Background: Proteinuria and/or albuminuria are widely used for noninvasive assessment of kidney diseases. Proteinuria is a nonspecific marker of diverse forms of kidney injury, therefore, more specific glomerular disease biomarkers are required. Podocyte depletion is a major mechanism driving glomerulosclerosis. Podocyte cell lineage specific mRNAs can be recovered from urine pellets of model systems and man. In model system, progressive glomerular disease was associated with low level urine nephrin mRNA excretion compared to urine podocin mRNA excretion (Sato Y et al. J Am Soc Nephrol 2009, Fukuda A et al. Kidney Int 2012). Thus, the urine podocin:nephrin mRNA ratio (U-PNR) could serve as a useful glomerular disease progression biomarker (Fukuda A et al. Nephrol Dial Transplant in press). The purpose of this study was to test whether the U-PNR could be a useful biomarker in patients with IgA nephropathy (IgAN).

Methods: Urine sample and kidney biopsy specimen from 34 patients with IgAN (15 males; mean age 38.6yr: range 17 to 60 yr) were analyzed. We examined the relationships between U-PNR and urine protein:creatinine ratio (U-PCR), or renal histological parameters defined by Oxford classification.

Results: Both the U-PNR and U-PCR were significantly elevated in patients with IgAN compared to healthy volunteers (0.85±0.10 vs 0.29±0.06 and 0.49±0.16 vs 0.03±0.01, respectively). U-PNR was significantly correlated with the severity of segmental glomerulosclerosis and of endocapillary hypercellularity lesions, on the other hand, U-PCR did those of mesangial hypercellularity and of endocapillary hypercellularity. These results suggest that U-PNR was highly correlated with glomerular lesions in patients with IgAN.

Conclusions: The U-PNR could be a useful biomarker in patients with IgAN.

Serum BAFF Is Elevated and Associated with Clinical and Histopathological Features of Patient with IgA Nephropathy Xuli Xia, Zhiming Ye, Shuangxin Liu, Ruizhao Li, Wei Shi. *Department of Nephrology, Guangdong General Hospital, Guangzhou, Guangdong, China.*

Background: B cell activating factor belonging to tumor necrosis factor family (BAFF) was found to have the function of activating B cell and participating in the class-switching of B cells, however, its clinical application needs further studies. In the present study, the serum BAFF level of patients with IgAN (IgAN) with different histopathological phenotypes was detected.

Methods: The levels of serum BAFF in 153 patients with IgAN and 55 healthy controls were detected using commercial available ELISA kits. Their correlations with clinical and histopathological features of patients with IgAN were further evaluated.

Results: The levels of serum BAFF in patients with IgAN were significantly higher than normal controls. Serum BAFF levels were significantly higher in patients with mesangial hypercelluarity and segmental glomerulosclerosis than those without. Serum BAFF levels

were associated with the severity of the tubular atrophy/interstitial fibrosis. Serum BAFF levels were significantly correlated positively with eGFR and serum creatinine. The patients with elevated serum BAFF levels showed significantly more severity in clinical and histopathological stages.

Conclusions: The levels of serum BAFF were elevated in patients with IgAN and were associated with clinical and pathological features of the disease. Serum BAFF levels could be a non-invasive biomarker for monitoring disease progression of IgAN.

Role of Innate Immunity in IgA Nephropathy Can Li,[1] Hong Bin Zou,[2] Bi Hu Gao,[3] Shang Guo Piao,[4] Chul Woo Yang.[4] *[1]Nephrology&Dialysis Unit, YanBian University Hospital, YanJi, JiLin, China; [2]Nephrology, The First Affiliated Hospital of JiLin University, ChangChun, JiLin, China; [3]Nephrology, The Affiliated Zhong-Shan Hospital of DaLian University, DaLian, LiaoNing, China; [4]Nephrology, The Catholic University of Korea, Seoul, Korea.*

Background: Recent studies demonstrated that toll-like receptor expression is increased in circulating mononuclear cells or mucosal B cells and dendritic cells in IgA nephropathy. However, its expression in human kidney tissues with IgA nephropathy is undetermined. This study was designed to investigate the expression of toll-like receptors (TLR) and MYD88 in kidney biopsy specimens with IgA nephropathy.

Methods: Total 94 biopsy-proven IgA nephropathy patients were enrolled and 13 patients with nephrectomy for renal cancer served as controls. Intrarenal expression of TLRs (TLR2 and TLR4) and MYD88 was examined by immunohistochemistry. Clinic characteristics such as age, systolic blood pressure (SBP), serum creatinine, glomerular filtration rate (GFR), serum albumin, and 24h urinary protein excretion were recorded.

Results: Compared with the control, IgA nephropathy patients showed a significant increase in the expression of TLR2 and TLR4 in the glomerulus. However, there is no relationship between TLRs expression and the degree of pathologic renal damage. Interestingly, TLR2 expression was significantly increased in the tubulointerstitum of IgA nephropathy but TLR4 expression was unaffected. Concomitantly, this increase in TLRs expression was paralleled with overexpression of MYD88. Furthermore, TLRs expression was positively correlated with 24h urinary protein excretion and negatively correlated with the GFR.

Conclusions: Thus, TLR2, TLR4, and MYD88 expression is upregulated in IgA nephropathy, and that this increase strongly associated with 24h urinary protein excretion and GFR. These findings suggest that innate immunity may be one of the molecular mechanisms in the pathogenesis of IgA nephropathy.

TH-PO428

Increase in CD208+ Dendritic Cells in Tonsils of Patients with IgA Nephropathy Hanako Takechi,[1] Takashi Oda,[1] Kojiro Yamamoto,[1] Naoki Oshima,[1] Daisuke Kamide,[2] Takeshi Matsunobu,[2] Kensuke Joh,[3] Osamu Hotta,[4] Akihiro Shiotani,[2] Hiroshi Nagura,[5] Hiroo Kumagai.[1] *[1]Department of Nephrology, National Defense Medical College, Saitama, Japan; [2]Department of Otolaryngology, National Defense Medical College; [3]Sendai Shakaihoken Hospital, Sendai, Japan; [4]Hotta Osamu Clinic, Sendai, Japan; [5]Tohokurosai Hospital, Sendai, Japan.*

Background: Therapeutic effect of tonsillectomy for IgA nephropathy (IgAN) has widely been reported. However, the exact mechanism how tonsil immunity leads to glomerulonephritis has been unclear. The participation of dendritic cells (DCs) in pathogenesis of IgAN has recently been suggested. We therefore investigated phenotypes and localization of DCs in tonsils of patients with IgAN. Furthermore, we examined the relationships between the tonsillar DCs with clinical features and renal histological change of IgAN patients.

Methods: We examined tonsils from twenty-two IgAN patients. The tonsils from recurrent tonsillitis patients and tonsil biopsy specimens from healthy controls were also used as controls. Five distinct markers of DCs (CD1a, CD1c, CD303, CD208, and CD209) were analyzed by immunohistochemically as well as by flow cytometry on isolated cells. The quantity of mRNAs of DCs was evaluated using real-time PCR. The clinical and histological data in renal biopsy were statistically compared with immunological data.

Results: Among the five phenotypes of DCs, CD208 (DC-lysosome-associated membrane glycoprotein; DC-LAMP), a marker of interdigitating DCs, positive cells significantly increased in the tonsils of IgAN compared with the tonsil of controls. By double immunofluorescence staining, CD208+DCs were found to localize touching with CD4+ and CD8+ T cells, and they aggregated as nodules in interfollicular area. Interestingly, the numbers per area of CD208+DCs in tonsils significantly correlated with the ratio of crescent positive per total glomeruli in renal biopsy ($p<0.05$). On the other hand, no relations were found between the level of DCs and clinical data.

Conclusions: These observations suggest that increased in CD208+DCs with sensitized T cells in tonsils relates with active lesions, especially crescents, in glomeruli of the patients with IgAN.

TH-PO429

Expansion of T Cell Nodule and Reduced Lymphoepithelial Reticulation Is Characteristic Features of IgA Nephropathy-Associated Tonsillitis and Correlates with Formation of Crescent and Segmental Sclerosis in the Kidney Kensuke Joh,[1] Atsuhiro Kanno,[2] Hideyuki Kosukegawa,[2] Toshinobu Sato,[2] Osamu Hotta.[3] *[1]Division of Pathology, Sendai Shakaihoken Hospital, Sendai, Miyagi-ken, Japan; [2]Kidney Center, Sendai Shakaihoken Hospital, Sendai, Miyagi-ken, Japan; [3]Kidney Center, Hotta Osamu Klinic, Sendai, Miyagi-ken, Japan.*

Background: Tonsillectomy (TL) with steroid pulse therapy (SPT) can be a choice of therapy against IgA nephropathy (IgAN). The purpose was to characterize histological features of the tonsil of IgAN (Tons A) and to know whether the tonsillar lesions can relate to the renal lesions.

Methods: Tonsils were obtained from the 77 IgAN patients (pts), who underwent TL with SPT including 14 pts with TL after SPT and 63 patients with TL before SPT. As control, tonsils of chronic tonsillitis (Tons C) were obtained from 21 pts. The number of T lymphocyte nodules with assembly of HLA-DR-positive cells in the center, were counted per 2.0mm^2. Cytokeratin-positive tonsillar crypt epithelium showed reticulation and partially non-reticular area indicating an involution of lymphoepithelial symbiosis. Therefore, the reduced area of lymphoepithelial reticulation (RLR) was scored by 5 grades. Histological grading (J Nephrol 2012) and the constituting lesions in the kidney were evaluated according to Oxford classification.

Results: The number of T nodule (3.9+-0.7) and grade of RLR (1.9+-1.0) in Tons A increased significantly than those of Tons C as (3.2 +-1.0) and (1.2+-0.9), respectively ($p<0.01$). Histological grade in the kidney correlated with the grade of RLR (B=0.29 (0.12-0.45), $p<001$), but not to the number of T nodule ($p>0.05$). In multivariate linear regression analysis, only crescent and segmental sclerosis were selected as independent parameters, which correlated with the number of T nodule and the grade of RLR, respectively ($p<0.05$). Between in a group of TL after SPT and of TL before SPT, there was no difference for the number of T nodule and for the grade of RLR.

Conclusions: The number of T nodule correlating with crescent and the grade of RLR correlating with segmental sclerosis, were not diminished by SPT, suggesting the underlying mechanism of the effectiveness of TL combined with SPT.

TH-PO430

Relationship between Asymmetric Dimethylarginine(ADMA) and Prognosis Factors in IgA Nephropathy Hyung-Jong Kim,[1] Dong Ho Yang,[1] Kyung Mi Park,[1] Hun Jeong,[2] Hyun Ju Oh.[1] *[1]Department of Internal Medicine, CHA Bundang Medical Center, CHA University, Seongnam, Gyeonggi-do, Korea; [2]Department of Internal Medicine, Seoul Bukbu Hospital, Seoul, Korea.*

Background: Because of the variety of the clinical course in IgA nephropathy, it is very difficult to predict the prognosis. The risk factors associated with poor prognosis in IgA nephropathy are hypertension, proteinuria, and renal biopsy classification. Asymmetric demethylarginine(ADMA), the intrinsic inhibitor of nitric oxide synthesis, has been known to be associated with cardiovascular disease. But, there is still not enough knowledge about the roles of serum ADMA in IgA nephropathy. Therefore, the goal of this study was to investigate the association between serum ADMA and valuable markers for predicting poor prognosis in IgA nephropathy.

Methods: Twenty patients confirmed IgA nephropathy by renal biopsy were enrolled. We measured insulin, fasting glucose, hsCRP, lipid profile, serum BUN/creatinine, total protein/albumin by patient's blood samples and urien protein/creatinine by urine samples. We divided them into two groups according to Hass histology(Group 1 = I, II vs. Group 2 = III, IV, V). Also, two groups were divided according to urien protein creatinine ratio(PCR) at the time when renal biopsy was performed(Group A<0.5 mg/mg, Group B ≥ 0.5 mg/mg).

Results: Level of serum ADMA(Group 1; 0.5 ± 0.07 vs. Group 2; 0.58 ± 0.1) and urine protein/creatinine ratio(Group 1; 0.76 ± 0.78 vs. Group 2; 2.12 ± 1.76) were increased in group 2 that included more severe pathologic sub-classifications($p<0.05$). There was positive correlation between level of serum ADMA and urine protein/creatinine ratio(PCR)($p<0.05$). Also, serum total cholesterol, triglyceride was positively correlated with urine PCR($p<0.05$). There was negative correlation between serum albumin and urine PCR(<0.05).

Conclusions: Serum ADMA in IgA nephropathy was associated with the amount of proteinuria, which is the well-known conventional risk factor associated with renal failure. These findings strongly suggest that serum ADMA is a valuable biochemistric marker for predicting poor prognosis in IgA nephropathy. Prospective studies may be necessary hereafter.

TH-PO431

Evaluation of Hyaline Change of Afferent Arterioles in Patients with IgA Nephropathy Using Cardio-Ankle Vascular Index (CAVI) Hideo Okonogi, Yasunori Utsunomiya, Keita Hirano, Akihiro Shimizu, Masato Ikeda, Tetsuya Kawamura, Tatsuo Hosoya. *Division of Kidney and Hypertension, The Jikei University School of Medicine, Tokyo, Japan.*

Background: Several studies reported that hyaline change of afferent arterioles (HAA) were related to adverse renal outcome of IgA nephropathy (IgAN). Up to now, there was no tool to evaluate the relationship between HAA and arterial stiffness which reflects athero- or arteriosclerotic disease. Recently, cardio-ankle vascular index (CAVI) was developed as a novel indicator of arterial stiffness. CAVI is non-invasive method and not influenced by the

blood pressure (BP). Therefore, we examined the relationship between clinicopathological findings and CAVI in patients with IgAN.

Methods: Thirty-six IgAN patients whose renal biopsy specimens contain afferent arterioles were included. The presence of HAA, hyaline change and/or wall thickening of interlobular arteries (HTILA) were analyzed. In addition, serum levels of inflammatory parameters were measured.

Results: As a result, 20 patients (55%) had HAA, and 28 patients (78%) had HTILA. In the histological examination, the presence of HAA did not correlate with the degrees of global glomerular sclerosis, segmental glomerular lesions, nor interstitial fibrosis, while HTILA correlated with global glomerular sclerosis and interstitial fibrosis. In clinical parameters, HAA significantly correlated with age, BP, and CAVI ($p<0.05$). By receiver-operating characteristic curves, the areas under the curve for diagnosis of the presence of HAA by CAVI was 0.72. While HAA tended to correlate with eGFR and serum levels of hs-CRP, it did not correlate with proteinuria, HbA1c, HOMA-IR, lipids profiles (LDLC, non-HDLC, RLPC) and thrombomodulin. In addition, HTILA correlated with age, BP and eGFR, but did not correlate with CAVI, proteinuria, HbA1c, HOMA-IR, lipids profiles and thrombomodulin.

Conclusions: These results indicate that HAA correlates with the individual age and BP, and that CAVI may be a novel clinical tool to presume the presence of HAA, not but HTILA, in patients with IgAN.

TH-PO432

Aberrantly Glycosylation Is Not a Characteristic of Minimal Change Disease with IgA Deposition Yu Yan, Wei Chen, Bao Dong, Mei Wang. *Renal Division, Peking University People's Hospital, Beijing, China.*

Background: Some IgAN patients with nephrotic syndrome (NS), who mostly have no hematuria, no hypertension and normal renal function were named minimal change disease (MCD) with IgA deposition (MCD-IgA). Whether it is a special phenotype of IgAN or MCD was in debate. Our previous study revealed that MCD-IgA may be MCD with non-specific deposition rather than a phenotype of IgAN according to clinical and pathological analysis. The current study was to investigate the differences of glycosylation of IgA1 in serum IgA1-containing macromolecules and serum IgA1 among MCD-IgA, with nephrotic proteinuria without hypoalbuminemia (HP-IgAN) and MCD.

Methods: 10 patients from each three groups were enrolled. Polyethylene glycol 6000 was used to precipitate the macromolecules from sera of patients and controls. Biotinylated lectins were used in ELISA to examine different glycans on IgA1 molecules. The a2,6 sialic acid (SA) was detected by elderberry bark lectin (SNA), the exposure of terminal galactose (Gal) and N-acetylgalactosamine (GalNAc) were detected by arachis hypogaea (PNA) and Helix asperas agglutinin (HAA)respectively.

Results: Serum IgA1 levels were comparable among three groups. Exposure of GalNAc was less profound in both MCD-IgA and MCD than in HP-IgAN ($P<0.05$). No significant difference of GalNAc exposure was found between MCD-IgA and MCD. Serum IgA1 from MCD patients had more SA than that from HP-IgAN patients, but similar with that from MCD-IgA patients. In precipitated macromolecules total protein amounts were similar among three groups. Coincided with serum IgA1, exposure of GalNAc in macromolecular IgA1 was less profound in both MCD-IgA and MCD than in HP-IgAN ($P<0.05$). No significant difference of GalNAc exposure was found between macromolecular IgA1 from MCD-IgA and MCD patients. More SA was detected in macromolecular IgA1 from MCD patients than that from HP-IgAN patients. However, comparable sialylation was found between MCD-IgA and MCD patients.

Conclusions: Aberrantly glycosylation is not a Characteristic of MCD-IgA, which implies that MCD-IgA might not be a special phenotype of IgAN.

TH-PO433

Tonsils of Patients with IgA Nephropathy Contain Cells Producing Aberrantly Glycosylated IgA1 and Anti-Glycan Antibodies: Implications for Tonsillectomy Hitoshi Suzuki,[1] Yusuke Suzuki,[1] Hiroyuki Yanagawa,[1] Jan Novak,[2] Yasuhiko Tomino.[1] *[1]Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan; [2]Microbiology, University of Alabama at Birmingham, Birmingham, AL.*

Background: IgA1 in circulating immune complexes and in the glomerular deposits of patients with IgA nephropathy (IgAN) is aberrantly glycosylated, galactose-deficient in *O*-glycans (Gd-IgA1) and is bound in the complexes by antiglycan IgG/IgA1 autoantibodies. However, the origin of cells producing Gd-IgA1 and the autoantibodies is unknown. Upper respiratory tract infections and/or tonsillitis are frequently associated with clinical presentation and exacerbation of IgAN, suggesting a link with the disease pathogenesis. There is increasing evidence that treatment including tonsillectomy and glucocorticoids prevents IgAN progression.

Methods: In this study, we studied 27 patients with IgAN who underwent tonsillectomy and glucocorticoid therapy (TSP). Tonsillar cells were immortalized with Epstein-Barr-virus, then Gd-IgA1 and anti-glycan IgG secreted by these cells were measured. In addition to urinary protein and hematuria, serum levels of Gd-IgA1, anti-glycan IgG and anti-glycan IgA were measured before and after the TSP therapy.

Results: Sixteen of twenty-seven patients showed less 0.3 g/gCr proteinuria and 5 red blood cells/HPF after TSP (Remission group). A rate of decrease in serum levels of Gd-IgA1, anti-glycan IgG, and anti-glycan IgA were greater in Remission group than in non-Remission group ($P<0.01$). Furthermore, tonsillar B cells from Remission group secreted higher amounts of Gd-IgA1 and anti-glycan IgG than those from non-Remission group ($P<0.01$).

Conclusions: In summary, tonsillar B cells are sources of Gd-IgA1 and anti-glycan antibodies in patients with IgAN. Moreover, these serum biomarkers may be useful disease markers for guiding the therapeutic approaches for IgAN.

TH-PO434

The Deposition of Secretory IgA in Patients with IgA Nephropathy Are Associated with Clinical and Pathological Phenotypes Yan Liang, Junjun Zhang, Liu Zhangsuo. *Zhengzhou University.*

Background: IgA nephropathy (IgAN) is the most common form of primary glomerulonephritis in the world especially in China. Mucosal infection associated with episodic macroscopic haematuria are observed in many patients with IgAN. Secretory IgA (sIgA) is a mainly immunoglobulin involved in mucosal immunity. Our previous study showed it could be deposited in kidney in about 1/3 of IgAN patients and played an important role in the pathogenesis of IgAN. However, the association between renal sIgA deposition and clinical manifestations as well as pathogical phenotypes are still not clear. The aim of this work is to investigate the characteristics of IgAN patients with or without renal sIgA deposition.

Methods: Frozen renal sections from 99 primary IgAN patients without IgM deposition were immunofluorescence stained and examined by confocal microscopy to detect the co-deposition of IgA and secretory component (SC). The association between deposition of sIgA and characteristics of IgAN patients was analysed.

Results: In 99 patients, 32 patients (32.32%) with sIgA deposition, the incidence of infection history and gross hematuria were higher in patients with sIgA deposition compared with patients without. The levels of 24h urinary protein, serum cystatin C and serum creatinine were tendency lower in patients with sIgA deposition than the patients without. The number of crescents was less and the degree of tubulointerstitial lesion was milder in sIgA deposition group than non- sIgA deposition group. However, arterial pressure,hemoglobin and plasma-albumin were not different in these two groups.

Conclusions: It was concluded that sIgA deposited in renal,at least partly, was originated from mucosal immune sites. The deposition of sIgA in kidney might be associated with different clinical manifestation and tubulointerstitial lesion in patients with IgAN.

Decrease of Perlecan LG3 Peptide and Free k-Light Chains Urine Excretion in IgA Nephropathy: New Insights for a Non-Invasive Evaluation of Disease Activity and Injury Maria Teresa Rocchetti,[1,3] Massimo Papale,[1,3] Salvatore Di Paolo,[2] Annamaria D'Apollo,[1] Ida Valentina Suriano,[1] Grazia Vocino,[1] Eustacchio Montemurno,[3] Leonarda Varraso,[1] Giuseppe Grandaliano,[1] Loreto Gesualdo.[3] *[1]Nephrology, Dialysis and Transplantation Unit, Dept. of Medical and Surgical Sciences, University of Foggia, Foggia, Italy; [2]Division of Nephrology and Dialysis, Hospital Dimiccoli, Barletta, Italy; [3]Nephrology, Dialysis and Transplantation Unit, DETO, University of Bari, Bari, Italy.*

Background: IgA nephropathy (IgAN) has a highly variable clinical presentation and progression. Its accurate diagnosis and prognosis requires renal biopsy. Therefore, the identification of biomarkers allowing non-invasive diagnosis and monitoring of disease is strongly required.We investigated urine proteome in order to identify a set of proteins potentially helpful in identifying IgAN.

Methods: Urine proteins from 49 biopsy-proven IgAN patients, 42 patients with non-IgA chronic kidney diseases (CKD: 16 Diabetic Nephropathy, 12 Nephroangiosclerosis, 14 Membranous Nephropathy) and 40 healthy subjects (CTRL) were analyzed by SELDI-TOF/MS. Mass peaks in the 3000-30000 m/z mass range were studied by univariate analysis. Mass peaks able to discriminate IgAN were identified by MALDI-TOF-MS/MS. Proteomic findings were confirmed by immunological methods.

Results: Univariate analysis identified 13 mass peaks able to discriminate IgAN from CKD and CTRL. Among them, two mass peaks were identified as LG3 peptide and Ig-k light chains. Western Blot analysis confirmed the decreased urinary excretion of LG3 in IgAN compared to CKD and CTRL. Then, Immunonephelometry analysis confirmed the lower urinary excretion of kappa free LC in IgAN patients compared to CKD and CTRL. Accordingly, tissue data showed an increase of k FLC deposition and a decrease of LG3 in IgAN biopsy specimens. Finally, urinary kappa FLC and LG3 inversely correlated with the severity of clinical and histologic features of IgAN patients.

Conclusions: In conclusion, higher urine level of k FLC and LG3 are associated to IgAN patients with a better prognosis. K FLC and LG3 peptide could serve as candidate non-invasive diagnostic and/or prognostic biomarkers of IgAN.

Interleukin 6 Has a Unique and Central Role in the Development of Renal Damage in Two Different Types of Glomerulonephritis Maria Stangou,[1] Aikaterinni Papagianni,[1] Christos Bantis,[1] Efstratios D. Kasimatis,[1] Irene Stavrinou,[1] George Toulkeridis,[1] Dimitrios Moisiadis,[1] Marie Skoularopoulou,[1] Nikoleta-maria Kouri,[2] George Efstratiades,[1] Demitrios Memmos.[1] *[1]Department of Nephrology, Hippokration Hospital, Thessaloniki, Greece; [2]Department of Biochemistry, Hippokration Hospital, Thessaloniki, Greece.*

Background: Focal segmental necrotizing gloemerulonephritis (FSNGN) is characterized by severe inflammation and necrosis leading to rapid decline of renal function. IgA nephropathy (IgAN) leads to kidney damage through gradual development of glomerulosclerosis and tubulointerstitial fibrosis. We evaluated the role of local cytokine production in these two different types of glomerulophritis.

Methods: Epidermal Growth Factor (EGF), Interleukins-1β, -2, -4, -6, -7, -8, -9, -10, -15, -17, Vascular Endothelial Growth Factor (VEGF), Monocyte Chemoattractant Protein-1 (MCP-1) were measured in first morning urine samples from 53 IgAN [M/F 35/18 age 40.5yrs(17-65)]and 38 FSNGN patients[M/F 21/17, age 59.5yrs(25-80)]collected at day of renal biopsy, using a multiplex cytokine assay. Results were correlated with histology and long term outcome of renal function.

Results: In IgAN, the degree of glomerulosclerosis had positive correlation with IL-1β, (p=0.007) and MCP-1 (p=0.007) and negative with EGF (p=0.02) urinary excretion. High IL-1β, IL-2, IL-4, IL-6, IL-8, IL-12, IL-17, MCP-1 and low EGF levels were associated with renal function deterioration. Urinary IL-6 was the only independent parameter correlated with the degree of renal failure (r^2=0.5, p=0.02) at the end of follow up (65±34months). In FSNGN, the percentage of crescents had positive correlation with IL-17 (p=0.008) and negative with EGF (p<0.0001). High IL-6, IL-15, VEGF levels were associated with poor outcome of renal function. The only independent predictor factor of long term outcome was IL-6 urinary levels (r^2=0.2, p=0.03). Follow up of the patients was 62±42months.

Conclusions: Different cytokines are involved in the progression of renal damage in two different types of glomerulonephritis, IgAN and FSNGN, but IL-6 seems to be implicated and play a key role in both of them.

Circulating microRNAs in Patients with *Escherichia coli* O104:H4-Associated Haemolytic Uraemic Syndrome Johan M. Lorenzen, Bernhard M.W. Schmidt, Mario Schiffer, Jan T. Kielstein, Hermann G. Haller, Thomas Thum. *Nephrology, Hannover Medical School, Germany.*

Background: In early May 2011, an outbreak of hemorrhagic colitis associated with hemolytic–uremic syndrome (HUS) first developed in Northern Germany and spread to 15 other countries in Europe. The outbreak-strain O104:H4, which combined virulence factors of typical enteroaggregative and Shiga-Toxin–producing E. coli was associated with an unusual high rate of hemolytic uremic syndrome. Also an unexpected high rate of coma and seizures leading to mechanical ventilation and ICU treatment was observed. MicroRNAs are small ribonucleotides orchestrating gene expression. We tested whether circulating microRNAs in serum of HUS patients during the 2011 epidemics are altered in this patient cohort and related to clinical manifestations.

Methods: We profiled microRNAs using RNA isolated from serum of patients and healthy age-matched controls. The results were validated in 38 patients at baseline, 29 patients during follow-up and 21 age-matched healthy controls by miRNA-specific quantitative RT-PCR.

Results: Circulating levels of miR-24, miR-126 were increased in HUS patients versus controls. There was no association between these microRNAs and renal function or the need for renal replacement therapy. In contrast, levels of miR-126 were associated with neurological symptoms at baseline and during follow-up. In addition, miR-126 (on admission) and miR-24 (on admission and during follow-up) were associated with platelet count.

Conclusions: Circulating microRNAs are strongly altered in this patient cohort and associated with neurological symptoms as well as platelet count.

Funding: Government Support - Non-U.S.

TH-PO438

The Number of Plasma Exchanges and the Extended Need of Dialysis Correlate with Poor Long Term Outcome in Adult Patients with Escherichia Coli Associated Hemolytic Uremic Syndrome during the 2011 German Outbreak Maria von Lewinski, Rolf A. Stahl. *Division of Nephrology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany.*

Background: During the 2011 German outbreak of E. coli associated hemolytic uremic syndrome (HUS) 129 patients with HUS were treated in our institution. 48% of these patients had neurologic symptoms and 51% needed hemodialysis (HD). Patients received supportive care or supportive care and additionally plasma exchange (PE) or Eculizumab or both depending on the severity of the disease.

Methods: In a single center approach we analyzed the ten months outcome of 122 patients. They were divided into two groups depending on the treatment. Group A (n=60) received PE (mean 3.2 courses) or only supportive treatment. Patients in Group B (n=62) were treated with Eculizumab and most individuals additionally with PE (mean 4 courses). Group B was divided into three subgroups according to the number of PE: B1 (n=5) 0-1 PE, B2 (n=33) 2-5 PE, and B3 (n=24) 6-13 PE.

Results: In group B, the course of the disease was much more severe with an average of 11.3 days on HD compared to 1.3 days in group A. In group A, 2.6% of patients had an elevated serum creatinine and 28% of patients had persistent albuminuria after ten months. 23% of patients in group B had an impaired renal function and 31% of patients had a persistent albuminuria.

In group B, patients had a more severe course of the disease and a worse outcome depending on the number of PE. In group B1, patients required renal replacement therapy for an average of two days versus 11 days in group B2 versus 13 days in group B3. The serum creatinine after ten months was above normal in 0% (B1), 21% (B2), and 29% (B3) of patients; the urine albumin-creatinine-ratio was elevated in 20% (B1) and in 33% (B2 and B3) of patients.

Conclusions: In patients who had been severely ill and were treated with Eculizumab, the number of plasma exchanges correlated with the time on dialysis. Furthermore a higher percentage of these patients had an impaired renal function after ten months. These findings suggest that the number of PE and the time on dialysis are predictors for a residual renal damage in severely ill patients with STEC-HUS.

TH-PO439

TCC Generation In-Vitro as a Possible Monitoring Parameter in Patients with Atypical Hemolytic Uremic Syndrome (aHUS) Treated with Eculizumab Magdalena Riedl,[1] Johannes Hofer,[1] Alejandra Rosales,[1] Giacomo D. Simonetti,[2] Tanja Maier,[3] Therese C. Jungraithmayr,[1] Reinhard Würzner.[1] *[1]Medical University, Innsbruck, Austria; [2]University Children's Hospital, Bern, Switzerland; [3]Phillipps-University, Marburg, Germany.*

Background: Eculizumab, an antibody blocking C5, is a novel treatment for aHUS. Here we present 5 patients with aHUS and factor H mutations in whom complement activation was determined during long-term Eculizumab treatment.

Methods: C3a, a marker of proximal complement activation, the terminal complement complex (TCC) concentration and degree of sheep erythrocyte lysis was measured by ELISA. Preincubation of serum with zymosan leads to in-vitro activation of complement and is a measure of the residual capacity of complement. Results are given as median and IQR, normal value (NV) is given as IQR of 92 healthy controls.

Results: Eculizumab, applied after plasma exchange withdrawal, led to decrease of in-vitro TCC formation from 1249 AU/ml (896-1476 AU/ml) prior treatment to 62 AU/ml (49-62 AU/ml) during biweekly Eculizumab application (NV 339-889 AU/ml). TCC concentration in plasma was reduced from 2.9 AU/ml (2.0-3.8 AU/ml) to 2 AU/ml (1.6-2.6 AU/ml; NV 0.7-2.0 AU/ml). C3a concentration was elevated prior to Eculizumab (3830pg/ml; 1412-6000pg/ml) and decreased to normal during biweekly administration (734pg/ml; 499-876pg/ml; NV 188-627pg/ml). In 2 patients lysis was detectable (12.6, 5.8%; NV 0-4.7%) prior Eculizumab, which resolved under treatment. 4/5 patients were switched to a three weeks interval, resulting in a rapid increase of TCC capacity to 366 AU/ml (195-554 AU/ml), an elevation of C3a levels to 1435pg/ml (1018-2278pg/ml) and lysis of 10% in 1 patient. A sustained reduction of renal impairment and an increase of platelet count was reported.

Conclusions: We report the successfull long-term treatment of 5 patients with Eculizumab. The determination of TCC generation in-vitro and C3a concentration seem to be promising monitoring parameters. A normalization of C3a levels during Eculizumab indicates a reduction of proximal complement activation. A three weeks interval, may lead to a less blocked complement activation and therefore an increased risk for recurrence.

The Challenge of Managing Hemophilia A and STEC-Induced Hemolytic Uremic Syndrome Dineke Westra,[1] Eiske Dorresteijn,[3] Auke Beishuizen,[4] Lambertus V. Heuvel,[1] Nicole Van De Kar,[1] Paul Brons.[2] *[1]Pediatric Nephrology, RUMC, Nijmegen, Netherlands; [2]Pediatric Hematology-Oncology, RUMC, Nijmegen, Netherlands; [3]Pediatric Nephrology, Erasmus MC-Sophia, Rotterdam, Netherlands; [4]Pediatric Oncology-Hematology, Erasmus MC-Sophia, Rotterdam, Netherlands.*

Background: Hemolytic uremic syndrome (HUS) is a thrombotic microangiopathy leading to acute renal failure in children. In most cases it is triggered by a STEC infection. Endothelial damage plays a central role in the pathogenesis of disease. Haemophilia A is a genetic disorder, leading to Factor VIII (FVIII) deficiency, an important factor in the coagulation system. Here we describe a haemophilia A patient that developed STEC -induced HUS.

Methods: Here we describe a hemophilia A patient in which severe gastro-intestinal and neurological complications occurred during STEC O26-induced HUS. Due to hemorrhagic colitis, severe neurological complications, hypertension, and bleeding at the exit site of the jugular catheter, all in combination with thrombocytopenia and persistently low FVIII levels in serum, FVIII treatment had to be increased enormously. The role of FVIII administration (oral or IV) in the severe outcome of disease is discussed.

Results: It is known that shiga toxin induces the secretion of von Willebrand Factor (vWF) from microvascular endothelial cells, a protein important in adhesion of platelets at the site of injury and a carrier of FVIII in plasma. The adhesion of platelets by vWF will probably lead to increased thrombus formation in the microvasculature of the kidneys of HUS patients The supraphysiological dose of FVIII needed in this case may have contributed further to the thrombotic microangiopathy after shiga toxin-induced endothelial damage in the affected organs.

Conclusions: To our knowledge, this is the first report of a haemophilia patient that developed severe HUS with complications after STEC infection. The patient's treatment schedule of rFVIII during the HUS period was a big challenge and we cannot exclude that it contributed to the severity of the HUS by enhancing the thrombotic microangiopathic process. Continous intravenous rFVIII gave the most stable FVIII levels in the acute phase of STEC HUS.

Several Genetic Aberrations in Different Complement Genes in a Patient with Dense Deposit Disease Dineke Westra,[1] Hans Van der Deure,[2] Elena Volokhina,[1] Lambertus V. Heuvel,[1] Nicole Van De Kar.[1] *[1]Pediatric Nephrology, RUMC, Nijmegen, Netherlands; [2]Pediatrics, Deventer Hospital, Netherlands.*

Background: Membranoproliferative glomerulonephritis type II or dense deposit disease (DDD)is characterized by onset of hematuria and/or proteinuria, acute nephritic or nephrotic syndrome. The exact pathogenesis is not known, but there is involvement of the alternative complement system. In some patients, it is associated with C3-nephritic factor (C3NeF), which stabilizes the C3 convertase C3bBb, with mutations in the complement factor H (CFH) and complement C3, or with autoantibodies against CFH (αFH). Here, we identify potentially pathogenic genetic aberrations in genes of the alternative complement pathway and the membrane attack complex (MAC) in a DDD patient with low C3 values.

Methods: In one DDD patient, mutational screening was performed in the alternative pathway genes *CFH*, *CFI*, *MCP*, *CFHR5*, *C3*, *CFB*, and *CFD*, and the MAC genes *C8A*, *C8B*, and *C9*. Potential pathogenicity of aberrations was checked in literature, evolutionary conservation, and *in silico* mutation prediction programs.

Results: The male patient presented at six years of age with hematuria without other symptoms. C3 values were low (<0,5 mg/l; normal values: 0.9-1.8 g/l). DDD was identified in a renal biopsy. The patient is C3NeF positive, but αFH negative; no drusen are present, yet. A genetic aberration was found in *CFD* (A41P), in *C3* (K155Q), and in *C8A* (A221E). Prediction models for structural influence of the mutations will be displayed. Family screening showed that only the patient carried all three genetic variations.

Conclusions: In our DDD patient, three potentially pathogenic variations are found in genes of the alternative complement pathway and the membrane attack complex. In the patient, a combination of three sequence variations was found, while healthy family members carried only one or two of these variations. This indicates that, next to C3NeF, a combination of genetic defects in the complement system may contribute to the low C3 level and might be needed to display DDD.

TH-PO442

Eculizumab (ECU) Is Effective in Patients (pts) with Atypical Hemolytic Uremic Syndrome (aHUS) Regardless of Underlying Genetic Mutations or Complement Factor H (CFH) Auto-Antibodies Tim Goodship, Richard J. Smith, Christophe M. Legendre, Christoph Licht, Petra Muus, Nancy MacDonald Rodig, Samhar I. Al-Akash, Camille Bedrosian, Veronique Fremeaux-bacchi, Chantal Loirat. *Newcastle University, Newcastle, United Kingdom.*

Background: aHUS is a life-threatening, genetic disease characterized by chronic uncontrolled complement activation and systemic thrombotic microangiopathy (TMA). Despite plasma exchange/infusion, 33-40% of aHUS pts progress to death/ESRD during the first clinical manifestation. Genetic mutations/CFH auto-antibodies are identified in 50-70% of aHUS pts.[1] Overall, risk of death/ESRD is similar in pts with/without an identified mutation.[1,2] ECU, a terminal complement inhibitor, is the only approved treatment for aHUS. In 3 studies, ECU was shown to continuously inhibit TMA and maintain/improve renal outcomes.

Methods: Efficacy parameters were analyzed across 3 studies (2 prospective and 1 retrospective [<18 yrs]), by

presence/absence of genetic abnormalities (Table).

Results: Across the 3 studies, 24-41% of enrolled aHUS pts had no identified complement abnormality. Efficacy of ECU was similar in pts with/without an identified genetic abnormality (Table).

Conclusions: Across 3 studies of ECU in aHUS, improved clinical outcomes were similar in pts with/without identified genetic mutations/CFH auto-antibodies, confirming treatment can be initiated immediately in patients with a clinical diagnosis of aHUS before the analyses of a genetic abnormality are undertaken or the results are available.[3]

Non Lupus Membranoproliferative Glomerulonephritis Classification According to Immunoglobulin Deposition on Immunofluorescence Raquel Maria Maia, Camila Hitomi Nihei, Loyana Teresa Teofilo Lima Silva, Cristiane Bitencourt Dias, Viktoria Woronik. *Nephrology, Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil.*

Background: A new classification of membranoproliferative glomerulonephritis (MPGN) according to immunoglobulin deposition has been proposed in literature. The aim of this study is to compare the initial clinical presentation and follow up of those patients.

Methods: This retrospective study assessed, among 1641 renal biopsies performed in one center from 1999 to 2011, the clinical and laboratory data at diagnosis and during follow up of patients with non lupus MPGN (n = 95 biopsies). We excluded 25 patients by insufficient clinical on histological data, remaining 70 patients for analysis.

Results: Immunoglobulin deposits on IF were observed in 54 patients (77.1%) while 16 (22.8%) showed no immunoglobulin deposits. Among patients without immunoglobulin deposits 6 showed C3 deposits and 10 were totally negative. Comparison of the initial data between MPGN with immunoglobulin and without immunoglobulin in IF showed no difference in age of 45.9 ±15.1 vs 42.3 ±19.4 years, serum creatinine of 1.8 (1.1-3.2) vs 2.2 ±1.5 mg/dL, proteinuria of 5.1 ±3.2 vs3.7 ±3.0 g/day, hematuria in 75.9 vs 75.0% and low C3 complement in 48.1 vs 50.0% . Among patients with positive immunoglobulin, 23 (42.6%) exhibited an associated disease: 5 schistosomiasis, 4 HCV, 1 HBV, 1 HIV, 2 HCV + HBV, 1 leprosy, 2 autoimmune disease, 2 neoplasia; 4 cirrhosis and 1 spherocytosis. In patients without immunoglobulin deposition we found an association with other disease in 6 (37.5%): HCV in 4 and neoplasia in 2. On follow up, end stage chronic disease was observed in 21.2% if immunoglobulin positive patients and 37.5% of negative patients, not different between both groups.

Conclusions: There was no difference between MPGN groups with and without deposition of immunoglobulin considering initial clinical and laboratory data, as well as, to evolution to chronic disease. Surprisingly in our series and not expected from literature data, HCV and neoplasias were associated with both MPGN groups (immunoglobulin positive and negative).

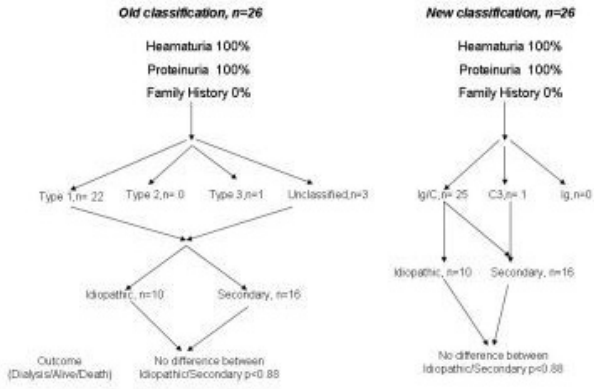
TH-PO444

A Ten Year Diagnostic Review of MPGN Cases in a Single Centre Arvind Ponnusamy, Darren Green, Shiv Bhutani, Edmond O'Riordan. *Renal, Salford Royal NHS Trust Foundation, Salford, United Kingdom.*

Background: MPGN is a rare glomerulonephritis in adults. The existing classification is based on electron microscopy appearances. A new complement-driven pathogenesis-based classification along 3 immuno-fluorescence pattern groups (Ig only, Ig and C3 and C3 only) has been proposed. Little is known of their clinical utility.

Methods: We reviewed the clinical notes of patients who presented to our hospital between 2001 and 2011. Cases were classified by the existing and proposed criteria. Laboratory, clinical parameters and outcome were also analysed.

Results: Mean follow up time was 3 years. The mean creatinine at presentation was 197umol/l ± 132 and proteinuria was 396 ± 251gm/day. On biopsy, 23 cases were Type 1, one was Type 3 and 3 cases were unclassifiable. Both immunoglobulin and complement deposition were present in 25 cases, one patient had only C3 deposition (previously classed type 1), and no patients were negative for both Ig and C3. We found the following secondary causes: SLE [4 patients], CLL [3 patients], IgAN [2 patients], Cryoglobulinemia [4 patients] and rheumathoid arthritis [1 patient], light chain [1 patient], with 10(42%) patients regarded as idiopathic. Comparison of both classification systems revealed neither was useful in predicting patient outcome ((patient/renal survival), p<0.88).



Analysis of baseline data suggests that age >65 years and creatinine > 250 ummo/l were associated with worse outcomes (OR 5.3, OR 4.8, p<0.05) respectively. One patient identified with hereditary C4 deficiency (Type 1) revealed both Ig and complement deposition.

Conclusions: Categorization either by existing or proposed classification results in clustering in 1 subgroup. Despite investigations, many remain idiopathic and patient outcomes are heterogenous. Genetic complement disorders also occur in patients with both Ig and C3 deposition.

TH-PO445

Treatment of C3 Glomerulopathies with Mycophenolate Mofetil or Rituximab: A Comparative Study Sophie Chauvet,[1] Alexandre Karras,[1] Isabelle Tostivint,[2] Eric Thervet,[1] Veronique Fremeaux-bacchi,[3] Aude Servais.[4] *[1]Nephrology, HEGP, Paris; [2]Nephrology, Pitié-Salpétrière, Paris; [3]Immunology, HEGP, Paris; [4]Nephrology, Necker, Paris.*

Background: C3 glomerulopathy is a newly described entity associated with acquired and/or genetic abnormalities in complement alternative pathway. Renal outcome is poor with a ten years renal survival of 50% but optimal treatment is not known. The aim of this study was to describe clinical and biological evolution of patients treated with mycophenolate mofetil (MMF) or rituximab (RTX).

Methods: This retrospective multicentric study included 20 patients. Data were collected at treatment start, at 6, 12 months and last follow up. Renal response was defined as partial (prteinuria Pu ≤ 2.5g/d or a ≥50% decrease of Pu, albuminemia ≥25g/l, stable serum creatinine (sCr)) or complete (Pu ≤ 0.5g/d, albuminemia ≥30gl and normal or stable sCr). Immunological response was defined by normal C3 level and/or negativation of C3 Nephritic factor (C3Nef).

Results: Twenty patients (sex ratio 1, median age 24 years, range 6 to 64) were included. Seventeen patients had low serum C3. C3Nef was found in all cases, associated in 3 with a factor H or I mutation.At the time of treatment start, sCr was 106µmol/l (range 29-600), Pu 6.24g/d (range 1.38-15), albuminemia 27g/l (range 13-38). Patients received MMF (n=9) or RTX (n=11).

Partial and complete renal responses were observed in both groups during follow up. After a median follow up of 49 months (range 6-156), 7 patients reached end stage renal disease (ESRD) (5 in RTX group).

complete and partial renal responses

	MMF	RTX
6 months	5/9	6/11
12 months	5/9	5/11
last follow up	4/9	4/11

Serum creatinine of others patients was 126µmol/l (range 30-575) and 100µmol/l (range 30-175) in MMF and RTX group, respectively. At 6 and 12 months, immunological response was observed in 5 and 3 patients, respectively.

Conclusions: Renal remissions were similar in both groups during the first year of treatment, independently of immunological response. Nevertheless, RTX seems to be associated with a higher risk of ESRD at last follow up.

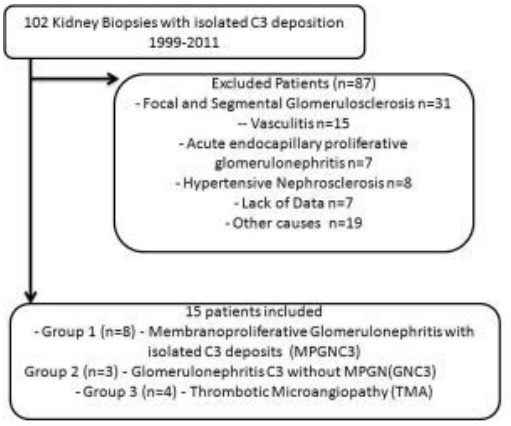
TH-PO446

Clinicopathological Features in Patients with Isolated C3 Deposits in Glomerular Diseases Maria Julia C.L.N. Araujo, Ligia Costa Battaini, Vivian Lumi Onusic, Lectícia Jorge, Cristiane Bitencourt Dias, Rui Toledo Barros, Viktoria Woronik. *Nephrology, University of Sao Paulo, Sao Paulo, SP, Brazil.*

Background: Glomerular nephropathies with isolated complement C3 deposits can be observed in different situations: MPGN type II, acute poststreptococcal glomerulonephritis, and glomerulonephritis C3. Glomerulonephritis C3 was associated in rare instances with haemolytic uraemic syndrome. The aim of our study was evaluate clinical and histological features associated with isolated C3 deposits in kidney biopsy.

Methods: A retrospective analysis of 102 kidney biopsies with isolated C3 deposits performed at our hospital was done. Relevant clinical and biological data were collected. A huge heterogeinety of histological diagnosis was found and we chose for analysis 3 pathologies known for their envolvement with imunocomplexes and/or complement cascade activation, as show in fig1.



Results: The results are summarized in Table1.

Clinical and Histological Features

	Group1 (MPGN 3)	Group2 (GN 3)	Group3 (TMA)
Age(y)	43,1±19,3	19,33±4,6	41±14,7
Male	5(63%)	1(33%)	1(25%)
eGFRin(ml/min)	51,4±21,8*†	115,3±52,6	9,3±2,4
Proteinuria(g/day)	3,9±2,2†	7,9±5,3§	1,2±0,4
C3 level<90mg/dl n(%)	3(37%)	0(0%) §	4(100%)
Hemoglobin(g/dl)	11,7±1,64†	14±2,3§	7,6±1,3
Platelets(cells/mm3)	210±61,3	329±12,9§	115±104,4
Hematuria n(%)	6(75%)	3(100%)	2(50%)
Crescents n(%)	3(38%)	0(0%)	2(50%)
Interstitial fibrosis	7(88%)	1(33%)	4(100%)
Vascular injury	2(25%)	0(0%)§	4(100%)
ESRD	4(50%)*	0(0%)§	4(100%)

***p<0.05 1 vs 2; †p<0.05 1 vs 3; §p<0.05 2 vs 3**

Only 15% of the patients are affected by pathologies related to complement cascade activation. Despite the small casuistics, TMA patients showed the worst scenario considering clinical presentation and follow up, while GNC3 was the less agressive disease.

Conclusions: Isolated C3 glomerular deposition should be cautiously overlooked and avaliated on the ground of the underlying clinical disease.

Funding: Government Support - Non-U.S.

TH-PO447

'Persistent' Post-Infectious Glomerulonephritis Is Associated with Abnormalities in the Alternative Pathway of Complement Sanjeev Sethi,[1] Fernando C. Fervenza,[1] Ladan Zand,[1] Yuzhou Zhang,[2] Samih H. Nasr,[1] Richard J. Smith.[2] *[1]Mayo Clinic, Rochester, MN; [2]University of Iowa, Iowa City, IA.*

Background: Post-infectious glomerulonephritis is a common type of glomerulonephritis (GN) that results following an infection. In the majority of cases, there is complete recovery of renal function. However, in a small percentage of patients there is persistence of the GN manifested by hematuria and proteinuria. The cause of 'persistent' post-infectious GN is unknown. We hypothesized that in such patients there is a defect in the regulating mechanisms of the alternative pathway (AP) of complement that prevents its down-regulation following resolution of the infection.

Methods: 11 patients with persistent hematuria and proteinuria were selected. Kidney biopsy showed a proliferative GN, bright C3 staining on IF and subepithelial humps on EM. The AP was evaluated by functional assays including C3 nephritic factors (C3Nefs) and genetic testing.

Results: There were 5 females and 6 males (age range 2 to 71). Serum creatinine ranged from 0.5 to 3.1 mg/dL (mean 1.43) with an eGFR of 53 to 280 ml/minute (mean 72.45). Ten patients had hypertension. C3 levels were low in 6 patients. C4 levels were normal in all patients. All patients had persistent hematuria and/or proteinuria (range 4 to 48 months, mean 15). Autoantibodies or mutations in complement genes were identified in 10 of 11 patients. Seven patients were positive for C3Nefs, and were associated with additional functional abnormalities of the AP in 6 patients. Four patients had mutations of complement genes including 3 patients with mutations in CFH and 1 patient with a mutation in CFHR5. The CFH mutations included a frameshift – c.2171delC, p.Thr724fsSTOP725 – and two missense variants – c.1699A>G,p.Arg567Gly and c.3350A>G,p.Asn1117Ser. The single missense variant in CFHR5 was c.646-647AA>TT,p.Asn216Phe.

Conclusions: Patients with 'persistent' post-infectious GN have a defect in regulation of the AP resulting in an inability to control the AP even after resolution of the infection. The sequela is continual glomerular deposition of complement factors with resultant inflammation and development of 'persistent' post-infectious GN.

TH-PO448

2,8-Dihydroxyadenine Crystal Nephropathy: Report of 11 Cases
Mohamad Zaidan,[1] Elodie Merieau,[2] Emilie Cornec-Le Gall,[3] Reda Sharobeem,[4] Patrice M. Deteix,[5] Christian H. Jacquot,[6] Umberto Maggiore,[7] Laure-Helene Noel,[1] Michel Daudon,[8] Bertrand Knebelmann.[1] *[1]Necker Hospial, Paris, France; [2]CHU de Tours, France; [3]CHU de Brest, France; [4]Centre de l'Archette, Olivet, France; [5]CHU de Clermont-Ferrand, France; [6]HEGP, Paris, France; [7]Parma University Hospital, France; [8]Tenon Hospital, Paris, France.*

Background: APRT deficiency is a rare autosomal recessive purine enzyme defect that results in recurrent 2,8-dihydroxyadenine (2,8-DHA) urolithiasis and more rarely crystal nephropathy.

Methods: Retrospective multicentric study of patients with 2,8-DHA crystal nephropathy diagnosed by infrared spectroscopy.

Results: 11 patients (5M/6F) were included (age 57±13 years). The mean interval between first consult and diagnosis was 6±5 years but 7 pts had a history of urolithiasis. All patients had CKD attributed to nephrolithiasis and chronic tubulointerstitial nephritis (4 pts), benign nephroangiosclerosis (2 pts) or undetermined nephropathy (5 pts). 8 pts had reached ESRD and 7 pts had a kidney graft before diagnosis presenting with delayed graft function (3 pts), chronic graft dysfunction (1 pt) or acute-on-chronic renal failure (2 pts). In one case, the diagnosis was established after transplantation without graft dysfunction. Mean eGFR at diagnosis was 16±11 ml/min/1,73m² with 4 pts requiring dialysis. In all cases kidney biopsies showed tubulointerstitial lesions with crytals that were birefringent under polarized light. Oxalosis was firstly suspected in 6 pts. Renal 2,8-DHA-crystals were eventually identified by infrared spectroscopy in all cases. Cristalluria showed 2,8-DHA crystals in 3/3 pts. Erythocyte APRT activity was undetectable in 7/7 pts. APRT gene mutations were identified in 6/6 pts. Under therapy including increased water-intake, low-purine diet and allopurinol, renal function improved in 6 pts leading to withdrawal of dialysis in 2 pts. At last follow-up, 4 pts were on dialysis and mean eGFR for 7 pts was 33±16 ml/mn/1.73m².

Conclusions: 2,8-DHA crystal nephropathy is an underdiagnosed cause of kidney injury leading to ESRD and graft loss. A better knowledge of this disease would allow earlier diagnosis and start of an efficient allopurinol therapy.

TH-PO449

Mortality and Renal Outcome of Biopsy-Proven Glomerulonephritis: A Review of 30 Years of Experience
Hajeong Lee,[1] Yun Jung Oh,[1] Yon Su Kim,[1] Dong Wan Chae,[2] Suhnggwon Kim,[1] Ho Jun Chin.[2] *[1]Internal Medicine, Seoul National University Hospital; [2]Internal Medicine, Seoul National University Bundang Hospital.*

Background: Previous epidemiologic studies have focused on the prevalence of glomerulonephritis (GN) and few studies have explored the long-term patient outcomes. This study was conducted to investigate long-term patient and renal outcome of GNs.

Methods: Patients performed a renal biopsy from 1979 to 2008 were included in this retrospective analysis. The outcomes were patient and renal death. The relative mortality rate of GNs was estimated by the standardized mortality ratio (SMR) with 95% confidence interval (CI).

Results: GN comprised 86.7% of 4,998 naïve kidney biopsies, with 3,235 of primary GNs and 1,100 secondary GNs. IgA nephropathy (IgAN) and lupus nephritis was the most common primary (n= 1,404, 43%), and secondary GN (n= 526, 48%), respectively. Membranoproliferative GN of primary GNs and diabetic nephropathy of secondary GNs showed worst prognosis in terms of both renal (20 year survival rate [YSR] 48.4% vs. 10YSR 46.6%) and patient survival (20YSR 64.2% vs. 10YSR 60.9%), respectively. Interestingly, IgAN and Henoch-Schonlein nephritis (HSN) patients revealed relatively fair patient survival (20YSR 89.6% vs. 86.8%), notwithstanding their significant renal progression (20YSR 60.3% vs. 62.9%). Mortality of GN patients is significantly higher than age/sex matched general population in both primary GN (SMR 1.67, 95% CI 1.42-1.95) and secondary GN (SMR 4.77, 95% CI 3.95-5.70). In primary GN, men showed comparable mortality except with focal segmental glomerulosclerosis (SMR 1.63, 95% CI 1.05-2.43), whereas most of women showed higher mortality except with minimal change disease (SMR 2.21, 95% CI 0.72-5.16), compared to general population. In secondary GN, most patients exhibited elevated mortality except men with HSN (SMR 1.72, 95% CI 0.47-4.41).

Conclusions: We demonstrated that mortality of GN is significantly higher than general population, especially in secondary than primary GN, and in women than men. IgAN and HSN revealed relatively fair survival rate, allowing for their significant renal progression.

TH-PO450

Recurrent and De Novo Glomerular Disease in Renal Allografts
Adil M.H. Gasim,[1,2] Alice Sandra Wilkman,[1,2] Volker Nickeleit,[1,2] Harsharan Singh,[1,2] J. Charles Jennette.[1,2] *[1]Pathology and Laboratory Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]UNC Kidney Center, University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: The usual question about glomerular disease in renal transplants is how often does each type recur. Here we answer 3 different questions: 1) What is the frequency of different types of glomerular disease in renal transplant biopsies? 2) When a specific type of glomerular disease is observed in a transplant, how often is it recurrent vs de novo? 3) When a transplant patient develops glomerular disease, how does the likelihood of recurrent vs de novo disease vary with the initial cause for ESRD?

Methods: Frequencies of specific categories of glomerular diseases were determined in 385 patients with glomerular disease in allograft biopsies evaluated at UNC. The frequency of recurrent versus de novo disease was determined in 84 patients who had paired native kidney and transplant biopsies.

Results: Selected glomerular disease frequencies were FSGS 139, membranous GN 45, IgA GN 31, TMA 30, immune complex GN NOS 29, diabetic GS 27, lupus GN 18, type I MPGN 11, C1q GN 5, ANCA GN 4, MIDD 3, DDD 3, amyloidosis 2, anti-GBM GN 1. 139 FSGS cases include 30 collapsing FSGS but only 2 tip lesion FSGS. 30 TMA cases include 7 in the setting of calcineurin inhibitor toxicity. Table 1 compares renal biopsy diagnosis in native kidney (x-axis) with transplant kidney (y-axis).

Native kidney diagnosis (x-axis), transplant kidney diagnosis (y-axis)

	FSGS	Mem GN	Lupus GN	IgA GN	GN NOS	Diabetes	Other
FSGS	20	1	2	1	2	0	4
Mem GN	2	6	0	0	1	0	3
Lupus GN	0	0	8	0	0	0	0
IgA GN	1	0	0	4	0	0	1
GN NOS	3	0	1	0	3	0	7
Diabetes	0	1	0	0	0	1	0
Other	1	0	0	1	0	0	4

When observed in a transplant biopsy, 100% lupus GN, 67% FSGS, 67% IgA GN, and 50% membranous GN were recurrent. Glomerular disease developing in a transplant was recurrent in approximately 75% of patients with native kidney lupus GN, membranous GN and FSGS; and less often recurrent in patients with other native glomerular diseases.

Conclusions: In our cohort, glomerular diseases in renal transplants is most often FSGS, membranous GN, and IgA GN; and all glomerular diseases in transplants are more often recurrent than de novo.

Profiling Human Urinary mRNA
Larysa T. Wickman,[1] Yan Yang,[1] Akihiro Fukuda,[2] Ryuzoh Nishizono,[1] Debbie S. Gipson,[1] David B. Kershaw,[1] Marie Tanzer,[1] Roger C. Wiggins.[1] *[1]University of Michigan, Ann Arbor, MI; [2]University of Miyazaki, Japan.*

Background: Depletion of podocytes drives the progression process in animal model systems and human glomerular diseases. Increased urine podocyte specific product measurements, such as podocin and nephrin, are associated with both acute glomerular injury and progression. We previously analyzed urine podocin and nephrin mRNAs in 4 different model systems of progression. Two model systems relied on initial podocyte injury to trigger progression (PAN and podocin hDTR transgenic rat), while two relied on growth to trigger progression (5/6 nephrectomy and podocin-AA4EBP1 transgenic rat). We defined patterns of podocyte injury as: "Podocyte Loss" (high podocin:creatinine ratio), and "Podocyte Stress" (high podocin:nephrin ratio). For comparison we used urine aquaporin2 mRNA as a marker of tubular injury and TGFb1 mRNA as a marker of pro-fibrotic milieu.

Methods: Using insights developed from the model systems we compared 682 urine samples from adult and pediatric kidney clinics to 110 control samples. Spot urine samples were collected, processed for RNA purification, reverse transcribed and assayed using the TaqMan system for podocin, nephrin, aquaporin2 and TGFb1 mRNA, protein and creatinine concentrations. A two sample comparison was used to analyze urine podocin:creatinine ratio and urine protein:creatinine ratio of clinic samples vs controls.

Results: Compared to controls, clinical samples had elevated urine protein:creatinine ratio ($P=3x10^{-21}$) and elevated urine podocin:creatinine ratio ($P=3.6x10^{-33}$). Podocin:nephrin mRNA ratio was increased in clinic samples compared to control samples ($P<0.001$). Urine podocin:creatinine ratio did not correlate highly with the urine protein:creatinine ratio ($r^2=0.12$), thereby demonstrating that urine podocin mRNA provides additional information.

Conclusions: Urine mRNA biomarkers can provide clinical information complimentary to proteinuria. Longitudinal analysis of phenotypically well-characterized patients will be required to establish the potential utility of urine mRNA biomarkers for clinical decision-making within defined settings.

TH-PO452

Comparison of Glomerular Density and Size Distributions in Renal Biopsies of Primary Glomerular Diseases
Nobuo Tsuboi, Kentaro Koike, Go Kanzaki, Yasunori Utsunomiya, Tetsuya Kawamura, Tatsuo Hosoya. *Division of Kidney and Hypertension, The Jikei University School of Medicine, Tokyo, Japan.*

Background: We have recently reported that glomerular number per renal cortical area in biopsies (glomerular density: GD) differs significantly between individuals, and that a low GD predicts a worse renal outcome in patients with IgA nephropathy (IgAN) and idiopathic membranous nephropathy (IMN) (CJASN2010, NDT2011). Differences in GD values between etiologically distinct glomerular diseases remain undetermined.

Methods: The values of the GD and the glomerular volume (GV) were measured in a total of 302 biopsies using a computed imaging analyzer. The measured values were compared between the patients including minimal change disease (MCD), IgAN, IMN, membranous proliferative glomerulonephritis (MPGN) and focal segmental glomerulosclerosis (FSGS). All biopsies were performed at the time of preserved renal function (eGFR≥60ml/min/1.73m²) and the biopsies of kidney transplant donors (KTD) were used as comparison.

Results:
Comparison of GD/GV

	KTD (n=34)	MCD (n=50)	IgAN (n=98)	IMN (n=65)	MPGN (n=32)	FSGS (n=23)
GD (/m^2)	3.1±1.1	3.6±1.1	3.5±1.5	3.4±1.1	3.4±1.1	2.1±1.0*
GV (x10^{6}µm^3)	2.6±0.8	2.5±0.8	2.9±1.1	4.1±1.1*	3.9±1.0*	5.0±0.3*
r (GD vs. GV)	-0.438	-0.420	-0.544	n.s.	n.s.	-0.420

*p<0.01 vs. KTD

Of note, there are three distinct patterns of the GD/GV distribution in primary glomerular diseases.The values of these measures in MCD and IgAN were similar to those of KTD. In this first patients group, the GD showed inverse correlations to the GV (normal pattern). In the second patients group of IMN and MPGN, the GV values were large regardless of the GD levels and there were no significant correlations between these measures (MN pattern). In the third group of FSGS patients, the GD was extremely low, and the GV showed marked enlargement (FSGS pattern). Analyses of the serial biopsies in IgAN (n=18) and IMN (n=10) patients showed the same trends toward FSGS pattern during the progressive loss of renal function.

Conclusions: The differences in the GD/GV distribution in primary glomerular diseases are independent of those observed between the individuals, and may represent the disease characteristic status.

TH-PO453

Glomerular Volume in Patients Who Died due to Intracranial Hemorrhage Marcin Adamczak, Katarzyna Kwiecien, Katarzyna Konat, Henryk Karkoszka, Magdalena Szotowska, Andrzej Wiecek. *Department od Nephrology, Endocrinology and Metabolic Diseases, Medical University of Silesia, Katowice, Poland.*

Background: Results of some quantitative histopathological studies suggest that patients with essential hypertension are characterized by lower number and higher mean volume of kidney glomeruli (MGV). Intracranial hemorrhage is one of the common causes of death in the patients with hypertension. The aim of the study was to evaluate MGV in kidney donors died due to intracranial hemorrhage.

Methods: Into the retrospective study medical records from cadaveric kidney donors harvested between 2005 and 2010 were included. In all cases preimplantation kidney biopsies ("zero biopsies") were performed. MGV was evaluated in specimens of "zero biopsies". The results were shown as a median and 95 CI.

Results: Analyzed group consisted of 34 cadaveric kidney donors who died due to intracranial hemorrhage [18 females and 16 males; age 49 years (42-51), kidney weight 191.0g (174.1-208.7) and serum creatinine concentration 104 µmol/l (89-174)]. The control group consist of 20 patients who died due to brain trauma [3 females and 17 males, age 41 years (30-44), kidney weight 187.0g (164.2-212.7) and serum creatinine concentration 97 µmol/l (81-236)]. Entire medical history of cadavers (including history of hypertension) were not available for all kidney donors. Kidney donors died due to intracranial hemorrhage characterized by significant higher MGV than donors died due to brain trauma [4.95x10^{6}µm^3 (4.02-6.14) vs 3.78 x10^{6}µm^3 (2.93-4.22); p<0.042]. There were also significant (p=0.025) differences of MGV in tercils of cadaveric donors age [tercile 1 (<42 years) – 3.62x10^{6}µm^3 (2.90-3.98), tercile 2 (42-49 years) – 4.68x10^{6}µm^3 (4.00-5.38) and tercile 3 (>50 years) – 5.11x10^{6}µm^3 (3.56-7.97)]. The significant positive correlation between median MGV and donors age (p=0.024, R=0.42) was found.

Conclusions: 1. Kidney from patients who died due to intracranial hemorrhage are characterized by higher MGV. 2. It is necessary to perform further studies analyzing long term results of transplantation of kidney with higher MGV.

TH-PO454

Changes in the Incidence of Glomerular Diseases in Uruguay during the Last Ten Years Oscar A. Noboa,[1,4] Liliana Gadola,[1,4] Hena Maria Caorsi,[2,4] Mariela Garau,[1,4] Nelson Acosta,[2,4] Panuncio Ana,[3] Maria Auchayna,[4] Silvia Melesi,[3] Ana Marino,[3] Francisco Gonzalez-martinez.[1,4] *[1]Centro de Nefrologia, Facultad de Medicina, Universidad de la Republica, Montevideo, Uruguay; [2]Sociedad Uruguaya de Nefrologia, Uruguay; [3]Depto Anatomia Patologica, Universidad de la Republica, Montevideo, Uruguay; [4]Program of Prevention and Treatment of Glomerulopathies.*

Background: The National Program of Prevention and Treatment of glomerular Diseases collects clinical and histological data from all the patients in whom a renal biopsy is performed in the country since 1980. In 2004 glomerulopathies were included among mandatory notifiable diseases.

The aim of this study is to analyze the changes in the incidence of glomerular diseases during the last ten years.

Methods: All Renal biopsies (RB) performed in three periods were analyzed, 1998-99 (I), 2003-4 (II) y 2008-09 (III), (728 biopsies). RB were processed for optical microscopy and immunofluorescence.

The Uruguayan population > 14 years old was 2.511.296, 2.555.068 and 2.625.826 in each period. The rate of each glomerular disease per millon population, per year was calculated (pmp). Statistic analysis was performed comparing the incidence rate ratio (IRR) per millon adult population during the period of time for each diagnosis along with their 95% confidence interval (CI).

Results: The frequency of renal biopsies performed pmp per year was similar for the three periods: 46.7 (I), 46.2 (II) and 51.9 (III). The incidence rate (IR) was calculated for each glomerulopathy. Focal and segmental glomerulosclerosis significantly decreased, IR, 10.2, 8.0 and 4.2 with an (IRR 2.49, CI 1,47-3.99) (p = 0.005). IgA Nephropathy significantly increased from, 5.6, 7.2 and 12.6 (IRR 0.44 CI 0.28- 0.69 (p= 3.10^{-4}) as well as Vaculitis IR increased from 3.0, to 7.0 and 6.3 (IRR CI 0.26-0.87 p= 0.02).

Conclusions: The incidence rate of glomerular diseases significantly changed in the last 10 years although the rate of biopsy performed pmp did not change. While Focal and segmental glomerulosclerosis significantly decreased, IgA nephropathy and vasculitis increased. This national epidemiologic surveillance would have an impact on public health policies and clinical practice.

Development of a Novel Technique to Visualize In Vivo Renin Activity and Analysis of the Renoprotective Actions of a Renin Inhibitor Kengo Kidokoro, Minoru Satoh, Tamaki Sasaki, Naoki Kashihara. *Nephrology and Hypertension, Kawasaki Medical School, Kurashiki, Okayama, Japan.*

Background: Despite the systemic renin activity is suppressed in diabetes, a renin-angiotensin system (RAS) inhibitor exert renoprotective effects in diabetes. Activation of local/tissue RAS, therefore, appears to be involved in pathogenesis of diabetic nephropathy. In an attempt to examine the possible involvement of local RAS in diabetic nephropathy, we tried to develop a novel technique to visualize tissue renin activity in vivo by using the fluorescence resonance energy transfer (FRET) system and multiphoton laser microscopy(MP-LM). We also examinedrenprotective mechanisms of aliskiren in diabetic nephropathy.

Methods: Streptozotosin (STZ)-induced diabetes model was made in C57/BL6 mice. Following 4 groups were prepared; Control (Cont), STZ, STZ + aliskiren (25 mg/kg/day, 4 weeks) (Alis), and the STZ + hydralazine (100 mg/kg/day, 4 weeks) groups (Hyd). Renin FRET peptide was given intravenously and generated fluorescence was detected by MP-LM in the kidney tissue in vivo. Glomerular hyperfiltration of macromolecules was also examined in vivo imaging system using fluorescence-labeled 70-kDa dextran. The production of reactive oxygen species (ROS) was also evaluated by a fluorescent indicator, dichlorodihydrofluorescin diacetate.

Results: Local renin activity was successfully visualized in the kidney tissue of living mice and was markedly enhanced in the glomeruli of the STZ group. Both plasma and tissue renin activities were significantly decreased in the Alis group. Hyperfiltration of the macromolecules precedent to the development of albuminuria and increased oxidative stress were observed in the STZ kidney. These changes were ameliorated in the Alis group.

Conclusions: We have successfully developed a novel in vivo imaging technique to directly visualize renin activity in living animal. Our data indicated that aliskiren inhibited both plasma and tissue renin activities, ameliorated tissue oxidative stress and attenuated urinary albumin excretion in a mouse diabetes model. The combination of in vivo imaging technique and FRET peptide will provide a novel approach to explore pathophysiology of kidney diseases.

eNOS Deficiency Predisposes to Renin Angiotensin Aldosterone System Sensitive Podocyte Injury in Diabetes Darren A. Yuen,[1] Kathryn E. White,[2] Tomoko Takano,[3] Lei Zhu,[3] Takamune Takahashi,[4] Raymond C. Harris,[4] Andrew Advani.[1] *[1]Dept. of Medicine, St. Michael's Hospital, Toronto, ON, Canada; [2]EM Research Services, Newcastle University, Newcastle, United Kingdom; [3]Dept. of Medicine, McGill University, Montreal, QC, Canada; [4]Dept. of Medicine, Vanderbilt University, Nashville, TN.*

Background: Endothelial nitric oxide synthase (eNOS) deficiency has been implicated in the pathogenesis of diabetic nephropathy in both experimental and clinical studies. In the present study we explored the mechanisms by which eNOS deficiency may lead to renal injury, focusing on two common sequelae of endothelial dysfunction in diabetes: glomerular capillary growth and effects on neighbouring podocytes.

Methods: Experiments were performed in control and diabetic wildtype and eNOS$^{-/-}$ mice treated with a VEGF receptor antagonist, ACE inhibitor (ACEi) or angiotensin II receptor blocker (ARB), as well as in cultured podocytes and in wildtype and eNOS$^{-/-}$ glomerular endothelial cells (GECs).

Results: After 12 weeks of diabetes, glomerular capillary volume was increased in both steptozotocin (STZ)-diabetic C57BL/6 and eNOS$^{-/-}$ mice. Although VEGF receptor inhibition attenuated glomerular capillary enlargement in both groups, and albumin excretion in STZ-C57BL/6 mice, the albuminuria that occurred in STZ-eNOS$^{-/-}$ mice was unaffected. Heavy albuminuria occurred in STZ-eNOS$^{-/-}$ mice as early as two weeks after diabetes induction, associated with an acute podocytopathy, also observed in hyperglycemic db/dbeNOS$^{-/-}$ mice. Treatment of STZ-eNOS$^{-/-}$ mice with the ACEi captopril prevented podocyte injury and albuminuria development, as did the ARB losartan when administered at non-hypotensive dosing. Exposure of cultured podocytes to conditioned medium derived from eNOS$^{-/-}$ GECs exposed to high glucose and angiotensin II activated podocyte RhoA, a pivotal actin cytoskeleton regulator.

Conclusions: Podocytopathy occurring as a consequence of eNOS deficiency and hyperglycemia highlights the importance of endothelial-podocyte crosstalk in diabetes. Elucidation of RAS-sensitive mediators of this communication may lead to the development of novel therapies targeting endothelial dysfunction in albuminuric individuals with diabetes.

Early Activation of RAS in Diabetic Mice Urine Is Angiotensinogen-Dependent and ACE-Independent Jan A. Wysocki, Laura Garcia-Halpin, Minghao Ye, Daniel Batlle. *Div. of Nephrology&Hypertension, Feinberg School of Medicine, Northwestern University, Chicago, IL.*

Background: Urinary renin-angiotensin system (RAS) components could be used as potential biomarkers of RAS overactivity to predict development of diabetic kidney disease. Urinary angiotensinogen (AOG) has been found to be increased in urine of diabetic patients. We studied urinary angiotensin in conjunction with other components of RAS system in the urines from the db/db model of type 2 diabetes at a time when urine albumin excretion is only slightly increased and kidney histology is normal.

Methods: Urinary AOG and angiotensin II were measured by ELISA. Urinary activities of Ang II-forming (ACE) and AngII–degrading enzyme (ACE2) were measured using synthetic fluorogenic substrates in urines from 8 weeks old female db/db and db/m mice.

Results: At 8 weeks of age, there was a slight increase in albumin/creatinine ratio (303±32vs. 87±4 ug/mg, respectively) but a marked increase in urinary AOG levels in db/db as compared to db/m mice (41.2±9.7 vs. 5.9±1.7 ng/mg creatinine, $p<0.05$, respectively). The increase in AOG levels was associated with an increase in urinary angiotensin II (203±54 vs. 45±13 pg/mg creatinine, $p<0.05$, respectively). At this early age, ACE2 activity in db/db mice was also increased as compared to db/m (38±5 vs. 19±3 RFU/ug creat/hr, $p<0.05$, respectively). In contrast to the increase in ACE2 activity and AOG levels, ACE activity in the urine from db/db mice was reduced as compared to that of db/m mice (1.42±0.36 vs. 2.78±0.34 RFU/ug creat/hr, $p<0.05$, respectively).

Conclusions: Early activation of the kidney RAS system in the db/db mice is evident from increased levels of urinary Ang II and high levels of this peptide result from increased angiotensinogen and not from increased ACE activity. ACE2 activity in the urine is increased likely reflecting the increased metabolism of angiotensin II.

Role of Angiotensin Type 2 Receptor in Diabetic Nephropathy Rita de Cassia Cavaglieri, Robert T. Day, Denis Feliers. *Medicine/Renal Disease, University of Texas Health Science Center at San Antonio, San Antonio, TX.*

Background: Angiotensin II plays a major role in the development of diabetic nephropathy through activation of the AT1 receptor. The other receptor, AT2 is believed to oppose the effect of AT1. Its role in the pathogenesis of diabetic nephropathy is the focus of this study.

Methods: We induced type 1 diabetes in AT2 knockout mice (KO) and their wild-type littermates (wt) by injection of streptozotocin and studied renal function after 3 months of diabetes. Markers of inflammation (monocyte/macrophage infiltration, MCP1 and VCAM1) and fibrosis were measured by immunohistochemistry, immunoblot and RT-qPCR.

Results: Absence of AT2 did not affect blood pressure in control and diabetic mice, but increased glycemia slightly in control mice and very significantly in diabetic mice. Interestingly, diabetic AT2KO mice did not lose body weight in spite of higher glycemia. Normoglycemic AT2KO mice showed signs of kidney injury: renal and glomerular hypertrophy and increased fibrosis. Induction of diabetes in AT2KO mice increased kidney weight, and worsened glomerular hypertrophy and fibrosis. Absence of AT2 did not affect development of albuminuria in diabetic mice, but it prevented development of inflammation (monocyte/macrophage infiltration, MCP1 and VCAM1 expression) in kidneys from diabetic mice. AT1 and AT2 receptor were upregulated in diabetic AT2wt mice. Absence of AT2 led to increased AT1 expression in kidneys from control mice to the same level as in diabetic wt-mice, that was not further increased with diabetes.

Conclusions: Our data show that absence of AT2 worsens some aspects of renal injury during diabetes but does not affect albuminuria and paradoxically prevents development of renal inflammation. Activation of AT2 in kidneys from diabetic mice could limit the extent of kidney injury.

Increased Renal Uptake of Exogenous Human Prorenin and Angiotensinogen Enhances the Renal Renin-Angiotensin System in Diabetic Rats Satoshi Kinugasa,[1] Akihiro Tojo,[1] Yasunobu Hirata,[1] Toshiro Fujita,[1] Christopher S. Wilcox.[2] *[1]Department of Internal Medicine, University of Tokyo, Tokyo, Japan; [2]Department of Medicine, Georgetown University Medical Center, Washington DC.*

Background: The renal renin-angiotensin system (RAS) is considered to be regulated independently of systemic RAS. Recently, renal tissue angiotensinogen (AGT) was shown to originate from the liver, uptaken by tubules via megalin. To clarify the mechanism of renal RAS, we examined the renal endocytosis of exogenous human prorenin and AGT, and the effect on blood pressure in diabetic rats.

Methods: Streptozotocin-diabetic rats with microalbuminuria (DM) and controls were injected iv with 20 μg human prorenin, and subsequently human AGT every 5 minutes with stepwise increased doses (0.02–20 μg). Arterial pressure was measured continuously. Kidneys were harvested, renal angiotensin II (Ang II) levels were measured, and both immunohistochemistry (IHC)and western blotting were performed for prorenin, AGT, and prorenin receptor (PRR).

Results: Light and electron microscopic IHC showed that human prorenin and AGT uptake was increased in endocytotic vesicles of podocytes, proximal tubules and cortical collecting ducts (CCD) in DM compared to controls, which was confirmed by western blotting (densitometry of bands for prorenin 116±11 vs. 60±11, $p<0.01$). PRR was expressed in podocytes, macula densa, and CCD, and weakly in proximal tubules. Immunoprecipitation of kidney homogenate with antibody against PRR or megalin showed increased binding of human prorenin with PRR or megalin in DM, implying enhanced prorenin endocytosis via these receptors. Renal Ang II levels did not differ between DM and controls. However, when human prorenin and AGT were selectively injected into the left kidney, renal Ang II increased by 37% compared to the contralateral kidney. Systolic blood pressure (sBP) increased dose-dependently in DM, which did not occur in controls (sBP variation after 20 μg AGT injection 33±5 mmHg vs. 8±2 mmHg, $p<0.01$).

Conclusions: The endocytosis of exogenous human prorenin and AGT was enhanced in podocytes and renal tubules in diabetic rats with microalbuminuria, causing increased blood pressure.

TH-PO460

Detailed Localization of Augmented Angiotensinogen mRNA and Protein in Proximal Tubule Segments of Diabetic Kidneys in Rats and Humans Masumi Kamiyama,[1] Michelle K. Garner,[1] Tadashi Sofue,[2] Takashi Morikawa,[4] Yoshio Konishi,[4] Masahito Imanishi,[4] Akira Nishiyama,[3] Hiroyuki Kobori.[1,3] *[1]Department of Physiology, and Hypertension and Renal Center of Excellence, Tulane University Health Sciences Center; [2]Department of Cardiorenal and Cerebrovascular Medicine, Kagawa University School of Medicine, Japan; [3]Department of Pharmacology, Kagawa University School of Medicine, Japan; [4]Department of Nephrology and Hypertension, Osaka City General Hospital, Japan.*

Background: Increased levels of intrarenal angiotensinogen (AGT) have been shown in diabetic humans, mice, and rats. However, the precise localization of the augmented AGT mRNA and protein in proximal tubule segments of kidneys in diabetes is still unknown.

Methods: To investigate the detailed localization of AGT in 3 proximal tubule segments of the kidneys in diabetes, we used Otsuka Long-Evans Tokushima fatty (OLETF) rats and Long-Evans Tokushima Otsuka (LETO) rats as genetic controls. Kidney tissues were also prepared from OLETF rats that were administered with angiotensin II type 1 receptor blocker, olmesartan or a combination of vasodilator agents (hydralazine, reserpine, and hydrochlorothiazide; HRH). In addition, biopsied samples of human kidney cortex were studied. Using kidney tissues, we examined the co-localization of AGT mRNA or protein with segment-specific protein markers by double staining technique.

Results: Results showed that AGT mRNA and protein were higher at 15 weeks in OLETF rats than in LETO rats. In the 15 week-old rat kidneys, AGT mRNA expression was not recognized much in Segment (S)1 segments of either OLETF or LETO rat kidneys. AGT mRNA expression area in S3 was augmented in the OLETF rats (2.31 ± 0.02-fold; $P = 0.0029$). AGT protein expression areas in S1 and S3 were also increased (8.50 ± 2.78-fold; $P = 0.0476$, and 3.71 ± 0.83-fold; $P = 0.0317$, respectively). Chronic treatment with olmesartan, but not with HRH, ameliorated the augmented AGT expression areas. Human kidney cortical biopsied samples confirmed that AGT protein in S1 was augmented in diabetes.

Conclusions: These data suggest that the augmented AGT mRNA in S3 and AGT protein in S1 and S3 play an important role in the development and the progression of diabetic nephropathy.

Podocyte JAK2 Augments Glomerular Injury Induced by Diabetes and Angiotensin II Hongyu Zhang, Jharna Saha, Kevin B. Atkins, Frank C. Brosius. *Internal Medicine/Nephrology, University of Michigan, Ann Arbor, MI.*

Background: In the best mouse models of diabetic nephropathy generally only the earlier manifestations of the human disease reliably occur. The lack of progression in diabetic mouse models could be due to absent or muted pathogenic responses and/or the presence of distinctive protective mechanisms. JAK2 has been implicated in the pathogenesis of human diabetic nephropathy (DN). In transcriptomic analyses, humans but not mice with type 2 diabetes were found to express enhanced JAK2 levels in podocytes early in DN (Berthier, et. al. Diabetes, 2009;58:469).

Methods: In order to test the role of increased JAK2 expression in podocytes in early DN we knocked in a STOP/FLOX JAK2 construct to the ROSA26 locus in 129S6 mice and generated homozygous podocyte-specific enhanced JAK2 expression with or without Akita type 1 diabetes in mice. To test the role of angiotensin II (Ang II) in this process, 10 wk-old mice received Ang II via osmotic minipump at 1.4 mg/kg/d.

Results: The podocyte JAK2 (pJAK2) mice had a 2-fold increase in total glomerular JAK2 mRNA and protein similar to the increase seen in humans with progressive DN. After 4 wks of Ang II infusion and 8 wks of diabetes, pJAK2 diabetic mice developed a ~35-fold increase in albuminuria compared to non-diabetic Ang II infused mice ($p<0.001$) and 2.5-fold increase compared to diabetic wild-type Ang II mice ($p<0.05$). In addition, mesangial expansion ($p<0.001$) and mesangial sclerosis were greater in the pJAK2 diabetic Ang II mice compared to diabetic wild-type Ang II mice. Podocyte number, though less in non-diabetic pJAK2 vs. non-diabetic wild-type mice ($p=0.01$) was similarly reduced in diabetic pJAK2 and wild-type mice.

Conclusions: These data demonstrate that increased expression of podocyte JAK2 enhances Ang II induced glomerulopathy in diabetic mice.

TH-PO462

Efficacy of Aliskiren, Compared with Angiotensin II Blockade, in Slowing the Progression of Diabetic Nephropathy in db/db Mice: Should the Combination Therapy Be a Focus? Guangyu Zhou, Alfred K. Cheung, Yufeng Huang. *Internal Medicine, University of Utah, Salt Lake City, UT.*

Background: Although Ang II blockade has become standard therapy for diabetic nephropathy, decline in kidney function is common. A feedback increase in renin often accompanies Ang II blockade. We therefore examined whether aliskiren, a direct renin inhibitor, confers better renoprotection than Ang II blockade and whether dual RAS blockers with aliskiren and ACEI or ARB would further slow nephropathy progression vs monotherapy.

Methods: We examined the uninephrectomized db/db mouse, a model of type 2 diabetes where overt nephropathy is evident by 18 wks of age.

Results: Untreated uninephrectomized db/db mice developed progressive albuminuria and mesangial matrix expansion between wks 18 and 22, associated with increased renal expression of TGFß1, PAI-1, fibronectin (FN) and type IV collagen (Col IV). Although body weight and blood glucose were comparable in all groups (n=9 for each group), aliskiren at all doses (3 to 50 mg/kg BW/d) from wk 18 to 22 significantly retarded the increases in albuminuria and glomerular matrix accumulation seen in db/db mice. However, increasing doses of aliskiren resulted in increasing reduction in renal FN and Col IV production, with the 30 mg/kg dose showing maximal reduction by 80% and 72% for FN and Col IV, respectively. Notably, the therapeutic effect of aliskiren given at this dose was similar to that of either enalapril or valsartan given alone at maximally effective doses ($p>0.05$). Combined therapy with aliskiren and enalapril/valsartan further reduced albuminuria but yielded no further reduction in markers of renal fibrosis and podocyte injury. Further, the groups received combined therapy lost 10% to 20% of total mice while all mice without treatment or with monotherapy survived.

Conclusions: These results suggest that aliskiren, enalapril and valsartan are almost identical in slowing the progression of diabetic nephropathy in db/db mice. Dual RAS blockade treatment yields no additional effect in diabetic nephropathy but may increase the mortality. Results from these animal studies do not support the use of combination therapy with aliskiren and ACEI/ARB.

Protective Effects of Enalapril in Uninephrectomized ZSF1 Rats: An Accelerated Model of Diabetic Renal Disease Steven M. Weldon,[1] Xiaomei Zhang,[1] Susan Goldrick,[1] Damian C. Matera,[1] Michael Thibodeau.[2] *[1]CardioMetabolic Disease Research, Boehringer-Ingelheim Pharm. Inc.; [2]Non-Clinical Drug Safety, Boehringer-Ingelheim Pharm. Inc., Ridgefield, CT.*

Background: The ZSF1 rat exhibits many features of human type 2 diabetes including obesity, hyperglycemia, dyslipidemia and hypertension, all of which contribute to progressive nephropathy and symptoms of renal failure within 12-18 months of age.

Methods: We performed uninephrectomy (UNx) in 9 wk old ZSF1 rats to accelerate the development of nephropathy and evaluate the effect of enalapril (ENA,30 mg/kg/d) initiated prophylacticaly (ENA-P) upon UNx or therapeutically (ENA-T) 6 weeks post-UNx. We measured blood pressure, glucose, creatinine, BUN, urine albumin excretion (UAE), tissue biomarkers (mRNA qPCR) and renal pathology at term, 12 weeks post UNx.

Results: Compared to naïve ZSF1 rats, UNx accelerated and exacerbated development of renal damage. Renal pathology in UNx ZSF1 included segmental glomerulosclerosis (GS), mesangial thickening and tubular nephropathy (TN) that included hyaline casts and fibrosis. BP, UAE, proinflammatory and profibrotic biomarker expression were also increased in vehicle treated UNx ZSF1. Treatment with ENA-P or ENA-T attenuated increases in BP and reduced UAE to near normal levels. GS was attenuated by both dosing regimens of enalapril however; the incidence and severity were less following treatment with ENA-T. Tubular nephropathy was attenuated by ENA-P only. Proinflammatory and profibrotic biomarker expression were increased in kidneys of vehicle treated UNx ZSF1 rats. ENA-P attenuated increases in MMP2, PAI-1, FN, TGFb, Osteopontin and MCP-1 expression while ENA-T attenuated only MCP-1.

Conclusions: Although we and others have successfully demonstrated that intact ZSF1 rats provide a robust preclinical model of diabetic complications, the time required for spontaneous disease development can be challenging. These new data show that UNx accelerates and exacerbates renal pathology in these animals over a shorter, 12 week study period. In addition, the accelerated disease process can be effectively attenuated by enalapril even following a therapeutic dosing regimen initiated up to 6 weeks after UNx.

Insulin Inhibits Angiotensinogen Gene Expression and Prevents Hypertension in Diabetic Akita Mouse Kidney via Heterogeneous Nuclear Ribonucleoprotein K Expression Shaaban Abdo,[1] Chao-Sheng Lo,[1] Isabelle Chenier,[1] Shao-Ling Zhang,[1] Janos G. Filep,[2] Julie R. Ingelfinger,[3] John S.D. Chan.[1] *[1]Res. Ctr., CHUM-Hotel Dieu Hospital, Montreal, QC, Canada; [2]Res. Ctr., Maisonneuve-Rosemont Hosp., Montreal, QC, Canada; [3]Pediatr Nephrol Unit, Mass Gen Hosp., Boston, MA.*

Background: Heterogeneous nuclear ribonucleoprotein K (hnRNP K) binds to the insulin-responsive element in the rat angiotensinogen (Agt) gene promoter and inhibits Agt gene transcription in vitro. We investigated whether insulin can stimulate hnRNP K expression in renal proximal tubular cells (RPTCs), inhibit Agt gene expression and prevent systemic hypertension (sHTN) in type 1 diabetic Akita mice.

Methods: Adult male Akita mice (12 weeks of age) were treated ± insulin implants for 4 weeks. Non-Akita mice served as controls. Plasma glucose, systolic blood pressure and albuminuria were monitored weekly. Kidneys were processed for histology. Renal proximal tubular (RPT) Agt and hnRNP K mRNA and protein expression were evaluated by real time- qPCR and Western blotting, respectively. Urinary Agt and angiotensin II (Ang II) levels were quantified by ELISA. We also studied immortalized rat RPTCs (IRPTCs) ± stable transfection with a plasmid, pGL4 containing the rat Agt gene promoter fused with a luciferase reporter *in vitro.*

Results: Akita mice developed sHTN (~136 ± 3.8 mm Hg vs. ~108 ± 0.7 mm Hg in non-Akita mice) and exhibited renal hypertrophy. Insulin treatment normalized plasma glucose levels and sHTN, attenuated renal hypertrophy, decreased urinary albumin/creatinine ratio and urinary Agt and Ang II levels in Akita mice. Furthermore, RPT Agt expression was significantly increased whereas hnRNP K expression was markedly decreased in Akita mice and these changes were normalized by insulin treatment. *In vitro*, high glucose (25 mM D-glucose) stimulated Agt gene promoter activity and inhibited hnRNP K expression in IRPTCs. Insulin reversed these effects, and its action was prevented by transfecting RPTCs with small interfering RNA of hnRNP K.

Conclusions: Our data suggest that insulin prevents sHTN and RPTC injury in diabetes through, at least in part, hnRNP K-mediated suppression of intrarenal Agt gene expression.

Insulin Increases Angiotensin Converting Enzyme 2 Short and Long Term Expression in Podocytes: A Renoprotective Effect on Diabetic Nephropathy? Eva Marquez, Marta Riera, Julio Pascual, Maria Jose Soler. *Kidney Disease Research Group, Nephrology Department, Hospital del Mar- IMIM, Barcelona, Spain.*

Background: Angiotensin-converting enzyme 2(ACE2) cleaves angiotensin II to angiotensin 1-7, a vasodilator and anti-proliferative peptide. ACE2 is present in glomerulus, mainly in the glomerular epithelial cells(podocytes). ACE2 inhibition in experimental diabetic nephropathy increases albuminuria and worsens glomerular injury. The podocyte is a key cell involved in the development of albuminuria since early stages of diabetic nephropathy. Our aim is to study the effect of short and long term insulin incubation on ACE2 expression in podocytes.

Methods: A conditionally immortalized mouse podocyte cell line proliferated in permissive conditions (32ºC γ-interferon). After that, cells were induced to differentiate in non-permissive conditions (37ºC without γ-interferon) for 14 days. Cells were then incubated without (control group; PODc) or with insulin(200nM) for 1 hour and 48 hours (POD1 and POD48; each group n=8). Podocyte were collected for protein studies (Western Blot; expressed as index ACE2/β-actin) and enzymatic activity (expressed as relative fluorescence units (RFU/µg protein/hour). Cells were stained for immunofluorescence using the antibody against ACE2.

Results: ACE2 protein expression, determined by Western Blot, was higher in podocytes after 1 hour of insulin incubation as compared to controls (POD1 1.29±0.4 vs PODc 0.74±0.2, $p<0,05$). After 48 hours of insulin incubation the increase in ACE2 expression was observed as compared to control group (POD48 1.07±0.07 vs PODc 0.8±0.1, $p<0,05$). In the immunofluorescence study, ACE2 expression was increased in insulin treated podocytes. The enzymatic activity was concordant with protein ACE2 expression but without statistical significance (POD1 1.91±0.5 vs PODc 1.65±0.8; POD48 1.75±0.9 vs PODc 1.53±0.4, p=ns).

Conclusions: In the podocyte, a cell that expresses a functional intrinsic RAS, insulin incubation increases ACE2 expression, and this elevation is maintained over the time. This finding may suggest a specific role of insulin in maintaining intraglomerular RAS balance and protect against the progression of diabetic kidney disease.

Apelin Ameliorates Renal Function in Diabetes Robert T. Day, Rita de Cassia Cavaglieri, Denis Feliers. *Medicine/Renal Disease, University of Texas Health Science Center at San Antonio, San Antonio, TX.*

Background: Apelin and its receptor APJ have pleiotropic effects in mice and humans, and play a protective role in cardiovascular diseases. We studied the effect of apelin administration on the progression of kidney disease in mice with established type 1 diabetes.

Methods: Ove26 mice with 10 weeks of type 1 diabetes received daily subcutaneous injections of apelin, for 2 weeks or for 14 weeks. Glycemia, blood pressure, kidney histology and albuminuria were measured. APJ and markers of inflammation were measured by immunohistochemistry and RT-qPCR.

Results: In the kidneys, APJ was localized in the glomeruli and blood vessels. Its expression was reduced in mice with 3 months of diabetes and was upregulated by apelin. Treatment with apelin did not affect glycemia, body weight or blood pressure in diabetic mice at any time point. Apelin significantly reduced albuminuria at 6 months. Kidney and glomerular hypertrophy, as well as renal inflammation (monocyte infiltration, MCP1 and VCAM1 expression) were inhibited by apelin at 3 and 6 months. Finally, expression of the anti-oxidant enzyme catalase was reduced in kidneys from diabetic mice and was upregulated by apelin.

Conclusions: These findings show for the first time that apelin exerts a protective effect on the diabetic kidney. A short treatment was sufficient to reduced kidney and glomerular hypertrophy as well as renal inflammation, but a prolonged treatment was required to improve albuminuria. Apelin may represent a novel tool in the therapeutic arsenal for the treatment of diabetic nephropathy.

Effect of Losartan on Epigenetic Changes in the Renal Glomeruli of Diabetic db/db Mice Marpadga A. Reddy,[1] Sumanth Putta,[1] Linda L. Lanting,[1] Hang Yuan,[1] Mei Wang,[1] Charles E. Alpers,[2] Karol Bomsztyk,[2] Rama Natarajan.[1] *[1]Beckman Research Institute of COH, Duarte, CA; [2]University of Washington, Seattle, WA.*

Background: Diabetic nephropathy (DN) is characterized by glomerular hypertrophy and ECM accumulation leading to proteinuria and renal failure. The renoprotective effects of Angiotensin II type 1 receptor blockers suggest a key role for AT1R signaling in DN. Epigenetic mechanisms such as histone H3 lysine methylation (H3Kme) and acetylation (H3KAc) are involved in gene regulation and metabolic memory implicated in vascular complications. However, the role of HKme/Ac and AT1R signaling in these events is not clear. Here we tested the hypothesis that AT1R blockade with Losartan (Los) can ameliorate DN and reverse epigenetic modifications associated with glomerular gene expression.

Methods: Male type 2 diabetic db/db mice were treated with Los (10 mg/kg/day) or without Los for 10 wks. Age-matched non-diabetic db/+ mice without Los were controls. We then determined DN parameters, glomerular gene expression (RT-PCR/PCR arrays) and histone modifications (Matrix chromatin immunoprecipitation (ChIP) assays) at gene promoters.

Results: There was significantly increased blood pressure, mesangial expansion, proteinuria and glomerular expression of RAGE, MCP-1, PAI-1 and Col1a2 genes in db/db mice relative to db/+. These were reversed by Los. Matrix ChIP assays showed decreases in repressive marks (H3K27me3) and increases in activation marks (H3K9/14Ac, H3K4me1, H3K4me2, H3K36me3) at the RAGE and PAI-1 promoters in db/db mice. PCR arrays revealed alterations in the expression of several histone modification enzymes in db/db mice. Los reversed some but not all changes in chromatin marks and expression of key histone modification enzymes.

Conclusions: These results demonstrate the involvement of epigenetic mechanisms in the expression of key glomerular genes associated with DN that may be mediated in part by AT1R. Thus, epigenetic therapies in conjunction with ARBs and other drugs may be more effective in DN treatment.

Effect of Losartan on the Glomerular Protein and miRNA Expression Profile of Type 2 Diabetic KKAy Mice Qiuling Fan. *Department of Nephrology, First Hospital, China Medical University.*

Background: To investigate the pathogenesis of diabetic nephropathy and to search novel therapeutic targets, the glomerular protein and miRNA expression profile of KKAy mice treated by losartan was analyzed.

Methods: The 8-week-old KKAy mice were divided into the losartan treatment group and the non-treatment group, and C57BL/6 mice were used as the control group. 12 weeks after the treatment, glomeruli were isolated by abdominal perfusion with magnetic beads.The glomerular protein expression profiles were investigated using 2D-DIGE and MALDI-TOF mass spectrometry. Western blot analysis was used to confirm the results of proteomics. miRNA expression profiles were analyzed using miRNA arrays. Real-time PCR was used to confirm the results.

Results: Losartan treatment improved albuminuria and renal pathological lesion of KKAy mice. 6 proteins were found to be differentially expressed between the KKAy non-treatment mice and C57BL/6 mice glomeruli, and their differential expression were suppressed by losartan treatment, including mitochondrial ATP synthase subunit d, GRP75 and selenium-binding protein 1 et al. The expression of 10 miRNAs was higher and the expression of 12 miRNAs was lower in the glomeruli of the KKAy non-treated mice than that of the CL57BL/6 mice. The expression of 4 miRNAs was down-regulated in the glomeruli of the KKAy losartan-treated mice compared with that of the non-treated mice. Among them, the expression of miRNA-503 and miRNA-181d was higher in the glomeruli of the KKAy non-treated mice and was inhibited by losartan treatment.

Conclusions: The over-expression of miR-503 and miR-181d in KKAy mice glomeruli may be responsible for the pathogenesis of DN by regulating the expression of the target genes, such as heat shock protein 75, GRP75 and GRP78 et al.

Renoprotective Effects of Dipeptidyl Peptidase IV Inhibition in Diabetic Nephropathy Yuliya Sharkovska,[1] Thomas Klein,[3] Sebastian C. Bachmann,[1] Berthold Hocher.[2] *[1]Charite Universitätsmedizin Berlin, Institute of Vegetative Anatomy, Berlin, Germany; [2]University of Potsdam, Institute for Nutritional Science, Potsdam, Germany; [3]Boehringer Ingelheim, Dept. CardioMetabolic Diseases Res. Ger., Biberach, Germany.*

Background: Inhibition of dipeptidyl peptidase IV (DPPIV) stabilizes glucagon-like-peptide-1 (GLP-1) levels and is considered as a new approach in the treatment of type 2 diabetes. We examined the renoprotective effects of linagliptin in diabetic nephropathy (DN) using *db/db* mice. Results were compared with the known, beneficial effects of RAS blockade by enalapril.

Methods: Biochemical and pathological analyses were performed in 10 week-old male diabetic *db/db* mice treated for 3 months with either vehicle (n=10), 3 mg linagliptin/kg/day (n=8), or 20 mg enalapril/kg/day (n=10). Heterozygous *db/+* mice treated with vehicle served as controls (n=8).

Results: Diabetic *db/db* mice showed elevatedfasting levels of glucose and insulin. Like enalapril, linagliptin did not affect plasma glucose levels. The urinary *albumin-to-creatinine ratio* was *4-fold elevated* in vehicle-treated *db/db* compared to controls ($p < 0.001$). Linagliptin decreased urinary *albumin-to-creatinine ratio in db/db mice at 8 weeks* (-35%; $p < .05$). Glomerular and tubulointerstitial injury was decreased by linagliptin, and to a lesser extent also by enalapril treatment in sirius red, PAS, collagen I, and a-SMA staining.The abundance of podocalyxin, a marker for glomerular damage, was decreased in db/db mice compared to controls (-40%, $P < .01$), whereas linagliptin and enalapril normalized its expression. DPPIV and GLP-1 receptor were colocalized in podozytes. At steady state, only GLP-1 receptor was lowered in db/db mice (-30%, $p < .05$). Linagliptin normalized its expression.

Conclusions: This study suggests that the DPPIV inhibitor linagliptin has beneficial effects on DN-associated kidney damage without affecting blood glucose levels. The renoprotective action of linagliptin may be due to the attenuation of podocyte injury and inhibition of myofibroblast transformation.

TH-PO470

Blockade of KCa3.1 Attenuated Diabetic Nephropathy Chunling Huang, Sylvie Shen, Xinming Chen, Carol A. Pollock. *Renal Medicine, Kolling Institute of Medical Research, University of Sydney, Sydney, New South Wales, Australia.*

Background: Transforming growth factor-β1 (TGF-β1) plays a central role in the development of renal fibrosis. KCa3.1, a potassium channel protein, is associated with vascular inflammation, atherogenesis, and proliferation of endothelial cells, macrophages, and fibroblasts. Blockade of KCa3.1 has been shown to ameliorate renal fibrosis in a mice model of unilateral ureteric obstruction. However, the role of KCa3.1 in the development of diabetic nephropathy associated with an elevation in TGF-β1 is unknown.

Methods: Primary interstitial fibroblasts isolated from human kidneys were incubated with TGF-β1 (2ng/ml) +/- the selective inhibitor of KCa3.1, TRAM-34 (2uM/L), for 48 hours. Markers of fibroblast activation (α-smooth muscle actin (α-SMA), fibroblast specific protein 1(FSP1), vimentin), inflammation (monocyte chemoattractant protein-1(MCP-1)), and fibrotic responses (CTGF (connective tissue growth factor), plasmin activator inhibitor-1(PAI-1), collagen 1 and 4, and fibronectin) were measured by qRT-PCR, western blot or ELISA. Downstream TGF-β1 signalling molecules Smad2/3, ERK1/2, P38, and JNK were measured by western blot. The activities of MMP2/9 were examined using gelatine zymography. ENos-/- mice with streptozotocin-induced diabetes were treated with TRAM-34 for 24 weeks and the expression of KCa3.1, α-SMA and collagen 1 in kidneys were examined using real-time qRT-PCR and immunohistochemistry.

Results: TRAM-34 reversed TGF-β1-induced upregulation of α-SMA, FSP1, vimentin, MCP-1, CTGF, collagen 1, collagen 4, fibronectin, PAI-1, and MMP2/9 activity ($P<0.01$) in renal interstitial fibroblasts. TRAM34 also reduced TGF-β1-induced phosphorylation of Smad2/3 and ERK1/2 but did not affect p38 and JNK MAPK pathway. In animal studies, TRAM-34 suppressed KCa3.1, α-SMA and collagen 1 expression in diabetic kidneys compared to vehicle control at both mRNA and protein levels ($P<0.05$).

Conclusions: KCa3.1 mediated TGF-β1-induced activation of renal interstitial fibroblasts and renal fibrogenesis through Smad2/3 and ERK1/2 but independent of p38 and JNK MAPK. Blockade of KCa3.1 could be an effective strategy for the treatment of diabetic nephropathy.

Acute Hemodynamic and Renal Effects of a Glucagon-Like Peptide 1 Analog in Rats Xiaoyan Zhou, Chin-hu Huang, Julie Lao, Alessandro Pocai, Olga Price, Gail M. Forrest, Michael J. Forrest, Kathleen A. Sullivan. *Merck Research Laboratories, Merck & Company, Rahway, NJ.*

Background: Liraglutide is a glucagon-like peptide 1 (GLP-1) receptor agonist approved for the treatment of type II diabetes. GLP-1 receptor agonism lowers blood glucose mostly by enhancing the secretion of insulin in a glucose dependent manner and by lowering plasma glucagon. GLP-1 analogs have demonstrated beneficial cardiovascular effects both pre-clinically and clinically. However, there is limited information on the renal effects of GLP-1 analogs. Therefore, we investigated the acute hemodynamic and renal effects of liraglutide.

Methods: Experiments were performed on anesthetized male Sprague-Dawley rats. Three ascending doses of liraglutide (30, 100, and 300 μg/kg/h) were administered by intravenous infusion. Blood pressure (BP) was recorded from an indwelling catheter. Glomerular filtration rate (GFR) and renal blood flow (RBF) were assessed by Inutest and para aminohippurate clearance, respectively. Renal excretory function was examined by recording urine volume and urinary electrolytes excretion.

Results: Heart rate was significantly increased by liraglutide (100 and 300 μg/kg/h), whereas BP was not affected at any tested dose. Liraglutide (100 and 300 μg/kg/h) also evoked significant diuresis (6.7 and 7.0 fold), natriuresis (38.3 and 56.4 fold), chloruresis (20.3 and 22.9 fold), kaliuresis (4.7 and 3.4 fold), and decreased urinary H^+ excretion. As a consequence of effects on renal excretory function, liraglutide caused hypokalemia, hypochloremia, and volume contraction. Moreover, Liraglutide (300 μg/kg/h) increased GFR (1.5 fold), but had no significant effect on RBF.

Conclusions: Liraglutide is a potent natriuretic/diuretic agent with a favorable effect on GFR. Our findings are consistent with previous reports of a natriuretic/diuretic effect of GLP-1 in rats and humans. The data support the hypothesis that GLP-1 receptor agonism may have a direct and/or indirect effect on the renal handling of sodium and water which may ultimately contribute to favorable cardiovascular effects.

TH-PO472

Renal Epigenetic Changes in Mouse and Rat Models of Type 1 Diabetes Karol Bomsztyk,[1] Oleg N. Denisenko,[1] Daniel S. Mar,[1] Terry T. Oyama,[2] Bei Xu,[2] Radko Komers.[2] *[1]UW Medicine SLU, University of Washington, Seattle, WA; [2]Division of Nephrology, Oregon Health and Science University, Portland, OR.*

Background: Epigenetic processes are likely to play a role in kidney disease including diabetic nephropathy (DN) via altered expression of genes involved in the pathophysiology of these disorders.We hypothesized that changes in expression of selected genes in DN are associated with epigenetic modifications mediated by alterations in histone modifying enzymes.

Methods: We used RT-PCR, immunoblots of histone modifying enzymes, and Matrix chromatin immunoprecipitations to examine renal gene expression, RNA polymerase II (Pol II) levels and epigenetic marks at genes in the mouse (OVE26) and streptozotocin-induced rat models of type 1 diabetes (T1D) that share DN features with human disease including common sets of aberrantly expressed genes. We focused on genes implicated in DN.

Results: Diabetes-induced expression of several renal transcripts in both the mouse and the rat models of T1D nephropathy were seen including Cox2, Fsp-1, vimentin (Vim) and laminin gamma 1 (Lamc1) genes. While the differences in mRNA levels between control and diabetic mice for some genes persisted (Cox2,Fsp-1), for others the differences seen at an earlier time points where not observed later (Vim, Lamc1). In the rat, where the DN is less severe, the mRNA differences between diabetic and normal animals were smaller and less sustained. In both the diabetic mice and rats elevated transcript levels were associated with increased Pol II suggesting that the mRNA alterations are transcriptionally mediated. These changes were associated with decreased levels of the histone H3K27m3 repressive epigenetic mark suggesting one cause for the increased transcription. Immunoblots showed higher levels of the H3K27m2/3 demethylase, Kdm6a, in kidneys of the diabetic OVE26 mice compared to controls. In contrast, Ezh2, a H3K27-specific methyltransferase, remained unchanged.

Conclusions: Increased expression of Kdm6a could be one of the primarily changes induced by diabetes contributing to the aberrant mRNA expression in DN. Kdm6a and other chromatin enzymes might be targets to explore biomarkers and DN epigenetic therapies.

TH-PO473

Increased Kinase Recruitment to Epigenetically Altered Renal Profibrotic Gene in a Mouse Model of Type 2 Diabetes Karol Bomsztyk, Steve Flanagin, Daniel S. Mar, Oleg N. Denisenko, Kelly L. Hudkins, Tomasz A. Wietecha, Charles E. Alpers. *UW Medicine, University of Washington, Seattle, WA.*

Background: The BTBR mouse strain with the ob/ob leptin-deficiency mutation develops severe type 2 diabetes (T2D) and diabetic nephropathy (DN). Connective tissue growth factor (CTGF) is key mediator of fibrogenesis in DN. We used this T2D model to test a hypothesis that increased expression of *CTGF* in DN is associated with aberrant epigenetic changes at this gene including direct recruitment of kinases to this locus.

Methods: RT-PCR and multiplex Matrix chromatin immunoprecipitations were used to compare renal gene expression, epigenetic marks, RNA polymerase II (Pol II) and levels of several kinases at the *CTGF* and other loci in the tubulointerstitium of BTBR wild-type (wt) and BTBR ob/ob.

Results: Diabetes-enhanced expression of *CTGF* mRNA in BTBR ob/ob kidneys (5.5±1.7-fold, $p<0.05$) was associated with increased Pol II levels at the gene (1.5±0.1-fold, $p<0.01$) suggesting that the *CTGF* mRNA alteration is transcriptionally mediated. Upregulation of *CTGF* in BTBR ob/ob mice was associated with increased levels of histone H3K9/14Ac activating epigenetic mark (1.5±0.2-fold, $p<0.05$) while H3 levels were not different (1.1±0.2-fold, n.s.) at this locus between the ob/ob and wt mouse strains. These results suggest that histone modifications contribute to increased transcription of *CTGF* in the tubulointerstitium of BTBR ob/ob mice. There was also higher density of the kinase Fyn (1.5±0.2-fold, $p<0.05$) along with increased levels of active B-Raf (1.4±0.1-fold, $p<0.01$) and Erk1/2 (1.6±0.2-fold, $p<0.05$) kinases at this locus suggesting that kinase recruitment to chromatin is directly involved in abnormal expression of *CTGF* in BTBR ob/ob mice.

Conclusions: Detailed knowledge of epigenetic and transcription changes in relation to gene-bound kinases at key fibrogenic loci provides comprehensive way to explore genomic processes that contribute to fibrosis in DN. The translational application of these findings is that kinases and other epigenetic enzymes tethered to fibrogenic genes provide identifiable targets for potential drug interventions to control expression of these genes and renal fibrosis.

Genome-Wide Cytosine Methylation Differences in the Tubule of Human Diabetic Kidney Sang Youb Han,[1,2] Ae Seo Deok Park,[1] James M. Pullman,[3] Katalin Susztak.[1] *[1]Renal Electrolyte and Hypertension Division, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; [2]Division of Nephrology, College of Medicine Inje University, GoYang, Republic of Korea; [3]Dept. of Pathology, Albert Einstein College of Medicine, Bronx, NY.*

Background: Diabetic kidney disease (DKD) remains one of the most devastating complications of diabetes. Clinical observational studies indicate the role of fetal and adult programming/long-term memory effect on disease development. In vitro studies suggest that epigenetic differences might mediate such long term changes. Here we analyzed differences of DNA cytosine methylation in tubule of patients with DKD (21), hypertension(23), diabetes(19) and healthy control (22).

Methods: Genomic DNA from 85 manually microdissected tubule tissue was used for hybridization on Infinium Human methylation 450K BeadChip. Corresponding gene expression was analyzed using Affymetrix U133 expression arrays.

Results: DKD group showed significantly lower eGFR (31.18±18.46 ml/min) compared to healthy controls (81.54±16.06) and samples with hypertension (76.62±14.94) or diabetes (73.55±12.10) and increased proteinuria. Histological analysis confirmed changes consistent with DKD.

The statistical analysis identified 4162 differential methylated regions (DMR), 2896 (70%) of them showed loss of methylation in DKD and 1266 (30%) loci were hypermethylated. We rarely observed differential methylation of CpG islands. Most differences localized to >2000 bp away from CpG islands. Most DMR localized to Refseq gene annotated gene body regions and we rarely observed differential methylation of promoters. Gene ontology analysis indicated the concordant differences both in gene expression and DNA methylation levels in genes related immune pathways, cell adhesion and development, genes and pathways that we and others have shown to play role in DKD development. Interestingly while diabetic samples in absence of renal disease showed significant gene expression changes, these samples showed little if any consistent differences in their cytosine methylation patterns.

Conclusions: In summary, human DKD is associated with changes in cellular epigenome and these changes may contribute to phenotype development.

TH-PO475

miRNA Microarray Expression Profiling in Human Diabetic Nephropathy Francesca Conserva,[1] Paola Pontrelli,[1] Matteo Accetturo,[1] Giorgia Cordisco,[1] Anna Maria Di Palma,[1] Giuseppe Grandaliano,[2] Loreto Gesualdo.[1] *[1]DETO-Nephrology Unit, Univ. of Bari, Italy; [2]Dept. of Medical and Surgical Sciences, Univ. of Foggia, Italy.*

Background: Diabetic Nephropathy (DN) is the primary cause of End Stage Renal Disease. Up to date there is no cure for DN and it is still unclear what determines its evolution in some individuals but not in others. Aim of our study was to identify a dataset of differentially expressed miRNAs in human biopsies of patients with type 2 DN.

Methods: Agilent miRNA arrays (8x15K slides) were used to characterize miRNA expression in Formalin-Fixed Paraffin-Embedded human kidney biopsies. Three sample groups were included: 8 DN patients with increased proteinuria and decreased glomerular filtration rate; 4 stage 1 membranous nephropathy samples, a condition also associated to glomerular basement membrane thickening and proteinuria not induced by hyperglycemia; 4 control kidney tissues from patients with no signs of nephropathy. Differentially expressed miRNAs in DN tissues *vs* controls, as well as membranous nephropathy tissues *vs* controls, were identified by unpaired t test and Benjamini-Hochberg multiple testing correction ($p\leq.05$; $FC\geq1.5$). Ingenuity Pathway Analysis was then employed to define the potentially deregulated pathways.

Results: We identified 76 differentially expressed miRNAs, 42 upregulated and 34 downregulated in DN tissues when compared to normal kidney, of which, 23 specific for DN (10 upregulated and 13 downregulated) and 54 in common with the membranous nephropathy group. The investigation of all miRNA potential targets in DN predicted a statistically significant upregulation of EphrinB ($p=3.16*10^{-5}$), Axon guidance ($p=3.12*10^{-4}$) and Notch ($p=1.48*10^{-3}$) pathways. *In silico* analysis on miRNA experimentally validated targets only, revealed vascular endothelial growth factor (VEGFA) and phosphatase and tensin homolog (PTEN) as the molecules targeted by a greater number of miRNAs in our DN tissues.

Conclusions: Our study profiles miRNA expression in DN human tissues and represents the first miRNA microarray benchmark study aimed to identify novel mechanisms of post-transcriptional modifications involved in type 2 DN pathogenesis and novel potential biomarkers.

Funding: Government Support - Non-U.S.

TH-PO476

Regulation of Ubiquitination in Diabetic Nephropathy: The Role of microRNAs Paola Pontrelli,[1] Francesca Conserva,[1] Matteo Accetturo,[1] Massimo Papale,[1] Giorgia Cordisco,[1] Anna Maria Di Palma,[1] Giuseppe Grandaliano,[2] Loreto Gesualdo.[1] *[1]DETO-Nephrology Unit, Univ. of Bari, Italy; [2]Dept. of Medical and Surgical Sciences, Univ. of Foggia, Italy.*

Background: Diabetic Nephropathy (DN) results from the unbalance of several pathways and ubiquitin has emerged as a novel key-player in its onset. Along with classical lys48, lys63 ubiquitination affects protein localization and signaling. Aim of our study was to explore DN, joining information from different high-throughput technologies, in order to identify new specific genes and microRNAs and clarify their role in DN onset and progression.

Methods: Agilent miRNA arrays (8x15K) were performed on formalin-fixed paraffin-embedded biopsies of 8 patients with DN and 4 healthy subjects. Gene expression arrays (Affymetrix HG-U133A) were obtained from human proximal tubular cells (HK2) grown in high glucose (HG) [30 mM], compared to normal glucose (NG) [5.5 mM] and mannitol [30 mM] as controls. Data were analyzed with GeneSpring GX12.0 (p-value<.05; FC≥1.5). qPCR, immunoblotting and immunohistochemistry were used for validation.

Results: miRNA arrays on DN patients showed that 42 out of 76 differentially expressed miRNAs belonged to the ubiquitination cascade, of which, 19 out of 34 downregulated miRNAs target the E2 class of the ubiquitinating enzymes. The second most down-regulated specifically targets UBE2V1 which mediates lys63-linked ubiquitin chain formation (26.1 fold). Microarray gene expression data confirmed an increase of UBE2V1 in HK2 under HG, validated by qPCR after 1h (1.51 fold HG vs NG). UBE2V1 protein expression after 24h (2.6 fold) and lys63 ubiquitinated proteins after 48h (2.05 fold) were detected by western blotting. Higher UBE2V1 tubular expression was observed in vivo (p=.004) along with lys63 ubiquitinated proteins (p=.008) in patients with DN vs normal controls. UBE2V1 expression and lys63 polyubiquitination are increased in DN and miRNAs could play a prominent role in this process.

Conclusions: The validation of miRNA data and the identification of ubiquitinated target proteins will provide a molecular signature of DN and lead to the identification of possible therapeutic targets and/or predictive biomarkers of disease.

Funding: Government Support - Non-U.S.

TH-PO477

Involvement of Inflammation-Related microRNAs: miR-155 and miR-146-a in Diabetic Nephropathy: Implication in Inflammation-Mediated Glomerular Endothelial Injury Ping Fu, Fang Liu. *Division of Nephrology, West China Hospital of Sichuan University, Chengdu, Sichuan Province, China.*

Background: The role of microRNAs (miRs) in diabetic nephropathy is unknown. Here, we sought to identify the repertoire of miRs in diabetic patients with diabetic nephropathy and their potential regulatory role on inflammation-mediated glomerular endothelial injury.

Methods: Microarray analysis was performed to examine the expression profile of miRs in kidney tissues from renal biopsies (7 from diabetic nephropathy patients and 3 from normal control). In situ hybridization was used to localize miR-155 and miR-146a. Meanwhile, the expressions of miR-155 and miR-146a were detected in STZ-induced type 1 diabetic nephropathy by real time PCR. Human renal glomerular endothelial cells (HRGEC) were cultured under high glucose, transfected with miR-155 and miR-146a mimics and inhibitors and PDTC (NF-κB inhibitor). Inflammatory cytokines (TNF-α, IL-1β, ICAM-1, MCP-1) were examined by western blot and real-time PCR. NF-κB activity was examined by EMSA.

Results: Ex vivo study showed there were 71 miRs with different expressions, 32 of which were up-regulated and 39 of which were down-regulated. Expressions of miR-155 and miR-146a of diabetic nephropathy were up-regulated by more than five-fold in kudney tissue of diabetic nephropathy patients compared with normal control. Furthermore, the expressions of the two miRs were not correlated with eGFR and urinary protein excretion. In situ hybradyzation showed up-regulated miR-155 and miR-146a mainly expressed in glomerular mesangial area and endothelial cells. In STZ-induced type 1 diabetic nephropathy, miR-155 and miR-146a were up-regulated in early stage. In vitro, high glucose induced the expressions of miR-155 and miR-146a in HRGECs and overexpressions of miR-155 and miR-146a increased the expressions of inflammatory cytokines via NF-κB pathway.

Conclusions: Increased expressions of miR-155 and miR-146a associated with increased expressions of inflammatory factors in diabetic nephropathy, which contribute to inflammation-mediated glomerular endothelial injury via NF-κB-dependent pathway.

FOG2, a Target of microRNA-200b/c, Controls Glomerular Mesangial Hypertrophy by Regulating TGF-β-Induced Akt Kinase Activation in Diabetic Nephropathy Jung Tak Park, Mitsuo Kato, Linda L. Lanting, Sumanth Putta, Rama Natarajan. *Department of Diabetes, Beckman Research Institute of City of Hope, Duarte, CA.*

Background: Diabetic nephropathy (DN) is characterized by glomerular hypertrophy. TGF-β-activated Akt kinase mediates cellular hypertrophy under diabetic conditions. Recently, miR-200 and its target FOG2 were reported to regulate the activity of PI3K (Akt activator) to modulate insulin signaling and body size in flies. However, the role of FOG2 in Akt activation by TGF-β in mammalian kidneys is not clear. We hypothesized that TGF-β activates Akt in glomerular mesangial cells (MC) by inducing miR-200b/c which target FOG2, a PI3K inhibitor, and this contributes to MC hypertrophy.

Methods: mRNA and protein levels were examined by RT-qPCR or Western blotting in TGF-β-treated mouse MC (MMC) with or without miR-200b/c mimic, inhibitor, or FOG2 siRNA transfection. Glomerular FOG2 was detected by immunostaining.

Results: FOG2 protein and mRNA expression were reduced while miR-200b/c levels were increased in diabetic mouse glomeruli compared to non-diabetic controls. In addition, FOG2 protein and mRNA levels were down-regulated while miR-200b/c were reciprocally up-regulated in TGF-β-treated MMC. Down-regulation of FOG2 in TGF-β treated MMC was accompanied by increased Akt activation, while FOG2 knockdown by siRNAs in MMC also activated Akt, suggesting a causal relationship between FOG2 down-regulation and Akt activation. Transfection of MMC with miR-200b/c mimics decreased FOG2 expression and increased Akt phosphorylation. Conversely, when miR-200b/c inhibitor oligos were transfected into MMC, TGF-β induced down-regulation in FOG2 expression and increases in Akt activation were both reversed. Furthermore, transfection of MMC with miR-200b/c mimics increased the protein content/cell ratio, while conversely, miR-200b/c inhibitors abrogated the TGF-β-induced increases in protein content/cell. Moreover, FOG2 knockdown with siRNAs increased protein content/cell ratio, suggesting cellular hypertrophy.

Conclusions: These results suggest a new mechanism of Akt activation by TGF-β through FOG2 down regulation by miR-200b/c which can lead to MC hypertrophy related to DN.

microRNA-26a Is Upregulated in Glomeruli of Diabetic Mice and Attenuates TGFβ1-Induced Extracellular Matrix Expression in Podocytes by Inhibiting Both CTGF and SMAD2 Kenichi Koga, Masashi Mukoyama, Hideki Yokoi, Kiyoshi Mori, Masato Kasahara, Takashige Kuwabara, Hirotaka Imamaki, Tomoko Kawanishi, Akira Ishii, Keita P. Mori, Yukiko Kato, Shoko Ohno, Naohiro Toda, Moin Saleem, Akira Sugawara, Kazuwa Nakao. *Department of Medicine and Clinical Science, Kyoto University Graduate School of Medicine, Kyoto, Japan.*

Background: MicroRNAs (miRNAs) are small non-coding RNAs which negatively regulate target genes. Recently, we showed miR-26a targeting connective tissue growth factor (CTGF) is upregulated in glomeruli of *db/db* mice and attenuates the expression of col1a1 and col4a3 in TGFβ1-stimulated podocytes.

Methods: We examined miR-26a expression in glomeruli of streptozotocin (STZ)-induced diabetic mice by TaqMan PCR and *in situ* hybridization (ISH). We transfected its mimic into podocytes by nucleofection and examined target gene expressions by Western blot and CTGF 3'UTR luciferase reporter assay. In addition, we analyzed smad activity in TGFβ1-treated podocytes using luciferase reporter plasmid containing smad binding element (SBE).

Results: miR-26a was upregulated in glomeruli of STZ mice by 2.7-fold compared with control mice by TaqMan PCR ($p < 0.05$) and was mainly localized in glomeruli of STZ mice by ISH. Transfection of miR-26a mimic into podocytes significantly decreased CTGF protein level by 49% and reduced CTGF 3'UTR luciferase activity by 30%. We also showed that miR-26a mimic inhibited SBE luciferase activity by 91% ($p < 0.001$), indicating that miR-26a inhibits TGF-β/SMAD signaling. We analyzed other target genes of miR-26a involved in TGF-β/SMAD signaling and identified SMAD2 as a target gene of miR-26a by showing that miR-26a mimic significantly reduced SMAD2 protein level by 39%.

Conclusions: These results indicate that miR-26a attenuates TGF-β/SMAD signaling and TGFβ1-induced fibrosis in podocytes by downregulating CTGF and SMAD2. We hypothesize that increased expression of miR-26a prevents the progression of DN via inhibiting TGF-β/SMAD signaling. miR-26a could be a therapeutic agent for DN.

Inhibitory Effect of the Benfotiamine on Hyperglycemia-Induced Inflammatory and Fibrogenic Signals in DM Nephropathy Eun Jin Cho,[1] Kyung Don Ju,[2] Eun Kyoung Shin,[2] Dong Ki Kim,[1] Kwon Wook Joo,[1] Yon Su Kim,[1] Curie Ahn,[1] Jin Suk Han,[1] Kook-Hwan Oh.[1] *[1]Department of Internal Medicine, Seoul National University Hospital, Seoul, Korea; [2]Clinical Research Institute, Seoul National University Hospital, Seoul, Korea.*

Background: Benfotiamine is an anti-oxidant and anti-inflammatory substance. We aimed at verifying the protective effect of benfotiamine against the development and progression of diabetic nephropathy in an in-vivo and in-vitro model.

Methods: Diabetic rats were prepared by injecting streptozotocin (STZ, 65mg/kg). Those that developed diabetes after 72 h were treated with benfotiamine (70mg/kg). Diabetic rats without benfotiamine treatment and nondiabetic rats were used for control. Rat mesangial cells were treated in high glucose (HG, 50mM) and normal glucose (NG, 5mM) conditions.

Results: Benfotiamine-treated diabetic rats exhibited decreased albuminuria, and NADPH-dependent ROS generation. Immunohistochemistry showed reduced type IV collagen and fibronectin deposition in the glomeruli compared with nontreated diabetic rat. Parallel changes were shown in the tissue mRNA and protein expression level of MCP-1, TGF-β1, fibronectin and type IV collagen in the kidney. These findings suggest that benfotiamine protects against kidney injury via transketolase upregulation.

Conclusions: Benfotiamine exhibited a renoprotective effect in the progression of experimental diabetic nephropathy. Future research is warranted to investigate the protective mechanism of benfotiamine more specifically and to help set the basis for clinical use of this substance in the prevention of diabetic nephropathy.

TH-PO481

Collagen XVIII and Endostatin Have Differential Roles in Early Stages of Diabetic Nephropathy Yuki Hamano,[1] Yoshihiko Ueda,[2] Makoto Ogawa.[1] *[1]Nephrology, Chiba University Hospital, Chiba, Japan; [2]Pathology, Dokkyo Medical University Koshigaya Hospital, Koshigaya, Japan.*

Background: Collagen XVIII is distributed throughout glomerular basement membrane, mesangial matrix and Bowman's capsule. Proteolytic cleavage within its C-terminal domain releases the fragment endostatin, which has antiangiogenic properties. Diabetic nephropathy is characterized by thickening of the glomerular basement membrane and excessive extracellular matrix accumulation in the mesangium. Streptozotocin (STZ) has been commonly used to induce hyperglycemic diabetes. Because its renal toxicity accompanies extracellular matrix accumulation and vascular injury, we investigated the role of collagen XVIII and endostatin in this disorder.

Methods: Diabetic nephropathy was induced in collagen XVIII/endostatin-null (KO) and wild-type (WT) mice by injection of STZ. Animals injected with citrate buffer only served as controls. At 14 weeks, blood and urine samples were collected and mice were sacrificed to obtain tissues. The resulting matrix accumulation and neovascularization were compared.

Results: No differences in the degree of hyperglycemia and blood pressure were seen between diabetic KO and WT mice. In diabetic KO mice compared with diabetic WT mice, the albuminuria, blood urea nitrogen and serum creatinine levels, mean glomerular volume and mesangial matrix accumulation were increased significantly, whereas the thickening of glomerular basement membrane was completely blocked. Lack of collagen XVIII/endostatin led to an elevation of the renal cortical expression of MCP-1, CTGF, SDF-1 and MMP-2 but not of VEGF-A, TGF-β1 and TSP-1. Levels of nephrin, CD2AP and podocin were not reduced in diabetic KO mice compared with diabetic WT mice. The microvascular density and influx of macrophages were increased in the glomeruli of diabetic KO mice compared with diabetic WT mice. The endothelial progenitor cells were detected in the peripheral blood and bone marrow of diabetic KO mice more than those of diabetic WT mice.

Conclusions: Collagen XVIII and endostatin play important roles in preserving the integrity of extracellular matrices and capillary vessels in the kidney and have a protective effect against diabetic kidney disease.

Oral Treatment with a Novel First-in-Class Anti-Fibrotic Compound PBI-4050 Reduces Kidney Hyperfiltration, Proteinuria and Hepatic Steatosis in the Diabetic db/db Mouse Model Lyne Gagnon, Lilianne Geerts, André Doucet, François Sarra-Bournet, Martin Leduc, Shaun Abbott, Jean-Simon Duceppe, Boulos Zacharie, Christopher Penney, Pierre Laurin, Brigitte Grouix. *ProMetic BioSciences Inc., Laval, QC, Canada.*

Background: Diabetic nephropathy is increasing in incidence and is now the number one cause of end-stage renal disease**.** Obese and diabetic db/db mice exhibit a consistent and robust increase in albuminuria and mesangial matrix expansion, and develop hepatic steatosis. PBI-4050, a potential treatment for fibrotic diseases, possesses a pleiotropic mechanism of action with anti-inflammatory, anti-oxidant and anti-fibrotic properties.

Methods: The aim of this study was to investigate the effect of PBI-4050 on uni-nephrectomized diabetic (db/db) mice. Total nephrectomy of the right kidney was performed on day 0 and animals were treated with vehicle or PBI-4050 (100 mg/kg, oral once a day) from day 1 through 130. Kidney function (urinary creatinine, GFR, albuminuria and proteinuria), kidney mesangium lesions and hepatic steatosis were examined.

Results: Urinary creatinine was significantly reduced in uni-nephrectomized db/db mice compared to background C57BL/6 mice, but returned to the normal level in PBI-4050-treated db/db mice. Albuminuria was also increased by 1.5 to 2 fold in uni-nephrectomized mice (C57BL/6 and db/db) compared to sham C57BL/6 mice. Treatment of db/db mice with PBI-4050 reduced both albuminuria and proteinuria to the sham C57BL/6 mice level. Kidney GFR was significantly reduced in uni-nephrectomized C57BL/6 mice. Uni-nephrectomized db/db mice demonstrated a significant increase in GFR (hyperfiltration), which was significantly reduced by treatment with PBI-4050. Db/db non-treated mice had larger glomeruli with increased mesangial matrix, as shown by periodic acid-Schiff (PAS) staining. Mesangium lesions score were also reduced in db/db mice treated with PBI-4050. Hepatic steatosis, observed in db/db mice, was significantly (50%) reduced with PBI-4050-treatment.

Conclusions: These results suggest that PBI-4050 offers the potential as a novel therapy for the reduction of diabetic kidney disease.

Endogenous Anti-Fibrotic Peptide N-Acetyl-Seryl-Aspartyl-Lysyl-Proline Inhibits Endothelial-Mesenchymal Transition and Diabetes-Associated Kidney Fibrosis Takako Nagai, Keizo Kanasaki, Daisuke Koya. *Diabetology and Endocrinology, Kanazawa Medical University, Kahoku, Ishikawa, Japan.*

Background: Fibrosis is critical determinant of the progression in kidney diseases. Endothelial to mesenchymal transition (EndMT) has emerged as one of the important source of kidney fibroblasts. Angiotensin-converting enzyme (ACE) inhibition increases plasma concentration of endogenous anti-fibrotic peptide N-acetyl-seryl-aspartyl-lysyl-proline (AcSDKP).

Methods: Human umbilical vein endothelial cells (HUVEC) and human microvascular endothelial cells (HMVEC) were stimulated with transforming growth factor (TGF)-β2 or combination of TGF-β2, interleukin (IL)-1β and tumor necrosis factor (TNF)-α, with or without AcSDKP incubation. In vivo experiments were performed in streptozotocin (STZ)-induced diabetic CD1 mouse, the model displaying diabetes-associated kidney fibrosis.

Results: Here we found that AcSDKP exhibited anti-EndMT, anti-apoptosis and anti-kidney fibrosis effects in vivo and in vitro. TGF-β2 induced HUVEC/HMVEC cells into spindle shapes and reduced endothelial markers CD31/VE-cadherin expression together with the induction of mesenchymal markers such as αSMA or SM22α expression, suggesting TGF-β2 induced EndMT. Such TGF-β2-induced EndMT was restored by the co-incubation with AcSDKP in either HUVEC or HMVEC. Furthermore, combination of TGF-β2, IL-1β and TNF-α stimulated HMVEC cells into EndMT and apoptosis; AcSDKP inhibited such cell phenotypic changes induced by these cytokines combination. When analyzing the kidney fibrosis in STZ-induced diabetic CD1 mice, the conventional ACE-inhibitor plus AcSDKP add-on therapy significantly ameliorated kidney fibrosis in association with EndMT inhibition. Interestingly microRNA array analysis revealed that anti-EndMT effects of AcSDKP were correlated with the restoration in TGF-β2-induced profibrotic microRNA profiles.

Conclusions: These results suggest that AcSDKP is potential valuable endogenous anti-fibrotic molecule via partially inhibition of EndMT.

TH-PO484

TGFβ Inhibition in the KK.CG-AY/J Mouse Differentially Affects Canonical and Non-Canonical TGFβ Signaling Stephen O'Brien, John N. Vassiliadis, Mandy M. Smith, Hong Ling, Steven R. Ledbetter, Cynthia M. Arbeeny, Stefan Wawersik. *Tissue Protection & Repair Unit, Sanofi-Genzyme R&D Center, Framingham, MA.*

Background: We previously reported that uninephrectomized KK^{y} mice fed a moderately high fat diet (24% of calories) develop renal injury characteristic of human diabetic nephropathy (DN). This model exhibits upregulation of genes associated with fibrosis (fibronectin 1, MMP9, Col3a1) and inflammation (IL-1b, IL-6, MCP-1), and decreased podocyte markers nephrin and podocin. We have also demonstrated that a 5m/kg dose of the TGFβ neutralizing antibody 1D11, administered 3x/week for 12 weeks, protects KK^{y} mice from renal injury.

Methods: To establish the PK/PD profile for TGFβ antagonism we examined the short-term effects of blocking TGFβ. Female KK^{y} mice were uninephrectomized at 8 weeks old and started on a 24% fat diet. At 12 weeks old, the 1D11 antibody was administered IP 3x/week at either 0 (vehicle control), 0.5, 1, or 5 mg/kg. After 3 weeks of treatment, animals were sacrificed and the effect of 1D11 treatment on markers of fibrosis and inflammation was analyzed by quantitative RT-PCR on total kidney RNA.

Results: Compared to untreated KK^{y} mice, Col3a1 expression was moderately reduced, but expression of the fibrotic markers fibronectin and MMP9 were unchanged. The inflammation markers Il-6 and IL-1b were also markedly downregulated. Since we observed only minor effects on fibrotic gene expression in this short-term study, we assessed the early effects of 1D11 treatment on canonical (Smad 2/3) and non-canonical (TAK1) TGFβ signaling pathways. At all 3 doses of 1D11, we see no measurable inhibition Smad2 phosphorylation in total kidney lysates, and a weak but not statistically significant trend towards inhibition of Smad3 phosphorylation. However, we find that 1D11 treatment at both 1 and 5 mg/kg significantly reduces phosphorylation of TAK1.

Conclusions: These data suggest that 1D11 has distinct effects on canonical and non-canonical TGFβ signaling, and that inhibiting signaling through TAK1 may play an important role in countering the inflammatory response that contributes to initiation and progression of renal pathology in this DN model.

TH-PO485

Differential Regulation of Tubule Endoplasmic Reticulum Chaperones in OVE26 Type I Diabetic Mice Michelle T. Barati, Susan M. Isaacs, Jon B. Klein. *Nephrology, University of Louisville, Louisville, KY.*

Background: Endoplasmic reticulum (ER) stress response occurs in diabetic nephropathy (DN), yet progression of this response in different tubule subtypes is not known. The goal of this study was to define progression of ER stress response markers in proximal and distal tubules and determine if severity of proteinuria during diabetes alters activation of the PERK branch of stress response signaling.

Methods: This study used OVE26 and OVE26-Nmt3 diabetic and FVB control mice. OVE26-Nmt are cross of OVE26 and Nmt mice (overexpress metallothionein in podocytes) and have decreased proteinuria. Expression of ER stress response-induced chaperones GRP78, GRP94, and PDI was determined in isolated cortical tubules of OVE26 and FVB mice. Tubule localization determined by immunofluorescent staining of kidneys for ER chaperones and FITC-lotus tetragonolobus agglutinin (LTA), to mark proximal tubules (PT). Phospho-PERK and CHOP analyzed by immunostaining in age-matched FVB and severe or mildly proteinuric OVE26 and OVE26-Nmt mice, respectively. For *in vitro* studies, cultured PT cell fibronectin (FN) secretion analyzed following knockdown of PERK by siRNA.

Results: GRP78, GRP94, and PDI were increased in isolated tubules of 7 month old diabetic mice. Immunostaining showed upregulation of GRP78 in all cortical tubule types and PDI in distal tubules. PDI and GRP78 were decreased in tubules of 2 and 3 month old diabetic mice, respectively, in all tubule subtypes. Phospho-PERK and CHOP were expressed similarly in abundance and tubule subtype between OVE26 and OVE26-Nmt diabetic mice. Knockdown of PERK by siRNA *in vitro,* increased FN secretion by PT cells, defining a role for PERK in PT function relevant to DN.

Conclusions: ER chaperones are differentially regulated in tubule subtypes in diabetes and functional outcome of decreased chaperone expression in young diabetic mice remains to be defined. ER chaperones may be subject to degradative or autophagy pathways. Severe proteinuria does not alter signaling via the PERK branch of ER stress response in tubules. Increased PT cell FN secretion with PERK knockdown suggests that the ER stress response may inhibit pro-fibrotic mechanisms in DN.

TH-PO486

Localization of the Apelinergic System within the Kidney Anastasia Z. Kalea,[1,2] Minghao Ye,[1] Jan A. Wysocki,[1] Ivy Hsieh,[1] Daniel Batlle.[1] *[1]Div. of Nephrology &Hypertension, Feinberg School of Medicine, Northwestern University, Chicago, IL; [2]Centre for Cardiovascular Genetics, University College London, United Kingdom.*

Background: The Apelin receptor (APJ)–Apelin system has been implicated in cardiovascular function. Apelin's effects appear related, in part, to an interaction with the RAS. Since Apelin, like angiotensin II, is a substrate for ACE2, which we previously showed to localize in glomerular epithelial cells (podocytes), we wanted to investigate the localization of this peptide within the glomerulus and the overall expression of apelin and its receptor APJ within the kidney.

Methods: We employed RT-real time PCR, western blot, immunostaining, tissue and cell confocal microscopy to study apelin and APJ in kidneys from female C57BLKS mice (8 wks of age) and in cultured immortalized podocytes. Mouse podocytes were stimulated with Pyr[1]Apelin-13 (100nM) for 0, 1, 5, 15 and 60min and tested for phospho-status of AKT, p70S6K and ERK.

Results: Immunohistochemical analysis showed that both Apelin and APJ were abundantly present in the kidney being expressed in most glomerular tufts, proximal tubules, and arterioles. In glomeruli, apelin colocalized with nephrin, PECAM-1, and a-SMA indicating its presence in podocytes, endothelial cells, and mesangial cells. APJ, by contrast, did not colocalize with PECAM-1 but also colocalized with several podocyte markers. In the proximal tubule, the APJ receptor colocalized with ACE2. In renal arterioles, APJ showed colocalization only with smooth muscle markers, while apelin colocalized both with endothelial and smooth muscle cell markers. Apelin and APJ mRNA were also expressed in cultured mouse podocytes where apelin-13 induced AKT, p70S6K and ERK signaling at 15min.

Conclusions: Apelin and its receptor are widely expressed in the kidney, including podocytes where apelin-13 is involved in AKT, p70S6K and ERK signaling. Since receptor expression usually correlates with its physiological function, the presence of the newly identified apelinergic system in the kidney and its possible interaction with the podocyte RAS could be relevant to disease conditions, such as diabetic kidney disease, where there is overactivity of the RAS.

TH-PO487

Acute Disruption of Megalin Expression in Renal Cortex Reveals Compensatory Reabsorption Capacity of Low Molecular Weight Proteins in S3 Segment of Proximal Tubules and Collecting Ducts Keita P. Mori,[1] Kiyoshi Mori,[1] Masashi Mukoyama,[1] Hideki Yokoi,[1] Masato Kasahara,[1] Takashige Kuwabara,[1] Hirotaka Imamaki,[1] Akira Ishii,[1] Kenichi Koga,[1] Yukiko Kato,[1] Akira Sugawara,[1] Tomomi Endo,[2] Motoko Yanagita,[2] Kazuwa Nakao.[1] *[1]Department of Medicine and Clinical Science, Kyoto University Graduate School of Medicine, Kyoto, Japan; [2]Department of Nephrology, Kyoto University Graduate School of Medicine, Kyoto, Japan.*

Background: Reabsorption activity of proximal tubules gives profound effects upon urinary excretion levels of chronic and acute kidney injury biomarkers such as albumin and low molecular weight (LMW) proteins, including neutrophil gelatinase-associated lipocalin (Ngal) and retinol-binding protein 4 (RBP). Megalin (fl/fl) x ApoE-Cre mice have been used to analyze the effects of megalin gene deletion, but the efficiency of disruption in the kidney was only 60%.

Methods: In the present study, to understand the impact of more efficient elimination of renal cortical megalin expression upon renal reabsorption activity after normal development, we generated megalin (fl/fl) [kindly provided from Prof. Thomas Willnow, Max-Delbrueck-Center] x N-myc downstream-regulated gene 1-CreERT2 (NDRG1) mice.

Results: By real-time RT-PCR, renal megalin gene expression was reduced by 80% after intermediate dose of Tam administration, and this dose was chosen for further analysis. (With higher dose, deletion efficiency became > 90%.) By ELISA, urinary albumin excretion was elevated by 8-fold and Ngal excretion was elevated by 20-fold after Tam injection in megalin (fl/fl) x NDRG1 mice. In normal mice, by immunofluorescence, megalin protein was expressed along brush borders in S1-S3 segments of proximal tubules, and reabsorption of iv injected RBP was observed selectively in S1 and S2. After Tam treatment, distribution of exogenously given RBP was shifted towards S3 and it was also observed in cortical and medullary collecting ducts.

Conclusions: These findings suggest that renal cortical tubules are the predominant site of LMW protein reabsorption in physiologic conditions, and S3 and collecting ducts have a reservoir capacity for reabsorption.

TH-PO488

Microalbuminuria: Is Proximal Tubule the Culprit? Elif Erkan,[1] Bob Monks,[2] Morris J. Birnbaum.[2] *[1]Pediatrics, University of Pittsburgh, Pittsburgh, PA; [2]University of Pennsylvania.*

Background: Diabetes mellitus (DM) is the leading cause of end-stage renal disease. Microalbuminuria (MA) is utilized as a marker for target organ damage. We previously reported that protein kinase B (Akt), a major protein involved in insulin signaling, mediates albumin endocytosis in the proximal tubule. We hypothesize that in DM where there is downregulation of insulin-Akt pathway, alterations in the function of endocytic machinery may lead to microalbuminuria.

Methods: We examined the effect of insulin (100nm) on albumin endocytosis in human kidney (HKC-8), opposum kidney and primary mouse proximal tubule cell lines by fluorometry and western blotting (WB). Inhibition of Akt was accomplished with a double dominant mutant (DDN). The role of upstream Akt mediator adaptor protein containing a PH domain, PTB domain, and leucine zipper motif (APPL1) was evaluated by transfecting the cells with siRNA. Protein-protein interactions between cytoplasmic tail (CT) of megalin and Akt substrate AS160 were assessed by coimmunoprecipitation (Co-IP) and GST pull down (PD) assays. Disabled-2 (Dab2), megalin and cubilin expression of Akt2 knock-out (KO) mice was examined by WB and immunofluorescence.

Results: We demonstrated that insulin induces albumin endocytosis in multiple proximal tubule cell culture models. Insulin induced albumin endocytosis was perturbed by downregulation of Akt and APPL1 showing that this novel pathway is driven by Akt activation. Over expression of AS160 potentiated the insulin induced albumin endocytosis in association with an increase in megalin expression. An interaction between AS160 and megalin CT was demonstrated by co-ip and GST-PD assays. Furthermore Akt2 KO mice displayed decreased renal expression of megalin, cubilin and Dab2 confirming the role of insulin-Akt cascade in albumin endocytosis.

Conclusions: We showed a novel pathway that connects insulin-Akt signaling to albumin endocytosis in the kidney. Further delineation of protein-protein interactions surrounding insulin-Akt signaling in the proximal tubule may allow us to implement early screening tools and develop strategies to prevent proximal tubule damage and MA in diabetic nephropathy.

TH-PO489

Thrombomodulin in the Renal Microcirculation in Diabetes Is Regulated by Protein Kinase C-alpha Joon-Keun Park, Torsten Kirsch, Jan Menne, Hermann G. Haller. *Clinic of Hypertension and Nephrology, Hannover Medical School, Hannover, Germany.*

Background: Thrombomodulin (TM) is a cell surface glycoprotein which is a cofactor for thrombin binding that mediates protein C activation and inhibits thrombin activity. In addition, TM, has potent anti-inflammatory function through a variety of molecular mechanisms. Its role in diabetic vascular complications has not been investigated. We hypothesized that TM contributes to the pathogenesis of diabetic nephropathy and tested whether glucose-induced activation of PKC is involved.

Methods: Expression of TM was analyzed in mouse models (SV) and in PKC-alpha and PKC-beta -/- mice using immunohistochemistry, immunoblotting and real-time PCR. Mice were made hyperglycemic by streptozotocin treatment. Microvascular endothelial cells were obtained from Lonza Inc.

Results: Exposure of cultured microvascular endothelial cells to high glucose concentration (20 mM) rapidly down-regulated TM. This down-regulation was accompanied by the loss of perlecan and other glycocalyx molecules. The effect of glucose was prevented inhibition of PKC-alpha (antisense) but not by other PKC isoforms. Hyperglycemia in a mouse model led to a rapid decrease in TM immunoreactivity in glomerular endothelial cells. TM was also less in interstitial capillaries, although to a lesser level. TM expression was not altered in larger renal vessels. The diabetes-induced down-regulation of TM was almost completely prevented in PKC-alpha -/- mice, while the deletion of PKC-beta did not influence TM expression. Inhibition of PKC-alpha with a specific inhibitor (Goe 8862) prevented the effect of glucose on TM.

Conclusions: TM is rapidly influenced by high glucose concentrations and disappears under diabetic conditions in microvascular endothelial cells. This effect is mediated specifically by PKC isoform-alpha. The loss of TM may contribute to the altered coagulation and the increased inflammatory state in the diabetic microvasculature. Specific inhibition of PKC-alpha ameliorates glomerular inflammatory mechanisms in diabetic nephropathy.

TH-PO490

CD2AP Phosphorylation Is Enhanced in the Diseased Kidney Irini Schaefer, Beina Teng, Kirstin Worthmann, Hermann G. Haller, Mario Schiffer. *Nephrology, Medical School Hannover, Hannover, Germany.*

Background: CD2AP is an adaptor protein that can transmit intracellular signals involved in survival and cytoskeletal regulation of the cell. We have shown that CD2AP phosphorylation determine binding to nephrin. Until now it is unknown if phosphorylation of CD2AP is regulated in renal diseases as it was shown for nephrin. The aim of these studies was to analyze the involvement of CD2AP phoshorylation in kidney diseases.

Methods: Highly conserved tyrosine residues are in every SH3 domain of CD2AP on positions Y4/8/10, Y119 and Y273/280. We analyzed localization of phosphorylated CD2AP in cultured podocytes, in mice and human biopsies by immunofluorescence, immunohistochemistry and subcellular fractionization.

Results: Stimulation of murine and human podocytes with VEGF showed a typical phosphorylation profile of CD2AP with the generated phospho-specific antibodies.

Immunofluorescence stainings on murine and human parafine sections reveal that the phospho-specific antibodies against Y119 and Y273/280 showed a specific slit-diaphragm staining whereas the phospho-specific antibody against Y4/8/10 showed a more cytosol-specific staining. To further investigate the localization of CD2AP phosphorylation we performed subcellular fractionization. We can show that fulllength CD2AP is phosphorylated on tyrosine position Y4/8/10 in the cytosol, but a band of approximately 40 kDa can be found at the membrane and in the nucleus which could be a spliced variant or a cleaved form of CD2AP. Furthermore in patients with diabetic nephropathy, where VEGF expression is enhanced and nephrin expression is downregulated in the kidney, CD2AP phosphorylation on position Y4/8/10 is increased in the cytoplasm and especially in the nucleus of podocytes. Lysates from glomeruli of diabetic mice show an increased phosphorylation on position Y4/8/10 of the short 40 KDa form of CD2AP in the nucleus.

Conclusions: These results propose that CD2AP phosphorylation in regulated in the diseased glomerulus and could be of fundamental importance to understand initiation and development of glomerulopathies. Furthermore a short phosphorylated form could be determined in the nucleus of podocytes especially in diseased conditions.

Circulating Klotho Levels Are Reduced in Type 2 Diabetes Mellitus Independent of Hyperglycemia Joris van Ark,[1] Hans-Peter Hammes,[3] Marcory van Dijk,[1] Harry Van Goor,[1] Bruce H. Wolffenbuttel,[2] Jan-luuk Hillebrands.[1] *[1]Pathology and Medical Biology, University Medical Center Groningen, Groningen, Netherlands; [2]Endocrinology, University Medical Center Groningen, Groningen, Netherlands; [3]5th Medical Department, University Hospital Mannheim, University of Heidelberg, Mannheim, Baden-Württemberg, Germany.*

Background: Circulating α-Klotho is produced in the kidney and is a putative anti-aging and vasculoprotective hormone. Reduced circulating Klotho levels may increase cardiovascular risk. Type 2 diabetes (T2DM) patients are at increased cardiovascular risk. We therefore investigated if T2DM is associated with reduced circulating Klotho levels and whether hyperglycemia alters renal Klotho production.

Methods: Peripheral blood was obtained from T2DM patients without documented diabetic nephropathy (n=8) and healthy control subjects (n=10). Serum Klotho levels were determined with ELISA. Primary proximal tubular epithelial cells (PTEC) were isolated and cultured *in vitro* in the presence of various concentrations of glucose (7.8, 15, 30 and 50 mM). Klotho expression in PTECs was determined after 4 days using real-time PCR analysis and quantitative Klotho immunofluorescence. To study the effect of hyperglycemia on renal Klotho production *in vivo*, serum Klotho levels and renal Klotho expression were determined using ELISA and real-time PCR, respectively in hyperglycemic $Ins2^{Akita}$ mice (n=7) and normoglycemic C57BL/6 mice (n=7).

Results: Serum Klotho levels were significantly reduced in T2DM patients compared with healthy control subjects (21.6± 3.1 vs 78.7 ± 11.5 ng/mL, resp., p<0.001). Cultured primary PTECs exposed to high glucose did not display altered Klotho mRNA or protein expression. Long-term hyperglycemic $Ins2^{Akita}$ mice were characterized by similar circulating Klotho and renal Klotho mRNA expression levels when compared with normoglycemic control mice.

Conclusions: Circulating Klotho levels are reduced in patients with T2DM without overt diabetic nephropathy. Our *in vitro* and *in vivo* data indicate that hyperglycemia *per se* does not reduce renal Klotho production. Future studies will have to elucidate the mechanism underlying the reduced circulating Klotho levels in T2DM.

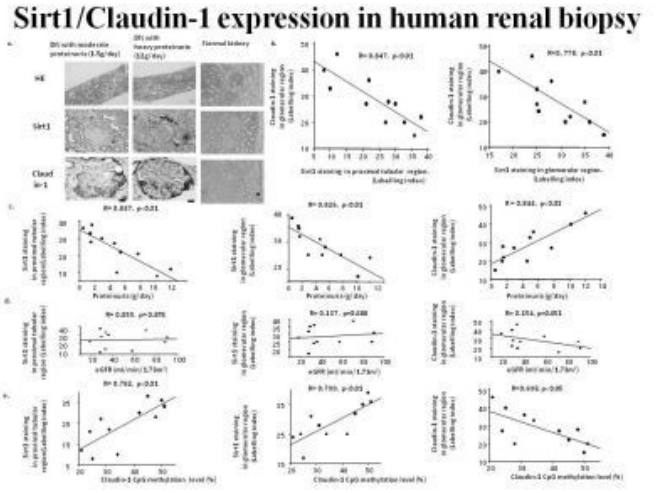
TH-PO492

Sirt1 and Claudin-1 Expression in Human Renal Biopsy Specimens of DN Kazuhiro Hasegawa, Shu Wakino, Koichi Hayashi, Hiroshi Itoh. *Internal Medicine, Keio University, Shinjuku-ku Shinanomachi 35, Tokyo, Japan.*

Background: We reported **epigenetic regulation of claudin-1** (oral presentation in 2010, 2011 ASN). In diabetic nephropathy (DN), reduced Sirt1 decreased claudin-1 CpG methylation and increased Cldn-1 in podocytes. Sirt1 overexpression reversed these changes. However, **the expression or role of Sirt1 and Cldn-1 in humans has not been reported**.

Methods: Renal biopsy specimens were obtained from 11 patients with DN. As controls, pre-transplant biopsies from 5 living donors were obtained. Written informed consent was obtained and the study was performed in accordance with the declaration of Helsinki.

Results: All patients were with an age of 61.8±13.2 years, and had a serum creatinine level of 1.57±0.66 mg/dl, daily urinary protein excretion of 4.79±3.80 g/day, eGFR of 48.8±24.9 ml/min/1.73m^2, and HbA_{1c} of 6.24±0.39%. Sirt1 in both proximal tubules (PTs) and podocytes (Pods) was lower with DN (a). In contrast, Cldn-1 in Pods increased with DN. As a reference, Sirt1 were detected in both PT and Pods, and no Cldn-1 in Pods was detected in controls. Cldn-1 was correlated with lower Sirt1 in both PTs and Pods (b). Of clinical parameters, only proteinuria was correlated with a lack of Sirt1 staining. In addition, proteinuria was correlated with Cldn-1 (c). There were no correlations between eGFR and the staining of these proteins (d). **Cldn-1 CpG methylation was correlated with a lack of Sirt1 staining and inversely correlated with Cldn-1 expression (e).**



Conclusions: We first found that in human kidney **1) Sirt1 decreased in DN, 2) Cldn-1, which is correlated with Sirt1 down-regulation, was up-regulated in DN, and 3) both increase in Cldn-1 and decrease in Sirt1 were correlated with the extent of proteinuria in DN.** Since the clinical data are consistent with the results in mice, these findings can provide useful insight into the pathogenesis and treatment of DN in clinical practice.

Podocyte-Specific Overexpression of SIRT-1 Increases Nephrin in Obese Mice Fed a High-Fat Diet Jae Won Yang,[1] Seung-Ok Choi,[1] Byoung Geun Han,[1] Minseob Eom.[2] *[1]Nephrology, Yonsei University Wonju College of Medicine, Wonju, Gangwon, Korea; [2]Pathology, Yonsei University Wonju College of Medicine, Wonju, Gangwon, Korea.*

Background: Obesity can lead to inflammation, hyperlipidemia, diabetes, hypertension, and renal dysfunction, and is also associated with proteinuria. Histopathological changes in the glomeruli in obesity were characterized by glomerulomegaly and focal segmental glomerulosclerosis. This study was designed to investigate the effect of sirtuin 1 (SIRT-1), podocyte-specific overexpressed, on nephrin levels in obese mice induced by high fat diet. SIRT-1 has been proposed as a chemotherapeutic target for type II diabetes mellitus.

Methods: After establishing the SIRT-1 transgenic mice, experimental groups were divided into following three groups: Normal diet-normal group (ND-NL), high fat diet-normal group (HFD-NL), and high fat diet-SIRT-1 group (HFD-SIRT1). The background of transgenic mice was C57BL/6. High fat diet group were fed with a high calorie diet (60%) for up to 21 weeks to examine a progressive development of obesity. Body weight, 6 hours fasting blood glucose, and HbA1c were regularly measured. Albumin-Creatinine Ratio (ACR) in 24 hours urine was measured 21 weeks after the experiment. The expression levels of SIRT-1 and nephrin in the kidney by using western-blot and RT-PCR were compared.

Results: With repeated measures ANOVA test, both high fat diet groups were showing that the body weight was significantly higher than normal diet group (P<0.0001) and showing that 6 hours fasting blood glucose was also significantly different (P<0.05). Although statistically not different, urinary ACR of the HFD-SIRT1 group was lower than the HFD-NL group (P=0.09). The nephrin protein expression in the HFD-SIRT1 group was significantly increased than the HFD-NL (P<0.05). The nephrin mRNA level in the HFD-SIRT1 group showed a tendency to increase compared with the HFD-NL group.

Conclusions: Taken together the results, deterioration of the kidney disease caused by obesity and hyperglycemia could be prevented by increasing the level of the nephrin expression through SIRT-1 activation. SIRT-1 may have the ability to protect the podocyte from injuries caused by obesity and hyperglycemia.

TH-PO494

Inhibition of TNFα Decreases Nephrin Endocytosis and Protects Mice against Hyperglycemia-Induced Proteinuria Magdalena Woznowski, Sebastian Alexander Potthoff, Eva Koenigshausen, Johannes Stegbauer, Lars C. Rump, Lorenz Sellin, Ivo Quack. *Nephrology, Heinrich Heine University, Duesseldorf, Germany.*

Background: In diabetes TNFα is upregulated and has been recognized as an important mediator of diabetic nephropathy and proteinuria. However, the underlying pathomechanism remained elusive so far. Thus we wanted to analyze if TNFα is critical for the regulation of slit diaphragm integrity in hyperglycemic states.

Methods: HEK293T cells and podocytes were treated with high levels of glucose (30mM). C57BL/6 mice were treated intraperitoneally with streptozotocin to induce hyperglycemia. For inhibition of TNF-alpha activity, Etanercept, a soluble dimeric fusion protein that binds soluble TNFα, was administered in cells and animals. For quantification of endocytosis in vitro and in vivo all extracellular proteins were labeled with a reactive sulfo-biotin-esther. Precipitation of nephrin with subsequent western blot analysis for the biotinylation status of was performed. Total mRNA was isolated from in vitro differentiated podocytes and subjected to a Real-Time-PCR analysis for the expression level of TNFα mRNA. TNFα serum levels were measured by ELISA. Albuminuria was quantified as albumin/creatinin ratio.

Results: Cell culture: treatment of HEK 293T cells or podocytes with high glucose leads to a rapid upregulation of TNFα and induces the endocytosis of nephrin. Simultaneous treatment with etanercept prevented nephrin endocytosis. Animal model: mice with streptozotocine induced diabetes develop elevated serum levels of TNFα and proteinuria within hours. Inhibition of TNFα via intraperitoneal administration of etanercept strongly reduces nephrin endocytosis and proteinuria.

Conclusions: Hyperglycemia leads to elevated TNFα serum levels. TNFα in turn induces the endocytosis of nephrin in podocytes and thereby weakens the integrity of the glomerular slit diaphragm. Inhibition of TNFα prevents proteinuria without influencing the hyperglycemia. Our results suggest TNFα as a pivotal mediator of hyperglycemia-induced damage of slit diaphragm integrity. Inhibition of TNFα might become a promising treatment option to prevent diabetic proteinuria.

A PAI-1 Mutant Slows Diabetic Nephropathy Progression in db/db Mice via Podocyte Protection Chunyan Gu, Jiandong Zhang, Alfred K. Cheung, Yufeng Huang. *Internal Medicine, University of Utah, Salt Lake City, UT.*

Background: PAI-1R, a mutant plasminogen activator inhibitor (PAI-1), aimed at reducing endogenous PAI-1 activity, has been shown to inhibit albuminuria and prevent glomerular mesangial matrix expansion in experimental diabetes. The mechanism of albuminuria reduction is unclear but may be related to amelioration of podocyte injury.

Methods: This study sought to determine whether administration of PAI-1R could protect podocyte from injury directly thereby slowing the progression of glomerulosclerosis in the db/db mouse, a model of type 2 diabetes.

Results: Untreated uninephrectomized db/db mice developed progressive albuminuria and mesangial matrix expansion between wks 20 and 22, associated with significant segmental podocyte foot process effacement, reduction of renal nephrin, podocin and ZO-1 production and induction of renal desmin and B7-1 production. Treatment with PAI-1R at 0.5mg/Kg BW, ip, twice daily from wk 20 to 22 repeatedly prevented the increased albuminuria and even lowed the levels of urinary albumin excretion than before treatment by 31.4% ($p<0.05$). PAI-R also repeatedly reduced glomerular matrix accumulation, FN and Col production by 36%, 62% and 65%, respective ($p<0.05$) without affecting body weight or blood glucose levels. Of note, the dramatic changes in podocyte morphology and podocyte markers seen in diabetes were all significantly ameliorated by PAI-1R administration. In vitro, recombinant PAI-1 at the concentration of 150 nM down-regulated nephrin and ZO-1 by more than 50% but increased desmin and B7-1 mRNA expression and protein production by podocytes by more than 2-fold compared with the normal cells ($p<0.05$), similar to the effects of TGFß1 at concentration of 2ng/ml.

Conclusions: These observations provide the evidence that PAI-1, similar to TGFß, may signal directly to regulate podocyte disorder particularly in diabetes, which is characterized by increased plasma and tissue PAI-1. Reducing the increased PAI-1 activity by PAI-1R in vivo may, in fact, restore podocyte injury; therefore PAI-1R may provide additional therapeutic effect in slowing progression of diabetic nephropathy through maintaining podocyte integrity.

TH-PO496

Fusion of Bone Marrow-Derived Cells with Podocytes Increases in Diabetic Nephropathy Tomohisa Yamashita,[1] Mineko Fujimiya,[2] Masayuki Koyama,[1] Yusuke Okazaki,[1] Marenao Tanaka,[1] Masato Furuhashi,[1] Hideaki Yoshida,[1] Tetsuji Miura.[1] *[1]2nd Department of Internal Medicine, Sapporo Medical University School of Medicine, Sapporo, Hokkaido, Japan; [2]2nd Department of Anatomy, Sapporo Medical University School of Medicine, Sapporo, Hokkaido, Japan.*

Background: We previously reported that diabetes induces appearance of proinsulin-producing bone marrow-derived cells (BMDCs) in various organs and their fusion with somatic cells including renal tubular epithelial cells, leading to diabetic nephropathy (FASBJ. 26, 1559-1568; 2012). However, it remains unclear whether BMDCs fuse with glomerular cells such as podocytes and have any adverse effects on kidney function in diabetes. We examined this issue by use of a mouse model of diabetes.

Methods: We performed bone marrow transplantation (BMT) from male green fluorescent protein (GFP) transgenic mice to female C57BL/6J mice before induced diabetes by streptozotocin. Non-diabetic controls received sham treatment (saline injection). Four months after streptozotocin or sham treatment, kidneys were removed, and fixed by Zamboni's fixation. Sections were immunoflurostained for analysis by confocal laser scanning microscopy (Nicon A1) and NIS element AR 4.0.

Results: First, in slides without immunostaining, we confirmed presence of GFP positive cells in the glomeruli. In the glomeruli of the diabetic mice with BMT, GFP positive area and the number of GFP positive cells were increased compared with those in non-diabetic mice (5.2% vs 2.5%, $p<0.01$ and 4.4 vs 9.1 cells /glomerulus, $p<0.01$). Three dimensional analysis showed that BMDCs were larger in diabetic mice than in controls and fused with the other cells. Detailed spectrum analysis indicated that approximately 10% of BMDCs contained triple spectrums of GFP, nephrin and desmin in diabetes.

Conclusions: Diabetes induces fusion between BMDCs and podocytes. Fusion with BMDCs might be responsible for podocytes injury in diabetic nephropathy.

TH-PO497

Podocyte Deletion of LKB1 Results in Increased Severity of Diabetic Nephropathy in Mice Kimberly J. Reidy,[1] Zhongfang Du,[1] Katalin Susztak.[2] *[1]Pediatrics/ Nephrology, Albert Einstein College of Medicine, Bronx, NY; [2]Medicine/ Nephrology, University of Pennsylvania, Philadelphia, PA.*

Background: LKB1 (also known as Par4 or stk11) is a serine-threonine kinase expressed in the developing kidney and in podocytes. LKB1 is a key regulator of cell polarity and metabolism. Recently LKB1 has been shown to play a role in regulation of AMPK kinase and cellular metabolism, suggesting it may play a role in cellular response to the diabetic milieu. In vitro studes showed decreased activation of LKB1 in podocytes exposed to high glucose. As LKB1 is a critical integrator of polarity and metabolism hypothesize that LKB1 contributes to maintenance of podocyte structure, and may be protective in the setting of metabolic stress.

Methods: Conditional deletion of LKB1 in podocytes was achieved by generating NPHS2-Cre:LKB1flox/flox mice. Diabetes was induced by intraperitoneal streptozotocin (STZ) injection (50mg/kg) for 5 days in five week old male mice. Controls were non-diabetic (vehicle injected) NPHS2-Cre:LKB1flox/flox and LKB1flox/flox male mice as well as diabetic (STZ injected) LKB1flox/flox littermates. Severity of diabetic nephropathy was assessed by urine albumin:creatinine ratios, and histologic examination of 14-20 week old male using light and electron microscopy.

Results: Nondiabetic mice with podocyte deletion of LKB1 were indistinguishable from controls on light microscopy, and appear to have normal polarity, with majority of foot process intact and normal distribution of Pard3 expression. Control diabetic mice developed only mild mesangial expansion and mild albuminuria, diabetic mice with podocyte deletion of LKB1 developed nephrotic range albuminuria, and Kimmelstein-Wilson like glomerular lesions.

Conclusions: Podocyte LKB1 deletion results in severe diabetic nephropathy, suggesting that podocyte LKB1 contributes to maintenance of the glomerular filtration barrier in the diabetic mileiu.

Ezrin Is Downregulated in Glomeruli of Streptozotocin-Induced Diabetic Rats and Regulates Glucose Transport in Cultured Podocytes Anita A. Wasik,[1] Susanna Koskelainen,[1] Mervi E. Hyvonen,[1] Luca Musante,[1] Eero Lehtonen,[1] Kerttu Koskenniemi,[2] Csaba Imre Szalay,[3] Pekka Varmanen,[4] Tuula A. Nyman,[5] Peter Hamar,[3] Harry B. Holthofer,[1] Sanna H. Lehtonen.[1] *[1]Haartman Institute, University of Helsinki, Finland; [2]Department of Veterinary Biosciences, University of Helsinki, Finland; [3]Semmelweis University, Budapest, Hungary; [4]Department of Food and Environmental Sciences, University of Helsinki, Finland; [5]Institute of Biotechnology, University of Helsinki, Finland.*

Background: Diabetic nephropathy is a major cause of end-stage renal disease but the pathophysiological mechanisms associated with its development are poorly characterized.

Methods: We performed quantitative proteomic profiling of glomeruli isolated from streptozotocin-treated diabetic or control rats by fluorescence-based two-dimensional difference gel electrophoresis followed by mass spectrometry.

Results: We identified 29 differentially expressed proteins in glomeruli four weeks after induction of diabetes. Among the proteins that were altered significantly, ezrin was found to be downregulated by 50% in the streptozotocin group compared with controls. The cytoskeletal protein ezrin functions as a cross-linker between the actin cytoskeleton and the plasma membrane and participates in insulin granule trafficking and docking to the plasma membrane in the pancreatic beta cells. Immunofluorescence and quantitative Western blot analyses confirmed downregulation of ezrin in glomeruli of streptozotocin-treated rats. We found that ezrin is expressed in cultured mouse podocytes and that its localization does not depend on an intact actin cytoskeleton. However, knockdown of ezrin led to loss of actin stress fibers. We also found that ezrin forms a complex with VAMP2, the regulator of vesicle trafficking on GLUT4 storage vesicles, and that depletion of ezrin by siRNA affects the insulin stimulated glucose uptake activity of podocytes. Furthermore, ezrin was activated via phosphorylation in a glucose- and insulin-dependent manner in podocytes.

Conclusions: Our findings suggest that ezrin may play an important role in the regulation of glucose transport in podocytes.

TH-PO499

Podocyte *VEGF-A*: Gain-of-Function Induces Nodular Glomeruloesclerosis in eNOS Knockout Mice Delma Veron, Pardeep Kumar Aggarwal, Heino Velazquez, Gilbert W. Moeckel, Michael Kashgarian, Alda Tufro. *Yale University, New Haven, CT.*

Background: Increased vascular endothelial growth factor-a (VEGF-A) and decreased nitric oxide (NO) availability play a pathogenic role in the development of diabetic nodular glomerulosclerosis in mice. The objective of this study was to define the role of local VEGF-A and NO availability in the development of glomerulopathy in the absence of diabetic milieu.

Methods: We examined the effects of increased podocyte VEGF-A in glomeruli from endothelial nitric oxide synthase (*eNOS*) knockout mice. *eNOS* knockout mice (*C57BL/6j-Nos3tm1Unc*) were crossbred with *podocin-rtTA:tet-O-VEGF*$_{164}$ mice that overexpress VEGF$_{164}$ in podocytes upon doxycycline exposure. *Podocin-rtTA:tet-O-VEGF*$_{164}$*: eNOS*$^{-/-}$ (PTE)mice were fed standard diet (control=PTE) or doxycycline containing diet for 1-3 months (VEGF$_{164}$ overexpressing mice=PTE+dox).

Results: PTE mice were viable, fertile and had normal litter size. Podocyte $VEGF_{164}$ overexpression for 1 month resulted in advanced glomerulosclerosis, increased systolic blood pressure and decreased glomerular filtration rate compared to control mice. The glomerular lesions in PTE mice progressed to nodular glomerulosclerosis after 3 months of podocyte $VEGF_{164}$ overexpression, associated to massive proteinuria and renal failure, in the context of normal blood glucose. Microaneurisms, mesangiolysis, glomerular basement membrane thickening and foot process effacement were also observed in PTE + dox mice by light microscopy and TEM. Immunoreactive collagen IV and laminin increased significantly in the nodules; nephrin expression decreased, whereas podocin and WT1 were not altered in PTE + dox mice.

Conclusions: The present findings suggest that simultaneous upregulation of podocyte VEGF-A signaling and decreased NO bioavailability is sufficient to induce the development of nodular glomerulosclerosis, massive proteinuria and renal failure, i.e. advanced diabetic nephropathy-like phenotype, in the absence of diabetic milieu.

Simultaneous or Separate Inhibition of Vascular Endothelial Growth Factor Receptors 1 and 2 Aggravates Diabetic Nephropathy in *db/db* Mice

Sungjin Chung, Cheol Whee Park, Ji Hee Lim, Min-Young Kim, Seok Joon Shin, Hyung Wook Kim, Yong-Soo Kim, Yoon-Sik Chang. *Department of Internal Medicine, The Catholic University of Korea College of Medicine, Seoul, Korea.*

Background: It is a still controversy over manipulating vascular endothelial growth factor (VEGF) receptors (VEGFRs) may be promising therapeutic tools in diabetic nephropathy. Therefore, we examined the renal effects of anti-flt 1 hexamer (VEGFR1 inhibitor) or anti-flk 1 heptamer (VEGFR2 inhibitor) or both of them in *db/db* mice treating for 12 wks in male *db/db* mice.

Methods: Male db/db amd db/m mice were treated with VEGFR1 inhibitor and VEGFR2 inhibitor simultaneously or separately for 12 weeks from 8 weeks of age.

Results: Induction of diabetes suppressed the VEGFR1 and increased VEGFR2 expressions in kidneys. In the >*db/db* mice with VEGFR1 or VEGFR2 inhibition, albuminuria, glomerular mesangial matrix expansion, and inflammatory cell infiltration were more prominent than those of control *db/db* mice although there were no differences in blood glucose levels in all *db/db* groups. They exhibited an increase in the number of apoptotic glomerular cells without cell proliferation and increased 24-h urinary 8-OH-deoxyguanosine concentrations. Interestingly, more severe albuminuria and renal lesions were noted in the *db/db* mice with both VEGFR1 and VEGFR2 inhibition compared with either VEGFR1 or VEGFR2 inhibition. All of these changes were associated with the inactivation of renal PI3K-Akt-eNOS-NO pathway. In contrast, VEGFR1 or VEGFR2 blockade-induced renal phenotypes were not observed in any *db/m* groups. In glomerular endothelial cells, high-glucose media containing VEGFRs inhibitors, especially media with both VEGFR1 and VEGFR2 inhibition, induced more apoptotic cell death and oxidative stress than did high-glucose media associated with an inactivation of both the PI3K-Akt-eNOS pathway and SOD1 and SOD2.

Conclusions: Our results reveal that the blockade of VEGFR1 or VEGFR2 or both VEGFR1 and VEGFR2 caused severe renal injury related to the inactivation of the PI3K-Akt-eNOS pathway resulting in the oxidative stress-induced apoptosis in type 2 diabetic nephropathy.

TH-PO501

A Small Bioactive Peptide of Pigment Epithelium-Derived Factor Reduces Diabetic Renal Injury

Alaa S. Awad,[1] Anzor Gvritishvili,[2] Ting Gao,[1] Hanning You,[1] Joyce Tombran-tink.[2,3] *[1]Medicine, Penn State University College of Medicine; [2]Neural and Behavioural Sciences, Penn State University College of Medicine; [3]Ophthalmology, Penn State University College of Medicine, Hershey, PA.*

Background: Pigment epithelium derived factor (PEDF) is a multifunctional, pleiotropic protein with antiangiogenic, anti-oxidative and anti-inflammatory properties. However, the direct role of PEDF in the kidney remains unclear. We hypothesize that a minimal fragment of PEDF (P78-PEDF) confers kidney protection in diabetic nephropathy (DN).

Methods: The expression, localization, and effects of P78-PEDF were determined in DBA mice following multiple low doses of streptozotocin (STZ; 50 mg/kg ip for 5 days; n=5 each group) treated with continuous subcutaneous infusion of vehicle or P78-PEDF for 6 weeks.

Results: Using immunohistochemistry, we confirmed the localization of PEDF in the kidney; mainly in the vasculature, interstitial space, tubules, glomeruli, and in the macula densa under normal condition. Kidney PEDF protein and mRNA expression were reduced significantly after 15 wks in a vehicle-treated STZ-induced mouse model. Continuous infusion with P78-PEDF for 6 wks resulted in kidney protection as evident by reduced albuminuria ($p<0.05$), reduced blood urea nitrogen ($p<0.0001$), decreased kidney macrophage recruitment ($p<0.05$), and reduced kidney inflammatory cytokines (TNF-α: $p<0.05$, IFN-γ: $p<0.05$) and urinary TNF-α ($p<0.05$) compared with vehicle-treated diabetic mice. The increase in albuminuria in the vehicle-treated diabetes group was associated with a reduction in nephrin expression, which was reversed by P78-PEDF treatment. *In vitro*, P78-PEDF blocked the increase in podocyte permeability to albumin and disruption of the actin cytoskeleton, induced by puromycin aminonucleoside (PAN)-induced injury.

Conclusions: These findings highlight the importance of P78-PEDF as a potential therapeutic modality in diabetic renal injury, at least in part, by reducing macrophage recruitment and levels of inflammatory cytokines. In addition, P78-PEDF has a direct effect on preserving the normal structure of podocyte foot processes, slit diaphragms, and actin cytoskeleton.

Autophagy in Diabetic Nephropathy and Non-Diabetic CKD In Vitro and In Vivo

Ying Wang,[1] Cynthia C. Nast,[2] Janine A. La Page,[1] Sharon G. Adler.[1] *[1]Internal Medicine, Los Angeles Biomedical Research Institute ar Harbor UCLA, Torrance, CA; [2]Pathology, Cedars-Sinai Medical Center, Los Angeles, CA.*

Background: Macroautophagy(Atg), a process activated by cell stress, culminates in the degradation of cytoplasmic constituents by lysosomes. Atg is regulated by major multifunctional signaling pathway nodes at mammalian target of mTORC1, AMP-kinase, PI3-kinase, and IP3. Atg fosters cell survival, but in insurmountable injury, induces cell death. In diabetes and DN, insufficient Atg may contribute to ineffective tissue repair and organ failure. Hematopoietic growth factor inducible neurokinin-1(HGFIN) acts downstream of the nodal signaling pathways to enhance Atg. We showed that HGFIN is a tissue and urine biomarker of CKD (KI 79:1138-48, 2011). Chloroquine (Cq) inhibits Atg.

Methods: 1. We present a case of chronic medicinal Cq intoxication leading to CKD. **2.** We stained human control and DN tissue to evaluate the expression of HGFIN. **3.** We cultured WT and HGFIN-overexpressing mouse distal convoluted tubule (MDCT) cells in 5.5 mM (NG) vs 10-25 mM (HG) to measure the relative capacity of HG and HGFIN overexpression to induce Atg, and used Cq to assess Atg flux by measuring the ratio of the Atg proteins LC3BII/BI over time.

Results: 1. We reported proteinuria and CKD due to Cq toxicity in the treatment of rheumatoid arthritis (Mod Pathol.18:733-8, 2005). Renal biopsy showed podocyte inclusions and dense mesangial granules, both in "lysosomes." New ultrastructural analysis (x320,000) shows the material as lamellae, sometimes with a trilamellar appearance, in autophagosomes defined by double-membrane structures. These data are consistent with the development of CKD from Cq-induced Atg inhibition. 2. In DN, HGFIN was increased in all renal cortical epithelia, including podocytes, parietal epithelial cells. 3. HGFIN overexpression was substantially more effective in increasing Atg and Atg flux than HG.

Conclusions: These data demonstrate that in vivo, inhibition of Atg may induce CKD. In vitro, the data show that in mDCT cells, HG and HGFIN overexpression both activate Atg. Methods to increase Atg may enhance renal repair in DN.

Autophagy-Deficiency in Obese Mice Exacerbates Proteinuria-Induced Tubulointerstitial Lesions

Kousuke Yamahara,[1] Shinji Kume,[1] Daisuke Koya,[2] Shin-ichi Araki,[1] Keiji Isshiki,[1] Masakazu Haneda,[3] Takashi Uzu,[1] Hiroshi Maegawa.[1] *[1]Medicine, Shiga University of Medical Science, Otsu, Shiga, Japan; [2]Diabetes and Endocrinology, Kanazawa Medical University, Kahoku-Gun, Ishikawa, Japan; [3]Medicine, Asahikawa Medical University, Asahikawa, Hokkaido, Japan.*

Background: Autophagy is an intracellular catabolic process to maintain intracellular homeostasis. It had been proposed that autophagy-deficiency is involved in the pathogenesis of obesity-related diseases. However, relationship between autophagy and obese-mediated renal damage has remained unclear. Thus, we examined the role of autophagy on the obesity-mediated exacerbation in a protein-overload mouse nephropathy model.

Methods: Recent studies have shown that excess free fatty acid (FFA) bound to albumin are filtered through glomeruli and reabsorbed into the renal proximal tubules, which causes tubulointerstitial inflammation in the kidney.

Intraperitoneal injection of FFA-bound albumin (0.3g/kg•BW) was also used to induce proteinuria-mediated tubular damage in this study. Autophagy was analyzed by measuring LC3II formation by immunoblotting and LC3-dot formation in GFP-LC3 transgenic mouse.

Results: We found that protein-overload-induced proximal tubular cell damages, (determined by histological analysis, cleavage of caspase 3 (an apoptosis marker), and Ngal expression), were significantly worse in obese mice (HFD: 60% of fat for 4 weeks) compared to lean mice. In addition, protein-overload induced autophagy in the proximal tubules of lean mice, whereas it was suppressed in obese mice. To clarify the pathological significance of autophagy-deficiency on proteinuria-induced tubular damage in obese mice, we generated proximal tubule-specific Atg5-deficient mice. Atg5-deficient mice developed exacerbated protein-overload-induced histological damage, proximal tubular cell apoptosis and Ngal expression, similar to obese mice.

Conclusions: Collectively, these results showed that a protective action of autophagy against proteinuria in proximal tubular cells was significantly suppressed in diet-induced obese mice. Restoration of autophagy activity may be a new therapeutic option to improve renal outcome in obese patients with proteinuric kidney disease.

TH-PO504

High Protein Diets Alter Renal Cortical Autophagy and Worsen Protein Oxidation in Early Streptozotocin-Induced Diabetes Harold A. Franch,[1,2] Sara Zoromsky,[1,2] Changlin Ding.[1,2] *[1]Renal Division, Atlanta VAMC; [2]Department of Medicine, Emory University.*

Background: Inhibiting autophagy leads to tissue damage from decreased destruction of protein oxidation by chaperone-mediated autophagy (CMA) and accumulation of protein aggregates by reducing macroautophagy (MA). In the renal cortex, diabetes increases MA, but reduces CMA. High protein diets increase diabetic kidney damage but their effect on renal cortical autophagy and oxidized proteins (OX) has not been examined.

Methods: Sprague-Dawley rats (200 g) were made diabetic with 60 mg/kg streptozotocin (D) or injected with citrate buffer (C) and fed isocaloric 12% (L) or 40% (H) protein diets for 21 days (n= 7-11/group). L diets had carbohydrates replacing protein. MA, CMA, were estimated by western blotting for light chain 3b II/I ratio, lysosome associated membrane protein 2a, p62/sequestisome 1 labeled aggregates (p62), targets for macroautophagy, were measured by western blotting, while OX was measured by Oxyblot.

Results: Blood glucose was lower in DH vs.DL (408±25 vs. 482±23 mg/dl, $p<0.05$), but kidney wt/body wt was greater in DH than DL (104±13 vs. 66±11% of CL, $p<0.02$). Compared to CL, DL reduced renal cortical CMA by 66±9%% ($p<0.05$), CH by 34±13%% (NS) and CD by 84±6% ($p<0.05$, but NS with DH). Compared to CL, DL increased renal cortical OX by 35±24% (NS), CH by 5±25% (NS) and DH by 95±31% ($p<0.05$, vs CL & DL). Compared to CL, MA increased ~ 3 fold with in CH and DL (both NS), but was ~30 fold higher in DH ($p<0.01$ vs CL, $p<0.02$ vs CH and DL). p62 did not change significantly with diet or diabetes.

Conclusions: Despite lower glucose in early diabetes, high protein diets diets worsen diabetic renal hypertrophy and cortical protein oxidation, while reducing CMA and accelerating MA. One mechanism of protein oxidation could occur via reduced destruction by suppressing CMA, while increases in MA serve to prevent p62 protein aggregates from accumulating. Reduced CMA could provide a mechanism for diabetic tissue damage from high protein diets.

TH-PO505

Selective Insulin Receptor Substrate 1 and Its Functions in Glomeruli of Diabetic and Insulin Resistant Rats Akira Mima,[1,2] George L. King,[2] Toshio Doi.[1] *[1]Nephrology, Tokushima University, Tokushima, Japan; [2]Vascular Cell Biology, Joslin Diabetes Center, Boston, MA.*

Background: Insulin resistance has been associated with the progression of chronic kidney disease in diabetes and obesity. However, detailed characterization of insulin signaling of the renal tissue has not been reported in these pathophysiological states.

Methods: Diabetes of eight weeks duration was induced by streptozotocin (STZ) in six weeks old Sprague-Dawley (SD) rats. Zucker lean (ZL) and fatty (ZF) rats of 14 weeks of age were used as models of obesity. Insulin (10mU/g) was injected via inferior vena cava and insulin signaling in the renal glomeruli and tubules were analyzed. Insulin signaling and actions on endothelial nitric oxide synthase (eNOS) in glomerular endothelial cells isolated from SD rats were studied on their responses to elevated levels of glucose.

Results: Insulin-induced phosphorylation of insulin receptor substrate-1 (IRS1), Akt, and eNOS were selectively inhibited in the glomeruli but not in the renal tubules of both STZ-diabetic and ZF rats compared to non-diabetic and ZL rats. Protein levels, but not the mRNA expression, of IRS1 were decreased only in the glomeruli of STZ-diabetic rats and increased its association with ubiquitination. RBX treatment enhanced insulin actions and elevated IRS1 expression. In rat glomerular endthelial cells (RGECs), high glucose levels (25mM) inhibited insulin-induced phosphorylation of Akt and eNOS, decreased IRS1 protein expression and increased association with ubiquitination. Also, in podocytes, insulin signaling was inhibited in high glucose condition.

Conclusions: There is selective inhibition of insulin signaling via the IRS1/PI3K/Akt pathway and loss of eNOS activation only in the glomeruli in diabetes and insulin resistance, partly due to increased IRS1 degradation and protein kinase C (PKC)β activation. The selective loss of insulin's effect on eNOS activation may contribute to the glomerular pathologies observed in diabetes and obesity.

Effects of Lipid-Lowering Treatment on Inflammatory Markers in Diabetic Patients with Chronic Kidney Disease Tora Almquist,[1,2] Stefan H. Jacobson,[2] Per-Eric Lins,[3] Paul Hjemdahl.[1] *[1]Karolinska Institutet, Dept. Medicine Solna, Clinical Pharmacology Unit, Karolinska University Hospital, Stockholm, Sweden; [2]Dept. Clinical Sciences, Div. Nephrology, Danderyd Hospital; [3]Dept. Clinical Sciences, Div. Diabetology, Danderyd Hospital, Stockholm, Sweden.*

Background: Diabetes mellitus (DM) is the most common cause of chronic kidney disease (CKD). Inflammation plays an important role in atherosclerosis and may contribute to the high incidence of cardiovascular disease in DM and CKD. Monocyte chemoattractant protein-1 (MCP-1) plays a central role in recruiting monocytes into early atherosclerotic lesions and is involved in the pathogenesis of diabetic nephropathy. Interferon gamma (IFNγ) is considered to be a key player in the progression of atherosclerosis and increases synthesis of endothelial cell chemokines including MCP-1. Lipid-lowering treatment (LLT) with statins may have favorable effects on inflammation, and ezetimibe co-treatment provides additional cholesterol-lowering.

Methods: After a placebo run-in period, the effects of simvastatin alone (S) or simvastatin+ezetimibe (S+E) were compared in a randomized, double-blind, cross-over study on inflammatory markers including proinflammatory cytokines, chemokines and adhesion molecules.18 DM patients with estimated glomerular filtration rate (eGFR) 15-59 ml/min x 1.73 m^2 (CKD stages 3-4) (DM-CKD) and 21 DM patients with eGFR >75 ml/min (DM only) were included.

Results: At baseline, levels of MCP-1 ($p=0.03$), IFNγ ($p<0.01$), tumor necrosis factor-α (TNF-α) ($p=0.001$), and soluble vascular adhesion molecule (sVCAM) ($p=0.001$) were elevated in DM-CKD compared to DM only patients. LLT with S and the combination of S+E reduced MCP-1 levels ($p<0.01$ by ANOVA; post hoc test $p=0.04$ and $p<0.001$ resp.) and IFNγ levels ($p<0.01$ by ANOVA; post hoc test $p=0.02$ and $p=0.001$ resp.) in DM-CKD patients but not in DM only patients. The reduction was most prominent with the combination treatment.

Conclusions: DM patients with CKD stages 3-4 had increased inflammatory activity compared to DM patients with normal GFR. Lipid-lowering treatment with simvastatin alone and in combination with ezetimbe decreased levels of MCP-1 and IFNγ in DM patients with concomitant CKD.

Urinary Proteomics Predict Onset of Microalbminuria in Normoalbuminuric Type 2 Diabetic Patients in the DIRECT 2 Study Morten Lindhardt,[1] Frederik I. Persson,[1] Petra Zürbig,[4] Angelique Stalmach,[3] Harald Mischak,[3,4] Dick de Zeeuw,[5] Hiddo Jan Lambers Heerspink,[5] Anne Katrin Sjoelie,[6] Ron Klein,[6] Trevor Orchard,[6] Massimo Porta,[6] John Fuller,[6] Rudolf W. Bilous,[6] Nish Charturvedi,[6] Hans-Henrik Parving,[6] Peter Rossing.[1,2] *[1]Steno Diabetes Center, Gentofte, Denmark; [2]University of Aahus, Denmark; [3]University of Glasgow, United Kingdom; [4]Mosaiques Diagnostics GmbH, Hannover, Germany; [5]University Medical Centre, Groningen, Netherlands; [6]The DIRECT Steering Group.*

Background: Early prevention of diabetic nephropathy is not successful as early interventions have shown diverging results. Urinary proteomics has shown promise as an early indicator of future development of diabetic nephropathy and could guide need for treatment.

Methods: In a post-hoc study of the DIRECT-Protect 2 study, a randomized, controlled clinical trial of candesartan for slowing the progression of retinopathy, we studied patients with type 2 diabetes and normoalbuminuria (n=792), followed for a mean of 4.7 years. We determined a previously defined CKD risk score based on proteomic measurement of 273 urinary peptides (CE-MS), the risk-score was selected from previous cross sectional case-control studies. A Cox regression model for progression of albuminuria was built. The primary endpoint was development of persistent microalbuminuria (MA) (3 out of 4 samples).

Results: Persistent MA developed in 92 patients (11,6%). At baseline the CKD risk score was able to predict development of MA during follow-up, independent of treatment (candesartan/placebo), age, gender, baseline systolic BP, baseline UAER, baseline eGFR, baseline HbA_{1c} and diabetes duration (HR 2.0 (95% CI 1.17-3.45), p=0.012). In the placebo treated group the HR was 2.1 (1.1 to 4.2) compared to 1.6 (0.8 to 3.1) in the candesartan group.

Conclusions: In this cohort of patients with type 2 diabetes and normoalbuminuria from a large intervention study, the CKD classifier was an independent predictor of MA. This may provide a better opportunity to select normoalbuminuric patients for early prevention of diabetic nephropathy as treatment with candesartan seems to mitigate this risk.

Urine Haptoglobin Predicts Development of Diabetic Nephropathy in Patients with Type 2 Diabetes Nishant M. Bhensdadia,[1] Kelly J. Hunt,[1] Maria Lopes-virella,[1,2] Michael Tucker,[1] Benjamin Neely,[1] Michael G. Janech,[1,2] John M. Arthur.[1,2] *[1]Medical University of SC; [2]Ralph H Johnson VA Medical Center.*

Background: Diabetic nephropathy(DN) is the leading cause of End Stage Renal Disease. Urine albumin to creatinine ratio(ACR) is commonly used as a predictor for the development of nephropathy but it is neither sensitive nor specific.

Methods: Liquid chromatography/mass spectrometry was performed on urine of 8 normoalbuminuric patients with type 2 diabetes(T2DM) from the VA Diabetes Trial(VADT) to identify candidate markers for loss of renal function. Verification of the ability to predict the future development of DN was done for 7 candidate markers by selective reaction monitoring(SRM) in urine from 30 patients. Finally we measured the concentration of the leading candidate, haptoglobin, by ELISA in 204 patients to determine the ability of haptoglobin to creatinine ratio(HCR) to predict early renal functional decline(ERFD) (≥3.3% eGFR decline per year).

Results: Proteomic analysis identified 24 candidate biomarkers to predict loss of renal function. Verification of 7 candidates (haptoglobin, angiotensinogen, agrin, mannan-binding lectin serine protease 2, LAMP-2, NGAL and uromodulin) by SRM in 30 patient's urine showed haptoglobin, angiotensinogen and NGAL predict ERFD. HCR was predictive of ERFD in 204 patients with eGFR≥60 ml/min and ACR<300 mg/g. In separate models comparing the highest to lowest tertile, the odds ratio for having ERFD was 2.70 (95% CI: 1.15, 6.32) for HCR and 2.50 (1.14, 5.48) for ACR after adjusting for treatment group and

use of ACE inhibitors. Although both HCR and ACR predicted the outcome, the Spearman rank correlation between them was only 0.25 suggesting that the two biomarkers reflect different pathophysiologic processes.

Conclusions: We identified urine HCR as a new biomarker which can predict ERFD in T2DM prior to the development of macroalbuminuria or reduced GFR. HCR appears equivalent to, but independent of ACR as a predictor; therefore, the discriminatory power of models that combine the two biomarkers may be superior to that of models using one biomarker. The clinical use of HCR may enable better prediction of patients at risk for adverse renal outcomes.

TH-PO509

Copeptin as Biomarker for Cardiovascular and All-Cause Mortality in Type 2 Diabetes (ZODIAC-31) Ineke J. Riphagen,[1] Wendy E. Boertien,[1] Alaa Alkhalaf,[2] Nanne Kleefstra,[1,2] Ron T. Gansevoort,[1] Klaas Groenier,[2,3] Kornelis J. Van Hateren,[2] Joachim Struck,[4] Gerjan Navis,[1] Henk Bilo,[1,2] Stephan J.L. Bakker.[1] *[1]Internal Medicine, UMC, Groningen, Netherlands; [2]Diabetes Centre, Isala Clinics, Zwolle, Netherlands; [3]Gerenal Practice, UMC, Groningen, Netherlands; [4]BRAHMS GmbH, Thermo Fischer Scientific, Hennigsdorf, Germany.*

Background: Copeptin, a surrogate marker for vasopressin, is associated with renal function and albuminuria and has been reported to be of prognostic value in type 2 diabetes (DM2) patients with acute cardiovascular (CV) events. It is not known whether copeptin is associated with outcome in stable DM2 patients. We investigated this issue in a cohort of community dwelling out-patients.

Methods: Patients with DM2 participating in the observational Zwolle Outpatient Project Integrating Available Care (ZODIAC) study were included. Cox regression analyses were used to assess the relation of baseline copeptin levels with CV and all-cause mortality.

Results: We included 1,195 patients (age 67±12 yrs,44% male). Baseline copeptin levels (median [IQR]; 5.4 [3.1-9.6] pmol/L) were associated with eGFR (r =-0.14, p<0.01) and albumin-to-creatinine ratio (ACR) (r=0.13, p<0.01). After median follow-up for 5.9 [IQR 3.2-10.1] yrs, 345 patients died (29%), with 148 CV deaths (12%). In univariate cox regression analyses, log(2) copeptin was significantly associated with CV (HR(95%CI)=1.74(1.42-1.74), p<0.001) and all-cause mortality (1.57(1.42-1.74), p<0.001). These associations remained significant after adjustment for age, gender, BMI, smoking, systolic blood pressure, cholesterol-HDL ratio, duration of diabetes, HbA_{1c}, ACE inhibitors/ARB, history of CV diseases, eGFR, and log ACR both for CV (HR=1.24(1.05-1.46), p=0.01) and all-cause mortality (1.25(1.11-1.39), p<0.001).

Conclusions: In stable DM2 patients, we found copeptin to be associated with CV and all-cause mortality independent of CV risk factors, eGFR, and ACR. Intervention studies should show whether the high CV risk in patients with DM2 can be reduced by suppression of vasopressin, e.g. by increasing water intake.

Bilirubin and Protection against Progression of Diabetic Nephropathy Ineke J. Riphagen,[1] Petronella E. Deetman,[1] Stephan J.L. Bakker,[1] Gerjan Navis,[1] Mark E. Cooper,[2] Julia Lewis,[3] Dick de Zeeuw,[1] Hiddo Jan Lambers Heerspink.[1] *[1]Clinical Pharmacology and Internal Medicine, UMC, Groningen, Netherlands; [2]Baker Heart Institute, Melbourne, Victoria, Australia; [3]Nephrology, Vanderbilt University, Nashville, TN.*

Background: Serum bilirubin is a potent endogenous antioxidant found to protect against progression of diabetic nephropathy (DN) in rodents. In humans, cross-sectional studies show an inverse relation between bilirubin and DN. We aimed to prospectively investigate this relation in a post-hoc analysis of the Reduction of Endpoints in Non insulin dependent diabetes mellitus with the Angiotensin II Antagonist Losartan (RENAAL) and Irbesartan Diabetic Nephropathy (IDNT) trials.

Methods: We included patients participating in RENAAL and IDNT trials (evaluating the effect of losartan and irbesartan vs placebo, respectively, on renal outcome in DN). Patients with liver enzymes (ALT, AST, bilirubin) 1.5 times above upper limit of normal were excluded. Cox regression analyses were used to assess the association of baseline serum bilirubin with the combined renal endpoint consisting of doubling of serum creatinine (DSCR) or end-stage renal disease (ESRD) during a median follow-up of ~3 years.

Results: Serum bilirubin was available for 1,498 patients in RENAAL and 1,707 in IDNT. Mean (SD) baseline bilirubin levels were 0.57 (0.19) and 0.54 (0.21) mg/dL. Age, gender, smoking, total cholesterol, and log albumin-to-creatinine ratio (ACR) were significantly associated with bilirubin levels in both trials. Log(2) transformed bilirubin was significantly inversely associated with the renal endpoint after adjustment for age and gender, with hazard ratios of 0.44 (95% CI 0.35-0.55; p<0.001) in RENAAL and 0.53 (0.45-0.64; p<0.001) in IDNT. The association persisted after further adjustment for race, BMI, smoking, total cholesterol, systolic blood pressure, HbA_{1c}, treatment, eGFR, and log ACR with HR of 0.68 (0.54-0.86; p=0.001) in RENAAL and 0.79 (0.65-0.96; p=0.02) in IDNT.

Conclusions: We found an independent inverse association of serum bilirubin with DSCR/ESRD in both the RENAAL and IDNT trials. These data suggest treatments raising serum bilirubin may confer renoprotective effects.

Relationship between Plasma Copeptin and Degree of Renal Function Impairment in Patients with Type 2 Diabetes María de la Luz Villela,[1] Anel Gomez Garcia,[2] Bengt Lindholm,[4] Elvia Garcia-lopez,[4] Cleto Alvarez Aguilar.[3] *[1]División de Posgrado, Ciencias Médicas y Biológicas, Universidad Michoacana, Morelia, Mexico; [2]Biomedical Research Center of Michoacan, Morelia, Mexico; [3]HGR No. 1, Instituto Mexicano del Seguro Social, Morelia, Mexico; [4]Renal Medicine and Baxter Novum, Karolinska Institutet, Stockholm, Sweden.*

Background: Copeptin, the carboxy-terminal fragment of the vasopressin precursor (pre-pro-vasopressin) is a surrogate marker of plasma levels of vasopressin. Copeptin is a prognostic marker of mortality in chronic heart failure and has been associated with microalbuminuria. Here we investigated the association between plasma copeptin and degree of renal function impairment in patients with type 2 diabetes (T2-DM).

Methods: Plasma copeptin and microalbuminuria were determined in a cross-sectional study of 643 T2-DM patients (mean age 58 ± 10 years) who were classified into six groups: Normal renal function (n=86), and chronic kidney disease (CKD) stages 1-5: CKD 1 (n=33), CKD 2 (n=246), CKD 3 (n=102), CKD 4 (n=34), and CKD 5 (n=142). Medical history, anthropometry, and blood pressure were recorded, and blood glucose, creatinine, lipids, and cystatin-C were determined. The estimated glomerular filtration rate (eGFR) was calculated by Cockroft-Gault equation.

Results: Copeptin correlated negatively with eGFR (r = - 0.445, p <0.0001) and positively with cystatin-C (r = 0.408, p = 0.0001). The highest concentrations of copeptin were found in CKD stage 5 (2.51 ± 1.33 ng / mL). Copeptin differed significantly between patients with normal renal function and CKD stage 1-3 versus CKD stage 5 (p<0.001). In a sub-group of 63 patients undergoing hemodialysis (HD), there was no difference between pre-and post-HD levels of copeptin.

Conclusions: Copeptin is associated with the degree of decline of renal function in T2-DM patients. Prospective studies are required to establish whether this marker vasopressin may be a predictor of progression rate of GFR and cardiovascular complications as well as mortality in T2-DM patients with CKD.

TH-PO512

Circulating Levels of FGF23 and TNFR1 and Their Effects on Progression to ESRD and Mortality Unrelated to ESRD in Type 2 Diabetes Jung Eun Lee, William Walker, Adam Smiles, Jan Skupien, Rita R. Holak, Kevin Patrick Mcdonnell, Jackson Jeong, Andrzej S. Krolewski, Monika A. Niewczas. *Research Division, Joslin Diabetes Center, Boston, MA.*

Background: We have recently reported that circulating Tumor Necrosis Factor Receptor 1 (TNFR1) is a very robust and independent predictor of progression to end-stage renal disease (ESRD) in a prospective study of subjects with type 2 diabetes (T2D) (JASN 2012). In the literature, circulating level of fibroblast growth factor-23 (FGF-23) has been reported to be associated with chronic diabetic complications and progression of chronic kidney disease to ESRD. We aimed to investigate the independent contributions of these two markers on nephropathy progression to ESRD and on mortality unrelated to ESRD in patients with T2D.

Methods: This study included 410 patients with T2D who were followed for 8-12 years and were used previously to examine the effect of TNFR1. Plasma FGF-23 levels detecting C-terminal form were measured at baseline with ELISA. The mean estimated glomerular filtration rate of the study group was 92 ± 31 ml/min per 1.73m^2. Eighty subjects (20%) had overt proteinuria at baseline. During follow-up, 59 patients (14%) developed ESRD and 84 patients (21%) died without ESRD.

Results: Baseline plasma concentrations of both markers, TNFR1 and FGF-23 were higher in subjects who developed ESRD in comparison with subjects that remained alive without ESRD. Cox proportional hazard model revealed that the strong predictive effect of TNFR1 on ESRD was not confounded by FGF-23 levels in the model adjusted by clinical covariates. Increased concentrations of FGF-23 were associated with increased risk of ESRD in the univariate analysis, however the effect of FGF-23 was no longer significant after controlling for TNFR1 (HR 1.25, p=0.15). FGF-23 remained an independent predictor of mortality unrelated to ESRD (HR 1.54, p<0.001).

Conclusions: In our study, TNFR1 was a superior predictor of progression to ESRD over FGF-23. However, circulating levels of FGF-23 had an independent effect on mortality unrelated to ESRD in subjects with T2D.

TH-PO513

FGF-23 and Cardiovascular Outcomes in Type 2 Diabetic with Mild to Moderate Kidney Disease Ana Paula Silva, André Fragoso, Ana Pinho, Cláudia Silva, Nélio Santos, Fatima Rato, Nelson Almeida Tavares, Marilia Faisca, Pedro Neves. *Nefrologia, Hospital de Faro, Portugal.*

Background: Increased levels of fibroblast growth factor 23 (FGF-23) are associated with a greater risk of cardiovascular and renal events. The mechanisms that lie beneath these association are unknown. It is possible that FGF-23 has a direct and harmful action on the heart muscle and the vascular wall. The aim of our study was to evaluate the relationship of FGF-23 and cardiovascular mortality in type 2 diabetics with mild to moderate kidney disease.

Methods: In this prospective study, we included 92 type 2 diabetic patients (f=38 m=54), with a mean age of 62.4 years and a mean eTGF of 42.1 ml/min. At baseline, the patients underwent a complete clinical history and physical examination and several laboratory parameters were analyzed: insulin resistance (HOMA-IR), inflammation (interleukin 6), mineral metabolism (phosphorus (P), PTH, vitamin D), and oxidative stress (oxLDL), adiponectin and eTFG. We evaluated the mean arterial pressure (MAP) and also the pulse pressure (PP), and the left ventricular mass index (LVMI) was calculated using the Penn convention criteria. We divided the population in 3 groups, according to the FGF-23 tertiles. GI (n=29) FGF-23 <65.4rU/mL; GII (n= 32) - FGF-23 >65.5 and < 168.6 rU/mL; GIII (n=31) FGF-23 ≥ 168.7 rU/mL.

Results: We found that G=III patients were older (p=0.0001) and showed higher levels of PTH (p=0.0001), IL6 (p=0.0001), oxLDL (p=0.0001), HOMA-IR (p=0.0001), LVMI (p= 0.042), MAP (p= 0.042), PP (p=0.0001) and lower levels of 25 (OH)D3 (p= 0.0001), adiponectin (p=0.0001) and eTFG (p=0.0001) when compared with the other groups. Using the Kaplan Meier analysis we found that the survival of the GI, GII, and GIII at 54 months was respectively: 100%, 92.8 %, 14.5% (Log-rank = 22.3 p=0.0001).

Conclusions: In our study, elevated levels of FGF-23 are associated with cardiovascular mortality in type 2 diabetics with mild to moderate kidney disease. Further studies are needed to elucidate these potential mechanisms and if an early intervention regarding the FGF-23 will be associated with improved outcomes in our patients.

Funding: NIDDK Support

TH-PO514

FGF-23 and Resistin: Are the New Predictors of Mortality Cardiovascular in Type 2 Diabetic? Ana Paula Silva, André Fragoso, Ana Pinho, Cláudia Silva, Nélio Santos, Nelson Almeida Tavares, Pedro Neves. *Nefrologia, Hospital de Faro, Portugal.*

Background: Cardiovascular disease is the primary cause of morbidity and premature mortality in chronic kidney disease. More recent data suggest that the mineral metabolism and adipokines, may play a role in the development of cardiovascular disease in chronic kidney disease The purpose of this study was to evaluate the role of new biomarkers on the cardiovascular mortality in type 2 diabetic with mild to moderate kidney disease.

Methods: In this cross-sectional study, we included 78 type 2 diabetic patients (f=30 m=48), mean age 61,9 years, mean eGFR 43,5ml/min. At baseline, the patients underwent a complete clinical history and physical examination and several laboratory parameters were analyzed: mineral metabolism (phosphorus (P), PTH, fibroblast growth factor 23 (FGF-23), vitamin D),oxidative stress (oxLDL), adipokines (visfatin, resistin). Our population was divided in two groups. G I (n=65) survivors and G II (n= 13)non survivors (CVD).

Results: We found that G=II II was older (73 *vs* 59.6 years p=0.0001) showed higher levels of P (5.2 *vs* 4.1 mg/dL p=0.0001), PTH (243.9 *vs* 114.7 mg/dL p=0.0001), FGF -23 (502.7 *vs* 118.4 Ru/mL p=0.0001), resistin (9.0 *vs* 5.3 pg/mL p=0.0001), visfatin (143.5 *vs* 43.8 pg/mL p=0.0001), LVMI (135.2 vs 97.8 g/m^2 p=0.0001), oxLDL (78.9 vs 38.3 U/L p=0.0001), and G II also showed lower levels of eGRF (23.6 vs 45.5 ml/min p=0.001), 25 (OH)D3 (9.3 vs 21.4 ng/mL p= 0.0001). In multivariate Cox proportional hazard stepwise LR to identify independent risk factors of cardiovascular mortality. FGF-23 and resistin were found to predict patient survival (HR= 0.2,95% CI, 0.4 to 0.6, p=0.015)and (HR= 40.7, 95% CI, 20.1 to 65, p=0.0001),respectively. ROC curve analysis showed that FGF-23 (AUC=0.962 p=0.001) and resistin (AUC=0.774 p=0.002) are predictors of mortality cardiovascular in type 2 diabetic with mild to moderate kidney disease.

Conclusions: In our study we found that FGF-23 and resistin are new biomarkers predictors of mortality cardiovascular in type 2 diabetic with mild to moderate kidney disease.

Funding: NIDDK Support

TH-PO515

Lower Magnesium and FGF-23 Level: New Predictors of Pulse Pressure in Chronic Kidney Disease Diabetic Patients André Fragoso, Ana Pinho, Anabela Malho, Hercilia Lopes Quintas Martins, Cláudia Silva, Nélio Santos, Ana Paula Silva, Pedro Neves. *Nephrology Department, Hospital de Faro, Faro, Portugal.*

Background: It is well documented that large-artery stiffness is the main determinant of Pulse Pressure (PP) and several epidemiological studies have shown that PP is an independent risk factor for cardiovascular morbidity and mortality. Magnesium deficiency has been associated with increased risk for arterial stiffness. The purpose of this study was to evaluate the relationship between magnesium deficiency with increased arterial stiffness.

Methods: In a cross-sectional study, we included 80 type 2 diabetic patients (63.75% males) with CKD stages 3 and 4. The mean age was 65.7 years and the mean eGFR was 49.8ml/min. We analyzed mineral metabolism (iPTH, 25(OH)D3, FGF23, osteocalcin, phosphorus, calcium, magnesium), inflammation (interleukin6), oxidative stress (malonaldehyde), insulin resistance (HOMA-IR) and lipid profile. Our population was divided in two groups:G-1(PP≥50mmHg, n=34) and G-2 (PP<50mmHg, n=46).

Results: We found that G-1 patients showed lower calcium (9.12 vs 9.56mg/dl p=0.004), GFR (41.64 vs 55.81ml/min p=0.001), magnesium (1.79 vs 2.50mg/dl p=0.000), osteocalcin (4.45 vs 15.62ng/ml p=0.000), 25(OH)D3 (12.51 vs 24.73ng/ml p=0.001), and higher PTH (162.51 vs 102.76 µg/ml p=0.001), FGF23 (214.32 vs 80.25ng/ml p=0.0001), malonaldehyde (4.46 vs 3.30mg/dl p=0.0001), Interleukin6 (7.45 vs 5.29pg/ml p=0.001) and HOMA-IR (4.22 vs 3.01 p=0.033). No differences were found between the two groups regarding age, duration of disease, Hg, HgA1c, cholesterol and phosphorus. In a multivariate analysis, we found that FGF23 and magnesium independently influenced the PP (OR=3.5, 95% CI, 0.1 to 7, p=0.045) and (OR=- 99.1, 95% CI, -100 to – 39.7, p= 0.028), respectively.

Conclusions: In our diabetic population with early stages of CKD the FGF23 and lower magnesium levels were associated with higher PP levels, a known marker of cardiovascular mortality. Further studies are needed not only to better understand the relationship between FGF-23 levels and PP but also to ascertain if magnesium correction in CKD diabetic patients would reduce PP and consequently cardiovascular events.

TH-PO516

Nephronectin Is a Novel Protein Associated with Diabetic Nephropathy Shinya Nakatani,[1,2] Eiji Ishimura,[1] Akihiro Tsuda,[2] Yu Tateishi,[2] Shinya Fukumoto,[2] Masaaki Inaba.[2] *[1]Nephrology, Osaka City University Graduate School of Medicine, Osaka, Japan; [2]Metabolism, Endocrinology, and Molecular Medicine, Osaka City University Graduate School of Medicine, Osaka, Japan.*

Background: Comparative proteome analysis is a new technology which can be used to identify disease-specific proteins, and is considered to be a powerful diagnostic tool for the definition of the onset, progression, and prognosis of human diseases. In the present study, we performed proteome analysis of diabetic glomeruli in human autopsy cases to identify new proteins which are related to diabetic nephropathy.

Methods: We performed proteome analysis for lasermicrodissected glomeruli from paraffin-embedded tissues of patients with diabetic nephropathy (n=10) and those of non-diabetic patients (n=10). Immunohistochemistry of identified proteins of renal biopsy was performed in a total of 190 patients.

Results: There were 55 up-regulated and 45 down-regulated proteins that were differently expressed in glomeruli of diabetic patients, compared to those of non-diabetic patients. Nephronectin, which is an integrin α8β1 ligand and functions as assembly of extracellular matrix, was found to be up-regulated. Nephronectin was strongly expressed in the mesangial matrix expansion of diabetic nephropathy, but was not significantly expressed in glomeruli from other kidney diseases. The percentage of nephronectin-positive areas in the glomeruli from diabetic nephropathy (15±4.7%, n=18) was significantly higher than that for any other kidney diseases[IgA nephropathy; 4.8±2.9% (n=46), membranous nephropathy; 6.0±3.9% (n=30), minimal change nephrotic syndrome; 4.1±2.0% (n=28), membranoproliferative glomerulonephritis; 7.0±5.7% (n=14), lupus nephritis; 4.0±3.0% (n=11), crescentic glomerulonephritis; 7.6±3.4% (n=9), focal segmental glomerulosclerosis; 4.5±3.3% (n=9), hypertensive nephrosclerosis; 8.1±4.7% (n=8) and others; 4.7±2.0% (n=17), p<0.05 respectively].

Conclusions: The present study demonstrated that nephronectin is a novel protein of increased extracellular matrix in diabetic glomerulosclerosis, and also suggests that nephronectin staining could be a novel, useful tool for the diagnosis of diabetic nephropathy.

TH-PO517

Expression of Podocyte-Associated Molecules in Various Stages of Diabetic Nephropathy and in Pre Diabetes Francisco José Veríssimo Veronese,[1] Jonathan Fraportti do Nascimento,[1] Patrícia Garcia Rodrigues,[1] Gabriel Joelsons,[1] Luis Henrique Canani.[2] *[1]Nephrology, Hospital de Clínicas de Porto Alegre, Universidade Federal do Rio Grande do Sul, Porto Alegre, RS, Brazil; [2]Endocrinology, Hospital de Clínicas de Porto Alegre, Universidade Federal do Rio Grande do Sul, Porto Alegre, RS, Brazil.*

Background: This study investigated the mRNA profile of podocyte-associated molecules (PAM) in the different stages of diabetic nephropathy (DN) and in pre diabetes (PD).

Methods: Fifty-seven diabetic patients (DM) were included: normoalbuminuric, NA (n=35), microalbuminuric, MI (n=14) and macroalbuminuric, MA (n=8); and also 19 patients with PD and 10 healthy individuals (controls, C). Nephrin (nephr), podocin (pod), podocalyxin (pdx), synaptopodin (syn), TRPC6, and alpha-actinin 4 (actin4) mRNA were quantified by real time PCR in the urinary sediment; TGFbeta (TGFb) was also measured. Gene transcripts were correlated with albuminuria, glomerular filtration rate (GFR) and glycemic control (HbA1C); mRNA was log transformed (median/IIQ).

Results: Comparing the five groups, PAM mRNA did not shown a good correlation with level of albuminuria. Only nephr was higher in NA (vs. PD, p=0.046), pdx was higher in NA (vs. C, p=0.028), syn was higher in MA (vs. PD, p=0.033) and in NA (vs. PD, p=0.04), and Actin4 was higher in NA (vs. C, p=0.023). However, comparing the patients by diabetes status (yes/no), almost all genes were significantly higher expressed in DM (table 1). mRNA of nephr, pod, pdx, syn and TRPC6 were associated with poor glycemic control (p<0.05), but did not correlate with GFR.

PAM mRNA in diabetics and nondiabetics

Urinary mRNA	Non diabetic (n=34)	Diabetic (n=57)	P
Nephr	2.00(1.24-2.65)	3.08(1.86-3.89)	0.001
Pod	2.14(1.46-2.96)	2.66(1.81-3.98)	0.045
Pdx	2.17(1.28-3.04)	3.07(2.09-3.80)	0.002
Syn	1.81(1.29-2.32)	2.96(1.77-3.39)	0.001
Actin4	2.48(1.77-3.18)	2.90(2.00-3.99)	0.048
TRPC6	1.56(1.02-2.61)	2.76(1.66-3.94)	0.008
TGFb	2.49(1.84-3.29)	2.76(2.09-3.85)	0.121

Conclusions: A higher expression of PAM was found in DM, even in the stage of normoabuminuria, suggesting podocyte damage and podocyturia. Poor glycemic control correlated with higher amounts of PAM mRNA. TGFb mRNA in DM did not differ from non-DM, probably due to less advanced disease.

TH-PO518

Clinical Validation of the Novel Panel of Urinary Biomarkers to Monitor the Progression of Type 2 Diabetic Nephropathy Tzu-ling Tseng,[1] Wei-ya Lin,[1] Yen-Peng Li,[1] Kuo-hsiung Shu,[2] Chi-Hung Cheng,[2] Han-hsiang Chen,[3] Chih-Jen Wu,[3] Chwei-Shiun Yang,[4] Yuh-feng Lin,[5] Jin-Shuen Chen.[5] *[1]Industrial Technology Research Institute; [2]Taichung Veterans General Hospital; [3]Mackay Memorial Hospital; [4]Cathay General Hospital; [5]Tri-Service General Hospital, Taiwan.*

Background: The development of new markers is critical to improving the diagnosis, staging and treatment of diabetic nephropathy (DN). In this study, we conduct a clinical validation study of a urinary marker panel, including Alpha2-HS-glycoprotein precursor (AHSG), alpha-1-antitrypsin (A1AT) and alpha-1 acid glycoprotein 1 (AGP1).

Methods: Urine samples were collected from subjects included healthy control (HC), type 2 diabetic mellitus (DM) and DN. Group DN were further subgrouped by microalbuminuria and macroalbuminuria.at participating medical centers of the Taiwan Renal Biomarker Consortium. In the discovery phase, a series of biomarkers were identified with by differential proteomics platforms established at ITRI. Western blot of urine and immunohistochemical staining of renal tissues were evaluated. In the next validation phase, the assay of candidate biomarkers was performed by ELISA in a large scale, +300 samples.

Results: With respect to immunohistochemistry, increased A1AT, AHSG and AGP1 staining were evident in DN renal tissues. Evaluating the performance of these three markers in combination revealed an apparent staging effect with high sensitivity and specificity for discriminating between early and late stages of DN. Moreover, the three proteins in this DN biomarker panel were assigned to the same functional network with the insulin receptor as one of the major hubs. Therefore, these three markers may be not only statistically associated with each other but also functionally related to each other.

Conclusions: We have successfully developed a novel biomarker panel in combination of diagnostic algorithms with three urinary markers, AHSG, A1AT and AGP. Combination of three biomarkers is superior in function to a single marker for the staging of DN. An on-going longitudinal study will further elucidate applications of the biomarker panel in disease diagnosis and monitoring.

TH-PO519

Urinary Exosomal WT1 Is Increased in T1DM Patients with Microalbuminuria Marcela Ururahy,[1,2] Karla Souza,[1] Yonara Monique Oliveira,[1] Melina Bezerra Loureiro,[1] Heglayne P. Silva,[1] Magali Araujo,[2] Francisco Paulo Freire Neto,[1] Joao F. Bezerra,[1] Ricardo Fernando Arrais,[3] Rosario D.C. Hirata,[4] Mario Hiroyuki Hirata,[4] Maria Das Graças Almeida,[1] Adriana Augusto de Rezende,[1] Sonia Q. Doi.[2] *[1]Clinical and Toxicological Analysis, UFRN, Natal, RN, Brazil; [2]Medicine, Uniformed Services University, Bethesda, MD; [3]Pediatrics, UFRN, Natal, RN, Brazil; [4]Clinical and Toxicological Analysis, USP, Sao Paulo, SP, Brazil.*

Background: Urinary exosomes are released by cells from every segment of the nephron, including podocytes, and may be a source of biomarkers. The Wilm's Tumor-1 (WT1), a marker of podocytes, has been found in urinary exosomes in various glomerular diseases. Using the bovine growth hormone transgenic (bGH) mouse, a model of glomerulosclerosis, we have shown that WT1 protein was decreased in the kidney and increased in exosomes of bGH compared to control mice, suggesting that increased exosomal WT1 is associated with glomerular podocyte damage.

Methods: Urine samples were collected from 13 patients with type 1 diabetes (T1DM) and 8 normoglycemic (NG) subjects, age 5-17 y.o. to measure urinary albumin/creatinine ratio (ACR) and WT1 in exosomes isolated by ultracentrifugation. Relative quantification of WT1 was obtained by immunobloting and densitometry of WT1 bands normalized to urinary creatinine.

Results: Five of 13 T1DM patients were microalbuminuric (MALB, ACR≥30mg/g) and 8 had ACR<30mg/g (N-MALB). The mean value of WT1/creatinine was significantly increased in MALB compared to both N-MALB and NG groups (Table 1). WT1 band was strongly positive in 4 out of 5 MALB patients. Conversely, only 1 out of 8 N-MALB patients showed a strong WT1 signal.

TABLE 1 – Relative quantification of exosomal WT1 according to ACR

	NG	N-MALB	MALB
ACR (mg/g of creatinine)	7.8 (6.7-12.9)	10.8 (8.2-22.1)	45.6 (38.4-128.7)*
WT1/creatinine	0.05±0.02	0.21±0.15	0.87±0.12*

Results are mean±SEM or (median interquartile range). * significant vs. NG and N-MALB ($p<0.05$).

Conclusions: This is the first demonstration that urinary exosomal WT1 can distinguish T1DM patients with from those without microalbuminuria. We are currently conducting a longitudinal study to determine whether exosomal WT1 precedes the increase in ACR.

Regulation of Urine Metabolomics in Diabetic Kidney Disease Bethany E. Karl, Joachim H. Ix, Robert K. Naviaux, Kumar Sharma. *Department of Medicine, University of California San Diego, San Diego, CA.*

Background: Analysis of urine metabolomic data in patients with diabetic kidney disease (DKD) may lead to better understanding of its pathophysiology to direct development of therapeutics, isolate biomarkers and determine risk of chronic disease or progression.

Methods: 106 diabetic patients with CKD (eGFR<75ml/min/m²), 52 diabetic patients without CKD and 24 controls completed 24hour urine collections after which targeted urine metabolites were measured by GC/MS. The targeted metabolites were selected for their role in inborn and acquired disorders of intermediary metabolism. This same metabolite panel was measured in the plasma of a subset of the DKD (n=12) and control (n=13) groups. Fractional excretions of each metabolite were then calculated.

Results: Mean serum creatinine in the DKD group was 2.18 mg/dl (+/- 1.05) and 0.85 (+/-0.13) in controls. Statistical analysis revealed 9 metabolites to correlate significantly with eGFR ($P<0.007$). These were in lower concentration in DKD compared to the other two groups. Of the 9 metabolites, only 3 had calculable fractional excretions including citric acid, glycolic acid and 3-hydroxyisobutyric acid. The other 6: aconitic acid, 3-hydroxyisovaleric acid, 3-methyl-adipic acid, tiglylglycine, uracil, and 2-ethyl-3-hydroxypropionic acid, had undetectable concentrations in either plasma or urine. In the DKD group, the median fractional excretion of citric acid was decreased over 40-fold ($p=0.0005$) while the fractional excretions of both glycolic acid and 3-hydroxyisobutyric acid were increased with difference between means of 36% ($p=0.01$) and 14% ($p=0.003$) respectively.

Conclusions: To our knowledge this is the first evaluation of fractional excretion of metabolites in the urine metabolome in DKD vs. controls. Though all 9 of the measured urinary metabolites are lower in DKD compared to those without, the fractional excretions were surprisingly varied. The results support renal excretion differences for individual metabolites which do not simply reflect differences in serum levels.

Funding: NIDDK Support

TH-PO521

Proximal and Distal Tubular Markers in Patients with Type 1 Diabetes Bernt Johan von Scholten, Simone Theilade, Maria Lajer, Christel Joergensen, Stine Nielsen, Peter Rossing. *Steno Diabetes Center, Gentofte, Denmark.*

Background: The isoenzymes alpha and pi glutathione S-transferase (α- and π-GST) are secreted from proximal and distal renal tubules, respectively. Enzyme levels are elevated in type 2 diabetes and acute tubular damage. We evaluate if levels of α- and π-GST were elevated and associated with albuminuria in patients with type 1 diabetes.

Methods: Cross sectional study including 187 patients and 16 controls (C). Patients were (mean±SD) 53±14 years, with 29±18 years diabetes duration, 123(66%) male. Normoalbuminuria (<30mg/24-h) (Na) was present in 54(29%), microalbuminuria (30-300mg/24-h) (Mi) in 63(34%) and macroalbuminuaria (>300mg/24-h) (Ma) in 70(37%). Controls were 40±12 years and 11(69%) were male. Morning spot urines were analysed with ELISA (Argutus Medical).

Results: Median(range) π-GST was in C, Na, Mi and Ma 9.4(1.5-77.5), 9.3(0.3-172.0), 9.0(0.3-340) and 6.1(0.3-138) ug/l, respectively ($p=0.191$). Alpha-GST was 9.3(0.3-50.5), 4.3(0.3-50.8), 2.5(0.3-170.8) and 3.0(0.3-18.3) ug/l, respectively ($p=0.025$). Pi-GST was lower in men *vs.* women 7.5(0.3-90.3) *vs.* 15.0(0.8-340.0) ug/l; ($p<0.001$). Alpha- and π-GST-levels were similar in patients with and without cardiovascular disease ($p>0.05$). In all patients *vs.* C, levels of α-GST were 3.0(0.3-170.8) *vs.* 9.3(0.3-50.5) ug/l, ($p<0.05$), while π-GST levels were 8.8(0.3-340.0) *vs.* 9.4(1.5-77.5) ug/l in C, ($p>0.05$). Alpha- and π-GST correlated with each other ($r=0.357$; $p<0.001$), and α-GST correlated with HbA_{1c} ($r=0.179$; $p=0.001$) and eGFR ($r=0.169$; $p=0.016$); whereas π-GST correlated with none of these covariates ($p>0.05$). Neither GST isoenzymes correlated with age, diabetes duration, total cholesterol, 24-h systolic blood pressure or urinary albumin excretion rate ($p>0.05$).

Conclusions: Urinary levels of π-GST were similar in controls and patients regardless of albuminuria degree, whereas urinary levels of α-GST were lower in patients and decreased further with increasing albuminuria degree. These findings of altered tubular marker levels in patients with type 1 diabetes with or without chronic renal damage are in contrast to findings in patients with acute tubular damage where increased levels of the markers are present.

TH-PO522

Neutrophil Gelatinase-Associated Lipokalin and Cathepsin as an Early Predictors of Kidney Dysfunction in Diabetic Children Jacek Zachwieja,[1] Jolanta Soltysiak,[1] Danuta Ostalska-Nowicka,[1] Piotr Fichna.[2] *[1]Department of Pediatric Nephrology, Poznan University of Medical Sciences, Poznan, Poland; [2]Department of Pediatric Diabetes and Obesity, Poznan University of Medical Sciences, Poznan, Poland.*

Background: One of the most dangerous complications of diabetes mellitus (DM) is diabetic kidney disease (DKD). At present, the measurement of albuminuria and glomerular filtration is used as a standardized non-invasive test for the diagnosis of DKD. However, early renal dysfunction may be overlooked despite using that method. On the other hand, the gold standard in DKD detection—that is, renal biopsy—is highly invasive.The aim of this study was to evaluate the level of neutrophil-gelatinase associated lipocalin in serum (sNGAL) and in urine (uNGAL) as well as urinary excretion of cathepsin L (uCathL) and angiotensinogen (uAGT) in children with type 1 DM (DM1) considered as not presenting DKD.

Methods: The study group consisted of 63 children with DM1 (28 males and 35 females) with mean age of 13.46±2.95 yr. The average time of DM1 treatment was 5.16±3.39 yr. All patients presented a normal albumin/creatinine ratio(ACR< 30 mg/g) and normal eGFR, based on cystatin C (>90 ml/min/1.73m²).

Results: Children with DM1 compared to controls showed significantly higher levels of uNGAL (43.02±45.68 vs. 6.85±6.05 ng/ml; p<0.001), as well as lower sNGAL (109.96±50.06vs. 151.34±53.95 ng/ml; p<0.001) and uCathL (4.32±1.61 vs 5.18±0.95 ng/ml).These changes were observed even in children with optimal glycemic control (HbA1c<7.5%), treated for less than 5 years. uAGT levels were similar in both groups

(0.148±0.474vs. 0.00 ng/ml; p=0.628). A possitive correlations between uNGAL and ACR (r=0.313; p=0.013) and between uCathL and eGFR (r=0.501; p=0.034) were found. HbA1c levels showed a positive correlation with eGFR (r=0.399; p=0.014) and with ACR (r=0.268; p=0.034).

Conclusions: Normal-range albuminuria and normal eGFR do not exclude DKD, if defined as changes of sNGAL, uNGAL and uCathL concentration. These changes may occur even in children with relatively short lasting diabetes and with optimal glycemic control. Our study highlights the value of sNGAL, uNGAL and uCathL as potential markers for early DKD detection.

TH-PO523

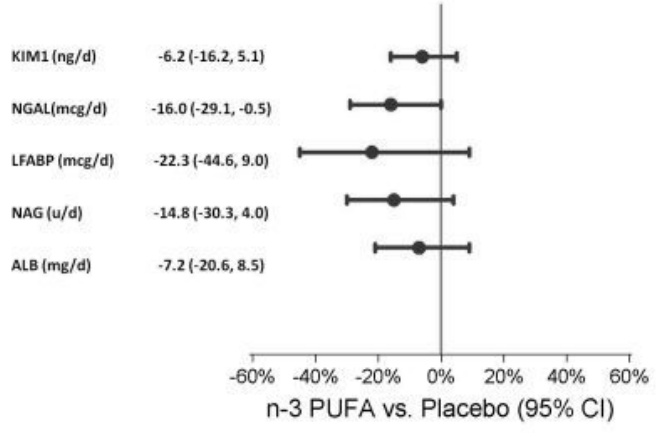
The Effects of N–3 Polyunsaturated Fatty Acid Supplementation on Biomarkers of Kidney Injury in Adults with Diabetes: Results of the GO-FISH Trial Edgar R. Miller, Stephen P. Juraschek, Cheryl A. Anderson, Sharon Turban, Eliseo Guallar, Lawrence J. Appel. *Medicine, Johns Hopkins University, Baltimore, MD.*

Background: The effect of n–3 long-chain polyunsaturated fatty acid supplementation (n-3 PUFA) on kidney disease is uncertain.

Methods: We conducted a randomized controlled trial to test the effects of n-3 PUFA supplementation on markers of kidney injury in patients with adult-onset diabetes and ≥ trace dipstick proteinuria. Participants were randomized in a 2-period cross-over trial to 4 g/d of n-3 PUFA or placebo. Each period lasted 6 weeks separated by a 2-week wash-out. Outcomes were urine markers of kidney injury [albumin, kidney injury molecule-1 (KIM-1), N-acetyl β-D-glucosaminidase (NAG), neutrophil gelatinase-associated lipocalin (NGAL) and liver fatty acid-binding protein (LFABP)] and serum markers of eGFR [cystatin C, β2-microglobulin, creatinine].

Results: Of the 31 participants, 29 finished both periods (55% were female, 61% were African-American, mean age was 67 years, 68% on medications that block the renin-angiotensin-aldosterone system (RAAS). At baseline, median eGFR was 75 ml/min/1.73m^2 and median 24-hour urine albumin excretion was 161 mg/d. By repeated measures analyses, n-3 PUFA lowered 24-hour urine excretion of NGAL by 16% (95% CI-29.1%, -0.5%) compared with placebo. There was a consistent trend of reduction in each of the other urine biomarkers.

Figure. Difference in urine markers of kidney injury in n-3 PUFA compared with placebo periods



There was no effect on serum markers of eGFR. In a secondary analysis, there was a significant decrease in 24-hour excretion of albumin, NGAL, LFABP, and NAG, in the subgroup of participants on RAAS blockers.

Conclusions: These results highlight the potential role of n-3 PUFA supplementation as a means to prevent further kidney injury in patients with diabetes and evidence of kidney disease. Long-term trials with clinical outcomes are warranted.

TH-PO524

Serum Albumin Globulin Ratio as a Predictor of Worsening Renal Function in the Diabetic Population Basem Azab, Suchita J. Mehta, Neeraj N. Shah, Deepak Asti, Morton J. Kleiner, Suzanne E. El Sayegh. *Staten Island University Hospital, Staten Island, NY.*

Background: Hypoalbuminemia has been associated with worse renal function in prior studies. The use of serum albumin globulin ratio (AGR) as a predictor for worsening renal function among diabetics has not been elucidated.

Methods: Our study included 334 diabetics followed at our clinic from 2007 to 2009. We divided them into quartiles based on the 2007 AGR. The primary outcome was a decrease of GFR > 12 with the last (2009) GFR < 60ml/minute. Linear & logistic regression models using respectively GFR at year 3 & primary outcome as the dependent variables were constructed. Additional analysis was performed after exclusion of patients with albumin<3gm/dl.

Results: Mean rate of decline of GFR per year was -0.11 ml/min/year (95% CI +0.69 to -0.91). 1st AGR quartile had a rate of decline of -1.97 ml/min/year (95% CI -0.78 to -3.17), while the 2nd, 3rd & 4th quartiles had GFR change of +1.06, +0.46 & +0.16 ml/min/year respectively. Linear regression with GFR at year 3 as the dependent and GFR at year 1 & AGR quartiles as the independent variables yielded coefficients of 9.4 (p=0.007), 7.8 (p=0.026) and 6.9 (p=0.048) of 2nd, 3rd & 4th AGR quartiles relative to 1st quartile, thus illustrating a linear relation between GFR at year 3 and AGR. In multivariate analysis, the coefficients of 2nd & 4th quartile relative to 1st quartile remained significant (p<0.05) at 8.0 & 7.6 respectively. 1st AGR quartile had the highest number of patients with primary outcome (14%) compared to 2nd, 3rd and 4th quartiles (7%, 5% and 4% respectively), with chi-square p of 0.04.

Dropping of GFR according to AGR.

	AGR < 1.10	AGR 1.10-1.25	AGR 1.26-1.42	AGR >1.42
Dropping of GFR > 12 ml/minute/3 years	12/84	6/84	4/83	3/83

Univariate logistic regression analysis showed odds ratio (OR) of 0.23 (p=0.025) of 4th vs. 1st AGR quartile, which persisted in multivariate analysis (OR 0.2, p=0.034) and after exclusion of patients with low albumin (OR 0.26, p=0.046).

Conclusions: Low serum AGR was an independent predictor of lower GFR and a worse renal function over a 3 year follow up period in diabetics. This effect was independent of hypoalbuminemia.

Abnormalities in 24-Hour Plasma Glucose Variation on CKD: Review of Using CGMs Kozi Hosoya, Shu Wakino, Hitoshi Minakuchi, Koichi Hayashi, Hiroshi Itoh. *Internal Medicine, Keio University School of Medicine, Sinjyuku-ku Sinanomati 35, Tokyo, Japan.*

Background: Although CKD patients were complicated with insulin resistance even without diabetes (DM), the more detailed information on temporal change in plasma glucose (PG) has not been reported. Recently, continuous daily plasma glucose (PG) profiles can be monitored by using CGMS (continuous glucose monitoring system). We studied one of CKD patients without diabetes mellitus (DM) using this system.

Methods: We compared various parameters in CGMS between 15 patients of Stage 5 CKD without DM (CKD) and 10 patients with normal renal function (control). The correlations were analyzed with multi-regression analysis (M-RA) and simple-regression analysis (S-RA). CGMS parameters analyzed were as follows; 24-hour average PG (ave-PG), standard deviation (SD) of 24-hour PG, area under the curve (AUC) of 24-hour PG, average PG of sleeping time, SD of PG of sleeping time, the difference between fasting PG and maximum PG for 2-hour postprandial (MAX-PG) (breakfast, lunch, dinner, sum of three meals(S-mesls)), the difference between 2-hour postprandial PG and fasting PG(2-hr PG), and postprandial 2-hour AUC(2-hr AUC) (breakfast, lunch, dinner, S-meals).

Results: Fasting glucose, HbA1c, and GA were not different between CKD and control. However, 24-hour ave-PG, SD of 24-hour PG and AUC of 24-hour PG were significantly higher in CKD than those in control. In 2-hour PG, significant differences in breakfast and sum of all meal were also observed between CKD and control. In 2-hr AUC, we also recognized a significant difference between CKD and control in breakfast, lunch, dinner, and S-meals.By S-RA, SD values were correlated with FFA (free fatty acid) and ave-PG was correlated with GA (Glycated albumin), FFA, and e-GFR. 2-hr PG was correlated with serum total protein, serum calcium, FFA, Hb (hemoglobin) and eGFR, and 2-hr AUC was correlated with GA, FFA, and eGFR. By M-RA, SD, ave-PG, and 2-hr PG were correlated with FFA.

Conclusions: CKD patient without DM have significant postprandial glucose spike. And this variation had strong relationship with FFA metabolism. It can be concluded that this glucose spike contributes to cardiovascular disease in CKD.

TH-PO526

Validation of a Novel Method to Determine the Renal Threshold for Glucose (RT_G) in Untreated and Canagliflozin (CANA)-Treated Subjects with Type 2 Diabetes David Polidori,[1] Sue Sha,[1] Paul Rothenberg,[1] Leona Plum-Mörschel,[2] Tim Heise.[2] *[1]Janssen Research & Development, LLC, Raritan, NJ; [2]Profil Institute for Metabolic Research, Neuss, Germany.*

Background: Nearly all glucose filtered by the kidney is reabsorbed until blood glucose (BG) exceeds RT_G. By inhibiting the sodium glucose co-transporter 2, CANA decreases RT_G, leading to increased urinary glucose excretion (UGE). The established method for determining RT_G requires stepwise hyperglycemic clamps. This study was performed to validate a new method for estimating RT_G using data collected from a mixed-meal tolerance test (MMTT).

Methods: Untreated (N=14) and CANA-treated (100 mg once daily for 8 days; N=14) subjects with type 2 diabetes (mean A1C=8%) underwent an MMTT and a stepwise hyperglycemic procedure on consecutive days. During the MMTT, UGE and BG were measured and the glomerular filtration rate was estimated. $RT_{G:MMTT}$ was estimated based on these data using an extension of the established method for determining $RT_{phosphate}$. During the clamp procedure, UGE rates during the 5 BG clamp steps were measured and $RT_{G:clamp}$ was determined by nonlinear regression. The 2 methods were compared using the concordance correlation coefficient and geometric mean ratio (GMR).

Results: In untreated subjects, the UGE versus BG relationship was well-described by a threshold relationship and CANA left-shifted the relationship (Figure A). There was strong agreement between $RT_{G:MMTT}$ and $RT_{G:clamp}$, with a concordance correlation coefficient

of 0.94 and GMRs (90% confidence interval) of 0.93 (0.89, 0.96) in untreated subjects and 1.03 (0.78, 1.37) in CANA-treated subjects (Figure B). The safety and tolerability of CANA were consistent with previously reported studies.

Conclusions: The effects of CANA on UGE are well-described by lowering RT_G and the new MMTT-based method for estimating RT_G provides good agreement with the clamp method.

Figure. (A) UGE versus BG during the clamps and (B) comparison of $RT_{G:MMTT}$ versus $RT_{G:clamp}$

TH-PO527

Vitamin D Analogue Therapy, Cardiovascular Risk and Kidney Function in Type 1 Diabetic Patients with Diabetic Nephropathy: A Randomized Trial Christel Joergensen,[1] Lise Tarnow,[1,2] Jens Peter Goetze,[2,3] Peter Rossing.[1,2] *[1]Steno Diabetes Center, Denmark; [2]Aarhus University, Aaarhus, Denmark; [3]Rigshospitalet, Denmark.*

Background: Vitamin D is associated with decreased cardiovascular morbidity and mortality and is suggested to have renoprotective effects. ProBNP is a plasma marker for cardiovascular risk and mortality in diabetic patients. Estimates of renal function decline with vitamin D analogue (VDA) therapy. We evaluated the impact of therapy with the VDA paricalcitol on cardiovascular risk and kidney function in patients with type 1 diabetes and diabetic nephropathy.

Methods: Double-blind, placebo controlled, randomized cross-over trial in 45 patients with type 1 diabetes and diabetic nephropathy, all in stable RAAS blockade and diuretic treatment. Paricalcitol (1-2µg/day) and placebo therapy was given in random order for 12 weeks interrupted by one month of wash-out. Before and after each treatment period the primary and secondary endpoint, a change in plasma proBNP concentration and urinary albumin excretion rate (UAER) from three consecutive 24h urines, were measured. End of therapy endpoints were estimated glomerular filtration rate (eGFR) and measured GFR (^{51}Cr-EDTA plasma clearance).

Results: At baseline mean (SD) age was 56(9) years, 32(71%) subjects were men, mean HbA_{1c} was 70(9)mmol/mol, mean eGFR was 47(15)ml/min/1.73m^2 and mean 24h blood pressure was 135(17)/76(11)mmHg. None of the patients had heart failure. Compared to placebo Paricalcitol had no significant effect on plasma proBNP concentrations, p=0.6. During paricalcitol therapy mean UAER was significantly reduced by 19% (range 1-35%) from 127mg/24h, $p = 0.019$ for comparison with change during placebo. eGFR was significantly lower at the end of paricalcitol therapy compared to placebo, 41 vs. 46ml/min/1.73m^2 respectively, p<0.001, whereas only a non significant reduction of 1.5ml/min/1.73m^2, p=0.2,was observed in GFR.

Conclusions: Therapy with the VDA paricalcitol has no effect on plasma proBNP concentrations but significantly lowers albuminuria in type 1 diabetic patients with diabetic nephropathy. Although estimates of GFR decline, "true" GFR is unchanged, suggesting paricalcitol therapy may affect creatinine handling.

Efficacy and Safety of the Glucagon-Like Peptide-1 Analogue Liraglutide in Diabetic Patients on Hemodialysis Masao Toyoda, Moritsugu Kimura, Tomoya Umezono, Daisuke Suzuki, Masafumi Fukagawa. *Division of Nephrology and Metabolism, Department of Internal Medicine, Tokai University School of Medicine, Isehara, Kanagawa, Japan.*

Background: Despite the development of several oral hypoglycemic agents and insulin preparations, glycemic control in hemodialysis (HD) patients still remains a task of great difficulty with high risk of hypoglycemia. Liraglutide (LG), a recently developed glucagon-like peptide-1 analogue, lowers the blood sugar levels through a glucose-dependent insulin secretagogue effect, thus with lower risk of hypoglycemia. Nevertheless, efficacy and safety of LG in HD patients have not been fully evaluated yet. In the present study, Japanese diabetes patients who were on HD and switched to LG from basal-bolus therapy or pre-mixed insulin therapy were evaluated to determine the efficacy of LG.

Methods: Blood C-peptide levels in these patients were measured, and patients without severe defects in endogenous insulin secretion were switched to LG. In these patients, we measured HbA_1c levels, dry weight, body weight gain between dialysis treatments (Δ BW), and number of hypoglycemic episodes at the time of switching (pre-LG) and 3 months later (post-LG). Further, the impact of the switch on the quality of life was investigated using a questionnaire.

Results: HbA_1c levels significantly improved from 6.0±0.6 at pre-LG to 5.8±0.6 at 3 months post-LG (p<0.05). Further, the dry weight and ΔBW decreased significantly after the switch. The number of hypoglycemic episodes also decreased after switching.

Conclusions: It is possible for LG to improve HbA_1c without increasing body weight and frequency of hypoglycemia in diabetic Japanese HD patients if it is used appropriately. Further studies are necessary in patients of different ethnic background and dietary habits.

TH-PO529

Vildagliptin Improves Glycaemic Control and Fluctuation in Hemodialysis Patients with Type2 Diabetes Kunihiro Ishioka, Machiko Oka, Hidekazu Moriya, Takayasu Ohtake, Sumi Hidaka, Shuzo Kobayashi. *Nephrology, Immunology, and Vascular Medicine, Shonan Kamakura General Hospital, Kamakura, Kanagawa, Japan.*

Background: Since the dipeptidyl peptidase-4 (DPP-4) inhibitor, therapeutic agent of diabetes mellitus through incretin, emerged, it has brought a paradigm shift in the treatment of diabetes mellitus. Among DPP-4 inhibitor, Vildagliptin is available not only for patients with renal insufficiency, but also for hemodialysis patients. The purpose of this study is to assess the efficacy and safety of vildagliptin (50mg once daily), and to see the effect on glucose fluctuations using continuous glucose monitoring (CGM) in hemodialysis patients with type 2 diabetes mellitus (T2DM).

Methods: The study included 42 hemodialysis patients (26 men: mean age ±SD, 68.0±11.2 years) with T2DM who had inadequate glycaemic control. We devided them into two groups. Fifty mg/day of vildagliptin was administered to one group (V group) in addition to the original treatment. The other group (C group) continued the original treatment. We assessed HbA1c, glycated albumin (GA), and blood glucose value in two groups before and 1 month after the treatment. Additionally, we evaluated averaged glucose value (AGV), blood glucose fluctuation (SD) for 24 hours using continuous glucose monitoring (CGM).

Results: In V group, HbA1c and blood glucose value decreased significantly 1 month after administration of vildagliptin (6.5±1.1% to 5.6±1.1%, 184±79mg/dl to 135±50mg/dl, p<0.05), respectively. GA also showed improvement in V group (25.1±5.3% to 22.9±4.4%, P=0.16). CGM showed that AGV and SD improved both one day and one month after vildagliptin administration.

Conclusions: Our data showed that vildagliptin improved blood glucose control very soon as well as glycaemic fluctuations without any adverse effects.

