of this study was to evaluate the safety of FCM compared to standard medical care (SMC) in hemodialysis (HD) and non-dialysis dependent (NDD) chronic kidney disease (CKD) patients.

Methods: Patient with CKD ages 18 to 85 were enrolled in this study. Iron was administered to NDD-CKD patients (n=204) as an undiluted IV dose of FCM (15 mg/kg to a maximum of 1000 mg) and to HD-CKD patients (n=50) as an undiluted IV push of 200 mg approximately 30 to 60 minutes into the dialysis session. Patients randomized to the SMC group (n=259) received either oral iron, IV iron, or no iron, as determined by the investigator.

Results: Single doses of 200 mg FCM in HD-CKD patients and up to 1000 mg in NDD-CKD patients were well tolerated. Incidences of treatment-emergent adverse events were similar between groups: 30.3% (77/254) in the FCM group and 32.8% (85/259) in the SMC group. Incidences of serious adverse events were higher in the SMC group (8.9% vs. 3.5%. p<0.02). In patients receiving FCM, the most commonly reported related adverse event was nausea and vomiting in NDD-CKD patients, and muscle spasm and hypotension in HD-CKD patients. For the total study population, which consisted of both HD and NDD patients, 25.7% of patients in the FCM group had an increase of ≥ 1 g/dL in hemoglobin vs. 22.1% in the SMC group. This difference was not statistically significant.

Conclusions: FCM was well tolerated, with an adverse event profile, which is in line with previous studies and were expected in this chronically ill patient population. There were no statistically significant differences between the FCM and SMC groups with regard to efficacy endpoints.

Induction of Erythropoiesis in Anemic Patients by Prolylhydroxylase Inhibitor in a Repeat Dose, Randomized Placebo Controlled Trial
Richard A. Brigandi,[1] Brendan Johnson,[2] Coreen Oei,[2] Mark E. Westerman,[3] Gordana Olbina,[3] Sanjay Kumar,[1] Steven F. Russ.[2] *[1]GlaxoSmithKline, King of Prussia, PA; [2]GlaxoSmithKline, Research Triangle Park, NC; [3]Intrinsic LifeSciences, LaJolla, CA.*

Background: GSK1278863A is a novel small molecule that has demonstrated *in vitro* and *in vivo* inhibition of the hypoxia-inducible factor prolyl hydroxylases.

Methods: Study PHI112844 was a randomized, single-blind, placebo-controlled, parallel-group study conducted in two parallel populations to evaluate the safety, pharmacokinetics (PK), and efficacy of 28-day repeat oral doses of GSK1278863A. Population 1 subjects were anemic non-dialysis, Stage 3, 4 and 5 chronic kidney disease (CKD) patients. Population 2 subjects were anemic hemodialysis (HD)-dependent Stage 5 CKD patients. Subjects in both populations were dosed once daily for 28 days with doses of 10, 25, 50 and 100 mg (Population 1) or 10 and 25 mg (Population 2) GSK1278863A or placebo.

Results: Oral administration of GSK1278863A was generally well tolerated with most AEs occurring at higher doses. A two compartment first-order oral absorption model with lag time was used to describe the PK data. The only significant PK covariate was a difference in apparent central volume of distribution between Population 1 and 2. Dose-dependent changes across hematologic and iron metabolism biomarkers were observed. The changes include increased erythropoietin, reticulocyte count, and hemoglobin with increasing GSK1278863A dose. Across all GSK1278863A treatment groups, multiple subjects were discontinued (early termination) due to high hemoglobin rate of rise or high absolute hemoglobin concentration per discontinuation criteria. Hepcidin was observed to decrease from baseline in a dose dependent manner. VEGF pre-dose and post-dose mean changes from baseline patterns were inconsistent with large variability and no clear separation between placebo and the GSK1278863A groups.

Conclusions: These data indicate that GSK1278863A was able to induce erythropoiesis in CKD patients with anemia.

Funding: Pharmaceutical Company Support - GlaxoSmithKline

SA-PO118

Modulation of Hepcidin by Prolylhydroxylase Inhibitor in Randomized Trials
Richard A. Brigandi,[1] Mark E. Westerman,[2] Gordana Olbina,[2] Coreen Oei,[3] Steven F. Russ,[3] Sanjay Kumar.[1] *[1]GlaxoSmithKline, King of Prussia, PA; [2]Intrinsic LifeSciences, LaJolla, CA; [3]GlaxoSmithKline, Research Triangle Park, NC.*

Background: Increases in hypoxia-inducible factor can suppress the production of hepcidin. GSK1278863A is a novel small molecule that has demonstrated *in vitro* and *in vivo* inhibition of the HIF prolyl hydroxylases.

Methods: Study PHI112844 was a randomized, single-blind, placebo-controlled, parallel-group study conducted in two parallel populations to evaluate the safety, pharmacokinetics, and efficacy of 28-day repeat oral doses of GSK1278863A. Both anemic non-dialysis, Stage 3, 4 and 5 chronic kidney disease (CKD) patients and anemic hemodialysis (HD)-dependent Stage 5 CKD patients were studied. Subjects in both populations were dosed once daily for 28 days with doses of 10 to 100 mg GSK1278863A or placebo. Plasma samples were collected both pre- and post-dose on days 1, 15 and 22 and on days 29 and 57 for hepcidin analysis.

Results: A dose dependent decrease in hepcidin from baseline was observed without any diurnal variation (40-93% decrease). In contrast, the placebo groups were unchanged, also with no diurnal variation. The anemic HD population had higher baseline hepcidin compared to the anemic non-dialysis population. This was consistent with data observed previously with HD and non-dialysis (stage 3 and 4) subjects in study PHI112843, asingle dose, 2-period crossover study. CKD patients had higher baseline hepcidin than matched healthy subjects (HS) in study PHI112843 and healthy males in study PHI112842, a 14-day placebo controlled repeat dose study. Data in the two previous studies also indicate that a single dose of GSK1278863A suppressed hepcidin by 24 hours post-dose with a greater magnitude observed at higher doses in all populations and also with greater magnitude in CKD patients versus HS.

Conclusions: These data indicate that GSK1278863A was able to induce hepcidin suppression in patients with anemia.

SA-PO119

Hepcidin Determinants and Its Relation with Anemia in Chronic Kidney Disease
Lucile Mercadal,[1] Marie Metzger,[1] Cedric Gauci,[2] Martin Flamant,[3] Jean-philippe Haymann,[4] Benedicte Stengel.[1] *[1]U1018, INSERM, Villejuif; [2]European G Pompidou CHU; [3]Bichat CHU; [4]Tenon CHU Paris, Paris, France.*

Background: Hepcidin plays a central role in iron metabolism and its level is markedly altered in chronic kidney disease (CKD). We studied its determinants and relation with CKD anemia in 199 CKD stage 2-5 patients, not treated by erythropoietin stimulating agent nor by IV iron.

Methods: All had glomerular filtration rate measured by ^{51}Cr-EDTA renal clearance (mGFR) together with measurements of erythropoietin (Quantitine IVD Epo double-antibody sandwich ELISA method, Minneapolis, MN) and hepcidin (immunochemical assay, Amgen, Thousand Oaks, CA). In all analyses, hepcidin was square-root transformed to meet normality criteria.

Results: Hepcidin levels varied from 0.2 to 193 ng/mL (median 27.9 ng/mL IQR 16.4-45.7). Women under 55 years had lower values (n=35, 15.6ng/mL IQR 8.8-40.2). Hepcidin increased from 23.3 ng/mL [8.8-28.7] to 36.1 ng/mL [14.1-92.3] with mGFR decline from ≥60mL/min/1.73m² to <15mL/min/1.73m²(p=0.02). Higher body mass index, albuminemia, C-reactive protein, ferritin,TSAT levels and oral iron therapy were associated with elevated hepcidin, while WHO-anemia, lower EPO and transferrin iron binding capacity (TIBC) values were associated with a decreased level. Absolute iron deficiency (ID) defined by TSAT <20%, TIBC≥50µmol/L, ferritin <40 ng/mL was associated with profound hepcidin collapse (5.0 ng/mL [0.7-11.7], n=12). In multivariate analysis, women under 55 years, absolute ID and higher EPO levels were associated with decreased hepcidin levels, while higher albuminemia, CRP and mGFR were associated with increased levels. Each ng/mL increase of hepcidin was associated with 0.01 ± 0.003 g/dL decrease in Hb (p=0.005), independent of diabetes, gender, mGFR and iron status.

Conclusions: Several factors including iron profile, EPO level, mGFR, nutrition and inflammation may affect hepcidin levels in CKD. Despite increasing level with mGFR decline, profound hepcidin collapse remains in patients with absolute iron deficiency. This study also showed a lack of down-regulation of hepcidin with Hb decrease suggesting a causal role of hepcidin in CKD anemia.

Neutrophil Gelatinase-Associated Lipocalin in Chronic Heart and Renal Failure Correlates with Endogenous Erythropoietin Levels and Decreases in Response to Low-Dose Erythropoietin Treatment
Carlo A. Gaillard,[1] Mireille E. Emans,[2] Adry Diepenbroek,[1] Karien Van der Putten,[3] Maarten Jan M. Cramer,[2] Dorine W. Swinkels,[4] Pieter Doevendans,[2] Branko Braam.[5] *[1]Nephrology, VU, Amsterdam, Netherlands; [2]Cardiology, UMC Utrecht, Netherlands; [3]Nephrology, LUMC, Leiden, Netherlands; [4]Clinical Chemistry, RUMC, Nijmegen, Netherlands; [5]Nephrology, University of Alberta, Canada.*

Background: In two recent studies, Neutrophil-gelatinase associated lipocalin (NGAL) levels were associated with disordered iron metabolism in haemodialysis patients. Iron metabolism plays a pivotal role in the pathophysiology of combined chronic kidney disease (CKD) and chronic heart failure (CHF). We investigated whether serum NGAL levels reflect iron metabolism in patients with CHF/CKD and whether treatment with erythropoietin (EPO) modulates serum NGAL levels.

Methods: In the EPOCARES trial (ClinTrialsNCT00356733) serum NGAL, hepcidin-25, transferrin saturation (TSAT), reticulocyte hemoglobin content (Ret-He) and endogenous EPO levels were measured in 56 patients with combined CKD (Cockroft-Gault 36±15 ml/min) and CHF. Subjects were randomized to receive EPO 50IU/kg/week (n=37) or not (n=19).

Results: Serum NGAL levels correlated positively with cystatin C (r=0.767, p<0.001) and showed an inverse correlation with Cockcoft-Gault (r=-0.571, p<0.001) and baseline EPO levels (r=-0.395, p=0.003). There was no correlation with TSAT (r=-0.316, p=0.32), Ret-He (r=-0.119, p=0.39) and hepcidin-25 levels (r=0.147, p=0.28). After two weeks, NGAL levels decreased in the EPO group (182 [122-219] vs baseline 189 [133-265] ng/mL,

p=0.01), while there was no change in the no-EPO group (256 [111-357] vs baseline 238 [129-313] ng/mL, p=0.31). The magnitude in NGAL decrease in the EPO group correlated with baseline EPO levels (r=0.431, p=0.01).

Conclusions: In combined CKD and CHF, elevated serum NGAL levels do not correlate with parameters of iron metabolism, as assessed by TSAT, hepcidin-25 and Ret-He, and hence might reflect tubular damage. NGAL levels inversely correlated with baseline EPO levels and decreased in response to short-term low-dose EPO treatment.

The Erythropoietic Effect of Low Fixed Dose Erythropoietin and Red Cell Turnover Are Related to Quality of Life and Cardiac Function in Cardiorenal Patients Carlo A. Gaillard,[1] Mireille E. Emans,[2] Maarten Jan M. Cramer,[2] Adry Diepenbroek,[1] Karien Van der Putten,[3] Pieter Doevendans,[2] Branko Braam.[4] *[1]Nephrology, VU Medical Centre, Amsterdam, Netherlands; [2]Cardiology, UMC Utrecht, Netherlands; [3]Nephrology, LUMC, Leiden, Netherlands; [4]Nephrology, University of Alberta, Canada.*

Background: The EPOCARES study was designed to differentiate erythropoietic from non-erythropoietic effects of low fixed dose erythropoietin (EPO) in combined chronic heart and kidney failure (CHF/CKD). Here we report cardiac function, quality of life (QoL) and exercise capacity.

Methods: Fifty-six anemic patients (median age 74 years) with CKD (Cockroft-Gault 36±15 ml/min) and CHF, on iron supplementation, were randomized into three groups: two groups received 50 IU/kg/week EPO during 26 weeks. In one group hemoglobin levels (Hgb) were allowed to increase (EPO-Hgb-rise); in the other group Hgb-levels were maintained at baseline level by phlebotomy (EPO-Hgb-stable). The control group did not receive EPO. The area under the curve (AUC) for the Hgb-change in time was calculated to assess the Hgb-response.

Results: The AUC after 26 weeks in the EPO-Hgb-rise group was 19.8 ± 17.1, in the EPO-Hgb-stable group 5.9 ± 9.6 and in the control group -2.2 ± 9.4 (rise vs stable group, p=0.009). Only the EPO-Hgb-rise group demonstrated an increase in QoL (RAND36 from 54.9 ± 13.8 to 63.6 ± 15.3, p=0.03) and ejection fraction (from 42 ± 8 to 45 ± 10%, p= 0.048) and a decrease in NT-proBNP levels (from 1373 [524-2151] to 941 [452-1721] pg/mL, p= 0.04). There was no significant change in the EPO-Hgb-stable and the control group. RDW levels, a measurement of anisocytosis, which may reflect red cell turnover, at baseline correlated negatively with QoL and exercise capacity (RAND-36 r=-0.363, p=0.008; pVO_2/kg r = -0.586, p< 0.001) and increased in both EPO groups. No significant changes were detected in parameters of inflammation.

Conclusions: In combined CHF/CKD low fixed dose EPO-induced improvement of cardiac function and QoL occurred only in patients in which Hgb-levels were allowed to increase. These data support the contention that low dose EPO to cardiorenal patients may have a positive impact on heart function and QoL.

Management of Renal Anemia in Patients with CKD Stages 3-5 Not on Dialysis Treated with C.E.R.A. in Catalonia Nephrology Units (The MICENAS II Study) Alberto M. Martinez-Castelao,[1] Aleix Cases,[2] Joan Fort,[3] Jordi Bonal,[4] Xavier Fulladosa,[1] J.M. Galceran,[5] J. V. Torregrossa,[2] Elisabeth Coll.[6] *[1]H. Bellvitge, Spain; [2]H. Clínic Barcelona, Spain; [3]H. Vall Hebron, Spain; [4]H. Germans Trias i Pujol, Spain; [5]Fundacio Althaia, Spain; [6]Fundacio Puigvert, Spain.*

Background: Therapeutic management of renal anemia with CERA in patients with CKD stages 3-5 not on dialysis in Catalonia is unknown.

Methods: Observational retrospective study conducted in Catalonia Nephrology Units. CKD anemic patients stages 3-5 not on dialysis, or 5-T, aged≥18years, treated with CERA during at least 6 months, who gave informed consent were recruited. Ferropenia (ferritin<100ng/mL or TSAT<20%) and Hb target at 6 months (Hb≥10.5g/dL) were assessed.

Results: 331 patients were recruited by 15 investigators, 267 valid for analysis. 52.1% were women, mean age 66.6±17.4years, 38.5% were kidney transplants. CKD stage distribution was 3:40.4%; 4:46.8% and 5:12.7%. 51.3% had been previously treated with ESA (naïve:48.7%); most common previous ESA was epoetin-beta(56.0%). At the beginning of CERA, mean Hb were 10.2±0.9 and 11.5±1.2g/dL for naïve and conversion, respectively(p<0.05); mean CERA initial dose/month 85.4±36.5 and 87.2±34.8µg and at 6 months 81.2±44.4 and 91.5±46.8µg (p>0.05). Likewise, no differences were found in mean CERA doses among transplanted and non transplanted. Regarding previous ESA and respective ranks of weekly dose administered:<8000UI;8000-16000UI;>16000UI; CERA dose administered monthly in conversion were 72.5±18.4; 79.5±22.7; 105.0±49.1µg, respectively. 50.0% of naïve patients started treatment at dose recommended by CERA Summary of Product Characteristics(SPC) (1.2±0.6µg/kg/month). At initiation with CERA 25.1% had ferropenia, only 49.3% of whom received iron. Mean Hb after 6 months with CERA showed a significant increase in naïve (1.5±1.5g/dL;p<0.05) and stable values in conversion (0.2±1.5g/dL;p>0.05). At 6 months 77.8% reached target Hb regardless of previous use of ESA (naïve:78.3%;conversion:77.4%).

Conclusions: Monthly use of CERA corrects anemia in ESA naïve CKD patients. In conversion lower CERA doses than those recommended by SPC were required to achieve target Hb.

SA-PO123

Anemia Management in Chronic Kidney Disease Patients Not on Dialysis in Clinical Practice Following the Recommendations from the Anemia Working Group of European Renal Best Practice (ERBP) Alberto M. Martinez-Castelao,[1] Aleix Cases,[2] Javier Torralba-iranzo,[3] Alberto Torre-carballada,[4] Daniel Toran,[5] Carmen Bernis,[6] Fernando Vallejo Carrión.[7] *[1]H Bellvitge, Spain; [2]H Clinic, Spain; [3]H Alicante, Spain; [4]H La Paz, Spain; [5]H Jerez, Spain; [6]H La Princesa, Spain; [7]H Puerto Real, Spain.*

Background: According to the TREAT study results, the Anemia Working Group of ERBP recommends maintaining Hb levels within 11-12g/dL, not intentionally exceeding 13g/dL and considering doses of ESA therapy to achieve the Hb target range. This study was designed to evaluate the impact of this statement in clinical practice.

Methods: Multicenter cross-sectional observational study in patients with anemia secondary to chronic kidney disease (CKD) not on dialysis who initiated anemia treatment (naïve) or converted from other ESAs from January 2011. Preliminary results at baseline after correction and conversion are presented.

Results: 182 patients were evaluated (naïve 59.3%;conversion 40.7% [mean ESA treatment duration 18.9±16.6months]). Mean age 72.9±12.6years. CKD 3/4/5 29.4%/44.6%/23.2%. Predominant etiologies 34.1% vascular and 23.6% diabetes. At baseline, 33.7% of naïve patients attained Hb range of 11-12g/dL(40.3% Hb<11g/dL,26% Hb>12g/dL) with mean Hb of 11.3±1.4g/dL vs starting treatment(9.9±0.7g/dL); 38.1% of those converted maintained Hb levels within the target range(14.3% Hb<11g/dL,47.6% Hb>12g/dL). Prior to study initiation, 91% of naïve patients had started treatment with Mircera®(mean monthly dose 58.7±26.3µg) and 67% of those on maintenance had converted to Mircera®(mean monthly dose 84±37.9µg) being a less frequent administration the main reason for ESA change(65.8%). At baseline, 89% naïve and 84.5% converted patients were on Mircera®(mean monthly dose 52.3±24.5µg, 79.8±40.8µg) and also oral iron therapy(72.7%,80%,respectively). 2 naïve patients required transfusions during the correction period.

Conclusions: An appropriate anemia management in CKD patients not on dialysis can be obtained by the achievement Hb levels of 11-12g/dL according to the ERBP Group recommendations. Hb target range is attained and maintained in most patients receiving once-monthly Mircera®.

SA-PO124

Decisive Indicator for Gastrointestinal Workup in Anemic Patients with Non-Dialysis Chronic Kidney Disease Eun Oh Kim,[1] Youn Mi Song,[2] Eun Sil Koh,[1] Sungjin Chung,[1] Sangju Lee,[1] Yoon-Kyung Chang,[1] Suk Young Kim,[1] Hyeonseok Hwang.[1] *[1]Division of Nephrology, Departments of Internal Medicine, College of Medicine, the Catholic University of Korea, Daejeon, Korea; [2]Division of Gastroenterology, Departments of Internal Medicine, College of Medicine, the Catholic University of Korea, Seoul, Daejeon, Korea.*

Background: Anemia and iron deficiency are universal problems in patients with chronic kidney disease (CKD). However, decisive indicators to guide the diagnosis of bleeding-related gastrointestinal (GI) lesions have not been determined.

Methods: This diagnostic test study included 104 anemic patients with nondialysis-dependent CKD stages 3–5 (38 patients at stage 3, 26 patients at stage 4, and 40 patients at stage 5), who were naïve for iron and erythropoiesis-stimulating agents. Lesions causing GI blood loss were identified by esophagogastroduodenoscopy and colonoscopy. Hemoglobin, serum ferritin,transferrin saturation (TSAT), mean corpuscular volume (MCV), and corrected reticulocyte count data were collected to evaluate their diagnostic utility for bleeding-related GI lesions.

Results: Bleeding-related GI lesions were found in 55 (52.9%) patients, and patients with stage 5 CKD had a higher prevalence of gastric lesions than patients with CKD stage 3 or 4 (all $P < 0.05$). The areas under the receiver operating characteristic curves used to predict bleeding-related lesions were 0.69 for TSAT ($P = 0.002$) and 0.61 for serum ferritin ($P = 0.09$). Hemoglobin, MCV, and corrected reticulocyte levels had no significant diagnostic utility. The sensitivity and specificity of a cutoff value for TSAT of < 20% were 59% and 74%, respectively. On multivariable logistic regression, the chance of GI lesions increased by 6% for each 1% reduction in TSAT and increased 4.1-fold for patients with CKD stage 5 (all $P = 0.01$).

Conclusions: Half the anemic patients with CKD stages 3–5 had bleeding-related GI lesions, and TSAT was a useful decisive indicator of the GI workup. Stage 5 CKD was independently associated with GI bleeding-related lesions and TSAT should be used cautiously in these patients.

SA-PO125

Pathologic Endothelial Response and Impaired Function of Circulating Angiogenic Cells in Patients with Fabry Disease Johan M. Lorenzen,[1] Christoph Wanner,[2] Hermann G. Haller,[1] Thomas Thum.[1] *[1]Nephrology, Hannover Medical School, Hannover, Germany; [2]Nephrology, Würzburg University, Würzburg, Germany.*

Background: Fabry disease is an X-chromosomal recessive deficiency of the lysosomal hydrolase alpha-galactosidase A. This results in an accumulation of globotriaosylceramide (GL-3) in a variety of cells and functional impairment. The impact of Fabry disease on the biology of circulating angiogenic cells (CACs) and endothelial response to transient ischemia was investigated.

Methods: Untreated patients with Fabry disease (n=26), patients after initiation of enzyme replacement therapy (ERT, n=16) and healthy controls (n=26) were investigated. Endothelial function was assessed by the EndoPAT2000 device. CAC numbers were assessed by flow-cytometry, CAC function by a modified Boyden chamber assay. The effect of supernatant of cultured CACs on endothelial cells was assessed by a tube formation and Boyden chamber assay.

Results: Fabry patients showed a pathologic endothelial response, which normalized after enzyme replacement therapy. CACs were increased in number, but functionally impaired. Immunofluorescence and electron microscopy identified an accumulation of GL-3 in Fabry CACs. ERT attenuated CAC dysfunction in Fabry patients via a reduction in GL-3 accumulation in vitro and in vivo. Silencing of alpha-galactosidase A in healthy CACs impaired their migratory capacity underlining a key function of this enzyme. Fabry CAC supernatant impaired angiogenesis and migratory capacity of HUVECs.

Conclusions: Fabry patients show a dysfunction of CAC and a pathologic endothelial response. Enzyme replacement therapy improves CAC and endothelial function and thus may attenuate development of cardiovascular disease in the long-term in this patient population.

SA-PO126

Paroxysmal Nocturnal Hemoglobinuria and the Kidney: An Underestimated Complication Julie Sohier Attias,[2] Marie-noelle Peraldi,[1] Martin Flamant,[2] Gérard Socié,[1] Régis Peffault delatour.[1] *[1]Hopital Saint-Louis, Université Paris 7, Paris, France; [2]Hopital Bichat, Université Paris 7, France.*

Background: Paroxysmal nocturnal hemoglubinuria (PNH) is a rare acquired stem-cell disorder characterized by an increased sensitivity of the erythrocytes to complement-mediated intravascular haemolysis. Renal manifestations are recognized since the 1950s, but their prevalence is still unknown. A potential effect of Eculizumab on kidney function is expected but is still not described.

Methods: Renal functional studies were performed in 7 patients suffering classic-PNH. For each patient, Glomerular Filtration Rate (GFR) was measured and tubular function tests were performed both before and after Eculizumab treatment.

Results: Before Eculizumab treatment, six out of the 7 patients had abnormal renal function: one had glomerular hyperfiltration and 5 chronic kidney disease (median GFR of the whole cohort: 78,1 ml/min/1,73m^2; range: 54,6- 133,2). Among the patients with chronic kidney disease, 2 had significant microalbuminuria. Three patients had proximal tubular dysfunction and one had a distal tubular defect. According to the hematologists, Eculizumab therapy was totally effective for 4 patients and partially effectve for 3 patients, with a residual hemolysis. After a median treatment duration of 9 months (range: 5-11 months), 3 patients had a decline of renal function (minus 5,1 ml/min/1,73m^2). The GFR of one patient with no microalbuminuria improved. Two of the 3 patients with persistant hemolysis developed a proximal tubulopathy. The proximal tubular dysfunction disappeared in only one case.

Conclusions: Renal failure in PNH seems to be more common than expected. The pathogenesis may be compared with other hemolytic anaemia such as Sickle Cell Disease. Over a short-time period, Eculizumab does not appear to have major beneficial effects on renal functions.

Complications of Renal Artery Embolization in Patients with Renal Angiomyolipoma: A US National Retrospective Cohort Study John J. Bissler,[1] Peter Sun,[2] Zhimei Liu,[3] Hearns Charles,[4] John C. Hulbert.[5] *[1]University of Cincinnati, Cincinnati, OH; [2]Kailo Research Group, Fishers, IN; [3]Novartis Pharmaceutical Corporation, East Hanover, NJ; [4]Langone Medical Center, New York University, New York, NY; [5]Urologic Physicians, PA, MN.*

Background: This study aims to examine the prevalence rates of complications from renal artery embolization (RAE) in US patients with renal angiomyolipoma (AML).

Methods: Retrospective cohort study design was used with three US national health claims databases (Years: 2000-2010; Covered Population: 60+ millions). Patients with sporadic AML(ICD9-CM: 223.0 but no 759.5) or with tuberous sclerous complex (TSC) related AML (ICD9-CM: 223.0 and 759.5), who had minimal two years of health plan enrollment (one year prior and one year after first observed RAE) were included in the analysis. Based on a literature review and experts' opinions, more than 25 clinical conditions were predefined as potential complications related to RAE. Prevalence rates of these conditions in the post-RAE year were estimated for and compared between the two cohorts using two-sample t-test for proportions.

Results: Patients (N=9,901) had mean age of 49.9 years at their first observed RAE. In the post-RAE year, 5.2% of patients had flank pain, 4.3% had renal insufficiency, 4.0% had fever, 3.9% had nephrotic syndromes, and 5.9% had other diseases related to kidney or ureter. A higher proportion of patients in the TSC AML subgroup had renal insufficiency (5.1% vs. 3.6%; $P<0.05$), while the sporadic AML group had higher occurrence of flank pain (5.5% vs. 4.9%, $P<0.05$) and other diseases related to kidney or ureter (6.4% vs. 5.4%, $P<0.05$). Among all AML patients who had RAE, 4.4% underwent a partial nephrectomy and 9.6% received a complete nephrectomy within the post RAE year.

Conclusions: Flank pain, renal insufficiency, nephrotic syndromes, fever and other kidney or ureter related diseases were among the most common RAE related complications. Future analysis with control for pre-existing conditions and with objective of identify feasible approaches to improve RAE outcomes is warranted.

Complications of Nephrectomy in Patient with Renal Angiomyolipoma: A US National Retrospective Cohort Study John C. Hulbert,[1] Peter Sun,[2] Zhimei Liu,[3] Judith A. Prestifilippo,[3] Hearns Charles,[4] John J. Bissler.[5] *[1]Urologic Physicians, PA, MN; [2]Kailo Research Group, Indianapolis, IN; [3]Novartis Pharmaceutical Corporation, NJ; [4]New York University, NY, NY; [5]University of Cincinnati, Cincinnati, OH.*

Background: This study aimed to estimate the prevalence rates of nephrectomy related complications in patients with sporadic renal angiomyolipoma (AML) or TSC-associated AML in the United States.

Methods: Our study used a retrospective study design and three US national health claims databases (Years: 2000-2010; Covered Population: 60+ millions). Based on their TSC claim history patients with health insurance for a period one year preceding and one year following their first claim of nephrectomy for AML were selected into TSC-AML cohort or sporadic AML cohort. More than 50 clinical conditions were identified as nephrectomy related complications based on a literature review and expert opinions. Prevalence rates of these conditions in the first post-nephrectomy year were estimated for each cohort and compared across the two cohorts using two- sample t-tests for proportions.

Results: The study included 15,381 AML patients (TSC-AML: 5,191; sporadic AML: 10,190) with a mean age of 52.2 years at the newly observed nephrectomy. Within the post-nephrectomy year, prevalence rates were: digestive system complications, 7.4% (paralytic ileus: 5.9%, others: 3.9%); tension headache, 6.5%; acute posthemorrhagic anemia, 4.0%; incisional hernia, 3.3%; postoperative hemorrhage, 3.0%; paresthesia, 2.8%; diaphragmatic hernia, 2.4%; as well as cerebrovascular diseases and pancreatitis, 1.3%. Some of these rates were slightly higher in the sporadic AML cohort than in TSC-AML cohort.

Conclusions: The most common nephrectomy complications were digestive system complications (including postoperative ileus), tension headache, acute posthemorrhagic anemia, incisional hernia and postoperative hemorrhage. Further research is warranted to identify approaches to improve the clinical outcome of nephrectomy in patients with angiomyolipoma.

SA-PO129

Pregnancy in Women with Chronic Pyelonephritis/Vesico-Ureteric Reflux (CPN/VUR): Fetal and Maternal Outcomes Sajeda Youssouf,[1] Matt Hall,[2] Liz Lightstone,[3] Graham Graham Lipkin,[4] Nigel J. Brunskill,[1] Sue Carr.[1] *[1]The John Walls Renal Unit, Leicester General Hospital, Leicester, United Kingdom; [2]Nottingham City Hospital, Nottingham, United Kingdom; [3]Imperial College Kidney and Transplant Institute, London, United Kingdom; [4]Queen Elizabeth Hospital, Birmingham, United Kingdom.*

Background: Pregnancy is associated with adverse fetal and maternal outcomes in women with advanced CKD. There is little evidence that the etiology of maternal renal disease has an effect on outcomes but most information is based upon retrospective, historical data. In this study we analyzed fetal and maternal renal outcomes in pregnancy in women with a diagnosis of chronic pyelonephritis/vesico-ureteric reflux at the time of conception.

Methods: Prospective data from three specialist renal obstetric services has been collected since 2003. In this analysis we identified those with a diagnosis of chronic pyelonephritis, recurrent UTI or vesicoureteric reflux at the time of conception and reviewed pregnancy outcomes and maternal renal outcomes in this group.

Results: We identified 57 pregnancies in 48 women aged 16-40. Follow-up post-partum ranged from 6-78 months. CKD stage at time of conception is shown in the table below.

CKD stage	Number of pregnancies	%
1-2	30	53
3a	8	14
3b	4	7
4	2	4
Unknown	13	22

56 pregnancies (98%) resulted in a live birth; there were two early neonatal deaths.

17 pregnancies (30%) had at least one adverse event:

- Low birth weight 24%
- Admission to neonatal intensive care 19%
- Preterm delivery 30%

4 women (7%), had a decline in renal function in pregnancy, including one who developed ESRD during pregnancy. 4 women (7%) had persistent loss of >25% of renal function postpartum, and two developed ESRD; both had CKD 3b at the time of conception. Three women with CKD 1-2 (10%) experienced a decline in renal function post partum, but none developed ESRD.

Conclusions: Fetal outcomes in women with chronic pyelonephritis are better than reported in historical case series of pregnancy in women with CKD, but adverse event rates remain high. There is no evidence that CPN/VUR has an impact on maternal renal dysfunction post-partum, except in those with pre-existing advanced CKD.

Kidney Disease Is Associated with a Higher Risk of Adverse Fetal Outcomes in Pregnancy Shailendra Sharma,[1] John R. Holmen,[2] M. Chonchol,[1] Gerard John Smits,[1] Jessica B. Kendrick.[1] *[1]University of Colorado School of Medicine, Aurora, CO; [2]Intermountain Healthcare, Salt Lake City, UT.*

Background: Pregnant women with kidney disease have an increased risk of adverse fetal outcomes, however, the degree of this risk is unclear. We tested the hypothesis that pregnant women with kidney disease have an increased risk of adverse fetal outcomes independent of other comorbid conditions.

Methods: Using the Intermountain Healthcare Data Warehouse we identified 646 women with kidney disease who gave birth between 2000 and 2011. 62,757 pregnancies from women without kidney disease were randomly selected for comparison. Kidney disease was defined by ICD9 code. Fetal outcomes were defined as low birth weight (< 2500 gm), number of admissions to the neonatal intensive care unit (NICU) and infant death. We used multivariate logistic regression to examine the association between kidney disease and fetal outcomes.

Results: In the whole study population the mean (SD) birth weight was 3324 ± 578 gm and there were 2,629 admissions to the NICU and 81 infant deaths. Of the women with kidney disease, the mean (SD) age and gestational age at delivery were 28 ± 5 years and 37 ± 3 weeks, respectively. Women with kidney disease had a higher prevalence of diabetes (11.9% vs. 1.4%) and chronic hypertension (27.5% vs. 7.1%) than women without kidney disease. There was a higher rate of infant mortality in women with kidney disease compared to those without kidney disease (12.5% vs. 4.1%). After adjustment for age, race, diabetes, chronic hypertension, liver disease and connective tissue disorders, infants born to women with kidney disease had a higher odds of low birth weight (OR 1.66, 95% CI 1.11-2.48), number of admissions to the NICU (OR 1.97, 95% CI 1.31-2.97) and infant death (OR 1.93, 95% CI 1.28-2.90) compared to infants born to women without kidney disease.

Conclusions: In this cohort study, kidney disease during pregnancy was an independent predictor of low birth weight, admission to the NICU and infant mortality. Further studies are needed to determine if early detection and appropriate management of kidney disease can improve fetal outcomes.

SA-PO131

Immunogenicity of Investigational HEPLISAV Compared with Licensed Hepatitis B Vaccine (Engerix-B) in Patients with Chronic Kidney Disease (CKD) and Additional Factors that Reduce Immune Responses to Vaccine Robert Janssen, Sophia Rahman, Hamid Namini, William Heyward, Tyler Martin. *Dynavax Technologies Corporation.*

Background: CKD patients are commonly hypo-responsive to hepatitis B vaccines. Additional factors such as diabetes mellitus, male sex, older age, and high BMI further reduce immune responses. A multicenter, observer-blind, phase 3 study was conducted among 521 patients 18-75 years of age with CKD (GFR ≤ 45 mL/min/1.73 m^2), comparing 3 doses of HEPLISAV™ (H: 20 mcg rHBsAg + 3000 mcg 1018 ISS adjuvant, a toll-like receptor 9 agonist) given at 0, 1, and 6 months to 4 double-doses of Engerix-B® (EB: 2x20 mcg rHBsAg+500 mcg alum) given at 0, 1, 2, and 6 months. The peak geometric mean concentration (GMC) of antibodies to hepatitis B surface antigen (anti-HBs) was significantly higher in subjects who received H (587.1 mIU/mL) than those who received EB (156.5 mIU/mL). Peak GMC correlates with duration of seroprotection.

Methods: Peak GMCs at Week 28 were analyzed by diabetes status, age, sex, and BMI. Anti-HBs serum levels were measured using the Ortho Vitros® assay.

Results: The table presents peak GMCs at Week 28 in the modified intent-to-treat population (H: 227; EB: 242).

	GMC (mIU/mL) (95% CI) (N)		Ratio of GMCs H/EB (95% CI)[a]
	HEPLISAV	Engerix-B	
Diabetes status			
Diabetes	448.2 (271.4, 740.1) (153)	109.3 (63.1, 189.1) (150)	4.10 (1.96, 8.59)
No Diabetes	1025.6 (483.0, 2178.1) (74)	280.8 (153.1, 515.2) (92)	3.65 (1.41, 9.43)
Age			
40 – 55 years	967.3 (390.8, 2394.4) (51)	159.1 (62.8, 402.9) (48)	6.08 (1.69, 21.90)
56 – 75 years	512.8 (318.2, 826.5) (174)	136.3 (84.7, 219.5) (185)	3.76 (1.92, 7.37)
Sex			
Women	1582.5 (917.8, 2728.5) (81)	217.5 (115.9, 408.1) (99)	7.27 (3.12, 16.97)
Men	338.7 (193.6, 592.4) (146)	124.5 (72.0, 215.4) (143)	2.72 (1.25, 5.93)
BMI			
≥ 30 kg/m²	524.1 (303.7, 904.7) (137)	94.7 (54.1, 165.7) (143)	5.53 (2.54, 12.06)
< 30 kg/m²	697.6 (361.0, 1348.0) (90)	323.1 (180.1, 579.5) (99)	2.16 (0.90, 5.16)

[a]The lower limit of the 95% CI greater than 1.0 indicates a statistically significant difference in GMCs.

Conclusions: In CKD patients with additional factors that reduce their immune response to hepatitis B vaccines, HEPLISAV induced significantly higher GMCs than Engerix-B.

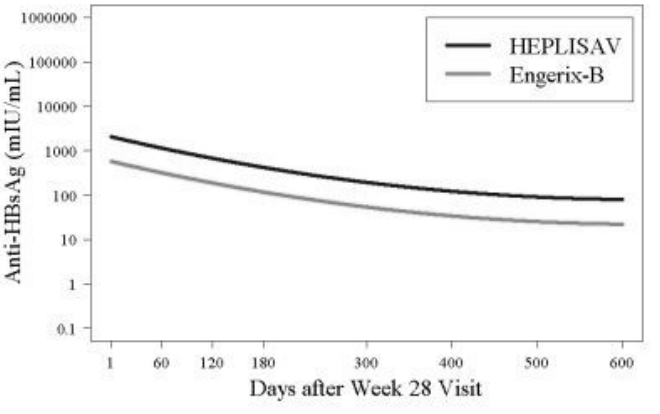
SA-PO132

Antibody Decay up to 1.5 Years after Last Dose of Investigational HEPLISAV Compared with Licensed Hepatitis B Virus (HBV) Vaccine (Engerix-B) in Patients with Chronic Kidney Disease (CKD) Robert Janssen, Fang Xie, William Heyward, Tyler Martin. *Dynavax Technologies, Berkeley, CA.*

Background: Because CKD patients have impaired immune responses, long-term protection against HBV depends on maintenance of antibodies against HBV surface antigen (anti-HBs).

Methods: A multicenter, phase 3 study among 521 adult CKD patients (GFR ≤ 45 mL/min/1.73 m^2) compared 3 doses of HEPLISAV™ (H: 20 mcg rHBsAg+3000 mcg 1018 ISS adjuvant, a toll-like receptor 9 agonist) to 4 double-doses of Engerix-B® (EB: 2x20 mcg rHBsAg). Anti-HBs serum levels were measured using the Ortho Vitros® assay at Weeks 28, 36, 44 and 52. A subset of 78 unselected subjects had one additional antibody level between 0 and 60 weeks after Week 52. After Week 28, antibody decay curves for individual subjects showed a generally linear pattern with antibody levels in log10 scale against time. Linear models using antibody levels in a log scale as the dependent variable, vaccine group as a factor, and time (days from Week 28) as a covariate were constructed with quadratic and interaction terms.

Results: 39 subjects in each vaccine group with anti-HBs ≥ 10 mIU/mL at Week 28 were included in the analysis. Vaccine group and time interaction were not significant variables, indicating a constant decay rate for both vaccine groups. The fitted model was T_i= 3.31-0.555*vaccine-0.00451*t+0.00000359*t^2, where T is the antibody level, t is time (in days) after Week 28 visit, and vaccine=0 for H and 1 for EB. Both vaccine group and time were statistically significant (<0.0001) in the model. The negative estimate for the vaccine term indicates that the superior antibody level of H in comparison to EB is constant across the decay period.



Conclusions: In CKD patients, antibody levels declined at the same rate for H and EB after Week 28, maintaining the superiority of the antibody response to H compared to EB.

SA-PO133

Strong Ion Gap Associates with Glomerular Filtration Rate Decline in Chronic Kidney Disease Akashi Togawa,[1] Satoko Uyama,[1] Seiko Takanohashi,[1] Takehiko Miyaji,[2] Hiroyuki Endo.[3] *[1]Nephrology, Shizuoka Saiseikai General Hospital, Shizuoka, Japan; [2]Miyaji Clinic, Shizuoka, Japan; [3]Tanpopo Clinic, Shizuoka, Japan.*

Background: Metabolic acidosis is known to accelerate the progression of chronic kidney disease (CKD). However, whether undetermined anions indicated from strong ion gap (SIG) associate with estimated glomerular filtration rate (eGFR) decline in patients with CKD is not known.

Methods: In retrospective, 22 patients with CKD (base line eGFR15 to 60 ml/min per 1.73m^2) were examined. Based on Stewart approach, SIG was determined from the gap between apparent strong ion difference (SIDa) and effective strong ion difference (SIDe) (Kellum et al, J Crit Care 1995).

Results: The average baseline eGFR was 27.5 ± 13.0 ml/min/1.73m^2 and the average eGFR decline rate per 6 months (ΔeGFR) was8.8 ± 22.2 %. Anion gap and SIG were 11.7 ± 1.70 and 6.29 ± 1.84, respectively. As previously reported, ΔeGFR was correlated with urinary protein-creatinin ratio (UPCR) (r=0.592, P<0.005), serum albumin concentration (r= - 0.534, p<0.01). ΔeGFR was positively associated with SIG(r=0.586, p<0.005) but not with anion gap(r=0.119, p=0.597). Furthermore, in multivariable linear regression analyses, SIG remained significantly associated with ΔeGFR (ß=0.61, P<0.05) after controlling for age, baseline eGFR, serum albumin concentration, UPCR, and HCO_3^- concentration.

Conclusions: These data suggest that SIG appears to be associated with the progression of CKD. Focusing on SIG during the course of CKD may be important for developing new therapeutic strategy to prevent CKD progression.

SA-PO134

Comparative Study of Matrix Metaloproteinase 9/Tissue Inhibitor of Metalloproteinase 1 System in All Stages of Chronic Kidney Disease
Maria Wanic-Kossowska,[1] Dorota Formanowicz,[2] Elzbieta Pawliczak,[1] Lidia Koziol.[1] *[1]Department of Nephrology, Transplantology and Internal Diseases, Poznan University of Medical Sciences, Poznan, Poland; [2]Department of Clinical Biochemistry, Poznan University of Medical Sciences, Poznan, Poland.*

Background: The matrix metalloproteinases (MMPs) and their tissue inhibitors (TIMPs) may play a key role in chronic kidney disease (CKD) atherosclerosis by their impact on extracellular matrix (ECM) accumulation. The MMP9/TIMP1 system received special emphasis because its disturbances has been discovered within the atherosclerotic plaques. In this study we demonstrated the analysis of MMP9/TIMP1 system in CKD and in patients with cardiovascular disease (CVD) but without kidney dysfunction.

Methods: To the study we enrolled 80 patients divided into 4 groups: CKD1-2 - the initial stage of CKD, CKD3-4 - pre-dialyzed, CKD5 - hemodialyzed, CVD – CVD patients without kidney dysfunction and 20 healthy volunteers (HV). All participants were sex- and age-matched and free of diabetes mellitus. Serum levels of MMP9 and TIMP1 were measured by an ELISA method and the carotid artery intima-media thickness (CA-IMT) was assessed by high-resolution ultrasonography.

Results: Compared to HV, CKD patients showed a significant TIMP1, MMP9 and CA-IMT increase. CKD1-2 and CKD5 differed in TIMP1 concentration, but no differences in MMP9 and CA-IMT were found between CKD groups. TIMP1/MMP9 ratio was higher in CKD5 than in other CKD groups. CVD patients showed higher MMP9, lower TIMP1, and lower TIMP1/MMP9 ratio if compared to CKD and HV. CA-IMT was comparable in all groups of patients. The positive correlations between TIMP1 and CA-IMT, MMP9 and HD vintage, cardiovascular disease and hypertension, and the negative correlations between TIMP1 and eGFR and HDL-cholesterol and between MMP9 and HDL-cholesterol were observed.

Conclusions: Our results showed that, on the one hand, CKD is characterized by MMP/TIMP disturbances, partially aggravated by the progression of CKD. On the other hand, CVD patients without kidney dysfunction showed also the propensity to this impairment. It seems that renal dysfunction is important but not crucial for the MMP9/TIMP1 system imbalance.

SA-PO135

High Plasma Levels of Fibroblast Growth Factor 23 Are Associated with Pulmonary Hypertension in Chronic Kidney Disease Patients
Anna Jeanette Jovanovich,[1] Jacob Joseph,[2] James S. Kaufman,[2] Alfred K. Cheung,[3,4] Tom Greene,[3,4] M. Chonchol,[1] Jessica B. Kendrick.[1] *[1]University of Colorado Denver Health Sciences Center; [2]VA Boston Healthcare System; [3]VA Salt Lake City Health Care System; [4]University of Utah.*

Background: Pulmonary hypertension (PAH) is characterized by increased pulmonary vascular resistance and is a cardiovascular (CV) complication in advanced chronic kidney disease (CKD) patients. High fibroblast growth factor 23 (FGF23) levels have been associated with impaired vasoreactivity and CV events in CKD. We hypothesized that high plasma FGF23 levels might be related to pulmonary hypertension in advanced CKD.

Methods: We identified 100 patients with advanced CKD (45 CKD and 55 ESRD) from the Homocysteine in Kidney and End Stage Renal Disease study who had echocardiograms performed for clinical indications during the study follow-up. C-terminal FGF23 levels were measured in stored plasma samples. Multivariate regression analyses were performed to evaluate whether higher plasma FGF23 levels were associated with a higher pulmonary artery pressure (PAP) and PAH (defined as PAP >40 mmHg) independently of other covariates.

Results: Participants had a mean age of 64±12 years, 45% were black, and 60% were smokers. Mean eGFR among those not requiring dialysis was 18±5 ml/min/1.73m^2. The median [IQR] plasma FGF23 level and mean estimated PAP at baseline were 1398 [589-6537] RU/mL and 43±14 mmHg, respectively. Median follow-up time was 1.9 years. After adjustment for age, gender, race, smoking, hypertension, diabetes, baseline PAP, body mass index, CKD status, albumin, and 1,25-dihydroxyvitamin D level, every $\log_{10}$ increase in FGF23 was associated with a PAP increase of 9.5 mmHg (p=0.01) during the follow-up period. Higher plasma FGF23 levels were also independently associated with an almost 4-fold increased risk of PAH in multivariate analysis (odds ratio 3.7, 95% CI 1.50 to 9.40; p=0.005).

Conclusions: Higher plasma FGF23 levels were independently associated with increased PAP and a greater risk for PAH in patients with advanced CKD during study period. These findings suggest a novel relationship between FGF23 and PAP that warrant further investigation.

SA-PO136

cFGF23 Levels in Patients with Iron Deficiency Anemia and Chronic Kidney Disease at High Risk of Cardiovascular Events
Myles S. Wolf,[1] David B. Bregman,[2] Angelia Butcher,[2] Todd Koch,[2] Andy He,[2] David D. Morris.[3] *[1]University of Miami, FL; [2]Luitpold Pharmaceuticals, PA; [3]WebbWrites, LLC, NC.*

Background: Fibroblast growth factor 23 (FGF23) is a hormone that regulates phosphate homeostasis. Elevated levels of C-terminal FGF23 (cFGF23) have been associated with greater risk of cardiovascular disease (CVD) events and mortality in patients with chronic kidney disease (CKD). Recent data suggest that iron deficiency (ID) is associated with elevated cFGF23 levels but there are limited data on the effect of iron replacement therapy on cFGF23 levels in ID patients with CKD.

Methods: We measured cFGF23 levels (Immutopics, San Clemente, CA) in a subset of 799 of 2561 subjects in a randomized trial (REPAIR-IDA) that compared the effects on hemoglobin (Hb) and iron indices of intravenous (IV) ferric carboxymaltose (Injectafer; 2 x 750 mg on Days 0 and 7) versus IV iron sucrose (Venofer; 5 x 200 mg on Days 0-14) in ID anemic CKD patients (hemoglobin [Hb] ≤ 11.5 g/dL) at high CVD risk due to low glomerular filtration rate (GFR) or other Framingham risk factors. Subjects underwent 120 days of follow-up for CVD events. cFGF23 levels were measured at baseline in all 799 subjects, and repeated on Days 7, 14, 28, and 56 in 37 of the 799 subjects (15 Injectafer; 22 Venofer).

Results: Baseline characteristics of the cFGF23 subset were similar to those of the overall study population. The mean baseline GFR was 32 mL/min/1.73 m^2, mean Hb was 10.4 g/dL and mean ferritin was 73.5 ng/mL. Mean baseline cFGF23 levels were 2-fold higher among subjects who developed a composite endpoint of death, myocardial infarction, stroke, unstable angina, congestive heart failure, or arrhythmia compared to those who did not (993 ± 1381, n=28 vs. 443 ± 671, n=771 Relative units [RU]/mL; P = 0.0001). In the 37 participants with repeated measurements, cFGF23 decreased from baseline to Day 56 (364 to 181 RU/mL; P = 0.0008).

Conclusions: These data confirm that elevated cFGF23 levels are associated with increased risk of adverse CVD events, and demonstrate for the first time that treatment of ID anemia using IV iron may be a novel approach to reduce markedly elevated cFGF23 levels in patients with CKD.

Urinary Phosphate Excretion and Left Ventricular Hypertrophy in Stage 4 and 5 CKD
Muhammad Salman Siddiqui, Jennifer C. Rodrigues, Sameena Z. Iqbal, Paul E. Barre, Istvan Mucsi, Ahsan Alam. *Division of Nephrology, McGill University Health Centre, Montreal, Canada.*

Background: Left ventricular myocardial hypertrophy (LVH) is an important complication in advanced CKD. Fibroblast growth factor-23 (FGF-23) has been shown to induce cardiac hypertrophy, and also regulates renal phosphate excretion. We hypothesized that phosphaturia may be used as a surrogate for the phosphaturic effect of FGF-23, and examined its association with LVH in a cohort of patients with stage 4-5 CKD.

Methods: Single-centre, cross-sectional study of consecutive patients with stage 4-5 CKD referred for pre-dialysis assessment. Twenty four hour urine phosphate excretion, corrected for creatinine excretion, (PO4:Cr) was tabulated. Left ventricular diastolic mass index (LVMI) was assessed by 2D echocardiography. Moderate or severe LVH was determined using gender-based LVMI cut-offs according to American Society of Echocardiography criteria. The association of phosphaturia with LVMI or LVH was examined using linear and logistic regression analyses, respectively.

Results: 129 patients (mean age 65 ± 16 years; 57% male; 50% diabetic; 68% hypertensive; median eGFR 18 ± 9 ml/min/1.73 m2) had both a 24-hour urine collection and an echocardiogram, and were included in the final analysis. The mean hemoglobin was 113 ± 18 g/L with 27% on ESA therapy. Moderate or severe LVH was detected in 23% of patients. There was no association detected between PO4:Cr and either LVMI or LVH in our main effects model; however a significant interaction was found with gender for both LVMI (p=0.01) and LVH (p=0.03). After adjusting for other determinants of LVMI in univariate analysis (underlying heart disease, serum albumin, hemoglobin, ESA and diuretic use, and log-transformed CRP), males had a positive association for PO4:Cr with LVMI, while females showed an inverse relationship.

Conclusions: In patients with stage 4-5 CKD, urinary phosphate excretion was significantly associated with LVMI and LVH after accounting for the interaction of gender. Whether urinary phosphate excretion indeed correlates with FGF-23 levels remains to be determined. Gender may be an important effect modifier for the development of LVH in patients with CKD.

SA-PO138

Can Parathyroidectomy Reverse Decreased Heart Rate Variability in End Stage Renal Disease Patients?
Jing Zhang,[1] Chang Ying Xing,[1] Xiaoming Zha,[2] Kejiang Cao,[3] Ningning Wang.[1] *[1]Department of Nephrology, First Affiliated Hospital with Nanjing Medical University, Nanjing, Jiangsu, China; [2]Department of General Surgery, ; [3]Department of Cardiology, .*

Background: Reduction of heart rate variability (HRV) in end stage renal disease (ESRD) patients implies high risk of cardiovascular disease (CVD). Secondary hyperparathyroidism (SHPT) is positively correlated with incidence of CVD. However, the relationship between mineral metabolism and HRV is obscure. It is also unclear whether the impaired HRV can be reversed by parathyroidectomy (PTX) in severe SHPT.

Methods: Eighty ESRD patients were received 24-hour Holter analysis to evaluate HRV.

Baseline characteristics of the subjects (N=80)

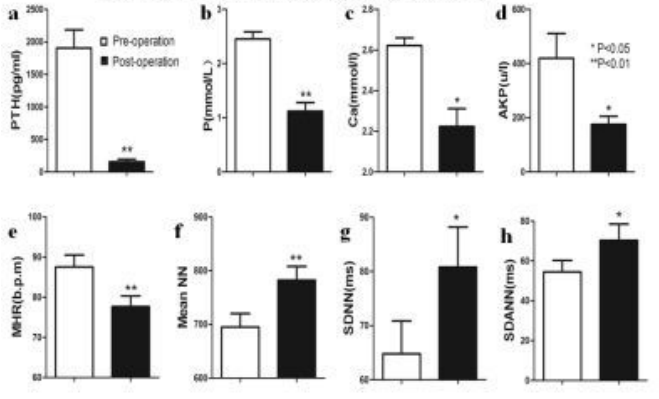
Variables	Value
Age(yr)	52.0±13.6
Male/female	40/40
Duration of dialysis(m)	36.0(96.0-9.0)
Hemoglobin(g/l)	95.2±22.8
Glucose(mmol/l)	5.1±2.0
Albumin(g/l)	37.2±5.6
Ca(mmol/l)	2.3±0.3
P(mmol/l)	2.0±0.6
ALP(u/l)	103.6(176.8-80.2)
PTH(Pg/ml)	442.3(1183.3-193.2)

Mean values ± SD, or median (IQR), as appropriate. PTH=Parathyroid hormone, ALP= Alkline phosphatase.

Eleven calcitriol resistant SHPT patients were followed for median of 4.5 months after total PTX with forearm autotransplantation.

Results: Serum PTH level was correlated with SDNN (standard deviation of normal RR intervals) and SDANN (standard deviation of the averages of 5-min normal RR intervals over 24h) (r=-0.293 and r=-0.305, P<0.01); Serum ALP was correlated with Mean 24h HR (Heart rate) (r=0.227, P<0.05) and SDNN (r=-0.237, P<0.05); Serum P was correlated with pNN50 (proportion of adjacent RR intervals with a difference by >50ms over 24h) (r=0.277, P<0.05). Improvement of HRV was noted in severe SHPT patients after PTX.

Figure 1. Comparison of mineral metabolism and HRV indices in severe SHPT patients before and after PTX



Conclusions: Disorders of mineral metabolism are important risk factors for sympathetic hyperactivity in ESRD. Successful PTX may reverse this CVD risk, as assessed by HRV in severe SHPT patients.

SA-PO139

Evaluation of Some Gene Polymorphisms Coding Selected Cytokines and Urinary Excretion of This Cytokines as Independent Risk Factors for the Progression of Primary Chronic Glomerulonephritis

Ilona Idasiak-piechocka,[1] Elzbieta Pawliczak,[1] Andrzej P. Oko.[1] *[1]Nephrology, Transplantology and Internal Diseases Department, Poznan University of Medical Sciences, Poznan, Poland.*

Background: The aim of the study was to estimate whether: 1/ carrying the genotype of the IL-6 gene G(-174)C, TGFβ1 gene C (-509)T, MCP-1 gene A(-2518)G, and TNFa gene G(-308)A polymorphism is associated with urinary excretion of some cytokines in patients with new recognized primary glomerulonephritis (GN); and 2/whether carrying some genotype or urinary IL-6, TGFβ1, MCP-1, TNFR1 and EGF excretion at baseline predict the progression of GN in prospective observation.

Methods: 150 Caucasian patients were included in the study. The identification of the SNP was carried out using PCR-RFLP with specific starters. Urinary cytokines excretions were measured using the ELISA methods. After 4-year follow-up, patients were divided into two groups: with loss of eGFR ≥ 5ml/min/y –PG and with loss of eGFR<5ml/min/y – NPG. The influence of traditional risk factors (TRF) and urinary excretions of cytokines (UEC) on eGFR and ΔeGFR calculated as the difference between eGFR measured at the end of follow-up and basal eGFR in multiple linear regression analysis were evaluated.

Results: No association between cytokine gene polymorphism and urinary excretions of correspondence cytokines were found. No differences in genotype distribution between PG and NPG patients were observed. UEC were significantly higher but U EGF excretion was significantly lower in PG when compared with the NPG. The comparison of the influence of UEC and TRF on eGFR showed that age (p< 0,0001), UPE (p<0,0001), UTNFR1 (p<0,003) and UEGF(p<0,003) were most significant factors. The most significant association of ΔeGFR were found with the initial measured: UPE, UEGF and UMCP-1.

Conclusions: The determination of UTNFR1, UEGF and UMCP-1 independent on genetic factors may serve as prognostic markers of deterioration of renal function in patients with primary GN.

SA-PO140

Prevalence of Bone Diseases and/or Soft Tissue Calcifications and Its Correlation with Se-iPTH Level in Dialyzed Patients

Zoltan Kiss, Csaba Ambrus, Andras Szabo, Dr.szegedi János, Jozsef Balla, Marietta Török, Botond Csiky, Erzsebet Ladanyi, Otto Arkossy, Sándor Túri, Imre Kulcsar, Istvan Kiss. *CKD-MBD Working Group, Hungarian Society of Nephrology, Budapest, Hungary.*

Background: One of the most life threatening consequences of CKD-MBD are bone disease (BD) and soft tissue calcification (STC) including vascular calcification. These diseases have several common pathomechanisms. Therefore, our aim was to examine the characteristics of these co-morbidities in dialyzed patients (CKD-5D).

Methods: It was a country wide observational, multicentre, retrospective, cross-sectional study among CKD-5D patients. From the enrolled 5008 patients we excluded pts with incomplete data and parathyroidectomy. We analyzed 4904 patient's data statistically. Bone disease (BD) was defined any fracture or any bone pathology detecting any imaging technique. All calcification in the body was defined as soft tissue calcification (STC). We allocated the pts into groups based on existence of their BD and/or STC (group I) and neither BD nor STC (group II).

Results: There was 2883 pts in group I (58,79 %), including the biggest population who has BD and STC concurrently. Between the I and II groups significant difference were in age (65,5±13,0 vs. 61,0±15,1), in se-Ca level (2,26±0,18 vs. 2,24±0,19), dialysis modality and prevalence of DM (35,9% vs. 29,5%). We revealed an "U" shaped significant association between se-iPTH level and number of pts in group I. The lowest prevalence (55,3 % and 55,1 %) occurred in groups with iPTH 151-300 and 301-500 pg/ml. The prevalence of group I increased significantly with increasing age. Significant and independent factors of co-morbidities are: age, DM, dialysis modality, se-PTH.

Conclusions: Among CKD-5D pts BD and/or STC occurred in more than a half of the pts. There is an "U" shape association between se-iPTH and co-morbidities (BD / STC). Depending on se-iPTH level the lowest prevalence of BD / STC are in the PTH target range recommended by the KDIGO guideline.

SA-PO141

Possible Contribution of Anemia to Brain Atrophy in Predialysis Patients with Chronic Kidney Disease (CKD)

Kazuhiko Tsuruya,[1] Hisako Yoshida,[1] Takanari Kitazono.[2] *[1]Department of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; [2]Department of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan.*

Background: Brain atrophy has been reported to be correlated with kidney dysfunction (Yakushiji Y, et al. Hypertens Res, 2010); however, its mechanism remains to be elucidated. In dialysis patients, brain atrophy was demonstrated to be associated with anemia and longer dialysis vintage (Kamata T, et al. Am J Nephrol, 2000). These findings suggest that anemia might be a major factor contributing to brain atrophy in CKD patients. Thus, in the present study, we investigated the association of hemoglobin (Hb) level and brain volume (BV) determined by magnetic resonance imaging (MRI) in predialysis CKD patients.

Methods: Eighty-five predialysis CKD patients (46 men, 39 women) aged 37–79 (63±10) years without history of cerebrovascular disease were recruited and underwent MRI scanning for this study. T1-weighted MRI images were analyzed with statistical parametric mapping software. Total gray matter (GM), total white matter (WM), and cerebrospinal fluid were segmented and each volume was quantified using MRI voxel-based morphometry. BV was normalized as a percentage of intracranial volume to adjust for variations in head size. The dependent variable was normalized BV (%GM and %WM), and the independent variables were Hb and other clinical parameters. Patients are divided into quartiles according to Hb level. Linear regression analysis was used to examine the association of Hb level with %GM and %WM.

Results: Hb level is positively associated with %GM, but not %WM. The association between Hb level and %GM remained significant even after adjustment of age, gender, eGFR, underlying kidney disease, history of smoking, diastolic blood pressure, and LDL-cholesterol. Jonckheere-Terpstra trend test showed a significant dose-response relationship (P for trend = 0.009) which remained significant in the multivariate analysis.

Conclusions: The present study demonstrates the association of Hb level with BV, suggesting that anemia might contribute to brain atrophy independent of aging in CKD patients.

SA-PO142

Relationship of Aortic Pulse Wave Velocity to Cognitive Function in Chronic Kidney Disease: The Chronic Renal Insufficency Cohort Study

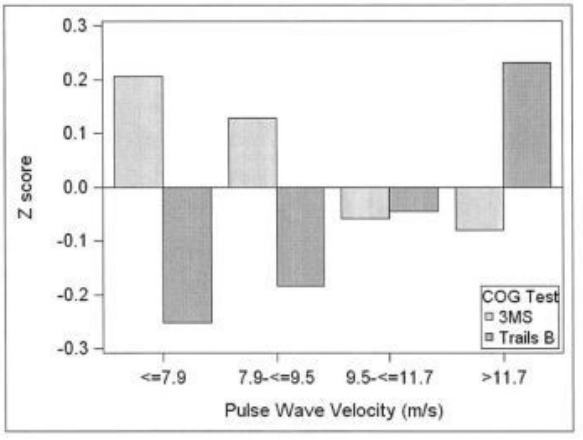
Raymond R. Townsend,[1] Mitchell Kling,[2] Stephen L. Seliger,[4] Steven Arnold,[2] Kristine Yaffe.[3] *[1]Medicine, University of Pennsylvania, Philadelphia, PA; [2]Neurology, University of Pennsylvania, Philadelphia, PA; [3]Neurology, University of California, San Francisco, CA; [4]Medicine, University of Maryland, Baltimore, MD.*

Background: Cognitive function is impaired in older patients with CKD and aortic stiffness may be involved. We evaluated the relationship of aortic (carotid-to-femoral) Pulse Wave Velocity (PWV) in 697 participants aged 55 years or more in the Chronic Renal Insufficiency Cohort (CRIC) at year 2 visit.

Methods: Participants were 66(+/-6) years old, half male, most white (50%) or AA (47%) with 3% Hispanic. Estimated GFR of 42(+/-14) mL/min. Cognitive function included Trails A/B, Modified-MMSE (3MS), BUSHKE A, Boston Naming, Verbal

Fluency and Recall. Carotid-femoral PWV was performed by tonometry of the carotid/femoral arteriesand divided into quartiles. Z-scores were used for each cognitive function test, analyzed by PWV quartile.

Results: Global cognition (3MS) decreased with increasing quartiles of PWV ($p = 0.013$). Increasing PWV showed decreased performance on Trails A ($p = 0.008$), Trails B ($p < 0.001$), verbal (category) fluency ($p < 0.001$), and the delayed recall component of the Buschke ($p < 0.015$). Immediate recall of the Buschke and Boston Naming Test did not differ by quartiles of PWV ($p > 0.2$). The graph shows results representative of frontal lobe function (Trails B, negative = better cognition) and global cognitive function (3MS, positive = better cognition).



Conclusions: PWV was associated with decreased performance on tasks of attention (Trails A), cognitive flexibility (Trails B), and verbal fluency, and deficits in memory and global cognition (3MS). These suggest PWV is associated with an impairment of frontal-executive functions in CKD.

Percutaneous Coronary Intervention for Acute Myocardial Infarction in the Elderly Patients with Renal Dysfunction: Results from the Korea Acute Myocardial Infarction Registry Eun Hui Bae, Chang Seong Kim, Soo Wan Kim. *Internal Medicine, Chonnam National University Hospital, Gwanju, Korea.*

Background: The question as to whether percutaneous coronary intervention (PCI) benefits for acute myocardial infarction (AMI) in elderly aged ≥ 75 years patients with renal dysfunction, is unresolved.

Methods: As part of the Korea Acute Myocardial Infarction Registry (KAMIR), 1,458 AMI patients with renal dysfunction (glomerular filtration rate [GFR] < 60 mL/min) received either medical (n = 439) or PCI (n = 1,019) therapy. Major adverse cardiac events (MACE) at 1-month and 1-year were compared between these 2 groups.

Results: On comparison with the medical therapy group, the PCI group showed a significantly lower incidence of in-hospital mortality. Moreover, the short term and long term MACE rate was significantly higher for the medical therapy group than for the PCI group (36.8% vs. 20.7%; 55.5% vs. 33.0%, $p < 0.05$), and this difference was mainly attributed to cardiac death (30.8% vs. 17.4%; 43.8% vs. 22.7%, $p < 0.05$). The MACE-free survival time after adjustment was also higher in PCI group in short term (hazard ratio (95% confidence interval) 0.67 (0.45-0.98) p=0.037) and long term (hazard ratio (95% confidence interval) 0.61 (0.45-0.83) p=0.002) follow up.

Conclusions: In elderly aged ≥ 75 AMI patients with renal dysfunction, PCI therapy has a favorable in-hospital and short-term and long-term MACE -free survival.

SA-PO144

Association of Cancer with Moderately Impaired Renal Function at Baseline in a Large, Representative, Population-Based Cohort Followed for up to 30 Years Anders G. Christensson. *Nephrology and Transplantation, Clinical Sciences, Malmö, Malmö, Sweden.*

Background: Epidemiologic studies have found that the prevalence of chronic kidney disease (CKD) in the United States is over 10%. higher incidence of malignancies in patients with chronic renal failure has been reported. There are also reports implicating increased risk of cancer in patients with earlier stages of CKD. We evaluated whether moderately impaired renal function at baseline influenced risk of cancer or cardiovascular disease during long-term follow.

Methods: The cohort included 33,346 subjects, aged 26-61 years at baseline, in a representative, population-based study enrolling subjects from 1974 to 1992. Median follow-up time was 28 years. Incident cases of cancer were identified from the Swedish Cancer Registry. To account for the unique sampling design, participants were divided by sex and age at baseline into 1,132 older men (age 60), 14,254 younger men (age 40–52), 7,498 older women (age 47–57) and 1,688 younger women (age 35–43). Glomerular filtration rate (GFR) was estimated using the CKD-EPI formula. Patients were classified as having either normal to mildly impaired kidney function (eGFR≥60 mL/min/1.73m^2), or moderate kidney dysfunction (eGFR<60 mL/min/1.73m^2). We calculated the risk of cancer using competing risks regression.

Results: Overall, 6,595 participants were diagnosed with cancer, and 854subjects (3.5%) had moderately impaired renal dysfunction at baseline. There was a nominal significant association between moderately decreased GFR at baseline and cardiovascular events in younger men and older women but no association with long-term cancer risk. The previously described association between low baseline GFR and subsequent risk of kidney cancer was confirmed in younger men (hazard ratio, 3.38; 95% CI, 1.48 to 7.71; *P*=0.004).

Conclusions: In conclusion, few studies, including ours, show an increased risk of kidney cancer among younger men with eGFR less than 60 mL/min/1.73m^2. These findings should be explored further to discover possible pathological mechanisms of carcinogenesis and identify more specific high-risk groups. Surveillance for kidney cancer may be appropriate for high-risk groups.

SA-PO145

High Prevalence of Sticky Platelet Syndrome in Patients with Chronic Kidney Disease Anja Susanne Muhlfeld,[1] Eray Yagmur,[2] Dario Frank,[3] Jürgen Floege.[1] *[1]Division of Nephrology and Immunology, RWTH Aachen University, Aachen, Germany; [2]Medizinisches Versorgungszentrum Stein und Kollegen, Mönchengladbach, Germany; [3]Department of Internal Medicine, Sankt Antonius Hospital Eschweiler, Eschweiler, Germany.*

Background: Sticky platelet syndrome (SPS) is a platelet disorder associated with arterial and venous thromboembolic events. It is defined as maximal aggregation of platelets in response to the inducers ADP and/or epinephrine despite decreasing doses. Patients with chronic kidney disease (CKD) have a high risk for thromboembolic complications. The prevalence of this syndrome in the normal population versus CKD patients has not been described to date.

Methods: Citrate blood samples were assessed for platelet aggregation using light transmission aggregometry in healthy volunteers and CKD patients. ADP and epinephrine in 4 different concentrations were used as stimuli for platelet aggregation. SPS type I was defined as platelet hyperaggregability in response to epinephrine and ADP. Hyperaggregability with only epinephrine indicated sticky platelet syndrome type II.

Results: Platelet aggregation was assessed in 34 healthy volunteers. Of these only one had increased platelet aggregation defined as SPS type II. In a population of 30 patients on hemodialysis 67% were positive for SPS type II with similar results before and after hemodialysis excluding mechanical platelet alteration. The effect of partial restoration of renal function in such patients was assessed in 34 renal transplant patients. 82 percent of these patients were positive for SPS II independent of their CKD stage. The dosage and type of immunosuppressive medication did not influence platelet aggregation. There was a trend towards more thromboembolic events in patients with SPS.

Conclusions: CKD patients exhibit a hitherto unappreciated high prevalence of platelet hyperaggregability. This may contribute to the high rate of vascular complications in patients with CKD.

SA-PO146

Hospitalization and Mortality in Elderly Iron Deficient, Anemic Patients with CKD and Heart Failure Receiving Intravenous Iron Therapy: A Five Year Follow-Up from a Pilot Study Jorge E. Toblli, Federico Di Gennaro. *Nephrology, Hospital Aleman, Buenos Aires, Argentina.*

Background: In a previous pilot, double-blind, placebo-controlled study (JACC 2007; 50:1657-65), intravenous (i.v) iron without erythropoeisis stimulating agents (ESA) substantially preserved LVEF(%), exercise capacity, NT-pro-BNP, CRP, renal function, and quality of life in iron deficient, anemic patients with CKD and heart failure (HF). The present study evaluates hospitalization and mortality in the same group of patients after a follow-up of 1 and 5 years.

Methods: 40 patients with CKD and HF (mean age >74years) from the original pilot study were evaluated after a follow-up of 1 and 5 years. Inclusion criteria: hemoglobin (Hb g/dl) <12.5 for men and <11.5 for women; TSAT<20%; ferritin<100ng/ml; CrCl <90ml/min and left LVEF% <35%. Group-A: isotonic saline solution (ISS); Group-B: Iron Sucrose Complex (ISC). Patients received a weekly infusion of ISS or 200mg ISC during 5 weeks. Patients did not receive ESA before or during the study.

Results:

Mean ± SD	Group-A # Baseline	Group-B # Baseline	Group-A 1 year	Group-B 1 year	Group-A 5 years	Group-B 5 years
Hb (gr/dl)	10.2 ± 0.5	10.3 ± 0.6	9.6 ± 0.6 *	11.4 ± 0.5	9.3 ± 0.5 *	11.0 ± 0.4
Ferritin (ng/ml)	70.6±21.4	73.0±29.9	83.9±16.3 *	220.6 ± 36.3	172.6 ± 58.0	166.5 ± 30.8
TSAT (%)	20.0±1.0	20.0±1.0	19.9±1.3*	23.2±1.8	19.3±1.5*	21.1±1.4
CrCl (ml/min)	37.7±10.2	39.8±10.1	27.0±10.2*	39.6±10.9	23.7±4.0*	34.6±7.5
LVEF (%)	30.8±1.7	31.3±3.7	28.5±1.8*	34.9±3.6	23.9±2.1*	34.4±2.4
NYHA	2.9±0.6	2.9±0.7	3.3±0.5*	2.3±0.6	3.6±0.5**	2.8±0.8
Hospitalization (%)	--	--	10 (50)*	2 (10	17 (85)*	4 (20)
Mortality (%)	--	--	4 (20)	1 (5)	11 (55)**	4 (20)

*p<0.01 vs. group-B. **p<0.05 vs. group-B. # Results of the pilot study.

Conclusions: Despite the small number of patients, the present data suggest that i.v. iron therapy without ESA may reduce hospitalization and mortality in iron deficiency, anemic CKD patients with HF.

SA-PO147

Combination Treatment of Primary Chronic Glomerulonephritis Using General Acteoside of Rehmanniae Leaves and Angiotensin Receptor Blocker: A Randomized Controlled Trial Ping Fu, Hongyu Qiu. *Nephrology Department, West China Hospital of Sichuan University, Chengdu, Sichuan, China.*

Background: This study aims to assess the efficacy and safety of general acteoside in Rehmanniae leavesused in combinationwith the angiotensin receptor blocker irbesartan to treat primary chronic glomerulonephritis.

Methods: This was a prospective, randomized, controlled study. A total of 479 patients diagnosed with primary chronic glomerulonephritis were recruited from outpatient clinics. Participants were randomly assigned to the treatment group (general acteoside of Rehmanniae leaves, two 200-mg tablets, bid; and irbesartan, one 150-mg tablet, qd) or the control group (irbesartan, one 150-mg tablet, qd). The primary outcome was 24-h urinary protein. Secondary outcome measures included blood pressure (BP), evaluated glomerular filtration rate (eGFR), erythrocyturia, serumalanine aminotransferase (ALT), aspartate transaminase (AST) and electrolytes. All outcome measures were assessed at baseline, 4 weeks, and 8 weeks over the 8-week study period, except BP, serum ALT, AST and electrolytes, which were assessed at baseline and 8 weeks.

Results: After 8 weeks of treatment, the treatment group showed a mean reduction in 24-h proteinuria of 36.42% compared to baseline, which was significantly higher than the mean reduction from baseline of 27.97% in the control group (P=0.0278). Neither group showed obvious changes between baseline and 8 weeks in eGFR, erythrocyturia, BP or electrolytes.In addition, adverse drug reactions occurred at a similar low rate in the treatment group (0.4%) and control group (1.2%, P = 0.3724).

Conclusions: In the treatment of chronic glomerulonephritis, the combination of general acteoside of Rehmanniae leaves and irbesartan can reduce proteinuria more effectively than irbesartan alone, and it can improve renal function and clinical symptoms to a similar extent as irbesartan by itself. In addition, general acteoside of Rehmanniae leaves is well tolerated.

SA-PO148

Serum Soluble Secreted α-Klotho Levels Decrease during Intensification of Antiproteinuric Therapy in Non-Diabetic Chronic Kidney Disease Patients Charlotte A. Keyzer,[1] Marc G. Vervloet,[2] Pieter M. Ter Wee,[2] Jan-luuk Hillebrands,[3] Gerjan Navis,[1] Martin H. De Borst.[1] *[1]Nephrology, University Medical Center Groningen; [2]Nephrology, Free University Medical Center Amsterdam; [3]Pathology, University Medical Center Groningen, on Behalf of NiGrAm, Netherlands.*

Background: Reduction of blood pressure (BP) and proteinuria (UP) by RAAS-blockade is the cornerstone of chronic kidney disease (CKD) management. Dual RAAS-blockade and dietary sodium restriction enhance the short-term effects on BP and UP. Preclinical data suggest that loss of renal and circulating Klotho plays a role in progressive CKD and its cardiovascular complications. We evaluated the effect of different RAAS-blockade-based treatments on soluble α-Klotho in the clinical setting.

Methods: A post-hoc analysis was performed on an RCT in 52 non-diabetic CKD patients (age 51±13 yrs) receiving lisinopril 40 mg/day (ACEi) and either valsartan 320 mg/day (ARB) or placebo, combined with either low sodium (LS; 106 mmol Na^+/d) or regular sodium (RS; 184 mmol Na^+/d) diet. Soluble secreted α-Klotho was measured in serum by ELISA (IBL). Paired t-tests were used to determine the effects of treatment on α-Klotho. Data are presented as mean±SD or median [interquartile range] where appropriate.

Results: At baseline (during ACEi+RS) UP was 1.9 [0.9-3.4] g/d and creatinine clearance (CrCl) was 69 [50-110] mL/min. During intensification of therapy, UP decreased to 0.7 [0.4-1.4] g/d and CrCl to 59 [42-81] mL/min during ACEi+ARB+LS (both p<0.001). Serum α-Klotho at baseline was 636±133 pg/mL, was reduced during ACEi+ARB+RS (625±141 pg/mL, p=NS), was reduced further during ACEi+LS (597±112 pg/mL, p<0.001 vs baseline) and was lowest during ACEi+ARB+LS (586±108 pg/mL, p<0.001 vs baseline). The decrease in α-Klotho correlated with the decrease in CrCl (β=0.321, p<0.05), but not with the decrease in UP.

Conclusions: Intensification of antiproteinuric therapy is associated with reduced serum α-Klotho levels in CKD patients. Considering the alleged protective effects of Klotho, this adjunct effect could potentially limit the therapeutic benefits of intensive treatment regimens in CKD, and warrants further investigation.

Funding: Government Support - Non-U.S.

SA-PO149

L/N-Type Calcium Channel Blocker, Cilnidipine, Ameliorates Albuminuria and Uric Acid Production in CKD Patients (J-CIRCLE Study) Shunya Uchida,[1] Hideki Kato,[1] Masayuki Tanemoto,[1] Takafumi Ito.[2] *[1]Internal Medicine, Teikyo University School of Medicine, Tokyo, Japan; [2]Nephrology, Shimane University School of Medicine, Izumo, Japan.*

Background: Cilnidipine, an L/N-type calcium channel blocker (CCB), shows a renoprotective effect as well as a blood pressure-lowering effect. We examined effects of cilnidipine on blood pressure, urine albumin excretion, and uric acid metabolism after switching from an L-type CCB amlodipine.

Methods: We enrolled 71 hypertensive patients with albuminuria > 30 mg/g creatinine who had been receiving amlodipine for three months or longer. Methods: Blood pressure, urinary albumin-creatinine ratio (ACR), serum uric acid (UA), urinary uric acid creatinine ratio (UA/Cr), and fractional excretion of UA (FEUA) were measured before and three months after cilnidipine treatment.

Results: Three months of cilnidipine treatment significantly reduced urinary ACR (p=0.032) whereas blood pressure were unchanged. On the other hand, neither serum UA, urinary UA/Cr ratio, nor FEUA significantly changed in all patients. In the patients whose urinary UA/Cr ratio exhibited 0.5 or greater, urinary UA/Cr ratio and FEUA significant decreased respectively (p=0.038 and p=0.013).

Conclusions: Urinary albumin excretion was significantly reduced by cilnidipine treatment as compared with amlodipine. A novel finding is that urinary uric acid excretion was dramatically reduced in response to cilnidipine. These findings are probably due to amelioration of sympathetic hyperactivity through inhibition of N-type calcium channel by cilnidipine.

SA-PO150

Increased Urinary Albumin Level within the Normal Range Has an Impact on Adverse Outcomes in HIV-Infected Individuals Naoki Yanagisawa,[1,2] Minoru Ando,[1,2] Atsushi Ajisawa,[1] Ken Tsuchiya,[2] Kosaku Nitta.[2] *[1]Department of Infectious Diseases and Nephrology, Tokyo Metropolitan Komagome Hospital, Tokyo, Japan; [2]Department IV of Internal Medicine, Tokyo Women's Medical University, Tokyo, Japan.*

Background: Microalbuminuria poses a risk of developing adverse outcomes; however, clinical significance of albumin excretion within the normal range has not been considered in an HIV-infected population.

Methods: A 3.5-year prospective cohort study was undertaken to test an association of low-grade albumin excretion and incidence of composite outcomes, including all-cause mortality, cardiovascular disease (CVD), and a decrease in renal function. A total of 515 subjects with urinary albumin-to-creatinine ratio (ACR) <30mg/g were enrolled. Albumin excretion within the normal range was arbitrarily classified into 3 grades according to ACR: 0-9, 10-19 and 20-29mg/g. The cumulative incidence of outcomes was depicted by the Kaplan-Meier curves, stratified by the 3 normal ACR grades. Univariate Cox proportional hazards regression analysis was used to determine clinical variables associated with developing such outcomes, adjusted for known risk factors.

Results: The frequencies of ACR of 0-9, 10-19 and 20-29mg/g were 59, 31, and 10%, respectively. Of 515, 41 (8.0%) developed at least one of the outcomes. A decrease in renal function, all-cause mortality and CVD occurred in 29(71%), 7(17%) and 5(12%) subjects, respectively. The Kaplan-Meier estimate of ACR 20-29 mg/g was significantly higher than that of ACR 0-9 mg/g (P=0.03), but that of ACR 10-19 mg/g was not (P=0.26). The Cox analysis showed that ACR 20-29mg/g, as well as presence of diabetes mellitus and CD4 cell count, was associated with developing adverse outcomes.

Variates	HR (95% CI)	P value
ACR 20-29 mg/g	2.44 (1.01-5.39)	0.0484*
ACR 10-19 mg/g	1.48 (0.73-2.94)	0.2711
ACR 0-9 mg/g (reference)	1	-
Age, per year	1.02 (0.99-1.05)	0.1331
Hypertension (+)	0.85 (0.29-1.98)	0.7314
Diabetes mellitus (+)	4.70 (1.41-11.7)	0.0158*
Log CD4 cell count, μL	0.16 (0.09-0.32)	<.0001*
Log HIV-RNA level, copies/mL	1.23 (0.94-1.56)	0.1199

Conclusions: The high level within the normal range of albuminuria likely carries the risk for the development of adverse outcomes in HIV-infected individuals.

SA-PO151

Plasma Proprotein Convertase Sutilisin-Kexin Type 9 Is Elevated in Proteinuric Subjects: Relationship with Lipoproteins Response to Antiproteinuric Treatment Arjan J. Kwakernaak,[1] Gilles Lambert,[2] Maartje C.J. Slagman,[1] Femke Waanders,[1] Francine Petrides,[2] Bert D. Dikkeschei,[3] Gerjan Navis,[1] Robin P.F. Dullaart.[4] *[1]Dept. of Nephrology, University Medical Center Groningen, Groningen, Netherlands; [2]The Heart Research Institute, Sydney, Australia; [3]Dept. of Clinical Chemistry, Isala Clinics, Zwolle, Netherlands; [4]Dept. of Endocrinology, University Medical Center Groningen, Groningen, Netherlands.*

Background: The proprotein convertase subtilisin–kexin type 9 (PCSK9) pathway plays a key role in lipoprotein metabolism by promoting LDL receptor degradation. Its contribution to atherogenic lipoprotein abnormalities in proteinuric states is unknown. We studied whether plasma PCSK9 is elevated in proteinuria, and determined the relationships of PCSK9 with lipoproteins and their responses to proteinuria reduction.

Methods: Thirty-nine CKD patients (eGFR 61±29 ml/min/1.73m^2, proteinuria 1.9 [0.9-3.3] g/day; 19 on statin treatment) were studied during 2 randomized double-blind 6-week periods on either lisinopril (40 mg/day) and a regular sodium diet (194±49 mmol Na^+/day; baseline treatment) or lisinopril and valsartan (320 mg/day) and a low sodium diet (102±52 mmol Na^+/day; maximal treatment), and compared to age- and gender-matched controls. Maximal treatment decreased proteinuria to 0.5 [0.3-1.1] g/day (P<0.001).

Results: Plasma PCSK9 was increased at baseline in proteinuric subjects (213 [161-314] vs. 143 [113-190] μg/L in controls, P≤0.001), irrespective of statin use, eGFR and BMI. PCSK9 correlated with proteinuria at baseline (R=0.449) and at maximal proteinuria reduction (R=0.434, both P=0.007). PCSK9 did not decrease during proteinuria reduction (P=0.841). However, individual changes in total cholesterol, non-HDL cholesterol, LDL cholesterol and apolipoprotein B (all P≤0.01) related significantly to individual PCSK9 responses. PCSK9 at baseline independently predicted total/HDL cholesterol ratio response to treatment (P=0.041).

Conclusions: Plasma PCSK9 levels are elevated in proteinuria, predict lipoprotein responses to proteinuria reduction but remain unaffected by reduction of proteinuria. Inhibition of the PCSK9 pathway may provide a novel treatment strategy in proteinuric subjects.

SA-PO152

Accelerated Thrombopoiesis in CRF Rat Megakaryocytes due to Compensatory Thrombopoietin Production from the Liver and Bone Marrow Itsuro Kazama. *Physiology I, Tohoku University Graduate School of Medicine, Sendai, Miyagai, Japan.*

Background: Decreased thrombopoiesis has been ascribed a role in the pathogenesis of uremic bleeding in chronic renal failure (CRF). However, serum thrombopoietin (TPO) levels are usually elevated in CRF patients, suggesting increased thrombopoiesis. The aim of this study was to determine the thrombopoietic activity in CRF.

Methods: Male Sprague-Dawley rats that underwent 5/6 nephrectomy were used as the model of CRF. Age-matched sham-operated rats were used as controls. Single megakaryocytes were isolated from the rat bone marrow, and their size distribution was examined. Megakaryocyte membrane invaginations were monitored by confocal imaging of di-8-ANEPPS staining, and patch-clamp whole-cell recordings of membrane capacitance. TPO gene expression was assessed in various tissues.

Results: Circulating platelet counts and the number of large megakaryocytes in the bone marrow were significantly increased in CRF rats. Massive di-8-ANEPPS staining and increased membrane capacitance per cell surface area in large megakaryocytes (12.16±0.91 vs. 9.19±0.22 uF/cm2 in intermediate megakaryocytes, P<0.05) demonstrated increased membrane invaginations. Unaffected Kv1.3-channel currents per cell surface area (0.92±0.08 in large vs. 0.98±0.06 mA/cm2 in intermediate megakaryocytes, P<0.05) demonstrated unaltered channel densities. TPO transcription was decreased in the renal cortex but significantly increased in the liver and bone marrow of CRF rats.

Conclusions: Increased thrombopoiesis in CRF was thought to be a reactive mechanism to platelet dysfunction. Increased TPO production from the liver and bone marrow compensated for the decreased production from damaged kidneys.

Electrolyzed Water with High Dissolved Hydrogen (H_2) Ameliorates Aged Cardiorenal Injury by Improving Anti-Oxidant Effect in Dahl Salt Sensitive Rat Wan-jun Zhu,[1] Masaaki Nakayama,[3] Shigeru Kabayama,[2] Takefumi Mori,[1] Sadayoshi Ito.[1] *[1]Center for Advanced and Integrated Renal Science, Tohoku University, Sendai, Japan; [2]Medical Device, Nihon Trim Co, Ltd., Osaka, Japan; [3]Fukushima Medical University, Fukushima, Japan.*

Background: Electrolyzed water (EW) exhibits high dissolved H2 (DH). We recently reported that EW protects kidney and heart tissue from renal ischemia reperfusion injury. Oxidative stress and inflammation play a crucial role for chronic kidney injury by aging. The present study aims to test the effect of EW drinking on the development of cardio-renal tissue injury by aging.

Methods: Dahl salt sensitive male rats (n=90) were divided into three groups: filter water (FW; DH 0.0mmol/L), de-gas EW (DW; DH 0.0 mmol/L), and EW (DH 0.35 mmol/L) for ad lib drinking (n=30 each). They were fed with 0.5% salt diet during the study. Blood pressure (BP) were measured by tail cuff method every 4weeks. Echocardiography, and tissue samplings of kidney and heart, were performed at 16th, 24th, and 48th week.

Results: There were no differences during the study in body weight, water and food consumption among the groups, but the BP was the lowest in EW (p<0.05). Regarding the test parameters, no differences were found at 16th, 24th week, but the following parameter levels or changes(increase ratio) (vs. 16th week) were significantly less in EW as compared to counterparts at 48th week (p<0.05); (Heart) left ventricle posterior wall thickness: FW 14.4%, DW 12.7%, EW 6.3%; cardiomyocyte size: FW 43.2%, DW 14.0%, EW 0%; heart tissue fibrosis: FW 300.4%, DW 155.2%, EW 25.1%; ED1 staining (number/slice): FW 28.1±1.46, DW 20.5±1.29, EW 12.1±2.41, Kidney: ED1 cells in cortex (number/slice): FW 113.5±13.11, DW 88.2±11.85, EW: 75.3±3.04; MDA staining in cortex (%/field): FW 60.5±1.18, DW 66.2±1.48, EW 57.2±1.20. Nrf2 and SOD2 protein expression in heart tissue: FW 1.02±0.35, DW 1.28±0.46, EW 2.42±0.63, (Nrf2) ; FW 2.90±0.39, DW 2.13±0.56, EW 4.35±0.39, (SOD2).

Conclusions: Ad lib drinking of high H2 water could suppress the development of cardiorenal tissue injury of Dahl Salt sensitive rat by aging, by upregulate anti-oxidant effect.

Altered Arginine Methylation, Oxidative Stress, and Vascular Dysfunction Contribute to Accelerated Atherosclerosis in an Animal Model of Chronic Kidney Disease Lixia Zeng, Anna V. Mathew, Jaeman Byun, Kevin B. Atkins, Frank C. Brosius, Subramaniam Pennathur. *Department of Medicine, Division of Nephrology, University of Michigan, Ann Arbor, MI.*

Background: Atherosclerotic cardiovascular disease is the leading cause of death in chronic kidney disease (CKD) patients. However, the molecular mechanisms underlying this increased risk remain poorly understood.

Methods: We developed a mouse model of CKD-accelerated atherosclerosis and investigated the role of oxidative stress and altered arginine methylation by liquid chromatography / mass spectrometry (LC/MS). Six week old male LDL receptor deficient mice were subjected to sham (CTL) or 5/6 nephrectomy (CKD) surgery. Subsequently, the mice were maintained in low (LFD) or high fat diet (HFD) for 24 weeks.

Results: As anticipated, the CKD mice had significantly higher plasma creatinine, lower hematocrit, decreased body weight and higher mortality. Quantification of lesions revealed that both LFD and HFD CKD mice had significantly elevated aortic plaque area fraction, necrotic core, fibrosis and greater luminal narrowing consistent with accelerated atherosclerosis compared with CTL mice. Additionally, cholesterol content and macrophage infiltration were elevated in the aortic lesions of the CKD mice. HFD accentuated these changes and reduced endothelium-dependent relaxation in isolated aortic rings in the CKD mice. LC/MS analysis of oxidation markers (nitrotyrosine and dityrosine) showed marked elevation in the aortic lesions of the CKD mice consistent with enhanced oxidative stress. Targeted LC/MS analysis of arginine methylation in plasma including asymmetric dimethyl arginine (ADMA), symmetric dimethyl arginine (SDMA), N-mono-methylarginine (NMMA), homoarginine, arginine and its catabolites (citrulline and ornithine) was performed. No significant changes were noted for NMMA, homoarginine and ornithine between groups. Although elevated plasma levels of ADMA and SDMA were found in the CKD mice, only higher ADMA levels correlated with aortic lesion area.

Conclusions: These findings strongly implicate the contribution of altered arginine methylation, oxidative stress and vascular dysfunction in CKD-accelerated atherosclerosis.

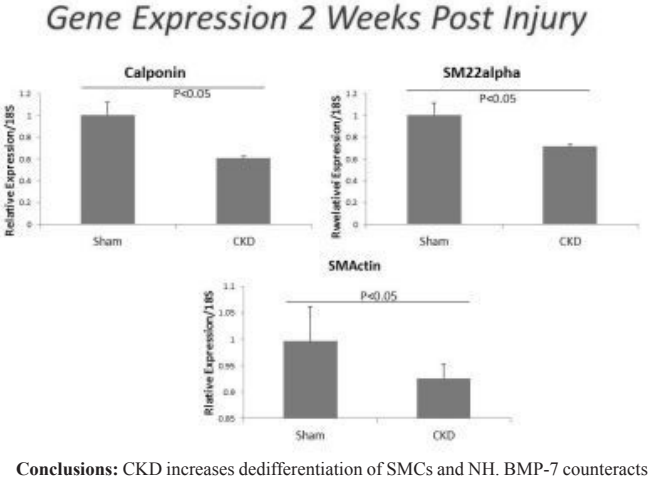
Smooth Muscle Dedifferentiation after Vascular Injury in Chronic Kidney Disease Senthil Nathan Jayarajan,[1] M. Alexandra Monroy,[1] Jianhua Fang,[1] Catherine Loveland-jones,[1] Shrenik Pankaj Shah,[1] Keith A. Hruska,[2] Eric T. Choi.[1] *[1]Department of Surgery, Temple University, Philadelphia, PA; [2]Department of Pediatrics, Washington University School of Medicine, St. Louis, MO.*

Background: Neointimal hyperplasia (NH) is accelerated in chronic kidney disease (CKD). Administration of bone morphogenetic protein -7 (BMP-7), an endogenous protein, reduces NH in animal models of vascular injury. SMC dedifferentiation (contractile to synthetic phenotype conversion) leading to cell proliferation and migration is required for NH. The purpose of this study was to investigate the effect of BMP-7 on SMC dedifferentiation after vascular injury in CKD.

Methods: Human aortic SMC treated with CKD patient serum were used to identify phenotypic changes in vitro. Left kidney ablation and right nephrectomy in mice created CKD. Carotid artery ligation caused vascular injury. Dedifferentiation was characterized by reduction of SM Actin, SM22α and calponin expression, gene markers of contractile phenotype, using real-time PCR.

Results: In cell culture, CKD reduced expression of contractile markers, SM Actin, calponin, and SM22α (p<0.05). BMP-7 increased calponin and SM22α mRNA expression in SMC exposed to CKD serum by 33% (p<0.05). SM Actin, SM22α and calponin mRNA expressions were measured at 1 and 2 weeks after carotid artery ligation injury in sham (no CKD) vs. CKD mice. At 1 and 2 weeks, the expression of SM Actin, calponin, SM22α was reduced when comparing CKD to sham (p<0.05). BMP-7 and vehicle alone were administered to CKD mice. At 1 week, BMP-7 increased expression of SM Actin when compared to the CKD vehicle mice (p<0.05). At 2 weeks, BMP-7 increased mRNA expression of SM22α (p=0.023) and calponin (p=0.022).



Conclusions: CKD increases dedifferentiation of SMCs and NH. BMP-7 counteracts the effect of CKD, reducing dedifferentiation and attenuates NH development.

SA-PO156

Effect of Lowering ADMA on Vascular Pathology in Atherosclerotic ApoE-Deficient Mice with Reduced Renal Mass Johannes Jacobi,[1] Renke Maas,[2] Nada Cordasic,[1] Karl F. Hilgers.[1] *[1]Nephrology and Hypertension, University of Erlangen-Nuremberg, Erlangen, Germany; [2]Clinical Pharmacology, University of Erlangen-Nuremberg, Erlangen, Germany.*

Background: Asymmetric dimethylarginine (ADMA) is a marker of cardiovascular disease but its causal role for vascular pathology remains largely unknown. We tested the hypothesis that lowering endogenous ADMA levels ameliorates atherosclerosis in ApoE-deficient (ApoE -/-) mice with reduced renal mass.

Methods: To reduce ADMA levels, a transgene overexpressing the ADMA degrading enzyme dimethylarginine dimethylaminohydrolase (DDAH) was introduced into the ApoE -/- line by crossbreeding. Male DDAH transgenic ApoE -/- (N=15) and non-transgenic ApoE -/- mice (N=15) underwent 5/6 nephrectomy (SNX, ablation) at 3 months of age. Nine months later, animals were sacrificed and plaque formation was evaluated in the entire aorta (Sudan IV stained en-face preparations). Sections of the truncus brachiocephalicus were evaluated histologically. Male ApoE -/- controls with normal kidney function were also studied (N=15 DDAH-transgenic and N=15 non-transgenic), as were SNX mice with a normal ApoE genotype (N=13 DDAH-transgenic and N=10 non-transgenic).

Results: At 12 months of age, plasma ADMA measured by LC-MS was significantly lower in DDAH-transgenic ApoE -/- than in non-transgenic ApoE -/- mice after SNX (0.41±0.02 vs. 0.62±0.03 µmol/L). Plaque burden of the entire aorta was reduced in SNX ApoE -/- DDAH-transgenic mice, compared with SNX ApoE -/- non-transgenic animals (12.5±1.0% versus 15.8±1.2% of aortic surface). In non-SNX ApoE -/- mice of the respective genotype, the DDAH transgene afforded a rather greater extent of protection (7.6±2.1% versus 12.4±1.9%). The DDAH transgene did not affect the extent of macrophage infiltration or calcification of the vascular wall. In contrast, wall-to-patent-lumen-ratio was reduced in SNX ApoE -/- mice with the DDAH transgene (0.77±0.05) compared to transgene-negative animals (0.94±0.12).

Conclusions: In summary, lowering ADMA reduced vascular remodeling and aortic plaque burden to some extent in ApoE -/- mice. However, the data do not support a major role in this model of atherosclerosis and reduced renal mass.

Regression of Heart Fibrosis in CKD Is Accompanied by Decrease in Plasma Marinobufagenin Grzegorz Piecha,[1] Nadezda Koleganova,[2] Marie-Luise Gross-Weissmann,[2] Eberhard Ritz.[3] *[1]Department of Nephrology, Endocrinology and Metabolic Diseases, Medical University of Silesia, Katowice, Poland; [2]Institute of Pathology, University of Heidelberg, Heidelberg, Germany; [3]Department of Internal Medicine, University of Heidelberg, Heidelberg, Germany.*

Background: Marinobufagenin is a causal factor in the genesis of uremic cardiomyopathy; it induces fibrosis, and its production is stimulated by the renin-angiotensin system. The purpose of the present study was to examine whether in subtotally nephrectomized rats reversal of cardiac hypertrophy and fibrosis by Losartan and Spironolactone is paralleled by changes in plasma marinobufagenin concentrations.

Methods: Seventy-two Sprague-Dawley rats were subjected to subtotal nephrectomy (SNX) or sham operation. Eight weeks after surgery, they were either euthanized or treated orally with vehicle, losartan (250 mg/kg/day), spironolactone (15 mg/kg/day), and their combination for the subsequent 4 weeks (n=9-12 per group). Heart morphology was evaluated by stereology in tissues obtained using pressure-controlled perfusion fixation. Concentration of marinobufagenin in plasma was measured by an immunoassay.

Results: Systolic blood pressure was significantly higher in SNX (173±18 mmHg) compared with sham-operated animals (116±8) and decreased in all treatment groups (losartan: 134±18; spironolactone: 133±26; combination: 116±18). The capillary density and fibrosis in untreated SNX deteriorated significantly compared with sham-op. Both parameters were improved in SNX treated with losartan+spironolactone, but not with spironolactone alone. Losartan alone reduced fibrosis but failed to improve capillary density. In parallel, 12 weeks after surgery, plasma marinobufagenin levels were elevated 8-fold in untreated SNX vs. sham-op, and lower compared to untreated SNX in the SNX treated with losartan, spironolactone, and particularly losartan+spironolactone.

Conclusions: The study documents in subtotally nephrectomized rats major regression of heart remodeling of after combined treatment with losartan and spironolactone. Whether the change in marinobufagenin concentration is the cause or the consequence of the cardiac changes is examined in ongoing studies.

The Role of Bone Marrow Derived Cells in Heart Capillary Rarefaction due to Chronic Kidney Disease (CKD) Yvonne Riedl, Katharina Bibl, Christoph Daniel, Kerstin U. Amann. *Nephropathology, University Erlangen-Nuremberg, Erlangen, Germany.*

Background: Mortality rate is still very high in patients with CKD. CKD patients show characteristical cardiovascular structural alterations. Present data suggest that impaired angiogenesis plays an important pathophysiological role. Using a well-established animal model we investigated if angiogenesis in CKD is associated with reduced recruitment of hematopoietic stem cells.

Methods: To investigate the impact of bone marrow derived cells (BMDC) in animals with moderate stable CKD, bone marrow from human placental alkaline phosphatase (hPAP) transgenic F344 rats was transplanted into wildtype F344 rats. Ten weeks after irradiation and bone marrow transplantation, reconstituted chimeric recipients were randomly assigned to two groups and subtotally nephrectomized (SNX) or sham operated (sham). The experiment was terminated 12 weeks after SNX and BMDC were subsequently analysed in hearts and kidney by confocal microscopy.

Results: In comparison to sham-operated animals, SNX rats showed increased proteinuria, serum creatinine and urea. Renal structural changes as determined by glomerulosclerosis and tubulointerstitial damage index were significantly higher in SNX rats. Capillary density was significantly decreased in both kidneys and hearts of SNX rats in comparison to sham-operated animals. Interestingly, the number of BMDC was 80% higher in hearts from SNX rats compared to sham-operated controls indicating higher influx of these cells into the heart muscle. However, endothelial cells from bone marrow origin were rarely found in hearts from rats with CKD as well as in healthy rats. In contrast, many hPAP positive cells were also positive for markers of inflammatory cells like macrophages and leucocytes. Further characterization of hPAP-positive cells is ongoing.

Conclusions: CKD is associated with cardiac hypertrophy and lower capillary supply leading to impaired cardiac blood flow and oxygen supply. BMDC seem not to be a substantial source for heart endothelial cells. Further characterization of hPAP-positive cells is needed to detect potential qualitative cell differences in hearts from CKD rats versus healthy controls.

Increased Wave Reflections Are Related to Capillary Density in Skin in Patients with Advanced Chronic Kidney Disease Camiel L.M. De Roij van Zuijdewijn, Muriel Grooteman, Menso Jan Nube. *Department of Nephrology, VU University Medical Center, Amsterdam, Noord-Holland, Netherlands.*

Background: Arterial stiffness contributes to the risk of cardiovascular events in patients with chronic kidney disease (CKD). Heart rate-adjusted augmentation index (AIx75) can be used as a measure of both wave reflections and arterial stiffness. In patients with advanced CKD we recently showed baseline capillary rarefaction and reduced capillary density after both arterial (functional impairment) and venous occlusion (structural impairment). In the present study we analyzed whether alterations in the macro-vasculature are accompanied by changes in the microcirculation.

Methods: AIx75 was measured in 26 healthy subjects and 54 patients with CKD stages 4 and 5. In both patients and controls, capillary density in skin was measured by nailfold microscopy at baseline, after post-occlusive hyperemia and after venous occlusion. A p-value ≤ 0.05 was considered significant.

Results: Baseline number of capillaries was 47±20/mm^2 in healthy subjects and 43 ± 15/mm^2 in CKD patients (controls versus patients p=0.05). Aix75 was 20 ± 11 in healthy controls and 25 ± 10 in advanced CKD ($p < 0.05$). In healthy controls, no correlations were found between AIx and capillary density, neither at baseline nor after arterial and venous occlusion. In patients with advanced CKD, AIx was positively correlated with the number of capillaries at baseline (p=0.008), after post-occlusive hyperemia (p=0.17) and after venous occlusion (p=0.04).

Conclusions: Measurements of AIx and capillary density in healthy controls were considerably different from patients with advanced CKD. In healthy individuals no correlation was found between arterial stiffness and wave reflections and microcirculatory function, as measured by capillary density in skin. In patients with advanced CKD however, Aix was positively related to the functional and structural number of capillaries in skin. As AIx depends not only on central arterial stiffness, but also on the reflective properties of the arterial tree, our data may indicate that capillary integrity in CKD patients is maintained to some extent by a transmitted forward pressure in the microcirculation.

SA-PO160

Use of Beta-Blockers Is Independently Associated with Arterial Stiffness in Patients with Advanced CKD Camiel L.M. De Roij van Zuijdewijn, Muriel Grooteman, Menso Jan Nube. *Department of Nephrology, VU University Medical Center, Amsterdam, Noord-Holland, Netherlands.*

Background: Carotid-femoral pulse wave velocity (PWV) is the gold standard for the measurement of arterial stiffness and an independent predictor of cardiovascular disease (CVD). Both age and chronic kidney disease (CKD) are positively associated with PWV. The aim of the present study was to assess clinical, laboratory and treatment-related determinants of PWV in patients with advanced CKD.

Methods: PWV was measured in 28 healthy subjects and 59 patients with CKD stages 4 and 5. In CKD patients, the plasma levels of phosphorus (P), FGF23, calcium, IL-6, hsCRP, 25-hydroxyvitaminD3 and 1,25 dihydroxyvitaminD3 were assessed. Antihypertensive medication was adopted from the patient files. Determinants of PWV in CKD patients were analyzed in a multi-linear regression model. A p-value of < 0.05 was considered statistically significant.

Results: Mean age in healthy subjects and CKD patients was 53 ± 15 and 62 ± 13 years, respectively. In these subjects, mean PWV was 7.3 ± 1.8 m/s and 10.1 ± 3.2 m/s, resp. Multivariate regression analysis of the total group of participants showed that both age (p= 0.000) and CKD (p= 0.01) are independent determinants of PWV. In patients with advanced CKD, multivariable linear regression analysis showed that only IL-6 (log Il-6: p=0.04) and β-blockers (p=0.009) are independent and positively correlated with PWV.

Conclusions: Interleukin-6 and especially the use of β-blockers are independently associated with arterial stiffness in patients with CKD. Whether the latter correlation is causal or confounded by indication cannot be concluded from this cross-sectional analysis.

SA-PO161

Comparative Efficacy and Adverse Effects of the Addition of Ezetimibe to Statin versus Statin Titration in Chronic Kidney Disease (CKD) Patients Hiromichi Suzuki, Tsuneo Takenaka, Hirokazu Okada, Tsutomu Inoue. *Department of Nephrology, Saitama Medical University, Iruma Gun, Saitama, Japan.*

Background: A recent SHARP trial has clearly demonstrated that reduction of LDL cholesterol [with] and a daily regimen of simvastatin plus ezetimibe safely reduced the incidence of major atherosclerotic events in patients with CKD. **Aim:** The aim was to compare the efficacy and adverse effects of statin up-titration vs. statin in combination with ezetimibe because only a few studies have been conducted bearing on this question.

Methods: This was a randomized, open-blind multi-center trial that included 286 patients with CKD whose LDL cholesterol levels were not reduced below 120 mg/dL in spite of statin therapy. Patients received double doses of statin or ezetimibe 10 mg daily. Observation period was one year. During the study, patients were checked on regular visits to the clinic for adverse effects as well as usual laboratory examinations. The key prespecified outcome was the incidence of adverse effects, which included skeletal muscle complaints, myalgia, muscle weakness, muscle cramps with and without elevated CK levels. Increases of ALT or AST levels <1.5 times the upper limit of normal (ULN) were considered as clinically significant adverse effects.

Results: The occurrence rates of all adverse events were 9/145 in the ezetimibe group and 24/141 in the statin up-titration group (P<0.01). Moreover, in patients with CKD of stages 3 to 5, the rates were 6/58 vs. 20/52 (P<0.01). No serious adverse effects such as rhabdomyolysis were noted in both groups. Serum creatinine levels remained essentially unchanged in both groups except in CKD stages 4 and 5. Reductions of LDL-cholesterol were similar between the two groups at the start of and at the end of the study. During the study, no atherosclerotic events were reported in both groups.

Conclusions: When statin up-titration produced adverse effects such as myopathy, combination therapy with ezetimibe is recommended instead of statin alone.

SA-PO162

Cessation of Cigarette Smoking Compared to Continued Smoking Preserves eGFR in Stage 2 Chronic Kidney Disease due to Hypertensive Nephropathy Bethany Kirkpatrick,[1] Jan Simoni,[2] Chanhee Jo,[3] Donald E. Wesson.[1,4] *[1]Internal Medicine, Texas A&M HSC College of Medicine, Temple, TX; [2]Surgery, Texas Tech University HSC, Lubbock, TX; [3]Biostatistics, Scott and White Healthcare, Temple, TX; [4]Internal Medicine, Scott and White Healthcare, Temple, TX.*

Background: Cigarette smoking might worsen eGFR in some nephropathies but whether its cessation preserves eGFR in hypertensive nephropathy is not clear.

Methods: We recruited 108 smoking and 108 non-smoking adults with chronic kidney disease (CKD) due to hypertensive nephropathy, stage 2 eGFR (60-90 ml/min), and urine albumin (mg)-to-creatinine (g) ratio (alb/cr) >200 mg/g in a spot specimen. Smokers received 12 weekly sessions of substance abuse counseling along with 4 weeks of nicotine patch and oral bupropion to encourage quitting determined by reduction of urine cotinine to pre-specified levels at 24 weeks. Non-smokers (NS, n = 108), continued smokers (S, n = 83), and quitters (Quit, n = 25) were followed 5 years on angiotensin converting enzyme inhibitors with yearly eGFR (CKD-EPI equation), urine alb/cr, and urine isoprostane 8-isoprostaglandin $F_{2\alpha}$ (a measure of oxidative stress) in a spot specimen, factored by g creatinine (8-iso/cr).

Results: There was no difference in entry eGFR (p=0.58) and urine alb/cr (p=0.20) but entry 8-iso/cr was higher (p<0.0001) in S (4.3 ug/cr) and Quit (4.1 ug/cr) than NS (1.6 ug/g). Systolic blood pressure was not different among groups at entry (p=0.29) and at 5 years (p=0.22). At 5 years, eGFR was lower (p<0.0001) in S (54.9 ml/min) than NS (66.8 ml/min) and Quit (64.1 ml/min) and was lower in Quit than NS (p=0.043). Urine alb/cr at 5 years was higher (p<0.0001) in S (627.9 mg/g) than NS (504.9 mg/cr) and Quit (415.0 mg/g) but was not different between Quit and NS (p=0.059). Urine 8-iso at 5 years was higher (p<0.0001) in S (3.7 ug/g) than NS (1.6 ug/g) and Quit (1.5 ug/g) but was not different between Quit and NS (p=0.928).

Conclusions: Continued smoking compared to non-smoking worsens eGFR in stage 2 hypertensive nephropathy. By contrast, smoking cessation compared to continued smoking preserves eGFR, possibly mediated through reduced oxidative stress.

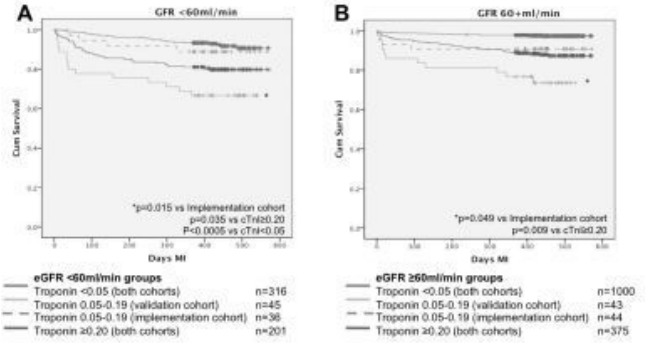
Interpretation of a Sensitive Troponin Assay in Patients with Chronic Kidney Disease and Suspected Acute Coronary Syndrome David A. Ferenbach,[1] Wendy Metcalfe,[2] Bryan Conway,[1] Nick Mills.[1] *[1]University of Edinburgh, Edinburgh, United Kingdom; [2]Department of Renal Medicine, Royal Infirmary of Edinburgh, Edinburgh, United Kingdom.*

Background: The significance of low level positive Troponin I (TnI) in patients with chronic kidney disease (CKD) remains controversial. We examine the impact of CKD on patient management and outcome of TnI +ve acute coronary syndrome (ACS), before and after implementation of a high sensitivity TnI assay.

Methods: We identified all consecutive patients presenting to Edinburgh Royal Infirmary with suspected ACS in two 6-month cohorts: Validation (V) (n=1019) and Implementation (I) (n=1043). These cohorts spanned a change in diagnostic threshold from >0.2 (V) to >0.05ng/L (I) for TnI, with figures below 0.2ng/ml reported as 'negative' to clinicans in the (V) cohort, but available for analysis. Data was collected on co-morbidity, inpatient management, discharge medication and 12-month outcome.

Results: CKD (eGFR<60ml/min) patients were older with more vascular co-morbidity than those with normal renal function (NRF). Reducing the ACS diagnostic threshold to TnI<0.05ng/ml resulted in an increase in ACS rates of 23% and >40% in NRF and CKD patients respectively (p<0.001). Patients with unreported TnI of 0.05-0.19 in the (V) cohort had rates of recurrent MI of 33.3% and 25.6% in CKD and NRF patients (p=0.43). This was reduced to 11.1% and 9.1% in CKD and NRF groups in the (I) cohort (p=0.015 and p=0.049 vs (V) cohort respectively).



Patients with CKD had significantly lower rates of inpatient revascularisation and less use of secondary preventative medication (aspirin, clopidogrel, β-blocker, ACE inhibitor or statin, all p<0.05).

Conclusions: This study validates high sensitivity TnI assays for risk stratifying ACS in the CKD population. Factors underlying altered prescribing and invasive management rates in CKD require further study.

SA-PO164

Lower Platelet Inhibition to Aspirin in CKD Nishank Jain,[1,2] Beverley Adams-huet,[3] Ravi Sarode,[3] Robert D. Toto,[1] Susan Hedayati.[1,2] *[1]Nephrology Division, UT Southwestern; [2]Veterans Affairs; [3]UT Southwestern.*

Background: High residual platelet aggregability (RPA) to antiplatelet agents (APA) is a novel modifiable risk factor predicting future cardiovascular (CV) events. Despite excess CV events, little is known about RPA in CKD. We hypothesized that compared to patients without CKD, those with CKD (eGFR <60 mL/min/1.73 m^2) have lower platelet aggregability at baseline and respond poorly to aspirin-induced inhibition of platelet aggregation.

Methods: Whole blood platelet aggregation (WBPA) to 0.5 mM arachidonic acid was measured at baseline in 63 participants of the Chronic Kidney Disease Antidepressant Sertraline Trial, a randomized trial to assess the safety and efficacy of sertraline vs. placebo in CKD patients with major depression, and assess sertraline effect on platelet aggregability. Patients were classified into on aspirin and not on aspirin groups. WBPA was compared between groups using Wilcoxon rank sum or Student's t-test. Percent of participants who had inhibition of WBPA <17 Ω was compared between groups using Fisher's Exact test.

Results: There were 19 CKD patients not on aspirin and 44 on aspirin. Mean (SD) age was 68 (11) years and eGFR was 35 (10) mL/min/1.73m^2. 63% were diabetic and 44% African American. Percent with inhibition of WBPA was not different in the not on aspirin vs. on aspirin groups (79% vs. 83% respectively, p =0.7). There was no difference in WBPA whether or not CKD patients were on aspirin (p =0.07). In those not on aspirin, WBPA was significantly lower in CKD patients than reported in normal controls (p<0.001). In the aspirin group, WBPA in CKD patients was higher compared to controls (p<0.001).

Whole Blood Platelet Aggregation (WBPA) in CKD patients and normal controls

Group	N	WBPA Not on Aspirin, Mean (SD), Ω	WBPA on Aspirin, Mean (SD), Ω
Normal controls	106	12 (4)	1 (4)
CKD	63	8.3 (8.7)	5.6 (9.9)

Conclusions: CKD patients vs. controls have lower platelet aggregability at baseline but respond poorly to aspirin, potentially explaining the increased CV events in those with CKD on APA. Future studies need to investigate the use of newer APA with better aggregability profiles in CKD patients.

The Prothrombotic State in Predialysis and Hemodialysis Is Related to an Impaired Fibrinolysis

Josefin L.G. Mörtberg,[1] Shu He,[2,3] Hakan Wallen,[3] Margareta Blombäck,[2] Stefan H. Jacobson,[1] Jonas Berglund,[1] Jonas Spaak.[3] *[1]Division of Nephrology, Department of Clinical Sciences, Danderyd Hospital, Karolinska Institutet, Stockholm, Sweden; [2]Division of Clinical Chemistry/ Coagulation Research, Department of Molecular Medicine & Surgery, Karolinska Institutet, Stockholm, Sweden; [3]Division of Cardiovascular Medicine, Department of Clinical Sciences, Danderyd Hospital, Karolinska Institutet, Stockholm, Sweden.*

Background: As CKD is associated with an increased risk of both thrombosis and bleeding, hemostasis was investigated with a method which investigates overall fibrin formation and fibrin degradation. We also measured PAI-1 antigen and TAFI activity in plasma.

Methods: 15 hemodialysis, 23 predialysis patients (CKD 4; mean eGFR 17 ml/min) and 13 healthy controls were studied. We used a global hemostasis assay developed by our group to determine fibrin formation and fibrin degradation in plasma over time when recombinant tissue factor, purified phospholipids, calcium and rt-PA were added to the sample. The fibrin turbidity was determined kinetically to obtain Coagulation activation profile (Cp) and Fibrinolysis activation profile (Fp). The Overall Hemostasis Index (OHI) is the ratio of Cp to Fp, reflecting the balance between coagulation and fibrinolysis.

Results: OHI was higher in the hemodialysis group; median 52.4 (range 17.8-364; $p<0.04$), and in the predialysis group 46.4 (2.5-124; $p<0.02$), compared to controls 27.9 (16.0-46.9) indicating a prothrombotic state. Cp was 17.1 (7.7-82.5) in the hemodialysis group and 16.8 (6.7-28.3) in controls (ns). Fp was lower in the hemodialysis group; 0.24 (0.15-1.18; $p<0.02$) compared to controls 0.58 (0.31-0.74), despite lower PAI-1 antigen ($p<0.05$ compared to controls). TAFI activity in plasma did not differ significantly between groups. Fibrinogen and von Willebrand factor levels in plasma were higher, and plasma albumin levels were lower in both CKD groups.

Conclusions: The prothrombotic state of severe renal impairment is characterized by impaired fibrin degradation despite low or normal plasma levels of PAI-1 and TAFI activity.

SA-PO166

Mild Renal Dysfunction Is Linked to Low HDL Cholesterol Level, Monocytosis, and Atherosclerosis in the Malmö Diet and Cancer Study

Anjali Ganda,[1] Martin Magnusson,[2] Olle Melander,[2] Robert Gerszten,[3] Alan Tall.[1] *[1]Columbia U., NY; [2]Lund U., Sweden; [3]Harvard U., MA.*

Background: Defects in HDL-mediated cholesterol efflux have recently been linked to increased production of monocytes in animal models. CKD patients have been shown to have monocytosis, which has been proposed to increase CV risk. We hypothesized that individuals with mild renal dysfunction would have reduced HDL levels, increased blood monocyte counts, and increased carotid IMT.

Methods: 5067 individuals (enrolled 1991-1994) without CV disease participated in the MDC-CV Cohort, designed to investigate the epidemiology of carotid artery disease. 4757 individuals had plasma cystatin C (cysC) measured at baseline. We divided these subjects into 5 cysC quintiles.

Results:

cysC quintile (mg/L)	cysC range (mg/L)	cysC mean (mg/L)	eGFR mean (ml/min/1.73m²)	HDL level (mg/dL)	Monocyte count (million cells/mL)	No. of subjects
1	0.28-0.67	0.62±0.002	81.5±0.50	57.6±0.47	0.48±0.005	1002
2	0.68-0.73	0.71±0.001	78.0±0.47	54.7±0.48	0.50±0.006	927
3	0.74-0.79	0.77±0.001	75.0±0.48	52.8±0.46	0.51±0.006	932
4	0.80-0.87	0.83±0.001	73.0±0.46	51.1±0.44	0.51±0.005	904
5	0.88-3.29	0.99±0.006	68.8±0.47	49.4±0.44	0.54±0.006	992
p-value				<0.0001	<0.0001	

Within quintile 5 cysC, HDL level was inversely related to monocyte count ($r= -0.2$, $p<0.001$). Among all 4757 subjects, via multivariate logistic regression analysis adjusted for age, diabetes, and quintiles 1-4 cysC, quintile 5 cysC independently increased the odds of being in the top quartile monocyte count (OR 1.6, 95% CI 1.207-2.006, $p=0.001$) and HDL level and female gender independently decreased the odds (OR 0.6, 95% CI 0.443-0.728, $p<0.001$ and OR 0.6, 0.529-0.738, $p<0.001$, respectively). Via multivariate linear regression analysis, age, diabetes, monocyte count, and quintile 5 cysC each independently were associated with increased carotid IMT and HDL level and female gender independently with decreased carotid IMT at baseline ($p<0.05$).

Conclusions: Subjects with mild renal dysfunction had significant monocytosis at baseline, associated with reduced HDL levels, and monocytosis was predictive of increased carotid atherosclerosis cross-sectionally. Reduced HDL levels may give rise to monocytosis and accelerated atherogenesis in subjects with mild renal dysfunction.

Renoprotective Effects of Statin in Patients with Chronic Kidney Disease

Takehiro Suzuki,[1] Daisuke Saigusa,[2] Eikan Mishima,[1] Yasutoshi Akiyama,[1] Yoichi Takeuchi,[1] Hiroshi Sato,[3] Sadayoshi Ito,[1] Takaaki Abe.[1] *[1]Division of Nephrology, Endocrinology, and Vascular Medicine, Tohoku University Graduate School of Medicine, Sendai, Japan; [2]Laboratory of Oncology, Pharmacy Practice and Sciences, Graduate School of Pharmaceutical Sciences, Tohoku University, Sendai, Japan; [3]Clinical Pharmacology and Therapeutics, Graduate School of Pharmaceutical Sciences, Tohoku University, Sendai, Japan.*

Background: The reduction of accumulated uremic toxins in patients with chronic kidney disease (CKD) protects against the development of cardiovascular diseases. We have revealed that 1) the overexpression of human kidney specific uremic toxin transporter SLCO4C1 in rat kidney promoted renal excretion of uremic toxins and reduced hypertension, cardiomegaly, and inflammation in renal failure, 2) statins up-regulated SLCO4C1 to enhance the uremic toxin clearance in renal failure rats (JASN 2009). We estimated renoprotective effects of statin by assessment of statin treatment on patients with CKD.

Methods: 41 patients with different stages of CKD received statin (pitavastatin 2mg/day). Serum creatinine (S-Cr), serum lipid profiles, and urine protein (Up) were measured before and three months after statin treatment started. Uremic toxins in blood were also measured by liquid chromatography mass spectrometry (LC-MS).

Results: S-Cr and estimated GFR (eGFR) were not significantly improved after statin treatment. T-chol, LDL-chol, and triglyceride were significantly decreased, however, HDL-chol was not changed. Up was significantly decreased. LC-MS revealed that representative uremic toxins, guanidinosuccinate (GSA) and asymmetric dimethylarginine (ADMA) significantly decreased.

Conclusions: After the statin treatment, eGFR was not improved, but Up excretion and plasma uremic toxins were also reduced. The reduction of plasma uremic toxins might be mediated by promoted tubular excretion through enhanced SLCO4C1.

Ventricular Arrhythmia in Chronic Kidney Disease: Prevalence and Associated Factors

Fabiana Oliveira Bastos Bonato,[1] Marcelo M. Lemos,[1] Jose Luiz Cassiolato,[2] Maria Eugenia F. Canziani.[1] *[1]Nephrology, UNIFESP, São Paulo, SP, Brazil; [2]Cardiology, Cardios, São Paulo, SP, Brazil.*

Background: Cardiovascular mortality in chronic kidney disease (CKD) has shown to be substantially elevated even in early stages of the disease. Complex ventricular arrhythmia (VA) has been pointed as one of the etiologies of sudden death. The aim of the present study was to evaluate the prevalence of VA and to investigate the factors associated with their occurrence in non-dialyzed CKD patients.

Methods: This is a cross-sectional study that evaluated one hundred and eleven patients with non-dialyzed CKD (57 ± 11.4 years, 60% male, eGFR: 34.7 ± 16.1 mL/min per 1.73m², 24% diabetics). Patients underwent laboratory tests, 24h electrocardiogram, 24-h ambulatory blood pressure monitoring (ABPM), echocardiogram and multi-slice computed tomography.

Results: Sixteen percent of the patients had VA. Non controlled hypertension was observed in 21% of the patients while absence of systolic decency in 29%. Left ventricular hypertrophy was found in 27% of the patients and heart failure in 20%. Coronary artery calcification was observed in 52 patients, from which 46% had severe calcification. Comparing to the patients without VA, the VA group was older ($p = 0.008$) and had higher eGFR ($p = 0.018$) and hemoglobin ($p = 0.007$). This patients had lower iPTH ($p = 0.049$) and triglycerides ($p = 0.003$) levels. The VA group also had higher left ventricular mass index ($p = 0.001$), coronary calcium score ($p= 0.025$) and lower ejection fraction ($p = 0.002$). In the multiple logistic regression analysis, age and ejection fraction were independently associated with the presence of VA.

Conclusions: VA is prevalent in non-dialyzed CKD patients, especially in the older ones. The factors associated with its occurrence were mainly related to alterations in cardiac structures, such as left ventricular hypertrophy, coronary calcification and heart failure.

SA-PO169

Increased NO Activity during Statin Treatment in Patients with Non-Diabetic Nephropathy

Frank H. Mose, Thomas Larsen, Janni Majgaard Jensen, Jesper N. Bech, Erling B. Pedersen. *Department og Medical Research, Holstebro Hospital, Holstebro, Denmark.*

Background: We investigated the effects of short term atorvastatin treatment on blood pressure (DBP and SBP), GFR and fractional excretion of sodium (FE-Na) during inhibition of nitric oxide synthase (NOS) in patients with non-diabetic nephropathy.

Methods: Twenty-five patients with chronic kidney disease stage IV-V (eGFR 90-30 ml/min/m²) were examined in a randomised, placebo-controlled, double-blinded, cross-over study. All subjects were given Atorvastatin 80 mg per day or placebo 5days prior to an examination day. During the treatment period subjects were on a standardized diet. ^{51}Chrom-EDTA clearance was used for GFR measurements and the nitric oxide (NO) synthase inhibitor, L-NMMA, were administered as a 4.5mg/kg bolus injection followed by 3.0 mg/kg/hour IV infusion for one hour. SBP, DBP and heart rate (HR) were repeatedly measured. Blood and urine samples were collected every 30 minutes during the 90 min baseline period, during L-NMMA infusion and 60 minutes after cessation of L-NMMA infusion. Differences are presented in means ± SD or medians with interquartile.

Results: IV infusion of L-NMMA increased both DBP and SBP and decreased HR (p less than 0.001). There were no differences in change in SBP (12±8 mmHg vs. 12 ± 8 mmHg), DBP (9 ± 3 mmHg vs. 9 ± 3 mmHg), and HR (-3± 2vs. -4±1) between groups. GFR (49.8 ± 16.0 ml/min vs. 49.3 ± 16.9 ml/min)and FE_{Na} (1.59 (0.72;3.41)% vs. 1.57 (0.70;3.08)%)were similar at baseline. GFR decreased dignificantly during L-NMMA infusion (-5.2±5.7 ml/min vs. -4.8±6.9 ml/min), but there were no differences between groups (p=0.818). L-NMMA infusion caused a significant reduction in FE_{Na} in both groups (-0.61±0.61% vs. -0.80±0.82%, p=0.001 in both groups) and the reduction was similar (p=0.224). In the post-LNMMA period FE_{Na} the decrease was more pronounced in atorvastatin group compared to placebo (-0.45±0.69% vs. -0.79±0.94%, p=0.024).

Conclusions: Short term Atorvastatin treatment significantly increased the reduction in FE-Na during NOS inhibition. Our results suggest that atorvastatin increases the bioavailability of renal NO and may be an explanation of the pleiotropic effects of statins.

SA-PO170

Increased Arterial Thrombo-Embolic Events and Major Bleeding in Patients with Atrial Fibrillation and Chronic Kidney Disease on Vitamin K-Antagonist Treatment Judith Kooiman, Bas Spaans, Wilke R. van de Peppel, Koen van Beers, Felix Van der Meer, Suzanne Cannegieter, Ton J. Rabelink, Menno V. Huisman. *Leiden University Medical Center, Netherlands.*

Background: To analyze the risk of arterial thrombotic events(ATEs), major bleeding and its predictors in patients with chronic kidney disease(CKD) compared with non-CKD patients, treated with vitamin K-antagonists(VKAs) for atrial fibrillation(AF).

Methods: Medical records of 417 CKD and 300 non-CKD(GFR>60ml/min) patients starting VKA therapy between 1997-2005 were searched for ATEs and major bleeding. ATE was defined by myocardial infarction, stroke/transient ischemic attack, claudicatio intermittens, unstable angina, carotid or peripheral bypass graft/angioplasty. Major bleeding was defined by bleeding being fatal, causing a drop in Hb level≥1,24mmol/L, requiring transfusion of≥2 units of whole blood/red cells, or being symptomatic in a critical area/organ.

Results: ATEs occurred in 108/737(14.7%,95%CI12.3-17.4) patients. Patients with a GFR<30ml/min were at increased risk of ATE compared with non-CKD patients(hazard ratio(HR)3.4(95%CI2.1-5.6). ATEs occurred as frequent in patients with GFR30-60ml/min as in non-CKD patients(HR1.1,95%CI0.7-1.7). Major bleeding occurred in 115/737 patients(15.6%,95%CI13.2-18.4). The risk of major bleeding increased in patients with a GFR<30ml/min compared with non-CKD patients(HR1.8,95%CI1.1-3.0). Major bleeding risk was not increased in patients with a GFR 30-60ml/min compared with non-CKD patients(HR0.9,95%CI0.6-1.4). Low GFR levels were associated with high variability within a patients INR values (correlation term-0.17,P=<0.001) and low serum albumin levels (correlation term-0.13,P0.03). Both INR variability>0.5(HR1.5,95%1.0-2.4) and serum albumin<34g/L(HR1.7,95%CI1.0-3.0) increased the major bleeding risk.

Conclusions: Patients with a GFR<30ml/min are at increased risk of ATEs and major bleeding compared with non-CKD patients. The increased bleeding risk may be due to low serum albumin levels and high INR variability, which is a marker of suboptimal VKA therapy.

Table 1.

	N	%
Mean age(SD)	75	10
Male	415	56
Mean duration VKA therapy in years(SD)	3.5	3.1
eGFR in ml/min		
>60	300	41

SA-PO171

The Safety and Efficacy of Endovascular Treatment of Peripheral Artery Disease in Chronic Kidney Disease Patients Aris Q. Urbanes, Gerald A. Beathard, Terry Litchfield. *Lifeline Vascular Access, Vernon Hills, IL.*

Background: Over 10 million Americans have Peripheral Artery Disease (PAD) with only 25% being diagnosed and treated. PAD is very common in the CKD population, with prevalence rates reported of 15% to 48%. Patients with impaired renal function have a greater than two-fold risk for developing PAD. KDOQI recommends at the time of dialysis initiation, all patients should be evaluated for the presence of PVD. A large system of outpatient vascular centers developed and implemented a coordinated care approach to PAD including outpatient endovascular interventions in the CKD population.

Methods: A coordinated program including nephrologists; dialysis units; podiatrist; primary care physicians and interventional center was observed. The program included patient identification; education of providers and patients; and treatment if indicated. Non invasive testing was performed and were conducted in accordance with TASC II guidelines. In 2011, 771 PAD interventions were performed in CKD patients, with outcomes entered into an electronic health record. Data were analyzed in SPSS.

Results: Technical success rate for the seven hundred and seventy one (771) cases was 93% with a complication rate of 1.9% with 2 major complications; 1 related to an expanding hematoma at the site where the closure device was deployed and the other related to embolization. Most of the minor complications were related to closure devices. The case mix was fairly complex with Angioplasty-55%; Atherectomy-32% and Stent placement-13%. Demographics were consistent with USRDS data.

In CKD 4 and 5 patients, special attention to contrast use (mean contrast volume of 46.2 ml) including adherence to renal preservation techniques yielded only 2 cases requiring dialysis within 30 days of the intervention.

Conclusions: P.A.D. is undertreated in the CKD population, which leads to amputation and other morbid events. Diagnosis and endovascular treatment can be successfully and safely performed in a controlled outpatient system. Patient outcomes and quality of life can be optimized in these patients using a collaborative approach.

SA-PO172

Utility of Cardiac Troponin I-Ultra as an Assessment of Myocardial Injury in Renal Insufficiency Prachi Aggarwal, Anubhav Kaul, Sonia Agarwal, Thara Basavaiah, Frantz M. Duffoo, Shitij Arora. *Internal Medicine, Wyckoff Heights Medical Center, Brooklyn, NY.*

Background: Evidence depicts the elevation of cardiac troponins(TnI) in patient with renal insufficiency, without the presence of myocardial ischemia. Patients with chronic kidney disease (CKD) are susceptible to silent ischemia and interpretation of ongoing myocardial ischemia is challenging using TnI assays. Numerous studies have discussed TnI elevation in hemodialysis patients; however, the data is insufficient regarding patients with CKD. Our study aims to evaluate the rise in TnI levels with respect to GFR.

Methods: In a retrospective design, 33 CKD patients were designated into two groups based on the GFR. CKD stages 2/3 were assigned as mild/moderate and stages 4/5 as the severe/fail group. Patients on hemodialysis, of age > 90, impaired ejection fraction or a history of coronary artery disease, myocardial infarction, coronary artery bypass surgery/stent were excluded. Ultra-sensitive troponin I test was used in the patients. Data was tabulated and analyzed using SPSS statistical analysis software.

Results: Group 1 (CKD stage 2 and 3; n=17) and Group 2 (CKD stage 4 and 5; n=16) were assessed with group statistics and comparison of means using the independent t-test. The average GFR was 52.9 ± 4.06 for Group 1 and 18.6 ± 1.49 for Group 2; the difference is significant (p = 0; sig. 1-tailed). The average troponin value for Group 1 was 3.66 ± 1.97 and 2.62 ± 0.763 for Group 2; the difference is not significant (p= 0.315 sig. 1-tailed). Using the Pearson correlation model for bivariate analysis, there is no significant correlation between GFR and troponin levels when assessing Group 1 and Group 2 collectively, with a correlation of -0.109 (p = 0.273 sig. 1-tailed).

Conclusions: Based on our results, elevated TnI in CKD patients are not dependent on the GFR. It is unlikely that the rising TnI in CKD are a result of decreased clearance by the kidney. Furthermore, if the theory of cardiac troponin re-expression in uremic skeletal muscle holds true, CKD stage 3/4 should have higher troponins levels as opposed to early CKD. Thus, the elevation of troponins in CKD patients remains unclear.

SA-PO173

Analysis of the Basal Timepoint in the Cohort of the Multicenter Prospective and Observational Study of Atheromatosis in CKD in Spain (NEFRONA Study): Data on Prevalence of Plaque Angels Betriu,[1] Montserrat Martinez-alonso,[1] Jose M. Valdivielso,[1] Elvira Fernandez.[1] *[1]IRBLleida.*

Background: There are no previous prospective studies assessing the impact of CKD on atheromatosis development, stratified by gender and age. The NEFRONA study is a multicenter prospective observational study monitoring, in patients CKD 3 to 5D, the changes in atherosclerosis, and their relationship with biochemical and genetic biomarkers.

In the present abstract we report the prevalence of atheromatous plaque in the baseline time point of the NEFRONA cohort (2455 patients without previous CV event, at different stages of CKD), compared with a control population of 559 individuals without CKD.

Methods: Data on presence of plaque (% of patients) was obtained with carotid ultrasound by the same team and assessed by one reader in a blinded fashion. Images from 8 different carotid territories were obtained (bulb, common, internal and external carotid in both sides). Plaque was defined as IMT≥1.5 mm. We analyze the trend according to degree of CKD stratified by age and sex using logistic regression analysis for the presence of carotid plaque. Moreover we also analyze the effect of sex stratified by degree of CKD and age group.

Results: 2455 patients were enrolled of which 61% are male, 25% diabetics and a population of 559 controls of which 53% are male and 11% diabetics. 98% Caucasian in both groups.

Age (y)	No CKD (n=559)		CKD3 (n=944)		CKD4-5 (n=821)		CKD 5D (n=690)		Trend p value along CKD stage	
	M	W	M	W	M	W	M	W	M	W
25-35	5.6	9.1	4	0	4.2	0	17.1	23.1	.097	.136
35-45	7.7	5.3	17	14.3	20.8	20.9	35.8	30.6	.001	.003
45-55	48	32*	49.3	34.7	44	38.5	66.7	42.6*	.035	.170
55-65	65.7	39.5*	65.9	43.2*	70.3	59.6	79.1	75.8	.017	< .001
65-75	70.5	54.3	80.2	64.9*	80.5	66.4*	88.9	81.8	.017	.004

Conclusions: The results show that the presence of plaque is lower in women than in men at all ages and stages of CKD and increases progressively with advancing CKD, being higher than in controls from CKD 3. There is a variable percentage of patients in every stage, age and sex who have not developed plaque. Prospective analysis of the study will identify the risk and protective factors for progression of atherosclerotic disease, distinguished by gender, age and stage.

Use of Secondary Preventative Therapies in Individuals with Acute Coronary Syndrome and Renal Dysfunction: An Analysis of the Myocardial Ischaemia National Audit Project (MINAP) Database Catriona Shaw,[1] Cornelia Junghans,[1] Sapna Shah,[1] Donal O'Donoghue,[2] Claire C. Sharpe.[1] *[1]Department of Renal Medicine, Kings College London, United Kingdom; [2]Department of Renal Medicine, Salford Royal NHS Foundation Trust.*

Background: CKD is a recognised risk factor for acute coronary syndromes (ACS) and mortality. Our aim was to assess the association between renal dysfunction and the use of secondary preventative therapies.

Methods: Data on 54,062 individuals with NSTEMI and 34,733 individuals with STEMI were included in univariable logistic regression models to investigate the association between eGFR and utilisation of secondary preventative therapies: aspirin, statins, ace inhibitors and cardiac rehabilitation. A multivariable model was developed to assess the association between eGFR and cardiac rehabilitation. An eGFR>90ml/minute was used as the baseline category.

Results: The overall prevalence of eGFR <60ml/minute was 49% in the NSTEMI population, and 30% in the STEMI population. As eGFR reduced, the odds of receiving aspirin, a statin, an ace inhibitor or cardiac rehabilitation declined compared with individuals with an eGFR>90ml/minute in both populations (p<0.0001). In the NSTEMI population, at an eGFR of 15-29ml/minute the OR of receiving aspirin was 0.57(95% CI 0.51-0.64), an ace inhibitor 0.35 (95% CI 0.32-0.38) and a statin 0.66 (95% CI 0.59-0.73). In the STEMI population an eGFR 15-29ml/minute was associated with an OR of receiving aspirin of 0.51 (95% CI 0.42-0.61), an ace inhibitor of 0.27 (95% CI 0.23-0.31) and a statin of 0.56 (95%CI 0.46-0.67). After adjustment for major co-morbidity, the adjusted OR of being offered cardiac rehabilitation decreased as eGFR declined (p<0.0001). With an eGFR 15-29ml/minute the adjusted OR for cardiac rehabilitation were 0.76 (95% CI 0.67-0.86) in the NSTEMI population and 0.68 (95% CI 0.54-0.84) in the STEMI population.

Conclusions: The substantial burden of cardiovascular disease in renal impairment is well documented. Data from this contemporary cohort suggests that at time of hospital discharge, individuals with renal impairment receive fewer secondary preventative therapies post ACS compared with individuals with normal renal function.

SA-PO175

Periodontal Disease Is Independently Associated with Vascular Stiffness in Patients with Progressive CKD Stephanie J. Stringer,[1,2] Praveen Sharma,[1,3] Khai Ping Ng,[1,2] Mark David Jesky,[1,2] Mary Dutton,[2] Charles Ferro,[1,2] Iain Chapple,[1,3] Paul Cockwell.[1,2] *[1]Immunity and Infection, University of Birmingham, Birmingham, United Kingdom; [2]Nephrology, University Hospital Birmingham, United Kingdom; [3]Dentistry, University of Birmingham, United Kingdom.*

Background: Periodontal disease is the commonest chronic inflammatory disease. Chronic diseases including CKD are associated with vascular stiffness, vascular stiffness is a determinant of poor outcomes. We hypothesised that periodontitis is independently associated with vascular stiffness in people with CKD.

Methods: Patients enrolled into a prospective observational cohort of progressive CKD underwent a full periodontal assessment (carried out by a dentist and a hygienist), arterial stiffness (PWV), AGEs and measurement of highly sensitive c-reactive protein (hsCRP) and polyclonal serum free light chains (FLC) kidney function, proteinuria and demographics.

Results: 196 patients with progressive CKD were included, 60% were male, the mean age was 61.6 years(+/-16.5) and the median eGFR was 23 (7-90) mL/min. Periodontal disease was classified using clinical attachment loss and probing depths; 3% were classified as healthy, 37% as moderate periodontitis, 46% as severe periodontitis and 14% were edentulous (these patients were removed from the analysis as it is impossible to comment on periodontal health in these individuals). In a univariate analysis AGEs**, PWV**, cystatin C* and eGFR* (** p <0.001, * p <0.05) correlated with severity of periodontal disease, hsCRP and sFLC did not. In the multivariate analysis only PWV was significantly associated with the severity of periodontal disease (p = 0.028).

Conclusions: In this prospective bioclinical study of progressive CKD the severity of periodontitis was the only independent risk factor associated with increased vascular stiffness. There was no association with serum hsCRP or polyclonal FLC, indicating that these markers are not sufficiently sensitive systemic biomarkers for this association or other pathophysiological pathways link these processes. Clinical trials to address the hypothesis that treatment of periodontitis improves outcomes in people with CKD are required.

Cardiac Troponin T Predicts All-Cause and Cardiovascular Mortality in Predialysis Non-Diabetic Patients Terumasa Hayashi,[1] Akira Suzuki,[1] Kodo Tomida,[1] Tatsuya Shoji,[1] Noriyuki Okada,[2] Yoshiharu Tsubakihara.[1] *[1]Kidney Disease and Hypertension, Osaka General Medical Center, Osaka, Japan; [2]Clinical Laboratory, Osaka General Medical Center, Osaka, Japan.*

Background: Asymptomatic elevation of cardiac troponin T (cTnT) is associated with higher mortality and cardiovascular events in patients on hemodialysis. Furthermore, recent analysis of TREAT (Trial to Reduce Cardiovascular Events With Aranesp Therapy) revealed that cTnT was predictive for cardiovascular events and mortality in patients with predialysis chronic kidney disease (CKD) and diabetes mellitus (DM). However, little is known about predictive value of cTnT in non DM patients with predialysis CKD.

Methods: We measured cTnT in 265 consecutive patients before the start of chronic dialysis treatment between March 2005 and October 2010. The relationship between cTnT level and all-cause and cardiovascular mortality was analyzed using Cox proportional hazards models.

Results: Median age was 68 (male gender, 58%) and the prevalence of DM was 39.6%. Detectable cTnT (>0.01ng/ml) was present in 80% of patients. 51 patients died (14 from cardiovascular disease) during the median follow-up period of 32 months. Asymptomatic elevation of cTnT (cTnT>0.01ng/ml) was observed in 248 patients and was associated with all-cause (HR1.433, 95%CI 1.056-1.946) and cardiovascular mortality (HR 1.991, 95%CI 1.128-3.516) after adjustment for age, sex, diabetes, cardiovascular history, smoking, C-reactive protein, albumin, hemoglobin and estimated glomerular filtration rate. Sensitive analysis in non DM group showed similar and significant association between cTnT and all-cause (HR 1.659, 95%CI 1.114-2.469) and cardiovascular mortality (HR 2.617, 95%CI 1.085-6.311).

Conclusions: In predialysis patients, regardless of DM or non DM, asymptomatic elevation of cTnT is strongly predictive for all-cause and cardiovascular mortality. These findings suggest ways to improve cardiovascular risk stratification of patients with predialysis CKD.

SA-PO177

Study of Vascular Calcification Progression in Elderly Patients with and without CKD Stephen G. John,[1] Paul J. Owen,[1] Jane H. Youde,[2] Chris W. McIntyre.[1,3] *[1]Renal Medicine, Royal Derby Hospital, Derby, United Kingdom; [2]Medicine for the Elderly, Royal Derby Hospital, Derby, United Kingdom; [3]School of Graduate Entry Medicine and Health, University of Nottingham, Derby, United Kingdom.*

Background: Chronic kidney disease (CKD) is highly prevalent in older people and is associated with changes in cardiovascular (CV) function and elevated CV risk. Vascular calcification (VC) predicts CV risk and mortality in CKD, but the contribution of CKD in older people and linkage to other markers is incompletely understood. We performed a prospective, controlled study of VC and CV function, body composition, functional capacity and falls in older (>70 yrs) non-diabetic patients with and without CKD 3/4.

Methods: We recruited 61 subjects (including non-CKD controls). Blood pressure (BP) was controlled to 130/80mmHg. Baseline assessment included VC (superficial femoral artery CT), CV function (carotid-femoral pulse wave velocity (PWV), baroreflex sensitivity (BRS), central haemodynamics), skin AGE, body composition (bioimpedance analysis) and function (Timed get Up and Go test (TUG)), bloods (inc. PTH, Ca, PO_4, Vitamin D), proteinuria and falls diaries. Assessment was repeated at 1 year (FU).

Results: Mean age was 76±4yrs, mean eGFR (CKD group) 42±14ml/min/1.73m^2, mean BP 128/69 mmHg, significant proteinuria in 18%. 50% had significant VC. Median VC (12±71units [0-1397]) and mean PWV (12.4±2.7m/s) were similar in CKD and non-CKD. VC was higher in men (28±11;81±57units;p=0.044), correlated with TUG (r=0.297;p=0.034) but not PWV, BRS or any other variable. VC increased at FU (12±71;28±125units;p<0.001), whilst PWV did not (12.4±2.7;12.4±2.5m/s;p=0.753). VC increased similarly (p=0.336) in both CKD (13±162;28±190units;p=0.001) and non-CKD (8±61;28±92units;p=0.026) and was independent of any other variable.

Conclusions: Over 1 year, with controlled BP, VC increased but there was no change in other markers of vascular health. VC is associated with falls risk. Although overall VC load was similar to that previously reported by our group, this cohort had earlier CKD but advanced age. Furthermore, as VC was similar in non-CKD and CKD groups this suggests a greater contribution from ageing than renal dysfunction in CKD 3/4.

SA-PO178

Ankle Brachial Index Predicts Cardiovascular Disease Risk and Mortality among Patients with Chronic Kidney Disease: A Prospective Analysis from the CRIC Study Jing Chen, L. Lee Hamm, Dawei Xie, Raymond R. Townsend, Jackson T. Wright, Matthew Jay Budoff, Lisa C. Nessel, Qiang Pan, Susan P. Steigerwalt, Pranav S. Garimella, Jiang He. *Tulane University.*

Background: Cross-sectional studies suggest that the proportion of individuals with an ankle brachial index (ABI) at the high or low extremes was increased among patients with chronic kidney disease (CKD).

Methods: We investigated the prospective relationship between baseline ABI and subsequent risk of cardiovascular disease (CVD) events and total mortality among 3,627 CKD patients who participated in the Chronic Renal Insufficiency Cohort (CRIC) Study and did not have a history of upper or lower extremity revascularization or amputation at

baseline examination. Peripheral arterial disease (PAD) and other CVD events [myocardial infarction (MI), congestive heart failure (CHF), and stroke] were adjudicated by an assessment committee.

Results: The event rates per 100 person-years for ABI<0.90, 0.90-0.99, 1.00-1.39, and ≥1.40 were 1.12, 0.54, 0.20, and 1.05 for PAD; 2.18, 1.81, 0.69, and 2.54 for MI; 4.70, 2.59, 1.91, and 2.89 for CHF; 6.66, 4.55, 2.80, and 5.02 for total CVD other than PAD; and 4.51, 2.78, 1.55 and 2.28 for total mortality. Compared to those with ABI of 1.00-1.39, those with ABI<0.90, 0.9-0.99, and ≥1.40 had hazard ratios (HR, 95% CI) of 4.03 (2.03, 7.97), 2.39 (1.11, 5.17) and 5.46 (1.59, 18.7) for PAD, p<0.001; 2.01 (1.33, 3.06), 2.42 (1.59, 3.68) and 2.81 (1.28, 6.21) for MI, P<0.001; and 1.49 (1.12, 1.99), 1.40 (1.02, 1.92) and 1.00 (0.44, 2.28) for total mortality, P=0.03, respectively, after adjustment for traditional CVD risk factors. The multivariable-adjusted HR for CHF and total CVD other than PAD was not statistically significant.

Conclusions: These data indicate that both higher and lower ABI was associated with higher risk of PAD and MI events, while lower ABI was associated with higher total mortality. In conclusion, our study suggested that ABI may be a useful index for risk stratification for PAD, MI and mortality among CKD patients. Furthermore, ABI cut points for diagnosis of PAD may need to be further defined in CKD patients.

Subclinical Left Atrial Enlargement in Stage 3-5 Chronic Kidney Disease

Angela Yee Moon Wang,[1] Ye Lu,[1] Sharon Cheung,[1] Man Chu,[2] Sharon Shee Yin Wong,[1] Iris Chan,[3] Christopher W. Lam.[2] *[1]Medicine, Queen Mary Hospital, University of Hong Kong, Hong Kong, Hong Kong; [2]Macau Institute for Applied Research in Medicine and Health, Macau University of Science and Technology, Macau, Macau; [3]Chemical Pathology, United Christian Hospital, Hong Kong, Hong Kong.*

Background: Left atrial enlargement (LAE) is a marker of diastolic dysfunction & predicts adverse outcomes in end-stage renal disease. However, little is known of its prevalence & factors associated with subclinical LAE in earlier stages of chronic kidney disease (CKD).

Methods: We prospectively recruited 261 stage 3–5 CKD patients without symptomatic cardiovascular disease(mean eGFR:34±17ml/min per1.73m^2)& performed 2D-echocardiography to determine left atrial volume index (LAVi)& other cardiac parameters.

Results: 109 patients (41.8%) had LAE of which it was mild[LAVi≥29-34ml/m^2],moderate[LAVi≥34-40ml/m^2] & severe[LAVi≥40ml/m^2] in 45, 28 & 36 patients,respectively. Mild & moderate/severe LAE were observed in 22.9% & 41.3% of patients with left ventricular hypertrophy (LVH) (n=109) *vs* 13.2% & 12.5% of patients without LVH (n=152), respectively(P<0.001). On univariate analysis, other than increasing age, systolic blood pressure (SBP), worsening anemia, serum albumin, phosphorus & declining eGFR being significantly associated with LAE, a significant increase in plasma sodium level was observed across patients with increasing severity of LAE (P=0.001). In the multiple stepwise logistic regression, plasma sodium level emerged as one of the most significant factors associated with LAE [adjusted odds ratio(OR), 1.31, 95% CI, 1.15–1.49; P<0.001]. Its significance was maintained [adjusted OR, 1.24, 95% CI, 1.07–1.44; P=0.004] when including LV mass & volume index & N-terminal pro-brain natriuretic peptide in the model while SBP and hemoglobin were displaced.

Conclusions: This is the first study to demonstrate an extremely high prevalence of subclinical LAE & a novel,positive association between plasma sodium level & subclinical LAE in stage 3–5 CKD patients. Longitudinal study is needed to determine whether high plasma sodium may be causally linked to LAE in CKD & the underlying mechanism. More attention is needed to target subclinical LAE in CKD.

SA-PO180

Advanced Glycation End-Products and Arterial Stiffness in Diabetic and Non-Diabetic Patients with Chronic Kidney Disease

Pawel Strozecki,[1] Robert Kurowski,[1] Mariusz Flisinski,[1] Anna Stefanska,[2] Grazyna Odrowaz-Sypniewska,[2] Jacek Manitius.[1] *[1]Dept of Nephrology and Hypertension, Nicolaus Copernicus University; [2]Dept of Laboratory Medicine, Nicolaus Copernicus University, Bydgoszcz, Poland.*

Background: The formation of advanced glycation end-products (AGEs) is increased in diabetic patients. Impaired renal function also elevates AGEs. Pulse wave velocity (PWV) is a measure of arterial stiffness and valuable prognostic parameter. The association between AGEs and arterial stiffness was found in hypertensive patients and in hemodialysed patients. The study investigated the relationship between plasma AGEs concentration and arterial stiffness in diabetic (DN) and non-diabetic (Non-DN) patients with chronic kidney disease (CKD).

Methods: The study population consisted of 60 CKD patients: 24 with DN, and 36 with Non-DN, and 19 controls. Carotid-femoral PWV was measured using Complior device. To assess plasma AGEs concentration fluorescence spectra were recorded with Fluoroscan Ascent FL Labsystems (excitation 355 nm/emission 460 nm). AGEs measurements were taken in duplicate, averaged, and expressed in arbitral units (AU/ml). Systolic (SBP), diastolic (DBP) blood pressure and estimated glomerular filtration rate (eGFR) were also investigated.

Results:

	Controls	Non-DN	DN
Age (years)	46±13	51±15	53±14
Male gender (%)	11(58%)	21(58%)	14(58%)
SBP (mmHg)	125±10	137±21[1]	148±24[2]
DPB (mmHg)	79±6	84±10[1]	80±10
eGFR (ml/min/1,73m^2)	81±15	33±13[2]	32±14[2]
AGEs (AU/ml)	7,8±1,2	12,3±3,1[2]	21,1±6,8[2,3]
PWV (m/s)	8,4±1,6	10,1±2,4[1]	13,7±4,3[2,3]

[1]– p<0,05 vs controls; [2]– p<0,001 vs controls; [3]– p<0,001 vs Non-DN. Significant correlation was found between AGEs and PWV in the whole study population (r=0,49;p<0,001;n=79), as well as in CKD patients (r=0,39;p<0,01;n=60), but not separately in DN (r=0,18;NS) and Non-DN (r=-0,06;NS) patients. In multiple regression analysis PWV was independently associated with age, diabetes and SBP, but not with eGFR and AGEs (R^2 for the model = 0,53).

Conclusions: Accumulation of AGEs and arterial stiffness are increased in CKD, particularly in diabetic CKD patients. However our results are not sufficient to confirm the role of AGEs accumulation in arterial stiffening in CKD patients.