TH-PO530

Renal Safety and Outcomes with Linagliptin: Meta-Analysis of Individual Data for 5466 Patients with Type 2 Diabetes Maximilian von Eynatten,[1] Angela Emser,[1] Mark E. Cooper,[2] Vlado Perkovic,[3] Julio Rosenstock,[4] Christoph Wanner,[5] Hans-Juergen Woerle.[1] *[1]Boehringer Ingelheim, Ingelheim, Germany; [2]The Baker IDI Heart and Diabetes Institute, Melbourne, Australia; [3]The George Institute for Global Health, Sydney, Australia; [4]Dallas Diabetes and Endocrine Center at Medical City, Dallas, TX; [5]University of Würzberg, Würzberg, Germany.*

Background: Long-term glycemic control in diabetes is associated with reduced risk of renal microvascular complications. Linagliptin has shown nephroprotective effects in animal models and significantly reduced albuminuria in type 2 diabetes (T2D)-associated nephropathy. As these effects do not appear to be directly related to short-term glycemic improvements, it was speculated that linagliptin may have potential nephroprotective effects. The aim of these analyses was to evaluate renal outcomes with linagliptin in completed Phase 3, randomized, double-blind, placebo-controlled trials (≥12 wks).

Methods: Predefined events from 13 trials were analyzed using a composite primary endpoint: new onset of a) micro- or b) macroalbuminuria, c) CKD (serum creatinine increase ≥2.83 mg/dL), d) worsening of CKD (loss in eGFR >50% vs baseline), e) acute renal failure (ARF; standardized MedDRA query), and f) death (any cause).

Results: Of 5466 participants (mean baseline HbA1c: 8.2% and eGFR: 91 mL/min/1.73m^2), 3505 received linagliptin 5mg qd and 1961 placebo; cumulative exposure (person yrs) was 1756 and 1057, respectively. Events occurred in 448 (12.8%) patients receiving linagliptin vs 306 (15.6%) for placebo. The HR of 0.84 (95% CI: 0.72-0.97, P<.05), was not significantly altered by race, but tended to be stronger in patients <65 vs >65 yrs (HR: 0.77 vs 1.04). The descriptive RRs for individual renal endpoints were: micro- (0.85) and macroalbuminuria (0.88), new onset (0.44) or worsening of CKD (0.76), ARF (0.93), and death (0.77).

Conclusions: In this large meta-analysis, renal safety and outcomes were significantly improved in patients with T2D treated with linagliptin. These data support a potential direct nephroprotective effect of linagliptin that warrants future long-term controlled trials designed to confirm these findings.

TH-PO531

Safety and Efficacy of Linagliptin in Combination with Insulin in Patients with Type 2 Diabetes (T2D) and Declining Renal Function Janet McGill,[1] Hannele Yki-Järvinen,[2] Angela Emser,[3] Maximilian von Eynatten,[3] Hans-Juergen Woerle.[3] *[1]Washington University in St. Louis, St. Louis, MO; [2]University of Helsinki, Helsinki, Finland; [3]Boehringer Ingelheim, Ingelheim, Germany.*

Background: Renal impairment (RI) and fluctuating kidney function limits glucose-lowering treatment options in T2D. Hence, insulin is commonly used in this population, despite the increased risk of hypoglycemia. Linagliptin, a primarily non-renally excreted oral DPP-4 inhibitor, can be given to T2D patients with any degree of RI, without dose adjustment. Two Phase 3 trials (n=1394) assessing linagliptin 5 mg qd vs placebo in combination with insulin were included in this pooled analysis of safety and efficacy in patients with T2D and RI.

Methods: In these trials, the primary efficacy endpoint was change from baseline to wk 12 (NCT00800683) or wk 24 (NCT00954447) in HbA1c. Adverse events (AEs) were also assessed.

Results: At baseline 565, 124, and 104 patients had mild, moderate, or severe RI, respectively, and were inadequately controlled on insulin; mean HbA1c was 8.3, 8.2, and 8.3% and mean daily insulin dose was 40.7, 42.7, and 64.9 IU, respectively. Over 85% of all patients had a diabetes duration >5 yrs. The placebo-adjusted mean change ±SE in HbA1c with linagliptin was -0.59± 0.07%, -0.71±0.15%, and –0.43±0.16%, respectively (all $P<0.01$). Drug-related AEs in mild, moderate, and severe RI occurred in 17.6, 14.3, and 46.3% of linagliptin patients vs 23.1, 25.9, and 43.6% of placebo patients; corresponding incidences of drug-related hypoglycemia were 6.5, 8.4, and 42.6% on linagliptin vs 6.6, 11.6, and 40.0% with placebo. Overall, most hypoglycemic events on linagliptin were of mild intensity and the incidence of serious hypoglycemic events was low with linagliptin (n=4) and placebo (n=1).

Conclusions: In T2D patients with mild, moderate, or severe RI, inadequately controlled on insulin, linagliptin was well tolerated and achieved clinically meaningful improvements in glycemic control without excess risk of hypoglycemia. These data support linagliptin as a treatment alternative in patients with declining renal function.

TH-PO532

The Effect to Sodium Excretion and Blood Pressure with DPP-4 Inhibitors Koichi Kanozawa, Hajime Hasegawa, Juko Asakura, Takatsugu Iwashita, Taisuke Shimizu, Tokushi Nakajima, Tetsuya Mitarai. *Division of Nephrology and Hypertension, School of Medicine, Saitama Medical University, Kawagoe, Saitama, Japan.*

Background: The diabetes patients are known to be easy to present with salt sensitive hypertension. On the other hand, the GLP-1 receptor is expressed in renal proximal tubule, and acts on sodium diuresis through Na(+)/H(+) exchanger NHE3. However, the effect to sodium diuresis and the blood pressure with the DPP-4 inhibitors were unknown. We examine sodium diuresis and the antihypertensive effect with the DPP-4 inhibitors by the short-term effect in the inpatient and the long-term effect in the outpatient.

Methods: We gave DPP-4 inhibitor (either of sitagliptin 50-100 mg, vildagliptin 50-100 mg, alogliptin 12.5-25 mg) for Japanese patients with Type 2 diabetes less than 2.0 mg/dl of serum creatinine level. In the inpatients, we calculated urinary salt excretion using urine collection for 24 hours within one week around administration. In the outpatients, we calculated sodium excretion quantity estimation level using first or second urinary in the morning, and measured the mean of home and office blood pressure, before and after administration. Futhermore, we examinated with sulfonyl ureas which strongly promoted insulin secretion, and between the drug of DPP4 inhibitors.

Results: In 23 inpatients, urinary salt excretion significantly increased 1.8±0.6g ($p<0.01$), for 24 hours with the DPP-4 inhibitors. On the other hand, systolic and diastolic blood pressure significantly had decreased 6±2mmHg ($p<0.01$) and 5±2mmHg ($p<0.05$), each. In 45 outpatients, quantity of salt excretion estimation level significantly increased 0.8±0.2g/day ($p<0.01$) with the DPP-4 inhibitors. The systolic home and office blood pressure significantly had decreased 2±1mmHg ($p<0.05$) and 4±2mmHg ($p<0.01$), each. In contrast, these changes were not seen with the sulfonyl urea. Furthermore, the meaningful these effects were seen in alogliptin and sitagliptin, but was not seen in vildagliptin.

Conclusions: By the administration of the urine excretion type DPP-4 inhibitors for the diabetes, urinary sodium excretion increase, and blood pressure decrease.

TH-PO533

Efficacy and Tolerability of Vildagliptin in Chronic Kidney Disease (CKD) Stage 3-5 Patients with Type 2 Diabetes Mellitus Yoshihiko Inoue, Tomoaki Miyazaki, Shinya Oomiya, Daisuke Komukai, Kiyoko Inui, Ashio Yoshimura. *Division of Nephrology, Showa University Fujigaoka Hospital, Yokohama, Kanagawa, Japan.*

Background: It is important to establish the efficacy and tolerability of a new antidiabetic agent in patients with renal impairment. Dipeptidyl peptidase-4 (DPP-4) inhibitor Vildagliptin (VG) is one of the newest class of oral antidiabetic agents. We evaluate the usefulness of it on CKD stage 3-5 patients with diabetes mellitus (DM).

Methods: 51 patients (25 cases with CKD stage 3 [eGFR 49.5±1.5 ml/min/1.73m^2], 16 with stage 4 [24.6±1.2], 10 with stage 5 [10.9±1.0]) were followed for 36 weeks after the start of VG treatment. 50mg/day (36 cases, VG50) or 100mg/day (15 cases, VG100) of VG was newly started or was added to current antidiabetic therapy. HbA_{1C}, eGFR, BMI and the amount of proteinuria were studied at before treatment, after 4-week, 12-week, 24-week and at the end of the study.

Results: Result 1: There was no difference in HbA_{1C}, serum albumin levels, BMI, or protein excretion between stages ofCKD before VG treatment. BMI was normal ranges (24.1±0.5 kg/m^2). After 4 weeks, VG elicited statistically significant decrease in HbA_{1C} to the end of the study (36-week of HbA_{1C}: 6.53±0.14 vs. baseline: 7.41±0.20 %, $p<0.001$). The statistical decrease in HbA_{1C} was also shown in each CKD-stage group respectively from after 4 weeks until the end of the study. There was no difference in serum albumin levels, BMI, urine protein excretion, or eGFR between baseline and the end of the study (36-week of eGFR: 36.09±2.81 vs. baseline: 34.32±2.78 ml/min/1.73m^2, p=0.072).

Result 2: There was no difference in eGFR between groups of VG100 and VG50 before treatment (36.5±3.8 vs. 33.2±3.0 ml/min/1.73m^2, p=0.53). The dosage of VG (mg/kg) was higher in VG100 group rather than VG50 group (1.75±0.43 vs. 0.84±0.24 mg/kg, $p<0.01$). Patients in VG100 group were higher than those in VG50 group in HbA_{1C} before treatment (8.1±0.6 vs. 7.1±0.2 %, $p<0.05$). HbA_{1C} was significantly suppressed in both groups of VG50 and VG100.

Result 3: There were no severe adverse events including hypoglycemia in all patients.

Conclusions: VG is effective and tolerated in CKD stage 3-5 patients with type 2 DM.

TH-PO534

Association between Milk Consumption and Cardiovascular Risk Factors in Children: NHANES 1999-2000 Kathleen Perez,[3] Kamyar Kalantar-Zadeh,[2] Keith C. Norris,[3] Gangadarshni Chandramohan.[1] *[1]Pediatrics, LA Bio-Medical Research Inst. at Harbor-UCLA Medical Center, Torrance, CA; [2]Department of Internal Medicine, University of California, Irvine, CA; [3]Charles Drew University School of Medicine, Lynwood, CA.*

Background: Recent studies have shown that low milk consumption is associated with increased risk of hypertension in adults. To date, there are no data on the association between milk and various cardiovascular (CV) risk factors in the pediatric population. In this study we looked at the relationship between milk consumption and age, gender, ethnicity and CV risk factors in children between the ages of 6 – 17 years using data from National Health and Nutrition Survey (NHANES) 1999-2000.

Methods: We analyzed data of 5387 children, 58% were 6-12 yrs and 51% males. Two or more days per week of milk consumption is considered as some.

Results: There was a significant difference in the rate of milk consumption by age and gender. A significant positive association with abnormal fasting blood sugar (FBS) and a negative association with hyperlipidemia were observed in those who drank some milk compared to those who never drank milk. No association noted between milk consumption and ethnicity, high BP, obesity and waist circumference.

Relationship Between Milk Consumption and Cardiovascular Risk Factors in Children Between Ages 6 - 17 years Using Chi Square Analysis

Variables	Never Drank Milk (%)	Drank Some Milk (%)	p Value
Normal WC	60	63	
High WC	47	37	0.47
Non-Obese	80	81	
Obese	20	19	0.88
Normal BP	88	91	
High BP	12	9	0.26
Normal Lipids	41	53	
Hyperlipidemia	59	47	0.01
Normal FBS	98	93	
Abnormal FBS	2	7	0.001

WC: waist circumference, High WC: >75th percentile for age and gender, BP: blood pressure, FBS: fasting blood sugar

Conclusions: The negative association between milk consumption and hyperlipidemia suggests that most children may be consuming low fat milk. However, a positive association between milk and abnormal FBS may suggest a high lactose intake from milk. This should be considered as a possible culprit for the development of Type 2 Diabetes. However, further prospective studies is warranted to confirm these findings.

TH-PO535

Combined Use of Amlodipine and Irbesartan in Patients with Diabetic Kidney Disease and Hypertension: A Multi-Center Randomized Prospective Controlled Trial Ping Fu, Hui Zhong. *Department of Nephrology, West China Hospital of Sichuan University, Chengdu, Sichuan, China.*

Background: We designed a multi-center randomized controlled trial (RCT) to investigate the efficacy and safety of combined use of Amlodipine and Irbesartan in reducing urinary protein excretion and blood pressure control in patients with diabetic kidney disease (DKD) and hypertension.

Methods: This is a multi-center, prospective, single-blind RCT study. A total of 200 patients (18<age≤80y) with type 2 DKD (phage 3 and 4) and hypertension were enrolled and randomly assigned to double dose Irbesartan group (II group, Irbesartan 300mg/d) or combined treatment group (AI group, Amlodipine 5mg/d and Irbesartan 150mg/d) at 1:1 ratio, followed up for 8 weeks. The primary endpoints included the change of urinary albumin: creatinine ratio (ACR) and the effective rate of the two groups (It was defined as effective if the change rate of ACR was over 50% or the ACR of 8th week was normal). The secondary endpoints included urinary protein: creatinine ratio (PCR), serum creatine, eGFR, and blood pressure.

Results: Data of 181 patients was analyzed as 19 patients were lost to follow-up. The effective rate was 16.48% in AI group and 8.89% in II group (P=0.1251), and there was no difference in change rate of ACR between the two groups either (AI group 0.28±0.24,

II group 0.22±0.21, P=0.0824). However, the change rate of PCR was significantly higher in AI group (0.34 ±0.81, 0.24±0.46, P=0.0032). Both groups showed favorable control of blood pressure when compared to baseline (all P value <0.0001), but the AI group deceases both SBP (P=0.0044) and DBP (P=0.0007) more than II group. There was no difference in changes of serum creatinine, serum glucose and eGFR (P>0.05).

Conclusions: There was no significant difference in decreasing ACR between Irbesartan 300mg/d and Amlodipine 5mg/d combined with Irbesartan 150mg/d, but the combination therapy had better effect on blood control and decreasing PCR. The combined therapy may bring benefits to both cardiovascular and renal protection, which needs to be confirmed by further studies.

TH-PO536

Efficacy and Safety of Canagliflozin (CANA) in Subjects with Type 2 Diabetes Mellitus (T2DM) and Moderate Renal Impairment George L. Bakris,[1] Jean-Francois Yale,[2] Ewa Wajs,[3] Liwen Xi,[3] Keith Usiskin,[3] Gary Meininger.[3] *[1]Univ of Chicago Pritzker School of Medicine, Chicago, IL; [2]Royal Victoria Hospital and McGill Univ, Montreal, Canada; [3]Janssen Research & Development, LLC, Raritan, NJ.*

Background: This Phase 3 study evaluated the efficacy and safety of CANA, a sodium glucose co-transporter 2 inhibitor, in subjects with T2DM and moderate renal impairment.

Methods: In this randomized, double-blind, placebo (PBO)-controlled study, subjects (N=269) with T2DM and moderate renal impairment (estimated glomerular filtration rate [eGFR] ≥30 and <50 mL/min/1.73m^2) received CANA 100 or 300 mg or PBO (mean baseline characteristics: age 68.5 y; A1C 8.0%; fasting plasma glucose [FPG] 164.0 mg/dL; BMI 33.0 kg/m^2; eGFR 39.4 mL/min/1.73m^2). Mean and median albumin/creatinine ratios (ACR) were 256.8 and 30.0 µg/mg. 31% of subjects were on sulfonylureas and 74% on insulin.

Results: At Week 26, CANA 100 and 300 mg significantly lowered A1C relative to PBO (least squares mean change vs PBO of –0.30% [*P*<0.05] and –0.40% [*P*<0.001]). Both CANA doses reduced FPG, body weight, and systolic blood pressure compared to PBO. Incidence of adverse events (AEs), serious AEs, and AE-related discontinuations was similar across groups. Slight increases in urinary tract infections and osmotic diuresis-related AEs were seen with CANA 300 mg, but led to few discontinuations. Modest decreases in eGFR were seen with CANA 100 and 300 mg relative to PBO; mean changes from baseline were maximal at Week 3 (–4.3, –6.4, and –0.5 mL/min/1.73m^2) and lessened over time (–3.6, –3.9, and –1.4 mL/min/1.73m^2 at Week 26). Decreases in ACR were observed with CANA 100 and 300 mg relative to PBO at Week 26 (median change from baseline: –7.2, –3.8, and –0.8 µg/mg).

Conclusions: CANA 100 and 300 mg improved glycemic control, reduced body weight, and was well tolerated in subjects with T2DM and moderate renal impairment.

Figure. Change in (A) eGFR and (B) ACR over time.

TH-PO537

Copeptin, a Surrogate Marker for Vasopressin, Is Associated with Progression of Diabetic Nephropathy (ZODIAC-33) Wendy E. Boertien,[1] Ineke J. Riphagen,[1] Iefke Drion,[2] Alaa Alkhalaf,[2] Klaas Groenier,[2] Stephan J.L. Bakker,[1] Joachim Struck,[3] Henk Bilo,[2] Nanne Kleefstra,[2] Ron T. Gansevoort.[1] *[1]Nephrology, UMC, Groningen; [2]Diabetes Centre, Isala Clinics, Zwolle, Netherlands; [3]BRAHMS, ThermoFisher Scientific, Hennigsdorf, Germany.*

Background: Vasopressin (VP) has been hypothesized to have deleterious renal effects. In rodent models of diabetes, it has been shown to cause hyperfiltration, albuminuria and glomerulosclerosis. A potential role of VP in diabetic nephropathy has not yet been investigated in human epidemiological studies. We aimed to investigate whether copeptin, a surrogate for VP, is associated with progression of diabetic nephropathy.

Methods: Type 2 diabetes patients treated in primary care were included in the ZODIAC cohort study. We analyzed the association of baseline plasma copeptin with (change in) albumin/creatinine ratio (ACR) and eGFR (MDRD). Linear regression models were applied, crude and adjusted for possible confounders: gender, age, baseline ACR/eGFR, and CKD risk factors (e.g. HbA1c, body mass index, smoking).

Results: Samples of 976 patients were available (46% male, median age 68 (IQR 58-75) y, ACR 16 (8-50) mg/g, eGFR 66.8 ±14.3 mL/min/1.73m^2). Copeptin (5.4 (3.1–9.5) pmol/L) was significantly associated with ACR (r=0.13, p<0.001) and eGFR (r=-0.14, p<0.001). These associations remained significant after adjustment for confounders (std B=0.09, p=0.005 and std B=-0.21, p<0.001 resp.). Patients were followed for 9.0 (6.0-9.9) y, during which change in ACR was 0.2 (-1.3 to 3.5) mg/g/y (n=439) and change in eGFR was -1.0 (-2.1 to 0.1) mL/min/1.73m^2/y (n=753). Baseline copeptin level was significantly associated with rate of change in ACR and eGFR during follow-up independent of potential confounders and baseline ACR and eGFR (std B=0.10, p=0.04; std B=-0.08, p=0.04, resp.). The association of copeptin with both increase in ACR and decrease in eGFR was stronger than that of several established risk factors for diabetic nephropathy.

Conclusions: In diabetic patients, higher baseline copeptin level is significantly associated with an increase in ACR and a decline in eGFR during follow-up, independent of and stronger than several traditional CKD risk factors.

TH-PO538

Structural–Molecular Relationship in Early Diabetic Nephropathy Claudiu V. Komorowsky,[1] Viji Nair,[1] E. Jennifer Weil,[2] Berne Yee,[3] Kevin V. Lemley,[4] Robert G. Nelson,[2] Matthias Kretzler.[1] *[1]Division of Nephrology, University of Michigan, Ann Arbor, MI; [2]Diabetes Epidemiology and Clinical Research Section, NIDDK, NIH, Phoenix, AZ; [3]Southwest Kidney Institute, Phoenix, AZ; [4]Children's Hospital LA, University of Southern California, Los Angeles, CA.*

Background: Morphological changes in kidney ultrastructure precede functional impairment in diabetic nephropathy (DN). Integrating structural changes with genome wide molecular profiles may identify molecular pathways associated with ongoing intra–renal damage in patients with minimal clinically detectable disease.

Methods: Protocol kidney biopsies were obtained from 40 participants with type 2 diabetes (T2DM) in the "Renoprotection in Early Diabetic Nephropathy in Pima Indians Trial" (NCT00340678). Urine albumin/creatinine ratio (ACR) near time of biopsy was 44 (15–106) mg/g and GFR was 139 (112–167) ml/min (geometric mean and interquartile range). Gene expression profiling and quantitative morphometric analysis of fractional interstitial area (FIA) were performed on the kidney tissue. Transcripts correlating significantly with FIA (False discovery rate q≤0.05, |r|=0.36–0.68) were analyzed for underlying regulatory concepts and related to clinical disease manifestation (ACR).

Results: FIA was higher in T2DM than in living donors (29.5% *vs*. 11.3%; p<0.05). Transcripts correlating positively with FIA suggested activation of migratory (*e.g*. CDC42 and integrin signaling) and inflammatory (*e.g*. interleukin signaling) pathways; negative correlations were seen for transcripts enriched for differentiated tubular metabolic functions. Morphogenomic signatures correlated with ACR at time of biopsy in only 3/651 FIA–linked genes. However, 345 FIA–linked genes correlated strongly (q≤0.05, |r|=0.50–0.75) with disease progression as determined by ACR 4.2 years (range 2–6) post biopsy.

Conclusions: Integration of intra–renal transcripts and quantitative structural changes facilitates identification of molecular mechanisms in DN. FIA–linked genes may enable identification of urinary markers of detrimental intra–renal disease processes already active in patients with no or minimal clinical disease activity.

The Association of Gene Variants within the Renin Angiotensin System with Diabetic Nephropathy in a Malay Population in Malaysia Joyce Siew Mei Tan,[1] Munavvar Zubaid Abdul Sattar,[2] Wan Ahmad Hafiz Wan Md Adnan,[1] Nor Azizan Abdullah.[1] *[1]University Malaya, Kuala Lumpur, Malaysia; [2]Universiti Sains Malaysia, Penang, Malaysia.*

Background: Diabetes mellitus (DM) could lead to microvascular complications such as diabetic nephropathy (DN) and this is the predominant cause of end stage renal disease in Malaysia. The renin-angiotensin system (RAS) has commonly been implicated in the development of DN. Association studies linking the development of DN and genetic variants within the RAS produce conflicting results because of the heterogeneity in a population. To rule out this discrepancy, we carried out a hospital-based study on a cohort of Malay population, the main ethnic group in Malaysia, to determine whether variants in the RAS genes were associated with the development of DN.

Methods: A total of ten single nucleotide polymorphisms (SNPs) within the RAS genes were analysed by real-time polymerase chain reaction in 497 malay individuals consisting of 290 cases with Type 2 DM and 207 patients with DN. The DN cases included in the study were T2DM cases with serum creatinine >132 µmol/L in men or >115 µmol/L in women and microalbuminuria (urine albumin-to-creatinine [uACR] >2.5 mg/mmol creatinine in men and >3.5 mg/mmol creatinine in women). Haplotypes were estimated using the Haploview software.

Results: A significant association was observed in ACE gene variant rs1800764 (T>C) SNP with DN (χ^2=8.309, p=0.016) and this association was shown to be influenced by the male gender (χ^2=6.295, p=0.043). The ACE Ins/Del polymorphism showed an almost significant association with DN and significant association was observed in the female gender (χ^2=7.285, p=0.026). Logistic regression analysis of a co-dominant model revealed that the Ins/Del genotype is significantly associated with less risk of DN (OR=0.426, CI 0.193-0.941) and stratification to female gender maintained that only the Ins/Del heterozygote confers protection against the progression to DN. Haplotype analysis exposed a tight linkage between the two variants.

Conclusions: Our data enables us to provide evidence of association between genetic variants in the RAS genes with type 2 diabetic nephropathy in the malay population in Malaysia.

Acidosis and Mortality in Intensive Care Unit (ICU) Patient's on Continuous Renal Replacement Therapies (CRRT): Classical versus Stewart's Approach Paolo Lentini,[1] Luca Zanoli,[2] Massimo de Cal,[3] Andrea Contestabile,[1] Anna Basso,[1] Claudio Ronco,[3] Graziella Berlingò,[1] Antonio Granata,[1] Valentina Pellanda,[1] Roberto Dell'Aquila.[1] *[1]Nephrology, St Bassiano Hospital, Bassano del Grappa (Vi), Italy; [2]University of Catania, Italy; [3]Nephrology, St Bortolo Hosp, Vicenza, Italy; [4]Neph, St G di Dio Hosp, Agrigento, Italy.*

Background: Acid-base disorders are common indications for CRRT in ICU.If unrecognized they may result in poor outcomes.Stewart approach may be superior for acid-base analysis in the critically ill. AIM:Assessment of Classical and Stewart approaches for the analysis of acid-base disturbances during CRRT and mortality risk at 30 days.

Methods: We enrolled 40 consecutive adult patients on CVVH and mechanical ventilation. All patients received a 35 ml/Kg/h infusion of a standard buffer [5 Liters(mmol/L):[HCO^{-3}]35,[Na^+]140,[K^+]2,[Ca^{2+}]1,75,[Mg^+]0.5,pH 7,4]. We calculated[pH] and SBE with the Henderson-Hasselbach and Siggaard-Andersen equations. Physicochemical analysis was performed using the Stewart equations modified by Figge et al.Apparent strong ion difference (SIDa) was calculated as:SIDa,mEq/L=[Na^+]+[K^+]+[Mg^+]+[Ca^{2+}]-[Cl^-]-[lactate]. Effective SID(SIDe) was calculated as:SIDe, mEq/L=1000x2.46x10-11x$PaCO_2$/(10-pH)+[albuminemia]x(0.123 x pH-0.631)+[PO4-]x(0.309xpH-0.469).Acidosis was defined by SBE<-5mEq/l, pH<7.35, SIDa<40mEq/l or SIDe<38mEq/l.

Results: The prevalence of acidosis,assessed by pH,SBE,SIDa or SIDe,was significantly different (P<0.001)at each step. At 0,6,12 and 24hr from start of CVVH,pH<7.35 was present in 60,33,20 and 10% of patients;SBE<-5mEq/l in 35,10,10 and 5%; SIDe<38mEq/l in 100,88,65 and88%; SIDa<40mEq/l in 73,60,48 and 43% respectively. 58% of patients (n=23)died within 1 month from ICU admission.The risk of death was significantly higher for reduction of SIDa(P<0.01), SIDe(P<0.05) and SBE(P<0.05) but not pH (P=NS),independently to APACHE II score and gender.16 of 17 patients (94%) with SIDa<40mEq/l at 24h died within 1 month from ICU admission(the relative risk of death was 3.1).

Conclusions: Stewart approach seems to be more sensitive for detection of acidosis in ICU patients on CRRT and has a greater impact to mortality than Classical approach.

Continuous Renal Replacement Therapy Outcomes in Acute Kidney Injury and End Stage Renal Disease Andrew Allegretti, David J.R. Steele, Jo Ann David-kasdan, John Niles, Ishir Bhan. *Department of Medicine, Division of Nephrology, Massachusetts General Hospital, Boston, MA.*

Background: Continuous renal replacement therapy (CRRT) is a resource-intensive therapy used in critically ill patients. Assessment of prognosis is needed to optimize use of limited resources and provide appropriate guidance to patients. CRRT is used in critically ill patients with either acute kidney injury (AKI) or end-stage renal disease (ESRD), but most prior studies have restricted inclusion to AKI.

Methods: All adult patients who were initiated on CRRT at an academic tertiary care center between January 1, 2008 and September 30, 2011 were followed prospectively. Baseline demographic and laboratory data were collected, and comorbid illness was assessed with the Charlson score. Subjects were followed to assess survival (in all patients) and renal recovery (in patients with AKI). Predictors of inpatient outcomes were assessed with univariate models and multivariate logistic regression. For patients who survived until discharge, predictors of survival post-discharge were assessed with Cox proportional hazards models.

Results: 725 patients with AKI and 138 patients with ESRD were included in the analysis, with similar in-hospital mortality in both groups (60.7% vs. 54.4%). In patients with AKI, factors independently associated with in-hospital mortality included age > 60 years (1.6, 95% CI 1.2-2.2) and Charlson score > 3 (HR 1.5, 95% CI 1.0-2.1. Outpatient predictors of mortality were unchanged from their inpatient counterparts for these subjects. In patients with ESRD, Charlson score > 3 (OR 2.8, 95% CI 1.1-6.8) and admission to a medical (vs. surgical) intensive care unit (ICU) (OR 2.6, 95% CI 1.2-5.5) predicted in-hospital mortality, but age demonstrated no such association. In contrast, age was the single independent predictor for survival in ERSD patients following discharge (HR 3.9, CI 1.4-11). 11% of subjects with AKI recovered renal function prior to discharge.

Conclusions: Mortality rates are similar in both AKI and ESRD associated CRRT. While age, comorbid illness, and ICU type predict outcomes, the relative weight of these predictors differs depending on baseline renal function.

RIFLE and Acute Kidney Injury: Old Recipe for New Problems? Pedro Francisco Azevedo,[1] Raquel Gil,[2] Hugo Mário Silva,[1] Pedro V.A. Aguiar,[1] Anibal Marinho.[3] *[1]Nephrology, CHP-HSA, Oporto, Portugal; [2]ICBAS, Oporto, Portugal; [3]Intensive Care Unit, CHP-HSA, Oporto, Portugal.*

Background: The wide variation in definitions for acute kidney injury (AKI) has made it difficult to compare results across studies and populations, with controversial results in incidence and prognosis. The RIFLE and AKIN classifications were proposed in an attempt to solve the dilemma and several studies support its clinical relevance in assessing AKI severity and predictive ability for mortality in the intensive care unit (ICU). However, the extent to which one classification is superior to another remains unanswered. The purpose of the study was to evaluate the incidence of AKI, defined and stratified according to the RIFLE and AKIN classification and its impact on mortality.

Methods: Prospective study conducted over a period of ten months, in a polyvalent ICU. Demographic data, mortality rate, serum creatinine prior to admission, variability in the amount of serum creatinine in the current admission and its stratification for RIFLE and AKIN. We excluded all patients with less than 5 days in this Unit.

Results: We studied 104 patients with a mean age of 66,5±14,8; 57,7% male (n=60), mostly admitted after emergent surgery, an average length of stay in ICU of 19,2±16,0 days and a mortality rate of 11,5%. In 2 patients (1,9%) it was not possible to obtain baseline serum creatinine. The remaining 102 patients were categorized, according to the RIFLE criteria: 19 patients in class R(mortality 0%), 25 patients in class I(mortality 8%) and 12 patients in class F(mortality 25%). Applying the AKIN criteria: 23 patients were in the stage 1(mortality 17,4%); 19 patients in stage 2(mortality 0%) and 7 patients in stage 3(mortality 42%).

Conclusions: The incidence of AKI in critically ill patients is high and with a significant impact on mortality. Applying both criteria, RIFLE and AKIN, we found that RIFLE classification was more sensitive evaluating the mortality rate in patients with AKI than AKIN classification. Contrary to some published studies, the AKIN classification did not further improve the sensitivity, robustness and ability of RIFLE to predict short-term outcome, such as in-hospital mortality in critically ill patients.

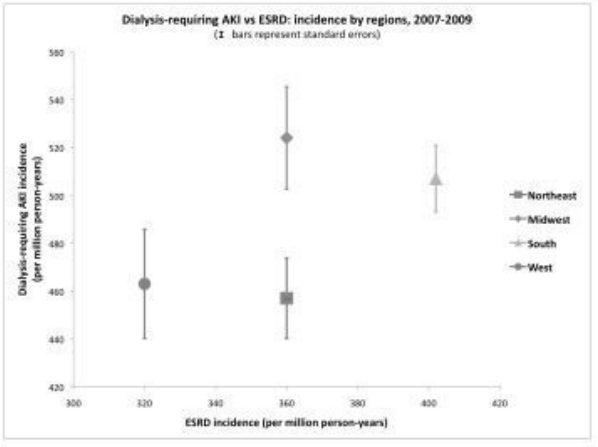
TH-PO543

Regional Variation in the Incidence of Dialysis-Requiring Acute Kidney Injury in the United States Raymond K. Hsu, Charles E. McCulloch, R. Adams Dudley, Chi-yuan Hsu. *UCSF.*

Background: While geographic variation in the incidence of end-stage renal disease (ESRD) in the U.S. is well characterized, little is known about geographic differences in the incidence of dialysis-requiring acute kidney injury (AKI).

Methods: We performed a cross-sectional analysis using data from the Nationwide Inpatient Sample (NIS), a nationally representative sample of hospitalizations, to determine the incidence rates of dialysis-requiring AKI between 2007-2009 amongst the four U.S. Census Bureau designated regions. Cases were identified using validated ICD-9-CM codes (Waikar JASN 2006). Poisson regression models were used to estimate overall regional rates and standard errors, accounting for the NIS survey sampling scheme. Results were compared with regional incidence rates of renal replacement therapy-requiring ESRD, obtained from the U.S. Renal Data System.

Results: In 2007-2009, the population incidence rates of dialysis-requiring AKI differed across the four Census designated regions. Incidence was highest in the Midwest (523 cases/million person-years, 95% CI 483-568) and lowest in the Northeast (457 cases/million person-years, 95% CI 426-492). The pattern of regional variation does not follow that for ESRD, as ESRD incidence was highest in the South and lowest in the West.



Conclusions: Based on the latest nationally representative hospital discharge data available, there appears to be notable regional variation in the incidence of dialysis-requiring AKI. The pattern of regional variation in incidence of dialysis-requiring AKI appears to differ from the pattern of regional variation in incidence of ESRD. More studies are needed to understand whether these observed geographic variations are due to regional differences in AKI risk factors, practice patterns, or some other cause.

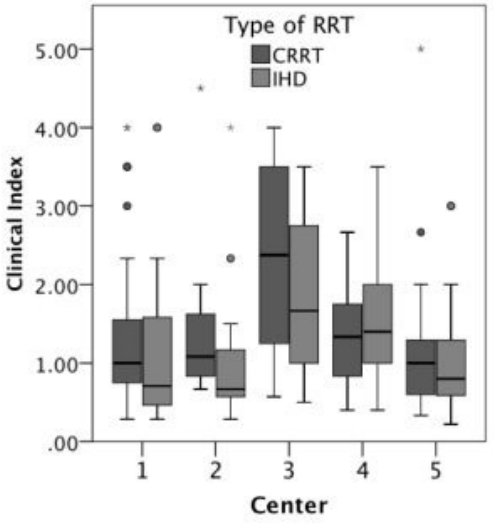
Practice Variations in Timing of Renal Replacement Therapy Initiation and Modality Choice in Acute Kidney Injury Etienne Macedo,[1] Glenn M. Chertow,[2] Jonathan Himmelfarb,[3] Emil P. Paganini,[4] T. Alp Ikizler,[5] Ravindra L. Mehta.[6] *[1]University of Sao Paulo; [2]Stanford University School of Medicine; [3]University of Washington; [4]Cleveland Clinic Foundation; [5]Vanderbilt University Medical Center; [6]University of California San Diego.*

Background: Currently, there is considerable variation in the timing of initiation for renal replacement therapy (RRT) in patients with AKI. Comparative data has been limited by the absence of standardized measurements for assessing the timing for RRT initiation. We have developed a clinical index (CI) based on clinical and lab data incorporating organ failure scores, solute and fluid balance and renal functional parameters to track changes in a patient's underlying condition. Within our CI, higher values represent a greater severity of renal and non-renal organ dysfunction. We evaluated the applicability of the CI to determine the extent of practice variations for RRT in AKI.

Methods: We analyzed data from 327 critically ill patients with AKI at 5 centers included in the PICARD study from Feb99 until Aug01. We computed a daily value for the CI starting from 48h prior to peak sCr (non dialyzed 140) and RRT start (dialyzed 187).

Results: The reasons for starting RRT were different across centers. The CI was progressively higher in dialyzed patients. There was a significant difference across centers at the level of CI at RRT initiation. Within each center, there was a wide range of CI to start RRT. Intermittent modalities tended to be started in less severely ill patients. The patterns for initiating RRT and modality choice remained consistent.



Conclusions: We demonstrated a considerable variation in the start of RRT and the choice of modality for management of AKI. The utilization of a standardized CI could help quantify changes in practice patterns for RRT within and across centers and providers.

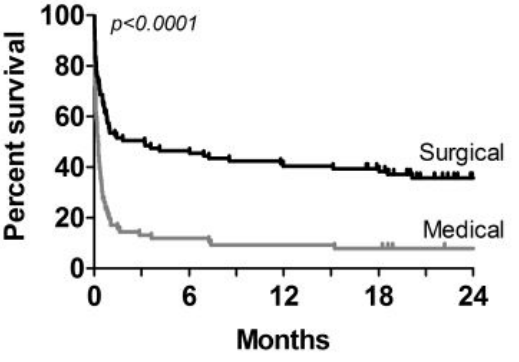
TH-PO545

The Use of Continuous Renal Replacement Therapy in Surgical versus Medical Patients Vijay G. Menon, Alagappan A. Annamalai, Rex Chung, Catherine Bresee, Hector J. Rodriguez, Steven D. Colquhoun. *Cedars-Sinai Medical Center.*

Background: The use of continuous renal replacement therapy (CRRT) is resource intensive. The optimal patient populations to benefit are yet to be defined. Two groups with different clinical end-points include those patients in surgical versus medical intensive care units. This study was carried out to discern difference in outcomes between those surgical vs. medical patients.

Methods: A retrospective study assessing survival of all patients undergoing CRRT in 2010. Surgical vs. Medical patients were compared. Surgical patients were defined as pre and post-operative at the time of CRRT initiation. Medical patients were defined as all others. All patients were first assessed by a single nephrology consult service using standard criteria: 1) oligura and volume overload with failure of non-renal replacement therapy, or severe metabolic acidosis requiring administration of high dose sodium bicarbonate, or severe alterations of extracellular fluid composition and 2) hemodynamic instability precluding intermittent dialysis.

Results: Data was from from 175 ICU patients undergoing CRRT. The median survival time for surgical was 97 days vs. 7 days for medical (p<0.0001). Further analysis showed significant differences in short and long term outcomes between surgical and medical cases, respectively, with one week, one month and one year survival rates of 73.7% vs. 50%, 53.5% vs. 19.7% and 41.4% vs. 7.9% (p<0.0001).



Conclusions: High costs and intensive resources required for the use of CRRT justify a closer assessment of candidacy. Different end-points in clinical care can be used to define and identify patients who may derive maximal benefit. Among patients undergoing CRRT, there is a significant difference in survival between patients defined as Surgical versus Medical. Further analysis of such sub-groups appears relevant to the decision to initiate CRRT.

TH-PO546

Sunday Dialysis Initiation: The Impact in Severe Acute Kidney Injury Francis P. Wilson, Wei (Peter) Yang, Harold I. Feldman. *Department of Medicine, Perelman School of Medicine at University of Pennsylvania, Philadlphia, PA.*

Background: Initiation of dialysis for acute kidney injury (AKI) occurs at a lower rate on Sundays, although the magnitude of the relationship between day of the week implementation of dialysis therapy has not been evaluated. It is unclear whether lower rates of dialysis on Sundays leads to adverse outcomes.

Methods: We identified adults who suffered severe in-hospital AKI from 1/1/2004 – 8/31/2010 at three hospitals in the University of Pennsylvania Health System. Patients were included if baseline creatinine was ≤1.4mg/dl for men or ≤1.2 mg/dl for women, and serum creatinine doubled during the hospital admission. A logistic regression model was fit to evaluate the likelihood of initiation of dialysis on a given day. Patients who initiated dialysis on a Sunday were propensity-score matched to patients not dialyzed on a Sunday. Cox proportional hazards models examining overall mortality were used to evaluate the potential benefit associated with dialysis therapy in this matched cohort.

Results: In the overall cohort (n=6,119), Sunday was negatively associated with dialysis with adjusted OR 0.55 (0.39 – 0.75) versus other days of the week. However, patients initiated on dialysis on a Sunday (n=56) were similar to those initiated on other days of the week (n=546) in terms of severity of illness and comorbidities, and suffered a similar rate of mortality. After propensity-score matching, the overall risk for Sunday initiation (vs. non initiation) was 0.93 (0.55 – 1.57, p=0.791). Initiation of dialysis on a non-Sunday (vs. non-initiation) carried an overall HR for mortality of 0.93 (0.78 – 1.10, p=0.390). These HRs were not statistically different (p=0.987). Stratifying across categories of BUN or serum creatinine did not modify this relationship.

Conclusions: Patients with AKI are less likely to initiate dialysis on a Sunday. Patients initiated on Sunday do not seem to be more ill than those initiating on any other day of the week. No excess mortality was detected that could be attributable to non-dialysis on a Sunday, even among those with markers of worse renal dysfunction.

Early Initiation of Continuous Renal Replacement Therapy Improves Survival in Severe Progressive Sepsis Patients with Acute Kidney Injury

Shin-Wook Kang,[1,2] Dae-Suk Han,[1] Mi Jung Lee,[1] Hye-young Kang,[2] Seong Hun Kim,[2] Seung Hyeok Han,[1] Dong Ho Shin.[1] *[1]Department of Internal Medicine, College of Medicine, Seoul, Republic of Korea; [2]Brain Korea 21, Yonsei University, Seoul, Republic of Korea.*

Background: The definition of 'early' in terms of continuous renal replacement therapy (CRRT) initiation has not been uniformly used. Therefore, we tried to elucidate whether the timing of CRRT application, based on the interval between the start time of vasopressors infusion and CRRT initiation, was an independent predictor of mortality in progressive sepsis patients with acute kidney injury (AKI).

Methods: Progressive sepsis patients with AKI, in whom the infusion doses of vasopressors were increased compared to the initial dose during the first 6-hour of vasopressor treatment and CRRT was performed between 2009 and 2011, were collected and divided into two groups based on the median interval between the two points. Cox proportional hazard analysis was performed to determine the independent prognostic power for all-cause mortality of early initiation of CRRT treatment. Kaplan-Meier curves were also constructed to compare the difference in all-cause mortality between the two groups.

Results: A total of 210 patients were included. The mean age was 62.4 years, and 126 patients (60.0%) were male. The most common comorbid disease was malignancy (53.8%), followed by hypertension (35.7%) and diabetes mellitus (29.0%). The median interval between the start time of vasopressor infusion and CRRT commencement was 2.0 days. During the study period, 156 patients (74.3%) died within 28 days of CRRT application. The interval between the two points was significantly shorter in the survivor compared to the death group (P<0.001). In addition, 28-day overall mortality rates in the early CRRT group were significantly lower than those in the late CRRT group (P=0.034). Moreover, early CRRT treatment was independently associated with lower mortality rates even after adjustment for age, gender, causative organisms, and infection sites (P=0.032).

Conclusions: Early initiation of CRRT may be beneficial in severe progressive sepsis patients with AKI, in whom the requirement dose of vasopressor is increasing.

TH-PO548

How Common Is Cardiorenal Syndrome in Patients Admitted to the Intensive Care Unit?

Kelly V. Liang,[1] Mark L. Unruh,[1] Florentina E. Sileanu,[2] John A. Kellum.[2] *[1]Renal, University of Pittsburgh; [2]Critical Care, University of Pittsburgh.*

Background: Critically ill patients with cardiorenal syndrome (CRS) have poor outcomes and commonly require renal replacement therapy (RRT). We aimed to examine characteristics associated with risk, timing, and modality of RRT as well as influence of RRT on outcomes in critically ill CRS patients.

Methods: We examined critically ill subjects admitted to UPMC ICU over 4 years (2000-2004) using the High Density Intensive Care (HiDenIC) database. CRS was defined based on heart failure (HF) ICD-9 code on admission and estimated GFR 15-60 mL/min. Three patient groups were identified: 1) CRRT (either initially or after IHD), 2) IHD only, and 3) No RRT. Prevalence of CRS and incidence of RRT were determined. Patient characteristics and clinical outcomes were compared.

Results: Of the 21,152 patients in the cohort, 3,680 had HF codes on admission, and 2,809 had both HF and renal dysfunction; thus, CRS was present in 76% of the HF population admitted to the ICU and 13.3% of the total ICU population. Of the 2,809 patients with CRS, 1,272 patients had acute kidney injury (AKI) with maximum RIFLE score of F. Of these patients, 362 (28.5%) received RRT (175 IHD, 187 CRRT). Patients receiving RRT were younger (62 vs. 70 years) and had higher APACHE 3 scores, especially the CRRT group (87.7 vs. 76.2 vs. 64.4 in CRRT vs. IHD vs. none). The CRRT group had higher hypotensive index than the IHD group (27.8 vs. 8.0). Hospital mortality was greater in patients receiving RRT, especially the CRRT group (mortality rates 64% vs. 25% vs. 16% in CRRT vs. IHD vs. none). Hospital and ICU LOS were greater in the RRT vs. no RRT group, especially the CRRT group (mean hospital LOS 35 vs. 26 vs. 16 days; mean ICU LOS 22 vs. 12 vs. 7 days in CRRT vs. IHD vs. none).

Conclusions: The majority (76%) of patients admitted to ICU with HF have CRS. Severe (RIFLE-F) AKI accounts for nearly a third of these patients and RRT is used in 28.5% of those with severe AKI. Hospital mortality, hospital LOS, and ICU LOS are greater in those receiving RRT. These findings underscore the need for further studies to determine the appropriate use and timing of RRT in the CRS population in order to improve outcomes.

Extracorporeal Oxygen Delivery and Carbon Dioxide Removal Using Hemodialysis Equipment

Scott D. Bieber,[2] Suhail Ahmad.[2] *[1]Medicine, Nephrology, University of Washington, Seattle, WA; [2]Scribner Kidney Center Research, Northwest Kidney Centers, Seattle, WA.*

Background: Abnormal pulmonary function is a common problem in acutely ill patients requiring dialysis in intensive care units. Lung protective ventilation and fluid removal by dialysis are often the only options for these patients with grave prognosis. Improving oxygenation and reducing pCO2 may help improve outcome. Extracorporeal membrane oxygenation systems (ECMO) have been utilized for such a purpose but they are expensive and require highly trained staff to operate them. As an alternative, a simple, cost effective modification of existing hemodialysis technology could provide enhanced gas exchange in critically ill patients already on continuous renal replacement therapy. The modified dialysis set up and preliminary in vitro data in support of our hypothesis is presented here.

Methods: A typical hemodialysis circuit was modified by placing an additional gas exchanging dialyzer in series with the traditional hollow fiber dialyzer used for dialysis. Oxygen was delivered at varying rates to the empty dialysate compartment of the gas exchanging dialyzer. Blood was then circulated in the blood compartment of both dialyzers and blood gas measurements were taken from sample ports in the circuit before and after each dialyzer.

Results: There was a significant increase in blood pO2 of 116 mm Hg and decrease in pCO2 of 18 mmHg across the dialyzer.

Results

	Before O2 Delivery	After O2 Delivery	Delta	p value
Mean pO2 (mmHg)	158 (SD 27.2)	273.5 (SD 46.7)	+116	0.01
Mean pCO2 (mmHg)	60.4 (SD 5.7)	42.4 (SD 5.8)	-18	0.009

Conclusions: Our data shows that significant gas exchange can be provided by dialysis machines with a simple modification of existing technology. Future studies will utilize additional modifications to further enhance gas exchange.

TH-PO550

Nationwide Japanese Survey of Continuous Renal Replacement Therapy for Acute Kidney Injury in Children

Shuichi Ito,[1] Mari Saito,[2] Masao Ogura,[1] Koichi Kamei,[1] Mayumi Sako Nakamura.[2] *[1]Division of Nephrology and Rheumatology, National Center for Child Health and Development, Tokyo, Japan; [2]Clinical Research Center, National Center for Child Health and Development, Tokyo, Japan.*

Background: Continuous renal replacement therapy (CRRT) and apheresis therapy are used for children with a life-threatening illness, including acute kidney disease (AKI). However, the current state of CRRT for childhood AKI is unknown in Japan.

Methods: A retrospective nationwide survey of CRRT in April 2007–March 2009 was performed. A total of 669 patients were reported from 121 institutions and 283 patients received CRRT due to AKI.

Results: The median age was 2.3 years (<1year; 40%), median weight was 12.8 kg (<10 kg; 40%). The median duration of CRRT was 15.3 d. Major treatment modalities were CVVHDF (n=139), CVVHD (n=113), CVVF (n=28), plasmapheresis (n=38), and direct hemoperfusion with polymyxin B (n=38). Major anticoagulant agents were nafamostat mesylate(80%) and heparin sodium (17%). Main primary diseases of AKI were renal (34%), cardiovascular (19%), hematological and oncological (14%), sepsis (8%), neuromuscular (7%) and gastrointestinal (5%). The total survival rate was 58%. Multivariate analysis for the risk of death showed that respiratory failure (odds ratio (OR)5.4; 95%CI, 1.6-18) and conscious disturbance (OR5.2; 95%CI, 1.6-18) had a high risk. However, sepsis (OR2.1; 95%CI, 0.9-4.6) and body weight less than 10 kg (OR1.6; 95% CI, 0.76-3.1) did not affect survival. The survival was poor for cardiovascular (74%), hematological and oncological (71%), sepsis (79%) and gastrointestinal (62%), but excellent for renal (6%) diseases. Long-term prognosis approximately 4 years after CRRT among 131 of 283 patients was evaluated (117 living, 5 dead, 9 unknown). Twenty-seven patients had progressed to end stage renal diseases (peritoneal dialysis n=15, hemodialysis n=2, renal transplantation n=2). Interestingly, 22 of 27 patients suffered renal disease as the primary disease.

Conclusions: Although many young children received CRRT for AKI, the survival was relatively satisfactory. Non-renal disease has a poor life prognosis in the acute phase, but renal diseases have poor long-term renal prognosis.

Funding: Government Support - Non-U.S.

TH-PO551

Phosphate Mobilization Clearance during Continuous Renal Replacement Therapies

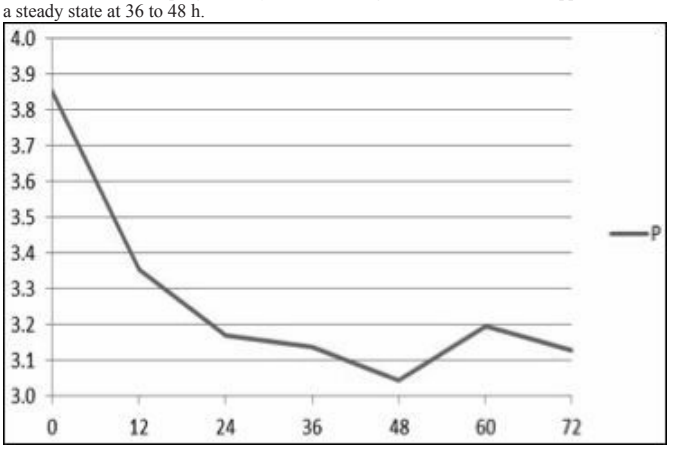
Rolando Claure-Del Granado,[1] Soo Young Yoon,[2] Ravindra L. Mehta.[3] *[1]Universidad del Valle, Bolivia; [2]Kwandong University, Korea; [3]University of California San Diego.*

Background: The kinetics of plasma phosphorus (P) during CRRT is incompletely understood. Various models for P kinetics have been described, however neither conventional one nor two-compartment models can be used. Leypolt et al have developed a pseudo one-compartment model to describe P kinetics. We evaluated the applicability of this model for P mobilization clearance (K_mP) in patients with AKI treated with CRRT.

Methods: We analyzed data from 76 critically ill patients with AKI treated with pre-dilution CVVHDF. P concentrations were measured at the begining and at the end of each treatment. Filter efficacy was assessed by measuring effluent to blood urea nitrogen ratio (FUN/BUN). We compute dialyzer P clearance (K_DP). K_mP was estimated using the

following equation: $K_mP = Pf((K_DP–Quf)/(Pi – Pf))$; where *Pi and Pf* are P at the begining and at the end of treatment, *Quf* is ultrafiltration rate, and K_DP is dialyzer P clearance.

Results: P levels progressively decline during CRRT treatment and appear to reach a steady state at 36 to 48 h.



K_DP (mL/min) was not constant during treatment (12 h 26.9±7.9; 24 h 24.5±7.8; 36 h 24.3±7.5; 48 h 26.8±8.0; 56 h 25.7±13.3; 72 h 25.3±10.0; p <0.001). K_mP(mL/min) increased in consecutive days of treatment (118.9±137.0, 144.7±101.5, and 161.3±198.6; p < 0.001). Mean FUN/BUN ratio was 0.98±010 (day 1), 0.93±0.17 (day 2), and 0.94±0.16 (day 3), filter efficacy appear not to influence K_mP. No correlation was found between K_mP and post CRRT body weight ($r^2 = 0.071$; p = 0.170), effective treatment time ($r^2 = 0.005$; p = 0.552), or net UF ($r^2 = 0.015$; p = 0.901).

Conclusions: The estimation of K_mP provides a tool to better assess P kinetics during CRRT. This parameter could help to optimize and individualize the CRRT prescription and determne the amount of phosphate supplementetion required.

TH-PO552

Inflammatory Mediator Clearance and Mortality among Critically Ill Patients on CRRT Ilson Jorge Iizuka,[2] Beata Marie Redublo Quinto,[1] Maria Dalboni,[1] Bento Santos,[2] Marcelo Costa Batista.[1,2] *[1]Medicine/ Nephrology Division, UNIFESP; [2]Hospital Israelita Albert Einstein.*

Background: Critically ill patients with acute kidney injury (AKI) present high mortality rates. The magnitude of inflammatory response ultimately determines the prognosis of such patients. Continuous renal replacement therapy (CVVHDF) may play role in removing inflammatory mediators in patients with AKI. The aim of this study was to investigate whether the magnitude of inflammatory mediators (TNF-a) removal is associated with mortality among critically ill patients on CVVHDF.

Methods: This study consisted of 64 critically ill patients requiring CVVHDF. Plasma levels of C3a, TNF-a, IL-10, IL-6, IL-1b, sTNFRI and sTNFRII were determined by enzyme-linked immunosorbent assay (ELISA) at the beginning of CVVHDF and after 24h (outlet). Clearance of cytokines during the first 24 hours of CVVHDF was calculated. Clinical and laboratory data were acquired from patient's records data. Statistical analyses were carried out using Q-Square test, T test and ANOVA. Binary logistic regression was processed to investigate mortality predictors in this population.

Results: Mean age of patients requiring CVVHDF was 63 years, 67.2% were men and 87.3% were caucasian. Thirty-five (35) patients (54.7%) died. Comparing non-survivors with the group of survivors we observed higher incidence of sepsis (68.6 versus 37.9%, p<0.05), higher APACHE II score (34.8±7.6 versus 29.2±7.1, p<0.05) and higher lactate levels (23.2±17.6 versus 16.4±6.6, p<0.05). According to the inter-tercile range of TNF-a clearance (ITR1 (<0.008); ITR2 (0.008–1.17); ITR3 (1.18–3.48)) we found that those patients with higher TNF-a removal by RRT (ITR3) had a better survival. Multivariable analysis showed that lower clearance of TNF-a remained independently associated with high mortality after adjustment for sex, age, use of vasoactive drugs, APACHE II score sepsis, creatinine and lactate before CVVHDF (HR: 0.179, 95% IC: 0.049 – 0.661, p<0.01).

Conclusions: The attenuation of inflammatory response may be related to the lower mortality observed on those patients with higher TNF-α removal by CRRT. This study was supported by FAPESP.

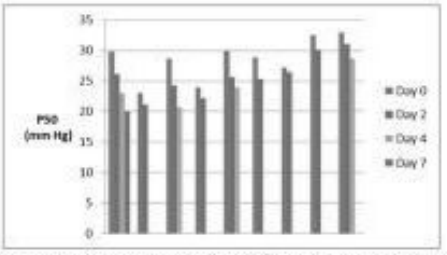
TH-PO553

Effects of Continuous Veno-Venous Hemofiltration on RBC Oxygen-Hgb Curve & 2, 3 Diphosphoglycerate (2,3-DPG) Levels Shilpa Sharma,[1] Carlo Brugnara,[2] Sushrut S. Waikar.[1] *[1]Brigham & Women's Hospital; [2]Children's Hospital, Boston, Boston, MA.*

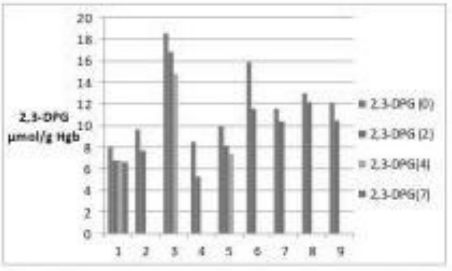
Background: Hypophosphatemia is a frequent complication during continuous renal replacement therapy(CRRT), and may contribute to poor patient outcomes due to phosphate's critical role in energy metabolism in every organ system. Because intracellular phosphate is a constituent of 2,3-DPG and therefore a determinant of the affinity of oxygen to hemoglobin, we sought to determine the physiological effect of phosphate depletion by measuring RBC 2,3-DPG concentrations and Hgb:O2 dissociation curves in critically ill patients with AKI during CRRT.

Methods: Venous blood was collected on day 0, 2, 4, 7 of Continuous Veno-Venous Hemofiltration (CVVH). P50 was calculated using blood gas analyzer with co-oximeter. 2,3-DPG measurement was done by enzymatic cleavage method. We calculated the difference in 2,3-DPG concentrations and P50 from baseline to the last sample collected during CVVH.

Results: We collected multiple blood samples on 9 critically ill, oligo-anuric patients with AKI undergoing CVVH. CVVH was used with citrate or bicarbonate solutions at 1600-3000ml/hr. Blood flow ranged between 200-250 ml/min. Both P50 and 2,3-DPG declined after initiation of CVVH as shown in Figure 1 (p< 0.001). Serum phosphate concentrations correlated with p50 (r=0.72; p<0.001) and 2,3-DPG (r= 0.5; p<0.05).



Mean P50 at CVVH initiation: 28.5 mmHg; Mean decrease at Day 2: 2.8 mmHg(10%)



Mean 2,3-DPG at CVVH initiation: 11.9µmol/g Hgb; Mean decrease at Day 2 by 1.9 µmol/g Hgb (17%)

Conclusions: CVVH can lead to significant phosphate depletion and may cause physiologically important effects on oxygen-hemoglobin affinity causing inadequate tissue oxygen extraction by reducing intracellular RBC 2,3-DPG levels and p50 levels. Our results suggest that CVVH may have unintended adverse effects from excessive small solute clearance. Hypophosphatemia should be anticipated and avoided during the course of therapy with CRRT.

TH-PO554

Fibroblast Growth Factor-23 Clearance by Continuous Veno-Venous Hemofiltration in Acute Kidney Injury Shilpa Sharma, Sushrut S. Waikar. *Brigham & Women's Hospital, Boston, Boston, MA.*

Background: Fibroblast Growth Factor (FGF)-23 is a bone derived regulator of phosphate homeostasis. Emerging evidence suggests FGF-23 levels are elevated in acute kidney injury (AKI) and may be associated with adverse clinical outcomes. We evaluated FGF-23 clearance during continuous veno-venous hemofiltration(CVVH).

Methods: We collected plasma/CVVH effluent samples using a partial effluent collection device, continuously sampling 1% of total effluent volume from 8 oligo-anuric patients with AKI. C-terminal FGF-23 levels were measured in effluent and corresponding plasma samples over multiple time points during the course of CVVH. CVVH was performed using biocompatible polyether sulphone membranes (hemofilter size:1.6 m^2), pre-dilution mode using bicarbonate or citrate replacement solution at 1600-3000ml/hr. Sieving coefficients (SC) were determined by dividing the effluent by plasma FGF-23 concentration. Clearance was calculated by multiplying SC's with 24 hr effluent volume.

Results: Baseline characteristics are shown in the table. Mean daily effluent volumes were 60L(range 50–76). We collected 23 timed CVVH effluent/plasma samples. Median plasma FGF-23 concentration at CVVH initiation was 6612.5 RU/ml(IQR: 2368.1–32566.9). Mean SC of FGF-23 was 0.27 (±0.08) and mean estimated FGF-23 clearance was 11.3 ml/min (± 3.25).

Table

Age/Sex	ICU Admission Cause	AKI cause	Peak Phos, mg/dl	Peak Cre, mg/dl	CVVH days	Outcome
54/M	S S	ATN	6	3.6	5	Death
50/M	S S	M	8	2.9	5	Death
66/M	O	ATN	5.9	5.3	15	Dialysis
54/M	S S	ATN	4	3.7	4	Death
56/F	S S	ATN	7.4	2.9	6	Death
79/M	U RF	M	7.1	5	1	Recovery
62/M	O	M	4.4	4.1	3	Death
47/F	U RF	ATN	7.6	3.6	1	Death

Legend: ATN, Acute tubular necrosis; M, Multifactorial; O, Causes of ICU admission other than major surgery, septic shock, respiratory failure; S S, Septic Shock; U RF, Respiratory failure secondary to ARDS

Conclusions: FGF-23 is a 26-kD protein with key role in maintenance of normophosphatemia. We found FGF-23 levels are markedly elevated in patients with AKI requiring CVVH, and that FGF-23 is cleared during CVVH. Future studies will need to clarify FGF-23's role in AKI as a biomarker or mediator of disease outcomes and whether therapies aimed at reducing FGF-23 levels may be beneficial.

TH-PO555

Enhanced Vascular Endothelial Growth Factor and Inflammatory Cytokine Removal with Online Hemodiafiltration overHigh-Flux Hemodialysis in Sepsis-Related Acute Kidney Injury Patients Khajohn Tiranathanagul,[1] Wiwat Chancharoenthana,[1] Nattachai Srisawat,[1] Paweena Susantitaphong,[1] Asada Leelahavanichkul,[1,2] Kearkiat Praditpornsilpa,[1] Kriang Tungsanga,[1] Somchai Eiam-Ong.[1] *[1]Division of Nephrology, Department of Medicine, King Chulalongkorn Memorial Hospital and Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand; [2]Department of Microbiology, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand.*

Background: Hypercytokinemia plays a central role in the pathogenesis and is related to the high mortality in sepsis-related acute kidney injury (AKI). Besides the established cytokines, vascular endothelial growth factor (VEGF) is demonstrated as an important factor in enhancing vascular leakage in sepsis.

Methods: This prospective randomized trial was conducted to compare the efficacy of cytokine removal between online hemodiafiltration (HDF), which combines convective and diffusive solute removal, and high-flux hemodialysis (HD). Twenty eight sepsis-related AKI patients were included and randomized into online HDF and high-flux HD. The percentages of the reduction ratio in plasma cytokines were measured as primary outcomes. Other clinical parameters were determined as secondary outcomes.

Results: When compared with high-flux HD Online HDF provided significantly greater percentages of the reduction ratio in plasma cytokine levels, including VEGF (52.6±47.6 vs. 11.7±18.9%, p<0.001), IL-6 (44.8±38.8 vs. 6.04±10.4%, p=0.001), IL-8 (58.4±53.8 vs. 13.1±13.9%, p=0.021), IL-10 (47.2±45.9 vs. 11.4±18.4%, p=0.011), and tumor necrosis factor-α (52.9±49.7 vs. 32.9±26.1 %, p=0.029). There were no significant differences in intradialytic blood pressure parameters. Online HDF revealed better 30-day dialysis free (60.7 vs. 35.7%, p=0.01) and shorter median length of hospitalization (16 vs. 24 days, p=0.04) than high-flux HD.

Conclusions: On-line HDF in sepsis-related AKI could provide significantly better removal of VEGF and other cytokines and these were associated with better renal outcome than high-flux HD. Thus, online HDF would offer a potential role in hypercytokinemic state in sepsis-related AKI.

TH-PO556

Hemodiafiltration with High-Flux Dialyzer as an Economic Alternative to High Cut-Off Dialysis among Patients with Kappa Cast Nephropathy Mathieu Rousseau-Gagnon, Mohsen Agharazii, Simon Desmeules. *Service of Nephrology, CHUQ-Hôtel-Dieu de Québec, Quebec, QC, Canada.*

Background: In acute kidney injury due to cast nephropathy, free light chain (FLC) removal with High Cut-Off (HCO) dialysers combined with chemotherapy may be associated with better renal recovery. However, HCO dialysers are expensive and their use is complicated by necessity to replace albumin losses. We examined whether FLC could be efficiently removed by hemodiafiltration (HDF) using less expensive high-flux dialysers.

Methods: In 16 patients with cast nephropathy, 3- to 6-hour HDF sessions were conducted on a daily or alternate-daily basis. Pre-dilution, low volume post-dilution and high volume post-dilution HDF were performed with high-flux dialysers (Bellco's Phylther HF22SD®, Gambro's Polyflux 210H®, Nephral 500® and Fresenius' F250®), and two HCO dialysers (HCO 1100® and Theralite 2100®). Serum free light chains were measured before and after each session to determine FLC reduction ratio for each dialyzer and dilution technique.

Results: Among the high-flux dialysers evaluated, only the Phylter HF22SD® showed clinically adequate kappa (Molecular Weight(MW): 22,500 kDa) FLC clearance. None of the high-flux dialysers cleared lambda (MW: 45,000kDa) FLC effectively. For lambda FLC, HDF with HCO dialysers was optimal with a median reduction ratio(RR) in Postdilution >15L of 82% using TheraLite®. Clearance of kappa FLC by Phylter HF22SD® was influenced by infusion volume and infusion mode. Median kappa RR were as followed; Postdilution >15L: 83%, Predilution >15L: 67%, Postdilution <15L: 59%. Considering that patients with kappa cast nephropathy received a median of 20 HDF treatments and a cost differential between HCO and HF dialysers of 850$, savings of 17,000$ per patient treated can be expected.

Conclusions: In conclusion, HDF with Phylther HF22SD® is a cost-effective alternative to HCO dialysis for kappa FLC removal, whereas HCO-HDF (Theralite®) provides the adequate reduction ratios for lambda FLC removal.

TH-PO557

Ultrafiltration Dosing in Continuous Renal Replacement Therapy: Are We on Target? William Weber, Sagar Patel, Nand K. Wadhwa. *Division of Nephrology, Stony Brook University, Stony Brook, NY.*

Background: The optimal target of ultrafiltration (UF) in continuous renal replacement therapy (CRRT) in fluid overloaded critically ill patients with acute kidney injury (AKI) remains a clinical challenge. The optimal delivery of UF depends on the accurate volume status assessment involving multidisciplinary health care professionals. We investigated physician's CRRT orders compared to actual delivered CRRT treatments to evaluate if goals were achieved.

Methods: We retrospectively reviewed the records on physician prescription orders compared to actual delivered treatments in critically ill patients with AKI. 18 consecutive patients (mean±(SD) age 53±17 years; 12 males, 6 females), admitted to the Intensive Care Unit (ICU) from Feb to Nov, 2011 with AKI requiring CRRT were monitored up to 5 consecutive days. All patients received CRRT using Prisma M100 set with AN69 hemofilter on citrate anticoagulation with an effluent rate of 25-30 ml/kg/hr. Data, including admission weight (WT), daily WT and daily fluid balance calculations, were obtained from electronic medical records and ICU flow sheets which were compared to physician prescription orders.

Results: The mean hours of filter survival was 53hrs. The mean hrs of treatment was 19.9±7.3.The mean pre-CRRT WT (99.0±25.6 kg) was markedly increased when compared to the mean admitting WT (80.2±24.9 kg). After 2 consecutive days on CRRT, the mean weight decreased to 98±23.1 kg which was not significant. However the mean weight on day 5 was 92.9±25.3 which was significantly (p=.01) lower from day 2. Mean total fluid loss over 5 days was 3200mL. The mean prescribed ultrafiltration (UF) rate was 35.3±28.4 mL/hr while delivered UF rate 52.7±48.6 mL/hr on day 2 (p=.02). On day 2, the mean fluid removal set on the Prisma machine was 6495 mL/day while mean net fluid removal was lower at 6014 mL/day which was significantly lower (p=.003).

Conclusions: The net fluid removal was significantly lower than what was set at the Prisma machine. The significant weight loss and fluid removal was achieved by day 5. The actual delivered UF during CRRT treatments exceeded physician prescription orders. However, UF goals still needed to be optimized.

TH-PO558

Lactated Ringer Can Be Safely Used as Part Replacement Fluid in Therapeutic Plasma Exchange (TPE) Chaitanya P. Prabhu, Rajanna Sreedhara. *Nephrology, Fortis Hospitals, Bangalore, Karnataka, India.*

Background: TPE is a major treatment option in GB syndrome (GBS), Myasthenia gravis (MG), etc. Routine TPE involves replacement of plasma with colloids such as albumin, fresh frozen plasma (FFP) and cryosupernatant. Use of colloids is attendant with excessive cost and complications. There have been very few studies looking at partial replacement of plasma by crystalloids such as lactated ringer (RL) and saline. In India, where cost is a major deterrent for TPE, part replacement of plasma by crystalloids can significantly reduce overall cost of treatment. Our study evaluates the safety and efficacy of partial replacement of plasma by RL in TPE.

Methods: This retrospective study included all patients who underwent TPE from July 2007 till June 2011. Up to 1/3 to ½ of replacement fluid was RL, the rest being 4% albumin and FFP. Clinical outcomes and treatment related adverse events were recorded. Other parameters analysed were number of plasma filters used, amount of heparin, serum albumin, serum calcium, haemoglobin, and PT-INR. Results were expressed as mean ± SD.

Results: A total of 35 patients underwent 194 sessions of TPE. Male/Female: 28/7; Age: 54.3 ± 18.2 years; Indication for TPE: MG in 15, GBS in 14, and other causes in 6 patients. Mean volume of plasma removed 3106 ± 417 ml per TPE session. Mean volume of replacement fluid: RL, 1239 ± 348 ml, 4% Albumin, 993 ± 379 ml; FFP, 930 ± 285 ml. Mean BP: Pre-procedure, 128/76 mmHg; lowest during TPE, 116/70 mmHg; and end-procedure 129/77 mm/Hg. Transient hypotension was recorded in 24 sessions and allergic reaction in 2 patients but controlled without interruption of TPE. Clinical Outcomes: Complete improvement in 18; partial improvement in 10, no improvement in 2 and worsening in 5 patients (4 of whom died and 1 left the Hospital against medical advice). All laboratory variables were stable despite 40% of plasma volume replacement done with crystalloid fluid. Cost of replacement fluid was 40% less when compared to use of colloids alone.

Conclusions: In TPE, partial replacement of plasma with RL is safe, clinically-effective and cost-effective. This strategy decreases the cost of replacement fluid by nearly 40% in India.

TH-PO559

Low Dose Enoxaparin versus Regional Citratefor Anticoagulation in Critically Ill Patients Undergoing Continuous Renal Replacement Therapy Ming Shi, Changjian Qiu, Hui Cheng, Wei Liang, Ruhan Jia, Guohua Ding. *Division of Nephrology, Renmin Hospital of Wuhan University, Wuhan, Hubei, China.*

Background: Continuous renal replacement therapy (CRRT) is widely used in the treatment of critically ill patients, but the extracorporeal circuit clotting is still one of the greatest problems. In the present, it recommend citrate as an anticoagulation agent in patients who require CRRT but are at high risk of bleeding. Complexity of the regional citrate anticoagulation (RCA) is the major hurdle preventing widespread application. Therefore, alternative anticoagulation methods should be more widely adopted. The purpose of this study is to evaluate the safety and efficacy of low dose enoxaparin for anticoagulation during CRRT.

Methods: From March 2010 to March 2012 a total of 76 patients were included in the study with a total of 305 filters. The patients undergoing predilute continuous venovenous hemofiltration (CVVH) were randomly divided into enoxaparin group and citrate group. The following recommendation for enoxaparin dosing during CVVH: a loading dose of 40IU/kg followed by a maintenance infusion rate (per 4-hours 20IU/kg). Citrate group adopt the 4% sodium citrate and conventional RCA anticoagulant regiment.The following indicators were collected for analysis, including the filter patency, ionized calcium level,blood pH, activated the partial thromboplastin time (APTT), prothrombin time (PT), platelet count and bleeding event.

Results: The circuit life span in the enoxaprin group was no significantly difference compared with that in the citrate group (23.5 ± 12.7 h vs. 25.1 ± 13.8 h, p = 0.04). Two patients developed minor bleeding and no patient developed severe bleeding episodes in enoxaparin group and only one patient developed minor bleeding in citrate group. Two patients with hypocalcemia and two patients with metabolic alkalosis in citrate group but are transient.

Conclusions: The efficacy of enoxaparin andcitrate anticoagulation for predilution CVVH was similar. We recommend low dose enoxaparin as an alternative anticoagulation agent in critically ill patients undergoing continuous renal replacement therapy.

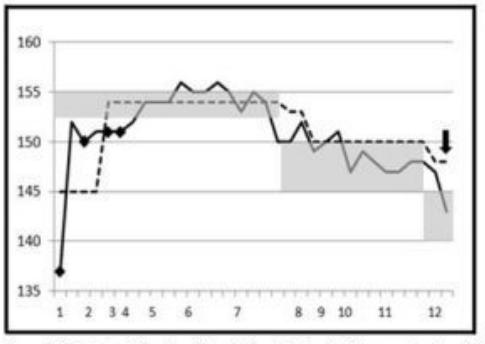
TH-PO560

High Sodium Continuous Renal Replacement Therapy for Liver Failure Patients with Renal Failure and Cerebral Edema Tamim Hamdi, Mark D. Faber. *Nephrology, Henry Ford Hospital, Detroit, MI.*

Background: Acute liver failure is a rare but devastating condition associated with a high mortality rate. Cerebral edema is the leading cause of death. Osmotherapy consisting of IV mannitol or hypertonic saline remains the cornerstone of managing of cerebral edema. Significant disadvantages of this approach include poor or unpredictable control of serum sodium concentration and extracellular fluid volume.

Methods: We used 24-hour sustained low efficiency dialysis with regional citrate anti-coagulation (SLED-RCA) to accurately control the serum sodium (S_{Na}) (150-155 mEq/L) in five patients with acute liver failure, renal failure, and cerebral edema. We used a Fresenius 2008 K machine in hemodialysis mode to deliver a blood flow of 60 ml/min and dialysate flow of 400 ml/min. Our previously published protocol results in complete removal of infused citrate by the dialyzer. On-line clearance calculations were used to model the time required to reach to target S_{Na}.

Results: All five patients achieved a S_{Na} within 2 mEq/L of target without fluctuations or rebound. Four patients had complete recovery of their renal and hepatic function with reversal of cerebral edema. One patient died of cerebral edema despite reaching the prescribed S_{Na} target. The course of a typical patient who recovered completely is shown.



Legend: X axis indicates time (days), Y axis indicates Na concentration (mEq/L). Solid line indicates achieved S_{Na}. Broken line indicates dialysate Na concentration. Diamonds indicate the administration of 23.4 % saline bullets to increase S_{Na} faster than SLED-RCA alone. Grey zone indicates desired S_{Na}. Arrow indicates end of SLED-RCA therapy.

Conclusions: We describe a novel approach for delivering continuous osmotherapy to patients with acute liver failure, renal failure, and cerebral edema. In comparison to standard therapy, SLED-RCA enables precise titration of SNa without undesirable fluctuations in extracellular fluid volume. A particular advantage of our high efficiency protocol, that results in zero delivery of citrate to patients, is the safety of use in patients with severe liver failure.

TH-PO561

High-Volume Hemofiltration Plus Hemoperfusion as an Adjuvant Therapy for Hyperlipidemic Severe Acute Pancreatitis Shiren Sun,[1] Lijie He,[2] Hanmin Wang.[3] *[1]Xijing Hospital, FMMU; [2]Xijing Hospital, FMMU; [3]Xijing Hospital, FMMU.*

Background: To evaluate the efficacy of high-volume hemofiltration (HVHF) in combination with hemoperfusion (HP) on hyperlipidemic severe acute pancreatitis.

Methods: Twenty patients with hypertriglyceridemic severe pancreatitis admitted to XiJing hospital between May 2009 and May 2011 were included in the present study. Patients were randomly divided into the control group (conventional treatment) and the HVHF+HP group. Patients in the HVHF+HP group received 48 h of HVHF and 2 sessions of hemoperfusion (HP) treatment in addition to conventional treatment after admission. The blood and effluent samples were taken to measure the changes of serum triglyceride and serum cytokines (TNF-α, IL-1, IL-2, IL-6, IL-8, IL-10).

Results: With 48 h of HVHF and 2 sessions of hemoperfusion (HP) treatment, there was an improvement in clinical features in HVHF plus HP-treated patients.The patients who accepted HVHF plus HP had significantly better Acute Physiology and Chronic Health Evaluation II scores and Sequential Organ Failure Assessment scores. The serum triglyceride levels were markedly decreased in the HVHF+HP group than in the control group. All serum cytokines after HVHF plus HP treatment were significantly lower than those at the start of HVHF plus HP treatment ($p<0.05$). In contrast, there was no significant change in control patients.

Conclusions: This study indicates that HVHF plus HP, as compared with routine treatment, is a safe and effective treatment for hyperlipidemic severe acute pancreatitis.

TH-PO562

Continuous Blood Purification in the Treatment of Patients with Multiple Organ Failure after Wasp Stings: A Report of 9 Cases Peng Zhang, Shiren Sun, Huang Chen. *Nephrology, Xijing Hospital, Xi'an, China.*

Background: The aim of this study was to evaluate of the effects of continuous blood purification (CBP) in the treatment of patients with multiple organ failure (MOF) after wasp stings.

Methods: Nine patients with multiple organ failure after wasp stings admitted to XiJing hospital between January 2007 and January 2012 were included in the present study. These patients all received CBP treatment in addition to conventional treatment after admission. Among them, six patientsreceivedtreatment of HP (2-3 h/day) using activated charcoal for two days and consecutive continuous veno-venous hemofiltration (CVVH) for 72 hours, three patientsreceivedtreatment of plasma exchange (3000ml) followed by CVVHfor 72 hours. Patients' clinical features, hemodynamics variables and serum chemical tests were monitored every day after admission.

Results: Eventually, 8 patients survived with complete clinical recovery, 1 case died. In the survived patients, there was a significant improvement in clinical features and hemodynamics variables during CBP treatment. Serum glutamic-pyruvic transaminase (GPT), glutamic-oxaloacetic transaminase (GOT), blood urea nitrogen (BUN) and creatinine (Cr) returned to normal level. The Glasgow scores increased significantly from 6.4±2.7 to 14.3±3.6 and APACHE II scores decreased significantly from 18.2±6.1 to 6.6±2.3 ($P<0.05$).

Conclusions: Our findings suggest that CBP treatment is significantly effective in improving the outcome of patients with MOF after wasp stings which may be due to its rapid removing the plasma wasp venom and inflammatory mediators from the circulation of patients.

TH-PO563

Citrate Dialysis: An Alternative to Heparin Free Dialysis in Intensive Care Unit (ICU) Patients Alan F. Almeida, Rajaram Rambhau Jagdale, Rasika A. Sirsat, Jatin Piyush Kothari. *Nephrology, P. D. Hinduja National Hospital, Mumbai, Maharashtra, India.*

Background: Renal Replacement Therapy (RRT) for Acute Kidney Injury [AKI] is often complicated by a bleeding tendency precluding the use of heparin. Citrate Dialysis [CD], an alternative to heparin-free saline flush dialysis (HFSFD) has not been prospectively studied in India till date. The present study seeks to compare the effectiveness of CD with and without flushing on dialyzer clotting, reuse of dialyzer and to compare it with HFSFD.

Methods: In this prospective study, 198 heparin free dialysis sessions were performed in 25 patients randomized to 3 groups (Group A-HFSFD, Group B- CD without saline flushing, and Group C- CD with saline flushing). Clinical, biochemical, dialyzer reuse data, etc were collected and analyzed.

Results: The study population was elderly [Mean ±SD 61.4±14.5 years] with high SAPS II scores [Mean ±SD 60.24±17.71]. Out of 198 dialysis sessions, 72, 66 and 60 sessions were done in group A, B and C respectively. When Groups A & B were compared, hemodynamic instability and hence the requirement of inotrope support was higher in group B [p=0.04] than group A. Inspite of this, average reuse of the dialyzer was higher in group B [p=0.018] than A. Though there was no significant difference in dialyzer clotting among the 3 groups, there was a trend towards significantly less dialyzer clotting in the citrate groups (B and C). The delivered dose of dialysis (urea reduction ratio in this study) was not different among the 3 groups. Pre to post Dialysis ionized calcium difference in patients with and without liver dysfunction was not different, indicating the safety of citrate use in patients with liver dysfunction. The dialysis sessions in Group A required more frequent flushing, was more time consuming and labor intensive.

Conclusions: Citrate dialysis appears to be a safe and effective alternative to heparin free saline flushing dialysis in ICU patients with AKI in terms of flushing frequency, dialyzer clotting and reuse of the dialyzer.

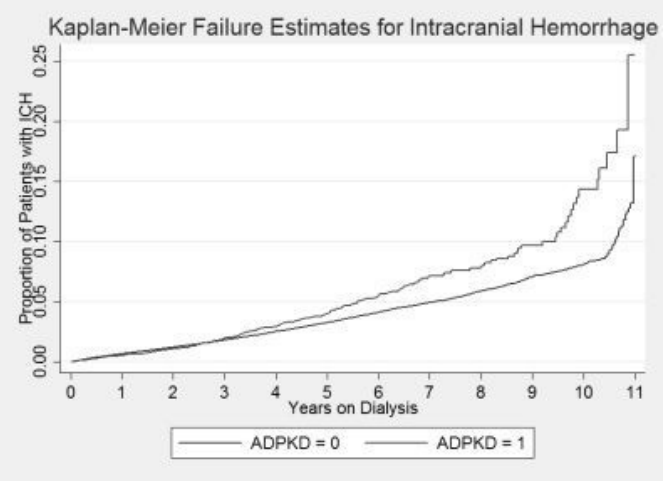
Intracranial Hemorrhage in Patients with Autosomal Dominant Polycystic Kidney Disease on Maintenance Dialysis Robert Nee,[1] David J. Yoo,[1] Lawrence Agodoa,[2] Kevin C. Abbott.[1] *[1]Nephrology, Walter Reed National Military Medical Center, Bethesda, MD; [2]NIDDK, National Institutes of Health, Bethesda, MD.*

Background: A ruptured intracranial aneurysm is a potentially life-threatening complication of autosomal dominant polycystic kidney disease (ADPKD). An analysis of intracranial hemorrhage (ICH) in a national sample of ADPKD patients receiving long-term dialysis has not been reported.

Methods: We identified 512,772 Medicare patients in the United States Renal Data System who were initiated on chronic dialysis between 1 January 1999 and July 2009, followed until 31 December 2009. We then assessed Medicare claims for subarachnoid and intracranial hemorrhage.

Results: A total of 8,793 patients (1.71%) developed ICH during the study period, and 6,749 (1.32%) had ADPKD as the primary cause of end stage renal disease. 3.67% of ADPKD patients developed ICH vs 1.96% of non-ADPKD patients (p<.001). ADPKD and non-ADPKD patients had 9.78 and 7.18 episodes of ICH per 1000 person-years, respectively, with an incidence rate ratio of 1.3 (95% CI 1.19-1.55). 0.71% of ADPKD patients had ruptured berry aneurysm vs 0.33% of non-ADPKD patients (p<.001). In Cox regression analysis, ADPKD was a significant predictor for ICH (AHR 1.45, 95% CI 1.26-1.66). Other significant risk factors in the regression included age/year (AHR/year 1.03, 95% CI 1.02-1.03), year of first dialysis treatment (AHR 1.07/year, 95% CI 1.06-1.08) and black race (AHR 1.11, 95% CI 1.06-1.17). Gender, diabetes mellitus, hypertension, alcohol dependence, tobacco use and malnutrition were not significantly associated with ICH.

Conclusions: ADPKD is a significant risk factor for ICH among patients on maintenance dialysis. "The views expressed in this abstract are those of the authors and do not reflect the official policy of the National Institutes of Health, the Department of Defense, or the US government".



TH-PO565

Characteristics and Outcomes of Dialysis Patients with Subarachnoid Hemorrhage Ankit Sakhuja, Jesse D. Schold, Sankar D. Navaneethan. *Cleveland Clinic, Cleveland, OH.*

Background: Chronic dialysis patients are at higher risk for subarachnoid hemorrhage (SAH). SAH has been shown to be associated with over 25% mortality in general population. We studied the characterisics and outcomes of chronic dialysis patients admitted with SAH.

Methods: Using Nationwide Inpatient Sample Database from 2005-2009, patients with primary discharge diagnosis of SAH were identified. Primary outcomes included all-cause inpatient mortality and discharge disposition. Logistic regression analysis was used to examine associations of inpatient mortality in those on chronic dialysis after adjusting for demographics, Charlson's comorbidity index (CCI), primary payer, hospital characteristics and year of admission. Predictors of mortality among those on chronic dialysis with SAH were also studied.

Results: Of 127,274 patients with primary SAH 1400(1%) were on chronic dialysis. Prevalence of SAH admissions by US Census & USRDS data was $77/10^5$ for dialysis vs $11/10^5$ for rest population. Dialysis patients with SAH were younger, more likely African Americans/Hispanics with higher CCI(≥3 in 88.2% vs 17.5%, p<0.0001). Patients on chronic dialysis were admitted less often to teaching hospitals(69% vs 75.3%, p=0.02) and to medium/high volume hospitals(60.8% vs 71.6%, p<0.001). In multivariate adjusted model chronic dialysis was associated with 2.62 times higher odds (95% CI 1.91, 3.62) of mortality. In patients with SAH who required mechanical ventilation, need for chronic dialysis was associated with 3.83 times higher odds(95% CI 2.42, 6.08) of death. Among those with SAH and on chronic dialysis increasing age and need for mechanical ventilation were independent predictors for inpatient mortality. Chronic dialysis patients with SAH were discharged more often to other health care facilities or with additional home care(35.9% & 12.3% vs 33.9% & 7.2% p=0.002).

Conclusions: Chronic dialysis patients appear to have a higher prevalence of SAH and higher mortality and need for specialized care post discharge than those not on chronic dialysis with SAH. Further studies are needed to devise specific treatment protocols to improve outcomes for this high risk population.

TH-PO566

Outcomes of Thrombolytic Treatment for Acute Ischemic Stroke among Dialysis Patients Fahad Saeed,[1] Nauman Tariq,[2] Saqib A. Chaudhary,[2] Malik M. Adil,[2] Adnan I. Qureshi.[2] *[1]Nephrology, Dartmouth Hitchcock Medical Center, Lebanon, NH; [2]Zeenat Qureshi Stroke Research Center, University of Minnesota, Minneapolis, MN.*

Background: The aim of this study was to determine the outcomes of IV thrombolytic therapy (tPA) for acute ischemic stroke among dialysis patients with in the United States.

Methods: We analyzed the data from Nationwide Inpatient Sample (NIS 2005-2008) for all thrombolytic treated patients presenting with acute ischemic stroke with or without dialysis dependence. Patients were identified using the ICD 9 CM codes. Baseline characteristics, in-hospital complications including secondary intracerebral hemorrhage (ICH), deep venous thrmobosis, urinary tract infections, sepsis, pneumonia, sepsis, pulmonary embolism and discharge outcomes (mortality, minimal disability, and moderate to severe disability) were compared between the groups.

Results: Of the 82142 patients with ischemic stroke who received thrombolytic treatment, 1072 (1.3%) were dialysis dependent. Out of 4215004 patients with ischemic stroke who did not receive thrombolytic treatment, 61400 (1.4%) were dialysis dependent. Baseline characteristics were mainly age, sex, race, medical comorbidities including hypertension, diabetes mellitus, presence of congestive heart failure and chronic lung diseases. The ICH rates did not differ significantly between patients with ischemic stroke with or without dialysis who received thrombolytics (5.2% vs 6.1%). The in-hospital mortality rate was higher in dialysis dependent patients treated with thrombolytics. (22% vs 11%) (*P*= <.0001). After adjusting for age and sex, and co morbidities, dialysis dependence was associated with higher rates of in-hospital mortality in patients treated with thrombolytics (odds ratio [OR], 2.47; 95% CI, 1.80-3.38 vs. odds ratio [OR], 3.06; 95% CI, 2.86-3.26) as compared to those who did not.

Conclusions: The three folds higher odds of in-hospital ischemic stroke mortality associated with administration of IV thrombolytics among dialysis patients warrants a careful assessment of risk benefit ratio before giving this therapy.

TH-PO567

Stroke Incidence and Risk Factors in Peritoneal Dialysis Albert J. Power,[1] Andrew Davenport,[2] Edwina A. Brown,[1] Neill D. Duncan,[1] Stanley Fan.[3] *[1]Imperial Renal & Transplant Centre, Imperial College Healthcare NHS Trust, London, United Kingdom; [2]Royal Free Hampstead NHS Trust, London, United Kingdom; [3]Barts & the London NHS Trust, London, United Kingdom.*

Background: Stroke is the leading cause of disability in the US with markedly higher rates in dialysis cohorts. There are very few studies examining stroke in peritoneal dialysis [PD] despite increasing numbers of patients on this modality. Of concern these suggested greater stroke mortality in PD compared to hemodialysis [HD] in analyses of cohorts over 10yrs old. We aimed to describe stroke epidemiology in contemporary PD cohorts.

Methods: This multicentre retrospective study [Jan 2002-Mar 2012] examined patients incident to PD. Stroke was defined as an acute neurological event >24hrs duration with compatible findings on neuroimaging. Subdural hematoma was excluded. Factors associated with stroke risk were examined with multivariate Cox models and a competing-risks approach. The effect of stroke on survival assessed using Weibull models.

Results: 1511 patients were studied [mean age 54.7±16.5yrs, 35% diabetic, 7% with pre-existing cerebrovascular disease] over 3672 total patient years follow-up. 36 strokes occurred [overall incidence 9.8/1000 pt years] of which 31/36 [86%] were ischemic, 14% hemorrhagic. Stroke occurred in older patients [mean age 60.5±12.5 vs 54.2±16.6yrs, p=0.01] after a median of 11 months on PD. After age-adjustment, established cerebrovascular disease was the only factor independently associated with a greater risk of stroke [HR 4.2, p<0.001] whereas gender, ethnicity, diabetes, atrial fibrillation were not. One year mortality after stroke was 19% with no significant difference by subtype. On multivariate analysis acute stroke was independently associated with worse patient survival [HR 4.6, p<0.001].

Conclusions: Stroke incidence is ten-fold greater in PD compared to the general population. In the largest study of its kind to date we found incidence rates lower in PD cohorts compared to HD [15-30/1000 patient years] and in contrast to previous studies. The relatively fewer hemorrhagic events seen may relate to casemix, anticoagulation exposure, residual renal function and volaemic control.

TH-PO568

Hemodialysis Patients with Atrial Fibrillation Have a 1.7-Fold Higher Risk for All-Cause Death Despite of Lacking the Elevated Risks for Cardiovascular Mortality Masaki Ohsawa. *Department of Hygiene and Preventive Medicine, Iwate Medical University, Iwate Prefecture, Japan.*

Background: Atrial fibrillation (AF) contributes to increased risks for cardiovascular morbidity and mortality in general populations. However, whether AF contributes to increased risks for these endpoints has not been fully examined in hemodialysis patinets (HD pts).

Methods: Two prospective cohort studies of 1,109 HD pts and 26,469 community-dwelling people (controls) were carried out. Sex- and age-adjusted mortality rates (all-cause, cardiovascular and infectious-related) and incidence rates (acute myocardial infarction (AMI) and stroke) and adjusted rate ratios were calculated using Poisson regression model (see table).

Results:
Sex- and age-adjusted mortality and incidence rates (/1000 pys) and incidence rate ratios in the groups stratified by AF

HD vs ctls	HD pts (n=1,109)		controls (n=26,469)	
AF groups	non-AF (n=1,074)	AF (n=35)	non-AF (n=26,067)	AF (n=402)
all-cause death	68.7 (60.0 to 77.4)	117 (67.8 to 166)	3.37 (3.01 to 3.74)	5.93 (4.22 to 7.65)
RR (95% CI)	REF	1.70 (1.13 to 2.56)	REF	1.76 (1.34 to 2.31)
CVD death	37.2 (30.5 to 43.9)	53.0 (30.0 to 76.0)	0.61 (0.46 to 0.76)	2.38 (1.27 to 3.49)
RR	REF	1.27 (0.64 to 2.50)	REF	3.91 (2.58 to 5.91)
Infectious death	16.5 (12.2 to 20.7)	36.5 (9.52 to 63.5)	0.15 (0.09 to 0.22)	0.29 (0.07 to 0.51)
RR	REF	2.22 (1.09 to 4.50)	REF	1.89 (0.99 to 3.61)
AMI	8.91 (5.74 to 12.1)	9.65 (0.00 to 23.8)	0.35 (0.23 to 0.46)	0.62 (0.03 to 1.20)
RR	REF	1.08 (0.26 to 4.56)	REF	1.78 (0.72 to 4.41)
stroke	45.4 (38.5 to 52.3)	38.9 (3.92 to 73.8)	3.13 (2.78 to 3.48)	10.7 (7.61 to 13.8)
RR	REF	0.86 (0.35 to 2.11)	REF	3.41 (2.59 to 4.51)

Adjustment for for persons aged 60 yrs old and male/female ratio beeing 1.0.

There were 1.7-fold higher risks of all-cause death in persons with AF as opposed to those without AF both in HD pts and controls. AF contributed to increases in risks for all-cause death and cardiovascular morbidity and mortality in a general population, whereas it only increased a risk for all-cause death without increasing risks for cardiovascular morbidity and mortality in HD pts.

Conclusions: AF increaseed a risk for death without increasing risks for cardiovascular morbidity and mortality in HD pts.

TH-PO569

Attributable Risk of Atrial Fibrillation for Stroke in Dialysis Patients

James B. Wetmore,[1] Jonathan D. Mahnken,[3] Milind A. Phadnis,[3] Sally K. Rigler,[2] Xinhua Zhou,[3] John Spertus,[5] Purna Mukhopadhyay,[3] Theresa I. Shireman.[4] *[1]Division of Nephrology, University of Kansas Medical Center, Kansas City, KS; [2]Medicine, University of Kansas Medical Center, Kansas City, KS; [3]Biostatistics, University of Kansas Medical Center, Kansas City, KS; [4]Preventive Medicine & Public Health, University of Kansas Medical Center, Kansas City, KS; [5]St. Luke's Mid America Heart Institute, University of Missouri - Kansas City, Kansas City, MO.*

Background: Both stroke and chronic atrial fibrillation (CAF) are common in dialysis patients. We sought to determine the association between CAF and stroke and to establish the incidence of new strokes.

Methods: A cohort of incident Medicare & Medicaid patients was constructed. A Medicare claims were used to determine the onset of CAF, which was treated as a time-dependent covariate. Strokes were determined from Medicare claims. Cox proportional hazards models were constructed to determine the association between predictor variables and times to stroke.

Results: CAF was independently associated with time to ischemic stroke (HR 1.26, P = 0.0005) and to all (combined) strokes (HR 1.21, P = 0.0019) but not with hemorrhagic stroke (HR 0.93, P = 0.70). Race played a striking role in hemorrhagic strokes: African-Americans (HR 1.46), Hispanics (HR 1.64), and other minorities (HR 1.76) all had significantly shorter times-to-event than did Caucasians (P < 0.001 for all). Overall, the ratio of ischemic to hemorrhagic strokes was approximately 4.5:1. There were 22.8 ischemic, 5.0 hemorrhagic, and 27.3 combined strokes per 100 patient-years. Stratifying CAF patients into $CHADS_2$ scores of 0-1, 2, or 3-6, Kaplan-Meier curves varied from each other at the level of P = 0.01.

Conclusions: CAF has a highly significant, but modest, association with ischemic stroke. The most striking association with hemorrhagic stroke is race/ethnicity. The ratio of hemorrhagic to ischemic strokes is much higher than in the general population. The $CHADS_2$ risk score appears to work well in broadly stratifying CAF dialysis patients for ischemic stroke.

Safety of Warfarin Use in Chronic Hemodialysis Patients: A Prospective Case-Control Study

Matsuhiko Hayashi, Ichirou Takamatsu, Yoshihiko Kanno, Tadashi Yoshida. *Apheresis and Dialysis Center, University of Keio, School of Medicine, Shinjuku-ku, Tokyo, Japan.*

Background: Since there are limited data concerning the risks associated with warfarin use in hemodialysis (HD) patients, we conducted a prospective case-control study in the patients on chronic HD in Japan.

Methods: The patients on chronic HD with warfarin and control HD patients were recruited from 103 HD centers in Japan. For each patient on warfarin, two dialysis-vintage matched controls were selected at each HD center. Clinical data were collected at the beginning and 12 months after the registration.

Results: At the end of the study, 344 cases with warfarin and 645 controls were qualified for further analysis. The occurrence of composite incidences (18.9%), which include death, new stroke, and new cardiovascular events, and the occurrence of each of these incidences were not significantly different as compared to the controls (composite incidences 17.7%). The incidence of major bleeding (gastrointestinal, intramuscular, and hemorrhagic stroke) in warfarin users (8.1%), however, was significantly higher than in the controls (2.6%, p<0.0001). By multivariate logistic regression model analysis, age (OR 1.039 for each 1-year increase, 95% CI 1.021-1.057, p<0.0001) and the history of cardio- and cerebrovascular events (OR 1.84, CI 1.27-2.67, p<0.05), but not warfarin use or atrial fibrillation (Af), were identified as the risk factors for composite incidences, while warfarin use was the sole risk factor for major bleeding (OR 3.22, CI 1.50 – 6.94), p<0.005). Patients with warfarin for preexisting Af (184 cases) and their corresponding controls (350 cases) were analyzed separately, and warfarin use did not significantly increase composite incidences, mortality, new stroke, and new cardiovascular events in the patients with Af, either.

Conclusions: The present study showed that warfarin use increased the risk of major bleeding, while the occurrences of composite and individual incidences except major bleeding were not significantly different from the controls in either total cases or in the cases with Af. Considering the high cardiovascular mortality in patients on chronic HD and Af, warfarin use may be beneficial for these patients.

TH-PO571

Appropriate Intensity Anticoagulation with Warfarin Reduces Risk of Mortality in Hemodialysis Patients with Atrial Fibrillation

Masayuki Koyama,[1] Tomohisa Yamashita,[2] Takahiro Fuseya,[1] Tomohiro Mita,[1] Yusuke Okazaki,[1] Shutaro Ishimura,[1] Marenao Tanaka,[1] Nobuhiko Togashi,[2] Masato Furuhashi,[1] Hideaki Yoshida,[1] Kazufumi Tsuchihashi,[1] Tetsuji Miura.[1] *[1]Second Department of Internal Medicine, Sapporo Medical University, Sapporo, Hokkaido, Japan; [2]Department of Nephrology, JR Sapporo Hospital, Sapporo, Hokkaido, Japan.*

Background: Atrial fibrillation (AF) is a common comorbidity in hemodialysis (HD) patients. However, there is a paucity of data concerning risk-benefit tradeoff in anticoagulation therapy with warfarin (WF). The aim of this study was to investigate the effects of WF use in HD patients with AF on clinical outcomes.

Methods: We registered all patients on regular HD (n=1110) in 24 affiliated hospitals on Jan 2009 and prospectively followed up for 3 years. After exclusion of 173 patients who had missing data or were dropped out during follow-up, 937 subjects (age 65.7 ± 12.2 years; mean duration of HD 82.0 months) were divided into Sinus Rhythm group (SR, n=819) and AF group (AF, n=118), and AF was subdivided into AF with WF (AFWF, n=31) and AF without WF (AFNWF, n=87). Pre-specified end-points were the new onset of stroke, bleeding events and death.

Results: The mortality in the AF was higher than in the SR (24.6% vs. 14.6%, P<0.01). Compared with SR, the AF was significantly older (70.9 ± 9.4 vs. 65.0 ± 12.4 years, P<0.01) and had previous history of stroke (23.7% vs. 14.5%, P<0.01), ischemic heart disease (21.2% vs. 12.1%, P<0.01), and peripheral artery disease (22.0% vs. 12.8%, P<0.01). Logistic regression analysis indicated that age, duration of HD, history of ischemic heart disease and peripheral artery disease, and $CHADS_2$ score were independent factors associated with the mortality. In Kaplan-Meier survival curves analysis, AFWF had significantly lower mortality (P = 0.03) and lower incidence of new-onset stroke (P = 0.02) compared with the AFNWF, though the incidence of bleeding events was similar (12.9% vs. 10.8%). In the AFWF, the prothrombin time-international normalized ratio was 2.2 ± 1.0.

Conclusions: The present results suggest that proper anticoagulation with WF reduces the risk of mortality and that of stroke without increasing bleeding events in HD patients.

TH-PO572

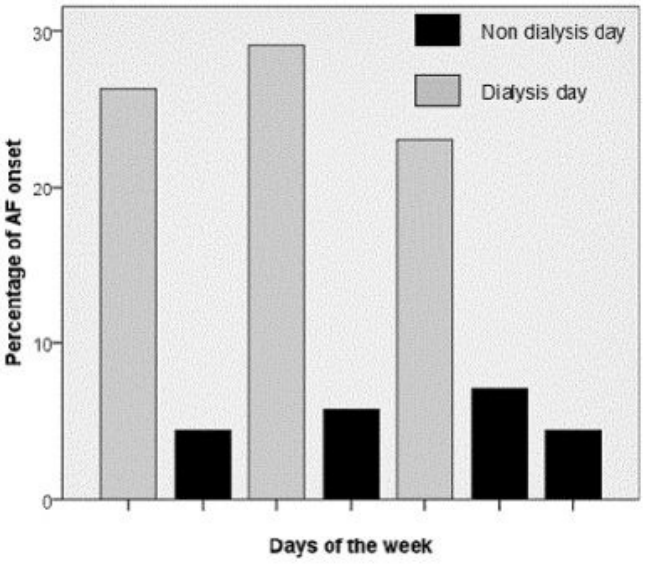
Is the High Prevalence of Atrial Fibrillation in End Stage Renal Disease Related to the Hemodialysis Procedure Itself?

Maurits S. Buiten,[1] Mihaly K. De Bie,[1] Joris I. Rotmans,[2] Bas A. Gabreels,[3] J. H.M. Groeneveld,[4] L. Van Erven,[1] Ton J. Rabelink,[2] Martin J. Schalij,[1] J. W. Jukema.[1] *[1]Cardiology, Leiden University Medical Center, Leiden, Nepal; [2]Nephrology, Leiden University Medical Center, Leiden, Netherlands; [3]Nephrology, Rijnland Hospital, Leiden, Netherlands; [4]Nephrology, Kennemer Gasthuis, Haarlem, Netherlands.*

Background: Atrial fibrillation(AF) is common in patients with end stage renal disease(ESRD) and is associated with increased morbidity. Pathophysiology might be related to common risk factors of both AF and ESRD or to hemodialysis(HD) specific factors. The purpose of this study was to determine the onset of AF in relation to the HD procedure itself.

Methods: All HD patients currently enrolled in the ICD2 trial, implanted with an ICD were included. All days recorded by the ICD were analyzed for AF onset and the relationship between AF and the HD procedure was assessed. All procedures during which AF developed were further analyzed and compared to procedures in which AF did not occur.

Results: A total of 41 pts were included (follow-up 27±16 mths, 81% male, 70±8 yrs). In this group, 14 pts developed a total of 428 AF episodes. The onset of AF was seen more frequently on the days of HD (p<0,001) with the highest percentage of episodes starting around the last hour(s) of the procedure. HD procedures in which AF developed were associated with a higher HD volume (p<0,008) and a lower potassium concentration in the HD fluid (p<0,001), compared to procedures in which AF did not occur.



Conclusions: This is the first study to show a clear relationship between the onset of AF and the HD procedure itself. Volume shifts are larger in HD procedures in which AF start and the time of onset clusters around the last hours of the HD procedure. These findings could point to an important role for intravascular volume depletion and potassium flux in the pathophysiology of AF.

TH-PO573

Evolution of Death Risk Following Initiation of Hemodialysis in the United States, 2005-2009 Robert N. Foley,[1,2] Allan J. Collins,[1,2] David T. Gilbertson,[1] Shu-cheng Chen.[1] *[1]USRDS Coordinating Center, MMRF, Minneapolis, MN; [2]Medicine, University of MN, Minneapolis, MN.*

Background: Although initiation of dialysis is a period of great clinical flux, the evolution of mortality risk early in the course of hemodialysis is not well understood. This lack of information is surprising, as it could help with clinical decision-making.

Methods: We studied the evolution of mortality risk in two-week increments for one year in US hemodialysis patients (2005-2009, N = 506,506, mean age 63.2 years).

Results: Mortality risk for the overall population (expressed as the probability of death at 1 year if risk remained constant) was at its lowest in the initial two-week interval (0.12, 95% confidence interval [0.11, 0.12], rose gradually to a peak at week 8 (0.41 [0.40, 0.42]) and declined gradually to an intermediate level at week 52 (0.18 [0.17, 0.19]). This biphasic mortality was present in all subgroups studied, whether defined by age, sex, race, cause of ESRD, presence of diabetes and cardiovascular disease, GFR, mode of vascular access and pre-dialysis nephrology care. Among the 21 subgroups examined, the median change in mortality risk between initiation of dialysis and week 8 was +0.30; the largest and smallest absolute changes were in patients ≥ 65 years (0.18 to 0.66) and patients < 40 years (0.03 to 0.09), respectively. Analysis of hemodialysis patients in other eras (1995-2000 and 2001-2004) also showed a biphasic mortality pattern.

Conclusions: Morality risk accelerates rapidly in the first two months following initiation of dialysis, especially in older patients.

TH-PO574

Comparative of Transplanted Listed Hemodialysis and Peritoneal Dialysis in the United States, 2005-2009 Robert N. Foley,[1,2] Allan J. Collins,[1,2] David T. Gilbertson,[1] Shu-cheng Chen.[1] *[1]USRDS Coordinating Center, MMRF, Minneapolis, MN; [2]Medicine, University of MN, Minneapolis, MN.*

Background: Although markedly different in terms of dialysis technique, many studies have shown similar survival expectations with hemodialysis (HD) and peritoneal dialysis (PD). Concern remains, however, that unmeasured comorbidity threatens the validity of existing survival comparisons. As exclusion of serious ongoing medical issues is a prerequisite for transplant listing, survival comparisons by mode of dialysis in listed patients has the potential to mitigate these concerns.

Methods: We compared annual dialysis mortality estimates by mode of dialysis at the time of first listing for transplantation in the United States between 2005 and 2009 (N = N 93459, 14.5% PD).

Results: Compared to HD, PD patients were younger (mean age 46.1 Vs. 50.8 years), and less likely to be male (55.6% Vs. 62.3%), on dialysis for ³ 1 year (47.1% Vs. 56.1%), Black (26.2% Vs. 35.0%), Hispanic (16.5% Vs. 20.0%) and to have diabetes as cause of ESRD (33.0% Vs. 41.6%). Death rates were similar, at 4.7 (4.6,4.9) Vs. 4.5 (4.1,4.9) per 100 person-years, respectively in the HD and PD populations. Unadjusted and adjusted PD-to-HD mortality hazards ratios were 0.96 and 1.02 (P = 0.6), respectively.

Conclusions: Among transplant-listed patients, survival on dialysis is similar for HD and PD.

TH-PO575

Temporal Trends in Sudden Cardiac Death in Incident US Hemodialysis Patients Shuling Li,[1] Charles A. Herzog.[1,2] *[1]CVSSC, United States Renal Data System, MMRF, Minneapolis, MN; [2]University of Minnesota, Minneapolis, MN.*

Background: The initiation of hemodialysis (HD) is a vulnerable period with a markedly heightened risk of death. Few published data exist regarding sudden cardiac death (SCD) in the first 90 days after dialysis initiation. We hypothesized that the rate of SCD is markedly higher in newly incident HD pts and we analyzed temporal trends in SCD over a decade.

Methods: Incident HD pts in 2000 (n= 84,526), 2005 (n= 97,090) and 2009 (n= 105,644) were identified in the USRDS database. Pts were followed from HD initiation to the earliest of death, transplant, recovery of kidney function, loss-to-follow-up, or one year after initiation. SCD was determined from CMS Form 2728. Cumulative probability of SCD and monthly SCD rates per 1000 pt-yrs, estimated by Kaplan-Meier method, were adjusted for age, sex, race, and ESRD cause with 2009 cohort as reference.

Results: Demographic characteristics of incident HD pts were similar from 2000-2009: 26-27% age 75+, 54-57% male, 64-65% white, 45-46% DM as primary cause of ESRD. One year unadjusted probability of SCD for 2000, 2005, 2009 were respectively 8.7%, 8.0%, and 7.0%, and after adjustment, 9.0%, 8.2%, and 7.2%. Peak SCD rates occurred 2 months after HD initiation: unadjusted monthly SCD rate/1000 pt-yrs for 2000, 2005, and 2009 were respectively 138, 131, and 122 and after adjustment 140, 132, and 123 SCD's/1000 pt-yrs (See Figure for adjusted rates).

Conclusions: The hazard of SCD is markedly increased in incident HD pts in the first 90 days after dialysis initiation, with the highest SCD rate at two months after initiation of HD. The rates of SCD have declined over the past decade, but even in 2009 7% of HD pts succumbed to SCD in the first year of dialysis.

TH-PO576

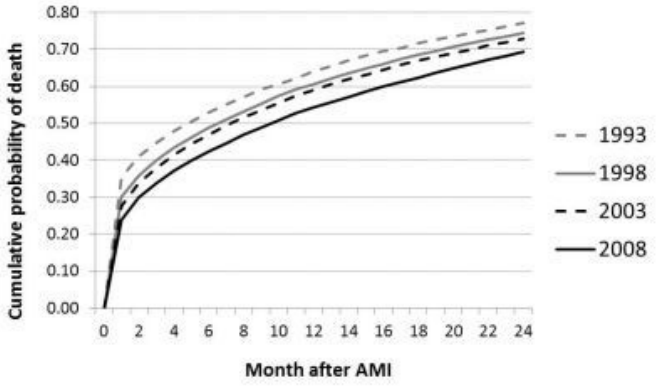
Long-Term Survival after Acute Myocardial Infarction among Patients on Long-Term Dialysis: Is It Still Dismal? Shuling Li,[1] Gautam R. Shroff,[2] Charles A. Herzog.[1,2] *[1]CVSSC, USRDS, MMRF, Minneapolis, MN; [2]Hennepin County Medical Ctr., Minneapolis, MN.*

Background: Acute myocardial infarction (AMI) is a catastrophic event associated with dismal long-term survival in dialysis pts (Herzog et al, NEJM, 1998): the one and two yr mortality for AMI was respectively 55% and 71% in 1977-84, 62% and 74% in1990-95. We sought to determine if there has been any change in outcome of dialysis pts sustaining AMI in the most recent treatment era.

Methods: We searched the US Renal Data System database to identify prevalent HD pts hospitalized for an index AMI in 1993, 1998, 2003, and 2008. Follow-up time was 2 yrs from the index AMI admission and censored at transplant, recovery of kidney function or loss-to-follow-up. Cumulative 2-yr mortality was estimated by Kaplan-Meier method with subsequent adjustment for age, gender, race, dialysis vintage (time on dialysis), and etiology of ESRD with 2008 as reference.

Results: There were 43,168 dialysis pts with AMI (4,494 in 1993, 8,081 in 1998, 14,232 in 2003, and 16,361 in 2008). Over time, there was a progressive proportional increase in older pts, black pts, diabetic ESRD, and older vintage, but no change in gender. For 1993 vs 2008 there were 23% vs 31% age 75+, 25% vs 31% black, 42% vs 55% diabetic ESRD, 15% vs 26% vintage 5+ yrs, (and 53% vs 54% male). In-hospital death decreased from 32% in 1993 to 19% in 2008 (P< .0001). The **Figure** shows adjusted cumulative probability of death by AMI yr. 30 day mortality for 1993, 1998, 2003, and 2008 were respectively 35%, 30%, 28%, and 24%. Mortality for 1993, 1998, 2003, and 2008 were respectively 64%, 61%, 59%, and 54% at 1 year and 77%, 75%, 73%, and 69% at 2 yrs.

Conclusions: There has been an improvement in survival in dialysis pts sustaining AMI in the most recent treatment era, predominantly due to a marked reduction in 30 day mortality. Aggressive interventions targeting long-term mortality are warranted.



Funding: NIDDK Support

TH-PO577

Comparative Survival of Hemodialysis Patients with Implantable and Wearable Cardioverter Defibrillators Shuling Li,[1] Charles A. Herzog.[1,2] *[1]CVSSC, United States Renal Data System, MMRF, Minneapolis, MN; [2]University of Minnesota, Minneapolis, MN.*

Background: Sudden cardiac death (SCD) accounts for 26% of all-cause mortality in dialysis pts, and implantable cardioverter defibrillators(ICD/CRT-D) are widely used for primary prevention (PP) to prevent SCD and secondary prevention (SP) of SCD (in cardiac arrest survivors). Few data exist on outcome of dialysis pts with wearable cardioverter defibrillators (WCD).

Methods: Prevalent HD pts receiving first ICD/CRT-D or WCD in 2005-2010 were identified in the US Renal Data System (USRDS) database (ICD-9-CM codes 37.94 and 00.51 for ICD/CRT-D and CPT codes 93292 and 93745 for WCD). SP was defined by ICD-9-CM codes 427.1, 427.4 and 427.5 on the same device claims. F/u time from first device use was two yrs (to 6/30/11) with censoring at transplant, device change, or switch to PD. Survival probability was estimated by Kaplan-Meier method with differences in survival between devices tested by Log-rank test.

Results: There were 10,082 HD pts with ICD/CRT-D (55% PP) and 57 pts with WCD (77% PP). Across prevention types, ICD/CRT-D cohort had more pts aged 65+ yrs, female and white, and fewer pts with ESRD vintage 5+ yrs than WCD cohort. More diabetic ESRD pts were seen in PP ICD/CRT-D (50%) than PP WCD (39%), but fewer in SP ICD/CRT-D (49%) than SP WCD (54%). 10 WCD pts subsequently received ICD's. Median time to switch was 40 days. The Figure shows 2-year cumulative survival probability comparing ICD/CRT-Ds with WCD by prevention type. For PP, WCD had similar survival with ICD/CRT-D. For SP, WCD had inferior survival than ICD/CRT-D. Both comparisons were not statistically significant.

Conclusions: Wearable defibrillators may provide comparable one yr survival to ICD's, particularly for primary prevention of SCD. Randomized clinical trials of WCD's for prevention of SCD in HD pts are warranted.

TH-PO578

Mortality Rates among Prevalent Hemodialysis Patients in Beijing: A Comparison with USRDS Data Li Zuo, Mei Wang, Wen Huang, Wenhu Liu, Xuemei Li, Kai Wang, Li Jijun, Chunhua Zhou, Xu-yang Cheng. *Department of Medicine, Peking University First Hospital, Peking University Institute of Nephrology, Beijing, China.*

Background: The reported rude mortality rate in Chinese patients on maintenance hemodialysis (MHD) was around 10%, it was around 20% in the US reported by the United States Renal Data System (USRDS). Our hypothesis was that the large survival difference was cause by difference in race, practice pattern between nations if baseline patients' characteristics were adjusted.

Methods: Annual mortality of Beijing prevalent MHD patients in each year of 2007 through 2010 was reported, and relative risks of death compared with corresponding mortality of USRDS prevalent MHD patients after age, gender and primary cause of end stage renal disease were adjusted were calculated. 11,675 MHD patients from 104 dialysis facilities in Beijing from December 31, 2006 to December 31, 2010 were included. 1,937,819 MHD patients (only White, African-American and Asian were eligible for inclusion) were subtracted from USRDS No-60-Day prevalent dataset from the year 2004 to 2009 using RenDER system. Rude annual mortality for each race was reported as number per 1000 MHD patients at risk for each year. Adjusted annual mortality and relative risk of death after age, gender and primary cause of ESRD was adjusted comparing Beijing and each of the USRDS race.

Results: The annual mortality for Beijing cohort increasing gradually from 47.8 per 1000 patient-years in 2007 to 76.8 in 2010. The annual mortality for White cohort2007 was 250.7 per 1000 patient-years, and gradually decreased to 236.3 in 2009. Annual mortality for African-American was much lower than that for White. Annual mortality for Asian was slightly lower than that for African-American. After adjustment, Beijing MHD still had survival benefit comparing each of the examined USRDS race.

Conclusions: Annual mortality for Beijing MHD patients was lower than their USRDS counterparts, and this difference existed after baseline demographics were adjusted. This survival difference between Beijing and USRDS MHD cohorts could be attributable to race or practice pattern difference. More study needed to validate our hypothesis.

TH-PO579

Pre-Dialysis Factors and the Comparative Effectiveness of Early versus Conventional Dialysis Initiation among Older Adults Deidra C. Crews,[1,4] Julia J. Scialla,[2,4] Haifeng Guo,[3,4] Jiannong Liu,[3,4] Karen J. Bandeen-roche,[1,4] L. Ebony Boulware.[1,4] *[1]Johns Hopkins Univ.; [2]Univ. of Miami; [3]Chronic Disease Research Group; [4]For the DeCIDE Network Patient Outcomes in ESRD Study.*

Background: Recent studies of the timing of dialysis initiation have not accounted for several pre-dialysis clinical factors that could contribute to poor outcomes observed among early initiators. These factors may be especially important among older adults.

Methods: We identified patients initiating dialysis at age ≥67 years from 2006-2008 with 2 prior years of Medicare coverage in the US Renal Data System. We reviewed 6 months of pre-ESRD claims for acute kidney injury (AKI), uremia, hyperkalemia, congestive heart failure (CHF) admissions, and total hospital days. We used Medicare claims and the Medical Evidence form to ascertain demographics, lab values, comorbidities at dialysis initiation and outcomes (mortality and hospitalization). Using propensity scores for likelihood to initiate dialysis early (eGFR ≥10 ml/min/1.73m^2) versus later/conventional (eGFR <10), we constructed a cohort matched 1:1. We estimated risks of post-ESRD mortality (all-cause and cause specific) and hospitalizations (Cox model) among early versus later initiators.

Results: Among 84,654 older US adults with pre-ESRD claims, 58% initiated dialysis early. Early initiators were more likely to have had AKI, CHF admissions and all-cause hospitalizations when compared to later initiators. Propensity matching was successful for 61,930, with 50% in each initiation group. Early initiation was associated with greater risk of all-cause, cardiovascular (CV) and infectious mortality; and greater risk of all-cause and infectious hospitalizations.

Hazard Ratios Comparing Early versus Later Dialysis Initiation

Outcome	Early Incidence per 1000 person yrs	Later Incidence per 1000 person yrs	Hazard Ratio (95% Confidence Interval) Comparing Early (referent) to Later
All-Cause Mortality	402.1	360.5	1.11 (1.08-1.14)
CV Mortality	146.7	131.8	1.11 (1.06-1.15)
Infectious Mortality	41.7	36.0	1.15 (1.06-1.24)
All-Cause Hospitalizations	2079.8	2017.8	1.03 (1.01-1.05)
CV Hospitalizations	623.7	629.9	0.99 (0.96-1.01)
Infectious Hospitalizations	538.5	487.5	1.10 (1.07-1.13)

Conclusions: After accounting for pre-dialysis clinical factors, early dialysis initiation is associated with greater mortality and infectious hospitalizations among older US adults.

TH-PO580

Trends in Mortality in Pediatric Chronic Dialysis Patients Blanche M. Chavers,[1,2] Julia T. Molony,[1] Craig Solid.[1] *[1]USRDS Coordinating Center, MMRF, Mpls, MN; [2]Dept. of Pediatrics, University of MN, Mpls, MN.*

Background: There are few published data describing survival trends over time of pediatric dialysis patients. Our goal is to describe mortality rates over a 15 year period.

Methods: From the USRDS database, we identified chronic dialysis (HD or PD) patients aged 18 and under for each year between 1995 and 2010. Patients were followed for up to 1 year and censored by a change in the type of renal replacement therapy. We calculated the number of deaths, percent of deaths, and the mortality rate per time at risk within each cohort year. Results were considered separately by type of dialysis and patient characteristics.

Results: The average yearly cohort of patients studied included about 1,200 at risk patients of whom 60% were HD and 40% were PD, and the majority were over 10 years of age. There were slightly more males (55%) than females (45%), and the most common causes of dialysis were congenital/reflux/obstructive (45%) and glomerulonephritis (30%). From 1995 to 2010, the yearly number of deaths has generally declined (Table 1). The mortality rates were higher for patients under 10 years old (average of 6.5 per 100 pt yrs) as compared to patients over 10 years old (average of 3.3 per 100 pt yrs). Mortality rates were also lower for PD patients than for HD patients. Overall, there appears to be some decline in the unadjusted mortality rates over the study period, although the change is slight.

Period Prevalent HD and PD Pediatric Patients from 1995-2010

Year	Patients at Risk	Deaths	Mortality per 100 pt years
1995	1221	47	5.21
1996	1255	47	5.13
1997	1263	45	4.74
1998	1214	39	4.33
1999	1173	50	5.83
2000	1103	33	4.05
2001	1136	34	4.06
2002	1215	31	3.49
2003	1282	55	6.00
2004	1271	29	3.10
2005	1290	46	3.80
2006	1227	40	4.56
2007	1176	34	4.05
2008	1146	29	3.52
2009	1179	28	3.37
2010	1161	26	3.10

Conclusions: In general, mortality rates among pediatric dialysis patients have not changed dramatically over the past 15 years. However, younger patients have almost double the mortality rate when compared to older pediatric patients, and PD patients have a lower mortality rate than HD patients. Of note are older pediatric PD patients who show some improvement in mortality rates over time.

TH-PO582

Valve Replacement in Patients with Dialysis-Dependent Renal Failure: Choice of Prosthesis and Impact of Hyperparathyroidism on Mortality Qi Qian,[1] Sameh M. Said,[2] Hartzell Schaff,[3] Joseph A. Dearani,[3] Soon J. Park,[3] Kevin L. Greason,[3] Rakesh M. Suri,[3] Richard C. Daly.[3] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Thoracic and General Surgery, Mayo Clinic, Rochester, MN; [3]Cardiovascular Surgery, Mayo Clinic, Rochester, MN.*

Background: Controversy exists regarding the prosthesis of choice in patients with dialysis-dependent renal failure.

Methods: Between Jan 1980 & Dec 2010, 95 pt (63 males, 66%) with dialysis-dependent ESRD underwent left-sided valve replacement with biological (n=44) or mechanical valves. The mean dialysis duration prior to valve replacement was 4.6±4.8 & mean age 63±14 yr. 27 pts (28%) were re-do valve replacement. Comorbidities included diabetes mellitus in 49%, chronic lung disease 17%, & hypertension 97%; 20 pt (21%) had bacterial endocarditis preoperatively. 68 pt (72%) underwent isolated aortic valve replacement, while 15 pt had isolated mitral valve replacement, and both aortic & mitral valves were replaced in the remaining 17 pt (13%). Preoperatively, the serum PTH, phosphate, calcium and calcium-phosphate product were 421±993 pg/ml, 5.9±1.4 mg/dl, 9.7±0.9 mg/dl, and 57.6±16 mg/dl, respectively.

Results: Early mortality was related to preop risk factors. Among pts without endocarditis operative risk was 9%. For pt having isolated AVR, early mortality was 4%. For pt with endocarditis, risk was 20%. For all pt, survival at 1-, and 5-yr was 62%, and 27%. Type of the prosthesis did not have a significant impact on survival. The 5-year survival was lower in pt with elevated PTH, phosphate, & calcium-phosphate product (25vs33%, 17vs38% and 21vs33%) but this difference was not significant. Late stroke occurred in 7 pt with biologic valves and only 1 pt with a mechanical valve (p=0.01). Reoperation due to structural valve degeneration was documented in two pt with biological valves.

Conclusions: Mortality, both early & late is relatively high for patients with ESRD undergoing valve replacement. There is no demonstrable survival advantage to bioprostheses. Hyperparathyroidism may have an impact on survival in dialysis-dependent pt undergoing valve surgery.

TH-PO583

Left Atrial Appendage Closure (LAAC) as New Option for ESRD-Patients with Atrial Fibrillation and Discontinued Oral Anticoagulation after Severe Bleedings: Pilot Data on Three Patients Karl August Brensing,[1] Peter M. Raab,[1] Thomas M. Gerhardt,[1] Uwe Poege,[1] Peter Heidkamp,[1] Heyder Omran.[2] *[1]Dialysis Unit, Nephrology Center Bonn, Bonn, NRW, Germany; [2]Internal Medicine, Marien Hospital, Bonn, NRW, Germany.*

Background: Patients with atrial fibrillation (AF) need oral anticoagulation (OAC), but for ESRD-patients this approach is unproven, since no prospective data exist, current scores for embolism (CHADS2-VASC) and bleeding (HASBLED) are not validated for ESRD and two large register studies reported higher morbidity and mortality in HD-patients on OAC (1, 2). Thus, HD/PD-patients with OAC related severe bleedings might benefit from left atrial appendage closure (LAAC) by avoiding further OAC but safety and outcome data are missing.

Methods: We report on three older ESRD patients (Pt 1: 81 yrs, HD; Pt 2: 84 yrs, HD; Pt 3: 77 yrs, IPD) with AF and discontinued OAC after severe bleedings (1x hematothorax, 2x gastrointestinal) with follow-up for 3, 10 and 21 months (Mo) after LAAC using an Amplatzer Cardiac Plug occluder set.

Results: LAAC was well tolerated without any interventional complications. After initial heparin (hirudoid Pt 2 due to HIT-II) for 2 days all patients received only low-dose aspirin (50-100 mg/day) and HD (3x/week=wk high-flux HD for 4 h, with heparin or hirudoid) or 3x/wk IPD (for cardio-renal syndrome, Pt.3). In Pt 1 a device fixed small thrombus (2 mm) was detected 1 Mo after LAAC which disappeared on increased hirudoid dose (at HD) after 2 Mo. Up to 10 (Pt. 1), 21 (Pt. 2) and 3 Mo (Pt. 3) we saw no embolic or bleeding event under low-dose aspirin therapy. However, 9.5 Mo after LAAC Pt. 1 needed shunt-thrombosis-OP and presented 2 wks later (mechanical) ileus but refused all (diagnostic/therapeutic) procedures and died.

Conclusions: 1. In our pilot data LAAC was safe and without apparent embolic (cerebral) or bleeding events up to 21 Mo. 2. In ESRD patients with AF and contraindicated OAC the new LAAC can prevent embolic events from the left atrium. 3. Now more long-term data is needed and even RCTs are warranted (LAAC vs. coumarin/new OAC) in ESRD patients with AF and known high bleeding risk.

TH-PO584

Trends of Infective Endocarditis in End Stage Renal Disease in the Last Decade Karthik Murugiah,[1] Gagan Kumar,[1] Priyanka Khatri,[2] Abhishek Deshmukh,[3] Puneet Sood.[1] *[1]Medical College of Wisconsin, WI; [2]Hospital of St. Raphael, CT; [3]University of Arkansas for Medical Sciences, AR.*

Background: Infective endocarditis (IE) is a common complication of vascular access in End Stage Renal Disease (ESRD). There is paucity of national level epidemiologic data.

Methods: Using the Nationwide inpatient sample (NIS) 2000-08 we identified patients ≥ 18 yrs with a discharge diagnosis of bacterial endocarditis using the ICD-9 code 421.x. Data was divided into 3 year periods to study trends. Population data was obtained from the US Census Bureau and for ESRD from the United States Renal Data system. Outcomes

of interest were in-hospital mortality, length of stay (LOS) and receipt of valve surgery. We used logistic regression to examine risk factors for in-hospital mortality.

Results: Incidence of IE in ESRD patients was 63.4 times that of general population. Proportion of patients >65 yrs was 40.2% in ESRD with IE group compared to 47.1% in all patients with IE. Among ESRD, 50.4% were male compared to 58% in all patients. LOS was 16.4±17 days vs 14.8±16 days in all patients with IE. Mortality was higher in ESRD patients at 20% vs 13% in all patients. (all p<0.001) In logistic regression analysis adjusting for age, sex, race, payer status, hospital characteristics and other comorbidities patients with ESRD and IE were 1.7 times more likely to die during the hospitalization and 2 times less likely to undergo valve surgery. During the study period there was a dramatic increase in IE among ESRD patients compared with the rest of the population. There has been an improvement in mortality albeit modest.

Trends of IE in ESRD (2000-08)

	2000-02	2003-05	2006-08	All Years
Estimated nationwide discharges with IE	91765	106970	117980	316715
Incidence (per 100000 person-years) in general population*	14.4	16.2 (12.7% increase)	17.3 (6.5% increase)	16
ESRD (%)*	11.3	13	15.8	13.5
Incidence (per 10000 person-years) in ESRD*	84.1	98.8 (17.4% increase)	117.3 (18.8% increase)	101.5
Valve replacement or repair (%)	5.2	4.6	6.1	5.4
In hospital mortality (%)*	23.2	20.2	17.9	19.9

*P value sig at <0.001

Conclusions: There is an alarming increase in IE in ESRD patients over the last decade with significant diagnostic and therapeutic implications.

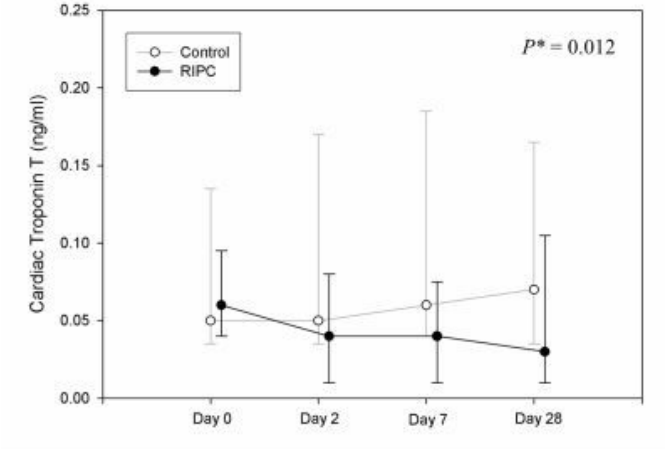
TH-PO585

Remote Ischaemic Pre-Conditioning in Haemodialysis: A Pilot Study
Kyung Sun Park, Jongha Park, Hyun Chul Chung, Jong Soo Lee. *Internal Medicine, Ulsan University Hospital, Ulsan, Korea.*

Background: Myocardial stunning induced by transient myocardial ischaemia has been reported during haemodialysis (HD) and it would be important issue to reduce it. Remote ischaemic pre-conditioning (RIPC) has a protective effect against myocardial ischaemia-reperfusion injury.

Methods: Chronic HD patients were randomized to the control, or the RIPC group. RIPC was induced by transient occlusion of blood flow to the arm with a blood-pressure cuff. The procedure was undertaken before every HD session for 1 month (total 12 times). The primary outcome was the change in cardiac troponin T (cTnT) level at day 28 from baseline.

Results: Demographic and baseline laboratory values were not different between the control (n=17) and the RIPC group (n=17). cTnT levels tended to decrease from day 2 in the RIPC group through to 28 days, in contrast to no change in the control group. There were significant differences in the change of cTnT level at day 28 from baseline [Control, median; -0.002 ng/ml (IQR; -0.008 ~ 0.018) versus RIPC, median; -0.015 ng/ml (IQR; -0.055 ~ 0.004), *p = 0.012*].



*Mann-Whitney U test was used to compare the change of cTnT level at day 28 from baseline.

Conclusions: RIPC reduced cTnT release in chronic conventional HD patients, suggesting that this simple, cheap, safe, and well-tolerated procedure has a protective effect against HD-induced ischaemia.

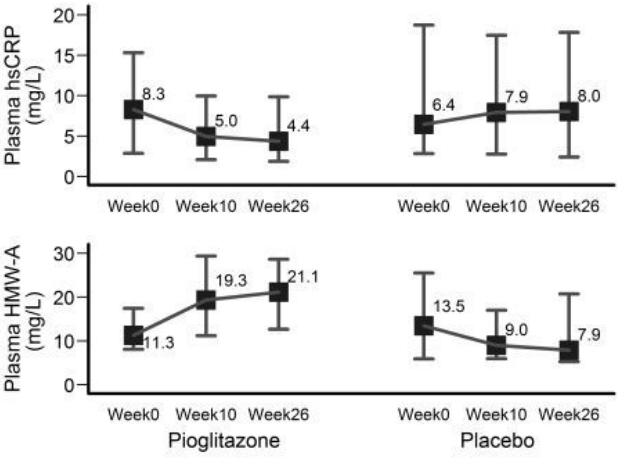
TH-PO586

RCT: Pioglitzaone ↓ Plasma hsCRP and ↑ HMW Adiponectin in Hemodialysis Patients
S. Beddhu,[1,2] Tom Greene,[1] G. Wei,[1] Jill L. Neilson,[1] R. Filipowicz,[1] Y. Zhang,[1] Alfred K. Cheung,[1,2] Abinash C. Roy,[1] Yufeng Huang,[1] Beverly Farmer,[3] M. Chonchol.[3] *[1]Univ of Utah; [2]VHASLC, SLC, UT; [3]Univ of Colorado, Denver, CO.*

Background: Inflammation is thought to play a major role in cardiovascular disease and is a strong predictor of mortality in hemodialysis (HD) patients (pts); however, there is no established Rx for ↓ inflammation in HD pts. Pioglitazone (pio) by inhibiting NFκB pathway ↑ anti-inflammatory adiponectin and ↓ pro-inflammatory cytokines in adipose tissue with consequent ↓ in systemic inflammation. We examined the effects of pio in a double-blind RCT on the primary endpoints of Δ in plasma high sensitivity C-reactive protein (hsCRP) and high molecular weight adiponectin (HMW-A) levels in HD pts.

Methods: 95 overweight or obese HD pts with diabetes mellitus or insulin resistance (HOMA > 2.1) were randomly assigned to pio 30 mg/d (n=48) or matching placebo (pla) (n= 47) for 26 wks. Immunoassays were used to measure hsCRP and HMW-A. Mixed effects models were used to compare Δ from baseline to weeks 10 and 26 in log hsCRP and HMW-A between treatment groups after controlling for their baseline level.

Results: Baseline characteristics were balanced between groups. 81% in pio and 79% in pla groups (p =0.8) completed the study. Baseline and follow-up hsCRP and HMW-A levels are summarized in figure.



Compared to pla, pio treatment resulted in 28% ↓ in hscCRP (p=0.053) and 53% ↑ in HMW-A (p=0.01) in mixed effects models.

Adverse advents were not different in either group: death (0% pio, 4% pla), fracture (2% pio, 6% pla), and fluid overload (6% pio, 0% pla), (all p>0.2). There were no incidences of serious hypoglycemia, liver failure or ↑ in liver enzymes in either group.

Conclusions: Pioglitazone treatment ↓ inflammation in HD pts. Larger RCTs with hard endpoints of cardiovascular events and mortality are warranted.

Heparin-Based Haemodialysis Is a Potent Inductor for sFlt1 Release
Frederic Lavainne,[1,2] Emmanuelle Meffray,[1] Ruth J. Pepper,[3] Melanie Neel,[1] Catherine Delcroix,[2] Alan D. Salama,[3] Fadi Fakhouri.[1,2] *[1]INSERM UMR 1064, ITUN, Université de Nantes, Nantes, France; [2]Nephrology Department, CHU de Nantes, Nantes, France; [3]Center for Nephrology, University College London, Royal Free Hospital, London, United Kingdom.*

Background: Soluble Flt1 (sFlt1) is a potent inhibitor of vascular endothelial growth factor secreted mainly by placenta, endothelial cells and monocytes. sFlt1 serum levels correlate with endothelial dysfunction and cardiovascular complications in chronic kidney diseases patients.

Methods: We first assessed sFlt1 kinetics during routine haemodialysis (HD) and post dilution haemodiafiltration (HDF) sessions for 48 patients. Then we compared kinetics with two different membranes in HD. Finally, we assessed the impact of heparin on the sFlt1 secretion with initially heparin free HD (with heparin delayed administration after 30 minutes) and predilution HDF without heparin.

Results: In 48 patients, sFlt1 serum levels increased as early as 1 minute after the start of dialysis and peaked at 15 minutes before returning to baseline at 4 hours (mean peak level 2551 pg/ml, vs 102 pg/ml before HD and 69 pg/ml in controls (p<0.0001)). There were no differences in the kinetics between the two membranes in HD. If either unfractionated heparin (UH) or low molecular weight heparin (LMWH) was omitted during the dialysis session (HD or predilution HDF), no significant increase in sFlt1 serum levels occurred. Conversely, delayed administration of LMWH (after 30 minutes of a heparin-free dialysis) induced a sharp increase in sFlt1. In vitro, UH and LMWH failed to induce sFlt1 release by monocytes from controls or HD patients. These findings suggest that either priming of monocytes on the extracorporeal circuit is required for heparin-induced sFlt1 release or that endothelial cells contribute to the increase in sFlt1 levels.

Conclusions: Our results indicate that heparin-based haemodialysis induces a major sFlt1 release and therefore may exacerbate the sFlt1associated anti-angiogenic state in end-stage renal disease (ESRD) patients and could aggravate their endothelial dysfunction and cardiovascular burden. This should be taken into account for the assessment and establishment of optimal dialysis procedures.

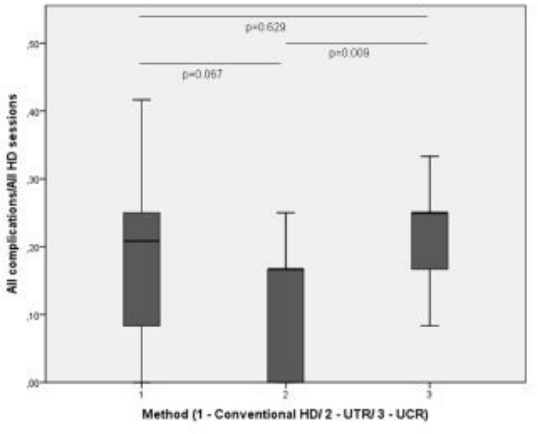
TH-PO588

Blood Volume-Monitored Regulation of Ultrafiltration in Fluid Overloaded Hemodialysis Patients Manfred Hecking, Marlies Antlanger, Walter Hoerl, Gere Sunder-plassmann, Marcus Saemann. *Medical University of Vienna, Nephrology, Vienna, Austria.*

Background: Chronic fluid overload in hemodialysis patients is associated with poor survival. We tested whether blood-volume monitored regulation of ultrafiltration and dialysate conductivity (UCR) and/or regulation of ultrafiltration and temperature (UTR) would facilitate dry weight reduction, in comparison to conventional hemodialysis.

Methods: Patients with fluid overload ≥15% extracellular water (ECW; by BCM [Fresenius/Germany]) were randomized 1:1:1 into conventional, UTR and UCR hemodialysis groups at 3 centers. Target dry weight was set as minus7% ECW postdialysis, in systematic steps following the DRIP-trial protocol (Agarwal et al., Hypertension 2009). Primary endpoint: complications (symptomatic and asymptomatic intradialytic hypotension, nausea, vomiting, cramps, malaise; NCT01416753).

Results: Of the 245 patients who were assessed for eligibility, 99 had fluid overload ≥15% ECW, 50 patients received the allocated intervention and all completed the study. The rate of intra- and postdialytic complications was 17% per 12 HD sessions for all groups (details in the figure).



Measurements of quality control indicated 26 of 79 randomly checked UCR treatments were inadequately executed, despite extensive training efforts. Dry weight reduction was 3.0±2.4% in the conventional group, 3.8±2.1% in the UTR, and 2.4±1.7% in the UCR group (mean±SD in % of body weight; all p ≥0.05).

Conclusions: Even in patients with bioimpedance-proven fluid overload, dry weight reduction was challenging, despite BVM-based dialysis techniques. A randomized controlled clinical trial is needed to demonstrate reduction of chronic fluid overload can prospectively reduce mortality and is therefore worth the strains imposed on patients and their caretakers.

Clinical Evaluation of Hemocontrol in Korean Hypotension-Prone Hemodialysis Patients: A Multicenter Prospective Crossover Study Hyo-Wook Gil,[1] Kitae Bang,[2] So-young Lee,[2] Byoung Geun Han,[3] Jin Kuk Kim,[1] Young Ok Kim,[5] Ho Cheol Song,[5] Young-Joo Kwon,[4] Yong-Soo Kim.[5] *[1]Medicine, Soonchunhyang University College of Medicine, Korea; [2]Medicine, Eulji University School of Medicine, Korea; [3]Medicine, Yonsei University Wonju College of Medicine, Korea; [4]Medicine, Korea University Medical College, Korea; [5]Medicine, The Catholic University of Korea College of Medicine, Korea.*

Background: The Hemocontrol biofeedback system automatically monitors and regulates blood volume contraction during HD through the adjustments of ultrafiltration rate and dialysate conductivity. The effect of hemocontrol on the incidence of intradialytic hypotension (IDH) in Korean hypotension-prone HD patients was evaluated.

Methods: In this prospective crossover study, 60 (males 32%; age 57±11 years; diabetics 67%; HD duration 58±46 months) hypotension-prone patients from 9 HD centers completed the study. Artis® machines were used. The study included period A (current best practice HD for 8 weeks), B0 (HD with Hemoscan blood volume monitoring for 2 weeks), and period B1 (Hemocontrol HD treatments for 8 weeks).

Results: The number of HD sessions symptomatic IDH occurred was significantly decreased (39% ↓) in period B1 compared with period A (37.6% vs. 61.4%, $p < 0.001$). The number of nursing interventions per HD session was also significantly decreased in period B1 compared with period A (0.56 vs. 0.96, $p < 0.001$). Although the pre-dialysis BPs were not different, the post-dialysis systolic, diastolic, and mean arterial pressures were significantly higher in period B1 compared with period A, leading to the small variation of BPs between pre- and post-dialysis (ΔBP) in period B1. Furthermore, ΔBP in period A was positively correlated with the incidence of IDH in period B1. The recovery time after dialysis was significantly faster in period B1 compared with period A. There was no difference in the interdialytic weight gain, URR, serum electrolytes, hemoglobin and serum albumin levels between period B1 and period A.

Conclusions: These data suggest that Hemocontrol biofeedback system may improve the patient tolerability to HD through the reduction of IDH occurrence in Korean hypotension-prone HD patients.

TH-PO590

Clinical Usefulness of a Bioimpedance Analysis Aimed to Control Ambulatory Blood Pressure in Hemodialysis Patients Jung-ho Shin, Youn-su Park, Min-jee Han, Su Hyun Kim, Suk-hee Yu. *Internal Medicine, Chung-Ang University College of Medicine, Seoul, Korea.*

Background: Hypertension is very common in hemodialysis patients and is strongly associated with an increased cardiovascular mortality. We investigated the relationship between ambulatory blood pressure monitoring (ABPM) and an edema index and investigated if the edema index can be used to control blood pressure in hemodialysis patients.

Methods: Patients who had hemodialysis for more than three months in Chung-Ang University Hospital were recruited. ABPM was measured for twenty four hours after hemodialysis. Bioimpedance analysis (BIA) was conducted before hemodialysis in the supine position. We checked clinical results including brain-natriuretic peptide (BNP) levels. Patients were divided into controlled and uncontrolled groups by ambulatory systolic blood pressure. We anticipated and adjusted accordingly dry weight based on BIA results.

Results: Thirty-three patients were recruited, there were nineteen men and fourteen women. In regards to ABPM, the mean systolic and diastolic blood pressures were 140.2±19.7 mmHg and 79.0±10.6 mmHg, respectively. There was significant association between mean systolic blood pressure and the edema index ($p=0.007$, $R^2=0.628$). Mean systolic blood pressure was also associated with the BNP level ($p=0.016$, $R^2=0.607$). At night, the edema index in controlled group was 0.384±0.008 and that in the uncontrolled group was 0.398±0.015 ($p=0.018$). However, the edema index during daytime hours was not different between the two groups. There was no difference in the BNP level both during daytime hours and at night. After adjustment of the dry weight, we compared the changes. The edema index had decreased from 0.395±0.014 to 0.386±0.032 ($p=0.150$). Office systolic blood pressure had significantly decreased from 135.2±26.0 mmHg to 126.1±14.2 mmHg ($p=0.039$). BNP level also decreased, but there was no statistical difference ($p=0.067$).

Conclusions: The edema index obtained by the bioimpedance analysis is more significantly correlated with ambulatory systolic blood pressure than the BNP level. An adjustment of dry weight regarding the edema index can be used to control blood pressure in hemodialysis patients.

TH-PO591

Long-Term Effects of a Negative Sodium Gradient on Blood Pressure, Arterial Stiffness and Left Ventricular Hypertrophy in Hypertensive Hemodialysis Patients Yi-Lun Zhou, Jing Liu, Li-jie Ma, Fang Sun, Yang Shen, T.G. Cui. *Department of Nephrology, Chao-Yang Hospital, Capital Medical University, Beijing, China.*

Background: Sodium overload plays an important role in the pathogenesis of hypertension, and has harmful effects on the cardiovascular system.The aim of the present study is to examine the long-term effects of a mild negative sodium gradient on cardiovascular risk factors in hemodialysis (HD) patients.

Methods: Sixteen hypertensive HD patients were enrolled in this pilot trial. These patients had achieved their "dry weight" assessed by bioimpedance methods, and their pre-HD plasma sodium levels were slightly higher than the facility dialysate sodium concentration (138mmol/L). After 1-month period of dialysis with standard dialysate sodium of 138mmol/L, the patients were switched to low sodium dialysis with dialysate sodium of 136mmol/L and followed up for a 12-month period. No changes in instructions to patients about dietary sodium control were made. During the period of study, the dry weight was adjusted monthly under the guidance of bioimpedance spectroscopy. 44h ambulatory blood pressure (BP),aortic pulse wave velocity, left ventricular mass index, interdialytic weight gain were measured, and adverse events were recorded.

Results: After 12-month period of dialysis with negative sodium gradient, there were significant reductions in 44-hour ambulatory systolic and diastolic BP (-12 and -7 mmHg), and a small reduction in interdialytic weight gain (-0.30kg). There were also significant decreases in pulse wave velocity (from 12.68±2.37 to 11.75±2.71 m/s, $p=0.001$), and left ventricular mass index (from 149.29±13.75 to 139.61±14.41 g/m^2, $P < 0.001$). The post-HD volume parameters were kept constant throughout the study period. There were no significant changes in the frequency of adverse events.

Conclusions: In selected hypertensive HD patients, a small negative sodium gradient for 12 months resulted in a significant reduction in BP, accompanied by improvements in aortic stiffness and left ventricular hypertrophy with good tolerance.

TH-PO592

Dialysis Dose and Intra-Dialytic Hypotension Finnian R. McCausland, Steven M. Brunelli, Sushrut S. Waikar. *Renal Division, Brigham and Women's Hospital, Boston, MA.*

Background: Intra-dialytic hypotension associates with increased morbidity and mortality in chronic hemodialysis patients. Intra-dialytic decline in osmolality from rapid urea removal may predispose to hypotension resulting from transcellular fluid shifts into the intracellular compartment. We wished to determine the association of clinical measures of urea removal with the occurrence of intra-dialytic hypotensive events in chronic hemodialysis patients.

Methods: We performed a post-hoc analysis of the HEMO Study (n=1826), a multi-center trial that randomized participants on the basis of dialysis dose (high vs standard Kt/V) and membrane flux (higher vs lower). Detailed hemodynamic and urea kinetic modeling data (URR) was abstracted from 62,557 dialysis sessions.

Results: In unadjusted analyses, higher target Kt/V was associated with a trend towards greater odds of intra-dialytic hypotension (OR 1.11; 95% CI 1.00-1.25). Upon adjustment for HEMO Study pre-specified covariates, this achieved significance (OR 1.13; 95% CI 1.01-1.26). In sensitivity analyses, higher URR (per 5%) was also associated with greater odds of intra-dialytic hypotension (OR 1.08; 95% CI 1.01-1.06).

Conclusions: Metrics of urea removal are independently associated with greater odds of developing intra-dialytic hypotension. These findings support a role for intra-dialytic decline in osmolality in the genesis of hemodynamic instability. Future studies should address the safety and efficacy of minimizing osmolality decline during hemodialysis.

TH-PO593

Isolated Ultrafiltration Induces Reduced Microcirculatory Flow without Changes in Systemic Blood Pressure in Chronic Hemodialysis Patients Marc H. Hemmelder,[1] Gerke Veenstra,[2] E.C. Boerma.[2] *[1]Nephrology, Medical Center Leeuwarden, Leeuwarden, Netherlands; [2]Intensive Care, Medical Center Leeuwarden, Leeuwarden, Netherlands.*

Background: It has been reported that microcirculatory blood flow decreases during hemodialysis with ultrafiltration treatment, while macrovascular hemodynamic parameters were unaffected. We tested whether this decrease of microcirculatory blood flow is dependent on the method of ultrafiltration in 9 chronic hemodialysis patients who had no previous hypotensive complications.

Methods: Three methods of ultrafiltration were performed at random order at a 4 hour midweek session during 3 consecutive weeks: 1. Isolated ultrafiltration after the hemodialysis session (IUF); 2. Linear ultrafiltration during hemodialysis (LUF); 3. Ultrafiltration by blood volume monitoring during hemodialysis (UF-BVM). Microcirculatory flow index (MFI) was assessed with sidestream darkfield imaging in the sublingual capillaries at each hour during the sessions. The amount of ultrafiltration was estimated by body composition measurement. Primary outcome parameter was the change in MFI from baseline to the end of a session. Differences were non-parametrically tested with Wilcoxon signed rank test ($p<0.05$).

Results: All patients were of Caucasian origin, with a mean age of 66±12 years and 37±29 months of dialysis vintage. Only IUF resulted in a significant decrease of MFI from 2.8 [2.8-2.9] to 2.5 [2.2-2.8], whereas MFI remained unchanged during LUF and UF-BVM. The amount of ultrafiltration did not differ between the sessions and amounted 1.7 [1.2-1.9] l, 1.7 [1.2-2.1] l and 1.9 [1.7-2.1] l respectively. During the sessions no differences in blood pressure, pulse or laboratory parameters were detected. No hypotensive period was present during the study.

Conclusions: We conclude that MFI only decreases during IUF, without a reduction of baseline blood pressure and pulse rate. In contrast LUF and UF-BVM had no adverse effects on MFI. Further research is needed to determine whether these observations are associated with adverse effects on the cardiovascular risk profile or residual renal function of chronic hemodialysis patients.

TH-PO594

Systolic Blood Pressure Was Reduced in Hypertensive Hemodialysis (HD) Patients during a Year-Long Quality Improvement Project on Fluid Management at One Facility Linda H. Ficociello,[1] Len A. Usvyat,[2] Michael Black,[1] Patrice B. Taylor,[2,3] Antoinette M. Ordish,[2,3] Paul Balter,[2] Paul M. Zabetakis,[2] Claudy Mullon,[1] Jose A. Diaz-Buxo.[1] *[1]Fresenius Medical Care - NA, Waltham, MA; [2]Renal Research Institute (RRI), New York, NY; [3]University of North Carolina Hospitals, Chapel Hill, NC.*

Background: Inadequate volume control is associated with hypertension in HD patients. An on-going quality improvement (QI) project on fluid management using Crit-Line® Blood Volume Monitors (CLM) has been conducted at an RRI clinic. CLM measure changes in hematocrit, oxygen saturation and relative blood volume during HD.

Methods: Systolic blood pressure pre (preSBP) and post dialysis (postSBP) were tracked from Month 0 (Baseline), month before QI project began, to Month 11 of QI project. Eligible patients were all 45 patients dialyzed at the clinic at start of Month 0. For this analysis, we classified patients with average preSBP≥140mmHg in Month 0 as "Baseline Hypertensive" (BL-HYP) and patients with preSBP<140 as "Baseline Normotensive" (BL-NOR). For patients with clinical data in Months 0 and 11 (n=36), paired t-tests compared monthly mean preSBP and postSBP before and after QI initiation. Longitudinal data analysis (linear mixed effects modeling) was conducted to estimate average change per month using all patients.

Results: The majority of patients were black (53%), hypertensive (62%), and without a catheter (80%). Reductions in preSBP and postSBP were observed in BL-HYP and not in BL-NOR.

	BL-HYP (n=26)			BL-NOR (n=10)		
	Month 0	Month 11	Pvalue	Month 0	Month 11	Pvalue
PreSBP (mmHg)	164.4±13.5	155.6±16.3	0.02	127.8±7.1	133.8±15.5	0.22
PostSBP (mmHg)	150.9±17.1	135.6±15.2	0.0003	121.5±12.3	123.1±13.3	0.78

The average change per month was modeled for BL-HYP to confirm changes observed Month 0 to 11. In BL-HYP, average change in PreSBP was -0.75 mmHg per month ($p=0.04$) and PostSBP was -1.86 mmHg per month ($p<0.0001$) in BL-HYP. There was no PreSBP or PostSBP decrease in BL-NOR.

Conclusions: Over a year-long QI project on fluid management, an average reduction of 8.9 and 15.3 mmHg was observed in preSBP ($p=0.02$) and postSBP ($p=0.0003$), respectively, among patients with hypertension.

Enhanced Sympathetic Activity Is Associated with Improved Long-Term Survival in Hemodialysis Patients Dvora Rubinger, Rebecca Backenroth, Yosef S. Haviv, Dan Sapoznikov. *Nephrology and Hypertension, Hadassah University Medical Center, Jerusalem, Israel.*

Background: Sympathetic activity is increased in patients with end stage renal disease, but its predictive value in chronic hemodialysis (HD) patients is not well established.

Methods: Multivariate analysis was performed to assess the prognostic role of blood pressure variability in the low frequency range (LF SBP) and of the standard deviation (sd) of interbeat intervals (sd IBI), two measures of sympathetic activity, as predictors of mortality and cardiovascular morbidity in HD patients. Continuous beat-to-beat IBI, systolic (SBP) and diastolic (DBP) blood pressure were monitored in 111 HD patients. LF SBP and sd IBI were calculated from recordings of SBP and IBI spontaneous variations. The study population was subdivided into tertiles for both variables. Primary (death) and secondary (fatal and non-fatal cardiovascular events) outcomes were recorded during a mean follow-up period of 60 months (range: 2-113).

Results: Kaplan-Meier analysis showed significantly decreased 5 year survival for patients with lower (1st tertile) LF SBP ($p=0.006$) and sd IBI ($p=0.040$) as compared with those with highest indices (3rd tertile). Patients in the lowest LF SBP and sd IBI tertiles had also an increased probability of cardiovascular events ($p=0.020$ and 0.025, respectively). On univariate analysis, age, diabetes mellitus, diffuse arterial disease, intradialytic hemodynamic stability, lower plasma albumin, increased CRP and decreased LF SBP, sd DBP and sd IBI were associated with both decreased survival and increased occurance of cardiovascular events. Multivariate Cox regression analysis with clinical data, biochemical and nutritional markers identified diffuse arterial disease, CRP and sd DBP, a marker of arterial mechanics, as the most significant predictors of mortality and cardiovascular morbidity.

Conclusions: Our data show that in HD patients, sympathetic activity is inversely correlated with mortality and cardiovascular morbidity. Lower sympathetic activity is significantly associated with diffuse arterial disease and increased inflammatory markers. In HD patients both outcomes are improved in the presence of a more robust autonomic nervous system.

TH-PO596

Interdialytic 44-Hours Ambulatory Blood Pressures Predict Left Ventricular Hypertrophy in Pediatric Hemodialysis Patients Chryso P. Katsoufis,[1] Wacharee Seeherunvong,[1] Nao Sasaki,[2] Carolyn L. Abitbol,[1] Jayanthi Chandar,[1] Michael Freundlich,[1] Gaston E. Zilleruelo.[1] *[1]Pediatric Nephrology, University of Miami, Miami, FL; [2]Pediatric Cardiology, University of Miami, Miami, FL.*

Background: Cardiovascular (CV) disease results in high mortality of patients with end-stage renal disease. Children undergoing chronic hemodialysis (HD) often exhibit left ventricular hypertrophy (LVH). 24-Hour ambulatory blood pressure monitoring (ABPM) has been shown to predict CV morbidity better than casual blood pressure (CBP). Given the extreme blood pressure (BP) variability attributed to interdialytic fluid overload, we hypothesized that 44-hour ABPM should better predict the CV morbidity in pediatric HD patients.

Methods: We conducted a cross-sectional study in 17 patients, 16.7±2.9 years, maintained on chronic HD. 44-Hour interdialytic ABPM was performed. Data of averaged pre and post-dialytic CBP measurements and routine echocardiogram within 6-month of ABPM were collected. Left ventricular mass index (LVMI) was calculated by the standard equation; LVH was defined as LVMI>95%ile for height-age and gender. Hypertension (HTN) was defined by the recommendations of the Fourth Report of the National High BP Education Program for CBP, and by those of the American Heart Association for ABP.

Results: 24% of patients had HTN by post-dialytic systolic CBP, whereas 47% were HTN by ABPM. 53% of patients had LVH, while 88% had abnormal cardiac geometry. 6/17 patients (35%) had masked HTN, including 2 with concentric LVH, 1 with eccentric LVH, 1 with concentric remodeling and 2 with normal cardiac geometry. LVMI correlated well with ABP, but not with CBP measurements. The strongest association with increased LVMI ($p=0.04$, $r^2=0.24$) and LVH ($p=0.04$) was seen in 2nd day ABP parameters, specifically nighttime measurements.

Conclusions: CBP underestimates HTN in pediatric HD patients and does not correlate with LVMI or LVH. In contrast, 44-hour interdialytic ABPM better characterizes HTN, with the nightime-BP of the 2nd day most strongly predicting increased LVMI and LVH. Prospective studies to investigate the benefit of targeting nocturnal HTN in this population are very much warranted.

TH-PO597

Mortality and the Variability of Blood Pressure and Heart Rate in Chronic Hemodialysis Patients Ying Wang, Jinghua Xia, Yan Qin, Xuemei Li, Xuewang Li, Limeng Chen. *Nephrology, Peking Union Medical College Hospital, Beijing, China.*

Background: To identify the association between the variability in blood pressure and heart rate and mortality in hemodialysis patients.

Methods: The variation in blood pressure and heart rate was examined in 14,704 times' hemodialysis of 99 patients in a single university hospital between Jan to Dec 2006. The mortality was recorded during the 5 years follow-up from Jan, 2007 to Jan 2012. The Coefficient of variation and standard deviation were used as indicators of variability in blood pressure and heart rate respectively. Baseline demographic data and predialysis and postdialysis weights were also reviewed. Albumin, serum creatinine, calcium, phosphate, Hb, iPTH, KT/V and nPCR, were averaged over a year period. Cox regression analysis was used to identify the independent predictors for mortality.

Results: During the 5 year follow up period 35 patients died. Cardiovascular event was the most common cause of death (62.9%). Predialysis systolic blood pressure(SBP)<120 mmHg was an independent predictor for mortality(HR19.28, 95%CI3.37-110.13). Predialysis SBP variability (HR1.18[95%CI:1.03-1.35]per 1% increase in SBP variability) and predialysis heart rate variability(HR1.23[95%CI:1.07-1.42]per 1-bpm increase in HR variability) were independent predictors of total mortality. Mutiple linear regression analysis identified the variability of weight lose during dialysis was positively correlated with the variability of systolic blood pressure(r=3.291, P=0.008), while serum albumin was negatively(-0.218, P=0.010).The variability of heart rate was only negatively correlated with the use of ACEI(-0.20,P=0.048).

Conclusions: Lower predialysis SBP, larger variability of SBP and HR appears associated incrementally with higher mortality in HD patients. The volume variation may be correlated with the blood pressure variability.

TH-PO598

Autonomic Dysfunction and Inflammation in Hemodialysis (HD) Eric Seibert,[1] Kristina Zohles,[1] Christof Ulrich,[1] Alexander Kluttig,[2] Sebastian Nuding,[3] Jan Kors,[4] Cees A. Swenne,[5] Karl Werdan,[3] Roman Fiedler,[1] Matthias Girndt.[1] *[1]Nephrology, Halle University, Halle, Germany; [2]Medical Epidemiology, Biostatistics, Informatics, Halle University, Halle, Germany; [3]Cardiology, Halle University, Halle, Germany; [4]Medical Informatics, Erasmus University, Rotterdam, Netherlands; [5]Cardiology, Leiden University, Leiden, Netherlands.*

Background: Autonomic nervous dysfunction (AD) is common in HD patients (pt). Sympathetic and parasympathetic activation may influence inflammatory responses. We investigated a role of AD for inflammation in HD pt.

Methods: 30 HD pt and 15 healthy controls (ct) were studied for heart rate variability (HRV) using Fourier analysis of 5 min ECG recordings according to the CARLA study protocol. HRV was estimated by standard deviation of the R-R distance (SDNN) and the percentage of pairs of adjacent RR intervals differing by >50 ms (pNN50). Sympathetic/Parasympathetic activity was estimated using high- and low-frequency variation of RR distances (HF, LF). Inflammation was detected by CRP, IL-6 and monocyte subpopulation numbers. Immune cells were characterized by ACh receptor expression. 323 additional ct for HRV were matched for gender and diabetes from CARLA.

Results: Pt differed from ct in terms of age (66.8±9.4yrs vs. 54.5±7.4yrs, p<0.05) and HRV (SDNN ctr. 40.7±20.2ms, pt. 23.4±24.7ms; p<0.01). This finding was not restricted to diabetics although diabetes is an important cause of AD (SDNN,diab. 20.9±19.6ms, non-diab.25.7±29.2ms). LF and HF were reduced to 1/3 of those in ct, being best attributed to lowered baroreflex sensitivity. CARLA ct population confirmed SDNN, HF and LF findings in an extenuated but statistical significant manner. Pt had chronic inflammation (CRP 11.2±11.5 mg/l, ctr 1.8±1.3 mg/l, p<0.01) and expanded proinflammatory monocyte subpopulations (CD14/CD16 pos. cells 47±25/µl, ctr 28±19/µl, p<0.01). ECG parameters did not correlate with inflammation. Monocyte ACh receptor expression was enhanced in pt.

Conclusions: HD pt show strongly impaired HRV and signs of AD. Chronic inflammation is not directly related to AD, although monocytes express the ACh receptor at enhanced density making them potentially more sensitive to parasympathetic effects.

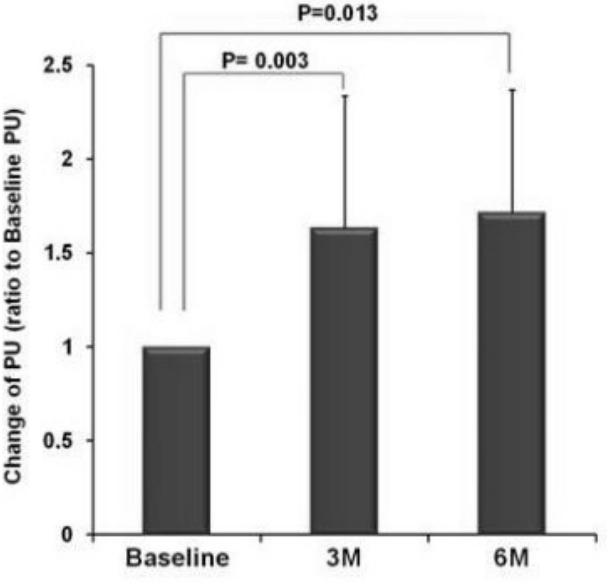
TH-PO599

AST-120 Improves Microvascular Endothelial Dysfunction in Hemodialysis (HD) Patients: A Preliminary Report Jung-hwa Ryu,[1] Mina Yu,[1] Shina Lee,[1] Sung Chul Hong,[1] Sang Hee Lee,[2] Dong-Ryeol Ryu,[1] Seung-Jung Kim,[1] Duk-Hee Kang,[1] Kyu Bok Choi.[1] *[1]Division of Nephrology, Department of Internal Medicine, Ewha Womans University School of Medicine, Seoul, Republic of Korea; [2]Division of Nephrology, Ewha Womans University Mokdong Hospital, Seoul, Republic of Korea.*

Background: Endothelial dysfunction(ED) is a pivotal phenomenon in the cardiovascular diseases(CVD), which are critical causes for mortality in HD patients. Indoxyl sulfate(IS) has been known to induce ED in chronic kidney disease. The aim of this study is to investigate whether AST-120, an absorbent for IS improves micorvascular or macrovascular ED in HD patients.

Methods: Twelve and 4 stable HD patients were included in AST-120group and the control, respectively. The subjects in AST-120 group were treated with AST-120(6g/day) for 6M. Microvascular function was assessed by laser Doppler flowmetry using iontophoresis of Acetylcholine(Ach) and sodium nitroprusside(SNP) at baseline,3M,and 6M,respectively. Change of Perfusion unit(PU) was measured.Carotid IMT and flow-mediated vasodilation(FMD) were assessed at baseline and 6M.

Results: Ach-induced iontophoresis(endothelium-dependent response) in AST-120 group was significantly improved in 3M and 6M than baseline, respectively.



Whereas, that of control didn't. SNP-induced response was not changed in either groups. The serum level of IS was decreased at 3M, but didn't show more decrease at 6M. IMT was significantly reduced at 6M than baseline in AST-120 group(meanIMT:0.78 at baseline *vs.*0.75mm at 6M,P=0.012). The FMD at 6M did not show significant changes compared to baseline in either groups. No specific side effect from AST-120 was not reported.

Conclusions: AST-120 ameliorated a microvascular ED in HD patients, furthermore, decreased IMT. Further studies with extended population will be needed to prove a crucial role of AST-120 for the prevention of CVD in HD patients.

TH-PO600

Lower Oxygen Saturation Levels and Lack of Its Stability Are Associated with Higher Hospitalization Rates in Non-Catheter Hemodialysis (HD) Patients Patrice B. Taylor,[1,3] Lisa A. Pacelli,[1] Antoinette M. Ordish,[1,3] Nancy Ginsberg,[1] Len A. Usvyat,[1] Linda H. Ficociello,[2] Michael Black,[2] Claudy Mullon,[2] Jose A. Diaz-Buxo,[2] Mary T. Sullivan,[1] Peter Kotanko,[1] Paul Balter,[1] Paul M. Zabetakis.[1] *[1]RRI, NY, NY; [2]FMC, Waltham, MA; [3]University of North Carolina, Chapel Hill, NC.*

Background: An on-going quality improvement (QI) project using Crit-Line Blood Volume Monitors (CLM) has been conducted in 5 RRI clinics. CLM measures changes in Hct, oxygen (O2_SAT) and relative blood volume during HD. We aim to understand if minimum O2_SAT and changes in O2_SAT are associated with differing outcomes.

Methods: Data from 178 active HD patients (pts) that utilize Crit-line on a routine basis bn May 1, 2011 and Apr 30, 2012 were analyzed. We included only pts with arteriovenous fistulas and grafts. For every pt, we calculated lowest O2_SAT (O2_MIN) during the tx and the % change in O2_SAT computed as [max O2_SAT – min O2_SAT]/[min O2_SAT] (O2_CHANGE). Pts were divided into tertiles of O2_MIN and O2_CHANGE.

Results: Mean O2_MIN=90.7±8.0%; mean O2_CHANGE=5.4±6.2%. In bivariate correlation, O2_MIN was significantly & positively associated with albumin (r=0.20, p<0.05) and blood flow (r=0.32, p<0.05) but not with age, gender, race, diabetic status,

body weight, systolic blood pressure or on-line clearance (OLC). O2_CHANGE was significantly & negatively associated with albumin (r=-0.18, p<0.05), blood flow (r=-0.26, p<0.05), and OLC (r=-0.17, p<0.05).

Tertiles of O2_MIN	O2_MIN Range	Hospital admissions per patient year	Hospital days per patient year
1	45-91	1.60	10.52
2	91-93	1.50	9.23
3	93-97	0.73	4.54

Tertiles of O2_CHANGE	O2_CHANGE Range	Hospital admissions per patient year	Hospital days per patient year
1	0.9-3.1%	0.92	6.87
2	3.1%-5.2%	1.23	8.36
3	5.3%-20%	1.70	9.11

Pts with highest O2_SAT have fewest hospitalizations; similarly, pts with the most stable O2 levels during the tx (tertile 1 of O2_CHANGE) have fewest hospitalizations.

Conclusions: In non-catheter pts, higher O2_SAT are associated with higher albumin. Higher O2_SAT during tx are associated with fewer hospitalizations; stability of oxygen saturation during the tx is also associated with improved outcomes.

TH-PO601

Blood Oxygen Saturation (SO2) and Intradialytic Hypotension (IDH): The Final Results of the SOGLIA Study Elena Mancini,[1] Stefano Severi,[2] Claudia Perazzini,[2] Antonio Santoro.[1] *[1]Nephrology Dialysis Hypertension, S.Orsola Malpighi, Bologna, Italy; [2]HST-CIRI, University of Bologna, Bologna, Italy.*

Background: IDH is a frequent problem complicating HD. SO_2 affected by cardiac output, pH, Hb concentration, can be considered a marker of hemodynamic instability. Online, non-invasive monitoring of SO_2 is today possible, by means of an optical sensor measuring SO_2 in blood entering the dialyzer. The aim of the present multicenter observational trial was to assess, in a large number of HD sessions, whether the short-term variability of SO_2 may predict the occurrence of symptomatic IDH.

Methods: Fifty-one hypotension-prone patients were enrolled and monitored along 3 months, during their regular HD treatment, without any change in the medical prescription. Mean dry weight 72±16 kg, weight loss 3.0±0.8 kg; blood flow and session duration, 292±16 mL/min and 230±10 min respectively. SO_2 signal was recorded from the *Hemox* (Formula Therapy, Bellco, Italy). Blood pressure, at 30-min interval, symptoms, and onset time of IDH were collected. Based on IDH definition (EBPG), sessions with symptomatic IDH were counted offline as *positive* (IDH yes) or *negative* (IDH no). SO_2 standard deviation (SD) was computed on a 5 min length mobile windows. In the *positive* sessions, the SO_2 variability analysis was truncated at IDH onset.

Results: Out of 1636 HD sessions collected, 274 were discarded due to incorrect data collection: a total of 1362 sessions were then analysed. On the basis of the IDH presence, 314 (23%) were classified as *positive* and 1048 (77%) as *negative*.

The ROC analyses on the whole data set was performed and the critical threshold of SO_2 SD was chosen equal to 2.2%.

Based on the SO_2 variability, sensitivity was 67% (211/314 *positive* sessions identified) and the specificity was 64% (667/1048 *negative* sessions identified).

Conclusions: The SO_2 short term variability seems to show, on a large number of sessions, a fair predictive power of IDH. This study may pave the way to the implementation in a future generation of dialysis monitors of an automatic alarm system including SO_2 variability oscillations as a warning variable, offering the opportunity of preventive manoeuvres to avoid hypotension.

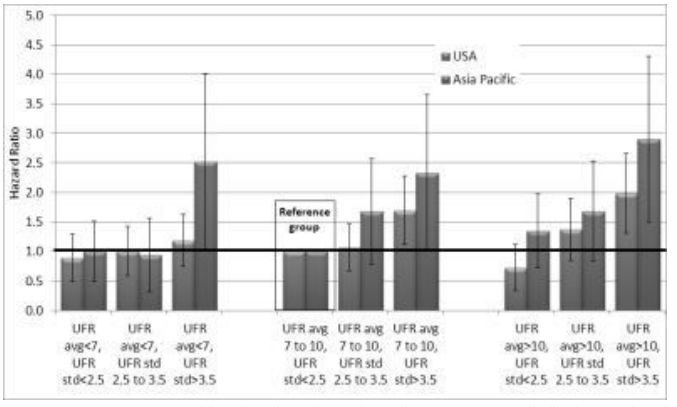
Variability of Ultrafiltration Rate Is Associated with Poor Outcomes in US and Asian Pacific Dialysis Patients Len A. Usvyat,[1] Paul Balter,[1] Penny Faith Sheppard,[1] Adrian Marcos Guinsburg,[4] Aileen Grassmann,[3] Adam Tashman,[1] Cristina Marelli,[4] Eric Liu,[2] Daniele Marcelli,[3] Frank van der Sande,[6] Inga Bayh,[3] Jeroen Kooman,[6] Laura Scatizzi,[3] Michael Etter,[2] Stephan Thijssen,[1] Edwin B. Toffelmire,[5] Yuedong Wang,[7] Nathan W. Levin,[1] Peter Kotanko.[1] *[1]Renal Research Institute, NY, NY; [2]Fresenius Asia Pacific Ltd, Hong Kong, Hong Kong; [3]Fresenius Medicare Care, Bad Homburg, Germany; [4]FMC, Buenos Aires, Argentina; [5]FMC Canada, Toronto, Canada; [6]Maastricht University Hospital, Maastricht, Netherlands; [7]University of California, Santa Barbara, CA.*

Background: We aim to determine whether level and variability in ultrafiltration rate (UFR) is associated with outcomes in incident HD patients (pts).

Methods: The MONitoring Dialysis Outcomes (MONDO) consortium consists of HD databases from RRI clinics (USA), FMC clinics in Europe, Asia, Latin America and Canada, Maastricht University (Netherlands) and KfH clinics (Germany). Only databases from RRI and FMC Asia were queried for incident HD pts who survived >12 months. "Baseline" UFR was computed as avg of <=6 months. "Follow up" UFR variability was computed as standard deviation (std) bn mns 7 and 12. Pts were stratified into 9 grps of baseline UFR and UFR variability. Pt survival was assessed in months 13 to 24 from HD initiation and Cox proportional hazards models were constructed.

Results: We studied 3979 pts from Asia and 6342 from US. Higher UFR variability was associated with poorer outcome in all pts. Notably, differences between pts with least UFR and highest variability were much more pronounced in Asia.



Conclusions: Our multi-national study confirms that UFR>10 mL/hr/kg is associated with poor survival. While the negative effects of higher UFR variability are noted in both US and Asian pts, it is particularly pronounced in the latter.

TH-PO603

Cardiovascular Risk in Hemodialysis Patients: Fluid Overload and Heart Rate Variability Anna Clementi,[1] Dinna N. Cruz,[1] Francesco Garzotto,[1] Manuela Ferrario,[2] Alessandra Brendolan,[1] Claudio Ronco.[1] *[1]Nephrology, Dialysis, Transplantation, St Bortolo Hosp, Vicenza, Italy; [2]Bioengineering, Politecnico, Milano, Italy.*

Background: Cardiovascular (CV) disease is the leading cause of mortality in hemodialysis (HD) patients. Fluid overload (FO) and abnormalities in the autonomic control of heart rate are important in its pathogenesis. We hypothesized that HD patients with high FO would have altered heart rate variability (HRV), and would experience worse CV outcomes.

Methods: We enrolled 76 stable chronic HD patients. FO was assessed with the Body Composition Monitor (Fresenius) before a mid-week HD session, and 24h ECG recordings were performed. The traditional HRV indices *SDNN*, *SDANN*, *RMSDD*, *pNN50%,VLF*, *LF*, *HF, LF/HF* were computed. Patients were classified into 5 groups depending on FO and pre-HD systolic blood pressure (SBP). Group I FO>2.5L-SBP>140mmHg; Group II normal hydration-SBP>140mmHg; Group III underhydration-SBP<140mmHg; Group IV FO>2.5L-SBP<140mmHg; Group N+Dx (reference group)-1L<FO<2.5L and 100<SBP<150 mmHg.The groups were compared using ANOVA for HRV indices, and survival curve analysis for death and hospital admissions.

Results: The patients were grouped as follws: Group I (n=34),II (n=4),III (n=0),IV (n=15),N+Dx (n=23). Group II was excluded from analysis due to small sample size. Group IV had significantly higher RMSSD, pNN50% and HF(p<0.05), which are related to parasympathetic nervous system (PNS). Group IV did worse in terms of all-cause death (p=0.02) and CV-related death (Fig.1,p=0.001). There was no difference among the groups with regards to all-cause or CV-related hospitalization.

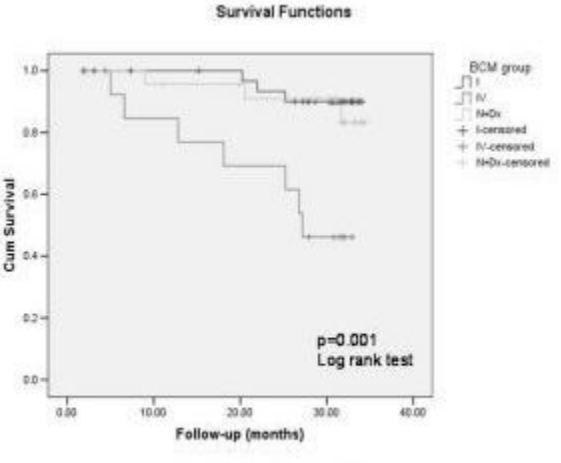


Fig. 1 CV-related death

Conclusions: In this study, HD patients with high FO(>2.5L) but low-normal SBP(<140mmHg) showed an overdrive of PNS, and this alteration in HRV may explain their higher mortality. This is the first study to analyze CV outcomes in HD patients considering both FO and HRV analysis.

TH-PO604

Time-Dependent Modeling of the Effectiveness of Cardioprotective Antihypertensives in Dialysis Patients Theresa I. Shireman,[1] Milind A. Phadnis,[1] James B. Wetmore,[1] Sally K. Rigler,[1] Qingjiang Hou,[1] John Spertus,[2] Jonathan D. Mahnken.[1] *[1]University of Kansas School of Medicine, Kansas City, KS; [2]Mid-America Heart Institute/UMKC, Kansas City, MO.*

Background: Cardiovascular disease is a leading cause of death in patients with end-stage renal disease (ESRD).There is limited clinical trial or observational data support for the benefits of renin-angiotensin system antagonists, beta-blockers, and calcium channel blockers in ESRD.

Methods: We developed a time-dependent model of medication exposure to determine the survival benefits of these medications in Medicare-Medicaid eligible ESRD patients linking Medicaid pharmacy claims with USRDS core files and Medicare institutional and physician/supplier service claims. We selected a cohort of hypertensive ESRD patients initiating dialysis between 1/1/2000 to 9/30/2005. We followed the cohort until death, loss of eligibility, or 12/31/2005. Medication exposure was defined with three time-dependent covariates: weekly drug availability (per days supply from claims), cumulative percentage of weeks with medication available (compliance), and cumulative number of weeks where drug availability switched (available vs not available). Models were adjusted for demographic, functional status, and comorbidity covariates. We used a Cox proportion hazards model with time-dependent covariates including a three-way interaction between the medication exposure measures.

Results: The final sample included 62,776 patients. Adjusted hazard ratios (AHR) for current use vs non-current use of any of the agents were significantly less than 1.0 for all combinations of switches and compliance: AHRs ranged from a low of 0.566 (1-2 switches with 90% compliance) up to 0.837 (10 switches with 10% compliance). For current users as compared to never users, AHRs ranged from 0.468 (0 switches & 100% compliance) up to 0.643 (1 switch & 10% compliance). We identified a significant 3-way interaction between time-dependent medication exposure that demonstrates a range of effectiveness for cardioprotective medications in ESRD.

Conclusions: The degree of mortality reduction associated with cardioprotective medications depends on the patterns of use over time.

Blood Pressure Medications during the First 6 Months of Dialysis Wendy L. St. Peter,[1,4] Stephen M. Sozio,[2,4] Tariq Shafi,[2,4] Jason Luly,[2,4] P. Zager,[3,4] L. Ebony Boulware.[2,4] *[1]University of Minnesota; [2]Johns Hopkins University; [3]Dialysis Clinic, Inc; [4]The DEcIDE Network Patient Outcomes in End Stage Renal Disease Study Investigators.*

Background: Most incident dialysis patients have hypertension, but, there is a paucity of data on blood pressure medication (BPMs) in these patients. Our study describes trends in BPM prescription in first 6 months of dialysis.

Methods: We studied 15,056 Dialysis Clinic, Inc. patients (2003-2008). Data were linked to United States Renal Data System data for added information on patient characteristics and comorbidities.

Results: Mean age was 61 ± 15 yrs, 55% were male, 60% were White and 36% were African American (AA), 91.5% were on hemodialysis; 43%, 54% and 62% had congestive heart failure, cardiovascular disease and diabetes, respectively. 88% were prescribed ≥1 BPM in month 6. Over 6 months, use of beta-blockers (BB), alpha-beta blockers (A-BB), renin angiotensin system (RAS) agents increased, while other BPMs remained relatively stable. (Figures) AAs and Whites had a mean (± SD) of 2.7 (1.4) and 2.3 (1.3) BPMs in month 6, respectively. Older patients were prescribed less BPMs than younger. BPMs varied considerably by race and by comorbidity, but not by sex. Among those on BPMs, the most common prescriptions were BB alone (9.7%); BB+ RAS(7.3%); BB+dihydropyridine calcium channel blocker (DHP)(5.3%); BB+RAS+DHP(6.1%); BB+RAS+other (not DHP)(9.4%); BB+DHP+other (not RAS) (8.0%); BB+other (not DHP or RAS) (8.9%) and BB+DHP+RAS+other (10%). 72% and 54% of patients on BPMs were prescribed combination regimens containing BB and RAS agents, respectively bu month 6.

Conclusions: BPM patterns are established early after dialysis initiation. Prescription of specific BPM classes varied by race, age and comorbidity. Except for BB, single BPM use was uncommon. Interventions to change prescription patterns should focus on this early period.

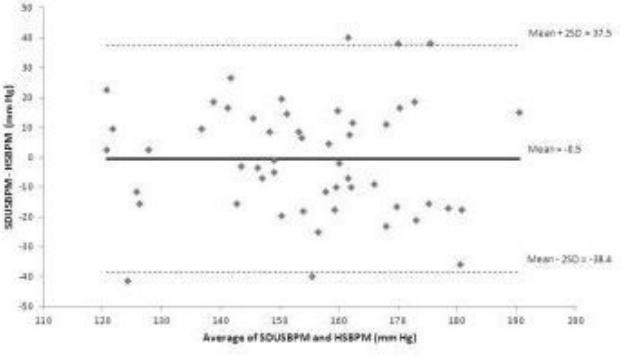
Adherence and Comparison of Standardized Dialysis Unit and Home Blood Pressure Measurements in the BID Study A. Gul,[1] D. Miskulin,[2] Jennifer J. Gassman,[3] B. Horowitz,[1] P. Zager.[1,4] *[1]UNM, ABQ, NM; [2]Tufts, Boston, MA; [3]Cleveland Clinic Foundation, Cleveland, OH; [4]DCI, ABQ, NM.*

Background: The best blood pressure measurement to guide treatment in hemodialysis (HD) patients is uncertain. Routine dialysis unit measurements of systolic blood pressure exhibit significant variability and are poor predictors of outcomes. Standardized systolic blood pressure measurements, made in accord with American Heart Association guidelines in the dialysis unit (SDUSBPM) and at home (HSBPM) may be less variable but long term adherence is uncertain. The BID (Blood Pressure in Dialysis) Study, a pilot randomized clinical trial (RCT) assessing usual vs. intensive control of systolic blood pressure (SBP), is comparing SDUSBPM and HSBPM.

Methods: We studied the first 52 BID participants. We assessed adherence by computing the percentages of the prescribed pre-dialysis SDUSBPM and HSBPM obtained. We compared midweek pre-dialysis SDUSBPM with HSBPM obtained the following day.

Results: During months 1, 2, and 3 the percentages of prescribed SDUSBPM and HSBPM obtained were 96.4, 92.7 and 97.9% and 84.5, 80.3 and 80.4%, respectively. The mean difference between SDUSBPM and HSBPM was -0.48 mm Hg (SD 18.9; range -41.5 to 40 mmHg). A Bland-Altman plot revealed no overall bias between SDUSBPM and HSBPM. Differences between paired readings were < 2 SD from the mean difference in 86% of participants.



However, some participants exhibited significant differences between the two measurements (mm Hg) 5-10 (21.2%), 11-20 (42.3%) and >20 (23.07%). Analyses of diastolic blood pressure had similar results.

Conclusions: It is feasible to obtain both SDUSBPM and HSBPM in a RCT of HD patients. The relative differences were modest and HSBPM were not systematically lower than SDUSBPM. However, some participants had large differences between the paired measurements.

Associations of Heart Failure and Cardiovascular Medications with Wall Motion Abnormalities during Hemodialysis Ruth F. Dubin,[1] Alexis L. Beatty,[2] John R. Teerlink,[2] Nelson B. Schiller,[2] Dean Alokozai,[3] Carmen A. Peralta,[1] Kirsten L. Johansen.[1] *[1]Nephrology, San Francisco VAMC/UCSF, San Francisco, CA; [2]Cardiology, San Francisco VAMC/UCSF, San Francisco, CA; [3]Cardiocore, South San Francisco, CA.*

Background: Worsening of cardiac wall motion abnormalities (WMA) during hemodialysis has been observed by prior investigators and may contribute to the high rate of cardiovascular death in persons with end-stage renal disease. We sought to identify risk factors and changes in biomarkers of ischemia (highly sensitive cardiac troponin T (hs-TnT)) associated with intradialytic WMA.

Methods: A trained sonographer performed echocardiograms before and during the last hour of dialysis in 40 patients (80 dialysis sessions). A single, blinded reader at a core laboratory analyzed WMA in 16 myocardial segments. In a subset of 26 patients (40 dialysis sessions) we measured pre- and post-dialytic hs-TnT, adjusted for hemoconcentration. We evaluated relative risk of worsening WMA using a generalized linear model and performed multivariable adjustment for covariates that were associated with WMA at $p<0.2$: dialysis vintage, post-dialysis fatigue, congestive heart failure (CHF), hemoglobin, angiotensin converting enzyme (ACE) or angiotensin receptor blocker (ARB) use, beta blockers, and aspirin.

Results: Among 40 patients, WMA worsened in 11(28%) and improved in 4(10%) during dialysis. Intradialytic hemodynamic measures, ultrafiltration, and baseline hs-TnT or changes in hs-TnT were not associated with WMA. After multivariable adjustment, participants with CHF had a 6.1-fold higher risk of worsened WMA (95%CI (2.8, 13), $p<0.001$). A reduced risk of worsened WMA was observed for participants using ACE/ARB (RR 0.22, 95%CI (0.1, 0.4), $p<0.001$) or beta blockers (RR 0.44, 95%CI (0.2, 0.8), $p=0.01$). Further adjustment for ultrafiltration, change in mean arterial pressure, diabetes or atherosclerosis did not significantly change these associations.

Conclusions: Subjects with CHF may be at increased risk of worsened WMA during hemodialysis. Further studies are needed to understand whether medications commonly used for CHF may ameliorate this risk.

TH-PO608

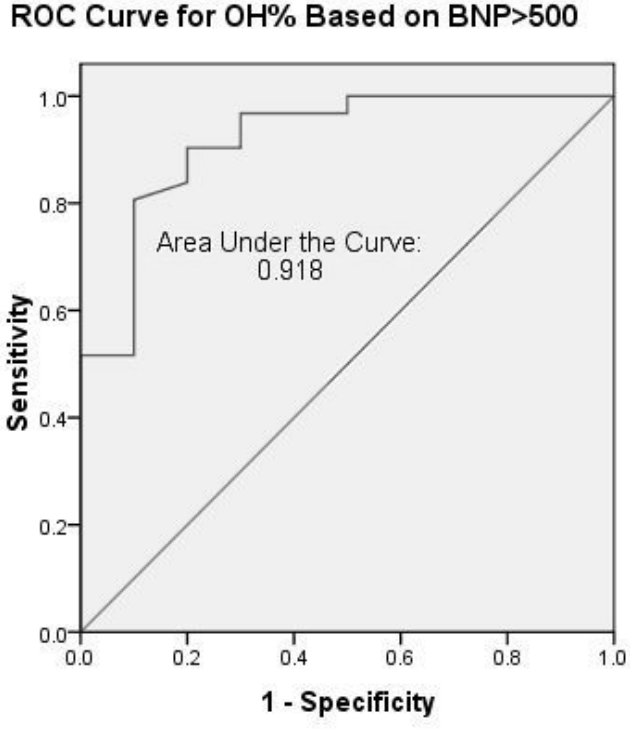
Volume Estimation in Dialysis Patients: The Concordance of Brain-Type Natriurtic Peptide Measurements and Bioimpedence Values

Mihaly Tapolyai,[1] Maria Faludi,[1] Virag Reti,[1] Zsolt Lengvarszky,[2] Tibor Szarvas,[2] Tibor Fulop,[4] Gabriella Beko,[3] Klara Berta.[1] *[1]Dialysis, Semmelweis University Budapest, Budapest, Hungary; [2]Mathematics, Louisiana State University Shreveport, Shreveport, LA; [3]Laboratory Medicine, Semmelweis University Budapest, Budapest, Hungary; [4]Nephrology, University of Mississippi, Jackson, MS.*

Background: The estimation of hydrational status in dialysis patients remains and important but difficult quest. Bioimpedance measurements have been validated by various physiological tests and the use of Brain-type natriuretic peptide (BNP) has been validated by inferior vena cava diameter measurements.

Methods: This is an observational study to evaluate the correspondence of bioimpedance measured overhydration percentage (OH%) over the extracellular water with concurrent BNP measurements. We measured OH% by a bioimpedance apparatus (BCM) and BNP pre-dialysis in 41 prevalent HD patients: 19/41 women, age 58.9 ±14.5 years.

Results: The average BNP was 2694 ±3278 pg/mL and 10 (24.4%) of the 41 patients had a BNP less than 500; average 260.7 ±108.5 pg/mL. The OH% was 8.5 ±7.0% among those with a BNP of less than 500 while the rest of the population had an OH% of 21.4 ±8.0%, corresponding to an excess volume of 1.6 ±1.3 and 4.4 ±3.8 L, respectively. The OH% vs. BNP relationship is best described by an exponential regression analysis: of $y = 216.4e^{0.097x}$ (r 0.6996). The regression line predicted BNP 216.4 pg/mL at 0% overhydration status. Receiver Operator Curves (ROC) revealed an AUC was 0.885 for the BNP when the OH% was set ≥15% of overhydration and an AUC for OH% is 0.918 when the BNP is set to be ≥500 pg/mL for the abnormal values.



Conclusions: We conclude that in our cohort there is a high degree of correspondence between these two tests with an exponential relationship between the measurements.

TH-PO609

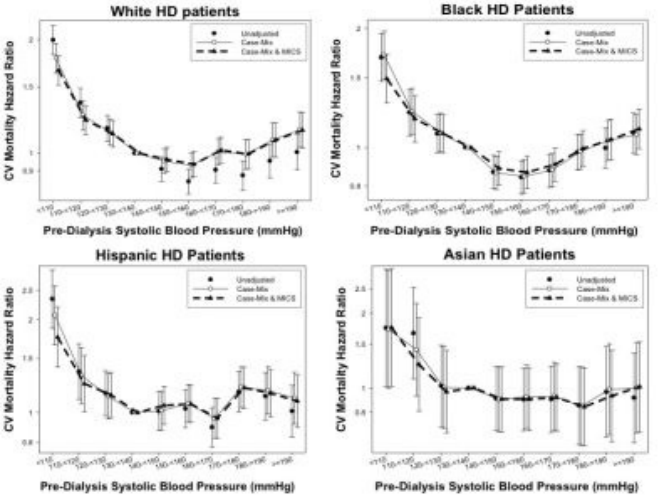
Racial-Ethnic Differences in the Association of Pre-Hemodialysis Systolic Blood Pressure and Cardiovascular Mortality

Joni L. Ricks,[1] John J. Sim,[2] Miklos Zsolt Molnar,[1] Csaba P. Kovesdy,[3] Kamyar Kalantar-Zadeh.[1,4] *[1]Harold Simmons Center for Chronic Disease Research & Epidemiology at Los Angeles Biomedical Research Institute at Harbor-UCLA; [2]Kaiser Permanente; [3]University of Tennessee; [4]Harbor-UCLA.*

Background: While stroke and mortality have been associated with rising systolic blood pressure(SBP), the relationship between cardiovascular(CV) disease and SBP has not been evaluated among maintenance hemodialysis patients(MHD). We sought to examine whether low vs. high SBP at the start of hemodialysis(HD) treatment session was a predictor of CV mortality across different racial-ethnic groups in a large cohort of MHD patients.

Methods: Pre-Dialysis SBP and CV mortality was examined in a cohort of 111,030 MHD outpatients including 47,813 White, 35,874 Black, 16,180 Hispanic and 3,304 Asian outpatients. Three levels of statistical adjustment are shown for each stratified Cox Proportional models. The pre-dialysis SBP group of 130 to <140 was used as the reference in each model.

Results: Among White, Black, Hispanic and Asian MHD patients, the mean age was 65±15, 57±15, 58±15 and 63±16 yrs and included 42%, 48%, 45% and 48% women; and 54%, 56%, 69%, 56% diabetics, respectively. Across the 10 a priori SBP groups from <110 to ≥190 mmHg, very low pre-dialysis SBP (<110 mmHg) was associated with higher CV mortality in all racial-ethnic groups examined. Additionally, the 3 lowest pre-dialysis SBP groups were associated with increased CV mortality in White MHD patients, while the 2 lowest pre-dialysis SBP groups were associated with of higher mortality among Black and Hispanic MHD patients.



Conclusions: Similarly worse CV mortality is observed in the lower pre-HD SBP groups across all racial and ethnic groups of MHD patients; although this association appears most pronounced among White MHD patients. Our findings beg the question of where optimal pre-HD SBP should be.

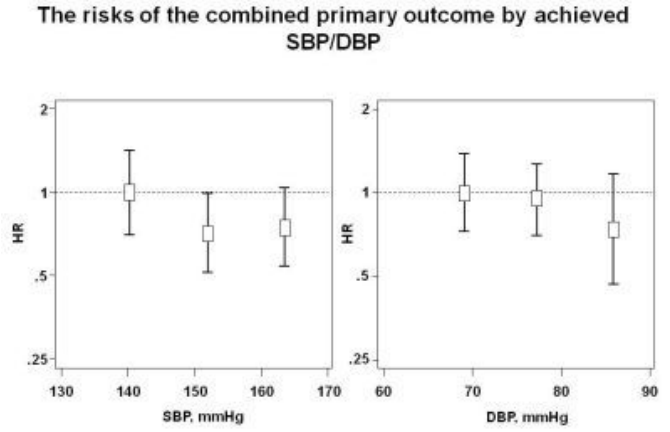
Association of Achieved Levels of Blood Pressure with Cardiovascular Disease and Death among Hypertensive Hemodialysis Patients: A Sub-Analysis of OCTOPUS

Kunitoshi Iseki,[1] Hisatomi Arima.[2] *[1]Dialysis Unit, University Hospital of the Ryukyus, Nishihara, Okinawa, Japan; [2]The George Institute for Global Health, Sydney, Australia.*

Background: Hypertension is a major risk factor for death and cardiovascular disease in patients with chronic haemodialysis (HD), but there is uncertainty surrounding the target levels of blood pressure (BP) in this high-risk patient group.

Methods: In a multicentre, prospective, randomised, open-label, blinded-endpoint trial, we assigned 469 patients with chronic HD and elevate BP (140-199/90-99 mmHg) to receive an ARB olmesartan (at a dose of 10-40 mg daily; n=235) or other treatment except for ARB and ACEi (n=234). A total of 449 patients with information on achieved BP were included in the present analysis. Three patient groups were defined by tertiles of achieved systolic (SBP) and diastolic BP (DBP). Primary outcomes were (1) composite of death, nonfatal stroke, nonfatal myocardial infarction, and coronary revascularization, and (2) all-cause death.

Results: During a mean follow-up of 3.9 years, 125 combined primary outcome events and 67 deaths were observed. Incidence rates of combined primary outcomes were 9.7% in achieved SBP<145 mmHg, 7.2% in achieved SBP 145-156 mmHg, and 8.6% in achieved SBP≥157 mmHg and those of achieved DBPs were 11.2% (<73 mmHg), 9.3% (73-81 mmHg) and 5.2% (≥82 mmHg). Mortality rates were 5.5% in achieved SBP<145 mmHg, 3.0% in achieved SBP 145-156 mmHg, and 4.0% in achieved SBP≥157 mmHg and that of achieved DBPs were 6.4% (<73 mmHg), 4.4% (73-81 mmHg) and 1.8% (≥82 mmHg). Although trends for both primary composite outcomes and mortality rate were not significant in both achieved SBP and DBP, events rates were lowest in patients who achieved SBP of 145-156 mmHg and DBP of ≥82 mmHg.



Conclusions: Target levels of blood pressure seemed to be higher than those of non dialysis CKD population.

Funding: Private Foundation Support

TH-PO611

Progression of Aortic Arch Calcification over 1 Year Is an Independent Predictor of Mortality in Incident Peritoneal Dialysis Patients Mi Jung Lee,[1] Dae-Suk Han,[1] Seung Hyeok Han,[1] Dong Ho Shin,[1] Hye-young Kang,[2] Seong Hun Kim,[2] Shin-Wook Kang.[1,2] *[1]Department of Internal Medicine, College of Medicine, Yonsei University, Seoul, Republic of Korea; [2]Severance Biomedical Science Institute, Brain Korea 21, Yonsei University, Seoul, Republic of Korea.*

Background: The presence and progression of vascular calcification have been demonstrated as important risk factors for mortality in dialysis patients. However, since most previous studies were conducted in hemodialysis, limited information was available in peritoneal dialysis (PD) patients. Therefore, this study was aimed to investigate the prevalence of aortic arch calcification (AoAC) and prognostic value of AoAC progression in PD patients.

Methods: We prospectively determined AoAC on chest X-ray at the time of PD commencement and after 12 months in 415 incident PD patients. Progression of AoAC was defined as an increase in AoAC score on the follow-up chest X-ray. Patients were divided into 4 groups according to the presence and progression of baseline AoAC. Cox proportional hazard analysis was performed to determine the independent prognostic value of the presence and progression of baseline AoAC for all-cause and cardiovascular mortality.

Results: Of 415 patients, 169 patients (40.7%) had AoAC at baseline with a mean of 18.1±11.2%. The presence of baseline AoAC was an independent predictor of all-cause (Hazard ratio [HR], 2.181; 95% confidence interval [CI], 1.336-3.561; P=0.002) and cardiovascular mortalities (HR, 3.582; 95% CI, 1.577-8.132; P=0.002). In addition, among 363 patients with available follow-up chest X-rays at 12 months after PD start, all-cause and cardiovascular death rates were significantly higher in the progression group compared with the non-progression group (P<0.001). Moreover, multivariate Cox regression analysis revealed that AoAC progression was an independent predictor for all-cause (HR, 2.491; 95% CI, 1.115-5.560; P=0.026) and cardiovascular mortalities (HR, 3.450; 95% CI, 1.044-11.401; P=0.042) in patients with AoAC at baseline.

Conclusions: The presence and progression of AoAC assessed by chest X-ray were independently associated with unfavorable outcomes in incident PD patients.

TH-PO612

Genetic Approach to Evaluate the Role of the PDE3 Subfamilies in Polycystic Kidney Disease (PKD) Hong Ye,[1] Xiaofang Wang,[1] Caroline R. Sussman,[1] Peter C. Harris,[1] Vincent C. Manganiello,[2] Christopher James Ward,[1] Vicente E. Torres.[1] *[1]Mayo Clinic, Rochester, MN; [2]NHLBI, NIH, Bethesda, MD.*

Background: A large body of evidence indicates that cAMP and protein Kinase A (PKA) play a central role in the pathogenesis of PKD. Accumulation of cAMP in cystic tissues may in part be due to enhanced adenylyl cyclase activity, but inhibition of cAMP degradation by phosphodiesterases (PDE) likely plays an important role. Of the large PDE superfamily, the PDE1 and PDE3 families may be particularly important. PDE1 accounts for most PDE activity in renal tubules, is the only PDE activated by calcium (which is reduced in PKD cells), and its activity is reduced in cystic kidneys (Wang etal KI 77:129 2010). PDE3 is inhibited by cGMP (which is degraded by PDE1) and affects tubular epithelial cell proliferation.

Methods: To assess the role of the two PDE3 subfamilies in PKD, we generated double *Pde3a* or *Pde3b* and *Pkd2* mutants that were sacrificed at 16 weeks. Blood was collected by cardiac puncture and kidneys (K) and liver (L) harvested to evaluate the extent of the cystic disease.

Results:

Pkd2$^{-/WS25}$ mice	BW, g	K/B Wt, %	Cyst area, %	Fibrosis area, %	L/B Wt, %
Pde3a$^{-/-}$ (M, n=11)	30.9±3.8	2.14±0.49	37.8±18.4	7.2±4.1	5.80±0.52
Pde3a$^{-/-}$(F, n=7)	21.9±4.6	2.21±0.76	39.1±15.6	8.4±4.1	5.58±0.63
Pde3a$^{+/+}$(M, n=11)	31.1±2.2	1.61±0.49	13.6±17.5	4.5±2.1	4.74±0.52
Pde3a$^{+/+}$(F, n=10)	21.2±2.5	1.60±0.34	16.8±9.0	4.7±1.9	4.88±0.32
Pde3a$^{+/+}$(M, n=10)	28.5±2.7	1.73±0.42	20.8±13.8	3.3±2.0	4.55±0.21
Pde3a$^{+/+}$(F, n=10)	20.7±2.8	1.74±0.72	19.7±8.9	3.7±1.9	4.55±0.58
P values*	NS	0.0013	<0.0001	<0.0001	<0.0001

* *Pde3a* genotype effect (two-way ANOVA)

The *Pde3a* knockout was associated with worse PKD and polycystic liver disease (PLD) in *Pkd2*$^{-/WS25}$ mice. The *Pde3a* knockout was also associated with worse PLD (but not PKD) in *Pkd2*$^{+/-}$ and *Pkd2*$^{+/WS25}$ mice (not shown). The *Pde3b* knockout, contrary to the *Pde3a* knockout, was not associated with detectable worsening of PKD or PLD in *Pkd2*$^{-/WS25}$ mice (not shown).

Conclusions: These results suggest that a *Pde3a* variant may regulate a cAMP pool important for cystogenesis. Triple *Pde3a/Pde3b/Pkd2* mutants are being generated to rule out functional redundancy of the two *Pde3* subfamilies.

TH-PO613

Effects of PDE1 or PDE3 Inhibition on Cyst Development in *Pkd2-/WS25* Mice Hong Ye, Xiaofang Wang, Caroline R. Sussman, Peter C. Harris, Christopher James Ward, Vicente E. Torres. *Mayo Clinic, Rochester, MN.*

Background: A large body of evidence indicates that cAMP plays a central role in the pathogenesis of Polycystic Kidney Disease (PKD). DDAVP administration markedly aggravates the renal cystic disease in PCK rats. However, it has no or only a negligible effect in *Pkd2*$^{-/WS25}$ mice. This may be due to higher PDE1 activity in murine compared to rat kidney (Wang et al Kid Int 77:129, 2010). PDE1 accounts for most PDE activity in renal tubules, is the only PDE activated by calcium (which is reduced in PKD cells), and its activity is reduced in cystic kidneys. PDE3 is inhibited by cGMP (which is degraded by PDE1) and affects tubular epithelial cell proliferation.

Methods: To determine whether a cystogenic effect of DDAVP in male (M) or female (F) *Pkd2*$^{-/WS25}$ mice can be unmasked by simultaneous treatment with a PDE1 or PDE3 inhibitor, we administered DDAVP (D) via osmotic pump (30 ng/100 g bw/hour, sc) together with vinpocetin (VP, a PDE1 inhibitor, 40 mg/kg bw/day by gavage), cilostazol (CZ, a PDE3 inhibitor, 60 mg/kg bw/day by gavage) or vehicle alone (CN) between 4 and 13 (VP) or 16 (CZ) weeks of age.

Results: In both cases administration of DDAVP aggravated PKD development.

Group (n)	BW, g	Kid cAMP [a]	Kid PDE [b]	Kid/B Wt, %	Cyst area, %	P Urea [c]
CN M (10)	26.1±2.4	2.7±0.9	10.1±2.0	1.52±0.19	15.1±9.2	62±12
CN F (10)	21.2±1.1	4.0±1.3	9.6±1.8	1.63±0.33	13.7±6.5	68±11
VP+D M (9)	23.0±1.5	7.2±4.2	8.3±1.3	2.22±0.75	31.5±19.3	80±21
VP+D F (9)	19.7±1.8	6.8±3.3	7.9±0.8	2.19±0.69	29.7±17.9	79±11
P value [d]	<0.001	<0.001	0.001	<0.001	0.001	0.005
CN M (14)	27.1±1.9	3.0±1.2	1.27±0.23	1.56±0.19	11.4±7.9	82±15
CN F (12)	21.3±1.9	3.8±1.3	1.10±0.19	1.64±0.38	16.4±11.8	75±12
CZ+D M (14)	25.6±1.8	7.3±3.4	0.80±0.23	2.03±0.34	22.2±15.7	94±13
CZ+D F (14)	21.5±1.8	5.6±1.8	0.33±0.26	2.12±0.36	27.7±16.5	98±22
P value [d]	NS	<0.001	<0.001	<0.001	0.003	<0.001

[a] pmol/mg renal lysate protein [b] PDE activity (pmol/min/mg renal lysate protein PDE1 in rows 2-5 and PDE3 in rows 7-10) [c] mg/dl [d] Treatment effect (two-way ANOVA)

Conclusions: Coadministration of DDAVP and either a PDE1 or a PDE3 inhibitor aggravates PKD development in *Pkd2*$^{-/WS25}$ mice. The results may underestimate the role of PDE1 and PDE3 since their activity was only moderately suppressed by VP or CZ administration.

TH-PO614

Hsp90 Inhibition Slows Cyst Growth in a Mouse Model of Autosomal Dominant Polycystic Kidney Disease (ADPKD) Tamina Seeger-Nukpezah,[1] David A. Proia,[2] Erica A. Golemis.[1] *[1]Fox Chase Cancer Center, Philadelphia, PA; [2]Synta Pharmaceuticals, Lexington, MA.*

Background: ADPKD affects about 1:700 individuals and typically manifests in middle age, with 50% of affected individuals progressing towards end stage renal disease. Development of ADPKD is associated with elevated activity of numerous signaling proteins that control proliferation and cell-environment interactions. These include SRC, STAT3, ERK, Aurora-A, and others. We recognized that many of these signaling proteins are clients and effectors of the molecular chaperone HSP90, suggesting that treatment with HSP90 inhibitors might provide a useful therapy for PKD by simultaneously depressing activity of multiple PKD-promoting signaling factors.

Methods: Tamoxifen-inducible PKD1 conditional knockout mice, in which cysts normally appear at 4 months of age, were used as a model for ADPKD. Mice were dosed with vehicle or the second generation HSP90 inhibitor STA-2842 once weekly for 10 weeks, from 4 - 6.5 months of age. Using monthly MRI-imaging, histopathology and blood urea nitrogen measurements we quantitated cyst growth and renal function. Reverse phase protein arrays (RPPA) were implemented to measure >150 protein analytes in vehicle and STA-2842 treated PKD1-/- cell lines.

Results: STA-2842 was well tolerated during treatment. Cyst growth was greatly reduced and renal function significantly improved in mice treated with STA-2842, in comparison to the control group. A follow-up experiment indicated that prevention therapy, with treatment starting directly after induced *PKD1* deletion, delayed cystogenesis. RPPA analysis showed a reduction in receptor tyrosine kinase expression (EGFR, HER2, IGF-1R) by STA-2842 in PKD-/- cell lines, as well as deactivation of numerous signaling proteins (AKT, SRC, MAPK, STAT3) and upregulation of pro-apoptotic factors (BIM, ANNEXIN).

Conclusions: Inhibition of HSP90, in a mouse model of ADPKD, demonstrates encouraging signs of activity, both in the reduction of cyst number and volume as well as improved renal function. With weekly dosing schedule being well tolerated and effective over a long period of time, HSP90 inhibition may be suitable for long-term treatment of ADPKD patients.

Network Analysis of a *Pkd1*-Mouse Model of Autosomal Dominant Polycystic Kidney Disease Identifies HNF4α as a Disease Modifier

Luis F. Menezes,[1] Fang Zhou,[1] Andrew Patterson,[3] Klaus B. Piontek,[2] Kristopher W. Krausz,[3] Frank J. Gonzalez,[3] Gregory G. Germino.[1] *[1]NIDDK, National Institutes of Health, Bethesda, MD; [2]Johns Hopkins School of Medicine, Baltimore, MD; [3]NCI, National Institutes of Health, Bethesda, MD.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD; MIM ID's 173900, 601313, 613095) is caused by mutations in *PKD1* or *PKD2* and leads to end stage kidney disease. Inactivation of *Pkd1* before or after P13 in mice results in distinct early- or late-onset disease.

Methods: Using a mouse model carrying floxed *Pkd1* alleles and inducible Cre recombinase, we applied network analysis to transcriptomics and metabolomics data, following disease progression in a large number of mice induced before P10. We analyzed 1114 published gene expression arrays, and tracked phenotypic and metabolomics changes in *Pkd1/Hnf4*α double conditional mice.

Results: Weighted gene co-expression network analysis suggests that *Pkd1*-cystogenesis does not cause developmental arrest and occurs in the context of gene networks similar to those that regulate normal kidney morphology/function. Pathway analysis identifies HNF4α as a network node. The results are supported by a meta-analysis of 1114 published gene expression arrays, and predict metabolic pathways are key elements in postnatal kidney maturation and cystogenesis. Urinary metabolomics show that *Pkd1* cystic mutants have a distinct profile of excreted metabolites, suggestive of altered metabolism. We perturbed metabolic networks by inactivating *Hnf4*α. *Pkd1/Hnf4*α double mutants have significantly more cystic kidneys, indicating that metabolic pathways could play a role in *Pkd1*-cystogenesis.

Conclusions: The data suggest that *Pkd1*-cystogenesis does not require/cause developmental arrest, and occurs in the context of gene networks essentially similar to those that regulate normal kidney morphology/function. We propose that postnatal kidney maturation is accompanied by changes in metabolic pathways that are likely modifiers of *Pkd1*-cystogenesis and could underlie the differences in the kinetics of cyst formation in early- or late-onset disease models. We show that HNFα is a modifier of *Pkd1*-cystogenesis.

A Novel Kidney-Selective AMPK Activator NT1021 Inhibits Proliferation and *In Vitro* Cyst Growth of ADPKD Cells

Gail Reif,[1] Emily Nivens,[1] Archana Raman,[1] Cibele S. Pinto,[1] Ken W. Batchelor,[2] Darren P. Wallace.[1] *[1]Kidney Institute, University of Kansas Medical Center, Kansas City, KS; [2]NovaTarg Inc, Research Triangle Park, NC.*

Background: In polycystic kidney disease (PKD), inappropriate activation of mTOR signaling increases proliferation of cyst-lining epithelial cells and contributes to PKD progression. AMP-activated protein kinase (AMPK) is an energy sensor that orchestrates energy utilization and regulates cell growth and protein synthesis through mTOR inhibition. AMPK also inhibits CFTR Cl^- channels. Metformin, an approved drug that activates AMPK, was shown to inhibit phosphorylation of S6 kinase, a downstream mediator of mTOR and reduce cyst growth in PKD mice, suggesting that AMPK is a therapeutic target for PKD. Metformin is transported by organic cation transporters, including OCT2 on the basolateral membrane of proximal tubules, and OCT1 expressed by hepatocytes. We generated a panel of 60 biguanide analogues for selective transport by OCT2 to increase renal drug exposure. NT1021 was identified as the most highly OCT2-selective biquanide.

Methods: Effects of NT1021on S6 kinase and S6 phosphorylation in human ADPKD cells were determined by Western blot analysis. To test the drug's effect on CFTR, ADPKD monolayers were treated with forskolin, a cAMP agonist, in the absence and presence of NT1021. Changes in anion current were measured by short circuit current. For cyst growth assays, ADPKD cells were seeded within a collagen matrix and treated with EGF and forskolin ± NT1021. Total surface area of the cysts per well was calculated from individual cyst diameters.

Results: EGF increased levels of phosphorylated S6 kinase and S6 and the rate of ADPKD cell proliferation, consistent with activation of mTOR signaling. NT1021 decreased EGF-induced S6 kinase and S6 phosphorylation and cell proliferation at lower concentrations compared to metformin. NT1021 also caused an inhibition of cAMP-induced anion secretion across ADPKD cell monolayers and completely blocked *in vitro* cyst growth.

Conclusions: A highly selective OCT2 transported biguanide NT1021 inhibits mTOR activation and cell proliferation and blocks *in vitro* cyst growth of human ADPKD cells.

Two Ranges of Rapamycin for Treatment of Autosomal Dominant Polycystic Kidney Disease: 12-Month Open-Label Pilot Study

William E. Braun, Jesse D. Schold, Rita A. Spirko, Brian R. Stephany, Brian R. Herts. *Glickman Urological and Kidney Institute, Cleveland Clinic, Cleveland, OH.*

Background: Rapamycin studies in human ADPKD that used change in total kidney volume (TKV) as the primary endpoint and change in estimated glomerular filtration rate (eGFR) have not substantiated the protective effect of rapamycin seen in animal models. Change in iothalamate GFR (iGFR) at 12 months was the primary endpoint here; rapamycin dosing was directed at different trough ranges.

Methods: Thirty patients with ADPKD were randomized in an open-label 12-month pilot study to low-dose rapamycin (trough level 2-5 ng/mL) (Group A, n=10), standard dose rapamycin (trough level >5-8 ng/mL) (Group B, n=10), or standard care (Group C, n=10). There were no significant differences in demographics or indicators of rapid progression between the groups. Evaluations were also done at 6 months and post-treatment at 18 months. Rapamycin levels were measured by liquid chromatography-tandem mass spectometry, and renal volume by non-contrast computed tomography (CT).

Results: 87% of patients (26/30) had 12-month data for the primary end-point of change in iGFR (9 in Group A, 8 in Group B, and 9 in Group C). Change in iGFR (mL/min/1.73m2) at 12 months was significantly improved in Group A (+7.7 ± 12.5) but not in Group B (+1.6 ± 12.1) when compared to Group C (-11.2 ± 9.1) (A vs C p=0.005, B vs C p=0.07, A vs B p=0.52, A + B vs C p=0.002). Group A iGFR change was also significant at 6- but not at 18-month follow-up. Change in TKV at 12 months was not significantly different: +196.7 ± 201.2 cc in Group A, +82.9 ± 111.3 cc in Group B, and +152.7 ± 129.4 cc in Group C (A vs C, B vs C, A vs B, A + B vs C, all p=NS). Trough rapamycin levels in Group A were significantly lower than in Group B: 6 months (n=9) (2.49 ± 0.75 vs 4.48 ± 1.33 ng/mL, respectively, p=0.001); 12 months (n=6) (2.75 ± 0.29 vs 5.28 ± 1.42 ng/mL, respectively, p=0.002). Adverse events were most frequent in Group B.

Conclusions: Low-dose rapamycin (Group A) was associated with significantly higher iGFR after 6 and 12 months of ADPKD treatment without improvement in TKV. Adverse events were most frequent in those receiving standard dose rapamycin (Group B).

mTORC1 and 2 Inhibition in Polycystic Kidney Disease

Kameswaran Ravichandran, Iram Zafar, Zhibin He, Charles L. Edelstein. *Univ of Col Denver.*

Background: mTOR exists in association with two different complexes, mTORC1 and mTORC2. Both mTORC1 and 2 are pro-proliferative. mTORC1 inhibition with rapamycin has been disappointing in human studies. mTORC1 and 2 inhibition with mTOR kinase inhibitors offers a new therapeutic approach. mTORC2 signals downstream via Akt1, PKCα, Rho and Rac1.

Methods: A mTOR kinase antisense oligonucleotide (ASO) that selectively binds to the ATP-binding site in mTOR catalytic domain, inhibiting mTORC1 and mTORC2 was injected at 50mg/kg/wk dose i.p. in PKD2WS25mice (an orthologous model of human ADPKD) from 4 to 16 weeks of age. The role of mTORC2 was validated in cyst formation by silencing Rictor the functional component of mTORC2 in an in vitro model of Type 1 MDCK cells that forms cysts in collagen culture.

Results: On immunoblot there was a 2 fold increase in PKC-α(P<0.05), a marker of mTORC2 activation, in kidneys of PkdWs25 vs wild type mice. In PKD2Ws25 mice, the 2K/TBW, CVD and BUN were significantly decreased in mTOR ASO treatment groups.

mTOR ASO in pkd2WS25 mice

	+/+ Veh	WS25 Veh	WS25 mTOR ASO
BW (g)	23 ± 0.3	30 ± 1.8	27± 2.2
2K/TBW (%)	1.27 ± 0.03	2.2 ± 0.3*	1.4 ± 0.1 **
CVD (%)	1.0 ± 0.01	29 ± 6*	10 ± 5 **
BUN (mg/dL)	18 ± 1	34 ± 5 *	25 ± 2 **

*P<0.001 vs +/+ Veh, **P<0.05 vs WS25 Veh, n=4

In MDCK cells in culture, on day7 the cyst diameter was decreased by 28.8% in Rictor silenced MDCK cells as compared to MDCK control cells (P<0.05) and cyst diameter was increased by 23.6% with addition of constitutively active Akt1. On day10 the cyst diameter was decreased by 48.2% in Rictor silenced MDCK cells as compared to MDCK control cells (P<0.05) and was increased by 42% with addition of constitutively active Akt1.

Conclusions: 1) mTOR ASO-treated mice had lower kidney weight, CVD and better kidney function than vehicle-treated Pkd2WS25 mice. The effect of mTOR inhibition on PKD in Pkd2WS25mice was more effective than we have previously published with rapamycin in the same model, 2) mTORC2 silencing in an in vitro model reduces the cyst size that is reconstituted by addition of constitutively active Akt1. In conclusion combined mTORC1 and mTORC2 inhibition may have better therapeutic potential in ADPKD and merits further study in ADPKD.

Folate-Conjugated Rapamycin Slows Progression of Polycystic Kidney Disease with Increased Renal Specificity Thomas Weimbs,[1] Jonathan M. Shillingford,[1] Christopher P. Leamon,[2] Iontcho Vlahov.[2] *[1]Department of Molecular, Cellular & Developmental Biology, University of California Santa Barbara, Santa Barbara, CA; [2]Endocyte Inc., West Lafayette, IN.*

Background: Autosomal-dominant polycystic kidney disease (ADPKD) frequently leads to renal failure necessitating kidney transplantation or life-long dialysis. Currently, no treatment is available to prevent or slow disease progression. The mTOR signaling pathway has been shown to be aberrantly activated in ADPKD. In PKD rodent models, treatment with mTOR inhibitors such as rapamycin is highly effective in ameliorating the disease. However, recent clinical trials did not show significant benefits of treatment with mTOR inhibitors in ADPKD patients. It is likely that the relatively low, tolerable doses of mTOR inhibitors are insufficient to achieve effective mTOR inhibition in the target tissue in humans.

Methods: To overcome this limitation we have synthesized a folate-conjugated form of rapamycin (EC0371, FC-rapa) designed to be taken up by folate-receptor (FR)-mediated endocytosis, and cleaved intracellularly to reconstitute the active drug.

Results: We show that the FR is highly expressed in renal cyst-lining cells in ADPKD and mouse models. *In vitro* experiments demonstrate that FC-rapa inhibits mTOR activity in a dose- and folate receptor-dependent manner. Treatment of a PKD mouse model with folate-rapa results in inhibition of mTOR in the target tissue, strong inhibition of proliferation and renal cyst growth, and preservation of renal function. Dosing experiments show that FC-rapa inhibits mTOR activity in the kidney but not in other organs.

Conclusions: These results suggest that renal drug targeting using FC-rapa may be useful to overcome the significant side effects and lack of renal efficacy observed in clinical trials with mTOR inhibitors in ADPKD patients.

Everolimus, an Oral mTOR Inhibitor, Is Not Nephrotoxic in Patients with Tuberous Sclerosis Complex or Sporadic Lymphangioleiomyomatosis John J. Bissler,[1] Chris Kingswood,[2] Bernard Zonnenberg,[3] Michael Frost,[4] Elena Belousova,[5] Elzbieta Radzikowska,[6] Petrus J. de Vries,[7] Karen Stein,[8] Gaurav Shah,[8] Sara Miao,[8] Jeremie Lincy,[8] Klemens Budde.[9] *[1]Cincinnati Children's Hosp Med Center; [2]Royal Sussex County Hosp; [3]University Hospital Utrecht; [4]Minnesota Epilepsy Group; [5]Moscow Research Institute of Pediatrics & Pediatric Surgery; [6]National Tuberculosis & Lung Diseases Research Institute; [7]University of Cape Town; [8]Novartis Pharmaceuticals Corp.; [9]Charite-Universitätsmedizin Berlin.*

Background: Tuberous sclerosis complex (TSC) is an autosomal dominant genetic disorder caused by mutations in the *TSC1* or *TSC2* gene, resulting in constitutive mTOR pathway upregulation. TSC is characterized by growth of nonmalignant tumors in multiple organs including the kidneys (angiomyolipoma, AML). AML is also associated with the rare pulmonary disorder sporadic lymphangioleiomyomatosis (sLAM).

Methods: EXIST-2 (NCT00790400) is an international, randomized, double-blind, placebo-controlled, phase 3 trial in patients with TSC or sLAM who have AML. Eligible patients (≥1 AML with longest diameter ≥3 cm) were randomized 2:1 to oral 10 mg/d everolimus (n=79) or placebo (n=39), stratified by TSC and enzyme-inducing anti-epileptic drug use, and presence of sLAM. As of 14 Oct 2011, 90 days of additional safety data from the original cutoff date (30 Jun 2011) became available and are presented herein.

Results: At the 90 day updated analysis, 53% and 41% of everolimus and placebo patients, respectively, had ≥48 weeks of exposure to study drug. Between the original cutoff and updated analysis, discontinuations occurred in only placebo patients, primarily due to disease progression. Glomerular filtration rate (GFR) remained stable for both treatment groups; 98% and 92% of everolimus and placebo patients maintained a GFR ≥30 mL/min/1.73 m^2. In the everolimus and placebo groups, respectively, blood creatinine increased in 3% and 8% and proteinuria was detected in 4% and 13%.

Conclusions: This updated safety analysis is consistent with the original analysis. Renal function data from everolimus patients suggests stable renal function in TSC patients with AML.

Identification of Novel Pathways Affected by Intracellular Ca^{2+} in Human ADPKD Cells by Comprehensive Gene Analysis Darren P. Wallace,[1] Gail Reif,[1] Corey White,[1] Yafeng Dong.[2] *[1]Kidney Institute, University of Kansas Medical Center, Kansas City, KS; [2]Obstetrics and Gynecology, University of Kansas Medical Center, Kansas City, KS.*

Background: In ADPKD, loss of polycystin function disrupts intracellular Ca^{2+} regulation and transforms renal epithelial cells into poorly differentiated hyperplastic cells that give rise to cysts. cAMP stimulates the proliferation of ADPKD cells, but inhibits the proliferation of normal renal cells. Restoration of intracellular Ca^{2+} by BayK8644, a Ca^{2+} channel activator, rescues a normal response, such that cAMP inhibits ADPKD cell proliferation; however, the underlying mechanism remains unclear.

Methods: ADPKD cells were treated with cAMP ± Bay K8644 for 24h. RNA was isolated and evaluated for integrity. Affymetrix Human Genome U133A 2.0 arrays were used to identify genes with a 1.3-fold expression change ($P<0.05$) and gene signaling pathways were analyzed by GeneGo MetaCore Bioinformatics software.

Results: Of 14,500 well-characterized genes, only 312 genes were altered by increased Ca^{2+}. The five top canonical pathways were "Cell cycle", "Inhibition of Telomerase Activity and Cellular Senescence", "Role of Parkin in the Ubiquitin-Proteasomal Pathway", "Regulation of G1/S transition", "Start of DNA Replication in Early S Phase", "Sister Chromatid Cohesion", and "Regulation of Actin Cytoskeleton by Rho". Specific genes included cyclin-dependent kinase 6 (CDK6), a recognized component of cystic disease, and novel genes including mini-chromosome maintenance protein MCM 4, retinoblastoma-associated protein p107, elongation factor E2F3, DBF4 homolog A (ASK), IGF-binding protein 2, Inhibitory G protein-specific GPCRs, Interleukon-1α and Proliferation-inducing gene-2. Ubiquitin conjugating enzyme UBC7 and alpha-synuclein, not normally expressed in adult kidney, had altered expression, suggesting a role of proteosomal degradation. Integrated pathway maps generated by Enrichment Pathway Network Analysis provided a comprehensive analysis of gene-gene interactions.

Conclusions: We identified unique genes involved in cell proliferation and ubiquitin-proteasomal pathways that may underlie the phenotypic switch induced by Ca^{2+}restoration in ADPKD cells.

TH-PO622

HIF-1α Causes Renal Cyst Expansion through Calcium-Activated Chloride Secretion Bjoern Buchholz,[1] Gunnar Schley,[1] Diana Faria,[2] Sven Kroening,[1] Johannes Schoedel,[1] Bernd Klanke,[1] Karl Kunzelmann,[2] Kai-Uwe Eckardt.[1] *[1]Department of Nephrology and Hypertension, University of Erlangen-Nuremberg, Erlangen, Germany; [2]Department of Physiology, University of Regensburg, Regensburg, Germany.*

Background: Polycystic Kidney Diseases (PKD) are characterized by a multitude of bilateral renal cysts that enlarge gradually and lead to a decline of kidney function. Cyst growth involves chloride-dependent transepithelial fluid secretion. Cyst enlargement causes regional hypoxia which results in the stabilization of the hypoxia-inducible transcription factor HIF-1α in the cyst epithelium.

Methods: To assess the functional relevance of HIF-1α activation for cyst growth, we interfered with the HIF pathway in two *in vitro* cyst models – MDCK cells in a collagen matrix and cultured embryonic mouse kidneys stimulated with forskolin. In addition, we performed Ussing Chamber analyses with MDCK cells deficient for HIF-1α. Furthermore, we used a forward genetic screen to identify novel HIF-1α target genes and analysed their expression and function in both cyst models. Beyond that, we analysed human ADPKD kidneys in regard to the expression of HIF-1α target genes that played a role in cyst growth.

Results: Chronic stabilization of HIF-1α promoted MDCK cyst growth and cyst enlargement in cultured embryonic kidneys stimulated with forskolin whereas genetic and pharmacological inhibition of HIF-1α inhibited cyst growth. In addition, MDCK cells deficient for HIF-1α lacked calcium-activated chloride secretion in Ussing Chamber analyses. In a forward genetic screen, we identified both, the purinergic receptor $P2Y_2R$, and the calcium-activated chloride channel anoctamin 6 (ANO6) as HIF-1α-regulated genes. Consistently, pharmacological inhibition of anoctamins, significantly impaired cyst growth in both cyst models. In addition, ANO6 was co-expressed with HIF-1α in the cyst epithelium of human ADPKD kidneys.

Conclusions: We conclude that in PKD regional hypoxia aggravates cyst expansion via HIF-1α-dependent calcium-activated chloride secretion. Thus the HIF pathway including the HIF-inducible genes ANO6 and $P2Y_2R$ may offer novel targets for inhibition of cyst growth.

Shh Inhibition Improves Renal Functions in *Pkd2 Mutant Mice* Yuan Li,[1,2] Wenyi Wang,[1,2] Ao Li,[1,2] Haichao Liu,[1,2] Elizabeth Green,[2] Dan Liang,[2] Guanqing Wu.[2] *[1]State Key Laboratory of Molecular Oncology, Cancer Hospital and Institute, Chinese Academy of Medical Sciences, Beijing, China; [2]Genetic Medicine, Vanderbilt University, Nashville, TN.*

Background: ADPKD is one of the most common monogenic diseases in the kidneys and is characterized by numerous fluid-filled renal cysts. ADPKD is caused by mutations in either *PKD1* or *PKD2*, each of which respectively encodes the proteins, polycystin-1 (PC1) and polycystin-2 (PC2). Recent studies indicate that PC1 and PC2 form a protein complex through interaction between their COOH-terminals, and loss of either polycystins dysregulates multiple cell signaling pathways. Such disruption may lead to aberrant ionic transportation, polarity, and proliferation/apoptosis in renal epithelial cells and eventually cause renal cyst formation.

Since Shh protein has been reported to closely associate with the cilia of diverse epithelial cells including those of the kidneys, we hypothesized that polycystins and Shh may have epistatic effects and contribute to cyst formation in ADPKD. To this end, we employed *Pkd2* and *Shh* mutant mice to study their functional relationship *in vivo*. In this study, we have crossed heterozygous *Shh* mice (*Shh*$^{+/-}$) and Vil-Cre-derived *Pkd2* conditional knockout mice (Vil-Cre:*Pkd2*$^{f3/f3}$) to generate compound Vil-Cre:*Pkd2*$^{f3/f3}$:*Shh*$^{+/-}$ mutant mice. We performed a cohort study for Vil-Cre:*Pkd2*$^{f3/f3}$ mice with and without *Shh*$^{+/-}$ mutant alleles (n>20 for each group). By examining their survival rate, kidney or liver/body ratio, renal cystic index, and renal function of these mice, we found that there are no significant differences in lethal phenotypes or renal cystic severity between mice with Vil-Cre:*Pkd2*$^{f3/f3}$:*Shh*$^{+/-}$ and Vil-Cre:*Pkd2*$^{f3/f3}$ alleles. However, significantly improved renal function (BUN and Cr) can be seen in Vil-Cre:*kd2*$^{f3/f3}$:*Shh*$^{+/-}$ mice compared to Vil-Cre:*Pkd2*$^{f3/f3}$ mice. We have also investigated PC2-deficient effects in *Shh*$^{+/-}$ mice. Interestingly, we found that the lack of PC2 induces solitary kidney in *Shh*$^{+/-}$ mice (20.6%). These results indicate that downregulation of Shh may have a protective role in ADPKD models/patients and PC2 may engage in Shh-associated kidney development.

Modulation of Wnt/β-Catenin Signaling by GSK3 Inhibition Accelerates Polycystic Disease Progression a Model of Nephronophthisis
Laurie A. Smith, Sarah E. Moreno, Kelly A. Rogers, Thomas A. Natoli, Oxana Beskrovnaya, Herve Husson. *Cell Biology, Genzyme Corp., a Sanofi Co., Framingham, MA.*

Background: Polycystic kidneys diseases (PKDs) are a family of genetic disorders characterized by renal cystic growth and progression to end stage renal disease. Cystogenesis is associated with dysregulation of multiple signaling pathways, including intracellular calcium homeostasis, cAMP signaling, mitogenic cascade, mTOR and Wnt signaling, some of which are regulated by the primary cilium. Because ciliary dysfunction appears to be a common abnormality leading to multiple forms of PKD, including nephronophthisis, we set out to address the role of the ciliary-regulated Wnt/beta-catenin pathway in promoting PKD in the jck mouse model of nephronophthisis. To understand whether canonical Wnt signaling is active in jck cystic kidneys, we performed RT PCR gene expression array analysis and found upregulation of several Wnt ligands, Frizzled receptors and downstream target genes. Also, changes in beta-catenin expression and subcellular distribution in cystic tissue early in disease suggested aberrant activation of Wnt/beta-catenin pathway. To clearly define whether this pathway is a key signaling component in promoting cytogenesis, we directly tested the effects of glycogen synthase kinase-3 (GSK-3) inhibition on PKD progression in jck mice. Treatment with GSK3 inhibitors lithium or SB216763 significantly accelerated disease progression resulting in increased cystic volumes and decreased renal function, accompanied by increased phosphorylation of GSK-3β at Ser9 and elevated expression of beta-catenin. Additionally, GSK-3 inhibition further elongated cilia of renal cystic epithelial cells. These data provide in vivo evidence that pharmacological activation of the Wnt/beta-catenin pathway promotes PKD.

Postnatal Inhibition of Glycogen Synthase Kinase-3 Reduces Renal Cystogenesis in cpk/cpk Mice
Reena Rao, Erin Suderman, Shixin Tao. *Kidney Institute, University of Kansas Medical Center, Kansas City, KS.*

Background: Polycystic kidney diseases are a large family of inherited disorders characterized by the formation of multiple fluid filled cysts in the renal tubules, often leading to end stage renal disease. Progressive cyst enlargement in PKD is known to be associated with elevated cAMP levels, and the inhibition of vasopressin mediated adenylate cyclase activity has been shown to dramatically diminish the formation and growth of renal cysts in rodents. We previously found that inhibition or gene deletion of glycogen synthase kinase 3ß (GSK3ß) reduces arginine vasopressin (AVP) -mediated adenylate cyclase activity and reduced cAMP levels in the kidney. GSK3 is a serine/ threonine protein kinase which plays a crucial role in Wnt signaling and cell proliferation. The aim of the current study was to examine if inhibition of GSK3 could ameliorate the development and progression of cysts in PKD.

Methods: For the studies we used cpk/cpk mice, a model for autosomal recessive PKD, characterized by rapid postnatal renal cyst progression resulting in death around weaning. Mouse litters were injected daily starting on P3 with vehicle or TDZD-8 (5mg/Kg BWt, IP), a highly specific ihhibitor of GSK3. Pups were sacrificed on P14.

Results: When compared to wild type mice, in the cpk/cpk mice we detected high GSK3ß expression in whole kidney lysate and specifically in the cyst-lining epithelia by immunoblot and immunostaining. Treatment with TDZD-8 retarded renal cyst development and progression in cpk/cpk mice. The kidney weight/body weight ratio was significantly lower in the TDZD-8 treated mice compared to vehicle treated mice. Examination of the gross morphology in H&E stained sections revealed more intact parenchyma in the TDZD-8 treated group than in the vehicle treated group. Renal cyst volume and BUN were also significantly reduced in the TDZD-8 treated mice compared to vehicle treated mice.

Conclusions: These studies suggest that inhibition of GSK3 reduces renal cystogenesis in cpk/cpk mice.

Very Low Dose Rosiglitazone Inhibits Cyst Growth in the PCK Rat Model of Polycystic Kidney Disease
Bonnie L. Blazer-Yost,[1,2] Stephanie Flaig,[1] Alexander J. Carr,[2] Vincent H. Gattone.[1,2] *[1]Biology, Indiana University Purdue University, Indianapolis, IN; [2]Anatomy and Cell Biology, Indiana University School of Medicine, Indianapolis, IN.*

Background: Autosomal dominant polycystic kidney disease (ADPKD), the most common genetic renal disease, is characterized by the slow growth of fluid-filled cysts in kidney tubules and liver bile ducts. Cyst enlargement is due, in part, to Cl^- secretion via the cystic fibrosis transmembrane conductance regulator (CFTR) Cl^- channel. Our previous studies demonstrated that PPARγ agonists, insulin sensitizing drugs used to treat diabetes, inhibit Cl^- secretion by collecting duct principal cells via decreased CFTR synthesis. For 4 PPARγ agonists tested, the IC_{50}s calculated from the dose response inhibition curves for Cl^- transport paralleled the EC_{50}'s for receptor transactivation with a leftward shift, suggesting an approximately 10 fold increase in sensitivity for drug induced inhibition of Cl^- secretion. These data suggest that the FDA-approved PPARγ agonists should be effective in inhibiting cyst expansion when used at very low doses. Our previous preclinical studies showed that high (20 mg/kg BW) dose pioglitazone, an FDA approved PPARγ agonist, inhibited cyst growth in the PCK rat model of PKD. The current study was designed to show a class action of PPARγ agonists by determining if rosiglitazone, another PPARγ agonist, inhibits cyst growth and if so, does this agonist work at concentrations lower than those typically used to treat diabetes.

Methods: A 24 week feeding study in the PCK rat model used 3 doses of rosiglitazone (4, 0.4, 0.04 mg/kg BW). 4 mg/kg BW rosiglitazone is analogous to the previous dose of 20 mg/kg BW pioglitazone.

Results: The lowest dose, 0.04 mg/kg BW, which is two orders of magnitude less than previously used concentrations, significantly slowed renal cyst growth.

Conclusions: Based on these preclinical findings it is hypothesized that PPARγ agonists could be used to inhibit cyst expansion at doses that are low enough to avoid the characteristic side effects of these drugs.

Genetic Modulation of Glycosphingolipid Network Identifies GM3 Synthase as a New Target for Polycystic Kidney Disease
Thomas A. Natoli,[1] Herve Husson,[1] Kelly A. Rogers,[1] Laurie A. Smith,[1] Bing H. Wang,[2] Yeva Budman,[2] Nikolay Bukanov,[1] Steven R. Ledbetter,[1] Katherine W. Klinger,[3] Oxana Beskrovnaya.[1] *[1]Cell Biology, Genzyme Corp., a Sanofi Co., Framingham, MA; [2]Analytical Research and Development, Genzyme Corp., a Sanofi Co., Waltham, MA; [3]Genetics and Genomics, Genzyme Corp., a Sanofi Co., Framingham, MA.*

Background: Sphingolipids and glycosphingolipids are important regulators of cellular proliferation, differentiation, and survival, all processes which are disrupted in polycystic kidney diseases (PKD), including ADPKD and nephronophthisis. Recent studies have demonstrated that inhibition of glucosylceramide (GlcCer) accumulation attenuates PKD in several preclinical models. Because GlcCer is a precursor to multiple complex glycosphingolipids, including LacCer, the globosides and gangliosides, it is important to determine which specific glycosphingolipid modulates cytogenesis in search of optimal therapeutic targets. We sought to define the role of the simplest ganglioside, GM3 in nephronophthisis-associated PKD using jck model. We show, for the first time, that GM3 plays a pivotal role in cystogenesis by crossing jck mice with mice carrying a targeted mutation in the GM3 synthase gene (*St3gal5*). Homozygous loss of GM3 synthase prevented GM3 synthesis and inhibited cystogenesis in jck mice. Several pathways were modulated in response to GM3 loss including cell cycle, apoptosis, mitogenic, Akt-mTOR and Wnt signaling. To assess the impact of GM3 synthase deletion on flux through the glycosphingolipid pathway, we measured changes in the levels of GlcCer, LacCer (the immediate precursor to both the gangliosides and globosides), and the globosides Gb3 and Gb4 in mutant mice. Only kidney GM3 and GlcCer were correlated with disease severity, identifying these two lipids as key mediators of cystogenesis. These data suggest that genes involved in glycosphingolipid metabolism may function as modifier loci to determine the severity of polycystic kidney disease, and further, suggest GM3 synthase as a new target for the treatment of PKD.

Curcumin and Analog 2a Inhibit ADPKD Cyst-Cell Proliferation and Cyst Growth *In Vitro* but Not in Cysts Growing in Nude-Mouse Implants
Ram Singh,[1] Moses Lee,[2] Elsa Bello-Reuss.[3] *[1]Pediatrics, Texas Tech University Health Sciences Center, Lubbock, TX; [2]Chemistry, Hope College, Holland, MI; [3]Internal Medicine, Texas Tech University Health Sciences Center, Lubbock, TX.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is characterized by progressive renal cyst development, destruction of the native normal kidney and finally kidney failure requiring dialysis or transplantation. Treatments using targeted inhibition of specific signaling pathways are presently actively pursued. However, since cyst growth is associated with concomitant activation of many proliferative pathways, multiple-pathway inhibition could be advantageous for ADPKD treatment. It is known that curcumin inhibits several cell-proliferation pathways activated both in cancer and in ADPKD cyst cells. However, no therapeutic levels are achieved by oral (PO) administration in rodents and humans due to poor intestinal absorption and liver inactivation.

Methods: We studied the effects of Curcumin and Analog 2a (a compound lacking glucuronidation sites, thus avoiding decreased absorption and liver metabolism) on the proliferation and cyst formation by ADPKD cyst cells in primary cultures and on the active β-catenin levels using normal kidney cells as control; the effects of intraperitoneal (IP) curcumin on cyst development in nude-mouse implants; and the blood and kidney levels of both drugs, after PO administration to mice.

Results: We found that: 1. Curcumin and Analog 2a were more cytotoxic to cyst cells than to normal kidney cells: curcumin IC50 = 19.6 ± 1.4 vs 46.5 ± 4.3 μM; $P < 0.003$ and Analog 2a IC50 = 1.0 ± 0.2 vs 4.4 ± 0.5 μM; $P < 0.001$, respectively. 2. Curcumin and Analog 2a inhibited active β-catenin in cyst cells. 3. Curcumin was undetectable in mouse blood after PO administration. 4. Its IP administration decreased cyst volume in the implants, but not cyst number. 5. Analog 2a was detectable in mouse blood and concentrated in the kidney after PO administration.

Conclusions: We conclude that Analog 2a increased effectiveness, decreased toxicity to normal cells and improved bioavailability supports the use of new curcumin analogs for ADPKD treatment.

Branched-Chain Amino Acid Supplementation Accelerates Cyst Growth in a Mouse Model of Autosomal Dominant Polycystic Kidney Disease
Yasunobu Ishikawa,[1] Saori Nishio,[1] Stefan Somlo,[2] Tasuku Nakagaki,[1] Sekiya Shibazaki,[1] Tatsuya Atsumi.[1] *[1]Department of Medicine II, Hokkaido University Graduate School of Medicine, Sapporo, Hokkaido, Japan; [2]Department of Internal Medicine, Yale University School of Medicine, New Haven, CT.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most commonly inherited renal disease. ADPKD is characterized by progressive development and enlargement of renal and liver cysts, leading to chronic kidney disease (CKD). Dietary protein restriction prevents progression of CKD, because most CKD symptoms, for example uremia, metabolic acidosis and bone disease, are caused by protein intolerance. However, the role of dietary protein restriction in patients with ADPKD is unknown. We investigated the effects of branched-chain amino acids (BCAA), which developed for the purpose of improving hypo-albuminemia in patients with uncompensated liver cirrhosis, We investigated the effects of BCAA in *Pkd1*$^{flox/flox}$: *Mx1-Cre* mice.

Methods: *Pkd1*$^{flox/flox}$*:Mx1-Cre* mice were intraperitoneally injected with 10 μg/g body weight of polyinosinic-polycytidylic acid for 6 consecutive days at 2 weeks of age. The ratio of Aminofeel BCAA is 0.250 g isoleucine/g, leucine 0.500 g/g and 0.250g/g valine. BCAA was dissolved in the drinking water of the mice at a concentration of 20mg BCAA/mL (BCAA treated group) for 18 consecutive weeks (4-22 weeks of age), whereas a control group received vehicle alone. Mice were sacrificed at 22 weeks of age, and measured body, kidneys and liver weight. Kidney and liver sections were stained with hematoxylin and eosin, and determined the cystic index (CI), defined as the percent of total cross-sectional area occupied by cysts.

Results: The two kidney/body weight ratio was signigficantly greater in BCAA treated group than in control group (2.86 ± 0.98 vs. 1.31 ± 0.16%, $p<0.01$). The liver/body weight ratio was no significantly different. CI was greater in BCAA treated group than in control group (kidney; 37.4 ± 15.3 vs. 7.0 ± 4.6%, $p<0.01$, liver; 29.6 ± 8.1 vs. 13.3 ± 10.2%, $p<0.05$).

Conclusions: Branched-chain amino acid supplementation accelerates polycystic kidney disease in *Pkd1*$^{flox/flox}$*:Mx1-Cre* mice.

Induction of Glycosuria via Phlorizin-Mediated SGLT Inhibition Prevents Renal Disease Progression in the Han:SPRD Rat Model of Polycystic Kidney Disease
Suhua Zhang,[1] Xueqi Wang,[2] Yang Liu,[3] Sarika Kapoor,[3] Daniela Spichtig,[3] Andreas L. Serra,[4] Stephan Segerer,[4] Olivier Devuyst,[3,4] Rudolf P. Wuthrich.[4] *[1]Department of Nephrology, Shanghai Renji Hospital, Jiaotong University, Shanghai, China; [2]Department of Nephrology, Shanghai Changzheng Hospital, Shanghai, China; [3]Institute of Physiology, University Zurich-Irchel, Zurich, Switzerland; [4]Division of Nephrology, University Hospital, Zurich, Switzerland.*

Background: The pathogenic role of the apical renal sodium-glucose cotransporters SGLT1 and SGLT2 in polycystic kidney disease (PKD) is not known. We hypothesized that induction of glycosuria and osmotic diuresis with the SGLT1/SGLT2 inhibitor phlorizin inhibits cyst growth and retards loss of renal function in the Han:SPRD rat model of PKD.

Methods: We induced glycosuria in 5-week old heterozygous Cy/+ male Han:SPRD rats (n=8) by s.c. injection for 5 weeks with phlorizin (400 mg/kg/d). Phlorizin induced immediate and sustained glycosuria which was accompanied by a 2.7-fold increase in the diuresis (64 vs. 24 ml/d), and by a 2.7-fold increase in osmolaluria (43 vs. 16 mosm/d).

Results: After 5 weeks the BUN and creatinine were 22% and 38% lower in the phlorizin- compared with the vehicle-treated group, whereas the creatinin clearance was 59% higher. Furthermore the protein/creatinine ratio was reduced from 113 ± 19 to 64 ± 9 mg/day ($P<0.05$). The 2 kidneys/total body weight (2K/TBW) ratio was 18% lower with phlorizin ($P<0.001$). A reduction in the size of megalin-positive cysts was apparent in the cortex upon phlorizin treatment, and the cyst index was 28% lower ($P<0.05$). Western blot analysis of Han:SPRD kidney extracts demonstrated that the activated MAPK pathway was inhibited, whereas the mTOR pathway remained activated. Ki67 staining revealed that phlorizin-treated rats displayed a 35% lower proliferation of epithelial cells in cysts.

Conclusions: The significant beneficial effect of phlorizin-mediated glycosuria and osmotic diuresis on cystic disease progression in the Han:SPRD model of PKD supports the hypothesis that renal SGLT inhibition and induction of glycosuria could have a therapeutic effect in polycystic kidney disease.

Hyperglycemia Accelerates Cystogenesis and Alters Wnt and mTOR Signaling in a Mouse Model of Polycystic Kidney Disease
Kelli Margot Sas, Monika Gooz, P. Darwin Bell. *Medicine, Medical University of South Carolina, Charleston, SC.*

Background: The rate of cyst formation and disease progression in polycystic kidney disease (PKD) is highly variable. The lack of predictability in disease progression may be due to accompanying environmental or pathophysiological processes. Diabetes, a growing epidemic worldwide, results in hypertrophic signaling in the kidney, which has previously been shown to enhance cystogenesis. The goal of this study was to determine if diabetes (hyperglycemia) enhances the rate of cyst formation and to identify the signaling pathways involved in this process.

Methods: Adult *ift88* conditional floxed allele mice were administered tamoxifen to induce cilia loss in the presence of cre. Subsequent administration of streptozotocin at 50 mg/kg for 5 days was used to induce hyperglycemia (blood glucose ≥ 200 mg/dL). Streptozotocin administration resulted in equivalent hyperglycemia in both cilia (+) and cilia (-) mice, although cilia (-) mice trended to have elevated blood glucose compared to cilia (+) mice. Histology, Western blot, and gene array analysis were used to assess cystic development and differences in signaling pathways.

Results: Hyperglycemia with loss of cilia increased the rate of cyst formation and cell proliferation, and resulted in interstitial inflammation, formation of primitive renal tubules, focal foot process effacement, polyuria, and increased proteinuria. Hyperglycemic cilia (-) mice had increased mTOR and Wnt signaling, including increased β-catenin staining specifically in cysts and primitive renal tubules. Additionally, hyperglycemic cilia (-) mice had increased markers of epithelial-mesenchymal transformation.

Conclusions: These data suggest that hyperglycemia in the absence of cilia accelerates cyst formation and expansion, through increased cell proliferation and loss of polarity, suggesting that diabetes is a risk factor in the progression of polycystic kidney disease.

Short-Term Renal Hemodynamic Responses and Safety of Tolvaptan in Subjects with ADPKD at Various Levels of Kidney Function
Wendy E. Boertien,[1] Esther Meijer,[1] Paul E. de Jong,[1] Frank S. Czerwiec,[2] Dorothee Oberdhan,[2] Holly B. Krasa,[2] Ron T. Gansevoort.[1] *[1]Nephrology, UMC, Groningen, Netherlands; [2]Otsuka Pharmaceutical Development & Commercialization Inc., Rockville.*

Background: Vasopressin V2-receptor antagonists may delay disease progression in autosomal dominant polycystic kidney disease (ADPKD). Human trials with these agents have been performed predominantly in patients with normal kidney function (eGFR >60 mL/min/1.73m^2). In this trial, we investigated renal hemodynamic responses and safety of initiating tolvaptan in patients at various levels of kidney function.

Methods: ADPKD patients were included in 3 groups based on eGFR (A: >60, B: 30-60 and C: <30 mL/min/1.73m^2) for a 3 week treatment period with tolvaptan (titrated up to 120 mg/day). Glomerular filtration rate (GFR, by ^{125}I-iothalamate clearance), effective renal plasma flow (ERPF, by ^{131}I-hippuran clearance), and safety variables were measured before, after 3 weeks of treatment, and 3 weeks after the last dose of tolvaptan.

Results: 29 subjects entered the study, with 27 completing, 9 patients in each study group. With tolvaptan, a reversible decrease in GFR was observed, which reached statistical significance in Groups A and B: median -8.2 (interquartile range -14.1 to -1.8) and -4.0 (-12.2 to -1.0) mL/min, resp. The percentage change in GFR, ERPF and filtration fraction with tolvaptan did not differ between the 3 study groups. No differences between groups were observed, besides increases in urine volume, free water clearance, ALP, ALT and GGT during tolvaptan treatment, which were significantly smaller in Group C. Tolvaptan was well tolerated, with only 2 subjects withdrawing study treatment (1 in Group A (polyuria) and B (dry mouth), resp.). The most frequently observed adverse events (AEs) were thirst, dry mouth, polyuria and nocturia. No differences in AE incidence rate between the 3 study groups were noted. All observed changes were reversed upon withdrawal of treatment.

Conclusions: Doses of tolvaptan typically used in ADPKD patients (60-120 mg/day) are not associated with a different safety profile (adverse event incidence or renal hemodynamic responses) in ADPKD patients with impaired kidney function.

Telmisartan Ameliorates Fibrocystic Liver Disease in an Orthologous Rat Model of Human ARPKD
Daisuke Yoshihara,[1] Masanori Kugita,[1] Shigeo Horie,[2] Harold M. Aukema,[3] Tamio Yamaguchi,[3] Shizuko Nagao.[1] *[1]Education and Research Center of Animal Models for Human Diseases, Fujita Health University, Toyoake, Aichi, Japan; [2]Department of Urology, Teikyo University School of Medicine, Itabashi, Tokyo, Japan; [3]Department of Human Nutritional Sciences, University of Manitoba, Winnipeg, MB, Canada.*

Background: We previously reported that a peroxisome proliferator-activated receptor (PPAR)-γ agonist ameliorated kidney and liver disease in PCK rats with autosomal recessive polycystic kidney disease (ARPKD). Telmisartan is an angiotensin receptor blocker (ARB) which is a partial PPAR-γ agonist. In the current study, we determined whether Telmisartan ameliorates polycystic kidney and fibrocystic liver disease progression in the PCK rat, an orthologous model of human ARPKD.

Methods: Male and female PCK and normal control (+/+) rats (n=10 per gender) were randomly assigned to one of two groups: treatment with 3 mg/kg Telmisartan or vehicle (0.3% DMSO) by gavage every day from 4 to 20 weeks of age. Blood pressure (BP), blood levels of urea nitrogen (BUN) and aspartate amino transferase (AST) were measured. Cystic area and fibrotic index were obtained from hematoxylin-eosin and sirius red stained kidney and liver sections. Ki67- and TGF-β-positive cells were detected by immunohistochemistry.

Results: Treatment of Telmisartan decreased BP in both PCK and +/+ rats. Liver weight (% of body weight, LB%), liver cystic area, hepatic fibrosis index, and the number of Ki67- and TGF-β-positive cells in interstitial tissue of the liver were significantly decreased in Telmisartan treated PCK rats. AST and BUN levels were in the normal range in both genders and were unaffected by Telmisartan treatment. No effect on kidney disease progression was observed.

Conclusions: Telmisartan ameliorates fibrocystic liver disease possibly through the inhibition of cell proliferation and TGF-β signaling in PCK rats, an orthologous model of human ARPKD. The current results support the potential use of ARB with partial PPAR-γ agonistic action as therapeutic agents for the treatment of fibrocystic liver disease in ARPKD patients.

Aliskiren Ameliorates Cyst Progression in an Orthologous Mouse Model of Autosomal Dominant Polycystic Kidney Tasuku Nakagaki,[1] Saori Nishio,[1] Sekiya Shibazaki,[1] Yasunobu Ishikawa,[1] Stefan Somlo,[2] Tatsuya Atsumi.[1] *[1]Internal MedicineII, Hokkaido University Graduate School of Medicine; [2]Department of Internal Medicine, Yale University School of Medicine, New Haven.*

Background: Hypertension is a well-recognized complication of autosomal dominant polycystic kidney disease (ADPKD). Hypertension relates to progressive kidney enlargement and is significant independent risk factor for progression to ESRD. It has been reported that renin-angiotensin system (RAS) inhibitors had a more favorable renoprotective effect than calcium channel blockers. However, the mechanisms leading to hypertension in ADPKD are not well understood. Involvement of the RAS has been postulated, but no consistent relationship has been found between blood pressure and plasma renin activity or plasma aldosterone concentrations.The purpose of this study is to examine the effects of antihypertensive drugs for *pkd1* conditional knockout mice.

Methods: We generated *Pkd1* conditional knockout mice carrying the Cre transgene under the control of the *Mx1* promoter (*Pkd1 $^{flox/flox}$;Mx1-Cre* mice). All mice were injected with polyinosinic-polycytidylic acid (pI:pC) to induce the expression of Cre recombinase and to inactivate *Pkd1* at 2 weeks of age. To evaluate the effects of antihypertensive drugs, *Pkd1$^{flox/flox}$;Mx1-Cre* mice were treated by osmotic mini-pumps with amlodipine or olmesartanor aliskiren, or vehicle for 12 weeks. Blood pressure, kidney weight to body weight ratio,cystic index, BUN, albuminuria, and proliferation rate as determined by PCNA were usedto assess efficacy of treatment. Fibrosis progression was examined by immunostaining for α-smooth muscle actin (α-SMA) and Elastica-Masson.

Results: There was no difference in kidney weight to bodyweight ratio, renal cystic index, urinary albumin excretion, and BUN between amlodipine, olmesartan and vehicle. Aliskiren treatment significantly reduced the kidney weight to bodyweight ratio, renal cystic index, urinary albumin excretion, and BUN.

Conclusions: These studies suggest RAS inhibition with aliskiren may be effective in slowing cyst growth in ADPKD.

TH-PO635

Cardiorenal Effects of Paricalcitol and ACE Inhibition in Rats with Polycystic Kidney Disease Kristina Gjerdrum Schwensen, David C. Harris, Gopala K. Rangan. *Centre for Transplant and Renal Research, Westmead Millennium Institute, University of Sydney at Westmead Hospital, Sydney, NSW, Australia.*

Background: Vitamin D receptor agonists (VDRAs) reduce tubular epithelial cell proliferation and interstitial inflammation/fibrosis, and attenuate proteinuria and hypertension in experimental and human chronic kidney disease. In this study, we tested hypothesis that VDRAs prevent cyst growth in the early stage of polycystic kidney disease (PKD), and have synergistic cardiorenal protective effects with angiotensin converting enzyme (ACE) inhibitors in established disease.

Methods: In **Study 1**, the preventative effects of VDRAs on cyst growth were assessed, and Lewis polycystic kidney disease (**LPK**) rats (a hypertensive rat model of cystic renal disease) received either paricalcitol (**P**, 0.2μg/kg/d by daily i.p.i) or vehicle (**V**) from postnatal weeks 3 to 10 (n=6). In **Study 2**, the therapeutic effects of VDRAs were assessed and LPK rats received either P (800 ng/kg by i.p.i. 3x/week), V (i.p.i 3x/week), enalapril (**E**, 50 mg/L in drinking water) or a combination of E+PC from postnatal weeks 10 to 20 (n=4-5).

Results: In **Study 1**, P did not affect the progression of serum calcium, proteinuria or renal dysfunction in LPK rats (data not shown). The increase in kidney enlargement in LPK rats was also unaffected by P (kidney to body weight ratio: Lewis±V: 0.8+0.0; Lewis±P: 0.8+0.0; LPK±V: 5.9±0.2;LPK+P: 5.7+0.5%; mean±SE). In **Study 2**, E, P and E+PC reduced proteinuria and improved endogenous creatinine clearance at week 20 (Table 1). E+PC attenuated hypertension and both E and E+PC reduced cardiac enlargement. However, neither E, PC or E+PC altered the progression of kidney enlargement (Table 1).

Table 1

Parameter	LPK+V	LPK+P	LPK+E	LPK+P/E
Proteinuria (mg/mmol)	1276±124	687±315*	345±68*	374±55*
CrCl (μl/min/g BW)	0.91±0.11	1.45±0.13*	1.58±0.07*	1.28±0.11*
Systolic BP (mm Hg)	129±8	130±8	119±10	93±4*#
Kidney weight:BW%	7.2±0.4	6.9±0.3	7.2±0.4	7.1±0.4
Heart weight:BW%	0.44±0.02	0.42±0.03	0.39±0.01*	0.39±0.03*

*P<0.05 vs LPK+V; #P<0.05 vs LPK+P

Conclusions: Although paricalcitol does not attenuate cyst growth, it reduces proteinuria, improves renal function and potentiates the anti-hypertensive effects of ACE inhibitors in established PKD.

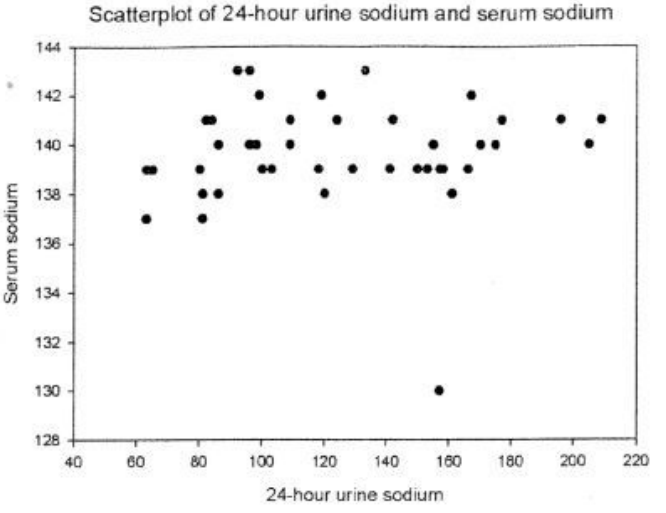
Apparent Safety of Low Salt Diet to Suppress Arginine Vasopressin (AVP) in Patients with Polycystic Kidney Disease (PKD) Nabil J. Haddad, Rose Marie Shim, Lee A. Hebert. *Division of Nephrology, The Ohio State University, Columbus, OH.*

Background: Mechanisms that contribute to cyst growth in PKD include generation of adenosine 3.5 cyclic monophosphate induced by increased AVP secretion. Increased water intake is recommended to suppress (AVP) release (ref). Another strategy to suppress AVP is to limit solute intake, especially NaCl (Kidney Int 81:407-411, 2012). The goal is to reduce average 24-h Uosm to 250 Uosm/kg. This can be achieved at 24-h urine volume of ~ 2 L/day by limiting solute intake, especially NaCl. However, it has been suggested that low salt intake along with a fluid intake adequate to achieve a urine output of 2 L/day could result in hyponatremia in PKD patients. We tested this hypothesis.



Methods: Seven PKD patients who were instructed in low salt diet were studied. Each provided at least one 24-h urine collection with sodium content ≤ 100 mmol. Completeness of the collection was assessed by the creatinine content.

Results: Patients (pts) mean age was 50.3 ± 18, weight 66.3 ± 14kg, sex M:F1:6, sCr 1.19 ± 10mg/dl, systolic blood pressure119 ± 10, 2 pts had HTN, 4 pts were receiving ACEI and/or ARB, 1 received a diuretic. There were 51 samples of paired 24-h urine collections and serum Na levels. There was no relationship between 24-h urine Na and serum Na.[figure]The range of urine Na was 60-210 mmol/day, median 135 mmol/day. The range of 24-h urine volume was 550-3500 cc, median 1490 cc/day. Only 1 instance of hyponatremia was identified. In that case, the 24-h urine Na was 159 mmol/day and urine volume was > 2 L, and pt was receiving a diuretic.

Conclusions: We found no relationship between salt intake and serum Na in PKD pts, who usually followed a low salt diet. This suggests that reducing salt (and other solute) intake to suppress AVP release should not lead to hyponatremia in PKD patients.

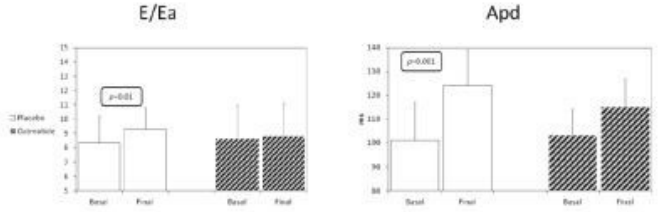
TH-PO637

Favorable Effects of Somatostatin Analogue on Left Ventricular LV Diastolic Function in Autosomal Dominant Polycystic Kidney Disease (ADPKD): A Prospective Randomized Echocardiographic Study Bianca Visciano,[1] Antonio Pisani,[1] Piero Ruggenenti,[2] Norberto Perico,[2] Giuseppe Remuzzi,[2] Giusi Rosaria Mozzillo,[1] Massimo Sabbatini,[1] Emiliano Assante di Panzillo,[1] Letizia Spinelli.[1] *[1]University of Neaples Federico II, Neaples, Italy; [2]Mario Negri Institute, Bergamo, Italy.*

Background: ADPKD is associated with early onset LV hypertrophy.Since LV hypertrophy is associated with LV diastolic function impairment,we aimed to assess the changes of LV diastolic function in ADPKD patients and whether they were affected by treatment with the somatostatin analogue,octreotide.

Methods: 35 ADPKD patients(14males)aged 34±8 years(GFR 82±26 mL/min/1.73m^2) were randomly assigned to 36 months treatment with placebo(18)or octreotide(17).An echocardiography was performed at baseline and study end.LV mass(M)and ejection fraction(EF)were calculated according to Devereux formula and biplane Simpson's algorithm,respectively.LV filling was assessed by mitral and pulmonary vein flow velocity curves and mitral annulus early diastolic velocity peak(Ea)by tissue Doppler imaging.

Results: At baseline and follow up blood pressure,heart rate,LVM,EF and the proportion of patients on ACEi or ARBS treatment were similar between groups.The ratio between mitral early diastolic flow velocity peak(E)and Ea and the duration of pulmonary vein reverse flow at atrial contraction(Apd)were also similar at baseline.They significantly increased on placebo (E/Ea,8.3±1.9and 9.3±1.5,p<0.01;Apd,101±16and 124±15,p<0.001,basal and final,respectively)and did not change appreciably(E/Ea,8.6±2.4and 8.8±2.3,ns;Apd,103±11 and 115±12,ns,basal and final,respectively)on octreotide.



Conclusions: In ADPKD patients there is a progressive worsening of LV diastolic function that appears to be prevented or limited by somatostatin therapy.Whether this functional effect may be cardioprotective in the long term is worth investigating.

TH-PO638

Young Women with Polycystic Liver Disease Benefit the Most from Treatment with Somatostatin Analogues: A Meta-Analysis on Individual Patient Data Tom J.G. Gevers,[1] Joanna Inthout,[2] Anna Caroli,[3] Piero Ruggenenti,[4] Marie C. Hogan,[5] Vicente E. Torres,[5] Frederik Nevens,[6] Joost P.H. Drenth.[1] *[1]Gastroenterology and Hepatology, Radboud University Nijmegen Medical Center; [2]Epidemiology, Biostatistics and HTA, Radboud University Nijmegen Medical Center; [3]Biomedical Engineering, Mario Negri Institute for Pharmacological Research; [4]Kidney Disease, Mario Negri Institute for Pharmacological Research; [5]Division of Nephrology and Hypertension, Internal Medicine, Mayo Clinic; [6]Hepatology, UZ Leuven.*

Background: Somatostatin analogues (SA) reduce polycystic liver volumes by 4.5-5.9% in patients with autosomal dominant polycystic liver or kidney disease (PCLD/ADPKD). However, it is unknown if certain patient subgroups have better treatment responses. The aim of this study is to estimate the impact of age, gender, baseline liver volume and diagnosis on treatment response to SA in patients with polycystic liver disease (PLD).

Methods: We performed a meta-regression analysis to estimate the impact of age, gender, baseline liver volume, and diagnosis on the effect of SA on liver volumes in 108 PLD patients (3 randomized controlled trials), including 12 patients of a cross-over trial that were measured twice (SA=67, placebo=53).

Results: SA therapy decreased polycystic liver volume with 5.3% (95% CI: 3.4–7.2%) when compared to placebo ($p<0.001$) using linear modeling, and this effect was not significantly affected by diagnosis, age, baseline liver volume or gender. Untreated young women (≤47y) showed the largest growth in polycystic liver volume (5.3%, 95% CI: 2.7–8.1%), whereas livers did not grow in older women and men. We performed an additional analysis including subgroups for gender combined with age, using the median of 47 years as a cut-off value. Women ≤47 and >47 years treated with SA experienced reductions in liver volume of 8.5% ($p<0.001$) and 4.0% ($p=0.017$) respectively when compared to placebo using linear modeling, with significantly better responses in the ≤47 years group ($p=0.044$).

Conclusions: Young female PLD patients appear to have the most substantial benefit from SA therapy, possibly by averting the progressive course of the disease observed in this specific group.

TH-PO639

Excessive Activation of the Complement System in the Progression of ADPKD Changlin Mei,[1] Zhen Su,[1] Xueqi Wang,[1,2] Jing Zhou,[3] Andreas L. Serra,[2] Rudolf P. Wuthrich.[2] *[1]Kidney Institute of PLA, Department of Nephrology, Shanghai Changzheng Hospital, SMMU, Shanghai, China; [2]Division of Nephrology, University Hospital, Zurich, Switzerland; [3]Harvard Institutes of Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, MA.*

Background: Mutations in the *PKD1* and *PKD2* genes are the primary cause of ADPKD, however, the additional molecular pathogenic mechanisms remain poorly understood. Here we analyzed the importance of the complement system in ADPKD disease progression.

Methods: We analyzed the glycoproteome of urine samples obtained from ADPKD by MS for components of the complement system. We also tested the effect of the complement inhibitor romaric acid in animal models of PKD. RMA (150 mg/kg/d and 300mg/kg/d) was administered by gavage from P29-P112 in Han:SPRD rats, and from P14-P49 in *Pkd1*$^{-/-}$ mice.

Results: Analysis of the glycoproteome of urine samples from ADPKD patients revealed that disease progression is associated with excessive activation of the complement system, which was characterized by significantly increased urine concentrations of complement factor B (CFB), SERPING1 and C9. In contrast, the levels of C1RL, CD55 and CD59 were markedly decreased. Enhanced expression of CFB and C9 was confirmed by IHC staining and Western blot in diseased kidneys from ADPKD patients, Han:SPRD Cy/+ rats and *Pkd1*$^{-/-}$ mice. Treatment with RMA which inhibits the complement system by covalently binding with activated C3b significantly delayed the deterioration of renal function in Han:SPRD rats and *Pkd1*$^{-/-}$ mice.

Kidney functional parameters in Han:SPRD rats after RMA treatment for 12 weeks

	Cy/+ (n=10)	Cy/+R150 (n=10)	Cy/+R300 (n=10)	+/+ (n=8)	+/+ R300 (n=8)
BUN(mmol/L)	24.4±5.32	19.6±4.63**	19.53±3.44**	6.06±0.87	6.8±0.84
SCr(umol/L)	92.4±5.58	74.5±9.89**	76.5±3.66**	26.7±4.61	23.0±3.15
Urine osmolarity (mosm/H2O)	694.5±127	1022.4±177*	1102.1±152*	1670.1±142	2213.3±174

TH-PO640

MicroRNA as Biomarkers in Autosomal Dominant Polycystic Kidney Disease Iddo Z. Ben-Dov,[1] Ying-cai Tan,[2] Pavel Morozov,[1] Hanna Rennert,[2] Jon D. Blumenfeld.[2] *[1]Rockefeller University, New York, NY; [2]Rogosin Institute, New York, NY.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) has unpredictable progression and complications. Biomarkers are needed to inform prognosis and guide treatment. MicroRNAs (miRNA) are present in biofluids and can be profiled efficiently. We profiled miRNAs in ADPKD to gain insight on molecular abnormalities and evaluate potential use as biomarkers.

Methods: MiRNA profiles were obtained by RNA sequencing of primary cultures of renal epithelium from cysts (N=10), normal (N=8) or fetal (N=7) kidneys, and from urine and plasma of ADPKD patients (N=20) and matched controls (N=20) with other chronic kidney diseases (CKD). The study was approved by Weill Cornell Medical College and Rockefeller University Institutional Review Boards.

Results: MiRNA profiles distinguished between cells cultured from healthy adult and ADPKD kidneys (panel A), with members of mir-98 (let-7s), mir-103, let-7i and mir-143 upregulated and mir-1 and mir-29a downregulated in ADPKD (panel B). With exception of the let-7s, expression of the noted miRNA in fetal cells resembled ADPKD rather than healthy cells. Compared to non-ADPKD patients, mir-143(2) was upregulated in ADPKD urine, while mir-1(4) and related mir-133b(2) were downregulated. Additional findings included increases in mir-223(1), mir-199a(3) and mir-199b(1) cluster members. miR-1(2), miR-133a(2) and miR-499 were decreased in ADPKD urine ultrafiltrate samples compared to other CKD. Several plasma miRNAs were linked with *stage* of CKD, but only negligible differences were noted between ADPKD and other CKD at similar stage.

Conclusions: MiRNA in ADPKD patients' urine correspond to patterns occurring in cyst-derived cells. Alterations in miRNA composition in ADPKD also imply mononuclear cell infiltration and fibrosis-related changes. We suggest a role for miRNA in pathogenesis and denote biomarker potential.

Systematic Analysis of microRNAs in Urine Exosome-Like Vesicles and Correlation with Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Christopher Y. Chen, Christopher James Ward, Katharina Hopp, Peter C. Harris, Marie C. Hogan. *Division of Nephrology & Hypertension, Mayo Clinic, Rochester, MN.*

Background: MicroRNAs (miRs) are non-coding RNAs that canonically bind to the 3' UTR of target mRNAs and inhibit their translation. Urine exosome-like vesicles (ELVs) shed from epithelial cells of the nephron may be involved in ADPKD pathogenesis and are enriched for miRs. The miR content of urine ELVs is currently unknown. To characterize ELV miR content, explore the role of miRs in cystogenesis, and identify new biomarkers for ADPKD progression, miR expression was analyzed in human and mouse urine ELVs.

Methods: We isolated urine ELV miRs from PKD1 patients, *Pkd1* hypomorphic mice, and age/gender matched controls. ELV miR expression was analyzed by Illumina MiSeq and RT-PCR then compared to miR data from normal human kidneys (NHK). Novel miRs were predicted by *miRDeep2*. Functions of mis-regulated miRs were determined by *mirPath*.

Results: Next-Gen sequencing of normal urine ELVs defined a specific subset of 478 miRs (134 miRs with >10 reads/million). Furthermore, 13 putative novel miRs were identified, including two related miRs on chrs 15 and 10 with 586 and 30 reads/million, respectively. Relative to NHK, urine ELVs were most enriched for miRs -200a*, -423-3p, 22*, -200b*, -28-3p, -101*, 23b*, 7a*, and 29* that are involved in regulating TGF-β, Wnt, focal adhesions, MAPK, mTOR, and ErbB pathways. Star (*) sequences, which comprised 3% of miRNA pairs in NHKs, were enriched to 24% in urine ELVs, suggesting a role for ELVs in transporting these generally rare miRs. Preliminary results comparing PKD and normal urine ELVs show the greatest depletion of miRs -451, -23a, -24, -29b, -199a-3p, -23b, -497, -365, and -29c, which are predicted to regulate the TGF-β, Wnt, and focal adhesion pathways, previously implicated in ADPKD pathogenesis.

Conclusions: We have established the first miR-nome for normal human urine ELVs and made a comparison with ADPKD ELVs. Our results show urine ELVs are enriched for miRs regulating several renal developmental pathways. Reduction of Wnt, TGF-β, and focal adhesion regulating miRs in *Pkd1* mutant ELVs suggests a novel mechanism for modulating cystogenesis.

Urine Sodium Excretion and Plasma proANP as Markers of Disease Progression in ADPKD

Maria V. Irazabal,[1] Wendy E. Boertien,[2] Doug Landsittel,[3] Jie Li,[3] Joachim Struck,[4] Michael F. Flessner,[5] Ron T. Gansevoort,[2] Vicente E. Torres.[1,6] *[1]Mayo Clinic, Rochester, MN; [2]U of Groningen; [3]U of Pittsburgh; [4]ThermoFisher Scientific; [5]NIDDK; [6]Consortium for Radiologic Imaging Studies of PKD (CRISP).*

Background: CRISP has shown that higher urinary sodium excretion (UNaE), lower serum HDL-cholesterol, and younger age at baseline associate with more rapid renal enlargement (CJASN 6:640 2011). High UNaE and plasma proANP have been associated with non-diabetic CKD progression (KI 75:408 2009; JASN 23:165 2012).

Methods: Associations of baseline UNaE plasma proANP (sandwich immunoluminometric assay) and their interaction with rates of renal enlargement (MRI) and GFR decline (iothalamate clearance) using mixed (with and without interactions with time) and regression models for specific time points adjusting for gender, age, height, MAP, plasma glucose, HDL cholesterol, smoking, and baseline GFR or TKV.

Results: Baseline lnTKV and UNaE, but not plasma proANP, predict lnTKV across all time points and show a significant interaction with time. Plasma proANP, but not UNaE, predict GFR in all longitudinal models; the significance level increases over time and shows a significant interaction with time.

lnTKV	**Baseline**	**Year 3**	**Year 6**	**Repeated**	**Interactions**
Variable	β | p-value	β | p-value	β | p-value	β | p-value	p-value
Time	--- | ---	--- | ---	--- | ---	0.045 | <0.001	---
lnTKV0	--- | ---	1.067 | <0.001	1.087 | <0.001	1.042 | <0.001	<0.001
lnANP	.185 | 0.04	-0.006 | 0.76	0.060 | 0.10	0.011 | 0.39	0.01
UNaE	0.060 | 0.21	0.024 | 0.03	0.043 | 0.03	0.019 | 0.01	<0.001
Age0	0.015 | <0.01	-0.001 | 0.20	-0.007 | 0.001	-0.001 | 0.05	<0.001
HDL	-0.005 | 0.18	-0.002 | 0.07	-0.005 | 0.001	-0.001 | <0.01	<0.001
GFR	**Baseline**	**Visit 30**	**Visit 60**	**Repeated**	**Interactions**
Variable	B | p-value	B | p-value	B | p-value	B | p-value	p-value
Time	--- | ---	--- | ---	--- | ---	-2.42 | <0.001	---
GFR0	--- | ---	0.63 | <0.001	0.60 | <0.001	.071 | <0.001	0.001
lnANP	-6.82 | 0.09	-10.34 | 0.01	-19.24 | 0.001	-9.41 | <0.001	<0.001
UNaE	-1.44| 0.50	3.48 | 0.08	-0.94 | 0.75	0.97 | 0.43	0.74
Age0	-0.97 | <0.001	-0.28 | 0.19	-0.74 | 0.03	-0.36 | 0.01	0.01

Conclusions: UNaE is an independent predictor of lnTKV increase whereas ANP is an independent predictor of GFR decline. Longer follow-up may be needed to detect an association of UNaE with GFR decline.

Urinary Extracellular Vesicles from Healthy and ADPKD Urine Prepared by Three Different Methods Display Consistent Lectin Microarray Profiles

Jared Q. Gerlach,[1] Anja Krüger,[1,2] Marie C. Hogan,[3] Christopher James Ward,[3] Lokesh Joshi,[1] Matthew D. Griffin.[2] *[1]Glycosciences Group, NCBES, National University of Ireland, Galway, Ireland; [2]Regenerative Medicine Institute, National University of Ireland, Galway, Ireland; [3]Dept Medicine, Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Background: Glycosylation of urinary extracellular vesicles (uEVs, "exosomes") may reflect aetiology/severity of kidney diseases but uEV isolation remains problematic. In this study, intact uEVs, isolated from healthy urine by 3 methods, were profiled for glycosylation using lectin microarrays and were compared with uEVs from ADPKD subjects.

Methods: uEVs were isolated from 3 healthy subjects by ultracentrifugation (UC) and centrifugal filter concentration then from an age-matched set of 7 ADPKD and 7 healthy controls by gradient UC and were fluorescently labeled (CM-DiI or PKH26). 43 lectins with affinity to a broad range of carbohydrate epitopes were printed on Nexterion hydrogel slides. After incubation with uEVs, arrays were washed and laser-scanned at 5 µm resolution. Numerical intensity values were extracted, normalized, and intensity profiles established. Arrays of purified AF647-labeled Tamm-Horsfall protein (THP) were similarly performed.

Results: Unsupervised clustering of normalized lectin intensity data showed that, while minor differences were detectable between the 3 uEV isolation methods, the degree of profile similarity was very high. uEVs demonstrated binding to lectins specific for a variety of carbohydrate epitopes indicative of both N- and O-linked glycans and these contrasted to the glycoprofiles of THP from multiple donors which displayed fewer and less diverse lectin interactions. Responses for healthy and ADPKD uEVs differed significantly at lectins AIA (Galβ-/T-antigen), RCA-I (Galβ-/LacNAc), and AAL (Fucα1-3/α1-6) although both sets of uEVs displayed similar overall profiles.

Conclusions: Filtration and simplified UC produced uEV lectin array glycoprofiles comparable to the gold standard of gradient UC. All uEV profiles were readily distinguishable from THP. uEV from ADPKD subjects have subtle changes in glycosylation compared to healthy subjects.

Identification of Novel Biomarkers for Vascular Complications Associated with Autosomal Dominant Polycystic Kidney Disease Using Patient-Specific iPSCs Kenji Osafune,[1] Daisuke Taura,[2] Fumihiko Shiota,[1] Masakatsu Sone,[2] Tomonaga Ameku,[1] Toshikazu Araoka,[1] Satoshi Matsui,[1] Isao Asaka,[1] Eri Muso,[4] Akio Koizumi,[3] Kazuwa Nakao,[2] Shinya Yamanaka.[1] *[1]Center for iPS Cell Research and Application (CiRA), Kyoto University, Kyoto, Japan; [2]Department of Medicine and Clinical Science, Kyoto University, Kyoto, Japan; [3]Department of Environmental and Health Sciences, Kyoto University, Kyoto, Japan; [4]Division of Nephrology and Dialysis, Kitano Hospital, Osaka, Japan.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most prevalent, potentially lethal, monogenic disorder, characterized by the development of multiple renal cysts and various extrarenal manifestations. Cardiovascular complications are the main cause of death in ADPKD patients and intracranial aneurysms, causing subarachnoid hemorrhage, are among the most serious. The pathogenesis of vascular lesions as well as cyst formation remains largely unknown.

Methods: We derived induced pluripotent stem cells (iPSCs) from skin fibroblasts from seven ADPKD patients, among whom four had intracranial aneurysms, and differentiated them into vascular endothelia and smooth muscle cells to model the vasculopathy in ADPKD.

Results: Vascular cells differentiated from ADPKD-iPSCs recapitulated the defective intracellular Ca^{2+} regulation, similar findings to those reported in vascular cells of mouse ADPKD models. By microarray analyses, we have identified several molecules whose expression levels are specifically altered in the iPSC-derived vascular cells from ADPKD patients and in those from ADPKD patients with aneurysms. Among the molecules, both mRNA and protein expression of an enzyme and its secretion into culture media show statistically significant elevations in the iPSC-derived endothelia from ADPKD patients with aneurysms as compared to the patients without.

Conclusions: Vascular cells differentiated from patient-specific iPSCs can be used for studying the mechanisms of vascular complications in ADPKD and for identifying novel molecular diagnostic and therapeutic targets in ADPKD.

Urine and Plasma Biomarkers Evaluation in a Cross-Sectional Cohort of Autosomal Dominant Polycystic Kidney Disease (ADPKD) Patients Carolina Haefliger,[1] Ivan Formentini,[1] Bengt C. Fellstrom,[2] Paolo Piraino,[5] Jan Melin,[2] Peter F. Barany,[3] Anders Fernstrom,[4] Markus Ramsauer,[1] Lucy Rowell,[1] Guillemette Duchateau-Nguyen,[1] Maria Bobadilla,[1] Jacques Mizrahi.[1] *[1]Roche, Switzerland; [2]Nephrology, Uppsala, Sweden; [3]CLINTEC, Karolinska, Sweden; [4]Nephrology, Linkoping, Sweden; [5]StatsConsulting.*

Background: Although the diagnosis of ADPKD is well established, no markers for predicting disease progression are available. Biomarkers for disease monitoring and for the identification of patients with higher risk of progression to end stage renal disease (ESRD) are key to support the development of new therapeutic interventions.

Methods: Fourteen candidate biomarkers were assessed in urine and plasma samples collected from a cross-sectional cohort of ADPKD patients (n=56) and controls (n=20). Renal function was characterized by estimated glomerular filtration rate (eGFR), creatinine clearance in 24 h urine, urine albumin, urine albumin to creatinine ratio (UACR), plasma BUN and cystatin C. All subjects were classified in chronic kidney disease (CKD) stages. Biomarkers were measured by multiplexed protein immunoassays.

Results: Controls and ADPKD patients had similar distribution of gender and ethnicity, whereas mean age was higher in the ADPKD group. Controls eGFR ranged between 114 and 70.1 mL/min/l whereas ADPKD patients ranged from 114.5 to 12.4 mL/min/l being CKD stages 2 and 3 the most prevalent ones. Candidate biomarkers in plasma such as alpha 1 microglobulin, NGAL, TIMP1, TFF3, VEGF and osteopontin increased with CKD stages. Most of the biomarkers had a similar, though less pronounced, increase in urine according to the degree of renal impairment whereas osteopontin urine levels decreased with CKD stages. Multivariate analysis will be performed to assess covariates.

Conclusions: Urine and plasma candidate biomarkers showed correlation with CKD stages in this ADPKD population. They have the potential to be used for monitoring of disease progression and therapeutic intervention in ADPKD patients. Further, longitudinal studies are required to confirm the applicability of the findings.

Expression of Biomarkers during Different Phases of Polycystic Kidney Disease in the *Pkd1*^{nl,nl} Mouse Model Danielle Leuning,[1] Hester Happe,[1] Wouter N. Leonhard,[1] Martijn H. Breuning,[1] Emile De Heer,[2] Dorien J.M. Peters.[1] *[1]Human Genetics, Leiden University Medical Centre, Leiden, Netherlands; [2]Pathology, Leiden University Medical Centre, Leiden, Netherlands.*

Background: We previously described the histopathology of the hypomorphic *B6Ola-Pkd1*^{nl,nl} mouse model for Polycystic Kidney Disease (PKD) with reduced expression of the normal *Pkd1* transcript (Happé *et al*, 2009: F-PO1658). These mice develop large cystic kidneys within 4 weeks. Interestingly, cyst expansion is followed by renal volume regression due to collapse of cysts accompanied by focal formation of fibrotic areas.

In this study, we analyzed renal function and the expression of genes encoding potential biomarkers at different stages of renal cystic disease in *B6Ola-Pkd1*^{nl,nl} mice. i.e. Neutrophil gelatinase-associated lipocalin (NGAL), Sulfated glycoprotein-2 (Clusterin), Prostaglandin D2 synthase, all tubular injury markers, and complement component 3 (*C3*), important in innate immunity.

Methods: Blood urea concentrations were determined using Reflotron Plus (Roche Diagnostics). RT-MLPA was used to analyze the expression of biomarker encoding genes in *Pkd1*^{nl,nl} and *Pkd1*^{wt,wt} mice at different ages (5,8,15,24,50 weeks old) and in inducible ksp-*Pkd1*^{del} mice (+1,2,3,4 months).

Results: After a dramatic drop within the first 4 weeks, renal function did not decline further and remained stable over time.

The genes encoding NGAL (*Lcn2)*, Clusterin (*Sgp2)* and Prostaglandin D2 synthase (*Ptgds)*, all showed increased mRNA expression levels in *B6Ola Pkd1*^{nl,nl}mice compared to wild-type animals, at all ages. The dynamics of expression of *Lcn2* and *Sgp2* was remarkably similar to that of renal volume, showing an initial peak at 4 weeks and a strong reduction afterwards. This correlation was less pronounced for *Ptgds* and in contrast with the pattern seen for C3, which continued to increase during disease progression.

Conclusions: In this hypomorphic mouse model, markers related to tubular injury are more indicative for the cyst expansion phase rather than for later fibrotic stages of renal cystic disease.

Wolffian Duct Involvement in Initial Cyst Formation of ADPKD: The Pkd1;Hoxb7-Cre Mouse James B. Tee. *Pediatrics, University of Calgary, Calgary, AB, Canada.*

Background: Autosomal dominant polycystic kidney disease type 1 (ADPKD) is a leading cause of kidney failure and is associated with a germ-line mutation of one of the two Pkd1 alleles. Evidence from the analysis of cystic epithelia in ADPKD indicate that for the disease to occur, a second event that disrupts the expression of the other inherited Pkd1 allele must occur. Cysts in ADPKD can be detected in embryos, but their earliest point of initiation remains unknown.

Methods: To evaluate this, Pkd1(+/flox);HoxB7-Cre and Pkd1(flox/flox) mice were mated to generate a novel mutant mouse strain that would model the inheritance of the mutant Pkd1 allele in humans, with the distinction that knockdown of the gene occurs only in the earliest kidney structure from which cysts can form: the Wolffian duct.

Results: In contrast to previously published models with targeted homozygous mutations of Pkd1 that have been uniformly characterized by embryonic lethality, the Pkd1(flox/flox);HoxB7-Cre mutant mice generated from these pairings survived delivery and died at an average of 18 days of age from complications of renal failure. H&E sections of these kidneys revealed enlarged kidneys and massive cyst formation. Pkd1(+/flox);HoxB7-Cre mutant mice with heterozygous knockdown of the Pkd1 gene did not demonstrate cysts at the same age. However, despite the phenotypic similarity between the kidneys of these heterozygous mice compared to wildtype (non-HoxB7-Cre expressing) mice, a striking difference in genotypic expression was revealed by whole-transcript mRNA microarray analysis. 40 genes in particular featured >= 2-fold change in ANOVA-1way differential expression (p-value+FDR < 0.05) and a unique hierarchical clustering. Pearson's correlation with miRNA expression in these kidneys also revealed significant differences between the heterozygote and wildtype kidneys.

Conclusions: The presented results suggest that the Pkd1;Hoxb7-Cre mouse is a novel model for ADPKD that will be useful in the study of the genotypic changes underlying cyst formation, in the study of perinatal factors given the model's survival postpartum, and for the first time reveals a role for the origin of cystogenesis in the earliest structure of kidney formation: the Wolffian duct.

TH-PO648

Reduced Ciliary Polycystin-2 in Induced Pluripotent Stem Cell Lineages from Patients with Polycystic Kidney Disease Benjamin S. Freedman,[1] Albert Q. Lam,[1] Jamie L. Sundsbak,[2] Rossella Iatrino,[1] Sarah J. Koon,[2] Maoqing Wu,[1] Jing Zhou,[1] Peter C. Harris,[2] Joseph V. Bonventre.[1] *[1]Renal Division/Center for PKD Research, Brigham and Women's Hospital, Harvard, Boston, MA; [2]Division of Nephrology and Hypertension and Translational PKD Center, Mayo Clinic, Rochester, MN.*

Background: Induced pluripotent stem (iPS) cells are a powerful new technology for investigating human disease and potential therapeutics in diverse cell types. We tested the potential of iPS cells to model the ciliopathy, polycystic kidney disease (PKD).

Methods: Fibroblasts with characterized mutations from three autosomal dominant (ADPKD) and two autosomal recessive (ARPKD) patients were reprogrammed into iPS cells by retroviral expression of OCT4, SOX2, KLF4, and c-myc. iPS cells were differentiated into ZO-1+ somatic epithelial cells or AFP+CK19+HNF4+ hepatic progenitor cells and quantitatively evaluated for ciliation, polycystin (PC)-1 and -2 protein expression patterns, and cyst formation, and compared to iPS and ES cells from five controls.

Results: Ciliation occurred efficiently in PKD iPS cells, but 50-75% fewer PC2-positive primary cilia were observed in undifferentiated iPS cells, derived epithelial cells, and hepatic progenitor cells from the three ADPKD patients ($p = 10^{-5}$). In contrast, PC2 staining was normal in iPS cell lineages derived from ARPKD patients or controls. The finding of a single PKD1 mutation in the ADPKD parental fibroblasts and iPS cells suggested that reduced ciliary polycystin-2 localization occurred without complete PC1 loss. During differentiation in 3D culture, ARPKD and ADPKD derived embryoid bodies showed a 2-3 fold increased tendency to form fluid-filled cysts, compared to controls ($p = 0.01$).

Conclusions: We show that features of polycystic kidney disease pathophysiology can be recapitulated in patient-derived iPS cells. Reduced PC2 at the primary cilium is specific to ADPKD, not ARPKD, consistent with differences in the pathophysiology of cystogenesis between these diseases. These PKD iPS cell lines provide a novel resource for understanding the cellular features of the disease and can serve as cellular substrates for drug screens and personalized or regenerative medicine approaches.

TH-PO649

Exome Sequencing Identifies a Novel *EEA1* Variant in Japanese Familial IgA Nephropathy Shin Goto,[1] Kazuyoshi Hosomichi,[2] Hiroyasu Tsukaguchi,[3] Ichiei Narita.[1] *[1]Division of Clinical Nephrology and Rheumatology, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan; [2]Division of Human Genetics, National Institute of Genetics, Shizuoka, Japan; [3]Second Department of Internal Medicine, Kansai Medical University, Osaka, Japan.*

Background: A genetic predisposition of IgA nephropathy (IgAN) has been suggested by the familial clustering of the disease. Previously, genome-wide linkage analyses of IgAN have revealed several susceptibility loci, however, causative gene have not been identified until now. From the point of view of genetic heterogeneity of familial IgAN, oligo/polygenic and multiple susceptibility gene model for the disease is proposed. Recently, exome sequencing has been demonstrated to be a powerful and cost-effective strategy for dissecting genetic basis of diseases.

Methods: To identify the genetic causality of familial IgAN, we applied exome sequencing to a family in which four biopsy-proven IgAN patients clustered in a dominant transmission mode. Whole exome sequencing of four affecteds, two asymptomatic carriers, and two non-affected individuals was performed on a HiSeq 2000 Platform. Several-step filtering including annotation and functional expectation was carried out.

Results: After exome sequencing, eight variants turned out to be the promising candidates. Among these, we found a novel missense variant F161Y in *EEA1,* encoding Early Endosome Antigen 1, a Rab5 effector protein that facilitate the docking and tethering incoming endocytic vesicles, located within a linkage locus with a maximum LOD score of 1.68 obtained by linkage analysis of the family. The F161Y variant furthermore co-segregated completely within the family and the amino acid position were highly conserved across zebrafish to human. A probabilistic prediction program, VAAST, placed *EEA1* F161Y in top 20 ranking among 23000 gene variants.

Conclusions: Identification of *EEA1* F161Y variant in our family indicate that defective endosomal trafficking may be implicated in the pathogenesis in familial IgAN. The possible role of *EEA1* F161Y variant in trans-cellular transport of IgAs is now being under investigation.

TH-PO650

The Effect of Kidney Function on Loci for Hematocrit (Hct) Identified from Genome-Wide Association Studies (GWAS) Adrienne Tin,[1] Wen Hong Linda Kao,[1] Santhi Ganesh,[2] Josef Coresh,[1] Eric Boerwinkle,[3] Meredith A. Atkinson.[4] *[1]Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [2]Department of Internal Medicine, University of Michigan, Ann Arbor, MI; [3]Human Genetics Center, University of Texas School of Public Health, Houston, TX; [4]Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: Anemia affects over half of the 10 million Americans with chronic kidney disease (CKD). Previous GWAS have identified 8 genetic loci for Hct, but it is not known whether the effects of these loci are modified by kidney function.

Methods: We conducted a GWAS of Hct in 8645 European Americans from the Atherosclerosis Risk in Communities (ARIC) study, adjusted for age, sex, and estimated glomerular filtration rate (eGFR, using the CKD-EPI equation) and stratified the analysis by CKD status, with CKD defined as eGFR<60mL/min/1.73m^2.

Results: After controlling for eGFR and its square term, the GWAS of Hct did not identify additional loci. The associations of the 8 known Hct loci were similar with and without controlling for eGFR. Two of the 8 Hct loci (*PRKAG2* and *SH2B3*) were also independently associated with eGFR. The A allele of *PRKAG2* rs10224002 was associated with higher levels of Hct ($p=8.7x10^{-5}$) and eGFR ($p=1.0x10^{-2}$). At *SH2B3*, the A allele of rs11065987 was associated with lower level of Hct ($p=4.5x10^{-4}$) but higher level of eGFR ($p=5.6x10^{-2}$). The association of the 8 loci with Hct were similar across CKD except for the *HFE* locus, where the A allele of rs1800562 (C282Y) showed stronger association with Hct among individuals with CKD (beta=1.7%, $p=1.0x10^{-2}$) than those without (beta=0.4%, $p=5.2x10^{-6}$, heterogeneity p=0.04).

Conclusions: In 8645 European Americans, adjustment for eGFR did not change the GWAS results for Hct. The missense variant of *HFE* (rs1800562), a known risk variant of hemochromatosis, showed a stronger association with Hct among individuals with non-dialysis CKD. This novel observation suggests common genetic factors may confer susceptibility or resistance to the anemia associated with CKD, and may have pathophysiologic and therapeutic implications.

TH-PO651

***APOL1* Is Associated with Proteinuria in HIV** Michelle M. Estrella,[1] Man Li,[1] Wen Hong Linda Kao,[1] Stephen J. Gange,[1] Rulan S. Parekh.[2] *[1]Johns Hopkins; [2]University of Toronto.*

Background: HIV-infected persons have increased risk for proteinuria likely due to viral and host factors.

Methods: To determine if APOL1 genotype is associated with proteinuria in HIV infection, 1498 Caucasian, African American or Hispanic other women in the Women's Interagency HIV Study were genotyped for APOL1 G1 (rs73885319) and G2 (rs71785313) and 168 ancestry markers. Ancestry was estimated by principal components using EIGENSOFT. Proteinuria (urine protine-to-creatinine ratio >200mg/g) was measured on 2 visits (median 355d) from 10/94-03/03. We used recessive logistic models to estimate the odds of proteinuria associated with 2 APOL1 alleles vs 1/0.

Results: Of 1285 women successfully genotyped, 124 and 78 had proteinuria at 1 and 2 visits, respectively; 80 had 2 APOL1 alleles. Characteristics were: mean age 36y; 22% Caucasian, 61% African American and 17% Hispanic other; 3% diabetic; and 25% hypertensive. Median CD4 count and HIV1 RNA were 389 cells/mm^3 and 5600 cps/mL respectively; 1/3 injected drugs, were hepatitis C coinfected, had prior AIDS or received HAART. In adjusted analyses, 2 APOL1 alleles were associated with 4-fold higher odds of proteinuria vs. 1/0 APOL1 variants in women without prior AIDS (Table). APOL1 was not associated with proteinuria in women with prior AIDS (P-int=0.02). Similar odds ratios were observed with proteinuria based on 2 visits. Hepatitis C or HAART did not modify the association between proteinuria and APOL1.

Odds of Proteinuria

	Unadjusted	Adjusted†	
		AIDS-	AIDS+
2 vs. 1/0 APOL1	3.26 (1.88, 5.57)	4.17 (2.08, 8.33)	0.56 (0.11, 2.79)
Age, per 1y older	1.05 (1.02, 1.07)	1.01 (0.98, 1.05)	1.03 (0.67, 1.61)
eGFR, per 10 mL/min lower	1.18 (1.10, 1.28)	1.12 (1.01, 1.25)	1.20 (1.02, 1.41)
Hypertension	2.22 (1.51, 3.27)	1.71 (0.96, 3.04)	1.83 (0.89, 3.75)
Hep C	1.64 (1.12, 2.42)	1.31 (0.75, 2.26)	0.57 (0.27, 1.19)
HIV RNA, per ln 1000 copies/mL higher	1.18 (1.10, 1.27)	1.13 (1.02, 1.26)	1.26 (1.09, 1.45)
HAART	0.57 (0.35, 0.92)	0.92 (0.46, 1.85)	1.26 (0.51, 3.08)
AIDS history	1.77 (1.20, 2.60)		

† Adjusted for all variables listed

Conclusions: APOL1 variants are associated with higher risk of proteinuria in HIV-infected women without prior AIDS independent of eGFR, traditional risk factors and HIV-related factors.

TH-PO652

Apolipoprotein L1 Risk Variants Associate with Lupus Nephritis-Induced End-Stage Renal Disease in African Americans Barry I. Freedman,[1] Carl D. Langefeld,[1] Mary E. Comeau,[1] Lee A. Hebert,[2] Mark S. Segal,[3] Jeff Edberg,[4] Bruce A. Julian,[4] Robert P. Kimberly.[4] *[1]Wake Forest School of Medicine, Winston-Salem, NC; [2]Ohio State University Medical Center, Columbus, OH; [3]University of Florida, Gainesville, FL; [4]University of Alabama at Birmingham, Birmingham, AL.*

Background: The G1 and G2 coding variants in the apolipoprotein L1 gene (*APOL1*) are strongly and reproducibly associated with focal segmental glomerulosclerosis (FSGS), HIV-associated collapsing glomerulopathy, and hypertension-attributed end-stage renal disease (ESRD) in AAs. The role of *APOL1* in lupus nephritis (LN) remains less clear. We tested for association between *APOL1* risk variants and severe LN in a national sample of unrelated AAs with systemic lupus erythematosus (SLE).

Methods: The study sample included 668 AA cases with LN-ESRD (456 with kidney biopsy documentation; 212 physician-reported) and 697 AA patients with longstanding SLE lacking nephritis. Allele frequency differences between LN-ESRD cases and SLE non-nephropathy cases were analyzed using logistic regression multivariable models, adjusting for non-muscle myosin heavy chain 9 gene single nucleotide polymorphism rs4821480 under a recessive genetic model.

Results: In cases with LN-ESRD, 87.1% were female, 89% received cytotoxic therapy, mean±SD age at SLE onset was 26.6±0.4 years, and duration of SLE to ESRD was 7.2±0.3 years. In non-nephritis patients, 93.5% were female with age at SLE onset 35.2±0.8 years. Contrasting all cases with and without ESRD, *APOL1* risk variants were significantly associated with LN-ESRD (odds ratio 2.35 (1.77-3.3 95% CI); p=4.25E-^{9}); significant differences in association were not observed when comparing cases with or without kidney biopsy documentation to those lacking lupus nephritis.

Conclusions: This study demonstrates strong association between *APOL1* and LN-associated ESRD in AAs. This finding extends the spectrum of *APOL1*-associated nephropathy to include that associated with SLE ESRD. It appears likely that *APOL1* contributes to nephropathy progression, as it strongly associates with LN-ESRD, FSGS, and other non-diabetic etiologies of ESRD in individuals with African ancestry.

APOL1 Rare Variants Do Not Contribute to Sporadic Focal Segmental Glomerulosclerosis in African or European Americans Sophie Limou,[1] Ping An,[1] George W. Nelson,[1] Jeffrey B. Kopp,[2] Cheryl Ann Winkler.[1] *[1]Frederick National Laboratory for Cancer Research, NIH, SAIC-Frederick, Frederick, MD; [2]NIDDK, NIH, Bethesda, MD.*

Background: Carriage of two common *APOL1* renal risk alleles (termed the G1 and G2 coding variants) explains much of the excess of HIV-associated nephropathy (HIVAN), primary focal segmental glomerulosclerosis (FSGS), and hypertensive nephrosclerosis (OR ~ 29, 17, and 7, respectively) in African Americans (AA). However, approximately 28% of FSGS and HIVAN AA cases carry only one or no *APOL1* risk alleles, and these risk alleles are rare to absent in European Americans (EA). We thus sought to determine if additional *APOL1* coding or non-coding variants contribute to glomerular disease in the subgroup carrying 0 or 1 *APOL1* risk alleles.

Methods: We resequenced the promoter, 5' and 3' untranslated region, 7 exons and all intron-exon junctions of *APOL1* in 468 FSGS cases (54% AA, remainder EA) and 737 (55% AA) healthy controls, as well as 57 HIVAN AA cases and 261 HIV-infected AA controls without kidney disease.

Results: Resequencing revealed only 2 novel (not present in dbSNP or the 1000 Genomes Project) non-synonymous SNPs in *APOL1*, both seen in AA. In addition, we observed 5 rare (frequency 0.1% to 0.3% in AA controls) and 6 private (identified in only one individual in the heterozygote state) novel non-coding variants among AA; also 2 additional rare and 2 private novel variants were observed in EA. No *APOL1* non-synonymous variants, either previously or newly observed, had a significant association with FSGS/HIVAN when G1/G2 were taken into account. Further, rare and private variations were not collectively associated with disease risk.

Conclusions: *APOL1* resequencing did not identify additional variants that are associated with glomerular disease beyond the known G1 and G2 variants.

TH-PO654

Apolipoprotein-L1 Kidney Risk Variants Demonstrate Differential Intracellular Retention and Altered Cell Biological Pathways Patrick Daniel Dummer,[1] Alison Hickman,[1] Dominic Esposito,[2] Cheryl Ann Winkler,[2] Trairak Pisitkun,[3] Jeffrey B. Kopp.[1] *[1]NIDDK, NIH, Bethesda, MD; [2]FNLCR, NIH, Frederick, MD; [3]NHLBI, NIH, Bethesda, MD.*

Background: Coding variants in *APOL1* (termed G1, G2, compared to ancestral G0) are strongly associated with kidney disease in the African American population. Over-expression of ApoL1 induces autophagic cell death in colon cancer cells, but effects of ApoL1 variants on cell function have not been studied.

Methods: Recombinant GST-tagged ApoL1 was expressed in insect cells and purified using a glutathione column. HeLa cells were used for transient transfection.

Results: Using immunostaining and western blotting for LC3B, we confirmed that ApoL1 G0 increased autophagy and found that G1 and G2 had a greater effect. In transiently transfected HeLa cells, ApoL1 subcellular distribution was similar among G0, G1, and G2 variants, but signal intensity was altered. Cycloheximide-chase experiments revealed that G1 had a 20.3% decreased steady-state protein level and similar half-life compared to G0, and G2 showed a 83.2% increased steady-state and 6.6-fold increased half-life. Using protein degradation inhibitors (MG132, epoxomicin, chloroquine, E64/pepstatin A) we found G2 was resistant to proteosomal degradation. No evidence was seen for lysosomal degradation among the variants. Size-exclusion chromatography of recombinant G2 protein and human cell lysates of G1 and G2 indicated altered multimerization, which may contribute to differences in degradation rates. ApoL1 decreased total proteasome activity, G0 by 20.2%, G1 by 46.2%, and G2 by 60.1%. Western blotting for canonical ER stress markers revealed that ApoL1 induced the unfolded protein response, and that the risk variants lead to significantly more ER stress (G0, G1, G2 compared to control: BiP protein 1.3, 1.8 and 3.9 fold; pPERK, 3.3, 7.9, 4.5 fold; and cleaved ATF6, 3.7, 6.0, 11.6 fold).

Conclusions: ApoL1 G1 and G2 variants exhibit distinct cellular profiles compared to G0, with enhanced autophagy, altered protein half-life, decreased proteosomal activity, increased ER stress and altered multimerization. It remains to be determined whether these phenomena, observed in cells with forced over-expression, are relevant to human glomerulopathy.

***APOL1* Null Alleles from a Village in India Do Not Correlate with Glomerulosclerosis** Duncan B. Johnstone,[1] V. Shegokar,[2] Deepak Nihalani,[1] Yogendra Singh Rathore,[3] Leena Mallik,[3] Fnu Ashish,[3] Halil O. Ikizler,[1] V. Zare,[4] Rajaram Powar,[2] Lawrence B. Holzman.[1] *[1]Renal, U Pennsylvania; [2]Microbiology, GMH, Nagpur, India; [3]CSIR-IMTech, Chandrigarh, India; [4]PHI, Nagpur, India.*

Background: African-American glomerulosclerosis correlates by genome wide association (GWAS) with the G1 and G2 alleles of *APOL1*. In the current hypothesis, individuals heterozygous for G1 and G2 benefit from increased resistance against Trypanosoma, resulting in positive allele selection, but individuals homozygous for G1 and G2 are predisposed to glomerulosclerosis. Although there is substantial circumstantial evidence, the causative effect of G1/G2 on glomerulosclerosis has not been proven, and it remains possible that the cause at this locus is linked to *APOL1* rather than *APOL1* itself. Linkage is an important caveat of GWAS and may explain why only 5% of individuals homozygous for G1 and G2 develop glomerulosclerosis.

Methods: We approached the possibility of linkage using classical genetic inference. G1 and G2 correlate with the incidence of glomerulosclerosis as recessive alleles, suggesting they are loss of function mutations. If so, causality for glomerulosclerosis can be tested by generating *APOL1* homozygous null alleles, but this cannot be done in rodents as the *APOL* gene cluster evolved in primates. However, there is one human being known to be *APOL1* homozygous null living in a rural village in India. We obtained clinical data, blood and urine from this patient and 50 related villagers.

Results: Based on blood pressure, BUN, creatinine, albuminuria, DNA sequencing and immunoblotting, this *APOL1* null individual does not have glomerulosclerosis, nor do relatives who carry *APOL1* null alleles.

Conclusions: This small study cannot be definitive but the absence of glomerulosclerosis in this Indian cohort is consistent with the possibility that African-American glomerulosclerosis is caused, not by *APOL1* loss of function, but either by subtle semi-dominance or by "genetic hitchhiking," a recently appreciated mechanism in which positive selection for one variant inadvertently caries along linked, deleterious mutations. Other tests for genetic hitchhiking are underway.

Diabetic Nephropathy Fails to Associate with the *APOL1/MYH9* Locus or Type 2 Diabetes Mellitus Susceptibility Genes: The Family Investigation of Nephropathy and Diabetes (FIND) Consortium Wen Hong Linda Kao.[1,2] *[1]Case Western Reserve University; [2]Johns Hopkins.*

Background: Diabetic nephropathy (DN), a devastating complication of types 1 and 2 diabetes mellitus (DM), is the leading cause of end-stage renal disease in the United States. Its molecular pathogenesis has not been clearly defined nor are there specific susceptibility alleles with strong effects leading to the development of DN. Variants in the *APOL1/MYH9* locus have not been rigorously tested in patients with DN across multiple ethnic groups.

Methods: We conducted candidate SNP case-control analyses using samples from FIND. DN cases and DM controls with no kidney disease of African American (AA, n=1932), American Indian (AI, n=1017), European American (EA, n=1020), and Mexican American (MA, n=2498) ancestry were genotyped for the *APOL1* G1 and G2 variants, the *MYH9* E1 risk haplotype, and sentinel SNPs previously associated with T2DM or estimated glomerular filtration rate (eGFR) and chronic kidney disease (CKD). Generalized estimating equations were used to determine the population-specific associations between SNPs and DN adjusting for age, gender, DM duration, center, and population substructure. Significance level was established at 0.001 (0.05/43 SNPs).

Results: Among AA, *APOL1* and *MYH9* variants were nominally associated with DN in a recessive model ($p = 0.0002$ to 0.02, model adjusted for age, sex, center, and duration), but not after correction for multiple testing. Neither *UMOD* nor *SHROOM3,* nor *SOD1 were* associated with DN in any FIND ancestry group. While several SNPs reached nominal significance, none were consistent across all populations, nor remained significant after multiple testing corrections were applied. An additive DM genetic risk score was also not associated with DN ($p = 0.04 – 0.67$ after adjusting for age, sex, center and duration).

Conclusions: Neither *APOL1/MYH9* risk variants nor previously reported DM or eGFR variants associate with DN. Additional approaches need to be implemented to define the underlying genetic architecture of DN. Determination of the molecular pathways altered by causal variants will lead to better approaches for prevention and treatment of DN.

Partial ADAMTS13 Deficiency in Atypical Hemolytic Uremic Syndrome Stephen J. Eyler,[1] Shuju Feng,[2] Yuzhou Zhang,[1] Tara Maga,[1] Carla M. Nester,[3] Michael Kroll,[2] Vahid Afshar-kharghan,[2] Richard J. Smith.[1,3] *[1]Department of Otolaryngology, University of Iowa, Iowa City, IA; [2]Division of Internal Medicine, Benign Hematology, University of Texas M. D. Anderson Cancer Center, Houston, TX; [3]Department of Internal Medicine, Division of Nephrology, University of Iowa, Iowa City, IA.*

Background: Thrombotic microangiopathies (TMAs) are a group of microvascular disorders characterized by microangiopathic hemolytic anemia and thrombocytopenia. Atypical hemolytic uremic syndrome (aHUS) and thrombotic thrombocytopenic purpura (TTP) are two such TMAs that share phenotypic similarities. Despite their clinical overlap, these two diseases have distinct etiologies: aHUS is caused by dysregulation of the alternative complement system, while TTP is caused by severe deficiencies in ADAMTS13. Given the phenotypic similarities, we hypothesized that ADAMTS13 deficiency may coexist with abnormalities in the alternative complement pathway in aHUS.

Methods: We screened 26 patients with the clinical diagnosis of aHUS for functional and genetic abnormalities of the alternative complement system and ADAMTS13. ADAMTS13 activity was assessed by measuring the cleavage of a recombinant von Willebrand factor-A2 domain (vWF-A2) and a fluoregenic peptide comprising 73 amino acids of vWF-A2 (FRETS vWF73). Genetic variants in *ADAMTS13* and complement genes were assessed by bidirectional Sanger sequencing.

Results: Mutations and/or variants in complement genes and *ADAMTS13* were identified in 14 (54%) and 19 (73%) patients, respectively. The *ADAMTS13* variants were associated with partially reduced activity (<60%) in 15 patients (58%) as measured by the FRETS vWF73 and recombinant vWF-A2 cleavage assays. The coexistence of both ADAMTS13 deficiency AND excessive complement activation was found in 13 (50%) patients.

Conclusions: Partial ADAMTS13 deficiency is a common finding among aHUS patients. Decreased activity of this von Willebrand factor-cleaving protease contributes to the pathogenesis of aHUS. Clinical evaluation of ADAMTS13 activity in aHUS patients may provide finer phenotypic characterization of aHUS, which may be of help in defining the role of various treatments for this disease.

Family-Based Association Analysis in the Joslin Study of Genetics of Nephropathy in Type 2 Diabetes Family Collection Further Confirms the Role of Chromosomes 9q21.32 and 13q33.3 in the Susceptibility of Diabetic Nephropathy in Diabetes

Marcus G. Pezzolesi,[1] Jackson Jeong,[1] Adam Smiles,[1] Jan Skupien,[1] Josyf Mychaleckyj,[2] Stephen Rich,[2] James Warram,[1] Andrzej S. Krolewski.[1] *[1]Section on Genetics and Epidemilogy, Joslin Diabetes Center, Boston, MA; [2]Center for Public Health Genomics, University of Virginia School of Medicine, Charlottesville, VA.*

Background: A genome-wide association scan of the GoKinD collections identified four novel diabetic nephropathy (DN) susceptibility loci, located on chromosomes 7p14.3, 9q21.32, 11p15.4, and 13q33.3, that were associated with DN in T1D and subsequently shown to be associated with DN in unrelated patients with T2D. To follow up these findings, we examined whether single nucleotide polymorphisms (SNPs) at these susceptibility loci were associated with DN in patients from the Joslin Study of Genetics of Nephropathy in Type 2 Diabetes Family Collection.

Methods: Six SNPs across the four loci identified in the GoKinD collections were genotyped in 1,221 individuals from 66 extended families of European ancestry. Pedigrees from this collection contained an average of 18.5 members (range: 6 to 39 members), with 4 to 26 individuals from each family, including 2 to 14 members with T2D, having DNA available. Genotype data were tested for association using FBAT.

Results: Among 798 family members, a significant association with DN was identified at the 9q21.32 locus (rs1888747, P=5.7x10^{-3}). This same locus was significantly associated with variation in urinary albumin excretion in all relatives (P=0.02) and in analyses restricted to those with T2D (P=0.03). Quantitative analysis of estimated glomerular filtration rate (eGFR) was strongly associated with variants at the 13q33.3 locus (rs1411766, P=2.2x10^{-3}) in diabetic relatives.

Conclusions: These data further increase support that associations identified in the GoKinD collections on chromosomes 9q21.32 and 13q33.3 are true DN susceptibility loci. Quantitative analysis of variation in urinary albumin excretion and renal function suggests that these loci may have distinct roles in the pathogenesis of DN.

The Discovery Phase of the CRIC Study GWAS Identifies Novel Candidate Markers Associated with Progression of CKD

Afshin Parsa,[1,3] Peter A. Kanetsky,[2,3] Nandita Mitra,[2] Jayanta Gupta,[2] Harold I. Feldman.[2] *[1]Nephrology, University of Maryland School of Medicine, Baltimore, MD; [2]Center for Clinical Epidemiology and Biostatistics, University of Pennsylvania School of Medicine, Philadelphia, PA; [3]Equal Author Contributions.*

Background: The rate of decline of renal function and development of end stage renal disease (ESRD) varies significantly among individuals with established chronic kidney disease (CKD). Traditional risk factors for CKD only partially explain this variability. To better understand the contribution of inherited genetics to CKD progression, we performed a genome-wide association study (GWAS) within the Chronic Renal Insufficiency Cohort (CRIC) Study cohort.

Methods: We genotyped over 900,000 SNP markers in a total of 1502 African-Americans (AA) and 1586 Caucasian study participants with established CKD. Outcome measures were either change in eGFR over time or the composite of occurrence of ESRD or 50% decline in eGFR from baseline (ESRD+). Linear regression models and Cox proportional hazards models were used to detect associations of SNP markers with eGFR slope and time to ESRD+, respectively. All primary analyses were stratified by genetically inferred race. Within race strata, analyses also were stratified by diabetes mellitus (DM) status.

Results: In our Caucasian cohort, we identified 3 markers associated with progression to ESRD+, one of which reached genome-wide significance. In our AA cohort, we discovered 3 SNP markers that were suggestively associated ($p<1.0 \times 10^{-7}$) with eGFR decline, one of which attained genome-wide significance ($p<5.0 \times 10^{-8}$) among participants without DM. Stratified analyses further revealed 2 markers that were associated with eGFR decline at genome-wide significance and 6 markers that were suggestively associated with progression to ESRD+.

Conclusions: We identified 4 genome-wide significant markers mapping to 4 unique genes associated with eGFR decline and/or renal events. We also have identified an additional 10 markers (10 unique genes) that have suggestive associations with CKD progression. Replication efforts to confirm these signals are underway. These findings may lead to a better understanding of genetic influences on progressive CKD.

Funding: NIDDK Support

TH-PO660

Homozygozity Mapping for Steroid-Sensitive Nephrotic Syndrome

Xuewen Song,[1] Pingzhao Hu,[2] Roser Torra,[3] Daniel C. Cattran,[1] Andrew D. Paterson,[2] York P. Pei.[1] *[1]Division of Nephrology, University Health Network and University of Toronto, Toronto, ON, Canada; [2]Program in Genetics and Genomic Biology, Hospital for Sick Children, Toronto, ON, Canada; [3]Nephrology Department, Fundacio Puigvert, Barcelona, Spain.*

Background: Familial and sporadic steroid-sensitive (SS-) nephrotic syndrome (NS) due to minimal change disease (MCD) and focal segmental glomerulosclerosis (FSGS) may be underpinned by mutations of rare recessive genes. Runs of homozygosity (ROH) analysis is a powerful approach for mapping recessive gene loci in inbred families and outbred populations.

Methods: We performed a genome-wide ROH scan in 58 patients with SS-MCD/FSGS including 7 families with 2 or 3 affected using Illumina Human CNV370 and 660W arrays. Using PLINK and genotype data from 862 unrelated ethnic-specific samples from HapMap III reference populations as controls, we assigned 58 patients to 5 ethnic groups by multidimensional scaling. We calculated the inbreeding coefficient F for each study subject and catalogued all ROHs ≥ 1Mb.

Results: We found a higher F-value only in our Caucasian cases compared to controls ($p<0.05$; Wilcoxon rank sum test) and cryptic relatedness in the parents of 5 patients ($F>0.016$). We catalogued 50 ROH tracts in 38 Caucasian pts, 50 ROH tracts in 10 Native Indian/Mexican pts, 5 ROH tracts in 4 South Asian pts, and 2 ROH tracts in 2 Black pts.

ROH analysis of 58 patients with SS-NS and 862 HapMap III control samples from 5 ethnic groups after LD-pruning

Groups	Sample Size	Ethnicity	No. SNP (with LD pruning)	# ROH (> 1MB)	# ROH shared by ≥ 2 persons	# ROH enriched in cases vs. controls ($p < 0.05$)*	# unique ROH shared by ≥ 2 pts
Pts	38 (including FSSN52, 6, 7, 8)	Caucasian	70,064	50 (1.3)**	68	2	2 ROH tracts each shared by 2 unrelated cases
CTRL	215	CEU_TSI		186 (0.76)			
Pts	10 (including FSSN54)	Native Indian	61,083	50 (5)	14	10	2 ROH tracts each shared by all 3 affected relatives (2 sibs and 1 cousin) from a Native Indian family; 1 ROH shared by 2 unrelated cases
CTRL	54	MEX		37 (0.68)			
Pts	4 (including FSSN53)	Chinese	59,556	0 (0)	36	0	0
CTRL	359	CHB_CHD_JPT		124 (0.35)			
Pts	4 (including FSSN55)	South Asian	67,690	5 (1.25)	153	0	0
CTRL	97	GIH		412 (4.25)			
Pts	2	Black	105,450	2 (1)	190	0	0
CTRL	140	ASW_LWK		660 (4)			
Total # Pts	58						
Total # CTRL	862						

*p-value by Fisher exact test; **mean number of ROH tracts/individual in bracket

Among these tracts, 2 and 10 were uniquely present in our Caucasian and Native Indian/Mexican pts, respectively, and several of them were shared by ≥2 pts. In one Native Indian family, only 2 ROH tracts were shared by all 3 affected relatives.

Conclusions: All ROH tracts enriched in cases compared to controls or shared by affected members within the same family are candidate regions for recessive genes in SS-NS. ROH mapping coupled with exome sequencing (currently in-progress) represent a promising approach to identify these genes.

TH-PO661

A Novel Mutation in KCNJ1 (ROMK1) in a Kindred with Bartter's Syndrome

Shalabh Srivastava,[1] Ann Marie Hynes,[1] Colin Miles,[1] Mohamed Al-hamed,[1] John Andrew Sayer,[1] David Reaich.[2] *[1]Institute of Genetic Medicine, Newcastle University, Newcastle-Upon-Tyne, United Kingdom; [2]Nephrology, James Cook University Hospital, Middlesbrough, United Kingdom.*

Background: We report clinical and genetic data of a Pakistani kindred with 3 affected female members with nephrocalcinosis and features of atypical Bartter's Syndrome.

Methods: The eldest sibling presented with developmental delay at 3 years of age and was diagnosed with rickets. She was treated with Vitamin D supplements. Subsequently, she developed hypercalciuria and nephrocalcinosis and was initially treated with thiazide diuretics and potassium supplements. She had learning difficulties but remained normotensive with no evidence of metabolic acidosis or alkalosis. The second sibling had an identical presentation and treatment and was left with nephrocalcinosis, learning difficulties and hypokalemia. She went on to develop gestational diabetes and advanced renal impairment. The third child was born premature with a history of maternal polyhydramnios.She was initially diagnosed with hypocalcaemia, followed upon correction by hypercalciuria. When hypercalciuria was observed, she was treated with indomethacin, thiazides and a low-salt diet. With such treatment she frequently showed a hypokalemic alkalosis.Once it was possible to determine the levels of renin and aldosterone in the youngest child a suspected diagnosis of Bartter's syndrome was made.There was no history of deafness. Because of possible parental consanguinity, we initially performed homozygosity mapping of the 3 affected individuals. However, there were very few regions of shared homozygosity by descent, and no overlap of these regions with SLC12A1, KCNJ1, CLCKNB, BSND or CASR. We proceeded to examine, using exon PCR and Sanger sequencing, known genes for Bartter's syndrome.

Results: We detected a compound heterozygous change in KCNJ1 gene, encoding the potassium channel ROMK1. In silico modelling of the missense amino acids suggested deleterious changes.

Conclusions: In this family, molecular investigation provided a precise diagnosis and allows further medical management and genetic counselling to be given appropriately.

TH-PO662

Mutation Identification in the Adenine Phosphoribosyltransferase Gene in a Rare Form of Chronic Kidney Disease due to Crystalline Nephropathy

Varun Agrawal,[1] Pamela C. Gibson,[1] Samih H. Nasr,[2] Jay A. Tischfield,[3] Amrik Sahota.[3] *[1]Fletcher Allen Health Care; [2]Mayo Clinic; [3]Rutgers University.*

Background: A 44 year old Caucasian woman was referred for chronic kidney disease (creatinine[Cr] 3.6mg/dl). She has mental impairment since childhood. She has an identical twin with similar cognitive limitation who developed renal failure requiring dialysis 1 year ago due to nephrolithiasis. Parents had a consanguineous marriage and two female siblings are healthy.

Methods: Kidney biopsy revealed numerous brown rod shaped crystals in tubular lumens, epithelium and histiocytes in the interstitium. Chronic tubulointerstitial nephritis was noted with interstitial inflammation due to lymphocytes and plasma cells. Crystals were strongly birefringent and appeared yellow when parallel to the polarizer suggesting uric acid composition, though uric acid levels in serum and urine were normal.

Results: Reference laboratory identified the crystals as 2,8-dihydroxyadenine (DHA) based on morphology, while X-ray microanalysis ruled out oxalate. Adenine Phosphoribosyltransferase (APRT) activity in red blood cells was absent (<0.01 nmol/min/mg protein, normal:0.26-0.46). Allopurinol 300mg/day improved renal function (follow-up Cr 1.7mg/dl at 4 months). For mutation analysis, DNA was isolated from blood and a 2.4 kb fragment spanning *APRT* was amplified and then sequenced. A single T insertion was identified at the intron 4 splice donor site (TGgtaa to TGgttaa:IVS4+2insT) in both alleles from the proband and her twin. The same mutation was identified in a younger sister, while an older sister and both parents were heterozygotes for the mutation. *Tru91* digestion of the PCR product spanning exon 4 confirmed the mutation.

Conclusions: APRT deficiency is an autosomal recessive disorder of purine metabolism that can cause DHA crystalline nephropathy. The IVS4+2insT mutation, known to lead to complete loss of APRT activity, has been identified in several families from Europe, suggesting a founder effect. Differentiating DHA from uric acid crystals and confirming APRT deficiency with enzyme assay and mutation analysis have important implications for preventing further renal injury to native or transplanted kidney.

TH-PO663

Genetic Variants in the Vitamin D Pathway Are Associated with End-Stage Renal Disease

Charlotte A. Keyzer,[1] Carolina R.C. Doorenbos,[1] Harold Snieder,[2] Gerjan Navis,[1] Martin H. De Borst.[1] *[1]Nephrology; [2]Genetics, University Medical Center Groningen, REGaTTA Group, Netherlands.*

Background: Vitamin D deficiency has been associated with progressive renal disease, and vitamin D analogues reduce RAAS activation, inflammation and proteinuria. Recent studies linked common variants in vitamin D-related genes to low vitamin D levels. We hypothesized that genetic variants in the vitamin D pathway are associated with the risk of end-stage renal disease (ESRD) or graft loss after kidney transplantation (KTx).

Methods: In 1271 KTx donor/recipient pairs we genotyped 44 single nucleotide polymorphisms (SNPs) in 4 genes in the vitamin D pathway: *CYP27B1* (1α-hydroxylase), *CYP24A1* (24-hydroxylase), *VDR* (vitamin D receptor) and *GC* (vitamin D binding protein). Minor allele frequencies of these SNPs were compared between donors and recipients. In survival analysis, the effect of SNPs in donors and recipients on the risk of death-censored graft loss and all-cause mortality was investigated by multivariate Cox regression adjusting for known risk factors of graft loss and mortality after KTx.

Results: Seven SNPs were identified with higher minor allele frequencies in ESRD patients than in donors: in *CYP24A1,* rs8124792 (odds ratio 2.2 [95%CI 1.8-2.9]), in *VDR,* rs757343 (2.7 [2.1-3.5]) and rs11574143 (0.5 [0.3-0.6]), and in *GC,* rs3755967 (1.5 [1.3-1.7]), rs4364228 (1.5 [1.2-1.9]), rs222017 (1.7 [1.4-2.0]) and rs3733359 (1.6 [1.3-2.0]) (all $p<0.0001$). The cumulative risk of these SNPs on ESRD expressed as a genetic risk score was highly significant (1.57 [1.44-1.70] per risk allele copy, $p=9\times10^{-28}$). At 5.4 [3.0-8.8] years after KTx, the minor allele of rs4809957 (*CYP24A1*) in recipients was the only locus in our study that was significantly associated with an increased risk of mortality (hazard ratio 1.45 [95%CI 1.15-1.84], $p<0.00001$). No associations with death-censored graft failure were found.

Conclusions: We identified 7 SNPs in the vitamin D pathway independently contributing to the risk of ESRD, and one SNP in the recipient *CYP24A1* gene associated with mortality after KTx. Genetic variations in the vitamin D pathway may contribute to progressive renal disease, and provide a target for intervention.

TH-PO664

A QTL for the Coefficient of Variation in 24-h Urinary Calcium in a Rodent Model of Hypercalciuria

Guy M.L. Perry,[1] Steven J. Scheinman,[1] Robert J. Reid,[1] Jyotirmoy Nandi,[1] Krista L. Lewandowski,[1] David A. Bushinsky.[2] *[1]Medicine, SUNY Upstate Medical University, Syracuse, NY; [2]School of Medicine and Dentistry, University of Rochester, Rochester, NY.*

Background: Genes for residual variation might represent an important source of error in linkage or association mapping of genes for renal solutes. Previous work of ours indicates the heredity of residual variation in urinary calcium, a major risk factor for stone disease. We investigated the effects of genes for residual variation on the estimation of classical genetic parameters.

Methods: We estimated heritability for the coefficient of variation in urinary calcium (CV_{Ca}) in a chromosome 1 congenic Genetic Hypercalciuric Stone-forming × normocalciuric Wistar-Kyoto rat pedigree being used to isolate a classically-acting locus for urinary calcium (*hc1*). Marker-CV_{Ca} association mapping was performed using PLINK.

Results: CV_{Ca} was heritable ($h^2_a=0.067\pm0.047$). We detected a quantitative trait locus (QTL) ($P_{FDR}<0.001$) for CV_{Ca}, termed here *hypercalciuria coefficient of variation 1* (*hccv1*; 170-227 MB; *D1Rat204–D1Rat73*) orthologous to human chromosomes 9 (70-80 MB) and 11 (0-70 MB) and enriched for insulin receptor genes ($-\log_{B\text{-}H}=1.58$). Within the *hccv1* region, estimates of error in untransformed mean calcium excretion were 2.4% higher than over the region for the classically-acting *hc1*.

Conclusions: Our findings indicate that *hccv1* influences the mapping of classically-acting loci for renal solute output. Such systems could affect the genetic mapping of other traits, including renal solute indicators of renal pathology.

Figure 1. Association of microsatellites with mean (blue solid line, triangles for markers) and *CV* (green dashed line; squares) urinary calcium on rat chromosome 1 (right axis). Proportions of error by marker from linear analysis (σ^2_e/σ^2_p) indicated as dots (left axis).

Genetic Loss of Function Mutations in Zebrafish and Human CRB2, a Regulator of Epithelial Polarity, Are Associated with Podocyte Foot Process Effacement and Focal Segmental Glomerulosclerosis

Arindam Majumdar,[1] Lwaki Ebarasi,[2] Shazia Ashraf,[3] Svjetlana Lovric,[3] Friedhelm Hildebrandt.[3] *[1]Immunology, Genetics, and Pathology, Uppsala University, Uppsala, Sweden; [2]Vascular Biology MBB, Karolinska Institute, Stockholm, Sweden; [3]Pediatrics, University of Michigan, Ann Arbor, MI.*

Background: Podocytes are polarized epithelial cells, central to the filtration barrier, and are a major pathological target in kidney glomerular disease. Podocytes cell polarity is manifested in different apical and basal membrane domains, slit diaphragms, and well defined actin rich foot processes. In published work, we identified a requirement for zebrafish *crb2b*, a conserved regulator of epithelial polarity, in protein trafficking events leading to podocyte morphogenesis. Crb2b is required for trafficking Nephrin to slit diaphragms. Crb proteins are EGF-like domain transmembrane proteins which regulate apical basal epithelial polarity and membrane biogenesis.

Results: We use zebrafish *crb2b* gene as an entrance point into exploring cell polarity in podocyte stucture and function. A recessive, null allele in zebrafish, *crb2b^{m}*, phenocopies the morpholino results and genetically confirms a need for *crb2b* in podocyte differentiation. Co-immunoprecipitation shows that Crb2b protein associates with Nephrin. Crb2b and Nephrin co-localize in vesicles when transiently expressed in cell culture.

We extended our zebrafish Crb2 studies into human nephrotic syndrome. SNP homozygosity mapping and exome re-sequencing were used to screen for mutations in human CRB2. Analysis of 30 consanguinous sibling pairs, displaying early onset FSGS, identified a homozygous missense mutation in CRB2.

Conclusions: Zebrafish Crb2 is required for podocyte differentiation. Mutations in human CRB2 are associated with FSGS, indicating an evolutionarily conserved function for CRB2 in podocyte structure and function. Cell polarity is central to podocyte function, and these studies suggest that a fraction of podocyte based nephrotic syndromes may be due to fundamental misregulation of podocyte apical basal polarity. Lastly, our studies underscore the importance of zebrafish in studying the genetics of human kidney diseases.

Role of Kynurenine 3-Monooxygenase for the Integrity of the Glomerular Filtration Barrier

Konstantin Deutsch,[1,2,3] Nils Hanke,[1,2] Hermann G. Haller,[1,2] Ron Korstanje,[3] Mario Schiffer.[1,2] *[1]Department of Nephrology, Hannover Medical School, Hannover, Germany; [2]Mount Desert Island Biological Laboratory, Salisbury Cove, ME; [3]The Jackson Laboratory, Bar Harbor, ME.*

Background: Kynurenine 3-monooxygenase (KMO), a flavin monooxygenase in the tryptophan pathway, hydroxylates L-Kynurenine to L-3-Hydroxykynurenine. While its inhibition seems to have a neuroprotective effect, a SNP in KMO has been associated with an elevated albumin/creatinin-ratio in a genome wide association study in mice. In order to investigate the functional role in an animal model, we used zebrafish (*Danio rerio*) as a model organism.

Methods: KMO was knocked down in zebrafish embryos using an ATG-blocking-morpholino. The fish were then screened for the development of edema. To assess renal protein leakage, we injected an FITC labeled dextran (70 kDa) into the cardinal vein of the zebrafish and compared the amount of systemic fluorescence in the retinal vessel plexus 24 and 48 hours post injection. In addition we performed KMO knockdowns in a transgenic fishline that expresses a GFP labeled liver-FABP (78 kDA) in the circulation and measured systemic fluorescence development over time as well. A significant loss of fluorescence in knockdown-fish would indicate glomerular leakage. To confirm our findings we examined zebrafish glomeruli on transmission electron microscopy (TEM).

Results: Morpholino injected fish displayed a severe edematous phenotype. In the functional assays, the knockdowns showed a significant loss of systemic fluorescence (28.79%, p<0.0001), compared to control injected animals (0.54%, p=0.86). The transgenic knockdowns developed only 1/30 of the fluorescence of the control-group. The TEM analysis revealed an intact basement membrane and endothelial cells, but wide stretches of podocyte effacement. Our current investigations focus on the KMO activity in NZM-mice, where the SNP was initially found. The mice develop spontaneous proteinuria and die within 12 months.

Conclusions: To our knowledge this is the first evidence provided that a dysregulated tryptophane metabolism can directly influence glomerular filtration barrier function.

A Clinical, Pathological and Genomic Targeted Customized Multi-Indexed Exome Sequencing Approach Identifies Novel and Rare Variants in Patients with Proteinuria, Atypical Alport Syndrome or CAKUT

Rajshekhar Chatterjee, Surya V. Seshan, Helen Liapis, Sanjay Jain. *Internal Medicine (Renal), Pathology & Immunology, Washington University School of Medicine, St Louis, MO.*

Background: There has been limited application of genomics in kidney diseases. This is much needed particularly in patients where clinical, radiological and pathological findings are equivocal and clinical presentation is atypical.

Methods: We performed custom targeted capture and exome sequencing of 292 genes using next generation sequencing (NGS) in an index case of a Caucasian woman with VUR who presented with nephrotic range proteinuria at 44 years of age. We then selected a panel of genes implicated in proteinuria and CAKUT and applied our approach on a small cohort of patients with either confirmed or presumed Alports or FSGS.

Results: Initial biopsy findings in the index case showed FSGS. Sequencing analysis of 4,041 exons revealed two deleterious nonallelic *COL4A3* mutations, one novel and the other previously reported in an Alport syndrome patient, and a novel deleterious *SALL1* mutation; all confirmed by Sanger sequencing. Bioinformatic analysis demonstrated that these variations altered highly conserved amino acids. Pedigree analysis suggested a compound recessive mode of inheritance. Immunohistochemistry in the renal biopsy revealed markedly diminished *COL4A3*. Several years after initial presentation, the patient presented with hematuria and sensorineural hearing loss. Later biopsies revealed histological findings of FSGS and ultrastructural changes diagnostic of Alport syndrome. We then extended this approach to a small cohort of proteinuria patients using multi-indexed targeted NGS. We found that five of nine patients with clinical diagnosis suggestive of Alports had mutations in *COL4A3, A4* or *A5*. *APOLI_G2* deletion was noted in 2 out of 3 African American patients (one homozygous) with FSGS. Further, novel deleterious *LAMA5* mutations were observed in 3 out of 5 FSGS patients.

Conclusions: These studies demonstrate that customized gene panels and targeted capture-based exome sequencing is a powerful approach in revealing genetic mutations as a potential factor in complex or atypical renal phenotypes.

TH-PO668

Refinement of the HIVAN1 Susceptibility Locus on Chr.3A1-A3 via Generation of Subcongenic Strains

Natalia Papeta,[1] Ami Patel,[1] Francesca Lugani,[1] Vivette D. D'Agati,[2] Ali G. Gharavi.[1] *[1]Medicine, Columbia University, New York, NY; [2]Pathology, Columbia University, New York, NY.*

Background: HIV-1 transgenic mice on the FVB/NJ background (TgFVB) represent a validated model of HIV- associated nephropathy (HIVAN). A mapping study between TgFVB and CAST/EiJ (CAST) strains previously identified a major susceptibility locus on chromosome 3A1-A3 (*HIVAN1*), with CAST alleles associated with increased risk of disease. Previously reported TgFVB-HIVAN1^{CAST}congenic strain, carrying a 50 Mb CAST interval (encompassing the *HIVAN1* locus), introgressed into the TgFVB genome, showed accelerated development of collapsing glomerulopathy compared to TgFVB strain.

Methods: We generated two sub-congenic strains (SubII and SubIII) which encompass proximal (5.8-41.8 Mb) or distal (37.7-55Mb) regions of the previously reported FVB-HIVAN1^{CAST} locus (build 37.1). These sub-congenic strains were crossed with TgFVB strain and HIVAN pathology traits were compared in F1 and backcross (BC) generations to better localize the *HIVAN1 gene.*

Results: At 6-9 weeks of age, HIV transgenic homozygous SubIII mice display significant glomerulosclerosis (54.8 %± 10.4% vs. 15.6 ±5, p<0.01) and tubulointerstitial injury (58% ± 11 vs. 14.1%± 4, p <0.01) compared to SubII-FVB-HIVAN1^{CAST} mice. In contrast, SubII-FVB-HIVAN1^{CAST} mice were not different from Tg-FVB (glomerulosclerosis score 15.6 %± 5.2% vs. 16.5 ±5, p=0.9) and tubulointerstitial injury (14.1% ± 4 vs. 8.3%± 2, p =0.24). The severity of disease correlated with the number of SubIII CAST alleles: glomerulosclerosis score (54.8 %± 10.4% vs. 30.1 ±8.1) and tubulointerstitial injury score (58% ± 11.1 vs. 31.9%± 6.6) were significantly higher in BC mice compared to F1 mice. The identified *SubIII-HIVAN1* locus spans 17.3 Mb and encodes 59 genes, of which 4 have been reported to play a role in kidney development and 8 have non-synonymous coding SNPs that differentiate CAST from FVB.

Conclusions: These data further confirm that a gene on chr3A1-A3 increases susceptibility to HIVAN and reduce the *HIVAN1* locus to a maximal 17Mb interval with 11 high priority candidate genes.

TH-PO669

Impact of Initial Serum Uric Acid Levels on Mortality in Diabetic Hemodialysis Patients

Sung Hee Chung,[1,2] Hyunjin Noh,[1] Jin Seok Jeon,[1] Soon Hyo Kwon,[1] Bengt Lindholm,[2] Dong-Cheol Han.[1] *[1]Hyonam Kidney Laboratory, Soon Chun Hyang University, Seoul, Korea; [2]Baxter Novum and Renal Medicine, Karolinska Institutet, Stockholm, Sweden.*

Background: Little is known about whether serum uric acid (UA) levels are independently associated with mortality in diabetic (DM) hemodialysis (HD) patients. The purpose of this study was to assess the predictive role of serum UA levels at initiation of dialysis therapy in DM HD patients.

Methods: A total of 319 incident HD patients (182 males; age of 60±14 years; estimated glomerular filtration rate of 7.5±3.8 ml/min; 193 DM) were included. Based on initial serum UA levels, and limit for normal UA in our laboratory (8.3 mg/dL for men, 6.6 mg/dL for women), patients were divided into hyperuricemia (HUA) group (n=165) and non-hyperuricemia (non-HUA) group (n=154).

Results: On Cox proportional hazards multivariate analysis including all patients, old age, presence of cardiovascular disease (CVD) and other comorbid disease (CMD), and low serum albumin were independent predictors of mortality but *not* high UA levels. In contrast, in DM patients, old age, presence of CVD and other CMD, and high UA were independent predictors of mortality. In all patients, patient survival was not different between HUA group and non-HUA group but in DM patients, 2-year patient survival was significantly lower in HUA group than in non-HUA group (74.5% and 88.9% respectively; log rank test, p=0.01). In the subgroups of DM patients, 2-year patient survival was worse among those with HUA and CVD (52.3%; n=30) than in those with non-HUA with CVD (81.1%; n=36), HUA without CVD (88.6%; n=62), and non-HUA without CVD (93.9%; n=65). In DM patients with HUA and CVD, the risk ratio for mortality was 5.98 times that of DM patients with non-HUA without CVD.

Conclusions: An initial high uric acid level is associated with increased mortality in those diabetic HD patients (but not in non-diabetic HD patients) and this risk is mainly attributed to higher risk of mortality in diabetic HD patients who had high UA and CVD at the start of HD. These data suggest that the predictive value of serum UA as a risk marker in end-stage renal disease patients is influenced by presence of diabetes and CVD.

TH-PO670

Decreased Plasma Formic Acid in Patients with End Stage Renal Disease (ESRD) and Its Contributing Factors

Emiko Miyazawa,[1] Hiroyuki Terawaki,[2] Masaaki Nakayama,[2] Sadayoshi Ito.[1] *[1]Department of Nephrology, Endocrinology, and Vascular Medicine, Tohoku University, Sendai, Miyagi, Japan; [2]Department of Nephrology and Hypertension, Fukushima Medical University, Fukushima, Japan.*

Background: Formic acid (FA) is an essential substance for de novo synthesis of purine nucleotides. FA is combined with folic acid and incorporated into purine synthesis pathway as formyl-tetrahydrofolate. FA is used as a constituent of C1 and C8 of purine bodies. Exogenous FA administration enhances nucleic acid production. In ESRD, it is known that nucleic acid metabolism is altered, e.g. enhanced elimination of nucleic acid in erythrocyte, and thus, it is supposed that there may be an altered FA consumption under this condition. Low concentration of endogenous FA exists in the healthy subjects, but only a limited number of reports examined about it, and FA levels in ESRD remain unknown.

Methods: Plasma FA levels and purine metabolite, uric acid (UA) were measured by High Performance Liquid Chromatography methods in (a) non-CKD (n=300), (b) CKD 5 (n=80), and (c) CKD 5 under dialysis (D) patients (n=30), and examined influencing factors for FA levels.

Results: Plasma levels (mean±SD) of FA and UA were as follows; FA (mg/L): (a) 3.71±1.17, (b) 1.43±1.07, (c) 1.96±1.10, UA (mg/dL): (a) 5.6±1.4, (b) 9.8±2.1, (c) 8.3±1.1. Significant differences were seen in respective levels by one-way analysis of variance (P<0.05), and furthermore, there was a significant difference in plasma FA levels between CKD5 and 5D (P=0.02). No relationships were found between FA and UA, and other parameters in respective groups. Regarding the influencing factors for FA levels, subjects with smoking habit exhibited lower FA levels in respective groups, and smoking was revealed to be an independent contributing factor in non-CKD by multivariate linear regression analysis.

Conclusions: In ESRD, there was a significant decrease in plasma FA level, and it was indicated that the dialysis therapy could partly restore it. Since plasma FA levels were low in smokers, and no relation was found between FA and purine metabolite in ESRD, the mechanism of the decreased FA needs to be addressed in relevance to cellular injury and FA consumption in uremic condition.

TH-PO671

Endothelial Glycocalyx Alterations in Hemodialysis Patients Tom Cornelis,[1] Jeroen Kooman,[1] Natascha Broers,[1] Karel M.L. Leunissen,[1] Frank van der Sande,[1] Hans Vink.[2] *[1]Internal Medicine, Division of Nephrology, Maastricht University Medical Center, Maastricht, Netherlands; [2]Cardiovascular Research Institute, Physiology, Maastricht University, Maastricht, Netherlands.*

Background: Chronic kidney disease patients are at increased risk for endothelial disease. Whether hemodialysis treatment itself exacerbates endothelial damage, is unknown. The endothelial glycocalyx mediates vascular protection. We speculated that hemodialysis might cause endothelial glycocalyx changes.

Methods: The glycocalyx forms the interface between flowing blood and the vascular wall. Red blood cells (RBCs) penetrate deeper into a damaged glycocalyx, suggesting that measurements of RBC column width might serve as a marker for glycocalyx damage. Glycocalyx damage can be tested by measuring the dimension of the RBC perfused boundary region (PBR), which fills up the space between median RBC column width and the outer edge of RBC permeable vascular lumen. PBR will increase when glycocalyx is damaged. We studied PBR in 21 prevalent hemodialysis patients with sublingual Sidestream Dark Field Imaging before the start of hemodialysis (baseline) and subsequently at 30, 60, 120, 180, 240 (end of treatment) and 270 minutes.

Results: A statistically significant increase of PBR in vessels with diameters between 5 – 30 microns was observed from 2.18 ± 0.06 microns to 2.35 ± 0.06 microns and 2.37 ± 0.07 microns at 30 and 120 minutes respectively. A similar trend persisted during the entire treatment. A secondary finding was a statistically significant greater baseline PBR and hence more damaged glycocalyx in the ultrafiltration patients (PBR = 2.27 ± 0.06 microns) as compared to the non-ultrafiltration group (PBR = 2.02 ± 0.09 microns).

Conclusions: Hemodialysis causes a significant increase in the width of the RBC accessible component of the sublingual microvascular glycocalyx, indicating loss of vascular protection and increased susceptibility to vascular complications. We also found a greater baseline PBR in the ultrafiltration group, suggesting that residual renal function may protect the endothelial glycocalyx. The pathophysiology and implications of these novel observations require further investigation.

TH-PO672

New Target of ACT in Heparin Anticoagulation during Hemodialysis Ki-won Kwon,[1] Young Hye Song,[1] Young-Il Jo.[1,2] *[1]Dialysis Center, Konkuk University Hospital, Korea; [2]Nephrology, Konkuk University Hospital, Konkuk University School of Medicine, Seoul, Republic of Korea.*

Background: Unfractionated heparin (UFH) is currently the most widely used anticoagulant during hemodialysis (HD). In order to prevent over-anticoagulation, UFH can be monitored using the activated coagulation time (ACT) aiming for ACT of 80% above baseline during HD and 40% above baseline at end of HD. However, even in the patients without significant bleeding risks, stressful bleeding complications may be caused by UFH anticoagulation despite ACT is maintained within the recommended ACT goal. This study was designed to evaluate the suitability of the recommended ACT goal and the proper level of ACT goal in HD patients.

Methods: A total 74 chronic HD patients without significant bleeding risks were enrolled. In phase I study, the doses of UFH were titrated to maintain the recommended ACT goal. In phase II study, the doses of UFH were titrated according to the time for needle sites to stop bleeding and visual assessment of clotting within the dialyzer for the patients who were dropped out from phase I study. ACT was monitored at 0, 120 min and 240 min after initiation of HD. All patients were divided into clotting (CG) and non-clotting group (NCG).

Results: All patients were dropped out from phase I study due to the increased time to stop bleeding from needling site after termination of HD. In phase II study, there were no significant differences in age, gender, cause of ESRD, Kt/V and use of anticoagulants between CG (n=13, 17.5%) and NCG (n=61, 82.4%). ACT at 120 min did not differ between two groups (CG vs. NCG; 123.9±6.2 vs. 136.3±3.5 sec, p>0.05) although ACT in NCG was slightly higher than in CG group. The doses of heparin in NCG group were significantly higher than in CG group (CG vs. NCG; 8.3±1.1 vs. 11.6±0.7 IU/kg of BW, p=0.038). ACT was significantly correlated with the dose of heparin (r=0.326, p<0.001).

Conclusions: These results suggest that the currently recommended ACT goal is too high even for the patients without significant bleeding risks and the new target of ACT for UFH anticoagulation during HD is needed. We are conducting the phase III study, a prospective randomized trial, to establish a new ACT goal.

TH-PO673

Use and Safety of Heparin-Free Maintenance Hemodialysis Jenny Shen, Aya Alice Mitani, Tara I. Chang, Wolfgang C. Winkelmayer. *Stanford University, Palo Alto, CA.*

Background: Although heparin is commonly used to anticoagulate the dialysis circuit for chronic hemodialysis (HD), some patients undergo heparin-free HD for reasons not well characterized. We describe the determinants of heparin-free HD and its association with clinically important outcomes using data from a national dialysis provider merged with Medicare claims.

Methods: We identified patients aged ≥67 years who initiated maintenance HD from 2007-08. Using logistic regression, we examined whether patient or provider factors were associated with the use of heparin-free HD on day 90 after dialysis initiation. We applied Cox regression to a propensity-score matched cohort to estimate the hazards of bleeding events (gastrointestinal (GI) hemorrhage, hemorrhagic stroke, other hemorrhage), thrombotic events (myocardial infarction, ischemic stroke, pulmonary embolism, deep vein thrombosis), and all-cause mortality.

Results: Among 12,917 patients, 885 (6.9%) were dialyzed heparin-free. In multivariable-adjusted analyses, a history of GI bleeding, hemorrhagic stroke, lower hemoglobin and platelet counts, and warfarin use were associated with higher odds of heparin-free HD; black race and central venous catheter use were associated with lower odds of heparin-free HD. The use of heparin-free HD also varied significantly by facility region (e.g., a 4-fold variation between the New England and West North Central census divisions). We found a modest association of heparin-free HD with all-cause mortality (hazard ratio (HR) 1.27; 95% confidence interval (CI): 1.07-1.52) compared to HD with heparin, but no significant association with bleeding events (HR 1.18; 95%CI: 0.79-1.78) or thrombotic events (HR 1.18, 95%CI: 0.98-1.44).

Conclusions: Patient markers of increased risk of bleeding along with facility region associated with use of heparin-free HD. Despite the potential benefits of avoiding heparin use, heparin-free HD was not associated with decreased hazards of bleeding or thrombotic events. The association between heparin-free HD and increased mortality may be residually confounded by indication, but suggests it is at least no safer than HD with heparin as currently practiced in the U.S.

TH-PO674

Variations in the Circulating Heparin Levels during Maintenance Hemodialysis in End Stage Renal Disease Patients Kristiyana Kaneva,[1] Vinod K. Bansal,[2] Debra Hoppensteadt,[1] Joesphine Cunanan,[1] Jawed Fareed.[1] *[1]Pathology, Loyola University Medical Center; [2]Nephrology, Loyola University Medical Center.*

Background: Unfractionated heparin has remained the anticoagulant of choice for hemodialysis patients but wide variations in the heparinization responses have been observed. The purpose of this investigation was to measure circulating heparin levels in patients prior to and after hemodialysis.

Methods: This study included 119 End Stage Renal Disease (ESRD) patients undergoing maintenance hemodialysis. For the 3-4 hour hemodialysis duration, a heparin loading dose of 1000 Units followed by two additional dosages of 500 Units/hour were administered. Citrated blood samples were collected prior to and immediately after the dialysis session and analyzed utilizing such clot based methods as Activated Partial Thromboplastin Time (APTT), Heptest and Prothrombinase Induced Clotting Time (PiCT). Circulating Anti-Xa levels, Antithrombin (AT) levels and Thromboplastin induced thrombin generation were also measured. The circulating levels of heparin were determined using a calibration curve constructed from the heparin used in the dialysis unit.

Results: Heparin levels ranged from 0 to 1.08 U/ml with a mean of 0.07 ± 0.11 for the APTT and a range of 0 to 1.98 for the Heptest with a mean of 0.09 ± 0.26 U/ml. There was no significant difference in circulating levels of heparin between pre and post hemodialysis samples using APTT, Heptest and PiCT, whereas the Thrombin generation and Anti-Xa resulted in a statistically significant p value < 0.05 when comparing the two groups.

Conclusions: The presence of detectable levels of heparin in the pre dialysis plasma samples for almost two thirds of the patients (87 out of 119) suggests that residual heparin circulates in these patients for a longer period of time. A significant number of post dialysis samples, 6 out of 119 (5%), contained greater than 0.25 U/ml of heparin. These results also suggest that the use of heparin in maintenance hemodialysis patients in repeated regimen results in a steady state hypocoagulation as evidenced by the inhibition of thrombin generation, circulating Anti-Xa level and the prolongation of various clotting times.

TH-PO675

Effects of Citrate-Enriched Dialysate and Reduced Heparin Dose on Reuse of Dialyzers Jorge P. Strogoff-de-Matos,[1] Amanda Rocha,[1] Esther Oliveira,[2] Marcia Guimaraes,[2] Vanessa Padua,[1] Jocemir R. Lugon.[1] *[1]Universidade Federal Fluminense, Niteroi, Brazil; [2]CDR- Clínica de Doenças Renais, Ingá, Niteroi, Brazil.*

Background: We evaluated if the use of citrate-enriched dialysate would allow the reduction of heparinization without affecting the efficiency of reprocessed dialyzers.

Methods: A cross-over study in which 30 patients on maintenance HD were randomized to 2 different regimens of heparinization and dialysate acid buffer along 12 HD sessions, split by a 2-week washout period: Phase A- regular 4.0 mmol/l acetic acid containing dialysate and standard heparin dose (~100 UI/Kg), and Phase B- 2.4 mmol/l citric acid containing dialysate and reduced heparin dose (~70 UI/Kg). Dialysate calcium concentration (1.25 mmol/l) was similar in both phases, as well as the remaining solutes. All patients used high flux polysulfone membrane dialyzers which were reprocessed with peracetic acid/hydrogen peroxide mixture. Dialyzers were discharged before the 12th use if total cell volume (TCV) <80% of baseline.

Results: Twenty eight patients accomplished both phases. Nine dialyzers were discharged before 12th use in Phase A and 11 in Phase B. The total of successful HD sessions accomplished in phases A and B were 290 and 286, respectively. The utilization rate of dialyzers was similar in both phases (86.3% and 85.1%, respectively; P=0.74). Urea Kt/V did not change along both phases. As expected, systemic anticoagulation during and post-HD was more intensive in Phase A (P<0.001). Activated partial tromboplastin time at pre, 120min and post-HD in Phase A was 38±8", 95±56" and 68±36", respectively, whereas it was 36±4", 73±48" and 47±18" in Phase B. Ionized calcium in post-dialyzer blood line segment significantly increased during HD in Phase A (P=0.03), but did not change in Phase B. The incidence of cramps (8.4% and 1.0% of sessions) and hypotensive episodes (9.1% and 3.1% of sessions) were significantly more frequent during Phase B.

Conclusions: Use of citrate-enriched dislysate allowed a 30% reduction in heparin dose and caused less systemic anticoagulation, without compromising reuse performance. However, a significant increase in cramps and acute hypotensive episodes were seen.

TH-PO676

Intradialytic Kinetic Shifts of Protein-Bound Solutes Sunny Eloot, Raymond C. Vanholder. *Nephrology, Ghent University Hospital, Gent, Belgium.*

Background: Patients with renal failure retain a large variety of solutes, of which urea is commonly applied as marker for dialysis adequacy. It was previously found that urea kinetics are not representative for the removal of other solutes. But to the best of our knowledge, no in depth kinetic analysis is available for protein-bound solutes, in spite of the known association between their concentration and outcome parameters. We therefore studied the kinetics of protein-bound solutes with different degree of protein binding.

Methods: This study included 10 stable patients on high flux hemodialysis with 300/700mL/min blood and dialysate flow. Blood samples were collected from inlet blood line at the start, and after 15, 30, 60, 120, and 240min, and from outlet blood line at 30 and 120min. Total and free concentrations of hippuric acid (HA), indoxyl sulfate (IS), indole acetic acid (IAA), 3-carboxy-4-methyl-5-propyl-2-furanpropionic acid (CMPF), p-cresylsulfate (PCS), and p-cresylglucuronide (PCG) were determined and used to calculate dialyzer clearance (K), reduction ratio (RR), and protein binding (PB). A two-pool kinetic model was fitted to the concentrations to calculate the plasmatic volume (V_1), total distribution volume (V_{tot}), and intercompartment clearance (K_{12}).

Results: K as well as RR correlate well with PB (R=0.94;P=0.006 and R=-0.91;P=0.013). V_1 is significantly different for PCG vs IAA, IS, and PCS (all P<0.01), and V_{tot} and K_{12} are different for PCG vs IAA and PCS (all P<0.05). CMPF (100%PB) was not found removed from the patient. V_1, V_{tot}, and K_{12} of IS and PCS, known to share the same binding site on albumin were correlated (R=0.89, R=0.84 and R=0.84; all P≤0.002).

Solute	V_1 (L)	V_{tot}(L)	K_{12} (mL/min)	K (mL/min)	PB (%)
HA	8.8 ± 4.0	23.4 ± 5.3	176 ± 87	132 ± 12	40 ± 14
IS	4.3 ± 1.9	17.5 ± 7.1	96 ± 78	27 ± 5	93 ± 3
IAA	5.2 ± 1.6	29.2 ± 14.8	127 ± 52	52 ± 8	70 ± 9
PCS	3.8 ± 0.9	11.5 ± 2.6	87 ± 44	21 ± 4	94 ± 3
PCG	8.2 ± 2.4	22.7 ± 12.4	103 ± 47	152 ± 28	13 ± 6

Conclusions: Protein-bound solute removal is complex and different per compound. Even related compounds show fairly divergent patterns (PCG vs PCS). Dialyzer clearance differs depending on %PB, but differences in intercompartment shifts further decrease removal possibilities as well.

TH-PO677

Kt/V Is a Poor Predictor of Uremic Toxin Concentration Sunny Eloot, Griet L.R.L. Glorieux, Raymond C. Vanholder. *Nephrology, Ghent University Hospital, Gent, Belgium.*

Background: Kt/V is used as marker of dialysis adequacy. The purpose of this study was to investigate whether Kt/V is representative for the concentration of a broad array of uremic toxins in patients on hemodialysis (HD).

Methods: Predialysis blood samples were taken during a midweek session in 75 stable chronic maintenance HD patients. Samples were analyzed by colorimetry, HPLC, or ELISA for urea, creatinine (Crea), uric acid (UA), symmetric dimethylarginine (SDMA), asymmetric dimethylarginine (ADMA), beta-2-microglobulin (β_2M), and free and total hippuric acid (HA), 3-carboxy-4-methyl-5-propyl-2-furanpropionic acid (CMPF), indoxyl sulfate (IS), indole acetic acid (IAA), p-cresylsulfate (PCS), and p-cresylglucuronide (PCG). Associations were evaluated between concentrations and different parameters: i.e. age, body weight (BW), Kt/V, Residual Renal Function (RRF), normalized Protein Catabolic Rate (nPCR), and vintage. Multifactor analyses were performed per solute.

Results: Kt/V only showed non consistent correlations with concentrations of Crea and UA (both R=-0.2), HA and free HA(both R=0.2), and ADMA (R=0.3), while all other correlations were non-significant. nPCR, on the contrary, showed significant associations for the majority of solutes with R~1 for urea, 0.4-0.6 for Crea, UA, SDMA, PCS, and free PCS, and 0.2-0.4 for ADMA, HA, IS, PCG, free HA, and free PCG. RRF showed inversed associations with β_2M (R=-0.5) and with Crea, ADMA, SDMA, HA, IS, PCG, free HA, free IS, free PCS, and free PCG (R=-0.2 to -0.4).In multifactorial analysis, nPCR and RRF but not Kt/V were significantly determining the concentrations of ADMA, SDMA, HA, IS, PCG, free HA, free PCS, and free PCG. Age, BW, and dialysis vintage did not contribute significantly to any correlation, except for Crea.

Conclusions: In HD patients, uremic toxin concentration seems more dependent on nPCR and RRF than on dialysis dose as assessed by Kt/V. Hence, Kt/V cannot be considered as a major representative for the evolution of solute concentration in HD patients, and by extension for the toxicity which conceivably is concentration-dependent. Nutritional intake and RRF seem to have a more substantial impact, and might thus be more interesting to modify.

TH-PO678

Direct Calculation of Kt/V as Total Blood Clearance of Urea over Total Body Water Volume Carlo Donadio. *Internal Medicine - Nephrology, University of Pisa, Pisa, Italy.*

Background: Most commonly Kt/V is estimated from the values of BUN (postdialysis/predialysis), ultrafiltration volume and postdialysis body weight. The aim of this study was to evaluate the possibility to calculate Kt/V as the total dialyzer urea clearance during the dialysis session, indexed for the volume of total body water of the patient, measured by electrical body impedance analysis (BIA).

Methods: Seventy eigth patients, 34-86 years, body weight 43-130 kg (mean 72.8), in maintenance hemodialysis treatment since 1-31 years (mean 6.5). All patients were on treatment with 3 dialysis, with bicarbonate dialysis (n=55), hemodiafiltration (n=16), or acetate free biofiltration (n=7). Dialysis monitors employed: Fresenius (n=37), Hospal (n=24), Gambro or others (n=17). BIA was measured using a single frequency tetrapolar impedance analyzer at the end of the dialysis session. TBW was calculated from the values of resistance and reactance, combined with body height and weight. Kt/VBIA was calculated as total blood clearance of urea during dialysis session over TBW. First, urea extraction ratio (UER) was calculated as (predialysis-postdialysis)/predialysis values of urea). The total volume of blood flow (QB, L) during dialysis was recorded. Then, Kt/V was calculated as: UER x QB / TBW; where UER x QB is the total dialyzer blood clearance of urea during the dialysis session. For comparison, Kt/V was calculated with Daugirdas formula (spKt/V).

Results: A very high correlation coefficient (r = 0.818) was found between the results of Kt/V measured with the two formulas. The slope was 1.13 x and the intercept non significantly different from 0. The mean difference sp Kt/V (Daugirdas) Kt/V (present study) was -0.03 (NS). The range of agreement between the two measurements was between -0.31 and + 0.37. The correlation between the two formulas was even better when clustering the patients in groups according to the dialysis monitor. Correlation coefficient r ranged 0.853-0.912, indicating that the accuracy of the measurement of blood flow is different according to the different monitors.

Conclusions: The adequacy of dialysis can be assessed from the direct calculation of Kt/V as total blood clearance of urea during dialysis session over TBW.

TH-PO679

Lung Ultrasound for the Evaluation of Extravascular Lung Water in Maintenance Hemodialysis Patients: Comparison with Total Body and Lung Electrical Impedance Carlo Donadio,[1] Laura Bozzoli,[1] Elisa Colombini,[1] Giovanna Pisanu,[1] Guido Ricchiuti,[1] Luna Gargani.[2] *[1]Internal Medicine, Nephrology, University of Pisa, Pisa, PI, Italy; [2]Insitute of Clinical Physiology, CNR, Pisa, PI, Italy.*

Background: In maintenance hemodialysis patients (MHD) dyspnea frequently occurs due to the increase in extra-vascular lung water (EVLW), due to heart failure or to the increase in extra-cellular water (ECW). In the presence of EVLW, the reflection of the ultrasound beam creates some reverberation artifacts, called B-lines. The direct evaluation of EVLW, by means of lung ultrasounds (LUS) together with the measurement of ECW, should help in assessing the "ideal" body weight and to evaluate the mechanism of dyspnea in individual MHD patients. Aim of this study is to compare LUS with total body and segmental lung electrical impedance analysis (BIA).

Methods: Eighteen adult MHD patients, aged 44-85 years, dialysis vintage 0.2-6.5 years, treated by standard or high-flux HD, have been examined immediately before and after a dialytic session. LUS was performed by means of a by-dimensional grey scale ultrasound apparatus equipped with a convex probe. Total body and segmental lung electrical impedance were analyzed by means of a single frequency (sf) and of a multiple frequency (mf) impedance analyzer.

Results: The mean reduction in body weight during the dialysis session was 2.8±1.3 kg. B-lines at LUS decreased significantly (from 36 to 16). In the mean time total body BIA demonstrated a significant reduction in ECW (from 20.2 to 17.6 kg sf-BIA, and from 18.8 to 16.8 mf-BIA), accompanied by a significant increase in resistance and reactance (sf) or impedance (mf). Lung BIA also demonstrated a highly significant increase in resistance and reactance (sf) or impedance (mf).

Conclusions: These preliminary data indicate that lung ultrasound can evaluate extra-vascular lung water in MHD patients and its results are correlated with total body and segmental lung electrical impedance analysis.

TH-PO680

A Potential Route to the Identification of Uremic Toxins: Use of Mass Spectrometry to Identify Solutes Efficiently Removed by the Native Kidneys Tammy L. Sirich,[1] Pavel A. Aronov,[1] Natalie Plummer,[1] Thomas H. Hostetter,[2] Timothy W. Meyer.[1] *[1]Medicine, VA Palo Alto HCS and Stanford University, Palo Alto, CA; [2]Medicine, Case Western Reserve University, Cleveland, OH.*

Background: Identifying uremic toxins has been notoriously difficult. We hypothesize that uremic toxins might be included in the group of solutes normally maintained at low plasma concentrations by very high native kidney clearances. The current study employed untargeted high accuracy mass spectrometry (MS) to identify such solutes.

Methods: LC-MS was performed with a C18 column and orbitrap mass spectrometer on samples of plasma, plasma ultrafiltrate, and urine from 5 normal subjects. The clearance k_{free} was calculated as the rate of solute excretion divided by the concentration in the plasma ultrafiltrate, representing the free solute concentration.

Results: Out of a total of 1808 features identified in both urine and ultrafiltrate by LC-MS, 379 had values for k_{free} which exceeded the renal plasma flow (eRPF) estimated as five times the creatinine clearance. For 82 of these 379 features, solutes with corresponding mass were found in the Human Metabolome Database, including solutes known to accumulate in renal failure of which examples are listed below (mean±sd).

Solute	% free	k_{free}(ml/min)	k_{free}/eRPF
Indolelactate	4 ± 1	8350 ± 905	11 ± 1
Androsterone glucuronide	2 ± 1	5270 ± 1819	6.9 ± 2.6
Indoxyl sulfate	2 ± 1	3289 ± 490	4.3 ± 0.8
1-Methylinosine	14 ± 2	1810 ± 836	2.9 ± 0.6
Hippurate	27 ± 5	2254 ± 512	2.3 ± 0.9
p-Cresol sulfate	2 ± 1	1149 ± 129	1.5 ± 0.2

Efficiently cleared solutes with k_{free} greater than eRPF were bound to plasma proteins as reflected by the free percentages of 2 to 27%. For such solutes, the combination of protein-binding and tubular secretion serves to keep the free plasma concentration to which tissues are exposed very low. Our results show that the number of such solutes is large and that many of them remain to be chemically identified.

Conclusions: Presumably, the kidneys have evolved to provide efficient removal of toxic solutes. Further analysis of the list of solutes most efficiently removed by the native kidneys may therefore provide a route to the identification of uremic toxins.

An Increased Permeability of the Dialyser Membrane Has a Positive Effect on the Removal Rate of the Protein-Bound Uremic Toxins Phenylacetic Acid and p-Cresylsulfate Falko Brettschneider,[1] Sonja Steppan,[2] Markus van der Giet,[1] Mirjam Peter,[2] Jutta Passlick-Deetjen,[2] Joachim Jankowski.[1] *[1]Med. Klinik IV, Charite, Berlin, Germany; [2]Fresenius Medical Care GmbH, Bad Homburg, Germany.*

Background: Innovative modifications are essential to improve the adequacy and permselectivity of dialyser membranes. This study focuses on the effect of opening up the support region of the dialyser membrane to increase permeability for middle molecules on the removal rate of protein-bound uremic toxin, since the hydrophobic, protein-bound uremic toxins contribute to the development of atherosclerotic vascular lesions, affecting endothelial cell, leukocyte, platelet and/or vascular smooth muscle cell function in CKD patients.

Methods: In a small prospective cross-over study, five CKD stage 5D outpatients were treated with a conventional high-flux hemodialyser (FX-800; Fresenius Medical Care) in comparison with a modified high-flux FX-800 hemodialyser (Helixone® plus membrane) with an increased permeability for middle molecules but the same sieving properties for albumin. The removal rate of phenylacetic acid and p-cresylsulfate were quantified at different time points by using gradient ion-pair reversed phase chromatography.

Results: The mean age of the patients was 63 ± 7, systolic RR 122 ± 15 mmHg and diastolic RR 68 ± 6. Removal rates of phenylacetic acid and p-cresylsulfate tend to increase using the modified high-flux FX-800 hemodialyser compared to the conventional high-flux FX-800hemodialyser (phenylacetic acid: 51.90 ± 13.5 vs. 72.4 ± 10.0; p-cresylsulfate: 29.2 ± 3.0 vs. 45.9 ± 8.9; in %).

Conclusions: An increased porosity of the support region of high-flux membranes is highly efficient for better removal of middle molecules and additionally, has a positive effect on the removal of protein-bound uremic toxins. Due to the high impact of protein-bound, hydrophobic uremic toxins on progression of CKD and CVD, the use of modified high-flux hemodialyser may be a therapeutic option to increase the removal rate of these uremic toxins. However, larger, long-term prospective clinical trials are needed to demonstrate the relevance for an improved outcome.

TH-PO682

Effects of Protein-Leaking Dialyzer on Plasma Pentosidine Concentration, a Marker of Carbonyl Stress, in Hemodialysis Patients Hidenori Yamazaki, Fumihiro Tomoda, Tsutomu Koike, Takeshi Hayashi, Satoshi Kagitani, Taizo Nakagawa, Hiroshi Inoue. *The Second Department of Internal Medicine, University of Toyama, Toyama, Japan.*

Background: Over 90% of plasma pentosidine (PEN), a marker of carbonyl stress is bound to albumin. Because only the free fraction of PEN is available for diffusion through dialysis membrane, the removal of PEN is low in conventional hemodialysis (HD). However, the effects of protein-leaking dialyzer on albumin-bound solutes such as PENT remained to be elucidated in hemodialysis patients.

Methods: In the present study, the removability of PEN was compared between two types of triacetate dialyzer with different membrane pore sizes, FB-UH and FB-G (having pore radius of 76 and 60Å, respectively). Eight HD patients were treated with FB-UH and FB-G by crossover manner in the same condition for three months each. Plasma PEN and the leakage of albumin into dialysate effluent were measured at the end of each treatment. Removal rate of solutes was calculated from their pre-HD and post-HD blood levels.

Results: Although the removal rate of small molecular solutes such as creatinine and urea did not differ between the two dialyzers, β_2-microglobulin was removed more efficiently by FB-UH compared with FB-G. At pre-HD levels, plasma PEN was lower in FB-UH compared with FB-G. Plasma PEN decreased after HD in FB-UH, but did not change in FB-G (0.35±0.10 to 0.26±0.07 vs 0.70±0.09 to 0.70±0.14 μg/mL; HD × dialyzer interaction, $p< 0.05$). Consequently, the removal rates of PEN were greater in FB-UH than in FB-G (24.7±2.5 vs 4.9±7.0 %, $p<0.05$). The leakage of albumin into dialysate effluent was also greater in FB-UH compared with FB-G (2.41±0.41 vs 0.51±0.02 g/HD, $p<0.05$). Additionally, the removal rate of PEN was correlated positively with the leakage of albumin into dialysate effluent ($r=0.56$, $p<0.05$) in the combined measurements during the treatment with both dialyzers.

Conclusions: The protein-leaking dialyzer, FB-UH reduced carbonyl stress efficiently in HD patients. The reduction of carbonyl stress in FB-UH might be attributed to the removal of albumin-binding PEN via leakage into dialysate effluent.

TH-PO683

High Flux Hemodialysis with New Membranes Is as Efficient as Hemodiafiltration for Middle Weight Molecules Extraction Patrick Fievet. *Néphrologie Hémodialyse, Groupement Hospitalier du Sud de l'Oise, Creil, France.*

Background: Previous studies suggest that middle weight molecules (MWM) removal is a determinant factor of dialysis patient's prognosis. New technologies provide better control of pore size of dialyser membranes allowing reaching greater permeability. We have studied MWM removal of 5 high flux (HF) membranes in order to verify their ability to get the same performance for removal of MWM in HF-HD as hemodiafiltration (HDF).

Methods: Following HF membranes (ultrafiltration rate > 25 ml/h/mmHg) have been studied in the same conditions (membrane surface = 2.0 to 2.2m², duration = 4h, blood flow =340 to 360 ml/min and dialysate flow = 500 ml/min): PMMA, AN69, Polyethersulfone, PEPA and Polyphenylene.

Results: 1st : On 144 dialysis sessions with Kt/V > 1.2 in 77 patients, no difference has been found for low molecular weight reduction rate (RR). Beta 2 microglobulin (β_2M) RR were significantly higher with Polyphenylene, PEPA and Polyethersulfone than with AN69 and PMMA (respectively: 73.2±4.2, 70.4±6.2, 70.0±4.7, 51.0±5.5, 46.8±12.0%) and myoglobin (MY) RR were significantly higher with Polyphenylene than with PEPA, Polyethersulfone, AN69 and PMMA (65.8±5.3, 50.8±12.4, 47.4±7.6, 47.8±4.4, 37.8±7.5%).

2nd: A non linear relationship (mathematical model: $y = k.(1-e^{-x})$) have been found between β_2M and KT/V with Polyphenylene, Polyethersulfone and PEPA membranes ($p<0.01$) and between MY RR and KT/V with Polyphenylene ($p<0.02$), Polyethersulfone ($p<0.05$) and PMMA ($p<0.05$).

3rd: 12 volunteers patients with predialytic β_2M > 27,5 mg/l treated with the less efficient membranes (AN69 and PMMA) have been switched on the most efficient membrane (Polyphenylene). β_2M significantly decreases (35.0±5.1 vs 30.3±4.5%, $p<0.01$) after 2 months.

Conclusions: 5 currently used HF membranes are significantly different as regard MWM RR whereas low molecular weight RR are identical. With polysulfone derived membranes β_2M RR is dependant of delivered dose of dialysis and can reach 80% at maximal level. These results are in the range of those published with HF-HDF. Polyphenylene membrane is the most effective and can reduce predialytic β_2M plasma level in patients previously treated with less effective HF membranes.

TH-PO684

Evaluation of Oxidative Stress and Inflammatory Markers on Hemodialysis Patients with and without Dialyzers Reuse Carla Barbosa Muraro Furlan,[1] Rosilene M. Elias,[1] Denise Frediani Barbeiro,[1] Manuel C. Castro,[1] Hugo Abensur,[1] Francisco Garcia Soriano.[1] *[1]Nephrology, University of São Paulo, São Paulo, SP, Brazil.*

Background: Dialyzers reuse (DR) is common practice in the United States and South America, but has been decreasing in several countries in Europe. The dialyzer reuse-associated mortality is still controversial, and the main reason for this continuing practice is economical. The effect of DR on oxidative stress and inflammation was not well investigated. Here, we evaluated whether there is any effect of DR on oxidative stress and inflammation markers in patients on hemodialysis (HD). Also, N-acetylcysteine (NAC) was tested for possible protective effect on patients submitted to DR.

Methods: We studied 29 patients on high-flux polysulfone membrane HD. Membraneswere reprocessed with hydrogen peroxide. We collected blood samples at baseline (patients on reuse) and at the end of each period (single use; reuse again and reuse plus NAC) for determination of serum thiobarbituric acid reactive substances (TBARS), superoxide dismutase (SOD), glutathione (GSH), albumin, interleukin 6 (IL6), ultrasensitive CRP (uCRP).

Results: TBARS was higher on single use period. All other variables showed no significant difference.

Variables (Mean ± SD)	Reuse	Single Use	Reuse	Reuse+ NAC	P value
TBARS, nmol / ml	7,27±5,47	11,24±4,95	9,90±6,45	7,12±4,99	0,002
uCRP, mg/L/L	3,69±3,43	6,60±8,15	5,26±6,95	5,01±6,38	0,136
GSH, μM/L	0,43±0,78	0,64±1,69	0,83±2,11	0,92±2,35	0,243
SOD ,U/mL	1,71±0,07	1,72±0,09	1,73±0,09	1,69±0,10	0,227
IL 6, pg/dL	6,50± 4,95	9,37± 10,94	6,87±5,99	8,93±8,57	0,053
Albumin, g/dL	4,24±0,29	4,21±0,31	4,25±0,33	4,14±0,20	0,069
KT/V standard	1,47±0,31	1,39± 0,21	1,37±0,21	1,38±0,26	0,108
Serum iron, mg / dL	65,03±22,61	63,48±23,79	62,72±29,72	60,21±19,01	0,775
Ferritin, ng / mL	645,5±358,6	571,5±483,7	559,3±440,0	598,8±468,9	0,271

Conclusions: These findings indicate that DR may provide an improvement on oxidative stress. The single use was even associated with higher oxidative stress. We found no additional benefit of NAC.

Funding: Government Support - Non-U.S.

TH-PO685

In Vitro Results for a Novel Device Designed for Selective Removal of Blood Phosphates in Hemodialysis Melanie S. Joy,[1] Quan Shi,[2] Michael Jolly,[2] Marian Mccord.[2,3] *[1]School of Medicine and Pharmacy, University of North Carolina, Chapel Hill, Chapel Hill, NC; [2]TECS, North Carolina State University, Raleigh, NC; [3]Joint Department of BME, UNC and NCSU, Raleigh, NC.*

Background: Hyperphosphatemia is prevalent in ~90% of hemodialysis patients and is linked to significant morbidity and mortality. Despite dietary modifications and oral phosphate binder therapy, 50% of patients fail to normalize blood phosphate levels to 3.5 to 5.5 mg/dL. The current abstract describes *in vitro* study results from a new technology being formulated as a medical device (the PHOSFILTER) to reduce blood phosphate levels during the hemodialysis procedure.

Methods: The efficiency of selective phosphate removal by the adsorptive material was tested in phosphate buffer solutions (concs 1- 10 mg/dL, pH=7.8), porcine plasma and bovine blood, respectively. Phosphate adsorption of the adsorbent material was tested up to 4 hours at 37°C. Phosphate concentrations were measured by a colorimetric assay kit for buffer solution and plasma or by the hospital lab for bovine blood with assessment of complete blood counts and chemistries to evaluate safety. The adsorptive material was then placed into the PHOSFILTER and evaluated in a simulated hemodialysis circuit to study phosphate adsorption over time.

Results: The PHOSFILTER adsorption material showed an adsorption capacity of 28 to 32 mg/g in buffer solution. Significant phosphate reduction (50-60%) was also observed in plasma and blood. Serum calcium was decreased by ~30%. No changes were noted in serum albumin, total protein, chloride, potassium, sodium or magnesium. No changes in red blood cell, white blood cell, or platelet counts were documented. In the studies performed in a simulated hemodialysis circuit, the phosphate level of bovine blood was reduced by 42% after 240 minutes.

Conclusions: The *in vitro* studies with the PHOSFILTER adsorbent material demonstrated high capacity, selectivity, and safety for removing phosphates from blood and plasma. Studies are ongoing to assess blood phosphate kinetics during combined use of a dialyzer and PHOSFILTER. Future studies are planned to assess the efficacy, utility, and safety in vivo.

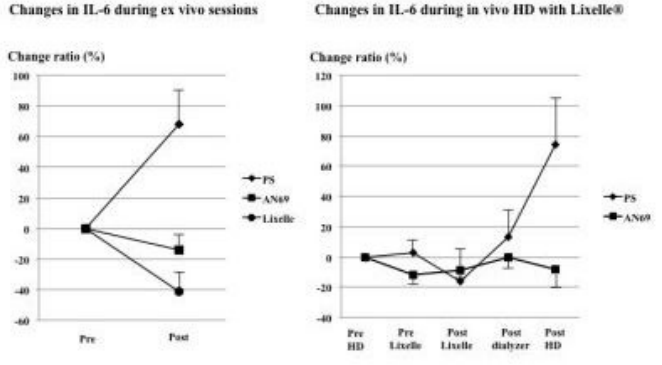
The Synergy Effect on Inflammatory Cytokines of Adsorbent Column for β2-Microglobulin and AN69 Membrane Takahiro Kuragano, Takeshi Nakanishi. *Internal Medicine, Division of Nephrology and Dialysis, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan.*

Background: Lixelle, an adsorption column, has been developed for the elimination of β2-microglobulin(MG) has been reported to remove other substance such as IL-6. AN69 also removed various cytokines by its negative charge at the surface of membrane. We estimated the synergy effect on inflammatory cytokines during hemodialysis(HD) with Lixelle using polysulfone(PS) or AN69.

Methods: EX vivo study: Mini-modules were made using PS, AN69, and Lixelle. 50 mL of whole blood was circulated for 2h in microcircuit through mini modules without dialysate compartments. Blood samples were drawn at 0 and 120min, and measured IL-6, and TNF-α. All experiments were repeated thrice. In vivo study: 5 HD patients were treated using PS with Lixelle, while 5 HD patients were treated using AN69 with Lixelle. IL-6 and TNF-α levels were measured at start and 15 minute, and the end of HD session. Blood samples were also collected in the circuit between Lixelle and PS or AN69(I) and after PS or AN69(A).

Results: There were no significant differences in TNF-α levels during EX vivo sessions with PS and Lixelle. IL-6 levels significantly decreased after EX vivo session with AN69 and lixelle, while, IL-6 increased with PS. TNF-α levels significantly decreased after HD with Lixelle using either PS or AN69 in vivo study. IL-6 levels significantly decreased at collection (I), however, using PS, it significantly increased at collection (A) and at the end of HD session. On the other hand, there was no significant increase in IL-6 levels during HD with Lixelle using AN69.



Conclusions: IL-6 was adsorbed to both Lixelle and AN69. PS significantly increased IL-6 levels while, the removal rate of β2MG is significantly lower in AN69 than PS. Therefore combination therapy of Lixelle and AN69 could effectively remove the β2MG and inflammatory cytokines.

TH-PO687

Results of Initial U.S. Mid-Dilution On-Line Hemodiafiltration Clinical Trial Leonard Stern,[1] Gregory Collins,[2] James Summerton.[2] *[1]Medicine/ Nephrology, Columbia University Medical Center, New York, NY; [2]Research and Development, Nephros, Inc, River Edge, NJ.*

Background: Hemodialysis (HD) is primarily a diffusive process with limited convective capability. Mid-dilution HDF is a unique configuration that optimizes convective and diffusive clearance in a single mid-dilution HDF filter (Nephros OLpur MD 220). The Nephros H_2H Module, when coupled with a conventional UF-controlled HD machine with ultrapure dialysate, and the Nephros MD 220 HDF filter are all the necessary components needed to perform on-line mid-dilution HDF therapy in the USA. Substitution fluid is produced on-line when the H_2H Module draws off a portion of fresh dialysate and passes it through its unique on board dual-stage ultrafilter producing a dialysate for infusion meeting AAMI RD52:2004 requirements.

Methods: A multicenter, prospective, non-randomized clinical trial was conducted to assess the safety and efficacy of on-line mid-dilution HDF using the Nephros OLpur MD 220 HDF Filter and H_2H Module compared to high flux HD. Adverse events, adverse symptoms and blood chemistries, including β_2-microglobulin (β_2m) and dialysis adequacy markers, were monitored. Dialysate and infusion fluid were evaluated for compliance with AAMI quality standards for bacteria and endotoxin. For 4 weeks, each patient received their normal 3X weekly high flux HD (control period). For the next 12 weeks, each patient underwent mid-dilution HDF with the H_2H Module and MD 220 HDF Filter (test period). The dialysis prescriptions (treatment times, blood and dialysate flow rates) were unchanged between the two periods. 28 and 23 patients completed the control and test period, respectively.

Results: There was no difference in adverse symptom or adverse event rates between HDF vs. HD (p=NS). For HDF vs HD, the mean Alk P decreased from 129.7 units/l to 121.5 units/l (p=0.019), the mean β_2m decreased from 37.3 mg/l to 30.3 mg/l (p=0.0016), and the β_2m reduction ratio increased from 57.1% to 79.7%. (p<0.001).

Conclusions: There are significant biochemical benefits associated with mid-dilution HDF compared to high flux HD. Longer term studies to fully assess the potential clinical benefits of mid-dilution HDF are needed.

TH-PO688

Role of Residual Renal Function in the Clinical Management in Hemodialysis Patients Sonoo Mizuiri,[1] Yoshiko Nishizawa,[1] Kazuomi Yamashita,[1] Touru Nakazono,[1] Kohji Usui,[2] Kenichiro Shigemoto.[1] *[1]Nephrology, Ichiyokai Harada Hospital, Hiroshima, Japan; [2]Nephrology, Ichiyokai Ichiyokai Clinic, Hiroshima, Japan.*

Background: The relationship between residual renal function (RRF) and improved phosphate and anemia control in HD patients has been reported.

Methods: We evaluated clinical data associated with RRF in 354 incident HD patients. Inclusion criteria were thrice weekly, 4 h HD using a high-flux dialyzer. GFR was calculated as (Ccr and Curea)/2 with 24 h urinary samples in patients with urinary output ≥100 ml/day (n=75), and urinary output <100 ml/day (anuria) for 279 patients. Univariate comparisons and multivariate comparisons with SPSS II were performed.

Results: There were significant differences in median values for duration of dialysis (23.0 vs. 95.1 months, P<0.001), prevalence of DM (45.3 vs. 32.6 %, P<0.05), predialysis diastolic blood pressure (77 vs. 81 mmHg, P<0.05), cystatin C (6.09 vs. 7.49 mg/L, P<0.001), ß2-microglobulin (ß2MG) (22.0 vs. 28.8 mg/L, P<0.001), calcium (Ca) (8.8 vs. 9.4 mg/dl, P<0.001), and nPCR (0.78 vs. 0.86 g/kg/day, P<0.01) in patients with RRF vs. anuric patients. However, there were no significant differences in age, water removal, CTR, the use of ACEI or ARB, PTH, Hb, phosphate, serum albumin, erythropoiesis stimulating index, high-sensitivity CRP, and Kt/Vurea in the groups. On univariate comparisons, DM, duration of dialysis, predialysis systolic blood pressure, water removal, cystacin C, β2MG and Ca were associated with urinary output. A multivariate comparison found a significant effect for duration of dialysis, ß2MG and cystacin C on urinary output. In univariate analysis, duration of dialysis, water removal, cystacin C, ß2MG, Ca, phosphate, serum albumin, K/ Vurea and nPCR were associated with (Ccr+Curea)/2. A multivariate comparison found a significant effect only with serum albumin on (Ccr+Curea)/2 and a correlation between (Ccr+Curea)/2 and serum albumin was observed (r=-0.49, P<0.001).

Conclusions: A relationship between urinary output and ß2MG and cystacin C was observed in this study. However, no relationship was observed between RRF and phosphate control or anemia, and maintenance of RRF may worsen hypoalbuminemia in proteinuric HD patients.

Funding: Private Foundation Support

TH-PO689

Cystatin C and β2-Microglobulin as Plasma Markers of Residual Renal Function in Hemodialysis Enric Vilar,[1,2] Capella Boltiador,[1] Ashwini Machado,[1] Adie Viljoen,[1] Ken Farrington.[1,2] *[1]Renal Unit, Lister Hospital, Stevenage, United Kingdom; [2]University of Hertfordshire, Hatfield, United Kingdom.*

Background: Residual Renal Function (RRF) is an important predictor of outcomes in peritoneal and hemodialysis(HD). Measurement of RRF in HD is useful for ensuring that minimum clearance targets are achieved but urine collection is inconvenient and expensive. We studied the potential use β2-microglobulin and cystatin C as plasma markers of RRF.

Methods: Patients on high-flux HD or hemodiafiltration were recruited. Over two consecutive HD sessions (HD1, HD2), blood was drawn pre and post-HD1 and pre-HD2 and analysed for urea, creatinine, cystatin C and β2-microglobulin. Inter-dialytic urine collection allowed GFR estimation (mean of urea and creatinine clearance). Relationship between β2-microglobulin and cystatin C plasma levels and RRF were examined. Receiver Operating Characteristic(ROC) curves were used to determine whether pre-dialysis middle-molecule levels may identify those with significant RRF.

Results: 341 subjects were recruited(111 high-flux HD and 230 on-line HDF). Mean Kt/V was 1.33±SD0.22 and dialysis time 190mins±SD32. Urea and creatinine clearance correlated closely(r^2=0.78). The parameter best correlating with GFR, urea and creatinine clearance was 1/pre-HD1 β2-microglobulin(r^2 0.67, 0.57 and 0.68 respectively). 1/pre-HD1 cystatin C level correlated less well(r^2=0.50, 0.44, 0.48 for GFR, urea and creatinine clearance respectively). The inter-dialytic cystatin C and β2-microglobulin rise correlated less well with GFR. Regression equations for GFR based on pre-HD1 cystatin C and β2-microglobulin levels were derived.Using ROC analysis we determined that pre-HD β2-microglobulin <19.2mg/L identified those with >2ml/min/1.73m^2BSA urea clearance with a 10% false positive rate but poor sensitivity(65%).

Conclusions: Pre-HD β2-microglobulin and cystatin C correlate closely with RRF but urea and creatinine are poor indicators. Regression equations for RRF based on pre-HD β2-microglobulin and cystatin C have been derived. Cutoff β2-microglobulin levels identify those with significant RRF. Use of plasma RRF markers may be useful as clinical or research tools and could be performed routinely in HD.

Effect of Lower Dialysate Bicarbonate Concentration on Pre-Dialysis Alkalosis in Patients on Maintenance Hemodialysis Anip Bansal, Pablo A. Casares, Clinton Colaco, Marcelo R. Barrios Gini, Ira S. Meisels. *Medicine, St Luke's Roosevelt Hospital Center, New York, NY.*

Background: The possible deleterious effects of acidemia in patients with End Stage Renal Disease(ESRD) have led to the emphasis on the avoidance of metabolic acidosis by the use of a high alkali concentration in dialysates. Recent studies have highlighted the association of high Pre-Dialysis Bicarbonate(PDB) i.e. >27 mmol/L with higher mortality and risk for cardiac arrest. The objective of this study was to assess the effect of the use of lower dialysate bicarbonate(DB) concentration on PDB levels.

Methods: This was a retrospective study from a single, urban dialysis center where the DB was decreased from 35 mmol/L to 33 mmol/L in January 2012. The medical charts of all patients on HD at any time between September 2011 & May 2012 were screened and all the PDB levels extracted. After exclusion of patients who did not have monthly test results, the means of the PDB levels before and after the intervention were compared using the paired t-test.

Results: A total of 170 HD patients' records were reviewed. The distribution of various PDB levels is summarized in the table below.

Frequency distribution of patients based on incremental PDB levels

PDB (mmol/L)	Mean % Patients while on Higher DB	Mean % Patients while on Lower DB	p value
0-18	4.20	6.21	0.23
18-22	25.42	37.62	0.19
0-22 (i.e. Acidosis)	29.62	43.83	0.19
22-26	55.92	47.50	0.19
26-30	13.13	8.26	0.25
>30	1.33	0.41	0.05
>26	14.46	8.67	0.23

The mean percentage of patients with acidosis (PDB<22 mmol/L) before and after was 29.03% (SD= 9.43) and 43.83% (SD =10.26) ; and of those with alkalosis(PDB>26 mmol/L) was 12.4% (SD= 5.6) and 8.67% (SD= 3.68) respectively. These differences were statistically not significant. There was a significant difference in the mean PDB before (Mean= 23.52 mmol/L, SD=2.01) and after the intervention (Mean=22.9 mmol/L, SD=2.09).

Conclusions: A reduction in the DB concentration lead to an expected decline in the PDB levels. There was a statistically insignificant trend towards increased incidence of pre-dialysis acidosis and decreased incidence of pre-dialysis alkalosis.The optimal DB concentration and PDB levels are unknown.

TH-PO691

In Acidotic Hemodialysis (HD) Patients, Mid-HD Alkalosis Occurs Even on 33.5-34 mEq/L and More on 40 mEq/L Dialysate Bicarbonate (BIC) Concentration, due to Large Initial 2 Hours Increase in Serum BIC Level (SBIC) Inversely Correlated with Pre-HD SBIC David Tovbin,[1] Seungjin Kim,[3] Lone Solling Avnon,[2] Moshe Zlotnik.[1] *[1]Nephrology, Soroka Medical Center; [2]Pulmonary, Soroka Medical Center; [3]Medical School for International Health, Ben-Gurion University; [4]Biomedical Engineering, Ben-Gurion University, Beer-Sheva, Israel.*

Background: Acidosis correction in hemodialysis (HD) is beneficial for outcome. However, NKF-K/DOQI guideline of pre-HD serum bicarbonate (BIC) level (SBIC) ≥22 mEq/L is frequently not achieved, since BIC-transfer increases end-HD SBIC but SBIC falls afterwards frequently to acidotic range. We hypothesized that in patients with pre-HD SBIC <22 mEq/L ("acidotic") on currently used dialysate BIC concentration (DBIC) of 33.5-34 mEq/L (CDBIC), high DBIC (HDBIC) of 40 mEq/L corrects inter-dialytic acidosis without inducing intra-dialytic alkalosis. Thus, intra-dialytic serum BIC changes and their relation with pre-HD SBIC on HDBIC vs CDBIC were assessed.

Methods: In a prospective bi-center study, 15 patients were assessed for 3-week periods on CDBIC and afterwards HDBIC. Blood gases & electrolytes were assessed weekly at start, after 2 hours (mid-HD) and end of HD. Data is presented as mean±SD. Statistical evaluation used non-parametric tests.

Results: On CDBIC, pre-HD & mid-HD SBIC were 21.5±2.7 and 27±1.9 mEq/L, respectively. Initial 2 hours SBIC increase (Δ2h) was 5.5±1.9 mEq/L and inversely correlated with pre-HD SBIC (r=-0.71,p<0.005). Mid-end SBIC increase (lateΔ) was 1.3±2 mEq/L. On HDBIC, pre-HD & mid-HD SBIC were 24.7±2.3 and 33.2±2 mEq/L, respectively. Δ2h was 8.5±1.7 mEq/L and inversely correlated with pre-HD SBIC (r=-0.85,p<0.05). LateΔ was 1.75±2 mEq/L. In the 8 acidotic patients, on CDBIC pre-HD, mid-HD & end-HD SBIC were 19.3±1.5, 26±2 and 28±2.9 mEq/L and on HDBIC 24±2.6, 33.2±2.4 and 34.9±3.2 mEq/L, respectively.

Conclusions: HDBIC corrects inter-dialytic acidosis. However, acidotic patients develop mid-HD alkalosis even on CDBIC and augmented intra-dialytic alkalosis on HDBIC, in line with inverse correlation of Δ2h with pre-HD SBIC. DBIC individualization, gradual increase between sessions & intra-dialytic changes may be suggested.

TH-PO692

Comparison of Techniques of Fluid Assessment in Hemodialysis Patients Flavio Basso, Sabrina Milan Manani, Dinna N. Cruz, Alessandra Brendolan, Monica Zanella, Catarina Teixeira, Claudio Ronco. *Department of Nephrology, St Bortolo Hosp, Vicenza, Italy.*

Background: Because volume status assessment is critical in hemodialysis (HD) patients, several methods have been developed to ascertain this parameter. Bioimpedence by Body Composition Monitor (BCM) is a validated method, B-type natriuretic peptide (BNP) levels increase with fluid overload (FO), ultrasound (US) Lung Comets Score (LCS) have a linear correlation with the extravascular lung water and inferior vena cava diameter (IVCD) US reflects volume status. We aim at comparing these four methods in the optimisation of UF prescription and dry weight estimation in HD.

Methods: We evaluated weight, BCM (L), LCS, ICVD (mm) during inspiration (IVCDmin) and expiration (IVCDmax), Collapsibility Index (IVCCI) and BNP (pg/mL) before and after HD in 31 patients. US measurements were performed by two trained operators with the same device.

Residual overload (RO) was calculated by the difference between BCM before HD and weight loss by HD. Overhydration (OH) was considered if RO after HD was >0.5.

Results: There was a significant reduction in mean BCM (1.7±1.8 to 0.0±1.8 p<0.001), in mean LCS (20±11.5 to 12.8±7.1 p<0.001), in mean IVCDmin (9.6±3.8 to 7.0±3.3 p<0.001), in mean IVCDmax (11.8±4.9 to 9.3±4.1) and in mean BNP(621.0±847.0 to 436.4±644.2) after HD. Less significant reduction was observed in IVCCI (p=0.13).

There was a significant correlation between BCM and LCS, BNP, IVCDmin and IVCDmax (p<0.05) before and after HD.

Between OH (n=5) and non-OH (n=26) groups, there was a significant difference in LCS (p<0.001), IVCDmin (p=0.019) and IVCCI (p=0.001). No differences were found for BNP and IVCDmax.

Conclusions: All parameters showed a significant decreasing trend along HD session. Assuming BCM as a standard, all others methods were statistically correlated before and after HD, allowing to assess possible residual FO. Both LCS and IVCD are reliable and useful techniques that should be considered for monitoring volume status and prescribing UF in HD patients.

TH-PO693

Radioistope Blood Volume (BV) Measurement in Conjuction with Crit-Line (CLM-III) in Hemodialysis (HD) Patients Jun-Ki Park, Aditya Mattoo, Frank Modersitzki, David S. Goldfarb. *Nephrology, NYVAMC & NYUSoM, New York, NY.*

Background: Accurate assessment of the BV and distribution of body fluids is essential for prescribing HD and for reducing complications related to hypovolemia and volume overload. Monitoring relative changes in BV using hematocrit (Hct), e.g. CLM-III, an indirect method, cannot be used to determine the absolute levels of BV. Here we report the first study of isotope BV measurement (IBVM) for assessing volume status in HD patients using indicator dilutional method.

Methods: 10 adult HD patients were enrolled in this prospective observational study. Multi-point IBVM before and after HD was performed using BVA-100 (Daxor, New York, NY). BVA-100 calculates BV with an accuracy of ±2.5%, by using <25μCi of iodinated I-131 albumin. It assumes normal BV for a given individual on the basis of patients' deviation from ideal body weight. Fluid loss from the extravascular component of the extracellular space (EV) was calculated by subtracting absolute BV change from total weight loss. Intradialytic relative BV changes were measured by CLM-III during the same HD session. Bland-Altman plot was used to compare relative BV change pre- and post-HD by IBVM and CLM-III.

Results: 8 of 10 cases had significant hypervolemia, 2 cases were normovolemic. The range of BV variation from predicted normal was 156ml to 1990ml. Higher pre-HD BV was associated with lower pre-HD albumin and higher pre-HD BNP. Significant interindividual differences in EV fluid loss ranged from 54% to 99% of total weight loss. In 8 of 10 patients Bland-Altman plot showed excellent agreement in the measurement of relative BV by IBVM and CLM-III with a mean difference of -0.8% ± 3.2% (mean ± SD) and the 95% CI -7.21% to 5.51% (p=NS).

Conclusions: IBVM is useful to determine absolute BV and changes in BV and correlates with CLM-III measurements. Fluid removal from EV space can be calculated based on absolute BV changes to describe individual refilling ability. This may prove useful in prescribing and monitoring ultrafiltration (UF) rates and establishment of optimal BV in HD patients. More accurate prescription of UF has the potential to reduce the morbidity and mortality associated with chronic HD.

TH-PO694

Accuracy of Whole and Segmental Bioimpedance Measurements to Assess Extracellular Volume in Hemodialysis Patients Samer Rateb Abbas,[1,2] Fansan Zhu,[1] Peter Kotanko,[1] Nathan W. Levin.[1] *[1]Nephrology, Renal Research Institute, New York, NY; [2]Nephrology, Beth Israel Medical Center, New York, NY.*

Background: If estimation of extracellular fluid volume (ECV) is accurate, the divergence between ultrafiltration volume (UFV) and change in the ECV (ΔECV) during HD should approximate zero. The aim of this study was to compare the whole body (wBIS) and segmental bioimpedance spectroscopy (sBIS) techniques in HD patients in terms of this divergence.

Methods: wBIS and sBIS (arm, trunk and leg) were performed simultaneously pre and post-HD on chronic HD patients using a a Hydra 4200 (Xitron technologies). ECV_{wBIS} (De Lorenzo, JAP 1997) and sum of ECV_{sBIS} (Zhu F, JAP 2006) were calculated pre- and post HD. ΔECV_{wBIS} and ΔECV_{sBIS} were obtained. Bland-Altman plots were used to compare the divergences obtained by wBIS and sBIS.

Results: 45 patients (53% males, age 62.6±14.5 year) were studied twice. Intradialytic weight loss was significantly decreased (ΔWt, 2.62±0.96 kg, p<0.01) and UFV was 2.7±0.92 L. Significant difference in the same patients at the same time between ΔECV_{wBIS} and ΔECV_{sBIS} (2.29±0.75 vs 2.83±0.89 L, p<0.001) was observed. Correlations (R^2) of UFV to ΔECV_{wBIS} and to ΔECV_{sBIS} were 0.72 and 0.73 respectively. Bland-Altman plots show the bias (divergences) in sBIS significantly (-0.14±0.48 vs 0.41±0.49 L, p<0.001) lower than in wBIS.

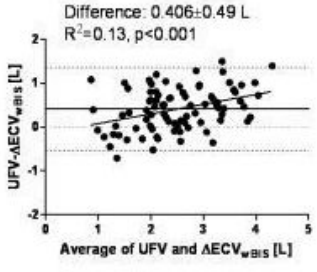

Fig. 1

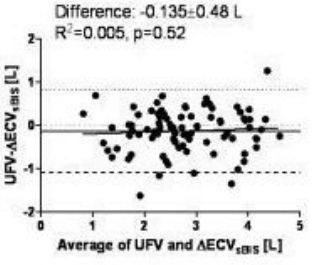

Fig. 2

In addition, the slope of the regression line was significant (p<0.001) with wBIS.

Conclusions: Study shows change in ECV by wBIS was significantly underestimated with proportional bias. This did not occur with use of sBIS. This error could be due to the incorrect assumption that the whole body can be modeled as a cylinder with uniform conductivity because in the trunk, resistance does not reflect its fluid volume. sBIS calculates ECV separately in each segment so that total ΔECV by sum of segments is close to UFV.

TH-PO695

The Role of Acetate-Free Biofiltration (AFB) on Hypotension and Nurse Workload Piergianni Calzavara,[1] Denis Steckiph,[2] Biagio Polverino,[1] Niloufar Tadayyon,[1] Giulia Adriana Nicolai,[1] Alessandro Ciavatti.[1] *[1]Conegliano's Hospital, Italy; [2]Gambro Hospal, Italy.*

Background: Intradialytic hypotension (IDH) is still the most common acute complication in hemodialysis (HD) patients and occurs in approximately 20% of patients on dialysis. The AFB is a dialysis treatment that can reduce the occurrence of IDH, eliminating the undesirable effects of acetate, customizing the control of acid-base and reducing the inflammatory status in ESRD patients. The purpose of this study was to evaluate if AFB therapy is able to reduce the load and the complexity of the work of the nursing staff associated to IDH.

Methods: Seven hypotension-prone patients (IDH monthly frequency> 40%), were selected for the study. In each patient 42 sessions in HD standard (control) and 42 AFB (intervention) were performed. The monitored variables were: number of sessions complicated by hypotension, number and type of nursing interventions, weight loss, blood pressure and heart rate pre and post dialysis. All treatments were performed with Integra and ARTIS dialysis machines (Gambro Dasco, Italy).

Results: The two treatments were found similar on the main dialytic parameters (UF: HD 2.3±0.8, AFB 2.1±0.6 L, p=0,386; Td: HD 218±221, AFB 21±22 min, p=0,189; Qb: HD 282±25, AFB 279±26 ml/min, p=0,583), except for the convective volume (HD 2.3±0.8, AFB 9.6±1.2 L, p<0.0001). The number of dialysis sessions with IDH was reduced by about 70% in treatment AFB (from 191 to 62, p<0.0001). In AFB the nursing workload was coherently reduced for all types of intervention: saline infusion (from 129 to 46, p<0.0001), infusion of NaCl 20mg (from 77 to 23, p<0.0001) and Stop UF (from 103 to 23, p<0.0001).

Conclusions: Our results confirm the usefulness of therapy AFB in the reduction of IDH frequencies in haemodynamically unstable patients, leading to a reduction of the load and the complexity of nursing work.

TH-PO696

Prediction of Intradialytic Morbid Events in Chronic Hemodialysis Patients Fansan Zhu, Peter Kotanko, Stephan Thijssen, Nathan W. Levin. *Research, Renal Research Institute, New York, NY.*

Background: Intradialytic morbid events (IME) complicate over 30% of all hemodialysis (HD) sessions because no reliable method is available to predict these. The aim of this study was to explore hemodynamic indicators to predict IME.

Methods: We reduced post-HD target weights systematically in chronic HD patients to achieve dry weight defined by calf bioimpedance spectroscopy (DW_{cBIS}). Systolic and diastolic blood pressure (SBP, DBP) and heart rate (HR) were measured every 10 minutes during HD. In addition, we calculated the SDH [min / beat] = (SBP/DBP)/HR at the same time points. IME were defined as low blood pressure (SBP<90 mmHg), or muscle cramps or dizziness during HD. SDH_{IME} denotes the nadir SDH prior to IME. Ultrafiltration rate (UFR) was recorded.

Results: 45 HD patients were studied during a total of 245 HD sessions. IME occurred in 124 sessions (51%). Pre-HD SBP, DBP, HR and UFR did not separately differ between sessions with and without IME (Table 1). SDH_{IME} was lower in the same sessions with IME (0.017±0.001 vs. 0.023±0.004, min/beat, p<0.001). SDH_{IME} was lower than average SDH in non IME sessions (0.017±0.001 vs. 0.024±0.005, min/beat, p<0.001). An SDH criterion defined as mean+2SD of SDH_{IME} (0.017+0.001*2=0.019) of <0.019 min/beat resulted in a sensitivity of 69 % and specificity of 57 % for prediction of IME. On average SDH_{IME} preceded an IME by 31 minutes (Interquartile range 7 to 55 min).

Conclusions: Physiologically, a blood pressure drop results in a HR rise. Absolute levels of SBP, DBP and HR vary greatly among HD patients while the SBP / DBP ratio shows less variability. The SBP / DBP ratio over HR may provide an improved signal-to-noise ratio to indicate intravascular hypovolemia and thus herald IME more accurately compared to the three components individually. Prospective studies in diverse populations of HD patients are required to further explore the clinical utility of SDH.

Table 1

	Pre-HD Weight, kg	Post-HD Weight, kg	Pre-HD SBP, mmHg	Pre-HD DBP, mmHg	Pre-HD HR, beat/min	SDH, min/beat	Ultrafiltration rate, mL/h

TH-PO697

Is There a Gold Standard for Measuring Dry Weight in Hemodialysis Patients? Fansan Zhu, Peter Kotanko, Nathan W. Levin. *Research, Renal Research Institute, New York, NY.*

Background: Dry weight (DW) has classically been assessed by clinical signs including blood pressure (SBP) changes and hypotensive symptoms. Many techniques, such as calf bioimpedance spectroscopy (cBIS) and relative blood volume (RBV), have been applied to assess dry weight. Our aim was to evaluate relationships of SBP, cBIS and RBV with progressive reduction of fluid status towards DW.

Methods: In 64 patients post HD weight was gradually reduced until DW (DW_{cBIS}) was obtained by two criteria: 1) flattening of the curve of change in calf resistance during HD and 2) reaching a normal range of calf normalized resistivity (CNR) post HD. cBIS (Hydra 4200) was continuously performed during HD. Patients who did not reach DW_{cBIS} by three months or quit the study were categorized as no DW (NDW).

Results: 32 patients (440 sessions) reached DW_{cBIS} and 32 patients (286 sessions) were NDW (Table 1). Pre and post Wt decreased between baselines (BL) and DW or NDW. CNR at DW reached the normal range (m: 18.5, f: 20, $Ohm*m^3/kg\ 10^{-2}$) but not at NDW. SBP was higher at NDW than in DW but decreased in both groups. RBV changes did not differ significantly between BL and at DW or NDW. The number of measurements at DW was higher than at NDW (13.8±7 vs 6.9±3.3 sessions, p<0.001).

Conclusions: 32 patients using two separate criteria (Zhu et al, Physiol Meas 2008) reached DW_{cBIS} after approximately 14 sessions. NDW patents with higher SBP and presumably more fluid overload did not reach DW_{cBIS} in about 7 sessions. RBV change in two groups did not reflect fluid status. We propose that the combination of the two criteria above may be considered currently as a candidate for a gold standard for assessment of DW.

Table 1

	Pre HD Wt, kg	Post HD Wt, kg	Pre HD SBP, mmHg	Post HD SBP, mmHg	Pre HD CND, Ohm*m^3/ kg*10^-2	Post HD CND, Ohm*m^3/ kg 10^-2	RBV. %
BL	75.1±15	72.3±15	127.1±18	122.6±22	14.4±2.3	18.1±3	84.5±6

Comparison and Reproducibility of Three Methods for Volume Assessment in Hemodialysis Patients Sabrina Milan Manani, Flavio Basso, Dinna N. Cruz, Alessandra Brendolan, Federico Nalesso, Claudio Ronco. *Nephrology, San Bortolo Hospital, Vicenza, Italy.*

Background: The assessment of fluid overload is critical in hemodialysis (HD) patients. It can be done using bioimpedance or ultrasonography (US) of inferior vena cava (IVC). Recently, lung US has also been shown to be useful to assess extravascular lung water. However, all ultrasound methods are somewhat operator dependent, precluding their generalized use. Our aim was to establish the reproducibility and ease of performance of these three techniques.

Methods: Two certified sonographers measured the following parameters in 28 stable HD patients in a blinded fashion: IVC diameter during inspiration (IVCDmin) and expiration (IVCDmax), Collapsibility Index(IVCCI) by US; lung comet score (LCS) by US; and overhydration by Body Composition Monitor (BCM). Subjects were also classified into 3 levels of hydration based on established cut-offs of IVCDmax, IVCCI and LCS. Correlation and agreement between the 2 observers were evaluated by Spearman correlation and kappa test, respectively.

Results: Correlation between the 2 observers were good to excellent for all US parameters: LCS (r=0.99) (Fig. 1), IVCDmax (r=0.85) (Fig.2), IVCDmin (r=0.95), IVCCI (r=0.93) (p<0.001 for all). The agreement for IVCDmax and IVCCI categories was good (k=0.79 and 0.78, respectively, p<0.001 for both), while that for LCS categories was perfect (k=1.0). Similarly, correlation between 2 observers of BCM overhydration was excellent (r=0.99 p<0.001). IVC US and lung US were considered both easy and quick to perform. Median time was 2.5 (IQR 2,3) min for IVC US and 6 (IQR 5,7) min for lung US.

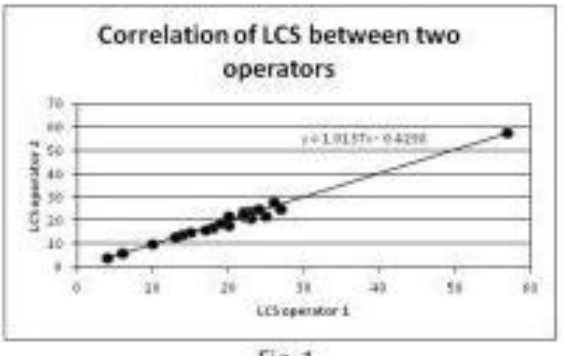

Fig. 1

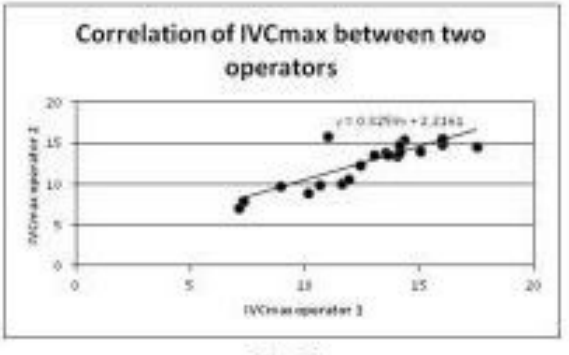

Fig. 2

Conclusions: The reproducibility of measurements from IVC US, lung US and BCM between two trained operators were very good. All methods were quick and easy to perform.

TH-PO699

Monitoring Intracellular, Intersititial and Intravascular Volume Changes during Dialysis Susie Q. Lew,[1] Manuel T. Velasquez,[1] Leslie Montgomery,[2] Wayne A. Gerth,[2] Richard W. Montgomery.[2] *[1]Medicine, George Washington University, Washington, DC; [2]LDM Associates, San Jose, CA.*

Background: Clinicians need to be able to measure the volume in the intravascular, interstitial, and intracellular compartments with a non-invasive real-time device. The aim is to test the feasibility and validity of a novel electrical impedance spectroscopic (EIS) technique that permits on-line measurements of compartmental volume changes in human subjects.

Methods: EIS technique validation was performed during 3 consecutive HD treatments in 20 ESRD patients by analyzing the timed profiles of fluid redistribution to mathematically derive *post hoc* hematocrit profiles. These profiles were then compared to the simultaneously measured hematocrit values recorded independently using the CritLine® monitor. Regression and Bland Altman analyses were used to compare the EIS data and Critline® hematocrits at sequential times during 60 routine HD sessions.

Results: The statistical and graphical evidence confirms that the EIS system reliably monitors the continuous and real-time *rates of change* of the fluid volumes of the three compartments. An example of one profile is shown in Figures 1 and 2.

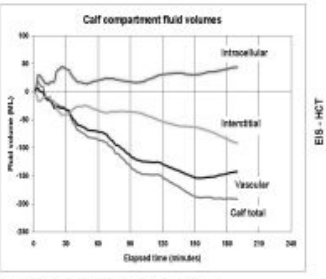

Figure 1. Kalman-smoothed fluid compartment volumes relative to initial values.

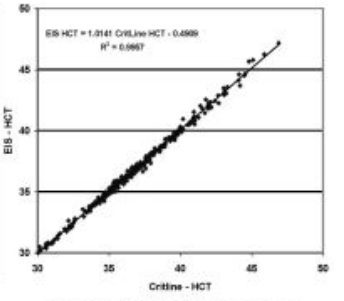

Figure 2. Correlation between optical sensor hematocrits (CritLine-HCT) and values predicted from EIS (EIS-HCT) measurements at 30, 60,90, 120 min elapsed time and from the last minute of the dialysis period.

Conclusions: The present study demonstrates for the first time that the EIS method can reliably provide on-line continuous measurements of compartmental intravascular, interstitial, and intracellular fluid volume changes that occur during HD treatment. Such information may prove valuable in the diagnosis and management of changes in body fluid balance in clinical situations such as hemodialysis, volume resuscitation or diuretic therapy.

TH-PO700

Blood Volume Monitoring Prevents Intradialytic Hypotension: A Pilot Study Anita Saxena, Raj K. Sharma, Amit Gupta. *Nephrology, SGPGIMS, Lucknow, Uttar Pradesh, India.*

Background: During dialysis, maintenance of blood pressure is related to two mechanisms, blood volume preservation and cardiovascular compensation. Arterial hypotension occurs when central hypovolemia causes an underfilling of the cardiac chambers, thereby compromising the circulatory load. Objectiive: Estimation of blood volume during hemodialysis.

Methods: Blood Volume (BVM) and Blood temperature(BTM) was monitored on 12 non diabetic ESRD patients on MHD who were prone to intradialytic hypotension. Plasma and water compartments were evaluated using bioelectrical impedance analysis.

Results: Patients, moderately malnourished, had not achieved dry weight. Critical relative blood volume was fixed at 90%. Changes in red blood volume and hematocrit were noted during dialysis. Mean Hemoglobin was 7.5 mg%, albumin 3.2 mg, CRP 1.5, KT/V 1.2. Predialysis to post dialysis changes were: Hematocrit changed from 20.2 to 26.5, plasma volume 3.8 to 3.6, TBW 30.4 to 25.5 ECW 18.9 to 14.5, ICW 14.7 to 13.1, plasma 3.8 to 3.4, interstitial fluid, 12.3 to 12.0, blood pressure 138/84HGmm to 131.5/81HGmm. Net ultrafiltratio was 3.2L. Discussion: Results show significant changes in blood volume and water compartments during dialysis. With use of BVM, none of the patients went into hypotension, or had headache and drop in blood pressure despite a net ultrafiltration ranging between 2.0 L to 4.5 L as the ultrafiltration is cut off automatically when the critical levels of blood volume (which was fixed at 90% in this study) and HCT are reached.

Conclusions: Study demonstrates that BVM can prevent intradialytic hypotension and save patient from life threatening condition.

TH-PO701

Rethinking Intradialytic Blood-Pressure: Asymptomatic Short-Term Blood Pressure Variability Is Common Scott Wilson, Eugenia Pedagogos, Gavin J. Becker. *Dept Nephrology, Royal Melbourne Hospital.*

Background: The prognostic significance of asymptomatic blood-pressure (BP) variability to independently predict cardiovascular disease is recognised in non-dialytic populations. BP swings during haemodialysis (HD) are commonly observed, however the magnitude and directions of such changes are usually unprofiled. By convention, intradialytic hypotension (IDH) is defined by a symptomatic absolute drop in systolic BP by 20mmHg, ignoring asymptomatic change and failing to consider the relativity of BP change to an individual patient's baseline.

Methods: We hypothesised that patients on HD would demonstrate significant short-term intradialytic BP fluctuations below symptomatic thresholds.

Systolic BP was continuously recorded by Finometer during standard 4-hour, short-break HD in 26 stable outpatients without clinical history of IDH. All patients underwent concomitant blood-volume monitoring.

Using the continuous BP time series, short-term BP variability was measured against a moving baseline of 500 heart-beat intervals. Dynamic changes in BP >15% (equating a change of 20mmHg at 135mmHg systolic) between sequential intervals defined significant BP variability.

Results: Haemodynamic instability was common, with 299 significant BP changes observed (mean 11/HD treatment). Sudden rises (n=173) in BP were more frequent than acute declines (n=126). Surprisingly no event was associated with a coincident variation in pulse rate. Whole-of-treatment linear trends identified a paradoxical intradialytic rise in BP in 17 (65%) HD sessions. BP variability was not predicted by blood-volume reduction slope, pre-HD electrolytes, renin, aldosterone or NT-ProBNP, dialysate prescription, or by the use of antihypertensives.

Conclusions: This study reveals that significant, clinically silent BP fluctuations are both common and unrecognised in standard HD when defined relative to an individual patient's baseline pressure and intradialytic BP trajectory. Such instability may be associated with the excess of cardiovascular mortality observed in this patient group. Current IDH definitions warrant reconsideration as they may miss these potentially important events by relying on an arbitrary absolute symptomatic BP change.

TH-PO702

The Effect of Oral Ferric Citrate on Intravenous Iron Dose and Serum Iron Markers T. Christopher Bond,[1] Tracy Jack Mayne,[1] Jamie P. Dwyer,[2] Mohammed Sika,[2] Robert M. Niecestro.[3] *[1]DaVita Clinical Research, Minneapolis, MN; [2]Vanderbilt University, Nashville, TN; [3]Keryx Biopharmaceuticals, New York, NY.*

Background: Ferric citrate is a phosphate binder in phase 3 clinical development to treat hyperphoshatemia in patients with end-stage renal disease. In addition to managing patients' serum phosphorus, earlier clinical studies have shown that some iron (Fe) in the drug is absorbed, increasing saturated transferrin (TSAT) and serum ferritin levels.

Methods: A 28-day, phase 2, multicenter open-label study was conducted to assess drug safety and tolerability in dialysis patients. Subjects received starting doses of 4.5 or 6.0 g/day ferric citrate, titrated until serum phosphate was in-range (3.5 to 5.5 mg/dL). The study design allowed concomitant intravenous (IV) Fe for subjects with serum ferritin <500 ng/mL, TSAT <25%, and/or at the discretion of the physician. We conducted a post-hoc analysis to compare the iron storage measures between patients receiving IV Fe prior to the study (visit 0), and those patients who did not receive IV iron prior to the study.

Results: 55 subjects were enrolled. 30 subjects were receiving IV Fe prior to beginning the study, and 25 of these 30 received IV Fe during the study. 5 subjects (17%) who received IV Fe prior to the study were able to discontinue its use while receiving ferric citrate. No subjects without IV Fe at baseline added IV Fe while taking ferric citrate.

	Visit 0 (Day 28)			
	Serum Fe, mcg/dL	Ferritin, ng/mL	*TIBC, mcg/dL	%TSAT
IV Fe at baseline [n=30]				
IV Fe during study [n=25]	67.5 (76.8)	513.9 (586.7)	226.6 (220.5)	30.1 (35.8)
No IV Fe during study [n=5]	61.2 (58.4)	639.8 (674.4)	202.8 (212.4)	29.4 (27.8)
No IV iron at baseline [n=25]				
No IV Fe during study [n=25]	71.2 (77.2)	603.2 (617.8)	233.8 (214.3)	30.8 (36.5)
IV Fe during study [n=0]	n/a	n/a	n/a	n/a

*TIBC=total iron-binding capacity

Conclusions: In this short-term study, some subjects were able to discontinue IV Fe while maintaining adequate Fe level with oral ferric citrate, with the added benefit of serum phosphorus maintenance. Results from a long-term, phase 3 clinical study of ferric citrate will be available in late 2012.

TH-PO703

Vancomycin Is Safe to Administer in Haemodialysis without Levels but Optimal Dosing Is Dependent on Body Weight Rhys David Russell Evans, Manish Verma, Mark Blunden, Ravindra Rajakariar. *Nephrology Department, Royal London Hospital.*

Background: Vancomycin is frequently used in haemodialysis. Most published literature uses an accepted lower limit of 5mg/l to achieve therapeutic benefit. This equates to a pre-haemodialysis concentration of 7.5mg/l based on the effect of haemodialysis on levels.

Methods: In this retrospective observational study, we compared two vancomycin dosing regimes in haemodialysis patients: Either 1g or 500mg loading followed by 500mg given during the last hour of each haemodialysis session. All patients were dialysed three times per week, for 3-4 hours, using a high flux polysulphone dialyser. The primary end-point was the proportion of patients achieving a mean pre-haemodialysis vancomycin concentration of greater than 7.5mg/l. We also investigated correlation with body weight.

Results: Out of 850 patients undergoing haemodialysis over a 6-month period, 24 patients met the selection criteria for this study. There were 13 in the 500mg loading group and 11 in the 1g loading group. The median length of treatment was 2 weeks in both groups (range 1-7 weeks). 89% of patients (9/11) in the 1g loading group had mean pre-haemodialysis vancomycin concentrations above the target of 7.5mg/l compared with only 46% (6/13) in the 500mg loading group (p=0.07). There was no drug accumulation in either group with pre-haemodialysis concentrations less than 25mg/l in all patients. Subsequent analysis of the 1g loading group demonstrated that 100% of patients less than 80kg achieved a mean level greater than 7.5mg/l compared with 0% of those greater than 80kg (p<0.01).

Conclusions: Vancomycin with a loading dose of 1g followed by 500mg given during the last hour of each haemodialysis provided better therapeutic concentrations than a 500mg loading dose. Both regimes were safe without evidence of drug accumulation in either group suggesting that levels do not need to be done to assess safety. Patient weight requires consideration as those who weigh greater than 80kg require a larger cumulative dose than was used in this study.

TH-PO704

Cardiac Dysautonomia in Patients on Chronic Hemodialysis: A One-Year Follow-Up Study Muhammad Zaman Khan Assir,[1] Syed Rizwan Bokhari,[1] Hafiz I. Ahmad,[1] Arif Asif.[2] *[1]Department of Nephrology, Allama Iqbal Medical College, Lahore, Punjab, Pakistan; [2]Division of Nephrology, University of Miami School of Medicine, Miami, FL.*

Background: Cardiac dysautonomia is associated with increased frequency of cardiac arrhythmias. However, the frequency of new onset cardiac dysautonomia in dialysis patients is not known.

Methods: We conducted a prospective study on cohort of fifty chronic hemodialysis patients. Of these thirty eight (76%) patients were alive at end of one year. These patients underwent three tests of cardiac autonomic dysfunction at base line (start of the study) and at end of 1-year follow-up. This tests included abnormal heart rate response to deep breathing (E:I ratio less than 1.17), abnormal Valsalva ratio (longest to shortest R-R ratio less than 1.2) and abnormal 30:15 ratio (30th to 15th R-R ratio on standing less than 1.03). Patients with 2 or more abnormal tests were considered to be having cardiac dysautonomia.

Results: Out of total fifty patients, 88% had dysautonomia at baseline. Of the remaining six (12%) patients who did not have cardiac dysautonomia at baseline, five (83%) developed cardiac dysautonomia at the end of one year. One patient was excluded from analysis due to inability to perform tests. Patients with baseline cardiac dysautonomia showed no change in dysautonomia scores at the end of one year.

Conclusions: Our study showed that majority of chronic hemodialysis patients who did not exhibit cardiac dysautonomia initially had developed this abnormality at the end of one year follow up.

TH-PO705

Cardiac Dysautonomia and Mortality in Chronic Hemodialysis Patients Hafiz I. Ahmad,[1] Syed Rizwan Bokhari,[1] Muhammad Zaman Khan Assir,[1] Ali Jawa,[1] Arif Asif.[2] *[1]Department of Nephrology, Allama Iqbal Medical College, Lahore, Punjab, Pakistan; [2]Division of Nephrology, University of Miami School of Medicine, Miami, FL.*

Background: Sudden cardiac death is common in chronic hemodialysis patients. Recent data have emphasized that cardiac dysautonomia is present in 88% of chronic hemodialysis patients (Ahmad et al: ASN 2011). Cardiac dysautonomia has been shown to be associated with increased frequency of cardiac arrhythmias and higher incidence of sudden cardiac death.

Methods: In this prospective analysis we followed a cohort of fifty patients who were diagnosed with cardiac dysautonomia. Patients were followed for a one-year period and mortality data were collected. Cardiac dysautonomia tests included abnormal heart rate response to deep breathing (E:I ratio less than 1.17), abnormal Valsalva ratio (longest to shortest R-R ratio less than 1.2) and abnormal 30:15 ratio (30th to 15th R-R ratio on standing less than 1.03).

Results: Of the fifty patients included in this prospective study, 12 (24%) had died at one-year follow-up. Sudden cardiac death was reported in 7(58%) of the 12 patients. Pneumonia, sepsis and hypertensive encephalopathy were reported to be the cause of death in rest of the 5 (42%) patients. All 7 patients who died of sudden cardiac death had three abnormal cardiac dysautonomia tests. On multivariate regression analysis age, sex, diabetic status and duration on dialysis had no effect on mortality.

Conclusions: In this study, a significant number of patients with cardiac dysautonomia had died at a one-year follow-up period. Cardiac dysautonomia appears to be strong predictor of death in end stage renal disease patients on long-term hemodialysis.

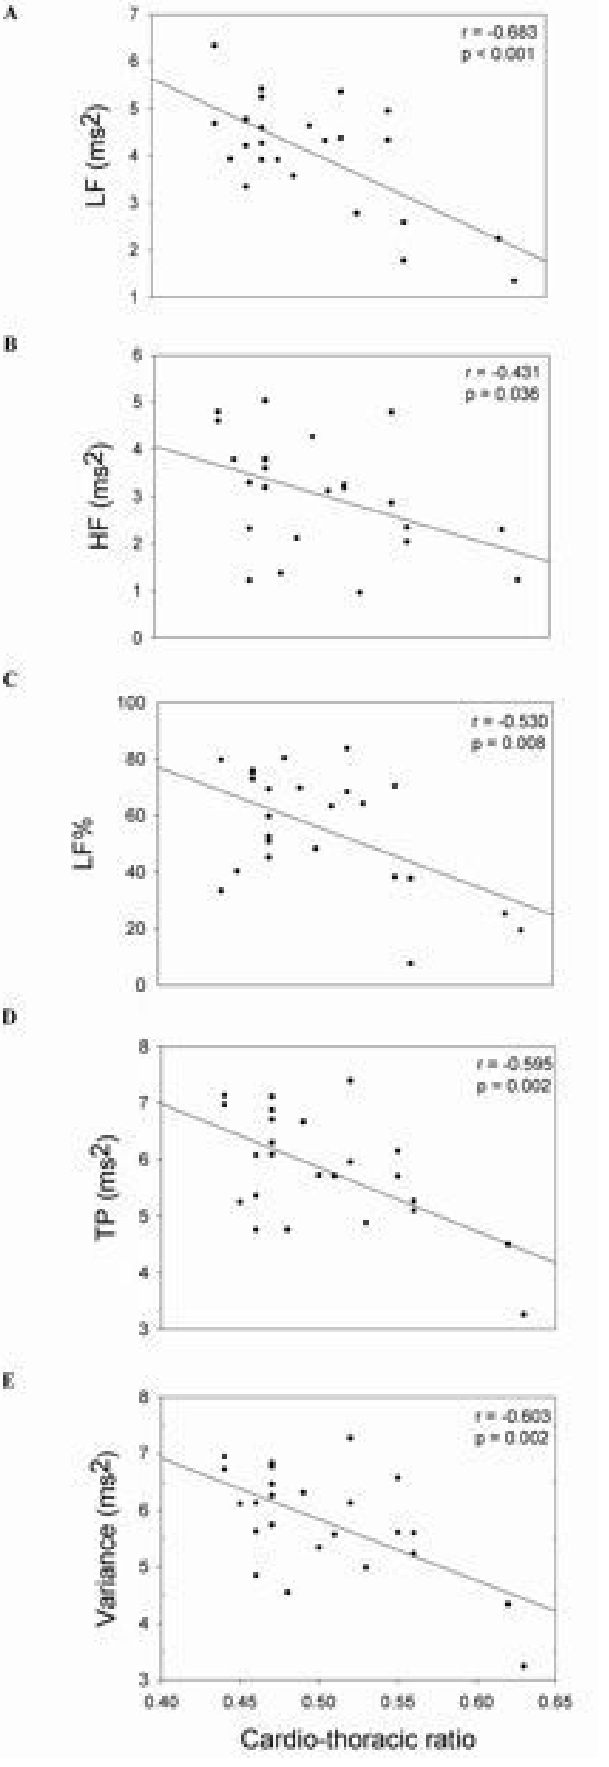
TH-PO706

Cardiothoracic Ratio in Hemodialysis Patients Predict Autonomic Function Yi Shin Chen,[1] Ming-Ju Wu.[2] *[1]Division of Nephrology, Department of Medicine, Taichung Tzu Chi General Hospital, Taichung, Taiwan; [2]Division of Nephrology, Department of Medicine, Taichung Veterans General Hospital, Taichung, Taiwan.*

Background: Autonomic dysfunction is common in dialysis patients and associated with mortality. Heart rate variability (HRV) assessment is a noninvasive measure of autonomic function. The cardiothoracic ratio is an indicator of fluid status in dialysis patients. This study investigated the correlation between cardiothoracic ratio and HRV in hemodialysis patients.

Methods: This was a cross-sectional study. 24 male dialysis patients were recruited in a hemodialysis center. Cardiothoracic ratio was calculated from chest X-ray and taken at the time of interdialytic day. Power spectral analysis of successive RRs from 5 minutes ECGs performed at the day of chest X-ray taken was performed to determine the variance (variance of RR-interval values), high-frequency power (HF), low-frequency power (LF), the ratio of LF power to HF (LF/HF) and total power (TP).

Results: There were significantly negative correlations between LF, HF, TP, and variance with cardiothoracic ratio.



In particular, TP decreased by 13 fold for each fold increase in cardiothoracic ratio.

Conclusions: Cardiothoracic ratio was found to be significantly related to TP and HF. Higher cardiothoracic ratio was associated with lower autonomic function and parasympathetic activity. Our findings suggest that the higher cardiothoracic ratio predicts autonomic dysfunction in hemodialysis patients.

TH-PO707

Evaluation of E.Coli Contamination in Dialysate by Bacteria Plate Counts, Flow Cytometry and LAL Test Huan Chen,[1] Mei Wang.[2] *[1]Renal Department, Beijing Hospital, Beijing, China; [2]Renal Department, Beijing University People's Hospital, Beijing, China.*

Background: Morbidity in hemodialysis patients is associated with chronic inflammation. Microbiological contaminants derived from dialysate are thought to be one inflammatory stimulus. According to AAMI standard from USA, dialysate should contain less than 200CFU/mL colonies and less than 2EU/ml of endotoxin. Whereas European Best Practice Guidelines recommend 0.1CFU/ml and 0.03EU/ml respectively.What is the most accurate method for bacterial contaminated dialysate and how about the relationship between bacterial counts and endotoxin level?

Methods: E.Coli ATCC25922 as contaminant source was diluted by serial 10-fold. 6 different contaminant concentations were obtained. We tested each sample of 6 different concentrations of E.Coli by TGEA culture plate counts, flow cytometry and LAL kinetic turbidimetric assay. Comparison of sensitivety of different methods and the correlation among 3 assays by Pearson correlation and Linear regression analysis were finished. To evaluate the sensitivity of TGEA culture plate counts, flow cytometry and LAL test for E.Coli contaminated dialysate in vitro and to exlpore the relationship between E.Coli counts and endotoxin level.

Results: E.Coli contaminated dialysate of 6 levels in ascending sequence, results from flow cytometry were 2.63×10^2, 2.63×10^3, 2.63×10^4, 2.064×10^5, 2.671×10^6, 2.02899×10^7 cells/ml. Corresponding values were 0.01687, 0.4665, 4.7663, 45.8333, 588.8333 and 4987.3333EU/ml by LAL test. TGEA plate counts were 0, 8±4.47, 36±27.02, 648±150.23CFU/ml and other two higher contaminated concentration samples couldn't be measured beacause of occurence of lamellar bacteria plaque. Linear correlation was observed between flow cytometry counts and LAL levels. One-dimensional linear regression equation was established as follow: Quantity of E.Coli by FCM(cells/ml) = 56240.545+4062.207×LAL(EU/ml). According to the equation, 60303 cells/ml E.Coli corresponded to 1EU/ml of endotoxin.

Conclusions: Flow cytometry is more accurate than TGEA plate counts in evaluation of E.Coli contaminated dialysate. It doesn't show the concordance in E.Coli plate counts and endotoxin level from guidelines defined limits.

TH-PO708

Cold Disinfection with Low-Dose Ozone Achieved High-Level Microbiological Fluid Quality in a Non-Heat Resistant PVC Water Loop and Favorable Outcome Data in Prevalent HD Patients Karl August Brensing,[1] Peter Heidkamp,[1] Eva Neugebauer,[2] Peter M. Raab,[1] Uwe Poege,[1] Thomas M. Gerhardt,[1] Thomas Kistemann,[2] Martin Exner,[2] Juergen Gebel.[2] *[1]Dialysis Unit, Nephrology Center Bonn, Bonn, NRW, Germany; [2]Institute for Hygiene & Public Health, University of Bonn, Bonn, NRW, Germany.*

Background: Good HD-outcome requires optimal fluid quality to avoid infections. However, frequent (≤weekly) water loop disinfection is costly and unfeasable (heat >80°C) for many PVC loops. Thus, cold disinfection by ozone may help but long-term efficacy is unknown.

Methods: During 3-months (=Mo) run-in and 60 Mo on ozone we tested permeate for colony forming units (=CFU/ml; water bacteria/R2A, mycobacteria/Middlebrook, pseudomonas/Cetrimid agars) and endotoxin (=ENDO; sensitive limulus assay: ≥0.005 EU/ml). Ozone was used weekly (9 Mo) then daily (51 Mo) by low levels (20-50 ppb: 0-3 pm) in an 8-year old PVC loop. In addition, we tested ozone (daily) impact on biofilm bacteria in dialysis inflow-stubs (used 3-5 Mo), dialysate fluid (CFU/100ml) and outcome data (quarterly albumin=ALB + CRP; survival) in 53 prevalent HD patients.

Results: Baseline permeate ENDO was 0.03 EU/mL (median; Range: 0.01-0.31) and we had in 12 probes 8x water bacteria (16/mL, range: 0-330), 4x mycobacteria or pseudomonas. Finally, ENDO (0.005 EU/ml, <0.005 – 0.069; $p<0.001$) and water bacteria CFU (4/mL, 0-12; $p<0.01$) declined significantly. Daily ozone reduced CFU in dialysis inflow-stubs biofilm (initial: $1.2x10^4$ per cm^2 final: $2.4x10^2$ per cm^2 ; $p<0.01$) and in dialysate fluid (CFU/100ml: 13; 2-32 vs. 0.0/ml; 0.0 - 0.9; $p<0.001$). We saw favorable biomarkers (ALB: initial: 41.7 g/L, 33-49; final: 40.1 g/L; 28-48; $p<0.01$ and CRP: initial: 0.6 mg/dl, 0.1-3.6; final: 0.6 mg/dl, 0.1-4.2; NS) and actual 5-year survival of 51% (27/53; = 9.8% mortality/year).

Conclusions: 1. Ozone achieved sustained high-level fluid quality and decreased biofilm contamination even in an 8-year old PVC loop. 2. Favorable inflammation biomarkers and a rather low mortality suggest clinical benefits. 3. Cold disinfection with low-dose ozone appears reliable and cost-effective to provide optimal microbiological fluid quality even in non-heat resistant PVC water loops.

TH-PO709

Implementation of Medication Therapy Management (MTM) Pharmacist Services in Dialysis Care and Impact on Patient Outcomes Amy W. Williams,[1] Lance J. Oyen,[2] Robert C. Albright,[1] Jan Anderson,[2] Robert Hoel,[2] Laura Odell.[2] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Pharmacy Services, Mayo Clinic, Rochester, MN.*

Background: The role of the pharmacist in providing care to dialysis patients has often been limited to hospital settings, or ambulatory settings or specific drug classes. Our hypothesis is that pharmacists providing comprehensive MTM services will reduce the risk of medication adverse events, identify nonadherence, and optimize drug therapy for outpatient hemodialysis patients.

Methods: As a quality improvement project we initiated pharmacist services for chronic dialysis patients focusing on patients new to dialysis or hospitalized within 60 days. The service was provided over a 6 month period in one dialysis unit which cares for the most medically complex dialysis population in our system. The goals were to reduce patient medication risks by optimizing drug therapies leading to a reduction in healthcare and patient costs and an improvement in patient outcomes.

Results: From November 2011 to April 2012, 3 pharmacists provided MTM services to 68 patients, average age of 61 years, averaging 1.7 visits per patient. Patients averaged 17.5 medications (range 6-35) and 13 unique conditions targeted by the medications. (range 6-25). The average patient medication burden was 25 unique doses/d at an average wholesale price drug cost of $5983/month. An average of 7 drug therapy problems (DTPs) per patient were identified and resolved by the pharmacist, with 85% of patients having 3 or more DTPs. DTPs were related to indication (32%), safety (15%), effectiveness (27%) and adherence (26%). Using a standardized tool for costs of care estimation, MTM resulted in estimated drug cost savings of $311/pt/yr and estimated healthcare savings of $3387/pt/year through avoidance of unnecessary lab testing and clinic visits, selection of cost effective therapy and avoidance of serious adverse drug reactions.

Conclusions: Comprehensive pharmacist provided MTM care to outpatient dialysis patients optimizes complex medication regimens leading to improved adherence, reduced patient risks, as well as both drug and total cost of care savings.

TH-PO710

Improving Comprehensive CKD & ESRD Care Using Quality & Design Methods Amy W. Williams, Kathryn Zavaleta, Krisa Ryan, John J. Dillon, Mary Tibor, Susan Dornack, Mary Ann Ryan, Michelle C. Hedin, Paul Klugherz, James T. McCarthy, Stephen F. Gudgell, Robert C. Albright. *Mayo Clinic, Rochester, MN.*

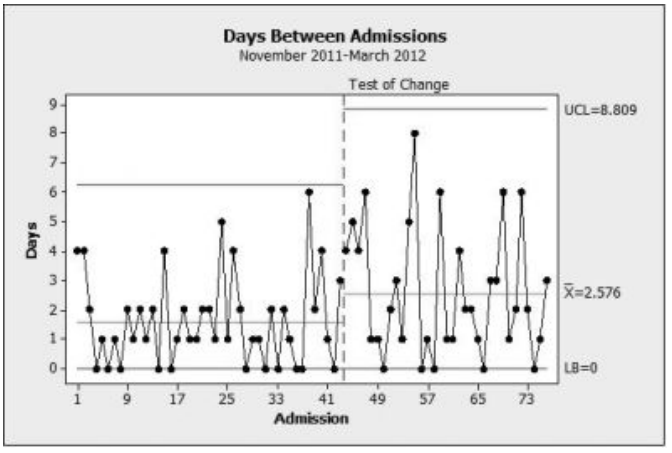
Background: CMS-mandated changes have the potential to fragment & increase total cost of care for ESRD patients. This quality project focused on achieving highest quality, lowest cost care in a multidisciplinary setting.

Methods: The multi-disciplinary team used design-engineering & quality improvement methods to create patient-centered care processes. Process mapping of current & future ideal states led to interventions tested with PDSA cycles. Research on advanced care planning & care management was incorporated. Improvement strategies were integrated into electronic information flows, clinic/hospital workflows & educational materials, establishing consistency among care teams & seamless patient transitions.

Results: Improvements paralleled disease trajectories from CKD to ESRD.

Process Gaps	Improvements
Early CKD referral	EMR alert for referral
Consistent CKD care	Standard template
Team communication	multi-authored EMR tool
Pt-centered ed	Design theory process for new ed
Discuss goals/preferences prior to dialysis referral	Decision aids,care team palliative care training,palliative care staff on CKD/ESRD team
High cost care overuse	Alert when pt in ER/hosp,Huddles:nursing/provider
Med therapy risks	Pharm D. med management
inpt unit assignment	Central process
inpt safety	Standard admit orders
Hosp dismissal	2/d huddles:inpt/outpt teams,Discharge checklist,Critical info packet

An initial 20-40% reduction in inpatient care(50% of total costs)& positive feedback from patients/staff were realized.



Conclusions: Design-engineering & quality improvement methods are valuable tools to determine needed improvements in CKD/ESRD care. The interventions discovered in this project can be translated to improve care in other chronic disease populations.

TH-PO711

In Dialysis: The Association between Social Support and Psychosocial Factors upon Mortality and Quality of Life Ali Mohammed Allehbi,[2] Archie Dumdum Bunani.[1] *[1]Clinical Services, DaVita Lehbi Care - Saudi Arabia, Riyadh, Central Province, Saudi Arabia; [2]Medicine - Nephrology, DaVita Lehbi Care - Saudi Arabia, Riyadh, Central Province, Saudi Arabia.*

Background: Treating End Stage Renal Disease (ESRD) by hemodialysis (HD) creates changes to relationship patterns, social life, activities of daily living and the ability to attain a satisfactory Quality of Life (QoL). There is an absence of information in Saudi Arabia on the impact of these changes in the renal population. This study investigated the influence of social support and other psychosocial factors upon mortality, adherence to medical care recommendations, and physical QoL amongst patients.

Methods: 272 HD patients were examined using the QoL questionnaire to determine self-reported inclinations. Logistics regression through Weighted K was used to analyze data.

Results: 53.5% of patients reported *health had interfered with their social activities* demonstrating a strong associated with risk towards All-Cause (sp=1.33) and Cause-Specific Mortality including cardiac diseases (sp=1.28). These patients had a greater risk of withdrawing (sp=1.67) from treatment, non- adherence to Phosphorus (sp=1.06) greater than 7.5 mg/dL and increased risk towards an albumin of less than 3.5 g/dL (sp=1.23). Patients reporting *dissatisfied with family support* (12.0%) were at highest risk to non-adherence to intra-dialytic weight gain (sp=1.27), shortening the dialysis session (sp=1.21) and increased risk of Potassium level greater than 6 mEq/L (sp=1.14). However, patients reporting *dissatisfied with staff support* (14.1%) revealed a higher risk of decreased physical QoL (sp=0.76).

Conclusions: This study demonstrated that physical QoL was not only affected by medications and other laboratory work-ups but also with additional psychosocial support. The study led to the development of programs empowering patients and families to participate in their treatment plans. The program includes various counselling approaches directed to patient, families, and health team.

Funding: Private Foundation Support

TH-PO712

Changes in Dialysis Social Workers' Caseloads and Job Tasks Since the Implementation of the 2008 Conditions for Coverage Joseph R. Merighi,[1] Teri Browne.[2] *[1]School of Social Work, Boston University, Boston, MA; [2]College of Social Work, University of South Carolina, Columbia, SC.*

Background: This study examines changes in U.S. dialysis social workers' caseloads and job tasks since the implementation of the 2008 Conditions for Coverage (CfC). Studies indicate that high caseloads are associated with a decreased ability to provide social work interventions (Browne, 2012), and high task demands with little time to provide psychosocial and counseling services are linked to suboptimal patient care (Callahan et al., 1998; Merighi & Collins, 2011).

Methods: 1,322 part-time (PT) and full-time (FT) social workers were obtained from all 18 End Stage Renal Disease Networks. Respondents were recruited between 3/31/10 and 6/21/10 using the Council of Nephrology Social Worker listserv. A 130-item online survey was administered by the National Kidney Foundation to gather data on renal social workers' caseloads, job responsibilities, and workplace resources.

Results: Since the implementation of the 2008 CfC, 41.2% of PT and 50.1% of FT dialysis social workers reported increases in their caseloads, with FT social workers reporting a greater proportionate increase ($p<.05$). The caseloads for PT social workers who reported that it increased (M=87.1) was significantly higher than those who reported that it stayed the same (M=73.2; $p<.001$). The caseloads for FT social workers who indicated that it increased (M=130.9) was significantly higher than those who reported that it stayed the same (M=111.9) or decreased (M=95.7; $p<.001$). With regard to job tasks, increases were reported by 80.2% of PT and 85.9% of FT social workers, with FT social workers reporting a greater proportionate increase in tasks being performed ($p<.01$). In addition, 70.4% of PT and 76.6% of FT social workers reported that they had insufficient time to provide psychosocial services to patients.

Conclusions: Findings demonstrate notable increases in social workers' caseloads and job tasks between 2008 and 2010. Together, these factors make it challenging for them to satisfy all CfC mandates. Additional research is needed to examine how these workload demands affect dialysis patients' quality of life and health outcomes.

TH-PO713

Incidence of Missed and Shortened Hemodialysis Treatments in a Large Urban Hemodialysis Unit: Effect on Mortality. Impact of QAPI Derived Multidisciplinary Protocol on Outcomes John F. D'Avella, Stephanie Antonelli, Maryjane Porado, Donna Kelly. *Dialysis, Hartford Hospital, Hartford, CT.*

Background: There is no recent data on the incidence of missed or shortened hemodialysis treatments particularly in a urban setting. There is little data on why it happens and whether it impacts on mortality. We track missed and shortened traetments as a quality indicator When the incidence was noted to increase a QAPI project was undertaken to study why and design a protocol to correct it.

Methods: Missed and shortened treatments are tracked by social workers. In 2010 a increase of 28% in missed treatments was noted. This was brought to QAPI as a problem .Patients were interviewed and a root cause analysis was done Results were discussed with the Nephrology section. A protocol was developed: This involved notifying the nephrologist for missed treatments. Barriers to treatment were discussed and the patient was educated about the risk of missing treatments. If a patient missed more then 3 treatments per quarter; the family is involved with patient consent. In addition there was a unit wide education initiative addressing the risks of missed /shortened treatments.

Results: The unit delivers approx 26208 treatments (RX)per yr In 2010 640 RX were missed(2.4%) Patients that missed 4 or more RX had a mortality of 31% vs unit mortality of 19.6%. With the protocol in 2011 missed RX fell to 516 (decrease 19%)and 2012 1st quarter data annualized to 392 (decrease 39%) This will result in added revenue of $55,056. Shortened RX did not initially change 198/199 2010/2011(they were included in the protocol)Since inclusion; the annualized rate for 2012 is 172(decrease of14%) The most common reason for missed treatments (RX) was not feeling well /similar for shortened RX along with cramping These improved with individual attention and patient education as to the risks of missing/shortening treatments.

Conclusions: Missed treatments have a negative impact on patient mortality and unit revenue. Through a protocol which discovers individual reasons for missed/shortened treatments ; relies on patient and family education and involves all members of the health care team; it is possible to reverse this trend.

TH-PO714

Incidence of False Positive PF4 Antibody Screen for Heparin Induced Thrombocytopenia in Hemodialysis Patients Using Rapid Assay by Akers Bioscience and a Unconvential Cause of Thrombocytopenia in Hemodialysis Patients John F. D'Avella, Debbie Cofrancesco, Donna Kelly. *Dialysis, Hartford Hospital, Hartford, CT.*

Background: Heparin is a necessary part of hemodialysis. The incidence of heparin-induced thrombocytopenia in patients is said to be 3.2%. This syndrome is the result of heparin-induced antibodies against platelet factor IV heparin complex. This not only can result in arterial and venous thrombosis but prohibits the use of heparin. This alone in hemopatients increases the risk and cost of dialysis. The testing for PF4 antibodies used for the diagnosis HIT is said to have a sensitivity of 95% and specificity 50 to 90%. False positive tests are known to occur in patient's with anti-phospholipid syndrome and lupus. There are reports of false positive tests in hemodialysis patients but the incidence is unclear and ther is no mention of specific test specificity or variation.

Methods: On screening 11 patient's had platelet count < 100,000. They were screened for HIT with the PF4 antibody rapid assay Akers Biosciences. None of the patient's had lupus or APS. Positive antibody screens were confirmed with a serotonin release assay. Two patient's after a negative workup for thrombocytopenia were tested for electron beam sterilized hemodialysis membrane induced thrombocytopenia.

Results: 11 patients with platelet cts <100,000 were screened with the rapid PF4 assay by Akers Biosciences. All 11 patient's were positive. All had the serotonin release assay to confirm HIT .Only 1 of 11 was positive. 91% were false positives. Two patient's because of persistent thrombocytopenia post dialysis had platelet counts drawn pre-and post dialysis with a F 160 NR dialyzer (electron beam sterilized) and post ethylene oxide sterilized dialyzer. Patient #1 Platelet counts fell 44% with E beam vs 12% with ethylene oxide. . Patient #2 platelet count fell 33% with E beam vs 12% with ethylene oxide.

Conclusions: Rapid PF4 assay by Akers Biosciencesis has too many false positivesand should not be used in hemodialysis patients In patients with persistent thrombocytopenia consideration should be given to electron beam sterilized hemodialysis membrane induced thrombocytopenia.

TH-PO715

Regional and Ethnic Variations in Adherence to Prescribed Dialysis Treatment and the Effect of Clinic Size on Missed and Shortened Hemodialysis Treatments Chamberlain I. Obialo,[1] O. Myers,[2] William C. Hunt,[2] P. Zager.[2] *[1]Medicine, Morehouse School of Medicine, Atlanta, GA; [2]Medicine, University of New Mexico, Albuquerque, NM; [3]Dialysis Clinic, Inc, Albuquerque, NM.*

Background: Differences between the United States [US] and other countries in the adherence to dialysis prescriptions have been well documented. However, ethnic and regional variations within the US have not been clarified. This study explores the relationship of race/ethnicity, geographic region and clinic size with the frequency of missed and shortened hemodialysis [HD] treatments.

Methods: We studied a prevalent cohort of 15,340 HD patients treated in facilities operated by Dialysis Clinic, Inc. [DCI] between January 2007 and June 2008. The cohort consisted of 48% non-Hispanic whites [NHW], 41% African Americans [AA], 6% Hispanics [H], 2% Native Americans [NA], 2% Asians [AS], and 1% unknown. We divided the US into 4 regions, Northeast [NE], Midwest [MW], South [S], and West [W].

Results: The demographics and select variables of the patients by geographic region are shown in the table below. Comparisons between regions revealed that patients were older in the NE vs. the S ($p<0.001$) and W ($p=0.0052$). Rates of missed and shortened treatments were lower in the NE vs. other regions ($p<0.0001$). Hospitalizations were lower in the W vs. NE ($p<0.01$). Mortality rates were similar across regions. Missed (odds ratio 1.31; 955 CI 1.14-1.52) and shortened (odds ratio 1.86; 95%CI 1.73-2.0) treatments were more common in clinics with >100 patients vs. those with <50 patients. Compared to NHW, the rates of missed and shortened treatments were higher in AA, H, and NA ($p<0.001$) and lower among AS ($p<0.001$).

	NE	MW	S	W
N (%)	3972 (25.9)	2237 (14.5)	7003 (45.7)	2128 (13.9)
Median Age (yr)	66	62	61	61
Missed HD (%)	1.6	2.6	2.7	2.8
Shortened HD (%)	13	15.4	16.8	15.5
Hospitalization/ pt-yr	1.88	1.87	1.74	1.39
Mortality/100 pt-yr	14.3	15.9	16.03	14.14

Conclusions: The frequency of missed and shortened treatments varies significantly by race/ethnicity, geographic region and clinic size. The association of missed and shortened treatments with larger clinic size should be considered when planning new HD facilities.

TH-PO716

Prospective Study of the Impact, Burden and Outcomes of Hospitalisation in Maintenance Hemodialysis Shiv Bhutani, Milind Nikam, Arvind Ponnusamy, Sandip Mitra. *Biomedical Research Centre, Manchester Royal Infirmary, Manchester, United Kingdom.*

Background: Hospitalization in dialysis patients leads to significant morbidity, huge impact on healthcare costs and provides an index of quality of care. Although hemodialysis (HD) patients are at a higher risk of hospitalization, its true rates and outcomes in the UK has not been studied prospectively. The objective was to obtain admission rates for HD patients and identify risk factors, outcomes and impact on resources.

Methods: Prospective admission episodes data were collected using electronic records on all HD patients (n=450) from tertiary centre and associated satellite unit between June to November 2011.

Results: 159 hospitalization episodes in 82 patients were recorded over 6-month period with total duration of 2137 inpatient bed days and hospitalization rate of 700 per 1000 patient-years. The leading causes of hospitalization were cardiovascular (24.5%), infection (16.4%) and access related (18.7%). 54% (n= 20) of cardiovascular related admission episodes were due to fluid overload or hypotension on dialysis. 81 % (n=67) patients were discharged and 12% (n=10) died. Total deaths of 20 were reported for same cohort during the follow up period.

In a multivariate analysis, higher risk of death was associated with cardiovascular (OR 39.5, p=0.03) and infective (OR 39.3, p=0.03) causes for hospitalization as well as underlying diabetes (OR 29.9, p=0.027).

42% (n=67) of episodes were re-hospitalization event and 28% (n=19) had more than two 2 hospital admissions. Multivariate analysis revealed that patients who were re-hospitalized were younger with a mean age of 56.7yr as compared to those with single hospitalization whose mean age was 61.1y (p=0.09).

An estimate of resource utilization suggested a cost of over $ 1.9 million annually ($462 per bed day).

Conclusions: The 2 leading causes of hospitalization in HD are also those predicting mortality. It appears that risk of re-hospitalization is related to younger age, this needs further exploration. Fluid imbalance on dialysis is the leading cause of admissions, and potentially amenable to intervention that may lead to significant reduction in healthcare costs for HD.

TH-PO717

Association of Health Literacy with Intermediate Outcomes in Hemodialysis Patients Divya Singh, James J. Paparello, Michael J. Fischer, Shubhada N. Ahya. *Division of Nephrology and Hypertension, Northwestern Memorial Hospital, Chicago, IL.*

Background: Health literacy is defined as the ability to understand basic health information to make appropriate health decisions. Low health literacy has been associated with a higher mortality in chronic hemodialysis patients. Little is known about the association of health literacy and dialysis related intermediate outcomes.

Methods: This is a single center, cross sectional study of 101 hemodialysis patients in whom the association of heath literacy and secondary outcomes was assessed. Health literacy was measured using the STOFHLA (Short form Test of Functional Health Literacy in Adults), where score <23 defined low (inadequate/marginal) and ≥23 defined adequate. Secondary outcomes such as infections, hospitalizations, dialysis access and laboratory parameters were examined. Descriptive statistics were used to characterize the findings.

Results: Among 101 subjects, the range of STOFHLA scores was 10-36, with a mean of 31 (SD 5.4). Eight had low (8%) health literacy. Of these, the mean age was 71 years (51-85), 2 were listed for transplant (25%), 3 had catheters (37.5%), 6 were women (75%), 6 were African-American (75%), 5 had high school education or less (62.5%). With the exception of age (P 0.01), no significant associations between health literacy and intermediate measures were found.

Health Literacy (STOFHLA) & Secondary Outcomes in Hemodialysis Patients

	Low	Adequate	P Value
Sex- Male/Female	2/6	47/46	0.672/0.539
#Hospitalization: 0	5	47	0.329
#Hospitalizations ≥1	3	46	0.577
# Infections 0	5	41	0.337
# Infections ≥1	2	52	0.432
Phos <5.5	3	39	0.346
Phos ≥.5	5	54	0.678
PTH <500	6	67	0.509
PTH ≥500	2	26	0.673
Albumin <2.5	0	6	0.804
Albumin ≥2.5	8	87	0.773
spKt/v<1.2	1	10	0.524
spKt/v≥1.2	6	83	0.487
HD Access- Catheter/ AVA	3/5	41/52	0.562/0.511
Dialysis Vintage <6mo	1	14	0.611
Dialysis Vintage ≥6	7	79	0.804
Received preHD Care	7	63	0.535

Conclusions: This study of prevalent urban hemodialysis patients showed no statistically significant associations between health literacy and intermediate outcomes. Studies are ongoing in a larger population with more intermediate outcomes.

TH-PO718

Reliability of Self-Report Co-Morbidity Questionnaire in Haemodialysis Patients Sivakumar Sridharan, Jocelyn Berdeprado, Ken Farrington. *Renal Department, Lister Hospital, Stevenage, United Kingdom.*

Background: Extra-renal co-morbidities have major influences on outcomes in haemodialysis (HD) patients. Obtaining co-morbidity data from medical records can be cumbersome and relies on the availability and quality of these records. A self-report co-morbidity questionnaire could be a useful adjunct. Our objective was to validate a self-report comorbidity questionnaire in HD patients.

Methods: Each study subject was administered a self-report co-morbidity questionnaire when they attended for HD sessions. The questionnaire was based on that developed by Sangha et al, previously validated in general medical and surgical patients. Patients were asked to indicate whether they suffered from any of eight co-morbid conditions, and for positive responses whether they received any treatment for the condition and whether it limited their activities. We examined the concordance between each of the reported conditions and data obtained from medical records using Cohen's kappa score. We also evaluated the influence of age, sex and ethnicity on the accuracy of co-morbidity reporting.

Results: 282 HD patients (105 female, 177 male) completed the self-report questionnaire. Mean age was 64.1 (±15.2). There were 201 White, 51 Asian and 30 Black patients. There was substantial agreement between reported and recorded co-morbidity for cardiovascular disease (Kappa=0.639), cancer (0.669) and liver disease (0.658), almost perfect agreement for diabetes mellitus (0.957) and only fair agreement for lung disease (0.272), arthritis (0.348) and depression (0.288). All levels of agreement were highly significant ($p<0.001$). There was no significant difference in concordance rates among different gender or ethnic groups. Whilst the presence of lung disease was over-reported in medical records compared to patient self-report, arthritis and depression were under-reported in medical records.

Conclusions: Self-report co-morbidity is a simple, reliable and useful tool to obtain co-morbidity data in HD patients. The poor concordance for arthritis and depression may be largely due to sub-optimal documentation of these conditions in medical records. The approach may be a useful tool in improving medical record-keeping.

TH-PO719

Serum Albumin Variability and Prognosis of Maintenance Hemodialysis Patients Pu Lei, Hong Daqing, Li Wang. *Renal Department, Sichuan Academy of Medical Sciences & Sichuan Provincial People's Hospital, Chengdu, Sichuan, China.*

Background: Serum albumin indicates patient nutritional status, its mean concentrations were reported to be initmate relationship with MHD patients' prognosis, but none was report to indetify the fluctuation of albumin and clinical situation. So the objective of this study was to analyze the serum albumin levels and fluctuation of maintenance hemodialysis patients, and its impaction on prognosis, retrospectively.

Methods: We retrospectively analyzed 129 MHD patients from Augsust 2010 to December 2012, serum albumin was measured more than 3 times. The occurrence of hospitalization and deaths were recorded. Hospitalization and/or deaths were defined as an adverse event. The average level of serum albumin of every patient was calculation .the mean serum albumin of all patients as a standard to measure the level fluctuation of serum albumin. SDALBmean=$\sqrt{\sum}(x_i\text{-}40)^2/N\text{-}1$ was the equation to calculation the fluctuation of serum albumin. Chi-square test analyze the association between the levels and fluctuation of serum albumin with the adverse events.

Results: 1) The occurrence of adverse events was 30%. 2) Adverse events rate 38.2% of patient in the ≤40g/L group significantly higher than those in the >40g/L group, the incidence of 21.3% (p=0.037). 3) Adverse events rate 38.2% of patient in the >2.5 group significantly higher than those in the ≤2.5 group, the incidence of 21.3%. 4)According to the mean serum albumin and SDALBmean, patients were divided into four groups: ALB≤40g/L+ SDALBmean>2.5group, ALB≤40g/L+ SDALBmean≤2.5group, ALB>40g/L+ SDALBmean>2.5group and ALB>40g/L+ SDALBmean≤2.5 group. The incidence of adverse events of every group was 45.7%, 27.3%, 27%, 20%, respectively. The incidence in the first group was significantly higher than that in the fourth group (p=0.022).

Conclusions: Serum albumin and its fluctuation is association with the adverse events of MHD patients. Serum albumin>40g/L, and SDALBmean≤2.5 may be help to reduce the incidence of adverse events, improve the prognosis of maintenance hemodialysis patients.

ESRD in the Very Elderly Population Jeena Sandeep,[1] Mark E. Williams.[2] *[1]Internal Medicine, Mount Auburn Hospital, Cambridge, MA; [2]Nephrology, Joslin Diabetic Center, Boston, MA.*

Background: Diabetes is a major risk factor for progression to ESRD in the geriatric population. However, data on incidence, prevalence and survival trends of diabetic (DM) and nondiabetic patients with ESRD on dialysis in the very elderly population (>90 years) are limited. The objective of this study was to compare the incidence, prevalence and mortality effect of diabetes on ESRD on dialysis in the very elderly population. We hypothesized that the mortality rates are higher in the group with DM and ESRD.

Methods: We have conducted a retrospective study using the USRDS database from 1999-2009 to evaluate the trends in incidence and outcomes in the very elderly group of patients with ESRD on dialysis, in the DM and non diabetic groups. Our patient population included all races, sex and ethnicity and all modalities of dialysis.

Results: The incidence of both DM and nondiabetic population above 90 years of age with ESRD on dialysis has increased over the years from 1999 through 2009 (P=0.0001). The percentage prevalence of DM-ESRD in the very elderly population on dialysis has gone up from 15.3 % to 20.3%. The unadjusted mortality rate per 1000 patient years was the same with both groups (P=0.086, 95 % CI-4.2 to 52.6). We studied the baseline characterestics, BMI and mean GFR between diabetic and nondiabetic population and found that mean eGFR in DM patients at intiation of dialysis was higher (P= 0.0058) than nondiabetic population and BMI was significantly higher in DM-ESRD (P=0.0001). For both groups combined, vascular access in the very elderly group was observed to be catheter only (76%) compared to catheter with AV graft and AV fistula. Among comorbidities during the same period, diabetes was reported in 27%, while hypertension was reported in 83 % and CHF in 48 %.

Conclusions: Mortality rates are comparable between diabetic and non diabetic groups with ESRD on dialysis in the very elderly population. Incidence and prevalence of diabetic population with ESRD on dialysis has increased over the period from 1999 to 2009.

TH-PO721

Characteristics of Peripheral Neuropathy and Quality of Life Evaluation in Hemodialysis Patients Huiling Wang. *Division of Nephrology, Jimin Hospital, Shanghai, China.*

Background: To investigate the characteristics of peripheral neuropathy and evaluation of their quality life in homedialysis patients.

Methods: 278 cases ofpatients undergoing hemodialysis treatment were enrolled in a hemodialysis center belong to hospital from January 2011 to June 2011. Patients were divided into the lesion group (110 cases) and non-lesion group (168 cases) according to with or without peripheral neuropathy. EMG was used to detect sensory nerve conduction velocity (SCV), sensory nerve action potential amplitude (SNAP), and motor nerve conduction velocity (MCV) and distal latency (ML). SF-36 scale was used to evaluate the quality of life.

Results: In lesions group, patients appeared paresthesia including numbness and burning sensation in upper limbs (3.6%) and lower limbs (48.2%) respectively. Weakness was accounted for 1.8% in upper limbs, and 11.8% in lower limbs. 9.09% tendon reflexes, 55.45% knee-tendon reflex and 35.5% Achilles'-tendon reflex were disappeared. Average subjects of nerve SCV, MCV and ML extending were slowing down in lesion group compared with non-lesion group (P <0.01). SF-36 score in the lesions group was lower than the control group, but the total score was not statistically different than the non-lesion group (t = 1.896, P = 0.060), only a statistical difference in body pain (t=5.301, P <0.001).

Conclusions: The common symptoms of peripheral neuropathy were numbness of the limbs, weakness in and signs for the change of the tendon reflexes. Sensory nerve abnormal was more popular than that in the motor nerve. Clinicians need to pay sufficient attention to peripheral neuropathy in patients undergoing hemodialysis.

TH-PO722

Is the Dialysis Amyloidosis (Carpal Tunnel Syndrome) Preventable? It Is the Cohort Study for 23 Years β2-Microgrobrin, Dialyzer Membrane Junji Uchino, Toyohiko Yoshida. *Mihama Hospital, Chiba, Japan.*

Background: Complications in long-term dialysis patients include dialysis amyloidosis (CTS;carpal tunnel syndrome). Gejyo et. al. reported that dialysis amyloidosis causes by accumulation of β2-Microgrobrin (β2-MG). **Purpose:** We examine relationship with dialyzer membrane, change of the serum β2-MG level and onset of the CTS in the dialysis patients. **Object:** Total of 3,639 patients received maintenance dialysis in our hospital for 1988-2011 year was included.

Methods: During this period, we measured β2-MG level before and after dialysis every year. We examined change the dialyzer membrane according to a year. Furthermore, we examined relationship with history of the carpal tunnel opening resection (including the universal subcutaneous endoscope), serum β2-MG level and the dialyzer membrane. We used ultrapure dialysis fluid (Endotoxin activity level, less than detection limit 0.001EU/mL) from 1994.

Results: The mean β2-MG level before dialysis decreased with maximum of 40.2+-9.3 (1993), 30.0+-5.6 (2001), at least 26.8+-6.0 mg/L (2007) over time. The mean β2-MG level after dialysis decreased with maximum of 18.4+-11.8 (1998), 10.2+-7.6 (2001), at least 7.5+-2.5 (2007) over time. The dialyzer membrane was all cellulose for 1988 years (86% of regenerated cellulose, CTA14%). We started use of Polyslufon(PS) in 1995 and used 7% of PS, cellulose 76%, EVAL 17% in this year. We used 83% of PS, cellulose 5%, EVAL 12% in 2001 and PS 95%, cellulose 2%, EVAL 3% in 2007. After 1996, there is no need to receive carpus trunk opening, and it was almost matched the spread of PS membrane. With the spread of PS membrane, there is no need to receive the carpal tunnel opening resection in patients with β2-MG before dialysis 35-30 mg/L or less and serum β2-MG afer dialysis 10 mg/L or less. These β2-MG level was supposed with the clinical management targeted value. This finding came from the effect of use of high β2-MG removal performance of the PS membrane and use of the ultrapure dialysis fluid.

Conclusions: It is considered that management of β2-MG before dialysis less than 30 mg/L and β2-MG after dialysis less than 10 mg/L can prevent dialysis amyloidosis.

TH-PO723

Medication Adherence and Its Relationship with Outcome in Pediatric Dialysis Patients Douglas M. Silverstein. *Office of Device Evaluation-Gastroenterology and Renal Devices Branch, Food and Drug Administration, Silver Spring, MD.*

Background: Medication adherence is a major factor determining outcome in children with chronic disease. Children with end-stage renal disease are challenged with requirements for renal replacement therapy in addition to complicated medication regimens.

Methods: We assessed medication adherence in 22 pediatric patients receiving chronic dialysis using a published adherence survey called the Adolescent Medication Barriers Scales (AMBS), designed to assess barriers to medication adherence in adolescent transplant recipients.

Results: Twenty-two patients were receiving chronic dialysis (63.6% receiving hemodialysis (HD) and 36.4% receiving peritoneal dialysis (PD); age 15.9±0.7 years with dialysis vintage 31.6±6.5 months. Adherence was assessed by a 16 question survey with a maximum score (difficulty) of 64. Among all patients, the mean adherence score was 30.9±2.4 (range 16-49; median=27.5). Adherence scores trended lower in patients receiving HD (27.5±2.9 [HD] compared to PD (36.8±3.7) [PD], p=0.06). Compared to HD patients, the mean overall score for all questions was significantly higher in PD patients (1.7±0.2 [HD] compared to PD (2.4±0.2) [PD], p=0.006). 5/16 questions resulted in a mean response ≤1.2 in HD patients compared to 0/16 in PD patients. Neither gender, age nor dialysis vintage was related to adherence scores. Finally, adherence scores trended higher in females compared to males (35.6±3.7 [Females] versus (27.5±2.9) [Males, p=0.1), but this did not reach statistical significance. Markers of mineral bone disease were similar in HD and PD patients. Among all targets in HD and PD patients combined, there was no relationship between adherence scores and the number of targets reached (r= -0.09, p=0.7).

Conclusions: We conclude that there are many barriers to medication adherence in pediatric patients receiving dialysis. The difficulties were more evident in patients receiving PD compared to HD.

TH-PO724

Neointima Formation in AV Fistulas: Role of the Transcription Factor ETS-1 Wenguang Feng,[1] Michael Allon,[1] James George,[1] Silvio H. Litovsky,[2] Ping Hua,[1] Phillip H. Chumley,[1] Gabriel Rezonzew,[1] Edgar A. Jaimes.[1,3] *[1]Nephrology, University of Alabama at Birmingham; [2]Pathology, University of Alabama at Birmingham; [3]Nephrology, VA Medical Center, Birmingham, AL.*

Background: Arteriovenous fistula (AVF) is the preferred vascular access for dialysis but still exhibits high rates of dysfunction, in large part due to excessive neointimal hyperplasia. Better understanding of the mechanisms of neointimal hyperplasia in AVF is essential to prevent access dysfunction. We have previously demonstrated the role of the transcription factor ETS-1 as mediator of neointima formation after balloon injury (HTN'10). Herein, we determined whether ETS-1 contributes to AVF neointimal hyperplasia in an animal model and in hemodialysis patients.

Methods: AVFs were surgically created in mice (C57BL/6) between the right carotid artery and right jugular vein. After AVF the mice were infused with either vehicle or an ETS-1 dominant negative peptide (ETS-1 DN, 1 mg/kg/day SQ, N=6 per group). ETS-1 was measured by immunofluorescence (IF) and RT-PCR. Quantification of wall thickness and lumen to cross-sectional ratio was performed in AVF sections. In human studies, ETS-1 was measured by IF in native vein samples from CKD patients at the time of AVF creation (N=6) and in fistula samples from the same subjects (N=6) at the time of surgical revision 2-7 months after AVF.

Results: In mice we observed ETS-1 expression in areas of neointima 7 days after AVF creation but not in control veins. ETS-1 mRNA expression increased 2.53 ± 0.23 and 4.22 ± 2.08 fold 1 and 3 weeks after AVF respectively ($p<0.05$, N=6). ETS-1 DN decreased neointima by 40% ($p<0.05$, N=6) and increased the lumen to cross-sectional ratio 7 days after AVF: 0.34 ± 0.05 µm to 0.52 ± 0.06 µm ($p<0.05$, N=6). In the human studies normal veins exhibited ETS-1 staining only in the adventitia. In contrast in human AVFs, ETS-1 staining was intense in both neointima and adventitia.

Conclusions: We have demonstrated increased ETS-1 in the neointima of mouse and human AVF. We also demonstrate that ETS-1 blockade reduces neointimal hyperplasia in mouse AVF suggesting that ETS-1 could be a potential target to prevent excessive neointima formation after AVF.

Elastin Modulates Outward Remodeling in a Murine Model of Arteriovenous Fistula Failure ChunYu Wong,[1] Margreet De Vries,[2] Carolien Rothuizen,[1] Anton Jan Van Zonneveld,[1] Ton J. Rabelink,[1] Paul Quax,[2] Joris I. Rotmans.[1] *[1]Nephrology, Leiden University Medical Center, Leiden, Netherlands; [2]Surgery, Leiden University Medical Center, Leiden, Netherlands.*

Background: AVFs have a 1 year primary patency of only 60%, mainly as a result of maturation failure that is caused by insufficient outward remodeling (OR) and neointimal hyperplasia (NH). Elastin is a key component of the extracellular matrix in the vasculature that contributes to the compliance of the vessel. Furthermore, elastin inhibits vascular smooth muscle cell proliferation and migration. We evaluated the effect on vascular remodeling in AVFs in haplodeficient elastin KO mice ($eln^{+/-}$) in comparison with wildtype (WT) C57bl6/j mice.

Methods: Using our novel murine model, we created an end-to-side AVF between the jugular vein and the carotid artery with interrupted 10.0 sutures in $eln^{+/-}$ and WT mice. Animals were sacrificed at 21 days and histological sections were stained with Hematoxillin, Phloxin and Saffron(HPS), Weigert's Elastin and against αSMA, ki67 and fibulin. Histomorphometric analysis was performed by using computer software and included the parameters: internal elastic lamina (IEL) area, lumen area and neointimal area.

Results: At day 21 after surgery, the mean IEL-area and luminal area was significantly higher in elastin KO mice compared to WT mice (both p=0.02, figure 1). No significant change was observed in neointimal area between the two groups. The underlying mechanisms responsible for this beneficial effect on vascular remodeling in AVFs are currently being evaluated.

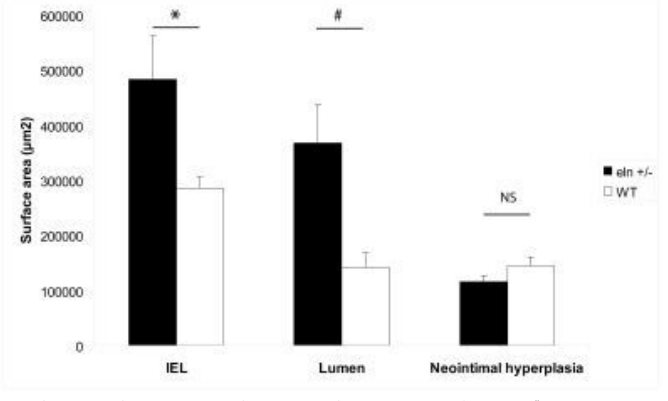

Fig.1 Vesselparameters at day 21.Data in mean±SEM. *p=0.02, #p=0.02, NS=not significant.

Conclusions: Elastin haplodeficiency results in improved outward remodeling in murine AVF. This suggests that elastin might be a suitable target for new interventions aimed to enhance maturation and to improve patency of AVFs.

In Vivo Tissue Engineered Blood Vessels for Hemodialysis Vascular Access Carolien Rothuizen,[1] Febriyani Damanik,[2] Martijn Cox,[3] Ton J. Rabelink,[1] Lorenzo Moroni,[2] Joris I. Rotmans.[1] *[1]Dept of Nephrology, LUMC, Netherlands; [2]Dept of Tissue Regeneration, University Twente, Netherlands; [3]QTIS/e, Netherlands.*

Background: Vascular access is the Achilles' heel of hemodialysis. A tissue engineered blood vessel (TEBV) may provide a durable vascular access. Here we present a novel in vivo tissue engineering approach where the TEBV is grown in the body.

Methods: Cylindrical polymer rods were developed that upon implantation evoke an inflammatory response culminating in the formation of a fibrocellular capsule around the rod. By modulating the implant material characteristics the tissue response can be tailored. Both unmodified, gas plasma treated, chemical etched and growth factor coated PEOT/PBT rods of 4.2mm diameter and 8cm length were implanted subcutaneously in pigs to assess its effect on the tissue response and form a solid basis for a TEBV. Tissue capsules formed around the rods were harvested 4 and 8 weeks after implantation and after extrusion of the rod characterized by histology and mechanical tests.

Results: Macroscopically the tissue capsules appeared as homogenous tubular capsules resembling a human vein (Fig.1). After 4 and 8 weeks the tissue capsules were mainly composed of collagen and α-SMA+ myofibroblasts, both circumferentially aligned (Fig.1). Tissue capsules exhibited burst pressures >2000mmHg and suture strength of >4N, both exceeding the mechanical properties of a human vein. The proof of concept was demonstrated by successful grafting of tissue capsules as arteriovenous (AV)-graft between the jugular vein and carotid artery in pigs.

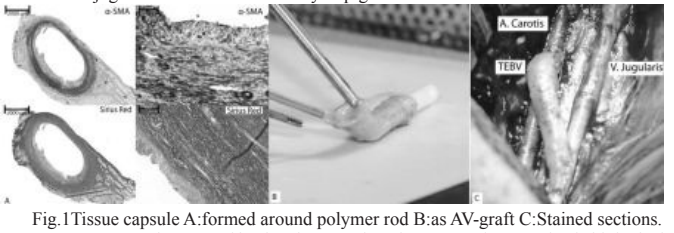

Fig.1Tissue capsule A:formed around polymer rod B:as AV-graft C:Stained sections.

Conclusions: Using a novel in vivo tissue engineering approach a completely biological and autologous TEBV was created with sufficient mechanical strength enabling autologous vascular grafting. Current studies will reveal functionality and durability as AV-graft.

TH-PO727

Chronic Kidney Disease Causes Endothelial Barrier Dysfunction in a Mouse Model of Arteriovenous Fistula Anlin Liang,[1,2] Yun Wang,[1] William E. Mitch,[1] Jizhong Cheng.[1] *[1]Division of Nephrology, Baylor College of Medicine, Houston, TX; [2]Department of Orthopedics, First Affiliated Hospital of Chongqing Medical University, Chongqing, China.*

Background: Hemodialysis patients depend on an arteriovenous (AV) fistula for permanent vascular access. The 2-yr primary patency rate is 60%, generally because AV fistula clogged due to intimal hyperplasia at the venous anastomosis. Chronic kidney disease (CKD) can increase neointima formation, but the mechanism is unknown.

Methods: We created AVFs in mice by anastomosing the common carotid artery and internal jugular vein. This new AVF model had the similar pathological changes as human's. CKD was created and the serum BUN from control and CKD mice were assessed (33.25 ± 3.92 mg/dl VS 114.23 ± 12.08 mg/dl, $P < 0.05$).

Results: There was endothelial loss and platelet aggregation ($CD41^+$ cells) especially in the venous anastomosis in 1 day after surgery. Macrophages and neutrophils were present and peaked at 1 week after AVF surgery. Neointima formation (smooth muscle cell accumulation plus extracellular matrix deposition) increased progressively over 1 to 4 weeks. Mice with CKD had ~ 45% more neointima formation VS results in control mice ($P < 0.05$). CKD decreased VE-cadherin expression in endothelial cells and delayed regeneration of the endothelium. There was more inflammatory cell ($Mac\text{-}2^+$ or $CD45^+$) in AVFs of CKD mice. Finally, the AVF was more "leaky" (increased accumulation of Evan's blue) in AVF of CKD mice at 7 days and 14 days VS results in control mice.

Conclusions: In conclusion, we created a new mouse model of AVF and documented that CKD increases neointima formation and endothelial barrier dysfunction. This model allows testing of new agents directed at improving AVF function in CKD patients.

Women Have Better Endothelial Function, but Need More Time for Arteriovenous Fistula Maturation Tamara K. Jemcov. *Clinic of Nephrology, Clinical Center of Serbia, Belgrade, Serbia.*

Background: Using arteriovenous fistulas (AVF) as vascular access for hemodialysis provides significant benefits, such as greater long term patency, fewer complications and lower infection rates than other vascular access options. Despite these advantages women are still underrepresented among the AVF population. Possible explanations could be the smaller vessels' diameters and the higher rates of primary fistula failure in female HD patients. The aim of the study was to explore morphological and functional parameters in men and women, which can influence the early AVF outcome in the first four weeks after creation.

Methods: Prospective, observational study was performed on 122 patients (66 male) who underwent primary non-dominant forearm AVF creation for HD. Internal diameter of cephalic vein (IDV) and radial artery (IDA), venous distensibility (VD), resistance index (RI) and endothelial function by flow mediated dilatation (FMD) were determined by Color Doppler ultrasound (CDU) examination before the AVF placement. AVF maturation was observed by measuring the blood flow (Qa) and IDV 0, 14 and 28 days after the creation. Depending on the time when the criteria of AVF maturation were reached (Qa≥500ml/min, IDV≥ 5mm, punction with two needles and blood flow ≥ 250ml/min during HD) pts were divided in three goups: group 1- successful maturation (within four weeks), group 2-prolonged maturation after eight weeks and group 3- failure to mature.

Results: Successful maturation was reached in 53% of patients, and prolonged maturation in 36%. Only 11% patients failed to mature the AVF. Sex differences were significant in IDA (p = 0.012) and FMD (p=0.02) and not in IDV, DV and RI. There were more successful AVFs in men (65% vs 39%) and more prolonged maturations AVF in women (46% vs 27%). Significant correlation was found between the successful AVF maturation and male sex (r=0,25; p=0.05). Univariate analysis found male gender to be associated with successful AVF maturation outcome (OR 2.85; 95% CI 0.17-0.72; p=0.005). Nevertheless, after maturation period of eight weeks,there were no differences in maturated AVFs of the two sexes.

Conclusions: Women have smaller IDA, better FMD, and their AVFs need longer period of maturation.

TH-PO729

Arterial Microalcification Is Associateid with Coronary Artery Calcium Score in Hemodialysis Patients Yu-seon Yun, Young Ok Kim, Young Soo Kim. *Department of Internal Medicine, Uijeongbu St. Mary's Hospital, Kyonggi-do, Korea.*

Background: Coronary artery calcium score (CACS) is known as independent predictor of future cardiovascular events, cardiovascular death, and all cause death in hemodialysis (HD) patients as well as general population. We have reported that radial artery micro-calcification (AMC) is closely related to early access failure and aortic stiffness, which is risk factor of cardiovascular mortality in HD patients. This study was designed to evaluate relation of AMC and CACS in HD patients.

Methods: Thirty-four HD patients who received vascular access operation were included in this study. The AMC was diagnosed by pathologic examination of arterial specimen by von Kossa stain, which was acquired during the operation. All patients underwent a multi-detector computed tomography (MDCT) imaging procedure and CACS was calculated. Patients were classified into two groups, according to the CACS, as low (<100), in 17 patients, and high (≥100), in 17 patients. We compared CACS between the patients with and without AMC.

Results: Mean age was 63.8 ± 12.7 years and the male gender was 16 (47.1%). The incidence of AMC was 52.9% (n=18). The mean CACS was 339.8 ± 968.8 (0-5674.1), and the median value was 89.25. Patients with the positive AMC group showed a significantly older age (63.8 ± 11.1 vs 58.8 ± 12.8, p=0.037) and a higher prevalence of diabetes (94.4% vs 37.5%, p=0.004). Positive AMC group showed high incidence of high CACS compared to negative AMC group (88.5% vs 11.8, p=0.000). By binary logistic regression, high CACS was independently associated with positive AMC (OR 25.967, 95% CI 1.361-495.315, p=0.030).

Conclusions: The present study suggests that AMC is closely associated with CACS in HD patients.

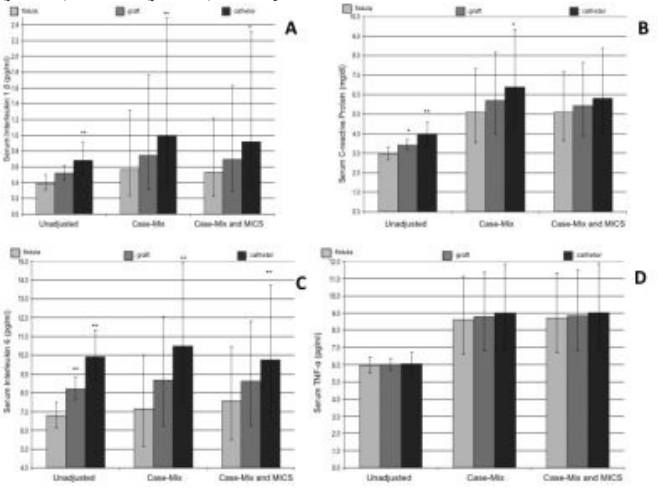
TH-PO730

Association of Vascular Access Type with Inflammatory Marker Levels in Maintenance Hemodialysis Patients Ramanath B. Dukkipati,[1,2] Miklos Zsolt Molnar,[1] Manoch Rattanasompattikul,[1] Jongha Park,[1] Jennie Jing,[1] Csaba P. Kovesdy,[4] Kamyar Kalantar-Zadeh.[1,2] *[1]Harold Simmons Center for Chronic Disease Research & Epidemiology, LABioMed at Harbor-UCLA; [2]Harbor-UCLA; [3]University of Tennessee.*

Background: High levels of inflammatory markers, which may also be associated with protein energy wasting, are common in hemodialysis (HD) patients and associated with increased mortality risk in these patients. The associations between inflammatory markers level and type of vascular access in HD patients are not clear.

Methods: In a cross-sectional cohort study of 790 HD patients, we examined the associations between inflammatory markers including serum interleukin (IL) 1β, IL-6, C-reactive protein (CRP) and tumor necrosis factor-α (TNF-α) and type of vascular access. Unadjusted and multivariate adjusted linear regression models were used.

Results: Mean age of patients was 53±15 years; 54% of patients were men, 52% were Hispanic, 30% were African-American and 53% were diabetic. At baseline 41%, 39% and 20% of patients had fistulas, grafts and catheters, respectively. Compared to patients with fistulas (0.34 [0.16-0.84] pg/ml), patients with grafts (0.41 [0.19-0.79] pg/ml) and catheters (0.61 [0.23-1.61] pg/ml) had significantly higher IL-1β level (p=0.002). Using multivariate linear regression analysis, patients with catheters had significantly higher levels of IL-1β (panel A) and IL-6 (panel C) after adjustment for co-variables.



Similar non-significant trend was found for CRP (panel B), but not for TNF-α (panel D) levels.

Conclusions: Compared to patients with fistulas, patients with catheters have higher levels of IL-1β and IL-6 including after adjustment for important co-variables. The association between types of dialysis access and inflammatory markers may be the underlying link between vascular access and mortality differential and warrant additional studies.

TH-PO731

A Computational Fluid Dynamic Model of Hemodialysis Fistula Access Mary S. Hammes,[1] Kevin Cassel,[2] Michael Boghosian,[2] Brian Funaki,[1] Jane E. Hines.[1] *[1]University of Chicago; [2]Illinois Institute of Technology.*

Background: The outcomes of ESRD patients on hemodialysis are directly dependent on their vascular access. Regional and national indicators promote placement of arteriovenous fistula (AVF). However, complications occur with cephalic arch stenosis (CAS) being a leading cause of access failure in patients with brachiocephalic fistula (BCF). The etiology of CAS is unknown. This study describes methods used to create computational fluid dynamic modeling (CFD) enabling an understanding of hemodynamic changes when a fistula is created.

Methods: ESRD patients receiving hemodialysis were referred for permanent vascular access with a decision to place an upper arm BCF. The subjects enrolled by written consent with a mapping venogram, Doppler and whole blood viscosity (WBV) preformed pre-fistula and three months. Geometric measurements (GM) and hemodynamic parameters (HDP) were preformed using CFD at stated time intervals.

Results: Two subjects had a venogram, Doppler and WBV measured at baseline and three months. Both had a past history of hypertension and one was diabetic. The Doppler blood flow measured 10 cm from the proximal cephalic arch was 3-6 cm/sec. The vein diameter increased from 0.36 and 0.21 mm pre-fistula to 0.45 and 0.4 mm at 3 months. The Reynolds number from baseline to 3 months, increased from 20.749/27.958 to 260.898/383.238. GM and CFD preformed in 6 subjects at 3 months are shown below.

GM and CFD at 3 months for BCF

Patient	Vein Diameter	Angle of Arch	Min WSS	Max WSS	Reynolds
1	0.52 mm	115°	0.0066	0.0304	101.048
2	0.39 mm	95°	-0.0101	0.0100	850.722
3	0.50 mm	131°	-0.0197	0.0186	245.503
4	0.45 mm	120°	-0.0021	0.0438	260.898
5	1.10 mm	141°	-0.0483	0.0164	422.187
6	0.40 mm	119°	-0.0216	0.0328	383.238

Conclusions: CFD was done using simple clinical tools. A lower Reynolds number was associated with a lower WSS. All subjects at 3 months had minimum WSS which was < 0.076 *Pa,* which is below the threshold where endothelial injury, which could lead to intimal hyperplasia, would be expected to occur. As the incidence of CAS is high in patients with BCF access, the tool of CFD will be used to follow these subjects to observe hemodynamic and geometric changes over time and association with development of stenosis.

TH-PO732

Effect of Outflow Vein Diameter on Wall Shear Stress Levels in a Benchtop Model of Arteriovenous Fistula Nicholas Franano,[1] Elyse G. Bailey,[1] Howard M. Loree,[1] Geoff D. Tansley.[2] *[1]Flow Forward Medical, LLC, Lowell, MA; [2]School of Engineering, Griffith University, Gold Coast, QLD, Australia.*

Background: Maturation of an arteriovenous fistula (AVF) is highly dependent on flow-mediated outflow vein and inflow artery dilation in response to persistently elevated wall shear stress (WSS) levels, in the setting of an intact and healthy endothelium. Prior studies suggest that moderately increased outflow vein WSS levels of around 2.5–5 Pa result in rapid AVF outflow vein dilation. Prior studies also indicate that very high WSS levels can damage endothelium, which can inhibit flow-mediated dilation. This study examined the effect of outflow vein diameter on WSS levels in a benchtop model of AVF.

Methods: A mock circulatory loop was constructed to model a radiocephalic fistula using a blood analog solution of 35% w/w glycerine at 22 °C. A HeartMate 2000 IP LVAS was used to generate a mean pressure of 120 mmHg in a 55 cm radial artery of 3 mm ID. Flow in the radial artery was adjusted to 41 mL/min (WSS = 0.9 Pa) prior to AVF creation. Cephalic outflow veins of 50 cm length and variously 2, 3, 4, 5, or 6 mm ID were connected to the radial artery in a side (artery) to end (vein) configuration. After AVF creation, arterial and venous flows were measured and WSS levels were calculated assuming Hagen-Poiseuille flow.

Results: As vein diameter increased from 2 to 6 mm, vein WSS decreased from 12.7 to 1.6 Pa, while artery WSS increased from 3.0 to 7.8 Pa (**Table 1**).

Table 1: Flow and WSS Levels in Radial Artery and Cephalic Vein after Mock AVF Creation

	Flow (mL/min)		WSS (Pa)	
Cephalic Vein Diameter (mm)	Radial Artery	Cephalic Vein	Radial Artery	Cephalic Vein
2	135	171	3.0	12.7
3	277	439	6.1	9.7
4	390	647	8.6	6.0
5	335	554	7.4	2.6
6	355	570	7.8	1.6

Conclusions: These data suggest that AVFs with smaller or larger outflow vein diameters have WSS levels that are not optimal for flow-mediated vasodilation, a finding that may shed new light on the causes of AVF maturation failure. Flow Forward Medical is currently developing a medical device to dilate peripheral veins prior to AVF creation that can maintain optimal vein WSS levels across a wide range of vessel diameters.

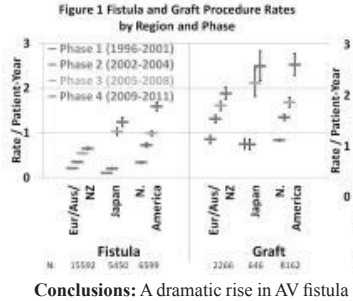
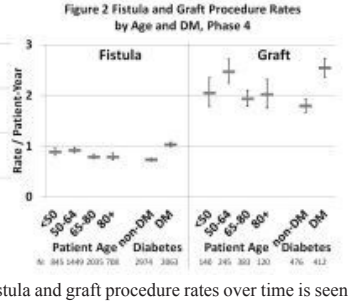
Rising Vascular Access (VA) Procedure Rates over Time Internationally: Findings from the DOPPS Charmaine E. Lok,[1] Keith McCullough,[2] Richard J. Fluck,[3] Lawrence M. Spergel,[4] Vittorio E. Andreucci,[5] Martin P. Gallagher,[6] Mahesh Krishnan,[9] Rachel B. Fissell,[8] Hideki Kawanishi,[11] Rajiv Saran,[10] Friedrich K. Port,[2] Bruce M. Robinson,[2,10] Ronald L. Pisoni.[2] *[1]U. Health Network; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Derby Hospitals Foundation Trust; [4]Dialysis Management Medical Group; [5]Italian Kidney Foundation; [6]Concord Repatriation & General Hospital; [7]Cleveland Clinic Foundation; [8]DaVita; [9]U. of Michigan; [10]Tauchiya General Hospital.*

Background: Interventional procedures are used to manage hemodialysis (HD) VA. We characterize procedure rates by VA type, region, patient characteristics, and year for AV fistulas and grafts.