SA-PO181

Left Ventricular Mass and Chronic Kidney Disease: A Cardiac MRI Study in Hypertensive Patients with Marked Cardiovascular Risk: A Substudy of SMART

Esther de Beus,[1] Matthijs F.l. Meijs,[2] Michiel Bots,[3] Peter J. Blankestijn.[1] *[1]Department of Nephrology and Hypertension, University Medical Centre Utrecht, Netherlands; [2]Department of Cardiology, University Medical Centre Utrecht, Netherlands; [3]Julius Centre for Health Sciences and Primary Care, Utrecht, Netherlands.*

Background: Increased left ventricular mass (LVM) is known to predict cardiovascular morbidity and mortality. Left ventricular mass is high in ESRD patients. Previous studies using echocardiography showed that in patients with mild to moderate chronic kidney disease (CKD) left ventricular mass is already increased. Our aim was to study the relationship between renal function and left ventricular mass with cardiac MRI in a population of patients at high risk for cardiovascular disease (CVD).

Methods: Cardiac MRI was performed in 529 hypertensive patients with manifest arterial disease or marked risk factors for CVD. All subjects had been screened for cardiovascular risk factors in a standardized way as part of SMART, a prospective single-centre cohort study. Multivariable linear regression was used to study the relationship of both eGFR (using the MDRD formula) and presence of albuminuria with left ventricular mass. Presence of albuminuria was defined as a urinary albumin/creatinin ratio above 2,5 mg/mmol in men and 3,5 mg/mmol in women.

Results: Mean LVM was 121 g for men (SD 26) and 87 g for women (SD 20). Mean eGFR was 82 ml/min/1.73m² (SD 19). 78% of the patients had stage I to III CKD, 22% had an eGFR >90 ml/min/m² and normoalbuminuria. 75 patients (14,1%) had albuminuria. After adjusting for known determinants of LVM (height, weight, sex and age) eGFR did not relate to LVM while presence of albuminuria did (B for eGFR 0.066, 95%CI -0.045 to 0.178, p=0.243, B for albuminuria 8.684, 95%CI 3.234 to14.135, p=0.002). Additional adjustment for systolic blood pressure did not change results (B for eGFR 0.039, 95%CI -0.072 to 0.150, p=0.490, B for albuminuria 7.453, 95%CI 2.029 to12.877, p=0.007).

Conclusions: In our MRI study in hypertensive patients with high vascular risk decreased eGFR was not related to increased LVM. Presence of albuminuria was related to increased LVM even after adjustment for systolic blood pressure.

SA-PO182

Fat Depots, Cardiovascular Disease Risk Factors, and Coronary Artery Calcification in Non-Dialysis Dependent Chronic Kidney Disease Patients

Antonio C. Cordeiro,[1] Bengt Lindholm,[2] Fernanda S. Lourenço,[1] Antonio T. Paladino Filho,[1] Marcela Perini,[1] Fernanda C. Amparo,[1] Ibraim M.F. Pinto,[1] Celso Amodeo,[1] Amanda G.M.R. Sousa,[1] Juan Jesus Carrero.[2] *[1]Dante Pazzanese Institute of Cardiology, Sao Paulo, Brazil; [2]Divisions of Renal Medicine and Baxter Novum, Karolinska Institutet, Stockholm, Sweden.*

Background: Specific fat deposition may be associated with variable metabolic risk. We sought to evaluate the correlations between pericardial fat, visceral fat and subcutaneous fat accumulation with anthropometric parameters, metabolic risk factors, surrogates of inflammation and the presence of coronary artery calcification (CAC) in non-dialysis dependent chronic kidney disease patients (NDD-CKD).

Methods: We cross-sectionally evaluated 234 NDD-CKD stages 3–5 patients (61 [52–67] years, 146 men). Pericardial, visceral and subcutaneous fat, as well as CAC were assessed by computed tomography.

Results: All studied fat depots showed significant positive correlations (although varying in strength) with BMI, waist circumference, LDL cholesterol, triglycerides, HOMA-IR index white blood cell count and C3, whereas they correlated negatively with HDL cholesterol. Pericardial and visceral fat, but not subcutaneous, positively correlated with age, 24h urine creatinine clearance (CrCl), serum albumin and CAC score (rho=0.19 and 0.20 for pericardial and visceral fat, respectively; P<0.01). Furthermore, only visceral fat correlated with CRP (rho=0.14; P<0.05). In a series of logistic regression analyses with specific fat depots and which included confounders such as age, sex, CrCl, diabetes, smoking, BMI, HDL, triglycerides and calcium-phosphorus product, visceral fat was the only fat compartment that remained significantly associated with the presence of CAC [CAC score ≥10 Agatston] (OR per 0.1 cm^2 of increase in visceral fat: 1.05; 95% CI=1.01–1.10).

Conclusions: Excess fat deposition in NDD-CKD patients correlates with multiple metabolic risk factors. Among the fat depots studied, visceral proved to be independently associated with the presence of CAC. Given its metabolic activity, our data altogether emphasizes the need for strategies to reduce visceral fat stores among NDD-CKD individuals.

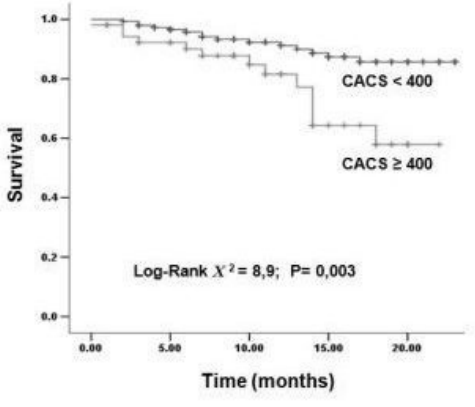
SA-PO183

Coronary Artery Calcium Score Predicts Adverse Events in Non-Dialysis Dependent Chronic Kidney Disease Patients Antonio C. Cordeiro,[1] Bengt Lindholm,[2] Antonio T. Paladino Filho,[1] Marcela Perini,[1] Celso Amodeo,[1] Ibraim M.F. Pinto,[1] Fernanda C. Amparo,[1] Amanda G.M.R. Sousa,[1] Juan Jesus Carrero.[2] *[1]Dante Pazzanese Institute of Cardiology, Sao Paulo, Brazil; [2]Divisions of Renal Medicine and Baxter Novum, Karolinska Institutet, Stockholm, Sweden.*

Background: Coronary artery calcium score (CACS) is a valuable cardiovascular (CV) risk stratification tool in the general population. However, its applicability in chronic kidney disease (CKD) patients is controversial, since these patients are already at high CV risk. We aimed to evaluate the prognostic power of CACS in non-dialysis dependent (NDD) CKD patients.

Methods: We cross-sectionally evaluated 203 NDD-CKD stages 3–5 patients (60 [52–67] years, 123 men). CACS (in Agatston) was assessed by computed tomography. All patients were followed-up for 12 [7 – 18] months, and a composite endpoint of mortality and cardiovascular events was registered.

Results: CACS was correlated with age (Rho=0.60; P<0.001), total cholesterol (TC, Rho=-0.16; P=0.01), HDL-cholesterol (HDL, Rho=-0.15; P=0.02) and PTH (Rho=-0.17; P=0.01). Patients were divided in two groups according to CACS (<400 [n=149] and ≥ 400 [n=54]). Patients with higher CACS were significantly older (68 vs. 57 years; P<0.001) and presented higher prevalence of diabetes (70 vs. 41%; P<0.001), as well as lower levels of TC and HDL. During the follow-up period, there were a total of 28 events (15 deaths), and patients with a high CACS presented an increased rate of events (**Figure**).



The crude hazard ratio for the composite endpoint was 2.94 (95% CI: 1.39–6.19) for patients with high CACS. This remained true after correcting for age, sex and diabetes (adjusted HR: 3.03; 95 % CI: 1.23–7.46).

Conclusions: Elevated CACS was predictive of adverse events in NDD-CKD patients. This data is suggestive of the potential utility of CACS as a risk stratification tool in this patient population.

SA-PO184

Is Plasma beta-2 Microglobulin a Better Predictor of Cardiovascular Outcomes than Traditional Risk Factors in Chronic Kidney Disease Patients? Sophie Liabeuf,[1 2] Aurélie Terrier Lenglet,[1 2] Lucie Desjardins,[1 2] Nathalie Neirynck,[3] Griet L.R.L. Glorieux,[3] Horst-Dieter Lemke,[4] Raymond C. Vanholder,[3] Momar Diouf,[2] Gabriel Choukroun,[1 5] Ziad Massy.[1 2 5] *[1]INSERM U-1088, Amiens, France; [2]Clinical Research Centre - Division of Clinical Pharmacology, Amiens University Hospital, Amiens, France; [3]Nephrology Dialysis Transplantation Department, Department of Internal Medicine, University Hospital, Gent, Belgium; [4]EXcorLab GmbH, EXcorLab GmbH, Obernburg, Germany; [5]Division of Nephrology, Amiens University Hospital, Amiens, France.*

Background: As beta-microglobulin (B2M) a surrogate marker for middle molecular weight uremic toxins and the major protein component in dialysis-related amyloidosis, B2M is frequently studied in dialysis patients. However, it is not known whether or not B2M has an impact in chronic kidney disease (CKD) patients not yet on dialysis.

Methods: We decided to perform a prospective, observational study of the impact of plasma B2M levels on clinical and cardiovascular outcomes in 142 patients at different CKD stages (mean age ± SD: 67 ± 12 years; 8% at CKD stage 2, 26% at stage 3, 26% at stage 4, 8% at stage 5 and 32% at stage 5D).

Results: B2M levels increased with CKD stage and thus were highest in hemodialysis patients. Baseline B2M levels were associated with vascular calcification but not with arterial stiffness or bone density. During the follow-up period (mean: 969 ± 374 days), 44 patients died and 49 presented a cardiovascular event. Higher B2M levels were independently associated with overall and cardiovascular mortality and cardiovascular events in the whole cohort. Moreover, B2M appears to be a better predictor than well known factors associated with outcomes in this population including eGFR (only for predialysis patients), inflammation biomarkers and others factors included in a propensity score.

Conclusions: In conclusion, our study confirmed the strong relationship between B2M levels and the estimated glomerular filtration rate. More importantly, we confirmed the power of the B2M level for predicting overall and cardiovascular mortality and cardiovascular events in patients at different CKD stages.

SA-PO185

Chronic Kidney Disease (CKD) in Children Impairs Normal Protective Functions of High Density Lipoprotein (HDL) Ryohei Kaseda, Kathy L. Jabs, Tracy E. Hunley, Deborah P. Jones, Valentina Kon. *Pediatric Nephrology, Vanderbilt University, Nashville, TN.*

Background: Trials to increase HDL levels have shown disappointing clinical effects and have given rise to the concept of dysfunctional HDL. Renal impairment can affect the composition of HDL, which has been revealed to be a key modulator in diverse biologic activities relevant to CKD complications. Recently, we showed that HDL of hemodialyzed adults has impaired cholesterol acceptor and anti-inflammatory capacities. Whether moderate CKD and end stage renal disease (ESRD) requiring dialysis in childhood disrupts the newly appreciated functions of HDL is unknown.

Methods: Inflammatory and chemotactic effects were assessed in human macrophage-like THP-1 cells exposed to HDL isolated from children with ESRD on peritoneal dialysis (ESRD-PD, n=5), children with CKD (stage III-IV, n=6) and normal kidney function (Control, n=4). Cytokine response of LPS-activated THP-1 macrophages (LPS 50 ng/ml x 4h) ± HDL (18 ug/ml) from the 3 groups was assessed by mRNA expression of inflammatory markers. Chemotaxis of THP-1 cells to monocyte chemoattractant protein-1 (MCP-1) was assessed in a modified Boyden transwell chamber.

Results: Compared with Control, HDL of CKD and ESRD-PD elicited a heightened inflammatory cytokine response: TNF-a Control:0.087±0.017, CKD-0.187±0.018*, ESRD-PD-0.157±0.019*; MCP-1: Control:1.136±0.203, CKD:2.509±0.146*, ESRD-PD:2.040±0.172*; IL-1b: Control:1.157±0.207, 2.439±0.566*, 2.905±1.237*, (*p<0.05 vs Control). Control HDL reduced chemotaxis of THP-1 cells while HDL from CKD or ESRD-PD had no effect (MCP-1alone:44.6±2.2, MCP-1+Control:12.6±1.2* MCP-1+CKD 44.2±2.6#, ESRD-PD:29.6±1.9#, *p<0.05 vs MCP-1 alone, #p<0.05 vs Control).

Conclusions: Compared to children with intact kidney function, HDL of children with CKD and ESRD-PD has dramatically impaired capacity to abrogate LPS-induced inflammatory response together with reduced anti-chemotactic ability. These results suggest that HDL of children with reduced renal function has compromised protective functions and may, instead, be harmful.

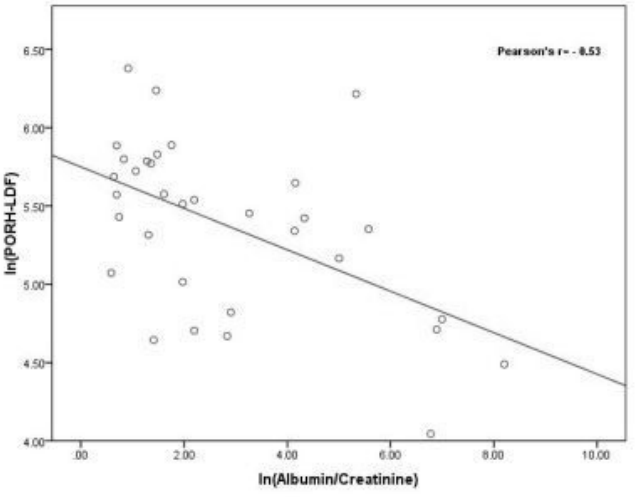
SA-PO186

Non-Invasive Measures of Cutaneous Microcirculatory Endothelial Function Are Associated with CKD and Albuminuria in Older Adults Afshin Parsa,[1] Shabnam Salimi,[1] Leslie I. Katzel,[1,2] Jamie Giffuni,[2] Stephen L. Seliger.[1] *[1]Medicine, U Maryland, Baltimore, MD; [2]GRECC, Baltimore VA Medical Center, Baltimore, MD.*

Background: Prior studies of endothelial dysfunction in CKD have mainly examined conduit-artery responses. However, micro-circulatory function may also be a significant determinant of the development and progression of albuminuria, CKD and associated CVD outcomes. We measured cutaneous microcirculatory endothelial function using laser Doppler flowmetry (LDF) to determine the association with albuminuria and CKD.

Methods: Study participants were older men (age 60-85) from the Baltimore VA Medical Center. Endothelial function was quantified with LDF measures of post occlusive reactive hyperemia (PORH) and thermal hyperemia (TH) responses in 17 CKD subjects and 18 age matched hypertensive non-CKD controls. Linear regression was used to estimate the association of CKD and urinary albumin to creatinine ratio (ACR) with LDF measures, adjusting for age, diabetes, and mean blood pressure.

Results: Mean age was 70 years, 50% had diabetes, median eGFR among CKD subjects was 44 mL/kg/1.73m^2. Peak PORH-LDF response was significantly lower in our CKD vs. non-CKD group at 260.7 ±156.8 vs 315.3 ±161.6 perfusion units, respectively (adjusted standardized β=-0.48, p=0.02). Peak PORH-LDF response also negatively correlated with ACR (standardized β=-0.69, p=0.001; Figure). TH LDF measures were not significantly lower in CKD subjects, but first TH peak response was negatively associated with ACR (standardized β=-0.64, p=0.004).



Conclusions: Among older adults with HTN, LDF measures of cutaneous microcirculatory endothelial function are significantly lower in CKD and in those with greater albuminuria. These findings suggest that cutaneous LDF measures may provide a practical and useful proxy of CKD related disturbances in microcirculatory endothelial function.

SA-PO187

Differences in Progression to End-Stage Renal Disease between Black and White Incident Patients on Pre-Dialysis Care in a Universal Health Care System Moniek C.M. de Goeij,[1] Tessa O. Van den Beukel,[1,2] Carl E.H. Siegert,[2] Friedo W. Dekker,[1] Nynke Halbesma.[1] *[1]Clinical Epidemiology, Leiden University Medical Center, Leiden, Netherlands; [2]Nephrology, Sint Lucas Andreas Hospital, Amsterdam, Netherlands.*

Background: Black CKD patients, mainly stages I-IV, have a faster progression to ESRD than whites. However, it is unknown whether this difference is also present in patients on pre-dialysis care in a universal health care system. Therefore, we investigated whether the rate of starting renal replacement therapy (RRT) and the decline in renal function was different between black and white patients on pre-dialysis care in the Netherlands.

Methods: In the Dutch observational multicenter PREPARE study, 1049 incident patients on pre-dialysis care (CKD stages IV-V) were included. Patients were followed until the start of RRT, death, or end of 2 years follow-up. Black and white ethnicity was assessed by the medical staff. A Cox proportional hazard regression analysis was used to estimate the hazard ratio (HR) for starting RRT and a linear mixed model to compare the rate of decline in renal function between blacks and whites. To explore mechanisms, adjustments were made for patient characteristics at the start of pre-dialysis care.

Results: 945 patients were white, 49 were black, and the 55 patients with another ethnicity were excluded. At the start of pre-dialysis care, blacks were younger, had more diabetes, more proteinuria, and a higher eGFR than whites (19.1 vs. 14.6 ml/min/1.73 m^2). In the crude analysis, blacks had a comparable rate of starting RRT as whites, HR 1.07 (95%CI, 0.74-1.54). After adjustment for eGFR the HR increased to 1.55 (95%CI, 1.04-2.32). During pre-dialysis care, blacks had a faster decline in renal function than whites, 0.20 ml/min/1.73 m^2/month (95%CI, 0.05-0.35). Further adjustment for patient characteristics did not change these results.

Conclusions: We demonstrated that black patients on specialized pre-dialysis care in a universal health care system show a faster progression to ESRD than white patients. Future studies should focus more on biological explanations and explore whether guidelines for pre-dialysis treatment should take data on ethnicity into consideration.

SA-PO188

Renal Function in Familial Longevity: The Leiden Longevity Study Moniek C.M. de Goeij,[1] Nynke Halbesma,[1] Friedo W. Dekker,[1] Ton De Craen.[2,3] *[1]Clinical Epidemiology, Leiden University Medical Center, Leiden, Netherlands; [2]Gerontology and Geriatrics, Leiden University Medical Center, Leiden, Netherlands; [3]Netherlands Consortium for Healthy Ageing, Leiden University Medical Center, Leiden, Netherlands.*

Background: Studying renal function in subjects with a familial propensity for longevity might provide new targets for treatment. We investigated whether renal function in middle aged individuals with a familial propensity for longevity is different compared to environment matched controls.

Methods: In the Leiden Longevity Study, middle aged offspring of nonagenarian siblings and their partners as environment matched controls were included. Information on life style, medical history, medication use, and a non-fasting blood sample were collected. Renal function was estimated with the Chronic Kidney Disease epidemiology collaboration (CKD-epi) formula. Analyses were stratified for sex. To account for familial dependencies within the offspring, a linear mixed model was used.

Results: A total of 1300 offspring (47% males, mean ± SD age 59.3 ± 6.5 years) and 596 partners (43% males, mean ± SD age 58.6 ± 7.1 years) were available for analyses. Female offspring and female partners had a similar eGFR, age adjusted difference of 0.44 (SE, 0.72; p=0.54) ml/min/1.73 m^2. Male offspring had a higher eGFR compared to male partners, age adjusted difference of 1.78 (SE, 0.78; p=0.022) ml/min/1.73 m^2. Further adjustment for known risk factors for decline in renal function such as history of cardio- and cerebrovascular disease, diabetes mellitus, anti-hypertensive and anti-diabetic medication changed the point estimates to 0.05 (SE, 0.74; p=0.94) ml/min/1.73 m^2 for females and 1.79 (SE, 0.79; p=0.024) ml/min/1.73 m^2 for males. Adjustment for blood parameters or lifestyle factors somewhat diluted the difference in males (p=0.048 and p=0.051 respectively).

Conclusions: Middle aged males, and not females, with a propensity for longevity have better renal function compared to environment matched controls. The better renal function in males could not be explained by differences in main known risk factors for renal dysfunction.

Funding: Government Support - Non-U.S.

SA-PO189

Association of GFR and Albuminuria with Mortality and End-Stage Renal Disease across Asians, Whites, and Blacks: A Collaborative Analysis of 45 Cohorts (for the CKD-PC Collaborators) Chi Pang Wen, Kunihiro Matsushita, Josef Coresh, Kunitoshi Iseki, Muhammad Islam, Ronit Katz, William M. McClellan, Carmen A. Peralta, Haiyan Wang, Dick de Zeeuw, Brad C. Astor, Ron T. Gansevoort, Andrew S. Levey, Adeera Levin. *CKD Prognosis Consortium.*

Background: Global interest in CKD has been increasing, but whether the impact of low GFR or high albuminuria, on clinical outcomes differs by race/ethnicity is yet unsettled.

Methods: We studied 1,102,660 individuals (827,089 Asians, 227,821 whites, and 47,750 blacks) from 45 cohorts inthe CKD Prognosis Consortium (CKD-PC). The hazard ratios (HRs) of all-cause mortality and ESRD for estimated GFR (eGFR) by the CKD-EPI equation and albuminuria (ACR or dipstick) were quantified in each race. Most Asian studies used dipstick, while others more frequently used ACR. Meta-regression analysis was used to compare HRs across races.

Results: For Asians, whites and blacks, mean age was 46, 63, and 59 years, and proportion with diabetes was 5%, 12% and 24%, respectively, with Asians having higher GFR and less albuminuria than others. Adjusted HR of mortality for eGFR and albuminuria compared to the reference group was similar in Asian, whites, and blacks (for example, for individuals with eGFR 30-44 ml/min/1.73m^2, the respective HR [95% CI] was 1.7 [1.5-2.0], 1.4 [1.3-1.6] and 2.0 [1.5-2.7] and for microalbuminuria [ACR 30-299 mg/g or dipstick 1+] 1.6 [1.4-1.8], 1.7 [1.5-1.9] and 1.8 [1.7-2.1], respectively). (Figure) Meta-regression comparisons were generally not significant and similar results were seen for ESRD.

Conclusions: Despite wide variability in clinical characteristics among cohorts and lower risk profile in Asians, the adjusted relative risks for mortality and ESRD according to low eGFR or high albuminuria were similar among Asians, whites and blacks.

Relative risk of mortality and ESRD according to eGFR and ACR/dipstick categories in whites, Asians, and blacks in general population cohorts

		All-cause mortality					ESRD				
		ACR/Dipstick					ACR/Dipstick				
	eGFR	<10 / Dip "-"	10-29 / Dip "±"	30-299 / Dip "1+"	300+ / Dip "≥2+"		<10 / Dip "-"	10-29 / Dip "±"	30-299 / Dip "1+"	300+ / Dip "≥2+"

			1.4	1.8	2.7			1.9	5.6	20.4	

Each number represents a pooled hazard ratio from meta-analysis adjusted for covariates and compared with the reference cell (REF) within each race. Bold numbers indicate statistical significance at $P<0.05$. Green, yellow, orange, and red colors indicate quartiles of risk from low to high, respectively. All hazard ratios for blacks and Asians are compared with those for whites for interaction using meta-regression, and stars (*) indicate a significant interaction at $P<0.05$. Colors reflect ranking of relative risk.

Prior Contact with a Nephrologist and Outcomes in Adults with Chronic Kidney Disease: The Chronic Renal Insufficiency Cohort (CRIC) Study

Ana C. Ricardo,[1,2] James P. Lash,[1,2] Jeffrey C. Fink,[2] Kelvin Tao,[2] Arnold B. Alper,[2] Jing Chen,[2] Paul E. Drawz,[2] Chi-yuan Hsu,[2] John W. Kusek,[3] Akinlolu O. Ojo,[2] Martin J. Schreiber,[2] Jason Roy,[2] Michael J. Fischer.[1,2] *[1]U. Illinois/ Jesse Brown VAMC; [2]CRIC Study Group; [3]NIH/NIDDK.*

Background: Pre-dialysis nephrology care for adults with advanced chronic kidney disease (CKD) is associated with improved outcomes. Less is known about the effects of nephrologist management in earlier stages of CKD.

Methods: We conducted cross-sectional analyses of baseline data from CRIC enrollees to assess the association between CKD management and self-reported prior contact with a nephrologist, which was elicited by answering "yes" to the question "Have you ever seen a nephrologist or a kidney doctor?" We also examined the association between prior contact with a nephrologist and outcomes ascertained up to 4 years of follow-up [CKD progression (≥50% eGFR loss or ESRD), incident cardiovascular disease (CVD), and death] using Cox-proportional hazards models.

Results: Of 3861 participants, 67% reported prior contact with a nephrologist. Enrollees who were older, female, of Hispanic ethnicity, had less than high school education, higher eGFR, and lower urine protein were less likely to report prior contact with a nephrologist ($p<0.05$). CKD management according to prior contact with a nephrologist in participants with eGFR 30-60 ml/min/1.73m² are in Table.

CKD Management Parameters by Prior Contact with a Nephrologist

	Prior Contact with Nephrologist	
Management Parameter, %	Yes (n=1760)	No (n=943)
Systolic BP	58	56
ACE-i/ARB use	74*	67
HbA1C <7%	36	34
Phosphate 2.7-4.6 mg/dl	89	91
LDL <100 mg/dl	53	50
iPTH, pg/ml, median	54*	45
Hemoglobin, g/dl, mean	12.7	12.7

*p<=0.01

After adjusting for demographic and clinical factors, prior contact with a nephrologist was not significantly associated with CKD progression, incident CVD or death ($p>0.05$).

Conclusions: One-third of CRIC participants reported they had not seen a nephrologist before enrollment, and this prior contact was subject to age, sex, and ethnic-related disparities. Self-reported prior contact with a nephrologist was not associated with an improvement in long-term adverse outcomes.

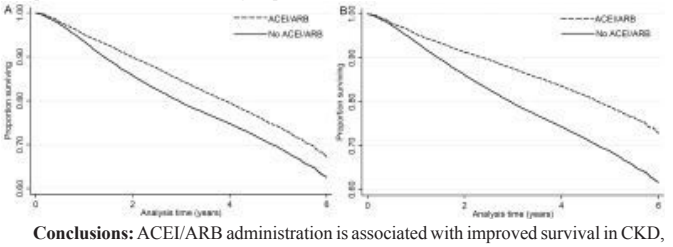
ACE Inhibitor and Angiotensin Receptor Blocker Use and Mortality in Patients with CKD

Miklos Zsolt Molnar,[1] Kamyar Kalantar-Zadeh,[1] Jun Ling Lu,[2] Sandra M. Malakauskas,[3,4] Jennie Z. Ma,[4] Leigh Darryl Quarles,[5] Csaba P. Kovesdy.[5,6] *[1]Harold Simmons Center at Harbor-UCLA, Torrance, CA; [2]Salem Research Institute, Salerm, VA; [3]Salem VA Medical Center, Salem, VA; [4]University of Virginia, Charlottesville, VA; [5]University of Tennesse Health Science Center, Memphis, TN; [6]Memphis VA Medical Center, Memphis, TN.*

Background: There is insufficient evidence about the association of angiotensin converting enzyme inhibitors (ACEI) or angiotensin receptor blockers (ARBs) with mortality in CKD.

Methods: We assessed the association of ACEI/ARB use with all-cause mortality in 141,413 US veterans with CKD stages 1-5 previously unexposed to ACEI/ARB treatment. Logistic regression analysis was used to calculate the propensity of ACEI/ARB initiation. The association of ACEI/ARB with mortality was examined in patients matched by propensity scores, using the Kaplan-Meier method and Cox models in "intention-to-treat" analyses, and a generalized linear model with binary outcomes and inverse probability treatment weighing (IPTW) in "as-treated" analyses.

Results: Over a median follow-up of 4.7 years there were 5,028 deaths (25%, mortality rate 22.6 [22.0-23.2]/1000 patient-years) in the treated group and 6,450 deaths (32%, 26.5 [25.9-27.2]/1000 patient-years) in the untreated group in the propensity score-matched cohort. ACEI/ARB use was associated with lower mortality in both intention-to-treat (HR, 95%CI: 0.81, 0.78-0.84, panel A) and in as-treated models (OR, 95%CI: 0.37, 0.34-0.41, panel B).(Figure) The association of ACEI/ARB treatment with lower risk of mortality was present in all examined subgroups.



Conclusions: ACEI/ARB administration is associated with improved survival in CKD, suggesting that ACEI/ARB may hold benefits beyond renoprotection in this vulnerable population.

Association between Variability in eGFR and Mortality

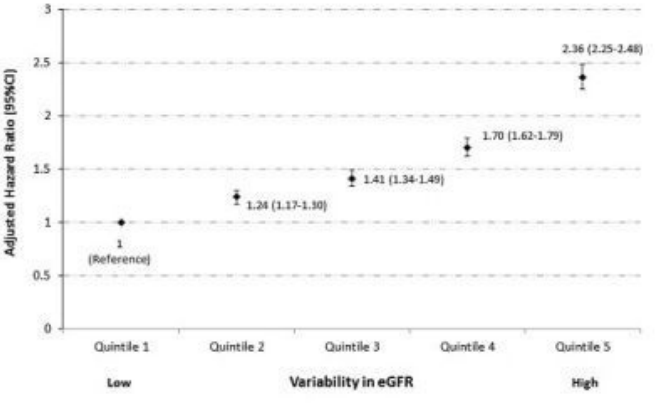
Tanvir Chowdhury Turin,[1] Min Jun,[2] Marcello Tonelli,[3] Braden J. Manns,[1] Hiddo Jan Lambers Heerspink,[4] Vlado Perkovic,[2] Brenda Hemmelgarn.[1] *[1]University of Calgary, Canada; [2]University of Sydney, Australia; [3]University of Alberta, Canada; [4]University of Groningen, Netherlands.*

Background: Change in kidney function, in particular variability in eGFR, and risk of death is not well understood. We aimed to investigate the association between variability in eGFR and risk of mortality among a community based population.

Methods: We included 529,312 adults from a province-wide laboratory registry in Alberta, Canada between 2002-2008, who had at least 3 outpatient eGFR measurements over a 4 year accrual period. Variability in eGFR was defined using the coefficient of variation(CV) across measurements for each participant during the accrual period. Variability was categorized by quintile, with the lowest quintile representing patients with the least variability (referent) and increasing quintiles reflecting greater degrees of variability. Cox proportional hazard model (adjusting for baseline covariates, kidney function, proteinuria, and rate of change in eGFR over time) was used to estimate the HRs of all-cause mortality associated with increasing quintiles of variability, with follow-up to March 31 2009.

Results: Among the participants (mean age 55.6 years, 41.9% male) there were 32,372(6.1%) deaths over a median follow-up of 2.5 years. Compared with the referent (lowest quintile), patients in the highest quintile of eGFR variability had more than two-fold increased risk of death.

Figure 1 Association between Variability in eGFR and All-Cause Mortality



Increasing magnitude of eGFR variability was associated with an increased risk of death (trend $p=0.04$). Similar patterns were observed when results were stratified by stages of baseline kidney function levels.

Conclusions: Our results demonstrate an independent and graded association between variability in kidney function and mortality. These results suggest that overall variation in eGFR over time may be an important prognostic marker.

SA-PO193

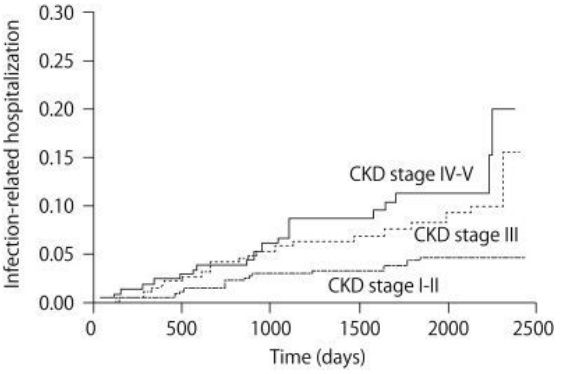
Renal Insufficiency, as Well as Diabetes Mellitus, Is a Risk Factor for Bacterial Infection

Tsutomu Inoue, Hirokazu Okada, Takahiko Sato, Tsuneo Takenaka, Hiromichi Suzuki. *Nephrology, Saitama Medical University, Iruma-gun, Saitama, Japan.*

Background: It has recently been shown that renal insufficiency is associated with increased morbidity from bacterial infections. The aim of this study was to evaluate the relative risk of renal insufficiency for bacterial infection in comparison with other known risk factors.

Methods: Nominal logistic regression analysis and a Cox proportional-hazards model were used for multivariate analysis. The event investigated was "bacterial infection making hospitalization necessary", and the investigation items consisted of age, diabetes mellitus, the use of statins and immunosuppressive agents, and several laboratory values. Subjects included all patients visiting our outpatient clinic between January and December 2005 for whom complete medical records were available for at least 3 years from 2005. Patients receiving renal replacement therapy were excluded.

Results: A total of 836 patients were surveyed. The mean period of observation was 4.87 ± 1.39 years. CKD stage 1-2 was observed in 36.1% of subjects in the infected group, and in 55.0% of those in the non-infected group. Nominal logistic regression analysis demonstrated that a CKD stage of 3 or more, the use of immunosuppressive agents, and diabetes mellitus were statistically significant risk factors for bacterial infection-related hospitalization, with relative risks (RR) of 2.533, 2.529, and 2.272, respectively. The RR for statin use was 0.475, and it appeared to decrease morbidity from bacterial infection-related hospitalization. A Cox proportional-hazards model also showed that advanced CKD stage was a statistically significant independent risk factor.



Conclusions: Renal insufficiency, the use of immunosuppressive agents, and diabetes mellitus were important risk factors for bacterial infection-related hospitalization, whereas the use of statins may be linked to a reduced risk.

SA-PO194

The Impact of Renal Dysfunction on Mortality after Coronary Artery Bypass Grafting Surgery in Contemporary Practice Piangwarin Phaosawasdi, Tonga Nfor, Kambiz Shetabi, Fengyi Shen, Molla Teshome, Samia Salih, Paul G. Jenkins. *Internal Medicine, Aurora Health Care, Milwaukee, WI.*

Background: Preoperative renal dysfunction (RD) has been known to affect outcomes following coronary artery bypass grafting (CABG) but with current advancements in medical care it is unclear how much impact it has. In this study we investigated the independent effect of RD on clinical outcomes in patients undergoing CABG.

Methods: We analyzed a retrospective cohort of 1036 patients who had CABG at a tertiary care center in 2009 and 2010. Multivariate logistic regression was used to assess the effect of RD on outcomes adjusting for demographics, baseline comorbidities and Society of Thoracic Surgeons (STS) surgical risk score.

Results: We categorized patients into CKD stage 1-5 based on their preoperative MDRD eGFR. The distribution was 16.4%, 48.2%, 28.6%, 4.7% and 2.1% for stage 1, 2, 3, 4/5 and chronic dialysis respectively. Table 1 shows 30-day and 1-year mortality by CKD stage. There was a progressive increase in mortality from CKD stage 1 to stage 4/5 and chronic dialysis, p for linear trend <0.001. In multivariate analysis the odds ratio of death increased with more advanced CKD. Days spent in the hospital and ICU were longer with worsening preoperative GFR. The need for post-CABG dialysis was 27.5% of CKD stage 4/5 compared to none in stage 1 patients. Actual 30-day mortality was nearly twice that of STS predicted mortality in stage 4-5 CKD (18.3% vs. 10.3% predicted) and dialysis patients (18.2% vs. 8.72% predicted).

CKD stage	stage 1	stage 2	stage 3	stage 4/5	Chronic dialysis	p
Patients	170	499	296	49	22	
30-day mortality	0.6 %	1.2 %	3.7 %	18.4 %	18.2 %	<0.001
OR (95% CI)	Ref	3.9 (0.2 to 5.6)	10.1 (0.4 to 13.6)	20.8(1.2 to 45.7)	32.2 (2.3 to 52.9)	
1-year mortality	2.9 %	2.4 %	8.4 %	28.6 %	45.5 %	<0.001
OR (95% CI)	Ref	1.0 (0.3 to 3.5)	2.47 (0.7 to 8.6)	7.4 (1.8 to 30.5)	14.6 (5.6 to 37.4)	
CKD chronic kidney disease; OR adjusted odds ratio compared to CKD stage 1 ; CI confidence interval						

Conclusions: Preoperative RD is a strong independent predictor of post-CABG mortality. STS score may underestimate mortality at tertiary care centers in patients with GFR < 30 ml/min.

SA-PO195

Extreme Low Blood Pressure *Is a Risk* for Cardiovascular Disease in the Japanese Population: The Gonryo Study Tae Yamamoto,[1] Mariko Miyazaki,[1] Masaaki Nakayama,[2] Toshinobu Sato,[3] Hiroshi Sato,[1] Sadayoshi Ito.[1] *[1]Tohoku University, Sendai, Japan; [2]Fukushima Medical University, Fukushima, Japan; [3]Sendai Shakaihoken Hospital, Sendai, Japan.*

Background: Controlled blood pressure in chronic kidney disease (CKD) is important to decrease a risk of developing *cardiovascular disease (*CVD). However, studies of lower blood pressure for predicting CVD risk in CKD is limited.

Methods: 2,656 CKD patients, the mean age 60 ± 16 years and males 53%, recruited from 11 outpatient nephrology hospitals and followed for two years. They were divided by systolic blood pressure (sBP) to 6 groups, <110 mmHg (group1, n=197), 110 to 119 (group2, n=360), 120 to 129 (group3, n=676), 130 to 139 (group4, n=687), 140 to 149 (group5, n=419) and ≥ 150 (group6, n=317), and group 2 used as reference. Risks of CVD incidence including events such as ischemic heart disease, congestive heart failure, brain disease and death due to CVD, as well as inducting renal replacement therapy (RRT) were examined.

Results: During the observation time, 170 patients progressed RRT and 95 patients occurred CVD events and CVD related death. The mean eGFR of all patients was 55.3 ± 29.5 ml/min and 74% were treated by anti-hypertensive drugs or/and diuretics. As expected, sBP correlated positively with age (ρ= 0.216, p<.0001), and negatively with eGFR (ρ= -0.174, p<.0001). RRT increased significantly in over 140 mmHg (group 5 and 6), while CVD incidence increased significantly in over 130 mmHg (group 4, 5 and 6) and also in under 110mmHg (group1) by logistic regression analysis. The significant high risks for CVD incidence remained in multivariate regression analysis adjusted for age, sex, diabetes, hemoglobin and eGFR levels. The relative risk was 5.36 with 95%CI (1.81 – 19.6) in group 1, 2.85 (1.09 – 9.76) in group 4, 2.83 (1.03 – 9.94) in group 5 and 2.83 (1.01 – 10.0) in group 6 compared to group 2.

Conclusions: We concluded that systolic blood pressure lower than 110 mmHg was an independent predictor of CVD, as well as the not fully controlled high blood pressure.

SA-PO196

Longitudinal Changes in Hematocrit in Hypertensive Chronic Kidney Disease Teresa K. Chen,[1] Michelle M. Estrella,[1] Brad C. Astor,[2] Tom Greene,[3] Xuelei Wang,[4] Lawrence J. Appel.[1] *[1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]University of Wisconsin School of Medicine, Madison, WI; [3]University of Utah School of Medicine, Salt Lake City, UT; [4]Case Western Reserve University School of Medicine, Cleveland, OH.*

Background: Anemia is common in chronic kidney disease (CKD) and is associated with worse outcomes. In cross-sectional studies, lower estimated glomerular filtration rates (eGFR) have been associated with higher prevalence of anemia; however, how hematocrit changes as eGFR declines and what factors impact this longitudinal association are unclear.

Methods: We used mixed-effects models to analyze 12 years of follow-up data from 1094 African-Americans with hypertensive CKD in the African-American Study of Kidney Disease and Hypertension (AASK). Primary exposure was annual eGFR; primary outcome was change in hematocrit. Covariates included gender, age at randomization, baseline eGFR, baseline proteinuria and randomized drug group.

Results: At baseline, mean hematocrit was 39%, and 441 (40%) individuals had anemia (hematocrit <40.5% for men; <36% for women). In longitudinal analyses, hematocrit decline per 10 ml/min/1.73 m² decline in eGFR was steeper for eGFR values <40 than ≥40 ml/min/1.73 m² (-2.2% versus -0.2%, respectively; p<0.01). For an eGFR less than 40 ml/min/1.73 m², there was a greater decrease in hematocrit per unit change in eGFR among those who were male (p-interaction=0.02), had baseline proteinuria (p-interaction=0.006) or were randomized to receive ramipril (p-interaction=0.04).

Table 1: Longitudinal analyses of change in hematocrit per change in eGFR, by gender, baseline proteinuria, and randomized drug group

	Subgroup	Absolute change in Hct (%) per 10 ml/min/1.73 m² decline in eGFR	95% CI	p-interaction
Time-Varying eGFR	**Gender***			
<40 ml/min/1.73 m²	Male	-2.4	(-2.6, -2.1)	0.02
	Female	-2.0	(-2.2, -1.7)	
≥40 ml/min/1.73 m²	Male	-0.3	(-0.5, -0.1)	0.05
	Female	-0.03	(-0.2, 0.2)	
Time-Varying eGFR	**Baseline Proteinuria***			
<40 ml/min/1.73 m²	No	-2.0	(-2.2, -1.7)	0.006
	Yes	-2.5	(-2.8, -2.2)	
≥40 ml/min/1.73 m²	No	-0.2	(-0.3, -0.1)	0.82
	Yes	-0.2	(-0.6, 0.1)	
Time-Varying eGFR	**Randomized Drug***			
<40 ml/min/1.73 m²	Ramipril	-2.5	(-2.8, -2.2)	0.04
	Metoprolol	-2.1	(-2.4, -1.8)	
≥40 ml/min/1.73 m²	Ramipril	-0.2	(-0.4, -0.003)	0.60
	Metoprolol	-0.2	(-0.4, -0.05)	

Each model was adjusted for age at randomization, gender, baseline proteinuria (defined as urine protein-to-creatinine ratio greater than 0.22), baseline eGFR, and time; Abbreviations: eGFR, estimated glomerular filtration rate; Hct, hematocrit; CI, confidence interval.
*From baseline to end of cohort phase; ^From baseline to end of trial phase.

Conclusions: Hematocrit decreases as eGFR declines, more so when eGFR falls below 40 ml/min/1.73 m² particularly in men, persons with baseline proteinuria and those assigned to ACE-inhibitors. Results suggest that anemia screening should be more individualized, with more intensive and frequent testing in these subgroups of patients with CKD.

SA-PO197

Association of Serum Bicarbonate with Risk of Renal and Cardiovascular Outcomes in Chronic Kidney Disease: A Report from the Chronic Renal Insufficiency Cohort (CRIC) Study Mirela A. Dobre,[1] Wei (Peter) Yang,[2] Jing Chen,[2] Paul E. Drawz,[1] L. Lee Hamm,[2] Edward J. Horwitz,[1] Thomas H. Hostetter,[1] Bernard G. Jaar,[2] Claudia M. Lora,[2] Lisa C. Nessel,[2] Akinlolu O. Ojo,[2] Julia J. Scialla,[2] Susan P. Steigerwalt,[2] Valerie L. Teal,[2] Myles S. Wolf,[2] Mahboob Rahman.[1] *[1]Case Western Reserve University; [2]CRIC Study Group.*

Background: The purpose of this study is to evaluate serum bicarbonate as a risk factor for renal outcomes, cardiovascular events and mortality in patients with chronic kidney disease (CKD).

Methods: Data from a prospective study of 3939 participants with CKD stages 2-4 who enrolled in the Chronic Renal Insufficiency Cohort (CRIC) between June 2003-December 2008 was analyzed. Renal outcomes were defined as end-stage renal disease (either initiation of dialysis or kidney transplant) or a 50% decline in eGFR. Adverse cardiovascular events were defined as myocardial infarction, congestive heart failure, stroke or peripheral arterial disease. Multivariable Cox proportional hazards models including serum bicarbonate modeled with linear splines were used to test the association between baseline serum bicarbonate and clinical outcomes.

Results: The mean (SD) eGFR was 42.8 (13.5)mL/min/1.73m^2, and the median serum bicarbonate was 24 mmol/L (interquartile range 22-26 mmol/L). During a median follow-up of 3.9 years, 374 patients died, 762 had a renal outcome, and 604 experienced a cardiovascular event. In adjusted analyses, the risk of developing a renal endpoint was 3% higher per 1mmol/L decrease in serum bicarbonate (hazard ratio [HR] 1.03; 95% confidence interval [CI], 1.01-1.06, p=0.01). The risk of adverse cardiovascular outcomes increased by 10%(HR 1.10, 95%CI 1.01-1.19) per 1mmol/L increase in serum bicarbonate over 24 mmol/L (p=0.03). Serum bicarbonate was not independently associated with all-cause mortality (HR 0.97;95%CI 0.93-1.00, p=0.08).

Conclusions: In a cohort of patients with CKD stages 2 to 4, low serum bicarbonate was an independent risk factor for renal disease progression. The risk of cardiovascular events was higher at the upper and lower extremes of serum bicarbonate. There was no significant association between serum bicarbonate and all-cause mortality.

Association of Serum Bicarbonate Level with Incident Functional Limitation

Robert H. Yenchek,[1] Joachim H. Ix,[2] Dena E. Rifkin,[2] Kushang Patel,[3] Mark J. Sarnak,[4] Michael Shlipak,[5] Melissa Garcia,[6] Suzanne Satterfield,[7] Tamara Harris,[6] Anne B. Newman,[1] Linda F. Fried.[8,1] *[1]Univ. of Pittsburgh, Pittsburgh, PA; [2]San Diego VA and UCSD, San Diego, CA; [3]Univ. of Washington, Seattle, WA; [4]Tufts Univ. Medical Center, Boston, MA; [5]San Francisco VA and UCSF, San Francisco, CA; [6]NIA/NIH, Bethesda, MD; [7]Univ. of Tennessee Health Science Center, Memphis, TN; [8]VAPHS, Pittsburgh, PA.*

Background: Cross-sectional studies have found that low serum bicarbonate (HCO_3) is associated with slower gait speed and quadriceps strength. CKD patients are at increased risk of functional impairment and acidosis.Whether HCO_3 levels independently predict the development of functional impairment has not been previously studied.

Methods: We assessed whether HCO_3 levels predicted incident lower extremity functional limitation in the Health, Aging and Body Composition Study, a cohort study of older individuals without functional limitation at baseline. HCO_3 levels were measured using arterialized venous blood gas. CKD was defined as eGFR < 60 ml/min/1.73m^2 using the CKD-EPI formula and functional limitation as difficulty walking 1/4 mile or climbing 10 steps on 2 consecutive reports in the same domain, 6 months apart.

Results: Of the 1634 individuals with complete data, the mean age was 75.5, 52% male, 25% Black, 14% CKD; 501 developed functional limitation over a median 4.4 yrs. Individuals with low HCO_3 (<23 meq/L, 9.7%) were more likely to be diabetic and have CKD and less likely to be on diuretics. Analyzed as a continuous variable with Cox proportional hazards analysis, each 1 meq/L lower HCO3 was associated with a 6% higher risk of functional impairment (HR 1.06 95% CI 1.02, 1.11, p=0.006), adjusting for age, race, sex, eGFR, BMI, blood pressure, smoking, obstructive lung disease, diabetes and gait speed. Categorized as < 23,≥ 23 meq/L, there was a CKD*HCO3 interaction (p=0.049) with an adjusted HR in CKD of 2.02 (1.23, 3.34) vs. 1.07 (0.74, 1.53) in individuals without CKD.

Conclusions: Low HCO_3 levels are associated with an increased risk of functional impairment, with a stronger relationship in CKD. Whether or not HCO_3 therapy decreases the risk of functional impairment requires further study.

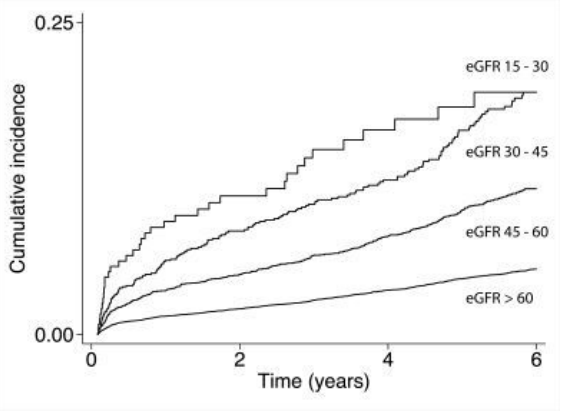
Renal Dysfunction and Long-Term Risk of Ischemic and Hemorrhagic Stroke Following Coronary Artery Bypass Grafting

Martin Holzmann,[1] Anders Jeppsson,[2] Ulrik Sartipy.[1] *[1]Karolinska Institutet, Stockholm, Sweden; [2]Sahlgrenska Academy, Gothenburg, Sweden.*

Background: Renal dysfunction is associated with increased long-term mortality and incidence of myocardial infarction following coronary artery bypass grafting (CABG). There is little information on the relationship between renal dysfunction and long-term risk of stroke following CABG.

Methods: All 29 602 patients who underwent primary isolated CABG 2000 to 2008 in Sweden, with no myocardial infarction within 14 days before surgery and no prior stroke were included from the SWEDEHEART registry. Cox proprotional hazards regression was used to calculate hazard ratios for first hospitalization for ischemic, hemorrhagic or unspecified stroke.

Results: During 4 years of follow-up there were 2836 (76%) ischemic, 300 (8%) hemorrhagic and 598 (16%) unspecified strokes. Glomerular filtration rates (eGFR) were estimated using the MDRD study equation and hazard ratios (HR) with 95 % confidence intervals (CI) were calculated for stroke. Adjusted HR with 95% CI for all stroke among patients with eGFR 45 to 60, 30 to 45 and 15 to 30 mL/min/1.73 m^2 were; 1.16 (1.02 to 1.32), 1.49 (1.22 to 1.81) and 1.72, (1.16 to 2.56), respectively, compared to patients with eGFR > 60 mL/min/1.73 m^2. Similar associations were find for ischemic and hemorrhagic stroke. There was a stronger relationship between eGFR 15 to 45 mL/min/1.73 m^2 and stroke for women than for men. The relative risk for stroke associated with renal dysfunction was smaller for elderly patients compared to younger patients. The cumulative incidence of all stroke increased gradually with decreasing eGFR during follow-up (Figure1).



Conclusions: Renal dysfunction is a long-term predictor of both ischemic and hemorrhagic stroke after primary isolated CABG both among men and women. The impact of renal dysfunction on risk for all stroke is greater for younger than for older patients.

Renal Artery Calcium, Cardiovascular Risk Factors and Renal Function

D. A. Roseman,[1] Shih-Jen Hwang,[2] Emily S. Manders,[2] Udo Hoffmann,[3] Caroline S. Fox.[2] *[1]Nephrology Division, Boston University Medical Center, Boston, MA; [2]National Heart, Lung, and Blood Institute Framingham Heart Study, Framingham, MA; [3]Cardiology Division, Massachusetts General Hospital, Boston, MA.*

Background: Observational studies show an association between atherosclerotic renovascular disease and coronary artery disease. Recent data suggests renal artery calcium (RAC) is associated with hypertension above and beyond traditional cardiovascular disease (CVD) risk factors. However, limited data exists focusing on the association of RAC, CVD risk factors and measures of renal function.

Methods: We examined 2618 Framingham Heart Study participants (mean age 60.3 years, 50.7% women) who were part of the multidetector computed tomography substudy (2008 to 2011). We applied a multivariable logistic regression model to evaluate the associations between RAC, CVD risk factors and renal function. Risk factors included age, sex, BMI, smoking, hypertension, diabetes, triglycerides, HDL cholesterol, total cholesterol, chronic kidney disease (CKD), and microalbuminuria. RAC was defined as an Agatston score greater than zero. CKD was defined as an eGFR less than 60mL/min/1.73m^2. Microalbuminuria was defined as ACR ≥17mg/g in men and ≥25mg/g in women.

Results: The prevalence of RAC was 28.8% in the study population and was similar in women (29.3%) and men (28.2%). RAC was associated with age (OR=4.1, 95% CI 3.6-4.7, p=<0.001), BMI (OR=1.1, 95% CI 1.0-1.3, p=0.03), smoking (OR=2.5, 95% CI 1.6-3.7, p=<0.001), hypertension (OR=2.2, 95% CI 1.7-2.8, p=<0.001), and microalbuminuria (OR=1.9, 95% CI 1.3-2.8, p=0.002). Results of the logistic regression model showed that individuals with RAC have a higher risk of hypertension (OR=2.1, 95% CI 1.7-2.7, p=<0.001), diabetes (OR=1.6, 95% CI 1.2-2.3, p=0.004), and microalbuminuria (OR=1.9, 95% CI 1.3-2.8, p=<0.001). The association between RAC and CKD was not statistically significant (OR=0.9, 95% CI 0.6-1.4, p=0.58).

Conclusions: RAC is associated with hypertension, diabetes, and microalbuminuria but not CKD. The prevalence of RAC increases with age and may be a marker of increased cardiovascular disease.

Cardiac Geometry Is Associated with Kidney Function and Markers of Inflammation: Findings from the Chronic Renal Insufficiency Cohort (CRIC) Study

Jayanta Gupta,[1] Shari T.S. Lewis,[2] Muredach Reilly,[1] Wei (Peter) Yang,[1] Ashte K. Collins,[2] Raymond R. Townsend,[1] Marshall M. Joffe,[1] Vaidyanathapura S. Balakrishnan,[5] Sylvia E. Rosas,[1] Jeffrey C. Fink,[4] Melanie Glenn,[1] Martin Keane,[1] Harold I. Feldman,[1] John W. Kusek,[3] Dominic S. Raj.[2] *[1]University of Pennsylvania; [2]George Washington University; [3]NIDDK; [4]University of Maryland; [5]Tufts Medical Center.*

Background: Left ventricular hypertrophy (LVH) is highly prevalent in patients with chronic kidney disease (CKD) and is an important predictor of mortality. We examined the relationship between biomarkers of inflammation and LVH in 3939 CRIC study participants with varying levels of kidney function.

Methods: Baseline serum/plasma levels of inflammatory cytokines (IL-6, IL-1RA, IL-1β, TNF-α and TGF-β) and acute-phase proteins (hs-CRP, fibrinogen and albumin), and baseline echocardiographic findings were used for this analysis. LVH was defined as LV mass index (LVMI) ≥103 g/m^2 for men and ≥89 g/m^2 for women. Associations between log-transformed values of individual biomarkers and LVMI (continuous) and LVH (binary) were investigated using linear and logistic regression models adjusted for age, sex, race/ethnicity, smoking status, diabetic status, blood pressure and albuminuria.

Results: LVH was present in 57.2% of subjects. eGFR was negatively associated with LVMI [coefficient β = -0.28 (95% Confidence Limits -0.35, -0.22), p < 0.0001] and LVH [Odds Ratio (OR) = 0.98 (0.97, 0.99), p < 0.0001]. Among biomarkers, IL-6, IL-1β and TNF-α were positively associated with LVMI [β = 1.71 (0.74, 2.70), p = 0.005; β = 0.21 (0.06, 0.35), p = 0.04 and β = 2.0 (0.8, 3.24), p = 0.01 respectively], whereas the association of serum albumin with LVMI was in the opposite direction [β = –17.30 (–25.05, –9.54), p < 0.0001]. Serum albumin was also negatively associated with LVH [OR = 0.29 (0.13, 0.62), p = 0.01].

Conclusions: In patients with CKD, inflammation was positively associated with LVMI and decreased kidney function with LVMI and LVH. Each 10 percent decrease in serum albumin was associated with 1.7 unit increase in LVMI.

Predictors of Subclinical Myocardial Injury in Chronic Kidney Disease Patients: The Chronic Renal Insufficiency Cohort Ruth F. Dubin,[1,2] Alan S. Go,[3] Martin Keane,[4] Christopher deFilippi,[5] Rakesh Mishra,[2] Myles S. Wolf,[6] Michael Shlipak.[2] *[1]Nephrology, University of California San Francisco, San Francisco, CA; [2]Medicine, San Francisco VAMC, San Francisco, CA; [3]Clinical Research, Kaiser Permanente, Oakland, CA; [4]Cardiology, University of Pennsylvania, Philadelphia, PA; [5]Cardiology, University of Maryland Medical Center, Baltimore, MD; [6]Nephrology, University of Miami, Miami, FL.*

Background: Chronic kidney disease (CKD) is a strong, independent risk factor for cardiovascular disease (CVD). Predictors of subclinical myocardial injury, as measured by highly sensitive cardiac troponin T (hs-TnT), have not been previously identified in a CKD cohort. We hypothesized that cystatin-based estimated glomerular filtration (eGFRcys) and urine albumin-creatinine ratio (ACR) would be independently associated with higher hs-TnT.

Methods: We evaluated cross-sectionally the associations of renal and non-renal factors with hs-TnT in 2464 participants without self-reported CVD in the multi-ethnic Chronic Renal Insufficiency Cohort (CRIC). Predictors of log hs-TnT were investigated using multivariable tobit regression, and coefficients were exponentiated to yield percentage effects of expected hs-TnT attributable to each predictor.

Results: Hs-TnT was detectable in 81% of subjects, and the median (IQR) hs-TnT was 9.4 pg/ml (4.3-18.3.) After multivariable adjustment lower eGFRcys was associated with higher expected hs-TnT; participants with eGFRcys<30 ml/min/1.73m^2 had 200% higher expected hs-TnT compared to subjects with eGFRcys>60. Compared to those with ACR<30 mg/g, subjects with ACR>1000 had 50% higher expected hs-TnT. In contrast, hemoglobin was not independently associated with hs-TnT. Independent of the renal predictors, older age, male gender, black race, diabetes, higher blood pressure, LV mass index≥100 g/m$^{2.7}$ and EF≤35% were all associated with higher expected hs-TnT.

Conclusions: Among CRIC participants without CVD, eGFRcys, ACR, age, male gender, black race, diabetes, higher blood pressure, LV mass index and ejection fraction were independently associated with higher hs-TnT.

Clinical Outcomes in Patients Admitted with Acute Myocardial Infraction and Chronic Kidney Disease in an Australian Setting Sradha S. Kotwal, Isuru Ranasinghe, Alan Cass, Martin P. Gallagher. *Renal and Metabolic Division, The George Institute for Global Health, Sydney, NSW, Australia.*

Background: International data suggests patients with CKD have a higher morbidity and mortality following AMI and are less likely to receive revascularisation. However, the impact of CKD on longer term clinical outcomes and health resource usage remains unclear.

Methods: New South Wales (NSW) is Australia's most populous state with an estimated population of 7.2 milllion, representing 32.3% of the total Australian population. The NSW admitted patient data collection (NSW APDC) is an administrative coding dataset collecting data on all admissions to NSW hospitals. Coding uses the International Classification of Disease 10 Australian Modification (ICD10 AM). All patients admitted to a NSW hospital with a principle diagnosis of AMI (ICD10 codes: I21.0-I21.3 and I21.4) between 2004 and 2008 were extracted from NSW APDC and linked to the NSW Registry of Births Deaths and Marriages. We analysed outcomes of 30 day, 1 year and medium term (median follow up) all cause mortality, length of stay (LOS) and revascularisation crude rates based on the presence or absence of a diagnostic code of CKD (N18, N19, Z49).

Results: A total of 40,482 patients with AMI were analysed, including 1565 with a CKD code, to a median follow up 3.5 years. Unadjusted analyses of patients coded as having CKD showed higher 30 day mortality (15% versus 7%, p<0.001), 1 year mortality (40% versus 14.5%, p<0.001), 3.5 year mortality (67% versus 25%, p<0.001), LOS (mean 10.4 days versus 7.5 days, p < 0.001) and lower revascularisation rates (14% versus 35%, p< 0.001) compared to those without a CKD code.

Conclusions: Patients admitted to NSW hospitals with an AMI and coding history of CKD have lower rates of intervention, despite, significantly higher mortality and length of stay. CKD coding was used infrequently and further research is required to explore the utilisation of CKD diagnostic codes and the poorer outcomes they portend.

SA-PO204

Association of Metabolic Syndrome and Renal Insufficiency with Clinical Outcome in Acute Myocardial Infarction Chang Seong Kim,[1] Joon Seok Choi,[1] Eun Hui Bae,[1] Seong Kwon Ma,[1] Soo Wan Kim.[1] *[1]Department of Internal Medicine, Chonnam National University Hospital, Gwangju, Republic of Korea; [2]Department of Physiology, Chonnam National University Hospital, Gwangju, Republic of Korea.*

Background: Metabolic syndrome (MS) is an independent risk factor for chronic kidney and cardiovascular diseases. However, few studies have examined the combined effects of MS and renal insufficiency after acute myocardial infarction (AMI). We examined the effect of MS on clinical outcomes in patients with AMI in the presence or absence of renal insufficiency.

Methods: From November 2005 to September 2008, 11,462 patients with AMI were enrolled in the prospective Korean Acute Myocardial Infarction Registry. Participants were analyzed according to presence or absence of MS and renal insufficiency, defined by a low estimated glomerular filtration rate (eGFR). The primary endpoints were major adverse cardiac events (MACE), including a composite of all cause-of-death, myocardial infarction, target lesion revascularization, and coronary artery bypass graft during the 1-year follow-up period.

Results: MS was higher in AMI patients with lower eGFR. In-hospital death and primary endpoints at 1-month were significantly higher in MS than in non-MS, regardless of renal insufficiency. However, composite MACE scores at 1-year were significantly higher only in those with MS and renal insufficiency. Multivariate analysis showed that old age, multi-vessel involvement, high levels of inflammation, diabetes and MS were associated with 1-year composite MACE in renal insufficiency. After adjusting for multiple covariates, the 1-year mortality rate was higher in MS with renal insufficiency than in MS without renal insufficiency, or in non-MS.

Conclusions: MS is associated with poor clinical outcomes and increases the mortality in patients with AMI, especially in association with renal insufficiency.

SA-PO205

Insulin Resistance Is Not Related to Development of Renal or Atherosclerotic Cardiovascular Outcomes or Death in Non-Diabetic Chronic Kidney Disease: Findings from the Chronic Renal Insufficiency Cohort (CRIC) Study Amanda Hyre Anderson,[1,4] Wei (Peter) Yang,[1,4] Raymond R. Townsend,[1,4] Jing Chen,[2,4] L. Lee Hamm,[2,4] Bruce M. Robinson,[3,4] Harold I. Feldman.[1,4] *[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]Tulane University School of Public Health and Tropical Medicine, New Orleans, LA; [3]Arbor Research Collaborative for Health, Ann Arbor, MI; [4]Chronic Renal Insufficiency Cohort (CRIC) Study Group.*

Background: Metabolic and inflammatory abnormalities including insulin resistance are common in chronic kidney disease (CKD), but their relationships to CKD progression, cardiovascular disease (CVD), and death in this setting remain unclear.

Methods: Data from a subset of CRIC Study participants with non-diabetic CKD (N=1,742, average follow-up 4 years) were used in Cox proportional hazards models to examine the association of homeostasis model assessment-estimated insulin resistance (HOMA-IR) and the risk of halving of estimated glomerular filtration rate (eGFR) or ESRD (Renal1), atherosclerotic CVD (ASCVD; myocardial infarction, stroke, peripheral arterial disease), and death with adjustment for demographics, anthropometrics, comorbidities, and health-related factors.

Results: Median (interquartile range) HOMA-IR was 3.1 (2.1-4.5). Mean (standard deviation) eGFR was 48.4 (17.8) mL/min/1.73m^2. Crude event rates for Renal1, ASCVD, death, and ASCVD plus death were 36, 15, 16, and 30 per 1000 person-years, respectively. HOMA-IR, whether examined continuously on the log scale or across quartiles, was not associated with any examined outcome (each P value > 0.2) in unadjusted or adjusted models, with and without additional adjustment for level of high-sensitivity C-reactive protein.

Conclusions: Previously reported associations of insulin resistance with renal/ASCVD events and death were not detectable in this study of individuals with reduced levels of kidney function. Variation in effects by level of eGFR merits further study.

Oral Disease in People with Chronic Kidney Disease: A Systematic Review and Meta-Analysis of Cohort Studies Suetonia Palmer,[1] Marinella Ruospo,[2] Mariacristina Vecchio,[3] Letizia Gargano,[2] Fabio Pellegrini,[3] Giovanni F.M. Strippoli.[2,3,4] *[1]University of Otago; [2]Diaverum Medical Scientific Office; [3]Mario Negri Sud Consortium; [4]University of Sydney.*

Background: Oral disease includes a wide spectrum of clinical abnormalities affecting the mouth including mucosa, teeth, periodontal tissue and salivary function. While observational data for oral and dental diseases are available in people with chronic kidney disease (CKD), existing published information has not yet been systematically evaluated. We aimed to summarize the overall prevalence of oral diseases in people with CKD and explore associations between oral disease and mortality in this clinical setting.

Methods: We conducted a systematic review and meta-analysis of observational studies reporting prevalence or clinical outcomes of oral disease in people with CKD. English-language studies were identified from systematic searching MEDLINE through April 2010. Multiple reviewers extracted details on participant characteristics, tools used to measure

oral disease, details of statistical analyses including adjustments for confounding. Estimates of prevalence, mean score, or risk of mortality were summarized using random-effects meta-analysis and expressed as rates or means and 95% confidence intervals (CI). Effects of severity of CKD on estimates were analyzed using subgroup analysis.

Results: 112 studies (150 cohorts) including 18 339 people with CKD and 16 310 controls were analyzed. 103 cohorts were in people on dialysis, 22 cohorts were in earlier stages of CKD and 25 cohorts were in kidney transplant recipients (15.6%). The mean decay/missing/filled teeth (DMFT) index in people with CKD was 13.7 and number of teeth was 19.4. Nearly 40% of people with CKD had enamel hypoplasia and over half had periodontitis. Overall, the mean plaque index was 1.62 and periodontal pocket depth (PPD) was 2.30 mm. Approximately 25% of people with CKD reported never brushing.

Conclusions: Data evaluating the prevalence and severity of oral disease in people with CKD are sparse and incomplete. Large longitudinal studies of the prevalence and clinical associations with oral disease in CKD are now needed.

SA-PO207

Meta-Analysis: Effects of Targets for Serum Phosphorus, Parathyroid Hormone and Calcium on Mortality in Chronic Kidney Suetonia Palmer,[1] Valeria Maria Saglimbene,[2] Jonathan C. Craig,[3] Mariacristina Vecchio,[2] Marinella Ruospo,[4] Giovanni F.M. Strippoli.[2,3,4] *[1]University of Otago; [2]Consorzio Mario Negri Sud; [3]University of Sydney; [4]Diaverum Medical Scientific Office.*

Background: International treatment guidelines suggest achieving target levels of serum phosphorus, parathyroid hormone (PTH) and calcium in people with chronic kidney disease (CKD). We evaluated the evidence that specifically targeted biomarker levels (phosphorus,parathyroid hormone, and calcium) improved clinical outcomes in people with CKD.

Methods: We conducted a systematic review of randomized controlled trials (RCT) that reported achievement of serum targets for phosphorus, PTH, and calcium in adults with CKD and that reported clinical outcomes (mortality, fracture, kidney function, and withdrawal due to treatment toxicity). We systematically searched Cochrane and Embase databases. We included RCT of interventions that reported biochemical for phosphorus, PTH, and calcium at study end. We summarized the effects of specific biochemical targets on specified outcomes using random-effects models.

We also summarized the non-randomized associations between the proportion of participants achieving biomarker targets and clinical outcomes using two-dimensional arrow plots. Subgroup and meta-regression analyses to evaluate the effects of patient and intervention characteristics on treatment effects were not possible due to insufficient data.

Results: We included 158 trials (24,965 people) evaluating interventions on serum biomarker values. No consistent associations between the proportion of participants achieving a biomarker target and clinical outcomes were observed. No consistent associations between biomarker values at study end and clinical outcomes were observed. An increasing proportion of participants achieving a serum PTH target with treatment was not consistently associated with lower mortality but may be associated with increased withdrawal from treatment due to adverse events.

Conclusions: Targeting specific levels of phosphorus, PTH, and calcium is not consistently associated with improved clinical outcomes in adults with CKD, but may be associated with treatment-related toxicity.

SA-PO208

Are Statin Effects Different Based on Stage of Chronic Kidney Disease: A Meta-Analysis Suetonia Palmer,[1] Jonathan C. Craig,[2] Sankar D. Navaneethan,[3] Marcello Tonelli,[4] Fabio Pellegrini,[5] Giovanni F.M. Strippoli.[2,5,6] *[1]University of Otago; [2]University of Sydney SPH; [3]Cleveland Clinic; [4]University of Alberta; [5]Consorzio Mario Negri Sud; [6]Diaverum Medical Office.*

Background: Cardiovascular events are the most frequent cause of death in people with chronic kidney disease (CKD). Statins lower cardiovascular events. Benefits of statins may depend on severity of CKD. Individual randomized trials may have insufficient power to determine treatment effects according to stage of CKD. We summarize the effects of statins on mortality, major cardiovascular events, and toxicity based upon stage of CKD.

Methods: We conducted a systematic review and meta-analysis of randomized controlled trials including adults with CKD and that compared statins with placebo or no treatment. We systematically searched Cochrane and EMBASE databases. Two reviewers extracted details on participant characteristics, interventions, and risk of bias. We summarized treatment effects on mortality, major cardiovascular events, and withdrawal of treatment using a random-effects model and explored the effects of stage of CKD on treatment effects using subgroup analysis.

Results: 80 trials (51 099 participants) included 48 comparisons with earlier stages of CKD, 21 comparisons on dialysis and 17 in kidney transplant recipients. Statin treatment reduced death in people with earlier stages of CKD (relative risk [RR] 0.81 [CI 0.74-0.88]), but had little effect in people on dialysis (RR 0.96 [0.88-1.04]) and uncertain effects in kidney transplant recipients (RR 1.05 [0.84-1.31]). Treatment effects of statins on major cardiovascular events also differed significantly based on stage of CKD. Statins prevented major cardiovascular events in people with earlier stages of CKD (RR 0.76 [0.73-0.80]), but had little effect in people on dialysis (RR 0.95 [0.87-1.03]) and were uncertain in transplant recipients (RR 0.84 [0.66-1.06]). Statins had little or no effect on risks of withdrawal from therapy.

Conclusions: Statins lower mortality and major cardiovascular events in people with CKD not yet on dialysis but have little effect in people on dialysis and efficacy is uncertain in kidney transplant recipients.

SA-PO209

Association between Diabetes, se-iPTH, Bone Disease and Vascular Calcification in Patients with ESRD Csaba Ambrus, Zoltan Kiss, Andras Szabo, Dr.szegedi János, Jozsef Balla, Marietta Török, Erzsebet Ladanyi, Botond Csiky, Otto Arkossy, Sándor Túri, Imre Kulcsar, Istvan Kiss. *CKD-MBD Working Group, Hungarian Society of Nephrology, Budapest, Hungary.*

Background: The association between diabetes and bone disease is still debated in the general population. However, in patients with ESRD, both relative hypoparathyroidism and low bone turnover have been associated with the presence of diabetes. If this association is mediated by PTH or diabetes has an independent effect on bone is not clear. We aimed to analyze this relationship in a large cohort of ESRD patients in Hungary.

Methods: In a country-wide, retrospective, cross-sectional survey, data was collected from 5334 patients. In addition, information about the presence of bone abnormality (BA) and soft tissue calcification (STC) were collected, both defined as abnormality detected on X-ray. Data are reported as mean±SD or median; interquartile range, as appropriate.

Results: Data from 5008 patients were eligible for analysis. Patients with diabetes were older (66±12 vs 62±15, p<0.001), had higher BMI (28.9±5.9 vs 25.5±5.3, p<0.001) and had lower PTH (151;230 vs 194;327pg/ml, p<0.001). Diabetes and PTH were highly correlated. In a multivariate model, this association was independent from age, gender, BMI, albumin and treatment modality. The odds ratio for PTH<150pg/ml in diabetes was 1.486 (95%CI 1.310-1.686).

BA and STC were more prevalent in diabetes (42.2% vs 36.9% (p<0.001) for BA and 56.1% vs 48.1% (p<0.001) for STC). The relationship between PTH and the prevalence of BA followed a U-shaped curve in both subgroups (46.2%, 33%, 40.9% vs 38.4%, 29.2%, 44.9% for PTH groups and DM vs non-DM groups, respectively). While similar U-shaped association was found between PTH and STC in patients without diabetes (48.3%, 44.1%, 55%), the prevalence of STC was not different between PTH levels in patients with diabetes.

Conclusions: In this large cross sectional cohort we confirmed that bone disease and soft tissue calcification are highly related and share common risk factors in patients with ESRD. Diabetes seems to have a distinct effect on bone independent from PTH.

SA-PO210

The Association between Parathyroid Hormone Levels and Hemoglobin in Diabetic and Non-Diabetic Participants in the National Kidney Foundation-Kidney Early Evaluation Program (KEEP) Imran A. Memon,[1] Carmen A. Peralta,[3] Suying Li,[7] Claudine T. Jurkovitz,[5] Peter A. McCullough,[6] Shu-cheng Chen,[7] Andrew S. Bomback,[4] Georges Saab.[2] *[1]University of Michigan, Ann Arbor; [2]Metrohealth Cleveland; [3]University of California, San Francisco; [4]Columbia University, New York; [5]Christiana Care Health System; [6]St. John Providence Health System; [7]Chronic Disease Research Group.*

Background: Parathyroid Hormone (PTH) has been speculated to contribute to anemia of chronic kidney disease.

Methods: The relationship between PTH and hemoglobin (Hgb) levels was investigated in 10,770 participants in the Kidney Early Evaluation Program with estimated GFR (eGFR) < 60 ml/min/1.73m^2.Multivariate linear regression was used to examine the effect of increasing iPTH on Hgb. Multiplicative interaction terms were generated to evaluate for effect modification of diabetes (DM).

Results: The mean age of the participants was 70.7 years and 32.4% were male. The majority were white (68.7%), followed by blacks (22%) and other races (9.3%). 47.3% had DM while the mean eGFR was 47.4 ml/min/1.73m^2. In unadjusted analysis, higher PTH levels were associated with lower Hgb levels. However, after multivariate adjustment for age, race, gender, smoking status, education, cardiovascular disease, hypertension, cancer, albuminuria, BMI, baseline eGFR, calcium and phosphorus, the direction of association changed. That is, higher PTH levels were associated with higher hemoglobin levels. Furthermore, significant effect modification for DM was seen (p for interaction = 0.0003). Among those with DM, each standard deviation increase in natural log transformed PTH was associated with a 0.10 (95% CI: 0.054-0.138, p <0.0001) g/dl in increase Hgb, while no association was seen among those without DM. Similarly, among those with DM, as compared to the first PTH quartile, Hgb levels were 0.15 mg/dl (95% CI 0.03-0.26), 0.22 mg/dl (95% CI 0.1-0.33) and 0.28 mg/dl (95% CI 0.16-0.41) higher for the second, third and fourth quartile respectively while no association was seen among those without DM.

Conclusions: There is a small positive association between iPTH and Hgb among diabetics but not non-diabetics.

SA-PO211

Bisphenol A Exposure and Low-Grade Urinary Albumin Excretion in US Children Howard Trachtman, Leonardo Trasande. *Pediatrics, NYU Langone Medical Center, New York, NY.*

Background: Bisphenol A (BPA) is an industrial chemical used in an array of consumer products with a consequent exposure to humans. In a recent study of 3,055 Chinese adults in the Shanghai area aged ≥40 years, urinary BPA was an independent determinant of the urinary albumin:creatinine ratio (ACR). There was a significantly increased risk of low-grade albuminuria with an adjusted odds ratio of 1.23 for the highest compared to the lowest BPA concentration quartiles. It is unknown whether there is a relation between BPA exposure and low-grade albuminuria in pediatric patients.

Methods: A cross-sectional study of a nationally representative sample of US children, the National Health and Nutrition Examination Survey (NHANES) data collected during 2009-2010, was performed. Patient gender, race/ethnicity, BMI, BP, cholesterol, and

HOMA-IR (in a subsample) were recorded. Patients were included if they had low grade albuminuria defined as an ACR <30 mg/g and had a measurement of BPA excretion. ACR and BPA excretion were determined using standard methods. Multivariate regression analysis was performed to determine the relationship betwen BPA excretion and ACR.

Results: In the total cohort of 10,253 children and adolescents (range 6-19 yr), 667 participants had determination of both ACR and BPA excretion. The mean age was 12±4 yr with 355 M and 312 F. The racial distribution was 34% White, 19% Black, 39% Hispanic/Mexican, and 8% other. The mean ACR was 1.87±0.58 mg/g and BPA excretion 3.83±10.9 ng/mL. After controlling for age, gender, BMI category, socioeconomic status, presence of prehypertension, hypercholesterolemia, urinary cotinine excretion, urinary concentration, and insulin resistance, patients in the highest quartile of BPA excretion had an increment in the ACR of 1.19 mg/g, a 23% difference *versus* those in the lowest quartile (P<0.03).

Conclusions: These findings suggest that, similar to adults, exposure to BPA independently increases low grade urinary albumin excretion in pediatric patients. These observations support efforts to limit exposure to this chemical from early childhood. Further studies are required to determine whether this is a sign of generalized endothelial dysfunction or intrinsic renal disease.

Progression to End-Stage Kidney Disease in Children with CKD: A Nation-Wide Cohort Study in Japan Kenji Ishikura, Osamu Uemura, Shuichi Ito, Naohiro Wada, Motoshi Hattori, Yasuo Ohashi, Yuko Hamasaki, Ryojiro Tanaka, Koichi Nakanishi, Tetsuji Kaneko, Masataka Honda. *The Pediatric-CKD Study Group in Japan.*

Background: In 2010, we conducted a nationwide epidemiologic survey of children (3 months to 15 years old) with pre-dialytic CKD (stage 3-5) in Japan, and 447 children (mean age 8.7 years, 271 male; 316 in stage 3, 104 in stage 4, and 27 in stage 5) participated in our cohort (FR-PO1478 in ASN 2011). Longitudinal follow-up has been required to explore their outcome and risk factors of disease progression.

Methods: We conducted a prospective cohort study, and investigated progression to end-stage kidney disease (ESKD) and death, and its risk factors. Progression of CKD stage was also evaluated.

Results: Follow-up data in 409 of 447 children with CKD as of April 1, 2011 were analyzed. Three patients died and 49 patients (11.0%; 9 from stage 3, 26 from stage 4, 14 from stage 5) developed to ESKD, including 1 death in 1-year follow-up. Renal replacement therapy was peritoneal dialysis (PD) in 28, preemptive kidney transplantation in 12, kidney transplantation after PD in 3, hemodialysis (HD) in 3, and PD after HD in 2, and death occurred after HD in 1 patient. Age at the observation (odds ratio, 1.13; 95% CI, 1.01-1.26), urine protein/creatinine ratio (1.37; 1.17-1.59), hypertension (3.59; 1.34-9.62), and CKD staging (odds ratio of stage 4 to 3, 14.7; 95% CI, 5.1-42.9; odds ratio of stage 5 to 3, 162; 95% CI, 25.5-1029.4) were independent risk factors for developing ESKD or death among several putative risk factors, including sex, background disease [CAKUT, non-CAKUT], syndromal stigmata, and premature delivery in multiple logistic analyses. Forty-one and 11 (9) of 316 children in stage 3 progressed to stage 4, and 5 (5D), respectively, and 34 (25) and 2 of 104 in stage 4 developed to stage 5 (5D) and death, respectively.

Conclusions: This study revealed that more than 10% of children with non-dialytic CKD (stage 3-5) in our cohort progressed to ESKD in 1-year follow-up. Proteinuria and hypertension are significant risk factors for developing to ESKD, suggesting necessity of anti-proteinuric intervention and anti-hypertensive drugs in children with CKD.

Baseline Characteristics of Korean Pediatric Patients with Chronic Kidney Disease: Pediatric Subcohort of KNOW-CKD Hye Jin Chang,[1] Hee Gyung Kang,[1] Jiwon L. Lee,[1] Yo Han Ahn,[2] Sang Taek Lee,[1] Min Hyun Cho,[3] Kook-Hwan Oh,[4] Hye Won Park,[5] Young Seo Park,[6] Curie Ahn,[4] Hae Il Cheong,[1] IL-Soo Ha.[1] *[1]Departments of Pediatrics, Seoul National University Children's Hospital, Seoul, Republic of Korea; [2]Center for Pediatric Oncology, National Cancer Center, Goyang-si, Gyeonggi-do, Republic of Korea; [3]Department of Pediatrics, Kyungpook National University Hospital, Daegu, Republic of Korea; [4]Department of Internal Medicine, Seoul National University Hospital, Seoul, Republic of Korea; [5]Health Promotion Center, Seoul National University Bundang Hospital, Seongnam-si, Gyeonggi-do, Republic of Korea; [6]Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea.*

Background: In Korea, nation-wide school urinary screening system has led to early detection of CKD; now, to assess the characteristics and relevant risk factors of CKD and its progression, KNOW-CKD (KoreaN cohort study for Outcome in patients With Chronic Kidney Disease) was launched in 2011, with pediatric subcohort as one of its five subcohorts.

Methods: Pediatric subcohort of KNOW-CKD enrolled children (younger than 20 years) with CKD stage I~V (pre-dialysis) from four major pediatric nephrology centers in Korea and collected medical and social data.

Results: Total 186 patients (M:F 123:63) were enrolled in 2011. Average age was 10.4 years (yrs). Etiology of CKD were congenital renal dysplasia (43%), reflux nephropathy/chronic pyelonephritis (25%), primary glomerular diseases (17%), secondary glomerular diseases (6%), and others. One third had histories of UTI and 10% had developmental delay. Growth delay was observed even in early stage of CKD stage; younger patients (< 6yrs) with advanced CKD (IV and V) had more profound growth delay. Deficiency of 25-hydroxyvitamin D3 (<20 ng/ml) and anemia were common (53% and 43%, respectively). LVH was observed in 11% of the patients.

Conclusions: This prospective, multicenter cohort study aiming to improve CKD outcome implies that our current management of pediatric CKD was suboptimal. We expect to obtain more information on pediatric CKD with this ten-year project KNOW-CKD, which can be translated to better management for this population.

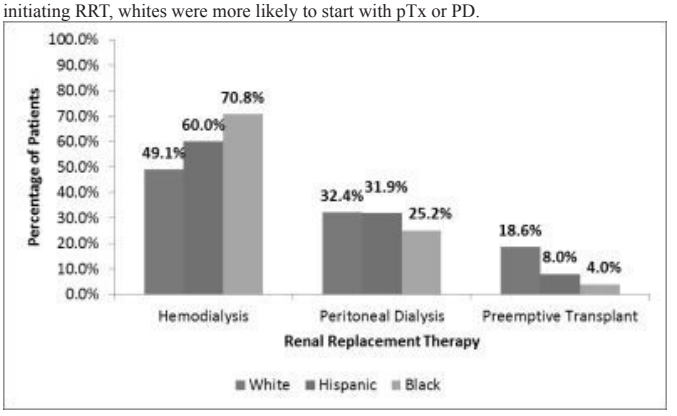
SA-PO214

Racial Disparities in Renal Replacement Therapy in the Pediatric End Stage Renal Disease Population Roshan P. George,[1] Laurence A. Greenbaum,[1] Allan Kirk,[2] Nancy G. Kutner,[3] Rachel E. Patzer.[2,4] *[1]Pediatric Nephrology, Emory Univ & Children's of Atlanta; [2]Surgery, Emory Transplant Center; [3]USRDS Rehabilitation/QoL Special Studies Center, Emory Univ; [4]Epidemiology, Rollins School of Public Health & Emory Univ, Atlanta, GA.*

Background: Limited data exists on racial disparities in the choice of renal replacement therapy (RRT) in pediatric ESRD patients. Blacks are more likely to receive hemodialysis (HD) vs. peritoneal dialysis (PD) or preemptive transplant (pTx). Ethnic differences and access to pre-ESRD nephrology care were not examined in prior studies.

Methods: Retrospective cross-sectional study of patients < 20 yrs, using USRDS from 01/01/05-09/30/09. Generalized logit models were used to calculate odds ratios (OR) and 95% confidence intervals (CI) of RRT choice by race/ethnicity. We adjusted for differences in age, sex, SES (zip code and insurance status), OPO region and access to nephrology care.

Results: Among 5,623 patients (43.3% whites, 30.3% blacks, and 26.4% Hispanics) initiating RRT, whites were more likely to start with pTx or PD.



Compared to whites, blacks were less likely to have pTx (OR=0.15; 95% CI: 0.11-0.20) or PD (OR=0.54; 95% CI: 0.47-0.63) vs. HD. Among Hispanics, pTx (OR=0.35; 95% CI: 0.29-0.44) or PD (OR=0.81; 95% CI: 0.70-0.93) vs. HD was lower than whites. More (67.4%) whites had access to pre-ESRD nephrology care than Hispanics (52.5%) or blacks (59.1%) (p< 0.0001). After adjusting for demographic, clinical, and SES differences, racial disparities were attenuated among Hispanics; however, compared to HD, pTx was 75% lower (OR=0.25; 95% CI: 0.18-0.35) and PD 22% lower (OR=0.78; 95% CI: 0.64-0.94) for blacks vs. whites.

Conclusions: Blacks and Hispanics are less likely to receive PD or pTx, compared to whites. SES, access to care and demographic factors explain this racial disparity among Hispanics, but not blacks.

SA-PO215

Hepcidin (Hepc) and Anemia in Children with CKD: Longitudinal Data from the Chronic Kidney Disease in Children (CKiD) Cohort Study Meredith A. Atkinson,[1] Christopher B. Pierce,[2] Cindy N. Roy,[1] Bradley A. Warady,[3] Colin T. White,[4] Alison G. Abraham,[2] Susan L. Furth.[5] *[1]Johns Hopkins University; [2]Johns Hopkins Bloomberg School of Public Health; [3]The Children's Mercy Hospital; [4]BC Children's Hospital; [5]The Children's Hospital of Philadelphia.*

Background: The iron-regulatory protein Hepc mediates iron-restricted erythropoiesis, is increased in both adults and children with CKD, and is a potential target for anemia treatment.

Methods: We examined baseline Hepc and 1) change in Hgb over time with linear mixed effects modeling (max follow-up time 2.5 yrs) and 2) incident anemia (defined as Hgb < 5th percentile for age/sex OR initiation of an ESA) using Cox proportion hazard models. Hepc was analyzed by quartile (≤ 35, 36-60, 61-130, and ≥ 130 ng/mL). Follow-up Hgb obtained annually. GFR measured by plasma iohexol disappearance.

Results: Baseline characteristics (median or percent) in 132 children: age 13 yrs, 58% male, GFR 43 ml/min/1.73m^2, 20% with glomerular dz, Hgb 12.8 g/dL, Hepc 58.3 ng/mL. Baseline Hepc level did not differ by age, sex, or race.

Baseline Characterstics by Hepc Quartile

	Baseline Hepc (ng/mL)				
Median [IQR] or %	≤35	36-60	61-130	≥130	p-value
iGFR, ml/min/1.73m2	51 [40, 58]	45[38, 56]	42 [31, 51]	34 [27, 50]	<0.001
Hgb (g/dL)	13.4 [11.8, 14.2]	13.2 [11.9, 13.7]	12.6 [11.9, 13.3]	12.4 [11.4, 13.4]	0.02
Ferritin (ng/mL)	20 [13, 29]	38 [29, 50]	45 [33, 54]	98 [59, 254]	<0.001
TIBC (µg/dL)	350 [327, 366]	303 [289, 325]	303 [281, 326]	271 [255, 302]	<0.001
ESA use	0	6	11	29	<0.001
Fe use	20	21	43	66	<0.001

Adjusting for anemia treatment, sex, race, age, GFR, and glomerular dz, baseline Hepc was not associated with Hgb change in follow-up. 23 subjects developed incident anemia; cumulative incidence of anemia by Hepc quartile was 12%, 29%, 56%, and 33% respectively (p=0.03 for trend). Multivariate Cox modeling revealed hazard ratio 1.20 (95% CI 0.91, 1.57, p=0.20) for risk of incident anemia per doubling of baseline Hepc.

Conclusions: Higher Hepc values are associated with lower GFR and Hgb, higher ferritin, and increased prevalence of anemia treatment. Baseline Hepc quartile was not independently associated with change in Hgb, but a trend for increased anemia incidence was noted.

SA-PO216

Urinary Tract Infection Characteristics in Children with Vesicoureteral Reflux: RIVUR Baseline Data Myra A. Carpenter,[1] Tej K. Mattoo,[2] Alejandro Hoberman,[3] Russell W. Chesney,[4] Marva M. Moxey-Mims,[5] Ranjiv I. Mathews,[6] Saul P. Greenfield.[7] *[1]Biostatistics, University of North Carolina, Chapel Hill, NC; [2]Children's Hospital of Michigan, Detroit, MI; [3]Children's Hospital of Pittsburgh, Pittsburgh, PA; [4]Le Bonheur Children's Medical Center, Memphis, TN; [5]NIDDK, NIH, Bethesda, MD; [6]Johns Hopkins School of Medicine, Baltimore, MD; [7]Women's and Children's Hospital of Buffalo.*

Background: Vesicoureteral reflux (VUR) is the most common congenital abnormality of the urinary tract in children. It is frequently undiagnosed until after a child has a urinary tract infection (UTI). VUR has been reported in approximately 30% to 40% of children with a UTI.

Methods: The Randomized Intervention for Children with Vesicoureteral Reflux (RIVUR) trial is designed to determine if antimicrobial prophylaxis is superior to placebo in preventing recurrent UTI in children with VUR grade I-IV enrolled following a first or second UTI (index UTI). Follow-up is on-going, but enrollment was completed in May 2011.

Results: RIVUR enrolled 607 children aged 2-71 months from 19 sites in the US. Participants were predominately female (558, 92%), white (482, 81%), grade II (254, 42%) or III (230, 38%) VUR, and without renal scarring (561, 96%) at baseline. The pre-enrollment (index) UTI required (1) presence of fever or urinary tract symptoms, (2) urinalysis-based pyuria, and (3) culture-proven infection with a single organism. Most children (554, 91%) were enrolled following their first UTI; the median age at enrollment was 12 months. The index UTI was symptomatic in 83 (14%), febrile in 197 (32%), and both febrile and symptomatic in 326 (54%) children. Escherichia was the infection organism in 541 (89%) of the index UTIs. In comparison with those having Escherichia infections, children with non-Escherichia infections had a higher grade of VUR (p=0.002), a non-febrile index UTI (p=0.01) and renal scarring (p=0.05). Findings are limited due to the small numbers of non-Escherichia infections (N=66), children with renal scarring (N=21), and children with grade IV VUR (N=50).

Conclusions: RIVUR participants are well-suited for evaluating benefits and risks of antimicrobial prophylaxis in children with VUR. Outcome data for 2 –year follow-up will be available in 2013.

Funding: NIDDK Support

SA-PO217

Disease Progression in Children with Chronic Kidney Disease Bradley A. Warady,[1] Alison G. Abraham,[2] George J. Schwartz,[2] Alvaro Munoz,[2] Craig S. Wong,[2] Mark Mitsnefes,[2] Frederick J. Kaskel,[2] Laurence A. Greenbaum,[2] Robert H. Mak,[2] Joseph T. Flynn,[2] Marva M. Moxey-Mims,[2] Susan L. Furth.[2] *[1]Nephrology, Children's Mercy Hospital, Kansas City, MO; [2]CKiD Investigator.*

Background: Few studies have evaluated the progression of CKD in children and factors influencing progression. The Chronic Kidney Disease in Children (CKiD) observational cohort study has evaluated risk factors for GFR decline in 492 children.

Methods: Analyses were anchored at the 2nd annual study visit. Baseline clinical and demographic factors were assessed as predictors of progression, the composite event defined as halving of iohexol or estimated glomerular filtration rate (ieGFR) or initiation of renal replacement therapy (RRT). Proteinuria was defined as Up/c >2 and elevated blood pressure (eBP) as systolic or diastolic BP >90th percentile. Parametric failure time models were used to explore adjusted associations between baseline levels of covariates and the composite event.

Results: Of 492 patients (pts), 93/396 (23%) with non-glomerular (NG) and 40/96 (42%) with glomerular (G) disease achieved the composite event. At baseline, NG pts with events compared to event-free pts (N=303) had a lower median GFR (31[24,40] vs 51[39,60] ml/min/1.73m2), higher proportion with Up/c > 2 (30% vs 3%) and a higher proportion with eBP (34% vs 23%). G pts with events compared to event-free pts (N=56) had a lower GFR (36[25,47] vs 53[43,72], a higher proportion with Up/c >2 (45% vs 0%) and a higher proportion with eBP (40% vs 16%). Subjects with ieGFR <30 at baseline achieved events faster: 82% and 91% faster in NG and G pts, respectively, compared to pts with an ieGFR ≥30, adjusted for rate of GFR decline (p<0.001). In stratified analyses, among NG pts, adjusting for baseline GFR, times to an event were significantly faster in pts with Up/c >2 (77% faster), eBP (44% faster), male sex (33% faster) and older age (5% faster/yr); in G pts, Up/c >2(91% faster), eBP (64% faster) and African American race (60% faster) were significant factors.

Conclusions: In both NG and G patients, proteinuria and elevated blood pressure are modifiable factors that significantly hasten the time to RRT/50% decline in GFR in children with CKD.

Tripterigium for the Treatment of Chronic Kidney Disease: A Systemic Review and Meta-Analysis Bin Zhu,[1,2] Ying Wang,[1] Meg J. Jardine,[1] Min Jun,[1] Jicheng Lv,[1,3] Alan Cass,[1] Yongjun Wang,[1] Vlado Perkovic.[1] *[1]Renal & Metabolic Division, The George Institute for Global Health, University of Sydney, Sydney, Australia; [2]Department of Nephrology, Hangzhou Hospital of Traditional Chinese Medicine, Hangzhou, Zhejiang, China; [3]Department of Nephrology, Peking University First Hospital, Beijing, China.*

Background: Tripterygium preparations are widely used for the treatment of people with chronic kidney disease (CKD) in some parts of the world, especially in China. The objective of this meta-analysis is to define the efficacy and safety of tripterygium in treating CKD.

Methods: We systematically searched Medline, Embase, Cochrane Library, VIP, Wanfang, CNKI and CBM for prospective, randomized, controlled trials assessing the effects of tripterygium compared to placebo, standard care or other treatment in CKD. Study quality was evaluated using Cochrane quality criteria and Jadad scale. Weighted mean difference and summary estimates of relative risk (RR) reductions were calculated with a random effects model. Outcomes analyzed included change in proteinuria, serum creatinine(Scr), as well as remission and relapse rate and drug-related adverse events.

Results: We identified 75 trials involving 4386 participants. Compared to control regimens, tripterygium therapy reduced proteinuria by 0.63g/d (95% CI:-0.74,-0.52) and Scr by 9.75µmol/L(15.12,-4.38)(P<0.001), with significant heterogeneity in the magnitude of the effect (both P<0.001). Meta-regression analysis suggested that the heterogeneity was partly explained by baseline proteinuria for proteinuria(P=0.046), baseline Scr(P<0.001) or age for Scr(P=0.035). Tripterygium increased the likelihood of complete remission by 56%(CI :32-85%, P<0.001), and complete or partial remission by 23%(CI:16-31%, P<0.001) while reducing relapse by 58% (CI:42-69%, P<0.001). It increased the likelihood of liver function abnormalities(RR:4.00, CI:1.48-10.78, P=0.006) and altered menstruation(RR: 24.37, CI:3.65-162.58, P=0.001). Overall study quality was suboptimal, meaning the results should be interpreted with caution.

Conclusions: Tripterygium is a promising nephroprotective agent, but high quality trials are required to reliably determine the balance of benefits and risks.

SA-PO219

Effect of Lowering LDL-Cholesterol on Kidney Function: Meta-Analysis of Data from 120,000 Participants in 21 Randomized Trials David A. Lewis, Jonathan R. Emberson, Lisa J. Blackwell, Rory Collins, Colin Baigent. *On Behalf of the Cholesterol Treatment Trialists' (CTT) Collaboration, Clinical Trial Service Unit and Epidemiological Studies Unit (CTSU), University of Oxford, Oxford, United Kingdom.*

Background: Randomized trials have shown that lowering LDL-cholesterol (LDL-C) reduces the risk of occlusive vascular events among a wide range of individuals. Lowering LDL-C might also slow the progression of kidney disease, but previous studies have been inconclusive.

Methods: We undertook meta-analyses of individual participant data from randomized trials comparing a statin vs control or a more intensive statin regimen vs a standard regimen which involved at least 1000 participants and at least 2 years' treatment duration. For participants with creatinine measurements at randomization, about 1 year follow-up and/or at study end (21 trials; 121,038 individuals; median follow-up 4.5 years), we used linear regression to assess individual rates of change in estimated glomerular filtration rate (eGFR) calculated using the CKD-EPI equation.

Results: At randomization, 73% were male, 20% diabetic and 58% had prior vascular disease. Mean eGFR was 71 mL/min/1.73m^2 and 25% had chronic kidney disease (CKD) as defined by eGFR <60 mL/min/1.73m^2. Allocation to active therapy yielded a highly significant reduction in the annual progression rate of about one quarter (absolute annual rate of change [mL/min/1.73m^2 per year]: -0.67 [SE 0.01] active vs -0.87 [0.01] control, weighted mean difference 0.22 [0.02]; p<0.00001). Among 91,100 participants without CKD at randomization, statin therapy produced a significant 10% reduction in the incidence of new CKD during follow-up (8377 [18.4%] vs 9006 [19.8%], RR 0.90, 95% CI 0.88-0.93, p<0.0001) with similar RRs seen across a wide range of individuals.

Conclusions: In addition to reducing the risk of occlusive events, lowering LDL-C also slows the progression of kidney disease in a wide range of individuals without CKD or with only modest renal impairment. The renal benefits of LDL-lowering therapy are small relative to the cardiovascular benefits but may be important in patients at low risk of cardiovascular disease but high risk of developing kidney disease.

Funding: Pharmaceutical Company Support - Most of the trials in this report were supported by research grants from the manufacturers of statins (Astra Zeneca, Bristol Myers Squibb, Merck, Novartis and Pfizer), but no support from the Pharmaceutical Industry Has Been Received for This Meta-Analysis Work

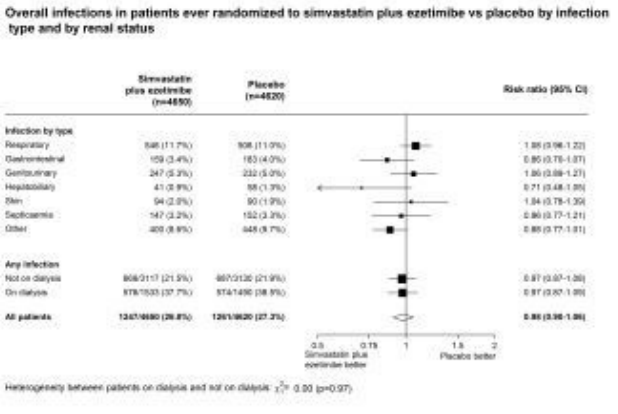
SA-PO220

Effect of Lowering LDL-Cholesterol with Simvastatin Plus Ezetimibe on Infection in Patients with Chronic Kidney Disease: Results from the Study of Heart and Renal Protection (SHARP) Christina A. Reith. *On Behalf of the SHARP Collaborative Group, CTSU, University of Oxford, Oxford, United Kingdom.*

Background: The Study of Heart and Renal Protection (SHARP) was a randomized controlled trial of LDL cholesterol-lowering in patients with chronic kidney disease (CKD) which showed that simvastatin plus ezetimibe reduced vascular events with no significant adverse effects on muscle, hepatobiliary outcomes or cancer. Infection is common in patients with CKD and is a major cause of morbidity. Low cholesterol is associated with infection in some cohorts, but other studies have suggested that statins may reduce the risk of infection.

Methods: 9270 patients with CKD were randomized, 6247 of whom were not on dialysis at baseline. All infectious serious adverse events were routinely recorded post-randomization. Post-hoc intention-to-treat analyses were performed of the effect of allocation to simvastatin plus ezetimibe on time to first infection overall, by infection type, by outcome (fatal or non-fatal) and by renal status.

Results: During 4.9 years median follow-up, similar numbers experienced infections in the two groups: 1247 [26.8%] in those on simvastatin plus ezetimibe *vs* 1261 [27.3%] in those on placebo (rate ratio 0.98, 95% CI 0.90-1.06; p=0.57). There were no significant differences in fatal or non-fatal infections or infection by system of disease between the treatment groups. Effects were similar in those on dialysis and those not (χ^2_1= 0.00; p=0.97).



Conclusions: In the SHARP cohort, combination therapy with simvastatin 20mg plus ezetimibe 10mg had no effect, beneficial or hazardous, on the incidence of infection, either overall, or by infection type, outcome or renal status.

Funding: Pharmaceutical Company Support - The SHARP Study Was Funded Mainly by Merck/Schering-Plough Pharmaceuticals (North Wales, PA, USA), Government Support - Non-U.S.

SA-PO221

Effect of Statin Therapy on Cardiovascular and Renal Outcomes in Patients with Chronic Kidney Disease: A Systematic Review and Meta-Analysis Wanyin Hou,[1] Jicheng Lv,[1] Vlado Perkovic,[2] Lihong Yang,[3] Na Zhao,[1] Meg J. Jardine,[2] Alan Cass,[2] Hong Zhang,[1] Haiyan Wang.[1] *[1]Renal Division, Peking University First Hospital, China; [2]The George Institute for Global Health, University of Sydney, Australia; [3]Guangdong Hospital of Traditional Chinese Medicine, China.*

Background: Guidelines provided uncertain evidence about the statin roles in patients with chronic kidney disease. We undertook a systematic review and meta-analysis to investigate the effects of statin on major clinical outcomes with cardiovascular event, renal outcomes included.

Methods: The study conducted according to the PRISMA guidelines for analyses. Relative risk (RR) reductions were calculated with a random effects model.

Results: We identified 31 trials with 48,429 patients with CKD, including 6690 major cardiovascular events and 6653 deaths. Statin produced a 23% RR reduction (16 to 30) for major cardiovascular events (p<0.001), an 18% RR reduction (8 to 27) for coronary events, and 9% (1 to 16) reduction in cardiovascular or all cause deaths,no significant effect on stroke (21%, –12 to 44) or kidney failure events (5%, -1 to 10). Adverse events were not significantly increased by statins including hepatic (RR 1.13, 95%CI 0.92 to1.39) or muscular disorders (RR 1.02, 95%CI 0.95 to1.09). Meta regression analysis showed an association between cardiovascular event and LDL–reduction among non-dialysis and dialysis patients. Subgroup analysis demonstrated the relative effects of statin therapy in CKD were significantly reduced in people with advanced CKD(p<0.001), (Figure 1) but the absolute risk reductions were comparable.

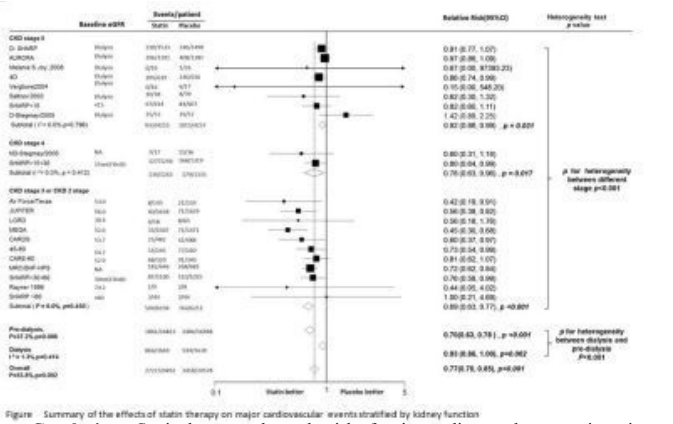


Figure Summary of the effects of statin therapy on major cardiovascular events stratified by kidney function

Conclusions: Statin therapy reduces the risk of major cardiovascular events in patients with chronic kidney disease including those receiving dialysis. Alternative approaches to reducing the substantial excess of cardiovascular events in people with advanced CKD are required.

SA-PO222

Impact of Phosphate Binder Choice on Outcomes among Pre-Dialysis Chronic Kidney Disease Patients in the Netherlands Edith M. Heintjes,[1] Jetty Overbeek,[1] Elizabeth Dunn,[2] Fernie Penning-van Beest,[1] Ron Herings.[1,3] *[1]PHARMO Institute, Utrecht, Netherlands; [2]Genzyme Corporation, Cambridge, MA; [3]Erasmus MC, Rotterdam, Netherlands.*

Background: Sevelamer has been shown to slow the progression of coronary artery calcification (CAC) relative to calcium based binders (CBB) in pre-dialysis CKD patients. Whether sevelamer's effects result in reduced progression to renal replacement therapy (RRT) or an overall survival benefit compared with calcium based binders (CBB) in this population is less understood. This study compared the risk of RRT and mortality between pre-dialysis CKD patients using sevelamer and those using CBB.

Methods: The PHARMO database network including clinical laboratory, outpatient pharmacy and hospitalization records of approximately 1.5 million residents in the Netherlands was linked to the Renine foundation dialysis registry data. From this database all pre-dialysis patients with hyperphosphatemia and CKD stage 3-5 were selected. Patients using sevelamer only were matched to patients using CBB only on age, phosphate level, eGFR, albuminuria severity and propensity score. Multivariate Cox proportional hazards regression modeling was performed to compare the incidence rate (IR) of RRT and all-cause mortality between sevelamer users and CBB users.

Results: The source population included 653 pre-dialysis patients with hyperphosphatemia and CKD stage 3-5 who also received phosphate binders. After applying the matching procedure, 94 patients using sevelamer only and 94 patients using CBB only were included in the study. Patients treated with sevelamer had a 50% reduced risk of progression to RRT compared to patients treated with CBB (crude IRs 22 and 28 per 100 person years (py) respectively, adjusted hazard ratio (HR) 0.5 (95%CI: 0.3-0.9)). Crude IRs for mortality were 14 (sevelamer) and 19 (CBB) per 100 py and the adjusted HR was 0.9 (95%CI: 0.5-1.6).

Conclusions: In this study of community dwelling stage 3-5 CKD pre-dialysis patients in the Netherlands, the risk of RRT for patients using sevelamer was significantly lower (50% reduction) than that of patients using CBB. No significant difference was found for all-cause mortality.

SA-PO223

Paricalcitol Induced Reduction of Proteinuria in Non-Dialysis Chronic Kidney Disease Patients Robert Ekart,[1] Nina Hojs,[2] Breda Pecovnik Balon,[1] Sebastjan Bevc,[2] Radovan Hojs.[2] *[1]Clinic for Internal Medicine, Department of Dialysis, University Clinical Centre Maribor, Maribor, Slovenia; [2]Clinic for Internal Medicine, Department of Nephrology, University Clinical Centre Maribor, Maribor, Slovenia.*

Background: Proteinuria is an independent predictor for chronic kidney disease (CKD) progression and cardiovascular disease. Existing treatment of proteinuria is not sufficient to halt the CKD epidemic. Therefore the aim of our study was to evaluate the effect of paricalcitol on proteinuria in non-dialysis CKD patients.

Methods: 41 non-dialysis CKD patients with secondary hyperparathyroidism (iPTH>65 pg/mL), serum calcium <2.6 mmol/L, serum phosphate <1.8 mmol/L and with proteinuria (>150mg/day) were treated with paricalcitol 1 µg/day. Most were treated for 6 months, with the exception of three patients having iPTH below 30 pg/mL after 3 months of treatment, in whom the therapy after 3 months was stopped. All patients were followed for 6 months. Fixed doses of ACE inhibitors and/or ARBs and/or statins were kept for 3 months before and during the study.

Results: 41 patients (30 men, 11 women; age 62.44±11.93 years, range 31-84 years) with different primary causes of CKD were enrolled in the study. Urinary albumin/creatinine ratio (UACR), 24-hour urinary albuminuria (24hUA) and 24-hour quantitative proteinuria (24hUQP) were measured. Values at 0 and 6 months of these parameters were log-transformed for statistical analysis. After treatment with paricalcitol statistically

significant reduction (paired t-test) in 24hUA (mean 5.99; p<0.01) and 24hUQP (mean -0.34; p<0.0001) were found. The difference in UACR was not significant (mean 5.49; p=0.074). In the observational period no statistically significant reduction in 24-hour ambulatory systolic (mean 135.4 vs mean 133.2 mmHg) and diastolic (mean 76.6 vs mean 76.5 mmHg) blood pressure was found.

Conclusions: Treatment with 1 µg paricalcitol daily according to clinical practice in non-dialysis CKD patients with secondary hyperparathyroidism and proteinuria significantly reduces 24-hour urinary albuminuria and 24-hour quantitative proteinuria without significant change in 24-hour blood pressure.

SA-PO224

Effect of Iron Isomaltoside 1000 on Phosphate Levels in Patients with Non-Dialysis Dependent Chronic Kidney Disease Philip A. Kalra,[1] Lars L. Thomsen.[2] *[1]Department of Renal Medicine, Salford Royal Hospital, Salford, United Kingdom; [2]Pharmacosmos A/S, Holbaek, Denmark.*

Background: Low serum (*s*)-phosphate values have been reported following treatment with some parenteral iron products, the nadir occurring approximately 2 weeks after dosing. When defined as a *s*-phosphate < 2 mg/dL, hypophosphatemia has been noted with an incidence ranging from 3.8 to 70.1 %. The objective of this study was to investigate, in an interim analysis of a randomized clinical trial (RCT), whether patients with non-dialysis dependent chronic kidney disease (NDD-CKD) treated with intravenous (IV) iron isomaltoside 1000 (Monofer®) developed low *s*-phosphate.

Methods: In an ongoing RCT, 350 NDD-CKD patients with renal-related anaemia are being randomised 2:1 to either IV iron isomaltoside 1000 (group A; 234 subjects) or oral iron sulphate (group B; 116 subjects). The patients in group A are equally divided into A1 (IV infusion of maximum 1000 mg or 20 mg/kg iron isomaltoside 1000 over 15 minutes; full iron replacement achieved by up to 2 doses at a weekly interval) and A2 (IV bolus injections of 500 mg iron isomaltoside 1000 administered over 2 minutes once weekly until full replacement dose is achieved). Group B are treated with 200 mg oral iron sulphate daily for 8 weeks. *S*-phosphate is measured prior to iron administration and at 1,2,3,4, and 8 weeks. The current analysis is a per protocol interim analysis including data from 100 patients treated with iron isomaltoside 1000.

Results: Two patients (2 %) who were infused with 750-1000 mg of iron isomaltoside 1000 experienced a decrease in *s*-phosphate below 2 mg/dL. One had *s*-phosphate of 1.2 and the other 1.8 mg/dl (baseline values 3.5 and 2.8 mg/dL, respectively) three weeks after dosing. In both patients, *s*-phosphate had returned to the normal range at the following visit. The low *s*-phosphate was not associated with any clinical symptoms. Furthermore, no drug related adverse events were observed in these patients.

Conclusions: Treatment with iron isomaltoside 1000 has not been associated with clinically significant hypophosphatemia in patients with NDD-CKD. In the two patients (2 %) with a transient low *s*-phosphate, this had normalised by the following visit.

SA-PO225

The Effect of Febuxostat on Uric Acid Level and Renal Function Nara Shin,[1] Jiwon Ryu,[1] Hajeong Lee,[1] Sejoong Kim,[2] Dong Wan Chae,[2] Ki Young Na,[2] Suhnggwon Kim,[1] Ho Jun Chin.[2] *[1]Internal Medicine, Seoul National University Hospital, Seoul, Republic of Korea; [2]Internal Medicine, Seoul National University Bundang Hospital, Republic of Korea.*

Background: Allopurinol has been the classic treatment of hyperuricemia. But when using allopurinol, we have to take renal function and adverse effect into account. Febuxostat, a new agent of a non-purine xanthine oxidase inhibitor has been identified as a safe and efficacious alternative. Therefore, we conducted a retrospective study to investigate the benefits of febuxostat treatment, based on the change of uric acid level and renal function and suggest recommended dosage.

Methods: A retrospective observational study was performed based on the outpatient clinic. The patients who started febuxostat and did regular follow-up were enrolled. All patients' serum uric acid, creatinine, glomerular filtration rate level and other laboratory data were collected.

Results: We excluded the patients under 18 year-old, who had gout attack and had missing value. A total of 69 patients was selected. We devided into two groups by the target uric acid level (serum uric acid <6.0mg/dl or not). Male sex, younger age and high BMI were associated with lower uric acid change. In Allopurinol group and Steroid group, uric acid level was less decreased .In multivariate logistic regression, male sex (OR 7.803, 95% CI 1.143-53.27, p=0.036) and allopurinol group (OR 6.316, 95% CI 1.214-32.85, p=0.028) were the significant factors related to less controlled uric acid level. In comparison of the group of eGFR<30 and eGFR≥30, there was no difference about the variation of uric acid and renal function. Compared with the variation of uric acid by febuxostat dose, there was no difference of uric acid variation between 20mg, 40mg and 80mg of febuxostat in two groups.

Conclusions: Our study showed that febuxostat is effective in improving serum uric acid. Male sex and allopurinol group were the significant factors related to less controlled uric acid level. In our study, low dose(20mg) for the group of eGFR under 30mg/dl/m2 was no inferior to high dose (40mg, 80mg). Large group and long-term follow-up studies are required to investigate the long term effect of febuxostat.

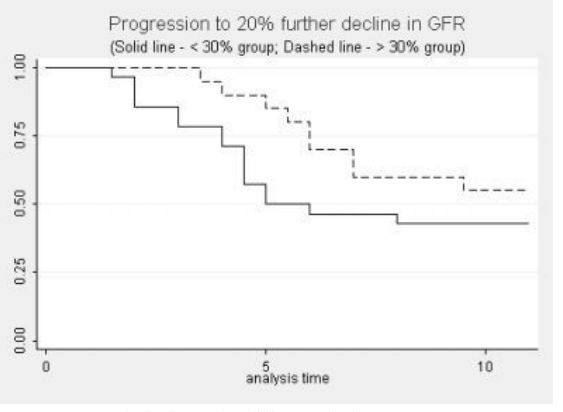
SA-PO226

Long-Term Outcomes in CKD Patients Treated with Renin-Angiotensin Inhibitors (RASI) Who Experience an Increase in Serum Creatinine Greater than 30% Sheldon M. Hirsch,[1] Jackie Hirsch,[1] Udayan Y. Bhatt,[2] Brad H. Rovin.[2] *[1]Lakeside Nephrology, Chicago, IL; [2]Nephrology, The Ohio State University, Columbus, OH.*

Background: RASIs slow progression of CKD. However, they may lead to an initial decline in eGFR. Current recommendations suggest tolerance of an initial increase in serum creatinine (sCr) only up to 30%. This may limit aggressive use of RASI. The purpose of this study was to evaluate the long-term follow-up of CKD subjects who experienced an initial increase in sCr, with RASI, greater than 30%, and in whom RASI was not reduced.

Methods: 48 patients at a community-based nephrology clinic were followed longitudinally. Patients were aggressively treated with RASI with goals of SBP ≤ 125mmHg and a dipstick urine protein of ≤ 30 mg/dl. Those whose sCr increased > 30% were compared to those whose sCr increased ≤ 30% using survival and longitudinal analysis.

Results: Patients in the group with sCr increase > 30% had a long-term decline in eGFR of 0.52cc/min/1.73m^2 compared to a decline of 1.8cc/min/1.73m^2 in the ≤ 30% group. The decline in eGFR was not different in the groups in a multivariate (MV) model (p=0.228). Cox proportional hazards regression was used to compare the time to a further 20% decrease in eGFR (after the initial decline associated with RASI maximization, Figure).



MV Cox analysis showed no difference in the groups (HR=0.60, 95% CI 0.26, 1.35). The incidence of End-Stage Renal Disease and death was also similar in the two groups, and, along with the slow decline in eGFR, compared favorably with previous large-scale CKD studies.

Conclusions: Important outcomes in patients who experienced sCr increase > 30% were not significantly different than those whose sCr remained unchanged or increased ≤ 30%. This suggests that an initial increase in sCr should not limit RASI dosing, contrary to current recommendations.

SA-PO227

Renin-Angiotensin-Aldosterone System Inhibition Is Associated with Lower Plasma Fibroblast Growth Factor 23 Levels and Decreased Mortality in Patients with Advanced Chronic Kidney Disease: A Propensity Score Analysis of the HOST Study Anna Jeanette Jovanovich,[1] Jessica B. Kendrick,[1] Alfred K. Cheung,[2,4] James S. Kaufman,[3] Tom Greene,[2,4] M. Chonchol.[1] *[1]University of Colorado; [2]VASLCHCS; [3]VA Boston HCS; [4]University of Utah.*

Background: Evidence suggests that the renin-angiotensin-aldosterone system (RAAS) intersects with vitamin D-FGF23-Klotho axis. Increased angiotensin II lowers renal klotho expression, thus increasing fibroblast growth factor 23 (FGF23) levels. We investigated whether FGF23 levels differ and modify the risk of outcomes in response to RAAS inhibition (ACEI/ARB usage) in advanced chronic kidney disease (CKD).

Methods: We studied 1753 patients with advanced CKD (1099 CKD not yet on dialysis, eGFR=18±6 ml/min/1.73m^2; and 654 ESRD) who participated in the Homocysteine in Kidney and End Stage Renal Disease study. Outcome measures were plasma C-terminal FGF23 levels and all-cause mortality in all participants and progression to ESRD in those with CKD not yet on dialysis. Linear and Cox regression models adjusted for important confounding variables and propensity score analysis were used to assess the association of ACEI/ARB usage with FGF23 levels, all-cause mortality, and dialysis initiation.

Results: Average age was 66±12 years, 38% were black, with 870 (50%) taking ACEI/ARB. Over a mean follow-up of 3 years, there were 714 (41%) deaths and 615 patients (56%) initiated chronic dialysis. In adjusted linear regression models, ACEI/ARB users had significantly lower plasma FGF23 levels (difference, -332 RU/mL; 95% CI -184 to -459; p=0.0009) compared with ACEI/ARB nonusers. Those treated with ACEI/ARB had significantly lower all-cause mortality with an adjusted hazard ratio of 0.81 (95% CI 0.69-0.94, p=0.005) and lower dialysis initiation 0.84 (95% CI 0.72-0.99, p=0.03) in those with CKD not yet on dialysis. Higher FGF23 levels did not attenuate the protective effect of ACEI/ARB use.

Conclusions: ACEI/ARB use was associated with lower plasma FGF23 levels and was protective for all-cause mortality and dialysis initiation in patients with advanced CKD, suggesting that RAAS inhibition may have an FGF23-mediated protective effect.

Reno-Protection with Renin-Angiotensin-System (RAS) Blockers in Type 2 Diabetes Mellitus (T2DM) and Chronic Kidney Disease (CKD): Examining the Implementation Gap

Elisha I. Lancaster,[1,2] Loretta Simbartl,[2] Charuhas V. Thakar.[1,2] *[1]Division of Nephrology, University of Cincinnati, Cincinnati, OH; [2]VAMC, Cincinnati, OH.*

Background: Several meta-analyses and a recent report from U.S. Preventive Task Force indicate that randomized controlled trials (RCT) of RAS blockade reduced the risk of end stage renal disease in diabetics with CKD, but do not support cardiovascular risk reduction. We examined the implementation gap between patients enrolled in RCT's and those seen in practice.

Methods: We searched MEDLINE (English) to include all RCT's examining reno-protective effects of RAS use in T2DM and cross referenced with citations in relevant systematic reviews. Also included were RCT's referenced in the appropriate KDOQI practice guideline. Eight RCT's were identified. Key baseline characteristics from the pooled RCT's were compared, using Chi-square tests, to a validated Veterans Affairs (VA) cross-sectional cohort of 2,889 ambulatory care patients with T2DM and CKD (one outpatient estimated glomerular filtration rate < 60 ml/min/1.73m2). Age estimates in pooled RCT's were derived from standard deviations (SD).

Results: Baseline characteristics of the pooled RCT cohort were: mean age 58 (SD 6.4), mean systolic blood pressure (SBP) 153 mm of Hg (SD 17), mean serum creatinine (SCr) of 1.8 mg/dl (SD, 0.5), and mean HbA1c 9.2 (SD 1.7). These were significantly different in our VA cohort: mean age 70 (SD, 10.3), mean SBP 134 mm of Hg (SD, 15), mean SCr 1.7 mg/dl (SD, 1.1), and mean HbA1c of 7.1 (SD, 1.6); [p value for each parameter < 0.0001]. RAS usage in VA cohort was 77%. RCT's had only 3% of patients > 71 years old, 26% with heart disease, and 12% with lipid disorders compared to 53%, 61%, and 74% respectively in the VA cohort (p value of <0.0001 for all).

Conclusions: The study outlines a wide implementation gap between characteristics of RCT participants and those encountered in practice; in practice patients were older, had a higher frequency of heart disease, lipid disorders, and different levels of blood pressure and glucose control. Reno-protective effect of RAS blockers in older adults is unclear; in contrast to RCT's their cardiovascular benefits may change with age and other co-morbidities.

Combination Therapy with Renin-Angiotensin System Inhibitors and an Oral Adsorbent, AST-120 Can Delay the Initiation of Dialysis

Daijo Inaguma,[1] Masato Ikeda,[2] Fumihiko Koiwa,[2] Yasuhiro Komatsu,[2] Nobuhiko Joki,[2] Takashi Shigematsu.[2] *[1]Nephrology, Nagoya Daini Red Cross Hospital, Nagoya, Japan; [2]Japan Study Group for Assessing Assessing Initiation of Renal Replacement Therapy, Wakayama, Japan.*

Background: An oral adsorbent, AST-120 (AST) can slow the progression of chronic kidney disease (CKD). Renin angiotensin system inhibitors (RASi) can prevent the progression of CKD as well. We therefore examined whether combination therapy with RASi and AST-120 has enhancing effects in delaying the initiation of dialysis.

Methods: The study was a multicenter cross-sectional study. The subjects were 2,335 CKD patients who were initiated on hemodialysis. The patients were divided into four groups (RASi-/AST-, RASi+/AST-, RASi-/AST+, RASi+/AST+) and we compared the parameters between the four groups. Multiple linear regression analysis was conducted to clarify the factors for the timing of initiation of dialysis.

Results: The results were shown in **Table 1**.

The comparison of parameters between four groups

	RASi-/AST- N=835	RASi+/AST- N=1092	RASi-/AST+ N=119	RASi+/AST+ N=289	p value
Age	67.0±14.5	66.3±13.1	67.9±15.2	64.8±13.1	0.102
Female	294	342	47	78	0.039
Cardiovascular disease	211	310	36	76	0.299
Duration of nephrologist care	826±1261	1056±1054	1040±1391	1294±1118	0.146
systolic blood pressure	149±28	153 ± 26	148 ± 28	152 ± 25	0.009
Cardiothoracic ratio	55.2 ± 7.7	54.2 ± 7.9	54.7 ± 7.0	52.8 ± 7.9	0.001
BUN	91.8 ± 32.0	86.4 ± 28.2	90.1 ± 23.9	93.6 ± 28.7	<0.0001
Creatinine	9.22 ± 3.91	8.85 ± 3.25	9.17 ± 3.17	9.52 ± 3.31	0.008
eGFR	5.87 ± 4.22	5.72 ± 2.67	5.20 ± 2.13	5.24 ± 2.07	0.014
Phosphorus	6.3 ± 2.0	6.0 ± 1.7	6.0 ± 1.6	6.1 ± 1.7	0.009
Albumin	3.17 ± 0.65	3.19 ± 0.61	3.28 ± 0.64	3.28 ± 0.58	0.032
Hemoglobin	8.6 ± 1.7	8.6 ± 1.5	8.6 ± 1.4	8.5 ± 1.5	0.888
C-reactive protein	2.57 ± 4.61	1.69 ± 3.83	1.91 ± 3.53	1.17 ± 3.51	<0.0001
Ferritin	257 ± 328	212 ± 255	181 ± 171	178 ± 162	<0.0001

Multiple linear regression analysis revealed a significant association of the use of AST-120 with the initiation of dialysis in patients who were administered RASi.

Conclusions: In conclusion, the above results suggested that the combination therapy with RASi and AST-120 delayed the initiation of dialysis by anti-inflammatory effects.

SA-PO230

Subgroup Analyses in Nephrology Randomized Controlled Trials

Steven Fishbane,[1] Hitesh H. Shah,[1] Ashish Kataria,[1] Rajiv Agarwal,[2] Shayan Shirazian.[3] *[1]Division of Nephrology, Hofstra North Shore-LIJ School of Medicine, Great Neck, NY; [2]Department of Medicine, Indiana University; [3]Division of Nephrology, Winthrop-University Hospital, Mineola, NY.*

Background: Subgroup analyses are commonly used in randomized controlled trials (RCT) to examine for heterogeneity of treatment effects. While they may be useful, when overused or inappropriately applied they can result in misleading conclusions. The purpose of our study was to describe how subgroup analyses are used and reported in Nephrology RCTs.

Methods: We used a search strategy that yielded RCTs from nephrology and major medical journals published between July 1, 2010 and June 30, 2011. Articles were excluded if they were from phase 1 trials, secondary analyses of previously published RCTs or appeared only as a letter to the editor. Abstraction was performed for all articles and then a secondary review of each was performed by a separate investigator. Meetings were held to reconcile differences in abstraction.

Results: In total, 83 articles were reviewed (Table 1). Subgroup analyses were reported in 31 articles (37.3%), and had a mean of 1.5 ±1.0 outcomes 4.6 ±4.0 subgroups per analysis. Only 7 of 31 subgroup analyses were prespecified (22.6%). The appropriate statistical method (test of interaction) was conducted in only 11/31 subgroup analyses (35.3%). Positive results of subgroup analyses were reported in 16/31 articles (51.6%). When results were positive, claims were made in the discussion section in 14/16 (87.5%) cases. Predictors of use of subgroup analyses included studies of dialysis, larger sample size and multicenter studies.

Conclusions: In conclusion, subgroup analyses are frequently used in nephrology trials, and the methodology is often suboptimal.

Characteristics of Subgroup Analyses

	n (%)
Number of Articles with Subgroup Analysis	31 (37.3)
Analysis Prespecified:	
Yes	7 (22.6)
No	24 (77.4)
Mean Number of Outcomes Reported	1.45±1.00
Mean Number of Analyses per study	4.6±4.4 (range 1-25)

SA-PO231

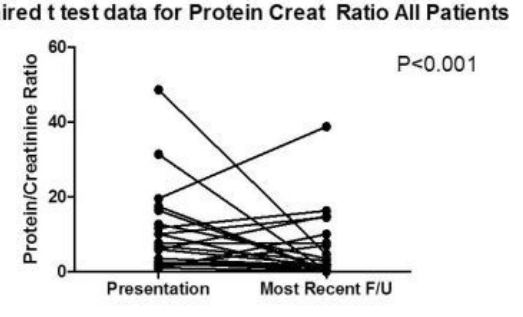
Efficacy of Tacrolimus in the Treatment of Children with Focal Segmental Glomerulosclerosis

Mahmoud Kallash, V. Matti Vehaskari, Diego H. Aviles. *Pediatric Nephrology, LSU Health Sciences Center, New Orleans, LA.*

Background: Focal segmental glomerulosclerosis (FSGS) is the most common glomerular condition leading to end stage renal disease (ESRD) and the third most common cause of ESRD in pediatric patients.

Methods: This is a retrospective study consisting of 22 pediatric patients with FSGS and heavy proteinuria. After demonstrating steroids resistance, patients were treated with tacrolimus, targeting a trough level 5-8 ng/ml. The primary outcome is the induction of proteinuria remission. Secondary outcomes are preservation of renal function and the incidence of tacrolimus toxicity.

Results: Thirteen patients (59%) achieved remission (complete in 31.8% vs. partial in 27.2%, P<0.001) (Figure 1) and 12 had stable or improved renal function over an average of 2.9 years (0.2-7) of follow up (P<0.0053).



Average eGFR and urine protein creatinine ratio

Parameter	Presentation	Most resent follow up	P value
eGFR	92.3 (31.3-138)	70.13 (9.3-161)	<0.053
P/Cr ratio	10.1 (0.86-48.64)	5.96 (0.05-38.8)	<0.001

Abbreviations: eGFR, estimated glomerular filtration rate (cc/min/1.73 m2), P/Cr ratio: Protein/ creatinine ratio (mg/mg). Data are presented as mean with the range in parenthesis.

Non- compliance with treatment was an important factor in 4 of the 9 non-responsive patients (44%). None of the patients had any significant side effects related to the use of tacrolimus. The repeat biopsies did not demonstrate an increase in interstitial fibrosis. The best renal outcome was for patients who achieved complete remission. Partially responsive patients had improved renal survival compared to resistant patients.

Conclusions: Tacrolimus is an effective and relatively safe option in the treatment of children with idiopathic steroid resistant FSGS.

SA-PO232

Agricultural Work, *Lija* and Water Consumption Associated with Chronic Kidney Disease in León, Nicaragua Jill Lebov,[1] Douglas Morgan,[1] Edgar M. Pena,[3] Scott Leonard Sanoff,[2] Yichun Hu,[1] Romulo E. Colindres,[1] Susan L. Hogan.[1] *[1]UNC, Chapel Hill, NC; [2]UVA, Charlottesville, VA; [3]Centro de Investigación e Intervenciones en Salud, León, Nicaragua.*

Background: Recent studies have suggested a non-traditional chronic kidney disease (CKD) etiology in Pacific coastal Central America, including possible influences from agricultural work, consumption of unregulated homemade alcohol (*lija*), and exposure to toxins in water and food. However, results across studies have been inconsistent and findings are based on small or non-population-based samples.

Methods: Using a population-based sample of residents of León, Nicaragua, we conducted a cross-sectional study of CKD and associated factors. Blood sample collection and structured interviews were conducted in participants' homes. Glomerular filtration rate was estimated (eGFR) using the MDRD equation, with CKD defined as eGFR<60 ml/min/1.73m^2. We used multivariate logistic regression to estimate prevalence odds ratios (POR) and 95% confidence intervals (CI), adjusted for sex, age, and self-reported hypertension and diabetes.

Results: In adjusted models, self-reported diagnosis of hypertension, rural residence, more years of agricultural work, *lija* consumption, and higher levels of average daily water consumption were significantly associated with CKD. Notably, self-reported diabetes was not associated with CKD in adjusted models.

Risk Factor	Number (%)	Adjusted POR (95% CI)

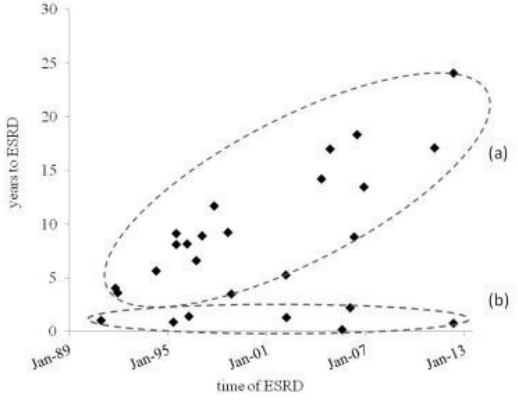
SA-PO233

End-Stage-Renal-Disease after Hematopoietic Stem Cell Transplantation Eric P. Cohen, Manpreet Bedi, William Drobyski. *Medicine, Medical College of Wisconsin, Milwaukee, WI.*

Background: Hematopoietic stem cell transplantation (HSCT) is often complicated by acute and chronic kidney disease. End-stage-renal-disease (ESRD) has a 16-fold higher incidence after HSCT compared to the age-matched general population. It has multiple causes and a variable time-of-occurrence after HSCT.

Methods: 2264 subjects have undergone HSCT at our center since 1986. In 26 cases of ESRD, we portrayed time from HSCT to ESRD as a function of the date of occurrence of ESRD, to obviate bias of follow-up time.

Results:



Conclusions: This shows two forms of ESRD after HSCT. The first (a) occurs at several or more years after HSCT, and its time to occurrence appears to be at ever increasing times after HSCT. This could result from changes in HSCT practice, e.g. less-intense conditioning regimens, or from improved care of patients with chronic kidney disease (CKD). The second form of ESRD (b) occurs at a lesser interval after HSCT, and its time of occurrence has not changed over time. 9 of the 19 type (a) ESRD cases had BMT nephropathy as their underlying diagnosis. 1 of the 7 type (b) ESRD cases had BMT nephropathy as their underlying diagnosis. BMT nephropathy can be treated and mitigated (Int J Radiat Onc Biol Phys, 2008). Other causes of CKD after HSCT require investigation for improved patient care. Mitigation of CKD after HSCT is important because it may occur in 15% of all HSCT, and evolution to ESRD is costly and has a poor prognosis.

Long-Term Renal Outcome in Patients with APRT Deficiency and 2,8-Dihydroxyadeninuria Vidar O. Edvardsson,[1,2] Hrafnhildur Linnet Runolfsdottir,[1] Inger Maria Agustsdottir,[2] Runolfur Palsson.[1,2] *[1]University of Iceland – National University Hospital of Iceland, Reykjavik, Iceland; [2]University of Landspitali – National University Hospital of Iceland, Reykjavik, Iceland.*

Background: Adenine phosphoribosyltransferase (APRT) deficiency is an autosomal recessive disorder of purine metabolism leading to excessive urinary excretion of the poorly soluble 2,8-dihydroxyadenine (DHA). The majority of reported patients have developed radiolucent kidney stones but the prevalence of chronic kidney disease (CKD) and end-stage kidney failure (ESKF) has not been well established. The aim of this study was to assess the long-term renal outcome in patients with this disorder.

Methods: The medical records of all 45 patients listed in the APRT Deficiency Registry of the Rare Kidney Stone Consortium were reviewed for clinical features including kidney stones, significant unilateral kidney damage, reduced kidney function and age at onset of renal replacement therapy. Data are presented as median and range.

Results: Of the 45 patients in the Registry, 20 were males. Median age at diagnosis was 27.3 (0.6-62.8) years. Clinical features included kidney stones in 24 patients (53%), CKD in 18 patients (40%) and reddish-brown diaper stain in 5 (11%) infants. Fifteen patients (33%) were asymptomatic at the time of diagnosis. Seven patients (16%) developed ESKF at a median age of 37 (15-54) years. In 4 of these patients, the diagnosis of APRT deficiency was not made until 4.8 (0.2-5.1) years after the development of ESKF. Severe unilateral kidney damage was observed in 4 additional patients leading to unilateral nephrectomy in 3 cases. Overall, a delay in diagnosis of 6.7 (0.4-39.2) years occurred in 24 patients. Causes for this delay included confusion of DHA calculi with uric acid stones and of renal histopathological findings with other forms of crystalline nephropathy. In addition, urinary crystals were not identified correctly in several patients.

Conclusions: CKD is a common manifestation of APRT deficiency in our series of patients. Unfortunately, a substantial proportion of patients progress to ESKF due to lack of timely diagnosis and treatment. Increased awareness of this disorder among both clinicians and pathologists is important.

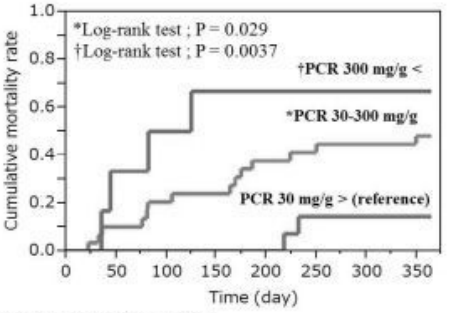
Proteinuria with Increased Serum Hepcidin-25 Level Is a Sign of Poor Prognosis in Patients with Non-Hodgkin Lymphoma Masaki Hara,[1] Minoru Ando,[1] Ken Tsuchiya,[2] Kosaku Nitta.[2] *[1]Department of Nephrology, Tokyo Metropolitan Komagome Hospital, Tokyo, Japan; [2]Department IV of Internal Medicine, Tokyo Women's Medical University, Tokyo, Japan.*

Background: Proteinuria is associated with mortality. Highly elevated serum hepcidin-25 levels may imply existence of strong inflammation related to cancer. An association between proteinuria and serum hepcidin-25 level was studied with special reference to mortality in non-Hodgkin lymphoma (NHL) patients.

Methods: A 1-year prospective cohort study was conducted in 54 NHL patients (male, 66.6%). Proteinuria was defined as protein to creatinine ratio (PCR) > 30 mg/g. Serum hepcidin-25 level was measured by mass spectrometry. Mortality rate was analyzed by the Kaplan-Meier method. Multivariate Cox's analysis was used to calculate hazard ratio (HR) with its 95% confidence interval (CI) of proteinuria for mortality, adjusted for gender, estimated glomerular filtration rate (eGFR) and international prognostic index (IPI) scores for lymphoma. Multiple linear regression analysis was employed to identify factors associated with presence of proteinuria, incorporating gender, IPI scores, hemoglobin, eGFR, serum hepcidin-25, serum c-reactive protein, serum ferritin and serum albumin.

Results: Prevalence of proteinuria was 25.9%. The mortality rate and HR were significantly increased according to increasing grades of PCR. The median [interquartile range] serum hepcidin-25 level was 10-fold higher than that in healthy controls (50.5 [22.6-97.7] vs 5.7 [1.6-12.7] ng/ml). serum hepcidin-25, but not other variables, was identified as a significant factor related to the presence of proteinuria (standardized $\beta = 0.43$, $P = 0.0016$).



Multivariate Cox's analysis for mortality

Variable	HR	95% CI	*P*
PCR 30 mg/g >	-	-	-
PCR 30–300 mg/g	**6.88**	1.75-47.46	**0.0036**
PCR 300 mg/g <	**13.97**	2.35-119.93	**0.0039**

Conclusions: Mortality of NHL patients is significantly associated with the presence of proteinuria, which might be induced by cancer-related inflammation.

SA-PO236

Determining Factors of Kidney Size and Its Association with Kidney Function Ylian S. Liem,[1] Peter J. Blankestijn,[1] Frank L.J. Visseren.[2] *[1]Department of Nephrology, University Medical Center Utrecht, Utrecht, Netherlands; [2]Department of Vascular Medicine, University Medical Center Utrecht, Utrecht, Netherlands.*

Background: Reports on factors that determine kidney size are conflicting. The aim of this study was to assess which factors are associated with kidney size in a population of patients with manifestations of atherosclerotic vascular disease. In addition, we assessed mean values of kidney size for different groups.

Methods: In a population with clinically manifest vascular disease, included in the Second Manifestations of ARTerial disease (SMART) study (n=5,840), kidney length was measured in cm on ultrasound, and the mean of the left and right kidney was calculated. We examined the association between age, gender, height, weight, smoking, blood pressure, presence of diabetes, hyperlipidemia, estimated GFR (eGFR), type of vascular disease, and extent of vascular disease with kidney length, using univariable and multivariable (corrected for age and gender) linear regression analysis. We excluded patients with known renal disease and patients with partial or complete agenesis of one kidney.

Results: Increasing age (B per year -0.021, 95% CI -0.023 to -0.019) and female gender (B -0.637; 95% CI -0.689 to -0.585) were associated with shorter kidney length. In the multivariable analyses, increasing height (B per m 3.302, 95% CI 2.975 to 3.629), weight (B per kg 0.025, 95% CI 0.023 to 0.027), and higher eGFR (B per ml/min 0.014, 95%CI 0.013 to 0.016) was associated with greater kidney length. The presence of diabetes mellitus was also associated with greater kidney length (B 0.257, 95%CI 0.197 to 0.316). Mean kidney length for age groups <55yr, 55-65yr and >=65yr were 11.6, 11.5 and 11.1cm for males and 11.0, 10.8 and 10.5cm for females. For eGFR groups <60, 60-90 and >= 90 ml/min, mean kidney lengths were 10.6, 11.2 and 11.7cm.

Conclusions: Increasing age, female gender, shorter stature, lower weight and lower eGFR are associated with shorter kidney length. In addition, diabetes mellitus is associated with greater kidney length; hyperfiltration – present in diabetes mellitus – might explain for this greater kidney length.

SA-PO237

Determinants and Heritability of Kidney Length: A Family-Based Population Study Menno Pruijm,[1] Belen Ponte,[2] Daniel Ackermann,[3] Philippe Vuistiner,[4] Ute Eisenberger,[3] Michel Burnier,[1] Pierre-Yves F. Martin,[2] Felix J. Frey,[3] Murielle Bochud.[4] *[1]Nephrology, University Hospital (CHUV), Lausanne, Switzerland; [2]Nephrology, University Hospital (HUG), Geneva, Switzerland; [3]Nephrology, University Hospital, Bern, Switzerland; [4]Institute of Social and Preventive Medicine (IUMSP), Lausanne, Switzerland.*

Background: Kidney length is an important parameter in renal clinical decision making, yet large population-based studies are sparse, and the heritability of kidney size is unknown. The aim of this study was to assess the heritability and some other determinants of kidney length in a family-based study.

Methods: The SKIPOGH study (Swiss Kidney Project on Genes in Hypertension) is a cross-sectional examination survey exploring the role of genes and kidney hemodynamics in blood pressure regulation and hypertension. Anthropometric parameters and renal ultrasound measurements were assessed in a randomly selected sample of index subjects and at least one first degree relative. The ASSOC program in SAGE (Statistical Analysis in Genetic Epidemiology) was used to estimate the age, sex, body weight and height, eGFR (CKD-EPI) and center-adjusted narrow sense heritability.

Results: In total, 793 participants coming from 205 nuclear families were included. Mean (±SD) kidney length in men (n=374, age 47±18 years, BMI 26.2±4 kg/m², eGFR 98±18 ml/min/1.73m²) was 11.4±0.8cm, as compared with 10.7±0.8cm in women (aged 48±17y, BMI 24.5±5, eGFR 95±17). There was no difference in length between the right and left kidney. In multilevel adjusted linear regression analysis, body height, weight and eGFR were positively associated with kidney length, whereas gender, diabetes and hypertension were not. There was a non linear association between age and kidney length. The heritability (h^2) of kidney length, adjusted for all mentioned confounders, was 52.4±8 %, p<0.001.

Conclusions: This study suggests that kidney length is an inherited trait, independently of other important determinants such as age, estimated kidney function, body height and weight.

Evidence of Altered Perception Causing Severe Fatigue in ANCA-Associated Vasculitis Andrew McClean,[1] Neil Basu,[2] Matthew David Morgan,[1] David A. Jones,[1] Jos A. Bosch,[1] Lorraine Harper.[1] *[1]University of Birmingham, United Kingdom; [2]University of Aberdeen, United Kingdom.*

Background: Up to 70% of people with ANCA-associated vasculitis (AAV) report severe fatigue, the main cause of reduced quality of life in this group. However, no studies have previously determined whether the mechanism for this fatigue is cardiovascular, neuromuscular, or central.

Methods: We recruited 46 patients with AAV in remission, and 28 matched healthy controls. Baseline fatigue was measured using the Multidimensional Fatigue Index (MFI-20). Participants underwent a submaximal graded exercise test; heart rate (HR) and VO2 measurements were used to estimate VO2max (cardiovascular fitness), and perception of exertion was assessed using the Borg scale. A DEXA scan was used to assess muscle mass. Quadriceps muscle strength and voluntary muscle activation were measured by repeated maximal voluntary contractions (MVC) with super-imposed stimulation. Stamina was assessed with a sustained 50% MVC; super-imposed stimulations allowed assessment of muscular reserve at the point of subjective exhaustion.

Results: The AAV group reported much more severe fatigue than the control group in all dimensions of the MFI-20 (all p<.001). During exercise, estimated VO2max was similar in both groups (p=.216), but perception of exertion was significantly greater in the AAV group (mean gradient of Borg score against heart rate=0.184 [SE=0.02] vs 0.106 [SE=0.01] p=.002). Muscle mass was not significantly different between groups (p=.737), and neither were muscle strength (p=.439) or percentage voluntary muscle activation (p=.096). The AAV group appeared to have less stamina than the controls, as assessed by time to volitional muscular fatigue (mean=73.68s [SE=5.58] vs 96.3s [SE=6.41], p=.011), but importantly they had more residual muscular reserve (mean=73.7% [SE=3.3] vs 61.25% [SE=3.6], p=0.018), suggesting perception of fatigue was more important than actual muscular fatigue.

Conclusions: This evidence suggests that fatigue in AAV is not due to reduced muscular or cardiovascular capacity, but is the result of altered perception of cardiovascular and muscular exertion. Future strategies to improve fatigue should target this mechanism.

SA-PO239

Severe Fatigue and Psychological Morbidity in ANCA-Associated Vasculitis Andrew McClean,[1] Neil Basu,[2] Matthew David Morgan,[1] David A. Jones,[1] Jos A. Bosch,[1] Lorraine Harper.[1] *[1]University of Birmingham, United Kingdom; [2]University of Aberdeen, United Kingdom.*

Background: Patients with ANCA-associated vasculitis (AAV) report fatigue as a main debilitating symptom, but little systematic research has been done to assess its impact. We aimed to characterize the severity of this fatigue, and its influence on patients' well-being and psychological morbidity.

Methods: We recruited 149 patients with AAV, 68 CKD disease controls, and 57 healthy controls to this cross-sectional study. Participants completed a questionnaire comprising the Multi-Dimensional Fatigue Index (MFI-20), and a number of other symptom rating scales including the Hospital Anxiety and Depression Scale (HADS).

Results: Both the AAV and CKD groups reported significantly higher levels of fatigue than the healthy group (Table 1, p<.001 multivariate), with scores comparable to the norm levels in chronic fatigue syndrome (CFS) patients. Both also reported that fatigue is a major impairment to professional, family, and social life (p<.001 for all, compared to healthy controls). Moreover, 27% of AAV patients had clinically significant anxiety or depression; this was comparable to the values found in the CKD group, and three-fold higher than in the healthy group (p<.001). Stepwise regression analysis showed that individual differences in fatigue explained differences in anxiety and depression, but not vice-versa, suggesting a causal association.

Table 1

	AAV	CKD	Healthy
MFI-20:General	14.27 (.355)	12.87 (.542)	7.71 (.481)
MFI-20:Physical	13.48 (.4)	13.39 (.572)	7.18 (.418)
MFI-20:Activity	11.95 (.384)	12.59 (.589)	6.73 (.467)
MFI-20:Motivation	10.54 (.317)	11.00 (.506)	6.63 (.374)
MFI-20:Mental	10.39 (.382)	9.66 (.567)	7.20 (.414)
HADS-Anxiety	6.90 (.384)	6.32 (.530)	4.49 (.466)
HADS-Depression	5.64 (.291)	5.60 (.490)	2.15 (.369)

Mean scores with SE for the 5 dimensions of fatigue (MFI-20), anxiety and depression (HADS)

Conclusions: Fatigue in AAV is comparable to the levels seen in CFS and CKD, and is associated with major role impairments. High levels of anxiety and depression are also seen in this group, possibly secondary to fatigue. This indicates the need for further research into the determinants and treatment of severe fatigue in AAV.

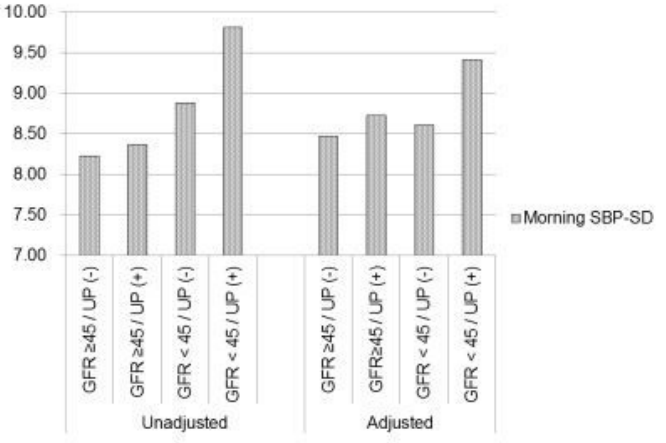
The Presence of Chronic Kidney Disease Is Related to Higher Day-by-Day Blood Pressure Variability: The Ohasama Study Hiroyuki Terawaki,[1] Masaaki Nakayama,[1] Masahiro Kikuya,[2] Takayoshi Ohkubo,[2] Yutaka Imai.[2] *[1]Department of Nephrology and Hypertension, Fukushima Medical University, Fukushima, Japan; [2]Department of Planning for Drug Development and Clinical Evaluation, Tohoku University Graduate School of Pharmaceutical Sciences, Sendai, Japan.*

Background: Both day-by-day blood pressure variability, defined as within-subject SDs of home measurement, and chronic kidney disease (CKD) are known to be linked with an increased risk of cardiovascular disease, however, their relationship remains unclear. The present study was aimed to evaluate the relationship between renal dysfunction, proteinuria and day-by-day blood pressure variability.

Methods: We recorded self-measured morning blood pressure (BP) at home in 1,383 individuals (mean 63.2 years old; males, 32.0%; mean glomerular filtration rate [GFR], 46.1 mL/min/1.73 m^2; positive proteinuria, 13.4%) and classified the subjects into four groups: higher GFR without proteinuria (GFR≥45/UP(-), n=637), higher GFR with proteinuria (GFR≥45/UP(+), n=69), lower GFR without proteinuria (GFR<45/UP(-), n=561), and lower GFR with proteinuria (GFR<45/UP(+), n=116).

Results: Compared with the GFR≥45/UP(-) group, the GFR<45/UP(+) group exhibited a significantly higher SD of systolic BP.



Conclusions: The presence of CKD is related to higher day-by-day blood pressure variability.

SA-PO242

Timing and Determinants of Low Urinary Creatinine Excretion in Chronic Kidney Disease Elena Tynkevich,[1] Jean-philippe Haymann,[3] Pascal Houillier,[4] Benedicte Stengel.[1] *[1]CESP U1018 INSERM, Villejuif, France; [2]U702 INSERM, Tenon Hospital, Paris, France; [3]U872 INSERM, HEGP, Paris, France.*

Background: Reduced muscle mass is common in patients with end-stage CKD, but less is known about its timing and determinants in early stage CKD.

Methods: After excluding patients with incomplete urine collection, we studied 24-hr urinary creatinine excretion (UCrV), a marker of muscle mass, in 1087 (726 men/361 women) non dialysis patients with all-stage CKD. All of them had glomerular filtration rate measured (mGFR) by ^{51}Cr-EDTA renal clearance. We used gender specific thresholds to define low creatinine excretion as a value < the 10th percentile of UCrV distribution in patients with mGFR ≥60 ml/min/1.73m^2, i.e., 0.13 mmol/kg/24h in men and 0.12 mmol/kg/24h in women.

Results: Mean mGFR was 42.4 ml/min/1.73m^2 in men and 40.1 ml/min/1.73m^2 in women; mean UCrV was 0.17 mmol/kg/24h and 0.14 mmol/kg/24h, respectively. In both genders, the percentage of low UCrV increased with increasing age and body mass index (BMI), was negatively associated with protein intake assessed by 24-hr urinary urea excretion and was lower in African patients. In men, this percentage was higher in patients with elevated serum prealbumin level, but lower in those with high serum fibrin level. After adjusting for age, ethnicity, BMI, prealbumin, serum fibrin and protein intake, the OR (95% CI) of low UCrV associated with decreasing mGFR from 30-44 to 15-29 and <15 compared to >=45 ml/min/1.73m^2 were 1.8 [1.0-3.4], 5.5 [3.0-10.0] and 6.2 [2.2-17.7] in men and 1.5 [0.7-3.5], 1.5 [0.7-3.4] and 3.1 [0.8-11.6] in women.

Conclusions: The observed decrease in UCrV associated with mGFR decline suggests that a reduction in muscle mass may appear early in CKD patients. An increase in extra-renal excretion of creatinine via the gut cannot be ruled out to explain this association, even though it is usually considered only significant in late stage CKD.

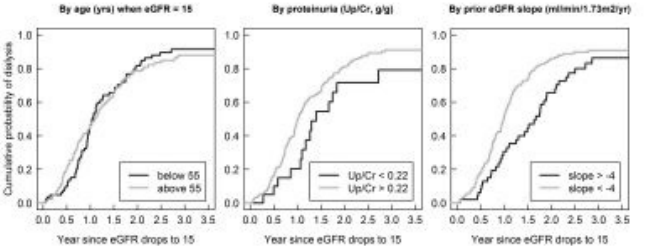
SA-PO243

Time-to-Dialysis when Estimated GFR (eGFR) Drops below 15 ml/min/1.73m2: Results from the African American Study of Kidney Disease (AASK) Study Liang Li,[1] Lawrence J. Appel,[2] Brad C. Astor,[3] Michael S. Lipkowitz,[4] Jackson T. Wright,[5] Tom Greene.[6] *[1]Cleveland Clinic; [2]Johns Hopkins University; [3]University of Wisconsin-Madison; [4]Georgetown University; [5]Case Western Reserve University; [6]University of Utah.*

Background: Preparation for renal replacement therapy is essential as GFR declines towards 15 ml/min/1.73m^2 (CKD stage V), but the time to subsequent initiation of the therapy and its relationship with patient conditions at first reaching eGFR of 15 have not been established.

Methods: Bayesian penalized splines were used to estimate the eGFR trajectory for each AASK patient with at least 3 yrs follow-up. From these trajectories, we identified pts whose eGFR declined to 15 ml/min/1.73m^2. The time from eGFR reaching 15 to dialysis was analyzed, with adjustment for competing risks by death and stratification by age, urine protein/creatinine ratio (Up/Cr) when eGFR dropped below 15, and the mean eGFR slope over the prior 3 yrs.

Results: An eGFR decline to 15 ml/min/1.73m^2 occurred in 175 of 846 (21%) of AASK pts with at least 3 yrs follow-up. Compared to those whose eGFR did not decline to 15, these pts were more likely female (50.3% vs. 36.4%), had lower eGFR (39 vs. 52.5 ml/min/1.73m^2) and higher Up/Cr (0.556 vs. 0.156 g/g) on average at enrollment. Of the 175 pts, 46% started dialysis within a year, 80% within 2 yrs, and 90% within 3 yrs. Longer gap between eGFR reaching 15 and dialysis was not significantly associated with younger age (p=0.6) and lower proteinuria (p=0.1) but was associated with less steep prior eGFR slope (p=0.02).



Conclusions: This study demonstrates considerable heterogeneity in the timing of dialysis among CKD patients whose eGFR drops to 15 ml/min/1.73m^2. These results highlight the importance of developing prediction models to guide personalized planning for initiation of dialysis.

SA-PO244

Using Machine-Learning to Predict Progression of Chronic Kidney Disease from Electronic Health Record Data Herbert S. Chase. *Departments of Medicine and Biomedical Informatics, Columbia University, New York, NY.*

Background: The individual rate of progression of Stage 3 Chronic Kidney Disease (CKD) varies considerably. Current calculators provide reasonable probability estimates of progression but require manual data input and cannot be used if data is missing. The purpose of this study was to use machine-learning tools to predict CKD progression using data from the electronic health record (EHR), even if incomplete.