Methods: DOPPS data were used from four study phases (1: 1996-2001, 2: 2002-04, 3:2005-08, and 4: 2009-11) to determine VA procedure rates. Rates are calculated as total numbers of VA procedures reported during follow-up divided by total VA follow-up time during the study. Procedures included angioplasty, stent, angiogram, surgical revision, banding, thrombectomy, thrombolysis, and other.

Results: VA procedure rates increased over time in each DOPPS region. Unadjusted procedure rates were significantly lower for fistulas vs grafts (Fig 1). In phase 4, procedure rates were ~40% higher in diabetic than in non-diabetic patients (p<0.001); rates declined slightly with age for fistulas (p=0.01) and had no significant trend for grafts (Fig 2).





Conclusions: A dramatic rise in AV fistula and graft procedure rates over time is seen in North America, Europe/Australia/New Zealand, and Japan. VA procedure rates were higher for diabetic patients, as expected, but they were not higher for older patients. Future work is needed to differentiate and assess whether VA procedures can facilitate initial VA use, and whether more procedures for VA maintenance translate into greater VA longevity.

TH-PO734

Exceeding DOQI Fistula Target-Successful Multidisciplinary Interventions for Arterio-Venous Fistula Creation: The Experience by NW Renal Network 16 Vascular Access Quality Improvement Program Vo D. Nguyen,[1] Chad Lennox,[2] Jim Buss,[2] Lynda K. Ball.[3] *[1]Nephrology, Memorial Nephrology Associates, Olympia, WA; [2]Northwest Renal Network, Seattle, WA; [3]Vascular Access, Fresenius Medical Corporation, Everett, WA.*

Background: In 2001, Network 16 fistula (AVF) prevalent rate was 44%. Substantial variation among individual units (20% to 90% AVF) suggested wide variation in physician practice patterns within the Network.

Methods: GOAL: providing education, tools to providers within INTERVENTION facilities (<40% AVF) to promote AVF creation. METHODS: In 2002, Network 16 sponsored 7 workshops for nephrologists, surgeons, interventional radiologists, vascular access managers. STRATEGIES: 1 Collaborative multidisciplinary teamwork-nephrologist as team leader. 2 Educating local medical community: early referral of CKD patients to nephrologists.3 Training nephrologists, surgeons, and radiologists in Hemodynamics of AVF creation, preop Mapping by physical exam, Doppler of all patients, long term vascular access planning to promote secondary AVF creation when grafts fail, all spectrum of AVF surgery, deep vein Transposition, prevention of Steal. 4 Establishment of Vascular Access Manager, training of dialysis staff in AVF cannulation, including Buttonhole.

Results: AVF in use rate in intervention units (43 facilities, 2913 patients): Pre-intervention: 31.4%. Post: 67.6%%, an increase of 116% (±7.0%) exceeding the 28% (±4.6%) increase in other facilities (49 facilities, 2561 patients). Network 16 AVF prevalent rate was 68.2% in 2011, exceeding DOQI target for AVF rate (65%).

December AVF in use Rate

	2001	2002	2003	2004	2011	2001-2011% Improvement	95% Confidence Int.
Network	44.2%	48.5%	52.9%	57.6%	68.2%	54.1%	±3.4%
Intervention	31.3%	39.8%	48.2%	54.0%	67.6%	116%	±7.0%
Others	53.9%	54.6%	54.7%	59.4%	69%	28%	±4.6%

Conclusions: The deficit of training in AVF creation during and after fellowship programs in the US prevents implementation of DOQI goal of 65% of AVF prevalent rate. The success of interventions at the NW Renal Network 16 in promoting increased use of AVF in units with <40% AVF demonstrates the need for Renal Network sponsored multidisciplinary educational meetings in the US.

Funding: Clinical Revenue Support

TH-PO735

Comparison of Vein Size on Maturation of Radiocephalic AVF Ajith Kumar Puram,[1] Amit Kumar Misra,[1] Andi Qipo,[1] Stuart M. Greenstein,[2] Amit Shah,[1] Erian Shehu,[1] Anjali Acharya.[1] *[1]Jacobi Medical Center, Bronx, NY; [2]Montefiore Medical Center.*

Background: Native AVF is the preferred modality for HD access due to lower rates of complications and a longer survival. KDOQI vascular access guidelines recommendations suggest that maturation rate would be high if the AVF is created with vein size greater than 2 mm. We looked into outcomes of Radiocephalic AVF created with vein size less than 2 mm and clinical factors that affect maturation.

Methods: Retrospective chart review was of patients with CKD/ ESRD with Radiocephalic AVF placement during 2008-2011 with vein sizes less than 2 mm. Various clinical variables were collected as given in the table. Size of the vein was determined by USG vein mapping, or by the impression of the surgeon during procedure.

Primary maturation is considered when fistula is mature at 8-12 weeks after AVF creation. Mature AVF is defined here as successful use of the AVF with blood flow of at least 300 ml/min during HD or removal of catheter. Secondary maturation is considered when the fistula is matured after 12 weeks.

Results: There were 30 patients who had a Radiocephalic AVF created. Results are tabulated in Table 1.

Results

	Vien size < 2 mm	Vien size > 2 mm	Mann Whitney
Total patients 30	14 (46.6%)	9 (30%)	
Age	50.5 (41.0;59.0)	52.0 (41.5;64.0)	P = 0.82
BMI (median, IQR)	24.6 (22.4;26.3)	29.0 (24.0;38.5)	P = 0.05
Diabetes	5 (35%)	6 (66.6 %)	P = 0.19
HTN	13 (92.8%)	7 (77.7 %)	P = 0.89
PVD	0	1 (11.1 %)	P = 0.79
CAD	3 (21%)	4(44.4 %)	P = 0.20
Smoking in past	4 (28.5%)	5(55.5 %)	
Smoking current	2 (14.2%)	3 (33.3 %)	
ASA	10 (71.4 %)	5(55 %)	P = 0.54
Plavix	0	1 (11.1 %)	P = 0.79
No of BAM procedures	10	3	
Average Catheter days	108 days	226 days	P = 0.004
Primary patency	4 (28%)	0 (0%)	P = 0.03
Secondary patency	7 (50 %)	8 (88.8 %)	P = 0.17
Total patency	11 (84.6%)	8 (88.8%)	P = 0.89

Conclusions: Our preliminary data shows that patients with vein size less than 2 mm can have functional AVF created with better outcomes. Vein size alone should not be exclusion criteria for placement of an AVF. This is important as it will help reach a higher AVF rate especially with the proposed new CMS QIP program. This data needs to be confirmed in a larger cohort of patients.

Funding: Clinical Revenue Support

TH-PO736

Vascular Function Prior to AV Fistula Creation in the Hemodialysis Fistula Maturation (HFM) Cohort Study Laura M. Dember,[1] Peter B. Imrey,[2] Maiann Duess,[3] Joseph Vita,[3] The HFM Study Group.[4] *[1]U Penn; [2]Cleveland Clinic; [3]Boston U; [4]NIDDK.*

Background: Little is known about the plausible relationship between hemodialysis fistula maturation and underlying vascular function, in part because previous studies have included small numbers of patients.

Methods: Prior to fistula creation surgery, participants in the ongoing NIDDK HFM Study undergo flow-mediated (FMD) and nitroglycerin-mediated (NMD) brachial artery dilation, carotid-femoral (CF) and carotid-radial (CR) pulse wave velocity (PWV), and venous occlusion plethysmography (VP) to assess endothelium-dependent and -independent arterial function, central and peripheral arterial stiffness, and venous distensibility, respectively. We examined the individual associations of age, sex, diabetes, and dialysis treatment with each vascular function measure in joint, additive multiple linear regression models.

Results: Measurements available as of 6/5/12 are summarized in the **Table**. For all tests, the range of values is broad. As in non-CKD populations, arterial function was better in female (FMD +1.10%, p=0.047; NMD +3.09%, p<0.0001; CR-PWV -0.46 m/sec, p=0.021), younger (FMD -0.50%/decade, p=0.012; NMD -0.99%/decade, p<0.0001; CF-PWV +0.74 m/sec/decade, p<0.0001), and non-diabetic (FMD +2.02%, P=0.0002; NMD +3.01%, p<0.0001; CR-PWV -0.44 m/sec, p=0.024; CF-PWV -1.67 m/sec, p<0.0001) patients. Venous distensibility did not vary with age or sex, but was lower in diabetics (-0.6%/mmHg, p=0.038). Patients treated with dialysis had better FMD than those not yet receiving dialysis (absolute difference 1.1%, p=0.033).

Vascular Function in HFM Participants

	FMD (%)	NMD (%)	PWV-CR (m/sec)	PWV-CF (m/sec)	VP Capacitance %/mmHg	VP MVO %/min/mmHg
	N=393	N=333	N=313	N=312	N=421	N=421
Median	3.85	5.90	8.8	10.5	0.048	0.35
25th-75th percentile	1.13-7.66	2.56-10.91	7.6-9.9	8.6-12.8	0.034-0.060	0.24-0.48

Abbreviations: MVO, maximum venous outflow

Conclusions: Among individuals with advanced CKD, older age, male sex and diabetes are associated with greater impairment in arterial function. The broad range of values for all types of vascular function tests will facilitate assessment of the association of vascular function with fistula maturation in the HFM study.

Funding: NIDDK Support

TH-PO737

Maturation of Arteriovenous Fistulas Placed Prior to Dialysis Initiation Craig Solid,[1] Robert N. Foley.[1,2] *[1]USRDS Coordinating Center, MMRF, Minneapolis, MN; [2]Medicine, University of MN, Minneapolis, MN.*

Background: Few data exist describing the percent of placed arteriovenous fistulas (AVFs) that reach maturation or how long they take to mature. Starting on July 1, 2010, Medicare claims billed by outpatient (OP) dialysis clinics include information on the type of vascular access (VA) used at each dialysis session.

Methods: Using the USRDS database, we identified patients who initiated hemodialysis (HD) between July and December of 2010, were aged 67 years or older at initiation, and had a Medicare claim for an AVF insertion within 1 year prior to initiating HD. OP dialysis claims were used to determine the type of VA the patient used at their first OP dialysis session. The percent of patients whose AVF was used at their first OP dialysis session was calculated, stratified by the number of days prior to initiation when it was placed.

Results: We identified a total of 2,476 patients aged 67+ who initiated in the last half of 2010 and had a AVF placed within a year prior. As Table 1 displays, only 3% of those who had their AVF placed less than 30 days prior used it at their first OP dialysis session. Almost one-third of those who had it placed at least 60 days prior had a functioning AVF upon initiation. However, only 37% of patients whose AVF was placed 6 to 12 months prior to initiation used it on their first OP dialysis session.

Patients Whose AVF Matures in Time for Initiation

Days Prior to ESRD that AVF was Placed	% Who use AVF at first OP dialysis session
< 30 Days	3%
31 - 60 Days	20%
61 - 90 Days	30%
91 - 180 Days	36%
181 - 365 Days	37%

Incident Patients July-Dec 2010, aged 67+ with an AVF insertion claim prior to ESRD

Conclusions: Within this population, less than 40% of patients who had an AVF placed prior to initiation used that access at their first OP dialysis session, although that percent was influenced by the length of time between placement and initiation.

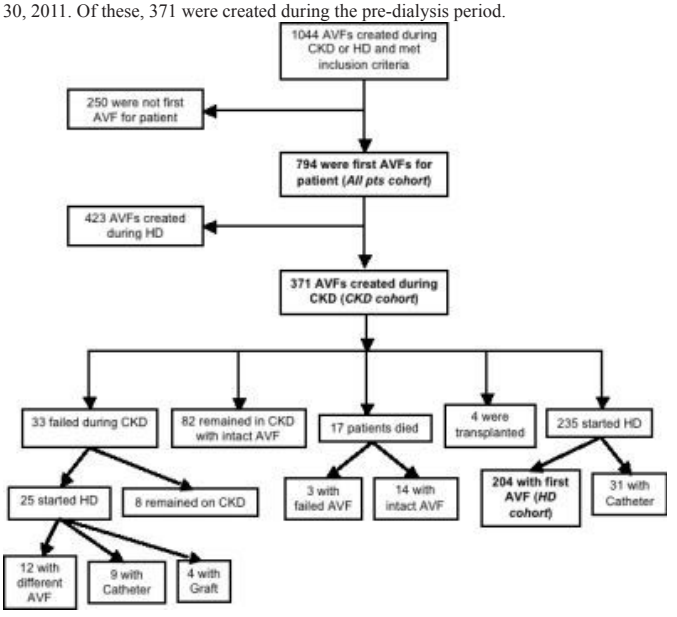
Funding: NIDDK Support

TH-PO738

Arteriovenous Fistulas Created before Dialysis Start: Ongoing Evaluation of Preemptive AVF Outcomes Monica C. Beaulieu,[1,2] Alexandra Romann,[2] Mercedeh Kiaii.[1] *[1]Division of Nephrology, University of British Columbia, Vancouver, BC, Canada; [2]BC Renal Agency, BC, Canada.*

Background: The Provincial Vascular Access Services Team in British Columbia (BC), focuses on improving vascular access (VA) outcomes. Since 2008 we have been able to capture 100% of key VA data elements due to provincial funding for data entry. We describe the outcomes of preemptive fistulas created in CKD patients between 2008-2010.

Methods: A retrospective analysis of prospectively collected data identified 794 first AVFs created between April 1, 2008 and March 31, 2010 with follow-up data until Sept 30, 2011. Of these, 371 were created during the pre-dialysis period.



Results: Patients with a preemptive fistula created were followed by nephrology for a median of 16 (5-39) months prior to creation. Median eGFR at AVF creation was 13 (11-16) mmol/L. In the CKD cohort (n=371), primary failure occurred in 81 (22%) of AVFs.

260/371 (72%) patients started HD by the end of follow-up. 216/260 (83%) started HD with a fistula (first fistula in 204, subsequent fistula in 12). 17 patients died prior to dialysis start (14 with a mature fistula, 3 with a failed fistula). Of first AVFs that were created during CKD and then used for HD, 1, 2 and 3 year patency rates were 78, 64, and 64% for primary patency; 99, 96, and 94% for secondary potency and 97, 94, and 91% for functional patency.

Conclusions: We report the outcomes of pre-emptive fistula creation in British Columbia. In our cohort, 72% of patients started dialysis within the follow-up period and very few died before dialysis start, indicating appropriate selection of patients. As vascular access guidelines continue to promote fistula creation in the pre-dialysis period, ongoing outcome evaluation is required to ensure appropriate patient selection.

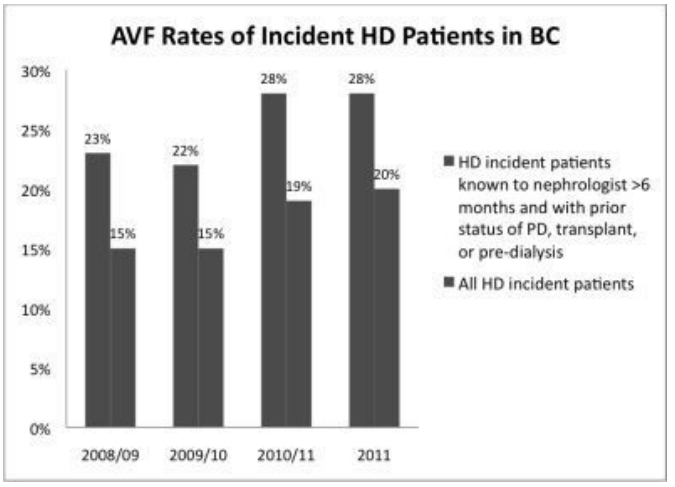
TH-PO739

The Power of Data: British Columbia's Provincial Initiative of Regular Vascular Access Outcome Reporting Improves Arteriovenous Fistula Rates Monica C. Beaulieu,[1,2] Alexandra Romann,[2] Mercedeh Kiaii.[1] *[1]Division of Nephrology, University of British Columbia, Vancouver, BC, Canada; [2]British Columbia Renal Agency, Vancouver, BC, Canada.*

Background: The interdisciplinary Provincial Vascular Access Services Team (PVAST) in British Columbia, supported by the BC Renal Agency, focuses on improving vascular access (VA) outcomes. Phase 1 of the initiative focused on ensuring standardized guidelines, clinical pathways, education and targets (2005-2008). Phase 2 of the initiative (2009-present) involves regular reporting of VA outcomes at the provincial, health authority, hospital, and provider level. We hypothesized that regular reporting of VA outcomes in a real world environment would improve AVF incidence over time.

Methods: Resources were required to ensure provincial engagement, development of metrics, and the accurate capture of data and data analysis. These included a part time project manager, physician champion, and statistical support. Estimated total provincial costs were $27,000/yr. Data capture was possible through an electronic provincial renal database with a customized vascular access module. Reports included patient demographics, vascular access incidence and prevalence, vascular access performance and wait times. A detailed "why catheter" report looked at provider, patient or system barriers.

Results: Through this initiative, the provincial AVF incidence rate improved from 15% in 2008/09 to 20% in 2011. For patients known to nephrologists > 6 months, an increased % of patients started HD with an AVF (23% in 2008/09 to 28% in 2011).



Conclusions: Regular reporting of vascular access outcomes has lead to an improvement in the AVF incidence rate in British Columbia despite no change in the resources available for creation and maintenance of AV fistulas. The regular reporting of VA outcome data may be an important and cost effective strategy to improve VA outcomes.

TH-PO740

Progression to End-Stage Renal Disease among Patients with Preemptive Vascular Access Placement Chenyin He, Kirsten L. Johansen, Chi-yuan Hsu, Nisha Bansal. *UCSF.*

Background: National guidelines recommend that patients approaching ESRD be referred for preemptive vascular access placement within 1 year prior to the start of hemodialysis (HD). Whether these recommendations translate into timely and appropriate vascular access placement is unknown. We studied the rate of progression to ESRD among patients with preemptive vascular access placement.

Methods: In this retrospective chart review, we examined the clinical course of consecutive adults with advanced chronic kidney disease (CKD) cared for in the nephrology ambulatory faculty practice at the University of California, San Francisco (UCSF) between July 1, 1999 and December 31, 2010 and the San Francisco Veterans Affairs Medical Center (SFVAMC) between July 1, 2009 and June 30, 2010. We reviewed all patients who had preemptive vascular access placement, defined as either an arteriovenous fistula (AVF) or graft (AVG).

Results: Among 116 patients from UCSF with preemptive vascular access (109 AVF and 7 AVG), mean age was 64 years, 48% were men, 24% were black, 40% had diabetes and mean estimated GFR 16.1 ml/min/1.73m^2 based on MDRD equation. Median follow-up time was 10.8 [IQR 3.1, 24.3] months. Within 1 year from vascular access placement, 57 (49%) began HD [Figure 1]. Extending following through December 31, 2011, a cumulative 81% patients started HD. Overall median time from vascular access placement to HD initiation was 9.1 (IQR 2.4, 18.9) months. Of the 20 patients from SFVAMC who had preemptive vascular access placement, 7 patients (35%) proceeded to hemodialysis within one year.

Conclusions: In a diverse population of advanced CKD patients followed at two academic medical centers, among those with preemptive vascular access placement, fewer than half started HD within one year. There is opportunity to improve the timing of preemptive vascular access by advancing tools to predict progression to ESRD.

Vascular Access Choice at Hemodialysis Initiation: A Decision and Cost Analysis David A. Drew,[1] Joshua Cohen,[1] Navdeep Tangri,[2] Charmaine E. Lok,[3] Daniel E. Weiner.[1] *[1]Tufts Medical Center; [2]University of Manitoba; [3]University of Toronto.*

Background: Current vascular access recommendations promote fistulas first; however there has been no demonstration that this strategy is optimal for all hemodialysis patients. Accordingly, we performed a decision analysis evaluating fistulas (AVF), grafts (AVG), and central venous catheters (CVC) for a patient initiating dialysis with a CVC, incorporating age, sex, and diabetes, to address the mortality and costs associated with each vascular access option attempted.

Methods: A decision tree model was constructed to reflect typical vascular access initiation and courses of incident hemodialysis patients. Patients were assigned one of three vascular access choices: maintain CVC, attempt fistula, or attempt graft. Probabilities of primary and secondary patency for each access type were explicitly modeled, with success modified by age, sex and diabetes. Access specific mortality was incorporated using pre-existing cohort data including terms for age, sex and diabetes. Costs were ascertained from the 2010 USRDS report for annual access-related costs and CMS for procedure costs.

Results: An AVF attempt strategy was superior in regards to mortality and cost compared to AVG and CVC for the majority of possible patient characteristic combinations, especially for younger, non-diabetic males. In contrast, female diabetic patients had more similar outcomes, regardless of access type.

Table: Mean Life Expectancy (Years) and Total Cost over this Life Expectancy

Model patient characteristics	AVF Attempt Strategy		AVG Attempt Strategy		Maintain CVC Strategy	
	Life Expectancy	Total Cost	Life Expectancy	Total Cost	Life Expectancy	Total Cost
40 year old, non-diabetic, man	8.6	$31,435	6.2	$43,962	5.0	$28,507
60 year old, non-diabetic, man	4.7	$19,084	3.6	$26,347	3.0	$18,128
80 year old, non-diabetic, man	2.6	$12,129	2.2	$16,690	2.0	$12,267
40 year old, diabetic, woman	5.7	$23,637	5.4	$39,380	4.6	$26,528
60 year old, diabetic, woman	3.2	$14,619	3.2	$25,880	2.8	$16,901
80 year old, diabetic, woman	2.0	$10,344	2.0	$17,025	1.9	$11,872

Conclusions: An AVF attempt strategy was superior in regards to mortality and cost in most patients, but this difference lessened considerably when patients were older, female and diabetic. Further decision analyses can evaluate the impact of other patient combinations and access complications, such as infections to assist in individualization of the optimal access.

TH-PO742

Predictors of Arteriovenous Fistula Use at the Time of Hemodialysis Initiation Varun Chawla, Ranil N. Desilva, Bhanu K. Patibandla, Akshita Narra, Yael Vin, Jan Flesche, Alexander S. Goldfarb-Rumyantzev. *Beth Israel Deaconess Med Ctr, Boston, MA.*

Background: One of the challenges we face to start patients on HD with AV fistulas is- primary fistula failure. In this study, we investigate the factors associated with primary fistula failure.

Methods: Study cohort (n =21,436) is derived from the USRDS data linked to Medicare Claims from 03-08 to identify the first access placed/tried on the patient and included incident HD patients from 05-08, >67 years of age, with AVF as the first access placed. Patients were excluded if they had been transplanted before the initiation of HD and if there was another AVF placed prior to HD initiation. After these exclusions, the study cohort consisted of 20,360 patients. We defined fistula as success when the AVF initially placed was used at the time of HD initiation (n=9,794) and as failure when the arteriovenous graft or catheter was used at the time of HD initiation (n=10,566). Multivariable logistic regression analysis was used to estimate the independent contribution of specific patient characteristics in predicting the success or failure of the AVF.

Results: Primary AVF success is associated with early fistula placement (OR 1.07 per month prior to HD initiation, p<0.001). Pre-ESRD nephrology care also has a significant impact on AVF success (i.e. OR for <6 months, 6-12 months and >12 months compared to no care were 3.22, 3.33, and 4.12 respectively). Glomerulonephritis as the primary cause of ESRD is associated with increased fistula success compared to those whose ESRD is due to diabetes (OR 1.22 p=0.01). Age (OR 0.99 per year, P=0.009), female gender (OR 0.64, P<0.001), black race (OR 0.75, P< 0.001), body mass index (^{3}30kg/m2 compared to <18.5 kg/m2 OR 0.86, P=0.001), history of diabetes (OR 0.84, P<0.001), cerebrovascular disease (OR 0.88, P=0.008), and congestive heart failure (OR 0.77, P<0.001) are associated with primary AVF failure.

Conclusions: Early timing of fistula placement and pre-ESRD nephrology care are the strongest predictors of primary AVF success. Furthermore, the results can be used to design a model to predict the success or failure of an AVF placed based on the patient characteristics.

TH-PO743

Disparities in Arteriovenous Fistula Placement Prior to Hemodialysis Initiation Varun Chawla, Ranil N. Desilva, Bhanu K. Patibandla, Akshita Narra, Yael Vin, Jan Flesche, Alexander S. Goldfarb-Rumyantzev. *Beth Israel Deaconess Med Ctr, Boston, MA.*

Background: In this study we assessed and quantified the effect of the clinical and nonclinical factors determining the access type initially placed on a hemodialysis patient by using a large national cohort.

Methods: Study cohort (N=111,953) is derived from the USRDS data with linked Medicare Claims (from 03-08). We identified the first access placed before HD initiation using medicare claims data. The data from form 2728 was used to identify the patient characteristics. Multivariable logistic regression analysis was used to estimate the independent contribution of specific patient characteristics on predicting the placement of AVF prior to start of HD.

Results: Pre-ESRD nephrology care significantly increases the likelihood of AVF being the first access placed(OR for < 6 months, 6-12 months, > 12 months compared to no care were 9.35, 9.78, and 17.21 respectively). Age (OR 0.98 per year; P < 0.001), females (OR 0.80; P < 0.001), blacks (OR 0.93; P = 0.005), history of diabetes (OR 0.79; P < 0.001), history of malignancy (OR 0.91; P=0.003), history of peripheral vascular disease (0R 0.96 P = 0.04), history of cardiac failure (OR 0.62; P < 0.001), and history of cerebrovascular disease (OR 0.88; P < 0.001) are the factors associated with decreased likelihood of AVF placement as the initial access compared to a catheter. In addition, hypertension (OR 0.85; P = 0.007) or glomerulonephritis (OR 0.95; P < 0.001) as the primary cause of ESRD (compared to diabetes as the primary cause of ESRD) are associated with decreased likelihood of AVF being the first access placed. Living in an urban location (compared to rural) was also associated with reduced chances of AVF as the initial access placed (OR 0.81; P < 0.001).

Conclusions: In spite of the increasing efforts to start hemodialysis patients on AVF, there still exist some differences based on age, race, sex, and comorbidities. Our results suggest that pre-ESRD nephrology care significantly increases the placement of AVF. Identification of these factors is important so that the potential interventions can be suggested to increase the prevalence of AVF.

TH-PO744

Pain Resulting from Arteriovenous Fistulae: Prevalence and Impact Emma L. Aitken, David Kingsmore, Marc J. Clancy. *Department of Renal Surgery, Western Infirmary, Glasgow, United Kingdom.*

Background: The burden of pain from cannulation of AVF and the impact on quality of life is poorly described in the literature.

Methods: We undertook a questionnaire-based study evaluating pain scores in all patients in the West of Scotland dialyzing via an AVF (n=480). Pain on cannulation and chronic pain were assessed using Visual Analogue scores (VAS) and McGill pain score. Chi-squared test was used to compare patients with "severe pain" (VAS >5) to those with minimal pain. Results are presented as median (IQR) (p<0.05 is significant).

Results: 97.5% of patients completed the questionnaire. Median VAS pain score on cannulation was 3 (IQR 2, 5). 24.4% had "severe" pain on cannulation and 3.2% had "severe" chronic pain. Compliance with dialysis was good, however 53 patients (11.3%) reported having cut a dialysis session short due to pain. Most pain was described as sharp (41.7%) or aching (25%). However, a number of patients used words such as "shooting" (4.5%), "burning" (5.3%) and "tingling" (12.4%) indicating a neuropathic element to their pain. 9.6% of patients with severe pain on cannulation and 46.7% of patients with severe chronic pain were found to have a physical complication affecting the AVF (e.g. venous stenosis/pseudoaneurysm). Following treatment of the underlying problem chronic pain improved in 71.4% and resolved completely 14.3% of patients. Brachiobasilic AVF were associated with a higher incidence of severe pain than either brachiocephalic or radiocephalic AVF (50%, 23.3% and 24.4% respectively; p=0.03). There was a trend towards more "severe" pain with rope-ladder cannulation (27.7%) compared to button-hole cannulation (18.2%), however this difference did not reach statistical significance (p=0.09).

Conclusions: Pain from AVF is a poorly recognised and under-reported problem. Whilst severe pain resulting in the avoidance of dialysis is rare, it can lead to significant difficulties and ultimate abandonment of an AVF. Pain is often suggestive of an underlying anatomical problem. This should always be investigated in the first instance. Our findings suggest that pain is multi-modal and neuropathic pain may play a significant role, particularly in chronic pain.

Venous Conductance: A Reliable Predictor of Fistula Thrombosis David H. King,[1] Graeme Taylor,[2] Mo Al-qaisi,[1] Anthony Chan,[1] Sumith C. Abeygunasekara,[1] Yiannis Panayiotopoulos,[1] William D. Paulson,[3] Eric Chemla,[4] Abdelgalil Abdelrahman Ali.[1] *[1]Renal Unit, Broomfield Hospital, Chelmsford, Essex, United Kingdom; [2]Department of Physics, Guy's and St Thomas Hospital, London, United Kingdom; [3]Medical Center, Georgia Health Sciences University, Augusta, GA; [4]Renal Department, St Georges Hospital, London, United Kingdom.*

Background: Venous stenosis is a major cause of thrombosis in native arterio-venous fistulae (AVF). The effectiveness of access surveillance in predicting thrombosis is controversial, and there is no consensus that any test is effective. In this study, we tested the hypothesis that Venous Conductance (VC) can fill this role.

Methods: VC is defined as AVF blood flow (Q) divided by mean blood pressure (MBP) in the feeder artery upstream to the arteriovenous anastomosis; thus VC = Q/MBP. Brachial artery Q was measured by colour duplex scanner. MBP in the distal brachial artery was measured by a novel non-invasive method (BlueDop* www.bluedop.co.uk). We determined the relation between AVF thrombosis and VC <10ml.min^{-1}.mmHg^{-1}. We have previously shown this threshold is associated with significant venous stenosis.

Results: We studied 111 AVF patients with 75 brachio-cephalic and 36 radio-cephalic AVFs, created between 0.5 and 30 months previously. Ninety-three AVFs had VC greater than threshold (range 10 to 52). 92 of these remained patent at 90 days and 1 thrombosed. Eighteen AVFs had VC below threshold; 14 thrombosed within 90 days (range = 0 to 85 days, mean = 24 days). Three had already thrombosed by the time of measurement, with VC values close to zero. One underwent intervention but then thrombosed; 4 remained patent at 90 days. Table shows VC sensitivity = 93%, specificity = 96% and accuracy = 95%.

Table 1 Prediction of thrombosis by VC

	Fail (VC <10)	Pass (VC>=10)
Thrombosed within 90 days	14	1
Patent at 90 days	4	92

Conclusions: Venous Conductance appears to be a practical first line test for AVF intervention. Further studies are needed to confirm these promising results.

TH-PO746

A Study of the Variability of Access Flow Measurements by Thermodilution Method Osasuyi A. Iyasere, Rachel Westacott, Mary Anastasia Quashie-howard. *John Walls Renal Unit, University Hospitals of Leicester NHS Trust, Leicester, United Kingdom.*

Background: Vascular access surveillance by blood flow measurements (Qa) is widely recommended but there is no conclusive evidence for use of any one technique.The blood thermodilution method (BTM) correlates well with the more established transonic method and offers advantages in terms of ease of use.Following the recent adoption of BTM at our dialysis unit, we noticed some unusually variable results. We sought to determine the extent of intraobserver and interobserver variability in access flow measurements by thermodilution (BTM) method and determinant factors.

Methods: Monthly BTM measurements were prospectively obtained from haemodialysis patients at a single centre ,between june and august 2011.Patients were selected into an intervention group,where all measurements were carried out by one person according to protocol, and a control group, with multiple unselected observers.Information relating to patient comorbidities, access and dialysis parameters were recorded for each patient.The coefficients of variability for measured access flow(cvBTM) were determined using SPSS.Measurements with a coefficient value greater than 20% were considered highly variable.

Results: Of the 60 dialysis patients selected, 48 had more than one BTM measurement, 27 of which were from the intervention group. 28.6% of BTM measurements from the intervention group had a coefficient value (cvBTM) greater than 20% (range – 0.3 to 54%;mean -17.86%), compared to 52.3% of measurements from the controls (range – 0.7 to 109.5%; mean – 26.06%). This difference was statistically significant (p -0.038). Whilst the coefficients of variability for mean arterial pressure (cvmap) and ultrafilration rate (cvuf) correlated positively with cvBTM in the control group (Rcvmap=0.426, Rcvuf=

0.242) and intervention group (Rcvmap=0.222, Rcvuf= 0.089), the relationship did not reach statistically significance. There were no significant associations between cvBTM and other dialysis parameters.

Conclusions: Access flow readings were more variable in the control group, suggesting that having a single user improves the reliability of BTM measurements.

TH-PO747

Elevated Pulse Pressure Predicts Arteriovenous Fistula Non-Maturation at 3 Months Austine Y. Mengnjo, Robert M. Perkins, Anil Kotru, Taher M. Yahya. *Geisinger Clinic.*

Background: Up to 50% of all newly created arteriovenous fistulas (AVF) fail to mature (FTM). Among factors previously associated with FTM, hemodynamic characteristics have not been reported.

Methods: Using prospectively collected hemodynamic data from all patients with stage 4 or 5 CKD not yet receiving renal replacement therapy evaluated in a single nephrology clinic in central Pennsylvania between January 1, 2010 and June 30, 2011 and referred for first AVF creation, we retrospectively tested the hypothesis that elevated pulse pressure independently predicts FTM at 3 months from date of access creation. Pulse pressure was defined as the mean of the difference between the 4 most recent systolic and diastolic clinic blood pressure readings prior to the date of surgery. Baseline demographic and clinical information was extracted from the electronic health record. AVF maturation was defined as attainment of all 3 of the following within 12 weeks of access placement: venous segment depth ≤ 6 mm, length ≥ 6 cm, and diameter ≥ 6 mm. Measurements were obtained by duplex scans performed by clinic protocol at 4, 8, and 12 weeks after surgery. A multivariate logistic regression model was created using all variables associated ($P \leq 0.10$) in univariate analysis with FTM at 12 weeks to quantify the association between pulse pressure and FTM.

Results: 79 patients met inclusion criteria. Median age was 62 years, 51% were female, 62% had diabetes, 38% had coronary artery disease, 28% had CHF, and the median estimated GFR was 18 ml/min/1.73 m^2. The baseline median (IQR) pulse pressure was 63 (55.5, 69.5) mm Hg. 49% of fistulas failed to mature at 3 months. In univariate analysis, only pulse pressure and diastolic blood pressure predicted FTM at 3 months. Adjusted for diastolic blood pressure, pulse pressure independently predicted FTM at 12 weeks: each 1 mm Hg increase in pulse pressure was associated with a 7.2% (95% CI 2.4-11.9%) increased risk of AVF non-maturation (P=0.003).

Conclusions: Wide pulse pressure independently predicts FTM at 3 months and may represent a clinically expedient discriminator for PTFE graft placement over AVF creation for individuals in need of timely permanent hemodialysis access.

TH-PO748

The Usefulness of Vasc-Alert® to Identify Significant Dialysis Access Stenosis Gerald A. Beathard, Aris Q. Urbanes, Terry Litchfield. *Lifeline Vascular Access, Vernon Hills, IL.*

Background: An optimally functional vascular access (VA) is the lifeline for a hemodialysis (HD) patient. As a result of FFBI and other QI programs, the use of AV accesses for HD is on the rise. VA is not without complications. The primary complication that causes AV accesses to fail is stenosis with subsequent thrombosis. Surveying for stenosis can be performed in a variety of ways. Clinical monitoring, measuring flow, determining pressure, and measuring recirculation are all methods of monitoring the VA. In addition, stenosis can be directly visualized, through noninvasive techniques such as CFD, or through minimally invasive venography.

Methods: In this study, several dialysis centers of a large dialysis organization (LDO) utilized a software system that has developed an algorithm that derived access pressure ratios (intra access pressure/MAP) Vasc-Alert®. 254 patients with functional vascular access were included in the study group. A referral for venogram and angioplasty (if the stenosis was greater than 50%) to a dedicated vascular access center was completed if the patient met the criteria for stenosis alert.

Results: One hundred twenty nine (129) patients were sent for diagnostic angiography. All but five (5) patients (3.8%) had a significant stenosis and were successfully treated with angioplasty. No patients had a thrombosis episode in the study period. None missed any dialysis treatments and the stenosis pre-procedure was significantly less than those sent from other methods of surveillance (71% stenosis for study patients vs. 89% for patients referred from other surveillance methods). In addition, procedure times were reduced as well by 5.3 minutes per procedure.

Conclusions: Vasc-Alert® is an effective tool to detect VA stenosis. To maintain the functionality of the access for the HD patient, a team approach is imperative. The collaboration and cooperation of the patient, nephrologist, dialysis nurse and technician, vascular access coordinator, interventionalist, and vascular surgeon is necessary to preserve this lifeline. The dialysis organization and interventional center can optimize access care with the use of tools to identify access stenosis.

TH-PO749

Should the Current Access Blood Flow Threshold for Arteriovenous Fistula Stenosis Repair Reassessed? Interim Analysis of a Randomized Controlled Trial Nicola Tessitore,[1] Valeria Bedogna,[1] Albino Poli,[2] Alessia Pendino,[1] Antonio Lupo.[1] *[1]Div. Nephrology - Hemodialysis Unit Policlinico Borgo Roma, Azienda Ospedaliera Universitaria Integrata, Verona, Italy; [2]Dept. Public Health, Azienda Ospedaliera Universitaria Integrata, Verona, Italy.*

Background: Current guidelines recommend to refer for imaging and treatment for stenosis arteriovenous fistulae (AVF) with an access blood flow (Qa) <400-500 ml/min. Significant (>50%) stenosis, however, can be detected in AVF with Qa>500 ml/min, but whether correcting such stenosis with "high" blood flow is of value, is currently unknown.

Methods: From July 2006, we performed a Randomized Controlled Trial enrolling adult pts with mature AVF with >50% stenosis and Qa>500 ml/min (measured by ultrasound dilution). AVFs were randomized either to elective stenosis repair by angioplasty or surgery (TX) or control (C) with intervention triggered by signs of impending thrombosis (Qa<350 ml/min or clinical abnormalities such as persistent difficult cannulation, low blood pump flow (Qb) or a decline in dialysis dose). Outcomes of the trial were access failure (a composite of thrombosis and impending thrombosis) and access loss.

Results: Until May 2012, 58 pts were enrolled, 26 in C and 30 in TX. The two arms had similar pts age, gender, diabetes, cardiovascular disease, AVF age, follow-up (28±18 vs 33+22 mo), and Qa (798[95%CI 710-886] vs 693[95%CI 613-773]). During the follow-up, 16 AVFs failed in C (10 thrombosed) and 9 in TX (7 thrombosed), while 12 were lost in C and 5 in TX. Failure rate was 0.27[95%CI 0.15-0.43] event/AVF-y in C and 0.12[95%CI 0.06-0.24] in TX, equal to an incidence rate ratio(IRR) for TX of 0.47[95%CI 0.18-1.13],p=0.066. Access loss rate was 0.19[95%CI 0.09-0.32] event/AVF-y in C and 0.06[95%CI 0.02-0.14] in TX, equal to a IRR for TX of 0.32[95%CI 0.09-0.92],p=0.024.

Conclusions: Our interim analysis shows that elective stenosis repair in AVF with Qa>500 ml/min portends an unsignificant halving in the risk of access failure and a significant three-fold reduction in the risk of access loss, raising the question of whether the Qa threshold for evaluation and treatment for stenosis recommended by the current guidelines should be reassessed.

TH-PO750

Time-Course Analysis of Access Blood Flow Revealed AVF Was Needed Much Longer Time to Maturate in Diabetic Patient Kyung Nam Lee, Dong Won Lee, Soo Bong Lee, Il Young Kim, Ihm Soo Kwak, Eun Young Seong, Harin Rhee, Byeong Yun Yang. *Pusan National University School of Medicine, Busan, Republic of Korea.*

Background: Access blood flow (Qa) is helpful for early identification of native arteriovenous fistula (AVF) stenosis in hemodialysis (HD) patients. Diabetes mellitus (DM) is one of the most important risk factors of AVF stenosis. Therefore, we analyzed the changes of Qa with time in DM and non-DM HD patients.

Methods: Forty five patients were enrolled, who started AVF cannulation for the first time in our dialysis center after a minimum maturation period of 12 weeks. Qa was measured monthly using ultrasound dilution (Transonic® Flow QC HD02) for 4 months after the first cannulation. Three patients were excluded, who have taken any intervention for AVF during follow up periods. Time courses of Qa in DM and non-DM groups were analyzed using general linear model for repeated measurement (SPSS18).

Results: We included 29 DM and 13 non-DM patients. There were no statistically significant differences in demographic, chemical, hemodynamic parameters and use of anti-platelets agents. Mean values of Qa at the first month were 576.6 ± 293.2 and 1003.9 ± 320.1mL/min respectively in DM and non-DM patients ($p < 0.001$). Eighteen patients showed Qa under 600mL/min in DM patients.Considering not only the first measurement per patient, but also another 3 times consecutive measurements, Qa was significantly lower in DM patients compared to non-DM patients (672.9 ± 392.0 vs. 933.9 ± 439.6mL/min, 679.7 ± 446.0 vs. 918.5 ± 372.9mL/min, 750.3 ± 552.6 vs. 933.9 ± 495.1mL/min respectively, p=0.030). Interestingly, Qa showed the tendency to increase continuously in DM patients. In contrast, Qa of non-DM patients showed no significant changes with time and were within normal range, over 600mL/min during follow up period.

Conclusions: In conclusion, Qa in DM patients was lower than in non-DM patients throughout the follow up period. However, Qa in DM showed improved slowly with time. It suggests that newly created AVF in DM patients should be needed longer time to be fully maturated, and have higher risk for stenosis in earlier period after first cannulation.

TH-PO751

Optimizing Vascular Access Outcomes: Surveillance Using Ionic Dialysance Based Vascular Access Flow Improves Fistula Survival Rates Thyago Proença de Moraes,[3] Zoe C.L. Pittman,[2] Chris W. McIntyre,[1] Maarten W. Taal,[2] Richard J. Fluck.[2] *[1]School of Graduate Entry Medicine and Health, University of Nottingham Medical School at Derby, Derby, United Kingdom; [2]Department of Renal Medicine, Derby Hospitals NHS Foundation Trust, Derby, United Kingdom; [3]Health and Biological Sciences, Pontificia Universidade Catolica do Parana, Curitiba, Parana, Brazil.*

Background: Vascular access in hemodialysis (HD) is crucial for patient outcomes but arteriovenous fistulas (AVF) survival rates remains low and the optimal surveillance strategy is still not defined. Intra-access flow measurement (Qa) has been used to monitor AVFs and grafts but data looking at its impact on clinical outcomes is lacking. The aim of

this study was to evaluate the impact of a regular access management program based on an iterative cycle of ionic dialysance based measurement of Qa and radiological intervention.

Methods: All 187 patients undergoing HD from a single center in January 2009 were followed during 3 years and their Qa assessed monthly by ionic dialysance technique. Those with either an initial Qa of less than 600ml/min, a decremental change of 25% or clinical suspicion of stenosis were referred for fistulogram studies. For each procedure, the lesion types, site, severity, the angioplasty balloon and the outcome were recorded. The Qa measurement was repeated after the procedure.

Results: A total of 158 fistulograms were performed in 92 patients with a mean of 0.45 interventions per patient per year. In only 9 studies no lesion was found. A single venous stenosis was confirmed in 77, 2 in 37 and >3 in 12 studies. An anastomotic stenosis was demonstrated in 31 exams, and arterial stenosis in 10. 20 studies had mixed lesions. 148 angioplasties were performed. Median Qa prior to vascular intervention was 373 ml/min increasing to 566 ml/min after angioplasty ($p < 0.001$). Overall patency rates of AVF in these prevalent patients at 1, 2 and 3 years were 99%, 94% and 90.7% respectively.

Conclusions: Routine use of this surveillance technique predicts the existence of functionally significant vascular lesions. A procedural program based on this is associated with high AVF survival rates and low per patient intervention burden.

TH-PO752

Vascular Access Management in Patients with Failing Kidney Transplants

Dalia Dawoud, James C. Harms, Timothy A. Williams, Vineeta Kumar, Michael Allon. *University of Alabama at Birmingham.*

Background: Despite recommendations by NKF/KDOQI and Fistula First to increase pre-dialysis vascular access (VA) placement in CKD patients, only ~20% of U.S. patients initiate HD with a permanent access. The proportion is higher among those patients with at least 1 year of pre-HD nephrology follow-up. There has been extensive publication on pre-HD VA management in patients with advanced CKD, but very little on VA planning in those with failing kidney transplants (KTx). The goal of our study was to compare pre-HD VA management in the 2 groups.

Methods: We compared VA management in 2 groups of patients who initiated HD during a 5-year period: (1) those with a failed KTx, and (2) those with advanced CKD. The analysis was restricted to patients with ≥1 year of follow-up and ≥3 nephrology visits prior to initiating HD. Patient demographics, comorbidities, and pre-HD VA surgery were extracted. Differences between groups were analyzed by the t-test and Chi-square test.

Results: As compared to patients initiating HD after advanced CKD, those initiating HD after a failed KTx were younger, less likely to be black, and less likely to have diabetes or CHF (Table). The proportion of patients with pre-HD VA surgery was lower in the group with the failing KTx (41 vs 60%; hazard ratio 0.69; 95% CI 0.54-0.87, p=0.0008). The proportion of fistulas placed was similar in both groups (70 vs 75%, p=0.54).

Variable	*Failed KTx*	*Advanced CKD*	*p-value*
N pts	123	219	
Pt age, yrs	47±14	60±14	<0.0001
Age >65 yrs	14 (11%)	84 (38%)	<0.0001
Male sex	67 (54%)	109 (50%)	0.40
Black race	71 (58%)	170 (78%)	<0.0001
Diabetes	57 (38%)	130 (59%)	0.02
CHF	11 (9%)	41 (19%)	0.02
Pre-HD VA surg	51 (41%)	132 (60%)	0.0008

Conclusions: Patients with a failing KTx are substantially less likely to receive VA surgery prior to initiation of HD, as compared to patients with CKD. This difference occurred despite the younger age and lower comorbidity in the failing KTx group, factors that would favor fistula success. The reason for this discrepancy is unknown, but may be due to a greater focus on salvaging the failing KTx, at the expense of advanced VA planning. Systematic efforts are needed to increase VA surgery in patients with failing KTx.

Buttonhole Cannulation versus Rope Ladder Technique and Hemodialysis Access Patency

Olatokunbo O. Shobande, Micah R. Chan, Hemender Singh Vats, Maureen J. Wakeen, Alexander S. Yevzlin, Janet Bellingham, Xinliu P. Meyer, Brad C. Astor. *University of Wisconsin Hospital and Clinics, Madison, WI.*

Background: Compared with the rope-ladder (RL) technique, buttonhole cannulation (BHC) provides a higher level of patient comfort, easier needle placement and reduction in hematoma and aneurysms. Recent studies have documented a higher risk of infection with the BHC technique. To the best of our knowledge, AVF patency has not been studied in this population. We analyzed the association of BHC with primary patency and clinical outcomes in our center.

Methods: 45 prevalent dialysis patients using BHC were compared with 38 patients using the RL technique over a median of 12 months (inter-quartile range: 4-27 months). We compared outcomes of primary unassisted patency, episodes of bacteremia, access blood flow (Qa), and quality of life (QoL) scores.

Results: The two groups did not differ significantly in demographics except that diabetes was more common in those with BHC as compared to RL (69% vs. 34%; p=0.002). The 3-month primary patency (PP) was 89.5% and 85.8% in the BHC and RL groups, respectively. The 12-month PP was 59.8% and 56.6% respectively. Risk factors associated with diminished PP were age (HR=1.19 per decade; 95% CI: 1.01-1.39; p=0.03) and female gender (HR=2.01; 95% CI: 1.13-3.58; p=0.02). Having BHC was not significantly associated with PP (HR=1.22, 95% CI: 0.65-2.28). Episodes of bacteremia (n=8; p=0.62), mean Qa before intervention (n=39; p=0.42) and after intervention (n=42; p=0.19) did not differ between BHC or RL technique. Having diabetes did not modify the association between BHC and patency (p=0.59). The physical and mental component, burden and symptoms scores from QoL were not different between groups (all p>0.05).

Conclusions: This study shows for the first time that there is no clear association between BHC use and access patency. Despite previous evidence on higher rates of bacteremia and better overall patient satisfaction, we found no significant differences in these clinical outcomes. Given the impending increase in home dialysis, quotidian therapies and emphasis on patient satisfaction, the role of BHC on access patency requires further study.

TH-PO754

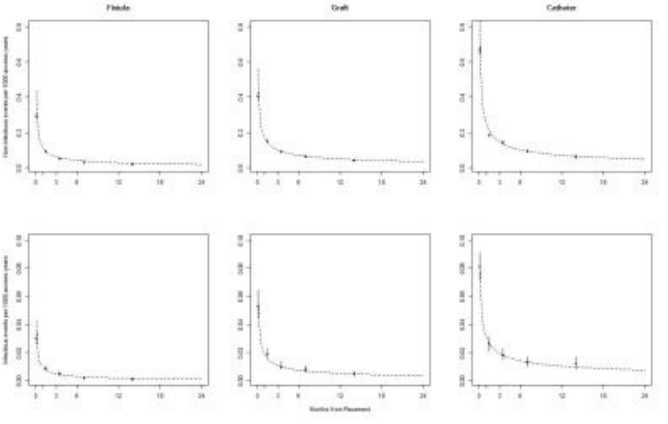
Risk of Infectious and Non-Infectious Complications of Permanent Hemodialysis Access

Pietro Ravani,[1] Brenda W. Gillespie,[2] Robert R. Quinn,[1] Jennifer M. MacRae,[1] Braden J. Manns,[1] David C. Mendelssohn,[3] Marcello Tonelli,[4] Brenda Hemmelgarn,[1] Matthew T. James,[1] Neesh I. Pannu,[4] Bruce M. Robinson,[5] Xin Zhang,[1] Ronald L. Pisoni.[5] *[1]University of Calgary, Canada; [2]University of Michigan; [3]Humber River General Hospital, Canada; [4]University of Alberta, Canada; [5]Arbor Research Collaborative for Health, Ann Arbor, MI.*

Background: Vascular access complications are a major cause of morbidity in hemodialysis patients. Understanding how the risks of different complications vary over time may help design prevention strategies.

Methods: We used data from the Dialysis Outcomes and Practice Patterns Study I-III to study temporal profiles of risk for infectious (access infection or sepsis) and non-infectious complications (dysfunction requiring interventions) of each permanent access type (fistula, graft and catheter) in incident hemodialysis patients. We used longitudinal data on access-related interventions and infections to define the risk set. We considered multiple accesses per subject, and baseline and time-varying covariates. We studied how rates changed over time to select the best survival model.

Results: Of 8,052 patients identified, 7,140 received at least one permanent access. During a median followup of 14 months there were 10,574 non-infectious events and 1169 access-related infections (568 hospitalizations for sepsis). The hazard for both non-infectious and infectious complications declined over time in all access types, without changing direction. The hazard for both complications declined more quickly in fistulas than in grafts and catheters (Figure 1); difference in Weibull parameter P<0.001). However, only 10% of the cohort had a followup >2.5 years.



Conclusions: The risks for non-infectious complications and access-related infections decline over time in all types of access. Prevention strategies should target the first 6 months after access placement.

Fistula Failure Leads to AV Grafts: Need for Re-Evaluation of CMS Standards

Shamik Bhadra, Maliha Ahmed, Ziauddin Ahmed. *Medicine, Drexel University College of Medicine, Philadelphia, PA.*

Background: The 2012 CMS payment schedule incorporates two sub-measures; fistula prevalence and catheter prevalence but dialysis graft prevalence not included. In anticipation of longer dialysis duration, access site availability needs to be preserved by acceptance of graft as viable alternative.

Since 2003 CMS effort has been successful in increasing fistula prevalence from 32.2% to 55.8% and decreasing catheter rate prevalence from 26.9% to 23.8 %. Catheter incidence rate of 82% remains unchanged. The drawback to this is a high primary fistula failure rate compared to grafts with need for catheter dependence. The performance standard is set at 58% with benchmark set at 74% for fistula prevalence. Catheter performance standard is set at 14% with benchmark set at 5%. Financial penalty is to be incurred for failing the goal. The current standards may actually cause patients to lose access sites. For example if the fistula creation is not possible, then instead of using a graft in the forearm, the upper arm fistula would be considered.

Methods: We reviewed amongst our 124 patients, 59(47.6%) have fistulas only, 11(8.9%) have a newly created fistula with catheters being used for dialysis, making the total fistula prevalence 56.4%. This would subject our unit to financial penalty. Forty four of 124 (35.5%) have grafts and only 9/124 catheters (7.3%). Of patients with grafts, 50%(

22/44) had functioning fistula in the past with grafts inserted only after fistula failure. Of 44 patients 13/44 (29.5%) had primary fistula failure, 9/44 (20.4%) had inadequate vessels for fistula and 2/44 (4.5%) patients had unclear reason. Counting all fistula at one time in patients, our unit fistula placement would be 80/124 or 64.5%, surpassing the current set performance standards for primary fistula placement.

Results: Our evaluation suggests that grafts are primarily placed after fistula failure. A graft in the same site after a failed fistula should be considered within the fistula category to avoid loss of access sites, unnecessary procedures and long term catheter use.

Conclusions: CMS recommendations need to be revised so that the dialysis units are not penalized for improving patient care.

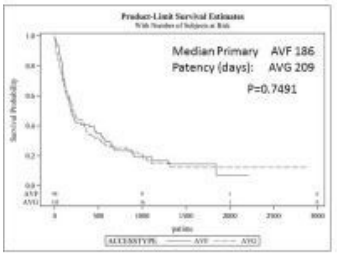
TH-PO756

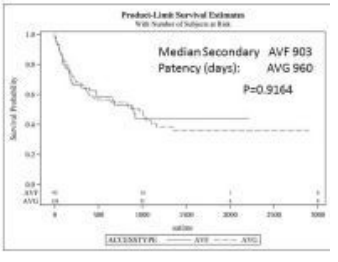
Arteriovenous Fistulae and Grafts Have Similar Outcomes in an Urban Population Senthil Nathan Jayarajan,[1] Abhigna Chowdary Madineni,[1] Sridhar K. Reddy,[2] Vishnu Koganti,[1] Jean Lee,[2] Iris J. Lee,[2] Eric T. Choi.[1] *[1]Department of Surgery, Temple University, Philadelphia, PA; [2]Department of Nephrology, Temple University, Philadelphia, PA.*

Background: Dialysis access failure is a major cause of morbidity in End-Stage Renal Disease patients. The Fistula First Initiative dictates arteriovenous fistulae (AVF) should be preferred over grafts (AVG) as first-line for surgically placed accesses. The purpose of this study was to compare patency rates of surgical dialysis accesses in the North Philadelphia.

Methods: Current dialysis patients with accesses placed between 2006 and 2011 were included. Patient characteristics, access outcomes, and interventions were analyzed. Primary patency was defined as time from access placement to first intervention, while secondary patency was the time from access placement to abandonment.

Results: 156 patients and 239 accesses were included in the study. Of the accesses, 101 were AVF and 138 were AVG. AVF was placed in younger patients than AVG (56 vs. 61 years, p=0.02), while AVG were more often black than AVF (96.4 vs. 83.3%, p = 0.001). The groups were evenly matched in terms of prevalence of hypertension, diabetes, CAD, and PVD. Average number of complications requiring intervention per access was greater with AVG than AVF (1.01 vs. 0.46, p=0.02). AVF and AVG had similar primary patency (median: 186 vs. 209 days, p=0.74) and secondary patency (median: 903 vs. 960 days, p=0.92).





Conclusions: More patients in North Philadelphia are likely to be dialyzed via AVGs. While complications requiring intervention are greater with AVG, primary and secondary patency rates are similar between AVF and AVG, despite implementation of Fistula First.

TH-PO757

Strategies to Maintain Primary Patency of Hemodialysis Arteriovenous Grafts: A Cost Utility Analysis Austin Parker,[1] Dustin J. Little,[1] Kevin C. Abbott,[1] Jonathan Himmelfarb,[2] Robert Nee.[1] *[1]Department of Nephrology, Walter Reed National Military Medical Center, Bethesda, MD; [2]Kidney Research Institute, Seattle, WA.*

Background: US Healthcare expenditures for ESRD reached $29 billion in 2009, including the placement of 33,600 new AV grafts (AVG) in hemodialysis patients. The probability of AVG loss is 75% at one year, primarily due to thrombosis. Attempted salvage of AVG is costly, and largely unsuccessful. Therefore, a cost-effective strategy to maintain AVG primary patency is needed.

Methods: We performed a cost utility analysis of pharmacologic interventions aimed at preventing loss of AVG patency; strategies included aspirin, dipyridamole alone, aspirin+dipyridamole, aspirin+dipyridamole with and without concurrent aspirin, and placebo. Probabilities were based upon published studies performed by the Dialysis Access Consortium Study Group while costs of medications and procedures were drawn from public sources. Utilities of health states were derived from published reports and the SF-6D tool. Calculations were performed using TreeAge Pro® decision analysis software.

Results: One-way sensitivity analysis showed that for any probability of AVG loss <0.75, aspirin therapy dominated alternate strategies. In a Monte Carlo probabilistic sensitivity analysis, aspirin was the optimal strategy in 72% of scenarios, while 21% favored dipyridamole monotherapy, at a willingness-to-pay of $50,000 per quality-adjusted life year (QALY).

Conclusions: In our analysis, aspirin monotherapy dominated other strategies based on cost per QALY. Aspirin therapy has the potential to significantly reduce healthcare costs through decreased vascular access interventions. If all patients with incident AVGs in the US were given aspirin, more than $33 million could be saved annually without decrement in QALY, as compared to no prophylaxis.

TH-PO758

Descriptive Analysis of Vascular Access Outcomes in a Single-Center 40-Year Home Hemodialysis (HHD) Experience Eric Goffin,[1] Tony Goovaerts,[1] Krystel Carlier,[2] Veronique Chapalain,[3] Michel Y. Jadoul.[1] *[1]Nephrology, Université Catholique de Louvain, Brussels, Belgium; [2]Keyrus Biopharma, Lasnes, Belgium; [3]Keyrus Biopharma, Paris, France.*

Background: In a context of expanding HHD with longer and more frequent dialysis sessions (nocturnal, short daily), there is a concern that frequent use of vascular access might lead to more complications. We analyzed vascular access outcomes and causes of failure in all our patients with HHD as first RRT over a period of 40 years.

Methods: A total of 246 ([169 males; mean age: 43 (15-79) years] patients started HHD during the study period. Median follow-up time on HHD was 2.4 (IC 95%: 2.1-3.0) years. The study duration was divided in four periods (before 1980; 1980-1990; 1999-2000; 2000-2011). All vascular access complications were recorded.

Results: During the study period, a mean (range) of 1.3 (1-5) vascular access/patient was created. Native AV Fistula (AVF) represent 92.2% overall, but only 81.9% during the last period due to an increase (transient or permanent) use of tunnelled venous catheter (p<0.001). The mean duration use was 3.5 years; 2.3 during the last period of the study (p<0.001). AVF cannulation was mainly performed by a family member until 1990 (86.8% for 1990-1999) but self cannulation concerned 51.1 % of the patients (p<0.001) after 2000. HHD practices changed over time: nocturnal, short daily and more than 3 sessions/week represented 58.5% of the HHD schedule during the last period. 82% of native AVF did not require any intervention. Incidence of AVF complication was 0.34, 0.01, 0.03 and 0.03 case/100 patients/months for thrombosis, infection, pseudo-aneurysms and stenosis, respectively, and 0.32 for catheter infection incidence. After 1997, the use of the buttonhole technique for AVF cannulation became systematic. Despite the use of this technique and an increase in self cannulation, infection, stenosis and pseudo-aneurysms rates did not increase; thrombosis incidence slightly increased (p: 0.09).

Conclusions: In this analysis, we did not observe a significant increase in vascular access complications despite the more frequent use of the AVF and of the buttonhole technique but a slight increase in thrombotic events.

Optiflow™ Anastomotic Connector: Safety and Efficacy: Results from the OPEN Study Milind Nikam,[1] Afshin Tavakoli,[1] Jackie Evans,[1] Angela M. Summers,[1] Paul E. Brenchley,[4] Eric S. Chemla,[2] Prabir Roy-Chaudhury,[3] Sandip Mitra.[1] *[1]Manchester Royal Infirmary, Manchester, United Kingdom; [2]St George's Healthcare NHS Trust, London, United Kingdom; [3]University of Cincinnati; [4]Manchester Royal Infirmary, Manchester, United Kingdom.*

Background: Early arteriovenous fistulae (AVFs) failure remains a significant clinical problem with high early failure rates. Optiflow™ is a novel device which acts as an anastomotic connector and could address some of the factors associated with early failure. The Optiflow™ Patency and Maturation (OPEN) study was set up to investigate the safety and efficacy of the Optiflow™ device.

Methods: Forty device and 40 hand-sewn control patients undergoing AVF creation were recruited prospectively. AVFs were created using the Optiflow™ device in an end-to-side configuration using a 3 or 4mm device. Device size was determined by arterial and venous diameter obtained pre-operatively by ultrasound vessel mapping and also by clinical evaluation intra-operatively. AVF patency was determined in this interim analysis by clinical evaluation and / or ultrasound scan and defined as an AVF with diameter ≥ 5mm and blood flow 500ml/min.

Results: Ultrasound measurements and/or clinical evaluation were performed at 2, 6 and 13 weeks post-operatively according to a defined protocol. Early results suggest that the average blood flow at 90 days was 1298 ml/min in the device group and 988 ml/min in the control group (p=0.037). The average diameter at 90 days, 3 cm from the anastamosis, was 8.2mm and 7.8mm in the device and control groups respectively (p=0.062). Primary unassissted maturation at 3 months was 71% in the device arm. It is expected that at the time of presentation, complete dataset from the trial would be available.

Conclusions: Optiflow™ device appears to be a safe and effective intervention in creation of primary AVFs. The potential advantages of the device are: standardisation of the procedure and thus reducing skill dependency, optimising anastomotic configuration and shielding the peri-anastomotic region from neo-intimal hyperplasia. Optiflow™ device is novel, safe and effective technology for creation and maturation of AVFs. Its potential for improving AVF outcomes is attractive and merits further consideration.

TH-PO760

Endovascular Salvage of Failed Arteriovenous Dialysis Access: Long Term Results and Factors Predicting Access Survival Milind Nikam, Leonard Ebah, Anuradha Jayanti, Angela M. Summers, Paul E. Brenchley, Nicholas Chalmers, Sandip Mitra. *Manchester Royal Infirmary, Manchester, United Kingdom.*

Background: A patent arteriovenous (AV) access is crucial to improving outcomes in patients on haemodialysis (HD). AV access failure, often as a result of thrombosis, is common and often leads to significant morbidity to the patient and increased costs. Here we report results of an interim analysis of endovascular salvage of AV access from our centre.

Methods: A regional AV fistula salvage service was set up in 2008 to cover 2 large renal centers. Failed AV access was defined as any AV access which could not be used for HD. Co-morbidity and follow up information was obtained from electronic case records.

Results: A total of 445 episodes of failed AV access were referred for treatment in the period between 1/1/2008 to 12/31/2011. Thrombosis accounted for 71% of episodes. Native fistulae accounted for 68% episodes whereas 32% were grafts (centre graft prevalence ~5%). Mean patient and access age were 58 years and 24 months respectively, with 18% diabetes prevalence. The initial anatomical success rate was 90%. Primary patency rates for fistulae and grafts were 43% and 14% at 6 months, 30% and 7% at 1 year; and 18% and 3.5% at 2 years respectively. Secondary patency rates were 66% and 38% at 6 months, 61% and 25% at 1 year; and 48% and 12% at 2 years respectively. Multivariate analysis of anatomical success outcome revealed no impact of having a graft vs. fistula, age, diabetic status and time from onset to procedure. Cox regression analysis revealed that poor access survival (primary patency) was associated with having a graft vs. fistula (OR 1.7, p=0.03), presence of ischemic heart disease (OR 5.9, p<0.001), peripheral vascular disease (OR 9.5, p=0.04) whereas improved survival was associated with being on statin therapy (OR 0.285, p<0.001) and antiplatelet therapy (OR 0.72, p=0.02).

Conclusions: Despite good anatomical patency, longer-term access patency after an episode of failure remains significantly poor especially for grafts. Statin and antiplatelet therapy seem to be associated with improved outcomes - these are simple interventions and merit further investigation.

TH-PO761

Treatment of Vitamin D Deficiency with Ergocalciferol Is Associated with Reduced Vascular Access Dysfunction in Chronic Hemodialysis Patients

Christine L. Gear, Neena M. Penagaluru, Jonathan A. Gelfond, Wajeh Y. Qunibi. *Nephrology, University of Texas Health Science Center, San Antonio, TX.*

Background: Vitamin D deficiency (VDD) is prevalent among CKD and Hemodialysis patients (HDP). Previous studies reported an association between VDD and various clinical disorders including cardiovascular disease, vascular calcifications, arterial stiffness, peripheral vascular disease and vascular endothelial dysfunction. Complications of vascular access in HDP contribute to morbidity and increased healthcare cost. In our previous observational study, we showed that VDD is an independent risk factor for the development of vascular access dysfunction (VAD) in HDP. The purpose of the current study was to examine the effect of treatment of VDD with ergocalciferol on future development of VAD.

Methods: Data from medical records of 256 HDP were analyzed to evaluate the relationship between treatment of VDD with ergocalciferol and VAD (defined as vascular access intervention for dysfunction).

Results: Of the 256 patients in the initial cohort, 145 patients were treated with ergocalciferol, and 73 were not. Mean age was 56±13 years; 51% females. Age and gender were not associated with treatment status (p>0.05). Mean 25OHD level was 19.1±11 ng/ml. Subjects treated with ergocalciferol had lower baseline 25OHD levels (17±11 vs. 23±14, p<0.001). The observed, unadjusted rate of any vascular intervention was 57% in the untreated group compared to 43% in the treated group (p=0.06). Logistic regression that adjusts for multiple factors including baseline 25OHD, and treatment with ergocalciferol was associated with a significant reduction in the risk of vascular access interventions for dysfunction (OR=0.37; 95%CI [0.19, 0.07], p=0.002).

Table 1.

Variable	Log Odds	Std Error	OR	CI 95	Pvalue
Ergocalciferol	-1.001	0.33	0.37	[0.19, 0.7]	0.0023
PreVit.D.level	-0.036	0.02	0.96	[0.94, 0.99]	0.0164
Ca	-0.474	0.19	0.62	[0.43, 0.9]	0.0122
Alb	-0.818	0.44	0.44	[0.19, 1.05]	0.0641

Conclusions: Our study suggests that treatment of VDD with ergocalciferol in HDP is associated with fewer vascular access interventions. Further randomized controlled trials are warranted to determine whether treatment of VDD contributes to reduction in VAD in HDP.

TH-PO762

The Effect of Lowering LDL-Cholesterol with Simvastatin Plus Ezetimibe on Vascular Access Patency: Results from the Study of Heart and Renal Protection (SHARP)

William G. Herrington. *On Behalf of the SHARP Collaborative Group, Clinical Trial Service Unit, University of Oxford, United Kingdom.*

Background: The SHARP trial, which randomized 9270 patients with chronic kidney disease to simvastatin 20mg plus ezetimibe 10mg daily versus matching placebo, showed that lowering LDL-cholesterol (LDL-C) for an average of five years safely reduces the risk of major atherosclerotic events. The potential effect on vascular access patency, however, is unknown.

Methods: Vascular access status was recorded at baseline and events related to vascular access were recorded routinely at each follow-up visit. Post-hoc analyses were performed of the potential effect of allocation to simvastatin plus ezetimibe on loss of vascular access patency (defined as any access revision procedure, access thrombosis, or the removal of old/formation of new permanent dialysis access). Analyses of the time to first event were done according to the intention-to-treat principle.

Results: 2353 patients had functioning vascular access at randomization (2204 had an arteriovenous fistula and 149 an arteriovenous graft). In these patients, allocation to simvastatin plus ezetimibe resulted in a 13% proportional reduction in loss of vascular access patency (355 [29.7%] simvastatin/ezetimibe *vs.* 388 [33.5%] placebo; rate ratio 0.87, 95% CI 0.75-1.00; p=0.05). Consistent results were seen for each measure corresponding to loss of patency. There was no significant heterogeneity of treatment effect among those treated with antiplatelet therapy and those not.

Conclusions: This analysis raises the hypothesis that lowering LDL-C may have beneficial effects on maintaining vascular access patency.

Life table plot of effects of allocation to simvastatin plus ezetimibe versus placebo on loss of patency among 2353 patients with a fistula or AV graft at randomisation

TH-PO763

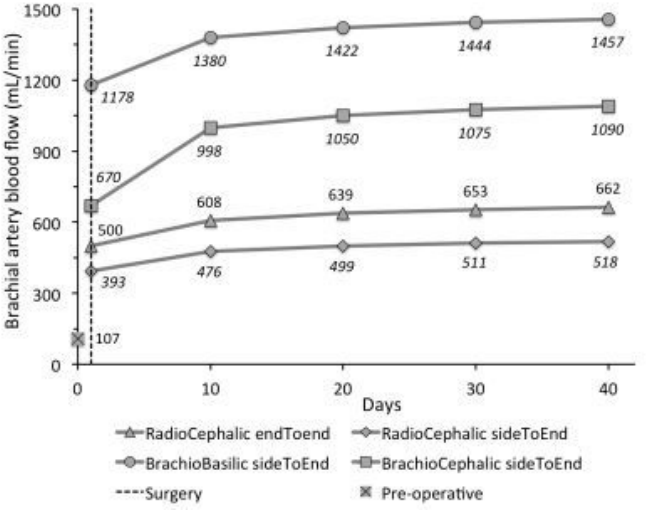
AVF.SIM: A Web-Application for Planning Vascular Access Surgery in Hemodialysis Patients

Simone Manini,[1] Anna Caroli,[1] Luca Antiga,[1,3] Andrea Remuzzi.[1,2] *[1]Biomedical Engineering Department, Mario Negri Institute, Ranica, Bergamo, Italy; [2]Industrial Engineering Department, Bergamo University, Bergamo, Italy; [3]Orobix S.r.l, Bergamo, Italy.*

Background: The planning of surgical procedure for vascular access (VA) is based only on physical examination and eventually on ultrasounds (US) investigation. These evaluations do not allow to predict the outcome of the VA surgery. We developed a computer-based simulation tool to quantitatively predict the post-operative VA blood flow and its changes during VA maturation.

Methods: AVF.SIM is a clinical web-application for predicting hemodynamic changes induced by different configurations of arteriovenous fistula (AVF) surgery at patient-specific level. AVF.SIM is based on a numerical solver (pyNS) which implements 1D wave propagation computational models and a vascular adaptation algorithm based on the assumption that vessel diameter changes upon increase in blood flow volume to maintain a physiological value of the peak wall shear stress. This tool allows to predict the increase in blood flow in arterial and venous segments of the arm vasculature, immediately after surgery and during VA maturation (about 6 weeks).

Results: On the basis of structural and functional information obtained by US on patient-specific vasculature AVF.SIM allows to simulate the potential results of different surgery procedures (distal and proximal, end-to-end and side-to-end) in terms of changes in time of vessel diameters and expected blood flow.



Conclusions: Simulation of the potential effects of different type of anastomosis, as well as different anastomosis location, may help the surgeon to select the most appropriate AVF surgical planning. The use of this simulation tool may reduce the incidence of AVF primary non-function and may allow to avoid very high blood flow in the VA, exposing the patient to the risk of cardiac failure.

TH-PO764

Analysis of Vascular Access Interventional Therapy: 6-Year Follow Up Survey in 2,000 Cases with Vascular Access Failure Teruhiko Maeba, Shigeru Owada. *Asao Kidney Clinic, Kawasaki, Kanagawa, Japan.*

Background: Keeping a functional vascular access (VA) is one of the most important factors in the maintenance of well controlled HD modality. The application of vascular access interventional therapy (VAIVT) for VA trouble is growing recently but the effectiveness of VAIVT has not been fully satisfactory because of the relatively higher rate of re-stenosis.

Methods: We have experienced 2,000 cases of VA trouble treated with VAIVT over the last 6 years in which primary assisted and secondary assisted rates were analyzed.

Results: 1. We have used a noncompliant type of balloon catheter for 96.4%of cases and primary assisted rates were 99.0%. 2. Assisted patency rates were 85.0% at one year, 75.3% at 3 years and 67.2% at 6 years in all patients. 3. In diabetic patients, assisted patency rate was 61.5% at 6 years and it was 70.8% in non-diabetic patients (p=0.03, Log rank). There were no significant differences found between the arteriovenous fistulas and the arteriovenous grafts (67.3% and 63.3% at 6 years, respectively). 4. Failure of the secondary assisted patency was observed in 135 patients. In these, a new arteriovenous fistula was made on the same side in 60.0% of the patients, a contralateral side shunt was made in 5.9% and an AV graft in 28.0%, superficialized reposition of brachial artery in 2.3% and death occurred in 3.7%.

Conclusions: 1. The results in primary assisted patency rates were good. 2. It was possible to reduce the economical burden for patients using a noncompliant type of balloon catheter. 3. Good patency rates for vascular access were maintained using management charts of VA.

TH-PO765

Early Changes in Upper Arm Blood Vessels Following Forearm Arteriovenous Loop Graft Placement Troy J. Plumb,[1] Michael Morris,[2] Valerie K. Shostrom,[3] Gernon Matthew Longo.[2] *[1]Internal Medicine, University of Nebraska Medical Center, Omaha, NE; [2]Surgery, University of Nebraska Medical Center, Omaha, NE; [3]Biostatistics, University of Nebraska Medical Center, Omaha, NE.*

Background: The timing and extent of changes in the vasculature of the upper arm following forearm arteriovenous loop graft (fAVG) placement are not known. When, and to what degree changes occur are important when considering the placement of a fAVG and the potential for future secondary AV fistula creation. In this study we describe the changes that occur in the artery and veins of the upper arm following fAVG placement.

Methods: We prospectively evaluated the basilic vein, cephalic vein and brachial artery of the upper arm in 10 subjects undergoing fAVG placement. Subjects underwent ultrasound imaging to assess vessel diameter at baseline and at 1, 4, 12 and 27 weeks following fAVG placement. The brachial artery was measured near the antecubital fossa. Cephalic and basilic vein diameters were measured at the antecubital fossa (AC), the mid upper arm (MID), and proximal upper arm (UP). A repeated measures model with adjustment for multiple comparisons was used to evaluate differences in artery and vein diameters across time points.

Results: Basilic vein diameters (millimeters) increased from baseline to 1 week at AC: 2.9±1.3 (baseline) to 5.8±1.9 (1 week), MID: 3.6±1 to 6.2±1.5, UP: 3.7±1.1 to 7.2 ±1.6 ($p<0.001$ for all locations). Brachial artery diameter in AC increased from 4.1±0.8 at baseline to 5±1.1 at 1 week (p=0.02). These early increases in artery and vein diameters persisted for the duration of the study. There were fewer patients with patent cephalic veins at baseline. Cephalic vein diameters increased to a lesser degree, and only became significant in the MID location.

Conclusions: Marked increases in upper arm artery and vein diameters occurred following fAVG placement. These changes occurred within one week and persisted for the duration of the study. Given the timing of these changes, even patients with early failure or failing fAVGs should be considered for prompt conversion to an upper arm AVF.

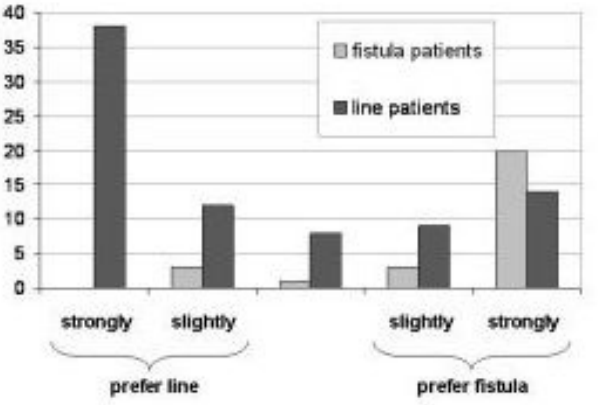
Haemodialysis Access: Determinants of Patient Preferences Damien Ashby,[1] James John Rowland Budge,[2] Courtney Burtenshaw,[2] Neill D. Duncan,[1] Jeremy Crane.[1] *[1]Imperial College Kidney and Transplant Institute, Imperial College, London, United Kingdom; [2]Imperial College School of Medicine, Imperial College, London, United Kingdom.*

Background: Compared to other forms of access, arteriovenous fistulae are associated with improved outcomes in haemodialysis patients. Various guidelines and incentives have been developed to increase fistula prevalence within institutions but some patients are reluctant to undergo fistula formation.

Methods: Patient opinions and the influences informing them were determined using structured interviewer led questionnaires in a group of prevalent haemodialysis patients.

Results: In 108 patients (aged 18 – 87, 69% male) opinions were highly polarised, with two thirds expressing a strong access preference and only 8% expressing no opinion.



Of 81 patients dialysing on a tunnelled line, 50 (62%) were unwilling to have a fistula. The principle reasons were body image and pain during dialysis, cited by 70 and 74% of patients respectively. Most of these patients claimed to understand the risks of non-fistula access, but failure to appreciate this was a contributory factor in 28%.

Opinions in patients who had never had a fistula were overwhelmingly informed by their interactions with other patients, with only 27% reporting any influence due to professional advice. Those who had previously had a fistula were informed by their own experience as much as other patients, and not at all by professionals. The negative effect of unsightly fistulae in other patients was clearly substantial.

Conclusions: Access opinions are polarised according to personal experiences and interactions with other patients, with large fistulae in particular having a strong negative impact. A better understanding of patient reasoning could lead to improved access choices.

Thigh Graft Outcomes in Hemodialysis Patients Song Ching Ong, Michael Allon. *Division of Nephrology, University of Alabama at Birmingham, Birmingham, AL.*

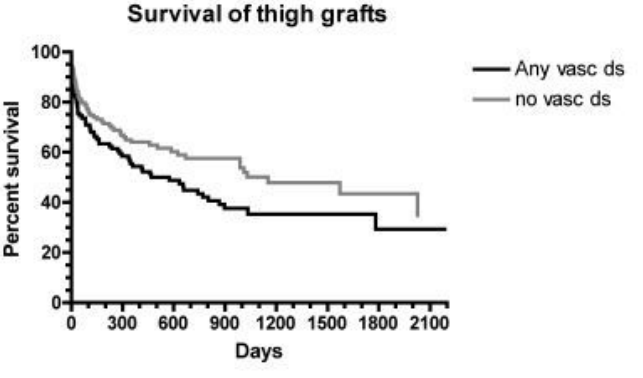
Background: Prosthetic arteriovenous thigh grafts are an important option for hemodialysis patients who have exhausted their upper limb vascular access sites. We evaluated our experience with the outcomes of thigh grafts at a large dialysis center.

Methods: We retrospectively analyzed a prospective vascular access database to identify all thigh grafts placed during an 8.5-year period. The rates of graft survival, thrombosis and infection were calculated. In addition, we evaluated the association of graft survival with patient demographics and comorbidities.

Results: A total of 255 grafts were placed during the study period. The surgical technical failure rate was 7.8%. The median graft survival was 802 days (2.2 years) and median time to thrombosis was 189 days (0.5 year). The 1, 3 and 5 year cumulative graft survival was 60%, 43% and 36% and the respective thrombosis free survival was 38%, 22% and 13%. Graft infection occurred in 55 cases (17%). Cumulative graft survival was lower among patients with vascular disease, as compared to those without vascular disease (HR 1.41, 95% CI 1.00-2.04, p= 0.05), but was not associated with patient age, sex, diabetes or heart failure.

Clinical factor	HR	95% CI	p-value
Any vascular disease (Y vs N)	1.41	1.00-2.04	0.05
Age (>65 vs <65yr)	0.78	0.50-1.24	0.30
Sex (male vs female)	0.87	0.61-1.25	0.46
Diabetes (Y vs N)	0.95	0.66-1.36	0.79
Congestive heart failure (Y vs N)	1.20	0.78-1.90	0.38

Conclusions: Thigh grafts have a fairly good cumulative survival rate and should be considered as the access of choice in patients who have exhausted options in both upper extremities. Thigh graft survival is decreased in patients with vascular disease.



TH-PO768

Surgical Management of Cephalic Arch Occlusive Lesions: Advantages and Limitations Shouwen Wang,[1] Ammar Almehmi.[2] *[1]AKDHC-ASC, Arizona Kidney Disease and Hypertension Center, Phoenix, AZ; [2]University Vascular Access Center, University of Tennessee College of Medicine, Memphis, TN.*

Background: Cephalic arch occlusive lesions (CAO) are common cause for dysfunction of upper extremity arteriovenous fistulas (AVFs). These lesions are usually resistant or not amenable to endovascular interventions. Therefore, various surgical interventions have been employed to manage CAO. We here report the outcomes of the largest case series of surgical interventions for CAO.

Methods: This series included 40 hemodialysis patients who had dysfunctional AVFs due to CAO and underwent surgical revisions from 2009 to 2012.

Results: Of the 40 patients: 65% were males, mean age was 59.4 ± 14.0 years, and 70% were diabetics. Mean age of fistulas was 2.1 ± 1.6 years and mean post-operative follow-up was 16.6 ± 7.9 months. The surgical indications were: frequently recurrent stenosis (17/40), high-grade elastic stenosis (5/40), occlusions (17/40), and localized tortuous stenosis (1/40). The procedures performed included: cephalic vein transposition (37/40), basilic vein transposition (1/40), stenotic segment resection (1/40), and cephalic-jugular vein bypass graft (1/40). Of the new cephalo-basilic anastomoses after cephalic transposition, 25% required no interventions (follow-up 8-24 months) and 75% required angioplasties (follow-up 1-32 months). The development of neo-anastomosis stenosis correlated with angioplasty of the cephalic veins prior to transposition (correlation coefficient 0.556, $p<0.001$). In a subset of 14 patients who presented with recurrent stenosis and had at least 12 months of follow-up after surgery, the number of angioplasties/year for cephalic lesions was decreased to 1.3 ± 1.4 after transposition from 4.2 ± 1.4 before transposition ($p<0.001$). The primary assisted patency of the AVFs at 12 months after cephalic transposition was 77.9%.

Conclusions: Surgical interventions are safe and effective in salvaging AVFs complicated with CAO. They can prolong access life and reduce the need for endovascular interventions in selected patients. Further investigations are needed to identify factors that may affect the outcomes of surgical interventions.

TH-PO769

A Comparative Analysis of Vascular Access and Immunization between For-Profit and Non-Profit Dialysis Facilities Using Medicare Claims Data Mahesh Krishnan,[1] Allen R. Nissenson,[1] Rachel Feldman,[2] Mark Desmarais,[2] Lianna Weissblum.[2] *[1]DaVita Inc., Denver, CO; [2]The Moran Company, Arlington, VA.*

Background: Previous limited analyses have suggested differences in outcomes between for- (FP) and non-profit (NP) dialysis providers. We hypothesized that FP facilities would have superior outcomes when compared with non-profit facilities for process-driven outcomes that are resource intensive. We used Medicare data to test this hypothesis.

Methods: 2009-10 Medicare Standard Analytic File Claims data were analyzed per dialysis facility to compare identification data for FP and NP providers from the files downloaded from that site. USRDS Annual Data Report definitions were used to determine immunization rates and v5, v6, and v7 modifiers in place on ESRD claims since July 2011 were used to determine vascular access status.

Results: We analyzed data from 4,242 dialysis clinics' Medicare claims for 2010. FP dialysis facilities showed better outcomes for vascular access than NP dialysis facilities as measured by the difference in percent of catheter use at (17.5% FP vs 20.1% NP).

Similarly, FP dialysis facilities showed better outcomes in percent of vaccination rates for influenza, (54.8% FP vs 52.3% NP). These trends continued for Pneumococcal Pneumonia immunization (26.1% FP, vs 21.3% NP) and Hepatitis B immunization (25.2% FP and 21.1% NP). All data reflect Medicare claims data rates only and differ from internal rates of the large dialysis organization population.

Conclusions: FP providers had superior vascular access and vaccination outcomes compared to NP providers. Intense focus on care processes like vaccination and vascular access can significantly augment population-based and patient-based goals, improving population health and constraining healthcare costs. Sufficient infrastructure support and scaling capability, however, are needed as well as high prioritization, as is seen in for-profit dialysis facilities.

TH-PO770

Association between Vascular Access Handling and the Outcome of Arteriovenous Fistula:International Comparison between Facilities Using Data from the Dialysis Outcomes and Practice Patterns Study (DOPPS) Manabu Asano,[1] Jyothi R. Thumma,[5] Kenichi Oguchi,[1] Ronald L. Pisoni,[5] Tadao Akizawa,[2] Takashi Akiba,[3] Akira Saito.[4] *[1]Renal Unit, Ikegami General Hospital, Tokyo; [2]Showa University School of Medicine, Tokyo; [3]Tokyo Women's Medical University, Tokyo; [4]Tokai University School of Medicine, Kanagawa, Japan; [5]Arbor Research Collaborative for Health, Ann Arbor, MI.*

Background: Vascular access (VA) failure is a momentous cause of morbidity in hemodialysis (HD) patients. Our objective was to corroborate whether VA handling factors are associated with arteriovenous fistula (AVF) survival by means of results obtained from the DOPPS 2 and 3.

Methods: Analyses included 1,183 incident HD pts (on HD≤7 days and using an AVF at study entry) and 949 prevalent pts (on HD>7 days). Medical directors and nurse managers from each participating facility were asked to complete a self-administered questionnaire that included questions on VA practices including: Physician-related factors (existence of preferred surgeon, prompt surgical/radiological VA procedure, technical skill of surgical/radiological VA procedure) and staff-related factors (response to a failed VA and cannulating skill). The hazard ratio of AVF failure with VA handling factors were compared by the three regions(Europe/Australia/New Zealand:EUR/ANZ, North America:North Am, Japan)using Cox regression models.

Results: The perception by unit staff that radiological VA procedures were performed "promptly" in their unit vs not promptly was associated with a tendency towards a lower hazard of final AVF failure in Japan and EUR/ANZ. (EUR/ANZ:HR 0.80, CI 0.54-1.19; Japan:HR 0.48, CI 0.09-2.46; North Am:HR 2.61, CI 0.63-10.75,). A tendency towards lower AVF failure also was seen in dialysis units in Japan and EUR/ANZ which reported that radiological VA procedures were performed with the highest level of skill. (EUR/ANZ:HR 0.73, CI 0.48-1.11; Japan:HR 0.23, CI 0.06-0.93; North Am:HR 2.77, CI 0.62-12.33).

Conclusions: Regional variability was observed in VA management. Both in Japan and EUR/ANZ, radiological VA procedures when performed promptly or with highest technical skill were inclined to contribute to greater AVF patency.

TH-PO771

Surgical Site Infection Surveillance Post Vascular Access Interventions Aris Q. Urbanes, Terry Litchfield, Kevin Graham. *Lifeline Vascular Access, Vernon Hills, IL.*

Background: By definition, a surgical site infection (SSI) is an infection that develops within 30 days after an operation or within one year if an implant was placed and the infection appears to be related to the surgery. Post-operative SSIs are the most common healthcare-associated infection in surgical patients, occurring in up to 5 percent of surgical patients. In the United States, between 500,000 and 750,000 SSIs occur annually. Patients who develop an SSI require significantly more medical care. Endovascular surgical procedures are quite common in the dialysis population and can be a cause of SSIs. A large outpatient vascular access system developed and implemented a surveillance program to measure and monitor SSI in their population.

Methods: This surveillance was achieved through a survey given at discharge to all patients having interventional procedure performed with the survey returned at 30 days. The annual implant data collection was done via a telephonic voice response system. The data was collected and analyzed using SPSS software.

Results: During the time period, 41,233 patients underwent interventional procedures. 6,218 of those patients returned the survey for a 15% response rate. The mean response was received 32.52 days post intervention. 99.6% of the respondents reports their surgical site healed well, without evidence of infection. Using a standard definition of SSI as being either antibiotic prescribed; 2 or more clinical signs; dehiscence, the rate of Surgical Site infection was 1.4%.

Conclusions: SSIs are a serious medical problem associated with increased morbidity and mortality and increased medical care costs. This study showed that the rate of post procedure SSIs are quite low in outpatient vascular access procedures. All providers should consider an active surveillance program after these types of procedures given the co-morbidities associated with the dialysis population.

TH-PO772

Intra-Access Pressure Change after Angioplasty and Post Interventional Patency Bushra Joarder,[1] Alexander S. Yevzlin,[2] Charmaine E. Lok.[1] *[1]Nephrology, Toronto General Hospital and University of Toronto, Toronto, ON, Canada; [2]Nephrology, University of Wisconsin, Madison, WI.*

Background: Fistula and grafts are often complicated by stenosis and thrombosis and require percutaneous transluminal angioplasty (PTA) to maintain graft patency. Generally, less than a 30% residual stenosis indicates intervention success. However, this subjective measure may not correlate with the hemodynamic effect and patency anticipated. Rather, direct intra-access pressure measurement before and after PTA may be an objective reflection of the effect of reducing the stenotic lesion. We aimed to determine an association between intra-access pressure change with PTA and the time to the next PTA.

Methods: We retrospectively evaluated a random 59 vascular accesses (36 fistulas) that underwent underwent PTA between 2004-2010. Pre and post PTA pressure measurements at different intra-access locations within an access were reviewed; the greatest difference in pressure (delta) at any location in the access largest (delta circuit), at the arterial (delta AP) and venous (delta VP) access segments were obtained. Associations between intra-access pressure changes and the time to the next angioplasty (TTAP) was determined by correlational statistics (SAS, 9.2).

Results: No correlation was found between delta circuit and TTAP; however the maximal delta VP was positively correlated to the TTAP ($r=0.38$; $p=0.02$). Further, delta circuit and delta AP was highly correlated ($r=0.94$; $p<0.0001$) as was delta circuit and delta VP ($r=0.85$; $p<0.0001$).

Conclusions: The maximal intra-access pressure change by AP anywhere in the circuit is not associated with primary patency and is more highly associated with changes in AP than VP; however, the maximal change in VP is positively correlated with a longer time before next PTA is required. Larger studies are required with specific evaluations of fistulas and grafts to further elucidate the role of intra-access pressure measurements to indicate PTA success and time to next procedure.

TH-PO773

Percutaneous Transluminal Angioplasty (PTA) in Cephalic Arch and Juxta-Anastomotic Stenosis of Hemodialysis Arteriovenous Fistula Gun Hee An, Yul Hee Cho, Myung Hyun Lee, Jeong Gwan Kim, Hyun Chul Whang, Yong-Soo Kim. *Section of Interventional Nephrology, Division of Nephrology, The Catholic University of Korea College of Medicine, Seoul, Republic of Korea.*

Background: Venous stenosis is a major cause of vascular access dysfunction. We evaluated the outcome of the PTA in cephalic arch stenosis (CAS) and juxta-anastomotic stenosis(JAS) of hemodialysis arteriovenous fistula (AVF).

Methods: A cohort of 171 PTA performed in 108 patients with dysfunctional AVF diagnosed by clinical assessment or intra-access flow surveillance, from January 2010 to February 2012 in Seoul St. Mary's Hospital were retrospectively reviewed. Out of 171 PTA, 20 PTA in 11 patients with CAS and 56 PTA in 26 patients with JAS were analyzed.

Results: The prevalence of CAS and JAS in total AVF dysfunction was 10% (11 of 108) and 24% (26 of 108), respectively. In 11 patients with CAS, mean age was 62 years old, male 63%, mean access age was 41 months. Ten out of 11 patients had brachiocephalic fistula. In 26 patients with JAS, mean age was 61 years old, male 63%, mean access age was 37 months. Seventy three percent patients of JAS had radiocephalic fistula, and the rest had brachiocephalic fistula.

In both CAS and JAS, the most reason for angiography were serial decrease in access flow (50% vs 38%) and a half had multiple stenotic lesion. Forty two percent of radiocephalic AVF group had JAS and 46% of brachiocephalic AVF group had CAS.

The primary patency of CAS and JAS after 3, 6 and 12 months was 80 / 57 / 57% (mean duration 7.6 months) and 85 / 68 / 37% (mean duration 8.6 months) respectively. No patient had any PTA-related complication.

Conclusions: Our results suggest that the location of stenosis can be specific to the fistula type and the outcome of PTA in cephalic arch and juxta-anastomotic stenosis is clinically acceptable.

TH-PO774

Medicare Reimbursement for Provider Visits and Mortality in Patients on Hemodialysis Kevin F. Erickson,[1,2] Wolfgang C. Winkelmayer,[1] Glenn M. Chertow,[1] Jay Bhattacharya.[2] *[1]Nephrology, Stanford University School of Medicine, Palo Alto, CA; [2]Health Research and Policy, Stanford University, Stanford, CA.*

Background: In January 2004, the Centers for Medicare and Medicaid Services changed reimbursement for physicians caring for patients on hemodialysis from a capitated system to a tiered fee-for-service system referred to as "G-code" reimbursement, creating an incentive for providers to see patients more frequently. The effects of this policy on outcomes and costs are unknown.

Methods: Using data from the United States Renal Data System (USRDS), we compared adjusted mortality hazards among patients commencing hemodialysis in the 3 years before and after enactment of G-code reimbursement. We used a difference-in-difference approach to compare adjusted mortality hazards in patients covered by: (1) Medicare (Parts A&B) versus Medicare Advantage HMOs (who remained on a capitated payment system); and (2) patients living in urban areas and large towns versus in remote areas (whose providers were less able to respond to the G-code incentive).

Results: While mortality rates for all Medicare beneficiaries on hemodialysis on fee-for-service plans declined 3.4% (95% CI 2.2 to 4.6%) after enactment of G-code reimbursement, mortality rates declined more among beneficiaries who remained under capitated payment plans. Medicare beneficiaries from rural areas and small towns experienced a more pronounced decline in mortality compared with those in more densely-populated areas. Inflation-adjusted physician payments for dialysis visits increased 6.0% per patient-month in the year following G-code enactment.

Conclusions: The tiered payment system designed to increase provider visits to hemodialysis patients led to a temporary increase in Medicare costs with no evidence of a benefit to survival.

TH-PO775

Variation in Medicare Prospective Payment System Drug Costs by Dialysis Organization and Projection to 2014 Wendy L. St. Peter,[1,2] Eric D. Weinhandl.[1] *[1]USRDS Coordinating Center, MMRF, Minneapolis, MN; [2]University of Minnesota, Minneapolis, MN.*

Background: Beginning in 2011, injectable dialysis-related medications and their oral equivalents were included in the ESRD Prospective Payment System (PPS). In 2014, cinacalcet and phosphate binders will also be included in the PPS. We examined variation in PPS drug costs by dialysis organization, according to the 2011 and 2014 designs, as well as variation in total Medicare drug costs and gross Part D costs.

Methods: Linked Medicare Parts A, B and D data were used. Prevalent adult patients who received dialysis during all of 2009, had Medicare Parts A and B as primary payer, and were enrolled in a standalone Part D plan were included (n=140,978). Adjusted per person per year (PPPY) total Medicare drug costs, ESRD PPS drug costs, and gross Part D costs in 2009 were calculated, with stratification by dialysis organization, low-income subsidy (LIS) status, and race. Costs were adjusted by age, sex, and either race or LIS status.

Results: Total Medicare drug costs in 2009 ranged from $10,312 to $12,021 PPPY in non-LIS (maximum:minimum, 1.17) and from $15,597 to $18,074 in LIS patients (1.16). Costs among DaVita patients were higher than among patients in other dialysis organizations, regardless of LIS status. In all organizations, black patients had the highest total Medicare drug costs. PPS drug costs in the 2011 and 2014 designs were highest for DaVita and generally lowest for small organizations and independent providers. Gross Part D costs were highest among DaVita patients and lowest among Fresenius patients; costs per medication per day were also highest among DaVita patients. When cinacalcet and phosphate binders are included in the PPS in 2014, the largest shift in gross Part D drug costs is projected to occur among DaVita patients: $2,409 and $5,020 PPPY will shift from Part D to the PPS in non-LIS and LIS patients, respectively.

Conclusions: There is significant variation in drug costs among dialysis organizations. Shifting coverage of cinacalcet and phosphate binders from Part D to PPS will increase costs for dialysis organizations. Some patients may face increased out-of-pocket drug costs attributable to higher copayments with the PPS versus Part D.

Funding: NIDDK Support

TH-PO776

Variation in Medicare Part D Prescription Drug Fill Rates and Coverage Phase Progression by Dialysis Organization Wendy L. St. Peter,[1,2] Eric D. Weinhandl.[1] *[1]USRDS Coordinating Center, MMRF, Minneapolis, MN; [2]University of Minnesota, Minneapolis, MN.*

Background: 73% and 61% of Medicare hemodialysis (HD) and peritoneal dialysis (PD) patients are enrolled in Part D, respectively. Number of medications, refill rates, and prescription costs influence whether patients progress from the initial coverage phase to the coverage gap (all costs paid out-of-pocket) and subsequently to catastrophic coverage (5% of costs paid out-of-pocket). We investigated whether patterns of coverage phase progression and medication utilization were similar across dialysis organizations.

Methods: Linked Medicare Parts A, B and D data were used. Prevalent adult patients who received dialysis during all of 2009, had Medicare Parts A and B as primary payer, and were enrolled in a standalone Part D plan without the low-income subsidy (LIS) were included (n=29,414). Percentage of patients reaching the coverage gap and catastrophic coverage and mean number of medications per day in each phase were calculated. Results were stratified by modality and dialysis organization and adjusted for age, race, and sex.

Results: Across organizations, 52-58% of HD and 55-67% of PD patients reached the coverage gap (CG), and 12-17% of HD and 14-24% of PD patients reached catastrophic coverage (CC) in 2009. DaVita had higher percentages of HD and PD patients reach each phase than other dialysis organizations. However, among patients who did not reach the CG (46%); who reached the CG, but did not reach CC (40%); and who reached CC (14%), DaVita patients uniformly had the lowest mean number of medications per day in each phase. There was more inter-organization variability in the mean number of medications per day in PD versus HD patients.

Conclusions: Independent of modality, a higher percentage of DaVita patients without the LIS reached the coverage gap and catastrophic coverage, despite the fact that they had the lowest mean number of Part D-covered medications per day. This combination is possible only if medications taken by DaVita patients are more costly, on average, than medications taken by patients in other organizations. Research is needed to assess whether higher Part D expenditures reduce costs of inpatient and outpatient care.

Funding: NIDDK Support

TH-PO777

Future Eligibility for Medicare Part D Medication Therapy Management among Dialysis Patients Eric D. Weinhandl,[1] Wendy L. St. Peter.[1,2] *[1]USRDS Coordinating Center, MMRF, Minneapolis, MN; [2]University of Minnesota, Minneapolis, MN.*

Background: Medicare Part D plan sponsors are required to provide medication therapy management (MTM) to targeted beneficiaries. One eligibility criterion in 2012 is that the beneficiary is likely to incur >$3,100 in annual drug costs. In 2014, coverage of cinacalcet and phosphate binders will shift from Part D to the ESRD Prospective Payment System (PPS) ("the dialysis bundle"), thereby reducing Part D drug costs among dialysis patients. We assessed the projected impact of this shift on MTM eligibility.

Methods: Linked Medicare Parts A, B and D data were used. Prevalent adult patients who received dialysis during all of 2009, had Medicare Parts A and B as primary payer, and were enrolled in a standalone Part D plan were included (n=140,978). Per person per year (PPPY) gross Part D costs in 2009, with and without cinacalcet and binders, were calculated, with stratification by low-income subsidy (LIS) status. Excluding cinacalcet and binders, predictors of annual drug costs <$3,100 were identified from logistic regression.

Results: With cinacalcet and binders, gross Part D costs were $7,897 and $4,410 PPPY in LIS (79%) and non-LIS (21%) patients, respectively. Percentages of LIS and non-LIS patients with costs <$3,100 were 26% and 52%, respectively. Without cinacalcet and binders, gross Part D costs were $3,904 and $2,599 PPPY in LIS and non-LIS patients, respectively. Percentages of patients with costs <$3,100 were 57% and 76%, respectively. In this setting, predictors of costs <$3,100 were age 18-44 (odds ratio, 1.51) vs. 45-64 yr; black (1.90) and Asian (1.47) vs. white race; Hispanic ethnicity (1.78); male sex (1.27); hypertension (2.02), glomerulonephritis (2.17), and cystic kidney (2.52) vs. diabetes as the primary cause of ESRD; and non-LIS status (3.37).

Conclusions: Cincalcet and phosphate binders account for almost half of gross Part D costs. Shifting coverage of these medications from Part D to the ESRD PPS will reduce Part D expenditures to such an extent that the majority of dialysis patients will be ineligible for MTM offered by Part D plan sponsors. The Centers for Medicare and Medicaid Services should consider how to encourage dialysis providers to offer MTM.

Association of Insurance Status and Outcome of Hemodialysis Patients Utilizing the Emergency Department for Acute Care Subodh J. Saggi, Moro O. Salifu, Eli A. Friedman. *Nephrology, SUNY Downstate, Brooklyn, NY.*

Background: End Stage Renal Disease patients on hemodialysis frequently use the emergency department (ED) for acute care. The aim of this study was to define the characteristics and the impact of insurance status specifically of being uninsured and undocumented on outcomes.

Methods: We evaluated 3065 patients over a three year period (2008-2010) who visited the ED at our public health safety net hospital necessitating the performance of emergent dialysis. The primary outcome was in-hospital mortality based on insurance classification. Secondary outcomes were presenting symptoms, distribution of ED visits, time to activation for dialysis and time to disposition. Data were abstracted from the existing electronic medical record system and analyzed using descriptive statistics, correlation and logistic regression.

Results: Mean age was 65.4±16.7 years, 54.3% were female, 88% were Black and 58.7% presented with volume overload. Average wait time in the ED for dialysis was 1.07±1.3 hours. During hospitalization 2.3% of these visitors died. Combined uninsured and undocumented patients represented 47.1%. When adjusted for age, race, time to dialysis and length of stay, the adjusted OR of death for undocumented patients was 2.56 (95% CI 1.56-4.82, p=0.003). Undocumented patients were older (p=0.01), had significantly higher rate of unknown race (p=0.001), time to dialysis (p=0.009) and length of stay (p=0.038) compared with documented patients.

Conclusions: Undocumented status predicted in-hospital mortality. Volume overload was highest in undocumented patient's visits but failed to predict in-hospital mortality. Further studies are needed to determine the mechanisms underlying the protective effect of sustainable medical insurance on mortality.

TH-PO779

Differences in Dialysis Modality and Mortality by Proximity to a Pediatric Dialysis Centre Anke M. Banks,[1] Andrea Soo,[1] R. Todd Alexander,[2] Bethany J. Foster,[3] Susan M. Samuel.[1] *[1]University of Calgary, Calgary, AB, Canada; [2]University of Alberta, Edmonton, AB, Canada; [3]McGill University, Montreal, QC, Canada.*

Background: Canadian children with end-stage renal disease (ESRD) may live a great distance from renal care. It is unknown if this geographical barrier influences dialysis modality or mortality.

Methods: Using data from the Canadian Pediatric ESRD Database, pediatric patients (<18 years) who began dialysis in Canada between 1992-2010 were followed until death, first kidney transplant, date of last contact or study end (December 31, 2010). We calculated the distance from a patient's residence to the nearest pediatric dialysis centre (PDC) using geographic information software and categorized them as <50 km, 50-150 km, 150-300 km or ≥300 km. We analyzed mortality by distance to PDC and modality using Cox proportional hazard models adjusted for etiology of ESRD, age at start of dialysis, gender, ethnicity and income quintile.

Results: 893 patients were followed for a median of 1.3 (IQR 0.7-2.4) years (total follow-up 1799 patient-years). The median age at dialysis onset was 13.1 (IQR 7.5-15.8) years. Most patients (49.9%) lived <50 km from a PDC. A larger proportion of Aboriginals than Caucasians lived ≥300 km from a PDC (50.0% vs. 21.0%, p<0.001). Of patients living <50 km away, more started on hemodialysis (HD) than peritoneal dialysis (PD) (59.2% vs. 40.8%, p<0.001), and 85.6% remained on HD after initiation. Almost equal numbers of patients living ≥300 km away started on HD and PD (45.6% vs. 54.4%, p=0.71), but 31.3% who started on PD changed to HD. There were 54 deaths prior to transplantation with a median age at death of 15.1 (IQR 3.7-20.2) years. In HD patients, living ≥300 km away was associated with an increased risk of mortality compared to those living <50 km away (hazard ratio 5.17; 95% CI 2.14-12.46).

Conclusions: The majority of Canadian pediatric ESRD patients living close to a PDC started on HD and stayed on HD. A large proportion of patients living ≥300 km from a PDC also started on HD or switched to HD from PD. Pediatric HD patients living ≥300 km from a PDC have an increased risk of mortality.

Centre/Provider Specific Performance Indicators for Renal Services Using Routine Linked Data: Survival, Frequency of Admission and Hospitalisation to Start Renal Replacement Therapy James Fotheringham,[2,3] Richard M. Jacques,[3] Damian G. Fogarty,[1] Meguid El-Nahas,[2] Michael J. Campbell.[3] *[1]The UK Renal Registry, Bristol, United Kingdom; [2]Sheffield Kidney Institute, University of Sheffield, Sheffield, South Yorkshire, United Kingdom; [3]School of Health and Related Research, University of Sheffield, Sheffield, South Yorkshire, United Kingdom.*

Background: Renal Replacement Therapy (RRT) registries have the capacity to report centre specific outcomes. Case-mix needs to be adjusted for and missing data minimised to allow robust comparisons, with measures meaningful to the patient and clinician.

Methods: 21,633 patients starting RRT between 2002 and 2006 in England were linked to 11,546 mortality records and 290,433 hospitalizations. Comorbid conditions at the start of RRT were identified from discharge diagnoses. In patients surviving beyond 90 days, survival, all cause frequency of admission, hospitalization to start dialysis and hospital standardized mortality were modelled using Cox proportional hazards, the negative binomial distribution and logistic regression. Centre specific survival proportions and observed/expected ratios for admissions and mortality rates were compared using funnel plots.

Results: Ninety-eight percent of incident patients were suitable for analysis across 46 centres. Age, ethnicity and socio-economic status explained a large proportion of performance variation. Following adjustment for these and comorbidity, the number of outliers for incident 3-year survival uncensored for transplantation reduced from 6 to 1. Outliers for admission rate in the first 12 months of dialysis changed from 4 to 3 in hemodialysis and 4 to 5 in peritoneal dialysis. Six centres remained outliers for hospital associated mortality and for hospitalization to start dialysis. All measures had centres moving both in and out of control following adjustment.

Conclusions: Routine linked data combined with robustly calculated and adjusted performance measures presents a powerful way of comparing centre performance. In England adjusted survival on RRT is similar across centres. However, patients in some centres are admitted four times as often as in others, with associated cost and reduction in quality of life.

TH-PO781

Early Referral to Nephrologist Improved Mortality of Newly Diagnosed End Stage Renal Disease Patients Do Hyoung Kim,[1,4] Jung Pyo Lee,[2,4] Yun Jung Oh,[1,4] Hyun-Seop Cho,[1] Jiwon Ryu,[1] Yong-Lim Kim,[3,4] Yon Su Kim.[1,4] *[1]Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Korea; [2]Department of Internal Medicine, National University Boramae Medical Center, Seoul, Korea; [3]Department of Internal Medicine, Kyungpook National University School of Medicine, Daegu, Korea; [4]Clinical Research Center for End Stage Renal Disease, Daegu, Korea.*

Background: Over the past several years, interest has evolved in evaluating the timing of nephrology referral as an important variable related to prognosis. The purpose of this study was to explore the impact of early referral to nephrologist on patient survival in a subset of patients from Comprehensive Prospective Study of Clinical Research Center for End Stage Renal Disease (CRC ESRD) in Korea.

Methods: A total of 1028 incidental ESRD patients newly diagnosed from July 2008 to October 2011 were enrolled. Data were served from CRC ESRD nationwide web-based multi-center joint network prospective cohort in the Korea. Patients were classified arbitrarily as early referrals if their first encounter with a nephrologist occurred longer than 1 year, number of visit to nephrologist >2 times, and education for dialysis (from nurse or nephrologist) prior to initiate dialysis.

Results: Time from referral to dialysis was significantly longer in 522 early referral patients (ER) than in 506 late referral patients (LR) (63.6±59.6 vs. 10.7±28.1 mo, P<0.001). Emergent hemodialysis was required in 217 (41.6%) of ER compared with 268 (53.0%) of the LR (P< 0.001). The survival rate in ER was better than that in LR (P =0.046). The 1-year and 2-year survival rates in ER were better than that of LR (p=0.049). The 1-year and 2-year survival rates of ER were 95.9% and 90.9%, respectively, compared to 92.1%, and 80.3% of LR. In diabetic ESRD patients, the survival rate of ER was significantly higher than that in LR (P=0.032). The difference was significant after adjusting for covariates (OR 0.16 95% CI 0.03-0.93, P=0.042).

Conclusions: Early referral to nephrologist is associated with reduced mortality especially in diabetic chronic kidney disease patients.

TH-PO782

Bouncing Back: Patterns of Early Hospital Readmissions in ESRD Patients on Dialysis Priyanka Khatri,[1] Lisa A. Pacelli,[2] Peter Juergensen,[2] Shirin Shirani,[2] Fredric O. Finkelstein.[2] *[1]Hospital of Saint Raphael, New Haven, CT; [2]Hospital of Saint Raphael, Renal Research Institute, New Haven, CT.*

Background: Hospital readmissions are an important measure for assessing performance of the health care system as well as dialysis facilities. According to the 2011 report by United States Renal Data System, up to 36% of ESRD patients are rehospitalized within 30 days of discharge. There is a need for investigations to examine the profile of readmissions in this population to identify potentially modifiable factors. Only a few studies have focused on readmissions specifically in ESRD patients.

Methods: We conducted a retrospective review of discharge summaries of all dialysis patients readmitted within 30 days of their last discharge during the year 2009-2011 at 3 dialysis centers in New Haven, CT. Data was collected regarding the basic patient demographic profile, cause of index hospitalization and cause of readmission. Two authors independently reviewed the causes of hospitalizations and characterized the readmissions as being for the same diagnosis, a problem directly related to, or a problem unrelated to the index hospitalization.

Results: Admissions averaged about 2 admissions per patient year. The 30 days readmission rate was 30.8 %. 237 readmissions amongst 121 patients were examined in detail .The mean+/- SD age of study population was 67+/- 14 years. 50% were male. 34% of the readmissions occurred within 1 week of discharge. 17 % of patients were readmitted with the same diagnosis and an additional 22 % with a cause related to the initial diagnosis.

Conclusions: This study suggests that nearly 40% of ESRD patients who are readmitted within 30 days of discharge are readmitted with the same or a diagnosis related to the index hospitalization. 1/3 of readmissions occur within the first week. These findings underscore the importance of improving immediate discharge planning and post hospitalization care as a means of trying to reduce the high rehospitalization rate observed in these patients. Further studies focusing on possible areas of intervention including better communication between hospital and dialysis care providers need to be done.

TH-PO783

Mortality Trends in Wait-Listed Dialysis Patients versus the General Population in the United States, 2000-2009 Robert N. Foley,[1,2] Allan J. Collins,[1,2] David T. Gilbertson,[1] Shu-cheng Chen.[1] *[1]USRDS Coordinating Center, MMRF, Minneapolis, MN; [2]Medicine, University of MN, Minneapolis, MN.*

Background: Apparently encouraging survival gains continue to accrue in the US dialysis population. It is unknown, however, whether these salutary trends reflect improving survival in the general population or differences in comorbidity in the dialysis population.

Methods: In order to minimize these potential effects, we evaluated annual mortality trends in US dialysis patients from the time of first transplant waitlisting between 2000 and 2009 and compared these estimates with expected mortality rates in the US general population over the same period.

Results: Among patients first wait-listed for transplant in 2000, the observed mortality on dialysis was 5.8 per 100 person years; based on the distribution of age, sex and race ethnicity, this value was 6.2 times that expected from general population estimates. By 2009, the ratio of actual-to-expected mortality ($M_{A/E}$) had declined significantly to 4.9, a change of 21%. When trends within subgroups were examined, there were notable disparities in findings by gender ($M_{A/E}$ declining from 4.8 to 4.1 in males and from 9.3 to 6.9 in females), race-ethnicity (White: 8.1 to 6.4; Black 5.0 to 3.4; Hispanic 7.0 to 7.9) and mode of dialysis (hemodialysis: 5.9 to 4.8; peritoneal dialysis 7.7 to 6.1).

Conclusions: Survival gains trends in patients wait-listed for transplant mirror those seen in the overall dialysis population and are greater than expected from general population estimates.

Funding: NIDDK Support

TH-PO784

Comparing the First Two Years of the CMS ESRD Quality Incentive Program (QIP) Alissa Kapke,[1] Jeffrey Pearson,[1] Marc Turenne,[1] Erik Roys,[2] Emily E. Messersmith,[1] Matthew Paul,[2] Claudia Dahlerus,[1] Joseph M. Messana.[2] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]University of Michigan KECC, Ann Arbor, MI.*

Background: The impact of the ESRD QIP on dialysis facility payments may vary over time due to changes in program design or facility performance. Changes in the QIP for payment year 2013 (PY13) include retiring the hemoglobin (hgb)<10 measure, equal weighting of hgb>12 and hemodialysis adequacy measures, payment reductions for any facility with less than the maximum total performance score (TPS<30), and elimination of the 0.5% reduction. Changes in clinical practice between performance years PY12 (2010) and PY13 (2011) may have occurred in anticipation of the PY13 QIP or due to the expanded ESRD PPS.

Methods: We compared actual PY 2012 results with 9 months of 2011 CMS data to simulate PY13 results.

Results: In PY12, 31% (1528) of scored facilities received a payment reduction while 12% (619) are projected to receive a reduction in PY13. Of those with a reduction in PY12, 20% (305) are also projected to receive one in PY13. Among facilities with no PY12 reduction, 9% (312) are projected to receive a reduction in PY13.

Comparison of facilities receiving PY 2012 payment reductions and simulated PY 2013 reductions

PY 2013 Simulation				
PY 2012	**No Reduction**	**Some Reduction**	**Not Scored**	*Total*
No Reduction	2991	312	108	*3411*
Some Reduction	1166	305	57	*1528*
Not Scored	226	2	639	*867*
Total	*4383*	*619*	*804*	*5806*

Among facilities with a reduction in PY12, 66% (1010) received a reduction due to their hgb<10 score. In PY13 only 109 of these facilities are projected to receive a reduction. Among facilities with hgb>12 scores in both years, maximum hgb scores are expected to increase from 98% in PY12 to 99.6% in PY13. Maximum URR scores are expected to increase from 85% to 87%. Finally, less than 4% of facilities with scores from 26-29 are estimated to incur a reduction in PY13 but would not have received a reduction using the PY12 scoring system.

Conclusions: In year two of the QIP substantially fewer payment reductions are expected due to removal of the hgb<10 measure. Changes in other aspects of the QIP and in clinical practices are expected to have a smaller impact on facility payments.

TH-PO785

Current Status of Dialysis in Developing Asian Countries and Future Support Toru Hyodo.[1,2] *[1]NGO Ubiquitous Blood Purification International, Yokohama, Japan; [2]The Program Committee of the 17th Annual Meeting of Japanese Society for Hemodiafiltration (JSHDF), Sagamihara, Japan.*

Background: In Asian countries, details of dialysis practices have not been clarified due to a lack of statistical data. The actual status was identified as a result of a special investigation conducted by the program committee of the 17th annual Meeting of Japanese Society for Hemodiafiltration.

Methods: With the cooperation of 9 dialysis-related companies that have sales distribution in Asia, the actual status of dialysis practices as of 1st July, 2011 was investigated. Based on the data collected by each company, we investigated the number of dialysis facilities and patients in each country, ranking of primary diseases at dialysis initiation, number of patients undergoing hemodialysis (HD), online hemodiafiltration (HDF), and continuous ambulatory peritoneal dialysis (CAPD), number of hemodialysis monitoring devices, number of online HDF monitoring devices, cost per dialysis session (US dollar) and the self-pay rate (%), and 1-year survival rate of dialysis patients (%).

Results: Dialysis facility numbers in Asia are increasing every year. Diabetes is now the most common cause for initiating dialysis in all Asian countries. The 1-year survival rate of dialysis patients was approximately 90% in developed countries. Although, there are many countries with an unknown survival rate, that in Myanmar was 30%, whereas, that in the Philippines and Malaysia was approximately 90%. The precise data is shown below.

Conclusions: Since explosive growth of the dialysis population is expected in developing countries, developed countries should provide support to facilitate proper dialysis practices by nurturing clinical engineers.

The Status of Asian Dialysis

Country	Dialysis patients number	Hospital number	On-line HDF patients number	HD patients number	CAPD patients number	The cost of HD(US dollar)	Private charge(%)
Cambodia	200	10	0	200	0	55	100
Myanmar	600	28	0	600	0	55	100
Philippine	10000	270	unknown	9300	700	50	80
Vietnam	12000	130	5-10	10000	2000	30	0
Malaysia	23500	600	unknown	21700	1800	50	0
Thailand	29500	500	1400	26500	1500	25	0-25
Corea	45009	614	4000	37391	7618	130	10
Taiwan	63655	552	2200	55825	6110	170	0
China	272000	3500	unknown	260000	12000	90	5-30
Japan	297126	4152	unknown	297126	9728	350	0

TH-PO786

Cleanliness of Hemodialysate and Future Support in South East Asian Developing Countries Toru Hyodo.[1,2] *[1]NGO Ubiquitous Blood Purification International, Yokohama, Japan; [2]The Program Committee of the 17th Japanese Society for Hemodiafiltration (JSHDF), Sagamihara, Japan.*

Background: There have been no studies reporting the cleanliness of dialysate used at dialysis facilities in Asian developing countries. Its actual status was identified as a result of a special investigation conducted by the program committee of the 17th Japanese Society for Hemodiafiltration (JSHDF) and NGO Ubiquitous Blood Purification International.

Methods: The research team including a specialist of dialysate purification was dispatched from the JSHDF, and investigated the quality of dialysis water used at dialysis facilities in Vietnam and Cambodia with the cooperation of three facilities in Vietnam (including one dialysis facility which was established in the Department of Nephrology with the support of NPO Ubiquitous Blood Purification International) and one facility in Cambodia (dialysis facility established with the support of NPO Ubiquitous Blood Purification International). The endotoxin (ET) level (EU/L) and bacterial count (CFU/mL) in tap water, in water purified by a reverse osmosis (RO) system, and in dialysates were measured.

Results: There were no facilities that fulfilled criteria for bacterial counts specified in the ISO 23500 guideline (Standard dialysate:<500 EU/L, <100 CFU/mL, Ultra pure dialysate: <30EU/L, <0.1CFU) in both standard and ultrapure dialysates. Two facilities fulfilled criteria for the ET level only in standard dialysate.

ET level and Bacterial Counts of Dialysate in Asian Developing Countries

Hospital	ET(EU/L)	Bacteria(CFU/mL)
A	741	500
	903	800
B	38	150
	49	100
C	201	1000
	395	1000
D	309	800
	245	800

Conclusions: Physicians in these countries have read many studies, and desire to adopt online HDF in their own countries. Not only the provision of medical devices, but also organic support for implementing dialysate purification are needed. A support program for nurturing clinical engineers in developing countries is now about to begin in Japan and South East Asia.

Funding: Private Foundation Support

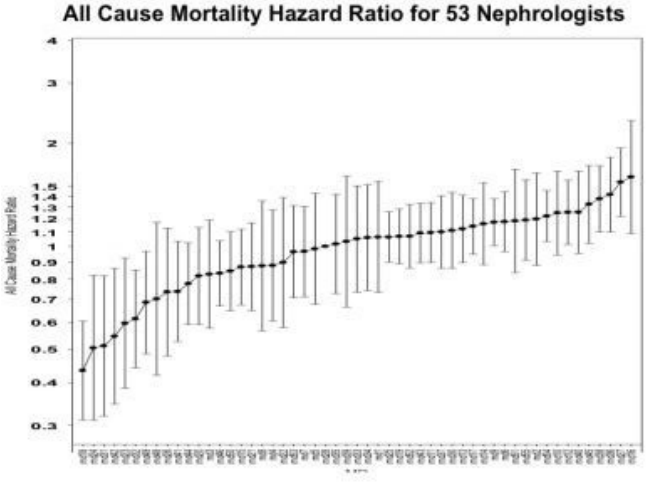
TH-PO787

Nephrologist Practice Pattern and Survival of Hemodialysis Patients in a Densely Populated Urban Area in California Kevin T. Harley,[1] Elani Streja,[2] Alpesh Amin,[2,3] Kamyar Kalantar-Zadeh.[2,3] *[1]Nephrology, University of California, Irvine; [2]Harold Simmons Center, LABioMed Harbor-UCLA; [3]David Geffen School of Medicine at UCLA.*

Background: California nephrologists care for a diverse group of maintenance hemodialysis (HD) patients. There is wide variability in patient characteristics and practice patterns. We examined the association between nephrologist-related factors and all-cause mortality in a densely populated urban area in California.

Methods: We anonymously ranked all nephrologists in the selected region according to their HD patient mortality rate (from lowest to highest) over a six year period (7/2001-6/2006), based on data derived from the dialysis clinics of a large dialysis organization and the United States Renal Data System. We calculated hazard ratios for all-cause mortality for each nephrologist and compared patient characteristics of the ten highest and ten lowest scoring nephrologists to detect meaningful differences.

Results: A total 53 nephrologists, each with at least 50 HD patients cumulatively over the study period, provided care to 8,947 HD patients. After ranking all 53 nephrologists according to their HD patient hazard ratios (see Figure), the ten nephrologists with the lowest mortality averaged 72 HD patients while the ten nephrologists with the highest mortality averaged 139 HD patients [72 (64- 80) vs. 139 (92- 185), p< 0.0001]. Additionally, the ten nephrologists with the lowest mortality ratios had patients whose average dialysis time was 10 minutes longer than their ten colleagues with the highest mortality ratios (212±26 vs 202±23, p < 0.0001).



Conclusions: Number of patients carried per nephrologist and longer dialysis treatment time appear associated with better quality of care including patient survival. These findings need to be examined in additional studies.

TH-PO788

Predictors of Provider-Patient Visit Frequency on Hemodialysis

Yelena Slinin,[1] Haifeng Guo,[2] Suying Li,[2] Jiannong Liu,[2] Benjamin R. Morgan,[1] Kristine E. Ensrud,[1] Areef Ishani.[1,2] *[1]Veterans Administration Health Care System, Minneapolis, MN; [2]Chronic Disease Research Group, Minneapolis, MN.*

Background: In 2004, CMS tied provider reimbursement for outpatient hemodialysis services to a number of times per month providers see their patients on dialysis. Determinants of provider visit frequency to patients on dialysis are uncertain. We aim to identify patient, provider, and facility characteristics associated with provider visit frequency to hemodialysis patients.

Methods: Using USRDS data for point-prevalent patients on in-center hemodialysis on 1/1/2006 (n = 144860), we defined patient characteristics during 1/1/2006-6/30/2006 and calculated provider-patient visit frequency during 7/1/2006-12/31/2006. Provider data were obtained from the AMA. We determined associations between patient, provider, and facility characteristics and provider visit frequency on dialysis using logistic regression.

Results: Patient characteristics independently associated with provider visit frequency (≥4 visits compared to <4 visits/month) included age: Adjusted Odds Ratio (95% Confidence Interval) 1.23(1.18-1.28) for 65+, compared to 20-44 years; African-American race:1.20(1.17-1.24), dialysis duration: 1.08(1.05-1.10) for > 5 vs 1-5 years; comorbidity score:1.13(1.0-1.17) for 4-8, 1.20(1.16-1.24) for ≥8, compared to <4; eligibility for Medicaid:1.06(1.03-1.08); urban status:1.21(1.17-1.25); and greater number of dialysis sessions:1.31(1.25-1.35). Provider characteristics associated with visit frequency included number of years in practice:1.13(1.09-1.16) for >22 compared to <8 years; being a foreign graduate:1.15(1.13-1.18); distance from the practice location to the dialysis unit: 0.70(0.68-0.72) for 2.5-11.5, 0.52(0.51-0.54) for >11.5, compared to<2.5 miles; and number of dialysis patients per provider:1.18(1.15-1.22) for 50-100, 1.49(1.44-1.54) for>100 compared to<50 patients. Facility characteristics associated with provider visit frequency included chain 0.85(0.83-0.88) and hospital 0.79(0.74-0.83) affiliations.

Conclusions: Several patient, provider, and facility characteristics were independently associated with frequency of provider-patient visits on dialysis.

TH-PO789

A Comparitive Study of Outcomes in Fellow Managed versus Non-Fellow Managed Dialysis Units in New York City

Adedoyin G. Akintide,[1] George N. Coritsidis,[1] Marie France R. DeLeon,[1] Kasun I. Navarathna,[1] Carol Lyden.[2] *[1]Division of Nephrology, Elmhurst Hospital Center, Elmhurst, NY; [2]IPRO, Lake Success, NY.*

Background: Many private dialysis units are staffed primarily by technicians and supervised by a few nursing staffs with overseeing nephrologists. The literature has suggested that for-profit units may have worse outcomes in terms of mortality than not-for-profit units. Our literature search did not find any studies looking at outcomes in fellow managed vs non-fellow managed dialysis units. We were interested to see what impact the involvement of an academic fellowship program has on outcomes in dialysis units.

Methods: We reviewed de-identified records from Network 2 of 19 units in the borough of Queens, New York for 2009 and 2010, and compared outcomes. Three fellow managed units (FM) were compared to the remaining sixteen non-fellow managed units (NF).

Results: In 2010, there were no significant differences in age or the prevalence of African Americans, Hispanics or diabetics. However, there were more Asians in the NF units (30 vs 14%, p=0.0065). The urea reduction ratio metric of ≥96% of patients per unit (URR metric) was met by more of the FM units than the NF units. However, the difference was not statistically significant. A higher percentage of the FM patients compared to NF patients met the URR metric (URR % pt, p=.0015). There were fewer hospitalized days per patient (Hosp) in the FM units (P=.0176). Fistula, graft, catheters in use for >90days as well as the standardized mortality ratio (SMR) did not differ. Similar findings were observed for 2009 data except only 47% of the NF units met the URR metric vs 100% of the FM units.

Table of Results

2010	age	DM	African Amer	URR(metric)	*URR(pt average)	*Hospitalizations	SMR
FM units N=3 (549 pts)	60±3.0	48%	40%	100%	99.8%	3.8±0.6	1.0± 0.9
NF units N=16 (3515 pts)	62±0.6	46%	48%	77%	97.6%	6.9±0.5	1.1± 0.3

Conclusions: The presence of academic fellows at dialysis centers may improve URRs and minimize hospitalization days. Our findings were consistent over a 2-year period in similar dialysis populations and may reflect greater physician presence. Mortality was not affected possibly due to small patient samples.

TH-PO790

Estimating US Dialysis Transportation Costs: An Exploratory Analysis

Mark Stephens,[1] Samuel Brotherton,[1] Stephan C. Dunning,[2] Larry C. Emerson,[3] David T. Gilbertson,[2] Ann C. McClellan,[4] William M. McClellan,[4] Sanatan Shreay,[5] Matthew Gitlin.[5] *[1]PHA; [2]CDRG; [3]Dialysis Ctr of Lincoln; [4]Emory; [5]Amgen.*

Background: The costs of transportation to dialysis for US patients have not been previously reported on a national level, but have been estimated in the billions of dollars annually, with a heavy share of costs borne by patients and their families. Previous research suggests that substantial cost savings could be achieved if medically-appropriate transport was made available and covered by insurance.

Methods: We estimated the total costs of transportation for 360,000 US dialysis patients for travel to routine dialysis. Per trip travel distance estimates were calculated from patient ZIP codes and dialysis facility addresses. The costs of ambulance trips were calculated from Medicare's 2012 Ambulance Fee Schedule. Other cost and utilization estimates were derived from government reports, transportation websites and peer-reviewed literature. We estimated potential savings of reduced ambulance use.

Results: The estimated annual cost of transportation to dialysis in the US is nearly $3 Billion, about 6-7% of total dialysis patient costs. Costs per patient per year are estimated at over $8000. One-third of these costs are not covered by patients' primary or secondary insurance. Ambulance services account for 46% of all costs, but only 5% of transports. Based on prior research on ambulance use, the potential savings of substituting more appropriate means of transport for ambulances could be $200-$700 million per year.

Estimated 2012 Transportation Costs For Routine Dialysis By Transport Type and Payer ($ Millions)

Transport Type	Medicare	Medicaid	Private Insurance	Patient/Other	Total
Ambulance	$996.5	$148.2	$35.7	$169.2	$1,349.6
Stretcher Van		$164.5	$25.8	$163.6	$353.9
Chair Car		$425.4	$85.7	$335.1	$846.2
Taxi, Public Transit		$74.9		$155.6	$230.5
Private Auto, Other		$27.2		$125.0	$152.2
Total	$996.5	$840.2	$147.2	$948.5	$2,932.4

Conclusions: Policy-makers should consider the potential to reduce unnecessary dialysis transportation costs, while providing appropriate levels of care.

State Level Variations in Nephrology Workforce and Dialysis Stations and Timing of Dialysis Initiation in the U.S.

Elaine Ku, Kirsten L. Johansen, Anthony A. Portale, Barbara A. Grimes, Chi-yuan Hsu. *UCSF, San Francisco, CA.*

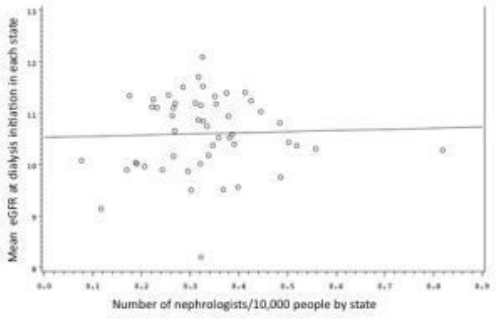
Background: Multiple factors influence timing of dialysis initiation. Impact of systems-based factors such as supply of nephrology workforce is not well known. We hypothesized that dialysis is initiated at higher eGFR in states with higher numbers of adult and pediatric nephrologists per capita and higher number of dialysis stations per capita.

Methods: We determined the number of board-certified pediatric and adult nephrologists in each state using American Boards of Pediatrics and Internal Medicine data as of 12/31/2010 and 2/17/2011, respectively. State population was derived from 2010 US Census. USRDS data were used to determine number of dialysis stations and mean estimated GFR at start of dialysis for children (< 18 years) and adults (≥18 years) using the revised Schwarz and MDRD equations respectively, among the subset with serum creatinine and height available.

Results: We included for analysis 1937 children initiated on peritoneal and hemodialysis between 2007-2009 and 100,983 adults initiated on hemodialysis in 2008. The median number of pediatric and adult nephrologists per state was 0.056 (IQR 0.038 to 0.078) and 0.32 (IQR 0.26 to 0.38) per 10,000 persons, respectively. Mean eGFR at

start of dialysis was 9.7 mL/min/1.73 m^2 (SD 6.0) in children and 10.8 mL/min/1.73 m^2 (6.0) in adults. No significant correlation between eGFR at start of dialysis and number of nephrologists/population/state was apparent with Pearson r of -0.15 (95% CI -0.41 to 0.13 p=0.29) for children and 0.04 (95% CI -0.24 to 0.31 p=0.80) for adults (Figure 1). eGFR at hemodialysis initiation also did not correlate with number of dialysis stations/ adult population/state, with r of -0.02 (95% CI -0.29 to 0.26 p=0.89).

Figure 1: Mean eGFR at dialysis initiation among adult patients vs. number of nephrologists per 10,000 adult population by state



Conclusions: Timing of dialysis initiation was not associated with state-level variations in nephrologists or availability of dialysis stations.

TH-PO792

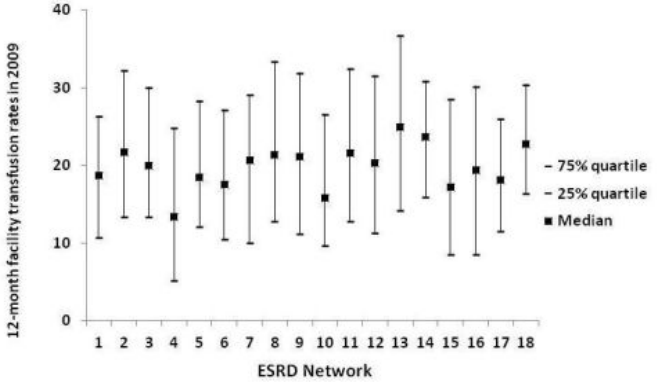
Regional Variation in RBC Transfusions in Hemodialysis Patients

Suying Li,[1] Jiannong Liu,[1] Keri Monda,[2] Tom Arneson,[1] Brian D. Bradbury,[2] David T. Gilbertson,[1] Allan J. Collins.[1] *[1]Chronic Disease Research Group, MMRF, Minneapolis, MN; [2]Amgen, Inc, Thousand Oaks, CA.*

Background: Transfusion avoidance is the primary indication for anemia treatment in dialysis patients. However, there are little data available describing recent trends in the use of transfusions. We investigated transfusion rates in 2008 and 2009 by ESRD network (proxy for geographic region) and facility size.

Methods: The study population was composed of prevalent hemodialysis patients on 1/1/2008 and on 1/1/2009 with ≥ 90 days on dialysis with Medicare as primary payer. To assess transfusions related more to anemia management, patients with sickle cell disease and inpatient (IP) transfusions concurrent with hospitalizations due to major bleeding, surgery, and trauma were excluded. Patients were followed from January 1 to the earliest date of death, transplant, lost to follow-up, or the end of follow up (Jun 30 or Dec 31, depending on 6- or 12-month analysis). Transfusion rates were obtained by dividing total events by the total follow-up time and expressed as per 100 patient-years (pt-yrs). Data were derived from Medicare claims.

Results: The overall 6-month transfusion rates were 23.5 and 22.9 and 12-month transfusion rates were 24.2 and 23.2 per 100 pt-yrs for 2008 and 2009, respectively. The majority of transfusions occurred in the IP setting (~70%). Transfusion rates were stable across provider size (12-month rate ranged from 22.6 to 25.5 in 2008 and 22.1 to 24.3 in 2009). As shown in figure, more variation was observed by ESRD network (12-month rate ranged from 17.9 to 28.5 in 2009).



Conclusions: RBC transfusions were relatively consistent between 2008 and 2009, although there was sizable variation in the rates across ESRD network within the US. Transfusion event evaluation may enable comparisons regarding direct assessment of anemia management practices.

The Initial Impact of Medicare's Bundled, Prospective Payment System for Renal Dialysis

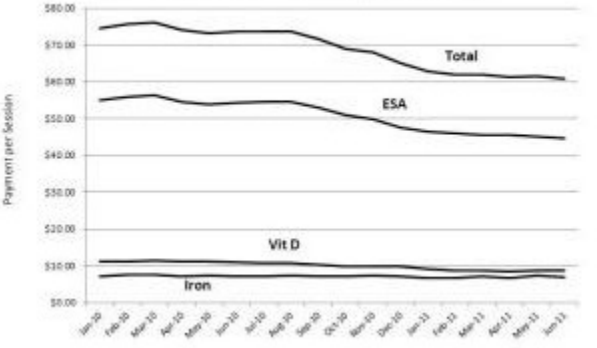
Richard Hirth,[1] Marc Turenne,[2] John R.C. Wheeler,[1] Tammie A. Nahra,[1] Kathryn Sleeman,[1] Wei Zhang,[1] Joseph M. Messana.[1] *[1]Univ. of Mich, Ann Arbor, MI; [2]Arbor Research, Ann Arbor, MI.*

Background: Medicare implemented an expanded prospective payment system (PPS) on January 1, 2011, including services previously paid on a fee-for-service basis. One intent of the PPS was to incentivize providers to be more efficient in providing dialysis services and modality choice.

Methods: We used Medicare claims to assess monthly trends during January 2010 to June 2011 for key injectable drugs that were previously billed separately. We evaluated dialysis modality trends during the first six months of each year from 2007 to 2011. Of note, incentives for reporting use of erythropoiesis stimulating agents (ESAs), iron and vitamin D analogs changed with implementation of the PPS. For 2010, we assessed actual spending. For 2011, we projected spending based on reported utilization.

Results: ESA use declined substantially in the months immediately before and after the PPS, while use of iron products, often therapeutic substitutes for ESAs, increased. For ESAs and vitamin D analogs, the largest changes occurred during the last quarter of 2010. Less expensive vitamin D products were substituted for more expensive ones. Drug spending fell by $14 per session, nearly three times the mandated reduction in the base payment rate of $5. The use of peritoneal dialysis increased from 6.45% in 2010 to 6.80% in 2011, representing a break from the flat 2007-2010 trend. The use of home hemodialysis increased from 1.20% in 2010 to 1.41% in 2011, representing a continuation of the pre-existing trend.

Payments per Session for Select Injectable Drugs



Conclusions: The expanded bundle dialysis PPS provided incentives for the use of lower cost therapies. These incentives seem to have motivated movement toward lower cost methods of care.

TH-PO794

Did the Dialysis Prospective Payment System (PPS) Result in More Patients Receiving Transfusions?

Richard Hirth,[1] Marc Turenne,[2] John R.C. Wheeler,[1] Tammie A. Nahra,[1] Kathryn Sleeman,[1] Wei Zhang,[1] Joseph M. Messana.[1] *[1]Univ of Michigan, Ann Arbor, MI; [2]Arbor Research, Ann Arbor, MI.*

Background: On January 1, 2011, Medicare implemented an expanded bundle PPS that included injectable medications previously paid via fee-for-service. This created incentives to use less of these services, particularly ESAs.

Methods: To assess the impact of this policy change on use of blood transfusion, an alternative to ESA for anemia treatment, we used Medicare claims to compare the % of patients receiving ≥1 transfusion during the first 6 months under the PPS (January–June 2011) (4.69%) to the % receiving ≥1 transfusion during the first 6 months 2008 (4.79%), 2009 (4.67%) and 2010 (4.42%). We estimated generalized logit models to control for patient race, sex, age, comorbidity count and year.

Results: Transfusions were more likely among patients who were female (adj. odds ratio (AOR) 1.105, p<.01), non-black (AOR 1.220, p<.01), older (AOR 1.004 per year, p<.01) or had more comorbidities (AOR 1.039, p<.01). The adjusted time trend was similar to the unadjusted transfusion rates, with the lowest rate in 2010 and the highest in 2008. A 2nd model specification added race*year and sex*year interactions to determine if relative use of transfusion by race and sex changed after implementation of the PPS. These interactions were insignificant.

Conclusions: A modestly higher % of patients received transfusions during the first 6 months of 2011 under the PPS than during the first 6 months of 2010. However, the 2011 rates were similar to the rates prevailing in 2008 and 2009. Therefore, it is not clear that the PPS caused a change in the % of patients receiving≥1 transfusion. Further research will explore if there was a change in the frequency of transfusions and ESA use among those patients who received at least 1. The clinical implications of a substitution of transfusions for ESAs among those being transfused may be different than the implications of expanding transfusions into a greater % of the patient population. It should be noted that the data used in this study primarily reflected outpatient transfusions because inpatient claims generally do not contain this level of detail.

TH-PO795

Recent Trends in Anemia Management in Small Dialysis Organizations: The STEPPS Study John M. Burkart,[1] Keri Monda,[2] Margarita Symonian Silver,[3] Susan V. Yue,[2] Robert J. Rubin.[4] *[1]Wake Forest University, Winston Salem, NC; [2]Amgen, Inc., Thousand Oaks, CA; [3]Private Practice, Los Angeles, CA; [4]Georgetown University School of Medicine, Washington DC.*

Background: In Jan 2011 the Prospective Payment System (PPS) was implemented for bundled dialysis care payment. Small dialysis organizations (SDOs, defined as ≤50 facilities) may be particularly susceptible to the financial implications of the PPS. The prospective observational Study to Evaluate the PPS Impact on SDOs (STEPPS) was designed to describe dialysis treatment and outcomes over this period. Herein we examine trends in anemia management between Oct 2010 and Jun 2011.

Methods: Data are collected monthly or quarterly. Trends were assessed via repeated cross-sectional measurements and limited to hemodialysis patients (94.5% in-center and 0.6% home) from 51 SDOs. Lab values are reported as the last quarterly measurement. Intravenous (IV) epoetin alfa (EPO) and darbepoetin alfa (DPO) dose is reported as cumulative monthly and per-administration during the last month of each quarter. Transfusion is expressed as incidence proportion and rate per 100 person-years.

Results: Between Q4 2010 and Q2 2011 median per-administration IV EPO and DPO doses decreased, disproportionately in the 75th percentile; cumulative monthly doses fell to an even greater degree; mean hemoglobin (Hb) declined 0.2 g/dL (table). The percent of patients with Hb <10 g/dL rose from 13% to 17% (32% change); those with Hb >12 fell from 29% to 19% (36% change). Percent increase in transfusion incidence and rate was 61% and 41%, respectively.

Mean±SD; median(p25, p75)	Q4 2010 (N=1730)	Q1 2011 (N=1699)	Q2 2011 (N=1597)
Labs			
Hb (g/dL)	11.3 ± 1.3	11.2 ± 1.3	11.1 ± 1.2
Ferritin (ng/mL)	645 (401, 966)	720 (487, 1034)	768 (485, 1053)
TSAT (%)	30.6 ± 12.1	32.2 ± 12.6	32.5 ± 12.6
Medications			
EPO (units)			
Cumulative monthly	36350 (17000, 71500)	32500 (15000, 62500)	31100 (14000, 60000)
Per-administration	3472 (2100, 6714)	3025 (2000, 5692)	3240 (2000, 6000)
DPO (mcg)			
Cumulative monthly	242.5 (125, 375)	100 (65, 180)	120 (75, 180)
Per-administration	56 (32.5, 95)	31.9 (25, 45)	32.5 (25, 45)
IV iron use (% of patients)	54.2%	56.6%	52.5%
Transfusions			
Proportion (95% CI) (%)	1.8 (1.2, 2.4)	3.0 (2.2, 3.8)	2.9 (2.1, 3.7)
Rate (95% CI)*	13.7 (10.3, 17.7)	21.2 (16.9, 26.3)	19.3 (15.2, 24.3)

*per 100 person-years; SD, standard deviation; p25, 25th percentile; p75, 75th percentile; TSAT, transferrin saturation; CI, confidence interval

Conclusions: During the initial phase and preparation of PPS implementation there was a marked reduction in ESA use, with the greatest reduction among the highest doses, and declines in Hb. Also observed were increases in transfusion outcomes.

TH-PO796

Improving Kidney Transplant Parity: Suggestions for Dialysis Providers Teri Browne,[1] Avrum Gillespie.[2] *[1]College of Social Work, University of South Carolina, Columbia, SC; [2]Department of Medicine, Temple University, Philadelphia, PA.*

Background: Research suggests that black dialysis patients are significantly less likely than their white peers to be evaluated and listed for a kidney transplant. We present the findings of two research studies that survey black dialysis patients in two different locations (Chicago and Philadelphia) about their attitudes and knowledge related to kidney transplantation, and use these findings to make recommendations to the interdisciplinary dialysis team members that may help reduce kidney transplant disparities.

Methods: In the Chicago study, 228 black hemodialysis patients in 5 dialysis centers in the Chicago area were surveyed about their kidney transplant status, interest, information, and attitudes about kidney transplant, and attributes of their social networks. In the Philadelphia study, 116 urban, predominantly black hemodialysis patients were surveyed using the *Dialysis Patient Transplant Questionnaire*, and we matched their survey data with their UNOS listing and computerized medical record at time of interview.

Results: In the Philadelphia study, the majority (80%) of patients were interested in a kidney transplant, (71.6%) had been evaluated, yet only 39% were on the transplant waiting list. Moreover, of the patients being evaluated 52.9% incorrectly believed they were on the kidney transplant waiting list. In the Chicago study the barrier was access to transplant, in the Philadelphia study patients had difficulty navigating the transplant system. In both studies, black patients had poor knowledge and understanding about the process related to getting a kidney transplant.

Conclusions: These findings suggest that barriers to kidney transplantation are complex and multidimensional. Furthermore, dialysis professionals can augment their standard course of patient care to identify and attend to this lack of knowledge and understanding.

TH-PO797

Kidney Waitlist and Transplant Rates by Dialysis Facility Characteristics: Race and Rural Classification Valarie B. Ashby, K.A. Wisniewski, Joseph M. Messana, Alan B. Leichtman. *University of Michigan, Ann Arbor, MI.*

Background: Kidney transplant waitlist and transplantation rates are inconsistent across the US. This study examines the contribution of dialysis facility characteristics to this disparity by analyzing the differences in waitlist and transplantation rates among dialysis patients < age 70 at rural vs. urban facilities and at facilities with predominantly Black patients.

Methods: Data were obtained from the 2011 Dialysis Facility Reports, which were derived from CMS and OPTN databases. All comparisons were made using Poisson (Standardized Transplantation Ratio for 2007-10) and linear (% of patients on waitlist in 2010) regression with adjustments for chain affiliation, profit status, hospital association, facility size, state, and facility case-mix for 2,959 dialysis facilities with at least 10 patients age < 70.

Results: Compared to urban, rural facilities had fewer patients on the waitlist (Δ=-2.9%, p<0.001). This difference was larger (Δ=-4.3%, p<0.001) when not adjusting for state. Facilities with predominantly black patients had fewer patients on the waitlist overall (Δ=-3.7%, p<0.001; Δ=-5.0%, p<0.001 when not adjusting for state). The White and Black waitlist rates were lower (Δ=-3.7%, p<0.001 and Δ=-4.0%, p<0.001, respectively) at predominantly Black facilities compared to the White and Black waitlist rates at facilities that are not predominantly Black. Transplantation rates were 23% lower at rural than at urban facilities (p<0.001) and 27% lower at predominantly Black facilities (p<0.001).

Conclusions: Kidney waitlist and transplantation rates for dialysis patients < age 70 are lower in rural dialysis facilities and in predominantly Black facilities. Of note, White patients dialyzing in predominantly Black facilities also have lower kidney waitlist rates than Whites not in predominantly Black facilities. These differences are not explained by chain affiliation, profit status, hospital association, facility size, case-mix, or state. Given the health and cost benefits of kidney transplant vs. dialysis, resources should be (re) allocated to improve the waitlist and transplant rates in rural dialysis facilities and in those with high percentages of Blacks.

Effect of Cinacalcet Availability and Formulary Listing on Parathyroidectomy Rate Trends Jean-Philippe Lafrance, Heloise Cardinal, Martine Leblanc, Francois Madore, Vincent Pichette, Louise Roy, Jacques Lelorier. *University of Montreal, Montreal, QC, Canada.*

Background: Recent trends in parathyroidectomy (PTX) rates are not known. The aim of this study was to investigate PTX rates trend, and to evaluate if recent availability and reimbursement of cinacalcet modified that trend.

Methods: Using a provincial administrative database, we conducted a time-series analysis including all adult patients receiving chronic dialysis treatments between 2001 and 2010 (incident and prevalent) in Quebec, Canada. We excluded patients with less than 90 days of follow-up, a prior PTX or a kidney transplant. PTX (primary outcome) was identified through hospital discharge summary procedure codes and physician claim codes. We modeled the effect of cinacalcet availability on PTX bimonthly rates using an ARIMA intervention model. Since cinacalcet became available progressively, we used different cut-off dates: Sept. 2004 (Health Canada approval), Jan. 2005, June 2005, Jan. 2006, June 2006 (provincial reimbursement), and Jan. 2007.

Results: We followed 12 795 chronic dialysis patients (mean age 64 years, 39% female, 82% hemodialysis) for a mean follow-up of 3.3 years. We identified 267 PTX during follow-up, translating to an average rate of 7.0 per 1000 person-years (py). The average parathyroidectomy rate before cinacalcet availability was 11.4 /1000 py, and 3.6 /1000 py after cinacalcet formulary listing. Only January 2006 as an intervention date in the ARIMA model was associated with a change in PTX rates (estimate: -5.58, p=0.03). Other intervention dates were not associated with lower PTX rates.

Conclusions: We found decreased rates of PTX after January 2006, corresponding to cinacalcet availability. However, decreased rates may be due to other factors occurring simultaneously with cinacalcet introduction and further studies are needed to confirm these findings.

Daily Patient Reported Outcome Reporting Is Practical and Demonstrates Differential Patient Experience in CKD Zoe C.L. Pittman,[1] Stephen G. John,[1] Suzanne K. Roberts,[1] Chris W. McIntyre.[1,2] *[1]Renal Medicine, Royal Derby Hospital, Derby, United Kingdom; [2]School of Graduate Entry Medicine and Health, University of Nottingham, Derby, United Kingdom.*

Background: Patient reported outcomes (PRO) are increasingly recognised as a critical metric in chronic disease. Whilst a variety of generic and disease specific tools have been reported in CKD, these are mainly cross-sectional with limited longitudinal data. Specifically, there are no data on frequent PRO assessment and no tool designed for frequent use. We therefore designed and implemented a CKD specific online PRO for daily use.

Methods: PRO selection was informed by integration of a patient survey with published data. 6 separate domains of interest (general well being (GWB), pain, sleep, breathing, energy, appetite) were selected. A custom website was built to capture these PRO daily utilising visual analogue scales (allows free selection of status from 0 (worst) to 100(best)). 44 haemodialysis (HD) and 30 pre dialysis patients (CKD) agreed to receive individual website registration details and to complete data daily from home.

Results: 19 HD and 21 CKD patients subsequently registered, 57% male, mean age 61±13 yrs. 3 HD patients withdrew (1 died, 2 transplanted). 75% (68% HD, 81% CKD) submitted data for >30 days, with 70% submitting at least three times per week. Patients reported lower scores (median ± IQR), for energy 78±44, GWB 83±35 and sleep 85± 55 than pain 90±41, appetite 94±44 and breathing 95±21 (p<0.001 overall). HD patients had significantly lower median scores for sleep (48± 53, 95± 22, p=0.012) and appetite (54±45, 97±13, p=0.020) and a trend to lower score for energy (60±53, 84±25, p=0.079). HD patients had greater individual variability for sleep (p=0.022) and appetite (P=0.015). 63% of registered patients still submit data at 90 days.

Conclusions: We have successfully introduced a web based system for recording frequent PRO. This is acceptable to patients and has shown ability to discriminate symptom severity cross-sectionally and longitudinally. Ongoing work will expand scope (other patient groups and vascular access), increase access (data input at HD sessions) and deepen analysis (linkage to other patient data).

TH-PO800

Peritoneal Dialysis and In-Center Hemodialysis: A Cost Effectiveness Analysis Frank Xiaoqing Liu,[1] Catrin Treharne,[2] Murat Arici,[3] Lydia Lees,[2] Ira D. Davis,[1] James A. Sloand.[1] *[1]Baxter Healthcare Corp., Deerfield, IL; [2]Abacus International, Oxfordshire, United Kingdom; [3]Baxter Healthcare Corp., Compton, United Kingdom.*

Background: The National Institute of Clinical Excellence has estimated that £37 million annual savings could be generated in England by increasing the number of prevalent peritoneal dialysis (PD) patients from current 15% to 39%. Achieving this goal will require that the number of new PD patients increases significantly from current 20%. The aim of this study is to estimate the benefits and costs associated with hypothetical scenarios of PD use vs. the current situation.

Methods: We constructed an Excel-based Markov model to estimate the costs and quality adjusted life years (QALYs) associated with different modality distributions from the UK payer's perspective. We modeled an incident patient population over a time horizon of 5 and 10 years. The current UK dialysis modality distribution (scenario 0) of 20% PD, 79% in-center HD (ICHD), and 1% home HD, was compared to 3 hypothetical scenarios: Scenario 1: 50% PD; Scenario 2: 39% PD; Scenario 3: 0% PD. In all of these scenarios, the level of ICHD changes accordingly while home HD stays constant. Model parameters and data inputs were from published articles, annual reports of the UK Renal Registry, NHS Payment by Results, and ERA-EDTA registry. All future costs and benefits were discounted to their present value at an annual rate of 3.5%.

Results: The number of incident dialysis patients was estimated to be 6,366 in UK in 2012. Scenarios 1 (50% PD) & 2 (39% PD) demonstrate lower costs and higher QALYs compared to scenario 0 (20% PD), whereas opposite findings were seen for scenario 3 (0% PD) compared to scenario 0. Increasing PD to 39%-50% saves between £2,519-4,579 per patient and results in an increase of 0.018-0.036 QALYs per patient. Reducing the PD use to 0% results in an increase of costs between £2,652-3,052 per patient and a decrease in QALY between 0.020-0.024 per patient.

Conclusions: Our analysis indicates that increasing the use of PD among incident ESRD patients can generate healthcare savings while improving health benefits. Our results are consistent with NICE PD clinical guideline.

TH-PO801

Measuring the Effect of ESRD Medicare Facility Surveys on Dialysis Facility Outcomes Joseph M. Messana, Deanna Chyn, Valarie B. Ashby, N. A. Lueth, Tempie H. Shearon, Richard Hirth. *Kidney Epidemiology and Cost Center, University of Michigan, Ann Arbor, MI.*

Background: Each year, CMS evaluates approximately 1500 chronic outpatient dialysis facilities for adherence to Medicare's ESRD Conditions for Coverage (CfCs). A facility's failure to fully meet a CfC results in a citation(s), classified as either standard or, for more severe violations, condition-level (CfC citation). This study explores the association between FY 2009 CfC citation status and changes in facility outcomes by comparing outcomes in the year before (CY 2008) and after (CY 2010) the survey.

Methods: Using survey data from the CMS Computing System, we determined the presence of any CfC on FY09 facility surveys. We combined these data with Dialysis Facility Report data, which are based on national CMS data, from CY 2008–10. Three years of outcomes data were available for 5177 facilities, of which 1083 were surveyed in FY09. Using each facility's citation status, we fitted linear models to predict changes in primary (mortality (SMR), hospitalization (SHR)) and clinically important intermediate (% patients with URR >65%, % patients with catheter as dialysis access) outcomes over the 2-year period. We weighted the models by facility size and adjusted for patient demographics and diabetes as cause of ESRD.

Results: Non-surveyed dialysis facilities experienced a magnitude and direction of two-year change in outcomes similar to that of surveyed facilities that received no CfC citations. In contrast, surveyed facilities that did receive a CfC citation had small but statistically significant improvements in % patients with catheter dialysis access and % patients with URR >65%. Primary outcomes did not differ by facility citation status.

Change in Facility Outcomes (2010 v 2008) by FY 2009 Facility Citation Status

Status	SMR	SHR	% Catheter	% URR >65%
Not surveyed	+0.004	-0.02	-3.67	+0.45
Surveyed, no CfC	+0.03	-0.001	-3.50	+0.30
Surveyed, at least 1 CfC	-0.02	-0.02	-4.83	+1.51
p-value (CfC vs. no CfC)	0.09	0.35	0.01	<0.001

Conclusions: Facilities cited for CfC deficiencies may be more strongly motivated than non-cited facilities to identify and improve modifiable intermediate outcomes.

Funding: Other U.S. Government Support

TH-PO802

Dialysis Treatment Time, Dialysis Frequency, and Dialysis Adequacy among Hemodialysis Patients in the Saudi Arabia Dialysis Outcomes and Practice Patterns Study (DOPPS) Ayman Karkar,[2] Brian Bieber,[1] Saad Alghamdi,[2] Faissal A. Shaheen,[2] Jamal S. Alwakeel,[2] Fayez F. Alhejaili,[2] Mohammed A. Al-Ghonaim,[2] Haroun Zakaria Ahmed,[2] Sylvia Paz B. Ramirez,[1] Ronald L. Pisoni.[1] *[1]Arbor Research; [2]Saudi Arabia DOPPS Country Investigators.*

Background: In order to understand practice patterns of hemodialysis (HD) care in Saudi Arabia (SA), a pilot study of SA DOPPS was conducted from November 2011-May 2012. We present practice patterns for HD prescription in SA compared to other DOPPS regions.

Methods: 20 HD facilities treating at least 23 chronic HD patients were randomly selected from a comprehensive roster of dialysis units to be representative of >95% of SA HD patients. Descriptive results shown for SA, based on a random sample of 20-25 HD patients in each study facility, are compared to other DOPPS regions. Preliminary results in SA are based on 315 HD patients from 16 dialysis units. Results are presented as weighted estimates, accounting for the sampling fraction in each unit.

Results: Mean # prescribed HD sessions/week was similar in SA (2.96) versus the 3 other DOPPS regions, with 5% of patients dialyzing <3x/week (Table). Mean HD session length in SA (205 min) was lower than in other DOPPS regions (range 220-245). The mean blood flow rate of 290 mL/min was lower than in EUR/ANZ (317) and North America [NA] (406), but higher than in Japan (203). Mean BMI was lower in SA than in EUR/ANZ and NA, but higher than in Japan. Mean URR in SA (66%) was slightly lower than in Japan (69%), but significantly lower than in EUR/ANZ (74%) and NA (74%).

Dialysis Adequacy Measures, by Region

Measure	Saudi Arabia (N=315)	EUR/ANZ (N= 4340)	North America (N= 4930)	Japan (N= 1575)
Prescribed dialysis sessions/week	2.96±0.53	3.02±0.48	2.99±0.43	2.96±0.37
< 3 dialysis sessions/week, %	5%	2%	3%	3%
Dialysis session length, min	205±60	245±63	220±53	238±50
Blood flow rate, mL/min	290±103	317±91	406±107	203±56
Urea reduction ratio (URR), %	66±22	74±13	74±12	69±13
URR ≥ 65, %	60%	89%	92%	72%
Body mass index (BMI), kg/m^2	25.1±15.9	26.0±8.8	28.3±10.2	21.3±6.2

mean values are shown with (± Standard Deviation); URR was restricted to patients having ESRD > 1 year, and receiving 3 HD sessions per week; EUR/ANZ includes Belgium, France, Germany, Italy, Spain, Sweden, United Kingdom, Australia, and New Zealand

Conclusions: The DOPPS represents a unique opportunity to evaluate practice patterns in SA, with comparisons to other DOPPS countries. A longitudinal component of SA DOPPS is planned, to determine the relationship of practice differences in SA on clinical outcomes.

Funding: Pharmaceutical Company Support - The Initial Cross-Sectional DOPPS Study in Saudi Arabia Was Supported by Amgen without Restrictions on Publications. The International DOPPS Is Supported by Scientific Research Grants from Amgen (Since 1996), Kyowa Hakko Kirin (Since 1999, in Japan), Sanofi Renal (Since 2009), and Abbott Laboratories (Since 2009)

TH-PO803

Twice Weekly Hemodialysis in China: Frequency and Determinants in a Cross-Sectional Analysis from the Dialysis Outcomes and Practice Patterns Study (DOPPS) Shuchi Anand,[1] Mei Wang,[2] Brian Bieber,[3] Mia Wang,[3] Li Zuo,[4] Ronald L. Pisoni,[3] Xueqing Yu,[4] Xiao Yang,[4] Jia Qi Qian,[4] Nan Chen,[4] Yucheng Yan,[4] Friedrich K. Port,[3] Bruce M. Robinson,[3] Sylvia Paz B. Ramirez.[3] *[1]Stanford University; [2]Co-First Author, China DOPPS Country Investigators; [3]Arbor Research; [4]China DOPPS Country Investigators.*

Background: While published studies on HD practices in China are limited, several single-center reports and city registries suggest widespread 2x/wk HD. To understand practice patterns of HD care in China, an initial cross-sectional study was conducted in Beijing, Guangzhou and Shanghai. This abstract reports data on prevalence and correlates of <3x/wk HD in these Chinese cities.

Methods: 1379 pts were randomly sampled from 45 HD units in 2011. Logistic regression was used to identify predictors of 2x/wk HD. Linear mixed models were used to explore the cross-sectional association with intermediate outcomes.

Results: 26% of pts were on <3x/wk, compared with < 5% in a majority of core DOPPS countries. The facility % of pts prescribed <3x/wk ranged from 4-55% (26% for avg facility). Females, and pts with residual kidney function (RKF) were more likely treated with 2x (vs 3x)/wk while those with DM, HTN, and more yrs on HD, were less likely on 2x/wk. Adjusting for pt characteristics in the table, 2x/wk was associated with longer treatment time (by 12 mins), lower s. Ca^{2+} and Hb, and higher s. PO_4, PTH, and albumin. Pt reported QoL was similar.

Table: Patient characteristics associated with twice weekly HD

Measure	2 sessions per week (vs. 3)					
	Unadjusted			Adjusted* OR		
	OR	95% CI	p	OR	95% CI	p
Age (per 10 years)	0.95	(0.86, 1.05)	0.31	0.97	(0.87, 1.09)	0.63
Female	1.33	(1.07, 1.64)	<0.01	1.32	(1.06, 1.63)	0.01
Vintage (per 1 year)	0.92	(0.88, 0.96)	<0.01	0.94	(0.90, 0.98)	<0.01
Urine output > 200 mL/day	3.05	(2.09, 4.46)	<0.01	2.81	(1.83, 4.32)	<0.01
Co-morbidity: Diabetes (DM)	0.56	(0.41, 0.76)	<0.01	0.49	(0.36, 0.67)	<0.01
Co-morbidity: Hypertension (HTN)	0.53	(0.33, 0.83)	<0.01	0.51	(0.32, 0.81)	<0.01

* Adjusted for all variables in table, plus body mass index and other cardiovascular co-morbidities. N=1339 patients; N with HD frequency 2x/week =323. Associations for, body mass index and other cardiovascular comorbidities were not significant. Once weekly HD accounted for < 2% of patients in the China sample and was excluded from analyses.

Conclusions: A substantial % of HD pts in 3 major Chinese cities receive <3x/wk HD. These pts had a lower co-morbidity burden, shorter yrs on HD, and greater RKF. Whether this practice is due mainly to provider preference or resource limitations remains to be determined. The long term impact of less frequent HD in this selected population is unclear and will be studied in the longitudinal China DOPPS.

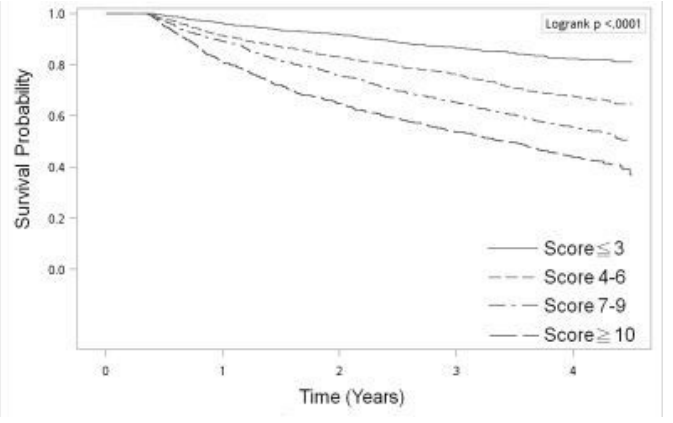
TH-PO804

A Novel Comorbidity Index for Outcome Analyses of Chinese Dialysis Patients Jinn-Yang Chen. *Division of Nephrology, Taipei Veterans General Hospital, Taipei, Taiwan.*

Background: Comorbid conditions are highly prevalent among patients with end-stage renal disease. In order to depict the comorbidity burden, to predict outcomes and to adjust confounders, we developed a new index for mortality analyses of Taiwan dialysis patients.

Methods: Cox proportional hazards model for mortality was used to estimate coefficient estimates of each comorbid condition. Numerical weights were assigned to 9 comorbid conditions, including atherosclerotic heart disease, congestive heart failure, cerebrovascular accident/transient ischemic attack, dysrhythmia, chronic obstructive pulmonary disease, gastrointestinal bleeding, liver disease, cancer, and diabetes. A patient's comorbidity score was the sum of the weights corresponding to the individual conditions present.

Results: This new index was developed among dialysis patients based on the 2006 (n=7999) incident cohort of Taiwan, and was validated using the 2005 (n=4071) and 2007 (n=8473) incident patients. Our new index performed almost identical to the individual comorbid conditions regarding model fit, predictive ability, and effect on inference. In Chinese ESRD patients, this index outperformed the Charlson's Comorbidity Index. The index predicted dialysis survival very well.



The new index also works well for hospitalization frequency and hospitalization days.

Conclusions: The index developed from Taiwan dialysis incident cohort was very suitable for outcome analysis of mortality and hospitalization. This index would be an important tool for observational research in Chinese ESRD patients.

TH-PO805

The Carbon Footprint of Satellite Hemodialysis in Australia Allan Lim, Anthony D. Perkins, John W.M. Agar. *Renal Unit, Geelong Hospital, Barwon Health, Geelong, Victoria, Australia.*

Background: HD services create a significant environmental footprint. Knowing the key service contributors to this footprint, and understanding how these are affected by geographical variations in resource emissions factors, will allow HD services to play a more effective role in primary climate-change mitigation.

This study aimed to determine the carbon footprint (CFP) of a 6-chair suburban satellite hemodialysis (HD) unit in Victoria, Australia: to calculate the per-patient CFP of satellite HD: and to understand the relative contributions of energy, transportation, pharmaceuticals and medical equipment to the total CFP.

Methods: Activity data were collected (01/01/11 – 31/12/11) for energy and water use, patient and staff travel, and procurement of the consumables, pharmaceuticals and medical equipment associated with the provision of satellite HD, and were converted to a common measurement unit of tonnes of CO_2 equivalents (t CO_2-eq) via established emissions factors.

Results: In 2011, the total unit CFP was 98.3 t CO_2-eq, corresponding to a per-patient CFP of 8.2 t CO_2-eq / year. In comparison, an average 4 person Australian household emits 18 t CO_2-eq / year. Emission data are shown in Table 1.

Table 1

SECTOR	SUB-SECTOR	EMISSIONS (tCO2-eq)	% of EMISSIONS
Energy	HD power	2.4	2.4
	Non-HD power	4.4	4.5
	SUB-TOTAL	6.8	6.9
Water	Mains supply & treatment	0.2	0.2
	Waste water disposal	1.3	1.3
	SUB-TOTAL	1.5	1.5
Travel	Staff	3.7	3.8
	Patient	7.0	7.1
	SUB-TOTAL	4.2	4.3
Waste	Landfill	1.4	1.4
	Incineration	3.8	3.9
	Recycled	-1.0	-1.0
	SUB-TOTAL	4.2	4.3
Procurement	Pharma	43.5	44.3
	Equipment	28.5	29.0
	Food	1.9	1.9
	Laundry/Sanitation	1.0	1.0
	Other	0.2	0.2
	SUB-TOTAL	75.1	76.4
TOTAL		98.3	100

Conclusions: Modest emissions reductions appear achievable through targeted energy-saving initiatives in our region. While energy use in other regions where less carbon-intensive electricity generation methods are used may contribute less to the overall CFP, financial and environmental benefits may still accrue if energy-saving initiatives are broadly introduced. More importantly, a more detailed analysis of pharmaceutical and medical equipment emission data should identify effective nation-wide interventions that will reduce HD-related carbon emissions.

TH-PO806

Problem-Solving Therapy to Improve Depression Scores among Older Hemodialysis Patients: A Pilot Randomized Trial Shiloh D. Erdley,[1] Zvi D. Gellis,[2] Hillary Bogner,[2] Robert M. Perkins.[1] *[1]Geisinger Clinic; [2]University of Pennsylvania.*

Background: Depression is the most common mental health problem reported among dialysis patients. Effective depression interventions in this population are limited.

Methods: In this randomized, controlled, un-blinded pilot study we examined the feasibility and impact of 6 protocolized, once-weekly, 30-minute problem solving therapy (PST) sessions conducted during routine maintenance hemodialysis sessions by a trained social worker on BDI and PHQ-9 depression scores in non-hospitalized adult patients with ESRD at a single dialysis unit in central Pennsylvania. Control subjects received standard interventions by the unit social worker according to unit policy. Outcomes were 6-week BDI and PHQ-9 scores, and change-from-baseline BDI and PHQ-9 scores.

Results: 35 subjects were randomized between January 1 and January 31, 2012. 33 subjects completed the study; one subject died and one subject withdrew due to illness (both randomized to intervention group). At baseline, subjects in each arm were similar with the exception that mean PHQ-9 and BDI scores were higher in the intervention group (P=0.009 and 0.05, respectively). At 6 weeks, there were no significant differences in mean PHQ and BDI scores between the control and intervention groups (PHQ-9 5.8 vs. 3.3, P=0.1; BDI 11.3 vs. 9.3, P=0.6); however, mean change-from-baseline scores were significantly improved in the intervention group relative to the control group (change in PHQ-9 7.2 vs. 0.3, P<0.001; change in BDI 6.3 vs. -0.6, P=0.008). When adjusted for baseline depression scores, mean 6-week BDI and PHQ-9 scores were significantly lower in the intervention group.

Conclusions: The results demonstrate that PST is feasible and well-tolerated, and may positively impact depression among maintenance hemodialysis patients.

TH-PO807

A Propose for Diagnostic Criteria Concerning Hemodialysis Related Amyloidosis Shinichi Nishi, Hideki Fujii, Keiji Kono, Kentaro Nakai. *Division of Nephrology and Kidney Center, Kobe University Graduate School of Medicine, Kobe, Hygo, Japan.*

Background: Hemodialysis related amyloidosis (HDRA) is a major complication of chronic hemodialysis patients and shows various kinds of bone-articular symptoms and sings. Among them carpal tunnel syndrome (CTS) and trigger finger are famous sings, however, we cannot easily determine their incidence is simply derived from HDRA, because pathological proof of B2MG protein is sometimes impossible in the operative specimens. We proposed a new diagnostic criteria concerning HDRA and evaluated its clinical availability in Japanese chronic HD patients.

Methods: We configured five major clinical findings; polyarticular pain, CTS, trigger finger, HD spondyloarthorpathy and bone cysts, and three associate findings; bone fracture, ischemic colitis and other minor findings. We determined a patient who has two or more major findings is a definitive case and one major finding and one or more associate findings is a probable one. We surveyed the prevalence of each finding and the rates of definitive and probable cases in 60 patients with long-time HD history.

Results: In the prevalence rate of each finding, polyariticular pain (48.3%), CTS (23.3%) and trigger finger (21.7%) were most frequent ones. These rates increased according to the duration of HD. The definitive cases were 26.7% (16/60) in total cases. The rates dramatically increased after 10 years HD duration; 6.7% (1/15 cases) in 5 to 10 years HD duration, 26.7% (4/15 cases) in 10 to 15 years HD duration and 73.3% (11/15 cases) in more than 15 years HD duration. However, there was a week relationship between ages and definitive rates.

Conclusions: The prevalence rate of HDRA increases according to duration of HD. Ten year duration may be necessary for incidence of HDRA. A combination criteria concerning HDRA is useful for the correct analysis of HDRA.

Funding: Government Support - Non-U.S.

Routine Use of an Abbreviated 4-Item Scale to Assess Dependence in Essential Activities of Daily Living amongst Elderly Hemodialysis Patients: A Validation Study Farhat Farrokhi,[1] Sarbjit Vanita Jassal.[1,2] *[1]Institute of Health Policy, Management and Evaluation, University of Toronto, Toronto, ON, Canada; [2]Division of Nephrology, University Health Network, Toronto, ON, Canada.*

Background: Poor functional status is associated with reduced survival and poor outcomes in older dialysis patients. The Geriatric Nephrology Advisory Group recommends routine evaluation of functional status on all older patients; however, assessments can be time consuming and burdensome to clinical care providers. The objective of this study was to validate an abbreviated 4-item self report screening tool for use in elderly hemodialysis patients.

Methods: The functional dependence of community-dwelling hemodialysis patients, aged≥65 years, was measured by trained evaluators. The accuracy of a 4-item self report activities of daily living (ADL) score was compared against formal evaluation by the Barthel Index and the outcomes using agreement statistics and Cox regression analysis.

Results: The cohort included 167 patients with a mean age of 74.8 ± 5.9 years (57% males). The 4-item scale correctly identified 83% of the patients dependent in ≥1 ADL. Those incorrectly identified as independent on the abbreviated scale were uniformly unable to climb stairs without assistance. The sensitivity and specificity, and coefficient for agreement between the 4-item scale and the Barthel Index were 83.2%, 100% and 0.78, respectively. The positive and negative predictive values of the 4-item scale were 100% and 76.9%, respectively. Using the 4-item scale, the presence of severe disability was predictive of increased mortality (HR, 12.5; 95%CI, 2.5–65.0; P=0.03).

Conclusions: The 4-item scale is a simple, valid screening test for disability which can be used in the elderly population on dialysis as a screening tool. Difficulties with stair-climbing may be overlooked using this score.

TH-PO809

Validation of the Perceived Kidney Disease Self-Management Scale in Hemodialysis Julia M. Steed, Kenneth A. Wallston, T. Alp Ikizler, Kerri L. Cavanaugh. *Vanderbilt University.*

Background: Self-management skills, such as adherence with diet, medication and dialysis prescriptions, are required to ensure effective hemodialysis therapy for treatment of end-stage renal disease (ESRD). High self-efficacy, or the perceived ability to perform self-management, may be an important factor related to optimizing self-care behaviors. Validated condition-specific self-efficacy assessments are available for other chronic conditions (HIV, arthritis, and diabetes), but an instrument for ESRD is lacking.

Methods: In a cross-sectional study, we adapted the 8-item Perceived Medical-Condition Self-Management Scale to kidney disease. We evaluated its internal consistency and pearson's correlations with a priori determined variables including: patient characteristics, affect (PANAS), perceived expectencies (PEI), despressive symptoms (CESD), dialysis knowledge (CHeKS), and self-care behaviors.

Results: In 146 prevalent maintenance hemodialysis patients, mean age 52(14) years, 50% male, 75% non-White, vintage 4.7 (5.4) years, the mean (SD) total PKDSMS score was 30.7 (6.0). Cronbach's alpha was 0.75. Correlations with PKDSMS included: depressive symptoms (r=-0.55, p<0.001), affect (negative: r=-0.44, p<0.001; positive: r=0.41, p<0.001), perceived expectencies (r=0.59, p<0.001), dialysis knowledge (r=0.20, p=0.01) and self-care (r=0.27, p=0.001). No differences by patient characteristics were observed.

Conclusions: Hemodialysis patent's perceived ability to perform goal-oriented tasks is significantly related to self-report of actual behaviors, dialysis knowledge, and an improved psychologic state. The PKDSMS is reliable and demonstrates evidence for construct validity. Evaluation of self-efficacy may be a target for nephrology providers and researchers to consider as a target for understanding and improving self-care in ESRD.

TH-PO810

Immune Response after Monovalent Influenza A (H1N1) Vaccine in Hemodialysis Patients Ellen T. McCarthy,[1] Karen Tamano,[1] Sumanth Mulamalla,[1] Lisa A. Clough.[2] *[1]Kidney Institute, University of Kansas Medical Center, Kansas City, KS; [2]Infectious Diseases, University of Kansas Medical Center.*

Background: Chronic hemodialysis (HD) patients have significant impairment of immunity, including decreased antibody response to vaccinations. Chronically ill patients, such as those on HD, are at increased risk for morbidity and mortality due to influenza. We hypothesize that patients with ESRD on chronic HD will have a blunted antibody response to the H1N1 vaccination.

Methods: We studied 45 patients on chronic HD. Of these, 57.8% were male; age range 32-85 (mean 56.4); 42% were ≥ 60 yrs of age. Patients received a single injection of monovalent H1N1 influenza vaccine administered in Dec 2009. Serum antibody titers were measured using hemagglutination-inhibition (HAI) assay at baseline and 21-28 days following immunization. A positive response to vaccination was defined as 1) pre-vaccination titer 1:10 with post-vaccination titer ≥ 1:40, or 2) ≥4-fold increase in antibody titer following vaccination.

Results: Twenty-seven of the 45 patients (60%) responded to vaccination with H1N1 vaccine. Patients ≥60 yrs of age were more likely to have post-vaccination titers ≥1:40 or four-fold rise in titers though the difference did not reach statistical significance. Responders did not differ from nonresponders in duration of dialysis, underlying disease, previous administration of seasonal influenza vaccine or baseline Hg, ferritin or vitamin D levels. Seven of 9 patients who had received prior renal allograft and were maintained on low-dose immunosuppression responded to vaccination.

Conclusions: Patients on chronic HD had an immunologic response to the H1N1 vaccine that was blunted compared to the general population (60% vs >80-90% reported in literature). Surprisingly, patients on chronic immunosuppression responded well. The introduction of the H1N1 vaccine was a unique opportunity to study immune response to influenza vaccines in this population. Despite lower response rates, an adequate response to the vaccine was seen in the majority of patients. Influenza vaccination is likely an important step in controlling influenza infections and outbreaks among dialysis patients.

TH-PO811

Analysis of USRDS Dataset Indicates Viral Infections Are Associated with Increased Risk of Fistula Failure in Incident Hemodialysis Patients Hari Garapati,[1] William D. Paulson,[1] John White,[1] Pamela J. Fall,[1] Mufaddal F. Kheda,[1] Tushar J. Vachharajani,[3] Earnest J. Baulkmon,[1] Kristina W. Kintziger,[1] Puja Chebrolu,[1] Rhonda E. Colombo,[1] Stephanie L. Baer,[1,2] N. Stanley Nahman.[1,2] *[1]Georgia Health Sciences University, Augusta, GA; [2]Charlie Norwood VAMC, Augusta, GA; [3]WG Hefner VAMC, Salisbury, NC.*

Background: ESRD is associated with arteriosclerosis and increased arterial stiffness. This stiffness impairs vessel dilatation after native arteriovenous fistula (AVF) creation, thereby promoting AVF thrombosis and failure (Kheda NDT 2010). Viral infections, such as HIV and hepatitis C (HCV), are also associated with increased stiffness. We tested the hypothesis that HIV, HCV, and hepatitis B (HBV) infection are independently associated with AVF failure in incident hemodialysis (HD) patients.

Methods: All incident HD cases in the USRDS dataset for calendar years 2005-07 were queried. Demographics were obtained from validated USRDS data, and access type was derived from form CMS-2728, submitted to Medicare on every new outpatient HD

patient. The criteria for AVF failure were derived from Medicare A datasets containing ICD-9 and CPT billing codes for AVF related complications. HIV, HCV or HBV infection was inferred from serologies and determined from the appropriate ICD-9 billing codes.

Results: For the 3 year study period, 259,224 patients with 80,825,083 claim observations were analyzed. AVF was the access used in the first dialysis in 33,925 patients, and 49.8% met criteria for AVF failure. Mean age was 64 years; 65% were male, 68% were Caucasian, 26% were African American. Positive viral serologies: HIV (N=204, 0.6%), HCV (N=712, 2.1%) and HBV (N=274, 0.8%). Relative risk (RR) of AVF failure was highest among HIV positive patients (RR 1.54, 95% confidence interval [CI] 1.42-1.68). RR of AVF failure in HCV was 1.25 (CI 1.20-1.31) and in HBV was 1.21 (CI 1.13-1.30).

Conclusions: AVF failure occurred in nearly 50% of incident HD patients. Positive serologies for HIV, HCV, and HBV were associated with increased risk of AVF failure, with HIV having the highest risk. We speculate that increased arterial stiffness in these patients may help explain these adverse outcomes.

TH-PO812

Detection of Antibodies to HCV Core among Anti-HCV-Screening-Negative Hemodialysis Patients at Risk of Occult HCV Infection Guillermina Barril,[1] Juan Antonio Quiroga,[2] Dolores Arenas,[3] Secundino Cigarran,[4] Nuria Garcia-Fernandez,[5] Jose A. Herrero,[6] Emilio E. Gonzalez-parra,[7] Adoración Martin,[8] Javier Bartolome,[9] Inmaculada Castillo,[9] Vicente Carreño.[9] *[1]Nephrology, H. Princesa, Madrid, Spain; [2]FEHV, Madrid; [3]H. Perpetuo-Socorro, Alicante, Spain; [4]H. DaCosta, Burela; [5]CUN; [6]Clinico, Madrid; [7]FJD; [8]Hospital Poniente; [9]FEHV.*

Background: Testing for HCV RNA in PBMC allows identification of occult HCV infection in a proportion of anti-HCV and serum HCV RNA-negative hemodialysis patients with abnormal liver enzymes (JASN2008). Antibodies HCVcore are detectable among anti-HCV-negative patients with occult HCV infection without renal disease. Up to now anticore has not been tested among hemodialysis patients to detect occult HCV.

Methods: To evaluate detection of antibodies HCV core and correlate to HCV RNA testing in PBMC for diagnosing occult-HCV infection in anti-HCV and serum HCV RNA negative hemodialysis patients with abnormal liver enzymes 113 HD patients were studied. HCV-RNA was tested in PBMC by real-time PCR. Antibodies to HCV anti-core were assessed by recently developed ELISA.

Results: HCV RNA was detected in PBMC from 40/113 (35%)patients indicating occult HCV infection.Anti-core antibodies were detectable in 26(23%) HDpatients supporting HCV exposure. Overall, 56/113 (49%had either marker detectable: 10 were positive for anti-core and RNA in PBMC; 30 only positive for viral RNA in PBMC whereas 16 had anti-core alone. Anti-core detection iidentified 16/73 anti-HCV-screening-negative HD-patients with undetectable HCV-RNA in PBMC may have occultHCV infection. 24patients were re-tested after 12 months who remained anti-HCV-screening-negative, including 10 with and 14 without anti-core detectable baseline 4/14 anti-core-negative at baseline seroconverted 30/113 reacted the anti-core assay at any time-point.

Conclusions: 1 Anti-core antibodies are often detectable among anti-HCV screening-negative HDpatients who may have an occult HCV infection, including 25% with confirmed occult infection and 22% of those exposed to HCV might have developed occult HCV infection

2 Repeated anti-core testing identifies 28% more cases.

TH-PO813

Variability in Response to Hepatitis B Vaccine in Hemodialysis Patients Majed Samarneh, Yorg Azzi, Pranab Sharma Acharya, Chadi Saifan, Morton J. Kleiner, Suzanne E. El Sayegh. *Nephrology, Staten Island University Hospital, Staten Island, NY.*

Background: Hemodialysis patients are exposed to blood and blood products more than the general population and are also at higher risk for Hepatitis B contamination. For these reasons, it is highly recommended that this patient population gets the Hepatitis B vaccine. The efficacy of the vaccine is measured by measuring titers of Antibody in the serum of the patient. A minimum titer of 10 mIU/mL is considered to be a response. The conversion rate in hemodialysis patients ranges from 50-80%, as compared to the general population where the conversion rate is over 95%. As opposed to the general population, end stage renal patients on hemodialysis do not always respond to the vaccine. The main objective in this study is to try to identify factors that may hinder the response. Correction of these factors in the future may help non-responders.

Methods: This was a retrospective chart review at a single hemodialysis center to compare the laboratory and clinical differences between responders and nonresponders. Inclusion criteria are hemodialysis patients who received the hepatitis B vaccine and patients with concomitant hepatitis C. Exclusion criteria are patients who refused the vaccine and patients who did not complete the vaccine course.

Results: There are a total of 108 subjects included in the study, out of which 44 (42.3%) are responders to the HepB vaccine. A multivariate logistic regression was performed using the statistically significant risk factors as identified by the univariate logistic regression, including age range, albumin, hemodialysis vintage, vascular access and diabetes status. The results from the multivariate logistic regression show that advanced age (P-value=0.005) and diabetes status (P-value=0.003) are found to be strong independent risk factors of responder status. The type of vascular access (AVF or other types) is also marginally statistically significant (P-value=0.05).

Conclusions: In this retrospective chart review comparing hepatitis B vaccine responders versus non-responders, we found that advanced age and a history of diabetes are independent risk factors in predicting responder status.

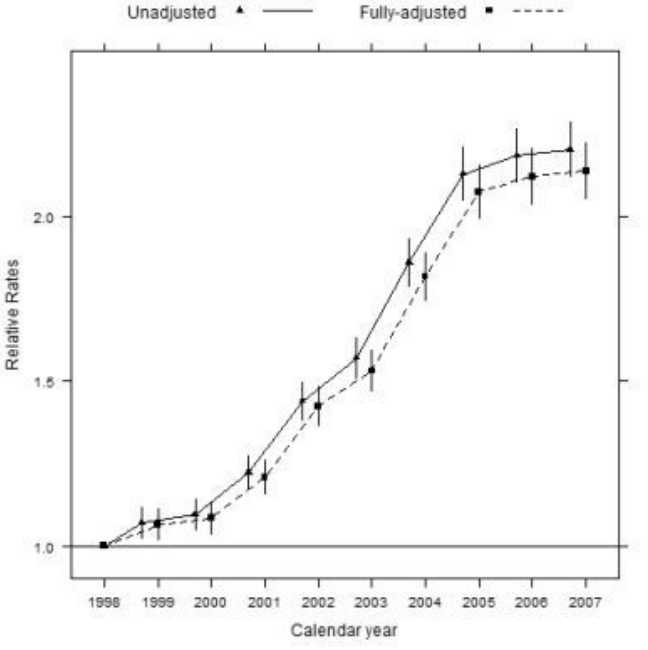
TH-PO814

Trends in the Incidence of *Clostridium difficile* Infection in U.S. Dialysis Patients (1998-2007) Juyeh Yang,[1] Tsung-chun Lee,[2] Maria E. Montez-Rath,[3] Glenn M. Chertow,[3] Wolfgang C. Winkelmayer.[3] *[1]Division of Nephrology and Department of Internal Medicine, Far Eastern Memorial Hospital, New Taipei, Taiwan; [2]Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan; [3]Divisions of Nephrology, Stanford University School of Medicine, Palo Alto, CA.*

Background: In the U.S., the number of *Clostridium difficile* (*C. diff.*) infections tripled between 2000 and 2009. Patients with ESRD are at particular risk for contracting and dying from >*C. diff.* infection, and have high recurrence rates. However, the current literature contains mostly cross-sectional data or small case series. Little is known about the long-term trends of the incidence and outcomes of *C. diff.* infections among dialysis patients.

Methods: We studied all dialysis patients (1998-2007) who had Medicare A+B as their primary payor. Episodes of *C. diff.* infection were ascertained from ICD-9 diagnosis code 8.45. We used Poisson regression and general estimation equation methods for correlated data to model the annual number of *C. diff.* infections.

Results: Overall, 948,345 patients contributed 2.3 Million patient-years. We observed 89,669 distinct *C. diff.* infections among 68,644 patients, corresponding to an occurrence rate of 39 infections per 1000 person-years (p-y). The occurrence rates increased from 25 episodes per 1000 p-y in 1998 to 52 episodes per 1000 p-y in 2007. After adjustment for socio-demographics and comorbidities, the occurrence rate increased by 10.1% per year (95% CI: 9.8% to 10.5%).



The 30-day mortality associated with *C. diff.* infection episodes was 15.5% and it did not change over the decade of study.

Conclusions: Our longitudinal study indicated that episodes of *C. diff.* infections doubled in U.S. dialysis patients between 1998 and 2007, and these episodes remained associated with high short-term mortality.

TH-PO815

Prevalence of Oral Lesions in Hemodialysis Patients: The Oral-D Prospective Multinational Cohort Study Suetonia Palmer,[1] Marinella Ruospo,[2] Patrizia Natale,[2] Letizia Gargano,[2] Mariacristina Vecchio,[3] Valeria Maria Saglimbene,[3] Fabio Pellegrini,[3] Eduardo Jorge Celia,[2] Paul Stroumza,[2] Jorgen B.A. Hegbrant,[2] Jonathan C. Craig,[4] Giovanni F.M. Strippoli.[2,3,4] *[1]University of Otago; [2]Diaverum Medical Scientific Office; [3]Mario Negri Sud Consortium; [4]University of Sydney.*

Background: Oral diseases are common in the general population and associated with socioeconomic status. It is plausible that the prevalence of oral diseases is increased in people on hemodialysis due to impaired role functioning and health status, but not formally established. We conducted a systematic prospective survey of oral lesions in adults on hemodialysis.

Methods: ORAL-D is a multinational prospective cohort study. We consecutively enrolled adults receiving hemodialysis in 75 outpatient clinics selected randomly from a collaborative dialysis network in Europe and South America. A dental surgeon conducted a standardized examination of dental, periodontal, mucosal and salivary lesions based upon standard dental practice methodology. We analyzed prevalence of oral diseases using descriptive statistics.

Results: 4720 (mean age 62.85 years (SD 15.76) adults on hemodialysis in the participating clinics received a complete oral examination. Of these, 922 (20%) were edentulous, 1693 (39%) had tooth attrition and dental erosion, and 109 (2%) had enamel hypoplasia. The mean decay/missing/filled teeth (DMFT) score was 21.9 (9.18), salivary pH was 7.48 (1.32). There was a high prevalence of patients with high buffer capacity (n=1834 [61%]), and only 96 patients (8%) with low buffer capacity. Salivary flow rate before dialysis was 0.84 ml/min (0.78), versus 0.77 ml/min (0.72) post dialysis. 1491 (32%) patients had mucosal lesions, 2074 (45%) patients reported mouth dryness, 229 (5%) had oral burning and 351 (8%) reported mouth pain. Periodontitis was present in 1516 (42%) of 3672 dentate patients.

Conclusions: Oral lesions are prevalent in people receiving hemodialysis and may indicate impaired healthcare practices, although further research on the predictors of oral disease in this population is needed.

TH-PO816

The Effect of Online Hemodiafiltration on Infections: Results from the CONvective TRAnsport Study (CONTRAST) Claire H. Den Hoedt,[1,2] Muriel Grooteman,[3] Michiel Bots,[2] Peter J. Blankestijn,[2] Neelke C. Van Der Weerd,[3] Renee Levesque,[4] Pieter M. Ter Wee,[3] Menso Jan Nube,[3] Marinus A. Van Den Dorpel.[1] *[1]Maasstad Hospital, Rotterdam; [2]UMCU, Utrecht; [3]VU MC, Amsterdam, Netherlands; [4]St-Luc Hospital, Montréal, Canada.*

Background: Hemodialysis (HD) patients have a high risk of infections. Immune function is worsened by uremia and frequent damaging of the skin facilitates the entry of micro-organisms into the body. Online hemodiafiltration (HDF) might reduce the infectious risk by ameliorating the uremic milieu by enhanced clearance of middle molecules. On the other hand the infusion of substitution fluid might impose a larger risk if endotoxin fragments are transferred into the bloodstream. Since there are no data on infectious outcomes in HDF, we compared the effects of HDF and low-flux HD on the incidence and type of infectious complications.

Methods: We used data of the 714 prevalent chronic HD patients (age 64 ±14, 62% men, 25% DM, 7% catheters) included in the CONvective TRAnsport Study (CONTRAST), a randomized controlled trial evaluating the effect of HDF as compared to low-flux HD. The risk of infectious events, adjudicated by an independent committee, was compared with Cox regression for repeated events and Cox proportional hazard models. The distributions of infection types were compared between the groups.

Results: The risk for infections during the entire follow-up did not differ between the two treatment arms (HDF 205 and HD 171 infections in 1073 and 1083 patient yrs respectively, hazard ratio HDF vs. HD 1.06 (0.86-1.30), P=0.58, adjusted for clinical center). No difference was found in the occurrence of the first infectious event (either fatal, non-fatal or type specific) except for an increased combined risk for catheter-related infection and sepsis in HDF patients, HR 1.94 (1.06-3.55), P=0.03. Miscellaneous infections (such as wound-/skin infections, osteomyelitis etc) were the most common (36% in HDF, 30% in HD), followed by respiratory infections (25% in HDF, 28% in HD).

Conclusions: HDF as compared to HD did not result in a reduced risk of hospitalization for infection. In the CONTRAST cohort, miscellaneous infections and respiratory infections were the most common infections.

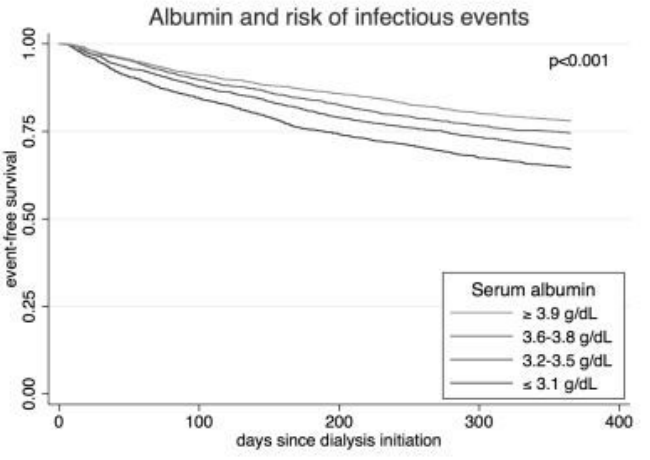
TH-PO817

Infection-Associated Events in Hemodialysis: Characteristics and Predictors Ishir Bhan, Elizabeth D. Ankers, Ravi I. Thadhani. *Division of Nephrology, Massachusetts General Hospital, Boston, MA.*

Background: Infection is commonly seen in patients on hemodialysis, but little is reported about the frequency and nature of infectious events or underlying risk factors.

Methods: We analyzed infection-associated deaths and hospitalizations in Accelerated Mortality in Renal Replacement, a cohort of 10,044 incident hemodialysis patients followed for one year. Cause of death was determined from discharge diagnosis forms. Diagnosis codes from hospital admissions were evaluated. Death diagnoses and admissions were classified as infection-associated based on physician review. Admissions were considered infection-associated if the primary or secondary diagnosis was consistent with an infectious cause. Laboratory, comorbidity, and demographic data were determined at the time of dialysis initiation. Predictors of infectious events were determined by multivariable Cox models, with continuous variables analyzed by quartile.

Results: A total of 16,661 hospital admissions occurred during the study period, representing 6620 individuals, or 66% of the cohort. 3,233 (19.4%) of admissions were consistent with infection, representing 23% of the overall population. Only 224 admissions (1.3%) were defined as being of viral etiology. 1,528 (15.2%) subjects died within one year of dialysis initiation, with infectious causes representing 10.5% of these deaths. In multivariate analysis, diabetes (HR 1.2), catheter use (HR 1.5), and higher calcium (HR 1.1) were associated with increased risk of infectious events, while black race (HR 0.84), high systolic blood pressure (HR 0.94), and higher albumin (HR 0.84) were protective.



Conclusions: Infection represents an important cause of death in hemodialysis, but is a more important contributor to hospitalization. The most potent risk factors for infectious events include non-black race, diabetes, catheter use, and low albumin.

TH-PO818

Association between Dialysis Facility Report (DFR) Infection Measures and Dialysis Survey Deficiencies Joseph M. Messana, Natalie Scholz, Deanna Chyn, Valarie B. Ashby, Tempie H. Shearon. *Univ of Michigan, Ann Arbor, MI.*

Background: There is increasing awareness of the burden of vascular access infections, particularly access-related bacteremia, in patients receiving dialysis in the US. This study evaluates the relationship between assignment of a condition level infection control deficiency citation (CFC V110) & facility hospitalization for septicemia in the years before, during & after survey and whether these citations are associated with subsequent improvement in facility outcomes.

Methods: Infection citation data (V110-148) from 2009 facility surveys were combined with 2008-10 DFR data, based on national CMS data. Analyses include 5092 facilities with septicemia data available for all 3 yrs, of which 1265 were surveyed in 2009. GLM models were fit to predict % of patients hospitalized due to septicemia in each year based on 2009 infection survey citations. The differences in hospitalization for septicemia between each pair of yrs were also fit to assess the relationship between survey & change in infection outcomes over time. The models were weighted by facility size & adjusted for patient demographics, diabetes as cause of ESRD, & catheter use >90 days.

Results: Facilities with a CFC V110 in 2009 had significantly more hospitalizations for septicemia each year compared to facilities without a CFC V110. From 2008-10, facilities not surveyed or surveyed without a CFC V110 had smaller decreases in % of patients hospitalized for septicemia (0.46% & 0.48%, respectively) than facilities with a CFC V110 (1.55%), although it was not statistically different (p=.057).

Percent of Patients Hospitalized due to Septicemia in 2008-10 by Infection Citation Status in 2009*

2009 Survey Status	2008	2009	2010	Change from 2008 to 2010
Received a CFC V110 citation (n=86)	14.6 (p<0.001)	12.3 (p<0.001)	13.1 (p=0.001)	-1.55 (p=0.057)
Surveyed - No CFC V110 citation (n=1,265)	11.9 (ref)	10.2 (ref)	11.5 (ref)	-0.48 (ref)
Not surveyed (n=3,741)	11.7 (p=0.23)	9.8 (p=0.03)	11.3 (p=0.23)	-0.46 (p=0.89)

*Values shown for facility with average patient characteristics

Conclusions: These findings suggest an association between ESRD surveyor citations & facility infection control practices that contribute to better patient outcomes.

TH-PO819

Infectious Events in Chronic Hemodialysis Patients: Risk Factors, Practice Patterns and Yield of Obtained Blood Cultures Golaun Odabaei, Don N. Chang, Burl R. Don, Andrew I. Chin. *Div. of Nephrology, UC Davis Medical Center, Sacramento, CA.*

Background: Infection is a major problem for chronic hemodialysis patients (pts) and nephrologists are generally contacted by the dialysis unit when an infectious event occurs. Blood cultures may be obtained during dialysis when pts manifest signs and/or symptoms of an infection. The practice patterns of community nephrologists in contending with an infectious event at an outpatient dialysis unit (where the nephrologist is generally not present) and the yield of an initiated evaluation for these events are not known.

Methods: Over a two year period of time (2010-2011), there were 100,050 dialysis treatments at the four DCI Sacramento dialysis units for an average prevalence of 347 pts.

Results: During this period, 512 new infectious events on dialysis were reported (fever, chills, signs of catheter infection etc.) in 242 unique pts with a frequency of 5 new infectious events per 1000 dialysis treatments. For the general dialysis population, the prevalence of catheters, fistulas and grafts were 23%, 58% and 19%, respectively, whereas in the

infectious events group, 51% had catheters, 42% had fistulas and 8% had grafts. For each new infectious event, the nephrologist was contacted and blood cultures were obtained in 355 of the 512 events (69%) in 189 unique pts. Empiric antibiotic therapy was initiated in 55% of the new infectious events. Only 59/355 blood cultures were positive (17%). The organisms isolated from blood cultures were gram + cocci (46/59), gram - rods (11/59) and yeast (1/59). In comparing the general dialysis population with the infectious event group, there was no significant relationship between gender, age, race and presence of diabetes mellitus and the occurence of infectious events.

Conclusions: Although infection is a major problem for chronic dialysis pts, the frequency of infectious events in an outpatient hemodialysis unit is low. When contacted, nephrologists order blood cultures and empiric antibiotics for a majority of the hemodialysis pts. Only a minority of blood cultures obtained (17%) were positive. The type of vascular access (catheter vs. fistula/graft) is the most important factor predicting an infectious event.

TH-PO820

Infection Rates for U.S. Dialysis Facilities: Comparing Sources

Erik Roys,[1] Natalie Scholz,[1] Casey Parrotte,[1] John Kalbfleisch,[1] Rajiv Saran,[1] Carol Chenoweth,[1] Stephen C. Hines,[2] Joseph M. Messana.[1] *[1]University of Michigan, Ann Arbor, MI; [2]HRET, Chicago, IL.*

Background: Reducing infections in hemodialysis facilities is a national priority to improve patient outcomes and reduce cost. Tracking infection rates at the facility level is essential for quality improvement. Several sources of infection rate information are currently available to facilities and other ESRD community members. This study examines the differences and similarities in infection rates based on Medicare claims and the CDC's National Health Safety Network (NHSN) data.

Methods: Four infection rates were examined for 34 facilities enrolled in the NOTICE project from 4 ESRD Networks for August-November 2011: 1) hemodialysis access-related infections based on ICD-9 code 996.62 reported on Medicare inpatient, physician/supplier, and outpatient claims; 2) vascular access-related bacteremia based on the V-modifier (V8) reporting in Medicare outpatient claims; 3) NHSN reported vascular access infections, defined as either a local access site infection or an access-related bloodstream infection; and 4) NHSN reported bloodstream infections, defined as any positive blood culture. Rates were expressed as events per 100 hemodialysis patient months. NHSN data were unavailable for 5 facilities.

Results: Rates obtained from NHSN were highly correlated with each other (r=.73, p<0.0001). However, there was a weak correlation between the vascular access infection rate from NHSN and the similar hemodialysis access-related infection rate based on ICD-9 reporting (r=.37, p=0.049). Infection rates based on V-modifier reporting were not correlated with any other source and had the lowest reported numbers of infections.

Correlation	n	r	p-value
ICD-9 vs V-Modifier	34	0.25	0.15
ICD-9 vs NHSN VA	29	0.37	0.05
ICD-9 vs NHSN Bact	29	0.03	0.87
V-Modifier vs NHSN VA	29	0.01	0.96
V-Modifier vs NHSN Bact	29	0.08	0.69
NHSN VA vs NHSN Bact	29	0.73	<0.0001

Conclusions: Despite these measures having somewhat different definitions, significant overlap would be expected. The lack of strong correlation between these measures suggests the need for additional investigation. Possible explanations will be explored including differences in definition and reporting factors.

Funding: Other U.S. Government Support

TH-PO821

Associations of Hemoglobin Concentration with Quality of Life and Mortality in Hemodialysis Patients on Erythropoietin in a Brazilian Population of Predominantly African Descent: A 6-Year Cohort Study

Gildete Barreto Lopes,[1] Cacia Mendes Matos,[2] Antonio Alberto Lopes.[1] *[1]Universidade Federal da Bahia; [2]INED, Salvador, Brazil.*

Background: Erythropoiesis stimulating agents improve outcomes in maintenance hemodialysis (MHD) patients but the target serum hemoglobin (sHb) level remains controversial. The objective was to investigate associations of baseline sHb with health-related quality of life (HRQOL) and survival in MHD patients on erythropoietin (EPO) in a population of predominantly African descent.

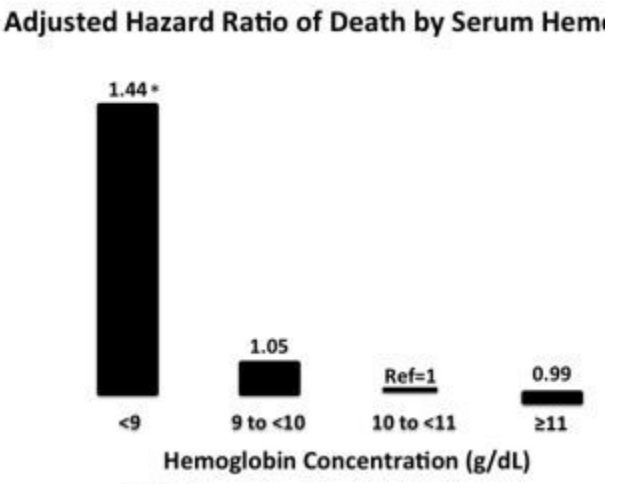
Methods: Prospective cohort study (PROHEMO) of 1244 MHD patients in Salvador, Brazil (2005-2011). Analysis restricted to 912 with more than 3 months on dialysis and on EPO (age 48.3±14.4 yr, 90.2% black or black-white admixture). SF-36 was used for physical (PCS) and mental (MCS) HRQOL. Cox regression was used for hazard ratios of death and linear regression for differences in HRQOL scores with adjustments for demographics, vintage and comorbidities.

Results: HRQOL scores were lower (P<0.05) in patients with sHb <9 and ≥11 compared with 10 to <11 g/dL (Table). Compared with sHb 10 to <11, the hazard of death was higher (P<0.05) for sHb <9 g/dL (Figure).

Mean Scores and Adjusted Differences in Health-Related Quality of Life by Serum Hemoglobin Concentration

	SERUM HEMOGLOBIN (g/dL)			
	<9 (N=230)	9 to < 10 (N=193)	10 to <11 (N=209)	≥11 (N=280)
PCS, mean(SD)	38.9(10.4)	41.1(10.2)	42.2(9.9)	39.9(9.8)
PCS, Adj Dif	-2.76*	-1.05	Ref=0	-2.00*
MCS, mean(SD)	47.0(12.3)	47.2(12.7)	49.8(12.3)	47.1(12.4)
MCS, Adj Dif	-2.79*	-2.47	Ref=0	-2.60*

* *P<0.05, MCS=Mental Component Summary, PCS = Physical Component Summary*, Adj Dif = Differences adjusted for several covariates



Conclusions: This study in a MHD population of predominantly African descent suggests a sHb between 10 and 11 g/dL to maximize the EPO benefits in terms of HRQOL and survival. The study could not assess effects of sHb variation on outcomes.

TH-PO822

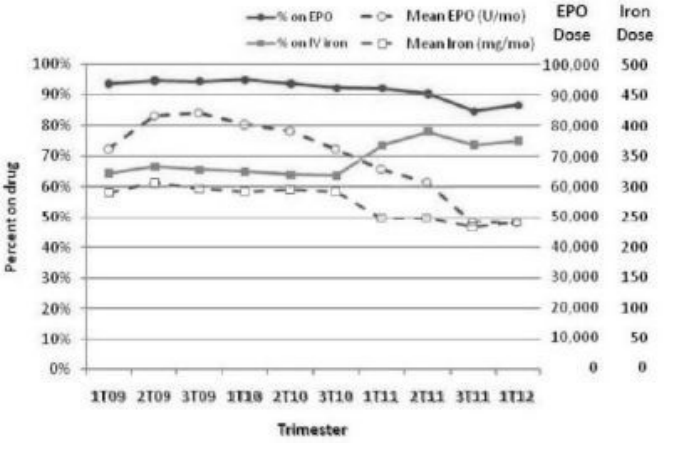
Changing Hemoglobin Targets: Effects on Epoetin Alfa, Intravenous Iron, and Iron Storage Measures from 2009-2012

T. Christopher Bond, Carey Colson, Tracy Jack Mayne. *DaVita Clinical Research, Minneapolis, MN.*

Background: The paradigm for anemia treatment in patients with end-stage renal disease (ESRD) is evolving in response to label revisions for erythropoiesis-stimulating agents and changes in Medicare reimbursement. A USRDS study reported that in 2011, epoetin alfa (EPO) dosing and hemoglobin (Hb) levels decreased significantly in dialysis patients. To better understand how anemia is being treated in patients with ESRD, we examined monthly EPO and intravenous (IV) iron dosing, Hb, as well as serum ferritin levels and percent saturated transferrin (TSAT).

Methods: Data were assessed from records of a large dialysis organization for incident and prevalent hemodialysis (HD) patients who received in-center HD between January 1, 2009 and April 30, 2012. Values were reported by 4-month periods (trimesters) over the study period.

Results: Between 2009 and 2012, the proportion of patients on EPO each month dropped from 95% to 85%, suggesting an increase in dose holds; mean EPO dose/month decreased >30,000 Units/month over the study period. While the average dose of IV iron was reduced over the study from 291 to 241 mg/month, the proportion of patients receiving any IV iron increased by 10-14%, as did the frequency of iron dosing in the population: from 2.54 doses/patient-month in April 2009 to 2.95 doses/patient-month in April 2012. These changes coincided with increases in mean serum ferritin (606 and 769 ng/mL in April 2009 and April 2012, respectively) and TSAT (29.9% and 30.9% in April 2009 and April 2012, respectively). Over the 3-year study period, patients' mean Hb fell from 11.6 to 10.8 g/dL.



Conclusions: Compared to 2009, in 2012 more HD patients received IV iron each month, leading to increased serum ferritin and TSAT levels. EPO administration fell considerably over the same time period, as did Hb levels. The effects of these dosing trends are unknown.

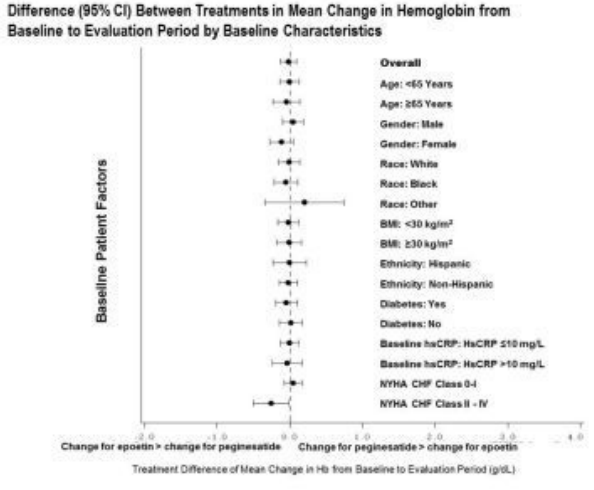
Efficacy of Peginesatide versus Epoetin by Baseline Characteristics in Hemodialysis (HD) Patients (Pts) with Anemia due to Chronic Kidney Disease (CKD)

Nathan W. Levin,[1] Bruce S. Spinowitz,[1] Carol Francisco,[2] Anne-Marie Duliege,[2] Krishna R. Polu,[2] Andrzej Wiecek.[1] *[1]AFX01-12 and -14 Peginesatide Study Groups; [2]Affymax, Inc., Palo Alto, CA.*

Background: In two large (N~1600) randomized open-label, active-controlled trials comparing peginesatide (OMONTYS®) vs epoetin alfa/beta for anemia treatment due to CKD in HD pts (EMERALD 1, 2), demographic and clinical characteristics were generally representative of the dialysis population. In these mutually supportive studies, peginesatide was noninferior to epoetin in maintaining hemoglobin (Hb) levels, with similar cardiovascular safety. Here we evaluate efficacy in subgroups defined by baseline characteristics.

Methods: Data were pooled from EMERALD 1 and 2, assessing (2:1 ratio) peginesatide Q4W (n=1066) vs epoetin 1-3X weekly (n=542) in HD pts on stable epoetin doses ≥4 weeks. Doses were titrated to maintain target Hb levels of 10-12 g/dL. The primary efficacy endpoint was mean change in Hb from baseline to evaluation period; noninferiority was defined as the lower limit of the two-sided 95% confidence interval (CI) ≥-1.0 g/dL (peginesatide minus epoetin).

Results: Overall, the peginesatide and epoetin groups, respectively, were well matched at baseline: mean age, 58.1 yr and 58.1 yr; male, 58.5% and 54.8%; Black, 37.4% and 38.9%; BMI ≥30 kg/m^2, 36.6% and 34.1%; diabetes as a primary cause of CKD, 37.1% and 39.5%; and high-sensitivity C-reactive protein >10 mg/L, 30.9% and 31.5%. Overall, peginesatide maintained Hb levels similarly to epoetin, least squares mean difference (95% CI) between groups: -0.02 (-0.13, -0.08) g/dL, with generally consistent results in subgroups (Figure).



Overall safety in subgroups was similar between agents.

Conclusions: In this pooled analysis, consistent with overall findings, peginesatide Q4W maintained Hb similarly to epoetin 1-3X weekly across a broad range of patient subgroups.

Linagliptin, a Dipeptidyl Peptidase-4 (DPP-4) Inhibitor, May Potentially Improve Glycemic Variability in Diabetic Hemodialysis Patients: Assessment Using Continuous Glucose Monitoring (CGM)

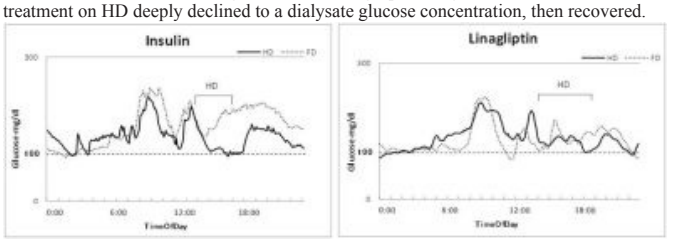
Satoshi Funakoshi,[1] Yoshiaki Lee,[1] Tomoya Nishino,[2] Yoko Obata,[2] Jyunichiro Hashiguchi,[1] Kenichi Miyazaki,[1] Takashi Harada,[1] Kazunori Utsunomiya,[3] Shigeru Kohno.[2] *[1]Nagasaki Renal Center, Japan; [2]Nagasaki University Graduate School of Medicine, Japan; [3]Jikei University, Japan.*

Background: Previous reports indicate that plasma glucose decreases during hemodialysis session, and then increases to relatively hyperglycemic state in diabetic hemodialysis patients. This glycemic variability may play a major role in the development and progression of cardiovascular diseases in hemodialysis patients with diabetes.

In this study we evaluated the efficacy of linagliptin, a biliary-excretion type of DPP-4 inhibitors, in controlling glycemic variability in diabetic hemodialysis patients using CGM.

Methods: Six relatively well-controlled (HbA1c<7.0) diabetic hemodialysis outpatients treated with insulin were enrolled in this study after appropriate IC. Subjects were then monitored overall 48-hours glycemic control, on both hemodialysis day (HD) and non-hemodialysis days (free day: FD), by CGM. Various types of insulin (<15 units per day) were converted to 5 mg of replaced with linagliptin, and glycemic controls were compared in each patient.

Results: As shown in Figure 1, the average plasma glucose curve under insulin treatment on HD deeply declined to a dialysate glucose concentration, then recovered.



On the other hand, the average plasma glucose in linagliptin-treated patients had the similar pattern on HD. More importantly, the mean amplitude of glycemic excursions (MAGE) under insulin treatment on HD was significantly higher than in linagliptin-treated group (38.0±10.5 mg/dL vs 25.1±14.7 mg/dL, p=0.021).

Conclusions: In our study, linagliptin, with its biliary excretion and low hepatic metabolism, could be promising candidate in the treatment in diabetic hemodialysis patients.

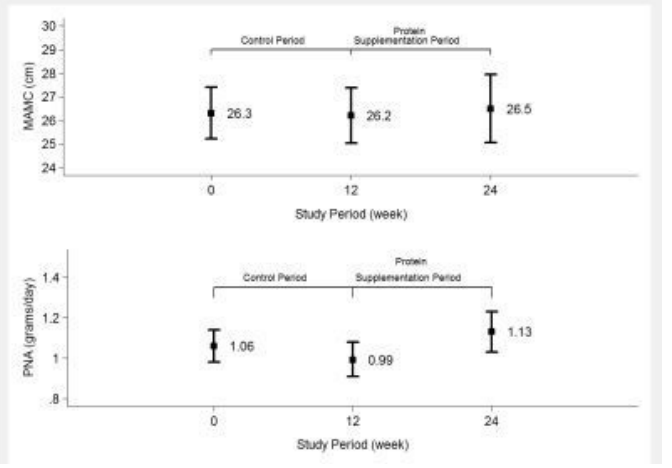
Oral Protein Supplementation during Dialysis in Patients with Elevated C-Reactive Protein

A. Agarwal,[1,2] Jill L. Neilson,[1] Y. Zhang,[1] R. Filipowicz,[1] G. Wei,[1] Tom Greene,[1] S. Beddhu.[1] *[1]Univ of Utah; [2]Nephrology of Northern Utah, PC.*

Background: Inflammation is thought to increase catabolism and it is unknown whether oral protein supplementation during hemodialysis (HD) treatment will increase muscle mass in chronic HD patients.

Methods: In this 24 week open labeled, prospective study, 49 chronic HD patients (pts) with a serum high sensitivity C-reactive Protein (hsCRP) of >3 mg/ were included. During the 12 week observation phase, participants received dietary advice to ↑protein intake to 1.2 g/kg/day. During the subsequent 12 week Rx phase, each participant was given 45 grams of oral liquid protein supplement during each HD Rx. Compliance and tolerance of the supplement were monitored. Primary outcome was mid-arm muscle circumference (MAMC). Secondary outcomes included serum albumin and Physical Composite Score (PCS) calculated from SF-12 questionnaire. Protein Nitrogen Appearance (PNA) was calculated using the pre/post BUN, body weight, ultrafiltration, and residual renal function. Statistical analysis was done using the mixed effect models.

Results: A total of 38 patients completed the study. The mean age was 64±17 yrs, 92% white, 14% had malignancy, 65% had DM, mand 14% had a catheter for dialysis access. As shown in the figure, PNA increased significantly in the study participants during the Rx phase. However, there was no significant change in MAMC. No changes in mean serum albumin (3.7 +/- 0.32 at 12 wks vs 3.7+/-0.34 at 24 wks) or the mean PCS scores (30.5+/- 9.9 at 12 wks vs 29.1 +/- 8.9 at 24 wks) were observed during the Rx phase of the study. Three patients experienced diarrhea and stopped taking the supplements.



Conclusions: In chronic HD with high hsCRP, protein supplementation during HD increases protein intake, but does not appear to increase muscle mass, physical quality of life, or serum albumin.

Funding: Private Foundation Support

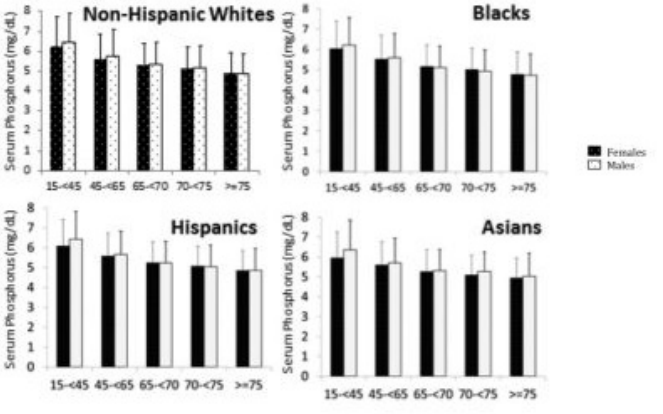
Serum Phosphorus Concentrations across Different Age Groups of Hemodialysis Patients with Different Races/Ethnicities
Paungpaga Lertdumrongluk,[1,2] Miklos Zsolt Molnar,[1] Wei Ling Lau,[3] Joshua Zaritsky,[6] Csaba P. Kovesdy,[4] Keith C. Norris,[5] Kamyar Kalantar-Zadeh.[1,6]
[1]Los Angeles Biomedical Research Institute, Harbor-UCLA; [2]Srinakharinwirot University, Thailand; [3]University of Washington; [4]University of Tennessee; [5]Charles R. Drew University; [6]David Geffen School of Medicine at UCLA.

Background: Previous studies have shown that elderly maintenance hemodialysis patients (MHD) tend to have worse nutritional parameters compared to their younger counterparts. The differences in serum phosphorus levels between young and elderly MHD across race/ethnicity have not been closely examined in large epidemiological studies.

Methods: We divided 111,302 outpatient MHD patients treated in a large dialysis organization including 50,741 Whites, 38,825 Blacks, 18,078 Hispanics and 3,658 Asians into 5 age groups (15-<45, 45-<65, 65-<70, 70-<75 and ≥75 years old). We compared serum phosphorous levels between different age groups across race/ethnicity and gender using trend analysis and adjusted for demographics, dialysis dose, residual renal function, serum calcium and intact parathyroid hormone concentrations.

Results: The average serum phosphorus levels (mean±SD) were progressively lower within each older age group, 6.24±1.4, 5.64±1.21, 5.25±1.08, 5.10±1.06 and 4.87±1.03 mg/dl, respectively (P-trend <0.001). In the subgroup analysis of each race and gender, this trend persisted whereby older MHD patients had significantly lower serum levels of phosphorus compared to younger MHD patients (P-trend<0.001).



Serum phosphorus did not differ across gender or race/ethnicity. The results remained similar after case-mix adjustment.

Conclusions: The serum phosphorus concentrations were significantly lower in elderly hemodialysis patients compared to younger patients. Our findings were consistent among both genders and each racial/ethnic group.

TH-PO827

Comparison of Outcomes for Veterans Receiving Dialysis from VA and VA-Outsourced Providers
Virginia Wang,[1,2] Matthew L. Maciejewski,[1,2] Karen M. Stechuchak,[1] Uptal D. Patel,[1,2] Morris Weinberger.[1,3] *[1]HSR&D, Durham VA Med Ctr, Durham, NC; [2]Dept of Medicine, Duke Univ Med Ctr, Durham, NC; [3]Dept of Health Policy & Mgmt, UNC-CH, Chapel Hill, NC.*

Background: Demand for dialysis exceeds its supply within the Department of Veteran Affairs (VA), requiring VA to purchase dialysis for Veterans in the private sector on a fee-for-service basis. It is unclear whether outcomes are similar for Veterans receiving dialysis in these settings. This study assessed the extent of dialysis utilization and differences in all-cause hospitalizations and mortality among Veterans receiving outpatient dialysis from VA and VA-outsourced providers.

Methods: We constructed a cohort of Veterans in 2 regions who received chronic dialysis financed by VA in 2007-2008. From VA administrative data, we identified Veterans who received outpatient dialysis in 1) VA, 2) VA-outsourced, and 3) both ("dual") settings. We used two-part and logistic regression to examine associations between dialysis setting and 1-year all-cause hospitalization and mortality.

Results: Of 1,388 patients who received outpatient dialysis treatment financed by VA 27% received dialysis in VA only, 47% used outsourced dialysis only, and 25% were dual users. VA users were more likely to be younger, non-White, unmarried, have higher comorbidity burden, and live closer to the nearest VA dialysis unit than patients in VA-outsourced or dual settings. Half of the Veterans in our cohort were hospitalized and 13% died. Veterans receiving VA-outsourced dialysis were less likely to be hospitalized (OR= 0.35, p<0.001) and incurred fewer hospitalizations (β= -0.16, p<0.05) and shorter hospital stays (β= -0.37, p<0.05) than VA dialysis users. Patients in dual-settings had lower 1-year mortality than Veterans receiving VA dialysis (OR=0.52, p<0.05).

Conclusions: A significant proportion of VA-funded dialysis is delivered through VA-outsourced providers. Veterans receiving outsourced dialysis are systematically less complex, less likely to be hospitalized, and had shorter lengths-of-stay but no difference in mortality than Veterans receiving VA dialysis. For dual dialysis patients, the likelihood of hospitalization is similar but mortality is reduced.

TH-PO828

Endothelial Progenitor Cells Induce Macrophage Phenotypic Switch and Improve Renal Recovery Capacity in Swine Renal Artery Stenosis
Alfonso Eirin,[1] Xiang-Yang Zhu,[1] Zilun Li,[1] Behzad Ebrahimi,[1] Xin Zhang,[1] Hui Tang,[1] Michael James Korsmo,[1] Alejandro Chade,[2] Amir Lerman,[1] Stephen C. Textor,[1] Lilach O. Lerman.[1] *[1]Mayo Clinic, MN; [2]Univ. of Mississippi, MS.*

Background: Endothelial progenitor cells (EPC) decrease inflammation and improve endothelial repair, but their potential for modifying the pro-inflammatory macrophage (M1) phenotype remains unknown. Inflammation is a key component of kidney injury in renal artery stenosis (RAS), and may account for its persistence despite restoring renal flow. We hypothesized that EPC would decrease M1 macrophages and improve renal recovery potential in RAS.

Methods: Pigs with 10 wks of RAS were studied 4 wks after percutaneous transluminal renal angioplasty (PTRA) or sham, with or without adjunct intra-renal delivery of autologous EPC expanded from peripheral blood, and compared to normal controls with or without EPC infusion (n=7 each). Single-kidney function, microvascular and tissue remodeling, inflammation, and fibrosis were evaluated.

Results: Mean arterial pressure (MAP), but not renal blood flow (RBF), was normalized 4 wks after PTRA. Injected EPC engrafted in RAS kidneys (~12%). Stenotic-kidney GFR was restored in RAS+EPC, RAS+PTRA, and RAS+PTRA+EPC pigs, while RBF and microvascular structure were improved and fibrosis attenuated only in EPC-treated pigs (Table). EPC decreased the ratio of M1/M2 (inflammatory/reparative) macrophages (Figure A) and induced a phenotypic switch (M1-to-M2) in cultured monocytes, which was blocked by vascular endothelial growth factor (VEGF) blockade (Figure B).

Conclusions: Intra-renal infusion of EPC after PTRA induced VEGF-mediated M1-to-M2 switch, preserved microvascular architecture and function, and decreased inflammation and fibrosis in the stenotic kidney, suggesting a novel mechanism and therapeutic potential for adjunct EPC delivery in improving renal repair in RAS.

Mitochondrial Targeted Peptides Attenuate Myocardial Damage after Renal Revascularization in Experimental Atherosclerotic Renovascular Hypertension
Alfonso Eirin, John A. Crane, Xin Zhang, Zilun Li, Xiang-Yang Zhu, Sandra Herrmann, Amir Lerman, Stephen C. Textor, Lilach O. Lerman. *Mayo Clinic, MN.*

Background: Atherosclerotic renovascular hypertension (ARVH) increases cardiovascular morbidity and mortality. Renal revascularization with percutaneous transluminal renal angioplasty (PTRA) may not fully regress cardiac remodeling and damage, likely due to persistent myocardial ischemic insults. Mitochondrial targeted peptides like Bendavia reduce ischemic cardiomyopathy by preventing mitochondrial dysfunction. However, their potential for attenuating myocardial damage in ARVH has not been explored. We hypothesized that treatment with Bendavia as an adjunct to PTRA would improve cardiac function and decrease myocardial inflammation and fibrosis in swine ARVH.

Methods: After 6 weeks of ARVH (unilateral renal artery stenosis) or control, pigs underwent PTRA+stenting (or sham), with adjunct continuous infusion of Bendavia (0.05 mg/kg IV, 30 min before to 3 hrs after PTRA) or vehicle (n=7 each). Four weeks later, systolic and diastolic function was assessed by multidetector CT and myocardial morphology, inflammation, mitochondrial biogenesis and fibrosis evaluated ex-vivo.

Results: PTRA restored blood pressure to normal levels, yet myocyte cross sectional area remained increased and E/A ratio decreased, while both were normalized in Bendavia-treated pigs (Table). Furthermore, mitochondrial biogenesis was upregulated, and myocardial inflammation and fibrosis normalized in ARAS+PTRA+Bendavia animals (Figure).

Conclusions: Adjunct Bendavia during PTRA prevented myocardial hypertrophy, improved diastolic function, and reversed myocardial inflammation and fibrosis, underscoring the benefits of this strategy for preservation of cardiac function and structure in swine ARVH.

Renal Vein Cytokine Release as an Index of Renal Parenchymal Inflammation in Chronic Experimental Renal Artery Stenosis

Alfonso Eirin, Xin Zhang, Hui Tang, Kyra L. Jordan, Xiang-Yang Zhu, Sandra Herrmann, Amir Lerman, Stephen C. Textor, Lilach O. Lerman. *Mayo Clinic, MN.*

Background: Renal parenchymal inflammation is a critical determinant of kidney injury in renal artery stenosis (RAS), but is difficult to assess in the single kidney without tissue samples. Whether renal vein (RV) levels of inflammatory markers reflect active parenchymal inflammation remains unknown. This study was designed to evaluate the relationship between net RV cytokine release and tissue inflammation in the post-stenotic kidney.

Methods: Pigs were studied after 10 weeks of RAS treated 4 weeks earlier with intra-renal vehicle or anti-inflammatory mesenchymal stem cells (MSC), or normal control. Single-kidney renal blood flow (RBF) was measured by fast CT. RV and inferior vena cava (IVC) levels of tumor necrosis factor (TNF)-α, interferon (IF)-γ, and monocyte chemoattractant protein (MCP-1) were measured by ELISA, and their net release calculated ((RV-IVC)*RBF). Immunostaining of the same inflammatory cytokines was correlated with their net release.

Results: Net release of TNF-α, IF-γ, and MCP-1 was higher in the RAS kidney compared to normal (all p<0.05), and decreased in MSC-treated pigs (Table). Similarly, TNF-α, IF-γ, and MCP-1 immunoreactivity was upregulated in RAS, but ameliorated in pigs treated with MSC (Figure A). Furthermore, net release of TNF-α, IF-γ, and MCP-1 directly correlated with their tissue expression (Figure B-D).

Conclusions: Our findings demonstrate that the net release of inflammatory markers from the affected kidney is a useful index of renal tissue inflammation in experimental RAS. Further studies are needed to establish the clinical value of these measurements.

Bendavia, a Mitochondrial Permeability Transition Pore Inhibitor, Preserves Oxygenation and Renal Blood Flow in Swine Atherosclerotic Renovascular Disease

Alfonso Eirin, Behzad Ebrahimi, Xin Zhang, James Krier, Michael James Korsmo, John A. Crane, Xiang-Yang Zhu, Sandra Herrmann, Amir Lerman, Stephen C. Textor, Lilach O. Lerman. *Mayo Clinic, MN.*

Background: The preservation of renal function in patients with Atherosclerotic Renovascular Disease (ARVD) remains challenging. Bendavia is a peptide drug that inhibits mitochondrial permeability transition pore (MTP) formation and is known to attenuate ischemia reperfusion injury. We hypothesized that chronic treatment with Bendavia would reduce renal fibrosis and dysfunction in ARVD pigs even without revascularization.

Methods: Domestic pigs were studied after 10 weeks of ARVD or sham, treated for the last 4 weeks with daily SC injections (5 d/wk) of Bendavia 0.1mg/kg (or vehicle). Single-kidney volume, perfusion, renal blood flow (RBF), and glomerular filtration rate (GFR) were studied using multi-detector CT, and cortical oxygenation using blood oxygen level-dependent (BOLD) MRI. Renal fibrosis was assessed by trichrome staining.

Results: All ARVD pigs achieved high-grade stenosis and hypertension (Table). Stenotic kidney volume, perfusion, RBF, and GFR decreased in ARAS+Vehicle, associated with cortical hypoxia (manifest as elevated cortical R2*). Daily treatment with Bendavia alone in ARAS pigs was associated with normal cortical R2*, RBF, and GFR, although blood pressure was unaffected.

Conclusions: Daily treatment with Bendavia improved function and cortical oxygenation, and decreased scarring in the stenotic kidney despite sustained renovascular hypertension.These findings support mitochondrial injury in kidney damage in ARVD and underscore a potential role for an MTP inhibitor such as Bendavia to protect the stenotic kidney.

A Novel Regulatory Mechanism of Blood Pressure by Midkine through Epoxyeicosatrienoic Acids (EETs) Yuka Sato, Waichi Sato, Tomoki Kosugi, Hiroshi Kojima, Kayaho Maeda, Shoichi Maruyama, Enyu Imai, Seiichi Matsuo. *Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Aichi, Japan.*

Background: The endothelium regulates vascular tone through the release of a number of vasoactive factors, including endothelin, NO and endothelium-derived hyperpolarizing factor (EDHF). Midkine (MK) is a multi-functional growth factor and affects the progress of ischemic renal injury, diabetic nephropathy and hypertension (HTN). We have previously reported that endothelial MK activated RAS through lung ACE after 5/6 nephrectomy. However, its regulatory mechanism remains unclear. In the present study, we focused on NO and EETs, and investigated the role of MK in HTN and endothelial dysfunction.

Methods: Wild-type mice (WT) and MK-deficient mice (MK-KO) were treated with unilateral nephrectomy and L-NAME, NO synthase inhibitor (UNx+L). They were measured BP and sacrificed on 4 months. We also administered charybdotoxin, K_{Ca} channel blocker, and 14, 15-EEZE, EETs blocker, respectively and recorded BP using radio-telemetry systems. Primary renal endothelial cells were isolated from WT and MK-KO, and evaluated EETs.

Results: In the UNx+L group, BP of WT developed marked HTN, while MK-KO exhibited normotension. Proteinuria and glomerular sclerosis were also attenuated in MK-KO. Urine nitrate/nitrite was decreased to the same extent in both WT and MK-KO with UNx+L. eNOS and cGMP showed no significant differences between WT and MK-KO. Consequently, HTN induced by NOS inhibitor was attenuated in MK-KO, however MK did not regulate NO-cGMP directly. Vasoconstractive factors; RAS and endothelin were also unchanged in MK-KO. We measured another vasodilatory factor; EETs. DHETs, EETs metabolites, were increased in urine and medium of primary endothelial cells of MK-KO compared to WT. The EETs pathway blockage by charybdotoxin or 14, 15-EEZE elevated BP higher in MK-KO than in WT. WT treated with MK antibody also exhibited marked BP elevation after 14, 15-EEZE injection.

Conclusions: MK regulated BP through EETs pathway. EETs have cardiovascular protective properties, and are of interest as therapeutics. MK might have the potential as a novel therapeutic target of HTN and endothelial dysfunction.

Thromboxane Receptors in Smooth Muscle Promote Hypertension, Vascular Remodeling, and Sudden Death Matthew A. Sparks, Natalia A. Makhanova, Thomas M. Coffman. *Division of Nephrology, Duke University, Durham, NC.*

Background: The prostanoid thromboxane (TxA_2) is a potent vasoconstrictor and platelet aggregant that has been implicated in the pathogenesis of cardiovascular diseases including hypertension (HTN). Actions of thromboxane receptors (TP-R) in platelets and the vasculature have both been implicated in cardiovascular pathogenesis. To distinguish the contributions of vascular TP-R in isolation, we generated mice with cell-specific deletion of TP-R in smooth muscle cells (TP-SMKOs) using Cre/Loxp technology.

Methods: To examine the contributions of TP-R in the vasculature, we generated mice with cell-specific deletion from vascular smooth muscle cells (VSMCs). We used the KISM22α-Cre mouse, with Cre recombinase "knocked-in" to the Sm22α gene locus, to excise the conditional Tp receptor allele specifically in smooth muscle.

Results: We crossed the KI*SM22*α-Cre with the mTmG reporter mouse to map Cre expression, documenting Cre in small arterioles in each organ including the kidney. Furthermore, we generated mice homozygous for the conditional *Tp* allele also bearing the KI*SM22*α-Cre allele (TP-SMKOs). mRNA for the TP-R was easily detected in aortae from control mice, but not from TP-SMKOs (P<0.005). Similarly, TP-R mRNA expression in mesenteric arteries, with intact endothelium and adventitia, was decreased by ~80% in TP-SMKOs (P=0.05). In TP-SMKOs, acute responses to the TP agonist U46619 were attenuated by ~60% in both the peripheral and renal circulations (P<0.05), whereas acute responses to AngII were unaffected. Infusion of high-dose U46619 caused circulatory collapse and death in a majority of control mice, but TP-SMKOs were completely protected from U46619-induced sudden death (P<0.05). Baseline BP measured by radiotelemetry were similar in TP-SMKOs (111±1 mmHg) and Controls (114±1 mmHg; P=NS). However, the absence of TP-R in VSMCs caused significant attenuation of AngII-induced HTN (controls: 159±2 mm Hg; TP-SMKO: 145±8 mm Hg, P<0.05) and diminished aortic medial hypertrophy in TP-SMKOs (59±4 μm) vs. Controls (79±7 μm; P<0.05).

Conclusions: Vascular TP-R play a major role in shock, AngII-induced hypertension, and vascular remodeling.

SIRT1 Activation Protects the Endothelial Dysfunction by Inhibiting MCP-1 and ICAM-1 Generation Hideyuki Negoro. *Medicine, Harvard Medical School, Boston, MA.*

Background: SIRT1 is a conserved NAD(+)-dependent deacetylase and possesses beneficial effects against aging-related diseases, but little information is available on a putative role of SIRT1 in endothelial and vascular homeostasis. Endothelial senescence causes endothelial dysfunction to promote atherosclerotic change and contribute to age-related vascular diseases. Cellular adhesion molecules, such as monocyte chemotactic protein-1 (MCP-1) and intracellular adhesion molecule-1 (ICAM-1) play an important part in the progression of age-related vascular diseases.

Methods: We established an in vitro senescence model by prolonged culture of primary endothelial cells isolated from bovine aorta. The freshly isolated young endothelial cells gradually underwent senescence during 1 month of repetitive passages. We knocked down SIRT1 to evaluate the protein levels of LKB1, phosphorylated AMPK, MCP-1 and ICAM-1 in the knocked down cells.

Results: It was observed that protein expressions of SIRT1 were decreased time dependently in the senescent endothelial cells. In contrast, the protein levels of LKB1, a serine/threonine kinase, the phosphorylation of its downstream target AMP-activated protein kinase (AMPK), MCP-1 and ICAM-1 generation were dramatically increased in the senescent cells. On the other hand, resveratrol activated SIRT1 in the endothelial cells. SIRT1 activation with resveratrol inhibited the increase of LKB1, AMPK. At the same time, SIRT1 activation with resveratrol reduced MCP-1 and ICAM-1 generation in the endothelial cells significantly. We knocked down SIRT1 and the protein levels of LKB1, phosphorylated AMPK, MCP-1 and ICAM-1 elevated in the knocked down cells. The protein levels of LKB1, phosphorylated AMPK, MCP-1 and ICAM-1 generation did not changed in the SIRT1 knocked down cells even if they were stimulated with resveratrol.

Conclusions: These findings indicate that activation of SIRT1 provides beneficial effects against the endothelial dysfunction to promote atherogenesis by inhibiting MCP-1 and ICAM-1 generation.

The Increase of Reactive Oxygen Species in Vascular Smooth Muscle Cells Using Juglone Results in Mineralization *In Vitro* Mirjam Schuchardt, Jasmin Pruefer, Markus Tolle, Markus van der Giet. *Med. Klinik mit SP Nephrologie, Charite - Campus Benjamin Franklin, Berlin, Germany.*

Background: Vascular alterations like mineralization of vascular smooth muscle cells (VSMCs) in the media of the vascular wall contributes to the high mortality in patients with chronic kidney disease (CKD). Different factors are known that induce calcification, but the underlying mechanisms are not fully understood so far. CKD patients suffer from an increased level of reactive oxygen species (ROS). The aim of this study was to investigate the influence of an increased ROS level on the mineralization of VSMCs *in vitro*.

Methods: VSMCs from rat aorta were used for this study. Differences in gene expression were measured via real-time PCR. The alkaline phosphatase enzyme activity

were determined photometrically. The extracellular calcium content was quantified using the o-cresolphtalaine method. The superoxide production was measured in dihydroethidium-labeled cells. The quantification of hydrogen peroxide was determined in CM-H_2DCFDA-labeled cells via flow cytometry.

Results: The chinone derivate juglone induces a dose-dependent increase in superoxide and hydrogen peroxide production in VSMCs. Stimulation of VSMCs for 21 days using juglone induces the *in vitro* mineralization detected via an increase in extracellular calcium content and an increase in alkaline phosphatase enzyme activity compared to the control. Furthermore, juglone stimulation increases the mRNA expression of osteogenic proteins like alkaline phosphatase and osteocalcin, as well as the transcription factors core-binding factor alpha-1 and osterix.

Conclusions: A chronic increase in the ROS level results in the mineralization of VSMCs *in vitro*. Therefore, the ROS level may play a central role in the molecular signal transduction pathway of vascular calcification.

p38 MAP Kinase Mediates Aldosterone-Induced Podocyte Injury in Natriuretic Peptide Receptor (GC-A)-Deficient Mice Yukiko Kato,[1] Masashi Mukoyama,[1] Hideki Yokoi,[1] Yoshihisa Ogawa,[1] Kiyoshi Mori,[1] Masato Kasahara,[1] Takashige Kuwabara,[1] Hirotaka Imamaki,[1] Akira Ishii,[1] Kenichi Koga,[1] Keita P. Mori,[1] Ichiro Kishimoto,[2] Akira Sugawara,[1] Kazuwa Nakao.[1] *[1]Department of Medicine and Clinical Sicinece, Kyoto University Graduate School of Medicine; [2]Department of Atherosclerosis and Diabetes, National Cerebral and Cardiovascular Center.*

Background: Aldosterone plays an important role in the pathogenesis of renal injury. Natriuretic peptide receptor/guanylyl cyclase-A (GC-A) signaling exerts renoprotective effects by eliciting natriuresis, reducing blood pressure, and inhibiting fibrosis. We demonstrated that uninephrectomized GC-A knockout (KO) mice with aldosterone and sodium overload exhibited accelerated hypertension with massive proteinuria (Ogawa et al. J Am Soc Nephrol 2012). These mice exhibited enhanced phosphorylation of p38 MAP kinase (MAPK) mainly in podocytes. To explore the interaction between p38 MAPK and GC-A signaling, we examined the effect of p38 MAPK inhibition on renal findings of GC-A KO mice with aldosterone.

Methods: GC-A KO mice or wild-type mice were uninephrectomized and then treated for 4 weeks with high salt diet and aldosterone infused subcutaneously using an osmotic minipump. They were also administered with hydralazine or p38 MAPK inhibitor (FR 167653) by drinking water. We examined BP, urinary albumin excretion, renal histology, and immunohistochemistry for nephrin, podocin and downstream targets of p38 MAPK including CHOP and p53.

Results: Administration of FR remarkably suppressed urinary albumin excretion by 90% in GC-A KO mice ($p < 0.01$). Glomerular hypertrophy, mesangial expansion and interstitial fibrosis were decreased in FR-treated aldosterone-given GC-A KO mice. Immunofluorescent study showed that FR treatment kept high intensity of nephrin and podocin in glomeruli. FR treatment abrogated the phosphorylation of p38 MAPK in podocytes, and greatly reduced glomerular expression of p53 protein.

Conclusions: These results suggest that renoprotective properties of the endogenous natriuretic peptide/GC-A system may result from the local inhibition of aldosterone/p38 MAPK pathway in podocytes, involving p53 singnaling.

Loss of Renal or Systemic Angiotensin Converting Enzyme 2 Contributes to the Hypertensive Response to Chronic Angiotensin II David I. Ortiz Melo, Natalie Mattocks, Thomas M. Coffman, Susan B. Gurley. *Medicine, Durham VA and Duke University Medical Centers, Durham, NC.*

Background: Angiotensin Converting Enzyme 2 (ACE2) is a carboxypeptidase that converts Angiotensin II (AngII) to Ang(1-7). Deletion of the *Ace2* gene in mice induces an exaggerated response to AngII-induced hypertension (HTN) associated with elevated renal AngII levels. We hypothesize that renal ACE2 regulates AngII levels and is therefore responsible for its anti-hypertensive effects. To test this hypothesis, we used renal cross-transplantation strategy to separate the effect of selective ACE2 deficiency within the kidney from ACE2 deficiency in all other tissues.

Methods: We studied male ACE2 knockout (KO) mice and wild-type (WT) littermates on (129/SvEv x C57BL/6)F_1 background. Kidney transplants were performed between genetically matched mice to generate four experimental groups: 1) WT, 2) renal ACE2 KO, 3) systemic ACE2 KO, and 4) global ACE2 KO. All kidney function was provided entirely by the single transplanted kidney. After baseline measurements, mice were infused with AngII (1µg/kg/min) for two weeks while mean arterial blood pressures (MAP) were measured with radiotelemetry.

Results: There were no significant differences in MAP at baseline among groups. Global ACE2 knockout mice had an enhanced hypertensive response to AngII as compared to WT mice (152±6 vs.144±7 mmHg; p=0.03), consistent with our previous report. However, the presence of ACE2 in either the kidney or systemic tissues restored MAPs to levels similar to that of the WT group (renal ACE2 KO 140±7mmHg, $p<0.01$ vs. global ACE2 KO; systemic ACE2 KO 140±5 mmHg, $p<0.01$ vs. global KO). This effect was similar between the renal KO and systemic KO groups.

Conclusions: ACE2 has the potential to regulate cardiovascular responses by metabolizing Ang II, thereby acting as a brake on the RAS. Global ACE2 deficiency leads to an exaggerated hypertensive response to chronic AngII administration. Our kidney transplant studies now show that restoration of ACE2 in either the kidney or in extra-renal tissues is sufficient to abrogate this enhanced hypertensive response. Our data suggest equivalent effects of both renal and extra-renal ACE2 in hypertension.

Liver-, but Not Kidney-Specific Angiotensinogen Gene Knockout Abrogates the Enhancement of Renal Angiotensin II Synthesis that Follows Podocyte Injury in Progressive Glomerulosclerosis Taiji Matsusaka,[1] Fumio Niimura,[1] Masafumi Fukagawa,[1] Akira Nishiyama,[2] Iekuni Ichikawa.[1,3] *[1]Tokai University, Japan; [2]Kagawa University, Japan; [3]Vanderbilt University.*

Background: Intrarenal angiotensin (A)II is increased in a variety of kidney diseases independently of plasma AII, and thought to act detrimentally on the renal architecture. The NEP25 mouse model allows induction of podocyte-specific injury leading to progressive glomerulosclerosis. Using this model, we have recently demonstrated that podocyte injury leads to a marked increase in renal angiotensinogen (Agt) and AII content (JASN 2012), suggesting that the integrity of the barrier function of podocytes is critically important to prevent augmentation of renal AII synthesis. Subsequently, we also found that podocyte injury concurrently enhances transcription of renal Agt.

Methods: To verify that renal AII is indeed originated to the liver/circulating Agt in glomerular diseases, we analyzed NEP25 mice in which liver or kidney *Agt* is selectively knocked out (KO).