Methods: Using EHR data, patients with Stage 3 CKD were identified as having MDRD-eGFR < 60 ml/min/1.73m2 consistently and for at least 90 days. Two cohorts of patients were identified: Progressors (P) (eGFR declined > 3 ml/min/1.73m2/year) and Non-Progressors (NP) (eGFR declined < 1 ml/min/1.73m2). The data from 2 years prior to 2 years after Stage 3 entry was collected for each patient, if available, and yearly averages were calculated. ICD-9 codes for co-morbid conditions and demographic information on each patient were extracted. Various machine-learning algorithms (Logistic regression, Naïve Bayes, and J-Rip) were used to develop a model predicting disease progression.

Results: The following attributes differed between the two arms and were used for machine learning models: serum albumin, calcium, phosphorous, hemoglobin, hemoglobin A1C, HCO3, Na, K and urine dipstick protein, diabetes mellitus, acute kidney injury, congestive heart failure, glomerulonephritis and African-American race. A minority of patients had all lab values recorded; over 30% lacked urine protein and phosphorous measurements. Of the three machine-learning models, Naïve Bayes provided the best results: sensitivity and positive predictive value were 55% and 56%, respectively; specificity and negative predictive value were 86% and 85%, respectively. The area under the ROC curve was 0.77.

Conclusions: Even when data is missing, machine-learning tools that utilize EHR data can differentiate with reasonable accuracy patients who are likely to proceed from stage 3 to stage 4 CKD from non-progressors. Accuracy should improve when patients receive all appropriate tests. The prediction tool could function automatically by extracting EHR data, without manual entry.

SA-PO245

Differential Risk of Dialysis versus Death in Black versus White Veterans Is Attenuated by Older Age and Lower Levels of Kidney Function

Jessica W. Weiss,[1] Thy P. Do,[2] Adam J. Batten,[2] Yoshio N. Hall,[2] Ann M. O'Hare.[2] *[1]Div. Nephrology, Oregon Health and Science Univeristy, Portland, OR; [2]Div. Nephrology, University of Washington, VA Puget Sound Healthcare, Seattle, WA.*

Background: Recent studies have reported a higher risk of progression to end stage renal disease (ESRD) as compared with death among Black patients versus White patients in the U.S. However, the relative risk of ESRD versus death may be modified by level of kidney function.

Methods: We conducted a retrospective cohort study of a national cohort of VA patients aged 18-100 years, who were either Black (n=225,942) or White (n=1,127,362) and with at least one outpatient measurement of serum creatinine, blood pressure, and body mass index from 10/1/2000 - 9/30/2001. We calculated incidence rate ratios (IRRs) to describe the time to ESRD versus time to death by race, age and estimated glomerular filtration rate (eGFR).

Results: Black-White differences in risk of ESRD vs. death were attenuated in older patients and those with lower levels of kidney function. With decreasing kidney function, progression to ESRD was more common as compared with death in both black and white patients. However, racial disparities in the relative incidence of these two outcomes were amplified by decreasing kidney function and increasing age. In cohort members age 60-74, Black patients with severe CKD experienced a relatively greater risk of ESRD than death (IRR 1.72), whereas the risk of death exceeded that of ESRD in White patients in this age group with any level of eGFR.

Conclusions: Racial differences in the relative frequency of ESRD and death vary as a function of age and kidney function.

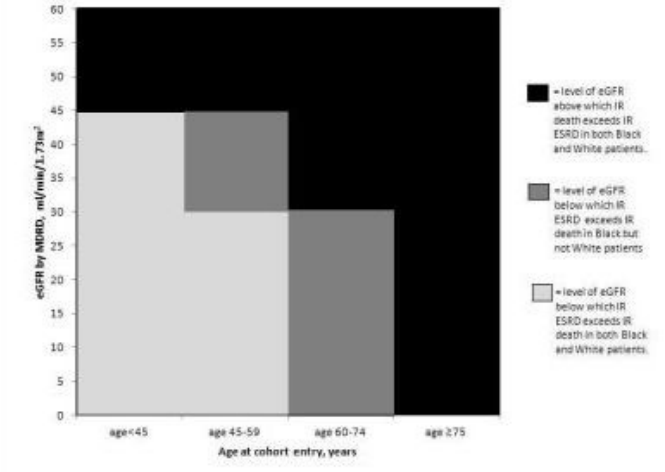

Figure 1: The threshold level of eGFR at which incidence rate (IR) of ESRD exceeded that of death differed for Black and White patients.

The Relationship between Blood Pressure and Mortality in Older Adults with Chronic Kidney Disease Is Modified by Age and Renal Function

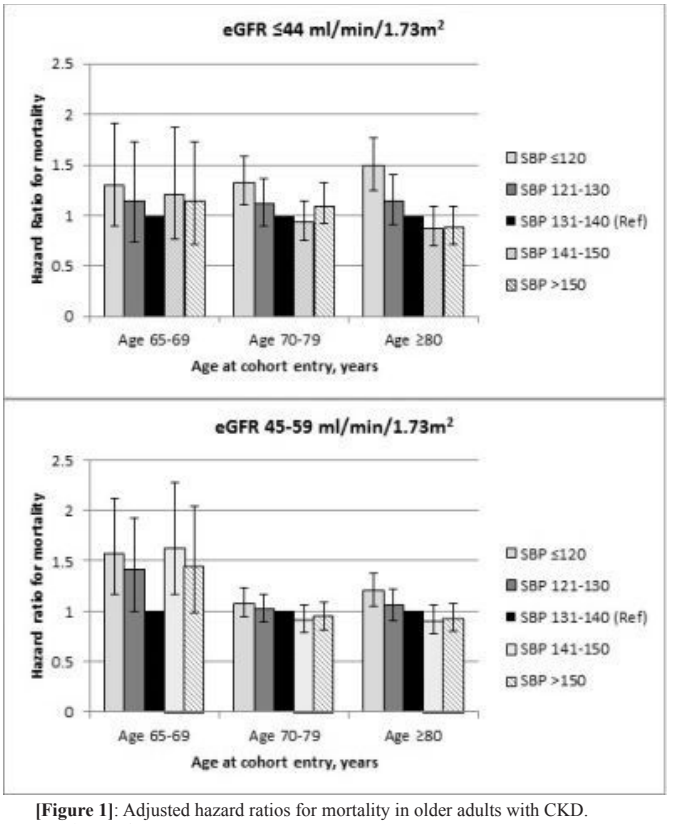
Jessica W. Weiss,[1] Dawn Peters,[2] Xiuhai Yang,[3] Amanda F. Petrik,[3] David Smith,[3] Eric S. Johnson,[3] Micah L. Thorp,[3] Cynthia Morris,[4] Ann M. O'Hare.[5] *[1]Div. Nephrology, Oregon Health and Science Univ. (OHSU), Portland, OR; [2]Div. Biostatistics, OHSU, Portland, OR; [3]Science Program, Center for Health Research, Kaiser Permanente NW, Portland, OR; [4]Medical Informatics & Clin. Epi., OHSU, Portland, OR; [5]Div. Nephrology, Univ. of Washington, VA Puget Sound Healthcare, Seattle, WA.*

Background: Few studies have evaluated the impact of renal function on age-related differences in the relationship between blood pressure and mortality.

Methods: We conducted a retrospective cohort study of older adults with CKD within a health maintenance organization (Kaiser Permanente Northwest) between 1999-2010 (n=23,511). We classified patients by baseline systolic blood pressure (SBP) in 10 mmHg bands (≤120…>150), severity of CKD (estimated glomerular filtration, eGFR, ≤44 versus 45-59 ml/min/1.73m^2), and age (65-69, 70-79, 80+ years). The relationship between SBP and mortality was measured with Cox Proportional Hazards regression, stratified by age group and level of renal function.

Results: In the youngest cohort members, there was a u-shaped relationship with SBP, with higher mortality at SBP levels both above and below the referent (SBP 131-140 mmHg); this difference was significant among those with higher baseline eGFR. In older cohort members (ages 70+), mortality was highest for those with the lowest levels of SBP, whereas mortality at the highest level of SBP was similar to the referent. This increase in mortality with low SBP in the older cohort was greatest for those age 80+ with low eGFR.

Conclusions: The relationship between blood pressure and mortality in older adults with CKD may vary with age and renal function.



[**Figure 1**]: Adjusted hazard ratios for mortality in older adults with CKD.

Albumin:Creatinine Ratio or 24 Hour Albumin Excretion for Albuminuria Staging?

Lieneke E. Scheven, Hiddo Jan Lambers Heerspink, Paul E. de Jong, Dick de Zeeuw, Ron T. Gansevoort. *Nephrology, University Medical Center Groningen, Netherlands.*

Background: New guidelines advocate the use of albumin:creatinine ratio (ACR) instead of 24h-urinary albumin excretion (UAE) for staging albuminuria. Concern has been expressed that this may result in misclassification because of interindividual differences in the urinary creatinine excretion. We examined the number of subjects that are reclassified and their cardiovascular (CV) outcome.

Methods: Included were subjects participating in the PREVEND study (N=5367) and the RENAAL study (N=701) of whom data on 24h-UAE, ACR (in a first morning void as well as 24h-urine sample) and fractional UAE were available at baseline. For categorization 3 albuminuria classes as advocated by KDIGO were used (<30, 30-300, >300 mg/24h and mg/g and corresponding fractional UAE classes).

Results: When using ACR in the first morning void instead of UAE 89% of subjects were classified in corresponding albuminuria categories. 234 (3.9%) participants were classified to a higher and 426 (7.0%) to a lower category. When 24hr ACR was used instead of the first morning void ACR the number of reclassified subjects was significantly lower (n=47 [0.8%] up and n=280 [4.6%] down, resp., both p<0.001), indicating that reclassification is for a large part due to (diurnal) variation in urinary albumin rather than creatinine concentration. Using data on fractional UAE it showed that 44/47 (94%) of upward reclassified subjects were correctly reclassified, suggesting that errors in 24hr urine collection also partly explain reclassification. In line, Cox regression analyses showed that upward reclassification when using first morning void ACR instead of UAE was associated with a tendency for increased CV risk, whereas downward reclassification was associated with lower risk: e.g. upward reclassification from UAE normo- to first morning void ACR microalbuminrua (n=203 or 3.4%) was associated with a Hazard rate (95%CI) of 1.71 (1.14-2.57) unadjusted and 1.48 (0.98-2.24) age and gender adjusted.

Conclusions: Our results indicate that although there is reclassification when using first morning void ACR instead of 24hr UAE, reclassification is often correct and indicative for prognosis.

SA-PO248

Is Albuminuria Associated with an Increase in Tubular Reabsorption of Uric Acid? Lieneke E. Scheven, Michel M. Joosten, Paul E. de Jong, Stephan J.L. Bakker, Ron T. Gansevoort. *Nephrology, University Medical Center Groningen, Netherlands.*

Background: In several studies serum uric acid (SUA) concentration has been found to be associated with albuminuria. This association has been explained as SUA causing vascular damage, resulting in an increase in albuminuria. We studied whether the opposite relation may also be true, i.e. whether albuminuria can be a cause for an increase in SUA, and -if so- what the underlying mechanism would be.

Methods: Included were 7,573 participants of the PREVEND Study (an observational general population based cohort study) with data on SUA and 24hr urinary UA excretion available, who were not using drugs that may influence SUA. Linear regression analyses were used to test associations of albuminuria with SUA and uric acid load (calculated as 24h UA excretion) and tubular UA reabsorption (calculated as (100-fractional UA excretion) %). Cox regression analyses were used to study the association of SUA and albuminuria with incident cardiovascular (CV) events.

Results: Albuminuria was positively associated with SUA, crude, as well as in models adjusted for potential confounders such as age, gender, alcohol consumption, BMI, eGFR and 24hr UA excretion (both p<0.001). When tubular UA reabsorption was added to the model, the association between albuminuria and SUA lost significance (p=0.79). In separate analyses albuminuria was found to be positively associated with tubular UA reabsorption, again crude, as well as in adjusted models (both p<0.001). During a median follow-up of 10.5 yrs 704 CV events occurred. After adjustment for CV risk factors CV event rate was predicted by albuminuria (HR=1.10 (95%CI 1.04-1.18) per SD, p=0.003) as well as SUA (HR=1.20 (1.11-1.31) per SD, p<0.001). When both were entered together into the Cox model a negative interaction between these variables was found (p=0.04), indicating that a high SUA has less predictive value for CV events when a high ACR is present, and vice versa.

Conclusions: Based on these data we conclude that albuminuria may cause an increase in SUA, by enhancing tubular UA reabsorption. This phenomenon may explain in part why albuminuria is associated with CV outcome.

SA-PO249

Prevalence of Vitamin D Deficiency According to Degrees of Albuminuria Yun Jung Oh,[1] Hajeong Lee,[1] Hayne C. Park,[1] Jeonghwan Lee,[1] Yon Su Kim,[1,2] Dong Ki Kim.[1] *[1]Internal Medicine, Seoul National University Hospital, Seoul, Republic of Korea; [2]Kidney Research Institute Medical Center, Seoul National University Hospital, Seoul, Republic of Korea.*

Background: Both albuminuria and vitamin D deficiency are common health problems associated with cardiovascular and kidney diseases. Although prevalence of albuminuria is increased with decreasing serum vitamin D levels, there is no clear threshold level of albuminuria that predicts vitamin D deficiency or changes in serum 25-hydroxyvitamin D (25OHD) levels.

Methods: We analyzed data from 7,709 adultswho had a voluntary routine health checkup at Seoul National University Hospital(Seoul, Korea) from Jan 2008 to Mar 2012. Vitamin D deficiency was defined as a serum 25OHD≤15 ng/ml, and a degree of albuminuria was evaluated with urinary albumin-to-creatinine ratio(ACR) from untimed urine samples and categorized as normal (ACR <10), mildly increased (ACR 10-29), moderately increased (ACR 30-299), and severely increased albuminuria (ACR >300 mg/g).

Results: The overall prevalence of vitamin D deficiency was 19.2%, and the mean serum 25OHD levels were22.4±8.2 ng/ml. The mean ACR was 23.2±180.3 mg/g, and the prevalence of normal, mildly increased, moderately increased, and severely increased albuminuria were 75.4%, 17.0%, 6.6%, and 1.0%, respectively. In univariate analysis, a stepwise increase inthe levels of 25OHD (P for trend 0.019) and the prevalence of vitamin D deficiency(P for trend 0.001) were observed with increasing degrees of albuminuria.The multivariate analysis with the use of dichotomized ACR levels adjusted for age, sex, season, vitamin D supplementation, hypertension, diabetes, anemia, and glomerular filtration rate, showed a significant increased risk of vitamin D deficiency, beginning at ACR ≥10 mg/g (Odds ratio, 1.204; 95% confidential interval, 1.018-1.423).

Conclusions: Even mildly increased albuminuria may have association with vitamin D deficiency in Korean adult population.

SA-PO250

Prevalence, Predictors and Outcomes Associated with Dysnatremia in CKD Sang-Woong Han,[1,2] Anca Tilea,[2] Brenda W. Gillespie,[2] Fredric O. Finkelstein,[3] Margaret A. Kiser,[4] George Eisele,[5] Peter Kotanko,[6] Rajiv Saran.[2] *[1]Hanyang University; [2]University of Michigan; [3]Metabolism Associates; [4]University of North Carolina; [5]Medical College of Albany; [6]Renal Research Institute.*

Background: The epidemiology of dysnatremia in patients with advanced pre-dialysis chronic kidney disease (CKD) in the ambulatory setting has not been systematically investigated.

Methods: This prospective cohort study enrolled 2,183 CKD patients (55% male, 65% white, baseline mean age 64 years, 86% hypertensive, 43% diabetic) followed at 78 US sites for an average of 1.8 years. Linear regression was used to find predictors of serum sodium (SNa) at baseline or over time. Associations between SNa and time to death, and time to ESRD in baseline and time-dependent Cox models were examined, adjusting for age, gender, race, diabetes, blood pressure and eGFR. SNa was categorized as 4 indicator variables in the models (≤135, 135<SNa≤140, 140<SNa<145[ref], ≥145 mEq/L).

Results: The mean±SD estimated GFR was 25±11 mL/min/1.73 m^2, and mean baseline SNa was 140.5±3.1 mEq/L. The prevalence of hyponatremia (≤135 mEq/L) and hypernatremia (≥145 mEq/L) were 6% and 9%, respectively. Higher baseline SNa was significantly associated with male sex, higher systolic blood pressure, BMI and serum albumin, and lower eGFR and BUN, with a stronger effect associated with the same variables in time-dependent models. Significant relationship between baseline SNa and mortality was observed, with mortality risk significantly greater at SNa≤135mEq/L, (hazard ratio, HR=2.09, p=0.01) and ≥145 mEq/L (HR=1.83, p=0.02) compared with 140<SNa<145 mEq/L. Risk for ESRD was significantly higher among patients with SNa≤135 mEq/L compared with 140<SNa<145 mEq/L in time-dependent models (HR=1.48, p=0.04).

Conclusions: Dysnatremia was seen in 15% of patients with CKD in the outpatient setting. CKD patients with SNa≤135mEq/L were at higher risk for progression to ESRD and both hyponatremic and hypernatremic CKD patients were at higher risk of mortality. Greater attention to sodium disorders in routine nephrology care may help to improve patient outcomes.

Hyponatremia Associates with Mortality in Virologically Suppressed HIV Infected Patients Fabrice Gankam Kengne,[1] Henning J. Drechsler,[2] Naim M. Maalouf,[1] Roger Bedimo.[2] *[1]Internal Medicine, UTSW Medical Center, Dallas, TX; [2]Internal Medicine, North Texas VA Hospital, Dallas, TX.*

Background: Hyponatremia is the commonest electrolyte disorder in HIV infected patients. It is associated with increased mortality in hospitalized HIV patients with low CD4 count, but its significance in HIV infected but virologically suppressed ambulatory patients is unclear.

Methods: We assessed the association between baseline and incident time-updated outpatient hyponatremia and all cause mortality in HIV-infected US veterans who maintained virologic control after starting HAART. We used data from the VA Clinical Case Registry to build a Cox regression model adjusting for time-updated comorbidity parameters of the VACS score and restricted index (age, Hgb, eGFR, FIB4-liver fibrosis score, HCV coinfection, CD4 count, and viral load). Additionally we controlled for HAART adherence as calculated from the patients medication refill history.

Results: We identified 15714 patients with follow-up time >1.5 years after starting HAART who remained virologically suppressed for a median time of 3.3 years (IQR 2.0-5.8). 1249 (7.93%) patients had hyponatremia at cohort entry (baseline). We observed 1139 (7.2%) deaths during the follow up time. Incident mild (Na 130-135 mEq/L) and severe (Na <130 mEq/L) hyponatremia was associated with an increased risk of death both in univariate analysis and after adjusting for the VACS and restricted index covariates (HR 1.62, CI 1.39-1.90 and 2.64, CI: 1.91-3.64 respectively, p< 0.0001 for both in multivariate analysis).

Conclusions: Incident hyponatremia carries an independent significant association with mortality in successfully treated HIV-infected patients. Further studies are needed to better understand the nature of this association and if therapies directed toward preventing the occurrence of hyponatremia will affect mortality in HIV-infected patients.

SA-PO252

Urinary Biomarkers of Kidney Injury Are Associated with Death in the Women's Interagency HIV Study (WIHS) Carmen A. Peralta,[1,2] Rebecca Scherzer,[1,2] Carl Grunfeld,[1,2] Alison G. Abraham,[3] Phyllis Tien,[1,2] Prasad Devarajan,[4] Michael R. Bennett,[4] Mark J. Sarnak,[5] Chirag R. Parikh,[6] Michael Shlipak.[1,2] *[1]UCSF; [2]SFVAMC; [3]JHU; [4]Cincinnati Children's Hospital; [5]Tufts; [6]Yale.*

Background: Urinary markers of kidney injury have been associated with kidney disease risk in both HIV-infected and uninfected populations. CKD is associated with death. We investigated whether these markers are associated with risk for death among HIV infected women.

Methods: We determined the association of urine biomarkers with 10-year, all-cause death in 908 HIV-infected women. Biomarkers measured from stored baseline urine included interleukin-18 (IL-18), liver fatty acid binding protein (L-FABP), albumin-to-creatinine ratio (ACR), kidney injury molecule-1 (KIM-1), and neutrophil gelatinase-associated lipocalin (NGAL).

Results: Mean (SD) age was 41 ± 8 years;mean eGFRcys was 88 ± 21 ml/min/1.73m^2 at baseline. Participants in the highest IL-18 tertile had an age-adjusted mortality rate of 32%, compared with 21% and 15% in middle and lowest tertiles. After multivariable adjustment for demographic, traditional, HIV-related factors, and eGFRcys, higher IL-18 and higher ACR were independently associated with increased mortality. We found a U-shaped association between levels of L-FABP with death, as persons in the middle tertile had the lowest risk for death (Figure). Persons in the highest tertile of KIM-1 and NGAL were at higher risk for death compared to lowest in demographic adjusted models, but associations were attenuated after full adjustment: KIM-1 HR 1.41 (0.99, 2.02), NGAL HR 1.05 (0.74, 1.51).

Conclusions: Among HIV-infected women, novel urine markers of kidney injury are associated with risk for death, independently of kidney function and albuminuria. These markers represent potential tools to identify high risk HIV-infected persons with early kidney injury.

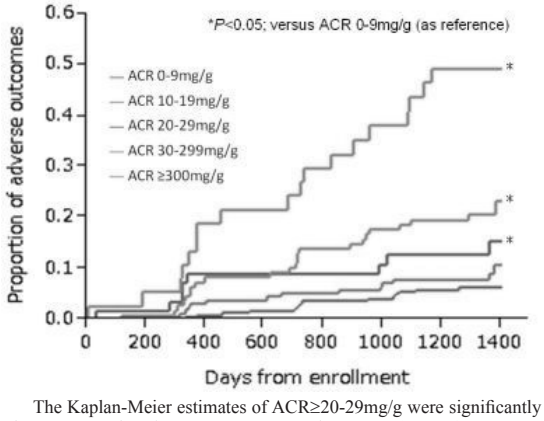
SA-PO253

Low-Grade Levels of Albumin Excretion Should Be Considered Significant in an HIV-Infected Population Naoki Yanagisawa,[1,2] Minoru Ando,[1,2] Atsushi Ajisawa,[1] Ken Tsuchiya,[2] Kosaku Nitta.[2] *[1]Department of Infectious Diseases and Nephrology, Tokyo Metropolitan Komagome Hospital, Tokyo, Japan; [2]Department IV of Internal Medicine, Tokyo Women's Medical University, Tokyo, Japan.*

Background: Albuminuria is a risk factor of overt kidney disease, mortality, and cardiovascular disease (CVD). A cut-off value that is relevant to such outcomes could be less than the conventional threshold in an HIV-infected population.

Methods: A 3.5-year prospective cohort study was conducted in 661 HIV-infected individuals (598 men, 63 women) to test a new cut-off relevant to the incidence of composite outcomes, including all-cause mortality, CVD, and a decrease in renal function. A decrease in renal function was defined as greater than 25% decrement of estimated glomerular filtration rate from baseline. Albumin excretion levels in spot urine were classified into 5 grades according to urinary albumin-to-creatinine ratio (ACR); 0-9, 10-19, 20-29, 30-299, and ≥300mg/g. The cumulative incidence of outcomes was analyzed by the Kaplan-Meier method, stratified by the grades of albumin excretion.

Results: All patients completed the follow-up period. The frequencies of ACR of 0-9, 10-19, 20-29, 30-300, and >300mg/g were 45.7, 23.9, 8.3, 16.5 and 5.6% respectively. Of 661, 82 (12.4%) developed at least one of the outcomes. A decrease in renal function, all-cause mortality, and CVD occurred in 60 (73%), 16 (19.5%), and 16 (19.5%), respectively. The cumulative incidence of outcomes increased with increasing grades of ACR.



The Kaplan-Meier estimates of ACR≥20-29mg/g were significantly higher than that of ACR 0-9 mg/g, whereas ACR 10-19mg/g was not (P=0.26).

Conclusions: The conventional cut-off value of ACR 30mg/g likely underestimates the number of HIV individuals at risk for developing adverse outcomes. Lowering the threshold of ACR to 20mg/g should be considered in medical care of HIV-infected persons.

SA-PO254

The Relationship between Ethnicity and Mortality within a Multi-Ethnic Population with Chronic Kidney Disease Mark David Jesky,[1,2] Paul Cockwell,[1,2] Andrew Felix Burden.[3] *[1]Nephrology Department, University Hospitals Birmingham NHS Foundation Trust, United Kingdom; [2]Department of Infection and Immunity, University of Birmingham, United Kingdom; [3]Birmingham and Solihull NHS Cluster of CCGs, United Kingdom.*

Background: People of South-Asian and Black ethnicity with chronic kidney disease (CKD) have more rapid progression to end stage kidney disease but better survival on dialysis than people of White ethnicity. However there are limited data on mortality differences by ethnicity in pre-dialysis CKD. We therefore assessed the relationship between ethnicity and mortality in a multi-ethnic, primary-care population with CKD stages 3 and 4.

Methods: Laboratory and clinical data are collated centrally in Heart of Birmingham Teaching Primary Care Trust (UK) for individuals 40 years of age or older in 63 of 74 primary-care practices. Using the May-June 2008 dataset, individuals with an estimated Glomerular Filtration Rate (eGFR) of 15-59 ml/min and a reported Albumin-Creatinine Ratio (ACR) within the previous 12 months were identified. Data on all deaths until February 2011 was obtained from the Office of National Statistics. Cox proportional hazards regression was used to analyse the association between ethnicity and mortality.

Results: 1909 individuals met criteria for analysis (1098 [57.5%] South Asian, 484 [25.4%] White and 327 [17.1%] Black). There were 224 (11.7%) deaths and a higher proportion of Whites died (White 15.5%, South Asian 10.6%, Black 10.1%, p=0.012). After adjusting for known risk factors, South Asians (hazard ratio [HR] of 0.728, 95% confidence interval [CI] 0.532 – 0.997, p=0.048) and Blacks (HR 0.642, 95% CI 0.42 – 0.98, p=0.04) had a lower risk of death than Whites. An increased risk of death was also independently associated with high ACR (above 30mg/g), decreased eGFR (below 30ml/min), age (above 80 years), male sex, current smoking status and the presence of ischaemic heart disease and heart failure.

Conclusions: In people with non-dialysis dependent CKD, individuals of South Asian and Black ethnicity have a lower risk of death than those of White ethnicity. This difference remains after correction for known risk factors.

Estimated Glomerular Filtration and Proteinuria in the Moroccan Population Marc E. De Broe,[1] Zamd Mohamed,[2] Monique M. Elseviers,[3] Abdelali Belghiti Alaoui,[4] Mohammed El Hassane Trabelssi,[4] Benyounès Ramdani,[4] Bayahia Rabia,[2] Mohammed Benghanem Gharbi.[2] *[1]International Society of Nephrology; [2]Moroccan Society of Nephrology, Morocco; [3]Epidemiology Research, University of Antwerp, Wilrijk, Belgium; [4]Ministry of Health, Morocco.*

Background: MaReMar (Maladies Rénales Chroniques au Maroc) is an epidemiological study estimating the prevalence of CKD, hypertension, diabetes type I and II in a representative randomized sample (n=10524) of the adult population of Morocco (26-70 y/age), identifying subjects at risk to develop CKD, establishing an intervention follow-up/program over 5 yrs.

Methods: The study was performed in 2 middle sized towns (Khemisset, El Jadida) with resp. a rural and industrialized character. We report on the eGFR (MDRD equation), microproteinuria (mPR), macroproteinuria (MPR). Serum creatinine (Scr) was determined using a methodology traceable to the Scr reference system (NIST) (GC-IDMS), microproteinuria (mPR) using the Hemocue method, MPR using dipstick (++ or more) on two morning midstream urine samples.

Results: 1.6% of the adult population of Morocco has a eGFR <60 ml/min/1.73m². In the age categories 26-40, 41-55, and 56-70 yrs of age, an eGFR<60ml/min/1.73m² was found in respectively 0.5%, 1.3%, and 6.6% of the subjects. In those with a eGFR below 60ml/min/1.73m², 63.7% had no proteinuria while 23.8% had mPR, 12.5% had MPR. 90% of them are categorized in the CKD3 class.

Glomerular Filtration Rate (MDRD)

		N	p5*	p25*	p50*	p75*	p95*	GFR<60
MALE	Total:	5122						3,0%
	age 26-29	466	83,7	102,1	114,4	129,8	165,1	0,4%
	age 30-39	1086	77,6	94,9	107,8	121,1	158,3	0,7%
	age 40-49	1026	73,5	89,1	101,9	116,3	143,3	0,9%
	age 50-59	1525	66,2	83,4	95,7	110,4	136,3	2,6%
	age 60-69	1019	51,1	73,8	87,3	99,8	122,9	9,1%
FEMALE	Total:	5402						2,5%
	age 26-29	411	87,9	104,6	118,3	134,5	176,0	0,0%
	age 30-39	1197	78,5	98,7	112,1	128,3	160,6	0,5%
	age 40-49	1393	73,1	89,6	102,2	117,1	150,4	0,6%
	age 50-59	1445	64,6	84,3	96,9	110,6	138,8	3,2%
	age 60-69	956	55,0	74,5	89,0	104,2	131,0	7,7%

* 5th, 25th, 50th, 75th and 95th percentile of the distribution within the gender and age category

Conclusions: The age and gender specific reference values of the eGFR in the Moroccan population is not substantially different from values found in other populations except that the median eGFR values are higher. 2/3 of the subjects with eGFR <60ml/min/1.73m² have no mPR nor MPR, and most likely not related to any form of renal disease. Follow up of MaReMar over the next 5 yrs will help in the unraveling of the clinical relevance of the KDOQI staging of CKD.

Funding: Government Support - Non-U.S.

SA-PO256

Decline in Kidney Function in the General Population: Results from the Reykjavik Study Anna Andrea Kjeld,[1] Runolfur Palsson,[1,2] Thor Aspelund,[1,3] Hrefna Gudmundsdottir,[1,2] Margret B. Andresdottir,[1] Vilmundur Gudnason,[1,3] Olafur S. Indridason.[2] *[1]Faculty of Medicine, University of Iceland; [2]Division of Nephrology, Landspitali - National University Hospital of Iceland; [3]Icelandic Heart Association, Reykjavik, Iceland.*

Background: The purpose of this study was to examine the change in kidney function over time among individuals with and without chronic kidney disease (CKD).

Methods: For subjects aged below 75 years who participated the Reykjavik Study, between 1967 and 1995, we retrieved all available measurements of serum creatinine from entry into the study until March 2011. Estimates of glomerular filtration rate (eGFR) were obtained using the MDRD Study equation and the slope of the change in eGFR in mL/min/1.73 m²/10 years calculated. Regression analysis was used to assess the relationship between risk factors (history of hypertension, diabetes and smoking, and measured blood pressure and cholesterol levels) and eGFR slope.

Results: Of 17,748 subjects with baseline data, 13,038 (73.4%) had at least one follow-up SCr value, of whom 5,818 (41.6%) were men. At baseline, 51.8% had hypertension, 3.0% had diabetes and 43.3% were smokers. Median (interquartile range) follow-up time was 29.4 (23.5-35.7) years.

Slope of eGFR in subgroups based on proteinuria and eGFR

Kidney function		≥ 60 mL/min/1.73 m²		< 60 mL/min/1.73 m²	
		No proteinuria	Proteinuria	No proteinuria	Proteinuria
Men	N	5418	133	238	29
	Slope*	-4.8 (-5.0 - -4.6)	-9.4 (-11.4 - -7.3)	-0.9 (-2.5 - 0.7)	-9.3 (-17.5 - -4.8)
Women	N	6347	48	806	19
	Slope	-3.7 (-3.9 - -3.6)	-8.1 (-11.4 - -4.8)	-0.4 (-1.2 - 0.3)	-7.6 (-14.2 - -1.1)

*in mL/min/1.73 m²/10 years (95% confidence interval)

The slope was steeper among diabetics and those with hypertension (P<0.05), and was associated with measured systolic blood pressure and smoking in both genders (P≤0.01). In men, higher cholesterol also associated with a steeper slope (P=0.006).

Conclusions: Our preliminary analysis indicates that the decline in kidney function is slow in this population-based cohort but is aggravated by proteinuria and traditional CVD risk factors. Smoking cessation and careful treatment of hypertension, diabetes and hypercholesterolemia might delay the progression of CKD.

Funding: Private Foundation Support, Government Support - Non-U.S.

SA-PO257

Overview of BC Patients with Chronic Kidney Disease Registered from 2003 to 2007 Gabriela Espino-Hernandez,[1] Lee Er,[1] Ognjenka Djurdjev,[1] Monica C. Beaulieu,[1,2] Adeera Levin.[1,2] *[1]BC Renal Agency, Vancouver, BC, Canada; [2]Division of Nephrology, UBC, Vancouver, BC, Canada.*

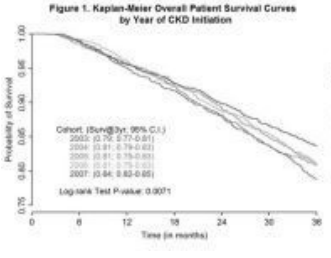
Background: British Columbia (BC) is the only Canadian province with formal registration and full data collection of patients with Chronic Kidney Disease (CKD) followed by nephrologists. This complete f/u permits accurate assessment of outcomes from 2003.

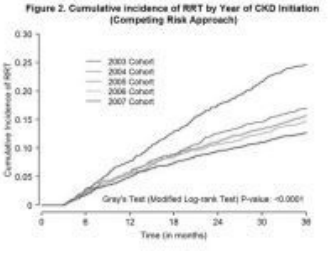
Methods: We created a cohort of 10,111 CKD patients registered in the provincial database from 2003 to 2007, with at least 3 yrs of f/u. Outcomes of interest: patient survival and Renal Replacement Therapy (RRT) event rate by year of CKD initiation, at 3 yrs, as well as eGFR at dialysis start.

Results: About 2,022 new CKD patients were registered each year. Cohorts remained similar: mean age 68 yrs, 44% female, 66% Caucasian, 38% diabetics, and 79% hypertensive. However, mean eGFR at entry went from 33mL/min in 2003 to 36mL/min in 2007. From the patients who reached RRT, 95% started dialysis, and 5% underwent pre-emptive transplant. Selection of PD vs HD as RRT remained at about 26% vs 74%, respectively.

The log-rank test indicated patient survival curves varied by CKD year (Figure 1). Based on a Cox proportional hazards model, after adjusting for age, gender, race, eGFR, uACR, and dialysis, the estimated hazard ratios went from 96% in 2004 to 76% in 2007. Figure 2 presents the cumulative incidence curves of RRT by year of CKD initiation, accounting for death as a competing risk factor. The Gray's test indicated differences in the RRT incident rate by CKD year. The adjusted hazard ratios decreased from 81% in 2004 to 65% in 2007.

Conclusions: This unique cohort serves the basis for ongoing evaluation of outcomes for clinical, CQI, and research purposes. Over time, there appears to be an improvement in the overall patient survival, and a delay in the progression of the disease. Reasons for this improvement warrant further study, and are currently under investigation.





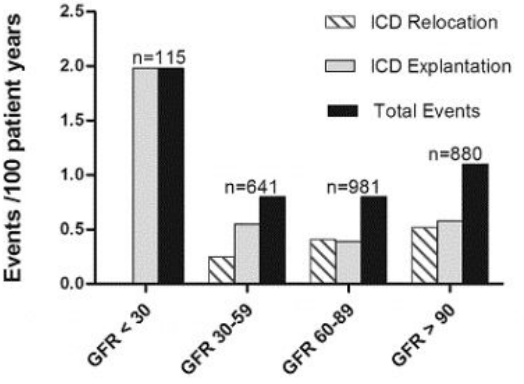
SA-PO258

Severe Renal Disease Increases the Risk for Device Related Complications in Patients with an Implantable Cardioverter Defibrillator Maurits S. Buiten,[1] Mihaly K. De Bie,[1] Joep Thijssen,[1] Joris I. Rotmans,[2] J. H.M. Groeneveld,[3] Ton J. Rabelink,[2] J. W. Jukema,[1] Martin J. Schalij,[1] L. Van Erven.[1] *[1]Cardiology, Leiden University Medical Center, Leiden, Netherlands; [2]Nephrology, Leiden University Medical Center, Leiden, Netherlands; [3]Nephrology, Medisch Centrum Haaglanden, Den Haag, Netherlands.*

Background: The implantable cardioverter defibrillator (ICD) has become a well-accepted therapy for the prevention of sudden cardiac death. However, serious comorbidities are influencing the ICD's positive effects. One of the most important comorbidities is renal disease, which might increase the risk for ICD related complications. In this study, the association between kidney function and the occurrence of ICD related complications was assessed.

Methods: All patients implanted with an ICD in the LUMC, the Netherlands, between '96 and 2011 were included. Patients were stratified according to the American Kidney Foundation stages of renal disease: GFR ≤30, 30-59, 60-89 or GFR≥90 mL/min. During follow-up all ICD explantations and relocations were monitored. Event rates were noted per 100 pt years.

Results: During follow-up (48±39 months) 3148 patients received an ICD (79% male, 62±13 yrs). In 97 (3%) patients, at least one ICD related complication occurred (43 relocations, 54 extractions). When stratified for GFR, the event rate was 2.0 per 100pt/years (95% CI 0.8–4.4) in patients with severe kidney disease (GFR≤30) and approximately 0.9(95% CI 0.7–1.1) in all other patients. When comparing severe kidney disease to patients with a GFR>30, the calculated rate ratios are 2.2 (95% CI 0.9–5.4, P=0.09) for all monitored complications and 4.0(95% CI 1.6–10.1, P=0.003) for ICD explantations.



Conclusions: This study demonstrates that severe kidney disease, is associated with an event rate for ICD related complications almost two times that of patients with a GFR≥30 mL/min.

SA-PO259

Blood Manganese Level, Diabetes and Chronic Kidney Disease Eun Sil Koh, Sungjin Chung, Hyun Chul Whang, Seok Joon Shin, Cheol Whee Park, Yong-Soo Kim, Yoon-Sik Chang. *Department of Internal Medicine, The Catholic University of Korea College of Medicine, Seoul, Korea.*

Background: The purpose of this study is to evaluate the association between blood manganese level and the prevalence of chronic diseases in Korean population.

Methods: Based on the Korean National Health and Nutrition Examination Survey (KNAHNES), a cross sectional study was done to analyze the association between blood manganese level and five chronic diseases, such as chronic kidney disease, hypertension, diabetes, ischemic heart disease and stroke. The study comprised 3996 participants aged ≥ 20, whose blood manganese had been measured. We defined renal dysfunction as eGFR < 65 ml/min/1.73m² and diabetes as fasting blood glucose ≥ 126 mg/dL.

Results: Serum manganese level was significantly decreased in renal dysfunction group than in normal renal function group (1.28±0.03 μg/L vs 1.35±0.01 μg/L, respectively; p=0.036). The level of serum manganese was also significantly lower in diabetes group than in non-diabetes group (1.26±0.02 vs 1.35±0.01 μg/L, respectively; p=0.001). There was no significant association with blood manganese level according to the presence of hypertension, ischemic heart disease or stroke. As results of multivariate logistic regression analysis adjusting for age, sex, and body mass index, the odds ratio for renal dysfunction was 0.589 (95% CI 0.394-0.881) and the odds ratio for diabetes was 0.649 (95% CI 0.478-0.879) when comparing the high quartile Q_{2-4} with the low quartile Q_1 of blood manganese level. The prevalence of renal dysfunction was 8.6% in low quartile Q_1, compared with 4.6% in high quartile Q_{2-4} (p=0.0148). Similarly, the prevalence of diabetes was 10.7% in low quartile but 7.4% in high quartile (p=0.0045).

Conclusions: The prevalence of renal dysfunction and diabetes was decreased in subjects with high blood manganese level, suggesting that blood manganese may have some role in renal function and glucose homeostasis.

SA-PO260

Association of Non-Alcoholic Fatty Liver Disease with Chronic Kidney Disease in the U.S. Population: Data from the National Health & Nutrition Examination Survey Jeffrey C. Sirota,[1] Kim Mcfann,[1] Giovanni Targher,[2] M. Chonchol,[1] Diana I. Jalal.[1] *[1]Division of Renal Diseases & Hypertension, University of Colorado, Aurora, CO; [2]Section of Endocrinology and Metabolism, University and Azienda Ospedaliera Universitaria Integrata of Verona, Verona, Italy.*

Background: Chronic kidney disease (CKD) is independently associated with non-alcoholic fatty liver disease (NAFLD) in other countries. This relationship has not been evaluated in the United States, where racial, ethnic, and dietary factors differ. We hypothesized that greater severity of NAFLD is associated with higher odds of CKD.

Methods: Cross-sectional analysis of 11,368 U.S. adult participants of the National Health and Nutrition Examination Survey 1988-1994. NAFLD, the exposure variable, was defined by ultrasonographic detection of steatosis in the absence of other liver diseases. CKD, the outcome, was defined as an estimated glomerular filtration rate (eGFR, by Modification of Diet in Renal Disease calculation) of ≤ 60mL/min/1.73m^2 or the presence of albuminuria in subjects with an eGFR of >60mL/min/1.73m^2.

Results: 2,891 (25.4%) patients in the cohort had CKD. NAFLD was associated with CKD in univariate regression analysis (OR 1.47, 95% C.I. 1.29-1.67, p <0.0001). Adjustment for demographics and metabolic syndrome components attenuated this relationship (adjusted OR 1.04, 95% C.I. 0.88-1.23, p=0.64). Moderate and severe NAFLD were increasingly associated with prevalent CKD in unadjusted analysis only.

Odds ratios for CKD (95% CI)

	mild NAFLD	moderate NAFLD	severe NAFLD
unadjusted model	1.11 (0.92-1.35, p=0.28)	1.64 (1.38-1.94, p<0.0001)	1.96 (1.53-2.51, p<0.0001)
adjusted model*	1.02 (0.81-1.27, p=0.89)	1.01 (0.82-1.24, p=0.92)	1.17 (0.83-1.66, p=0.38)

*adjusted for age, race, gender, history of hypertension or diabetes, systolic blood pressure, waist circumference, triglycerides, HDL-C, and HOMA-IR

Conclusions: Ultrasound-diagnosed NAFLD is associated with prevalent CKD among US adults in univariate analysis. This association is most likely due to the shared cardio-metabolic risk factors, as the relation is attenuated after adjusting for components of metabolic syndrome.

SA-PO261

Creatinine Excretion Rate and Mortality in Type 2 Diabetes and Nephropathy Arjan J. Kwakernaak,[1] Steef Jasper Sinkeler,[1] Stephan J.L. Bakker,[1] Gerjan Navis,[1] Hiddo Jan Lambers Heerspink,[2] Dick de Zeeuw.[2] *[1]Nephrology, University Medical Center Groningen, Groningen, Netherlands; [2]Clinical Pharmacology, University Medical Center Groningen, Groningen, Netherlands.*

Background: Creatinine excretion rate (CER) is associated with premature mortality in the general population and renal transplant recipients, possibly due to its close relationship with muscle mass. Whether CER has prognostic impact in diabetes is unknown, we therefore investigated whether CER is a determinant of mortality in diabetic nephropathy.

Methods: The RENAAL and IDNT trial databases were used for analysis. In total, 1.872 subjects (58% of the overall cohort) with type 2 diabetes and nephropathy with 24-hour urinary creatinine excretion data available were included. Primary endpoint for this analysis was all-cause mortality.

Results: Mean age was 60±8 years and median CER was 1400 mg/day (range 366–3400 mg/day). Body Surface Area, hemoglobin levels, non-Caucasian race, and albuminuria were independent, positive determinants of CER, while age, female gender, smoking and diabetes duration were independent negative determinants of CER. After a median follow-up of 36 (29-45) months, 300 subjects died. A Kaplan Meier analysis using sex-stratified tertiles of CER showed that each tertile of lower CER was associated with increased risk for mortality. In a multivariable Cox regression analysis, lower CER (as a continuous variable) was associated with higher risk for mortality (HR=0.45 (0.34 – 0.59), P<0.001) independent of other patient characteristics including age, gender and body weight. In sensitivity analyses with exclusion of subjects deviating more than 50% or 30% from estimated CER, as calculated by anthropometric data, the association of CER with mortality did not change materially.

Conclusions: Lower CER was strongly associated with increased mortality in patients with type 2 diabetes and nephropathy. As CER can be considered a proxy for muscle mass, this places renewed emphasis on physical condition in this population.

SA-PO262

Renal Artery Embolization, Nephrectomy and Repeated Procedures in Patients with Renal Angiomyolipoma: A US National Retrospective Cohort Study Hearns Charles,[1] Peter Sun,[2] Zhimei Liu,[3] Judith A. Prestifilippo,[3] John C. Hulbert,[4] John J. Bissler.[5] *[1]NYU Langone Medical Center; [2]Kailo Research Group; [3]Novartis Pharmaceuticals Corporation; [4]Urologic Physicians; [5]University of Cincinnati.*

Background: This study aimed to estimate the prevalence rates of newly observed and repeated renal artery embolization (RAE), partial and complete nephrectomy, in patients with sporadic renal angiomyolipoma (AML) or tuberous sclerosis complex (TSC) related AML in the United States.

Methods: We used a retrospective cohort study design and three US national health claims databases (2000-2010). Inclusion criteria were:1) diagnosis of sporadic AML (ICD9-CM: 223.0 but no 759.5) and AML associated with TSC (ICD9-CM: 223.0 and 759.5); 2) minimum data availability of one year prior to and 5 years following newly observed AML diagnosis. Prevalence rates of the first and repeated RAE, partial and complete nephrectomy for each cohort (TSC AML versus sporadic AML) were estimated. Cross cohort differences in these prevalence rates were examined using two-sample t-tests for proportions.

Results: Patients (N=2,813) meeting the inclusion criteria had a mean age of 51.5 years at the newly observed AML diagnosis; 47.1% were male. Within 5 years after the newly observed AML diagnosis, more TSC AML patients than sporadic AML had embolization (90.7% versus 30.5%, P<0.05), partial nephrectomy (68.3% versus 21.4%, P<0.05), and complete nephrectomy (77.2% versus 68.7%, P<0.05). Rate of repeated embolization was higher for sporadic AML (10.5% versus 2.6% P<0.05,) but rates of repeated partial nephrectomy (3.2% versus 2.0%) and complete nephrectomy (1.5% versus 1.4%) were similar between the two groups. In the TSC AML subgroup, more than half of the patients had at least two procedures (embolization, partial nephrectomy or complete nephrectomy) within 5 years after the newly observed AML diagnosis.

Conclusions: The prevalence rates of RAE and nephrectomy were relatively high and differed between TSC AML and sporadic AML patients. The prevalence rates of repeated RAE and nephrectomy also differed between the two groups. Future research to understand their impact on clinical outcomes is needed.

SA-PO263

Predictive Value of the HAS-BLED Score in Patients with Atrial Ffibrillation and Chronic Kidney Disease Judith Kooiman,[1] Koen van Beers,[1] Bas Spaans,[1] Jonna R. Bank,[1] Gregory Y. Lip,[2] Felix Van der Meer,[1] Suzanne Cannegieter,[1] Ton J. Rabelink,[1] Menno V. Huisman.[1] *[1]Leiden University Medical Center, Netherlands; [2]City Hospital, University of Birmingham for Cardiovascular Sciences, United Kingdom.*

Background: The HAS-BLED score enables a risk estimate of major bleeding in patients with atrial fibrillation (AF) on vitamin K-antagonist (VKA) treatment, but has never been validated in patients with chronic kidney disease (CKD). We analyzed the predictive value of the HAS-BLED score in CKD compared with non-CKD patients.

Methods: Medical records of 416 CKD(GFR0-30 ml/min, 30-60 ml/min) and 300 non-CKD patients starting VKA treatment for AF between 1997-2005 were searched for items on the HAS-BLED score (hypertension; renal or liver disease; stroke; major bleeding or anemia; labile INR, (time within therapeutic range<60%), age>65 years; use of NSAIDs, anti-platelet therapy or alcohol) and major bleeding events. Areas under the curves (AUC) of the receiver operating characteristic (ROC) were calculated for the total population and CKD patients.

Results: Mean HAS-BLED score in CKD patients was 3.1 versus 2.6 in non-CKD patients(P<0.01). Major bleeding occurred in 115/716(6.1%,95%CI12.8-19.9%) patients. AUC of the ROC analysis in the total population was 0.50(95%CI0.44-0.56); 0.53(95%CI0.43-0.62) in patients with a GFR30-60 ml/min, and 0.35(95%CI0.21-0.49) in patients with a GFR<30 ml/min. In a Cox regression analysis performed in all patients, renal impairment, labile INR and age>65 years were predictive of major bleeding, hazard ratios 2.5(95%CI1.2-5.2), 2.2(95%CI1.2-3.7) and 5.2(95%CI1.6-16.8), respectively.

Conclusions: Performance of the HAS-BLED score was limited in the total population and further reduced in patients with a GFR<30ml/min. Further research is needed before the HAS-BLED score can be used in CKD patients.

Table 1

	N	%
Mean age(SD)	74	10

Incident Atrial Fibrillation and Risk of End-Stage Renal Disease in Adults with Chronic Kidney Disease Nisha Bansal,[1] Chi-yuan Hsu,[1] Gregory Marcus,[1] Alan S. Go.[1,2] *[1]UCSF; [2]KPNC.*

Background: Atrial fibrillation (AF) frequently occurs in patients with chronic kidney disease (CKD). However the long-term impact of AF on the risk of adverse renal outcomes is unknown. In a large, diverse community-based population with CKD, we examined the association between incident AF and risk of end-stage renal disease (ESRD).

Methods: We studied adults with CKD (defined as $eGFR_{CKD-EPI}$ <60 ml/min/1.73 m^2) enrolled in Kaiser Permanente Northern California (identified between 2002-2010) who did not have prior ESRD or previously documented AF. Incident AF was identified using primary hospital discharge diagnoses and/or two or more outpatient visits for AF based on validated ICD-9 codes. Incident ESRD was ascertained from a healthplan registry for chronic dialysis and renal transplant. We identified demographic characteristics, comorbidity and medication use based on validated algorithms from healthplan databases.

Results: Among 206,229 adults with CKD, 16,463 developed incident AF. During a mean follow-up of 5.1± 2.5 years, 343 cases of ESRD occurred after development of incident AF (73 per 1000 person-years) compared with 6495 cases of ESRD during periods without AF (64 per 1000 person-years, P<0.001). In multivariable extended Cox regression analysis, incident AF was associated with a twofold increase in rate of ESRD(Table).

Conclusions: Incident AF independently increases the risk of developing ESRD in adults with CKD.

Table. Association between incident AF and subsequent risk of ESRD among adults with CKD

	HR (95% CI)
Unadjusted	1.16 (1.04-1.29)

Kidney Protection by Anti-β1-Adrenergic Receptor Autoantibodies in CKD Patients Masaya Yamato,[1] Keiko Yasuda,[2] Koichi Sasaki,[1] Terumasa Hayashi,[1] Hiromi Rakugi,[2] Yoshitaka Isaka.[2] *[1]Nephrology, Rinku General Medical Center, Izumisano, Japan; [2]Geriatric Medicine and Nephrology, Osaka University Graduate School of Medicine, Suita, Japan.*

Background: It has been reported that autoantibodies against the β1-adrenergic receptor (β1AR) induce progressive development of DCM. Recently, the existence of autoantibodies against the β1AR was reported in rats with adenine-induced CRF. Therefore, we examined clinical significance of anti-β1AR antibodies in CKD patients.

Methods: We prospectively enrolled 258 patients (males 71.3% and mean age 66.4 years) with CKD stage3-5 not on dialysis, from a single department of nephrology between February 2005 and September 2011. Mean estimated glomerular filtration rate (eGFR) was 23.5 mL/min/1.73m^2. Mean left ventricular ejection fraction (EF) was 62.5%. Among 111 patients (43.0%), the primary cause of CKD was diabetic nephropathy. Circulating anti-β1AR autoantibodies were detected in 127 patients (49.2%) by ELISA. Relationships between autoantibodies and kidney end point (defined as doubling of serum creatinine or initiation of maintenance dialysis) were measured using Kaplan-Meier analysis and Cox models for case-mix and laboratory variables.

Results: During a median follow-up period (1.73 years, IQR 0.63-3.37), 137 patients (53.1%) reached the kidney end point. The value of anti-β1AR antibodies was not correlated with EF. Kaplan-Meier analysis revealed that autoantibody-negative patients more frequently reached the kidney end point than autoantibody-positive patients (Log-rank test P=0.026). After adjustment for age, gender, diabetes mellitus, systolic/diastolic blood pressure, EF, eGFR, Hb, Alb, Ca, IP, iPTH, urinary protein, use of RAS inhibitors and use of β-blockers, multivariable Cox regression analysis identified autoantibody-negative as an independent predictor of kidney end point (adjusted HR 1.64 [95%CI, 1.15-2.34], P=0.006).

Conclusions: These results suggest that anti-β1AR autoantibodies might play a self-protective role in CKD progression. Our data support the hypothesis that these autoantibodies shifted the renal β1AR into the agonist-coupled high-affinity state, thereby leading to these receptors down-regulation and ultimately kidney protection.

SA-PO266

Meta-Analysis of over 130,000 Individuals of European Ancestry Reveals New Loci Associated with Creatinine-Based Glomerular Filtration Rate in the CKDGen Consortium Matthias Olden. *Framingham Heart Study, National Heart, Lung, and Blood Institute, Framingham, MA.*

Background: Reduced levels of glomerular filtration rate (GFR) and chronic kidney disease are major health issues associated with end stage renal disease and cardiovascular mortality and morbidity. We conducted a large-scale meta-analysis of genome-wide association studies (GWAS) for creatinine-based GFR (eGFRcrea) with the goal of uncovering additional new loci for renal function.

Methods: A total of 133,728 individuals of European descent from 50 population-based studies were included. Each participating study performed a GWAS of ~2.5 million single nucleotide polymorphisms on log transformed eGFRcrea, estimated using the 4-variable Modification of Diet in Renal Disease formula, adjusting for age and sex. The results were then meta-analyzed using an inverse-variance weighted fixed effects model. Statistical significance threshold was set to 5E-8.

Results: We identified a total of 46 loci for eGFRcrea that exceeded genome-wide significance, with 16 loci being novel. The strongest signal was rs13329952 near *UMOD* (P-value=9E-44), which has been previously reported. The strongest novel signals were located in or near *CYP24A1* locus at 20q13 (P-value=3E-11) and at the *MANBA* locus at 4q22-q25 (P-value=5E-10). *CYP24A1* encodes a protein involved in vitamin D metabolism, synthesis of cholesterol and other lipids, while mutations in *MANBA* are associated with lysosome storage disease. We also confirmed 30 loci previously identified in association with eGFRcrea.

Conclusions: Large-scale meta-analyses continue to uncover new loci for renal function. While our findings require independent replication, they advance our understanding of the biologic mechanisms of kidney function.

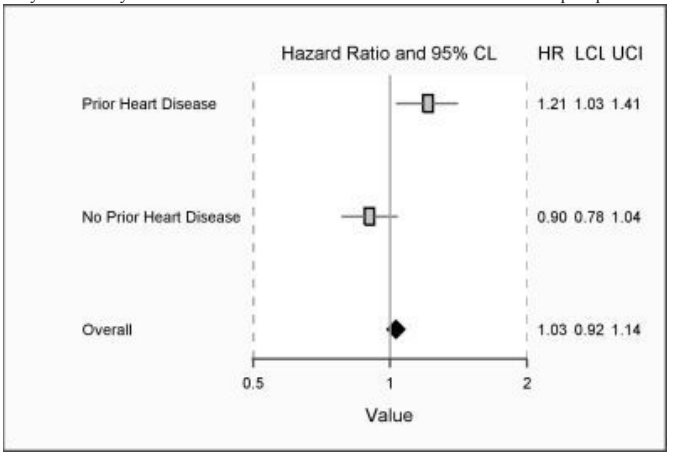
SA-PO267

CKD, Prevalent Cardiovascular Disease, and the Risk of Death among Female Patients Prescribed Bisphosphonates Robert M. Perkins,[1] H. Lester Kirchner,[1] Kunihiro Matsushita,[2] Ion D. Bucaloiu,[1] Evan Norfolk,[1] James E. Hartle.[1] *[1]Geisinger Clinic; [2]Bloomberg School of Public Health.*

Background: Whether bisphosphonates impact cardiovascular morbidity and mortality is controversial. We have previously shown that among female patients with CKD and without clinically manifest cardiovascular disease (CVD), treatment with bisphosphonates is associated with a modest all-cause mortality risk reduction.

Methods: We tested the hypothesis that, among patients with CKD, prevalent CVD (prior MI, CHF, stroke, or TIA) would modify the effect of bisphosphonates on the risk of death. Adult female patients receiving primary care through Geisinger Clinic, an integrated health care system in central PA, between January 1, 2004 and March 31, 2011, with stage 3 or 4 CKD but without a history of advanced malignancy, ESRD, or solid-organ transplantation were eligible for the study. Subjects were followed through September 30, 2011 for the outcome of death. For non-bisphosphonate users at entry, we treated such therapy as a time-dependent exposure, and prevalent (prior to January 1, 2004) CKD status was accounted for using left-truncation in a multivariate-adjusted Cox proportional hazard model. The primary analysis examined the multivariate-adjusted mortality hazard associated with bisphosphonate treatment and its interaction with baseline CVD status.

Results: 6,756 females (2,173 with history of prior CVD) were followed for a median 4.3 years. Nearly 40% of those with and without CVD were treated with bisphosphonates.



Conclusions: Among females with CKD in this cohort, bisphosphonates were associated with increased mortality if CVD pre-existed but not if there was no history of CVD. The test of interaction was significant (interaction p-value = 0.004). Bisphosphonate treatment may increase the risk of death among those with CKD and pre-existing CVD, and warrants further investigation.

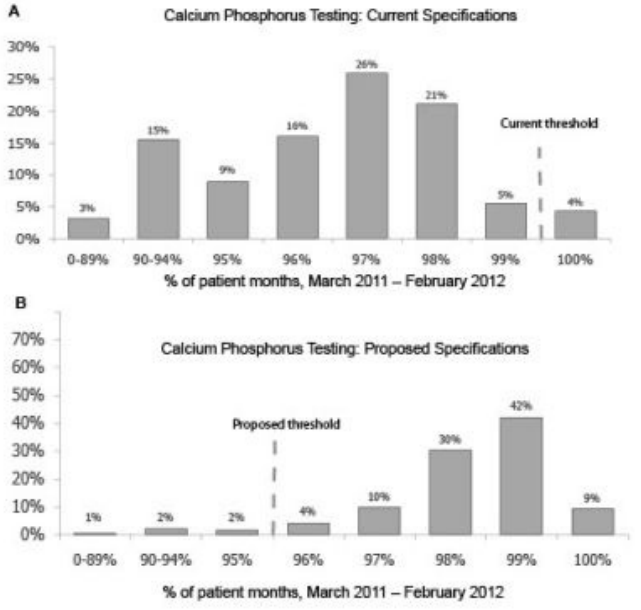
SA-PO268

Analysis of the 2014 Quality Improvement Program Reporting Measures for Calcium Phosphate in Dialysis Patients Michael Phillips, Andrew Barba, Mahesh Krishnan, Allen R. Nissenson. *DaVita Inc., Denver, CO.*

Background: The aim of the End-Stage Renal Disease (ESRD) Quality Improvement Program (QIP) is to promote patient health by encouraging renal dialysis facilities to deliver high-quality patient care. This incentive program will result in a payment reduction up to 2% if a facility does not meet or exceed the minimum Total Performance Score as set forth by CMS. For the 2014 QIP, calcium and phosphorus testing contribute 3.3% of the total score. Currently, a facility must test every Medicare patient in every month to receive the points associated with this metric. The revised specifications for the calcium and phosphorus metric presented here will report the percentage of eligible months in which ESRD Medicare patients were tested for calcium and phosphorus. Each provider/facility would be required to test 95% of eligible patient-months to attest to completion of the measure.

Methods: The measurement duration is a 12-month period. Under the proposed specifications, only ESRD patients with at least 4 months of eligible Medicare claims are included. Claims are included if at least 7 hemodialysis equivalent treatments were reported. Calcium and phosphorus lab results were extracted from the central laboratories of a large dialysis organization to determine which patients received a test in each of the 12 months being measured. The numerator for the facility measure was eligible Medicare patient months with a lab result. The denominator for the facility measure was total eligible Medicare patient months.

Results:



Conclusions: Only 4% of facilities would be able to attest to the current standard, as seen in Figure 1A. Ninety five percent of facilities would be able to attest to the proposed standard, as seen in Figure 1B. The proposed standard is designed to align with clinical practice and the inclusion criteria of other QIP metrics.

The Correlation between Pathological Findings and Independent Clinical Prognostic Parameters in IgA Nephropathy Ryuta Sato,[1] Kensuke Joh,[2] Hideki Wakui,[3] Shigeaki Muto,[1] Eiji Kusano.[1] *[1]Division of Nephrology, Department of Internal Medicine, Jichi Medical University, Shimotsuke, Tochigi, Japan; [2]Department of Pathology, Sendai Shakaihoken Hospital, Sendai, Miyagi, Japan; [3]Department of Hematology, Nephrology and Rheumatology, Akita University Graduate School of Medicine, Akita, Japan.*

Background: Pathological prognostic findings of IgA nephropathy (IgAN) were shown in Oxford study. However, clinical parameters were not included. Therefore, the present study was to elucidate the correlation between pathological findings and clinical parameters such as proteinuria (PU), estimated glomerular filtration rate (eGFR) and mean atrial blood pressure (MAP) in IgAN.

Methods: 203 patients with IgAN were collected since 1981 to 2001 in Akita University Hospital. Clinical data and renal biopsy specimens were obtained from these patinets. Patients were 47% male, median 42 y/o age, and median follow up period was 11.7 years. Progression of end-stage renal disease or 50% drop in eGFR was defined as a first endpoint in multivariate Cox regression analysis. Annual decline of eGFR was defined as a dependent variable in multivariate linear regression analysis. Clinical parameters were also analyzed by two regression models. The correlation between pathological findings and clinical parameters such as PU, eGFR and MAP was investigated by multivariate linear regression analysis.

Results: 1g/day≤ PU (HR 2.1, P=0.01), eGFR <60ml/min./1.73m^2(HR 3.2, p<0.0001) and 100mmHg≤ MAP (HR 1.8, p=0.02) were shown to be independent risks in multivariate Cox regression analysis. 1g/day≤ PU significantly promoted decline of eGFR in multivariate linear regression analysis. High PU values were significantly correlated with endocapillary hypercellularity (ENDO) and acute glomerular lesions (AL: cellular crescent, fibro-cellular crescent or tuft necrosis). There were positive correlations among the drop of eGFR, the increment of MAP and the severity of tubular atrophy/interstitial fibrosis (TA/IF).

Conclusions: Our study indicated that ENDO, AL and TA/IF were potential risk factors for the disease progression of IgAN since these findings strongly correlated with the changes of PU, eGFR and MAP.

SA-PO270

10-Year Incidence of Tuberculosis in Chronic Kidney Disease Patients of South Asian Origin in Lancashire Laurence R. Solomon,[1] John S. Cheesbrough,[3] Reuben Roy,[1] Kate Platt,[2] Sharmila Bandyopadhay.[1] *[1]Renal Unit, Lancashire Teaching Hospitals, Preston, United Kingdom; [2]Health Protection Agency, Chorley, United Kingdom; [3]Dept Microbiology, Lancashire Teaching Hospitals, United Kingdom.*

Background: Patients with chronic kidney disease (CKD) on renal replacement therapy (RRT) have a high risk of active tuberculosis (TB), but it is unknown whether prophylaxis of at risk patients is warranted. In the UK, migrants from South Asia (SA) have high incidences of TB and RRT. All cases of TB are notified to the Health Protection Agency (HPA). Our aim was to determine the incidence of tuberculosis in CKD and whether prophylaxis in SA patients is justified.

Methods: Names of all patients on our renal unit database up to 2012 were correlated with TB notifications to the HPA between 1998 and 2010. The database contained 13579 patients and all 2166 patients who were on or started RRT from a population of 1.5 million in Lancashire. SA patients were identified by declared ethnicity or typical name. Dates of presentation, start of RRT and TB notification were noted.

Results: 199 SA patients received RRT, of whom 27 were notified with TB. 170 received dialysis only, 22 of whom developed TB. 1 patient was diagnosed post-mortem and 2 within 3 months of death. A cumulative incidence function indicated that 10% of patients on dialysis for 5 years developed TB. 29 received a kidney transplant. 3/25 (12%) patients who received prophylaxis with isoniazid after renal transplant were notified compared to 2/4 (50%) patients who did not receive this (P=0.07).

Conclusions: Most cases of TB in UK RRT patients occur in South Asians. The data indicate a NNT of 10 (95% CI 6, 15) for fully effective prophylaxis of TB at the onset of RRT to prevent one case in 5 years. This greatly exceeds the risk of isoniazid hepatitis. Treatment might have avoided the need for prophylaxis in a further 14% of patients who had transplants reducing risk of drug interaction. Isonaizid prophylaxis substantially reduced the incidence but did not eliminate TB, but newer drug regimes may have a higher therapeutic index. Prophylaxis for TB is indicated in SA patients starting RRT and may be warranted in other high risk populations.

SA-PO271

The Size of Palatine Tonsils Cannot Decide the Indication of Tonsillectomy for IgA Nephropathy Mitsuhiro Sato,[1] Mika Adachi,[2] Hideyuki Kosukegawa,[1] Toshinobu Sato,[1] Yoshio Taguma.[1] *[1]Nephrology, Sendai Shakaihoken Hospital, Sendai, Miyagi, Japan; [2]Otorhinolaryngology, Sendai Shakaihoken Hospital, Sendai, Miyagi, Japan.*

Background: We previously reported clinical remission (CR: disappearance of hematuria and proteinuria) could be obtained by the treatment using tonsillectomy with steroid pulse (TSP) in IgA nephropathy (IgAN, Hotta O et al. Am J Kidney Dis 38, 2001). However, the relationship between the indication of tonsillectomy and the size of palatine tonsils (PT) in patients with IgAN has not yet been reached.

Methods: To clarify the influence of the size of PT on the histopathological findings and the effect of TSP, we performed the retrospective cohort study dividing the patients into two groups according to the weight of their excised PT : (1) hypertrophic group (HG), PT weight≥2.85g (n=30), and (2) non-hypertrophic group (NHG), PT weight<2.85g (n=31). We compared clinical parameters, therapeutic parameters in addition to TSP, histopathological findings of PT, and the endpoints, CR and 50% increase of serum creatinine from baseline, between the two groups.

Results: No significant differences in age, serum creatinine, GFR, proteinuria, hematuria, serum IgA, presence of hypertension, use of anti-plt. drugs, use of ACE-inhibitor, and use of ARB were observed between the two groups. There were also no significant differences in the presence of the macroscopic pusplug on the surface of PT and the distribution of bacterial flora which was detected from the core of the crypt between the two groups. Microscopically, pusplug in the crypt was observed in all specimens. Moreover, the unmatured folliculi and the enlarged interfollicular area that are considered to be specific pathological findings to PT of IgAN were observed in all specimens. In the mean follow-up term of 43months, no significant difference in the incidence of the endpoints was observed between the two groups (HG vs. NHG: CR rates, 83.3 vs. 80.6% ; 50% increase of serum creatinine, 0 vs. 3.2%).

Conclusions: These results indicate that there are the same histopathological findings and the equal treatment effect regardless the hypertrophy; therefore the size of PT cannot decide the indication of tonsillectomy for IgAN.

SA-PO272

The Long-Term Prognosis of IgA Nephropathy Patients Treated by Tonsillectomy Plus Steroid Pulse Therapy Takayuki Toyoyama, Daigo Nakazawa, Junya Yamamoto, Naoko Matsuoka, Akiko Sato, Tasuku Nakagaki, Yasunobu Ishikawa, Sekiya Shibazaki, Saori Nishio, Tatsuya Atsumi. *Department of Medicine 2, Hokkaido University, Sapporo, Japan.*

Background: It has been reported that tonsillectomy plus steroid pulse therapy (T/S) is effective for IgA nephropathy (IgAN). However there is a little report observed for long time. In this study we analyzed long-term renal prognosis and remission rate of IgAN treated by T/S.

Methods: Between 1995 and 2012, we retrospectively followed 108 patients who treated by T/S based on the diagnosis of IgAN by renal biopsy at Hokkaido University hospital. All patients received intravenous methylprednisolone pulses of 0.5 g/day for three consecutive days, followed by oral prednisolone at an initial dosage of 0.5 mg/kg per day. The oral prednisolone was gradually tapered by 5 mg every 2 month, then discontinued by 12~18 month after the initial therapy. We recorded their age, gender, serum-Cre (S-Cre), proteinuria, hematuria, blood pressure, and histological severity at initial therapy. We evaluated the remission rate (disappearance of both hematuria and proteinuria) and 8-year renal survival rate ([1] renal death and [2] impaired renal function;1.5 fold increase of S-Cre or S-Cre≥2 mg/dl). And we analyzed the risk factors for impaired renal function by the univariate and multivariate regression analysis.

Results: Patients findings at initial therapy were the following; Age 32 years, S-Cre 0.9 mg/dl, proteinuria 1.31 g/g•Cre (these data show average), men/women 46/62.

Remission rate at 1 year after treatment was 74 %. 8 year survival rate was 97 % ([1]renal death), and 78 % ([2]S-Cr 1.5 fold or ≥2.0 mg/dl). By cox hazard model risk factors for impaired renal function were male, age, histological severity. Furthermore, in recalcitrant cases (at 1 year after treatment) odds risk for impaired renal function was 5.8 fold compared to remission cases.

Conclusions: The long-term prognosis of IgA nephropathy patients treated by tonsillectomy plus steroid pulse therapy was extremely favorable, due to high rate of clinical remission.

SA-PO273

Characteristics and Burden of Renal Angiomyolipomas in Patients with Tuberous Sclerosis Complex: Results of a Patient and Caregiver Survey

Anne M. Rentz,[1] Chris Leo Pashos,[1] Sarrit Kovacs,[1] Zhimei Liu,[2] Corey Pelletier,[2] Judith A. Prestifilippo,[2] Jo Anne Nakagawa,[6] James Wheless,[5] Michael Frost,[3] David W. Dunn.[4] *[1]United BioSource Corporation, Bethesda, MD; [2]Novartis Pharmaceuticals Corporation, East Hanover, NJ; [3]Minnesota Epilepsy Group, PA, St. Paul, MN; [4]Riley Hospital for Children, Indianapolis, IN; [5]Le Bonheur Children's Medical Center, Memphis, TN; [6]TS Alliance, Silver Spring, MD.*

Background: Patients with tuberous sclerosis complex (TSC), a genetic disorder characterized by benign tumor growth in multiple organs, may experience non-cancerous kidney tumors known as renal angiomyolipomas (AML). This analysis aimed to assess the prevalence, presentation, and associated impact of AMLs in patients with TSC in the United States (US).

Methods: An Institutional Review Board-approved Web-based survey of US TSC patients and their caregivers obtained information on prevalence of different TSC manifestations, their treatment and management, and epidemiological, clinical, economic and health-related quality of life (HRQL) burden impact on patients and caregivers. This analysis focused on the prevalence, presentation, and management of AMLs.

Results: The online survey is on-going. Of 380 TSC patients whose data have been collected to date, 59% were women and mean age was 30.4 years (median: 32.5, range: 0-70). Twenty-three percent of patients had been diagnosed with AMLs. Patients with AMLs also experienced skin lesions (75.9%), seizures (74.7%), and cognitive concerns (57.5%). Seventy-five percent of TSC-AML patients were bilaterally affected with lesions on both kidneys. Within the population experiencing involvement of only one kidney, 22.7% had multiple tumors within the affected kidney. Almost three-quarters of AML patients (72.4%) had some type of invasive procedure including but not limited to embolization and nephrectomy.

Conclusions: Initial survey data have demonstrated that TSC-AML is associated with significant epidemiological and clinical burden. The complete survey data will provide further insights on the clinical profile and economic and HRQL impact of TSC-AML.

Rosuvastatin Reduces Urinary Protein Excretion in Patients with Chronic Glomerulonephritis Compared to the Pravastatin Use: A Crossover Trial

Hirofumi Ikeda, Yoriko Ura, Masaru Nakayama. *National Kyushu Medical Center Hospital, Division of Nephrology and Clinical Research Institute, Department of Internal Medicine, National Kyushu Medical Center Hospital, Fukuoka City, Fukuoka Pref, Japan.*

Background: Experimental evidence suggests that lipid abnormalities contribute to the progression of kidney disease. However, very few studies have evaluated the effect of statins on the proteinuria reduction in patients with glomerulonephritis. The purpose of this study was to determine the effect of rosuvastatin on the proteinuria reduction in patients with chronic glomerulonephritis compared to the pravastatin use.

Methods: Seventeen stable chronic glomerulonephritis patients with proteinuria (urinary protein excretion (UPE)> 0.2g/gCr) and hypercholesterolemia (LDL-cholesterol(C)>120mg/dl) were randomized to receive rosuvastatin 5mg/ day or pravastatin 10mg/day for 6 months, 4-8 weeks wash-out, and then the opposite drug for 6 months. There were no changes in medications (doses of ACEi/ARB and steroids) and food intake. Serum(s) LDL-C, sHDL-C, sMalondialdehyde-Modified LDL (MDA-LDL), as a marker of oxidized LDL, s-creatinine, and UPE were measured at baseline and after each 6-months treatment.

Results: All patients completed the study. As compared to pravastatin treatment, rosuvastatin significantly decreased %changes in both LDL-C (-17.7% vs. -46.7%, $p<0.05$) and %changes in MDA-LDL (-32.1% vs. -44.2%, $p<0.05$). In contrast, in both treatment groups, there were no significant changes in HDL-C and eGFR throughout the study. Rosuvastatin treatment significantly reduced UPE (1.36+/-1.04 to 1.02+/-0.62 g/gCr, $p<0.05$), whereas pravastatin treatment did not reduce UPE (1.07 +/- 0.72 to1.42 +/- 0.96g/gCr). A modest correlation between %changes in LDL-C and in UPE was also present ($R^2=0.21$, $p<0.05$).

Conclusions: In the present study, rosuvastatin reduces UPE in chronic glomerulonephritis patients, together with a remarked reduction in LDL-C, compared to the pravastatin use. This result suggests that aggressive lipid-lowering therapy with rosuvastatin might be a useful treatment for patients with chronic glomerulonephritis.

Study on the Transcription Factor C/EBPα in Primary Glomerulonephritis

Fang Zhong, Weiming Wang, Hong Ren, Jingyuan Xie, Qiuhua Huang, Nan Chen. *Ruijin Hospital, Shanghai Jiao Tong University, Shanghai, China.*

Background: Early diagnosis of CKD by the biological markers of blood or urine has a high practical value.

Methods: Forty-five patients with primary glomerulonephritis (PG): IgA nephropathy (IgAN, n=15), focal segmental glomerulosclerosis (FSGS, n=15) and membranous nephropathy (MN, n=15) were enrolled. We enrolled patients had proteinuria (> 0.5g / day) and GFR> 15ml/min/1.73m^2. Patients had immunosuppressant before renal biopsies were excluded. 15 healthy subjects were used as a control group. The samples were removal of high abundance proteins using the Multiple Affinity Removal LC Column, desalined, quantitied and marked.

Results: The male:female ratio is 7:8 in all three groups. Average age is 29.6 ± 10 ys, 39.8 ± 13.4 ys and53.2 ± 12.6 ys, 24-hr urine protein output is 1491 ± 752 mg/d, 877 ± 640 mg/d and 3988 ± 2332 mg/d, and Scr is 112 ± 56 μmol/L, 121 ± 50 μmol/L and 91 ± 55 μmol/L in the IgA group, FSGS group and MN group, respectively. 1956 proteins were identified with mass spectra (MS). Compared with controls, 447 differentially expressed protein peaks were found in serum from PG patients. Compared with the controls, 68, 48 and 120 proteins in FSGS, IgAN and MN patients were significantly different respectively. In the expression profile, there are some differences in the expression of specific proteins. Through bioinformatic analysis, we studied the protein modification sites, sub-cellular localization and interactive network of the proteins and one of the target proteins C/EBPα (CAAT/enhancer binding proteins, C/EBP) was identified. We found that serum C/EBPα decreased while urine C/EBPα increased in patients with primary glomerulonephritis, compared with normal control group. Urine C/EBPα level was significantly different between MN group and IgA group ($P<0.05$) by ELISA method.

Conclusions: There are differences in serum protein expression profiles in primary glomerulonephritis compared with normal healthy people; There are also differences among the different protein expression profiles in different types of PG. These findings suggested that C/EBPα might serve as a biomarker of renal inflammation.

Analysis of the Genomic Profile Associated with the Development of a Vascular Phenotype in Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Sandro Rossetti, Maria V. Irazabal, Katharina Hopp, Vickie J. Kubly, Jamie L. Sundsbak, Marie C. Hogan, Vicente E. Torres, Peter C. Harris. *Mayo Clinic, Rochester, MN.*

Background: The development of intracranial aneurysms (IAs) and subarachnoid hemorrhage (SAH) is the most life threatening phenotype in ADPKD. ADPKD patients have a prevalence of IAs of ~8%, with SAH and death occurring in ~6%. Familial clustering and intrafamilial variability of IAs/SAH in ADPKD pedigrees suggests the involvement of genetic factors other than the *PKD1*/*PKD2* germline mutation.

Methods: We identified 30 ADPKD pedigrees where at least one individual developed IAs/SAH. In each pedigree, the severity of the vascular phenotype was graded as a quantitative trait based on clinical and imaging data (presence of familial clustering, rupture, requirement for surgery and IA size). In each proband, we captured exons from 116 genes (RainDance method) encoding proteins involved in the structure/maintenance of the arterial wall, receptors for structural proteins, or candidate genes identified by genome-wide association study (GWAS). Sequencing was performed using the Illumina HiSeq2000 and ultra-rare variants were filtered and classified for likely pathogenicity in each pedigree.

Results: We identified 46 ultra-rare variants in 25 pedigrees in 31 genes. Overall, genes with a structural role (collagens, laminins and elastin) accounted for ~50% of these variants (22/46). We identified likely recessive or dominant hypomorphic pathogenic variants in genes playing key roles in: arterial wall structure (*ELN*, *FBN1*, *LAMA* and *LAMB* genes, *COL4A4*, *COL18A1*), associated with IA syndromes (*COL4A1*, *LAMA5*, *TGFBR2*), mapped by GWAS (*STARD13*), encoding receptors for structural proteins (integrins), and involved in extracellular matrix maintenance (MMP genes). Known pathogenic variants were found in *BCAM*, *COL18A1*, *COL5A1*, and *SERPINA1* in 8 pedigrees.

Conclusions: The finding of ultra-rare variants in mutation characterized *PKD1/PKD2*-IAs patients suggests that the co-inheritance of these variants promotes the development of the vascular phenotype on the background of the inherited ADPKD mutation, hence, working as genetic modifiers of the vascular disease presentation.

SA-PO277

Characterization of the Genomic Origin of PKD1 Gene Conversions in Autosomal Dominant Polycystic Kidney Disease (ADPKD) Sandro Rossetti,[1] Terry J. Watnick,[2] Ellis D. Avner,[3] Akio Koizumi,[4] Peter C. Harris.[1] *[1]Mayo Clinic, Rochester, MN; [2]John Hopkins University, Baltimore, MD; [3]Medical College of Wisconsin, Milwaukee, WI; [4]Kyoto University, Kyoto, Japan.*

Background: ADPKD is caused by mutations at two genes, *PKD1* and *PKD2*. *PKD1* is duplicated on chromosome 16 (*PKD1P1-P6)*. Gene conversions (GCs) transfer sequence variants from segmental duplications into the master gene. GCs have been previously suspected in ADPKD, but their genomic origin and extension have not been characterized.

Methods: We developed a strategy for the genomic characterization of *PKD1* GCs. By deep sequencing locus-specific amplicons (specificity in *PKD1* intron 1, exon 15 and single copy area) using the Illumina HiSeq2000, detailed sequence data are generated. Careful comparison with the *PKD1P1-P6* sequence validates GCs and traces their genomic origin.

Results: We deep sequenced 5 previously suspected GCs identified in ADPKD pedigrees. In pedigree P150, used to develop the methodology, we characterized an 8.5 Kb GC with *PKD1P6* (Rossetti 2012). In pedigree M525, we identified 6 intronic and 3 exonic variants, all matching *PKD1P1* and tracing the GC over 5.8 Kb of contiguous sequence (IVS16-ex23). In pedigrees JHU086 (Watnick 1997) we identified 8 intronic and 5 exonic variants, while in pedigree JHU273 (Watnick 1997) we identified 11 intronic and 6 exonic variants: in both pedigrees these variants were all matching *PKD1P1* and traced the 2 GCs over 6.9 Kb of contiguous sequence (IVS16-IVS24 for both). In pedigree C (Inoue 2002) we identified 3 intronic and 4 exonic variants, all matching *PKD1P6* and tracing the GC over 624 bp of contiguous sequence (IVS22-ex23). These GCs introduce likely disease-causing changes and suggest that *PKD1P1-P6* serve as a reservoir of mutations in ADPKD.

Conclusions: Deep sequencing of ADPKD pedigrees with suspected GCs will help prove that they are genuine GCs, determine their genomic origin and precisely define their extension, thereby emphasizing their disease association. GCs may be an underappreciated cause of *PKD1* mutations, particularly in mutation negative cases, and may be missed due to the locus-specific primers employed to screen the *PKD1* duplicated portion.

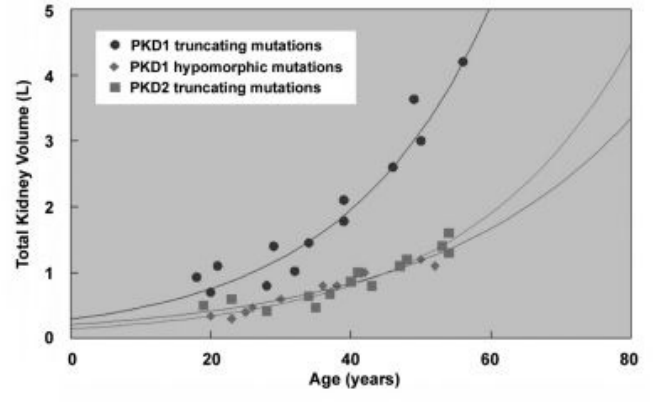
Hypomorphic *PKD1* Mutations Are a Common Cause of Mild ADPKD Young-Hwan Hwang,[1] John Conklin,[2] Karen Campbell,[1] Ning He,[1] Kairong Wang,[1] Jamie L. Sundsbak,[3] Christina M. Heyer,[3] Masoom Haider,[2] Peter C. Harris,[3] York P. Pei.[1] *[1]Divisions of Nephrology and Genomic Medicine, University Health Network and University of Toronto, Toronto, ON, Canada; [2]Department of Medical Imaging, University Health Network and University of Toronto, Toronto, ON, Canada; [3]Division of Nephrology, Mayo Clinic, Rochester, MN.*

Background: Comprehensive *PKD1* and *PKD2* mutation screening in large clinical cohorts has identified protein-truncating (PT) mutations in ~2/3 of cases (JASN 18:2143-60, 2007). By contrast, non-synonymous mutations/small in-frame deletions comprised most of the remaining cases and their clinical significance is not well defined. Emerging data suggest that some of the latter mutations may function as "hypomorphic alleles" associated with mild ADPKD (Kidney Int 81:412-7, 2012).

Methods: In this single center study, we examined the genotype-phenotype correlation of 228 probands from unrelated families ascertained through a PKD Clinic in Toronto between 2005-2012. All study patients underwent a detailed reveiw of their family history, a standardized protocol to quantify their renal disease severity, and for most, a comprehensive *PKD1* and *PKD2* mutation screen.

Results: Overall, 82% of our probands were of European descent and 46%, male. The mean (±SD) age and eGFR at their 1st clinic visit were 43±13 yrs and 80±28 ml/min, respectively. At least 19% of them had an affected relative who remained renal sufficient or developed ESRD ≥70 years of age. Preliminary results show that 40%, 21%, 27%, and 12% of 151 probands who completed their mutation screen had PT *PKD1* mutations, hyomorphic *PKD1* mutations, PT *PKD2* mutations, and no mutation detected, respectively. Renal disease severity as measured by total kidney volume associated with hypomorphic *PKD1 and* PT *PKD2* mutations appears similar.



Conclusions: Hypomorphic *PKD1* mutations are a common cause of mild ADPKD.

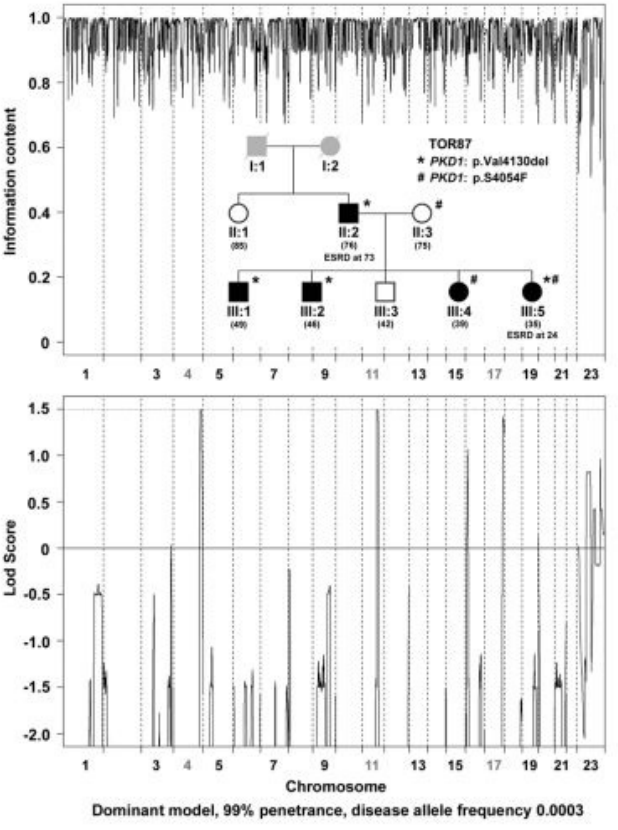
Complex Genetic Inheritance Underpinning a Family with Putative PKD3 Young-Hwan Hwang,[1] Kairong Wang,[1] Karen Campbell,[1] Alessia C. Borgo,[1] Jamie L. Sundsbak,[2] Christina M. Heyer,[2] Nicole M. Roslin,[3] Andrew D. Paterson,[3] Peter C. Harris,[2] York P. Pei.[1] *[1]Divisions of Nephrology, University Health Network and University of Toronto, Toronto, ON, Canada; [2]Division of Nephrology, Mayo Clinic, Rochester, MN; [3]Program in Genetics and Genomic Biology, Hospital for Sick Children, Toronto, ON, Canada.*

Background: The documentation of several families unlinked to both *PKD1* and *PKD2* has led to the speculation for the presence of at least one rare gene (PKD3) (Kidney Int 54:1759-61, 1998) whose identification has remained elusive.

Methods: We ascertained a family with ADPKD (TOR87) unlinked to both *PKD1* and *PKD2* in which complications such as DNA mix-up, genotyping errors, and non-paternity had been rigorously excluded. We performed a genome-wide linkage scan in 8 available family members including 5 affected using the Illumina Linkage-24 SNP arrays and screened 2 key affected members (II:2 and III:4) for *PKD1* and *PKD2* mutations.

Results: Our genome scan revealed 3 suggestive linkage signals with multipoint lod-scores ~1.5 on chr. 4, 11, and 17.



Mutation screening in II:2, however, identified a de-novo *PKD1* mutation (p.V4130del) that segregated in 3/4 affected children (III:1, III:2, III:5). By contrast, mutation screening in III:4 identified a 2nd *PKD1* mutation (S4054F; scored 0.988 by Polyphen-2) originating from II:3 (who was assumed to be unaffected at age 75 with normal renal function). With the exception of III:5, all family members affected with one of the *PKD1* mutations had very mild disease. By contrast, III:5, who inherited both mutations *in-trans*, had early and severe disease.

Conclusions: Complex genetic inheritance can give rise to a disease segregation pattern mimicking the presence of a novel gene by genome-wide linkage scan. Interaction of 2 putative hypomorphic *PKD1* mutations *in-trans* can modify renal disease severity in ADPKD.

Genetic and Phenotypic Characteristics of Subjects with Autosomal Dominant Polycysitic Kidney Disease in the Japanese Mahiro Kurashige,[1,2] Kazushige Hanaoka,[1] Yoshindo Kawaguchi,[1,3] Toshio Hasegawa,[1,3] Minako Imamura,[2] Shiro Maeda,[2] Tatsuo Hosoya.[1] *[1]Division of Kidney and Hypertension, Department of Internal Medicine, The Jikei University, School of Medicine, Minato, Tokyo, Japan; [2]Laboratory for Endocrinology and Metabolism, RIKEN Center for Genomic Medicine, Yokohama, Kanagawa, Japan; [3]Department of Medicine, Kanagawa Prefectural Shiomidai Hospital, Yokohama, Kanagawa, Japan.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is common hereditary kidney disease, and most of its heritability could be explained by mutations in two genes, *PKD1* and *PKD2* in Caucasian populations. However, little is known about genetic and/or phenotypic characteristics for Japanese ADPKD patients.

Methods: We screened the entire coding regions for the *PKD1* and *PKD2* by direct sequencing using 100 Japanese ADPKD patients from 91 unrelated families. Regarding novel candidate mutations found in the present ADPKD patients, their frequencies in ~1,500 individuals from Japanese general population were determined by using multiplex PCR invader assay. We also investigated correlation between eGFR decline, mutated genes and plasma arginine vasopressin (ADH) by multiple linear regression analysis.

Results: Among 91 families examined in the present study, we identified 54 mutations within 66 families (72.5%), including 44 *PKD1* mutations (24 truncated, 20 missennse) and 10 *PKD2* mutations (8 truncated, 2 missennse). Twenty-nine out of the 54 mutations have not been reported previously; these novel mutations were not detected in the Japanese general population, except for two missense mutations found in 1 of ~1,500 individuals. Decline of eGFR was significantly slower in patients with *PKD2* mutation than those in patients with *PKD1* mutation or patients who were not detected causal mutation (-1.97, -3.21, -3.55 ml/min/year in *PKD2*, *PKD1*, unknown respectively, p=0.038). Plasma ADH concentrations were significantly associated with eGFR decline in patients with *PKD1* mutation (r=-0.433, p=0.018).

Conclusions: Our present finding suggests that patients with *PKD2* mutation have milder clinical manifestations, and that plasma ADH concentrations affects the eGFR decline in patients with *PKD1* mutation.

SA-PO281

Clinical Course and Genetic Analysis of 39 Japanese Children with Autosomal Recessive Polycystic Kidney Disease Akinori Miyazono,[1] Yuriko Yoneda,[2] Takuya Fujimaru,[1] Mai Sato,[1] Masao Ogura,[1] Koichi Kamei,[1] Hirotomo Saitsu,[2] Shuichi Ito.[1] *[1]National Center for Child Health and Development, Tokyo, Japan; [2]Yokohama City University, Yokohama, Japan.*

Background: Autosomal recessive polycystic kidney disease (ARPKD) is characterized by bilateral kidney cysts and hepatic fibrosis or Caroli's disease. Although *PKHD1* mutations cause ARPKD, the clinical course varies widely in each case. Geographical and ethnic differences regarding mutation sites have not been well investigated.

Methods: Thirty-nine Japanese children clinically diagnosed with ARPKD were enrolled in this study. The clinical course was examined by a questionnaire. Analysis of *PKHD1* mutations was performed by high-resolution melting analysis (HRM) and multiplex ligation-dependent probe amplification (MLPA). Some patients without mutations detected by HRM and MLPA were additionally examined by microarray analysis and next-generation sequencing.

Results: The mean age was 5.8±6.0 years. Fifteen patients (39%) needed mechanical ventilation in the neonatal period, 22 (57%) developed hypertension, and 25 (64%) had hepatic manifestations. Ultrasound showed swollen kidneys (n=29, 76%), cystic kidneys (n=23, 61%), and bright kidneys (n=24, 63%). Eight patients (21%) progressed to end-stage renal disease at a mean age of 1.8 months. Overall, 23 patients (59%) had compound heterozygous mutations or one heterozygous mutation accompanied by one deletion and 6 (15%) had one heterozygous mutation in *PKHD1*. We found 27 novel mutations. Four of these mutations were common to several patients, suggesting unique mutations among Japanese. Interestingly, some patients with the same mutations showed different clinical manifestations and courses. In addition, one patient without *PKHD1* mutations but with typical clinical manifestations had an *MKKS* gene mutation responsible for Bardet–Biedl syndrome.

Conclusions: We found no correlations between mutation sites and clinical manifestations. However, most of the detected mutations had not previously been reported, and 4 novel mutations could be unique and common among Japanese. It is important to distinguish between *PKHD1* and *MKKS* mutations, because some patients showed similar clinical manifestations.

SA-PO282

Mutation Analysis of PKD1 and PKD2 Genes Reveals Novel Mutations and Evidence for Hypomorphic Alleles in Taiwanese Patients Ming-Yang Chang,[1] Yah-huei Wu-chou.[2] *[1]Kidney Research Center and Department of Nephrology, Chang Gung Memorial Hospital, Chang Gung University College of Medicine, Taoyuan, Taiwan; [2]Human Molecular Genetics Laboratory, Chang Gung Memorial Hospital, Taoyuan, Taiwan.*

Background: ADPKD is a common genetic disease caused by mutations in the PKD genes. Mutational analysis for ADPKD has become increasingly important in recent years. However, interpretation of the pathogenicity for identified missense mutations remains a challenge. Recent studies suggest that multiple hypomorphic alleles of *PKD1* may occur simultaneously and these mutations could modify disease progression of ADPKD.

Methods: Here we describe our experience in a Taiwanese patient cohort using direct sequencing for all PKD1 and PKD2 exons.

Results: We found 118 sequence variants in 46 unrelated patients who had the ultrasonographic diagnosis of ADPKD. Among these variants, fifteen are definite pathogenic mutations and 15 are missense mutations with highly likely pathogenicity. Overall, 21 patients are PKD1, six are PKD2, and 19 remain undetermined although some of them carry non-pathogenic PKD1 variants. Seven definite pathogenic mutations and 10 pathogenic missense mutations were novel. Furthermore, we found two PKD1 hypomorphic alleles, R2477H and R3439W, in one family. The two mutations are segregated in two affected sisters who developed small renal cysts in the age of 20s, but their parents, each carries only one mutation, had no cysts in their age of 50s. None of the 21 PKD1 patients had family history of dialysis after 70 years old compared to two in six PKD2 patients. The mean ESRD age of PKD1 was 49.0±6.0 (n=5) and PKD2 was 65.5±2.1 (n=2).

Conclusions: Our data support the existence of PKD1 hypomorphic alleles in patients with atypical presentations. The results suggest that missense mutations need to be carfully interpreted for making a correct diagnosis of ADPKD using mutational analysis.

SA-PO283

Revisiting the "PKD3" Gene in ADPKD Binu M. Paul,[1] Moonnoh Ryan Lee,[1] Mark B. Consugar,[1] Jamie L. Sundsbak,[1] Christina M. Heyer,[1] Sandro Rossetti,[1] Vickie J. Kubly,[1] Vicente E. Torres,[1] Eliecer Coto,[2] Daniel G. Bichet,[3] Maurizio Clementi,[4] Peter C. Harris.[1] *[1]Nephrology & Hypertension, Mayo Clinic, Rochester, MN; [2]HUCA, Spain; [3]Univ of Montreal, Canada; [4]Univ. of Padova, Italy.*

Background: Mutations in two different genes, *PKD1* (16p13.3) and *PKD2* (4q21) are associated with autosomal dominant polycystic kidney disease (ADPKD). However, a number of ADPKD families unlinked to either of these genes have been described, suggesting a third locus, *PKD3*. Our previous work revealed a *PKD1* mutation in a formerly unlinked Portuguese family by microsatellite marker analysis and direct sequencing (JASN 16:358A).

Results: Here, we report *PKD1* mutations in two other described unlinked families. The mother and son in a two-generation Italian family were described with multiple bilateral renal cysts at 46 and 21 yrs, respectively (Turco 1996). The son progressed to ESRD at 51 yrs, whereas the mother had no additional cysts by 75 yrs. Direct sequencing showed a *PKD1* mutation (R4228X) in the son; however, the mother was negative for this mutation in blood, urine and buccal smear DNA. A *de novo* mutation in the son and simple cysts in the mother seems the most likely explanation, but low-level mosaicism in the mother cannot be ruled out. Re-sampling and direct sequencing of the previously reported French-Canadian family with six affected members (Daoust 1995) showed the *PKD1*: D3782_V3783insD mutation in four of them. Repeat ultrasounds in two mutation negative cases previously defined as affected, indicated that they were misdiagnosed. A sample mix-up between an affected and unaffected case further confounded the linkage analysis. Direct sequencing of the unlinked Spanish case (Ariza 1997) did not identify a *PKD1* or *PKD2* mutation. However, the PKD phenotype is atypical, with mild disease and an atrophic kidney in one affected individual.

Conclusions: In conclusion, three of the published "PKD3" cases now are PKD1, questioning the existence of a third gene for ADPKD. Nevertheless, consistent findings of ~10% mutation negative cases in sequenced ADPKD cohorts leaves open the possibility of a further locus that candidate gene and/or whole exome analysis may help identify.

SA-PO284

Identification of *TRIM21* as a Novel Disease Gene in Autosomal Dominant Glomerulocystic Kidney Disease Monica Tucci Cramer,[1] Howard Wiener,[2] Hemant Tiwari,[2] Lisa M. Guay-Woodford.[3] *[1]Pediatrics, UAB, Birmingham, AL; [2]Biostatistics, UAB, Birmingham, AL; [3]Center for Translational Science, CNMC, Washington, DC.*

Background: Glomerulocystic kidney disease (GCKD), a rare form of polycystic kidney disease, has both sporadic and familial occurrence. In previous studies, we have identified a five generation African-American family in which GCKD segregates as an autosomal dominant trait. The disease locus is distinct from the ADPKD genes, *PKD1* and *PKD2*, as well *BICC1*, the human orthologue of the mouse *jcpk* gene. We propose that the disease-susceptibility gene in this family is a novel PKD gene that likely has glomerular function.

Methods: Using the Illumina Cyto-SNP12 assay, we genotyped 19 individuals (13 affected; 6 unaffected) for 294,655 SNPs and performed a genome wide association study (GWAS). We further analyzed these data for evidence of linkage. Whole exome sequencing was performed in 4 individuals (3 affected;1 unaffected). Results were filtered as follows: 1) pathogenic variants present on one allele; and 2) variants present in exons or involving splice sites. Novel variants (not present in dbSNP Database) were further prioritized based on: 1) localization to candidate chromosomal intervals; and 2) gene expression pattern in the GUDMAP database.

Results: Using renal ultrasound or renal biopsy, we classified 13 family members as affected. GWAS analysis identified 6 putative intervals of interest on chromosomes 4, 6, 9, 11 and 18. Whole exome sequencing identified 19 candidate genes within these intervals. One chromosome 11 gene, *TRIM21*, harbored a predicted pathogenic missense variant (Q315P) in all affected individuals. This variant was absent in all unaffected family members, as well as 91 African-American controls. Linkage analysis supported disease locus linkage to this candidate interval (LOD score >3). *TRIM21* is mammalian-specific gene expressed in renal vesicles and the S-shaped body of the developing mouse kidney (GUDMAP database).

Conclusions: We have identified *TRIM21* as a novel disease-susceptibility gene in this GCKD family. We are currently evaluating the function of this mammalian-specific gene in glomerular development and differentiation.

SA-PO285

A Functional Variant of Angiopoietin-1 Is Associated with Hypertension and Severity of Renal Structural Damage in Patients with ADPKD

Wei Wang, M. Chonchol, Robert W. Schrier, Berenice Y. Gitomer. *Department of Medicine, University of Colorado Denver, Aurora, CO.*

Background: Angiogenesis has been implicated in promotion of renal cyst growth in autosomal dominant polycystic kidney disease (ADPKD). Angiopoietin 1 (Ang-1), an angiogenic growth factor functions to stabilize blood vessels but overexpression has been associated with increased angiogenesis. We previously reported that serum Ang-1 level in ADPKD patients is significantly correlated with structural changes in both the kidney and heart. Recently a functional variant in the 3'-UTR of Ang-1 (rs2507800) was reported to interfere with binding of microRNA-211 (miR-211). We hypothesized that this variant might be associated with severity of cardiovascular complications and renal structural changes in ADPKD.

Methods: We genotyped DNA from 274 ADPKD patients using Taqman SNP assays from Applied Biosystems. Clinical data for all subjects was collected during a 2-day inpatient evaluation at our clinical center.

Results: Variant rs2507800 is an A to T change. The characteristics of the population were as follows: mean age 35.5±12.7 years, 44.3% males, 72.9% hypertensive, 35.7% had reached ESRD, and eGFR60.6 ml/min/1.73m^2 (55.6-66.00, geometric mean and 95CI). There were 34 patients (12.4%) with AA genotype, 138 patients (50.4%) with AT genotype and 102 patients (37.2%) with TT genotype. Age did not differ between genotype groups. Significantly less hypertension were observed in the AA group than in other two groups (51.6% vs 78.5% in AT and 72.2% in TT respectively, p=0.02). Renal volumes were not different among the three groups when males and females were combined. However, when genders were analyzed separately, renal volume differed significantly in female patients based on genotype. The AA group had significantly lower renal volume than the other genotype groups without age differences between groups (483±303mm^3, n=34 vs 792±54mm^3 n=138 in ATand 712±470mm^3, n=102 in TT, p<0.001).

Conclusions: The AA genotype of Ang-1 variant rs2507800 is associated with less severe cardiovascular disease and renal phenotype in female ADPKD patients. This may be due to suppression of Ang-1 expression by facilitated miR-211 binding.

Autosomal Dominant Polycystic Kidney Disease Patients Express a Distinct Cardiovascular Risk Profile

Chern L. Chow,[1,2] Albert C. Ong.[1,2] [1]*Academic Unit of Nephrology, University of Sheffield, Sheffield, South Yorkshire, United Kingdom;* [2]*Sheffield Kidney Institute, Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, South Yorkshire, United Kingdom.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common genetic cause of renal failure. The commonest cause of death in this disease is cardiovascular. In addition to hypertension, insulin resistance has been reported. We investigated whether ADPKD patients could express a distinct vascular risk profile compared to other patients with chronic kidney disease (CKD).

Methods: In a cross sectional study on 59 ADPKD and 41 chronic kidney disease (CKD) patients, vascular risk was assessed by clinical data, oral glucose tolerance test and arterial stiffness (pulse wave velocity, PWV). Fasting samples were assayed for biomarkers including highly sensitive C-reactive protein (hsCRP), E-selectin, insulin and nitrate. Insulin resistance was calculated using the HOMA index.

Results: Both groups were comparable in age, blood pressure, body mass index, estimated glomerular filtration rate (eGFR), smoking status and glucose tolerance. PWV was lower in the ADPKD group (9.5 v 11.3 m/s; p<0.001) and was associated with 8-fold higher serum nitrate (78.5 v 9.3 µmol/l; p<0.001) but lower hsCRP (3229 v 7512 ng/ml; p=0.029), E-selectin (32.8 v 45.7 ng/ml; p=0.002) and insulin (58.6 v 96.7 pmol/l; p=0.034). In an overall multivariate model for PWV, ADPKD (p=0.002), age (p<0.001), systolic (p<0.001), diastolic blood pressure, 2 hour plasma glucose, E-selectin and triglyceride were significant factors. When analysing the 2 study groups separately for PWV, age was a significant factor in both; blood pressure was significant only in ADPKD.

Conclusions: ADPKD patients had lower vascular stiffness with a biomarker profile indicative of better endothelial function and a less inflammatory phenotype indicating a different vascular risk profile than in CKD. There was no difference in glucose tolerance categories or HOMA index between ADPKD and CKD patients despite differences in fasting insulin. The results highlight the importance of blood pressure control in reducing vascular risk in ADPKD.

SA-PO287

Prevalence of Cardiovascular Events in Patients with Autosomal Dominant Polycystic Kidney Disease

Imed Helal, Berenice Y. Gitomer, Pamela Mettler, Kim Mcfann, Oleksandra O. Tkachenko, Xiang-Dong Yan, Robert W. Schrier. *Division of Renal Diseases and Hypertension, University of Colorado Denver, Aurora, CO.*

Background: Cardiovascular problems are a major cause of morbidity and mortality in patients with autosomal dominant polycystic kidney disease (ADPKD). This study evaluates the prevalence of cardiovascular events in several stages of chronic kidney disease in ADPKD patients.

Methods: We distributed surveys to 1439 subjects from our ADPKD research database. 426 subjects with ADPKD (30%) completed and returned surveys. Seven of 426 surveys returned were children and were excluded from the study.

Results: ADPKD patients responding were likely to be female (63.2%), non-Hispanic (88.1%) and white (93.6%). The mean age of total group was 53.2 ± 13.7 years. 82.8% had a family history of ADPKD and 32.5% had reached end-stage renal disease. Among respondents analysis of cardiovascular risk factors demonstrated that 86.6% had hypertension with mean age of diagnosis of 36.9 ± 12.9 years with significantly higher prevalence in males, 19.6% were obese, 20.8% were smokers, 8.7% had diabetes, 45.7% had high cholesterol and 17.8% were sedentary. The most prevalent self reported cardiovascular events were arrhythmia (25.9%) with mean age of diagnosis of 43.3 ± 16.4 years, evidence of peripheral vascular disease (16.5%) with mean age of diagnosis of 45 ± 13 years, heart valve problem (14.4%) with mean age of diagnosis of 41.2 ± 16.5 years, cardiac enlargement (9.5%) with mean age of diagnosis of 42.6 ± 13.9 years, stroke or cerebral bleeding (7.5%) with mean age of diagnosis of 50.8 ± 13.4 years, myocardial infarction (6%) with mean age of diagnosis of 53.4 ± 9.6 years and brain aneurysm (5.0%) with mean age of diagnosis of 43.4 ± 13.7 years. The most commonly used antihypertensive medications were angiotensin converting enzyme inhibitors with 46.8% of hypertensive ADPKD patients.

Conclusions: These findings confirm the high prevalence of cardiovascular risk factors and events in ADPKD patients and associate risk for mortality. Due to the prevalence and early onset of cardiovascular risk factors in the ADPKD population, early diagnosis and clinical intervention are recommended.

SA-PO288

Changing Pattern of End-Stage Renal Disease Treatment in Autosomal Dominant Polycystic Kidney Disease Patients over Time

Imed Helal, Berenice Y. Gitomer, Kim Mcfann, Oleksandra O. Tkachenko, Xiang-Dong Yan, Robert W. Schrier. *Division of Renal Diseases and Hypertension, University of Colorado Denver, Aurora, CO.*

Background: This study was undertaken to determine whether there has been an improvement in the treatment of end-stage renal disease (ESRD) in autosomal dominant polycystic kidney disease (ADPKD) patients over two separate periods, before and after 2000.

Methods: We distributed surveys to 1439 subjects from our ADPKD research database. 426 subjects with ADPKD (30%) completed and returned surveys. 133 ADPKD patients who ESRD were included in descriptive analyses, 33 were reached ESRD during or before the year 2000 (Period A) and 100 were reached ESRD after the year 2000 (Period B).

Results: The mean age of ESRD in the total group was 51.5 ± 9.1 years, the majority of ADPKD patients (68.4%) received kidney transplant after less than one year on dialysis. Of them, 49 (37.1%) underwent preemptive transplantation. The majority of patients (97.7%) have hypertension at time of onset of ESRD. 16.2% had enlarged heart, 18 % have heart valve problem, 12.2% had heart attack, 9.3% had brain aneurysm and 15% had stroke or cerebral bleeding. There were no differences in gender, ethnic or race distributions between the two periods; however, those in Period B were younger than those in Period A at the time of the survey. Family history of ADPKD and BMI were the same in the two periods. Mean ESRD age was significantly younger in Period A than Period B (45.2 ± 7.8 versus 53.5 ± 8.5, p < 0.0001) and more patients in Period A underwent dialysis than in Period B. Patients in period B received a kidney transplant at an earlier age or underwent preemptive transplantation (p < 0.0001).There were no differences in distribution of cardiovascular events between the 2 periods, but those in Period B underwent heart surgery at an earlier age than those in Period A (54.3 ± 7.4 versus 65.0 ± 1.0, p = 0.0007), respectively.

Conclusions: This study demonstrates a significant improvement in patient management and treatment of end stage in ADPKD over time. In fact, these patients reach ESRD at older age, receive kidney transplantation at an earlier age or undergo preemptive transplantation.

SA-PO289

Endothelial Dysfunction and Vascular Inflammation in ADPKD

Jelena Klawitter,[2] Jacek Klepacki,[2] Alexander T. Pennington,[2] Jost Klawitter,[2] Robert W. Schrier,[1] M. Chonchol,[1] Berenice Y. Gitomer,[1] Uwe Christians.[2] *[1]Department of Medicine, University of Colorado Denver, Aurora, CO; [2]Department of Anesthesiology, University of Colorado Denver, Aurora, CO.*

Background: We have reported that autosomal dominant polycystic kidney disease (ADPKD) patients with normal GFR have higher levels of 9-HODE and 13-HODE suggesting an increase in lipid peroxidation and oxidative stress. They had an abnormal clearance of asymmetric (ADMA) and symmetric dimethylarginine (SDMA) and higher levels of homocysteine (HCy), indicating a role of endothelial dysfunction in ADPKD. We hypothesized that the above established markers will change in ADPKD patients with poorer eGFR and thus may be used as markers of disease progression.

Methods: We analyzed serum from 49 ADPKD patients with eGFR < 65 mL/min. Several targeted multi-analyte tandem mass spectrometry assays were used to analyze markers of oxidative stress and endothelial dysfunction.

Results: See table 1.

Changes in pro-inflammatory, oxidative stress and endothelial dysfunction markers in serum of ADPKD patients.

	ADPKD (n=5) eGFR: 68-134 TKV<800ml	ADPKD (n=18) eGFR:56-114 TKV>1500ml	ADPKD (n=49) eGFR: 29-65	Normal range
9-HODE9ng/ml)	25.3±11.4	43.1±14.7	120.5±114.9	8-24
13-HODE (ng/ml)	21.4±9.9	37.6±13.3	74.2±67.4	3-18
HCy(μM)	11.4±3.2	14.9±4.5	16.4±2.0	3.7-12.9
SAM (μM)	0.36±0.13	0.34±0.11	0.12±0.05	0.07-0.13
SAH (μM)	0.17±0.03	0.20±0.0	0.60±0.09	0.01-0.04
ADMA ((μM)	0.81±0.14	0.98±0.21	0.92±0.16	0.4-0.77
SDMA (μM)	1.38±0.29	2.26±1.13	1.96±0.62	0.31-0.55

S-adenosylhomocysteine (SAH), S-adenosylmethionine (SAM), total kidney volume (TKV); eGFR in mL/min/1.73m2. All markers, except ADMA, significantly inversely correlated with the eGFR in the 29-65 mL/min group.

Conclusions: Higher serum levels of 9-HODE and 13-HODE in ADPKD patients with higher TKV suggest an increase in lipid peroxidation and oxidative stress. The increased serum ADMA, SDMA, Hcy and SAH levels indicate high cardiovascular risk in these patients. Interestingly, all these markers showed more pronounced changes with disease progression. Future studies will evaluate if this marker panel can serve as a clinical monitoring tool for disease progression and indicator of adverse cardiovascular events.

SA-PO290

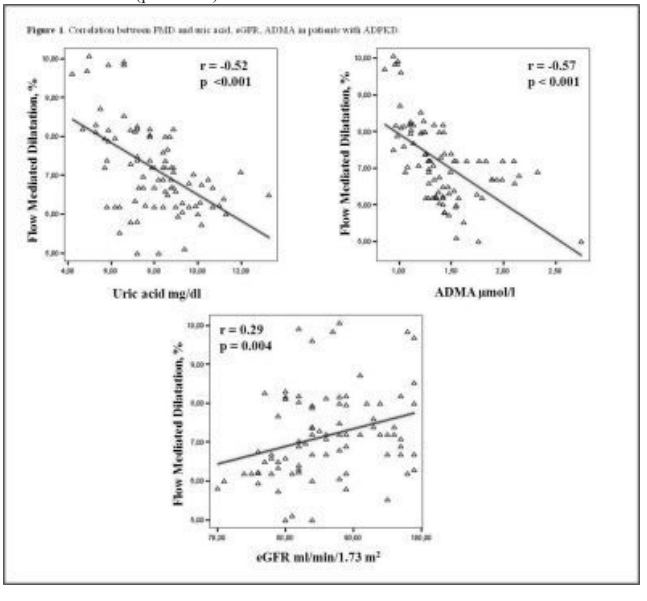
The Relation between Uric Acid Level and Endothelial Dysfunction in Patients with Early Autosomal Dominant Polycystic Kidney Disease

Ismail Kocyigit,[1] Mahmut Ilker Yilmaz,[2] Murat H. Sipahioglu,[1] Aydin Unal,[1] Bulent Tokgoz,[1] Oktay Oymak.[1] *[1]Nephrology, Erciyes University Medical School, Kayseri, Turkey; [2]Nephrology, Gulhane Medical Center, Ankara, Turkey.*

Background: We investigated the association of serum uric acid levels with endothelial dysfunction as determined by measuring the asymmetric dimethylarginine (ADMA) and the flow mediated dilation (FMD) in patients with early autosomal dominant polycystic kidney disease (ADPKD).

Methods: 91 early ADPKD patients (patients with normal kidney function and stage 1-2 chronic kidney disease) were included. Endothelial dysfunction was assessed by flow mediated dilatation measurement and serum ADMA levels.

Results: Early ADPKD patients with higher serum uric acid levels had higher ADMA levels (p = 0.018), higher selective C reactive protein (hs-CRP) levels (p < 0.001) and lower FMD rates (p < 0.001).



Multiple regression analysis demonstrated that uric acid (β = -0.32, p < 0.001), ADMA (β = -0.33, p < 0.001), hs-CRP (β = -0.30, p < 0.001) and estimated glomerular filtration rate (eGFR) (β = 0.30, p < 0.001) were statistically significant predictors of the FMD.

Multiple regression model predicting of flow mediate dilatation in all study subjects (n=91).

Variables	β	p
Uric acid mg/dl	-0.32	< 0.001
ADMA µmol/l	-0.33	< 0.001
hs- CRP mg/dl	-0.30	< 0.001
eGFR ml/min/1.73 m2	0.30	< 0.001

hs-CRP, high sensitivity C-reactive protein; eGFR, estimated glomerular filtration rate; FMD, flow mediated dilatation; ADMA, asymmetric dimethyl arginine. Adjusted r2=0.57 for FMD

Conclusions: Uric acid level is associated with endothelial dysfunction in patients with early ADPKD patients.

SA-PO291

Phosphorus and Disease Progression in Autosomal Dominant Polycystic Kidney Disease

Maria V. Irazabal,[1] Doug Landsittel,[2] Arlene B. Chapman,[3] Jared J. Grantham,[4] Michal Mrug,[5] Kyong Tae Bae,[2] Michael F. Flessner,[6] William M. Bennett,[7] Vicente E. Torres.[1,8] *[1]Mayo Clinic; [2]U of Pittsburgh; [3]Emory U; [4]U of Kansas; [5]U of Alabama Birmingham; [6]NIDDK/NIH; [7]Legacy Good Samaritan; [8]Consortium for Radiologic Imaging Studies of PKD (CRISP).*

Background: A high phosphorus diet aggravates the progression of polycystic kidney disease in PCK rats, more severely in females (Wang et al, this meeting). Here we use data from CRISP to inquire whether the phosphorus content of the diet might aggravate the progression of human ADPKD.

Methods: CRISP is a prospective, observational, longitudinal, multicenter study of 241 ADPKD adults who had preserved renal function at enrolment. A multiple regression model to ascertain the effect of urine volume and excretion of sodium, potassium, phosphorus, calcium, oxalate and citrate on the slope of log transformed total kidney volume (lnTKV) in female and male CRISP participants during the first six years of the study, without and with adjustment for gender, height and baseline lnTKV was used.

Results: Without gender or height adjustment, urine sodium (p=0.001) and phosphorus (p=0.02) excretions were positively correlated with lnTKV slope. Adjusting for height, phosphorus excretion was positively (p=0.02) and calcium excretion was negatively (p=0.03) correlated with lnTKV slopes in females. No significant correlations between phosphorus or calcium excretions and lnTKV slopes were detected in males. Adjusting for baseline lnTKV (with or without height) has the same effect as adjusting for height, where phosphorus becomes non-significant in males, but is still significant within females. We also tested the same models with the outcome of GFR slopes and found no significant associations, or specific trends by gender, between phosphorus excretion and GFR slope.

Conclusions: Together with the animal study results, these observations suggest a possible effect of dietary phosphorus on the progression of ADPKD, particularly in females.

Comparison of Total Kidney Volume (TKV) Measurements by MRI or CT to Predict Disease Progression in Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Maria V. Irazabal, Vickie J. Kubly, Sara L. Osborn, Amber Harmon, John A. Crane, Eric J. Bergstralh, Bradley J. Erickson, Vicente E. Torres, Bernard F. King. *Mayo Clinic, Rochester, MN.*

Background: Previous studies have shown TKV measured by MRI to be an excellent surrogate for disease progression in ADPKD. However, MRI may be contraindicated or not available in some patients. To date, no comparison between measurements by both methods is available. The purpose of this study is to assess the degree of agreement between TKV measured by MRI and CT.

Methods: We identified from our ADPKD database 43 patients (16M/27F;45±13 yo at imaging) who had abdominal CT and MRI obtained within 15 days. Patients with images with incomplete coverage of the kidneys, interventional procedure/acute event in between images or images acquired after ESRD were excluded. Axial non-contrast CT/MR images, of 3-5mm, were used to calculate TKV by stereology method, using Analyze software.

Results: At imaging, SCr=1.5±1 mg/dL. Median TKV=974 (273-9,282) mL. CT plotted against MR TKV are close to the identity line and show an excellent correlation (FigA). A plot of the % difference between the measurements against their mean is more informative to assess between-measurements differences (FigB). The mean % difference in TKV=0.29±1.68, and 42/43 measurements lay within the mean±2SD. The combined % measurement error=1.53 (0.79 MR;0.83 CT;p=NS). The probability of seeing a ≥5.3% increase in TKV in a single patient in the absence of a true change, due to switching MRI or CT, is 0.0008.

Conclusions: Difference in TKV (MRI-CT) is within 3.1% below to 3.6% above true TKV (MRI,CT mean). This is less than the annual mean increase of 5.3% reported in ADPKD. The probability that an MRI-CT switch could account for a change of this magnitude is extremely small (0.0008). This data suggests that MRI and CT could be used interchangeably if necessary to measure TKV.

SA-PO293

UMOD Gene Polimophysms Affect GFR Decay in ADPKD Maria Teresa Sciarrone Alibrandi,[1] Marina Nuzzo,[1] Simona Delli Carpini,[1] Lino Merlino,[1] Elena Brioni,[1] Laura Zagato Villa,[1] Marco Simonini,[1] Rodolfo F. Rivera,[2] Paolo Manunta.[1] *[1]San Raffaele Scientific Institute, Milan, Italy; [2]San Gerardo Hospital, Monza, Italy.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common monogenetic nephropathy and an important cause of ESRD, accounting for about 5% of patients requiring dialysis. The number of cysts and their complications are variable among single patients as well as the renal outcome. Phenotypic variability is due to the genetic heterogeneity, with the more common PKD1. However, in ADPKD, eGFR decay (Δ) is related to other "gene modifier" involved in Na handlyng and hypertension. Uromodulin (Tamm-Horsfall glycoprotein) is the most common protein excreted in the urine of healthy individuals, yet its function remains unclear. Mutations in the UMOD gene result associated to CKD and hypertension. Aim of the study is to evaluate the influence of UMOD in renal outcome in APKD.

Methods: 108 pts with APKD regularly followed in outpatient clinic of Nephrology Division of our Hospital, DGFR was evaluated at the follow up. Statistical analysis has been performed by GLM adjusted for sex, age, blood pressure, comorbid conditions, therapy and previous renal function.

Results: ADPKD patients carrying UMOD CC genotype present a significant (p=0.013) loss of renal function vs TT ones, after 18 months of average follow-up. Recoding patients in two groups (UMOD CC+GC vs TT) data were further confirmed (ΔGFR -25.5 ml/min vs -6.05 ml/min p=0.004).

Conclusions: Mutations in the UMOD gene result in a marked decrease in the synthesis of uromodulin, as well as the accumulation of abnormal uromodulin in tubular cells, leading to tubular cell death. This phenomena may play a key role in the worsening of renal failure in APKD.

SA-PO294

Affected Parent Gender and Severity of ADPKD Berenice Y. Gitomer, Kim Mcfann, Xiang-Dong Yan, Wei Wang, Imed Helal, Godela M. Brosnahan, Robert W. Schrier. *Department of Medicine, University of Colorado Denver, Aurora, CO.*

Background: Autosomal dominant polycystic disease (ADPKD) is the most common potentially lethal disorder. Morbidity and mortality associated with this disorder represents a significant economic burden both in the US and worldwide. Understanding the factors that impact disease severity and progression is therefore of crucial importance. While ADPKD is a genetic disorder there is considerable variability in severity even among members of the same family all of whom carry the same germ line mutation. This variability has been attributed to the effects of modifier genes or environmental influences. We hypothesized that ADPKD affected children born of an affected mother may have more severe disease influenced by the *in utero* environment.

Methods: We identified 897 PKD1 patients from our clinical database, with known affected parent gender and available clinical information. Subjects were stratified according to gender of the affected parent. Chi Square test of independence or Fisher's Exact tests were used to test the differences in distribution of categorical variables. Kaplan-Meier survival analysis and Log-Rank statistic were used to test the difference in survival times to onset of end-stage renal disease or hypertension.

Results: Children born of an ADPKD affected mother were more likely to have very early onset disease (VEO) ADPKD defined as onset of clinical symptoms within the first 18 months of life compared to those with an affected father, 28/246 versus 4/206, P <0.0001. Male children with an affected father developed ESRD and at an earlier age compared to those with an affected mother, 52 (49-54) years and 54 (51-57), p= 0.0005. Likewise children with an affected father developed hypertension at an earlier age compared to those with an affected mother 32 (28-34) years and 33 (30-36), p = 0.0036.

Conclusions: Affected parent gender does affect severity of ADPKD. Children born of an affected mother are more likely to develop VEO. Surprisingly, affected male but not female offspring with an affected father develop ESRD at an earlier age. This may be related to earlier development of hypertension in male offspring with an affected father.

SA-PO295

Tubular Creatinine Secretion in Autosomal Dominant Polycystic Kidney Disease: Consequences for Cross-Sectional and Longitudinal Performance of Renal Function Estimation Equations Edwin M. Spithoven, Esther Meijer, Wendy E. Boertien, Steef Jasper Sinkeler, Hilde Tent, Paul E. de Jong, Gerjan Navis, Ron T. Gansevoort. *Nephrology, UMC Groningen, Netherlands.*

Background: ADPKD is characterised by renal tubular cell proliferation and dedifferentiation, which may influence tubular creatinine secretion. Therefore, we investigated tubular creatinine secretion in ADPKD patients and controls and studied consequences for the performance of GFR estimation equations.

Methods: GFR was measured in ADPKD patients and healthy controls as ^{125}I-iothalamate clearance (mGFR), simultaneously with creatinine clearance (CrCl). Tubular creatinine secretion was defined as difference between CrCl and mGFR. CKD-EPI and MDRD equations were used to estimate GFR (eGFR).

Results: In 121 ADPKD patients (56% males, age 40±11y) and 215 controls (48% males, age 53 ± 10y), mGFR was 78±30 and 98±17mL/min/1.73m^2 and tubular creatinine secretion 16±11 and 11±11mL/min/1.73m2, resp.(p<0.001). The higher tubular creatinine secretion in ADPKD patients remained significant after adjustment for covariates and appeared to be dependent on mGFR, with a difference observed only at high-normal mGFR. mGFR correlated highly with CKD-EPI and MDRD eGFR (R=0.95 and 0.93, both p<0.001). Values for bias, precision and accuracy were similar or slightly better than in controls (table). In addition, change in mGFR during 3 years of follow-up in 45 ADPKD patients correlated well with change in CDK-EPI and MDRD eGFR (R=0.73 and 0.71, both p<0.001).

Conclusions: Tubular creatinine secretion in ADPKD patients is increased compared to controls, but this effect is limited to subjects with high-normal mGFR. Consequently, the CKD-EPI and MDRD equations perform relatively well to estimate GFR as well as change in GFR in ADPKD patients.

Performance of CKD-EPI and MDRD equations to estimate GFR.

	ADPKD	Controls	p-value
eGFR CKD-EPI	75 ± 30	90 ± 14	<0.001
-Bias	2.7	8.0	<0.001
-Precision	9.6	13.4	
-Accuracy	99	97	0.16
eGFR MDRD	72 ± 28	89 ± 15	<0.001
-Bias	6.2	9.3	0.028
-Precision	10.8	14.4	
-Accuracy	97	97	0.98

Bias = mGFR minus eGFR. Precision = one SD of bias. Units are ml/min/1.72m2. Accuracy = percentage of eGFR values within 30% of corresponding mGFR value.

Funding: Clinical Revenue Support

SA-PO296

A New Metric to Predict Autosomal Dominant Polycystic Kidney Disease (ADPKD) Progression: Cyst Parenchyma Surface Area (CPSA) Joshua D. Warner,[1] Maria V. Irazabal,[1] Bradley J. Erickson,[1] Bernard F. King,[1] Kyong Tae Bae,[2] Jared J. Grantham,[3] Arlene B. Chapman,[4] Michal Mrug,[5] Doug Landsittel,[2] Michael F. Flessner,[6] William M. Bennett,[7] Vicente E. Torres.[1,8] *[1]Mayo Clinic, Rochester, MN; [2]U. Pittsburgh; [3]U. Kansas; [4]Emory U; [5]U. Alabama Birmingham; [6]NIDDK/NIH; [7]Legacy Good Samaritan; [8]For the Consortium for Radiologic Imaging Studies of Polycystic Kidney Disease (CRISP).*

Background: Cyst development and growth cause renal enlargement and destruction of parenchyma due to mechanical compression and release of inflammatory mediators, eventually leading to renal failure. Although total kidney volume (TKV) is a strong predictor of GFR decline, cases where large TKV are determined by a relatively small number of large cysts weaken the strength of the association. We hypothesize that CPSA which depends on the number, volume and location of the cysts will have a stronger association with GFR decline.

Methods: Ten Mayo CRISP participants with rapid GFR decline (rapid progressors,RP) and 10 patients with stable GFR (slow progressors,SP) over 6 years of follow-up were randomly selected. Four additional CRISP participants were selected because their baseline MRI showed atypical large kidneys with small number of cysts (atypical cases,AC). T2 MRI TKV were measured using stereology.CPSA was obtained by tracing cyst surface area and removing borders not in contact with parenchyma.

Results: TKV was higher in RP (1707±614), compared to SP (671±291) but not AC (1625±742 mL), whereas CPSA was higher in RP (111609±52662) compared to both SP (31211±19500) and AC (40829±6720 u). GFR declined faster in RP (-4.53±1.47), compared to both SP (1.47±0.55) and AC (-1.68±1.92 mL/min/1.73 m^2). Baseline lnCPSA (r -0.733,p <0.0001) correlated better than lnTKV (r – 0.38,p=0.0008) with year 6 eGFR when the atypical cases were included. In the absence of the atypical cases both metrics performed equally well (r -0.724 p=0.0003 and r -0.723 p=0.0003 respectively).

Conclusions: CPSA is a better predictor of GFR decline than LnTKV in atypical ADPKD patients with large TKV and a relatively small number of cysts. In the majority of cases, both metrics perform equally well.

SA-PO297

Diagnostic Utility of Magnetic Resonance Imaging in Autosomal Dominant Polycystic Kidney Disease York P. Pei,[1] Young-Hwan Hwang,[1] John Conklin,[2] Jamie L. Sundsbak,[3] Christina M. Heyer,[3] Kairong Wang,[1] Ning He,[1] Mostafa Atri,[2] Peter C. Harris,[3] Masoom Haider.[2] *[1]Division of Nephrology, University Health Network and University of Toronto, Toronto, ON, Canada; [2]Department of Medical Imaging, University Health Network and University of Toronto, Toronto, ON, Canada; [3]Division of Nephrology, Mayo Clinic, Rochester, MN.*

Background: The clinical utility of ultrasonography (US) in autosomal dominant polycystic kidney disease (ADPKD) is currently limited by its reduced diagnostic sensitivity (SEN~80%) in at-risk subjects younger than 30 years of age (JASN 20:205-212, 2009). With increased spatial resolution for detecting smaller renal cysts, magnetic resonance imaging (MRI) may provide improved diagnostic capability.

Methods: In this single center study, we compared the diagnostic performance of MRI vs. US in a prospective cohort of 115 subjects between 17-40 years of age who were born with a 50% risk of ADPKD. All these subjects underwent a standardized renal US and MRI as well as mutation and/or linkage-based genetic testing to define their disease status. Concurrently, 44 age-matched healthy control subjects without a family history of ADPKD underwent the same imaging protocol to provide specificity data.

Results: Our preliminary results were derived from 91 at-risk subjects from 81 families (including 14 with *PKD1* hypomorphic mutations and 16 with *PKD2* mutations) whose disease status was unequivocally defined genetically ("gold standard") and 44 presumably unaffected control subjects. Using "a total of ≥ 3 renal cysts" as a test criterion, we found that US provided a higher than expected diagnostic SEN (>95%) but reduced specificity (SPEC~93%) particularly in the 30-40 age group. By contrast, using "a total of ≥ 5 renal cysts" as a test criterion, MRI provided a high SEN and SPEC both at ~98%.

Conclusions: Pending confirmation by the complete analysis of our study cohort, these data suggest that improved diagnostic SEN can be achieved in an experienced center with modern US scanners but at the expense of modest reduction of SPEC. By contrast, MRI may provide improved diagnostic accuracy by maintaining both high SEN and SPEC.

SA-PO298

Is There Any Role of Urogenital Cysts on Semen Parameters in Autosomal Dominant Polycystic Kidney Disease? Sami Uzun,[1] Savas Ozturk,[1] Meltem Gursu,[1] Abdullah Sumnu,[1] Egemen Cebeci,[1] Serhat Karadag,[1] Zeki Aydin,[1] Rumeyza Kazancioglu.[2] *[1]Department of Nephrology, Haseki Training and Research Hospital, Istanbul, Turkey; [2]Department of Nephrology, Bezmialem Vakif University Medical Faculty, Istanbul, Turkey.*

Background: Autosomal dominant polycystic kidney disease(ADPKD) is a systemic disease with cysts in many organs including the urogenital tract. The aim of the study is to evaluate relationship between urogenital cysts, semen pathologies and infertility in ADPKD.

Methods: Male ADPKD patients aged 18-60 with creatinine clearance higher than 60ml/min were included. All patients had MRI of the urinary system and pelvis; and scrotal Doppler ultrasonography besides sperm analysis. The results were compared with those of a healthy control group.

Results: 27 patients and 17 volunteers were included. Seminal vesicle and prostate cysts were detected in four(15%) and six(22%) patients, respectively. Five of the 23 married patients(21%) had infertility which was more frequent than in control group(p=0.044). Ratio of sperms with normal morphology and progressive motility were lower; and the rate of hypospermia, oligozoospermia, azospermia, asthenozoospermia and teratozoospermia were higher in patient group.

Comparison of semen analysis of the patient and the control groups.

	Patient group	Control group	p
Semen volume (ml)	2.4±1.4	2.9±1.4	0.26
Number of sperms (X106 /mm3)	20 ±17	47±19	<0.0001
Total sperm count (X103)	55±65	155±12	<0.0001
Liquefaction time (min)	18±6	18±7	0.85
Normal morphology (%)	11±14	17±10	0.008
Abnormal morphology (%)	89±14	83±10	0.008
Progressive motility (%)	29±20	54±15	<0.0001
Immobile (%)	62±23	38±16	0.001
Nonprogressive motility (%)	8.1±3.7	7.2±2.7	0.37
Hypospermia[n (%)]	14 (52)	4 (22)	0.063
Asthenospermia [n (%)]	20 (74)	7 (41)	0.005
Oligozoospermia [n (%)]	13 (48)	0 (0)	<0.0001
Teratozoospermi [n (%)]	21 (78)	8 (47)	0.036

There was no significant difference between patients with/without urogenital cysts regarding seminal pathologies.

Conclusions: Seminal abnormalities and infertility are more frequent in patients with ADPKD. Defects in spermatogenesis and sperm motility as well as ciliary pathologies may be responsible.

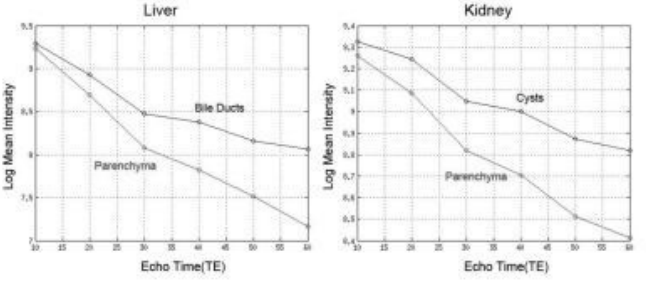
SA-PO299

T2 Relaxation Magnetic Resonance Imaging to Assess Kidney and Liver Disease in an Autosomal Recessive Polycystic Kidney Disease Model Ying Gao,[1,2] Huaiqiang Sun,[2] Lan Lu,[1] David L. Wilson,[1,2] Christopher A. Flask,[1,2] Katherine MacRae Dell.[3,4] *[1]Dept of Radiology; [2]Dept of Biomedical Engineering; [3]Dept of Pediatrics; [4]CWRU Center for the Study of Kidney Disease and Biology, Case Western Reserve University, Cleveland, OH.*

Background: ARPKD causes significant morbidity and mortality in affected children. There are currently no methods for measuring disease severity or progression, severely limiting clinical trial development. Quantitative MRI techniques may provide these important methods. The aim of this study was to develop T_2 relaxation assessments of renal cysts and biliary dilatation in the PCK rat, while limiting variable effects of tissue perfusion.

Methods: Axial kidney and liver images were obtained from 3 PCK rats using a 7T Bruker Biospec MRI scanner with a respiratory-gated,multiecho RARE acquisition. T_2 relaxation maps were generated via linear least squares fitting of conventional monoexponential decay models using all 6 echo images (TE=10-60ms) or the last 4 (TE=30-60ms). A region of interest (ROI) analysis was used to identify biexponential decay effects suggestive of tissue perfusion. Histogram analysis was used to establish thresholds, generate separate compartments and calculate mean T_2 values for normal kidney/cysts and normal liver/dilated bile ducts.

Results: Kidney and liver data showed biexponential T_2 decay characteristics suggestive of tissue perfusion.



Histogram analysis of T_2 maps from the TE=30-60ms data showed consistent segmentation thresholds for kidney (130ms) and liver (100ms). Mean T_2values (ms) were: normal kidney/cysts=83/184;normal liver/dilated bile ducts=51/175.

Conclusions: Initial *in vivo* MRI results in PCK rats suggest that quantitative T_2 assessments can provide a rigorous, high resolution characterization of ARPKD kidney and liver disease severity while correcting for confounding effects of tissue perfusion.

SA-PO300

Systematic Analysis of Polycystic Liver Disease in the ADPKD HALT: A Cohort Marie C. Hogan,[1] Kaleab Z. Abebe,[2] Arlene B. Chapman,[3] Robert W. Schrier,[4] Theodore I. Steinman,[7] Kyong Tae Bae,[2] Michael F. Flessner,[6] William E. Braun,[8] Franz Winklhofer,[9] Godela M. Brosnahan,[3] D. Miskulin,[4] Frederic F. Rahbari-Oskoui,[2] Ronald D. Perrone,[5] Vicente E. Torres.[1] *[1]Mayo Clinic; [2]U Pittsburgh; [3]U Emory; [4]U Colorado; [5]Tufts U; [6]NIH/NIDDK; [7]Beth Israel; [8]Cleveland Clinic; [9]U Kansas; [10]HALT PKD Study Group.*

Background: Few studies have analyzed the clinical correlates of polycystic liver disease (PLD) in large cohorts of ADPKD patients. HALT-PKD study A includes 558 ADPKD patients (51% male) systematically studied with standardized abdominal MRI.

Methods: Correlation and multiple regression cross-sectional analyses to determine associations of baseline clinical, laboratory and QOL variables with log transformed height (ht), adjusted total liver (htTLV) & cyst volumes (htLCV) & with combined ht(TLV+TKV).

Results: Mean (±std) age, TLV, LCV, and eGFR were 37±8yo, 1963±807ml, 292±816ml and 92±8ml/min/1.73 m2. 5.36% had severe PLD (defined as htTLV>1800ml/m) (2.70% in males; 7.98% in females; p=0.007). In the multivariate analysis in females,weight, alk phos & lower eGFR, albumin and platelets associated with lnhtTLV and lnhtLCV associated with age, weight, lnhtTKV, alk phos and lower platelets. LnhtTLV and lnhtLCV univariately associate with various biochemical, hematologic and QOL parameters (Table). These associations were stronger for females. Lnht (TKV+TLV) strongly correlated with back pain in males.

	Ln HtTLV			Ln HtLCV			Ln Ht (TKV+TLV)		
Variable	N	R	P	N	R	P	N	r	P
AST (U/L)	522	0.09514	0.0298*	385	0.07785	NS	513	0.04230	NS
ALT (U/L)	522	0.16271	0.0002*	385	0.03109	NS	513	0.11387	0.0098*
Alk Phos (U/L)	522	0.12525	0.0042*	385	0.11301	0.0266*	513	0.03183	NS
sAlbumin (mg/dL)	519	-0.13125	0.0027*	384	-0.14312	0.0050*	510	-0.09272	0.0363*
Platelets (Cells/µL)	518	-0.11142	0.0112*	382	-0.07382	NS	509	-0.08735	0.0489*
QOL: RP	512	-0.13856	0.0017*	378	-0.10202	0.0478*	503	-0.10504	0.0185*
QOL: GH	514	-0.11327	0.0102*	378	-0.02952	NS	505	-0.05974	NS
QOL: PCS	511	-0.12307	0.0053*	376	-0.04215	NS	502	-0.05853	NS

Table: Pearson correlations. (RP, GH are SF36 QOL subdomains for physical role, general health. PCS is physical component score.)

Conclusions: This study confirms the association of female gender with severity of PLD and reveals that the degree of liver enlargement is associated with the presence of biochemical and hematologic abnormalities, pain and impaired QOL.

SA-PO301

Increased Prevalence of Renal Cysts in Patients with Sickle Cell Disease
Arunraj Navaratnarajah,[1] Ounali Jaffer,[2] Emma Drasar,[3] Swee Lay Thein,[3] Christopher Jason Wilkins,[2] Claire C. Sharpe.[1] *[1]Renal Medicine, King's College Hospital, London, United Kingdom; [2]Radiology, King's College Hospital, London, United Kingdom; [3]Haematological Medicine, King's College Hospital, London, United Kingdom.*

Background: The availability and use of abdominal ultrasound and CT has led to frequent detection of simple renal cysts. Though generally regarded as benign and incidental, some develop complications of haemorrhage, infection, rupture and malignant transformation. Our aim was to investigate whether the presence of Sickle Cell Disease (SCD) is associated with an increased prevalence of simple renal cysts.

Methods: We identified 198 adults with SCD and normal renal function (eGFR<60 ml/min) who had undergone abdominal US or CT within the past 5 years. The number of reported cysts, location and diameter were recorded. We then re-examined the abdominal CT scans of the 43 patients who had been imaged within the previous 5 years and specifically looked for the presence of cysts. In addition, abdominal CT scans were examined from 180 trauma patients from similar ethnic background (Black African or Black Caribbean) and age who had been scanned within the same time period to act as a control group. All CT scans were examined by 2 radiologists who came to a consensus opinion.

Results: Standard CT reports were approximately twice as likely to mention the presence of renal cysts than ultrasound reports. On re-examination of the CT scans, approximately twice as many cysts were present as had been previously reported. 58% of the SCD patient group had cysts compared with 20% of the black control population (OR 5.4 (CI 2.6-11.0), RR 2.8 (CI 1.9-4.2)). Of those with SCD 28% had cysts bilaterally compared with 5% of the control group. The average number of cysts in the SCD population was 3.76 compared with 1.94 in the control population.

Conclusions: CT is a more sensitive method of detecting simple renal cysts than ultrasound scanning. Unless specifically requested, the presence of simple cysts is not always mentioned in imaging reports. When compared with an ethnically matched control population, patients with sickle cell disease are much more likely to have simple renal cysts, which are often multiple and bilateral.

SA-PO302

A Risk-Stratified Approach to Screen for Intracranial Aneurysms in ADPKD Patients and Its Potential Implications
Bruno E. Balbo, Luiz F. Onuchic. *Univ. São Paulo, Brazil.*

Background: Intracranial aneurysms (ICA) are found in 8% of patients (pts) with autosomal dominant polycystic kidney disease (ADPKD). Although rupture is an uncommon event, its high mortality justifies presymptomatic screening (PS) in high-risk pts. Apart from classical risk factors, such as family history (FH) of subarachnoidal hemorrhage (SAH)/ ICA, little is known about the impact of other risk factors on screening.

Methods: A retrospective study was conducted in an ADPKD referral center from 2007 to 2012. From 181 pts, 66 were evaluated for ICA based on symptoms (group A, 13 pts, several imaging methods) or based on risk factors (group B, 53 asymptomatic pts evaluated with magnetic resonance angiography, MRA).

Results: In group A, pts with severe, new-onset headache or focal neurological deficit presented more abnormal findings (6 in 7 pts; 5 ICA, 1 arterial dissection) than those with worsening headache (2 in 6 pts; 1 ICA, a non ADPKD-related diagnosis, NR). In group B, 18 pts displayed 19 abnormal findings: 7 ICA, 3 arachnoidal cysts (AC), 4 vascular ectasias (VE) and 5 NR. PS performed as follows: FH of SAH/ICA (16 pts: 3 ICA, 2 AC, 2 VE); possible FH of SAH/ICA (16 pts: 1 ICA, 3 NR); absent/unknown FH of ADPKD (9 pts: 2 ICA); need for anticoagulation (2 pts: 1 NR); previous to major surgery (4 pts: 1 ICA, 1 AC, 1 NR); imaging for other neurologic disorders (2 pts, 1 VE); without identifiable risk (4 pts, all normal). In total, 13 pts with a mean age of 42 ys had 18 ICA with a mean diameter of 5.36 mm (1.6-11.0), most in the middle cerebral artery (61.1%). Rupture occurred in 3 pts. Pts with ICA presented with lower eGFR (MDRD) than those with normal MRA (55.1 vs 80.5 mL/min/1.73m^2, p<0.05). There were no significant differences regarding age, gender, tobacco use, diagnosis of hypertension or dyslipidemia.

Conclusions: Our results show that 19.7% of risk-stratified pts had ICA, being this group associated with lower GFR. In addition, nonaneurysmal but ADPKD-related manifestations were detected in 12.1% of the pts. While PS in the presence of definite risk factors such as FH of SAH/ICA is strongly advised, these data suggest that alternative risk factors, such as absent/unknown FH of ADPKD, should be also considered.

High-Throughput Mutation Analysis in Patients with Nephronophthisis-Associated Ciliopathies by Multiplex PCR and Next-Generation Sequencing
Jan Peter Halbritter,[1] Katrina A. Diaz,[1] Moumita Chaki,[1] Susan J. Allen,[1] Constantinos J. Stefanidis,[2] Neveen Soliman Elshakhs,[3] Edgar Otto,[1] Friedhelm Hildebrandt.[1] *[1]Pediatric Nephrology and Human Genetics, University of Michigan, Ann Arbor, MI; [2]Pediatric Nephrology, A. and P. Kyriakou Childrens Hospital, Athens, Greece; [3]Center of Pediatric Nephrology & Transplantation, Cairo University, Cairo, Egypt.*

Background: To identify disease-causing mutations within coding regions of 11 known NPHP genes (*NPHP1-NPHP11*) in a cohort of 192 patients diagnosed with nephronophthisis-associated ciliopathies.

Methods: Mutation analysis was carried out using PCR-based Access Array microfluidic technology (Fluidigm™) with consecutive next-generation sequencing. We applied a 10-fold primer multiplexing approach allowing PCR-based amplification of 475 amplicons (251 exons) for 48 DNA samples simultaneously. After 4 rounds of amplification followed by indexing all 192 patient-derived products with different barcodes in a subsequent PCR, 2x100 paired-end sequencing was performed on one lane of a HiSeq2000 instrument (Illumina™). Bioinformatics analysis was performed using "CLC Genomics Workbench™" software. Potential mutations were confirmed by Sanger sequencing, shown to segregate with the affected status, and to be absent from 96 control individuals.

Results: NGS sequencing and bioinformatics analysis resulted in 62.1 million mapped reads with a median exon coverage depth of 449-fold per patient. Furthermore, 168/192 DNA samples (87.5%) and 134/251 exons (93.2%) consistently showed sufficient coverage depth above 30-fold. We identified pathogenic mutations in 34/192 patients (18%) and discovered 21 novel mutations in the genes *NPHP3* (7), *NPHP4* (3), *IQCB1* (4), *CEP290* (5), *RPGRIP1L* (1), and *TMEM67* (1). Additionally, we found 40 different single heterozygous missense variants of unknown significance.

Conclusions: We conclude that the combined approach of array-based multiplexed PCR-amplification on a Fluidigm™ Access Array platform followed by NGS is highly cost-efficient and strongly facilitates diagnostic mutation analysis in broadly heterogeneous Mendelian disorders.

Mutation of the Renal Magnesium Transporter *SLC41A1* Causes a Nephronophthisis-Like Phenotype
Toby W. Hurd,[1] Edgar Otto,[1] Eikan Mishima,[4] Heon Yung Gee,[1] Hana Inoue,[2] Masato Inazu,[2] Masato Konishi,[2] Gianluca Caridi,[3] Gian Marco Ghiggeri,[3] Takaaki Abe,[4] Friedhelm Hildebrandt.[1] *[1]Pediatrics and Communicale Diseases, University of Michigan, Ann Arbor, MI; [2]Physiology, Tokyo Medical University, Tokyo, Japan; [3]Istituo G Gaslini, Genova, Italy; [4]Clinical Biology, Tohoku University Graduate School of Medicine, Tohuku, Japan.*

Background: Nephronophthisis-related ciliopathies (NRCs) are the leading genetic cause of end-stage renal failure in the first three decades of life. To identify novel causative mutations for NRCs, we performed whole exome resequencing in a consanguineous Italian family with an apparent NRC phenotype.

Methods: An Affymetrix Genome-Wide Human SNP Array 6.0 was utilized to perform homozygosity mapping on two affected siblings. Exome capture was performed using the Nimblegen SeqCap EZ Human Exome Library v2.0 followed by resequencing on an Illumina HiSeq2000 platform.

Results: An NPHP diagnosis on two affected sibs of family F438 was based on clinical findings of polyuria, renal failure and increased echogenicity by RUS. Histological analysis of renal biopsies revealed the typical NPHP triad of tubular ectasia, tubular basement membrane disruption and tubularinterstitial infiltrations. Homozygosity mapping in the two affected sibs yielded 8 homozygosity peaks. Whole exome capture revealed a homozygous splice acceptor site mutation (c.698G>T) in the renal Mg^{2+} transporter *SLC41A1*, resulting in skipping of exon 6 of *SLC41A1* leading to an in frame deletion. Analysis of Mg^{2+} efflux on cells transfected with either wild type or DExon6 SLC41A1 revealed that deletion of exon 6 completely blocked the Mg^{2+} transport function of SLC41A1. Finally, we demonstrate that endogenous SLC41A1 localizes to renal tubules situated at the corticomedullary boundary consistent with the region of the kidney where the increased echogenicity was observed.

Conclusions: We have identified by whole exome capture a novel causative mutation in the Mg^{2+} transporter *SLC41A1*. This data suggests that defects in maintenance of renal Mg^{2+} homeostasis may lead to tubular defects that phenocopy nephronophthisis analogous to *CLDN16* mutation in a bovine model of nephronophthisis.

SA-PO305

Genetic Diagnosis of Nephronophthisis of Korean Children Using Traditional and New Methods: Stratified Sanger Sequencing and Targeted Exome Sequencing Hee Gyung Kang,[1] Su Jung Park,[1] Jiwon L. Lee,[1] Hye Jin Chang,[1] Hye Won Park,[3] Hae Il Cheong.[1] *[1]Pediatrics, Seoul National University Children's Hospital, Seoul, Korea; [2]Pediatrics, Center for Pediatric Oncology, National Cancer Center, Korea; [3]Pediatrics, Seoul National University Bundang Hospital, Seong Nam-Si, Korea.*

Background: Nephronophthisis (NPHP) is the most common genetic cause of end stage renal failure with insidious onset in childhood and adolescence. Recently, genetic diagnosis of this disease became available; Gene locus heterogeneity, allelism, and modifier genes are considered to govern genotype-phenotype correlation of NPHP. Here we report our result of genetic diagnosis in Korean children with NPHP.

Methods: Using Sanger sequencing, all the patients with clinical diagnosis of NPHP (n=71, M:F 38:33) were screened for total homozygous deletion of *NPHP1*. Other known genes of NPHP were tested after stratification; *NPHP2/INVS* for infantile type (n=7), *NPHP5* for those (n=12) with retinitis pigmentosa, *NPHP6/CEP290* for those (n=8) with cerebellar involvement, and *MKS/TMEM67* for those (n=7) with hepatic fibrosis. Then, exome sequencing, targeting 112 ciliopathy-related genes, was done for patients whose genetic diagnosis was not obtained by traditional method (n=59).

Results: Stratified Sanger sequencing of five genes revealed 4 juvenile cases with total deletion of *NPHP1*, 3 cases (Senior-Løken syndrome) with *NPHP5* mutations, one case (Joubert syndrome) with *NPHP6* mutations, and 4 cases (Meckel-Gruber syndrome) with *MKS3* mutations. Targeted exome sequencing confirmed mutations of ciliopathy-related genes in additional 8 patients; single cases of *NPHP1, NPHP3, NPHP4, NPHP12/TTC21B, SDCCAG8, PLXDC2,* and two cases of *PKHD1* mutations. In addition, a heterozygous mutation in single gene, in 2 genes and in 3 genes were detected in 22, 10 and 5 cases, respectively.

Conclusions: In total, 20 (28%) of 71 NPHP patients were genetically diagnosed either by traditional Sanger sequencing or by targeted exome sequencing. In addition, the latter method revealed candidate genes in 37 (52%) additional patients. Further studies on candidate genes found in exome capture would improve our understanding of NPHP.

SA-PO306

Retinal Macular Degeneration: A Pathognomic Finding of Nephronophthisis Type 1 with *NPHP1 Total Deletion?* Hee Gyung Kang,[1] Yo Han Ahn,[2] Su Jung Park,[1] Hye Jin Chang,[1] Jiwon L. Lee,[1] Sang Taek Lee,[1] Hyewon Park,[3] IL-Soo Ha,[1] Hae Il Cheong.[1] *[1]Depts of Pediatrics, Seoul National University Children's Hospital, Seoul, Republic of Korea; [2]Center for Pediatric Oncology, National Cancer Center, Goyang, Republic of Korea; [3]Health Promotion Center, Seoul National University Bundang Hospital, Seongnam, Republic of Korea.*

Background: Nephronophthisis (NPHP) is the most common genetic cause of end-stage renal disease of childhood and adolescence. More than thirteen genes are known to cause NPHP, among which *NPHP1* of nephrocystin-1 is the most common causative gene. While extrarenal symptoms, such as retinal pigmentosa, cerebellar vermis aplasia, and oculomotor apraxia, are commonly found in NPHP patients, NPHP type 1 is generally known as of isolated kidney involvement.

Methods: Genetic analysis and clinical correlation of NPHP type 1 patients.

Results: Five patients (M:F 4:1) with chronic kidney disease (CKD) were diagnosed as NPHP1 by genetic analysis, revealing homozygous total deletion of *NPHP1*. Their presentation of CKD was typical of NPHP at 7-15 years of age with nocturia or fatigue. Kidney biopsy findings were also compatible with NPHP in 4 patients. Renal function was lost between ages of 9 to 20. All patients had progressive decrease of visual acuity with various onset age (age 2-17) and one complained of night blindness. Ophthalmologic examination revealed the macular degeneration in 4 patients (age 14-23), which is quite compatible with Stargardt macular dystrophy; findings of one representative case was as follows. Fundoscopic examination showed parafoveal retinal pigment epithelium atrophy and degeneration. Electroretinography showed decreased amplitude of cone and rod responses. Fluorescein angiography revealed multiple flecks with choroidal silence.

Conclusions: While 6-10% of NPHP1 patients have been reported to have eye involvement, all of our patients with total deletion of *NPHP1* had progressive degenerative condition of eye, especially Stargardt disease in four out of five cases. These cases suggest that the possibility of *NPHP1* total deletion should be considered in CKD patients with progressive disturbance of visual acuity with typical findings of Stargardt disease.

SA-PO307

RITAZAREM: An International, Open Label, Randomized, Controlled Trial Comparing Rituximab with Azathioprine as Maintenance Therapy in Relapsing ANCA-Associated Vasculitis David R.W. Jayne,[1] Rona M. Smith,[1] Peter A. Merkel.[2] *[1]Vasculitis Office, Addenbrooke's Hospital, Cambridge, United Kingdom; [2]Division of Rheumatology, University of Pennsylvania, Philadelphia, PA.*

Background: Rituximab is an established induction agent in ANCA-associated vasculitis (AAV), especially for those with relapsing disease. Its role as a maintenance agent is less clear. 50% of patients with AAV will pursue a chronic relapsing course, despite standard maintenance immunosuppression. Therefore, there is unmet need in the prevention of relapses. Pilot data suggests that fixed interval repeat dose rituximab reduces relapse rate and may lead to sustained remission after a two-year treatment period. T his needs to be confirmed in a prospective, randomized controlled trial.