Results: Western analysis and immunohistochemistry revealed that renal Agt protein was markedly increased in NEP25 and similarly in Kidney Agt KO/NEP25 mice 8 days after podocyte injury. By contrast, in Liver Agt KO/NEP25 mice, the level of renal Agt was undetectably low both before and after podocyte injury. In parallel, renal AII, measured by RIA, was markedly increased in NEP mice (750±87 (n=7) vs. 134±21 (n=10) fmol/g tissue). Liver KO, but not kidney KO, reduced the level of renal AII measured after podocyte injury (103±8.2 (n=10)($p<0.001$) and 746±128 (n=10), respectively). Renal AII had no relationship with renal Agt mRNA, which was low in Kidney Agt KO, or with renal renin activity, which was elevated in Liver Agt KO. Moreover, edema was significantly attenuated in Liver Agt KO/NEP25, but not Kidney Agt KO/NEP25. Kidney and Liver dual Agt KO (n=12) showed phenotypes similar to those of Liver Agt KO mice.

Conclusions: The results establish that the detrimental increase in renal AII synthesis in glomerular diseases that follows podocyte injury results from increased filtered Agt of liver origin, not from increased transcription of renal Agt.

TH-PO839

Angiotesin II Regulation of Blood Pressure via Modulation of DPPIV Activity and Sodium Hydrogen Exchange (NHE3) in the Renal Proximal Tubules Vinayak Ramanath, James R. Sowers, Adam Whaley-Connell, Ravi Nistala. *Nephrology, University of Missouri-Columbia, Columbia, MO.*

Background: Sodium homeostasis and blood pressure regulation is modulated by the effector peptide (angiotensin II, Ang II) for renin angiotensin system (RAS) via activation of Na^+/H^+ exchanger-3 (NHE3) in the kidney proximal tubule (PT). Excessive sodium retention and activation of RAS in obesity and diabetes is thought to contribute to hypertension. Recently, the role of nutrient sensor mTOR/S6K1 (mTORC1) has been implicated in hyperfiltration seen in early diabetes. Similarly, obesity is characterized by increased mTORC1 signaling and NHE3 activity. In addition, the incretin Glucagon-Like Peptide-1 (GLP-1) or exendin-4 has been shown to decrease NHE3 activity, increase sodium excretion and ameliorate hypertension. However, it is unknown how Akt-mTORC1 interacts with DPPIV enzyme and if nephron hypertrophy is related to NHE3 activity. Therefore, we hypothesized that DPPIV inhibition may suppress Ang II-mediated activation of mTORC1 and NHE3 activity.

Methods: Opossum PT cells stably expressing rat Ang-II Type-1 receptor (AT1R) were stimulated with Ang II (100nM) and pre-treated for 60min, with either MK-0626 (5uM) or olmesartan (1uM). Western blots, IHC and enzyme inhibitor assays were used. Mice fed high sucrose-high fat diet (DIO) for 16 wks were analyzed for BP, proteinuria, NHE3/DPPIV activity and mTORC1 activation.

Results: Ang II stimulation of PTCs for 10min, activated mTORC1 and ERK1/2 as demonstrated by increased P-S473-Akt, P-S2448-mTOR, P-T389-S6K1 and P-T202/204-ERK respectively. Ang II increased NHE3 activity and decreased megalin protein and endocytosis. Olmesartan completely blocks Ang II activation of mTORC1 and ERK while MK-0626 inhibition was partial. MK-0626 also improved megalin-mediated albumin endocytosis. In addition, MK-0626 abrogated Ang II-mediated activation of DPPIV in the PTCs. DPPIV binds to GLP1R, NHE3, megalin and PI3-K/Akt pathway components possibly via PH domains and adaptor proteins.

Conclusions: These results suggest that NHE3 regulation, renal hypertrophy and proteinuria by Ang II may be via activation of DPPIV in the brush border of PTCs.

TH-PO840

Angiotensin-Stimulated Nitric Oxide and Superoxide Are in Different Compartments in the Thick Ascending Limb Jagannath H. Saikumar,[1] Katherine J. Massey,[2] Mark D. Faber,[1] Jerry Yee,[1] Jeffrey L. Garvin.[2] *[1]Nephrology, Henry Ford Hospital, Detroit, MI; [2]Hypertension and Vascular Research, Henry Ford Hospital, Detroit, MI.*

Background: Angiotensin (Ang II) stimulates both nitric oxide (NO) and superoxide (O_2^-) in the thick ascending limb (TAL). In this segment, Ang II stimulates NO production by activating NOS3 via the AT_2 receptor while Ang II induced O_2^- production is via the AT_1 receptor. Luminal flow-induced NO inhibits flow-mediated O_2^- in the TAL via a cGMP/PKG dependent pathway. Therefore, we hypothesized that Ang II-stimulated NO inhibits Ang II induced O_2^- in the TAL.

Methods: To address this hypothesis, we measured the ability of Ang II to stimulate NO production in the presence and absence of a O_2^- scavenger and O_2^- in the presence and absence of L-arginine, the substrate for NO, and L-NAME, a NOS inhibitor. NO production was measured by fluorescence microscopy in isolated TALs and O_2^- production was measured using the lucigenin assay.

Results: Ang II dose-dependently increased NO production in TALs across the physiological range of 1pM to 1nM by 59±8% ($p<0.03$), 79±49% ($p=0.15$), 129±32% ($p<0.05$) and 91±20% ($p<0.001$). O_2^- production was stimulated by 49% over baseline when the TALs were exposed to Ang II at 1nM (589±88 vs. 875±121 AU/mg/sec, $p<0.05$). NO production was not different when Ang II was used to stimulate the TAL in the presence of the O_2^- scavenger, tempol. When TALs were stimulated with 1nM Ang II in the presence of L-arginine, no difference was seen in O_2^- production (764±97 vs. 779±74 AU/mg/sec). L-NAME reduced O_2^- production from 633±114 to 360±49 AU/mg/sec. L-arginine in the presence of L-NAME did not affect O_2^- production (651±139 vs. 594±71 AU/mg/sec).

Conclusions: These data suggest that Ang II-stimulated NO and Ang II-induced O_2^- do not interact with each other and are likely in different compartments of the TAL epithelial cell. Also Ang II likely causes NOS uncoupling.

Decreased Blood Pressure in Tamm-Horsfall Protein Deficient Mice during Chronic Salt Loading James M. Bates, Hajamohideen S. Raffi, Satish Kumar. *Medicine/Nephrology, University of Oklahoma Health Sciences Center, Oklahoma City, OK.*

Background: The Tamm-Horsfall Protein (THP) deficient mouse ($THP^{-/-}$) displays a reduced ability to concentrate urine. The activity of the Na^+, K^+ $2\,Cl^-$ cotransporter (NKCC2) is reduced in the $THP^{-/-}$ mouse. Recent genome wide association studies have shown that a single nucleotide polymorphism in the promoter region of the THP gene is correlated with blood pressure. In this study, we compared the effect of chronic dietary salt loading between $THP^{-/-}$ mice and wild-type ($THP^{+/+}$) mice, on blood pressure, urine volume, food consumption, water consumption, urine sodium and urinary THP.

Methods: Six each of $THP^{-/-}$ and $THP^{+/+}$ mice were fed a high salt diet (8 % NaCl) for 5 months. On day 5, 40 and 140, systolic and diastolic blood pressure (BP), pulse, body weight, urine volume, and water and food intake were measured. Twenty four hour urine samples were collected and analyzed for sodium, THP and creatinine. The data were analyzed with Student's t test and linear regression.

Results: Systolic and diastolic BP and pulse were lower in the $THP^{-/-}$ mice on day 140 (mean systolic BP ± SE, $THP^{+/+}$ 122 ± 2 mm Hg vs $THP^{-/-}$ 114 mm Hg ± 3, $p = 0.03$; mean diastolic BP $THP^{+/+}$ 86 ± 3 mm Hg vs $THP^{-/-}$ 75 mm Hg ± 4, $p = 0.005$; mean pulse $THP^{+/+}$ 595 ± 7 mm Hg vs $THP^{-/-}$ 627 mm Hg ± 10, $p = 0.007$). Urine volume and water consumption were lower in the $THP^{-/-}$ mice on day 5 (mean urine volume ± SE, $THP^{+/+}$ 10.7 ± 1.5 ml vs $THP^{-/-}$ 6.7 ± 1.2 ml, $p = 0.032$; mean water consumption ± SE, $THP^{+/+}$ 19.1 ± 1.9 ml vs $THP^{-/-}$ 14.0 ± 1.7 ml, $p = 0.037$) and day 140 (mean urine volume ± SE, $THP^{+/+}$ 14.8 ± 1.8 ml vs $THP^{-/-}$ 9.9 ± 1.7 ml, $p = 0.04$; mean water consumption ± SE, $THP^{+/+}$ 21.9 ± 2.5 ml vs $THP^{-/-}$ 15.7 ± 2.3 ml, $p = 0.047$). Twenty four hour urinary excretion of sodium was not different between the two groups on day 5 and day 40. Urinary THP excretion (measured on day 40) was positively correlated with excretion of urinary sodium ($R^2 = 0.92$).

Conclusions: We conclude that THP plays a role in renal sodium handling and impacts systemic blood pressure.

TH-PO842

Differential Regulation of Ste20/SPS1-Related Proline/Alanine-Rich Kinase (SPAK), Na-Cl Cotransporter (NCC), and Na-K-2Cl Cotransporter (NKCC) in the Cortex versus Medulla in Angiotensin II (AngII)-Infused Rats Mien T.X. Nguyen, Donna Lee, Alicia A. McDonough. *Cell and Neurobiology, USC Keck School of Medicine, Los Angeles, CA.*

Background: SPAK colocalizes with and phosphorylates NKCC and NCC in the TAL and DCT, respectively. We aimed to determine whether SPAK differentially regulates NKCC and NCC in the cortex vs. medulla in AngII-dependent hypertension.

Methods: Male Sprague-Dawley rats were infused with AngII (400 ng/kg/min) via osmotic minipumps. Kidney cortex and medulla were separated, homogenized and subjected to immunoblotting.

Results: AngII-infused rats developed hypertension after 2 wks: increased mean arterial pressure (161.97 ± 7.09 vs. control 115.23 ± 4.75 mmHg, $p<0.05$), increased heart weight (0.35 ± 0.01 vs. control 0.26 ± 0.004 g/100 g BW, $p<0.05$), and increased overnight urinary Na excretion (2.52 ± 0.18 vs. control 1.50 ± 0.14 mmol, $p<0.05$). Immunoblot density values in AngII-infused rats were normalized to those in control, defined as 1.00 ± SEM (*$p<0.05$).

	Control (n=8)	AngII-infused (n=8)
Cortex		
NKCC	1.00 ± 0.06	1.58 ± 0.23 *
NKCC-P	1.00 ± 0.05	2.14 ± 0.31 *
NCC	1.00 ± 0.05	2.17 ± 0.24 *
NCCpS71	1.00 ± 0.14	3.28 ± 0.53 *
SPAK	1.00 ± 0.08	2.27 ± 0.42 *
Medulla		
NKCC	1.00 ± 0.07	0.55 ± 0.06 *
NKCC-P	1.00 ± 0.15	1.47 ± 0.37
SPAK	1.00 ± 0.04	0.79 ± 0.04 *

Conclusions: AngII infusion significantly increased SPAK abundance, NCC and NKCC total abundance and phosphorylation in the cortex while decreasing SPAK and NKCC total abundance in the medulla. This suggests more Na reabsorption in the distal nephron and less in the loop of Henle, contributing to hypertension in this model.

TH-PO843

Regulation of NKCC1 by AMP-Activated Protein Kinase (AMPK) Matthew R.P. Davies,[1,2] Scott Andrew Fraser,[3] Marina Katerelos,[3] Kurt Gleich,[3] Peter F. Mount,[1,2] David A. Power.[1,2,3] *[1]Department of Nephrology, Austin Health, Melbourne, VIC, Australia; [2]Department of Medicine, Austin Health, Melbourne, VIC, Australia; [3]Institute for Breathing and Sleep, Austin Health, Melbourne, VIC, Australia.*

Background: The Sodium-Potassium-Chloride cotransporter NKCC1 plays a significant role in regulating blood pressure via modulation of vascular tone. Phosphorylation at regulatory sites (including Thr203, Thr207,Thr212 & Thr 217) increases NKCC1 activity and is a major mechanism through which the cotransporter is regulated. The energy-sensitive kinase AMPK plays a key role in cellular metabolism. Activators of AMPK produce vasorelaxation and a fall in blood pressure, the mechanisms of which are largely undetermined. AMPK has previously been shown to regulate the function of NKCC2 in the kidney. We sought to determine if AMPK also regulates the function of NKCC1.

Methods: We studied the effects of stimulating AMPK on the function of NKCC1 in MDCK cells using bumetanide-sensitive $Rb86^+$-flux. Phosphorylation of NKCC1 was analysed with Western Blotting using R5 antibody (recognises phosphorylated Thr212 & Thr217). The effect of AMPK on expression of NKCC1 was compared using transfection of Cos cells. Membrane localisation of NKCC1 was determined by immunofluorescence with confocal microscopy and surface biotinylation.

Results: Stimulation of AMPK in MDCK cells with A769662 resulted in a dramatic reduction of bumetanide-sensitive $Rb86^+$-flux ($p<0.001$) and reduced phosphorylation of NKCC1 detected with R5 antibody ($p<0.005$). Surprisingly, co-transfection of AMPK with NKCC1 resulted in enhanced expression of NKCC1. However, active but not kinase-dead AMPK led to a reduction in membrane localisation of NKCC1 despite increased expression.

Conclusions: This data suggests that activation of AMPK leads to dephosphorylation of NKCC1 at key regulatory sites, possibly by recruitment of a phosphatase, so reducing its membrane localisation and co-transporter activity. Binding of AMPK appears to provide structural stability to NKCC1, indicating the importance of AMPK in its function. The data helps explain the blood pressure lowering effects of AMPK activators and provides a potential link between metabolic disease and hypertension.

TH-PO844

Acute Adrenergic Stimulation Activates the Renal Sodium Chloride Cotransporter Andrew Terker, Chao-Ling Yang, James A. McCormick, David H. Ellison. *Division of Nephrology and Hypertension, Oregon Health and Science University, Portland, OR.*

Background: The sodium chloride cotransporter (NCC) in the distal nephron is a key regulator of sodium reabsorption and blood pressure homeostasis. The kinase SPAK activates NCC. It has been shown that adrenergic stimulation causes salt-sensitive hypertension and upregulates NCC, but a detailed molecular mechanism and the timing of this pathway remain unclear.

Methods: Blood pressure (BP) was measured by tail-cuff. **Chronic adrenergic stimulation**:Baseline BP was measured for 1 week. Vehicle (V) or norepinephrine (NE, 2.5 mg/kg/d) infusion was administered by osmotic minipump for weeks 2 and 3. Diet was 0.49% NaCl during weeks 1 and 2 and 8% NaCl during week 3. **Acute adrenergic stimulation**: Mice were injected IP with V, NE (750 ug/kg), phenylephrine (750 ug/kg), or isoproterenol (750 ug/kg) as indicated. Kidneys were harvested 30 min later for Western blot. **Western blots** were performed on whole kidney lysate. **Immunofluorescence** was performed on kidneys that were fixed 30 min post-treatment.

Results: Chronic norepinephrine infusion has been shown to stimulate NCC and cause salt-sensitive (SS) hypertension in mice. As this finding was controversial, we first reproduced this observation. During chronic norepinephrine (NE) infusion, blood pressure increases were shown to be SS and both total (tNCC) and phosphorylated NCC (pNCC, a marker of activation) were increased 50-100%. Given this finding, we hypothesized that adrenergic stimulation activates NCC acutely. Kidneys from mice acutely treated with NE showed 300% increases in pNCC with no changes in tNCC. This experiment was then repeated using α- and β-adrenergic specific agonists and both stimulated pNCC. Lastly, SPAK KO mice were given acute injections of NE. These mice also experienced increases in pNCC with no changes in tNCC. Results were demonstrated by Western blot and immunofluorescence.

Conclusions: Chronic adrenergic stimulation causes salt-sensitive hypertension in the mouse. While changes in blood pressure are seen after several days of adrenergic stimulation, NCC is upregulated within minutes This mechanism is mediated by both α- and β-adrenergic receptors and is SPAK-independent.

TH-PO845

The Kidney Cyp2c44 Epoxygenase Regulates Distal Sodium Excretion and the Blood Pressure Response to Increased Dietary Salt Jorge H. Capdevila,[1] John D. Imig,[2] WenHui Wang.[3] *[1]Medicine, Vanderbilt University Medical School, Nashville, TN; [2]Pharmacology, Medical College of Wisconsin, Milwaukee, WI; [3]Pharmacology, New York Medical College, Valhalla, NY.*

Background: Roles for the mouse Cyp2c44 and rat CYP2C23 arachidonic acid (AA) epoxygenases in blood pressure regulation were suggested by reports that: a) their kidney expression was dietary salt sensitive, b) CYP2C23 inhibition caused salt sensitive hypertension, and c) their 11,12- and 14,15-epoxyeicosatrienoic acid (EET) metabolites inhibited the kidney epithelial sodium channel (ENaC).

Methods: To define roles for the Cyp2c44 epoxygenase in kidney physiology and blood pressure control, we develop a line of mice carrying a disrupted *Cyp2c44* gene, and used polarized collecting duct (CD) cells for mechanistic studies of EET effects on transcellular sodium transport.

Results: Mice lacking a functional Cyp2c44 epoxygenase develop dietary salt sensitive hypertension, a common form of the human disease. Thus, *Cyp2c44(-/-)*(KO) mice are normotensive and become hypertensive when fed high salt diets (systolic pressures: 124± 8 and 168 ±18 mm Hg, respectively). Compared to salt loaded WTs, hypertensive KO mice show a hyperactive ENaC and Amiloride, an ENaC inhibitor, normalizes the pressures of hypertensive KO mice. Moreover, KO mice on high salt fail to induce AA epoxidation, and their urinary output, body weights and free fluid volumes are higher than those of salt loaded WT controls (by approximately 27; 3.7; and 30%; respectively). Studies in polarized M1 cells show that 14,15-EET inhibits amiloride-sensitive transcellular sodium transport by increasing an ERK1/2-catalyzed phosphorylation of the ENaC beta and gamma subunits.

Conclusions: These studies: a) identify an anti-hypertensive role for the Cyp2c44 epoxygenase as an endogenous regulator of distal sodium re-absorption, and b) point to a mechanism that involves a Cyp2c44/EET-controlled, ERK1/2 catalyzed, phosphorylation of ENaC subunits. It is expected that these studies could serve as a basis for future efforts to develop novel strategies for the early diagnosis and treatment of hypertension.

TH-PO846

Regulation of Water and Sodium Balance in Erythropoietin-Induced Hypertension Jeonghwan Lee,[1] Nam Ju Heo,[2] Sejoong Kim,[3] Kwon Wook Joo,[1] Jin Suk Han.[1] *[1]Internal Medicine, Seoul National University Hospital, Seoul, Korea; [2]Healthcare System Gangnam Center, Seoul National University Hospital, Seoul, Korea; [3]Internal Medicine, Seoul National University Bundang Hospital, Seoul, Korea.*

Background: The present study was designed to investigate the regulation of sodium and water homeostasis in erythropoietin (EPO)-induced hypertension.

Methods: Renal failure was induced by a two-stage 5/6 nephrectomy. Uremic rats were divided into two groups and received vehicle and EPO (150 U/kg, intraperitoneal injection, two times per week) for 4 weeks.

Results: Serum creatinine, hematocrit, body weight, and systolic blood pressure (BP) were similar in both groups of uremic rats before treatment. After 1 week of treatment, hematocrit increased significantly in the EPO group (50.9±1.2% vs. 43.8±1.6%, *P*=0.002). Systolic BP was significantly higher in the EPO group than the control (155.5±8.8 mmHg vs. 140.0±6.7 mmHg, *P*=0.007). Although intake of diet and water were almost same, urine output (13.7±2.0 ml/d vs. 18.2±4.7 ml/d, *P*=0.034) and urinary excretion of sodium (0.77±0.10 mmol/d vs. 0.90±0.06 mmol/d, *P*=0.018) decreased significantly in the EPO group. After 4 week of treatment, increased systolic BP was sustained (159.5±8.7 mmHg vs. 146.6±6.2 mmHg, *P*=0.007). Urine output (17.1±4.2 ml/d vs. 21.2±5.4 ml/d, *P*=0.141) and urinary excretion of sodium (0.70±0.10 mmol/d vs. 0.79±0.09 mmol/d, *P*=0.142) decreased in the EPO group, but the statistical significance were insufficient. The renal abundances of ENaC α, γ, and NHE3 significantly decreased (56.1±16.0%, 49.4±25.6%, and 38.6±24.8% of the control, *P*=0.011, 0.026, and 0.007, respectively) in the EPO group. Other apical sodium transporters did not change in abundance. Aquaporin-2 significantly increased in the EPO group (116.7±9.0% of the control, *P*=0.002). Renal endothelin levels seemed to be higher in the EPO group (56.1±26.2 pg/ml vs. 50.1±27.9 pg/ml), but the difference was not significant (*P*=0.8048). Plasma renin and serum aldosterone levels were not different between groups.

Conclusions: EPO induces sodium and water retention, which can contribute the EPO-induced hypertension in uremic remnant kidney model.

TH-PO847

Role of Bradykinins in Renal Development of Diabetic Complications Syed J. Khundmiri,[1] Michael Merchant,[1] Jon B. Klein.[1,2] *[1]Medicine-Nephrology, University of Louisville, Louisville, KY; [2]Robley Rex VAMC, Department of Veterans Affairs, Louisville, KY.*

Background: A role for kinins in the development and progression of diabetic nephropathy (DN) remains controversial. Largely research has focused on bradykinin (BK) and des-Arg(9)-BK (DABK) and their signaling through constitutive (BK2R) or inducible (BK1R) receptors. Recent plasma peptidomic studies of type-1 DN patients with microalbuminuria indicated a correlation between BK, DABK and related prolyl-hydroxylated kinins and the onset of early progressive renal function decline. We hypothesized these kinins play a role in the development of the early diabetic nephropathy phenotype. To address this hypothesis we measured the glucose modified kinin-mediated regulation Na-K ATPase (Na-K) activity in renal tubular cells lines.

Methods: Immortalized canine distal tubular (MDCK), human or mouse proximal tubule (HKC11 and MPTEC) cell lines were cultured in normal glucose (NG), high glucose (HG), or NG plus osmotic control culture conditions and the effects of kinin peptides on ouabain sensitive Na-K activity was measured. Receptor specificity for kinin regulation of Na-K activity was characterized using BK2R and BK1R specific antagonists.

Results: As expected in NG conditions BK increased ($p<0.05$) Na-K activity by 25% through BK2R. Unexpectedly, hydroxyprolyl-3-BK (BK3) decreased ($p<0.05$) Na-K activity by 40% in NG conditions through BK1R in MDCK, HKC11 and MPTEC cell lines. In HG conditions, both BK (49%) and BK3 (76%) increased ($p<0.05$) Na-K activity via BK1R. The novel BK variant, bis-3,7-hydroxyprolyl-BK (BK3,7) decreased ($p<0.05$) Na-K activity by 20% in all culture conditions through BK2R signaling.

Conclusions: These results suggest BK signaling in renal tubular cells is affected by both kinin post-translational modification and by hyperglycemia. HG shifts BK signaling from BK2R to BK1R, BK continues to inhibit natriuresis. While HG does not shift BK3 signaling away from BK1R, HG shifts BK3 from natriuresis toward sodium retention. These data suggest a pathophysiologic role of modified kinins in the dysregulation of Na+ transport in periods of uncontrolled hyperglycemia such as occur during poorly controlled diabetes.

TH-PO848

Characteristic Expressions of GABA Receptors and GABA Producing/ Transporting Molecules in Rat Kidney Kozue Takano,[1] Junichi Yatabe,[1,3] Midori Sasaki Yatabe,[1] Hironobu Sanada,[2] Tsuyoshi Watanabe,[3] Junko Kimura.[1] *[1]Pharmacol., Fukushima Med. Univ., Fukushima, Japan; [2]Health Science Res., Fukushima Welfare Federation of Agricultural Cooperatives, Fukushima, Japan; [3]Nephrol., Hypertens., Diabetol., Endo. and Metab., Fukushima Med. Univ., Fukushima, Japan.*

Background: γ-Aminobutyric acid (GABA) production and signaling have been found in peripheral non-neural tissues. Administration of GABA induces natriuresis and lowers blood pressure, which suggests renal GABA targets. However, precise compositions of GABA receptors and other GABA-related molecules in the kidney have not been elucidated.

Methods: Messenger RNAs of 16 GABA(A) receptor subunits, two GABA(B) receptor subtypes, three GABA(C) receptor subunits, two GABA producing enzyme (glutamate decarboxylase; GAD) subtypes, three GABA transporter (GAT) subtypes, and GABA degrading enzyme (4-aminobutyrate aminotransferase; ABAT) were examined by RT-PCR in the kidney cortex of Wistar-Kyoto rats (WKY) and spontaneously hypertensive rats (SHR). Quantitative PCR, western blot and immunohistochemistry for GABA(A) α1, β3 and π subunits were also performed.

Results: WKY kidney cortex expressed GABA(A) receptor subunits α1, β3, δ, ε and π, whereas α2, α3, α4, α5, α6, β1, β2, γ1, γ2, γ3 and θ were not detectable. Both types of GABA(B) receptor, R1 and R2, and GABA(C) receptor ρ1 and ρ2 subunit mRNAs were also found, but not ρ3. Kidney cortex showed expressions of GAD65, GAD67, ABAT and peripheral-type GABA transporter, GAT2, but not GAT1 or GAT3. As this is the first report of π subunit in the kidney, western blot and immunohistochemistry were also performed to confirm the protein expression of GABA(A) receptor π subunit in addition to α1 and β3 subunits. Renal cortical levels of α1 and β3 subunits were not different between WKY and SHR. However, GABA(A) receptor π subunit expression was significantly less in SHR, which may be involved in the pathophysiology of hypertension.

Conclusions: A unique set of GABA receptor subunits and subtypes were found in rat kidney cortex. As GABA producing enzymes, transporters and degrading enzyme are also expressed, we suggest a possible existence of local renal GABAergic system with an autocrine/paracrine mechanism.

TH-PO849

Renalase Metabolizes Catecholamines Using a Mechanism Distinct from that of Monoamine Oxidase A and B Gary V. Desir, Heino Velazquez. *Med, Yale Sch Med, VACHS.*

Background: Renalase, a flavoprotein secreted from kidney and heart, uses NADH to metabolize catecholamines via a superoxide (O_2^-) dependent mechanism. Its crystal structure was recently solved, and it confirmed its flavoprotein nature, and its ability to bind NADH. However, the mechanism mediating its enzymatic function, and the identity of the metabolites generated are not well understood. Recombinant renalase decreases plasma epinephrine (EPI), L-DOPA and dopamine (DA), measured 24 hours post injection, by 82, 63 and 31% respectively. However, the urinary excretion of the deaminated (DOPAC), methylated (3-MT) and deaminated plus methylated (HVA) metabolites does

not change, suggesting that renalase's action on catecholamines differs significantly from that of catechol-O-methyl-transferase (COMT) and monoamine oxidase (MAO) A and B.

Methods: Given that O_2^- formation is critical for the action of renalase on catecholamines, we hypothesized that the enzyme generates adrenochrome, dopachrome and noradrenochrome from the oxidation of EPI, DA and norepinephrine (NE) respectively. These metabolites have an absorption maximum at 480 nm, and their rate of formation were studied by spectrophotometry.

Results: *In vitro* studies using steady state kinetics analysis indicate that, in the presence of NADH, renalase catalyzes the formation of adrenochrome from EPI (kcat=33.33 min^{-1}, Km=822.52 μM). The oxidation rates for DA, NE and L-DOPA are ~10 fold slower than that for EPI. Renalase does not require the presence of NADH to metabolize EPI, L-DOPA, DA, and NE. The reaction can proceed as shown in equations 1 and 2, but the overall reaction rate is ~ 6 fold slower than in the presence of NADH (EPI: kcat= 5.68 vs 33.33 min^{-1}).

FAD_{ox} + EPI → EPI_{ox} + FAD_{red} Eq 1

FAD_{red} + O_2 → FAD_{ox} + O_2^- Eq 2

FAD_{ox}, oxidized FAD; FAD_{red}, reduced FAD; O_2, oxygen; O_2^-, superoxide anion; EPI, epinephrine; EPI_{ox}, adrenochrome.

Conclusions: In summary, renalase metabolizes catecholamines (EPI>>L-DOPA>DA=NE) by a mechanism distinct from than of MAO-A and MAO-B, and does not have an absolute requirement of NADH as a cofactor. These findings should help achieve a full understanding of renalase's physiological and pathophysiological roles.

TH-PO850

Kidney Restricted, siRNA-Mediated Gene Silencing: A Novel Subcapsular Approach Laureano D. Asico, Van Anthony M. Villar, Crisanto Escano, Yu Yang, Santiago Cuevas, Jun B. Feranil, Ines Armando, Pedro A. Jose. *Medicine, University of Maryland-School of Medicine, Baltimore, MD.*

Background: Essential hypertension represents a set of genetic dysfunctions that involve several organ systems, including the kidney. Elucidating the mechanistic underpinnings of hypertension was facilitated by the availability of knockout mouse models that allow the functional analysis of specific genes on the regulation of blood pressure (BP) and ion transport. Recently, innovations on knockout mouse models, e.g., conditional knockouts, allow the reversible silencing of genes in specific tissues; however, this technology is tedious, costly and not always successful.

Methods: As an alternative, we tested the feasibility and efficiency of using gene-specific siRNA infused into the subcapsular space of the kidney of previously uninephrectomized and acclimated mice to evaluate renal mechanisms involved in hypertension.

Results: A 7-day siRNA infusion—which ensured optimum gene silencing—did not result in gross or histological changes in the renal parenchyma or spill over into other organ systems. We tested several siRNAs (vs. *DJ-1*, and *PON2*, whose absence should increase BP) which resulted in about 55% decrease in gene expression and an increase in systolic BP (DSBP=34±4 and 41±5 mm Hg, n=4), but not when non-silencing siRNA was infused. Conversely, infusion of siRNA against a gene (e.g., *USP48*) whose absence should decrease BP effectively decreased the SBP (DSBP=-21±2 mm Hg, n=4). We also compared the effect of unilateral infusion of *DRD2*-specific siRNA in mice with both kidneys intact; *DRD2* encodes for the dopamine D2 receptor (D_2R) whose absence results in hypertension. The BP was unchanged after a 7-day infusion (n=7), but increased after 28 days (DSBP=26±2 mm Hg, n=5), suggesting that the contralateral, non-infused kidney could initially compensate for the D_2R loss but not for long-term. The D_2R expression was unchanged in the non-infused kidney, regardless of the duration.

Conclusions: Our novel subcapsular siRNA infusion offers the advantage of restricted gene silencing in one kidney only and precludes unforeseen compensatory mechanisms that may develop in classical knockout models.

Morphological Evidence for Afferent Reinnervation after Renal Denervation in Rats Tilmann Ditting,[1] Christian Fiedler,[1] Wolfgang Freisinger,[1] Kirsten Siegel,[1] Sonja Heinlein,[1] Winfried Neuhuber,[2] Stephanie T. Schmidt,[1] Christian Ott,[1] Roland E. Schmieder,[1] Kerstin U. Amann,[3] Roland Veelken.[1] *[1]Med 4, Nephrology & Hypertension, Friedrich-Alexander Universtiy Erlangen, Erlangen, Germany; [2]Dept. of Anatomy, Friedrich-Alexander Universtiy Erlangen, Erlangen, Germany; [3]Friedrich-Alexander Universtiy Erlangen, Erlangen, Germany.*

Background: Renal denervation is a new treatment for refractory arterial hypertension. Howerever, the underlying mechanisms are not completely clear: Efferent sympathetic renal nerves play a key role in salt retention and renin release, but the role of the afferent nerves is not clearly defined, although evidence exists for sympathoinhibitory action. It is accepted that there is some re-innervation of efferent sympathetic nerves after the denervation, but re-innervation of afferent nerves is doubted. We wanted to test the hypothesis that besides renal sympathetic reinnervation a considerable afferent renal reinnervation occurs after renal denervation in rats.

Methods: 50μm kidney slices from 12 male SD rats were stained for thyrosin hydroxylase (TH), calctonine gene related peptide (CGRP) and smooth muscle actin (SMA). Kidneys were examined at 1, 4 and 12 weeks after left sided surgical renal denervation. The right kidney served as control. Image stacks were generated with a confocal laser scanning microscope. Analysis of nerve density was done visually by 4 blinded investigators in 183 image stacks. Staining for TH (i.e. efferent) and CGRP (i.e. afferent) was scored (0-3). Fiji Image J software was used.

Results: At week 1 both efferent (TH+) and afferent (CGRP+) fiber density was reduced (right 2.43±0.10 vs. left 1.47±0.11 [TH+]; right 1.96±0.17 vs. left 0.86±0.12 [CGRP+]; *P<0.001, each*). After 4 weeks an increase in nerve densities were detected, which increased until week 12 (right 2.67±0.07 vs. left 3.35±0.12 [TH+], *P<0.03*; right 2.06±0.16 vs. left 1.82±0.17 [CGRP+], *P=ns*).

Conclusions: Our study shows that there is not only a relevant sympathetic re-innervation but also afferent re-innervation. The afferent re-innervation process even seems to be more complete. Further studies have to be performed to prove the functional relevance of our findings.

TH-PO852

Defective Dopamine D1 Receptor Function and Na^+, K^+-ATPase Phosphorylation in Ovariectomized Adult Wistar Rats during Salt Loading Luis Di Ciano,[1] Pablo J. Azurmendi,[1] Elisabet Monica Oddo,[1] Gloria Levin,[2] Jorge Toledo,[1] Veronica De Luca Sarobe,[1] Elvira Arrizurieta,[1] Fernando Raul Ibarra.[1] *[1]Lab de Riñón Experimental, Instituto de Investigaciones Médicas A Lanari, UBA, Buenos Aires, Argentina; [2]Hospital de Niños R Gutierrez, CEDIE-CONICET.*

Background: We showed that ovariectomized (oVx) Wistar rats consuming high sodium (HS) had both a less phosphorylated Na+, K+-ATPase (NKA) and a reduced natriuresis resulting in Na^+ sensitive hypertension (ASN 2011). Being NKA phospho-state regulated by dopamine (DA) via D1 receptor mediated mechanism, we test whether NKA and renal DA may be involved in the hypertensive response to salt load.

Methods: Rats oVx at 60 days old and intact female (IF) were studied at 150 days of life consuming the last 5 days normal (NS) or HS diet (1% NaCl in drinking water). Afterwords, rats received D1R antagonist (SCH 23390, 1 mg/kg bwt/d sc), DA infusion (1 μg/kg bwt/min) or vehicle. Mean blood pressure (MBP), urinary volume (V), Na^+ excretion (UNa^+*V) and DA (uDA) were measured. Expression of D1R, NKA α1 subunit (t-NKA) and its phospho-state at Ser23 (p-NKA) were determined in renal homogenates.

Results: Under HS, MBP increased in oVx to 135±4 ($p<0.05$) while UNa^+*V was lower in oVx 2.09±0.12 vs IF 2.88±0.21 mmol/d/100g bwt ($p<0.05$). uDA increased from NS to HS in all groups (465±25 to 660±35 ng/100 bwt/day, $p<0.05$).

After D1R antagonist treatment in IF HS UNa^+*V and V diminished by 50% and MBP increased to 140±2 mmHg ($p<0.05$), while its effect was negligible in oVx HS.

D1R blockade blunted the increase in p-NKA induced by HS in IF ($p< 0.01$). Instead, D1R antagonist had no effect in oVx. t-NKA expression was similar in all groups.

DA infusion enhanced UNa^+*V (μEq/30 min/100g bwt) in IF HS from 14.63±5.2 to 42.2±7.6 ($p<0.05$). This response was absent in oVx HS.

Abundance of D1R was not different in IF vs oVx.

Conclusions: These findings suggest that natriuresis following salt loading in IF is accompanied by an *in vivo* increment of NKA phosphorylation mediated by renal DA through D1R. oVx HS, instead, had a decreased p-NKA and a diminished response to D1R blockade or stimulation pointing to a defect in D1R regulation of NKA as a possible mechanism of hypertension.

TH-PO853

A Protective Role for Interleukin 17A in Hypertension Induced Renal Injury in Mice Sascha Lange,[1] Alexander Lehners,[1] Ulf Panzer,[1] Joachim Velden,[2] Rolf A. Stahl,[1] Christian Krebs,[1] Ulrich O. Wenzel.[1] *[1]Department of Internal Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]University Medical Center Erlangen, Erlangen, Germany.*

Background: T cells are required for the full development of Ang II-induced hypertension. However, the specific subsets of T-cells that are important in the endorgan damage are unknown. Th17 cells are a new subset that produces interleukin 17A (IL-17A).

Methods: Hypertension was induced with DOCA + Ang II in wildtype (WT, n=30) and IL-17A knockout mice (KO, n=25). Hypertensive renal and cardiac endorgan damage was evaluated at day 4 and day 14.

Results: An increased infiltration of IL-17-producing T cells was found in the kidney from WT hypertensive mice. 3 days after induction of hypertension with DOCA + Ang II a significantly higher albuminuria was found in IL-17 KO than in WT mice (197±65 vs. 45±15 mg/mg albumin/creatinine, controls 0.09±0.02). The table shows the data of day 14.

	Systolic blood pressure (mmHg)	Albuminuria (mg/mg)	Glomerular injury (score)	Protein casts (number/high power field)	Urea-N (mg/dl)	Plasma cholesterol (mg/dl)
Controls	93±4	0.11±0.0	0.05±0.1	0.15±0.1	27±2	90±7
DOCA+Ang II wildtype	140±3	111±27	0.67±0.01	6.0±1.5	39±2	216±19
DOCA+Ang II IL-17 KO	139±4	116±35	1.04±0.06**	17.2±3.9**	54±8*	311±44*

*=p<0.05, **=p<0.01 vs. wildtype DOCA + Ang II

Although blood pressure and albuminuria did not differ between hypertensive IL-17A KO and WT mice at day 14, the histological analysis revealed significantly more glomerular injury and more proteineous casts in IL-17A KO than in WT mice. In addition, serum urea N and cholesterol levels were significantly higher in IL-17A KO than in WT mice. DOCA + Ang II also induced a massive cardiac damage as assessed by heart weight, cardiac fibrosis as well as expression of fetal and matrix genes but no significant difference was found between IL-17A KO and WT mice at both time points.

Conclusions: IL-17A deficiency has no effect on the DOCA + Ang II induced cardiac endorgan damage. In contrast, IL-17A deficiency aggravates early albuminuria in response to DOCA+Ang II and induces more renal injury at the late time point.

TH-PO854

Renoprotective Effect of Sildenafil in DOCA-Salt Hypertensive Rats

Eun Hui Bae, Joon Seok Choi, Chang Seong Kim, Soo Wan Kim. *Internal Medicine, Chonnam National University Medical School, Gwangju, Korea.*

Background: Sildenafil was the first selective inhibitor of phosphodiesterase-5 (PDE5) to be widely used for treating erectile dysfunction. Many recent studies have investigated the cardioprotective role of sildenafil in animal models. We evaluated the protective effects of sildenafil represent potential mechanisms for the treatment of end-organ damage in hypertension. This study has investigated the effects of sildenafil (50 mg/kg/day) on renal function impairment, glomerulosclerosis and tubulointerstitial fibrosis in deoxycorticosterone acetate (DOCA)-salt hypertensive (DSH) rat.

Methods: Rats were implanted with DOCA strips (200 mg/kg) on 1 week after unilateral nephrectomy. Rats received control diet with or without sildenafil for 2 weeks. The systolic blood pressure (SBP) was measured by tail cuff method and urinary albumin excretion ratio (UAE) was calculated by urine microalbumin and creatinine. The glomerulosclerosis and tubulointerstitial fibrosis was determined by masson's trichrome stain. The expression of ED-1, transforming growth factor-β (TGF-β), Bax, and Bcl-2 was determined in the kidney by semiquantitative immunoblotting and immunohistochemistry. TUNEL stain was performed for detecting apoptic cell.

Results: In DSH rats, SBP was increased, which was not attenuated by sildenafil treatment. Creatinine clearance was decreased while UAE was increased in DSH rats compared with controls, which were attenuated by sildenafil treatment. Glomerulosclerosis and tubulointerstitial fibrosis in DSH rats were attenuated by sildenafil treatment. The expression of ED-1, TGF-β, and Bax was increased and its of Bcl-2 was decreased in the kidney of DSH rats, which was counteracted by sildenafil treatment. The number of apoptic cells was increased in DSH rats, which was attenuated by sildenafil treatment.

Conclusions: Sildenafil is effective in preventing progression of renal injury in DSH rat, the mechanism of which is associated with anti-inflammatory anti-fibrotic and anti-apoptotic effects.

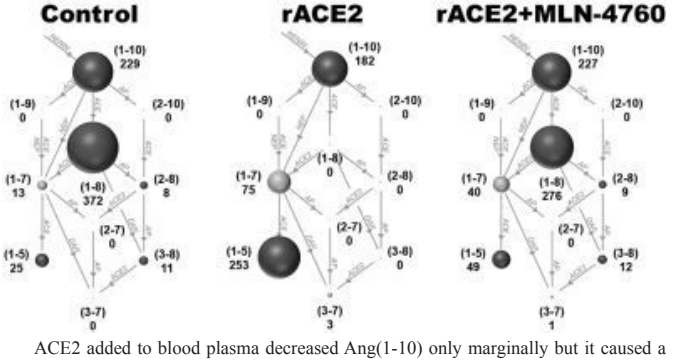
RAS Fingerprinting: A Novel Paradigm to Concurrently Evaluate Multiple Angiotensin Peptides and Their Enzymatic Regulation

Jan A. Wysocki,[1] Minghao Ye,[1] Manfred Schuster,[2] Daniel Batlle.[1] *[1]Div. of Nephrology&Hypertension, Feinberg School of Medicine, Northwestern University, Chicago, IL; [2]Apeiron Biologics AG, Vienna.*

Background: RAS overactivity is implicated in diabetic nephropathy, hypertension and cardiovascular disease but the evaluation of the various components of an increasingly complex system has been limited by available techniques. Here we used a newly developed LC-MS/MS based method to concurrently measure 10 angiotensin peptides to examine their steady state and their regulation by murine recombinant ACE2 in the presence and absence of a specific inhibitor, MLN-4760.

Methods: We produced mrACE2 and its effect on ten endogenous RAS peptides was studied ex vivo in plasma using LC-MS/MS analysis and data processing by Marko Poglitsch, APEIRON-Biologics AG.

Results: In control plasma (no rACE2 added), there was a high abundance of Ang I(1-10) and Ang II(1-8) while other Ang metabolites were present in relatively low concentrations. The diameter of the spheres and the numerical value given next to it reflect concentration of the respective Ang metabolite.



ACE2 added to blood plasma decreased Ang(1-10) only marginally but it caused a complete disappearance of (1-8) and lead to the formation of Ang(1-7). As a result of the increase in Ang(1-7) formation, ACE2 lead also to the formation of Ang(1-5), a process driven by ACE which, like other peptidases, is present in the plasma ex vivo assay. The effects on the above mentioned Ang peptides were ACE2-specific as they all were inhibited by the selective ACE2 inhibitor, MLN-4760 (10-5M).

Conclusions: mrACE2 added to blood plasma degrades Ang(1-8) forming Ang(1-7) and, in the presence of endogenous ACE, leads to increased formation of large amounts of Ang(1-5). RAS fingerprinting is a powerful novel approach to simultaneously evaluate several Ang peptides and their regulation by key enzymes present in plasma.

TH-PO856

Vitamin D Increases Plasma Renin Activity Independently of Plasma Calcium, through Polyuria-Induced Dehydration

Douglas K. Atchison,[1] Kevin L. Gordish,[2] David L. Szandzik,[1] William H. Beierwaltes.[1] *[1]Dept. Internal Med., Hypertension and Vascular Research Div., Henry Ford Health System, Detroit, MI; [2]Dept. of Physiology, Wayne State Univ. School of Med., Detroit, MI.*

Background: 1,25 OH_2 dihydroxycholecalciferol (Calcitriol) is the active form of Vitamin D and has been reported to inhibit the renin-angiotensin system. However, Calcitriol also increases plasma Ca^{2+}, which can cause polyuria, dehydration, and volume contraction. We hypothesized Calcitriol increases plasma renin activity (PRA) due to hypercalcemia-mediated polyuria and dehydration.

Methods: All experiments were run in male Sprague-Dawley rats over 6 days.

Results: 500 ng/day Calcitriol, i.p., increased PRA from 4.4±0.5 to 17.4±4.6 ngAngI/ml/hr ($p<0.05$). Calcitriol increased plasma Ca^{2+} from 1.26±0.02 to 1.64±0.06 mM ($p<0.001$) and increased urine flow from 9.0±1.1 to 26.3±1.1 ml/day ($p<0.01$). To test the role of plasma Ca^{2+}, we treated rats with 100 ng/day of the vehicle, Calcitriol, or Paricalcitol, a non-calcemic analog of Vitamin D. 100 ng/day Calcitriol increased plasma Ca^{2+} from 1.24±0.01 to 1.52±0.03 mM ($p<0.001$), while Paricalcitol plasma Ca^{2+} (1.23±0.02 mM) did not differ from control. However, Calcitriol and Paricalcitol both increased PRA from 3.1±0.3 to 10.3±1.0 and 8.8±2.0 ngAngI/ml/hr, respectively ($p<0.01$). Also, Calcitriol and Paricalcitol both increased urine flow from 11.3±1.0 to 29.3±3.4 and 24.6±3.2 ml/day, respectively ($p<0.01$). Thus, Vitamin D increased PRA *independently* of the increase in plasma Ca^{2+}. To test if Calcitriol increased PRA *via* polyuria-induced dehydration, we rehydrated Calcitriol-treated rats subcutaneous 0.9% NaCl. Rehydrating Calcitriol-treated rats completely normalized PRA from 9.2±1.8 to 3.1±0.8 ngAngI/ml/hr ($p<0.05$).

Conclusions: Thus, our data demonstrate that Vitamin D increases PRA *independently* of increased plasma Ca^{2+}, *via* polyuria-induced dehydration. Contrary to the recent literature, our data demonstrate that treatment with Vitamin D does not inhibit PRA, but actually *increases* it. Our data suggest that treatment with Vitamin D is not a candidate to directly decrease renin-angiotensin system activity.

TH-PO857

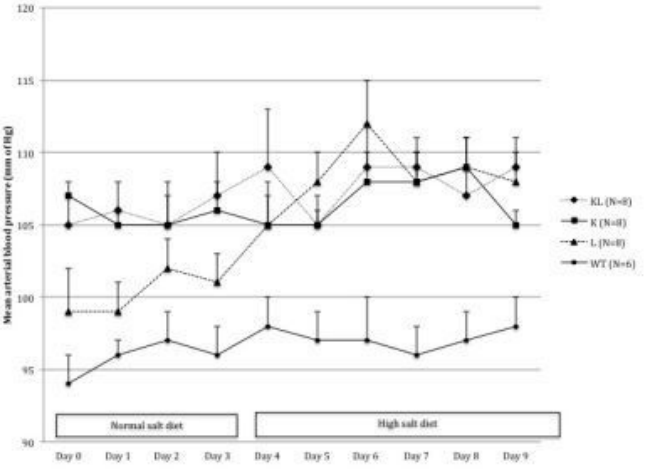
Evidence for an Interaction between Systemic and Renal Angiotensinogen in the Control of Arterial Pressure

Nirupama Ramkumar, Donald E. Kohan. *Division of Nephrology and Hypertension, University of Utah, Salt Lake City, UT.*

Background: Both the liver and proximal tubule make angiotensinogen (AGT), and overexpression of AGT in either region increases blood pressure (BP). To determine the relative contributions of renal and systemic AGT in modulating BP, mice were used with AGT overexpression in kidney (K), liver (L) or both sites (KL).

Methods: Male transgenic and wildtype (WT) controls aged 24 weeks underwent BP recording via telemetry and metabolic cage studies on normal (0.25%) and high (3.2%) sodium diets.

Results: Mean BP (MAP) was higher in K and KL vs L and WT mice fed normal salt, while MAP in L mice was higher than controls. High salt intake did not alter MAP in WT, K or KL mice but increased it in L mice. Plasma AGT levels, plasma renin concentration, urine Na excretion and urine volume were similar between groups regardless of sodium intake. Urinary AGT (ng/day) on normal sodium intake was: WT: 5±1, L: 4±1, K: 20±5 and KL: 34±9. High salt increased urine AGT in all groups (WT: 19±4, L: 42±8, K: 290±75, KL: 407± 72). High salt did not alter plasma AGT levels but reduced plasma renin concentration in all groups.



Conclusions: Taken together, these data show a correlation between urinary AGT and BP. Mice with renal AGT overexpression may be maximally hypertensive on a normal sodium diet since renal AGT is already high. Mice with liver AGT overexpression have mild hypertension on a normal sodium diet that is exacerbated by high sodium intake; this is associated with a significant increase in urinary AGT as compared to WT animals. Thus, systemic AGT may have the potential to regulate renal AGT and this effect may be a key determinant of BP.

TH-PO858

Renal and Vascular Response to Angiotensin II after Experimental Preeclampsia Anne Marijn van der Graaf,[1,2] Mienke van der Wiel,[1] Tsjitske Toering,[3] Anne-Roos Sophie Frenay,[2] Harry Van Goor,[2] Pieter A. Klok,[2] Robert H. Henning,[4] Hendrik Buikema,[4] Gerjan Navis,[3] Titia Lely,[1] Marijke M. Faas.[2] *[1]Obstetrics & Gynaecology; [2]Pathology and Medical Biology; [3]Nephrology; [4]Clinical Pharmacology UMCG, Groningen, Netherlands.*

Background: Formerly preeclamptic women (PE) have an increased risk for cardiovascular (CVD) and renal disease, possibly due to persistent alterations in the renin-angiotensin system. Previously, we have shown vascular hypersensitivity to angII in rats during experimental PE as compared to healthy pregnant (HP) rats. We investigated whether vascular hypersensitivity to angII persists postpartum in these rats.

Methods: Never-pregnant (NP), formerly HP (fHP), and formerly experimental PE Wistar rats (low dose endotoxin on day 14 of pregnancy; fPE) were treated with angII (200ng/kg/min; i.p.) or sham treated (n=10-14 in all groups), starting 6 weeks after delivery. Systolic blood pressure (SBP) and proteinuria was measured at baseline and weekly for 3 weeks. Aortic rings of sham treated rats were mounted for isotonic measurement of vasotonus. AngII sensitivity was assessed by obtaining response curves in the presence of vehicle, AT2-R blocker PD123319 or AT1-R blocker losartan.

Results: SBP was higher in NP vs fPE at baseline (NP:129(±11); fPE:123(±9); p=0.012; fHP:128(±10)), with no difference in proteinuria (mg/24h) (NP:4.3(±1.2); fHP:4.2(±2.3); fPE:3.3(±1.8); p=0.1). After 3 weeks of angII, a trend was found towards a higher increase in SBP in fPE vs NP (50.2(±21)% vs 41.3(±20)%; p=0.07), and a significantly higher increase in proteinuria in fPE (24.8(±12) vs both NP (21.9 (±20);p=0.04) and fHP (18.7(±14);p=0.05). No differences in in-vitro angII sensitivity were seen between the groups.

Conclusions: These data show that fPE rats have an increased response to angII, as reflected by increased proteinuria and a trend towards increased SBP, compared to fHP and NP rats. Our data show that experimental PE per se induces permanent increased angII sensitivity which may be involved in the higher risk for CVD and renal disease in formerly preeclamptic women. The exact mechanism by which PE induces such permanent changes is subject of further research.

TH-PO859

Genetic Variants in Pre-Eclampsia: A Meta-Analysis Aletta Buurma,[1] Rosanne Jane Turner,[1] Annemariek Driessen,[2] Antien Mooyaart,[1] Jan W. Schoones,[3] Jan A. Bruijn,[1] Kitty Bloemenkamp,[4] Olaf Dekkers,[5] Hans J. Baelde.[1] *[1]Pathology, Leiden University Medical Center; [2]Medical Statistics and Bio Informatics, Leiden University Medical Center; [3]Walaeus Library, Leiden University Medical Center; [4]Obstetrics, Leiden University Medical Center; [5]Epidemiology, Leiden University Medical Center.*

Background: Preeclampsia (PE) frequently affects the kidney, resulting in proteinuria and hypertension. PE has a clear familial component, suggesting that the syndrome may be partly attributable to genetic susceptibility. The search for susceptibility genes has lead to a massive increase in the number of published studies involving genetic associations in PE. However, attempts to replicate these findings have yielded inconsistent results. This meta-analysis aims to assess the pooled effect of each genetic variant that is reproducibly associated with PE.

Methods: Studies assessing the association between genes and PE were searched up to February 2012 in PubMed, EMBASE and Web of Science. We selected all genetic variants that were significantly associated with PE in an initial study and then independently reproduced in at least one additional study. Subsequently, all studies (regardless of p-values) assessing these reproduced variants were included. The association between genetic variants and PE was calculated at the allele level and the main measure of effect was a pooled odds ratio in a random effects model.

Results: The literature search resulted in 2965 citations, of which 542 were genetic association studies investigating PE. We identified 23 replicated genetic variants, of which 8 remained significantly associated with PE in a random-effects meta-analysis. These variants were in or near the following genes: *ACE, AGT, CTLA4, F2, FV, LPL* and *SERPINE1.*

Conclusions: This meta-analysis found eight genetic variants associated with PE. Importantly, many of the variants that were associated with PE are risk factors for the development of hypertension and cardiovascular disease, indicating that PE and cardiovascular disease have shared genetic risk factors. The relative contribution and relevance of the identified genes in the pathogenesis of PE should be the focus of future studies.

TH-PO860

Plasmin Plays Deleterious Roles in Aldosterone-Induced Kidney Injury: A Beneficial Effect of Serine Protease Inhibitor Tomoaki Onoue,[1] Yutaka Kakizoe,[1] Manabu Hayata,[1] Kohei Uchimura,[1] Jun Morinaga,[1] Rika Yamazoe,[1] Teruhiko Mizumoto,[1] Miki Ueda,[1] Sakai Yoshiki,[2] Kimio Tomita,[1] Kenichiro Kitamura.[1] *[1]Department of Nephrology, Kumamoto University Graduate School of Medical Sciences, Kumamoto, Japan; [2]Research Headquarters, Ono Pharmaceutical Co., Ltd, Osaka, Japan.*

Background: Recently deleterious effects of aldosterone (ALD) have been reported on many organs independent of its hemodynamic effect. However, the mechanisms of these unfavorable effects have been poorly understood. Previously we reported that administration of a synthetic serine protease (SP) inhibitor camostat mesilate (CM) attenuated hypertension and kidney injuries in Dahl salt-sensitive rats fed high salt diet (HSD). Therefore, we hypothesized that SP (s) is/are involved in the pathogenesis of salt-sensitive hypertension and organ damages.

Methods: To prove this hypothesis, we extracted kidney proteins from uninephrectomized rats treated with ALD and HSD, and performed proteomics analysis combined with a fluorescent zymography. We also examined the effect of a SP inhibitor on ALD-induced kidney injury in rats and on SP-induced fibrotic and inflammatory changes in renal fibroblast cells.

Results: LC-MS/MS analysis revealed that plasmin is a candidate SP in the development of kidney injuries mediated by ALD and HSD. Induction of plasmin by ALD was significantly reduced by eplerenone, suggesting that it is mediated by the mineralocorticoid receptor activation. Since CM suppressed plasmin activity in vitro, we administrated CM to rats treated with ALD and HSD. CM significantly ameliorated glomerulosclerosis and tubulointerstitial fibrosis, suggesting the possibility that plasmin could be involved in the pathogenesis of kidney injuries induced by ALD and HSD. In addition, treatment of renal fibroblast cells with plasmin substantially increased mRNA expressions of fibrotic and inflammatory markers and they were significantly reduced by CM.

Conclusions: Our results suggest that plasmin plays deleterious roles in the development of kidney injuries induced by ALD and HSD, and a SP inhibitor CM might be a new class of therapeutic strategy for the treatment of ALD-mediated kidney injuries.

TH-PO861

CXCL116 Regulates Angiotensin II-Induced Inflammation, Proteinuria, and Renal Fibrosis Yunfeng Xia, Jiyuan Chen, William E. Mitch, Yanlin Wang. *Medicine-Nephrology, Baylor College of Medicine, Houston, TX.*

Background: Recent studies have shown that inflammation plays a critical role in the pathogenesis and progression of hypertensive kidney disease. However, the signaling mechanisms underlying the induction of inflammation are poorly understood. We have found that CXCL16, a recently discovered chemokine, is induced in the kidney in a murine model of angiotensin II (Ang II)-induced hypertension. Therefore, we examined whether CXCL16 regulates Ang II-induced inflammation and renal injury.

Methods: Wild-type (WT) and CXCL16-KO mice were treated with Ang II via subcutaneous osmotic minipumps at 1500 ng/kg/min for up to 4 weeks.

Results: WT and CXCL16-KO mice had virtually identical blood pressure at baseline. Ang II treatment led to an increase in blood pressure that is similar between WT and CXCL16-KO mice. Immunohistochemical analysis showed that targeted disruption of CXCL16 inhibits infiltration of $F4/80^+$ macrophages and $CD3^+$ T cells in the kidney of Ang II treated mice compared with WT mice. Real time RT-PCR demonstrated that targeted disruption of CXCL16 reduced gene expression of inflammatory cytokines in the kidney of Ang II treated mice. Furthermore, targeted deletion of CXCL16 reduced Ang II-induced proteinuria and podocyte loss. Histological analysis revealed that CXCL16 deficiency inhibited Ang II-induced renal injury and fibrosis. Moreover, CXCL16 deficiency suppresses bone marrow-derived fibroblast accumulation in the kidney of Ang II treated mice.

Conclusions: Our results indicate that CXCL16 plays a pivotal role in the development of Ang II induced renal injury through regulation of macrophage and T cell infiltration and bone marrow-derived fibroblast accumulation.

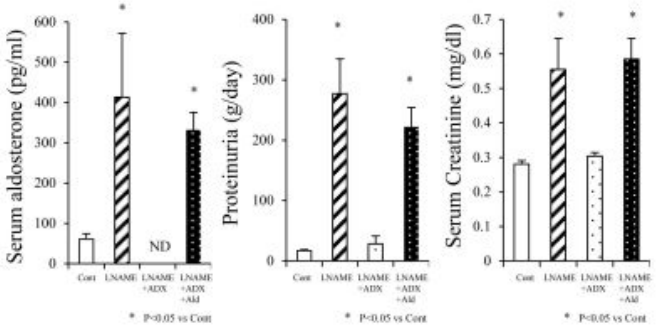
TH-PO862

Aldosterone Plays a Central Role in the Pathogenesis of Renal Injury in Nitric Oxide-Deficient Rat Takaichi Suehiro,[1] Kazuhiko Tsuruya,[1] Hirofumi Ikeda,[2] Toshiaki Nakano,[1] Takanari Kitazono.[1] *[1]Kyushu University; [2]National Kyushu Medical Center Hospital.*

Background: Nitric oxide synthase (NOS) inhibition is a known cause of a renin-angiotensin-aldosterone system (RAAS) activation, hypertension and renal injury. We previously reported both Angiotensin II (AII) receptor blocker and aldosterone (Ald) antagonist almost completely suppressed the renal injury induced by N^{ω}-nitro-L-arginine methyl ester (L-NAME). We hypothesize Ald is a main player of this injury. In this study, we investigated the direct effect of Ald on renal injury under chronic NOS inhibition.

Methods: Male Wistar rats were divided into the following four groups; control rats given vehicle (Cont, n=10), L-NAME rats given 50 mg/kg/day L-NAME (L-NAME, n=11), adrenalectomized rats given L-NAME (L-NAME+ADx, n=10) and adrenalectomized rats with Ald infusion given L-NAME (L-NAME+ADx+Ald, n=12). All rats fed 4% salt diet.

Results: Following treatment for 8 weeks, plasma Ald and AII levels were elevated in L-NAME rats. Ald were not detectable in L-NAME+ADx rats, but elevated in L-NAME+ADx+Ald rats. AII were elevated in L-NAME+ADx rats, but were not different from Cont rats in L-NAME+ADx+Ald rats. Blood pressure were elevated in three L-NAME treated groups, but comparable among those groups. L-NAME rats developed proteinuria, elevated serum creatinine, glomerulosclerosis, interstitial fibrosis and vascular injury. Adrenalectomy almost completely prevented the changes, whereas Ald infusion reversed the effects. The cortical mRNA expression of Sgk1, OPN, MCP-1 and infiltrating macrophages were significantly elevated in L-NAME rats. Adrenalectomy markedly suppressed the changes, but Ald infusion counteracted the effects.



Conclusions: The present study demonstrates that Ald plays a central role in the pathogenesis of renal injury by chronic NOS inhibition, independent of its systemic hemodynamic effects.

TH-PO863

AT_{1a} and/or Mas Receptor-Mediated Long-Term Blood Pressure and Renal Responses to Low Doses of Angiotensin II and Angiotensin (1-7) in Mice

Jia L. Zhuo, Brianne Ellis, Elisa Miguel-qin, Xiao C. Li. *Department of Pharmacology and Toxicology, University of Mississippi Medical Center, Jackson, MS.*

Background: The blood pressure and renal responses to angiotensin II (Ang II) or Ang (1-7) are most commonly studied in rodents with acute or short-term infusion of high doses of Ang II or Ang (1-7) .

Methods: In the present study, we infused equi-low doses of Ang II or Ang (1-7) (400 ng/kg/day, i.p.) alone or together for 3 months in C56BL/6J (WT) or AT_{1a}-KO mice. Systolic blood pressure (SBP) and renal responses were determined before and weekly after Ang II or Ang (1-7) was infused.

Results: In WT mice, the low dose of Ang II caused moderate and time-dependent increases in SBP (basal: 110 ± 4; week 4: 120 ± 3; week 8: 139 ± 5; and week 12: 134 ± 3 mmHg, $p<0.01$ vs. basal). Infusion of a higher dose of Ang II (800 ng/kg/day, i.p.) further increased SBP to 150 ± 7 mmHg 3 months later ($p<0.01$). These responses were blocked by losartan and were absent in AT_{1a}-KO mice. 24 h urinary sodium excretion were lower in WT mice infused with Ang II than in AT_{1a}-KO or losartan-treated, Ang II-infused WT mice ($p<0.05$). The heart wt to body wt ratio was higher in Ang II-infused WT mice than in Ang II-infused AT_{1a}-KO mice ($p<0.01$). Infusion of an equi-dose of Ang (1-7) alone (800 ng/kg/day, i.p.) had no effect on SBP (week 12: 119 ± 3 mmHg, vs. basal, n.s.) or on Ang II-induce SBP responses in WT mice (week 12: 146 ± 8 mmHg, n.s.). In the kidney, Ang II increased the levels of phosphorylated MAP kinase ERK1/2 ($p<0.01$) and the sodium and hydrogen exchanger-3 (NHE-3, $p<0.01$) in the renal cortex of WT mice. However, Ang (1-7) had no effect on 24 h urinary sodium responses, nor on MAP kinases ERK1/2 and NHE-3 levels in WT mice. Nevertheless, Ang (1-7) decreased blood pressure (basal: 97 ± 3 vs. week 12: 90 ± 2 mmHg, $p<0.01$) and increased 24 h urine excretion in AT_{1a}-KO mice ($p<0.05$).

Conclusions: These results suggest that infusion of Ang II, even at an initially non-pressor dose, for 3 months can increase blood pressure and cause cardiovascular and renal injury. These effects are mediated by AT_{1a} receptors and may not significantly be altered by the Ang (1-7)/Mas receptor axis.

TH-PO864

Renoprotective Effects of DSP-9599, a Novel Human Renin Inhibitor, in Double-Transgenic Rats

Masaya Mori, Tomoyuki Hirata, Hiromichi Nagano, Setsuko Yamamoto, Nobuhisa Fukuda, Tomoaki Tochitani, Hiroshi Kato. *Drug Research, Dainippon Sumitomo Pharma. Co., Ltd., Osaka, Japan.*

Background: Inhibition of the renin-angiotensin-aldosterone system (RAAS) pathway is important in hypertensive patients with CKD. The rate-limiting enzyme in the RAAS is renin. We have assessed renoprotective effects of DSP-9599 in double-transgenic rats (dTGR), over-expressing both human renin and angiotensinogen genes.

Methods: The inhibitory effects of compounds on enzymes were examined using plasma and recombinant enzymes. The antihypertensive effect after single oral administration was determined by telemetry in enalapril-pretreated dTGR. The renoprotective effects were evaluated in dTGR [urinary albumin creatinine ratio (UACR), 2-6 mg/mg] by 3-week treatment with DSP-9599 (3 and 10 mg/kg, p.o., DSP3 and 10) or aliskiren fumarate (30 mg/kg, p.o., ALI30). Kidney damage was assessed every 1 week by measuring UACR and at the end of experiment by histochemical analysis.

Results: DSR-35894 free base, an active metabolite of DSP-9599, selectively inhibited the human renin activity, and its efficacy was almost equal to ALI (IC_{50} 0.75±0.17 nM vs 0.68±0.20 nM). A single oral administration of DSP-9599 (1-10 mg/kg) and ALI (10-100 mg/kg) decreased mean blood pressure in a dose-dependent manner, and the antihypertensive effect of DSP-9599 at a dose of 1.8 mg/kg was estimated equivalent to that of ALI at a dose of 30 mg/kg. Three-week treatment with DSP-9599 or ALI improved the survival rate (DSP3 83%, DSP10 100%, ALI30 67%, vehicle 0%). DSP10 effectively lowered systolic blood pressure (225±20 mmHg) compared with ALI30 (257±3 mmHg). In addition, DSP10 showed significantly lower albuminuria (UACR 0.5±0.5mg/mg), compared with ALI30 (6.1±5.2 mg/mg). Histological severity score (including incidence and mean severity of hyaline cast, tubular basophilia and tubular dilatation) showed that DSP10 lowered kidney damage compared with ALI30 (0-4 scale, 0.4±0.5, 1.2±0.4 and 0.2±0.4 for DSP10, 1.8±1.0, 2.3±0.5 and 2.3±0.5 for ALI30, respectively).

Conclusions: DSP-9599 showed stronger antihypertensive and renoprotective effects than ALI in dTGR that develop severe hypertension with end-organ damage.

TH-PO865

Renal Human L-Type Fatty Acid Binding Protein Attenuates Angiotensin II-Induced Renal Injury without Affecting Blood Pressure

Daisuke Ichikawa,[1] Atsuko Ikemori,[2] Takeshi Sugaya,[1] Takashi Yasuda,[1] Kenjiro Kimura.[1] *[1]Nephrology and Hypertension, St. Marianna University, Kawasaki, Kanagawa, Japan; [2]Anatomy, St. Marianna University School of Medicine, Kawasaki, Kanagawa, Japan.*

Background: Angiotensin II (Ang II) causes renal disorder due to hypertension and oxidative stress. L-type fatty acid-binding protein (L-FABP) is expressed in human proximal tubules and has an endogenous anti-oxidative function.

Methods: In order to investigate the dynamics of human L-FABP (hL-FABP) and its role in an Ang II-induced renal injury model, systemic Ang II infusion into mice (5μg/kg/min; subcutaneous osmotic minipumps) was performed for 14 or 28 days using hL-FABP chromosomal transgenic (Tg) mice and wild-type (WT) mice (Tg-Ang II, WT-Ang II). Control mice in each group of Tg mice and WT mice were injected with saline only (Tg-control, WT-control).

Results: Although mouse L-FABP was not expressed in WT mice, hL-FABP was expressed in the proximal tubules of Tg mice. After a high-dose injection of Ang II, renal gene and protein expression of hL-FABP in Tg-Ang II increased significantly compared to Tg-control. Urinary excretion of L-FABP was significantly greater in Tg-Ang II than in Tg-control mice. Blood pressure levels and urinary albumin levels in both groups increased to a similar extent for 28 days. The degree of glomerular sclerosis in Tg-Ang II was similar to that in WT-Ang II. Up-regulation of gene or and protein expression of monocyte chemoattractant protein-1, macrophage infiltration in the interstitium, tubulointerstitial damage and depositions of type I and III collagens were observed in both Tg-Ang II and WT-Ang II mice. However, these effects were less pronounced in Tg-Ang II compared to WT-Ang II mice. The level of renal N-(hexanoyl)lysine, which is known to be a oxidative stress marker, was significantly higher in WT-Ang II than in Tg-Ang II mice.

Conclusions: In conclusion, renal hL-FABP reduced oxidative stress in Ang II-induced renal injury and attenuated tubulointerstitial damage. The renal protective function of hL-FABP was not associated with blood pressure-dependent effects.

Lack of Vasohibin-1 Exacerbates Renal Alterations Induced by Infusion of Angiotensin-II

Hiroko Yamasaki,[1] Yohei Maeshima,[1] Hiroyuki Watatani,[1] Masaru Kinomura,[1] Norikazu Hinamoto,[1] Haruyo Ujike,[1] Hitoshi Sugiyama,[1] Yasufumi Sato,[2] Hirofumi Makino.[1] *[1]Medicine and Clinical Science, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan; [2]Vascular Biology, Institute of Development, Aging, and Cancer, Tohoku Univ., Sendai, Miyagi, Japan.*

Background: Hypertensive nephrosclerosis is one of the major pathogenic disorders predisposing ESRD. Angiotensin-II (A-II) infusion induces hypertension and glomerular as well as focal renal tubulointerstitial injuries in experimental animal models. We recently reported the protective role of Vasohibin-1(VASH-1), a negative feedback regulator of angiogenesis, in diabetic nephropathy, but its role on hypertensive nephrosclerosis remains to be elucidated. In the present study, we aimed to evaluate the role of endogenous VASH-1 in regulating renal alterations in an A-II-infusion model.

Methods: Male VASH1+/- or wild-type (VASH1+/+) littermates (C57/BL6J background) received continuous infusion of saline or A-II (1000 ng/kg/min) via osmotic minipumps. Mice were sacrificed on Day 28 and the kidneys were obtained. Morphometric analysis, immunohistochemistry and real-time PCR were performed.

Results: Hypertension was observed in the A-II-infused animals, and blood pressure was not significantly different between A-II-infused wild-type and VASH1+/- mice. A-II-induced increase of proteinuria, glomerular volume and mesangial matrix index (assessed by the computer-image analysis) were significantly exacerbated in the VASH1+/- mice compared with the VASH1+/+ mice. Increase in the glomerular accumulation of type IV collagen, interstitial accumulation of $F4/80^+$ monocytes/macrophages, renal mRNA levels for TGF-beta1, CTGF, PAI-1, type IV collagen and CCL2 in the A-II-infused wild-type mice were significantly aggravated in the A-II-infused VASH1+/- mice.

Conclusions: Taken together, these results suggest the protective role of endogenous VASH1 on A-II-induced glomerular as well as tubulointerstitial alterations via regulating inflammation and fibrosis, and thus suggesting its beneficial effects on hypertensive nephrosclerosis.

Cardiovascular and Renal Implications of the Ang II/AT1Rs-Jak2-Rho Kinase Pathway Activation Salt Sensitive but Not in Salt Independent Hypertension Ramiro Juncos,[1,2] Kiranmai Chadipiralla,[1] Ming-sheng Zhou,[2] Leopoldo Raij.[1,2] *[1]Renal-Hypertension, VAMC, Miami, FL; [2]Renal-Hypertension, University of Miami, Miami, FL.*

Background: Aortic (Ao) stiffness is a determinant of increased systolic (SBP) and pulse-pressure (PP). Clinically, increases in central SBP and PP (hemodynamic changes linked with Ao stiffness), are associated with CKD progression. In hypertension increased pressure-workload has been considered cause and effect of Ao stiffening but the mechanisms are poorly understood. Rho Kinase decreases eNOS and NO production in the endothelium. In VSMC Ang II via AT1Rs specifically activates Rho Kinase via phosphorylation of Jak2/Arhgef1 which phosphorylates (inhibits) myosin light chain phosphatase (MYPT1) thereby promoting vasoconstriction/remodeling.

Methods: Groups (n= 6) of DS rats fed either 0.5% or 4% NaCl diets for 10 weeks were matched with SHR of similar age (6 and 16weeks old) and SBP (147±8 & 211±7).

Results: Hypertensive DS rats, but not SHR showed increased Ao weight/length (17%, P<0.05) and LV/ body weight (16%, P<0.05). Compared to normotensive DS, in hypertensive DS Ao AT1Rs rose 230% accompanied by increased pJak2/Jak2, 3.5 fold and pMYPT1/MYPT1 3.95 fold, (W.blot) p<0.05. Switch of hypertensive DS to 0.5 % NaCl diet for 4 weeks reduced neither SBP nor the activated Ang II/Rho Kinase pathways. ARB prevented Angll/AT1-Jak2-Rho Kinase activation in hypertensive DS fed 4% NaCl diet and normalized SBP, LVH and Ao weight/length in DS switched to a 0,5% NaCl diet. Hypertensive SHR neither showed Ao upregulation of AT1Rs nor activation of the Angll/Jak2-Rho Kinase pathway.We previously reported that hypertensive DS but not SHR develop progressive kidney disease.

Conclusions: We show for the first time that in salt sensitive but not in salt independent hypertension there is specific Ao activation of the Ang II/Jak2-Rho Kinase pathway. Clinically the variable CVD and renal disease observed in individuals with similar severity of hypertension may be linked, at least in part, to genetically conditioned differences in Angll/AT1Rs, Jak-2 activation in response to high dietary salt.

An Excess of Circulating Prorenin Results in Hypertension, Renal and Cardiac Fibrosis in cyp1a1-Prorenin Transgenic Rats Guangyu Zhou, Alfred K. Cheung, Yufeng Huang. *Internal Medicine, University of Utah, Salt Lake City, UT.*

Background: To examine if prorenin is an effector of organ injury, independent of its ability to generate renin, a transgenic, inducible, hepatic prorenin-overexpressing rat model was generated.

Methods: In this model, the rat prorenin was incorporated under the cytochrome p450 (cyp1a1) promoter. Four groups of 5 rats (transgenic and wild-type male and female rats) were assigned to receive a diet containing 0.3% of the gene activator, indole-3-carbinonl (I3C) for 4 wks. Four corresponding groups of 5 rats receiving normal diets served as controls.

Results: Plasma prorenin concentration rose from 23±6 µg/ml to 208±44µg/ml and mean arterial pressure increased from 77±5 to 138±17 mm Hg, whereas renal prorenin/renin protein expression was suppressed, in transgenic rats treated with I3C diet. These alterations in plasma prorenin and arterial pressure were not observed in transgenic rats receiving the normal diet or the wild-type rats. Western blot analysis further suggested that this circulating prorenin was in the precursor former with its prosegment attached. Plasma aldosterone concentrations increased by 10-fold for a period of 4wks in transgenic rats. Importantly, after 4 wks of treatment with I3C, transgenic rats developed significant albuminuria, glomerular mesangial matrix expansion and tubulointerstitial fibrosis in the kidney associated with significantly increased expression of TGFß1, PAI-1, type 1 and type IV collagen and fibronectin mRNA and protein production when they were chronically exposed to the high levels of prorenin. After 4 wks of I3C, the rats also exhibited cardiac hypertrophy, with the ratio of heart weight to body weight being 6.3±1.2 vs 3.3±0.5 mg/g (p<0.05). Cardiac interstitial fibrosis and perivascular fibrosis were prominent, accompanied by a significant increase in mRNA contents of ANP, BNP, TGFß1, PAI-1, collagen I and collagen III in the heart tissue. These genes are known to be the markers of cardiac hypertrophy and fibrosis.

Conclusions: These results indicate that high circulating prorenin levels are pathogenic and cause arterial hypertension, renal and cardiac fibrosis in both male and female rats.

Relationship between Marrow Adipocyte and Aortic Calcification in Chronic Dialysis Patients Aiji Yajima,[1,4] Yasuo Imanishi,[2] Masaaki Inaba,[2] Kosaku Nitta.[3] *[1]Medicine, Indiana University, Indianapolis, IN; [2]Medicine, Osaka City University, School of Medicine, Osaka, Japan; [3]Medicine, Tokyo Women's Medical University, Shinjuku-ku, Japan; [4]Renal Replacement Therapeutic Science, Akita University, Akita, Japan.*

Background: Mesenchymal stem cells give rise to adipogenic or osteogenic differentiation and vascular smooth muscle cellls are transformed to osteoblast-like cell in uremic patients. Relationship of bone marrow adipocyte with aortic calcification was investigated.

Methods: 1, Total marrow adipocyte volume (Ad.V), adipocyte number (N.Ad) and marrow volume (Ma.V) were measured in cancellous bone in 28 hemodialysis (HD) patients (Age; 59.7 ± 6.0 (46-70) yrs, HD duration; 13.6 ± 8.0 (2-28) yrs, intact PTH; 755.1 ± 525.5 (5-1750) pg/mL). And adipocyte volume (Ad.V/Ma.V;%) and adipocyte number (N.Ad/Ma.V; N/mm^2) were calculated. Ten slices of the abdominal aorta above the bifurcation were obtained on CT scan at 1 cm intervals and a total of 120 regions of the abdominal wall were obtained to calculate aortic calcification index (ACI). The relationship between adipocyte parameters and aortic calcification was investigated by linear regression analysis.

2, ACI was compared between Group I (the patients with severe suppression of marrow adipogenesis (Ad.V/Ma.V<15.0 % (n=6), N.Ad/Ma.V<110.0 N/mm^2 (n=7))) and Group II (those without severe suppression of marrow adipogenesis).

Results: 1, As to Ad.V/Ma.V (33.6 ± 21.0 (6.2-81.1) %) and N.Ad/Ma.V (183.2 ± 76.8 (63.1-384.8) N/mm^2), they were nearly associated with ACI (42.2 ± 21.8 %) in 28 patients ((r=-0.311, p=0.107) and (r=-0.315, p=0.102), respectively).

2, As to Ad.V/Ma.V and N.Ad/Ma.V, ACI was greater in Group I than Group II (66.8 ± 12.3 vs 35.6 ± 18.9, p=0.001 and 68.0 ± 10.8 vs 33.7 ± 17.3, p<0.001, respectively).

Conclusions: Mesenchymal stem cells are present in many adult tissues. Decreased marrow fat mass is associated with high bone mass phenotype and osteoblast-like cells increase bone-like lesion on the vascular walls. As a conclusion, it is possible that there is a reciprocal relationship between adipogenesis in bone marrow and osteogenesis presented by aortic calcification in HD patients.

TH-PO870

Better Correlation of Pulse Wave Velocity (PWV) than Coronary Artery Calcium Score (CACS) with Parameters of Mineral Bone Disturbance in Chronic Kidney Disease (MBD-CKD) Shin-young Ahn,[1] Hayne C. Park,[2] Kook-Hwan Oh,[2] Ho Jun Chin,[1] Curie Ahn,[2] Dong Wan Chae.[1] *[1]Department of Internal Medicine, Seoul National University Bundang Hospital, Republic of Korea; [2]Department of Internal Medicine, Seoul National University Hospital, Republic of Korea.*

Background: CACS, a hallmark of vascular calcification (VC) in many studies about MBD-CKD, mainly reflects intimal calcification, while VC in MBD-CKD occurs largely in media. Hence we hypothesized that PWV, reflecting vascular stiffness from medial VC, might correlate with the parameters of MBD-CKD better than CACS.

Methods: KNOW-CKD (KoreaN cohort study for Outcome in patients With Chronic Kidney Disease) is an on-going prospective, hospital-based, observational cohort study being conducted in 10 major university hospitals under the sponsorship of Korean Center for Disease Control and Prevention. We performed cross-sectional analysis of a relationship between PWV and CACS and parameters of MBD-CKD in this cohort. Upper most tertile value of PWV was regarded as a significant arterial stiffness. Severe CAC was defined as calcium score ≥ 100 Agatston units.

Results: 753 adult patients were enrolled from Aug 2011 to Nov 2011, 58.4% were male and median age was 53 years (20 – 75 years). The prevalence of hypertension, diabetes, and coronary heart disease (CHD) was 89.9%, 26.3%, and 5.6%. In univariate analysis, both the CACS and PWV were associated with traditional risk factors of atheroscrelosis and also the parameters of MBD-CKD. But, after binary logistic regression analysis, only traditional risk factors such as age, male, diabetes, and CHD were significant risk factors for severe CAC (p<0.001, p<0.001, p=0.014, and p<0.001 respectively). In case of arterial stiffness, parameters of MBD-CKD such as P, CaxP product, eGFR, random urine protein to creatinine ratio, and T-score of DEXA were independent risk factors for significant arterial stiffness (p=0.014, p=0.021, p=0.041, p=0.024, and p=0.005 respectively).

Conclusions: We compared the adequacy of CAC and PWV in analyzing VC in MBD-CKD in this cohort. Because PWV correlated with parameters of MBD-CKD better than CACS, PWV rather than CACS is suggested as a marker of VC in MBD-CKD.

Smooth Muscle Phenotype in Medial Arterial Calcification W. Charles O'Neill,[1] Amy Adams.[2] *[1]Renal Division, Emory University; [2]Department of Pathology, Emory University.*

Background: Development of medial arterial calcification in patients with chronic kidney disease (CKD) has been ascribed to phenotypic changes in vascular smooth muscle but histologic analysis in humans has been limited to advanced lesions in vessels also prone to atherosclerosis and intimal calcification. We have previously shown that breast arterial calcification is exclusively medial and is increased in CKD. Thus, breast tissue provides an opportunity to examine early stages of medial calcification in arteries devoid of atherosclerosis.

Methods: Tissue was obtained from prior breast excisions in 9 women with CKD (serum creatinine 1.2 to 3.9 mg/dl) and 10 with end-stage kidney disease (duration 0 to 7 yr). Sequential sections were prepared and stained for calcification (von Kossa stain) and apoptosis (TUNEL stain), as well as immunostaining for the bone-specific protein osteocalcin, the osteoblastic transcription factor Runx2, and the smooth muscle marker SM22α.

Results: Arterial calcification was present in 18 specimens and was exclusively medial, unrelated to intimal thickening, and occurred in vessels as small as arterioles. No atherosclerosis was observed. The mildest calcification appeared as small punctate lesions scattered throughout the media (all 18 specimens), with linear calcification of the internal elastic lamina in 9 specimens. Large confluences of calcification were seen in 4 specimens. Smooth muscle cells appeared normal, even in heavy calcifications, with no apoptosis. Staining for osteocalcin was absent in regions of early calcification. Osteocalcin was detected

in more advanced lesions (9 specimens) but was not associated with cells and appeared bound to calcifications. There was no staining for Runx2, even in heavily calcified regions. All medial cells stained for SM22α, indicative of a normal smooth muscle phenotype.

Conclusions: Medial arterial calcification in humans can occur in the absence of atherosclerosis in vessels of all sizes, without osteogenic trans-differentiation or apoptosis of smooth muscle cells. This indicates that medial calcification is distinct from intimal disease and that neither osteogenic trans-differentiation nor apoptosis of smooth muscle is a necessary initiating event.

TH-PO872

Determinants of Arterial Stiffness, Valvular and Vascular Calcifications in Prevalent Hemodialysis Patients Anabela Malho, Ana Pinho, André Fragoso, Elsa Morgado, Ana Paula Silva, Pedro Neves. *Centro de Hemodiálise de Faro, NephroCare, Portugal.*

Background: Large-artery stiffness is the main determinant of pulse pressure (PP) and it has independent predictive value for total and cardiovascular mortality. Vascular and valvular calcifications are highly prevalent complications associated with exceedingly high cardiovascular mortality in ESRD patients. The aim of this study was to evaluate the determinants of arterial stiffness, vascular and valvular calcifications, using a 11 point score, in a population of hemodialysis patients.

Methods: We included all stable patients attending our clinic and evaluated the relationship of arterial stiffness, valvular and vascular calcifications with inflammation, mineral metabolism, magnesium and bicarbonate levels in a cohort of hemodialysis patients. Arterial stiffness was accessed by calculating the PP, valvular calcifications were determined by echocardiography and vascular calcifications were diagnosed using plain X-ray of hands and hips. An 11 point score was applied (1 point if PP >75 mmHg, 8 point Simple Vascular Calcification Score, and 1 or 2 points for the affected valves). Statistical analysis was based on descriptive statistics and multiple linear regression.

Results: A total of 162 patients (70 females, 92 males, 19.5 % diabetic), with mean age of 64.1 years and mean time on dialysis of 61.5 months were included. In this population 30.8%, 86.8% and 30.6%of the patients presented PP above 75 mmHg, vascular and valvular calcifications, respectively. The mean values of the evaluated parameters were: CaxP=37.4 mg^2/dL^2, PTH=442.8 pg/mL, magnesium=2.2 mg/dL, bicarbonate=23.8 mmol/L, ferritin=559.3 ng/mL, mean score=3.5. Using multiple linear regression we found a correlation between higher score and age (r=0.355, p=0.001), time on hemodialysis (r=0.424, p=0.001), male gender (r=-0.152, p=0.033), ferritin (r=0.141, p=0.046) and diabetes (r=0.336, p=0.001).

Conclusions: In our population, the arterial stiffness, vascular and valvular calcifications score was directly associated with age, dialysis vintage, male gender, inflammation and diabetes. More studies are needed to validate such score as a predictor of cardiovascular mortality.

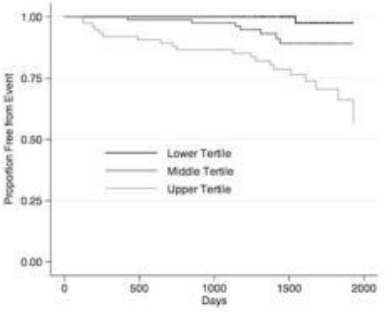
TH-PO873

Coronary Artery Calcification Predicts Death and Cardiovascular Events Independent of Traditional Risk Factors in Patients with Stages 3-5 CKD David C. Wheeler,[1] Ben Caplin,[1] Michael B. Rubens,[2] Joanne Marks,[1] John Cunningham.[1] *[1]UCL Medical School; [2]Brompton and Harefield NHS Foundation Trust, United Kingdom.*

Background: The clinical significance of arterial calcification in CKD patients is uncertain.The aims of the London Arterial Calcification, Kidney and Bone Outcomes (LACKABO) study were to investigate the risk factors for coronary calcification (CoCa) in CKD patients and to evaluate if screening for calcification is useful in predicting clinical outcomes.

Methods: A cohort of 289 patients with CKD stages 2-5 (median MDRD eGFR 39.7 ml/min/1.73m^2, IQR 26.8-51.1) consented to baseline electron beam tomography (EBT) scans (Agatston protocol). Subjects attended follow-up scans (n=154) after a mean of 49 months and were followed for cardiovascular (CV) events and death over a similar period. Determinants of baseline calcification scores, progression of calcification and outcomes were examined using logistic regression and cox proportional hazards models.

Results: Baseline CoCa was detectable in 68% patients, with scores predicted by history of CV events and recognised CV risk factors i.e. age, male gender, smoking and a surrogate for blood pressure (number of antihypertensive medications) but not by eGFR. Progression of CoCa was associated with age, the surrogate for blood pressure and baseline levels of fibroblast growth factor 23. Baseline CoCa scores predicted the combined outcome of death and CV events in both univariable (figure) and multivariable models (Hazard Ratio: 19.8, 95%CI 1.9-210.7 for highest versus lowest tertile of CoCa).



Kaplan-Meier Plot of Proportion of Subjects Remaining Free from the Combined Endpoint of Death or Cardiovascular Event Stratified by Tertile of Baseline Coronary Calcification

Conclusions: CoCa reflects underlying vascular disease in stages 3-5 CKD. Progression of calcification may be driven in part by metabolic disturbances associated with the mineral bone disorder. Assessment of calcification allows more accurate prediction of clinical outcomes compared to knowledge of traditional CV risk factors alone.

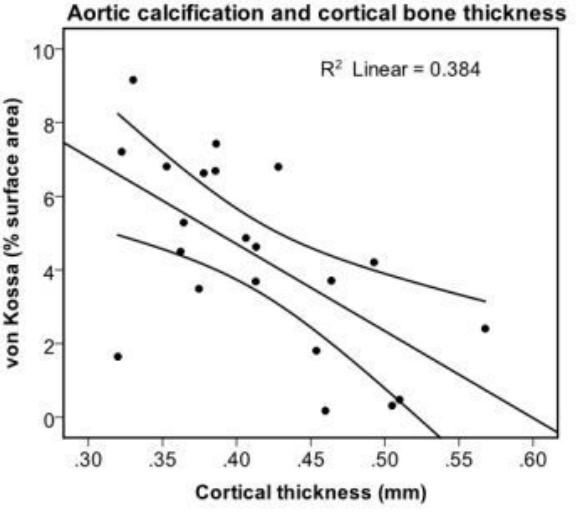
TH-PO874

Vascular Calcification Development and Bone Anomalies in Uremic Rats Fabrice Mac-Way, Alexandra Gauthier-bastien, Caroline Basoni, Roth-visal Ung, Richard Lariviere, Mohsen Agharazii. *CRCHUQ, L'Hotel-Dieu de Quebec, Laval University, Quebec, QC, Canada.*

Background: Anomalies of bone metabolism have been linked to vascular disorders in chronic kidney disease (CKD). We aimed to evaluate the anomalies of bone microarchitecture and mineral density in the development of vascular calcification in uremic rats under Doxycyclin (anti-Matrix Metalloproteinase) and Tempol (antioxidant).

Methods: Forty eight male Wistar rats were included in this sudy. CKD was induced by 5/6 nephrectomy. Vascular calcification was induced by high Ca/P and 1.25 (OH)vitamin D diet (Ca/P/Vit D diet). Four groups were studied: (1) CKD + standard diet (control); 2) CKD + Ca/P/Vit D diet; 3) CKD + Ca/P/Vit D diet + Doxycycline; 4) CKD + Ca/P/Vit D diet + Tempol. After 4-6 weeks of diet, the animals were sacrificed for blood biochemistry, bone specimens and thoracic aorta removal. Von Kossa quantification was used for aorta calcification and left tibiae of each rats were imaged with high resolution micro-CT for architectural analysis.

Results: Von Kossa analysis showed a significantly higher thoracic aorta calcification in the high Ca/P/Vit D diet compared to standard diet (0,30 vs 5,79 %, p<0.05). Neither Doxyxyclin or Tempol diet have affected the degree of calcification. Analysis of cortical BMD, trabecular BMD, inner and outer cortical perimeter of the left tibia with micro-CT did not show any differences between groups. However, the cortical thickness was significantly lower in the CKD + Ca/P/Vit D vs control. Globally, the thoracic calcification was inversely correlated to the cortical bone thickness.



Conclusions: High aortic calcification is related to decreased cortical bone thickness of tibiae in uremic rats, which is probably explained by an increased bone resorption at the expense of Ca/P deposition in vessels.

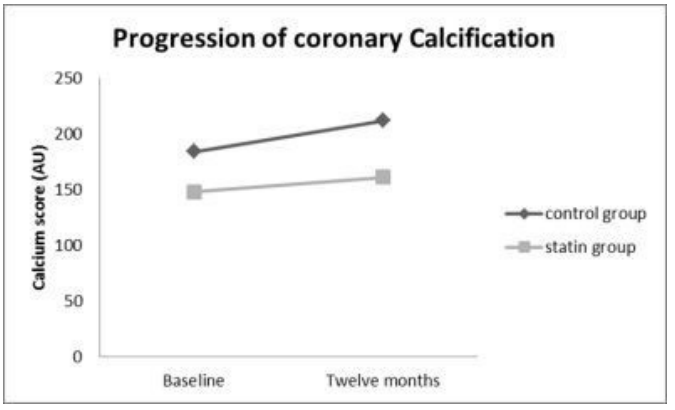
TH-PO875

Is There an Impact of Statin on Coronary Calcification Progression in Kidney Transplantation Recipients? Daniel Constantino Yazbek, Aluizio B. Carvalho, Cinara Barros de Sá, J. Medina-Pestana, Maria Eugenia F. Canziani. *Nephrology, Federal University of São Paulo, São Paulo, SP, Brazil.*

Background: Coronary artery calcification (CAC) is highly prevalent among chronic kidney disease (CKD) patients even after kidney transplantation. CAC strong association with mortality has been recognized in all stages of CKD. The aim of the present study was to test the effect of statin on the progression of CAC in kidney transplant recipients (KTRs).

Methods: A randomized, controlled and open-labeled pilot study was conducted including 100 KTRs (56% men, 41.1±10.0 years). Fifty one patients were randomly assigned to statin (10 mg/day), and 49 to the control group. CAC (multislice computed tomography) and biochemical analyses were performed at baseline and after 12 months.

Results: Statin treatment was associated with increase of eGFR (drug effect p=0.60; time-effect p<0.001; interaction p=0.008) and decrease in LDL-cholesterol (drug effect p=0.83; time-effect p<0.001; interaction p<0.001). At baseline, CAC was observed in 20% and 13% of patients in the statin and control groups, respectively (p=0.18). Calcium score at baseline as well as its absolute and relative changes during 12 months were similar among the groups. The analysis showed that the time but not the statin treatment was associated with the progression of CAC (drug effect p=0.56; time-effect p=0.002; interaction p=0.43).



Conclusions: Despite improvement of kidney function and LDL-cholesterol, the treatment with statin was not able to delay the progression of CAC in KTRs.

TH-PO876

High Glucose May Not Directly Affect High Phosphate-Induced Calcification of Vascular Smooth Muscle Cells Tadashi Yoshida, Maho Yamashita, Matsuhiko Hayashi. *Apheresis and Dialysis Center, School of Medicine, Keio University, Tokyo, Japan.*

Background: Vascular calcification is often seen in patients with chronic kidney disease and diabetes and is associated with increased mortality, myocardial infarction, stroke, and limb amputation. Results of the previous studies by our laboratory and others showed that high phosphate-induced phenotypic switching of vascular smooth muscle cells (SMCs) into osteogenic cells plays an important role in the calcification process. In the present studies, we examined if glucose concentration affected high phosphate-induced calcification of vascular SMCs.

Methods: (1) Male Sprague-Dawley rats were divided into 4 groups: adenine-fed uremic group; streptozotocin-injected diabetic group; adenine-fed and streptozotocin-injected uremic/diabetic group; and controls. Vascular calcification in the aorta of these rats was analyzed. (2) Cultured rat aortic SMCs were incubated in the medium with various concentrations of phosphate (0.9, 1.8, 2.7, and 4.5 mmol/L) and glucose (5, 25, and 50 mmo/L) for 2, 4, 6, and 8 days, and calcium deposition was measured.

Results: (1) By using von Kossa staining, aortic calcification was obvious in adenine-induced uremic rats and adenine-fed/streptozotocin-injected uremic/diabetic rats, whereas it was not observed in diabetic rats and controls. In addition, calcium deposition in uremic/diabetic rats was more abundant than in uremic rats, as determined by the o-cresolphthalein complexone method. (2) High phosphate concentration significantly increased calcium content in cultured SMCs in a dose-dependent manner. However, glucose concentration did not affect the amount of calcium deposition in SMCs incubated with various concentrations of phosphate.

Conclusions: Results suggest that the diabetic status enhances vascular calcification in uremia, but this effect may not be directly mediated by high glucose concentration.

TH-PO877

Study on the Relationship among Circulating Soluble Receptor of Advanced Glycation End Product (sRAGE), S100A12 (EN-RAGE) Levels and Vascular Calcification in Patients with Hemodialysis Ji Yong Jung,[1] Jiyoon Sung,[1] Han Ro,[1] Jae Hyun Chang,[1] Hyun Hee Lee,[1] Chungsik Lee,[2] Wookyung Chung.[1] *[1]Department of Internal Medicine, Gachon University of Medicine and Science, Incheon, Republic of Korea; [2]Department of Internal Medicine, Cheju Halla General Hospital, Jeju, Republic of Korea.*

Background: The soluble receptor for advanced glycation end products (sRAGE) exerts a protective effect on the development of atherosclerotic vascular complications by inhibiting RAGE-mediated inflammatory response. In contrast, extracellular newly identified S100A12 (EN-RAGE) contributes to increased vascular damage as a pro-inflammatory ligand for RAGE. We determined the levels of sRAGE and EN-RAGE in hemodialysis (HD) patients and evaluated their relationship with vascular calcification.

Methods: We performed a cross-sectional study with 199 hemodialysis patients. Plain X-ray images of lateral lumbar spine from all subjects were studied for calculation of semiquantitative vascular calcification scores (VCS) as described by Kauppila. For quantification of serum concentration of sRAGE and EN-RAGE, commercially available ELISA kit were used according to the instructions of the manufacturer.

Results: Patients were 57.1 ± 13.7 years of age, 54.3% males, 49.2% diabetics and 36.2% with a history of CVD. We also found a high prevalence of vascular calcification (180 patients, 54.3%) in this population. Kauppila scores revealed 40 patients (20.1%) with higher VCS (>7). In univariate analysis, serum sRAGE was negatively associated with higher VCS (P = 0.003), whereas EN-RAGE showed a positive tendency (P = 0.235). Even after adjustments for confounding risk factors, sRAGE was independently associated with higher VCS (OR = 0.505, 95% CI: 0.269 – 0.948, P = 0.033).

Conclusions: This study shows circulating sRAGE levels are associated in an inverse manner to VCS in HD patients. Longitudinal observations and intervention studies are warranted to establish whether this link is causal in nature.

TH-PO878

The German Calciphylaxis Registry Vincent Brandenburg,[1] Jürgen Floege,[3] Markus Ketteler.[2] *[1]Cardiology, RWTH University Hospital Aachen, Aachen, Germany; [2]Nephrology, Klinikum Coburg, Coburg, Germany; [3]Nephrology, RWTH University Hospital Aachen, Aachen, Germany.*

Background: Calcific uremic arteriolopathy (CUA, calciphylaxis) is a rare disease associated with high morbidity and mortality. CUA is characterised by painful, ischemic, partly necrotic skin ulcerations due to malperfusion based on media calcification of cutaneous arterioles. The aims of the German CUA registry are 1) to collect data about incidence and potential risk factors; 2) to gain overview about current treatment strategies; 3) to link these data to the clinical course.

Methods: The internet-based registry (www.calciphylaxis.eu) allows online notification for all cases of established or suspected CUA. The diagnosis is based on clinical judgement and / or histology by evaluation of both treating physician as well as registry leaders. A comprehensive data base including 66 items concerning patient characteristics, laboratory data, clinical background and presentation as well as therapeutic strategies was established. Follow-up of the patients has been performed by queries of long-term outcome.

Results: Altogether 151 CUA patients have been documented during 5.5 yrs: 60% female; median age 68 yrs (range 21 – 89); 78% dialysis patients. PTH levels were overall low with 54% below 150 pg/mL. Oral anticoagulation with coumadins was common among all patients (45%). Cutaneous lesions were typically localized at the lower extremities or gluteal region (> 80%). Median survival time after registry notification was 516 days. Both serum fetuin-A and MGP levels were significantly lower in CUA dialysis compared to non-CUA dialysis pts. Treating physicians commonly applied i.v. sodium-thiosulfat three times per week, which influenced survival insignificantly (uncontrolled intervention; Kaplan-Meier analysis).

Conclusions: CUA is a rare disease among ESRD pts which increases mortality. PTH levels vary substantially but do not exceed current KDIGO target levels in most cases. Decisions on therapeutic strategies also vary significantly among centers. The present internet based ICCN registry is a valuable tool to collect data upon CUA cases and may become a basis for prospective systematic evaluations of treatment modalities in the near future.

Serum Sclerostin Levels and Clinical Outcomes in Incident Dialysis Patients: Results from the NECOSAD Study Vincent Brandenburg,[1] Marc G. Vervloet,[4] Friedo W. Dekker,[4] Markus Ketteler,[3] Johanna Van den Broek,[4] Christiane Drechsler.[2] *[1]Cardiology, RWTH University Hospital Aachen, Aachen, Germany; [2]Nephrologie, Universität Würzburg, Würzburg, Germany; [3]Nephrology, Klinikum Coburg, Coburg, Germany; [4]Nephrology, VU Medical Center, Amsterdam, Netherlands.*

Background: Sclerostin is Wnt pathway antagonist which regulates osteoblast activity and bone turnover. Sclerostin offers interesting perspectives as novel biomarker for CKD-MBD. The present study tests the hypothesis that serum sclerostin levels may be associated with outcome in incident dialysis patients.

Methods: We used data from a prospective cohort study of incident dialysis patients (NECOSAD). All patients for whom serum analysis for sclerostin was available at three months after initiation of dialysis (baseline) were included (n= 362, age = 63±14 yrs; 59% males, 93% hemodialysis). Serum sclerostin was assessed by TECO® Sclerostin EIA Kit. Based on the median of serum sclerostin (1.10 ng/mL) the pts were stratified into two groups for statistical analysis. Cumulative mortality curves were calculated using Kaplan-Meier analysis for all-cause mortality and we calculated Cox proportional hazard ratios (HR) with 95% confidence intervals to assess the impact of sclerostin upon mortality.

Results: Median serum sclerostin levels were similar between PD pts (1.12 ng/mL) and HD pts (1.10 ng/mL). There was a negative correlation to PTH levels (Spearman corr. coeff. r= -0.22 p<0.001) and bone alk phos (r= -0.19, p<0.001) at baseline in the entire cohort. After 3 yrs of FU, 31% of the pts had died. After adjustments for potential confounders including age, sex, dialysis modality and primary kidney disease, there was no significant difference in terms of survival between the two groups with a trend for better survival for those pts with higher serum sclerostin (HR 0.79, 95% CI 0.54 to 1.16).

Conclusions: Serum sclerostin levels in incident dialysis patients were negatively correlated to biomarkers for bone metabolism (PTH, BAP) supporting its role as bone-suppressive factor also in ESRD. In the NECOSAD cohort, there was a trend for improved survival over 3 yrs with higher baseline serum sclerostin levels at three months after start of dialysis.

TH-PO880

Acetylsalicylic Acid, an Antiplatelet Agent Prevents Arterial Calcification in Chronic Kidney Disease: An Old Drug for a New Application Tzong-Shi Lu,[1] Kenneth Lim,[1,2] Daniel Zehnder,[2] Li-Li Hsiao.[1] *[1]Renal Division, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [2]Clinical Sciences Research Institute, Warwick Medical School, Coventry, United Kingdom.*

Background: Vascular calcification (VC) is a significant contributor to cardiovascular mortality in patients with chronic kidney disease and coronary artery disease. Aspirin, also known as acetylsalicyclic acid (ASA) is a widely used antiplatelet medication. However, the role of ASA in the development of VC is unknown. Our preliminary data showed that inducible heat shock protein 72 (HSP72) prevents VC. Previous reports suggested that ASA

can induce HSP72 expression. We postulate that ASA may exert cardio-protective effects by stabilizing smooth muscle cell phenotype and inhibiting mitochondrial dysfunction through the induction of HSP72.

Methods: *In vitro* long-term calcification model: human aortic smooth muscle cells (HA-SMCs) treated with calcification medium (CM) containing 5mM $CaCl_2$ and 5mM β-glycerophosphate for 21 days. ASA treatment: 4mM, daily.

Results: We have shown that ASA significantly inhibited the development of VC through the induction of HSP72 in our long-term vascular calcification model, in vitro. Furthermore, anti-calcific effects of ASA were abolished by HSP72 SiRNA. Similar observations were found using heat shock treatment, an established HSP72 inducer, as a control. We next showed that by inducing HSP72, ASA suppressed Runx2, Osteocalcin and Alkaline Phosphatase, major osteogenic regulators involved in the initiation and progression of VC. ASA also restored myocardin and serum response factor (SRF), regulators of HA-SMC contractile genes. In addition, ASA treated HA-SMCs under CM stress had preserved JC-1 complex, indicating stabilization of mitochondrial membrane potential.

Conclusions: ASA inhibits VC through a HSP72-dependent pathway by inhibiting osteogenic transformation and stabilizing smooth muscle cell contractile phenotype. Furthermore, its anti-calcific effects may be associated with stabilization of mitochondrial membrane potential. We suggest treatment strategies involving ASA or other inducers of HSP72 as a new approach to inhibit VC.

TH-PO881

Study on the Function of Nrf2 in Vascular Calcification in ESRD Li Wang. *Renal Department, Sichuan Academy of Medical Sciences & Sichuan Provincial People's Hospital, Chengdu, Sichuan, China.*

Background: Advanced glycation end-products were reported to be a cause of oxidative stress. Nrf2 was a defensive factor against ROS and inflammation in vascular smooth cells. The role of AGEs and its induction of oxidative stress in vascular calcification remains unclear. So the objectives were to explore the relationship between oxidative stress caused by Nrf2 of AGEs-RAGE signaling pathway and vascular calcification.

Methods: 29 ESRD patients were enrolled and samples of radial arteries were taken during the arteriovenous fistula surgery. Six patients with upper extremity injuries and normal renal function were enrolled as control with samples of internal radial artery taken in the operation. The vessels were examined for calcification by alizarin red staining and for the presence of bone matrix protein (osteopontin,OPN), marker of antoxidative stress (nuclear factor erythroid-2-related factor2,Nrf2), marker of oxidative stress(malondialdehyde-LDL, MDA-LDL), Runx2, SM22α, and receptor for advanced glycation end products(RAGE) by immunohistochemistry. Plasma dvanced glycation end products (AGEs) were measured. Relationship between vascular calcification and other markers and clinical parameters including gender, age, BMI, Cr, HB, PTH, Ca, P, ALP, ALB, CHOL, hs-CRP and so on were analyzed.

Results: Vascular calcification was found in the media of the vessels of 15 uremic patients, while none in the controls. OPN, MDA-LDL, RAGE and Runx2 expressed in the vessels and plasma levels of AGEs of uremic patients were significantly higher than those in the control, while Nrf2 and SM22α expressed in patients with ESRD was significantly lower than those in the control($P<0.01$). Pearson correlation analysis showed that the degree of calcification positively correlated with plasma AGEs($r=0.838$, $P<0.001$), MDA-LDL($r=0.922$, $P<0.001$), RAGE($r=0.911$, $P<0.001$), Nrf2($r=-0.711$, $P<0.001$), plasma phosphate($r=0.623$, $P=0.001$), serum iPTH($r=0.398$, $P=0.032$), age($r=0.591$, $P=0.001$), and duration of dialysis ($r=0.437$, $P=0.018$).

Conclusions: Decreased Nrf2 which expressed in the vessels were found in patients with ESRD, the Nrf2 levels were closely related to vascular calcification which maybe induced by AGEs-RAGE signal transmission.

TH-PO882

L-Lysine Ameliorates Vascular Calcification in Adenine-Induced Uremic Rats Akihiro Shimomura,[1] Isao Matsui,[1] Takayuki Hamano,[2] Kazunori Inoue,[1] Yoshitsugu Obi,[1] Chikako Nakano,[1] Yasuo Kusunoki,[1] Yoshiharu Tsubakihara,[2] Hiromi Rakugi,[1] Yoshitaka Isaka.[1] *[1]Department of Geriatric Medicine and Nephrology, Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [2]Department of Comprehensive Kidney Disease Research, Osaka University Graduate School of Medicine, Suita, Osaka, Japan.*

Background: Vascular calcification (VC) is common in patients with chronic kidney disease (CKD) and is associated with increased cardiovascular morbidity and mortality. Although numerous studies have revealed the pathogenic mechanism of VC, it still remains unresolved, and satisfactory therapies have not been established. Price et al. reported that low protein diet exacerbates VC in adenine-induced uremic rats Kidney Int. 2006;70(9):1577-83]. We hypothesized that insufficiency of some amino acids worsened VC in this model. Because L-lysine is the first-limiting amino acid in most of cereal grains, we examined whether L-lysine supplementation ameliorates VC.

Methods: Male Sprague-Dawley rats at age 13 weeks were divided randomly into four groups; low protein (LP) diet (group LP), LP diet + 0.75% adenine (group Ade), LP diet + 0.75% adenine + 2.5% glycine (group Gly), or LP diet + 0.75% adenine + 2.5% L-lysine•HCl (group Lys). Glycine, the simplest amino acid was served as control.

Results: At age 18 weeks, rats in group LP showed no VC, whereas those in groups Ade and Gly exhibited comparable levels of severe VC. L-lysine supplementation almost completely ameliorated VC. Body weight, food intake, water intake, serum levels of creatinine, urea nitrogen, and phosphate were not different among groups Ade, Gly, and Lys. Intriguingly, serum calcium level in group Lys was slightly but significantly higher than those of groups Ade and Gly. To investigate the underlying mechanism for VC-prevention, we performed in vitro analysis and found that L-lysine, but not glycine, dose-dependently attenuates spontaneous precipitation of minerals in a solution of supersaturated calcium/phosphate.

Conclusions: L-lysine ameliorated vascular calcification in adenine-induced uremic rats. Our findings provide a novel approach for the treatment of VC in CKD.

TH-PO883

Hemodialysis Reduces the Calcification Propensity of Serum Andreas Pasch,[1,2] Stefan Farese,[1,2] Georg Schlieper,[3] Jürgen Floege,[3] Dominik E. Uehlinger,[1] Willi Jahnen-dechent.[2] *[1]Department of Nephrology and Hypertension, University Hospital Bern, Inselspital, Bern, Switzerland; [2]Biomedical Engineering, Biointerface Laboratory, RWTH Aachen University, Aachen, Germany; [3]Department of Nephrology, RWTH University of Aachen, Aachen, Germany.*

Background: Vascular and soft tissue calcification is a major cause of death in hemodialysis (HD) patients.We have developed an in vitro test, which measures serum calcification propensity by detecting the spontaneous transformation of colloidal primary calciprotein particles (CPPs) to crystalline secondary CPPs. The effect of hemodialysis on serum calcification propensity has not been determined yet.

Methods: The intrinsic calcification propensity of pre- and post-HD sera obtained from 98 prevalent HD patients were analyzed with our novel nephelometry test. Calcium, phosphate, magnesium, fetuin-A, albumin, and total protein concentrations were related to the test results and integrated into a multivariate model with stepwise selection.

Results: HD treatment reduced serum calcification propensity by delaying transformation time (T_{50} pre-HD 244 ± 112 min., post-HD 340 ± 114 min., $p < 0.0001$) and reducing precipitation intensity (relative nephelometric units, RNU_{50} pre-HD 6892 ± 2404, post-HD 5234 ± 1789, $p < 0.0001$). A multivariate model showed, that the T_{50} of pre-HD sera depended mainly on magnesium (transformation delay, $p < 0.0001$) and fetuin-A (delay, $p < 0.0001$), and the HD-induced delay of T_{50} on phosphate (acceleration, $p < 0.0001$), magnesium (delay, $p = 0.0094$) and fetuin-A (delay, $p < 0.0001$) serum concentrations. In contrast, the reduction of precipitation intensity RNU_{50} induced by HD depended on the change of the total serum protein concentration ($p = 0.0407$), which was closely correlated to the albumin and fetuin-A concentration changes induced by HD ($p < 0.0001$). Calcium concentrations did not contribute significantly to the test results.

Conclusions: HD vastly improves the intrinsic calcification propensity of patient sera, with phosphate, magnesium and fetuin-A as major influencing factors. Monitoring serum-inherent calcification propensity may help improve morbidity and mortality of HD patients in the future.

TH-PO884

Chronic Kidney Disease Leads to Osteogenesis and Calcification of Intraperitoneally Transplanted Mesenchymal Stem Cells in Rats Rafael Kramann,[1,2] Rebekka K. Schneider,[2] Vincent Brandenburg,[3] Barbara Mara Klinkhammer,[1] Uta Kunter,[1] Jürgen Floege.[1] *[1]Nephrology, RWTH University, Aachen, Germany; [2]Pathology, RWTH University, Aachen, Germany; [3]Cardiology, RWTH University, Aachen, Germany.*

Background: Once considered as a passive process, vascular calcification has emerged as a tightly regulated, coordinated and osteoblastic process resembling bone morphogenesis. Executive cell types familar to bone biology are seen in calcified vasculature. As osteoblasts, smooth muscle cells, adipocytes, fibroblasts and chondrocytes all share a common mesenchymal progenitor stem cell (MSC), the present study is based on the hypothesis that MSC contribute to vascular calcification and ectopic osteogenesis in chronic kidney disease (CKD).

Methods: Rat MSC were intraperitoneally transplanted in an established 3D collagen-based model of the vascular wall in healthy control animals (n=12) and two rat models of CKD and vascular calcification: a) 5/6 nephrectomy + high phosphorus diet b) adenine nephropathy (n=18 each). As internal controls, collagen gels without MSC were transplanted in the same animals.

Results: After 4 and 8 weeks, MSC were still detectable and proliferating in the collagen gels (FACS analysis and confocal microscopy after PKH26-labelling prior to implantation). Aortae and MSC-containing collagen gels in the CKD animals showed distinct similarities in calcification (von Kossa-staining, micro-computed tomography, EDX analysis, calcium content measurement) and up-regulation of osteogenic markers as BMP-2, Runx2, ALP and the osteocytic marker sclerostin. An equivalent extracellular matrix (ECM) remodelling process occurred in both the aortae and the heterotopically implanted MSC in CKD with up-regulation of osteopontin, collagen I/III/IV, fibronectin and laminin. Neither calcification nor osteogenesis or matrix remodelling were observed in healthy control animals and non-MSC containing collagen gels of all groups.

Conclusions: CKD induced similar calcification, osteogenesis and ECM remodelling in the vascular wall and heterotopically implanted MSC supporting our hypothesis of MSC as critical cells in heterotopic calcification processes of CKD patients.

TH-PO885

The Responsiveness of Serum Calcium Level on Soluble Klotho in CKD Patients Ichiro Ohkido, Keitaro Yokoyama, Yukio Maruyama, Tatsuo Hosoya. *Division of Nephrogy and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan.*

Background: The extracellular domain of Klotho is cleaved and released into various extracellular fluids, such as blood, urine, and cerebrospinal fluid, as circulating soluble Klotho (sKlotho). Circulating sKlotho might be a biologically active molecule. However, there are few reports concerning sKlotho level in human.

Methods: we measured sKlotho using enzyme-linked immunosorbent assay kits in 157 CKD patients (CKD1-CKD5=109, CKD5D=48) to examine its role in CKD-MBD.

Results: The sKlotho level of the CKD patients without dialysis patients was 654 pg/mL (280-1777 pg/mL), which was higher than that of hemodialysis patients 430 pg/mL (386-540 pg/mL). In single regression analysis, the serum sKlotho level showed a positive correlation with serum corrected Calcium (cCa) (rho=0.22, P<0.05) and eGFR (rho=0.27, P<0.01), while serum phosphorus (Pi) tended to be negatively correlated with sKlotho (rho=-0.34, P<0.01) and intact-PTH (rho=-0.21, P<0.05). However, there was no significant association between serum sKlotho and age or FGF23. Multiple regression analysis showed that cCa was independently associated with the serum sαKl levels (P=0.05) in CKD patients without dialysis, on the other hand, in CKD 5Dpatients, Pi was independently associated with the serum sKlotho levels (P<0.05). In CKD patients without dialysis, the positive correlation between serum sKlotho level and cCa level in single regression analysis should be recognized as renal function. However those also were found in multiple regression analysis.

Multiple regression model for circulating sKlotho (log-normalized)

Variable	Regression Coefficient	Standard error	t value	95% Confidence Interval	p value
Male gender	0.118	0.0663	1.78	-0.0139 to 0.249	0.08
Age	-0.000351	0.00217	-0.16	-0.00466 to 0.00396	0.87
eGFR	0.000914	0.00122	0.75	-0.00151 to 0.00334	0.46
Collected Ca	0.105	0.044	1.92	-0.00332 to 0.212	0.05
Pi	-0.0432	0.0266	-1.62	-0.0960 to 0.00970	0.11
intact PTH	0.000463	0.000323	1.43	-0.000178 to 0.00110	0.16

total adjusted R2=0.30, P=0.01

Conclusions: These results might indicate that the responsiveness of calcium on sαKl impair in CKD status. Soluble Klotho may thus plays a role in CKD/MBD.

TH-PO886

Circulating Sclerostin Levels and Vascular Calcification in Chronic Kidney Disease: A Complex Relationship Kathleen Claes,[1] Liesbeth Viaene,[1] Sam Heye,[1] Bjorn Meijers,[1] Patrick C. D'Haese,[2] Pieter Evenepoel.[1] *[1]Nephrology, University Hospitals Leuven, Leuven, Belgium; [2]Laboratory of Nephrology, University Antwerp, Antwerp, Belgium.*

Background: Sclerostin, a Wnt antagonist, regulates osteoblast activity and is a key player in bone turnover. The Wnt pathway may also play an important role in the process of vascular calcification. We tested the hypothesis that serum sclerostin levels are associated with vascular calcification in patients with chronic kidney disease (CKD) not yet on dialysis.

Methods: 154 CKD patients were recruited from an observational study evaluating the natural history of mineral metabolism. Aortic calcification (AC) was assessed by lumbar X-ray and scored according to Kaupilla. In addition to traditional and non-traditional risk factors, serum sclerostin levels were measured (ELISA, Tecomedical). Regression analysis was performed to identify determinants of serum sclerostin levels and AC.

Results: AC was present in 59% of patients. Patients with AC had higher sclerostin levels. Higher age (p <0.0001), male gender (p= 0.004), and lower eGFR (0.004) were independent determinants of higher serum sclerostin levels. In univariate logistic regression, age, diabetes, cardiovascular history, BMI, serum CRP and sclerostin were all directly associated with the presence of AC, whereas eGFR was inversely associated. However, in multivariate analysis lower, not higher, sclerostin levels (p=0.04; OR per ng/ml decrease 0.237), higher age (p<0.0001, OR per year increase 1.172) and cardiovascular history (p=0.02,OR for a positive cardiovascular history 3.83) were identified as independent determinants of AC.

Conclusions: In CKD patients not yet on dialysis we found that patients with aortic calcifications had higher sclerostin levels. However, in multivariate analysis we observed an inverse association between sclerostin and aortic calcification. We speculate that extraskeletal sclerostin may contribute significantly to circulating levels and may be part of a local feedback suppressing further progression of vascular calcification. Additional clinical and experimental studies are required to elucidate whether or not sclerostin protects against progression of vascular calcification.

TH-PO887

Changes in Skeletal Osteopontin Expression Occur in Response to Skeletal Mineralization R.C. Pereira,[1] Harald Jüppner,[2] Isidro B. Salusky,[1] Katherine Wesseling-Perry.[1] *[1]Pediatrics, David Geffen School of Medicine at UCLA, Los Angeles, CA; [2]Endocrine Unit, Harvard Medical School and Massachusetts General Hospital, Boston, MA.*

Background: Defects in skeletal mineralization persist in pediatric ESKD despite suppression of bone turnover with active vitamin D sterols. OPN, a mineralization inhibitor, is regulated by $1,25(OH)_2D$. However, the effect of active vitamin D on skeletal OPN and its relationship to skeletal mineralization are unknown.

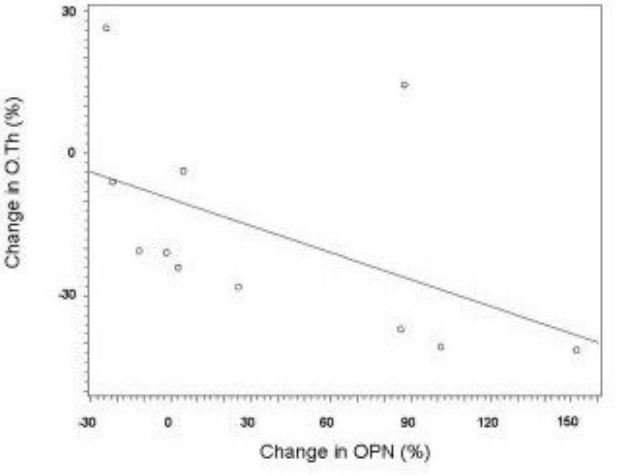
Methods: 11 ESKD pts (7M, 4F), age 16 ± 1 years, underwent BBx before and after 8 months of active vitamin D therapy. OPN protein expression was assessed in undecalcified bone by immunohistochemistry and quantified by Ariol scanning. Biochemical values were obtained at the time of BBx.

Results: Biochemical values and OPN expression remained unchanged during therapy, while osteoid accumulation decreased.

	Pre	Post
Biochemicals		
Calcium (mg/dl)	8.6 ± 0.2	8.8 ± 0.2
Phosphorus (mg/dl)	6.3 ± 0.4	6.0 ± 0.4
Alk p'tase (IU/l)	298 (146, 488)	175 (124, 414)
PTH (pg/ml)	517 (378, 1048)	559 (375, 922)
FGF23 (RU/ml)	705 (318, 1196)	1696 (565, 3973)
Bone Histomorphometry and Osteopontin Expression		
BFR/BS (um3/mm2/d)	50.0 ± 10.4	30.4 ± 7.5
OV/BV (%)	7.0 ±1.1	4.4 ± 0.8*
O.Th (um)	12.7 ± 0.9	10.2 ± 0.6*
OS/BS (%)	41.1 ± 3.9	31.7 ± 3.8*
OMT (d)	15.3 ± 1.4	14.6 ± 2.1
MLT (d)	28 (24, 47)	36 (30, 46)
BV/TV (%)	37.2 ± 3.7	36.1 + 2.7
Tb.Th (um)	173 ± 19	159 ± 6
OPN (pixels/mm2)	22,823 ± 3,969	26,300 ± 2,549

*p<0.05 from baseline

OPN correlated with osteoid accumulation (OV/BV: r= - 0.44, o<0.05; OS/BS: r= - 0.46, p<0.05; O.Th: r= - 0.39, p=0.07) and changes in O.Th were inversely related to changes in OPN expression (r= -0.65, p<0.05).



Conclusions: Skeletal OPN expression increases in response to mineralization. Whether OPN can be used as a target for therapies directed at healing mineralization defects remains unknown.

TH-PO888

Circulating and Bone Sclerostin Expression in Peritoneal Dialysis Patients Rodrigo Azevedo de Oliveira,[1] Fellype Carvalho Barreto,[1,2] Monique Mendes,[1] Juliana C. Ferreira,[1] Luciene M. dos Reis,[1] Fabiana G. Graciolli,[1] Rosa M.A. Moyses,[1] Vanda Jorgetti.[1] *[1]Nephrology, Universidade de São Paulo, São Paulo, SP, Brazil; [2]Medicine, Health Science, Universidade Nove de Julho, São Paulo, SP, Brazil.*

Background: Sclerostin (SOST) is a soluble inhibitor of wnt signaling, produced by osteocytes, that inhibits osteoblast function. Previous studies have shown that SOST is increased in hemodialysis, as well as in predialysis patients. Trying to elucidate the role of SOST in peritoneal dialysis (PD) patients, this study sought to investigate the association between circulating and bone SOST expression with biochemical and bone histomorphometric parameters in this population.

Methods: In this cross-sectional study, thirty PD patients (50% male; 49 ± 10.4 years; mean length on PD: 19 months) were submitted to an iliac crest bone biopsy followed by histomorphometric analyses. Levels of circulating SOST, iPTH, 25(OH)vitamin D and other biochemical markers of mineral metabolism were analyzed. Bone expression of SOST was evaluated by imunohistochemistry.

Results: Serum SOST was increased in PD patients, and correlated with age, iPTH and alkaline phosphastase (r = 0.63, -0.44 and -0.48, respectively; p< 0.05 for all). Higher serum SOST was found in patients with lower trabecular bone volume [BV/TV (2.56±0.92 vs 1.74 ± 0.75 ng/ml in those with normal BV/TV; p=0.02). We also found significant differences between those patients with low bone turnover in comparison with high bone turnover (2.46±0.76 vs 1.58 ± 0.78 ng/ml; p=0.009). Furthermore, serum levels of SOST were negatively associated to osteoblast surface, osteoid thickness, mineralizing surface and bone formation rate (r = -0.68 -0.66, -0.59, -0.58, respectively; p<0.05). Regarding the bone expression of SOST, it was higher in PD patients compared to normal subjects (65.6 ± 44.3 vs 24.6 ± 18.4 ng/ml; p= 0.02) and negatively associated to bone formation rate (r =-0.41; p <0.05).

Conclusions: Serum levels of SOST are increased in PD patients, as well as its bone expression. Our data confirms SOST as a biochemical marker of bone volume and formation. The role of SOST in the pathogenesis of CKD-MBD, by affecting bone structure and turnover, remains to be determined.

Funding: Government Support - Non-U.S.

TH-PO889

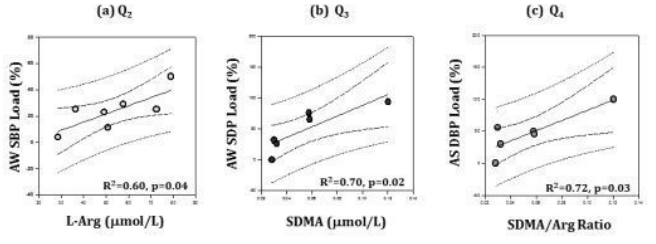
CKD-MBD in Children: Mineral and Vascular Inter-Relationships Are Mediated by FGF23 Ellen Brooks, Craig B. Langman, Heather E. Price, Nisa Desai, Neziha Celebi. *Pediatric Kidney Diseases, Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: ↑FGF23 is the 1st hormonal change of CKD-MBD producing ↓ of both Pi reabsorption (%TRP) & $1,25(OH)_2D_3$ [1,25D] synthesis. Ca dynamics change too, with ↓bone balance & ↑vascular calcification & dysfunction. We studied these relationships in pediatric CKD using biomarkers.

Methods: We collected cross-sectional data on 28 pts (CKD stage 1-4; Mean±SD eGFR=40.9±13.7 ml/min/1.73m^2; Age=12.3±3.9y) & 10 healthy sibling controls (C) & measured Pi, intact PTH (*i*PTH), c-terminal FGF23, & bone markers: OPG, RANKL, TRAP, BALP. Vascular factors included were plasma methylated arginine derivatives (MADs) [L-Arg, ADMA & SDMA]. 24-hr ambulatory BP (ABP) for awake (AW) & asleep (AS) BP loads was measured. Data were log transformed & analyses completed using Student's T test, Spearman Rank Correlation & Linear Regression.

Results: CKD had ↑FGF23 v C (148±196 v 29±25 RU/mL; p=0.004). Inverse correlations in the highest CKD FGF23 quartile ($FGF23Q_4$) were with %TRP (r= -0.86,p=0.006) & OPG/RANKL ratio (r= -0.88, p=0.03). Other associations included [CaxPi] & eGFR (r =-0.75,p=0.040), *i*PTH & [L-Arg] (r= -0.90, p=0.02), Pi & Arg/ADMA ratio (r= -0.94, p=0.02), BALP & TRAP (r=0.89, p=0.03) & %TRP with OPG/RANKL ratio (r=0.94, p=0.02). In Q_4 regression models, [L-Arg] explained 83 & 99% of TRAP & BALP variability (p=0.01; p<0.001), respectively. In Q_4, FGF23 & 1,25D explained 42% of CKD [CaxPi] variability in stepwise regression (p=0.003; 0.03). For ABP, $FGF23Q_3$-Q_4 had ↑AW SBP loads v C & $FGF23Q_4$ had ↑AS SBP & DBP loads v C (p<0.05-0.008). $FGF23Q_2$-$Q_4$24 hr ABP loads correlated with MADs.

Figure 1a-c. ABP Loads Explained By MADs in Quartiles of CKD-FGF23 Q_2-Q_4



Conclusions: Taken together our findings suggest a coordinated activation of CKD-MBD mechanisms of bone loss & vascular dysfunction in children with moderate CKD through upregulation of FGF23.

Funding: Private Foundation Support

TH-PO890

A Cross-Sectional Chronic Kidney Disease-Mineral and Bone Disorder in MHD Patients Hong Daqing, Li Wang, Pu Lei. *Renal Department, Sichuan Provincial People's Hospital, Chengdu, Sichuan, China.*

Background: As risk factors for cardiovascular disease in maintenance hemodialysis (MHD) patients, CKD-MBD has become a challenge for nephrologists. It's important to find out prevalence, risk factors and treatment status of mineral disorders, and it's the objective for this study.

Methods: 217 MHD patients were enrolled from July, 2010 to March, 2011 with a questionare, serum biochemistry, X-ray, pulse wave velocity (PWV), ankle-brachial index (ABI), and coronary artery CT taken. Prevalence of CKD-MBD and its components were analyzed, single and multiple logistic regression was applied to study the risk factors. Relationship between different techniques for vascular calcification (VC) were analyzed.

Results: The prevalence of hyperphosphatemia, hypophosphatemia, hypercalcemia, hypocalcemia, decreased PTH and elevated PTH was 45.16%, 10.14%, 31.80%, 21.66%, 20.74% and 48.39% respectively (Figure 1~3). Patients in biochemistry treatment targets were only 9.22%. 71% patients had VC by X-ray (Figure 4). 96.31% patients was diagnosed CKD-MBD by biochemistry abnormalities, VC or combination of both. Risk factors for VC were old age, serum ALP, hyperphosphatemia and high level of CRP.

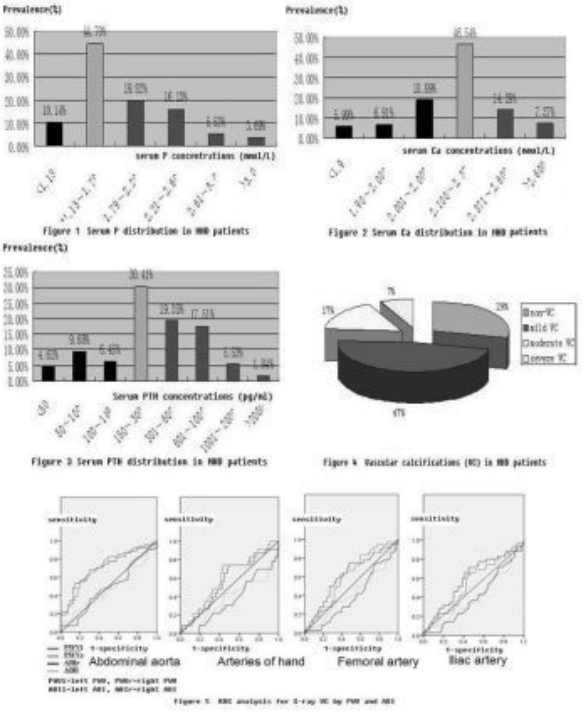
Table 1 Risk factors for vascular calcifcation in MHD patients

Parameters	ß	OR	95% CI	p
Age (year)	0.117	1.124	1.003-1.260	0.045
ALP(mmol/L)	0.026	1.026	1.001-1.052	0.040
P(mmol/L)	1.283	3.608	1.033-12.598	0.044
CRP(mg/L)	0.557	1.745	1.060-2.874	0.029

PWV correlated better than ABI in diagnosis of VC by X-ray (Figure 5). Iliac and femoral showed best correlation with coronary artery calcification in 36 MHD patients (table 2).

Table 2 Various and combined parts of the X-plain film of two categorical variables mode (ie, calcification or without) and CACs ≥ 100

	OR	*P*	sensitivity	specificity
Illiac artery	12.250	0.007	91.30%	53.85%
Femoral artery	8.556	0.015	60.87%	84.62%
Abdominal aorta	5.714	0.036	86.96%	46.15%
Radial artery	1.778	0.467	34.78%	76.92%
Finger artery	1.158	0.877	17.39%	84.62%



Conclusions: Prevalence of CKD-MBD in MHD patients is high. Risk factors for VC are old age, serum ALP, hyperphosphatemia and CRP. PWV is better than ABI in diagnosis of VC. Femoral and iliac X-ray may be better than lateral abdominal X-ray as a subsitute for coronary artery calcification evaluated by CT.

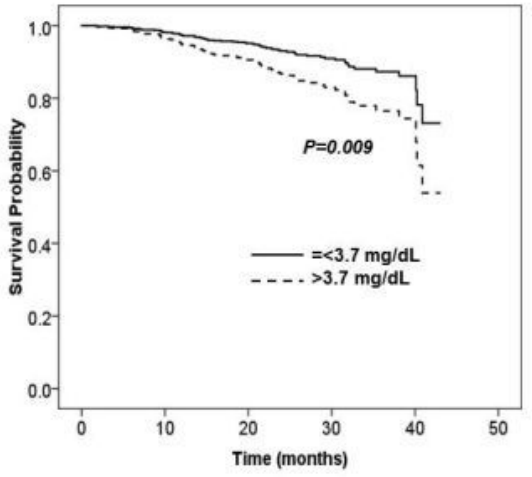
Mineral Metabolism and Outcomes in Predialysis Chronic Kidney Disease Sinee Distha-Banchong, Kotcharat Vipattawat, Arkom Nongnuch. *Division of Nephrology, Department of Medicine, Faculty of Medicine, Ramathibodi Hospital, Mahidol University, Phayathai, Bangkok, Thailand.*

Background: Marked hyperphosphatemia and hyperparathyroidism and 25-hydroxyvitamin D deficiency are known to predict mortality in dialysis patients. Less data is available in predialysis chronic kidney disease (CKD) population. It was suggested that high-normal serum phosphate might be associated with worse renal and patient outcomes. The data regarding PTH in the predialysis population is limited.

Methods: The present study examined the abnormalities of mineral metabolism and their associations with the development of end-stage renal disease (ESRD) and mortality in 446 predialysis CKD patients. Mineral parameters were obtained from all patients and the patients were followed prospectively for 25 (1-44) months or until they reached the endpoints of ESRD or mortality.

Results: Hyperparathyroidism and 25-hydroxyvitamin D deficiency occurred since CKD stage 2, whereas significant hyperphosphatemia only developed in CKD stage 4 or later. Increasing serum phosphate (>3.7 mg/dL) and PTH (>42 pg/mL) despite being within the normal ranges were associated with the development of ESRD and the composite outcomes of ESRD and mortality after adjustments with cardiovascular risk factors and other mineral parameters (Figure 1). 25-hydroxyvitamin D deficiency (<15 ng/mL) was also associated with worse outcomes.

Figure 1. Adjusted survival curves for serum phosphate



Conclusions: In the course of CKD, hyperparathyroidism developed prior to significant hyperphosphatemia confirming the presence of a state of phosphate retention since the early CKD period. The associations between the increasing serum phosphate and PTH, despite the values being within the normal limits, and worse renal and patient outcomes emphasized the need for early intervention in the care of CKD patients.

TH-PO892

Osteoprotegerin Replaces Coronary Artery Calcification Score as a Predictor of Incident Cardiovascular Events in Diabetic Chronic Kidney Disease Chikako Nakano,[1] Takayuki Hamano,[2] Naohiko Fujii,[3] Yoshitsugu Obi,[1] Isao Matsui,[1] Kazunori Inoue,[1] Akihiro Shimomura,[1] Yasuo Kusunoki,[1] Yoshiharu Tsubakihara,[2] Hiromi Rakugi,[1] Yoshitaka Isaka.[1] *[1]Geriatric Medicine and Nephrology, Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [2]Comprehensive Kidney Disease Research, Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [3]Internal Medicine, Hyogo Prefectural Nishinomiya Hospital, Nishinomiya, Hyogo, Japan.*

Background: Coronary artery calcification score (CACS) was reported to predict cardiovascular disease (CVD). However, CACS has several disadvantages, such as radiation exposure and inconvenience. Our aim was to identify a more readily-measurable predictor of CVD among vascular calcification-related factors: osteoprotegerin (OPG), fibroblast growth factor 23, fetuin-A, and fetuin mineral complex (FMC).

Methods: This is a prospective cohort study of 97 diabetic outpatients with chronic kidney disease (CKD). CACS was measured by multi-detector computed tomography. The endpoint was a fatal/non-fatal CVD requiring hospitalization. Multiple imputation method was performed for missing values. After confirming that CACS predicted CVD with adjustment for conventional risk factors, further adjustment for which biomarker changed the coefficient of CACS by ≥15% was scrutinized in Cox models. We compared model performance between models with that biomarker or CACS by computing C-statistics, Bayesian information criterion, net reclassification improvement, and integrated discrimination improvement.

Results: Median estimated GFR was 25 mL/min/1.73m^2. During a median follow-up period of 5.0 years, 32 patients reached the endpoint. At baseline, only OPG and FMC were related to CACS. CACS predicted CVD after adjusting for conventional risk factors. Among 4 factors, only further adjustment for OPG changed the coefficient of CACS by ≥15%. The effect size was higher for OPG than for CACS (hazard ratios of CACS and OPG, 4.34 [1.07-17.6] and 18.1 [2.60-125] in the highest vs. lowest quartile, respectively). Model performance was better for the model with OPG than that with CACS.

Conclusions: In diabetic patients with CKD, OPG is more useful than CACS in predicting incident CVD.

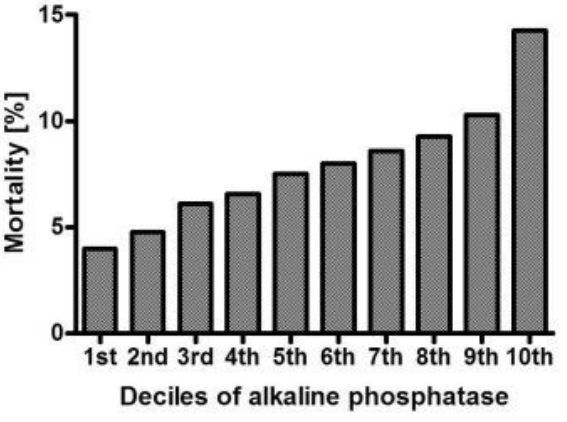
TH-PO893

A Higher Serum Alkaline Phosphatase Is Associated with Increased Mortality among Patients Receiving Hemodialysis in Japan Yukio Maruyama,[1] Keitaro Yokoyama,[1] Takashi Shigematsu,[2] Masatomo Taniguchi,[3] Junichiro J. Kazama,[4] Tatsuo Hosoya.[1] *[1]Division of Kidney and Hypertension, The Jikei University School of Medicine, Tokyo, Japan; [2]Division of Nephrology and Blood Purification Medicine, Wakayama Medical University, Wakayama, Japan; [3]Department of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; [4]Division of Blood Purification Therapy, Niigata University Medical and Dental Hospital, Niigata, Japan.*

Background: The monitoring of serum alkaline phosphatase (ALP), a biochemical marker of bone turnover, is widely recommended in the management of chronic kidney disease-mineral and bone disorder (CKD-MBD). However, unlike calcium, phosphate, or parathormone, the relationship between serum ALP and mortality of the patients receiving hemodialysis (HD) in Japan is unknown.

Methods: We collected the baseline data of 187,792 patients receiving HD thrice weekly (66 ± 12 years, 116,314 males, and median HD vintage of 7.9 years) extracted from a nationwide dialysis registry at the end of 2009 in Japan. Then we evaluated the patient survival using the registry at the end of 2010.

Results: A rise in baseline serum ALP was incrementally associated with increasing death risk (Figure 1), and a receiver operating characteristic (ROC) curve revealed that the sensitivity was 57% and the specificity was 58% when a serum ALP of 253 IU/L was taken as the cut-off value.



In a multiple logistic regression analysis including serum ALP, Ca, P, PTH, medication and comorbidity, higher serum ALP was independently associated with increased mortality.

Conclusions: In this large observational cohort study, higher levels of serum ALP were independently associated with increased mortality among HD patients. Close monitoring of serum ALP may be useful for consideration of the therapy for CKD-MBD.

TH-PO894

Relationship of Bone-Specific Alkaline Phosphatase to Parathyroid Hormone in Hemodialysis Patients Ghassan Bandak, Beth Adams, Meredith Mahan, Anatole Besarab. *Henry Ford Hospital, Detroit, MI.*

Background: Metabolic bone disease (MBD) is common in patients with chronic kidney disease (CKD) and is a major source of morbidity and mortality in this patient population. Control of parathyroid hormone (PTH) levels is a major aspect in managing MBD. Reliability of PTH assays has been questioned. Other markers of bone disease have been suggested to help with MBD management, such as alkaline phosphatase (ALP) and bone specific ALP (bSAP). We therefore assessed the relationship of PTH to bSAP and ALP levels over a period of one year in which MBD management depended chiefly on active vitamin D therapy with only a small subset receiving a calcimimetic.

Methods: 251 prevalent HD patients as of March 2011 had measurements made of serum ALP, bSAP, total calcium (Ca), and ionized calcium (Ca2+), phosphorus (P) and PTH levels every 3 months using methods available at Spectra Laboratories over a period of 9 months. Most patients had 4 measurements. All patients in our unit were included to avoid selection bias.

Results: The population was predominantly Afro-American. At the first time point The PTH averaged 611±450 (±SD), the bSAP 38.6±35.1, P 4.8±1.4, Ca 8.9±0.8, Ca2+ 4.8±0.5. These remained unchanged over the next 9 months except for bSAP which decreased to 25±17 and as a percent of ALP from 32 to 23%. bSAP was strongly significantly correlated to ALP at all time points (r=0.75 to 0.83, p<0.001). Moderate correlations of bSAP to PTH, (r=0.37 to 0.52, p<0.001), weak correlations of bSAP with URR (r=0.14 to 0.34, p<0.05) and no significant correlations with Ca, Ca2+ or P were noted at any time point. Using a repeated-measures mixed model we found that female gender and changes in PTH, Ca2+,

and P, had significant effects on bSAP. Although within-subject variance was smaller than between-subject for PTH and bSAP, the intra class correlations were 0.64 and 0.57 indicating a high degree of variability between and within subjects.

Conclusions: PTH has moderate positive correlations with ALP and bSAP and changes in PTH over time significantly affects the levels of both. PTH in turn is strongly affected by both Ca2+ and P. Future studies should evaluate the possible need to use both parameters for MBD management.

Accumulated Indoxyl Sulfate Aggravate Bone Mechanical Property with Chronic Kidney Disease Yoshiko Iwasaki,[1] Junichiro J. Kazama,[2] Hideyuki Yamato,[3] Masafumi Fukagawa.[4] *[1]Oita Univ. of NHS, Oita; [2]Niigata Univ. Medical and Dental Hospital, Niigata; [3]Kureha Industry, Tokyo; [4]Tokai Univ. School of Medicine, Isehara, Japan.*

Background: Progression of renal dysfunction is associated with increasing fracture risk in chronic kidney disease (CKD) patients. Recent clinical studies have failed to find out the significant relationship between the severity of hyperparathyroidism and fracture risk. Thus, accumulated uremic toxins other than PTH may play an important role in the promotion of bone fragility in CKD condition. We investigated the role of indoxyl sulfate (IS), which is one of uremic toxins, in the bone mechanical property in experimental CKD rats.

Methods: We made CKD rats without hyperparathyroidism using method by partial nephrectomy, thyroparathyroidectoy (TPTx) and continuous exogenous PTH supplementation. CKD rats were divided into two groups; those administered oral charcoal absorbent which decreases the circulating levels of IS (CKD-A), and those received vehicle (CKD-V). The Control (C) group underwent TPTx and PTH supplementation only. Femoral bone elasticity was non-invasively assessed by a DMA method. Bone chemical compositions were analyzed by a raman spectroscopy.

Results: Compared with the C group, bone elasticity was significantly deteriorated in the CKD-V group, indicating decreased mechanical strength in the uremic cortical bone. However, the elasticity was maintained in the CKD-A group. Raman spectroscopic analyses revealed that mineral and collagen compositions, including carbonate phosphate ratio and non-physiological collagen crosslinks pentosidine were increased while crystallinity was decreased in the CKD-V group. These parameters were comparable between the CKD-A and the C groups. Serum parameters were comparable between the CKD-A and the CKD-V groups except the IS level was significantly higher in the CKD-V group. Multiple regression analysis revealed that IS concentration and collagen crosslinks were independently associated with bone elasticity.

Conclusions: Accumulated IS and possibly other uremic toxins other than PTH are likely candidate that promote bone fragility by deteriorating bone elasticity through changing the chemical compositions in CKD.

The Relationship between Sclerostin, FGF23 and PTH in Dialysis Patients: A Multicenter Study Joanna Matuszkiewicz-Rowinska,[1] Mariusz Mieczkowski,[1] Pawel Zebrowski,[1] Ewa Wojtaszek,[1] Tomasz Stompor,[2] Antoni Sokalski,[3] Jerzy Przedlacki,[1] Wieslaw Klatko,[4] Edyta Gieglis,[5] Janusz Grochowski,[6] Ignacy Jarzyllo,[7] Robert Malecki,[8] Stanislaw Niemczyk,[9] Zofia Wankowicz.[9] *[1]Medical University of Warsaw; [2]Warmia-Mazury University; [3]Radom Hospital; [4]Ciechanow Hospital; [5]Otwock Nephrocare; [6]Makow Hospital; [7]Wolomin Hospital; [8]MSSW Miedzylesie; [9]Military Institute of Medicine, Poland.*

Background: Sclerostin, an inhibitor of Wnt/beta-catenin signaling pathway, has emerged as a potent regulator of bone formation. Recently, its increased serum levels have been described in pts on hemodialysis (HD). The aim of our study was to assess the possible relationships between sclerostin and the other mineral metabolism regulators in HD and peritoneal dialysis (PD) pts.

Methods: 252 pts (age 59±15 years, on dialysis 45±49 months, 210 HD & 42 PD) and 36 healthy controls (age 56±20 years) were enrolled. Pts taking vitamin D or calcimimetics were excluded. Serum sclerostin (ELISA), iPTH, cFGF23 & routine tests were analysed.

Results: Compared to the controls, in pts sclerostin levels were 4x higher (117±64.5 vs 26.9±11.1 pmol/l; p<0.001), with lower values in women (106±62.1 vs 126±65.3 pmol/l in men; p=.016), diabetics (98±53 vs 123±66 pmol/l; p=.014) and non-significantly in PD pts (103±65.0 vs 120±64.2 pmol/l; p=.057). Serum sclerostin highly correlated with dialysis vintage (r=0.35, p<.001 in all, r=0.29, p<.001 in HD, r=0.54, p<.001 in PD), serum creatinine (0.39, p<.01 in all, r=0.30, p<.001 in HD, r=0.61, p<.001 in PD), FGF23 (r=0.31, p<.001 in all, r=0.22, p<.001 in HD, r=0.60, p<.001), and negatively with PTH (r=-0.24, p<.001) in all, r=-0.28, p<.001 in HD). Serum PTH correlated weakly with FGF23 in all (r=0.18, p=.007) and HD pts (r=0.17; p=.02). There were no differences in serum PTH between HD and PD groups.

Conclusions: Serum sclerostin levels are much higher in dialysis pts compared to healthy controls, with the lower values in women, diabetics and PD pts. Its negative correlation with PTH may reflect its role in the PTH signal transduction in osteocytes.The high positive correlation with FGF23 deserves further study.

TH-PO897

KDOQi- or KDIGO-Recommended PTH Levels Are Associated with Low Bone Turnover in Pre-Dialysis Chronic Kidney Disease Patients Romulo Nina Azevedo,[1] Fellype Carvalho Barreto,[2] Maria Eugenia F. Canziani,[1] Aluizio B. Carvalho.[1] *[1]Nephrology, Federal University of São Paulo, São Paulo, Brazil; [2]Nephrology, University of São Paulo, São Paulo, Brazil.*

Background: KDOQi and KDIGO-recommended PTH levels have been based on opinions and not in the bone turnover of pre-dialysis chronic kidney disease (CKD) patients. The aim of this study was to evaluate if the guidelines target PTH levels proposed are in accordance with bone turnover in that population.

Methods: Fifty consecutive asymptomatic CKD outpatients (51.7±10.4 yrs, 68% male, 36% african-american, body mass index: 26.2±4.3kg⁄m², eGFR:36.3±18 mL⁄min⁄1.73m² by CKD-EPI) were submitted to a tetracycline pre-labeled bone biopsy, followed by histomorphometric analysis. Bone turnover was classified as low, normal or high according to bone formation rate (BFR⁄BS; reference values: 0.13±0.07 and 0.07±0.03 μ^3/μ^2⁄day, for male and female, respectively). Low bone turnover was defined as BFR⁄BS < -1 standard deviation (SD) below mean (< 0.06 or < 0.04 μ^3/μ^2⁄day, for male or female, respectively). Normal to high bone turnover was defined as BFR⁄BS ≥ 1SD above mean (≥ 0.06 or ≥ 0.04 μ^3/μ^2⁄day, for male or female, respectively). Laboratorial evaluation included intact-PTH (iPTH) whose levels were classified as normal or high based on KDOQi or KDIGO recommendations.

Results: BFR/BS was 0.02±0.02 μ^3/μ^2⁄day, for male and female. Low turnover bone disease (LTBD) was found in 86% of the patients. Median of iPTH levels were 83 pg/mL (26 - 548). A positive correlation between iPTH and BFR⁄BS was observed (r=0.40;p=0.04). According to KDOQi, iPTH levels were normal or high in 42 and 58%, respectively. According to KDIGO, iPTH levels were normal or high in 28 and 72% of the patients, respectively. Overall, 56% or 70% of the LTBD patients had high iPTH levels, according to KDOQi or KDIGO, respectively.

Conclusions: In CKD patients: 1. PTH levels are frequently high, according to KDOQi or KDIGO targets recommendation; 2. PTH is correlated with bone formation rate; 3. However, high PTH levels are associated with LTBD.

Correlations of Tubular Reabsorption of Phosphate (TRP) According to Renal Function in CKD Patients Gun Hee An, Yu Ah Hong, Yul Hee Cho, Myung Hyun Lee, Jeong Gwan Kim, Hyun Chul Whang, Chul Woo Yang, Cheol Whee Park, Yong-Soo Kim. *Division of Nephrology, Department of Internal Medicine, Seoul St. Mary's Hospital,College of Medicine, the Catholic University of Korea, Seoul, Republic of Korea.*

Background: Hyperphopshatemia are key contributors to chronic kidney disease-mineral and bone disorder. Recently, FGF23 and soluble α-Klotho is an emerging potential biomarker of phosphorus and vitamin D metabolism bur its use is limited. A tubular reabsorption of phosphate may be a simple and effective biomarker in CKD patients. The aim of this study investigates the correlation between TRP and renal function in CKD patients.

Methods: We performed an observational study in stable patients with CKD stage 1-5. TRP was calculated with the formula; 1- [(Up/Pp) x (Pcr/Ucr)] x100. Normal TRP was defined as over the 80%. The renal function was evaluated by calculating the estimated GFR with MDRD equation. Serum FGF23 and urine soluble α-Klotho were determined by a sandwich enzyme-linked immunosorbent assay system.

Results: From April 2011 to February 2012, 76 stable patients with CKD stage 1-5 enrolled. In normal TRP (>80%) group, while renal function was significantly higher than that of low TRP group (<80%), serum phosphate, alkaline phosphatase, intact PTH were significantly lower than those of low TRP group. Serum FGF23 level in lower TRP group was higher than that of normal TRP group. Urine Klotho level was the other way round. As glomerular filtration rate declined, TRP significantly decreased (R^2=0.561, P<0.001) and intact PTH increased (R^2=0.330, P<0.001) for the augmentation of phosphaturia. In predialysis CKD stage 1-4, TRP was significantly correlated with serum FGF23 (r=-0.348, P= 0.013), intact PTH (r=-0.411, P=0.003), whereas was not correlated with urine Klotho and serum phosphate. TRP also showed a significant association of GFR and intact PTH, but did not associate with FGF23 and soluble α-Klotho in multivariate linear regression analysis.

Conclusions: TRP is a useful early surrogate marker compared with serum FGF23 and urine soluble Klotho for the assessment of the phosphate metabolism of CKD patients.

TH-PO899

Pulse Wave Analysis Predicts Cardiovascular Mortality in Pre-Dialysis Chronic Kidney Disease Darren Green, Richa Sinha, James Ritchie, Smeeta Sinha, Helen Eddington, Philip A. Kalra. *Dept Renal Medicine, Salford Royal Hospital, United Kingdom.*

Background: Vascular stiffness is an independent predictor of outcome in end-stage renal disease. The aim was to assess whether it also predicts outcome in pre-dialysis CKD.

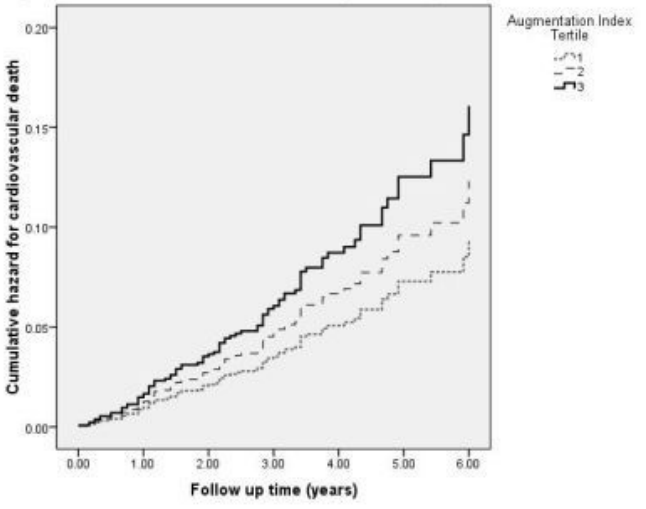
Methods: We performed pulse wave analysis using applanation tonometry in a cohort of 956 patients with CKD stages 3-5. We measured ejection duration (ED), augmentation index corrected for ED and heart rate (AIx), and systolic peak times (T_1 & T_2). Patients also had serum biochemistry. Follow up was to dialysis, death, or last appointment. Predictors of outcome were from forward stepwise Cox regression (inclusion in model if $\alpha \leq 0.05$ on univariate analysis). End-points were all-cause mortality (ACM) & cardiovascular death (CVD).

Results: Cohort characteristics were age 66±14 years, eGFR 45±12 mL/min/1.73m^2, 61% male, 29% diabetes, follow up 3.4±1.7 years, 201 deaths (21%), 98 CVD (49% of ACM).

The predictors of ACM were AIx, T_2, old age, low serum albumin, high urea and parathyroid hormone (PTH), smoking, coronary artery disease (CAD), and peripheral vascular disease (PVD). For CVD, only AIx, age, smoking, CAD, and PVD remained significant. eGFR was a better predictor of CVD than urea. Phosphorus & calcium were not significant in any model that included AIx.

The hazard ratios (HR) of AIx were: ACM HR=1.045 per % increase; CVD HR=1.040 (figure 1). The HR of AIx for CVD became less significant as eGFR fell: CKD 3 HR=1.090, p<0.001; CKD 4 HR=1.048, p=0.008; CKD 5 HR=1.007, p=0.877.

Figure 1. Rates of cardiovascular mortality according to tertiles of AIx



Conclusions: AIx is predictive of ACM and CVD in CKD. Serum biochemistry associated with vascular stiffness & previously shown to predict CVD are not significant in this model. Thus, these factors may increase CV risk by way of their role in vascular stiffness. The impact of AIx on outcome falls with eGFR. This is likely because of the influence of other risk factors.

TH-PO900

Changes in Insulin-Like Growth Hormone-1 (IGF-1) during First Year on Dialysis: Implications for Bone Status, Nutritional Status and Patient Survival Ting Jia, Thiane Gama Axelsson, Hong Xu, Sun-Hee Park, Tobias E. Larsson, Olof Heimburger, Peter F. Barany, Bengt Lindholm, Peter Stenvinkel, Abdul Rashid Tony Qureshi. *Renal Medicine and Baxter Novum, Karolinska Institutet, Stockholm, Sweden.*

Background: Abnormalities in the IGF-1/growth hormone system contribute to catabolism in chronic kidney disease (CKD) patients (pts). In incident dialysis pts, a low IGF-1 level has been reported to be associated with low bone mineral density (BMD). We investigated relations between changes in IGF-1, nutritional status and BMD during the first year of dialysis, and the predictive power of changes in IGF-1 on mortality.

Methods: In 207 CKD stage 5 pts (median glomerular filtration rate 7 mL/min, median age 56 years, male 61%) starting on dialysis, fasting samples were obtained at baseline and after one year on dialysis for measurements of IGF-1 and biochemical parameters. Nutritional status was assessed by subjective global assessment (SGA) and bone mineral density (BMD) was measured by dual energy X-ray absorptiometry. Determinants of IGF-1 changes were analyzed by Mixed Model. Associations between levels of IGF-1, IGF-1 variation and mortality were evaluated by Kaplan Meier curve, and conventional and competing risks Cox proportional hazards models.

Results: The median concentration of IGF-1 increased from 181 (87-320) to 240 (113-413) ng/ml (p<0.05) after one year on dialysis. Both at baseline and after one year, IGF-1 was negatively associated with signs of poor nutritional status (SGA score >1) and correlated with BMD (baseline: rho=0.17; p<0.001; one year: rho=0.16; p=0.03). According to the Mixed model, phosphate, calcium and fat mass were significant determinants of IGF-1 change during first year dialysis. After adjusting for confounding factors, patients with stable high or increased IGF-1 had improved survival during 5-years follow-up.

Conclusions: During the first year on dialysis, a low IGF-1 level was associated with low BMD and poor nutritional status. Changes in IGF-1 were associated to phosphate, calcium and fat mass, and predicted survival. These results suggest that IGF- 1 has a key role in the interplay between nutritional status, fat mass and bone status in dialysis pts.

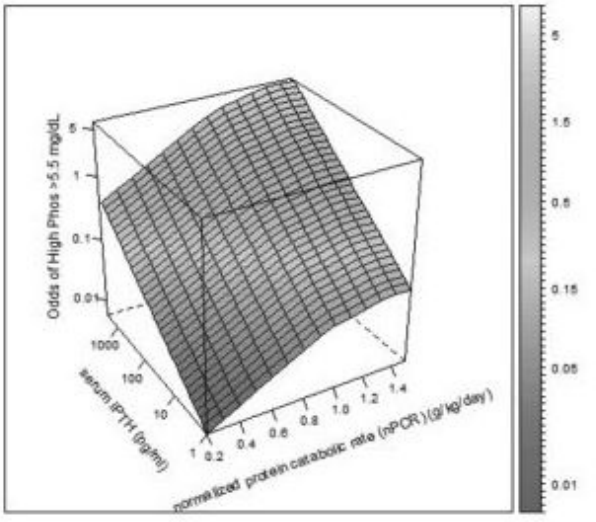
TH-PO901

Modeling the Likelihood of Hyperphosphatemia as a Combined Function of Serum Parathyroid Hormone and Dietary Protein Intake in Chronic Kidney Disease Leanne Streja,[1,2] Miklos Zsolt Molnar,[1] Elani Streja,[1] Joshua Zaritsky,[3] John J. Sim,[4] Csaba P. Kovesdy,[5] Kamyar Kalantar-Zadeh.[1,3] *[1]Harold Simmons Center for Chronic Disease Research & Epidemiology, LABioMed at Harbor-UCLA; [2]City of Hope; [3]David Geffen School of Medicine at UCLA; [4]Kaiser Permanente; [5]University of Tennessee.*

Background: High phosphorus levels are associated with higher risk of death in hemodialysis patients. Previous studies have suggested that both higher serum intact parathyroid hormone (iPTH) levels and higher dietary protein intake may contribute to higher serum phosphorus. However, it is not well known how these two factors contribute to the risk of hyperphosphatemia simultaneously if both are taken into account. We hypothesized that the likelihood of hyperphosphatemia increases across higher serum iPTH and higher normalized protein catabolic rate (nPCR), a surrogate of protein intake.

Methods: Over an eight-year period, we identified 69,355 MHD patients with iPTH, nPCR and phosphorus data in a large dialysis provider. Logistic regression models were examined to assess the association between likelihood of hyperphosphatemia (P>5.5 mg/dL) across serum iPTH and nPCR increments.

Results: Patients were 61±15 years old and included 46% women, 33% blacks, and 57% diabetics. Both higher serum iPTH level and higher protein intake were associated with higher risk of hyperphosphatemia.



Compared to patients with iPTH level 150-<300 pg/ml and nPCR level 1.0-<1.2 g/kg/day, patients with iPTH>600 pg/ml and nPCR>1.2 g/kg/day had a 3 fold higher risk of hyperphosphatemia (OR:3.17, 95%CI:2.69-3.75).

Conclusions: Our findings demonstrate an association between higher serum phosphorus levels with both dietary protein intake and serum PTH level in MHD patients. Dietary interventions and correction of hyperparathyroidism should be considered in hyperphosphatemia management.

TH-PO902

Parathormone and Bone-Specific Alkaline Phosphatase for the Follow-Up of Bone Turnover in Hemodialysis Patients: Is It so Simple? Pierre Delanaye, Francois Jouret, Jean-marie H. Krzesinski, Olivier Moranne, Etienne Cavalier. *Nephrology-Dialysis-Transplantation, University of Liège, CHU Sart Tilman, Liège, Belgium.*

Background: Chronic kidney disease (CKD) is associated with mineral and bone disorders (MBD). International guidelines suggest that levels of serum parathormone (PTH) or bone-specific alkaline phosphatase (b-ALP) can be used to evaluate MBD in dialysis patients. The evidence for such recommendation remains moderate and mostly based on transversal studies.

Methods: We retrospectively investigated the variations of PTH (ΔPTH) and b-ALP (Δb-ALP) serum concentrations over a short (6-weeks) and a long (one-year) period in a monocentric hemodialysis population. The proportion of patients reaching the critical difference (CD) (50% for PTH and 25% for b-ALP) was calculated.

Results: Seventy-seven patients were included. A significant correlation between PTH and b-ALP levels was found at baseline (r=0.75). By contrast, no correlation was observed between ΔPTH and Δb-ALP over a 6-week interval (r=0.14). Furthermore, contradictory variations were observed in 39 patients (51%). The CD for PTH and b-ALP was reached by 19 and 11 patients, respectively, with 2 patients showing consistent variations of both biomarkers. One year later, measurements of PTH and b-ALP were repeated in 48 survivors. No correlation was found between ΔPTH and Δb-ALP (r=0.27). Contradictory evolution

of PTH and b-ALP was observed in 39 patients (81%). The CD for PTH or b-ALP was reached by 24 patients and 28 patients, respectively, with 6 patients (12.5%) showing opposite results for both biomarkers.

Conclusions: This study shows the lack of correlation between ΔPTH and Δb-ALP over time in patients under chronic hemodialysis. Such discrepancy urges prospective and longitudinal trials to identify which biomarkers clinicians should rely on.

TH-PO903

CKD-MBD Therapy in Peritoneal Dialysis: Multicenter Retrospective Analysis (OPTIMHYST Study) Roberto Dell'Aquila,[1] Gianpaolo Amici,[2] Graziella Berlingò,[1] Laura Cappuccino,[3] Alex Cosaro,[4] Mario Cozzolino,[5] Emilio Giulio Galli,[6] Paolo Ghiringhelli,[7] Gian Maria Iadarola,[8] Alessandro Laudon,[9] Carlo Rugiu,[10] Stefano Saffioti,[3] Roberto Scarpioni,[11] Alessandra Trubian.[10] *[1]Neph & Dial, Hosp, Bassano; [2]Hosp, Treviso; [3]University, Genova; [4]Hosp, S Bonifacio; [5]Hosp, Milano; [6]Hosp, Treviglio; [7]Hosp, Cremona; [8]Hosp, Torino; [9]Hosp, Trento; [10]University, Verona; [11]Hosp, Piacenza, Italy.*

Background: CKD-MBD therapy in peritoneal dialysis (PD) is prescribed specifically orally. Our study evaluates clinical evolution and therapy of CKD-MBD with a data collection of 11 PD centers.

Methods: A retrospective, polycentric cohort study of PD patients (2010-2011) was carried out with a 1 year follow-up of 371 pts at baseline, 362 at 6 months and 326 at 12 months, 287 (77%) were prevalent and 84 (23%) were incident. At baseline, 6 and 12 months have been recorded: Ca, P, PTH, ALP, Alb, BMI, CLCR, KT/V, comorbidity and mortality. Therapy records were collected: VDRAs, natural vitamin D, phosphate binders and cinacalcet. A MANOVA RM model and Kaplan-Meier curves with the Log-Rank test were applied.

Results: Patients were 64±15 yrs-old, median time on dialysis was 15 months (IQ range 6-35). We recorded 30 deaths, 15 for CV causes. Prescription was: CAPD 38%, APD 54% and incremental 8% at baseline, baseline PTH was 314±264, at 6 months 317±272, at 12 months 329±282 ng/ml (p=ns); baseline P was 4.98±1.30, at 6 months 4.97±1.29, at 12 months 5.12±1.34 mg/dl (p=ns); baseline Ca was 9.06±0.79, at 6 months 9.15±0.78, at 12 months 9.10±0.75 mg/dl. At start 227 patients (61%) were treated with VDRAs, paricalcitol therapy was 10%, natural vit D was 7.8%, binders therapy was 75.5%, cinacalcet was 12.9%. We observed a significantly lower PTH level in paricalcitol vs calcitriol treated patients at 6 months (p=0.013). Survival analysis showed an advantage in patients treated from baseline with VDRAs (Log-Rank p=0.044).

Conclusions: At the first analysis of this PD database we found a good control of CKD-MBD with oral therapy. Similar to hemodialysis, in PD we observed a survival advantage in patients treated with VDRAs.

TH-PO904

The Costs of Treating Mineral Bone Disease in Dialysis Patients: Results of All Wales MBD Audit Shafi Malik,[1] Rajiva Ibakkanavar,[1] James A. Chess,[2] Aled O. Phillips,[1] Steve Riley.[1] *[1]Institute of Nephrology, University Hospital of Wales, Cardiff, United Kingdom; [2]Renal Medicine, Swansea Marriston Hospital, Swansea, United Kingdom.*

Background: Mineral bone disease significantly adds to the morbidity and mortality associated with CKD. CKD-MBD treatment targets are still disputed and we await outcome data to confirm benefit for patients. Newer agents that help achieve targets have led to increased treatment cost. We set out to audit the use and associated expenditure of CKD-MBD medications in Wales.

Methods: Renal units in Wales were contacted to provide information on all dialysis patients over a 3-month period in 2010. Demographics,dialysis adequacy and MBD results were collected. MBD drugs and dosages were confirmed with patients in the middle of the data collection period. A 3 month average for Calcium,Phosphate and a single PTH result was used for each patient. Drug expenditure was calculated by using publicly available prices.

Results: 1193 patients were included (76% HD, 19% PD, 5% HHD).

Mean phosphate level for the population was 1.59 ± 0.46 mmol/l. 62%, 72% and 55% of patients reached the phosphate, calcium and PTH targets respectively. The achievement of all 3 targets was seen in 17% of patients on UHD, 19% on PD and 20% on HHD.

25% were not on a phosphate binder. 42% were on calcium-based binders and 75% were on non-calcium binders(44% Sevelamer,15% Lanthanum,5% Aluminium). 46 patients with phosphate >1.8 mmol/l were not on a binder. Of those patients who did not achieve the phosphate target majority were on a non-calcium binder(75% v 50%).

The total annual cost was £1.2 million for all MBD medications. £970k came from non-calcium based phosphate binders(£695k Sevelamer, £275k Lanthanum) and £180k from Cinacalcet. The mean total cost per patient per year is around £1000. Cost decreased as number of MBD targets achieved increased(zero £1070; 1 £1050; 2 £1000; 3 £795).

Conclusions: Achievement of targets were similar across the different renal units and modalities. There was no significant difference in MBD control. The cost of achieving these targets is substantial and with increasing financial constraint further work is needed to optimize cost benefit ratio in this area of prescribing.

TH-PO905

Impact of Mineral Metabolism on Mortality in Hemodialysis Patients: Serum Phosphate Level Should Be Primarily and Consistently Controlled Masatomo Taniguchi,[1] Masafumi Fukagawa,[2] Naohiko Fujii,[3] Takayuki Hamano,[4] Kunitoshi Iseki,[5] Yoshiharu Tsubakihara.[4] *[1]Department of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; [2]Division of Nephrology, Endocrinology and Metabolism, Tokai University School of Medicine, Isehara, Japan; [3]Medical and Research Center for Nephrology and Transplantation, Hyogo Prefectural Hospital, Nishinomiya, Japan; [4]Department of Comprehensive Kidney Disease Research, Graduate School of Medicine, Osaka University, Osaka, Japan; [5]Dialysis Unit, University Hospital of the Ryukyu, Naha, Japan.*

Background: Mineral metabolism is affects mortality in hemodialysis patients and is identified by imbalances in serum phosphate (P), calcium (Ca), and parathyroid hormone (PTH).Most of previous studies have examined associations between baseline values at the start and subsequent survival.

Methods: We examined associations between annual mineral values (P, Ca, PTH) and mortality in a 3-year cohort (Dec 2006-2009) of 128,125 hemodialysis patients using three models, i.e. baseline, time-dependent and time-average Cox models. We also examined associations between achieved Japanese guideline targets (P: 3.5-6.0 mg/dL, corrected Ca 8.4-10.0 mg/dL, intact PTH 60-180mg/dL) and all-cause survival to elucidate which parameter should be controlled as a priority.

Results: High and low serum P (> 6.0 or ≤ 3.5 mg/dL), high Ca (> 9.5 mg/dL), higher PTH (> 300 pg/mL) and lower PTH (≤ 60 pg/mL) were significantly associated with high mortality in all three models (p< 0.01). A hazard ratio for mortality in hyperphosphatemia was higher when compared to other mineral levels. Patients (20% of subjects) who achieved all parameters simultaneously showed lowest mortality. Those who only met P targets had a lower risk of death (hazard ratio=1.17) compared to those that achieved Ca and PTH targets (1.41, 1.47, respectively). As time increased post achieving P and Ca targets, all-cause death risks diminished incrementally.

Conclusions: Among mineral values, Pwould be the strongest predictor for high mortality and should be the priority for control. Consistent achievement of P and Ca targets would lead to good survival in hemodialysis patients.

TH-PO906

Cinacalcet Increases FGF Receptor 1 Expression in Hyperplastic Parathyroid Glands from Uremic Patients Keiichi Sumida, Yoshifumi Ubara, Koki Mise, Masayuki Yamanouchi, Tatsuya Suwabe, Junichi Hoshino, Kenmei Takaichi. *Nephrology Center, Toranomon Hospital, Tokyo, Japan.*

Background: In uremic patients, the depressed expression of both fibroblast growth factor receptor 1 (FGFR1) and its co-receptor Klotho in hyperplastic parathyroid glands has been demonstrated to underlie the pathogenesis of secondary hyperparathyroidism (SHPT) and its resistance to extremely high FGF23 levels, however, there have been no reports regarding the expression of both Klotho and FGFR1 in patients with SHPT after administration of cinacalcet hydrochloride (cinacalcet). This study was aimed to elucidate the effect of cinacalcet on the expression of FGFR1 and Klotho in hyperplastic parathyroid glands.

Methods: A total of 77 parathyroid glands, including 73 hyperplastic parathyroid glands from 18 dialysis patients with severe SHPT who required parathyroidectomy and 4 normal parathyroid glands resected together with thyroid tumor, were obtained at our institute. The 18 dialysis patients were divided into those treated with (cinacalcet group, n = 10) and without (non-cinacalcet group, n = 8) cinacalcet. Immunohistochemical staining for Klotho and FGFR1 was performed and the expression of Klotho and FGFR1 were semiquantitatively analyzed.

Results: Compared with normal glands, the hyperplastic parathyroid glands in each group showed significantly decreased Klotho and FGFR1 expression. Compared with the non-cinacalcet group, FGFR1 expression was significantly increased in the cinacalcet group (39 glands) ($P < 0.05$), while Klotho expression was not different between the groups ($P > 0.05$).

Conclusions: Our results suggest that cinacalcet increases the expression of FGFR1 in hyperplastic parathyroid glands with severe SHPT, and may contribute to an inhibitory effect on progression of SHPT in uremic patients. Furthermore, the insufficient Klotho expression may imply one of the reasons that parathyroidectomy is necessary in patients showing cinacalcet resistance.

TH-PO908

Treatment of Secondary Hyperparathyroidism in Maintanence Hemodialysis Patients: A Randomised Clinical Trial Comparing Paricalcitol, Calcitriol and Cinacalcet Siren Sezer,[1] Emre Tutal Tutal,[1] Zeynep Bal,[1] Fatma Nurhan Ozdemir Acar.[2] *[1]Nephrology, Baskent University, Ankara, Turkey; [2]Nephrology, Baskent University, Istanbul, Turkey.*

Background: Secondary hyperparathyroidism is a common complication of chronic kidney disease. Treatment of SHPT includes VDR analogs and calcimimetics. The aim of this study is to evaluate and compare the effectiveness of these treatments as monotherapies and in combination in maintenance hemodialysis (MHD) patients with SHPT.

Methods: 114 subjects were included. After a washout period, patients who were already receiving calcitrol and having PTH levels >300 pg/mL were randomized into 4 groups: a) total serum calcium < 10.5mg/dL, serum Ca × P <75 and PTH level between

300-1000 pg/ml were randomized to recieve either paricalcitol (n: 31, group 1) or calcitriol (n: 32, group 2), b) normalized total serum calcium > 10.5mg/dL, serum Ca × P<75 and PTH level >1000 pg/ml were randomized to recieve either cinacalcet plus paricalcitol (n: 29, group 3) or cinacalcet plus calcitriol (n: 22, group 4).

Results: Study groups were similar in means of demographic characteristics. Patients in group 3 and 4 had significantly higher Ca, P and CaxP product levels at the first 3 months of study (p<0.01) however in following 9 months these levels were statistically similar in all groups. When PTH levels were assessed and compared to basal values we observed a significant reduction (-9.8%) in group 1 while there was an increament in group 2 (%24.3, p< 0.008). When we compared groups 3 and 4 in means of iPTH reduction ratio at the end of 1 year group 3 had higher reduction ratios (-33.7%) compared to group 4 (-6.1%, p:0.011). The mean cinacalcet dose initiated were similar in group 3 and 4 while the mean cinacalcet dose significantly increased in patients receiving calcitriol versus paricalcitol (42.0±15.2 mg and 25.2±16.1 mg, p<001).

Conclusions: This study showed that paricalcitol treatment reduced PTH concentrations more effectively without causing hypercalcemia and hyperphosphatemia than calcitiriol therapy either alone or in combination with calcimimetics. We suggest that paricalcitol should be prefered to calcitriol for the treatment of MHD patients with moderate to severe SHPT.

TH-PO909

Beneficial Effects of Paricalcitol on Left Ventricular Hypertrophy and Myocardial Fibrosis in Rats with Chronic Renal Failure Sara Panizo, Natalia Carrillo-Lopez, Sara Barrio-Vazquez, Amalia Fernandez-Vazquez, Jose L. Fernandez-martin, Manuel Naves, Jorge B. Cannata-Andia. *Bone and Mineral Research Unit, HUCA, Instituto Reina Sofía de Investigación, REDinREN del ISCIII.*

Background: Cardiovascular disease is the main cause of death in CKD patients. Abnormalities of left ventricular structure and function are frequent among these patients. Vitamin D is associated with decrease in cardiovascular mortality. To further explore this topic we investigated in rats with chronic renal failure (CRF) the heart morphological and molecular effects of an active vitamin D compound, paricalcitol (PC).

Methods: CRF Wistar rats, carried out by 7/8 nephrectomy, were treated intraperitoneally with 30ng/kg/day of PC 5 days per week over 4 weeks. CRF+vehicle and Sham groups served as control. Morphological and molecular parameters were measured to evaluate cardiomyocytic and fibrotic changes.

Results: PC reduced the adaptive left ventricular hypetrophy (LVH) that has 2 main components 1)the hypertrophy of the muscular tissue evidenced by the increase of cardiomyocytes size, 2)the increase of fibrosis triggered by the hypertrophic myocytes and the increase of collagen by fibroblasts. On one hand, PC decreased the morphological parameters of LVH, wall thickness (2.29±0.2 vs 1.88±0.18) and cardiomyocytes size (10.67±1.16 vs 9.78±0.48), as well as the molecular parameters: BNP heart expression (5.64±2.45 vs 0.94±0.70) (marker of ventricular myocyte stress that precedes the cardiac hypertrophy) and erk1/2 phosphorilation (1.95±0.37 vs 0.85±0.19) (hypertrophic growth signal). On the other hand, PC reduced the fibrosis assessed by Masson and Sirius staining by increasing heart levels of collagenase MMP1 (0.55±0.26 vs 2.07±0.24) avoiding collagen accumulation.

Conclusions: In non-treated CRF rats all these changes lead to an increase of heart fibrosis at the expense of losing muscle tissue. In contrast, in the PC treated rats a significant reduction in the fibrosis was observed. The advantageous proportion of muscle/fibrotic tissue observed with the use of PC that can not be detected using conventional methods (nuclear magnetic resonance/echocardiography) can have a beneficial effect on cardiac function.

TH-PO910

Fibroblast Growth Factor 23, Left Ventricular Mass Index, and Left Ventricular Hypertrophy in Community-Dwelling Older Adults Anna Jeanette Jovanovich,[1] Joachim H. Ix,[2] Kim Mcfann,[1] Ronit Katz,[3] Bryan R. Kestenbaum,[3] Ian H. de Boer,[3] Mark J. Sarnak,[4] Michael Shlipak,[5] Kenneth J. Mukamal,[6] David Siscovick,[3] M. Chonchol.[1] *[1]University of Colorado; [2]University of California San Diego; [3]University of Washington; [4]Tufts Medical Center; [5]University of California San Francisco; [6]Beth Israel Deaconess Medical Center.*

Background: Fibroblast growth factor 23 (FGF23) regulates phosphorus and calcitriol homeostasis. In chronic kidney disease (CKD), high FGF23 levels are associated with left ventricular hypertrophy (LVH) and death. The relationship between FGF23 with left ventricular mass index (LVMI) and LVH in the general population and the influence of CKD remains uncertain.

Methods: Plasma C-terminal FGF23 concentrations were measured in 2255 women and men >65 years in the Cardiovascular Health Study with echocardiogram data for LVMI and LVH. Cross-sectional associations of plasma FGF23 levels with LVMI and LVH were examined with linear and logistic regression models adjusted for age, sex, race, body mass index, clinic site, smoking, diabetes, hypertension, systolic blood pressure, C-reactive protein, Cystatin C-estimated glomerular filtration rate ($eGFR_{cys}$) and urine albumin-creatinine ratio (ACR).

Results: Participant characteristics were as follows: mean age, 78±5 years; 64% women; 29% black; 32% CKD ($eGFR_{cys}$ < 60ml/min/1.73m^2or ACR ≥ 30mg/g); and median FGF23 level 70 (IQR 53-99) RU/mL. Higher plasma FGF23 levels were associated with greater LVMI (ß=3.90, [95% CI 2.58, 5.22]) and greater odds of LVH (OR=1.35 [95% CI 1.17, 1.57]) per doubling FGF23 after multivariate adjustment. These associations were stronger among those participants with CKD (p interaction=0.005): LVMI β=5.66 [95% CI 3.51, 7.81] and LVH OR=1.46 [(95% CI 1.20, 1.77] per doubling FGF23. The corresponding associations in those without CKD were (β=2.01 [95% CI 0.58, 3.57]) for LVMI and (OR=1.19 [95% CI 0.96, 1.47]) for LVH per doubling FGF23.

Conclusions: In a large cohort of community-dwelling adults >65 years, higher FGF23 levels were associated with greater LVMI and LVH, with a stronger relationship in participants with CKD.

TH-PO911

2MD, a Highly Potent Analog of Calcitriol, Suppresses Parathyroid Hormone Levels in Rat Models of Hyperparathyroidism Julia B. Zella,[1,2] Lori A. Plum,[1,2] Margaret Clagett-Dame,[1,2] Hector F. Deluca.[1,2] *[1]Biochemistry, University of Wisconsin-Madison, Madison, WI; [2]Deltanoid Pharmaceuticals, Inc., Madison, WI.*

Background: 1α,25-Dihydroxyvitamin D and its analogs have been used successfully to suppress parathyroid hormone (PTH) levels in chronic kidney disease (CKD) patients with secondary hyperparathyroidism (SHPT). In order to identify new vitamin D analogs with therapeutic potential, we screened over two dozen novel vitamin D compounds with modified side chains and/or A-rings using the 5/6 nephrectomy (NX) rat model of CKD. Select compounds were also evaluated in combination with the angiotensin-converting enzyme inhibitor, enalapril. A novel, less-invasive model of hyperparathyroidism secondary to vitamin D deficiency in normo-calcemic rats is also described.

Methods: Young male Sprague-Dawley rats were used for both models of SHPT. A high phosphorus-containing purified diet was used to induce elevated PTH levels in NX rats. Rats were administered vitamin D analogs either orally or intraperitoneally, depending on the experiment. In a second model of hyperparathyroidism, normal calcium levels were restored in vitamin D deficient rats through the use of a purified diet containing high levels of lactose, calcium and phosphorus.

Results: Of the compounds we tested, one particular analog, 2-methylene-19-nor-20S-1α,25$(OH)_2D_3$ (2MD or DP001), shows particular promise. 2MD is a highly-potent analog of calcitriol that has recently been shown to suppress PTH in post-menopausal women. In NX rats, 2MD significantly suppresses PTH levels without raising serum calcium and when combined with enalapril, significantly decreases proteinuria compared to untreated NX rats. 2MD also normalizes PTH levels in vitamin D deficient rats, independent of calcium.

Conclusions: We have identified several new analogs of vitamin D that have potential therapeutic use for the treatment of SHPT. 2MD is the lead candidate for development due to its potency and safety profile. An oral formulation of 2MD is currently in Phase 2 clinical trials in hemodialysis patients with SHPT.

TH-PO912

The Switch from Calcitriol to Paricalcitol Decreases Calciuria in Predialysis CKD Patients Isabel Martínez,[1] Ramon M. Saracho,[2] Adriana S. Dusso.[3] *[1]Nephrology, Hospital de Galdakao, Usansolo, Vizcaya, Spain; [2]Nephrology, Hospital Universitario de Alava, Vitoria, Alava, Spain; [3]Experimental Nephrology Lab, IRBLleida, Lleida, Spain.*

Background: Serum levels of calcitriol decrease early in the course of CKD. Because reductions in serum calcitriol (CTRL) contribute to the development of secondary hyperparathyroidism (SHPT), CTRL replacement has been the therapy of choice to prevent/slow the progression of SHPT. However, the doses of CTRL required to suppress SHPT in CKD can cause hypercalcemia and/or hyperphosphatemia. Therefore, a CRTL analog, paricalcitol, was developed to suppress SHPT with less hyperphosphatemic and hypercalcemic actions. Several reports dispute the actual achievement of this goal. Thus, the aim of this study is to compare the effects of paricalcitol and CTRL treatment on plasma and urinary calcium and phosphate levels and on serum PTH.

Methods: We studied 73 patients (40 women) CKD stages 3 to 5, with average (SD) values for Age: 73 (11) years; CrCl corrected by 1.73 m^2= 34.9 (17) ml/min. Patients were treated with CTRL first and then switched to paricalcitol.

Results: The table shows similar levels of serum calcium, phosphate and PTH, urinary phosphate excretion, and proteinuria during CTRL or paricalcitol treatments. Importantly, calciuria was lower during paricalcitol treatment (p= 0.04). As expected, paricalcitol reduced serum CTRL through inducing its degradation.

	Mean(SEM) Calcitriol	Mean(SEM) Paricalcitol	**p (significance)**
Serum Creatinine. mg/dl	2.7(0.2)	2.8(0.2)	NS
eGFR (MDRD) ml/min	26.4(2.1)	25.8(2.1)	NS
Creat. Clearance ml/min	31.1(2.4)	28.8(2.3)	NS
Calcitriol pg/ml	32.7(2.6)	28.5(2.0)	NS
PTH pg/ml	135.0(12.0)	134.0(8.8)	NS
Total Calcium mg/dl	10.11(0.10)	10.08(0.10)	NS
Phosphorus mg/dl	3.7(0.1)	3.8(0.1)	NS
Ionized Calcium mg/dl	5.08(0.05)	5.06(0.05)	NS
Calciuria mg/day	58.1(7.4)	48.9(6.1)	0.04
Phosphaturia mg/day	591.1(27.8)	581.4(34.4)	NS
TPR %	58.7(2.0)	58.4(1.8)	NS
Urinary Protein/Creat. g/g	1.10(0.21)	1.17(0.26)	NS

Conclusions: A lower effect of paricalcitol on intestinal calcium absorption decreases urinary calcium excretion compared to CTRL, suggesting that paricalcitol treatment of SHPT results in a lower systemic calcium overload.

Loss of Function Mutations of *CYP24A1*, the Vitamin D 24-Hydroxylase Gene, Cause a Novel Adult Dent-Like Kidney Stone Disease

Dganit Dinour,[1] Pazit Beckerman,[1] Liat Ganon,[1] Zemach Eisenstein,[2] Karen Tordjman,[3] Eliezer J. Holtzman.[1] *[1]Nephrology and Hypertension, Sheba Medical Center, Tel-Hashomer, Israel; [2]Maccabi Health Organization, Petach-Tikva, Israel; [3]Institute of Endocrinology, Metabolism and Hypertension, Tel-Aviv Sourasky Medical Center, Israel.*

Background: Kidney stone disease is a common problem with diverse etiology, including genetic and environmental factors. Dent's disease is an X-linked hereditary renal tubular disorder, characterized by nephrolithiasis, nephrocalcinosis, hypercalciuria, low-molecular-weight proteinuria and renal failure**.** Recently, loss-of-function mutations of *CYP24A1*, the gene encoding for 1,25-dihydroxyvitamin D_3, 24-hydroxylase, were identified in idiopathic infantile hypercalcemia. Here we describe the clinical and molecular basis of a long standing kidney stone disease, with a hypercalcemic adult Dent-like phenotype caused by *CYP24A1* mutations.

Methods: Three subjects from two Jewish Israeli families with a Dent-like phenotype were clinically characterized. DNA was extracted and the genes responsible for Dent's disease, *CLCN5* and *OCRL1*, as well as *CYP24A1*, were sequenced.

Results: All subjects presented with nephrolithiasis at a young age and had hypercalcemia, hypercalciuria and nephrocalcinosis. Serum PTH levels were very low, serum $25(OH)D_3$ and $1,25(OH)_2D_3$ were high and serum $24,25(OH)_2D_3$ was low. All subjects suffered from severe kidney stone disease, the cause of which was not deciphered for decades despite extensive workup. The oldest subject had low-molecular-weight proteinuria and developed chronic renal failure (serum creatinine is 2.3 mg%). Sequencing of *CLCN5* and *OCRL1* was normal. Instead, we detected three *CYP24A1* loss-of-function mutations: a homozygous deletion (del E143) in family 1 and compound heterozygous mutations, L409S and the novel W268-stop, in family 2.

Conclusions: Mutations in *CYP24A1* gene may cause severe kidney stone disease with a Dent-like phenotype. It may present in adults with no vitamin D supplement and may lead to chronic renal failure. Our results support a recessive mode of inheritance. Further studies are needed to ascertain the prevalence and clinical significance of altered *CYP24A1* function.

Role of Parathyroid Hormone in Renal Failure Induced Downregulation of Liver Cytochrome P450 in a Knockout Mouse Model

François A. Leblond,[1] Christopher Dumayne,[1] Melina Dani,[1] Josée Michaud,[1] Judith Naud,[1] Andrew C. Karaplis,[2] David Goltzman,[3,4] Vincent Pichette.[1] *[1]Maisonneuve-Rosemont Hospital Research Center, Department of Pharmacology, Université de Montréal, Montréal, QC, Canada; [2]Lady Davis Institute for Medical Research, Jewish General Hospital Montreal, Montreal, QC, Canada; [3]Calcium Research Laboratory and Department of Medicine, McGill University Health Centre, Montreal, QC, Canada; [4]Centre for Bone and Periodontal Research, McGill University, Montreal, QC, Canada.*

Background: Chronic renal failure (CRF) is associated with a decrease in drug metabolism secondary to a reduction of cytochromes P450 (CYP450) and phase II metabolism enzymes such as N-acetyltransferase. This downregulation was observed in rat and mouse models of chronic renal failure. However, the mechanisms involved remain poorly understood. One potential mechanism involves parathyroid hormone (PTH). Indeed, it was shown, in rats, that parathyroidectomy prior to nephrectomy prevented the decrease in Cyp3a expression and activity. The purpose of this study is to confirm these results using PTH knockout (PTH-/-) mice.

Methods: Four groups of mice were studied: CRF induced by 3/4 nephrectomy in PTH-/- and WT (PTH+/+) mice and two control groups of mice which underwent sham surgeries (CTL-/-, CTL+/+). Liver protein expression and mRNA level of the major CYP450 isoform Cyp3a11 was measured by western blot and real-time PCR, respectively. Cyp3a activity was also assessed by the N-demethylation of erythromycin.

Results: Our results demonstrate that liver Cyp3a11 protein and mRNA expression is similar in CTL+/+ and CTL-/- mice. While CRF+/+ mice exhibit a 30% decrease in Cyp3a11 liver protein expression (as observed in WT C57BL/6 mice), CRF-/- mice do not show any significant reduction in Cyp3A11. Similar results were obtained for Cyp3a11 specific mRNA. Finally, Cyp3a11 activity was similar in CTL+/+, CTL-/- and CRF-/- mice, while we found a reduction of Cyp3a11 activity in CRF+/+ mice.

Conclusions: These results strongly support a significant role for PTH in the downregulation of liver CYP450 enzymes in CRF. We have yet to identify the mechanisms by which PTH can downregulate CYP450 expression and activity.

TH-PO915

Impact of Lanthanum Carbonate on FGF23 in Chronic Kidney Disease Stages 3-5

Neenoo Khosla, Shonny Fettman, Helen Gerseny, Stuart M. Sprague. *Nephrology, Northshore University HealthSystem, University of Chicago Pritzker School of Medicine, Evanston, IL.*

Background: FGF23 plays an important role in the regulation of phosphate (PO4), vitamin D and parathyroid hormone (PTH) metabolism. As CKD progress, PO4 retention with hyperparathyroidism develops. Serum PO4 levels are not a good early marker of PO4 retention, whereas increases in FGF23 which help maintain normal PO4 balance may be a better indicator of PO4 retention and subsequent development of hyperparathyroidism. The purpose of this study was to determine if reducing FGF23 levels with lanthanum could prevent or reverse the development of hyperparathyroidism.

Methods: A double blind randomized placebo controlled study was performed in subjects with CKD stages 3-5 to determine if treatment with lanthanum carbonate 500 mg pc or placebo could reduce FGF23 and PTH. Subjects were treated for 60 days and doses increased to 1000 mg pc for phosphorus > 5.5 mg/dl. We report data on 19 randomized patients. One way ANOVA was used to assess significance.

Results: Twenty two patients were randomized to placebo versus treatment. Two patients in treatment group and 1 in placebo group dropped out secondary to GI side effects. Data from 10 patients on Lanthanum and 9 patients in placebo are presented. There was no change in FGF23(%) calcium, PO4, 25 vitamin D and change in PTH (%) levels in patients treated for 60 days with placebo. There were significant declines in FGF23 (%) levels treated with lanthanum for 60 days.

Impact of Lanthanum Carbonate versus Placebo on Markers of Mineral Metabolism

	PLACEBO GROUP			LANTHANUM GROUP		
Serum values	Time 0 (Mean) SD	60 Days (Mean) SD	P value	Time 0 (Mean) SD	60 Days (Mean) SD	P value
% Change FGF23 (RU/ml)	100	4.92±25.3	0.69	100	-30.5±23.5	**0.03**
Calcium (mg/dl)	9.7±0.5	9.6±0.4	0.98	9.7±0.3	9.6±0.3	0.598
Phosphorus(mg/dl)	3.9±0.7	4±0.67	0.51	4±0.6	4.2±0.6	0.644
% Change PTH	100	37±123.1	0.54	100	-19.6±27	0.10
25(OH) Vitamin D(ng/ml)	42.1±12.7	41.7±16	0.96	32.9±14.7	28.5±14.9	0.78
1,25 Vitamin D(ng/ml)	37.7±19.3	28.2±12.4	0.24	23.5±4.6	28.1±9.4	0.30

Conclusions: Lanthanum carbonate given with meals significantly reduces FGF23 with no changes in calcium, PO4 and vitamin D levels.

Upregulation of FGF23 by Glucocorticoid Decreases Bone Longitudinal Growth and Mineralization

Luis F. Michea,[1,2] Rodrigo Andaur,[1,2] Magdalena Gonzalez,[1,2] Facundo Las Heras,[3] Solange C. Valdés,[1,2] Mario Galindo,[1] Francisco Villanueva,[1] Angela Delucchi.[4] *[1]ICBM, CEMC, U. de Chile; [2]IMII; [3]Clínica las Condes; [4]Hospital Luis Calvo Mackenna, Santiago, Chile.*

Background: Glucocorticoids (GC) are used as immunosuppressant therapy in renal transplant. However, in pediatric kidney transplant (PKT) patients GC reduce bone mineralization and longitudinal growth. FGF23 is a phosphaturic protein secreted by osteocytes that reduces mineralization of bone cells in culture. In a previous clinical study we demonstrated a increased $[FGF23]_p$ in PKT patients treated with GC, as compared to patients that didn't receive GC. We hypothesize that GC directly stimulate FGF23 synthesis in bone, increasing $[FGF23]_p$.

Methods: Male SD rats (60-80g) were treated with prednisone (PD, 2mg/Kg) or vehicle (control) for 20 days. We evaluated longitudinal bone growth and mineralization, $[FGF23]_p$, bone FGF23 mRNA and protein abundance (10 and 20 days).

Results: PD treated rats showed lower weight gain (79±6 %, P<0,05). As compared to control group, the length and weight of tibia in PD group were lower (92±4% and 86±5%, 10 and 20 days respectively; P<0,01), with thinner epiphyseal cartilage (39±5%, P<0,01). PD group showed a significant increase of $[FGF23]_p$ at 10 and 20 days (324±23% and 160±39% of control levels respectively, P<0,03). Moreover, bones from PD rats showed uprgulation of FGF23 mRNA and protein (5 fold vs control; P<0,05). To evaluate the direct effect of GC on FGF23 expression, rat metatarsal bones were cultured with dexamethasone (Dex; 1nM) or vehicle for 8 days. Dex decreased the longitudinal growth, but increased the osseous abundance of FGF23 (3±1 fold vs control; P<0,05). Pharmacological blockade of GC receptor (RU486) prevented the effects of Dex. Finally, we evaluated the effect of recombinant FGF23 on metatarsal growth in vitro (6 days). 450 pM FGF23 decreased growth and mineralization, an effect prevented by PD173074 (competitive inhibitor of the FGF23 receptor, FGFr1c.)

Conclusions: Our results suggest that GC directly upregulate FGF23 in bone via the glucocorticoid receptor, reducing mineralization and growth.

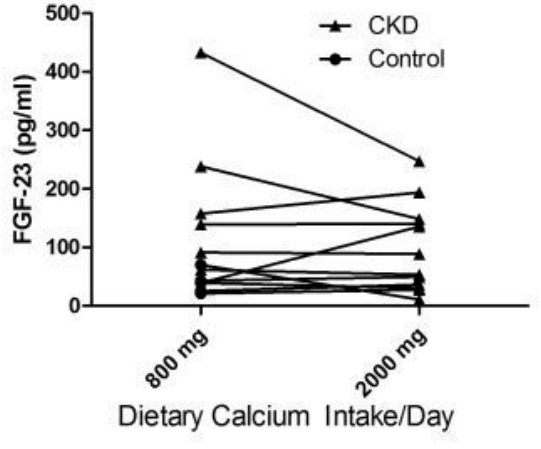
Dietary Calcium Intake Does Not Modulate FGF-23 Levels David M. Spiegel,[1] Leigh Darryl Quarles,[2] Valentin David.[2] *[1]Division of Renal Diseases and Hypertension, University of Colorado, Aurora, CO; [2]Division of Nephrology, University of Tennessee Health Science Center, Memphis, TN.*

Background: The understanding of mineral and bone disorders seen in progressive chronic kidney disease (CKD) now incorporates FGF-23 as an early hormonal marker of the disease process. The factors responsible for the regulation of FGF-23 include serum $1,25(OH)_2D$, phosphorus levels and PTH and bone mineralization. There is some evidence in VDR null mice that a diet containing high calcium also stimulates FGF-23, either through changes in serum concentrations or modulation of bone mineralization.

Methods: We questioned whether dietary calcium modulates FGF-23 in 6 control and 6 subjects with advanced CKD (eGFR 20-33 ml/min/1.73m^2) who received 2 experimental diets for 9 days each in a cross-over study with at least 1 week between diets. Diets contained either 800 or 2000 mg of elemental calcium and 1600 mg of phosphorus. Following 7 days of outpatient diet subjects were admitted to the clinical trials unit and continued on the control diet for 48 hrs while formal calcium balance studies were performed (KI 81:1116-22,2012). For this analysis, FGF-23 levels were measured fasting on the AM of their second inpatient day. CKD subjects were compared to controls by the unpaired t-test while differences within individuals on the 2 diets were evaluated by the paired t-test.

Results: FGF-23 levels were significantly higher in CKD than control subjects (187±55 vs. 40±7; p=0.02). There was no significant change in FGF-23 levels in the entire group (p=0.43) or in either the control (p=0.69) or CKD (p=0.27) subgroups when ingesting the 800 or 2000 mg calcium diets (fig). The serum calcium levels were not different on these 2 diets.



Conclusions: While calcium may modulate FGF-23 in some experimental setting, we found no evidence for an effect of dietary calcium on serum FGF23 levels.

Broadening of the Target Range for Parathyroid Hormone Levels: The Impact on Facility-Level Practice Patterns and Patient Control David M. Spiegel,[1] Jamie Heise,[2] J. Brian Copley,[2] Moshe Fridman.[3] *[1]University of Colorado Denver; [2]Shire Pharmaceuticals; [3]AMF Consulting.*

Background: In chronic kidney disease, management of mineral and bone disorders is challenging, and a lack of randomized outcome trials means optimal therapeutic targets are controversial. Over-suppression of parathyroid hormone (PTH) can lead to low turnover bone disease and high levels promote high bone-turnover. While both are associated with increased fracture risk, the optimal PTH level remains uncertain. A large dialysis organization modified their target PTH range in Sep 2010 from 150–300 pg/mL to 150–600 pg/mL to be more consistent with KDIGO guidance (~130–600 pg/mL). This analysis aimed to identify changes in practice patterns and achievement of target PTH levels following this change.

Methods: Attainment of the PTH target range by ≥50%, and ≥75% of facility patients during Sep 2010 and Aug 2011 was compared. The proportion of patients receiving active vitamin D analogues, cinacalcet, and different phosphate binders during these two months was also compared. Data were provided by 1930 facilities (112,724 patients), and 1993 facilities (105,882 patients), in Sep 10 and Aug 11, respectively.

Results: Comparing Sep 10 with Aug 11, the percentage of facilities with ≥50% of patients in the target PTH range decreased from 93.2% to 90.6% (p=0.003), and those with ≥75% of patients in range decreased from 37.4% to 31.2% (p<0.0001). For the same months, the proportion of patients using active vitamin D compounds increased from 81% to 84% (p<0.0001), the use of cinacalcet decreased from 30% to 28% (p<0.0001), calcium-based binder use increased from 44% to 46% (p<0.0001), and the use of lanthanum and sevelamer decreased from 15% to 13% (p<0.0001) and 66% to 64% (p<0.0001) respectively.

Conclusions: Between Sep 10 and Aug 11, the percentage of facilities achieving the target PTH range of 150–600 pg/mL decreased. This may have occurred if physicians placed less emphasis on PTH control following the range revision. This finding also highlights the differences between targeted and achieved outcomes and suggests that if the PTH goal is <600 pg/mL, intervention needs to be implemented before this value is reached.

Targeted Deletion of Klotho in Kidney Distal Tubules Causes a Disturbed Mineral Metabolism Hannes Olauson,[1] Karolina Lindberg,[1] Risul Amin,[1] Ting Jia,[1] Annika Wernerson,[2] Göran Andersson,[2] Tobias E. Larsson.[1] *[1]Department of Clinical Science, Intervention and Technology, Karolinska Institutet, Stockholm, Sweden; [2]Department of Laboratory Medicine, Karolinska Institutet and Karolinska University Hospital Huddinge, Stockholm, Sweden.*

Background: Renal Klotho controls mineral metabolism through direct regulation of tubular phosphate (Pi) and calcium (Ca) reabsorption, and functions as an obligate co-receptor for the phosphaturic and vitamin D regulating hormone fibroblast growth factor-23 (FGF23).

Methods: We generated a novel mouse model with a partial deletion of Klotho in distal tubular segments by crossing floxed Klotho to Ksp-cadherin-Cre mice (Ksp-KL$^{-/-}$).

Results: In contrast to systemic Klotho *null* mice, Ksp-KL$^{-/-}$ mice were fertile, had a normal gross phenotype and an essentially normal renal histology without signs of vascular or tubular calcification. However, Ksp-KL$^{-/-}$ mice were hyperphosphatemic with an abundant expression of the sodium-Pi co-transporter Npt2a at the brush border membrane and increased FGF23 levels corresponding to the degree of Klotho deletion. Serum Ca and 1,25D were unaltered, whereas parathyroid hormone was decreased. TRPV5 protein, which mediates tubular Ca reabsorption, was reduced paralleled by a mild increase in Ca excretion. Renal expression of vitamin D regulatory enzymes Cyp27B1, Cyp24A1 and the vitamin D receptor (VDR) were higher compared to wild-type controls, suggesting increased turnover of vitamin D metabolites and possibly a functional increase in VDR signaling. There was a threshold effect of residual Klotho expression, where approximately 70% deletion of Klotho resulted in an exponential increase in FGF23. Importantly, FGF23 was elevated in a subgroup of Ksp-KL$^{-/-}$ mice with normal serum Pi and 1,25D levels, suggesting a Klotho-derived renal-bone feedback loop.

Conclusions: Renal FGF23-Klotho signaling, which is disrupted in chronic kidney disease, is essential for homeostatic control of mineral metabolism.

Fibroblast Growth Factor 23 Is a Risk Factor for Left Ventricular Hypertrophy in the Chronic Kidney Disease in Children (CKiD) Cohort Anthony A. Portale,[1] Lisa Aronson Friedman,[2] Mark Mitsnefes,[2] Myles S. Wolf,[3] Susan L. Furth,[2] Bradley A. Warady,[2] Harald Jüppner,[4] Isidro B. Salusky.[5] *[1]Pediatrics, UCSF, San Francisco, CA; [2]CKiD Investigator; [3]Medicine, Univ. of Miami, Miami, FL; [4]Massachusetts General Hospital, Boston, MA; [5]Pediatrics, UCLA, Los Angeles, CA.*

Background: Cardiovascular disease is the leading cause of death in children with chronic kidney disease (CKD). Plasma fibroblast growth factor 23 (FGF23) concentration increases early in the course of progressive CKD, and in adults is a risk factor for left ventricular hypertrophy (LVH) and death. Whether FGF23 is associated with cardiovascular outcomes in children across the spectrum of CKD is not known.

Methods: We performed echocardiograms and measured plasma C-terminal FGF23 in 385 children, ages 1-19 years, mean 11 ± 4 (SD), with CKD stages 2-4 enrolled in the observational CKiD study. A second assessment was made in 175 patients, and a third in 23, at 2 year intervals. GFR was determined by plasma clearance of iohexol (n=313) or the CKiD estimating equation. We used multivariate, longitudinal regression analysis to model the prevalence of LVH using all available data, accounting for repeated measures.

Results: Median GFR was 45 ml/min/1.73 m^2 (IQR: 34-57). The overall prevalence of LVH, defined as LVMI/height^2.7 >95%tile for age and gender, was 16%. The overall prevalence of either systolic (11%) or diastolic (10%) hypertension was 17%. Median FGF23 was 133 RU/ml (IQR: 88-199), 2.3-fold higher than that in healthy children, and values increased progressively with declining GFR. Median FGF23 was 23 RU/ml higher in the children with LVH than in those without LVH. We found that log FGF23 was a significant predictor of LVH (OR 1.6, 95% CI 1.1-2.4, p=0.025), after adjusting for diastolic hypertension (OR 2.8, CI 1.3-5.9, p<0.01), female gender (OR 2.5, CI 1.3-4.6, p<0.005), body mass index (OR 1.1, CI 1.1-1.2, p<0.001), age (OR 0.9, CI 0.8-0.97, p<0.01), and age-adjusted serum phosphorus (OR 1.2, CI 0.98-1.4, p=0.08); GFR was not a predictor.

Conclusions: Increased plasma FGF23 concentration is an independent risk factor for the presence of LVH in children with pre-dialysis CKD.

Intravenous Phosphate Loading Increases Fibroblast Growth Factor 23 in Uremic Rats Ai Nakazawa,[1] Masahide Mizobuchi,[1] Hiroaki Ogata,[2] Chiaki Kumata,[2] Fumihiko Koiwa,[3] Eriko Kinugasa,[2] Tadao Akizawa.[1] *[1]Division of Nephrology, Department of Medicine, Showa University School of Medicine, Japan; [2]Department of Internal Medicine, Showa University Northern Yokohama Hospital, Japan; [3]Division of Nephrology, Department of Medicine, Showa University Fujigaoka Hospital, Japan.*

Background: Fibroblast growth factor 23 (FGF23) plays a crucial role in phosphate metabolism in chronic kidney disease (CKD). Oral phosphate loading and calcitriol stimulate FGF23 secretion although precise mechanisms underlying the stimulation of FGF23 remain to be studied. We compared the effect of oral phosphate loading with that of intravenous loading on FGF23 levels in normal and 5/6th nephrectomized uremic rats.

Methods: Uremic rats (Nx) and sham-operated rats (Sham) were fed a 0.5% phosphate diet for 2 weeks and then divided by 3 groups, 1) with the same 0.5% phosphate diet (NP), 2) with a high phosphate (0.8%) diet (HP), and 3) the NP rats with intravenous phosphate infusion (2M of solution, 20μl/hr) using a micro infusion pump (IV). Blood and urine were obtained 1 day (acute phase) and 7 days (chronic phase) after the interventions.

Results: Both in acute and chronic phases, serum phosphate levels and fractional excretion of phosphate (FEP) were comparable between HP and IV in both Sham and Nx rats, respectively. Serum phosphate levels in both HP and IV were significantly higher than those in NP only in chronic phase of Sham and Nx rats, respectively. FEP in both HP and IV were significantly higher than that in NP in acute and chronic phase of Sham and Nx rats, respectively. In acute phase of Sham and Nx rats, FGF23 levels were comparable among 3 groups (NP, HP, and IV) while in case of chronic phase FGF23 levels in HP were significantly higher than those in NP, and this increase was further pronounced in IV only in Nx rats.

Conclusions: These results show that chronic intravenous phosphate loading increases FGF23 indicating alternative sensing mechanisms for FGF23 other than dietary route (gut) may exist in CKD.

TH-PO922

Fibroblast Growth Factor 23, Interleukin-6 and Mortality in CKD Jair Munoz Mendoza,[1] Tamara Isakova,[1] Julia J. Scialla,[1] Amanda Hyre Anderson,[2] Jing Chen,[3] Jiang He,[3] Matthias Kretzler,[4] Sankar D. Navaneethan,[5] Lavinia A. Negrea,[6] Lisa C. Nessel,[2] Dawei Xie,[2] Sylvia E. Rosas,[2] Huiliang Xie,[1] James P. Lash,[7] Dominic S. Raj,[8] Myles S. Wolf.[1] *[1]U Miami; [2]U Pennsylvania; [3]Tulane U; [4]U Michigan; [5]Cleveland Clinic; [6]Case Western U; [7]U Illinois; [8]G. Washington U.*

Background: Elevated levels of FGF23 are associated with inflammation and each is associated with increased mortality. We tested whether interleukin-6 (IL6) contributes to the relationship between FGF23 and death in CKD.

Methods: We used Cox proportional hazard regression in 3879 individuals enrolled in the Chronic Renal Insufficiency Cohort Study. We adjusted for demographics, kidney function, and traditional risk factors.

Results: During a median follow-up of 3.5 years, 268 participants died (20.4/1000 person-years). Individually, higher levels of natural log (ln) transformed FGF23 (HR per 1SD of lnFGF23, 1.6; 95%CI 1.4-1.8) and IL6 (HR per 1SD of lnIL6, 1.4; 95%CI 1.3-1.6) were independently associated with greater risk of death in adjusted analyses. When lnFGF23 and lnIL6 were both included in a single model, the risk of death associated with lnFGF23 (HR per 1SD of lnFGF23 1.4; 95% CI 1.3-1.6) and lnIL6 (HR per 1SD of lnIL6, 1.4; 95%CI 1.2-1.5) were minimally attenuated. In crude analyses, there was significant interaction between IL6 and FGF23 on the risk of death (p for lnFGF23 x lnIL6=0.03). In stratified analyses above and below the respective medians, participants with high levels of both FGF23 and IL6 had the highest event rates. However, there was no interaction in adjusted analyses (p for interaction=0.6).

	Rate/1000-person-years	HR (95% CI)	
		Crude	Adjusted
Low IL6 low FGF23	6.2 (3.9-8.5)	Ref	Ref
Low IL6 high FGF23	16.5(11.4-21.5)	2.7(1.6-4.3)	2.2(1.3-3.8)
High IL6 low FGF23	17.0(11.8-22.1)	2.7(1.7-4.6)	2.2(1.3-3.7)
High IL6 high FGF23	40.8(34.5-47.1)	6.6(4.4-9.9)	4.2(2.6-6.8)

Conclusions: Elevated levels of FGF23 and IL6 are each independently associated with greater risk of death in CKD. These independent and additive risks suggest that high FGF23 and IL6 levels may influence risk of mortality through distinct pathways.

TH-PO923

What Do We Get when We Measure Serum 25(OH)Vitamin D Levels? Ramon M. Saracho,[2] Isabel Martínez,[1] Iratxe Ajuria Morentin,[3] Edurne Bereciartua,[3] Carmen Mar,[3] Adriana S. Dusso.[4] *[1]Nephrology, Hospital de Galdakao, Usansolo, Vizcaya, Spain; [2]Nephrology, Hospital Universitario de Alava, Vitoria, Alava, Spain; [3]Clinical Lab, Hospital de Galdakao, Usansolo, Vizcaya, Spain; [4]Experimental Nephrology Lab, IRBLleida, Lleida, Spain.*

Background: CKD patients have a high prevalence of nutritional vitamin D (VitD) deficiency. Guidelines recommend to correct it through supplementation with this pro-hormone, based on its potential beneficial effects. However, a previously unrecognized determinant of the "VitD deficiency epidemic" could be an underestimation of serum VitD levels. In fact, several cases of VitD intoxication with hypercalcemia, and even ARF presented at our institution, which were caused by excessive VitD supplementation. These findings raised concerns about the accuracy of current methods to measure VitD status. The aim is to compare the accuracy of the 5 most commonly used immunochemical methods to measure serum 25(OH)D3+25(OH)D2 compared to the gold standard: liquid chromatography-mass spectrometry LC-MS/M.

Methods: We measured 25(OH)D2+D3 in aliquots of 107 serum samples from CKD patients obtained during the same month using all 5 available methods: Architect, Advia Centaur®, Cobas® e411, Liaison®, IDS-iSYS and LC-MS/MS. Results were compared using Passing Bablok regression.

Results: The table depicts the estimates of the regression lines comparing all 5 methods vs. LC-MS/MS. There is a clinically significant variability between different analytical methods of 25(OH)D3+25(OH)D2. The Liaison method used in our institution underestimated serum 25(OH)D2+25(OH)D3 levels by 27.3%. Only one method, Cobas, has a regression line superimposed to that of LC-MS/MS. Equations are provided to correct serum values from any of the available methods by the most accurate reference LC-MS/MC.

	Slope	Intercept	R coefficient
Architect	.750 (.681;.850)	4.7 (3.0;5.9)	.877
Centaur	.631 (.562;.690)	5.3 (4.3;7.0)	.921
Cobas	.993 (.900;1.116)	-.7 (-2.5;1.3)	.907
Liaison	.727 (.667;.818)	.5 (-1.2;1.7)	.824
IDS-iSYS	1.030 (.961;1.123)	5.8 (4.4;7.5)	.924

Conclusions: When considering initiating VitD supplementation, we should be cautious about the analytical method used in our medical center to measure VitD to avoid overdosage.

TH-PO924

Serum FGF-23 Levels Predicts Low Bone Turnover in Adult CKD-5D Patients Marie-Claude M. Faugere,[1] Valentin David,[2] Hanna W. Mawad,[1] Leigh Darryl Quarles,[2] Hartmut H. Malluche.[1] *[1]Division of Nephrology, University of Kentucky, Lexington, KY; [2]Division of Nephrology, University of Tennessee, Memphis, TN.*

Background: Low bone turnover (LBT) is a common histologic finding of renal osteodystrophy. It has deleterious consequences, including increased risk of fractures and vascular calcifications.

Methods: To test the hypothesis that serum levels of FGF-23 may reflect the level of bone turnover in CKD-5D patients better than customarily used tests, 36 CKD-5D patients (15 men and 21 women, mean age: 50±2 yrs, dialysis vintage: 65±5.83 mos.) underwent iliac crest bone biopsies and blood drawings for determination of concentrations of FGF-23, intact PTH (iPTH), bone specific alkaline phosphatase (BAP), tartrate-resistant acid phosphatase (TRAP), calcium and phosphorus.

Results: There were 19 patients with LBT and 17 patients with normal to high bone turnover. Serum FGF-23 levels ranged from 18 to 37,349 pg/mL. Patients with LBT had significantly lower serum FGF-23 than patients with normal to high bone turnover (3,128±1,294 vs. 15,094±3,207 pg/mL, resp., $p<0.001$). FGF-23 correlated with parameters of bone mineralization, in particular with mineralization lag time (rho=-0.654, $p<0.001$), but not with osteoid thickness (rho=0.113, ns). In addition, it correlated weakly with serum phosphorus (rho=0.53, $p=0.001$) and iPTH (rho=0.39, $p<0.05$). IPTH correlated with histomorphometric parameters of static and dynamic parameters of bone remodeling (rho=0.42-0.78), but not with mineralization parameters. Logistic regression to predict LBT showed that among FGF-23, iPTH, BAP and TRAP, the only significant predictor was FGF-23 ($p<0.01$). With a cut-off level of FGF-23<2,000 pg/mL, the sensitivity of FGF-23 to diagnose LBT was 79% with a specificity of 80%. The positive predictive value was 94% and the negative predictive value was 80%. No comparable cut-off level could be established for iPTH and the other measured parameters.

Conclusions: Determination of FGF-23 in serum is useful for noninvasive diagnosis of LBT (adynamic bone disease) in patients with CKD-5D. Serum measurements of iPTH, BAP and TRAP do not provide the same diagnostic information.

Funding: NIDDK Support

TH-PO925

Cinacalcet Lowers Serum Fibroblast Growth Factor-23 Concentration Independently from Serum Ca, P, PTH and Active Vitamin D Treatment in Peritoneal Dialysis Patients Hyo-jin Kim, Yon Su Kim, Curie Ahn, Ki Young Na, Kook-Hwan Oh. *Division of Nephrology, Department of Internal Medicine, Seoul National University Hospital, Seoul, Republic of Korea.*

Background: Elevated serum levels of fibroblast growth factor-23 (FGF23) is associated with adverse outcomes in dialyzed patients. The CUPID study compared the efficacy of a cinacalcet-based regimen with conventional care (vitamin D and P binders) for achieving the stringent NKF-K/DOQI targets for PD patients. Additionally, we analyzed change in FGF23 levels between two treatments to explore the cinacalcet effect in lowering FGF23.

Methods: This is a multicenter and open-label study. Sixty six patients were randomly assigned to treatment with either cinacalcet + oral vitamin D (cinacalcet group, n=33) or oral vitamin D alone (control group, n=33) to achieve K/DOQI targets. CUPID included a 4-week screening for vitamin D washout, a 12-week dose-titration, and a 4-week assessment phases. We calculated mean values of iPTH, Ca, P, Ca x P, during assessment phase and final FGF23 to assess the outcome.

Results: 72.7% (n=24) of the cinacalcet group and 94% (n=31) of the control group completed the study. Cinacalcet group received 30.2±18.0 mg/day of cinacalcet and 0.13±0.32 μg/d oral vitamin D ($P < 0.001$ vs control with 0.27±0.18 μg/d). Achievement of iPTH goal of 150 to 300pg/ml (24.3% vs 18.2%, $P = 0.764$) was not different for both groups. Cinacalcet group achieved targets of Ca x P and Ca earlier than control group($P < 0.01$) and significantly decreased corrected Ca level ($P < 0.01$). Cinacaclet group had a significant decrease in median FGF23 levels (from 3,960 to 2,325 RU/ml, $P = 0.002$), compared with control group (2,085 to 2,415 RU/ml) and a significant difference in percent change of FGF23 (-42.54% vs 15.83%, $P = 0.008$). In multivariate regression analyses, cinacalcet treatment was an independent determinant of the serum FGF23 reduction, which was not associated with age, sex, diabetes, serum Ca, serum P, serum iPTH, and active vitamin D dose.

Conclusions: Cinacalcet lowers the FGF23 independently from its effects on the serum Ca, P, and iPTH.

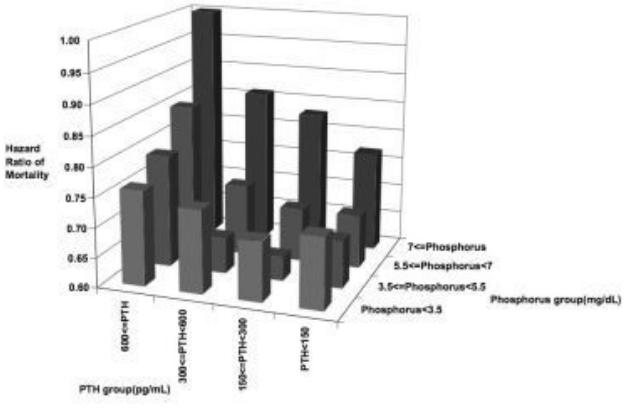
TH-PO926

Association of the Combined Serum Parathyroid Hormone and Phosphorus Levels with Mortality in 107,000 Maintenance Hemodialysis Patients Hsin-yi Wang,[1] Miklos Zsolt Molnar,[1] Joshua Zaritsky,[2] John J. Sim,[3] Elani Streja,[1] Csaba P. Kovesdy,[4] Isidro B. Salusky,[2] Kamyar Kalantar-Zadeh.[1,2] *[1]Harold Simmons Center for Chronic Disease Research & Epidemiology, LABioMed at Harbor-UCLA, Torrance, CA; [2]David Geffen School of Medicine at UCLA, Los Angeles, CA; [3]Kaiser Permanente; [4]Nephrology, University of Tennessee, Memphis, TN.*

Background: Both high and low phosphorous and parathyroid hormone (PTH) levels are associated with higher mortality risk in patients on maintenance dialysis (MHD). However, the associations of PTH and phosphorus combinations are based on cross-sectional studies; therefore this study is aimed to explore the influences of survival rate in MHD patients based on different combinations of PTH and phosphorus levels.

Methods: We examined the survival impact of serum PTH and phosphorous level in a 5-year (7/2001-6/2006) cohort of 107,299 outpatients in dialysis clinics of a large dialysis organization using Cox models adjusted for case-mix and surrogates of Malnutrition-Inflammation Complex.

Results: In this cohort the mean age (mean±SD) was 64±15 years old and included 45% women, 33% African-Americans, and 59% diabetics. In the fully adjusted models, patients with highest level of PTH (≥600 pg/mL) combined with highest phosphorus (≥7 mg/dL) had the highest mortality risk, whereas the best survival (HR: 0.64, 95%CI: 0.61-0.67) was observed with PTH of 150-300 pg/mL was combined with phosphorus of 3.5 to 5.5 mg/dL(Figure).



Conclusions: Patients with PTH between 150 and 300 (pg/mL) combined with phosphorus between 3.5 and 5.5 (mg/dL) have the best survival; thus, new target serum P levels in MHD will need to be defined.

TH-PO927

Fibroblast Growth Factor 23 Is a New Predictor of Aortic Artery Calcification in Maintenance Haemodialysis Patients Zijin Chen,[1] Xiaonong Chen,[1] Jingyuan Xie,[1] Xiaobo Ma,[1] Fang Zhong,[1] Liang Hou,[2] Huawei Ling,[2] Xiao Li,[1] Hong Ren,[1] Nan Chen.[1] *[1]Nephrology Department, Ruijin Hospital, Shanghai Jiaotong University, Shanghai, China; [2]Radiology Department, Ruijin Hospital, Shanghai Jiaotong University, Shanghai, China.*

Background: To investigate the risk factors associated with high plasma FGF23 levels in MHD patients and to determine whether plasma FGF23 level is related to aortic artery calcification(AAC).

Methods: The study included 120 MHD patients and 20 healthy controls. We collected clinic data and pre-dialysis blood tests. FGF23 was measured by ELISA. AAC was detected by a lateral lumbar X-ray plain and read by two radiologists who were blinded to the participants using a semi-quantitative scoring method independently.

Results: Plasma FGF23 levels were significantly higher among MHD patients compared to controls(median FGF23 level 5601.27RU/m in MHD patients).Significant correlations were observed between FGF23 and LgVintage($r=0.413, P<0.001$),LgiPTH ($r=0.283, P=0.002$),P($r=0.587, P<0.001$),Ca($r=0.419, P<0.001$),25(OH)D($r=0.195, P=0.033$),BUN($r=0.263, P=0.004$) and SCR($r=0.415, P<0.001$).Stepwise multiple regression analysis showed that multiple variables were independently associated with FGF23. They were P($\beta=0.206, P<0.001$),Ca($\beta=0.392, P<0.001$),LgPTH($\beta=0.318, P<0.001$), SCR($\beta=0.001, P=0.001$) and prealbumin($\beta=-0.002, P=0.015$)(adjusted for sex,age,LgVintage,ALP,25(OH)D,BUN,UA,TG,TC,HDL and LDL).There were 60.83% patients had visible calcification in the abdominal aorta.Median AAC score was 2.0(0-21) and median AAC segments affected was 1.0(0-4).According to the FGF23 quartiles, AACscore(AACS) in the first quartile was 0.97±1.59,increased to 6.50±6.92 in the forth. Bivariate analysis showed that AACS correlated with LgFGF23($r=0.371, P<0.001$),P($r=0.201, P=0.028$),Ca($r=0.216, P=0.018$),Lgvintage($r=0.404, P<0.001$),age($r=0.395, P<0.001$) and DBP($r=0.395, P=0.026$).Stepwise logistic analysis showed that the independent parameters associated with AAC were age (OR=1.088,P<0.001),TP(OR=2.366,P=0.005) and LgFGF23(OR=0.921,P=0.06).

Conclusions: Plasma FGF23 level is significant increased in MHD patients and is independently associated with aortic artery calcification detected by simple X-ray plain.

TH-PO928

Long-Term Cholecalciferol Supplementation in Hemodialysis Patients: A One-Center Randomized Pilot Study Mariusz Mieczkowski,[1] Pawel Zebrowski,[1] Jerzy Przedlacki,[1] Stanislaw Niemczyk,[2] Janusz Sierdzinski,[3] Joanna Matuszkiewicz-Rowinska.[1] *[1]Nephrology, Medical University of Warsaw; [2]Nephrology, Military Institute of Medicine; [3]Medical University of Warsaw, Poland.*

Background: Vitamin D plays an essential role not only in mineral metabolism, but has also potent pleiotropic extraskeletal effects. Despite a widespread 25(OH)D (25D) deficiency, data on its supplementation in hemodialysis (HD) pts are scarce with only one small unpublished randomized study.We assessed the effect of cholecalciferol on vitamin D status, parathyroid activity and bone mineral density (BMD) in this population.

Methods: 19 pts (age 53±10years, on dialysis 55±63 months) with 25D<20 ng/ml were randomized into: Group A receiving cholecalciferol (2000 IU p.os 3x/week) during HD) and Group B (control). Patients with hypercalcemia, hyperphosphatemia and those receiving vitamin D or calcimimetics were excluded. In addition to routine testing serum 25D, 1,25D, iPTH and alkaline phosphatase (ALP) were examined every 2 months. Dual-energy X-ray absorptiometry was performed at the proximal femur, lumbar spine and forearm, before and after the study.

Results: There was a significant increase in serum 25D in Group A, from 13.5±4.67 to the average of 43.5±8.44 ng/ml (vs 14.0±3.09 to 19.3±7.42 ng/ml in Group B, $p<0.001$). As a result, in Group A serum 1,25D increased from 18.2±14.6 to the average of 41.6±8.86 pmol/l, while in Group B, the corresponding values were 12.1±5.50 and 25.0±9.85 pmol/l ($p=0.009$). Opposite to 25D, serum 1,25D didn't demonstrate any seasonal variations in both groups.The treatment was associated with a moderate increase in serum calcium (from 2.22±0.20 to the average of 2.31±0.15 mmol/l, $p=0.043$) and phosphates (from 1.66±0.32 to 1.98±0.25, mmol/l NS), while serum iPTH and ALP, as well as BMD Z-scores remained unchanged in both groups.

Conclusions: Oral cholecalciferol at a weekly dose of 6000 IU is a cheap and safe way to treat vitamin 25D deficiency in HD pts leading to a significant increase in serum1,25D, however it may be insufficient for parathyroid glands suppression.

TH-PO929

FGF-23 in Patients with Chronic Kidney Disease Stage 5D: Intact or C-Terminal? Mariusz Mieczkowski,[1] Pawel Zebrowski,[1] Ewa Wojtaszek,[1] Antoni Sokalski,[2] Edyta Gieglis,[3] Tomasz Stompor,[4] Wieslaw Klatko,[5] Janusz Grochowski,[6] Ignacy Jarzyllo,[7] Jerzy Przedlacki,[1] Stanislaw Niemczyk,[8] Janusz Sierdzinski,[1] Zofia Wankowicz,[8] Joanna Matuszkiewicz-Rowinska.[1] *[1]Nephrology, Medical University of Warsaw; [2]Radom Hospital; [3]Otwock Nephrocare; [4]Warmia@Mazury University; [5]Ciechanow Hospital; [6]Makow Hospital; [7]Wolomin Hospital; [8]Military Institute of Medicine.*

Background: High serum FGF-23 concentration is an important negative predictor of morbidity and mortality in patients with chronic kidney disease (CKD). The aim of the study was to assess the usufulness of two assays evaluating different FGF23 fragments: intact FGF and C-terminal in this population.

Methods: 252 patients with CKD stage 5D from 9 units were enrolled into the study. 210 were on hemodialysis (HD) and 42 on peritoneal dialysis (PD). Mean age was 59±15 years, and dialysis vintage 45±49 months. All blood samples were centrifuged and serum immediately transferred on ice to our core lab, where stored in -70°C until further use. Both iFGF-23 and cFGF23 concentrations were measured using the immunoenzymatic sandwich type assays (ALPKO, Salem, USA).

Results: Both studied tests correlated positively (r=0.24, p<0.001) with each other. The study showed very high serum iFGF23 (438±362 pg/ml) and cFGF23 (4447±3783 RU/ml) in all patients. The values were more than 1.5 x lower in PD group and about 3 x lower in diabetics. There were high correlations of both iFGF23 and cFGF23 with serum phosphate: in all patients (r=0.51, P<0.001 and r=0.45, p<0.001), in HD (r=0.50, p<0.001 and r=0.43, p<0.001) and PD (r=0.48, p=0.002 and r=0.53, p<0.001) and the weaker correlations with serum calcium: in all patients (r=0.20, p=0.002 and r=0.23, p<0.001) and in HD r=0.22, p=0.00 and r=0.28, p<0.001), as well as with serum iPTH in all patients (r=0.24, p<0.001 and r=0.18, p=0.007) and in HD (r=0.25, p<0.001 and r=0.17, p=0.02). A positive correlation between FGF-23 and the dialysis vintage may reflect the impact of residual renal function, diminishing with time.

Conclusions: The usefulness of both FGF-23 tests in patients with CKD stage 5D is similar.

TH-PO930

New Insights into Vitamin D-Related Mineral Metabolism in Nephrotic Syndrome Michelle Denburg,[1] Ian H. de Boer,[2] Dean Carlow,[1] Amy York,[1] Rene Chun,[3] Martin Hewison,[3] Mary B. Leonard.[1] *[1]Children's Hosp of Philadelphia, Philadelphia, PA; [2]Univ of Washington; [3]UCLA Orthopaedic Hosp.*

Background: Patients with nephrotic syndrome (NS) have low 25-hydroxyvitamin D (25D) levels, attributed to urinary loss of vitamin D-binding protein (DBP) and albumin (Alb), but vitamin D (vitD) metabolism in NS remains poorly understood.

Methods: Cross-sectional study of 20 NS and 30 control participants (ages 3-40 yr). NS participants were younger (p <0.001); sex, race and season did not differ between groups. Serum measures: 25D, 24,25D, DBP, Alb, PTH, fibroblast growth factor 23 (FGF23), ionized calcium (ICal), and phosphorus (Pi). Free 25D was calculated using total 25D, DBP and Alb. Urine measures: total protein, creatinine (cr), DBP, and 25D, the latter by a novel HPLC-MSMS assay. Multivariate linear regression was used to identify correlates of 25D and PTH.

Results: Total and free 25D, 24,25D, and ICal were lower, and FGF23 higher in NS. Serum DBP and PTH did not differ between groups.

Comparison of NS vs. Control

Measure*	NS	Control	p**
SERUM			
25D ng/ml	8.8 ± 8.8	22.4 ± 8.5	<0.0001
Alb g/dl	2.6 (2.1, 3)	4.3 (4.2, 4.5)	<0.0001
DBP mg/dl	16.9 (9.6, 27.6)	17.1 (10.1, 24.6)	0.81
Free 25D pg/ml	2.9 (2.2, 3.8)	8.8 (6.9, 16.6)	<0.0001
24,25D ng/ml	1.5 (1.0, 1.7)	2.5 (1.8, 4.0)	0.0034
ICal	1.17 ± 0.06	1.22 ± 0.05	0.0015
Pi mg/dl	4.7 ± 0.9	4.1 ± 0.8	0.021
PTH pg/ml	32.8 (20.8, 47.0)	42.3 (32.4, 51.7)	0.14
FGF23 pg/ml	52.1 (37.7, 65.1)	31.2 (28.1, 39.5)	0.0012
URINE			
Protein:cr	6.2 (3.5, 9.2)	0.04 (0.03, 0.05)	<0.0001
DBP:cr	0.004 (0.0005, 0.02)	0.00003 (0.00002, 0.00005)	<0.0001
25D pg/ml	197 (64.1, 685)	0 (0, 0)	0.019

*Median (IQR) or mean ± SD. **Rank-sum or t-test.

In multivariate analysis, the association between NS and both forms of 25D was explained by Alb but not serum DBP. The expected inverse relationship between PTH and 25D was found in the control (p <0.02) but not the NS group (p=0.6; interaction p=0.07). Higher FGF23 levels in NS were independent of Pi and eGFR.

Conclusions: This is the first study to demonstrate reduced free 25D in NS. Despite heavy urinary loss of DBP in NS, serum DBP was preserved. PTH was not increased in NS despite lower ICal and vitD. These findings suggest that aberrant vitD-related mineral metabolism in NS extends beyond DBP loss.

TH-PO931

α-Klotho in CKD Sandro Mazzaferro, Silverio Rotondi, Lida Tartaglione, Cristiana Leonangeli, Giuliana Pirrò, Marzia Pasquali. *Cardiovascular, Respiratory, Nephrologic and Geriatric Sciences, Sapienza University, Rome, Italy.*

Background: Membrane α-Klotho is a co-factor for FGF23 and a decrease in membrane a-Klotho in CKD may prevent the actions of FGF23. Secreted α-Klotho results from the shedding of membrane α-Klotho, which is expressed in renal tubules. A decrease in soluble α-Klotho could indicate a decrease of membrane α-Klotho. The possible clinical significance of circulating α-Klotho in CKD is still a matter of debate.

Methods: We assayed serum α-Klotho, FGF23, vitamin D and parameters of mineral metabolism in 70 pts(59±16y) with CRF stage 2 to 4(eGFR 45±22ml/min) and in 10 controls(34±12y;eGFR 95±19ml/min).

CKD parameters

Klotho,pg/ml	Ca s,mg/dl	P s,mg/dl	BALP,U/l	PTH,pg/ml	25D,ng/ml	1,25D,pg/ml	FGF23,pg/ml
519,8±183,4	9,4 ±0,6	3,5 ±0,7	24,2 ±13,0	60,0 ±31,7	23,7 ±11,1	24,8 ±13,2	73,8 ±51,8

Results: Levels of α-Klotho were lower than normal(519±184vs983±523 pg/ml,p<.0001), a difference that was evident since stage 2 CRF(611±191vs983±523,p<.007). In front of mild vitamin D insufficiency(25D:23±11) patients had 1,25D values at the lower limit of normality, mild increment of PTH and normal mean values of Ca, P and bone AP. Serum levels of FGF23 were increased as compared to controls(73±51vs30±12,p<.03).

α-Klotho correlated with renal function(r=.427,p<.001) but not with age. Moreover, the relationship was negative with FGF23(r=-.331,p<.01), P(r=-.251,p<.05) and PTH(r=-.279,p<.05) and positive with Ca(r=.305,p<.01). Importantly no correlation existed with fractional excretion of P.

Conclusions: Our data indicate a significant negative effect of renal function on circulating levels of α-Klotho which seems to start very early in the disease. Low circulating α-Klotho could be responsible for reduced phosphaturia(lower direct effect) thus becoming a stimuli for FGF23 secretion. In addition, if soluble Klotho mirrored transmembrane Klotho, low circulating levels could indicate the occurrence of FGF23 resistance in renal tubuli. As for Ca homeostasis, soluble α-Klotho, even though reduced, seems to preserve its direct action on serum Ca. In summary, soluble α-Klotho drops early in the course of renal disease and seems to contribute, in this setting, to some derangements of mineral metabolism.

TH-PO932

Low PTH and High Circulating Sclerostin Levels Are Independently Associated with Low Bone Specific Alkaline Phosphatase Levels in Hemodialysis Patients Liesbeth Viaene,[1] Geert J. Behets,[2] Pieter Evenepoel,[1] Patrick C. D'Haese.[2] *[1]Laboratory of Nephrology, Catholic University Leuven, Leuven, Belgium; [2]Laboratory of Pathophysiology, University of Antwerp, Antwerp, Belgium.*

Background: Sclerostin, a Wnt antagonist, produced by osteocytes inhibits osteoblastic activity and is hypothesised to counteract PTH-induced high bone turnover. Preliminary bone histomorphometry data indicate that sclerostin may be superior to PTH as a non-invasive indicator of bone turnover. The present study aimed to identify determinants of circulating sclerostin levels in hemodialysis patients and tests the hypothesis that sclerostin and PTH have opposite effects on bone-specific alkaline phosphatase (bsAP) and carboxyterminal cross-linking telopeptide(CTX).

Methods: Biochemical parameters of bone and mineral metabolism, including whole PTH (in-house bio-intact immunoradiometric assay and Liaison, Diasorin), calcidiol (Total 25 OHD, Liaison, DiaSorin), calcitriol (RIA, DiaSorin), FGF23 (ELISA, Kainos), DKK-1 (ELISA, Biomedica), sclerostin (ELISA, Biomedica), bsAP(BAP Ostase, Liaison, DiaSorin) and CTX (Serum Crosslaps ELISA, IDS) were assessed in 100 hemodialysis patients (40 male, age 68±13yrs, dialysis vintage 40 (16-69) months, residual renal function (RRF) 0.6±1.3 ml/min/1.72m^2).

Results: In multivariate linear regression analysis, the presence of diabetes (p=0.04), male gender (p=0.01), lower bsAP (p<0.0001) and lower RRF (p=0.002) were identified as independent determinants of higher levels of circulating sclerostin levels(R^2=0.33, p<0.0001). The correlation between both PTH assays was good (r^2=0.99; p<0.0001). Both higher PTH and lower serum sclerostin levels are independently associated with higher bsAP levels (R^2=0.34, p<0.0001). Serum PTH, but not sclerostin was independently associated with serum CTX levels in hemodialysis patients (R^2=0.11, p=0.005).

Conclusions: Diabetes mellitus, male gender, low bsAP, and low RRF are independent risk factors for high circulating sclerostin levels. High circulating sclerostin levels and low PTH levels are independently associated with low bsAP levels, reflecting low bone formation.

TH-PO933

Association between Vitamin D Receptor Polymorphisms and PTH Levels in CKD5 Patients on Dialysis Olynka Vega,[1] Maria de Los Angeles Mendoza-De la Garza,[1] Mara Medeiros,[2] Ricardo Correa-Rotter.[1] *[1]Nephrology, National Institute of Medical Sciences, Mexico, Distrito Federal, Mexico; [2]Nephrology, Hospital Infantil de Mexico, Mexico, Distrito Federal, Mexico.*

Background: The possible influence of vitamin D receptor (VDR) gene polymorphisms on the regulation of the calcium-PTH-vitamin D axis is highly relevant in chronic kidney disease. The aim of the study was to explore the frequency of VDR polymorphism rs7975232 (Apa 1), rs731236 (Taq 1), and rs1544410 (Bsm 1) and their association with PTH, calcium, and phosphate serum levels in Mexican patients on dialysis.

Methods: 143 prevalent dialysis patients were included. Biochemical determinations: calcium, phosphate, and PTH. VDR genotypes were analyzed as RFLPs using Apa 1, Bsm 1, and Taq 1 enzymes.

Results: Mean age 45.6±16.9, 60% male, 55.5% HD. All allelic and genotypic frequencies were in Hardy-Weinberg equilibrium. Genotypic frequencies for Apa 1: 73% Aa, 20% aa and 7% AA; for Bsm 1: 77% Bb, 15% BB and 8% bb; for Taq 1: 52% Tt, 46% TT and 2% tt. Patients who were homozygous for allele A and B had lower serum PTH concentrations (p=<0.001), independent to calcium and phosphate levels. Five patients were homozygous for A, B and T and presented lower PTH levels [median PTH 301 (range: 76 - 475) Vs 548 (range: 114 - 5422), P= 0.001]. Patients homozygous for T had higher serum calcium concentrations (9.8 vs 9.5, p=0.028). There were no significant differences in use of phosphate binders and oral calcitriol between compared groups (Table 1). Likewise, time on dialysis was also no different between groups.

Table 1. Biochemical parameters between different groups of polymorphisms.

	AA n=9	Aa + aa n=134	p	BB n= 22	Bb+ bb n= 121	p
PTH, pg/mL**	337 (77-979)	727 (23-5423)	0.003	429 (77-1240)	760.9 (23-5423)	0.008
Ca+, mg/dL	9.9±1.2	9.6± 0.9	0.49	10.2±1.1	9.5±0.9	0.06
P+, mg/dL	5.1±2.1	5.8±2.0	0.29	6.0±2.1	5.7±2.0	0.50

**Median (min-max)

Conclusions: The most common genotype for Apa 1, Taq 1 and Bsm 1 in Mexican patients on dialysis is the heterozygous. Homozygous patients for the allele A or B had lower PTH levels. This diversity of the VDR gene expression may confer variable sensitivity to the vitamin D in specific individuals.

TH-PO934

Vitamin D Insufficiency or Not? It Depends on the Used Assay! Hamid R. Dezfoolian, Ola G. Samuelsson, Maria Svensson. *Department of Nephrology, Sahlgrenska Academy, Sahlgrenska University Hospital, Gothenburg, Sweden.*

Background: Vitamin D deficiency and insufficiency have been linked to a variety of chronic diseases. Vitamin D deficiency is defined as a serum concentration of 25-OH-vitamin D <20 ng/mL (50 nmol/L) and insufficiency as 21–29 ng/mL (50-75 nmol/L). Different assays may show different levels of serum 25-OH-D, and thereby affect treatment strategies. The aim of this sub-study was to evaluate the performance of two different assays of serum 25-OH-D and how vitamin D_3 supplementation may affect the performance of these methods.

Methods: Twenty-one non-diabetic patients with chronic kidney disease (CKD stage 3-4) and vitamin D insufficiency measured by the radioimmunoassay (RIA) method were included. Patients were randomized in a placebo-controlled, two-way cross-over study to receive daily either 3200 IU (80 µg) vitamin D_3 (cholecalciferol) or placebo in 10 weeks. At the end of each treatment period we measured the serum 25-OH-D levels using both a radioimmunoassay (RIA) (DiaSorin®) and a High-Performance Liquid Chromatography (HPLC) (Shimadzu®) to compare these methods.

Results: After placebo treatment vitamin D insufficiency was found in all 21 patients (100%) using the RIA method, while only in 15 patients (71%) using the HPLC method. Mean (SD) serum 25-OH-D level was 52 (13) nmol/L using RIA, compared with 66 (15) nmol/L using HPLC, P<0.0001. After treatment with vitamin D3 there were still five patients (23%) with vitamin D insufficiency using RIA, but only one patient (4%) using HPLC method. The mean (SD) serum 25-OH-D levels rose 67% to 87 (17) nmol/L using RIA, (P<0.0001) compared with 58% to 104 (17) nmol/L using HPLC, (P<0.0001). The difference between the means using these different methods was significant (P=0.001). The Pearson correlation's coefficient between the two methods was 0.8 (P<0.0001).

Conclusions: Results from these two different 25-OH-D assays differed markedly, when measuring serum 25-OH-D among non-diabetic patients in chronic kidney disease (stage 3-4). Diagnosis of vitamin D deficiency or insufficiency and consequential recommended supplementation may thus, depends on analysis method. Methods for analysis of 25-OH-D should therefor be standardized.

TH-PO935

Vitamin D Seasonal Variations in Dialysis Patients: A Prospective Multicenter Study Joanna Matuszkiewicz-Rowinska,[1] Mariusz Mieczkowski,[1] Ewa Wojtaszek,[1] Pawel Zebrowski,[1] Antoni Sokalski,[2] Tomasz Stompor,[3] Janusz Grochowski,[4] Edyta Gieglis,[5] Wieslaw Klatko,[6] Jerzy Przedlacki,[1] Robert Malecki,[7] Ignacy Jarzyllo,[8] Stanislaw Niemczyk,[9] Zofia Wankowicz.[9] *[1]Nephrology, The Medical University in Warsaw; [2]Radom Hospital; [3]Warmia@ Mazury University; [4]Makow Hospital; [5]Otwock Nephrocare; [6]Ciechnow Hospital; [7]MSSW Warsaw; [8]Wolomin Hospital; [9]Military Institute of Medicine, Warsaw, Poland.*

Background: The prevalence of 25(OH)D (25D) deficiency is widespread in pts on dialysis, and has recently been shown to be associated with increased mortality. As most of 25D is of skin origin and sunshine dependent, its levels differ according to a season. This cross-sectional study is the most extensive prospective assessment of these fluctuations to date in this population.

Methods: It involved 252 prevalent pts (210 on hemodialysis (HD), 42 on peritoneal dialysis (PD), age 59±15 years) from 9 units. Pts taking any vitamin D derivatives were excluded. In all of them serum 25D (RIA), PTH and routine parameters were measured (centrally), 3x a year: in summer, autumn and winter.

Results: The study showed a significant 25D deficiency in the studied population. Its serum levels decreased from 23.0±10.4 (summer) to 14.3±9.4 ng/ml (winter). Normal serum 25D was observed in summer in 22%, in autumn in 11%, and only in 3.5% in winter! The proportion of pts with the deficiency (<20 ng/ml) rose from 43 to 82%, and severe deficiency (<10 ng/ml) from 7.2 to 32%. PD pts were particularly prone to the deficit: in autumn and winter, none of them had normal serum 25D, while its deficiency was observed in 89 and 96%(vs 51 and 80% of HD patients), and severe deficiency in 32 and 61% (vs 3.6 and 28% of HD, p <0.001). Multivariate analysis showed that independent predictors of 25D deficiency were: female gender (OR 3,45, CI 95%, 1,97–6,12, p<0,0001) and age >65 years (OR 1,87, 95% CI, 1,05–3,34, p=0,034).

Conclusions: Prevalence of 25D deficiency is widespread in our dialysis population, in winter being present in 78 to 96% pts. It can be very deep in PD pts, in whom in autumn and winter serum 25D can reach dramatically low levels posing a risk of osteomalacia.

TH-PO936

Effects of a High Protein Diet on Regulation of Phosphorus Homeostasis Robin Amy Kremsdorf,[1] Andrew N. Hoofnagle,[2] Mario Kratz,[2] Holly Callahan,[2] Angela Horgan,[3] Jonathan Q. Purnell,[3] David S. Weigle,[2] Ian H. de Boer,[2] Bryan R. Kestenbaum.[2] *[1]Seattle Children's Hospital, Seattle, WA; [2]University of Washington, Seattle, WA; [3]Oregon Health and Science University, Portland, OR.*

Background: High protein diets that are typically used for weight loss contain large quantities of phosphorus. Phosphorus excess and associated regulatory hormones are implicated in cardiovascular disease, in populations with and without kidney disease. It is not known whether moderate changes in dietary phosphorus from natural sources can impact phosphorus responsive hormones in the general population.

Methods: We studied 19 healthy subjects from a sequential dietary modification trial for weight loss. Subjects received the following prepared diets in order: (1) a two-week isocaloric, low-protein (15%) diet, (2) a two-week isocaloric, high-protein (30%) diet, and (3) a 12-week *ad libitum* high-protein (30%) diet. We measured fibroblast growth factor-23 (FGF-23), parathyroid hormone (PTH), 1,25-dihydroxyvitamin D, and 24,25-dihydroxyvitamin D from integrated plasma samples that that were collected at 8 timepoints at the end of each diet phase.

Results: Mean phosphorus intake during each diet phase was 1,556, 2,071, and 1,622 mg/day, respectively. There were minimal changes in plasma concentrations of FGF-23, PTH, and vitamin D metabolites upon changing to an isocaloric or *ad libitum* high protein diet.

	N	Isocaloric 15% protein diet	Isocaloric 30% protein diet	Ad Libitum 30% protein diet
Dietary phosphorus (mg/day)		1,556	2,071	1,622
FGF-23 (pg/mL)	19	33.6±7	29.1±5.7	32.6±10.7
PTH (pg/mL)	19	35.4±11.1	35±11	35.4±11.7
1,25(OH)2D (pg/mL)	16	49.1±10.7	50±10.2	46.9±12.2
24,25(OH)2D (ng/mL)	19	3.8±2.3	3.8±2	4.1±2.3

Values shown as mean ± SD

Conclusions: Among healthy people, an approximately 33% increase in dietary phosphorus from a high-protein diet does not meaningfully alter plasma levels of phosphorus regulatory hormones.

Funding: NIDDK Support, Private Foundation Support

TH-PO937

Serum Fibroblast Growth Factor 23 Is Independently Correlated with Inflammation and Chemokine Expression in Healthy Predialysis CKD Patients Nihil Chitalia, Geeta Hampson, David Goldsmith. *King's Health Partners, London, United Kingdom.*

Background: Serum vitamin D, along with FGF23, is an independent risk factor for CV disease and overall survival in CKD. Evidence now supports an immunoregulatory effect of vitamin D, but the effect of FGF23 on the immune system is unknown. To investigate effects of these on immune system, we measured serum FGF-23, along with substrate and active serum vitamin D levels, and circulating markers of inflammation and chemokine expression, in a CKD cohort.

Methods: 114 adult stage 3-5 pre-dialysis ambulant vitamin D naïve outpatients were examined. A 25-plex panel Invitrogen™ immunoassay was used for quantitative analysis of inflammatory cytokines. Serum FGF-23 was measured by two-site ELISA detecting both C-terminal and intact fragments. Serum 25 hydroxy vitamin D [25(OH)D] and 1,25 dihydroxy vitamin D [1,25$(OH)_2$D] were measured by radioimmunoassay. Panels for Inflammation, Cytokine II, Chemokine and Th1/Th2 protein expression were statistically analysed using canonical correlation analysis (CCA) with known 'clinical variables', namely 25(OH)D, 1,25$(OH)_2$D and eGFR.

Results: The patients were aged 55±15 years, males 60% and MDRD eGFR 45±23ml/min/1.73m^2. Median±IQR FGF-23, PTH & hsCRP concentrations were 65±75 RU/ml, 58±69ng/L and 2.03±3.07mg/L respectively. Mean±1SD serum 25 hydroxy vitamin D and1,25$(OH)_2$D concentration were 51±24 nmol/L and 64±39 pmol/L respectively.

On CCA, there was a positive correlation between inflammatory panel variables and clinical variables at 5% significance (Wilk's=0.659,df=24,p=0.031). FGF23 positively correlated with IL8 accounting for 58.02% of the overall correlation variance of the model. On testing clinical variables with the Chemokine panel, there was a positive correlation (Wilk's=0.616,df=28,p=0.022). Monokine induced by INFγ (MIG) was positively correlated with FGF23, accounting for 54.14% of the correlation variance. Serum vitamin D did not show an independent correlation with cytokines when adjusted for eGFR.

Conclusions: Serum FGF-23 may have pro-inflammatory, and chemoattractant, roles in CKD via expression of inflammatory cytokines and chemokines. This hypothesis now needs testing in an in-vitro model.

TH-PO938

Differential Associations of 25-Hydroxyvitamin D and 1,25-Dihydroxyvitamin D with Impaired Renal Function in Patients with Diabetes Keitaro Yokoyama,[1] Akio Nakashima,[1] Ichiro Ohkido,[1] Tatsuo Hosoya,[1] Mitsuyoshi Urashima.[2] *[1]Division of and Hypertension, Department of Internal Medicine, the Jikei University School of Medicine, Tokyo, Japan; [2]Division of Molecular Epidemiology, the Jikei University School of Medicine, Tokyo, Japan.*

Background: Among patients with diabetes, both 25-hydroxyvitamin D (25OHD) and 1,25-dihydroxyvitamin D (1,25OHD) were shown to associate with urinary albumin-to-creatinine ratio (UACR) in patients with diabetes, separately, through either cross sectional studies or double blinded placebo controlled randomized trials. By measuring both 25OHD and 1,25OHD simultaneously, we aimed to clarify differential associations of 25OHD and 1,25OHD with eGFR stage and UACR as well as other metabolic parameters.

Methods: Cross sectional study of 542 patients with type 2 diabetes from eGFR stage 1 to 5. eGFR stages and UACR were set as primary outcomes and their associations with 25OHD and 1,25OHD were evaluated with multiple linear regression models with adjustments using age, gender, body mass index, usage of ACEI or ARB, usage of statin, and duration of diabetes.

Results: Mean (SD) of 25OHD and 1,25OHD were 24.2 (9.5) ng/mL and 43.6 (22.0) pg/mL, respectively. Under multi-variate adjustment, eGFR stages were negatively associated with 1,25OHD (P<0.001), but not with 25OHD. Similarly, 1,25OHD, but not 25OHD, was positively associated with levels of Ca (P=0.001), while negatively with levels of Pi (P<0.001). On the other hand, UACR were negatively associated with 25OHD (P=0.002), but not with 1,25OHD, in patients within eGFR stage 2 and stage 3.5. Similarly, fasting blood glucose levels were significantly associated with 25OHD (P=0.015), but not with 1,25OHD.

Conclusions: Our data suggest that 25OHD may associate with UACR in diabetic patients with mild to moderate-severe renal dysfunction, independent of serum Ca levels. Long term and relatively large scaled and randomized, placebo-controlled trials are needed to conclusively determine whether vitamin D supplementation reduces renal insufficiency complicated in patients with diabetes.

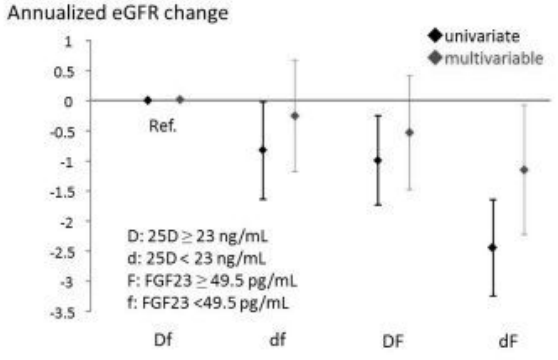
TH-PO939

FGF23 and 25-Hydroxyvitamin D Levels Predict Annualized Estimated GFR Decline Chikako Nakano,[1] Takayuki Hamano,[2] Naohiko Fujii,[3] Isao Matsui,[1] Yoshitsugu Obi,[1] Kazunori Inoue,[1] Akihiro Shimomura,[1] Noriyuki Okada,[4] Yoshiharu Tsubakihara,[2] Hiromi Rakugi,[1] Yoshitaka Isaka.[1] *[1]Geriatric Medicine and Nephrology, Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [2]Comprehensive Kidney Disease Research, Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [3]Internal Medicine, Hyogo Prefectural Nishinomiya Hospital, Nishinomiya, Hyogo, Japan; [4]Nephrology and Hypertension, Osaka General Medical Center, Osaka, Japan.*

Background: We already reported that high fibroblast growth factor 23 (FGF23) and low 25-hydroxyvitamin D (25D) levels in chronic kidney disease predicted renal event (serum creatinine doubling / initiation of dialysis) independent of other mineral bone disorder (MBD)-related factors (CJASN 2012). Our aim was to examine the relationships between these 2 factors and eGFR decline.

Methods: This is a prospective cohort study of 738 predialysis outpatients in 2 nephrology units. The outcome was an annualized eGFR decline calculated by the following formula: (final eGFR – baseline eGFR) / follow-up duration (years). We utilized restricted cubic spline in multiple regression analyses to explore potential non-linear relationships.

Results: At baseline, mean eGFR was 35 mL/min/1.73m^2. During a median follow-up period of 4.4years, 146 patients started maintenance dialysis. In univariate analyses, a non-linear relationship was observed between 25D and eGFR decline (P for linearity: 0.02). The eGFR decline was greater in patients with 25D below 25 ng/mL. Above this threshold, eGFR decline plateaued. As to FGF23, higher levels were related to a greater eGFR decline (p for linearity: 0.43). Similar trends were observed in multiple regression analyses. The analysis treating 25D and FGF23 as categorical variables was shown in Figure 1.



Conclusions: There was a cut-off below which lower 25D levels were associated with steeper eGFR decline.

TH-PO940

Fibroblast Growth Factor 23 in Pediatric Heart Failure Tamara Isakova,[1] Jessica Houston,[1] Laura Santacruz,[2] Eva Schiavenato,[1] Gabe Somarriba,[2] William Harmon,[2] Tracie Miller,[2] Steven Lipshultz,[2] Myles S. Wolf,[1] Paolo Rusconi.[2] *[1]Medicine, UM; [2]Pediatrics, UM.*

Background: FGF23, a bone-derived hormonal regulator of mineral metabolism, has been shown to be elevated in adults with heart failure, in whom it was associated with risks of future hospitalization and mortality. Data on FGF23 levels in pediatric heart failure are lacking.

Methods: We conducted a cross-sectional study of 20 children (mean age 11±6 years; mean eGFR 109.4±56 ml/min/1.73 m^2) with heart failure who underwent echocardiography and the following measurements: FGF23, PTH, phosphate, serum creatinine, and NT-proBNP. Assessment of symptom severity was performed using the NYHA classification system.

Results: Eleven children had dilated cardiomyopathy (DCM); the remaining etiologies included congenital heart disease (n=4), hypertrophic cardiomyopathy (3), failing heart transplant (1), and pulmonary hypertension (1). Loop diuretics were prescribed to 9 patients, and 40% had NYHA class ≥2. Mean serum phosphate and median PTH levels were in the normal range. In contrast, the median FGF23 was elevated (110.9; interquartile range 78.4 – 187.1 RU/ml), and FGF23 levels were higher in patients treated with diuretics compared to untreated patients (P=0.01). FGF23 also correlated significantly with NT-proBNP (r=0.47, P=0.04), and there was a trend for higher levels in patients with higher NYHA class (P=0.05). These associations were independent of eGFR, which was not a significant predictor of FGF23. Among patients with DCM, FGF23 correlated with echocardiographic indicators of hypertrophy and dilation.

Echocardiographic Measures (normalized to age z-score)	FGF23		NT-proBNP	
	r	P Value	r	P Value
Indicators of Systolic Function				
Left ventricular ejection fraction	−0.49	0.12	−0.61	0.046
Left ventricular fractional shortening	−0.53	0.12	−0.53	0.12
Indicators of Hypertrophy				
Left ventricular wall thickness	0.59	0.06	0.02	0.96
Left ventricular septal thickness	0.50	0.12	0.15	0.67
Left ventricular mass	0.61	0.06	0.45	0.19
Indicators of Dilation				
Left ventricular systolic diameter	0.60	0.05	0.59	0.06
Left ventricular diastolic diameter	0.63	0.04	0.57	0.07

Conclusions: FGF23 levels are elevated in children with heart failure and are associated with symptom severity and echocardiographic measures of function and remodeling. Future studies should evaluate the longitudinal relationship between FGF23 and outcomes in children with heart failure.

TH-PO941

Fibroblast Growth Factor 23, High-Sensitivity Cardiac Troponin, and Left Ventricular Hypertrophy in Chronic Kidney Disease Kelsey T. Smith, Christopher deFilippi, Tamara Isakova, Orlando M. Gutierrez, Karen A. Laliberte, Stephen L. Seliger, Walter Kelley, Show-hong Duh, Michael K. Hise, Robert Christenson, Myles S. Wolf, James Januzzi. *The Division of Nephrology and Hypertension, Department of Medicine, University of Miami Miller School of Medicine, Miami, FL.*

Background: Detectable levels of cardiac troponin (cTn) are common among individuals with chronic kidney disease (CKD), even in the absence of symptomatic cardiovascular disease. Abnormal cTn values are associated with coronary artery disease (CAD) and left ventricular hypertrophy (LVH), and predict poor clinical outcomes. Elevated levels of fibroblast growth factor 23 (FGF23) contribute to LVH in CKD. We investigated the association of FGF23 and high-sensitivity (hs) cTnI and cTnT in CKD, and examined the role of LVH in this association.

Methods: In this cross-sectional observational study, we measured hs-cTnI, hs-cTnT and FGF23 in 153 stable outpatients with pre-dialysis CKD and low prevalence of CAD (15%). Left ventricular mass index (LVMI) was assessed by echocardiography and coronary artery calcification (CAC) was measured by computed tomography.

Results: Mean (± standard deviation) age was 64 ± 12 years, mean estimated glomerular filtration rate was 34 ± 11 ml/min/1.73m^2, median (interquartile range) FGF23 was 120 RU/mL (79 - 223 RU/ml), median hs-cTnI was 6.5 pg/ml (3.5 - 14.5 pg/mL), and median hs-cTnT was 16.8 pg/ml (11.1 - 33.9 pg/mL). Concentrations of cTnI and cTnT were >99th percentile of a normal population in 42% and 61% of patients, respectively. In unadjusted and multivariable adjusted analyses, both hs-cTns were significantly associated with FGF23 (β=0.33, *P*=0.003 for hs-cTnI; β=0.24, *P*<0.001 for hs-cTnT in fully adjusted models).

Adjusting for LVMI (β=0.20, *P*=0.07 for hs-cTnI; β=0.20, *P*=0.008 for hs-cTnT), but not CAC (β=0.36, *P*=0.002 for hs-cTnI; β=0.22, *P*=0.002 for hs-cTnT), weakened the association of FGF23 and both hs-cTns.

Conclusions: Minimally elevated cTnI and cTnT, detectable by high-sensitivity assays, are associated with elevated FGF23 levels in stable outpatients with CKD. FGF23-associated LVH may contribute to detectable cTn levels observed in pre-dialysis CKD.

Control of Secondary Hyperparathyroidism Using Cinacalcet with/without Active Vitamin D Sterols in Incident Dialysis Patients Serge Cournoyer,[1] Ian Matthew Bridges,[2] Cynthia R. Christiano,[3] Mourad Farouk,[2] Nelson P. Kopyt,[4] Mariano Rodriguez,[5] Pablo A. Urena,[6] Daniel Zehnder,[7] Kerry Cooper.[2] *[1]Hôpital Charles LeMoyne; [2]Amgen; [3]East Carolina University; [4]LehighValley Hospital; [5]Hospital Universitario Reina Sofia, IMIBIC; [6]Clinique Du Landy; [7]Warwick Medical School.*

Background: Initial treatment of SHPT in incident dialysis patients often includes phosphate binders and active vitamin D sterols (vitD). Cinacalcet (Cin) is commonly added when PTH levels are not controlled adequately. In the Incident Dialysis study, Cin with low-dose vitD, if prescribed, more effectively decreased PTH than flexible doses of vitD alone (Urena et al, ASN 2011). We report post hoc results in subgroups of the Cin arm according to use/non use of vitD during the treatment phase.

Methods: Subjects with SHPT (PTH>300 pg/mL) on dialysis for >3–12 mo were randomized 1:1 to Cin (+low-dose vitD, if prescribed) or vitD (if prescribed) alone. VitD was prescribed according to standard treatment guidelines. Treatment duration was 12 mo, with primary endpoint assessed at 6 mo. Of153 Cin-treated subjects, 48 received no vitD at any time during the treatment phase.

Results: There were no obvious differences in baseline characteristics between the vitD and noVitD subgroups. Efficacy and safety were similar in both subgroups. Subject incidence of biochemical hypocalcemia was greater in the vitDthan noVitD subgroup; most incidences occurred in the titration phase.

	Cin arm		
	Overall (N=153)	noVitD (N=48)	VitD (N=105)
Baseline PTH, pg/mL, mean±SD	559±338	556±372	561±324
Achieved ≥30% PTH reduction vs baseline, % subjects			
6 mo*	63	67	61
12 mo	63	65	63
PTH, pg/mL, mean (95% CI)			
6 mo	321 (285, 358)	283 (243, 322)	339 (289, 389)
12 mo	332 (294, 371)	302 (255, 349)	346 (294, 399)
Hypocalcemia (≤7.5 mg/dL), % subjects	33	23	38
Treatment-emergent adverse events, subject incidence (%)†		n=49	n=106
Any event	90	88	91
Serious event	46	43	48

*Primary endpoint; †safety analysis set

Conclusions: In this post hoc analysis, Cin therapy reduced serum PTH similarly both with and without concurrent vitD.

Oral Cholecalciferol Decreases Albuminuria and Improves Secondary Hyperparathyroidism in Non-Dialysis Chronic Kidney Disease Patients Pablo Molina,[1,2] Jose L. Gorriz,[2] Sandra Beltrán,[2] Avila Ana,[2] Romero Ramón,[1] Luis M. Pallardo.[2] *[1]Department of Medicine, Universitad Autonoma Barcelona, Spain; [2]Department of Nephrology, Hospital U. DrPeset, Valencia, Spain.*

Background: Beyond its effect on controlling bone metabolism parameters,vitamin D(VD) may have antiproteinuric effects in patients with chronic kidney disease(CKD). This renoprotecive property has been defined in randomized trials using active VD analogs,whereas the antiproteinuric effect of nutritional VD supplementation has been described in only one uncontrolled study.The present study evaluated the effect of cholecalciferol on proteinuira and glomerular filtratrion rate as well as bone metabolism parameters in CKD.

Methods: This controlled,intervention study enrolled 230 non-dialysis CKD patients(3-stage:77%;4-stage:23%;age:75±11y;women:49%)divided into 2 groups according to PTH basal levels.Patients with high PTH levels(n=117;51%) received oral cholecalciferol(666UI/day)whereas patients without hyperparathyroidism(n=113;49%)were considered as control group.Patients previously treated with phosphate binders,calcitriol or paricalcitol were excluded.Mean follow-up:7.2±3.7 months.

Results: A significant increase in calcidiol levels and reduction in PTH levels were observed in the cholecalciferol group.

Evolution of renal function and bone metabolism parameters

	Cholecalciferol (n=117)			Control (n=113)		
	Basal	Post	p	Basal	Post	p
25(OH)D(ng/mL)	16.5±5.9	25.1±7.3	0.000	21.9±6.2	20.4±8.0	0.000
PTHi(pg/mL)	117.9±53.4	98.4±56.3	0.000	59.4±17.2	70.3±30.2	0.000
Caalb(mg/dL)	9.3±0.4	9.4±0.4	0.127	9.3±0.4	9.3±0.4	0.213
P(mg/dL)	3.6±0.5	3.7±0.6	0.000	3.6±0.6	3.7±0.6	0.050
CaxP (mg2/dL2)	33.3±4.6	34.9±5.9	0.000	33.3±5.2	34.5±5.0	0.039
Cr(mg/dL)	1.8±0.5	1.8±0.6	0.119	1.6±0.5	1.7±0.5	0.014
eGFR(mL/min/1.73m2)	38.0±11.0	36.8±12.8	0.127	41.5±10.8	39.7±11.4	0.013
Albuminuria(mg/g)	305.3±551.3	221.1±353.2	0.008	206.9±379.7	262.2±464.6	0.036

In absence of significant changes in blood pressure levels or antihypertensive treatment,stabilization of renal function and reduction in albuminuria were observed only in the cholecalciferol group.

Conclusions: In addition to improving hyperparathyroidism,VD repletion with cholecalciferol had a beneficial effect in decresing albuminuria and delaying the progression of CKD.

TH-PO944

Prospective, Randomized Trial of the Differential Effects of Cholecalciferol versus Calcitriol on Monocytes in CKD Jason R. Stubbs, Shiqin Zhang, Ryan Gillihan, Kerri A. Mcgreal, Alicia Zeiger. *The Kidney Institute, Univ. of Kansas Medical Center.*

Background: Monocytes utilize the local conversion of 25(OH)D to 1,25$(OH)_2$D for autocrine/paracrine functions that result in systemic actions unrelated to mineral metabolism. CKD patients receiving 1,25$(OH)_2$D analogues often exhibit low 25(OH)D levels, but it remains unclear if 25(OH)D repletion provides any benefit to these patients. We therefore performed a prospective trial testing the differential in vivo effects of cholecalciferol and calcitriol on monocytes in patients with CKD.

Methods: A total of 30 CKD patients (eGFR 10-45 ml/min) were randomized to receive cholecalciferol 50,000 U twice weekly or calcitriol 0.25mcg daily for 8 weeks. Monocytes were isolated from patients at baseline and post-therapy and were evaluated by flow cytometry for changes in targets with suspected regulation by vitamin D.

Results: We observed a substantial increase in 25(OH)D levels in the cholecalciferol arm following therapy (16.8 ± 7.8 to 53.3 ± 16.0 ng/ml, P<0.001), with no change in the calcitriol arm (24.3 ± 6.5 to 21.6 ± 6.5 ng/ml, P=NS). Post-treatment flow cytometry analysis of monocytes from patients in the calcitriol arm revealed a significant decrease in total monocyte CD16 expression, a surface marker of "inflammatory" monocytes (from 5441 ± 625.4 to 4214 ± 373.9 MFI, P<0.05). No significant change in CD16 was observed in the cholecalciferol group (4635 ± 618.3 to 5062 ± 622.2 MFI, P=NS). Analysis of monocyte vitamin D receptor expression revealed a 40% increase in monocyte VDR with cholecalciferol therapy (2053 ± 198.2 to 2891 ± 285.6 MFI, P<0.05) and a 50% increase following calcitriol therapy (2376 ± 475.6 to 3579 ± 918.5 MFI, P=NS). We observed no change in monocyte CD14, HLA-DR, Mac-1 or LFA-1a levels with either therapy.

Conclusions: Taken together, our data suggest cholecalciferol and calcitriol to increase monocyte VDR expression, yet have differing effects on monocyte CD16 levels in patients with CKD. This data may provide evidence for unique in vivo roles of these two treatments on immune pathways. Further analysis is ongoing to compare changes in inflammatory cytokines and alterations in monocyte subsets with these therapies.

Binding of Circulating Sialylated Angiopoietin-Like-4 (Angptl4) to Its Glomerular Endothelial Receptor Reduces Proteinuria Camille E. Mace, Lionel C. Clement, Sumant S. Chugh. *Medicine / Nephrology, University of Alabama at Birmingham, Birmingham, AL.*

Background: We have previously shown that a sialylated form of Angptl4 is noted in the circulation of patients with different forms of nephrotic syndrome (Nature Medicine 2011, on line supplement). Next, we showed that circulating Angptl4 binds to, and has protective effects on the glomerular endothelium (ASN 2011).

Results: We now show that Angptl4 binds to a transmembrane protein on the endothelial surface (provisionally identified as protein X) in vivo by confocal imaging, and in vitro using plate adhesion assays. Global knockout of gene X in mice preserves glomerular phenotype, and does not result in proteinuria. Induction of proteinuria in gene X knockout and wild type mice using gamma2 NTS results in significantly higher proteinuria in the knockout mice (2-fold difference, P<0.01) 5 to 7 days after induction of proteinuria, at a time when circulating Angptl4 levels are elevated. Adipose tissue specific Angptl4 overexpressing transgenic rats (aP2-Angptl4), that have elevated circulating Angptl4 levels, develop less proteinuria than wild type rats after induction of single intravenous dose puromycin nephrosis (PAN) (P<0.05). However, intravenous injection of antibodies against protein X in aP2-Angptl4 PAN rats increases proteinuria to the level of wild type PAN rats, suggesting that the protective, anti-proteinuric effects of circulating Angptl4 are mediated via protein X. Moreover, injection of antibodies against protein X in wild type rats with PAN beyond the peak of proteinuria delays the recovery of proteinuria compared to PAN rats injected with preimmune serum (P<0.05 to P<0.001).

Conclusions: These studies suggest that the interaction of circulating Angptl4 with protein X on the glomerular endothelial surface stabilize / reduce proteinuria in primary glomerular disease.

TH-PO946

Transcytosis of Intact Albumin from Primary Urine Is FcRn Dependent
Verena Tenten, Uta Kunter, Claudia R.C. van Roeyen, Jürgen Floege, Bart Smeets, Marcus J. Moeller. *Nephrology and Immunology, RWTH University of Aachen, Aachen, NRW, Germany.*

Background: Under physiological conditions, about 1 gr. of albumin passes the glomerular filter per day in humans. Filtered albumin is reabsorbed from the primary filtrate by tubular cells and the cubilin/megalin complex. In our preliminary work in transgenic rats, we have already shown that albumin is retrieved intact from the primary urine into the serum. In the present study, we have confirmed transcytosis of albumin in transgenic inducible mice and examined its molecular mechanism.

Methods: Murine albumin with different charge (anionic versus neutral) was expressed under the Tet-inducible promoter in transgenic mice. To express transgenic albumin specifically in podocytes, mice were crossed with the Pod-rtTA transactivator mice. Finally, these mice were bred into the FcRn knock-out mouse line. FcRn is ubiquitously expressed and retrieves albumin from the early endosome to rescue it from lysosomal degradation.

Results: Transgenic mice expressed both albumins with different charge in an inducible fashion directly into the primary filtrate behind the glomerular filter. Transgenic albumin was retrieved by proximal tubular cells (not by parietal epithelial cells). Both albumins were detectable within the serum independent of their charge. This confirmed our findings in transgenic rats. Backfiltration within the glomerulus was ruled out as a possible mechanism, since both anionic and neutral albumins were retrieved into the circulation. When FcRn was inactivated, transgenic albumin was no longer detectable within the serum.

Conclusions: This study shows that filtered albumin is retrieved intact from primary filtrate back into the serum. FcRn is required for albumin transcytosis.

Proteinuria Triggers Renal Lymphangiogenesis Prior to the Development of Interstitial Fibrosis
Saleh Yazdani,[1] Fariba Poosti,[2] Andrea B. Kramer,[1] Arjan J. Kwakernaak,[1] Menno Hovingh,[1] Maartje C.J. Slagman,[1] Klaas A. Sjollema,[3] Gerjan Navis,[1] Harry Van Goor,[2] Jacob van den Born.[1] *[1]Nephrology, UMCG, Netherlands; [2]Pathology, UMCG, Netherlands; [3]Imaging Center, UMCG, Netherlands.*

Background: Proteinuria is an important cause of progressive tubulo-interstitial damage. Whether proteinuria could trigger a renal lymphangiogenic response has not been established. Moreover, the temporal relationship between development of fibrosis, inflammation and lymphangiogenesis in chronic progressive kidney disease is not clear. Therefore, we evaluated the time course of lymph vessel (LV) formation in relation to proteinuria and morphological damage in chronic unilateral adriamycin nephrosis.

Methods: Proteinuria and kidneys were evaluated 6, 12, 18, 24 and 30 weeks after induction of nephrosis. LVs were identified by podoplanin/VEGFR3 IF double staining. Myofibroblasts (α-SMA), collagen I and III, macrophages (MQ), focal glomerulosclerosis (FGS) and osteopontin (OPN) were also quantified.

Results: After 6 weeks proteinuria was well-established, without influx of interstitial MQ, α-SMA, collagen I and III deposition, induction of OPN, development of FGS and LV formation. At 12 weeks, a significant increase in cortical LV density was found, gradually increasing over time. This corresponded with a significant increase in tubular osteopontin expression ($p<0.01$) and interstitial myofibroblast numbers ($p<0.05$), whereas collagen deposition and macrophage influx was not yet increased. LV size increased over time as well. VEGF-C was mostly expressed by tubular cells rather than insterstitial MQ and α-SMA. HK-2 cells stimulated with FCS showed a dose-dependent increase in mRNA and protein expression of VEGF-C.

Conclusions: We conclude that established nephrotic range proteinuria up to week 6 was not associated with a renal lymphangiogenic response. However, chronic proteinuria provoked lymphangiogenesis in temporal conjunction with the pro-fibrotic response of tubular activation and influx of myofibroblasts, that preceded deposition of collagen I and III, macrophage influx and development of fibrosis.

TH-PO948

Albuminuria Associated with CD2AP Knockout Mice Is Quantitatively due to Tubular Uptake Dysfunction of Filtered Albumin
Wayne Comper,[1] Subhashini Srivastan,[2] Hani Suleiman,[2] Ruben M. Sandoval,[3] Andrey S. Shaw,[2] Leileata M. Russo.[1] *[1]Exosome Diagnostics, New York, NY; [2]Washington University, St Louis, MO; [3]Indiana University, Indianapolis, IN.*

Background: CD2AP knock out mice (CD2AP-/-) die in 5-6 weeks with accompanying massive proteinuria. In order to test that changes in glomerular permeability are responsible for this proteinuria we measured plasma elimination (PE) of fluorescently labelled albumin and dextran mol wt 70,000. Kaysen (1994) previously demonstrated that the increase in PE of albumin in nephrotic states is due to the increase in urinary excretion of albumin. An increase in the PE for dextran in albuminuric states should reflect alterations in glomerular permeability.

Methods: 5 week old mice were maintained in a metabolic cage for 24h prior to being injected with fluorescent labelled polymers in order to determine urine flow rate and albumin excretion rate. Post iv injection, blood samples were taken at 15min, 3h and 24h. The mice were sacrificed and the kidneys examined via microscopy.

Results: CD2AP-/- mice exhibited intact albuminuria without changes in urine flow rate or total protein excretion rate. Their kidneys exhibited nephron occlusion and podocyte effacement. Contrary to what might be expected from a glomerular defect, PE rates actually decreased in CD2AP-/- mice; percentage of material remaining in the plasma at 3h for dextran 70,000 PE for CD2AP+/+ was 28.5±5.9 (n=7) whereas for CD2AP-/- it was 42.4±10.0 (n=8) (P=0.006) and for albumin in CD2AP+/+ was 63.9±8.1 (n=7) whereas for CD2AP-/- it was 74.6±9.3 (n=8) (P=0.03). Albumin peptide excretion in CD2AP-/- mice was completely inhibited.

Conclusions: The massive change in albumin excretion rate in CD2AP-/- mice was not accompanied by an equivalent change in glomerular permeability. The onset of albuminuria could be accounted by inhibition of the degradation pathway in proximal tubules. CD2AP-/- mice do not exhibit the 'classic' nephrotic state where albumin PE is increased but have reduced PE due to occluded nephrons. The progression of these changes in CD2AP-/- mice mimic chronic renal failure with remnant nephrons compensating for hyperfiltration.

Immunohistochemical Analyses of Serum Proteins in Puromycin Aminonucleoside Nephrosis of Living Rat Kidneys by In Vivo Cryotechnique
Eri Kawashima,[1,2] Yurika Saitoh,[1] Nobuo Terada,[1] Kiyoko Inui,[2] Ashio Yoshimura,[2] Shinichi Ohno.[1] *[1]Anatomy and Molecular Histology, Interdisciplinary Graduate School of Medicine and Engineering, University of Yamanashi, Chuo, Yamanashi, Japan; [2]Medicine of Nephrology, Showa University Fujigaoka Hospital, Yokohama, Kanagawa, Japan.*

Background: "In vivo cryotechnique (IVCT)" is a useful method to identify native immunolocalizations of serum proteins in tissues of living animals, by which we have examined dynamic states of serum proteins in each segment of nephron in puromycin aminonucleoside (PAN) nephrosis model rat.

Methods: For PAN nephrosis model, PAN was injected into peritoneal cavity of Sprague-Dawley rats (5, 10 or 15mg/100g BW) once. Their total urine was collected to check proteinuria each day. At day3 or day9 after the injection of PAN, IVCT was performed for anesthetized rat kidneys, followed by freeze-substitution with 2% paraformaldehyde at -80°. Serial sections were stained with hematoxylin-eosin (HE) or immunostained for albumin and IgG1.

Results: The excretion of urinary proteins increased at day3, and exceeded 300mg/day at day9 in 15mg PAN injection group. By plasma protein analyses, PAN nephrosis induced typical hypoalbuminemia and renal dysfunction. By HE staining, no remarkable changes were detected at day3, but congestion of erythrocytes in glomerular capillary loops (GCL) and some casts of renal tubules were observed at day9. At day3, albumin was more immunolocalized in podocytes and reabsorbed into epithelial cells of proximal renal tubules more than the control rats. At day9, immunoreactivity of albumin in the GCL got weak and casts of renal tubules were strongly immunostained. IgG1 was immunolocalized in blood capillaries, but its immunolocalization was also detected in podocytes, and its reabsoaption into epithelial cells of proximal tubules was also detected at day3. At day9, immunoreactivity of IgG1 got weaker in the podocytes, and those casts were strongly immunostained.

Conclusions: Thus, IVCT enabled us to visualize a process of excreting proteins at each segment of nephron and to get the morphofunctional data for analyzing nephrotic kidney disease.

Identification and Characterization of Urinary Vesicle Proteins Interacting with the Tamm-Horsfall Glycoprotein
Dorota Ewa Tataruch, Luca Musante, Barry Byrne, Brian Shortt, Mayank Sarawat, Harry B. Holthofer. *Centre for BioAnalytical Sciences, Dublin City University, Dublin, Ireland.*

Background: Tamm-Horsfall Protein (THP), also known as uromodulin is the most abundant glycoprotein in urine. It is expressed and secreted into urine in the loop of Henle and early distal convoluted tubule. THP contains the most varied glycans of any human glycoprotein, which suggests a variety of functions including a capacity for adhesion to e.g. urinary exosome vesicles. In fact, electron microscopy analyses have demonstrated that exosome vesicles are entrapped within urinary THP polymers. In the urine THP may precipitate due to many factors of the immediate physico-chemical microenvironment and THP is the main constituent of hyaline urinary casts. The aim of this study was to identify the variety of exosomal proteins interacting with uromodulin. Firstly THP was purified by Diatomaceous Earth Filter (DEF) and then an aliquote was labelled with biotin. In Western blot analysis biotinylated THP was able to recognise several bands in the 18,000 and 200,000g centrifugation pellets, respectively. As a demonstration of its binding ability to vesicle sediment, DEF-extracted THP was assayed in both nanovesicle populations by Surface Plasmon Resonance (SPR). Subsequently, purified THP was bound to cyanogen bromide activated sepharose and an affinity chromatography was carried out to enrich exosome-interacting proteins. In-gel mass spectrometry identification revealed several unique proteins, some of those classified as proteases by a gene ontology (GO) analysis. Finally, purified native THP was shown to interact with bovine pancreatic trypsin. THP underwent a partial proteolysis with the production of a major fragment at 65kDa. Here we describe for the first time the presence of THP interacting proteins in the urinary vesicle fraction. Identification of such targets will allow a better understanding of the role of the interacting vesicles and design of specific inhibitors for a better recovery of vesicles. Finally, THP interaction with bovine pancreatic trypsin and the strong resistance to the enzymatic digestion support an active role as trypsin protease inhibitor.

TH-PO951

Inhibition of β-Catenin Signaling Reverses an Established Proteinuria and Kidney Injury Li Li Zhou,[1,2] Jing Nie,[2] Fan Fan Hou,[2] Youhua Liu.[1] *[1]Department of Pathology, University of Pittsburgh, Pittsburgh, PA; [2]Division of Nephrology, Nanfang Hospital, Southern Medical University, Guangzhou, Guangdong, China.*

Background: The progression of chronic kidney diseases is believed to be an irreversible process, eventually leading to end-stage renal failure. Once the kidney injury is established, current therapies only slow, but seldom reverse or completely halt the progressive loss of kidney function. In this study, we sought to test whether inhibition of β-catenin signaling by peptidomimetic small molecule ICG-001 can reverse an established proteinuria and kidney injury.

Methods: To assess the therapeutic efficacy of ICG-001, we designed two different treatment protocols. In the withdrawal protocol (ICG-w), ICG-001 was administered at 7 days after adriamycin (ADR) injection, and treatment lasted for 2 weeks, and then stopped. The experiments were terminated at 5 weeks after ADR injection. In the therapeutic protocol (ICG-t), ICG-001 was given at 3 weeks after ADR injection.

Results: In mouse model of ADR nephropathy, either transient therapy (withdrawal protocol) or late administration of ICG-001 was able to abolish an established proteinuria and kidney lesions. ICG-001 restored nephrin, podocin and WT1 expression, and abolished desmin induction, resulting in marked preservation of podocyte integrity. ICG-001 therapy also blunted renal expression of numerous β-catenin target genes such as Snail1, plasminogen activator inhibitor-1, matrix metalloproteinase-7 and fibroblast-specific protein-1, which was accompanied by preservation of renal expression of E-cadherin. ICG-001 therapy inhibited myofibroblast activation; repressed the expression of fibronectin, type I and type III collagens; and reduced renal interstitial fibrosis. Furthermore, inhibition of β-catenin signaling by ICG-001 inhibited pro-inflammatory cytokines expression, reduced renal infiltration of macrophages and repressed NF-κB signaling activation.

Conclusions: These studies indicate that inhibition of β-catenin signaling by ICG-001 reversed an established proteinuria and kidney injury. Therefore, blockade of β-catenin signaling could be an effective therapy for established chronic kidney diseases.

Advanced Oxidation Protein Products Induce Podocyte Epithelial-Mesenchymal Transition via Activating Wnt1/β-Catenin Signaling Li Li Zhou,[1,2] Jing Nie,[1] Fan Fan Hou,[1] Youhua Liu.[1,2] *[1]Division of Nephrology, Nanfang Hospital, Southern Medical University, Guangzhou, Guangdong, China; [2]Department of Pathology, University of Pittsburgh, Pittsburgh, PA.*

Background: Podocyte dysfunction plays a crucial role in the pathogenesis of proteinuria and glomerulosclerosis. After injury, podocytes may undergo epithelial-mesenchymal transition (EMT). Recent studies indicate that accumulation of advanced oxidation protein products (AOPPs) is implicated in the pathogenesis of podocyte apoptosis. However, whether AOPPs also induces podocyte EMT remains unknown.

Methods: Mice or podocyte cell line (MPC5) were treated with AOPPs-modified mouse serum albumin (AOPP-MSA). Albuminuria and podocyte phenotypes were assessed. To determine the potential role of Wnt/β-catenin signaling in mediating AOPP action, conditional knockout mice in which β-catenin was selectively ablated in glomerular podocytes were utilized.

Results: Chronic administration of AOPPs induced albuminuria, suppressed nephrin and upregulated the expression of fibronectin, desmin, Snail1 and MMP-9 in podocytes in mice. These pathologic changes were largely abolished by administrating a neutralizing antibody against the receptor for advanced glycation end products (RAGE) in vivo. AOPP also induced Wnt1 and Wnt7a expression and activated β-catenin in glomerular podocytes in mice. In vitro, AOPP triggered podocyte EMT, as shown by loss of nephrin, podocin and ZO-1, and upregulation of fibronectin, desmin, MMP-9 and Snail1. AOPP induced ROS generation in cultured podocytes, and stimulated Wnt1 expression, which was prevented by N-acetyl cysteine (NAC). Furthermore, knockdown of β-catenin almost completely abolished podocyte EMT induced by AOPP in vitro. Finally, in conditional knockout mice in which β-catenin was selectively ablated in podocytes, AOPP failed to induce podocyte dysfunction and proteinuria.

Conclusions: These results demonstrate that chronic exposure to AOPPs induces podocyte EMT and proteinuria. This is attributable to the AOPP/RAGE-mediated oxidative stress, Wnt1 induction and β-catenin activation. Our studies delineate a novel pathway in which oxidative stress triggers Wnt/β-catenin signaling in proteinuria.

Opening K_{ATP} Channels with Nicorandil in the Podocytes and Macrophages Improves Chronic Renal Disease in the Rats Yoshifuru Tamura,[1] Katsuyuki Tanabe,[1] Wataru Kitagawa,[1] Shunya Uchida,[2] Richard J. Johnson,[1] Takahiko Nakagawa.[1] *[1]Division of Renal Diseases and Hypertension, University of Colorado Denver, Aurora, CO; [2]Division of Renal Disease, Teikyo University, Itabashi, Tokyo, Japan.*

Background: Nicorandil causes vasodilatation by opening ATP-dependent potassium channels and donating nitric oxide.

Methods: We evaluated the effect of nicorandil in the rat remnant kidney model (RK) of chronic kidney disease. RK rats were divided into three groups: Sham operated rats (SHAM), Untreated remnant kidney rats (RK), RK rats treated with nicorandil 30 mg/kg/day (NICO).

Results: Blood pressure (tail cuff) was unchanged by a 10 week course of nicorandil. However, nicorandil prevented both albuminuria and histological injury in this model (Table). Oxidative stress, (renal nitrotyrosine level, urine 8-OhdG and heme oxygenase-1) was elevated in this model and was significantly reduced by nicorandil treatment. Consistent with this finding, we found a reduction in podocyte MnSOD and an increase in macrophage xanthine oxidase in the RK model that was prevented by nirocandil. Both podocytes and macrophages express SUR2 which is a binding site of K_{ATP} channels, suggesting that nicorandil might stimulate these cells to open K_{ATP} channels. Indeed, niocrandil increased MnSOD expression in cultured podocytes and blocked angiotensin II-induced xanthine oxidase activation in cultured macrophages. In contrast, this enzyme activity was enhanced by glibenclamide which closes K_{ATP} channel.

Table.

	Serum creatinine	Urinary aibumin	Oxid stress	Glomeruli	Tubulointerstitium
	mg/dl	mg/day	Nitrotyrosine/β-actin	%Glomerulosclerosis/glom.	Collagen III (+) area/field (%)
SHAM (n = 7)	0.32 ± 0.03***	0.6 ± 0.3***	0.07 ± 0.01**	6.7 ± 0.4***	4.9 ± 0.8***
RK (n = 7)	0.71 ± 0.08	16.3 ± 3.3	0.21 ± 0.02	32.9 ± 3.5	14.3 ± 1.5
NICO (n = 7)	0.56 ± 0.03	3.2 ± 1.2**	0.10 ± 0.02*	13.6 ± 1.5***	8.0 ± 0.4**

***P<0.001. **P<0.01. *P<0.05 vs. RK.

Conclusions: In conclusion, nicorandil reduces albuminuria and ameliorates renal injury by upregulating podocyte MnSOD and blocking macrophage oxidative stress in chronic kidney disease. Nicorandil may represent a novel treatment for chronic kidney disease.

TH-PO954

Downregulation of Podocyte Vitamin D Receptor Expression Upregulates HIV Gene Expression in HIV-Associated Nephropathy Partab Rai, Dileep Kumar, Mohammad Husain, Pravin C. Singhal, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY.*

Background: The activation of renin -angiotensin system (RAS) has been demonstrated to play an important role for the progression of HIV-associated nephropathy (HIVAN). Since kidney cell HIV gene expression contribute to the development of HIVAN, we hypothesize that alteration of podocyte VDR expression might be enhancing HIV gene expression through the activation of the RAS.

Methods: Immortalized differentiated human podocytes (IDHP) were transdudced with either empty vector (EV/IDHP) or HIV (NL4-3, HIV/CIDHP) and incubated in media for 72 hours. Immunoblots were probed or VDR and actin. To silence VDR in IDHPs, EV/IDHPs and HIV/IDHPs were transfected with siRNA VDR(siRNAVDR/HIV/IDHPs) or scrambled (Scr-siRNA/HIV/IDHP) siRNA.Immunoblots of IDHP, HIV/IDHPs, siRNAVDR/HIV/IDHP, ScrsiRNA/IDHPs were probed for renin and actin. mRNA expression of HIV genes were quantified by real time PCR. To establish the role of RAS IDHP and HIV/IDHPs were treated with losartan (Ang II blocker) and then assayed for mRNA expression for HIV genes. To activate endogenous RAS, HIVAN mice (Tg26) in control and experimental cells were were bred witn angiotensinogen (Agt) transgenic mice having four Agt copies; this strategy allowed us to develop Tg26 mice with 2, 3 and 4 copies of Agt. Kidneys from 4 weeks and 8 weeks old Tg26 mice with different Agt copies were harvested and analyzed for mRNA expression of HIV genes.

Results: HIV down regulated VDR expression and enhanced renin expression in human podocytes. Podocytes silenced for VDR also displayed activation of the RAS. HV/IDHPs also displayed activation of the RAS and this effect was more pronounced in siRNAVDR/HIV/IDHPs. Silencing of VDR in HIV/IDHPs enhanced expression of Nef, Tat, and Vif. On the other hand, losartan inihbitied expression of HIV genes in HIV/IDHPs. Renal tissues of 8 weeks old Tg26-Agt-4 displayed 2-4 fold increase in mRNA expression of gp120, Vpr, Tat, Nef and Vpu when compared to Tg26 having two copies of Agt.

Conclusions: VDR-induced activation of the RAS contributes to enhanced HIV gene transcription in HIVAN.

Role of p38 MAPK Activation in the Slit Diaphragm Dysfunction and Proteinuria Caused by a Direct Stimulation to Nephrin Yuichi Takahashi, Mihoko Yamazaki, Aya Takahashi, Asami Takasaki, Yoshiyasu Fukusumi, Masayuki Tomita, Hiroshi Kawachi. *Department of Cell Biology, Institute of Nephrology, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan.*

Background: p38 MAPK inhibitor, FR167653 is reported to ameliorate proteinuria in PAN- and ADR-nephropathy. It is postulated that FR167653 inhibited the rearrangement of cytoskeleton and ameliorated podocyte injury, since the effacement of foot process was diffusely observed in these models. However, since p38MAPK is postulated to play critical role in producing cytokines and cell survival, the precise pharmacological mechanism of FR167653 is not clear. We have reported that the injection with the antibody against nephrin, a critical component of the slit diaphragm (SD) caused severe proteinuria. Because the effacement of foot process was sparsely observed, we proposed the molecular rearrangement in the SD is important and the rearrangement of cytoskeleton is not essential in the development of proteinuria in this model.

Methods: In this study, we investigated whether p38MAPK in glomeruli is activated in anti-nephrin antibody (ANA) nephropathy, and analyzed the effect of FR167653. ANA nephropathy was induced in rats by an injection of ANA. FR167653 treatment (50 mg/kg BW/day) started 2 days before the disease induction. The expressions of the SD molecules were analyzed with real-time PCR, western blot and confocal microscopy.

Results: Phosphorylation of p38 MAPK in glomeruli was detected already at 1 h. FR167653 ameliorated proteinuria (day 5: 44.3 vs. 15.1 mg/day, p<0.05). Reduced mRNA expression of the SD molecules was inhibited by FR167653 treatment (% to normal control expression, vehicle vs. FR167653 treatment: nephrin, 4.7 vs. 51.8%: podocin, 16.6 vs. 58.7%: NEPH1, 19.0 vs. 55.5%). Redistribution of nephrin, podocin and NEPH1 on day 14 was partially inhibited by FR167653 treatment.

Conclusions: These results indicated p38MAPK was phosphorylated by direct stimulation to nephrin, and the p38MAPK activation is essential for the rearrangement of the SD molecules and the development of proteinuria. p38 MAPK could become a potential target for therapeutic intervention in proteinuric glomerulopathies.

Bisphenol A Induces Podocitopathy with Proteinuria and Hypertension in Mice Ricardo J. Bosch, Nuria Olea, Carmen Muñoz, Rafael Moreno, Marta González-Santander, María I. Arenas. *Physiology, University of Alcalá, Alcalá de Henares, Spain.*

Background: Bisphenol A (BPA) is a chemical used in plastic exposed to humans, which has a significant presence in diabetic patients (JAMA 300:1303, 2008). Recently, BPA has been associated with proteinuria in Chinese adults (Kidney Int. 81:1131, 2012). Herein we explore the renal effects of BPA.

Methods: The effects of BPA were studied in murine podocytes, mesangial cells and tubuloepithelial cells. Cell viability and apoptosis were measured by MTT assay, flow cytometry and DAPI, respectively. Cell hypertrophy was assessed by cell protein content and [H3]-leucine incorporation. Protein expression was analyzed by Western blot. Moreover, mice (n=17) were intraperitoneally injected with BPA at 50mg/Kg Monday through Friday for five weeks. Arterial pressure was determined by the tail-cuff method.

Results: BPA decreased cell viability and induced apoptosis in all cells studied. While these effects were observed in podocytes starting from 50mM, other renal cells were only affected at 200mM. On podocytes, BPA induced -in a dose dependent manner (from 0.5 to 10nM) - hypertrophy and the upregulation of p27kip1, TGF-β and collagen IV, in a fashion similar to that of high glucose -25mM(HG)-, while diminishing the expression of both nephrin and podocin. BPA-injected mice displayed an increase in both urinary albumin excretion (controls © 2,31±1,4 mg/24h vs BPA 5,13±1,5, p<0,05) and creatinine clearance (C 0,05 ml/min vs BPA 0,08, p<0,05). These animals also displayed an increase in both systolic and diastolic blood pressure (C 79, 75±,15 mmHg vs BPA 88,75±14, p<0,05) and (C 65,27±13 mmHg vs BPA 69, 32±14, p<0.05), respectively. Renal histology showed glomerular hypocellularity and mesangial expansion.

Conclusions: On podocytes, BPA is able to induce apoptosis, hypertrophy and the upregulation of p27kip1, TGF-β and collagen IV in a fashion similar to that of HG. BPA-injected animals develop proteinuria, hyperfiltration, glomerular hypocellularity, mesangial expansion and hypertension. Further studies are needed to clarify the potential role of BPA in the pathogenesis of renal diseases, particularly in diabetic patients.

TH-PO957

The Essential Role of Akt2 in Stressed Podocytes Frank Bienaime,[1] Guillaume Canaud,[1] Amandine Viau,[1] Clement Nguyen,[1] Andrea Onetti-muda,[2] Gerard Friedlander,[1] Christophe M. Legendre,[1] Fabiola Terzi.[1] *[1]INSERM U845 - Universite Paris Descartes - APHP; [2]Campus BIo-Medico University.*

Background: In chronic kidney disease (CKD), the loss of functional nephrons results in the overload of the remaining ones. This leads to a metabolic and mechanical stress triggering, in turn, further nephron loss. The molecular pathways engaged to counteract this stress are still unknown. The aim of this study was to evaluate the potential role of AKT proteins in the adaptation of glomerular cells to nephron reduction.

Methods: On that purpose, we combined different models of nephron reduction (subtotal and unilateral nephrectomy, aging nephropathy), glomerular isolation through laser capture microdissection and *Akt1*, *Akt2, Akt2*$^{\Delta pod}$ mutant mice. In addition, we assessed the impact of sirolimus, in terms of AKT pathway activation and adverse effects incidence (proteinuria), in a cohort of renal transplant recipients with different degrees of renal function.

Results: We showed that the activation of the serine/threonine kinase AKT2 plays an essential role in the survival of podocytes and in their adaptation to nephron reduction, without affecting tubular cells. We demonstrated that this function is isoform specific. In fact, glomerular lesions and albuminuria were dramatically increased in *Akt2*$^{-/-}$, but not in *Akt1*$^{-/-}$ mice. Specific gene deletion in podocytes revealed that the protective effect of AKT2 is cell autonomous. Mechanistically, AKT2deficiency acts by preventing the triggering of the compensatory genetic program which involve MDM2, GSK3 and RAC1 functional regulation. This is associated with increased apoptosis and foot processes effacement in *Akt2*$^{-/-}$ podocytes. Remarkably, these data are relevant to human CKD where AKT2 activation by mTORC2 is essential for podocyte survival in patients with severe nephron reduction. More importantly, we provide evidence that AKT2 activation in podocytes could serve as a prognostic marker to predict the deleterious proteinuric effect of sirolimus.

Conclusions: In conclusion, our results disclose a novel function played by AKT2 in podocytes and identify a potential therapeutic target for the maintenance of glomerular function in CKD.

TH-PO958

Role of Podocyte Extracellular Sulfatase in Regulation of Glomerular Permeability Yasutoshi Takashima,[1] Hanako Yamashita,[1] Kazuo Sakamoto,[1] Satoshi Hara,[1] Namiko Kobayashi,[1] Toshiharu Ueno,[1] Kazuko Keino-masu,[2] Masayuki Masu,[2] Michio Nagata.[1] *[1]Renal Pathology, University of Tsukuba, Tsukuba, Ibaraki, Japan; [2]Molecular Neurobiology, University of Tsukuba, Tsukuba, Ibaraki, Japan.*

Background: Heparan sulfate proteoglycan(HSPG) plays a pivotal role for maintaining local concentration of growth factors and may be important to explain glomerular pathophysiology. Extracelluar sulfatase(Sulf) 1 and 2 are the core regulator of HSPG and Sulf1 was expressed glomerular podocytes. Since Sulf1 and 2 have been suggested to compensate, Sulf1 and 2 double knockout mice (DKO) are useful to determine the function of Sulf on the glomerular permeability. We suppose that Sulfs alter the bioavailability of signaling molecules transmitting between podocyte foot processes,and examine expression of growth factors and those receptors produced by podocyte.

Methods: DKO were used to examine urinary albumin and glomerular morphology. In addition, mRNA expressions for slit membrane proteins, cytoskeletons, and several growth factors and those receptors by Real time PCR were estimated. Cellular events are analyzed by the immortalized podocyte cell line.

Results: DKO revealed significant increase in albuminuria than wild type. Histology showed frequent mesangiolysis followed by mesangial proliferation in DKO. Ultrastructure showed predominant foot process effacement and increased incidence of out pocket in GBM in DKO than wild type. However presence of anionic sites revealed by PEI stain did not show any difference between DKO and wild type. Kidney lysate in DKO revealed significantly decreased expression of synaptopodin by Real time PCR. Double knock down in Sulf1 and 2 in cultured podocytes revealed down-regulation of podocyte molecules as found DKO *in vivo*, and several growth factors including PDGF, VEGF, FGF. Double knock down in Sulf1 and 2 by siRNA showed induction of PDGFR-β in podocytes *in vitro*.

Conclusions: Endosulfatase may regulate growth factor and receptor expression in podocytes because PDGFR-β is localized in podocytes. Foot process effacement and significant albuminuria in DKO suggests that podocyte sulfatase may participate in glomerular permeability *via* growth factor regulation on podocyte.

TH-PO959

Dual Blockade of Angiotensin II and Prorenin Receptors Ameliorates Podocytic Apoptosis in IgA Nephropathy through Inhibition of the Notch Signaling Pathway Joseph C.K. Leung, Ai Ing Lim, Loretta Y.Y. Chan, Sydney C.W. Tang, Kar Neng Lai. *Department of Medicine, University of Hong Kong, Hong Kong.*

Background: Glomerulo-podocytic communication plays an important role in podocytic injury in IgA nephropathy (IgAN). We examined the roles of podocytic angiotensin II receptor subtype 1 (ATR1) and prorenin receptor (PRR) in podocytic apoptosis in IgAN.

Methods: Conditioned medium was prepared from growth arrested mesangial cells incubated with polymeric IgA from patients (IgA-medium, n=28) or controls (Ctl-medium, n=25). An immortalized human podocyte cell line was used to study the regulation of ATR1, PRR, TNF-α and TGF-β by IgA-medium. Expression of p53 and cleaved caspase 3 was used as functional readout of podocytic apoptosis.

Results: Podocytic expression of ATR1 and PRR were up-regulated by IgA-HMC medium dose and time dependently (p<0.01). There was increased expression of ATR1 and release of TGF-β, but not PRR, by podocyte cultured with TNF-α (p<0.05). The IgA-medium, TNF-α or TGF-β induced podocytic apoptosis. We further examined the anti-apoptotic effects of mono- or combined blockade of ATR1, PRR, TNF-α and TGF-β; with losartan, PRR siRNA transfection and anti-TNF-α and anti-TGF-β antibodies. Mono-blockade of ATR1, PRR or TNF-α partially reduced podocytic apoptosis. Dual blockade of ATR1 and PRR, or mono-blockade with anti-TGF-β, effectively rescued podocyte from IgA-medium induced apoptosis. Interestingly, IgA-medium or TGF-β up-regulated the expression of Jag1, notch1 and Hes1 by podocyte. The related podocytic apoptosis was abolished by the γ-secretase blocker, suggesting the important role of notch signaling pathway in this apoptotic process. Blockade of PRR or ATR1 decreased the IgA-medium induced TGF-β release and notch1 expression by podocyte, and these TGF-β release and notch1 expression were further reduced through dual blockade of ATR1 and PRR.

Conclusions: Our data suggest that the TGF-β and notch signaling pathway are the key players in podocytic apoptosis induced by glomerulo-podocytic communication in IgAN. Targeting the notch signaling pathway, AT1R and prorenin receptor could be a potential therapeutic option to reduce the podocytic injury in IgAN.

TH-PO960

Over-Expression of Heme Oxygenase-1 in Rattus Podocytes Antagonizes Puromycin Aminonucleoside Nephrosis Pu Duann,[1] Ling-Mei Chiang,[2] Shing Li.[1] *[1]Medicine / Nephrology Div, Robert Wood Johnson Medical School, New Brunswick, NJ; [2]Paediatric, Chang Gung Medical Center, Keelung, Taiwan.*

Background: Induction of heme oxygenase (HO)-1 is a key defense mechanism against oxidative stress. Compared with tubules, glomeruli are refractory to HO-1 upregulation in response to injury. It may be associated with insufficient production of cytoprotective heme-degradation metabolites. We, therefore, explored whether targeted HO-1 expression

can be achieved in glomeruli without altering their physiological integrity. A transgenic mice was achieved in FVB mice (Am J Physiol. 297[5]:F1476, 2009). But the established glomerulopathy stdies previously done in rat model was unable to be repeat in mice. Mice glomeruli isolation is sophisticated thus prevent mechanism exploration.

Methods: By microinjection Sleeping Beautytransposon vector (*SB10*) with pNeph-FLAG-hHO1expression cassette we obtained transgenic rats with GEC targeted HO-1 overepression. Assessed by linker mediated genomic sequencing, at least five independent gene integration in different chromosomes were confirmed.

Results: The transgene show stable inheritance confirmed by both southern blot analysis and PCR based gene typing. These rats show no apparent changes in weight, eating habits, fur color or motility, infertility or deviated Mendelian ratio. Screen all organs with Western blot analysis, FLAG-tagged transprotein was detected only in the kidney, and furthermore, in isolated glomeruli it show 20 folds high than in crude kidney extract. It was immunolocalized in podocyte overlayed with the nephrin. SB-HO1 transgenic rats show less proteinuria than age- weight-matched wild type control Sprague Dawley rats at 12 hour (UpUc[mg/mg]: 23.12 ± 6.91 vs. 14.81 ± 3.60, p value = 0.013) and 24 hours (UpUc[mg/mg]: 54.14 ± 18.67 vs. 25.15 ± 6.53, p value < 0.01) after tail vein injection of puromycin aminoglycoside (100 mg/Kg BW/100 µl DMSO).

Conclusions: We generated a transgenic rats, SB-HO1, with GEC targeted HO-1 overexpression. The GEC targeted HO-1 overexpression antagonize puromycin aminonucleoside nephrosis and reduce proteinuria. This animal model could help us study the role of renoprotective HO-1 in the GEC pathobiology.

TH-PO961

Inhibition of Notch Signal Reduced Extra-Capillary PEC Lesion and Deteriorated Proteinuria in Mouse Model of Collapsing Focal Segmental Glomerulosclerosis (cFSGS) Toshiharu Ueno,[1] Namiko Kobayashi,[1] Yasutoshi Takashima,[1] Taiji Matsusaka,[2] Michio Nagata.[1] *[1]Department of Renal Pathology, University of Tsukuba, Tsukuba-city, Ibaraki, Japan; [2]Department of Medicine, Tokai University School of Medicine, Isehara, Kanagawa, Japan.*

Background: Parietal epithelial cell (PEC) hyperplasia is the hallmark of cFSGS. We presented aberrant Notch signals may provoke PEC lesion though Epithelial-Mesenchymal-Transition and migration during the morphogenesis of cFSGS both in mouse model of cFSGS and PEC cell line at ASN 2011. In this study, we aimed to investigate the effect of Notch inhibition in the development of cFSGS in mice.

Methods: NEP25 mice (10-24 weeks of age) indicate podocyte-specific injury upon injection of immunotoxin (LMB2). They were injected LMB2 (4 ng/g B.W, iv) on day 0, treated either with γ-secretase inhibitor (Dibenzazepine; DBZ, 5µg/g B.W, ip) from day 6 to 12 or with vehicle (controls), and sacrificed on day 12 (n=5 per group). Histologically, incidence of PEC lesion (PEC score) and podocyte number (WT-1 positive cell) were analyzed. Proteinuria and area of urinary cast in kidney cortex (cast ratio) were measured.

Results: Controls showed severe proteinuria and histological feature of cFSGS. In light microscopy, number of WT-1 positive cell was similar in both group (2.36±0.09 vs. 2.42±0.07per glomerulus) indicating that same degree of podocyte injury was induced. DBZ treated mice showed significant reduction of PEC lesion represented by PEC score (2.2±0.2 vs. 3.7±0.4;P<0.01). Electron microscopy revealed migration of PEC onto collapsed glomeruli in controls, whereas such lesion was not observed in DBZ treated mice. Podocyte on collapsed glomeruli indicated severe foot process effacement, however, PECs surrounding such collapsed glomeruli showed almost normal morphology in DBZ treated mice. Larger amount of proteinuria was estimated in DBZ treated mice represented by cast ratio compared with controls (24.72±3.06 vs. 8.16±1.07%;P<0.01).

Conclusions: Notch signal is essential for emergence of PEC lesion and inhibition of Notch signal deteriorated proteinuria in mice cFSGS; this implies a potential protective role of PEC for injured filtration barrier accompanied by severe podocyte injury.

TH-PO962

APOL1 Expression and Localization Pattern in Kidney Diseases with and without Association to Risk Genotype John F. O'Toole,[1] Sethu M. Madhavan,[1] Martha Konieczkowski,[1] Santhi Ganesan,[1] Laura M.C. Barisoni,[2] David B. Thomas,[2] Leslie A. Bruggeman,[1] John R. Sedor.[1] *[1]Case Western Reserve University; [2]University of Miami.*

Background: Genetic variants in *APOL1*, encoding apolipoprotein L1 (APOL1), associate with non-diabetic kidney diseases in patients of African ancestry. We have localized APOL1 to podocytes, basolateral domains of proximal tubules, and arteriolar endothelium of normal human kidney. The localization pattern changes in non-diabetic kidney diseases. We hypothesized that APOL1 was synthesized in kidney and variants would alter APOL1 localization and distribution.

Methods: APOL1 localization and expression was examined in cultured cells, normal and diseased human kidney with immunohistology, immunogold electron microscopy (IEM), *in situ* hybridization (ISH), and RT-PCR.

Results: Using ISH and RT-PCR, *APOL1* transcripts were identified in normal human glomeruli but not tubules, despite the presence of APOL1 protein in both locations. IEM localized APOL1 to the cytoplasm of podocytes and the mitochondria of proximal tubules, confirmed by colocalization with the alpha subunit of ATP synthase. In FSGS, HIVAN, HTN, minimal change, diabetes and normal kidney, we used semi-quantitative methods to examine proximity of APOL1 to podocyte markers and its colocalization with mitochondrial markers in tubules. Contrary to our hypothesis, APOL1 distribution patterns, its relationship to podocyte and mitochondrial markers, and APOL1 expression levels did not vary with disease diagnosis or genotype. In cell culture, wild type and variant APOL1 proteins had similar localization under basal conditions and after treatments to mimic ER stress, growth factor-/starvation-induced autophagy and mitochondrial dysfunction.

Conclusions: Podocytes synthesize APOL1, suggesting locally expressed APOL1 regulates non-diabetic CKD pathogenesis. APOL1 in proximal tubules may represent uptake from glomerular filtrate or circulation. Since APOL1 distribution patterns changed concordantly in all diseases and cell culture conditions examined regardless of genotype, we conclude *APOL1* variants do not mediate renal injury by changing APOL1 localization or trafficking, but rather through aberrant protein function.

Podocyte Specific Myh9 Deletion in C57BL/6 Mice Results in Susceptibility to Glomerulopathy in Experimental DOCA-Salt Uninephrectomy Model Philip A. Bondzie, Mostafa Belghasem, Felita Agus, Joseph S. Coppola, Hui Chen, Joel M. Henderson. *Pathology and Laboratory Medicine, Boston University School of Medicine, Boston, MA.*

Background: Single nucleotide polymorphisms in the gene MYH9 encoding the protein non-muscle myosin heavy chain IIA (NMHCIIA), have been found to be associated with an increased incidence of chronic kidney disease in African Americans. In this study we seek to investigate the role of Myh9 in glomerular response to chronic hypertension.

Methods: C57BL/6 podocyte specific Myh9 knockout (KO) mice and controls were subjected to uninephrectomy and deoxycorticosterone acetate (DOCA)-salt treatment for 6 weeks. Kidney tissue morphology was evaluated by light and electron microscopy, and kidney function was assessed with urine and serum biomarkers. We also profiled gene expression in laser captured glomeruli from these mice.

Results: Podocyte Myh9 KO mice developed widespread juxtamedullary glomerulosclerosis, segmental cellular proliferation within glomeruli, protein casts and mild glomerular ultrastructural changes in normal-appearing glomeruli, as well as significant proteinuria. In contrast, control mice showed milder changes. In podocyte Myh9 KO mice, differential glomerular expression was observed in several genes involved in cell motility.

Conclusions: In summary, Myh9 deficiency in podocytes in C57BL6 mice is associated with susceptibility to glomerulopathy in a DOCA-salt uninephrectomy model. Changes in glomerular expression of genes associated with cell motility may play a role in this process.

TH-PO964

Glomerular Expression of Renin-Angiotensin System Components in Rats with Podocyte Dysfunction Mihoko Yamazaki, Aya Takahashi, Yuichi Takahashi, Yoshiyasu Fukusumi, Masayuki Tomita, Hiroshi Kawachi. *Department of Cell Biology, Institute of Nephrology, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan.*

Background: The local renin-angiotensin system (RAS) is reported to have essential roles in maintaining the local tissue function. We have previously reported angiotensin II (AII) treatment reduced the expression of the slit diaphragm (SD) components (Am J Pathol 2007). The report indicated that AII is involved in the regulation of the barrier function of the glomerular capillary wall. However, the role of the local RAS in glomeruli remains uncertain.

Methods: In this study, the glomerular expressions of RAS components, angiotensinogen (AGG), renin, ACE, ACE2, aminopeptidase A, neprilysin, AII type1 and type 2 receptors (AT1R, AT2R) were analyzed in rats with puromycin aminonucleoside (PAN) nephropathy and anti-nephrin antibody (ANA)-induced nephropathy. We also analyzed the glomerular expressions of the RAS and the SD components in rats treated with RAS blockers, ARB and angiotensin converting enzyme inhibitor (ACE-I). Then, we investigated the effects of ARB on the expressions of RAS components and on proteinuria in these models. The expressions of RAS components in cultured podocyte were also analyzed.

Results: mRNA expressions of all RAS components were detected in normal rat glomeruli and in cultured podocytes. mRNA expression of AGG was increased in PAN nephropathy(483%). The expression of renin and ACE was downregulated, whereas that of neprilysin converting angiotensin-(1-10) to (1-7) was upregulated. The increase of AGG is also observed in ANA-nephropathy (426%). The expression of ACE was increased in rats treated with ACE-I (224%). The increase of ACE in rats with ARB is milder than that with ACE-I. The expression of AT2R was lowered and that of the SD molecules was increased in both groups. Proteinuria in PAN nephropathy is reduced with ARB treatment (358 vs. 204 mg, p<0.05). The decrease of SD components and the increase of AGG were inhibited by ARB treatment.

Conclusions: Altered expression of local RAS components and the consequent decreased expression of the SD molecules are involved in the development of podocyte dysfunction.

Podocytes Detaching from the GBM in Glomerular Diseases Frequently Adhere to the Parietal Basement Membrane Wilhelm Kriz. *Anatomy, Medical Faculty Mannheim, University of Heidelberg, Germany.*

Background: As known from previous studies of inflammatory glomerular diseases (Le Hir et al. 2001, JASN 12:2060; Moeller et al. 2004, JASN 15:61)podocytes may penetrate in between two parietal epithelial cells of Bowman's capsule and attach to the parietal basement membrane (PBM). Thereby, a cell bridge is established between the tuft

and Bowman's capsule that frequently acts as the nidus for the progression of the injury to complete degeneration of the concerned nephron. It was thought that unknown inflammatory mediators increased the motility of podocytes initiating such contacts with the PBM.

Methods: The interconnections between the tuft and the parietal epithelium were analysed by transmission electron microscopy in several models of non-inflammatory glomerular diseases, including DOCA-salt hypertension in rats, long-term growth stimulation by bFGF in rats, uninephrectomy in young rats, the Fawn-hooded hypertensive rat, the Fa/Fa rat, among others.

Results: These studies revealed that active adhesion of podocytes to the PBM is not restricted to inflammatory diseases but is also seen in degenerative and genetic models of glomerular diseases. It is frequently seen that podocytes undergoing detachment from the GBM fix to the PBM with apical cell portions. Podocytes in danger of detachment from the GBM appear to search for a firm fixation at other sites and may find the PBM. A prerequisite to this kind of migration from the GBM to the PBM appears to consist of a frequently observed surface change of podocytes, called "microvillous transformation". Diseased podocytes (in danger of detachment?) may form countless microvilli that spread into all directions. In case that such a microvillus attaches to some other site (GBM or PBM) it may initiate the migration of the entire cell to this new contact site.

Conclusions: Podocytes in danger of detachment from the GBM seek halt at other sites. In case of a "successful" fixation to the PBM, cell bridges between the tuft and Bowman's capsule may be formed that may lead to a firm adhesion of the tuft to Bowman's capsule, thus to a committed lesion progressing to crescent formation and finally to the loss of the entire nephron.

TH-PO966

Amyloid-Like Protein 1: A Biomarker for Podocytes Injury? Zhao-hong Chen, Shaolin Shi, Junnan Wu, Cai-hong Zeng, Ming-chao Zhang, Zhi-Hong Liu. *Research Institute of Nephrology, Jinling Hospital, Nanjing University School of Medicine, Nanjing, Jiangsu, China.*

Background: Amyloid-like protein 1 (APLP1) is a membrane-associated glycoprotein that is cleaved by secretases. This cleavage liberates an intracellular cytoplasmic fragment that may act as a transcriptional activator. APLP1 may play a role in endocytosis, apoptotic process and cell adhesion. APLP1 was found upregulated in the glomeruli of several glomerular injury models. Here we explore if APLP1 is a potential biomarker for podocyte injury.

Methods: 10 cases of biopsy-proven focal segmental glomerulosclerosis were included in this study. Unaffected normal renal tissues from kidneys with cancer (n=5) were used as control. APLP1 mRNA was quantified by qRT-PCR using glomeruli microdessected from renal biopsies. APLP1 protein and localization in glomeruli of FSGS patients were detected by immunohistochemistry (IHC) and immunofluorescence (IF). The effect of TGF-β on APLP1 mRNA and protein expression in podocytes was determinined by qRT-PCR and western blotting.

Results: The results of qRT-PCR showed that APLP1 mRNA was upregulated in glomeruli of FSGS patients as compared to normal controls. Gene expression of APLP1 in kidney biopsies was significantly related (R= 0.468, p= 0.023) to the level of proteinuria. Colocalization studies detected APLP1 protein along with the podocyte marker synaptopodin in glomeruli. No colocalization was observed between APLP1 protein and endothelial (CD31) marker. The results of IHC also showed that APLP1 was expressed in glomerular podocytes and its expression was significantly increased in the patients with FSGS and podocyte disease as compared to normal control (Intensity Score: 6.98±0.8 vs 3.6±0.4, P <0.05). In vitro studies showed that TGF-β upregulated APLP1 mRNA and protein expression in podocytes, which accompanied by podocin decreased expression.

Conclusions: APLP1 is exclusively upregulated in podocytes of FSGS patients, and its upregulation positively correlates with urinary protein level of the patients, thus representing a potential biomarker of podocyte injury. We are determining the role for APLP1 in podocyte injury.

Basement Membrane Changes and Loss of Podocyte-Glomerular Basement Membrane (GBM) Interactions in Adult Mouse Kidney after Deletion of WT1 Sharada Mokkapati,[1] Fei Gao,[2] Weihua Tian,[1] Vicki Huff,[1] Qianghua Hu.[1] *[1]MD Anderson Cancer Center; [2]Chinese Academy of Sciences.*

Background: *Wt1* is a zinc finger transcription factor known to be important for normal kidney function. Previous studies have shown that mutation of this gene results in glomerulosclerosis and end stage renal failure in both humans and in mice. The cellular mechanism by which this mutation leads to the renal phenotype remains to be elucidated in detail.

Methods: Towards this we used two different mouse models in which we ablated *Wt1* in the adult kidney. In the first model, we crossed $Wt1^{fl}$ mice with a podocyte specific Cre transgenic mouse line, *NPHS2-Cre*. At one week of age these mice had no renal pathology but by two weeks these mice developed massive proteinuria with severe glomerulosclerosis and massive podocyte depletion and died between 3-4 weeks of age due to end-stage renal failure. In the second model we ablated *Wt1* in the adult kidney postnatally using the *TM-Cre* transgenic mouse line where the expression of Cre was ubiquitous when induced by tamoxifen treatment.

Results: As early as 10 days after the tamoxifen injection these mice developed proteinuria, which developed into glomerulosclerosis and end-stage renal failure. The phenotype was more dramatic than the mutants with the *NPHS2-Cre*. We further analysed GBM changes in the kidneys after deletion of Wt1 by real time PCR, protein analysis and immunofluorescence. There was a marked increase in the expression of basement membrane components by both real time PCR analysis and by western blotting. Expression of podocyte specific integrins was dramatically reduced in the mutant mice.

Conclusions: Our data, therefore suggests that *Wt1* is critical for podocyte GBM interactions and deletion of *Wt1* leads to loss of this interaction, GBM changes which then lead to glomerulosclerosis and end stage renal failure.

TH-PO968

Endothelial Ablation of Sirtuin 1 (SIRT1) Leads to Down-Regulation of MMP-14, Spontaneous Interstitial Fibrosis and Exaggerated Fibrotic Response to Injury Jun Chen,[1] Sandhya Xavier,[1] Radovan Vasko,[1] Julien Maizel,[1,2] Jian Cao,[3] Michael S. Goligorsky.[1] *[1]New York Medical College, Valhalla, NY; [2]INSERM, Unit 1088, Jules Verne University of Picardie, Amiens, France; [3]State University of New York, Stony Brook, NY.*

Background: SIRT1 deficiency is a constant companion of aging process and stress-induced premature senescence (SIPS). We have recently demonstrated that various stressors deplete SIRT1 through cathepsin cleavage due to lysosomal membrane permeabilization.

Methods: We used cre-lox strategy to generate mice with truncated SIRT1 gene in Tie-2-expressing endothelial (EC) and endothelial progenitor cells (EPC).

Results: Endo-SIRT1(-/-) mice are fertile, normotensive, thrive normally, but exhibit mild suppression of acetylcholine-induced vasorelaxation and matrigel angiogenesis, elevated numbers of senescent EC and EPC with reduced resistance to stress, as well as interstitial fibrosis, but no proteinuria or elevation of serum creatinine. When challenged with folic acid, mice develop an exaggerated acute loss of function compared to controls, but all recover renal function within 1 month. Three months later, Endo-SIRT1(-/-) mice develop proteinuria and renal insufficiency significantly more severe than their controls. The degree of tubulointerstitial fibrosis is much enhanced in Endo-SIRT1(-/-) mice. To disclose the pathogenetic link between endothelial SIRT1 deficiency and exaggerated renal fibrosis, we examined expression of a master regulator of matrix metalloproteases, MMP-14. qRT-PCR showed down-regulation of MMP-14, confirmed by immunoblot analyses. The promoter region of MMP14 was sequenced and analyzed. It contains consensus binding sites for NF-kB and p53, both controlled by SIRT1 expression. Concanavalin A treatment of cultured EC up-regulated MMP-14 expression regardless of the activity of SIRT1. Sirt inhibitor suppresses angiogenesis of HUVEC and mouse aortic rings in matrigel and ConA restores angiogenesis.

Conclusions: Data obtained in Endo-SIRT1(-/-) mice demonstrate the pathogenetic link between defective SIRT1 expression, SIPS and fibrosis. The latter is a result of the MMP-14 deficiency that develops as a consequence of SIRT1 deficiency.

PBI-4419, a Novel First-in-Class Anti-Fibrotic Compound, Inhibits CTGF and Collagen Production in Murine and Human Fibroblasts and Reduces Kidney Fibrosis in 5/6-Nephrectomized and Unilateral Ureteral Obstruction Rat Models Martin Leduc, Lilianne Geerts, Brigitte Grouix, François Sarra-Bournet, Liette Gervais, Shaun Abbott, Jean-Simon Duceppe, Boulos Zacharie, Christopher Penney, Pierre Laurin, Lyne Gagnon. *ProMetic BioSciences Inc., Laval, QC, Canada.*

Background: Interstitial fibroblasts are the principal effector cells of organ fibrosis. Transforming growth factor (TGF)-β-stimulated fibroblasts secrete connective tissue growth factor (CTGF) that functions as a downstream mediator of TGF-β action on fibroblastic cell types, and are important in collagen production.

Methods: The aim of this study was to investigate the effect of PBI-4419, a novel first-in-class anti-fibrotic compound, on CTGF and collagen production in TGF-β-stimulated murine (NIH/3T3) and human fibroblasts (normal human dermal fibroblast, NHDF).

Results: In both cell types, TGF-β induced a robust increase of the mRNA expression of CTGF (10 to 25 fold increase) and collagen 1 (2 fold increase). In TGF-β-stimulated NHDF, PBI-4419 reduced CTGF and collagen 1 expression to the control level (untreated). Furthermore, in non-stimulated NHDF, PBI-4419 reduced basal CTGF (80%) and collagen 1 (50%) expression. Modulation of mRNA expression was also translated at the protein level, as TGF-β-induced CTGF production was significantly inhibited by PBI-4419 in NHDF. In NIH/3T3 fibroblasts, TGF-β-induced CTGF and collagen 1 mRNA overexpression were also significantly reduced by PBI-4419. These results correlate with in vivo inhibition of CTGF and collagen 1 mRNA expression observed in different models of kidney fibrosis. In 5/6-nephrectomized rats, oral administration of PBI-4419 significantly decreased the overexpression of CTGF (down to sham level) and collagen 1 (reduction of 60%) mRNA expression in the remnant kidney. In the unilateral ureteral obstruction rat model, a significant dose-dependent inhibition of the expression of CTGF and collagen 1 is also observed in animals treated with PBI-4419.

Conclusions: These results indicate a direct effect of PBI-4419 on fibroblasts as observed by an inhibition of CTGF and collagen 1 mRNA expression and this is translated by a reduction of fibrosis in the kidney.

Exploring Transcriptional Regulation of Renal Fibrosis in the Rat UUO Model Using Next Generation Sequencing Steven M. Weldon,[1] Thomas B. Freeman,[2] Hu Sheng Qian,[1] Damian C. Matera,[1] Tobias Hildebrandt,[3] Ramona Schmid,[3] Detlev Mennerich,[3] Glenn A. Reinhart,[1] William Loging.[2] *[1]CardioMetabolic Disease, Boehringer-Ingelheim Pharm. Inc; [2]Scientific Knowledge Discovery, Boehringer-Ingelheim Pharm. Inc; [3]Target Discovery Research, Boehringer-Ingelheim Pharm. Inc, Ridgefield, CT.*

Background: Tubular interstitial fibrosis (TIF) is a major factor in the progression of chronic kidney disease (CKD). Current therapy for CKD is limited to ACEi and ARBs which provide only modest protection. As such, it is critical to gain a better understanding of the molecular mechanisms modulated by renal injury and CKD.

Methods: We used unilateral ureteral obstruction (UUO) combined with next generation sequencing (NGS) to explore the transcriptional regulation of molecular pathways associated with TIF in rats. SD rats were treated with enalapril (ENA; 3,30,100 mg/kg) or the anti-fibrotic agent BIX-006 (1,10 mg/kg) one day prior + 5 days following UUO. TIF was assessed by multiphoton microscopy using second harmonic signal generation (SHG) for imaging fibrillar collagen. mRNA from renal cortical tissue was subjected to NGS followed by computational analysis to indentify differentially regulated genes.

Results: ENA and BIX treatment resulted in dose-dependent inhibition of TIF, 27-60% and 16-50%, respectively. Effects on mechanistic genes/pathways (Col1, Fn, serpine1, igf1,ren) predicted to be modulated following treatment correlated with fibrosis. A variety of transcript pathways differed between treatment groups. BIX affected fibrotic, whereas ENA affected cell proliferative pathways. These pathways and their component transcripts also displayed dose dependent modulation.

Conclusions: These are the first data to describe the use of NGS to identify and quantitate transcriptional regulation of fibrotic and other selected pathways in the UUO model. Further, we show that changes in the rat transcriptome following UUO correlate to developing TIF and are differentially regulated by enalapril and an anti-fibrotic agent BIX-006. These data offer a novel approach to identifying new target pathways and potential biomarkers of fibrotic renal disease associated with CKD and subsequent renal failure.

Brilliant Blue G, a P2X7 Antagonist, Attenuates Renal Inflammation and Fibrosis in Unilateral Ureteral Obstruction in Rats Maurilo Leite,[1] Jose Monteiro Pereira,[3] Andre Barreira,[1] Conrado Rodrigues Gomes,[1] Christina Maeda Takiya.[2] *[1]Division of Nephrology, Universidade Federal do Rio de Janeiro (UFRJ), Rio de Janeiro, RJ, Brazil; [2]Biophysics Institute, UFRJ, RJ, Brazil; [3]Division of Urology, UFRJ, RJ, Brazil.*

Background: We have previously documented that purinergic P2X7 receptor (P2X7R) knockout mice, submitted to unilateral ureteral obstruction (UUO), presented less inflammation and interstitial fibrosis compared to wild type mice. The present study investigated the effect of BBG (brilliant blue G), a selective purinergic P2X7R antagonist, on rat kidneys after 14 days UUO.

Methods: Male Wistar rats were submitted to left kidney UUO. Four groups (G) were applied as follows: G1, sham operated and saline infusion; G2, sham and BBG 25mg/kg intravenously (IV); G3, UUO and saline infusion; G4, UUO and BBG 25mg/kg IV. Saline and BBG infusion were given on days 1 and 7. On day 14, the rats were sacrificed, and the left kidneys removed for Sirius red staining, immunohisthochemistry (IH) and PCR studies. For IH, antibodies (Ab) for macrophages (ED-1), myofibroblasts (SMA), PCNA and P2X7 were used. PCR was done for IL-1β.

Results: Sirius red staining revealed higher collagen surface density (SD) on G3 as compared with G1, G2 and G4 (0.017, 0.004, 0.005 and 0.007%, respectively, P<0.0001). ED-1 positive SD was higher on G3 as compared to G1, G2 and G4 (0.015, 0.001, 0.001 and 0.005%, respectively, P<0.0001). Also, SMA positive SD was higher in G3, compared with G1, G2 and G4 (0.046, 0.002, 0.004 and 0.008%, respectively, P<0.0001). However, PCNA tubular proliferative index was higher in G4, as compared to G3, G1, and G2 (32, 8, 10 and 2%, respectively, P<0.0001). G3, but not G4, showed P2X7R Ab positive cells, mainly on tubular epithelium, suggesting some interference of BBG on receptors epitope. PCR study clearly showed weaker appearance of IL-1β mRNA in G4.

Conclusions: In rats submitted to UUO, BBG was able to attenuate renal interstitial inflammation, collagen deposition and promoted tubular cell proliferation. P2X7 antagonism decreased IL-1β mRNA expression. These results constitute evidence that the use of P2X7R antagonists can be a strategic tool for the treatment of progressive kidney disease.

Implication of Connexin37 in Obstructive Nephropathy Ahmed Abed,[1] Ludwig Scheckenbach,[2] Bernard Foglia,[2] Christos Chatziantoniou,[1] Brenda Kwak,[2] Christos E. Chadjichristos.[1] *[1]INSERM UMRS 702, INSERM, Paris, France; [2]Dept. of Pathology and Immunology, University of Geneva, Geneva, Switzerland.*

Background: Chronic kidney disease (CKD) is promoted by a variety of factors that induce chronic inflammation and fibrosis. We have recently demonstrated that altered expression of the gap junction protein connexin37 (Cx37) is an early signal of CKD. The objectives of our study were to characterize the different cell types that express Cx37 in the kidney under normal conditions, and to investigate the role of this Cx in obstructive nephropathy.

Methods: Co-localization studies for Cx37 and appropriate markers of different nephron segments and vascular compartments were performed in renal cortical sections of C57BL/6 mice. In separate experiments, 3 month-old $Cx37^{-/-}$ and wt mice underwent unilateral ureteral obstruction (UUO) for 7 days before tissue collection (n=8 per group).

Results: Cx37 was abundantly expressed in the glomerular and peritubular endothelium (co-localized with MECA-32) of WT mice. Cx37 was also expressed in distal convoluted tubules and collecting ducts as evidenced by its co-localization with NCCT and AQP2, respectively. Seven days after UUO, Cx37 mRNA (qPCR) and protein (immunofluorescence) expressions were dramatically reduced. Interestingly, $Cx37^{-/-}$ mice were protected in terms of tubular dilation (tubular index: 1.0±0.2 for $Cx37^{-/-}$vs. 2.5±0.2 for WT mice, P<0.05), showed less tubulo-interstitial proliferation (Ki67 positive cells/field: 11±1 vs. 20±1 for $Cx37^{-/-}$ and WT, respectively, P<0.05) and lower tubular apoptosis (Tunel positive cells/field: 4.0±0.3 and 8.0±0.5 for $Cx37^{-/-}$ and WT, respectively, P<0.05). At the same time period, F4-80 staining showed reduced monocyte infiltration in the renal cortex of $Cx37^{-/-}$ mice compared to WT littermates (15±2% and 25±2% of cortex surface, respectively, P<0.05). Finally, the expression (western blot) of E-cadherin, a marker of normal renal epithelial cells, was preserved $Cx37^{-/-}$ mice.

Conclusions: Our study highlights the importance of connexins in obstructive nephropathy and suggests that reducing Cx37 may have beneficial effects on the development of renal disease.

TH-PO973

miR-205 Expression Correlates with Severity of Renal Involvement in a Mouse Model of Congenital Obstructive Nephropathy Michael Wilhide,[1] Ashley R. Carpenter,[1] Kirk M. McHugh,[1,2] Susan E. Ingraham.[1,2] *[1]The Research Institute at Nationwide Children's Hospital, Columbus, OH; [2]Department of Pediatrics, Division of Nephrology, College of Medicine at Ohio State University, Columbus, OH.*

Background: Congenital obstructive nephropathy (CON) is a leading cause of chronic kidney disease (CKD) and end stage renal disease (ESRD) in children. CON is a complex disease process involving pathological changes in kidney development and function that occur as a result of obstructed antegrade urine flow beginning *in utero*. We hypothesize that microRNAs (miRs) play important roles in the renal response to urinary obstruction and in regulating gene expression in the pathogenesis of CON. Thus, miRs may represent an important novel class of potential biomarkers and therapeutic targets in CON.

Methods: The megabladder (*mgb-/-)* mouse is an animal model of CON that develops kidney disease secondary to a bladder development defect. Specific miR expression levels were measured by quantitative PCR (qPCR) of kidney samples from wild type and *mgb-/-* mice.

Results: There was increased expression of miR-205 across an unstratified panel of *mgb-/-* kidneys compared to wild-type controls (Relative Quantitation [RQ] =3.49, *P*=0.004). Furthermore, upon stratification of the *mgb-/-* population by severity of kidney involvement, relative miR-205 expression levels rise with worsening grade of hydroureteronephrosis (Mild: RQ=1.60, *P*=0.59; Moderate: RQ=2.73, *P*=0.007; Severe: RQ=6.32, *P*=0.001; all values are relative to wild-type control). This suggests that miR-205 expression correlates with the severity of CON in this animal model. Additional preliminary studies indicate that miRs, including miR-205, can be measured by qPCR from urinary exosomes, including human urine samples.

Conclusions: In summary, our results show that miR-205 correlates with disease severity in a mouse model of CON, and is quantitatively detectable in urine samples. Future studies will explore the target molecules and pathways affected by miR-205 in the *mgb-/-* model of CON, as well as the potential of miR-205 as a non-invasive biomarker of renal injury in congenital urological obstruction.

TH-PO974

A Model of Reversible Unilateral Ureteral Obstruction in Mice Haichun Yang, Agnes B. Fogo. *Pathology, Microbiology and Immunology, Vanderbilt University, Nashville, TN.*

Background: Unilateral ureteral obstruction (UUO) is widely used to study mechanisms of renal fibrosis. Complete UUO leads to severe hydronephrosis within 2 weeks. Several studies have described reversible UUO model by using ties or clips that were then removed. However, these techniques lead to variable degrees of partial obstruction, and longitudinal measurement of renal function was not possible. Surgical reimplantation of the obstructed ureter into the bladder has also been used, but is technically challenging, and also does not allow distinction of function in obstructed vs nonobstructed kidney. The present study aimed to develop a new reversible UUO model that would be technically reproducible and allow comparison of renal function in obstructed vs nonobstructed kidneys.

Methods: Collagen I-luciferase mice underwent unilateral ureter obstruction (UUO) at day 0. Obstruction was released by inserting a PE20 catheter into the obstructed ureter at day 7, with exteriorization of the catheter. Mice were followed for two additional weeks. Urine was collected from the obstructed side from the catheter, while the urine from the contralateral side was collected from the urethra. Collagen I expression, as a measure of fibrosis, was monitored at intervals by detection of bioluminescence signal of luciferase activity after luciferin i.p. injection.

Results: At day 7, there were more collagen I expression in obstructed kidneys (2.59±0.34 Xe^6) than in the contralateral side (1.33±0.04 Xe^6). At day 10, the collagen I activity continued to increase to 4.95±1.35 Xe^6 in the obstructed side after reversal, while

there was no change in the contralateral side (1.13±0.04 Xe^6). Albuminuria was also detected in the urine from the obstructed kidney (ACR, 888.25±102.23 μg/mg), with no proteinuria from the contralateral side (52.70±10.70μg/mg). In 8 of 10 mice, reestablished urine flow at obstructed side continued till mice were sacrificed.

Conclusions: Our study demonstrates feasibility of a novel reversible UUO model that allows functional assessment of each kidney after reversal of obstruction. This may provide a useful model to test therapeutic strategies for reversing renal fibrosis and restoring renal function.

Funding: NIDDK Support

TH-PO975

Activation of TGF-β/Smad3 Signaling in *Megabladder* Mice with Congenital Obstructive Nephropathy Ashley R. Carpenter, Brian Becknell, Michael Wilhide, Susan E. Ingraham, Kirk M. McHugh. *The Research Institute at Nationwide Children's Hospital and College of Medicine at the Ohio State University, Columbus, OH.*

Background: Congenital obstructive nephropathy (CON) is the leading cause of chronic kidney disease in children. The megabladder (*mgb*) mouse serves as a unique animal model of CON. Mutants develop a functional lower urinary tract obstruction due to a lack of proper detrusor muscle organization *in utero*. This leads to formation of a distended hypomuscular bladder, renal failure and death in early adulthood. To better understand the molecular mechanisms responsible for the pathophysiology of CON, we performed transcriptome analysis of *mgb* kidneys compared to wild type controls.

Methods: Kidneys from age-matched adult $mgb^{-/-}$(mutant) and $mgb^{+/+}$(control) mice were harvested and prepared for evaluation by the Agilent cRNA microarray, qPCR and immunohistochemistry (IHC). ELISA was performed on embryonic day 15 (E15), E18, postnatal day 1-3 (P1-P3), P10, and adult kidney lysates. Gene expression data was analyzed using Ingenuity's IPA software.

Results: Transcriptome analysis of *mgb* kidneys identified a number of changes in genes involved in the canonical TGF-β pathway. Specifically, the expression of receptor-regulated Smad3 and Smad4 (p-value of overlap = 2.31×10^{-9} and 4.42×10^{-5} respectively) were identified as the most transcriptionally active (regulation z-score = 2.896 and 2.108 respectively) based on number of target genes with increased expression. Of the 26 differentially expressed mRNAs regulated by Smad3, 22 were upregulated in mutant kidneys. We confirmed upregulation of Smad3 target genes, Egr1 and Fos by qPCR, and genes implicated in TGF-β-dependent renal fibrosis such as CTGF by IHC. ELISA confirmed a significant increase ($p \leq 0.05$) in TGF-β3 and related TGF-β1 secreted proteins in adult mutant kidneys. Preliminary findings suggest that TGF-β1 may be increased as early as P10.

Conclusions: In the *mgb* mouse model of CON, TGF-β and Smad3/4 profiles are upregulated. The unique progression of renal failure observed in the *mgb* mouse may provide an approach for the investigation of time-point dependent pharmacological inhibition of the molecular pathways responsible for CON.

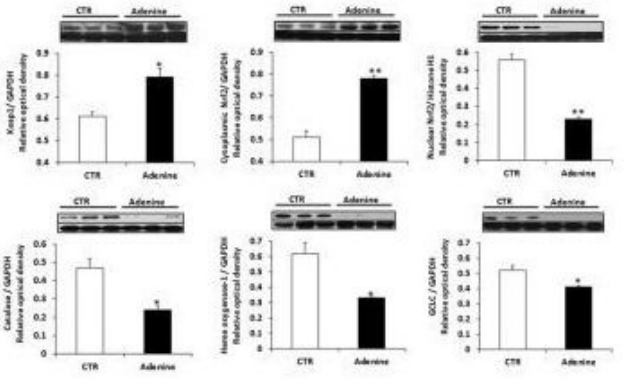
Oxidative Stress and Inflammation in Chronic Tubulo-Interstitial Nephropathy Are Associated with and, in Part, due to Impaired Nrf2 Activation Mohammad A. Aminzadeh,[1] Susanne B. Nicholas,[2,3] Keith C. Norris,[2,3] Nosratola D. Vaziri.[1] *[1]University of California, Irvine; [2]University of California, Los Angeles; [3]Charles R. Drew University of Medicine and Science, Los Angeles, Los Angeles, CA.*

Background: Consumption of adenine leads to the accumulation of 2, 8-dihydroxyadenine in the renal tubules triggering intense tubulointerstitial nephropathy (TIN) and progressive decline in kidney function. Kidney disease in this model is associated with and largely driven by oxidative stress and inflammation. Oxidative stress and inflammation in the Imai rats with spontaneous focal segmental glomerulosclerosis and in rats with CKD induced by 5/6 nephrectomy is associated with impaired activation of Nrf2 which is the master regulator of genes encoding antioxidant, and cytoprotective enzymes. However, the effect of TIN on Nrf2 pathway and its key target genes is unknown and was investigated here.

Methods: Sprague-Dawley rats were randomized to control and adenine-treated (rat chow containing 0.7% adenine for 2 weeks) groups and followed for 4 weeks.

Results: The adenine-treated animals exhibited marked azotemia, impaired urinary concentrating capacity, intense tubular and glomerular damage, and interstitial inflammation and fibrosis. This was associated with increased expressions of NAD(P)H oxidase, cyclooxygenase-2 and 12-lipoxygenase, and activation of NF-κB which is the master regulator of pro-inflammatory and pro-fibrotic cytokines and other mediators. Oxidative stress and inflammation in the kidney tissue of adenine-treated animals was accompanied by impaired activation of Nrf2 and down-regulation of its target gene products including, catalase, heme oxygenase-1, and glutamate-cysteine ligase.



Conclusions: Adenine-induced TIN is associated with impaired Nrf2 activation which renders the kidney exceedingly vulnerable to the ravages of the prevailing oxidative stress and inflammation.

TH-PO977

CTP-499, a Novel Drug for the Treatment of Chronic Kidney Disease, Ameliorates Renal Fibrosis and Inflammation In Vivo Ara Aslanian, Kristine Hogan, Kara West, Gary W. Bridson, Lijun Wu. *Concert Pharmaceuticals, Lexington, MA.*

Background: Chronic Kidney Disease (CKD) is a complex, multifactorial disease in which renal function is progressively compromised. Decreased glomerular filtration due to dysregulated extracellular matrix (ECM) deposition is a hallmark of progressive CKD. However, oxidative imbalance, inflammation and exaggerated proliferation of fibroblasts and myofibroblasts are now increasingly recognized as major pathogenic mechanisms in CKD. Previously, we have shown that CTP-499, a novel, deuterated analog of 1-((S)-5-hydroxyhexyl)-3,7-dimethylxanthine (HDX), the active M1 metabolite of pentoxifylline, exhibits efficacy in key cellular pathological mechanisms involved in CKD including inhibition of pro-fibrotic gene expression, inflammatory cytokines and oxidative stress.

Results: In the current studies, we demonstrate that CTP-499 ameliorates renal fibrosis *in vivo*. Kidney collagen content was significantly reduced in rats dosed with CTP-499 compared to controls in the unilateral ureteral obstruction (UUO) model. We also extended our previous studies of the anti-inflammatory properties of CTP-499 *in vivo*. The expression of kidney MCP-1 and TNF-α were significantly reduced in CTP-499-treated rats. Also, dosing rats with CTP-499 significantly reduced *ex vivo* LPS-induced expression of MCP-1, TNF-α and IL-6.

To further understand the renoprotective mechanism of CTP-499, we investigated the effects of mitogenic stimuli on kidney cells. CTP-499 prevented the TGF-β-mediated loss of the epithelial marker E-cadherin and induction of the mesenchymal marker vimentin, suggesting CTP-499 may prevent the formation of matrix-forming fibroblasts from proximal tubule cells. Also, CTP-499 significantly inhibited PDGF-induced proliferation of rat mesangial cells.

Conclusions: Taken together, these data show that CTP-499 possesses anti-fibrotic and anti-inflammatory properties *in vivo*. Inhibition of TGF-β-induced kidney cell differentiation and mesangial cell proliferation may contribute to the anti-fibrotic mechanism of CTP-499. These results further support our continued interest in CTP-499 as a novel agent for the potential treatment of CKD.

Loss of Tubular Hepatocyte Growth Factor Signaling Results in an Exaggerated Epithelial-Mesenchymal Transition in Kidney Fibrosis Dong Zhou, Youhua Liu. *Department of Pathology, University of Pittsburgh, Pittsburgh, PA.*

Background: Epithelial-mesenchymal transition (EMT) is thought to be a mechanism contributing to renal fibrosis. However, while EMT in vitro is universally accepted, whether EMT does occur in vivo in kidney fibrosis remains highly controversial. EMT is shown to be negatively regulated by hepatocyte growth factor (HGF) signaling. We hypothesize that due to the presence of endogenous antagonists, EMT in vivo probably requires 'two hits', resulting from both activation of pro-EMT program and loss of anti-EMT mechanisms.

Methods: To test this hypothesis, we used conditional knockout mice (Ksp-met-/-) in which c-met, the tyrosine kinase receptor for HGF, was ablated in tubule-specific manner. Ksp-met-/- mice and control littermates were subjected to obstructive injury induced by unilateral ureterl obstruction (UUO). In addition, these mice were also treated with a single dose of folic acid for 2 months to induce chronic kidney disease (CKD).

Results: More severe renal fibrotic lesions and interstitial fibrosis were found in Ksp-met-/- mice after both folic acid and obstructive injury, compared with control littermates, as shown by an increased expression of fibronectin, collagen I, collagen III, α-SMA, PAI-1, Snail1, TGF-β, and connective tissue growth factor (CTGF) in Ksp-met-/- mice. Furthermore, serum creatinine level was higher in Ksp-met-/- mice than that in the controls at 2 months after folic acid injection. Interestingly, using confocal microscopy we demonstrated a marked increase in tubular expression of mesenchymal marker vimentin, a

sign of EMT, in Ksp-met-/- mice. Co-staining revealed that these vimentin-positive tubule cells migrated across the basement membrane and entered the interstitial compartment in Ksp-met-/- kidneys after injury.

Conclusions: These results indicate that tubule-specific loss of HGF/c-met signaling, a negative inhibitor of EMT, resulted in an exaggerated EMT, worsened fibrosis and more severe kidney dysfunction. Our data illustrate that EMT in vivo necessitates both activation of pro-EMT program and loss of anti-EMT mechanisms.

Characterization of Adenine-Feeding Mice Model of Tubulointerstitial Damage with Renal Dysfuction

Izumi Yamamoto,[1] Keitaro Yokoyama,[1] Ichiro Ohkido,[1] Taketo Uchiyama,[1] Ichiaki Ito,[2] Jun Yanagisawa,[2] Tatsuo Hosoya.[1] *[1]Kidney and Hypertension, The Jikei University School of Medicine, Tokyo, Japan; [2]Graduate School of Life and Environmental Science, University of Tsukuba, Ibaragi, Japan.*

Background: Adenine is produced endogenously as a by-product of the polyamine pathway and is salvaged by adenine phosphoribosyltransferase (APRT:EC 2.4.2.7). APRT deficiency leads to the accumulation of 2,8-dihydroxyadenin(DHA)crystals in human(OMIM:102600).We have reported that mice fed the overload of the adenine-containing diet were mimic to APRT deficiency mice and both were used as human DHA disease model that showed DHA crystals in the tubular lumens with fibrosis and renal dysfunction. The aim of this study is to evaluate the effect of carcitoriol, which have antifibrotic effects,in our established mice model of tubulointerstitial damage (TID) with renal dysfunction induced by adenine feeding.

Methods: Inbred male C57BL/6 mice (10 weeks old) were fed a standard laboratory powder diet containing 0.25% adenine (0.25%Ad) for 7days, then they were fed a standard laboratory diet foraddditional 7days. Mice with subcutaneous injection (s.c) of carcitriol were euthanized on days 3, 7, and 14 (Group 2,4,6), and mice with DMSO s.c. were euthanized on days 3, 7, and 14 (Group 1,3,5) as controls.

Results: Mice fed 0.25%Ad showed nephrolithiasis, extensive tubular dilation, inflammation, necrosis and fibrosis (estimated by Masson's Trichrome stain) with the elevation of serum creatinine (Cr) and TID area (%) in a time-dependent manner (Group 1 vs 3; $p<0.01$). The observation of 0.25%Ad days 7+DMSO and 0.25%Ad days 7 + carcitriol(+) showed that carcitoriol exposure have the protective effectsfor Cr and TID (**$p<0.01$) but this protecitive effect did not prolong for additional 7days observation.

Cr(mg/dl) and TID(%)

	Group1	Group2	Group3	Group4	Group5	Group6
Cr (mg/dl)	0.6±0.045	0.5	0.74±0.05	0.6±0.07**	0.52±0.04	0.44±0.1
TID (%)	1.43±0.73	1.69±0.73	14.5±2.0	5.2±3.2**	13.1±6.5	10.1±5.8

**$p<0.01$

Conclusions: These datum showed that carcitoriol have the prophiractic protective effects in mice fed 0.25%Ad models morphologically and functionally.

The New Immunosuppressive Drug FTY720 Attenuates Tubulointerstitial Inflammation and Fibrosis in 5/6 Nephrectomized Rats

Haifeng Ni, Junfeng Chen, Bi-Cheng Liu. *Institute of Nephrology, Zhong Da Hospital, Southeast University School of Medicine, Nanjing, Jiangsu, China.*

Background: Tubulointerstitial fibrosis is the common pathway that lead to kidney failure, while persistent tubulointerstitial inflammation is a key event in the development of tubulointerstitial fibrosis. The new immunosuppressive drug FTY720 modifies lymphocyte migration into injured tissues by lymphocyte sequestration to secondary lymphoid organs. This study was designed to explore the effect of FTY720 on tubulointerstitial inflammation and fibrosis in 5/6 nephrectomized rats.

Methods: Seven days after surgery, SD rats were allocated to the following groups: sham, 5⁄6 subtotal nephrectomy(SNX), and SNX+FTY720. Rats were killed on week 12 after surgery and blood, urine and kidneys were collected for analyses. Tubulointerstitial infiltrating inflammatory cells such as T cells ,B cells and macrophages were detected by immunohistochemical staining. Protein expression of pro-inflammatory molecules and pro-fibrotic molecule were analyzed by immunohistochemical staining and western blot. Protein expression of α-SMA and E-cadherin were detected by immunofluorescence analysis and western blot.

Results: FTY720 attenuated the rise in BP, proteinuria, SCr,BUN and NAG in SNX($P<0.01$). Treatment with FTY720 was found to reduce the numbers of peripheral blood Lymphocyte($P<0.01$). Morphological study showed severe tubulointerstitial inflammation and fibrosis in SNX, but the lesions were attenuated in FTY720-treated group ($P<0.01$). Tubulointerstitial infiltrating inflammatory cells expressing CD3, CD4, CD8, CD20, CD68, CD163 and CCR-7 in SNX were attenuated in FTY720-treated group($P<0.01$). FTY720 decreased the expression of pro-inflammatory molecules(IL-6, TNF-α,and MCP-1) and pro-fibrotic molecule(TGF-β1) ($P<0.01$). The protein expression of E-cadherin was down-regulated, while the expression of α-SMA, was up-regulated in kidneys of SNX rats when compared with those in sham group ($P<0.01$). FTY720 administration attenuated these abnormalities($P<0.01$).

Conclusions: FTY720 ameliorates progression of tubulointerstitial injury in SNX by inhibiting tubulointerstitial inflammatory response and tubular epithelial-to-mesenchymal transition.

Platelet-Derived Growth Factor-C Neutralization Reveals Differential Roles of PDGF Receptors in Liver and Kidney Fibrosis

Tammo Ostendorf,[1] Ina V. Martin,[1] Erawan Borkham-kamphorst,[2] Stephanie Zok,[1] Claudia R.C. van Roeyen,[1] Ulf P.E. Eriksson,[3] Peter Boor,[1] Kanishka Hittatiya,[4] Hans-peter Fischer,[4] Ralf Weiskirchen,[2] Frank Eitner,[5] Jürgen Floege.[1] *[1]Division of Nephrology, RWTH Aachen University, Aachen, Germany; [2]Institute of Clinical Chemistry and Pathobiochemistry, RWTH Aachen University, Aachen, Germany; [3]Department of Medical Biochemistry and Biophysics, Karolinska Institute, Stockholm, Sweden; [4]Institute of Pathology, University Hospital Bonn, Bonn, Germany; [5]Bayer Pharma AG, Wuppertal, Germany.*

Background: Platelet-derived growth factors (PDGFs) are key mediators of organ fibrosis. Nonetheless, the specific role of isoform PDGF-C for kidney and liver fibrosis is not well known.

Methods: We investigated whether PDGF-C -/- mice or mice treated with neutralizing PDGF-C antibodies are protected from bile duct ligation-induced liver fibrosis and compared the effects with those of PDGF-C deficiency or neutralization on kidney fibrosis induced by unilateral ureteral obstruction.

Results: Unexpectedly, and in contrast to kidney fibrosis, PDGF-C deficiency or antagonism did not protect from liver fibrosis or functional liver impairment. Furthermore, the hepatic infiltration of monocytes/macrophages/dendritic cells and chemokine mRNA expression (CCL5, CCL2 and CCR2) remained unchanged. Transcript expression of PDGF ligands increased in both liver and kidney fibrosis and was not affected by neutralization of PDGF-C. In kidney fibrosis, PDGF-C deficiency or antagonism led to reduced expression and signaling of PDGF-receptor-α- and -β-chains. In contrast, in liver fibrosis there was either no difference (PDGF-C -/- mice) or even an upregulation of PDGFR-β and signaling (anti-PDGF-C group). Finally, *in vitro* studies in portal myofibroblasts pointed to a predominant role of PDGF-B and -D signaling in liver fibrosis.

Conclusions: In conclusion, our study revealed significant differences between kidney and liver fibrosis in that PDGF-C mediates kidney fibrosis, whereas antagonism of PDGF-C in liver fibrosis appears to be counteracted by significant upregulation and increased signaling of PDGFR-β. PDGF-C antagonism therefore may not be effective to treat liver fibrosis.

Renal Carcinoma Stem Cells Are Induced by MEK/MAPK/FRA2 Signaling Cascade-Mediated Epithelial-Mesenchymal Transition: Evidence for a Dynamic and Renewable Stem Cell Phenotype

David H. Lovett,[1] Rajeev Mahimkar.[2] *[1]Medicine/Nephrology, San Francisco VA Medical Center/ University of California San Francisco, San Francisco, CA; [2]BioMarin Pharmaceutical, Inc., Novato, CA.*

Background: Cancer stem cells (CSC) are defined by: self-renewal, growth in suspension (spheroids), multi-lineage differentiation, tumorigenesis, and metastasis. One hypothesis states that CSC are derived from genomically unstable adult mesenchymal stem cells. Alternatively, CSC could be continuously generated as a consequence of epithelial-mesenchymal transition (EMT) in response to genomic stress or environmental cues. We reported (Lovett, et al., Carcinogenesis 2011;32:1806) that the MEK1/MAPK signaling cascade induces EMT in MDCK epithelial cells which is dependent on MEK1 and MT1-MMP activities. We directly correlated these to renal cell carcinoma (RCC) tumor grade and invasion. We hypothesized that these features are mediated by EMT-dependent generation of CSC.

Methods: The MEK1 response element (AP1) in the MT1-MMP promoter was mapped and characterized using standard methodology. The molecularly more amenable LLC-MK2 renal epithelial cell line generated, using MEK1 expression, clones spanning the phenotypic range of EMT. Microarray analysis of the ENT clones, spheroid cultures and orthotopic renal injections were performed using standard methodology.

Results: A MEK1 response element in the MT1-MMP promoter was identified as an AP1 site binding FRA2/JUNB heterodimers. FRA2 activity is enhanced by MAPK phosphorylation and FRA2 expression predicts survival in metastatic RCC. FRA2 transfection induced EMT, enhanced MT1-MMP expression and invasive activity. Microarrray identified the CSC-EMT transcription factor TWIST1 as a possible FRA2 target. Mesenchymal LLC-MK2 clones grow as spherules in defined medium and display both mesenchymal-epithelial transition and invasive acivity in the orthotopic model, consistent with a CSC phenotype.

Conclusions: We propose that renal epithelial cells are dynamically converted to CSC through the combined action of MEK1/MAPK/FRA2 signaling and MT1-MMP expression. Inhibition of FRA2 or MT1-MMP could potentially inhibit the generation of renal CSC and affect RCC outcomes.

TH-PO983

Transforming Growth Factor β Stimulates Profibrotic Epithelial Signaling to Activate Pericyte-Myofibroblast Transition in Obstructive Kidney Fibrosis Szu Yu Pan,[1] Ching-fang Wu,[1] Fan-Chi Chang,[1] Yi-Ting Chen,[1] Wen-Chih Chiang,[1] Yung-ming Chen,[1] Jeremy S. Duffield,[2] Shuei-Liong Lin.[1] [1]*Renal Division, National Taiwan University Hospital, Taipei, Taiwan;* [2]*Renal Division, University of Washington, Seattle, WA.*

Background: Pericytes and perivascular fibroblasts have been identified as the major source of precursors of scar-producing myofibroblasts during kidney fibrosis. The underlying mechanisms triggering pericyte-myofibroblast transition are poorly understood. Transforming growth factor β (TGFβ) is well recognized as a pluripotent cytokine that drives organ fibrosis. Here we show the role of TGFβ in inducing profibrotic signaling from epithelial cells to activate pericyte-myofibroblast transition.

Methods: We studied the *in vivo* effect of activated TGFβ signaling on pericyte-myofibroblast transition and epithelial cell responses using pan anti-TGFβ antibody (1D11) or TGFβ receptor type I inhibitor (SB431542) in collagen I (α1) GFP reporter mice after unilateral ureteral obstruction. Primary cultures of tubular epithelial cells and pericytes were used to study the *in vitro* effect of TGFβ1 and the cross talk between epithelial cells and pericytes.

Results: Increased expression of TGFβ was detected predominantly in injured epithelium after unilateral ureteral obstruction, whereas downstream signaling from the TGFβ receptor increased in both injured epithelium and pericytes. In mice with ureteral obstruction, treated with antibody 1D11 or chemical SB431542, kidney pericyte-myofibroblast transition was blunted. The consequence was marked attenuation of fibrosis. In addition, epithelial cell cycle G2/M arrest and production of profibrotic cytokines were both attenuated. Although TGFβ1 alone did not trigger pericyte proliferation *in vitro*, it robustly induced α smooth muscle actin. In cultured kidney epithelial cells, TGFβ1 stimulated G2/M arrest and production of profibrotic cytokines that had the capacity to stimulate proliferation and transition of pericytes to myofibroblasts.

Conclusions: This study identifies a novel link between injured epithelium and pericyte-myofibroblast transition through TGFβ during kidney fibrosis.

TH-PO984

A Hepcidin Inhibitor Mobilizes Iron in an Adenine-Induced Renal Failure Model in Rats Valentina Vaja, Chia Chi Sun, Herbert Y. Lin, Jodie L. Babitt. *Program in Membrane Biology, Nephrology Division, Center for Systems Biology, Massachusetts General Hospital, Harvard Medical School, Boston, MA.*

Background: Anemia is prevalent in patients with chronic kidney disease (CKD). A key feature of the anemia of CKD is limited iron availability for efficient erythropoiesis despite adequate body iron stores. It is now well established that excess levels of the iron regulatory hormone hepcidin in CKD are responsible for decreasing expression of the iron exporter ferroportin, thereby blocking iron absorption from the diet and iron release from body stores. Adenine treatment in rats has been proposed as an animal model of anemia of CKD with high hepcidin levels that mirrors the condition in patients.

Methods: We developed a modified adenine-induced kidney disease model of anemia in rats by giving a diet supplemented with 0.75% adenine for 3 weeks followed by a normal diet for 3 weeks. We then tested whether the small molecule bone morphogenetic protein (BMP) inhibitor LDN-193189, which has previously been shown to lower hepcidin levels, was able to mobilize iron into the plasma and improve iron-restricted erythropoiesis in adenine-treated rats.

Results: The modified adenine model had a higher survival rate than previously reported models, while maintaining irreversible renal failure and anemia. Adenine-treated rats had increased hepatic hepcidin mRNA, decreased serum iron, increased spleen iron content, low hemoglobin, and inappropriately low EPO levels relative to the degree of anemia. LDN-193189 lowered hepatic hepcidin mRNA and mobilized stored iron into plasma in adenine-treated rats. Moreover, the iron was efficiently incorporated into hemoglobin in reticulocytes. However, LDN-193189 alone did not prevent anemia progression in our model.

Conclusions: Lowering hepcidin improved iron availability, but did not improve anemia in an adenine-induced kidney disease model in rats. Co-administration of hepcidin lowering agents with erythropoiesis stimulating agents (ESAs) may be useful as a combination therapy to correct iron balance and thereby reduce the ESA dose needed to achieve target hemoglobin levels.

TH-PO985

Recombinant Human Soluble Thrombomodulin Attenuates Anti-Glomerular Basement Membrane Glomerulonephritis in Wistar-Kyoto Rats Masayuki Iyoda, Takanori Shibata, Kei Matsumoto, Yukihiro Wada, Yuki Hirai, Yoshihiro Kuno, Tadao Akizawa. *Division of Nephrology, Department of Medicine, Showa University School of Medicine, Tokyo, Japan.*

Background: Recombinant human soluble thrombomodulin (RH-TM) is newly developed for the treatment of DIC. Since RH-TM has anti-inflammatory properties, the protective effects of RH-TM were examined in nephrotoxic serum nephritis (NTS-N) of Wistar-Kyoto (WKY) rats, in which CD8+ T cells and macrophages are major pathogenetic factors.

Methods: NTS-N (N=26) was induced in WKY rats on day 0. Groups of animals were given either RH-TM (1.5 mg/kg x 2/day, n=13) or vehicle (an equal volume of saline, n=13) daily by intraperitoneal injection from day 0 to day 6; all rats were sacrificed at day 7. Proteinuria, serum creatinine (Cr), and kidney weight were measured at sacrifice. Routine histology, immunohistochemistry for ED1 and CD8, and real-time RT-PCR for cytokines in renal cortex were performed.

Results: There was no significant difference in rabbit IgG, rat IgG, and rat C3 glomerular staining and the levels of serum anti-rabbit IgG antibody between vehicle- and RH-TM-treated rats with NTS-N. Compared to controls, RH-TM-treated rats had less proteinuria (68.6 ± 3.26 vs. 45.15 ± 8.51 mg/day, $p < 0.01$), serum Cr (0.35 ± 0.01 vs. 0.32 ± 0.05 mg/dl,$p< 0.01$) level, and kidney weight (1.49 ± 0.02 vs. 1.25 ± 0.06 g, $p < 0.01$), as well as reduced glomerular tuft area (8572.69 ± 151.21 vs. 7044.46 ± 530.75 mm^2, $p < 0.01$), and percentage of glomeruli with crescent (95.15 ± 1.16 vs. 81.54 ± 3.47 %,$p< 0.001$). Furthermore, RH-TM-treated rats had significantly reduced glomerular macrophage accumulation (ED1 score: 1.51 ± 0.05 vs. 1.25 ± 0.10,$p < 0.01$) as well as reduced renal cortical IL-6 mRNA expression (IL-6/GAPDH mRNA: 1.04 ± 0.09 vs. 0.66 ± 0.16,$p< 0.05$). The CD8+ cell numbers per glomerular cross-section and renal cortical TNF-a, IL-1b, MCP-1, INF-g, IL-4, and IL-17 mRNA expression were identical between the two groups.

Conclusions: RH-TM treatment attenuates the progressionof renal injury in experimental anti-glomerular basement membrane glomerulonephritis through the suppression of macrophages infiltration.

TH-PO986

Inhibition of p38 MAPK Attenuates Renal Atrophy in a Murine Renovascular Hypertension Model Diping Wang, Ping Yin, Bruce Knudsen, Jingfei Cheng, Gina M. Warner, Karen R. Lien, Catherine Gray, Joseph P. Grande. *Mayo Clinic, Rochester, MN.*

Background: Renovascular hypertension (RVH) is an important cause of chronic renal dysfunction. Recent studies have implicated signaling through CCL2 and other chemokines in the development of chronic renal disease, suggesting that CCL2 may provide a therapeutic target in patients with RVH. Although our *in vitro* studies have demonstrated that p38 MAPK is a necessary intermediate for CCL2 expression, its role in renal disease progression in RVH has not been previously established. We tested the hypothesis that blockade of p38 would ameliorate renal damage in mice with experimental RVH.

Methods: RVH was established using the murine two-kidney, one-clip (2K1C) model. Mice were treated with the p38 inhibitor SB203580 (10 mg/kg/d) or vehicle after surgery. Blood pressure was measured before, 1 and 2 weeks after the surgery. Kidneys were harvested at 2 weeks after surgery. Histologic examination, Western blotting, and real-time PCR were performed to evaluate the impacts of p38 inhibition on renal atrophy and to identify chemokines modulated by SB203580. We also investigated the *in vitro* effects of p38 inhibitor in rat mesangial cells to confirm our observation *in vivo*.

Results: As expected, the clipped kidney developed interstitial fibrosis, tubular atrophy, and interstitial inflammation. SB203580 significantly reduced the level of renal atrophy in stenotic kidneys (70% vehicle vs. 39% SB203580, $p<0.05$) but did not prevent hypertension. SB203580 reduced interstitial fibrosis (6.0% vehicle vs. 2.7% SB203580, $p< 0.01$; trichrome stain). SB203580 prevented induction of *Ccl2*, *Ccr2*, *Tgf*-β, and *Col4a1* mRNA expression. We also observed that SB203580 could block upregulation of CCL2 and COL4A1 expression at protein level (Western blotting, immunohistochemistry). *In vitro*, p38 inhibition prevented TGF-β and TNF-α-induced upregulation of *Ccl2* in rat mesangial cells.

Conclusions: SB203580 prevents CCL2 induction and alleviates renal atrophy and fibrosis in a murine RVH model. We propose that p38 plays a critical role in the development of renal atrophy in 2K1C mice and may provide a therapeutic target to slow progression of RVH.

TH-PO987

Ameliorating NO Bioavailability via ROS Reduction by Nicorandil Suppresses the Hypertensive Nephropathy in Salt-Sensitive Dahl Rats Ken Aizawa, Kenji Yogo, Yoshihito Tashiro, Ken-ichi Serizawa, Keigo Yorozu, Michinori Hirata, Nobuhiko Ishizuka, Koichi Endo. *Product Research Department, Chugai Pharmaceutical Co., Ltd., Gotemba, Shizuoka, Japan.*

Background: In hypertensive nephropathy, tight blood pressure control is known to be a crucial factor in preventing progression of renal disease, but other factors are undoubtedly involved. Nicorandil, an antianginal drug that has cardioprotective effects, was reported to reduce reactive oxygen species (ROS) and upregulate endothelial nitric oxide synthase (eNOS) expression, suggesting it could be beneficial in treating hypertensive nephropathy under conditions of endothelial dysfunction. In this study, we evaluated the effect of nicorandil on renal failure induced by oxidative stress in salt-sensitive Dahl (DS) rats.

Methods: Male DS rats were divided into three groups; NS (normal diet: 0.3% NaCl), HS (high salt diet: 8% NaCl) and HS + nicorandil (15 mg/kg/day: drinking water). Four weeks after treatment, systolic blood pressure, renal damage parameters in urine and histopathology were determined. The protein level of eNOS and the uncoupling state in glomeruli were quantified with western blotting method.

Results: HS increased proteinuria with hypertension and nicorandil suppressed the proteinuria, without lowering blood pressure. Nicorandil also reduced urine levels of NAG, cystatin-C and 8-hydroxydeoxyguanosine, an oxidative stress marker. Histopathological analysis revealed that nicorandil prevented dilation of renal tubules; the deposition of hyaline casts andperivascular fibrosis. Although both the expression of total eNOS and the coupling state of eNOS (eNOS dimer/monomer ratio) in glomeruli were reduced by salt loading, nicorandil prevented those changes.

Conclusions: Nicorandil may be beneficial in treating hypertensive nephropathy by improving NO bioavailability via the reduction of ROS. Together with cardioprotective effects, the renoprotective effects of nicorandil, achieved by ameliorating endothelial dysfunction, would be efficacious for hypertensive CKD patients with angina.

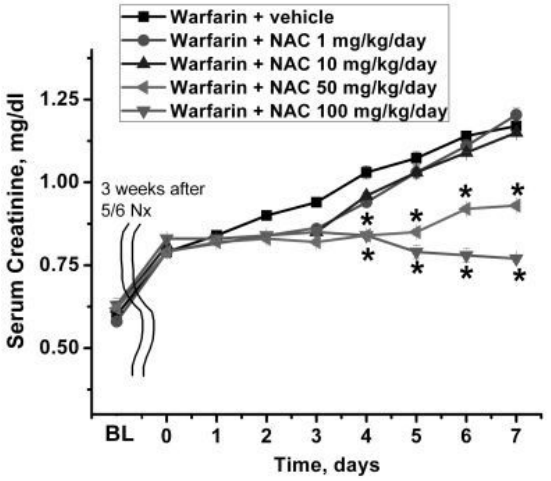
TH-PO988

N-Acetylcysteine (NAC) Prevents Acute Kidney Injury but Not Glomerular Hemorrhage in an Animal Model of Warfarin Related Nephropathy (WRN) Sergey V. Brodsky, Kyle M. Ware, Zahida Qamri, Edward P. Calomeni, Anjali A. Satoskar, Gyongyi Nadasdy, Brad H. Rovin, Lee A. Hebert, Tibor Nadasdy. *Pathology and Medicine, The Ohio State University, Columbus, OH.*

Background: We described earlier that 5/6 nephrectomy (Nx) in rats is an appropriate animal model to study WRN, which we discovered previously in humans. WRN is characterized by glomerular hemorrhage with occlusive tubular red blood cell (RBC) casts, leading to acute kidney injury. The pathogenesis of glomerular hemorrhage is unclear. Herein we tested the hypothesis that oxidative stress plays a significant role in the pathogenesis of WRN.

Methods: 5/6 Nx rats were treated with warfarin (0.04 mg/kg/day) alone and with 4 different doses of NAC per os for 1 week. Prothrombin time (PT) and serum creatinine (SCr) were measured daily. Renal pathology was evaluated after 1 week of treatment.

Results: Warfarin resulted in more than 3-fold PT increase in all experimental groups. SC increased progressively in the animals treated with warfarin + vehicle. However, addition of NAC dose-dependently prevented the increase in SCr starting at 50 mg/kg/day and completely prevented warfarin-induced SCr increase at 100 mg/kg/day (Figure 1).



SCr changes were significantly correlated with PT increase in warfarin and vehicle-treated 5/6 Nx rats (R^2=0.88) with SCr even decreasing in rats treated with warfarin and 100 mg/kg/day of NAC (R^2=0.38). Morphologically, all 5/6 Nx rats treated with warfarin, regardless of NAC dose, showed RBC in the tubules and RBC tubular casts. Acute tubular injury was prominent in warfarin + vehicle treated 5/6 Nx rats, but not in warfarin + 100 mg/kg/day of NAC treated animals.

Conclusions: 1. Oxidative stress plays an important role in the development of acute kidney injury in animals with WRN. 2. NAC does not prevent glomerular hemorrhage seen in WRN, but ameliorates acute tubular injury.

TH-PO989

Glomerular Infiltration of MPO-Positive Cells and Diffuse-Type MPO Deposition on Glomerular Capillary Walls Cause Glomerular Capillary Injury Soko Kawashima, Yoshihiro Arimura, Yoshinori Komagata, Shinya Kaname, Akira Yamada. *Frst Department, Kyorin University School of Medicine, Mitaka, Tokyo, Japan.*

Background: We have previously reported that MPO exists along the glomerular capillary walls near infiltrated MPO-positive neutrophils, which may play some direct roles in the pathogenesis of necrotizing lesion in human MPO-ANCA-associated glomerulonephritis (GN). Here we investigated a possible role of MPO in the pathogenesis of glomerular capillary injury for other types of GN.

Methods: We analyzed 914 renal specimens obtained from 13 patients with IgA nephritis, 12 patients with Henoch-Schoehnlein purpura nephritis (HSPN), 2 patients with post-streptococcal acute glomerulonephritis (PSAGN), 2 patients with anti-GBM GN and compared them with those from 20 patients with MPO-ANCA-associated GN. Glomerular infiltration of MPO-positive cells, deposition of extracellular MPO and endothelial cell injury were analyzed in glomeruli at each stage of the diseases. Colocalization of MPO and CD34 deposition was also examined.

Results: Glomerular infiltration of MPO-positive cells and deposition of extracellular MPO were observed along the glomerular capillary walls in all types of GN especially at an active injury phase. Interestingly, diffuse-type MPO deposition were frequently observed along the glomerular capillaries and seemed to be related to glomerular capillary injuries in anti- GBM GN, IgA GN and HSPN as well as in MPO-ANCA associated GN, whereas it was rarely seen in PSAGN where only limited type deposition without necrosis was observed despite an infiltration of many MPO positive cells.

Conclusions: These results suggest that the diffuse-type MPO deposition with infiltrating MPO-positive cells may be associated with glomerular capillary injuries in various types of GN in addition to MPO-ANCA –associated GN.

TH-PO990

Inactivating Notch3 by Antisense Strategy Alleviates the Development of Glomerulonephritis Fala El Machhour, Laurent Mesnard, Jean-Claude Dussaule, Christos Chatziantoniou. *Inserm UMR 702, Tenon Hospital, Paris, France.*

Background: We have previously shown that Notch3 is involved in the control of renal hemodynamics and function under control conditions. The aim of this work was to study the role of Notch3 receptor in the progression of chronic renal disease, using as model the nephrotoxic serum-induced glomerulonephritis.

Methods: Glomerulonephritis was induced by nephrotoxic serum administration in mice treated daily either with a Notch3 oligo-nucleotide antisense (ODN) or with a scrambled sequence. Mice were sacrificed 10 days after nephrotoxic serum administration, and tissues, urine and plasma samples were obtained and used for subsequent analyses.

Results: Administration of nephrotoxic serum was accompanied by a progressive increase of proteinuria and plasma urea concentration (3.4±0.9 g/mmol and 48±9 mmoL, respectively at day 10, $p<0.001$) associated to histological alterations typical of glomerulonephritis. In parallel, Notch3 expression was induced in glomeruli as evidenced by mRNA and protein expression measurements. The glomerular expression of Notch3 was significantly reduced in mice receiving Notch3 ODN antisense ($p<0.05$), whereas scrambled sequences had a negligible effect. The 2 groups progressed to chronic renal disease, but mice injected with Notch3 ODN antisense were relatively protected compared to scrambled group as evidenced by the values of plasma urea (18±8 vs 41±7 mmoL, $p<0.05$) and proteinuria (0.7±0.2 vs 2.4±0.7 g/mmol $p<0.05$). The improvement of renal function was accompanied by fewer deposits of fibrin within glomeruli, less peritubular and glomerular inflammation and decreased expression of pro-inflammatory mediators ($p<0.01$). Moreover, the inhibition of Notch3 was associated with blunted activation of growth factor signaling pathways well known to be involved in the development of glomerulonephritis such as the PDGF and EGF pathways.

Conclusions: These results show that the activation of Notch3 is a major player in the progression of renal disease by promoting proliferative and pro-inflammatory pathways. Targeting the expression and/or activation of Notch3 could be a novel, promising approach to treat chronic renal disease.

The Best Offense Is a Good Defense: Expression and Function of Beta Defensins in the Infected Kidney and Urinary Tract Brian Becknell,[1] Ashley R. Carpenter,[2] Sheryl S. Justice,[3] Kirk M. McHugh.[4] *[1]Division of Nephrology, Nationwide Children's Hospital; [2]Integrated Biomedical Sciences Program, The Ohio State University; [3]Center for Microbial Pathogenesis, The Research Institute at Nationwide Children's Hospital; [4]Center for Molecular and Human Genetics, The Research Institute at Nationwide Children's Hospital, Columbus, OH.*

Background: Beta defensins (BDs) are cationic peptides with immunomodulatory and antimicrobial properties. BD expression and function in the kidney and urinary tract are incompletely defined.

Methods: Tissues were collected from female C57BL/6 mice that remained naïve or were inoculated with uropathogenic *Escherichia coli* (UPEC). BD mRNA and protein expression was evaluated by QRT-PCR and immunoblotting. BD protein and mRNA were localized by immunohistochemistry and *in situ* hybridization. The bactericidal activity of BD peptides was evaluated *in vitro*, and *in vivo* by quantifying the bacterial burden following transurethral challenge of wildtype versus *BD1* knockout mice with UPEC.

Results: *BD1* mRNA was preferentially expressed in kidney, whereas *BD3* and *BD14* mRNAs were enriched in ureter and bladder. BDs displayed unique localization patterns within the kidney and lower urinary tract. *BD1* mRNA was expressed in renal collecting ducts and bladder urothelium. BD3 localized to endothelial cells and papillary collecting ducts of naïve kidneys. BD3 was restricted to the apical surface of bladder umbrella cells, whereas BD14 protein was expressed throughout the urothelium. UPEC decreased bladder expression of *BD1* mRNA, whereas *BD3* mRNA levels increased. BD peptides were detectable in infected urine and demonstrated differential activity toward UPEC *in vitro*. *BD1* knockout and wildtype mice had comparable UPEC colony counts in bladder and kidney homogenates.

Conclusions: BDs are differentially expressed throughout the naïve kidney and urinary tract, and are subject to unique local regulatory changes following UPEC challenge. BDs exhibit microbicidal activity toward UPEC, and further *in vivo* studies are required to delineate their bactericidal and immunomodulatory roles in the infected kidney and urinary tract.

TH-PO992

Pharmacological Inhibition of Plasminogen Activator Inhibitor (PAI)-1 Ameliorates Glomerular Podocyte Injury in Anti-Thy1.1 Glomerulonephritis Hideyasu Kiyomoto,[1,2,3] Kumiko Moriwaki,[4] Sachiko Matsumoto,[3] Atsuhiko Ichimura,[3] Takashi Nakamichi,[2] Takashi Dan,[3] Takefumi Mori,[2] Sadayoshi Ito,[2] Toshio Miyata.[3] *[1]Division of Integrated Nephrology and Telemedicine, Tohoku University, Sendai, Japan; [2]Division of Nephrology, Tohoku University, Sendai, Japan; [3]Department of Molecular Medicine and Therapy, Tohoku University, Sendai, Japan; [4]Department of CardioRenal and CerebroVascular Medicine, Faculty of Medicine, Kagawa University, Kagawa, Japan.*

Background: Plasminogen activator inhibitor (PAI)-1 is involved in glomerular disease processes including thrombosis, fibrosis and inflammation. The specific PAI-1 antagonist, TM5275, was newly synthesized by an *in silico* screening based upon the human PAI-1 tertiary structure. This study is to test the effects of TM5275 on anti-Thy1.1 glomerulonephritis (GN) in rats.

Methods: GN was induced by an injection of ER4G in male SD rats that received daily by gavages either vehicle, clopidogrel (30mg/kg/day) or TM5275 (30mg/kg/day) beginning at 3 days before induction of GN. The rats were sacrificed at day 7, and their perfused kidneys were processed for pathological evaluation. The mRNA expressions in the kidney were estimated by RT-PCR with heat-mapping exhaustive analysis. We also investigated the protective effect of TM5275 in cultured podocyte *in vitro.*

Results: An ER4G injection induced proliferative GN with focal and segmental microaneurysm formation in glomeruli. TM5275 improved the pathological abnormality, i.e. augmented incidence of glomerular microaneurism, macrophage infiltration and thrombi formation in glomeruli concomitant with inhibition of plasma PAI-1 activity, while clopidogrel exerted no protective effects on GN. Interestingly, TM5275 ameliorated the deterioration of podocyte estimated by staining for WT-1 and desmin. The confocal microscopy showed the partial colocalization of synaptopodin and PAI-1 in merge. Moreover, the synaptopodin in cultured podocyte was significantly suppressed by the existence of PAI-1, and this was restored by the presence of TM5275.

Conclusions: Our in vivo and in vitro data suggest that TM5275, a specific PAI-1 inhibitor, may provide potential therapeutic benefits in GN involving the podocyte injury.

TH-PO993

Genetic Analysis of Intracapillary Glomerular Deposits in Aging Mice Gerda A. Noordmans,[1] Yuan Huang,[1] Christina R. Caputo,[2] Marcory van Dijk,[1] Peter Heeringa,[1] Jan-luuk Hillebrands,[1] Ron Korstanje,[2] Harry Van Goor.[1] *[1]Pathology and Medical Biology, University Medical Center Groningen, Netherlands; [2]The Jackson Laboratory, Bar Harbor, ME.*

Background: Decline in renal structure and function is common in aging individuals. Understanding aging related renal damage provides tools for preventive and therapeutic means. To gain insight in pathways involved in aging, we analyzed glomerular intracapillary changes in aged mice. Haplotype association mapping (HAM) was used to identify genes associated with morphological changes.

Methods: Glomeruli from 20-months old male mice from 26 inbred strains were analyzed. Intracapillary PAS-positive deposits were a significant finding in some strains and we quantified the mean severity of deposit formation in 50 glomeruli (max score 400). Affected strains were also analyzed at 10 months. Electron microscopy and immunohistochemistry for apoE, apoB and apoA-IV was performed to characterize the lesion. Additional sections were used to study amyloid (Congo Red) or fibrin (MSB). HAM was used to identify loci associated with glomerular deposits. Strains containing a minimum of two affected mice were considered positive. Associations with a P-value of less than 10^{-4} were considered significant.

Results: Six strains showed PAS-positive deposits, varying in severity: B10 (mean=21 ± 47.5 SD), C57BR (7 ± 24.1), NOD (97 ± 135.7), NZW (41 ± 46.6), C3H (9 ± 19.4) and NON (30 ± 54.8). At 10 months of age only NOD (8 ± 21.4) and NON (33 ± 59.8) already contained glomerular deposits. Intracapillary deposits were strongly positive for apoE and weakly positive for apoB and apoA-IV. They were negative for amyloid and fibrin. HAM showed one peak above 10^{-6} on chromosome 1. The only gene found within this haplotype block is *Esrrg.*

Conclusions: PAS-positive glomerular intracapillary deposits were seen in six aged mouse strains. The lesion mimics human lipoprotein glomerulopathy, which is also characterized by deposition of lipoproteins in glomerular capillaries. Our data indicate that estrogen-related receptor gamma (*Esrrg*) which is highly expressed in the kidney and involved in lipid metabolism, is associated with the development of these glomerular deposits.

Effects of Dietary Salt Restriction on Renal Tubulointerstitial Injury in Rats with Glomerular Proteinuria Gheun-Ho Kim, Il Hwan Oh, Joon-sung Park. *Internal Medicine, Hanyang University College of Medicine, Seoul, Korea.*

Background: Proteinuria is a major promoter to induce tubulointerstitial injury in glomerulopathy, and dietary salt restriction may reduce proteinuria. Although high salt intake is believed to hasten progression of chronic kidney disease, whether low salt intake may relieve proteinuria-mediated tubulointerstitial injury is not clear. We investigated the effects of dietary salt restriction on rat kidneys using puromycin aminonucleoside (PA) and Adriamycin (ADR) to induce glomerular proteinuria.

Methods: In Protocol I, PA was intraperitoneally administered to male Sprague-Dawley rats at a dose of 150 mg/kg BW at time 0, followed by 50 mg/kg BW on days 28, 35, and 42. Sodium-deficient rodent diet with and without additional NaCl (0.5%) were provided for normal-salt rats and low-salt rats, respectively. On day 63, kidneys were harvested for histopathologic examination and immunohistochemistry. In Protocol II, ADR was intravenously given into the femoral vein as a single bolus (7.5 mg/kg). Five weeks later, kidneys were harvested for histopathologic studies, immunohistochemistry and immunoblot analysis.

Results: Both PA and ADR treatment produced overt proteinuria and renal damage. When the tubulointerstitial injury was semiquantitatively evaluated, it had a positive correlation with proteinuria in both animal experiments. Although dietary salt restriction failed to significantly decrease proteinuria, the increased tubulointerstitial injury score was significantly reversed by low-salt diet in both animal experiments. ED1-positive infiltrating cells and immunostaining for interstitial collagen III were increased in PA- and ADR-treated rat kidneys, and they appeared relieved by dietary salt restriction but did not reach statistical significances. In ADR-treated rat kidneys, however, the increased fibronectin expression was significantly reversed by dietary salt restriction.

Conclusions: Our results suggest that glomerular proteinuria-induced tubulointerstitial injury and its process may potentially be improved by dietary salt restriction. Non-hemodynamic mechanisms induced by low-sodium diet might contribute to renoprotection.

Prevention of Kidney Fibrosis by Regulator of G Protein Signaling 2 (RGS2) Hee-Seong Jang, Jee In Kim, Kwon Moo Park. *Anatomy and BK21 Project, Kyungpook National University School of Medicine, Daegu, Korea.*

Background: Regulator of G protein signaling 2 (RGS2), is a GTPase-accelerating protein that terminates Gq signaling, including angiotensin II (AngII) signaling, which play a critical role in kidney fibrosis. However, the role of RGS2 in kidney fibrosis remains to be defined.

Methods: Here, we investigated the role of RGS2 in kidney fibrosis following ureteral obstruction (UO).

Results: UO significantly increased expression of RGS2 mRNA and protein in the kidney. UO increased the collagen deposition and α-smooth muscle actin in the kidney. These increases in the kidney of RGS2 knock-out ($RGS2^{-/-}$) mice were significantly greater than in the kidney of RGS2 wild-type ($RGS2^{+/+}$) mice. After UO plasminogen activator inhibitor-1, PAI-1, and phosphorylated extracellular signal-regulated kinase, p-ERK, expression in the kidney of $RGS2^{-/-}$ mice, which is mediator of kidney fibrosis, were also greater than $RGS2^{+/+}$ mice. In addition, UO-induced inflammatory responses were greater in $RGS2^{-/-}$ mice than $RGS2^{+/+}$ mice. Increases of phospholylated-STAT3, which is associated with anti-inflammatory signaling, induced by UO were lower in the kidney of $RGS2^{-/-}$ mice than that of $RGS2^{+/+}$ mice. Moreover, UO-induced increase of AngII type 1 receptor (AT1R) was greater in the kidney of $RGS2^{-/-}$ mice than that of $RGS2^{+/+}$ mice. Losartan, a blocker of AT1R, treatment into $RGS2^{-/-}$ mice remarkably reduced kidney fibrosis with reduction of inflammation.

Conclusions: Our findings demonstrate for the first time that RGS2 plays as a negative regulator of kidney fibrosis by inhibition of Gq protein signaling including AngII/AT1R signaling, suggesting that RGS2 could be a useful target for the development of therapeutics of kidney fibrosis.

Proliferation of Bone Marrow-Derived Cells Contributes to the Increase of Fibroblast Population during Kidney Fibrosis Hee-Seong Jang, Jee In Kim, Kwon Moo Park. *Anatomy and BK21 Project, Kyungpook National University School of Medicine, Daegu, Korea.*

Background: An increase in the number of fibroblasts in the kidney interstitium is critical in progression of kidney fibrosis. However, the origin of the increase in the number of fibroblasts remains to be determined.

Methods: Here, we investigated the contribution of bone marrow-derived cells (BMDC) and renal slow-cycling cells, stem- or progenitor-cells, in the kidney fibrosis caused by ureteral obstruction (UO) using eGFP bone marrow-reconstituted chimeric mice.

Results: UO caused dramatic increases in the numbers of interstitial cells and expansion of the interstitium. Most kidney interstitial cells expressed GFP, indicating that these cells are derived from bone marrow. Interstitial BMDCs were to possess fibroblast specific protein-1 and morphological characteristics of fibroblasts. Twenty nine percent of interstitial cells were cells that had proliferated and approximately 89% among them were BMDCs. Proliferation of fibroblasts differentiated from BMDCs significantly occurred in the interstitium of UO-kidney. Treatment with apocynin, an inhibitor of reactive oxygen species production, reduced infiltration of BMDCs into the UO-kidney, leading to reduction of kidney fibrosis. In normal kidney, only a few slow-cycling cells were observed in the interstitium. Even after UO, no change in the number of those cells was observed, indicating that slow-cycling cells in the interstitium may not have, or may have minimal involvement in kidney fibrosis.

Conclusions: BMDCs are a major contributor to kidney fibrosis via infiltration into damaged sites, differentiation to fibroblasts, and subsequent proliferation.

TH-PO997

Nitric Oxide Attenuates Renal Fibrosis via Phosphorylation of Beta-Catenin Hajime Nagasu, Minoru Satoh, Hiroyuki Kadoya, Tamaki Sasaki, Naoki Kashihara. *Nephrology and Hypertension, Kawasaki Medical School, Kurashiki, Okayama, Japan.*

Background: Renal fibrosis is the final common pathway in the development of renal dysfunction. The activation of Wnt/catenin pathway is involved in several renal dysfunction models. Although it is well known that lack of endothelial nitric oxide synthase, an endothelial dysfunction, promotes renal fibrosis, the relationship between the nitric oxide (NO)-protein kinase G (PKG) pathway and the Wnt/catenin pathway in the kidney remains unclear. We hypothesized that PKG activation by NO phosphorylates beta-catenin and downregulates the Wnt/catenin pathway in the development of renal fibrosis.

Methods: We used wild type (WT) and eNOS-deficient (eNOSKO) mice. WT and eNOSKO mice underwent unilateral-ureteral obstruction (UUO). We then used Bay41-2272 as a soluble guanylate cyclase (sGC) stimulator to determine the role of the NO-sGC-PKG pathway on fibrosis process. In some experiment, WT and eNOSKO mice were crossed with BAT-LacZ mice, Wnt reporter mice. Two weeks after surgery, mice were sacrificed to obtain blood and kidney samples.

Results: Increased interstitial renal fibrosis was found in eNOSKO-UUO mice compared with WT-UUO mice. Pro-fibrotic factors (TGF-beta, CTGF, and fibronectin) were also more prevalent in kidney from eNOSKO-UUO compared with WT-UUO mice. The protein expression of beta-catenin and Wnt-1 inducible signaling pathway protein 1 was remarkably increased in eNOSKO-UUO mice. Following crossing of WT and eNOSKO mice with BAT-LacZ mice, increased beta-catenin signaling was detected by beta-galactosidase activity in WT-UUO mice compared with WT-sham mice. Furthermore, this activity was more prevalent in eNOSKO- UUO mice than in WT- UUO mice. Such phenotypic changes in eNOSKO-UUO mice were suppressed by Bay41-2272 treatment.

Conclusions: The present results suggest that the Wnt signaling pathway plays a pivotal role in renal interstitial fibrosis in the UUO model. Furthermore, NO inhibited Wnt signaling via the sGC-PKG pathway. These findings indicate the potential therapeutic utility of NO-sGC-PKG stimulation for the prevention of renal fibrosis.

TH-PO998

Systemic Smad4-siRNA Administration Prevents Interstitial Fibrosis Partially by Inhibiting the Proliferation of Myofibroblasts Derived from Pericytes in Renal Fibrosis Mouse Model Yoshiyuki Morishita, Hiromichi Yoshizawa, Akira Onishi, Minami Watanabe, Eiji Kusano. *Division of Nephrology, Department of Internal Medicine, Jichi Medical University, Shimotsuke-city, Tochigi, Japan.*

Background: The proliferation of myofibroblasts derived from pericytes has been reported to contribute to renal fibrosis (RF). TGFβ_1/Smad4 pathway plays pivotal roles in the development of RF; however, the effects of the regulation of pericytes with systematic siRNA delivery that targets this pathway as a therapeutic approach for RF remain to be determined. In the present study, we investigated the effects of systemic smad4-siRNA administration for treatment of RF and the regulation of pericytes in an RF mouse model.

Methods: RF mouse model was produced by the intraperitoneal injection of folic acid (250 mg/kg) in C57BL/6 mice. Smad4-siRNA (5 nmol) was injected into each mouse via the tail vein three times per week (smad4-siRNA group). RF mice injected with non-targeted siRNA (5 nmol) and no siRNA served as control groups. The mice were sacrificed on the 21st day after folic acid injection. RF was evaluated by histological analysis. The expression levels of smad4, α-smooth muscle actin (αSMA) and pericyte markers such as platelet-derived growth factor receptor-b (PDGFR-b) and NG2 chondroitin sulfate proteoglycan (NG2) in kidney were analyzed by qRT-PCR and/or immunohistochemistry.

Results: The histological analysis showed that RF with increased interstitial myofibroblasts was markedly inhibited in the smad4-siRNA group compared with those in control groups. The qRT-PCR analysis showed that *smad4* expression in kidney was up-regulated and the expression of PDGFR-b, NG2 and αSMA was markedly increased in control groups, and these changes were suppressed in the smad4-siRNA group. The immunohistochemistry showed that double-positive cells with PDGFR-b and αSMA were increased as a part of the increased interstitial myofibroblasts in control groups; however, these cells were markedly fewer in the smad4-siRNA group.

Conclusions: The results of the present study suggested that systemic smad4-siRNA administration prevents RF partially by inhibiting the proliferation of myofibroblasts derived from pericytes *in vivo.*

TH-PO999

Lack of Vasohibin-1 Exacerbates Tubulointerstitial Injuries Partly via Activating Smad3 and Excessive Matrix Production in Renal Fibroblasts Hiroyuki Watatani,[1] Yohei Maeshima,[1] Hiroko Yamasaki,[1] Norikazu Hinamoto,[1] Haruyo Ujike,[1] Hitoshi Sugiyama,[1] Yasufumi Sato,[2] Hirofumi Makino.[1] *[1]Dept. of Medicine and Clinical Science, Okayama University Graduate School of Medicine, Okayama, Japan; [2]Dept. of Vascular Biology Institute of Development, Aging, and Cancer, Tohoku Univ, Sendai, Miyagi, Japan.*

Background: Tubulointerstitial injuries are crucial histological alterations predicting deterioration of renal function in chronic kidney disease. We recently reported the protective role of Vasohibin-1(VASH-1), a negative feedback regulator of angiogenesis as well as a maturation factor of neovessels, in diabetic nephropathy, but its role on tubulointerstitial injuries remains to be elucidated. In the present study, we aimed to evaluate the role of endogenous VASH-1 in regulating tubulointerstitial alterations and assessed its role on fibrogenesis and activation of Smad3 in renal fibroblasts.

Methods: Unilateral ureteral obstruction (UUO) was induced in female VASH1+/- or wild-type (VASH1+/+) littermates (C57/BL6J background). Mice were sacrificed on Day 3 or 7 after inducing UUO and the obstructed kidneys (OBK) were obtained. Cultured normal rat kidney fibroblasts (NRK-49F) were transfected with rat VASH1 siRNA prior to stimulation with TGF-beta1. Western blot, immunohistochemistry and real-time PCR were performed.

Results: Interstitial fibrosis, accumulation of type I and III collagen and F4/80$^+$ monocytes/ macrophages in the OBK were significantly exacerbated in VASH1+/- mice compared with VASH1+/+ mice on Day 7 after inducing UUO. Increase in the renal levels of TGF-beta1, phosphorylated Smad 3, CCL2 mRNA and the number of interstitial fibroblast specific protein (FSP)1$^+$ fibroblasts as well as reduction of IL-10 and IL-10ralpha mRNA in the OBK were significantly aggravated in VASH1+/- mice. Knockdown of VASH1 by siRNA led to the increase of pSmad3 and type I/III collagen mRNA in NRK-49F cells.

Conclusions: Taken together, these results suggest the protective role of endogenous VASH1 on tubulointerstitial alterations via regulating inflammation and fibrosis, and the direct anti-fibrotic effects of VASH1 on renal fibroblasts through modulating TGF-beta signaling.

TH-PO1000

Silencing of TGF-b Signaling in the Endothelium Improves Angiogenesis and Blunts Fibrotic Response to Chronic Renal Injury Sandhya Xavier, Radovan Vasko, Robert Chen, Julien Maizel, Praveen N. Chander, Michael S. Goligorsky. *New York Medical College, Valhalla, NY.*

Background: TGF-b is the prototype member of a family of evolutionarily conserved pleiotropic cytokines. Untargeted interference with TGF-b signaling is less informative than its manipulation in distinct cell types.

Methods: To examine the link between TGF-b signaling, fibrosis and endothelial cell (EC) functions we generated mice with deletion of TGF-b receptor type II (TbRII) in the vascular endothelium by mating mice homozygous for floxed TbRII allele with mice heterozygous for Cre-recombinase under the control of Tie2-promoter to obtain Tie2-Cre;TbRII$^{flox/+}$ which were crossed with TbRII$^{flox/flox}$ mice.

Results: Genotyping offsprings identified heterozygous (Tie2-Cre;TbRII$^{flox/+}$) and wild-type pups (TbRII$^{flox/flox}$ or TbRII$^{flox/+}$) while Tie2-Cre;TbRII$^{flox/flox}$ mutant mice were embryonic lethal. TbRII$^{endo+/-}$ mice showed no abnormal renal function at 6 weeks of age. In contrast, TbRII$^{endo+/-}$ mice had accelerated sprouting in aortic ring matrigel assays. In a folic acid nephropathy (FAN) acute injury model, both WT and Het mice showed elevated serum creatinine and urinary albumin:creatinine ratio, with focal mild-to-moderate tubular dilatation and rare tubular necrosis, more pronounced in Het mice. In contrast, during chronic injury (6 weeks of FAN), interstitial fibrosis was much more prominent in TβRII$^{endo+/+}$ than in TβRII$^{endo+/-}$ mice. Consistent with these results expression of collagen I and III was markedly increased in WT+FAN mice, while expression of these genes in Het+FAN mice was ameliorated. Moreover, analysis of capillary density in kidneys revealed better preserved microvasculature in Het+FAN mice compared to WT+FAN group. Ex vivo cultured vessels obtained from TβRII$^{endo+/-}$ mice in the EC had better angiogenic potential after the challenge with FA in comparison with WT mice.

Conclusions: The data collectively document that partial ablation of TbRII in the endothelium supports increased angiogenesis and reduced fibrosis during chronic, but not in acute, kidney injury. These data indicate a critical role of endothelial TGF-b signaling in defective angiogenic response to injury and development of fibrosis.

Defect in Runx2 Gene Accelerated Unilateral Ureteral Obstruction-Induced Kidney Fibrosis via Increased TGF-β Signal Jee In Kim, Hee-Seong Jang, Kwon Moo Park. *Anatomy and BK21 Project, Kyungpook National University School of Medicine, Daegu, Korea.*

Background: Runt-related transcription factor x2 (Runx2) regulates osteoblast-specific genes inducing osteoblast differentiation and bone formation. Runx2 has known to negatively regulate TGF-β signal, which involves in the progression of fibrosis of the vascular smooth muscle cells. However, the role of Runx2 gene in the kidney fibrosis is unknown.

Methods: Here, we investigated the effect of partial deletion of Runx2 gene on the progress of kidney fibrosis induced by unilateral ureteral obstruction (UUO) using heterozygous (Runx2 wild type/C-terminus of Runx2 truncated) type of mouse (Runx2+/-).

Results: We observed Runx2 gene decreased by UUO in both Runx2 +/+ and Runx2 +/- mice. Runx2+/- mice revealed higher collagen3 deposition, and higher expression of collagen1 and α-smooth muscle actin (α-SMA) in the kidney indicating exacerbated fibrosis compared to Runx2+/+ mouse kidney. Activation of TGF-β was higher in the Runx2+/- kidney than in the Runx2+/+ kidney, suggesting an inhibitory effect of Runx2 on the TGF-β signal in the kidney fibrosis. Furthermore, overexpression of Runx2 gene using adenoviral vector transfection attenuated TGF-β–induced α-SMA expression in the Mardin Darby canine kidney tubular (MDCK) cells indicating inhibited trans-differentiation of kidney tubule cells into myofibroblasts.

Conclusions: Conclusively, defect in Runx2 gene increased UUO-induced TGF-β signaling and kidney fibrosis, providing Runx2 as a noble target for the protection against kidney fibrosis.

CHOP Deficiency Attenuates UUO-Induced Renal Fibrosis by Reduction of Tubular Injury Kai-ti Chang,[3] Cheng-tien Wu,[1] Ching-chin Yang,[1] Chih-Kang Chiang,[1,2,3] Shing-Hwa Liu.[1] *[1]Institute of Toxicology, College of Medicine, National Taiwan University, Taipei, Taiwan; [2]Department of Integrated Diagnostics & Therapeutics, National Taiwan University Hospital, Taipei, Taiwan; [3]Department of Internal Medicine, College of Medicine, National Taiwan University, Taipei, Taiwan.*

Background: CCAAT/enhancer-binding protein (C/EBP) homologous protein (CHOP) is a key component in endoplasmic reticulum (ER) stress-mediated apoptosis and acts as the chemoattraction of mononuclear cells. The goal of the study was to investigate the role of CHOP in unilateral ureteral obstruction (UUO)-induced kidney injury.

Methods: Tubulointerstitial injury and renal fibrosis were assessed in wild-type (WT) and CHOP-deficient mice following unilateral ureteral ligation. Renal injury and fibrosis was assessed by the H&E stain and Masson's trichrome stain. Immunohistochemistry stain was arranged to evaluate the expression of fibronectin and Ly6G. Renal apoptosis was evaluated by TUNEL staining. Tissue malondialdehyde level and NADPH oxidase 4 (NOX4) expression was conducted for evaluating the severity of oxidative stress. In order to clarify the role of CHOP in innate immunity of UUO-induced fibrosis, we arranged bone marrow transplantation (BMT) of chop knockout to wild type mice.

Results: In WT kidney, UUO induced overexpression of CHOP and Bax, a downstream target in the CHOP-mediated ER stress pathway. Renal fibrosis was attenuated in CHOP-knockout mice. Expression levels of α-smooth muscle actin, extracellular matrix, and plasminogen activator inhibitor-1 were reduced, and apoptotic death was attenuated in CHOP-deficient mice. Furthermore, CHOP deficiency reversed UUO-induced apoptosis via JNK and Bcl2 pathway, ameliorated the Ly6G expression and decreased ROS production, which accompanied by NOX4 suppression. This BMT model did not reverse the tubulointerstitial injury and fibrosis induced by UUO fibrosis model.

Conclusions: In conclusion, UUO induces CHOP-mediated ER stress and triggers renal cell death, and CHOP deficiency attenuates this cell death and subsequent renal fibrosis. The results demonstrate an essential role of CHOP in development of renal fibrosis due to UUO damage.

Funding: Government Support - Non-U.S.

Hemizygous Deletion of Connective Tissue Growth Factor (CTGF/CCN2) Does Not Suffice to Prevent Fibrosis of the Severely Injured Kidney Lucas Falke,[1] Amelie Dendooven,[1] Jan Willem Leeuwis,[1] Tri Q. Nguyen,[1] Rob Van Geest,[2] Dionne M. Van der Giezen,[1] Roel Broekhuizen,[1] Karen M. Lyons,[3] Reinout Stoop,[4] Hans Kemperman,[5] Jaap A. Joles,[6] Roel Goldschmeding.[1] *[1]Pathology, UMC, Utrecht, Netherlands; [2]Ophtalmology, AMC, Amsterdam, Netherlands; [3]Molecular & Cell Biology, UCLA, Los Angeles, CA; [4]Metabolic Health Research, TNO, Leiden, Netherlands; [5]Clinical Chemistry & Haematology, UMC, Utrecht, Netherlands; [6]Nephrology & Hypertension, UMC, Utrecht, Netherlands.*

Background: Inhibition of CTGF can prevent development of mild kidney fibrosis, but its influence in severe kidney disease is uncertain. We tested several models of severe kidney disease in mice with hemizygous knockdown for CTGF.

Methods: Both hemizygous CTGF $^{+/-}$ mice and wild type littermates were injected with Streptozotocin or Aristolochic Acid or were unilaterally obstructed at the ureter (UUO). These procedures led to diabetes-induced glomerulosclerosis after 6 months, toxic nephropathy after 25 days and IF/TA after 14days, respectively. The kidneys were analysed by qPCR, Western blot, histochemistry and hydroxyproline measurements.

Results: CTGF$^{+/-}$ mice showed a 50% reduction of both mRNA and protein expression when compared to the appropriate wild type littermate controls ($p<0,05$). This reduction in available CTGF did not lead to a difference in morphology or reduction in fibrosis as measured by scoring PAS/Sirius red stained sections, hydroxyproline content and α-Smooth Muscle Actin expression. Furthermore no reduced inflammatory response as measured by MCP-1 mRNA expression and immunohistological F4-80 positivity was seen.

Conclusions: Unlike previous studies of mild diabetic nephropathy and short-term UUO, scarring of severely and chronically damaged kidneys is not attenuated by a 50% reduction of CTGF. This suggests that CTGF is either redundant in severe and chronic kidney disease, or that it is a limiting factor only at subnormal concentrations requiring further reduction to prevent fibrosis of the severely injured kidney.

Dot1l-Deficiency Enhances High Na+-Induced Renal Fibrosis Possibly by Upregulating V-ATPase Wenzheng Zhang,[1] Hongyu Wu,[1] Lihe Chen,[1] Xi Zhang,[1] Qiaoling Zhou.[2] *[1]UTHSC, Houston, TX; [2]Central South Univ, Changsha, China.*

Background: Our preliminary studies suggest that Dot1l^{AC} mice, which lack histone H3 K79 methyltransferase Dot1l and thus H3 dimethylation (H3m2K79) in Aqp2^{+} cells, significantly increased intercalated cells (IC) in the expense of principal cells (PC) vs. controls (Wu et al, 2011 ASN abstract # 21278), and developed features of chronic kidney disease (CKD) after chronic Na+ loading (Wu et al. 2011 ASN abstract #20636).

Methods: Mice fed a 8% NaCl diet for 32 days were analyzed by metabolic assay, Masson's trichrome staining, RT-qPCR, IB, IF, IHC, ELISA, and ChIP. Kidney biopsies from 8 minimal change disease (MCD) and 9 CKD patients were stained for AQP2 and V-ATPase subunits B1/B2 (B1B2) as PC and IC markers, respectively.

Results: 1) UAR (mg/g), [BUN] (mg/dl) and blood pH were significantly elevated from 20, 37 and 7.2 in Dot1l$^{f/f}$ to 36, 51 and 7.3 in Dot1l^{AC} mice, respectively. The two groups had similar urine pH; 2) Dot1l^{AC} vs. Dot1l$^{f/f}$ mice significantly increased Masson's trichrome staining and mRNA and protein expression of all fibrotic markers (collagen 1a1, aSMA, TGFb, TIMP1, FSP1, PAI1, and Vimentin) and V-ATPase subunits (A, B1 and B2) examined; 3) Dot1l and H3m2K79 bind V-ATPase B2 promoter in ChIP; 4) Dot1a overexpression significantly decreased a V-ATPase B2 promoter-luciferase reporter in IMCD3 cells; 5) Injection of V-ATPase-specific inhibitor Bafilomycin A1 into Dot1l^{AC} mice significantly improved renal function and decreased expression of the fibrotic markers; 6) PC (AQP2+B1B2-) was decreased from 44% in MCD to 17% in CKD, and IC (AQP2-B1B2+) was increased from 22% in MCD to 43% in CKD. Both groups had 15-22% of AQP2+B1B2+ or AQP2-B1B2- cells; 7) In MCD, only 15% of IC cells lost H3m2K79. This number was significantly increased to 50% in CKD.

Conclusions: Loss of Dot1l-mediated H3m2K79 facilitates derivation of IC from Aqp2+ cells in mouse and possibly in human; Dot1l deletion causes Na+-sensitive renal fibrosis that can be partially blocked by V-ATPase inhibitor Bafilomycin A1. Blockade of V-ATPase may offer a potential therapeutic strategy for some CKD.

Thymosin β4 and AcSDKP Ameliorate AngII-Induced Tubulointerstitial Fibrosis in Mice with Deficient TGF-β Activation Sebastian Alexander Potthoff,[1,2] Yiqin Zuo,[2] Haichun Yang,[2] Li-Jun Ma,[2] Agnes B. Fogo.[2] *[1]Department of Internal Medicine / Nephrology, Heinrich-Heine University - Medical Faculty, Düsseldorf, Germany; [2]Department of Pathology, Microbiology and Immunology, Vanderbilt University Medical Center, Nashville, TN.*

Background: β6 knockout (β6-/-) mice lack αvβ6-integrin dependent TGF-β1 activation and are resistant to tubulointerstitial fibrosis after unilateral ureteral obstruction (UUO). However, in these mice, angiotensin II (AngII) in addition to UUO restores tubulointerstitial fibrosis, along with increased PAI-1 and thymosin β4 (Tβ4) expression. Tβ4 is degraded by prolyl oligopeptidase (POP) to the anti-fibrotic AcSDKP. We previously showed that Tβ4 is necessary for AngII induction of PAI-1 in glomerular endothelial cells, exogenous Tβ4 decreases late UUO fibrosis, and that Tβ4 has been linked to TGF-β. We now investigated whether modulation of the Tβ4-AcSDKP-axis impacts fibrosis in β6-/- mice.

Methods: β6-/- mice (C57/Bl6 background) underwent UUO and AngII infusion (40μg/kgBwt/hr), and additional treatment: no further treatment, AcSDKP (800 μg/kgBwt/day), POP-Inhibitor (40mg/kgBwt/day by gavage) + Tβ4 (150μg i.p. every 3rd day), or Tβ4 alone. Mice were sacrificed on day 5 or14 after UUO (n=5-8 each group).

Results: Targeted genes (collagen I, collagen III, RANTES, POP, Tβ4, TIMP, PAI-1, IL1β) analyzed by qPCR showed no difference amongst groups at day 14. However, on day 5, profibrotic and inflammatory markers (collagen III, Tβ4, POP, TIMP, RANTES, IL1β) were decreased in AcSDKP vs. other groups. AcSDKP significantly reduced fibrosis assessed by Sirius red staining (day 5 and 14). Tβ4 alone also significantly decreased fibrosis at day 14. On day 14, Tβ4 expression assessed by immunohistochemistry was similar in mice with or without AcSDKP (AngII 46.1±6.0; AngII+AcSDKP 43.8±5.4; p=NS). Macrophage infiltration was similar in AcSDKP vs. Tβ4+POP inhibitor.

Conclusions: In summary, AcSDKP reduced fibrosis in β6-/- mice injured with UUO and AngII. Tβ4 administration significantly decreased tubulointerstitial fibrosis at late stage. We conclude that the Tβ4-AcSDKP-axis can modulate fibrosis independent of TGF-β activation.

Leukemia Inhibitory Factor Ameliorates Renal Fibrosis via Suppressing Signal Transducers and Activators of Transcription 3 Tyrosine 727 Phosphorylation Chen Yu,[1] Ying Yu,[1] Lunjun Fu,[1] Eugene Chin.[2] *[1]Division of Nephrology, Tongji Hospital, School of Medicine, Tongji University, Shanghai, China; [2]Institute of Health Sciences, Shanghai Institutes for Biological Sciences, Chinese Academy of Sciences& Shanghai Jiao Tong University School of Medicine, Shanghai, China.*

Background: Leukemia inhibitory factor (LIF) is a pleiotropic glycoprotein belonging to the interleukin-6 family and its function in the kidney under pathophysiologic conditions is largely unknown. The aim of this study was to investigate the effects of LIF on renal fibrosis and the underlying mechanism.

Methods: Rat renal fibroblast cells (NRK-49F) and wild type or STAT3$^{-/-}$ mouse embryo fibroblast-MEF cells were used for in vitro study and unilateral ureter obstruction(UUO) rats for in vivo study.

Results: 1) LIF inhibited AngII-induced expressions of collagen 1 (col1), collagen 3 (col3) and fibronectin (FN1), and reversed AngII-induced reduction of matrix metalloproteinase 9, which led to the depredation of collagens, in NRK-49F cells.2) In the wild type STAT3$^{+/+}$MEF cells, LIF inhibited AngII-induced col1, col3 and FN1 protein and mRNA expressions. However, these effects were not seen in STAT3$^{-/-}$ MEF cells.3) Exposure of NRK-49F cells with AngII markedly increased STAT3 Ser727 phosphorylation, which was followed by STAT3 Tyr705 phosphorylation. LIF treatment however, attenuated AngII-induced STAT3 phosphorylation, more pronouncedly on Ser727.4) Mice were divided into 3 groups: a) sham group, b) UUO group and c) LIF + UUO group (LIF, 25mg/kg/day, daily for 6 days, intraperitoneal) (n=4). LIF treated UUO mice had less severity of renal fibrosis. LIF treatment markedly inhibited the expressions of col1, col3 and FN1 in UUO mice.5) In UUO model, STAT3 phosphorylation on both Tyr705 and Ser727 sites increased

markedly as compared with that in the sham group. However, STAT3 Ser727 and Tyr705 phosphorylation intensity was obviously decreased in LIF treatment group.

Conclusions: Our study uncovered LIF treatment attenuated the severity of renal fibrosis. The renoprotective effect of LIF could be mediated by inhibition of STAT3 Ser727 phosphorylation.

Angiopoietin-1 Protects against Renal Fibrosis Marie Jeansson,[1] Susan E. Quaggin.[1,2] *[1]Mount Sinai Hospital, Samuel Lunenfeld Research Institute, Toronto, ON, Canada; [2]St Michaels Hospital, University of Toronto, Toronto, ON, Canada.*

Background: The presence of renal tubulointerstitial fibrosis is predictive of progressive decline in kidney function. It is characterized by an increase in alpha-smooth actin-positive (VSMA+) fibroblasts that produce collagen. Identification of factors that regulate the fibrotic response are excellent candidate targets for treatment of kidney diseases. We previously showed that loss of Angiopoietin-1 (Angpt1) in adult mice predisposes to systemic fibrosis in an ear punch model. Angpt1 is expressed in pericytic lineages and acts through the Tie2 tyrosine-kinase receptor expressed on adjacent endothelium. Here, we test the hypothesis that the Angpt1-Tie2 system is protective in the unilateral ureter obstruction (UUO) model of renal fibrosis and loss of Angpt1 will result in a more aggressive fibrotic response.

Methods: To better understand the origin of fibroblast populations in renal fibrosis, we first performed lineage tagging experiments using Z/EG reporter mice that were bred to 4 independent Cre-driver strains and subjected to UUO. This is an important foundation to understand potential mechanisms. These Cre strains mark the tubular epithelium, renal pericytes, renal endothelium and intrinsic renal fibroblasts, respectively (Pax8-rtTA/tetOCre, Pdgfrb-Cre, Tie2-Cre and Tcf21-Cre). Secondly, we performed UUO on Angpt1 conditional knockout mice.

Results: Kidneys were analyzed and co-stained for the lineage tag (eGFP) and VSMA, 10 days post-UUO. We found that only 6.8% and 8.9 % of VSMA+ cells in the tubulointerstitium stained for eGFP, from pericytes and endothelial lineages respectively, suggesting that only a small proportion of interstitial fibroblasts originate from these linages. Studies to determine the contribution of tubular and intrinsic renal fibroblast populations to VSMA+ cells following UUO are currently underway. In adult Angpt1 conditional knockout mice, pilot studies suggest an increase in tubulointerstitial collagen following UUO, more studies are ongoing.

Conclusions: Together, our results support a model whereby Angpt1-Tie2 signaling protects against fibrosis.

TH-PO1008

Dependence of Renal Fibrosis on a Cell Cycle Regulator Peter M. Price,[1,2] Judit Megyesi,[1] Adel Tarcsafalvi,[1] Rawad Hodeify,[1] Nang San Hti Lar Seng,[1] Shenyang Li,[1] Didier Portilla.[1,2] *[1]UAMS; [2]VA Med Ctr.*

Background: Expression of a cell cycle regulatory protein, $p21^{WAF1/Cip1}$, is associated with fibrotic changes and progression. Although p21 is an inhibitor of cyclin-dependent kinases-1 and -2 (Cdk1, Cdk2), the mechanism of how its expression contributes to fibrosis is unclear. It is also unclear in which cells of the kidney p21 expression is necessary to cause fibrosis.

Methods: Cultured mouse kidney proximal tubule cells were used *in vitro*, either exposed to 0.5 µg/ml aristolochic acid (AA), or transduced with a p21-expression adenovirus. Also, several mouse models of renal fibrosis were used *in vivo*, either mimicking effects of acute kidney injury or effects of loss of renal mass.

Results: Expression of p21 *in vitro* caused significant elevations of TGFβ1 (5.5 to 8.2 times control) and collagen 1A1 (2.3 to 2.8 X) mRNAs, even greater than AA exposure (1.5 to 2.2 X, and 1.5 to 2.1 X, respectively), a known inducer of these fibrotic markers. A mutant p21 that still inhibited Cdk's did not result in high elevations of these fibrosis-associated mRNAs (1.3 to 1.7 X, and 1.2 to 1.5 X, respectively), so that the gene induction by p21 may be a direct effect of p21 on gene transcription. We reported previously that p21 knock-out mice were protected from renal fibrosis using 5/6 nephrectomy or UUO and release and that transgenic mice over-expressing p21 in proximal tubules had more α-smooth muscle actin 14 days after unilateral ureteral obstruction. We now report that p21 knock-out mice in which p21 could be induced specifically in proximal tubules developed more fibrotic markers than even wild-type mice after either 28 or 42 days following unilateral ischemia or 14 days after UUO that was released after 4 days, showing that proximal tubular cells are a significant source of the signal for induction of fibrosis.

Conclusions: Induction of p21 alone is a causative mechanism for development of fibrotic markers *in vitro* and kidney fibrosis *in vivo*. Whether expression of fibrogenic p21 is required exclusively in proximal tubules or in other kidney cells for development of chronic renal failure will be addressed by similar cell-specific p21 induction in a p21 knock-out background.

TH-PO1009

Angiotensin II Induces Renal Fibrosis through Upregulation of Cyp4a14 Expression Yunfeng Zhou, Youfei Guan. *Department of Physiology and Pathophysiology, Peking University Health Science Center, Beijing, China.*

Background: Angiotensin II (Ang II) plays an important role in the pathogenesis of hypertension and its associated cardiovascular and renal injury.

Methods: To elucidate the molecular mechanism by which AngII induces renal damage, we measured expression profile of genes involved in arachidonic acid metabolism and its metabolites' function in the kidneys of mice receiving chronic AngII infusion for 14 days.

Results: Cyp4a14 was found to be significantly induced by AngII, which was associated with a marked increase in systolic blood pressure and proteinuria. Real-time PCR, Western blot and immunohistochemistry assays demonstrated that cyp4a14 expression was predominantly upregulated in the proximal tubules of AngII-infused mice. 24-hour urinary excretion of the major cyp4a14 metabolite, 20-HETE, was also significantly increased in the Ang II-treated mice. To determine whether cyp4a14 mediates the effects of AngII, cyp4a14-/- mice were utilized. Compared to wild-type (WT) mice, cyp4a14-/- mice exhibited significantly lower levels of blood pressure and proteinuria following AngII infusion. Histologically, AngII infusion resulted in renal glomerulosclerosis and tubulointerstitial fibrosis in WT mice, which was significantly reduced in $cyp4a14^{-/-}$ mice. Consistently, expression levels of renal collagen I was significantly lower in $cyp4a14^{-/-}$ mice than in WT mice following Ang II treatment. Furthermore, we used a rat proximal tubule cell line (RPTC) to examine the effect of Ang II on cyp4a14 expression and 20-HETE production. Treatment of RPTC cells with Ang II significantly induced cyp4a14 expression, which was associated with an increased level of supernatant 20-HETE. 20-HETE treatment resulted in a marked increase in transforming growth factor β1 and collagen I expression.

Conclusions: Collectively, these findings suggest that Ang II-mediated renal fibrosis may result from increased cyp4a14 expression and 20-HETE levels. Cyp4a14 could be a useful target for the treatment of Ang II-elicited renal damage.

Pigment Epithelium-Derived Factor Ameliorates Renal Fibrosis Xuemin He, Rui Cheng, Jian-xing Ma. *Department of Physiology, University of Oklahoma Health Sciences Center, Oklahoma City, OK.*

Background: Pigment epithelium-derived factor (PEDF) is a multifunctional protein in the serine proteinase inhibitor family and has been shown to be decreased in the kidney of diabetic animal models, and decreased PEDF levels are believed to contribute to progression of diabetic nephropathy (DN). As DN is characterized by excessive deposition of extracellular matrix in the kidney which leads to fibrosis, the purpose of this study is to establish the anti-fibrosis activity of PEDF in the kidney.

Methods: Human renal proximal tubular cell line (HKC8) was exposed to 4 ng/ml TGF-β1 and treated with different concentrations of purified recombinant human PEDF (rhPEDF) (40, 80, 160 and 320 nM). Loss of tubular epithelial phenotypes was evaluated by detecting E-cadherin, and fibrogenic event was determined by measuring α-smooth muscle actin (α-SMA), fibroblast specific protein 1 (FSP1), and fibronectin (FN) using Western blot analysis. In 8-week-old $PEDF^{-/-}$ mice and aged-matched wild type (WT) mice, sham surgery or unilateral ureteral obstruction (UUO) was operated on the left kidney. Seven days after the surgery, the left kidneys were collected; E-cadherin, α-SMA, FSP1, FN and collagens were determined by Western blot analysis and immunohistochemistry.

Results: In HKC8, TGF-β1 treatment increased the expression of α-SMA and FN dramatically, which was suppressed by rhPEDF in a concentration-dependent manner; in contrast, TGF-β1 decreased E-cadherin levels, while rhPEDF prevented the TGF-β1-induced E-cadherin decrease. UUO induced TGF-β1 and FSP1 expression in the kidneys of WT and $PEDF^{-/-}$ mice, while $PEDF^{-/-}$ UUO mice showed more prominent increase in TGF-β1 levels, compared to that in WT UUO mice. As shown in immunohistochemistry, $PEDF^{-/-}$ UUO mice exhibited more intense staining of collagen IV compared to WT UUO mice.

Conclusions: PEDF exhibits a potent anti-fibrogenic function on renal proximal tubular cells, and knockout of PEDF in the kidney exacerbates renal fibrosis.

TH-PO1011

Kidney Fibrosis: Evidence for a New Treatment Based on Selective Blockade of SnoN Degradation Yuanyuan Shi,[1,2] Yanlin Wang,[1] William E. Mitch,[1] Zhaoyong Hu.[1] *[1]Internal Medicine, Nephrology Division, Baylor College of Medicine, Huston, TX; [2]Renal Section, The Second Hospital of Shanxi Medical University, Taiyuan, Shanxi, China.*

Background: Several mechanisms causing renal fibrosis have been uncovered. TGFb1 is a major mediator because it stimulates fibrosis by upregulating collagen, fibronectin, smooth muscle actin (SMAa) and other proteins. But, there are few available therapies that will block or suppress TGFb1 and hence, fibrosis. In animal models of fibrosis (e.g., pulmonary fibrosis), thalidomide exerts anti-inflammatory and anti-fibrotic properties by poorly defined mechanisms.

Methods: in mice with unilateral ureteral obstruction (UUO) treated with or without 200 mg/kg thalidomide, we evaluated the degree of kidney fibrosis and inflammation plus TGFb1 expression. We investigated the TGFb1 repressor, SnoN, and how thalidomide might influence SnoN levels to regulate TGFb1 in cultured kidney tubular cells and fibroblast.

Results: UUO stimulated the expression of collagen, fibronectin and SMAa. Thalidomide blocked the induction of collagen I (>50%), fibronectin (>60%) and SMAa (>40%) and suppressed tubulointerstitial fibrosis in kidneys of UUO mice. Thalidomide virtually eliminated the mRNA expression of TGFb1 plus the phosphorylation of Smad3 as

well as UUO-induced TNFa, IL1a, IL6, and bFGF. Thus, thalidomide blocking TGFb1 could be the mechanism induced by thalidomide which suppresses fibrosis mediators. In cultured kidney fibroblasts and tubular cells, we determined how thalidomide suppresses TGFb1 by studying SnoN, a transcription repressor. Thalidomide can selectively inhibit ubiquitin (Ub) conjugation by binding to CBRN-DDP1, an Ub E3 ligase. Indeed, thalidomide decreased Ub conjuagtion to SnoN in cultured fibroblast or mice with UUO. This led to an increase in SnoN to suppression of its degradation in the Ub-proteasome system (UPS). The result was a decrease in TGFb1 and hence, reduced expression of fibrotic proteins.

Conclusions: Thalidomide initiates its anti-fibrotic effects by selectively inhibiting an Ub E3 ligase which regulates the degradation of SnoN. It could become a treatment strategy for kidney fibrosis since this drug is already used to treat leprosy.

TH-PO1012

Rheb/mTORC1 Signaling Activation Promotes Kidney Fibroblast Activation and Interstitial Fibrosis Lei Jiang,[1] Junwei Yang,[2] Chunsun Dai.[3] *[1]Center for Kidney Disease, 2nd Affiliated Hospital, Nanjing Medical University, Nanjing, Jiangsu, China; [2]Center for Kidney Disease, 2nd Affiliated Hospital, Nanjing Medical University, Nanjing, Jiangsu; [3]Center for Kidney Disease, 2nd Affiliated Hospital, Nanjing Medical University, Nanjing, Jiangsu, China.*

Background: Ras homolog enriched in brain (*Rheb*), a small GTPase that regulates cell growth, differentiation and survival through up-regulating mTORC1 signaling, has been studied in many cell types. However, the role and mechanisms of Rheb/mTORC1 signaling in kidney fibroblast activation and kidney fibrosis remain largely unknown.

Methods: pCAG-Rheb transgenic mice and and sex matched control littermates were used in this study. Rapamycin was given intraperitoneally at a dose of 2.5mg/kg/day for 4 weeks on pCAG-Rheb transgenic mice .pCAG-Rheb mice and control littermates were performed with UUO model.NRK-49F cells treated with TGF-β1 were used for in vitro study.

Results: In this study, we found that Rheb/mTORC1 signaling was activated in the kidney interstitial cells from the fibrotic kidneys. Rheb/mTORC1 signaling was also sharply activated in NRK-49F cells treated with TGFb1. Blocking Rheb/mTORC1 signaling with rapamycin or Rheb siRNA abolished TGFb1-induced fibroblast activation. Ectopic expression of Rheb activated kidney fibroblast. In the Rheb transgenic mice, mTORC1 signaling in both kidney tubular and interstitial cells was activated and progressive kidney interstitial fibrosis was detected. Rapamycin remarkably inhibited mTORC1 signaling activation and fibrosis in the transgenic kidneys. Indeed, mice with fibroblast specific deletion of Tsc1 exhibited mTORC1 signaling activation in kidney interstitial cells and kidney fibrosis.

Conclusions: Together, these results suggest that Rheb/mTORC1 signaling plays an extremely important role for promoting kidney fibroblast activation and interstitial fibrosis, which may act as a potential therapeutic target for kidney fibrosis.

TH-PO1013

Assessment of Anti-Fibrotic Effects of Klotho with a High-Throughput Cell Migration Assay Using Scratch Wound Healing Ken Tsuchiya, Hidekazu Sugiura, Takumi Yoshida, Shunji Shiohira, Kosaku Nitta. *Department of Medicine IV, Tokyo Women's Medical University, Shinjuku-ku, Tokyo, Japan.*

Background: The renal expression of the Klotho gene is markedly suppressed in chronic kidney disease (CKD). Acceleration of renal fibrosis is a basic pathophysiology for progression of CKD, and TGF-β1 plays a key role in that process. Previously, we showed that he renal interstitial fibrosis was severer in the kl/+ mice than those in the wild-type mice by UUO treatment. In this study, we clarify the direct relationship between Klotho and TGF-β1 using recombinant protein, siRNA and scratch assay.

Methods: The expression levels of fibrotic marker, such as α-SMA, fibronectin and TGF-β1 was immunohistochemically stained and TGF-β1 levels were assayed. Internal expression of Klotho was modified by siRNA transfection. The growth and migration of cultured cells was quantified by using CL-Quant software to analyze time-lapse images in a Nikon BioStation CT.

Results: TGF-β1 reduced Klotho expression in renal cultured epithelial cells (IMCD and HK2). In addition, in cultured renal fibroblast cells (NRK49F) in which internal Klotho expression was negligible, expression levels of α-SMA and PAI1 were significantly suppressed by addition of recombinant Klotho protein to the medium. These effects were also suppressed by a TGF-β1 receptor inhibitor (ALK5 inhibitor) suggesting that Klotho inhibited TGF-β1 activity. Migration of NRK49F cells was accelerated and expression of fibrotic markers was up-regulated by addition of TGF-β1, in contrast, Klotho addition suppressed the effect. SiRNA reduced the expression of Klotho in epithelial cells, however, Klotho knockdown tended to accelerate cell migration but was not significant.

Conclusions: Taken together, it is likely that there is a cross-link between Klotho and TGF-β1 expression in the progression of renal fibrotic changes. Klotho itself plays a significant role in the fibrotic mechanism was not clear in the present study. Thus, there must be a vicious cycle that suppresses Klotho expression and up-regulates TGF-β1 that aggravates the fibrotic process in damaged kidneys, such as in CKD.

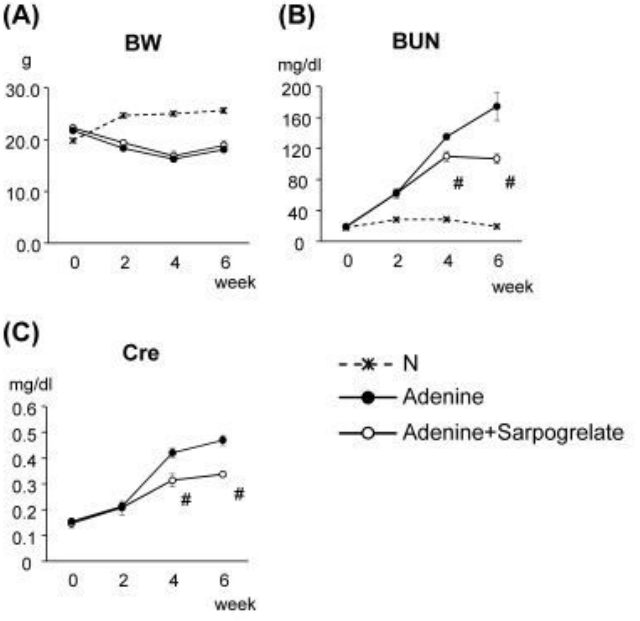
TH-PO1014

A 5-HT Receptor Antagonist Sarpogrelate Ameliorates Renal Tubulointerstitial Fibrosis via Suppressing PAI-1 Yoshifumi Hamasaki, Kent Doi, Masaomi Nangaku, Eisei Noiri. *Nephrology and Endocrinology, University of Tokyo, Tokyo, Japan.*

Background: Chronic hypoxia and subsequent fibrosis in renal tubulointerstitium have been recognized as final common pathway of chronic kidney disease (CKD) progression to end-stage renal disease. Sarpogrelate, a clinically available selective antagonist of 5-hydroxytryptamine (5-HT) 2A receptor, blocks platelet aggregation and causes vasodilatation. We hypothesized that sarpogrelate will reduce renal fibrosis by improving microcirculation in the renal interstitium.

Methods: A mouse renal fibrosis model induced by feeding a 0.2% adenine-containing diet for 6 weeks was used for evaluating whether sarpogrelate would reduce renal interstitial injury. In vitro analysis with mProx cells derived from proximal tubular epithelial cells was conducted to clarify the role of plasminogen activator inhibitor-1 (PAI-1) in the mechanism of action of sapogrelate.

Results: C57BL/6 mice fed a 0.2% adenine-containing diet for 6 weeks developed severe tubulointerstitial fibrosis with kidney dysfunction and sapogrelate treatment (30 mg/kg/day) for 4 weeks significantly improved these changes.



We found that sarpogrelate suppressed fibrinogen deposition, infiltration of F4/80-positive inflammatory cells, and the expression of PAI-1 in the kidney. Intravital microscope revealed that sarpogrelate significantly increased peritubular blood flow in the fibrotic area. In vitro experiments using mProx cells demonstrated that mProx cells incubated with TGF-β1 and 5-HT showed increased expression of PAI-1; sarpogrelate significantly reduced it.

Conclusions: Sarpogrelate contributes to prevent tubulointerstitial fibrosis by multiple pathways; suppressing infiltration of inflammatory cells and fibrin deposition, maintaining peritubular capillary blood flow, and reducing expression of PAI-1.

TH-PO1015

Glucosamine Hydrochloride Protects against Unilateral Ureteral Obstruction-Induced Renal Fibrosis by Attenuating TGF-β Signaling Dong Ho Yang,[1] So-young Lee,[1] Yoon Hee Lee,[2] Hoon Jung.[3] *[1]Internal Medicine, Bungdang CHA Medical Center, Seongnam, Gyeonggi-do, Republic of Korea; [2]Pathology, Gangnam CHA Medical Center, Seoul, Republic of Korea; [3]Internal Medicine, Seoul Bukbu Geriatric Hospital, Seoul, Republic of Korea.*

Background: Increased TGF-β signaling is recognized as a key mediator of renal fibrosis, and considerable efforts have focused on targeting TGF-β signaling for antifibrotic therapy. The extracellular domain of the type II TGF-β receptor (TβRII) is modified by N-linked glycoslyation. Recently, we demonstrated that N-linked glycosylation of TβRII was required for its trafficking to the cell surface and increased ligand binding affinity (in press). Glucosamine hydrochloride (GS-HCl) is recognized to inhibit the translational N-glycosylation of specific proteins, including glucose transporter 1, apolipoprotein B-100, ICAM-1, EGFR and COX-2. Inhibition of N-glycosylation decreases secretion, increases protein turnover and/or reduces phosphorylation of affected proteins. Here, we demonstrate that GS-HCl inhibits TGF-β signaling by modifying the N-glycosylation status of TβRII.

Methods: Human proximal tubular epithelial cells (HKC-8) and human kidney proximal tubular cells (HK-2) were used for in vitro experiments. In addition, primary renal epithelial cells were isolated from mouse kidney. The mouse unilateral uretheral obstruction (UUO) model was used for in vivo experiments.

Results: GS-HCl inhibits N-glycosylation of TβRII; this results in inefficient trafficking of TβRII to the cell surface, thus preventing binding to its ligand TGF-β1. In murine UUO kidney cells and renal epithelial cells, GS-HCl exerts an antifibrotic effect by suppressing renal expression of α-smooth muscle actin, collagen I, and fibronectin. Ultimately, suppression of these proteins inhibits renal fibrosis. In addition, UUO- or TGF-β1-induced Smad3 phosphorylation, a downstream transcriptional mediator of TGF-β1 signaling, is significantly reduced in the presence of GS-HCl.

Conclusions: In conclusion, our study demonstrates that GS-HCl may be a promising therapeutic target against TGF-β1-induced renal fibrosis.

TH-PO1016

Peroxisome Proliferator-Activated Receptor Dual Agonist, AZ242, Ameliorates Renal Injury in Unilateral Ureteral Obstruction Model

Hyunwook Kim,[2] Ji Eun Lee,[2] Mihwa Lee,[1] Jung Eun Kim,[1] Jin Joo Cha,[1] Young Sun Kang,[1] Kum Hyun Han,[3] Sang Youb Han,[3] Young Youl Hyun,[4] Jee Young Han,[5] Nam Ho Kim,[6] Dae R. Cha.[1] *[1]Korea University Ansan Hospital; [2]Wonkwang University; [3]Inje University; [4]Kangbuk Samsung Hospital; [5]Inha University; [6]Chonnam University, Republic of Korea.*

Background: Tubulointerstitial injuries are crucial histological alterations that predict the deterioration of renal function in chronic kidney disease. In the present study, we examined the therapeutic efficacies of AZ242, a novel peroxisome proliferator-activated receptor(PPAR) α/γ agonist on tubulointerstitial alterations induced by unilateral ureteral obstruction(UUO).

Methods: Male C57/BL6J mice were divided into three groups: sham-operated, vehicle-treated UUO, and AZ242-treated UUO group. After inducing UUO, AZ242 (1uM/kg/day) and vehicle were treated for 14 days. Animals were sacrificed and blood, urine from bladder and obstructed pelvis, and kidney tissue samples were collected for analyses.

Results: Vehicle-treated UUO group showed marked proteinuria and high blood pressure compared with sham-operated group. As compared with untreated mice, AZ242 treatment showed a little effect on blood pressure, but remarkably attenuated proteinuria in obstructed kidneys. Treatment with AZ242 significantly suppressed the increase of the renal mRNA expressions of Type I collagen, CTGF, MCP-1, TGF-β, PAI-1 in obstructed kidneys. In the histologic study, AZ242 treatment prominently ameliorated renal inflammation and tubulointerstitial fibrosis induced by UUO. These were further confirmed by Sirius red staining and immunohistochemistry with a marked inhibition of tubulointerstitial accumulation of α-SMA+ fibroblasts, F4/80+ macrophage, Type I and Type IV collagen in AZ242-treated mice. Treatment with AZ242 significantly decreased TGFβ1 and p-Smad3 protein expression in UUO kidneys. Additionally, urinary isoprostanes were significantly higher in UUO group and AZ242 treatment decreased urine isoprostane levels.

Conclusions: Taken together, AZ242 treatment attenuated proteinuria and tubulointerstitial fibrosis in UUO mice through reduction of TGFβ /Smad3 signaling and renal oxidative stress.

TH-PO1017

Ecto-5'-Nucleotidase (CD73) Promotes the Development of Renal Fibrosis

Isabel Anna Carota,[1] Barbara Reich,[2] Katharina Mederle,[1] Matthias Mack,[2] Klaus Höcherl,[1] Hayo Castrop.[1] *[1]Institute of Physiology, University of Regensburg; [2]Department of Internal Medicine II, University of Regensburg, Germany.*

Background: Renal fibrosis develops upon renal injury and is associated with progressive deterioration of kidney function. Ecto-5'-nucleotidase (CD73) catalyzes the extracellular formation of adenosine from AMP, and CD73 has been shown to be involved in the progression of fibrosis in the lung and liver. In this study we addressed the role of CD73 in renal fibrosis using CD73-/- mice.

Methods: To induce renal fibrosis, mice were subjected to unilateral ureter obstruction (UUO, 7d).

Results: UUO induced renal fibrosis in both genotypes, and this was accompanied by an increase in CD73 protein in CD73+/+ kidneys (196±35% of the contralateral kidney; n=6; p=.026). Compared to UUO kidneys from CD73+/+, UUO kidneys from CD73-/- showed lower expression levels of several fibrotic markers like alpha-SMA, fibronectin, TGF-beta, Ki67, MMP-2, MMP-13, MMP-14, monocytes chemotactic protein-1, and of the collagens Col 1a1, Col 1a2, Col 3a1 and Col 4a3, as determined by qRT-PCR, western blotting (p<.01 for CD73+/+ vs. CD73-/-), immunohistochemistry, and Sirius Red/Fast Green staining (p=.008). Extracellular matrix-generating cells were quantified by FACS analysis. In fibrotic kidneys from CD73-/- mice, the number of e.g. fibrocytes (collagen-producing monocytes) was decreased by 57±6% compared to fibrotic CD73+/+ kidneys (n=8; p=.004). The differentiation of CD11b+ monocytes into collagen-producing fibrocytes could be stimulated in vitro by co-culture with CD4+ T-lymphocytes. However, monocytes isolated from CD73-/- showed a reduced differentiation into fibrocytes after co-incubation with CD4+ T-lymphocytes, when compared to CD73+/+ monocytes (-21±1%; p=.01). The differentiation of CD11b+/CD73+/+ monocytes in vitro was similar in the presence of CD4+/CD73+/+ and CD4+/CD73-/- T-lymphocytes, suggesting a critical role of CD73 on monocytes rather than on T-lymphocytes.

Conclusions: In summary, CD73 is induced in the UUO model, and CD73 enhances fibrotic cell recruitment and the development of renal fibrosis. Consequently, CD73 may constitute a therapeutic target for the management of renal fibrosis.

Liver X Receptors α and β Differentially Regulate Fibroblast Activity and Renal Fibrosis

Eva Kiss,[1,2] Shijun Wang,[1] Mahnaz Bonrouhi,[1] Sophie Domhan,[3] Amir Abdollahi,[3] Knut R. Steffensen,[4] Hermann-Josef Groene.[1] *[1]Cellular and Molecular Pathology, German Cancer Research Center, Heidelberg, Germany; [2]Anatomy and Cell Biology, University of Heidelberg, Germany; [3]National Center for Tumor Diseases, University of Heidelberg, Germany; [4]Biosciences and Nutrition, Karolinska Institute, Sweden.*

Background: The nuclear receptors LXRα and β are transcriptional regulators of lipid metabolism and innate immunity. Specific natural LXR ligands are generated in inflammatory micromilieu.

Methods: The potential role of LXR signaling in development of renal chronic fibrosing inflammation was investigated.

Results: Early (day 1), subchronic and chronic (day 7 and 21) tubulointerstitial damage in unilateral ureteral obstruction was accentuated in both LXRα and β deficient (-/-) mice in comparison to WT. The number of infiltrating mononuclear cells (F4/80,CD3) remained unchanged. Corresponding to the high expression of LXRβ in tubular epithelial cells, LXRβ-/- kidneys showed a more prominent tubulointerstitial damage and an increase of interstitial myofibroblasts and collagen I/III (αSMA:WT:27.4±1,9; LXRα:35.2±1.5; LXRβ:47.5±1.9 cells/HPF; p<0.001 and p<0.05 LXRβ vs WT and LXRα, respectively, day 21). However, the administration of the LXR specific agonist GW3965 (GW) significantly reduced tubulointerstitial inflammation/fibrosis not only in WT but also in LXRα and β-/- mice, indicating the involvement of both isoforms in renal fibrogenesis (Collagen I/III:p<0.01 with vs without GW in WT, LXRα and LXRβ-/- kidneys, day 21). *In vitro*, without and with bFGF stimulation or when co-cultured with macrophages both LXRα and β-/- dermal fibroblasts showed higher proliferation than WT (25-30%); proliferation was reduced by GW. In addition, in co-culture, pretreatment with GW of macrophages or/and fibroblasts reduced their proinflammatory/profibrotic activity as evidenced by significantly reduced expression of collagen I, MCP-1 and MIP-1β.

Conclusions: The findings suggest that LXR signaling plays an important role in the regulation of fibroblast activation, production of extracellular matrix and development of renal interstitial fibrosis. LXR activation may have therapeutic potential for fibrotic kidney diseases.

Inhibition of TGF-β1-Receptor Post-Translational Core Fucosylation Attenuates Rat Renal Interstitial Fibrosis

Hong Li Lin, Shen Nan, Yan Ling Sun. *The First Affiliated Hospital of Dalian Medical University.*

Background: The vigorous profibrotic cytokine transforming growth factor-beta1(TGF-β1) causes renal interstitial fibrosis (RIF). TGF-β1 can bind to fourteen known receptors, however, it is not clear which of these receptors are responsible for RIF. Studies have indicated that reducing the expression of TGF-β1 can protect against kidney injury; however, this also inhibits the other vital functions of TGF-β1, including cell growth and immune responses. Therefore, we chose the specific "profibrotic receptors" of TGF-β1, TGF-βRII and TGF-βRI (ALK5) as targets for interference. Our previous study showed that core fucosylation was essential for the proper function of both TGF-βRII and ALK5 in HK-2 cells in vitro. However, to date, the blockade of protein function in vivo by inhibiting core fucosylation has not yet been reported in kidney disease.

Methods: Rats in UUO group underwent left unilateral ureteral ligation. We designed and synthesized fluorescently labeled FUT8shRNA adenovirus(Ad-FUT8shRNA) and injected intravenously into the rat tail vein, as 1,6-αFucosyltransferase(FUT8) is known to catalyze core fucosylation. In all experiments, control rats were injected with Ad-GFP.

Results: The expression of activin receptor-like kinase-5 (ALK-5), ALK-7 and transforming growth factor-beta receptor II (TGF-βRII) mRNA significantly increased, and ALK-6 mRNA significantly decreased, in the kidneys of rats with UUO. Core fucosylation plays a crucial role in profibrotic function of the TGF-β1 receptors, and blocking it with FUT8 small hairpin RNA successfully abolished the activation of TGF-β/Smad signaling and attenuated UUO-induced rat renal interstitial fibrosis.

Conclusions: This study demonstrates that inhibition of TGF-βRII and ALK5 core fucosylation successfully suppressed the profibrotic function of these key TGF-β1 receptors, inhibited activation of TGF-β/Smad signaling and prevented rat renal interstitial fibrosis in the UUO kidney. Our results suggest the posttranslational modification of key proteins by core fucosylation could provide an attractive novel approach for treatment of renal fibrotic disease by preventing matrix deposition and tubular EMT.

Nuclear Factor Erythroid Protein 2 (NF-E2) Is a Negative Regulator of Renal Tubular Fibrosis

Madhavi J. Rane,[1] Wenpeng Cui,[2] Lu Cai,[2] Michelle T. Barati,[1] Songyan Wang.[1] *[1]Medicine, University of Louisville, Louisville, KY; [2]Pediatrics, University of Louisville, Louisville, KY.*

Background: TGF-b induced Hsp27 mediates renal fibrosis yet the exact mechanisms are unknown. Hsp27 promotes proteasomal protein degradation and NF-E2/Hsp27 associate in human renal proximal tubular cells (HK-11). We hypothesized TGF-b induced Hsp27 regulates renal fibrosis by regulating NF-E2 expression.

Methods: HK-11 cells were cultured in 10 ng/ml TGF-b or MG132 (proteasome inhibitor) for 24 hrs and immunoblotted with various protein markers. NF-E2 over-expression on TGF-b stimulated CTGF and fibronectin expression was examined. Association of Hsp27/NF-E2 was examined in control and TGF-b treated cell lysates by performing anti-Hsp27 and anti-NF-E2 immunoprecipitation and immunoblotting techiques. NF-E2 expression was examined by immunohistochemistry (IHC) and immunoblot analysis of tissue sections and tissue homogenates from control FVB, and 1,3, and 6 months male STZ-diabetic mice. NF-E2 expression was examined by IHC in control FVB, 6 months OVE26 mice and 3 months OVE26 mice treated with 10 micro g/Kg MG132 for additional 3 months.

Results: TGF-b markedly decreased NF-E2 expression concurrent with increased CTGF and fibronectin expression in HK-11 cells compared to control. Akt phosphorylation was decreased, while pp38 MAPK and pHsp27 levels were markedly increased by TGF-b treatment of HK-1 cells. NF-E2 over-expression inhibited TGF-b induced CTGF and fibronectin expression in HK-11 cells. Additionally, MG132 treatment prevented TGF-b induced NF-E2 degradation and blocked CTGF and fibronectin expression. TGF-b treatment of HK-11 cells enhanced Hsp27/NF-E2 association compared to control. Furthermore, NF-E2 expression was markedly decreased in 6 month STZ mice as documented by western blotting. IHC analysis documented luminal NF-E2 staining in control FVB mice while a punctate pattern was detected in STZ and OVE26 diabetic mice. MG132 treated mice demonstrated a more luminal NF-E2 staining similar to controls.

Conclusions: These results suggest that TGF-b treatment promotes CTGF and fibronectin expression by promoting NF-E2 degradation at the proteasome possibly by binding to Hsp27.

Functional Role of Serine-204 in the Linker Region of Smad3

James A. Browne, Tomoko Hayashida, H. William Schnaper. *Division of Kidney Diseases, Department of Pediatrics, Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: TGF-β/Smad3-mediated fibrogenesis is regulated through complex interactions among signaling pathways. The Smad3 linker region (LR) contains several phosphoacceptor sites (Thr179, Ser204, Ser208 and Ser213) differentially targeted by multiple kinases. We have shown that ERK MAP kinase is required for optimal collagen-I reporter activity; and that an intact Ser204 (S204) is required for collagen-I promoter activation by Smad3. MEK/ERK inhibition (PD98059) blocks both TGF-β-induced S204 phosphorylation (ASN 2011) and collagen induction. Here, we evaluated potential molecular roles for S204.

Methods: Immunoprecipitation was performed to identify Smad3-binding proteins and test if the S204 phospho-site is important for such binding. Smad3-null mouse embryonic fibroblasts were reconstituted with HA-tagged wild-type (WT) or S204A mutant Smad3 constructs. After treatment with vehicle or TGF-β (2ng/ml, 1h) cell lysates were subjected to anti-HA immunoprecipitation for Smad3-binding partners.

Results: Overexpressed WT and S204A Smad3 mutants interacted with ERK, AKT, STAT1 and p300. Surprisingly, all interactions were enhanced by the S204A mutation. The interactions of both Stat1 and p300 with Smad3 (WT and the S204A site mutant) were enhanced by TGF-β. In contrast, TGF-β supressed the binding of AKT with either Smad3 construct.

Conclusions: ERK-Smad3 interaction supports our hypothesis that ERK targets the Smad3LR. The ability of the S204A mutant to bind more ERK than WT-Smad3 suggests that only a transient ERK-Smad3 interaction is needed to support the collagen response, and raises the notion that S204 phosphorylation may be needed to disrupt the interaction to allow the collagen response. AKT is known to counteract TGF-β signaling by directly binding cytoplasmic Smad3. The S204A mutation intensifies this interaction, consistent with our model in which S204 phosphorylation enhances the collagen response to TGF-β. The role of STAT1 as an enhancer or inhibitor of the response remains to be determined. Together, these data suggest potential mechanisms by which S204 phosphorylation of Smad3 may modulate the fibrogenic response to TGF-β.

Wnt4 Is Expressed in Proliferating Myofibroblasts during Kidney Fibrosis

Derek Paul DiRocco,[1,3] Akio Kobayashi,[1,3,4] Andrew P. McMahon,[2,4] Benjamin D. Humphreys.[1,3,4] *[1]Renal Division, Brigham and Women's Hospital, Boston, MA; [2]Stem Cell and Regenerative Biology, Harvard University, Cambridge, MA; [3]Harvard Medical School, Boston, MA; [4]Harvard Stem Cell Institute, Cambridge, MA.*

Background: A critical role for Wnt4 during nephrogenesis is well characterized, but the expression pattern and function for Wnt4 in the adult kidney are poorly defined. Since kidney injury recapitulates some aspects of renal development, we hypothesized that Wnt4 would be induced in dedifferentiated epithelia after injury as part of an epithelial to mesenchymal transition.

Methods: To test this hypothesis, we used Wnt4 reporter and conditional knockout models to define the cellular expression and fate of Wnt4+ cells in kidney injury. We employed the unilateral ischemia reperfusion injury model and the unilateral ureteral obstruction injury model. Wnt4 expression was also determined using immunologic detection and qPCR.

Results: Using a Wnt4-GFP knockin, we report that Wnt4 expression is restricted to papillary collecting duct principal cells and urothelium in normal kidney. In two models of chronic kidney injury Wnt4 is upregulated in medullary myofibroblasts, but not cortical myofibroblasts or epithelium. Exogenous Wnt4 drove myofibroblast differentiation of a pericyte cell line, suggesting that Wnt4 may regulate pericyte to myofibroblast transition. To test this possibility we performed genetic fate mapping of Wnt4+ cells using a Wnt4-CreERt2 knockin and also knocked Wnt4 out of FoxD1+ stromal cells using a Wnt4 conditional allele. Fate mapping showed that Wnt4+ medullary myofibroblasts proliferate during fibrosis but do not migrate out of the medulla. We successfully deleted Wnt4 in interstitial cells but this did not reduce myofibroblast proliferation, cell number, or fibrotic gene expression.

Conclusions: Wnt4 is significantly increased in medullary myofibroblasts during fibrosis. These myofibroblasts do not migrate into the cortex and are distinct from cortical myofibroblasts based on Wnt4 expression. Although kidney injury/repair shares certain signaling pathways with nephrogenesis it is not simply a recapitulation of development and must be understood independently.

VEGF Overexpression Inhibit TGF-β1 Induced EMT and miR192 Expression of HKC Cells through PI3K/Akt Signal Pathway

Hong Jun Ping, Xuemei Li, Mingxi Li, Falei Zheng. *Division of Nephrology, Peking Union Medical College Hospital, Beijing, China.*

Background: TGF-β1-induced epithelial-mesenchymal transition (EMT) is one of the important processes of renal fibrosis.This study is undertaken to examine the effect of VEGF overexpression on miR-192 in TGF-β1-induced EMT of HKC cells.

Methods: Firstly, human kidney cell lines with stable over-expression of VEGF(HKC-SOEV cells)were successfully established. The normal HKC cells and HKC-SOEV cells were treated with TGFβ1 (5μg/l) or/and LY294002(20μmol/l) for 24H and 48H. LY294002 is a specific inhibitor for PI3K activity. E-cadherin and α-SMA were detected with western blot and laser scanning confocal microscope (LSCM). The expression of miR-192 was determined by real-time PCR. The proteins of P-PI3K, PI3K, P- Akt and Akt were measured with western blot.

Results: a-SMA in HKC-SOEV cells treated with TGF-β1 *was* significantly lower than that in HKC cells treated with TGF-β1 ($p<0.05$) and that in HKC-SOEV cells treated with TGF-β1 and LY294002 ($p<0.05$). E-cadherin in HKC-SOEV cells treated with TGF-β1 *was* significantly higher than that in HKC cells treated with TGF-β1 ($p<0.05$) and that in HKC-SOEV cells treated with TGF-β1 and LY294002 ($p<0.05$). miR-192 expression in HKC-SOEV cells treated with TGF-β1 for 48H was lower than that in HKC cells treated with TGF-β1 ($p<0.05$) and that in HKC-SOEV cells treated with TGF-β1 and LY294002 ($p<0.05$). P-PI3K/PI3K and P-Akt/Akt in HKC-SOEV cells treated with TGF-β1 *was* significantly higher than that in HKC cells treated withTGF-β1 ($p<0.05$) and that in HKC-SOEV cells treated with TGF-β1 and LY294002 ($p<0.05$).

Conclusions: The results demonstrated that overexpression of VEGF may downregulate TGFβ1-induced expression of miR-192 in EMT through PI3K/Akt signal pathway in HKC cells.

Differential Role of Endoplasmic Reticulum Stress on Epithelial-to-Mesenchymal Transition (EMT) & Apoptosis in Human Peritoneal Mesothelial Cells (HPMC)

Hyun-soo Shin, Duk-Hee Kang. *Division of Nephrology, Ewha Womans University School of Medicine, Seoul, Korea.*

Background: Endoplasmic reticulum (ER) stress is known to be implicated in both apoptosis and EMT of epithelial cells from lung and kidney. The aims of this study were to investigate the role of preconditioning of ER stress as well as ER stress per se in EMT of HPMC. We characterized the pattern of ER stress-induced EMT and apoptosis with an elucidation of mechanisms of protective effect of ER stress preconditioning on TGF-β-induced EMT.

Methods: EMT was evaluated by morphological changes of HPMCs and the expressions of E-cadherin and α-smooth muscle actin after treatment with ER stress inducer tunicamycin (TM) or thapsigargin (TG). Apoptosis was assessed by FACscan. Effect of pretreatment TM (0.01ng/ml) or TG (0.01nM) on TGF-β (1ng/ml)-induced EMT was also evaluated. Mechanisms suggested for peritoneal EMT such as phosphorylation of Smad2/3,snail and nuclear translocation of β-catenin were investigated by WB and ICC. Expression and deglycosylation of TGF-β receptor I and II were studied by WB with IP and lectin.

Results: Lower concentration of TM or TG per se induced a reversible EMT of HPMC at 6 hours with an activation of Smad2/3 and snail whereas prolonged exposure to TM or TG for 48 hours resulted in an apoptosis and irreversible EMT. However, higher concentration of TM or TG induced an apoptosis at 6 hours. Interestingly, preconditioning with low concentration of TMor TG for 6 hours protected HPMC from EMT with an amelioration of Smad2/3 phosphorylation and nuclear translocation of β-catenin in TGF-β-stimulated HPMC. Protective effect of ER stress pre-conditioning on TGF-β-induced EMT was also associated with deglycosylation of TGF-β receptor I and II.

Conclusions: ER stress per se induced EMT and apoptosis in a dose- and time-dependent manner, however adequate preconditioning with low concentration of ER stress inducer for short period of time protected cells from TGF-β-induced EMT via an induction of deglycosylation of TGF-β receptors which blocked the downstream signalingin HPMC exposed to TGF-β. These findings suggest the potential therapeutic implication of ER stress preconditioning in peritoneal fibrosis.

TH-PO1025

HIF-TGF-β Interaction in Mesenchymal Cell Type-I Collagen Accumulation Christian Hanna, Susan C. Hubchak, H. William Schnaper. *Pediatrics, Kidney Diseases, Lurie Children's Hospital, Northwestern University, Chicago, IL.*

Background: Cellular adaptation to hypoxia is mediated by hypoxia-inducible factors (HIFs), transcription factors consisting of an oxygen-sensitive α-subunit binding a β-subunit to promote the expression of pro-survival genes. Previously, we showed that transforming growth factor (TGF)-β, a central profibrotic cytokine in progressive kidney disease, increases HIF-1α expression in normoxic as well as hypoxic renal tubular epithelial cells, and promotes fibrosis through functional cooperation with TGF-β. It is unclear whether this interaction depends upon tissue hypoxia. Models of kidney injury leading to glomerular fibrosis may involve less hypoxia than models of renal tubulointerstitial injury, permitting potential evaluation of the role of HIFs in normoxic renal fibrogenesis.

Methods: In normoxia, HIF-1α/2α protein expression was analyzed by western blot in human mesangial cells (HMC) stimulated with TGF-β1, pretreated with vehicle, phosphatidylinositol-3-kinase (PI3K) inhibitor LY-294002 (LY) or the TGF-β1 receptor (TβR1) inhibitor, SB-431542 (SB). To determine the effect on collagen I transcriptional activity, HMC were transfected with COL1A2 or HRE-luciferase reporter constructs, along with empty vectors, mutant HIF-1α constructs, or HIF-1α/2α siRNA before stimulation with TGF-β1. Transfection efficiency was corrected with co-transfected β-Gal.

Results: TGF-β stimulated a 3-fold increase in normoxic HIF-1α/2α expression by 4-6 h. SB blocked TGF-β stimulated HIF-1α/2α expression, indicating that the effect is TGF-β receptor dependent. LY reduced basal and TGF-β-stimulated HIF-1α/2α protein expression, implicating PI3K in normoxic HIF expression. TGF-β induced a 2-fold increase in collagen promoter activity. Expressing a non-degradable HIF-1α increased basal collagen promoter activity by 50%. TGF-β promoter stimulation was increased 4-fold. HIF-1α or -2α siRNA decreased basal and TGF-β-stimulated COL1A2 promoter activity.

Conclusions: HIF-1α and HIF-2α play a significant role in normoxic HMC collagen expression and support our model of a role for TGF-β/Smad3 and HIFs in normoxic kidney fibrogenesis via TβR1 kinase and PI3K pathways.

TH-PO1026

Oncostatin M Inhibits TGF-β1-Induced CTGF Expression via Stat3 in HK-2 Cells Rita Sarkozi, Viktoria Maria Haller, Markus Pirklbauer, Gert J. Mayer, Herbert Schramek. *Department of Internal Medicine IV, Nephrology and Hypertension, Innsbruck Medical University, Innsbruck, Austria.*

Background: In kidneys, increasing evidence exists that matricellular proteins are involved in the development of tubulointerstitial fibrogenesis and renal disease progression. Connective tissue growth factor (CTGF), for example, has been implicated in the development of tubulointerstitial lesions in human and experimental diabetic nephropathy. We have recently established oncostatin M (OSM) as a novel inhibitor of basal and TGF-ß1-induced CTGF expression in proximal tubular human kidney-2 (HK-2) cells. In the present study we investigated the molecular mechanism of OSMs inhibitory effect on CTGF expression.

Methods: Cell culture, Western blot, real-time PCR, siRNA transfection.

Results: In HK-2 cells, induction of CTGF mRNA expression by TGF-ß1 (10 ng/ml) started after 15 min, reached a maximum after 2 h and remained elevated for at least 24 h. OSMs inhibitory effect on basal and TGF-ß1-induced CTGF mRNA expression was effective as early as 2 h after ligand administration and lasted for at least 24 h. In contrast to TGF-ß1, OSM (10 ng/ml) led to a rapid phosphorylation of both Stat1 and Stat3, which lasted for at least 6 h and 48 h, respectively. siRNA-mediated knockdown of Stat1 or Stat3 in HK-2 cells resulted in almost complete suppression of the respective mRNA and protein levels. These siRNA treatments did not interfere with TGF-β1-stimulated phosphorylation of Smad2/3 but blocked OSM-induced phosphorylation of the respective Stat isoforms after 1 h of stimulation. Silencing of Stat1 as well as Stat3 gene expression attenuated basal CTGF mRNA expression, suggesting that both Stat1 as well as Stat3 play a role in the regulation of basal CTGF mRNA levels in HK-2 cells. More importantly, siRNA-mediated silencing of Stat3 but not Stat1 abolished the inhibitory effect of OSM on TGF-β1-induced CTGF mRNA expression.

Conclusions: In conclusion, OSM represents a novel and potent inhibitor of TGF-β1-induced CTGF mRNA expression in proximal tubular HK-2 cells. This inhibitory effect is mainly driven by OSM receptor-stimulated Stat3 signaling.

TH-PO1027

Alteration of Hypoxia-Associated Gene Transcripts in Acquired Nephropathies Maja Lindenmeyer,[1,2] David Hoogewijs,[2] Roland H. Wenger,[2] Clemens D. Cohen.[1,2] *[1]Nephrology, University Hospital; [2]Physiology, University, Zurich, Switzerland.*

Background: Most chronic kidney diseases (CKD) are initiated as glomerular damage with loss of glomerular capillaries. The pathogenesis of the glomerular insult can be manifold. The best morphologic indicator of disease progression and development of end-stage renal disease, however, is interstitial fibrosis accompanied by a reduction of capillary density. As hypoxia - a potential consequence of the capillary rarefaction - has been associated with fibrosis the question arises whether renal cells indeed face hypoxia in CKD and respond with a transcriptional program which could lead to progression of renal disease.

Methods: Gene expression profiles from human glomeruli and tubulointerstitium were obtained from more than 160 renal biopsies from patients with different CKD stages using Affymetrix arrays. Proximal tubular cells and podocytes with stable HIF1a and/or HIF2a suppression were generated using a lentiviral approach. Protein levels were studied by Western Blot and immunohistochemistry. Results were validated using qPCR.

Results: Expression of hypoxia-associated genes was assessed in genome-wide expression profiles. From a total of 84 established HIF-target genes 27 correlated with renal function (eGFR) in the tubulointerstitium and 22 in glomerular samples, respectively. These correlations were both positive and negative and in part compartment-specific. Celltype-specific response to hypoxia and the relevance of given hypoxia-induced transcription factors (HIFs) on HIF-target genes were tested by qPCR in the knock-down derivates and revealed specific HIF1/HIF2-dependencies in the different cell lines. To validate the results on protein level we are currently establishing immunohistochemistry of HIF-target genes in human biopsies from patients with a wide range of renal function.

Conclusions: Our gene expression studies do not indicate an over-all hypoxic milieu in acquired kidney diseases. However, the data clearly point to compartment- and celltype-specific dysregulation of hypoxia-associated gene transcripts in CKD. Elucidation of the mechanisms involved may help to understand the pathogenesis of anemia in CKD, interstitial fibrosis, and renal failure.

Funding: Government Support - Non-U.S.

TH-PO1028

Polycystin-1 (PC-1), Ciliary, and Focal Adhesion (FA) Abnormalities Associated with Fibrotic Changes in Autosomal Dominant Polycystic Kidney Disease (ADPKD) Fibroblasts Siobhan M. Moyes, Jill T. Norman, Patricia D. Wilson. *Centre for Nephrology, UCL, London, United Kingdom.*

Background: ADPKD is a very common, monogenic disease where aberrant PC-1 function leads to end-stage renal disease in ~50% of patients with a highly variable age of onset. As ADPKD cyst expansion is associated with variable degrees of pericystic fibrosis we hypothesize that alterations in ADPKD fibroblast function disrupt normal epithelial-fibroblast interactions and play an important role in renal functional decline. In ADPKD cystic epithelia, alterations in PC-1 function, found in primary cilia, cell-cell adherens junctions and cell-matrix FAs are well described, but little is known in ADPKD fibroblasts. Previously we reported a stage-related hyper-proliferative defect in human early-stage (pre-dialysis, E) and end-stage (ES) fibroblasts compared to normal human kidney (NHK) cells.

Methods: Here we used Western blot and immuno-localization techniques *in vivo* and *in vitro* to compare PC-1, fibrotic, ciliary and FA proteins.

Results: Fibrotic markers: interstitial collagen deposition, TGF-β and stress fiber-associated α-SMA increased markedly with disease-stage. PC-1 was detectable in all types of fibroblasts but ADPKD cells were characterized by loss of full-length (~460kD) and ~250kD protein fragments but increased abundance of multiple low molecular weight forms. However, down-regulation of the putative C-terminal (~30kD) fragment appeared to be associated with reduced nuclear localization of PC-1 in ADPKD fibroblasts. Cilia were detected in all fibroblasts, but decreased in length with ADPKD stage (NHK=5.8±1.5μm; E-ADPKD=4.3±0.6μm; ES-ADPKD=3.8±0.3μm). Primary cultures of NHK, E- and ES-ADPKD fibroblasts showed disease stage-related increases in matrix-adhesion and cell spreading associated with increased expression of FAK, paxillin and integrin-linked kinase and altered phosphorylation of these FA proteins; similar to changes seen *in vivo.*

Conclusions: We suggest that altered processing, cellular distribution and function of PC-1 in ADPKD fibroblasts is associated with ciliary and FA functional changes with deleterious impact on epithelial-fibroblast interactions and fibrotic changes, respectively.

TH-PO1029

Anti Phospholipase A2 Receptor Antibodies Diminish Cell Adhesion by Interfering with the Interaction of the Receptor to Collagen Type IV Andrej Skoberne,[1] Astrid Behnert,[2] Kirstin Worthmann,[2] Beina Teng,[2] Hermann G. Haller,[2] Mario Schiffer.[2] *[1]Department of Nephrology, University Medical Centre Ljubljana, Ljubljana, Slovenia; [2]Clinic for Nephrology, Hannover Medical School, Hannover, Germany.*

Background: Recently, antibodies against the phospholipase A2 receptor (PLA2R) have been discovered in patients with primary membranous nephropathy (MN). As of yet, no clear pathogenic role for these antibodies has been established. Fibronectin type II (FNII) domain of the rabbit PLA2R can bind to collagen. The aim of our study was to establish a possible role of human PLA2R in cell attachment to collagen and to establish whether PLA2R antibodies interfere with cell adhesion.

Methods: We constructed a recombinant human PLA2R with a GFP tag. Cell adhesion assays were done in duplicates or triplicates in a 24 well plate coated with human collagen type IV, using wild type and mock transfected HEK cells. During cell incubation we added a commercial PLA2R antibody (cPLA2R) or different patient samples with or without PLA2R antibodies. Cells were counted per power field at a magnitude of 200x, using a DAPI stain.

Results: Attachment of wild type HEK cells was significantly higher than mock transfected cells (mean 316.3 vs. 48.3 cells/power field, p 0.001). Samples with added cPLA2R to wild type cells showed significantly lower cell adhesion as compared to controls (mean 184 vs. 321.2 cells/power field, p 0.019). There was a trend toward a lower cell attachment in patient samples containing PLA2R antibodies as compared to controls. There was no significant difference in cell attachment of wild type cells that had serum from patients without the PLA2R antibodies added to the well as compared to controls.

Conclusions: Our study shows that human PLA2R enhances the ability of HEK cells to attach to collagen IV. Anti PLA2R antibodies diminish cell attachment, possibly by interfering with the PLA2R-collagen interaction, which might have a pathogenic role in MN.

Matrix Composition Is Important for IgA Nephropathy to Develop Kerstin Ebefors,[1] Peidi Liu,[1] Johannes Elvin,[2] Borje Haraldsson,[2] Jenny C. Nystrom.[1] *[1]Neuroscience and Physiology, University of Gothenburg, Sweden; [2]Molecular and Clinical Medicine, University of Gothenburg, Sweden.*

Background: Depositions of undergalactosylated IgA (uIgA) in the mesangium are one of the key findings in IgA nephropathy (IgAN) together with matrix expansion and mesangial proliferation. However, uIgA can be found in asymptomatic individuals as well. Although many have tried to find a receptor for the IgA on the mesangial cells, there is still no clear answer to how the IgA binds to the cell and how this leads to loss of kidney function. We hypothesize that patients with IgAN have an altered matrix composition which makes the uIgA able to bind to the matrix and cause IgAN.

Methods: To investigate the matrix composition in IgAN, two protocols were used. Firstly, we microdissected biopsies from patients with IgAN (n=14) and kidney donors (n=23). Global gene expression of glomeruli was investigated with focus on matrix-associated genes. Selected genes were analyzed with Q-PCR from another set of patients with IgAN (n=10) and kidney donors (n=10). Secondly, we developed a unique method for culturing mesangial cells from patients with IgAN and healthy controls. These cells were treated with purified IgA1 and the expression of ECM genes was studied.

Results: Array analysis showed that patients with IgAN have increased expression of several ECM genes. The ECM-receptor interaction pathway was the most up-regulated pathway. Q-PCR analysis showed similar results as the array and validated the data. Mesangial cells cultured from patients with IgAN had changed basal gene expression of several ECM genes including: COL1A1, DCN and SDC1 compared to control cells. Treatment of the cells with purified IgA showed a more significant response in the cells from patients compared to control. The difference in the ECM composition may be necessary for the IgA depositions to bind and to be pathological.

Conclusions: These experiments show that the gene expression of matrix genes is affected in IgAN, both on a systemic and cell-specific level, and strengthen the hypothesis that the matrix composition is important for IgAN to develop and may differ between individuals.

Reversibility of AngiotensinII-Induced Early Markers of Renal Damage Anne-Roos Sophie Frenay, Miriam Boersema, Saleh Yazdani, Anne Marijn van der Graaf, Inge Hamming, Femke Waanders, Jacob van den Born, Ruud A. Bank, Gerjan Navis, Harry Van Goor. *University Medical Center Groningen.*

Background: Elucidating the dynamics of renal interstitial damage can provide exciting tools for treatment. We studied whether early interstitial changes induced by AngII are reversible after cessation of AngII. Since salt intake can modify renal fibrosis, rats were given various salt diets after cessation of AngII.

Methods: Rats were infused with AngII (435 ng/kg/min) or saline (VEH) via osmotic pumps (i.p.). At 3 wks pumps were removed and biopsies were taken. Rats were randomized to 3 salt diets (0.05% NaCl (LS), 0.4% NaCl (NS) or 4.0% NaCl (HS)) for 8 wks (n=10/group). VEH rats (n=10) received NS. SBP, creatinine (Cr) and proteinuria (Uprot) were determined. Kidneys were studied for macrophages and fibrosis (α-SMA, collagen I, III), tubular damage (KIM-1) and lymphangiogenesis (LA, Podoplanin).

Results: Compared to VEH, AngII induced hypertension (199 ± 5 vs 146 ± 3 mmHg in VEH), Uprot (51 ± 6 vs 15 ± 2 mg/24hr), raise in plasma Cr (31 ± 2 vs 20 ± 1 μmol/l), inflammation (macs (8.0 ± 0.7 vs 1.3 ± 0.2)), interstitial fibrosis (α-SMA mRNA (10.7 ± 0.9 vs 3.7 ± 0.7) and -protein (169.2 ± 14.0 vs 20.9 ± 2.0); collagen I mRNA (5.7 ± 0.8 vs 1.4 ± 0.2); collagen III mRNA (17 ± 2.7 vs 3.5 ± 0.6) and -protein (169.4 ± 11.3 vs 80.9 ± 13.8)), tubular damage (KIM-1 mRNA (20 ± 4 vs 1.0 ± 0.8) and -protein (0.5 ± 0.1 vs 0.1 ± 0.0)) and LA (Podoplanin (4.4 ± 0.3 vs 2.2 ± 0.4)); all $p<0.01$. After cessation of AngII, SBP and plasma Cr returned to control values in all groups. Uprot returned to control values in LS and NS, but not in HS. Interstitial macrophages, epithelial damage and LA were reduced to control values in all groups ($p<0.01$). Prefibrotic α-SMA protein reduced 10-fold ($p<0.01$) in all groups. Interstitial collagens reduced to control levels at mRNA level ($p<0.01$), but not at protein level.

Conclusions: Clinical and structural early changes induced by AngII are largely reversible over time, depending on sodium consumption. Remaining delicate fibrils of degradation resistant collagen may predispose for future vulnerability to renal events.

TH-PO1032

Hypoxia-Inducible Factor-α Isoforms Are Differentially Regulated in Glomerular Cells, and Modulate Fibrogenesis in Podocyte-Injury Mouse Models Tomoko Hayashida, H. William Schnaper, Susan C. Hubchak, Christian Hanna, Xiaoyan Liang. *Pediatrics, Northwestern University, Chicago, IL.*

Background: Hypoxia-inducible factors (HIF) also have physiological functions in normoxia. We reported that transforming growth factor (TGF)-β upregulates HIF-1α expression in normoxic kidney cell culture and overexpression of non-degradable HIF-1α enhances TGF-β-induced COL1A2 promoter activity (Basu, 2011). Here, we evaluate HIFα isoform expression and their roles in mouse models of kidney fibrosis.

Methods: Human mesangial cells were treated with TGF-β1 in normoxia or hypoxia (1.5%) for 24 hrs to assess HIF target gene induction. NEP25 mice develop FSGS-like lesion by podocyte targeting of a chimeric toxin, LMB2 (Matsuzaka, 2005). The day after LMB2 injection, some mice were subjected to hypoxia (10% O_2). Alternatively, mice with CD2AP haplosufficiency (Kim, 2003), were treated with L-mimosine, a HIF degradation inhibitor, to upregulate HIF in nomoxia. Mice were sacrificed 4 weeks later, and glomeruli were laser-captured from frozen sections for gene expression analyses.

Results: In culture, TGF-β increased normoxic VEGF-A mRNA, a universal HIF target, and was additive to the hypoxic increase (3.6x by TGF-β, 2.6x by hypoxia, 6.1x hypoxia+TGF-β, compared to normoxic control). HIF-1α-specific target genes (BNIP3, HMOX, PGK1) showed a trend similar to VEGF-A, but TGF-β did not further increase HIF-1 specific genes in hypoxia. Conversely, HIF-2α-specific genes (MMP9, PAI1, cyclin D1) were increased by TGF-β to a similar degree in both normoxia and hypoxia, while hypoxia alone did not significantly affect their expression. HIF upregulation by either ambient hypoxia or PHD inhibition aggravated glomerular sclerosis, determined by Jones staining, in NEP25 and CD2AP(+/-) models, and glomerular COL1A2 mRNA expression was enhanced. VEGF-A and HIF2-target genes were increased in NEP25/LMB2 glomeruli even in normoxia housing, which hypoxia enhanced. Interestingly, HIF1-target genes were not significantly increased either in normoxic or hypoxic NEP25 glomeruli.

Conclusions: HIFα isoforms are differentially regulated in normoxia and hypoxia, and they may play different roles in chronic kidney fibrosis.

Overexpression of PGC-1α Inhibits Aldosterone-Induced Podocyte Phenotypic Changes and Detachment by Blocking Mitochondrial Dysfunction Aihua Zhang, Yanggang Yuan, Songming Huang, Guixia Ding, Min Su. *Nephrology, Nanjing Children's Hospital, Nanjing Medical University, Nanjing, Jiangsu, China.*

Background: A growing body of experimental and clinical literature show that podocyte number is a critical determinant for the development of glomerulosclerosis and that podocyte loss leads to progressive renal failure. It has shown that mitochondrial dysfunction (MtD) is associated with many types of kidney disease. This study investigated whether MtD is involved in the pathogenesis of podocyte loss and whether the transcriptional coactivator, peroxisome proliferator activated receptor-g coactivator 1α (PGC-1α), a major regulator of mitochondrial function, prevented podocyte phenotypic changes and detachment by blocking MtD.

Methods: The podocyte cell line MPC-5 was cultured in the presence or absence of aldosterone. The PGC-1α-transgenic (Tg) mice were established. Podocyte phenotypic changes were examined by the expression of podocyte markers nephrin and P-cadherin and mesenchymal cell markers α-smooth muscle actin, desmin and MMP9. MtD was evaluated by several independent parameters: reactive oxygen species (ROS) production; mitochondrial morphology; mitochondrial membrane potential, ATP levels, and mitochondrial DNA copy number.

Results: Aldo dose and time-dependently induced podocyte phenotypic changes, as evidenced by downregulation of nephrin and P-cadherin and upregulation of α-SMA, desmin and MMP9. Meanwhile, Aldo dose and time-dependently induced podocyte detachment, as evidenced by downregulation of α3-integrin and cell adhesion ability. Mitochondrial DNA depletion by ethidium bromide induced MtD, further promoting podocyte phenotypic changes and detachment. Furthermore, overexpression of PGC-1α prevented Aldo-induced MtD and inhibited podocyte phenotypic changes and detachment. Finally, PGC-1α transgenic mouse were resistant to Aldo infusion-induced podocyte loss and MtD.

Conclusions: These findings, which implicate a role for the MtD in podocyte phenotypic changes and detachment and suggest that PGC-1α improve mitochondrial function and prevent podocyte phenotypic changes and detachment, may guide us in therapeutic strategies for podocyte loss.

Anti-dsDNA Antibodies Induce Epithelial-to-Mesenchymal Transition and Fibrotic Processes in Human Proximal Renal Tubular Epithelial Cells Shirli S.K. Ho, Susan Yung, Kwok Fan Cheung, Wan Wai Tse, Daniel Tak Mao Chan. *Department of Medicine, University of Hong Kong, Hong Kong.*

Background: Tubulo-interstitial pathology predicts renal prognosis. We investigated the role of anti-dsDNA antibodies in the pathogenesis of tubulo-interstitial pathology in lupus nephritis, focusing on proximal renal tubular epithelial cells (PTEC) and epithelial-to-mesenchymal transition (EMT).

Methods: Female NZBWF1/J mice at different stages of nephritis were sacrificed and kidneys harvested to assess the tubulo-interstitial changes over time. Growth-arrested primary human PTEC were cultured with human polyclonal anti-dsDNA antibodies or control IgG (10μg/ml for both) for periods up to 48h, and investigated for the synthesis of mediators of fibrosis and EMT.

Results: NZBWF1/J mice showed progressive tubular damage over time, as denoted by tubular atrophy, protein cast deposition, mononuclear cell infiltration and increasing tubulo-interstitial expression of fibronectin, collagen type I and fibroblast specific protein-1 (FSP-1). Anti-dsDNA antibodies significantly induced the synthesis of soluble and insoluble fibronectin in PTEC after 24h incubation ($P<0.01$ for both). Anti-dsDNA antibodies induced FSP-1 and β-catenin synthesis ($P<0.001$ for both), which was accompanied by increased ERK and PKC-α phosphorylation. Inhibition of ERK and PKC-α activation using specific inhibitors reduced anti-dsDNA antibody induced EMT markers and fibronectin synthesis, and preserved normal PTEC phenotype.

Conclusions: Our data demonstrate that anti-dsDNA antibodies contribute to tubulo-interstitial pathology in lupus nephritis via direct effects on PTEC which are mediated through ERK and PKC-α activation.

CD154 Controls Matrix Metalloproteinase-9 Secretion in Human Podocytes
Claire Rigothier,[1,2] Richard Daculsi,[1] Magalie Genevieve,[1,2] Sebastien Lepreux,[1,3] Chantal Bourget,[1] Christian Combe,[1,2] Jean Ripoche.[1] *[1]INSERM U1026, Université Bordeaux Segalen, Bordeaux, France; [2]Service de Néphrologie, CHU Bordeaux, Bordeaux, France; [3]Service d'Anatomie Pathologique, CHU Bordeaux, Bordeaux, France.*

Background: Glomerular basement membrane (GBM) matrix remodelling is observed in glomerulosclerosis. CD154, the CD40 ligand, is an inflammatory mediator expressed by activated platelets and controls matrix remodelling in endothelial cells through the synthesis of matrix metalloproteinases (MMPs) and tissue inhibitors of MMPs (TIMPs).

We have studied podocyte CD40 expression and whether the CD154/CD40 signalisation was involved in GBM matrix remodelling through the control of MMPs and TIMPs expression by human podocytes.

Methods: CD40 localization and CD40 messenger RNA (mRNA) or protein expression were assessed by immunocytolocalisation (IC) on kidney tissue sections and cells, reverse transcriptase (RT)-PCR and Western blot (WB) on human podocytes exposed to recombinant human CD154 (rhCD154).

The expression and/ or the function of MMPs (MMP-2 and -9) and TIMPs (TIMP-1 and -2) were determined by zymography, WB, ELISA and qRT-PCR.

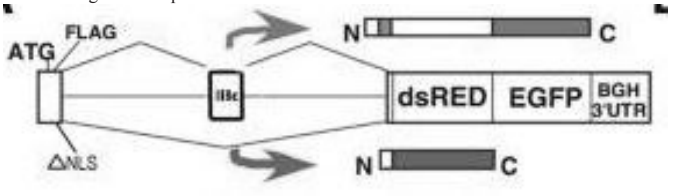
Results: CD40 was expressed by podocytes as shown in kidney tissue sections (optical and electron microscopy). RT-PCR and WB confirmed CD40 mRNA and protein expression in human cultured podocytes. The CD40 signaling pathways were activated by rhCD154: MAP kinase, NFkB, IkB, STAT3 and JNK. Cell stimulation with rhCD154 significantly induced the pro-MMP-9 secretion and the expression of its mRNA by podocytes. No changes in the secretion and expression of MMP-2, TIMP-1 and TIMP-2 were observed. Platelet-derived CD154 induced an increase of MMP-9 mRNA expression and the secretion of pro-MMP-9 by podocytes.

Conclusions: CD40 is expressed by human podocytes. Its ligand CD154 induces MMP-9 expression by podocytes. In glomerular diseases such as in hypertensive glomerulosclerosis and lupus nephritis, platelet activation and an increase of plasma soluble CD154 are observed. The release of CD154 by activated platelets may play a role in the altered GBM matrix remodelling observed in these diseases through the upregulation of MMP-9 by podocytes.

TH-PO1036

Use of Splicing-Sensitive Fluorescent Reporters for Fibroblast Growth Factor Receptor-2 to Investigate Pathological Mechanisms in Kidney Fibrosis
Sebastian Oltean, Jialing Xu. *Microvascular Research Laboratories, Physiology and Pharmacology, University of Bristol, Bristol, United Kingdom.*

Background: Alternative splicing (AS) of fibroblast growth factor receptor-2 (FGFR2) is cell-type specific with exon 8 (IIIb) present in epithelial cells and exon 9 (IIIc) present in mesenchymal ones. Epithelial splicing regulatory proteins (ESRPs) have been recently reported as main regulators of the AS events associated with epithelial-mesenchymal transitions (EMT), including FGFR-2. We have previously reported the development of splicing-sensitive fluorescent reporters that are able to follow accurately EMT both *in vitro* in single cells and *in vivo* in the whole organism (Clin Exp Met (2008) 25:611, PNAS (2006) 103:14116 and figure). Kidney fibrosis is the main end-point of many renal diseases and a better understanding of this pathological process would be invaluable for development of novel targeted therapies.



Methods: We describe herein the use of FGFR2 SSFR as a tool to investigate molecular mechanisms of kidney fibrosis. Proliferating conditionally immortalized podocytes (PCIPs) and Denys-Drash podocytes (DDS) maintained at a permissive temperature of 33 degrees Celsius were stably transfected with the FGFR2 SSFR. To assess for the expression of ESRPs in podocytes western blotting was performed in PCIPs and DDS podoytes differentiated for 3, 7, 10 and 14 days.

Results: The cells showed GFP fluorescence as expected for proliferating podocytes, which display mesenchymal-like characteristics. Differentiation of podocytes towards an epithelial phenotype (obtained by shifting them to the non-permissive temperature of 37 degrees Celsius) increases RFP fluorescence. Indeed, as expected, ESRPs expression increased progressively during differentiation.

Conclusions: In conclusion, we have constructed a molecular tool useful for investigation of EMT and fibrosis in kidney pathology.

TH-PO1037

Role of Palladin in Activation of Tubular Epithelial Cells
Emily H. Chang,[1,2] J. Charles Jennette,[3] Patricia M. Lenhart,[1] Carol A. Otey.[1] *[1]Dept of Cell and Molec. Physiology, University of North Carolina, Chapel Hill, NC; [2]UNC Kidney Center, University of North Carolina, Chapel Hill, NC; [3]Dept of Pathology and Laboratory Medicine, University of North Carolina, Chapel Hill, NC.*

Background: Chronic hypertension is a leading cause of interstitial fibrosis and ESRD. A genetically engineered mouse line, designated RTG+, displays high renin levels and chronic hypertension. Palladin is an actin-binding protein with a role in both cytoskeletal organization and regulation of gene expression in vascular smooth muscle cells which has been implicated as an early marker of fibrosis in skin, but its role in the kidney has not yet been clarified. Previous studies suggest that palladin expression may be regulated by angiotensin II.

Methods: We used both immunoblot and IHC to explore the expression of palladin in RTG+ mice as well as human kidney. A proximal tubule cell culture model, LLCPK, was treated with TGF-β1 and examined by immunoblot.

Results: Immunoblot of RTG+ kidney lysate detected a ~2-fold increase in palladin compared to wild type litter mates. By IHC, we detected a focal increase in palladin levels in tubular epithelial cells of RTG+ mice, prior to development of overt fibrosis. Furthermore, IHC of human biopsy specimens revealed regions of fibrosis with atrophic and dilated tubules that displayed increased staining for palladin. In both human and mouse, palladin upregulation preceded the development of overt disease. LLCPK cells were treated with TGF-β1 to mimic the pathways that induce renal fibrosis. By day 1 after treatment, palladin levels were significantly increased, reaching a peak by day 4. When siRNA was used to knock down palladin in LLCPK cells, α-smooth muscle actin (α-SMA) was upregulated in control cells treated with TGF-β1 but not in knock down cells.

Conclusions: These results show a correlation between the early stages of tubular epithelial cell injury and an increase in palladin levels. More importantly, they suggest that palladin may play a critical role in regulating the expression of α-SMA and other genes associated with fibrosis, and implicate a palladin-dependent signaling pathway in this process and in the initiation of fibrosis.

Results of the HERAKLES Trial: Efficacy and Safety of Three Different Treatment Regimens in De Novo Renal Transplant Patients
Ingeborg A. Hauser,[1] Hans-Hellmut Neumayer,[1] Martin G. Zeier,[1] Wolfgang Arns,[1] Claudia Sommerer,[1] Oliver Witzke,[1] Klemens Budde,[1] F. Lehner,[1] Manfred J. Stangl,[1] Christoph May,[2] Daniel Baeumer,[2] Eva-Maria Paulus,[2] Peter Weithofer,[1] Johannes Jacobi.[1] *[1]The Herakles Study Group; [2]Novartis Pharma.*

Background: Comparison of safety and efficacy of 3 immunosuppressive regimens in first year after renal transplantation (Tx).

Methods: 802 patients (pts) were enrolled in 1-year, open-label, randomized, multi-center study. After Basiliximab induction all pts received Cyclosporine A (CsA), enteric-coated mycophenolate sodium (EC-MPS) and steroids. 3 mth post tx 499 pts were randomized 1:1:1 to a) standard EC-MPS treatment CsA (100-180 ng/ml) (n=166), b) convert to everolimus calcineurin inhibitor (CNI)-free (EVE; 5-10 ng/ml) and EC-MPS (n=171) c) convert to CNI-low regimen with EVE (3-8 ng/ml) and reduced CsA (50-75 ng/ml) (n=162).

Results: For the randomized study period (M 3-12) BPAR was reported in 13 (8.0%) standard, 16 (9.6%) CNI-free and in 13 (8.1%) CNI-low pts. Patient survival was 98.7% in the standard, 99.4% in the CNI-free and 98.8% in the CNI-low group. One graft loss was observed in either group. The number and proportion of pts discontinued prematurely were 39 (24%) in the standard, 61 (36%) in the CNI-free and 38 (24%) in the CNI-low group. Withdrawal because of an adverse event was the most frequent reason for discontinuation (61.5% standard, 72.1% CNI-free, 71.1% CNI-low).

	Standard N=166 [% of pts]	CNI-free N= 171 [% of pts]	CNI-low N= 162[% of pts]
Serious adverse events	61.4	60.5	55.9
Infections	82.5	87.8	84.5
Serious Infections	30.7	31.4	32.3
CMV	23.5	16.9	14.3
BKV	9.6	4.7	4.3
Anaemia	10.2	14.0	9.9
Leucopenia	17.5	25.0	18.0
Thrombocytopenia	4.2	4.7	3,1
Hyperlipidaemia	5.4	12.2	9.9
Hypertriglyceridaemia	3,0	1,7	5,0
Mouth ulceration	0.6	16.9	6.8
Diarrhoea	25.9	32.0	26.7
Oedema	25.9	16.3	27.3

Renal function cGFR (Nankivell) improved from baseline to Mo 12 by 5.6 mL/min/1.73m² in favor of the CNI-free regimen (63.0 ml/min standard; 68.6 ml/min CNI-free; 63.1 ml/min CNI-low).

Conclusions: The Herakles study showed that immunosuppressive regimens with low dose CNI exposure or without CNI reflect an efficacious and safe therapeutic approach.

4 Years Follow-Up of the ZEUS Trial: Better Renal Function after Calcineurin Inhibitor Withdrawal by Substitution with an Everolimus/ Enteric-Coated Mycophenolate Sodium Regimen in De Novo Renal Transplant Patients: Petra Reinke,[1] F. Lehner,[1] Oliver Witzke,[1] Wolfgang Arns,[1] Ute Eisenberger,[1] Eva-Maria Paulus,[2] Daniel Baeumer,[2] Christoph May,[2] Klemens Budde,[1] Claudia Sommerer.[1] *[1]ZEUS Study Group; [2]Novartis Pharma.*

Background: Efficacy and safety (from Tx to Mo 48) in de novo allograft kidney recipients after conversion to an Everolimus (EVE)/Enteric Enteric-Coated Mycophenolate Sodium (EC-MPS) regimen after Cyclosporine (CsA) withdrawal.

Methods: In this 12 Mo prospective, open-label, controlled, multi-center study renal allograft patients (pts) were switched at randomization (4.5 Mo post Tx) to either a immunosuppressive regimen consisting of EVE/EC-MPS or CsA/EC-MPS. After completion of the core study at Mo 12, pts were included in an observational follow up study.

Results: At Mo 4.5, 300 pts were randomized to either EVE/EC-MPS (n=155) or CsA/EC-MPS (n=145), 228 (76%) completed the Mo 48 visit. At baseline both groups had a similar renal function measured by cGFR (Nankivell) with an improvement in the ITT population at Mo 48 by 5.0 mL/min/1.73m in favor of the EVE/EC-MPS regimen (ITT: p=0.03) (62.5 ± 17.3 CsA vs. 67.5 ± 22.1 mL/min/1.73m EVE) compared to 10.6 mL at Mo 12. In comparison, all pts who remained on the assigned EVE/EC-MPS therapy (OT=on treatment) had a high improvement at Mo 48 of renal function (OT: 8.4 mL; 71.3 ± 17.8 (n=71) vs. 62.9 ± 17.3 mL, (n=79)) at Mo 48. The observed GFR change in the ITT population from randomization to Mo 48 was +2.9 [95%CI: -2.1, +7.9] for EVE/EC-MPS and -1.1 [-6.2, +3.9] mL/min/1.73m for CsA/EC-MPS pts. BPAR was reported in 22 (14.3%) EVE/EC-MPS-treated vs. 9 (6.2%) CsA/EC-MPS treated pts between M 4.5 and Mo 48 (p=0.02).Two deaths and 4 graft loss were observed in the EVE group vs. 3 deaths and 2 graft loss in the CsA/EC-MPS group. A similar rate of infections (20%) and hospitalisation EVE (21.9%) vs. CsA (26.9%) in both groups was reported.

Conclusions: Conversion to EVE/EC-MPS in *de novo* renal transplant patients after CNI withdrawal early after transplantation reflects a novel therapeutic approach which maintains better renal function over a period of 48 months without compromising efficacy and safety.