Methods: RITAZAREM is a multi-center, international, open label, randomized controlled trial in relapsing AAV. Patients with granulomatosis with polyangiitis (Wegener's) (GPA) and microscopic polyangiitis (MPA) will be recruited at the time of relapse, and all will receive induction therapy with rituximab (375mg/m^2/week x 4). At four months patients who have achieved remission will be randomized, 1:1 to receive maintenance therapy with either fixed-interval, repeat dosing of rituximab (1g every 4 months (5g in total)) or azathioprine. Glucocorticoid therapy will be protocolized and fully withdrawn by month 20.

Results: This study has three phases: i) four months induction; ii) 20 months maintenance; and iii) 24 months follow-up. The primary outcome is time from remission to relapse. Centers have been selected from the European Vasculitis Study Group (EUVAS; www.vasculitis.org) and the Vasculitis Clinical Research Consortium (VCRC). Recruitment will commence in summer 2012. Results are anticipated in late 2016.

Conclusions: This RITAZAREM study will address the efficacy and safety of fixed-time interval, repeat therapy with rituximab as a maintenance strategy in AAV. The outcome of this trial will help define optimal therapy for AAV.

Funding: Other NIH Support - National Institute of Arthritis and Musculoskeletal and Skin Diseases

SA-PO308

Long Term Outcome of Low Dose Cyclophosphamide (CYC) and Plasma Exchange (PLEX) Induction in ANCA Associated Vasculitis (AAV) Wladimir M. Szpirt,[1] Elizabeth Krarup,[2] Martin Egfjord.[1] *[1]Nephrology, Rigshospitalet; [2]Herlev Hospital, Copenhagen, Denmark.*

Background: Adverse events to the treatment of AAV have a greater threat for 1 year's outcome than the active vasculitis. The use of PLEX in AAV is not commonly accepted in patients (pts.) with plasma creatinine <500 µmol/L (<500), despite evidence of the involvement of ANCA and complement in the pathogenesis of vasculitis. We combined low dose of CYC and PLEX in order to minimize the infection/sepsis rate which mostly is due to the immunsuppression.

Methods: A prospective cohort study of all AAV pts. referred to our centre between 2000-2010 was performed. All pts. had AAV based on positive ANCA and a compatible clinical syndrome. The use of PLEX was decided on severity of renal biopsy and ANCA titres. Immunsuppression consisted of prednisolone 1 mg/kg/day and a low dose of daily oral CYC (100 mg/day in pts. <65 years and 50 mg/day in pts. >65). AZA/MMF was given for maintenance of remission.

Results: 132 pts. were admitted and 118 followed for a mean of 5.7 years (range 0.2-12.3; 676 patient years). 57% were male, 47% were MPO-ANCA positive. 36% had high creatinine >500. 40% were aged >65. 105 pts. received PLEX (mean 7 (5-11)). Only 5 pts (4%) died during CYC treatment (2 sepsis, 2 AMI, 1 lung haemorrhage, all on HD). In total 11 pts. (9%) died within 1 year and 14 more pts. died < 5 years. The total number of deaths was 33 (28%) with an expected 12 years patient survival of 62% (Kaplan Meier). 27 pts. (23%) developed ESRD, with an expected 12 years kidney survival of 75% (K.M). 43 pts. (36%) died or developed ESRD during the study, resulting in an expected 12 years dialysis free patient survival of 62% (K.M.). Pts. aged <65 or <500 had significantly better dialysis free survival. 29 pts. (23%) had infection <first 4 months, 15 (13%) being leucopenic. 41 (34%) relapses occurred during the 12 years of follow up.

Conclusions: The use of low dose CYC and PLEX for induction resulted in a high survival rate and good preservation of renal function together with low rate of complications. As the septicaemia and mortality was low, the combination of PLEX and low CYC seems to be less toxic, than the conventional AAV induction treatment regimen.

SA-PO309

ANCA-Negative Pauci-Immune Crescentic Glomerulonephritis: Clinical Characterestics and Outcome Amit Gupta, Narain Prasad, Anita Saxena, Raj K. Sharma. *Department of Nephrology, SGPGIMS, Lucknow, UP, India.*

Background: There is paucity of data on clinical characteristics and outcome of the ANCA negative pauci immune crescentic Glomerulonephritis(PCrGN). This analysis was done to compare the clinical profiles and outcome of ANCA negative (-ve) and ANCA positive (+ve) PCrGN.

Methods: The renal and extra-renal clinical characteristics, histological evidences and outcomes of all ANCA +ve and -ve patients seen from January 2006 to June 2011 were compared. The criteria for the PCrGN was the intensity of glomerular immunoglobulin staining (scale 0 to 4+) by direct immunofluorescence assay. The renal remission (complete- serum creatinine ≤1.4 mg/dl; partial- serum creatinine>1.4 mg/dl and dialysis free) between the two groups were compared.

Results: Of the 102 patients with PCrGN, 41(40%) were ANCA -ve and 61(60%) +ve (c- ANCA=28,p-ANCA=33). The extra renal manifestations were significantly high in ANCA +ve patients compared to ANCA -ve patients. The differing clinical characteristics of ANCA +ve versus -ve PCrGN were age (47±12 vs 40±8 years=0.04); fever (70% vs 44%, p=0.01); fatigue(82%vs56%,p=0.007),weight loss (41% vs 24.40%,p=0.09); arthralgia (46%vs 12%,p=0.001); muscle pain(36% vs 10%,p=0.003); gross hematuria (15% vs 32%,p=0.05); thrombocytosis (18% vs 2.4%,p=0.025); nephrotic range proteinuria (18% vs 41.40%,p=0.005). GIT, skin, sinus, eye involvement & BP similar in both groups. Although the glomerulosclerosis was significantly higher in ANCA -ve (27%) compared to ANCA +ve (11%),p=0.04 patients, the grade of interstitial fibrosis and tubular atrophy were similar(p>0.05). Complete or partial renal recovery was observed in 42/61(69%)ANCA +ve and 29/41(71%) in ANCA -ve patients.19/61(31%) ANCA +ve patients progressed to ESRD while 12/41(29.29%) ANCA -ve patients progressed to ESRD (p>0.05).

Conclusions: The ANCA negative PCrGN patients are relatively younger. Athough the extra renal manifestations are significantly higher in ANCA positive compared to ANCA negative PCrGN, the renal outcome is similar in both groups.

SA-PO310

Efficacy of Reduced Dose Intravenous Cyclophosphamide Induction Regime on Relapse Rates of ANCA Associated Vasculitis: A Single Centre Experience Nileshkumar Shah, Yadullah Syed, Fiona E. Harris, David Makanjuola. *Renal Unit, St. Helier Hospital, Carshalton, Surrey, United Kingdom.*

Background: Anti neutrophil cytoplasmic antibody associated systemic vasculitis (AASV) remains an important cause of renal disease. The aim of treatment is to induce a stable remission with minimum toxicity. We adapted our local protocol from published studies but reduced the duration of intravenous (i.v) cyclophosphamide treatment to minimise total exposure.

Intravenous Cyclophosphamide dosing schedule

Age (years)	Creatinine (µmol/L) <300	Creatinine (µmol/L) >300			
<60	15 mg/kg/pulse	12.5 mg/kg/ pulse			
>60 - <70	12.5 mg/kg/ pulse	10 mg/kg/pulse			
>70	10 mg/kg/pulse	7.5 mg/kg/pulse			
Dose 1	Dose 2 (2/52)	Dose 3 (4/52)	Dose 4 (7/52)	Dose 5 (10/52)	Dose 6 (13/52)

The aim of this study was to see whether the reduced dose at induction therapy increased the possibility of relapses of AASV.

Methods: We reviewed 90 patients with AASV diagnosed between June 2004 and Jan 2011 Patients were treated with i.v cyclophosphamide, Maintenance therapy was with azathioprine (1.5mg/Kg) in 68 (75%) patients and with other agents including Mycophenolate in the rest. We collected data on ANCA, creatinine and eGFR at the end of induction treatment (4 months), 12 months and at most recent follow up.

Results: 87/90 were Caucasian, M:F = 46:44, mean age was 64yrs; mean duration of follow up was 1317 days. 18 (20%) patients relapsed during follow up, 7 patients within the first 12 months, 11 between 12 - 96 months (PR3 positive n=11, MPO positive n=7) 14 of the relapsers were on Azathioprine and 4 were on Mycophenolate as maintenance treatment.

Conclusions: 7.7% of our patients had a relapse in the first 12 months. This compares favourably with 15.5% in the CYCAZAREM study, despite Cyclophosphamide exposure at induction in our patients being much less. We also found relapse to be more common in patients with PR3 positivity.

Our data suggest that our regime is equipotent at inducing remission and maintaining remission, without increased incidence of relapses. The lower cumulative Cyclophosphamide dose would be expected to cause fewer infectious complications and less gonadal toxicity.

SA-PO311

Reduced Dose Intravenous Cyclophosphamide Regime in Induction of ANCA Associated Vasculitis: A Single Centre Experience Yadullah Syed, Nileshkumar Shah, David Makanjuola, Fiona E. Harris. *Renal Unit, St. Helier Hospital, Carshalton, United Kingdom.*

Background: Anti neutrophil cytoplasmic antibody associated vasculitis (AASV) remains a significant cause of renal disease. There is evidence to support the use of intravenous (i.v) Cyclophosphamide for treatment. There is a constant desire to reduce treatment related toxicity in the care of such patients, whilst still seeking to induce and maintain a successful remission. We adapted our local protocol from published studies, but our regimen gives a reduced total dose of cyclophosphamide.

i.v Cyclophosphamide dosing schedule

Age (years)	Creatinine <300µmol/L	Creatinine >300µmol/L			
<60	15 mg/kg/pulse	12.5 mg/kg/ pulse			
>60-<70	12.5 mg/kg/ pulse	10 mg/kg/pulse			
>70	10 mg/kg/pulse	7.5mg/kg/pulse			
Dose 1	Dose 2 (2/52)	Dose 3 (4/52)	Dose 4 (7/52)	Dose 5 (10/52)	Dose 6 (13/52)

Methods: We reviewed patients with AASV diagnosed between June 2004 and Jan 2011; median follow up was 1323 days. We collected data at the end of induction treatment (4 months), 12 months and most recent follow up. Changes in creatinine and eGFR were defined as improved (>25% improvement), stable </= 25% change, or worse (>25% deterioration) from renal function at presentation.

Results: 87/90 were Caucasian; M:F = 46:44; mean age was 64.06±14.80. 35 (39%) needed dialysis on admission (Group A). 55 (61%) did not (Group B). 82 (91%) patients went into remission at the end of induction; 32(35.55%) in group A and 50 (55.55%) in group B. 5 (5.55%) patients did not achieve remission 1(1.11%) in group A and 4 (4.44%) in group B. (3.33%) died during the induction phase, 1 of whom did not achieve remission.

At the end of induction, 14(40%) patients in group A became dialysis independent. In group B, renal function improved in 33(60%), was stable in 16 (29.09%) and worse in 3(5.45%) patients at the end of induction.

Conclusions: 91 % of our patients went into remission at the end of 4 months of induction therapy. This is comparable to the remission rates in the CYCLOPS study (88%), in spite of the fact that the cumulative dose in our patients was less. We believe that our regime limits Cyclophosphamide exposure and maintains efficacy with regard to inducing remission.

SA-PO312

Gestational Rituximab Exposure in Women with Vasculitis William Franklin Pendergraft,[1-3] Martina M. McGrath,[1,3] Andrew P. Murphy,[3] Patrick Murphy,[3] Karen A. Laliberte,[3] John Niles.[2,3] *[1]Nephrology Fellowship Program, Massachusetts General Hospital (MGH) and Brigham and Women's Hospital, Boston, MA; [2]Div. of Nephrology, MGH, Boston, MA; [3]Vasculitis Clinic, MGH, Boston, MA.*

Background: Historically, cyclophosphamide (CYC) has been the mainstay of therapy for ANCA vasculitis. Rituximab (RTX) has proven to be an effective alternative to CYC in women of child-bearing age, but little is known about fetal effects of RTX exposure during pregnancy.

Methods: While being treated with RTX, women were counseled to avoid or plan pregnancy. Urine hCG was checked before each dose. Among pregnancies, patients and fetuses were monitored for recurrent disease and complications associated with RTX and immunosuppression. Where possible, maternal and fetal cord blood was tested for CD20+ B cells at delivery.

Results: 157 women (age range 16-93yrs, mean [SD] 58.9yrs [17.3]), including 22 women under 40yrs, were treated with RTX from 2002-present. Only one patient (40yrs) who desired pregnancy was unable to conceive. Six women achieved eight pregnancies (see Table), four planned and four unplanned. Patient 3a had progressive airway disease despite absence of B cells, ANCA and other features of active vasculitis. Patient 2b had a miscarriage at 15 wks. Remaining pregnancies were uneventful. Maternal CD20+ B cells were absent at delivery in most patients; however, B cells were at normal levels in fetal cord blood.

Characteristics of patients treated with RTX who achieved pregnancy

PATIENT	AGE	ANTENATAL RTX EXPOSURE (months)	WEEKS GESTATION	CHILD SEX/ APGAR	CHILD WT (g)	MATERNAL B CELLS (%)	FETAL B CELLS (%)
1	31	8	31	M/8,9	1625	<0.01	NR
2a	25	16.5	41	F/9,9	3790	2.79	NR
2b	27	7.5•	miscarriage 15wks	NR	NR	<0.01	NR
3a	20	8.3	40	M/9,9	2945	<0.01	3
3b	22	0.5*	TBD	M/TBD	TBD	<0.01#	TBD
4	29	13.5	38	F/8,9	3270	<0.01	5
5	40	9	38	M/8,10	3515	<0.01	NR
6	32	2.8*	TBD	F/TBD	TBD	<0.01#	TBD

•=months b/f D&C @ 15wks, *=months b/f estimated conception, #=trimester 3

Conclusions: Most women were able to achieve and complete pregnancy after RTX treatment, and fetal CD20+ B cells do not appear to be affected. Further study is needed to determine perinatal safety of RTX, especially as it is replacing CYC as the mainstay of therapy.

SA-PO313

Characterization of Drug-Induced ANCA Vasculitis at Massachusetts General Hospital (MGH): 1989-2012 William Franklin Pendergraft,[1,2,3] Martina M. McGrath,[1,3] Andrew P. Murphy,[3] Patrick Murphy,[3] Karen A. Laliberte,[3] John Niles.[2,3] *[1]Joint Nephrology Fellowship Program, Massachusetts General Hospital (MGH) and Brigham and Women's Hospital, Boston, MA; [2]Division of Nephrology, MGH, Boston, MA; [3]Vasculitis Clinic, MGH, Boston, MA.*

Background: The etiology of vasculitides associated with anti-neutrophil cytoplasmic autoantibodies (ANCA) remains largely unknown; however, drug-induced forms of disease exist. Reported culprits include hydralazine, minocycline, penicillamine, propylthiouracil (PTU), sulfasalazine and as recently described by our group, levamisole in the presence of cocaine. Our group has been the main clinical ANCA laboratory in New England and evaluation of positive patients is needed to identify exposures to known and potential culprit drugs.

Methods: We conducted a systematic retrospective analysis of patients from 1989-2012 with an initial positive ANCA test by indirect capture ELISA directed against either MPO and/or PR3. For each new ANCA-positive patient, a limited discussion was held with the ordering clinician to review implications of the positive test and to identify exposure to any known culprit drugs (discussions noted in MGH ANCA test registry were used for initial data analyses).

Results: A total of 2257 patients with positive ANCA tests were identified: 1428 (63%) were MPO-ANCA, 793 (35%) PR3-ANCA, and 38 (2%) dual MPO- and PR3-ANCA. 139 (6%) patients were exposed to drugs known to cause disease: 46 (33%) received hydralazine, 45 (32%) levamisole and cocaine, 33 (24%) PTU, 12 (9%) minocycline, 2 (1%) sulfasalazine and 1 (<1%) penicillamine.

Conclusions: This study represents the first and largest of its kind. The true number of drug-induced cases is likely underrepresented given that medications in use at the time of a positive ANCA test, in many cases, were unknown. Most importantly, the number of cases of ANCA vasculitis associated with many of these drugs is of concern given their ubiquitous use in the general population. Based on these results, measures should be implemented to limit hydralazine and propylthiouracil use and counsel against cocaine use.

Treatment and Outcome of Elderly Patients with ANCA-Associated Systemic Vasculitis Maria Weiner,[1] Aladdin Mohammad,[2] Zdenka Hruskova,[3] Kerstin W. Westman,[2] Per Eriksson,[1] Vladimir Tesar,[3] Alan D. Salama,[4] Marten Segelmark.[1] *[1]Medical and Health Sciences, Linköping University, Linköping, Sweden; [2]Clincial Sciences, Lund University, Lund, Sweden; [3]Nephrology, Charles University, Prauge, Czech Republic; [4]UCL Centre for Nephrology, Royal Free Hosptial, London, United Kingdom.*

Background: Age is a well known risk factor for patients with ANCA-associated vasculitis (AAV), but as few elderly patients have been included in clinical trials and there is little evidence concerning their optimal treatment.

Methods: In this multicenter study we analyzed baseline data and treatment during the first three months and related that to outcome between 3 months and 2 years in patients aged 75 years or more. We included consecutive patients with a clinical diagnosis of AAV according to Chapel Hill nomenclature from Linköping, Lund, Malmö, Prague and London diagnosed between 1997 and 2009.

Results: Data on treatment were available for 87 patients with a mean age at diagnosis of 79.8 years. During the first three months 16 patients died and 20 patients died between three months and two years giving a mean survival of 545 days. Mortality was significantly higher among those above 80 years (mean survival 475 days vs. 598; p=0.045). 51 patients were MPO-ANCA positive and 28 PR3-ANCA positive; serology did not affect survival. Among the 71 patients surviving the first 3 month Cyclophosphamide was given to 61 patients with a median cumulative dose of 3350 mg, 7 patients received Retuximab and 23 plasma exchange. Overall there were no significant differences in survival related to therapy or dose. However, when comparing patients who received less intense therapy (<3g of Cyclophosphamide and no Retuximab) with standard therapy, the standard therapy group did better (mean survival 712 vs 573 days, p=0.47).

Conclusions: Mean survival for AAV patients >75 years of age was 18 months, being significantly worse for those above 80 years. Insufficient treatment may contribute to mortality, but we cannot rule out that patients with adverse prognosis were treated less intense.

Small Vessel Vasculitis with Renal Involvement in Patients over 75 Years: A 24-Year Retrospective Study Helena Marco,[1] Emilia Corica,[2] Montserrat Picazo,[1] Yolanda Arce,[3] Jm Llobet,[2] Montserrat M. Diaz Encarnacion,[1] Jose Ballarin.[1] *[1]Nephrology, Fundacio Puigvert, Spain; [2]Rheumatology, Hospital Sant Pau, Spain; [3]Pathological Anatomy, Fundacio Puigvert, Spain.*

Background: Recent studies have shown a late onset of small vessel vasculitis (SVV), reaching up to 75 years or more. However, the differences in disease presentation and outcome between older and younger patients remain controversial. In our study we compare a group of very elderly patients (≥75 years) versus a group of younger patients (<75 years) with SVV and renal involvement.

Methods: We performed a single center retrospective review of 111 cases of SVV (1985-2009). We evaluated clinical and laboratory variables at diagnosis, presence of ANCA, kidney biopsy, immunosuppression therapy and renal/patient survival.

Results: Diagnoses were Wegener Granulomatosis(9%), Microscopic Polyangiitis(85%), Goodpasture's syndrome(6%). Patients ≥75 years old were 21%. The median age of all patients was 68(12-89)years: 79(75-89)years in very elderly patients and 65(12-74)years in patients <75 years. Creatinine at the treatment onset was 449(+/-211)µmol/L in the first group and 453(+/-267)µmol/L in the second.

95% of all patients received immunosuppressive induction treatment, 91% of the first group and 97% of the younger group. 72% of the oldest patients received Cyclophosphamide versus 93% of the youngest patients (p=0.01) and 14% of the oldest patients received Mycophenolate Mofetil versus 2% of the youngest patients (p=0.05).

The amount of patients that received definitive dialysis was similar (47% and 49% respectively). 30% of the elderly and 38% of patients <75 years had leukopenia. We observed similar number of infections in both groups (50% and 43% respectively).

The median follow up was 39.5(1-201) months, the actuarial patient survival was 70% in very elderly patients and 81% in the younger group at 24 months of follow-up (p=0.17).

Conclusions: The proportion of patients ≥75 years old with SVV is high (21%). Oldest patients received less induction treatment with Cyclophosphamide although there were no statistically significant differences in terms of complications, renal survival and patient survival with the younger patients.

SA-PO316

Clinical Characteristics and Outcome of Pauci-Immune Glomerulonephritis in African Americans Duvuru Geetha,[1] Caroline Jennette Poulton,[2] Yichun Hu,[2] Philip Seo,[1] JulieAnne G. McGregor,[2] Patrick H. Nachman,[2] Susan L. Hogan.[2] *[1]Johns Hopkins University; [2]University of North Carolina, Chapel Hill.*

Background: Pauci-immune glomerulonephritis is rare in African Americans (AA) and the clinical presentation and treatment outcomes of vasculitis have not been well described.

Methods: We identified patients 2 to 92 years of age between 1983 and 2011 with a diagnosis of biopsy proven pauci-immune glomerulonephritis (GN) at any point during their disease course. Comparing AA to Caucasian patients, we examined demographics, clinical features at presentation, treatment and outcomes of relapse, end stage renal disease (ESRD) and death.

Results: Of the 701 patients, 79 were AA with the remainder Caucasian. Compared to Caucasians, AA disease onset was at an earlier age (52 vs. 57 yrs, p=0.04), was more often MPO-ANCA positive (70% vs 53%, p=0.01), and trended toward being more frequent in females (56% vs 45%, p=0.07). Median (Interquartile range (IQR)) follow-up in months was 26 (5, 54) in AA and 28 (11, 59) in Caucasian patients. AA patients were less likely to have renal disease at diagnosis (92% vs 98%, p=0.02), but extra renal manifestations were similar. Induction drug treatment regimens were similar. Median eGFR was similar at presentation (23 vs. 21 ml/min/m^2). AA were less likely to have a renal relapse (20% vs 31%, p=0.07). Overall, controlling for age, race, MPO vs PR3-ANCA, there was no difference in reaching ESRD by race over the entire time of follow-up. There were no differences in relapse or death rates by race.

Conclusions: AA patients with vasculitis are younger and more often MPO-ANCA positive compared to Caucasians. There were no differences in ESRD, relapse or death rates by race over the entire time of follow-up.

SA-PO317

BK Virus Replication in Patients with Granulomatosis with Polyangiitis and Microscopic Polyangiitis Duvuru Geetha, Stuart M. Levine, Rebecca Manno, Alex Valsamakis, Philip Seo. *Johns Hopkins University.*

Background: Current immunosuppressive drug treatment regimens to induce and maintain remission of vasculitis in patients with granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA) are associated with substantial morbidity, including opportunistic infections. BK virus (BKV) is an important cause of renal dysfunction in renal transplant (TX) recipients and the intensity of overall immunosuppression is a major risk factor for BKV replication in these patients. The prevalence of BKV replication in immunosuppressed vasculitis patients without transplant is not known.

Methods: We prospectively screened 30 consecutive patients with a diagnosis of GPA or MPA who were on immunosuppressive drug treatment for induction or maintenance of remission for BKV replication. We collected data on demographics, disease duration, organ involvement, renal function and immunosuppressive drug use. Plasma BKV load was measured by quantitative PCR. We compared BKV replication in this non-transplant vasculitis cohort to BKV replication in a historical cohort of vasculitis kidney TX recipients.

Results: Thirty patients (20 GPA, 10 MPA) had mean disease duration of 77 months. Mean age was 51 yrs, 53% female. The mean time from vasculitis onset to BKV testing was 33 months, with 15/30 patients tested within 24 months of induction therapy. At the time of BKV testing, 70% were on prednisone (P) with azathioprine, mycophenolate mofetil (MMF), methotrexate or leflunomide. 30% were on P monotherapy. None of the non-transplanted vasculitis patients had BKV replication in plasma. 5/33(15%) transplanted GPA/MPA patients had BKV replication in plasma or allograft on surveillance testing or when tested to evaluate allograft dysfunction at a mean of 15 months post TX (P=0.05). These patients were on maintenance therapy with MMF, P and tacrolimus.

Conclusions: In immunosuppressed patients with GPA/MPA without renal TX, we found no evidence of BKV replication in the plasma. However, BKV replication was common in GPA/MPA patients after renal transplantation suggesting that BKV replication may be related to specific immunosuppressive agents, alloimmune activation or differences in host defense mechanisms.

SA-PO318

Prognosis of ANCA-Associated Glomerulonephritis (ANCA-GN) Requiring Dialysis at Presentation Taewoo Lee, Vimal K. Derebail, Caroline Jennette Poulton, Sophia Lionaki, JulieAnne G. McGregor, Susan L. Hogan, J. Charles Jennette, Ronald J. Falk, Patrick H. Nachman. *UNC Kidney Center, University of North Carolina.*

Background: ANCA-GN commonly presents with a rapidly progressive course and severe renal failure requiring dialysis. In such cases, treatment with corticosteroids, cyclophosphamide and plasmapheresis is recommended. This study aims at determining predictive factors of response to therapy and outcomes of patients who required dialysis at presentation.

Methods: The rate of renal recovery, patient and renal survival at 12 months and causes of death were assessed. To determine the prognostic factors of renal survival at 12 months, clinical and pathologic variables at presentation were evaluated as covariates in a binary logistic regression model. The primary outcome was dialysis independence for ≥3 months.

Results: Of 116 patients (mean age 60.4 ± 19.4 yrs; 85% white; 26% treated with plasmapheresis), 54 (46%) recovered renal function in a median of 4.4 weeks [IQR 2 -8.7]; median GFR at recovery 28.9 ml/min/1.73m^2 [IQR 21.9-36.9]. Of these 4 relapsed leading to ESRD. At 12 months, 50 patients (43%) were dialysis-free, 51 (44%) were dialysis-dependent and 21 (13%) had died. The main causes of death were cardiovascular events (n=8, 38%), pulmonary hemorrhage (n=5, 24%) and infections (n=5, 24%). In those who recovered renal function, patient and renal survival rates were 94% and 89% respectively at 12 months and 70% and 61% respectively at 36 months. Compared to patients who recovered renal function, those who did not had significantly greater degree of glomerular sclerosis, interstitial fibrosis, arteriosclerosis, and higher frequency of MPO-ANCA than PR3- ANCA. In a multivariable model, arteriosclerosis (≥ moderate) was an independent predictor of lack of renal recovery after adjusting for the other variables (Odds ratio 0.35, P-value 0.026).

Conclusions: The likelihood of recovery of renal function in patients with ANCA-GN requiring dialysis is about 50%, and is associated with measures of histologic chronicity at presentation, in particular, arteriosclerosis. Renal recovery is associated with a sustained independence from dialysis.

SA-PO319

ANCA-Associated Vasculitis: A Comparison of Patients Presenting to Renal and Rheumatology Services Bairbre A. McNicholas,[1] Tomas Patrick Griffin,[1] Louise Ryan,[1] John Joseph Carey,[2] Louise Giblin,[1] David Lappin,[1] Donal N. Reddan,[1] Matthew D. Griffin.[1] *[1]Nephrology Centre, Galway University Hospital, Galway, Ireland; [2]Rheumatology Centre, Galway University Hospital, Galway, Ireland.*

Background: ANCA associated vasculitis is a life-threatening disease but patients are cared for by different specialities depending on presentation. The aim of this study was to compare patients with ANCA-associated vasculitis under the care of the renal and rheumatology services at a tertiary referral centre.

Methods: A retrospective study of two cohorts with a diagnosis of ANCA positive vasculitis between 1993 and 2012. Cases were identified from biopsy reports and chart review. Presentation, induction and maintenance treatment, relapses, mortality and incidence of major treatment complications between cohorts was compared.

Results: 51 subjects met study eligibility: 30 renal, 19 rheumatology, with mean follow-up time of 41 months and 49 months respectively.

Feature	Renal	Rheumatology	P Value
Mean Age (SD)	63 (10)	52 (12)	0.01
% Female	42	46	0.5
Mean ANCA titre (AU/L)	67	24	0.01
c-ANCA %	40	63	0.14
Mean C-reactive Protein	112	54	0.03
ENT Manifestations (%)	40	73	0.04
% Relapsed	30	57	0.22
Mortality	5(22%)	1(5%)	0.22
% Infection	33	15	0.19
% Cancer	16	0	0.14

All renal patients had biopsy proven glomerulonephritis and 6 rheumatology patients had renal involvement. Renal patients were older, more likely to be p-ANCA positive, and had fewer ENT manifestations. Renal patients were more likely to be treated with IV steroids, IV cyclophosphamide, and plasmapheresis, but less likely to be treated with methotrexate. Renal patients had a trend towards being less likely to relapse but towards increased mortality. Treatment related complications were more common among renal patients.

Conclusions: Patients with ANCA-associated vasculitis represent a heterogenous group who may receive primary care from different medical subspecialties. Compared to rheumatology patients, renal patients were older and more likely to be p-ANCA positive, had lower relapse rates but also higher number of treatment related complications. Differences in speciality based cohorts should be considered in clinical trial design and interpretation.

SA-PO320

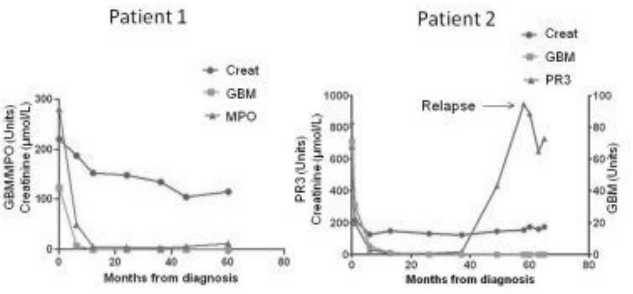
Long Term Outcomes in Patients with Both ANCA and Anti-GBM Antibodies Anisha Tanna,[1] Jeremy B. Levy,[1] Stephen Paul McAdoo,[1] Alan D. Salama,[2] Charles D. Pusey.[1] *[1]Imperial College, London, United Kingdom; [2]UCL, London, United Kingdom.*

Background: Anti-Neutrophil Cytoplasmic Antibodies (ANCA) have been reported in up to 40% of patients with anti-glomerular basement membrane(anti-GBM)disease whilst anti-GBM antibodies are present in 5-10% of patients known to have ANCA positivity. The impact of "double positivity" on long term renal and patient outcome has yet to be fully ascertained.

Methods: A search was conducted on records of patients currently being followed up at our centre with dual antibody positivity. Information on outcomes was collated using both electronic and paper records.

Results: 9 patients were identified, 3 male and 6 female with mean age at presentation of 54 years. 55% of patients were Caucasian,44% Indoasian. 5 patients were positive for both GBM and MPO antibodies and 3 for GBM and PR3. One patient was GBM, PR3 and MPO positive. 8/8 biopsies revealed crescentic glomerulonephritis. 1 patient was too unwell for biopsy. 4 patients were dialysis dependent on presentation. All patients had cyclophosphamide induction and 7 received plasma exchange. The mean follow up was 84 months. 4 patients experienced clinical relapses of their disease (2 GBM/MPO and 2 GBM/PR3). All relapses were associated with recurrence of ANCA not GBM.

Figure 1



7/9 patients currently maintain independent renal function, including 2/4 patients who presented dialysis dependent. The patient with "triple positivity" presented and remained dialysis dependent throughout. Of note, 5 patients developed interstitial lung disease during follow up.

Conclusions: Patients with "dual positivity" are reported to experience poorer outcomes than those with an isolated ANCA. Despite this, 50% of our patients presenting at end stage have maintained independent renal function for at least 5 years. It is important to test for both antibodies on a regular basis in these patients and to tailor treatment accordingly.

SA-PO321

Cardiovascular Outcomes in ANCA-Vasculitis Patients Claudia Yuste,[1] Alina L. Casian,[2] Cristina Jironda,[3] David R.W. Jayne.[2] *[1]Nephrology, Gregorio Marañón, Madrid, Spain; [2]Lupus and Vasculitis, Addenbrooke's Hospital, Cambridge, United Kingdom; [3]Nephrology, Carlos Haya, Malaga, Spain.*

Background: ANCA associated vasculitis (AAV) (granulomatosis with polyangiitis (GPA), and microscopic polyangiitis (MPA)) is associated with an increased frequency of cardiovascular events (CVE). **Objectives:** To identify predictors, including the role of vasculitis therapies, for CVE in AAV.

Methods: A single centre retrospective review of 307 AAV patients (173 GPA, 134 MPA, 47% male, 12% diabetic; mean age 53 [±17] years with follow-up 6.1 (±5.3) years. The primary end-pointy was CVE defined as acute coronary syndrome, new onset angina, symptomatic peripheral vascular disease, stroke or transient ischemic attack, or death. Potential predictive factors were assessed by Cox proportional regression analysis.

Results: 51 CVE occurred in 42 patients (13.6%) with 28 (9%) deaths and the end-point was more frequent in MPA (16.4% and 14.9% respectively) than in GPA patients (11.6% and 4.6%) (p= 0.003). It was associated with lower PR3-ANCA levels in PR3-ANCA patients and higher MPO-ANCA levels in MPO-ANCA patients, assessed at diagnosis (p= 0.011). Independent predictors for the end-point were: maintenance prednisolone dose >5mg/day (hazard ratio (HR) 0.047 (95% CI 0.005-0.418), cumulative cyclophosphamide dose <10g (HR 0.08 [1.5 -7.6]), haemoglobin level at the end of follow up (HR 0.6[0.378-0.96]) and history of prior CVE (HR 2.84 [1.07-7.49]). A cumulative RTX dose <6g was associated with higher prednisolone dose (p=0.016).

Conclusions: Patients with MPA have higher risk of CVE or death than GPA. ANCA level at diagnosis carried different associations in PR3-ANCA and MPO-ANCA patients. A higher maintenance prednisolone dose and lower cumulative cyclophosphamide or RTX dose were also predictors for CVE and death.

SA-PO322

Computerized Instersitial Fibrosis Is the Most Powerful Histological Predictor of Renal Outcome in ANCA-Associated Vasculitis Charlene Levi,[1] Vannary Meas-yedid,[2] Cristina Daniliuc,[1] Luc Mouthon,[3,4] Jean-christophe Olivo-marin,[2] Elsa Guiard,[1,4] Melanie Roland,[1] Loïc Guillevin,[3,4] Christian H. Jacquot,[1,4] Alexandre Karras,[1] Eric Thervet.[1,4] *[1]Nephrology, Hopital Europeen G.Pompidou, Paris, France; [2]Image Analysis, Pasteur Institute, Paris, France; [3]Internal Medicine, Hopital Cochin, Paris, France; [4]Universite Paris Descartes, Paris, France.*

Background: Renal involvement in ANCA-associated vasculitis (AAV) is characterized by necrotizing crescentic glomerulonephritis(GN) and can result in severe renal dysfunction. Although a new pathologic classification of the glomerular lesions has been recently proposed, its predictive value is unknown compared to interstitial fibrosis (IF) or renal function.

Methods: We retrospectively included 78 patients with recently diagnosed AAV and biopsy-proven renal involvement between 2001 and 2011. All renal biopsies were analyzed and classified according to the recently defined classification and divided in focal GN (fGN≥50% normal glomeruli), crescentic GN (cGN≥50% cellular crescent), mixed GN (mGN) or sclerotic GN (sGN≥50% globally sclerotic). Among this population, computerized interstitial fibrosis was analyzed in 62 patients using a specific software already described. To summarize, a cortical section was analysed by a program of colour segmentation imaging, which automatically extracts green colour areas characteristic of IF.

Results: Median follow-up was 22 months. Median creatinine at presentation was 212µmol/l (45 to 1448). Renal prognosis, defined as the proportion of patients with CKD stage 4/5 at 12 months was not statistically different according to the initial glomerular classification. The mean IF was 29±11,6% (range 9-58%). There was no correlation between the glomerular score and computerized IF. Compurized IF % correlated significantly with renal function (eGFR) at baseline and at 12 months ($p<0.001$) and with the risk of CDK 4/5 at 12 months. Baseline GFR also correlated with 1-year GFR ($p<0.001$).

Conclusions: In our cohort of patients, the glomerular classification of renal AAV doesn't predict the 12-months renal outcome. Initial renal function and computerized IF quantification are better prognostic markers than glomerular lesions in AAV.

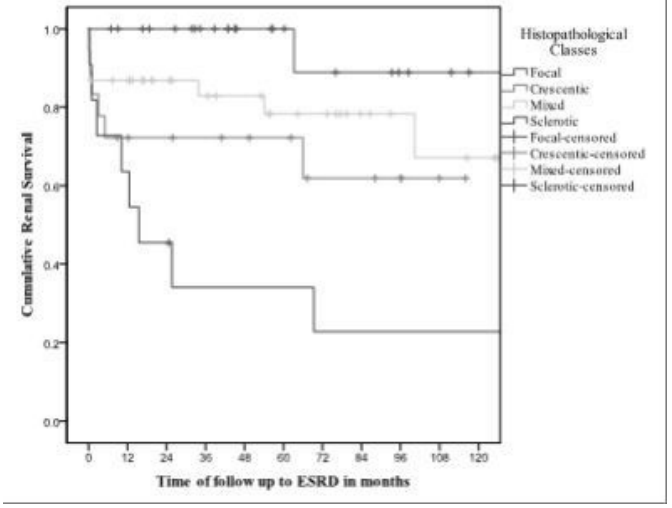
Renal Histopathological Classification of ANCA Associated Glomerulonephritis: A Validation Study of 92 Patients

Alina L. Casian,[1] Erika De Sousa Amorim,[2] Amaia Ros Abando,[2] David R.W. Jayne.[1] *[1]Nephrology, Addenbrooke's Hospital, Cambridge, United Kingdom; [2]Nephrology, Hospital Universitario La Paz, Madrid, Spain.*

Background: A novel histopathological classification was proposed for ANCA associated glomerulonephritis (GN): focal (>50% normal glomeruli), crescentic (affecting >50% of glomeruli), mixed and sclerotic (>50% sclerosed glomeruli). We performed a validation study to determine the prognostic value of the classification.

Methods: 92 renal biopsies with ANCA+ GN were classified retrospectively, with a mean number of 18 glomeruli. eGFR was corrected for baseline eGFR. Age,sex,ANCA subtype, baseline eGFR and histological category were covariates in the Cox regression model. Renal survival was assessed by Kaplan-Meier analysis, comparing histological classes using the log rank test.

Results: Mean follow-up 62 months. Median age 61.9 years, 53.3% male, 61.9% microscopic polyangiitis vs 38% granulomatosis with polyangiitis. 26% of biopsies were classified as focal, 20% crescentic, 14% sclerotic, 40% mixed. Renal survival at 1 year was 100% in the focal class, 86% in mixed, 72% in crescentic and 61% in sclerotic class (p=0.002).



Median Baseline eGFR (ml/min)	Focal 50.0 ± 30.4	Crescentic 12.7 ± 7.8	Mixed 15.5 ± 17.2	Sclerotic 16.54 ± 11.2
Median eGFR at 5y (ml/min)	50.4 ± 26.1	51.7 ± 28.4	35.6 ± 17.8	16.75 ± 15.84

The sclerotic group displayed a higher mortality (38%) than average (23%)($p<0.05$).

Conclusions: Similar to the previous study the focal group did best, and the sclerotic group worst in terms of ESRD. In contrast, our crescentic group had higher ESRD rates than the mixed group, which we associate with lower baseline eGFR. However, those crescentic patients without ESRD had better recovery than the mixed group, due to the predominance of reversible acute lesions. Renal histology in conjunction with baseline eGFR predicted renal outcome better than eGFR alone.

SA-PO324

New Histopathologic Classification of Anti-Neutrophil Cytoplasmic Antibody Associated Pauci-Immune Glomerulonephritis: Correlation with Renal Outcome

Carla L. Ellis, Rebecca Manno, Lorraine C. Racusen, Duvuru Geetha. *The Johns Hopkins Hospital and School of Medicine, Baltimore, MD.*

Background: Renal biopsy is of diagnostic and prognostic value in ANCA associated glomerulonephritis and a new classification for prognostication of pauci-immune glomerulonephritis (GN) based on four categories (Mixed, Crescentic, Sclerotic and Focal) was proposed by an international working group of renal pathologists (IWGRP). The goal of our study was to apply the proposed classification system to a United States cohort of vasculitis patients and correlate IWGRP class to the estimated glomerular filtration rate (eGFR) at baseline, six months and one year.

Methods: Cases of pauci-immune glomerulonephritis diagnosed from 1995 to 2011 were identified and clinical data were collected. Histology was reviewed by a pathologist and classified according to the new classification. MDRD formula was used to calculate e-GFR. We correlated IWGRP class to renal function at presentation, at six months and at one year. X^2, one way ANOVA and linear regression analysis were performed as appropriate.

Results: Seventy-six cases of pauci-immune glomerulonephritis were identified; mean age: 58 years, 57% males, 82% Caucasian. 82 %were ANCA positive. Seventy-four patients were treated with induction therapy. Renal biopsies were categorized as focal: n=21, crescentic: n=18, mixed: n=27, sclerotic: n=10. The baseline e-GFR was lowest in the crescentic class and highest in the focal class. Table 1 shows the renal outcome according to class. In linear regression analysis investigating e-GFR at 6 months and 1 year; age, baseline e-GFR and renal biopsy category were independent predictors of e-GFR at both time points.

Conclusions: The e-GFR at diagnosis and the IWGRP class were predictors of e-GFR at 1 year, making both values important predictors of long term renal outcome in ANCA associate vasculitis patients.

Table 1

Class	Baseline e-GFR - mean (SD)	1 year e-GFR - mean (SD)
Focal (n=21)	50 (62)	69 (38)
Crescentic (n=18)	16 (10)	38 (26)
Mixed (n=27)	27 (23)	36 (23)
Sclerotic (n=10)	25 (15)	27 (17)

SA-PO325

Renal Function and Sclerotic Glomerular Injury Predicts Poor Prognosis in Patients Presenting with Anti-Neutrophil Cytoplasmic Antibody Associated Vasculitis

Sharon Lee Ford, Kevan Polkinghorne, Anthony Longano, Stephen R. Holdsworth, A. Richard Kitching, Shaun A. Summers. *Departments of Nephrology, Pathology and Medicine and Monash University, Monash Medical Centre, Australia.*

Background: In ANCA associated vasculitis (AAV) treatment regimes are universally applied; no laboratory or histological variables have proven prognostic value. An international collaborative pathology group has published a predictive glomerular classification which requires validation. We sought to determine predictors of mortality and renal outcome in AAV.

Methods: 113 consecutive AAV patients (1993-2011) who had adequate renal biopsies and clinical information from a single centre were studied. Demographics, laboratory results and outcomes were collected. Kidney biopsies were classified, by three pathologists blinded to clinical data, into the patterns: focal, mixed, crescentic and sclerotic. The primary outcome was time to end stage renal disease (ESRD) or all cause mortality modelled using Cox regression analysis.

Results: Sclerotic injury and reduced GFR at presentation predicted poor outcomes. Median age was 66 years (IQR 56-74) with follow up of 3.9 years, 58% were male. Biopsies were: focal (26%), mixed (29%), crescentic (29%) and sclerotic (16%). No difference was seen amongst the groups for: age, sex or ANCA subtype. Compared to sclerotic injury, focal (HR 0.29, 95% CI 0.12-0.68, P<0.01), mixed (HR 0.37, CI 0.17-0.84, P<0.05) and crescentic (HR 0.46, CI 0.21-0.99, P<0.05) injury had a lower risk of ESRD/death, after age adjustment. Median GFR at presentation was different amongst biopsy groups (focal 35mls/min, mixed 22mls/min, crescentic 9mls/min and sclerotic 9mls/min $p < 0.001$). The addition of baseline GFR, the strongest predictor of ESRD/death (HR 0.96 per 1ml/min increase in GFR, CI 0.93-0.98 $p = 0.001$) attenuated the prediction of outcome by biopsy classification. Interestingly, crescentic injury was associated with a short duration of symptoms and increased prevalence of lung involvement (P<0.05).

Conclusions: Reduced presenting GFR and a sclerotic pattern of glomerular injury predict poor patient and renal survival. Treatment protocols should be adjusted accordingly.

Anti Neutrophil Cytoplasmic Antibody Vasculitis in a Single Centre in North West UK and Outcomes Following Rituximab or Cyclophosphamide

Mrityunjay Hiremath, Noshaba Naz, Harsha Wodeyar, Victoria Stewart, Neville Nicholas, Yaser Shah, Anindya Banerjee. *Wirral University Hospital NHS Foundation Trust.*

Background: The annual incidence of ANCA associated systemic vasculitis is around 20/million in UK.We noticed high number of patients with ANCA positivity in our centre. Some were treated for systemic vasculitis with Rituximab as first line while rest were treated with Cyclophosphamide.

Methods: Local incidence of ANCA positive systemic vasculitis.Renal outcome in each treatment arm (Rituximab vs Cyclophosphamide) -Retrospective analysis of patients with ANCA-associated systemic vasculitis between 2007-2011. Data was collected using Hospital Electronic record system.We analysed data for relapse, creatinine levels, ESRD leading to dialysis and deaths.

Results: 77 patients were identified to have ANCA positivity between 2007-2011,an incidence of 140/million population over 5 years. -45 patients with renal failure and systemic features were treated.Incidence of ANCA associated systemic vasculitis requiring immunosuppressions at our centre ranged between 7/million in 2007 to 23/million in 2010. Age of 70 or more with creatinine higher than 550 micromols/L on presentation predicted ESRD requiring dialysis. Most relapses occurred more than 2 years after initial treatment with Rituximab, Only 1 patient relapsed in Cyclophosphamide group.There was no significant difference in relapse rates, deaths or ESRD between 2 groups.

Conclusions: Rituximab is not superior to Cyclophosphamide as an induction agent for treating ANCA associated systemic vasculitis. We had similar incidence rates of systemic ANCA vasculitis as rest of UK.

(Table 1)sets out results in 45 patients

Patient Characteristics	Rituximab (n=31)	Cyclophosphamide(n=14)	p -value
Age(years)	67.6	72.4	0.21
Sex	17 M ; 14 F	8 M ; 6 F	
Creatinine(micromoles/ litre)	501	554	0.60
Plasma Exchange	6	0	
Lung Haemorrhage	3	0	
Relapse	7 (22%)	1 (7%)	0.4
Pts. requiring dialysis	9 (29%)	2 (14.28%)	0.3
Dialysis dependant on presentation	12 (38.7%)	2 (14.28%)	0.37
Dialysis dependant at 3 months	9 (29%)	2 (14.28%)	0.3
Survival 1 year	22(70.96%)	12(85.71%)	0.19
Death	9 (29.04%)	2 (14.29%)	0.3
Initial therapy	Methyl prednisolone	Methyl prednisolone	

SA-PO327

Vaccine Responses in ANCA Vasculitis Patients Matthew David Morgan, Alex Richter, Constantina Paulo Yiannakis, Lorraine Harper. *University of Birmingham.*

Background: Serious infection is a significant cause of morbidity and mortality in immunosuppressed patients with antineutrophil cytoplasm antibody associated vasculitis (AAV). Vaccination is recommended to reduce the incidence of infection. This study explores AAV patient responses to routine vaccination and factors associated with infection and poor vaccine responses.

Methods: All patients attending a tertiary centre vasculitis clinic were offered vaccination with conjugate vaccines against pneumococcus, haemophilus and meningococcus as routine care if in remission for more than 6 months, not pregnant and not within 6 months of rituximab or cyclophosphamide therapy. Functional IgG antibodies were measured at baseline, 4, 8 and 16 weeks post vaccination. Serum IgG and peripheral blood lymphocyte subsets were measured at baseline. Clinical data was collected for cumulative steroid and cyclophosphamide exposure, previous relapse rates and infective episodes. Patients were followed for 2 years post-vaccination. Ethics committee approval and patient informed consent was obtained for the study.

Results: 92 patients (median age 65, median 6 years post diagnosis, 52 men, 55 granulomatosis with polyangiitis, 22 microscopic polyangiitis, 11 other) participated. 22% had serum IgG<6g/L, 55% had lymphopenia and 73% low B cell counts at baseline. Serum IgG correlated with B cell count (correlation coefficient (cc)=0.3; p<0.01), CD4 count (cc=0.3; p<0.01) and maintenance immunosuppression.

Improvement in functional antibody titres following vaccination correlated with serum IgG (cc=0.4; p<0.01), B cell count (cc=0.35; p<0.01) and withdrawal of immunosuppression (no immunosuppression vs azathioprine or mycophenolate p=0.04). No increase in annual relapse rate was seen following vaccination (0.15/year pre vs 0.12/year post vaccination; p>0.05). Infection rate correlated with cumulative steroids (cc=0.24; p=0.02), lymphocyte count (cc=-0.23; p=0.04), serum IgG (cc=-0.2; p=0.06) and continued immunosuppression.

Conclusions: AAV patients on continued immunosuppression with impaired immune function have increased infection rates and poor responses to routine vaccination.

Improved strategies are needed to reduce infection risk in this group of patients.

SA-PO328

Infection and Mortality in Anti-Neutrophil Cytoplasmic Antibody-Associated Vasculitis Roberto Negrete, JulieAnne G. McGregor, Caroline Jennette Poulton, Yichun Hu, Patrick H. Nachman, Ronald J. Falk, Susan L. Hogan. *Division of Nephrology and Hypertension, University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: Infectious complications of immunosuppression impacts patient outcomes in anti-neutrophil cytoplasmic antibody (ANCA) associated vasculitis (AAV).

Methods: An inception cohort of 225 patients diagnosed with AAV from 2000-2011 and treated with immunosuppressive therapy (methylprednisolone pulses 72%, prednisone 96%, intravenous (IV) cyclophosphamide 67%, oral cyclophosphamide 51%, azathioprine 42%, mycophenolate mofetil 44% and rituximab 22%) was studied. Number of infections, severe infections (requiring IV antibiotics or intensive care unit [ICU] hospitalization), leukopenia, number of relapses, diabetes mellitus (DM), use of prophylactic antibiotic therapy (trimethoprim/sulfamethoxazole, atovaquone, dapsone), and death were recorded. Patients were analyzed based on number of infections: 0, 1 to 2 or >3. Statistical comparison between the groups were done with Fisher's exact test or Kruskal-Wallis test.

Results: A total of 417 infectious episodes were recorded over a median follow-up of 26 months (IQR 13,52). Most frequent infections found were bronchopulmonary infections (34%). There was no difference with respect to age at the time of diagnosis, sex, or ANCA specificity between the 3 groups. See table for comparisons across the groups.

Outcomes with Respect to Infection Occurrence

	0 Infections (N=66)	1 to 2 Infections (N=137)	≥3 Infections(N=22)	p values
PR3/C-ANCA positivity	26(40%)	60(44%)	10(45%)	0.87
ICU Hospitalizations	0(0%)	14(10%)	7(32%)	<0.0001
IV Antibiotics	0(0%)	53(39%)	13(60%)	<0.0001
DM at time diagnosis	4(6%)	11(8%)	1(5%)	0.92
New onset DM	21(32%)	50(37%)	11(50%)	0.29
Prophylactic Antibiotic Therapy	28(42%)	56(41%)	12(55%)	0.5
Leukopenia	20(30%)	64(47%)	12(55%)	0.04
Death	1(2%)	14(10%)	2(9%)	0.05
Number of Relapses	0.3±0.6	0.7±1.2	1.45±1.3	0.0001

Conclusions: In AAV, leukopenia and relapses were associated with an increased number of infections. Infections were also associated with a greater mortality risk. Higher number of infections increased the likelihood of severe infections. Broncopulmonary infections were the most common found in our cohort.

SA-PO329

Audit of Infective Complications of Immunosuppressive Therapy in Vasculitis and Relationship with Lymphocyte Count Memuna Hussain, Ajay Prabhakar Dhaygude. *Renal Medicine, Royal Preston Hospital, Preston, United Kingdom.*

Background: Cyclophosphamide (CYP) has transformed ANCA associated systemic vasculitis (AASV), from a potentially fatal disease to a relapsing remitting condition. However, treatment-related toxicity remains a major concern and recently published meta-analysis of four EUVAS trials suggest that infection has overtaken active vasculitis as the leading cause of death during induction therapy, accounting for majority of deaths in the first 12 months. Cyclophosphamide, an alkylating agent, interferes with DNA transcription and replication and predominantly causes lymphopenia. In this retrospective study we analyzed the relationship between lymphocyte counts and major infections in AASV patients.

Methods: Data regarding demographics, renal function, details of CYP treatment, serial total and differential nadir white cell count and infective complications was collected for 71 consecutive patients with AASV treated between 2006 and 2010. Major infections were defined as those requiring hospitalization and/ or intravenous antibiotics.

Results: Median age was 62 years. Twenty-two episodes of major infections occurred in 21 patients. There was a significant difference in the mean lymphocyte count between patients who had major infections and patients who did not have major infections. Average lymphocyte count for patients with major infection group was 0.76 and for patients with no infection group it was 1.21. (p=0.0005 assuming unequal variances).

Conclusions: Patients with lower lymphocyte counts during cyclophosphamide treatment were more likely to have major infections. Current protocol suggests adjustment of cyclophosphamide dose with respect to the age, renal function and total white cell count. Adjusting the dose with respect to the nadir lymphocyte count may reduce the infective complications in this patients.

SA-PO330

Increased Prevalence of Antineutrophil Cytoplasmic Antibodies Associated Renal Vasculitis (AAV) in Immigrant Central & South American Patients (CSA) Sudhanshu Jain, George N. Coritsidis, Salwa Rhazouani. *Elmhurst Hospital Center, New York, NY.*

Background: AAV is uncommon with most epidemiologic studies arising from Europe, United States and Australia. Data from South America is limited. The US 5-year period prevalence rate (PPR) is 26/million and 30/million in New York City (NYC). Elmhurst and Queens Hospital Centers serve the most ethnically diverse county in the US, with a large CSA population. Noting an increased incidence of AAV in CSA, we were interested in assessing their course and prevalence.

Methods: Review of all renal biopsies (2001 – 2011) was undertaken assessing: age, gender, proteinuria (gms/d), MDRD glomerular filtration rate (eGFR, ml/min/1.73m^2), renal outcomes and histology [granulomatosis polyangiitis (GPA) vs microscopic polyangiitis (MPA)] at presentation. Data presented as average ± standard error of mean. PPR for 2006-11 was calculated using our demographic data from Queens's community district 4 of the NYC department of city planning.

Results: Of 165 biopsies reviewed: AAV represented 8% (n= 13); 16% of all CSA biopsies (n=71) and 2% of all non-CSA biopsies (n=94). In CSA, AAV was the second most common glomerulonephritis after SLE (29.7% vs. 45%). Among 11 CSA with AAV, 55% (n=6) had MPA and 45% (n=5) GPA. CSA age was 54.4 ± 5.5 years with females (n=6) presenting older (60.8± 8.2 vs 47± 6.3). Proteinuria and eGFR were 4.4 ± 1.1 and 11.4 ± 2.1, respectively. Pulmonary symptoms were present in 77% (n=7). In addition to standard treatment with cyclophosphamide and prednisone, two patients received plasmapharesis. 45% (n=5) presented with eGFR<8 and were the only dialysis dependent (DD) patients. MPA were older (60.5 ± 8.2 vs. 47.4± 6.5 yrs), female (83% vs 20%) and had better renal outcomes (DD 33% vs 60%) when compared to GPA patients. Local Queens PPR of AAV was 42/million and for CSA 80/million.

Conclusions: PPR of AAV in CSA was almost 4 times greater than that of the US and almost 2 times greater than non-CSA Queens' patients. Unlike other populations, CSA had worse renal function and were more likely to become DD. This may be related to aggressive disease or delayed access to medical care. CSA with MPA were older, female and had better outcomes than GPA.

SA-PO331

The Deleterious Impact of Anti-Neutrophil Cytoplasmic Antibody on the Outcome of Lupus Nephritis: A Case-Control Study Vivian Lumi Onusic, Maria Julia C.L.N. Araujo, Ligia Costa Battaini, Lectícia Jorge, Cristiane Bitencourt Dias, Rui Toledo Barros, Viktoria Woronik. *Nephrology, School of Medicine University of Sao Paulo, Sao Paulo, Brazil.*

Background: Few studies have analyzed the impact of anti-neutrophil cytoplasmic antibody (ANCA)on the outcome of lupus nephritis (LN). The aim of this study was to evaluate the influence of ANCA Seropositivity in the renal outcome of LN.

Methods: A retrospective analysis was carried out on all SLE patients (345) submitted to a kidney biopsy between 1999-12. Patients that fulfilled ACR lupus criteria and tested for ANCA were enrolled. Positive ANCA patients (POS) were randomly matched to ANCA seronegative patients (NEG) according to the type of LN and baseline clearance(MDRD simplified formula). Clinical and laboratory data were collected at baseline, after one year and at the end of follow up. Treatment was decided by the clinical staff based on conventional literature protocols.

Results: We included 128 patients (32 POS/96 NEG). Perinuclear ANCA was detected in 87,5% (n=28) of POS patients. At baseline, POS and NEG groups were similar regarding age, complement level, ANA, anti-DNA antibody, eGFR (46±36vs44±29ml/min/1.73), proteinuria (3.4±2.6 vs 4.6±4.4 g/day), WHO LN classes, histological activity index, chronicity index, vascular lesions and follow up time. Interestingly, after one year of follow up, Pos group was significantly associated with a lower serum C3 (86,7±22vs106,5±32mg/dl p=0,01) and positive Anti-dsDNA (66%vs31% p<0,01). At the end of follow up, the POS group showed a tendency to have a lower eGFR (56±37vs71±36ml/min/1.73 p=0.09) as well as more patients with eGFR<60ml/min(56,3%vs33,3% p=0,03). Finally, logistic regression analysis showed that ANCA is an independent predictor of eGFR<60ml/min during follow up, even after adjustments for inicial eGFR and chronicity index (table 1).

Logistic Regression Analysis

	OR	95%IC	p
ANCA	3,62	1,3-9,96	0,013
Inicial eGFR	0,98	0,97-1,0	0,064
CI	1,4	1,1-1,7	0,002

Conclusions: In our study, positive ANCA was significantly associated with a worse renal outcome of LN when compared to matched negative ANCA patients.

SA-PO332

Rituximab in Lupus Nephritis: Analysis of Clinical Variables Associated with Renal Response in African-Americans in the LUNAR Trial Kajal Rao,[1,2] Maria Dallera,[3] David Wofsy,[3] Brad H. Rovin,[4] Romeo Maciuca,[1] Paul Brunetta.[1] *[1]Genentech, South San Francisco, CA; [2]Nephrology, UCSF, San Francisco, CA; [3]Rheumatology, UCSF, San Francisco, CA; [4]Nephrology, Ohio State University, Columbus, OH.*

Background: LUNAR was a randomized trial evaluating the efficacy of add-on therapy with rituximab (RTX) to MMF and prednisone in patients (pts) with active class III-IV (+/- V) lupus nephritis. The overall renal response (ORR) endpoint was not met (56.9% and 45.8%, p=0.18). But, in a pre-specified analysis of African-Americans (AA), week 52 ORR was higher with RTX (70%) vs. placebo (Pbo, 45%) (p=0.20). This difference was driven by a higher partial response rate (35% versus 5%). Our aim was to characterize the clinical parameters that might have accounted for this difference.

Methods: We undertook an exploratory post-hoc analysis of the 40 AA pts from LUNAR, comparing RTX versus Pbo, and comparing those with ORR to non-response (NR).

Results: Baseline characteristics were similar between the Pbo and RTX arms (data not shown). Patients with NR (vs. ORR) had higher serum Cr, proteinuria, and BP.

Table 1: Baseline Characteristics of African-Americans

Baseline Values	Non-response (n=17) (placebo n=11; rituximab n=6)	Overall Renal Response (n=23) (placebo n=9; rituximab n=14)
Serum Cr[a]	1.27 (.96-1.58)	0.95 (.81-1.10)
Proteinuria (UPCR)[a]	4.4 (2.87-5.94)	3.0 (2.26-3.81)
SBP (mmHg)[a]	142 (130-153)	124 (115-132)
DBP (mmHg)[a]	88 (80-96)	77 (72-83)
HTN [b]	65% (11/17)	17% (4/23)

[a]Values reported as means with Confidence intervals. [b]HTN defined as either SBP >= 140 or DBP >= 90

None of the 8 pts with partial renal response had hypertension (HTN), and 7 of these 8 pts were in the RTX arm. Over 70% of pts without HTN (79% RTX, 73% Pbo) achieved a renal response versus only 27% of those with HTN (3/6 RTX, 1/9 Pbo).

Conclusions: AA pts with HTN, high proteinuria or high serum Cr had markedly lower renal response rates in LUNAR regardless of treatment arm. This however was not seen consistently in the non-AA subgroup in LUNAR (data not shown). Thus, the interpretation of the results, and its implications regarding treatment with RTX are uncertain, particularly in the context of the small size of the AA subgroup.

Abstract Withdrawn

SA-PO334

Mycophenolate Sodium (MPS) versus Cyclophosphamide (CY) in Lupus Nephritis (LN): Histopathology after Induction Ana Valeria Malvar Perrin,[1] Bernarda Fazzini,[1] Bruno Jorge Lococo,[1] Paola Pirruccio,[1] Cecilia Aleman Cuestas,[1] Ricardo M. Heguilen,[1] Valeria Gabriela Alberton,[2] Brad H. Rovin.[3] *[1]Nephrology, Hospital Fernandez, B. Aires, Argentina; [2]Pathology, Hospital Fernandez, B. Aires, Argentina; [3]Nephrology, Ohio State University, Columbus, OH.*

Background: Mycophenolic acid has been shown to be an alternative for the treatment of LN.The purpose of this study was to compare the histopathological response to treatment with ivCY or MPS evaluated through the changes in the activity(AI) and chronicity(CI) indices in paired renal biopsies.

Methods: All biopsies performed in patients with LN between January 2008 and December 2011were reviewed.The samples were categorized according to the ISN/RPS classification and the AI and CI were calculated by a pathologist blinded to induction therapy.Thirty nine Latin patients with class IV LN were included. Mean age was 30±6 and GFR was ≥75 ml/min.Induction therapy was ivCY(1 gm/mo X 6) or MPS(1440 mg/dX 6 mos).Mixed class V and crescentic LN were excluded.Complete remission (CR) was considered a decrease in proteinuria to ≤ 0.5 gm/day and GFR ≥75 ml/min. Data are expressed as mean±SD or median (range).

Results:

Results are presented in the table.

	sex M/F	Proteinuria 1st Bx gm/day	Proteinuria 2nd Bx gm/day	AI 1st Bx median	AI 2nd Bx median	CI 1st Bx median	CI 2nd Bx median
ivCY(n=23)	1/22	3,5 ± 2	1 ± 1,1	10(3-16)	4(0-9)	3(1-6)	4(2-6)
MPS(n=16)	2/14	3,1 ± 1,5	0,8 ± 0,7	9(6-16)	4(1-9)	3(0-5)	4(3-6)

After 6 months the fall in AI and the changes in the CI were not different between both therapies. Eleven patients who received ivCY and 7 who received MPS achieved CR. The AI in the remitters was similar to that of the non-remitters (R: ivCY: 4(0-8) MPS: 4(2-6); NR: ivCY: 4(0-8) MPS: 4(2-9)). Also, there was no difference in the CI of remitters and non-remitters.

Conclusions: MPS and ivCY induction therapy achieved the same level of AI reduction after 6 months, and the same number of patients attained CR. Despite achieving CR based on proteinuria and GFR, remitters still had considerable histologic activity in their biopsies, suggesting that clinical markers alone are insufficient to follow response to therapy in LN.

SA-PO335

Mycophenolate Mofetil (MMF) versus Cyclophosphamide (CY) as Induction Therapy in Severe Lupus Nephritis (LN) Brad H. Rovin,[1] Samir Parikh,[1] Lee A. Hebert,[1] Daniel Tak Mao Chan,[2] Chi Chiu C. Mok,[3] Ellen M. Ginzler,[4] Lai Seong Hooi,[5] Paul Brunetta,[6] Romeo Maciuca,[6] Neil Solomons.[7] *[1]Internal Medicine, The Ohio State Medical Center, Columbus, OH; [2]University of Hong Kong, Hong Kong; [3]Tuen Mun Hospital, Hong Kong; [4]State University of New York Downstate Medical Center, Brooklyn, NY; [5]Sultanah Aminah Hospital, Johor Bahru, Malaysia; [6]Genetech, Inc, San Francisco, CA; [7]Aspreva International, LTD, Victoria, BC, Canada.*

Background: Clinical trials have shown that MMF compares favorably to CY for remission induction of mild-moderate LN, but its role in severe LN is unclear.

Methods: A systematic review of outcomes after treating severe LN with MMF or CY was done using published or personal data. Severe LN was defined as indicated in table 1. Partial and complete remissions were determined and long-term outcomes compared.

Results: The pooled results suggest MMF and CY are equally effective in inducing remission (Table1). Long-term data, available from 4 studies, showed CY was associated with fewer LN relapses and less risk for ESRD (Table2).

Conclusions: MMF and CY appear equal in inducing remission for severe LN, but over time renal function may be better preserved with CY.

Table 1

Criteria of Severe LN	Treatment	N	PR (%)	CR (%)	Response Time (Mo)

Therapeutic Effect of FK506 on Murine Lupus Nephritis and Its Mechanisms Haiyan Tu, Jianghua Chen. *Zhejiang University, The First Affiliated Hospital, College of Medcine, Zhejiang University, Hangzhou, Zhejiang, China.*

Background: To systematically evaluate the clinical effects of FK506, which are calcineurin inhibitors, on progression of renal damage and its immunopathology in MRL-lpr/lpr lupus-prone mice and to explore the related mechanisms.

Methods: We treated MRL/lpr mice with FK506 intraperitoneally at dose of 2mg/kg/day, starting at week 8 of age and continuing through week 12.We evaluated level of proteinuria, urinary creatinine, serum anti-dsDNA antibody, and kidney histopathology changes. We also determined the expression and localization of calcineurin with synaptopodin in addition of the effect of FK506 on them.

Results: After 4 weeks of FK506 therapy, significant reduction in proteinuria was achieved compared with vehicle-treated control mice (0.29 ±0.20 g/24h vs 0.91±0.24g/24h., p< 0.01). In parallel, a significant decrease in urinary creatinine is found (1.23±0.72 umol vs 3.01±0.11 umol, p< 0.01). Meanwhile, the serum anti-dsDNA antibody is lower in FK506 treatment group than the control mice (73.5±31.7 u/ml vs 119.9 ±16.4 u/ml, p <0.01) and histopathology renal lesions are also less severe. Double immunofluorescent staining shows calcineurin colabeling with synaptopodin. Calcineurin increased expression in lupus-prone mice compared to controls. In contrast, synaptopodin diminished and distributed discontinuously. However, we observed decreased expression of calcineurin, accompanied by the increased expression of synaptopodin after FK506 treatment.

Conclusions: FK506 suppressed the development of kidney disease in MRL/lpr lupus-prone mice. Mechanistically, decreased glomerular expression of calcineurine which might protect synaptopodin from degradation may partly explain the antiproteinuric effects of FK506 in our experiment. We propose that FK506 may represent a valuable treatment for patients with lupus nephritis.

SA-PO337

Outcome of Long-Term Treatment with Mycophenolate Mofetil in Patients with Severe Lupus Nephritis Desmond Y.H. Yap, Maggie Kam Man Ma, Daniel Tak Mao Chan. *Department of Medicine, Queen Mary Hospital, Hong Kong, China.*

Background: Corticosteroids with mycophenolate mofetil (MMF) has proven efficacy when used as induction or maintenance immunosuppression for proliferative lupus nephritis, but data on long-term mycophenolate mofetil treatment is lacking.

Methods: This was a single-centre retrospective study of patients with Class III/IV±V lupus nephritis who have received prednisolone and MMF continuously as treatment in the early phase and the long-term maintenance phase.

Results: 65 patientswere included. 31 patients were treated with only prednisolone and MMF throughout (Group I). 23 patients had their MMF substituted with azathioprine (AZA)(Group II) and 11 patients with calcineurin inhibitors (CNI)(Group III) at some point during the maintenance phase. The follow-up was 91.9±47.7 months. The 10-year patient and renal survival rates were 91% and 86% respectively, with no difference between the three groups. Relapse-free survival was higher in Group I than Group II and Group III (76% vs 56% vs 43% respectively at 5-year; 69% vs 32% vs 0% respectively at 10-year; I vs II, p=0.049; I vs III, p=0.019; II vs III, p=0.490). Patients who received MMF for more than 24 months showed better relapse-free survival than those treated for shorter durations (88% vs 48% respectively at 5-year; 81% vs 28% respectively at 10-year; p<0.001). Serum creatinine was lower in Group I at 10 years. Apart from more anemia with MMF treatment, the side-effects profile was similar in patients during MMF, AZA, or CNI treatment.

Conclusions: Continuous treatment with corticosteroids and MMF as both induction and long-term maintenance immunosuppression is associated with favorable long-term outcome and possibly a lower risk of disease flare compared with other maintenance immunosuppressive medications.

SA-PO338

Efficacy and Safety of Multitarget Therapy by Combination with Tacrolimus, Mycophenolate Mofetil and Steroid in Patients with Active Lupus Nephritis Hidekazu Ikeuchi, Keiju Hiromura, Satoshi Takahashi, Keiichiro Mishima, Noriyuki Sakurai, Toru Sakairi, Yoriaki Kaneko, Akito Maeshima, Yoshihisa Nojima. *Department of Medicine and Clinical Science, Gunma University Graduate School of Medicine, Maebashi, Gunma, Japan.*

Background: In a previous study, we reported that tacrolimus (TAC) was effective as induction therapy for active lupus nephritis (LN). The complete remission (CR) rate was 84.6% (11/13 patients), which was achieved at 7.7 months in average (Mod Rheumatol 2011). In this study, we retrospectively analyze the efficacy and safely of multitarget therapy using TAC, mycophenolate mofetil and prednisone as induction therapy for active LN.

Methods: All 16 consecutive patients were included, who were treated with the multitarget therapy for active LN between 2009 and 2011 in our department.

Results: The mean patient age was 33.7 years (range, 21-50). Eight patients were treated for LN flares. The mean serum creatinine level and urinary protein/creatinine ratio before treatment were 0.73 mg/dl (0.45-1.36) and 4.6 g/gCr (1.21-10.79), respectively. The renal biopsy was performed on all patients; III (n=1), III+V (n=1), IV (n=6), IV+V (n=6), V (n=2), according to the ISN/RPS2003 classification. All patients achieved CR at 4.1 months in average (Figure). There was one serious adverse event; gastric ulcer due to cytomegalovirus infection, which was successfully treated by anti-viral therapy and proton pump inhibitor. Cytomegalovirus antigenemia was observed in 5 patients without signs of serious organ damage expect for thrombocytopenia, which was also recovered by anti-viral therapy.

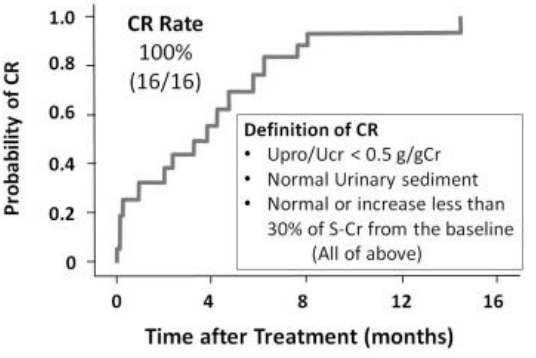

Figure. Probability of Complete Remission (CR)

Conclusions: The multitarget therapy was effective as induction therapy for active LN to achieve early remission and high remission rate. Although this therapy was generally well-tolerated, the potential risk of cytomegalovirus infection should be taken into consideration.

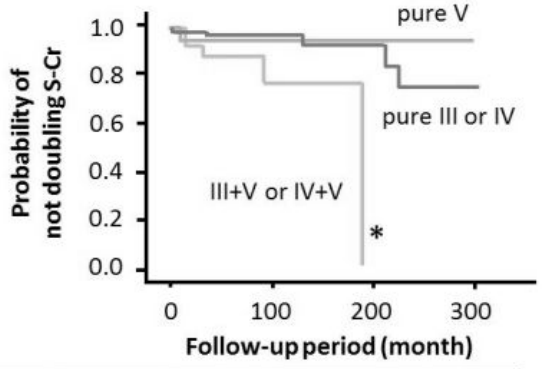
Mixed Lesion of Membranous (Class V) and Proliferative (Class III/IV) Lupus Nephritis Predicts Poor Renal Prognosis Hidekazu Ikeuchi, Keiju Hiromura, Satoshi Takahashi, Keiichiro Mishima, Noriyuki Sakurai, Toru Sakairi, Yoriaki Kaneko, Akito Maeshima, Yoshihisa Nojima. *Department of Medicine and Clinical Science, Gunma University Graduate School of Medicine, Maebashi, Gunma, Japan.*

Background: We have previously reported that glomerular chronic lesions are associated with poor renal outcome among patients with diffuse global lupus nephritis (LN) (Rheumatology 2008). In this study we sought to examine the effect of membranous lesions on renal prognosis in LN.

Methods: We retrospectively analyzed 119 LN patients, 18 male and 101 female, who had class III (focal LN), IV (diffuse LN), V (membranous LN) by ISN/RPS2003 classification in our hospital between 1986 and 2011. Renal endpoint was defined as the doubling serum creatinine (S-Cr) or end-stage renal disease.

Results: The mean patient age at renal biopsy was 36.8 years (range, 12-68) and the mean observation period was 104.9 months (0.8-301). The mean S-Cr level and urinary protein/creatinine ratio were 0.84 mg/dl (0.30-2.94) and 4.1 g/gCr (0.6-21.3), respectively. The relative frequency of each class was as follows; III 18%, IV 66%, and V 16%. The combination of class V was observed in 15% of class III and 37% of class IV. Kaplan-Meier analysis showed that patients with mixed lesions (III+V or IV+V) had poor renal outcome compared to patients with proliferative lesions alone (pure III or IV) (P=0.030, Figure). Multivariable analysis indicated that S-Cr at the time of biopsy and the combination of membranous and proliferative lesions are the independent risk factor for poor renal prognosis, with hazard ratios of 8.08 (95% CI 2.04-32.07, P<0.003) and 19.33 (95%CI 2.79-133.86, P<0.003), respectively.



pure V	20	12	8	5	3	2	0
pure III or IV	80	58	40	22	12	5	1
III+V or IV+V	19	10	4	3	0	0	0

Figure. Kaplan-Meier curves for renal survival

* P=0.030, vs pure III or IV

Conclusions: This study demonstrated that mixed lesion of membranous and proliferative LN by ISN/RPS2003 classification is associated with poor renal prognosis.

Reproductive Factors and Response to Induction Therapy in Systemic Lupus Erythematosus with Nephritis

Elizabeth W. Dehmer, Keisha L. Gibson, Susan L. Hogan, Mary Anne Dooley. *University of North Carolina, Chapel Hill, NC.*

Background: Systemic lupus erythematosus (SLE) predominantly affects women during their reproductive years, and estrogen may play a pathogenic role. We evaluated the association between baseline reproductive factors, a proxy for estrogen exposure, and response to induction therapy in female SLE nephritis.

Methods: Women enrolled in a clinical trial of mycophenolate mofetil vs. cyclophosphamide completed a menstrual history questionnaire. Response to therapy, defined as complete (return to ≤10% of normal values of serum creatinine, proteinuria, and urine sediment) or partial (improvement of 50% in all abnormal renal measurements) remission at 24 weeks, was examined via logistic regression adjusted for age, race, body mass index (BMI) and treatment, with odds ratios (OR) and 95% confidence intervals (CI) reported.

Results: N=120 females (57% African American, 20% Hispanic, 23% Caucasian or other race) participated and had a mean age and BMI of 31.9 ± 5.0 years (range 15-58) and 27.7 ± 6.6 kg/m^2 (range 15-59) respectively. Mean baseline serum creatinine was 1.07 ± 0.52 mg/dl, proteinuria was 4.43 ± 3.15 grams/day. No measures were statistically associated with response to therapy (see table). The magnitude of effect suggests breastfeeding may influence response to therapy (OR=2.35, 95% CI=0.86, 6.41). This association persisted after adjustment for age, race, BMI and treatment (OR=2.51, 95% CI=0.72, 8.77).

Odds of treatment response based on reproductive factors

Predictor Variable	N (%)	Adjusted OR (95% CI)
Pregnancies		
0	24 (24)	1.
1-2	40 (39)	1.16 (0.33, 4.05)
>2	38 (37)	1.75 (0.44, 6.95)
Pregnancy Losses		
0	57 (59)	1.
1-2	34 (35)	0.65 (0.23, 1.82)
>2	5 (5)	2.06 (0.24, 18.09)
Breastfeeding		
No	35 (51)	1.
Yes	33 (49)	2.51 (0.72, 8.77)
Oral Contraceptive Use		
No	93 (80)	1.
Yes	24 (20)	1.05 (0.37, 2.97)
Menopause		
No	103 (87)	1.
Yes	16 (13)	0.93 (0.21, 4.17)

Conclusions: A prior history of breastfeeding may be associated with response to induction therapy in SLE nephritis. More detailed evaluation and analysis of reproductive history, especially breastfeeding, is warranted in future trials.

SA-PO341

Urine Vitamin-D Binding Protein Levels Distinguish Class III/IV Proliferative, from Class V Membranous Lupus Nephritis

Michael R. Bennett, Rina Mina, Shannen Nelson, Jessica Hummel, Prasad Devarajan, Hermine Brunner. *Cincinnati Children's Hospital.*

Background: Nearly 80% of childhood-onset SLE patients have lupus nephritis (LN). The ISN/RPS Morphologic Classification of LN reports on histological features that differentiate between various forms of LN, most notably between Diffuse Proliferative Class III/IV and pure Membranous Class V lesions. There is a lack of non-invasive biomarkers that can discriminate LN subtypes so that appropriate therapies can be planned. Using liquid chromatography tandem mass spectrometry proteomics, we identified Vitamin-D Binding Protein (VDBP) to discriminate between Class III/IV and Class V LN. We set out to validate this finding in an independent cohort on a clinically applicable platform.

Methods: Urine was collected from 53 patients with LN. Renal biopsies had classified these patients as having either Class III (10), Class IV (17), or Class V (26) LN. VDBP was measured using a commercially available ELISA. Urine creatinine (UCr) was measured by modified Jaffe reaction on an automated clinical analyzer. Results were reported as medians and analyzed both raw and normalized to UCr using a non-parametric Mann-Whitney rank sum analysis.

Results: Median urinary VDBP levels were significantly higher (p=0.046) in Class III/IV LN (90.9 ng/ml, IQR 28.9 - 948.4) than Class V LN (33.5 ng/ml, IQR 21.3 - 124.1). The results remained significant (p=0.045) when corrected for UCr - Class III/IV LN (22.2 ng/mg, IQR 29.0 - 1822.9), Class V (44.1 ng/mg, IQR 14.8 - 139.5).

Conclusions: We validated our proteomic finding that urinary VDBP can distinguish Class III/IV proliferative, from Class V membranous LN. Class III/IV and Class V LN require different therapeutic approaches, and therapies must be initiated early to be most effective. A kidney biopsy is currently considered the "gold standard" for the diagnosis of SLE nephritis. However, biopsies cannot be done serially within a short period of time to screen for pathological changes in LN in a given patient. The discovery of a non-invasive biomarker that could possibly be used to screen for such changes could have a tremendous impact on treatment strategies for patients with LN.

SA-PO342

Outcome of Treatment of Lupus Nephritis in Older People

Susan Tadros,[1] Marie Condon,[1] Megan Griffith,[1] Jeremy B. Levy,[1] Tom Cairns,[1] Liz Lightstone.[1,2] *[1]Imperial College Renal and Transplant Centre; [2]Imperial College London.*

Background: The outcomes of treatment of lupus nephritis (LN) in older patients are not well documented. We compared outcomes of patients aged >60 with LN treated with Rituximab induction & MMF maintenance therapy with a control group <60yrs.

Methods: Patients aged >60, with active Class III or IV &/or V LN**,** were treated with 2 doses of Rituximab 1g plus methylprednisolone 500mg iv and MMF maintenance therapy +/- low dose oral steroids. Complete (CR) or Partial (PR) renal response, where CR = urine protein:creatinine ratio (PCR) <50mg/mmolno & no >15% rise in creatinine, and PR = ≥50% improvement in proteinuria and non-nephrotic & no >15% rise in creatinine, were compared at 6 months & 1 year with control patients <60 years matched for gender, ethnicity & class of LN.

Results: 12 patients >60 were treated (9 Class V, 3 III/IV) vs. control group: Mean age 67 (range 60-74) vs 39 (31-52); mean creatinine at biopsy 139µmol/l (73-383) vs 103µmol/l (56-250) and mean PCR 605mg/mmol (112-1944) vs 551mg/mmol (98-1555). By 6 months: CR achieved in 3/12(25%) & PR in 4/12(33%) of patients >60 vs. CR 5/12 (42%) & PR 4/12(33%) in controls. By 1yr CR in 6/12(50%) & PR in 6/12(50%) of those >60 vs. 8/12(67%) & 2/12(17%) in controls (all: p=ns). In those >60yrs, proteinuria fell from a mean PCR of 605 to 121mg/mmol at 1 year, similar to controls (from 551 to 59 mg/mmol at 1 year). Median time to CR was similar in both groups (267 vs 279 days, p=0.4). There were 2 deaths in the >60 group. One patient initially achieved PR. 3 years later she developed CMV colitis with associated renal relapse, progressed to dialysis & died 18/12 later age 78. The other patient was initially a non-responder but achieved PR with Rituximab re-dosing. He died suddenly at home 10 months later age 71.

Conclusions: These data suggest that older patients with LN treated with Rituximab + MMF achieve remission rates comparable with younger patients. The elderly do well but may have lower rates of CR, possibly reflecting more chronic damage. Treatment related adverse events were infrequent but further studies in this subgroup of patients are warranted to optimise greatest efficacy with least toxicity.

SA-PO343

Cytomegalovirus Infection in Patients with Lupus Nephritis Lei Zhang,[1] Jianling Tao,[1] Yubing Wen,[1] Li Li,[2] Xueyi Wu,[1] Xuemei Li,[1] Xuewang Li.[1] *[1]Nephrology, Peking Union Medical College Hospital, Beijing, China; [2]Nephrology, Traditional Chinese Medicine of Fangshan Hospital, Beijing, China.*

Background: Cytomegalovirus infection in patients with lupus nephritis has been paid more attention to in recent years. However, very few reports are available on cytomegalovirus infection in lupus nephritis, and the clinical features and therapeutic strategy for this group of patients are still elusive.

Methods: Cases occurring within the last 10 years were collected, and detailed clinical and laboratory data were analyzed.

Results: A total of 40 cases were included in this study, and positive antigenemia (pp65) was detected in all the patients. The main cytomegalovirus symptoms of these patients were fever, raised transaminases, hematological disorders and pulmonary disease. Infectious complications other than cytomegalovirus were observed in 15 cases. High SLEDAI score (16±5), low C3 (0.46±0.26g/L), low C4 (0.10±0.10g/L), a moderate amount of proteinuria and hematuria, normal creatinine clearance (77.82±25.19ml/min), hypertriglyceridemia (3.16±2.57mmol/L), and strong immunosuppressive therapy history were observed as the main characteristics for these 40 lupus nephritis patients. Besides, renal histological classes of the 40 cases were identified, of which classIV was the most common type (37.5%). Ganciclovir was administered to 33 patients, and the need for early anti-viral treatment was observed among the symptomatic ones. Additionally, the doses of steroids and immunosuppressants were not reduced after the diagnosis of cytomegalovirus infection in this study. All the 40 patients survived, and the symptoms of cytomegalovirus infection alleviated satisfactorily.

Conclusions: Our results suggest that the symptoms of cytomegalovirus infection are characteristic in lupus nephritis. There are certain clinical features of patients with lupus nephritis which may indicate the infection of cytomegalovirus: active systemic lupus erythematosus, hypertriglyceridemia, classIV lupus nephritis, and strong immunosuppressive therapy history. The symptomatic patients need early anti-viral treatment.

SA-PO344

Systemic Flares of Lupus Are Common in Patients with End Stage Renal Disease Secondary to Lupus Nephritis Whether on Dialysis or Transplanted Daniel M. McGuinness,[1] Christopher Wincup,[1] Adam Mclean,[1] Liz Lightstone.[1,2] *[1]Imperial College Healthcare NHS Trust Renal and Transplant Centre, Hammersmith Hospital, London, United Kingdom; [2]Renal Section, Department of Medicine, Imperial College London, London, United Kingdom.*

Background: A proportion of patients with lupus nephritis (LN) progress to End Stage Renal Disease (ESRD). Systemic lupus flares are said to be rare once patients are on dialysis (Dx) or transplanted (Txp). Experience tells us otherwise. We retrospectively reviewed the presence of flares in a patient cohort with ESRD due to LN.

Methods: Retrospective notes review of the 53/72 ESRD patients alive in Jan '11 with ESRD due to LN for whom notes were available. Patients were either on Dx or Txp & their notes interrogated from first presentation up to Jan '12.

Results: 45F & 8M patients; median age at ESRD 37yrs (range 14-79). Median time from lupus diagnosis to ESRF-36 mths (0-316). Median f/up post ESRD 7.6yrs (1.8-30.5). At Jan '12 census point, 34 had functioning Txp, 15 on Dx (of whom 8 had failed Txp) & 4 had died (3 HDx, 1 Txp). Systemic lupus flares were common: overall, 1 or >1 flares in 23/53 (43.4%) & more common in Dx patients (11/18, 61%) vs. Txp patients (12/35, 34.2%). Most patients had multiple symptoms: arthralgias (in 7 Dx & 8 Txp), skin (5 & 5), haematological (5 & 2), cerebral (1 & 1) & other (3 & 9). Markers of lupus activity: low complement in 23/53, raised dsDNA abs in 22, thrombocytopenia in 34 & lymphopaenia in 39. Of those with low complement **plus** high dsDNA abs (16), only 5 had no flares. Immunosuppression (IS) was very different in the 2 groups: 13/18 Dx patients were on oral steroids & rarely on other agents. We use a steroid sparing Txp protocol & of those with Txp who flared, 5 were on tacrolimus alone (+/- low dose maintenance steroid) & 4 also on MMF. Two grafts were lost to recurrent LN.

Conclusions: ESRD does not protect from systemic lupus flares which can be severe. Flares are more common in Dx than in Txp patients, probably reflecting IS differences. Lupus markers may predict flares. Future work will include morbidity related to lupus flares in RRT patients & explore the apparently high mortality.

SA-PO345

Disease Activity, Health-Related Quality of Life, and Transition/Self-Management in Adolescents with Systemic Lupus Erythematosus May Doan,[1] Maria E. Ferris,[1] Keisha L. Gibson,[1] Nicole M. Fenton.[2] *[1]Nephrology, University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]Psychology, University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: SLE has a >95% five-year survival rate among adolescents. Several factors such as disease activity, health-related quality of life (HRQOL), and mood may interact and contribute to successful transition into adult-focused care. We examined the relationships among disease activity, HRQOL, mood, and transition/self-management in adolescents with SLE.

Methods: Youth ages 12-25 years with SLE completed the UNC TR$_x$ANSITION Scale™ (health-provider administered, 32 questions) to assess transition/self-management skills, and the PedsQL to assess HRQOL. Disease activity was measured using the SELENA SLEDAI Scale. Relationships were determined using Pearson's correlation, and comparative analyses were performed between lupus patients with and without nephritis. Significance levels were set at $p<.10$.

Results: Of 25 patients, 64% were female, 52% were African American, and the mean age at assessment was 16.8±3.1 years old. Mean age at diagnosis was 13.2±3.7 years. Disease activity did not significantly correlate with total UNC TR$_x$ANSITION Scale™ scores, but did correlate with domains of Nutrition knowledge (r=.43, p=0.03) and Ongoing support (r=.36, p=0.08). Disease activity was not associated with physical, emotional, social, or cognitive QOL, and was not associated with mood. Patients with SLE nephritis (N=20) had more knowledge about reproductive issues (mean 0.63 vs. 0.25, p=.056) and better mood (mean 4.1 vs. 2.6, p=.09) than those without SLE nephritis.

Conclusions: In this ongoing study, there seems to be a trend that patients with greater disease activity have more skills managing their own disease, particularly regarding nutrition and future disease self-management. Further, patients with SLE nephritis have more knowledge about reproductive issues and report better moods than lupus patients without nephritis.

SA-PO346

Intrarenal Expression of Toll-Like Receptors in Lupus Nephritis Ying Xiang,[1] Shang Guo Piao,[1,4] Hong Bin Zou,[2] Bi Hu Gao,[3] Chul Woo Yang,[4] Can Li.[1] *[1]Nephrology, YanBian University Hospital, YanJi, JiLin, China; [2]Nephrology, The First Affiliated Hospital of JiLin University, ChangChun, JiLin, China; [3]Nephrology, The Affiliated Zhong-Shan Hospital of DaLian University, DaLian, LiaoNing, China; [4]Nephrology, The Catholic University of Korea, Seoul, Korea.*

Background: Recent studies demonstrated that the expression of toll-like receptors (TLRs) is upregulated in lupus mice models. However, the expression of TLRs and the role of innate immunity in human lupus nephritis has yet to be illustrated. The aim of this study was to investigate the expression of TLRs and its ligands in human biopsy specimens with lupus nephritis (LN).

Methods: We studied 14lupus nephritis patients with renal biopsy, and 14 patients with nephrectomy for renal cancer served as controls. Clinical characteristics were recorded, and intrarenal expression of TLRs (TLR2 and TLR4) and MYD88 was examined by immunohistochemistry.

Results: The intrarenal expression of TLR2 was significantly increased in the glomerulus of the LN group compared with the controls (55.07 ± 0.29%/mm^2 vs. 30.92 ± 5.34%/mm^2, $P<0.01$), whereas TLR4 expression was decreased (49.13 ± 5.75%/mm^2 vs. 128.99 ± 6.62%/mm^2, $P<0.01$).This trend of TLRs expression was accompanied by suppressing MYD88 expression (59.39 ± 7.60%/mm^2 vs. 104.83 ± 12.64%/mm^2, $P<0.01$). Correlation analysis revealed that TLRs expression was correlated with the 24h urinary protein excretion and the eGFR.

Conclusions: These findings suggest that adifferent expression in TLR2 and TLR4 is closely associated with lupusnephritis, and that innate immunity may be one of important molecular mechanisms in lupusnephritis.

MYH9 and APOL Gene Polymorphisms: CKD Progression in Lupus Nephritis in a Highly Admixtured Population Vinícius Sardao Colares,[1] Silvia M. Titan,[1] Patrícia Malafronte,[1] Rui Toledo Barros,[1] Alexandre Costa Pereira,[2] Viktoria Woronik.[1] *[1]Nephrology, Sao Paulo University, Sao Paulo, Brazil; [2]Laboratorio de Cardiologia Molecular, Instituto do Coração, Hospital das Clinicas, Sao Paulo University, Sao Paulo, Brazil.*

Background: Polymorphisms of MYH9 have been recently associated with CKD progression in non-diabetic chronic kidney disease, FSGS and HIV nephropathy patients. However, the association of MYH9 E-1 haplotype with CKD seems to be confounded by the strong linkage disequilibrium with apolipoprotein(APOL) genes, as shown in certain populations. In our study, we have analysed the effect of MYH9 and APOL 1 and 3 gene polymorphisms on CKD risk in Brazilian lupus nephritis patients.

Methods: Retrospective analysis of 196 patients with LN followed in our outpatient glomerular disease service from January 1999 to December 2010. Clinical and laboratorial data were retrieved and genotypying of MYH9 (rs4821480, rs2032487, rs4821481 and rs3752462- E1 haplotype) and APOL1 (rs73885319 and rs71785313) polymorphisms were performed. Primary outcome (PO) was defined as doubling of serum creatinine and/or end stage renal disease (ESRD).

Results: The mean follow-up time was 6.1 years, with an initial mean creatinine of 1.6 g/dL and mean proteinuria 3.9 g/day. Of the initial 196 patients, 62 (31.6%) presented the PO. The four MYH9 polymorphisms segregate as an haplotype, according to the Hardy-Weinberg model. Analysing each polymorphism, only TT/CT genotype from rs3752462 polymorphism was associated with the PO (p= 0.01). MYH9 E1 haplotype was associated with PO (OR 1.85, 95%CI 1,09 - 3,24, p=0,02; haplotype presence in 29,7% of cases and 18,5% of controls), whereas APOL 1 and 3 gene polymorphisms were not.

Conclusions: MYH9 E1 haplotype, and not APOL1 polymorphisms, is associated with a worse renal prognosis in lupus nephritis patients. Future studies should focus on the possible mechanisms underlying this association.

SA-PO348

"Class II" Lupus Nephritis with Nephrotic Syndrome: A Podocyte Disease

Wei-Xin Hu, Jin Liu, Hui-ping Chen, Zheng-zhao Liu, Hai-tao Zhang, Zhi-Hong Liu. *Research Institute of Nephrology, Jinling Hospital, Nanjing University School of Medicine, Nanjing, Jiangsu, China.*

Background: Lupus podocytopathy, a newly recognized but not well defined renal lesion of lupus nephritis(LN), is still in the classII of LN. In this study, we analyzed the clinical and histological features of class II LN with nephrotic syndrome(NS) and further explored the association of podocyte lesion with nephrotic syndrome in LN class II.

Methods: 120 patients with class II LN were included and were divided into the NS group and non-NS group based on the amount of urinary protein excretion. The degree of mesangial proliferation was graded as mild(M1),moderate(M2) and severe(M3). Diffuse foot process effacement was defined as more than 50% of the glomerular capillary loops showing glomerular foot process effacement by EM. Clinical, immunological and pathological features were compared between the two groups.

Results: 26 patients(21.7%) were in the NS group, 94 patients in the non-NS group. No significant differences in gender, age, LN duration, the levels of serum autoantibodies and complements were found between the two groups. Compared to non-NS group, the patients in NS group had a much higher incidence of renal manifestations as the first onset symptom(50% vs 19%, P<0.05) and AKI (22% vs 0, P<0.01), but much lower incidence of malar rash(48% vs 67%,P<0.05), fever(22% vs 61%, P<0.05), arthritis(39% vs 72%, P<0.05) and hematuria(0 vs 45%,p<0.01). In renal histology, the NS group had less severe mesangial proliferation(M2+M3: 9% vs 100%, P<0.01), but significantly higher incidence of diffuse foot process effacement(82% vs 3%, P<0.01) than that in non-NS group. Three patients in NS group had no glomerular immune deposition by IF. 19 patients (86.4%) in the NS group achieved complete remission and 3 patients partial remission after the steroid treatment for 1-9 months(median 2 months), but 9 of them(41%) relapsed during the 6-124 months (median 56 months) follow-up.

Conclusions: This study indicates that the nephrotic "class II" LN is a podocyte disease which should be differentiated from the class II LN with mesangial proliferation and be described as minimal change disease(MCD)-like LN.

SA-PO349

Long-Term Outcome of Patients with IgG4-Related Kidney Disease

Takako Saeki,[1] Mitsuhiro Kawano,[2] Ichiro Mizushima,[2] Motohisa Yamamoto,[3] Yoko Wada,[4] Tomoyuki Ito,[1] Hajime Yamazaki,[1] Hitoshi Nakashima,[5] Takao Saito,[5] Ichiei Narita.[4] *[1]Department of Internal Medicine, Nagaoka Red Cross Hospital, Nagaoka, Niigata, Japan; [2]Division of Rheumatology, Kanazawa University Hospital, Kanazawa, Ishikawa, Japan; [3]First Department of Internal Medicine, Sapporo Medical University, Sapporo, Hokkaido, Japan; [4]Division of Clinical Nephrology and Rheumatology, Niigata University, Niigata, Japan; [5]Division of Nephrology and Rheumatology, Fukuoka University, Fukuoka, Japan.*

Background: In the kidney lesion associated with IgG4-related disease [IgG4-related kidney disease (IgG4-RKD)], steroid therapy has been shown to elicit rapid amelioration. However, few data on long-term outcome are available.

Methods: We retrospectively analyzed the long-term clinical course in 43 patients diagnosed as having definite IgG4-RKD (median follow-up 32 months).

Results: Forty of the 43 patients were treated with steroids, and 95% of them were still being maintained on steroid at the last review. Before treatment, the estimated glomerular filtration rate (eGFR) had decreased to less than 60 ml/min (31.6 ± 16.0 ml/min) in 24 of these 40 patients. At 1 month after treatment, it was significantly improved (43.5 ±14.0 ml/min, P<0.01), and renal function was maintained at a similar level at both 12 months and the last review, although maintenance hemodialysis became necessary in one patient. Among the patients whose eGFR exceeded 60 ml/min, there was no difference between the eGFR before therapy and that at the last review. Renal radiologic abnormalities characteristic of IgG4-RKD were present in 28 of the 40 patients, and improvement was evident at 1 month after treatment in all of them. Although renal atrophy was not evident in any of 40 patients before treatment, it had developed in 11 of 25 (44%) evaluated patients (2/9 in the eGFR ≥60 group and 9/16 in the eGFR <60 group) at the last review. Relapses of IgG4-RKD and extra-renal organ involvement were evident in 3 and 5 patients, respectively.

Conclusions: IgG4-RKD shows rapid improvement with steroid therapy and the recovered renal function persists for a long time with maintenance steroid therapy, although renal atrophy progresses in many patients.

SA-PO350

Immunosuppressive Therapy in Fibrillary Glomerulonephritis

Vincent Javaugue,[1] Frank Bridoux,[1-5] Alexandre Karras,[3] Francois Glowacki,[4] Jean-Michel Goujon,[2] M. Guy Touchard.[1] *[1]Nephrology, CHU, Poitiers, France; [2]Pathology, CHU, Poitiers, France; [3]Nephrology, HEGP, Paris, France; [4]Nephrology, CHU, Lille, France; [5]CNRS UMR 6101, Limoges, France.*

Background: Non-amyloid fibrillary glomerulonephritis (FGN) is a rare disorder with poor renal prognosis in the absence of efficient therapy. The aim of the present retrospective study was to evaluate the effect of immunosuppressive regimens on long-term renal outcome.

Methods: Sixteen men and ten women (median age: 60 years) were included, according to the following criteria: 1) presence of glomerular extra-cellular Ig deposits 2) Congo-red-negativity 3) fibrillary organization at the ultrastructural level. Patients with immunotactoid GN and cryoglobulinemic GN were excluded. Clinicopathological characteristics and renal outcome were evaluated in 13 untreated patients (control group) and in 13 patients who received at least 1 of the following regimens: steroids (2 cases), steroids plus rituximab (7 cases)/cyclosporine (4 cases)/cyclophosphamide (3 cases) or bortezomib (1 case).

Results: At baseline, all patients had proteinuria (median: 2.9 g/day) associated with nephrotic syndrome (38%), hematuria (69%), renal insufficiency (58%) and hypertension (69%). Eight patients had a history of auto-immune disease but none had haematological malignancy. Light microscopic studies showed mesangial GN (73%), atypical membranous GN (15%) and atypical membranoproliferative GN (12%). By immunofluorescence, deposits stained for C3 (96%) and IgG in all cases (IgG4 14/14, IgG1 9/14). IgG deposits were polyclonal in 92% of cases. Serum IgG subclasses distribution was normal in 7 patients tested. After a mean follow-up of 62 months, renal response occurred in 6/13 patients with cyclophosphamide (1 case) or rituximab (5 cases). Median eGFR was 74 and 42 ml/min/1.73m2 at the time of treatment introduction, in responding and non-responding patients, respectively (p = 0.079). By contrast, CKD progressed in 12 control patients, 10 reaching end-stage renal disease.

Conclusions: The present data indicate that early introduction of immunosuppressive drugs may improve renal prognosis of FGN. Efficacy of rituximab remains to be confirmed in larger collaborative studies.

SA-PO351

Renal and Survival Outcome of Patients with Combined Renal Light Chain Deposition Disease (LCDD) & Myeloma Cast Nephropathy (MCN)

Ladan Zand, Samih H. Nasr, Nelson Leung. *Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Background: LCDD is due to over production of monoclonal light chains and typically associated with multiple myeloma. At the time of biopsy, between 16-46% of patients with LCDD also have evidence of MCN. The clinical and renal outcome of patients with both LCDD and MCN is not well-established.

Methods: We retrospectively reviewed 69 patients with pure LCDD, LCDD + MCN, & MCN alone at Mayo Clinic Rochester and compared their clinical, renal, and survival outcome.

Results: Between 1999 and 2011, there were 26 patients with LCDD, 30 MCN and 13 had both LCDD and MCN on renal biopsy. Patient characteristics were shown in Table 1. Creatinine at time of biopsy was significantly lower in LCDD group compared to the other 2 groups, but no difference in the need for dialysis at time of biopsy. In LCDD group, 69% had diagnosis of multiple myeloma compared to 100% in the other two groups. There was no difference in the type of therapy amongst the three groups (Bortezomib vs IMiD-based vs stem cell transplantation). The median patient survival was significantly lower in MCN and LCDD + MCN compared to LCDD, but no difference when comparing MCN to MCN + LCDD group. The median renal survival was higher in LCDD group compared to MCN and LCDD + MCN (p=0.005). The death-censored renal survival, however, was not different amongst the three groups.

Patient demographics and outcomes

Characteristics	LCDD (n=26)	MCN (n=30)	LCDD+MCN (n=13)	p value
Gender (M/F)	18/8	17/13	7/6	NS
Age (yr) at time of biopsy	56.4±2.47	64.2±2.30	60.0±3.49	0.07
Creatinine at time of biopsy	3.5±0.44	5.0±0.43	5.1±0.63	0.03
Dialysis at time of biopsy	5	9	4	NS
Multiple myeloma at time of biopsy	15	30	12	0.0006
Progression to ESRD	7	14	7	NS
Death	9	21	9	0.01
Median patient survival (m)	97	12	39	0.007
Median renal survival (m)	86	4	6	0.005
Death-censored median renal survival (m)	not reached	23	39	0.2

Conclusions: Patient with both LCDD and MCN on renal biopsy are similar to those with MCN alone as opposed to LCDD alone with a trend towards older age and higher creatinine at time of renal biopsy, higher mortality rate and lower renal survival (not censored for death).

SA-PO352

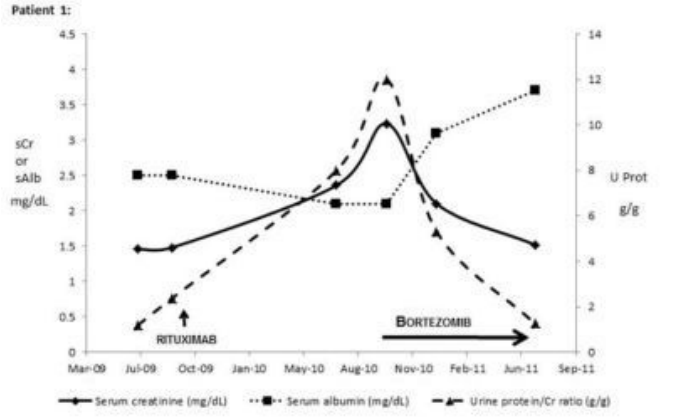
Bortezomib for Heavy Chain Deposition Disease: A Report of Three Cases

Kinjal Patel,[1] John J. Dillon,[2] Nelson Leung,[2] Andrew S. Bomback,[3] Gerald B. Appel,[3] Pietro A. Canetta.[3] *[1]Department of Medicine, Columbia University College of Physicians and Surgeons, New York, NY; [2]Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [3]Division of Nephrology, Columbia University College of Physicians and Surgeons, New York, NY.*

Background: Heavy chain deposition disease (HCDD) is a plasma cell dyscrasia in which monoclonal heavy chains deposit in glomerular and tubular basement membranes. Literature describing effective therapies is sparse, and historically prognosis has been very poor.

Methods: We describe 3 cases of HCDD with biopsy proven glomerular involvement but without myeloma on bone marrow biopsy who were successfully treated with bortezomib (BTZ), a proteasome inhibitor.

Results: Case Histories: Case 1: 60 yo man with nephrotic syndrome (NS) & rising serum creatinine (sCr), refractory to RAAS inhibition, diuretics, and rituximab. He began BTZ/dexamethasone (DEX). In 6 mos sCr improved from 3.23 to 1.52 mg/dl, proteinuria (UPCR) from 12 to 1.26 g/g.



Peripheral neuropathy led to cessation of BTZ at 7 mos. He began lenalidomide and remains stable 1yr later. Case 2: 75 yo man with refractory NS, rising sCr, and transfusion-dependent anemia. BTZ/DEX over 6 mos led to sCr improving from 3.0 to 1.3 mg/dl, UPCR from 4.2 to 1.9 g/g, and NS and anemia resolved. At 9 mos he developed peripheral neuropathy which stabilized with decreasing BTZ frequency. He remains stable on q2wk BTZ 20 mos later. Case 3: 56 yo man with refractory NS and rising sCr. He received cyclophosphamide/BTZ/DEX x4 cycles, with sCr 2.7 to 2.0 mg/dl and proteinuria 7.4 to 0.6 g/24h. He remained stable at 1yr with sCr 1.8, proteinuria 80 mg/24h.

Conclusions: In these HCDD cases, BTZ-based therapy resulted in sustained resolution of NS and improvement in renal function. Treatment was well-tolerated, but 2/3 cases developed peripheral neuropathy.

SA-PO353

Autologous Stem Cell Transplantation in 18 Patients with Primary AL Amyloidosis: Long-Term Outcome Masahiro Kawada, Kenmei Takaichi, Yoshifumi Ubara, Junichi Hoshino, Tatsuya Suwabe, Noriko Hayami, Keiichi Sumida, Koki Mise. *Nephrology, Toranomon Hospital, Tokyo, Minato-ku, Japan.*

Background: AL amyloidosis shows a wide spectrum of organ involvement and is well known to have a poor long-term prognosis. High-dose melphalan and autologous stem cell transplantation (HDM/ASCT) have been reported to prolong the survival of patients with AL amyloidosis. Induction with VAD therapy (vincristine, doxorubicin, and dexamethasone) before HDM/ASCT has been proposed to reduce the risk of relapse and improve the response rate. In Japan, this treatment is only performed for patients who meet certain eligibility criteria with regard to their general condition and complications. The long-term outcome of VAD with HDM/ASCT was investigated in this study.

Methods: In 18 patients with AL amyloidosis, HDM/ASCT was carried out after one or two courses of VAD therapy (performed according to the criteria and regimen of Gono) between 2004 and 2010.

Results: The median follow-up time was 43 months (21-85). The patients had a mean age of 52 years (6 women), mean serum Cr of 0.86 mg/dL, serum Alb of 2.23 g/dL, and proteinuria of 7.11 g/day before treatment. Three patients died (2 of AL amyloidosis and 1 of infection), and 15 patients remained alive. Proteinuria declined to <0.1 g daily in 2 patients after 1 year and in 7 patients after 2 to 3 years. It also decreased to <2 g daily in 2 patients, but proteinuria persisted in the other 6 patients. There was no treatment-related mortality. Overall survival (OS) was 84.7% at 3 years and 63.5% at 5 years. Renal reaction was seen in 47%. Compared with patients who showed mild to moderate amyloid deposition in the glomeruli, patients who had severe amyloid deposition were refractory to treatment (p=0.083).

Conclusions: VAD + HDM/ASCT may be an effective treatment for patients with AL amyloidosis who meet the eligibility criteria.

SA-PO354

Tacrolimus in the Treatment of HBV Associated with Membranous Nephropathy: A Prospective Study Kailong Li, Yani He. *Department of Nephrology, DaPing Hospital, Third Military Medical University, ChongQing, China.*

Background: Hepatitis B virus-associated membranous nephropathy(HBVMN)is the major pathological types of hepatitis B virus-associated glomerulo- nephritis(HBV-GN), and now, there is no specific treatment for the adult HBVMN. We conducted a prospective randomized trial evaluating the combination therapy of tacrolimus, corticosteroids and entecavir to achieve complete or partial remission in adult patients with biopsy-proven HBVMN.

Methods: Thirty-five patients were diagnosed as having chronic glomerulonephritis associated with chronic hepatitis B. Histopathological findings of the renal biopsy specimen from all the patients indicated membranous nephropathy.Seventeen of the patients received combination therapy of tacrolimus (0.05 mg/kg/day), corticosteroids(0.5mg/kg/day)and entecavir (0.5mg/day)over 12 months with a 6-month taper to tacrolimus, whereas eighteen of the patients were in the control group(entecavir monotherapy 0.5mg/day).

Results: The probability of remission in the treatment group was 82.4,and 100% after 6 and 12 months but only 11.1and 22.2%, respectively in the control group. The decrease in proteinuria was significantly greater in the treatment group. entecavir was started for the treatment of hepatitis in all patients, which caused the disappearance of serum hepatitis B virus DNA and the normalization of ALT and AST level in 2 months. Notably, three patients in the control group and no patient in the treatment group reached the secondary end point of a 50% increase in their serum creatinine. No patient in the tacrolimus group showed a relapse during the taper period. Nephrotic syndrome reappeared in almost 1/4 of the patients who were in remission by the 18th month after tacrolimus withdrawal.

Conclusions: We conclude that the combination therapy of tacrolimus,corticosteroids and entecavir is a very useful therapeutic option for patients with HBVMN and preserved renal function. The majority of patients experienced remission with a significant reduction in the risk for deteriorating renal function and Hepatitis B virus replication.

SA-PO355

Treatment of Refractory Idiopathic Membranous Nephropathy with Steroid and Tacrolimus Ping Fu, Tao Ye, Xiao Xiao Yu, Jin Qiaoling, Mian Wei. *Department of Nephrology, West China Hospital of Sichuan University, Chengdu, Sichuan, China.*

Background: To investigate the efficacy and safety of steroid and tacrolimus (FK506) in the treatment of refractory idiopathic membranous nephropathy.

Methods: Fifteen patients with idiopathic membranous nephropathy (IMN) who failed the previous therapy including steroid and cyclophosphamide or mycophenolate mofetil(MMF) and other immunosuppressive treatments from May 2009 to September 2011 in our hospital were treated with steroid and tacrolimus(FK506). The initial dose of prednisone was 30-40mg/d.The dose continued 4-6 weeks and then tapered gradually to 10mg/d.The dose of FK506 was 1mg/d.At the same time, Wuzhi capsule or Diltiazem was used to adjust the blood concentration of FK506.The target blood concentration was 5-8ng/mL and would be increased to 8-12ng/mL if the clinical parameters shwoed no improvement after three months.The blood concentration of FK506, urine protein,liver and renal function,blood glucose,blood lipids and infection were recorded in the regular follow-up.

Results: After 6 months of treatment,seven(46.7%)patients achieved complete remission(CR), three(20%) achieved partial remission(PR), while five(20%) failed this treatment.After 1 year of treatment, nine patients (60%)obtained CR, two patients(13.3%) obtained PR and four patients(26.7%) had no response. Four patients developed glucose intolerance,One developed respiratory infection, and three experienced gradual increasing in the serumcreatinine.One patient withdrew the sdudy, and no patient died because of the side effects.

Conclusions: The therapy with steroid and small dose of FK506 is an effective and safe therapy for refractory inpatients with IMN. However, futher sdudy is necessary to conducted to research the optimum blood concentration and course of treatment.

SA-PO356

Long-Term Survival after Dialysis Therapy in Patients with IgA Nephropathy Hiroyuki Komatsu,[1] Akihiro Fukuda,[1] Masao Kikuchi,[1] Yuji Sato,[1] Shouichi Fujimoto.[2] *[1]First Department of Internal Medicine, University of Miyazaki Hospital, Miyazaki, Japan; [2]Department of Hemovascular Medicine and Artificial Organ, Faculty of Medicine, University of Miyazaki, Miyazaki, Japan.*

Background: Little is known about how dialysis affects the survival of patients with biopsy-proven IgA nephropathy. The present long-term cohort study quantifies the survival rates and incidence of cardiovascular events among such patients in Japan.

Methods: Fifty-two of 433 patients with IgA nephropathy who had reached end-stage kidney disease underwent renal replacement therapy (RRT) between 1981 and 2010 and were followed-up for 11.3 ± 6.4 years. The overall survival rate and incidence of cardiovascular events in these 52 patients were evaluated during the follow-up.

Results: Initial RRT in 46 and 6 patients comprised hemodialysis and peritoneal dialysis, respectively. The mean age at starting RRT was 42.8 ± 13.3 years. Only seven patients died during follow-up and Kaplan-Meier analysis revealed favorable survival rates of 93.3% and 65.1% at 10 and 20 years, as compared with that of patients with glomerulonephritis who required RRT in Japanese Society for Dialysis Therapy registry (49.0% and 27.8% at 10 and 20 years). Cardiovascular disease and malignancy were causes of death at 3.9 ± 1.3 and 13.6 ± 4.8 years respectively after starting RRT. Cardiovascular events developed in 15 patients (incidence, 2.7 per 100 person-years) and acute coronary syndrome and cerebral hemorrhage developed relatively soon after starting RRT. Cox proportional hazards models revealed that age at the time of starting RRT was a significant factor affecting the onset of cardiovascular events.

Conclusions: Although the survival of patients with IgA nephropathy is favorable after dialysis, the onset of cardiovascular events during the early phase of dialysis should be carefully monitored.

SA-PO357

Prospective Study to Compare Efficacy of Tacrolimus versus Cyclyophosphamide in Inducing Remission in Idiopathic Membranous Nephropathy Sanjay K. Agarwal, Pavitra Manu Dogra, Sanjay Gupta, Dipankar M. Bhowmik. *Department of Nephrology, All India Institute of Medical Sciences, New Delhi, Delhi, India.*

Background: Steroid alone is not useful for Idiopathic Membranous nephropathy (IMN). There are reports on use of Tacrolimus (Tac) in IMN. However, none has compared it with Modified Ponticelli regimen (MPR). This study has prospectively compared efficacy of Tac with MPR in IMN.

Methods: In this, prospective study adult patients of IMN (eGFR > 30 ml) and nephrotic syndrome inspite of adequate Telmisartan were included. Patients were randomized in 1:1 ratio. In group-A, Tac (0.1 mg/Kg/day for 6 months, then taper off in next 6 months) and Prednisolone (0.5 mg/Kg/day till remission, then tapered by 5 mg/week with minimal maintenance dose) was used. In group-B, MPR was used. Duration of therapy was 12 months in Gr-A and 6 months in Gr-B. Primary end point was any remission (AR) at 6 month, secondary end points was partial remission (PR) at 6 month, AR and renal survival at 12 months. Written informed consent was taken from each patient. Study was ethically approved and registered with Clinical Trials Registry of India (CTRI/2010/091/000231).

Results: A total of 41 patients included. Mean age (38 years), mean duration of edema (8 months), number of female (7), degree of blood pressure was similar in both groups. Gr-A had Stage II histology in 90% and stage III in 10%. In Gr-B, all had stage II disease. Primary endpoint was seen in 100 % patients of Gr-A and 85% in Gr-B (p=0.04). PR at 6 months was seen in 95% patients in Gr-A and 85% in Gr-B. AR at 12 months was obtained in 94.4% patients in Gr-A (33.3% PR + 61.1% CR) as against 85% in Gr-B (35% PR + 50% CR), (p=0.52). 1 patient in each group expired due to infection. Remission was more rapid and statistically significant in Gr-A. At any given time, proteinuria reduced more in Gr-A than Gr-B with a mean difference of 1.24 g/day (p=0.012). There was minor reduction seen in eGFR (6 ml/min) in both groups, at the end of follow-up.

Conclusions: Our study shows that Tacrolimus with steroid is a good option for management of idiopathic Membranous Nephropathy. This drug when compared with Modified Ponticelli protocol has a rapid reduction in proteinuria.

SA-PO358

Comparison of Treatment Strategies in Idiopathic Membranous Nephropathy Jan A.J.G. van den Brand,[1] Alfonso Segarra,[2] Manuel Praga,[3] Jack F. Wetzels.[4] *[1]On Behalf of the Study Group; [2]Servicio de Nefrología, Hospital 12 de Octubre, Madrid, Spain; [3]Nefrologia, Hospital Vall d'Hebron, Barcelona, Spain; [4]Nephrology, Radboud University Medical Centre, Nijmegen, Netherlands.*

Background: Treatment of patients with idiopathic membranous nephropathy is debated, and various regimens are used. We compared two strategies consisting of supportive treatment with anti-proteinuric drugs and statins in low risk patients, and cyclophosphamide (CP) in high risk patients (Therapy I); the latter of supportive treatment, calcineurin inhibitors (CNIs) and CP in low, intermediate and high risk patients, respectively (Therapy II).

Methods: We merged datasets from prospective cohorts of patients from Spain and the Netherlands, including adult patients with biopsy proven iMN who presented with the nephrotic syndrome. We defined the end-point as doubling of serum creatinine, end stage renal disease (ESRD) or mortality. To achieve pseudo-randomization we used a logistic regression model to create 0.05-wide propensity score strata. Subsequently, we calculated a Mantel-Haenszel odds ratio (OR) to compare both strategies, excluding strata for which no comparison could be made.

Results: Table 1 shows confounder balance achieved by the propensity score stratification. During a median follow-up of 81 months (IQR 39 - 115), 50 patients reached the end-point, 18 of whom died, 15 developed ESRD and 17 showed a doubling of serum creatinine. The OR for the Therapy II compared to Therapy I was 0.94 (95%CI 0.46 to 1.91).

population characteristics

	Therapy I	**Therapy II**
n (% male)	188 (66)	89 (64)
age	52 (14)	50 (17)
year of biopsy	2000 (6.0)	1998 (7.8)
mean arterial pressure	97 (15)	99 (20)
eGFR	70 (23)	75 (34)
serum albumin	25 (6.4)	24 (5.3)
serum cholesterol	7.7 (2.6)	8.3 (2.1)
proteinuria	9.5 (5.2)	9.1 (4.4)
ACEi/ARBs (%)	68	67
statin (%)	48	61
Therapy (%)		
none or steroids	100 (53)	40 (45)
CP	87 (46)	17 (19)
CNI	1 (0.5)	32 (36)

Data are presented as mean (SD) unless stated otherwise

Conclusions: We observed no statistically significant difference in mortality, ERSD or doubling of serum creatinine between the two therapeutic strategies. Therefore, treatment choice may be determined by patient characteristics and potential side effects.

Funding: Private Foundation Support

SA-PO359

Maliginancy Risk after Cyclophosphamide Treatment in Membranous Nephropathy Jan A.J.G. van den Brand,[1] Peter R. Van Dijk,[2] Julia M. Hofstra,[1] Jack F. Wetzels.[1] *[1]Nephrology, Radboud University Medical Centre, Nijmegen, Netherlands; [2]Diabetes Centre, Isala Clinics, Zwolle, Netherlands.*

Background: Cyclophosphamide treatment improves renal survival in patients with membranous nephropathy (MN). However, its use is associated with late malignancy. We determined the incidence and risk of cancer after cyclophosphamide treatment in MN patients.

Methods: We included 269 biopsy proven MN patients in a prospective cohort since 1995. We defined outcome as incident malignancy or death, and calculated exposure time as the time between start of cyclophosphamide therapy and either outcome or end of follow-up. Conversely, for patients not receiving therapy, exposure time was calculated from biopsy until outcome or the end of follow-up, respectively. We then calculated incidence densities and relative risks, and subsequently stratified incidence by exposure time to estimate the latency period from cyclophosphamide exposure to outcome. Finally, we used a poisson regression model to correct for confounding by gender, smoking and age at biopsy.

Results: We observed 19 cases over 685 personyears in the cyclophosphamide treated group, compared to 7 cases over 1138 personyears in the untreated group. The table shows the overall unadjusted relative risk and relative risks by exposure time. The overall adjusted relative risk was 3.6 (95% confidence interval [CI] 1.5 - 8.7).

Unadjusted relative risk of cancer or death

Exposure time (years)	RR	95%CI
0-3	4.3	0.9 - 20
3-6	8.5	1.0 - 70
6-9	6.9	0.3 - 143
9-12	2.7	0.3 - 24
Total	4.5	1.7 - 17

Conclusions: Cyclophosphamide therapy was associated with malignancy and mortality. We observed an increased risk directly after the start of treament. Cyclophosphamide is unlikely to be causative for these early malignancies, as studies in other patient groups have shown a five year latency period for cancer to occur. We hypothesize that early unrecognized malignancies may be the cause of MN, and contribute to progressive disease, necessitating the use of cyclophosphamide. This explains the association of cyclophophamide with early malignancies, which means the association may be inflated.

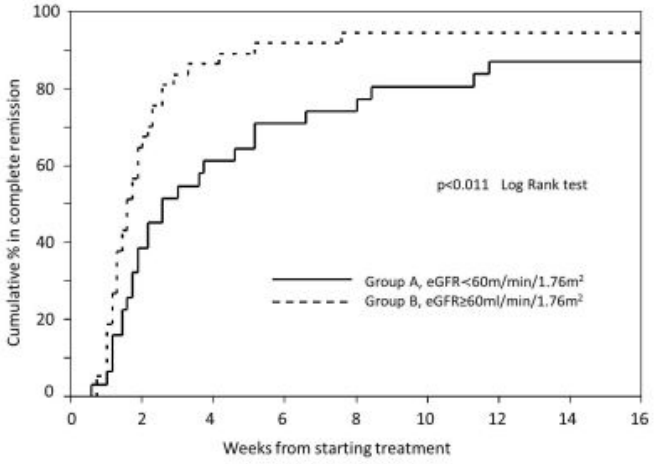
Renal Function and Age at Onset Are Independently Associated with Subsequent Induction of Complete Remission in Adult Minimal Change Nephrotic Syndrome Daisuke Komukai, Yoshihiko Inoue, Fumihiko Sasai, Mamiko Takayasu, Ashio Yoshimura. *Div. of Nephrology, Showa University Fujigaoka Hospital, Yokohama, Kanagawa, Japan.*

Background: Renal insufficiency is a common feature of minimal change naphrotic syndrome (MCNS) at onset especially in adults, however its impact on subsequent steroid-responsiveness and the rate of complete remission (CR) are still unclear. We analyzed factors at onset affecting clinical course of adult MCNS patients.

Methods: 68 patients with MCNS (41 male and 27 female with a mean age of 43.6 years, range:16-76), all have been diagnosed by kidney biopsy, were studied retrospectively. Clinical data at onset including age, gender, serum creatinine, serum albumin, daily urinary protein excretion and the time to CR were studied. To compare the cumulative rates of CR between the groups of decreased eGFR (<60 ml/min/1.73m^2, group A) and preserved eGFR (≥60 ml/min/1.73m^2, group B), we used life-table analysis with Kaplan-Meier method. Cox proportional-hazards model was used to determine independent effects of clinical factors.

Results: The mean follow-up period was 43.2 months (median 41.2, range:1.3-269.0). The decrease in eGFR was shown in 31 patients (group A). All patients were treated with oral prednisolone (mean 0.72 mg/kg/day) and 33 patients (48.5%) received methylprednisolone pulse therapy (500 mg iv. for 3 days) followed by oral prednisolone. CR was achieved 54.4% of patients at 2 weeks after the start of treatment and 86.8% at 8 weeks. The time to CR in group A was significantly longer.



In Cox analysis, higher age and the decrease in renal function were both independently associated with longer duration necessary for CR after adjustment for gender, serum albumin and urinary protein.

Conclusions: Renal function and patient age at onset were independently associated with the rate of CR in adult MCNS.

SA-PO361

Long-Term Outcome of Primary and Secondary Membranous Nephropathy: Single Center Experience Mi Hyun Jang, Eun-Ah Hwang, Sung Bae Park. *Internal Medicine, Keimyung University Kidney Institute, Daegu, Korea.*

Background: Membranous nephropathy (MN) is common cause of adult onset nephritic syndrome and one of leading cause of renal failure within glomerulonephritis group. MN may be associated with other diseases such as hepatitis virus infection and lupus. This study addressed the long-term outcome of MN. We compared the rate of renal function decline according to primary or secondary MN and renal outcome among primary MN patients with a partial remission (PR), complete remission (CR) and no remission (NR) of proteinuria.

Methods: From 1985 to 2011, a total of 3648 cases of renal biopsy was performed in our center. Among them, 208 patients were diagnosed MN and followed up at least 6 months. We reviewed the medical records of these patients and compared long-term outcomes according to etiologies. The impact of treatment responses was evaluated.

Results: The mean age of studied patients was 45.6±15.6 years and M:F ratio was 1.1:1. 147 patients(70.7%) were diagnosed of primary MN and remaining 61 patients(29.3%) were secondary MN. The most common cause of secondary MN was lupus(52.5%), followed by Hepatitis B infection(45.9%). Within the patients with primary MN, 34 patients(23.1%) were received only steroids and 29 patients(19.7%) were received steroids combined with cyclophosphamide. Remaining 80 patients(54.4%) were received conservative treatment such as ACE inhinbitor and antiplatelet agents. During the follow up (average 91 months), 25% of primary MN patients and 42.6% of secondary MN patients reached renal failure. The 5 years and 10 years of renal survival rate of primary MN was 86.1% and 71%, respectively. In primary MN patients treated with steroids and/or cyclophosphamide, 39.5% of the patients had a CR, 21.8% had a PR and 12.9% had a NR. 10 years renal survival rate of patients with CR or PR was significantly higher than that of patients with NR(100% vs. 47%, p<0.000).

Conclusions: In our study, the long-term outcome of primary MN was better than secondary MN. In primary MN, patients with CR or PR showed excellent renal outcome compared to patients with NR. In primary MN patients, treatment with steroid or cytotoxic agents for reducing proteinuria can improve renal outcome.

SA-PO362

Renal Flare (RF) as a Biomarker of Incident and Progressive Chronic Kidney Disease (CKD) in Patients with Lupus Nephritis (LN) Samir Parikh, Alison Marie Mckinley Neal, Brad H. Rovin. *Internal Medicine, Ohio State University Medical Center, Columbus, OH.*

Background: Acute kidney injury (AKI) leads to CKD. In patients with LN, RF is an AKI equivalent.

Methods: To determine whether RF frequency and duration can be used as a marker of new CKD or progression of established CKD, we correlated RF with starting and ending serum creatinine (SCr) levels in the Ohio SLE Study (OSS) cohort.

Results: New onset CKD occurred in 12/41 patients over a median follow up of 4.5 years. The CKD group had more RF events than the non-CKD group: 31 (2.59/pt) vs 17 (0.59/pt), respectively, and spent more time in RF (Table 1). Only 8% of the CKD group versus 59% of the non-CKD group had no RF. In those OSS patients with established CKD, those who progressed had more RF events than non-progressors: 13 (1.63/pt) vs. 2 (0.29/pt), respectively. In the non-progressor group 71% had no RF, compared to 37.5% of progressors. Progressors had a significant change in SCr over the study period (p=0.0078). Differences in number of RF and RF duration were not significant between the 2 groups but tended to be higher in the progressors (Table 2).

Conclusions: In patients with LN, the frequency and duration of RF are biomarkers of new CKD and progression of existing CKD. As new LN therapeutic regimens are developed, targeting RF prevention will be an important consideration.

Table 1

	No CKD (n=29)	New CKD (n=12)	P-Value
Age	31.3	34.3	NS
% Male	14%	0%	-
% African American	28%	50%	-
Mean starting SCr (mg/dl)	0.85±0.15	0.75±0.15	NS
Mean end SCr(mg/dl)	0.83±0.12	1.78±1.95	0.0001
Median time in flare (mo)	0	20	0.0003
New RF/year	0.14	0.72	0.0001
Median time in renal health (mo)	52	30.4	0.0038

Table 2

	Non-progressors (n=7)	Progressors (n=8)	P-Value
Age	39.1	40.5	NS
% African American	14%	62.5%	-
Mean starting SCr(mg/dl)	1.94±0.83	2.15±0.81	NS
Mean end SCr(mg/dl)	1.56±0.87	4.0±2.45	0.0093
Mean new RF per year	0.10±0.19	0.41±0.42	NS
Median time in Renal Health (mo)	48	25	0.0560

SA-PO363

Immunosuppression Induced Partial Remission in Idiopathic Membranous Nephropathy Durga A.K. Kanigicherla, Paul E. Brenchley, Milind Nikam, Colin Short, Michael Venning. *Nephrology and Transplantation, Central Manchester University Hospitals, Manchester, United Kingdom.*

Background: About 2/3 of patients with IMN achieve Partial Remission (PR), yet 15-40% progress to renal insufficiency. PR is associated with lower incidence of ESRD/death. It is unclear how immunosuppression induced PR (PR-IS) compares with spontaneous PR (PR-S).

Methods: 1. Biopsy proven IMN followed for ≥1 year

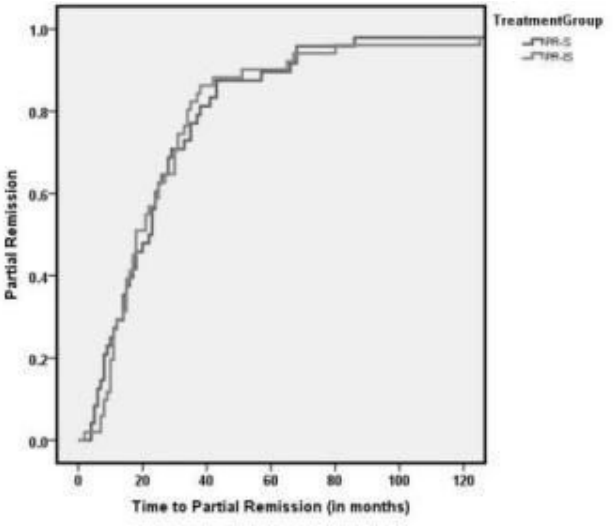
2. IS used for standard indications.

3. PR: 50% proteinuria reduction & 0.3-<3.5gm/24hrs, CR: Proteinuria <0.3gm/24hrs & stable eGFR, Relapse: proteinuria ≥3.5gm/24hrs.

Results: Of 128 patients followed for a median of 9.5 years, 100 (78%) achieved PR, and 28 had persistent active disease (PAD).

51/100 achieved PR with IS treatment (PR-IS) & 49 spontaneously (PR-S). IS regimes included steroids (n=18), CsA (7), Cyclophosphamide (23) & Rituximab (3). IS was initiated at 6 months (IQR5-11) after biopsy. Age, DM, use of ACEi/ARBs, statins was not different. At presentation, proteinuria was higher (10.6 v 6.6, p<0.001) and albumin was lower (24 v 30, p<0.0001) in PR-IS cf. PR-S. In PR-IS eGFR was lower at treatment than at presentation (54 v 70mL/min, p<0.001) In PR-IS, eGFR slope improved from -0.9 pre-IS to +0.39 ml/min/month post-IS treatment. After PR, eGFR was similar in PR-IS and PR-S (-0.02 Vs -0.02 ml/min/month).

	PR-S	PR-IS	p
Time to PR (months)	22	18	0.92
CR (%)	65	51	0.16
Relapse (%)	22	31	0.37
Relapse after PR (months)	101	21	0.002*
Doubling of creatinine	3	7	0.32



Doubling of creatinine was seen in 2/73 of non-relapsers cf. 8/27 relapsers (p=0.02) / ESRD in 0/73 non-relapsers cf. 3/27 relapsers.

Of 28 patients with PAD, 18 (64%) reached ESRD of whom 7 died.

Conclusions: PR-IS is associated with similar outcomes as those with PR-S despite more severe disease. Relapse, however, with worse outcome, occurs sooner in PR-IS than in PR-S. 29% of patients who achieved PR did so in 1 year, and 82% in 3 years.

SA-PO364

Respiratory Manifestations of ANCA-Associated Vasculitis Kerry Greenan,[1] Darren Green,[2] Smeeta Sinha.[2] *[1]University of Manchester; [2]Department of Renal Medicine, Salford Royal NHS Foundation Trust, United Kingdom.*

Background: The prevalence of pulmonary manifestations of ANCA-associated vasculitis (AAV) is not well understood. This study assesses the prevalence of respiratory complications of AAV in patients presenting to a tertiary renal centre with primarily renal disease, not initially requiring dialysis; evaluates whether such complications are recognised and investigated appropriately, and examines the relationship between pulmonary vasculitis and mortality.

Methods: 58 patients with AAV were identified from the Chronic Renal Insufficiency Standards Implementation Study database, which is a prospective epidemiological study of patients with CKD stages 3-5, not requiring dialysis. Patients were identified as having AAV between 2000 and 2012. Presentation data was only available for 38 patients.

Results: A chest x-ray on presentation was available for 36 out of 38 patients, of which 16 (44.4%) had changes that could be associated with vasculitis. Only 31.3% of these were followed up with pulmonary function tests, a CT scan or respiratory review. 14 patients from the entire cohort of 58 had had a CT thorax during the course of their disease: 100% of these showed abnormalities, the most common being fibrosis (71.4%) and bronchiectasis (64.3%). 15 of 58 patients (25.9%) had confirmed pulmonary vasculitis, either as documented after respiratory review or as demonstrated by changes associated with vasculitis on a CT scan. There was no evidence of a link between pre-existing respiratory disease and this diagnosis (Fisher's Exact Test: p=0.103). The relationship between survival and pulmonary vasculitis was analysed using Cox-regression (correcting for age, smoking status, pre-existing respiratory disease and diabetes) and was not found to be statistically significant (p=0.086), although there was a trend towards increased mortality in those with pulmonary vasculitis.

Conclusions: Pulmonary manifestations of ANCA-associated vasculitis occurred in a significant proportion of patients. Only a small proportion of patients had had thorough respiratory investigations, even after an abnormal chest x-ray, suggesting that the pulmonary manifestations of AAV may be under-diagnosed.

SA-PO365

Anti-PLA2R-Associated Membranous Nephropathy in Adolescents and Young Adults Laurence H. Beck,[1] Rivka Ayalon,[1] Howard Trachtman,[2] David J. Salant.[1] *[1]Medicine, Boston University Medical Center; [2]Pediatrics, New York University Langone Medical Center.*

Background: Primary membranous nephropathy (MN) is most prevalent in Caucasian males aged 30-60 years. It is an uncommon cause of MN in pediatric cases which tend to be associated instead with secondary causes such as SLE or hepatitis B, or rarely with antibodies to bovine serum albumin (BSA) in younger children. We have assessed the prevalence of anti-PLA2R-associated MN in subjects whose disease was manifest prior to the age of 30.

Methods: A database of 275 subjects with MN, tested for anti-PLA2R at our institution, was queried for those whose initial disease presented at an age < 30 yr. We excluded those whose MN was associated with secondary causes, such as SLE (n=6), NSAIDs (n=1), or Hg exposure (n=1). We tested sera by western blot against PLA2R as well as neutral and cationic BSA.

Results: 21/29 cases (72%) were positive for anti-PLA2R antibodies. The age of disease onset in this group was 19.4±4.6 yr, 71% were male (15M:6F) and two cases exhibited symptoms as early as 12 years of age. At the time of sample collection, the mean age was 23.1±6.0, and values for serum Cr, albumin, and urine protein were 1.1±0.6 mg/dl, 2.8±0.9 g/dl, and 6.3±4.5 g/g Cr, respectively. In the remaining 8/29 (28%) who had no antibodies to PLA2R at the time of sample collection, age of disease onset was 15.9±6.2 and 75% were male (6M:2F). In this group, age at sample collection was 18.1±6.9, and mean values for serum Cr, albumin, and urine protein were 0.7±0.3 mg/dl, 3.1±1.4 g/dl, and 0.8±1.1 g/g Cr, respectively. None of the anti-PLA2R-negative cases had antibodies to neutral or cationic BSA.

Conclusions: Primary anti-PLA2R-associated MN is not limited to older adults and the prevalence in a pre-teen, adolescent, and young adult (< 30) age group is similar to that found in adults. Primary MN should be strongly considered in this age group. Although antibodies to PLA2R (or BSA) were not detected in 28%, this group had much lower proteinuria at the time of sample collection, suggesting that some of them might have already entered immunological remission. Further research is required to elucidate this possibility and other potential antigens in this group.

Anti-Phospholipase A_2 Receptor Antibodies: Correlation between Indirect Immunofluorescence and Western Blot Immunoassay with Clinical Status in Idiopathic Membranous Nephropathy Nuria S. Pérez,[1] Rivka Ayalon,[2] Carola Arcal Cunillera,[1] Laurence H. Beck,[2] Josep Maria Campistol Plana,[1] David J. Salant,[2] Luis F. Quintana.[1] *[1]Nephrology and Renal Transplantation, Hospital Clinic, Barcelona, Spain; [2]Nephrology and Renal Transplantation, Boston University Medical Center, Boston, MA.*

Background: Cumulative data from serum samples have shown that 70-80% of patients with idiopathic membranous nephropathy (IMN) have anti-PLA_2R antibodies that are reactive with native glomerular extract using a western blot (WB). Levels of circulating anti-PLA_2R show correlation with disease activity and may provide a tool for monitoring treatment efficacy. An alternative assay using an indirect immunofluorescence test (IIFT) enables the easy detection of anti-PLA_2R antibodies in serum.Using IIFT, anti-PLA_2R antibodies were reported in 52% of patients with biopsy-proven IMN, but in none of those with secondary MN . This discrepancy could be associated with different sensitivities of the two methods and requires evaluation in the same cohort. To do so we assessed the prevalence of anti-PLA_2R in a Spanish cohort of IMN patients by WB and IIFT in order to establish the correlation between these two methods for detecting anti-PLA_2R.

Methods: Anti-PLA_2R was assayed by WB and IIFT in serum samples from 30 patients with IMN collected at various stages of disease activity and correlated with other parameters.

Results: WB detected anti-PLA_2R in 50.0% of IMN patients in our cohort whereas the IIFT was positive in 46.7% suggesting similar sensitivity of the two tests. However, discrepant results were found in three cases. One might have been a false positive IIFT reaction because of the presence of anti-mitochondrial antibodies in a patient with primary biliary cirrhosis but the other two have no clear explanation. The antibody levels measured by IIFT in these patients correlated strongly with proteinuria (P =0.02).

Conclusions: This study reveals the limitation of existing methodologies–high specificity but limited ability to quantify anti-PLA_2R levels by WB and potential false-positive reactions with IIFT–and highlights the need for an antigen-specific quantitative immunoassay.

SA-PO367

Autoantibody against Phospholipase A_2 Receptor in Korean Patients with Membranous Nephropathy Yun Jung Oh,[1] Seung Hee Yang,[2] Hajeong Lee,[1] Jung Pyo Lee,[3] Dong Ki Kim,[1] Yon Su Kim.[1,2] *[1]Internal Medicine, Seoul National University Hospital, Seoul, Republic of Korea; [2]Kidney Research Institute Medical Center, Seoul National University Hospital, Seoul, Republic of Korea; [3]Internal Medicine, Seoul National University Boramae Medical Center, Seoul, Republic of Korea.*

Background: Membranous nephropathy (MN) is an autoimmune disease and a common cause of nephrotic syndrome in adults. Since the M-type phospholipase A_2 receptor (PLA_2R) was identified as a target autoantigen in adult idiopathic MN, the prevalence of autoantibodies against PLA_2R has been reported in Caucasian, African American, and Chinese patients recently. However, the prevalence is unknown among Korean patients with MN.

Methods: We explored the prevalence of autoantibodies against PLA_2R in Korean patients with idiopathic MN using Western blot immunoassay. Western blotting was performed in 65 patients with idiopathic MN who were in various stage of clinical disease. We isolated glomeruli from normal kidney tissue obtained after radical nephrectomy for renal cell cancer with graded sieving. Human glomerular protein extraction was electrophoresed under nonreducing condition, and human serum was used as the primary antibody at a dilution of 1:100 and 1:25 in case of negative results. We assessed the reactivity of serum samples to PLA_2R blindly without knowledge of the clinical status.

Results: 25(67.6%) patients had detectable autoantibodies against human PLA_2R among 37 patients with nephrotic ranged proteinuria(>3.5g/day). Anti-PLA_2R was negative in all patients(n=17) who had entered clinical remission after treatment. Proteinuria was more severe in MN patients with anti-PLA_2R antibody(Ab) than those without (7,300 mg/g versus 97mg/g, P<0.001). However, the anti-PLA_2R Ab level was not significantly correlated with the severity of proteinuria.

Conclusions: A majority of Korean patients with idiopathic MN had autoantibodies against PLA_2R. These results confirmed the role of PLA_2R as a target antigen in idiopathic MN in Korean patient cohort.

Funding: Government Support - Non-U.S.

SA-PO368

Prevalence of Autoantibody against PLA2R1 in Patients with Membranous Nephropathy in Japan Shin'ichi Akiyama,[1] Takenori Ozaki,[1] Shoichi Maruyama,[1] Hitoshi Yokoyama,[2] Gerard J. Lambeau,[3] David J. Salant,[4] Seiichi Matsuo,[1] Enyu Imai.[1] *[1]Internal Medicine, Nagoya University Graduate School of Medicine, Nagoya, Japan; [2]Nephrology, Kanazawa Medical University, Kanazawa, Japan; [3]Institute of Molecular and Cellular Pharmacology, CNRS and University of Nice, France; [4]Medicine, Boston University.*

Background: Membranous nephropathy (MN) is the leading cause of the nephrotic syndrome in adults. The M-type phospholipase A2 receptor (PLA2R1) was recently identified as a major target antigen of idiopathic MN (iMN), but the prevalence of anti-PLA2R1 immunoglobulin G (anti-PLA2R1) is unknown among Japanese patients with MN. In this study, we determined the prevalence of anti-PLA2R1 from Japanese patients with MN.

Methods: We studied 109 patients with biopsy-proven iMN and 49 patients with secondary MN, and as controls, 5 each of patients with IgA-N, MPGN, MCNS and 5 healthy volunteers. Plasma samples were collected before treatment. Anti-PLA2R1 was analyzed in plasma by Western blotting under non-reducing condition with human glomerular extract (HGE) or recombinant internal fragment, 21-633 aa of PLA2R1 protein (rPLA2R1) as antigen. The HGE was made from human glomeruli after removing contaminating endogenous IgG. rPLA2R1 was produced in HEK293 cells transfected with a plasmid DNA vector coding for thePLA2R1 sequence.

Results: Anti-PLA2R1 was only found in MN, and was not detected in any of the patients with other glomerular diseases or healthy volunteers. The anti-PLA2R1 was detected in 54 out of 109 patients with iMN and 3 of 49 patients with secondary MN. Causes of 3 cases of secondary MN with presence of anti-PLA2R1 were one bucillamine-induced nephrotic syndrome, and 2 other diseases. The major subclass of anti-PLA2R1 was IgG4.

Conclusions: The prevalence of anti-PLA2R1 in Japanese patients with idiopathic and secondary MN was49.5% and 6.1%, respectively. The prevalence of iMN caused by anti-PLA2R1 may be lower in Japanese iMN compared with those in Caucasian and Chinese. Some types of secondary MN might be linked to the presence of anti-PLA2R1.

SA-PO369

How to Distinguish between Idiopathic and Malignancy-Associated Membranous Nephropathy Jennie Lönnbro-widgren,[1] Jenny C. Nystrom,[3] Johan C. Molne,[2] Borje Haraldsson.[1] *[1]Sahlgrenska Academy, University of Gothenburg, Institute of Medicine, Gothenburg, Sweden; [2]Sahlgrenska Academy, University of Gothenburg, Institute of Biomedicine, Gothenburg, Sweden; [3]Sahlgrenska Academy, University of Gothenburg, Institute of Neuroscience and Physiology, Gothenburg, Sweden.*

Background: Membranous nephropathy (MN) is a common cause of nephrotic syndrome in adults, and presents either as idiopathic (I-MN) or secondary to other diseases. Approximately 5-20% of the cases of MN are malignancy-associated. Previous studies have suggested that deposition of glomerular IgG4, as well as PLA2-receptor antibodies, may play an important role in the pathogenesis of I-MN. The clinical and renal pathological manifestations of I-MN and malignancy-associated membranous nephropathy (M-MN) are similar, and the diagnostic tools to distinguish between I-MN and M-MN are not clearly validated, but of great importance.

Methods: In this retrospective study, 41 patients were included, 27 with I-MN and 14 patients with M-MN diagnosed between 2000 and 2011. Demographic and clinical data were analyzed. Furthermore, we analyzed the histopathological pattern of IgG4 by immunohistochemistry.

Results: The histopathological pattern, with positive IgG4 was present in 15/27 patients with I-MN, but only in 3/14 patients with M-MN. ($p<0.001$). The patients with M-MN were significantly older (63±10 years) compared to those with I-MN (45±14 years) $p<0.001$. However, serum albumin and the degree of albuminuria did not differ between the two groups.

Conclusions: By combining parameters in a new algorithm, we were able to discriminate patients with M-MN from those of idiopathic disease with even higher precision. We conclude that it is possible to identify patients with MN more likely to have an underlying malignant disease based on the absence of IgG4 in the renal biopsy.

SA-PO370

Subendothelial Electron-Dense Deposits May Provide a Clue to the Diagnosis of Malignancy-Associated Membranous Nephropathy Kana Iwazu, Yoshitaka Iwazu, Shin-ichi Takeda, Tetsu Akimoto, Yoshiyuki Morishita, Wako Yumura, Taro Sugase, Eiji Kusano. *Division of Nephrology, Department of Medicine, Jichi Medical University, Shimotsuke, Tochigi, Japan.*

Background: Cancer patients occasionally develop renal disorders independently of tumor invasion into the kidneys. However, it is often unclear in such cases whether there is a direct relationship to the pre-existing malignancies or not. We recently reported that tumor-bearing rats showed features of glomerulopathy (Nephrol Dial Transplant 27: 1786, 2012). Of particular interest is that subendothelial electron-dense deposits (EDDs) were observed in glomeruli of this animal model, whereas such ultrastructure is usually located in the subepithelial area among patients with idiopathic membranous nephropathy (I-MN). **Aim:** To elucidate distinctive characteristics of malignancy-associated MN (M-MN) from the perspectives of clinical use.

Methods: 7 patients who have malignancies in addition to membranous nephropathy (MN; group M) and 35 patients with I-MN (group I) were included in this study. The clinical and pathological profiles in group M were compared with those in I-MN (group I). The localization of EDDs and immunohistochemical IgG3-affinities were investigated, respectively.

Results: Subendothelial EDDs were evident exclusively in group M (3 out of 7 patients), whereas only one case in 35 I-MN cases in which the electron micrograms were available. Although EDDs were observed also in the mesangial area, there was little difference in the degrees between the two groups. The IgG3 score was significantly greater in group M (n=7) than in group I (n=18).

Conclusions: The present study indicates that subendothelial EDDs and IgG3 deposition in glomeruli are the prominent features of M-MN. These findings might provide new insights into the clinical management of malignancy-associated nephropathies.

SA-PO371

Kidney Injury Molecule-1 and Neutrophil Gelatinase-Associated Lipocalin as Prognostic Markers in Idiopathic Membranous Nephropathy Rutger J. Maas,[1] Femke Waanders,[2] Julia M. Hofstra,[1] Hilde P. Peters,[1] Esther Meijer,[2] Harry Van Goor,[2] Jan A.J.G. van den Brand,[1] Jack F. Wetzels.[1] *[1]Nephrology, Radboud University Nijmegen Medical Center, Netherlands; [2]Kidney Center, University Medical Center Groningen, Netherlands.*

Background: Urinary excretion of beta 2-microglobulin (β2m) and alpha 1-microglobulin predict progression of idiopathic membranous nephropathy (iMN) with reasonable accuracy (±80%). KIM-1 and NGAL are novel urinary biomarkers of tubular damage. We investigated if these markers can improve the prediction of progression in iMN.

Methods: We measured KIM-1 and NGAL concentrations in frozen stored urine samples of a previously described cohort of patients with iMN, nephrotic proteinuria and normal kidney function (CJASN 2011;6:2846). Progression was defined as a serum creatinine rise >50%, a rise in serum creatinine of >25% and an absolute value of ≥135µmol/l, or a clinical decision to start immunosuppressive therapy. Remission was defined as proteinuria <3.5 g/d and >50% reduction.

Results: 69 urine samples were available for measurement of KIM-1 and NGAL. Baseline patient characteristics were comparable to the entire cohort. Median survival time was 31 months (IQR 17-58 months). Progression occurred in 30 patients (44%), and spontaneous remission occurred in 36 patients (52%). In univariate analysis both KIM-1 and NGAL were predictors of progression (Table). In multivariate analysis, β2m was the strongest independent predictor. Combining β2m with KIM-1 and NGAL improved specificity, at the expense of sensitivity (Table).

Conclusions: KIM-1 and NGAL predict progression of iMN, and may be used in combination with β2m to increase specificity of outcome prediction.

Prognostic accuracy of urinary proteins in progression of iMN

	ROC-AUC (95% CI)	Optimal cut-off	Sensitivity (%)	Specificity (%)
β2m*	0.80 (0.69-0.91)	1.0 µg/min	75	78
KIM-1	0.75 (0.62-0.87)	1.6 ng/min	77	67
NGAL	0.74 (0.62-0.87)	30 ng/min	67	82
β2m + KIM-1 + NGAL		combined tresholds	54	92
β2m		4.5 µg/min**	46	92

* β2m concentration could not be determined in four samples because of a urinary pH < 6.0
** Elevated cut-off value with specificity equal to combined tresholds of β2m, KIM-1, and NGAL

Clinical and Histological Prognostic Factors in Idiopathic Membranous Nephropathy: Long Term Evaluation Antonello Pani, Floris Matteo, Patrizia Melis, Maura Conti, Riccardo Cao, Matteo Floris, Andrea Angioi, Valeria Matta. *Nephrology, G Brotzu Hosp, CA, Italy.*

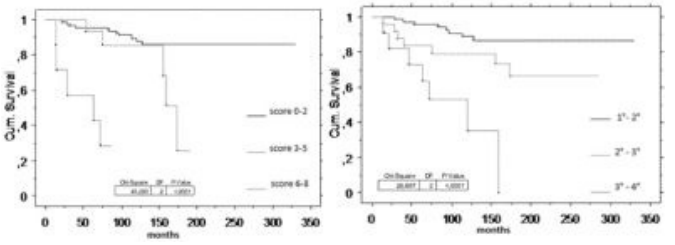
Background: We review our cumulative series of pts (>20yrs) with IMN and Nephrotic Syndrome (NS) in order to evaluate the long term outcome, the role of therapy in influencing remission, the histological prognostic factors and the clinical course of relapses.

Methods: Our report includes 114 pts (M=70, F=44) with biopsy-proven IMN and NS at presentation treated with IS therapy (80.7% Ponticelli's Scheme; 18.4 steroids alone; 0.9 Cyclosporin). Histological lesions (HL) were graded according to: **a**) glomerular stage: from 1 to 4; **b**) percentage of glomerular sclerosis (GS); **c**) tubulo-interstitial damage: from 0=absent to 3=severe; **d**) arteriolar lesions: from 0=absent to 3= severe**.** 1 year after the beginning of therapy**,** response was evaluated as: complete (**CR** proteinuria ≤0.3), partial (**PR**≤3.5 and>0.3), and non remission (**NR**>3.5).

Results: At diagnosis eGFR was below 60 in 29% of pts. At the end of follow up ESRD occurred in 20.1% and 25.4% had died. The censored renal survival rates at 5 and 20 yrs were 91.1 and 71.1%; we observed 53 relapses in 31 pts. Cumulative survival at 5 and 20 yrs was 90.9 and 66.5%. We obtained the histological score by summing the scores of parameters listed in **tab1** and then performing a correlation with long-term renal survival.

Parameter	Score (%)			
	0	1+	2+	3+
Tubulo-interstitial damage	65.4	26.1	6.5	2.8
Arterial-arteriolar lesion	73.8	18.6	6.5	0.9
Glomerular sclerosis		<15%	15-30%	>30%
		87.8	6.5	5.6
Glomerular stage		1° - 2°	2° -3°	3° - 4°
		67.5	22.5	9.9

Tab.1: Biopsy findings at presentation



Severity of lesions and glomerular stage predicted lower renal survival. No significant differences were observed in renal outcome between pts who had 1 or more relapses and those who never relapsed.

Conclusions: An overall response rate (**CR**+**PR**) of 63% was obtained,with a favourable trend in PR compared to NR (all in ESRD after 15 yrs). Pts with severe HL at presentation had worse prognosis, and glomerular stage statistically correlated to lower renal survival. The main prognostic negative factors at presentation were elevated SCr and low GFR. GS has been identified as an independent prognostic factor.

SA-PO373

Efficacy and Safety of Rituximab Plus Cyclosporine in Idiopathic Membranous Nephropathy: Initial Report of an Ongoing Prospective Trial

Meryl A. Waldman, Michelle Braun, Howard A. Austin. *National Institute of Diabetes and Digestive and Kidney Diseases, National Institute of Health, Bethesda, MD.*

Background: Cyclosporine (Csa) reduces proteinuria in idiopathic membranous nephropathy (IMN) but partial remissions(PR) rather than complete remissions(CR) are common & relapse upon drug withdrawal is problematic. Extending treatment may increase remissions & reduce relapses but potential for nephrotoxicity is a concern. Rituximab (RTX) has shown promise in IMN but PRs are more common & effect on proteinuria tends to be delayed for many mos exposing pts to the effects of nephrotic syndrome (NS) for longer periods. We are conducting a prospective trial (NCT00977977) in IMN pts to investigate whether "induction"with RTX +Csa followed by "maintenance" RTX achieves greater reduction in proteinuria than either agent alone, increases % CRs & reduces relapse rate. Here we report the interim data.

Methods: Patients with high grade proteinuria despite conservative treatment for minimum(min) 6 mos & eGFR≥40 ml/min/1.73 m^2 receive RTX (1 gm day 1,15) +Csa x6 mos (then tapered); 2nd course of RTX given after min of 6 mos *and* evidence of B cell recovery.

Results: To date 8 pts have been treated. All pts showed progressive rise in proteinuria (± decline in renal fxn) during conservative treatment. Mean eGFR:57 ml/min/1.73 m^2(range 37 -90); Proteinuria 11.2 g/24 hrs (8-14). 5 pts completed a min of 6 mos f/u. At 6 mos,cumulative remission rate: 80%; 3 (60%) PR(def: proteinuria ≤3.5g/d+ ≥ 50% reduction);1(20%)CR (def: ≤0.3 g/d). No relapses. Regimen was well tolerated. 1 pt developed late onset neutropenia.

Table: Trend in Proteinuria

Pt #	Baseline	2 mos	3 mos	6 mos	9 mos	12 mos	15 mos
1	11.2	8.9*	10.9	10.8	14	5.7	1.5*
2	10.5	0.8*	1.1	0.2	0.3	0.1	0.2
3	14.1	-	6.4	3.4	2.1		
4	14	1.7*	1.1	0.9	0.35		
5	8.0	2.7	1.9	1.2			
6	9.8	8.2	7.2				
7	9.6	0.5					
8	12.6	4.1					

24 hr urine collections (g/24 hrs) unless indicated; * spot pr/cr ratio (mg/mg)

Conclusions: "Induction" with combination RTX + Csa followed by "maintenance" RTX may be an approach for IMN to achieve more rapid remission of the NS & may obviate the need for long term immunosuppression. It appears to be well tolerated. Enrollment continues. Long term f/u is needed.

Intravenous Methylprednisolone Therapy Accelerated Complete Remission of Proteinuria in Adult Patients with Minimal Change Nephrotic Syndrome

Maki Shinzawa,[1] Ryohei Yamamoto,[1] Yasuyuki Nagasawa,[1] Susumu Oseto,[2] Daisuke Mori,[3] Kakuya Niihata,[4] Kodo Tomida,[5] Masaaki Izumi,[5] Megumu Fukunaga,[2] Atsushi Yamauchi,[3] Yoshiharu Tsubakihara,[4] Hiromi Rakugi,[1] Yoshitaka Isaka.[1] *[1]Geriatric Medicine & Nephrology, Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [2]Internal Medicine, Toyonaka Municipal Hospital, Toyonaka, Osaka, Japan; [3]Nephrology, Osaka Rosai Hospital, Sakai, Osaka, Japan; [4]Kidney Disease and Hypertension, Osaka General Medical Center, Osaka, Japan; [5]Internal Medicine, Kansai Rosai Hospital, Amagasaki, Hyogo, Japan.*

Background: The effects of intravenous methylprednisolone therapy (mPSL) on complete remission (CR) of urinary protein in patients with minimal change nephrotic syndrome (MCNS) are controversial because of insufficient sample size study. The present study aimed to clarify the effects of mPSL on CR in the largest cohort of adult patients with new-onset MCNS in the world.

Methods: The present Japanese multicenter retrospective cohort study included 125 patients who were ≥15 years, diagnosed as new-onset MCNS by renal biopsy in 5 major nephrology centers between 2000 and 2009, and initiated corticosteroid therapy. Predictors of CR were identified using Log-rank test and univariate and multivariate Cox proportional hazards models. To control confounding by indication, we used propensity score (PS), an estimated probability of use of mPSL.

Results: Baseline characteristics of 125 patients before initiated corticosteroid therapy were age 40(23-62) yr (median (interquartile)), male 64%, creatinine 0.9(0.7-1.3)mg/dL, and urinary protein 8.4(4.0-14.5)g/day. Time to CR was significantly shorter in 65 patients with initial mPSL than 60 patients without initial mPSL (11[8-20] vs. 19[12-37] days, P<0.001). Patients with mPSL had significantly higher cumulative probability of CR, compared with those without mPSL (P=0.006). Use of mPSL was identified as predictor of early CR in multivariate Cox proportional hazards model (HR1.54 [95%CI 1.05-2.26], P=0.026) and PS-stratified model (1.47[1.01-2.14], P=0.042).

Conclusions: In adult patients with new-onset MCNS, mPSL accelerated complete remission of proteinuria.

SA-PO375

Rituximab in Steroid-Dependent or Multirelapsing Nephrotic Syndrome of Adults and Children: Results from the NEMO Trial

Piero Ruggenenti,[1,2] Barbara Ruggiero,[1] Paolo Cravedi,[1] Marina Vivarelli,[3] Laura Massella,[3] Maddalena Marasa',[1] Annalisa Perna,[1] Antonietta Chianca,[1] Nadia Rubis,[1] Mauro Abbate,[1] Francesco Emma,[3] Giuseppe Remuzzi.[1,2] *[1]Mario Negri Institute for Pharmacological Research, Bergamo, Italy; [2]Ospedali Riuniti di Bergamo, Italy; [3]Bambino Gesù Children Hospital, Roma, Italy.*

Background: Treatment of steroid dependent or multirelapsing minimal change disease (MCD) and focal-segmental glomerulosclerosis (FSGS) is burdened by major side effects.

Methods: In this prospective, sequential, open-label, multicentre trial, 24 patients (10 children) with steroid-dependent or multirelapsing MCD (n=16) or FSGS on remission while on maintenance immunosuppression, received one (n=22) or two (n=2) 375 mg/m^2 rituximab (RTX) infusions to deplete B cells. Concomitant treatment back-titration up to withdrawal was planned over 6-9 months. Primary aim was to compare intra-patient incidence of NS relapses 1 year post vs pre RTX.

Results: Over 1 year post-RTX there were 19 relapses compared to 72 in the year before [p<0.0001]. Event reduction was similar in children vs adults and MCD vs FSGS.

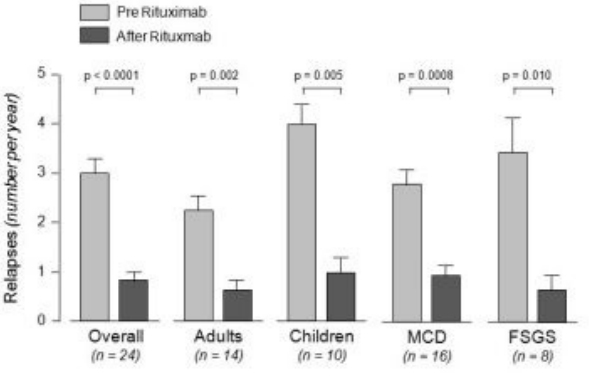

Figure1. Incidence of NS relapses before and after rituximab in the study group as a whole (Overall) and according to age and diagnosis

Eleven patients never relapsed after RTX and 14 were in remission at 1 year post-RTX without any immunosuppression. In parallel with reduced cumulative doses of steroids, calcineurin inhibitors and anti-proliferative agents (p=0.005, p<0.01, p<0.005 vs pre RTX, respectively), hypertension and dyslipidemia improved in all patients. Children resumed normal growth. There were no RTX-related side effects.

Conclusions: RTX is a valuable option to safely maintain remission and avoid /limit chronic immunosuppression in steroid-dependent or multirelapsing MCD and FSGS, in adults as well in children.

Funding: Government Support - Non-U.S.

SA-PO376

Impact of Rituximab on Growth, Weight and Bone in Children with Intractable Steroid Dependent Nephrotic Syndrome Mai Sato, Akinori Miyazono, Takuya Fujimaru, Masao Ogura, Koichi Kamei, Shuichi Ito. *Division of Nephrology and Rheumatology, National Center for Child Health and Development, Tokyo, Japan.*

Background: Treatment for childhood steroid-dependent nephrotic syndrome (SDNS) is still challenging. Patients often suffer a lot of serious adverse events due to steroid such as growth retardation, obesity and osteoporosis. These adverse events impair the adherence and also cause behavioral and psychological difficulties. There is increasing evidence of the efficacy of rituximab (RTX) against intractable SDNS. We examined the impact of RTX on growth retardation, obesity and osteoporosis in SDNS.

Methods: Fourteen patients with SDNS, who has been intractable despite of multiple immunosuppressive agents, were treated with RTX. RTX infusion was given 1 to 7 times and the mean follow-up after the first RTX infusion was 2.4 years. We compared height (standard deviation), obesity index and bone mass density (BMD) between before RTX infusion and the last visit. We assessed improvement of these items before and after RTX use.

Results: Number of relapses and the cumulative dose of prednisone were significantly decreased by RTX. Thirteen (92.8%) of the 14 patients had significantly improved height SD (n=14, before vs after: -1.28 SD vs -0.69SD; paired t- test. P=0.03) and obesity index (n=14, 23.6% vs 9.19%: paired t-test, p=0.026). All patients had significantly improved BMD z-scores (n=5, -3.52 vs -1.94; paired t-test, p=0.03). There were no severe adverse events except for treatable agranulocytopenia in one patient.

Conclusions: RTX could confer significant improvement of growth, obesity and osteoporosis in children with intractable SDNS, which may contribute to in improvement of activities of daily living and quality of life.

SA-PO377

Immune Modulatory Mechanism of Rituximab in Steroid Refractory Heavy Proteinuria Ching-Yuang Lin.[1,2] *[1]Clinical Immunology Center, China Medical University Hospital, Taichung, Taiwan; [2]College of Medicine, China Medical University, Taichung, Taiwan.*

Background: Heavy proteinuria was a risk factor for chronic kidney disease in later life. Rituximab has been suggested is a one of the therapeutic options. We hypothesized that rituximab may induce remission of heavy proteinuria and preserve $CD8^+FoxP3^+$ regulatory T (Treg) cell function, decrease IL-17 secreting T cell (T17) cell and serum IL-17A level.

Methods: We studies 66 refractory heavy proteinuria patients with open-label randomized controlled study with or without rituximab treatment for 6 months. All of them received renal biopsy. 33 of whom were treated with rituximab. $CD4^+FoxP3^+$, $CD8^+FoxP3^+$, $CD4^+T17$ and $CD8^+T17$ cells in peripheral blood mononuclear cells and renal biopsy specimens, suppressive activity and granzyme B expression of $CD8^+FoxP3^+$ Treg cells and serum IL-17A level were studied before and after rituximab treatment.

Results: Rituximab treatment was associated with induction of remission and recovery of circulating T17/Treg ratio in patients with IgM nephropathy (IgMN) and focal segmental glomerular sclerosis (FSGS). Treg cells were rare and T17 cells were abundant in renal tissue from FSGS and IgMN patients. After rituximab therapy, T17 cells almost disappeared and Treg cells were noted particalarly in renal tissue of responsive cases. The decreased population of T17 cells were concurrent with decreased plasma IL-17A levels and suppressive activity in $CD8^+FoxP3^+$ Treg cells after rituximab treatment. $CD8^+T17/CD8^+$ Treg ratio in PBMCs were correlated with Δ dailyurine protein in rituximab responsive cases. Rituximab was no effectiveness in IgA nephropathy, idiopathic crescentic glomerulonephritis.

Conclusions: Our study suggests that treatment of refractory heavy proteinuria in patients with IgMN or FSGS by rituximab might induce remission by modulating Treg/T17 cell number and function.

SA-PO378

Longterm Effects of LDL Apheresis for the Drug Resistant Nephrotic Syndrome Evidenced in a Prospective Observational Cohort Study (POLARIS) Eri Muso,[1] Takao Saito.[2] *[1]Nephrology and Dialysis, Kitano Hospital, the Tazuke Kofukai Medical Research Institute, Osaka, Japan; [2]Nephrology and Rheumatology, Fukuoka University Hospital, Fukuoka, Japan.*

Background: LDL apheresis (LDL-A) has been applied for drug-resistant nephritic syndrome (NS) as an alternative therapy to induce remission via improving hyperlipidemic condition. A multicenter prospective study, POLARIS (Prospective Observational Survey on the Long-Term Effects of the LDL-Apheresis on the Drug Resistant Nephrotic Syndome) was conducted and final data were analyzed under the preliminary results of nearly half of enrolled patients being provided early relief from NS (ASN 2009).

Methods: Refractory nephrotic syndrome patients who had been resistant to primary medication for at least 4 weeks were prospectively recruited to the study and treated with LDL-A (2 sessions/week, max. 12 sessions). The clinical efficacy was evaluated based on the rate of the patients who achieved remission of nephrotic state defined as proteinuria (UP) level of <1.0g/day after 2years follow-up. Parameters before start or at the completion of LDL-A that affect clinical efficacy were also examined.

Results: 58 refractory NS patients were recruited to the POLARIS study and treated with LDL-A in 40 facilities. Two-year follow-up data were obtained in 44 patients and 21 (47.8%) had preferable outcome achieving UP level <1.0g/day. Moreover 11 (25.0%) maintained remission state throughout follow-up period without any relapse. The UP level at the completion of the LDL-A in these patients ware significantly lower than the others (1.68±1.75 g/day vs 6.18±3.54 g/day, p<0.001). The improvement rate of UP, serum albumin, and serum creatinine during LDL-A also affected clinical efficacy.

Conclusions: Nearly half of drug-resistant NS showed remission even 2 years after LDL-A. Prognosis of patients who responded LDL-A and exerted an improvement of nephrotic parameter are likely to be favorable.

Funding: Private Foundation Support, Government Support - Non-U.S.

SA-PO379

Plasmapheresis in Steroid-Resistant FSGS Tej K. Mattoo,[1] Mark Mentser,[2] Frederick J. Kaskel,[3] William E. Smoyer,[2] Lena Peschansky.[1] *[1]Pediatrics, Children's Hospital of Michigan, Detroit, MI; [2]Pediatrics, Nationwide Children's Hospital, Columbus, OH; [3]Pediatrics, The Children's Hospital at Montefiore, Bronx, NY; [4]Pediatrics, Nationwide Children's Hospital, Columbus, OH; [5]Pediatrics, Children's Hospital of Michigan, Detroit, MI.*

Background: FSGS causes end-stage renal failure in about 15% of children and 5% of adults. Only about 30%-50% of patients with FSGS respond to any therapeutic intervention. Experimental findings support the possibility of a circulating factor as the cause for FSGS.

Methods: The primary objective of this randomized, prospective study was to evaluate the role of plasmapheresis with and without tacrolimus in patients with steroid-resistant native kidney FSGS. A total number of 14 patients were randomized to tacrolimus only (Group I) or tacrolimus with 15 sessions of plasmapheresis (Group II). The primary study end-point point was the number of patients in complete remission (urine protein/creatinine ≤ 0.2) at 6 months.

Results: The results of the study primary end-point for group I and 2 are shown in the table. No significant differences existed in age (13 ± 4.2 Vs 13.6 ± 2.7), gender and racial distribution of the patients in the two groups. The mean serum creatinine (1.15 ± 1.1 Vs 1.4 ± 0.8), mean serum albumin (3.4 ± 0.8 Vs 3.8 ± 0.4) and the mean serum tacrolimus (6.9 ± 1.0 Vs 6.7 ± 3.3) levels between group 1 and 2 at the time of study conclusion were also not significantly different. Additional data were collected in patients who continued follow-up at 12 months after randomization.

	Mean Urine Pr/Cr Ratio				Number of Patients in Remission At 6 Months	Extended Follow-UP At 12 Months	
	Baseline	6 Weeks	3 Months	6 Months		Urine Pr/Cr	Patients in Remission
Group 1 (n=8)	6.8±5.7	4.4±5.3	4.2±4.4	2.0±2.5	1 (12.5%)	3.9±7.8 (n=5)	2
Group 2 (n=6)	5.1±2.8	2.3±2.0	1.8±2.1	1.3±1.1	2 (33%)	4.4± 6.8 (n=6)	1*
P Value	<0.5	<0.3	<0.2	<0.5			

*The second patient became non-compliant with medication and follow-up

Conclusions: The study did not reveal any significant difference in proteinuria at 6 months. The major limitation of the study was the sample size; invasive nature of plasmapheresis made patient recruitment difficult.

Funding: NIDDK Support

SA-PO380

Role of Immunosuppressive Therapy in Renal Survival in Collapsing Focal Segmental Glomerulosclerosis (FSGS) Louis-Philippe Laurin,[1] JulieAnne G. McGregor,[1] Vimal K. Derebail,[1] Susan L. Hogan,[1] Caroline Jennette Poulton,[1] Adil M.H. Gasim,[2] J. Charles Jennette,[2] Ronald J. Falk,[1] Patrick H. Nachman.[1] *[1]Division of Nephrology and Hypertension, University of North Carolina, Chapel Hill, NC; [2]Department of Pathology and Laboratory Medicine, University of North Carolina, Chapel Hill, NC.*

Background: Idiopathic collapsing FSGS has historically been associated with poor renal prognosis. Minimal clinical data exists on the efficacy of immunosuppressive therapy, specifically calcineurin inhibitors.

Methods: Inception cohort study of biopsy-proven collapsing FSGS patients diagnosed between 1989 and 2012. Statistical analysis performed with Mann-Whitney or Fisher's exact tests. Time to end-stage renal disease (ESRD) was reported with Cox regression hazard ratio (HR) with 95% confidence interval (CI).

Results: 42 patients studied: age 34±16 years; 64% Black; and 52% female. Baseline eGFR 53±29mL/min/1.73m^2; proteinuria 12±7g/d; serum albumin 2.5±1.0g/dL; and follow-up time 37±30mo. 32 patients (76%) treated with immunosuppression (7 with steroids alone and 23 with calcineurin inhibitors). Treated patients had a trend towards a higher baseline eGFR (55±29 vs. 43±24mL/min/1.73m^2, p=0.2). More treated patients had either complete (proteinuria <0.3g/d) or partial (decrease in proteinuria >50% and <3.5g/d) remission [18/29 (62%) (treated) vs. 1/7 (14%) (untreated), p=0.04]. 17 patients (40%) reached ESRD. Patients receiving immunosuppressors were less likely to reach ESRD [9/32 (28%) vs. 8/10 (80%), p=0.008]. In univariate analyses, immunosuppression (HR 0.38, 95%CI 0.14-0.99, p=0.049) and higher baseline eGFR (HR 0.97, 95%CI 0.948-0.995, p=0.02) were associated with a better renal survival. In multivariate analysis, baseline eGFR predicted better renal survival (HR 0.97, 95%CI 0.948-0.997, p=0.03), and effect

of immunosuppression on renal survival persisted after controlling for baseline eGFR, but was not statistically significant (HR 0.61, 95%CI 0.2-1.8, p=0.4).

Conclusions: Immunosuppression may be associated with an improved renal survival in collapsing FSGS. A larger cohort of patients is needed to better define response to therapy.

SA-PO381

Treatment of Resistant Primary Focal Segmental Glomerulosclerosis (FSGS) with Adrenocorticotropic Hormone (ACTH) Gel Jonathan J. Hogan, Andrew S. Bomback, Pietro A. Canetta, Maya K. Rao, Gerald B. Appel, Jai Radhakrishnan. *Department of Internal Medicine, Division of Nephrology, Columbia University Medical Center, New York, NY.*

Background: Immunosuppression-resistant FSGS often leads to ESRD. ACTH has shown efficacy in resistant nephrotic syndrome, but data are limited with ACTH treatment of FSGS.

Methods: In this retrospective case series, 12 patients with primary FSGS and nephrotic syndrome resistant to previous immunosuppression were administered ACTH gel (median dose 80 units subcutaneously SC twice weekly) for a median of 26 (range 12-56) weeks of therapy. Complete remission was defined as stable/improved serum Cr and a sustained fall in proteinuria to <500 mg/day by last follow-up, and partial remission as stable/improved serum Cr with 50% reduction proteinuria to 500-3500 mg/day by last f/u.

Results: Median age was 41 (range 18-66) years and median time from diagnosis to treatment was 30 (range 2-276) months. Median eGFR was 33 (range 17 to 116) mL/min/1.73m^2 and median proteinuria 6100 (range 1600 to 16,800) mg/day. FSGS subtypes were tip lesion (n=6), NOS (n=4) and cellular (n=2). All patients had previously received prednisone and had failed or relapsed after at least 2 (median 3) prior immunosuppressive therapies, and 10 patients had failed at least 3 therapies. Five of 12 patients experienced partial remission at last follow-up (median follow-up time 58 (range f/u 4-82) weeks after stopping ACTH).

Serum Creatinine and Proteinuria for Patients Experiencing Partial Remission with ACTH

Pre-ACTH Cr (mg/dL)	Pre-ACTH Proteinuria (mg/day)	Post-ACTH Cr (mg/dL)	Post-ACTH Proteinuria (mg/day)	Cr at last f/u (mg/dL)	Proteinuria at last f/u (mg/day)	F/U (wks) after stoping ACTH
2.3	4000	1.3	963	1.3	1297	11
1.1	5200	0.7	1500	0.7	960	28
1.2	2100	1.4	272	1.3	641	82
1.6	10,300	1.2	5380	1.6	1277	56
3.6	15,200	1.3	891	1.1	1810	4

The median time-to-remission was 6 (range 6-24) weeks. No severe adverse events were reported. No clinical or biopsy characteristics predicted response to ACTH therapy.

Conclusions: ACTH gel is a useful treatment option for some patients with nephrotic syndrome due to immunosuppression-resistant primary FSGS, with partial remissions observed in 5 of 12 patients.

SA-PO382

Long-Term Follow Up of Rituximab Treatment for Fibrillary Glomerulonephritis Jonathan J. Hogan, Michaela Restivo, Pietro A. Canetta, Jai Radhakrishnan, Gerald B. Appel, Andrew S. Bomback. *Department of Internal Medicine, Division of Nephrology, Columbia University Medical Center, New York, NY.*

Background: Approximately 50% of patients with fibrillary glomerulonephritis (GN) progress to ESRD within 2 yrs of diagnosis, and no standard therapy exists. A previous case series reported short-term disease remission in 3 pts treated with rituximab, but data on larger cohorts with longer f/u are lacking.

Methods: We retrospectively reviewed all cases of fibrillary GN at Columbia University Medical Center treated with rituximab. Nonprogression of disease was defined as stable/improved serum Cr with a minimum of 1 yr of f/u for those who did not reach ESRD.

Results: Eleven pts (8 women, all caucasian) with fibrillary GN were treated with rituximab (1 gm IV X 2 doses or 375 mg/m^2 X 4 doses); 4 received concomitant oral steroids. All were on ACEI or ARB therapy. Median age at diagnosis was 57 yrs (range 38-68). Median time from diagnosis to treatment was 5 mo (range 1.2-83). Median Cr at rituximab initiation was 2.1 mg/dl (range 0.7-3.0) and median proteinuria 4497 mg/day (range 210-7400). Light microscopy findings were mesangioproliferative GN(n=2), MPGN(n=7), endocapillary proliferative GN(n=1), and diffuse proliferative/crescentic GN (n=1). Four pts had received immunosuppression before rituximab and 9 received immunosuppression after rituximab, with 4 pts receiving a second rituximab course. At last f/u, 2 pts were non-progressors; 5 progressed to more advanced CKD and 4 reached ESRD.

Detailed Data for Nonprogressors

Age, Gender	Light Microscopy Finding	Pre-Rituximab Cr (mg/dL)	Pre-Rituximab Proteinuria (mg/day)	Last Cr (mg/dL)	Last Proteinuria	F/U time (mo) after Rituximab (mg/day)	Immunosuppression after Rituximab
46, Female	MPGN	0.7	3000	0.7	4065	76	Tacrolimus, *Rituximab
67, Female	MPGN	2.3	1300	2.0	135	26	Steroids, *Rituximab

*Both pts received a second course of rituximab

Median f/u after rituximab for non-ESRD pts was 33 mo (range 24-76). No significant adverse events were reported.

Conclusions: In the largest case series describing long-term f/u of fibrillary GN after rituximab, 2/11 pts had nonprogression of disease, 5/11 progressed to more advanced CKD and 4/11 reached ESRD.

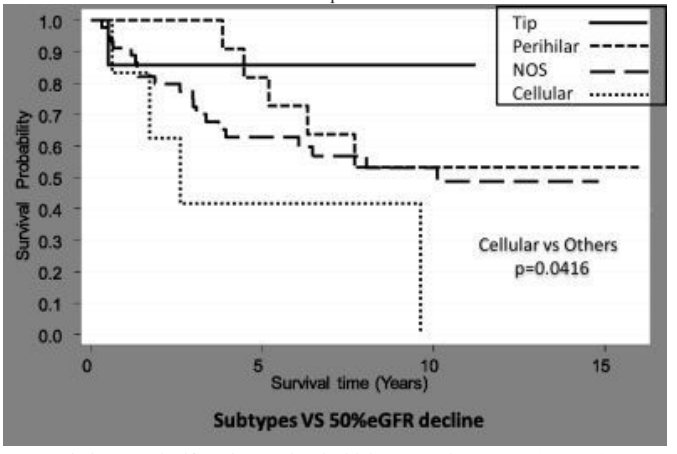
SA-PO383

Impact of Pathological Subtypes on Long-Term Outcomes of Focal Segmental Glomerulosclerosis Montira Assanatham,[1] Panas Chalermsanyakorn,[2] Suchin Worawichawong,[2] Vasant Sumethkul,[1] Pinkaew Klyprayong,[1] Chagriya Kitiyakara.[1] *[1]Renal Division, Department of Internal Medicine, Ramathibodi Hospital, Mahidol University, Bangkok, Thailand; [2]Department of Pathology, Ramathibodi Hospital, Mahidol University, Bangkok, Thailand.*

Background: It has been proposed that primary Focal Segmental Glomerulosclerosis (FSGS) can be divided into different histopathological subtypes. Initial data from western population show that different subtypes may have different characteristics and outcomes. To date, there is no long-term outcome data in Asian populations. Our main goal is to define the frequency and long-term outcome for each subtypes in Thai patients.

Methods: A retrospective analysis of primary FSGS diagnosed at Ramathibodi Hospital from 1993 to 2006 was conducted. FSGS subtypes were classified by 2 experienced renal pathologists. Duration from diagnosis to remission (complete and partial), 50% GFR decline and end stage renal disease (ESRD) was documented. Log-rank survival and multiple logistic analysis was performed.

Results: The median follow-up was 79 months for all FSGS (n=84). The frequency of each subtype was: NOS 56%, perihilar 26.2%, tip 9.5%, cellular 8.3%, and collapsing 0%. Baseline demographic characteristics for each subtype were similar. Tip variant had a better presenting renal function and higher remission rates. By multivariate analysis, cellular variant was associated with more rapid GFR decline.



Remission was significantly associated with better renal outcomes (p<0.001).

Conclusions: In our cohort, NOS was the most common subtype. In contrast to western studies, the collapsing variant was not found. Tip variant tended to had better renal outcomes while cellular variant was independently associated with rapid GFR decline. Finally, remission was associated with better renal outcomes regardless of subtypes.

SA-PO384

Clinical and Laboratorial Findings of 26 Patients with Collapsing Glomerulopathy: A Single Center Experience Andrea C.E.P. Valenca, Maria Carolina N.R. Neves, Luis H.B.C. Sette, Gisele Vajgel Fernandes, Maria Alina G.M. Cavalcante, Lucila Maria Valente. *Nefrologia, Hospital das Clinicas-UFPE, Recife, Pernambuco, Brazil.*

Background: Collapsing glomerulopathy (CG) is an aggressive form of kidney disease. Is characterized by heavy proteinuria associated with rapidly progressive renal failure and poor renal outcome. Originally described as a condition associated with HIV infection, it is known that there are several etiological factors involved with this histological finding. Here we describe an experience of clinical series followed in our institution.

Methods: We retrospectively analyzed 26 patients with biopsy proven CG from 1998-2012; all of them had at least one glomerulus with defining features: glomerular capillary tuft collapse and overlying podocyte hypertrophy and hyperplasia.

Results: Epidemiological, clinical manifestations and outcomes are described below. Etiological classification showed that the idiopathic form was most common 17 cases, followed by: HIV 3; lupus 2; interferon 1; anabolic steroids 1; lymphangioleiomyomatosis 1; pamidronate 1.

Demographics, Clinical Presentation and Outcomes

	N=26
Age (mean)	34 ± 14.4
Female (%)	61.5
Black (%)	7.6
Nephrotic syndrome (%)	69.2
HTN (%)	38.5
MAP (mmHg)	96 ± 17.6
sCr (mg/dl) (mean)	2.96 ± 2.6
sCr > 1.2 mg/dL (%)	88
Albumin (g/dL)	2.13 ± 0.75
Proteinuria (g/day)	11.2 ± 5.7
Follow up (mean)	37.8 ± 42
ESRD 12-months follow up (%)	46
ESRD (during follow up) (%)	69.2
Time to ESRD (mean)(months)	10.5 ± 8.8
Steroids therapy (%)	73

HTN Hypertension ;MAP=mean arterial pressure;ESRD= End Stage Renal Disease; Numbers are means ± or percentages; sCr= Serum Creatinine

Conclusions: We described series of cases of CG. We found heavy proteinuria and high proportion of patients developing ESRD. These findings are consistent with the results of other studies. Some etiological factors were identified, although the most common was idiopathic.

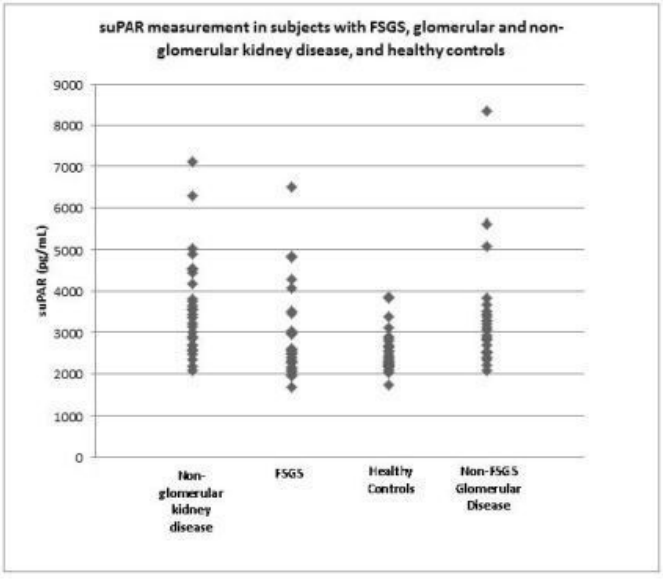
SA-PO385

Circulating Serum Soluble Urokinase Receptor (suPAR) Is an Unlikely Cause of Childhood Focal Segmental Glomerulosclerosis Margret E. Bock, Heather E. Price, Craig B. Langman. *Pediatrics, Northwestern University, Feinberg School of Medicine, Chicago, IL.*

Background: Focal segmental glomerulosclerosis (FSGS) is the primary cause of childhood nephrotic syndrome leading to end-stage kidney disease. Permeability factors, recently including circulating serum soluble urokinase receptor (suPAR), have been postulated as putative causes in adults with primary FSGS. Similar results have yet to be proven in children.

Methods: We investigated the pathogenic role of suPAR in children with FSGS or other glomerular and non-glomerular kidney disease.

Results: We studied 110 subjects, aged 1-21 years, of which 28 patients had FSGS, 25 had non-FSGS glomerular disease, 28 had non-glomerular chronic kidney disease, and 29 subjects were healthy controls. Age, gender and race were similar across study groups (p>0.05). suPAR levels did not differ in subjects with FSGS, non-FSGS glomerular disease and healthy controls (p>0.05). However, suPAR levels (mean ± SD) were higher in children with non-glomerular chronic kidney disease (3607±1201 pg/mL) as compared to healthy controls (2522 ±507 pg/mL; p = 0.001). Notably, only in African American (AA) children were suPAR concentrations higher in those with FSGS as compared to AA children with other kidney diseases (p = 0.01); this trend was not found in Latino or Caucasian patients. Males with nephrotic range-proteinuria (UPr/Cr >2), independent of primary kidney disease, had higher suPAR levels than those without significant proteinuria (4434 ±1916 vs. 3245±1012, respectively, p = 0.015). This trend was not seen among females, and suPAR levels in all female subjects were lower than in males, p=0.036.



Conclusions: Although we found an interaction with ethnicity and gender in suPAR, we cannot implicate its levels as a relevant biomarker for all childhood FSGS. The mechanisms for the high suPAR in AA children with FSGS remain uncertain.

SA-PO386

Human Ultrastructure Changes of Podocyte Foot Processes during the Remission Phase of Minimal Change Disease Gang Liu, Xiaojing Liu, Jing Huang, Yi-miao Zhang, Su-xia Wang. *Renal Division, Department of Medicine, Peking University First Hospital, Beijing, China.*

Background: To observe the ultrastructure changes of podocyte foot processes and its relationship with the amount of the proteinuria in the remission phase of patients with minimal change disease (MCD).

Methods: Electron micrographs of glomerular capillaries were randomly taken from 36 adult cases with MCD, including 14 cases with nephrotic syndrome, 17 cases in partial remission (PR) and 5 cases in complete remission (CR). The "ridges", projections from "fused" podocyte foot process, were classified into two groups by the ratio of the height to basal width (0.5 or ≥1.0). Similarly, the foot processes were classified into three groups by the ratio (0.5-1, 1-2 and ≥2). The foot process width (FPW), the number of "ridge" and the number of foot processes per 10 μm of glomerular basement membrane (GBM) were measured. Twelve age- and gender-matched renal tissues, obtained from the nephrectomized specimens of renal tumors, were enrolled as controls.

Results: There were statistical differences in the mean FPW among the nephrotic group (1598.4±417.3nm), PR group (997.5±225.3nm), CR group (1031.5±224.8nm) and normal controls (471.9±51.8nm) (*P<0.001*). The mean FPW is positively related with the amount of proteinuria (r=0.51, *P=0.001*). For the height-to-width ratio ≥0.5, the number of "ridges" per 10 μm GBM was significantly greater in the CR group than that in the nephrotic group (1.66±0.35 vs 0.87±0.49, *P=0.001*) and normal controls (1.66±0.35 vs 0.84±0.4, *P=0.001*). As for the "ridges" with height-to-width ratio ≥1, the results were similar (the CR group vs the nephrotic group: 1.17±0.22 vs 0.52±0.36, *P<0.001*; the CR group vs normal controls: 1.17±0.22 vs 0.68±0.36, *P=0.003*).

Conclusions: In patients with MCD, as the amount of proteinuria decreased, the mean FPW decreased and the number of "ridges" and foot processes increased. Especially in CR phase, more and higher "ridges" occurred in the still "fused" foot processes before mature foot processes recovered.

SA-PO387

Role of Serum Level of Soluble Urokinase Receptor in Various Biopsy-Proven Kidney Diseases and Staging Effect in Diabetic Nephropathy Jin-Shuen Chen,[1] Yuh-feng Lin,[1] Wei-ya Lin,[2] Kuo-hsiung Shu,[3] Chi-Hung Cheng,[3] Han-hsiang Chen,[4] Chih-Jen Wu,[4] Chwei-Shiun Yang,[5] Tzu-ling Tseng.[2] *[1]Tri-Serv General Hosp, Taiwan; [2]ITRI; [3]Taichung Veterans General Hosp; [4]Mackay Memorial Hosp; [5]Cathay General Hosp, Taiwan.*

Background: To date, the role of soluble urokinase receptor (suPAR) in various biopsy-proven kidney diseases, including nephrotic, nephritic, and tubulointerstitial kidney diseases, and staging effect in diabetic nephropathy is still unknown.

Methods: First, serums were collected from groups including healthy control/HC, nephrotic cases (minimal change disease/MCD, membranous nephropathy/MN, FSGS, DN), nephritic cases (IgA nephropathy/IgAN, lupus nephropathy/LN) and tubulointerstitial cases/CIN at medical centers of the **Taiwan Renal Biomarker Consortium**. More than 140 cases of disease groups were proved by renal biopsy. Second, serums from different stages of diabetic nephropathy were also studied. Soluble uPAR ELISA kits were used to study all serum samples. Also, the expression of uPAR in renal tissues was tested by immunohistochemistry. Finally, the relationship among serum suPAR, renal function (represent by estimated glomerular filtration rate, eGFR) and the amount of daily protein loss (DPL) was investigated.

Results: As for the first part, the serum level of suPAR in various kidney diseases was CIN>FSGS, DN, MN, LN, IgAN>MCD, HC, suggesting group CIN had highest suPAR level. Furthermore, correlation between the serum level of suPAR of all kidney diseases and eGFR and DPL was calculated. We demonstrated that suPAR is significantly negative related to the eGFR (r = -0.67) and positive related to the amount of proteinuria (r = 0.26). Finally, the expression of uPAR in renal tissue from all kidney diseases showed MCD>MN, FSGS>CIN. Regarding the second part,the level of serum suPAR was as significantly increased as the staging development of DN and amount of proteinuria.

Conclusions: suPAR had the highest serum level and lowest expression in renal tissue in group CIN when compared to those samples with other kidney diseases. In addition, serum suPAR had a good correlation with stages of diabetic nephropathy, eGFR and amount of proteinuria.

SA-PO388

Serum Levels of Soluble Prorenin Receptor and Prorenin Are Modulated in Chronic Kidney Disease Patients Kazu Hamada,[1] Yoshiko Shimamura,[1] Koji Ogata,[1] Kosuke Inoue,[1] Toru Kagawa,[1] Masayuki Ishihara,[1] Kenji Yuasa,[2] Atsuhiro Ichihara,[3] Yoshio Terada.[1] *[1]Department of Endocrinology, Metabolism and Nephrology, Kochi Medical School, Kochi University, Naokoku, Kochi, Japan; [2]Kochi-Takasu Hospital, Kochi, Japan; [3]Department of Endocrinology and Hypertension, Tokyo Women's Medical University, Tokyo, Japan.*

Background: Prorenin is a precursor of renin and recent years it has been attracting attention that prorenin may be bound to the prorenin receptor (PRR) and prorenin may have a physiological activity. Also it has been elucidated that ligand binding sites of PRR are cleaved and present in the serum as soluble PRR. However dynamics of serum prorenin and soluble PRR in patients with CKD are unclear. We therefore examined the

clinical significance of measurement of the concentration of prorenin and soluble PRR in CKD patients.

Methods: Subjects are 315 CKD patients in our hospitals. After ethics committee approval of each facility, with informed consent, we measured the concentration of soluble serum PRR and the concentration of serum prorenin and general indicators of renal damage such as serum Cr and concentration of serum αKlotho which is known to be regulated by RAS.

Results: Concentration of soluble serum PRR was significantly higher in CKD stage 3-5 patients compared with stage 1-2 and they were positively correlated with serum Cr, BUN and UA ($p<0.0001$). On the other hand serum concentration of prorenin was significantly higher in patients with diabetes (n=46) than non-diabetic patients (n=268) ($p<0.0001$). Also in the group complicated with hypertension (n=169), serum prorenin concentration was higher than non-hypertension group (n=145). There was positive correlation between prorenin level and serum Cr, BUN and UA.

Conclusions: We demonstrate that concentration of soluble serum PRR is significantly higher in CKD stage 3-5 and it is suggested that soluble serum PRR may be involved in organ damage in patients with CKD. We also demonstrate that serum levels of prorenin is significantly higher in patients with diabetes and hypertension in patients with CKD. Therefore it is suggested that serum prorenin may be involved in CKD pathogenesis induced by diabetes and hypertension.

SA-PO389

Expression of Podocyte-Associated Molecules in Proteinuric Glomerulopathies Francisco José Veríssimo Veronese, Patrícia Garcia Rodrigues, Jonathan Fraportti do Nascimento, Gabriel Joelsons. *Nephrology, Hospital de Clínicas de Porto Alegre, Universidade Federal do Rio Grande do Sul, Porto Alegre, RS, Brazil.*

Background: Podocyte proteins may be a marker of kidney damage in proteinuric glomerulopathies (GP). This study investigated the mRNA profile of podocyte-associated molecules in GP.

Methods: Seventy-five adult patients were included; 35 with nonproliferative GP (NPG): FSGS, membranous, minimal change and diabetic nephropathy; and 41 with proliferative glomerulonephritis (PG): lupus nephritis, IgA nephropathy, membranoproliferative and crescentic nephritis. Eighteen controls (C) were included. Nephrin (nephr), podocin (pod), podocalixin (pdx), synaptopodin (syn) and alpha-actinin 4 (actin4) mRNA were quantified by real time PCR in kidney tissue and urinary sediment (at biopsy, 6 and 12 months). Standard immunosuppression and/or ACEi/ARB were used. mRNA was log transformed (median/IIQ).

Results: Tissue and urinary mRNA were presented in table 1. In tissue, all genes (except syn) were significantly decreased in both NPG and PG groups as compared to C. Urinary mRNA at biopsy was higher in the PG group (table 1), and gene transcripts of both PG and NPG groups did not differ from C at 6 and 12 months ($p>0.05$). Urinary mRNA correlated with proteinuria ($p<0.05$), but not with renal function.

mRNA tissue and urinary profile of podocyte molecules

Tissue mRNA	Controls	NPG	PG	P
Nephr	2.00(1.07-2.56)	0.87(0.02-1.10)	0.86(0.51-2.08)	0.009
Pod	2.04(1.43-3.04)	0.89(0.24-1.60)	1.12(0.05-1.85)	0.007
Pdx	1.86(1.21-2.53)	0.76(0.38-1.22)	0.96(0.39-1.75)	0.031
Actin4	1.70(1.39-2.57)	0.66(0.40-1.47)	1.01(0.41-1.60)	0.019
Urinary mRNA (at biopsy)				
Nephr	2.29(0.64-2.58)	2.13(1.69-3.17)	2.87(2.16-3.64)	0.015
Pod	1.92(0,85-3,05)	2.85(1.97-3.64)	4.82(4.15-5.52)	<0.001
Pdx	2.33(0.90-3.01)	2.98(2.41-3.94)	3.97(3.63-4.42)	<0.001
Actin4	1.42(1.11-2.23)	2.38(1.87-2.99)	2.42(2.05-3.16)	0.011

Conclusions: Expression of podocyte molecules were reduced in the kidney (for both NPG and PG) and increased in the urine (for PG), suggesting podocyte damage in tissue and podocyturia, as evidenced by lower and higher amounts of their mRNA in these compartments, respectively. Overall, after six months of immunosuppressive treatment, urinary mRNA in proteinuric GP did not differ from controls.

SA-PO390

Osteopontin (Opn) and Transforming Growth Factor Beta 1 (TGFb1) in Steroid Resistant Primary Focal Segmental Glomerulosclerosis (FSGS), FSGS-Clinical Trial (FSGS-CT) Experience Robert Woroniecki,[1] Zhongfang Du,[2] Milena Radeva,[4] Jennifer J. Gassman,[4] Debbie S. Gipson,[3] Howard Trachtman,[5] Aaron L. Friedman,[6] Frederick J. Kaskel.[1] *[1]Pediatric Nephrology, New York-Presbyterian, Columbia University Medical Center, New York, NY; [2]Pediatric Nephrology, Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY; [3]Michigan Institute for Clinical and Health Research, University of Michigan, Ann Arbor, MI; [4]Cleveland Clinic, Cleveland, OH; [5]Pediatric Nephrology, NYU Langone Medical Center, New York, NY; [6]University of Minnesota, Minneapolis, MN.*

Background: Urine and renal tissue Opn levels correlate with response to steroids (high Opn in minimal change disease (MCD), low in FSGS), and urinary TGFb1 level is increased in children with FSGS, but does not predict steroid response. We hypothesized that in steroid resistant subjects with FSGS, who do subsequently respond to other immunosuppressive therapy (RS), urinary Opn and TGFb1 levels will be lower than in those who do not respond to treatment (nRS).

Methods: Urine samples were obtained from 24 random subjects out of 138 recruited in the FSGS-CT (http://clinicaltrials.gov) that evaluated effectiveness of 2 arms of immunosuppressive treatment (IT); Cyclosporine/Prednisone(CsP) vs. MMF/dexamethasone (MD) in steroid resistant primary FSGS at 0, 26, 52, and 78 weeks. Opn and TGFb1 were measured by immunoassay (R&D). RS was defined as urine protein/Cr (UPC) ≤0.2 and nRS as UPC >0.2 during the 52 weeks after randomization.

Results: We analyzed 23 subjects (1 had missing data at week 52) in both arms of treatment (results at week 52, Table).

Subjects (N=23)	RS (N=6)	nRS (N=17)	p value
Age (years)	16.2 ± 12.1	21.4 ± 10.7	0.33t
BMI	25.5 ± 5.4	27.3 ± 7.2	0.58t
Caucasians	4 (66.7%)	8 (47%)	0.83F
Male	3 (50%)	11 (64.7%)	0.63F
in CsP arm	5 (83.3%)	7 (41.2%)	0.15F
GFR 0	140.9 ± 45.9	115 ± 48.8	0.27t
GFR 52	121.1 ± 41.3	103.4 ± 58.6	0.50t
TGFb1 (pg/ml)	5167 ± 589	5459 ± 701	0.37t
Opn (ng/ml)	8.4 ± 1.2	8.1 ± 3.4	0.82t

F-fisher exact, t-t test

Conclusions: We found no difference in Opn and TGFb1 and no significant correlation between Opn, or TGFb1 and eGFR at 52 weeks of IT.

Funding: Private Foundation Support

SA-PO391

Increased Urinary Biomarkers of Inflammation, Angiogenesis, and Epithelial Adhesion in HIV+ African Americans with and without CKD Mark A. Kraus,[1,2] Krishnamurthy P. Gudehithlu,[1,4] Kathleen Weber,[3] Ashok K. Singh,[1,4] Audrey French.[2,3] *[1]Nephrology, John H Stroger Jr Hospital of Cook County, Chicago, IL; [2]Medicine, Rush University, Chicago, IL; [3]Infectious Disease, Ruth M Rothstein CORE Center/Cook County Health & Hospitals System, Chicago, IL; [4]Hektoen Institute of Medicine, Chicago, IL.*

Background: Despite improved viral suppression with highly active antiretroviral therapy, HIV+ adults remain at high risk for chronic kidney disease (CKD) with a reported two-fold increased risk of developing end stage renal disease over the general population. This study tested for changes in discrete urine biomarkers hypothesized to contribute to this increased risk.

Methods: We collected random urine samples from African American (AA) HIV+ and age matched HIV uninfected (HIV-) women with eGFR>60ml/min (n=9 & 15) and HIV+ AA with eGFR<60ml/min (HIV+CKD, n=5) from the Chicago Women's Interagency HIV Study (WIHS) cohort and the HIV Nephrology clinic at our institution. Using ELISA kits, we analyzed urine for the presence of biomarkers of inflammation, hypoxia, angiogenesis, monocyte activation, and cell adhesion. Biomarker concentrations were normalized to urine creatinine concentrations.

Results: Fetuin-A concentration was 2.3 fold higher in HIV+ ($p=0.007$) and 6 fold higher in HIV+CKD ($p=0.05$) groups vs. HIV- controls. E-Cadherin rose 2 fold in HIV+ ($p=0.02$) and 6.3 fold in HIV+CKD from HIV- levels. Angiopoietin-2 concentrations were comparable in HIV- and HIV+ groups and increased 19.8 fold in HIV+CKD ($p=0.02$) vs. HIV- controls. NGAL rose 2.2 fold in HIV+ ($p=0.02$) and 16.6 fold in HIV+CKD ($p=0.02$) groups vs. HIV- controls. Although detectable, there were no differences among the groups in TGF-beta, MCP-1, and IL-8 concentrations. In all groups, HIF-1alpha, TNF-alpha, FGF, IL-6, IL-10, and MMP-9 were not detectible.

Conclusions: These results are the first to test the involvement of discrete biological systems in the development of CKD in HIV+ AA. Our data support a possible role of angiogenic factors (angiopoietin-2), inflammation mediators (fetuin-A), endothelial adhesion (E-cadherin), and ischemia (NGAL) in the pathogenicity of CKD in the setting of HIV.

Renin Angiotensin System Modulates Sclerotic but Not Collapsing Lesions in HIV-Associated Nephropathy Andrei Plagov,[1] Partab Rai,[1] Dileep Kumar,[1] Ashwani Malhotra,[1] Guohua Ding,[1] Praveen N. Chander,[2] Pravin C. Singhal.[1] *[1]Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY; [2]Pathology, New York Medical College, Valhalla, NY.*

Background: Although collapsing glomerulopathy has been considered a hallmark of HIV-associated nephropathy (HIVAN) but significant numbers of glomeruli in HIVAN patients also display sclerotic lesions. We hypothesize that both collapsing and sclerosing lesions are manifestation of HIVAN and their display is dependent on associated host factors. We studied the role of the activation and down regulation of renin-angiotensin system (RAS) on the frequency of sclerotic and collapsing lesions in a mouse model of HIVAN.

Methods: To have the activated RAS, HIV transgenic (Tg26) mice were genetically engineered to have variable copies of angiotensinogen (Agt). Twelve weeks old Tg26 mice having two (Agt-2), or four copies (Agt-4) of Agt in groups of six were evaluated for number of sclerotic or collapsing glomeruli in their renal cortices. To down regulate the RAS, four weeks old Tg26 mice were treated with either saline, captopril (angiotensin converting enzyme inhibitor, 50 mg/Kg), aliskiren (renin activity inhibitor, 50 mg/Kg), aliskiren + captopril, telmisartan (Ang II blocker, 50 mg/kg, or aliskiren + telmisartan for 4 weeks. Subsequently, renal cortices were studied for number of sclerotic and collapsing glomeruli.

Results: Tg26/Agt-2 mice displayed greater number of sclerotic glomeruli vs. collapsing glomeruli. In Tg26/Agt-2, one out of 7 glomeruli showed sclerotic lesion; whereas, one out of 33 glomeruli displayed collapsing lesion. Tg26/Agt-4 mice showed higher number of sclerotic glomeruli (one out four glomeruli) when compared to Tg26/Agt-2 mice. Interestingly, all treatment groups predominantly displayed decreased percentages of sclerotic glomeruli.

Conclusions: Sclerotic lesions are more common in HIVAN and are correlated with the activation of the RAS. Since majority of biopsy specimen often may not have adequate number of glomeruli to display one collapsing glomerulus but may display sclerotic one, both sclerotic and collapsing glomerulus should be considered the manifestation of HIVAN.

Minimal Change Disease due to Mercury-Containing Skin Lightening Cream: Clinical and Pathological Analysis Yan-yan Wang,[1] Hong Cheng,[1] Guo-qin Wang,[1] Hong-rui Dong,[1] Chang-jiang Wang,[2] Yan-ling Tang,[3] Yi-Pu Chen.[1] *[1]Division of Nephrology, Beijing Anzhen Hospital, Capital Medical University, Beijing, China; [2]The Central Hospital of Jiamusi City, Heilongjiang, China; [3]Tang Shan People's Hospital, Hebei, China.*

Background: To investigate the clinicapathological characteristics and the treatment of minimal change disease (MCD) due to mercury-containing skin lightening cream.

Methods: 5 cases with mercury-induced MCD were enrolled in this study. The feature of mercury toxicity, mercury in urine and skin lightening cream, the clinical and pathological change and the treatment were analyzed.

Results: 1. All cases were female (mean age 37.6) and had a history of continuous use of mercury containing skin lightening cream from 3 to 5 months. 2. All cases had edema, heavy proteinuria, hypoalbuminemia, hyperlipidemia and no hematuria. 2. Renal biopsy showed no changes of glomeruli on light microscopy. The immunofluorescence was negative. On electron microscopy, there is a characteristic fusion of epithelial foot. They were diagnosed as MCD. Case 5 had renal tubular epithelial cell lysosome increase and some microvilli fall off. Renal tubules and interstitial had no obvious lesions in the other 4 cases. 3. The urinary mercury concentration was more than 2.2-75 times the upper limit of normal value. 3 cases' cosmetic cream was found to contain mercury levels of 1.20×10^3-1.56×10^3mg/kg. 4. All cases ceased application of the cream, and were treated with prednisone and chelation therapy. 3 cases had started to use prednisone before admission and they already had complete remission before chelation therapy. The other 2 cases took prednisone while using chelation therapy. They all had complete remission within 1-2months. The urinary mercury concentration of case 1 and case 4 had normalized after two course of chelation therapy. However, the other 3 cases' urinary mercury is still above the normal level after one or three course of chelation therapy. All cases are stable and on a reducing dose of prednisone.

Conclusions: The clinicapathological presentation and the response to prednisone of MCD due to mercury-containing skin lightening cream are like that of primary MCD.

SA-PO394

HIV Immune Complex Kidney Disease: Clinical Features and Impact of Anti-Retroviral Therapy Matthew Foy,[1] Gregory Lucas,[2] Faryal Tahir,[3] Michelle M. Estrella,[1] Derek M. Fine,[1] Mohamed G. Atta.[1] *[1]Division of Nephrology, The Johns Hopkins Hospital, Baltimore, MD; [2]Division of Infectious Disease, The Johns Hopkins Hospital; [3]Dow University of Health Sciences.*

Background: HIV-associated nephropathy (HIVAN) is well-described, but the clinical features of HIV-immune complex kidney disease (HIVICK) have not been well-established. Our study evaluated the clinical features associated with HIVICK and the impact of antiretroviral therapy (HAART) on end-stage renal disease (ESRD).

Methods: This was a nested case-control retrospective study of HIV-infected individuals followed in the Johns Hopkins HIV Clinical Cohort from 1/1996 to 6/2010. Groups were compared using X2 test or rank-sum analysis. Conditional logistic regression was used to estimate odds ratios for HIVICK. Incidence of ESRD for HIVICK/HIVAN and ESRD with/without HAART exposure were calculated using Kaplan-Meier analysis.

Results: Of 139 patients examined, 83 had HIVICK and were predominantly African-American (92%). Comparing HIVICK to HIVAN: HIVICK had more HAART exposure, lower HIV viral loads, and higher CD4 counts and estimated GFR. Adjusting for race, injection drug use, increased HIV RNA, CD4 < 200, HCV infection, diabetes, and hypertension, those with higher HIV RNA (OR=1.56, 95%CI 1.13-2.14), diabetes (OR=2.59, 95%CI 1.04-6.4) and hypertension (OR=2.32, 95%CI 1.19-4.53) had higher odds of HIVICK versus 332 matched controls. ESRD was less common in the HIVICK group versus HIVAN (30% vs. 82%, p<0.001). While HAART was associated with lower ESRD incidence in the HIVAN group (44% vs. 72%, p=0.023), it was not in the HIVICK group.

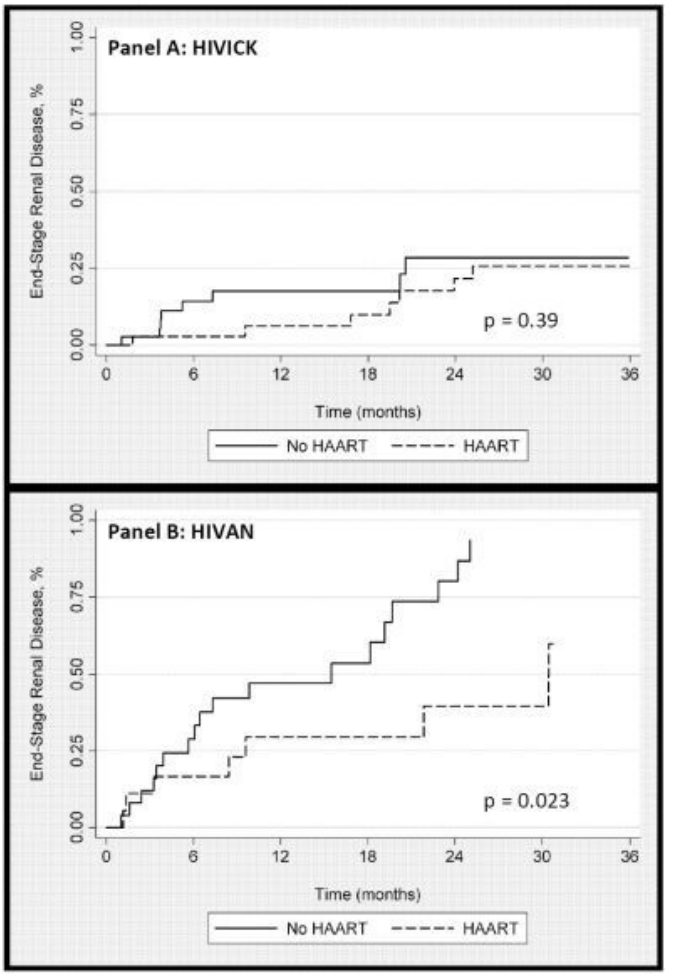

Figure 1. Incidence of ESRD among patients with HAART vs. no HAART exposure.

Conclusions: HIVICK occurs commonly in African-American patients. These patients are more likely to have higher HIV RNA. ESRD incidence is lower in HIVICK patients compared to HIVAN. Unlike HIVAN, HAART does not impact incidence of ESRD in HIVICK.

Renal Safety Profile of Lopinavir/Ritonavir-Based Regimens in the PROGRESS Study Boris Renjifo, Christos Argyropoulos, Roxann Stubbs, Dilek Arikan, Roger N. Trinh, Angela M. Nilius. *Abbott Laboratories, Abbott Park, IL.*

Background: There is an increasing need to identify alternative antiretroviral (ARV) combinations for HIV(+) patients that avoid Nucleoside/Nucleotide Reverse Transcriptase Inhibitors (NRTI) to minimize long term organ toxicity. The PROGRESS study (NCT00711009) compared the novel NRTI-sparing regimen LPV/r + raltegravir (RAL) to LPV/r + TDF and emtricitabine (FTC) in ARV-naïve patients. Through 48 weeks of follow up LPV/r + RAL was noninferior in efficacy and exhibited comparable safety and tolerability profiles compared to LPV/r + TDF/FTC. As a component of a secondary endpoint, we evaluated the renal safety profile associated with each ARV regimen during the entire follow up time.

Methods: Creatinine clearance (CrCl) was estimated by the Cockroft-Gault equation, and changes from baseline (BL) were assessed by one way ANOVA. Subjects were followed through 96 weeks or until discontinuation from the study based on the investigator's best clinical judgment.

Results: Study participants (n=172, LPV/r + TDF/FTC = 90) were 39.9±10.7 years old, 88.4% White, 11.6% women, BL CrCl of 120.3±34.9 ml/min, and 28.9 % had a diagnosis of hypertension. There were no differences in BL demographics between arms. Mean change from BL to week 96 in CrCl was statistically significantly greater with LPV/r + TDF/FTC compared to LPV/r + RAL (Δ -7.3 versus -1.5 ml/min, p=0.035). Four subjects experienced a renal serious adverse event (SAE) for which clinical course, renal biopsies, laboratory abnormalities, concomitant comorbidities and medications will be presented.

Age in years	33	42	52	55

Renal diagnosis	Obstructive stone	AKI	Fanconi	AKI with tubulointerstitial nephritis (biopsy)
Outcome	Ureteral Stent Placed	Dialysis dependent	Persistent	Persistent

M=Male, F=Female, W=White, B=Black, LR: LPV/r + RAL, LT: LPV/r + TDF/FTC

Conclusions: At week 96 the majority of patients had a CrCl in the normal range. Decline in CrCl was larger with LPV/r + TDF/FTC. Renal SAEs were temporally related to exposure to non ARV meds, except for one Fanconi case considered by the investigator to be related to LPV/r + TDF/FTC exposure.

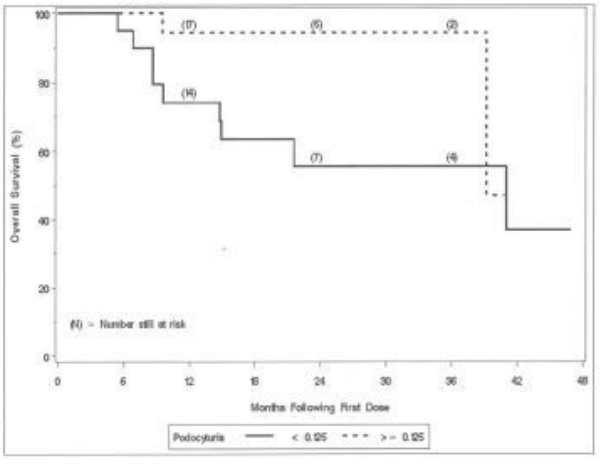
Podocyturia May Predict Response and Survival in Patients with Solid Organ Tumors Treated with Anti-VEGF Medications Juan C. Calle,[1] Suzanne R. Hayman,[2] Joseph P. Grande,[3] Vesna D. Garovic.[1] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Hematology and Oncology, Mayo Clinic, Rochester, MN; [3]Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN.*

Background: Anti-angiogenic agents targeting VEGF are being used increasingly for solid organ tumors, particularly in advanced disease. The two most common renal side effects are proteinuria and hypertension, thought to be secondary to the removal of VEGF trophic effects by these agents. Proteinuria has recently been shown by our group to be associated with increased levels of podocyturia (excretion of viable podocytes in the urine) in patients treated with anti-VEGF medications.

Methods: In forty patients treated with anti-VEGF medications urinary podocyte culture was performed to detect viable podocytes.

Results: Among the 40 patients, 11 died during the period of the study with a median time to death of 9.6 months (range, 5.4 – 41.0 months). Among the remaining 29 patients, the median duration of follow-up was 20.3 months (range, 5.1 – 69.5 months). Overall survival was better in those who developed podocyturia (cutoff ≥ 0.125 cell/mg of creatinine, p=0.05).



Conclusions: Previous studies have shown that treatment-related hypertension may predict response to anti-angiogenic treatments. Our data indicate possible predictive roles of early proteinuria and podocyturia in overall survival in those patients treated with anti-VEGF medications.

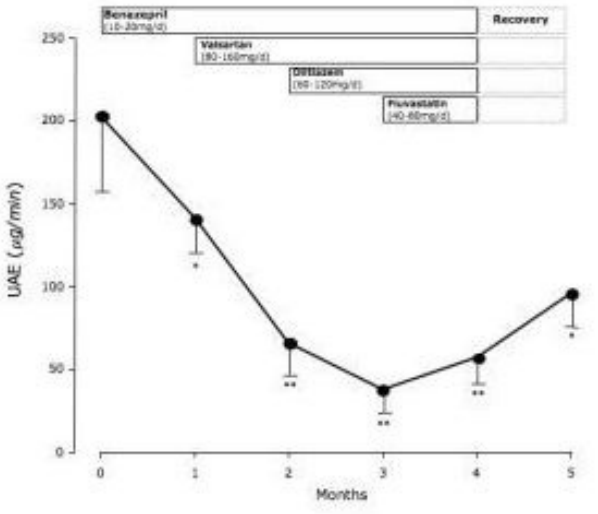
SA-PO397

Effects of the Remission Clinic Approach in Alport Syndrome: Results from a Prospective, Sequential Cohort Study Erica Daina,[1] Sara Gamba,[1] Piero Ruggenenti,[1,2] Mirella Alpa,[3] Dario Roccatello,[3] Paolo Cravedi,[1] Flavio Gaspari,[1] Giuseppe Remuzzi.[1,2] *[1]Mario Negri Institute, Bergamo, Italy; [2]Ospedali Riuniti di Bergamo, Italy; [3]Ospedale S.G. Bosco, Torino, Italy.*

Background: Combined use of ACE inhibitors, ARBs, ndCCBs and statins (the Remission Clinic approach) reduced proteinuria and halted progression to ESKD in patients with non-diabetic proteinuric nephropathies (JASN,2008;19:1213). We tested the effects of this strategy in Alport syndrome, a disease orphan of specific treatment so far.

Methods: After 1-month wash-out from RAS inhibitor therapy, 9 consecutive patients (3 males) aged 33.0±15.2yrs with diagnosis of Alport syndrome and cr. cl. >20ml/min/1.73m^2 entered a 4-month sequential, add-on treatment period with benazepril, valsartan, diltiazem, and fluvastatin followed by 1 month wash-out (recovery). Drugs doses were up-titrated as already described (JASN,2008;19:1213). Albuminuria (primary outcome) and other parameters were evaluated at baseline and monthly thereafter. GRF and RPF were directly measured by Iohexol and PAH clearances at baseline, and at the end of the treatment and recovery periods.

Results: Albuminuria significantly declined over 1-month benazepril therapy and further progressively decreased over the treatment period. After washout it again tended toward baseline values.



Over the treatment period mean arterial BP and LDL/HDL cholesterol ratio progressively declined ($p<0.05$) from 102.2±10.9 to 87.5±10.2mmHg and from 2.5±0.9 to 1.9±0.4, respectively. They increased to 96.6±9.9mmHg and 2.4±0.8 after recovery. GFR, RPF and serum potassium levels were stable throughout the study. Treatment was well tolerated.

Conclusions: The Remission Clinic approach safely reduced albuminuria and BP, and ameliorated dyslipidemia in patients with Alport syndrome. Whether these effects may translate into long-term renoprotection is worth investigating.

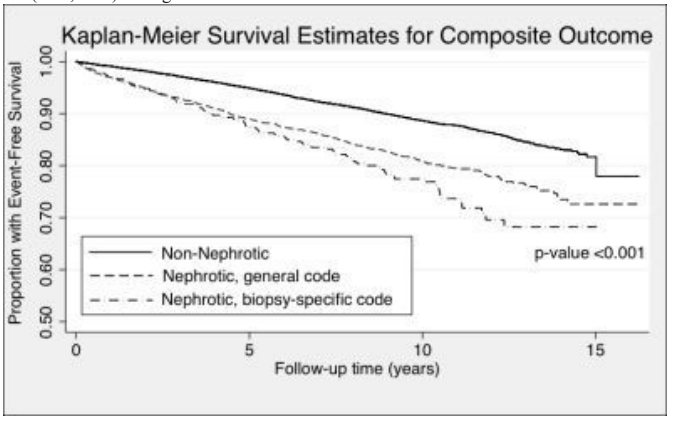
Risk of Cardiovascular Disease in Primary Nephrotic Syndrome: A Population Based Cohort Study Laura H. Mariani, Michelle Denburg, Kevin Haynes, Mary B. Leonard. *Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA.*

Background: Cardiovascular disease (CVD) is the major morbidity for patients with chronic kidney disease (CKD). The magnitude of risk and impact of specific risk factors in the subset of CKD patients with primary nephrotic syndrome (NS) is unknown. The Health Improvement Network (THIN) is a primary care database of >9 million patients in the United Kingdom and allows for population-based studies of rare diseases.

Methods: We conducted a retrospective cohort study of 4,729 NS patients in THIN and 23,585 unexposed patients who were matched based on age, gender and practice location from 1994-2010. Nephrotic patients were identified by diagnostic code and those with prior diabetes, other glomerular diseases and CVD were excluded. Survival analysis was performed using Cox proportional hazards multivariable regression with a composite outcome of myocardial infarction, revascularization procedure, stroke and death.

Results: 838 patients had a biopsy specific diagnosis of minimal change disease, focal segmental glomerulosclerosis or membranous nephropathy. An additional 3,891 had a general code for nephrotic syndrome. Mean (SD) age at diagnosis was 34 (24) yr. 53.4% were male. The unadjusted HR (95%CI) was 2.33 (1.93, 2.82) for patients with a biopsy-specific code and 1.88 (1.70, 2.08) for a general code as compared to non-nephrotic patients (Figure 1). Adjusting for age, sex, hyperlipidemia, hypertension, smoking and obesity, the HR (95%CI) was 1.98 (1.63, 2.42) for those with a biopsy-specific code and 2.1 (1.88, 2.33) for a general code.



Conclusions: Primary NS is associated with an increased risk of CVD. Adjusting for traditional CVD risk factors did not eliminate the increased risk. Further study is needed to identify non-traditional, modifiable risk factors in this subset of patients with CKD who are at high risk of CVD.

SA-PO399

An Observational Study of ACTH in Combination with Cyclosporine for Treatment of Membranous Nephropathy Anna-lena Berg, Anneli Jonsson, Sten-erik Bäck. *Lund University, Lund, Sweden.*

Background: We previously reported that synthetic $ACTH_{1-24}$ (Synacthen Depot; ACTH) had both lipid-lowering and antiproteinuric effects in patients with nephrotic syndrome due to membranous nephropathy (MN). We now report our observational data adding low dose immunosuppression with cyclosporine (CsA) to ACTH in a subset of MN patients who achieved partial remission of proteinuria on ACTH monotherapy.

Methods: CsA (maximal dose 100 mg twice daily) was added to ACTH in 10 patients with MN who had partial remission of proteinuria on ACTH monotherapy. The median age of the patients was 73.5 yr (range 31-81). Median time from initial diagnosis of MN was 6 months (range 0.25-300). All patients were treated with standard of care, including ACE-inhibitors/ARB, statins and other symptomatic therapies. Treatment with ACTH started at a dose of 1 mg weekly and was increased to a maximum dose of 1 mg twice weekly. The median duration of ACTH monotherapy was 9 months (range 4-24), and ACTH/CsA combination therapy continued for an additional median duration of 9 months (range 4-18). All patients achieved partial remission (proteinuria reduced by 50% and < 2000 mg/L) on ACTH monotherapy. After the addition of low dose CsA, 8 of 10 patients achieved complete remission (proteinuria < 200 mg/L). Urinary albumin decreased from a mean (±SE) pre-ACTH value of 9389±1921 mg/L to 1076±190 mg/L with ACTH monotherapy, and remained improved (130±57 mg/L) after combination therapy with ACTH/CsA ($p \leq 0.0001$ at both time points compared with baseline). Serum albumin increased from a pre-ACTH mean (±SE) of 21.2±1.9 g/L to 29.2±1.7 g/L with ACTH monotherapy ($p<0.01$), and further increased with ACTH/CsA combination therapy to 36.5±1.4 g/L ($p<0.0001$ compared with baseline and ACTH monotherapy). Serum creatinine and eGFR did not change significantly after ACTH alone, or after the combination of ACTH/CsA.

Conclusions: These data suggest that the combination of ACTH and a low dose immunosuppressant may be beneficial for inducing complete remission of proteinuria in patients with MN who are only partially responsive to ACTH monotherapy. Controlled clinical trials will be required to confirm the findings from this observational cohort.

SA-PO400

Identification of *TRAP1* as a Novel CAKUT-Causing Gene by Whole Exome Capture and Next Generation Sequencing Pawaree Saisawat,[1] Ethan Douglas Sperry,[1] Alina Christine Hilger,[1,5] Heon Yung Gee,[1] Daw-yang Hwang,[1] Stefan Kohl,[1] Velibor Tasic,[2] Iris Van Rooij,[3] Radovan Bogdanovic,[4] Heiko M. Reutter,[5,6] Friedhelm Hildebrandt.[1,7] *[1]Department of Pediatrics, University of Michigan, Ann Arbor, MI; [2]Department of Pediatric Nephrology, University Children's Hospital, Skopje, Macedonia, the Former Yugoslav Republic of; [3]Department of Epidemiology, Biostatistics and HTA, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands; [4]Medical Faculty, University of Belgrade, Belgrade, Serbia; [5]Department of Human Genetics, University of Bonn, Bonn, Germany; [6]Department of Neonatology, University of Bonn, Bonn, Germany; [7]Howard Hughes Medical Institute, Chevy Chase, MD.*

Background: Congenital abnormalities of the kidney and urinary tract (CAKUT) account for 50% of all chronic kidney disease in children. Although there are several mouse models of recessive non-syndromic CAKUT, only a few genes are known to cause CAKUT in humans.

Methods: To identify new CAKUT genes we performed homozygosity mapping and whole exome resequencing using NimbleGen's SeqCaP EZ Exome™ protocol in 13 CAKUT families (27 patients). NextGen sequencing was performed using Illumina Genome Analyzer II.

Results: We detected a homozygous missense mutation (R469H) in *TNF Receptor Associated Protein 1 (TRAP1)* in two unrelated CAKUT families. The R469 residue was conserved down to bacteria and R469H was predicted to be 'damaging' by PolyPhen algorithm. The mutation segregated in the families and it is not present homozygously in the Exome Variant Server database. Additionally, we screened 384 more CAKUT patients for mutations in *TRAP1* in a Cel1 restriction enzyme assay, in which we found another affected carrying a compound heterozygous mutation (R469H and R13C).

Conclusions: *TRAP1* is a likely new cause of recessive CAKUT in humans.

Glucose Transport in the Proximal Tubule: Disruption of Urate Transport in Familial Renal Glucosuria and Report on SGLT2 Expression in Normal and Pathological Kidney Ines Aires,[1,2] Ana Rita Santos,[2] Gurkan Genc,[3] Roberto Bogarin,[4] Joaquim T. Calado.[1,2] *[1]Department of Genetics-Faculty of Medical Sciences, Universidade NOVA de Lisboa, Lisbon, Portugal; [2]Division of Nephrology, Hospital de Curry Cabral, CHLC, Lisbon, Portugal; [3]Department of Pediatric Nephrology, Ondokuz Mayis University Faculty of Medicine, Samsun, Turkey; [4]Department of Pediatric Endocrinology, Hospital Nacional de Niños, San José, Costa Rica.*

Background: Mutations in SGLT2, the major Na^+-glucose cotransporter of the proximal tubule, underlie Familial Renal Glucosuria (FRG). We aimed at characterizing the molecular and phenotype findings of a FRG cohort and detailing the SGLT2 expression in the kidney.

Methods: Direct sequencing for the identification of SGLT2 mutations, as well Western blotting and immunofluorescence for the expression of SGLT2. In the absence of renal biopsies from FRG individuals, we selected nucleoside analogs induced proximal tubular toxicity as a model for glucosuric nephropathies.

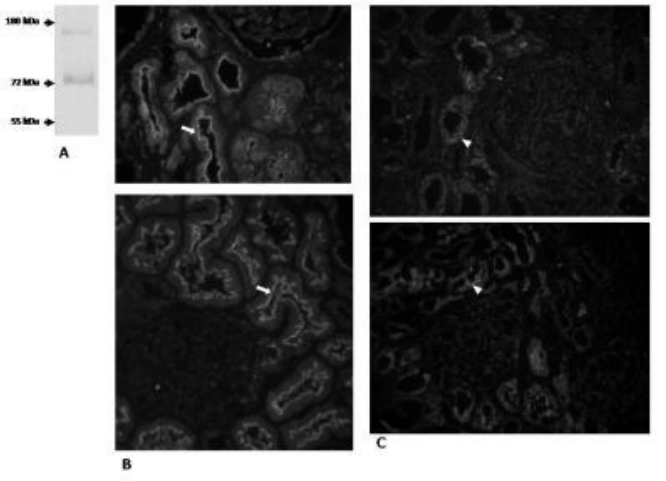
Results: Six novel SGLT2 mutations are reported. We describe hyperuricosuria with associated hypouricemia as part of the the most severe FRG phenotypes.

Phenotype evaluation and mutational analysis

proband	glucosuria (g/1.73m2/24h)	uric acid (serum; mg/dl)	uric acid (urine; mg/1.73m2/24h)	genotype
1	87.8	1.9	1242	R345fsX108/ R345fsX108
2	43.7	3.5	990	W649X/wt
3	30	na	na	Q448L/IVS7+5g>a
4	25	na	na	C522X/C522X
5	14	na	na	T191P/T191P
6	4.5	na	na	G492V/wt

na: not available

SGLT2 expression is localized to the brush-border of the proximal tubular epithelia cell A, B.



This normal pattern is disrupted in cases of nucleoside analogs induced tubulopathy C.

Conclusions: We present 6 novel SGLT2 mutations and describe hyperuricosuria/hypouricemia as part of the FRG phenotype. The disruption of the normal SGLT2 brush-border expression pattern may underlie the glucosuria seen with the use of adefovir and tenofovir.

SA-PO402

The Metabolic Basis of Primary Hyperoxaluria Type III Yaacov Frishberg,[1] James Pitt,[2] Ruth Belostotsky.[1] *[1]Pediatric Nephrology, Shaare Zedek Medical Center, Jerusalem, Israel; [2]Victorian Clinical Genetics Services, Murdoch Childrens Research Institute, Melbourne, Australia.*

Background: Primary hyperoxaluria type III (PHIII) is a recently identified type of childhood kidney stone disease caused by mutations in *HOGA1* (formerly DHDPSL). HOGA1 encodes a mitochondrial 4-hydroxy-2-oxoglutarate (HOG) aldolase which cleaves HOG to pyruvate and glyoxylate in the 4-hydroxyproline catabolic pathway. Paradoxically, glyoxylate is an immediate precursor of oxalate.

Methods: Hydroxyproline metabolites in the urine of patients with PHIII were measured using gas chromatography – mass spectroscopy (GC-MS). This was complemented by GC-MS and biochemical studies in a human hepatocyte cell line (SK-HEP-1).

Results: Significant increases in concentrations of HOG, its reduced product 2,4-dihydroxyglutarate and 4-hydroxyglutamate, the immediate precursor of HOG, were found in the urine of PHIII patients compared to carriers of the corresponding mutations or healthy controls. These data confirm that *HOGA1* mutations result in loss of function and that accumulating HOG can exit the mitochondria. *In vitro* studies using a non-PHIII human hepatocyte cell line demonstrated significant HOG aldolase activity in mitochondrial and cytosolic fractions. No HOGA1 protein was detected in the cytosolic fraction indicating that it contains other enzyme(s) with HOG aldolase activity. Aldolase enzymes are known

to have broad substrate specificity and several cytosolic aldolases could fill this role. We propose a model for PHIII whereby accumulating HOG exits the mitochondria and is partially metabolized to glyoxylate and oxalate in the cytosol.

Conclusions: Our data provide a diagnostic tool for screening larger cohorts for PHIII and shed light on glyoxylate metabolism and the pathogenesis of the primary hyperoxalurias.

Molecular Effects of Four Mutations Identified in the ATP Binding Domain on Transporter Activity of hClC-5 in Japanese Patients with Dent's Disease

Akira Ashida,[1] Daisuke Yamamoto,[2] Takashi Sekine,[3] Takashi Igarashi,[4] Motoshi Hattori,[5] Hiroshi Tamai.[1] *[1]Pediatrics, Osaka Medical College, Osaka, Japan; [2]Biomedical Computation Center, Osaka Medical College, Osaka, Japan; [3]Pediatrics, Ohashi Medical Center, Toho University, Tokyo, Japan; [4]National Center for Child Health and Development, Tokyo, Japan; [5]Pediatric Nephrology, Tokyo Women's Medical University, Tokyo, Japan.*

Background: Dent's disease, characterized by low-molecular-weight proteinuria, hypercalcinuria, and nephrolithiasis, is caused mainly by inactivating mutations in the human chloride channel 5 (hCLC-5) gene. Binding of ATP to the ATP binding domain (ABD) of hClC-5 is known to play an important role in regulating the transport activity of hClC-5. The X-ray crystal structure of the cytoplasmic domain of hClC-5, including the ABD, has been established, thus making it possible to construct a model of this domain and examine the effect of its mutations.

Methods: We examined four missense mutations in the hClC-5 ABD that were included among 29 such mutations identified in 114 Japanese patients with Dent's disease.

Results: Only four mutations-F703S, L706P, C711W and K725E-were identified as ABD mutation points (ASN 2011 FR-PO1508). Structural mapping indicated that K725 might interactively affect ATP binding via electrostatic interaction between ATP and the ABD, due to the charge inversion resulting from K725E mutation. Two L706 side-chains provided mutual stability for each other in the dimer structure, and F703 and C711 were positioned on the line between L706 and K725. We virtually simulated these mutation structures in the molecular model, and confirmed that the K725E mutation could weaken the binding of ATP. F703S and C711W, on the other hand, appeared to change the volume and shape of the hydrophobic core of the ABD, and L706P was considered to change the dimer interaction between ABDs.

Conclusions: We postulate that the above residues have an important relationship to intermolecular signaling upon ATP binding, and that their mutations might result in failure of channel function, in view of the predicted changes in interaction between the ABD and trans-membrane domain that would result from ATP binding.

SA-PO404

LMX1B Mutation with Residual Transcriptional Activity as a Cause of Nail-Patella-Like Renal Disease

Tsuyoshi Isojima,[1] Noriko Sugawara,[2] Yutaka Harita,[1] Ken-ichiro Miura,[1] Motoshi Hattori,[2] Sachiko Kitanaka,[1] Takashi Igarashi.[1] *[1]Department of Pediatrics, University of Tokyo, Bunkyo-ku, Tokyo, Japan; [2]Department of Pediatric Nephrology, Tokyo Women's Medical College, Shinjyuku-ku, Tokyo, Japan.*

Background: Nail-patella syndrome (NPS) is an autosomal dominant disorder caused by mutations of the LMX1B gene. Dysplasia of the nails, absence or hypoplasia of the patellae, and the kidney disease are cardinal features. Patients with typical renal lesions of NPS without skeletal nor nail findings were also reported known as nail-patella-like renal disease.It is unknown whether nail-patella-like renal disease is also caused by LMX1B mutation.

Methods: The subject was a 6-year-old girl with proteinuria and hematuria. There was no familial history. She had neither skeletal nor nail abnormalities. Renal biopsy showed ultrastructual changes of the irregularly thickened glomerular basement membrane consisted of fibrillar material. We diagnosed her as nail-patella-like renal disease. We analyzed the LMX1B gene from peripheral leukocyte genome DNA of the subject and her parents. For examining the functional consequences of the detected mutation, wild-type and mutant LMX1B were transiently overexpressed in Cos-1 cells, and the transcriptional activity was analyzed by luciferase reporter assay.

Results: A novel heterozygous mutation (R223Q) was identified. R223Q was not found in the parents. R223Q is not registered in SNP databases, and the absence of each DNA sequence abnormality in 100 alleles from 50 unrelated normal individuals indicated R223Q was a mutation .Transcriptional activity of R223Q were significantly lower than that of wild-type.However, it was higher than that of other mutation found in a patient with typical NPS.

Conclusions: This the first report a LMX1B gene mutation was identified in a patient with nail-patella-like renal disease. As R223 is located in the homeodomain and well conserved region, R223Q would have the passibility tha function of LMX1B was damaged. Functional analyses revealed R223Q transcriptional activity was impaired but remained. It is suspected that nail-patella-like renal disease may be caused by LMX1B mutations with residual transcriptional activity.

SA-PO405

The Rennin Producing Cell Recruitment in Patients with Gitelman Syndrome

Lanping Jiang,[1] Chen Chen,[1] Tao Yuan,[2] Peng Xia,[1] Yubing Wen,[1] Yan Qin,[1] Min Nie,[2] Xuemei Li,[1] Xuewang Li,[1] Limeng Chen.[1] *[1]Nephrology, Peking Union Medical College Hospital, Beijing, China; [2]Endocrinology, Peking Union Medical College Hospital, Beijing, China.*

Background: This study is trying to observe the clinical pathologic features and the local RAS activation of the kidney in Gitelman syndrome (GS) patients.

Methods: 33 patients with a clinical suspicion of GS were recruited. Genomic DNA was isolated from peripheral blood and used for PCR amplification of individual exon of the SLC12A3gene. Direct sequencing was performed. The general clinical data of genetic diagnosed GS patients was collected. Plasma renin activity (PRA), angiotensin II and aldosterone levels were detected by radioimmunoassay. 14 GS patients did renal biopsy. Renin and α-actin immunofluoescense (IF) double staining and COX2 immunohistochemistry (IHC) were performed.

Results: The average onset age was 23.4±11.8 (3-47)years old of the 27 GS patients with 22 SLC12A3 gene mutants, including 4 novel mutants. The upper respiratory tract infection, strenuous exercise, emotion change, diarrhea were the common incentives. Episodes of hypokalemia (1.2-2.8mmol/L) was the universal presentation of all patients, companied with fatigue (88%), convulsion (36%), numbness (32%), palpitation (32%) and flaccid paralysis(24%). Metabolic alkalosis occurred in 87.5% patients, urine Ca^{2+} to Cr ratio decreased in 94% patients. Hypomagnesaemia (80.9%), elongation of QT interval of ECG (54.2%) and hypochloremia (40.9%) were also observed in GS patients. Significantly increasing of PRA (35%), Ang II(85.7%) and Aldosterone(64%) levels were observed in GS patients even when serum potassium level was approaching normal. Almost GS patients (13/14) showed amplification of juxtaglomerular apparatus(JGA) in kidney. Renal local renin and COX2 expression were significantly higher in JGA .than normal control. Renin and α-actin co-expression was observed in both microartery and JGA of GS patients by confocal laser scanning microscopy.

Conclusions: After a physiologic challenge of Na^+ and Cl^- wasting, induced the transformation of arteriolar smooth muscle cells into renin-expressing cells may result the local RAS activation in GS patients.

SA-PO406

Identification of Novel Mutations in the SLC12A3 Gene in Chinese Patients with Gitelman Syndrome

Jun Ma, Hong Ren, Zhaohui Wang, Chunli Zhang, Yuhua Ma, Nan Chen. *Nephrology Department, Ruijin Hospital, Shanghai Jiaotong University, Shanghai, China.*

Background: Gitelman syndrome(GS) is an autosomal recessive disorder characterized by hypokalaemic metabolic alkalosis, significant hypomagnesemia and low urinary calcium. The GS phenotype is usually caused by mutations in the SLC12A3 gene. Hundreds of mutations have been reported in the literature, but very few of these mutations were identified in Chinese. The aim of this study is to investigate the features of SLC12A3 gene mutations in Chinese GS patients.

Methods: From Feb 2009 to Apr 2011, 28 unrelated patients suspected of having GS were enrolled in this study. 100 healthy persons were used as controls. Biochemical parameters were measured and documented. We analyzed DNA samples of these patients with a clinical suspicion of GS by direct sequencing of all 26 exons of the SLC12A3 gene. Reverse-transcription polymerase chain reaction and complementary DNA sequence analysis were performed to confirm deletion or splicing variants.

Results: In these 28 patients(18 men and 10 women),21 patients suffered from severe symptoms interfering with daily activities, such as paralysis, tetany or cramp. All patients had hypokalaemia, metabolic alkalosis, hypomagnesaemia and normal blood pressure. 15 patients had hypocalciuric and six patients were found to have proteinuria. All patients showed normal hearing and serum calcium. For the genotype, 20 patients were identified to carry two SLC12A3 mutant alleles,while only one mutant allele was found in the other 8 patients.In total, 24 different mutations were identified,10 of which have not been reported before. These novel mutations include one insertion, seven missense, one splice site and one nonsense mutation.Thr60Met mutation was found to have a high frequency in the cohort, two patients carried homozygous T60M mutation,while 5 other patients carried heterozygous T60M mutation.Phenotype-genotype correlation was difficult to build in our cohort.

Conclusions: We have totally identified 24 mutations, including ten novel mutations in the SLC12A3 gene in 28 patients with GS. T60M is the most frequent variant in our patients. There was no significant correlation between genotype and phenotype in our patients.

SA-PO407

The Fabrazyme®, Angiotensin Receptor Blocker and ACE Inhibitor Treatment Study in Fabry Nephropathy (for the FAACET Investigators)

David G. Warnock,[1] Christie P. Thomas,[2] Antonio Guasch,[3] Bojan Vujkovac,[5] Christoph Wanner.[4] *[1]Medicine, UAB, Birmingham, AL; [2]Medicine, University of Iowa, Iowa City, IA; [3]Medicine, Emory University, Atlanta, GA; [4]Nephrologie, Universität Würzburg, Würzburg, Germany; [5]Fabry Center, General Hospital, Gradec, Slovenia.*

Background: Patients with Fabry nephropathy lose kidney function despite treatment with enzyme replacement therapy (ERT). The FAACET study (NCT00446862) examined control of urine protein/creatinine ratio (UPCR) with antiproteinuric therapy in patients receiving agalsidase beta (1 mg/kg every two weeks). Ten international study sites participated.

Methods: Adults with confirmed Fabry disease, treated with agalsidase beta at 1 mg/kg every two weeks were included if baseline estimated GFR (eGFR) was <60 ml/min/1.73 m² and UPCR >0.5 g/day, or baseline eGFR <125 ml/min/1.73 m² and UPCR >1 g/day. ACE inhibitor or ARB therapy was titrated during 3 monthly visits to a UPCR ≤0.5 g/day, and the patients were then followed with visit every 3 months for the next 18 months. The primary objective was reduction of first morning UPCR to < 0.5 gram/gram. The primary outcome measure was the regression slope of estimated GFR with time in years.

Results: Twenty four patients (9 females/15 males) completed the protocol. Average age was 44±9(SD) yrs, with 1.8±0.2 yrs follow up. Thirteen achieved target UPCR ≤0.5 g/day, and 6 had averaged UPCR >0.5 and ≤1.0 g/day.

eGFR Slopes in Groups Stratified by Achieved UPCR

		Initial Baseline Values		Averaged	Active Treatment Period	
Number	Gender (F/M)	eGFR	UPCR	UPCR Strata	eGFR Slope	Averaged UPCR
13	6 F/7 M	70.6 (27.0)	0.6 (0.5)	≤0.5	–1.0 (6.1)	0.3 (0.1)
6	1 F/5 M	62.4 (26.3)	0.8 (0.4)	>0.5 & ≤1.0	–4.5 (7.0)	0.7 (0.2)
5	2 F/3 M	77.7 (24.4)	0.8 (0.7)	>1.0	–6.6 (11)	1.5 (0.5)

UPCR (g/day (SD)), eGFR Slope (ml/min/1.73 m²/year (SD)

Conclusions: The eGFR slope was associated with achieved UPCR in adult patients with Fabry nephropathy treated with ERT and antiproteinuric therapy. The majority of patients could be titrated to UPCR ≤0.5 g/day, and had eGFR slopes not different from zero. Effective antiproteinuric therapy is an important adjunct to ERT in treating patients with Fabry nephropathy.

SA-PO408

Impact of Agalsidase beta on Renal Function in 60 French Patients with Fabry Disease Morgane Wetstein,[1] Claire Trivin,[2] Bruno Moulin,[3] Gabriel Choukroun.[1] *[1]Nephrology and Transplantation, CHU Amiens - Hopital Sud, Amiens, France; [2]Nephrology, HEGP, Paris, France; [3]Nephrology and Transplantation, Hopitaux Civils, Strasbourg, France.*

Background: Fabry disease is responsible for the progressive accumulation of Gb3 in the lysosomes of many cell types, causing significant cardiac, renal and neurological morbidity and mortality. Treatment with enzyme replacement therapy by agalsidase beta has been available for over 10 years, thus an evaluation of its efficacy on renal function is warranted.

Methods: We conducted a retrospective study in 24 Nephrology centres to assess the impact of algasidase beta at a dose of 1 mg/kg every 2 weeks on renal function in 60 patients (46 men).

Results: Mean age was 48±13 yrs and mean duration of treatment was 84±35 mo. Treatment was started on average at 40±13 yrs. In the 47 patients who were not on dialysis at the start of ERT, the eGFR was 79±43 ml/min and proteinuria averaged 1.1±1.6 g/d. Twenty-four patients were receiving antihypertensive therapy, including 12 on RAAS blocking agents. At the initiation of ERT, SBP was 130±17 mmHg and DBP was 75±10 mmHg. Calculating the slope of eDFG on the duration of follow-up demonstrates a stabilization of renal function with a loss of GFR averaged -0.59 ml/min/yr. An analysis conducted on populations stratified according to sex and stage of CKD at the time of the introduction of the ERT shows an average slope of eDFG in men and women at CKD 1-2, of -0.28 ml/min/year and 0.62 ml/min/year respectively (proteinuria <1.0 g/24 h in both populations). For men treated by ERT at a more severe stage (CKD 3 and proteinuria of 1.75 g/24 h before ERT), the calculated average slope was more pronounced (eDFG decline of -3.80 ml/min/yr). However, these rates were lower than that observed in the natural history of Fabry disease. At the end of follow-up, 4 patients progressed to ESRD, including 3 patients who were already in stage 5 before starting treatment; 4 patients died.

Conclusions: This study shows that treatment with agalsidase beta can significantly slows the progression of renal failure in patients with Fabry disease. This benefit is more pronounced if the treatment can be started early.

SA-PO409

Structural-Functional Relationships of Fabry Nephropathy Michael Mauer,[1] Chester B. Whitley,[1] Einar Svarstad,[2] Camilla Tøndel,[2] Marie-Claire Gubler,[3] Michael L. West,[4] Behzad Najafian.[5] *[1]Pediatrics and Medicine, University of Minnesota, Minneapolis, MN; [2]Medicine, Haukeland University, Bergen, Norway; [3]Pathology, Université René Descartes, Paris, France; [4]Medicine, Dalhousie University, Halifax, Canada; [5]Pathology, University of Washington, Seattle, WA.*

Background: There is a clear need for discovery of biomarkers to predict renal dysfunction and risk in Fabry disease. Renal biopsy structural parameters would be promising biomarker candidates. We studied which parameter(s) correlate best with glomerular filtration rate (GFR), urine albumin creatinine (UACR) and protein creatinine ratios (UPCR) in patients with Fabry disease.

Methods: Renal biopsies from 46 (M/F=1.9) treatment naive patients with Fabry disease, age 25 [4-63] years with UPCR 51 [0-290] ug/min and GFR 103±27 ml/min/1.73 m² were studied. Foot process width (FPW), fractional volume of globotriaosylceramide (GL3) inclusions per podocytes [Vv(Inc/PC)], mesangial [Vv(Inc/Mes)], and endothelial cells [Vv(inc/Endo)] were estimated using electron microscopy stereology.

Results: UACR correlated with Vv(Inc/PC) (r=0.52, p=0.048) and Vv(Inc/Mes) (r=0.51, p=0.04). UPCR correlated with Vv(Inc/Mes) (r=0.47, p=0.03). Multiple regression analysis (MRA) in all Fabry patients showed that 37% of UACR variability was explainable by Vv(Inc/PC), Vv(Inc/Mes) and Vv(Inc/Endo) (p=0.04) with Vv(Inc/PC) and Vv(Inc/Mes) being independent predictors of UACR. However, MRA with same predictor variables in male patients, explained up to 76% of UPCR variability (p=0.007).

GFR inversely correlated with age (r=-0.48, p=0.004). With MRA the combination of age and UPCR explained 31% and age, UPCR and FPW explained up to 47% of GFR variability in all patients with Fabry disease.

Conclusions: These studies for the first time show that glomerular structural parameters alone or in combination with clinical data can explain a substantial portion of early renal dysfunction in patients with Fabry disease. These studies will help us better identify pathologic lesions that closely correlate with early GFR decline and likely play a causal role in progression of Fabry renal disease.

High-Throughput Screening Identified Disease-Causing Mutants and Functional Variants of α-Galactosidase A Gene in Japanese Male Hemodialysis Patients Kent Doi,[1] Eisei Noiri,[1] Tomoko Ishizu,[1] Kousuke Negishi,[1] Yoshifumi Hamasaki,[1] Masaomi Nangaku,[1] Hitoshi Sakuraba.[2] *[1]Nephrology and Endocrinology, University of Tokyo, Tokyo, Japan; [2]Analytical Biochemistry, Meiji Pharmaceutical University, Tokyo, Japan.*

Background: Fabry disease is a genetic disorder caused by deficient activity of lysosomal enzyme α-galactosidase A (GLA) and end-stage renal disease (ESRD) will be present after accumulation of glycosphingolipids within the kidney. Undiagnosed atypical variants of Fabry disease, which are limited to renal involvement, were found in several ESRD patient populations. On the other hand, unexpectedly high frequencies of male subjects having the p.E66Q showing low α-GLA activity have been reported on Japanese and Korean screening for Fabry disease. However, several evidences indicate the p.E66Q is not a pathogenic mutation but is a functional polymorphism.

Methods: Serum α-GLA activity of 1080 male Japanese ESRD patients treated by hemodialysis was measured with 96-well based four-hour assay and confirmation by leukocyte α-GLA activity measurement and genetic analysis were subsequently conducted.

Results: Serum screening identified 10 patients with low enzyme activity (<1.5 nmol/h/ml). Leukocyte α-GLA activity measurement confirmed defect of enzyme activity in two patients and eight other patients had residual enzyme activity. Genetic analysis of the two Fabry disease patients revealed two genetic mutation of p.G195V in exon 4 and p.M296I in exon 6. All of the other eight patients had a functional polymorphism of p.E66Q. Notably, serum α-GLA activity measurement distinguished two disease-causing mutations from the p.E66Q. Functional analysis revealed p.E66Q leads to instability of the enzyme protein and subjects harboring the E66Q enzyme exhibited no increased level of plasma globotriaosylsphingosine in these subjects.

Conclusions: Our high-throughput serum enzyme assay distinctly identified two disease-causing mutants and functional variants of α-galactosidase A gene in Japanese male hemodialysis patients. In addition, functional analysis clearly demonstrated p.E66Q is not a pathogenic mutation but is a functional polymorphism.

Increased Platelet Count and Aggregability due to Urinary Loss of PACAP in Congenital Nephrotic Syndrome Benedicte Eneman,[1] Kathleen Freson,[2] Chris Van Geet,[2] Elena N. Levtchenko.[1] *[1]Development and Regeneration, Catholic University (KUL), Leuven, Belgium; [2]Department of Molecular and Vascular Biology, Catholic University (KUL), Leuven, Belgium.*

Background: Thrombotic complications occurring in up to 15% of patients represent a severe burden in nephrotic syndrome (NS). The underlying mechanisms are mainly unraveled in regard of venous thrombosis, while elevated blood platelet count and hyperaggregability increase the risk of arterial thrombosis.

A role of the neuropeptide PACAP (pituitary adenylate cyclase-activating polypeptide) as an inhibitor of megakaryocyte maturation and platelet function has recently been established. PACAP interferes with the regulation of apoptosis in megakaryocytes, via stimulation of NFκB signaling. We assumed that urinary losses of PACAP bound to ceruloplasmin in NS might lead to PACAP deficiency, leading to thrombocytosis and increased platelet reactivity.

The aim of this study was to investigate plasma PACAP levels in relation to blood platelet counts and aggregability in patients with congenital NS (CNS).

Methods: Four patients with CNS of the Finnish type, aged 0.5-19 months were tested. Plasma and urinary levels of PACAP were measured semi-quantitatively by western blot.

Results: All patients had plasma PACAP deficiency (14-40% of control, p<0.001) and excessive urinary PACAP excretion. In one patient aged 19 months both kidneys were removed as a routine treatment of CNS. Plasma PACAP levels progressively increased during the first days after nephrectomy and blood platelet count normalized.

In analogy to PACAP deficient mice, an increased platelet aggregation response to collagen was found in patients in nephrotic state, while platelets after bilateral nephrectomy showed normal reactivity towards collagen.

Conclusions: Our observation provides new insights on the mechanisms of arterial thrombosis in NS and indicates that PACAP deficiency exists in CNS. In analogy to mice, PACAP deficiency seems to play an important role in the thrombocytosis and platelet hyperaggregability in CNS. When confirmed in larger studies, PACAP replacement or stimulation of PACAP receptors might become a valuable therapeutic option for prevention of arterial thrombosis in CNS.

Clinical Analysis of the Largest Number of Fabry Patients in China
Yan Ouyang, Xiaoxia Pan, Weiming Wang, Zhaohui Wang, Xiaobei Feng, Hong Ren, Liyan Ni, Wen Zhang, Nan Chen. *Nephrology, Ruijin Hospital Affiliated to Shanghai Jiaotong University School of Medicine, Shanghai, China.*

Background: Our study is to evaluate the clinical features of patients with Fabry disease (FD).

Methods: We enrolled 47 FD patients in this survey which is the largest cohort in China.

Results: Among all participants, 31 were male and 16 were female, the average age was 28.89±11.80 years (12 to 64 years). The mean onset age was 16.85±12.53 years. Correct diagnosis was made by 1 to 30 years' delay. First symptoms included acroparesthesia and angiokeratoma, the incidence rate of 40.4% and 23.4%, respectively. 27.4% of patients has proteinuria, including five cases (10.6%) of ESRD, 3 cases had renal transplantation. Hypertension and stroke presented in 19.1% and 10.3% of all patients, respectively. Echocardiography showed left ventricular hypertrophy, valve involvement in 41.7% of patients .17 patients (13 males and 4 females) had presumably ischemic lesions on brain MRI .Compare to female patients, males had higher proteinuria ($p<0.05$), more hypertension ($p<0.05$) and lower MDRD-GFR ($p<0.01$), five cases of ESRD were males. Additionally, according to the Clinical classification of FD, our patients are divided into three groups: 31cases are classic type,12 cases are renal variant type, 4 cases are cardiac variant type, eGFR did not show significant statistical differences among three groups ($P> 0.05$).In contrast, proteinuria ($P <0.01$) and serum creatinine ($P <0.05$) has significant differences in the groups. Finally, patients with blood type AB and B were associated with higher serum creatinine ($p<0.01$), more proteinuria ($p<0.05$) and lower eGFR ($p<0.05$) when compare to patients with type A and O.

Conclusions: As the first study of the largest number of Chinese FD patients, it defines the clinical features in patients with FD, in order to improve early intervention. The classic phenotype is the most common in China, and the other types are also confined. Hypertension and proteinuria were associated with worse renal outcome, therefore they should be treated more intensively and it is necessary to establish long-term follow-up system to manage those patients.

SA-PO413

Cystinuria: A Large French Cohort
Caroline Prot Bertoye,[1] Said Lebbah,[2] Michel Daudon,[3] Isabelle Tostivint,[4] Gerard Friedlander,[6] Olivier Traxer,[5] Bertrand Knebelmann,[2] Marie Courbebaisse.[6] *[1]Nephrology, Bichat Hospital, Paris; [2]Nephrology, Necker Hospital, Paris; [3]Physiology, Tenon Hospital, Paris; [4]Nephrology, Pitie Salpetriere Hospital, Paris; [5]Urology, Tenon Hospital, Paris; [6]Physiology, Europeen Georges Pompidou Hospital, Paris.*

Background: Cystinuria is an autosomal recessive disorder and is the cause of 1% and 8% of stones in adults and children respectively. Objectives of our study were to determine epidemiological and clinical characteristics, medical and surgical treatments and co morbidities among cystinuric patients.

Methods: We conducted a retrospective cohort study in France involving 47 centers of adult and pediatric nephrology and urology.

Results: We collected data from 442 cystinuric patients (sex ratio = 1, median age at last follow-up = 32.5 years [range:0.3 – 86.6]). Median age at first symptoms was 16.7 years [0.3 – 72.1]. The main diagnosis modality was a renal colic in 60.6% of cases. Diagnosis, which lagged behind first symptoms by 1.3 years [0.0 – 45.7], was based on stone analysis in 57.7% of cases and on cystinuria assessment in 27.9%. Ninety one percent of patients were treated medically. Cystine chelators were prescribed in 55.3% of patients and induced side effects in 25% of cases. Eighty two percent of patients had at least one urological procedure. After 2000, flexible ureteroscopy was more frequently used than rigid ureteroscopy. In patients followed for over 10 years, the median annual rate of surgical procedures per patient was 0.2 [0.0 – 2.0]. Thirty one percent of adult patients (>16 years) followed for over 10 years had impaired renal function (MDRD estimated glomerular filtration rate < 60 mL/min/1.73 m^2) and 27% of adult patients had hypertension. In univariate analysis, impaired renal function was significantly associated with age, obesity, hypertension and a past history of partial or total nephrectomy.

Conclusions: We report the largest cohort of cystinuric patients. The burden of urological interventions in this disease is high. In particular, chronic renal failure is an underestimated consequence of cystinuria and hypertension prevalence is surprisingly high considering the young age of this population.

SA-PO414

Schimke Immunoosseous Dysplasia Caused by Segmental Paternal Uniparental Disomy for Chromosome 2
Yanqin Zhang, Fang Wang, Huijie Xiao, Jie Ding. *Peking University First Hospital.*

Background: Schimke immunoosseous dysplasia (SIOD) is an autosomal recessive multisystem disorder caused by mutations in the *SMARCAL1* gene. The main clinical findings are spondyloepiphyseal dysplasia (SED), nephropathy, and T-cell deficiency.

Methods: We describe a 7-year-old boy with SIOD. Genetic analysis of *SMARCAL1* was performed in the child as well as his parents.

Results: Molecular analysis showed that the child was homozygous for the mutation, c.1930C>T (p.R644W) in the exon 12 of*SMARCAL1* gene. Carrier testing on the parental samples revealed that the father was heterozygous for the mutation whereas the mother did not carry the mutation. Seven microsatellite markers of chromosome 2 and 12 single-nucleotide polymorphisms around the mutation in the *SMARCAL1* gene were selected to analyse the origins of the patient's chromosome2. Copy-number variants of the exon 12 of *SMARCAL1* gene in the patient and his parents were identified by real time PCR. The results showed that the child has segmental paternal uniparental disomy.

Conclusions: This is the first case of SIOD resulting from uniparental disomy and discloses an alternate mechanism of SIOD. It is also very important for the genetic counseling of the family.

SA-PO415

Uromodulin Mutations Hamper Trafficking of Urate Transporters
Paul Probst, Magdalena Woznowski, Eva Koenigshausen, Ivo Quack, Johannes Stegbauer, Lars C. Rump, Lorenz Sellin. *Nephrology, Heinrich Heine University, Duesseldorf, Germany.*

Background: Point mutations in the uromodulin (UMOD) are the cause for the uromodulin associated kidney disease (UAKD). The earlieast sign of UAKD is a hyperuricemia in adolescents. The retention of mutated UMOD in the secretory pathway leads to a reduced expression and secretion at the plasma membrane. It is known that mutated UMOD interferes with the proper function of ROMK. We postulate that disturbed trafficking of UMOD mediates a retention of renal uric acid transporters such as GLUT9, ABCG2 and OAT4 in the secretory pathway.

Methods: HEK293T-cells transiently expressing uric acid transportes (GLUT9, ABCG2, OAT4) and UMOD are lysed and coimmunoprecipitations are performed. To examine cell surface expression of UMOD and its mutant P236L non permeabelized cells are labeled with UMOD antisera. Susequent immunoprecipitation of UMOD is done. Cells expressing transiently GLUT9, UMOD-WT or UMOD P236L are homogenized in a sucrose buffer. A subcellular fractionation is performed to visualize the distribution of UMOD and urate transporters. By immunofluorescence cos7 cells expressing GLUT9 and either UMOD-WT or UMOD P236L are used for visualization of their subcellular localization of UMOD and the uric acid transporters.

Results: UMOD co-immunoprecipitates with GLUT9, ABCG2 and OAT4. The UMOD mutant P236L shows a considerably reduced cell surface expression compared to UMOD WT. The coexpression of UMOD P236L with GLUT9deltaN results in an augmented retention within the secretory pathway. UMOD P236L and GLUT9 are coexpressed a reduced GLUT9 staining at the plasma membrane and an increased GLUT9 staining in the cytoplasm are seen.

Conclusions: The urate transporters GLUT9, ABCG2 and OAT4 are interaction partners of UMOD. Proper trafficking of UMOD to the plasma membrane is essential for cell surface expression of GLUT9. Furthermore, UMOD mutations impair the cell surface expression of GLUT9.

SA-PO416

Uromodulin Mutation P236R Is Associated with Long-Segment Bilateral Renal Artery Stenosis
Lorenz Sellin,[1] Aleksadner Prejbisz,[3] Elzbieta Szwench,[3] Magdalena Woznowski,[1] Dariusz Sajnaga,[5] Ilona Michalowska,[7] Magdalena Januszewicz,[6] Mieczyslaw Litwin,[8] Andrzej Wiecek,[4] Udo Helmchen,[2] Lars C. Rump,[1] Andrzej Januszewicz.[3] *[1]Nephrology, Heinrich Heine University, Duesseldorf, Germany; [2]Nierenregister Hamburg, Universitaetsklinikum Eppendorf, Hamburg, Germany; [3]Hypertension, Institute of Cardiology, Warsaw, Poland; [4]Nephrology, Endocrinology and Metabolic Diseases, Medical University of Silesia, Katowice, Poland; [5]Cardiology, Railway Hospital, Pruszkow, Poland; [6]Radiology, Medical University of Warsaw, Warsaw, Poland; [7]Radiology, Institute of Cardiology, Warsaw, Poland; [8]Nephrology and Hypertension, Children's Memorial Health Institute, Warsaw, Poland.*

Background: Uromodulin (UMOD) associated kidney disease (UAKD) is associated with juvenile hyperuricemia, followed by progressive interstitial fibrosis leading to endstage renal disease with about 20 years after disease onset. A minority of the effected individuals with this autosomal dominant disease present renal cysts. Here we present a polish-german family with 39 members out of 3 generations with UAKD. Within this pedigree we found a long-segement bilateral renal artery stenosis as a novel phenotype.

Methods: The members of the polish-german family received a physical examination, doppler ultrasound of the kidneys and lab tests for renal function, RAAS und urine analysis. 8 family members (WT and UMOD P236R) had contrast enhanced renal artery imaging by angio CT or MRI done. Genotyping was done by PCR and sequencing.

Results: In the polish-german family with 39 members 11 family members carried the mutation which. All family members having bilateral renal artery stenosis carried the UMOD mutation P236R (c707C>G). Overall 11 family members carried the mutation. Statistical analysis showed a strong correlation (r=0,84) between the reduced renal artery caliber and decreased eGFR. The earliest symptom is hyperuricemia in childhood.

Conclusions: The uromodulin mutation c.707C>G results in a single aminoacid exchange p.P236R. This is closely correlated with long-segment bilateral renal artery stenosis. Hyperuricemia might cause proliferation of vascular smooth muscle cells within the renal artery wall causing the stenosis.

SA-PO417

Inflammation Is an Early Event of Pathogenesis in Uromodulin-Associated Kidney Disease Celine Schaeffer,[1] Matteo Trudu,[1] Michela Riba,[2] Paola Brambilla,[2] Ilenia Bernascone,[1] Sylvie Janas,[3] Masami Ikehata,[4] Antonio Amoroso,[5] Gian Marco Ghiggeri,[5] Francesco Scolari,[5] Filippo Martinelli Boneschi,[2] Maria Pia Rastaldi,[4] Olivier Devuyst,[6] Luca Rampoldi.[1,5] *[1]Division of Genetics and Cell Biology, Dulbecco Telethon Institute c/o San Raffaele Scientific Institute, Milan, Italy; [2]San Raffaele Scientific Institute, Milan, Italy; [3]Université Catholique de Louvain, Brussels, Belgium; [4]Fondazione D'Amico per la Ricerca Sulle Malattie Renali, Milan, Italy; [5]MCKD Consortium, Italy; [6]University of Zurich, Zurich, Switzerland.*

Background: Uromodulin-associated kidney disease (UAKD) is an autosomal dominant disorder caused by mutations in *UMOD*, the gene encoding uromodulin. We previously demonstrated that transgenic mice expressing mutant uromodulin ($Tg^{UmodC147W}$) are a remarkable model of UAKD that recapitulates the main features of the disease, i.e tubulo-interstitial nephritis and progressive renal failure.

Methods: To gain insight into the disease pathogenesis, we performed microarray profiling, qRT-PCR and biochemical analysis on kidneys from $Tg^{UmodC147W}$ mice and from expression-matched transgenic mice for the wild-type protein.

Results: Kidney microarray analysis performed on young pre-symptomatic mice (4 and 8 weeks) showed significant upregulation of pathways related to inflammation and fibrosis. Interestingly, some key pro-inflammatory signals (eg IL-6, TNFa) were already upregulated as early as at 1 week of age, well before the presence of any sign of renal damage but soon after first detection of the accumulation of misfolded mutant uromodulin in the endoplasmic reticulum (ER). Uromodulin ER retention was never accompanied by induction of the unfolded protein response or apoptosis.

Conclusions: These data suggest that chronic inflammation plays a key role in the onset and progression of UAKD. Uromodulin mutations seem to exert a non cell-autonomous proteotoxic effect, mediated by the induction of pro-inflammatory signals. The identification of such signals downstream of mutant uromodulin ER retention could represent a significant step towards therapeutic intervention and might have broad relevance for tubulo-interstitial nephritis and other conformational diseases.

SA-PO418

Two New Mutations in *NPHS2* Represent an Egyptian Founder Mutation in Nephrotic Syndrome Virginia Vega-Warner,[1] Neveen Soliman Elshakhs,[2,3] Hanan Fathy,[4] Heon Yung Gee,[1] Pawaree Saisawat,[1] Svjetlana Lovric,[1] Shazia Ashraf,[1] Gil Chernin,[1] Friedhelm Hildebrandt.[1,5] *[1]Pediatric and Human Genetics, University of Michigan, Ann Arbor, MI; [2]Department of Pediatrics and Center of Pediatric Nephrology & Transplantation, Cairo University, Cairo, Egypt; [3]Egyptian Group for Orphan Renal Diseases (EGORD), Cairo, Egypt; [4]Pediatric Nephrology Unit, Alexandria University, Alexandria, Egypt; [5]Howard Hughes Medical Institute, Ann Arbor, MI.*

Background: Mutations in *NPHS2* (podocin), a recessive gene, cause nephrotic syndrome (NS) in children and rarely in adults. Kidney biopsies reveal focal segmental glomerulosclerosis (FSGS) or diffuse mesangial sclerosis. In general, NS resulting from *NPHS2* mutations is resistant to steroid treatment (SRNS).

Methods: Blood samples of children with NS from Egypt were received between 2006 and 2012. Genomic DNA was extracted using Puregene sytem (Qiagen). Mutation analysis was performed by direct Sanger sequencing of all 8 exons of *NPHS2*.

Results: During this period 132 Egyptian families (175 individuals) were studied. Most of the families had SRNS and kidney biopsies showed FSGS. In 20 families (15%), we detected both causative *NPHS2* mutations. Among these, 18 families had homozygous and 2 families showed compound heterozygous mutations. Two mutations were novel: Ex1:c.1A>T(H); p.M1L and Ex 5:c.596dupA(H); p.N199K*fs*14. These were present in 6 and 4 families, respectively. One of these mutations was presented in families from different cities in Egypt. Both mutations were absent from 90 healthy controls and from 1,732 families with other ethnicities received in the same period. Interestingly, in one of the families with multiple consanguinities, both founder mutations segregated in different members.

Conclusions: Given the concentration of these novel mutations in the Egyptian population and the absence from patients of other ethnicities, we conclude that both are founder mutations in the Egyptian population allowing for more directed mutation analysis.

SA-PO419

The Spectrum of Genes Causing Nephrotic Syndrome in Saudi Arabia Mohamed Al-hamed,[1] John Andrew Sayer,[1] Essam A. Alsabban,[2] Abbas Alabbad,[2] Naffaa Nafe Alharbi,[2] Ibrahim A. Alhassoun,[2] Eissa Ali Faqeih,[3] Brian F. Meyer.[2] *[1]Insitute of Genetic Medicine, Newcastle University, Newcastle, Tyne and Wear, United Kingdom; [2]King Faisal Specialist Hospital and Research Centre, Riyadh, Saudi Arabia; [3]King Fahad Medical City, Saudi Arabia.*

Background: Nephrotic Syndrome (NS) is a renal disease characterized by heavy proteinuria, hypopalbuminemia, odema and hyperlipidemia. Its presentation within the first 3 months of life (congenital NS) and in multiple family members suggests an underlying inherited cause. Inherited NS is genetically heterogeneous and to date defects in at least ten genes have been recognized. Proteins encoded by these genes influence the function of podocytes and the slit diaphragm. The Saudi Arabian population has a tribal structure and the overall rate of consanguineous marriage is reported to be over 55%. In such a population, the identification of mutations in known disease genes causing inherited NS is a robust method to allow appropriate diagnosis and clinical management.

Methods: To determine the frequency of inherited NS, sixty six cases (representing 53 families with NS) from Saudi Arabia were screened for mutations in the following genes: *NPHS1, NPHS2, PLCE1, LAMB2,* and *CD2AP.*

Results: We detected likely causative mutations in 25 out of 53 families studied. In 15 families where familial NS was suspected, we found mutations in 12 families (80%). We found that the most common genetic cause of NS in our cohort was a homozygous mutations in the *NPHS2* gene, found in 10 of the 53 families (19%). Mutations in the *NPHS1* and *PLCE1* genes allowed a molecular genetic diagnosis in 13% and 7% of families, respectively. Mutations in *LAMB2* and *CD2AP* remained rare. We detected 11 novel sequence variants in this study and their pathogenicity was analysed by in silico tests and by genetic screening of control populations.

Conclusions: This is the first report describing the molecular genetics of NS in an Arabian peninsula population.

SA-PO420

The Use of Exome Sequencing in Families with Focal and Segmental Glomerulosclerosis to Obtain Genetic Diagnoses Moumita Barua,[1] Giulio Genovese,[1,2,3] Michael Fischereder,[4] Katrin Uhlig,[5] Andrea Uscinski Knob,[1] Martin R. Pollak.[1] *[1]Division of Nephrology, Department of Medicine, Beth Israel Deaconess Medical Center, Boston, MA; [2]Department of Genetics, Harvard Medical School, Boston, MA; [3]Program in Medical and Population Genetics, Broad Institute of MIT and Harvard, Cambridge, MA; [4]Nephrology Division, Department I of Internal Medicine, University Hospital Munich-Campus Grosshadern, Ludwig-Maximilians-University, Munich, Marchioninistrasse 15, Germany; [5]Division of Nephrology, Department of Medicine, Tufts Medical Center, Boston, MA.*

Background: Advances in sequencing technology now makes it feasible to sequence the entire coding region of an individual's genome, termed exome sequencing. The majority of Mendelian disease-causing mutations have been found in the exome.

Methods: We aim to sequence the exome of two related individuals from autosomal dominant families with focal and segmental glomerulosclerosis (FSGS) to identify known and novel disease-causing genes.

Results: 29 individuals from 15 families with nephrologist reported proteinuria and/or a pathologic diagnosis of FSGS had exome sequencing performed. Each individual yielded 33 to 92 novel heterozygous and homozygous non-synonymous (NS) variants after filtering. Affected family members shared 1 to 46 novel NS variants. Capture of the known renal disease-causing genes was heterogeneous though adequate for most genes, with the notable exception of INF2. To illustrate the clinical utility of exome sequencing, we provide the example of uncovering a novel WT1 mutation, p.P382T, in one family with FSGS, when this diagnosis had not been previously suspected. The mutation was subsequently confirmed by Sanger sequencing in four affected family members while absent in nine unaffected members. Affected individuals presented during childhood with isolated nephrotic syndrome in the absence of associated syndromic features of WT1 disease.

Conclusions: Exome sequencing is powerful technology with the promise to identify known and novel disease causing genes. Its main limitation is heterogeneous capture of the exome.

Funding: NIDDK Support, Government Support - Non-U.S.

SA-PO421

Whole Exome Sequencing Diagnoses NPHP3 in a Consanguineous Family Originally Diagnosed with FSGS Moumita Barua,[1] Giulio Genovese,[1,2,3] Andrea Uscinski Knob,[1] Martin R. Pollak.[1] *[1]Division of Nephrology, Department of Medicine, Beth Israel Deaconess Medical Center, Boston, MA; [2]Department of Genetics, Harvard Medical School, Boston, MA; [3]Program in Medical and Population Genetics, Broad Institute of MIT and Harvard, Cambridge, MA; [4]Clinical Study Group Iran, IR of Iran Academy of Medical Sciences, Tehran.*

Background: Accurate diagnoses can be difficult given the overlapping clinical and histopathologic features of many kidney disorders. We show here the benefit of genetic testing in obtaining an accurate diagnosis of a consanguineous family originally diagnosed with FSGS but found to have NPHP3 disease with whole exome sequencing.

Methods: We enriched and sequenced the exome of one affected individual using the Nimblegen 2.1M Human Exome kit and Illumina HiSeq 2000, respectively. For validation, interesting variants were sequenced in 3 affected and 11 unaffected individuals by Sanger method. Phenotypic data were collected from review of medical records.

Results: Family FG-CR is an Iranian consanguineous family with autosomal recessive inheritance. A marriage between related individuals resulted in 9 children, 3 of whom were affected. The exome of individual FG-CR 6 yielded 165 novel non-synonymous variants but only 2 that were homozygous. Given its known association with kidney disease, we selected the NPHP3 gene for further study. The variant p.R301T in the gene NPHP3 segregated with disease when Sanger sequenced in the 14 available samples. All 3 affected individuals presented with nephrotic range proteinuria and developed end-stage renal disease. Individual FG-CR 6 had a native kidney biopsy, which was interpreted to be consistent with FSGS.

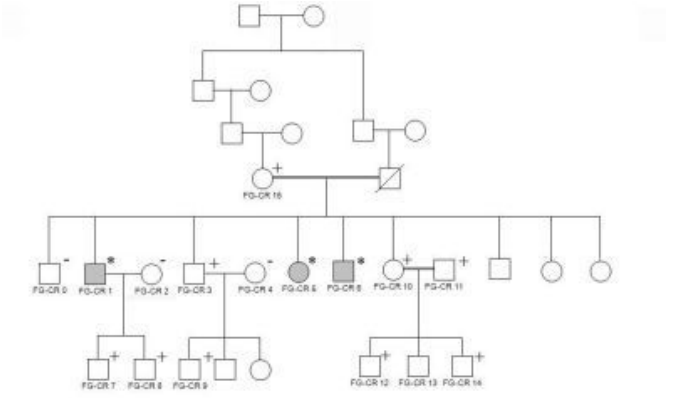

Figure 1. Pedigree of family FG-CR. Affected individuals are shaded grey. Individuals with the NPHP3 p.R301T variant who are homozygous are denoted with * to the upper right while those who are heterozygous are denoted with +. Individuals without the variant are indicated with -. The DNA sample belonging to FG-CR 13 was not tested.

Conclusions: Exome sequencing is a useful clinical diagnostic tool to arrive at accurate diagnoses in inherited kidney disease.

Funding: Government Support - Non-U.S.

SA-PO422

A Novel Mutation outside of the Candidate Region for Diagnosis in the Formin Gene INF2 Causes Focal Segmental Glomerulosclerosis Not Associated with Charcot-Marie-Tooth Neuropathy

Maria Sanchez-ares,[1] Marina Garcia-vidal,[1] Antucho Espinosa-estévez,[1] Lisbeth S. Silva,[1] Julio Pardo,[2] Eduardo Vazquez-martul,[3] Xose Lens-neo,[1] Miguel A. Garcia-Gonzalez,[1] Miguel A. Garcia-Gonzalez.[1] *[1]Group of Genetics and Developmental Biology of Renal Diseases, Clinical University Hospital (CHUS), Health Research Institute of Santiago de Compostela (IDIS, Santiago de Compostela, Galicia/A Coruña, Spain; [2]Department of Neurology, Clinical University Hospital (CHUS), Santiago de Compostela, Galicia/A Coruña, Spain; [3]Anatomy Pathology Unit, Universitary Hospital (CHUAC), A Coruña, Galicia/A Coruña.*

Background: Focal and segmental glomerulosclerosis (FSGS) is a histological pattern derived from several etiologies, including genetics. The autosomal dominant (AD) form of FSGS is a heterogenic disease with three known genes: α-actinin 4 (*ACTN4*), canonical transient receptor potential 6 (*TRPC6*) and inverted formin 2 (*INF2*), which was recently discovered. More recently, *INF2* mutations have also been attributed to Charcot-Marie-Tooth neuropathy associated with FSGS.

Methods: In this study, we performed direct sequencing, histological characterization and functional studies in a cohort of families with AD-FSGS.

Results: We detected a novel mutation in exon 6 of *INF2* gene. This mutation is predicted to alter a highly conserved amino acid residue within the 17th α-helix of the diaphanous inhibitory domain (DID) of the protein. A long-term follow-up of this family showed that all patients were diagnosed in adulthood and progressed to end-stage renal disease (ESRD) at different times without clinical or electrodiagnostic evidence of neuropathy.

Conclusions: This is the first study to describe a mutation in *INF2* linked non-syndromic FSGS outside of the candidate region used for rapid diagnosis (exons 2 to 4), indicating the necessity for full gene sequencing if no mutation was found in this region of the gene.

Funding: Government Support - Non-U.S.

SA-PO423

Highly Parallel Mutation Analysis in 21 Known Nephrotic Syndrome Genes by Next-Generation Sequencing

Svjetlana Lovric,[1] Humphrey Fang,[1] Virginia Vega-Warner,[1] Pawaree Saisawat,[1] Shazia Ashraf,[1] Edgar Otto,[1] Friedhelm Hildebrandt.[1,2] *[1]Pediatrics and Human Genetics, University of Michigan, Ann Arbor, MI; [2]Howard Hughes Medical Institute, University of Michigan, Ann Arbor, MI.*

Background: In nephrotic syndrome (NS), more than 21 single-gene causes are known, but mutation analysis in these genes is time and cost intensive. Here we develop a new method for mutation analysis using a PCR-based microfluidic technology (48.48 Access Array System from Fluidigm™) with consecutive next generation sequencing (NGS).

Methods: As a proof of principle, we evaluated 48 patients with confirmed homozygous or heterozygous mutations in various NS genes. We applied a 10-fold primer multiplexing approach allowing PCR-based amplification of 499 amplicons (424 exons) for 48 DNA samples simultaneously. The maximal length of each PCR Product was 290 bp. In our analysis we included the recessive NS genes: *NPHS1*, *NPHS2*, *LAMB2, PLCE1, COQ6, SMARCAL 1,COQ2, PDSS2, CD2AP, SCARB2, CFH, CUBN, PTPRO, MYO1E, NEIL1, ITGA3* and the dominant NS genes *ACTN4*, *WT1*, *LMX1B, TRPC6 and INF2.* In a second PCR we indexed all 48 patient-derived PCR-products uniquely with different barcodes. Bidirectional (150 bases) sequencing was performed on one lane of a GA II instrument (Illumina™). Bioinformatics analysis was performed using "CLC Genomics Workbench™" software.

Results: NGS and bioinformatics analysis resulted in 15.2 million mapped reads with a median exon coverage depth of 374-fold per patient. All DNA samples (100%) and 468/499 exons (93.78%) consistently showed sufficient coverage depth above 25-fold. We identified the disease causing mutation in 42/48 patients (87.5%) of our cohort.

Conclusions: We conclude that the combined method of array-based multiplexed PCR amplification on a Fluidigm™ Access Array platform followed by NGS is a novel highly efficient approach towards mutation analysis in the heterogeneous single-gene forms of NS.

A Recurrent Homozygous Missense Mutation in *TTC21B* Encoding the Cilia Protein IFT139 Unexpectedly Causes Nephrotic Syndrome/FSGS

Stephanie Woerner,[1] Albane A. Bizet,[1] Evelyne Huynh Cong,[1] Emilie Filhol,[1] Olivier Gribouval,[1] Sophie Thomas,[2] Anais Raia,[1] Flora Silbermann,[1] Christine Bole-feysot,[3] Patrick Nitschke,[3] Guillaume Canaud,[4] Jamil Hachicha,[5] Marie-Claire Gubler,[1] Geraldine Mollet,[1] Sophie Saunier,[1] Corinne Antignac.[1] *[1]Inserm U983; [2]Inserm U781; [3]Genomic Platform Institut Imagine; [4]Nephrology Unit, Necker Hospital, Paris, France; [5]Nephrology Unit, Sfax, Tunisia.*

Background: To identify novel genes involved in hereditary steroid-resistant nephrotic syndrome (SRNS), we performed exome sequencing in consanguineous families.

Results: We found a recurrent pathogenic homozygous missense mutation, P209L, in *TTC21B* in2 families with SRNS and focal and segmental glomerulosclerosis (FSGS). Further screening revealed the same homozygous mutation in 5 additional families with SRNS/FSGS. *TTC21B* encodes the retrograde intraflagellar transport protein IFT139 and intriguingly, this mutation was previously reported to cause isolated nephronophthisis (NPH). Indeed, 3 unrelated patients diagnosed as NPH and carrying the homozygous P209L mutation also have proteinuria and FSGS. All patients display hypertension,glomerulopathy with proteinuria (1-7 g/24h), FSGS, and severe tubular basement membrane anomalies characteristic of NPH. End-stage renal failure occurred at a mean age of 23 (15-34 years). All patients were from North Africa or Portugal and shared a common haplotype at the locus. The P209L variation was not found in 161 ethnic controls. We found that IFT139 was expressed by podocytes and distal tubules in fetal and adult human kidneys. Developing podocytes in fetal kidney and undifferentiated podocytes in culture have a cilium, whereas it was absent in differentiated podocytes. While IFT139 localizes at the cilia base in undifferentiated podocytes, its staining follows the extended microtubule network in non-ciliated differentiated cells.

Conclusions: Our results point to a critical function of IFT139 in podocytes in addition to tubular epithelial cells, likely via dysregulation of ciliary transport and microtubule network essential for cell polarity and proper organization/maintenance of intercellular junctions, including the slit diaphragm.

Comparison of the Clinical Features in X-Linked and Autosomal Recessive Alport Syndrome

Judith A. Savige,[1] Vanessa Sivakumar,[1] Mardhiah Binti Mohammad,[1] Deb J. Colville,[1] Helen Storey,[2] Frances Anne Flinter,[2] Yanyan Wang.[1] *[1]Medicine (Northern Health), University of Melbourne, Melbourne, Victoria, Australia; [2]Genetics, Guy's and St Thomas' Hospital, London, United Kingdom.*

Background: X-linked Alport syndrome accounts for 85% patients and recessive disease for 15% but the distinction is important because of the different implications for their families. We have compared clinical features in adults with the two modes of inheritance.

Methods: Patients with X-linked disease were identified on the basis of a mutation in the COL4A5 gene, and those with recessive disease with two COL4A3 or COL4A4 mutations. All patients were examined by the same nephrologist and ophthalmologist.

Results: Patients included 18 males and 24 females from 24 families with X-linked Alport syndrome, and 15 patients from 10 families with autosomal recessive disease. Most men with X-linked disease had renal failure (14/18, 78%), hearing loss (17/18, 94%), lenticonus (11/17, 65%) and the central (9/17, 53%) or peripheral (12/15, 80%) retinopathy. Most females with X-linked disease had an affected male relative (15/19, 79%), but renal failure (3/24, 13%), and central retinopathy (4/24, 17%) were uncommon, and lenticonus did not occur. However hearing loss (10/24, 42%) and peripheral retinopathy (6/15, 40%) were frequently present. With recessive Alport syndrome, males (8/15, 53%) and females (7/15, 47%) were affected equally often, and another family member with renal failure was uncommon (2/10, 20%). Most patients had proteinuria (15/15, 100%), renal failure (14/15, 93%), hearing loss (15/15, 100%), lenticonus (12/15, 80%) and the central (10/14, 71%) or peripheral (9/11, 82%) retinopathy. End-stage renal failure developed at 20 years (median, range 14 – 50) in males with X-linked disease, and at 25 (range 15 – 35) in recessive disease. Mutations resulting in a stop codon occurred in 46% (11/24) patients with X-linked disease and 80% (8/10) with recessive disease.

Conclusions: Autosomal recessive Alport syndrome should be considered in all patients, especially from consanguineous families, where the father has haematuria, and in females with proteinuria, renal impairment, hearing loss, lenticonus or a central retinopathy.

SA-PO426

Copper Deficiency in Cystinosis Patients Martine T. Besouw,[1] Jerry A. Schneider,[2] Francesco Emma,[3] Francois Nobili,[4] Fransiska Malfait,[5] Flemming Skovby,[6] Sofie Symoens,[5] Anne De Paepe,[5] Elena N. Levtchenko.[1] *[1]Development and Regeneration, Catholic University (KUL), Leuven, Belgium; [2]Pediatrics, University of California, San Diego, CA; [3]Nephrology and Urology, Bambino Gesù Children Hospital and Research Institute, Rome, Italy; [4]Pediatric Nephrology, University Hospital, Besançon, France; [5]Medical Genetics, University Hospital, Ghent, Belgium; [6]Clinical Genetics, Juliane Marie Centre, University Hospital, Copenhagen, Denmark.*

Background: Cystinosis is an autosomal recessive disorder, marked by intralysosomal cystine accumulation in various tissues, causing renal Fanconi syndrome (FS). The disease is treated by cysteamine. Recently, 8 cystinosis patients were reported with skin lesions and some - with severe bone and muscular weakness, caused by cysteamine. Electron microscopy of skin biopsies showed "cauliflower" collagen fibres caused by decreased collagen cross-linking. We hypothesized that cysteamine might interfere with this process in analogy to D-penicillamine. Furthermore, since the generation of aldehydes required for cross-linking is catalyzed by the enzyme lysyl oxidase, which needs copper as a co-factor, we measured serum copper and ceruloplasmin levels and urinary copper excretion in cystinosis patients, since copper deficiency might contribute to cysteamine toxicity.

Methods: 35 cystinosis patients were included: 21 with FS (including 6 with cysteamine toxicity), 12 with renal graft, 1 was on hemodialysis and 1 with ocular cystinosis.

Results: Mean ± SD serum copper and ceruloplasmin levels were lower in patients with cysteamine toxicity (63±7 vs 98±27 µg/dL and 0.20±0.02 vs 0.31±0.08 g/L respectively; $p<0.01$), urinary copper excretion was increased in patients with FS (169±75 vs 35±20 µg/g; $p<0.01$).

Conclusions: Increased urinary copper excretion leading to copper deficiency might decrease lysyl oxidase activity resulting in decreased aldehyde formation. Subsequent administration of cysteamine can block the remaining aldehydes, further diminishing collagen cross-linking. This mechanism is likely to be responsible for cysteamine toxicity in cystinosis patients, therefore, copper suppletion might prevent cysteamine toxicity.

Role of the Renin-Angiotensin System in TSC Renal Angiomyolipoma Progression Brian J. Siroky,[1] Ryan J. Reichert,[2] Lu Lu,[1] Robert Lou,[1] Ej Kathman,[1] John J. Bissler.[1] *[1]Nephrology & Hypertension, Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]Medicine, Northeast Ohio Medical University, Rootstown, OH.*

Background: Tuberous Sclerosis Complex (TSC) is a multi-system hamartomatous disease that is genetically linked to disruptions of *TSC1* or *TSC2*. TSC lesions are highly vascularized and associated to aberrant signaling of mTOR. Previous studies have focused on the blockade of the mTOR pathway for disease management. It has been suggested clinically that disease progression is also decelerated when the hypertensive manifestations of TSC are managed with renin-angiotensin system (RAS) blockade. In this study, we utilized a renal cell model of TSC to investigate the effects of angiotensin II (ANG II) on intracellular Ca^{2+} levels, and also VEGF release. Intracellular Ca^{2+} is a known signaling effector of ANG II mediated AT_1 G protein-coupled receptor activation. VEGF release, which has been linked to ANG II signaling, is elevated in TSC cells, and is an important factor in angiomyolipoma vascularization.

Methods: We measured changes in intracellular Ca^{2+} levels using fura-2/AM, and VEGF secretion by ELISA in *TSC2*-deficient human renal angiomyolipoma cells (TRI102), and in cells in which TSC2 has been re-expressed (TRI103).

Results: We found that TRI102 cells had higher baseline Ca^{2+} levels, and that ANG II (1 µM) produced a greater increase in intracellular Ca^{2+} in TRI102 cells compared to TRI103. We also observed greater baseline VEGF release in TRI102 compared to TRI103 cells. mTOR inhibition (20 nM RAD001, 24 hrs) lowered VEGF release in TRI102 cells while TRI103 cells were not affected. ANG II (10 and 100 nM, 24 hrs) increased VEGF release in TRI102 and not TRI103 cells.

Conclusions: These results suggest hypersensitivity of *TSC2*-deficient angiomyolipoma cells to ANG II, which may contribute to aberrant cellular activity. Furthermore, these findings support a possible role of RAS signaling in TSC disease progression, and suggest the potential of utilizing RAS blockade for tumor/patient management in TSC.

Sporadic Renal Angiomyolipoma and Tuberous Sclerosis Complex Related Renal Angiomyolipoma in the United States Peter Sun,[1] Zhimei Liu,[2] Judith A. Prestifilippo,[2] Hearns Charles,[3] John C. Hulbert,[4] John J. Bissler.[5] *[1]Kailo Research Group; [2]Novartis Pharmaceuticals Corporation; [3]NYU Langone Medical Center; [4]Urologic Physicians; [5]University of Cincinnati.*

Background: This study aimed to assess the proportion of sporadic renal Angiomyolipoma (AML) versus tuberous sclerosis complex (TSC) related AML in the United States.

Methods: A retrospective cohort study was conducted using three US national healthcare claims databases (Years 2000-2010, 60+ million population). Patients with an AML diagnosis (ICD9-CM 223.0) and a minimal 2year health plan enrollment (one year prior to and one year following newly observed AML diagnosis) were included. AML patients with a TSC diagnosis (ICD9-CM 759.5) were grouped as TSC AML patients; the rest were grouped as patients with sporadic AML. Proportions for each group, as stratified by age, health plan types, were compared using two-sample t-tests.

Results: Patients (N=18,146) had a mean age of 55.4 years at newly observed AML diagnosis; 47.1% were male. In all AML patients, 26.1% were TSC related and 73.9% were sporadic AML. These rates were different across age groups (TSC-AML: 26.8-53.6%; sporadic AML: 46.4-73.3%), and varied by data sources. The proportion of TSC AML was much higher than sporadic AML in the Medicaid database (88.6% versus 11.4%), but was lower than sporadic AML in the commercial databases (database# 1: 42.2% versus 57.8%; database# 2: 1.3% versus 98.7%).

Conclusions: The proportions of patients with sporadic AML or TSC related AML varied by age groups and data sources. This should be taken into account when analyzing outcomes related to AML treatment.

Measurement of 2,8-Dihydroxyadenine Excretion in Patients with APRT Deficiency Using UPLC-MS/MS Runolfur Palsson,[1,2] Baldur Bragi Sigurdsson,[3] Margret Thorsteinsdottir,[2,3] Vidar O. Edvardsson.[1,2] *[1]Landspitali - National University Hospital of Iceland; [2]University of Iceland; [3]Arctic Mass, Reykjavik, Iceland.*

Background: Adenine phosphoribosyltransferase (APRT) deficiency results in excessive urinary excretion of poorly soluble 2,8-dihydroxyadenine (DHA), causing recurrent kidney stones and/or chronic kidney disease (CKD) in affected patients. Treatment with allopurinol has proved effective but reliable methods for therapeutic monitoring are lacking. We evaluated a new ultra-performance liquid chromatography-electrospray tandem mass spectrometry (UPLC-MS/MS) method for measuring urinary DHA excretion in patients with APRT deficiency.

Methods: UPLC-MS/MS was used to measure the concentration of DHA and adenine in urine samples from 2 patients with APRT deficiency, before and during treatment with allopurinol 300 mg/day and the alternative agent, febuxostat 80 mg/day. Urine samples from 4 healthy subjects were used as controls. Aliquots of urine were collected immediately after the urine container had been inverted several times to suspend settled particles. The pH of the aliquots was adjusted to 10 using 20 mM NH_4OH to dissolve all precipitates before testing. The urinary excretion of DHA and adenine are expressed as DHA-to-creatinine and adenine-to-creatinine ratio (mmol/mmol).

Results: In 4 healthy controls, the average DHA-to-creatinine ratio was 0.08 mmol/mmol and the adenine-to-creatinine ratio was below a quantifiable level (<2.96 mmol/mmol). In the patient treated with allopurinol, the DHA-to-creatinine ratio decreased from 34.0 to 11.0 mmol/mmol and the adenine-to-creatinine ratio increased from 4.0 to 24.0 mmol/mmmol. In the patient treated with febuxostat the DHA-to-creatinine ratio decreased from 22.0 to 3.0 mmol/mmol and the adenine-to-creatinine ratio increased from 7.0 to 21.0 mmol/mmol.

Conclusions: Marked reduction in urinary excretion of DHA was observed after pharmacotherapy was initiated. However, both patients continued to excrete substantial amounts of DHA on conventional doses of both drugs. These preliminary data suggest that the novel UPLC-MS/MS assay will greatly enhance monitoring of pharmacotherapy in patients with APRT deficiency.

LRRC6 Identified as a Novel Single-Gene Cause of Primary Ciliary Dyskinesia by Homozygosity Mapping and Whole Exome Resequencing Katrina A. Diaz,[1] Heon Yung Gee,[1] Moumita Chaki,[1] Toby W. Hurd,[1] Edgar Otto,[1] Jan Peter Halbritter,[1] Maimoona A. Zariwala,[3] Michael R. Knowles,[3] Friedhelm Hildebrandt.[1,2] *[1]Departments of Pediatrics and Human Genetics, University of Michigan, Ann Arbor, MI; [2]Howard Hughes Medical Institute, University of Michigan, Ann Arbor, MI; [3]Cystic Fibrosis/Pulmonary Research and Treatment Center, University of North Carolina, Chapel Hill, NC.*

Background: Primary ciliary dyskinesia (PCD) is a rare autosomal recessive disorder with a complex phenotype caused by impaired motility of cilia. The disease is characterized by abnormal function and/or ultrastructural defects of the ciliary mechanism. Mutations in genes encoding for parts of the ciliary ultrastructure have been recently implicated in the pathogenesis of the disease. The objective of this study was to identify novel single-gene causes of PCD by whole exome resequencing (WER).

Methods: To identify novel PCD-causing genes, homozygosity mapping was performed as well as WER in a cohort of 44 families with the disease. Homozygous recessive mutations were further evaluated for candidacy.

Results: A homozygous frameshift mutation (p.W210CfsX12) in the gene *LRRC6* was identified in a Pakistani family with two affected siblings. This mutation segregated with the affected status of each individual in the family and was confirmed with Sanger sequencing. *LRRC6* is a gene involved in ciliary assembly and maintenance similar to *LRRC50*, a gene with known association with inner and outer dynein arm ultastructural defects. This is congruent with the phenotype of the affected individuals. Additionally, there is a *D. rerio* homolog model (*Lrrc6l*) as well as a *D. melanogaster* homolog model (*tilB*) available for *LRRC6* that exhibit dynein arm defects and impaired ciliary motility.

Conclusions: There is strong evidence that *LRRC6* is associated with inner and outer dynein arm defects and is a novel single-gene cause of PCD.

***GSTT1* Gene Abnormality in Minimal Change Nephrotic Syndrome with Hyper Immunoglobulin E** Kohei Miyazaki, Shinsuke Fujita, Hitomi Nishi, Keisuke Sugimoto, Mitsuru Okada, Tsukasa Takemura. *Pediatrics, Kinki University School of Medicine, Osakasayama, Osaka, Japan.*

Background: The cause of minimal change nephrotic syndrome (MCNS) is considered to involve abnormalities of cellular and humoral immunity such as increases in T-helper (Th) 2 cytokines reflecting a Th2-dominant state among T lymphocytes, as well as hypersensitivity of $CD8^+$ cells to antigenic stimuli. Imbalance between Th1 and Th2 lymphocytes and effects of reactive oxygen species (ROS) upon glomerular capillary walls have been implicated in MCNS. In addition, Oxidant/antioxidant imbalance has been reported to be involved in development of the nephrotic syndrome (NS).

Methods: Among 63 pediatric patients with MCNS at our institution, we identified 29 children with MCNS accompanied by allergic disease. Among the 29 patients, 15 who experienced remission without immunosuppressant treatment including corticosteroids, were enrolled in the present study. By polymerase chain reaction and comparative genomic hybridization, we evaluated mutations of the GSTT1 gene (*GSTT1*), a member of the glutathione S-transferase (GST) supergene family associated with both protection of cells from ROS and control of allergic reactions and serum IgE.

Results: Among 15 children with MCNS, IgE elevation (over 2000 IU/L) and *GSTT1* abnormality (complete deletion of *GSTT1* identified by Array CGH) was found in 2 who showed severe allergic symptoms. Serum ROS concentrations in these 2 patients were significantly higher than in healthy controls or other MCNS patients. The serum dROM/ROS ratio was significantly low in this patient with *GSTT1* abnormality (2.07 in patient 1, 2.48 in patient 2) compared with that in MCNS patients with no *GSTT1* abnormality (median, 3.54) or that in healthy control subjects (3.47), indicating deficient ROS degradation. In addition, IL-4 in both patients was very high, indicated that a Th2 shift caused by increased serum IL-4 was observed.

Conclusions: These results suggest presence of a *GSTT1* abnormality in some children with MCNS having marked serum IgE elevations and various allergic complications. Defective ROS degradation and Th1/Th2 imbalance caused by *GSTT1* abnormality could initiate proteinuria leading to MCNS.

SA-PO432

Mitochondrial Stability Is Important to High Glucose Induced Podocyte Injury Dae Eun Choi,[1] Jin Young Jeong,[1] Yoon-Kyung Chang,[2] Ki Ryang Na,[1] Kang Wook Lee,[1] Young Tai Shin.[1] *[1]Internal Medicine, Chungnam National University Hospital, Daejeon, Republic of Korea; [2]Internal Medicine, Daejoen Saint Mary Hospital, Daejeon, Republic of Korea.*

Background: Podocyte injury plays a major role in diabetic glomerulosclerosis. High glucose induces oxidative stress, the changes of actin dynamics, and apoptosis in podocyte. Our previous report showed mitochondrial injury of podocyte induces massive albuminuria, glomerular sclerosis. Using crif1 deletion in podocyte. we evaluated that mitochondrial injury aggravate high glucose induced podocyte injury.

Methods: We used a conditionally immortalized mouse podocyte cell line and podocyte specific crif1 half deletion mouse (crif1 (Δ/+)). Crif1 siRNA in podocyte was used for inducing mitochondrial injury. We compared high glucose (25mmol/L) to low glucose (5.5mmol/L) in Crif1 siRNA treated podocyte. We make the phenotype of crif1 (Δ/+) in streptozotocin (75mg/kg, i.p., 3 days) induced diabetes mice. Using confocal microscopy, we observed actin and mitochondria in immortalized podocyte. In mice, we evaluated renal histology and metabolic finding including blood glucose, urine albumin and creatinine.

Results: High glucose with Crif1 siRNA treated podocyte showed decrease of actin to cell ratio comparing to low glucose with Crif1 siRNA and high glucose with wild type podocytes. In mice, it showed normal range of albuminuria, normal renal histologic finding and normal mitochondria morphology in both control mice and podocin specific half deletion of crif1 (crif1 (Δ/+)). After 10 weeks streptozotocin treatment, podocin specific heterozygous deletion of crif1 (crif1 (Δ/+)) showed massive albuminuria. However, Control mice showed normal range of albuminuria.

Conclusions: In conclusion, damage and instability of mitochondria induced by podocyte crif1 deletion aggravate high glucose induced podocyte injury.

P2X7 Receptors and the Oxidative Stress in the Kidneys of Diabetic Rats Submitted to Aerobic Training Elisa M.S. Higa,[1,2] Adelson M. Rodrigues,[1] Cassia T. Bergamaschi,[3] Guilherme B. Nogueira,[1] Fabiane R. Maciel,[1] Giovana R. Punaro,[1] Marcello Franco,[1] Maria José S. Fernandes.[4] *[1]Nephrology, UNIFESP; [2]Emergency Division, UNIFESP; [3]Cardiovascular, UNIFESP, Brazil; [4]Neurology, UNIFESP.*

Background: Previous studies in our Laboratory showed the role of oxidative stress and the favorable effects of exercise training, on the progression of diabetic nephropathy (DN) in rats. $P2X_7$ receptors ($P2X_7$-R), in pathological conditions, are significantly up-regulated, increasing the levels of oxidative stress. The aim of this study was to evaluate the $P2X_7$-R and the oxidative stress in the kidneys of diabetic rats submitted to aerobic training.

Methods: Diabetes mellitus (DM) was induced in adult Wistar rats, with streptozotocin (60mg/kg, i.v.); control animals (CTL) received its vehicle. The animals were submitted to aerobic training on treadmill at a work rate of 16m/min for 60 min/day, 5 days a week/8weeks (DM+EX and CTL+EX); DM+SE and CTL+SE were kept resting on the treadmill at the same schedule (n=12 for each group). The animals all groups were treated with N-acetylcysteine (NAC). Data = mean ±SEM; one way ANOVA; significance at $P<0.05$.

Results: DM+SE vs CTL+SE increased the urinary excretion and renal tissue thiobarbituric acid reactive substances (TBARS), all $P<0.05$; there was also a reduced urinary excretion and renal tissue nitric oxide (NO). NAC reduced TBARS and increased NO in urine and the kidney, in DM+SE vs CTL+SE; exercises had similar effects. Immunohystochemistry analysis of $P2X_7$-R in the kidneys showed a significant increase in DM+SE vs CTL+SE (43.3±5.5 vs 0.6±0.1;%). In DM rats, all these effects were attenuated by NAC (34.9±4.3%) or by aerobic training (25.6±3.4%). However, the association of NAC with exercises significantly reduced the concentration of these receptors (3.8±0.6%).

Conclusions: Our data show that the routine of exercise associated with NAC expressively decrease the activation of $P2X_7$-R in the kidneys of diabetic rats. The attenuation of oxidative stress through this mechanism, which also resulted in the increase of NO bioavailability, suggests that the control of these receptors' up-regulation could be useful to delay the progression of diabetic nephropathy.

SA-PO434

Rosuvastatin Activates Transcription Factor Nrf2 and Protects Prevents Albuminuria through Preservation of the Glomerular Endothelial Integrity in Akita Diabetic Mice Chieko Ihoriya, Minoru Satoh, Tamaki Sasaki, Naoki Kashihara. *Nephrology and Hypertension, Kawasaki Medical School, Kurashiki, Okayama, Japan.*

Background: Statins also have been shown to reduce urinary albumin excretion and to maintain glomerular filtration rate in diabetic kidney disease;however, the mechanism is not fully elucidated. The renoprotective effects of statins are independent of lipid-lowering effect and presumably involve their pleiotropic effects, especially to anti-oxidant activity. Nuclear factor-erythroid 2-related factor 2 (Nrf-2) is a basic leucine zipper transcription factor that binds to antioxidant response element (ARE) sequences in the promoter regions of a series of genes in response to oxidative stress. The aim of this study is to investigate possible involvement of Nrf2 in statin-mediated effects on the glomerular permselectivity and development of albuminuria in diabetic mice.

Methods: Male wild type (WT) and Akita diabetic mice (AKITA) were treated with rosuvastatin for 4 weeks. Using in vivo imaging technique with laser microscopy, alterations in glomerular permeability of macromolecules were was examined. Nrf2- ARE activity was measured in human umbilical vein endothelial cell (HUVEC) with with luciferase assay after transfection of reporter plasmids containing AREs. The expressions of Nrf2- regulated genes (NADPH/quinone oxidoreductase1, heme oxygenase-1, and glutamate cysteine ligase catalytic subunit) were also examined.

Results: The amount of lectin-stained glomerular endothelial surface layer important for permselectivity in vascular wall was significantly reduced in AKITA mice. Increased urinary albumin excretion in AKITA mice was significantly reduced by rosuvastatin treatment. Furthermore, in vivo-imaging study revealed massive leakage of 70-KDa dextran in AKITA mice and suppression of this hyperfiltration of macromolecules by rosuvastatin. Rosuvastatin significantly increased the transcriptional activity of the AREs and subsequent expressions of Nrf2- regulated genes in HUVEC.

Conclusions: These data indicate that rosuvastatin has anti-oxidative effect through activation of Nrf2, thereby, restores glomerular endothelial dysfunction and prevents development of albuminuria in diabetes.

SA-PO435

P66shc-Mediated Mitochondrial Dynamic Alterations Contribute to Tubular Oxidative Injury in Human Diabetic Nephropathy Ming Zhan, Li Xiao, Xun Zhou, Shikun Yang, Fuyou Liu, Lin Sun. *Department of Nephrology, Second Xiangya Hospital, Central South University, Changsha, Hunan, China.*

Background: Renal tubular injury is an early characteristic of diabetic nephropathy (DN) that is related to mitochondrial injury and oxidative stress. We investigate mitochondrial dynamic changes and reactive oxygen species(ROS) production in DN patients, and determine the role of the adaptor protein p66Shc in mitochondrial regulation and oxidative injury during high-glucose(HG) treatment of renal tubular cells .

Methods: Renal biopsy specimens from recruited patients, and HK-2 cells were studied. Mitochondrial dynamics was measured by electron and confocal microscopy, the expression of mitochondria-shaping proteins and p66Shc were evaluated by immunohistochemistry, immunoflurescence, PCR and western blot assays. Cellular and mitochondrial ROS production was detected. In addition, p66Shc wide-type or siRNA plasmid was transfected in vitro.

Results: Filamentous mitochondria became fragmented mainly in renal tubules of patients with DN. Compared with the control group, Drp1 was significantly increased and Mfn1 was decreased in DN tissues. These changes were accompanied by p66Shc elevation and ROS overproduction. In HK-2 cells, the percentage of cells with mitochondrial fragmentation and Drp1 expression were both elevated with HG treatment in a time- and dose-dependent manner. Drp1 inhibitor mdivi-1 attenuated mitochondrial fragmentation and also ROS overproduction, whereas ROS scavenger did not alter mitochondrial dynamics. Notably, siRNA knockdown of p66Shc down-regulated HG-induced Drp1 expression, alleviated mitochondrial fragmentation and ROS production, whereas over-expression of p66Shc could promote these changes under low-glucose condition.

Conclusions: This study provides first evidence of mitochondrial fragmentation in human diabetic nephropathy. Alteration in mitochondrial dynamics is mediated by p66Shc through its interaction with Drp1, which may serve as an upstream trigger of mitochondrial ROS overproduction that result in tubular oxidative injury under hyperglycemic conditions.

SA-PO436

Relevance of Myo-Inositol Oxygenase (MIOX) in Pathogenesis of Tubulo-Interstitial Injury in the Context of Diabetic Nephropathy Yashpal S. Kanwar,[1] Fu-You Liu,[2] Lin Sun.[1,2] *[1]Department of Pathology, Feinberg School of Medicine, Northwestern University, Chicago, IL; [2]Department of Nephrology, Second Xiangya Hospital, Central South University, Changsha, Hunan Province, China.*

Background: MIOX is a renal cortical tubular enzyme that channels glucose intermediaries, regulates osmoregulation, and modulates the activity of Redox-sensitive transcription factor Nrf2 (JBC 2011).

Methods: In view of the above we investigated if it plays any role in the generation of reactive oxygen species (ROS) in tubular compartment with ensuing perturbation in mitochondrial homeostasis and tubulo-interstitial injury under high glucose ambience while accelerating the events of Glucuronate-Xylulose (GX) pathway.

Results: Our initial observations indicated a concomitant increased expression of MIOX and NOX4 in tubules of patients with diabetic nephropathy. Transfection of MIOX pCDNA into LLCPK1 cells resulted in increased expression of MIOX/activity, perturbation of NADPH:$NADP^+$ and NAD^+:NADH ratios in the GX pathway, and an increase in DCF and Monobromobimane (MBB) staining under high glucose ambience. This increased ROS generation was associated with early adaptive changes in the scavenging system, where an increased expression of SOD1, SOD2, NOX 4, HO-1 and Catalase was observed. The redox imbalance was accompanied with hyperacetylation of cellular proteins and decreased expression of NAD^+-dependent SIRT1/SIRT3 enzymes and transcription factor PGC1-alpha, increased mitochondrial DNA fragmentation, mitochondrial fission, leakage of cytochrome C, perturbation in membrane potential and apoptosis. In addition, a marked increase in fibronectin expression, attenuated by MIOX-siRNA, was observed. Increased expression of MIOX with redox imbalance and apoptosis in proximal tubules was also observed in CD1 mice with STZ-induced diabetes and AKITA mice that exhibited upregulation of glutathione S-transferase. The increased expression of fibronectin in the diabetic mice was inhibited by ZOPOL, an inhibitor of MIOX/ALR1 complex.

Conclusions: These data suggest that MIOX plays a role in pathogenesis of tubulo-interstitial injury/fibrosis while generating ROS in diabetic nephropathy.