Funding: Pharmaceutical Company Support - Novartis Pharma

TH-PO1040

Results of the APOLLO Trial: Renal Function of an Everolimus Based Therapy after 3 Years of Calcineurin Inhibitor Withdrawal in Maintenance Renal Transplant Recipients Petra Reinke,[1] Claudia Sommerer,[1] Wolfgang Arns,[1] Hermann G. Haller,[1] Oliver Witzke,[1] Thomas Rath,[1] Christoph May,[2] Daniel Baeumer,[2] Eva-Maria Paulus,[2] Klemens Budde,[1] Barbara M. Suwelack.[1] *[1]The Apollo Study Group; [2]Novartis Pharma.*

Background: Assessment of renal function, safety and efficacy of an Everolimus (EVE) regimen after Calcineurin-Inhibitor (CNI) withdrawal in maintenance kidney allograft recipients.

Methods: In an open-label, randomized, controlled, multi-center study 93 patients on a stable immunosuppressive therapy consisting of CNI, Enteric-Coated Mycophenolate Sodium (EC-MPS) with or without corticosteroids were randomized to either continue CNI treatment and EC-MPS or convert to an EVE/EC-MPS based regimen. After completion of the core study at M12, patients were included in a 36 month observational follow-up study.

Results: 93 pts with a mean time of 6.4 years since the most recent transplantation were randomized to either EVE/EC-MPS (n=46) or CNI/EC-MPS (n=47), 74 (79.6%) pts completed the 36 month visit. Trough levels were 98.1 ± 48.8 ng/ml in CsA, 5.4 ± 1.9 ng/ml in Tacrolimus and 6.4 ± 1.9 ng/ml in EVE treated pts. At Month 36 after randomization mean calculated GFR (Nankivell) was higher by 5.12 mL/min/1.73m^2 for the EVE compared to the CNI group (65.66±18.55 vs 60.54±15.49 mL/min/1.73m2; p=n.s.). EVE pts who remained on their assigned treatment (PP) had a better renal function (7.9 min/1.73m^2, 68.0 ± 19.9 (n=25) vs. 60.1 ± 14.7 mL/min/1.73m^2(n=31); p=0.08). The observed GFR change from conversion to month 36 was +5.2 [95% CI: -0.6;+10.9] for EVE/EC-MPS and 0.3 [95% CI: -4.7;+5.2] mL/min/1.73m^2 for CNI/EC-MPS pts. Three deaths and one graft loss were observed in the CNI/EC-MPS group, two death and one graft loss in the EVE/EC-MPS group and no BPAR was observed in either group. The number of patients with infections was 9 pts (19.6%) in the EVE vs. 8 pts (17.0%) in the CsA group. Four (8.5%) malignancies occurred in the CNI group compared to one (4.3%) case in the EVE group.

Conclusions: Late conversion to an EVE/EC-MPS treatment in maintenance renal transplant patients after CNI withdrawal is safe and associated with a tendency towards better renal function after 3 years.

Funding: Pharmaceutical Company Support - Novartis

TH-PO1041

Enteric-Coated Mycophenolate Sodium (EC-MPS) versus Mycophenolate Mofetil (MMF) in De Novo Kidney Transplant Patients: 4-Year Data from the Mycophenolic Acid Observational Renal Transplant (MORE) Registry L. Chan,[1] Fuad S. Shihab,[2] Oleh G. Pankewycz,[3] Cataldo Doria,[4] A. Wiland,[5] Kevin M. Mccague,[5] Anthony J. Langone.[6] *[1]University of Colorado, CO; [2]University of Utah, UT; [3]Buffalo General Hospital, NY; [4]Thomas Jefferson University Hospital, PA; [5]Novartis, NJ; [6]Vanderbilt University, TN.*

Background: Randomized trials of EC-MPS vs MMF are largely restricted to cyclosporine recipients. Mycophenolic acid (MPA) exposure, however, is higher with tacrolimus (TAC).

Methods: Data from the MORE Registry, a prospective, observational study of *de novo* adult renal transplant patients receiving MPA and managed according to local practice at 40 US sites, were interrogated to analyze effectiveness, tolerability and safety of EC-MPS and MMF in TAC-treated patients.

Results: 904 patients (616 EC-MPS, 288 MMF) were followed for up to 4 years. The two groups were similar other than fewer living donor grafts with EC-MPS vs MMF (39% vs 49%, p=0.04). The full recommended dose of MPA (i.e. 1.44g EC-MPS, 2.0g MMF) was maintained in more patients receiving EC-MPS vs MMF at month 1 (79% vs 72%, p=0.02), month 3 (68% vs 57%, p<0.01) and month 6 (53% vs 44%, p=0.03) but was similar thereafter. Mean MPA dose was higher in EC-MPS patients than MMF patients up to month 6 post-transplant. At 4 years, graft survival was 93% vs 95% in the EC-MPS vs MMF groups (log rank p=0.52, Kaplan-Meier estimates); patient survival was 96% vs 94% (p=0.28). Biopsy-proven acute rejection occurred in 14% EC-MPS and 10% MMF patients (p=0.20); mean(SD) serum creatinine was 1.5(1.1)mg/dL and 1.7(1.8)mg/dL, respectively (p=0.25). Adverse events were similar in the EC-MPS and MMF groups, including gastrointestinal complications (73% vs 75%, p=0.57).

Conclusions: In this real-life population, patients in the EC-MPS group received a significantly higher MPA dose vs the MMF group, and were more likely to remain on the full recommended MPA dose, up to month 6 post-transplant. Efficacy outcomes were similar with EC-MPS or MMF to 4 years, despite fewer living donor grafts in the EC-MPS group, and safety profiles were similar despite higher early EC-MPS dosing.

Likelihood of Improving or Sustaining Renal Function over Four Years with Belatacept or CsA: Insights from the BENEFIT Long-Term Extension Study K. Rice,[1] L. Chan,[2] Lionel Rostaing,[3] B. Bresnahan,[4] J.H. Helderman,[5] M.B. Harler,[6] F. Vincenti.[7] *[1]Baylor Univ Med Ctr, US; [2]Univ of CO; [3]Univ Hosp, Toulouse, FR; [4]Univ of WI; [5]Vanderbilt Univ, US; [6]BMS, US; [7]UCSF Transplant Svc, US.*

Background: A consistent safety profile and sustained renal function benefit over 4 years were observed in pts who entered the long-term extension (LTE) of BENEFIT. Changes in cGFR stage of pts in the BENEFIT LTE cohort are reported.

Methods: In BENEFIT, recipients of living or standard-criteria deceased donor kidneys were randomized to a more or less intensive (LI) regimen of belatacept or CsA. Pts who remained on assigned therapy after 3 yrs were eligible to enter the LTE. This posthoc analysis assessed shifts in cGFR staging between Months (Mos) 3 and 48 in the LTE population. cGFR stages were defined per the KDOQI classification of CKD stages. cGFR was imputed as 0 for death or graft loss. 138/166 belatacept LI and 109/136 CsA pts had data available at both Mos 3 and 48.

Results: GFR stage at Mo 3 and 48 in LI and CsA pts are shown in the Figure. Among pts in Stage 2 at Mo 3, GFR stage was sustained or improved through Mo 48 in 68 (96%) LI and 17 (47%) CsA pts. In Stage 3 pts, GFR stage from Mo 3–48 was sustained or improved in 44 (98%) LI and 58 (88%) CsA pts. At Mo 3, 3 LI and 5 CsA pts were in Stage 4; all pts (100%) sustained or improved their GFR stage through Mo 48. One LI pt who was in Stage 5 at Mo 3 improved to Stage 2 at Mo 48; there were no CsA pts who were in Stage 5 at Mo 3 and had cGFR measurements through Mo 48. Trends from Mo 12–48 were similar to those seen from Mo 3–48.

Conclusions: In the BENEFIT LTE cohort at 48 months, a higher percentage of belatacept-treated pts were in Stages 1 and 2 vs CsA pts. Belatacept pts were more likely than CsA pts to experience sustained or improved renal function over 4 yrs.

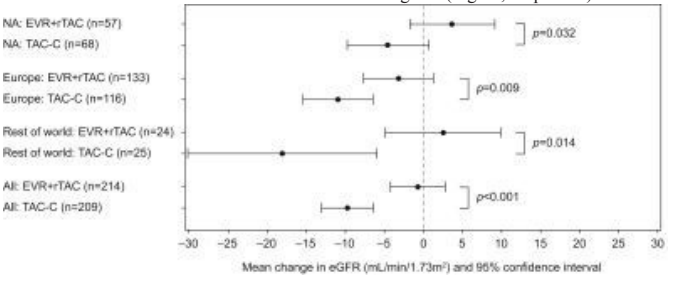
TH-PO1043

Renal-Sparing Effect of Early Everolimus-Facilitated Reduction of Tacrolimus in De Novo Liver Transplant Recipients: 12-Month Data from North America R. S. Brown,[1] B. Koneru,[2] M. A. Huang,[3] G. Junge,[4] A. Wiland,[5] J. M. Hexham,[5] G. Dong,[4] J. Fung.[6] *[1]Columbia U; [2]UMDNJ; [3]Henry Ford Hosp; [4]Novartis AG; [5]Novartis NJ; [6]Cleveland Clinic.*

Background: Study H2304, a large international RCT in de novo liver transplant recipients (LTxR), confirmed that use of early everolimus (EVR) facilitates reduction of tacrolimus (TAC) & significantly reduces TAC-related nephrotoxicity at Month (M) 12. Because of the disparity of preexisting renal dysfunction in LTxR, driven by higher MELD & creatinine at OLT in North America (NA), we report results of the NA subpopulation.

Methods: 24-M, randomized, multicenter, open-label study in 211 NA de novo LTxR comparing EVR (C0 3–8ng/mL)+reduced TAC (C0 3–5ng/mL; EVR+rTAC; n=65) or EVR (C0 6–10ng/mL)+TAC withdrawal (TAC-WD; n=68) to std TAC (C0 6–10ng/mL; TAC-C; n=78); all with steroids. LTxR were randomized 1:1:1 after a 30-day post-LTx run-in period with TAC±MMF. Primary endpoint was composite efficacy failure rate of treated biopsy proven acute rejection (tBPAR), graft loss, or death. Renal function from randomization (RDN) to M12 was based on eGFR (MDRD4).

Results: Enrollment in TAC-WD arm stopped early due to a higher rate of tBPAR. At RDN, mean eGFR (mL/min/1.73m2) was lower in NA vs Europe (EU)/rest of world (ROW); imbalance favoring TAC-C (EVR+rTAC: 69.3 vs 85.9/80.8; TAC-C: 76.4 vs 80.2/79.7); MELD scores were higher in NA vs other regions (EVR+rTAC: 22.8 vs 17.9/17.8; TAC-C: 22.6 vs 16.8/18.9). At M12, the composite efficacy failure rate was lower with EVR+rTAC vs TAC-C in NA (10.9% vs 13.1%) & overall (6.7% vs 9.7%). Mean change in eGFR from RDN to M12 favored EVR+rTAC vs TAC-C in all regions (Figure; all p<0.05).



Conclusions: As seen for the overall population, in patients from NA, early use of EVR at 1M allowed substantial TAC reduction resulting in improved eGFR vs TAC-C while maintaining excellent efficacy.

TH-PO1044

The HERAKLES Study: Improved Renal Function in an Everolimus-Based Calcineurin Inhibitor Free Regimen Compared to Standard Cyclosporine/ Mycophenolate and Low Cyclosporine/Everolimus Claudia Sommerer,[1] F. Lehner,[1] Martin G. Zeier,[1] Oliver Witzke,[1] Johannes Jacobi,[1] Klemens Budde,[1] Hans-Hellmut Neumayer,[1] Manfred J. Stangl,[1] Christoph May,[2] Daniel Baeumer,[2] Eva-Maria Paulus,[2] Volker Kliem,[1] Wolfgang Arns.[1] *[1]The Herakles Study Group; [2]Novartis Pharma, Nuremberg, Germany.*

Background: Renal function in 3 immunosuppressive regimens with different calcineurin inhibitor (CNI) exposure.

Methods: 802 patients (pts) were enrolled in this 1-year, prospective, open-label, randomized, multi-center study. After Basiliximab induction all pts received Cyclosporine A (CsA), enteric-coated mycophenolate sodium (EC-MPS) and steroids. 3 months post tx 499 pts were randomized 1:1:1 to a) standard CsA (100-180 ng/ml) with EC-MPS (n=166), b) convert to CNI-free regimen with everolimus (EVE; 5-10 ng/ml) and EC-MPS (n=171) c) CNI-low regimen with EVE (3-8 ng/ml) and reduced CsA (50-75 ng/ml) (n=162) pts continued on steroids.

Results: CsA trough level at M12, was 118.7 ± 33.3 ng/ml, for standard and 79.5 ± 35.2 ng/ml for CNI-low pts. EVE trough level was 6.8 ± 2.2 ng/ml in CNI-free and 6.1 ± 2.7 ng/ml in CNI low pts. Renal function was similar at Mo 3 post tx with improvement (p<0.0001) by 5.6 mL/min/1.73m [95% CI 2.9; 8.3] in favor of the CNI-free regimen at Mth 12 when compared to standard.

eGFR (Nankivell) [mL/min/1.73 m] Month 12

Treatment Group	N	LS-Mean (95%CI)	Difference vs. standard	p value vs. standard
Standard	159	63.0 (60.6;65.5)	-	-
CNI free	163	68.6 (66.1;71.1)	5.6 (2.9;8.3)	0.0001
CNI low	160	63.1(60.7;65.6)	0.1(-2.7;2.8)	0.9586

Results from ANCOVA model (ITT)

Results of renal function were confirmed by other formulas. 69.5% of CNI-free, 53.8% of CNI low and 54.0% of standard pts had an improvement in renal function. All three groups had a similar rejection rate (8.0% standard CNI, 9.6% CNI-free, 8,1% CNI-low) with an overall comparable safety profile data. Proteinuria was reported in 8.4%, 9.9% and 14.9% of pts (stand., CNI-free and CNI-low).

Conclusions: Results confirm reports of improved renal function after CsA withdrawal with EVE and EC-MPS. However, the profound reduction of CsA in combination with EVE did not result in better renal function compared to standard therapy with EC-MPS.

TH-PO1045

Central Fat Distribution Is a Risk Factor for Graft Failure, and Cardiovascular, and All-Cause Mortality in Renal Transplant Recipients Arjan J. Kwakernaak, Steef Jasper Sinkeler, Dorien M. Zelle, Stephan J.L. Bakker, Gerjan Navis. *Dept. of Nephrology, University Medical Center Groningen, Groningen, Netherlands.*

Background: A central body fat distribution is an independent determinant of increased long term renal risk in native kidney disease. Whether a central body fat distribution is a risk factor for renal allograft failure is unknown. In the current study, we therefore prospectively investigated the impact of a central body fat distribution, assessed by waist-to-hip ratio (WHR), on renal allograft failure, and in addition, on cardiovascular and all-cause mortality in renal transplant recipients (RTRs) ≥ 1 year post-transplantation.

Methods: We studied 498 RTRs (mean age 50±12 years, 56% male) with a functioning renal allograft at a median time of 6.0 [2.6 – 12.1] years post-transplantation. Median WHR was 0.97 [0.90-1.04].

Results: At baseline, a higher gender-specific WHR was associated with higher BMI, higher systolic blood pressure despite more antihypertensive medication, a more unfavorable lipid and glucose profile and higher protein excretion. After a median follow-up of 7.0 [6.2 – 7.5] years, 52 death-censored graft losses had occurred, 107 recipients died, with 54 deaths being cardiovascular in origin. In multivariable Cox regression analyses, WHR was associated with death-censored graft loss (HR=2.0 [1.4-2.8], P<0.001), cardiovascular (HR=1.5 [1.1-2.0], P=0.024) and all-cause mortality (HR=1.3 [1.0-1.6] P=0.034), independent of BMI and potential confounders.

Conclusions: In conclusion, a central body fat distribution, assessed by WHR, was a strong and independent predictor of allograft failure, and cardiovascular, and all-cause mortality in RTR late after kidney transplantation. Of note, this association was independent of BMI. Further research is needed to elucidate the mechanisms underlying the association between a central body fat distribution and renal allograft loss.

TH-PO1046

Interventions to Reduce Clinical Inertia in Cardiac Risk Factor Management in Renal Transplant Recipients Dhanashri Kohok, Silvi Shah, Rakesh Kumar, Gregory D. Gudleski, Rocco C. Venuto. *University at Buffalo, Buffalo, NY.*

Background: Cardiovascular disease (CVD) is the leading cause of death in renal transplant recipients (RTRs). Improvement in key risk factors such as hypertension (HTN), dyslipidemia and diabetes reduces the probability of CVD. Clinical inertia (CI) defined as "recognition of the problem, but failure to act" may hinder attaining Kidney Disease Improving Global Outcome (KDIGO) guideline goals. We assessed the effect of educational interventions (EI) in minimizing CI.

Methods: A total of 198 RTRs and 8 physicians enrolled in this interventional study. Knowledge of CVD and its risk factors was assessed in RTRs. Physicians were surveyed for limiting factors in achieving treatment goals. An EI comprised of a one on one session with RTRs and printed material was used to enlighten RTRs about goals for blood pressure (BP) <130/80mmHg, low-density lipoprotein (LDL) < 100mg/dL and hemoglobin A1C (HbA1C) < 7.5%. RTRs were given a card with targets titled 'I need to know' to encourage their participation. Physicians were given 'I should check' card as a reminder to check risk factor control. CI was measured as 'no action' or 'appropriate action' and compared pre and post intervention.

Results: Only 7.4% of RTRs knew that death is the most common cause of graft failure while 32.5% were aware that CVD is their most common cause of death. Physicians recognized non-compliance, time constraints and drug-interactions as limiting factors in achieving goals. Post intervention percentage of patients with 'no clinical action' for BP, LDL and HbA1C control decreased from 10.8% to 3.8% (p=0.02), 28.2% to 11.1% (p=0.008) and 10.3% to 4.5% (p=0.05) respectively while those with 'appropriate action' increased from 66.2% to 83.3% (p<0.001), 68.7% to 79.4% (p=0.008) and 85.1% to 93.2% (p=0.03) respectively.

Conclusions: Interventions to increase awareness about CVD in a post transplant clinic and to encourage active participation by both physicians and RTRs in the care plan seem effective in influencing behavior and overcoming clinical inertia. Sustained effects of such interventions on CI and clinical outcomes need further evaluation.

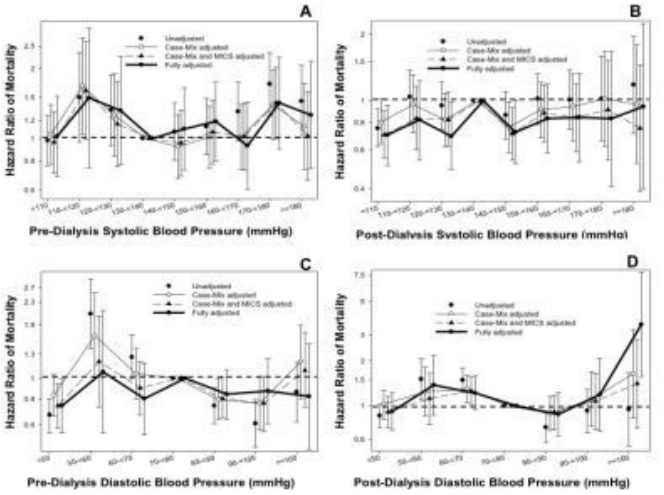
Examining the Association of Pre-Transplant Blood Pressure with Post-Transplant Outcomes Miklos Zsolt Molnar,[1] Joni L. Ricks,[1] John J. Sim,[2] Adam Remport,[3] Clarence E. Foster III,[4] Csaba P. Kovesdy,[5] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center, LABioMed at Harbor-UCLA; [2]Kaiser Permanente; [3]Szent Imre Hospital; [4]University of California, Irvine; [5]University of Tennessee.*

Background: Previous observations in dialysis patients have demonstrated a U-shaped relationship between blood pressure (BP) and mortality. The associations between pre-transplant systolic(SBP) and diastolic BP(DBP) and post transplant outcomes are largely unknown.

Methods: Data of the Scientific Registry of Transplant Recipients were linked to the 5-year cohort of a large dialysis organization in the United States. All patients who received a kidney transplant during this period were identified and categorized groups according to pre-transplant SBP and DBP. Unadjusted and multivariable adjusted predictors of transplant outcomes were examined.

Results: The 13,881 patients were 47±14 years old and included 42% women. There was no association between pre-transplant SBP and mortality, except for a decreased risk in those with low post-dialysis SBP.



Compared to patients with pre-dialysis DBP 70-<80 mmHg, DBP<50mmHg showed a lower risk of death (HR:0.74,95%CI:0.55-0.99). Comparison in post-dialysis DBP groups revealed that patients with DBP≥100 mmHg had higher risk of death (HR:3.50,95%CI:1.57-7.84) compared to 70-<80 mmHg. In addition, the lowest pre-transplant BP's were associated with better graft survival. There was no association between pre-transplant BP and delayed graft function.

Conclusions: Low post-hemodialysis treatment session SBP and low pre-HD treatment DBP were associated with better post-transplant patient survival, whereas very high post-dialysis DBP was associated with higher risk of death after transplantation. Whether targeting different BP ranges during dialysis treatment has implications on post-transplant outcomes needs to be examined in additional studies.

TH-PO1048

Validation of Pre-Transplant Risk Score for New Onset Diabetes Mellitus after Kidney Transplantation Harini A. Chakkera,[1] Asad Ayub,[2] Thomas A. Gonwa,[2] Yu-hui Chang,[1] E. Jennifer Weil,[3] William Knowler.[3] *[1]Mayo Clinic Arizona; [2]Mayo Clinic Jacksonville; [3]NIDDK- Phoenix.*

Background: New-onset diabetes mellitus after kidney transplantation (NODAT) has adverse clinical and economic implications. A risk score for NODAT could help identify patients for intervention studies. We published results from a single center study describing a pre-transplant predictive risk score for NODAT using 7 simple pre-transplant clinical and laboratory measurements. **Aim:** Validate the pre-transplant risk score in a second cohort.

Methods: All the methods and entry criteria were the same in both the initial and the validation model. The simple risk score was calculated as the sum of points from the 7 variables (age >50 years, BMI >30 kg/m2, fasting glucose>/=126 mg/dL and triglycerides>/=200 mg/dL, and family history of type-2 DM, planned corticosteroid therapy post-transplant, prescription for gout medicine) where each variable was given 1 point. Thus, a score for each patient ranged from 0 to 7.The summary scores were grouped as low (0 or 1), intermediate (2 or 3) or a high risk group (4, 5, 6 or 7). NODAT was defined by hemoglobin A1c ≥6.5%, fasting serum glucose ≥126 mg/dL, or prescribed therapy for diabetes.

Results: Validation cohort included 474 non-diabetic patients who underwent kidney transplantation (March 2001-July 2010). Incidence of NODAT = 27%.The prevalence of some risk factors (planned use of corticosteroids, BMI, fasting glucose, fasting triglycerides, and family history of diabetes) differed significantly between the 2 cohorts. Despite these differences in the 2 groups the predictive value of the score was similar in the 2 groups (Table below)

Comparison of prediction of NODAT by risk group

Risk category	% of patients who develop NODAT in initial sample	% of patients who develop NODAT in validation sample
Low risk	12	11
Intermediate Risk	29	29
High risk	56	51

Areas under receiver operating curves for the initial and validation cohorts were 0.70 and 0.66 (p=0.26) respectively.

Conclusions: A simple risk score computed from 7 pre-transplant variables was validated in a second cohort and can provide the basis to identify risk of NODAT for future clinical intervention studies.

TH-PO1049

Serum Uric Acid Is an Independent Predictor of New-Onset Diabetes after Transplantation (NOADT) in Living-Donor Kidney Transplantation Kentaro Tanaka,[1] Ken Sakai,[1] Masaki Muramatsu,[1] Yoji Hyodo,[1] Yasushi Ohashi,[1] Yoshihide Tanaka,[1] Takeshi Kawamura,[1] Seiichirou Shishido,[1] Sonoo Mizuiri,[1] Akifumi Kushiyama,[2] Atsushi Aikawa.[1] *[1]Department of Nephrology, Toho University Faculty of Medicine, Tokyo, Japan; [2]The Division of Diabetes and Metabolism, The Institute for Adult Diseases, Asahi Life Foundation, Tokyo, Japan.*

Background: We investigated whether serum uric acid (SUA) level before kidney transplantation predicts new-onset diabetes after kidney transplantation (NODAT), and compared with known risk factors for NODAT and type 2 diabetes mellitus(T2DM).

Methods: 191 non-diabetic adult kidney allograft recipients underwent living-donor kidney transplantation between 2001 and 2011. 151(male84, female67) recipients underwent 75gOGTT at pre-transplant were studied. NODAT was defined as FPG≥126mg/dl, RPG≥200mg/dl confirmed by repeated testing on a different day and starting therapy for diabetes after the first two weeks post-transplant. The following data were collected from the electric record: recipient age, gender, BMI, family history of diabetes, A1C, HCV status, medication usage (anti-hyperuricemic, diuretics, induction immunosuppressive agents). SUA and other data were based on before transplant operation. Statistical analysis was used by Cox proportional-hazards models.

Results: 32 recipients (21.2%) developed NODAT. When SUA was stratified into tertile, patients in the highest tertile (8.6mg/dl>for men, >7.7mg/dl for women) had a significantly (log-rank test, p=0.03) higher risk of NODAT than the lower two tertiles presented by survival analysis. In univariate model, SUA was associated with NODAT (Hazard ratio1.27, 95%CI 1.04-1.55, *p*=0.01). In multivariate model 1, SUA (1.33, 1.08-1.64, 0.006) was significant after correction for the factors directly affect SUA value. In model 2, Age (1.04, 1.01-1.08, 0.005) and SUA (1.32, 1.09-1.61, 0.004) was significant after correction for risk factors for the onset of T2DM. In model 3, Age (1.04, 1.01-1.07, 0.01) and SUA (1.31, 1.05-1.62,0.01) was remained significant after correction for previously reported factors for NODAT and model 1 and 2.

Conclusions: SUA is an independent predictor of NODAT in living-donor kidney transplantation.

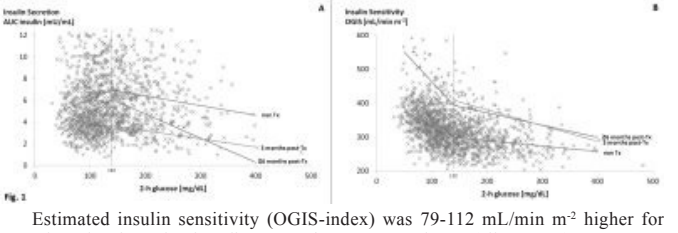
TH-PO1050

Impaired Glucose Metabolism Despite Decreased Insulin Resistance after Renal Transplantation Manfred Hecking,[1] Alexander Kainz,[1] Johannes Werzowa,[1] Michael Haidinger,[1] Angelo Karaboyas,[2] Walter Hoerl,[1] Friedrich K. Port,[2] Marcus Saemann.[1] *[1]Medical University of Vienna, Nephrology, Vienna, Austria; [2]Arbor Research Collaborative for Health, Ann Arbor, MI.*

Background: Current treatment strategies for new-onset diabetes after transplantation (NODAT) follow type 2 diabetes, however the pathophysiology underlying NODAT is still unresolved. The purpose of this study was to determine NODAT prevalence, risk factors, phenotype and pathophysiological mechanisms.

Methods: Demographics and laboratory data were obtained from 1064 stable patients ≥6 months post-transplantation. 307 patients without previously diagnosed type 1 or type 2 diabetes or NODAT were randomly assigned to a 2-hour oral glucose tolerance test (OGTT). Metabolic results were compared to a cross-sectional cohort of 1356 non-transplanted subjects.

Results: Among stable renal transplant patients, 11% had a history of NODAT, and 12% had type 1 and type 2 diabetes. Of all OGTTs, 43% were abnormal (11% diabetic), predominantly in older patients who received tacrolimus. Compared to non-transplanted subjects, basal glucose was lower, glycated hemoglobin higher, insulin secretion worse, and insulin sensitivity superior in stable renal transplant patients, throughout three subgroups of 2-hour glucose. These findings were reinforced in linear spline interpolation models of insulin secretion and sensitivity (all p<0.0007; tx vs non-tx).



Estimated insulin sensitivity (OGIS-index) was 79-112 mL/min m^{-2} higher for transplanted patients despite adjustments for age, sex and BMI (all p<0.001).

Conclusions: Glucose metabolism differs substantially between transplanted and non-transplanted subjects. Because impaired insulin secretion appears to be the predominant pathophysiological feature after renal transplantation, therapeutic regimens that preserve beta cell function are potentially beneficial in this population.

TH-PO1051

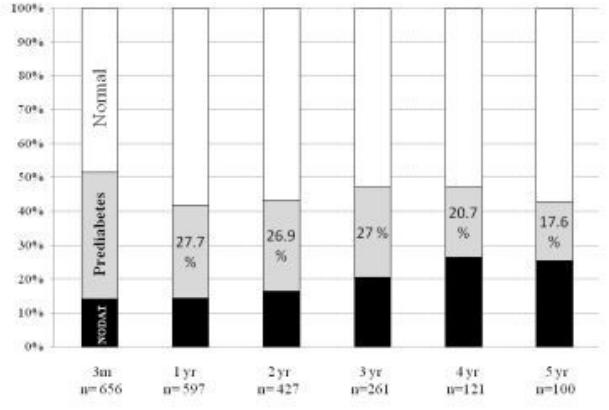
The Natural History of Prediabetes and New Onset Diabetes after Transplantation Esteban Porrini,[1] Irene Silva,[2] Meritxell Ibernon,[2] Benitez Rocio,[3] Joan Manuel Diaz,[2] Patricia Delgado Mallen,[1] Jose Manuel Osorio,[5] Francesc J. Moreso,[4] Armando Torres.[1] *[1]Hospital Universitario de Canarias, Spain; [2]Fundació Puigvert; [3]Hospital de Cruces; [4]Hospital Vall d´Hebron; [5]Hospital Virgen de las Nieves.*

Background: Long-term data on the evolution of pre-diabetes or new-onset diabetes after transplantation (NODAT) are scarce.

Methods: Eight Spanish centers contributed 50-100 non-diabetics scheduled for renal transplantation. Post-operatively, patients underwent oral glucose tolerance test (OGTT) at 3months and annually during 5 years. Patients were categorized in each period as **Normal**, **Prediabetic**: impaired fasting glucose (IFG: glucose ≥100 <126 mg/dL), impaired glucose tolerance (IGT: 2-h glucose ≥140 <200 mg/dL) or **NODAT** (ADA criteria). Prevalence and changes of category were analyzed. Immunosuppresive therapy was CNI+MMF+low dose steroids in 82.9%.

Results: We evaluated 656 patients at 3-m, 597 (1yr), 427 (2yr), 261 (3yr), 121 (4yr) and 100 (5yr). At each period~50% had prediabetes or NODAT. NODAT ranged from 14% (3-m) to 25.3 % (5yr), and prediabetes from 37.4% (3-m) to 17.6% (5yr).

Figure 1



The most frequent prediabetic alteration was IGT: 23.8 % (3-m) to 13.6 % (5yr). Prediabetes evolved into NODAT (16.3%) or normality (37.2%) and 46.5% remained prediabetic (3 year incidence). Most normal and NODAT patients remained stable during follow-up.

Conclusions: NODAT and prediabetes are highly frequent after renal transplantation. The prevalence of prediabetes seems higher than in the general population (6-8% in Spain) and its consequences (cardiovascular disease, evolution to diabetes) deserve further study.

Funding: Government Support - Non-U.S.

TH-PO1052

Cotinine Compared to Self-Reported Smoking Exposure: Dose-Dependent Effect of Smoking on Poor Outcome after Renal Transplantation Merel E. Hellemons, Marc Seelen, Gerjan Navis, Stephan J.L. Bakker. *Internal Medicine, Nephrology, University Medical Center Groningen.*

Background: Smoking exposure is emerging as a risk factor for poor outcome in renal transplant recipients (RTR). It can be assessed by self-report and cotinine measurements. We aimed to investigate (1) whether use of cotinine as a biomarker for smoking exposure can serve as an alternative for self-report and (2) to compare associations of smoking exposure by self-report and cotinine with outcome in RTR and assess potential dose-dependency.

Methods: Firstly, we assessed the agreement of self-reported smoking exposure and smoking exposure according to urinary and plasma cotinine in 603 RTR (age 51.5±12.1 yrs, 55% male). Patients were classified as never, former, light (≤10 cigarettes/day) and heavy smokers (>10 cigarettes/day) according to self-report and analogous categories for urine and plasma cotinine, and compared associations with graft failure (GF) and mortality.

Results: By self-report, 217 (36.0%) RTR were never smokers, 255 (42.3%) former smokers, 64 (10.6%) light smokers and 67 (11.1%) heavy smokers at inclusion. Agreement between self-reported cigarettes/day and cotinine was very strong. The majority of non-smokers had non-detectable cotinine, however, 14 and 13 RTR reporting no active smoking had urine or plasma cotinine consistent with active smoking. Misclassification was 12.2% for urine cotinine, and 11.5% for plasma cotinine.

Heavy smokers had highest risk of GF compared to never- and former smokers, light smokers had intermediate risk. Regarding mortality, both heavy smokers and formers smokers had increased risk compared to never smokers. Importantly, for self-reported smoking there was no sign of a dose-dependent association with poor outcome, whereas there was a dose-dependent association of cotinine levels with both GF and mortality, independent of potential confounders.

Conclusions: There was good agreement of both plasma and urinary cotinine-based measures of smoking exposure with self-reported smoking exposure. Plasma and urinary cotinine were dose-dependently associated with poor outcome in RTR and may serve as a good alternative to self-report.

TH-PO1053

Outcomes after Kidney Transplantation of Patients with Pre-Existing Atrial Fibrillation Colin R. Lenihan, Maria E. Montez-Rath, Wolfgang C. Winkelmayer. *Division of Nephrology, Stanford University School of Medicine, Palo Alto, CA.*

Background: Atrial Fibrillation (AF) is common in the dialysis population and associated with increased mortality. However, little is known about the prevalence and outcomes of patients with pre-existing AF who receive a kidney transplant.

Methods: From the US Renal Data System, we identified all patients who had >1 year of uninterrupted Medicare A and B coverage before receiving their first kidney transplant in 1996-2009. The presence of pre-transplant AF was ascertained from diagnosis codes (1 inpatient or 2 outpatient) in Medicare claims. Detailed demographic and clinical characteristics were extracted for all patients. We studied the post-transplant outcomes of death, all-cause graft failure and death censored graft failure using multivariable Cox regression.

Results: Of 62,706 eligible first kidney transplant recipients studied, 4933 (7.9%) were diagnosed with AF prior to kidney transplant. Patients with AF were older and had a higher burden of co-morbidities. Over a mean follow-up of 4.9 years 41.2% of AF patients and 24.5% without AF died. All cause graft failure and death censored graft failure were 47.6% and 17% respectively in the AF group and 36.2% and 19.5% respectively in those without AF. Table 1 shows the hazard ratios for death, all cause graft loss, and death censored graft loss in patients with AF compared to those without AF.

Table 1

Model Adjustment (all stratified by year)	Demographics	+Co-morbidities	+Transplant Factors
	HR (CI)	HR (CI)	HR (CI)
Death	1.74 (1.66,1.83)	1.51 (1.43,1.58)	1.50 (1.42,1.57)
All-cause Graft Loss	1.63 (1.56,1.70)	1.45 (1.39,1.52)	1.44 (1.38,1.51)
Death Censored Graft Loss	1.41 (1.31,1.52)	1.31 (1.21,1.41)	1.29 (1.20,1.39)

HR - hazard ratio, CI - Confidence Interval

Conclusions: Pre-existing AF is associated with poor post-transplant outcomes. Special attention should be paid to AF in the pre-transplant counseling, evaluation and risk stratification of kidney transplant candidates.

Funding: NIDDK Support, Government Support - Non-U.S.

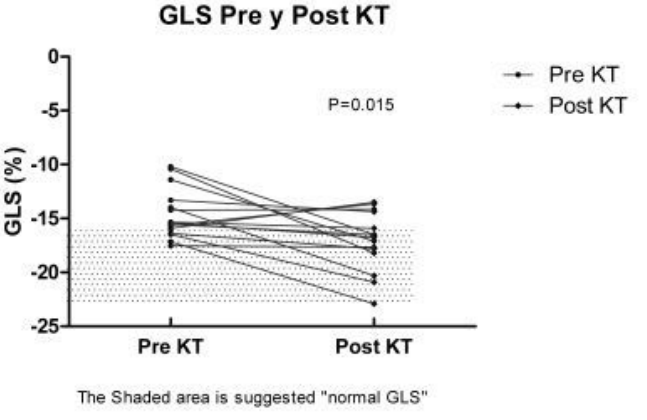
TH-PO1054

Longitudinal Myocardial Deformation in Uremic Cardiomyopathy Had a Excellent Recovery after Kidney Transplantation Omar Israel Salas-Nolasco, J. Pablo Hernandez-Reyes, Fausto E. Barrera- Gomez, Luis E. Morales-Buenrostro. *Nephrology & Mineral Metabolism and Cardiology, Instituto Nacional de Ciencias Medicas y Nutricion "SZ", DF, Mexico.*

Background: Strain imaging allows a more precise characterization of the mechanics of myocardial contraction and relaxation (deformation imaging). Abnormal left ventricular deformation (LVD) is an independent predictor of poor cardiovascular outcome and survival in different cardiomyopathic conditions including end-stage renal disease (ESRD). Usually cardiomyopathy related to uremia is reversible after successful kidney transplant (KT) opposite to ischemic one. The aim of this study is evaluate the impact of kidney transplant on LVD.

Methods: Cohort study of kidney transplantation recipients (KTR). Echocardiography (ECG) was performed at baseline and 6 months after KT. Ischemic heart disease was excluded. Measurement of LVD was performed offline through two-dimensional (2D) Speckle Tracking. Global Longitudinal Strain (GLS) pre and post KT was measured; we compare both measures (paired).

Results: Fifteen KTR were included. Median age was 40 years(18-57 y), 8 were female, cause for ESRD was 33 % unknown, 20 % diabetes, 47 % others. Six were in hemodialysis, 6 were in peritoneal dialysis, 2 were anticipated. Median time on renal replacement therapy was 2.4 years (0.33-9.9 y). Median ejection fraction (EF) pre KT was 67 %(40-74%) and post KT was 69%(48-83%). Standard measures of ECG were abnormal in 46% pre KT and only 6.6% post KT remained whit abnormal ECG. Figure shows GLS pre and post KT.



Conclusions: Pre transplant LVD was abnormal in this cohort and improved after kidney transplantation. It was independent of time in dialysis, structural or functional cardiac alterations. An abnormal GLS in uremic cardiomyopathy shouldn´t be an excluding factor for kidney transplantation by assuming poor cardiovascular outcomes and survival in this population.

Renal Allograft Dysfunction Is Independently Associated with Subclinical Cardiovascular Disease as Indicated by Left Ventricular Mass and Aortic Pulse Wave Velocity Maggie Kam Man Ma, David Chung Wah Siu, Desmond Y.H. Yap, Susan Yung, Daniel Tak Mao Chan. *Department of Medicine, Queen Mary Hospital, Hong Kong, Hong Kong.*

Background: To investigate the prevalence of and determining factors for subclinical cardiovascular disease (CVD) in stable renal transplant recipients.

Methods: This was a cross-sectional single-center study. Adult renal transplant recipients with no prior history of cardiovascular disease were included. All underwent non-invasive cardiac investigations including treadmill stress test and transthoracic echocardiography. Aortic stiffness was assessed by measuring the aortic pulse wave velocity (aPWV).

Results: 38 stable renal transplant recipients (21 male and 17 female, mean age 51.7±8.8 years) were included. All patients had negative treadmill test. 10 patients (26.3%) had left ventricular (LV) hypertrophy (LV mass >255g for men and >193g for women by 2D echocardiogram with modified Simpson's rule). Serum creatinine (SCr) was associated with LV mass (R=0.541, p=0.00) but not aPWV (R=0.313, p=0.056), systolic function (LV ejection fraction, R=0.264, p=0.109) and diastolic function (mitral peak velocity of early filling (E) to early diastolic mitral annular velocity (e') ratio, R=0.143, p=0.399). By multivariant regression analysis, SCr was significantly associated with LV mass (β 0.526, p=0.001) and aPWV (β 0.348, p=0.048), independent of age, gender, hypertension, hyperlipidemia or diabetes mellitus.

Conclusions: The degree of renal allograft dysfunction was associated with subclinical CVD as indicated by LV mass and aPWV, independent of traditional cardiovascular risk factors.

TH-PO1056

Fractional Excretion of Creatinine Predicts Risk of Cardiovascular Events and All-Cause Mortality in Renal Transplant Recipients Mohammad Esmaeil Barbati,[1] Steef Jasper Sinkeler,[1] Ali Abbasi,[2,3] Arjan J. Kwakernaak,[1] Stephan J.L. Bakker,[1] Gerjan Navis.[1] *[1]Nephrology, University Medical Center Groningen, Groningen, Netherlands; [2]Epidemiology, University Medical Center Groningen, Groningen, Netherlands; [3]Internal Medicine, University Medical Center Groningen, Groningen, Netherlands.*

Background: Several studies showed that tubular damage markers are associated with adverse outcome in renal patients, including renal transplant recipients (RTRs). The predictive power of markers of tubular functional capacity has not been established. Therefore, we studied whether fractional excretion of creatinine (FE_{creat}), as a marker of tubular excretory capacity, is associated with graft failure, cardiovascular (CV) events and all-cause mortality in RTRs.

Methods: A cohort of 454 RTRs (54% male; age 52±15 years) with a functional graft for at least 1 year were included (2006-10). All patients were on standard immunosuppressives and underwent GFR assessment by ^{125}I-iothalamate. FE_{creat} was calculated as ratio of $(urine/plasma)_{creat}$ to $(urine/plasma)_{^{125}I\text{-}iothalamate}$.

Results: In cross-sectional analyses, FE_{creat} (mean±SD: 110±15) was positively associated with male sex, body surface area and true GFR, but inversely with age (all P<0.001). During median (IQR) follow-up for 7.6 (5.4-12.7) years, 28 RTRs developed graft failure, 77 developed a CV event and 45 died. In multivariable Cox regression analyses, higher FE_{creat} was significantly associated with lower rates of CV events (HR=0.83 [0.70-0.97], P=0.02) and all-cause mortality (HR=0.68 [0.54-0.85], P=0.001), independent of age, sex and cardiovascular and renal risk factors, but not with graft failure (HR=1.23 [0.93-1.63] P=0.14).

Conclusions: FE_{creat} did not predict graft failure, but, remarkably, independently predicted CV events and all-cause mortality in RTRs. These data suggest that adequate tubular excretory function is protective against CV disease, for instance by removal of uremic toxins. Monitoring and preservation of tubular function might help to improve overall outcome in RTRs.

TH-PO1057

Cystatin C in Renal Transplant Recipients: Marker of Cardiovascular Risk Mira T. Keddis, Nick Voskoboev, Andrew D. Rule, Hatem Amer, Walter K. Kremers, John C. Lieske. *Mayo Clinic, Rochester, MN.*

Background: Cystatin C is a powerful predictor of cardiovascular disease and has been shown to be highly correlated with GFR in renal transplant recipients (RTR). In this study, we assess whether cardiovascular risk factors associate with Cystatin C independent of glomerular filtration rate (GFR) in RTR.

Methods: Adult RTR with stable renal function presenting for their annual transplant evaluation at a single center were studied. GFR was measured using iothalamate clearance (mGFR) and a simultaneous serum Cystatin C was assayed using particle-enhanced immunoturbidimetry (PETIA). Cystatin C was regressed on GFR and other cardiovascular risk factors in a multivariable model. All continuous variables were log-transformed.

Results: 492 RTR were studied; mean age was 55 ± 14 years, BMI 30 ± 7 kg/m^2, 58% male and 93% Caucasian. Median time from transplant was 69 months (11,469). DM was present in 35%, 20% had a major cardiovascular event and 62% were on statin therapy. Post-transplant cardiac troponin T (cTNT) at the time of the visit was elevated (>0.01 ng/L) in 6% of patients. Table 1 shows significant associations with Cystatin C adjusted for mGFR and the independent predictors of cystatin C after mGFR adjustment in a multivariable model.

Clinical Associations with Cystatin C

Variables	Parameter estimate, mGFR adjusted	Parameter estimate, Multivariate adjusted
mGFR (ml/min/1.73m^2)	-	-0.59**
BMI (kg/m^2)	0.094**	-
Female gender	-0.019**	-
DM	0.016*	-
Smoking history	0.021**	0.031*
Statin use	-0.017*	-0.034*
HDL (mg/dL)	-0.096**	-0.054*
LDL (mg/dL)	0.04*	-
Triglycerides (mg/dL)	0.058**	0.036*
Albumin (g/dL)	-0.178*	-
Proteinuria (mg/24hrs)	0.031**	0.027**
Elevated cTNT	0.031*	0.08*

*p<0.05 **p<0.01

Conclusions: Independent of GFR, Cystatin C associates with clinical variables that are predictive of cardiovascular events and mortality post-transplant, in particular, proteinuria, elevated cTNT, and dyslipidemia. Cystatin C should be considered both a marker of GFR and of cardiovascular risk in renal transplant recipients.

TH-PO1058

Use of Cystatin C and Creatinine Based Equations to Estimate Glomerular Filtration Rate in Renal Transplant Recipients Mira T. Keddis, Nick Voskoboev, Andrew D. Rule, Hatem Amer, Walter K. Kremers, John C. Lieske. *Mayo Clinic, Rochester, MN.*

Background: Performance of established cystatin C (CysC) based equations for GFR estimation have not been evaluated in a large cohort of renal transplant recipients (RTR) with stable allograft function. In this cross-sectional study we assessed the performance of 3 published CysC-based eGFR equations in a large sample of RTR more than 1 year out from transplant.

Methods: Adult RTR presenting for a routine annual transplant evaluation were actively enrolled. GFR was measured by iothalamate clearance (mGFR). Plasma CysC was analyzed by particle-enhanced turbidimetric immunoassay, while serum creatinine (Cr) was measured with an enzymatic assay, both standardized to international reference materials. eGFR was calculated using CysC-based equations published by Rule (developed in RTR), Flodin and Stevens (both developed in non-RTR) and the widely used Cr-based MDRD equation. The Rule equation was corrected for bias by dividing CysC by a factor of 1.206, determined by remeasurement of CysC in an independent biobanked sample from 2000 when the formula was derived. Overall bias and accuracy for each eGFR equation within 10 and 30% were assessed.

Results: 492 RTR were studied; mean age was 55 ± 14 years, 59% male and 93% Caucasian. Mean+SD mGFR was 57 ± 21 ml/min/1.73^2. The CysC- based equation developed by Rule had the lowest overall bias and classified patients best within 10 or 30% of mGFR.

Cystatin C Equation Performance

eGFR equations	GFR mean, median (range)	Percentage bias overall (95% CI)	Within 10% accuracy, N(%)	Within 30% accuracy, N(%)
MDRD	52.2, 50.1 (13.7, 170.2)	-11 (-24, 2)	156 (31)	411 (83)
Rule	58.7, 56.8 (19.4, 123.2)	-7 (-14, -1)	201 (41)	417 (85)
Stevens	44.0, 42.0 (13.4, 100.2)	-27 (-32, -22)	86 (17)	353 (72)
Flodin	44.6, 42.1 (11.2, 110.2)	-14 (-21, -8)	87 (18)	354 (72)

Conclusions: A CysC-based eGFR equation developed in RTR outperformed 2 CysC equations developed in non-RTR and the Cr-based MDRD equation. Understanding the influence of transplant related variables may further improve performance of CysC-based equations in RTR and other populations.

TH-PO1059

Comparison of Cystatin C, Beta Trace Protein, Urinary Albumin/Creatinine Ratio and 24 Hour Urine Protein Excretion as Predictors of Renal & Cardiovascular Outcomes in Renal Transplant Recipients Hari Manoharlal Talreja, Ayub Akbari, Greg A. Knoll. *Division of Nephrology, Department of Medicine, The Ottawa Hospital, Otatwa, ON, Canada.*

Background: Cardiovascular disease is the leading cause of mortality in kidney transplant recipients [KTR]. Current risk predictors underestimate their cardiovascular risk. Novel risk predictors such as Cystatin C & Beta-trace protein [BTP] have been studied in non-transplant patients. The aim of our study was to compare novel markers, cystatin C and BTP and 24 hour urinary protein excretion & urinary albumin to creatinine ratio [U-ACR] as predictors of renal & cardiovascular outcomes in KTR.

Methods: 200 stable renal transplant recipients from outpatient transplant clinic at The Ottawa Hospital who consented for undergoing DTPA GFR scan with measurements of Cystatin C, BTP, 24 hour urine protein & random urinary ACR in 2004-2005 were included in the study. Follow-up data was available on 125 subjects.

Subjects underwent the baseline tests in 2004-2005, and baseline demographic data was collected, and were followed until October 2011 or until occurrence of any of composite outcomes consisting of renal, cardiovascular outcomes and mortality, whichever was earlier. Renal outcomes were defined as graft loss [need for renal transplant or dialysis] or doubling of serum creatinine; cardiovascular outcomes as acute coronary syndrome, need for intervention, stroke, intervention for peripheral vascular disease; mortality as death due to any cause. Logistic regression was used to estimate Odds Ratio [OR] for any composite outcome using SAS software.

Results: In this retrospective study, out of 125 subjects with mean age of 52.6 ± 12 years, mean corrected GFR 57.9 ± 24.4ml/min/1.73m2], 17 had a composite outcome. OR estimate for any composite outcome for 24 hour urine protein was 0.917 [CI 0.250-1.001], for U-ACR was 1.002 [CI 0.993-1.011], for cystatin C was 0.529 [CI 0.186-1.502] & for BTP was 0.499 [CI 0.145-1.717].

Conclusions: Preliminary data suggests that 24 hour urine protein excretion, U-ACR, cystatin C & BTP are comparable predictors of renal and cardiovascular outcomes in kidney transplant recipients. Complete data will be analyzed soon for final results.

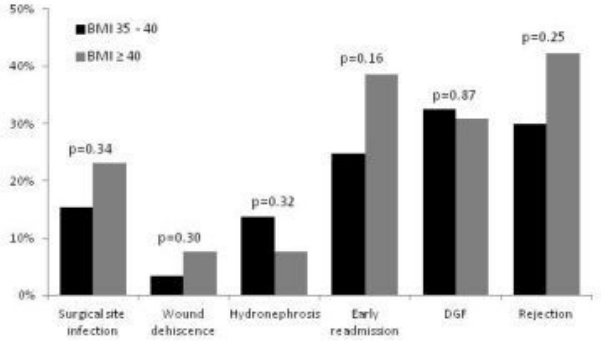
TH-PO1060

Surgical Complications and Outcomes of Renal Transplantation in Morbidly Obese Recipients Yelena Rekhtman, Sumit Mohan, Demetra Tsapepas, Anthony Watkins, Zouhair M. Kabbara, Sowmini Medavaram, David J. Cohen, Lloyd Ratner, Jai Radhakrishnan. *Columbia University.*

Background: Rising obesity rates in the general population are reflected in the rising BMI of prospective renal transplant recipients. Previous studies reporting high rates of surgical complications and poor graft outcomes have discouraged renal transplantation in morbidly obese patients. We report outcomes in morbidly obese patients at our center.

Methods: We performed a retrospective study of adult renal transplant recipients with BMI ≥35 kg/m^2 who received an allograft between January 2004 and April 2012 at our center. Recipients were stratified into two groups, BMI 35 – 40 kg/m^2 and BMI ≥ 40 kg/m^2, and compared with respect to surgical site infection (superficial and deep tissue), wound dehiscence, length of stay, early readmission, and graft outcomes.

Results: Of 143 patients, 117 had BMI between 35 and 40 (mean 37.1, SD 1.4) and 26 had BMI ≥ 40 (mean 43.1, SD 2.3). While morbidly obese patients required longer hospitalizations (7.2 days vs. 11.7 days, p=0.0027), we found no statistically significant differences between the two groups in the incidence of surgical site infection (15.4% vs. 23.1%, p=0.34), wound dehiscence (3.4% vs. 7.7%, p=0.30), hydronephrosis (13.7% vs. 7.7%, p=0.32), or early readmission (24.8% vs. 38.5%, p=0.16). There were no significant differences in delayed graft function (DGF) (32.5% vs. 30.8%, p=0.87), rejection (29.9% vs. 42.3%, p=0.25), rejection-free graft survival (p= 0.079), or overall graft survival (p=0.275).



Conclusions: Surgical complication rates among patients with BMI ≥ 40 are lower than previously reported, and are similar to the rates among patients with BMI between 35 and 40, with similar graft outcomes. Though careful recipient selection is imperative, our results suggest that morbid obesity should not preclude patients from renal transplantation.

TH-PO1061

The Prognostic Significance of Iliac Vessel Calcification in Renal Transplantation Emma L. Aitken, Marc J. Clancy, David Kingsmore. *Department of Renal Surgery, Western Infirmary, Glasgow, United Kingdom.*

Background: Peripheral vascular disease (PVD) is common in patients with ESRF and is associated with considerable morbidity. Nevertheless there is minimal literature on the incidence of amputation following renal transplantation.

Methods: We undertook five year follow-up on the cohort of patients on our renal transplant waiting list in January 2007. All patients to had pelvic x-rays to assess iliac vascular calcification at the time of activation onto the waiting list. Any patients with moderate/ severe calcification were referred for CT angiogram (CTA) of their aorto-iliac vessels. Mortality, transplantation outcomes and amputation rates at five years were correlated with the severity of calcification on pre-operative imaging.

Results: 187 patients were on the waiting list in January 2007 (92 male; mean age 58.3+/-6.2 yrs). By January 2012, 82 patients had a functioning transplant; 45 remained on the waiting list; 40 had died and 20 were alive but no longer on the waiting list. 73 (39.5%) had moderate-severe calcification. Of these, 21.9% had extensive calcification affecting all the iliac vessels and were removed from the waiting list. 50% of patients who developed vascular complications were dead at 5 year follow-up. Mortality and amputation rates were higher in patients with moderate-severe calcification than minimal calcification (30.1% *vs* 16.6% ; p=0.02 and 10.9% *vs* 1.8% p=0.003 respectively). There was no difference in rates of DGF, BPAR or creatinine at 1 year between patients who were transplanted with moderate-severe calcification, however intra-operative vascular complications (26.7% vs. 3%; p<0.001), graft loss (28.1% vs. 3.4%; p=0.01) and death with a functioning transplant (9.7% vs 1.6%; p=0.04) rates were higher in patients with extensive calcification.

Conclusions: Pelvic x-ray is a useful screening tool to identify patients who may require further vascular assessment prior to transplantation. Amputation rates following renal transplantation are low and PVD in isolation should not preclude transplantation. Nevertheless, significant vascular calcification is predictive of mortality both with and without transplantation and graft loss in patients with a renal transplant.

TH-PO1062

Risk Factors for Venous Thromboembolism in Renal Transplant Recipients in the Absence of Known Hypercoagulable State Bhavani Adusumilli,[1] Reem Daloul,[1] Dilip Samarapungavan,[2] Steven Cohn,[2] Vandad Raofi,[2] Francis Dumler,[2] Gampala Harish Reddy,[2] Leslie L. Rocher,[2] Alan Koffron,[2] Raviprasenna K. Parasuraman.[2] *[1]Internal Medicine, William Beaumont Hospital; [2]Division of Transplant, William Beaumont Hospital.*

Background: The prevalence of venous thromboembolism (VTE) in renal transplant recipients (RTR) varies between 4-57%, however the prevalence and risk factors in the absence of known hypercoagulable state prior to transplantation is unclear.

Methods: A Retrospective analysis of all adult renal transplants performed at our center between 1/1/2008 -12/31/2009. Patients with prior known hypercoagulable conditions and/or on anticoagulation at the time of transplantation were excluded. The data was analyzed by using Chi-square, Kruskal-Wallis test and Kaplan–Meier methods.

Results: A total of 111/124 patients met the criteria with mean follow up of 30.4±12.9 months. The mean age was 54.1±12.4 yrs, 38.7 % women and 64.4% Caucasians. The prevalence of VTE was 11.7% (13/111), median time 1.7 months (0.1 to 16.8) with 23.1 % occurring in first 30 days, 69.2% < 3 months and 30.7% > 3 months. Among the recipients with VTE, 84.6% (11/13) received deceased donor and 15.4% live donor transplants. The Mean serum creatinine at the time of VTE was 2.4±1.4mg/dL. A total of 22.5% (25/111) had complications (infection, delayed graft function and/or rejection) and 77.5% (86/111) had no complications. VTE was significantly higher in the group with complication at 32% (8/25) vs 5.8%(5/86) in no complication group (p=0.0014) with Odds ratio of 7.64 (95% CI, 2.2-26.2). VTE was higher in those who received anti-thymocyte globulin (rATG) induction at 23.5% (4/17) vs 10.8% (9/83) with IL-2 RA (p=0.37). Only 38.5% (5/13) of patients with VTE had hypercoagulable work-up with 3 showing protein C and S deficiency.

Conclusions: The prevalence of VTE in RTR was 11.7% in this study and it was significantly higher in those with post-transplant complications with Odds ratio of 7.6. Induction with rATG was associated with higher VTE but not significant mostly due to smaller number. Presence of above mentioned complications should increase the index of suspicion for VTE.

TH-PO1063

Risk Factors in Venous Thrombosis of Renal Grafts from Deceased Non Heart-Beating Donors Maria Molina, Esther Gonzalez Monte, Eduardo Gutierrez, Manuel Praga, Amado Andres. *Nephrology, Hospital 12 de Octubre, Madrid, Spain.*

Background: The deceased donor kidney transplant to non heart-beating may have a higher rate of venous thrombosis.The aim of this study is to analyze whether resistance index (RI) high (≥ 0.8), measured by Doppler ultrasound can be a predictor of venous thrombosis. We also analyzed whether early anticoagulation may decrease graft loss associated with venous thrombosis.

Methods: We analyzed 197 patients with renal transplant non heart-beating donor made since 2005-2012. In November 2009 began prophylactic anticoagulation if RI were elevated. Patients were divided in group I(no anticoagulation historical group) and group II(anticoagulated by RI).

Results: The Table compares the Group I to Group II. In univariate analysis cold ischemia time, body mass index of the donor and high RI were factors that were associated with venous thrombosis of the graft.

Table

	Group I (n =87)	Group II (n = 110)	p
RECIPIENT			
Age (years)	45,78 ± 11,16	50,07 ± 12,06	0,01
Men	56,3%	60,9%	ns
First transplant	94,3%	92,7%	ns
Hyperimmunized	1,1%	0,9%	ns
Mismatch	4,20 ± 1,19	4,67 ± 1,00	0,003
Cold ischemia time (minutes)	872,61 ± 304,57	710,25 ± 276,79	< 0,001
DONOR			
Age (years)	38,36 ± 9,81	47,03 ± 10,86	< 0.001
Men	92%	85,5%	ns
Weight (kg)	85,10 ± 13,85	77,48 ± 11,38	0.001
Creatinine (mg / dl)	1,15 ± 0,35	1,24 ± 0,47	ns
EVOLUTION			
Primary graft function	14,9%	13,6%	ns
Acute tubular necrosis (days)	13,64 ± 5,82	13,86 ± 7,43	ns
Resistance indices in the doppler	0,77 ± 0,11	0,78 ± 0,12	ns
High resistance rates	36,8%	44,5%	ns
Loss of graft	10,3%	6,4%	ns
Anticoagulation	0 %	23,6%	<0,001
Venous thrombosis	6,9%	0%	0,007
Biopsy-proven rejection	16,1%	7,3%	0,06
Receptor survival	98,9%	100%	ns

In multivariate analysis the variable that was associated with venous thrombosis was the prolonged cold ischemia time (0.04).We analyzed the subgroup of 79 patients with high RI, 27 patients were anticoagulated, and none had a venous thrombosis compared with 52 patients who received no anticoagulation, of which 6 had vascular thrombosis (0% vs 11,5% p 0, 07).

Conclusions: This study suggests that a careful choice of donor, reduced cold ischemia time, monitoring of the RI and anticoagulation may decrease the rate of venous thrombosis in in these transplants.

TH-PO1064

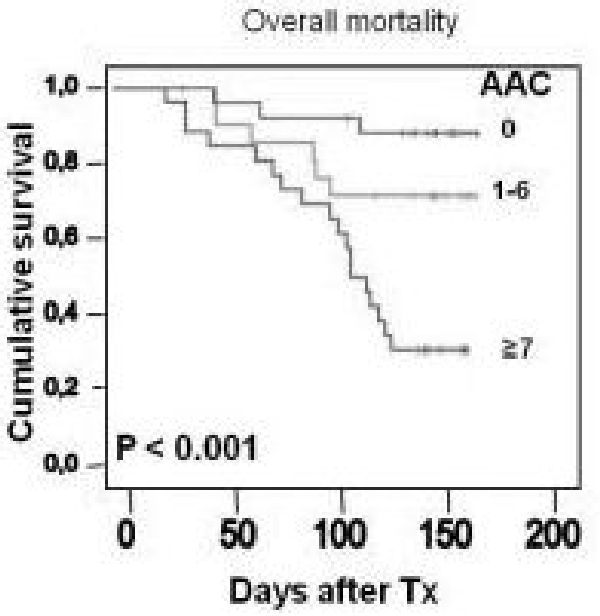
Influence of Abdominal Aortic Calcification on Long-Term Survival in Renal Transplant Recipients

Megan E. Roerink, Henk W. Van Hamersvelt. *464 Nephrology, Radboud University Medical Centre, Nijmegen, Netherlands.*

Background: Despite extensive pretransplant screening, it remains difficult to predict long-term survival in renal transplant recipients. In search for a more accurate method, we tested the predictive value of abdominal aortic calcification (AAC).

Methods: We determined AAC on lateral lumbar radiographs in a cohort of 74 transplant recipients, transplanted between 1997-1999. Radiographs were performed within 3 months of transplantation and were AAC-scores ranging from 0 to 24 using a previously described scoring system. During mean follow-up of 10 years, cardiovascular events (coronary artery disease, cerebrovascular events and peripheral vascular disease) and mortality were recorded.

Results: Mean age in our cohort was 48±13 years. AAC was present in 64% of patients with a mean score of 6. In patients with a AAC-score ≥7 69.2% died compared to 28.6% with a score of 1-6 and 11.1% without calcifications (P=<0.001, figure). Recipients with a high AAC-score had more cardiovascular events (50%) compared to patients with a moderate (29%) or low (26%) AAC-score (P= 0.045). In Cox multivariate analysis, the hazard ratio of each point AAC-score for event-free survival was 1.10 (1.03-1.18, P=0.005). Other factors independently associated with survival were age and diabetes at time of transplantation. The hazard ratio of AAC-score for cardiovascular complications was 1.07(1.01-1.14), with diabetes, cardiovascular medical history and gender as other independent predictors.



Conclusions: The presence of abdominal aortic calcification significantly influences long-term survival and cardiovascular risk in renal transplant recipients and can easily be assessed by lateral lumbar radiography. In future renal transplant recipients, determination of AAC can be used as a tool to predict the risk of long-term complications and survival.

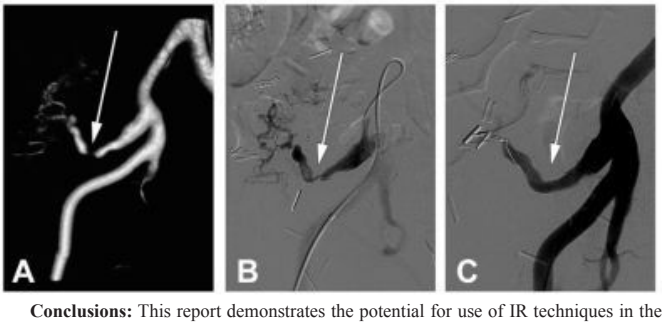
Interventional Management of Late Vascular Complications in Simultaneous Pancreas-Kidney Transplantation: A Case Series of 3 Patients

Kerem Atalar, Jeremy Crane. *Department of Transplantation, Imperial College London, Hammersmith Hospital, London, United Kingdom.*

Background: Simultaneous pancreas-kidney (SPK) transplantation is a highly effective therapeutic option for a subset of patients with diabetes mellitus (DM) and chronic kidney disease, allowing for the restoration of normoglycaemic control and consequent improvements in diabetic complications. Much progress has been made in determining the optimal surgical technique for this procedure, and major advances in immunosuppression have reduced the rate of rejection. As a result, long-term outcomes have continued to improve for all categories of pancreas transplantation. It has been reported that technical failure is the most common cause of pancreatic graft loss in SPK transplants, with immune-mediated rejection being the second most common. The majority of cases of technical failure are due to vascular complications, with graft thrombosis accounting for more than 50% of these cases. There are limited data regarding the use of interventional radiology (IR) techniques in order to prevent vascular complications progressing to graft loss.

Methods: We have recently performed interventional procedures for three patients in whom vascular complications had arisen, comprising two cases of transplant arterial stenosis and one pseudoaneurysm.

Results: In all three cases, vascular patency and optimal graft perfusion were maintained without deterioration in graft function. Figure 1 shows a case in which transplant arterial stenosis (seen with magnetic resonance angiography in (A) and intra-arterial angiography in (B)) was successfully treated with balloon angioplasty and stenting (C). In all cases there were no significant intra- or post-procedure complications.



Conclusions: This report demonstrates the potential for use of IR techniques in the management of graft-threatening vascular complications.

TH-PO1066

Dual Kidney Transplantation without Allocation by Preimplantation Biopsy: A Single Center Experience Alexander Weidemann,[1] Marie-Therese Rotter,[1] Johannes Jacobi,[1] Katharina M. Pressmar,[1] Maike Julia Buettner,[2] Kerstin U. Amann,[2] Kai-Uwe Eckardt.[1] *[1]Nephrology and Hypertension, University of Erlangen-Nuremberg, Erlangen, Germany; [2]Nephropathology, University of Erlangen-Nuremberg, Erlangen, Germany.*

Background: Kidney transplants from expanded criteria donors (ECD) have become generally accepted due to the increasing organ shortage. Dual kidney transplantation (DKT) of marginal kidneys not suitable for single kidney transplantation (SKT) is a possibility to further expand the ECD kidney pool. Still, DKT remains underused and potentially eligible kidneys are often discarded. In order to evaluate whether DKT can be performed savely without allocation by histological scores, we analysed outcomes of DKT in our center and compared them to SKT and to an ideal kidney transplantation (IKT), a living donor kidney transplantation with old donor and recipient.

Methods: In a retrospective analysis 10 DKT and 16 SKT were matched by recipient age, HLA and ischemia time. 13 pts. were in the IKT group. Statistical analyses were performed by one way ANOVA, Chi^2 and student's t-tests.

Results: Donor age and creatinine was significantly higher in DKT compared to SKT and IKT. Patient survival was 100% in all groups. No graft was lost during follow-up in the IKT and DKT group, but one in SKT. No difference in renal function at discharge was observed between DKT and SKT, with a trend towards more delayed graft function in DKT. Best-creatinine in the follow-up period was not significantly different in all three groups. DKT patients had significantly higher incidence of lymphocele and blood transfusions compared to SKT and IKT. However, the duration of hospitalization was not significantly longer. Rejection episodes were lower in DKT compared to IKT and SKT.

Conclusions: Two marginal kidneys allocated by eGFR and careful recipient selection but not histological scores can be performed safely and successfully. Although surgical complications are increased, best creatinine levels in the follow up are not different compared to SKT and to IKT. Although a larger cohort of patients and longer follow up is needed, our results suggest that DKT can be used to transplant kidneys which otherwise might have been discarded.

The Integration of Donor Kidney Function into the Assessment of Post-Transplant Function Identifies Differences between Kidney Transplants from Living versus Deceased Donors Otherwise Not Detectable Riyadh Nasir Alsehli,[1] Scott O. Grebe,[2] Valerie A. Luyckx,[1] Thomas F. Mueller.[1] *[1]Medicine, University of Alberta, Edmonton, AB, Canada; [2]Medicine, University of Witten-Herdecke, Helios Kliniken, Wuppertal, Germany.*

Background: Donor nephron supply has a major impact on post-transplant function. However, measurements of transplant kidney function rely exclusively on recipient creatinine or GFR measurements. We have developed a formula integrating recipient (R) metabolic demand and donor (D) nephron mass to predict the expected post-transplant creatinine (exp R-Cr). Here we compare this formula to the standard measures of kidney function in recipients of deceased (DD) vs. living donor (LD) kidneys, latter known to have better function and outcome.

Methods: We calculated the exp R-Cr based on D and R age, weight, gender, D crea and renal adaptive capacity for recipients of 79 LD and 67 DD kidneys. The exp R-Cr was compared to the observed kidney function as measured by serum creatinine (obs R-Cr) or estimated GFR (Cockcroft Gault, MDRD, CKD-Epi) during the post-transplant course.

Results: The mean period of post-transplant follow-up was 66 months. D and R demographics were similar between the LD and DD groups at time of transplantation. The 4 year graft survival rates were 96% and 88% for the recipients of LD vs. DD kidneys, resp. Transplant function measured by Cr, CG, MDRD or CKD-Epi was similar between LD and DD recipients. However, calculating the exp R-Cr vs. the obs R-Cr demonstrated a significant difference between LD and DD kidney function (p<0.01). As shown in table 1 DD organs function about 40 % less than expected compared to about 10 % less function in LD organs.

Transplant function in LD vs. DD kidneys

	D-Cr [umol/L]	R-Cr y1 [umol/L]	R-Cr y4 [umol/L]	exp R-Cr [umol/L]	exp-obs R-Cr y1 [%]	exp-obs R-Cr y4 [%]
LD [n=79]	72	127	122	120	-14	-11
DD [n=69]	68	120	126	99	-41	-47
p-value	n.s.	n.s.	n.s.	0.004	0.004	0.002

Conclusions: The integration of donor kidney information into the assessment of post-transplant function detects poorer function of DD organs that is missed by the conventional measurements.

Acceptable Patient and Allograft Outcomes Can Be Achieved Using Expanded Criteria Donors for Re-Transplantation Janani Rangaswami,[1] Po Nan Chang,[2] Mahbub Jamil,[1] Campos Stalin,[1] Kamran Khanmoradi,[1] Radi Zaki,[1] Afshin Parsikia,[1] Jorge Ortiz.[1] *[1]AEMC; [2]Drexel University.*

Background: Extended criteria donors (ECD) are an important means of expanding the donor pool. Data on outcomes using ECD kidneys in patients with a history of a failed allograft are limited.

Methods: We compared three groups. 1) patients who were transplanted with ECD kidneys after a history of failed allograft (ECD re-transplant), 2) patients who were transplanted with Standard criteria donor (SCD) kidney after failed allograft (SCD re-transplant). 3)First time ECD transplant recipients. We generated Kaplan Meier curves for patient and allograft survival at 1 and 3 years using the log rank test. We ran a Cox Proportional Hazards regression model to evaluate the effects of delayed graft function(DGF), BMI, HTN, DM, donor age, and cold ischemia time(CIT) on survival.

Results: There were 19 ECD re- transplants, 95 SCD re- transplants and 169 first- time ECD transplants. 1 year patient survival was 88.6%, 97.5%, 87.8%,in, re-ECD, re-SCD, first ECD groups. 3 year patient survival was 73%, 95%, 74%. 1 and 3 years patient survival between the 3 groups was statistically different (P-value=0.0265and 0.0006 respectively). 1 year graft survival was 94.5%, 94.6%, 88% for the re-ECD, re-SCD, first ECD group respectively. 3 year allograft survival was 79.4% and 79.6%, 75%. Graft survival at 1 and 3 years was not statistically different (P-value=0.1952and 0.6228 respectively). One and 3year patient and allograft survival was not statistically significant between first ECD vs re ECD. The Cox regression model showed that differences in DGF, BMI, race, DM, HTN, donor age and CIT, were not statistically significant (p-value > 0.05).

Conclusions: 1 and 3 years patient survival was best in the re-SCD group. There was no difference in allograft survivals between the three groups.ECD patient and allograft survivals are similar to established norms. Re-ECD patient and allograft survivals are statistically similar to ECD transplants. Therefore, re-ECD represents an appropriate option for patients awaiting a second transplant.

TH-PO1069

Role of Donor Glomerula Filtration Rate & Recipient Body Mass Index on Outcomes of Cadaver Renal Transplantation Kadiyala V. Ravindra, William Irish, Anthony W. Castleberry, Deepak S. Vikraman, Matthew Jay Ellis, Debra L. Sudan. *Surgery, Duke Univerisity, Durham, NC.*

Background: There is scant data on role of recipient BMI (rBMI) on outcomes of deceased donor renal transplants. This has particular relevance with increased use of ECD organs. Aim: To assess role of donor GFR & recipient BMI on graft survival in cadaver kidneys using OPTN/UNOS registry.

Methods: Adult recipients of primary, solitary, kidney from cadaver donor (2002-'10) were studied. GFR was calculated with MDRD equation. The groups were: eGFR: >90, 60-90 and 30-59 & rBMI: <25, 25 – 29, 30-34 and ≥35. Graft survival was estimated by Kaplan-Meier method. Impact of donor eGFR & recipient BMI on graft failure was assessed with Cox's proportional hazards model. Hazard ratios and 95% confidence intervals were used as measures of association and precision. Effect modification was assessed by incorporating relevant two-way interactions into model.

Results: Study patients (n=54,600) were mean age 53 years, 61% male, 32% Black, median follow-up of 4 years. Of these, 22% received ECD organs. Graft survival at 4-years was 78 ± 0.2% in SCD and 66 ± 0.5% in ECD. Multivariable results of donor eGFR and rBMI on risk of graft failure are in Table 1. The impact of donor eGFR was independent of recipient and donor BMI (p=0.591 and p=0.897) and ECD (p=0.483). Also, impact of rBMI was independent of donor BMI (p=0.458) and ECD (p=0.199).

Table 1: Impact of donor eGFR and recipient BMI on graft failure and evaluation of effect modification

Effect	HR*	95% CI	p-value
Donor eGFR Group(ref=>90)			
60-90	1.08	1.12	<0.0001
30-59	1.17	1.12-1.22	<0.0001
Recipient BMI(ref=<25)			
25-29	1.07	1.03-1.12	0.0008
30-34	1.15	1.10-1.20	<0.0001
>=35	1.27	1.19-1.34	<0.0001

* Adjusted for donor BMI, ECD vs. SCD kidneys and peak PRA & immunosuppression at discharge

Conclusions: Recipient BMI and donor eGFR are both independently&significantly associated with risk of graft failure following deceased donor kidney transplantation. This has implications for emphasizing weight reduction prior to deceased donor renal transplantation. Matching donor eGFR to recipient may help to improve long-term prognosis of kidney transplant recipients.

TH-PO1070

Donor Age >45 Years Is Associated with Poor Outcomes Following Donation after Cardiac Death (DCD) Kidney Transplantation Hani Wadei,[1] Michael Heckman,[2] Bhupendra Rawal,[2] Martin L. Mai,[1] Waleed Farahat,[1] Cynthia Leaphart,[1] Mary B. Prendergast,[1] Thomas A. Gonwa.[1] *[1]Transplantation, Mayo Clinic, Jacksonville, FL; [2]Biostatistics, Mayo Clinic, Jacksonville, FL.*

Background: Kidney transplantation (tx) from DCD donors confers similar patient and graft survivals compared to tx from brain dead donors (DBD). However, information regarding kidney function in DCD tx is lacking.

Methods: Included were 64 DCD and 248 DBD kidney tx performed between 11/2000 and 9/2008. Living donor, extended criteria tx, multi-organ and dual kidney tx were excluded. Recipients, donors and tx characteristics were retrospectively collected and compared between DCD and DBD. Iothalamate GFR was measured annually. The primary outcome was the cumulative incidence of poor graft function defined as graft loss, death, or 2 consecutive GFR<50 ml/min within 5 years from tx.

Results: Patients' characteristics are presented in **Table 1**

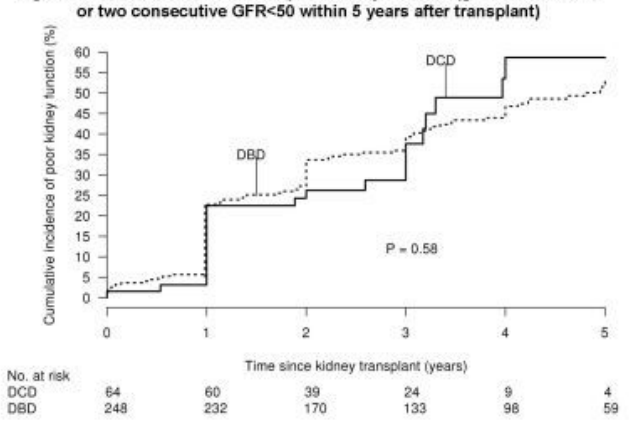
Table 1:Recipient, donor and transplant characteristics in DCD and DBD

	DCD (N=64)	DBD (N=248)	P
Median age at tx (yrs)	56	57	1
% male	62	57	0.5
% Pre-tx diabetes	19	27	0.3
% Preemptive tx	16	10	0.3
Median CIT (hr)	16	19	0.002
Median WIT (min)	43	44	0.3
Median donor age	30	36	1
% DGF	45	28	0.01
% rejection	33	25	0.3

CIT: cold ischemia time; WIT: warm ischemia time; DGF: delayed graft function

142 (46%) experienced the primary outcome. There was no difference between DCD and DBD regarding the primary outcome (RR: 1.14,CI:0.7–1.8,P=0.58) **Figure1**

Figure 1: Cumulative incidence of poor kidney function (graft loss, death, or two consecutive GFR<50 within 5 years after transplant)



Of the 64 DCD tx, 25 (39%) experienced the primary outcome. On multivariate analysis, donor age was the only factor that related to the outcome in DCD tx (RR:1.64 (per 10-yr increase),CI:1.2-2.3,P=0.005) with the highest risk observed for donor age >45 years (RR:5.27,CI:2.2–12.5, P<0.001).

Conclusions: 1) Outcomes are similar between DCD and DBD kidney tx. 2) Donor age >45 yrs is associated with poor graft function in DCD kidney tx.

TH-PO1071

Validation of the CKiD Bedside Formula as eGFR in Children Post Renal Transplant

Khurrum Siddique,[1,2] Leisa Borders,[2] Mouin Seikaly.[1,2]
[1]Pediatric Nephrology, UT Southwetern Medical Center, Dallas, TX; [2]Pediatric Nephrology, Children's Medical Center, Dallas, TX.

Background: Serum creatinine (S_{Cr}) and S_{Cr} based formulae are used as markers to estimate glomerular filtration rate (eGFR) following renal transplantation. It has been recognized that such formulae are inaccurate. Recently the Chronic Kidney Disease in Children (CKiD) study reported a "bedside formula" to eGFR in non-transplanted children (CKID-BS= 0.412 x ht/S_{Cr}). The objective of our study is to validate the CKiD-BS to eGFR in children post-renal transplant.

Methods: Plasma disappearance of ^{125}I-iothalamate was used to measure GFR (C_{IO}). Data collected included: patient demographics, diagnosis, height, weight, S_{Cr}, serum albumin (S_{alb}) and BUN. Multiplicative models of C_{IO} were fit by regressing log C_{IO} on log-transformed covariates using mixed linear regression to account for correlation among repeated measurements within patients. Sensitivity and specificity of estimates for predicting C_{IO} < 90 mL/min /1.73 m^2 were evaluated at the nominal level.

Results: 220 C_{IO} studies were performed on 123 post-transplant renal patients. Mean age at C_{IO} was 13.8 ± 4.6 (age range: 2.7-20.8 years). CKiD-BS underestimates C_{IO} in our cohort by an average of 11% with underestimates exceeding 20% at high GFR. K in the CKiD-BS was recalibrated (eGFR= 0.461 x ht/S_{Cr}) in post-transplant children (R-Bedside). We also developed a GFR model = 10.73 x (ht)$^{0.51}$ /(S_{Cr})$^{0.90}$ x (BUN)$^{0.23}$ (GFR-M). Incorporating gender, ethnicity and S_{alb} did not affect the predictive value of our GFR model. In eGFR in <90 ml/min/1.73m^2 range, our GFR-M shows the highest specificity at 55.6% compared to 22.2% for CKiD-BS formula. Sensitivities of both estimates were similar (98.9% and 94.9% respectively).

Conclusions: Our R-Bedside formula, although more accurate than CKiD-BS, has the same diagnostic performance, the two differing only by a multiplicative factor. Our GFR-M did outperform the CKiD-BS by achieving higher specificity. Despite continued refinement, formulae to eGFR remain inaccurate and complex for clinical use. GFR measurement remains the gold standard in estimating renal function in children with renal transplant.

TH-PO1072

CKD-EPI GFR Estimating Equations in Kidney Transplantation: Which Added Value for the New Cystatin C-Based Equation?

Ingrid Masson,[1] Nicolas Maillard,[1] Pierre Delanaye,[2] Nassim Kamar,[3] Christopher R. Mariat.[1]
[1]Renal Dpt, University Hospital, Saint-Etienne, France; [2]Dialysis Dpt, University Hospital, Liege, Belgium; [3]Transplantation Dpt, University Hospital Toulouse, Toulouse, France.

Background: The absence of a standardized measurement for serum cystatin C (Scyst) has hindered a thorough evaluation of Scyst to predict GFR in renal transplantation. We took advantage from the recent validation of a reference calibrator for Scyst and from the re-expression of the CKD-EPI Scyst-based equations to reassess its role as a biomarker of renal graft function.

Methods: We studied (i) the relationship of Scyst and Screat with inulin clearances performed in 670 stable transplant patients, (ii) the influence of non-GFR determinants upon Scyst concentration, and (iii) compared the performance of the CKD-EPI Scyst-based equations with that of the CKD-EPI serum creatinine (Screat) equation.

Results: Scyst level alone was significantly superior to Screat to discriminate patients at different GFR thresholds with ROC AUC superior to 0.90. The non-GFR determinants independently associated to Scyst were BMI, gender, proteinuria and CRP. As compared to the CKD-EPI Screat equation, the Scyst CKD-EPI equations performed better. However they did not significantly ameliorate the classification of patients across CKD stages nor the detection of patients with severe dysfunction defined as an inulin < 20.

Our data do not support implementation of Scyst for the evaluation of renal graft function in clinical practice. However, given (i) that Scyst remains a better endogenous GFR marker than Screat in transplant patients and (ii) that the non GFR determinants of Scyst are also well-defined cardiovascular risk factors, Scyst might be a surrogate for cardiovascular complications after transplantation.

Conclusions: In conclusion, while offering a better GFR estimation, Scyst equations have limited clinical added value. The possibility of using Scyst not solely as a GFR predictor but rather as a predictor of patient outcome should however stimulate further research in renal transplantation.

TH-PO1073

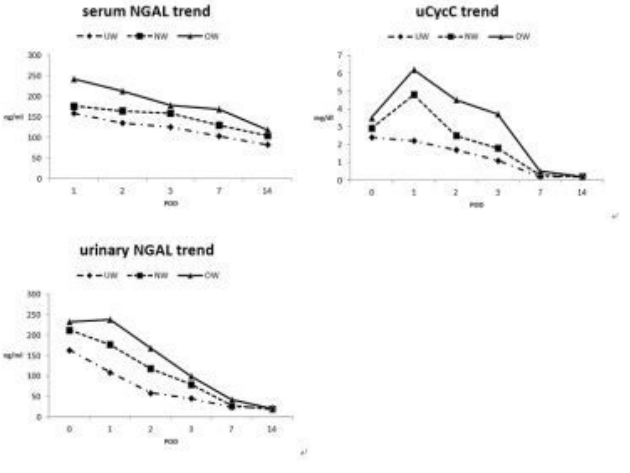
NGAL and Cystatin C Elevations Were Associated with Short-Term Graft Function in Over Weight Recipients after Kidney Transplantation

Junko Kohei, Shunji Shiohira, Ken Tsuchiya, Kosaku Nitta. *Fourth Department of Internal Medicine, Tokyo Women's Medical University, Shinjuku, Tokyo, Japan.*

Background: Recent studies have shown that pre-transplant over weight (OW) and obesity has no significant impact on long-term post-transplant outcomes comparing with normal weight (NW) recipients. On the other hand, it still has been reported opposite results that obesity has influenced on short-term graft function, graft survival and mortality. We studied that whether pretransplant body mass index (BMI) influenced short-term graft function or not immediately after kidney transplantation by measuring biomarkers.

Methods: This study was prospective, single-center study of living-donor kidney transplant patients. We collected serial urine and blood specimens first 6 hours and 1,2,3,7,14 postoperative days and examined concentration of serum and urinary neutrophil gelatinase-associated lipocalin (NGAL), urinary interleukin 18 (IL-18), urinary liver-type fatty acid binding protein (L-FABP), urinary cystatin C(uCysC), urinary N-acetyl-β-D-glucosaminidase (NAG).Patients were divided into three groups, UW (Under Weight:BMI<20kg/m^2), NW(BMI20-24.9kg/m^2) and OW(BMI>25 kg/m^2) by pretransplant BMI.

Results: In the results, 35 patients were in UW, 37 were in NW, and 19 were OW group, only two cases in OW were slow graft function. UCysC, Serum and Urinary NGAL in OWhad remained the highest for over a week, it suggested that association with short-term graft function. Other biomarkers did not show any significant differences among the three groups.



Conclusions: This is a first report showing an correlation of BMI and short-term graft function.Kidney injury immediately after kidney transplantation is difficult to diagnose with only serum creatinine, therefore this research has a high possibility of helping to diagnose delayed graft function in the postoperative early stage.

TH-PO1074

Predictive Value of Contrast Enhanced Sonography in the Early Period after Kidney Allograft Transplantation Lars Kihm, Joerg Seckinger, Christian Morath, Claudia Sommerer, Martin G. Zeier, Vedat Schwenger. *Nephrology, University of Heidelberg, Heidelberg, Germany.*

Background: Real-time contrast-enhanced sonography (CES) can assess microvascular tissue perfusion using gas-filled microbubbles. The study was performed to evaluate the feasibility of CES in predicting early allograft function in comparison to color Doppler ultrasonography (CDUS).

Methods: A total of 50 consecutive renal transplant recipients were prospectively studied using CES and conventional CDUS investigation at day 7 post transplant. Transplant tissue perfusion imaging was performed by low-power imaging during intravenous administration of the sonocontrast Sonovue™. Renal tissue perfusion was assessed quantitatively using flash replenishment kinetics of microbubbles to estimate renal blood flow A *ß (A = peak signal intensity, ß= slope of signal intensity rise). The obtained sonography values were correlated with clinical selected data on day 7, 90 and 365 in the post-transplant period.

Results: In contrast to conventional CDUS resistance and pulsatility indices, renal blood flow estimated by CES at day 7 post transplant was significantly related to kidney allograft function at day 90 ($r = 0.81$, $p < 0.001$) and day 365 ($r = 0.74$, $p < 0.001$). An estimated renal blood flow of A *ß > 11.2 dB/s was able to predict a GFR of above 45ml/min one year after kidney transplantation with high specifity and sensitivity. Determination of renal blood flow by CES revealed a significant correlation to donor age ($r = -0.55$, $p < 0.001$) but not recipient age, whereas conventional CDUS resistance index was significantly related to recipient age ($r = 0.49$, $p < 0.001$) but not donor age.

Conclusions: This is the first prospective study demonstrating the prognostic value of CES early after kidney transplantation. In contrast to CDUS, CES reveals information of kidney allograft perfusion independent of the recipients vasculature.

TH-PO1075

Early-Onset Anemia after Transplantation Is an Independent Risk Factor for Graft Loss in Renal Recipients Julio Pascual,[1] Manuel Arias,[2] Josep Maria Campistol Plana,[3] J. Grinyo,[4] Domingo Hernández,[5] J. Morales,[6] Luis M. Pallardo,[7] Daniel Seron.[8] *[1]H.Mar, Barcelona, Spain; [2]H.U.Marqués Valdecilla, Santander, Spain; [3]H.Clínic, Barcelona, Spain; [4]Ciutat Sanit. Bellvitge, Hospitalet, Spain; [5]H.Carlos Haya, Málaga, Spain; [6]H.12 Octubre, Madrid, Spain; [7]H.U.Dr. Peset, Valencia, Spain; [8]H.Vall Hebron, Barcelona, Spain.*

Background: Our aim was to explore the relationship between post-transplant anemia and graft survival after renal transplantation(RT).

Methods: Multicenter, retrospective, observational study in patients(pts) with RT in 2007 in Spain who were followed up until 3 years(y), graft loss or death. We used multivariate Cox regression to predict death-censored graft survival.

Results: We included 675 pts (65% male, mean(SD) age 52(13)y, 7% PRA>10%, donor age 51(15)y and 57% of donors with stroke); 17% suffered acute rejection(AR) and 10% lost their graft. The prevalence of post-RT anemia (hemoglobin[Hb]<11 g/dL and/or treatment with erythropoietin[EPO] and/or transfusion) over time was: 84% at 7 days(d), 76% 14d, 59% 1 month(m), 41% 2m, 34% 3m, 26% 6m, 16% 12m, 14% 2y, 18% 3y. Anemia at 1m was the most strongly associated to evolution of graft function. MDRD-GFR at 14d in subgroups defined by anemia at 1m was: 22(15)ml/min in untreated anemics (Hb<11g/dl without EPO,n=60), 25(18)ml/min in anemia non-responders (Hb<11g/dl with EPO,n=134), 35(19)ml/min in anemia responders (Hb≥11 g/dl with EPO,n=176) and 45(19) ml/min in non-anemics (Hb≥11g/dl without EPO,n=253). By 2m, pts with Hb<11g/dl at 1m (with or without EPO) had still a lower renal function than non-anemics. After adjusting by change in MDRD-GFR between 14d-2m (hazard ratio[HR](95%CI) 0.97(0.95-0.99) for each +1ml/min,p=0.02), untreated or non-responding anemia at 1m remained as an independent predictor of graft loss (HRs 4.6(0.98-21.8) and 3.9(1.1-13.6) for Hb<11 without or with EPO, respectively vs Hb≥11 without EPO[ref.];p=0.05/0.03), along with a PRA>10% (HR 3.3(1.1-10.0),p=0.04), a donor with stroke (HR 3.4(1.1-10.5),p=0.04) and >1 AR (HR 6.6(1.2-35.4) vs no AR,p=0.03).

Conclusions: In RT recipients, untreated or non-responding anemia at 1m seems to be an independent risk factor for graft failure.

Funding: Pharmaceutical Company Support - Amgen, S.A.

TH-PO1076

Independent Risk Factors for the Development of Urinary Tract Infection (UTI) in 1175 Renal Transplant Recipients and the Relationship between UTI with Bacteremia, Acute Cellular Rejection, and Allograft Function in the First Year of Transplantation John R. Lee, Thangamani Muthukumar, Manikkam Suthanthiran. *Nephrology and Hypertension, Weill Cornell Medical College, New York, NY.*

Background: UTI is the most common infection in renal transplant recipients and earlier studies have been limited in size and scope. Herein, we examined risk factors for the development of UTI and its impact in 1175 consecutive renal transplant recipients.

Methods: We reviewed the records of 1175 transplant recipients who underwent renal transplantation from 2005 to 2010 for the development of UTIs, defined as greater than 10^4 cfu/mL, within the first three months of transplantation. We collected demographical data and performed logistic regression analyses to identify independent risk factors for the development of UTIs. We also evaluated the following outcomes: bacteremia within 3 months, acute cellular rejection (ACR) within 1 year, and eGFR at 1 year.

Results: 583 of 1175 transplant recipients (49.6%) developed an episode of UTI. In a multivariable logistic regression, the independent risk factors for development of UTIs were: female gender (Odds Ratio [OR]:4.9,P<0.001), age > 65 years (OR:1.9,P<.001), stent placement (OR:1.5,P=.002), and lack of bactrim prophylaxis (OR:2.1,P=.030). Type of intra-operative antibiotic prophylaxis, type of induction therapy, and steroid utilization were not significantly associated with UTI development. Bacteremia within 3 months was strongly associated with UTIs (7.2%[UTI group] vs. 2.2%[no UTI group], p<.001). At 1 year, ACR and eGFR were not significantly different between transplant recipients with UTI and those without UTI (ACR: 6.3%[UTI] vs. 5.9%[no UTI],p=.112) (eGFR: 51.0 mL/min/1.73m^2[UTI] vs. 51.6 mL/min/1.73 m^2[no UTI],P=.636).

Conclusions: Independent risk factors for the development of UTI include female gender, age > 65 years, stent placement, and lack of bactrim prophylaxis. UTI was associated with bacteremia within 3 months but not associated with ACR or decline in renal function at 1 year. Prevention of bacteremia, a serious transplant complication, may warrant further studies on antibiotic prophylaxis targeting a population at high risk for UTI.

TH-PO1077

The Impact of Early and Late Acute Rejection on Graft Survival in Renal Transplantation Min Su Kim,[1] Eun Hee Koo,[1] Hye Ryoun Jang,[1] Jung Eun Lee,[2] Yoon-Goo Kim,[1] Dae Joong Kim,[1] Ha Young Oh,[1] Wooseong Huh.[1] *[1]Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea; [2]Joslin Diabetes Center, Boston, MA.*

Background: Previous studies investigated whether the timing of acute rejection (AR) episode influences long-term graft survival after kidney transplantation and showed that late acute rejection (LAR) has a detrimental impact on long-term graft survival compared to early acute rejection (EAR). We evaluated whether EAR or LAR influences graft survival or patient survival, and analyzed risk factors for EAR and LAR.

Methods: We performed a retrospective cohort study including 1126 patients who received kidney transplantation between Feb 1995 and Dec 2009 at Samsung Medical Center. Patients who were under 18 years of age or had multiple organ transplants (e.g. kidney and liver or kidney and pancreas) or had primary non-functioning allografts were excluded. All patients were divided into 3 groups: no rejection, EAR, or LAR. EAR and LAR were defined as rejection before 3 months and after 3months, respectively. Differences in graft survival and patient survival among the 3groups were analyzed.

Results: Of the total 1067 patients, 278 patients (26.1%) had biopsy- proven AR. EAR and LAR developed in 142 patients (51.1%)and 136 patients (48.9%), respectively. Further, 789 patients had no rejection episode (73.9%). Initial immunosuppression regimen was different between EAR and no rejection group. Donor recipient relationship was different from EAR and LAR group as compared to no rejection group. Recipients with EAR were more likely to be male compared to the no rejection group (P= 0.000). EAR and LAR primarily had older donors than no rejection group (P=0.000, P=0.002 respectively). There was no difference in patient survival among the 3 groups. And there was no difference between EAR and LAR in overall graft survival (P= 0.207) and patients survival (P=0.972).

Conclusions: There were no differences in graft survival and patient survival between EAR and LAR. AR, regardless of its timing, significantly worsened graft survival. A treatment targeted at reducing the incidence of AR and improving the prognosis is needed.

TH-PO1078

Long-Term Graft Outcome in a Large Cohort of Renal Transplant Recipients with Protocol Biopsies Wilfried Gwinner,[1] Irina Scheffner,[1] Tanja Abeling,[1] Jan U. Becker,[1] Verena Broecker,[3] Michael Mengel,[2] Hans H. Kreipe,[1] Anke Schwarz,[1] Hermann G. Haller.[1] *[1]Hannover Medical School, Germany; [2]University of Alberta, Canada; [3]University of Cambridge, United Kingdom.*

Background: This study examines renal graft losses over a period of up to 10 years in patients (pts) with protocol biopsies (pBx) (total observation: 4805 pts-years).

Methods: 529 male and 363 female pts with a kidney (or kidney+other solid organ) transplantation (Tx) between 2000-2007 were included. pBx were taken at 6 weeks (n=738), 3 (n=776) and 6 months (n=737) post-Tx. 862 biopsies for cause were taken within the first year and 262 thereafter. Lost-to follow-up was negligible (n=15).

Results: Patient and graft survival was 80% at 5 years and 68% at 10 years. Graft survival was 88% at 5 years and 82% at 10 years. Graft loss occurred in 119 pts and was related to acute rejection (26%), chronic rejection (5%), non-specified function decline (19%), infection (8%), recurrent GN (3%), primary marginal function (14%). Graft losses were less frequent in living-donor or combined kidney/pancreas Tx and more frequent in extended donor criteria-Tx. After correcting for potential confounding by these factors, the following variables were related to graft loss: higher donor's age & S-creatinine, pre-formed antibodies, delayed graft function, lower GFR within first 6 weeks, cardiovascular disease and higher body mass index. In pBx, BANFF IA/B rejections were more frequent in pts with graft loss compared to pts without graft loss (0.31 vs 0.17/patient). In biopsies for cause, frequencies for borderline rejections (0.36 vs. 0.19), BANFF IA/B rejections (0.39 vs. 0.13) and BANFF IIA/B rejections (0.32 vs. 0.05) were higher in pts with graft loss, as well as signs for humoral rejection (glomerulitis/±c4d: 0.40 vs. 0.06, peritubular capillaritis/±c4d 0.16 vs. 0.05).

Conclusions: Donor-derived organ quality, recipient's cardiovascular disease and immune-mediated injury remain as important challenges to improve the long-term outcome of renal Tx pts. Immune-mediated injury/inflammation is clearly increased in protocol biopsies from pts with graft failure.

Long-Term Patient Outcome in a Large Cohort of Renal Transplant Recipients with Protocol Biopsies Wilfried Gwinner,[1] Tanja Abeling,[1] Irina Scheffner,[1] Jan U. Becker,[1] Verena Broecker,[2] Michael Mengel,[3] Hans H. Kreipe,[1] Anke Schwarz,[1] Hermann G. Haller.[1] *[1]Hannover Medical School, Germany; [2]Cambridge University, United Kingdom; [3]University of Alberta, Canada.*

Background: This study examines the deaths over a period of up to 10 years in renal transplant (Tx) patients (pts) with protocol biopsies (pBx) (total observation: 4805 patient-years).

Methods: 529 male and 363 female pts with a kidney Tx (or kidney+other solid organ) between 2000-2007 are included. pBx were taken at 6 weeks (n=738), 3 (n=776) & 6 months (n=737) post-Tx. 862 biopsies for cause were taken in the 1st year and 262 thereafter. Lost-to follow-up was negligible (n=15). Subclinical & clinical acute rejections and clinical borderline rejections in pBx were treated.

Results: Patient and graft survival was 80% at 5 years and 68% at 10 years. Patient survival was 92% at 5 years and 82% at 10 years. 98 deaths occurred, relating to infection (24%), cardiovascular disease (15%), malignancy (16%), other specified causes (8%); 37% were unclear. Deaths were less in living-donor and kidney/pancreas Tx and more frequent for extended donor criteria-Tx. After correcting for potential confounding by these factors, the following variables related to death: higher age, prolonged cold ischemia time, delayed graft function, lower GFR in the first 6 weeks, HLA-DR mismatch, cardiovascular disease, diabetes mellitus. In pts who died, cellular and humoral rejections in pBx were as frequent as in survivors. In biopsies for cause, BANFF IA/B acute rejections were more frequent in pts who died, with 0.18 rejections/patient compared to 0.13 in survivors. Signs for humoral rejection (glomerulitis/peritubular capillaritis, ±c4d) were more often seen in pts who died (0.16 vs. 0.11). The proportion of anti-rejection treatments/increase in the maintenance immunosuppression was not higher in pts who died from infections or malignancies, compared to pts dying from other causes.

Conclusions: Inferior graft function is related to death, besides the classical risk factors age, cardiovascular disease and diabetes mellitus. Increased treatment of rejections detected in pBx apparently does not lead to fatal malignancy or infectious complications.

TH-PO1080

Long Term Outcomes of Kidney Transplantation in Patients above Age 70: A Single Center Experience Samia Sheikh, Tim E. Taber, Muhammad Ahmad Mujtaba, Dennis P. Mishler, William Goggins, Asif A. Sharfuddin, Muhammad S. Yaqub. *Indiana University School of Medicine/ IU Health, Indianapolis, IN.*

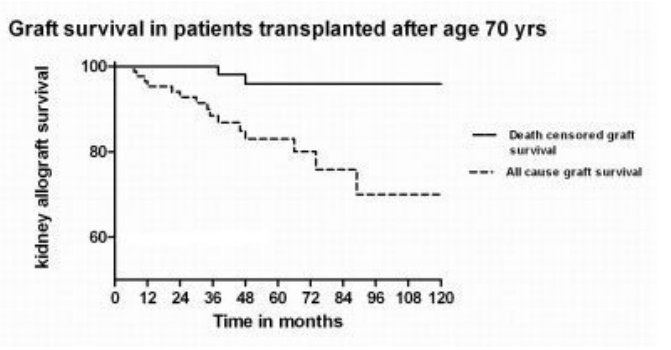
Background: Over the last decade elderly patients (70 yr and older) are the fastest growing ESRD group requiring renal replacement therapy. With its increasing success, kidney transplantation has been offered to a growing number of elderly patients.

Methods: To evaluate our institutional outcomes of geriatric renal transplants over a 10 year period and examine graft and patients survival rates with respect to both living and deceased donor kidney transplants in patients aged more than 70 years. Retrospective chart review from clinical database from 2001- 2010 of recipients who were age 70 or above at the time of kidney transplant. Baseline characteristics are in table 1.

Baseline Charecteristics n= 86

Mean age	76.1±3.6
Age 70-75	55 (64%)
Age > 75	33 (36%)
Male	53 (61%)
White	71 (82%)
Blacks	9 (10%)
Deceased Donor	67 (77%)
ESRD Cause	
HTN	29 (33%)
DM	17 (19%)
GN	19 (22%)

Results: Mean age was 76.1± 3.1. Mean follow up was 54± 29.7 months. Death with functioning graft was the most common reason for graft loss. 1 and 5 yr graft survival were 95 and 83% respectively. 1 and 5 yr patient survival were 95 and 89% respectively. Rejection rate was 8% at 1 year. SCr was 1.334± 0.48 at 1 yr and 1.26 ± .48 at 5 years. There was no significant difference in patient and graft survival in recipients between age 70 to 75 and above 75 years.



Conclusions: With careful selection elderly recipients above age 70 have excellent patient and graft survival.

TH-PO1081

Very Long Term Survivors of Kidney Transplantation Carol A. Traynor, Patrick O'Kelly, Peter J. Conlon. *Nephrology and Transplantation, Beaumont Hospital, Dublin 9, Ireland.*

Background: There have been few studies of patients with renal allografts functioning for more than 30 years. We sought to identify clinical factors associated with 30 year renal allograft survival and to determine the prevalence of comorbidities in these patients.

Methods: The National Renal Transplant Database was retrospectively analysed. All kidney transplants (n=349) between 1st January 1970 and 31st August 1981 were included. Data extracted included baseline recipient and donor demographic data, and occurrence of acute rejection. Follow up analysis was until August 1, 2011. Patients charts were reviewed and data regarding comorbidities was recorded.

Results: During the study period, there were 349 transplants in 324 patients. Of these, 44 patients (12.6%) had a renal transplant functioning for in excess of 30 years. Table 1 compares the characteristics between those who had a functioning kidney transplant for in excess of 30 years (survivors) to those whose transplant functioned for less than 30 years (non survivors). Those with a transplant functioning for in excess of 30 years were more likely to be younger, have fewer HLA mismatches and have a living related donor. Acute rejection occurred in 60.6% of non survivors and 48.7% of survivors (p=0.157).

Median creatinine was 102 µmol/L (range 66-386µmol/L).

The prevalence of ischaemic heart disease, skin malignancy and other malignancy was 13.6%, 45.4% and 18% respectively.

Baseline Demographics of Patients

Variable	Non Survivors (n=280)	Survivors (n=44)	p value
Recipient age (years)	35.0+/-11.6	28.4+/-10.1	<0.001
Donor age (years)	27.8+/-15.3	25.7+/-10.1	0.940
Recipient gender (male)	67.2%	63.6%	0.638
Donor gender (male)	62.9%	51.3%	0.160
Cold ischaemia time(hours)	11.1+/-5.0	11.1+/-6.1	0.794
No. of HLA mismatches(mean)	1.36+/-1.2	0.26+/-0.75	<0.001
Living donor	12.5%	52.3%	<0.001

survivors=single functioning transplant for 30 years

Conclusions: We identified important clinical factors associated with very long term transplant survival. These results highlight the importance of promoting the use of a living donor. We also identified a high incidence of cancer emphasising the need for continued close surveillance of these patients following their prolonged exposure to immunosuppression.

Rejection Is Comparable in Matched African- and Caucasian-American Recipients of Kidney Transplants with Lupus Gabriel Contreras, Hua Li, Roque A. Diaz-Wong, Tamara Isakova, Leonardo Tamariz, Adela D. Mattiazzi, Giselle Guerra, Amna Ilahe, Yoel Brito, Warren L. Kupin, David Roth, Myles S. Wolf. *Medicine, University of Miami Miller School of Medicine/Jackson Memorial Hospital, Miami, FL.*

Background: African-American recipients of a kidney allograft with lupus have high prevalence of predictors for rejection, which can explain their poor outcomes.

Methods: Of 1627 African- and 1869 Caucasian-Americans who received kidney transplants between 1987 and 2006 with complete UNOS records, a cohort of 780 pairs of recipients were matched in 16 baseline predictors employing a predicted probability of group membership based on observed predictors obtained from a multivariable logistic regression model. Primary outcome was rejection. Secondary outcomes were delayed graft function, mortality, and composite of allograft failure or mortality.

Results: The matched pairs were predominantly female recipients (82.6%) with a mean age of 39.2±11.3 years. 91.4% recipients received kidneys from deceased donors with 23.3% from expanded criteria donors. African- and Caucasian-Americans matched well (P>0.05): recipient age, gender, education and insurance; donor age, gender and race; and the predictors of need of dialysis prior to transplant, kidney from expanded criteria donor, cold ischemia time, history of prior kidney transplant, panel reactive antibodies, HLAs mismatch, ABO blood type compatibility and transplant Era. Only donor type was significantly different between both groups (deceased donor 89.9% vs. 93%, p=0.03).

Contrary to the unmatched groups with significantly higher rejection events in African-compared to Caucasian-Americans (39.9% vs. 34.4%, p=0.0007), matched pairs had similar rejection events (38.3% vs. 36.8%, p=0.53). Matched pairs had similar delayed graft function (23.1% vs. 20.6%, p=0.24), and mortality (13.3% vs. 15.8%, p=0.17), but different composite event of allograft failure or mortality (43.5% vs. 38.5%, p=0.04).

Conclusions: In lupus recipients of kidney allograft, African- and Caucasian-Americans have similar incidence of rejection when predictors are matched between groups.

Renal Phosphate Handling and Long-Term Outcome after Kidney Transplantation Leandro Cunha Baia,[1] Stephan J.L. Bakker,[1] Marc G. Vervloet,[2] Gerjan Navis,[1] Martin H. De Borst.[1] *[1]Nephrology, University Medical Center Groningen; [2]Nephrology, VU-MC, Amsterdam, Netherlands, for NIGRAM.*

Background: In the first year after kidney transplantation (Tx) a renal phosphate leak frequently develops due to persistently elevated FGF23 and PTH levels. Whether this leak persists >1 year after Tx for a Western population and whether this has consequences for patient or graft survival is unknown.

Methods: Serum phosphate, fractional phosphate excretion (PE) and TmP-GFR were determined in 598 stable kidney transplant recipients (KTR) >1 yr (7.9±6.4 yrs) after Tx and in 146 kidney donors as healthy controls. Both groups were compared by t-test or Mann Whitney. In KTR we subsequently assessed the association of serum phosphate, PTH, FGF23, TmP-GFR and 24h-urinary PE with the composite endpoint of all-cause mortality and graft failure by multivariable Cox regression with adjustment for age, gender, creatinine clearance (CrCl), proteinuria, 24h-urea excretion, traditional cardiovascular risk factors and graft vintage. Data are presented as mean±SD or median[interquartile range] where appropriate.

Results: Serum phosphate was similar between KTR and controls (3.3±0.7 vs 3.3±0.6 mg/dl), but TmP-GFR (2.4±0.7 vs 2.8±0.7 mg/dl, p<0.05) was lower in KTR and fractional PE was higher in KTR (29±11 vs 12±5, p<0.05), suggesting phosphate leak. KTR with CrCl >60 ml/min had lower serum phosphate (3.1±0.6 mg/dl), but KTR with CrCl <30 ml/min had higher (4.1±0.8 mg/dl) serum phosphate than controls (both p<0.05). At follow-up of 6.4±1.7 yrs, 134 (22%) KTR had died and 54 (9%) had lost their graft. Higher FGF23 (full model hazard ratio 1.68[95% CI 1.30-2.18] per 1 SD, p<0.001) and serum phosphate (1.36[1.04-1.77] per 1 mg/dl, p=0.02) were associated with an increased risk of the composite endpoint. TmP-GFR (1.24[0.93-1.65], p=0.15) and PTH (1.25[0.94-1.66], p=0.13) showed similar trends. Higher PE protected against graft loss (0.61 (0.47-0.81) per 1 g/d, p=0.001).

Conclusions: Our data suggest that renal phosphate leak persists >1 year after kidney Tx, but it is overruled by a CrCl <60 ml/min. Elevated FGF23 and serum phosphate are associated with mortality and graft failure after Tx, independent of traditional risk factors.

TH-PO1084

25-Hydroxy Vitamin D Status and the Incidence of Acute Cellular Rejection in Kidney Transplant Recipients Amanda Ingemi,[1] Megan Rech,[1] James Fleming,[1] Nicole R. Pinelli,[2] Carol Moore.[1] *[1]Henry Ford Hospital, Detroit, MI; [2]College of Pharmacy, UNC, Chapel Hill, NC.*

Background: Vitamin D is a steroidal hormone that can elicit immunomodulatory properties. Limited human and animal data have shown that active 1,25-OH vitamin D may improve renal transplant outcomes; however, the influence of its precursor, 25-OH vitamin D, on renal transplant outcomes is unknown.

Methods: This retrospective cohort study included patients transplanted from 1/1/04-8/30/10 who were ≥18 years, had at least one 25-OH vitamin D level following transplantation, and had 1 year follow-up. The patients were divided into 2 groups based on their mean 25-OH vitamin D levels taken from their first year post-transplant or until first rejection: vitamin D insufficient (VDI) ≤20ng/mL and vitamin D sufficient (VDS) >20ng/mL. The primary outcome was treated or biopsy proven acute cellular rejection. The secondary outcomes were BK viremia, CMV infection, delayed graft function (DGF) (defined as HD within 7 days of transplant), and graft loss. A multivariate logistic regression model was built with backward selection.

Results: A total of 669 patients were screened; of those, 203 met the inclusion criteria (53% VDI group, 53±13 years, 58% male, 51% African American, 9% with a previous kidney transplant, and 82% received dialysis) were included in the analysis. Baseline demographics were comparable between groups except for additional extended criteria donations (ECD) in the VDI group (19% vs. 7%, p=0.04). Compared to the VDS group, acute rejection occurred more often in the VDI group (22% vs. 8%, p<0.01). On multivariate analysis, after adjusting for ECD, panel reactive antibody >20%, and deceased donors, the VDI group was independently associated with rejection (OR 3.1; 95%CI 1.3-7.3). The incidence of developing BK viremia (21% vs. 18%, p=0.54), CMV infection (14% vs. 20%, p=0.25), and graft loss (7% vs. 4%, p=0.45) was comparable between groups. In contrast, DGF occurred more often in the VDI group (34% vs. 18%, p=0.01).

Conclusions: This data suggests low vitamin D levels are associated with an increased incidence of acute cellular rejection. Future prospective studies are needed for validation and to examine supplementation.

Prediction of Kidney Failure after Liver Transplantation Tobias J. Weismüller,[1] Christian Lerch,[2] Eleni Evangelidou,[3] Christian P. Strassburg,[1] Hermann G. Haller,[3] Mario Schiffer.[3] *[1]Gastroenterology, Hannover Medical School; [2]Pediatrics, Hannover Medical School; [3]Nephrology, Hannover Medical School.*

Background: Kidney failure after orthotopic liver transplantation (OLT) is a serious concern and currently no concepts exist to predict GFR development in these patients. We performed a retrospective analysis in 320 patients after OLT and followed their kidney function for 3 years.

Methods: We developed models for predicting CKD stages at 1 and 3 years after liver transplantation. Models were fitted for (i) covariables available before Tx, (ii) peri- and postoperative factors and (iii) immunosuppression. We checked discrimination, calibration and internal validity of the models.

Results: We detected within the group of patients 3 subgroups with a distinct pattern for their GFR development. We identified patients starting with a GFR (˜73ml/min) that developed a significant loss of GFR within the first year (GFR ˜36ml/min) after transplantation with no improvement over the time period of 3 years. A second group of patients starting with a GFR (˜69 ml/min) developed a significant loss of kidney function at year 1 after transplantation (GFR ˜51ml/min) and showed a significant improvement of kidney funktion at year 3 with a GFR of ˜63 ml/min. A 3rd group started with a GFR of ˜61ml/min and showed an improvement of kidney function at year 1 (GFR ˜69ml/min) that was maintained over the 3 years. Comparing baseline characteristics of the respective groups, short CIT, lower age and short ICU stay were associated with a better development of kidney function. In a clinical prediction model we found predicted probabilities for GFR very close to observed probabilities for development of CKD 3 or worse. However, prediction of CKD 4 or 5 was less stable.

Conclusions: Imputing the classical risk factors in a prediction model leads to a good prediction of loss of kidney function, but cannot predict whether a patient would lateron require dialysis. The patterns that we recognized further underline that OLT patients are a very heterogeneous patient group and that even if kidney function deteriorates in the first post transplant year we cannot foresee if the patients kidney function recovers or not.

TH-PO1086

Liver Transplantation for Hereditary Renal Amyloidosis: the United Kingdom Experience Arie J. Stangou, Bridget Gunson, Peter Ashcroft, Paolo Muiesan. *Liver Unit, Queen Elizabeth Hospital, Birmingham, United Kingdom.*

Background: The liver is the exclusive source of the amyloidogenic protein in hereditary fibrinogen α-chain amyloidosis (AFib) and responsible for production of 50% of the variant apolipoprotein in ApoAI amyloidosis (AApoAI). Variant lysozyme production is extrahepatic but liver and kidneys can be targets for amyloid deposition in hereditary lysozyme amyloidosis (ALys). We evaluated the role of liver transplantation (LT) in the hereditary renal amyloidoses and present the long-term outcomes in AFib, AApoAI and ALys amyloidosis.

Methods: Between 1993-2011, fifteen patients with hereditary renal amyloidosis received LT in the UK. Ten patients (median age 58 years) with AFib amyloidosis and renal failure had combined liver/kidney transplant (LKT). Three patients aged 50, 52 and 56 years received LKT for AApoAI amyloidosis with renal and liver failure. Two siblings with ALys amyloidosis and extensive hepatic amyloid received LT as emergency at 15 and 24 years old for spontaneous liver rupture.

Results: At median posttransplant fol-up of 77 (range 12-175) months, 7/10 AFib patients are alive with no amyloid progression after LKT (cumulative survival 70%). Two AFib patients transplanted before dialysis, retain stable native kidney function at 8 and 7 years post-LKT. Three fatal outcomes occurred in long-term dialysis cases and were due to vascular or biliary complications. All 3 patients with AApoAI amyloidosis maintain normal dual graft function with no amyloid progression at 36, 109 and 152 months post-LKT. The first of the 2 ALys patients who received urgent LT died at 12 years with massive haemorrhage related to intestinal amyloidosis, while the second is alive at 8 years with good graft function.

Conclusions: 1. Combined LKT for end-stage renal failure in AFib is curative, but incurs significant risks. Preemptive isolated LT at early stages of amyloid nephropathy may halt renal amyloid progression. 2. The addition of LT to kidney transplant is curative in AApoAI amyloidosis, however, the indication of LT in AApoAI is reserved for liver failure. 3. LT is life-saving, albeit not curative, in ALys patients with amyloid liver failure and posttransplant life expectancy is acceptable.

TH-PO1087

The Impact of Preoperative Renal Function and Proteinuria in Patients Following Heart Transplantation Lutfi Alkorbi, Mamdouh N. Albaqumi. *Medicine, KFSHRC.*

Background: Preoperative conditions play a major role in solid organ transplantation outcome. The purpose of this study is to assess the clinical impact of preoperative impaired renal function and proteinuria in heart transplant recipients.

Methods: Patients with heart transplant from 2003 until 2010 were included. Clinical and laboratory data were collected. Based on their preoperative eGFR, they were divided into two groups: patients with impaired renal function (GFR <60 ml/min/1.73m^2) and patients

with normal renal function (GFR ≥ 60 ml/min1.73m^2). Outcome was measured as acute kidney injury using AKI Network Definition, the need for renal replacement therapy, and mortality at both 7 and 30 days.

Results: A total of 92 patients were identified. There was no difference between patients with impaired renal function and those with normal renal function in terms of acute kidney injury or the need for renal replacement therapy in the first 7 days. However, patients with impaired renal function had a higher mortality rate in the first 7 days compared to patients with normal renal function (15.4% vs. 3%, P=0.008). Mortality rate at 30 days was also significant in patients with impaired renal function (27% vs. 3%, P=0.008) as well as the need for renal replacement therapy (18.2% vs.3.1%, P=0.017) at 30 days but with no difference in AKI between the two groups. When we used preoperative proteinuria to divide the patients into two groups, we found that patients with proteinuria had a higher mortality rate (12.9% vs. 1.7%, P=0.024) and higher need for renal replacement therapy in the first 7 days (13.8% vs. 1.7%, P=0.020) than those without proteinuria. This difference disappeared at 30 days post heart transplant. Patients with both proteinuria and impaired renal function have a significant mortality rate at 30 days (57%).

Conclusions: Impaired renal function has a significant impact on mortality and the need for renal replacement therapy at 30 days. Proteinuria alone has no significant impact in the first 30 days, but when combined with renal impairment, it has a detrimental impact on 30 days mortality and need for renal replacement therapy.

TH-PO1088

Treatment of Cirrhosis-Associated Hyponatremia Refractory to Vasopressin 2-Receptor Antagonist Ajay Yadlapati, Minhtri K. Nguyen. *Nephrology, UCLA, Los Angeles, CA.*

Background: Hyponatremia is a common laboratory finding and reason for admission in patients with end stage liver disease (ESLD). In cirrhotic patients whose hyponatremia fails to correct with free water restriction, vasopressin 2 receptor antagonist (V2RA) is an effective alternative therapy. In this case report, we describe a patient with hepatorenal syndrome (HRS) whose hyponatremia failed to improve with tolvaptan and conivaptan but subsequently corrected with treatment with midodrine and octreotide.

Methods: A 51-year-old female with history significant for ESLD was admitted for a serum sodium of 118mmol/L. The patient's hyponatremia failed to improve with free water restriction, so tolvaptan was started. Despite adequate up-titration, her serum sodium level remained unchanged. Due to the potential concern for inadequate GI absorption she was started on IV conivaptan, which did not help. On day 13, she was started on midodrine and octreotide for treatment of acute kidney injury thought to be due to HRS, which slowly brought the patient's serum sodium level from 122 to 132mmol/L over a 5 day course coinciding with the resolution of the HRS. Repeat laboratory values revealed a stable serum sodium level of 135mmol/L nearly 2 weeks after initiation of the drugs.

Conclusions: Hyponatremia is a common medical finding in patients with cirrhosis, and is a reflection of the severity of the underlying liver disease as well as a predictor of morbidity and mortality. Free water restriction and V2RAs are the main therapeutic option, which failed in our patient. The lack of response to the V2RAs in our patient was likely due to avid renal proximal fluid reabsorption due to decreased effective circulatory volume, thereby resulting in diminished fluid delivery to the collecting tubule. The improvement in her hyponatremia with midodrine and octreotide was likely due to increased distal fluid delivery to the collecting tubule as reflected in the simultaneous increase in urinary output and relatively constant urinary osmolality. To date, this is the first case report of a cirrhotic patient with hyponatremia refractory to V2RAs which resolved with treatment with midodrine and octreotide.

TH-PO1089

Triiodothyronine: An Iatrogenic Cause of Thyrotoxic Hypokalemic Periodic Paralysis Ekamol Tantisattamo, Chuong Dinh, Alexander L. Pan. *Medicine, University of Hawaii John A. Burns School of Medicine, Honolulu, HI.*

Background: Being a potential life-threatening condition, thyrotoxic hypokalemic periodic paralysis (THPP) is curative if early recognized and treated. Exogenous stimuli can trigger severe hypokalemia and muscle weakness. We report a case of a man who presented with THPP from triiodothyronine use.

Methods: A 30-year-old Japanese man presented with acute bilateral lower extremity weakness which was worse until he was unable to stand up. He denied prior episode of this symptom, family history of muscle weakness, vomiting, diarrhea, vigorous exercise, or high carbohydrate intake. His heart rate was 107 beats/minute and BP was 156/75 mmHg. BMI was 34.95 kg/m^2. Neurological exam revealed motor power of grade 2/5 in the proximal and distal muscles both upper and lower extremities. Deep tendon reflexes were diminished throughout. Laboratory data revealed serum K of 1.7 mmol/l, CK of 86 IU/L, TSH of <0.07 uIU/ml, FT4 of 0.5 ng/dl, and total T3 of 486 ng/dl. EKG was normal. He reported a 50-pound intentional weight loss over 1 year from taking triiodothyronine (T3) which he bought online. He adjusted the T3 dose between 50 to 150 µg depending on his heart rate. He was taking 150 µg of T3 daily and denied diuretic use. T3 was discontinued and KCl was replaced for a total of 130 mEq. Serum K increased to 3.8 mmol/l in 10 hours. His muscle strength gradually improved and returned to normal within 24 hours. No rebound hyperkalemia occurred.

Conclusions: Acute proximal muscle weakness in our patient resulted from severe hypokalemia and rapidly resolved after KCl replacement. Evidences of hyperthyroidism including tachycardia and systolic hypertension with a wide pulse pressure were consistent with his abnormal thyroid function tests. These features support THPP, an acquired form of periodic paralysis. T3 intake increases the activity of the Na^+/K^+-ATPase causing intracellular shift of K. Our patient from Asian ethnicity may be susceptible to THPP during the hyperthyroid state. Thyroid function tests and a history of exogenous thyroid hormone use are crucial to approach hypokalemic periodic paralysis and differentiate other causes of periodic paralysis.

TH-PO1090

Oncogenic Osteomalacia: A Case of Phosphaturic Invasive Pleomorphic Spindle Cell Sarcoma Presenting with Upper Airway Compromise Ekamol Tantisattamo,[1] Wichit Sae-Ow,[2] Kristi Adachi,[3] Roland C.K. Ng.[1] *[1]Medicine; [2]Pathology; [3]Otolaryngology, University of Hawaii.*

Background: Oncogenic osteomalacia (OOM), also known as tumor-induced osteomalacia, is a rare paraneoplastic syndrome commonly caused by benign mesenchymal tumors of mixed connective tissue in soft tissue. OOM-related malignant tumors occur in only 10% of cases. We report one case of a man presented with a malignant sarcoma of the neck complicated with upper airway compromise and isolated renal phosphate wasting.

Methods: A 36-year-old man presented with a progressively enlarging right-sided neck mass for 1 month. He had voice change and odynophagia but no difficulty breathing. Physical exam revealed muffled voice but clear lungs. SpO_2 was 100% on ambient air. Chest x-ray showed trachea deviation to the left side. Neck CT scan revealed 6-cm complex solid and cystic mass in the right neck. He was emergently intubated and underwent tumor removal at the right parapharyngeal space with total right parotidectomy. Postoperatively, he did well and airway was secured by tracheostomy tube. Pathology revealed high grade pleomorphic spindle cell sarcoma involving the right parapharyngeal, masseteric spaces, and the right parotid gland. He also developed persistent hypophosphatemia with the lowest serum phosphorus level at 1.1 mg/dl despite phosphorus replacement. His serum phosphorus returned to normal on postoperative day 4. TMP/GFR was 0.775 µmol/L (normal range 0.96–1.44 µmol/L). Fibroblast growth factor (FGF) 23 was elevated to 17.7 pg/ml (normal range ≤6.5 pg/ml). One month later, serum phosphorus remained normal and followup FGF 23 has normalized.

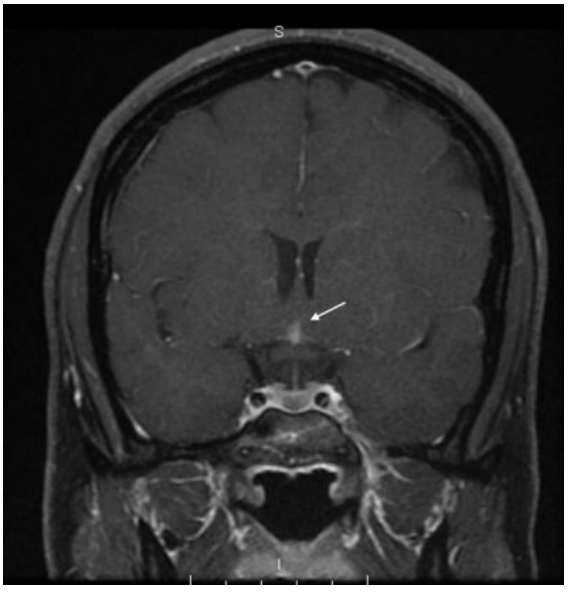
Conclusions: Our patient had persistent hypophosphatemia and low TMP/GFR which supports renal phosphate wasting. The elevated FGF 23 level and normalized serum phosphorus after tumor removal confirm OOM. Even though benign mesenchymal tumor is the most common tumor causing OOM, malignant tumors like rapidly growing high grade pleomorphic spindle cell sarcoma causing upper airway compromise in our patient is unique. OOM can occur in almost any tumor, more often benign but also malignant. In both types of tumor, FGF 23 is elevated, and the mechanism appears to be the same.

TH-PO1091

An Unusual Case of Hypernatremia Gearoid M. McMahon, Jennifer M. Joe, David J.R. Steele. *Nephrology, Massachusetts General Hospital, Boston, MA.*

Background: Serum osmolality is tightly regulated by both ADH and the stimulation or suppression of thirst. Defects in thirst sensation are often accompanied by diabetes insipidus (DI) because the thirst center is located near the site of hypothalamic ADH production. We present a case of a patient who developed hypernatremia and adipsia due to a hypothalamic lesion.

Methods: A 41 year old woman presented with a 3-month history of fatigue, myalgias and dyspnea. Serum chemistries were normal, but computed tomography (CT) of the thorax revealed hilar lymphadenopathy and a subsequent biopsy found confluent granulomas consistent with sarcoidosis. Her symptoms improved spontaneously and she was not treated with steroids. One year later, she presented with recurrent symptoms. A repeat CT thorax was unchanged. Serum chemistries were significant for Na 159mmol/L, Cl 123mmol/L, creatinine 0.93mg/dl and osmolality 321mosm/kg. She reported drinking 3-6 glasses of water daily and denied polydipsia and polyuria. Examination was significant for normotension, tachycardia (107 bpm), and euvolemia. Urine chemistries were significant for Na 146mmol/L, K 76mmol/L Cl 189mmol/L and osmolality 1103mosm/kg. The presence of a maximally concentrated urine indicated preservation of ADH secretion and suggested the possibility of a lesion in her thirst center. A T1 post-contrast brain MRI revealed focal hypothalamic enhancement consistent with sarcoidosis. She was prescribed regularly scheduled free water and her Na normalized.



Conclusions: Adipsia is an unusual cause of asymptomatic hypernatremia. It is usually related to surgery although sarcoidosis is a recognized cause. Patients who do not have associated DI can be treated with free water alone and the utility of steroids remains unclear.

TH-PO1092

Hypokalemic Hypertension with Hypercalcaemia Husham Rasheed, Calum Neil Ross, Gary Campbell. *Renal Medicine, Norfolk & Norwich University Hospital, Norwich, Norfolk, United Kingdom.*

Background: We present the case of a teenage girl diagnosed with two rare and unrelated autosomal dominant conditions during investigation for secondary hypertension. Liddle's syndrome (hyper-function of the epithelial sodium channel - ENaC) was confirmed genetically whilst a clinical diagnosis of Familial Hypocalciuric Hypercalcaemia (FHH) was predicated on the presence of hypercalcaemia, non-suppressed parathyroid hormone and a low urinary calcium/creatinine clearance ratio.

Methods: A 17 year old girl was referred with hypertension. This was incidentally noted aged 14 and was confirmed on 24 hour ABPM: at the time she was hypokalemic, [K+] 3.1 mmol/L (3.5-5.0) with a normal [HCO3-] of 26 mmol/L (21-28). Secondary causes of hypertension were not investigated by paediatricians. Subsequent interval BP readings were noted to be increased to 160/100. Random renin and aldosterone levels were low - renin 4 mU/L (5.4-60) and aldosterone <65 pmol/L (100-450). Initial (post-sampling) therapy with ramipril was changed to amiloride (ENaC antagonist) with effect. Genetic analysis confirmed Liddle's syndrome. Relatives have been referred for genetic screening: there is a family history of hypertension praecox diagnosed in her father in his late twenties. The serum [Ca]c was increased at 2.81 mmol/L (2.2-2.62) with a non-suppressed [PTH] at 3.4 pmol/L (1.6-6.9). A 24 hour urinary calcium/creatinine ratio was extremely low at 0.0058 (<0.01), confirming FHH: both the father and sister were found to have increased [Ca] and [PTH] establishing autosomal dominant inheritance. Genetic analysis is pending.

Conclusions: This is the first reported case of a patient with both Liddle's syndrome and FHH, two rare and unrelated autosomal dominant conditions. This case demonstrates the importance of methodical investigation of hypertensive patients with biochemical abnormalities, particularly in the context of a relevant family history. The co-inheritance of two chromosomally discrete autosomal dominant conditions is a medical curiosity with no, apparent, pre-reproduction lethality. Genetic counselling will be complex.

TH-PO1093

A Challenging Case of Hypomagnesaemia in an Alcoholic Patient Rabih Nasr, Chadi Saifan, Suzanne E. El Sayegh. *Nephrology, Staten Island University Hospital, Staten Island, NY.*

Background: Hypomagnesaemia has been reported to cause cardiac dysrhythmias especially torsade de pointe. The diagnosis and treatment are crucial to prevent complications and mortality. Chronic alcoholism causes tubular dysfunction leading to persistent hypomagnesemia.

Methods: 53 year old man with a history of alcohol abuse presented with dizziness and palpitations. In the ED, he was found to have afib, that was treated with cardizem. His hospital course was complicated with cardiac arrest and acute respiratory failure. On admission, his BUN was 11mg/dL, creatinine 0.68mg/dL, Na 136meq/L, K 4.6mmol/L, Ca 9mg/dL, Mg 1.5mg/dL and P 4.3mg/dL. U/A showed 1+ protein, glucose, and blood with RBC's 6-12/hpf. On cardiac monitoring, he developed tachyarrhythmia, torsade de pointe requiring several shocks. His repeated magnesium level revealed persistent low magnesium even after 4 weeks of hospitalization requiring numerous repletion.

table1

Mg repletion rate	Mg oxide PO and Mg sulfate IV	Mg oxide PO and Mg sulfate IV	Mg oxide PO	Mg oxide PO and Mg sulfate drip	Mg oxide PO	Mg oxide PO	Mg oxide PO
Serum Mg level	1.8	1.6	1.7	2.3	1.7	1.7	1.7

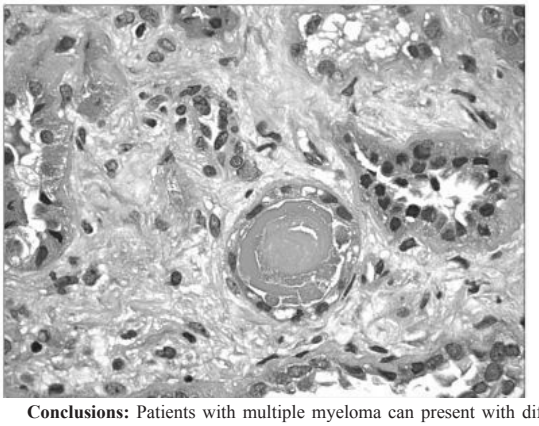
A 24-hour urine collection showed creatinine 1623.38 mg, volume 2925 ml, urine magnesium 394.88 mg, urine calcium 225.23 mg. The calculated fractional excretion of magnesium was 9% consistent with renal magnesium wasting.

Conclusions: The fractional excretion of magnesium is an important tool to differentiate between renal and extra renal causes. Hypomagnesaemia usually occurs in association with hypokalemia and hypocalcaemia. A study about chronic alcoholism shows renal magnesium wasting due to tubular dysfunction as evidenced by glycosuria and hypercalciuria "Renal Tubular Dysfunction in Chronic Alcohol Abuse -- Effects of Abstinence NEJM 1993". Magnesium level may remain low for up to 4 weeks after abstinence. Treatment requires frequent administration of magnesium and careful monitoring of the level. If possible, oral route is the preferred method of supplementation. In our case, we touch on the aspect of hypomagnesaemia in the setting of chronic alcoholism and the relevance of frequent measurement of the level to avoid subsequent increase in mortality and morbidity.

TH-PO1094

Myeloma Cast and Light Chain Nephropathy: A Challenging Diagnosis Rabih Nasr, Chadi Saifan, Suzanne E. El Sayegh. *Nephrology, Staten Island University Hospital, Staten Island, NY.*

Methods: A 70 year old man with history of hypertension, diabetes, hyperlipidemia, and kidney stones, presented to the hospital for a creatinine of 5 mg/dl on routine blood work. Two weeks ago, he was seen for right sided flank pain and his creatinine was 3.5 mg/dl. His physical examination was unremarkable. His blood test showed Na: 138 mg/dl, K:4 mg/dl, Cr: 5.28 mg/dl, BUN: 55 mg/dl, and Hb: 11.6 g/dl. His U/A showed 30 mg/dl protein with no cells or casts. The UTP/Cr was 0.72. The kidney ultrasound was normal. Additional blood work was normal including the SPEP with immunofixation. A kidney biopsy was performed. (Refer to pictures). A diagnosis of light chain deposition disease, kappa type and focal atypical casts suspicious of myeloma cast nephropathy was made. He was started on bortezomib and corticosteorids. His creatinine improved and reached a level of 3.8 mg/dl. The rest of his blood work showed a urine immunofixation positive for free kappa light chain, a free kappa level in the serum of 3120 mg/l, and a free kappa/lambda ratio of 234.59.



Conclusions: Patients with multiple myeloma can present with different forms of renal manifestations. Four forms are encountered: primary amyloidosis, myeloma cast nephropathy, monoclonal immunoglobulin deposition disease, and rarely proliferative glomerulonephritis. The presence of two or more forms is rarely described. Qian Q et al. reported in 2010 a coexistence of myeloma cast nephropathy, light chain deposition disease, and nonamyloid fibrils. Our patient had myeloma cast nephropathy and kappa light chain deposition disease with minimal proteinuria and showed a good response to treatment. Therefore, clinical presentation can not predict the pathologic findings in patients with multiple myeloma, despite the fact that it is essential for treatment, management and prognosis.

TH-PO1095

Modified Continuous Veno-Venous Haemodiafiltration (CVVHDF) to Correct Life Threatening Hyponatremia Elanchezzian Balakumar, Mangalakumar Veerasamy, Andrew Gratrix. *Hull Royal Infirmary, United Kingdom.*

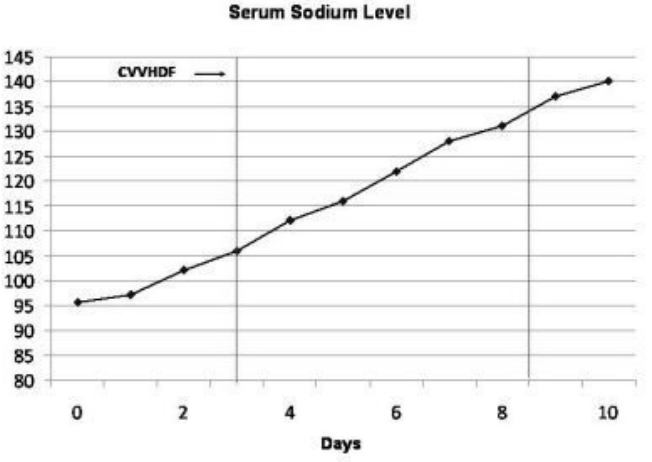
Background: Rapid correction of severe hyponatremia can lead to osmotic demyelination syndrome(ODS). We describe the management of a patient admitted with life threatening hyponatremia (Serum Sodium 95.6mmol/L) and acute kidney injury (AKI), who was successfully managed with a ***modified*** CVVHDF.

Methods: 55 year old male was admitted with confusion and vomiting. He was suffering with flu like illness in the preceding week. His oral intake was poor and was managing only water. Past medical history included ethanol abuse. On admission GCS was 14/15 without any focal neurology; jugular venous pressure was low and was in type I respiratory failure due to left lower lobe pneumonia. ECG was consistent with hyperkalaemia.

Laboratory results on admission

pH	7.44
Bicarbonate	22.1mmol/L
Na	95mmo/L
K	6.8mmol/L
Chloride	55mmol/L
Urea	43.6mmol/L
Craetinine	1628micromol/L
ALT	146IU/L
CRP	98mg%
WCC	15100
Hb	11.3gm%
Platelet	186000

Patient was treated with 0.9% saline resuscitation, antibiotics and multiorgan support. Since he was non-oliguric and there was a risk of ODS due to rapid correction of hyponatraemia, hyperkalaemia was managed conservatively rather than by renal replacement therapy (RRT). Inspite of optimal fluid therapy sodium level remained low and he developed new metabolic acidosis. Hence we instituted modified CVVHDF on day 3, which resulted in gradual correction of sodium over 96 hours without any permanent neurological deficit.



Conclusions: Patients with AKI and severe metabolic derangement require RRT. The dialysate fluid marketed in UK for CVVHDF has a sodium concentration of 140mmol/L. Use of this in patients with AKI and hyponatraemia would result in rapid correction of sodium and ODS. Hence, we customised the dialysate fluid sodium concentration by adding sterile water (Ostermann M *et al, 2010)*. The latter allows safe and effective correction of hyponatraemia.

TH-PO1096

A Case of Familial Pseudohyperkalemia Naomi Matsuo, Taku Miyoshi, Kimio Tomita, Kenichiro Kitamura. *Department of Nephrology, Kumamoto University School of Medicine, Kumamoto, Japan.*

Background: Hyperkalemia has been reported to occur in 1.0% to 10% of all hospitalized patients. The cause of hyperkalemia is multifactorial, but reduced renal function, medications, and hyperglycemia are the most frequent contributing factors.

Methods: A previously healthy 84-year-old woman was referred to our hospital because of severe hyperkalemia. Her serum potassium (K^+) level was 10.9 mEq/L at a physician's office where she was seen for lumbago. She had no past medical history and was not taking medications. Physical examination found no abnormalities and ECG showed no signs of hyperkalemia. Laboratory examination revealed a serum K^+ level of 4.4 mEq/L with euglycemia. Reduced renal function, hematological abnormalities such as hemolysis, leukocytosis, thrombocytosis, or morphological abnormalities of red blood cells (RBC) were not found. Therefore, we considered the possibility of pseudohyperkalemia. Her plasma K^+ level was markedly elevated after 6 hr incubation of blood at 4 °C without hemolysis, but not at 37 °C, indicating that hyperkalemia was caused by abnormal leakage of K^+ from RBC at lower temperatures without coagulation. We also confirmed the same phenotype in her two daughters, suggesting hereditability of this disorder. Finally we reached the diagnosis of familial pseudohyperkalemia (FP).

Conclusions: FP is an autosomal dominant disorder characterized by fragility of erythrocyte membranes, which causes abnormal leakage of K^+ from RBC at low temperature (below 20 °C). The leakage of K^+ persists when the Na-K ATPase or Na-K-2Cl cotransporter is inhibited, indicating passive leakage of K^+. Several families from Europe and one from Japan with FP were reported and three types of FP are described based on the leak–temperature dependency curve, 1) FP Edinburgh and FP Lille, 2) FP Chiswick and FP Falkirk, and 3) FP Cardiff. This case closely resembles FP Edinburgh and FP Lille. Microsatellite analysis is currently being performed to confirm a genetic basis for this trait. This is a rare disorder, but offers valuable insight for electrolyte pathophysiology. In addition, to our knowledge, this is the second Japanese case of FP.

TH-PO1097

A Case of Light Chain Deposition Disease Associated with Multiple Myeloma Diagnosed by LC-MS/MS Analysis Yoshimi Nakashima,[1] Keiko Tajiri,[1] Taku Miyoshi,[1] Hiroyuki Hata,[2] Masayoshi Tasaki,[3] Konen Obayashi,[4] Yukio Ando,[3] Kimio Tomita,[1] Kenichiro Kitamura.[1] *[1]Department of Nephrology, Kumamoto University School of Medicine, Kumamoto, Japan; [2]Department of Hematology, Kumamoto University School of Medicine, Kumamoto, Japan; [3]Department of Neurology, Kumamoto University School of Medicine, Kumamoto, Japan; [4]Diagnostic Unit for Amyloidosis, Department of Laboratory Medicine, Kumamoto University School of Medicine, Kumamoto, Japan.*

Background: Renal impairment is common and often associated with multiple myeloma (MM). Although the diagnosis of these light chain deposition disease (LCDD) is usually made by the immunohistochemical demonstration of immunoglobulin (Ig) light chain (LC) deposits, studies may be falsely negative due to the variable reactivity of the antibodies against LC deposits. Therefore, we tried to diagnose LCDD by LC-MS/MS analysis in our patient.

Methods: A 70-year-old Japanese woman was referred to our hospital for renal impairment (Cr 1.8mg/dL) and heavy proteinuria (3g/day). Laboratory examination revealed a suppression of all serum Ig classes (IgG, IgA, IgM, IgE, and IgD), but no monoclonal protein was detected by serum or urine immunoelectrophoresis. Serum free LC analysis demonstrated substantially increased free Igκ LCs (5870ng/mL) and κ/λ ratio, and bone marrow aspiration showed a significant increase in plasma cells (28.8%). These findings indicated a diagnosis of Bence-Jones protein-type MM. Renal biopsy showed membranoproliferative glomerulonephritis-like features and electron microscopy demonstrated amorphous deposits in the mesangium and in the subendothelial space. However, Congo red staining and immunostaining against Igs including κ and λ LCs were all negative, resulting in no definitive diagnosis for the renal lesions. Therefore, we analyzed the LC deposits from kidney biopsy specimens by LC-MS/MS and found large amounts of Igκ LC. Consequently, the patient was diagnosed as LCDD associated with MM.

Conclusions: Our case shows that LC-MS/MS analysis of biopsy specimens should be considered for patients who are suspected of having LCDD but who have no evidence of immunostaining for LC deposits in the affected organs.

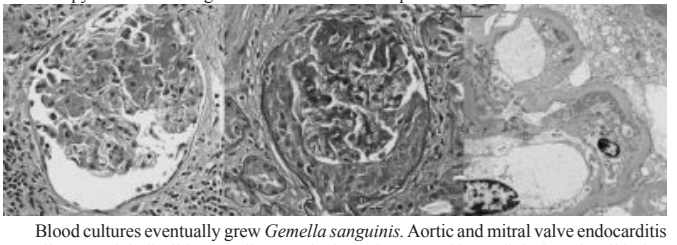
TH-PO1098

Gemella Sanguinis Endocarditis with Anti-PR3/c-ANCA-Associated Immune Complex Necrotizing Glomerulonephritis with Full House Pattern on Immunofluorescence Mathieu Rousseau-Gagnon,[1] Julie Riopel,[4] Anne Desjardins,[3] Daniel Garceau,[2] Mohsen Agharazii,[1] Simon Desmeules.[1] *[1]Nephrology, CHUQ, Quebec, QC, Canada; [2]Nephrology, IUCPQ, Quebec, QC, Canada; [3]Infectious Diseases, CHUQ, Quebec, QC, Canada; [4]Pathology, CHUQ, Quebec, QC, Canada.*

Background: Kidney manifestations of bacterial endocarditis include septic emboli and proliferative glomerulonephritis. Recently, cases of bacterial endocarditis have been associated with c-ANCA/anti-PR3 necrotizing glomerulonephritis. We report the first case of c-ANCA/anti-PR3 positive immune complex glomerulonephritis with "full house" immunofluorescence pattern due to bacterial endocarditis.

Methods: A 67 year-old man was referred for progressive renal failure. He had lost 30 lbs in the last month and had been treated for lower back pain. On admission, he was afebrile and had a creatinine of 10.3 mg/dL. C-ANCA/anti-PR3 were positive. A kidney biopsy was performed, revealing focal necrotizing glomerulonephritis with crescents and immune complex deposits with a "full house" pattern on immunofluorescence. Electron microscopy showed mesangial and subendothelial deposits.



Blood cultures eventually grew *Gemella sanguinis*. Aortic and mitral valve endocarditis as well as spondylodisciitis were diagnosed. The patient started hemodialysis and antibiotics. Prednisone was added for 14 days due to dialysis requirement in the presence of necrotizing glomerulonephritis. Aortic and mitral valve were replaced on day 17 and renal function recovered completely on day 93.

Conclusions: This first case of *Gemella sanguinis* endocarditis-associated necrotizing glomerulonephritis with anti-PR3/c-ANCA and immune complex deposits with "full house" pattern underscores the importance to consider subacute bacterial endocarditis in the differential diagnosis of ANCA vasculitis and lupus nephritis. This is crucial as these conditions involve different treatment strategies.

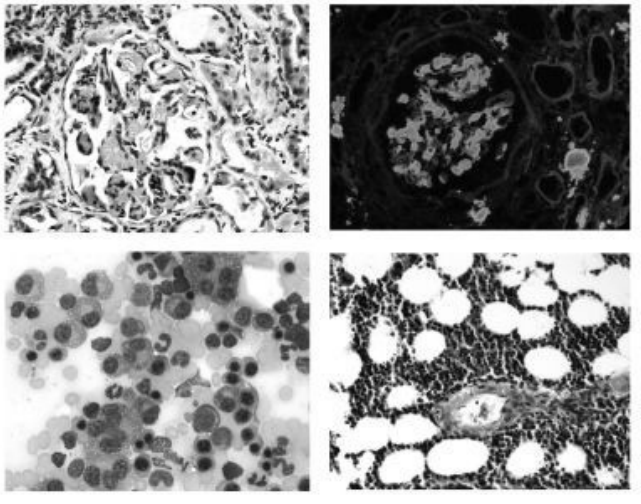
TH-PO1099

Plasma Cell Myeloma with Amyloidosis Presenting as Hypotension, Nephrotic Syndrome and Renal Failure Omkar U. Vaidya,[1] Sara A. Monaghan,[2] Xin J. Zhou,[2] Robert D. Toto.[1] *[1]Nephrology, UT Southwestern, Dallas, TX; [2]Pathology, UT Southwestern, Dallas, TX.*

Background: Plasma cell myeloma without amyloidosis and primary amyloidosis without plasma cell myeloma can independently present both nephrotic syndrome and renal failure.

Methods: Case report: A 45yr old Hispanic male with a medical history of diabetes presented with a 3-week history of fatigue and lower extremity edema. Review of his systems was unremarkable. He was found to have asymptomatic hypotension with a blood pressure of 95/60 and a pulse rate of 90 /min. Physical exam was unremarkable except for edema and macroglossia. Laboratory revealed creatinine 3.83 mg/dl and 24 hour urine protein of 18 g; urinalysis revealed microhematuria and pyuruia; urine free light chain excretion 144.37 mg/24 hr, serum IgG level 2101 mg/dl (700-160 mg/dl), Ig kappa free light chain 2.94(0.33-1.94mg/dl) and Ig lambda free light chain- 31.2(0.57- 2.63 mg/dl). An EKG showed low voltage QRS complex. Two-dimensional echocardiogram showed biventricular hypertrophy, ejection fraction of 62 % and grade II diastolic dysfunction. Skeletal survey was negative for lytic lesions. Congo red stain of a renal biopsy showed apple green birefringence under polarized light involving the mesangium and segmentally involving capillary walls. Immunofluorescence staining revealed extensive deposition of lambda light chain in the mesangium and segmentally in capillary walls with scattered interstitial positivity. Staining for kappa light chain was negative. A bone marrow biopsy revealed increased atypical plasma cells, accounting for 15% of the cellularity, throughout the interstitium and in focal dense collections. Congo red stain confirmed amyloid deposition in vessel walls. The patient was started on bortezomib and dexamethasone. However, on the 14th day of admission he had ventricular arrhythmia and failed to regain pulse.

Conclusions: Plasma cell myeloma presenting initially with amyloidosis is uncommon.



TH-PO1100

Clinical Utility of Mass Spectrometry-Based Proteomics in the Diagnosis of Monoclonal Gammopathy-Associated MembranoProliferative Glomerulonephritis Deepika Jain,[1] Khaled Abdel-Kader,[1] Robert H. Yenchek,[1] Sanjeev Sethi,[2] Jamie Green.[1] *[1]The Renal-Electrolyte DIvision, University of Pittsburgh Medical Center, Pittsburgh, PA; [2]Division of Anatomic Pathology, Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN.*

Background: Monoclonal gammopathy is increasingly being recognized as a common cause of membranoproliferative glomerulonephritis (MPGN), however establishing the diagnosis may sometimes be challenging.

Methods: We present the case of a 58 year old asymptomatic woman with a history of longstanding hypertension who presented with 5 gram proteinuria and microscopic hematuria. Renal biopsy was consistent with MPGN pattern of injury. Immunofluorescence (IF) studies showed staining for IgM and C3, suggesting immune-complex mediated MPGN. Electron microscopy showed subendothelial, subepithelial and mesangial electron dense deposits. The work up was negative for any infectious causes or autoimmune disease; however an IgG kappa monoclonal protein was identified in the serum at 0.4 mg/dL. Serum free light chain kappa to lambda ratio was elevated at 2.96. Bone marrow biopsy revealed 8% plasma cells, and and there was no evidence of any lytic lesions, hypercalcemia, anemia, or renal dysfunction. Due to the discordance between the serum monoclonal protein (IgG kappa) and IF findings (IgM, no light chain restriction), it was unclear if the the patient's MPGN was related to the monoclonal gammopathy. Therefore, the renal biopsy specimen was analysed further with laser microdissection and mass spectrometry at Mayo Clinic (Rochester, MN) which identified the deposits as monoclonal IgG kappa. Hence, the diagnosis of monoclonal gammopathy-associated MPGN was made.

Conclusions: This case emphasizes the importance of searching for an underlying etiology causing MPGN before labelling it as idiopathic. Laser microdissection and mass spectrometry provides a good ancillary technique for the diagnosis of monoclonal protein related glomerulonephritis when IF studies are inconclusive.

TH-PO1101

A Case of Membranoproliferative Glomerulonephritis with Cryoglobulinemia due to Both Hepatitis C Infection, and B-Cell Lymphoma Amarpreet S. Sandhu, Helbert Rondon-Berrios. *Nephrology, University of New Mexico School of Medicine, Albuquerque, NM.*

Background: Membranoproliferative glomerulonephritis (MPGN) is characterized by mesangial cell proliferation and thickening of the capillary walls due to subendothelial extension of the mesangium. It can be subdivided into idiopathic and secondary forms. Secondary forms are due to infectious diseases, systemic immune complex diseases, neoplasms, liver diseases, and miscellaneous. We encounter a patient who had MPGN with cyroglobulinemia from hepatitis C and B cell lymphoma, both seen on kidney biopsy.

Methods: A 60-year-old man with no significant past medical history presented with mild dyspnea and lower extremity edema. Initially diagnosed with new-onset congestive heart failure but later found to have nephrotic syndrome with a urine protein-to-creatinine ratio of 4.3. His serum creatinine on admission was 1.4 mg/dL and during his hospitalization it ranged from 1.4 to 2 mg/dL. His urinalysis showed dysmorphic RBCs but no acanthocytes or RBC casts. His work up revealed elevated WBC count with variant lymphocytes, a new diagnosis of hepatitis C infection with a viral load of 1.8 million IU/mL, serum protein electrophoresis with immunofixation demonstrated an IgM kappa monoclonal protein. Other important findings were: extremely elevated rheumatoid factor titer of 120,000 IU/mL, high C4 and normal C3 levels, a cryocrit of 6%, elevated kappa light chain with and elevated kappa-to-lambda ratio. The kidney biopsy showed cryoglobulinemic glomerulonephritis with an MPGN pattern of injury and immune deposits suggestive of an IgM-kappa paraprotein along with interstitial aggregates of atypical lymphoid cells. Flow cytometry of whole blood showed a kappa light chain restricted B-cell population and the bone marrow biopsy revealed a low grade B-cell lymphoma compatible with a splenic marginal zone lymphoma.

Conclusions: In previously reported MPGN cases with cryoglobulinemia were either associated with hepatitis C infection or B- cell lymphoma. However, our patient had findings of both, making his treatment choice difficult. Given low intensity B-cell lymphoma, decision was made to treat his hepatitis C first and then the malignancy.

TH-PO1102

Pseudoleukocytosis in an Immunosuppressed Patient with Essential Mixed Cryoglobulinemia (EMC) and Glomerulonephritis: Case Report Andrea C.E.P. Valenca, Edmir R.B. Dias, Marclebio M.C. Dourado, Maria Carolina N.R. Neves, Luis H.B.C. Sette, Maria Alina G.M. Cavalcante, Lucila Maria Valente. *Nefrologia, Hospital das Clinicas-UFPE, Recife, Pernambuco, Brazil.*

Background: EMC is an immune complex-mediated vasculitis that involves small-medium-size vessels. Renal involvement is associated with a poor prognosis. Treatment depends on the severity of symptoms and includes: steroids, cyclophosphamide and plasma exchange. Commonly these patients develop infections associated with immunosuppression. Here we describe a case of pseudoleukocytosis associated with EMC and glomerulonephritis.

Methods: A 46-year-old male had 1 year history of arthritis of large joints, fatigue and palpable purpura in lower extremities. He had a skin biopsy consistent with vasculitis leucocytoclastic and was followed by a rheumatologist using azathioprine and prednisone for the last 6 months. One month before admission he developed edema, weight gain and hypertension. He was referred to nephrology consultation when laboratory tests showed sCr 1.6mg/dL (last 0.8mg/dL), serum albumin of 2.0g/dL and anemia. Urinalysis revealed hematuria and proteinuria (10g/24h). His purpura became painful and fever was reported. Blood and urine cultures were negative. His white blood cell count (WBC) was 43,000 cells/mL. Complement C3 level was normal and C4 was low. Cryoglubulins were positive. ANA, serology for hepatitis B, C (fourth-generation ELISA), syphilis and HIV were negative. Kidney biopsy showed a membranoproliferative glomerulonephritis secondary to EMC type II. Manual leukocyte counting showed 6,500 cells/mL. The patient was started on plasmapheresis and prednisone. After 6 sessions his kidney function improved and WBC count was 10,300 cells/mL.The leukocytosis in our patient was secondary to the cryoglobulins. Patients with EMC may have a temperature increase in leukocyte counts due to various sizes of precipitated cryoglobulin particles. Therefore the counter "recognize" cryoglobulin particles as WBC.

Conclusions: We reported a case of pseudoleukocytosis due to EMC and glomerulonephritis. This is a differiencal diagnosis in immunosuppressed and febrile patients that could have either active disease or infection.

TH-PO1103

A Case Report of Secondary Hemosiderosis on Renal Biopsy in a Patient with a Left Ventricular Assist Device Jennifer C. Rodrigues,[1] Ahsan Alam,[1] Chantal Bernard,[2] Tiina Podymow.[1] *[1]Nephrology, McGill University, Montreal, QC, Canada; [2]Pathology, McGill University, Montreal, QC, Canada.*

Background: Continuous flow left ventricular assist devices (LVADs) are used both as a bridge to transplantation and as destination therapy. Moderate to severe renal dysfunction may persist chronically in some LVAD recipients; the etiology is unknown and there are no renal biopsy data.

Methods: We report a 19 year old previously healthy female requiring LVAD implantation post viral cardiomyopathy. She developed compartment syndrome and rhabdomyolysis with acute kidney injury (AKI) requiring continuous renal replacement for 3 weeks, intermittent hemodialysis for 8 weeks, then partial recovery with a new baseline creatinine of 140 mmol/L (1.5 mg/dL). Urine analysis throughout her hospitalization showed trace to large amounts of blood. A hemolysis work up as part of her chronic anemia demonstrated elevated lactate dehydrogenase values between 569-1562 U/L (reference 110-210 U/L) and decreased levels of haptoglobin 0.06 U/L (reference 0.69-1.69 U/L). The patient's renal function continued to deteriorate and her GFR by nuclear medicine scan was 23 mL/min. Transjugular renal biopsy was performed for dual cardiac/renal transplant work and revealed acute tubular necrosis (ATN) with marked iron/hemosiderin deposition. Mild tubular atrophy and interstitial fibrosis were also noted; glomeruli were unremarkable, with no thrombi or sclerosis, and there were no immune deposits. Renal biopsy was repeated 6 months later due to clinical deterioration and demonstrated similar pathology with glomerulosclerosis in 15% of glomeruli.

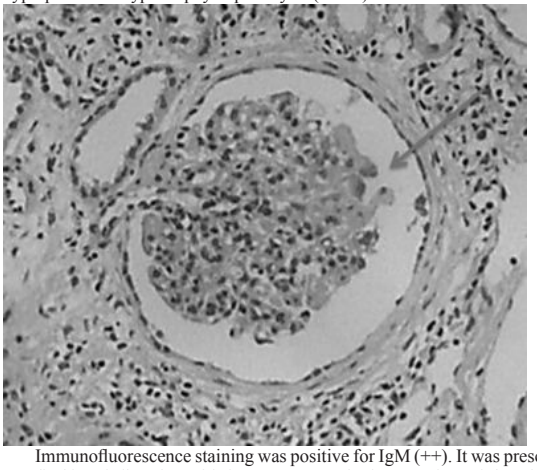
Conclusions: We report ATN, hemosiderosis, and renal dysfunction in a patient with LVAD. The etiology of renal dysfunction post LVAD is unknown and could include ATN secondary to toxicity from hemolysis and iron deposition or ATN due to a chronic "low flow state" with LVAD use. Hemosiderosis on renal biopsy secondary to hemolysis has been shown post-valvular repair. This is, to our knowledge, the first reported renal biopsy in a patient with a LVAD. Secondary hemosiderosis with acute tubular necrosis should be considered in patients with LVAD and unexplained kidney disease.

TH-PO1104

Collapsing Glomerulopathy in a Patient with Lymphangioleiomyomatosis: Case Report Maria Carolina N.R. Neves, Andrea C.E.P. Valenca, Luis H.B.C. Sette, Edmir R.B. Dias, Marclebio M.C. Dourado, Maria Alina G.M. Cavalcante, Lucila Maria Valente. *Nefrologia, Hospital das Clinicas da Universidade Federal de Pernambuco, Recife, Pernambuco, Brazil.*

Background: Collapsing Glomerulopathy (CG) is a glomerular injury that can occur in association with various etiologic factors. It also leads to a poor renal prognosis. We describe a case of CG in a patient with the diagnosis of Lymphangioleiomyomatosis (LAM). This is an uncommon disease characterized by smooth muscle cell infiltration and cystic destruction of the lung. The association between this two pathologies had never been descrbed.

Methods: A 27-year-old female reported sudden onset of edema, dyspnea, nausea and vomiting, for the past month. She had no significant past medical history and was not taking any medications. Physical exam revealed periorbital swelling and bilateral lower extremity edema.Urinalysis showed no microscopic hematuria and 24-h urine protein 6,1g. Blood evaluation showed normal blood count, albumin 1,4mg/dl, Cr 2,5mg/dl; negative ANA, normal complement, serology for hepatitis B, C and HIV were negative. Chest x-ray was normal. Kidney biopsy was performed [figure 1] and revealed 10 collapsed glomeruli with hyperplasia and hypertrophy of podocytes (arrow) and moderate tubule-interstitial damage.



Immunofluorescence staining was positive for IgM (++). It was prescribed prednisone 1mg/kg/d and diuretics with improvement of edema and renal function. Last sCr was 1.4mg/dl. Two months later, she complained of sudden dyspnea. CT scan revealed bilateral pneumothorax and diffuse cystic changes on both lungs. She underwent to a thoracic drainage and an open lung biopsy that showed proliferation of spindle and epithelioid cells consistent with LAM.

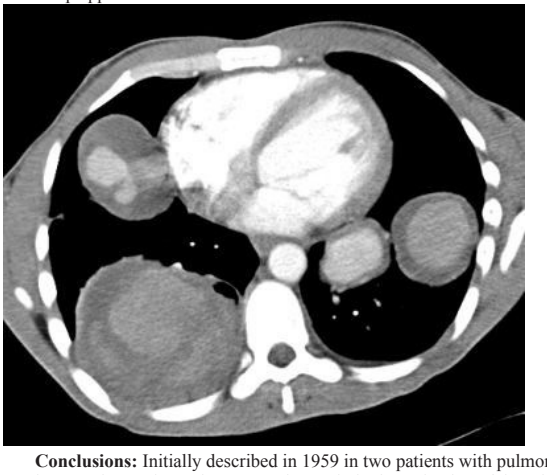
Conclusions: This is a report describing a patient with LAM and CG.

TH-PO1105

An Uncommon Cause of Hemoptysis Jason M. Kidd, JulieAnne G. McGregor, Ronald J. Falk. *Division of Nephrology and Hypertension, University of North Carolina Kidney Center, Chapel Hill, NC.*

Background: Hemoptysis is a common symptom leading to medical evaluation. Nephrologists are often involved in the care of patients with pulmonary-renal syndromes. In this case, we used our expertise in the treatment of vasculitis for the management of a pulmonary limited process.

Methods: A 28 year old male presented to a local emergency room with teaspoon sized hemoptysis. Medications included warfarin for a deep venous thromboembolism in his right leg diagnosed 3 months prior to the onset of hemoptysis. He noted one month of dyspnea, cough, fevers and weight loss. Chest radiography revealed bilateral rounded pulmonary masses. Computed tomography of his chest showed seven large pulmonary artery aneurysms; the largest in the right lower lobe (Figure). The patient was transferred to our institution for further management. The diagnosis of Hughes-Stovin Syndrome was made. Our patient underwent right lower lobectomy. Pathology showed no evidence of active vasculitis. Azathioprine and prednisone were started. Repeat imaging 1 month later showed decreased size of the remaining aneurysms. Unfortunately, patient has not attended follow up appointments. Chest CT.



Conclusions: Initially described in 1959 in two patients with pulmonary aneurysms, Hughes-Stovin Syndrome is a rare entity. Pathologic evaluation of the original aneurysms noted a high degree of inflammatory cellular infiltrate.[1] It has been characterized as a subcategory of Behcet's disease.[2] Untreated disease results in fatal hemoptysis and death. Our case illustrates the use of immunosuppression in the treatment of this disease.

TH-PO1106

A Non-Glomerular Cause of Dysmorphic Hematuria Jason M. Kidd, Lindsay Kruska, Gerald A. Hladik. *Department of Nephrology and Hypertension, University of North Carolina Kidney Center, Chapel Hill, NC.*

Background: In their seminal manuscript[1], Fairley and Birch suggested that glomerular bleeding is differentiated from other causes of hematuria based on the presence of dysmorphic red blood cells on urine microscopy. This case illustrates a unique, non-glomerular cause for dysmorphic hematuria.

Methods: A 59 year old white male with a history of deceased donor kidney transplant presented for follow up. His initial kidney disease was due to autosomal dominant polycystic kidney disease. He noted a 1 week history of gross hematuria. Urine microscopy revealed 15 red cells per high powered field. Scattered acanthocytes were present. Three months prior, renal allograft biopsy was performed and was significant only for moderate arterionephrosclerosis. He had no fevers, cough, abdominal pain or skin rash.

Estimated glomerular filtration rate was 33.6 ml/min/1.73m^2, which was stable from prior tests, and he had a urine protein to creatinine ratio of 0.206. Cystoscopy was normal. The presence of dysmorphic hematuria was concerning for glomerulonephritis.

Renal biopsy was planned, but due to his history of polycystic kidney disease, ruptured cyst was also considered. The patient underwent magnetic resonance imaging without contrast, which showed multiple cysts containing internal hemorrhage. Hematuria resolved several weeks later.

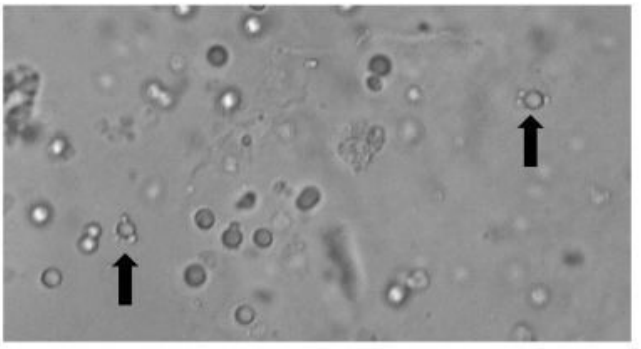

Figure 1: Dysmorphic red blood cells (arrows) due to ruptured cysts in a patient with polycystic kidney disease

Figure 1: Dysmorphic red blood cells (arrows) due to ruptured cysts in a patient with polycystic kidney disease.

Conclusions: While highly sensitive for glomerular lesions, the presence of dysmorphic erythrocytes on microscopy should not preclude investigation of other causes of hematuria. This case illustrates a common cause of hematuria presenting with unique findings on urine microscopy.

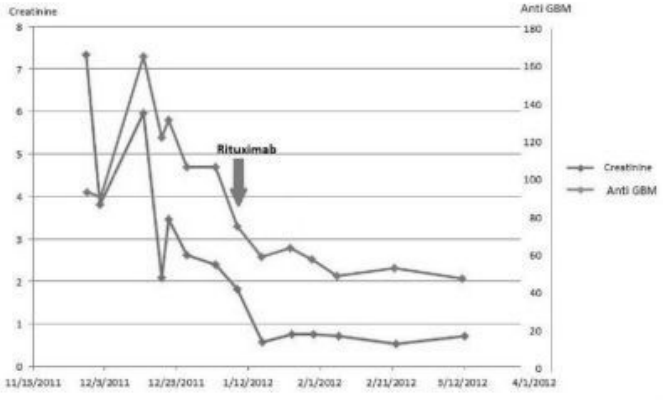
TH-PO1107

Rituximab for a Refractory Case of Simultaneous Anti-GBM and Membranous Nephropathy Ghassan Bandak, Bruce A. Jones, Jian Li, Kausik Umanath. *Henry Ford Hospital, Detroit, MI.*

Background: Anti-GBM antibody disease is a rare autoimmune disorder causing rapidly progressive glomerulonephritis. Membranous nephropathy is a disease manifesting as nephrotic syndrome. Their co-existence is rare.

Methods: A 24 y.o. male smoker presented with hemoptysis and gross hematuria of 2 weeks' duration. The serum creatinine (SCr) increased to 4.3 mg/dL in one week, in conjunction with an ACR of 1000 mg/g and red cell casts in the urine sediment. Kidney biopsy showed crescenteric glomerulonephritis with linear immunofluorescence of the basement membrane staining by IgG and epimembranous electron-dense deposits, when the anti-GBM titer was 165 units. Intravenous methylprednisolone, oral cylcophosphamide (CTX) and plasma exchange (PLEX) were initiated, with a modest response to treatment, SCr ~4 mg/dL. Kidney function deteriorated with decreasing PLEX frequency resulting in dialysis dependence. Daily PLEX was reinstituted, with renal improvement and discontinuation of dialysis. However, after 8 wks of PLEX and CTX, anti-GBM titers were maintained at ~50 units, prompting additional treatment by rituximab. This agent permitted discontinuation of PLEX and a reduction of anti-GBM titer to < 20 units and SCr to 1.76 mg/dL.



Conclusions: Untreated anti-GBM disease portends a poor prognosis with a high probability of end-stage renal disease. The dual diagnosis of membranous nephropathy and anti-GBM disease is rare but has been documented previously. The response rate to traditional therapy of CTX, PLEX and steroids is nearly 50%. This patient manifested an extremely high antibody titer that proved resistant to traditional therapy. Given the pathophysiology of this disorder, directed B-cell depletion with rituximab was attempted and proved efficacious, with rapid anti-GBM titer reduction, and discontinuation of PLEX. Rituximab is a potential, alternative therapy for anti-GBM disease.

TH-PO1108

Outcome of Severe Thrombotic Microangiopathy with Cortical Necrosis in IgA Nephropathy Rapeepat Lekkham,[1] Talerngsak Kanjanabuch.[2] *[1]Medicine, Albert Einstein Medical Center, Philadelphia, PA; [2]Medicine, Chulalongkorn University, Bangkok, Patumwan, Thailand.*

Background: There are several studies on the clinical and pathological features that aid in predicting outcome of IgA nephropathy. In addition to the known clinical variables, the new Oxford classification also provides the pathological features that help in predicting renal outcome. However, thrombotic microangiopathy (TMA) is not included in the classification, so the clinical significance of TMA in this setting is not well understood.

Methods: A healthy 25-year-old Asian man who reported an episode of productive cough and oligoarthritis 6 months earlier, presented with fever with chills, productive cough, severe vomiting and blurred vision. He found to have acute renal failure (Cr of 14.7mg/dl, normal 2 months earlier) with nephrotic-range proteinuria (8.5 gm/day), severe hypertension (BP190/120), volume overload, respiratory failure required a mechanical ventilation and an emergent hemodialysis. Blood tests showed mild anemia, leukocytosis, and normal platelets. Urinalysis showed red blood cells with board coarse granular casts. Complement levels were normal. ANA, p-ANCA, c-ANCA,cryoglobulin and viral hepatitis profiles were negative. Kidney ultrasonography showed bilateral renal parenchymal disease. A renal biopsy was consistent with the mesangial IgA nephropathy;M1 E1 S1 T2 (by Oxford IgA classification) with severe thrombotic microangiopathy, necrotizing glomerulitis, focal cortical necrosis and hemorrhage. Patient received several hemodialysis sessions, intravenous steroid and plasmapheresis were tried. He was not improved hence intravenous immunoglobulin was initiated. His condition was later improved. He was discharged with oral corticosteroids and mycophenolate mofetil but need to be continued on long-term hemodialysis as outpatient.

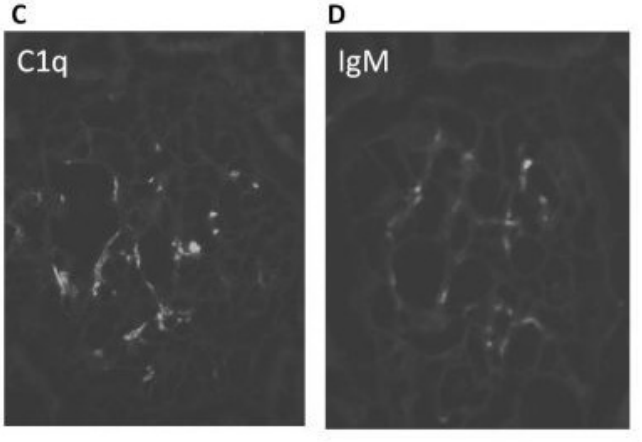
Conclusions: According to our patient who had evidence of TMA and cortical necrosis developed the worst renal outcome required long-term renal replacement therapy. Hence, we suggest that even rare but once presents in IgA nephropathy, TMA is likely to be the useful factor to predict worse renal outcome in addition to standard Oxford classification and clinical factors.

TH-PO1109

C1 q Nephropathy and BK Virus Replication in a Renal Transplant Recipient: Occam's Razor versus Hickam's Dictum Purva D. Sharma,[1] Serena M. Bagnasco,[2] Duvuru Geetha.[1] *[1]Medicine, Johns Hopkins University School of Medicine, Baltimore, MD; [2]Pathology, Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: C1 q nephropathy is a rare glomerular disease characterized by dominant mesangial C1q deposits in the absence of SLE.We report the first case of a deceased donor (DD) kidney transplant recipient who developed proteinuria in the setting of rising plasma BK virus (BKV) titers and had biopsy proven de novo C1q nephropathy.

Methods: A 44 year old male received a DD kidney transplant in Feb 2007. His course in August 2007 was complicated by BKV nephropathy.Mycophenolate mofetil (MMF) was stopped and he was treated with leflunomide (LEF).LEF was stopped after 5 months due to transaminitis and he was restarted on low dose MMF. His serum creatinine remained stable with low level BK viremia.In 2012,he was treated with steroids for gout. His plasma BKV titer rose from 700 copies/ml to 2500 copies/ml and he developed new onset proteinuria. Allograft biopsy revealed mild glomerulitis and focal mesangial expansion with mild focal tubulitis.The interstitium showed edema and inflammatory infiltrate of lymphocytes and plasma cells. Immunostaining for SV 40 was negative.Indirect immunofluorescence revealed fine granular staining, segmental for IgG2+, IgM2+,C1q 2-3+.



Electron microscopy revealed focal mesangial deposits.One month after stopping steroids,his plasma BKV titer fell to 500 copies/ml and proteinuria resolved.

Conclusions: The use of steroids in our patient increased BKV replication. Although serum creatinine was stable, the proteinuria was new and was evaluated with allograft biopsy which revealed C1q nephropathy. After stopping the steroids, the BKV titer decreased with resolution of proteinuria. The temporal relationship of BKV replication and proteinuria suggests that C1q nephropathy was triggered by BKV.

TH-PO1110

Complement C4 Deficiency: Juvenile Central Eastic Arteries after 28 Years of Renal Replacement Therapy Emanuel Zitt,[1,3] Florian Knoll,[1] Dennis Intemann,[2] Karl Lhotta.[1,3] *[1]Department of Nephrology and Dialysis, LKH Feldkirch, Feldkirch, Austria; [2]Department of Internal Medicine, Clinical Institution of Angiology, LKH Felkdirch, Feldkirch, Austria; [3]Vorarlberg Institute for Vascular Investigation and Treatment, LKH Feldkirch, Feldkirch, Austria.*

Background: Complement activation products are present in atherosclerotic plaques. Recently, binding of complement to elastin and collagen in the aortic wall has been demonstrated, suggesting a role of complement in the development of aortic stiffness and atherosclerosis. The definitive role of complement in arteriosclerosis and atherosclerosis, however, remains unclear.

Methods: We here describe a patient with hereditary complete deficiency of complement C4 suffering from Henoch-Schoenlein purpura who has been on renal replacement therapy for twenty-eight years now. The patient has experienced the full range of risk factors for vascular damage such as hypertension, volume overload, hyperphosphatemia and hyperparathyroidism. Despite that, his carotid artery intima media thickness was below the normal range and his aortic pulse wave velocity was normal. In contrast, the patient's peripheral muscular arteries were found to be heavily calcified.

Conclusions: This case supports the hypothesis that complement plays an important role in the development of arterio- and atherosclerosis of central elastic arteries. We speculate that inability to activate complement by the classical or lectin pathways protected the patient from arteriosclerosis with stiffening and calcification of the aorta and atherosclerotic plaque formation of the carotid arteries. This idea is supported by recent experimental data that found complement C3 and C4 accumulation in the external elastic lamina of healthy old mice and extending complement accumulation into the internal elastic lamina and intimal plaques in atherosclerosis-prone ApoE(-/-) mice (Shields K. et al, Clin Transl Science 2011). Inhibition of complement activation may be a potential target for prophylactic and therapeutic interventions.

TH-PO1111

Renal Ascites: Lymph Weep from Allograft Associated with Homozygous NPHP1 Deletion Tomoki Tsukahara, Christie P. Thomas. *Nephrology, University of Iowa, Iowa City, IA.*

Background: NPHP1 gene encodes nephrocystin-1 and its homozygous deletion causes juvenile nephronophthisis (NPHP). NPHP often leads to ESRD and NPHP transplant recipients are thought to have excellent outcomes. We report 2 cases with NPHP1 deletion that presented with intractable ascites from late post-transplant renal lymph leakage.

Methods: The first case is a 15-year-old man who developed an enlarged edematous allograft with ascites 14 month after his third transplant. Kidney biopsy showed acute cellular rejection and hypertrophic tubules. Laparotomy revealed clear fluid weeping from the surface of the intraperitoneal kidney. Transplant nephrectomy was performed because of intractable ascites and failure to thrive. He received his fourth transplant but developed a massively enlarged allograft 54 months later with a perinephric fluid collection. His graft function deteriorated slowly and kidney biopsy showed chronic vascular rejection and hypertrophied remnant tubules. The second case is a 24-year-old woman who developed an enlarged edematous renal allograft with ascites 19 month after her third transplant. Laparoscopy revealed clear fluid weeping from the surface of the intraperitoneal kidney. Kidney biopsy showed positive C4d in peritubular capillaries and interstitial edema, though her graft function is excellent. Her ascites is controlled by a peritoneo-venous shunt and paracentesis as needed.

Conclusions: In both cases serum-ascites albumin gradient was high with ascitic fluid chemistry consistent with lymph. There was no evidence of cirrhosis, portal hypertension, right heart failure, urine leak, peritonitis, or malignancy. We suspect that ascites was caused by lymph seeping from allograft. Obstruction to hilar lymphatic drainage may lead to a weeping of lymph via the superficial capsular network. Renal lymph leakage may be immune-mediated since both patients were highly sensitized and had the same gene deletion. When transplanted, such patients may develop antibodies against nephrocystin or an interacting protein that was previously shielded from the immune system. Further studies are needed to elucidate the mechanisms of post-transplant 'renal ascites'.

TH-PO1112

The Use of CRRT for Removal of Dabigatran in an Anuric Patient with Life-Threatening Bleeding Tomoki Tsukahara, Lisa M. Antes. *Nephrology, University of Iowa Hospitals and Clinics, Iowa City, IA.*

Background: Dabigatran is an oral direct-thrombin inhibitor which has been approved for stroke prevention for non-valvular atrial fibrillation. While it has been associated with at least 260 fatal bleeding events worldwide, no specific antidote exists for dabigatran reversal.

Methods: A 71-year-old woman with atrial fibrillation on dabigatran 75 mg twice daily presented with hemorrhagic shock due to right hemothorax after sustaining a fall. Lab data on presentation included: hemoglobin 4.1 g/dl, creatinine 4.4 mg/dl, PT-INR 5.3 and aPTT 70 seconds. She underwent 2 emergent thoracotomiesand bled an estimated 9.2 liters. In spite of extensive coagulation factor and blood product support, her PT-INR remained 1.7 and aPTT 49 seconds.

Continuous renal replacement therapy (CRRT) was initiated on day 2 when she became anuric. She remained oligo-anuric for 6 hours after CRRT. Vasopressors were discontinued on day 3. She became independent of blood products on day 4. PT-INR and aPTT gradually improved, normalizing on day 5 when CRRT was discontinued. She was discharged home on day 13 with a GFR of 23 ml/min.

Conclusions: Hemodialysis has been proposed as a treatment in cases of severe bleeding with dabigatran, as it is dialyzable based on its properties of low protein binding (35%), volume of distribution (50-70L), and relatively small molecular weight (471 daltons). The fraction of the drug removed by intermittent hemodialysis is 68% in 4 hours. No studies have examined the efficacy of CRRT in removing dabigatran.

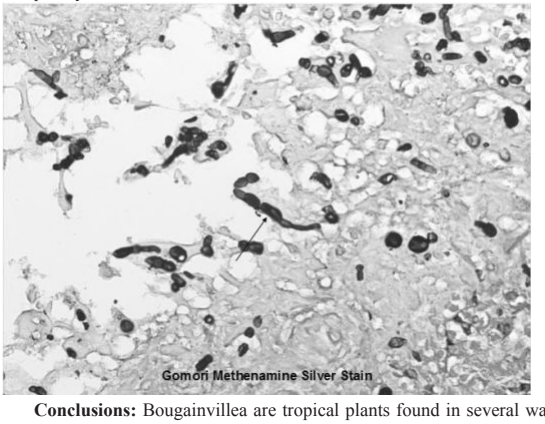
In our case we believe normalization of PT and PTT was achieved more quickly with CRRT. Even a single administered 150-mg dose of dabigatran, leading to moderate INR elevation, will take 4 days to be eliminated if the GFR is < 30 ml/min. The magnitude of the initial coagulation studies in our patient suggest dabigatran accumulated to a much greater degree and it would have taken longer to be eliminated without CRRT. With the more widespread use of dabigatran, it will be important to consider the potential role of CRRT to aid in dabigatran removal in unstable anuric patients with life-threatening bleeding.

TH-PO1113

Alternaria Phaeohyphomycosis from Exposure to Bougainvillea in Kidney Transplant Recipient Jaudat H. Khan,[1] Ashfaq S. Balla,[1] Venu Velagapudi,[1] Sonia Nagy Chimienti.[2] *[1]Renal Medicine, University of Massachusetts Medical School, Worcester, MA; [2]Infectious Disease, University of Massachusetts Medical School, Worcester, MA.*

Background: Alternaria is a cosmopolitan fungus isolated from plants and soil that rarely causes disease in healthy humans but can cause opportunistic infection in immunocompromised individuals. We hereby present a case of a kidney transplant recipient with cutaneous alternaria infection from exposure to Bougainvillea bushes.

Methods: A 69 year old Kenyan male received a living related donor kidney transplant done for diabetic nephropathy. He was induced with alemtuzumab and steroids. His maintenance immuno-suppression regimen consisted of Mycophenolate Mofetil, Tacrolimus, and Prednisone. His post-transplant course was uncomplicated with stable allograft function and acceptable Tacrolimus levels. Seven months after transplantation, the patient visited Kenya for an extended vacation where he regularly tended to Bougainvillea plants. Tacrolimus levels during overseas stay were not available. He developed non-tender papulo-nodular violaceous skin lesions on his upper and lower extremities at 12 months post-transplant with no other systemic symptoms. Biopsy of the skin lesions and culture revealed Alternaria species-septate fungal hyphal elements. The patient was initiated on itraconazole and immunosuppression was reduced. His lesions began to slowly improve and he was also referred for surgical excision as antifungal treatment alone may not completely cure lesions.



Conclusions: Bougainvillea are tropical plants found in several warm states in US and immunosuppressed patients should be counseled about using protection barrier during exposure.

TH-PO1114

Disseminated Bartonella Henselae Infection Inducing Hemophagocytic Lymphohistiocytosis in a Kidney Transplant Recipient Atul Poudel,[1] Vikas R. Dharnidharka.[2] *[1]Department of Pediatric Nephrology, University of Florida, College of Medicine, Gainesville, FL; [2]Department of Pediatric Nephrology, Washington University School of Medicine, St Louis, MO.*

Background: Bartonella Henselae (BH) is a bacterium that lives under the nails of cats and can cause infection in human. Presentations include lymphadenopathy and fever, but can include more systemic lesions in the liver, spleen, bone, eyes and/or brain. Hemophagocytic Lymphohistiocytosis (HLH) can present with similar systemic symptoms with pathognomonic findings of raised ferritin levels and hemophagocytic activity in the bone marrow.

Methods: A 14 year old Caucasian girl presented at 13 months post-kidney transplant with 10 day history of intermittent fever, diarrhea and weight loss. Examination was notable for pallor and dehydration.Laboratory tests showed marked drop in hemoglobin, thrombocytopenia, elevated serum creatinine, elevated LDH, high haptoglobin. Abdominal ultrasound showed hypodense lesions in spleen, ring-enhancing by CT scan. She had recently obtained a kitten, so azithromycin was started for putative BH infection. Soon after presentation, she developed septic shock, acute lung injury requiring mechanical ventilation, and acute kidney injury. All blood and urine cultures were negative for bacteria and fungi, CMV and EBV PCR were undetectable, Toxoplasma IgM was negative. BH IgM was strongly positive at 1:128 and doxycycline was added. In the presence of

worsening clinical picture and hemolytic anemia and thrombocytopenia, continuing fever and high serum ferritin level of 5025 ng/ml, HLH was investigated. Bone marrow aspirate confirmed hemophagocytic activity. Intravenous steroids were instituted and the patient's condition improved. She recovered from septic shock, was extubated, acute kidney injury, hemolytic anemia and thrombocytopenia resolved. Ferritin levels dropped to 1221 prior to hospital discharge.

Conclusions: Review of literature revealed that among a series of 17 cases of HLH in renal transplant patients, a solitary case was secondary to BH. Treatment in these cases has been with 2 agents and for several months.

BH infection is rare but can induce HLH in transplant recipients.

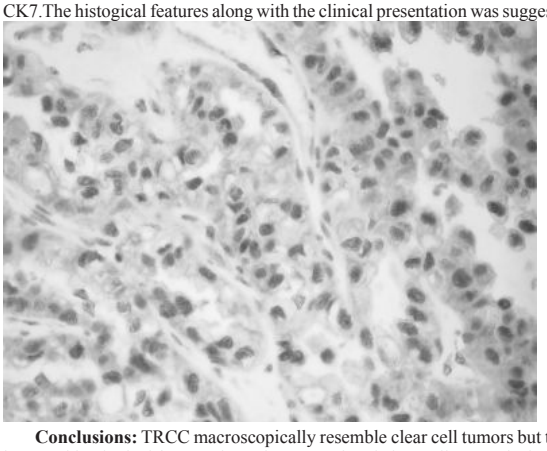
TH-PO1115

All that Grows in Pregnancy Is Not "BABIES": A Rare Case of Translocation Renal Cell Carcinoma in Pregnancy and Review of Literature

Bhavani Adusumilli, Murali Veluru. *Internal Medicine, William Beaumont Hospital.*

Background: Renal cell carcinomas (RCC) associated with Xp11.2 translocations are rarely seen in pregnancy. To the best of our knowledge, the case herein presented is the second report of Xp11.2 translocation RCC (TRCC) occurring during pregnancy.

Methods: A 30-year-old pregnant lady with past history significant for hypertension and RCC treated with radical nephrectomy 4 years ago presented with difficult to control hypertension. Labs including cell counts, serum creatinine, electrolytes, hepatic function panel, renin and cortisol levels and 24 hr urine catecholamines were all within normal limits. Blood pressure was adequately controlled by adjusting her oral regimen. The patient delivered a healthy child at 34 weeks and subsequently underwent a screening MRI 2 weeks later for follow up of RCC which showed a 10 cm x 5.6 cm x 6.1 cm non-homogeneously enhancing mass in the right renal fossa consistent with RCC for which she underwent resection. Microscopy revealed a carcinoma with papillary and clear cell features. The tumor cells stained positive for TFE3(transcription factor gene fusions), but negative for CK7.The histogical features along with the clinical presentation was suggestive of a TRCC.



Conclusions: TRCC macroscopically resemble clear cell tumors but the most distinct immunohistological feature absent in conventional clear cell RCCs, is the nuclear staining for the chimeric (mutant) TFE3 protein .Surgical resection is the preferred therapy and may be performed in pregnant women. There is some evidence that hormonal changes and increased immune tolerance during pregnancy predispose pregnant women toTRCC. They are inherently more aggressive in adults, thus early diagnosis and treatment plays a vital role in the management of these patients.

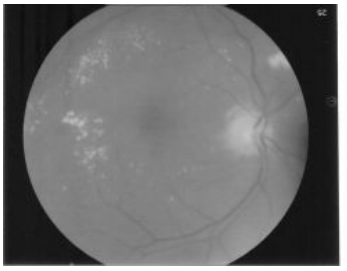
TH-PO1116

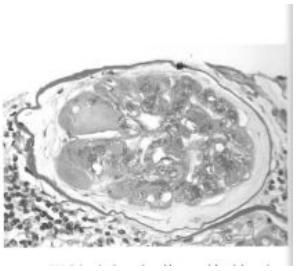
Nodular Glomerulosclerosis Preceding Overt Diabetes

Iqbal Masood, Alejandro Diez. *Nephrology, Lankenau Medical Center & Lankenau Institute for Medical Research, Wynnewood, PA.*

Background: Chronic diabetes leads to alterations in glomerular architecture (mesangial expansion, glomerular basement membrane thickening and glomeruloscelrosis) leading to albuminuria and progressive kidney disease. Current dogma states these changes are seen in patients with 10 to 15 years of overt disease. We are presenting a case of a patient with retinopathy and nodular glomeruloscelrosis on renal biopsy characteristic of diabetes, with impaired glucose tolerance (IGT) as the only manifestation of diabetes.

Methods: A 60 year old obese white female with past medical history of newly diagnosed hypertension and retinopathy was referred for proteinuria (2.7 grams/day). Renal work-up for proteinuria was unrevealing: creatinine, Hemoglobin A1c, infectious and autoimmune serology, and ultrasound were all negative or normal. A renal biopsy showed diffuse and nodular glomerulosclerosis and basement membrane thickening consistent with Kimmelsteil-Wilson syndrome.





Based on renal biopsy and fundoscopy the most likely etiology for proteinuria was diabetes; despite having normal hemoglobin A1c and non-diabetic range fasting blood sugars on multiple occasions. A 2-hour oral glucose tolerance test revealed impaired glucose tolerance(IGT). Initiation of Lisinopril reduced the proteinuria to 400mg/day within three months.

Conclusions: Idiopathic Nodular golermuloscelrosis has been linked to IGT, smoking and long standing hypertension. IGT and smoking promotes formation of advanced glycation end products, which alters the extracellular matrix, especially in the presence of pre-existing pro-sclerotic insult like hypertension. Classically, changes in glomerular architecture caused by diabetes are sine qua non of long-standing overt diabetes. This case presents an uncommon presentation for a common disease in which renal histological changes are seen in the absence of overt underlying disease.

TH-PO1117

A Case of Type B Lactic Acidosis in a Patient with Large Cell Lymphoma

Iqbal Masood, Geoffrey S. Teehan. *Nephrology, Lankenau Medical Center & Lankenau Institute for Medical Research, Wynnewood, PA.*

Background: Lactic acidosis most commonly occurs during tissue hypoperfusion, but can occur in its absence, and is called either Type B or D lactic acidosis. We present a case of Type B lactic acidosis refractory to hemodialysis due to large cell lymphoma.

Methods: An 81 year old Caucasian male with baseline creatinine of 1.6mg/dl and Chronic Lymphocytic leukemia(CLL) for 5 years, not on treatment, presented to the hospital feeling weak, found to be in ATN and profound lactic acidosis with lactate of 12.3 mmol/L, BUN 95, Creatinine 9.2 and PH of 7.10. No hypotension or sepsis was present. Physical exam was essentially normal. CT scan of abdomen and pelvis revealed a 4.4 cm infrarenal aneurysm.

Patient was started on IV fluids, but lactate levels remained high, requiring hemodialysis which had little effect on his lactic acid levels.

He underwent CO2 angiogram which ruled out aortic and renal artery dissection. A diagnostic laparoscopy showed no evidence of mesenteric ischemia. Liver function test were normal as was a liver biopsy which did not show lymphomatous infiltration. Volatile acid screen was negative. WBC count was 17200 with 70% lymphocytes. There was no evidence of heavy CLL burden as there was no significant adenopathy or evidence of bone marrow involvement. A course of steroids was unsuccessful. Patient was administered thiamine without effect and Riboflavin levels were elevated. Patient underwent bone marrow biopsy which showed large B cell lymphoma. Due to deteriorating condition, patient was made hospice and died.

Conclusions: Tissue hypoperfusion is the most common cause of lactic acidosis. In type B lactic acidosis there is no evidence of tissue hypoperfusion. Usual causes include alcoholism, Metformin, HIV, Malignancy including leukemia, lymphoma and solid tumors. The mechanism for lactic acidosis in malignancy is unclear. An anaerobic mechanism due to dense cluster of tumor cells, and or metastatic replacement of liver parenchyma by tumor cells has been proposed. Alternatively, lactic acid may be produced by tumor cell. Removal of the tumor by surgery, chemotherapy or radiation can correct lactic acidosis.

TH-PO1118

Acute Kidney Injury with Bluish Green Urine,Highest Possible FENa and Rapid Recovery after Methylene Blue Infusion

Iqbal Masood, Paul Robbins. *Nephrology, Lankenau Medical Center, Wynnewood, PA.*

Background: Methylene blue is used as a tissue marker,for the treatment of methemoglobinemia and refractory vasodilatory shock after cardiac surgery.It leads to bluish green discoloration of the urine .We are presenting a case of acute kidney injury in a patient who received Methylene blue for refractory shock with a rather quick recovery along with interference in urine creatinine assay leading to a very high FENa.

Methods: 77 Year old white male with CKD II/CHF, EF 10% underwent insertion of left ventricular assist device complicated by refractory hypotension due to bleeding requiring Methylene blue infusion with improvement. Patient became oliguric with creatinine of 4mg/dl and was noted to have bluish green discoloration of the urine and skin along with edema. U/A consistent with ATN with urine creatinine noted to be less than 10, in spite of having urine urea nitrogen of 108 and urine Na of 130 on 2 occasions ,giving a very high variable FENa between 39-350%.Urinary creatinine started to rise once urine color cleared up in 3 days. Jaffe method was used to check creatinine assay and manufacturer did not mention methylene blue affecting the assay, but based on urine creatinine it probably did. Patient's creatinine came down to 0.9mg/dl in few days with good urine output without needing dialysis.

Conclusions: Methylene blue has been shown to cause a decrease in Nitric Oxide (which is associated with proximal tubular injury in sepsis) and attenuation of the urinary excretion of renal tubular injury markers in refractory septic shock. Our patient in spite of having a lots of co-morbidities had good renal recovery, unclear whether methylene blue played a role in recovery or not.In our patient, a possible interference with urinary creatinine assay was noted, therefore in patients who receive methylene blue, urinary creatinine may not reflect true creatinine clearance.

TH-PO1119

Double Trouble: The Importance of Examining Nonneoplastic Tissue in Nephrectomy Specimens with Neoplasia Suzanne Wilhelmus,[1] Ingeborg M. Bajema,[1] Natascha Goemaere,[2] Marinus A. Van Den Dorpel,[3] Reinout M. Swart.[3] *[1]Pathology, Leiden University Medical Center, Leiden; [2]Stichting Pathan, Rotterdam; [3]Nephrology, Maasstad Hospital, Rotterdam, Netherlands.*

Background: A nephrectomy for an epithelial neoplasia not only yields tumor but also normal tissue. Often this tissue is glanced at, but not looked at as one would look at a renal biopsy. This case demonstates the importance of careful examination of nonneoplastic tissue in resection specimens.

Methods: A 63 year old woman was diagnosed with right sided renal cell carcinoma after she was referred with non-specific complaints and an increased ESR. A nephrectomy was performed. The first postoperative day her creatinine increased to 358 µmol/l (from 96 µmol/l one month earlier). The deterioration of renal function could not be attributed solely to reduction in glomerular number. Further tests excluded pre- or postrenal causes. Urine analysis showed erythrocyturia and subnephrotic range proteinuria. With a differential diagnosis of tubulointerstitial nephritis or a glomerulonephritis the nonneoplastic renal tissue was re-examined showing a necrotizing crescentic glomerulonephritis, mixed class. Frozen tissue for immunofluorescence was not available. Electron microscopy showed no deposits or podocyte lesions, consistent with a pauci-immune glomerulonephritis. ANCA-testing revealed positivity for MPO-ANCA, although at a very low level. ANCA-associated vasculitis (limited to the kidney) was diagnosed and treatment with steroids and cyclophosphamide started. An initial response was seen, but treatment was discontinued early because of a severe pulmonary infection.

Conclusions: In the initial pathology work-up, only a small amount of nonneoplastic tissue was examined in the HE-staining. During the re-examination, extra tissue was embedded and silver and PAS stainings were performed, by which the glomerulonephritis became apparent. This case demonstrates the importance of careful examination of nonneoplastic renal tissue of nephrectomy specimens as others have also recognized (Henriksen et al. Arch Pathol Lab Med 2009). It gives the opportunity to detect and treat early in the course of incidental kidney disease, thereby improving outcome.

TH-PO1120

Urothelical Carcinoma of the Renal Pelvis Mimicking Acute Pyelonephritis with Abscess Jinuk Jeong, Kitae Bang, Jongho Shin. *Department of Internal Medicine, Eulji University of Medicine, Eulji Medical Center, Daejeon, Korea.*

Background: Primary tumors of the renal pelvis and collecting system are relatively uncommon. Their clinical presentation is nonspecific and variable, and they can be mistaken for acute pyleonephritis or renal abscesses. This report presents an unusual case of urothelial carcinoma in which was at first mimicking acute pyelonephritis and presented as renal abscess several months later.

Methods: A 75-year-old man presented with a week history of left flank pain.His urinalysis did not show protein and RBC. Uine cytology revealed no atypical cells.Computed tomography showed left renal pelvic and ureteral wall thickening with enhancement, mild hydronephrosis with multifocal wedge shaped decreased enhancing lesions on Lt renal lower pole (Figure 1). Oral treatment with ciprofloxacin was given for 2-weeks period, And clinical improvement was observed.3 months later patients developed abdominal pain on Lt upper quadrant again. Rechecked abdominal CT revealed 8*8cm lobulated abscess with septation in the lower pole of the left kidney (Figure 2). But irregular thickend abscess wall with enlarged enhanced peripheral rimmed central necrotic paraaortic lymph nodes and absense of fever and elevated immflamatory markers were thought to be malignancy or tuberculosis. So percutaneous nephrostomy was done and about 200 ml/day of hemorrhagic fluid were drained.The microbiologic features including tuberculosis were sterile.Cytology revealed no malignancy. So the patient underwent laparoscopic excisional biopsy of paraaortic lymph nodes. The pathologic diagnosis was urothelical carcinoma (Figure 3).

Figure 1-1

Figure 1-2

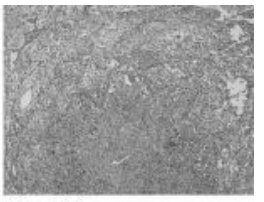


Figure 1-3

Conclusions: Urothelial carcinoma present in a variety of ways mimicking acute pyelonephritis or renal abscesses.We should suspect malignancy if there is no inflammatory sign or symptoms in the finding of acute pyelonephritis or abscess in various imaging including CT.

TH-PO1121

Unusual Complication in Chronic Renal Failure: Cervical Tumoral Calcinosis with Severe Secondary Hyperparathyroidism Sham Sunder, Himanshu Verma, Venkataramanan K. *Nephrology, PGIMER & Dr. Ram Manohar Lohia Hospital, New Delhi, Delhi, India.*

Background: Cervical tumoral calcinosis due to severe secondary hyperparathyroidism is an uncommon and severe complication of chronic renal failure.

Methods: A 50 year-old female on thrice weekly maintenance hemodialysis for the last three years presented with a solitary, tumour-like swelling over the nape of the neck. On physical examination the swelling was large, smooth, non lobulated,and firm.

The patient was investigated and was found to be having high serum calcium x phosphate product with high serum iPTH, CT Scan of the cervical spine showed a well defined calcified mass along the spinus process, radionucleide parathyroid scan suggested parathyroid hyperplasia ,and biopsy from the mass confirmed the diagnosis of tumoral calcinosis.The patient was treated with vitamin D withdrawl, strict control of serum phosphate levels with sevelamer, and sub-total parathyroidectomy. Postoperatively the neck swelling gradually decreased but again started increasing in size after two years of parathyroidectomy. The patient was prescribed cinacalcet along with sevelamer and the swelling again decreased in size with improvement of biochemical parameters.

	Pre Parathyroidectomy	6 months post Parathyroidectomy	2 years post parathyroidectomy	After Cinacalcet therapy
S. Calcium	10.10 mg/dl	8.9 mg/dl	10.30 mg/dl	9.5 mg/dl
S. Phosphate	8.1 mg/dl	7 mg/dl	8.4 mg/dl	7.40 mg/dl
S. iPTH	1324 pg/cc	253 pg/cc	551 pg/cc	123.20 pg/cc

Conclusions: The prevalence of tumoral calcinosis in hemodialysis patients is 0.5% to 1.2%. Uremic tumoral calcinosis usually occurs after long duration of hemodialysis (approximately 10 years). In our patient tumoral calcinosis occurred after 3 years of maintenance hemodialysis. The metastatic calcification occurring in the patient was most likely related to high calcium x phosphate product with secondary hyperparathyroidism.

TH-PO1122

Life Threatening Hypocalcemic Tetany Following the Use of Sodium Phosphate Enemas Elizabeth I. Anyaegbu. *Pediatric Nephrology, Washington University in St Louis, St Louis, MO.*

Background: The clinical spectrum of hypocalcemia ranges from a dearth of symptoms to life threatening tetany. Common causes of hypocalcemia include renal insufficiency, tumor lysis syndrome, hypoparathyroidism, rhadbomyolysis and exogenous administration of phosphorus-containing compounds. With excessive phosphate administration, calcium phosphate precipitation occurs in the skeleton and microvasculature, resulting in hypocalcemia.

Methods: A 6-year-old female with a history chronic constipation presented to the ED with altered mental status, muscle rigidity and tetany. Her home bowel regimen consisted of daily polyethylene glycol and 2 sodium phosphate enemas administered every other day. She complained of abdominal pain attributed to constipation, the day of presentation. She received 3 adult enemas within 12 hours to achieve an explosive passage of stool and became unresponsive within a few hours. An EKG showed sinus tachcardia with non-specific ST and T wave abnormalities. Results included serum phosphorus of 45.2mg/dl, potassium 1.8 mmol/L, bicarbonate 20 mmol/L, total calcium 5.1 mg/dl, ionized calcium 1.8 mg/dl, albumin 4.5mg/dl, magnesium 1.5 mg/dl, and serum creatinine of 0.8 mg/dl, increased from 0.3 mg/dl 8 months prior. She received normal saline and a calcium gluconate infusion was commenced. She improved dramatically with a decrease in serum phosphorus to 7.3 mg/dl within 8 hours and increase in ionized calcium to 2.8 mg/dl. By hospital day 2, her mental status and electrolyte disturbances normalized. Her serum creatinine was 0.4 mg/dl at discharge.

Conclusions: Sodium phosphate enemas deliver a massive exogenous phosphate load which can produce fatal acute hyperphosphatemia. Increasing urinary phosphate excretion is essential; therefore aggressive intravenous hydration is the first line of treatment. Symptomatic hypocalcemia requires prompt treatment with intravenous calcium salts. Coexisting hypomagnesemia should always be corrected. Acute hyperphosphatemia usually resolves quickly in patients with normal renal function. Hemodialysis may be necessary if renal function is impaired. The indication for hemodialysis is oliguria or anuria, rather than absolute serum phosphorus levels.

TH-PO1123

Hypercalcaemia and Renal Failure: A Diagnostic Conundrum Louise E. Ross, Konstantinos Koutroutsos, Debasish Banerjee. *Renal Department and Transplantation Unit, St George's Healthcare NHS Trust, London, United Kingdom.*

Background: Hypercalcaemia and renal failure is not an uncommon clinical problem for a nephrologist. When associated with a serum calcium of >3mmol/L the differential diagnoses are few and initial blood tests, including phosphate, parathyroid hormone and serum electrophoresis narrows the differential to even fewer. However, we describe a case which required a multidisciplinary approach, therapeutic trial and several investigations before the diagnosis was made.

Methods: A 50-year-old Caucasian man presented with a two week history of nausea and constipation. Examination was normal.

Biochemical Investigations

Investigation	Result	Reference Range
Creatinine	387	60-110 umol/L
Adjusted Calcium	3.71	2.2-2.6 mmol/L
Phosphate	1.6	0.8-1.5 mmol/L
PTH	2.5	1.1-6.9 pmol/L
PTHrP	<0.7	<2 pmol/L
ALP	52	30-130 U/L
ACE	38	20-70 U/L
25 hydroxy vitamin D	137	75-200 nmol/L
1,25 dihydroxy vitamin D	102	40-150 nmol/L
Urine Calcium	18.7	2.5-7.5 mmol/24hrs

A renal ultrasound, chest X-ray, bone scan, and myeloma screen showed no abnormality. A CT chest, abdomen, pelvis reported bilateral small pulmonary nodules of uncertain significance. A renal biopsy showed tubulointerstitial scarring and tubular dystrophic calcification in keeping with nephrocalcinosis. An MRI of the neck suggested an enlarged parathyroid gland and hence a parathyroidectomy was performed but the serum calcium remained elevated. To investigate further a PET scan highlighted a single nodule in the right lower lobe of the lung. The biopsy of the nodule demonstrated non-caeseating granulomas establishing a diagnosis of sarcoidosis. Treatment with high dose corticosteroid improved the serum calcium and partially improved the renal function.

Conclusions: This case shows how a relatively common presentation of hypercalcaemia with renal failure, which was due to sarcoidosis can be difficult to diagnose. The patient underwent a kidney biopsy and parathyroidectomy but the diagnostic tissue biopsy was after a PET scan. It highlights the importance of PET scan to search for sites of inflammation which cause hypercalcaemia. Every effort should be made in such cases as the diagnosis may be difficult to make but easy and satisfying to treat.

TH-PO1124

Severe Hypophosphatemia due to Oncogenic Osteomalacia Associated with Metastatic Colon Adenocarcinoma David E. Leaf,[1] Harald Jüppner.[2] *[1]Renal Medicine, Brigham and Women's Hospital, Boston, MA; [2]Pediatric Endocrinology, Massachusetts General Hospital, Boston, MA.*

Background: Oncogenic osteomalacia, also known as tumor-induced osteomalacia, is a paraneoplastic syndrome associated with elevated levels of the phosphaturic hormone Fibroblast Growth Factor 23 (FGF23). It is usually associated with benign mesenchymal tumors of bone or soft tissue, however, 10% of cases are due to malignant tumors. To date, no cases of oncogenic osteomalacia associated with colon cancer have been described.

Methods: An 80-year old woman with recently diagnosed stage IV adenocarcinoma of the cecum with liver metastases was referred to nephrology for evaluation of severe symptomatic hypophosphatemia. She had several days of fatigue and muscle weakness and labs revealed a serum phosphate of 0.4 mg/dl. She had no personal or family history of hypophosphatemia. Initial serum and urine studies are shown in the table.

Laboratory Values

	Reference Range	Patient's Value
Calcium (mg/dl)	8.5-10.5	9.2
Phosphate (mg/dl)	2.6-4.5	0.4
Creatinine (mg/dl)	0.6-1.5	0.7
Fractional Excretion of PO4 (%)	<5	34
25(OH)D (ng/ml)	33-100	33
1,25(OH)2D (pg/ml)	18-78	13
PTH (pg/ml)	10-60	36
PTH-rP (pmol/L)	<2.0	1.1
c-terminal FGF-23 (RU/ml)	7-71	674

Fractional excretion of phosphate was inappropriately elevated, suggesting renal phosphate wasting as the etiology of her hypophosphatemia. Elevated levels of FGF23 and decreased levels of 1,25-dihydroxyvitamin D confirmed the diagnosis of oncogenic osteomalacia. Tissue obtained from biopsy of a metastatic liver lesion stained positively for a highly specific FGF23 antibody. She was treated with palliative chemotherapy (Fluorouracil and Oxaliplatin) as well as supplements containing 750mg phosphorus three times daily, and her serum phosphate levels normalized.

Conclusions: Reported malignant tumors associated with oncogenic osteomalacia include prostate adenocarcinoma, small cell lung carcinoma, and multiple myeloma. We report the first case of colon adenocarcinoma associated with oncogenic osteomalacia, a paraneoplastic syndrome which should be considered in patients with malignancy, hypophosphatemia, and renal phosphate wasting.

TH-PO1125

Idiopathic Hypercalciuric Nephrotlithiasis with 1,25 Dihydroxy D_3 Hypervitaminosis, Growth Retardation and Osteopenia: Testing for Renal Epithelial Calcium Channel TRPV5 and Long Term Response to Hydrochlorothiazide and Growth Hormone Swati Arora,[1] Anke Lameris,[2] Joost G. Hoenderop,[2] Barbara A. Clark.[1] *[1]Nephrology, Allegheny General Hospital, Pittsburgh, PA; [2]Physiology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [3]Physiology, Radboud University Nijmegen Medical Centre, Njmegen, Netherlands; [4]Nephrology, Allegheny General Hospital, Pittsburgh, PA.*

Background: Idiopathic hypercalciuric nephrolithiasis has varying phenotype with no specific gene yet identified. It is not well rcognized that excess endogenous 1,25 $(OH_2)D_3$ could be the cause or that the initial presentation may be bone/ growth problems. The role of the renal epithelial calcium channel, TRPV5, in this disorder is unknown.

Methods: A short stature 17yo WM with fam hx of stones in F and PGF presented with his first episode of nephrolithiasis. Workup revealed hypercalciuria (457 mg/day); (PO_4, citrate, oxalate wnl); pH 6; sCa 9.9 mg/dL; PO_4 3.8 mg/dL; sCr and HCO_3 wnl; iPTH < 3 pg/ml; low 25 OH vitamin D (14 ng/ml); but elevated 1,25 (OH_2) D_3 at 160 pg/mL and osteopenia (bone age 14; Z score -3.8; 15th % ht). Because of phenotypic similarity to the hypercalciuria model of knockout mice deficient in TRPV5 (also increased 1,25 $(OH_2)D_3$ due to over expression of 1,25 alpha hydroxylase), his genomic DNA was sequenced for TRPV5. No mutations were discovered. He was treated with hydrochlorothiazide (HCTZ) and Norditropin (hrGH). Teriparatide was considered but deferred due to uncertain longterm side effects at his age. At age 21 he has not had any recurrent symptomatic stones. Repeat calcium excretion has been as low as 238 mg/day; latest Z score is -2.6 and height is now 50th%.

Conclusions: Some cases of idiopathic hypercalciuria have significant elevations of 1,25 (OH_2)Vitamin D_3 that can contribute to the hypercalciuria. Initial presentation may be bone/growth problems even before symptomatic stones. Suppressed PTH levels may be a clue. The genetic defect does not appear to involve TRPV5 in this patient. Response is good to HCTZ. In adolescents with associated growth retardation and bone demineralization hrGH may help. Use of PTH might be considered in older individuals.

TH-PO1126

Tuberous Sclerosis and Polycystic Kidney Disease: A Are Finding Chadi Saifan, Rabih Nasr, Suzanne E. El Sayegh. *Nephrology, Staten Island University Hospital, Staten Island, NY.*

Background: Polycystic kidney disease is a cause of chronic kidney disease. The association with tuberous sclerosis is linked to a genetic defect because of the proximity of genes: TSC1 and TSC2. It is known by tuberous sclerosis complex.

Methods: 30 y/o man presented for a 1-day history of right flank pain and vomiting. Past medical history was significant for tuberous sclerosis, seizure disorder, and hypertension. Family history was irrelevant. Physical examination revealed speech and hearing impairment, multiple faical angiofibromas, and hypomelanotic macules on bilateral upper extremities. Lab tests revealed BUN of 22 mg/dl and Cr of 3.59 mg /dl. CT of the abdomen and pelvis showed innumerable cysts within the both kidneys. Fatty soft tissue masses were also seen in the liver and the right kidney suggestive of angiomyolipoma. Multiple calcified tubers were detected on a CT of the head within the areas lining the ventricles, a feature consistent with tuberous sclerosis.

Patient was started on IV fluids and improved clinically. He significantly felt better over three days and his kidney function mildly recovered with BUN of 18 mg /dl and creatinine of 2.13 mg/dl.

Conclusions: Tuberous sclerosis is a rare genetic disease. PKD is a multisystemic and progressive genetic disorder characterized by the formation and enlargement of cysts in the kidney and other organ. Clinical features usually begin in the third to fourth decade of life, but cysts may be detectable in childhood and in utero. Early imaging study can detect the APKD in the tuberous sclerosis patient which can subsequently help assess and manage the deterioration in kidney function.

TH-PO1127

A Novel *UMOD* Mutation in a Family with Medullary Cystic Kidney Disease Type 2 Masafumi Kamijo,[1] Masahito Tamura,[1] Nana Ishimatsu,[1] Tetsu Miyamoto,[1] Ryota Serino,[1] Narutoshi Kabashima,[1] Kaori Kanegae,[1] Yumi Furuno,[1] Kenichiro Bando,[1] Junichi Nakamata,[1] Akihiro Kuma,[1] Shingo Ishimori,[2] Naoya Morisada,[2] Kazumoto Iijima,[2] Yutaka Otsuji.[1] *[1]Department of Cardiology and Nephrology, University of Occupational and Environmental Health, Kitakyushu, Fukuoka, Japan; [2]Department of Pediatrics, Kobe University Graduate School of Medicine, Kobe, Hyogo, Japan.*

Background: Mutations in the *UMOD* gene cause medullary cystic kidney disease (MCKD) type 2, which is an autosomal dominant tubulointerstitial kidney disease. We report the case of a family with MCKD type 2 characterized by a novel mutation in the *UMOD* gene.

Methods: A 31-year-old woman developed moderate kidney dysfunction (estimated glomerular filtration rate, 59.7 mL/min/1.73 m^2) without any abnormality in urinalysis. She had mild hyperuricemia and had never experienced gout attacks. Her grandfather, father, and aunt developed end-stage kidney failure, and were introduced to maintenance hemodialysis when they were in their forties. Histological analysis revealed diffuse tubulointerstitial fibrosis with moderate inflammatory cell infiltration and tubular atrophy. Renal cysts were not detected. Peripheral blood mononuclear cells were isolated from the patient and her father, DNA was extracted from these cells, and a mutation analysis of the *UMOD* gene was conducted. This analysis revealed a novel missense C135G mutation in exon 3. We did not detect any mutation in 100 healthy volunteers.

Conclusions: MCKD type 2 is a rare disorder, and about 50 *UMOD* mutations other than the one detected in the present cases have been reported thus far. Similar to the mutation in the present cases, most of the *UMOD* mutations are missense changes in one of the conserved cysteine residues, and the mutations are clustered in exons 3 and 4 encoding the N-terminal half of the protein. In patients with MCKD type 2, chronic renal failure generally occurs between the second and fourth decade of life. There is no specific therapy for this condition other than the correction of water and electrolyte imbalance that may occur. Genetic testing is necessary for definite diagnosis of MCKD type 2, and accumulation of data on such cases is required.

TH-PO1128

Cystic Kidney Disease in a Patient with Systemic Toxicity from Long-Term D-Penicillamine Use Farrukh M. Koraishy, Neera K. Dahl. *Internal Medicine/ Nephrology, Yale University School of Medicine, New Haven, CT.*

Background: D- Penicillamine (PCA) has been extensively used in the management of cystinuria. It forms a polymer with cysteine to make it more soluble and hence reduces stone formation. PCA has also been known to cause impaired collagen deposition and dysfunction in the elastic fibers resulting numerous systemic toxicities. Renal disease associated with PCA therapy has been reported to be at the glomerular level; typically a membranous glomerulonephritis pattern with proteinuria.

Methods: Here we describe a patient with severe bilateral cystic kidney disease associated with long-term PCA use (one gram per day for over twenty years) for cystinuria. The cysts in the kidneys were noted during imaging as part of the work up of a new onset of renal dysfunction. A pancreatic cyst was also noted. This was associated with the subsequent development of other systemic toxicities of PCA including cutis laxa (elastolysis). All potential causes of bilateral kidney cysts were ruled out. Of note, the patient had no evidence of cysts on renal imaging three year prior when his kidney function was also normal. Over the next two years, the size/ number of his kidney cysts continued to progress and his renal function declined. At the same time, the PCA-related systemic toxicities also progressed. PCA was consequently stopped and replaced with Captopril. The progression of cystic disease in the kidney halted since the discontinuation of PCA therapy and the renal function became stable. Other systemic toxicities (including the pancreatic cyst) have also remained stable.

Conclusions: To our knowledge, this is the first report of cystic kidney disease associated with PCA therapy in the setting of known systemic toxicities from PCA. The etiology of cyst formation due to PCA is not clear. The possible mechanism is the malfunction of the elastic fiber proteins and extra-cellular matrix of the kidney leading to tubular dilatation and cyst formation. Clinicians should be alerted to the potential of cystic renal disease in association with systemic Penicillamine therapy.

TH-PO1129

Vancomycin Causing Acute Allergic Interstitial Nephritis as a Part of Drug Rash with Eosinophilia and Systemic Symptoms (DRESS) Syndrome Dhwanil Vyas, Anuja Vyas, Mamta Shah, Nancy Day Adams. *University of Connecticut.*

Background: Vancomycin causes nephrotoxicity at a frequency of 5-35%. The most common mechanism of injury is increased oxidative stress in renal tubules leading to reversible ischemic injury. However, since its first description by Eisenberg et al. in 1981, only a few cases of Acute Interstitial Nephritis (AIN) due to Vancomycin have been reported. Recently, Vancomycin has also been associated with DRESS Syndrome. We describe a case of Vancomycin induced AIN as a part of DRESS Syndrome improving dramatically with glucocorticoid therapy.

Methods: A 50 year-old man with stage IV Squamous Cell Cancer of the left tonsil developed neutropenia and MRSA sepsis after induction chemotherapy. After 4 days in the hospital, he was discharged home on IV Vancomycin. Vancomycin trough upon discharge was 18 ug/ml. 2 weeks later, the patient was readmitted with fever, transaminitis, acute kidney injury with creatinine of 3.4 mg/dl and random Vancomycin level of 68 ug/ml. Over next few days, along with worsening liver and kidney function, he developed a confluent erythematous rash and leukocytosis with prominent eosinophilia (35%). Due to these findings, the diagnosis of DRESS Syndrome was considered. The kidney biopsy was consistent with AIN pattern with a predominantly eosinophilic infiltration. The patient was promptly started on 60 mg/day of IV Methylprednisolone (1mg/kg/day of Prednisone equivalent). At the time of discharge, after 6 days of glucocorticoid therapy, his rash had disappeared and the fever, leukocytosis, eosinophilia, liver and kidney dysfunction had resolved.

Conclusions: A thorough literature search yielded less than 10 cases of biopsy proven AIN and even fewer cases of DRESS syndrome attributable to Vancomycin. However, these entities are possibly missed often due to a low index of suspicion. Clinico-pathologically, they represent a spectrum of allergic reactions, so glucocorticoid therapy is highly effective. Vancomycin induced AIN and DRESS Syndrome, albeit rare, should be considered in appropriate clinical settings as significant morbidity can be avoided by prompt therapeutic interventions, as depicted in this case.

TH-PO1130

Rasburicase Therapy for Acute Urate Nephropathy in an Adult Patient with Lesch-Nyhan Syndrome Kalanie Mendis, John A. Walker. *Medicine, UMDNJ - Robert Wood Johnson Medical School, New Brunswick, NJ.*

Background: Lesch-Nyhan Syndrome (LNS) is an X-linked recessive disorder due to mutations in the *HPRT1* gene, resulting in a deficiency of the purine salvage enzyme hypoxanthine-guanine phosphoribosyltransferase 1. The resultant overproduction of uric acid leads to hyperuricemia, hyperuricosuria, nephrolithiasis, and gout. Children with LNS present typically with impaired motor development, dyskinesias, and compulsive self-mutilation. Acute kidney injury (AKI) due to acute urate nephropathy (AUN) may complicate LNS.

Methods: A 28 year old man with LNS treated chronically with allopurinol (300 mg PO daily) was admitted with shortness of breath and fever. Baseline laboratory values included a serum creatinine of 0.7 mg/dL and a serum uric acid (UA) of 6.1 mg/dL. Sputum culture was positive for Klebsiella sp. and the patient was treated with levofloxacin. On hospital day 19 the patient pulled out his nasogastric tube and for the next 3 days did not receive allopurinol. During this 3 day period his serum creatinine and UA increased to 3.5 mg/dL and 20.9 mg/dL, respectively, and he became oliguric. His urine sediment contained many uric acid crystals, and urine fractional excretion of sodium and uric acid were 2.9% and 47.02% respectively. A presumptive diagnosis of AUN was made. Nasogastric intubation was reestablished and enteral allopurinol was resumed, accompanied by intravenous isotonic sodium bicarbonate and one intravenous dose of rasburicase (0.2 mg/kg). 2 days later, serum creatinine and UA had declined to 2.1 mg/dL and 6.1 mg/dL respectively, and non-oliguria ensued.

Conclusions: In AUN, kidney injury results from intratubular deposition of uric acid crystals with attendant tubular obstruction and granulomatous inflammation accompanied by macrophage and T-cell infiltration. Rasburicase is a recombinant urate oxidase used in the prophylaxis or treatment of hyperuricemia associated with tumor lysis syndrome. There has been one report of a neonate with LNS and AUN treated successfully with rasburicase. To our knowledge this is the first report of the safe and successful use of rasburicase in the treatment of acute hyperuricemia and presumed AUN in an adult patient with LNS.

TH-PO1131

Maintenance of Residual Renal Function with Low Dose Immunosuppressive Therapy in Peritoneal Dialysis Patient with Allograft Failure Nadear A. Elmahi, Tibor Fulop, Kenneth E. Kokko. *Department of Medicine, Division of Nephrology, University of Mississippi Medical Center, Jackson, MS.*

Background: Many patients with failed allograft progress to end stage renal disease (ESRD) and require dialysis. Immunosuppressive therapy is often withdrawn in those patients and this can lead to an accelerated loss of residual renal function (RRF). While maintenance of RRF appears to provide a survival benefit to peritoneal dialysis (PD) patients, it is not clear whether this benefit of maintaining RRF in failed allograft patients returning to PD outweigh the risks of maintaining immunosuppression. This case report addresses the role of minimal dose of immunosuppression in maintaining RRF in PD patient with failed allograft.

Methods: A 49 year-old Caucasian male developed progressive allograft failure nine years after living-donor renal transplantation (LDRT). Hemodialysis was initiated via tunneled dialysis catheter (TDC) and immunosuppression was gradually withdrawn. Two weeks after the withdrawal of the immunosuppressive therapy he developed a febrile illness, which necessitate removal of the TDC and conversion to PD. He was maintained on small dose of tacrolimus (1 mg daily) and prednisone (5 mg daily). Currently (1 year later) he is doing exceedingly well on cycler-assisted PD. Residual urine output ranges between 600-1200 mL/day. Total weekly Kt/V achieved 1.82.

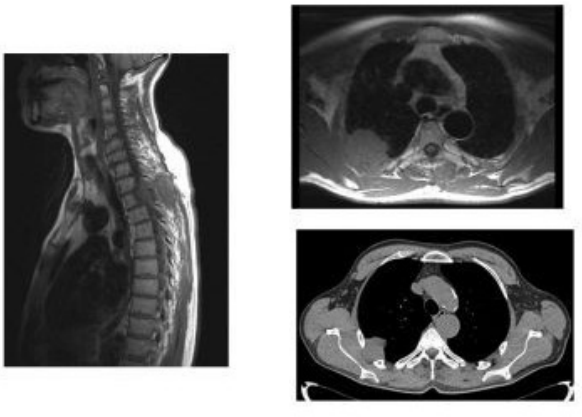
Conclusions: When a renal transplant fails, the nephrologists will be challenged by two major decisions: optimal management of immunosuppression and whether or not to perform graft nephrectomy. The use of low dose immunosuppressive medications in failed renal allograft is the most reasonable approach. There is no clear evidence to support the superiority of hemodialysis or peritoneal dialysis in the treatment of patients with failed allograft who progress to ESRD. Our patient failed renal transplant and was declared ESRD. Peritoneal dialysis was initiated and he was maintained on minimal immunosuppressive regimen, which helped to maintain good RRF. This strategy will need further study in well-defined cohorts of PD patients with failed allografts and residual renal function to determine efficacy and safety.

TH-PO1132

A Rare Case of Multiple Solitary Plasmocytoma in a Peritoneal Dialysis Patient Pietro Claudio Dattolo, Alma Mehmetaj, Stefano Michelassi, Giulia Sansavini, Sergio Sisca, Francesco Pizzarelli. *Nephrology, S M A Hospital, Florence, Italy.*

Background: Extramedullary plasmacytoma, solitary plasmacytoma of bone and multiple solitary plasmacytoma are rare clinical entities, different from multiple myeloma. We report a case of multiple solitary plasmacytoma extended to the surrounding soft tissues. The clinical picture case is remarkable because of the scarcity of similar cases in literature.

Methods: A 57 year old male started peritoneal dialysis in July 2011. In september 2011 a rapidly-growing swelling interesting soft tissues appeared in the median region of the back and physical examination showed ataxic gait. Imaging studies (chest HRCT, MRI of spine, contrast CT) found pleural-extrapleural solid tissue associated with lytic changes of DII and DIII and a mass lesion substituting most of the vertebral body of DIII, extended to the vertebral canal and dislocating the dural sac.



A biopsy of the soft tissue swelling revealed monotypic lambda plasma cells infiltrating both skin and pleura. A bone-marrow biopsy from the posterior iliac crest was not significant (< 10 % interstitial plasmacytosis). Serum calcium levels were in normal range. Serum and urine tests were negative for monoclonal immunoglobulins and free light chains. A multifocal solitary plasmacytoma was diagnosed.

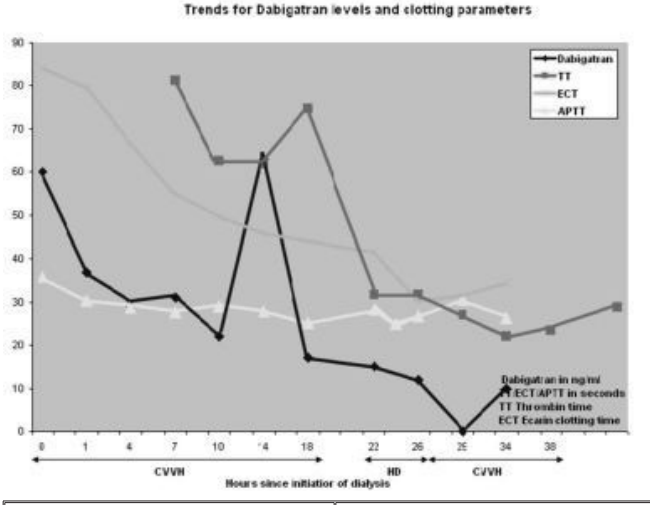
Conclusions: Solitary plasmacytoma is defined as the association of monoclonal plasma cell infiltrate in a "single" lytic lesion of bone which may eventually spread to surrounding soft tissues, no lytic changes of other bones, no pathological plasma cell proliferation on random bone biopsy, no systemic abnormalities possibly due to myeloma (anaemia, hypercalcemia, renal impairment, serum or urine monoclonal protein). All these fetaures perfectly fitted to our patient but one, that is more than one bone were affected. So, the case falls within the rare entity of solitary multiple plasmacytoma.

TH-PO1133

Role of Dialysis in Dabigatran Related Bleeding Ashish Verma, Reenu Nathan, Konstantin Abramov, Matthew J. Trainor, Jeffrey S. Stoff. *Renal Medicine, University of Massachusetts Medical School, Worcester, MA.*

Background: Dabigatran (DG), an anticoagulant for stroke prophylaxis in patients with non-valvular atrial fibrillation was the leading drug reported to FDA for serious reactions including hemorrhage, kidney failure and death. Dialysis is recommended for reversal of its anticoagulant effect when life threatening bleeding occurs. DG has a molecular weight of 628g/mol and volume of distribution is 50 - 70liters. Thus, it should be cleared by dialysis. We report the impact of 36 hours of renal replacement therapy (RRT) on DG's half-life (t1/2) and clotting parameters in a patient who developed spontaneous intracranial hemorrhage on DG.

Methods: 72 year old male had AF and CKD III (GFR 40ml/minute). He took the last dose of DG 150mg, 14 hours earlier (t1/2 12-17 hours). He presented with severe headache and was somnolent, dysarthric and had nystagmus. Imaging revealed cerebellar and intraventricular bleeding. Fresh-frozen plasma, factor VII and DDAVP were administered. CVVH was begun 3 hours after presentation and 17 hours after DG dose. After 19 hours of CVVH, 4 hours of hemodialysis and then another 12 hours of CVVH were performed. He continued to deteriorate despite clot evacuation and died 4 weeks later. DG levels, clotting parameters and t1/2 trends are shown below.



CVVH duration (hours)	Half-life (hours)
0	15
0-9	2.3
0-19	4

Conclusions: CVVH was chosen to minimize hemodynamic instability and has not been reported in this scenario. As intrinsic kidney function was unchanged, the significantly improved t1/2 is attributable to CVVH. A third of the drug is protein-bound and that may necessitate prolonged treatment for sustained clearance of the drug and reversal of anticoagulant effect. Ecarin clotting time (ECT) and Thrombin time (TT) are reliable markers of DG's anticoagulant effect but are not readily available. APTT is not suitable for monitoring.

TH-PO1134

The Spectrum of Acute Kidney Injury in Bath Salts Intoxication Jonathan McNeely, Samir Parikh, Nabil J. Haddad, Christopher Valentine, Ganesh B. Shidham, Brad H. Rovin, Anil K. Agarwal. *Internal Medicine, Division of Nephrology, The Ohio State University Medical Center, Columbus, OH.*

Background: Bath salts are a substance of abuse with negative toxicology screening. Although illegal in several U.S. states, they remain easily obtainable elsewhere and via the Internet. Detection of novel toxins that cause acute kidney injury (AKI) is a diagnostic challenge, particularly if the manifestations of the toxin mimic those of well established mechanisms of AKI.

Methods: A 29-year-old white male was observed wandering the streets, behaving erratically. In the local emergency department he reported recent use of bath salts, confirmed by family members. His past medical history included hepatitis C, polysubstance abuse, and tobacco use. His blood pressure was 91/52 mm Hg, pulse rate 93 bpm, and temperature 107 degrees F. He was agitated, but had no focal neurologic deficits. The remainder of the exam was unremarkable. Laboratory data showed creatine kinase 201,410 U/L, creatinine 2.28 mg/dL, potassium 8.1 mmol/L, and uric acid 21.2 mg/dL. Serum toxicology was negative. Urine toxicology detected lorazepam and cotinine, but was negative for >80 other substances. Within 24 hours, in addition to rhabdomyolysis, he developed shock, lactic acidosis, disseminated intravascular coagulation (DIC), and nSTEMI. He received intravenous fluids, vasopressor support, empiric antibiotic coverage, dantrolene, and rasburicase. Within two days of presentation he was oliguric; two days later, he was dialysis-dependent.

Conclusions: Bath salts are synthetic stimulants, reported to include mephedrone and MDPV. Methods for detecting mephedrone and MDPV are published, but are not yet commonly available. The spectrum of AKI due to bath salt abuse has not previously

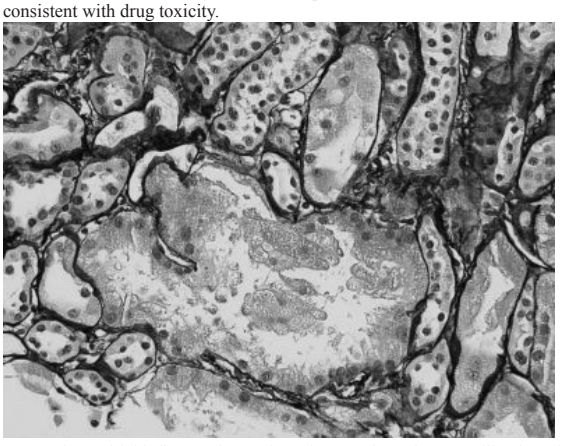
been described. We present a case of AKI and dialysis-dependence after self-reported bath salt abuse and negative toxicology results. The clinical course was marked by severe hyperthermia, rhabdomyolysis, DIC, oliguria, shock, lactic acidosis, and nSTEMI. Our patient demonstrates clinical presentation, difficulty in definitive diagnosis, differential diagnoses, and multiple potential mechanisms of AKI related to bath salt toxicity.

TH-PO1135

Deferasirox-Induced Acute Kidney Injury and Fanconi's Syndrome
Mohsen Elramah, Micah R. Chan, Hemender Singh Vats. *Department of Nephrology, UW Hospital and Clinics, Madison, WI.*

Background: a 21-year-old male survivor of Ewing sarcoma who had progressive decline in renal function and Fanconi's syndrome after being treated with Deferasirox for a ferritin level of 1502ng/ml and an MRI showing iron deposition in multiple organs. Hemochromatosis gene mutations were negative,iron overload was thought to be due to multiple transfusions.

Results: The patient was started on Deferasirox in April 2011 ;his serum creatinine was 1.0mg/dl.The patient's renal function declined with a creatinine of 1.25mg/dl in 08/2011 and 1.5mg/dl in 01/2012.During the months he received deferasirox,his urinalyses showed 3+ proteinuria and 3+ glucosuria.In 03/2012,the patient was admitted with pancreatitis and had a creatinine of 2.5mg/dl, bicarbonate of 16mmol/L, potassium of 2.7mmol/L, proteinuria (spot protein /creatinine ratio of 1.9),and glucosuria.Urine sediment was bland. Serum protein electrophoresis was normal.Kidney biopsy revealed nromal glomeruli. Tubules showed severe injury.Tubular epithelial cells showed isometric vacuolization consistent with drug toxicity.



No interstitial inflammation and no electron-dense immune-like deposits.Deferasirox was stopped;electrolytes were supplemented.Eleven days later,his creatinine improved to 1.5mg/dl and bicarbonate was 24mmol/L.sixty days later his creatinine remained at 1.5 mg/dl,the rest of electrolytes normalized.

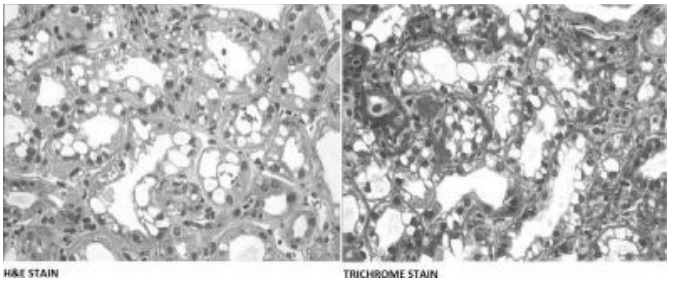
Conclusions: Our literature review revealed few cases of acute kidney injury secondary to Deferasirox .reports include Fanconi's syndrome, acute interstitial nephritis, and acute kidney injury.In all cases,after cessation of drug,kidney function returned to baseline.To our knowledge, this is the first biopsy-documented case of Deferasirox-induced Fanconi's syndrome and AKI.This case documents an often unrecognized cause of drug-induced renal failure which may not be totaly reversible and should be used cautiously.

TH-PO1136

Acute Kidney Injury Secondary to Bedbug Insecticide
Babar Bashir,[1] Shree G. Sharma,[2] Harold D. Stein,[1] Robert A. Sirota,[1] Vivette D. D'Agati.[2] *[1]Medicine, Abington Memorial Hospital, Abington, PA; [2]Pathology, Columbia University, New York, NY.*

Background: Bedbug infestation is becoming a world-wide epidemic due to the emergence of insecticide-resistant strains. Pyrethroids are approved by the EPA for use against bedbugs and are considered minimally toxic to humans, with known respiratory, neurologic and gastrointestinal effects.

Methods: We present the first case of pyrethroids-induced toxic acute tubular necrosis (ATN). A 65 year old healthy female on no potentially nephrotoxic medications presented to the ER with extreme weakness, decreased urine output and acute kidney injury. Over the preceeding 2 weeks, she had administered several applications to her bedroom of a bedbug spray (permethrin) and a fogger (pyrethrin), exceeding the manufacturer's recommended amounts. She was found to be in non-oliguric renal failure with features of type 1 renal tubular acidosis. Laboratory findings included BUN 91 mg/dL, creatinine 13 mg/dL, blood pH 7.18, serum bicarbonate <5 meq/L, anion gap (AG) 28 meq/L, serum potassium 1.8 meq/L, transtubular potassium gradient 9.4 mmol/L and positive urine AG. Urinalysis showed 100 mg/dL protein and scattered granular casts. Biopsy revealed toxic ATN with extensive tubular degenerative changes and cytoplasmic vacuolization. She was treated with fluid and electrolyte support followed by renal functional recovery 2 weeks later.



Literature review uncovered no prior report of ATN in humans induced by pyrethroid-based insecticides. However, 2-week exposure to pyrethroid causes similar ATN with tubular vacuolation in rats (Sakr, SA et al. 2001).

Conclusions: Bedbug insecticides containing pyrethroids should be used with caution due to potential development of toxic ATN from excessive exposure.

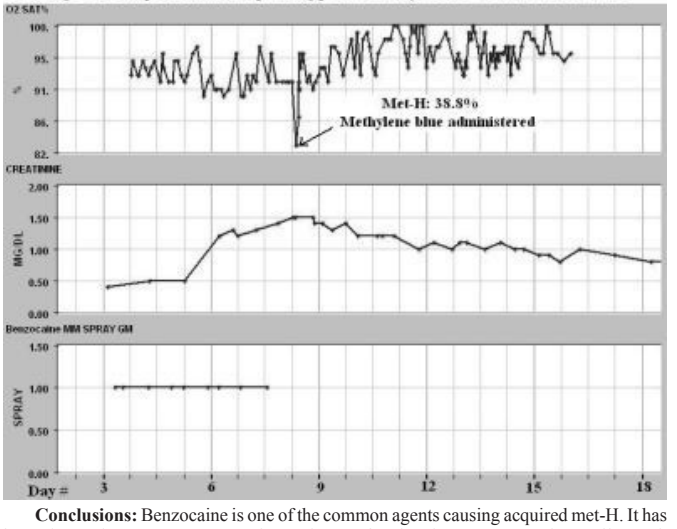
TH-PO1137

Benzocaine Induced Methemoglobinemia and Acute Tubular Necrosis: A Case Report
Wei Chen, Jason Matos, Maria Coco. *Department of Nephrology, Albert Einstein Montefiore Medical Center, Bronx, NY.*

Background: Methemoglobinemia (met-H) occurs when hemoglobin is oxidized to form methemoglobin (metHb). MetHb impedes oxygen delivery to tissue and may lead to tissue hypoxia. We describe a case of benzocaine induced acute met-H with concurrent acute tubular necrosis (ATN).

Methods: A 46 year old woman with hypertension and morbid obesity was admitted for anastomotic leak status post gastric bypass. On day 6, the patient began to develop non-oliguric acute kidney injury with peak creatinine (Cr) of 1.5 mg/dl on day 8. She had no signs or symptoms of hypovolemia. Medications include vancomycin (without high serum level), piperacillin/tazobactam (given until day 10), albuterol, ipratropium, pantoprazole, hydromorphone, ketorolac (received only one dose on day 1) and the benzocaine spray (prescribed on day 3). No contrast study was performed. There was no peripheral eosinophilia and no evidence of hemolysis or rhabdomyolylsis. On day 8, she became cyanotic with pulse oximeter saturation (SpO2) of 83%. An ABG was done, and revealed metHb level of 38.8%. Urine sediment showed many muddy brown casts, suggestive of ATN. Methylene blue was administered with the resolution of met-H and increase in oxygenation, immediately followed by a significant improvement in renal function, which returned to baseline on day 18.

Figure 1. Temporal relationship among pulse oximetry, creatinine and benzocaine use



Conclusions: Benzocaine is one of the common agents causing acquired met-H. It has been shown that SpO2 can overestimate the true fractional oxygen saturation until metHb reaches about 35%, so the degree of tissue hypoxia in this patient was more profound than that being detected by SpO2. Furthermore, the temporal relationship among SpO2, Cr, benzocaine use and metHb level implies a cause and effect relationship. Therefore, we hypothesize that benzocaine induced met-H caused ATN in this case, likely from prolonged severe renal hypoxia.

Focal Segmental Glomerulosclerosis (FSGS) in Association with Neurofibromatosis Type 1 (NF1): Proposal of Molecular Pathways
Farsad Afshinnia, Paul D. Killen, Matthias Kretzler, Virginia Vega-warner, Friedhelm Hildebrandt. *University of Michigan, Ann Arbor, MI.*

Background: NF1 is a rare genetic disorder. FSGS is also a rare glomerulopathy. In this abstract clinical course of a patient with NF1 and FSGS is presented and the molecular pathways which may potentially explain this association are discussed.

Methods: Case Report: Patient is a 42 years old female with history of NF, referred for evaluation of nephrotic range proteinuria diagnosed 6 months earlier. In her clinic visit she was asymptomatic. Family history was remarkable for NF in her maternal grandmother, mother and her daughter. She denied history of smoking, or drug abuse. Physical examination reveled normal vital signs. She had no developmental delay. Examination of heart, lung, an abdomen was unremarkable, but she had multiple neurofibromas in chest, abdomen, and posterior trunk. She also had multiple café-au-lait spots. Her serum creatinine was 0.5 mg/dL. Protein-creatinine ratio was > 11 g/mg. Kidney biopsy showed FSGS. DNA analysis confirmed a heterozygous truncating mutation in NF1 gene on chromosome 17. All 8 exones of NPHS2 gene were negative for podocine mutation. Lisinopril 20 mg once a day was started and after 10 months she had a gradual decrease of protein-creatinine ratio to 0.33 g/mg.

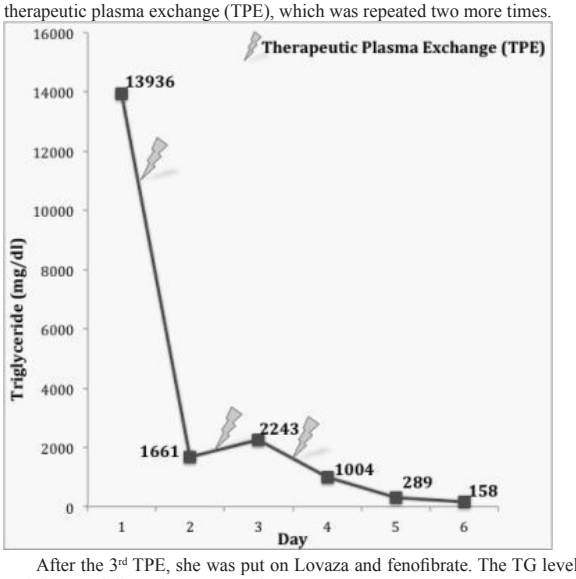
Conclusions: Discussion: NF gene locates on chromosome 17 and its product is neurofibromin. Neurfobromin belongs to a family of GTPase activating proteins (GAPs) which downregulates cellular proto-oncogene p21-ras. Ras activates Stem Cell Factor (SCF)/c-kit, mTOR and MAPK signaling pathways. Activation of MAPK and mTOR are linked to podocyte injury and focal segmental sclerosis in animal models. In other model systems, mutation at NF1 gene resulted in reduction of the number of glomeruli in metanephrons, hypoplasia and developmental delay of kidney. We hypothesize that mechanisms for development of FSGS in NF1 may include activation of MAPK, and mTOR signaling pathways, in association with possible reduced nephron numbers and developmental delay of the kidney. MTOR signaling pathway is partially mediated through angiotensin-II activation, therefore ACE inhibition may serve as an effective treatment.

TH-PO1139

Extreme, Refractory Hypertriglyceridemia and Plasma Exchange: Poorly Defined Endpoints Sasan Raeissi,[1] Hamid Emamekhoo,[1] Angel Mena,[1] Amir Izhar.[2] [1]*Internal Medicine, Good Samaritan Hospital, Cincinnati, OH;* [2]*Nephrology, Good Samaritan Hospital, Cincinnati, OH.*

Background: Therapeutic plasma exchange (TPE) is used for treatment of hypertriglyceridemia predominantly in cases of pancreatitis. Literature recommends TPE prophylactically in asymptomatic cases of triglycerides (TG) >2000 mg/dL, although case reports are rare, and recommendations are not clearly defined.

Methods: A 39-year-old Hispanic female known case of Familial Hypertriglyceridemia (FHTG) and history of pancreatitis 9 years ago, presents with throat pain. She reported a spontaneous abortion 2 months ago at 12 weeks gestation. Her mother and two sisters also have FHTG. She was compliant with her diet and medicines, which included colesevelam. Vital signs and physical exam were normal, with no symptoms of pancreatitis. BMP, CBC, amylase, and lipase were unremarkable. Her last serum TG level 5 months before admission, was 89 mg/dl. Lipid profile revealed a TG level of 13936 mg/dl and total cholesterol 1004 mg/dl, which were both confirmed on repeat testing. The patient underwent urgent therapeutic plasma exchange (TPE), which was repeated two more times.



After the 3rd TPE, she was put on Lovaza and fenofibrate. The TG level normalized and she was followed as an outpatient.

Conclusions: Our patient underwent TPE without evidence of pancreatitis because of her extraordinarily high TG. The patient had a normal TG level five months before admission and she was compliant with her medications. The short time course over which her TG level rose makes the lost pregnancy a possible instigating factor. Very rarely, repetitive use of TPE is reported. Distinctively, our patient required multiple sessions of TPE to adequately reduce TG burden, although the goal TG is unclear in an asymptomatic patient. We applied centrifugal TPE with Albumin 5% and Anticoagulant Citrate Dextrose (ACD-A).

TH-PO1140

Use of ACTH Gel in a Patient with Progressive Nephrotic Syndrome Secondary to Transplant Glomerulopathy (TG) Ankita B. Patel, Mariana S. Markell. *Nephrology, SUNY Downstate, Brooklyn, NY.*

Background: TG represents a severe form of chronic allograft nephropathy(CAN) that leads to morbidity from nephrotic syndrome(NS). ACTH gel has been used in resistant native kidney NS. We report a case where ACTH gel led to a significant decrease in proteinuria in a woman with TG.

Methods: A 44 year old white woman with history of ESRD due to medullary cystic disease received a living related donor (LRD) kidney transplant from her mother in 1995. She developed non-Hodgkin's lymphoma associated with de novo EBV infection in 1998 which was successfully treated with CHOP.Her allograft failed in 2005 and she received a second LRD kidney transplant from her sister. In Mar '11, she complained of bilateral swelling of her feet.She had 8 g/day of proteinuria.Her creatinine was 1.82.She underwent a renal biopsy which revealed chronic transplant glomerulopathy.Despite addition of valsartan and Mycophenolate to her tacrolimus regimen, her proteinuria continued to rise, reaching 12g by Nov '11. She started ACTHAR(Repository corticotropin injection) gel 80 mg twice weekly in Dec '11. By Mar '12, her proteinuria decreased to 6.1 g/day where it has remained for 3 months. Her serum albumin rose from 2.8 g/dl to 3.5 g/dl with resolution of edema. Her latest creatinine is 1.48 mg/dl. She has no evidence of recurrent lymphoma.