Is Oxidized Albumin, a Mediator and a Biomarker of Systemic Inflammation in Diabetic Nephropathy? Batya Kristal,[1,3] Shifra Sela,[2,3] Teuta Zeitun,[1] Galina Shapiro,[2] Yoav Fridman,[2] Ronit Geron,[1] Regina Michelis.[2] *[1]Nephrology Department, Western Galilee Hospital, Nahariya, Israel; [2]Eliachar Research Laboratory, Western Galilee Hospital, Nahariya, Israel; [3]Faculty of Medicine in the Galilee, Bar Ilan University, Zefat, Israel.*

Background: Hypoalbuminemia, Oxidative Stress (OS) and systemic inflammation are common in patients with diabetic nephropathy (DN). Oxidative modification of serum albumin was shown to impair its quantification by the bromocresol-green assay (BCG) in patients on hemodialysis therapy, linking OS to hypoalbuminemia. In this study we examined whether hypoalbuminemia in DN is also due to impaired quantification of modified albumin and assessed if modified albumin activates neutrophils to release ROS and proteases, accelerating systemic OS and inflammation.

Methods: Blood samples from a cohort of 19 DN patients and 15 healthy controls were used to determine "albumin-detection index", defined as the ratio between the albumin read-out by BCG assay to the albumin concentration measured by optical density (OD) at 280 nm after albumin purification according to its size. This index was correlated with: sera albumin levels, various OS and inflammatory markers and with eGFR. Activation of separated neutrophils by glycoxidized-modified albumin was assessed by the release of neutrophil gelatinase associated lipocalin (NGAL) and myeloperoxidase (MPO).

Results: The albumin-detection index of DN patients was significantly lower compared to healthy controls, correlating positively with serum albumin and kidney function, and negatively with glycoxidized albumin and inflammatory markers. Glycoxidized-albumin had a direct role in neutrophil activation, resulting in NGAL and MPO release.

Conclusions: Hypoalbuminemia in DN patients, partially results from the low detection efficacy by BCG of modified/oxidized molecules, as expressed by a low albumin detection index. Modified/oxidized molecules initiate reciprocal process by activating neutrophils, commencing a vicious cycle a of accelerated OS and inflammation. We imply that albumin detection index, a new marker of OS, may also serve as a biomarker, correlating to the severity of diabetic nephropathy.

The Antioxidant Silybinin Prevents High Glucose-Induced Production of Superoxide and Apoptosis in Podocytes, Both *In Vitro* and *In Vivo* Khaled Khazim,[1,3] Yves C. Gorin,[1] Hanna E. Abboud,[1,2] Paolo Fanti.[1,2] *[1]Nephrology, Univ. of Texas Health Science Center, San Antonio, TX; [2]Nephrology, ALM VA Memorial Hospital, San Antonio, TX; [3]Nephrology, W. Galilee Hospital, Nahariya, Israel.*

Background: Damage and loss of podocytes is associated with proteinuria in patients with diabetic nephropathy (DN) and in animal models of diabetes. Oxidative stress participates in the pathogenesis of DN, including podocyte injury and alteration of the glomerular filtration barrier. Here, we explored the potential protective effect of the antioxidant silybinin, a polyphenolic flavonolignans from silybum marianum (milk thistle), against diabetes-induced podocyte injury.

Methods: *In vitro*, we exposed conditionally immortalized mouse podocytes to high glucose concentration (HG) and measured intracellular superoxide (O_2^-)generation by confocal laser scanning microscopy and by high performance liquid chromatography, with dihydroethidium (DHE) as a probe; NADPH oxidase (Nox) activity by chemiluminescence; Nox4 protein expression by Western blot; and cell apoptosis by DNA fragmentation. *In vivo*, we treated OVE26 type 1 diabetic mice with silybinin or vehicle for 6 weeks and counted the glomerular podocyte number adopting confocal immunohistochemistry of podocyte-specific synaptopodin and of GBM-specific type-IV collagen. We used FVB mice as non-diabetic controls.

Results: Exposure of podocytes to HG for 24 h resulted in a robust increase in intracellular O_2^-production and NADPH-dependent O_2^-generation, along with increased Nox4 protein expression and apoptosis. These effects of HG were all blocked by pretreatment of the cells with 10 μM silybinin. In addition, administration of silybinin to OVE26 mice significantly reduced the glomerular loss of podocytes and the decrease of synaptopodin expression.

Conclusions: We confirm that HG induces oxidative stress, Nox4 expression, and cell apoptosis in podocytes. Moreover, we report the novel finding that the flavonolignan silybinin protects against HG-induced oxidative stress and podocyte injury, both *in vitro* and *in vivo*. Silibynin may act by blocking the expression of Nox4, and O_2^- generation known to play a key role in podocyte injury.

Role of Renal Hypoxia in the Progression of Experimental Diabetic Nephropathy Naoki Takahashi,[1] Hideki Kimura,[1] Kazuko Kamiyama,[1] Seiji Yokoi,[1] Yoshinari Yokoyama,[1] Daisuke Mikami,[1] Kenji Kasuno,[1] Haruyoshi Yoshida,[2] Masayuki Iwano.[1] *[1]Division of Nephrology, Fukui University, Fukui, Japan; [2]Department of Internal Medicine, Sugita Genpaku Memorial Obama Municipal Hospital, Obama, Japan.*

Background: Renal hypoxia has been proposed to be one of the important pathophysiologic features of diabetic kidney disease in experimental diabetic mice. Previously, we have reported that chronic hypoxia exacerbated diabetic glomerulosclerosis in db/db mice. In this study, to disclose the molecular mechanisms of the chronic hypoxia-induced progression of experimental diabetic glomerulosclerosis, we examined and compared glomerular mRNA levels of various cytokines with proinflammatory, angiogenic and sclerotic functions in db/db mice.

Methods: Eight w.o. male db/db mice were bred in a normobaric hypoxic chamber (12%O_2). The mice in hypoxia were kept in this chamber for 4 weeks (n=11) or 16 weeks (n=11) and the mice in normoxia were bred in room air for 4 weeks (n=12) or 16 weeks (n=12). Mice were sacrificed at 12 and 24 w.o. in order to evaluate histological changes and extracted mRNA (VEGF-A, VEGF-R1, VEGF-R2, PAI-1, MCP-1, TGF-β1, CTGF, eNOS, CD34, Nephrin, Ang-1 and Ang-2) from 50-150 glomeruli/mouse obtained by laser capture microdissection.

Results: No significant differences in blood pressure and s-Cr levels were found between normoxic mice (NM) and hypoxic mice (HM). Urinary albumin levels were consistently increased in the 10, 12, 16, 24 w.o. HM and severe glomerulosclerosis was observed in 24 w.o. HM, as compared with NM. The number of glomerular F4/80+macrophages in HM was significantly greater than that in NM. Real time PCR analysis showed significant increases in glomerular mRNA levels of MCP-1 in HM at 12 w.o. and 24 w.o. and a significant increase in glomerular mRNA levels of TGF-β1, CTGF and eNOS in HM at 24 w.o. as compared with in NM. However, glomerular mRNA levels of VEGF-A, VEGF-R1 and VEGF-R2 were not significantly increased in HM at 12 w.o. and 24 w.o.

Conclusions: The development of diabetic glomerulosclerosis associated with chronic hypoxia in db/db mice may result from the increased macrophage infiltration via glomerular MCP-1 induction, but not from VEGF-A axis.

SA-PO440

Metallothionein Deficiency Accelerates Diabetic Nephropathy by Inducing Oxidative Stress and Inflammation in Proximal Tubular Epithelial Cells Hiromi Tachibana, Daisuke Ogawa, Naoto Terami, Chikage Sato-horiguchi, Jun Eguchi, Jun Wada, Kenichi Shikata, Hirofumi Makino. *Department of Medicine and Clinical Science, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan.*

Background: Oxidative stress and inflammation play an important role in diabetic complications, including diabetic nephropathy. We recently reported that metallothionein (MT) is induced in proximal tubular epithelial cells as an antioxidant in diabetic kidney (Exp Diabetes Res, 2011), however, the role of MT in renal function still remains unclear. Therefore, we investigate whether deficiency of MT accelerates DN through oxidative stress and inflammation.

Methods: Diabetes was induced by injection of streptozotocin into MT deficient ($MT^{-/-}$) and $MT^{+/+}$ mice. We analyzed urinary albumin excretion, histological changes, and gene expression of inflammatory mediators in the kidney at 12 weeks after inducing diabetes. Mitochondrial reactive oxygen species (ROS) were measured using MitoTrackerRed. In addition, we performed siRNA experiments to further elucidate the role of MT in high glucose condition. mProx24 cells, a murine proximal tubular epithelial cell line, were transfected with MT siRNA or scrambled siRNA.

Results: Despite equivalent hyperglycemia, albuminuria, mesangial matrix accumulation, and glomerular hypertrophy, along with markers for inflammation including MCP-1, TGF-β, and osteopotin were more accelerated in diabetic $MT^{-/-}$ mice than in diabetic $MT^{+/+}$ mice. Macrophage infiltration, mitochondrial ROS production, and interstitial fibrosis were exacerbated in diabetic $MT^{-/-}$ mice compared with diabetic $MT^{+/+}$ mice. Electron microscopy revealed that impaired mitochondrial morphology in proximal tubular epithelial cells was also observed in diabetic $MT^{-/-}$ mice. In vitro studies demonstrated that knockdown of MT by siRNA enhanced the high glucose-induced oxidative stress and inflammation in mProx24 cells.

Conclusions: These findings provide previously unrecognized evidence that high glucose-induced ROS and subsequent inflammation exacerbates diabetic nephropathy and that MT plays an important role in protecting kidney from diabetic stress as an antioxidant protein.

SA-PO441

Effects of Streptozotocin-Induced Diabetes Mellitus on Glutamine Transport and Metabolism in the Rat Kidney Hassane Amlal, Rashma Faroqui, Ali Al-fraihat, Xiaoyi Lin. *Internal Medicine, University of Cincinnati, Cincinnati, OH.*

Background: Total ammonia ($NH_4^+ + NH_3$) causes renal cell hypertrophy, and diabetes mellitus (DM) is associated with increased kidney mass. However, whether DM alters glutamine transport and metabolism and stimulates ammoniagenesis in the kidney is poorly understood.

Methods: Rats were housed in metabolic cages and had free access to food and water. After adjustment, rats were injected with vehicle or streptozotocin (STZ) to induce DM and were sacrificed after 6 days (6d) or 2 weeks (2wk) later. At the end of treatment, blood composition was analyzed, urinary NH_4^+ and protein excretion were measured and the expression of various genes involved in glutamine transport and metabolism was examined.

Results: STZ-treated rats exhibited massive polyuria, polydipsia and significant hyponatremia with normal serum [HCO_3^-] vs. vehicle. Kidney mass (kidney weight/BW x 1000) significantly increased from 3.75 to 6.21 and 6.58 (gm/gm) in vehicle vs. 6d and 2wk STZ, respectively. This correlates with massive proteinuria and significant increase in urinary NH_4^+ excretion (mmol/day) from 1.05 to 4.12 and 5.87 in vehicle vs. 6d and 2wk STZ, respectively. The expression of glutamine transporters BoAT1 and SNAT3 increased significantly by 99 and 28 % and by 200 and 32% after 6d and 2wk STZ vs. vehicle, respectively. Ammoniagenic enzymes glutaminase (GA) and glutamate dehydrogenase (GDH) both increased significantly by 75 and 93% and by 87 and 119% after 6d and 2wk STZ vs. vehicle, respectively. The gluconeogenic enzyme phosphoenolpyruvate carboxy kinase (PEPCK) also increased significantly by 130 and 207% after 6d and 2wk STZ vs. vehicle, respectively.

Conclusions: STZ-induced DM is associated with the stimulation of ammoniagenesis, which results from increased glutamine transport and metabolism in the proximal tubule cells. The stimulation of ammonia production is not mediated by acidosis and correlates with increased renal mass and proteinuria, indicating that ammoniagenesis likely contributes to the development of renal hypertrophy and kidney disease during diabetes mellitus.

A Murine Model of Diet-Induced Insulin Resistance and Metabolic Syndrome Tomasz A. Wietecha, Kelly L. Hudkins, Jinkyu Kim, Antonio Haw Sta. Teresa, Kristina M. Sorg, Kevin D. O'Brien, Charles E. Alpers. *Pathology, Univ of WA.*

Background: BTBR is an inbred mouse strain that is susceptible to development of diabetes and advanced diabetic nephropathy in the presence of the leptin-deficiency mutation (ob/ob) (JASN. 2010; 21:1533-42). Heterozygous BTBR mice (BTBR ob/+) are not hyperglycemic on chow diet, but have abnormal insulin and glucose tolerance tests. We tested whether dietary modification could induce diabetes and diabetic nephropathy (DN), and whether the glucose lowering drug Metformin reduced diabetic complications in this model.

Methods: At 4 weeks of age, female BTBR ob/+ mice were given Chow or DD (diet high in fat and refined sugar) diet. At 14 weeks of age, the DD group was further divided: both groups continued on the DD diet, but half of the mice also received Metformin in drinking water for 6 weeks.

Results: Oral glucose tolerance tests (OGTTs) and fasting serum glucose (FSG) were performed at 8, 12, 16, and 20 weeks of age. At all time points the DD group had significantly impaired OGTT responses compared with Chow fed mice ($P<0.001$) in addition to increases in FSG ($P=0.001$, Chow vs. DD at 20 weeks). Introduction of Metformin did not significantly lower OGTTs and FSG in DD-fed mice. Increased body weight in DD diet group compared to Chow fed mice ($P=0.001$) was only slightly reduced by Metformin. Increased kidney weight in the DD group ($P=0.019$) was significantly reduced by Metformin treatment. Kidney function (albumin/creatinine ratio) was unchanged despite intervention. Histologically, the DD group had significantly increased matrix accumulation compared to Chow fed mice. Introduction of Metformin in DD fed mice lowered the Col IV positive glomerular matrix area to the Chow control group levels (18.5, 11.9, 11.4 % in DD, DD+Metformin, and Chow respectively, $P<0.01$). In all groups, the level of Mac-2 positive cells in glomeruli remained unchanged. Mild glomerular hypertrophy in the DD group was only slightly reduced with Metformin ($P>0.05$).

Conclusions: These results characterize early changes of diet-exacerbated insulin resistance, and present the possibility that an intact insulin-leptin signaling axis retards the development of DN in BTBR mice.

Distinct Metabolomic Profiles Are Associated with Severe Diabetic Nephropathy in Mice Susan B. Gurley, Svati H. Shah, Damian M. Craig, Natalie Mattocks, Christopher B. Newgard, Thomas M. Coffman. *Department of Medicine, Duke University Medical Center, Durham, NC.*

Background: Diabetic nephropathy (DN) is a leading cause of ESRD worldwide but the pathophysiology of DN has not been clearly defined. One limitation to deciphering DN pathogenesis has been the lack of animal models recapitulating the characteristics of human DN. We have found that activation of the renin-angiotensin system (RAS) with a constitutively active renin transgene (RenTg) superimposed on a genetic model of type 1 DM (Akita mouse) causes exaggerated kidney injury resembling human DN. Thus, RAS activation and diabetes have synergistsic effects to promote glomerular disease on a permissive strain background. We hypothesized that the combination of diabetes and RAS activation may trigger specific metabolic pathways in the kidney resulting in enhanced disease.

Methods: To test this, we performed MS-based targeted metabolomic profiling (80 individual metabolites) of tissue homogenates from 129 Akita-RenTg mice compared to 129 mice with diabetes alone, RAS activation alone, or WT mice.

Results: 129-Akita mice with a transgene expressing renin under control of the albumin promoter develop pronounced hyperglycemia, hypertension, marked albuminuria, and glomerulosclerosis, whereas 129 mice with the Akita mutation or RenTg alone develop only modest renal injury. Kidneys from 129-Akita-RenTg mice had increased levels of the branched-chain amino acids (BCAA), valine (28.1±2 vs 23.9±1 μM, $p<0.01$) and leucine/isoleucine (26.7±1.9 vs. 23.1±0.8 μM, $p<0.01$) compared to controls. This pattern was also observed in liver, skeletal muscle, heart, and plasma and has been associated with increased risk of metabolic disease and coronary artery disease in humans. In addition, hexanoyl (C6) acylcarnitine levels in kidney were significantly reduced in 129-Akita-RenTg mice ($p=0.004$) compared to controls.

Conclusions: Thus, we have identified distinct metabolic signatures associated with accelerated nephropathy in diabetic mice, and these resemble profiles that have been observed in cardiometabolic disease in humans. Further understanding of these pathways may lead to new strategies for diagnosis and treatment of DN.

The Role of Potent Lipid Second Messenger Sphingosine 1-Phosphate in the Development of Diabetic Nephropathy Dania Yaghobian,[1] Anthony Don,[2] Sarina Yaghobian,[1] Xinming Chen,[1] Sonia Saad,[1] Carol A. Pollock.[1] *[1]Medicine, Kolling Institute of Medical Research, University of Sydney, Sydney, NSW, Australia; [2]Medicine, Lowy Cancer Insitute, University of New South Wales, Sydney, NSW, Australia.*

Background: Hyperglycaemia and all TGFβ isoforms are involved in the development of diabetic nephropathy. S1P is derived from sphingosine by sphingosine kinase (SPHK-1/2) and is considered a key mediator of biological processes mimicking TGFβ signalling. However the role of SPHK1 in inducing fibrotic and inflammatory responses in diabetic nephropathy is unknown. The aim is to determine the role of the potent lipid second messenger sphingosine 1-phosphate (S1P) in the development of diabetic nephropathy.

Methods: Human proximal tubular cells (HK2) were exposed to 5mM, 30mM D-glucose or 0.5ng/ml TGFβ 1,2,3 in the presence or absence of a SPHK inhibitor (SKI-II; 2μM) or SPHK1/2 siRNA (30nM) for 72 hours. Exposure to S1P (0.1-5μM) demonstrated the biological effect of SPHK activation. Wild type (WT) and $SPHK1^{-/-}$ mice with or without 24 weeks of diabetes were studied. In both in-vitro and in-vivo models, mRNA and protein expression of fibrotic and inflammatory markers were determined. Sphingolipid pathway metabolites were measured by mass spectrometry (MS).

Results: HK2 cells exposed to high glucose or TGFβ1,-2,-3 independently increased SPHK1 enzymatic activity, mRNA and protein expression. TGFβ1,-2,-3 and S1P induced fibronectin, collagen IV, chemokine ligand 2, vimentin and downstream phospho-p44/42 expression, which were reversed by both SKI-II and SPHK1/2 siRNA. WT diabetic mice exhibited a lower creatinine clearance, higher urinary albumin excretion, increased renal cortical fibronectin, collagen IV and phospho-p44/42 mRNA and protein expression compared to $SPHK1^{-/-}$ diabetic mice. MS demonstrated an increased in S1P in the kidneys of WT diabetic mice.

Conclusions: This study suggests limiting the formation of S1P inhibits renal inflammation and fibrosis in diabetic mice. This may be due to the reduced S1P receptor activation or indirectly due to inhibition of the p42/44 MAP kinase pathway.

Funding: Government Support - Non-U.S.

SA-PO445

Fructose Production and Fructokinase Activation in the Proximal Tubule Mediate Tubular Injury in Ciabetic Nephropathy Christina Cicerchi, Carlos Alberto Roncal-jimenez, Takuji Ishimoto, Yoshifuru Tamura, Katsuyuki Tanabe, Nanxing Li, Takahiko Nakagawa, Richard J. Johnson, Miguel A. Lanaspa. *Medicine, University of Colorado Denver, Aurora, CO.*

Background: Fructose consumption has been shown to induce and exacerbate features of metabolic syndrome including type 2 diabetes. Besides dietary intake, fructose is endogenously produced from glucose by the activation of the polyol pathway in the cortex of the kidney in diabetic states. The aim of this study is to determine the specific role of

this endogenous fructose and its metabolism by fructokinase (KHK) in the pathogenesis of diabetic nephropathy.

Methods: Diabetes was induced by injection for 5 consecutive days of a low-dose of streptozotocin (STZ) in 8 week old wild type or littermate KHK knockout (KHK-KO) mice with similar body weights. Diabetic nephropathy was assesed by determination of parameters of renal function, and kidney tubular injury was assessed by NGAL urinary excretion, histology, collagen III and macrophage infiltration.

Results: STZ-induced diabetes significantly elevated serum glucose in both wild type and KHK-KO mice with no significant difference between groups (330±46 vs 322+56 mg/dl, p>0.05). Activation of the polyol pathway in the kidney cortex was confirmed in both conditions by the up-regulation of aldose reductase (AR), the first and rate-limiting enzyme of this pathway and increased accumualtion of sorbitol and fructose. Diabetic KHK-KO mice demonstrated reduced phosphate and urate fractional excretion (75±3 and 68±13 % reduction respectively, p<0.01) and lower albuminuria levels (3.2±1.5 vs 0.7±0.2 μg/mg of creatinine, p<0.01) as compared to diabetic wild type mice suggesting improved reabsorption ability. This data was corroborated by decreased NGAL urinary concentration (17.3±2.8 vs 12.4±3.6 ng/ml, p<0.05), urinary excretion (72±10 % reduction, p<0.01), and improved tubulointerstitial injury.

Conclusions: In summary, this data demonstrate that endogenous fructose generated in proximal tubules during diabetic nephropathy may have a deleterious role in the pathogenesis of diabetic nephropathy. Therefore, KHK-KO mice are partially protected against diabetic nephropathy.

SA-PO446

Liver X Receptor Agonist Ameliorates Diabetic Nephropathy by Inhibiting High Glucose-Induced Osteopontin Expression in Proximal Tubular Epithelial Cells Daisuke Ogawa, Hiromi Tachibana, Jun Wada, Jun Eguchi, Chikage Sato-horiguchi, Naoto Terami, Kenichi Shikata, Hirofumi Makino. *Department of Medicine and Clinical Science, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan.*

Background: Osteopontin (OPN) is a proinflammatory cytokine implicated in the chemoattraction of monocytes and the development of diabetic nephropathy. Synthetic agonists for the Liver X Receptor (LXR), prevent the development of atherosclerosis by regulating cholesterol homeostasis and suppressing inflammatory gene expression, however, the role of LXR in diabetic nephropathy is poorly understood.

Methods: We administered LXR agonist T0901317 (10 mg/kg/day) to STZ induced-diabetic mice for 8 weeks after inducing diabetes, and evaluated the effects for diabetic nephropathy. The mechanism of OPN expression was also analyzed in mProx24 cells, a mouse renal proximal tubular epithelial cell line, stimulated with high glucose medium and pretreated with T0901317. OPN promoter activity was analyzed by transient transfection experiments with deletion series, heterologous promoter assays, and chromatin immunoprecipitation assays.

Results: The LXR agonist T0901317 ameliorated albuminuria, glomerular mesangial expansion, and interstitial fibrosis without affecting blood glucose and triglyceride levels in STZ-induced diabetic mice. T0901317 treatment markedly decreased the expression of OPN, macrophage infiltration, and the expressions of inflammatory genes, including MCP-1, TNF-α, and TGF-β, in the diabetic kidney. Furthermore, in vitro experiments revealed that high glucose-induced OPN expression in proximal tubular epithelial cells is dependent on AP-1 binding to the proximal OPN promoter. T0901317 inhibits high glucose-induced OPN expression and negatively interferes with AP-1 binding to the proximal OPN promoter by inhibiting c-Fos and phospho-c-Jun protein expressions.

Conclusions: These findings uncover a previously unrecognized mechanism for the inhibition of renal OPN expression by activation of LXR and support the concept that LXR agonists may offer a novel therapeutic approach for the treatment of diabetic nephropathy.

SA-PO447

Nuclear Hormone Receptor Expression in Mouse Kidney and Cell Lines Naoto Terami, Daisuke Ogawa, Hiromi Tachibana, Chikage Sato-horiguchi, Jun Eguchi, Jun Wada, Kenichi Shikata, Hirofumi Makino. *Department of Medicine and Clinical Science, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan.*

Background: Nuclear hormone receptors (NHRs) are transcriptional factors that regulate carbohydrate and lipid metabolism, immune response, and inflammation. Although several NHRs have shown a renoprotecitve effect in the context of diabetic nephropathy, the expression and role of NHR in kidney are still unclear. In this study, we have comprehensively analyzed the expression of all 49 of the NHR superfamily in mouse kidney and cell lines in both normal and high glucose condition.

Methods: We used normal and streptozotocin-induced diabetic C57BL/6 mice, db/m (control) and db/db (diabetic) mice, and renal cell lines including mesangial cells (MES13), podocytes (MPC), proximal tubular epithelial cells (mProx24), and collecting duct cells (mIMCD3). RNA was isolated from tissue samples or cultured cells. To evaluate the mRNA expressions of NHR in the kidney and cultured cells, quantitative real-time PCRwas performed using TaqMan® Array Fast Plates (Applied Biosystems).

Results: 25 NHR members were expressed in the kidney of normal C57BL/6 and db/m mice, and 6 NHRs were not expressed in mouse kidney.(Figure1).

Figure 1 The Composition of Nuclear Hormone Receptors in Kidney

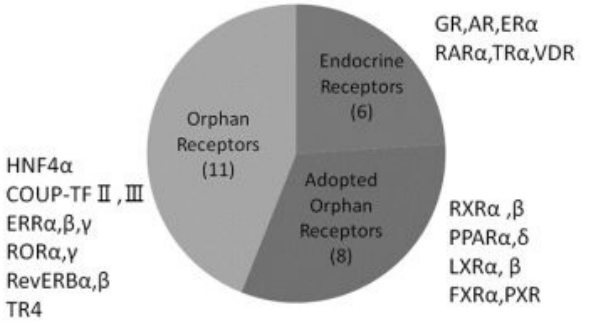

Figure 2 C57BL6 (DM) / C57BL6 (control)

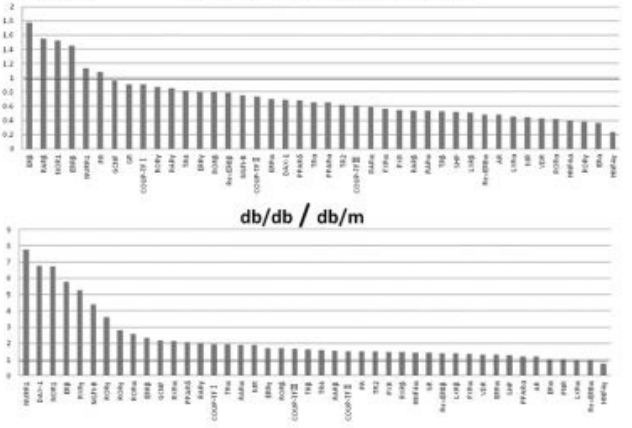

In addition, 5 NHRs were upregulated in diabetic C57BL/6 and db/m mice (Figure 2). In cell lines, PPARδ was highly expressed in mesangial and proximal tubular epithelial cells, and COUP-TF II/III was highly expressed in podocytes and collecting duct cells. The expression profile of NHR was different between under normal and high glucose conditions. NGFI-B was highly upregulated in mesangial and collecting duct cells by high glucose stimulation.

Conclusions: These findings identify NHR present in mouse kidney and cultured cell lines and suggest potential therapeutic targets in kidney for the treatment of diabetic nephropathy.

SA-PO448

Alteration of Renal Lipid Deposition and Gene Expression Induced by Fasting and High-Fat Diet Feeding Keita P. Mori, Kiyoshi Mori, Masashi Mukoyama, Hideki Yokoi, Masato Kasahara, Takashige Kuwabara, Hirotaka Imamaki, Yoshihisa Ogawa, Tomoko Kawanishi, Akira Ishii, Kenichi Koga, Yukiko Kato, Naohiro Toda, Shoko Ohno, Akira Sugawara, Kazuwa Nakao. *Department of Medicine and Clinical Science, Kyoto University Graduate School of Medicine, Kyoto, Japan.*

Background: Renal triglyceride (TG) contents increase by high-fat diet (HFD) and also by fasting, but their detailed mechanism remains elusive. In this study, we investigated whether increase of renal TG contents induced by fasting or by HFD is correlated with extrarenal energy-supplying factors, such as blood levels of non-esterified fatty acid (NEFA) and insulin, or with intrarenal lipid-regulating factors, such as peroxisome proliferator-activated receptors (PPARs) and sterol regulatory element-binding protein (SREBP)-1.

Methods: Male C57BL/6J mice were fed either normal diet (ND) or HFD for 5 weeks. Mice were killed under ad libitum-fed or 12 h-fasted conditions.

Results: HFD resulted in acceleration of weight gain, elevation of serum glucose, insulin, and total cholesterol levels, and mild increase of renal and hepatic TG contents. Overnight fasting in ND-fed mice caused significant reduction of serum glucose and insulin levels, elevation of serum NEFA levels, and marked increase of renal (3-fold) and hepatic TG contents (9-fold). Fasting in HFD-fed mice, however, showed diminished changes in serum glucose, insulin and NEFA levels. Notably, renal TG contents did not increase, and hepatic TG contents increased slightly by fasting in HFD conditions. Both in the kidney and liver, PPAR-alpha gene expression was elevated and SREBP-1a,c was reduced by fasting as shown by real-time RT-PCR, which were not influenced by HFD.

Conclusions: Fasting induces marked elevation of renal TG contents, but pretreatment with HFD blunts this elevation potentially by diminished changes in serum glucose, insulin, and NEFA levels. Changes in gene expression of PPAR-alpha and SREBP-1a,c both in kidneys and livers appear not to be the causes of tissue TG deposition but rather the results or compensatory changes.

SA-PO449

LXR-Dependent Gene Expression in Human Diabetic Nephropathy Michal Herman-Edelstein,[1] Ana Tobar,[1] Pnina Scherzer,[1] Moshe Levi,[2] Uzi Gafter.[1] *[1]Department of Nephrology, Rabin Medical Center, Petah Tikva, Israel; [2]Division of Renal Diseases and Hypertension, University of Colorado, Denver, CO.*

Background: Liver X receptors (LXR) α and β are nuclear receptors that are master regulators of lipid and cholesterol metabolism and also have anti-inflammatory effects. In the current study, we investigated the expression levels of LXRs and their target genes of lipid metabolism, lipid accumulation and inflammation in kidneys biopsies from DN patients.The purpose of this study was to investigate the protective role of LXRs in the pathogenesis of human DN.

Methods: Renal lipid contents, inflammation and genes involved in cholesterol and fatty acid metabolism and most of the known LXRs target genes, were studied in RNA isoleated from formalin-fixed, paraffin-embedded (FFPE) renal biopsy from patients with established DN (n=32) versus normal kidneys (n=12).

Results: The DN kidney exhibited a significant inverse relationship between LXR expression and the degrees of glomerulosclerosis; tubulointerstitial injury; heavy lipid accumulation and inflammation. We studied LXRα and LXRβ target genes expression in the kidneys. We found up-regulation of modified low-density lipoprotein receptors: lectin-like oxidized low-density lipoprotein receptor-1 (LOX-1), scavenger receptor A1 (SR-A1), and CD36, whereas lipid efflux ATP binding cassette transporters ABCA-1 and ABCG-1were down-regulated. Furthermore we found down-regulation of factors involved in fatty acid oxidation (PPAR-α, CPT1 and L-FABP). There was an inverse correlation between LXRs expression and fibrotic markers, macrophage load, lipid and cholesterol accumulation, eGFR, and renal outcomes.

Conclusions: We showed for the first time that renal LXR expression is inversely and significantly associated with lipid accumulation, pro-inflammatory markers, and the profibrotic molecules in kidney biopsies from patients with DN. Our results suggest that decreased expression of LXR is an important feature of DN**.**These results support the concept that LXRs and related downstream pathways may be important in modulating diabetic lipid burdenand inflammation and suggest LXR agonists as a novel therapeutic target for human diabetic nephropathy.

SA-PO450

Role of Bile-Acid-Activated Receptors TGR5 and FXR in Human Diabetic Nephropathy Michal Herman-Edelstein,[1] Pnina Scherzer,[2] Ana Tobar,[1] Renana Eshet-leon,[1] Moshe Levi,[3] Uzi Gafter.[1] *[1]Felsenstein Medical Research Center and Department of Nephrology, Rabin Medical Center, Petah Tikva, Israel; [2]Nephrology, Hadassah, Jerusalem, Israel; [3]Division of Renal and Hypertension, Med Center and University of Colorado Health Sciences Center, Denver, CO.*

Background: Bile acids (BA) act as signaling molecules that activate BA receptors, which regulate glucose, lipid homeostasis and energy expenditure. Two major receptors for BA have been identified: (1) the nuclear receptor, farnesoid X receptor (FXR), and (2) the membrane-bound, G protein-coupled receptor (TGR5). The expression of TGR5 and its function are distinct from FXR.TGR5 is a key factor in energy expenditure by activating the mitochondrial biogenesis regulatorPPARγ coactivator (PGC), which enhances metabolic pathways, such as fatty acid oxidation, and also increases antioxidant defense mechanisms. The purpose of the present study was to determine the expression and role of BA receptors and signaling pathways in human diabetic nephropathy (DN) kidney biopsies.

Methods: Renal lipid contents, FXR, TGR5, and BA receptor targets were studied by immunofluorescence staining and RNA isolated from formalin-fixed, paraffin-embedded (FFPE) renal biopsies from patients with established DN (n=32) versus normal kidneys (n=12), who have been treated in our department.

Results: TGR5 and FXR protein and mRNA abundance were significantly decreased in DN kidneys. FXR and TGR5 expression negatively correlated with disease progression and lipid accumulation. We found in DN decreased expression of transcription factors, nuclear receptors (ERRα,Rev-Erbα/β, NRF-1, NRF-2, PPARα,and PPARγ) and members of the PGC-1 family of regulated coactivators (PGC-1α, PGC-1β). Furthermore, we showed the expression of gluconeogenic enzymes phosphoenol pyruvate carboxykinase (PEPCK) and glucose-6-phosphatase (G-6-Pase) in diabetic kidneys.

Conclusions: As yet there is little information focused specifically on TGR5, PGC1-α, and ERRα in the regulation of mitochondrial energy metabolism in the diabetic kidney. The available data indicate that these pathways may become promising areas for study in the modification of renal disease and diabetic nephropathy.

ER Stress-Mediated Unfolded Protein Response Protects Renal Proximal Tubular Cells against Free Fatty Acid-Mediated Damage Naoko Takeda,[1] Shinji Kume,[1] Daisuke Koya,[2] Shin-ichi Araki,[1] Keiji Isshiki,[1] Masakazu Haneda,[3] Takashi Uzu,[1] Hiroshi Maegawa.[1] *[1]Medicine, Shiga University of Medical Science, Otsu, Shiga, Japan; [2]Diabetes and Endocrinology, Kanazawa Medical University, Kahoku-Gun, Ishikawa, Japan; [3]Medicine, Asahikawa Medical University, Asahikawa, Hokkaido, Japan.*

Background: Free fatty acid (FFA)-bound albumin is filtered via glomeruli and reabsorbed in proximal tubular cells. FFA-mediated tubular damage is strongly associated with progressive renal dysfunction, although the underlying mechanism has not been determined. ER stress-mediated unfolded protein responses (UPRs) is known as cellular adaptive mechanisms. However, the relationship between FFA-induced tubular damage and UPR is unclear. The objective of this study was to elucidate the role of UPR in FFA-induced apoptosis and inflammation in cultured proximal tubular cells (PTCs).

Methods: To induce apoptosis and inflammation, cultured PTCs were exposed to palmitate (150μM), a saturated FFA. Apoptosis and inflammation were determined by caspase 3 and PARP cleavages, and *MCP-1* mRNA expression, assessed by western blotting and real-time PCR, respectively. UPRs were determined by PERK phosphorylation, ATF6 cleavages, XBP1 splicing, and BiP expression level (a stress-inducible molecular chaperone).

Results: In cultured PTCs, palmitate increased apoptosis and *MCP-1* expression together with UPRs. Pretreatment with the exogenous chemical chaperone, tauroursodeoxycholic acid (TUDCA 1mM), inhibited palmitate-induced apoptosis and *MCP-1* expression with a reducing UPRs. To clarify the role of UPRs in tubular damage, we examined the effects of the silencing three independent key genes of UPR signaling, IRE1, PERK and ATF6, by siRNA. Gene silencing of each UPR signaling pathway exacerbated the palmitate-induced apoptosis and *MCP-1* expression and reduced the palmitate-induced BiP expression. Meanwhile, TUDCA ameliorated the UPR-deficiency-mediated-exacerbation of palmitate-induced apoptosis and *MCP-1* expression.

Conclusions: These results indicate that UPRs play protective roles against palmitate-induced tubular cell damage, and that the refilling of molecular chaperones may be a new therapeutic strategy in FFA-mediated tubular injury.

Bilirubin Regulates the Expression of SREBP-1, LXRα, and PPARγ in Liver and Kidney of Type I DM Animal Model Jianwei Xu, Shin-young Ahn, Ho Jun Chin. *Internal Medicine, Seoul National University Bundang Hospital, Seong Nam, Kyeong ki do, Korea.*

Background: The abnormal lipid metabolism was proposed as an important mechanism in the pathogenesis of diabetic nephropathy. Bilirubin was reported to have inverse relationship with prevalence of diabetes and diabetic nephropathy in human. We investigated the role of bilirubin on lipid metabolism in type I DM model.

Methods: The SD rats were injected with streptozotocin through intra-peritoneum (IP) route and checked the serum glucose level to define diabetes with the criteron of more than 300 mg/dL at 3 days after injection. We injected unconjugated bilirubin dissolved in DMSO (60 mg/kg, IP) every other day at 1 day after induction of diabetes and continued for 4 weeks. Serum glucose level was maintained less than 600 mg/dL with insulin every other day. We sacrificed rats of control (group 1, 5 rats), diabetes (group 2, 8 rats), and diabetes injected with bilirubin (group 3, 5 rats).

Results: At scarification, the amount of food and water intake and the levels of fasting glucose and HbA1c were not different between group 2 and 3. The weight of kidney was not different but the liver weight was lower in group 3 than group 2 (606±143 vs 418±120 mg, p=0.030). The levels of serum total cholesterol (111.5±30.7 vs 73.2±10.4 mg/dL, p=0.033), triglyceride (791.0±297.0 vs 162.6±69.8 mg/dL, p=0.002), and creatinine (0.71±0.22 vs 0.45±0.05 mg/dL, p=0.012), were lower in group 3 than group 2. The fold changes of protein expressions, compared to that of control, in liver were significantly improved in group 3 than group 2 (SREBP- 1, 3.28±1.25 vs 0.94±0.56, p=0.002 ;LXRα, 1.63±0.30 vs 1.07±0.32, p=0.008; PPARγ, 0.20±0.07 vs 0.79±0.14 folds, p<0.001). The same trends of expressions of SREBP-1, LXRα, and PPARγ were also notified in the kidney. The precent of area of mesangium to glomerulus was lower in group 3 compared to group 2 (16.5±0.78 vs 15.2±0.68 %, p=0.012).

Conclusions: Bilirubin improved dyslipidemia through decrease in expressions of SREBP-1 and LXRα and increased PPARγ expression in liver and kidney of Type I DM animals. Normalization of dyslipidemia by bilirubin was associated with preservation of kidney function and improvement of renal pathology.

Genetic Deletion of Growth Differentiation Factor 15 Augments Renal Damage in a Type 2 Model of Diabetes Magdalena Mazagova, Hendrik Buikema, Maria Sandovici, Dick de Zeeuw, Robert H. Henning, Leo E. Deelman. *Clinical Pharmacology, University Medical Center Groningen, University of Groningen, Groningen, Netherlands.*

Background: Growth differentiation factor 15 (GDF15) is emerging as a valuable biomarker in cardiovascular disease and diabetic kidney disease. Also, GDF15 represents an early response gene induced after tissue injury and studies performed in GDF15 knockout mice suggest that GDF15 plays a protective role after injury. In the current study, we investigated the role of renal GDF15 in type 2 diabetes.

Methods: The progression of diabetic nephropathy was monitored in male db/db GDF15-/- (diabetic GDF15 ko), db/db GDF15+/+ (diabetic wt) and in db/+ GDF15-/- control mice (non-diabetic GDF15 ko) from an age of 6 weeks onwards. Body weight and blood pressure were measured weekly. Mice were placed in metabolic cages for 24 hours when aged 6, 8, 10, 12, 14, 16 and 18 weeks, and food and water intake were measured. Urine samples were collected. At an age of 18 weeks mice were anesthetized with isoflurane (2%) and blood samples were collected. Kidney sections were frozen for isolation of mRNA and protein. Remaining kidney sections were fixed in paraformaldehyde and examined by immunohistochemistry.

Results: Genetic deletion of GDF15 in a model of type 2 diabetes resulted in more renal damage in GDF15 ko mice over wt mice, as demonstrated by increased urinary glucose loss and increased urine production. These changes were accompanied by increased levels of renal damage markers in the GDF15 ko mice. Kidneys from type 2 diabetic GDF15

ko mice showed increased KIM-1 mRNA and KIM-1 protein expression over diabetic wt control, indicating more tubular damage in the diabetic GDF15 ko mice. Furthermore, plasma creatinine levels were increased only in the diabetic GDF15 ko mice, indicating impaired kidney function in the diabetic GDF15 ko mice.

Conclusions: These data indicate that GDF15 both protects the kidney from diabetic damage and maintains renal tubular function in type 2 diabetic mice model.

Aggravation of Inflammatory and Fibrotic Alterations of Diabetic Nephropathy in Mice Lacking Vasohibin-1 Norikazu Hinamoto,[1] Yohei Maeshima,[1] Daisuke Saito,[1] Masaru Kinomura,[1] Hiroko Yamasaki,[1] Hiroyuki Watatani,[1] Haruyo Ujike,[1] Hitoshi Sugiyama,[1] Yasufumi Sato,[2] Hirofumi Makino.[1] *[1]Medicine and Clinical Science, Okayama University, Okayama, Japan; [2]Vascular Biology, Tohoku University, Sendai, Miyagi, Japan.*

Background: Diabetic nephropathy is the leading cause of end-stage renal disease, and the involvement of proangiogenic factors such as VEGF had been reported. We previously reported the protective role of exogenous Vasohibin-1 (VASH-1), a negative feedback regulator of angiogenesis, in mouse models of diabetic nephropathy. In the present study, we aimed to examine the mechanisms involved in the potential protective role of endogenous VASH-1 in diabetic nephropathy.

Methods: Type 1 diabetes was induced in male VASH-1 heterozygous knockout mice ($VASH1^{+/-}$) or wild-type ($VASH1^{+/+}$) littermates (C57/BL6J) by intraperitoneal injections of streptozotocin (STZ, 50 mg/kg) for 5 consecutive days. Mice were sacrificed on week 16 after inducing diabetes. Immunohistochemistry, real-time PCR and immunoblot were performed.

Results: Glomerular alterations were not observed in non-diabetic $VASH1^{+/-}$ mice. Although hyperglycemia, blood pressure or glomerular hyperfiltration were not altered, renal/glomerular hypertrophy, albuminuria, glomerular accumulation of type IV collagen and mesangial matrix, glomerular nephrin/ZO-1 redistribution, glomerular monocyte/macrophage infiltration, GBM thickness, foot process density (TEM) and glomerular $pp65^{+}$ (active NF-kB) cellularity were significantly exacerbated in the diabetic $VASH1^{+/-}$ mice compared with diabetic $VASH1^{+/+}$ mice. Renal levels of transforming growth factor (TGF)-beta1, VEGF-A, angiopoietin-2, pIk-Bα (immunoblot) and MCP-1 (PCR) were significantly increased, and the levels of angiopoietin-1, Total Ik-Bα (immunoblot) and arginase-1 (PCR) were decreased in the diabetic $VASH1^{+/-}$ mice.

Conclusions: These results suggest that endogenous VASH-1 may possess renoprotective effects in type 1 diabetic nephropathy, via suppressing inflammation and fibrosis, thus implicating its potential use to serve as a novel therapeutic reagent for diabetic nephropathy.

SA-PO455

P2X4 Promotes Renal Tubulointerstitial Inflammation in Diabetic Nephropathy through Activating NLRP3 Inflammasome Kehong Chen, Jinhua Zhang, Jurong Yang, Yani He. *Department of Nephrology, DaPing Hospital, Third Military Medical University, Chongqing, China.*

Background: NLRP3 inflammasome has been implicated in the pathogenesis of type 2 diabetes mellitus. NLRP3 inflammasome activation can be triggered by membrane P2X receptors leading to maturation of IL-1β and IL-18. In this study, We investigated the involvement of P2X4 in NLRP3 inflammasome activation and renal tubulointerstitial inflammation in type 2 diabetic nephropathy (DN).

Methods: Human proximal tubular epithelial cell line (HK-2) cells were incubated to normal (5mM) or high glucose (35mM, 48h) with and without the presence of apyrase (an enzyme that degrades extracellular ATP), suramin (P2 receptor inhibitor), TNP-ATP (P2X receptor inhibitor), or 5-BDBD (P2X4 receptor inhibitor). HK-2 cells were transfected with P2X4 siRNA. P2X4 activity was detected by measuring intracellular K+ and Ca2+. 30 patients with type 2 DN and 10 renal hamartoma patients subjected to nephrectomy were recruited in this study. P2X4, NLRP3, IL-1β and IL-18 in renal biopsies were detected by immunohistochemistry and immunofluorescence.

Results: The expression of NLRP3, IL-1β and IL-18 in HK-2 cells under high glucose stimulation increased significantly. NLRP3 inflammasome activation was completely blocked by apyrase which implied that high glucose-associated NLRP3 inflammasome activation was dependent on extracellular ATP. 5-BDBD prevented NLRP3 inflammasome activation through blocking P2X4 open. Silencing P2X4 diminished the high glucose-induced expression of NLRP3, IL-1β and IL-18. Meanwhile, P2X4, NLRP3, IL-1β and IL-18 in tubular epithelial cells were upregulated in type 2 DN patients. P2X4 was co-expressed with NLRP3, IL-1β and IL-18 in the tubular epithelial cells. P2X4, as well as NLRP3 expression was correlated directly with pathological scores of tubulointerstitial inflammation, renal interstitial fibrosis, tubular atrophy respectively.

Conclusions: These results demonstrate that the ATP-P2X4 signaling axis is indispensable for high glucose-induced NLRP3 inflammasome activation. P2X4 and NLRP3 may be exploited for renal tubulointerstitial inflammation in diabetic nephropathy.

The Effects of Fibroblast Growth Factor 21 on db/db Mouse Model of Type 2 Diabetic Nephropathy Hyunwook Kim,[1] Ji Eun Lee,[1] Jin Joo Cha,[2] Young Youl Hyun,[3] Jung Eun Kim,[2] Mihwa Lee,[2] Hye Kyung Song,[2] Kum Hyun Han,[4] Sang Youb Han,[4] Young Sun Kang,[2] Nam Ho Kim,[5] Dae R. Cha.[2] *[1]Department of Internal Medicine, Wonkwang University College of Medicine Sanbon Hospital, Gunpo-si, Kyunggi-do, Korea; [2]Department of Internal Medicine, Korea University College of Medicine Ansan Hospital, Ansan-si, Kyunggi-do, Korea; [3]Department of Internal Medicine, Sungkyunkwan University School of Medicine Kangbuk Samsung Hospital, Seoul, Korea; [4]Department of Internal Medicine, Inje University College of Medicine Ilsan Baik Hospital, Koyang-si, Kyunggi-do, Korea; [5]Department of Internal Medicine, Chonnam University College of Medicine, Gwangu-si, Jeollanam-do, Korea.*

Background: Fibroblast growth factor 21 (FGF21) is an emerging metabolic hormone assumed to have an important role in regulating energy balance by exerting adaptive starvation responses. However, there has been no study exploring its direct effects on renal changes in diabetic milieu. Therefore, we tested the effects of exogenous FGF21 administration on db/db mouse model of type 2 diabetic nephropathy.

Methods: db/db mice were injected with FGF21 intraperitoneally once daily for 12 weeks from the age of 8 weeks and compared to control db/db mice with vehicle treatment or lean normal mice.

Results: At 20 weeks of age, FGF21-treated db/db mice, compared to control db/db mice, showed significantly improved lipid profiles and insulin tolerance test results. Further, serum adiponectin level was significantly higher, whereas serum insulin level, serum and urinary 8-isoprostane levels, and the homeostatic model assessment (HOMA) index were significantly lower in the FGF-treated db/db mice than control db/db mice. In addition, epididymal adipose tissue of the FGF21-treated mice presented more small-differentiated features with relevant changes in mRNA expressions of adipokines. Furthermore, FGF21 administration significantly reduced both mesangial expansion and expression of fibrotic markers, such as TGF-β, collagen-IV, and plasminogen activator inhibitor-1 in renal pathology as well as urinary albumin excretion.

Conclusions: These results suggest that FGF21 is a potential candidate for therapeutic strategy for obesity-related diabetic nephropathy.

SA-PO457

FGF23 and Klotho Expression in the Kidney of Zucker Diabetic Fatty (ZDF) Rats and Modulation by ACE Inhibitor Carlamaria Zoja,[1] Cristina Zanchi,[1] Monica Locatelli,[1] Daniela Corna,[1] Susanna Tomasoni,[1] Giuseppe Remuzzi,[1,2] Ariela Benigni.[1] *[1]Mario Negri Institute, Bergamo, Italy; [2]Ospedali Riuniti, Bergamo, Italy.*

Background: Fibroblast growth factor (FGF) 23 is a phosphaturic hormone mainly produced by bone that acts in the kidney after binding to FGF receptor in the presence of the cofactor Klotho. In CKD, circulating FGF23 increases likely to counteract phosphate retention, and serum FGF23 is an independent predictor of renal outcome in patients with DN. The kidney apparently produces FGF23 at very low level, if any, both in control and CKD animals. However, data in animals with chronic renal disease only derive from 5/6 nephrectomy model that does not necessarily reflect the most common clinical condition. Here we investigated renal expression of FGF23 in a model of human type 2 diabetes.

Methods: Renal expression of FGF23 and Klotho was assessed by real time PCR and immunohistochemistry in ZDF and lean rats at 2,4,6,8mo of age (n=5/each group). To evaluate whether the renoprotective effect of ACEi in type 2 diabetes was associated with changes in FGF23 and Klotho, ZDF rats received ramipril from 4mo of age, when proteinuric, until 8mo.

Results: ZDF rats developed progressive proteinuria, glomerulosclerosis and interstitial inflammation. FGF23 mRNA was not detectable in the kidney of lean rats, nor in ZDF rats at 2mo but became measurable at 4mo and further increased thereafter. Focal expression of FGF23 protein was found in distal and proximal tubules of ZDF rats at 6 and 8mo. Concomitantly, renal Klotho mRNA progressively decreased. ACEi limited the signs of renal injury and attenuated FGF23 upregulation while normalized Klotho expression. Serum P levels were similar in ZDF and lean rats. Total urinary P content and fractional excretion of P were increased ($p<0.05$) in ZDF vs lean rats at 8mo (U_P: 23±3 vs 4±0.5 mg/d; FE_P: 4.5±1.1 vs 0.7± 0.1 %). After ACEi, U_P was reduced by 36%, FE_P by 23%.

Conclusions: These data suggest that the kidney contributes to FGF23 production that is limited but not abrogated by ACE inhibition, and may offer new clues to understand how to interfere with the delicate balance of FGF23 and phosphorus in diabetes with potential implications in clinics.

Vitamin D Receptor Activation Prevents ER Stress, Oxidative Stress, and Lipid Accumulation in db/db Mice with Type 2 Diabetes Xiaoxin Wang, Liru Qiu, Hannah Danielle Santamaria, Moshe Levi. *Medicine, University of Colorado, Aurora, CO.*

Background: Decreased serum concentration of 1,25-dihydroxyvitamin D, the hormonally active form of vitamin D, and of its precursor 25-hydroxyvitamin D are reported with increasing frequency in subjects with obesity and type 1 or type 2 diabetes. Treatment with vitamin D receptor (VDR) agonists has been proposed to play an important role in

the prevention of diabetic nephropathy. The purpose of these studies was to determine the effects of Paricalcitol in db/db mice with type 2 diabetes mellitus.

Methods: We treated db/m and db/db mice with vehicle or Paricalcitol for 12 weeks.

Results: We found that VDR agonist treatment (Paricalcitol) decreased urinary albumin excretion, and prevented podocyte injury, mesangial expansion, tubulointerstitial fibrosis, and macrophage infiltration. Treatment with Paricalcitol also prevented renal lipid accumulation and the increased expression of the lipid droplet proteins Plin4 and Plin5. In addition treatment with Paricalcitol decreased endoplasmic reticulum stress as determined by decrease in CHOP, a transcription factor that controls genes encoding components involved in apoptosis. Consistent with this Paricalcitol restored the expression of spliced X-box binding protein 1 (XBP1s) and glucose-regulated protein 78 (GRP78). Furthermore Paricalcitol also prevented expression of Cyp4a10 of the cytochrome P450 of the 4A family (CYP4A) associated with ROS and restored glutathione peroxidase GPX2. These effects suggest a role of Paricalcitol in regulation of oxidative stress.

Conclusions: Our data, thus, indicates a novel and an important role for VDR activation for prevention of lipid accumulation, ER stress, and oxidative stress, which are important mechanisms for prevention and treatment of diabetic nephropathy.

SA-PO459

Novel Effects of the G Protein Coupled Receptor TGR5 Activation in db/db Mice with Type 2 Diabetes and in Human Podocyte Cells Liru Qiu, Xiaoxin Wang, Hannah Danielle Santamaria, Moshe Levi. *Medicine, University of Colorado, Aurora, CO.*

Background: Diabetic nephropathy is the most common cause of chronic renal failure in the world. In spite of aggressive glucose and blood pressure control the incidence of diabetic complications including nephropathy are on the rise. The purpose of the present study was to determine the effects of the G Protein Coupled Receptor TGR5 activation in db/db mice with type 2 diabetes.

Methods: We treated db/m and db/db mice with vehicle or the selective TGR5 agonist INT-777 for 12 weeks.

Results: We found that treatment of db/db mice with INT-777 decreased proteinuria, podocyte injury, mesangial expansion, and tubulointerstitial fibrosis. Urinary H2O2 and TBARS levels which were increased in db/db mice, were significantly decreased after INT-777 treatment. The decrease in oxidative stress induced by INT-777 was further demonstrated by reduced total protein carbonylation in diabetic kidneys. Treatment with INT-777 also increased renal phosphorylated AMPK protein level as well as PGC-1α and ERRα protein abundance, which are master regulators of mitochondrial biogenesis and inhibitors of oxidative stress. We also performed additional studies in human podocytes grown in culture. We found that palmitic acid complexed to BSA (FFA) in concentration of 250 uM resulted in increased activity of caspase 3/7. The pretreatment of the podocytes for 24 hours with INT-777 prevented the FFA induced apoptosis. FFA also induced increased ROS generation. INT-777 decreased ROS generation as determined with MITOSOX staining. In addition INT-777 also increased PGC-1α and ERRα protein expression which are master regulators of mitochondrial biogenesis.

Conclusions: These data suggest a novel role for TGR5 in preventing oxidative stress and inducing mitochondrial biogenesis, which indicate a potential important role for TGR5 in preventing kidney injury in diabetes.

Inhibition of Apoptosis Signal-Regulating Kinase 1 Prevents Progressive Diabetic Nephropathy in Mice Haichun Yang,[1] John Liles,[2] David G. Breckenridge,[2] Agnes B. Fogo.[1] *[1]Pathology, Microbiology and Immunology, Vanderbilt University, Nashville, TN; [2]Gilead Sciences, Inc., Foster City, CA.*

Background: Apoptosis Signal-Regulating Kinase 1 (ASK1), a ubiquitously-expressed MAPKKK, is implicated inapoptosis,differentiation, and inflammation. ASK1 is activated by oxidative stress and high glucose in mesangial cells and endothelial cells in vitro. We aimed to investigate effects of a selective ASK1 inhibitor (GS-444217) on progressive development of diabetic nephropathy in db/db eNOS$^{-/-}$ mice.

Methods: By 10 weeks of age, db/db eNOS$^{-/-}$ mice developed early diabetic injury with proteinuria, mild glomerulosclerosis, and hyperfiltration (Baseline, n=8). db/db eNOS$^{-/-}$ mice received normal chow (Placebo, n=14) or chow with 0.3% GS-444217 by weight (GS-444712 group, n=9) from 10 until 18 weeks. Renal function and histopathology at week 18 in Placebo and GS-444217 were compared to 10 weeks in Baseline.

Results: GFR (inulin clearance) decreased significantly in untreated db/db eNOS$^{-/-}$ mice from 10 to 18 weeks, which was attenuated by GS-444217 (Baseline 10.3±0.9, Placebo 4.4±0.5 vs. GS-444217 6.2±0.6 µl/min/g BW, p<0.05). GS-444217 also decreased albuminuria (Baseline 4022.6±752, Placebo 4796.3±610, GS-444217 3145.6±452 µg/mg) and reduced glomerular injury (Baseline injury score 0.6±0.1, Placebo 1.5±0.2 vs. GS-444217 0.7±0.1, 0-4 scale, p<0.05). Db/db eNOS$^{-/-}$ mice treated with GS-444217 had significantly decreased glomerular collagen IV immunostaining, decreased glomerular and tubulointerstitial apoptosis (Baseline 0.3±0.1, Placebo 0.7±0.1 vs.GS-444217 0.3±0.1 TUNEL^{+} cells/HPF, p<0.05), lower HbA1C, and lower blood pressure (Baseline 102.0±3.0, Placebo 130.5±3.4 vs. GS-444217 114.9±6.8 mmHg, p<0.05) compared to Placebo. Kidney Phospho-p38, a downstream mediator of ASK1 signaling, was reduced by GS-444217 treatment.

Conclusions: Our data demonstrate that an ASK1 inhibitor markedly slows progression of diabetic nephropathy in mice as assessed by GFR, and halts progressive glomerulosclerosis and apoptosis in the kidney. The data support the ASK1 pathway as a therapeutic target in diabetic nephropathy with the potential to ameliorate or slow disease progression in patients.

SA-PO461

Protective Effect of PPARalpha against Diabetic Nephropathy through Inhibition of the Canonical Wnt Pathway Rui Cheng, Xuemin He, Jianxing Ma. *Department of Physiology, University of Oklahoma Health Sciences Center, Oklahoma City, OK.*

Background: Peroxisome proliferator-activated receptor-α (PPARα) plays a crucial role in the regulation of lipid metabolism. PPARα deficiency has been shown to aggravate diabetic nephropathy by increasing extracellular matrix formation and inflammation. Recently, we have reported that aberrant activation of the canonical Wnt pathway plays a pathogenic role in diabetic nephropathy. The purpose of the present study is to investigate whether PPARα ameliorates diabetic nephropathy via inhibiting the Wnt pathway.

Methods: Expression levels of PPARα and activity of the Wnt pathway were measured in the renal cortex of streptozotocin (STZ)-induced diabetic rats. Fenofibrate, a specific agonist of PPARα, was administrated in the diabetic model. To identify the protective role of PPARα under diabetes conditions, PPARα was over-expressed using adenovirus in primary human renal proximal tubular epithelial cells (HRPTCs).

Results: In HRPTCs, both high glucose and Wnt3a activated the Wnt pathway and up-regulated expression of CTGF and fibronectin, target genes of the Wnt pathway, which were attenuated by over-expression of PPARα. Similarly, Fenofibrate suppressed the activation of the Wnt pathway and over-expression of CTGF and fibronectin in a concentration- and time-dependent manner. Compared to non-diabetic rats, PPARα expression was down-regulated in the kidney of STZ-induced diabetic rats, which is negatively correlated with Wnt signaling activity. Fenofibrate reduced albuminuria and decreased collagen IV and fibronectin expression in the kidney of the diabetic rats. Fenofibrate also attenuated the over-renal expression of inflammatory factors ICAM-1 and TNF-α, target genes of the Wnt pathway, in the diabetic rats. Furthermore, Fenofibrate decreased renal levels of LRP6 and β-catenin in the diabetic rats.

Conclusions: These results suggest that diabetes-induced down-regulation of PPARα in the kidney plays an important role in diabetic nephropathy. PPARα has a protective effect against diabetic nephropathy through inhibiting the canonical Wnt pathway, which renders a new therapeutic target for diabetic nephropathy.

Aquaporin 11 Insufficient Mice Are Predisposed to the Development of Diabetic Kidney Disease Elena E. Tchekneva,[1] Elena N. Atochina-vasserman,[2] Elena Abramova,[3] Liberty Foye,[1] Andrew J. Gow,[3] Raymond C. Harris.[1] *[1]Vanderbilt University Medical Center; [2]University of Pennsylvania; [3]Rutgers University.*

Background: Accumulating evidence suggests proximal tubules (PT) as a primary target in diabetic kidney disease. The factors predisposing PT to hyperglycemia-induced injury and initiating diabetic kidney disease remain uncertain. In the kidney, the water channel, aquaporin 11 (Aqp11), is exclusively expressed in PT, resides in the ER and maintains cytosolic and/or vesicle osmolality. Loss-of-function of Aqp11 resulted in PT-specific injury and kidney failure in *Aqp11* deficient mutant mice with *sudden juvenile death syndrome (sjds/sjds)* mutation. *Aqp11* insufficient mice (*sjds/+)* were phenotypically normal (JASN 10:1955, 2008).

Methods: The *sjds* mutation was crossed with *Ins2Akita* mice, which develop type I diabetes.

Results: *Sjds* carriers showed significantly higher levels of ROS in renal cortex than +/+ littermates. In *sjds/+* mice repetitive injections with high glucose significantly increased BUN that was abrogated by antioxidant sulforaphane. We hypothesize that *sjds/+* mice are susceptible to hyperglycemia-induced PT-specific injury and predisposed to diabetic kidney disease. By the age 5 months, *sjds/Ins2Akita*mice exhibited severe PT injury, renal hypertrophy, tubulointerstitial fibrosis and glomerular mesangial expansion compared with wild type *+/Ins2Akita* littermates. The histopathologic changes were associated with significantly increased BUN (40.48±7.56 *vs*. 28.04±7.08mg/dl; p<0.05), ROS (3.02±0.29 *vs*.2.3±0.04 AU/ug; p<0.05), and albumin/creatinine ratio (ACR) (135±35 *vs*.40±6ug/mg; p<0.005) in *sjds/Ins2Akita* progeny compared to control diabetic *+/Ins2Akita* littermates. Non-diabetic *sjds/+*mice exhibited a compensatory 40% higher Aqp11 expression than +/+ mice. Importantly, hyperglycemia also increased the Aqp11 expression in diabetic *+/Ins2Akita*, but expression was not further increased in diabetic *sjds/Ins2Akita* mice.

Conclusions: We showed that Aqp11 insufficiency in PT is a novel risk factor for the development of diabetic kidney disease. ROS-mediated PT-specific injury induced by hyperglycemia triggers diabetic kidney disease in mice with Aqp11 insufficiency.

Null Mutations at the p66 and Bradykinin 2 Receptor Loci Induce Divergent Phenotypes in the Diabetic Kidney Himanshu Vashistha,[1,3] Pravin C. Singhal,[2] Ashwani Malhotra,[2] Krzysztof Reiss,[3] Leonard G. Meggs.[1,3] *[1]Nephrology, Ochsner Clinic Foundation, New Orleans, LA; [2]Nephrology, Feinstein Research Institute, New York, NY; [3]Neurological Cancer Research, SSSCC, LSUHSC, New Orleans, LA.*

Background: Candidate genes have been identified that confer increase risk for diabetic glomerulosclerosis (DG). Mice heterozygous for the Akita ($Ins2^{+/C96Y}$) diabetogenic mutation with a second mutation introduced at the bradykinin 2 receptor ($B2R^{-/-}$) locus, express a disease phenotype that approximates human DG. The p66 longevity gene controls mitochondrial metabolism and cellular responses to oxidative stress, aging and apoptosis.

Methods: We generated p66-null Akita mice to test whether loss of function mutations at the p66 locus will rescue kidneys of Akita mice from disease causing mutations at the Ins2 and B2R loci. Here we show null mutations at the p66 and B2R loci interact with the Akita ($Ins2^{+/C96Y}$) mutation, independently and in combination, inducing divergent phenotypes in the kidney.

Results: The $B2R^{-/-}$ mutation induces detrimental phenotypes, as judged by increased systemic and renal levels of oxidative stress, histology and urine albumin excretion, whereas the p66-null mutation confers a powerful protection phenotype. Furthermore, we provide a rationale for the protection phenotype in p66-null Akita mice, by revealing previously unrecognized crosstalk between p66 and the redox sensitive transcription factor p53, that controls hyperglycemia-induced ROS metabolism, transcription of p53 target genes (angiotensinogen, angiotensin II type-1 receptor; bax), angiotensin II generation and apoptosis. Finally, protein levels of p53 target genes were upregulated in kidneys of Akita mice, but unchanged in p66-null Akita mice.

Conclusions: We speculate p66 is the most promising molecular target for therapeutic intervention in DG, since the discovery of ACEI and ARB.

Diabetes-Associated SORCS1 Gene Regulates Water Balance in Mice Melkam Kebede,[1] Brendan J. Floyd,[1] Angie Oler,[1] Arjang Djamali,[2] Alan Attie.[1] *[1]Biochemistry, University of Wisconsin-Madison, Madison, WI; [2]University of Wisconsin School of Medicine and Public Health, Madison, WI.*

Background: Genome Wide Association Studies in humans and an F2 mouse cross in our laboratory have linked the *sortilin-related receptor CNS expressed 1* (*SorCS1*) gene to type 2 diabetes mellitus and its complications, including retinopathy, neuropathy, and nephropathy. SorCS1 is a member of a family of five proteins (sortilin, SorLA and SorCS1–3) that contain a vacuolar protein sorting-10 (VPS10) domain. It is highly expressed in the brain, heart and kidney and at low levels in other tissues such as pancreatic islets. To identify the direct role of *SorCS1* gene in diabetes susceptibility and complications, we have generated a whole-body *SorCS1* knockout (KO) mouse on a C57BL/6 background with and without the *Leptin^{ob}* mutation.

Methods: Urine collection: Mice were acclimated to metabolic cages with food and water, and then transferred to a fresh cage without food for urine collection over 8 hours during the light cycle. Values are adjusted to 24 hours.

Urine analysis: Osmolality was measured by vapor pressure osmometry (Vapro) and chemistry was measured at Marshfield Laboratories, Marshfield, WI.

Results: The most notable phenotype observed in the female *SorCS1* KO mice was a reduction in urine volume both in the lean and Ob background. Lean SorCS1 KO mice showed a ~50% reduction in urine output compared to their WT littermates (173 ± 44 vs. 380 ± 80, $p<0.05$). When in the Ob background, the WT mice increased their urine output by two-fold compared to their lean counterparts (685 ± 106 vs. 380 ± 80, $p<0.05$). Interestingly, knockout of the SorCS1 gene abolishes the polyuria phenotype of $Leptin^{ob/ob}$ mice, despite glucosuria, and hyperglycemia.Further urine analysis revealed that urine from SorCS1 KO animals has elevated [Na^+], [K^+], and [Cl^-], but reduced Na^+/creatinine and Cl^-/creatinine ratios compared to WT controls. Both KO strains have reduced blood urine nitrogen, a potential sign of serum dilution. In addition, SorCS1 KO urine has lower pH compared to their WT littermates (5.56± 0.18 vs. 6.09 ± 0.15, $p<0.05$).

Conclusions: Taken together, these results demonstrate that SorCS1 is an important regulator of water and electrolyte balance in mice and studies are now underway to identify the mechanism(s) of such regulation.

SA-PO465

Serum Amyloid A and Inflammatory Cytokine Expression in Kidney Cells Exposed to Diabetes-Like Conditions Rick L. Meek,[1] Robert J. Anderberg,[1] Sheryl K. Cooney,[1] Katherine R. Tuttle.[1,2] *[1]Providence Sacred Heart Medical Center and Children's Hospital, Spokane, WA; [2]Nephrology Division, University of Washington School of Medicine, Spokane, WA.*

Background: Inflammation is increasingly recognized as a pathogenic mechanism in diabetic kidney disease. Serum amyloid A (SAA) is a potent cytokine that binds pro-inflammatory receptors including the receptor for advanced glycation end products (RAGE). We recently discovered that kidney SAA expression is increased in mouse models of types 1 and 2 diabetes. The study aims were to assess: 1) SAA expression in podocytes, mesangial cells and tubular cells exposed to AGE, aberrant metabolic factors characteristic of diabetes; 2) effects of SAA on inflammatory cytokine expression in these kidney cells; 3) impact of RAGE on expression of SAA and caspase 4, another novel cytokine, in podocytes.

Methods: Mouse podocytes and mesangial cells (MES-13),and human proximal tubule cells (HK-2) were cultured with AGE, SAA or control conditions. SAA protein (ELISA) and mRNA (real-time PCR) and mRNA for other inflammatory mediators (caspase 4; monocyte chemotactic protein-1: MCP-1; inducible nitric oxide synthase: iNOS) were also measured. Blocking antibody for RAGE was used as an inhibitor of receptor activation.

Results: Both SAA and AGE induced expression of SAA, caspase 4, MCP-1, and iNOS in podocytes and mesangial cells. SAA induced autocrine expression of itself as well as expression of caspase 4 in HK-2 cells. Anti-RAGE antibody inhibited expression of AGE-induced SAA, caspase 4, MCP-1, and iNOS mRNA in podocytes.

Conclusions: SAA expression is up-regulated by AGE in cells derived from both glomerular and tubular compartments. SAA also induces expression of inflammatory mediators, including an *autocrine effect on its own expression. RAGE may be a key receptor for induction of novel cytokines including SAA and caspase 4 in podocytes.*

SA-PO466

Serum Amyloid A and Podocyte Apoptosis in Mouse Models of Diabetic Kidney Disease Rick L. Meek,[1] Sheryl K. Cooney,[1] Robert J. Anderberg,[1] Charles E. Alpers,[2,3] Kelly L. Hudkins,[3] Katherine R. Tuttle.[1,4] *[1]Providence Sacred Heart Medical Center and Children's Hospital, Spokane, WA; [2]Mouse Metabolic Phonotyping Center; [3]Pathology Department; [4]Nephrology Division, University of Washington School of Medicine, Spokane and Seattle, WA.*

Background: Serum amyloid A (SAA) is a pro-inflammatory cytokine and ligand for the receptor for advanced glycation end products (RAGE). Activation of RAGE induces podocyte apoptosis. The potential contribution of SAA to kidney damage is unknown. The specific aims of this study were to determine if SAA expression is increased in the diabetic kidney and whether SAA induces podocyte apoptosis via RAGE.

Methods: SAA mRNA (real-time PCR) and/or protein (immunocytochemistry) expression were examined in kidneys of streptozotocin-injected C57BL/6 mice (mRNA and protein after 20 weeks) and BTBR obob mice (protein after 24 weeks), models of types 1 and 2 diabetes, respectively. Mouse podocytes were cultured with SAA, AGE, or control conditions. Levels of mRNA for SAA and caspase 4 (indicator of early phase apoptosis) were quantified by real-time PCR. Later phase apoptosis was measured by TUNEL staining. Blocking antibody for RAGE was used as an inhibitor of receptor activation.

Results: Expression of SAA mRNA was elevated (~4-fold) in kidney cortex of type 1 diabetic mice compared to non-diabetic controls. SAA protein was greater in the proximal tubules of both mouse models compared to kidneys of their respective non-diabetic control mice. Exposure of cultured podocytes to AGE induced expression of SAA mRNA. Similarly, in podocytes exposed to SAA, production of SAA mRNA and protein increased along with caspase 4 mRNA and TUNEL staining. RAGE inhibition prevented induction of apoptosis in response to SAA.

Conclusions: SAA expression is up-regulated in kidneys of mouse models of types 1 and 2 diabetes as well as in cultured podocytes exposed to AGE. Notably, SAA directly promotes its own expression and apoptosis in podocytes. RAGE activation may be a pathway for increasing expression of SAA as well as in mediating autocrine effects of SAA in podocytes.

SA-PO467

A Novel Glycosaminoglycan Formulation Prevents Mesangial Expansion, Albuminuria, Macrophage Infiltration and Attenuates Podocyte Loss in Experimental Diabetic Nephropathy Conrado Rodrigues Gomes, Carolina Venturotti, Cristina Leão, Andre Barreira, Roberto Fonseca, Christina Maeda Takiya, Paulo Mourão, Alvimar Delgado, Maurilo Leite. *Internal Medicine, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil.*

Background: Diabetic nephropathy (DN) is characterized by thickening of glomerular basement membrane, mesangial matrix (MM) expansion, albuminuria (ALB) and progressive kidney damage. Glycosaminoglycan (GAG) have been shown to decrease ALB in DN. This study used fucosylated condroitin sulfate (FuCS), a novel GAG from marine invertebrate, and a low molecular weight heparin (LMWH), in experimental DN.

Methods: Diabetes Mellitus (DM) was induced in 15 rats by streptozotocin (65mg/Kg) via the caudal vein. They were divided into 4 groups: 1) control, 2) DM without GAG, 3) DM + FuCS, 8mg/kg, 4) DM + LMWH, 4 mg/kg. G1 received citrate buffer. After week 8 (G:3 and 4), the GAGs were given SC daily for 6 weeks, and then on alternate days for other 6 weeks and then the groups were sacrificed.

Results: There was an increase in ALB of G2: 16.38±4.3 compared to G1: 3.04±0.98, G3: 5.35±3.05; G4: 5.06±3.07 (mg/24hs, $p<0.002$). We observed expansion of MM in the DM group compared to the other groups (G2: 14.19±3.01; G1: 9.5± 2.8; G3: 10.2±2.6 and G4: 8,19±2.5 (%mesangial area, $P<0.001$), and an increase in macrophages in gomeruli of G2 compared to other groups (G2: 0.12±0.09 x G1:0.04±0.05, G3:0.05±0,05 and G4:0.05±0.06, %ED-1-stained area/mm^2, $P<0.001$). There was a reduced immunoreactivity to nestin antibody in podocytes of G2, compared to G1 (2.8±0.3 vs 7.6±0.5 % glomerular area, $P<0.05$), which was prevented in G3 and G4 groups (6.7±0.36 and 5.6±0.34 %, $P<0.05$,compared with G2). TGF-β1 stained area in glomeruli (%) was increased in G2 (4.6±0.3) compared to treated groups (G3: 1.2±0.15 and G4: 1.9±0.2, $P<0.05$) and G1 (0.7±0.1, $P<0.05$).

Conclusions: Both GAGs prevented ALB, MM expansion, macrophage infiltration, and promoted attenuation of TGF-β1 expression in diabetic rats. Also, podocytes were preserved by the treatment with GAGs. We conclude that FuCS may be a useful option for the prevention of DN.

SA-PO468

Interferon Beta Dramatically Reduces the Development of Albuminuria in Strepzotocin-Induced Diabetic DBA2J RccHSD Mice

Georgina Cope,[1,2] Yan Qiu,[2] David O. Bates,[2] Gavin Iain Welsh,[1] Peter W. Mathieson,[1] Simon C. Satchell.[1] *[1]Academic Renal Unit, University of Bristol, Bristol, United Kingdom; [2]Microvascular Research Laboratories, University of Bristol, Bristol, United Kingdom.*

Background: We have previously described the anti-proteinuric actions of interferon beta (IFNβ) in 3 different rat models of glomerulonephritis and have shown that IFNβ has direct effects on cells of the glomerular filtration barrier. The aim of the current study was to determine whether IFNβ is effective in inhibiting proteinuric diabetic renal disease.

Methods: Eight week old male DBA2J-RccHSD mice were made diabetic via a 5 day regimen of 40mg/kg STZ *i.p*. This produced a robust hyperglycaemia in all animals with similar starting plasma glucose values (sham 28.8mmol/l +/-3.9 vs. 26.3+/-2.4). After four weeks of hyperglycaemia and prior to production of albuminuria, animals were randomised into two groups with one group given daily *i.p*. injection of 1000 units of IFNβ the other group were given an equivalent volume of saline. The study was carried out with no insulin supplementation.

Results: Weekly analysis of individual animal weights showed no significant difference between the two treatments (Sham 21.1 +/-1.5g vs. IFNβ 20.14+/-1.86g P<0.198). Albuminuria increased in sham control animals from week 2 of treatment with the albumin: creatinine ratio (ACR) attaining a 9 fold increase over baseline by week 3 (3236.4µg/mmol +/-194.7 vs. own baseline 347.02+/-229.6.) and reaching a 84 fold increase 28983.3 µg/mmol+/- 2905.3 at culling (week 5). By week three IFNβ treated animals had 9-fold less albumin excretion than sham controls (373.5 µg/mmol +/- 148.6 vs. 3236.4 +/- 194.7 P<0.001), with IFNβ treatment continuing to retard albumin excretion to culling (Sham 28983.3 +/-2905.3 vs. IFNβ 3942.3+/416.1 P<0.001).

Conclusions: IFNβ treatment therefore significantly inhibited the diabetes mediated increase in ACR with treated animals displaying 90% less albumin excretion than saline treated animals at culling. IFNβ and the glomerular cellular pathways it modulates present a potential target for therapy in proteinuric renal disease including diabetic nephropathy.

SA-PO469

P2X7 Deficiency Attenuates Renal Inflammation and Pancreatic Beta Cell Injury in Experimental Diabetes

John W. Booth,[1] Jill T. Norman,[1] Frederick W.K. Tam,[2] Robert J. Unwin.[1] *[1]Centre for Nephrology, University College London; [2]Imperial College London.*

Background: Inflammation is a key pathogenic mechanism in both diabetes and diabetic nephropathy (DN). The P2X7 receptor is an ATP-gated cation channel with roles in inflammation and cell death; it is expressed in immune cells and also resident renal cells and pancreatic islets. We investigated the role of P2X7 in early DN and pancreatic injury using a mouse model of type 1 diabetes as well as human mesangial cells (HMC) cultured in a diabetic milieu.

Methods: Low dose (50mg/kg) streptozotocin injections (x5) were administered to wildtype (WT) and two strains of P2X7 knockout mice with differing profiles of residual receptor expression: Glaxo (GSK) and Pfizer (PF). Random blood glucose (BG) and pancreatic insulin staining were assessed at 3 weeks. Renal CD68 staining was assessed at 12 weeks in persistently diabetic mice. HMCs were grown for 2 days in 4mM or 30mM glucose media. Secreted MCP-1 was measured by ELISA, and the effect of the selective P2X7 antagonist A438079 (10µM) and the P2X7 agonist BzATP (0.1M) were tested.

Results: 20/22 (91%) WT and 13/18 (72%) GSK achieved a BG >16mM at 3 weeks. In a separate experiment, 6/7 (86%) WT and 1/6 (17%) PF achieved this. Islet insulin staining was relatively preserved in PF (p=0.036 vs WT). At 12 weeks, renal macrophage accrual was reduced in GSK in both glomerular (p<0.0001 vs WT) (Figure 1) and interstitial (p=0.01 vs WT) compartments; urine albumin excretion was not increased at this time.

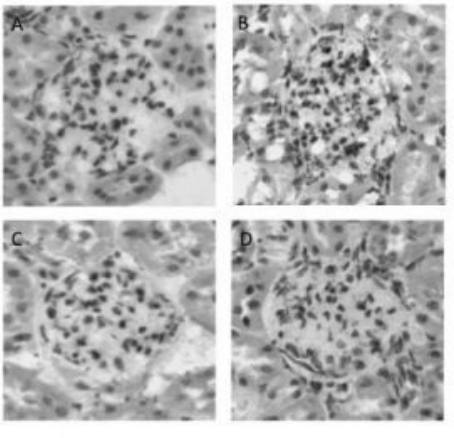

Figure 1. Glomerular CD68 macrophage immunohistochemistry at 12 weeks. A: WT vehicle-injected control; B: WT diabetic animal; C: GSK vehicle-injected control; D: GSK diabetic animal.

In vitro, hyperglycemia enhanced MCP-1 secretion from HMCs, which was reduced 51-100% by A438079. BzATP further augmented glucose-induced MCP-1 release (p=0.028 vs glucose alone).

Conclusions: P2X7 contributes both to early renal inflammation and beta cell injury in experimental diabetes. P2X7 appears to regulate glucose-induced MCP-1 release from HMCs which may, in part, explain the renal findings.

SA-PO470

Macrophage-Mediated Glucolipotoxicity Contributes to Progression of Diabetic Nephropathy through MRP8/TLR4 Signaling

Takashige Kuwabara,[1] Kiyoshi Mori,[1] Masashi Mukoyama,[1] Masato Kasahara,[1] Hideki Yokoi,[1] Hirotaka Imamaki,[1] Akira Ishii,[1] Kenichi Koga,[1] Keita P. Mori,[1] Yukiko Kato,[1] Naohiro Toda,[1] Shoko Ohno,[1] Akira Sugawara,[2] Kazuwa Nakao.[1] *[1]Medicine and Clinical Science, Kyoto University Graduate School of Medicine, Kyoto, Japan; [2]Nephrology, Osaka Red Cross Hospital, Osaka, Japan.*

Background: We have identified that toll-like receptor 4 (TLR4) and its endogenous ligand myeloid-related protein 8 (MRP8) are upregulated in diabetic nephropathy (DN) using glomerular cDNA microarray. We have also observed that high-fat diet (HFD) feeding upon streptozotocin (STZ)-treated mice results in further upregulation of glomerular MRP8/TLR4 along with doubling of albuminuria. Here, we investigated the pathophysiological role of MRP8/TLR4 signaling in DN.

Methods: In vivo, STZ-treated wild-type (WT) and TLR4 knockout (KO) mice fed with HFD for 6 weeks were analyzed. In vitro, effects of high-glucose, fatty acid and MRP8 were examined in macrophages (Mφ) derived from WT and KO bone marrow. In 65 human biopsy samples, MRP8 expression was evaluated with immunostaining.

Results: In STZ-treated WT and KO mice, addition of HFD similarly enhanced hypertriglyceridemia and renal lipid accumulation. Although HFD aggravated DN in STZ WT mice, as indicated by increase of albuminuria, mesangial expansion and inflammatory and fibrotic gene upregulation, effects of HFD upon renal lesions were almost completely abolished in STZ KO mice. MRP8 positive cells were abundantly found in glomeruli of STZ-HFD-treated WT mice and colocalized with Mφ marker MAC2. Recombinant MRP8 markedly induced expression of IL-1β and TNFα as potently as LPS, and triggered auto-induction of MRP8 in Mφ. Palmitate amplified MRP8 expression only under high-glucose conditions in Mφ from WT, but not in Mφ from KO. In human DN, punctate MRP8 signals were observed in glomeruli and tubulointerstitium. Glomerular MRP8-positive cell counts were strongly correlated to extent of proteinuria.

Conclusions: These findings suggest that hyperlipidemia complicated with diabetes activates TLR4 on Mφ, induces MRP8, and deteriorates DN. We propose "Mφ-mediated glucolipotoxicity" through MRP8/TLR4 signaling as a novel mechanism of DN progression.

SA-PO471

The Role of Cellular Inflammation and STAT3-SOCS3 in Early Obesity-Related Nephropathy in the Zucker Rat

Bairbre A. McNicholas,[1] Michelle Aherne,[1] Hans J. Anders,[2] Matthew D. Griffin.[1] *[1]Regenerative Medicine Institure (REMEDI), National University of Ireland, Galway, Galway, Ireland; [2]Department of Nephrology, Medizinishe Polikinik, University of Munich, Munich, Germany.*

Background: Inflammation, regulated by STAT3 signaling, contributes to renal damage in obesity/metabolic syndrome/diabetes. STAT3 signaling is negatively regulated by suppressor of cytokine signaling 3 (SOCS3). The aim of the study was to assess cellular inflammation and relative STAT3/SOCS3 expression in the kidneys of Zucker rats with early obesity related nephropathy.

Methods: 14 and 18 week old male Obese Zucker rats (OZR) were compared to lean Zucker rats (LZR) with regard to weight, proteinuria, cellular inflammation and expression of STAT3 and SOCS3 in the kidney. Analyses included histology, immunohistochemistry (IHC) and multi-color flow cytometry of kidney cell suspensions.

Results: By 18 weeks OZR were heavier (555±16 vs 391±17g p=0.005) with increased albuminuria (391±89 vs 27.6±9mg/dl p=0.03). Light microscopy showed no overt glomerular or tubulinterstitial abnormalities of OZR kidney. Flow cytometry for total kidney myeloid and T cell subset numbers were similar for OZR vs LZR. However IHC revealed increased glomerular $CD68^+$ macrophages in OZR (3.3±0.3 vs 1.5±0.25 cells/glom p=0.002). At both 14 and 18 weeks, there was increased distal tubular STAT3 expression in OZR (4.4±0.07 vs 2.3±0.05 %area/HPF p=0.05) associated with clusters of $p\text{-}STAT3^+$ cells. SOCS3 was widely expressed in tubular epithelium of OZR and LZR while OZR glomeruli had increased staining for SOCS3 (73±0.05 vs 17±0.05 %+ve glom p=0.001). Active glomerular injury in OZR was confirmed by increased desmin expression (14±2 vs 9±1%area/glom p=0.03) which was higher in $SOCS3^+$ vs $SOCS3^-$ glomeruli (27±2 vs 18±2%area/glom p=0.02).

Conclusions: Overt cellular inflammation is absent in the OZR model of obestiy-related nephropathy to 18 weeks. OZR glomeruli have increased macrophages and desmin expression accompanied by increased SOCS3. Increased tubular STAT3/pSTAT3 is also accompanied by widespread tubular SOCS3 expression. SOCS3 counterregulation of STAT3-mediated inflammatory events may be critical for renal integrity in obesity/metabolic syndrome.

SA-PO472

Irbesartan Attenuates Inflammation in Diabetic Nephropathy through Modulation of TLR4/MyD88 Pathway Jinlei Lv, Hong-bo Xiao, Qinkai Chen. *Nephrology, The First Affilliated Hospital of NanChang University.*

Background: The pathogenesis of Diabetic nephropathy(DN) is not completely understood so far. Some researchers prefer that DN is an "innate immune disease", Toll-like receptor 4(TLR4) modulate immune responses and inflammatory diseases, but its role in DN remains to be under active consideration. The aims of this study were to reveal the possible role of TLR4 and its signal pathway in DN model and in vitro, and to explore the novel mechanisms of Irbesartan in the treatment of diabetic nephropathy.

Methods: In vivo, rats were randomly assigned to four groups, which are N(normal control group), M(DN model group), ARB(irbesartan treated group) and SiRNA group. Biochemical indicators were measured at the end of 8W. Morphological changes of renal tissue were observed by HE,Masson and PASM stain. RealTime-PCR were performed to investigate the mRNA expression of TLR4/MyD88, Immunofluorescence method was used to observe the protein expression of TLR4,MCP-1 and IL-1; In vitro, we use SiRNA transfection and Real-time Polymerase Chain Reaction(RT-PCR) technique to analyze TLR4 signal under high glucose condition, identifying the relationship between TLR4 signal and inflammation factor.

Results: In this study, we found upregulated expression of TLR4/MyD88 in the renal tubules and mesangial cell of diabetic nephropathy compared with expression of TLR4/MyD88 in normal kidney. The intensity of tubular TLR4/MyD88 expression correlated directly with interstitial macrophage infiltration as well as MCP-1,IL-1, and inversely with irbesartan treated group. In vitro, high glucose induced TLR4 /MyD88 expression in a dose-dependent manner, resulting in upregulation of MCP-1,IL-1 IL-6 expression in NRK-52E cell. Silencing of TLR4 with small interfering RNA attenuated high glucose-induced TLR4 /MyD88 activation, inhibited the downstream synthesis of MCP-1,IL-1. We observed similar effects using irbesartan.

Conclusions: These data suggest that TLR4/MyD88 pathway may promote tubulointerstitial inflammation in diabetic nephropathy, Irbesartan attenuates inflammation in DN through modulation of this pathway.

Funding: Government Support - Non-U.S.

SA-PO473

Impaired Glomerular Capillary Repair with Persistent Glomerular Inflammation in Streptozotocin Induced Diabetic Nephropathy Hideki Takano,[1,2] Taiko Yoshida,[1,2] Yukinari Masuda,[1] Akira Shimizu.[1] *[1]Department of Pathology, Nippon Medical School, Tokyo, Japan; [2]Division of Nephrology, Tokyo Teishin Hospital, Tokyo, Japan.*

Background: Microvascular injury is considered the essential precipitating factor in diabetes mellitus (DM) nephropathy, the mechanism of glomerular capillary repair after microvascular injury in DM nephropathy is still uncertain. We assessed the process of glomerular healing in streptozotocin (STZ)-induced DM rats, with particular focus on glomerular capillary regeneration and maturation.

Methods: DM was induced in rats by STZ (DM group). Three days later (day 0), glomerular capillary injuries were induced in both DM and non-DM groups by OX-7 antibody injection. Glomerular healing variables including glomerular capillary repair; changes in expression of vascular endothelial growth factor (VEGF), angiopoietin-1 (Ang-1) and angiopoietin-2 (Ang-2); and renal function were assessed until day 28.

Results: Following OX-7 antibody injection, both groups developed diffuse mesangial cell lysis on day 1, followed by segmental glomerular capillary destruction by days 3 to 7. In non-DM control rats, glomerular healing with mesangial cell proliferation by day 14. Glomerular capillary regeneration and maturation developed with increased expression of VEGF and Ang-1, most glomeruli recovered by day 28. In DM rats, in contrast, capillary regeneration ($P<0.01$) and endothelial cell proliferation ($P<0.05$) were rare in damaged glomeruli, which showed decreased expression of VEGF on days 7 (VEGF/actin ratio: non-DM 3.95±0.90 versus DM 1.28±0.21, $P<0.01$). DM rats also showed impaired glomerular capillary maturation, with decreased expression of Ang-1 and increased expression of Ang-2 (Ang-2/actin ratio: non-DM 1.20±0.78 versus DM 3.77±0.74, $P<0.01$). Mesangial proliferation and desmin+ glomerular epithelial damage remained on day 28, accompanied by glomerular infiltration of ED1+ macrophages.

Conclusions: Glomerular healing, especially glomerular capillary repair, was impaired after glomerular injury in STZ-induced DM rats. The development of DM nephropathy may be associated with not only glomerular injury but also subsequent impaired glomerular healing with the persistence of glomerular inflammation.

SA-PO474

The Prostaglandin E2 EP1 Receptor Promotes Glomerular and Tubular Dysfunction in OVE26 Diabetic Mice Jean-Francois Thibodeau,[1,2] Anthony Carter,[2] Chris R. Kennedy.[2] *[1]Cellular and Molecular Medicine, Univerisity of Ottawa, Ottawa, ON, Canada; [2]Kidney Research Center, Ottawa Hospital Research Institute, Ottawa, ON, Canada.*

Background: Cyclooxygenase (COX)-derived prostanglandin E2 (PGE2) synthesis and downstream EP receptor activation contributes to diabetic nephropathy (DN). COX inhibition lowers albuminuria and renal damage in human DN and experimental models. Given that pharmacological EP1 antagonism is beneficial in diabetic rats, we hypothesized that the Gq-coupled EP1 receptor promotes glomerular and/or tubular damage in DN.

Methods: Our prior studies revealed that gene-targeted EP1 knockout mice (EP1-/-), subjected to the low-dose streptozotocin (STZ) model of type 1 diabetes (T1DM), were significantly less albuminuric than wild-type (WT) mice at 16 weeks. Despite comparable glomerular damage, EP1-/- mice were protected from megalin downregulation, a marker of proximal tubule (PT) injury. We backcrossed EP1-/- mice onto the OVE26 transgenic model of T1DM (OVE26EP1-/-) and measured various functional and structural parameters.

Results: At 8 and 26 weeks, albuminuria was exacerbated in the OVE26 cohort compared to the OVE26EP1-/- mice (8 weeks: OVE26, 865±119 vs. OVE26EP1-/-, 508±66 μg/24 hrs, $p<0.001$; 26 weeks: OVE26, 2762±1067 vs. OVE26EP1-/-, 1022±395 μg/24 hrs, $p<0.05$) mirroring our STZ-study findings (WTstz, 1546±282 vs. WT, 525.8±110 μg/24 hrs, $p<0.001$). EP1 receptor deletion reduced the extent of glomerular hypertrophy (OVE26, 9447±396vs. OVE26EP1-/-, 7397±315 μm^2, $p<0.001$) as well as mesangial expansion (OVE26, 35.07±1.19vs. OVE26EP1-/-, 26.34±1.01% of glomerular area, $p<0.001$) while dramatically increasing survival rates. Semi-quantitative PCR revealed that OVE26EP1-/- mice were protected from DN-induced megalin downregulation, while nephrin mRNA decreased in both diabetic groups.

Conclusions: These results implicate the EP1 receptor in DN, downstream of the classic COX2/ PGE2 pathway. Our data are consistent with the idea that EP1 activation may exacerbate filtration barrier damage in DN by increasing podocyte and/or mesangial cell damage while promoting dysfunctional post-glomerular albumin processing via the PT's megalin/ cubilin complex.

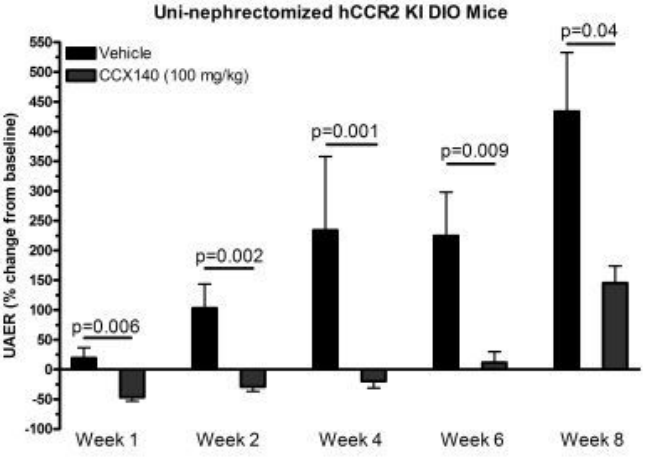
SA-PO475

The CCR2 Chemokine Receptor Antagonist CCX140 Improves Renal Function in Diabetic Mice Expressing Human CCR2 Tim Sullivan, Zhenhua Miao, Robert D. Berahovich, Jay P. Powers, Trageen Baumgart, Linda Ertl, Shichang Miao, Thomas J. Schall, Juan C. Jaen. *ChemoCentryx, Inc., Mountain View, CA.*

Background: Diabetic Nephropathy is a major consequence of uncontrolled diabetes. The chemokine receptor CCR2 has been implicated in the recruitment of blood monocytes into kidney in response to hypertension and hyperglycemia. In addition, parenchymal renal cells are thought to upregulate CCR2 under those pathological conditions. We set out to assess the therapeutic benefit of CCR2 antagonism in a mouse model of diabetic nephropathy utilizing CCX140, which is currently being studied in two Phase 2 diabetic nephropathy clinical studies.

Methods: Given the high selectivity of CCX140 for human CCR2, gene knock-in mice were generated which express human CCR2 in place of mouse CCR2 (hCCR2 KI). CCX140 was dosed daily to male human CCR2 knock-in (hCCR2) db/db mice (age 12-19 weeks) or to uni-nephrectomized human CCR2 knock in mice placed on a high fat/ high protein diet for 36 weeks (hCCR2 DIO). Assessments included body weight, fasting plasma glucose, serum clinical chemistry, and 24 hr urinary volume and output of albumin, creatinine and glucose.

Results: Treatment with CCX140 significantly reduced urinary albumin excretion (UAER) and albumin:creatinine ratio (ACR) in both hCCR2 db/db mice as well as uni-nephrectomized hCCR2 DIO mice. Statistically significant improvements in UAER and urinary ACR were noted as early as 5 days after initiation of CCX140 treatment. The benefits seen on renal function preceded significantly reduced fasting plasma glucose levels.



Conclusions: Robust and rapid improvements of albuminuria and hyperglycemia were seen following pharmacological intervention with the clinical molecule CCX140 in two rodent models of diabetic nephropathy. These results support the continued clinical evaluation of CCX140-B for the treatment of diabetic nephropathy.

An Oral Adsorbent AST-120 Decreased Proteinuria and Albuminuria in Metabolic Syndrome/Diabetes Rats Ryoko Tateoka, Yoshiharu Itoh, Fujio Sekine, Kaori Kikuchi, Hideyuki Yamato. *Kureha Corporation, Tokyo, Japan.*

Background: An oral sorbent AST-120 is clinically used in Japan for the treatment of chronic kidney disease(CKD) patients to slow the progression of CKD. There is little clinical evidence when AST-120 should be prescribed for subjects with early stage overt diabetic nephropathy. In this research, we examined the effect of AST-120 on the early stage of nephropathy using SHR/NDmc-cp, a rat model of metabolic syndrome/ type 2 diabetes. In addition, we applied the metabolomic analysis in the serum of normal and SHR/NDmc-cp rats with or without AST-120 by capillary electrophoresis mass spectrometry with time-of -flight(CE-TOFMS).

Methods: Male SHR/NDmc-cp(SHR/ND) rats, aged 7 weeks, were administered AST-120 with the chow containing 0%, 8% for 16 weeks. WKY rats were used as a normal. Every 4 weeks, serum and 24-hour urine samples were collected for biomedical studies. We analyzed the serum metabolites in normal and SHR/ND rats with or without AST-120 for 8 weeks by CE-TOFMS and applied CE-TOFMS data to principal component analysis(PCA).

Results: AST-120-administered SHR/ND rats showed significantly lower level of urinary albumin excretion and urinary protein excretion as compared with SHR/ND rats. PCA score plot showed clear separation among three groups(Normal, SHR/NDand AST-120-administered SHR/ND). Normal group and SHR/ND group could be distinguished by a line of PC1. SHR/ND group and AST-120-administered SHR/ND group could be distinguished by a line of PC2. The PC1 and PC2 were supposed to reflect the effect of disease and AST-120, respectively. In addition, we could detect 40 metabolites which accumulated in the serum of SHR/ND rats, and their serum levels were reduced by administration of AST-120. In these metabolites, o-hydroxybenzoic acid, hippuric acid and indole-3-acetic acid had the highest loading on PC2.

Conclusions: AST-120 decreased proteinuria and albuminuria in SHR/ND rats. It indicated that the administration of AST-120 at an early stage has a protective effect on the progression of diabetic nephropathy. We could detect 40 metabolites of which serum levels were increased in SHR/ND rats as compared with normal rats, and were reduced by administration of AST-120.

SA-PO477

The Role of Adenosine Generation and Signaling in Diabetic Nephropathy Douglas Ridyard, Eunyoung Tak, Almut Grenz. *Anesthesiology, UC Denver, Denver, CO.*

Background: DN is the leading cause of end-stage renal failure in developed countries. Only limited therapeutic approaches are available, including dialysis or kidney transplantation. Therefore, novel therapeutic approaches to prevent or at least treat DN are presently an area of intense investigation. Adenosine represents an endogenous signaling molecule to balance inflammatory reactions under different pathophysiological conditions. Extracellular adenosine is derived mainly via phosphohydrolysis of adenosine 5'-monophosphate (AMP) by the ecto-5'-nucleotidase (CD73). Once generated into the extracellular space, adenosine can activate four individual adenosine receptors (A1AR, A2AAR, A2BAR and A3AR). At present, the role of adenosine generation and signaling in DN is unknown.

Methods: At 8 weeks of age, mice received daily streptozotocin injections intraperitoneally (50 mg/kg, made fresh in 0.1 M citrate buffer, pH 4.5) for 5 consecutive days. Vehicle-injected mice served as controls. The fasting level of blood glucose was examined weekly with a B-Glucose Analyzer. The mice were considered diabetic if the blood glucose concentration (BGC) was above 500 mg/dl.

Results: Sixteen weeks after induction of STZ-induced diabetes histological evaluation by PAS staining showed significantly more glomerular sclerosis in CD73-/- compared to WT controls. Furthermore we could show a selective induction of the renal A2B adenosine receptor transcript and protein 16 weeks following STZ-induced diabetes. Treatment with an A2BAR agonist (BAY60-6583) via Alzet pumps in wild type STZ-induced mice ameliorated the severity of apoptosis thereby indicating a protective role of extracellular adenosine by stimulating the A2BAR. Interestingly we could show an increase of the A2BAR in renal vessels during STZ-induced diabetes mellitus in an A2BAR reporter mouse by utilizing XGal staining.

Conclusions: In summary we show that adenosine generation by CD73 and stimulation of the endothelial A2BAR ameliorates renal damage occurring during diabetic nephropathy. We hope these studies will lay the groundwork for novel and specific therapeutic approaches in the treatment of DN, which are urgently needed for improving the outcome of Type 1 diabetic patients.

High Glucose Mediates Endothelial-to-Chrondrocyte Transition in Human Aortic Endothelial Cells Rining Tang, Min Wu, Hong Liu, Xiaoliang Zhang, Bi-Cheng Liu. *Institute of Nephrology, Zhong Da Hospital, Southeast University, Nanjing, Jiangsu, China.*

Background: Vascular calcification is the common complications in diabetes mellitus. Many studies showed high glucose (HG) could cause cardiovascular calcification, but its underlying mechanism is not understood. Recent studies showed that conversion of endothelial-to-mesenchymal transition (EndMT) into mesenchymal stem cells (MSCs) could be triggered into chondrocytes. Our previous research indicated that HG induced EndMT in human aortic endothelial cells (HAECs).In this study, we firstly addressed the questions of whether HG-induced endothelial mesenchymal transition (EndMT) could be transitioned into chondrocytes and be involved in vascular calcification.

Methods: HAECs were divided into three groups: a normal glucose (NG) group, HG group (30mmol/L), and mannitol (5.5 mM NG + 24.5 mM) group. Immunofluorescence staining was performed to detect the co-expression of CD31 and fibroblast markers, such as fibroblast-specific protein 1 (FSP1). The expressions of FSP1 and α-SMA were detected by PCR and Western blot. Endothelial-derived MSCs were grown in MSC medium for one week. The expressions of MSCs marker STRO-1, CD44 and chondrocyte marker SOX9 were detected by immunofluorescence staining and Western blot. Chondrocyte expression was detected by alcian blue staining.

Results: The incubation of HAECs exposure to HG resulted in a fibroblast-like phenotype, wherein increased microfilamentation and a roughened endoplasmic reticulum structure were observed in the cytoplasm. Double staining of the HAECs indicated a co-localization of CD31 and FSP1. The expressions of FSP1 and α-SMA were significantly increased in the HG group and the undergoing EndMT cells also showed expression of the STRO-1, CD44 and SOX9 comparing to controls($P<0.05$). And alcian blue staining in HG group was positive comparing to NG group. Specifically, we showed that HG-induced EndMT is accompanied by activation of the canonical snail pathway.

Conclusions: Our study demonstrated that HG could induce endothelial cell transdifferentiation into chondrocyte-like cells via EndMT, which is mediated in part by activation of the snail signaling pathway.

Hepatocyte Growth Factor Switch the Balance M1/M2 Inducing Renal Repair in a Mouse Model of Diabetic Nephropathy Maria Flaquer,[1] Marcella Franquesa,[1] August Vidal,[2] Nuria Bolanos,[1] Joan Torras,[1] J. Grinyo,[1] Josep M. Cruzado.[1] *[1]Experimental Nephrology, IDIBELL, Hospitalet de Llobregat, Barcelona, Spain; [2]Pathology Service, Hospital Universitari de Bellvitge, Hospitalet de Llobregat, Barcelona, Spain.*

Background: Experimental studies have demonstrated the involvement of two different subtypes of macrophages (MØ) in kidney disease. M1 is classically activated by pro-inflammatory cytokines and can induce renal fibrosis. On the other hand, M2, induced by anti-inflammatory cytokines, has been associated with kidney repair and regeneration. The aim of our study was to evaluate whether an HGF-induced anti-inflammatory environment influences the presence of MØ subtypes and tissue regeneration in a mouse model of diabetic nephropathy.

Methods: Db/db mice received bone marrow transplantation (BMT) from C57BL/6J–EGFP+ transgenic donor mice and were divided in different groups (n=10-12/group):db/db–BMT (diabetic animals with BMT);db/db+HGF (diabetic animals with BMT and HGF treatment);db/db-G-CSF (diabetic animals with BMT and G-CSF treatment);db/db+HGF+G-CSF (diabetic animals with BMT,HGF and G-CSF treatment). We used db/-(non-diabetic animals) and db/db (diabetic animals) as age-matched control groups.After a follow-up of 4 weeks,renal samples were collected for MØ, M1, M2 and Bowman's Capsule parietal epithelial cells(PECs) histological analysis. Blood samples were also collected and pro-inflammatory and anti-inflammatory serum cytokine expression was analyzed by cytometric bead array.

Results: HGF reduced pro-inflammatory cytokines (IFNγ, TNFα, IL-6) and enhanced anti-inflammatory cytokines (IL-4, IL-10) in peripheral blood. After HGF treatment, we found MØ mainly around glomeruli and some in the interstitial area. Nearly all of the MØ expressed $EGFP^+$, which means that these cells derived from bone marrow. Moreover, M2 periglomerular MØ were enhanced by HGF. There was also a small number of $EGFP^+$ PECs in HGF-treated groups, suggesting MØ-PECs cell fusion. Altogether, HGF was associated with glomerulosclerosis reduction and podocyte preservation.

Conclusions: HGF induces an anti-inflammatory environment that promotes M2 MØ differentiation which may participate in renal repair in diabetic nephropathy.

Association between Major Depression and Chronic Kidney Disease in an Outpatient Diabetic Population Margaret K. Yu,[1] Bessie A. Young.[1,2] *[1]Nephrology, University of Washington, Seattle, WA; [2]Nephrology, VA Puget Sound Healthcare System, Seattle, WA.*

Background: Depression is an independent predictor of mortality in end-stage renal disease. Little is known about the impact of depression in a general primary care population with diabetes and chronic kidney disease (CKD) who are not yet on dialysis. The objective of this study is to evaluate the association between major depression and CKD in an outpatient diabetic cohort.

Methods: The Pathways Study is a prospective cohort of ambulatory, diabetic patients from a large managed care population in Seattle, WA. Estimated glomerular filtration rate (eGFR) was calculated using CKD-EPI equations. CKD was defined as an eGFR <60 ml/min/1.73 m^2 or microalbuminuria (urine albumin/creatinine >30 mg/g). Patients with Patient Health Questionnaire (PHQ-9) scores ≥10 including either depressed mood or loss of interest were considered to have major depression. Logistic regression was used to determine the association between major depression and CKD, adjusting for age, gender, race, marital status, education, hemoglobin A1c, smoking, and body mass index ≥30 kg/m^2.

Results: 546 of the 4,757 total subjects met criteria for major depression (11.5%). Subjects with major depression tended to be younger, were more likely to be female, and less likely to be married compared to subjects without depression. Major depression was associated with smoking, higher hemoglobin A1c, diabetes complications, and obesity. Patients with CKD had a higher prevalence of major depression than patients without CKD (12.9% vs. 10.5%, p=0.03). Major depression was associated with 35% greater odds of

CKD (95% CI 1.06-1.71), which was primarily associated with microalbuminuria and not eGFR <60 ml/min/1.73 m^2 (microalbuminuria OR 1.48, 95% CI 1.19-1.84; eGFR <60 ml/min/1.73 m^2 OR 1.17, 95% CI 0.86-1.60).

Conclusions: The prevalence of major depression in patients with pre-dialysis CKD was 12.9% in this study. Major depression was associated with greater odds of CKD, which is primarily accounted for by the strong association between depression and microalbuminuria. Further investigations into the effect of depression on CKD progression in diabetes are warranted.

First Ever 24-Hour Central Blood Pressure in Patients with Type 1 Diabetes Simone Theilade,[1] Maria Lajer,[1] Christel Joergensen,[1] Frederik I. Persson,[1] Gudbjörg Andrésdóttir,[1] Henrik Reinhard,[1] Stine Nielsen,[1] Peter S. Lacy,[2] Bryan Williams,[2] Peter Rossing.[1,3] *[1]Steno Diabetes Center, Denmark; [2]Department of Cardiovascular Sciences, University of Leicester, United Kingdom; [3]Aarhus University, Aarhus, Denmark.*

Background: We investigated the association between 24-hour ambulatory central blood pressure and diabetes duration, albuminuria and complications in patients with type 1 diabetes (T1DM).

Methods: Cross-sectional study including 86 controls (C), 69 patients with short diabetes duration (<10 years), normoalbuminuria (<30mg/24-hour) and not receiving antihypertensive treatment (SN); 211 with longstanding diabetes (≥10 years) and normoalbuminuria (LN); 163 with microalbuminuria (30-300mg/24-hour) (Mi) and 186 with macroalbuminuria (>300mg/24-hour) (Ma). 24-hour central aortic systolic pressure (CASP) was measured with tonometry (Bpro, HealthStats, Singapore), previously validated according to ESH and AAMI. Central dipping (CD) was percentage decrease in BP from day- to night time (12pm-6am).

Results: For the groups (C, SN, LN, Mi, Ma): mean±SD age was 49±12; 39±13; 57±11; 58±13 and 55±10 years; diabetes duration: nil; 6±3; 38±11; 35±15 and 38±11 years; and eGFR; 96±16; 107±21; 90±20; 85±26; and 62±29 ml/min/1.73m^2; (p<0.001 for all). Mean 24-hour CASP was 114±17; 115±13; 121±13; 119±16 and 122±14mmHg; (p<0.001). CD was 10.0±5.9; 11.1±7.9; 8.7±6.1; 8.9±6.6 and 6.6±6.6%; (p<0.001). Following multivariate adjustment (age, gender, 24-hour mean arterial pressure, 24-hour heart rate, eGFR) 24-hour CASP increased and CD decreased with diabetes duration and albuminuria (p<0.001 and =0.013). Furthermore, 24-hour CASP was higher in patients with CVD, LVH, retinopathy and autonomic neuropathy (AN), and CD was lower in patients with CVD and AN, independent of covariates (p<0.05 for all).

Conclusions: 24-hour CASP measurements were feasible in T1DM. 24-hour CASP increased and CD decreased with diabetes duration and albuminuria. Furthermore, 24-hour CASP increase while CD decrease in presence of diabetic complications, independently of covariates.

SA-PO482

Arterial Stiffness Is Associated with Cardiovascular, Renal, Retinal and Autonomic Disease in Type 1 Diabetes Simone Theilade, Maria Lajer, Frederik I. Persson, Christel Joergensen, Peter Rossing. *Steno Diabetes Center, Denmark.*

Background: In patients with type 1 diabetes, we investigated the association between arterial stiffness and diabetic complications.

Methods: Cross-sectional study including 676 Caucasian patients with type 1 diabetes (349(55%) men, mean±SD age 54±13 years) and 51 non-diabetic controls (28(55%) men, age 47±13 years).

Aortic pulse wave velocity (PWV) was measured with SphygmoCor (AtCor Medical, Australia) on 635 patients and all 51 controls.

Results: PWV (mean±SD) in patients and controls were 10.4±3.4 and 7.6±1.9 m/s, respectively (p<0.001).

Following multivariate adjustment, PWV correlated with age, diabetes duration, urinary albumin excretion rate, heart rate and blood pressure (p<0.05 for all). ANCOVA was used for comparisons between groups, adjusted for gender, age, eGFR, heart rate, HbA_{1c} and 24-hour mean arterial pressure.

PWV in normo-, micro- and macroalbuminuric patients was 9.5±3.2; 11.0±3.6 and 11.4±3.0 m/s, respectively (adjusted p<0.001). PWV in patients with *vs.* without previous cardiovascular disease was 12.1±3.5 *vs*. 10.0±3.2 m/s, respectively (adjusted p<0.001). PWV in patients with high (≥140/90 mmHg) *vs.* intermediate (130-40/80-89 mmHg) and low (<130/80 mmHg) blood pressure was; 11.8±3.6; 10.0±3.0 and 9.8±3.3 m/s, respectively (adjusted p<0.001). Furthermore, PWV increased with increasing degree of retinopathy 8.0±2.5 (nil); 10.0±2.8 (simplex); 12.1±3.5 (proliferative) and 12.7±2.4 (blind) m/s, respectively (adjusted p<0.001). Finally, PWV increased with abnormal heart rate variability 11.5±3.3 *vs.* 10.1±3.1 (borderline) and 8.1±2.1 (normal) m/s, (adjusted p=0.027).

Conclusions: Arterial stiffness increased with presence and duration of type 1 diabetes. Furthermore, PWV increased with all the investigated diabetic complications (cardiovascular, renal, retinal and autonomic disease) independently of other risk factors.

SA-PO483

Ultrasonographic Resistive Index Could Noninvasively Predict Renal Outcome in the Patients with Diabetic Nephropathy Koji Harada,[1] Kouichi Sumida,[1] Hiroshi Shintani,[1] Yukinari Yamaguchi,[1] Yasuhiro Akai.[2] *[1]Department of Nephrology, Rakuwakai-Otowa Hospital, Kyoto, Japan; [2]Center for Postgraduate Training, Nara Medical University, Kashihara, Nara, Japan.*

Background: Performing renal biopsy in the patients with diabetic nephropathy (DMN) is important because it could demonstrate the tubulointerstitial and vascular damages, which are pivotal markers for the renal and overall outcome, as well as definite histological diagnosis. But performing renal biopsy is not feasible for all the patients with DMN. Ultrasonographic marker of resistive index (RI) is reported be useful in noninvasively detecting renal histological damages. We conducted this study to evaluate the significance of RI in detecting tubulointerstitial and vascular injuries in diabetic patients with proteinuria/renal impairment using renal biopsy as a standard.

Methods: Forty-five patients with type 2 diabetes mellitus (DM) and proteinuria/renal impairment were enrolled in this study. Renal biopsy was performed for all the patients in order to obtaining definite renal diagnosis.

Results: Renal biopsy revealed that 32 patients (71.1%) had diabetic lesions and were diagnosed as DMN. Patients with DMN had severer tubulointerstitial (p=0.0281) and vascular (p=0.0003) injuries than those without histological diabetic changes. To evaluate the significance of RI, we examined the correlation between histological severity index of tubulointerstital and/or vascular damages and RI. The severity of vascular damage was significantly correlated with RI (Spearman rank correlation [r_s] = 0.322; p = 0.0325), irrespective of diabetic renal changes. Notably, RI was significantly correlated with the severity index of tubulointerstitial (r_s = 0.388; p = 0.0308) and vascular (r_s= 0.525; p = 0.0035) injuries in the patients with DMN.

Conclusions: RI could reflect the tubulointerstitial and vascular damages and could serve as a useful index to determine the renal and overall prognosis in the patients with DMN.

SA-PO484

Albuminuria and Arterial Stiffness in Type 2 Diabetics with Well-Preserved Renal Function Lee Ying Yeoh, Xiaowei Ng, Su-chi Lim. *Medicine, Khoo Teck Puat Hospital, Singapore.*

Background: Objective of this study is to determine if various cardiovascular risk factors and measures of arterial stiffness were associated with the degree of albuminuria in type 2 diabetes patients (T2DM) with preserved renal function.

Methods: This is a cross-sectional study which recruited T2DM clinic patients from July 2011 to April 2012. Pulse wave velocity (PWV) was measured by applanation tonometry (SphymoCor®) to estimate aorto-iliac arterial compliance. Albuminuria was quantified using spot urine albumin creatinine ratio. The patients were stratified into 3 groups based on albuminuria: normo-albuminuria (< 30ug/mg), micro-albuminuria (30-300 ug/mg) and macro-albuminuria (>300ug/mg). Univariate analysis using ANOVA and multivariate using linear regression model were performed.

Results: There were 635 T2DM patients, 50.2% male, 51.7% Chinese, mean age was 56.7 ±11.5 years and mean GFR (MDRD equation) was 92.9 ± 37.0 ml/min/1.73m^2. Higher pulse pressures (PP), $HbA1_C$, total cholesterol, triglyceride, PWV and augmentation index were associated with increasing albuminuria.

	Normo-albuminuria (N=332) 10.3 ± 8.3ug/mg	Micro-albuminuria (N=113) 98.0 ± 72.1ug/mg	Macro-albuminuria (N=102) 1364 ± 1190 ug/mg	p (ANOVA)
PP (mmHg)	56.7 ± 14.2	59.3 ± 15.2	74.0 ±18.0	< 0.001
HbA1c (%)	7.7 ± 1.3	8.0 ± 1.3	8.1 ± 1.3	0.002
Total cholesterol (mmol/l)	4.41 ± 0.91	4.42 ± 0.84	4.85 ± 1.15	< 0.001
Triglyceride (mmol/l)	1.48 ± 0.68	1.76 ± 1.31	2.16 ± 2.15	< 0.001
PWV (m/s)	9.27 ± 2.63	10.00 ± 2.64	12.59 ± 14.14	< 0.001
Augmentation index	24.07 ± 26.51	26.17 ± 29.11	26.76 ± 31.47	0.003

PP, PWV, total cholesterol and triglyceride remained significantly associated with albuminuria using multivariate analysis (p< 0.05). For each 1 mmHg increase in PP and each 1m/s increase in PWV, there was a 10.5 ug/mg (95%CI: 2.5-18.6) and 10.7ug/mg (95%CI: 7.5-13.9) increase in albuminuria respectively.

Conclusions: In T2DM patients with normal renal function, measures of arterial stiffness such as PP and PWV, as well as more the traditional risk factor cholesterol, were significantly associated with the amount of albuminuria. Vascular effects on albuminuria seem to precede the decline in GFR.

SA-PO485

Adipokines: The Cinderella of Cardiovascular Risk in Type 2 Diabetic Patients with Nephropathy Ana Paula Silva, André Fragoso, Anabela Malho, Cláudia Silva, Nélio Santos, Marilia Faisca, Pedro Neves. *Nefrologia, Hospital de Faro, Portugal.*

Background: Epidemiologic studies have demonstrated that the carotid intima media thickness (CIMT) is a strong, independent predictor of cardiovascular events in both the general population and among those with renal disease.

Recently, it was also showed that several adipokines, oxidative stress, inflammation and abnormalities of mineral metabolism are associated with arterial media calcification. The purpose of this study was to determine the relationship between these new risk factors with the carotid intima-media complex thickness.

Methods: In this cross- sectional study we included 78 type 2 diabetic patients (f = 30, m = 48), with a mean age of 61 years and a mean estimated glomerular filtration rate (MDRD) of 43.5 ml / min, followed in our outpatient nephrology clinic. The right and left common carotids and internal carotids were measured using high-resolution-B-mode ultrasonography.

We analyzed several laboratory parameters, such as: interleukin 6 (IL6), adipokines (visfatin, resistin, adiponectin (APN), oxidative stress (oxLDL), mineral metabolism (PTH, phosphorus, FGF-23, 25 (OH)D3), renal function as well as the carotid intima media thickness.

Results: In a simple linear regression model the CIMT was positively correlated with, age (r=0.113 p=0.006), phosphorus (r=0.592 p=0.0001), PTH (r=0.601 p=0.0001), FGF-23 (r=0.663 p=0.0001), IL6 (r=0.763 p=0.0001), oxLDL (r=0.819 p=0.0001), resistin (r=0.944 p=0.0001), visfatin (r = 0.912 p=0.0001), and inversely with eGFR (r= - 0.388 p=0.0001), APN (r= - 0.842 p=0.0001), 25 (OH) D3 (r= - 0.907 p=0.0001).

In a multiple regression model, resistin (r=0.415 p=0.0001), visfatin (r=0.200 p=0.0015), 25 (OH)D3 (r= - 0.206 p=0.006) and APN (r= - 0.162 p= 0.003), independently influenced the CIMT (R^2 =0.890 p=0.0001).

Conclusions: In our study we found that vitamin D and adipokines are new biomarkers preditors of the carotid intima media thickness in type 2 diabetic with mild to moderate kidney disease.

Even in the early stages of diabetic nephropathy, several are the factors associated with CIMT, such as inflammation, oxidative stress, adipokines and the mineral metabolism.

Funding: NIDDK Support

SA-PO486

Risk Factors of Subclinical Atherosclerosis in Type 2 Diabetic Patients with Nephropathy André Fragoso, Ana Pinho, Anabela Malho, Cláudia Silva, Nélio Santos, Ana Paula Silva, Pedro Neves. *Nephrology Department, Hospital de Faro, Faro, Portugal.*

Background: Carotid Intima-Media Thickness (CIMT) is an early marker of atheromatous disease and a strong predictor of cardiovascular (CV) events. Recently, the disturbances of the mineral metabolism and oxidative stress were also related to CV disease, even in the early stages of CKD. The purpose of this study was to determine the relationship between these new risk factors with the CIMT.

Methods: In a cross-sectional study, we included 78 type 2 diabetic patients (61.5% males) with CKD stages 3 and 4. The mean age was 66 years and the mean eGFR was 43,53ml/min. We analyzed mineral metabolism (PTH, 25(OH)D3, FGF23, phosphorus, calcium), inflammation (IL-6), oxidative stress (oxLDL) and lipid profile. We measured the CIMT using the high-resolution B-mode ultrasonography and our population was divided in two groups according to that parameter: G-1(CMIT<0,9mm n=42) and G-2 (CMIT≥0,9mm n=36). In the analysis we used for comparison between groups the Student's t-test. To evaluate the factors that influenced the CIMT we used a multiple regression model and the receiver operating characteristic (ROC) curve analysis.

Results: We found that G-2 patients showed higher FGF23 (327,59 vs 58,07ng/ml p=0,0001), PTH (204,84 vs 77,56 µg/ml p=0,0001), Phosphorus (5,08 vs 3,66mg/dl p=0,0001), oxLDL (65,01 vs 38,05mg/dl p=0,0001), IL6 (9,19 vs 3,42pg/ml p=0,0001) and lower 25(OH)D3 (11,56 vs 26,21ng/ml p=0,0001) and eGFR (33,43 vs 52,19ml/min p=0,0001). In a multiple regression model, IL6 (r=0.288 p=0.003), PTH (r=0.289 p=0.004), 25(OH)D3 (r=-0.294 p=0.018) and oxLDL (r=0.294 p=0.001) independently influenced the CIMT (R^2=0.856). ROC curve analysis showed that PTH (AUC=0,915; p=0.0001), IL6 (AUC=0,942; p=0.0001) and oxLDL (AUC=0,984; p=0.000) are predictors of CIMT (cut-off=0.9mm).

Conclusions: Our results confirm that the pathophysiology of atherosclerosis is complex. Even in the early stages of diabetic nephropathy, several are the factors associated with CIMT, such as inflammation, oxidative stress and the mineral metabolism. Further studies are needed to validate the clinical significance role of these new markers in the pathogenesis of atherosclerosis.

SA-PO487

Insulino Resistance, Inflammation and Vitamin D: New Predictors of Left Ventricular Hypertrophy André Fragoso, Ana Pinho, Anabela Malho, Nelson Almeida Tavares, Marilia Faisca, Ana Paula Silva, Pedro Neves. *Nephrology Department, Hospital de Faro, Faro, Portugal.*

Background: Left ventricular hypertrophy (LVH) is an independent predictor of cardiovascular disease in type2 diabetics with CKD. Although the etiologies for altered myocardial structure and function in CKD are multiple, there is a bulk of evidence suggesting that disturbances of mineral metabolism, inflammation, oxidative stress and insulin resistance may play important roles. The aim of this study was to evaluate how these new players are related to LVH.

Methods: In this cross-sectional study, we included 92 type2 diabetic patients (m=54), with a mean age of 62years and a mean eGRF of 42ml/min. At baseline, several laboratory parameters were analyzed: insulin resistance (HOMA-IR), inflammation (IL-6), mineral metabolism (phosphorus(P), calcium, PTH, vitaminD, FGF23), oxidative stress (oxLDL), adiponectin and albumin-creatinine ratio. We evaluated the mean arterial pressure (MAP) and the left ventricular mass index (LVMI) was calculated. Our population was divided in two groups: G-I (n=44) without LVH and G-II (n= 48) with LVH stratified according to gender. For comparison between groups we used the Student's t-test and a multiple regression model was used to determine predictors of risk for LVH.

Results: We found that G-II was older (65*vs*59 p=0.0001) and showed higher levels of P (5.1 *vs* 3.7mg/dL p=0.0001), PTH (212.5 *vs* 77.08mg/dL p=0.0001), FGF23 (306.1 *vs* 62.9 Ru/mL p=0.0001), IL6 (8.7 *vs* 3.1pg/mL p=0.0001), oxLDL (59.3 *vs* 28.1U/L p=0.0001), HOMA-IR (3.5 *vs* 0.69 p=0.0001), albumin-creatinine ratio (265.5 *vs* 119.9 p=0.0001) and MAP (96.0 *vs* 90.4mmHg p=0.032); G-II also showed lower levels of 25(OH)D3 (12.4 *vs* 25.9 ng/mL p=0.0001) and adiponectin (12.8 *vs* 43.6 p=0.0001). In the multiple regression model we found that HOMA-IR (r=0.280 p=0.009), IL6 (r=0.208 p=0.0 44) and 25(OH)D3 (r=-0.263 p=0.020) independently influenced the LVMI (R^2=0.870 p=0.0001).

Conclusions: In our study inflammation, insulin resistance and insufficiency/deficiency of vitaminD are independent predictors of LVH. Further prospective studies are required to clarify if the control of these players is associated with the regression of the LVH in CKD.

SA-PO488

Insulin Resistance: Marker or Mediator of Increased Cardiovascular Risk in Diabetic Nephropathy? André Fragoso, Ana Pinho, Anabela Malho, Nelson Almeida Tavares, Marilia Faisca, Ana Paula Silva, Pedro Neves. *Nephrology Department, Hospital de Faro, Faro, Portugal.*

Background: Cardiovascular disease is the main risk factor of morbidity and mortality in Chronic Kidney Disease (CKD) patients and its relevance increases when diabetes is the etiology of the renal disease. Insulin resistance is associated with the progression of atherosclerosis and has been reported to be a strong risk factor for cardiovascular disease. The purpose of this study was to examine the usefulness of insulin resistance as a predictor of cardiovascular mortality.

Methods: We followed during a period of 56 months 119 type 2 diabetic patients in stage 3 and 4 of CKD without history of cardiovascular disease at the beginning of the study. Several laboratory parameters were analyzed: hemoglobin, albumin, estimated glomerular filtration rate (MDRD), mineral metabolism, markers of inflammation (interleukin-6), insulin resistance (HOMA-IR) and the left ventricular mass index (LVMI). According with the presence or absence of cardiovascular mortality our population was divided in two groups: G-1 with cardiovascular mortality (n=48) and G-2: survivors (n=71).

Results: We found that G-1 patients showed higher age (67,08 vs 59,85 years, p=0,002), iPTH (204,41 vs 83,78pg/ml, p= 0,0001), phosphorus (4,92 vs 3,92mg/dl, p= 0,0001), Interleukin-6 (8,27 vs 2,83pg/ml, p= 0,0001), HOMA-IR (3,79 vs 0,77, p= 0,0001), LVMI (130,08 vs 93,52g/m, p= 0,0001) and lower Hg (12.32 vs 12,99g/dl, p=0,047), Albumin (4,05 vs 4,30g/dl, p=0,016), eGFR (33,66 vs 52,45ml/min, p=0,0001). In multivariate Cox proportional hazard stepwise LR to identify independent risk factors of cardiovascular mortality iPTH, HOMA-IR and LVMI were found to predict patient survival, (HR= 0.4, 95% CI, 0.1 to 0.6, p=0.015), (HR= 38, 95% CI, 8.7 to 75.3, p=0.008) and (HR=4.7, 95% CI, 2.4 to 7, p=0.0001), respectively.

Conclusions: In our study, insulin resistance is an important risk factor for cardiovascular mortality in diabetic patients in stage 3 and 4 of chronic kidney disease. Further studies are needed to better understand the mechanisms that link insulin resistance to cardiovascular morbidity e mortality.

Metabolic Renal Imaging Using Proton Magnetic Resonance Spectroscopy (1H-MRS) In-Vivo Aiko P.J. De Vries,[1] Sebastiaan Hammer,[2] Ton J. Rabelink,[1] Hildo Lamb.[2] *[1]Nephrology; [2]Radiology, Leiden University Medical Center, Netherlands.*

Background: Lipid accumulation in kidney (*Fatty Kidney*) is a putative biomarker for obesity-associated renal disease. Clinical research is hampered, however, by the lack of a non-invasive method to assess Fatty Kidney. We aimed to develop a protocol for quantification of renal triglyceride (TG) content by 1H-MRS in-vivo, and test feasibility, reproducibility, and necessity of respiratory motion compensation.

Methods: Measurements were performed on a 1.5T MR scanner (Philips, Netherlands) using a 10cm surface coil. Spectral quality was quantified as the 'Full Width at half Maximum' (FWHM) of the unsuppressed water signal. Cortical TG content of left kidney was measured using single voxel 1H-MRS in 15 healthy young subjects. Water suppressed & unsuppressed spectra with(out)compensation for respiratory motion using navigator echoes were collected. Subjects were removed and repositioned to determine reproducibility. Spectra were fitted using dedicated software. TG content at 1.3 ppm was expressed as a percentage of the water signal.

Results: Spectral quality without compensation was 10.8±0.4 Hz (mean±SE) and improved to 10.2±0.4 Hz with use of respiratory motion compensation (P<0.05). **Mean TG content with use of compensation was 0.34±0.05%, and 0.31±0.05% after repositioning (P>0.05).** Mean TG content without respiratory motion compensation was 0.42±0.08%, and 0.36±0.05% after repositioning, P>0.05 compared to navigator measurements (4 spectra without motion compensation could be no be fitted due to insufficient quality). Use of respiratory motion compensation showed more narrow limits of agreement in Bland-Altman analyses.

Conclusions: In-vivo assessment of *Fatty Kidney* by 1H-MRS is feasible to non-invasively study its role as a biomarker for obesity-related renal disease. Respiratory motion compensation improves spectral quality and reproducibility.

Early Renal Function Decline in Non-Proteinuric Patients with Type 1 Diabetes Estimated by Serial Measurements of Serum Cystain C and Creatinine Jan Skupien,[1] Monika A. Niewczas,[1] Adam Smiles,[1] Rita R. Holak,[1] Kevin Patrick Mcdonnell,[1] John H. Eckfeldt,[2] James Warram,[1] Andrzej S. Krolewski.[1] *[1]Section on Genetics and Epidemiology, Joslin Diabetes Center, Boston, MA; [2]Department of Laboratory Medicine and Pathology, University of Minnesota, Minneapolis, MN.*

Background: Renal function decline can be observed when patients have normo- or microalbuminuria. We compared renal function decline estimated using cystatin C or creatinine.

Methods: We followed 230 patients with normoalbuminuria and 325 with microalbuminuria for median 6.4 years with annual determinations of serum cystatin C and creatinine. We estimated rates of renal function decline (linear decline expressed as annual percent change) from glomerular filtration rate (eGFR) calculated with Stevens (cystatin C) and CKD-EPI (creatinine) formulas. To assess effects of clinical predictors on slopes we used mixed effects models.

Results: Median renal function decline of creatinine-eGFR was 1.25% per year and 2.25% per year of cystatin C-eGFR. Using a threshold 3.3% decline per year, 22% of patients were decliners with creatinine slopes and 38% with cystatin C slopes. There was also only moderate rank correlation between the two slopes, 0.47. A linear mixed effects model in which both creatinine and cystatin C eGFR decline were modeled simultaneously eliminated within-patient inconsistency of rates of decline. Cystatin C-based eGFR decline was, however, systematically steeper than the creatinine-based by 1.0% ($p<0.0001$). Impact of clinical predictors on two slopes is shown in Table. We compared mean rate of decline between 1st and 4th quartile of predictors.

Predictor	Creatinine Slope	Cystatin C Slope	P for difference between two slopes
ACR	2.4% (p<0.0001)	3.3% (p<0.0001)	0.015
HbA1c	2.4% (p<0.0001)	2.8% (p<0.0001)	0.22
TNFR1	2.0% (p=0.0006)	1.2% (p=0.044)	0.05

Conclusions: Renal function decline estimated from cystatin C eGFR is faster than estimated from creatinine eGFR by 1%. Using linear mixed effect model we can eliminate discrepancies in rates of decline that arise from random variation of creatinine and cystatin C measurements. Certain clinical predictors show stronger association with either cystatin C or creatinine-based decline.

SA-PO491

Poor Glycemic Control Is Significantly Associated with Overestimation of Glomerular Filtration Rate (GFR) Assessed by Estimated GFR (eGFR): An Inulin Clearance (C_{in}) Study in Patients with Chronic Kidney Disease (CKD) Akihiro Tsuda, Eiji Ishimura, Yoshiteru Ohno, Mitsuru Ichii, Shinya Nakatani, Shinsuke Yamada, Katsuhito Mori, Masaaki Inaba. *Osaka City University Graduate School of Medicine, Osaka, Japan.*

Background: Serum creatinine levels are lower in CKD patients with diabetes mellitus (DM) than in their non-DM counterparts, leading to possibly higher values of eGFR in the former than in the latter. The extent of and the factors associated with the higher evaluation of eGFR in predialysis DM-CKD patients is not well known. The aim of the present study is to explore the factors associated with the dissociation of eGFR and C_{in} in CKD patients.

Methods: Forty eight CKD patients (age 57.7±2.1 years; 25 males and 23 females; 31 DM and 17 non-DM) were enrolled. eGFR was calculated from serum creatinine and age (Matsuo, et al. Am J Kidney Dis 2008). C_{in} was measured with 90-min. continuous infusion technique of inulin (Horio, et al. Clin Exp Nephrol 2009). Creatinine clearance (C_{cr}) was estimated by the formula of Horio et al (Clin Exp Nephrol 1997). $eGFR/C_{in}$ ratio was assessed as the dissociation, and C_{cr}/C_{in} ratio was evaluated as a parameter of tubular secretion of creatinine.

Results: Between eGFR and C_{in}, DM-CKD showed a weaker correlation ($r=0.567$, $p=0.0007$) than non-DM-CKD ($r=0.936$, $p<0.0001$). $eGFR/C_{in}$ ratio was significantly higher in DM-CKD than in non-DM-CKD (1.169±0.368 vs. 0.943±0.040, $p<0.05$), indicating higher eGFR in the former. There were significant and positive correlations between $eGFR/C_{in}$ ratio and hemoglobin A1c (HbA1c) ($r = 0.471$, $p = 0.0006$) and serum glycated albumin (GA) ($r = 0.471$, $p = 0.0025$), indicating that dissociation of eGFR and C_{in} was associated with poor glycemic control. There were significant and positive correlations between C_{cr}/C_{in} ratio and HbA1c ($r=0.426$, $p=0.0023$) and GA ($r=0.469$, $p=0.0019$), suggesting increased tubular secretion of creatinine in patients with poor glycemic control.

Conclusions: eGFR overestimated GFR as glycemic control became poorer in predialysis CKD patients. It is suggested that a factor of overestimation of eGFR in CKD patients is increased tubular secretion of creatinine affected by poor glycemic control.

SA-PO492

Effect of Diabetic Cystopathy on Decline of Renal Function in Patients with Diabetes Mellitus Sun Ryoung Choi, Youngki Lee, Min-Gang Kim, Myung Jin Choi, Jwa-kyung Kim, Soo Jin Kim, Taejin Park, Young Rim Song, Sung Gyun Kim, Ja-Ryong Koo, Hyung Jik Kim, Jung-woo Noh. *Department of Internal Medicine, Hallym University College of Medicine, Seoul, Korea.*

Background: Diabetic cystopathy is one of autonomic complications in diabetes. The identification of bladder dysfunction is critical complication of this disease. Diabetic cystopathy is characterized with impaired sensation, decreased contractility, and impaired emptying, which result in overflow incontinence. Until now, the effect of diabetic cystopathy on the progression of diabetic nephropathy is unclear. Therefore, we performed this study to evaluate the effect of post-voiding residual urine volume (PVR) on the decline of glomerular filtration rate (GFR) in type 2 diabetic patients.

Methods: We enrolled type 2 diabetes patients who were treated for more than 1 year. Exclusion criteria were as follows; cerebrovascular disease, parkinson's disease, benign prostate hyperplasia, disc herniation, and urinary incontinence, which resulted in bladder symptoms. We measured PVR by urodynamic evaluation. A PVR of greater than 50mL was defined as abnormal PVR group. We evaluate whether PVR is the risk factor for the decline of GFR.

Results: 97 patients were enrolled. Male was 34(35%). The mean age was 63.0±10.6 years. The duration of diabetes was 12.7±8.2. The portion of patients with abnormal PVR was 35.1% (n=34). The GFR was significantly lower at baseline (50.6±27.1 vs 64.3±28.1 mL/min/1.73m2, P=0.02) and had a trend to more rapid decline over 1 year (7.0±13.3 vs 2.3±11.6 mL/min/1.73m2/y, P=0.07) in abnormal PVR group than in normal PVR group. However, PVR had no relationship between duration of diabetes, hemoglobin A1c, hypertension, and proteinuria. But, there was significant correlation between PVR and decline of GFR (r=0.31, P=0.002). In the multivariate analysis, PVR was independent risk factor for decline of GFR (P=0.02).

Conclusions: Diabetic cystopathy was independent risk factor of the decline of GFR. Therefore, the active diagnosis and treatment of diabetic cystopathy may help to ameliorate the progression of GFR in T2DM.

SA-PO493

Assessment of Glomerular Filtration Rate in Chinese Patients with Type 2 Diabetes Using a Radial Basis Function Neural Network Xun Liu,[1,2] Chenggang Shi,[1] Linsheng Lv,[3] Cailian Cheng,[1] Hua Tang,[1] Xiaoming Wu,[2] Tan-qi Lou.[1] *[1]Division of Nephrology, Department of Internal Medicine, The Third Affiliated Hospital of Sun Yet-sun University, Guangzhou, Guangdong, China; [2]College of Biology Engineering, South China University of Technology, Guangzhou, Guangdong, China; [3]Operating Room, The Third Affiliated Hospital of Sun Yet-sun University, Guangzhou, Guangdong, China.*

Background: In the previous study, a radial basis function (RBF) neural network had been established in a group of 327 chronic kidney disease (CKD) patients. In this study, we verified the accuracy of the RBF model in a group of Chinese type 2 diabetic patients.

Methods: 207 type 2 diabetic patients in the third affiliated hospital of Sun Yet-sun University, China, were enrolled. GFR was estimated by the RBF network, reexpressed 6-variable MDRD equation and reexpressed 4-variable MDRD equation.

Results: On the Bland–Altman plot, the precision of the RBF network was much less than those of the reexpressed MDRD equations. However the mean of difference and the median of difference showed that the eGFR of the RBF network more overestimated the sGFR. R-square from simple linear regression of eGFR vs. sGFR were 0.715, 0.714 and 0.689, and intra-correlation coefficients were 0.869, 0.880 and 0.895 for reexpressed 4-variable MDRD equation,reexpressed 4-variable MDRD equation and the RBF network, respectively. All agreements of the prediction models reach almost perfect. The ROC curve analysis showed that the maximum diagnostic accuracy of all the equations for the diagnosis of moderate renal failure was not statistically significant. The 30% accuracy of the RBF network was significantly higher compared with the other prediction models. The absolute differences of the RBF network was less than the other prediction models, and the 15% accuracy and 50% accuracy of the RBF network were higher than those of the other prediction models, but all without statistical significance.

Conclusions: The performances of this simple RBF network model is at lease not wore than the reexpressed MDRD equations. Especially in terms of accuracies and agreements, this RBF network performed better than the reexpressed MDRD equations.

Glycated Albumin (GA), Not Hemoglobin A1c (HbA1c), Predicts Cardiovascular Hospitalizations and Length of Stay (LOS) in Dialysis Patients with Diabetes Mariana Murea,[1] Gregory B. Russell,[2] Anthony J. Bleyer,[1] Barry I. Freedman.[1] *[1]Internal Medicine-Nephrology, Wake Forest School of Medicine, Winston-Salem, NC; [2]Pathology and Biostatistical Sciences, Wake Forest School of Medicine, Winston-Salem, NC.*

Background: Relative to glycated hemoglobin (HbA1c), glycated albumin (GA) more accurately predicts mortality and all-cause hospitalizations in diabetics on dialysis. We evaluate here relationships between GA, HbA1c, and casual plasma glucose (PG) with cause-specific hospitalization rates and length of stay (LOS).

Methods: Prevalent dialysis patients with type 1 (n=38) or type 2 (n=406) diabetes, mean±SD diabetes duration 18.5±10.8 years and dialysis vintage 2.9±2.6 years, were followed for 2.33 years. Monthly PG, quarterly GA, and random HbA1c were included. Hospitalization rates and LOS for cardiovascular (CV), infectious disease (ID), and vascular access (VA) complications occurring within 17days and 30 days of glycemic testing were evaluated. Best-fit, time-dependent Cox models with incremental adjustments were constructed. Fully adjusted model included age, sex, race, BMI, diabetes duration, dialysis vintage, Hb, albumin, and phosphorus.

Results: In the fully adjusted models, CV hospitalization rates were significantly associated with increasing GA (Hazard Ratio [HR] 1.32; 95%CI 1.11-1.57; P=0.002 at 17 days; HR 1.21; 95%CI 1.02-1.43; P=0.02 at 30 days) and PG (HR 1.10; 95%CI 1.02-1.17; P=0.01 at 17 days; HR 1.07; 95%CI 1.00-1.14; P=0.03 at 30 days), not with HbA1c (HR 1.24; 95%CI 0.89-1.73; P=0.21 at 17 days; HR 1.26; 95%CI 0.96-1.65; P=0.10 at 30 days). LOS for CV hospitalization positively associated with GA (HR 1.18; 95%CI 1.01-1.39; P=0.03), not PG (HR 1.04; 95%CI 0.99-1.10; P=0.15) or HbA1c (HR 1.03; 95%CI 0.92-1.15; P=0.21). ID and VA admission rates and their associated LOS did not correlate with these assays.

Conclusions: Improved glycemic control in dialysis based on GA predicted CV hospitalizations and CV-related LOS. HbA1c fails to predict any cause-specific hospitalization or LOS in dialysis. Prospective trials targeting various GA and fasting PG concentrations should be performed in patients with diabetes on dialysis to determine optimal glycemic targets to reduce CV morbidity.

SA-PO495

Relationship between HbA1c or Glycated Albumin and Circadian Blood Glucose Using Continuous Glucose Monitoring in Diabetic Patients Undergoing Hemodialysis Izumi Nyumura, Tetsuya Babazono, Michino Takagi, Naoshi Yoshida, Ko Hanai, Nobue Tanaka, Junnosuke Miura, Yasuko Uchigata. *Department of Medicine, Diabetes Center, Tokyo Women's Medical University School of Medicine, Tokyo, Japan.*

Background: Both glycated hemoglobin (A1C) and glycated albumin (GA) are routine markers of glycemic control in diabetic populations; however, the credibility may be undermined in uremic patients with anemia for A1C and in those with hypoalbuminemia for GA. Continuous glucose monitoring (CGM) can provide more information regarding circadian glycemic variability than intermittent self-monitoring of blood glucose. We conducted this study to compare efficacy of A1C and GA as a measure of circadian blood glucose using CGM in diabetic hemodialysis patients.

Methods: A total of 93 diabetic patients undergoing hemodialysis were studied. There were 35 type 1 and 58 type 2 diabetic patients, 44 women and 49 men, and the mean (± SD) age and duration of diabetes were 56 ± 13 years and 22±10 years, respectively. Among type 2 diabetic patients, 40 patients were treated with insulin. Interstitial glucose concentrations were monitored at least 48 hours including a 4-hour hemodialysis session. Mean glucose, standard deviation (SD) of glucose, coefficient of variation (CV) of glucose, duration of hyperglycemic time (≥ 10 mmol/l), and mean amplitude of glycemic excursions (MAGE) were calculated.

Results: The mean GA and HbA1c values were 6.4±1.3% and 22.8±7.0%, respectively. The levels of GA were significantly associated with the mean glucose (r=0.44, p<0.001), SD (r=0.53, p<0.001), CV (r=0.36, p<0.001), duration of hyperglycemia time(r=0.47, p<0.001) and MAGE (r=0.40, p<0.001). Similar association was observed between A1C and the mean glucose (r=0.28, p=0.008), SD (r=0.39, p<0.001), CV (r= 0.31, p=0.004), duration of hyperglycemia time(r=0.32, p=0.003) and MAGE (r=0.34, p=0.003); however, all these parameters were correlated more strongly with GA than HbA1c.

Conclusions: GA may more accurately reflect mean glycemic control and glycemic variability than A1C in diabetic patients undergoing dialysis.

SA-PO496

Developing a New Hemoglobin A1C Based Equation to Estimate Blood Glucose in Maintenance Dialysis Patients Junichi Hoshino,[1,2] Miklos Zsolt Molnar,[1,3] Kunihiro Yamagata,[4] Yoshifumi Ubara,[2] Kenmei Takaichi,[2] Csaba P. Kovesdy,[5] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center for Chronic Disease Research & Epidemiology, LA BioMed at Harbor-UCLA, Torrance, CA; [2]Nephrology Center, Toranomon Hospital, Tokyo, Japan; [3]Institute of Pathophysiology, Semmelweis University, Budapest, Hungary; [4]Department of Nephrology, University of Tsukuba, Ibaraki, Japan; [5]University of Tennessee, Memphis, MN.*

Background: Hemoglobin A1c (A1c) has been widely used as a clinically important assessment tool for outcome analyses related to glycemic control. However, because of special conditions in dialysis patients including the uremic milieu, there is no A1c-blood glucose (BG) equation formula specific for patients on dialysis.

Methods: We examined associations between A1c and random serum BG over time in a contemporary cohort of diabetic patients with dialysis treated in DaVita dialysis clinics. We identified 12,836 patients (63±12 years old and 50% male) with 74,330 paired measurements of A1c and BG over 5 years (2001-2006). Bootstrapping method was used to estimate average BG and corresponding A1c. The association was adjusted by patient factors using linear regression.

Results: Linear regression analyses yielded the following three regression equations, BG=52.2+29.2·A1c-18.7·Alb (model 1, R^2=0.480), BG=97.7+29.5·A1c-16.3·Alb-4.7·Hb (model 2, R^2=0.484), and BG=77.1+30.4·A1c-14.5·Alb-5.4·Hb+0.3·Age+Race (model 3, R^2=0.488). All our models showed stronger association than previous equation models (R^2=0.467 in the DCCT and ADAG equations).

Model	Formula	Adjusted R^2
DCCT	BG=35.6 HbA1c-77.3	0.467
ADAG	BG=28.7 HbA1c-46.7	0.467
Model 1 (+Alb)	BG=52.2+29.2 HbA1c-18.7 Alb	0.480
Model 2 (+Alb,Hb)	BG=97.7+29.5 HbA1c-16.3 Alb-4.7 Hb	0.484
Model 3 (complex)	BG=77.1+30.4 HbA1c-14.5 Alb-5.4 Hb+0.3 Age +Race	0.488

* Race: +0.0 if Caucasian, +2.1 if Asian, -11.5 if African American, -2.8 if Hispanic

Conclusions: The association between A1c and BG in dialysis patients is different from patients with normal kidney function. Our analysis suggests that equations including serum albumin and/or hemoglobin are better for dialysis patients.

SA-PO497

Diabetes Mellitus Increases Cancer Specific Mortality in Patients with Renal Cell Carcinoma: Role of OGG1 and Tuberin S. Simone,[1] M. Cariello,[1] Antonio Vavallo,[1] Monica Rutigliano,[1] E. Ranieri,[2] M. Battaglia,[1] P. Ditonno,[1] Francesco Paolo Schena,[1] Loreto Gesualdo,[1] Giuseppe Grandaliano,[2] G. Pertosa.[1] *[1]Dept. of Emergency and Organ Transplantation, Univ of Bari, Bari, Italy; [2]Dept. of Medical and Surgical Sciences, Univ of Foggia, Foggia, Italy.*

Background: Cancer has been recognized as one of the main cause of mortality in diabetes mellitus (DM) patients (pts). 8-oxoG-DNA glycosylase (OGG1) is a specific DNA repair enzyme and its deficiency may increase the risk of cancer. In an animal model of DM, hyperglycemia leads to phosphorylation/inactivation of tuberin and downregulation of OGG1 via a redox-dependent Akt pathway activation in renal tubular epithelial cells. Aims of the study were to investigate whether DM may influence the survival in pts with renal cell carcinoma (RCC) and to explore the hypothesis that the diabetic milieau may lead to increased tumor aggressiveness through tuberin inactivation and subsequent OGG1 downregulation.

Methods: We enrolled 462 pts treated with radical nephrectomy between 1979 and 2009 for unilateral sporadic RCC with (Group I, n=76) and without DM (Group II, n=386) with a median follow-up of 43 months.

Results: At the time of surgery, Group I showed a larger tumor size (p=.02), a higher % of necrosis (<.001) and metastases (<.001) compared with Group II. Multivariate analysis proved that independent predictors of death from RCC included DM, TNM stage grouping, tumor size and UISS stage system. Interestingly, DM was an independent predictor of progression-free survival in pts with RCC (HR 4.1; 95% CI; 2.6-6.4, p<.0001). A significant increase (p<.05) in tuberin and S6p70 (p=.04) phosphorylation and a downregulation of OGG1 protein expression (p=.002) was observed in renal tissue samples (13) from Group I compared to Group II (immunoblotting, immunohistochemical/immunofluorescence analysis). Both normal kidney and tumor tissue samples of DM pts showed a striking increase in nuclear 8-oxo-dG levels (immunofluorescence analysis), a marker of DNA oxidation.

Conclusions: DM may significantly reduce overall and cancer specific survival in pts with RCC and this observation might be at least partially explained by the reduced expression of OGG1.

SA-PO498

Diabetes and Risk of Renal Cell Carcinoma Samy L. Habib,[1,2] Deepika Sirohi,[3] Sherry L. Werner.[1,3] *[1]Geriatric Research, Education, and Clinical Center, South Texas Veterans Healthcare System, San Antonio, TX; [2]Cellular and Structural Biology, University of Texas Health Science Center, San Antonio, TX; [3]Pathology, University of Texas Health Science Center, San Antonio, TX.*

Background: Epidemiological evidence indicates that individuals with diabetes are at higher risk of cancer. Poor glycemic control in diabetic patients may play a role in increased cancer risk. We showed a strong association between diabetes and renal cell carcinoma in a cohort of kidney cancer patients. Whether renal cell cancer (RCC) and the nonneoplastic tissue morphology in diabetic and nondiabetic patients differ has not been evaluated.

Methods: A retrospective analysis of 78 patients who underwent nephrectomy for renal cell cancer was performed. Diabetic RCC and nondiabetic RCC patients were screened for age, gender, HgA1C and glucose levels. RCC subtypes were classified, Fuhrman nuclear grading was used and tumors were staged based on standard TNM system. Nonneoplastic tissue around the tumor of diabetic and nondiabetic RCC cases was assessed for morphology.

Results: Of the 78 cases with RCC, 26 (33.3%) had a history of diabetes. diabetes. Most of cases of RCC alone were male while cases of RCC+diabetes were female. There were more subjects between 50-59 years old (61.5%) in RCC+diabetes compared to subjects with RCC alone (52%). All RCC+diabetes cases showed clear cell type of RCC. In both groups, Furman nuclear grade of 2-3 predominated. The majority of RCC+diabetes showed tumor size 1-5cm (57.7%) and tumor size 5-10cm (30.1%). HgA1C values showed a negative correlation with tumor size in RCC+diabetes subjects. Importantly, tumors in nondiabetics were well-circumscribed tumors, whereas tumors in diabetics showed an infiltrative pattern. Nonneoplastic tissue in both groups showed mild to severe interstitial fibrosis and mild to severe vascular disease. Glomeruli in the diabetic patients were normal or showed basement membrane.

Conclusions: Our findings suggest that diabetes predisposes to RCC with an infiltrative pattern and that the degree of glomerular, interstitial and vascular disease was not significantly different in diabetic and nondiabetic patients.

A Dose-Response Study to Determine the Minimal Dose of Sevelamer Carbonate that Reduces Cardiovascular Disease Risk Factors in Type 2 Diabetic Hemodialysis Patients Gary E. Striker,[1] Elena M. Yubero-Serrano,[1] Helen Vlassara.[1] *[1]Geriatrics and Medicine, Mount Sinai School of Medicine, New York, NY; [2]Epidemiology, Johns Hopkins University, Baltimore, MD.*

Background: Morbidity and mortality in hemodialysis patients (HD) due to cardiovascular disease (CVD) is directly associated with elevated inflammation and reactive oxygen species (infl/ROS). Cytopathic advanced glycation endproducts (AGEs) increase infl/ROS in T2D, and restriction of food AGEs reduces them. Sevelamer carbonate (SC) binds AGEs in food, reducing AGEs and CVD risk factors in. Calcium carbonate reduced phosphorous levels, but does not affect infl/ROS or AGEs. Ouraim was to determine the relationship(s) between increasing dose(s) of SC and cytopathic AGEs (CML) and methylglyoxal derivatives (MG), lipids, and phosphorus in T2D HD patients.

Methods: We studied serum samples from T2D HD hyperphosphatemic patients enrolled in a randomized, double-blind, placebo-controlled, dose-ranging study. After a 2 week washout of all phosphate binders patients were given a daily dose of 2.4, 4.8 or 7.2 grams of SC with meals for 3 weeks. Cytopathic AGEs, lipids, ROS and inflammation were measured as previously reported.

Results:

Serum AGEs

	Baseline	Placebo	Sevelamer (2.4 gm/d)	Sevelamer (4.8 gm/d)	Sevelamer (7.2 gm/d)
#		74	16	23	19
CML (U/ml)	30.1±14.5	30.1±9.3	30.7±7.7	22.8±8.1	22.9±8.9
p vs. baseline		N.S	N.S.	0.012	0.04
MG (nMol/ml)	3.3±1.4	3.2±1.1	3.2±1.9	2.3±1.1	2.4±0.6
p vs. baseliine		N.S.	N.S.	0.002	0.007

There was also a dose-dependent decrease (trend) for serum phosphate ($p<0.0001$), total cholesterol and LDL-cholesterol ($p=0.0001$).In addition, VCAM1 was decreased ($p=0.002$) at 7.2 gm/day. Tests for trend by dose: HDL 0.76; TC $p<0.0001$; LDL $p<0.0001$; Trigs $p=0.06$.

Conclusions: The high serum levels of cytopathic AGEs and lipids in T2D HD patients can be decreased by sevelamer carbonate within 3 weeks. Since AGEs raise risks for CVD, sevelamer carbonate treatment may be efficacious against this complication. Since 2.4 g/day did not reduce cytopathic AGEs, assuring that patients reach the 4.8 g/day dosage level may represent an important therapeutic goal.

Positive Association of Serum Levels of Dipeptidyl Peptidase-4 with Advanced Glycation End Products in Humans Kumiko Kaifu,[1] Nobuhiro Tahara,[1] Seiji Ueda,[1] Sho-ichi Yamagishi,[2] Miyuki Yokoro,[1] Nana Obara,[1] Ryotaro Ando,[1] Yosuke Nakayama,[1] Yusuke Kaida,[1] Masayoshi Takeuchi,[3] Kei Fukami,[1] Seiya Okuda.[1] *[1]Department of Medicine, Kurume University School of Medicine, Kurume, Japan; [2]Department of Pathophysiology and Therapeutics of Diabetic Vascular Complications, Kurume University School of Medicine, Kurume, Japan; [3]Department of Advanced Medicine, Medical Research Institute, Kanazawa Medical University, Kanazawa, Japan.*

Background: Dipeptidyl peptidase-4 (DPP-4) is an enzyme which mainly degrades incretins such as glucagon like peptide-1 (GLP-1) and is altered in a variety of inflammatory disorders. DPP-4 and GLP-1 receptor are abundantly expressed in the kidney cells. We have recently found that DPP-4 inhibitors ameliorate vascular injury in diabetic rats by blocking the harmful effects of advanced glycation end products (AGEs). However, how circulating DPP-4 level is regulated remain unknown.

Methods: We examined which anthropometric and metabolic valuables, including AGEs are independently correlated with circulating DPP-4 levels in 432 consecutive outpatients. We further investigated the effects of AGEs on DPP-4 in cultured human renal proximal tubular epithelial cells (RPTECs).

Results: Mean serum AGEs and DPP-4 levels in our patients were 8.96±2.57 U/mL and 520±33.9 ng/mL, respectively. Multiple regression analysis revealed that female ($p<0.001$), HDL-cholesterol ($p<0.001$), HbA1c ($p<0.001$), and serum AGEs ($p<0.03$) were independent determinants of DPP-4. *In vitro*, AGEs significantly increased DPP-4 expression in RPTECs and stimulated the secretion of soluble DPP-4, both of which were completely blocked by an anti-oxidant N-acetylcysteine.

Conclusions: These present results suggest that AGEs may stimulate renal DPP-4 expression via oxidative stress, which could partly explain for the positive association between serum DPP-4 and AGEs.

SA-PO501

Pre-Operative Clinical Assessment of Insulin Resistance and Pancreatic beta Cell Reserve (Insulin Sensitivity) in Renal Allograft Recepients: Prediction of Post Transplant Diabetes Mellitus Pratik Das, Soumava Gupta, Debmalya Sanyal. *Nephrology, Manjula Ben Mehta Kidney Hospital, Kolkata, West Bengal, India.*

Background: Post-transplant diabetes mellitus (PTDM) has negative impact on renal allograft survival, cardiovascular risk and patient survival. Pre-tansplant evaluation may alter the outcome.

Methods: The predictive value of a fasting plasma glucose (FPG) level, fasting serum insulin, fasting serun C peptide, HbA1C, BMI and Waist-hip ratio 2 days before transplantationon (before initiation of immunosuppression) were prospectively evaluated in 100 *de novo* nondiabetic renal allograft recipients. The data were subjected to Homa scale for insulin resistance and sensitivity (beta cell reserve). Retransplantation, cadaver transplant and patients with hepatitis B and C seropositivity were excluded. PTDM was defined as the uninterrupted need for glucose-lowering medication for at least 3 months.

Results: 15 patients (15%) developed PTDM (follow-up 18.25 ± 9.8 months). Recipient age, body mass index (BMI), biopsy-proven acute rejection (BPAR), early graft function and proteinuria, tacrolimus-based therapy, cumulative corticosteroid dose and thiazide diuretics were associated with PTDM (univariate analysis). Multivariate logistic regression analysis identified age [OR (odds ratio): 1.08 (95% confidence interval: 1.023–1.099)], BMI [OR: 1.05 (1.015–1.172)] and insulin resistance on Homa scale[OR: 1.31 (1.022–2.29)], BPAR [OR: 1.92 (1.223–4.604)] as independent risk factors for PTDM while high insulin sensitivity and beta cell reserve on Day 2 pre-transplantation was associated with a strongly reduced risk for PTDM [OR: 0.04 (0.007–0.152)]. High insulin sensitivity and beta cell reserve had the best sensitivity (89.6%) and specificity (68.99 %) with a high negative predictive value (94.32%).

Conclusions: Pre-transplant insulin resistance and beta cell reserve are independent predictors of PTDM that can be used for identifying recipients at high or reduced risk for PTDM, other than the impact of independent clinical risk factors like age, BMI and BPAR (treatment). This information can help clinicians to modify therapeutic plan to improve graft and patient survival after transplantation.

Diabetes Occuring Post Transplant Has a Different Course Depending on Ethnic Background when Using a Steroid Sparing Protocol Georgina H. Aldous, Vaarisan Ganeshalingam, Dawn Goodall, Jack Galliford, Adam Mclean, David Taube, Andrew H. Frankel. *Imperial College Renal & Transplant Centre.*

Background: Few studies describe the natural history of new onset diabetes after transplant (NODAT). We describe the natural history of NODAT using a steroid sparing regime.

Methods: NODAT was diagnosed upon treatment of diabetes and diet-controlled diabetes used ADA criteria. Follow-up was from diagnosis to one year. Treatment and HbA_{1c} at 3, 6, 9 & 12 months were recorded. They were compared to 90 patients with pre-existing Type 2 diabetes (T2DM) [75M, 15F; mean age 58.1±9.9 yrs]. Patients received monoclonal induction and our Tacrolimus based steroid sparing protocol. Rejection was treated with Methylprednisolone and oral Prednisolone.

Results: 73/778 [9.4%] patients developed NODAT and 12/778 [1.5%] diet-controlled diabetes [51M, 34F; mean age 51.1±11.1 yrs]. 25/85 [29.4%] Caucasian and 38/85 [44.7%] Asian. Asian patients had worse glycaemic control than Caucasian patients from 6 months [Table 1], with HbA_{1c} similar to preexisting T2DM [6.9%, 7.1%, 7.9% & 8.1% at 0, 1, 6 & 12 months].

HbA1c levels of Asian & Caucasian NODAT/diet-controlled DM patients compared using Mann Whitney U Test.

Months from diagnosis	Asian HbA1c (%)	Caucasian HbA1c (%)	p-value
0	7.6	7.3	0.643
3	6.6	6.7	0.831
6	7.3	6.8	0.050*
9	7.5	6.6	0.024*
12	7.7	6.5	0.026*

Asian and Caucasian patients had similar initial BMI [27.4 vs 29.4kg/m^2, p=0.19] with no significant difference in weight gain. 10 Asian and 11 Caucasian patients had rejection [p=0.15]. Prednisolone use was greater in Caucasians at diagnosis [52% vs 22%, p=0.02]. There was no significant difference in Tacrolimus dose at diagnosis [0.097mg/kg Caucasian vs 0.079mg/kg Asian, p=0.17]. MDRD eGFR was better in Asian patients [54.6 vs 44.5ml/min (p=0.04) at diagnosis]. HbA_{1c} at transplant was similar in both groups [5.4% Caucasian (n=8) vs 5.5% Asian (n=18)]. Random glucose was similar at transplant [5.6mmols Caucasian (n=19) vs 5.5mmols Asian (n=22)] and diagnosis [16mmols Caucasian (n=19) vs 18mmols Asian (n=30)].

Conclusions: Asian patients behave similarly to patients with pre-existing T2DM whereas Caucasian patients have more stable glycaemic control.

SA-PO503

Body Weight Increase and Congestive Heart Failure during Treatment with Avosentan: A Post-Hoc Analysis of the ASCEND Trial Jarno Hoekman,[1] Hiddo Jan Lambers Heerspink,[1] G. Viberti,[2] Damian Green,[4] Johannes F. Mann,[3] Dick de Zeeuw.[1] *[1]Dept Clinical Pharmacology, University Medical Center Groningen, Groningen, Netherlands; [2]King's College London School of Medicine, London, United Kingdom; [3]Dept of Medicine IV, University of Erlangen, Erlangen, Germany; [4]Quintiles Ltd., Strasbourg, France.*

Background: The ASCEND trial tested the renoprotective effect of the endothelin-1 antagonist avosentan in subjects with type 2 diabetes and nephropathy. Despite the drug's ability to decrease albuminuria, an excess of congestive heart failure (CHF) events occurred in the avosentan treatment arms which was likely due to increased sodium/fluid retention and led to premature termination of the trial. We questioned whether the rise in body weight during the first weeks of avosentan treatment can be used to monitor increased susceptibility to develop CHF during follow-up.

Methods: In a post-hoc analysis of the ASCEND trial (N=761) we assessed change in body weight after 1 month between placebo and combined avosentan treatment arms (25mg and 50mg). Using cox regression we then analysed whether a 1 month change in body weight is associated with increased CHF risk.

Results: The increase in body weight after 1 month was +1.0kg (95%CI 0.8 – 1.2) in the combined avosentan treatment groups, while body weight did not change in the placebo group (0.0kg (95%CI -0.2 - 0.3) P vs. avosentan <0.001). Between 1 month and end of study 28 CHF events occurred in the avosentan group and 9 in the placebo group. Among patients with a CHF event, body weight changed with +1.8kg in the avosentan arm vs. -0.3kg in the placebo arm, whereas patients without a CHF event experienced a body weight change of +0.9kg in the avosentan arm and 0.0kg in the placebo arm. The rise in body weight was associated with increased CHF risk in the avosentan arms (HR=1.15 (95% 1.01 - 1.30) P=0.030) but not in the placebo arm (HR=0.93 (95%CI 0.68 - 1.29) P=0.669). Body weight change in the avosentan arm remained associated with CHF risk after controlling for history of CHF, age, and gender (HR=1.20 (95%CI 1.04 - 1.37) P=0.012).

Conclusions: Short-term change in body weight during treatment with an endothelin-1 antagonist can be used to monitor CHF risk.

Non-Alcoholic Fatty Liver Disease Is Associated with Cardiovascular Risk in Adults with Diabetes Jeffrey C. Sirota,[1] Pamela Mettler,[1] Kim Mcfann,[1] Giovanni Targher,[2] M. Chonchol,[1] Diana I. Jalal.[1] *[1]Division of Renal Diseases and Hypertension, University of Colorado, Aurora, CO; [2]Section of Endocrinology and Metabolism, University and Azienda Ospedaliera Universitaria Integrata of Verona, Verona, Italy.*

Background: While some studies have linked non-alcoholic fatty liver disease (NAFLD) to cardiovascular disease (CVD), it remains uncertain if NAFLD is associated with an increased prevalence of CVD in the US.

Methods: Cross-sectional study examining the relationship between ultrasound-diagnosed NAFLD and CVD in the National Health and Nutrition Examination Survey 1988-1994 (n=11,317). CVD was defined as a composite of angina, myocardial infarction, or stroke. In addition, we tested interactions between NAFLD & chronic kidney disease (CKD) and between NAFLD & diabetes on CVD.

Results: 875 (8%) participants had CVD and 3720 (33%) had NAFLD. Subjects with CVD were older, more likely to have hypertension and diabetes, and had higher waist circumference, triglycerides, & homeostatic model of insulin resistance (HOMA-IR) scores. NAFLD prevalence was 35.6% and 45.3% in patients without and with CVD, respectively (p<0.0001). NAFLD was associated with CVD (OR 1.74, 95% CI 1.41-2.14, p<0.0001) in univariate regression analysis. After adjusting for demographics and other CVD risk factors, the OR for CVD in NAFLD was 1.10 (95% CI 0.88, 1.37, p=0.42). The interaction between NAFLD and CKD on CVD was not significant (p=0.89). The interaction between NAFLD and diabetes on CVD was significant (p=0.049). Stratified analysis showed NAFLD was independently associated with CVD among diabetic subjects.

Table

	with diabetes n=824	no diabetes n=10,493
Unadjusted OR (95% CI)	2.38 (1.37-4.15, p=0.002)	1.45 (1.15-1.83, p=0.002)
Adjusted OR* (95% CI, P)	1.98 (1.05-3.73, p=0.034)	0.99 (0.78-1.28, p=0.98)

* Adjusted for age, sex, race, h/o hypertension, waist circumference, systolic blood pressure, HOMA-IR, HDL-cholesterol, triglycerides

Conclusions: Ultrasound-diagnosed NAFLD is associated with CVD among US adults. This association is attenuated by cardiovascular risk factors. In people with diabetes, however, NAFLD is independently associated with CVD.

SA-PO505

Role of Innate Immunity in Diabetic Nephropathy Can Li,[1] Ying Shun Jin,[1] Hong Bin Zou,[2] Shang Guo Piao,[3] Bi Hu Gao,[4] Chul Woo Yang.[3] *[1]Nephrology, YanBian University Hospital, YanJi, JiLin, China; [2]Nephrology, The First Affiliated Hospital of JiLin University, ChangChun, JiLin, China; [3]Nephrology, The Catholic University of Korea, Seoul, Korea; [4]Nephrology, The Affiliated ZhongShan Hospital of DaLian University.*

Background: There is growing evidence that innate immunity plays a potential role in the pathogenesis of various renal diseases. However, the role of innate immunity in diabetic nephropathy (DN) has yet to be demonstrated. The aim of this study was to investigate the expression of toll-like receptors (TLR) and its ligands in human kidney tissue of DN.

Methods: We studied 12 type 2 DN patients with renal biopsy, and 12 patients with nephrectomy for renal cancer served as controls. Clinical characteristics were recorded, and intrarenal expression of TLRs (TLR2 and TLR4) and its ligands (heat shock protein70, HSP70 and MYD88) was examined by immunohistochemistry.

Results: The intrarenal expression of TLR2 was markedly decreased in glomerulus of the DN group (1.30 ± 0.21%/mm^2 vs. 28.50 ± 3.45%/mm^2, P<0.01), whereas its expression was increased in the tubulointerstitum (16.55 ± 0.75%/mm^2 vs. 8.93 ± 0.62%/mm^2, P<0.05), and this trend was accompanied by MYD88 expression (Glomerulus: 1.76 ± 0.60%/mm^2 vs. 90.92 ± 10.69%/mm^2; tubulointerstitum: 24.48 ± 2.38%/mm^2 vs. 16.15 ± 1.12%/mm^2, P<0.01, respectively). In contrast, TLR4 immunoreactivity was significantly increased in the glomerulus of DN group (45.65 ± 3.08%/mm^2 vs. 31.61 ± 1.32%/mm^2, P<0.01) but not in the tubulointerstitum. HSP70 expression, a TLR ligand, was significantly increased in the DN group compared with the Con group (Glomerulus: 91.40 ± 13.88%/mm^2 vs. 50.91 ± 4.07%/mm^2; tubulointerstitum: 19.27 ± 1.23%/mm^2 vs. 9.25 ± 0.74%/mm^2, P<0.01, respectively). Correlation analysis revealed that TLRs expression was correlated with the proteinuria and the eGFR.

Conclusions: Our findings suggest that an alteration in TLRs and its ligands expression is closely associated with diabetic renal injury, and that innate immunity may be one of important players in type 2 DN.

SA-PO506

Homeostatic Model Assessment Indices in Evaluation of Insulin Resistance, and Secretion in the End Stage Renal Disease Stanislaw Niemczyk,[1] Katarzyna Szamotulska,[2] Kinga Giers,[1] Mariusz Jasik,[3] Zbigniew Bartoszewicz,[3] Katarzyna Romejko-ciepielewska,[1] Ewa Paklerska,[3] Malgorzata Gomolka,[1] Joanna Matuszkiewicz-Rowinska.[3] *[1]Military Institute of Medicine, Warsaw, Poland; [2]National Research Institute of Mother and Child, Warsaw, Poland; [3]Medical University of Warsaw, Warsaw, Poland.*

Background: There are no conclusive studies on indices of the effectiveness of insulin action in the end stage renal disease (ESRD) pts.

Aim. The purpose of the study was to compare Homeostatic Model Assessment indices (HOMA-%B, HOMA-%S, HOMA-%IR) and Disposition Index (DI) in HD patients without diabetes with healthy control subjects.

Methods: The groups comprised 33 non-diabetic ESRD HD pts and 33 healthy controls matched for age (50-80y.o.), gender (25 M, 8 W) and BMI. Fasting level of glucose and insulin were measured. HOMA-%B, HOMA-%S, HOMA-IR indices and DI were calculated using: HOMA 1 and HOMA 2 as measures of IR. The indices were assessed also in subgroups divided according to BMI (<25; 25-30; ≥30 kg/m^2). Relationships between leptin, LAR, CRP and HOMA were evaluated.

Results: Glucose concentrations were lower in ESRD pts (82.4±10.4 vs. 93.9±11.6, p=0.001). Insulin concentrations were similar (median 6.8 vs 6.0 mU/l, p=0.698). HOMA1-%B were higher in ESRD pts (median 137.1 vs. 81.6, p=0.002). HOMA1-%S (median 75.6 vs. 71.5) and HOMA1-IR (median 1.3 vs. 1.4) were not significantly different (p=0.264 and p=0.189). DI1 levels were higher for HD pts (median 1.16 vs. 0.53, p<0.001). In subgroups analysis all statistically significant differences were restricted to persons with BMI<25kg/m^2. Similar results, as for HOMA 1 model, were obtained for HOMA 2. Among HD patients, significant correlations were found between HOMA-%B, HOMA-%S, HOMA-IR indices and serum leptin, leptin/adiponectin ratio and CRP levels.

Conclusions: The Homeostatic Model Assessment-B (HOMA-%B) and Disposition Index (DI) are strongly correlated with insulin resistance level in the end stage renal disease.

In non-diabetic and end stage renal disease patients undergoing hemodialysis the Homeostatic Model Assessment indices and Disposition Index may be useful and important models in interpretation of glucose metabolism disturbances.

SA-PO507

New Pathologic Classification of Diabetic Nephropathy: Clinical Correlations Loyana Teresa Teofilo Lima Silva, Camila Hitomi Nihei, Raquel Maria Maia, Elerson Costalonga, Michell Alves Oliveira, Denise M.A.C. Malheiros, Lectícia Jorge, Cristiane Bitencourt Dias, Rui Toledo Barros, Viktoria Woronik. *Nephrology, School of Medicine University of Sao Paulo, Sao Paulo, Brazil.*

Background: The aim of this study was to evaluate the new pathological classification of diabetic nephropathy (DN) according to the Research Committee of the Renal Pathology Society in 2010.

Methods: We analyzed 77 diabetic patients submitted to renal biopsy at our center from 1999 to 2010. Thirty-eight patients with biopsy-proven DN meet inclusion criteria of biopsies containing at least 8 glomerulus and follow up longer than 1 year. Biopsies were reviewed and classified according to new pathological classification of DN. Two pathologists scored all biopsies independently.

Results: In these 38 DN patients, none was classified as type I, 1 as type IIa, 6 as type IIb, 29 as type III and 2 as type IV; 16 patients had mild interstitial injury, 12 had moderate interstitial injury, while 9 had severe interstitial injury. Arteriosclerosis was present in 9 biopsies while arteriolar hyalinosis was present in 23. The agreement between the reports of the pathologist was 100%. We couldn't analyze the impact class IIa and IV of DN on outcome because the low number of patients. The clinical features and laboratory findings of patients was classified as type IIb and III are summarized in Table I.

Clinical Features

Class	IIb	III	
N=35	N=6	N=29	
Age(y)	42,3±19,7	51,6±12,1	p=0,15
Male	3(50%)	16(55%)	pNS
Initial eGFR(ml/min)	54,5(±26,5	30±20,5	p=0,01
Final eGFR(ml/min)	41,6±30,3	16,2±13,6	p=0,004
Proteinuria(g/day)	3,8±3,2	5,4±2,9	p=0,2
Glycated hemoglobin(%)	10,9±4	8,9±2,8	p=0,15
Hypertension	6(100%)	28(96,6%)	pNS
ESRD	3(50%)	20(69%)	pNS
Follow up(mo)	46,7±47	25±22,9	pNS
Interstitial Fibrosis			
0 (0%)	0 (0%)	0 (0%)	pNS
1 (<25%)	3 (50%)	14 (48%)	pNS
2 (25-50%)	2 (33%)	9 (31%)	pNS
3 (>50%)	1 (17%)	6 (21%)	pNS

Results are showed as mean ± SD or n(%)

Conclusions: The new pathological classification of DN seems to correlate with baseline renal function and can increase the diagnosis rate and attract more attention to interstitial damage in DN.

Funding: Government Support - Non-U.S.

SA-PO508

Glomerular Filtration and Albumin Excretion Rate Variability in Type 1 Diabetic Patients Are Largely Explainable by Glomerular Lesions Alone Behzad Najafian,[1] Maria Luiza A. Caramori,[2] Michael Mauer.[2] *[1]Pathology, University of Washington, Seattle, WA; [2]Pediatrics and Medicine, University of Minnesota, Minneapolis, MN.*

Background: Structural-functional relationship (SFR) studies are powerful tools to understand the natural history of diabetic nephropathy (DN). We studied SFR in a large cohort of type 1 diabetic (T1D) patients (pts) with a wide spectrum of renal function.

Methods: Renal biopsies from 161 (M/F=60/101), age 35[19-64] years, diabetes duration 22±9 years, albumin excretion rate (AER) 31[2-4630] ug/min, glomerular filtration rate (GFR) 101[31-178] ml/min/1.73 m^2 T1D pts were studied by electron microscopy stereology and correlated with renal function.

Results: Simple regression showed that AER directly correlated with Hb_{A1C} (r=0.21, p=0.007), mean blood pressure (MBP) (r=0.41, p=0.0001), volume fraction of mesangium per glomerulus [Vv(Mes/glom)] (r=0.78, p=0.0001), glomerular basement membrane width (GBMW) (r=0.67, p=0.0001) and inversely with age at the onset of diabetes (r=-0.17, p=0.03) glomerular filtration surface density [Sv(PGBM/glom)] (r=-0.72, p=0.0001). Multiple regression analyses (MRA) showed Vv(Mes/glom) and GBMW explained 68% of AER variability (p=0.0001). Maximum prediction of AER variability (75%) was obtained by piecewise linear regression analyses (PLRA) with these two variables at an AER breakpoint about 40 ug/min. Simple regression showed that 27% of GFR variability can be explained by Vv(Mes/glom). This was increased to 29% when sex and GBMW were added to Vv(Mes/glom) in a MRA model. However, Vv(Mes/glom) alone explained about 70% of GFR variability using PLRA at a GFR breakpoint of 115 ml/min/1.73 m^2.

Conclusions: These studies show that majority of renal functional abnormalities in T1D pts with a wide range of AER and GFR is explainable by the presence of glomerular lesions. If appropriate SFR models are applied, glomerular structural abnormalities can be potentially used as surrogates of GFR decline, especially in future longitudinal studies of early DN.

SA-PO509

Clinical Predictors of Non-Diabetic Kidney Disease in Type II Diabetics Undergoing a Kidney Biopsy: A Retrospective Analysis Gaurav Jain, Gautam K. Bhanushali, Michael Allon. *University of Alabama at Birmingham.*

Background: Diabetic nephropathy (DN) is usually diagnosed in patients with long-standing DM with typical clinical features (slow progression, proteinuria, hypertension). Kidney biopsy is reserved for patients with "atypical" clinical features (acute kidney injury, rapid progression, severe proteinuria, hematuria, or absent retinopathy) that suggest non-diabetic kidney disease (NDKD). We evaluated the association between clinical features and renal pathology in Type II diabetics undergoing kidney biopsy.

Methods: 146 patients with Type II DM underwent native kidney biopsies at our center over 8 years. Two investigators who were blinded to the renal pathology retrospectively extracted clinical information from the electronic medical record. The association between clinical features and kidney pathology was evaluated by Chi square analysis.

Results: Of 146 kidney biopsies, 43 (or 29%) had DN, 80 (or 55%) had NDKD and 23 (16%) had DN+NDKD. The most common NDKD lesions were ATN (20 pts), IgA nephropathy (15 pts), FSGS (12 pts) and pauci-immune glomerulonephritis (11 pts). We combined patients with NDKD and those with DN+NDKD, and compared them to patients with isolated DN. The likelihood of NDKD was increased in patients with AKI, non-nephrotic range proteinuria, absence of diabetic retinopathy, and excellent BP control. In contrast, hematuria, rapid progression of CKD, and good glycemic control did not increase the likelihood of NDKD.

Results

Clinical Features	HR for NDKD	95% CI	p-value
Biopsy due to proteinuria	0.68	0.57-0.82	0.0004
Biopsy due to AKI	1.46	1.22-1.76	0.0004
Hematuria	1.13	0.92-1.39	0.25
Proteinuria <3.5 gm/day	1.56	1.20-2.02	0.0006
No retinopathy	1.57	1.07-2.30	0.009
Rapid progression	1.03	0.79-1.35	0.82
Good glycemic control	1.26	0.97-1.65	0.07
Excellent BP control	1.49	1.24-1.78	0.0004

CI (confidence interval), HR (Hazard Ratio)

Conclusions: NDKD is present in over two-thirds of type II diabetics undergoing a kidney biopsy, and comprises a variety of pathologies. Simple clinical criteria can be used to estimate the likelihood of NDKD, and thereby guide the decision about proceeding with a kidney biopsy.

SA-PO510

Nation-Wide Survey of Body Mass Index in Prevalent Dialysis Patients in Japan Yukitoshi Sakao,[1] Akihiko Kato,[1] Yoshihide Fujigaki,[2] Seiji Hashimoto,[3] Takeshi Hasegawa,[3] Kunitoshi Iseki,[3] Yoshiharu Tsubakihara.[3] *[1]Blood Purification Unit, Hamamatsu University School of Medicine, Hamamatsu, Shizuoka, Japan; [2]First Department of Medicine, Hamamatsu University School of Medicine, Hamamatsu, Shizuoka, Japan; [3]Committee of Renal Data Registry, Japanese Society for Dialysis Therapy (JSDT), Bunkyo-ku, Tokyo, Japan.*

Background: The prevalence of overweight (body mass index (BMI) ≥25kg/m^2) is gradually increased in men aged from 20 to 60 years old, while decreased in women aged from 40 to 60 years old in Japanese general population. However, the prevalence of overweight, normal (18.5≤BMI<25 kg/m^2)and lean BMI (<18.5kg/m^2) is still unknown among the dialysis population in Japan.

Methods: A nation-wide data were obtained from Renal Data Registry of JSDT. We calculated BMI by body height and weight at post-dialysis in 165,215 patients (age: 65.2±12.5, time on HD: 7.3±7.2 years, male: 62%). We compared BMI in the general population reported from the Nation Health and Nutrition Survey by Ministry of Health, Labour and Welfare.

Results: Mean BMI were 21.5±3.5 kg/m^2 in male and 20.7±3.9 kg/m^2 in female, lower than those in the general population (M: 23.5 kg/m^2, F: 22.3 kg/m^2). Lean BMI was more prevalent when compared both in men (16.8 vs. 4.3%) and in women (30.1 vs. 10.8%) across all generation. The prevalence of lean BMI in male was 20.2% in chronic glomerulonephritis (CGN), 18.2% in diabetic nephropathy (DN) and 13.7% in benign nephrosclerosis (BN). Lean BMI was more prevalent in DN (33.9%) and CGN (32.9%) when compared to BN (20.4%) in female. The prevalence of overweighed BMI was also lower both in men (12.8 vs. 28.6%) and women (11.7 vs. 20.6%) respectively. The rate of overweighed BMI was almost identical to that in general subjects in patients aged from 20 to 40 years old, while it decreased with ageing over 40 years old. Overweighed BMI was observed more often in DM (M: 17.0%, F: 19.7%) than in CGN (M: 9.9%, F: 8.5%) and in BN patients (M: 11.6%, F: 10.5%).

Conclusions: The prevalence of lean BMI was 3 to 4-fold higher in the dialysis population in Japan. However, the prevalence of overweighed BMI was almost identical to that in general population in young patients aged from 20 to 40 years old.

SA-PO511

Association between Body Composition and Quality of Life in ESRD Patients Somchai Yongsiri,[1] Jiranuch Thammakumpee,[2] Pongtip Unprasert,[1] Ouppatham Supasyndh.[3] *[1]Internal Medicine, Faculty of Medicine Burapha University, Mueng, Chonburi, Thailand; [2]Internal Medicine, Chonburi Hospital, Mueng, Chonburi, Thailand; [3]Internal Medicine, Pharmongkutklao Hospital, Bangkok, Thailand.*

Background: Protein-energy wasting is a significant problem in ESRD patients that compromise the patient's Quality of life (QOL). Multifrequency Bioimpedance Spectroscopy (BIS) is a validated method to assess body composition in dialysis patients. Objective. The study objective is to explore the association between body composition and QOL in ESRD patients who received different treatment modalities.

Methods: Body composition were measured by Body Composition Monitor®, the device provided body composition and quantified hydration status. QOL was measured by WHOQOL-BREF instrument comprises 26 items, which measure the following domains: physical health, psychological health, social relationships, and environment. Pearson's correlation coefficient was used to measure the correlation, $p<0.05$ was considered as statistically significant.

Results: Sixteen predialysis-CKD5, 26 PD and 34 HD patients were included in this study. There were no statistically difference in baseline characteristics including Charlson comobidity index, dietary intake, BMI and blood pressure between groups.Mean QOL score in each group were in the middle range and not significantly difference. PD patients had more over hydration when compare to HD patients (16.18±11.24 vs. 2.36±11.07 %OH/ECW $p<0.0001$).There were inverse correlation between overhydration and physical health in HD patients ($r=-0.372$, $p=0.033$) but not in PD and CKD5 patients. CKD5 patients had more lean tissue index than PD and HD patients (LTI=14.34±3.13, 12.26±3.65, 11.48±3.48 kg/m^2 respectively, $p=0.023$). There were correlation between LTI and overall QOL in CKD5 ($r=0.690$, $p=0.002$) and PD patients ($r=0.498$, $p=0.010$). In HD patients, LTI was associated with better physical health ($r=0.464$, $p=0.007$).

Conclusions: QOL in predialysis-CKD5, PD and HD patients were not statistically different. HD patients had better volume control than PD patients. Higher LTI were associated with better QOL in ESRD patients.

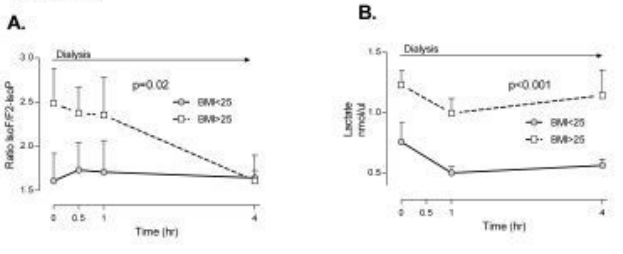
Obesity Influences Oxidative Stress and Mitochondrial Dysfunction in Maintenance Hemodialysis (MHD) Patients Jorge Gamboa,[1] Mias Pretorius,[1] Delia M. Woods,[1] Charles Anthony Dematteo,[1] Jonathan Himmelfarb,[2] T. Alp Ikizler.[1] *[1]Medicine, Vanderbilt University Medical Center; [2]Medicine, University of Washington.*

Background: Patients undergoing MHD have increased cardiovascular morbidity and mortality that cannot be explained by traditional risk factors. Increased oxidative stress burden, usually consequence of increased production of reactive oxygen species (ROS), is associated with increased CV events in MHD patients. The mitochondria is one of the main sources of ROS. In this study we tested the hypothesis that markers of oxidative stress and mitochondrial dysfunction are increased in patients undergoing MHD.

Methods: We evaluated fifteen (15) patients undergoing MHD for at least 6 month. Serial blood sampling was taken during hemodialysis.

Results: We found that F2-Isoprostanes (F2-Iso) and Isofurans (IsoF) were increased at baseline in MHD patients, but did not change during the course of hemodialysis. Interestingly the ratio of IsoF to F2-IsoP was higher than one during hemodialysis, a phenomenon described in mitochondrial dysfunction. Lactate, a marker of mitochondrial dysfunction, was elevated at baseline but did not change significantly during hemodialysis. When patients were categorized by being or not overweight/obese (BMI higher or lower than 25), patients with BMI>25 had higher IsoF to F2-IsoP ratios at the beginning of HD, which resolved by the end of HD (Figure 1A). Higher lactate levels were observed in obese patients at baseline and during hemodialysis (Figure 1B) suggesting a higher extent of mitochondrial dysfunction in these patients.

Figure 1.



Conclusions: MHD patients have increased mitochondrial dysfunction, which is more pronounced in obese individuals. Mitochondrial dysfunction is not affected by hemodialysis procedure. Further studies are required to elucidate the relation between mitochondrial dysfunction, oxidative stress and obesity in MHD patients.

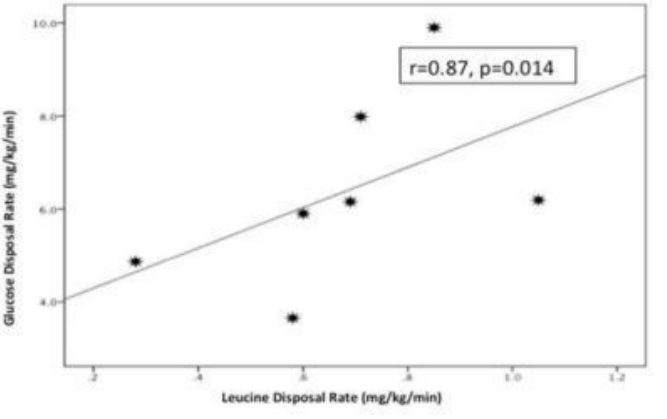
Insulin Resistance of Carbohydrate and Protein Metabolism Are Correlated in Chronic Hemodialysis Patients Serpil Muge Deger,[2] Adriana Hung,[1,2] Cindy Booker,[1,2] Feng Sha,[2] Phyllis Ann Egbert,[2] Mary B. Sundell,[2] Charles D. Ellis,[2] T. Alp Ikizler.[1,2] *[1]Nephrology, VA THS, Nashville, TN; [2]Nephrology, Vanderbilt University, Nashville, TN.*

Background: Sarcopenia is associated with increased morbidity and mortality in CHD patients. Peripheral insulin resistance has been proposed as a critical player in the development of sarcopenia. Measurement of glucose disposal rate (GDR) by clamp studies is the gold standard of assessing peripheral IR. There are no studies examining the amino acid disposal rate (AADR) in relation to GDR in CHD patients. Here, we investigated the relationship between AADR and GDR using a novel hyperinsulinemic eugylcemic and euaminoacidemic dual clamp technique to assess the effects of IR on amino acid metabolism in prevalent CHD patients.

Methods: Seven male CHD patients underwent hyperinsulinemic euglycemic euaminoacidemic clamp protocol to measure GDR and AADR. Variable infusion of 20 % dextrose and AA solution were infused to maintain the plasma levels at the post-absorptive state. The primary outcome was the correlation between GDR and AADR concentrations in response to insulin administration.

Results: Mean age was 54± 13 years and 29% had previous diagnosis of T2DM. Mean BMI was 29.8±5.5 kg/m^2. During the dual clamp procedure, basal leucine concentrations significantly increased from their basal values [94.5 ±16.2 micromol/L vs. 113.4±17.3 micromol/L ($p=0.018$)]. There was a significant correlation between Leucine disposal rate and GDR(spearman coefficient $r= 0.857$, $p=0.014$).



Conclusions: The results of this study demonstrate that the severity of IR of carbohydrate metabolism is associated with a similar resistance to anabolic actions of insulin in CHD patients. Insulin resistance represents a potential mechanism for development of sarcopenia and can be targeted for treatment of Protein Energy Wasting in CHD patients.

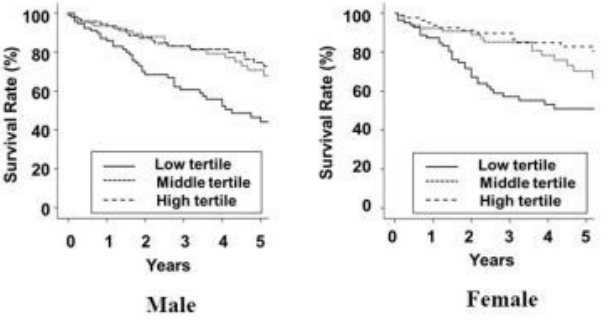
SA-PO514

Limb/Trunk Lean Mass Ratio as a Risk Factor for Mortality in Peritoneal Dialysis Patients Seokhui Kang, Jun-Young Do, Kyu-hyang Cho, Kyung Woo Yoon, Jong-Won Park. *Department of Internal Medicine, Yeungnam University Hospital.*

Background: This study was performed to determine the clinical relevance of limb/trunk lean mass ratio (LTLM) in continuous ambulatory peritoneal dialysis (CAPD) patients.

Methods: This retrospective cohort study included 534 CAPD patients. Body compositions were measured using a DEXA apparatus.

Results: In males, the sensitivity and specificity for the diagnosis of sarcopenia were 70.3% and 85.9%, respectively. In females, the sensitivity and specificity for the diagnosis of sarcopenia were 62.3% and 83.8%, respectively. The initial low LTLM tertile was associated with mortality in male CAPD patients and in female CAPD patients.



Among patients who maintained CAPD for a year, the maintenance of low LTLM tertile was associated with mortality.

Conclusions: The LTLM is associated with other lean mass indices, nutritional status, and mortality in CAPD patients. Therefore, LTLM may be used as a new marker useful for the prediction of the nutritional status and mortality in patients with CAPD.

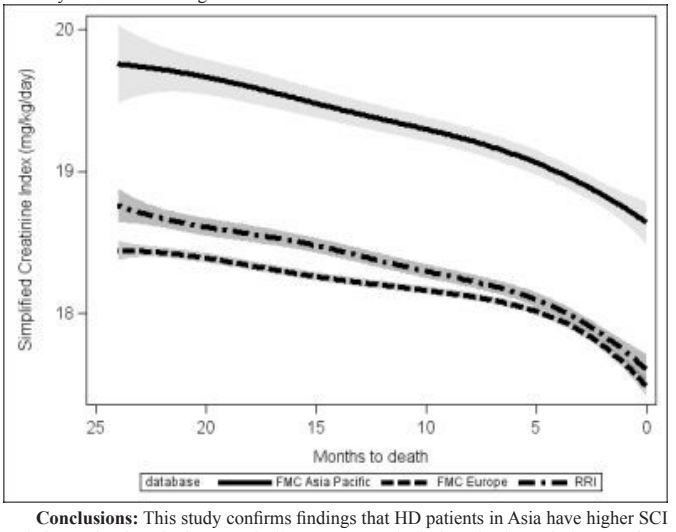
SA-PO515

Muscle Mass Dynamics before Death in Incident Hemodialysis Patients as Represented by a Simplified Creatinine Index: Results of an International Study Bernard J. Canaud,[1] Daniele Marcelli,[1] Len A. Usvyat,[2] Aileen Grassmann,[1] Michael Etter,[3] Yuedong Wang,[4] Adrian Marcos Guinsburg,[5] Cristina Marelli,[5] Adam Tashman,[2] Nathan W. Levin,[2] Peter Kotanko.[2] *[1]FMC, Bad Homburg, Germany; [2]Renal Research Institute, New York, NY; [3]Fresenius Asia Pacific Ltd, Hong Kong; [4]University of California, Santa Barbara, CA; [5]FMC, Buenos Aires, Argentina.*

Background: Muscle wasting is common in hemodialysis (HD) patients and associated with mortality. Previous studies showed HD patients share characteristic trends even weeks before death e.g. deterioration in nutritional, inflammatory and cardiovascular status. This study evaluates the behavior of the new muscle mass indicator SCI (Simplified Creatinine Index) over the 2 years prior to death.

Methods: The MONitoring Dialysis Outcomes (MONDO) consortium encompasses HD databases from Fresenius Medical Care (FMC) clinics in Europe, Asia, Latin America, Canada, RRI clinics in US, Maastricht University in the Netherlands, and KfH clinics in Germany. Databases from RRI, FMC Europe and Asia were queried for $spKt/V_{urea}$, pre-dialysis serum creatinine and demographic characteristics. SCI was calculated using the Canaud formula: SCI (mg/kg/day) = 16.21 + 1.12 x [1 if male; 0 if female] - 0.06 x age (years) - 0.08 x $spKt/V_{urea}$ + 0.009 serum creatinine pre-dialysis (µmol/L). Pre-death SCI dynamics were analyzed by estimating cubic splines.

Results: 13620 HD patients from 22 countries were studied: Europe 16 [N=9883]; Asia 5 [N=800]; USA [N=2937]. Irrespective of region, SCI fell by ~1 mg/kg/day in the 2 years before death. The rate of decline accelerated a few weeks before death and was virtually identical in all regions.



Conclusions: This study confirms findings that HD patients in Asia have higher SCI and shows that lean body mass declines even months before death. Early interventions may change the negative trend.

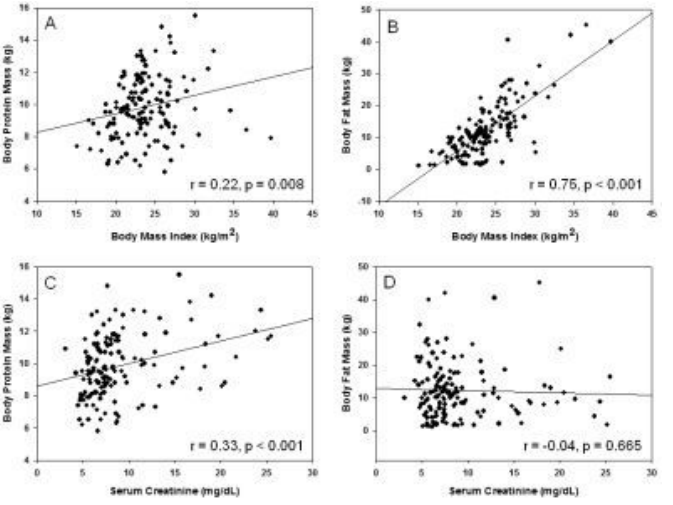
SA-PO516

Body Mass Index and Serum Creatinine: Relation to Body Composition in Incident versus Prevalent Dialysis Patients Jongha Park,[1,2] Kyung Sun Park,[1] Kamyar Kalantar-Zadeh,[2] Miklos Zsolt Molnar,[2] Jong Soo Lee,[1] Hyun Chul Chung.[1] *[1]Ulsan University Hospital, University of Ulsan College of Medicine, Ulsan, Republic of Korea; [2]Harold Simmons Center for Chronic Disease Research & Epidemiology, LA BioMed at Harbor-UCLA, Torrance, CA.*

Background: Body protein and fat mass may influence clinical outcomes via different pathways in end-stage renal disease. Reliable surrogate measures to discriminate among these body compositions may help classify different types of malnutrition more accurately in individual patients and across populations.

Methods: Relationships of body mass index (BMI) and serum creatinine level (Cr) with body protein and fat mass estimated by bioimpedance method were evaluated in 144 new dialysis (HD 117, PD 27) and 70 prevalent HD patients in South Korea using linear regression models.

Results: Incident dialysis patients were 54.7±13.8 yrs old and included 46.5% women and 56.3% diabetics. BMI was strongly correlated with fat mass ($r = 0.75$, $p < 0.01$), while serum Cr was associated with protein mass ($r = 0.33$, $p < 0.01$).



An increment of 1.0 kg/m² in BMI could independently predict to increase in fat mass by 1.74 kg (95%CI: 1.48-2.00), while a change of 1.0 mg/dl in serum Cr could predict a parallel change of 0.13 kg in protein mass (95%CI: 0.04-0.21) in adjusted models (R^2 = 0.63 and 0.38, respectively). In prevalent HD patients (age, 51.8±13.5 yrs; female 48.6%; diabetes 37.1%) similar but even stronger relationships were observed; BMI to fat mass ($r = 0.78$, $p < 0.01$) and serum Cr to protein mass ($r = 0.48$, $p < 0.01$).

Conclusions: BMI and serum Cr level can be used as clinical surrogates of body fat and protein mass, respectively, in dialysis patients. Since serum Cr is influenced by not only protein mass but also residual renal function, its relation to protein mass seems to be more relevant in long-term maintenance rather than new dialysis patients.

SA-PO517

Sarcopenia as a Predictor of Patient Vulnerability Grahame J. Elder,[1,2] Avalon Moonen,[3] Sjorjina Green,[3] Nathan Hewitt.[3] *[1]Department of Renal Medicine, Westmead Hospital, Sydney, NSW, Australia; [2]Osteoporosis and Bone Biology Program, Garvan Institute of Medical Research, Sydney, NSW, Australia; [3]Clinical School, University of Notre Dame, Sydney, NSW, Australia.*

Background: Patients ≥age 60 on satellite dialysis have ~20% annual mortality. Sarcopenia assessment may identify vulnerable patients in order to target modifiable risks. Sarcopenia has been defined by reduction in the lean tissue index (LTI; mass/height²) adjusted for age and sex, tests of functional ability, muscle strength, relative grip strength and the short physical performance battery (SPPB; balance, repeated chair stands and gait speed). Nutritional assessment; the Subjective Global Analysis (SGA) and laboratory biomarkers are also used to predict increased risk.

Methods: We evaluated 80 stable haemodialysis patients aged ≥60 for sarcopenia using bioimpedance analysis (BIA; Fresenius Medical Care), functional ability; 6 minute walk, timed up-and-go (TUG), repeated chair stands (RCS), grip and knee extension strength and SGA. A further 60 patients were assessed by age and sex adjusted grip strength and SPPB. Blood was tested for laboratory biomarkers, and stored for further analyses.

Results: LTI was below the 10th centile of the reference population in 43%, with no difference in prevalence by age or gender. Values correlated to strength (grip 0.34, p=0.003; knee extension 0.45, p<0.001), distance covered in a 6 minute walk (0.34, p=0.002), inversely to RCS time (-0.42, p<0.001) and TUG (-0.27, p=0.019) but not to SGA, dialysis vintage or laboratory markers. For patients above and below age 70, sarcopenia was present in 75% and 62% respectively, defined by adjusted grip strength, and 54% and 45% defined by SPPB.

Conclusions: While some measures of sarcopenia increase with age, LTI does not, consistent with those patients at lower risk surviving longer. Ongoing assessment will determine which test or combination provides capacity to identify more vulnerable patients.

SA-PO518

Adjusting Dialysis Dose to Metabolic Rate or Body Surface Area Would Deliver Greater Dialysis to Under-Dialysed Groups Enric Vilar,[1,2] Laura Mawer,[1] Ashwini Machado,[1] Ken Farrington.[1,2] *[1]Renal Unit, Lister Hospital, Stevenage, United Kingdom; [2]University of Hertfordshire, Hatfield, United Kingdom.*

Background: In renal failure metabolic waste products accumulate which dialysis must remove. HD dose is adjusted according to body water using the equation Kt/V but this may under-dialyse women and those of low BMI. We studied the relationship between Watson volume, Resting Energy Expenditure(REE), and Body Surface Area(BSA) to determine whether an alternative denominator to V (Kt/REE or Kt/BSA) would provide more dialysis to at-risk groups.

Methods: Survival data were gathered retrospectively in 1016 patients dialysed over a 21 year period, excluding those transferred, transplanted or changing modality. At intervals residual renal function, Kt/V and V were recorded. BSA by the Dubois formula and REE by a novel formula were calculated, allowing Kt/BSA and Kt/REE to be estimated for

each patient. Survival was compared between genders and between those with BMI < or ≥22. Cox models compared survival between those with average Kt/V, Kt/BSA and Kt/REE above or below the median.

Results: Survival was similar between genders(p=0.9). Those with BMI<22 had inferior survival (HR for death 0.78[CI 0.64-0.96]) compared to those whose BMI was ≥22(p=0.03, median survival 3.9 v 4.6 years). REE/V was higher in women than men (p<0.0001) indicating that using Kt/REE instead of Kt/V would increase HD dose in females. BSA/V was higher in women than men (p<0.0001) and in those with BMI<22 (p=0.006), indicating that use of Kt/BSA would increase HD dose in females and slim individuals. Below median Kt/V was associated with a hazard for death of 1.31(CI 1.1-1.6,p<0.001) compared to above median Kt/V. This hazard was greater for Kt/BSA(1.44 [CI 1.2-1.7]) and Kt/REE (1.47 [CI 1.2-1.8] suggesting that Kt/REE and Kt/BSA may predict survival better than Kt/V.

Conclusions: BSA and REE are closely related. In HD worse survival in low BMI patients may be due to higher BSA/V or REE/V ratios. Kt/BSA and Kt/REE appear better survival predictors than Kt/V. A modified HD dose algorithm with these denominators will increase dose to apparently under-dialysed groups. Use of Kt/BSA or Kt/REE should be explored in prospective studies.

SA-PO519

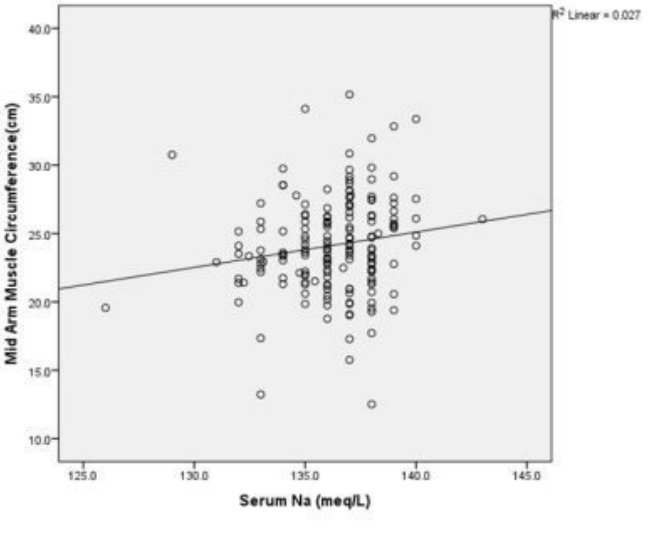
Low Serum Na Is Associated with Decreased Lean Body Mass and Increased Interdialytic Weight Gains Dimitrios J. Poulikakos, Nicholas Jason Lelos, Victoria Marks, Debasish Banerjee. *Renal and Transplantation, St George's Hospital NHS Trust, London, United Kingdom.*

Background: Low serum Na has been associated with increased mortality in hemodialysis patients. Hyponatremia is a recognised complication of inflammation and cytokine induced altered hypothalamic osmoregulation has been postulated. Hypothalamic inflammation is linked with muscle mass wasting in chronic kidney disease. Mid-arm muscle circumference (MAMC) is a good surrogate of muscle mass in haemodialysis patients. We examined the relationship between serum Na and muscle mass in dialysis patients.

Methods: 172 hemodialysis patients were included. Triceps skinfold thicknesses (TSF), mid-arm circumference (MAC), handgrip strength and subjective global assessment (SGA) were assessed using standard techniques. MAMC was calculated with the formula MAMC(cm) =MAC (cm)-3.142X TSF (cm). Annually averaged predialysis sodium and monthly routine laboratory measurements were used.

Results: Age was 66.1 ±14.37, female 62 (36%), diabetes 48 (28.9%), asian 34(19.8%), blacks 56 (32.6%), TSF (cm)1.95±.83, MAMC(cm) 24.1 ±3.52, TSF percentile ≥75th 86 (50%), MAMC percentile ≤10th 66 38%, Handgrip (kgs)25.1±13.1, SGA 5.36±1.14, dialysate Na 138(mEq/L), Serum Na 136.2±2.25, predialysis systolic BP (mmHg) 144.7±34.9, %IDWG 2.51±1.46, dry weight (kgs) 73.62±15.4, albumin 32.5±4.3,CRP 21.98±40.8.

Serum Na correlated positively with MAMC, handgrip and SGA (Pearson correlation r= 0.165, p=0.031, r=0.229 p=0.038 and r= 0.224 p=0.006 respectively) and negatively with %IDWG. Serum albumin correlated positively with lean body mass markers.Patients with serum Na <136.2 meq/L had larger interdialytic weight gains (T-test p=0.016).



Conclusions: This study demonstrates an association between low serum sodium and decreased muscle mass. In this cohort of muscle depleted patients large interdialytic weight gains may be related primarily to thirst.

SA-PO520

Serum Aldosterone Concentrations Relate to Fluid Overload (FO) and Serum Potassium Levels (SK^+) in Hemodialysis (HD) Patients (pts) Jochen G. Raimann,[1] Li Liu,[2] Fansan Zhu,[1] Adam Tashman,[3] Andrew S. Bomback,[4] Philip J. Klemmer,[5] Nathan W. Levin,[1] Peter Kotanko.[1] *[1]Renal Research Institute; [2]Peking University First Hospital; [3]University of California, Santa Barbara; [4]Columbia University; [5]UNC Chapel Hill.*

Background: Water and salt homeostasis and SK^+ stimulate aldosterone secretion. In HD pts a right-shifted relation between extracellular volume (ECV) and serum aldosterone was demonstrated (Bomback, 2009). This study aimed to investigate relations between FO [reflected by the ratio of ECV over total body water (TBW)] and SK^+.

Methods: Chronic HD pts underwent gradual reduction of post-HD weight. ECV/TBW [by whole body bioimpedance (DeLorenzo, 1997)], SK^+ (by direct potentiometry) and aldosterone (by ELISA) were measured pre-HD at baseline (BL) and repeatedly during post-HD weight reduction until end of study (End). T-Test, linear regression (LR), linear mixed models (LMM) and Likelihood Ratio Test (LRT) with two degrees of freedom for LMM comparison were employed.

Results: We studied 13 pts (age 55±14 years, 9 females, 8 Blacks, aldosterone 40±24 ng/dL, ECV/TBW 0.43±0.06, SK^+ 4.6±0.6) for 57±40 days. Pre HD weight changed (BL 76.4±14.8, End: 75.0±14.3; P<0.01), but no significant changes in ECV/TBW [0.01 (95% CI -0.012 to 0.04), SK^+ [0.12 (95% CI -0.4 to 0.6) mEq/L] and aldosterone [16.3 (95% CI -80 to 112) ng/dL] were found. LR showed a positive correlation between SK^+ and aldosterone at BL only (R^2=0.48; P=0.02). LRT determined a LMM with random slopes and intercepts (patients and days into the study) as appropriate. LMM showed significant fixed effects of ECV/TBW and SK^+ on aldosterone concentrations (**Table 1**).

Fixed Effects of serum potassium (SK+), ECV/TBW on serum aldosterone in a LMM with random slope and intercepts (pts and days into the study).

	Estimate	Standard error	P-value
Intercept	-2922.52	1020.85	0.008
ECV/TBW	6528.12	2410.02	0.011
SK+	874.30	252.18	0.002
ECV/TBW * SK+	-1733.64	593.36	0.006

Conclusions: Aldosterone concentrations related significantly to SK+ and ECV/TBW in the studied pts during gradual ECV reduction. The response mechanisms of aldosterone secretion to changes in ECV/TBW and SK+ appear intact in HD pts.

SA-PO521

Proton-NMR Metabolomics Reveals Impaired Lactate Metabolism in DM-Derived HD Patients Kazuhisa Takeuchi,[1,2] Itiro Ando,[1] Hiroshi Sekino,[2] Masako Fujiwara.[1] *[1]Graduate School of Pharmaceutical Science, Tohoku University, Sendai, Miyagi, Japan; [2]CKD Center, Koujinkai, Sendai, Miyagi, Japan.*

Background: Lactate has recently been shown as a factor that stimulates production of vascular endothelial growth factor (VEGF). We have tried to analyze the metabolites in HD patients using proton-NMR metabolomics, in which we have identified the signal corresponding to lactate. The aim of this study was to analyze the metabolites including lactate during HD by proton-NMR metabolomics.

Methods: Patients were enrolled after their informed consents had been obtained. The plasma and HD waste fluid were collected at several HD time points. Proton-NMR was measured by 600 MHz NMR spectrometer (JEOL ECA). For quantitation of signals, the flip angle for detection pulse was set to 90^o , and spectra were recorded with the repetition time 37.4 sec which ensure 99% signal recovery. For data analysis, "Alice2 for Metabolome" (JEOL) was used.

Results: The NMR metabolomics clearly demonstrated sharp peak signals of Cr, trimethylamine-*N*-oxide (TMAO), glucose, lactate, pyruvate and some amino acids. The signals of plasma Cr and TMAO were diminished during HD, whereas plasma lactate signals were not decreased but rather significantly increased in CGN-derived HD patients. In HD waste fluid, lactate signal was identified, and during HD the signal was also significantly increased in accordance with that of plasma. In DM-derived HD patients, however, the increase in lactate signals was absent. Pyruvate signal was also identified, and the ratio (Pyr/Lac) was almost half of normal levels.

Conclusions: By proton-NMR metabolomics, a change of metabolite during HD in both plasma and HD waste fluid can be analyzed. Lactate is produced during HD. In DM-derived HD patients, the lactate production is impaired, possibly leading to less VEGF production resulting in their more frequent cardiovascular complications.

SA-PO522

Normalized Protein Catabolic Rate, Not Muscle Mass, Is an Outcome Predictor in Patients Undergoing Maintenance Hemodialysis Ja Seon Kim,[2] Shin Sook Kang,[1] Eun Hee Kang,[1] Jai Won Chang,[2] Jung-Sik Park,[2] Kyung Sun Park.[3] *[1]Dietetics and Nutrition Service, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea; [2]Division of Nephrology, Internal Medicine, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea; [3]Division of Nephrology, Intenal Medicine, Ulsan University Hospital, University of Ulsan College of Medicine, Ulsan, Korea.*

Background: Detection of malnutrition is important because malnutrition is associated with the morbidity and mortality in end-stage renal disease (ESRD) patients on maintenance hemodialysis (MHD). This prospective observational study examined the relationship

among body composition, appetite, malnutrition inflammation score (MIS), nutrition intake, biochemical data, hospital stay and mortality in this population.

Methods: One hundred thirty seven patients (M:F=77:60, age 57.9±12.5 years) were enrolled. Individual patient's recent appetite status was scaled from 1 to 5 (very good, good, fair, poor, very poor). Bioimpedance analysis (BIA) was applied to estimate percentage body fat and muscle mass. We estimated nutrient intake by 1 day dietary recall. The MIS was used to evaluate the malnutrition inflammation complex syndrome. The patients were prospectively followed up for 5 years regarding mortality and hospitalization.

Results: During follow-up period, 25 patients died. Three patients who died from head trauma, traffic accident, and suicide were excluded. Compared with the survival group (n=112), non-survival group (n=22) revealed significant lower level of normalized protein catabolic rate (nPCR, 0.94±0.20 vs. 1.10±0.24, p=0.002), serum creatinine (9.5±2.8 vs. 11.1±2.7, p=0.019) and higher level of MIS (6.6±2.0 vs. 5.5±2.4, p=0.031) and hemoglobin (Hb, 11.3±1.2 vs. 10.7±1.0, p=0.016). Multivariate logistic regression analysis showed that nPCR (p=0.026) and Hb (p<0.01) were significant factors influencing the mortality of MHD patients.

Conclusions: Clinical parameter determining nutritional adequacy, nPCR, would be more important than anthropometric or bioimpedance indices for the survival in MHD patients. On the other hand, relatively high level of hemoglobin could be associated with the mortality in these patients.

SA-PO523

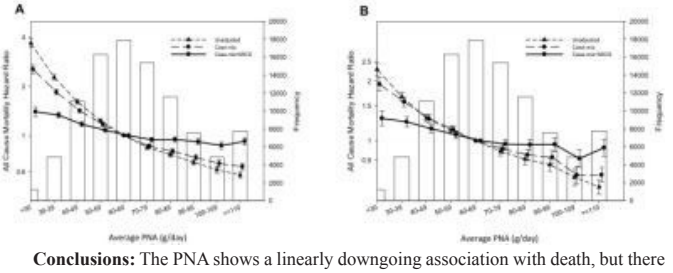
Implications of Dietary Protein Intake on Mortality in Long-Term Hemodialysis Patients

Vanessa A. Ravel,[1] Miklos Zsolt Molnar,[1] Elani Streja,[1] Jun Chul Kim,[1,4] Alla Victoroff,[1] Jennie Jing,[1] Keith C. Norris,[2] Csaba P. Kovesdy,[3] Joel D. Kopple,[4] Kamyar Kalantar-Zadeh.[1,4] *[1]Harold Simmons Center; [2]Charles R. Drew University; [3]University of Tennessee; [4]Harbor-UCLA.*

Background: Low and very high dietary protein intake, as measured by protein nitrogen appearance (PNA)(also known as protein catabolic rate [PCR]) have both been shown to influence mortality risk in maintenance hemodialysis patients (MHD). We examined 8-year all-cause mortality and PNA association.

Methods: Using clinical data from large dialysis provider's clinics, we identified 98,489 MHD patients. Mortality risks were estimated using unadjusted and malnutrition–inflammation complex syndrome (MICS) adjusted Cox proportional hazards regressions. PNA was calculated by multiplying nPCR times averaged dry weight.

Results: Patients were 64±15 years old and included 45% women and 59% diabetics. Compared with the reference level (60-69 g/day) low PNA (≤30 g/day, HR:1.40, 95%CI:1.30,1.50) was associated with higher mortality in each level of analysis (Figure A). In all patients, the best survival was associated with a PNA between 100 and 109 g/day. This range was shown to be optimal among hypoalbuminemic (serum albumin <3.5 g/dl) patients as well (Figure B).



Conclusions: The PNA shows a linearly downgoing association with death, but there is no association between high PNA and mortality. Using PNA as a dietary protein intake estimate per each individual was associated with increased risk of death in MHD patients using traditional case mix adjustments. However, after adjusting for MICS only a low daily protein intake is associated with increased risk of death in MHD patients. It is possible that the association between protein intake and survival is mediated by anorexia secondary to protein energy wasting, or additional factors. This possibility should be examined in intervention trials.

SA-PO524

Normalized Protein Catabolic Rate Is an Independent Predictor of Long-Term Survival in Peritoneal Dialysis Patients

Morrell M. Avram, Paul A. Fein, Priyanka Singh, Jyotiprakas Chattopadhyay. *Avram Division of Nephrology, S.U.N.Y. Downstate Medical Center UHB at Long Island College Hospital, Brooklyn, NY.*

Background: Normalized protein catabolic rate (nPCR) which reflects daily dietary protein intake in stable dialysis patients (pts) has been reported to be a predictor of mortality in hemodialysis pts. Objective of this study was to investigate the association between nPCR and long term survival in peritoneal (PD) pts.

Methods: Fifty seven PD pts were enrolled in the study from November 2000 to May 2008. On enrollment, demographic, clinical and biochemical data were recorded. Pts were followed through September 2011.

Results: The mean age was 56 years. Fifty-six percent were female and the majority (61%) were African descent. Mean and maximum follow-up were 2.83 and 10.80 years respectively. Mean and median nPCR were 0.944 and 0.910 g/kg/day respectively. Thirty-five per cent of the pts had nPCR below 0.8g/kg/day. Levels of albumin (p=0.049) and prealbumin (p=0.026) were significantly lower in pts with nPCR<0.8 compared to those with nPCR≥0.8g/kg/day. nPCR correlated directly with albumin (r=0.34, p=0.012), prealbumin (r=0.30, p=0.017), magnesium (r=0.48, p<0.0001) and phosphorus (r=0.42, p=0.002). Upon 11 years of observation, cumulative observed survival of pts with enrollment nPCR ≥0.8 was significantly better than those of pts with <0.8 g/kg/day (p=0.048). In multivariate Cox's regression analysis, after adjusting for confounding variables (table footnote), nPCR was an independent predictor of all cause mortality. For each 0.01 unit rise in nPCR, there was a 5.2% decrease in relative risk of mortality.

Multivariate Cox's Regression Analysis

Variable	Relative Risk	p
nPCR (g/kg/day) (x100)	0.948	0.018
Age (years)	1.044	0.03
Albumin (g/dL)	0.077	0.001

Other nonsignificant variables included in the model were body mass index, gender, race, diabetes, hypertension, dialysis vintage at enrollment, creatinine, blood urea nitrogen, hemoglobin and white blood cell count (WBC).

Conclusions: In conclusion, lower nPCR is associated with poorer nutritional status in PD pts. Lower nPCR is independently associated with increased risk of all cause mortality in PD pts followed up to 11 years.

SA-PO525

Improved Outcome by Application of Integrative Clinical Nutrition Dialysis Score (ICNDS) for Assessing of Nutritional Risk in Hemodialysis Patients

Zvi Barnea, Sara Blumberg Benyamini, Relu Cernes, Biro Alexander, Ze'ev Katzir. *Nephrology, Wolfson Medical Center, Holon, Israel.*

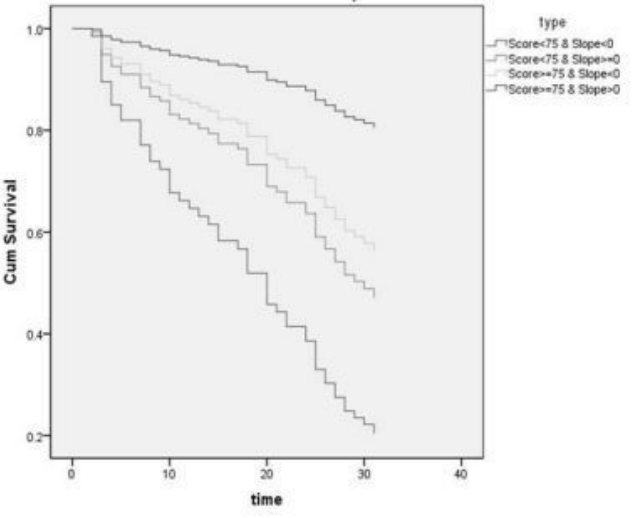
Background: The ***Integrative Clinical Nutrition Dialysis Score (ICNDS)*** is a new quantitative method for identifying nutritional risk in hemodialysis patients.

Methods: The method is based on monthly routine biochemical measures: Albumin, creatinine, urea, cholesterol, Kt/V, CRP, & dry weight change. Each parameter was given a scoring value from 1-5. A score of 5 for a NKF-K/DOQI recommended value & a lower one for sub-optimal values. The Scoring results are between 0-100 given for each patient. High & low Scores reflect a good & poor nutritional status respectively.

Components of ICNDS Score

	Score				
	1	**2**	**3**	**4**	**5**
Albumin	<2.0	2.01 - 2.99	3.0 - 3.49	3.5 - 4.0	>4.0
% Weight change	=>10%	-8% - -9.99%	-6% - -7.99%	-2 % - 5.99%	-2% - 0%
Creatinine	2 - 3.99	4 - 5.99	6 - 7.99	8 - 9.99	=>10
Urea	40 - 59	60 - 79	80 - 99	100 - 149	=>150
Cholesterol	<79.99	80 - 99	100 - 129	130 - 149	=> 150
CRP	>5	3 - 4.99	1.1 - 2.99	0.5 - 1.0	<0.49
Kt/V	<1.0	1.0 - 1.09	1.1 - 1.19	1.2 - 1.39	>1.4

Results: In 59 patients Score results were significantly correlated with SGA score. In 179 patients, baseline *score* was a significant inverse predictor of mortality & hospitalization: each 1-unit increase in score reduced mortality risk by 7.1%, & hospitalization risk by 6.5%. A 1- unit increase of *slope of monthly scores* (31 months) reduced mortality risk by 23.6% & hospitalization risk by 20.1%. A *threshold* Score => 75 reduced mortality by 64.2%. Patients were divided to 4 categories based on baseline *score* (above/below a threshold of 75) & *slope* of monthly scores (smaller/larger to 0).



Worsening nutrition status over time as indicated by both *score* & *slope*, significantly increased death hazard.

Conclusions: The ICNDS is a simple, useful & reliable tool for assessing HD patients' nutrition status which leads to early intervention & improving outcome.

SA-PO526

Determinants of Energy Expended during Physical Activity in Haemodialysis Patients Sivakumar Sridharan,[1] Jocelyn Berdeprado,[1] Enric Vilar,[2] Ken Farrington.[1] *[1]Renal Medicine, Lister Hospital, Stevenage, United Kingdom; [2]Renal Medicine, Basildon Hospital, Basildon, United Kingdom.*

Background: Haemodialysis(HD) patients have reduced levels of physical activity(PA). PA assessment may help to design further interventions in HD patients. Standard methods of measuring PA through accelerometers are not practical for routine clinical use.Self-report activity questionnaires could be a useful alternative.

Methods: Each study subject was administered the Recent Physical Activity Questionnaire(RPAQ) on attendance for a HD session. RPAQ has been validated for ranking individuals according to time spent in vigorous-intensity activity and overall energy expenditure.RPAQ enquires about time spent on activities at home, at work and during various recreational activities in the preceding 4 weeks. We assigned MET(metabolic equivalent of task) values for each activity. Resting energy expenditure(REE) was estimated using a novel predictive equation validated in renal failure. Total energy expenditure(TEE) was estimated from MET and REE. TEE estimation assumed 8 hours sleep and that the remaining unreported hours from RPAQ were spent in light activity.Energy Expenditure during physical activity(PAEE) was calculated as (TEE x 0.9) – REE.

Results: 282 HD patients(105 female, 177 male) completed the RPAQ. Mean age was 64.1(±15.2).There were 201 Whites, 51 Asians and 30 Blacks. Mean REE was 1535 kcal/day(±247), mean TEE 2149 kcal/day(±446) and mean PAEE 399 kcal/day(±214).Male patients, those aged < 65 and those who were employed had significantly higher REE, PAEE and TEE($p<0.001$ for all). There were significant differences in the above among different ethnic groups. TEE and PAEE were significantly less in those with heart disease.In stepwise multiple regression analysis, the independent determinants of log transformed PAEE were age, sex, employment status($p<0.001$ for all) and the presence of heart disease($p=0.01$) with these factors accounting for 57% of the variance in PAEE.

Conclusions: Mean daily MET values of the study subjects indicate a sedentary lifestyle for most HD patients. Age, sex, employment status and heart disease are the principal determinants of energy expended during physical activity in HD patients.

SA-PO527

Prognostic Utility of Plasma S100A12 Levels in Maintenance Hemodialysis Patients: A Novel Score System for Predicting Mortality Yasukiyo Mori,[1] Yayoi Shiotsu,[1] Eiko Matsuoka,[1] Keiichi Tamagaki,[1] Atsushi Kosaki.[2] *[1]Division of Nephrology, Department of Medicine, Kyoto Prefectural University of Medicine, Kyoto, Japan; [2]Faculty of Nursing, Setsunan University, Hirakata, Osaka, Japan.*

Background: S100A12 is an endogenous receptor ligand for advanced glycation end products. Here, we assessed plasma S100A12 levels as an independent mortality predictor and examined their utility in clinical settings.

Methods: We have measured plasma S100A12 levels in 550 maintenance hemodialysis (HD) patients to assess the association with the prevalence of cardiovascular disease (CVD) as the cross-sectional study, previously. In this study, we explored the prospective observation to examine the risk of two-year mortality.We also developed an integer scoring system with plasma S100A12 levels to predict mortality.

Results: We found that higher plasma S100A12 levels (≥ 18.79ng/mL) were associated with higher all-cause mortality compared with lower plasma S100A12 levels (< 18.79ng/mL) (P=0.001). Multivariable Cox proportional hazards analysis revealed higher plasma S100A12 levels (hazard ratio [HR], 2.267; 95% confidence interval [CI], 1.195-4.302; P = 0.012), age ≥ 65years (HR, 1.961; 95% CI, 1.017 - 3.781; P = 0.044), serum albumin < 3.5g/dL (HR, 2.198; 95% CI, 1.218 - 3.968; P = 0.012), and prevalence of history of CVD (HR, 2.068; 95% CI, 1.146 - 3.732; P = 0.016) to be the independent predictors of two-year all-cause mortality. The integer score was derived by assigning and totaling the points for these factors and was developed with trends across increasing score values for predictions of all-cause mortality (c-statistic = 0.730 [0.656 – 0.804]). The resulting model demonstrated good discriminative power for distinguishing the validation population from 303 HD patients (c-statistic = 0.721 [0.627 – 0.815]).

Conclusions: We concluded that the plasma S100A12 level is an independent predictor for two-year mortality. We therefore established the simple integer score for predicting mortality based on plasma S100A12 levels.

SA-PO528

The Association of the Geriatric Nutritional Risk Index and Total Lymphocyte Count with Mortality in Korean Hemodialysis Patients: A Single Center Study Yeon Soon Jung, Ye Na Kim, Ho Sik Shin, Hark Rim. *Internal Medicine, Kosin University College of Medicine, Busan, Republic of Korea.*

Background: Malnutrition is highly prevalent in maintenance HD patients and is associated with an increased risk of mortality. Recently, Kobayashi reported that GNRI was a significant predictor of mortality in HD patients. Evaluation of TLC was helpful in monitoring the nutritional status and assessing prognosis in PD patients. To date, there have been few longitudinal studies investigating the effect of the relationship between GNRI and TLC on mortality in hemodialysis patients. Thus, we sought to examine these outcomes.

Methods: We enrolled 120 patients receiving stable maintenance HD at Kosin University Gospel Hospital. Blood laboratory tests including TLC were performed once per month, and the data over three months were averaged. The GNRI was calculated by modifying the nutritional risk index for elderly patients, which was reported by Yamada. Survival curves were generated by the life table method. The relative risk of mortality for different parameters was estimated using the Cox proportional hazards model.

Results: Life table analysis revealed that subjects with GNRI < 90 (n = 19) had lower survival rates than did those with GNRI ≥ 90 (n = 101) (Wilcoxon test, P = 0.048), but subjects with TLC < 1500/mm^3 (n = 76) had similar survival rates compared to subjects with TLC ≥ 1500/mm^3 (n = 44) (Wilcoxon test, P = 0.500). TLC was marginally correlated with GNRI and significantly correlated with phosphorus.The association of GNRI ≥ 90 with TLC ≥ 1500/mm^3 excludes the occurrence of complications with moderate reliability.

Table 1. Main patient characteristics and outcomes

Variables	All patients (n = 2211)	Non-cancer patients (n = 1360, 61.5%)	Cancer patients (n = 851, 38.5%)	P-value
Age (years)	61.1 ± 14.1	61.4 ± 15.3	60.7 ± 12.1	0.221
Male gender	1356 (61.3%)	789 (58%)	567 (66.6%)	0.001
DM	833 (37.7%)	687 (50.5%)	146 (17.1%)	0.001
Sepsis	687 (31.1%)	442 (32.5%)	245 (28.7%)	0.001
Hospital mortality	671 (30.3%)	306 (22.5%)	365 (42.8%)	0.001
ICU admission	523 (23.7%)	385 (28.3%)	138 (16.2%)	0.001
ICU mortality	340 (65.0%)	230 (59.7%)	110 (79.9%)	0.001
Inotropics	607 (27.4%)	441 (30.2%)	166 (19.5%)	0.001
Mechanical ventilator	480 (21.7%)	385 (28.3%)	95 (11.2%)	0.001
Chronic hepatitis B	211 (9.5%)	93 (6.8%)	118 (13.8%)	0.001
Chronic hepatitis C	185 (8.4%)	114 (8.4%)	71 (8.3%)	0.512
Cause of death				
cancer	234 (34.9%)	NA	234 (64.2%)	
cerebrovascular disease	58 (8.6%)	51 (16.7%)	7 (1.9%)	0.001
heart disease	49 (7.3%)	45 (14.7%)	4 (1.0%)	0.001
DM	1 (0.2%)	1 (0.3%)	0	0.001
infection	273 (40.8%)	160 (52.3%)	113 (31.0%)	0.001
liver diease	53 (7.7%)	46 (15.0%)	7 (1.9%)	0.001
hypertensive disease	3 (0.5%)	3 (1.0%)	0	0.001
Type of cancer				
Locoregional solid tumor	189 (8.5%)		189 (22.2%)	NA
Metastatic solid tumor	604 (27.4%)		604 (71.0%)	
Hematological malignancy	58 (2.6%)		58 (6.8%)	
Cancer status				
controlled	143 (6.4%)	NA	143 (16.8%)	
uncontrolled/newly diagnosed	81 (3.6%)	NA	81 (9.5%)	
uncontrolled/recurrence progression	627 (28.3%)	NA	627 (73.8%)	

Conclusions: Our results indicate that GNRI is a significant predictor of mortality in HD patients and the use of TLC might improve the evaluation of nutritional risk, but additional studies are needed to confirm these findings.

SA-PO529

Subjective Global Assessment (SGA) and Effects of Aging on Biomarkers in Hemodialysis (HD) Patients (pts) Peter F. Barany,[1] Bengt Lindholm,[1,2] Olof Heimburger,[1] Abdul Rashid Tony Qureshi,[1,2] Peter Stenvinkel,[1] Thiane Gama Axelsson.[1,2] *[1]Renal Medicine, CLINTEC, Karolinska Institutet, Stockholm, Sweden; [2]Baxter Novum, CLINTEC, Karolinska Institutet, Stockholm, Sweden.*

Background: SGA is a simple and valid assessment of protein-energy wasting (PEW). Since the proportion of elderly dialysis patients grow, it is of interest to investigate how biomarkers behave in different age groups.

Methods: 224 non-selected prevalent HD pts were studied during a three month period and survival observed up to 42 months. Nutritional, inflammatory and cardiac biomarkers in plasma were measured before a HD session at baseline and weekly CRP values were obtained during 3 months. The pts were divided into two groups according to age, <65 y (n=110) and >65 y (n=114).

Results: As expected, comorbidity and the analyzed biomarkers (except adiponectin and leptin) differed significantly between the groups. However, the prevalence of poor nutritional status (SGA score >1) did not differ between pts <65 y and pts >65 y (46 vs. 48 %). Inflammatory activity as measured by median CRP over three months was higher in pts>65 y (median 8.2 vs. 4.9 mg/l in pts <65 y.

Spearman rank correlations (rho) to SGA in the two age groups

	<65 y	>65 y
Albumin	-0.47 [c]	-0.24 [a]
Creatinine	-0.41 [c]	-0.37 [c]
IGF-1	-0.30 [b]	-0.19 [a]
Leptin	-0.15	-0.07
Adiponectin	0.15	0.20 [a]
Ghrelin	0.20 [a]	0.02
CRP	0.36 [c]	0.16
IL-6	0.33 [c]	0.26 [b]
NT-proBNP	0.36 [c]	0.27 [b]

[a] $p<0.05$, [b] $p<0.01$, [c] $p<0.001$

In a logistic regression model the odds ratios for having SGA >1 were significant for albumin and creatinine in the <65 y-grp and for creatinine and NTproBNP in the >65 y-grp. SGA strongly predicted survival in both age groups. In Cox regression models including sex, comorbidity and SGA, a lower pre-dialysis s-creatinine was significantly associated with death in pts<65 y whereas in pts >65 y, a lower albumin was associated with a worse outcome.

Conclusions: Ageing, comorbidity and PEW needs to be accounted for when studying biomarkers in ESRD. The differences in the biomarkers in relation to age, SGA and survival suggests that causes of PEW partly may differ between age groups.

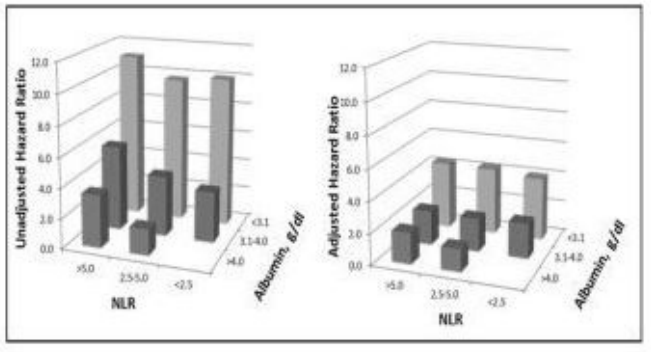
SA-PO530

Prognostic Significance of the Combination of Neutrophil-Lymphocute Ratio and Serum Albumin Levels in Incident Hemodialysis Patient
Rakesh Malhotra,[1] Len A. Usvyat,[2] Stephan Thijssen,[2] Yuedong Wang,[3] Nathan W. Levin,[2] Peter Kotanko.[2] *[1]UMDNJ-Newark; [2]Renal Research Institute; [3]University of California-Santa Barbara.*

Background: Neutrophil-Lymphocyte ratio (NLR) is a measure of systemic inflammation. The aim of the present study was to evaluate the prognostic significance of the combination of NLR and serum albumin in HD patients.

Methods: Incident HD patients treated in RRI clinics between 1/2000 & 12/2010 were included. In all patients contemporaneous measurements of neutrophil & lymphocyte counts & serum albumin levels were available. The analysis was restricted to first available lab parameters after the start of HD. NLR was calculated as simple ratio of absolute neutrophil & lymphocyte counts. The primary outcome was mortality over 3 years. Cox Model was used to determine the association of trichotomized NLR (< 2.5,2.5-5, >5.0) & albumin levels (<3.1,3.1–4.0,>4.0 g/dL) with mortality. The final model was adjusted for age, gender, race, diabetes, access type, BMI, residual function, body temp, SBP, nPCR, eKt/V, serum creatinine, & (total counts of WBCs, neutrophils, lymphocytes, platelets, platelet:lymphocyte ratio & PNI categories).

Results: 3297 patients were studied (median (IQR) age at start of dialysis 63 (51-73) yrs, 55% male, & 41% Blacks). During a follow-up of 3 yrs, there were 880 (26.7%) deaths. NLR>5.0 vs. <2.5 (unadjusted HR:2.1; P<0.0001) and albumin <3.1 g/dL vs. >4.0 g/dL (unadjusted HR:5.6; P<0.0001) was associated with poor survival. There was significant increase in hazard ratio with each stepwise increase in NLR or decrease in serum albumin levels.



Conclusions: The prognostic tool based on combination of NLR and serum albumin levels may be useful to identify incident HD patients who are at high risk of mortality. Addition of NLR and albumin to existing mortality risk prediction models may further improve their discriminatory ability.

SA-PO531

Correlations between Serum Albumin and Number of Intact Teeth in Relation to Selected Biomarkers (IL-G, FGF-23, PTH) in a Chronic Hemodialysis Randomized Cohort
Judith Beto,[1,2] Miriana Jelebinkov,[2] Ella Trepashko,[2] Kristiyana Kaneva,[1] Louis Scannicchio,[2] Vinod K. Bansal.[1] *[1]Nephrology, Loyola University Healthcare System, Maywood, IL; [2]Nutrition and Biological Sciences, Dominican University, River Forest, IL.*

Background: Hypoalbuminemia in chronic hemodialysis (HD) patients is multifactorial. Purpose: The purpose of this prospective study was to examine correlations between serum albumin (Alb) and number of intact teeth in relation to selected biomarkers in a randomized cohort of 72 chronic HD patients from a single independent dialysis unit.

Methods: Laboratory data collected from single blood draw in Jan 2012. Serum alb, standardized oral exam during prior quarter (Oct-Dec 2011). Analysis: FGF-23, IL-6 by standard ELISA (R&D, Millipore); alb by bromcresol purple. PTH, PO_4, calcium, vit D by assay; oral exam to count number of intact teeth. LOW (<3.6 mg/dl) and HIGH (≥3.6) alb categories calculated. T-test statistics by alb group and gender.

Results: LOW and HIGH alb groups were significantly different (p <0.05) by not by gender. A correlational relationship was seen between alb group and FGF-23, PTH, PO_4. An inverse relationship was seen for CRP-hs, IL-6A, and vitamin D. All patients deficient in Vitamin D. A linear trend relationship was seen for PTH, FGF-23, and PO_4. HIGH alb patients had significantly more intact teeth (p <0.05) compared to LOW alb patients.

TABLE 1:

	Alb g/dl	CRP-hs ug/ml	FGF-23/ PTH pg/ml	Phos mg/dl	IL-6 pg/ml	Vit D ng/ml	% Intact Teeth
Total n=72	3.36(0.3)	1.41(1.0)	2019(1679)/ 638(520)	5.5(1.4)	0.19(0.1)	24.2(13.3)	65(32)
LOW Alb n=52	3.24(0.2)**	1.56(1.1)	1807(1629)/ 609(464)	5.3(1.2)	0.21(0.1)	26.6(15.3)	63(33)**
HIGH Alb n=20	3.70(0.1)**	1.02(0.8)	2503(1728)/ 716(638)	5.9(1.2)	0.15(0.1)	21.7(10.4)	70(30)**
Female n=36	3.35(0.2)	1.38(1.0)	1454(1528)/ 645(508)	5.2(1.3)	0.20(0.1)	23.5(9.7)	62(36)
Male n=36	3.38(0.04)	1.44(0.9)	2546(1654)/ 621(615)	5.8(1.5)	0.18(0.1)	24.4(14.5)	67(29)

Results as mean (SD); **p<0.05 between groups

Conclusions: The percentage of intact teeth may be a simple screening method for albumin risk; no other factors appear to be significantly related in this prospective randomized cohort of HD patients.

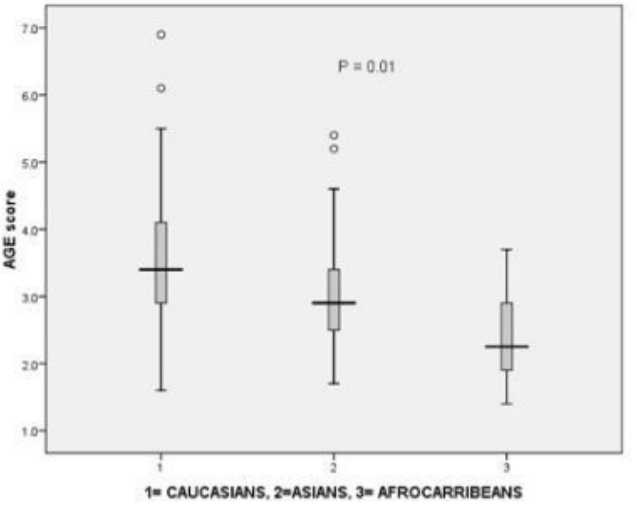
SA-PO532

Advance Glycation End Products (AGEs) in Chronic Dialysis Patients
Arkom Nongnuch,[1,2] Andrew Davenport.[2] *[1]Faculty of Medicine, Department of Medicine, Ramathibodi Hospital, Mahidol University, Bangkok, Thailand; [2]Centre for Nephrology, Royal Free Hospital, University College London, London, United Kingdom.*

Background: Cardiovascular disease (CVD) is the major cause of death in dialysis patients. There are both traditional and nontraditional risk factors for CVD in dialysis patients, including anemia, hyperphosphatemia, and biomarkers of inflammation. Advanced glycation end products (AGEs) are generated by the Maillard reaction and increased by oxidative stress, and normally metabolized and excreted by kidney, so accumulate in the chronic kidney disease (CKD). Many studies have reported elevated AGEs as cardiovascular risk factors.

Methods: We measured AGEs using a skin autofluorescence (AF) method (DiagnOptics, Groningen, Netherland) in the non-fistula arm of 178 chronic hemodialysis patients.

Results: The patients mean age 63 ± 14.9 years, 58 (32.6%) female, 66 (37%) diabetic and 102 (57.3%) Caucasian, skin AF score for AGEs 3.2 ±9.6 AU, and highest 3.56 ± 0.9 AU in Caucasian population, vs 2.98 ±0.88 AU in Asians and 2.38 ± 0.61 AU in AfroCarribeans (Figure 1), despite diabetes being lowest in Caucasian group.



There was no association between AF-AGEs and age, gender, dialysis vintage, hemodiafiltration, smoking status, history of hypertension, diabetes, peripheral vascular disease, CRP, B2 microglobulin and HbA1C, but AF AGEs were increased in patients with known cardiovascular disease (3.78 ± 0.97 VS 3.01 ± 0.88, p =0.01).

Conclusions: Skin AF AGEs were measured in a multi-ethnic dialysis population and found highest in those with known cardiovascular disease, and may prove to be a simple method for assessing cardiovascular risk.

SA-PO533

Reliability of Measuring Advanced Glycation End Products by Non Invasive Technique in a Multiethnic Haemodialysis Population
Andrew Davenport, Saurabh Chaudhri. *Department of Nephrology, Royal Free Hospital, London, United Kingdom.*

Background: Advanced Glycation end products (AGE) have long been implicated in increasing cardiovascular risk in chronic systemic diseases. Non-invasive methods are now available using its property to fluoresce when exposed to certain wavelength of light. This has led to development of autofluorescence readers (AFR) to measure AGE.

Methods: We measured AGE values using AGE Reader by Diagnoptics Technologies. Mean of 3 values was used to measure AGE concentration in both arms of patients on haemodialysis or haemodiafiltration. Pre and post dialysis readings were also taken in a randomly selected group.

Results: 139 patients were tested (65% males). Data was also collected for ethnicity, gender, access, diabetes, HbA_1C, Beta 2 microglobulin, urine output and RRT modality (HD or HDF).

AGE readings by autofluorescence were found to be to be significantly higher in Caucasians in comparison to Black (mean difference 0.61, p=0.041) and South Asian (mean difference 0.86, p=0.04) population.

In patients with L sided fistula (N= 71) AGE levels were significantly lower in the L arm (3.20 ± 0.79 vs 3.46 ± 0.69, p=0.04) in comparison to the R arm.

AGE levels were also significantly lower in the fistula arm post dialysis in these patients (3.4± 0.54 vs 3.89 ± 0.66, p=0.007).

There was no difference in either arm predialysis (3.23±0.83 in R vs 3.10±0.87 in L) or post dialysis (pre vs post dialysis: p value 0.64 for L arm and 0.85 for R arm). No difference was seen based on variation in gender or modality of RRT.

Conclusions: We have applied this non-invasive technique to a multiethnic group of patients on HD/HDF to show it can be used in a clinical setting.

The results show AGE values to be lower in the (L) fistula arm predialysis and reduce significantly post dialysis.

In patients dialysing with a catheter there was no difference in the AGE reading between the two arms or pre or post dialysis in each arm.

This would suggest measurement of AGE levels in dialysis patients should be done in the non fistula arm and irrespective of the timing (pre or post dialysis). Levels can be done in either arm in patients dialysing with a catheter using this technique.

SA-PO534

Patients in Chronic Hemodialysis Present Increased Indoleamine 2,3-Dioxygenase (IDO) Activity: A Clue for Uremic Immunodeficiency?

Davide Defedele,[2] Elisa Loiacono,[1] Maria Paola Puccinelli,[2] Licia Peruzzi,[1] Stefano Maffei,[3] Roberta Camilla,[1] Rachele Gallo,[1] Giorgio Triolo,[3] Daniela Bergamo,[3] Elena Palazzo,[2] Alessandro Amore,[1] Rosanna Coppo.[1] *[1]Nephrology, Dialysis, Transplantation, R. Margherita Hospital, Turin, Italy; [2]Diagnostic Department, R. Margherita Hospital, Turin, Italy; [3]Nephrology and Dialysis, CTO-M. Adelaide Hospital, Turin, Italy.*

Background: T cell activity has been reported to be depressed in patients in dialysis (HD), in whom regulatory Tcells (Tregs) have been poorly investigated. Since the enzyme indoleamine 2,-dioxygenase (IDO) is known to trigger the suppressive activity of Tregs, we aimed this study at investigating IDO's activity in HD patients looking at the effect of dialysis and correlations with markers of oxidative stress.

Methods: IDO activity was assessed in sera of 52 HD patients (21-88 y.o.) and 20 healthy controls (HC) as change in the ratio between tryptophan (Trp) and its catabolic product kynurenine (Kyn), determined by isocratic RP HPLC with UV detection. Patients were tested before and after HD (26 bicarbonate HD, 26 hemodiafiltration). Markers of oxidative stress (advanced oxidated protein products-AOPP and C reactive protein-CRP) were also tested.

Results: Before HD session Trp levels were significantly lower than in HC (20.44± 7.39 vs 54.37 ± 5.97 µmol/l, P< 0.0001), Kyn levels were significantly higher (4.32± 2.06 vs 2.02± 0.32 µmol/l, P< 0.0001) and the Kyn/Trp ratio, indicating IDO activity, was significantly increased (21.78± 8.06 vs 3.73± 0.55, P< 0.0001). During HD sessions, Trp levels remained unchanged, while Kyn levels significantly decreased (2.49± 1.09 µmol/l, P< 0.0001) producing a significant decrease in Kyn/Trp ratio (11.75± 4.02, P< 0.0001). No correlation was found with signs of oxidative stress (AOPP or CRP levels). No difference was found between patients receiving bicarbonate HD or HDF.

Conclusions: In patients in chronic HD we detected an enhanced activity of IDO, not related with signs of oxidative stress and dialysis modalities, which was partially corrected by the dialysis sessions. The activation of IDO's regulated pathways is expected to depress immune system functions, a feature well known in uremic patients.

SA-PO535

Identifying the Uremic Compounds Specifically Involved in the Pathophysiology of Hemodialysis Patients by Capillary Electrophoresis Mass Spectrometry

Yasutoshi Akiyama,[1,2] Yoichi Takeuchi,[2,5] Eikan Mishima,[2] Takehiro Suzuki,[2] Sadayoshi Ito,[2] Tomoyoshi Soga,[3] Takaaki Abe.[2,4,5] *[1]Department of Community Health Promotion, Tohoku University Graduate School of Medicine, Sendai, Japan; [2]Division of Nephrology, Endocrinology and Vascular Medicine, Tohoku University Hospital, Sendai, Japan; [3]Institute for Advanced Biosciences, Keio University, Tsuruoka, Japan; [4]Division of Medical Science, Tohoku University Graduate School of Biomedical Engineering, Sendai, Japan; [5]Department of Clinical Biology and Hormonal Regulation, Tohoku University Graduate School of Medicine, Sendai, Japan.*

Background: It is suggested that uremic toxins are involved in the pathophysiology of hemodialysis (HD) patients, such as malnutrition-inflammation-atherosclerosis (MIA) syndrome. However, the profile of the uremic compounds in HD patients remains largely unknown.

Methods: We collected serum samples of both pre- and post-HD from 11 HD patients and comprehensively evaluated the concentrations of 119 compounds (53 anions and 66 cations) by capillary electrophoresis mass spectrometry (CE-MS). And the results of pre- and post-HD were compared with those of the CKD patients not undergoing HD we previously reported (Hypertens Res 2010).

Results: Serum concentrations of 33 compounds (19 anions and 14 cations) were significantly higher in pre-HD than those in the patients with CKD stage 5. Among them, 13 anions and 10 cations were removed to the same or below the level of CKD stage 5 by HD. However, serum concentrations of 6 anions (malonate, fumarate, adipate, decanoate, benzoate, N-acetylneuraminate) and 4 cations (Indole-3-acetate, tyrosine, glycerophosphorylcholine and ADMA) were significantly higher in both pre- and post-HD than those of CKD stage 5. On the other hand, 9 compounds (4 anions and 5 cations), which were detected in CKD patients not undergoing HD, were not detected in HD patients.

Conclusions: It was shown that HD patients have the different profile of uremic compounds compared with that of CKD patients not undergoing HD. These 33 compounds whose serum concentrations were higher than those in the patients with CKD stage 5 may be involved with the HD patients-specific pathophysiology.

Metabolic Profiling Detects Metabolites Associated with Mortality in Hemodialysis Patients

Quinlyn A. Soltow,[1] Rebecca H. Zhang,[1] Tess Bowles,[1] Dean P. Jones,[2] Nancy G. Kutner,[1] George A. Kaysen.[3] *[1]USRDS Rehabilitation/QoL Special Studies Ctr, Emory Univ., Atlanta, GA; [2]Medicine; Clinical Biomarkers Laboratory, Emory Univ., Atlanta, GA; [3]USRDS Nutrition Special Studies Ctr, UCSF/UCDavis, Davis, CA.*

Background: Circulating biomarkers may identify high-risk hemodiaysis (HD) patients. The ongoing USRDS special study, ACTIVE/ADIPOSE, includes serial collection of blood biomarkers. In an adjunct study, our group is using metabolomics to investigate specific metabolites and metabolic patterns that may be associated with clinical outcomes, including mortality.

Methods: Prevalent patients undergoing HD in Atlanta GA clinics supplied plasma samples at 6-month intervals over an 18-month period. Metabolic profiles of 17 patients who died after study start were compared with profiles of 21 surviving patients who had similar age, race, sex, and HD vintage, using a dual chromatography-LTQ-Velos Orbitrap mass spectrometry (DC-Orbi) method developed at Emory University to generate global metabolic profiles.

Results: The mean (S.D.) ages of deceased and surviving patients, respectively, were 56.7 (13.1) and 58.7 (12.6) at study start, with mean (S.D.) vintage 5.6 (5.0) and 5.5 (4.2) years. All patients were African-American with 57% and 43% male. The DC-Orbi-based metabolomics method detected over 40,000 metabolic features from the 72 plasma samples. Data reduction techniques separated metabolic patterns associated with subsequent mortality (principal component analysis) and identified 81 metabolic features changing significantly between survivors and non-survivors over time (false discovery rate, q=20). Among these features, pathway analysis matched metabolites related to carnitines, biopterins, amino sugars, and amino acids as significantly overrepresented.

Conclusions: Metabolic patterns detected by DC-Orbi indicated metabolic features relating to carnitines (reduced in deceased patients) and amino sugars (increased in deceased patients) which changed over time. Metabolic profiling allows detection of metabolic patterns that may identify HD patients who are at significantly increased risk for mortality and who could potentially benefit from targeted interventions.

SA-PO537

Elimination of Proteins by Dialysis and Different Hemodiafiltration Methods

Jaromir Eiselt, Jan Mares, Jiri Moravec, Jan Klaboch. *Internal Dept. 1, Charles University, Plzen, Czech Republic.*

Background: Various arrangements of hemodiafiltration (HDF) have been introduced to increase the efficacy of hemodialysis (HD). However, also concerns regarding elimination of vital substances emerge.

Methods: The aim of our study was to evaluate elimination of proteins across a wide range of molecular weights (MW) in HD and two HDF methods. A total of 8 dialysis patients were treated in a cross-sectional design with 1) mixed HDF (mHDF, a combination of pre- and postdilution administration of substitution solution), 2) postdilution HDF (pHDF), and 3) HD; all procedures were performed with high-flux polysulfon (Helixon FX1000) dialyzers. Dialysate was collected with the Dialysate Sampling System (Fresenius); the ratio between dialysate sampled and produced was 1:60. A total volume of substitution was 44±4.5 L (pre/post ratio 1.16) in mHDF, and 22±2.3 L in pHDF. Protein concentration in dialysate was measured and proteins resolved by 2D-PAGE and identified by mass spectrometry (MALDI-TOF/TOF). Elimination selectivity of a specific protein was calculated as a ratio of spot volume of mHDF/HD, and pHDF/HD, respectively.

Results: The highest protein elimination was found in mHDF [13.7 g (8.9-17.7), median (interq. range), p<0.05 vs. HD and pHDF], lower in pHDF [6.8 (5.2-10.3, p<0.05 vs. HD] and the lowest in HD [1,9 (1.8-2.2)], ANOVA and Tukey test. In the dialysate 17 proteins with MW from 10 to 80 kDa were identified and matched among the three groups. Elimination selectivity of each protein (ratio of the spot volume in HDF/HD) was 9.6±25.4 (mean±SD) for mHDF and 1.9±4.3 for pHDF. In mHDF the elimination selectivity increased linearly with MW (r=0.59, p=0.015; Spearman correl.), whereas in pHDF it was independent of MW (r=0.26, p=0.3). mHDF seems to remove preferentially larger molecules. Proteins falling into this category were vitamin D binding protein, fetuin A, transthyretin, zinc-α-2-glycoprotein etc.

Conclusions: mHDF removes plasma proteins more effectively than pHDF or HD. Due to high filtration volume mHDF has the potential to remove high MW toxins but at the expense of elimination of useful proteins. Clinical relevance of this ambivalent effect must be tested in long term studies.

Vitamin D and Cognitive Function in Maintenance Hemodialysis Patients

Saeed K. Shaffi,[1] David A. Drew,[1] Hocine Tighiouart,[1] Kristina Lou,[1] Daniel E. Weiner,[1] Mark J. Sarnak.[1] *[1]Nephrology, Tufts Medical Center, Boston, MA; [2]Tufts University.*

Background: Vitamin D deficiency and cognitive impairment are both prevalent in US hemodialysis patients. We hypothesized that Vitamin D deficiency may be associated with cognitive impairment due to the vasculo-protective, neuro-protective and immune-modulatory effects of (25 OH) Vitamin D.

Methods: We conducted a cross sectional analysis of 255 patients from the Dialysis and Cognition Study. In linear regression models, Vitamin D was the exposure variable; used first as a continuous variable and then stratified according to the Institute of Medicine guidelines as deficient (<11.9 ng/dl), insufficient (12-19.9 ng/dl) and sufficient (> 20 ng/dl). Principal component analysis was used to obtain the memory and the executive function domains from the individual neuro-cognitive tests. Scores on the individual tests as well as on the memory and executive function domains were used as the outcome variables. Multivariable models were adjusted for age, sex, race, education and other potential confounding variables.

Results: Mean (SD) serum Vitamin D was 17.2 ± 7.4 ng/dl, with 36, 139 and 80 patients in the deficient, insufficient and sufficient groups, respectively. Patients in the deficient group were more likely to be women, African American, diabetic and have longer dialysis vintage. Higher Vitamin D levels were independently associated with better performance on tests assessing executive function, with no association seen with tests assessing memory.

Table: Association between Vitamin D Level and Cognitive Performance

Cognitive Test/Component	Function Tested	Unadjusted		Adjusted	
		Beta	p-value	Beta	p-value
Executive Factor	Composite of 'executive' tests	0.11	0.09	0.14	0.01
Memory Factor	Composite of 'memory tests'	-0.14	0.03	-0.05	0.41
Mini-Mental State Exam	Screen	0.05	0.80	0.22	0.23
Short Delayed Recall	Working memory, recognition, and memory	-0.18	0.33	0.08	0.63
Delayed Recall		-0.30	0.09	-0.05	0.75
Recognition		-0.31	0.11	-0.21	0.28
Block Design	Executive function, processing speed and attention	0.20	0.78	0.24	0.71
Digit Symbol Coding		0.48	0.68	2.02	0.03
Trails A		-4.04	0.15	-5.85	0.04
Trails B		-7.55	0.33	-11.52	0.08

Adjusted for age, sex, race, education, diabetes, smoking, high (May-August) and low (all other months) sunlight months, dialysis vintage and BMI.
Principal component analysis was used to calculate scores on Executive and Memory components, which have a mean of 0 and SD of 1, with positive values representing better performance. Beta coefficients represent a difference in performance on cognitive tests per 1 SD (7.4 ng/dl) higher Vitamin D level. Higher coefficients represent better performance except for Trails A and B where a higher score denotes worse performance.

Conclusions: In conclusion, Vitamin D deficiency in hemodialysis patients is associated with worse cognitive function, particularly in executive domains which are associated with cerebrovascular disease.

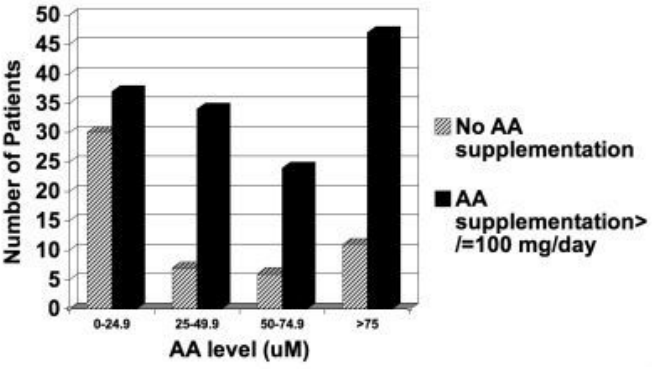
SA-PO539

Relationship of Ascorbic Acid Levels to Vitamin Supplementation in a Prevalent Hemodialysis Population Garry J. Handelman,[2] Nathan W. Levin,[3] Peter Kotanko,[3] Robert L. Benz,[4] Amanda Logan,[1] Jose Albert Avila,[1] Deepali Prasad,[1] Lawrence S. Weisberg,[1] William D. Sirover.[1] *[1]Division of Nephrology, Cooper Medical School of Rowan University, Camden, NJ; [2]Dept of Nutrition, Univ. of Mass at Lowell, Lowell, MA; [3]Renal Research Institute, NY, NY; [4]Division of Nephrology, Lankenau Hospital, Wynnewood, PA.*

Background: Ascorbic acid (AA) is critical for supporting erythropoiesis. AA is cleared by hemodialysis (HD) and patients have the potential to become deficient. AA deficiency is a significant issue as it may require patients to receive higher dosages of erythropoiesis stimulating agents (ESA) in an effort to achieve target hemoglobin level. Some patients take 100 mg/day of supplemental AA that is part of a specially-formulated multivitamin. One cross-sectional study suggests that plasma AA levels <75 μM lead to ESA hyporesponsiveness. We hypothesize that HD patients can have low AA levels even with AA supplementation.

Methods: Pre-HD plasma samples for 196 patients were obtained in the outpatient setting on a Monday or Tuesday after a 72-hour hiatus from HD. Patients' supplemental vitamin intake were reviewed.

Results: One hundred and thirty eight patients (70%), 95 (69%) of whom were taking at least 100 mg of supplemental AA, had plasma AA levels< 75.



Conclusions: These results indicate that the majority of patients will require more than 100 mg of supplemental AA to achieve a plasma AA level >75 μM. Without supplementation, these patients may require higher ESA doses. AA is metabolized to oxalate. Due to decreased urinary oxalate excretion in end stage renal disease, oxalate has the potential to pathologically deposit in organs and cause oxalosis. Further research is needed to determine the risk of oxalosis in HD patients who receive supplemental AA in amounts greater than that in a multivitamin.

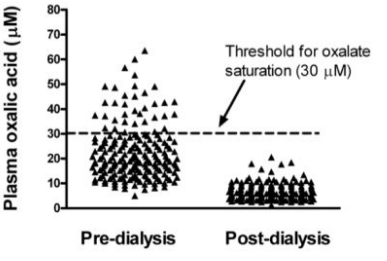
SA-PO540

Plasma Oxalate and Ascorbic Acid Levels in a Prevalent Hemodialysis Population William D. Sirover,[1] Yuguan Liu,[2] Jose Albert Avila,[1] Deepali Prasad,[1] Amanda Logan,[1] Craig B. Langman,[4] Nathan W. Levin,[3] Peter Kotanko,[3] Jeffrey S. Berns,[5] Lawrence S. Weisberg,[1] Garry J. Handelman.[2] *[1]Division of Nephrology, Cooper Medical School of Rowan University, Camden, NJ; [2]Dept of Nutrition, Univ. of MA at Lowell, Lowell, MA; [3]Renal Research Institute, NY, NY; [4]Division of Nephrology, Northwestern University, Chicago, IL; [5]Division of Nephrology, Univ. of PA, Philadelphia, PA.*

Background: Oxalate (Ox) is a metabolite of ascorbic acid (AA) and oxalosis may occur in hemodialysis (HD) patients, as oxalate may pathologically accumulate due to decreased urinary excretion. AA increases iron availability and utilization for erythropoiesis. More information about Ox kinetics is needed before administering AA in a placebo-controlled trial. At plasma Ox levels>30uM, calcium-oxalate supersaturation threshold is reached and oxalosis may occur. Additional evidence in pediatric patients suggests that oxalosis does not develop when pre-HD Ox is >30uM, if post-HD Ox is <30uM. This study tested the hypotheses that pre-HD Ox directly correlates with pre-HD AA and that contemporary HD treatments result in post-HD Ox<30 uM.

Methods: Pre-HD and post-HD plasma samples for 196 patients were obtained in the outpatient setting on a Monday or Tuesday after a 72-hour hiatus from HD.

Results: Pre-HD Ox values ranged from 5.01 to 63.6 uM (mean 22.5 +/- 11.1 uM). Post-HD Ox levels ranged from 1.3 to 20.6 uM (mean 6.4 +/- 3.2 uM). Pre-HD AA ranged from 1.8 to 409.3 uM (mean 65.6 +/- 71.5 uM). Pre-HD Ox correlated directly with pre-HD AA ($p<0.05$).



Conclusions: While oxalate may precipitate temporarily if pre-HD Ox is >30 uM, we demonstrate in adults that oxalate clearance by HD yields post-HD Ox levels that will likely prevent the development of oxalosis. Further research is needed to determine if oxalosis is present if pre-HD Ox is >30 uM.

SA-PO541

The Impact of Vitamin K_1 Supplementation on Biomarkers of Vitamin K in Hemodialysis Patients: A Randomized Trial Rachel M. Holden,[1] Wilma M. Hopman,[3] Amanda Antczak.[2] *[1]Medicine, Queen's University, Kingston, ON, Canada; [2]Jean Mayer USDA Human Nutrition Research Center of Aging, Tufts University, Boston, MA; [3]Clinical Research Center, Kingston General Hospital, Kingston, ON, Canada.*

Background: Sub-clinical vitamin K deficiency is common in hemodialysis (HD) patients and may be a modifiable risk factor for cardiovascular disease. We aimed to investigate whether short-term vitamin K_1 supplementation improved biomarkers of vitamin K status in HD patients, assessed by circulating vitamin K and uncarboxylated prothrombin (PIVKA-II [protein induced by vitamin K absence]).

Methods: Ths was an interventional randomized placebo-controlled crossover trial. Investigators and patients were blinded to the participant's order of treatment allocation. Twenty (male=12, female=8) prevalent stable HD patients were treated with 1 mg of vitamin K_1 daily versus matching placebo for 2 weeks with a 4 week wash-out period between treatments. Absolute and percent change in plasma levels of vitamin K_1 and PIVKA-II were determined by HPLC and ELISA respectively.

Results: Two subjects were withdrawn from the study due to acute hospitalization. The baseline mean vitamin K_1 level was 0.9±1.0 nmol/L and 0.7±0.6 nmol/L for vitamin K_1 and placebo respectively (p=0.3). The mean increase in vitamin K_1 level in response to supplementation was 6.7 nmol/L (4.0-10.0, P<0.0001) versus 0.6 nmol/L (0.3-1.0, p=.001) in the placebo group (p<0.001). There was a 36.5% reduction in PIVKA-II levels with vitamin K_1 supplementation (1.9 ± 1.3 to1.0 ± 0.5, p=0.002) versus a 10% increase (1.5±1.2 to 1.7±1.4, p=0.07) with placebo (p<0.001). Post-vitamin K_1 supplementation, 94.1% of subjects were in the normal range for PIVKA-II.

Conclusions: This study shows that biomarkers of vitamin K status respond to short-term supplementation with vitamin K_1. Studies evaluating the impact of vitamin K_1 supplementation on cardiovascular outcomes are warranted.

SA-PO542

Phosphate Binders and Thyroid Replacement Therapy in Dialysis Patients: Retrospective Review Yin L. Win, Nnamdi K. Nwaohiri, Farhanah Yousaf, Haroon Rashid, Chaim Charytan, Bruce S. Spinowitz. *Division of Nephrology, New York Hospital Queens, Flushing, NY.*

Background: Prevalence of hypothyroidism among ESRD patients is increased. These patients are frequently prescribed levothyroxine. Many hypothyroid ESRD patients are also taking phosphate binders which could interact with levothyroxine. We explored the prevalence of hypothyroidism and studied the effect of phosphate binders on thyroid profile and thyroid replacement therapy in dialysis patients.

Methods: Medical records of prevalent dialysis patients were reviewed. Patients with prescription order of levothyroxine were grouped according to phosphate binder use; none (G0), sevelamer only (G1), calcium acetate (G2), calcium acetate plus sevelamer (G3), and calcium acetate plus lanthanum carbonate (G4). TSH, T3, T4 as well as monthly doses of levothyroxine and phosphate binders were tabulated.

Results: 342 patients were registered at Trude Dialysis Center between Sep 2008 and Mar 2012. 54 (16%) of 342 patients (27M/27F) had a prescription order for levothyroxine. Fifteen patients were excluded for non-compliance with prescribed phosphate binders or insufficient data.

Table 1: Thyroid Profile

	G0 (n=7)	G1 (n=11)	G2 (n=9)	G3 (n=9)	G4 (n=3)
TSH	2.40	4.81	3.19	5.53	4.15
T3	0.71	0.70	0.76	0.65	0.78
T4	5.31	7.28	8.10	5.83	5.51
Levothyroxine Dose (µg)	80	108	80	100	216*

*p<0.05

Table 2: Relationship of Binder Dose Increase with Levothyroxine Dose Increase

	G1 n=11	G2 n=9	G3 n=9	G4 n=3	Total
Stable Binder Dose	0/5[¶]	0/5	0/4	0/2	0/16
Increase in Binder Dose	5/6	2/4	2/5	1/1	10/16*

*p<0.05

[¶] number of patients with levothyroxine dose increase / total number of patients in group

Conclusions: Our study confirms a high prevalence of hypothyroidism among dialysis patients. TSH was higher in the phosphate binder groups versus no phosphate binder group. Patients taking lanthanum carbonate with calcium acetate may require higher doses of levothyroxine. A statistically significant number of dose increases of levothyroxine were necessary following a dose increase in phosphate binders. Larger longitudinal studies are warranted to define the impact of phosphate binders on thyroid profile and thyroid replacement therapy in dialysis patients.

SA-PO543

Effects of Intradialytic Whey Protein Supplementation on Body Composition in Non-Malnourished Hemodialysis Patients Peter J. Fitschen,[1] Brandon Kistler,[1] Pei-tzu Wu,[1] Hae Ryong Chung,[1] Jin Hee Jeong,[1] Shane Phillips,[2] Ken Wilund.[1] *[1]University of Illinois, Urbana, IL; [2]University of Illinois - Chicago, Chicago, IL.*

Background: Malnutrition is common in maintenance hemodialysis (MH) patients and results in a significantly increased risk of mortality. Moreover, an inverse relationship between body mass index (BMI) and mortality has been shown in MH patients suggesting that an increased BMI may be protective in this population. However, it is not clear if the protective effect of BMI is due to lean or fat mass. Previous nutritional interventions in malnourished MH patients (albumin ≤3.5g/dl) have shown that nutritional supplementation (NS) improves albumin, survival, and bodyweight. However, the effects of NS on body composition in non-malnourished MH patients are not clear.

Methods: The purpose of this study was to examine the effects of intradialytic whey protein supplementation on body composition in non-malnourished MH patients. MH patients (n=23, albumin = 4.0±0.1g/dl) were randomly assigned to intradialytic whey protein (Whey, n=13) or non-nutritive placebo (Con, n=10). All beverages were consumed at the beginning of the dialysis session thrice weekly for 6 months. Body composition was assessed by DXA at baseline and 6 months. Scans were performed 24±3 hrs after dialysis to reduce variations in water balance.

Results: After 6 months, there were no significant changes in BMI. However, change in fat mass was significantly different between groups (p=0.003). A significant increase in fat mass was observed in Con (p=0.042) and a significant decrease in fat mass was observed in Whey (p=0.033). There was a trend for an increase in lean mass in Whey (p=0.051); however, no change in lean mass was observed in Con.

Conclusions: These preliminary results from our ongoing trial suggest that 6 months of intradialytic whey protein supplementation may result in changes in body composition in non-malnourished MH patients. Future studies are needed to determine the effects of interventions that change body composition on outcomes in MH patients.

Gastrointestinal Factors and Glucometabolic Disturbances in Non-Diabetic Patients with End-Stage Renal Disease Thomas Idorn,[1] Filip K. Knop,[2,3] Morten Jørgensen,[1] Jens Juul Holst,[3] Mads Hornum,[1] Bo Feldt-Rasmussen.[1] *[1]Department of Nephrology, Rigshospitalet, Copenhagen University Hospital, Copenhagen Ø, Denmark; [2]Diabetes Research Division, Department of Internal Medicine, Gentofte Hospital, Hellerup, Denmark; [3]Department of Biomedical Sciences, The Panum Institute, University of Copenhagen, Copenhagen N, Denmark.*

Background: Non-diabetic patients with end-stage renal disease (ESRD) have disturbed glucose metabolism. The underlying pathophysiology remains to be elucidated. We evaluated gastrointestinally-mediated glucose disposal (GIGD), incretin effect and secretory responses of glucagon and the two incretin hormones glucagon-like peptide-1 (GLP-1) and glucose-dependent insulinotropic polypeptide (GIP) (parameters, which are all impaired in diabetic subjects with normal kidney function) in non-diabetic ESRD patients.

Methods: Three groups were investigated: ESRD with normal glucose tolerance (NGT; *N*=10), ESRD with impaired glucose tolerance (IGT; *N*=10) and healthy control subjects (CTRL; *N*=11). Examinations included 75 g-oral glucose tolerance test and isoglycemic intravenous (iv) glucose infusion on separate days. Plasma glucose, insulin, glucagon and total forms of GLP-1 and GIP were measured repeatedly. GIGD, based on glucose amounts utilized, and incretin effect, based on incremental insulin responses, were calculated.

Results: GIGD was significantly reduced in both ESRD groups compared to CTRLs (P<0.016). Incretin effects were 64±5% (CTRL), 54±5% (ESRD+NGT) and 38±8% (ESRD+IGT), with significant difference between CTRLs and ESRD+IGTs (P=0.014). Fasting concentrations of glucagon, GLP-1 and GIP were significantly increased in ESRD patients (P<0.005). Glucagon suppression (% of baseline) was significantly impaired in both ESRD groups compared to CTRLs (P<0.001), while total responses of GLP-1 and GIP (baseline-corrected) were unaltered among groups (P>0.12).

Conclusions: Non-diabetic ESRD patients are characterized by 1) reduced GIGD, 2) diminished incretin effect in those with IGT, and 3) severe fasting hyperglucagonemia that seems irrepressible in response to both oral and iv glucose stimuli. These perturbations may contribute to the disturbed glucose metabolism in ESRD.

Funding: Private Foundation Support

SA-PO545

Glycemic Load(GL) Is Independent Determinant of Oxidative Stress and Inflammation among Prevalent Maintenance Hemodialysis (MHD) Patients Chutatip Limkunakul,[1] Mary B. Sundell,[1] Amy J. Graves,[2] Ayumi Shintani,[2] T. Alp Ikizler.[1] *[1]Nephrology, Vanderbilt University, Nashville, TN; [2]Biostatistics, Vanderbilt University, Nashville, TN.*

Background: High glycemic index (GI) and glycemic load (GL) are associated with increased levels of oxidative stress and inflammation in the general population. MHD patients are known to have excessive oxidative stress burden and inflammation. We examined whether dietary GI or GL is associated with markers of oxidative stress (F2-isoprostanes) and inflammation (C-reactive protein) among MHD patients and, if so, whether body composition or adipokines, i.e. leptin and adiponectin (ADPN) modulate these associations.

Methods: A registered dietitian obtained GI, GL and other dietary data. Two 24-hour diet recalls (a hemodialysis day and a non-hemodialysis day) were analyzed using the Nutrition Data System for Research software. F2-isoprostanes, CRP, leptin, and ADPN were measured in a fasted state. Cross-sectional associations between GI, GL and markers of interest were examined by multiple regressions with adjustment for potential variables.

Results: Fifty-eight MHD patients (mean age 47 ± 12 years, BMI 29.5±6.8 kg/m^2 and DEXA truncal fat 16.4±8.8 kg) were studied. Dietary GI was not associated with F2-isop and log CRP but had significant correlation with truncal fat (r=-0.182, P=0.05). In contrast, GL was significantly associated with F2-isop (P=0.002), both in non-adjusted and adjusted analysis, (P=0.005 after adjustment for age and sex; P=0.004 after including BMI, trunk fat and waist/hip ratio in the model). Addition of leptin or ADPN did not alter the significance of the association. GL also correlated with log CRP (p=0.03) but this association was dependent on BMI and trunk fat. Log CRP correlated with trunk fat and BMI (r=0.05, P=0.01 and r=0.06, P=0.02, respectively).

Conclusions: Dietary GL, but not GI, is significantly associated with markers of oxidative stress and inflammation among prevalent MHD patients, independent of body composition and adipokines. These data may indicate the importance of dietary nutrient intake and its potential role in determining the dysregulated metabolic profile in MHD patients.

SA-PO546

Influence of Hemodialysis on Incretin Axis and Insulin Secretion Anna Masajtis-zagajewska, Ilona Kurnatowska, Malgorzata Jadwiga Wajdlich, Michal P. Nowicki. *Department of Nephrology, Hypertension and Kidney Transplantation, Medical University, Medical University, Lodz, Poland.*

Background: Incretin hormones are secreted in the gut after a meal and stimulate insulin production. Both main incretins, i.e. GLP-1 (glucagon like peptide-1) and GIP (glucose-dependent insulinotropic polypeptide) are eliminated by the kidneys. Little is known about the changes of incretin axis in end-stage renal disease (ESRD). The aim of the study was to assess the influence of elective start hemodialysis therapy on serum GLP-1 and GIP and insulin sensitivity in diabetic and non-diabetic ESRD patients.

Methods: The study comprised 56 patients (23 F, 33 M, mean age 57±14 years) with ESRD in the course of diabetic nephropathy (n=23) and non-diabetic renal diseases (n=34) who were qualified to start chronic HD. Glucose metabolism, including incretin hormones concentration, was assessed before the first HD session and after 6 months of the therapy.

Results: After 6 months of HD a significant increase of GLP-1 concentration was observed in both diabetic and non-diabetic patients (by 2.27 pmol/l (45%) and 1.28 pmol/l (22%); respectively, p=0.0003). Serum GIP increased significantly only in diabetic patients (by 30.9 pg/ml (55%); p=0.008). No significant changes of fasting glucose was found but HOMA-IR and serum insulin decreased significantly in diabetic patients (p=0.01 and p=0.008, respectively). In contrast, HOMA-β was unchanged in both groups of patients.

Conclusions: Our results indicate that hemodialysis therapy helps to restore incretin axis in particular in patients with diabetic kidney disease.

Effect of Insulin Infusion on Insulin-Like Growth Factor I during Hemodialysis Mark Reinhard,[1] Jan Frystyk,[2] Bente Jespersen,[1] Per R. Ivarsen.[1] *[1]Department of Renal Medicine, Aarhus University Hospital, Aarhus N, Denmark; [2]Department of Endocrinology and Internal Medicine & Medical Research Laboratories, Aarhus University Hospital, Aarhus C, Denmark.*

Background: Hemodialysis (HD) is a catabolic procedure that probably contributes to the high frequency of protein-energy wasting among patients on maintenance HD. In fasting patients undergoing a midweek HD session, a marked reduction in serum levels of bioactive insulin-like growth factor I (IGF-I) has been observed. Accordingly, the aim was to investigate whether it was possible to stimulate bioactive IGF-I by a meal with or without concomitant infusion of glucose±insulin.

Methods: In a randomized cross-over study, 11 non-diabetic HD patients (M/F:8/3, median age 57 years, range 33-79) received a meal after fasting overnight and started either 1) no treatment, 2) glucose infusion (10% glucose, 2.5 mL/kg/h), or 3) glucose-insulin infusion (10% glucose added 30 units of NovoRapid® per liter, 2.5 mL/kg/h) for 2 h before a standardized 4-h HD session. Infusion with either glucose or glucose-insulin was continued throughout the HD session. During infusion blood glucose was maintained at 8.0-10.0 mmol/L by additional glucose infusion. Blood samples were collected at baseline and until 2 h after the HD session.

Results: Data are presented as mean±SD. From baseline to end of HD there was no significant difference in the change in either serum bioactive IGF-I (p=0.99) or total IGF-I (p=0.22) between groups, but there was an overall increase in both bioactive IGF-I (from 0.83±0.27 to 1.01±0.34 µg/L, p<0.001) and in total IGF-I (from 124±43 to 132±52 µg/L, p=0.001). Similarly, from baseline to end of HD there was no significant difference in the change in either serum IGF-binding protein 1 (IGFBP-1) (p=0.43) or IGFBP-2 (p=0.40) between groups. There was an overall decrease in IGFBP-1 (from 267±147 to 143±92 µg/L, p<0.001), whereas IGFBP-2 rose transiently at 120 to 180 min with a maximum of 9% (p<0.001) before returning to baseline levels at the end of HD.

Conclusions: A meal at the beginning of HD increased both total and bioactive IGF-I; there was no further effect of adding either glucose or glucose-insulin infusion.

SA-PO548

Physical Functionality in Hemodialysis Patients: Body Composition as a Predictor of Functional Capacity M. A. Martinson,[1] T. Alp Ikizler,[3] Y. Zhang,[1] R. Filipowicz,[1] G. Wei,[1] Tom Greene,[1] G. Morrell,[1] S. Beddhu.[1,2] *[1]Univ of Utah; [2]VHASLC, Salt Lake City, UT; [3]Vanderbilt Univ, Nashville, TN.*

Background: Hemodialysis (HD) patients have decreased functional capacity. It is not known if body composition (muscle and/or fat) is a better predictor of physical functioning in this population than body size alone.

Methods: The Protein Intake Cardiovascular Disease and Nutrition in CKD stage V study (PICNIC) is an ongoing longitudinal study of HD patients. In 114 patients, generalized estimating equations (GEE) were used to perform simultaneous cross-sectional regressions relating the 6-min distance walked at baseline, 6 and 18 months to mid-thigh muscle area (MTMA), intra-abdominal fat area (IAFA) measured at the same time points. A similar analysis was used with BMI as the predictor variable. Adjustments were made for age, gender, race, duration of ESRD, vascular access type and study site.

Results: Mean age was 51± 17 years with 59% men, 22% black, 43% with DM, 24% with CAD, and 20% with PVD. Median duration of HD was 33 (IQR 12, 52) months. Average MTMA, IAFA and BMI were 107 ± 28 cm^2, 133 ± 79 cm^2 and 28.5 ± 6.3 kg/m^2, respectively. Average 6-min distance walked was 323 ± 101 m. The regressions of distance walked with body composition and body size indices are summarized in Table 1.

Associations between body composition, body size and 6-min distance walked

	Distance Walked (m) beta [95% CI], p-value
Model 1	
For each SD ↑ MTMA (cm^2)	18 [-3, 38], p=0.09
For each SD ↑ IAFA (cm^2)	-28 [-43, -13], p<0.001
Model 2	
For each SD ↑ BMI (kg/m^2)	-21 [-36, -6], p=0.01

Age, gender, race, duration of ESRD, vascular access type, and study site were adjusted for in both models.

Conclusions: Increased body size and decreased intra-abdominal fat area are associated with decreased physical functionality, whereas higher muscle area may be associated with increased physical functionality. Interventions that target increasing muscle mass and decreasing fat mass may improve physical functioning in the dialysis population.

SA-PO549

Relation between Physical Performance and Daily Physical Activity in Maintenance Hemodialysis Patients Jun Chul Kim,[1] Bryan B. Shapiro,[2] Yinan Li,[2] Min Zhang,[2] Janos Porszasz,[2] Kamyar Kalantar-Zadeh,[2,3] Joel D. Kopple.[2,3] *[1]Division of Nephrology, CHA Gumi Medical Center, Korea; [2]LA BioMedical Research Institute at Harbor-UCLA Medical Center; [3]UCLA Schools of Medicine & Public Health, Los Angeles, CA.*

Background: Maintenance hemodialysis(MHD) patients often display diminished physical performance(PP), and this might influence daily physical activity(DPA). We therefore assessed this relationship in MHD patients and Normal of similar age and gender mix.

Methods: PP and DPA were assessed in 76 patients undergoing MHD and 40 Normals using 3 measures of PP: 6-minute walking distance(6MW), sit-to-stand(STS) and stair climbing. DPA was measured with an Actigraph GT3X+ Activity Monitor®. The daily vector magnitude for DPA was calculated as the square root of the sum of the squares of the three dimensional axes. All comparisons were age and gender adjusted.

Results: Patients were 52±12SD years, 33% female, 40% diabetic; dialysis vintage was 55±45 mos. Normals were 51±13 years and 40% female. The DPA, averaged over 7 consecutive days, was greatly reduced in MHD vs. Normals(p<0.0001). DPA averaged for 7 days correlated with 6MW(r=0.275, p=0.023)(Fig. 1) but not with STS (r= 0.181, p= 0.149) or 22 stair climb(r= 0.157, p=0.201). The 6MW correlated negatively with the % time in sedentary or sleep activity(r=-0.324, p=0.009) and positively with % time in ≥moderate physical activity(r=0.292, p=0.018)(Fig. 2). The STS did not correlate with % time in sedentary or sleep activity(r= -0.142, p= 0.261) nor with time in ≥moderate physical activity(r= 0.175, p= 0.164).

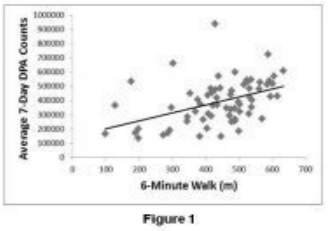

Figure 1

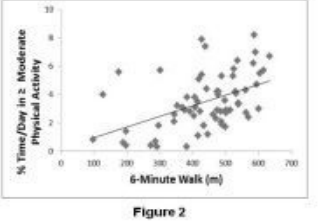

Figure 2

Conclusions: These findings indicate that in MHD patients measures of PP correlated with average DPA; increased PP may be a cause and/or result of greater DPA. Measures that increase 6MW might enhance DPA. 6MW was a more sensitive indicator of DPA than either STS or stair climb measurements.

SA-PO550

Muscle Size and Co-Morbid Conditions Do Not Explain Low Physical Function in Dialysis Patients R. Marcus,[1] Paul Lastayo,[1] R. Filipowicz,[1] G. Wei,[1] Patricia Lynn Painter,[1] G. Morrell,[1] Mary B. Sundell,[2] T. Alp Ikizler,[2] S. Beddhu.[1,3] *[1]Univ of Utah, Salt Lake City, UT; [2]Vanderbilt Univ, Nashville, TN; [3]VHASLC, Salt Lake City, UT.*

Background: Frailty is common in end-stage renal disease (ESRD). We examined whether muscle mass accounts for ESRD associated decreased physical functioning.

Methods: Demographic and co-morbidity baseline data from 3 previous studies (1 HD, 2 non-HD) were utilized. Comorbid conditions included CAD, CHF, PVD, CVD, cancer, diabetes, and lung disease. All subjects underwent baseline testing that included MRI derived mid-thigh muscle area (MTMA) and distance walked in 6 minutes (6MW). Multiple linear regression was used to relate 6 MW to dialysis and non-dialysis groups adjusted for comorbidities and muscle mass.

Results: Clinical characteristics in the HD and non-HD participants are summarized in Table 1.

Characteristics of HD and no-HD participants

	HD, n=122	non-HD, n=109
Age (yrs)	49±16*	74±7
Male (%)	57*	29
White (%)	64*	95
CAD (%)	23	14
CHF (%)	18*	3
PVD (%)	17*	4
CVD (%)	15	17
Lung disease (%)	13	7
Diabetes (%)	42*	17
Alcohol intake	34	45
BMI (kg/m²)	28.6±5.6	28.1±6.5
MTMA (cm²)	110±27	97±24
6MW (m)	316±112*	410±120

*Difference between groups p<0.05

In a multiple linear regression model, 6 MW distance was substantially lower in HD participants compared to non-HD participants (-147.0 m, 95% CI -197 to -97 m, p<0.001) even after adjusting for muscle area and other factors listed in Table 1.

Conclusions: There was a clinically significant difference in physical functioning between non-HD and HD patients, as measured by 6MW. This difference in 6MW was not explained by muscle size or measured co-morbid conditions. HD participants walked substantially shorter distances than non-HD participants despite greater muscle area and younger age. Whether the impaired functional ability of muscle in HD patients is related to other metabolic disturbances such as oxidative stress, inflammation, or other muscle structural abnormalities associated with uremia should be examined in future studies.

Effects of Exercise and Nandrolone on Frailty among Hemodialysis Patients

Cynthia Delgado, Julie W. Doyle, Kirsten L. Johansen. *Medicine, University of California, San Francisco, San Francisco, CA.*

Background: Frailty is common among patients with CKD and has been linked to decreased survival and loss of independence. The extent to which frailty can be reversed, particularly among patients with ESRD, is unclear. The purpose of this study was to evaluate the effect of exercise and anabolic steroids on frailty among HD patients.

Methods: Patients undergoing HD for ≥ 3 mo with evidence of malnutrition or poor quality of life assessed by questionnaire were eligible to participate in the Nandrolone and EXercise Trial (NEXT). Frailty was defined as 3 or more points from: SF-36 Physical Function score of < 75 (2 pts), Vitality score <55 (1pt), and the lowest quintile of weekly energy expenditure PASE questionnaire using normative data (1pt). The intervention consisted of intradialytic resistance exercise training of the lower extremities and/or weekly nandrolone decanoate (ND) by IM injection (2x2 factorial) for 12 weeks. The effect of the interventions on frailty was assessed using general estimating equations (GEE).

Results: 79 patients were enrolled, 66 of whom had measures of frailty before and after the intervention. The majority were male (63%) with a median dialysis vintage of 26 months and a mean KT/V of 1.4 ± 0.3. Hypertension (91%), diabetes (48%) and CAD (42%) were common. At baseline 58% of participants met frailty criteria. Among frail patients assigned to exercise, 36% no longer met criteria for frailty at the follow-up visit. 40% of patients who were not initially frail and did not exercise became frail at f/u (vs. 15% of nonfrail exercisers;p=0.04). There was no statistically significant improvement in frailty among patients who received ND (p=0.77).

Change in Frailty after Exercise

Table 1					
Study Group	Frail-> Frail	Frail -> Not Frail	Not Frai l -> Frail	Not Frail -> Not Frail	Total
Exercise	14	8	2	11	35
No Exercise	13	3	6	9	31
Total	27	11	8	20	66

Conclusions: Almost 40% of frail patients who exercised no longer met frailty criteria after 3 mos, and a similar percentage of nonexercisers became frail. These findings demonstrate that frailty is potentially reversible through exercise and suggest that deterioration is common without intervention.

Progressive Resistance Exercise Training for Skeletal Muscle Anabolism in Hemodialysis Patients: A Randomized Controlled Trial

Danielle Kirkman,[1,2] Naushad Ali Junglee,[1,2] Mick John Kumwenda,[2] Mahdi Jibani,[2] Jamie Hugo Macdonald.[1] *[1]College of Health and Behavioural Sciences, Bangor University, Wales, United Kingdom; [2]Betsi Cadwaladr University Health Board, Wales, United Kingdom.*

Background: Progressive resistance exercise training (PRET) may reverse muscle wasting but the anabolic response to such exercise in hemodialysis patients remains unclear. This efficacy study determined whether a novel intradialytic PRET technique could reverse atrophy and consequently improve strength and physical function in hemodialysis patients. A second aim was to compare any anabolic response to that of healthy participants completing the same program.

Methods: In a single blind, controlled study 22 hemodialysis patients (mean (SD), age: 53(16) years) and 9 healthy individuals (51(16) years) were randomly allocated to a PRET or an attention control (SHAM) group. PRET completed a high intensity leg extension exercise (3 sets of 10 repetitions at 80% of regularly reassessed maximal strength) using novel equipment. SHAM completed low intensity stretching exercises using ultralight (1.5kg) latex bands. Exercise was completed thrice weekly, during dialysis in hemodialysis patients, over 12 weeks. Outcomes included thigh muscle volume by magnetic resonance imaging, knee extensor strength by isometric dynamometer, lower body tests of physical function and harms. Data were analysed *per protocol* by analysis of variance.

Results: PRET elicited an anabolic response in both hemodialysis patients (PRET +84(123)cm^3; SHAM -109(118)cm^3) and healthy participants (PRET +136(163)cm^3; SHAM -32(54)cm^3) (Omnibus ANOVA: p=0.01). PRET also increased knee extensor strength in both hemodialysis patients and healthy participants. In contrast, PRET only significantly enhanced lower body functional capacity in the healthy participants. Harms possibly related to PRET included one case of muscle soreness and five episodic hypotensive events. All harms were resolved without late effects or sequelae.

Conclusions: Intradialytic PRET safely elicited normal anabolic and strength responses in hemodialysis patients. The lack of a change in functional capacity was surprising and warrants further investigation. *Registered clinical trial NCT01007838.*

Subclinical Hypothyroidism and Mortality among Dialysis Patients

Connie Rhee,[1] Ishir Bhan,[2] Steven M. Brunelli.[1] *[1]Division of Nephrology, Brigham and Women's Hospital, Boston, MA; [2]Division of Nephrology, Massachusetts General Hospital, Boston, MA.*

Background: Subclinical hypothyroidism is highly prevalent in the general and dialysis populations, but its clinical significance and the benefits of thyroid hormone replacement remain unclear.

Methods: We examined the association between hypothyroidism and all-cause mortality in 2715 prevalent adult dialysis patients with baseline thyrotropin levels measured between January 2004 and April 2011. Mortality was ascertained by the Social Security Death Master Index and local registration systems. In parallel analyses, hypothyroidism overall and subclinical hypothyroidism, defined by thyrotropin levels, and associations with mortality were estimated using Cox proportional hazards models. To reduce risk of observing reverse-causal associations, analyses included 30-day lag periods between thyrotropin measurement and start of at-risk time.

Results: There were 2365 (87.1%) euthyroid controls and 350 (12.9%) hypothyroid subjects (thyrotropin > assay upper limit normal), of whom 238 (68.0%) had subclinical hypothyroidism (upper limit normal < thyrotropin ≤ 10 mIU/L). Hypothyroidism overall and subclinical hypothyroidism were each associated with increased mortality: adjusted HRs (95% CIs) 1.27 (1.06-1.52; p=0.009) and 1.32 (1.07-1.63; p=0.01), respectively. Hypothyroidism treated with thyroid hormone replacement was not associated with increased mortality compared to euthyroidism, whereas untreated hypothyroidism was: HR (95% CI) 1.58 (1.26-1.98; p<0.001); findings were similar when treatment status was considered only in the context of subclinical hypothyroidism. Sensitivity analyses indicated that cardiovascular mechanisms may mediate associations between hypothyroidism overall, subclinical hypothyroidism, and death.

Conclusions: Hypothyroidism overall and subclinical hypothyroidism are associated with increased all-cause mortality in dialysis patients, which may be ameliorated by thyroid hormone replacement.

SA-PO554

Is New Anemia Protocol Resulting in Iron Overload in Hemodialysis Patients?

Samer Bani-hani, Therese A. Mangold, Arif Showkat. *Nephrology, University of Tennessee Health Sciences Center, Memphis, TN.*

Background: Recently several trials reported significant adverse effects associated with Erythropoietin stimulating agents (ESA) therapy. This has led to alterations in protocols used for anemia management in end stage renal disease (ESRD) patients (pts.). The new protocols involve lower hemoglobin (Hb) target and higher threshold for increase ESA dose. Aim of this study is to evaluate the effect of new anemia protocol on Hb and iron storage in ESRD pts.

Methods: Total of 173 were included in this retrospective study from several dialysis units. Data were collected for 6 months before (Pre-protocol) and after (Post-protocol) implementation of new protocol: demographic data, body mass index, dialysis providers, number and days of hospital admission, ESA and iron doses and result of Hb, serum iron, ferritin, total iron binding capacity, and albumin. These variables were used in a logistic regression model for high post-ferritin level (>800 ng/ml).

Results: 107 (62%) pts. were male, average age 53±12 yr, 168 (97%) were African-American.There were 31% reduction in ESA dose (P<0.0001) and 24% increase in serum ferritin level (P<0.0001) with no change in Hb level.

Results before and after change in anemia protocol

Variables	Pre-protocol	Post-protocol	P
Average serum ferritin >800 (ng/ml)	26%	46%	<0.0001
Average serum ferritin >1200 (ng/ml)	8.7%	17.3%	<0.0001
Hb g/dl	10.5±3.6	10.98±1.2	0.1567
Serum iron (mcg/dl)	66.3±24.6	73.1±25.5	0.0002
Serum TSAT (%)	28.9±9.4	32.7±11.5	<0.0001
Iron dose (mg/month)	131±136	103±103	0.0001
Serum Ferritin (ng/ml)	636±423	833±485	<0.0001
Serum albumin (gm/dl)	3.9±0.4	3.9±0.4	0.0218
Erythropoietin dose (IU/session)	4220±6165	2895±4235	<0.0001
Hospital days	5±10	5±11	0.7398

In multivariable model high post-ferritin level (>800 ng/ml) was predicted by low post-serum albumin, low post-iron dose and dialysis provider.The inverse response of serum ferritin to iron dose most likely represent lag effect of iron dosing on serum ferritin.

Conclusions: With the new anemia management protocol a significant reduction in ESA dose was achieved without any change in Hb level at the expense of significant increase in serum ferritin level. This can increase the risk iron overload in pts. with hypoalbuminemia.

SA-PO555

The Comparative Short-Term Effectiveness of Intravenous Iron Dosing on Anemia Parameters among US Hemodialysis Patients Abhijit V. Kshirsagar,[1] Janet K. Freburger,[1] Alan R. Ellis,[1] Lily Wang,[1] Wolfgang C. Winkelmayer,[2] M. Alan Brookhart.[1] *[1]University of North Carolina at Chapel Hill; [2]Stanford University.*

Background: Intravenous (IV) iron is in widespread use in the US hemodialysis population, yet there is limited data on the comparative effectiveness of different dosing strategies. Previous studies have not directly compared doses that are now routinely used in practice, or have had limited sample sizes and follow-up.

Methods: We conducted a retrospective cohort study using data from the clinical database of a large dialysis provider (years 2004-2008) merged with administrative data from the United States Renal Data System. Exposures were 2 sets of dosing patterns assessed over a 1 month period: (1) bolus (consecutive doses of 100 mg with the potential to exceed 600 mg during one month versus maintenance (all other iron dosing), and (2) high (> 200 mg) versus low dose (≤ 200 mg). Outcomes were achieved differences in hemoglobin levels, epoetin alfa (EPO) dose, transferrin saturation (TSAT), and serum ferritin, during a 6 week follow-up period, adjusted for a demographic and medical covariates.

Results: 117,050 patients met study entry criteria. Most individuals received maintenance dosing (47.4 %), 16.3 % received bolus dosing, and 36.3% received no iron. 29% of patients received high dose and 34% received low dose iron. The average dose of iron during the exposure period was 709 mg for the bolus group and 203 mg for maintenance, 558 mg for the high dose group and 140 mg for the low dose. Bolus dosing was associated with higher average hemoglobin (+0.23 g/dl,95% C.I. 0.21-0.26), TSAT (+3.31% 95% C.I. 2.99-3.63), and ferritin (+151 mcg/L, 95% C.I. 134.9- 168.7), and lower average EPO dose (-464 u 95% C.I. -583 to -343) compared to maintenance. High dose of intravenous iron was associated with higher hemoglobin (+0.19 g/dl, 95% C.I. 0.17-0.21), lower EPO dose (-606 u, 95% C.I. -701 to -511), higher TSAT (+3.27%, 95% C.I. 2.99- 3.56) and ferritin (+141 mcg/L, 95% C.I. 133.3-163.6) relative to low dose.

Conclusions: In a large dialysis cohort, both bolus and high dose IV iron led to improved anemia parameters; these benefits should be weighted against any potential harms.

Funding: Other U.S. Government Support

SA-PO556

The Comparative Short-Term Effectiveness of Iron Sucrose versus Ferric Gluconate on Anemia Parameters among US Hemodialysis Patients Abhijit V. Kshirsagar,[1] Janet K. Freburger,[1] Alan R. Ellis,[1] Lily Wang,[1] Wolfgang C. Winkelmayer,[2] M. Alan Brookhart.[1] *[1]University of North Carolina at Chapel Hill; [2]Stanford University.*

Background: Iron sucrose (IS) and ferric gluconate (FG) are the two most commonly used formulations of intravenous (IV) iron among US hemodialysis population. Although they are generally believed to be interchangeable in clinical practice, there is limited data on their comparative effectiveness in anemia management.

Methods: We conducted a retrospective cohort study using data from the clinical database of a large dialysis provider (years 2004-2006) merged with administrative data from the United States Renal Data System. The two exposures were iron sucrose and ferric gluconate delivered in a one-month period. Outcomes were differences in hemoglobin levels, epoetin alfa (EPO) dose, transferrin saturation (TSAT), and serum ferritin, between the formulations measured during a 6 week follow-up period.

Results: 66,207 patients comprised the sample. 39% received iron sucrose 12% received ferric gluconate, and 39% were non-users. The IS and FG users had a comparable baseline distributions of demographic, clinical, and laboratory parameters. The average dose during the exposure period was 325 mg for IS and 329 mg for FG. Iron sucrose was associated with higher average hemoglobin (+0.16 g/dl, 95% C.I. 0.12-0.19) than ferric gluconate during the follow-up period. There were no observed differences in EPO dose, TSAT or serum ferritin.

Conclusions: In a representative population of US hemodialysis patients, these results suggest that iron sucrose is slightly more effective than ferric gluconate at raising hemoglobin.

Funding: Other U.S. Government Support

SA-PO557

Modifying Effects of Iron-Biomarkers on Hemoglobin Changes in Hemodialysis Patients Adam E. Gaweda,[1] Premila Bhat,[2] Gregory A. Maglinte,[3] Chun-lan Chang,[4] Jerrold W. Hill,[4] Grace S. Park,[3] Akhtar Ashfaq,[3] Matthew Gitlin.[3] *[1]U of Louisville; [2]Ridgewood Dialysis Ctr; [3]Amgen Inc; [4]IMS Health.*

Background: KDOQI guidelines recommends concurrent use of erythropoiesis stimulating agents and iron supplements for anemia in end-stage renal disease patients, targeting levels of transferrin saturation (TSAT) >20% and ferritin >200 ng/mL. The relationship between iron biomarkers, iron and Epoetin alfa (ESA) dosing, and subsequent changes in hemoglobin (Hb) levels were evaluated.

Methods: Electronic medical records of 1,902 hemodialysis patients from 25 hospital-based dialysis clinics and 20 independent dialysis organizations across the US were retrospectively analyzed. From June 1, 2009 to June 30, 2010, patients had ≥1 Hb value during each 4-week interval for 4 consecutive intervals (k-2, k-1, k and k+1, where k is the index interval), ≥1 intravenous (IV) ESA dose during interval k-1 or k, and ≥1 TSAT and ferritin value at interval k. Using a generalized estimating equation approach, the change in Hb (g/dL) from k to k+1 was regressed on the change in ESA (units) and IV iron (mg) from k-1 to k, Hb levels at interval k-2, k-1, and k, TSAT and ferritin at interval k, and interactions of ESA dose change with TSAT and ferritin fit to a polynomial function.

Results: Patients were mean (SD) 62 (15) years of age; 41% Caucasian, 35% African American; 65% had hypertension and 39% diabetes. Polynomial model results indicated TSAT levels had a significant interactive effect ($p<0.05$) on Hb change relative to ESA dose change, but ferritin did not. At an ESA dose change of 1000 units/kg/month, relative Hb response was maximized when TSAT was 35% and ferritin was >600ng/mL (Figure).

Conclusions: Higher TSAT and ferritin values had minimal incremental impact to Hb change. Overall, TSAT had a significant and more pronounced modifying effect on Hb change compared to ferritin.

Figure. Relative Hb response to an Epoetin alfa dose change of 1000 units/kg/month across values of TSAT and ferritin

Therapeutic Effect of Intravenous Ascorbic Acid in Hemodialysis Patients with Normoferritinemic Anemia Byung Chul Shin, Wan Soo Lee. *Internal Medicine, Chosun University Hospital, Gwangju, Republic of Korea.*

Background: Hemodialysis (HD) patients with functional iron deficiency often develop resistance to recombinant human erythropoietin (rhEPO). Recent studies showed that intravenous ascorbic acid (IVAA) administration could override rhEPO resistance in HD patients. This study was undertaken to test the effects of IVAA in HD patients with normoferritinemic functional iron deficiency accompanied with EPO-hyporesponsive anemia.

Methods: Fifty-eight HD patients with normoferritinemic (between 100 and 500 ug/liter) anemia were included and divided into the controls (N = 25) and IVAA (N = 33) groups. IVAA patients received 500 mg of intravenous ascorbic acid with each dialysis session for 3 months and additional 4 month follow-up after the end of the therapy.

Results: Twenty patients has a response to IVAA with significantly increase in their hemoglobin (Hgb > 1.0 g/dL) and reduction of weekly rhEPO dosage compared with control group after three months treatment ($p < 0.05$). Compared with non-responders, transferring saturation (TSAT) was significantly decreased in responders group (26 ± 11 vs. 35 ± 14%, $p < 0.05$) on baseline data. There was a significant rise in serum iron and TSAT (baseline vs. 3 months, serum iron 57 ± 22 vs. 108 ± 22 ug/dL, TSAT 26 ± 11 vs. 52 ± 7%, $p < 0.05$) and a fall in serum ferritin (377 ± 146 vs. 233 ± 145 ng/mL, $p < 0.05$) of responders group (N = 20) but no significant changes in controls and non-responders group (N = 13) at 3 month treatment.

Conclusions: IVAA can be a potent and effective adjuvant therapy for hemodialysis patients with rhEPO-resistant normoferritinemic anemia.Also IVAA can reduce the dosage of rhEPO for anemia correction.

SA-PO559

Diagnostic Biomarkers to Appraise Protein-Energy Wasting and Association of Inflammation in Maintenance Hemodialysis Patients Byung Chul Shin, Wan Soo Lee. *Internal Medicine, Chosun University Hospital, Gwangju, Republic of Korea.*

Background: Protein-energy wasting (PEW) contribute significantly to the increased cardiovascular mortality among dialysis patients. However, there is no isolated marker capable of assessing the nutritional status of patients with chronic kidney disease. We investigated several parameters to appraise PEW and association of inflammation in maintenance hemodialysis patients.

Methods: Sixty patients were enrolled in this cross-sectional study. The nutritional status of the patients were divided three groups according to Subjective Global Assessement (SGA). 1) Severe malnutrition (SGA 1 to 3), 2) Mild to moderate malnutrition (SGA 4 to

5), 3) Well nutrition (SGA 6 to 7). We also simultaneously checked inflammatory markers, nutritional markers and performed an anthropometric measurement.

Results: Of all patients, sixteen patients (26.7%) were malnourished. PEW-positive patients had a difference in body mass index, % usual body weight, % standard body weight, Geriatric nutritional risk index, skinfolds, fat mass, air circumference, cardiovascular disease, albumin, high-sensitivity C-reactive protein (hsCRP), transferrin, ferritin, hemoglobin and hematocrit compared with PEW-negative patients. CRP levels were significantly higher in the malnourished group. Compared with patients without PEW, the presence of PEW was associated with incrementally higher cardiovascular disease ($p<0.05$).

Conclusions: Serum hsCRP is a strong predictor of malnutrition and inflammation in hemodialysis population. The sensitivity can be increased by associating serum albumin with other nutritional and anthropometry markers to correctly evaluate the nutritional status of hemodialysis patients. Also, SGA is a simple and inexpensive method in clinical practice for detection in the patients with PEW.

SA-PO560

Are Greater Cumulative IV Iron Doses in Hemodialysis Patients Associated with Mortality? D. Miskulin,[1,4] Navdeep Tangri,[2,4] Jing Zhou,[3,4] Karen J. Bandeen-roche,[3,4] Wieneke Michels,[3,4] L. Ebony Boulware.[3,4] *[1]Tufts Medical Center; [2]University of Manitoba; [3]Johns Hopkins University; [4]The DECIDE Network Patient Outcomes in ESRD Study Investigators.*

Background: Intravenous (IV) iron use in US hemodialysis (HD) patients has increased and erythropoiesis stimulating agents (ESA) use has declined following studies showing increased mortality with targeting higher hemoglobin (Hb) and recent changes in Medicare payments for ESAs. IV iron impairs phagocytic function, is a mediator of oxidative stress, and deposits in organs, all of which may increase mortality. Toxicity may be greater among patients with higher transferrin saturation (TSat) and ferritin values.

Methods: We studied a cohort of patients initiating HD between 2003-2008 in Dialysis Clinic Inc. dialysis units. We followed patients until death, transplant, loss-to-follow-up or Dec 31, 2008. In a discrete time interval Cox Proportional Hazards model adjusting for age, sex, race, cause ESRD, BMI, eGFR at HD start, and time varying TSat / ferritin, Hb, EPO dose, comorbidity, vascular access, post-HD weight, pre-HD systolic BP, serum albumin, and creatinine, we determined the relationships of cumulative iron dose, defined in 1-, 3-, and 6- month rolling windows, with mortality. We tested for interactions between iron dose and TSat/ferritin level.

Results: Among 12,468 incident patients (median follow up 1.6 years), 3817 (30.6%) died. Median [interquartile range] cumulative iron doses over 1-, 3-, and 6- month rolling windows were 100 [0,300], 500 [150,1000], and 1075 [550, 1600] mg, respectively. Greater cumulative iron doses were not statistically significantly associated with mortality (Table), even among patients with higher TSat/ ferritin values.

1-Month Iron	**None**	**1-100 mg**	**101-200 mg**	**201-300 mg**	**>300 mg**
	Ref	0.99 (0.91,1.08)	0.96(0.88,1.04)	1.00 (0.90,1.12)	1.01(0.94,1.08)
3-Month Iron	**None**	**1-200 mg**	**201-600 mg**	**601-1000 mg**	**>1000 mg**
	Ref	0.99 (0.90, 1.10)	1.00 (0.93, 1.07)	0.94 (0.87,1.02)	1.02 (0.94, 1.10)
6-Month Iron	**None**	**1-700 mg**	**701-1000 mg**	**1001-1800 mg**	**>1800 mg**
	Ref	0.96 (0.88, 1.04)	0.95 (0.86, 1.04)	0.96 (0.89, 1.03)	1.06 (0.98, 1.16)

Conclusions: There was no increase in mortality with greater cumulative 1,3- or 6-month IV iron doses, even among patients with higher TSat/ferritin values.

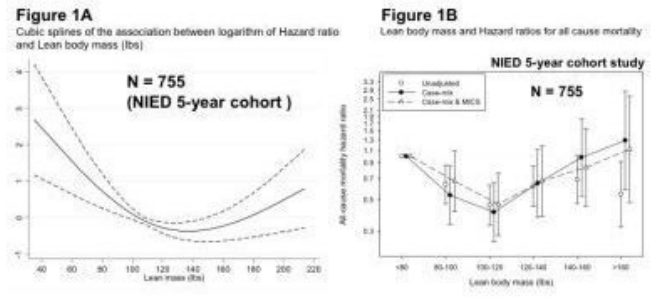
SA-PO561

Association between Lean Body Mass and Mortality in Maintenance Hemodialysis Patients Manoch Rattanasompattikul,[1] Miklos Zsolt Molnar,[1,2] Jongha Park,[1] Rachelle Bross,[3] Jennie Jing,[1] Csaba P. Kovesdy,[4] Kamyar Kalantar-Zadeh.[1,3] *[1]Harold Simmons Center, LA BioMed at Harbor-UCLA, Torrance, CA; [2]Institute of Pathophysiology, Semmelweis University, Budapest, Hungary; [3]Harbor-UCLA, Torrance, CA; [4]Nephrology, University of Tennessee, Memphis, TN.*

Background: The link between inflammation and malnutrition resulted in the description of a syndrome called protein-energy wasting (PEW). The mechanisms underlying the associations between PEW and survival are not well established. We hypothesized that lean body mass (LBM) is a predictor of mortality in maintenance hemodialysis patients (MHD).

Methods: In a 5-year prospective cohort study of 755 MHD patients, we examined the impact of LBM on survival. We used near-infrared (NIR) interactance to assess LBM and divided MHD patients into six categories: <80, 80-100, 100-120, 120-140, 140-160, >160 lbs. Cox proportional hazards models estimated death hazard ratios (HRs) (and 95% CIs), and cubic spline models were used to examine associations with mortality over 5 years (2001-2006).

Results: Mean age of patients was 54±15 years, 53% were diabetic and 49% Hispanic. The group with the highest LBM (>160 lbs) had more blacks (60%) and Hispanics (76%). In the unadjusted model, HRs were significantly lower in the LBM 80-100, 100-120, 120-140 and >160 lbs groups (0.64(0.47-0.87), 0.45(0.33-0.63), 0.62(0.45-0.85) and 0.54(0.32-0.92), respectively) compared to the LBM < 80 lbs group. Cubic splines illustrated a J-shape association of LBM with mortality (Figure1A). The associations after case mix and MICS adjustment are shown in Figure 1B.



Conclusions: In MHD patients, the survival advantage of higher LBM appears to be unclear. Many abstruse factors affect mortality in patient with higher LBM. Clinical trials to examine the outcomes of interventions that modify body composition in MHD patients are indicated.

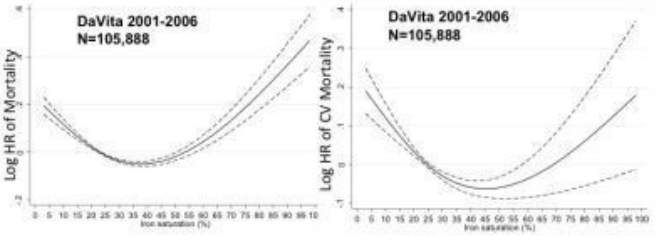
SA-PO562

Mortality-Predictability of Iron Saturation Ratio across Different Racial and Ethnic Groups of Hemodialysis Patients Manoch Rattanasompattikul,[1] Miklos Zsolt Molnar,[1,2] Jongha Park,[1] Joshua Zaritsky,[3] Jennie Jing,[1] Keith C. Norris,[4] Csaba P. Kovesdy,[5] Kamyar Kalantar-Zadeh.[1,3] *[1]Harold Simmons Center, LABioMed at Harbor-UCLA, Torrance, CA; [2]Institute of Pathophysiology, Semmelweis University, Budapest, Hungary; [3]David Geffen School of Medicine at UCLA, Los Angeles, CA; [4]Charles R. Drew University; [5]University of Tennessee, Memphis, TN.*

Background: Iron stores may be related to outcomes in maintenance hemodialysis (MHD) patients. It is unclear to what extent serum levels of iron saturation (TSAT) are associated with outcomes in this population in different racial and ethnic groups of MHD patients.

Methods: We examined mortality-predictability of iron markers in a contemporary cohort of adult MHD patients, including 36% African Americans (AAs).

Results: We identified 105,888 MHD patients (age, 62±16 years and 55% men) with iron saturation ratio (TSAT) data. In a case mix, malnutrition–inflammation complex syndrome (MICS) adjusted model, TSAT below 20% was associated with all-cause death hazard ratio (HR) [95% confidence interval] of 1.08(1.02-1.15) in AAs, 1.08 (1.03-1.14) in Caucasians and 1.08 (0.98-1.18) in Hispanics. In Hispanic MHD patients, the HR for all-cause of death was increased in the subset with TSAT above 50% (1.13, CI 1.01-1.28, p=0.04). Cubic splines confirmed a reverse J-shaped association of TSAT with all-cause mortality and cardiovascular mortality.



Conclusions: A reverse J-shaped association between TSAT and mortality exists across all races and ethnicities of MHD patients. The reason for significantly different racial/ethnic differences in adjusted mortality risk at lower TSAT levels is unclear and deserves further exploration.

SA-PO563

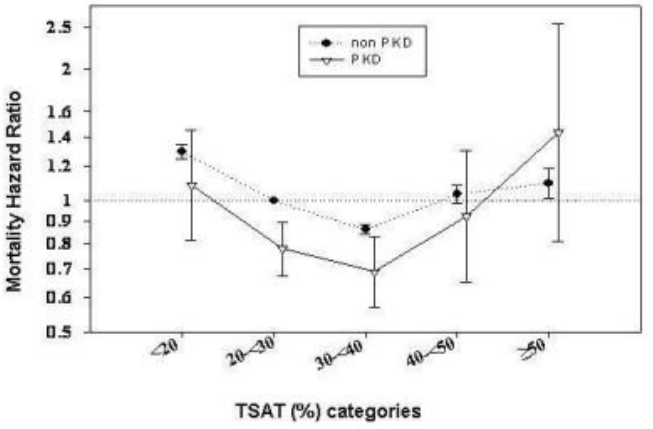
Optimal Level of Transferrin Saturation in Maintenance Hemodialysis Patients with and without Polycystic Kidney Disease Parta Hatamizadeh,[1,2] Joshua Zaritsky,[3] Lilia R. Lukowsky,[1] Miklos Zsolt Molnar,[1] Csaba P. Kovesdy,[4] Kamyar Kalantar-Zadeh.[1,3] *[1]Harold Simmons Center, LABioMed at Harbor-UCLA, Torrance, CA; [2]University of Michigan, Ann Arbor, MI; [3]David Geffen School of Medicine at UCLA, Los Angeles, CA; [4]University of Tennessee, Memphis, TN.*

Background: Transferrin saturation (TSAT) is one of the indices used to guide management of anemia. Anemia is thought to be less prominent in patients with chronic kidney disease (CKD) due to polycystic kidney disease (PKD) compared to other CKD patients. Therefore, iron metabolism might vary between PKD patients and other CKD patients. Optimal level of TSAT in CKD patients is unclear and is more so in those with PKD.

Methods: We studied 2,969 maintenance hemodialysis (MDH) patients with PKD (57.9±12.9 years old; 46% female) and 128,054 without PKD (62.0±15.4 years old; 45% female). Survival predictability of TSAT was studied using baseline, time-averaged and

time-dependent values with multivariable case-mix and malnutrition inflammation complex syndrome (MICS) adjusted Cox regression models.

Results: In both PKD and non-PKD MHD patients, there was a U-shaped association between TSAT and mortality hazard ratio. A baseline TSAT between 40% and 50% was associated with the best survival in both PKD and non-PKD patients and that of time-averaged TSAT was between 30% and 40% in both groups. A time dependent TSAT between 30% and 40% was associated with the best outcome in PKD patients; however, that of non-PKD patients was a TSAT range of 40% to 50%.



Conclusions: In both PKD and non-PKD patients on MHD, a time-averaged T-SAT between 30% and 40% was associated with the best survival. Additional studies in both PKD and non-PKD dialysis patients are required to determine whether or not therapeutic attempts to keep TSAT levels in that range will improve survival.

SA-PO564

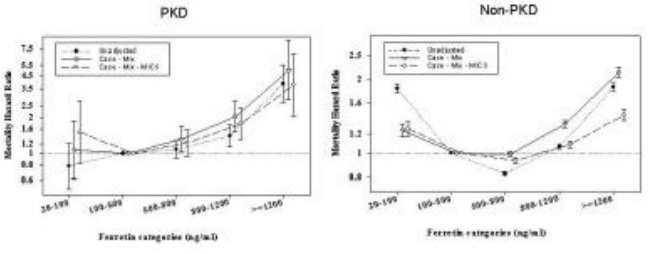
Association between Ferritin Level and Survival in Maintenance Hemodialysis Patients with and without Polycystic Kidney Disease

Parta Hatamizadeh,[1,2] Lilia R. Lukowsky,[1] Joshua Zaritsky,[3] Miklos Zsolt Molnar,[1] Csaba P. Kovesdy,[4] Kamyar Kalantar-Zadeh.[1,3] *[1]LABioMed at Harbor-UCLA, Torrance, CA; [2]University of Michigan, Ann Arbor, MI; [3]David Geffen School of Medicine at UCLA, Los Angeles, CA; [4]University of Tennessee, Memphis, TN.*

Background: Ferritin level is used as a guide for anemia management. Patients with chronic kidney disease (CKD) due to polycystic kidney disease (PKD) have less severe anemia compared to other CKD patients. Therefore, their supplemental iron requirement may also be different. The most favorable level of ferritin in CKD patients, in general, is still unclear and it has not been studied specifically in PKD patients.

Methods: We studied 131,023 maintenance hemodialysis (MDH) patients including 2,969 with PKD. Survival predictability of ferritin (divided into 5 subgroups: 20-<100ng/mL, 100-<500, 500-<800, 800-<1,200, ≥1,200) was studied using time-averaged values via Cox regression models adjusted for case-mix and Malnutrition Inflammation Complex Syndrome (MICS) variables.

Results: In survival analyses of 2,969 PKD (57.9±12.9 years old; 46% female) and 128,054 non-PKD (62.0±15.4 years old; 45% female)patients on MHD using ferritin 100-<500 ng/ml as reference group, a more prominent J-shaped association was observed in non-PKD patients, with the best survival rate in the 500-<800 ng/mL range, whereas for PKD patients ferritin values above 500 ng/ml exhibited a trend towards incrementally higher mortality.



Conclusions: Time-averaged ferritin displays a J-shaped relationship with mortality with best survival at 100-<500 ng/mL for PKD patients and 500-<800ng/mL for non-PKD patients even after adjustment for demographics, comorbidities and surrogates of inflammation and nutrition. Whether iron stores have differential risk implications across PKD vs. non-PKD warrants additional studies.

Association between Variability of Serum Ferritin Level and Mortality in Maintenance Hemodialysis (MHD) Patients

Takahiro Kuragano, Yoshinaga Otaki, Yukiko Hasuike, Takeshi Nakanishi. *Internal Medicine, Division of Nephrology and Dialysis, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan.*

Background: We have been already reported that ferritin variability is associated with that of Hb in maintenance hemodialysis (MHD) patients. In this study, we evaluated the association between ferritin variability and mortality and morbidity in MHD patients.

Methods: Prospective, observational multi center study. In 1086 MHD patients, we measured serum ferritin, Hb, and TSAT levels every 3 month. Cardiovascular disease (CVD), infectious disease, hospitalization, and all cause death were registered during 24 months. According to fluctuation patterns of serum ferritin, patients were divided into 5 groups: persistently low ferritin (LOW:<100 ng/mL), persistently high ferritin (HIGH : ≥100), decrease form high ferritin to low (H to L), increase from low to high (L to H) and high amplitude (HA). The association between fluctuation patterns of ferritin levels and events were investigated with Cox Proportional Hazards Model for Time-Dependent Variables.

Results: At the start of the study, the mean Hb level was 10.6±1.0g/dL and mean ferritin was 125.4±147.0ng/mL. During observational period (24 months), 79 CVD, 368 infectious diseases, 324 hospitalizations, and 36 deaths were occurred. Patients with HIGH group showed elevated risk for CVD (HR: 95%CI: 2.22, p=0.003), infectious disease (HR: 95%CI: 1.76, p<0.0001) compared with those of LOW group. The risk for hospitalizations in H to L ferritin group was significantly (HR: 95%CI: 1.59, p=0.013) higher than those of LOW group. Moreover, the risk for death of L to H (HR: 95%CI: 6.18, p=0.002) group and HA (HR: 95%CI: 3.75, p=0.029) group were significantly higher than those of LOW group.

Conclusions: MHD patients with ferritin ≥ 100 ng/mL bear an increased risk for CVD and infectious disease. Furthermore, MHD with increased ferritin levels or high amplitude of ferritin fluctuation also increased risk for death.

SA-PO566

Low Hepcidin Level Is Associated with Increased Erythropoiesis in Maintenance Hemodialysis (MHD) Patients with Less Iron Storage

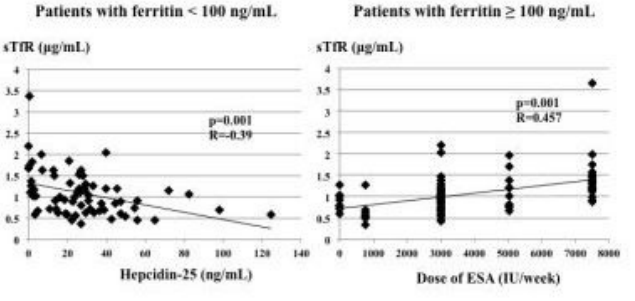
Takahiro Kuragano, Takeshi Nakanishi. *Internal Medicine, Division of Nephrology and Dialysis, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan.*

Background: It has been believed that repleted iron storage is essential for erythropoiesis. However, in Japan (J-DOPPS), 40%>MHD patients can maintain hemoglobin(Hb)>11g/dl even in the condition of serum ferritin level<100 ng/ml. For clarifying the determinants of erythropoiesis in MHD patients with low iron storage, we evaluated the regulating factors of serum levels of soluble transferrin receptor (sTfR) in MHD patients.

Methods: 153 MHD patients were recruited in this study and classified into two groups (I: ferritin<100 and II: ferritin≥100) according to iron storages. sTfR, Hb and serum levels of iron, ferritin, albumin, high sensitivity CRP, creatinine, TIBC, intact-parathyroid hormone were measured. Serum levels of hepcidin-25 were also quantified using LC-Ms/MS.

Results: Hepcidin-25, TIBC, and TSAT levels in Group II were significantly higher than Group I. There were no significant differences in Hb, iron, sTfR, and dose of ESA between two groups. In the multivariate analysis, hepcidin-25(p= 0.004, β=-0.3), iron(p= 0.003, β=-0.3), and albumin(p=0.03, β=0.2) were selected as the independent predictors of sTfR in Group I, while iron(p=0.005, β=-0.3), and dose of ESA(p=0.012, β=0.3) were selected in Group II.

Correlation between serum sTfR and hepcidin-25, and dose of ESA



Conclusions: Irrespective of iron storage, serum iron was the significant predictor of sTfR, which could be linked to iron availability for erythroid cells via transferrin. In the patients with low ferritin, the negative correlation between sTfR and hepcidin-25 indicated that iron availability could be paralleled with erythropoiesis, because the release of iron and its transport from reticuloendothelial system and iron absorption from the gut is tightly regulated by hepcidin-25. On the other hand, in the patients with repleted iron storage erythropoiesis was fully dependent on the dose of ESA.

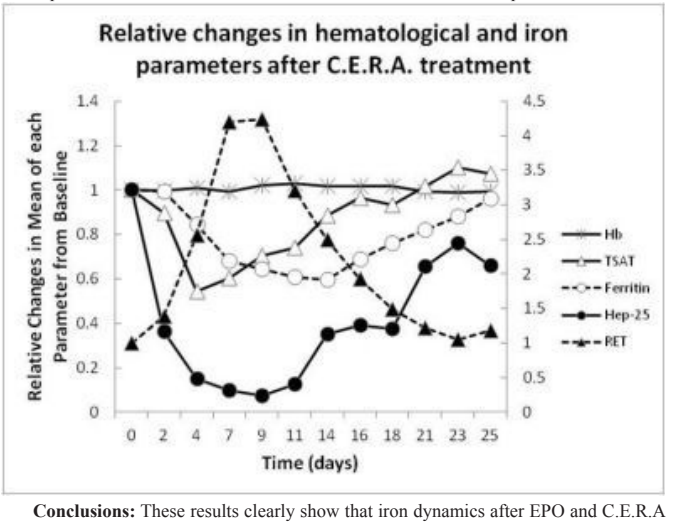
SA-PO567

Iron Dynamics in Hemodialysis Patients Receiving Epoetin-Beta or Continuous Erythropoietin Receptor Activator (C.E.R.A.) Masanobu Horie,[1] Eizou Hasegawa,[1] Ken-ichi Minoshima,[1] Yasushi Shimonaka.[2] *[1]Department of Urology, Daiyukai Daiichi Hospital, Japan; [2]Product Research Department, Chugai Pharmaceutical Co., Ltd., Japan.*

Background: C.E.R.A., methoxy polyethylene glycol-modified epoetin-beta, is a long acting erythropoiesis stimulating agent (ESA), proven to maintain hemoglobin levels with monthly administration. The difference in iron dynamics and erythropoiesis after C.E.R.A. and epoetin-beta (EPO) treatment were investigated.

Methods: Fourteen hemodialysis (HD) patients receiving 100 μg C.E.R.A. Q4W and 8 HD patients receiving 4500 IU/week EPO, who had been stably maintained hemoglobin levels by these ESA, were enrolled. All patients were received anemia treatment with same ESA before registration. Prior to every dialysis during 25 days observation period, blood samples were obtained and hematological and iron parameters including serum hepcidin-25 were measured.

Results: Hemoglobin levels were stably maintained in both groups. Although transferrin saturation (TSAT) declined weekly, no consistent change of other parameters were observed in EPO-treated group. On the contrary, rapid and continuous suppression of hepcidin-25 and reciprocal increase of reticulocytes were observed in C.E.R.A.-treated group. TSAT reduction followed by gradual recovery and gradual reduction of ferritin were also observed. These parameters were recovered toward the end of the observation period.



Conclusions: These results clearly show that iron dynamics after EPO and C.E.R.A treatment are quite different. EPO treatment induces stable iron mobilization. On the other hand, C.E.R.A. induces rapid increase of iron demand triggered by intensive expansion of erythropoiesis, leads to rapid TSAT decline and gradual reduction of ferritin, nevertheless continuous hepcidin-25 suppression. This study demonstrates that C.E.R.A. induces intensive iron mobilization and effective iron usage for erythropoiesis.

SA-PO568

Iron Dynamics and Erythroblast Maturation Kinetics after C.E.R.A. Treatment Yasushi Shimonaka, Yuki Omori, Mariko Noguchi-sasaki, Yusuke Sasaki, Keigo Yorozu. *Product Research Dept., Chugai Pharmaceutical Co., Ltd., Kamakura, Kanagawa, Japan.*

Background: The mechanism of iron mobilization by erythropoiesis stimulating agents (ESA) and the effects of continuous erythropoietin receptor activator (C.E.R.A.), a methoxy polyethylene glycol-modified erythropoietin (EPO), on iron dynamics and erythroblast maturation kinetics were investigated.

Methods: C57BL/6N (B6) mice with total body irradiation (TBI) or TBI followed by bone marrow transplantation (BMT) were intravenously injected EPO or vehicle. EPO or carbamylated EPO (C-EPO) was intravenously injected into B6 mice. These mice were sacrificed and analyzed hematological and iron parameters including serum hepcidin. B6 mice intravenously treated with 2, 10 μg/kg of C.E.R.A. or vehicle were sacrificed and analyzed hematological and iron parameters, as well as the maturation status of bone marrow erythroblast by flow cytometry stained with TER119 and CD71.

Results: Although TBI abolished the reduction of serum hepcidin by EPO injection which was observed in control mice, BMT recovered the reduction of serum hepcidin by EPO. C-EPO, which conserves *in vitro* inhibitory effect of hepcidin production but no erythropoietic activity, did not reduce serum hepcidin in B6 mice. C.E.R.A.-treated mice showed significantly higher hemoglobin than in vehicle treated mice for 14 days after treatment, reciprocally, serum hepcidin was continuously suppressed in C.E.R.A.-treated mice, nevertheless serum iron was markedly decreased at day 5. Rapid increase followed by gradual decrease of TER119(+)CD71(high) immature erythroblast and delayed increase of TER119(+)CD71(low) mature erythroblast were observed in C.E.R.A.-treated mice.

Conclusions: These results indicate that erythropoietic activity of ESA is essential for iron mobilization through serum hepcidin reduction. C.E.R.A. stimulates effective erythropoiesis with marked iron consumption and leads to effective iron recruitment for erythroblasts by remarkable hepcidin reduction. Delayed erythroblast maturation after C.E.R.A. treatment suggests the process might be controlled by iron supply. These unique features of C.E.R.A. might contribute to prevent rapid increase of hemoglobin after C.E.R.A. treatment.

SA-PO569

The Change of Reticulocyte Hemoglobin Equivalent Levels after Administration of Continuous Erythropoietin Receptor Activator in Hemodialysis Patients Midori Kakimoto-Shino,[1] Tetsuya Fujikawa,[1] Tadashi Kuji,[1,2] Nobuhito Hirawa,[1] Yoshiyuki Toya,[1] Satoshi Umemura.[1] *[1]Yokohama City University, Japan; [2]Yokodai Central Clinic, Japan.*

Background: Epoetin beta pegol called CERA (continuous erythropoietin receptor activator), recently approved, has been reported to be well effective in renal anemia control; however, relation between iron status and efficacy of CERA remains unknown. The aim of this study was to investigate iron status and response to erythropoiesis stimulating agents (ESAs) including CERA and epoetin beta (EPO) in hemodialysis patients.

Methods: A total of 106 outpatients received chronic hemodialysis at a satellite clinic were randomized to CERA or EPO. Hb levels and reticulocyte hemoglobin equivalent (RetHe) levels were measured weekly for a month. Baseline serum hepcidin levels as a key regulator of iron homeostasis were measured with mass spectrometry. In the CERA arm, patients who had received 0-750 IU, 750-4499 IU or 4500-9000 IU of EPO per week were given 0 μg, 75 μg or 100 μg of CERA per month, respectively. Target Hb level was 10-11 g/dl. ESAs resistance index (ERI) was defined as weekly weight-adjusted dose of ESAs divided by hemoglobin concentration.

Results: A total of 101 participants (mean age 67.1±11.6 (SD), 31.7% of female, 48.5 % of diabetes) were analyzed. There was no significant difference in mean Hb levels between two groups during the study period (CERA 10.8±0.97 g/dl vs. EPO 10.8±0.60 g/dl, p=0.962). Decline in RetHe level in the first week in CERA group was greater than in EPO group (-4.44±2.57 vs -2.44±1.42, p<0.001). The estimation of ESAs doses to maintain target Hb value was 1μg of CERA corresponded to 286 IU of EPO. Change of RetHe in the first week were negatively correlated with ERI in CERA arm (r = -0.383, p = 0.006), but not in EPO arm. Decline of RetHe in the first week remained significant after adjusting for potential confounders.

Conclusions: Patients with CERA showed greater decline in RetHe value in the first week than those with EPO. Higher hepcidin at baseline was correlated with poor responsiveness to CERA. The efficacy of CERA treatment may be changed by the iron metabolism during the first week.

SA-PO570

Importance of Intensive Iron Supplementation for Dialysis Patients with Continuous Erythropoietin Receptor Activator Toko Hashimoto, Yusuke Tsugawa, Masataka Tsunoda, Ryota Ikee, Naomi Sasaki, Nobuo Hashimoto. *H.N.Medic, Sapporo, Hokkaido, Japan.*

Background: Impact of different iron supplementation protocols for dialysis patients treated with Continuous Erythropoietin Receptor Activator (CERA) is unknown.

Methods: Dialysis patients with stable hemoglobin (Hb) levels for 12 weeks were eligible for this study (N=130). Erythropoietin was switched from short acting agent to CERA and followed up for 13 weeks. Participants were treated with either intensive iron supplementation (intravenous iron administration 120 mg/week for 12 weeks) or conventional treatment (40 mg/week for 4 weeks). The outcomes were change in Hb level at 13 weeks, required CERA dosage, and total costs necessary to control anemia. We constructed multivariable regression models adjusted for the potential confounders.

Results: intensive iron supplementation was associated with 0.9 (95% CI: 0.4 to 1.3) g/dL higher Hb level (p<0.001), 74.7 (95% CI: 141.1 to 8.2) μg lower required dosage of CERA, and US $198.2 (95% CI: 30.0 to 366.4) lower anemia-related mediation costs after 13 weeks.

	Change in Hb level *1 (g/dL) (95% CI)	p-value	Required CERA dosage (μg) (95% CI)	p-value	Related medication costs (US$) (95% CI)	p-value
Intensive iron supplement strategy	0.9 (0.4 to 1.3)	<0.001	-74.7 (-141.1 to -8.2)	0.03	-198.2 (-366.4 to -30.0)	0.02
Conventional iron supplement	Reference		Reference		Reference	
Age	0.0008 (-0.01 to 0.01)	0.9	2.3 (0.4 to 4.3)	0.02	4.9 (-0.006 to 9.9)	0.05
Female	-0.03 (-0.3 to 0.3)	0.8	-3.0 (-46.6 to 40.6)	0.9	-10.5 (-120.9 to 99.8)	0.9
Baseline Hb level	-0.9 (-1.1 to -0.6)	<0.001	-34.1 (-66.8 to -1.4)	0.05	-61.6 (-144.6 to 21.3)	0.1

SA-PO571

Effect of Low-to-Moderate Aluminum Exposure on Iron Status and Bone Markers in Chronic Hemodialysis Patients Paweena Susantitaphong,[1] Khajohn Tiranathanagul,[1] Pisut Katavetin,[1] Kearkiat Praditpornsilpa,[1] Marc E. De Broe,[2] Patrick C. D'Haese,[2] Somchai Eiam-Ong.[1] *[1]Medicine, Chulalongkorn University, Bangkok, Thailand; [2]Department of Biomedical Sciences, University of Antwerp, Antwerp, Belgium.*

Background: The incidence of aluminum (Al)-related toxicity has declined in hemodialysis (HD) patients. However, some patients continue to receive Al-based phosphate binders due to costs. This study was conducted to explore the effect of low-to-moderate doses of Al-based phosphate binders and their discontinuation on markers of bone disease and iron status in HD patients.

Methods: Following a first screening of serum Al level in 37 HD patients receiving low-to-moderate doses of Al-based binders, a second screening was performed in 22 of the 37 patients after a 2-year follow-up period during which the use of Al-based phosphate binders was phased out. Desferrioxamine test (DFO; 5mg/kg), iron status and bone marker assessment were performed to explore the association between serum Al level, iron status and bone markers in the second screening.

Results: At first screening, the mean serum Al level was 27.8±10.3 µg/L. Thirteen patients had a serum Al level >30 µg/L, considered a level of possible toxicity. There was a positive correlation between the serum Al level and HD duration (r=0.6; p<0.001) as well as with cumulative dose of Al-based binder. At the second screening, the mean serum aluminum level decreased to 12.5±7.4 µg/L and only one patient had a pre-DFO serum Al level >30 µg/L. The mean serum Al level increased to 26.0±14.7 µg/L post-DFO but in none of the patients did the post-DFO change in serum Al exceed 50 µg/L, a threshold which has previously been associated with Al-induced bone disease. The decrease in serum Al level was associated with a significant increase in iPTH whereas total alkaline phosphatase did not change. At both screenings serum Al and ferritin were inversely associated with each other. Dialysate Al levels were below 2µg/L throughout the study period.

Conclusions: If the use of low-to-moderate doses of Al-based binders is required in HD patients with no available substitution, serum Al level, iron and bone markers should be closely monitored to ensure safe use of these drugs.

SA-PO572

Roles of Hepcidin Isoforms in Hemoglobin Variability and Therapeutic Effects of Recombinant Human Erythropoietin in Maintenance Hemodialysis Patients Takashi Yokoyama,[1] Yasushi Shimonaka.[2] *[1]Dept. of Nephrology and Dialysis, Sapporo Higashi-Tokushukai Hospital, Sapporo, Hokkaido, Japan; [2]Product Research Department, Chugai Pharmaceutical Co., Ltd, Kamakura, Kanagawa, Japan.*

Background: We examined to clarify the roles of hepcidin isoforms in hemoglobin variability and effects of recombinant human erythropoietin (rHuEpo) therapy in patients undergoing maintenance hemodialysis (HD) patients with renal anemia.

Methods: 72 HD patients (M:F=48:24, age=62.63±12.84 years old) were observed in 2011. All patients were treated with intravenous administration of rHuEpo (750~9000units/week). The weekly average values of several clinical markers such as ferritin (FRN), high sensitive C-reactive protein (hsCRP), interleukin-6 (IL-6) and Hb were measured at 2-day intervals just before HD. Serum hepcidin isoforms (hepcidin-20, -22, -25) were measured as reported by Murao, et al (Rapid Common Mass Spectrum 2007;21:4033-8). The Hb variability classified as reported by Ebben, et al was measured throughout the year and erythropoiesis stimulating agents resistance index (ERI) in each patient were also examined.

Results: 1) The mean Hb level and hepcidin isoform levels were as follows: low amplitude low (LAL:n=26, Hb=9.93±0.73 g/dL, hepcidin-20=15.29±11.80 ng/mL, -22=2.37±2.57, -25=34.00±25.07), low amplitude high (LAH:13, 11.43±0.42, 6.31±5.22, 0.98±1.09, 14.58±15.26), high amplitude (HA:21, 11.00±0.38, 13.29±10.58, 1.86±1.26, 28.72±29.91) and target (T:7, 11.00±0.23, 11.46±11.48, 1.98±2.17, 30.82±36.08). Significant differences were found between LAL and LAH (p<0.01), HA(p<0.001) and T(p<0.001) in Hb levels. Marked differences were also detected in hepcidin isoforms (-20:p=0.002, -22:p=0.024, -25:p=0.005) between LAL and LAH. 2) Remarkable differences were detected between LAL and LAH in FRN(LAL:81.97±10.75 ng/mL vs LAH:40.71±7.63, p=0.003) and in IL-6 (16.55±6.00 pg/mL vs 4.55±2.30, p<0.05). 3) In ERI (19.15±8.65 units/kg/g.Hb vs 7.65±5.04, p=0.005), marked differences were detected between LAL and LAH.

Conclusions: These results indicate that three different hepcidin isoforms, togerther with FRN and IL-6, affect strongly the therapeutic effects of rHuEpo in maintenance HD patients.

SA-PO573

Serum Hepcidin-25 Level Is Correlated with Serum Levels of Ferritin and Transferrin Saturation in Hemodialysis Patients Noriko Saito,[1] Kazuhide Saito,[2] Masaaki Shimotori,[1] Kozo Ikarashi,[1] Tetsuo Morioka,[1] Hisaki Shimada,[1] Shigeru Miyazaki.[1] *[1]Nephrology, Shinraku-en Hospital, Niigata, Japan; [2]Urology, Niigata University Graduate School of Medicine, Niigata, Japan.*

Background: Hepcidin-25(HPC) is a crucial player of iron metabolism. Iron-overload and inflammation stimulate HPC production, whereas anemia, iron depletion, growth differentiation factor 15(GDF15) and soluble hemojuvelin(sHJV) inhibit HPC production.

Serum HPC level is elevated in hemodialysis patients, however, the correlation with other iron parameters such as Hb, ferritin, transferrin saturation(TSAT), high sensitive CRP(hs-CRP) and soluble transferrin receptor(sTfR) is not well understood.

Methods: 40 hemodialysis patients(HD) and 20 normal healthy volunteers(N) were studied. Serum HPC level was determined by LS-MS/MS, using HPC-25 as an internal standard. GDF15, sHJV and sTfR levels were measured using ELISA. Standard hematological parameters including hs-CRP were also evaluated.

Results: HPC level (ng/ml) was higher in HD than N (48.2±42.3 vs 11.1±11.9, p<0.01). GDF15 level (ng/ml) and sTfR level (nmol/l) were also higher in HD than N (8.5±3.2 vs 0.6 ± 0.2, p<0.001 and 25.7±16.7 vs 16.3±6.5, p<0.01, respectively).

sHJV level(ng/ml) did not show any differences (85.7 ± 35.8 vs 120.5±73.3, NS).

HPC level of N was correlated to Hb (r=0.662, p<0.005), ferritin (r=0.761, p<0.001), TSAT (r=0.728, p<0.005), hs-CRP(r=0.471, p<0.05) and GDF15 (r=0.539, p<0.05), but not to sHJV or sTfR.

HPC level of HD was correlated to ferritin (r=0.898, p<0.0001), TSAT (r=0.677, p<0.0001) and sTfR (r=-0.454, p<0.005), but not to Hb, hs-CRP, GDF15 or sHJV.

Conclusions: In HD, serum HPC level was strongly correlated to iron metabolism markers and not to inflammation or hypoxia markers. Thus HPC level in HD might be mainly regulated by the state of iron utilization.

SA-PO574

Serum Uric Acid Is Associated with Abdominal Adiposity, Inflammation, and Insulin Resistance in Hemodialysis Patients J. Abraham,[1,2] T. Alp Ikizler,[3] R. Filipowicz,[1] Mary B. Sundell,[3] G. Wei,[1] Y. Zhang,[1] Nestor E. Almeida,[1] Kalani L. Raphael,[1,2] S. Beddhu.[1,2] *[1]University of Utah, Salt Lake City, UT; [2]VA Healthcare System, Salt Lake City, UT; [3]Vanderbilt University, Nashville, TN.*

Background: Uric acid (UA) is thought to play a major role in metabolic syndrome but there is a paucity of data on the association of UA with adiposity, insulin resistance (IR), and inflammation in hemodialysis (HD) patients. Therefore, we investigated these associations in the ongoing Protein Intake, Cardiovascular disease and Nutrition in CKD stage V (PICNIC) study of chronic HD patients.

Methods: Fasting non-HD plasma was used to measure UA, high sensitivity C reactive protein (hsCRP) and insulin levels. MRI was used to measure intra abdominal fat area (IAFA) at baseline and 6 months follow-up. Separate multiple linear regression analyses were used to relate hsCRP, insulin and IAFA at baseline to plasma UA concentration at baseline (cross-sectional model), and to relate hsCRP, insulin and IAFA at 6 months to baseline serum uric acid (lagged model). Adjustments were made for age, gender, race, vascular access, ESRD duration, and study center.

Results: 119 hemodialysis patients were included in the analysis. The mean age was 52 ±16 yrs, 59% were men, 82% were Caucasians and 47% had diabetes. Mean UA was 5.5 ± 1.8 mg/dL. Plasma UA correlated positively with abdominal adiposity, plasma UA correlated positively with hsCRP and insulin both at baseline and at 6 months.

Association for each standard deviation ↑ in uric acid with log hsCRP, log insulin and intra abdominal fat area (IAFA)

	Baseline	Follow up
	Beta, 95% CI, p-value	Beta, 95% CI, p-value
Log hsCRP (g/dL)	0.27 (0.0004, 0.54), 0.05	0.51 (0.10, 0.92), 0.02
Log insulin (IU/L)	0. 30 (0.08, 0.51), 0.01	0.27 (-0.03, 0.58), 0.08
IAFA (cm²)	17.2 (2.3, 32.1), 0.02	27.1 (5.9, 48.3), 0.01

Adjusted for age, gender, race, duration of hemodialysis, vascular access, and study center.

Conclusions: Serum UA is associated with abdominal adiposity, inflammation and IR in HD patients. Interventions that target UA might decrease inflammation in HD patients.

Circulating Bacterial-Derived DNA Fragments as a Marker of Systemic Inflammation in Peritoneal Dialysis Cheuk-Chun Szeto, Bonnie Kwan, Kai Ming Chow, Chi-bon Leung, Philip K.T. Li. *Department of Medicine & Therapeutics, The Chinese University of Hong Kong, Shatin, Hong Kong.*

Background: Endotoxemia is common in peritoneal dialysis (PD) patients, and circulating lipopolysaccharide (LPS) level is related to the degree of systemic inflammation and atherosclerosis. We hypothesize that circulating bacterial DNA, another microbial component, correlates with the degree of systemic inflammation and predicts the survival of new PD patients.

Methods: We measured plasma bacterial DNA level in the archive blood samples of 300 consecutive new PD patients. The result was compared to serum C-reactive protein (CRP) level, patient survival and peritonitis-free survival.

Results: The average age was 57.8 ± 12.1 years; average plasma bacterial DNA level was 34.3 ± 1.3 cycles; average follow up 37.9 ± 22.2 months. Plasma bacterial DNA level correlated with serum CRP (r = 0.565, p < 0.001) and LPS level (r = 0.224, p = 0.029).

At 36 months, the patient survival was 77.5%, 78.3%, 74.6% and 65.2% for plasma bacterial DNA level quartiles I, II, III and IV, respectively (log rank test, p = 0.034). By multivariate analysis with the Cox proportional hazard model to adjust for confounders, plasma bacterial DNA level had no independent effect. Similarly, peritonitis-free survival was 60.6%, 59.8%, 60.3% and 50.4% for plasma bacterial DNA level quartiles I, II, III and IV, respectively at 36 months (p = 0.020), and the difference was not significant after adjusting for confounding factors.

Conclusions: We found that plasma bacterial DNA level correlated with the degree of systemic inflammatory state in PD patients. Although plasma bacterial DNA level seems to predict patient survival and peritonitis-free survival, the association disappears after adjusting for confounding factors. Further prospective studies are needed to delineate the role of plasma bacterial DNA as a prognostic marker of renal failure patients.

Tumor Necrosis Factor-α Modifies the Relationship between Obestatin and All-Cause and Cardiovascular Mortality in Maintenance Hemodialysis Patients Ilia Beberashvili,[1] Inna Sinuani,[2] Ada Azar,[3] Hadas Kadoshi,[3] Gregory Shapiro,[1] Leonid Feldman,[1] Zhan Averbukh,[1] Joshua Weissgarten.[1] *[1]Nephrology, Assaf Harofeh Medical Center, Zerifin, Israel; [2]Pathology, Assaf Harofeh Medical Center, Zerifin, Israel; [3]Nutrition, Assaf Harofeh Medical Center, Zerifin, Israel.*

Background: We hypothesized that obestatin, an anorexogenic gut hormone, increase may link to protein-energy wasting in maintenance hemodialysis (HD) patients, predisposing to increased mortality risk.

Methods: We performed a prospective cohort study of 94 prevalent hemodialysis patients (38% women) with a mean age of 64.8±11.2 years. In total, the study period extended 45.8±26.7 months.

Results: Among various nutritional markers only fat mass index (FMI) exhibited statistically significant linear association (r=0.210, p=0.042) with obestatin. Surprisingly, patients with serum obestatin concentrations below the median (<7.12ng/ml) had lower cumulative incidences of survival (log rank χ^2=5.65, p=0.017). The crude all-cause (HR 2.43, 95% CI 1.22-4.86) and cardio-vascular mortality hazard ratios (HR 2.97, 95% CI 1.24-8.77) in these patients persisted to be significant after adjustments for various confounders. We then studied the implications of obestatin levels in combination with TNF-α levels. A significant obestatin x TNF-α interaction was found for daily energy intake: patients with high obestatin and low TNF-a values exhibited the lower daily energy intake. Survival analysis showed the modulating effect of TNF-α on obestatin Across the four obestatin-TNF-α categories, the group with high obestatin and low TNF-α exhibited a worse outcome in both, all-cause (log rankχ^2=10.86, p=0.012**)** and cardio-vascular (log rankχ^2=11.19, p=0.011) mortality.

Conclusions: Low serum obestatin concentration is an independent predictor of mortality in prevalent hemodialysis patients. High obestatin values in HD patents are linked to a markedly decreased mortality risk (especially because of cardio-vascular causes) in co-existence of high TNF-α levels. This interction of obestatin with TNF-α in hemodialysis patients should be further elucidated.

TAM Ligand and Receptor Expression in Chronic Renal Failure Iris J. Lee,[1] Brendan A. Hilliard,[2] John Madara,[3] Swati Rao,[1] Tapan H. Patel,[1] Jean Lee,[1] Crystal A. Gadegbeku,[1] Eric T. Choi,[4] Philip L. Cohen.[2] *[1]Nephrology, Temple University, Philadelphia, PA; [2]Rheumatology, Temple University, Philadelphia, PA; [3]School of Medicine, Temple University, Philadelphia, PA; [4]Vascular Surgery, Temple University, Philadelphia, PA.*

Background: The vitamin K dependent proteins Gas6 and protein S are ligands for the TAM receptors (tyro3, axl, and mer) and function as crucial regulators of pro-inflammation and mediators of vascular disease in animal models. We examined whether TAM ligands and receptor expression is altered in patients with chronic renal failure.

Methods: After informed consent, blood samples were obtained from 23 controls, 53 hemodialysis patients (HD), and 72 patients with chronic kidney disease (CKD). Expression of TAM ligand/receptor and vitamin K deficiency was evaluated by ELISA flow cytometry (FACS) and western blots.

Results: We observed significant increases in plasma Gas6 in CKD and HD with levels correlating with eGFR (r= -0.28 p=0.02), dialysis vintage (r=0.36, p=.008) and variables linked to chronic inflammation, such as low albumin, (r= -0.34, p=.01). Protein S was also increased in the plasma of CKD. (p<0.001) Further, a marginally-significant association between Gas6 and a history of coronary artery disease was found (r=0.26, p=.058).

We studied whether vitamin K deficiency in HD affected Gas6 levels. By PIVKA-II assay, we found >70% had levels >2ng/ml indicating functional vitamin K deficiency (mean=4.48ng/ml). However we observed no relationship between Gas6 and PIVKA-II (r^2=0.12, p=.11). Furthermore, by western blot, HD sera was able to phosphorylate axl suggesting carboxylation of TAM ligands are not essential for axl signaling. By FACS, increased expression of mer and axl was seen on CD14++ monocytes in HD, a specific subset linked to pro-inflammation and vascular disease. In addition, we found increased turnover of the axl receptor, as soluble axl were markedly increased in the plasma of HD compared to controls. (110.1ng/ml vs. 14.8ng/ml, p<0.0001).

Conclusions: We demonstrate dysregulation of the TAM-ligand receptor pathway in HD. This pathway may be critical in inflammatory-mediated vascular disease in CKD.

Patterns of C-Reactive Protein and Mortality in Dialysis Patients Gero D. von Gersdorff,[1] Len A. Usvyat,[2] Mathias Schaller,[1] Inga Bayh,[5] Michael Etter,[6] Aileen Grassmann,[5] Adrian Marcos Guinsburg,[3] Jeroen Kooman,[7] Eric Liu,[6] Daniele Marcelli,[5] Cristina Marelli,[3] Laura Scatizzi,[5] Stephan Thijssen,[2] Edwin B. Toffelmire,[4] Yuedong Wang,[8] Nathan W. Levin,[2] Claudia Barth,[9] Peter Kotanko.[2] *[1]University Hospital Cologne, Germany; [2]Renal Research Institute, New York, NY; [3]Fresenius Medical Care (FMC), Argentina; [4]FMC, Canada; [5]FMC Europe, Germany; [6]FMC Asia Pacific, Hong Kong; [7]University Hospital Maastricht, Netherlands; [8]UC- Santa Barbara; [9]KfH Kuratorium für Dialyse und Nierentransplantation, Germany.*

Background: Monitoring of CRP for risk assessment in hemodialysis (HD) patients (pts) has been questioned. We explore if longitudinal analysis of CRP is useful in HD pts.

Methods: MONDO consortium consists of HD databases from RRI (USA), FMC in Europe, Asia, Canada and Latin America, KfH Germany and from University of Maastricht. We assessed CRP and CRP-variability in HD pts in their 1st year and observed survival in the following year. CRP means and coefficients of variation (CoV) were calculated and pts were grouped into tertiles of baseline CRP and CRP-CoV. A Cox model was constructed for hazard ratios (HR) of survival adjusted for risk factors.

Results: CRP was available in 9918 pts, 3822 from Germany (KfH) and 6096 from 15 other European countries (FMC), including 10 in (South)-Eastern Europe. Results are presented separately. Higher CRP were associated with higher HRs. HRs declined with larger CRP variability when the mean CRP was medium or high.

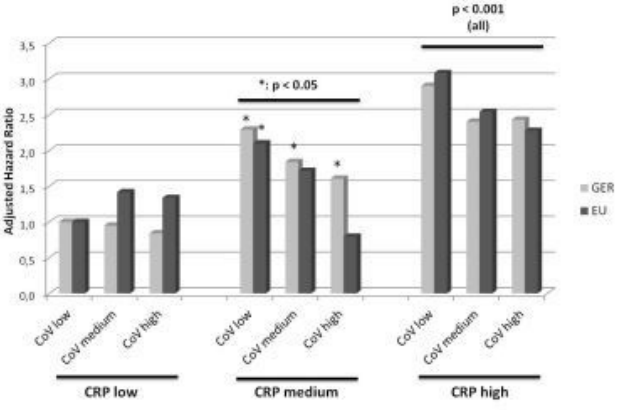

Figure 1: Hazard Ratios of death associated with CRP-elevation and CRP-variability, respectively. Levels of CRP were grouped into low (<7.7 mg/L), medium (7.7 – 18.7 mg/L) and high (>18.7 mg/L), respectively. Similarly, CoV was grouped into low (<0.74), medium (0.74-1.21) and high (>1.21). Hazard ratios were adjusted for age, sex, weight, diabetes, blood pressure, weight gain, and albumin

Conclusions: Not only absolute levels of CRP but also low variability conferred the highest HRs. This suggests that chronic elevations of CRP carry a higher risk than acute CRP increases, such as occur with infections.Longitudinal trends of CRP offer important information for risk prediction in HD pts.

SA-PO579

Circulatory Mitochondrial DNA in Patients on Maintenance Hemodialysis Cao Hongdi, Junwei Yang. *Center for Kidney Disease, 2nd Affiliated Hospital of Nanjing Medical University.*

Background: Chronic sterile inflammation plays a crucial role in the development and progression of cardiovascular disease (CVD) in patients with chronic kidney diseases (CKD). Mitochondrial DNA (mtDNA) released into circulation after cell damage can promote chronic inflammation in patients and animal models. However, the role and mechanisms of circulatory mtDNA in chronic sterile inflammation in patients on maintenance hemodialysis (MHD) remains unknown.

Methods: In this study, 74 MHD patients in our dialysis center and 20 health controls were included. The circulatory mtDNA was detected by real-time PCR assay. Plasma C-reactive protein (CRP) and tumor necrosis factor α (TNF α) were quantitated by using ELISA assay.

Results: The results showed that circulatory mtDNA was significantly elevated in MHD patients comparing to those in the health control. The mtDNA level was closely correlated with the levels ofCRP and TNF α in MHD patients. The circulatory mtDNA was also higher in MHD patients with CVD or secondary hyperparathyroidism than those in the others. The effect of different dialysis patterns, including low-flux hemodialysis (LF-HD), high-flux hemodialysis (HF-HD) and online hemodiafiltration (OL-HDF) on the clearance of circulatory mtDNA was evaluated. The results revealed that only HF-HD and OL-HDF but not LF-HD could partially remove plasma mtDNA. In vitro, the human acute monocytic leukemia cell line (THP-1) was treated with purified mtDNA isolated from humanskeletal muscles. The results demonstrated that mtDNA could induce the production and secretion of IL-1β and TNF α in the THP-1 cells, suggesting a direct causal relationship between mtDNA and inflammation.

Conclusions: Collectively, it is concluded that circulatory mtDNA is elevated and its level is closely correlated with chronic inflammation, CVD and secondary hyperparathyroidism in MHD patients. HF-HD and HDF but not LF-HF can partially remove circulatory mtDNA.

Elevated Toll-Like Receptor 4 Expression and Signaling in Muscle from Patients with Chronic Kidney Disease (CKD) Giacomo Garibotto,[1] Alice Bonanni,[1] Irene Mannucci,[1] Antonella Sofia,[1] Stefano Saffioti,[1] Giuliano Brunori,[2] Elena D'Amato,[1] Valeria Cademartori,[1] Daniela Verzola.[1] *[1]Nephrology Division, IRCCS San Martino-IST, Genoa, Italy; [2]Ospedale Santa Chiara, Trento, Italy.*

Background: Toll-like receptors (TLRs) play a pivotal role in pathogen recognition and cytokine synthesis in several tissues, such as immune cells and skeletal muscle. A systemic inflammatory response is common in CKD patients and is associated with a wasting syndrome and a worse prognosis.

Methods: In this study we used both an ex-vivo and an in vitro approach to examine if TLRs can contribute to the development of inflammatory changes in skeletal muscle of CKD patients.

In ex-vivo studies, TRLs (TLR2,TLR3,TLR4),as well as their downward proinflammatory cascade, including IL-6 (RT-PCR and immunohistochemistry), p-p65 and p38 (immunohistochemistry) were evaluated in muscle biopsies (rectus abdominis) of patients with ESRD (21M/5F, age 69±11 yrs) and in 9 controls (7M/2F, age 66±4 yrs).

Results: Muscle from CKD patients showed significantly elevated TLR4 (mRNA and protein + 30-50%, $p<0.05$), while TLR3 and TLR2 were unchanged. Moreover, NFkB signaling (p-p65 and p-ikBα) was ~6-7 fold increased ($p<0.02$- 0.01) and was associated with elevated expression of the NFkB-regulated genes IL-6 and p-p38.

As a next step, to study if circulating factors can cause the observed inflammatory events we studied the effects of uremic serum in a mouse myoblast cell line (C2C12 cells).Uremic serum increased TLR4 mRNA and protein expression (~2-3 folds vs. basal, $p<0.01$), as well as phosphorylated p38 (by 2-3 fold vs. basal, $p<0.01$). Additional studies revealed that p38 and protein kinase C (PKC) inhibition significantly abrogated serum–induced TLR4 upregulation, NF-κB activation and cytokine secretion.

Conclusions: The data suggest that in CKD patients, before the dialytic stage, skeletal muscle recognizes circulating pathogen-associated molecules with specific TLRs to initiate an IL-6 transcriptional response. Collectively, these data suggest that uremic milieu induces TLR4 expression via PKC-α .Abnormal TLR4 expression may play a role in the susceptibility of such patients to protein wasting and altered energy regulation.

SA-PO581

Influence of Variation of Pentraxin 3, Homocysteine and Albumin on the Survival in Hemodialysis Patients Bodil Sjoberg, Abdul Rashid Tony Qureshi, Sunna Snaedal Jonsdottir, Olof Heimburger, Peter F. Barany. *Renal Medicine Karolinska Hospital, Karolinska Institutet, Stockholm, Sweden.*

Background: Persistent micro-inflammation is a strong risk factor for cardiovascular disease and mortality in HD patients. Longitudinal inflammation variation and mortality risk have been sparsely studied. We studied the relation of the variation of three potentially important plasma biomarkers (pentraxin 3 (PTX-3), albumin (Alb) and homocysteine (Hcy)) to mortality.

Methods: In 188 prevalent HD patients (age 63±14 years, 103 males, 26% diabetes, dialysis vintage median (IQR) 28 (13-56) months), PTX-3, Alb and Hcy levels were measured at inclusion and after three months, with median follow-up of 41 (11-50) months. Inflammatory marker variation was categorized according to tertiles at both occasions. The variation of PTX-3, Alb and Hcy was calculated as the intra-class correlation (ICC) from estimates of between-patient and within-patient variance (mixed model). Lower ICC indicates relatively less between-patient variation and higher within-patient variation. Mortality was analyzed by Kaplan-Meier and Cox proportional hazards model, adjusted for age, gender, DM, CVD, PEW and vintage.

Results: ICC for PTX-3 was 0.47 (95% CI: 0.35 to 0.57), ICC for Alb was 0.64 (95% CI: 0.55 to 0.72) and ICC for Hcy was 0.84 (95% CI: 0.79 to 0.88). Within-patient variation of PTX-3 levels was higher than Alb and Hcy variation. During follow-up 88 patients (46%) died. Persistently elevated PTX-3, a decrease in Alb levels and persistently low levels of Hcy were associated with higher mortality (fig).

Conclusions: Persistently high PTX-3 levels were associated with worse outcome. PTX-3 varied more within patients than between patients. Moreover, Low Hcy levels' association with a worse outcome may be linked to protein-energy wasting and hypoalbuminemia.

SA-PO582

Effect of Inflammation on the Relationship of Arteriovenous Fistula Blood Flow Dynamics and Cardiovascular Morbidity among Hemodialysis Patients Rui Zeng,[1] Wenhui Liao,[2] Nan Zhang.[1] *[1]Division of Nephrology, Tongji Hospital, Huazhong University of Science & Technology, Wuhan, Hubei, China; [2]Division of Geriatric, Tongji Hospital, China.*

Background: Cardiovascular disease is the leading cause of death among maintenance hemodialysis patients. Although the presence of an arteriovenous fistula (AVF) has an adverse effect on cardiac function, the exact role of the arteriovenous fistula blood flow in contributing to this morbidity is unclear. The purpose of this study is to investigate how arteriovenous fistula blood flow dynamics(Qa)increase cardiovascular event among maintenance hemodialysis patients.

Methods: Eighty-one maintenance hemodialysis patients bearing an AVF and twelve healthy controls were recruited into the study. Qa and cardiac output (CO) were measured by means of Transonic Hemodialysis Monitor HD02. Predialysis blood samples were taken before Qa mornitoring. HsCRP was measured by immunoturbidimetry(KYOMA). Inflammatory cytokines (IL-2, IL-4, IL-6, IL-10, INF-ϒ and TNF) were measured by Cytometric Bead Array (BD™). Cardiovascular morbidity was monitored prospectively over a nineteen months period.

Results: During the follow-up period, 21% patients (17/81) developed at least one episode of cardiovascular event. Qa, the serum IL-6 and hsCRP levels were significantly higher in patients with CVD than that without(1105±176)vs.(918±215)ml/min, $P<0.05$;6.00(4.40~11.49)vs. 2.60(1.96~4.73)pg/ml, $P<0.01$;8.75(3.83~18.40)vs. 3.80(1.00~7.20)mg/L, $P<0.05$).The risk factors of CVD morbidity was assessed by binary logistic regression analysis. It demonstrated that serum IL-6 was an independent and stronger risk factor for CVD morbidity(HR=1.456, P=0.014, 95%CI (1.078~1.967)) among HD patients. Spearman rank correlation analysis and liner regression analysis showed that Qa was positively correlated with serum IL-6(β=0.429, $P<0.01$). Path analysis suggested that Qa contributed to CVD mortality via the increase of serum IL-6 in HD patients.

Conclusions: IL-6 is an independent risk factor of CVD in maintenance HD patients. AVF blood flow dynamics increases cardiovascular disease morbidity among HD patients via its upregulation of serum inflammatory IL-6.

SA-PO583

Progressive Upregulation of Thrombomodulin, C-Reactive Protein, and D-Dimer in Chronic Kidney Disease versus End Stage Renal Disease Can Be Used to Stratify Risk of Thrombotic Events Korosh Sharain,[1] Debra Hoppensteadt,[1] Vinod K. Bansal,[2] Jawed Fareed.[1] *[1]Pathology, Loyola University Medical Center, Maywood, IL; [2]Nephrology, Loyola University Medical Center, Maywood, IL.*

Background: The progression through the stages of chronic kidney disease (CKD) and into end stage renal diease (ESRD) is unpredictable and thus prognosis and risk are also difficult to predict. Cardiovascular events such as ACS, DVT, and PE are the most common complications in kidney disease. Several studies suggest an elevated inflammatory and thrombotic state in kidney disease, however, the clinical utility of such biomarkers have not been evaluated. This study evaluates the progression of CKD to ESRD through the pro-thrombotic markers Thrombomodulin (TM), C-Reactive Protein (CRP), and D-Dimer.

Methods: 48 patients with CKD, 104 patients with ESRD, and 79 age matched control samples were evaluated. TM, CRP, and D-Dimer were measured simultaneously by Cerebral II biochip immunoassay technology (Randox Evidence Investigator,United Kingdom).

Results: TM levels were 1.24±0.042mg/L (mean±SEM) in controls, 3.44± 0.27mg/L in CKD, and 7.08±0.25mg/L in ESRD, with p<0.0001 by ANOVA. CRP levels were 1.64±0.28mg/L, 4.03±0.55mg/L, and 7.11±0.59mg/L in Controls, CKD, and ESRD respectively, with a p<0.0001 by ANOVA. D-Dimer levels were 89.12±8.61mg/L in controls, 184.76±13.73mg/L in CKD, and 323.64±20.76mg/L in ESRD, with p<0.0001 by ANOVA. Compared to controls, TM levels in CKD and ESRD were increased by 2.76 and 5.68 times respectively, with r^2=0.979. CRP levels were increased 2.45 and 4.33 times in CKD and ESRD respectively, with r^2=0.995 and D-Dimer levels in CKD and ESRD were increased by 2.07 and 3.63 times respectively, with r^2=0.988.

Conclusions: Compared to controls, D-Dimer, TM, and CRP were significantly elevated in the CKD. Compared to the CKD, D-Dimer, TM, and CRP were significantly elevated in the ESRD. When relative concentrations were evaluated, an almost linear progression from control to CKD to ESRD was appreciated. The linear progression of increasing thrombotic state from control to CKD to ESRD can be used as an indicator of cardiovascular disease risk in kidney disease.

SA-PO584

An Evaluation of the Novel Fibrosis Marker Galectin-3 in Hemodialysis Patients Christiane Drechsler,[1] Christoph Wanner,[1] Katja Blouin,[1] Stefan Pilz,[2] Andreas Tomaschitz,[2] Vera Krane,[1] Winfried März,[3] Eberhard Ritz,[4] Pim Van der Harst,[5] Rudolf Allert De Boer.[5] *[1]Div of Nephrology, University of Würzburg; [2]Dept of Internal Medicine, Medical University of Graz; [3]Synlab Center of Laboratory Diagnostics, Heidelberg; [4]Div of Nephrology, University of Heidelberg; [5]Dept of Cardiology, UMC Groningen.*

Background: Galectin-3 is involved in fibrosis and inflammation and has emerged as a biomarker in heart failure. Experimental data suggest that galectin-3 is also linked to renal fibrosis associated with renal failure. Galectin-3 targeted therapy may inhibit this process. We evaluated if plasma galectin-3 concentrations are associated with adverse outcomes in dialysis patients.

Methods: This study investigated the role of galectin-3 in 1168 diabetic hemodialysis patients participating in the German Diabetes and Dialysis Study. Galectin-3 was measured in blood samples taken at baseline by ELISA. We correlated Galectin-3 concentrations with demographic, clinical and biochemical markers. By Cox regression analysis we assessed the association of galectin-3 concentrations with specific cardiovascular endpoints, infectious deaths and mortality during 4 years of follow-up.

Results: Study participants were on average 66±8 years and 54% were male. Mean Galectin-3 concentration was 54±20 ng/µl, being highly elevated as compared to healthy subjects. In multivariable analysis, we identified gender, CRP, HDL-cholesterol, potassium, calcium, NT-pro-BNP, creatinine and thrombocyte count as important factors, which most strongly predicted variation in galectin-3 concentrations. Increased Galectin-3 concentration (log transformed, per standard deviation) independently associated with stroke (HR 1.25 (1.01-1.55)), deaths due to heart failure (1.39 (1.00-1.93)) and infectious deaths (1.25 (1.03-1.52)), thus contributing to a significant rise in all-cause mortality.

Conclusions: Galectin-3 concentrations are highly elevated in dialysis patients and associated with poor outcome including excess stroke, deaths due to heart failure, infectious deaths and all-cause mortality. Further study is needed to assess if interventions targeted at galectin-3 may be useful for patients with kidney disease.

SA-PO585

Changes of Serum Albumin, Body Mass Index, C-Reactive Protein and Interleukin 6 over Time in End Stage Kidney Disease (ESKD) Patients and the Impact of Conventional Risk Factors Claire H. Den Hoedt,[1,2] Michiel Bots,[3] Muriel Grooteman,[4] Neelke C. Van Der Weerd,[4] Erik L. Penne,[4] Pieter M. Ter Wee,[4] Renee Levesque,[5] Menso Jan Nube,[4] Peter J. Blankestijn,[2] Marinus A. Van Den Dorpel.[1] *[1]Maasstad Hospital, Rotterdam; [2]UMCU, Utrecht; [3]UMCU, Utrecht; [4]Centre Hospitalier de l'Université de Montréal, Montréal.*

Background: Inflammation and malnutrition are important features of ESKD patients but data on changes over time are scarce. Therefore we studied changes over time of serum albumin, body mass index (BMI), high sensitivity C-reactive protein (CRP) and interleukin 6 (IL-6). We also evaluated the impact of age, sex, presence of diabetes mellitus (DM), cardiovascular disease, residual kidney function and dialysis vintage on these changes.

Methods: We analyzed data of the CONvective TRAnsport Study (CONTRAST), a randomized controlled trial in 714 chronic ESKD patients (62% men, age 64 ±14, median vintage 2 yrs, 25% DM) comparing online hemodiafiltration with low-flux hemodialysis. Albumin and BMI were measured every 3 months up to six years and predialysis CRP and IL-6 were measured at 6 months and yearly up to three years. The rates of change over time of serum albumin, BMI, CRP and IL-6 were estimated across strata of risk factors with linear mixed effects models.

Results: Albumin concentrations and BMI decreased but CRP and IL-6 increased over time. For every incremental year of baseline age, there was a yearly excess decline in albumin of 0.03 g/L (P<0.001) and an excess decline in BMI of 0.02 kg/m2 (P<0.001). In patients with DM there was a yearly excess decline in albumin of 0.52 g/L (P=0.002) and the decline in BMI doubled as compared to patients without DM (P=0.21). In men, there was an excess decline in albumin of 0.30 g/L per year (P=0.05), and an excess increase in IL6 of 11.5 % (P=0.04) per year as compared to women.

Conclusions: Despite best efforts of care all inflammatory and nutritional parameters worsened over time. In older patients, patients with DM and men the deterioration of these parameters was more pronounced. Special focus on patients at risk by individualizing medical care might improve their prognosis.

SA-PO586

On-Line Hemodiafiltration Treatment Using a New Fx CorDiax: Helixone Plus Membranes: Short Term Observation Katarzyna Bladek, Irena Pietrzak. *Fresenius NephroCare, Poznan, Wielkopolska, Poland.*

Background: OL-HDF and capillary haemodiafilters –helixone plus is the most advanced form of extracorporeal renal replacement therapy. This approach gives a higher sieving coefficient for middle molecules and ensures a low albumin loss. The role of OL- HDF with helixone plus in anaemia treatment still is unknown. Anaemia in ESRD pts is commonly associated with inadequate EPO production an its endogenous resistance cause by uremic toxins. Our objective was to compare effectiveness of FX OL- HDF and CorDiax- plus OL-HDF.

Methods: In this study participated 37 uremic pts- treated by OL-Fx HDF for at least 12 mth. Changes in dose of dialysis, hemoglobin level (Hb), Fe, serum albumin, dose-response effect of ESA were determined at the beginning and after 4 mth of CorDiax HDF treatment. Dose of dialysis (eKt/V) was calculated from pre- and post-treatment urea concentrations according to Daugirdas. To evaluate the dose-response effect of ESA we used the erythropoietin resistance index (ERI), calculated as the weekly dose of ESA (µg) divided by the dry body weight (DBW kg) and Hb level (g/dl).

Results: There were no differences between eKt/V at the beginning (1,45±0,11,) and after 4mth (1,44,±0,13,) of observation. Mean levels of Hb (11,02±1,19, 11,26±0,99) and Fe (71,32±27,30, 68,89±21,81) did not changed during observation. ERI decreased significantly (p=0,05) from 0,019±0,021 to 0,012±0,019 and ESA dose decreased from 12,97±12,88, to 8,92±13,29 (p=0,07). There was a trend for serum albumin concentration to increase from 3,28,±0,35, to 3,92, ±0,27.There was found significant correlation (r = - 0,45) between ERI and serum albumin levels after 4 mth of treatment.

Conclusions: 1. OL-HDF with CorDiax helixone plus membrane influences ESA dose and ERI during 4 mth of treatment. It allows considerable anaemia correction and reduces ESA doses.

2. CorDiax membrane with greater clearences of some uremic toxins in comparison to FX gives significant decreased of ERI even stable dose of dialysis in this study.

3. Increasing serum albumin levels may suggest lower loss of it using CorDiax membranes in postdilution OL-HDF as compared with FX-OL-HDF.

4. Further research to confirm these findings is needed.

SA-PO587

The Cardiovascular Effects of Cinacalcet Hydrochloride in Hemodialysis Patients with Secondary Hyperparathyroidism Sun Ryoung Choi,[2] Yu Ah Hong,[1] Ji Hee Lim,[1] Min-Young Kim,[1] Bumsoon Choi,[1] Cheol Whee Park.[1] *[1]Department of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine,The Catholic University of Korea, Seoul, Korea; [2]Department of Internal Medicine, Hallym University College of Medicine, Seoul, Korea.*

Background: Secondary hyperparathyroidism (SHPT) in hemodialysis patients has an essential role in the endothelial and cardiac dysfunction. We performed this study to evaluate the impact of cinacalcet hydrochloride on cardiovascular system by investigating the clinical cardiovascular parameters, oxidative stress and surrogate markers of endothelial dysfunction in hemodialysis patients with SHPT.

Methods: We studied 12 hemodialysis patients who had high levels of intact PTH(iPTH, >300pg/mL) and corrected calcium (cCa, >9.0mg/dL) with cinacalcet treatment over 20-weeks.Our study consisted of 3 phases;wash-up period for 12 weeks (phase I),medication period for 20 weeks (phase II), follow-up period at 20 weeks after end of treatment (phase III). We performed flow-mediated dilation (FMD), cadio-ankle vascular index (CAVI), and echocardiographic analyses at the end of each phase. Furthermore, we measured serum NOx (nitrate and nitrite), isoprostane, and sICAM-1 to evaluate the degree of oxidative stress and endothelial dysfunction during three phases of this study.

Results: Treatment significantly decreased levels of iPTH, calcium, phosphorus, calcium x phosphorus. But the level of C-reactive protein was not affected by treatment. There were no differences in blood pressure.There was significant improvement in diastolic dysfunction (E/e', P <0.05). There were notable reduction trends in the left ventricular mass index (P=0.06). In contrast, cinacalcet significantly improved FMD (P < 0.01) and enhanced

CAVI (P < 0.05) .The oxidative stress and endothelial dysfunction were improved during the phase II, but returned to the baseline levels at the phase III (NOx, P < 0.05; isoprostane, P < 0.05; sICAM-1, P < 0.05).

Conclusions: Cinacalcet may ameliorate endothelial and diastolic dysfunction by decreasing the oxidative stress as well as increasing the NOx production in hemodialysis patients with secondary hyperparathyroidism.

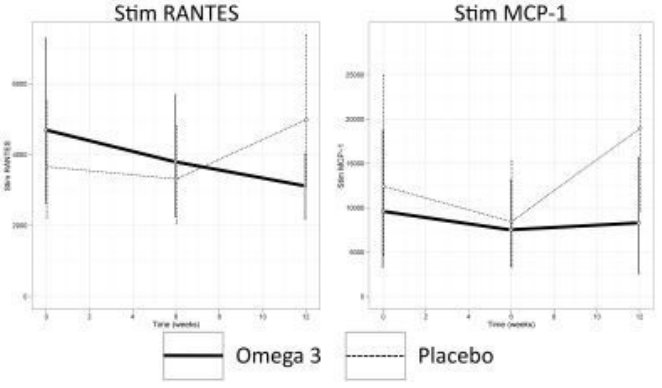
SA-PO588

Omega-3 Fatty Acids Inhibit the Up-Regulation of Endothelial Chemokines MCP-1 and RANTES in CHD Patients Adriana Hung,[1,2] Cindy Booker,[1,2] Edward D. Siew,[1,2] Amy J. Graves,[3] Ayumi Shintani,[3] Charles D. Ellis,[2] Jonathan Himmelfarb,[4] T. Alp Ikizler.[1,2] *[1]CSR&D, Veterans Administration TVHS, Nashville, TN; [2]Nephrology, Vanderbilt University, Nashville, TN; [3]Biostatistics, Vanderbilt University, Nashville, TN; [4]KRI, University of Washington, Seattle, WA.*

Background: One of the early events in inflammation is the upregulation of endothelial chemokines, monocyte chemoattractant protein-1 (MCP-1) and RANTES (Regulated on Activation, Normal T Cell Expressed and Secreted). In this study we tested the hypothesis that Omega-3 fatty acid (O3FA) supplementation will be effective in attenuating chemokine expression.

Methods: This is a double blinded RCT of the supplementation of omega-3 fatty acid in prevalent chronic Hemodialysis patients (CHD). Patients were randomly assigned in a 1:1 fashion to receive 3 gms of eicosapentaenoic acid (EPA) (C20:5 omega 3) plus docosahexaenoic acid (DHA) (C22:6 omega 3) versus placebo for 12 weeks. Blood samples were collected before and after the intervention. MCP-1 and RANTES were measured from LPS stimulated PBMC. Analysis of covariance (ANCOVA) was used to compare percent change from baseline to 12 weeks.

Results: 38 CHD patients were randomized and 31 completed the trial. Mean age was 51 ± 14 years, 73% African American and 79% males. Supplementation of O3FA effectively decreased both lipopolysaccharide (LPS)-induced expression of RANTES (p=0.04) and, with borderline significance, monocyte chemo attractant protein-1 (MCP-1) (p=0.06).



There was no significant effect of the intervention on IL-6 (p=0.08).

Conclusions: The data obtained from this study suggest that omega-3 fatty acids supplementation is beneficial in decreasing the levels of pro-inflammatory chemokines RANTES and MCP-1. Larger studies evaluating the impact of omega 3 supplementation on CV mortality and PEW in ESRD are needed.

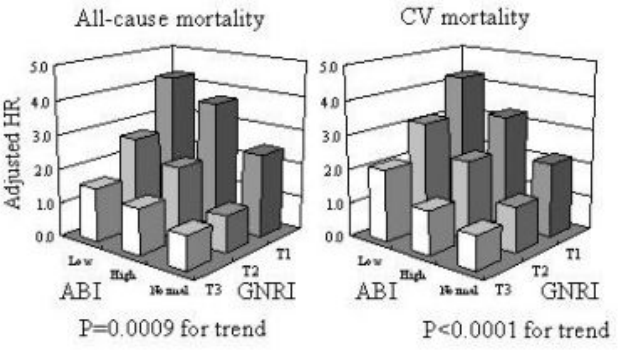
SA-PO589

Association of Ankle Brachial Index and Protein-Energy Wasting with Mortality in Hemodialysis Patients Yasuhiko Ito,[1] Hirotake Kasuga,[2] Masashi Mizuno,[1] Yasuhiro Suzuki,[1] Shoichi Maruyama,[1] Enyu Imai,[1] Seiichi Matsuo.[1] *[1]Nephrology, Nagoya University, Nagoya, Japan; [2]Nephrology, Nagoya Kyoritsu Hospital, Nagoya, Japan.*

Background: Ankle brachial index (ABI) has been widely recognized as a marker of systemic atherosclerosis. Protein-energy wasting (PEW), currently considered to be due to inflammatory process, is highly prevalent in HD patients, and is associated with increasing risk of mortality. We investigated the association of ABI and PEW with mortality in HD patients.

Methods: A total of 1036 hemodialysis (HD) patients were divided into 3 groups according to ABI levels; normal group: 0.9-1.4 (n=682), high group: >1.4 (n=150) and low group: <0.9 (n=204), and were followed up for 8 years. Patients were also divided into tertiles according to geriatric nutritional risk index (GNRI) levels as a simplified marker of PEW state; tertile 1 (T1): <90.8, T2: 90.8-97.3 and T3: >97.3. GNRI = (14.89 × albumin) + [41.7 × (body weight / body weight at BMI of 22)].

Results: Declined GNRI levels were independently associated with abnormal ABI (odds ratio 0.97, 95%CI 0.96-0.99, p=0.0009). By Kaplan-Meier analysis, 8-year event-free survival rates from mortality were 62.8%, 46.2% and 27.3% among normal, high and low ABI group (p<0.0001), and were 34.3%, 59.7% and 68.0% among T1, T2 and T3 of GNRI, respectively (p<0.0001). In the combined setting of ABI and GNRI, the risk of mortality was 4.26-fold (95%CI 2.63-6.90) higher in the low ABI group with T1 of GNRI and 3.69-fold (95%CI 2.30-5.91) higher in the high ABI group with T1 of GNRI compared to the normal ABI group with T3 of GNRI, respectively (Figure). Similar results were also obtained from cardiovascular mortality.



Conclusions: Abnormal ABI and lower GNRI, might reflect PEW state, were closely linked, and were interactively associated with increasing risk of mortality in HD patients.

SA-PO590

Arterial Stiffening Is Related to Changes in Body Composition in Patients on Regular Hemodialysis Akihiko Kato,[1] Yukitoshi Sakao,[1] Takayuki Tsuji,[2] Naro Ohashi,[2] Hideo Yasuda,[2] Yoshihide Fujigaki.[2] *[1]Blood Purification Unit, University Hospital, Hamamatsu University School of Medicine, Hamamatsu, Shizuoka, Japan; [2]First Department of Medicine, Hamamatsu University School of Medicine, Hamamatsu, Shizuoka, Japan.*

Background: In the elderly, arterial stiffness is associated with low thigh muscle mass in men but not in women, probably due to reduced testosterone level in men (Atherosclerosis, 2010). We showed that thigh sarcopenia is related to carotid arteriosclerosis in hemodialysis (HD) patients (NDT 2011). However, it remains unclear whether a sex-dependent association may be present in the dialysis population. The purpose of this study was to evaluate the relationship of the mid-thigh muscle cross-sectional area to arterial stiffness in male and female HD patients, respectively.

Methods: The study population consisted of 82 male and 41 female HD patients with a mean age of 61±11 years (time on HD: 11±10 years). We calculated abdominal subcutaneous fat-mass area (ASFA), abdominal visceral fat-mass area (AVFA) and thigh muscle area (TMA) form CT images, and then adjusted these by body mass index (BMI). We also measured brachial-ankle pulse wave velocity (baPWV) automatically using a volume plethysmographic apparatus (VeraSera VS-1000, Fukuda Denshi, Tokyo, Japan).

Results: In both sexes, baPWV was significantly correlated positively with age and systolic blood pressure (SBP) (p<0.01) while negatively with peripheral total lymphocyte count (p<0.05). There was a significant association between TMA/BMI ratio and baPWV in men (r=-0.32, p<0.01). In women, baPWV was negatively correlated with AVFA/BMI ratio (r=-0.38, p=0.02). A multiple regression analysis revealed that TMA/BMI ratio was inversely correlated with baPWV independent of other clinical variables that associated with baPWV in men. In contrast, AVFA/BMI ratio was independently and negatively associated with baPWV in women.

Conclusions: The findings suggest that arterial stiffening is related to skeletal muscle atrophy in men, while with reduced abdominal adiposity in women in HD patients.

SA-PO591

Effect of a Single Hemodialysis Session on Lipid Particle Number and Size Determined by Nuclear Magnetic Resonance Lipoprotein Analysis Anjali Gupta, Frank Modersitzki, Manish P. Ponda. *New York University Langone Medical Center, New York, NY.*

Background: Atherosclerotic vascular disease is the main cause of mortality for patients with end-stage renal disease (ESRD). Mild degrees of renal impairment have been shown to be associated with lipoprotein abnormalities including greater concentrations of small Low-Density Lipoprotein (LDL) and Intermediate-Density Lipoprotein using Nuclear Magnetic Resonance (NMR) lipid analysis. The aim of our study is to evaluate changes in various lipoprotein subclasses during a single hemodialysis (HD) session.

Methods: Thirteen patients on maintenance HD were enrolled into the study. Fasting NMR lipid analysis was obtained before initiation of HD (t1), after two hours of HD (t2), end of HD session (t3) and the next day of dialysis (t4). Measured lipoproteins levels were adjusted for ultrafiltration, based on calculated plasma volume changes from hematocrit values obtained at various time points during the HD session.

Results: Our study shows a decrease in mean concentration of Very Low Density Lipoprotein (VLDL) and chylomicon particles by 67% at t2 and 52% at t3 as compared with t1 (P < 0.05). The reduction was mainly in small and medium VLDL particles, large VLDL particles did not show significant changes. The concentration of triglycerides (TG) decreased by 40% (P < 0.05) during dialysis and was lowest at two hours into dialysis. LDL and high-density lipoprotein (HDL) particle concentrations did not change significantly during a HD session. However, mean concentrations of LDL particles (total, large and small) were 20% higher (p <0.05) on the day after dialysis as compared to t1. Similarly, concentrations of HDL particles were 12% higher (P < 0.05).

Conclusions: Our pilot study shows a significant fluctuation in concentrations of VLDL and chylomicron particles especially, small and medium VLDL particles during a single hemodialysis session. Further investigations are needed to see if these fluctuations contribute to the increased cardiovascular mortality of hemodialysis patients.

SA-PO592

Lipoprotein Associated Phospholipase A2 (LP-PLA2) Activity in CKD Stage 5 Patients Is Associated with Atherosclerosis Christof Ulrich, Felix Kohler, Bogusz Trojanowicz, Antje Spens, Roman Fiedler, Eric Seibert, Matthias Girndt. *Martin-Luther University Halle-Wittenberg, Halle (Saale).*

Background: LP-PLA2, an enzyme mainly derived from macrophages, hydrolyses oxidized phospholipids, thereby producing proatherosclerotic lyso-phosphatidylcholine and free oxidative radicals. We recently demonstrated a significant association between proinflammatory monocytes and atherosclerosis in CKD patients. The aim of the study was to evaluate LP-PLA2 activity and – gene expression in HD patients with and without signs of atherosclerosis and to link these data to inflammatory monocytes.

Methods: 63 HD patients (age 63.2±15.2 years, 40 m/23f, 23 diabetics) were enrolled in the study. Atherosclerosis was diagnosed by ultrasound evaluation of the carotid arteries using a recently established atherosclerosis score system (CJASN 2011; 6:505-511). LP-PLA2 activity was measured in frozen plasma samples. For real time gene expression analysis RNA was isolated from whole blood using the PAX gene system. Monocytes were classified by flow cytometry according to expression of CD14 and CD16.

Results: 21 of 63 patients were scored atherosclerosis positive (At+). These patients were older (70.8±10.9 vs. 59.5±15.7, p=0.04) and had significantly higher LP-PLA2 activity compared to patients without atherosclerosis (At-) (LP-PLA2-activity [nmol/min/ml], At+: 20.1±4.2 vs. At-: 17.6±4.5, p=0.04). Both groups did not differ regarding the soluble inflammatory marker CRP and the frequency of CD14++CD16+ monocytes. Normalized LP-PLA2 gene expression did not correlate with LP-PLA2 activity. However, the frequency of CD14++CD16+ monocytes was significantly associated with both LP-PLA2 gene expression (r=0.26, P=0.03) and CRP (r=0.31, P=0.02).

Conclusions: Our data show that CKD-5 patients with relevant atherosclerosis have higher LP-PLA2 activity compared to patients without severe atherosclerosis. This seems to be independent from CRP. As demonstrated by other studies LP-PLA2 activity and gene expression do not necessarily correlate. The inflammatory monocyte subset CD14++CD16+ is a potential source of LP-PLA2. Further studies will show if differentiation of CD14++CD16+ is linked to higher LP-PLA2 activity levels.

SA-PO593

Is There Association between Electronegative LDL and Bone Mineral Density in Hemodialysis Patients? Julie Lobo,[1] Milena Barcza Stockler-pinto,[2] Viviane Oliveira Leal,[1] Najla Elias Farage,[3] Dulcinéia Saes Parra Abdalla,[4] Denise Mafra.[1] *[1]Federal Univ Fluminense, Brazil; [2]Federal Univ of Rio de Janeiro, Brazil; [3]RenalCor, Brazil; [4]University of São Paulo, Brazil.*

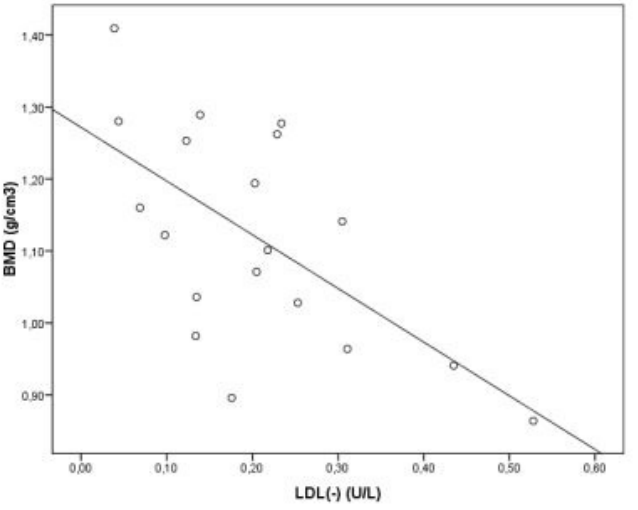
Background: Electronegative LDL [LDL(-)] plays an important role in atherosclerosis and also in bone remodeling. However, there is no information concerning hemodialysis (HD) patients. Our aim was verify the relationship between inflammatory markers, LDL(-) levels and bone mineral density (BMD) in HD patients.

Methods: Twenty HD patients (11M/9F; 52.4±12.8 years) from RenalCor Clinic, Brazil, were studied. LDL(-) and parathyroid hormone (PTH) were measured by ELISA; tumor necrosis factor alpha (TNF-α), interleukin-6 (IL-6), vascular cell adhesion molecule 1 (VCAM-1) and intercellular adhesion molecule 1 (ICAM-1) were measured by a multiplex assay kit. BMD was evaluated by dual energy X-ray absorptiometry (DXA). SPSS for Windows (version 11.0) was used for statistics.

Results: Results are showed in Table 1. Patients presented significantly high levels of LDL(-) and inflammatory markers compared to normal values (Lobo et al., Clin Chim Acta 412:1788-92, 2011). There was a negative correlation between BMD and LDL (-) (r=-0.62, p=0.005) (Figure 1), BMD was not correlated either with PTH or inflammation markers.

Table 1: Biochemical parameters in HD patients

Parameters	HD Patients
Body Mass Index (Kg/m2)	24.1±4.4
Average dialysis time (Months)	69.1±39.7
LDL(-) (U/L)	0.32 ± 0.30
TNF-α (pg/mL)	5.4 ± 1.6
IL-6 (pg/mL)	4.1 ± 1.6
VCAM-1 (ng/mL)	48.5 ± 8.5
ICAM-1 (ng/mL)	20.5 ± 15.9
BMD (g/cm3)	1.11 ± 0.15
PTH (pg/mL)	359 (26-1700)



Conclusions: Our results suggest that LDL(-) might play a role not only in atherosclerosis, but also on bone remodeling, probably contributing to alterations in bone metabolism found in HD patients. More comprehensive studies are needed to better understand this association.

Funding: Government Support - Non-U.S.

SA-PO594

Is Dyslipidemia a Risk Factor for Cardiovascular Disease in Hemodialysis? Milagros Ortiz Librero,[1] Carmen Mon Mon,[1] Juan Carlos Herrero Berron,[1] Olimpia Ortega,[1] Isabel Rodriguez,[1] Paloma Gallar Ruiz,[1] Julie Hinostroza Yanahuaya,[1] Manuel Praga.[2] *[1]Nephrology, Hospital Severo Ochoa, Madrid, Spain; [2]Nephrology, Hospital 12 de Cctubre, Madrid, Spain.*

Background: Cardiovascular(CV)disease is the most common cause of mortality in chronic hemodialysis(HD)patients.Dyslipemia is a cardiovascular risk factor in healthy population.Its treatment has been shown to improve CV prognosis.However,in HD population,this association is less clear.Asses risk factors of mortality in HD,considering:Classical CV risk factors:hypertension,diabetes,lipid abnormalities.Comorbidity,malnutrition,inflammation.

Methods: 64 chronic HD patients followed for 8 years were analyzed(2003-11).71.9% were men with a mean age of 59.97±13.41 years.Follow-up on dialysis was 54.40±38.02 months.65.6% had hypertension,28.1% diabetes and 37.5% had suffered a CV event.In a cross-section at baseline were analyzed:Lipid abnormalities,Charlson comorbidity index (CCI),malnutrition-inflammation parameters(albumin,cholesterol,CRP).Overall and CV mortality were evaluated.

Results: Abnormalities lipid profile:Col>200mg/dl:18.75%.TAG>150mg/dl:43.75%. HDL<40mg/dl:43.75%.LDL>100:32.8%.Atherogenic Index>4.4:31.25%.87.5% had altered lipid profile,48.4% received statins and 42.2% sevelamer.CCIadjusted for age:3.48±1.43. Malnutrition-Inflammation parameters:albumin:4.02±0.3,Cholesterol:166.26±41.01,PCR:12.65±15.21.50% of patients died,65.2% of cardiovascular etiology.Univariated analysis showed age>59 years(p50),cholesterol<137(p25),CCI (>5),CRP>12.7(p75),sevelamer treatment and previous CV disease were associated to overall mortality (OM). In Cox analysis only CCI adjusted for age(Exp:3.82,95%CI:1.63-8.89),elevated CRP(Exp:2,174,95%CI:1.05-4.49) and low levels of cholesterol(Exp:0.29,95%CI: 0.12-0.74)were associated with OM.None of the factors described were correlated with CV mortality.

Conclusions: Despite the high prevalence of abnormal lipid profile,lipids are not predictors of long-term mortality in HD population.Malnutrition-inflammation and comorbidity will be the determinants of mortality in this population.

SA-PO595

Parathyoid Dysfunction in Elderly Hemodialysis Patients with Hemodialysis and Its Related Factors Huiling Wang. *Division of Nephrology, Jiming Hospital, Shanghai, China.*

Background: In this study, we observe the relevant indicators related to calcium and phosphorus metabolism disorders and parathyroid abnormalities for hemodialysis patiens with the age over 65, and analyze its related factors.

Methods: 286 stabile patients with maintenance hemodialysis (MHD), who came from Jimin Hospital of Shanghai from 2010.01 to 2010.12, were divided into two groups according to age: elderly group (≥ 65 years) and non-elderly group (<65 years).All patients underwent conventional HD, among which, most patients took hemodiafiltration(HDF) 1-2 times per month. According to KDIGO guideline, patients with different conditions used erythropoietin, rocaltrol and calcium carbonate when needed. Fasting blood specimen before dialysis were drawn to assay Hb, Scr, BUN, calcium, phosphorus, intact parathyroid hormone (iPTH), high-sensitivity C-reactive protein (Hs-CRP), and albumin (Alb).

Results: Elderly patients accounted for 51.4% of the total people. The major cause was hypertension(35.4%), followed by chronic glomerulonephritis(21.1%) and diabetes(19.7%). While in the non-elderly patients group, the main cause was chronic glomerulonephritis(43.2%), followed by diabetes(23.7%) and hypertension(12.2%). Comparing with those of non-elderly patients, the elderly patients' dialysis ages were shorter, dry weight was lighter, the number of patients who used vitamin D and/or calcium was fewer, systolic blood pressure was higher, diastolic blood pressure was lower, serum BUN, Scr, P, iPTH, Alb((35.3±2.1) vs (37.1±2.7),g/l), standard-protein nitrogen present rate (nPNA) concentration were also lower. The level of Hs-CRP was much higher((7.24±2.41) vs (6.52±2.68),mg/l) (P <0.05).The incidence of emerging lower iPTH (<150pg/L) was much higher(55.8% vs 36.7%)(P <0.05).While the level of Hb, AC-Ca and Kt / V in the two groups showed no differences(P> 0.05).In logistic multiple regression analysis,it showed that the age, plasma phosphorus, Alb and nPNA of patients with MHD were independent factors of secondary hypoparathyroidism.

Conclusions: Most elderly patients with HD have the phenomenon of hypoparathyroidism, its occurrence may be related to age, malnutrition and other potential factors.

Relationship between Body Composition, Change of Body Weight and Prevalence of Cardiovascular Disease, Usefulness of a Home Body Composition Analyzer in Hemodialysis Patients Yukie Kitajima,[1] Yuzuru Sato.[2] *[1]Tokyo Healthcare University, Tokyo, Japan; [2]Sato Junkanki Hospital, Matsuyama, Ehime, Japan.*

Background: The risk factors for cardiovascular disease in hemodialysis patients include age, duration of hemodialysis, diabetes mellitus and hyperphosphatemia. We investigated the relationship among visceral fat area, percentage of body fat with a home body composition analyzer, a multifrequency bioelectrical impedance analysis and anamnesis of cardiovascular complication, between body weight change and body fat mass change.

Methods: Area of visceral fat was measured using CT in 84 non-diabetic patients. Body composition was measured using a home body composition analyzer(OMRON CO., LTD) and a multifrequency bioelectrical impedance analysis(Biospace CO., LTD). Patients were divided into two groups according to visceral fat area; those with visceral fat area < 100cm^2 (Group A) and with > 100cm^2 (Group B). Next, body weight change and body fat mass change were evaluated in 59 stable hemodialysis patients for three years.

Results: Group B showed higher rate of cardiovascular complication, especially ischemic heart disease (p<0.01). Visceral fat area correlated with BMI (R^2=0.523), total body fat (R^2=0.544), percentage of body fat (R^2=0.283). Furthermore, Patients with ischemic heart disease showed higher percentage of body fat (p<0.05). With regard to the relationship between body weight change and body fat mass change over the three-year period, a significant positive correlation was showed between percentage of body weight change and percentage of body fat mass change (male: R^2=0.521, female: R^2=0.786). Percentage of body fat of a home body composition analyzer and a multifrequency bioelectrical impedance analysis showed positive correlation(R^2=0.741).

Conclusions: Higher visceral fat area was found to have the high rate of cardiovascular disease, especially ischemic heart disease in hemodialysis patients. In addition, BMI and percentage of body fat can be measured more easily than CT. Results also showed that body weight change reflect body fat mass change. Those assessments will evade the risk of cardiovascular disease. Use of a home body composition analyzer is effective and inexpensive.

SA-PO597

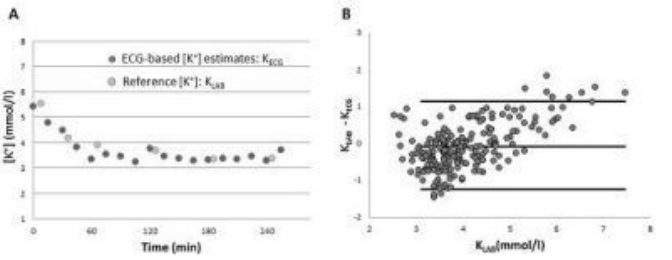
Noninvasive Intradialytic Potassium Estimation in HD Patients Cristiana Corsi,[1] Emanuele Mambelli,[2] Stefano Severi,[1] Antonio Santoro.[2] *[1]Department of Electronics, Computer Science and Systems, University of Bologna, Cesena, Italy; [2]Nephrology, Dialysis and Hypertension, Policlinico S. Orsola-Malpighi, Bologna, Italy.*

Background: The K^+ changes have a strong influence on the T-wave morphology in the ECG signal. Both hypo- and hyperkalemia influence cardiac repolarization and are associated with increased mortality in HD patients. Intradialytic K^+monitoring could be extremely useful to maintain or modify the K^+ balance in patients with high risk of cardiac arrhythmias by means of a sort of closed loop control.

The aims of the study were to develop a new method to estimate serum K^+ from the real-time T-wave analysis and to validate it in HD patients.

Methods: We performed Holter ECG (Mortara H12+) in 13 HD patients (39 sessions, 3 per patient over three weeks). A 2-minute window median value of the ratio of the T-wave slope to amplitude ($T_{S/A}$) was used to estimate K^+. Reference values (K_{LAB}) were obtained from blood samples. The ECG estimate K^+ (K_{ECG}) has been compared to K_{LAB} by correlation and Bland-Altman analyses.

Results: K_{LAB} varied from 5.15±0.88 mM (range: 3.11 – 7.46) at the beginning of HD to 3.28±0.29 (range: 2.63 – 3.95) at the end (-47%±15%).The K_{ECG} estimator gave consistent results in 33/39 sessions. A patient specific calibration of the estimator based on data from the first session allowed a good agreement with the reference measurements (Figure 1A) in all the patients in the two following sessions, with an error of -0.04±0.61 mM (Figure 1B).



Conclusions: The estimate of serum K^+ from the ECG can be realistic. After a more comprehensive validation and assessment of potentially interfering factors (contemporary other electrolytes and/or cardiac electrophysiology abnormalities, etc.) this simple and noninvasive measure could help in preventing K^+ changes-related intradialytic dangerous arrythmias.

SA-PO598

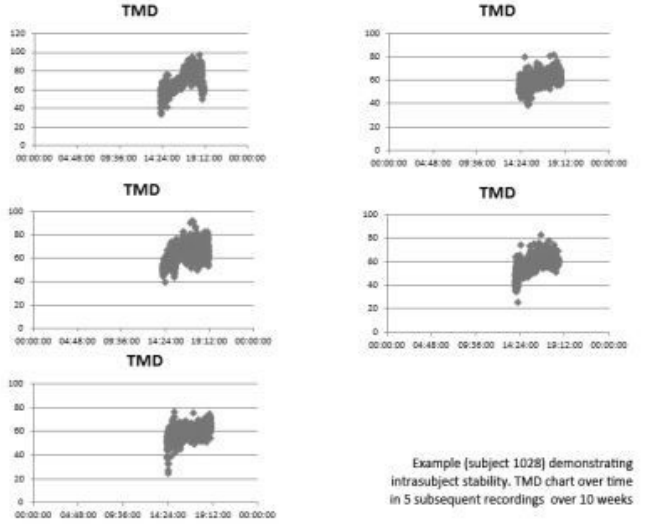
Analysis of T-Wave Morphology for Risk Stratification in Hemodialysis Patients Dimitrios J. Poulikakos, Debasish Banerjee, Marek Malik. *St George's University of London, London, United Kingdom.*

Background: Risk stratification for sudden cardiac in hemodialysis is an urgent clinical need. We hypothetised that dialysis represents a stable cardiovascular challenge for each patient generating a subject-specific repolarisation profile. We prospectively study dynamic repolarisation indices derived from Holter ECG monitoring on dialysis.

Methods: 12-lead Holter ECG recordings are performed during dialysis for five sessions at two weeks intervals. QTC interval, proportion between the principal axes of the T wave loop (CRa), T wave morphology dispersion (TDM), proportion between the dimension and the length of the T wave loop (Loop Ratio), absolute and relative T wave residua (ATWR) and total cosine R to T (TCRT) are calculated automatically and blindly.

Results: 42 out of 49 subjects so far have analysable data (210 recordings). Two sustained cardiac arrest. Mean age is 58.84 ±13, females 17 (39%), diabetic 12(27.9%) and 7 (16.3%) have coronary artery disease. Mean repolarisation values are QTC 437.64±22.9, CRa 0.21±0.09, TDM 34.2±21, Loop Ratio 0.12±0.03,RTWR 0.001±0.001, ATWR= 2124.4±1688, TCRT 0.204±0.61.

QTC, CRA, TMD, Loop Ratio, Absolute TWR, showed intra-subject stability (Repeated measure ANOVA F=0.47, 0.39, 0.87, 0.52, 0.92 and intra-class correlation coefficients ICC 0.9.69, 0.961, 0.967, 0.919, 0.894, respectively) and inter-subject variability (F= 7384, 75.52, 39.8, 199, 34.6 respectively, p <0.001).



Example (subject 1028) demonstrating intrasubject stability. TMD chart over time in 5 subsequent recordings over 10 weeks

Subjects with cardiac arrest had significantly higher mean TDM, relative TWR and absolute TWR (76.38±1.99, 0.0025±.0027, 4784±853 respectively) and lower TCRT (-0.7677±.044). These differences are consistent with risk prediction in cardiac patients.

Conclusions: Repolarisation indices on dialysis can depict subject-specific profiles. Further data is needed to characterise high risk profiles.

SA-PO599

Predicting Mortality in Dialysis Patients: Does a Simple Chest X-Ray Have Prognostic Value? Ethan Bohn, Brent Gali, Navdeep Tangri, Manish M. Sood, Paul Komenda, Claudio Rigatto. *University of Manitoba, Winnipeg, Canada.*

Background: Clinical outcomes of dialysis patients are variable, and improved knowledge of prognosis would inform decisions regarding patient management. We assessed the value of simple, chest x-ray derived measures of cardiac size (cardiothoracic ratio (CTR)) and vascular calcification (Aortic Arch Calcification (AAC)), in predicting death in a prevalent cohort of hemodialysis (HD) patients.

Methods: We used a database of patients starting HD between 2000 and 2010 in Manitoba, Canada. At least one electronically accessible and technically adequate postero-anterior (PA) chest x-ray was available in 791 patients. Two observers measured CTR and AAC independently in all films; disputes were settled by consensus. AAC was graded as 0 to 3 as per Hashimoto et al (Atherosclerosis 2010, 210:137). Cox regression was used for multivariate modelling.

Results: The median age of the study population was 58 years and median dialysis vintage was 1.3 years. 47% of participants were male and 35% were of aboriginal descent. Mean CTR was 0.53±0.07. Of 791 patients, 137 died during follow-up. Age, diabetes, heart failure, and baseline serum creatinine and calcium were the strongest predictors of survival in a base Cox model. Both CTR (HR 1.71 [1.33, 2.20] per 0.1 unit change, AUC= 0.60 [0.55, 0.65]), and AAC>1 (HR 2.48 [1.70, 3.62] AUC=0.62 [0.56, 0.67) were highly associated with death in univariate Cox analysis. CTR remained significant after adjustment for base model variables (adjusted HR 1.36 [1.04, 1.78]), but did not increase the AUC of the base model (0.71 [0.66, 0.76] vs. 0.72 [0.67, 0.77]) and did not improve net reclassification performance (NRI=0). AAC was not associated with mortality after adjustment for age in multivariate Cox models.

Conclusions: Neither CTR nor AAC assessed on routine chest x-ray improved prediction of mortality in this prevalent cohort of HD patients. Our data does not support the utility of simple x-ray derived measures of cardiac size and vascular calcification. More advanced imaging techniques such as cardiac MRI and coronary CT may be needed to improve prognostication in this population.

SA-PO600

Electrocardiographic Early Repolarisation: A Marker for Sudden Cardiac Death: Is Three Times More Common in Patients with Chronic Kidney Disease, and Increases with Disease Severity Reza Hajhosseiny,[1] Frederic Sebag,[2] Ronak Rajani,[2] Kaivan Khavandi,[2] Matthew James Wright,[2] David Goldsmith.[1] *[1]Renal and Transplantation Department, Guy's Hospital, London, United Kingdom; [2]Department of Cardiology, St Thomas' Hospital, London, United Kingdom.*

Background: Although electrocardiographic (ECG) early repolarisation (ER) occurs infrequently (<5%) in general and atherosclerotic populations and is a marker of sudden cardiac death (SCD), the prevalence of ER in patients with chronic kidney disease (CKD), in whom SCD is common, is unknown. We aim to determine the frequency and causes of ER in patients with CKD.

Methods: We retrospectively studied 197 patients with stage 3-5 CKD. Demographic cardiovascular risk data, cardiac history, co-morbidities, and medications were recorded, with bone/mineral biochemistry and C-reactive protein levels. All patients underwent a 12-lead ECG analysed for the presence of ER, bundle branch block, left ventricular hypertrophy and relevant electrical durations (PR, QRS, QTc intervals). ER was defined as an elevation of the QRS-ST junction (J point) of at least 0.1mV from baseline with slurring/notching of the QRS complex. To determine whether the presence of ER was a manifestation of CKD, we also evaluated the ECGs of 39 healthy renal transplant donors.

Results: The patients with CKD had a mean age of 61.5 (±16.1) of whom 57% were male. The prevalence of ER in pre-dialysis patients with CKD stage 4 and 5 (N=106, 54%) was higher than in the transplant donors (26.4% vs. 7.7%, p=0.02). ER frequency increased with CKD stage (stage 3: 8%, stage 4: 30% and pre-dialysis stage 5: 25%), but decreased post-dialysis (13%, p=0.02). On multivariate analysis with ER as the dependent variable, and QRS duration, QTc duration, heart rate, PR interval, dialysis, COPD, anti-aldosterone and age as the covariates, only the QRS duration remained a significant independent predictor of ER (OR 0.97, 95% CI, 0.94-0.99, p=0.01).

Conclusions: ER is more common in patients with pre-dialysis CKD compared to healthy renal transplant donors. Further longitudinal studies are indicated to determine whether this increased prevalence of ER is associated with the increased rate of SCD in this population.

SA-PO601

Non-Compressible Arteries in Hemodialysis Patients: Does a High Ankle Brachial Index Mask the Presence of Peripheral Vascular Disease? Kristopher Joel Swiger,[1] Ronald Walden Milam,[2] Stephen Vance,[2] Alan L. Hinderliter.[2] *[1]Johns Hopkins Department of Internal Medicine, Baltimore, MD; [2]Univeristy of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: The Ankle Brachial Index (ABI) is an effective screening tool for peripheral arterial disease (PAD), but is falsely elevated in some chronic kidney disease (CKD) patients with noncompressible arteries due to medial wall calcification. The Toe Brachial Index (TBI) may be a more reliable indicator of occlusive atherosclerotic disease in these individuals. We hypothesized that a high percentage of patients with CKD and noncompressible arteries, characterized by high ABI levels, would have low TBI values suggesting occlusive PAD.

Methods: To compare ABI and TBI values, we measured both indices in a cohort of patients with stage 4 or 5 CKD undergoing renal transplantation evaluation.

Results: The 88 patients averaged 56±12 years of age; 44% were female; 59% were African-American; 64% had diabetes and 52% had a history of tobacco use. The mean blood pressure was 153±32/83±13 mmHg. The non-HDL cholesterol averaged 121±40 mg/dl. The majority (88%) had end-stage renal disease.

The ABI was low (< 0.9), suggesting occlusive PAD, in 27%; borderline (0.9-1.0) in 24%; normal (1.0-1.3) in 33%; and high (> 1.3), indicating noncompressible arteries, in 16%. Of those with a high ABI, 29% had a TBI < 0.9, suggesting occlusive PAD; additionally, 10% of patients with a normal ABI had a TBI < 0.9.

Conclusions: In summary, in our cohort of patients with stage 4 or 5 CKD, the prevalence of PAD was high, as evidenced by a low or borderline ABI in 51%; and noncompressible arteries, characterized by an ABI > 1.3, were observed in 16%. Low TBI values, suggesting occlusive PAD, were observed in 29% of those with a high ABI, and in an additional 10% who had a normal ABI. These results suggest that a high ABI may mask occlusive PAD in a significant proportion of patients with noncompressible arteries. Our findings support further research to examine the accuracy and prognostic significance of the TBI in patients with advanced CKD, and the incremental value of TBI measurements in patients with noncompressible vessels.

SA-PO602

Penultimate Pulse Wave Velocity, More than Baseline Pulse Wave Velocity, Predicted Mortality in Italian ESRD Cohort Study Macaulay A. Onuigbo,[1,2] Antonio Bellasi,[3] Domenico Russo,[4] Biagio Raffaele Di Iorio.[5] *[1]College of Medicine, Mayo Clinic, Rochester, MN; [2]Nephrology, Mayo Clinic Health System; [3]Nefrology, "S. Anna" Hospital, Como, Italy; [4]Nephrology, "Federico II" University, Naples, Italy; [5]Nephrology, "A. Landolfi" Hospital, Solofra (AV), Italy.*

Background: Cardiac disease, the major cause of death in ESRD is difficult to prognosticate. In 2011, our group for the first time showed that PWV variations determined mortality differences. We examined translational PWV changes vs ESRD mortality.

Methods: PWV was measured by the foot-to-foot method and repeated after six months. Coronary artery calcification (CAC) was measured at 0, 12 and 24 months. Mortality outcomes were analyzed.

Results: In 2007-2010, 466 ESRD patients, 229 M:237F, age 19-97 (65.6) years, were followed up for 28.9 months. 128 patients (74M:54F) died. Causes of death - acute myocardial infarction (AMI) in 47 (37%) (age 70, 26M:21F), sudden death (SD) in 29 (23%) (age 72, 19M:10F). Paired PWV available in 308 surviving patients and 106 patients who died. Baseline PWV was lower in surviving vs dead patients – 8.46 +/- 1.8 vs 9.43 +/- 3.75 (p=0.0005). Repeat PWV values were unchanged in 308 survivors (8.46 +/- 1.8 vs 8.53 +/- 1.85, p=0.5, NS). Repeat PWV increased in the 106 who died from 9.43 +/- 3.75 to 12.11 +/- 4.18 (p<0.0001). Of the 29 dead from SD, death occurred <12 hours after the last dialysis (ATLD) in 7, >24 hours ATLD in 20 and >48 hours ATLD in 17. Of the 47 dead from AMI, 6 died <12 hours ATLD, 35 died >24 hours ATLD and 23 died >48 hours ATLD. CAC values scatter did not allow for analysis but baseline CAC values were higher in the AMI/SD patients vs surviving patients.

Conclusions: This is the first report to show a scalable direct relationship between translational PWV and mortality in ESRD. Penultimate PWV, more than baseline PWV predicted mortality. Higher ESRD deaths from AMI/SD occurred during the long inter-dialytic (weekend) period. We propose that PWV be monitored among all ESRD patients. Patients with high and/or increasing PWV values may require more intense cardiovascular analysis. Further research into new preventative/therapeutic options in this area of ESRD care is warranted.

SA-PO603

Blood Pressure Variability (BPV) and the Risk of Death in Incident Hemodialysis (HD) Patients Tariq Shafi,[1 3] Stephen M. Sozio,[1 3] Wendy L. St. Peter,[1 2] Karen J. Bandeen-roche,[1 3] L. Ebony Boulware.[1 3] *[1]Johns Hopkins University; [2]University of Minnesota; [3]The DEcIDE Network Patient Outcomes in End Stage Renal Disease Study Investigators.*

Background: BPV has been associated with poor outcomes in HD patients, but prior studies did not account for potential confounders including volume status and antihypertensive medications.

Methods: We quantified within-person predialysis systolic BPV among 13,331 incident HD patients treated at Dialysis Clinic, Inc. (DCI), using standard deviation of the residual obtained from mixed-effects linear regression models estimating changes in log SBP over time. This measure reflects the summary of each person's SBP variation from their own mean SBP over time. We estimated the association of BPV with mortality (all-cause and cardiovascular disease [CVD]) overall and after stratifying by quintiles of baseline SBP using discrete time proportional hazards regression adjusted for demographics, comorbidities and treatment factors including interdialytic weight gain, lab tests and antihypertensive medications.

Results: Patients' (mean age 62 yrs; 37% black; 45% female) average baseline SBP was 149±19 mmHg. There were 3,625 deaths (1,773 from CVD) during follow-up (median, 1.9 yrs). Higher BPV was associated with increased risk of mortality and this effect was seen overall and in all SBP quintiles.

Predialysis SBP Variability and the Risk of Death

		Deaths	HR (95% CI) for BPV*	p
All-Cause Mortality				
Overall		3625	1.50 (1.41-1.60)	<0.001
By SBP Quintiles	BP (mmHg)			
Q1	<135	1024	1.57 (1.38-1.78)	<0.001
Q2	135-146	672	1.42 (1.22-1.66)	<0.001
Q3	146-154	569	1.32 (1.13-1.55)	0.001
Q4	154-166	589	1.69 (1.46-1.96)	<0.001
Q5	>166	668	1.40 (1.22-1.61)	<0.001
CVD Mortality				
Overall		1773	1.44 (1.31-1.58)	<0.001
By SBP Quintiles				
Q1	<135	480	1.51 (1.25-1.82)	<0.001
Q2	135-146	298	1.31 (1.04-1.66)	0.02
Q3	146-154	273	1.23 (0.97-1.55)	0.09
Q4	154-166	297	1.61 (1.31-1.98)	<0.001
Q5	>166	358	1.41 (1.17-1.71)	<0.001

*Adjusted HR per 2-SD increase in SBPV

Conclusions: Predialysis SBP variability is an important predictor of both overall and CVD mortality in incident HD patients, even after accounting for BP level and comorbidities. Interventions to reduce BPV are warranted, as potential ways to reduce excess mortality in ESRD.

Funding: NIDDK Support, Other U.S. Government Support

SA-PO604

30-Day Outcomes and Predictors of Mortality in Dialysis Patients Undergoing Abdominal Surgery Arley F. Diaz, Gurmukteshwar Singh, Philip Huh, Mihaela Stefan. *Medicine and Renal Division, Baystate Medical Center/ Tufts University School of Medicine, Springfield, MA.*

Background: Dialysis patients not infrequently undergo abdominal surgery, large studies evaluating and quantifying the post-operative risks and mortality in this population have not been performed.

Methods: We analyzed data from the 2007-08 American College of Surgeons National Surgical Quality Improvement Program to calculate the 30-day mortality risk and post-operative complication rates in chronic dialysis patient who underwent abdominal surgery. We also identified predictors for cardiac (acute MI and cardiac arrest) and respiratory (acute respiratory failure and pneumonia) complications. We used a multiple logistic regression analysis to examine associations between preoperative risk factors and postoperative events, in this model we adjusted for preoperative data, such patient's demographics, co-morbid conditions and laboratory results.

Results: 5178 dialysis patients from 189 hospitals were included in the analysis, 2144 abdominal surgeries were performed; overall 30-day mortality was 18.9%, the rates of cardiac and respiratory complications were 5.4 and 25.6% respectively. Functional status, ASA classification and emergency procedures conferred the highest risk factors for mortality with O.R of 2.7, 2.4, and 1.6 ($P<0.05$) respectively, patients with previous history of coronary disease were 2 times more likely to have cardiac complications (O.R 2.0, 95% C.I 1.2-3.2) and laparoscopic procedures were less likely to have respiratory complications (O.R 0.62, 95% C.I 0.46-0.82). Table 1 shows predictors of mortality.

Conclusions: Dialysis patients are at a very high risk of 30-day post-operative mortality, knowledge of predictive parameters may aid in the identification of patients at risk and help prevent mortality and complications after abdominal surgery.

Predictors of 30-day Mortality in Chronic Dialysis Patients After Abdominal Surgery

	Odds Ratio	P Value
Age	1.41 (1.27-1.57)	<0.001
Functional Status	2.77 (1.9-3.9)	<0.001
ASA Classification	2.46 (1.85-3.27)	<0.001
Emergency Procedure	1.69 (1.24-2.31)	0.001
Sepsis	1.24 (1.12-1.37)	<0.001
Ascites	1.60 (1.11-2.31)	0.012

Pulmonary Hypertension Predicts Cardiovascular Mortality and Events in Hemodialysis Patients Zhilian Li, Wei Shi, Xinling Liang, Shuangxin Liu, Wenjian Wang, Penghua Hu, Lixia Xu, Ruizhao Li. *Guangdong General Hospital, Guangdong Academy of Medical Sciences.*

Background: Our previous study observed a close link between cardiovascular(CV) event and pulmonary hypertension(PH) in different stages of chronic kidney disease(CKD), particularly in maintenance hemodialysis(MHD) patients. However, whether PH predicts CV mortality and events remains unknown.

Methods: We did a retrospective cohort study to evaluate the predicative value of PH for CV events in 278 MHD patients. 78 patients with PH and 200 patients without PH were followed up for 2 years. Systolic pulmonary artery pressure(SPAP) was evaluated using Doppler echocardiography and calculated using Bernoulli equation, a value of >40mmHg was defined as PH. CV events were evaluated according to records from the computerized hospital database, which included acute heart failure, angina, acute myocardial infarction (AMI), arrhythmia requiring hospitalization, transient ischemic attack, thromboembolic or hemorrhagic stroke, peripheral vascular disease, or sudden cardiac arrest (or sudden death). The time to the first episode within the 2 years was taken for survival analysis.

Results: Among 278 MHD patients, 53(19.1%) died during the follow-up as a result of all causes, 22(28.2%) in the group with PH, and 31(15.5%) in the group without PH. 28(10.1%) died of CV events (52.8% of the death causes), 15(19.2%) in the group with PH, and 13(6.5%) in the group without PH. Survival curve showed the all-cause and CV mortality and new onset CV events of patients with PH were higher than that of patients without PH. In a multivariate Cox proportional hazard model, the adjusted HR for all-cause mortality, CV mortality and CV events (PH vs non-PH) was 2.38 (95%CI: 1.33-4.26), 4.06 (95%CI: 1.86-8.88) and 2.62 (95%CI: 1.66-4.13), respectively.

Conclusions: Our study in the first time showed the impact of PH on predicting CV mortality and events in MHD patients. Evidence of PH in predicting CV events in non-dialysis CKD patients is needed.

Left Ventricular Mass Is Associated with Increased Risk of Sudden Death in End Stage Kidney Disease Patients Irina Mostovaya,[1] Muriel Grooteman,[2,3] Marinus A. Van Den Dorpel,[4] Erik L. Penne,[1,2] Neelke C. Van Der Weerd,[2] Albert H. Mazairac,[1] Claire H. Den Hoedt,[1,4] Renee Levesque,[5] Menso Jan Nube,[2,3] Pieter M. Ter Wee,[2,3] Peter J. Blankestijn.[1] *[1]Nephrology, Univ. Medical Ctr. Utrecht, Utrecht, Netherlands; [2]Nephrology, VU Univ. Medical Ctr., Amsterdam, Netherlands; [3]Institute for Cardiovasc. Research, VU Univ. Medical Ctr., Netherlands; [4]Internal Medicine, Maasstad Hospital, Rotterdam, Netherlands; [5]Nephrology, Ctr. Hospitalier de l'Univ. de Montréal, Montreal, Canada.*

Background: Left ventricular mass (LVM) is a known predictor of overall and cardiovascular (CV) mortality in end stage kidney disease (ESKD) patients. The aim of this study is to determine whether LVM is 1) associated with overall and CV mortality in our population of ESKD patients and 2) whether LVM is associated with certain types of CV events.

Methods: Analysis was performed with data of 321 ESKD patients from the COnvective TRansport STudy (CONTRAST), a randomized controlled trial comparing online HDF and HD. The primary endpoint of CONTRAST was all-cause mortality. The main secondary endpoint was a composite of major CV events, including death from CV causes, vascular intervention, cerebrovascular accident (CVA) and amputation. Echocardiography was performed at initiation of the study. LVM was divided into tertiles. Multivariate Cox regression analysis was used to determine whether LVM tertiles were associated with the above described clinical events.

Results: After adjustment for age, sex, dialysis vintage, history of cardiovascular disease, diabetes and smoking, the highest tertile of LVM (>260g) was significantly and independently associated with increased risk of overall mortality (HR:1,82; p=0,015), CV mortality (HR:4,01; p=0,004), and sudden death (HR:14,2; p=0,012). No significant relationship was found with risk of overall CV events (HR:1,54; p=0,097), vascular interventions (HR 0,95; p=0,865), CVA (HR:1,60; p=0,758), and amputations (HR:1,09; p=0,886).

Conclusions: LVM is significantly and independently associated with an increased risk of overall mortality, CV mortality and sudden death. No relationship was found between LVM and risk of nonfatal CV events, vascular intervention, CVA and amputation.

SA-PO607

Effects of Hemodiafiltration on Change in Left Ventricular Mass over Time in End Stage Renal Disease Patients Irina Mostovaya,[1] Muriel Grooteman,[2,3] Marinus A. Van Den Dorpel,[4] Erik L. Penne,[1,2] Neelke C. Van Der Weerd,[2] Albert H. Mazairac,[1] Claire H. Den Hoedt,[1,4] Renee Levesque,[5] Menso Jan Nube,[2,3] Pieter M. Ter Wee,[2,3] Peter J. Blankestijn.[1] *[1]Nephrology, Univ. Medical Centertrecht, Utrecht, Netherlands; [2]Nephrology, VU Univ. Medical Center, Amsterdam, Netherlands; [3]Institute for Cardiovascular Research, VU Univ. Medical Center, Amsterdam, Netherlands; [4]Internal Medicine, Maasstad Hospital, Rotterdam, Netherlands; [5]Nephrology, Centre Hospitalier de l'Univ. de Montréal, Montreal, QC, Canada.*

Background: Left ventricular mass (LVM) predicts overall and cardiovascular mortality in end stage kidney disease (ESKD) patients. Stabilization or regression of LVM improves the prognosis in patients with ESKD. Recently, a small (n=22) randomized controlled trial showed that hemodiafiltration (HDF) is associated with a decrease in LVM when compared to standard hemodialysis (HD). The aim of this study is to determine the effect of online HDF versus low flux HD on the rate of change in LVM over time in ESKD patients.

Methods: Analysis was performed with data of 321 ESKD patients from the COnvective TRansport STudy (CONTRAST), a randomized controlled trial comparing online HDF and HD. Patient characteristics and dialysis properties were recorded at baseline every 3 months. M-mode echocardiography was performed on an inter-dialysis day at baseline, after 6 months, 12 months and yearly thereafter. LVM was calculated with Devereux formula. Data on echocardiography and patient characteristics from the first 3 years of follow-up was used for analysis. Differences in rate of change in LVM over time were assessed with linear mixed effect models. Treatment effect was evaluated in subgroups of: age, gender, residual renal function, dialysis vintage, history of cardiovascular disease or diabetes, convection volume and dialysis center.

Results: LVM did not change over time (p=0.356). There was no difference in rate change in LVM between treatment groups (p=0.858). No evidence was found for different effect is the subgroups.

Conclusions: Online HDF does not affect change in LVM over time different from HD. We found no change of LVM over time in a period of 3 years in our patient population.

Severe Left Ventricular Dysfunction Predicts Early Mortality in Incident Asian Dialysis Patients Sabrina Haroon,[1] Nan Luo,[2] Horng Ruey Chua,[1] Boon Wee Teo,[1] Evan J.C. Lee,[1] Titus W. Lau.[1] *[1]Division of Nephrology, National University Health System, Singapore; [2]School of Public Health, National University of Singapore, Singapore.*

Background: Cardiac disease is a leading cause of death amongst dialysis patients. Left ventricular ejection fraction (LVEF) by 2D echocardiography maybe a useful tool in risk stratification of patients starting dialysis. It is however unclear at what level of LVEF (just prior to starting dialysis) predicts early mortality.

Methods: In this retrospective analysis of consecutive patients starting dialysis from Jan 1, 2005 to Dec 31, 2010, we examine 3 different levels of LVEF and its association with early mortality (first 90 days of dialysis). It is part of the protocol in our institution to have a screening echocardiography for all patients just prior to starting dialysis (within a 6 months window). SAS was used for analyses. Logistic regression analysis was used to determine if different LVEF levels in a given model predicts endpoint (90 days mortality).

Results: 870 patients were included in the analysis with 92 deaths (10.6%) occurring within the first 90 days. There were 633 (72.7%) patients with LVEF > 45% (this serve as our reference group of near normal-normal LV function), 173 (19.9%) patients with LVEF 30-45% (this being the group with moderate degree of LV dysfunction) and 64 (7.4%) patients with LVEF < 30% (this being the group with severe LV dysfunction). Multivariate analysis (with inclusion of age, gender, diabetic status, ischemic heart disease status, stroke status, periphery vascular disease status, baseline hemoglobin, albumin and planned start with access into the model) showed amongst different LVEF groups, the group with severe LV dysfunction (LVEF < 30%) was significantly associated with early (90 days into dialysis) mortality (OR 4.27; CI 95% 2.01 - 9.07; p = 0.0002). Interestingly, in this model, presence of ischemic heart disease was not a significant predictor of early mortality and was also not associated with low LVEF.

Conclusions: Severe LV dysfunction (LVEF < 30%) is a strong predictor of early mortality in an incident Asian dialysis cohort but not the group with moderate LV dysfunction and those with known ischemic heart disease.

SA-PO609

Differences in Assessment of Left Ventricular Hypertrophy with Echocardiography Compared to Cardiac Magnetic Resonance Imaging in End Stage Renal Disease: Implications for Clinical Trials Patrick Barry Mark, Rajan K. Patel, Kathryn K. Stevens, Alan G. Jardine. *Institute of Cardiovascular and Medical Sciences, University of Glasgow, Glasgow, Scotland, United Kingdom.*

Background: Left ventricular hypertrophy (LVH) is a risk factor for reduced survival in end stage renal disease (ESRD). Left ventricular (LV) mass is conventionally assessed using echocardiography (echo) although echo may overestimate LV mass compared to cardiac magnetic resonance imaging (CMR). We studied the relationship between LV remodelling and LVH using CMR and echo in ESRD patients.

Methods: 117 haemodialysis patients (63.2% male; median age 54.0, range 24-74) underwent echo and CMR (1.5 Tesla scanner) on the same, non-dialysis day. Echo LV mass was determined using the ASE formula. Characterisation of remodelling (concentric-pressure induced vs. eccentric- volume overload induced) was based on regional wall thickness. CMR LV mass was calculated using analysis software (Siemens Argus). LV mass index (LVMI) was calculated by normalising to body surface area. Power calculations for clinical trials targeting LVH were derived from the data.

Results: 98 patients had suitable images for analysis by both echo and CMR. Mean LVMI was 144.3 g/m^2 by echo and 94.5g/m^2 by CMR. 63.3% of patients had LVH by echo of which 56.5% had eccentric LVH and 43.5% had concentric LVH. 67.5% had LVH by CMR. Echo overestimated LV mass compared to CMR by mean of 48.4g/m^2 (Bland-Altman plot). There was no difference in the degree of overestimation in patients with eccentric compared to concentric LVH (overestimate 46.3 vs. 50.9g/m^2, p=0.77). Based on these data, using CMR in a randomised clinical trial of patients with LVH, 266 patients (133 per group) would be required to have an 80% chance of detecting a reduction in LV mass index of 10g with an intervention, at significance of 5%. A similar trial with echo would require 694 patients.

Conclusions: Overestimation of LV mass with echo compared to CMR in ESRD does not appear to be due to LV remodelling and may reflect other inherent differences between the techniques. CMR does allow for reduction in sample size for clinical trials targeting LVH but not to the dramatic extent previously described.

SA-PO610

Left Ventricular Diastolic Dysfunction Is Associated with Coronary and Carotid Atherosclerosis in Dialysis Patients Jwa-kyung Kim, Myung Jin Choi, Min-Gang Kim, Jisuk Han, Sung Gyun Kim. *Department of Internal Medicine, Hallym University Sacred Heart Hospital, Kidney Research Institute, Republic of Korea.*

Background: Left ventricular diastolic dysfunction (LVDD) is common among patients with chronic kidney disease. We evaluated whether LVDD is associated with atherosclerosis in two major vessels, coronary and carotid arteries in incident dialysis patients.

Methods: Myocardial ischemia and the carotid intima-media thickness (cIMT) was evaluated using single photon emission computed tomography and B-mode ultrasonography. The presence of LVDD was considered when the ratio of early peak transmitral inflow velocity (E) to early diastolic mitral annular velocity (E') (E/E') was >15, and carotid atherosclerosis was defined as cIMT >1.0 mm and/or the presence of plaque.

Results: Among 108 patients, LVDD was observed in 27 patients. Those with LVDD had significantly more perfusion defects [relative risk 4.1, 95% CI 1.8-10.2], a higher summed stress score (SSS, p=0.004) and an increased aortic pulse wave velocity (p=0.022) than subjects without LVDD. Similarly, the cIMT was greater in those with LVDD than patients without (1.04 ± 0.15 vs. 0.82 ± 0.17 mm, p<0.001), and the risk of carotid atherosclerosis was 25 times greater for those with LVDD. Multiple logistic analyses showed that old age [odds ratio (OR) 1.10, 95% CI 1.01-1.19], diabetes (OR 1.82, 95% CI 1.11-3.51), 1 mg/L increase of high-sensitivity C-reactive protein (OR 4.48, 95% CI 1.54-13.04), E/E' >15 (OR 17.94, 95% CI 2.12-35.55) and SSS (OR 1.34, 95% CI 1.04-1.73) were significant predictors for carotid atherosclerosis.

Conclusions: Abnormal LVDD is closely associated with coronary ischemia and carotid atherosclerosis in incident dialysis patients. Further studies are warranted to clarify the cause-effect relationship.

SA-PO611

Analysis of Risk Factors for Cardiac Events in End-Stage Renal Disease Patients with Normal Stress Myocardial Perfusion Imaging Jwa-kyung Kim, Jisuk Han, Myung Jin Choi, Min-Gang Kim, Sung Gyun Kim. *Internal Medicine, Hallym University Sacred Heart Hospital, Kidney Research Institute, Republic of Korea.*

Background: Normal myocardial perfusion imaging is closely associated with very low rates of cardiac events and better long-term prognosis in patients with end-stage renal patients (ESRD). However, it is uncertain whether subsets of these patients are at increased risk for serious cardiac events, even in the presence of a normal perfusion scan. The purpose of this work is to determine the characteristics of the patients who had normal perfusion scan but had cardiac events during follow-up.

Methods: A total of 260 consecutive ESRD patients underwent baseline echocardiography and stress/rest single photon emission computed tomography (SPECT) at the start of dialysis. One hundred sixty (61.5%) of patients showed a summed stress score ≤3, which was considered normal.

Results: During the 4-year follow-up period, there were a total of 79 cardiac events (30.4%). Patients with normal SPECT had significantly lower rates of cardiac event than those with abnormal SPECT (HR, 0.54; 95% CI, 0.31-0.94; *P*=0.029). Among normal SPECT patients, 31 (19.3%) of patients had cardiac events within a mean duration of 25 months. Patients with cardiac events were significantly older (p=0.014), had higher prevalence of diabetes (p=0.013) and lower serum hemoglobin (Hb) and albumin level than patients without cardiac events. In addition, baseline left ventricular (LV) ejection fraction was significantly lower and LV mass index was higher in these patients. Cox proportional hazard analysis showed that diabetes mellitus (HR, 2.57; 95% CI, 1.16-5.68), age >60 years (HR, 2.05; 95% CI, 1.05-4.22), hypoalbuminemia (<3.0 g/dL, HR, 4.15; 95% CI, 2.10-8.17) and anemia (Hb <9.0 g/dL, HR, 4.08; 95% CI, 1.76-9.45) were independent predictors of all cardiac events.

Conclusions: The well-known traditional risk factors for cardiac events are also important in patients with normal perfusion scan. Optimal management of these risk factors is necessary in ESRD patients.

SA-PO612

Chronic Fluid Overload (CFO) Is Associated with Increased Left Ventricular Mass Index (LVMI) & LVMI Improves over Time in Euvolemic (noCFO) Pediatric Patients (Ped Pts) Maintained with Chronic Peritoneal Dialysis (CPD) Kimberly A. Burrows, Heather A. Dickerson, Poyyapakkam Srivaths, Eileen D. Brewer. *Pediatric Renal & Cardiology, Baylor College of Medicine, Houston, TX.*

Background: Ped pts with ESRD have increased cardiovascular mortality. Risk factors include CFO, hypertension, no residual renal function (RRF), anemia and inflammation, all of which contribute to increased LVMI as well as abnormal cardiac remodeling and subsequent diastolic dysfunction. Few ped studies have assessed the relationship between CFO & LVMI, & no ped study has assessed prevalence of CFO in ped pts maintained on CPD. **Aim:** To determine prevalence of CFO & increased LVMI in ped CPD pts & whether LVMI changes with time on CPD.

Methods: Prospective monthly follow-up over 1y for ped pts 6-25yo without underlying primary cardiac disease, who were treated with home cycler CPD for >3m. Fluid status was assessed by bioimpedance, weight (wt) & BP at each monthly visit. CFO was defined as >4% over target dry wt for at least 3m in each 6m period or median value >4% for

an entire 6m period. ECHOcardiogram with LVMI was done initially & at end of study. Monthly serum Ca, P, iPTH, 25OHvit D, & Hgb were measured as part of routine care.

Results: 10/15 pts enrolled completed at least 9m of study; 3 were transplanted, 1 changed modality & 1 is still in study. 2/10 (20%) had CFO, & LVMI at the end of study was significantly higher compared to 8/10 noCFO pts (mean LVMI 57.5 vs. 37.5 g/m$^{2.7}$, p=0.006). In CFO pts, LVMI remained elevated throughout the study (initially 61 & 49.7 g/m$^{2.7}$ and at end of study 60.3 & 54.8 g/m$^{2.7}$). In the 8 noCFO pts, LVMI was increased initially, but improved significantly by end of study (median LVMI 48.6 vs. 36.2 g/m$^{2.7}$, p=0.025). There was no difference in total time on CPD or time averaged monthly BP (indexed for gender, age, ht%ile), Hgb, serum Ca, P, iPTH & 25OHvit D between CFO and noCFO pts. 1/2 CFO & 4/8 noCFO pts had no RRF.

Conclusions: In ped CPD pts CFO is associated with increased & persistent LVMI. In noCFO pts, LVMI improves over time with CPD. These data emphasize the importance of maintaining euvolemia in ped CPD pts to reduce future cardiac morbidity.

Resource Utilization in Patients with Heart Failure Who Develop End Stage Renal Disease Kimberly N. Hong,[1] Sumit Mohan,[2] Mark J. Russo,[3] Deborah D. Ascheim,[1] Jai Radhakrishnan.[2] *[1]Mount Sinai School of Medicine, New York, NY; [2]Columbia University Medicine Center, New York, NY; [3]University of Chicago Medical Center, Chicago, IL.*

Background: While hemodialysis improves volume control, arteriovenous shunting can also impact the progression of heart failure. The purpose of this study was to characterize resource utilization in Medicare beneficiaries with heart failure who were initiated on hemodialysis (HD).

Methods: De-identified inpatient claims data for all Medicare beneficiaries with a Chronic Conditions Warehouse (CCW) heart failure (HF) flag ((N=10,331,062) were obtained from the Centers for Medicare and Medicaid services for the period of 1/1/2001 to 12/31/2005. Medicare beneficiaries with at least 1 year of data prior to converting to an ESRD status code (11, 21) were included (N=68,196). Index hospitalization was defined as the first admission with dialysis that was preceded by at least one admission without dialysis. All outcomes were assessed using paired t-test and included annualized all-cause and HF associated hospitalization rates, LOS and time to rehospitalization before and after HD was started. Principle diagnosis code was used to classify HF hospitalization using the CCW ICD-9 codes definition for HF. Patients were censored following heart/kidney transplant and ventricular assist device use.

Results: Annualized hospitalization rates decreased after the initiation of HD. Specifically, all-cause and HF admissions decreased by 0.48 admissions/yr (7.9±37.5 vs 8.0±12.8, p<0.0067) and 0.62 admissions/yr (1.1±10.2 vs. 0.5±3.0 p<0.0001). Mean LOS, however, was longer following initiation of HD (6.6±9.5 vs 7.4±8.9, p<0.0001).

Conclusions: Patients with HF who were started on HD had lower rates of HF related admissions in the first year of ESRD but tended to have longer hospitalizations suggesting lower utilization among these patients overall but greater utilization among those needing admission. Further analysis is required to identify patients and risk factors that predict continued readmission for HF.

Table - Descriptive Statistics

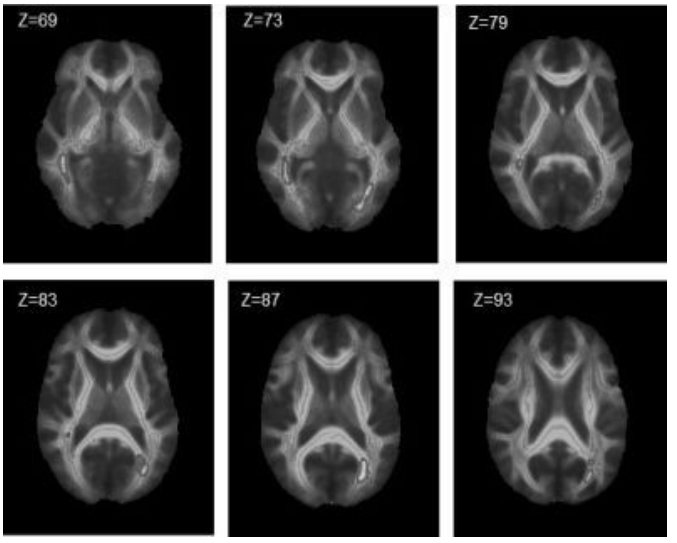
Brain White Matter Microstructure Using Diffusion Tensor Imaging Is Associated with Cognitive Impairment in Haemodialysis Patients Mohamed Tarek Eldehni,[1,2] Aghogho Odudu,[1,2] Chris W. McIntyre.[1,2] *[1]Graduate Entry Medical School, University of Nottingham, United Kingdom; [2]Department of Renal Medicine, Royal Derby Hospital, United Kingdom.*

Background: Structural and functional brain white matter (WM) abnormalities are poorly characterised in Haemodialysis (HD) patients despite the observed deterioration in functional status after initiating HD. We aim to examine the brain WM microstructure using Diffusion Tensor Magnetic Resonance Imaging (DTI) and its correlation with cognitive impairment.

Methods: DTI was done in 71 subjects, 48 incident HD patients and 23 age-matched normal controls (NC). Images were analysed using FSL software. Maps of Fractional anisotropy (FA) (a measure of WM tracts organisation) were computed then a voxelwise statistical analysis of the FA data was done between the groups using TBSS (Tract-Based Spatial Statistic). Cognitive assessment was done using the Montreal Cognitive Assessment (MoCA) and Trail Making Tests (TMT) A & B. Pulse wave velocity (PWV) was done in all subjects.

Results: There were bilateral areas of reduced FA in HD patients compared to NC with statistical significance (P<0.05) indicating distorted WM structure (Figure). MoCA scores were lower in HD patients (25 IQR 22-28 vs 28 IQR 26-30, P=0.004). TMT A & B times were higher in HD patients (TMT A 35s IQR 26-49 vs 22s 21-30, P=0.001) (TMT B 80s IQR 57-121 vs 56s IQR 43-87). PWV did not differ between the groups (P=0.08).

Conclusions: HD patients have significant WM structural abnormalities manifest as cognitive impairment and reduced attention and mental flexibility compared to aged-matched normal controls. The lack of difference in large vessel characteristics could indicate that WM distortion in HD patients is linked to the circulatory and inflammatory stress of HD.



TBSS Projection of all subjects' FA data onto a mean skeleton highlighting voxels with significant FA reduction in multiple levels.

SA-PO615

Anatomic Brain Disease in Hemodialysis Patients David A. Drew,[1] Rafeeque Bhadelia,[2] Hocine Tighiouart,[1] Tammy Scott,[1] Saeed K. Shaffi,[1] Daniel E. Weiner,[1] Mark J. Sarnak.[1] *[1]Tufts Medical Center; [2]Beth Israel Deaconess Medical Center.*

Background: Although dialysis patients are at high risk for stroke and have a high burden of cognitive impairment, there are few reports on anatomic brain findings in the hemodialysis (HD) population. Using brain magnetic resonance imaging (MRI), we compared the prevalence of brain abnormalities in hemodialysis patients to a non-end stage renal disease (ESRD) control population.

Methods: We assembled a cross-sectional cohort of 45 maintenance HD patients and 67 non-ESRD controls, both without prior history of stroke. The primary predictor was dialysis status. Covariates included demographics (age, race, sex), vascular risk factors (diabetes and hypertension) and vascular disease (coronary artery disease, congestive heart failure). The primary outcomes were severity of white matter disease and cerebral atrophy (sulcal prominence and ventricular atrophy) as assessed by a semi-quantitative scale (0 to 9), hippocampal size (0 to 3), and prevalence of small and large vessel infarcts. Multivariable linear or logistic regression was used to evaluate the relationship of dialysis status to MRI findings.

Results: The mean (SD) age of HD patients and controls was 55 (17) and 53 (13) years, respectively. HD patients had more severe white matter disease (1.6 v 0.7) and cerebral atrophy (sulcal prominence = 2.3 v 0.6; ventricular enlargement = 2.3 v 0.9; hippocampal size = 1.3 v 1.0) with all p-values <0.001. In multivariable analyses, hemodialysis status was significantly associated with worse white matter and atrophy grades. HD patients had a higher prevalence of small (17.8%) and large (7.8%) vessel infarcts than controls (combined 22% vs 0%, p<0.0001).

Table 1. Association of Hemodialysis Status with MRI findings

MRI finding	Hemodialysis β Coefficient [95% CI]	p	Hemodialysis adjusted† β Coefficient [95% CI]	p
White Matter Grade	0.88 [0.37, 1.38]	0.001	0.69 [0.04, 1.33]	0.04
Sulcal Grade	1.71 [1.23, 2.19]	<0.001	1.36 [0.87, 1.84]	<0.001
Ventricular Grade	1.37 [0.77, 1.97]	<0.001	1.06 [0.39, 1.74]	0.002
Hippocampal Grade	11.82 [2.50, 55.92]*	0.002	13.52 [1.09, 168.19]*	0.04

*presented as OR (odds ratio)
†: adjusted for age, gender, race (African American or other), vascular disease and vascular disease risk factors

Conclusions: Hemodialysis patients have more white matter disease and cerebral atrophy compared to non-ESRD controls. Hemodialysis patients also have a high prevalence of unrecognized infarcts.

A 12 Months Randomized Controlled Trial Evaluating the Effects of a Vitamin E Bonded Dialysis Membrane on Inflammation, Oxidative Stress, Fibrin Clot Parameters, Cardiovascular Events and Mortality

Simon W. Lines,[1,2] Angela M. Carter,[2] Emma Jane Dunn,[1] Mark J. Wright.[1] *[1]Dept Renal Medicine, St James's University Hospital, Leeds, United Kingdom; [2]Dept Cardiovascular & Diabetes Research, University of Leeds, Leeds, United Kingdom.*

Background: Inflammation, oxidative stress and alterations in fibrin clot phenotype have all been linked to cardiovascular (CV) disease in hemodialysis (HD) patients. Vitamin E (VE) bonded HD membranes are purported to improve a number of these parameters which we investigated in a 12-months randomized controlled trial.

Methods: All HD patients managed by our unit were screened for the study; principle exclusion criteria were HD<3 months or C-reactive protein (CRP) >50 mg/L. Patients were randomized to HD with either a VE-bonded polysulfone (PS) membrane or a non-VE bonded PS equivalent. Data were collected prospectively on CV events and mortality and blood samples taken at baseline and 12 months for determination of oxidized LDL (ox-LDL), CRP, complement (C3, sC5b9, factor D and properdin) and fibrin clot parameters.

Results: Of the 260 patients enrolled in the study 123 were assigned to VE and 215 completed 12 months. Comparing the change in each parameter after 12 months between groups revealed no significant effects of the VE on the levels of ox-LDL, CRP, C3, sC5b9, factor D or properdin or on fibrin clot parameters (all p>0.30). Similarly there were no statistically significant differences between the VE and control groups in the numbers of deaths (7 vs 8; p=0.96), CV events (27 vs 17; p=0.11) or hospital admissions (98 vs 124; p=0.48). However, there were fewer non-infective dialysis access complications in the VE group (26 vs 54; p=0.04).

Conclusions: In this study, switching prevalent HD patients to a VE-bonded membrane for a period of 12 months was not associated with improvements in the pre-dialysis measures of inflammation, oxidative stress and fibrin clot function tested, the number of CV events or mortality. Larger studies of longer duration are required to fully evaluate the potential of VE membranes to influence CV risk.

Increased Fibrin Clot Density Is Associated with Prevalent and Incident Cardiovascular Disease in Hemodialysis Patients

Simon W. Lines,[1,2] Angela M. Carter,[2] Emma Jane Dunn,[1] Mark J. Wright.[1] *[1]Dept Renal Medicine, St. James's University Hospital, Leeds, United Kingdom; [2]Dept Cardiovascular & Diabetes Research, University of Leeds, Leeds, United Kingdom.*

Background: The formation of denser fibrin clots and prolonged fibrinolysis times are associated with cardiovascular (CV) disease (CVD) in several patient groups including a small study of chronic hemodialysis (HD) patients. We sought to characterize the determinants of fibrin clot parameters and their association with prevalent and incident CVD and CV risk factors in a larger cohort of HD patients.

Methods: Fibrin clot density and fibrinolysis times, in conjunction with clinicopathological data, were available for 219 HD patients who were followed for 12 months.

Results: Fibrin clot density was significantly higher in the 93 patients with a prior history of CVD (0.556[0.529-0.583] vs 0.509[0.487-0.531] absorbance units (au); p=0.007) and in the 28 patients who experienced a new CV event during follow up (0.578[0.526-0.630] vs 0.522[0.503-0.540] au; p=0.03). Fibrinolysis times were not associated with prevalent or incident CVD. Fibrin clot density was significantly correlated with a variety of CV risk factors on univariate analyses. Independent predictors of clot density (identified using backwards stepwise regression) were: fibrinogen, C-reactive protein, triglycerides, weight, diastolic blood pressure and ethnicity which together accounted for 85% of variance. In a logistic regression model, including factors associated with prevalent CVD in univariate analysis at baseline, clot density was independently associated with CVD (odds ratio for increase of 0.1 au: 1.51[1.16-1.96]). This association persisted after adjusting for medications. Age, smoking history, diabetes, malignancy and oxidized low density lipoprotein were also independently associated with CVD in this model. Clot density was not independently associated with incident CVD in a similar logistic regression model, in which smoking and previous history of CVD were the only independent determinants.

Conclusions: This study indicates that increased fibrin clot density is associated with both prevalent and incident CVD in HD patients.

SA-PO618

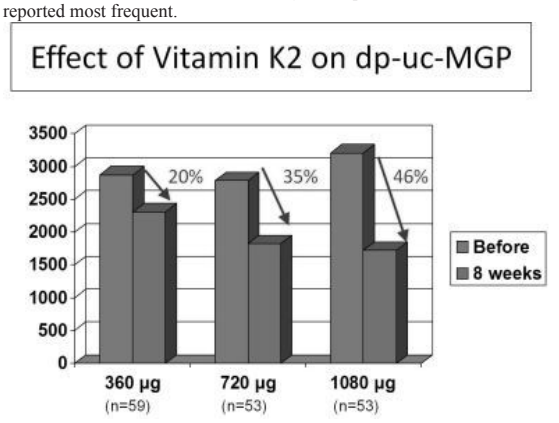
Study of the Optimal Dose of Vitamin K2 in Hemodialysis Patients

Rogier Caluwé,[1] Stefaan J. Vandecasteele,[2] Jean Marie Gustave Billiouw,[1] Bruno Van Vlem,[1] An S. De Vriese.[2] *[1]Nephrology, OLV Hospital, Aalst, Belgium; [2]Nephrology and Infectious Diseases, AZ St.-Jan Hospital, Brugge, Belgium.*

Background: Hemodialysis patients suffer from accelerated vascular calcification. The Vitamin K2 dependent Matrix Gla Protein (MGP) is one of the most powerful inhibitors of vascular calcification. Hemodialysis patients may benefit from pharmacologic doses of Vitamin K2 to improve the biologic activity of MGP. The optimal dose of Vitamin K2 required for this purpose is unknown.

Methods: We randomized 200 chronic hemodialysis patients from 2 tertiary non-university hospital dialysis units to receive uncoated tablets of 360 (group A), 720 (group B) or 1080 µg (group C) of Vitamin K2 thrice weekly for 8 weeks. The inactive form of MGP (dp-uc-MGP) was measured at baseline and after 8 weeks. Patients on coumarin treatment were excluded.

Results: For various reasons (death n=5, study withdrawal n=6, side effects n=15, incompliance n=3, missing samples n=6) 35 patients had no complete analysis. Study groups A (n=59), B (n=53) and C (n=53) had a reduction in dp-uc-MGP levels of 20, 35 and 46% respectively. 13% of patients suffered from gastro-intestinal side effects, unrelated to the dose. Nausea caused by the unpleasant smell of the uncoated tablets was reported most frequent.



Conclusions: Oral Vitamin K2 supplementation in chronic hemodialysis patients effectively and dose-dependently reduces dp-uc-MGP levels. Gastro-intestinal side-effects were frequent but may be overcome by coating the tablets.

Dental Health and All Cause and Cardiovascular Mortality in Hemodialysis Patients: A Prospective Multinational Cohort Study

Suetonia Palmer,[1] Marinella Ruospo,[2] Fabio Pellegrini,[3] Jonathan C. Craig,[4] Giovanni F.M. Strippoli,[2,3,4] Jorgen B.A. Hegbrant.[2] *[1]University of Otago; [2]Diaverum Medical Scientific Office; [3]Mario Negri Sud Consortium; [4]University of Sydney.*

Background: Oral disease may be associated with increased risks of death due to inflammation or as a general indicator of healthcare practices. We evaluated the association between dental status and the risk of all-cause and cardiovascular mortality in adults on hemodialysis.

Methods: ORAL-D is an ongoing multinational prospective cohort study of consecutive adults on hemodialysis in 75 outpatient clinics selected randomly from a collaborative dialysis network in Italy, Hungary, Poland, Argentina, Portugal, France and Spain. A dental surgeon evaluated dental status by using the DMFT (decayed, missing, filled, permanent teeth) score. Quality of dental health was defined based upon WHO criteria as low, moderate and high DMFT scores of ≤2.6, 2.7-4.4 and >4.4. We assessed survival at 12 months using centralized mortality data. We conducted analyses using Cox regression controlling for age, gender, previous cardiovascular events, income status, clinical performance measures, dialysis prescription and performance indicators, and depressive symptoms.

Results: 4720 hemodialysis patients in the participating clinics received a complete evaluation of their dental status and completed follow up. Median follow up was 19.9 (17.0 to 28.0) months and 516 (11%) died during follow up. The overall DMFT score was 21.67 (9.40). Dental health (DMFT scores) had uncertain associations with all-cause or cardiovascular mortality.

Exposure	Unadjusted risk	p value	Adjusted risk	p value
All-cause mortality				
Low DMFT score	1.36 (0.46-3.96)	0.58	0.63 (0.19-2.08)	0.45
Moderate DMFT score	2.89 (1.14-7.36)	0.03	1.51 (0.58-3.88)	0.40
High DMFT score	5.98 (2.48-14.42)	<0.001	2.07 (0.85-5.07)	0.11
Cardiovascular mortality				
Low DMFT score	1.02 (0.29-3.60)	0.98	0.40 (0.09-1.79)	0.23
Moderate DMFT score	1.76 (0.59-5.19)	0.31	1.02 (0.34-3.05)	0.97
High DMFT score	3.86 (1.44-10.4)	0.007	1.38 (0.50-3.78)	0.54

Conclusions: Dental health has uncertain associations with all-cause and cardiovascular mortality in patients on hemodialysis. ORALD will be completed by end of 2013.

Periodontal Disease and All Cause and Cardiovascular Mortality in Hemodialysis Patients: A Prospective Multinational Cohort Study
Suetonia Palmer,[1] Marinella Ruospo,[2] Fabio Pellegrini,[3] Jonathan C. Craig,[4] Jorgen B.A. Hegbrant,[2] Giovanni F.M. Strippoli.[2,3,4] *[1]University of Otago; [2]Diaverum Medical Scientific Office; [3]Mario Negri Sud Consortium; [4]University of Sydney.*

Background: In the general population, periodontal disease is associated with increased cardiovascular mortality. We have evaluated the association between periodontitis and all-cause and cardiovascular mortality in adults on hemodialysis.

Methods: ORAL-D is an ongoing multinational prospective cohort study of consecutive adults receiving hemodialysis in 75 outpatient clinics selected randomly from a collaborative dialysis network in Italy, Hungary, Poland, Argentina, Portugal, France and Spain. A dental surgeon evaluated presence of periodontitis with standard methods, defined as a Community Periodontal Index (CPI) score ≥3 during a standardized oral examination. We assessed survival at 12 months using centralized mortality data. We conducted analysis with Cox regression controlling for age, gender, previous cardiovascular event, income status, clinical performance measures, dialysis prescription and performance indicators and depressive symptoms.

Results: 3672 dentate hemodialysis patients in the participating clinics received a complete evaluation for periodontitis and completed follow up. Median follow up was 19.9 (17.0 to 28.0) months. 1516 patients (42%) had periodontitis and 339 (10%) died during follow up. Periodontitis had uncertain associations with risks of all-cause (HR 0.86 [95% CI 0.68-1.10]) or cardiovascular (HR 0.85 [95% CI 0.63-1.15]) mortality.

Conclusions: Contrary to data in the general population, periodontitis has uncertain associations with all-cause or cardiovascular mortality in patients on hemodialysis. ORALD will be completed by end of 2013.

Serum Bicarbonate Is Not Associated with Arterial Stiffness in Hemodialysis Patients
Kalani L. Raphael,[1,2] T. Alp Ikizler,[3] R. Filipowicz,[2] Mary B. Sundell,[3] Y. Zhang,[2] G. Wei,[2] Tom Greene,[2] S. Beddhu.[1,2] *[1]Salt Lake City VA Health Care System, Salt Lake City, UT; [2]University of Utah, Salt Lake City, UT; [3]Vanderbilt University Medical Center, Nashville, TN.*

Background: Limited data suggest that metabolic alkalosis may provoke vascular calcification, which increases arterial stiffness. Therefore, we investigated the association between serum bicarbonate with pulse wave velocity (PWV), as a measure of arterial calcification, in the ongoing Protein Intake, Cardiovascular disease and Nutrition in CKD stage V (PICNIC) study of chronic hemodialysis patients.

Methods: Carotid and femoral pulses were used to measure aortic PWV with a Sphygmacor PVX device. Measurements were conducted at baseline, 6, and 12 months. Linear regression models related PWV at (i) baseline and (ii) 6 and 12 month follow-up values (lag model) with each standard deviation increase in predialysis serum bicarbonate concentration. Adjustments were made for age, gender, race, vascular access, ESRD duration, and study center.

Results: One hundred eighteen hemodialysis patients had non-missing data at baseline and were included in the analysis. The study is ongoing and follow-up PWV data were available in 93 and 74 participants at the 6 and 12 month visits. The mean age was 52 ± 16 years, 59% were men, 81% were Caucasians and 47% had diabetes. Mean serum bicarbonate at baseline was 23.4 ± 5.0 mmol/L and mean (SD) PWV for the three times points were 9.8 (3.4), 10.2 (3.8), and 10.1 (3.4) m/sec, respectively. Each standard deviation increase in predialysis serum bicarbonate concentration was not associated with PWV at baseline or follow-up.

Association of predialysis serum bicarbonate concentration with (i) baseline and (ii) 6 and 12 month (lag) aortic PWV (m/s)

	Coefficient	95% CI	p
Baseline model	-0.36	-0.89 -0.17	0.18
Follow-up (lg) model	0.01	-0.55 0.58	0.96

Conclusions: Higher predialysis serum bicarbonate concentration is not associated with aortic stiffness in hemodialysis patients.

25-Hydroxyvitamin D Is Associated with Faster Gait Speed, but Not Muscle Area, in Hemodialysis Patients
Kalani L. Raphael,[1,2] T. Alp Ikizler,[3] Mary B. Sundell,[3] R. Filipowicz,[2] Y. Zhang,[2] G. Wei,[2] Tom Greene,[2] S. Beddhu.[1,2] *[1]SLC VA Health Care System; [2]Univ of Utah, Salt Lake City, UT; [3]Vanderbilt University, Nashville, TN.*

Background: Interventions to improve frailty in maintenance hemodialysis (MHD) patients are limited. Therefore, we investigated whether serum 25-hydroxyvitamin D (25-D) is associated with gait speed and mid-thigh muscle area in MHD patients in the ongoing Protein Intake, Cardiovascular disease and Nutrition in CKD stage V (PICNIC) study.

Methods: Linear regression models were used to relate each SD increase in baseline 25-D as the predictor variable to gait speed, assessed by 6-minute walk (6MW), and mid-thigh muscle area, assessed by MRI as outcome variables at (i) baseline (cross-sectional) and (ii) 6 and 12 month follow-up values (lag). Logistic regression models were used to determine if 25-D predicted completion of the 6MW. Age, gender, race, vascular access, ESRD duration, and study center were included in each model.

Results: The mean age of 93 MHD patients in this analysis was 52±16 years, 53% were men, 75% were white and 43% had diabetes. Mean serum 25-D at baseline was 21.8±11.9 ng/mL. Mean gait speed was 0.85 (±0.32) m/sec and mean muscle area was 103.0 (±24.6) cm^2. Seventy-three, 58, and 55 individuals performed the 6MW at baseline, 6- and 12-months. Baseline 25-D in those that did and did not perform the 6MW were similar and did not predict completion of the 6MW at any time point. Higher 25-D was associated with faster gait speed at baseline and after 6-12 months. Seventy-three and 63 individuals had muscle MRI at baseline and 6-months. 25-D was not associated with muscle area in this cohort of MHD patients.

Table 1. Association of each SD increase in 25-D with gait speed and muscle area at (i) baseline and (ii) with follow-up values (lag).

	Baseline Model	Lag Model
	Coefficient (95% CI)	Coefficient (95% CI)
Model 1: Gait Speed (m/s)	0.09 (0.02–0.16)	0.08 (0.03–0.13)
Model 2: Muscle Area (cm2)	-2.3 (-7.3–2.8)	-3.8 (-8.9–1.4)

Conclusions: In MHD patients, higher 25-D is associated with faster gait speed but not with muscle area. Interventional studies are warranted to determine whether 25-D therapy could improve/slow the decline in gait speed in MHD patients.

Significant Association of Klotho, FGF-23 and Arterial Stiffness in End Stage Renal Disease Patients on Maintenance Hemodialysis
Hong Joo Lee, Joo Hee Cho, Jungkook Wi, Wha-young Suk, Tae-won Lee, Ju-Young Moon, Sang-Ho Lee, Eun Young Kim, Chun-Gyoo Ihm, Kyung-hwan Jeong. *Departments of Nephrology, Kyung Hee University School of Medicine, Seoul, Republic of Korea.*

Background: Arterial stiffening characterizes the vasculature of end-stage renal disease (ESRD) patients and is a strong predictor of their cardiovascular morbidity and mortality. Pulse wave velocity (PWV) has been widely recognized as a marker of systemic atherosclerosis.Recently emerging evidence suggests the role of Klotho and FGF-23 against endothelial dysfunction that is a determinant of impaired vasoreactivity. We hypothesized that the level of Klotho and FGF-23 may relate with arterial stiffness presented by PWV in ESRD patients.

Methods: We analysed 90 ESRD patients including 51 male and 39 female on hemodialysis. Mean age was 57.8 ± 12.7 years. Patients were tested for plasma level of FGF-23, Klotho, biologic markers of cardiovascular disease and arterial stiffness presented by PWV and simple aortic calcification with plain radiograph of chest. Endothelial function was assessed by flow-mediated dilation(FMD).

Results: Mean concentration of Klotho and FGF-23 were 640.14±256.42 pg/ml and 6432.67±14702.86 pg/ml. The mean aortic PWV was 8.74±2.02m/s at baseline. The aortic PWV and the level of FGF-23 were significantly increased in patients with diabetes compared non-diabetic group. Aortic PWV correlated with age, aortic arch calcification scores and level of log-formed FGF-23 positively. In addition, it correlated with diastolic blood pressure, PTH level and level of Klotho inversely. However, it didn't correlate with serum calcium, phosphorus, 25-vitamin D level and Kt/Vurea.

Conclusions: The level of Klothoand FGF-23 were useful for assessment of arterial stiffness that precedes cardiovascular complicationsin ESRD patients on maintenance hemodialysis.