Conclusions: In the last 2 decades, adrenocorticotropic hormone (ACTH) has re-emerged as a potentially effective therapy for nephrotic syndrome, particularly for patients who have failed more conventional therapies.ACTH stimulates the adrenal cortex to secrete corticosteroids through melanocortin-2 receptor.It has shown to improve glomerular morphology, podocyte ultrastructure, and tubulointerstitial fibrosis in multiple animal models of nephrotic diseases.ACTH performed comparably to steroids and alkylating agents in a randomized study of idiopathic membranous nephropathy patients.In an observational study of 21 patients with NS, 11 of 21 patients achieved complete or partial remission of which 4 achieved a complete remission.ACTH thus may be a viable treatment option for treatment of transplant glomerulopathy, and appears to have produced a partial remission in our patient.

TH-PO1141

Collapsing Glomerulopathy Associated Lupus in a Black Female with Homozygous APOL1 Mutation Tomek Kofman,[1] Celine Narjoz,[2,3] Gary S. Hill,[1] Eric Thervet.[2,4] [1]*Anatomopathologie, APHP, HEGP, Paris;* [2]*INSERM UMR-S 775, Université Paris Descartes, Paris;* [3]*Biochimie, Pharmacogénétique et Oncologie Moléculaire, APHP, HEGP, Paris;* [4]*Néphrologie, APHP, HEGP, Paris.*

Background: We present the first case of collapsing glomerulopathy (CG) and systemic lupus erythematosus (SLE) in a young Afro-American (AA) female carrier of a homozygous mutation of APOL1.

Methods: The diagnosis of SLE was made in 2008 because of nonerosive polyarthritis, fever, pancytopenia and positive antinuclear antibodies (ANA) and anti-double strand DNA antibodies (ds-DNA). Despite proteinuria, no renal biopsy was performed. An association of prednisone at 0.5 mg/kg/d and hydroxyquinine induced a clinical and laboratory improvement. In April 2011, she was admitted for polyarthralgia, a nephrotic syndrome (albumin 16.4 g/l, nonselective proteinuria at 4.6 g/d) and an acute renal failure (creatinine 676 µmol/l). There was no hematuria but leucocyturia was positive. ANA and ds-DNA were strongly positive. She also presented a general seizure. Beside, symptomatic treatment, she received since admission high doses of methyl prednisolone (1 g/d for 3 days). A transjugular renal biopsy was performed 12 days after admission.

Most glomeruli on the renal biopsy displayed segmental or global collapse with sclerosis without proliferative lesion corresponding to CG. Widespread tubular atrophy and interstitial fibrosis were present. Direct immunofluorescence showed strong granular staining of glomeruli and in a vascular and tubulointerstitial pattern with predominant staining with polyclonal anti IgG, anti-C1q and anti-C3. There was no risk factor associated with CG. We performed genotyping of APOL1 in our patient and found that she is was a homozygous carrier for the G2 allele of APOL1.

Immunosuppressive treatment associating cyclophosphamide and plasma exchange was started. Her neurologic symptomatology improved, but she remains on chronic dialysis.

Conclusions: We describe the first case of CG in the context of a flare of lupus in a patient carrier of a homozygous mutation of APOL1. This case report suggests that this pattern of glomerular injury is related to aggression of the podocytes carrying this homozygous mutation.

TH-PO1142

Nephrotic Syndrome with Compound *NPHS1* Heterozygous Mutations Kirsten A. Kusumi, Stephen D. Cha, Andrew L. Schwaderer. *Pediatrics, Ohio State University/ Nationwide Children's Hospital, Columbus, OH.*

Background: Although classical dogma has taught that mutations of *NPHS1* gene were exclusively found in congenital nephrotic syndrome (NS), we now know that there exists greater variability in the genotype of mutations with subsequent variability in phenotype. Of note, patients were found to have a mean age of onset of NS of 3.0 yr (6 mo to 8 yr) and thus represented a wide departure from the previous understanding of *NPHS1* disease presenting at than 3 months of age. These patients were universally resistant to corticosteroid treatment. While a variety of treatments were undertaken, approximately 45% progressed to ESRD.

Methods: *NPHS1* Gene sequencing in a 2 year old female with steroid resistant nephrotic syndrome followed by clinical case review with literature search.

Results: Genetic testing revealed a compound heterozygote for *NPHS1* mutations despite a negative family history and unremarkable urine dipstick evaluation of the parents. A frame shift mutation at 45_46 resulting in two base pair duplication of GG as well as a point mutation at nucleotide position 2928 leading to a transversion of G > T were identified.

Conclusions: Previously, the identified point mutation has been associated with phenotypically mild disease. With phenotypically unaffected parents, the compound heterozygous *NPSH1* mutations raises the possibility that nephrotic syndrome may result from a "2 hit" phenomenom with one mutation inherited from each parent. Ongoing mutation analysis of the parents will lend further insight into the genetic etiology of *NPHS1* associated nephrotic syndrome with absent family history.

TH-PO1143

Dent's Disease Presenting as Global Glomerulosclerosis Alfonso Eirin, Maria V. Irazabal, John C. Lieske, Samih H. Nasr, Sanjeev Sethi, Fernando C. Fervenza. *Div. of Nephrology and Hypertension and Laboratory Medicine and Pathology, MN.*

Methods: An 18-year-old Caucasian presented with fever, proteinuria (1.5g/24h), and serum creatinine 2.0mg/dL. Kidney biopsy showed focal global sclerosis and minimal interstitial fibrosis. IF was negative. EM not done. A presumptive diagnosis of minimal change disease was made and treatment with prednisone (1mg/kg) was initiated, without proteinuria response. He was switched to Cyclosporine (125 mg bid) for a presumptive diagnosis of FSGS, but remained proteinuric and was referred to our institution. Blood pressure = 96/62 mmHg. Family history was positive for unspecified chronic kidney disease (CKD) in a maternal grandfather. Repeat biopsy demonstrated mild global glomerulosclerosis and interstitial fibrosis. Cortical tubules were plugged with von Kossa-positive crystals. A 24-hour urine collection showed albuminuria (193 mg) but very high levels of the low molecular weight (LMW) proteins, retinol binding protein (212,573 mcg; normal <163 mcg) and α-1 microglobulin (656 mg, nl <19 mg). There was no glucosuria or aminoaciduria. These findings raised suspicion of Dent's Disease. Genetic analysis confirmed a (novel frame-shifting change of CLCN5, c.92delA, p.Val31fs15X in hemizygosity). The patient has been on a thiazide diuretic to treat the hypercalciuria (24-h calciuria 169 mg on therapy), and an ACE inhibitor.

Conclusions: Dent's disease is a rare X-linked recessive disorder characterized by LMW proteinuria, hypercalciuria, and CKD. Some but not all patients also suffer from kidney stones and bone disease. Mutations in the CLCN5 gene, which encodes for a chloride channel found within endocytic vesicles in proximal tubular cells and elsewhere are causative. Marked increase in urinary excretion of LMW is diagnostic, and points to the tubular (rather than glomerular) source of the proteinuria. Dent Disease should be considered in all male patients that present with unexplained CKD and mild to moderate proteinuria. Establishing the correct diagnosis avoids unnecessary and potentially harmful treatments, such as immunosuppressive agents.

TH-PO1144

Subacute Progressive Chronic Renal Failure: A Clinical Presentation of IgG4 Related Systemic Disease Jiwan K. Thapa, Amr El Toukhy, Saul Nurko. *Nephrology and Hypertension, Cleveland Clinic, OH.*

Background: IgG4 related systemic disease (IgG4-SD) is a newly described entity which encompasses autoimmune multi-organ involvement which shares same pathologic and clinical features. Kidney is one of the many target organs. Herein, we present a case of IgG4-SD diagnosed based on progressive kidney insufficiency in a patient with remote pancreatic disease.

Methods: Our patient is a 76 year old white male who developed pancreatic insufficiency (late onset DM and steatorrhea) 4 years before presentation.

Now he came with worsening fatigue concordant with rise in Serum Creatinine (S.Cr-2 to 4.3 over 6 weeks), swollen & tender b/l submandibular glands, dry mouth & dry eyes. Examination was remarkable only for enlarged, tender submandibular nodes.

Lab work revealed - +ve ANA with –ve SSA & SSB. Serum immunofixation showed abnormal IgM and Kappa bands. Knees, spine, chest & sinus imaging were negative. Renal USG showed 10.4 and 11.9 cm kidneys with simple cysts. There was no proteinuria and urine sediment had few granular casts.

Bone Marrow biopsy and Flow cytometric analysis showed no evidence of abnormal cell population. Given progressive renal failure, renal biopsy was done which showed – severe plasma cell-rich interstitial inflammation, severe tubulointerstitial atrophy and fibrosis, Immunofluorescence revealed positive tubular basement membrane (TBM) staining for C3C. Immunohistochemistry showed marked increase in IgG4 (+) plasma cells with ratio between IgG4 to IgG>50%. Electron microscopy showed TBM electron dense deposits.

Diagnosis of IgG4-SD and chronic interstitial nephritis was made. Treatment was initiated with prednisone 40mg qday which led to resolution of submandibular swelling and gradual downtrend in S.Cr.

Conclusions: IgG4 related kidney disease involves Tubulointerstitial Nephritis, glomerular disease, and obstructive uropathy related to retroperitoneal fibrosis. Our patient had AIP and subacute renal failure spaced in time with kidney biopsy clinching the diagnosis. IgG4-SD should be suspected when there is multi-organ involvement which is not easily explained otherwise. Subacute renal failure is a rare but unique clinical presentation of IgG4 related systemic disease.

TH-PO1145

Lupus-Like Glomerulonephritis in a Patient Treated with Interferon-alpha for Hepatitis C Subhasish Bose,[1] Avrum Gillespie.[1] *[1]Department of Nephrology, Temple University Hospital, Philadelphia, PA; [2]Department of Pathology, Temple University School of Medicine, Philadelphia, PA.*

Background: Introduction:

Chronic hepatitis C virus (HCV) infection and anti-viral treatment with interferon-alpha (INF-a) has been associated with the development of autoimmune diseases like systemic lupus erythematosus (SLE) and Sjogren's syndrome.

Methods: Case Description:

51 year old male with background history of hepatitis C (on treatment with Ribavirin and INF-a for 1 year), presented with 1 week history of fever, malaise and generalized weakness. On exam: temperature 101F, BP 150/90, basal crackles in lungs and bilateral pitting pedal edema. He had patchy erythematous lesions on his legs. On initial labs, hemoglobin was 4.9. He was also noted to have acute renal failure (BUN 58, creatinine 7.6) with nephrotic range proteinuria (urine protein : urine creatinine = 4). Microscopy of urine sediment was notable for RBC and WBC cast and presence of tubular cells.

Serological tests such as ANA, anti-dsDNA antibody, anti-proteinase3 antibody, anti-myeloperoxidase antibody, HIV 1&2 antibody and P24 antigen, hepatitis B surface antigen & core antibody and rheumatoid factor were all negative/normal. Serum C3 and C4 were low and cryoglobulin was positive. Anti-RNP antibody and anti-SSA antibody were positive.

Patient underwent skin rash biopsy which was inconclusive. His kidney biopsy showed immune complex glomerulonephritis with subepithelial, subendothelial and mesangial deposits suggestive of lupus-like collagen vascular disease. There were also presence of organized glomerular capillary immune deposits and "fingerprint" type subendothelial deposits that was suggestive of cryoglobulins.

Conclusions: Given the clinical history of interferon therapy for hepatitis C virus infection in this patient, he was treated as a therapy-induced autoimmune disease. The treatment included Cyclophosphamide and plasmapharesis. He needed intermittent hemodialysis for a duration of 3 weeks and was discharged home with close follow up. His serum creatinine on 3 month follow up is stable at around 3.0 mg/dl.

Funding: Clinical Revenue Support

TH-PO1146

Calcineurin Inhibitor Associated Posterior Reversible Encephalopathy Syndrome: Case Report in a Child with Minimal Change Nephrotic Syndrome Xamayta Negroni- Balasquide, Joseph R. Angelo, Joshua A. Samuels. *Pediatric Nephrology and Hypertension, UT Houston Medical School, Houston, TX.*

Background: Posterior reversible encephalopathy syndrome (PRES) is a clinical and neuroradiological diagnosis presenting with headache, visual changes, altered level of consciousness and seizures. PRES is commonly described in association with hypertension but infrequently with calcineurin inhibitors (CNI).

Methods: We describe a case of a 5 year old Caucasian male with minimal change nephrotic syndrome (NS) who achieved remission on steroid therapy shortly following initial diagnosis. However, three months after initial presentation he had his first relapse which was followed by multiple subsequent relapses. Due to frequently relapsing NS, Tacrolimus (Tac) 1.5mg/kg/dose twice a day was added to his steroid and ACE inhibitor therapy.

Five days after starting treatment with Tac, pt presented with headache, emesis and blood pressures of 140/90; and subsequently, tonic clonic seizure activity. He was admitted to the pediatric intensive care unit; electrolytes were within normal limits and workup for infectious etiology was negative. Tac levels were 14. CT scan of brain was negative and EEG was without definitive abnormality. MRI of brain showed focal regions of FLAIR hyper-intensity within the subcortical white matter of bilateral occipital lobes, changes consistent with PRES. Tac was held and HTN was treated. Subsequently, he was re-started on Tac at a lower dose of 1mg/kg/dose twice a day. He had no further seizures during admission. Pt was discharged on Lisinpril, prednisone and adjusted dose of Tac.

Conclusions: There have been few cases in pediatric literature describing PRES in association with CNI, and most of these are in the setting of solid organ transplantation. Increasingly, the use of Tac is expanding outside of the realm of transplantation. This case demonstrates the importance of maintaining a high index of suspicion for PRES in pts treated with CNI; particularly in those pts with concurrent risk factors such as underlying HTN and kidney disease.

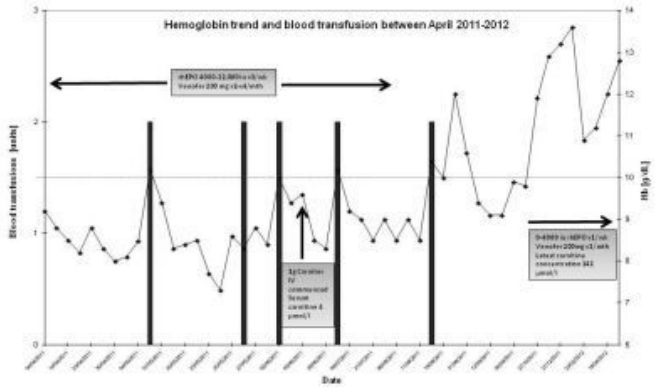
TH-PO1147

Carnitine Deficiency in Poorly Responsive Anemia of Renal Disease Naushad Ali Junglee, Siva Shrikanth. *Ysbyty Gwynedd, Bangor, United Kingdom.*

Background: Reaching target hemoglobin (Hb) in hemodialysis (HD) patients may involve excessive use of erythropoetin (rhEPO) and blood transfusions. We describe a 25 year old HD patient with hepatosplenomegaly who was not reaching target Hb. Following a detailed screen for apparent EPO resistance, marrow trephine and liver biopsy suggested ineffective erythropoesis. His serum carnitine levels was low and so L-cartinine was instituted after each HD session. Within a few months, his Hb normalized with reduced use of rhEPO and blood.

Methods: Over several months, a 25 year old male HD patient was requiring very high rhEPO (Eprex) dosing of upto 12000 iu thrice weekly with iron and periodic blood transfusion to maintain Hb > 10 g/dl. Compliance with HD and treatment of renal bone disease was satisfactory (av. Kt/V 1.4, PTH 22 pmol/l). Clinically, he exhibited marked

hepatosplenomegaly - confirmed on CT imaging. A liver biopsy supported extramedullary hematopoesis and marrow trephine suggested ineffective erythropoesis but was otherwise normal. Extensive investigations including hematinics, gastrointestinal endoscopy, extended infection screens, aluminium levels and rhEPO antibodies were all unremarkable. Serum carnitine was 4 µmol/l (normal range 15-153 µmol/l) and thus he was started on Carnitor 1 mg IV after each dialysis. This resulted in normalisation of Hb with lower rhEPO, iron and blood transfusion requirements.



Conclusions: The features of ineffective erythropoesis prompted conisderation of cartinine deficiency. Due to a lack of randomised-controlled trials, use of L-carnitine is uncommon despite deficiency being well-recognised in HD patients. Nevertheless, our case illustrates that 1) carnitine deficiency can blunt response to anemia treatment; and 2) correction can avoid copious investigations, excessive rhEPO and blood transfusion - all of which are costly, potentially harmful and may jeopardize future transplantation.

TH-PO1148

Hemolytic Uremic Syndrome Associated with Clostridium Difficile Colitis

Anthony Alvarado,[1] Sergey V. Brodsky,[2] Tibor Nadasdy,[2] Todd E. Pesavento,[1] Neeraj Singh.[1] *[1]Division of Nephrology, Ohio State University, Columbus, OH; [2]Department of Pathology, Ohio State University, Columbus, OH.*

Background: We report three cases of clostridium difficile associated hemolytic uremic syndrome (HUS) with biopsy proven renal thrombotic microangiopathy(TMA). HUS is reported to be cause by Shiga-like toxin produced by E. coli O157: H7 and shigella dysenteriae. Clostridium difficile associated HUS is rare; with few cases in children and two in adults.

Methods: Two patients received kidney transplant whereas the third developed acute renal failure (ARF) in the native kidneys. Presentation was preceded by acute diarrhea and stool clostridium difficile toxin was detected in all cases.

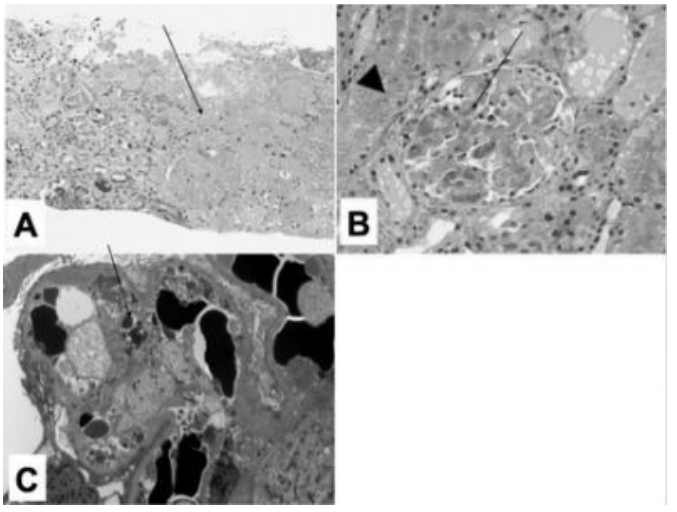
Differences between patients

	Case #1	Case #2	Case #3
Age in years	29	52	33
Gender	Female	Female	Female
Cause of ESRD	Diabetes	Hypertension	N/A
Renal transplant	LRRT	DDRT	N/A
Hemoglobin gr/dl	9.3	10.3	7.6
Platelets(150-400K/uL)	188	40	60
LDH 100-190U/L)	529	590	1992
Schistocytes	1+	2+	2+
Haptoglobin(27-139mg/dl)	12	6	10
Stool C.diff toxin by PCR	+	+	+
Treatment	Oral Vancomycin	Oral Metronidazole	Oral Vancomycin
Outcome	Complete recovery	Allograft Failure	HD for 3 months
ADAMTS-13	Low normal	Low normal	Low
Plasmapheresis	No	Yes	Yes

LRRT(live related renal donor), DDRT (deceased donor renal transplant)

Clostridium difficile associated HUS was suspected due to thrombocytopenia, microangiopathic hemolytic anemia, and biopsy proven renal TMA. Two patients were treated with oral vancomycin and one with oral metronidazole. Two underwent plasmapheresis. One patient had complete recovery in 4 weeks, one remained dialysis dependent for few months, and the third never recover renal function.

Conclusions: This case series shows that clostridium difficile is a rarely recognized but an important cause of ARF due to renal TMA, renal biopsies were not performed in the prior case reports.



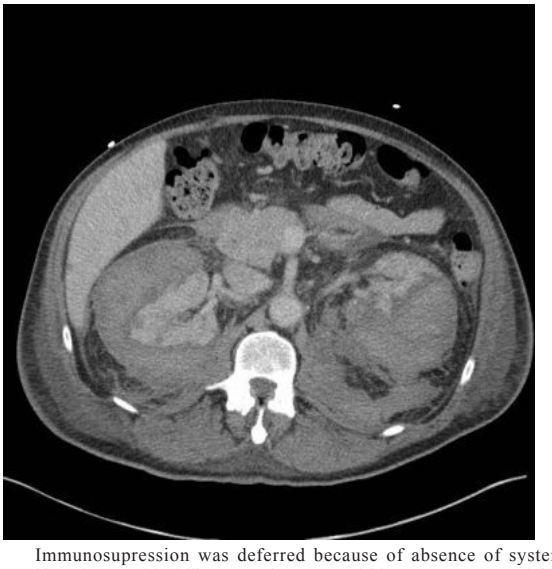
TH-PO1149

Spontaneous Bilateral Renal Sub-Capsular Hematoma: Secondary to Microscopic Polyangiitis

Srinivasa Iskapalli,[1] Deepthi Panjam,[2] Raviprasenna K. Parasuraman.[3] *[1]Internal Medicine, Beaumont Health System, Royal Oak, MI; [2]Internal Medicine, McLaren Regional Medical Center; [3]Nephrology and Transplantation, Beaumont Health System, Royal Oak, MI.*

Background: We report a rare case of spontaneous bilateral renal hematoma and renal failure as the presenting manifestation of microscopic polyangiitis (MPA); an anti-neutrophil cytoplasmic antibody (ANCA) mediated vasculitis.

Methods: A 69y-old male presented with acute back pain and severe acute kidney injury with blood urea nitrogen of 115 mg/dL and serum creatinine of 8.93 mg/dL. Ultrasound showed large globular kidneys and CT scan revealed massive bilateral sub-capsular renal hematoma and relevant investigations were negative except for perinuclear-ANCA with a titer of 1:80.



Immunosupression was deferred because of absence of systemic vasculitis manifestations and inability to perform a renal biopsy. He presented five months later with severe peripheral neuropathy and bilateral hemorrhagic pleural effusion and P-ANCA titer was elevated at 1:320. Open lung biopsy was significant for alveolar hemorrhage, necrotizing capillaritis, and organizing arterial thromboemboli. A diagnosis of MPA was made and started on 150mg of cyclophosphamide and 60mg of prednisone daily along with trimethoprim-sulfamethoxazole. Patient had complete resolution of symptoms but no recovery of renal function and P-ANCA titer decreased from 1:320 to less than 1:20.

Conclusions: This is the first reported case of spontaneous,massive, bilateral renal hematoma as the presenting manifestation of MPA.Spontaneous renal hematoma can occur from renal tumors, vascular disease, infections and vascular disease accounted for 17% of cases in a meta-analysis by Zhang et al. ANCA-positive vasculitis despite low titer should be considered in the initial differential diagnosis of spontaneous renal hematoma so that early treatment can be initiated to avoid complications.

TH-PO1150

Is Idiopathic Nodular Glomerulosclerosis Idiopathic? Syed Muhammad Mohsin Raza, Lakshminarayanan Nandagopal, Unnikrishnan Ponnamma Kunjan Pillai, Xu Zeng, Atul Singh. *Nephrology, Wayne State University/ Detroit Medical Center, Detroit, MI.*

Background: Idiopathic Nodular glomerulosclerosis(ING) is associated with hypertension(HTN) and smoking.

We present a case of 56 year old woman with HTN and nephrotic proteinuria with ING.

Methods: A 56-year-old African American woman with hypertension was evaluated for nephrotic syndrome. The patient has never smoked and has no known history of diabetes mellitus(DM). Her examination was remarkable only for bilateral pitting pedal edema. Serum creatinine was elevated at 3.7 mg/dL with estimated Glomerular Filtration Rate [eGFR] of 16 ml/min/1.73 m2. She had a normal two hour glucose tolerance test and a hemoglobin A1c (HbA1c) 5.4%. Serologies for hepatitides, antinuclear antibody, and human immunodeficiency virus were negative. Complement levels were normal, and serum immunofixation was negative. Urine exam was unremarkable other than random urine protein-creatinine ratio of 4.2.

Renal histopathology revealed focal nodular glomerulosclerosis, moderate tubular atrophy, interstitial fibrosis and severe hyalinization of the arterioles with negative congo red stain.

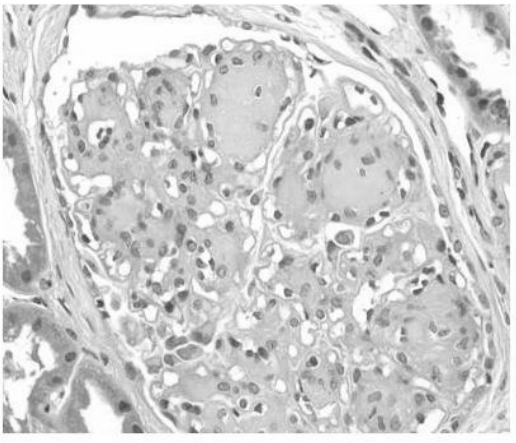


Figure 1

Conclusions: ING has been reported in patients with history of HTN and smoking. Pathogenesis is unclear, advanced glycation end products (AGE) and activation of Renin-Angiotensin System (RAS) may play a role. AGE binds with receptors for AGE (RAGE) in podocytes, activating inflammatory cascade, leading to extracellular matrix deposition as in diabetic nephropathy. Hypertension has also shown to up regulate RAGE expression in a study on rats. The coexistence of nodular glomerulosclerosis with the histological changes associated with HTN, as in our patient raises the possibility for a causative association between HTN and ING. While glomerular sclerosis is well described in HTN, whether ING represents one end of the spectrum remains to be answered.

TH-PO1151

An Immune Reaction to an Oocyte Donor Pregnancy: A Novel Trigger for Preeclampsia Randy L. Luciano,[1] Gilbert W. Moeckel,[2] Ursula C. Brewster.[1] *[1]Section of Nephrology, Dept of Internal Medicine, Yale University School of Medicine, New Haven, CT; [2]Department of Pathology, Yale University School of Medicine.*

Background: A 33-year old woman with an in vitro fertilization pregnancy presented with acute onset of proteinuria at 18 weeks gestation.

Methods: This pregnancy was conceived with an anonymous egg donor and her husband's sperm. She had one previously successful pregnancy using her own egg and her husband's sperm 4 years prior. Urine was positive for protein at 18 weeks +3days and by 20 weeks increased to 4.2 grams. By 21 weeks she was edematous, severely hypertensive and had 22 grams on a spot P/Cr ratio. Serologic workup (Table 1) was unrevealing and several ANAs returned borderline positive with negative ENA and dsDNA. Kidney biopsy revealed severe glomerular endotheliosis and immune complex deposits. No TRIs were seen. Donor Specific Antibody testing showed an abnormal antibody in the patient, not directed to self. Five days after D&C, HTN resolved and proteinuria dramatically improved without further therapy. Repeat ANA was negative. By 12 weeks post-partum, urine P/Cr ratio was 0.5 mg/mg Cr. A repeat biopsy showed resolving glomerular endotheliosis and no residual immune complex deposits. Full HLA studies of fetal tissue pending and will be available by the time of the ASN meeting.

Laboratory Data

Lab Test	4 Days Prior to Delivery	1 week postpartum	Normal Range
Serum Creatinine	0.7 mg/dl	0.6 mg/dL	0.5-1.2 mg/dl
C3	99mg/dL	113 mg/dL	80-145 mg/dL
C4	14 mg/dL	14 mg/dL	16-43 mg/dL
Albumin	1.9 g/dL	2.8 g/dL	3.5-5.0 g/dL
ANA	Positive 1:40	Negative	Negative
dsDNA	Negative	Negative	Negative
Extractable Nuclear Antigen-Antibody Screen (ENA)	Negative	Negative	Negative
Urine Prot:Creat Ratio	22.6 mg/mgCr	4.5 mg/mgCr	<0.1 mg/mgCr

Conclusions: We propose the following pathogenesis of the immune complex formation and early, severe preeclampsia: Egg donor placentas have been shown to induce an immune response at the placental-uterine interface. In this case, an immune reaction staged by the foreign pregnancy led to immune complex deposition in the kidney and glomerular injury. This process resulted in a severe and early pre-eclamptic syndrome that resolved upon termination of the pregnancy.

TH-PO1152

Strongyloides Stercoralis Transmission by Renal Transplantation in Two Recipients from a Common Donor D.A. Roseman, Dima Kabbani, Joann Kwah, Dorothy Bird, Robin Ingalls, Amitabh Gautam, Matthew Nuhn, Jean M. Francis. *Boston University Medical Center, Boston, MA.*

Background: S. stercoralis is an infectious disease with a high mortality rate. Clinical symptoms may be vague and non-specific including pulmonary and gastrointestinal complaints. Immunocompromised patients are the most vulnerable population at risk of developing a life-threatening hyperinfection syndrome characterized by disseminated strongyloidiasis and sepsis. Risk factors include steroid use and solid organ transplantation. Donor-derived S. stercoralis by renal transplantation is an uncommon diagnosis and is difficult to prove.

Methods: We report two cases of renal allograft recipients who developed strongyloidiasis early after transplant from the same deceased donor who was treated with high-dose steroids prior to organ procurement. The first recipient presented with abdominal pain and then a small bowel obstruction with CT findings of proximal bowel wall thickening. Larvae were demonstrated on a duodenal biopsy and isolated from gastric, pulmonary, and stool samples. The patient was seronegative for S. stercoralis when tested locally however the same sample tested positive at the CDC. The patient had a protracted hospital course complicated by a hyperinfection syndrome requiring subcutaneous ivermectin due to an ileus. Subcutaneous ivermectin is not approved for human use and required emergency FDA and IRB approval on a compassionate use basis. The patient survived but the renal allograft was lost. The second recipient had larvae detected in stool samples after complaints of diarrhea and this was treated with oral ivermectin. The donor was seropositive on retrospective testing at the CDC.

Conclusions: These cases add to the limited data of confirmed donor-derived S. stercoralis in renal transplantation and highlight classic presentation features. This report also adds more evidence to the safety of subcutaneous ivermectin in humans which was well tolerated and should be considered in the setting of malabsorption. Finally, there is testing center variability for strongyloidiasis serologies and the CDC is available for help with high risk patients.

Reactivation of Hepatitis B: A Dilemna in Immunosuppressive Therapy but Preventable Kashaf A. Rasheed, Zohreh S. Soltani. *Nephrology and Hypertension, Louisiana Health Science Center, New Orleans, LA.*

Methods: This is a case of a 38 year old male who presented to the hospital with bilateral lower extremity edema, twenty five pound weight gain, and fatigue. His chemistry panel revealed that he was in acute renal failure with BUN of 53 and Creatinine of 7.1 mg/dL. He has no past medical history.

He was found to have proteinuria of 25 gram/day, hyperlipidemia, and hypoalbuminemia of 2.4 mg/dL, which is consistent with a diagnosis of nephrotic syndrome. Renal US showed mildly enlarged kidneys and increased cortical echogenicity. The remainder of workup was unremarkable except his Hepatitis B serology was consistent with chronic persistent hepatitis with no evidence for cirrhosis. HBV DNA did reveal 3,317 copies.

Kidney biopsy pointed to a diagnosis of Minimal Change Disease. Patient posed a treatment dilemma. Patient was started on prednisone because of the severity of the proteinuria and renal failure. He never required renal replacement therapy during the hospital course. He was promptly referred to GI and started on antiviral therapy which closely coincides with initiation of Prednisone therapy. Patient has had significant positive response within 2 weeks to steroid therapy with improvement of proteinuria to 3 grams/day and serum creatinine to 1.9 mg/dL. His liver function has been normal in follow-up visit.

Conclusions: This case is an excellent example of the consideration that we as clinicians should have when starting a patient on immunosuppressive medications who has chronic or past HBV infection (even carrier state). A systematic review of 14 studies shows that in patients who did not receive prophylactic antiviral therapy before initiation of immunosuppressive therapy, 36.8% had HBV reactivation, 33.4% had HBV-related hepatitis, 13% had liver failure, and 5.5% died. If immunosuppression is to be used in treatment of renal disease or any condition, it is imperative that any chronic Hepatitis B be treated with antiviral therapy prophylactically to prevent reactivation and also antiviral therapy is less effective once hepatitis ensues.

TH-PO1154

Antibody Mediated Rejection Associated with CFHR1 Deficiency Successfully Treated with Eculizumab Damien Gerard Noone,[1] Kathryn J. Tinckam,[2] Paul S. Thorner,[1] Walter H. Kahr,[1] Diane Hebert,[1] Christoph Licht.[1]
[1]The Hospital for Sick Children, Toronto, ON, Canada; [2]University Health Network - Toronto General Hospital, Toronto, ON, Canada.

Background: Antibody mediated rejection (AMR) can be accompanied by thrombotic microangiopathy (TMA). TMA post transplant can represent recurrence of a preexisting aHUS disease or it can occur de novo, in association with AMR or other factors known to induce endothelial damage such as drugs (CNIs) or ischemia-reperfusion injury. Eculizumab, a monoclonal C5 antibody blocks the terminal complement cascade and has recently emerged as a promising therapy for AMR.

Methods: A highly sensitized 13 y/o girl with ESKD secondary to spina bifida and reflux nephropathy developed severe steroid-, ATG- and plasmapheresis-resistant AMR with TMA 1 week post 2nd kidney transplant despite previous desensitization therapy. Eculizumab rescue therapy resulted in a complete biochemical (C3; creatinine) and hematological (platelets) recovery within 6 days. The patient was deficient in CFHR1, a plasma protein that regulates the complement cascade and has been involved in the pathogenesis of aHUS caused by CFH autoantibodies (DEAP HUS).

Results: CFHR1 is a regulator of the alternative pathway (AP) C5 convertase and terminal complement cascade. The CFHR1 deficiency may have contributed to the clinical course of our patient (i) by contributing to the severity of her sensitization, as CFHR1 deficiency is a susceptibility factor for autoantibody development (DEAP-HUS), and (ii) by having allowed for faster, more efficient C5-conversion. The rapid response to treatment with Eculizumab supports a crucial role of the complement cascade for the manifestation and/or course of AMR in our patient and further confirms recent evidence for the efficacy of Eculizumab.

Conclusions: We conclude that AP dysregulation may have an accentuating role in AMR and should be considered in severe cases of AMR particularly when accompanied by TMA. Eculizumab may not only be an effective therapy in patients with AMR, but may also prove useful in the prevention of rejection in other organ transplant rejection.

FR-PO001

Renalase Protects against Ischemic Acute Kidney Injury in Mice H. Thomas Lee,[1] Mihwa Kim,[1] Gary V. Desir.[2] *[1]Anesthesiology, Columbia University, New York, NY; [2]Medicine, Yale University, New Haven, CT.*

Background: Acute kidney injury (AKI) is a devastating clinical problem without effective therapy and renal ischemia reperfusion (IR) injury is a major cause of AKI. Renalase is a novel, renal proximal tubule secreted flavin adenine dinucleotide dependent amine oxidase. Renalase degrades circulating catecholamines, regulates blood pressure and its deficiency markedly aggravates ischemic myocardial necrosis.

Methods: Here, we tested the hypothesis that renalase protects against ischemic AKI in mice. After Columbia University IACUC approval, mice deficient in renalase (KO) and their littermate wild type (WT) mice were subjected to 30 min renal ischemia and 24 hr reperfusion or to sham-operation.

Results: Renalase KO mice subjected to renal IR developed exacerbated renal injury (Cr=2.8±0.1 mg/dL, N=6) compared to renalase WT mice (Cr=2.3±0.1 mg/dL, N=6, p<0.05). Compared to renalase WT mice, ischemic AKI in renalase KO mice resulted in drastically worse renal tubular inflammation, necrosis and apoptosis. Furthermore, renalase WT mice subjected to renal IR had reduced kidney (>60%) and plasma (>90%) renalase levels compared to sham-operated mice. Administration of recombinant renalase (1.5 mg/kg given s.c. 10 min before renal ischemia) ameliorated ischemic AKI in renalase WT mice (Cr=1.4±0.2 mg/dL, N=4, p<0.01). In cultured human proximal tubule epithelial (HK-2) cells, recombinant renalase (10 mg/ml) significantly reduced necrosis induced with 2 mM H_2O_2 (LDH released at 6 hr=28+2%, N=3) compared to vehicle-treated HK-2 cells subjected to H_2O_2 necrosis (LDH=47±3%, N=3, p<0.01).

Conclusions: Taken together, our data show that renalase serves to protect against ischemic AKI by reducing renal tubular necrosis, apoptosis and inflammation. In addition, as plasma renalase dramatically fall after ischemic AKI, it may serve as a novel and sensitive biomarker for the detection of AKI. Finally, recombinant renalase therapy may provide a novel therapeutic approach for the prevention and treatment of AKI.

Endogenous Toll Like Receptor 9 Regulates Acute Kidney Injury Shaun A. Summers, Sharon Lee Ford, Joanna Ghali, A. Richard Kitching, Stephen R. Holdsworth. *Department of Medicine and Nephrology, Monash Medical Centre and Monash University, Melbourne, Victoria, Australia.*

Background: Acute Kidney Injury (AKI) is a major cause of morbidity and mortality. The severity of cisplatin induced AKI is influenced by leukocytes, including regulatory T cells (Tregs). Toll like Receptors (TLRs) are innate pattern recognition receptors which recognise environmental 'danger signals' and then recruit leukocytes and promote host immunity. Endogenous TLR9 has both pro-inflammatory and protective properties. We sought to define the role of TLR9 in cisplatin induced AKI.

Methods: We administered cisplatin (20mg/kg) to C57BL/6 wild type (WT) and $TLR9^{-/-}$ mice (BL/6 background). We measured kidney inflammation, histological injury and blood urea nitrogen (BUN). CD25 negative(-) splenocytes (effector cells) were isolated by magnetic bead selection. For Treg depletion we used monoclonal anti-CD25 antibodies.

Results: Kidney injury and leukocyte recruitment were enhanced in the absence of TLR9. Functional (BUN: WT 43.6±11.1 vs. $TLR9^{-/-}$ 98.9±15.0mmol/l, P<0.01) and histological injury (WT 2.8±0.1 vs. $TLR9^{-/-}$ 3.4±0.1, Score 0-4, P<0.001) were increased in $TLR9^{-/-}$ mice. Interstitial neutrophil recruitment and kidney mRNA CXCL1 and CCL2 expression were significantly increased in $TLR9^{-/-}$ mice, while FoxP3 expression was decreased. Recombinant gene activation-1 $(RAG\text{-}1)^{-/-}$ mice (lacking adaptive immunity) reconstituted with effectors (CD25- splenocytes) from WT and $TLR9^{-/-}$ mice showed no difference in functional (BUN: WT reconstituted 43.5±6.4 vs. $TLR9^{-/-}$ reconstituted 39.2±7.9mmol/l, P=n/s) or histological injury between groups after cisplatin. These results proved that CD25- effector capacity was similar in WT and $TLR9^{-/-}$ mice. Treg depletion prior to cisplatin treatment in WT and $TLR9^{-/-}$ mice showed no difference in functional (WT 56.5±8.9 vs. $TLR9^{-/-}$ 50.0±10.7mmol, P=n/s) or histological injury, experiments ended early due to severe disease. These results suggested that Tregs require TLR9 for their maximal protective effects in cisplatin induced AKI.

Conclusions: Endogenous TLR9 is protective in experimental AKI, an effect mediated by regulatory T cells.

HMGB1 in Renal Ischemic Injury May M. Rabadi, Savneek S. Chugh, Michael S. Goligorsky, Brian B. Ratliff. *New York Medical College, Valhalla, NY.*

Background: Factors that initiate cellular damage and trigger the inflammatory response cascade and renal injury are incompletely understood in AKI. HMGB1 is a DAMP molecule that in stress situations is released into the circulation, where it acts as a danger signal.

Methods: Immunohistochemical and Western blot analysis were used to identify time course HMGB1 nuclear-cytoplasmic translocation (NCT) and release from renal cells in vivo during increased duration of ischemia. In vitro, HUVEC were transfected with HMGB1-GFP plasmid and analyzed, using time-lapse videomicroscopy, for HMGB1 translocation during treatment with H_2O_2 to simulate oxidative stress. The effects of ethyl pyruvate (EP) inhibition of HMGB1 redistribution were evaluated in vivo by assessing serum creatinine, albuminuria, cyto-/chemokine release and long-term residual fibrosis.

Results: HMGB1 release into the venous circulation progressively increased in parallel with increased duration of ischemia. Time-lapse videomicroscopy of HMGB1-GFP-transfected cells showed that H_2O_2 induced HMGB1 NCT and release from HUVEC within 3 hours of treatment. This effect was significantly blocked by EP. In vivo, EP resulted in nuclear retention and significant blunting of HMGB1 release into the circulation after ischemia and improved parameters of acute (serum creatinine, albuminuria, cyto-/chemokine release) and chronic injury (albuminuria and fibrosis.) The renoprotective effect of EP was abolished by intravenous injection of exogenous HMGB1 suggesting that EP's therapeutic efficacy is mediated by blocking HMGB1 NCT. Exogenous HMGB1 administered to healthy animals at a pathophysiologically relevant dose induced a rapid surge in systemic circulation of cyto-/chemokines (TNFα, eotaxin, G-CSF, IFNγ, IL-10, IL-1α, IL-6, IP-10, and KC) and led to mobilization of bone marrow CD34+Flk1+ cells into the circulation.

Conclusions: Our results indicate that increased ischemic duration and oxidative stress causes progressively enhanced HMGB1 release into the circulation triggering damage/repair signaling. This effect is inhibited by EP because of its ability to block HMGB1 nuclear-cytoplasmic translocation.

Pharmacological Targeting of Sphingosine-1-Phosphate Receptor 1 Improves Peritubular Capillary Function during Sepsis in the Mouse Philip R. Mayeux, Zhen Wang. *Pharmacology and Toxicology, University of Arkansas for Medical Sciences, Little Rock, AR.*

Background: Microcirculatory failure and vascular leakage are hallmarks of sepsis in humans. Studies in rodents indicate that renal microvascular failure and increased microvascular permeability occur early during the course of sepsis and contribute to the development of AKI. There is growing evidence suggesting that sphingosine-1-phosphate (S1P) signaling pathways regulate vascular permeability. Stimulation of S1P receptor 1 (S1PR1) reduces permeability whereas stimulation of receptor 2 (S1PR2) enhances permeability.

Methods: To investigate the mechanism of microvascular leakage and its role in peritubular capillary hypoperfusion, we used the cecal ligation and puncture (CLP) model of sepsis in male 40 wk C57BL/6 mice and the S1PR1 agonist SEW2871 and S1PR2 antagonist JTE-013. Evans blue dye leakage was used to measure renal microvascular permeability and intravital video microscopy was used to quantitate renal peritubular capillary perfusion.

Results: CLP caused a rapid increase in capillary permeability beginning at 2h (prior to capillary hypoperfusion) and was sustained through 18h. SEW2871 at doses of 1, 3, 10 or 30 mg/kg ip or JTE-013 at doses of 0.1, 1, or 10 mg/kg, ip administered at the time of CLP partially reduced to a similar extent renal capillary leakage but neither restored capillary perfusion. However, when administered 6h post CLP, only SEW2871 reduced capillary leakage at 18h. SEW2871 also restored capillary perfusion at 18h and improved renal function as assessed by reduced levels of serum BUN and creatinine.

Conclusions: Overall, our studies suggest that in CLP-induced septic mice, S1PR1 and S1PR2 signaling pathways do not regulate the early decline in renal capillary perfusion. However, later in the course of sepsis, pharmacological stimulation of S1PR1 signaling, even after injury has occurred, not only reduces capillary leakage but also restores capillary perfusion and renal function. These findings also suggest that pharmacological stimulation of S1PR1 signaling should be tested further as an adjunct therapy for sepsis-induced AKI.

FR-PO005

Delayed Restoration of Renal Blood Flow and Peritubular Capillary Perfusion by Inhibition of Phosphodiesterase 4 Partially Protects against Sepsis-Induced AKI in Mice Philip R. Mayeux, Zhen Wang, Joseph H. Holthoff. *Pharmacology and Toxicology, University of Arkansas for Medical Sciences, Little Rock, AR.*

Background: In animal models of septic AKI, renal dysfunction is correlated with microcirculatory failure that has been attributed to several pathological insults including reactive nitrogen species (RNS) and a decline in renal blood flow (RBF). Pharmacological agents that increase endothelial cyclic AMP levels have been shown to improve the microcirculation. Thus, we hypothesized that administration of the phosphodiesterase 4 (PDE4) inhibitor, rolipram, would improve the renal microcirculation and protect against septic AKI.

Methods: To test our hypothesis, sepsis was induced in C57/BL6 male mice aged 38-40 weeks using cecal ligation and puncture (CLP). RBF was measured by Doppler flow and peritubular capillary perfusion, cellular redox stress and RNS generation were measured by intravital video microscopy (IVVM).

Results: Rolipram (0.3, 1, 3, or 10 mg/kg i.p.) or vehicle was administered at 5.5 h post CLP and the renal microcirculation was evaluated using IVVM. Rolipram acutely restored the renal cortical microcirculation in a dose-dependent manner. Furthermore, rolipram (1 mg/kg) acutely raised RBF. At 6h post CLP, RNS generation is associated with capillary hypoperfusion, both of which likely play a role in the development of AKI. To evaluate the potential clinical efficacy to protect against AKI, rolipram (1 mg/kg) was administered at 6h post CLP (after the onset of sepsis) and mice were examined at 18h. Rolipram significantly improved the renal microcirculation and reduced cellular redox stress. Interestingly, rolipram did not reduce the generation of RNS measured by rhodamine fluorescence but delayed therapy did reduced serum levels of creatinine although not urea nitrogen.

Conclusions: These data establish that PDE4 inhibition can acutely increase RBF and restore the microcirculation in septic mice. Importantly, even delayed therapy

targeting PDE4 partially improved renal function suggesting that improving the renal microcirculation can seemingly offset the damaging effects of RNS generation in the peritubular microenvironment.

FR-PO006

Circulating, but Not Pulmonary, IL-6 Mediates Lung Injury via CXCL1 Production after Acute Kidney Injury (AKI) in Mice Rhea Bhargava, Nilesh Ahuja, Ana Andres-hernando, Chris Altmann, Zhibin He, Sarah Faubel. *Renal Diseases and Hypertension, CU Denver, Aurora, CO.*

Background: Inhibition of IL-6 in mice with AKI reduces lung injury that is associated with a reduction in the chemokine CXCL1 and lung neutrophils. Whether circulating IL-6 or locally produced lung IL-6 mediates lung injury after AKI is unknown; whether CXCL1 plays a role in AKI-mediated lung injury is also unknown.

Methods: Ischemic AKI was induced by 22 minutes of bilateral renal pedicle clamping in adult male C57Bl/6 mice. IL-6 and CXCL1 was determined by ELISA.

Results: To examine the role of pulmonary IL-6 in AKI-mediated lung injury, we first administered intratracheal (IT) IL-6 to normal mice and found that lung MPO activity (a marker of lung neutrophils), BAL fluid CXCL1, lung CXCL1, and serum CXCL1 were not different versus vehicle. Next, IT IL-6 was administered to wild type mice with AKI and lung CXCL1 production and MPO activity were not increased, demonstrating that excess IL-6 in the lung does not exacerbate AKI-mediated-lung injury. Finally, IT IL-6 was administered to IL-6 deficient mice with AKI; although BAL fluid CXCL1 was increased, no increase in whole lung CXCL1 or lung MPO activity occurred. These data suggest that lung IL-6, and specifically, intra-alveolar IL-6, does not contribute to lung injury after AKI. To test the role of circulating IL-6 in AKI-mediated lung injury, recombinant murine IL-6 was administered intravenously to IL-6 deficient mice with AKI which increased serum CXCL1, lung CXCL1, and lung MPO activity versus vehicle. To test the role of CXCL1, CXCR2 deficient and CXCL1 antibody treated mice with AKI were studied and both had reduced lung neutrophil content versus wild type/vehicle treated (CXCR2 is the receptor for CXCL1).

Conclusions: In summary, we demonstrate for the first time that *circulating* IL-6 is a mediator of lung injury after AKI via CXCL1 production. Serum IL-6 is increased in patients with AKI and predicts prolonged mechanical ventilation and increased mortality; thus, our data suggest that serum IL-6 is not simply a biomarker of poor outcomes but a pathogenic mediator of lung injury.

FR-PO007

Macrophage IL-4/JAK3/STAT6 Pathway Is Involved in Recovery from Acute Kidney Injury Bing Yao, Shilin Yang, Raymond C. Harris, Ming-Zhi Zhang. *Department of Medicine, Vanderbilt University School of Medicine, Nashville, TN.*

Background: Acute kidney injury (AKI) is characterized by abrupt and reversible kidney dysfunction. We have developed transgenic mice selectively expressing the human diphtheria toxin receptor in renal proximal tubule epithelial cells (DTR mice) and have shown that a single injection of DT induces reversible and reproducible proximal tubule injury in these mice. We have previously shown an important role for M2-polarized renal monocytes in the recovery from AKI.

Methods: Male DTR mice were administered DT (100 ng/kg) to induce AKI, with or without the JAK3 inhibitor CP-690550 (15 mg/kg/day via osmotic minipump). In addition, IL-4 null mice crossed with DTR mice were studied.

Results: Following DT-induced injury, there was an early increase in renal expression of interleukin-4 receptor α (IL-4Rα), a common receptor subunit for both IL-4 and IL-13, and increases in the expression of STAT6 and p-STAT6. These increases were blunted by macrophage/dendritic cell depletion with clodronate, indicating activation of the macrophage/dendritic cell IL-4 and/or IL-13/JAK3/STAT6 pathway. Pharmacologic inhibition of this pathway with CP-690550 significantly inhibited p-STAT6 expression, markedly delayed functional recovery and led to increased tubulointerstitial fibrosis and albuminuria. To investigate further the role of IL-4 in recovery from acute kidney injury after DT, DTR mice/IL4 null mice were studied. Similar to CP-690550 institution, deletion of IL-4 led to delayed functional and structural recovery from acute kidney injury after DT injection. Neither pharmacologic or genetic inhibition of the IL-4/JAK3/STAT6 pathway decreased the number of renal F4/80+ monocytes.

Conclusions: These studies demonstrate that IL-4 plays an important role in renal tubule regeneration following acute kidney injury induced by DT. The mechanism by which IL-4 mediates recovery is under investigation.

FR-PO008

Differential Gene Expression in Macrophage Subpopulations Following Renal Injury Meghan Clements, Michael Gershenovich, Christopher Chaber, Juanita Campos Rivera, Pan Du, Mindy Zhang, Steven R. Ledbetter, Anna Zuk. *Genzyme R&D.*

Background: Macrophages are a heterogeneous cell type implicated in injury, repair and fibrosis following acute kidney injury (AKI).

Methods: In this study, we used a renal bilateral ischemia-reperfusion injury model in C57BL6 mice to explore different macrophage subpopulations and functions by microarray analysis.

Results: Three distinct subpopulations were identified by differential expression of Ly6C. The $CD11b^{+}/Ly6C^{high}$ population is associated with a robust burst of tissue pro-inflammatory cytokines shortly after reperfusion and onset of injury while the $CD11b^{+}/Ly6C^{intermediate}$ population peaks during repair of the tubular epithelium. The $CD11b^{+}/Ly6C^{low}$ population emerges when numerous genes associated with fibrosis are upregulated in the kidney which include: TGF-b, collagen I and III. Each subpopulation was sorted and whole genome mRNA profiling was performed with Affymetrix mouse 430 2.0 array. Comparative analysis ($p<0.001$) identifies gene signatures unique to each subpopulation of cells. The $Ly6C^{low}$ subpopulation has the greatest number of unique transcripts, 740, while the $Ly6C^{int}$ and $Ly6C^{low}$ have 102 and 72, respectively. Interestingly, similar gene signatures could be identified in each subpopulation in the sham and ischemic mice indicating these populations are present in the uninjured kidney. Correlation analysis using the NextBio database identifies similarities between the $Ly6C^{int}$ signature and activated macrophages as well as studies linked to tissue repair. Genes known to be reparative or anti-inflammatory were identified in this signature including: chitinase-3-like-1 and-3, matrix metalloproteinase-8, lipocalin-2 and plasminogen activator, urokinase receptor. In the $Ly6C^{low}$ population, gene correlations were found with a mouse model of pulmonary fibrosis and kidney transplant patients with interstitial fibrosis suggesting a potential role in developing fibrosis following AKI. Using linguamatic I2E software, genes upregulated in the $Ly6C^{low}$ population were linked to kidney and fibrotic diseases in patients.

Conclusions: Ongoing studies are evaluating the interrelationships between these populations.

FR-PO009

Assessment of Renal Morphology and Hemodynamics in Acute and Chronic Kidney Failure with Advanced Unenhanced Magnetic Resonance Imaging (MRI) Techniques Zohar Milman, Nathalie Corchia (Nachmansson), Jonathan H. Axelrod, Samuel N. Heyman, Rinat Abramovitch. *Hadassah Hebrew Univrtsity Hospitals, Jerusalem, Israel.*

Background: Contrast-enhanced imaging techniques are limited in the presence of renal dysfunction due to nephrotoxicity or to the risk of developing nephrogenic systemic fibrosis. We have recently demonstrated the sensitivity of Hemodynamic Response Imaging (HRI), a functional blood oxygenated level (BOLD) magnetic resonance imaging (MRI) method combined with transient hypercapnia and hyperoxia (Barash, Radiology 2007), for the evaluation of renal vascular reactivity without the use of contrast agents (ISMRM 2011). True-FISP is another unenhanced MRI method, providing high-resolution anatomical images in short acquisition times. The aim of the present study was to establish the use of these MRI methods for the non-invasive evaluation of changes in renal hemodynamics and morphology during renal impairment, without the need for contrast-agents.

Methods: Renal-HRI maps during hypercapnia and hyperoxia and True-FISP images were repeatedly acquired in two models of kidney injury in mice: along 4 weeks in adenine-induced progressive CKD model, and over 3 weeks during the induction and recovery from rhabdomyolysis-induced AKI. Contrast enhanced (CE)-MRI was used in parallel experiments for comparison.

Results: In intact animals renal HRI maps show profound changes (ΔS) during hypercapnia and with subsequent hyperoxia. By contreast, ΔS response was markedly blunted during changes in inspired gases with evolving kidney dysfunction in the two models, reflecting hampered renal vascular reactivity and perfusion. True-FISP images showed high sensitivity to renal morphological changes, comparable to CE-MRI, with different patterns characterizing each model. Calculated data obtained from HRI and True-FISP maps during the evolution of renal failure and upon recovery, closely correlated with the degree of renal impairment.

Conclusions: This study illustrates the potential utilization of HRI combined with True-FISP for the non-invasive assessment of renal dysfunction, without the potential risk associated with the administration of contrast-agents.

Identification of Novel Biomarkers of Cardio-Renal Syndrome in Adult Cardiac Surgery Patients Michael Haase,[1] Rinaldo Bellomo,[2] Anja Haase-Fielitz.[1] *[1]Nephrology, Otto von Guericke University, Magdeburg, Germany; [2]Intensive Care, Austin Health, Melbourne, Australia.*

Background: Novel technologies are being advanced for the purpose of identification and validation of new renal biomarkers.

Methods: In a nested cohort study of 100 adult cardiac surgical patients, we assessed the value of biomarkers of cardiorenal syndrome for the prediction of acute kidney injury (RIFLE-AKI), acute dialysis and mortality. A proteomic approach for antibody-free targeted protein quantitation based on high-end mass spectrometry was used to measure serum concentrations of the LG3 fragment of perlecan, latent transforming growth factor binding protein 2 (LTBP2) and cathepsin L at baseline, on arrival in the intensive care unit (ICU) and at 24 hours postoperatively. We calculated AUC-ROC values for all biomarkers including serum creatinine, cystatin C, plasma/urine NGAL.

Results: On arrival in ICU all *serum* biomarkers were not useful for prediction of AKI, N=21 (all AUC-ROC ≤0.70). *Urine* NGAL had an AUC of 0.74 [95% CI 0.62-0.86] for AKI prediction. The predictive value of uNGAL increased to AUC 0.83 [0.69-0.98] for *severe* AKI (RIFLE I+F) whereas *serum* biomarkers had AUC ≤0.70 at this timepoint. On ICU arrival, in patients without preoperative chronic kidney disease (CKD), uNGAL

predicted acute dialysis (AUC 0.80 [0.55-0.99]) but not in patients with CKD. At 24hrs postoperatively in all patients, *serum* LG3 (AUC 0.89 [0.81-0.96]) and *serum* LTBP2 (AUC 0.88 [0.80-0.96]) had very good AUC values for dialysis prediction. In patients with normal preoperative renal function uNGAL at 24 hours was the best predictor for mortality with AUC-ROC 0.95 [0.89-0.99]. At 24hrs postoperatively, Cathepsin L had the highest AUC-ROC (0.88 [95% CI 0.79-0.96]) for AKI prediction. After exclusion of patients with preoperative renal impairment (N=40), the predictive performance of Cathepsin L further increased. Cathepsin L levels showed a good correlation with mean arterial pressure (r^2=0.36)and lactate (r^2=0.24).

Conclusions: Novel serum markers including LG3, LTBP2 and Cathepsin L can precisely predict acute dialysis and mortality at 24hrs postoperatively and uNGAL predicts AKI and acute dialysis (without preoperative CKD) at ICU arrival.

FR-PO011

Partial Recovery from AKI, Followed by Sepsis, Worsens Kidney Injury and Mortality, but Protects Other Organs Takayuki Tsuji,[1,2] Ana Carolina Souza,[1] Xuzhen Hu,[1] Peter S.T. Yuen,[1] Robert A. Star.[1] *[1]NIDDK, NIH, Bethesda, MD; [2]1st Department of Medicine, Hamamatsu University School of Medicine, Hamamatsu, Japan.*

Background: The Program to Improve Care in Acute Renal Disease (PICARD) observational study found that 40% of hospitalized patients who were not septic at the time of AKI diagnosis subsequently developed sepsis. The in-hospital mortality of late onset sepsis patients was 20% higher than patients remaining sepsis-free. Thus, sepsis frequently develops after AKI and portends a poor prognosis. Based on our prior work with CKD before sepsis, we hypothesized that AKI before sepsis might amplify the susceptibility to multiple organ failure and hence worsen prognosis. We investigated the acute impact of partial recovery from AKI on sepsis.

Methods: We used 10-12 week old male C57BL/6 mice. We performed sham surgery or 40 min bilateral renal ischemia/reperfusion (I/R), waited 48 hrs, then induced polymicrobial sepsis by cecal ligation and puncture (CLP) surgery. We measured outcomes 24 hrs after CLP, and performed a 4-day survival study.

Results: As expected, I/R significantly intensified renal injury after sepsis [I/R->CLP: BUN 189±20.0 and serum creatinine (Scr) 1.40±0.58 vs. sham->CLP: BUN 117.7±7.4 mg/dl ($p<0.05$) and Scr 0.82±0.37 mg/dl ($p<0.05$)]. Death occurred significantly faster in I/R->CLP than sham->CLP (40 vs 68 hrs). In contrast, AST, LDH, CPK, and spleen apoptosis (by active caspase 3 immunohistochemistry) were significantly lower in I/R->CLP than sham->CLP. Systemic inflammatory cytokines (HMGB-1, TNF-α, IL-10 and IL-6) in I/R->CLP were modestly (but not significantly) lower in I/R->CLP than sham->CLP.

Conclusions: Partial recovery from AKI, followed by sepsis, worsened kidney function and survival compared to sepsis alone, although there was less liver, muscle, and spleen damage. Thus, partial recovery from AKI unexpectedly dissociates the renal and systemic effects of sepsis. Mortality follows the kidney injury--not other organ injury--in this acute-on-acute model. The uncoupling of multiple organ failures from each other requires further investigation, but highlights the difficulty of substituting organ-specific endpoints for mortality in sepsis trials.

Sepsis Inhibits Mitochondrial Biogenesis While Stimulating Mitochondrial Oxygen Consumption in Acute Kidney Injury L. Jay Stallons, Ryan Whitaker, Rick G. Schnellmann. *Pharmaceutical and Biomedical Sciences, Medical Univ of South Carolina, Charleston, SC.*

Background: Most cases of acute kidney injury (AKI) result from sepsis, renal ischemia, or acute drug or toxicant exposure, affecting up to 5% of all long-term hospital patients. Mortality from AKI remains near 50%, and the added comorbidity of sepsis increases mortality of AKI to 70%. Because AKI and sepsis are both known to have mitochondrial pathologies, we examined renal mitochondrial dysfunction in a mouse model of sepsis-induced AKI.

Methods: Male C57BL/6 mice were injected with 10 mg/kg lipopolysaccharide (LPS) and 18 h later with 10 ml/kg saline. Renal function was evaluated using serum creatinine and urine volume. Renal mitochondrial biogenesis and protein were measured using RT-qPCR and immunoblot analysis for PGC-1α, NDUFB8, COXI, and ATP synthase β (ATPSβ). ATP levels were measured using a bioluminescence assay. Mitochondria were isolated from the kidney and assayed on a Seahorse Bioscience XF96 Analyzer to measure state 2 and 3 respiration.

Results: Renal function was impaired 42 h after LPS injection as shown by increased serum creatinine and reduced urine volume. Mitochondrial biogenesis (PGC-1α) and protein (NDUFB8, COX1, ATPSb) markers exhibited reduced transcript levels at 18 h and reduced protein levels at 42 h. Renal ATP was reduced at both 18 and 42 h. Isolated renal mitochondria displayed normal state 2 respiration 18 h after LPS injection, but state 3 respiration increased and remained increased at 42 h.

Conclusions: We have shown decreased mitochondrial biogenesis and ATP in a model of LPS-induced AKI. Transcript levels of mitochondrial genes were reduced at 18 h in advance of the development of AKI at 42 h. At 42 h, mitochondrial proteins were depleted. Renal mitochondrial deficiency is supported by reduced ATP 18 and 42 h after LPS injection. Remarkably, we found that isolated renal mitochondria have increased state 3 respiration at 18 and 42 h after LPS, while the state 2 respiration was unchanged. We hypothesize that while renal mitochondrial biogenesis is suppressed in endotoxic AKI, an alternative pathway is activated to directly stimulate electron transport chain (ETC) activity and ATP synthesis.

Complement and AKT Pathway Regulate Endothelial to Mesenchymal Transition (EndMT) in Renal Ischemia Reperfusion (I/R) Injury G. Castellano,[1] Claudia Curci,[1] Antonia Loverre,[1] Alessandra Stasi,[1] S. Simone,[1] M. Cariello,[1] Vincenzo Montinaro,[1] P. Ditonno,[1] M. Battaglia,[1] Antonio Crovace,[1] F. Staffieri,[1] Beatrijs D. Oortwijn,[2] Edwin S. Van Amersfoort,[2] Francesco Paolo Schena,[1] Loreto Gesualdo,[1] Giuseppe Grandaliano.[3] *[1]DETO, Univ of Bari, Italy; [2]Pharming Group NV, Leiden, Netherlands; [3]Medical and Surgical Sciences, Univ of Foggia, Italy.*

Background: EndMT may significantly contribute to the development of tissue fibrosis. However, the pathogenic factors and signaling pathways regulating EndMT are poorly understood.

Methods: In an experimental model of I/R, 10 pigs underwent 30 min of renal warm I and 24h of R. Just before R, recombinant human C1-inhibitor (C1INH) was administered in 5 animals. CD31, αSMA and FSP1 protein expression were investigated by confocal microscopy and Western blot.

Results: Renal I/R injury reduced the density of peritubular capillaries (t24h 1.2±.4; t0 2.4±.8 CD31 pixel$^+$/total area ratio, p=.03). We observed also an increased interstitial expression of the myofibroblast marker αSMA (t24h 5.19±.58; t0 1.75±.13, p=.04) and the appearance of CD31$^+$/FSP1$^+$ renal endothelial cells (t24h 18.9±4.4; t0 8.2±3.0, p=0.04), suggesting EndMT. After C1INH administration, CD31$^+$/FSP1$^+$ endothelial cells were significantly reduced in the renal interstitium (t24h C1INH 7.7±1.1, p=.03 vs t24h ctr), peritubular capillary density was preserved (t24h C1-INH 2.15±.2, p=0.04 vs t24h ctr)and α-SMA staining disappeared.Activation of cultured endothelial cells by C3a led to EndMT, as shown by a decrease in von Willebrand Factor (C3a 4.6±.8, basal:7.3±.6, p=.04) and an increase of αSMA expression (C3a .9±.1; basal .3±.1, p=.003) along with a significant increase in AKT phosphorylation. The increase of αSMA was significantly reduced by inhibiting AKT in vitro (C3a .6±.1, C3a+AKT inh .3±.1, p=.03). Accordingly, C1INH infusion in vivo abrogated AKT phosphorylation in renal endothelial cells.

Conclusions: In conclusion, our data demonstrate a critical role for Complement in the acute induction of the EndMT process via the AKT pathway. Therapeutic inhibition of these systems may be essential to prevent the development of vascular-derived tissue fibrosis.

FR-PO014

Coupled Plasma Filtration Adsorption Prevents Renal Fibrosis by Inhibition of Endothelial to Mesenchymal Transition in a Swine Model of Sepsis-Induced Acute Kidney Injury G. Castellano,[1] Alessandra Stasi,[1] Anna Maria Di Palma,[1] Giuseppe Stefano Netti,[2] Claudia Curci,[1] Angelica Intini,[1] C. Divella,[1] Enrico Fiaccadori,[3] Clelia Prattichizzo,[2] Giovanni Pertosa,[1] Giuseppe Grandaliano,[2] Loreto Gesualdo.[1] *[1]Nephrology Unit, DETO, Univ of Bari, Italy; [2]Dept of Medical and Surgical Science, Univ of Foggia, Italy; [3]Internal Medicine and Nephrology Dept, Univ of Parma, Italy.*

Background: Activation of endothelial cells (EC) plays a key role in acute kidney injury (AKI). Aim of our study was to investigate the contribution of EC on renal fibrosis and to test the efficacy of CPFA (Coupled Plasma Filtration Adsorption) in modulating EC activation in a swine model of sepsis-induced AKI.

Methods: After 3h from LPS infusion (300μg/Kg), 8 pigs were treated with CPFA for 6h; 8 control pigs received no treatment. Renal biopsies were performed before (T0) and 9h (T9) after LPS infusion.

Results: In septic pigs, Masson's trichrome staining revealed extensive collagen deposition at the interstitial level and diffuse glomerular thrombi at T9. By immunofluorescence, we observed an interstitial increase of the myofibroblast marker α-SMA at T9 compared to T0 in septic pigs(7.58±0.49fold change, p=0.001). Immunohistochemical analysis for Caspase-3 showed rare apoptotic peritubular and glomerular EC in sepsis, while double immunofluorescence analysis revealed CD31$^+$/Ki-67$^+$ proliferating EC(T9 12.5±0.7fold change vsT0, p=0.01). CD31$^+$EC expressed the fibroblast marker FSP1(T9: 14.14±0.97fold change vsT0,p=0.02) and α-SMA in sepsis, indicating the occurrence of Endothelial to Mesenchymal Transition (EndMT) at tubulointerstitial level. In vitro, LPS induced EC proliferation and EndMT, confirming the in vivo data. Septic pigs treated with CPFA showed a significant reduction in collagen deposits and glomerular thrombi compared to untreated animals. α-SMA expression(2.43±0.31fold change,p=0.001), as well as EndMT(CD31$^+$/FSP1$^+$3.73±1.02fold change,p=0.001)was strongly reduced by CPFA treatment.

Conclusions: Our data demonstrate a critical role of EndMT in sepsis-induced renal fibrosis. CPFA treatment seems to counteract the activation of EC, thereby inhibiting the vascular-derived tissue fibrosis.

Iodinated Contrast Media Decrease Nitric Oxide Bioavailability and Induce Oxidative Stress in Afferent Arterioles of Mice Zhi Zhao Liu, Andrea Perlewitz, Mauricio Michalak Sendeski, Andreas Patzak. *Institute of Vegetative Physiology, Charite - Universitaetsmedizin Berlin, Berlin, Germany.*

Background: Contrast induced acute kidney injury (CI-AKI) is a common hospital-acquired case of renal failure. We showed recently that contrast media constrictafferent arterioles of mice. Here we investigate the influence of contrast media on nitric oxide bioavailability and superoxide in afferent arterioles to understand the underlying mechanism of reduced renal perfusion in CI-AKI.

Methods: Afferent arterioles from C57Bl/6 mice were perfused with either vehicle solution or contrast media (ioxaglate or iodixanol, 23mg iodine/ml), followed by angiotensin II administration. The fluorescent dyes DAF-FM and dihydroethidium (DHE) were used for quantification of nitric oxide bioavailability and superoxide concentration in the afferent arteriolar wall, respectively.

Results: Compared to control group, ioxaglate and iodixanol reduced afferent arteriole diameters significantly and similarly by 10% within 20min and enhanced the response to angiotensin II. DAF-FM fluorescence decreased during iodixanol treatment (-7.4%) and by nitric oxide synthase inhibition (L-NAME, -7.5%), whilst it increased by 11.0% in the control group. This indicates an impaired nitric oxide bioavailability. Further, iodixanol increased DHE fluorescence ratio by 13.8%, implying oxidative stress in the arteriolar wall. The superoxide dismutase mimic tempol blunted the increase of DHE ratio during iodixanol administration.

Conclusions: The study shows that contrast media with different physicochemical properties exert a similar impact on afferent arteriolar function *in vitro*. Decreased nitric oxide bioavailability and increased superoxide concentration may play a role in mediating the constrictive effects of contrast media. The findings indicate an endothelial dysfunction by contrast media which is combined with oxidative stress in preglomerular vessels.

FR-PO016

Glomerular Endothelial and Permeability Barrier Dysfunction Induced in Early Bacterial Sepsis Ruben M. Sandoval,[1] George Rhodes,[1] Silvia B. Campos-bilderback,[1] Sarah E. Wean,[1] Bruce A. Molitoris.[1,2] *[1]Medicine/ Division of Nephrology, IU School of Medicine, Indianapolis, IN; [2]Roudebush VAMC, Indianapolis, IN.*

Background: Sepsis remains the leading cause of acute kidney injury (AKI) characterized by hemodynamic effects and a reduction in GFR.

Methods: To determine if there is glomerular involvement we studied surface glomeruli in Munich Wistar Frömter rats using intravital 2-photon microscopy in a cecal ligation and puncture (CLP) model of sepsis at 0, 4, 12 and 24hrs post injury.

Results: The permeability of a 150kDa dextran, as determined by glomerular sieving coefficient (GSC), increased progressively ($P \leq 0.05$) from control values (0.0068±0.0030) to 0.0203±0.0072, 0.0407±0.0085, and 0.0968±0.0462 at 4, 12 and 24hrs post CLP, respectively. A dramatic reduction ($P \leq 0.05$) in speed of flowing RBC's within capillary loops from control values (1,771±467 μm/sec) to 910±414, 182±50, and 576±327 μm/sec was seen at 4, 12 and 24hrs post CLP, respectively. Since activated white blood cells (WBC's) are known to occlude flow within capillary loops we measured adherence of WBC's and found an increase ($P \leq 0.05$) from control values (0.4±0.3 per standardized volume) to 3.4±1.1, 3.7±1.0, and 7.3±5.8 at 4, 12 and 24hrs post CLP, respectively. The presence of Rouleaux formations was scored (values of 0-4 progressively worsening), and appeared at 12hrs and remained present at 24 hrs post CLP. Serum creatinine values did not elevate above control values (0.2±0.1 mg/dL) until 24hrs post CLP (0.8±0.2, $P \leq 0.05$). Mean blood pressure values became progressively more variable between rats.

Conclusions: These results indicate the reduction in renal function may be due in part to interactions of RBC's and WBC's to reduce flow, and along with podocyte injury; cause an increase in glomerular permeability associated with proteinuria.

Total B Cells (Expressing CD19) Prostaglandin I_2 Attenuates Initial Renal Injury Following Warm Ischemia-Reperfusion Injury in Mice Hye Ryoun Jang,[1] Minsu Kim,[1] Jung Eun Lee,[1] Dae Joong Kim,[1] Wooseong Huh,[1] Kwon Wook Joo,[2] Jin Suk Han,[2] Ha Young Oh,[1] Yoon-Goo Kim.[1] *[1]Medicine, Sunkyunkwan University School of Medicine, Samsung Medical Center, Seoul, Korea; [2]Medicine, Seoul National University Hospital, Seoul, Korea.*

Background: Inflammation is a major pathophysiologic process during kidney ischemia reperfusion injury (IRI). Prostaglandin I2 (PGI2) was reported to have an anti-inflammatory function. We tested the hypothesis that PGI2 attenuates initial renal injury following warm IRI in mice.

Methods: C57BL/6 mice were randomly allocated into PGI_2-sham, control, and PGI_2-IRI groups. PGI_2 was diluted with DMSO and 10 mg/kg was injected into peritoneal cavity right before reperfusion. Serum creatinine was measured for 48 hours. The expression of cytokines and major sodium transporters were measured at 48 hours after IRI with bioplex array and western blotting, respectively. Immunofluorescent staining for F4/80 was performed for comparing the monocyte infiltration.

Results: Early renal injury was functionally and structurally attenuated in the PGI_2-IRI group compared with the control (serum creatinine, Day 0: 0.37±0.014 in PGI_2-sham, 0.52±.035 in control-IRI, 0.35±0.033 in PGI_2-IRI, Day 1: 0.52±0.053 in PGI_2-sham, 2.72±0.167 in control-IRI, 1.40±0.206 in PGI_2-IRI, Day 2: 0.44±0.051 in PGI_2-sham, 2.33±0.427 in control-IRI, 0.73±0.114 in PGI_2-IRI). The expression of IFN-γ was augmented in the postischemic kidney, but this augmentation was significantly attenuated by PGI_2 treatment (pg/mg of whole kidney protein extract, 95.25±8.95 in PGI_2-sham, 115.65±.7.56 in control-IRI, 68.05±10.72 in PGI_2-IRI). However, there was no difference in the expression of IL-10 among 3 groups (pg/mg of whole kidney protein extract, 179.3±9.45 in PGI_2-sham, 139.3±.16.11 in control-IRI, 121.0±18.18 in PGI_2-IRI). The down-regulation of Na^+-K^+-$2Cl^-$ cotransporter and Na^+-Cl^- cotransporter was attenuated in PGI_2-IRI group. There was no difference in the infiltration of F4/80 positive mononuclear cells into the post-ischemic kidney between groups.

Conclusions: PGI_2 treatment attenuated early renal injury by down-regulation of IFN-γ through humoral effects and prevented down-regulation of NKCC2 and NCC following IRI.

Renal Peritubular Capillary Injury with Impaired Renal Microcirculation in Hepatic Acute Kidney Injury after Severe Hepatic Failure in Rats Akira Shimizu,[1] Yukinari Masuda,[1] Ayako Sato,[2] Tetsuo Morioka.[2] *[1]Department of Pathology, Nippon Medical School, Tokyo, Japan; [2]Institute of Nephrology, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan.*

Background: Acute kidney injury (AKI) is a common complication in the acute liver dysfunction. However, the mechanisms of AKI during the development of acute liver dysfunction are still uncertain. In the present study, we characterize a rat model of AKI during the development of acute liver dysfunction following liver transplantation.

Methods: Acute hepatic failure was induced in rat by liver transplantation from DA (RT1a) to Lewis (RT1l) rats without immunosspression. Acute rejection progressed, and rats were dead around day 11 with severe acute liver dysfunction. We examined the clinical and laboratory data and pathological characteristics of kidneis at day 5, day 7, and day 9 to 11, focusing on the tubular and peritubular capillary (PTC) injury. In addition, hemodynamic events in PTCs in vivo were evaluated functionally and quantitatively by the use of a real-time confocal laser-scanning microscope (CLSM) system (Kidney Int 59: 252-259, 2001).

Results: During the progression of rejection in hepatic graft, acute liver dysfunction (T-Bil 7.9±1.8; AST 711.3±98.2, $p<0.01$) and acute kidney injury (BUN 112.0±22.5; Cr 0.6±0.1, $p<0.05$) developed by day 11. During the development of AKI, renal tubular degeneration with bile pigment accumulation, mitochondrial degeneration, KIM-1 expression, and severe disruption of f-actin. TUNEL+ dead cells were noted in tubules and PTCs with increased expression of caspase-3. In addition, endothelial dysfunction in PTCs developed with decreased expression of eNOS, vascular endothelial growth factor (VEGF), angiopoietin-1 (ang-1), and ang-2. Indeed, marked reduced blood flow of PTCs (320±122 μm/sec at days 9 to 11 vs 860±145 μm/sec in control, $p<0.001$) was noted in the kidney in hepatic AKI. Interstitial edema also occurred with CD68+ macrophage infiltration.

Conclusions: AKI developed in rats during the development of acute liver dysfunction and was characterized by renal tubular injury as well as endothelial dysfunction in PTCs with marked impaired microcirculation.

Serum microRNAs Are Accurate Biomarkers of Acute Kidney Injury in ICU Patients Elia Aguado Fraile,[1] Edurne Ramos,[1] Elisa Conde,[1] Esperanza Macarena Rodriguez Serrano,[1] Aurora Lietor,[2] Maria Teresa Tenorio,[3] Angel M. Candela-Toha,[2] Fernando Liano,[3] Laura Garcia-Bermejo.[1] *[1]Pathology Dpt., Hospital Ramon y Cajal, IRYCIS, Madrid, Spain; [2]Critical Care Dpt., Hospital Ramon y Cajal, IRYCIS, Madrid, Spain; [3]Nephrology Dpt., Hospital Ramon y Cajal, IRYCIS, Madrid, Spain.*

Background: microRNAs are small endogenous RNA molecules which regulate every cellular process. Recent studies have demonstrated that these molecules are secreted to the extracellular environment and they could be detected in body fluids, such as serum. Serum microRNAs profiles have been associated to physiological and pathological conditions, becoming accurate diagnostic biomarkers of several diseases, including kidney diseases.

Our aim to identify and validate a serum microRNA profile for Acute Kidney Injury (AKI) precise diagnosis in Intensive Care Units patients.

Methods: Total RNA was extracted from ICU patient serum using an optimized protocol. Previous work of our lab identified, by massive screening experiments, a set of serum microRNAs which are modulated in AKI patients. We have studied if these microRNAs are AKI biomarkers in an ICU setting. microRNAs were detected by qRT-PCR in 32 ICU patients with AKI (20 Acute Tubular Necrosis (ATN) and 12 transient AKI) and compared with those found in 20 healthy people. In the ICU-AKI patients blood samples for measuring microRNAs and serum creatinine levels were withdrawn from Day 0 (diagnosis) to day 7.

Results: Our results demonstrate that miR-101-1, miR-210, miR-26b, miR-146a and miR-10a are diagnostic biomarkers of AKI in ICU patients, compared to healthy control, showing areas under the curve values higher than 0.95 in ROC analysis. Moreover, miR-210 and miR-146a can significantly discriminate between AKI and transient AKI patients. Remarkably, serum levels of these microRNAs also correlate with AKI severity estimated by AKIN classification.

Conclusions: In summary, the serum microRNA profile here identified has a diagnostic value of AKI in ICU population. Moreover, these accurate biomarkers also indicate AKI severity. Both features could have important implications in ICU patients management allowing more precise and early therapeutic intervention.

Funding: Government Support - Non-U.S.

FR-PO020

Renal Hemodynnamics and Metabolism in Septic AKI Prabhleen Singh,[1,2] Hai Pham,[2] Scott C. Thomson,[1,2] Francis B. Gabbai,[1,2] Roland C. Blantz.[1,2] *[1]UCSD; [2]VASDHS.*

Background: AKI in the setting of sepsis is frequently observed. The traditional archetype of septic AKI caused by renal vasoconstriction has been challenged by recent experimental data demonstrating reduction in GFR even with preserved renal blood flow (RBF) in some models of sepsis. Hence, the underlying pathophysiology of septic AKI remains unclear and is a significant barrier to progress in this field. We aimed to to characterize in-vivo renal hemodynamics, metabolism, and glomerular hemodynamics at 24 hours after injury to explain the underlying pathophysiology.

Methods: We used the cecal ligation and puncture (CLP) model of sepsis in rats. Experiments included measurement of blood pressure, renal blood flow (RBF) by flowprobe, renal oxygen consumption (QO2), GFR by 3-H inulin clearance and single nephron GFR (SNGFR) and glomerular hemodynamics by micropuncture.Data presented as mean±sem.

Results: GFR was significantly lower in CLP vs. shams (1.9±0.4 vs. 3.7±0.9 ml/min, p=0.04). Blood pressure was not different between CLP and shams (108 vs. 105 mm Hg) nor was the RBF (5.7±0.3 vs. 5±0.8 ml/min). The filtration fraction was significantly lowered in CLP vs. shams,0.25 vs. 0.44, p<0.001. Renal oxygen extraction and QO2 factored for GFR (an estimate of filtered load) were both significantly higher in CLP compared to shams, p<0.001 and p=0.004 respectively. Micropuncture data showed a proportional decrease in SNGFR in CLP (42.5±3.7 vs. 20±1.4, p<0.0001). Glomeular hemodynamic measurements revealed higher ΔP in CLP 37.4 vs. 30.6 mmHg, lower single nephron plasma flow 89.7 vs. 141.5 nl/min, and higher afferent (0.32 vs. 0.24) and efferent resistances (0.25 vs. 0.14).

Conclusions: These data demonstrate increased renal oxygen utilization in CLP rats in the setting of lower reabsorptive load, thus suggesting either inefficiency in oxygen utilization for sodium transport or diversion of oxygen for non-transport processes. This may contribute to tubular injury. Glomerular hemodynamics in CLP reveal increased vascular resistances with decreased nephron plasma flow with increased effective filtration pressure, suggesting a reduction in ultrafiltration co-efficient to explain the reduction in SNGFR.

TNF Increases Kidney Glomerular Endothelial Permeability via Modification of Glomerular Endothelial Glycocalyx Chang Xu, Bradley K. Hack, Michael T. Eadon, Patrick Cunningham. *Medicine, University of Chicago, Chicago, IL.*

Background: TNF released in conditions such as sepsis or ischemia increases endothelial permeability to macromolecules in pulmonary and brain microvascular endothelial cells (ECs). Whether TNF induces an increase in permeability to macromolecules in renal glomerular ECs and the relevance of this phenomenon to renal function such as sepsis-induced albuminuria have not been well studied. In this study, we analyze the effect of TNF on the endothelial barrier in mouse renal and human kidney glomerular ECs.

Results: TNF treatment reduced trans-endothelial electrical resistance in mouse renal ECs by 45%, increased albumin passage across the mouse renal EC monolayers by 81%, and human kidney glomerular EC monolayers by 41%. The TNF-induced increase in endothelial permeability was significantly reduced by inhibitors of Rho kinase and myosin light chain kinase (MLCK), but was not associated with disruption of tight junction proteins ZO-1, or claudins -5, -12, or -15, as determined by real time PCR or immunofluorescence. We confirmed the existence of fenestrae in these ECs, via scanning EM and stimulated emission depletion (STED) nanoscopy. We hypothesized that a layer of glycocalyx covering the fenestral domains of the glomerular EC surface is responsible for the endothelial permeability, and we then examined the effect of TNF on the glomerular endothelial glycocalyx, whose main constituents are heparan sulfates. Endothelial glycocalyx was visualized by confocal immunofluorescence of heparan sulfate and by wheat germ agglutinin labeling. TNF disrupted the endothelial surface glycocalyx and induced the endothelial cells to secrete heparanase, which degrades heparan sulfate. TNF treatment increased heparanase expression by 100% in mouse renal ECs by immunoblot.

Conclusions: These results show that TNF increases glomerular endothelial cell heparanase expression and thus causes disruption of the glomerular endothelial glycocalyx, which contributes to the increased endothelial permeability induced by TNF. This study suggests that during sepsis, TNF may disrupt the function of glycocalyx in the restriction to protein passage and contribute to albuminuria.

Formation of Endothelial Microparticles in Ischemic Acute Kidney Injury Dylan Burger,[1] Jonathan G. Boucher,[1] Andreea Slatculescu,[2] Todd Fairhead.[1,2] *[1]Kidney Research Centre, Ottawa Hospital Research Institute, Ottawa, ON, Canada; [2]University of Ottawa, Ottawa, ON, Canada.*

Background: Acute kidney injury (AKI) occurs in about 5% of hospitalized patients with a 50% mortality. Endothelial injury in AKI is characterized by changes in microvascular bloodflow, coagulation, and permeability and contributes to tubular epithelial injury and subsequent chronic kidney disease. Microparticles (MPs) are small, anuclear fragments shed from the cell membranes under conditions of stress/damage. MPs have procoagulant activity and may promote crosstalk between cell types. Endothelial MPs are found at low concentrations in the plasma of healthy subjects and at increased concentrations in conditions of chronic vascular injury such as vasculitis and chronic kidney disease. However, it is not known whether MP levels are increased in AKI. We hypothesized that endothelial MP levels would be increased in AKI and would contribute to inflammation.

Methods: We examined MP formation in male C57BL6 mice subjected to bilateral renal ischemia-reperfusion (I/R) for 45 minutes. Blood was collected 2 hours after reperfusion and MPs were isolated from platelet-free plasma by differential centrifugation. MPs were then quantified by flow cytometry and distinguished as VE-Cadherin^{+ve} (Endothelial MPs) and/or Annexin V^{+ve} (Total MPs) events ranging between 100-1000 nm in size.

Results: Compared with sham-operated mice, mice subjected to I/R displayed significantly higher plasma levels of endothelial microparticles (3149±902 MPs/ml vs.1059 ±152, P<0.05). Conversely, the total number of circulating microparticles was not significantly altered (6009±2126 vs. 6804±2126, P<0.05). To assess whether endothelial MPs could activate neighboring endothelial cells, MPs collected from human microvascular endothelial cells (HMVECs) were incubated with healthy HMVECs in culture. After 12 and 24 hours, no difference in endothelial expression of CD31 (PECAM), or CD144 (VE-Cadherin) was observed.

Conclusions: Our results show that endothelial microparticles are increased early after reperfusion in an animal model of ischemic AKI. Such increases may be indicative of underlying vascular injury, and could serve as an early biomarker of AKI.

In Vivo Imaging of the Host-Pathogen Interaction in the Urinary System with the Biomarker NGAL Neal A. Paragas,[1] Ritwij Kulkarni,[2] Jonathan M. Barasch.[1] *[1]Medicine, Columbia University, New York, NY; [2]Pediatrics, Columbia University, New York, NY.*

Background: NGAL is a critical component of innate immunity because it binds catecholate-siderophores which constitute the dominant iron capture mechanism of urinary pathogenic *E. coli* (UPEC). Urinary(u) NGAL is maximally expressed at mg/L levels after either septic or aseptic injuries of the kidney. It has two potential functions, epithelial growth or iron scavenging leading to bacteriostasis. Here we determined the dominant role of uNGAL as an inhibitor of urinary tract infections (UTI).

Methods: (1) We designed a conditional allele of NGAL. (2) We created a bioluminescent mouse that expresses Luciferase and mCherry when the NGAL locus is activated. (3) We developed a model of bacterial cystitis.

Results: In mouse cystitis, the intensity and timing of urinary CFUs (uCFUs) were mirrored by uNGAL levels, including their onset, their peak and their resolution. To determine uNGAL's physiological role, we constructed a global NGAL KO which poorly defended itself from UPEC. In vitro we found NGAL significantly inhibited UPEC growth, due to reversible depletion of bacterial iron. To visualize NGAL expression *in vivo*, we developed a NGAL reporter mouse (NGAL-*Luc2/mC*). UPECs introduced into the bladder induced NGAL-*Luc2/mC* distantly in the kidneys. Reporter expression was consistent with kidney *Ngal* expression measured by QPCR, *in situ* hybridization and IHC which located *Ngal* to alpha intercalated cell.To determine whether UPEC signaling directly activated kidney epithelia, we developed *in vitro* assays using explants from the reporter mouse. These cells express Ngal-*Luc2/mC* in response to co-culture with UPECs. An intercalated cell line expressed NGAL in the presence of LPS. TLR4 was the critical local sensor of infection.

Conclusions: uNGAL is essential for clearance of a UPEC in a model of cystitis. The kidney responds to infections localized to the bladder by secreting NGAL. These findings provide an explanation for the intensive expression of NGAL in the kidney in both septic and aseptic diseases, demonstrating that the kidney defends the urinary system via exocrine delivery of NGAL.

Low Dose Paclitaxel Ameliorates Endotoxemic Kidney Injury by Binding MD-2 to Block TLR4-Mediated NF-κB Signaling and Inflammation Dongshan Zhang, Zheng Dong. *Cellular Biology and Anatomy, Georgia Health Science University and Charlie Norwood VA Medical Center.*

Background: Paclitaxel is used for cancer therapy. Recent research has suggested that it may have other potential therapeutic effects.

Methods: This study examined the effect of low-dosage paclitaxel on lipopolysaccharide (LPS)-induced acute kidney injury (AKI) in mice.

Results: It was shown that paclitaxel significantly prevented LPS-induced AKI and improved animal survival. The beneficial effects of paclitaxel were accompanied by the inhibition of NF-κB-p65 expression, normalization of F4/80 and MCP-1 expression, and down-regulation of serum TNF-a,IL-1,IL-6 and HMGB-1. In cultured renal tubular HK2 cells, paclitaxel decreased the expression of TLR4, MCP-1 and HMGB-1 during LPS treatment, inhibited the degradation of IkBa, and blocked the expression and activation of NF-κB-p65 and NF-κB DNA binding activity. In addition, paclitaxel reduced LPS-induced interaction of MD-2 with TLR 4 in co-immunoprecipitation analysis. Paclitaxel also bound to recombinant MD-2, and siRNA knockdown of MD-2 significantly decreased TNF-a,IL-1,IL-6,MCP-1 and HMGB-1 levels and NF-κB DNA binding activity during LPS treatment. Furthermore, paclitaxel also significantly reduced HMGB-1-induced cytokines expression, and the interaction of HMGB1 with TLR4. Anti-HMGB-1 antibody ameliorated renal dysfunction by down-regulating cytokines levels *in vitro and vivo*.

Conclusions: These resultsprovide evidence that paclitaxel at low-doses has an anti-inflammatory effect via inhibiting NF-κB activity by binding MD-2 and down-regulating cytokines and HMGB1 expression.

Novel Mouse Model of Albumin Overload with Enhanced Renal Damage and Proteinuria Shipra Agrawal,[1] Melinda Chanley,[1] David B. Thomas,[3] Ruma Pengal,[1] Rainer Benndorf,[1,2] William E. Smoyer.[1,2] *[1]Clinical & Translational Research, The Research Institute at Nationwide Childrens Hospital, Columbus, OH; [2]Department of Pediatrics, The Ohio State University, Columbus, OH; [3]Department of Pathology, University of Miami Hospital, Miami, FL.*

Background: Inducible models of glomerular disease in mice are limited by generally poor susceptibility to injuring agents. Moreover, current models are strain-dependent, limiting their use in many knockout and transgenic mice. We hypothesized that glomerular disease resistance in mice can be overcome by combining PAN or adriamycin (ADR) with albumin overload.

Methods: 129/SvJ male mice (16-18 wk) received either low-endotoxin bovine serum albumin (BSA) I.P. for 4 days (D1-D4) at 400 mg/d, or saline control. PAN or ADR was injected I.V. on D1 at 150mg/kg and 10mg/kg, respectively, alone or with BSA. Albuminuria was analyzed by SDS-PAGE of urine samples on D0-D5, and BUN was measured on D0, D3 and D5. At D5, kidneys were processed for histology and western blotting.

Results: BSA-treated mice developed a moderate albuminuria at D2-D5, which was greatly enhanced with combination treatments (i.e. ADR+BSA; PAN+BSA). In contrast, singly (ADR or PAN) treated mice exhibited only a minor or no albuminuria. Serum BUN was notably higher in combination treatments (50-96 mg/dl) vs. controls or single treatments (30-40 mg/dl). Both BSA alone and combination treatments induced diffuse acute tubular epithelial cell injury, with tubular dilatation slightly greater in combination vs. BSA alone treatment. No renal injury was seen in controls or after PAN or ADR treatment alone. Stress response proteins (Hsp25; Hsp70i) were induced in renal cortices after BSA alone or combination treatments, but not in controls. In contrast, GRP78 expression was decreased after BSA alone and further decreased after combination treatments.

Conclusions: The combination of albumin overload with PAN or ADR treatment appears to enhance susceptibility of mice to renal damage compared to PAN, ADR, or BSA alone. This approach may have potential utility for induction of glomerular disease in otherwise resistant mouse strains commonly used for genetic manipulations.

FR-PO026

Endotoxemia Differentially Regulates Renal Ca^{2+}-Transport Proteins in Mice Klaus Höcherl. *Institute of Physiology, University of Regensburg, Regensburg, Germany.*

Background: Hypocalcemia is frequently reported in critically ill patients, most commonly in association with sepsis syndrome, and is associated with increased mortality in septic patients. The kidney is an important organ for the maintenance of the body Ca^{2+} homeostasis through Ca^{2+} reabsorption along the nephron. The influence of sepsis on renal calcium transport proteins has yet to be defined. Therefore, we examined the effects of endotoxemia on renal calcium excretion and on the regulation of major calcium transport proteins in mice.

Methods: Male C57BL/6 mice, 8-10 wk old weighing 22-25g, were used. Endotoxemia was induced by the administration of a single dose of lipopolysaccharide (LPS; 3 mg/kg; i.p.). The mRNA levels were measured by quantitative real-time RT-PCR. Immunoblotting and immunoflourescence studies were performed for the quantification of protein levels. Calcium and creatinine levels were measured in urine and blood samples by commercially available assay kits.

Results: Administration of LPS (3 mg/kg; i.p.) caused a time-dependent hypocalciemia and an increase in the urinary calcium-to-creatinine-ratio 16 hours after injection of LPS. The renal mRNA expression of the epithelial calcium channels TRPV5 and TRPV6 were increased 2.3- and 4.5-fold, respectively, 16h after the administration of LPS. Further, LPS decreased the expression of the calcium binding protein calbindin-D_{28K} to about 40% of control values, whereas the abundance of calbindin-D_{9K} was unchanged. In addition, the basolateral natrium/calcium exchanger NCX1 was decreased to about 20% of control levels, whereas the abundance of the plasma membrane ATPase type 1b (PMCA1b) was unaltered in response to LPS. Semiquantitative immunoblotting and immunohistochemistry confirmed changes in renal protein abundance of TRPV5, NCX1 and calbindin-D_{28K}.

Conclusions: We conclude that LPS decreases renal calcium reabsorption mainly via the downregulation of calbindin-D_{28K} and of the natrium/calcium exchanger NCX1. This may contribute in part to the development of hypocalcemia in response to endotoxemia.

FR-PO027

Serotonin (5-HT) 1F Receptor Agonism as a Potential Treatment for Acceleration of Recovery from Acute Kidney Injury Sara M. Garrett, Rick G. Schnellmann. *Pharmaceutical and Biomedical Sciences, Medical University of South Carolina, Charleston, SC.*

Background: Mitochondrial dysfunction is common in acute kidney injury (AKI) and chronic kidney disease. We have proposed that stimulation of mitochondrial biogenesis (MB) may accelerate cellular repair and recovery from AKI. Unfortunately, very few chemicals/drugs have been identified that induce MB and we have initiated a drug discovery program to identify such agents. The goal of these experiments was to explore 5-HT receptors in MB.

Methods: A MB assay incorporating FCCP-induced uncoupled oxygen consumption rate (OCR) in a Seahorse Biosciences analyzer was used (Beeson et al., 2010). PGC-1a, the master regulator of MB, 5-HT1F, and mitochondrial proteins Cox1, ATP synthase β, and NDUFB8 were measured by real time RT-PCR and immunoblot analysis on rabbit renal proximal tubule cells (RPTC) and murine tissues. Mitochondrial copy number was determined using real-time RT-PCR. siRNA knockdown of 5-HT1F was used in RPTC.

Results: Immunoblot and qPCR analyses revealed 5-HT1F receptor expression in RPTC. Two 5-HT1F receptor agonists, LY334370 and LY344864, increased uncoupled OCR at 1nM-100nM. Both agonists increased the nuclear-encoded mitochondrial proteins ATP synthase β and NDUFB8, and mitochondrial-encoded Cox1. Knockdown of 5-HT1F receptor with siRNA decreased 5-HT1F receptor protein levels and agonist-induced up-regulation of MB proteins. In renal cortical tissue of naïve mice, PGC1α, Cox1, and NDUFB8 transcript levels increased in response to LY334370 and LY344864. Both agonists also increased mitochondrial copy number, PGC1α, Cox1, and NDUFB8 transcript levels in the hippocampus and liver. Sumatriptan and related drugs, 5-HT1F receptor agonists used for the treatment of migraines, also increased uncoupled OCR in RPTC (1-3 nM).

Conclusions: In summary, these studies reveal the novel observation that 5-HT1F receptors are linked to MB and that 5-HT1F receptor agonists induce MB in renal cells and in the kidney. Based on our results, we suggest that a treatment potential exists for the acceleration of recovery from AKI via 5-HT1F agonist-mediated MB in the kidney.

FR-PO028

Early Endothelial Outgrowth Cells (eEOCs) and BMP-5 in Acute Ischemic Kidney Injury (AKI) Daniel Patschan, Susann Patschan, Gerhard A. Mueller. *Nephrology and Rheumatology, University Hospital Göttingen, Göttingen, Niedersachsen, Germany.*

Background: Early Endothelial Outgrowth Cells (eEOCs) protect mice from acute ischemic kidney injury. Bone morphogenetic protein-5 has been shown to act antifibrotic in chronic hypertensive nephropathy. Aim of the study was to evaluate modulatory effects of BMP-5 in the setting of an eEOC-based therapy of AKI.

Methods: Male, 8-12 weeks C57/Bl6N mice were subjected to bilateral renal ischemia (40 minutes) with subsequent systemic injection of either untreated or BMP-5 pretreated syngeneic murine eEOCs (stimulation concentration 100 ng/ml, incubation time 1 hour). Cultured murine eEOCs were analyzed for migratory activity and production / release of proangiogenic / proinflammatory mediators.

Results: Postischemic mice with administration of untreated eEOCs showed significantly impaired renal function (Creatinine post-ischemia: 1.09 ±0.23 mg/dl and post-ischemia + untreated eEOCs: 1.26 ±0.21 mg/dl vs. Controls: 0.26 ±0.1 mg/dl, p=0.02 und p=0.005). Pretreatment of eEOCs with BMP-5 dramatically increased renoprotective effects of the cells (Creatinine post-ischemia + eEOCs + BMP-5: 0.2 ±0.05 vs. Creatinine post-ischemia: + eEOCs 1.26 ±0.21 mg/dl, p=0.0006 and Creatinine post-ischemia + eEOCs + BMP-5: 0.2 ±0.05 vs. Controls: 0.26 ±0.1 mg/dl, p=0.6). BMP-5 did not stimulate cellular production / release of IL-6, TGF-b, or VEGF, but migratory activity of cultured eEOCs was significantly increased (wound area reduction: BMP-5 33 ±0.9% vs. Controls 8.2 ±6.1%, p=0.01).

Conclusions: In summary, BMP-5 could be established as very potent eEOC agonist in AKI. Cellular activation is reflected by increased migratory activity of eEOC, paracrinic actions are not affected.

FR-PO029

Phosphodiesterase Inhibitors Stimulate Mitochondrial Biogenesis: A Potential Therapy for AKI Ryan Whitaker, Lauren P. Wills, Rick G. Schnellmann. *Drug Discovery and Biomedical Sciences, Medical University of South Carolina, Charleston, SC.*

Background: Our laboratory has demonstrated persistent mitochondrial dysfunction and depletion of mitochondrial proteins following renal ischemia/reperfusion (I/R) injury in rodents that correlates with sustained renal tubular dysfunction. These results support the hypothesis that restoration of mitochondrial function through stimulation of mitochondrial biogenesis (MB) may be an effective therapeutic strategy for accelerating recovery from AKI.

Methods: We tested PDE3, 4 and 5 inhibitors for MB due to the established role of cAMP and cGMP in the regulation of PGC-1α. PDE3 inhibitors increase cGMP and cAMP, PDE4 inhibitors increase cAMP, and PDE5 inhibitors increase cGMP. FCCP-uncoupled respiration was measured in primary cultures of renal proximal tubule cells (RPTC) using the Seahorse Biosciences Analyzer as a marker of MB. In addition, C57BL/6 mice were treated with cilostamide, trequinsin, sildenafil or vehicle control (IP) and euthanized 24 hr later. Kidneys were collected for RT-PCR and immunoblot analysis.

Results: PDE3 inhibitors anagrelide, cilostamide, enoximone and trequinsin, and the PDE5 inhibitor sildenafil stimulated MB as assessed by increases in FCCP-uncoupled respiration in RPTC following a 24 hr treatment. Additionally, mRNA expression of PGC-1α and complex I proteins ND6 and NDUFB8 increased. In contrast PDE4 inhibitors did not stimulate MB. Exposure of RPTC to 8-Br-cGMP stimulated MB, while 8-Br-cAMP did not. These data suggest cGMP serves as a primary mediator of MB in RPTC. Cilostamide, trequinsin and sildenafil increased mRNA expression of PGC-1α, NDUFB8, ATPβ, COX1 and ND1 and increased mitochondrial DNA copy number in the kidney cortex.

Conclusions: These data demonstrate that classes of PDE inhibitors that increase cGMP stimulate MB in RPTC and kidney, and suggest that these compounds may serve as viable pharmacological agents to stimulate MB in the treatment of AKI.

Y-Box Binding Protein Regulates Innate Immune Response *In Vivo*

Tammo Ostendorf,[1] Lydia Hanßen,[1] Sonja Djudjaj,[1] Peter Boor,[1] Thomas Rauen,[1] Peter R. Mertens,[2] Jürgen Floege,[1] Ute Raffetseder.[1] *[1]Division of Nephrology, RWTH Aachen University, Aachen, Germany; [2]Department of Renal Medicine and Hypertonia, University Hospital Magdeburg, Magdeburg, Germany.*

Background: The Y-box binding protein (YB)-1 is involved in multiple inflammatory processes. To understand the molecular mechanisms of YB-1 during acute inflammation, we studied a model of endotoxemia, mimicking sepsis-induced acute kidney injury in wildtype (WT) and heterozygous YB-$1^{+/d}$ knockout mice, which exhibit half maximal YB-1 levels.

Methods: Hepatic and renal expression of YB-1, inflammatory receptors and chemokines in YB-$1^{+/d}$ *versus* WT mice were studied 6h and 48h following i.p. injection of lipopolysaccharide (LPS; 1.5 mg/kg). Bone marrow derived granulocytes were assessed for chemotaxis, and livers and kidneys for immune cell infiltration. Renal tubular damage was assessed via kidney injury molecule (KIM)-1 expression. Cylosporine A treatment (CsA; 30 mg/kg; s.c.) was performed following a low-sodium diet.

Results: Following LPS injection, enhanced YB-1 expression and activation temporarily occurred in immune cells, liver and kidney and secreted YB-1 was detectable in the abdominal cavity and urine. In YB-$1^{+/d}$ mice we noted a decreased influx of immune cells, which coincided with a significantly reduced expression of toll-like receptor (TLR)-4 on bone-marrow derived immune cells and a reduced CCR5 expression in the kidney. In addition, a markedly altered expression of chemokines (e.g. CCL5, CCL2) in infiltrating cells, kidneys and livers of YB-$1^{+/d}$ mice was detected. Consistent with this, granulocytes derived from YB-$1^{+/d}$ mice exhibited a reduced migration capability towards CCL5. Upregulation of KIM-1 was reduced in YB-$1^{+/d}$ mice. Thus, an impaired immune response occurred in YB-$1^{+/d}$ mice. This resulted in 50% mortality coinciding with an enhanced bacterial infection when the immunosuppressant CsA was administered.

Conclusions: In conclusion, our data identify YB-1 as an important factor in sepsis-induced acute kidney injury and in the innate immune response.

Spironolactone Administration after Severe Acute Kidney Injury Prevents Chronic Kidney Disease Development

Jonatan Barrera-Chimal,[1,2] Rosalba Pérez-villalva,[1,2] Roxana Rodriguez,[1,2] Norma O. Uribe-uribe,[2] Gerardo Gamba,[1,2] Norma Bobadilla.[1,2] *[1]Molecular Physiology Unit, Instituto de Investigaciones Biomédicas, UNAM; [2]Instituto Nacional de Ciencias Médicas y Nutrición SZ, Mexico.*

Background: Acute Kidney Injury (AKI) has been recognized as a risk factor to promote Chronic Kidney Disease (CKD). We previously demonstrated that prophylactic spironolactone (Sp) administration prevents CKD induced by an episode of renal ischemia (I). Because, in many cases AKI cannot be predicted, this study was designed to determine if Sp administration after an ischemic insult could protect against CKD development.

Methods: Thirty-five male Wistar rats were divided in: sham-operated, rats underwent 45 min of bilateral I, rats receiving a low dose of Sp (20 mg/kg) immediately, 1.5 or 3 hours after I, and rats receiving a high dose of Sp (80 mg/kg) immediately or 1.5 hours after I. All groups were followed throughout 90 days. Proteinuria (UProt) was evaluated every 30 days. At the end, creatinine clearance (CrC) and renal blood flow (RBF) were measured. Right kidney was used for molecular studies and the left for histopathological analysis.

Results: Rats underwent to I developed CKD characterized by a progressive increase in UProtV, together with a moderate reduction in CrC and RBF. Glomerular hypertrophy, tubular dilation and tubule-interstitial fibrosis were also observed after 90 days of inducing I. These alterations were associated with an up-regulation of MCP-1, αSMA, TGFβ and pSmad3. In contrast, in all Sp-treated groups, Uprot was prevented and the renal dysfunction was not observed. In addition, glomerular hypertrophy was partially prevented in the rats treated with the lower Sp dose and totally prevented in rats receiving the higher dose. Renal architecture preservation in the rats treated with the higher dose was associated with prevention of αSMA, MCP-1 and TGFβ up-regulation.

Conclusions: We show for the first time that Sp administration even after the renal insult has occurred is a novel strategy to prevent CKD induced by a single episode of AKI. The Sp renoprotective mechanisms included prevention of glomerular and tubular hypertrophy, as well as activation of fibrotic and inflammatory processes.

Peroxisomal and Lysosomal Dysfunction in LPS-Induced AKI

Radovan Vasko, Brian B. Ratliff, Jun Chen, Sandhya Xavier, Michael S. Goligorsky. *New York Medical College, Valhalla, NY.*

Background: In a model of defective lysosomal autophagy, Lyst-mice, we have previously demonstrated that LPS treatment results in a more severe renal injury than in wt-type mice. We implicated impaired autophagy of peroxisomes (POS), pexophagy, as important contributor to injury by LPS.

Methods: We used in vitro and in vivo approaches to study POS function in LPS-induced AKI, and the impact of defective lysosomal autophagy.

Results: POS harbor the highest cellular content of catalase, their crucial antioxidant enzyme. In vivo, wt-mice had lower kidney catalase abundance but higher enzymatic activity than Lyst-mice under basal conditions. This difference was further aggravated after treatment with LPS. Ex vivo, lysosome-defective cells also exhibited decreased catalase activities and higher reactive oxygen species under basal conditions, with further increase and longer persistence after LPS. Our time-lapse microscopy studies with POS-targeting-sequence (PTS1)-GFP revealed decreased peroxisomal protein import after LPS, which additionally compromised peroxisomal balance of catalase possessing an atypical weaker PTS1. Renal expression of PPARα, primarily involved in activation of POS, was higher in Lyst- than wt-mice, reflecting an adaptive response to stimulate impaired POS. Endothelial cells isolated from Lyst-mice exhibited enhanced basal and LPS-induced inflammatory responses, with higher levels of IL-6, IL-8, G-CSF, GM-CSF and MCP-1. Cytokine profiles of cell secretomes matched those obtained from sera of experimental animals. LPS decreased PPARα and ACOX1 (the first enzyme in POS β-oxidation) in wt-mice; opposite occurred in lysosomal dysfunction, where LPS caused increase of PPARα, ACOX1 and hence hydrogen peroxide (byproduct of POS β-oxidation), resulting in redox imbalance due to impaired catalase.

Conclusions: Impaired pexophagy results in a worsening of LPS-induced renal injury. We identified 2 mechanisms governing this phenomenon: 1) imbalance between increased H_2O_2 generation by activated POS oxidases and concomitantly decreased antioxidative defense due to catalase deficiency; and 2) exaggerated pro-inflammatory endothelial secretome potentially orchestrating a systemic inflammatory response.

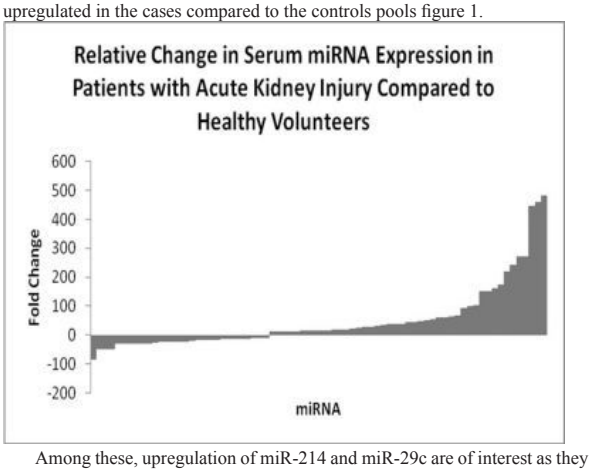
Circulating Micro-RNAs in Acute Kidney Injury after Liver Transplantation: Early Observations

Berenice Y. Gitomer,[1] Charles L. Edelstein,[1] Wei Wang,[1] Eric Lader,[2] Jonathan Michael Shaffer,[2] M. Chonchol.[1] *[1]Department of Medicine, University of Colorado Denver, Aurora, CO; [2]Sample & Assay Technologies, Qiagen, Frederick, MD.*

Background: MicroRNAs (miRNAs) are small non-coding RNAs that regulate gene expression and are present in the blood in a stable form. We tested whether circulating miRNAs in the serum of acute kidney injury (AKI) patients post-liver transplant are deregulated when compared to healthy controls.

Methods: We performed miRNA profiles using RNA isolated from n=10 healthy volunteers (controls) and n=7 subjects (cases) who developed AKI after liver transplantation. AKI was defined using the Acute Kidney Injury Network (AKIN) definition.miRNA profiles were analyzed using a custom quantitative PCR array containing 372 miRNAs previously determined to be readily detectable in serum (Qiagen, Frederick, MD). Arrays were analyzed as 1 case pool and 3 control pools.

Results: We identified 10 healthy volunteers (M/F: 7/3) with a mean (SD) age of 58 ± 2 yrs who had ideal cardiovascular health. AKI patients (M/F: 4/3) had a mean (SD) age of 59 ± 4 yrs. Based on a cut off of $C_t \geq 35$ cycles and all miRNA that demonstrated ≥ 10 fold difference, 29 miRNAs were significantly downregulated and 46 miRNAs were upregulated in the cases compared to the controls pools figure 1.



Among these, upregulation of miR-214 and miR-29c are of interest as they have been associated with kidney injury in rodent models.

Conclusions: Expression of miR-214 and miR-29c were upregulated in AKI patients post-liver transplant compared with healthy subjects, consistent with a miRNA profile of kidney damage. The utility of this profile for prediction of AKI will need validation and testing in a larger population.

Renal Proximal Tubule Epithelial Cells Regulate Immunological Danger through Expression of Kidney Injury Molecule-1

Yifei Zhong,[1,3] Sahra Nathoo,[1,3] Xizhong Zhang,[2,3] Lakshman Gunaratnam.[1,2,3] *[1]Dept of Microbiology and Immunology, Western University, London, ON, Canada; [2]Division of Nephrology, Dept of Medicine, Western University, London, ON, Canada; [3]Matthew Mailing Center for Translational Transplant Studies, London Health Sciences Centre, London, ON, Canada.*

Background: Phagocytosis of apoptotic cells is vital to preventing inflammation. Uncleared apoptotic cells can undergo secondary necrosis and release endogenous danger signals such as high mobility group box protein 1 (HMGB1) into the extracellular milieu. The existing pool of professional phagocytes can be overwhelmed during acute tissue

injury. Kidney injury molecule-1 (KIM-1) is a scavenger receptor for apoptotic cells that is upregulated on kidney proximal tubule epithelial cells (PTECs) following acute kidney injury, transforming surviving PTECs into avid phagocytes. We hypothesized that clearance of apoptotic cells by KIM-1-expressing PTECs prevents release of HMGB1 and activation of innate immune responses.

Methods: We added varying doses of apoptotic cells to cultures of PTECs expressing or not expressing KIM-1. After 24hrs incubation, the resultant conditioned cell media and lysates were analyzed for HMGB1 by Western blot. Next, conditioned cell media from both cell types were added to cultures of dendritic cells. We performed flow cytometry after 24hrs incubation to assess dendritic cell activation as a marker of innate immunity.

Results: Compared to that of control cells not expressing KIM-1, we observed significantly more intracellular HMGB1 in the lysates and less HMGB1 in the conditioned media of KIM-1-expressing cells that were exposed to apoptotic cells. Further, dendritic cells exposed to conditioned media from KIM-1-expressing cells showed less activation, compared to dendritic cells exposed to media from cells not expressing KIM-1. This suggests that there were more uncleared apoptotic cells in the conditioned media of cells not expressing KIM-1.

Conclusions: KIM-1-expressing PTECs may regulate innate immunity through clearance of apoptotic cells. We propose that upregulation of KIM-1 during acute kidney injury is a host defense mechanism that curtails inflammation through this mechanism.

FR-PO035

Mechanisms by Which Chronic Nicotine (NIC) Suppresses Heme Oxygenase-1 (HO-1) and Exacerbates Ischemia-Reperfusion-Induced Acute Kidney Injury (I/R-AKI) Istvan Arany,[1] Dustin Reed,[1] Robert Kampen,[1,2] Luis A. Juncos.[2] *[1]Pediatrics, University of Mississippi Medical Center, Jackson, MS; [2]Medicine/Nephrology, University of Mississippi Medical Center, Jackson, MS.*

Background: HO-1 constitutes a potent protective mechanism against IR-AKI; its deficiency promotes inflammation, fibrosis and injury. Chronic NIC exacerbates pro-inflammatory and pro-fibrotic signaling in a mouse model of IR-AKI in part via attenuation of HO-1 induction.

Methods: In vivo: The impact of chronic NIC (4 weeks) on expression of renal HO-1, phosphorylation of STAT3 and ERK, and I/R-AKI were determined in the kidneys of mice exposed to 18-minutes of bilateral warm renal ischemia followed by 24 hours of reperfusion. In vitro: Cultured renal proximal tubule cells (LLC-PK1) were treated with 200 mM NIC for 24 hours aftetr which cell injury was induced by H_2O_2 (400 mM). The roles of tyrosine phosphorylation of STAT3, serine/threonine phosphorylation of ERK (pERK), and HO-1 were evaluated by manipulating their expression or activity using pharmacological and genetic means (AG490, Y705F-STAT3 for STAT3; U0126, dnMEK, for ERK; and CoPP and SnPP for inducing and inhibiting HO, respectively).

Results: Chronic NIC exposure attenuated IR-AKI-induced increases in tyrosine phosphorylation of STAT3 and also HO-1, but exacerbated I/R-AKI-induced increases in pERK.

In vitro, H_2O_2-mediated activation of the HO-1 promoter was dependent on tyrosine phosphorylation of STAT3 and the antioxidant response element (ARE). NIC reduced this induction of the HO-1 promoter through a pERK-dependent attenuation of STAT3 binding element (SBE) and ARE.

Conclusions: Our data demonstrates that I/R-AKI/oxidative stress induces HO-1 through SBE and ARE, protecting renal proximal tubules. Chronic NIC, via sustained activation of ERK- attenuates HO-1 transcription by inhibiting both SBE and ARE activation. Manipulation of those pathways may present therapeutic means to ameliorate adverse effects of chronic NIC/smoking.

FR-PO036

Vitamin D Deficiency Is a Potential Risk Factor for the Progression of Chronic Kidney Disease after Ischemia/Reperfusion-Acute Kidney Injury Janaina Garcia Gonçalves, Ana C. de Bragança, Daniele Canale, Maria Heloisa M. Shimizu, Lucia Andrade, Antonio C. Seguro, Rosa M.A. Moyses, Rildo A. Volpini. *Nephrology, University of Sao Paulo School of Medicine, SP, Sao Paulo, Brazil.*

Background: Vitamin D deficiency (VDD) is highly prevalent in chronic kidney disease (CKD) patients. Ischemia/reperfusion-Acute Kidney Injury (IR-AKI) is considered a risk factor for CKD progression. VDD is known to be associated with increased metabolic syndrome (MetS) risk; serum cholesterol and triglyceride levels; and insulin resistance. There is an association between CKD and MetS, and decreased Klotho expression is an early marker of stage 1 CKD. We hypothesized that VDD-induced MetS is a pathway linking AKI and CKD.

Methods: For 90 days, Wistar rats were fed a standard diet (control [C] and IR-AKI groups, n=8 each) or a 25-hydroxyvitamin D [25(OH)D]-free diet (VDD and VDD+IR-AKI groups, n=8 each). On day 28, IR-AKI and VDD+IR-AKI rats were submitted to 45-min clamping of both renal arteries. On day 90, we measured inulin clearance (Cin); proteinuria, glycosuria; serum 25(OH)D, triglycerides and total cholesterol. We estimated fibrosis by fractional interstitial area (FIA) and immunoblotted renal tissue for Klotho. Data are mean±SEM.

Results:

Variable	C	VDD	IR-AKI	VDD+IR-AKI
Cin (ml/min/100 g)	0.64±0.03	0.56±0.04	0.58±0.04	0.59±0.03
25(OH)D (ng/ml)	15.4±1.0	<1.5*	15.0±0.6	<1.5*
Proteinuria (mg/day)	23.5±2.0	22.8±2.6	26.1±2.4	33.2±1.0[a,b,c]
Glycosuria (mg/dl)	10.5±1.1	17.6±1.2[a]	12.4±0.7[b]	21.6±2.1[a,c]
Total cholesterol (mg/dl)	41.0±4.7	66.7±4.6[a]	60.0±3.4[a]	61.7±4.5[a]
Triglycerides (mg/dl)	10.0±2.8	171.5±32.6[a]	47.5±7.4[b]	87.2±18.1[a,b]
FIA (%)	7.3±0.5	17.2±0.8[a]	24.4±2.9[a,b]	34.9±0.55[a,b,c]
Klotho† (%)	98.7±0.7	47.5±6.0[d]	53.3±7.6[d]	46.7±2.5[d]

*undetectable; †protein expression; [a]p<0.05 vs. C; [b]p<0.05 vs. VDD; [c]p<0.05 vs. IR-AKI; [d]p<0.001 vs. C

Conclusions: The increased proteinuria/fibrosis in VDD+IR-AKI rats suggests progressive renal injury. MetS-related lipidic metabolism and glycosuria could explain progressive renal injury after IR and progression to CKD. Downregulation of Klotho is a possible marker of chronification. The mechanistic role of VDD-induced MetS in progressive CKD merits further study.

FR-PO037

Natural Triggering of p21 Upregulation Is Decreased in Vitamin D-Depleted Rats with Ischemic Acute Kidney Injury Ana C. de Bragança, Daniele Canale, Janaina Garcia Gonçalves, Rildo A. Volpini, Maria Heloisa M. Shimizu, Rosa M.A. Moyses, Antonio C. Seguro, Lucia Andrade. *Nephrology, University of Sao Paulo School of Medicine, Sao Paulo, SP, Brazil.*

Background: Prior vitamin D deficiency (VDD) is a major predictor of mortality in critically ill patients. Renal ischemia/reperfusion injury (IRI), activates pathways of cell proliferation and cell death. Acute kidney injury (AKI) induces cell cycle inhibitors, including the cyclin-dependent kinase inhibitor p21, which protects against AKI. In many cell types, p21 is a genomic target of 25-hydroxyvitamin D [25(OH)D], which, acting via vitamin D receptors (VDRs), has potent immunomodulatory and antiproliferative effects, suggesting that it plays a role in the pathophysiology of renal disease.

Methods: Wistar rats were fed 25(OH)D-depleted or normal diets for 30 days. On day 28, some rats were induced to IRI by 45-min clamping of both renal arteries. We studied four groups: control (C), VDD, IRI and VDD+IRI. At 48 h after IRI, we measured inulin clearance (Cin); proteinuria; and serum 25(OH)D, Ca, and P. In renal tissue, we immunoblotted for p21, VDR and klotho. Data are means±SEM.

Results:

	Cin (ml/min/100g)	Proteinuria (mg/day)	Renal weight/body weight	25(OH)D (ng/ml)	p21* (%)	VDR* (%)	klotho* (%)
C (n=7)	0.93±0.05	21±1.1	0.4±0.02	14.8±0.08	99±6.0	99.5±0.5	98±1.2
VDD (n=6)	0.76±0.03[a]	33±2.1	0.41±0.01	4.1±0.8[a]	100±27	57.5±8.5[a]	76±2.4[b]
IRI (n=7)	0.43±0.04[a,c]	33±6.1	0.52±0.01[a,c]	13±1.0[c]	290±4.8[d,e]	198.5±0.7[d,e]	22±6.0[d,e]
VDD+IRI (n=8)	0.29±0.03[a,c,f]	48±6.5[a]	0.58±0.02[a,c,f]	3.8±0.23[a,f]	182±29[a,c,g]	172.7±10.9[c,e,f]	16.7±2.4[d,e]

* protein expression; [a] p<0.05 vs. C; [b]p<0.01 vs. C; [c]p<0.05 vs. VDD; [d]p<0.001 vs. C; [e]p<0.001 vs. VDD; [f]p<0.05 vs. IRI; [g]p<0.01 vs. IRI

VDD, IRI and VDD+IRI rats showed higher renal vascular resistance, higher urinary volume, lower urinary osmolality and lower serum P and Ca than did controls.

Conclusions: We speculate that, by altering the levels of p21 in IRI AKI, via VDRs, 25(OH)D controls renal inflammation, proliferation and cell injury. Further studies are needed to determine whether correction of VDD provides clinical benefits in AKI.

Critical Role of Interleukin-11 (IL-11) Signaling in A_1 Adenosine Receptor Mediated Renal Protection Joo Yun Kim,[1] Ahrom Ham,[1] Mihwa Kim,[1] H. Thomas Lee,[1] George N. Cox.[2] *[1]Anesthesiology, Columbia University, New York, NY; [2]Bolder BioTechnology, Inc., Boulder, CO.*

Background: Acute kidney injury (AKI) occurs in ~20% of all hospitalized patients and renal ischemia reperfusion (IR) injury is a major cause of AKI. We previously demonstrated that renal A_1 adenosine receptor (ARs) activation ameliorated renal IR injury by attenuating multiple pathways of cell death including necrosis, apoptosis and inflammation. However, extra-renal side effects (bradycardia and hypotension) may limit the A_1AR agonist therapy for ischemic AKI. IL-11 is a multi-functional hematopoietic cytokine clinically approved to treat chemotherapy-induced thrombocytopenia.

Methods: Here, we show that selective A_1AR activation protects against IR injury by direct induction of renal tubular IL-11 synthesis.

Results: In cultured human proximal tubule epithelial (HK-2) cells, a selective A_1AR agonist 2-chlorocyclopentyladenosine (CCPA) dose-dependently induced IL-11 mRNA and protein expression. CCPA also induced IL-11 mRNA and protein synthesis in mouse kidney. CCPA-mediated induction of IL-11 was significantly attenuated by a specific inhibitor of ERK MAPK (PD98059) but not by an inhibitor of Akt (wortmannin). In addition, IL-11 receptor (IL-11R) wild type mice subjected to 30 min of renal ischemia and 24 h of reperfusion developed severe AKI (Cr=2.3±0.2mg/dL, N=6). Supporting a critical role of IL-11 in A_1AR-mediated renal protection, A_1AR agonist CCPA protected IL-11R wild type mice against ischemic AKI (Cr=1.4±0.2mg/dL, N=6, P<0.01) but failed to protect IL-11R deficient mice (Cr=2.3±0.2mg/dL, N=6). In addition, IL-11 neutralizing antibody completely abolished the renal protection provided by CCPA (Cr=2.4±0.2mg/dL,

N=5). Finally, exogenous administration of recombinant human IL-11 protected against ischemic AKI in mice (Cr=1.5±0.2 mg/dL, N=5) mimicking the renal protective effects A_1AR activation.

Conclusions: Taken together, we show that induction of renal tubule IL-11 is critical for A_1AR-mediated renal protection. Selective renal tubular induction of IL-11 or exogenous administration of IL-11 may provide a novel therapeutic approach for the prevention and treatment of ischemic AKI.

The Inflammasome in Cisplatin-Induced AKI Hyun-Jung Kim, Dong Won Lee, Zhibin He, Danica Ljubanovic, Charles L. Edelstein. *Univ. of Col. Denver.*

Background: We have demonstrated that there is increased caspase-1, IL-1α, IL-1β and IL-18 in cisplatin (Cis)-induced AKI (CIA). As IL-1α, IL-1β and IL-18 are activated by caspase-1 in the inflammasome, the aim of the study was to further investigate the inflammasome in CIA. The NALP3 inflammasomes is a cytosolic complex consisting NALP3 protein, ASC protein and caspase-5. BID is a pro-apoptotic protein that is secreted by the inflammasome.

Methods: Mice were injected with Cis (25 mg/kg) and developed AKI on day 3. ATN was graded as to the number of tubules with histological features of ATN.

Results: On immunoblot of whole kidney, there were a 1.3-fold increase in NALP3 on day 2 (P=0.05, n=9) and a 2.6-fold increase in NALP1 (P<0.05, n=9) on day 3 of CIA. On immunoblot, there were a 2-fold increase in ASC on day 2 (P<0.05, n=10), a 3-fold increase in caspase-5 protein on day 2 (P<0.05, n=10), a 2-fold increase in BID on day 2 (P<0.05, n=10), and a 1.2-fold increase in caspase-1 (P<0.05, n=9). As the increase in NALP3 occurred on day 2 at the same time as the increase in ASC, caspase-5, BID and caspase-1, and before the AKI, we considered that inhibition of NALP3 may play an injurious role. To determine whether the increase in NALP3 plays an injurious role in CIA, $NALP3^{-/-}$ mice were studied. Serum creatinine (mg/dL) was 0.22 in vehicle (Veh)-treated, 2.0 in Cis-treated wild type (P< 0.001 vs. Veh, n=10) and 1.2 in Cis-treated $NALP3^{-/-}$ mice (NS vs. wild type, n=9). BUN (mg/dL) was 23 in Veh-treated, 209 in Cis-treated wild type (P< 0.001 vs. Veh, n=10) and 201 in Cis-treated $NALP3^{-/-}$ mice (NS vs. wild type, n=9). ATN score was 1.8 in Cis-treated wild type and 1.5 in Cis-treated $NALP3^{-/-}$ mice (NS vs. wild type, n=5). Apoptosis score (apoptotic cells per 10 HPF) was 8.4 in Cis-treated wild type and 1.4 in Cis-treated $NALP3^{-/-}$ mice (NS vs. wild type, n=5).

Conclusions: Inflammasome proteins NALP3, caspase-1, caspase-5, ASC and BID are increased in whole kidneys on day 2 of CIA. However, $NALP3^{-/-}$ mice are not functionally or histologically protected suggesting that the NALP3 inflammasome does not play an injurious role in CIA. Further investigation of the NALP1 imflammasome is warranted.

FR-PO040

Upregulation of Hypoxia Inducible Factor-1 Prevents Development of Hepatorenal Syndrome Meghana Awad, Siddhartha S. Ghosh, Todd W. Gehr, Arun Sanyal, Daniel E. Carl. *Internal Medicine, Commonwealth University of Virginia, Richmond, VA.*

Background: The pathophysiology of hepatorenal syndrome (HRS) is not clearly understood due to lack of suitable animal models. Carbon tetrachloride (CCl4) is used in mice to induce cirrhosis. Hif-1 is a well known factor produced in tissues in response to ischemia. The potential role of Hif-1 in HRS is not known. We hypothesized that failure to upregulate Hif-1 would be associated with functional renal failure in our model of HRS. **AIMS: 1) To evaluate expression of Hif-1 in our mouse model of HRS, 2) to evaluate the effect of dimethyloxalylglycine (DMOG), which upregulates Hif-1.**

Methods: Cirrhosis in C57bl mice was induced with CCl4 (1 ml/kg) given for 6 weeks. Mice were divided into (n=5 in each):Vehicle (corn oil), CCl4(1mg/kg) for 6 weeks, CCl4+ LPS, CCl4+DMOG, CCl4 +DMOG +LPS. DMOG (100mg/kg/day)was administered from day 38 to sacrifice. Lipopolysaccharide (LPS) was administered (1.5 mg/Kg) intraperitoneally and mice were sacrificed 16 hours later.

Results: There was no change in urine volume, urine sodium (UNa) and serum creatinine (SCr) between controls and controls+LPS. The table below highlights the changes in urine volume, UNa, and SCr between groups. There was a 30% decrease in kidney Hif-1 expression in CCl4 +LPS mice. Administration of DMOG abrogated this response and was associated with preserved renal function after CCl4 + LPS. Animals receiving CCl4 + DMOG had a modest rise in Hif-1 without changes in renal function. There were no changes in urine sediment. Liver histology confirmed cirrhosis and renal histology revealed intact renal tubules and glomeruli.

	Vehicle	LPS	CCl4 +LPS	CCl4+ DMOG	CCl4/LPS/ DMOG
Urine volume (ml)	1.32±0.06	1.7±0.7	0.85±0.38	1.37±0.73	1.36±0.4
SCr (mg/dL)	0.25±0.04	0.54±0.1	0.97±0.35	0.41±0.03	0.33±0.02
UNa (mmol/hr)	118.4±21.6	136.9±26.3	45.7±12	119.8 ±19.8	86.2±20.1
HIF1α	100	96	71	114	90

Conclusions: A mouse model of CCL4 treatment followed by LPS produces functional renal failure and mimics type 1 HRS. In this model, onset of renal failure is associated with decreased Hif-1 expression; enhanced Hif-1 expression prevents development of renal failure. These data suggest Hif-1 as a novel therapeutic target for type 1 HRS.

FR-PO041

Antiapoptotic Effect of Paricalcitol in Gentamicin-Induced Kidney Injury Sang Heon Suh,[1] Koeun Lee,[1,2] Chang Seong Kim,[1] Joon Seok Choi,[1] Eun Hui Bae,[1] Soo Wan Kim.[1] *[1]Internal Medicine, Chonnam National University Hospital, Gwangju, Korea; [2]Physiology, Chonnam National University Medical School, Gwangju, Korea.*

Background: Beneficial effects of paricalcitol in gentamicin (GM)-induced kidney injury were previously reported. It is, however, not yet clear whether paricalcitol attenuates the apoptosis, which mainly contributes to the development GM nephropathy. We investigated the effect of paricalcitol on apoptotic pathways in rat kidneys damaged by GM.

Methods: Rats were randomly divided into three groups: 1) Control group (n=5), where only vehicle was delivered, 2) GM group (n=5), where rats were treated with GM (100 mg/kg/day) intramuscularly for 14 days, 3) PARI group (n=5), where rats were co-treated with paricalcitol (0.3 μg/kg/day) and GM for 14 days.

Results: Paricalcitol attenuated renal dysfunction by GM administration in biochemical profiles. In TUNEL staining, increased apoptosis was observed in GM group, which was reversed by paricalcitol co-treatment. Immunoblotting using protein samples from rat cortex/outer stripe of outer medulla showed increased Bax/Bcl-2 ratio and cleaved form of caspase-3 in GM group, both of which were reversed by paricalcitol. The phospholyation of phosphatidylinositol 3-kinase (PI3K) and Akt (protein kinase B) was enhanced in PARI group compared with GM group. The phosphorylated JNK (Jun-N-terminal kinase) expression was increase in GM, which was inhibited by paricalcitol.

Conclusions: Conclusively, paricalcitol protects GM-induced renal injury by antiapoptotic mechanisms, including inhibition of intrinsic apoptosis pathway and JNK, and activation of PI3K/Akt pathway.

FR-PO042

Hepatic Sulfotransferase Inhibitors Prevent Progression of Ischemia/ Reperfusion-Induced Acute Kidney Injury in Rats by Suppressing Indoxyl Sulfate Accumulation Misato Yoshimura,[1] Masataka Sagata,[1] Megumi Komori,[1] Chika Saigo,[1] Yuko Yamamoto,[1] Yui Nomura,[1] Go Yoneda,[1] Kazuhiko Nishi,[3] Hirofumi Jono,[2] Hideyuki Saito.[2] *[1]Department of Clinical Pharmaceutical Sciences, Kumamoto University School of Pharmacy, Kumamoto, Japan; [2]Department of Pharmacy, Kumamoto University Hospital, Kumamoto, Japan; [3]Department of Hemodialysis and Apheresis, Kumamoto University Hospital, Kumamoto, Japan.*

Background: Ischemia/reperfusion (IR)-induced AKI is evoked by diverse pathophysiological and/or surgical situations in association independently with increased morbidity and mortality. Despite early detection of AKI followed by prompt treatments are required, adequate therapeutic management has not yet been established. In this study, we evaluated renal preventive effects of AST-120, oral spherical adsorptive carbon (Kremezin), and phytochemical sulfotransferase (SULT) inhibitors, which hamper hepatic IS generation in IR-AKI model rats.

Methods: AKI was evoked by clamping isolated arteries of right and left kidneys for 30 min, followed by reperfusion of the kidneys. AST-120 or SULT inhibitors was orally administered to rats at -24, -1 h before and 24 h after IR.

Results: IR of the kidney caused renal injury with the increases in Scr (12-fold vs sham-operated rats) and BUN (13-fold), in association with the significant accumulation of serum IS (23-fold), and urinary excretion of Kim-1. Oral administration of AST-120 to IR rats resulted in the restoration of Scr and BUN levels with the suppression of serum IS and urine Kim-1 levels. Administration of quercetin and resveratrol, potent SULT inhibitors, appeared to lower serum IS level, accompanied with a significant amelioration of renal injury. The expression of Nuclear factor (erythroid-derived 2)-like 2 (Nrf2), an antioxidant protein inducer, in the renal nuclear fractions was markedly elevated 48 h after IR, but was suppressed by the treatment with AST-120 or SULT inhibitors.

Conclusions: These results suggested that the IS accumulation contributed to renal generation of oxidative stress and the following progression of kidney injury, and suppression of hepatic IS generation could be a novel strategic approach for AKI treatment.

A Triphasic Model of Kidney Injury Induced by Adenine in the Rat Amnon Gil,[1] Vera Brod,[2] Victor Frajewicki.[1] *[1]Department of Nephrology and Hypertension, Carmel Medical Center, Haifa, Israel; [2]Ischemia-Shock Research Laboratory, Carmel Medical Center, Haifa, Israel.*

Background: Adenine is a nephrotoxic agent which induces tubule- interstitial injury. Aim: investigate the dynamic characteristics of the injury caused by adenine to the kidneys of rats.

Methods: The study group (Group A) was composed of 6 rats, which were fed by an adenine enriched diet for 4 weeks and switched to regular chow for an additional period of 4 weeks. In the control group (Group B) were included 6 rats, which were on a normal diet during the 8 weeks. Blood samples for chemistry analysis, were drawn from each rat, at the beginning of the study, and after 1, 3, 4, 5, 6, 7, 8 weeks. Urea and creatinine values of the study group were compared in each interval to baseline and control group.

Results: Urea and creatinine in the study group were significantly higher than in the control group at each time interval, except for the baseline values, which were similar. These parameters in the study group were also significantly higher at each interval, compared to the baseline values. Blood urea level increased gradually from a baseline level of 37±6mg%

to a maximal value of 249±77mg% after 4 weeks of adenine diet, compared to 35±7mg% and 40±3mg% simultaneously in the control group. After switching from adenine to normal diet, urea gradually decreased to a new plateau, higher than the baseline (134±60mg%) after 8 weeks, while in the control group it was 42±5mg%. Creatinine values followed the same pattern: 0.3±0.07mg% at the start of the experiment, 1.87±0.7mg% after 4 weeks of adenine diet and 1±0.33mg% after 8 weeks. The values were significantly different from that of the control group.

Conclusions: Adenine induced kidney injury in the rat may be used as a triphasic model for acute injury- while on adenine diet, partial recovery of kidney function- after switching to normal diet and chronic kidney disease- after stabilization of renal function. The simplicity and avoidance of traumatic insult of this model may be an advantage over the traditional surgical/ traumatic models of kidney damage.

FR-PO044

Comparison of Serum Cystatin C, Serum Creatinine and Blood Urea Nitrogen as Predictors of Mortality after Sepsis-Induced Acute Kidney Injury in Mice Ana Carolina Souza,[1] Asada Leelahavanichkul,[1,2] Richard Chen,[1] Robert A. Star,[1] Peter S.T. Yuen.[1] *[1]NIDDK, NIH, Bethesda, MD; [2]Department of Microbiology, Chulalongkorn University, Thailand.*

Background: Mortality from sepsis is increased when complicated by acute kidney injury (AKI), and early detection of AKI is crucial in septic patients. Serum creatinine (Scr) has several limitations that delay recognition of AKI. We have found that after cecal ligation and puncture (CLP)-induced sepsis, serum cystatin C (SCysC) peaks more rapidly, and is better correlated with FITC-inulin, than Scr or blood urea nitrogen (BUN). The aim of this study was to compare the performance of SCysC, Scr and BUN on predicting mortality after CLP-induced sepsis.

Methods: 12-16 week old male CD-1 mice (35-50g) were used (N=35). Six hours after CLP, 50 µl of blood was collected via retro-orbital sinus and SCysC (ELISA), Scr (HPLC) and BUN were measured. Mice received fluids and buprenorphine immediately after CLP and were given fluids, antibiotic, and buprenorphine at 6 h after surgery and every 12 hours until death. Morbidly ill mice were euthanized per protocol.

Results: The higher values of all biomarkers (above the 50th percentile) were associated with decreased survival (median values: SCys C 1.19 µg/ml, SCr 0.24 mg/dl and BUN 54.6 mg/dl). After simple regression analysis, both SCysC and Scr but not BUN correlated with time to death ($p < 0.001$, R^2 0.352 and 0.339, respectively). Adding mouse body weight into a multiple regression analysis only slightly improved the results ($p < 0.001$, R^2 0.401 and 0.419, respectively). Receiver Operating Characteristics analysis was performed between high (top 50th percentile) vs. low (bottom 50th percentile) values for each biomarker as predictors of time of death. The Area Under the Curve was calculated for each biomarker at different times after sepsis induction, but SCysC and Scr were not statistically different.

Conclusions: SCysC did not outperform Scr on predicting mortality after CLP-induced sepsis. BUN did not predict mortality. Both correlations of SCysC or Scr with time to death have $R^2 < 0.7$, probably because dysfunction of non-renal organs also contribute to mortality from sepsis.

FR-PO045

Dexamethasone Attenuates Renal Ischemia Reperfusion Injury through Inhibiting HMGB1 Secretion Junhua Li, Jiong Zhang, Lili Liu, Gang Xu. *Tongji Hospital.*

Background: Our previous research showed that blockage of HMGB1, an inflammatory mediator released in renal ischemia reperfusion injury (IRI), could protect kidney from IRI. In this study, we demonstrated HMGB1 in renal IRI might be regulated by dexamethasone (DM).

Methods: Renal IRI was induced by clamping the left pedicle for 60 minutes in uninephrectomized C57BL/6 mice. DM (4mg/kg) was administrated intravenously 1 hour before renal ischemia. Mice treated with saline or without clamping pedicle were used as controls. 24 hours after reperfusion, sera and renal tissues were collected for renal function and pathologic analysis. Expression of HMGB1, p-p38, p-ERK, HIF and VEGF-C in kidney was detected by Western blot. Furthermore, expression of HMGB1 was analyzed by immunohistochemistry.

Results: Compared with control subjects, levels of BUN and serum creatinine in mice treated with DM were significantly decreased Pathological examination demonstrated that tissue damage caused by IRI was markedly reduced by DM treatment. Through immunohistochemistry and western blot, the expression of HMGB1 was higher in DM treated renal cells which may be maintained intra-cellular compared with IRI kidney cells. It demonstrated that some of HMGB1 might be released from renal cells in blood circulation through IRI. In comparison to control group, western blot showed a significant up-regulation p-p38, p-ERK, HIF and VEGF-C in DM treated mice. DM intervention significantly attenuated mice lethal kidney ischemia injury in survival experiment.

Conclusions: These data suggest that DM could inhibit HMGB1 secretion, which could reduce inflammatory effect of HMGB1. Reduced secretion of HMGB1 could induce rapid phosphorylation of ERK and p38, increase HIF and VEGF-C expression, therefore inhibit apoptosis and infiltration of inflammatory cells, finally DM attenuates kidney ischemia reperfusion injury.

FR-PO046

CD44-Deficiency Delays LPS-Induced Acute Renal Injury Elena Rampanelli, Nike Claessen, Gwendoline J.D. Teske, Jaklien Leemans, Sandrine Florquin. *Dept. Pathology, AMC, Amsterdam, Netherlands.*

Background: Sepsis is a severe and dysregulated inflammatory response to infection. Acute kidney injury (AKI) is a frequent complication of sepsis as it occurs in 20-50% of septic patients. CD44 is a cell-surface transmembrane receptor expressed by many cell types including inflammatory, epithelial and endothelial cells. CD44 plays a role in proinflammatory cytokines production, TLR signalling regulation, leukocytes migration and adhesion.

Methods: To study the role of CD44 in sepsis-induced AKI, Wt and CD44 KO mice (n=8/group), received an intraperitoneal injection of 10 µg/g body weight of LPS. Two, 4, and 24 hours after injection, mice were sacrificed; kidneys and blood were collected for analysis.

Results: At 2 and 4 hours after LPS injection, the plasma and renal levels of the pro-inflammatory cytokines MCP-1, TNF-α, IL-1β were lower in CD44 KO mice in respect to the Wt, and the opposite was found for the anti-inflammatory cytokines IL-10 and HGF. Furthermore, TLR4 gene expression in the CD44 KO kidneys was induced later and to a lesser extent than in the Wt; while the mRNA expression of the protective HO-1 (heme oxygenase-1) was higher in the CD44 KO kidneys than in the Wt. This could explain the cytokines pattern of the CD44 KO mice, as TLR4 signaling leads to secretion of pro-inflammatory molecules and HO-1 controls the balance pro-/anti-inflammatory cytokines. This was associated with preserved renal function in CD44KO compared to Wt at 2 and 4 hours after LPS, decreased T cells influx and apoptosis rate of tubular and interstitial cells in the CD44 KO kidneys.

Conclusions: In conclusion, these data suggest that the lack of CD44 protects against sepsis-induced AKI by impairing the leukocytes influx in the kidney parenchyma, the pro-inflammatory cytokines secretion via HO-1 induction and delayed TLR4 expression and therefore maintaining a better renal function.

FR-PO047

Rats with an Inactivating Mutation of CD26 (Dipeptidyl Peptidase 4) Have Lower Serum SDF-1α/CXCL12 Levels and Increased Susceptibility to Acute Kidney Injury Jon D. Ahlstrom,[1] Anna Gooch,[1] Elizabeth Phillips,[1] Erin Birch,[1] Christof Westenfelder.[1,2] *[1]Medicine, University of Utah and VA Medical Centers, Salt Lake City, UT; [2]Physiology, University of Utah, Salt Lake City, UT.*

Background: We demonstrated that the chemokine SDF-1α/CXCL12 (SDF-1) and its receptor CXCR4 are dramatically upregulated in mouse kidneys post IRI AKI (Kidney Int 2005), and that this response mediates the recruitment to the kidney of CXCR4-expressing cells, such as infused Mesenchymal Stem Cells (MSC), which are renoprotective (Am J Physiol Renal 2005). F344/CD26mut rats (F344/DuCRlCrlj, Charles River Japan) have an inactivating mutation of the CD26/Dipeptidyl Peptidase 4 gene (DPP4), which leads to the loss of DPP4 activity on the surface of most cells. DPP4 inhibits SDF-1 activity by removal of the two N-terminal amino acids.

Methods: We tested in F344/CD26mut the hypothesis that reduced inactivation of SDF-1 in the kidney should result in improved outcome post-AKI (activation of its receptors, increased recruitment of MSCs).

Results: However, contrary to our hypothesis, we discovered that F344/CD26mut rats have significantly lower plasma SDF-1 levels than sex and age-matched wt F344 rats with normal CD26 function (F344/DuCrl, Charles River). Furthermore, bilateral renal pedicle clamping x 38-40 min resulted at 24 hrs in drastically higher animal mortality in F344/CD26mut rats (0% survival), while an identical IRI insult in age and sex matched wt F344 rats was well tolerated (100% survival). It has previously been shown that decreasing renal SDF-1 expression in mice increases renal damage following AKI (Nephrol Dial Transplant 2010 25:3852).

Conclusions: We conclude that F344/CD26mut rats have increased sensitivity to IRI AKI due to reduced serum levels of SDF-1. Although unknown, these findings may have implications for type 2 diabetic patients taking CD26/DPP4 inhibitors such as sitagliptin, which, if it were to similarly lower serum SDF-1 levels, it could potentially increase these patients' risk for AKI. Furthermore, the F344/CD26mut model will be useful to elucidate the role that CD26 may have in the physiological regulation of circulating SDF-1 levels.

FR-PO048

MCP-1, a Target of Meprin A during Acute Kidney Injury? Christian Herzog, Sudhir V. Shah, Gur P. Kaushal. *Medicine, UAMS, Little Rock, AR.*

Background: Meprin A, an astacin like protease, is highly enriched in the brush border membrane (BBM) of kidney proximal tubular cells. As a heterotetramer of α and β subunits it is bound by its β subunit to the BBM. During acute kidney injury (AKI) meprin A is redistributed within the proximal tubular environment and may become damaging to the kidney. Meprin A has been shown to activate proinflammatory cytokines proIL-1β and proIL-18. In this study we examined its effect on osteopontin (OPN) and the chemokine MCP-1, both of which accumulate during tubular interstitial injury.

Methods: Meprin A was purified from rat kidney by differential centrifugation, DEAE chromatography and dialysis. The recombinant promeprins α and β were overexpressed in HEK-cells and purified by affinity chromatography and characterized by Western blot and enzymatic activity with fluorogenic substrate OCK^{+}. OPN and MCP-1 were digested with

meprin A and the activated promeprins α and β. Digestions were visualized by Western blot and cleavage sites of MCP-1 determined by peptide sequencing. Urinary excretion of MCP-1 was monitored by ELISA following cisplatin-induced AKI. Double immunofluorescence staining was used to monitor redistribution of meprin A in kidneys of mice after ischemia/reperfusion injury (IR) or cisplatin treatment (CP).

Results: Mice subjected to CP or IR injury showed altered localisation of meprin A from the BBM towards the cytosol and the basolateral membrane. Meprin α, β and A cleaved MCP-1 to products of different molecular sizes. MCP-1 was cleaved by meprin α and meprin A to a product of 10 kDA (N-terminally of ^{7}Ala and C-terminally most likely after ^{73}Arg) whereas meprin β cleaved only C-terminally after ^{74}Ser as determined by LC/MS/MS. OPN was degraded rapidly by meprin β, albeit slower by meprin α and A.

Conclusions: Meprin α, β and A cleave MCP-1 into defined peptide fragments with yet unknown biological function whereas OPN is degraded completely. The altered localisation of meprin A following AKI and its capability to process proinflammatory cytokines and chemokines indicate a regulatory function of meprin A during inflammation. Meprin A therefore presents a valuable target for pharmaceutical intervention.

FR-PO049

NGAL Lacks Specificity for Detection of Renal Damage in Ischemia-Induced Acute Kidney Injury Anja H. Bienholz,[1] Philipp Ickerott,[1] Oliver Witzke,[1] Herbert De Groot,[2] Frank Petrat,[2] Andreas Kribben,[1] Thorsten Feldkamp.[1] *[1]Department of Nephrology, University Duisburg-Essen, Essen, Germany; [2]Institute of Physiological Chemistry, University Duisburg-Essen, Essen, Germany.*

Background: Early and specific biomarkers for the detection of acute kidney injury (AKI) are urgently needed to enable the development and early application of therapeutic interventions and improve patient outcome. Therefore, the time course of the appearance and the specificity for renal damage of Neutrophil gelatinase-associated lipocalin (NGAL) and Kidney injury molecule-1 (KIM-1) were evaluated in a rat model of ischemic AKI.

Methods: Ischemia (I) was induced in male Sprague Dawley rats by clamping both renal pedicles for 40 min, followed by reperfusion (R). Plasma creatinine, the appearance and mRNA expression of NGAL and KIM-1 in rat kidneys were measured after 45 min and 4 h of reperfusion by immunhistochemistry (IHC) and quantitative real-time PCR.

Results: Plasma creatinine was significantly increased after 45 min and 4 h of R. After 45 min of R NGAL was already detectable by IHC in the kidneys compared to sham controls and persisted at 4 h. KIM-1 was not detectable by IHC after 45 min of R, but was also clearly detectable after 4 h of R. Surprisingly, I did not significantly induce renal mRNA expression for NGAL either after 45 min or 4 h of R. Inline with IHC, renal mRNA expression was significantly increased for KIM-1 after 4 h of R (*p = 0.028; n = 4). In contrast to the strong staining effects, mRNA expression was only 4-fold increased (n. s. vs. control) for NGAL while the increase was 27-fold for KIM-1 compared to controls after 4 h of R.

Conclusions: The time course and intensity of IHC staining for NGAL was not paralleled by renal mRNA expression. Therefore, most NGAL detected in the kidney is probably not of renal origin. These data show that NGAL is no specific biomarker for renal damage in ischemia-induced AKI.

Inflammation Is Present 7 Days after Ischemic Acute Kidney Injury in Mice Ana Andres-hernando,[1] Chris Altmann,[1] Rhea Bhargava,[1] Zhibin He,[1] Sarah Faubel.[1] *[1]University of Colorado Denver; [2]Clinical Hospital Dubrava.*

Background: Increased mortality occurs in patients with AKI that may be due to systemic complications. AKI is associated with lung, liver, brain, and gut injury that occur within 48 hours in animal models. To date, systemic complications of AKI have not been examined beyond 48 hours after AKI. Given the association between AKI and systemic complications in patients, we hypothesized that lung injury and other systemic complications would be present 1 week after AKI in mice.

Methods: Surgery for sham operation or ischemic AKI (22 minutes of renal pedicle clamping) was performed and lung inflammation (lung MPO activity [a marker of neutrophils] and lung neutrophils by flow cytometry), lung CXCL1 (a neutrophil chemokine), kidney injury (serum creatinine and BUN), serum proinflammatory cytokines, serum AST and serum glutamate, were determined at day 7. Weight was determined daily. Urine NGAL was measured on days 1, 4, and 7.

Results: Urine NGAL was significantly higher in AKI at days 1, 4 and 7 compared to sham. Serum creatinine (mg/dL) was 0.34±0.02 in sham and 0.43±0.1 (P=NS), BUN (mg/dL) was 22.5±0.8 in sham and 79.7±20 in AKI (P=0.02). Serum pro-inflammatory cytokines IL-6 and CXCL1 were significantly higher in AKI versus sham. Lung MPO activity was 0.69±0.16 in sham and 1.36±0.2 in AKI (P<0.02). Lung neutrophil by flow cytometry was (% of CD45+ cells) 12.9±3.2 in sham and 36.6±5.1 in AKI (P<0.02). Lung CXCL1 (pg/mg of protein) was 53±14 in sham and 167±44 in AKI (P<0.04). All mice lost weight 24 hours post procedure, but sham operated mice returned to their baseline weight by day 7; mice with AKI were 11% below baseline body weight by day 7. Serum AST (a marker of liver injury) was (mU/mL) 46±3 in sham and 62±4 in AKI (P<0.05).Serum glutamate, a marker of muscle wasting, was higher in AKI mice 35±5mM versus sham 20±3mM (P<0.02).

Conclusions: In summary, these data demonstrate that lung injury and other systemic complications are present up to 1 week post-AKI. These data lend further support to the notion that AKI is a multisystem disease. Interventions that target these later systemic complications of AKI may be the key to reducing mortality in patients with AKI.

FR-PO051

Clinical Significance of Plasma Cell-Free DNA in Hemodialysis Patients Ju-Young Moon, Eun Young Kim, Wha-young Suk, Joo Hee Cho, Hong Joo Lee, Jungkook Wi, Young Wook Choi, Kyung-hwan Jeong, Tae-won Lee, Chun-Gyoo Ihm, Sang-Ho Lee. *Department of Internal Medicine, Division of Nephrology, Kyung Hee University, Seoul, Korea.*

Background: Plasma levels of cell-free DNA (cfDNA) are elevated in various proinflammatory or apoptotic conditions. Previously, increased cfDNA were reported during hemodialysis. However, there is limited data regarding its clinical relevance in HD patients. The aim of this study was to investigate the clinical significance of cfDNA in patients on maintenance HD.

Methods: We measured the pre-dialysis plasma levels of cfDNA and evaluate its clinical significance in 95 HD patients. cfDNA levels were determined using real-time EIF2C1 gene sequence amplification and analyzed the association with clinical parameters and hsCRP before 6, 3, 0 and after 3 months of cfDNA measurement.

Results: Plasma level of cfDNA was significantly elevated in HD patients compared to 15 healthy controls (3884 ± 407 vs. 1420 ± 121 GE/mL, respectively, $p < 0.05$). In HD patients, cfDNA levels were significantly higher in patients with diabetes compared to non-diabetic patients (4612 ± 640 vs. 2858 ± 358 GE/mL, respectively, $p < 0.01$). Intriguingly, cfDNA was significantly correlated with current HbA1c ($r = 0.38$, $p < 0.01$), but not with those of other time points. Patients with history of cerebrovascular or cardiovascular disease had also higher cfDNA. Among clinical parameters, systolic blood pressure was correlated with the levels of cfDNA. Current WBC counts was significantly associated with higher level of cfDNA, but there was no association between cfDNA and inflammatory parameters of different time points. Interestingly, the concentration of cfDNA was negatively correlated with the dose of erythropoietin stimulating agent. Other parameters of dialysis adequacy including KT/V, nPCR and iPTH, were not associated with the plasma levels of cfDNA.

Conclusions: Our results indicate cfDNA could be a potential biomarker of proinflammatory or apoptotic milieu in maintenance HD patients. However, the underlying reasons for the release of cfDNA and its functional role in uremic condition should be further defined for its clinical application.

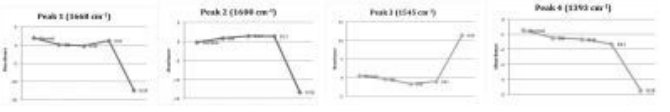
FR-PO052

Detection of Urine Renal Biomarkers Using Fourier Transform Infrared Spectroscopy Mei-Ching Yu,[1] Peter R. Rich,[2] Amandine Marechal,[2] Robert J. Unwin,[3] Frederick W.K. Tam.[1] *[1]Kidney and Transplant Institute, Imperial College London; [2]Structural and Molecular Biology, University College London; [3]Centre of Nephrology, University College London, United Kingdom.*

Background: More reliable biomarkers are desirable to improve early detection of asymptomatic patients with renal injury. Infrared (IR) spectroscopy has been widely used in biomedical research but its application in renal disease remains limited. Particularly useful is the 1800-900 cm^{-1} mid-IR. Most molecules have characteristic absorption bands in this range that can be used as molecular fingerprint. An advantage of this technique is spectra of potential markers may be obtained quickly and without subjecting biological materials to chemical manipulations.In this work,FTIR spectroscopy has been employed to analyse urine collected from a rodent model of GN with the aim of identifying potential renal biomarkers.

Methods: Nephrotoxic nephritis was induced in Wistar Kyoto rats. Urine samples from nephritic rats on day8 (n=7), day14 (n=5), day21 (n=7) and day28 (n=7) were compared with normal rats (n=20).Urine was analysed by FTIR. All original spectra were recorded in between 4000 to 900 cm^{-1} and analysed with Bruker OPUS 6.5 software. For detailed analyses, the second derivatives of absorption spectra were generated and components of interest were quantitated by integration analysis. The peak intensities of interest were normalized to the intensity of the 1450 cm^{-1} peak of urea.

Results: Bands at 1668,1660,1545 and 1393 cm^{-1} normalized with the urea peak, all appeared to change in concert with renal progression.



Conclusions: Several urinary biomarkers relevant to progression of experimental GN have been identified by FTIR spectra. Future work includes identification of the biochemical species responsible and extension of analyses to FTIR microscopy of renal tissues to identify the cellular origins of these biomarkers.

Patterns of Gene and Metabolite Define the Effects of Extracellular Osmolality on Kidney Collecting Duct Hyo-jung Choi, Tae-Hwan Kwon. *Department of Biochemistry and Cell Biology, School of Medicine, Kyungpook National University, Daegu, Korea.*

Background: A variety of different extracellular microenvironments are formed in the tubular lumen and interstitium, to which renal tubular epithelial cells and interstitial cells are directly exposed. We hypothesized that altered extracellular osmolality *per se* could change a broad spectrum of cellular processes by affecting transcriptomic and metabolomic

profiles in IMCD cells, and hence it could produce the changes in renal tubular function, particularly in water and sodium reabsorption.

Methods: This was directly investigated by exploiting an integrated omics analysis of the primary cultured IMCD cells of rat kidney. We generated the metabolomic profiles through ^{1}H-NMR-based metabolomic analysis and identified the differentially expressed metabolites (DEMs) by the changes of extracellular osmolality. Gene expression profiles were generated via transcriptomic analysis and identified differentially expressed genes (DEGs) by the changes of extracellular osmolality. Cellular processes affected by the changes of extracellular osmolality were then identified through functional enrichment analysis of the DEGs. Quantitative real-time RT-PCR analysis and immunoblotting analysis were performed to confirm the changes of mRNA expression of genes and their protein abundance in the IMCD cells.

Results: Integrated analysis revealed that decreased extracellular osmolality was associated with decreased levels of organic osmolytes, glucose, intermediates of citric acid cycle, and branched-chain amino acids in the IMCD cells, along with significantly decreased gene expression and protein abundance of P-type transporters (ATP1B1), ABC transporters (ABCC5 and ABCG1) and insulin signaling pathways (IRS2). Quantitative real-time RT-PCR and semi-quantitative immunoblotting confirmed the changes of transcript levels of differentially expressed genes and protein levels.

Conclusions: Taken together, integrated analysis of omics data demonstrated that changes of extracellular osmolality per se could contribute to altered water and sodium reabsorption in the kidney collecting duct cells by affecting transcriptome and metabolome.

FR-PO054

Ontology for Fluid and Solute Transport Processes in Peritoneal Dialysis (PD)

Bengt Lindholm,[2] Teresa Podsiadly-Marczykowska,[1] Joanna Stachowska-Pietka,[1] Magda Galach,[1] Malgorzata Debowska,[1,2] Jacek Waniewski.[1,2] *[1]Institute of Biocybernetics and Biomedical Engineering, Warsaw, Poland; [2]Baxter Novum and Renal Medicine, Karolinska Institutet, Stockholm, Sweden.*

Background: Computational models, formulated as a set of mathematical equations, are used for studying the dynamic behavior of physiological processes. The standard formats of their representation, as Systems Biology Markup Language, allow for expressing the mathematical structure of models, but they lack the means for describing the model semantics (meaning) that still requires human interpretation. However, semantic information on physiological models can be addressed using ontology, defined as the formal, explicit specification of a domain of the knowledge. Our objective was to formulate the Fluid and Solute Transport Processes in PD Ontology (FSTPPD-O) that can be read and processed by computers and contains a reusable standard for the description of models of peritoneal transport.

Methods: The ontology was built using the Methontology methodology and was formalized in OWL-DL sublanguage using Protégé-2000 ontology editor.

Results: FSTPPD-O has normalized, modular structure and includes 210 classes and 88 properties. It contains standardized, formal, semantic knowledge underlying mathematical models of fluid and solute transport that are used in clinical and experimental PD research such as: thermodynamic model, three-pore model for the capillary wall, three pore model for peritoneal dialysis and two layer model. The knowledge associated with the models is divided into two components: semantic and procedural. The semantic component describes the transport phenomena, transport barriers, model parameters and their interpretation and relationships, solute features, and patient population characteristics. The procedural part contains selected characteristics of model equations.

Conclusions: FTSPPD-O provides formalized semantic knowledge underlying models of fluid and solute transport in PD. Its modular structure is transparent for human interpreters and supports the model reuse and maintainability. The potential users of the ontology are researchers who create and/or apply transport models in their studies.

Long-Term Maintenance of Bioartificial Renal Epithelial Cell System (BRECS) in a Hemodialysis (HD) Circuit

Angela J. Westover,[1] D. Buffington,[1] Junfeng Liu,[2,3] K. Johnston,[1] C. Pino,[1] David Humes.[1,4,5] *[1]Innovative BioTherapies, Inc.; [2]Huashan Hospital; [3]Fudan University; [4]CytoPherx, Inc.; [5]University of Michigan.*

Background: Clinical experience has demonstrated that renal cell therapy incorporated into conventional CRRT circuit has provided therapeutic efficacy in acute renal failure (ARF). Treatment has been limited to 72 hours. However, hospitalization due to these acute events lasts approximately 2 weeks with ICU stays closer to 1 week. Methods to ensure patency and continued sterility of the HD circuit through cartridge exchanges, as well as the retention of cell viability within the BRECS was determined over the projected 7 day time course for clinical therapy.

Methods: Hemofiltration was established in 4 sheep with incorporation of the BRECS into an immune-isolated ultrafiltrate loop, allowing for maintenance of cell viability and communication between BRECS and host. The experiment was designed to represent the potential manipulations projected for clinical handling, during which the circuit must be interrupted daily to allow for hemofilter replacement and for clinical procedures not compatible with HD. Sheep underwent HD daily for 7 days, with the BRECS maintained in a secondary perfusion loop during and between HD sessions. Animal general health and hemodynamic stability was monitored. To investigate infection risk, blood cultures were taken. BRECS viability was monitored daily by O_2 consumption and glutathione (GSH) metabolism, followed by post-study verification via a fluorescein diacetate based viable dye. Preservation of differentiated phenotype of human renal epithelial cells was confirmed using immunohistochemistry.

Results: The BRECS maintained O_2 consumption and GSH metabolism remained stable through the seven day time-course without compromising the animal health. The immunoisolating filter design of the circuit was demonstrated to protect from bacterial transmission to the animal.

Conclusions: BRECS maintained viability and functionality in extracorporeal UF circuit for over 7 days, demonstrating feasibility and safety of clinical application in patients with ARF.

Development of a Neo-Kidney Augment Product Intended to Prevent or Delay the Need for Dialysis or Transplantation in CKD Patients

Deepak Jain, Richard Payne, Craig Halberstadt, Toyin Knight, Neil Robbins, Elias Rivera, Rusty Kelley, John W. Ludlow, Kelly I. Guthrie, Tim Bertram. *Tengion Inc., Winston-Salem, NC.*

Background: Chronic Kidney Disease (CKD) affects over 26 million in the US alone. Disease progression typically leads to dialysis and eventually a kidney transplant. Current standard of care is to treat the underlying conditions of CKD to slow down progression of disease. Tengion is developing regenerative medicine solutions to CKD with a Neo-Kidney Augment (NKA) product intended to catalyze kidney tissue regeneration to prevent or delay the need for dialysis or transplantation in this growing patient population.

Methods: NKA is composed of autologous, homologous Selected Renal Cells (SRC) that are primarily of tubular epithelial phenotype, and a gelatin-based hydrogel. Renal cells are obtained from a biopsy of the patient's kidney, isolated using enzyme digestion and expanded in culture. SRC are obtained by density gradient separation of harvested cells after a brief exposure to hypoxia. Cells are characterized with multiple markers to ensure tubular phenotype. SRC are formulated with the hydrogel to produce NKA. Biomaterial addition to SRC provides cell stability, enhanced shelf life and targeted delivery. Cell viability and function in NKA product was evaluated by testing for ability to metabolize Presto Blue, uptake albumin and presence of LAP and GGT enzyme activity.

Results: *In vivo* response to NKA implantation was evaluated by direct injection into the kidney cortex in animal models of CKD. NKA treatment was well tolerated with no morphological alterations observed in the tubular or glomerular compartments and histology confirmed reduction of kidney disease. NKA is packaged for implantation in the clinic via a product delivery device. The delivery system utilizes a syringe and needle compatible for NKA delivery. The system is designed to enable distribution of the product at multiple sites in the patient's kidney via a laparoscopic procedure.

Conclusions: Taken together, these data suggest that NKA implantation into the kidney has the potential to catalyze regeneration of kidney tissue and provide a much needed treatment of CKD.

Evaluation of Bioartificial Renal Tubule Device Prepared with Human Renal Proximal Tubular Epithelial Cells Cultured in Serum-Free Medium

Hiroo Takahashi, Kaichiro Sawada, Takatoshi Kakuta, Masafumi Fukagawa, Akira Saito. *Department of Nephrology, Tokai University School of Medeicine, Isehara, Japan.*

Background: Acute kidney injury (AKI), accompanied by the development of systemic inflammatory response syndrome and multiorgan dysfunction syndrome, is associated with a high risk of death. Bioartificial renal tubule device (BTD) is a cell therapy that improves the conditions common to artificial kidney recipients treated for kidney diseases. We previously reported significant improvements of conditions of AKI animals by treatment with BTD which was produced with lifespan-extended human renal proximal tubular cells (RPTEC). However, when the BTD is used for human patients, the major obstacle is the safety of BTD, because the RPTEC have been cultured in medium containing fetal calf serum.

Methods: In this study, we evaluated BTD produced with lifespan-extended human RPTEC cultured in available serum-free medium (RELAR, Nipro, Osaka), comparing to BTD peoduced with same cells cultured in serum-containing medium (REGM, LONZA, Basel).

Results: Lifespan-extended human RPTEC cultured in serum-free medium can proliferate as in serum-containing medium. Comparison of leakage and reabsorption of small molecules in BTD produced with RPTEC cultured in serum-free medium to those in BTD produced with RPTEC cultured in serum-containing medium showed almost equal abilities of transportation in these two types of BTDs. When AKI goats were treated with these BTDs individually for 24hrs, almost same extents of extension of lifespan and suppression of cytokine expression in blood cells were observed with comparison to sham-BTD.

Conclusions: All these data indicated that lifespan-extended human RPTEC cultured in serum-free medium is functionally equal to that cultured in serum-containing medium, and that the safety of BTD for human patients could be elevated without loss of functional ability by being produced with RPTEC cultured in serum-free medium.

FR-PO058

Contribution of Structural Domains to Ribonuclease 7's Gram-Positive and Gram-Negative Activity against Uropathogens David S. Hains,[1,2] Huanyu Wang,[2] John David Spencer,[1,2] Andrew L. Schwaderer.[1,2] *[1]Department of Pediatrics/Division of Nephrology, Nationwide Children's Hospital, Columbus, OH; [2]Center for Clinical and Translational Research, The Research Institute at Nationwide Children's Hospital, Columbus, OH.*

Background: Ribonuclease 7 (RNase 7) is a 14.5 kDa peptide that possesses potent antimicrobial properties against Gram-negative and Gram-positive bacteria and is expressed in a variety of epithelial tissues. Little is known about its mechanisms of action and the determinants of its antimicrobial properties. The objective of this study is to identify the intrinsic functional domains of RNase 7 that influence its activity against uropathogenic Gram-negative and Gram-positive bacteria.

Methods: In this study, a series of RNase 7 fragments were generated that contained different numbers of its secondary motifs starting from both N-terminus and C-terminus of RNase 7. We determined antimicrobial properties of each fragment against both Gram-positive and Gram-negative uropathogenic bacteria.

Results: RNase 7 fragments displayed significant differences in their antimicrobial activity profiles. Compared to N-terminal fragments, C-terminal fragments showed uniformly decreased activity against *Escherichia coli* and *Staphylococcus saprophyticus*. In addition, the fragments that lack β-sheets 1, 3 and 4 demonstrated significantly decreased activities. We have also identified one fragment with at least four-fold increased potency against both *E. coli* and *S. saprophyticus* compared to full-length peptide. We have also identified distinct regions of the peptide that are independently responsible for Gram-negative and Gram-positive activity.

Conclusions: Our results suggest that RNase 7 has antimicrobial activity against both Gram-positive and Gram-negative bacteria but with distinct mechanisms. We also have identified a peptide fragment with increased activity compared to the naturally occurring peptide. These findings serve as the foundation to design future novel antimicrobial and therapeutic agents.

FR-PO059

Peritoneal Cell Sheet Engineering Suppress Abdominal Adhesion and Inflammatory Angiogenesis in Rat Model Kunio Kawanishi,[1] Ryoichi Sakiyama,[2] Kazuho Honda,[1] Ken Tsuchiya,[1] Kosaku Nitta.[1] *[1]Department of Medicine, Kidney Center, Tokyo Women's Medical University, Shinjuku-ku, Tokyo, Japan; [2]Department of Clinical Engineering, Tokyo Women's Medical University, Shinjuku-ku, Tokyo, Japan.*

Background: Surgical enterolysis or noble plication for Encapsulating peritoneal sclerosis (EPS) improved the survival rate. However, the recurrence or re-surgery for EPS still remains a huge clinical and economical problem. Aim of this study is developing a new therapeutic method to prevent intra-abdominal adhesions by cell sheet engineering.

Methods: Primary mesothelial cells and fibroblasts were isolated from parietal peritoneum of 8-week old male Lewis rats. Mesothelial cells were seeded over the confluent fibroblast layer on temperature-responsive culture dishes at 37°C. Transplantable peritoneal cell sheets were harvested by incubation at 20°C. Eight weeks old female Lewis rats were anesthetized and the cecum were isolated and cauterized. Then peritoneal cells sheets from male were transplanted without suturing. Thirty female rats were divided into sham group (n = 10), transplantation group (n = 10), and control laparotomy group (n = 10) received open abdominal surgery without cauterization. Seven days after operations, they were sacrificed and examined by adhesion score, Y-FISH, immunohistochemistry of cytokeratin, vimentin, fibrin, CD31, podoplanin,CD68 and CD163.

Results: Peritoneal cell sheet transplantation resulted in adhesion prevention. Y-FISH analysis or immunohistochemistry revealed that transplanted male cell sheets were engrafted successfully to female in the transplantation group. Fibrin deposition, CD31 or podoplanin positive vessel increasing and CD68 or CD163 positive macrophages infiltration were significant restricted in the transplantation group than in the sham.

Conclusions: We developed peritoneal cell sheets composed of mesothelial cells and fibroblasts with temperature-responsive culture dishes. Transplantation of peritoneal cell sheets prevented abdominal adhesion, fibrin deposition, angiogenesis, lymphangiogenesis and macrophage infiltration in rat cecal cauterization adhesion model. This novel technique would be useful to prevent postoperative tissue adhesion in clinical settings.

FR-PO060

Systems Biology in Diabetic Nephropathy: Building a Useful Model from Multiple Markers and Profiles Gert J. Mayer,[1] Paul Mayer,[2] Bernd Mayer.[2] *[1]Department of Internal Medicine IV (Nephrology and Hypertension), Medical University Innsbruck, Innsbruck, Austria; [2]Emergentec Biodevelopment GmbH, Vienna, Austria.*

Background: The pathophysiology of diabetic nephropathy (DN) is driven by a complex, multi-facetted interplay of numerous molecular processes (protective as well as damaging) and the balance between these, rather than the activity of a single pathway determines the clinical presentation and outcome. The goal of this study is to derive a biomarker panel, which characterizes the different molecular processes involved.

Methods: We used a hybrid gene/protein interaction network that holds ample information on molecular features (nodes) and their relations (edges), by this providing a basic structure for navigation in molecular content and context being identified as relevant in DN.

Results: Extensive literature search on omics studies in DN provided a molecular feature lists mapping to a total of 2,175 unique protein coding genes (13 from SNPs, 12 as targets from relevant miRNAs, 1,583 from transcriptomics, 5 from proteomics, and 53 from metabolomics via linking to enzymes; 509 features are identified from multiple sources). Further data were derived from searching NCBI Pubmed (utilizing MeSH and gene-to-pubmed) for human protein coding genes associated with DN, resulting in 287 such genes. Text mining of patents and clinical trial descriptors in the context of DN adds further about 1,000 features. These data were used to label the respective nodes in the interaction network, by this obtaining a DN specific subgraph. Using a segmentation algorithm applied on this subgraph allowed identification of DN specific units, each unit characterizing a cluster of genes/proteins with a high internal functional association. We interpret each unit as a functionally relevant molecular process contributing to the presentation of DN, and the total set of such units as a molecular model of DN.

Conclusions: We propose that selecting appropriate biomarkers from each unit might allow describing a patient specific "type" of DN, ultimately leading to a better stratification of patients regarding progression risk and optimal interventional approach.

Effects of Pressure and Electrical Charge on Macromolecular Transport across Bovine Lens Basement Membrane: Implications for Glomerular Permeability Nicholas J. Ferrell,[1] Kathleen O. Cameron,[1] Joseph J. Groszek,[1] Ross A. Smith,[1] Andrew L. Zydney,[2] William Fissell.[1,3] *[1]Biomedical Engineering, Cleveland Clinic, Cleveland, OH; [2]Chemical Engineering, Pennsylvania State University, State College, PA; [3]Nephrology and Hypertension, Cleveland Clinic, Cleveland, OH.*

Background: The mechanisms by which the glomerulus retains proteins in plasma are still not fully understood despite implications for renal physiology and disease. Evaluating glomerular permselectivity *in vivo* can be challenging due to the complex nature of the capillary wall. We set out to study the effects of pressure and charge on the filtration properties of collagen IV rich extracellular matrix using the lens capsule of the bovine eye as a model experimental system.

Methods: We measured sieving of fluorescently tagged Ficoll across lens basement membrane (LBM) at pressures ranging from 1-3 psi. We used mathematical transport modeling to evaluate the relative role of diffusion, convection, and altered membrane permeability in determining the sieving properties of the membrane. The effect of electrical charge on filtration was evaluated by comparing the sieving of negatively charged and neutral Ficoll and by measuring the streaming potential generated by electrolye flow through the membrane.

Results: A decrease in the sieving coefficient was observed with increased pressure for a range of molecular radii. Based on transport modeling, the altered sieving properties could be accounted for, at least in part, by changes in Peclet number (ratio of convective to diffusive transport). No evidence was found for pressure dependent changes in the structure of the membrane (i.e. membrane compression) based on consistent Darcy permeability. A slight, but consistent increased passage of negatively charged Ficoll was observed relative to neutral Ficoll. While this is counter to the traditional model of increased retention of negatively charged solutes, it was consistent with our measured streaming potential.

Conclusions: LBM provides a convenient model to evaluate macromolecular transport across biological basement membrane and may provide additional insights into the mechanisms of glomerular permselectivity.

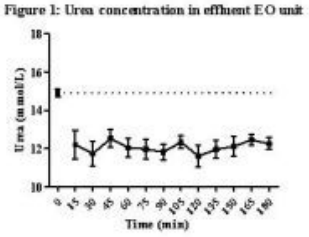
FR-PO062

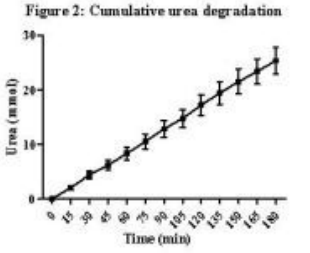
Removal of Urea via Electro-Oxidation and Elimination of Resulting Chloramines in a Prototype Wearable Artificial Kidney Device Maarten Wester,[1] Frank Simonis,[2] Jeroen Kooman,[3] Walther H. Boer,[1] Jaap A. Joles.[1] *[1]Nephrology, UMC Utrecht, Utrecht, Netherlands; [2]Nanodialysis BV, Oirschot, Netherlands; [3]MUMC, Maastricht, Netherlands.*

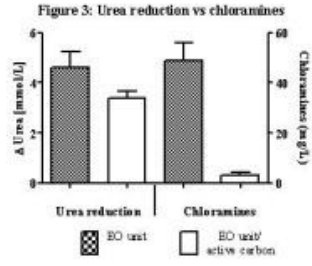
Background: In the consortia iNephron & NEPHRON+ we are developing a wearable artificial kidney device (WAKD). For detoxification we propose to combine adsorption (e.g. removal of potassium and phosphate) with electro-oxidation (EO), which degrades nitrogen-containing toxins like urea and creatinine. This offers the possibility to regenerate dialysate and thus miniaturize the WAKD. Chloramines are byproducts of EO which can cause hemolysis. We studied the feasibility of urea degradation by EO combined with chloramine removal by active carbon plus vitamin C, a potent reducing agent.

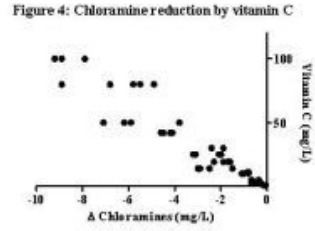
Methods: A urea solution (15mmol/l) was pumped through an EO unit (50ml/min) in a single pass and effluent urea and chloramine concentrations were measured for 3 hrs (n=3). This was repeated with active carbon incorporated in the EO unit. Finally, we evaluated whether vitamin C further reduced chloramines.

Results: EO reduced urea from 15 mmol/l to 12.1±0.8 mmol/l after a single pass for 3 hrs (Fig 1). The cumulative urea removal by the device in 3 hours was 25.4±4.2 mmol (Fig 2). Active carbon in the EO unit substantially lowered chloramines in the effluent ($p<0.05$) without compromising urea removal (Fig 3). Vitamin C dose-dependently reduced chloramines (Fig 4).









Conclusions: EO is a promising technique for prolonged urea removal allowing effective recycling of dialysate in the WAKD. Incorporation of active carbon in the EO unit combined with vitamin C infusion in the effluent can effectively reduce toxic chloramines offering the perspective of in vivo tests.

FR-PO063

The Efficiency of Microdialyzer System Using Nanoporous Polyethersulfone Membrane Yoshihiko Kanno,[1] Hikaru Ito,[2] Matsuhiko Hayashi,[1] Gunawan Setia Prihandana,[2] Norihisa Miki.[2] *[1]Apheresis and Dialysis Center, School of Medicine, Keio University, Tokyo, Japan; [2]Department of Mechanical Engineering, School of Science and Technology, Keio University, Yokohama, Japan.*

Background: Over 300 thousand patients who need renal replacement therapy in our country still struggled from daily life restriction and complications by receiving dialysis therapy. They have to spend 3 half day a week for hemodialysis therapy which account for 95% of renal replacement therapy in Japan. Although the complications in hemodialysis patients are almost came from the shortage of dialysis quantity, we could not improve the usual system of hemodialysis therapy using extracorporeal circulation. Recently, portable dialysis system was clinically investigated,and small devices are demanded. We have developed a microdialyzer containing polyethersulfone (PES) membranes, which could remove urea nitrogen and electrolytes from the dissolved solution.

Methods: Microdialyzer system was consisted of 24x24 mm^2 laminable PES membrane sandwiched between 2 titan made thin layers made by deep wet etching. The membrane was made by wet phase inverse method and estimated pore sizes were 2-5 nanometer. 50ml of whole cattle blood containing 100 mg/dl of urea nitrogen and 6.0 mEq/L of potassium was dialyzed with single layer membrane (38.3 mm^2) using in closed circuit system for up to 48hours. Blood flow rate was 3 mL/min.

Results: Blood concentrations of urea nitrogen and potassium were slowly decreased with dialysis as in table.

	Urea Nitrogen (mg/dl)		Potassium (mEq/L)	
Time(hours)	Blood	Dialyzate	Blood	Dialyzate
0	140	0	8.4	2.1
1	142	0	8.3	2.1
4	132	11	7.8	2.5
24	73	47	5.8	3.7
48	55	61	5.4	3.8

Occlusion in the circuit system and hemolysis were not observed during the dialysis session. Any thrombus on the PES membrane was not observed after 48 hour dialysis.From the present results, it is expected to increase the diffusion efficiency to support human life by multiplies PES membrane layer to 60 sheets.

Conclusions: Diffusing function and durablility of the microdialyzer were investigated. Thus our new dialysis device could remove enough urea and potassium from whole blood to use it in vivo.

Funding: Private Foundation Support

FR-PO064

Extractable and Leachable Residues from Extended Use of Hemodialysis Blood Treatment Set, Dialysate Circuit and Dialyzer Bruce F. Culleton,[1] Matthew R. Muller,[2] Angelito A. Bernardo.[1] *[1]Clinical/Medical Affairs, Baxter Healthcare, Deerfield, IL; [2]Research & Development, Baxter, Roundlake, IL.*

Background: Small quantities of chemicals are released by components of dialysis circuits (blood tubing, dialysate tubing, and dialyzers) during routine hemodialysis. The aim of this study was to characterize chemical residues from a hemodialysis system (consisting of blood treatment set, dialysate circuit and dialyzer) after initial citric acid disinfection and after multiple hot water disinfections. We hypothesized that any chemical residues measured on first use would progressively dissipate with multiple disinfections.

Methods: Toxicological analysis was conducted per ISO 10993-1. Samples for "worse case" (T1A) were drawn after the dialysis circuit was treated with hot citric acid (5%-6%) followed by hot water disinfection (85°±5° C, 60 min). The T1B sample was obtained after hot water disinfection only (before any treatment would be initiated). Samples for extended use cycles were done after 15 (T15) and 30 (T30) hot water disinfections. Analyses of extractable and leachable chemicals were done by gas chromatography, mass spectrophotometry and total organic carbon.

Results: Concentrations of acetone, 2-butanone (methyl ethyl ketone), cyclohexanone, methylene chloride, and trimethylsilanone were present at baseline (T1A and T1B). At T15, only acetone and methylene chloride were present. Minute amounts of acetone were detected at T30.

Average of three replicates of leachable chemicals (μg/L) at baseline and after 15 and 30 hot water disinfections

Chemical	T1A	T1B	T15	T30
Acetone	92.6	58.7	26.9	22.7
Methyl-ethyl ketone	17.8	3.73	BDL	BDL
Cyclohexanone	0.441	0.314	BDL	BDL
Methylene chloride	108	66.8	BDL	BDL
Trimethylsilanol	29.9	7.8	BDL	BDL

BDL- Below Detection Limit

Conclusions: The amount of volatile organic residues progressively declined after multiple hot water disinfection cycles of the same dialysis circuit. Although the clinical relevance of this finding is uncertain, limiting exposure to chemical residues in chronic HD patients may confer a safety benefit over single-use systems.

Non-Invasive Detection of Glomerulonephritis by MRI-Based Molecular Imaging Natalie J. Serkova,[1] Kendra Huber,[1] Brandon Renner,[2] Matthew C. Pickering,[3] Joshua M. Thurman.[2] *[1]Anesthesia, University of Colorado Denver School of Medicine, Aurora, CO; [2]Medicine, University of Colorado Denver School of Medicine, Aurora, CO; [3]Medicine, Imperial College, London.*

Background: The diagnosis of glomerulonephritis requires a renal biopsy, but biopsies are susceptible to sample error, and the risk of complications limits their use.

Methods: We have developed a molecular imaging contrast agent that targets tissue-bound complement activation fragments (iC3b and C3d). The contrast agent is comprised of a C3-targeting protein attached to superparamagnetic iron-oxide (SPIO) nanoparticles. The SPIO nanoparticles decrease T2 relaxation time and negatively enhance (i.e. darken) T2-weighted magnetic resonance images (MRI) in proportion to the abundance of the target molecule. We tested this contrast agent in mice with targeted deletion of the gene for the complement regulator factor H ($fH^{-/-}$ mice). These mice develop glomerulonephritis characterized by glomerular deposits of iC3b and C3d. We injected $fH^{-/-}$ mice with targeted SPIO nanoparticles and performed T2-weighted MRI of the kidneys 4, 24, 48, and 72 hours after injection.

Results: The T2-relaxation times in the cortex of the $fH^{-/-}$ mice were significantly reduced with tmax at 48 hours after injection with the targeted nanoparticles (-13.35±1.44 msec in T2 values, $n = 6$, $P < 0.001$). Mice injected with untargeted (control) SPIO nanoparticles did not demonstrate significant changes at any time-point (-1.00±2.58 msec T2-decrease at 48 hrs, $n = 5$, $P = NS$). We also tested $fH^{-/-}fB^{-/-}$ mice, which do not develop glomerular C3 deposits. No changes in the kidneys were seen by MRI after injecting the $fH^{-/-}fB^{-/-}$ mice with targeted nanoparticles (-1.53±1.76 msec T2-decrease, $n = 4$, $P = NS$), confirming that the reduced T2-relaxation times were due to the C3 deposits.

Conclusions: Molecular imaging of the kidneys using targeted SPIO by T2-weighted MRI may provide a quantitative, non-invasive alternative for monitoring disease activity in patients with glomerulonephritis.

Evaluation of UUO Kidney Injury Using High Resolution Magnetization Transfer Ratio Mapping Feng Wang,[1] Keiko Takahashi,[2] Raymond C. Harris,[2] Christopher Chad Quarles,[1] Takamune Takahashi.[2] *[1]Vanderbilt University Institute of Imaging Science, Nashville, TN; [2]Vanderbilt O'Brien Mouse Kidney Physiology and Disease Center, Nashville, TN.*

Background: Magnetic resonance imaging (MRI) complements the physiological information obtained from conventional assays of kidney function and facilitates our understanding of pathological mechanisms in kidney disease. Magnetization transfer ratio (MTR) provides indirect information about the macromolecular component in tissues. In this study, we optimized MRI methods for MTR mapping in mouse kidneys and assessed its application in studying progressive kidney injury using the unilateral ureteral obstruction (UUO) mouse model.

Methods: MRI protocols were optimized on Agilent 7T MRI. Rapid acquisition and respiration gating were applied to minimize motion artifacts. MTR was measured based on a 2D RF-spoiled gradient echo sequence(α=7°,TR=24ms,TE=3.3ms,FOV=25 .6×25.6mm^2,matrix size=128×128,thickness=0.5mm,81accumulations). Off-resonant RF irradiation was accomplished with use of Gaussian RF pulses(6000Hz,12ms). To calculate MTR, additional acquisitions were performed without MT pulses. Each measurement was preceded by a 20s period of dummy scans to drive the spin system into steady state. MTR maps were obtained for UUO mice on day 1, 3, and 6 after obstruction. Sham-operated mice were used as a control.

Results: MT imaging detected fine structural changes (size, shape, contrast, thickness) of renal compartments in UUO kidney as early as day 1 post obstruction. The overall MTR of the UUO kidney declined as the disease progressed (day 1: 27%, day 3: 34.0%, day 6: 52%) and its reduction was pronounced in renal medulla, especially in inner medulla and papilla (>64%, day 3), perhaps due to cell apoptosis. In contrast to renal medulla, MTR changes were minimal (<10%) in UUO renal cortex. Through the duration of the study, structural features and MTR were unchanged in the contralateral kidney and sham kidney.

Conclusions: MTR mapping detects progressive UUO renal injury, especially in renal medulla. This MRI method could be used for the assessment of kidney injury associated with the change of macromolecular components(apoptosis/fibrosis).

Automated Renal Scintigraphy Modeling Mohammed Noor Tantawy,[1] Dana Zemel,[2] Todd E. Peterson,[1] Keiko Takahashi,[2] Raymond C. Harris,[2] Christopher Chad Quarles,[1] Takamune Takahashi.[2] *[1]Vanderbilt University Institute of Imaging Science, Nashville, TN; [2]Vanderbilt O'Brien Mouse Kidney Physiology and Disease Center, Nashville, TN.*

Background: Renal scintigraphy using ^{99m}Tc-MAG3 is widely used in human and animal studies. We previously reported a method to extract biological parameters from the time-activity curves (TACs), including peak activity (renal blood volume), time-to-peak (TTP, renal perfusion), and the slope of the initial influx (RBF', renal blood flow). However, extracting these parameters is tedious and time consuming especially when there is a large influx of data. To automate the parametric analysis, this study was aimed to identify a highly flexible, non-linear arbitrary analytical model that fits a heterogeneous range of MAG3 TACs.

Methods: ^{99m}Tc-MAG3 was injected to mice and TACs of each kidney were generated by planar dynamic acquisition on NanoSPECT. The analytical model was developed using the formula (Muzic & Cornelus 2001) with some modification: $f(t)=(at-b-c)e^{-gt}+be^{-hk+l}+ce^{-lt}$ [a, b, c, g, h, k, and l are constants]. The fit was assessed by both X^2 and visual inspection. MATLAB was used to carry out the fit. The t (TTP) was calculated by taking the derivative of the formula and setting it equal to zero, then substituted in the original formula to determine the peak activity. The t^* at which the peak begins was calculated by setting the third derivative of the formula to zero, then df(t)/dt (at $t = t^*$)= RBF' was determined. The model was validated using both normal and UUO (day1,3,6) mice.

Results: The correlation between the manually extracted parameters and those obtained via the formula was ~0.99 in normal mice. In UUO mice, similar correlation was obtained for peak(plateau) and RBF'. The TAC's plateaued in UUO kidney due to no secretion of urine. Determining the time-to-plateau visually may include many errors. However, using the formula we were able to determine an exact time-to-plateau.

Conclusions: We have developed the formula that can be used for the parametric analysis of MAG3 TACs. Further evaluation of the formula and the development of executable software should provide a standardized protocol of MAG3 TACs analysis.

Relationship between Hemodynamics and Later Lumen Changes in a Porcine Arteriovenous Graft Model Yan-Ting E. Shiu,[1] Daniel B. Pike,[2] Christi M. Terry,[1] Yong He,[3] Huan Li,[1] Ilya S. Zhuplatov,[1] Alfred K. Cheung.[1,4] *[1]Medicine, Univ of UT, Salt Lake City, UT; [2]Bioengineering, Univ of UT, Salt Lake City, UT; [3]Surgery, Univ of FL, Gainesville, FL; [4]Medicine, VASLCHCS, Salt Lake City, UT.*

Background: Hemodialysis arteriovenous grafts (AVGs) often fail due to neointimal hyperplasia (NH) at the venous anastomosis (VA), resulting in stenosis and clotting. Aberrant hemodynamics may play a role in the focal nature of NH formation, but a clear correlation has not yet been demonstrated. We have developed an advanced and efficient technological pipeline to investigate this correlation in a porcine model of AVG stenosis.

Methods: AVG was placed between the common carotid artery and the external jugular vein in swine. At 1, 2, 3 or 6 weeks (wk) (n=3 at each wk), the AVG lumen geometry and blood flow at the in- and out-flow sites were obtained by black-blood and cine phase-contrast MRI, respectively, and used as input for computational fluid dynamics analyses to model hemodynamic parameters, including the oscillatory shear index (OSI) (a measure of change in flow direction and value over a cardiac cycle). OSI was co-registered with later lumen areas using the VA as an anatomic landmark.

Results: Disturbed flow patterns (e.g., spiral and retrograde flow) occurred early and were common particularly at the VA. On average, early (1, 2 wk) OSI at the VA region was higher than that in proximal (downstream) vein segments. The venous flow and lumen changes were asymmetrical across upstream and downstream regions of the VA. In one pig monitored serially, the VA distal (upstream) region OSI increased early and remained high, but OSI at the VA downstream region increased early then dropped to almost control vein levels by 6 wk. Of note, the distal vein had the largest lumen increase and the least amount of change in OSI compared to proximal vein.

Conclusions: We have developed a robust pipeline of techniques to assess hemodynamic parameters with later lumen area changes in porcine AVG. Further serial analyses in larger studies will illuminate the relationship between early hemodynamics and subsequent focal NH development, with the objective of improving grafts and surgical techniques that lead to AVG longevity.

Process Management Reengineering in Healthcare: Why Old and New Paradigms Have Failed: The Roles of Critical Healthcare-Specific Complex Unidentified Bottlenecks in a Complex Adaptive System: Do We Need More MD MBAs? Macaulay A. Onuigbo,[1,2] Mark Onuigbo,[3] Nnonyelum T. Onuigbo,[4] Obi Egbuniwe.[5] *[1]Medicine, Mayo Clinic, Rochester, MN; [2]Nephrology, Mayo Clinic; [3]Aeronautics Engineering, University of Michigan; [4]Information Technology, NTEC Solutions LLC; [5]Information Technology, Nurture Healthcare Service LLC.*

Background: The limitations of the straight juxtaposition of process management (PM) theories and practices with proven effectiveness in manufacturing into the healthcare service industry, often without adequate analysis and strategization, and the consequent poor outcomes is well known to healthcare managers. The introduction of the EMR/EHR to limit medical errors while increasing productivity has often led to the exact opposite outcomes. Early hospital discharge strategies have failed. Strategies to improve access have not materialized.

Methods: Literature Review.

Results: Attempts at simply juxtaposing manufacturing PM paradigms into healthcare have failed to achieve desired goals. The healthcare system is a complex adaptive system (CAS) that demands a far better understanding of its function, before solutions are proffered. A constraint is something that limits the performance of a process or system in achieving its goals. In PM, one often overlooked constraint is a bottleneck, leading to unbalanced systems. Bottleneck management is therefore an important operational strategy to increase effective capacity or productivity, and therefore throughput. In healthcare, due to the unfamiliarity of the managers (IT, HR) with the system, very often, unique and unidentified bottlenecks are neglected in PM strategization, leading to failed solutions. Such bottlenecks include Cognitive Drift (EMRs), excessive workaround (EMRs), EMRs out of sync with workflow, and patients preferring to have lunch before hospital discharge.

Conclusions: Current PM changes introduced into healthcare to solve problems and accelerate throughput and productivity have often failed due to unfamiliarity of the PM experts with the CAS. New better informed approaches are warranted - Either a far-more integrated collaborative stratagem between physicians and managers or guess what? We need more MD MBAs!!!

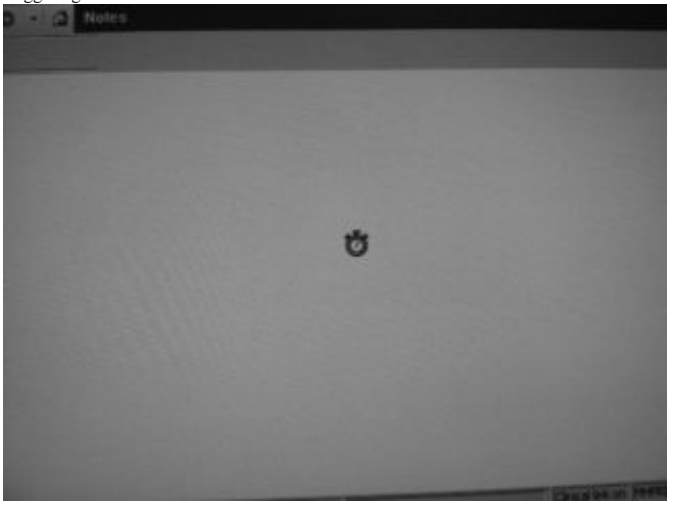
FR-PO070

Cognitive Drift in the Electronic Medical Record System: An Unrecognized Source of Physician Stress and a Silent Cause of Medication Errors: Results of a Small Physician Survey Macaulay A. Onuigbo,[1,2] Nnonyelum T. Onuigbo.[3] *[1]Nephrology, Mayo Clinic Health System; [2]Medicine, Mayo Clinic; [3]IT, NTEC Solutions.*

Background: Medications represent the most common intervention in healthcare but lead to an estimated 1.5 million adverse drug events and tens of thousands of hospital admissions annually in the USA. The 98,000 deaths/year and many more injuries resulting from medical errors have propelled patient safety as top priority. Many authorities had hoped that many medication errors - the most common cause of preventable injuries in hospitals - can be prevented by computerized physician order entry (CPOE), a component of the electronic medical record (EMR). EMRs have become ubiquitous in the US, mandated by the Affordable Care Act. According to Levitt and Dubner, (Superfreakonomics), a person using a computer experiences "cognitive drift" (CD) if more than one second elapses between clicking the mouse and seeing new data on the screen. If ten seconds elapsed, the person's mind is somewhere else entirely and this leads to medical errors. For our survey, we defined CD as elapsed time >10 seconds.

Methods: Survey - Ten randomly selected ICU physicians in 2012.

Results: 10 of 10 (100%) of the ICU physicians reported experiencing CD several times a day. All physicians cited CD as a source of significant frustration, stress and possible burnout. A definition of CD as >1 second would have produced even more staggering statistics.



Conclusions: Cognitive drift is a common and unrecognized source of physician stress. CD causes physician distraction, CPOE and medication errors. EMRs must deploy more robust and faster servers, networks and work stations to eliminate these consequences. Our other study of stress in the healthcare workplace identified EMR-induced stress (EIS) as a major cause of employee stress/burnout; CD was a major driver of EIS. CD warrants further study.

Multicopy Crystallographic & Biophysical Analyses of the N-Terminal Domain of NBCe1-A: Illumination of the Human R298S Mutational Defect Harry S. Gill. *Medicine, The Medical Faculty Associates & the George Washington University, Washington, DC.*

Background: NBCe1-A membrane-embedded macromolecules cotransport sodium and bicarbonate ions across the bilayer that serve to maintain acid-base homeostasis throughout the body. Defects are linked to a number of disorders, including proximal renal tubule acidosis, mental retardation, dental defects, and cataracts. Previously, we demonstrated the N-terminal domain of NBCe1-A (Nt) is in a pH-sensitive monomer-dimer equilibrium. At neutral pH, bicarbonate ions bind the Nt, stabilizing dimerization and intermolecular self-associations of dimers.

Methods: We determine and analyze the X-ray crystal structure of the Nt as a dimer at 2.4-Å resolution using molecular-replacement methods, and a multicopy crystallographic structure of the monomer using 5 atomic models and strict 4-fold NCS constraints in refinement procedures. We measure the pH-sensitivity of a truncated Nt mutant by light-scattering techniques, and bicarbonate, bisulfite, mutant self-association bindings by surface plasmon resonance techniques.

Results: The structures reveal that R298 implicated in the disorders is part of a putative conduit that transverses the Nt. The conduit opens to the transmembrane domain (TMD) on one end and an apparent foyer entrance on the opposite end. The naturally occurring mutation R298S disrupts an electrostatic pocket within the conduit that disables substrate binding. We also report similar conducts in family member AE1 (Band 3) when exploring its crystal structure. Further, we identify by biophysical analyses on a truncated Nt that the autoregulatory domain (ARD) at the N-terminus of the Nt is responsible for self-associations.

Conclusions: The Nt responds to changes in pH or bicarbonate fluctuations. In proximal tubule cells, we propose a model where the ARD is a gate for the foyer. When self-associated, the foyer entrance is accessible, allowing substrate entry into the conduit. During acid loads, the gates close entry into the foyer, preventing bicarbonate from leaving the cell. The R298S defect similarly prevents bicarbonate ions from being transported to blood, giving rise to metabolic acidosis that results from the renal tubule acidosis.

Sulfatides Are Required for Renal Adaptation to Metabolic Acidosis Hermann-Josef Groene,[1] Paula Stettner,[1] Soline Bourgeois,[2] Carsten A. Wagner.[2] *[1]Cellular and Molecular Pathology, German Cancer Research Center, Heidelberg, Germany; [2]Institute of Physiology, University of Zurich, Zurich, Switzerland.*

Background: Urinary ammonia excretion by the kidney is an essential process to maintain blood pH in the physiological range. A key step in renal ammonia handling is the generation of a steep cortico-papillary ammonia gradient providing the driving force for ammonia secretion by the collecting duct into urine. In this study we demonstrate that sulfatides i.e. anionic glycolipids of the outer plasma membrane are important for papillary ammonium retention and increased urinary acid elimination during metabolic acidosis.

Methods: Sulfatide synthesis was inhibited by tubular epithelial-specific, genetic disruption of cerebroside sulfotransferase (Cst) in the mouse kidney (Pax8 cre); compensatory synthesis of other negatively charged glycosphingolipids was inhibited by simultaneous deletion of glucosylsceramide synthase (Ugcg) activity.

Results: Renal Ugcg-, Cst-, and Ugcg/Cst-deficient mice had an abnormal acidic urinary pH which was - similar to type II diabetics - accompanied by higher urinary net acid- but lower ammonia excretion as compared to control littermates (pH: 5.95 ± 0.03 vs 5.35 ± 0.02). Upon acid diet, renal Ugcg/Cst-deficient mice were not able to increase urinary ammonia adequately (123 ± 2 vs 176 ± 8 mM/mM creatinine) and developed chronic metabolic acidosis (day 9 pH: 7.02 ± 0.04 vs 7.21 ± 0.04). Systematic analyses including transporter expression studies, tissue ammonia measurement, and in vitro microperfusion with ammonia transport study of collecting ducts of acid-loaded Ugcg/Cst-deficient mice indicated normal transepithelial NH_3 transport, but decreased ammonia retention in the papilla resulting in a blunted axial ammonia gradient.

Conclusions: We therefore propose that renal sulfatides, by their negative extracellular charge, act as counterions for ammonia binding and storage in the papillary interstitium. This study highlights an instrumental role of sulfatides in renal ammonia handling, urinary acidification, and acid-base homeostasis.

FR-PO073

Upregulation of Mice Carbonic Anhydrase XII in the α-Intercalated Cell of Outer Medullary Collecting Duct during Acidosis Yukiko Yasuoka,[1,2] Yuichi Sato,[3] Hiroshi Nonoguchi,[4] Katsumasa Kawahara.[1,2] *[1]Physiol., Kitasato U. Sch. of Med, Sagamihara, Japan; [2]Cell & Mol. Physiol., Kitasato U. Grad. Sch. of Med. Sci., Sagamihara, Japan; [3]Mol. Diag., Kitasato U. Grad. Sch. of Med. Sci., Sagamihara, Japan; [4]Internal Med., Kitasato U. KMC Hospital, Kitamoto, Japan.*

Background: In mammalian kidneys, various types of carbonic anhydrase (CA) play important role for net HCO_3^- reabsorption at the proximal tubule and for HCO_3^- formation and reabsorption through the distal nephron. We investigated regulation of mice CA isozymes mRNAs along the nephron in response to NH_4Cl loading.

Methods: Localization and expression of both CAs (CAII, CAIV, CAXII, and CAXIV) and anion exchanger (AE1) mRNAs were assessed by a quantitative in situ hybridization (ISH) technique along the mouse (C57BL/6J, male, 10 weeks) nephron, in proximal convoluted and straight tubules (PCT and PST), descending and ascending thin limbs (DTL and ATL), medullary and cortical TAL (MTAL and CTAL), distal convoluted tubule (DCT), and cortical, outer medullary, and inner medullary collecting ducts (CCD, OMCD, and IMCD). Under the microscope, abundance of CAs and AE1 mRNAs (brown dots) was counted and evaluated during normal condition and acidosis (0.28 M NH_4Cl solution drinking, 6 days in metabolic cages).

Results: In normal condition, localization and expression of CAII mRNA was at PCT, CCD, and OMCD > DTL, MTAL, CTAL, and IMCD. Similarly, CAIV was at PCT and MTAL > CTAL and intercalated cell (IC) of OMCD, CAXII was at CCD-IC and OMCD-IC > PCT, CAXIV was at DTL > PCT. There was no expression of CAs at PST and DTL and ATL of inner medulla. Moreover, AE1 mRNA expressed at CCD-IC and OMCD-IC. During NH_4Cl loading, the CAII mRNA expression increased only at PCT. Similarly, CAIV increased at PCT and MTAL and CAXII increased at PCT, CCD-IC, and OMCD-IC. AE1 mRNA increased at OMCD-IC. However, there was no change in the CAXIV mRNA expression. Interestingly, cell height of the CAXII and AE1 mRNA-positive cell (α-IC of OMCD) increased specifically and significantly ($P < 0.005$) by 39.1% during acidosis.

Conclusions: Induction of CAXII may contribute to formation and reabsorption of HCO_3^- in α-IC of mice kidney OMCD, especially during acidosis.

Funding: Government Support - Non-U.S.

FR-PO074

Effect of Metabolic Acidosis on miRNA Expression in Rat Kidney Cortex and Isolated Proximal Convoluted Tubules Norman P. Curthoys, Lynn Taylor. *Biochemistry and Molecular Biology, Colorado State University, Fort Collins, CO.*

Background: Computational predictions and genome wide identification of targets suggest that expression of at least half of the human transcriptome is regulated by miRNAs. In mammalian cells, miRNAs inhibit gene expression primarily by enhancing the rate of degradation of specific mRNAs. Proteomic analysis identified >100 proteins that are increased in the rat proximal convoluted tubule during onset of metabolic acidosis. Many of the corresponding mRNAs contain AU-rich elements that have >85% sequence identity to the pH-response element that mediates stabilization of glutaminase mRNA during acidosis.

Methods: To investigate their possible role in this adaptation, miRNAs were isolated from renal cortex and proximal convoluted tubules derived from control and 4-h acidotic rats. Acidosis was induced by stomach loading with 20 mmol NH_4Cl/100g bd.wt. This protocol produced pronounced decreases in arterial blood pH (7.18 ± 0.03) and HCO_3^- (12.6 ± 0.3 mM). The miRNAs were screened using a Rat miFinder PCR Array (Qiagen).

Results: Of the 84 miRNAs profiled on this array, only miR-22, miR144 and miR-182, were decreased significantly (3- to 4-fold) during acute acidosis. miR-182 is derived from a pre-miRNA that also encodes miR-96, miR-183 and miR-3553. Therefore, specific miScript miRNA qPCR assays were used to quantify the temporal changes in the 4 miRNAs from this cluster. As a control, miR-23a and miR-23b were also assayed. The individual qPCR assays established that within this cluster only miR-96 and miR-182 were decreased 2.5-fold in the 4-h acidotic samples. miR-96 was also decreased 3-fold in the samples prepared from isolated proximal convoluted tubules. However, the level of miR-182 was unchanged, suggesting that the decrease observed in cortex occurs in some other segment of the nephron. Array analysis of miRNAs obtained from isolated proximal convoluted tubules indicated that miR-22, -210, -32, -144, -let-7b, and RNU 6-2 were also decreased >3-fold.

Conclusions: The observed decreases in specific miRNAs may contribute to the stabilization of mRNAs that occur following onset of acidosis.

FR-PO075

Renal Adaptation to Metabolic Alkalosis in Mice Nilufar Mohebbi,[1,2] Alessandro Genini,[1] Carla Bettoni,[1] Carsten A. Wagner.[1] *[1]Institute of Physiology, University of Zurich, Zurich, Switzerland; [2]Division of Nephrology, University Hospital Zurich, Zurich, Switzerland.*

Background: In the collecting duct, the fine-tuning of salt and acid-base homeostasis is regulated by transport proteins located in at least two different cell types, intercalated and principal cells. The Cl^-/HCO_3^- exchanger AE1 expressed on the basolateral membrane characterizes acid-secretory type A intercalated cells while the apical anion exchanger pendrin is localized to bicarbonate secretory type B intercalated cells. AQP2 identifies principal cells. During acidosis, acid-secretory intercalated cells proliferate which may

contribute to the remodelling of the collecting duct. Several transcription factors such as Foxi1, GDF-15, and CP2L1 have been also reported to be involved in intercalated cell proliferation and differentiation.

Methods: This study aimed to investigate acute and chronic adaptive responses in the collecting duct to metabolic alkalosis. Mice were subjected to either tap water (control), 0.28 mmol/L NaCl, or 0.28 mmol/L $NaHCO_3$ in drinking water for either 12 hours, 24 hours, 2 days, or 7 days, respectively. Quantitative real-time rt-PCR was performed for different cell markers (AE1, pendrin, AQP2) and (transcription) factors implied in intercalated cells differentiation (Foxi1, GDF-15, and CP2L1). Western blotting was performed for AE1, pendrin, and AQP2.

Results: Pendrin mRNA was significantly increased after 24 hours of alkali load. In contrast, AE1 mRNA levels were diminished after 12 hours in $NaHCO_3$ treated mice. AQP2 mRNA was markedly increased in the $NaHCO_3$ group compared to control and NaCl treated animals. Notably, protein abundance of AE1 was decreased after 24 hours, pendrin protein expression was not different between groups, and AQP2 protein levels were significantly elevated after 24 hours, 2 and 7 days. Foxi1 mRNA levels were increased after 24 hours and 2 days, and GDF-15 after 2 days alkali load.

Conclusions: In conclusion, during alkalosis key acid base transport proteins in the collecting duct are regulated. Factors implied in regulating intercalated cell proliferation and differentiation show transient and distinct patterns of regulation and may have an impact on this adaptive response.

Funding: Government Support - Non-U.S.

FR-PO076

An Evidence of Transdifferentiation of Principal Cells Into Intercalated Cells in Hypokalemic *AQP2-cre;ROSA Mouse Kidney* Sun-ah Nam, Jules Kun Hyoe Rhoo, Yumi Kim, Jin Kim, Wan-Young Kim. *Anatomy and Cell Death Disease Research Center, The Catholic University of Korea, Seoul, Republic of Korea.*

Background: In K^+-depleted animals, there was a reversible increase in number of intercalated cells (ICs) in the inner stripe part of outer medullary collecting duct (OMCD), but the cell proliferation had been mainly detected in the principal cells (PCs). A suggested mechanism to explain the increase of ICs in K^+-depleted animal was a direct or indirect conversion of PCs to ICs. The purpose of this study was to propose the possible transdifferentiation of PCs to ICs using a kidney of hypokalemic *AQP2-cre;ROSA mouse.*

Methods: Adult male transgenic mice *AQP2-cre;ROSA)* were used in the study and the experimental group was fed with K^+-depleted diet for two weeks. Each Ics and PCs were immunolabeled with specific markers for H^+-ATPase and AQP2, respectively.

Results: As a result, in the control group, ROSA-positive signal was mainly evidenced in PCs (35.4% of H^+-ATPase-negative/AQP2-positive PCs), but a few ICs showed ROSA-positive signal (5.5% of H^+-ATPase-positive/AQP2-negative ICs) even in the normal kidney. In hypokalemic kidney, the proportion of ROSA-positive cells in ICs was significantly increased to 16.2% but the proportion of ROSA-positive cells in PCs (37.0% of H^+-ATPase-negative/AQP2-positive PCs) was comparable to the control group.

Conclusions: In conclusion, we propose a mechanism of transdifferentiation of the ICs from AQP2-ROSA-positive PCs in OMCD, causing the increase in number and proportion of ICs at least in hypokalemic mice.

FR-PO077

Double Knockout of Carbonic Anhydrase II (CAII) and Na-Cl Ctransporter (NCC) Causes Robust Salt Wasting, Volume Depletion and Kidney Failure in Mice Jie Xu,[1,2] Sharon Barone,[1,2] Kamyar A. Zahedi,[1,2] Manoocher Soleimani.[1,2] *[1]Research Services, Veterans Administration Hospital; [2]Medicine, University of Cincinnati.*

Background: The Cl^-/HCO_3^- exchanger pendrin and the NaCl cotransporter NCC are expressed in the distal nephron and mediate salt absorption. NCC KO mice display no salt wasting under baseline conditions but demonstrate upregulation of pendrin in their kidneys (JASN 2007). CAII is abundantly expressed in intercalated cells and plays an important role in acid base transport in intercalated cells. CA II KO (Car2 null) mice display significant reduction in the number of intercalated cells and pendrin expression (AJP:Renal 1995 and Cell Physiol Biochem 2008).

Methods: We hypothesized that pendrin plays an essential role in distal tubule salt absorption in the setting of NCC inactivation. To test our hypothesis, CAII KO (Car2 null) mice which show significant pendrin downregulation were crossed with NCC KO mice to generate double NCC/CAII KO mice.

Results: Northern and western blots showed that the kidney expression of pendrin is reduced by 80% in CAII KO KO or NCC/CAII double KO mice Vs. WT mice ($P<0.01$). Balanced studies demonstrate the presence of significant salt and water wasting in NCC/CAII double KO mice, with urine output of 3.5 ± 0.3 ml/24 hr in double KO mice Vs. 0.8-1.2 ml/day in WT or single KO mice ($p<0.01$). Excretion of sodium and chloride increased by 40 and 60%, respectively, in CAII/NCC double KO mice Vs. other genotypes ($p<0.01$). Western blots demonstrated that the expression of renin increased by ~300% in kidneys of double CAII/NCC KO mice Vs. other genotypes. BUN levels increased in double CAII/NCC KO mice, consistent with prerenal failure. High salt diet for 7 days significantly improved the expression of renin and reduced BUN levels in double CAII/NCC KO mice.

Conclusions: We conclude that pendrin upregulation is essential for the prevention of salt wasting in NCC KO mice and its downregulation in the setting of NCC inactivation will lead to salt wasting and volume depletion. We propose that the combined inhibition of pendrin and NCC can be a novel and potent diuretic regimen for the treatment of fluid overloaded states, such as CHF.

FR-PO078

The Carbonic Anhydrase Inhibitor Acetazolamide (ACTZ) Downregulates Pendrin in the Kidney and in Conjunction with Hydrochlothiazide (HCTZ) Causes Massive Diuresis, Salt Wasting, and Volume Depletion Sharon Barone,[1,2] Jie Xu,[1,2] Kamyar A. Zahedi,[1,2] Manoocher Soleimani.[1,2] *[1]Department of Medicine, University of Cincinnati, Cincinnati, OH; [2]Research Services, Veterans Administration Hospital, Cincinnati, OH.*

Background: The Cl^-/HCO_3^- exchanger pendrin and the thiazide-sensitive Na-Cl cotransporter NCC are expressed in the distal nephron and mediate salt absorption. Treatment with ACTZ for 2 weeks decreases the number of B-intercalated cells in rat kidney (Bagnis et al, AJP:Renal 2001). Hypothesis: ACTZ downregulates pendrin and primes the kidney for salt wasting when HCTZ is added, subsequent to combined NCC/pendrin inactivation.

Results: Male Sprague Dawley rats (150-200 gm) were treated with daily injection of ACTZ for two weeks. Urine output increased from 11 ± 1 to 27 ± 3 ml/day after 14 days of ACTZ injection ($p<0.01$, $n=5$). Northern and western blots showed ~80% reduction in pendrin expression and immunofluorescence labeling indicated significant downregulation of pendrin labeling in kidneys of ACTZ-treated rats. In separate studies, daily injection of rats with HCTZ alone for 4 days mildly increased the urine output, from 11.5 ± 1 to 13.7 ± 2 ml/day. However, treatment of rats that were pretreated with ACTZ for 14 days with daily HCTZ injection increased the urine output from 27 ± 3 to 59 ± 8 ml/day on day 4 of HCTZ injection ($p<0.01$, $n=5$). Animals treated with ACTZ plus HCTZ displayed significant salt wasting and developed severe volume depletion, as determined by a 3-fold increase in renin mRNA and protein abundance in their kidneys. BUN levels increased significantly in ACTZ plus HCTZ group Vs. other groups ($p<0.01$).

Conclusions: 1. ACTZ downregulates the expression of pendrin and primes the kidneys for profound salt and water wasting when thiazide is added. 2. The thiazide sensitive Na-Cl cotransporter plays a major role in the maintenance of vascular volume in the setting of pendrin inactivation and increased delivery of salt from proximal tubule caused by ACTZ. 3. Despite being considered mild agents individually, we propose that the combination of ACTZ and HCTZ is a powerful diuretic regimen for the treatment of fluid overloaded states.

FR-PO079

Localization, Regulation, and Relevance of the (Pro)renin Receptor/Atp6ap2 for H^+-ATPases in Kidney Arezoo Daryadel,[1] Marta Figueiredo,[1] Soline Bourgeois,[1] Nicole Beate Kampik,[1] Nilufar Mohebbi,[1] Marcel Meima,[2] Alexander H. Danser,[2] Carsten A. Wagner.[1] *[1]Inst of Physiology, Univ of Zurich, Zurich, Switzerland; [2]Depart of Internal Medicine, Erasmus Medical Center, Rotterdam, Netherlands.*

Background: The (Pro)renin receptor (PRR) has been identified as a cell surface protein capable of binding and non-proteolytically activate prorenin. Surprisingly, PRR is associated with H^+-ATPases and alternative functions in H^+-ATPase regulation as well as in Wnt signalling have been suggested. The kidneys express very high levels of H^+-ATPase which are involved in multiple functions in endocytosis, membrane protein recycling as well as urinary acidification and salt absorption.

Methods: In this study we investigated the expression pattern of PRR in kidney and its possible role in H^+-ATPase function using real-time PCR, immunoblotting, immunohistochemistry, animal and cell culture studies, and micropferfusionof isolated collecting ducts.

Results: qPCR and immunohistochemistry demonstrated expression of the PRR along the entire mouse and rat nephron with highest levels in the collecting system coinciding with H^+-ATPases. Further experiments demonstrated expression in all types of intercalated cells colocalizing with H^+-ATPases. In mice treated with NH4Cl, NaHCO3, KHCO3, NaCl, or DOCA for 7 days, PRR and the B1 H^+-ATPase subunit were increased following the NaHCO3 treatment in both cortex and medulla at protein and mRNA levels whereas NH4Cl reduced PRR and B1 expressions only in cortex. Lastly, microperfusion experiments of isolated cortical collecting duct and application of 20 nM prorenin did not stimulate H^+-ATPase activity.

Conclusions: Our results suggest that the PRR may form a complex with H^+-ATPases in renal intercalated cells but that prorenin has no direct or acute effect on H^+-ATPase activity.

Expression of Rh B Glycoprotein (RhBG) in Human Kidney Hyun-Wook Lee,[1] Ki-Hwan Han,[2] Florence M. Whitehill,[1] Jill W. Verlander,[1] Mary E. Handlogten,[1] Jesse M. Bishop,[1] Byron P. Croker,[3] William L. Clapp,[3] I. David Weiner.[1,4] *[1]Renal Division, University of Florida, Gainesville, FL; [2]Department of Anatomy, Ewha Womans University, Seoul, Korea; [3]Pathology Department, University of Florida, Gainesville, FL; [4]Renal Section, NF/SGVHS, Gainesville, FL.*

Background: Rh B Glycoprotein is critical for renal ammonia metabolism in mice, but whether it is expressed in human kidney is controversial. This study's purpose was to reassess human kidney RhBG expression.

Methods: We used standard gene sequencing, site-directed mutagenesis, cell-expression, immunoblot and immunohistochemistry methods. Human mRNA and protein homogenates were from commercial sources. Tumor-free portions of kidneys removed for treatment of renal cancer were used for immunohistochemistry.

Results: We identified reports of two distinct human RhBG mRNA sequences encoding different carboxy termini. Sequencing human kidney and liver mRNA in the region of difference showed 8 consecutive cytosines beginning at nt 1537, not 7 as has been reported, and was otherwise identical to both published sequences. Genomic DNA confirmed these mRNA findings. Sequencing the commonly used GFP-RhBG vector showed only 7 cytosines, indicating it encodes a frame-shift mutation of human RhBG. We mutated the RhBG vector to the correct sequence and expressed it in HEK-293 cells. An antibody against the first extracellular loop labeled non-glycosylated and glycosylated RhBG protein from RhBG-transfected cells, but not protein from mock- or human RhCG-transfected cells. Immunoblot analysis of human kidney showed RhBG protein expression. Immunohistochemistry identified basolateral RhBG immunolabel in the connecting segment and the cortical and outer medullary collecting ducts. Double-immunolabel of RhBG with H^+-ATPase or pendrin identified RhBG expression in CNT cells and A-type and non-AB intercalated cells; Type B intercalated cells and principal cells did not express detectable RhBG.

Conclusions: We show for the first time that RhBG protein is expressed in the human kidney in CNT cells and both A-type and non-AB intercalated cells, where it is ideally located to mediate an important role in human renal ammonia transport.

Colonic α-H^+,K^+-ATPase and B1-H^+-ATPase mRNA Expression Declines in GPR4-/- Mice with Aging Juan Codina,[1] Snezana Petrovic,[2] Xuming Sun,[2] Raymond B. Penn,[3] Thomas D. DuBose.[1] *[1]Sections on Nephrology and Molecular Medicine, Departments of Internal Medicine and Physiology and Pharmacology, Wake Forest School of Medicine, Winston-Salem, NC; [2]Section of Nephrology and Molecular Medicine, Department of Physiology and Pharmacology, Wake Forest School of Medicine, Winston-Salem, NC; [3]Department of Medicine, University of Maryland, Baltimore, MD.*

Background: The H^+,K^+-ATPase and H^+-ATPase participate importantly in systemic acid-base homeostasis to defend against metabolic acidosis. We have shown that plasma membrane expression of the colonic α H^+,K^+-ATPase ($HK\alpha_2$) is increased in response to a reduction in both pH_a and extracellular $[K^+]$. Furthermore we have shown that pH-dependent regulation of $HK\alpha_2$ is dependent on an increase in phosphorylation mediated by PKA to promote maturation and plasma membrane expression. Co-expression of GPR4, a proton-sensing Gs coupled receptor, increases $HK\alpha_2$ protein abundance in HEK-293 cells stably transfected with $HK\alpha_2$.

Methods: In the present study, we applied quantitative real time RT PCR to determine mRNA expression of $HK\alpha_2$ and the B1-subunit of H^+-ATPase in whole kidney of a mouse model of genetic ablation of GPR4 (GPR4-/-) in which the phenotype includes spontaneous metabolic acidosis.

Results: Our study demonstrates that while the mRNA expression of $HK\alpha_2$ and the B1-subunit of H^+-ATPase are similar in young GPR4+/+ and GPR4-/- mice (2.5±0.8 vs. 2.17±0.5 for $HK\alpha_2$, and 2.5±0.3 vs. 2.42±0.2, N=5, for B1). However, expression is dramatically decreased in age-matched older GPR4+/+ vs. GPR4-/- (2.42±0.5 vs. 0.83±0.1 units, N=7 and 13, respectively, $p<0.001$, for $HK\alpha_2$, and 1.75±0.2 vs. 1.1±0.1, N=7 and 13, respectively, $p<0.05$) for B1.

Conclusions: In summary these data demonstrate that GPR4 ablation is associated with a marked decrease in $HK\alpha_2$ and B1- H^+-ATPase subunit mRNA expression in older mice. Therefore, $HK\alpha_2$ and B1- H^+-ATPase mRNA expression in aging rats may be dependent on the presence of GPR4, a putative pH sensor in the kidney.

FR-PO082

Microarray Analysis of Gene Expression in Kidneys of Proton Receptor Knockout Mice Doris P. Molina,[1] Xuming Sun,[1] Snezana Petrovic.[1,2] *[1]Physiology and Pharmacology, Wake Forest School of Medicine, Winston-Salem, NC; [2]Internal Medicine Section of Nephrology, Wake Forest University School of Medicine, Winston-Salem, NC.*

Background: GPR4 is a GPCR activated by protons. It couples with Gs and stimulates cAMP/PKA signaling. GPR4-/- develop dRTA, suggesting that GPR4 may function as a pH sensor required for acid-base homeostasis.

Methods: To further examine GPR4's role in the kidney, we performed microarray analysis of gene expression in the kidney tissue from GPR4-/- and +/+, using Operon Array-Ready Mouse Genome Oligo Set from Qiagen (38,784 optimized 70-mer oligos used for microarrays). Genes with $p<0.01$ were further analyzed with IPA, Ingenuity Systems Software.

Results: We found that deletion of GPR4 upregulated 509 and downregulated 362 genes. Changes in several genes involved in response to acidosis like the a4 subunit of H^+-ATPase (ATP6V0A4) and ammonium transporter Rhcg and the PKA signaling pathway (AKAP12, PKAr, filaminA) corroborated GPR4 involvement in acid-base regulation and its Gs coupling. Phosphate transporter Slc17a2 was increased 3.6x, consistent with lower urine phosphate excretion in GPR4-/- vs. GPR4+/+. A number of genes involved in salt and volume homeostasis were upregulated: SGK1, aENaC, renin, angiotensin converting enzyme (ACE), and Cyp4a14. Another significantly modulated group of genes was linked to the metabolism of arachidonic acid included gluthathione peroxidase 6 and several microsomal monooxygenases.Genes involved in tissue remodeling and fibrosis were also affected: adiponectin, erythropoetin, hexokinase, hypoxia-inducible factor 3α, renin, ACE were upregulated, NF kB transcription factor was activated, and Kim1, uric acid transporter (URAT1) and xanthine dehydrogenase were downregulated. Significant changes were also found among cancer related gene networks (including p21 and IGF2), consistent with reports showing that GPR4 influences tumor growth and angiogenesis.

Conclusions: In summary, the analysis of the kidney transcriptome of GPR4-/- vs. +/+ suggests that GPR4 may mediate pH dependent regulation of genes involved in salt and volume homeostasis, cancerous transformation, and tissue remodeling and fibrosis.

FR-PO083

Basolateral P2X Receptors Trigger a Marked Alkalinization of Mouse Thick Ascending Limb Pauline I.A. De Bruijn, Thomas Pudlarz, Rita D. Marques, Helle A. Praetorius, Jens G. Leipziger. *Department of Biomedicine, Aarhus University, Aarhus, Denmark.*

Background: Extracellular ATP is an important regulator of renal tubular transport. Recently, we found that basolateral ATP markedly inhibits NaCl absorption in mouse medullary thick ascending limb (mTAL) via a P2X receptor. However, the underlying mechanism of this ATP-dependent transport inhibition in mTAL remains unclear.

Methods: In this study, we investigated basolateral ATP-induced alterations of pH_i in single perfused mouse mTALs using the pH indicator dye BCECF.

Results: Interestingly, basolateral ATP (100 μM) caused a prominent and reversible alkalinization of mTAL, with an average pH_i increase of 0.14 ± 0.01 (n=12). This effect was completely abolished in presence of the P2X receptor antagonist oxidized-ATP (50 μM). Typically, G-protein coupled receptors that trigger an increase of $[Ca^{2+}]_i$ cause a significant acidification of tubular epithelial cells. This was also observed in this study, when $P2Y_2$ receptors were stimulated with 100 μM UTP. The pH_i decrease was 0.04 ± 0.01 (n=6). When the CaSR was stimulated with 5 mM Ca^{2+}, a similar acidification was observed.

Conclusions: This study describes the surprising finding of a basolateral P2X receptor-triggered alkalinization in isolated mouse mTAL. These data may provide the basis to understand the signaling mechanism responsible for the pronounced ATP-induced transport-inhibition in mouse mTAL.

FR-PO084

Aurora Kinase A (AURKA) Regulates the Vacuolar H^+-ATPase (V-ATPase) in Human Kidney Carcinoma Cells via a Subunit Phosphorylation Mohammad M. Al-bataineh, Rodrigo Alzamora, Fan Gong, Allison L. Marciszyn, Nuria M. Pastor-Soler. *Renal-Electrolyte Division, Department of Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA.*

Background: The V-ATPase mediates ATP-driven transport of H^+ and is present at the apical membrane of some kidney proton secreting cells. The V-ATPase has been implicated in the process of metastasis. Phosphorylation of the V-ATPase A subunit at S175 is important for PKA-mediated V-ATPase activity in intercalated cells. We hypothesized that AURKA, a kinase that when overexpressed leads to aggressive carcinomas, regulates the V-ATPase in human kidney carcinoma cells (Caki2) by phosphorylating S175.

Methods: In vitro and in vivo phosphorylation assays of the V-ATPase WT and S175AA subunits by AURKA were performed. Wound healing assays of Caki2 cells were performed in the presence/absence of an AURKA activator. V-ATPase distribution was examined by immunofluroescence labeling.

Results: AURKA is abnormally expressed in the cytoplasm of Caki2 cells. AURKA phosphorylates the V-ATPase A subunit at S175 in vitro. AURKA activation increased WT A subunit phosphorylation in Caki2 cells, but failed to increase phosphorylation levels of the S175A mutant. Immunoprecipitation assays of Caki2 cells transfected with A subunit constructs were performed followed by immunoblots for anti-phospho-S175. Higher levels of phospho-S175 were detected from Caki2 cells transfected with WT A subunit and treated with an AURKA activator, compared to untreated cells, and compared to cells expressing the S175A mutant. Immunofluorescence labeling of Caki2 cells revealed that the AURKA activator induced a more marked V-ATPase membrane accumulation in cell projections after wounding compared to untreated cells. Furthermore, AURKA activation enhanced the rate wound healing in Caki2 cells compared to untreated cells.

Conclusions: Overexpressed cytoplasmic AURKA in kidney carcinoma cells phosphorylates a key V-ATPase residue that induces V-ATPase membrane accumulation. The AURKA-mediated V-ATPase regulation may have a role in the metastatic potential of kidney carcinomas and may represent a potential therapeutic target (supported by NIH/NIDDK).

FR-PO085

Hypoxia-Inducible Factor (HIF)-3α Is a HIF-1 Target Gene and Counteracts Migration of Proximal Tubular Cells in Hypoxia Tetsuhiro Tanaka,[1] Kumi Shoji,[2] Junna Yamaguchi,[2] Masaomi Nangaku.[2] *[1]Division for Health Service Promotion, University of Tokyo, Tokyo, Japan; [2]Division of Nephrology and Endocrinology, University of Tokyo School of Medicine, Tokyo, Japan.*

Background: Tubulointerstitial hypoxia is a common mediator in progressive renal disease. The expression of two major isoforms of HIF-α, HIF-1α and HIF-2α, is determined by the posttranslational escape from prolyl hydroxylation and proteasomal degradation, and they display preferential spatial distribution in the tubular (HIF-1α) and interstitial (HIF-2α) compartments of the kidney. On the other hand, the expression of the HIF-3α gene seems to undergo transcriptional regulation, and the spatial distribution as well as the functional role of HIF-3 in the kidney has not been investigated in depth.

Methods: mRNA of HIF-3α splicing variants was quantified by real-time PCR. Localization of HIF-3α protein was immunohistochemically characterized in kidneys subjected to experimental infarction. Hypoxia-responsive enhancer in the HIF-3α promoter was identified by luciferase reporter assays and chromatin immunoprecipitation (ChIP) analyses. Migration of tubular epithelial cells was evaluated by scratch assays.

Results: Out of multiple splicing variants of mouse HIF-3α mRNA, the expression of splicing variant 2 (sv2) and the inhibitory PAS domain protein (IPAS) was observed in mouse cortical tubular cells (MCT), in a hypoxia-inducible manner. In vivo, systemic hypoxia in mice led to 2.7±0.4 and 23.0±9.3 fold increases in renal HIF-3α sv2 and IPAS mRNA, respectively. Immunohistochemical analysis of the infarcted kidney identified immunoreactive HIF-3α protein in HIF-1α- positive, hypoxic tubules. Promoter analysis of the mouse HIF-3α gene identified a novel hypoxia-responsive element at 709 nucleotides upstream of the IPAS translational start site. ChIP assays confirmed recruitment of HIF-1α to the identified enhancer. Functionally, stable overexpression of HIF-3α in human proximal tubular cells (HK-2) resulted in suppression of cell migration under hypoxia.

Conclusions: Results of these studies signify the hypoxic, HIF-1-mediated induction of HIF-3α mRNA and suggest a possible involvement of HIF-3 in the pathogenesis of hypoxic renal disorders.

Indoxyl Sulfate Induces Cbp/p300-Interacting Transactivator, with Glu/Asp-Rich Carboxy-Terminal Domain, 2 (CITED2), via the Mitogen-Activated Protein Kinase Cascade and Impairs Hypoxia Response of Tubular Epithelial Cells Tetsuhiro Tanaka,[1] Junna Yamaguchi,[2] Masaomi Nangaku.[2] *[1]Division for Health Service Promotion, University of Tokyo, Tokyo, Japan; [2]Division of Nephrology and Endocrinology, University of Tokyo School of Medicine, Tokyo, Japan.*

Background: Chronic hypoxia in the tubulointerstitium serves as a final common pathway in progressive renal disease. Hypoxia-inducible factor (HIF)-1α is expressed in the ischemic tubular epithelial cells, but the functional operation of HIF-1 may be influenced in a CKD milieu, and we hypothesized that indoxyl sulfate (IS), a representative uremic toxin, might impair cellular hypoxia response by HIF-1.

Methods: In human proximal tubular cells (HK-2), the expression of HIF-1α, CITED2 and the hypoxic induction of HIF-1-target genes were measured by immunoblotting and real-time PCR. Binding of HIF-1 to the target gene promoter was evaluated by chromatin immunoprecipitation (ChIP). Association of the cofactor p300 with HIF-1α was assessed by mammalian two-hybrid assays. mRNA stability of CITED2 was measured by actinomycin D treatment. The role of MAP kinase pathways was evaluated by using specific inhibitors.

Results: IS reduced the hypoxic induction of HIF-1-target gene mRNA and protein. This effect was not accompanied by a parallel quantitative change in the HIF-1α protein, but was associated with the functional impairment of the HIF-1α C-terminal transactivator domain (CTAD). Out of candidate factors which impede the recruitment of transcriptional cofactors to the HIF-1αCTAD, CITED2 protein was markedly upregulated by IS. The induction of CITED2 was mediated by posttranscriptional mRNA stabilization, which was blunted by treatment with an inhibitor of extracellular signal-regulated kinase (ERK)1/2, U0126. A series of luciferase assays using various CITED2 mRNA fragments as a synthetic 3'untranslated region (3'UTR) of the luciferase gene revealed that the entire coding region of CITED2 was required for the IS-mediated mRNA stabilization.

Conclusions: Results of these studies uncover a novel role of IS in modulating the transcriptional response by HIF-1, which is mediated through activation of the MAP kinase signaling and stabilization of CITED2 mRNA.

Funding: Private Foundation Support, Government Support - Non-U.S.

FR-PO087

Dipeptidyl Peptidase (DPP) IV Inhibitor Attenuates Kidney Injury in Rat Remnant Kidney Shin-young Ahn,[1] Sejoong Kim,[1] Ho Jun Chin,[1] Kwon Wook Joo,[2] Dong Wan Chae,[1] Ki Young Na.[1] *[1]Department of Internal Medicine, Seoul National University Bundang Hospital, Seongnam, Gyeonggi-do, Republic of Korea; [2]Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: DPP IV inhibitor has been reported to reduce renal damage in streptozotocin induced diabetic rat. Forkhead box O (FoxO) transcriptional factors regulate glucose metabolism, cell cycle, and detoxification of reactive oxygen species. The aim of this study was to investigate whether DPP IV inhibitor, sitagliptin, could attenuate kidney injury and to evaluate the status of FoxO in the rat remnant kidney.

Methods: After a subtotal (5/6) nephrectomy (Nx), rats were randomly assigned to control or treatment group. Rats in treatment group received food mixed with 200mg/kg/day of sitagliptin for 8 weeks. We measured physiological data, evaluated histological renal injury, performed immunohistochemical staining with ED-1, and assessed apoptosis via TUNEL assay. We examined the expression level of glucagon-like peptide-1 receptor (GLP-1R) and the phosphorylation status of FoxO3a.

Results: Sitagliptin ameliorated renal dysfunction (sCr and CrCl, Nx vs Nx + sitagliptin: 0.9±0.03 vs 0.7±0.07 mg/dl, p=0.021 & 0.3±0.01 vs 0.4±0.04 ml/min/100g, p=0.037). It also attenuated the extent of glomerulosclerosis (score: 3.2±0.6 vs 1.9±0.8, p=0.004) and tubulointerstitial injury (score: 2.7±0.5 vs 1.9±0.6, p=0.019). GLP-1R expression was increased (p=0.016) and the level of phosphorylated FoxO3a was decreased in the treatment group (p=0.013). Consequently, the expression of catalase, anti-oxidant, was increased (p=0.047), the number of apoptotic cells were reduced (absolute No.: 57.4±12.9 vs 17.6±4.6, p<0.001), and the expression levels of cleaved caspase-3, -9 and Bax were also decreased in this group (p=0.009, 0.016, & 0.009 respectively). As well the number of ED-1 positive cells was decreased (p=0.003) and the TGF-ß expression tended to decrease but it was statistically insignificant (p=0.172).

Conclusions: In rat remnant kidneys, DPP IV inhibitor increased the expression of GLP-1R and attenuated kidney injury by anti-oxidative, anti-apoptotic, and anti-inflammatory action through FoxO3a pathway.

FR-PO088

Regulation of Tubule Cell Nrf2 Phosphorylation by Diabetes and High Protein Concentrations Michelle T. Barati, Susan M. Isaacs, Jason R. Parks, Abuhusnain S. Khundmiri, Jon B. Klein. *Nephrology, University of Louisville, Louisville, KY.*

Background: Tubule cell dysfunction is significant to diabetic nephropathy pathogenesis. Tubule cell exposure to high glucose and protein concentrations in diabetes increases reactive oxygen species (ROS). Activation of nuclear factor erythroid-derived 2-related factor 2 (Nrf2) is a compensatory mechanism to alleviate oxidative stress, accomplished in part by transcriptional induction of enzymes which synthesize glutathione, and NAD(P) dehydrogenase, quinone-1 (NQO1). Activated Nrf2 undergoes Ser-40 phosphorylation and nuclear translocation and regulation of this process by diabetes specifically in renal tubule cells, is not defined. This study addressed the hypothesis that Nrf2 phosphorylation would be altered in tubules of diabetic mice and proximal tubule (PT) cells exposed to high protein concentrations, mimicking proteinuria, conditions known to induce oxidative stress.

Methods: Phospho-Ser-40 Nrf2 (P-Nrf2) was analyzed by immunohistochemistry of kidney sections from 3 and 7 months old OVE26 diabetic and FVB control mice, followed by quantification of staining in cortical regions. For *in vitro* studies, human PT cells (HK2) were treated with 1mg/ml human serum albumin (HSA). Total, cytosol, and nuclear extracts were analyzed for Nrf2, P-Nrf2, and the Nrf2 target NQO1.

Results: P-Nrf2 was decreased in cortical tubules of 7 month old mice in both groups, compared to 3 month old mice. Furthermore, cortical tubules of 7 month old diabetic mice had >50% less nuclear P-Nrf2 compared to age-matched non-diabetic mice. Exposure of HK2 cells to HSA increased P-Nrf2, its nuclear translocation, and NQO1 expression, demonstrating Nrf2 activation.

Conclusions: Decreased Nrf2 phosphorylation in cortical tubules of older mice suggests dysregulation of this compensatory pathway with age and further attenuation with diabetes may exacerbate oxidative stress. Activation of Nrf2 and induction of NQO1 expression in HK2 cells following exposure to high protein concentrations suggests that the diabetic milieu alters tubule cell compensatory responses to known inducers of oxidative stress, such as proteinuria.

Signaling Downstream of p38 MAPK Is Channeled towards HSPB1 and HSPB5 Dimers in Podocytes and Mesangial Cells Ruma Pengal,[1] Adam J. Guess,[1] Rainer Benndorf,[1,2] William E. Smoyer.[1,2] *[1]Clinical & Translational Research, The Research Institute at Nationwide Childrens Hospital, Columbus, OH; [2]Department of Pediatrics, The Ohio State University, Columbus, OH.*

Background: Cells respond to unfavorable conditions with a complex signaling pattern that constitutes the stress response. Activation of p38 MAPK signaling is part of this stress response, and is transduced downstream largely via the protein kinase MK2. MK2 itself can phosphorylate ~25 known effector molecules, including the small heat shock proteins (sHSP) HSPB1 and HSPB5. In nephrotic syndrome (NS), increased p38 MAPK signaling in podocytes was reported to be associated with injury, whereas its inhibition protected cells from injury and also ameliorated proteinuria in animal models. However, the molecular pathways downstream of MK2 that are involved in cell injury and protection are not understood.

Methods: *In vitro* cultured podocytes and mesangial cells were exposed to various stress conditions (osmotic, oxidative and metal toxicant stress) relevant to kidney physiology. Activation of p38 MAPK→MK2 signaling was determined via phosphorylation of MK2 substrates, including HSPB1, HSPB5 and others. To determine the intracellular spatial distribution of p38 MAPK→MK2 signaling, the subcellular distribution of phosphorylated vs. total HSPB1 was determined by immunofluorescence microscopy.

Results: The applied stress treatments greatly activated p38 MAPK→MK2 signaling in both podocytes and mesangial cells. Surprisingly, the signal was transduced primarily towards HSPB1 and covalently-linked HSPB5 dimers (a novel species of this sHSP), while

other tested MK2 substrates were not notably phosphorylated in response to these stress treatments. In podocytes, phosphorylated HSPB1 appeared enriched in the perinuclear space, whereas total HSPB1 was evenly distributed throughout the cytoplasm.

Conclusions: Activation of p38 MAPK→MK2 signaling in podocytes and mesangial cells is channeled primarily towards HSPB1 and HSPB5 dimers, rather than other MK2 substrates. This suggests that phosphorylation of HSPB1 and/or HSPB5 dimers may play a pathophysiologic role in cell injury in NS.

FR-PO090

The Molecular Basis of the Renal and Vascular Consequences of Uremia

Sachin Jhawar,[1] Jiri Zavadil,[2] Jerome Lowenstein.[1] *[1]Medicine, NYU Medical Center, New York, NY; [2]Pathology, NYU Medical Center, New York, NY.*

Background: Chronic renal failure is characterized by progressive renal scarring and accelerated cardiovascular disease. In animal models, this has been attributed to non-dialyzable uremic toxins – small, protein-bound molecules normally secreted via Organic Anion Transporters (OATs) in the proximal renal tubule rather than filtered at the glomerulus. The best studied of these is indoxyl sulfate (IS).

Methods: We examined global gene expression in cultured normal human renal tubular cells (Innovative BioTherapies) incubated with control plasma (n=5) or pre- and post-dialysis uremic plasma (n=10). After 24 hours of exposure, total cellular RNA was extracted and analyzed with Affymetrix cDNA microarrays.

Results: Incubation with uremic plasma significantly altered expression of 2016 genes. The expression of 537 genes normalized in post-dialysis plasma, suggesting removal of low molecular weight uremic toxins by dialysis. The expression of the majority of dysregulated genes (1479) was not normalized in post-dialysis plasma. These likely represent the effects of substances such as IS, not effectively removed by dialysis (protein-bound uremic toxins). Addition of IS to control plasma simulated most effects (81.1%) of uremic plasma; the addition of probenecid, an OAT inhibitor, to uremic plasma reversed most changes in gene expression. Analysis of molecular programs with the NIH-curated DAVID database, confirmed by Gene Set Enrichment Analysis (GSEA), revealed patterns common to IS-treated control plasma, pre-dialysis, and post-dialysis uremic plasma; these included increased cell turnover, pro-inflammatory, and pro-fibrotic molecular programs, particularly effectors and targets of the TGF-β pathway.

Conclusions: Changes in the gene expression profile were observed in human renal cortical cells cultured with plasma from uremic patients: most were not corrected by dialysis. The emergent patterns confirm that inflammatory and pro-fibrotic programs are active and there is increased cellular proliferation. These findings suggest an important role of non-dialyzable, protein-bound uremic toxins in the pathogenesis of renal scarring and uremic vasculopathy.

Erythropoietin Activates NAD(P)H Oxidase via Erythropoietin Receptor and Beta Common Receptor on Vascular Endothelial Cells

Chieko Ihoriya, Minoru Satoh, Hiroyuki Kadoya, Kengo Kidokoro, Yuko Nishi, Tamaki Sasaki, Naoki Kashihara. *Nephrology and Hypertension, Kawasaki Medical School, Kurashiki, Okayama, Japan.*

Background: Recent clinical trials have demonstrated that erythropoietin (EPO) is not always beneficial in preventing cardiovascular diseases. Nevertheless, most of experimental studies performed in animal models, higher doses are usually used, indicated that EPO exerts vascular-protective activities through non-hematopoietic actions. Thus, it is still controversial whether clinically applicable doses of EPO are beneficial for cardiovascular protection. There are two putative receptors for EPO. One is the homo-dimeric EPO receptor (EPO-R) responsible for erythropoiesis. Another is a hetero-dimeric receptor that consists of the EPO-R and the beta common receptor (bcR). We investigated whether administration of therapeutic doses of EPO could accentuate oxidative stress and modulate endothelial function.

Methods: In-vivo experiments, normal male Sprague–Dawley (SD) rats were treated with either EPO (20 IU•kg-1•week-1 subcutaneously) 3 times a week or darbepoetin (D-EPO; 0.1 μg•kg-1•week-1 subcutaneously) once a week for 4 weeks. Endothelial-dependent vasodilatory response, NADPH oxidase activity, and gene expression of intercellular adhesion molecule-1 (ICAM-1) and monocyte chemoattractant protein-1 (MCP-1) were assessed. Human umbilical vein endothelial cells were stimulated with EPO to assess NADPH oxidase activity. Possible involvement of either EPO-R or bcR in signal transduction of EPO was identified in small interfering RNA knockdown experiments.

Results: The acetylcholine-dependent vasodilatory response was impaired significantly in both EPO and D-EPO treatment groups. NAD(P)H oxidase activity and aortic gene expression of ICAM-1 and MCP-1 augmented in both groups. We confirmed EPO-mediated superoxide production and extracellular signal-regulated kinase (ERK) activation in vitro. Both EPO-R and bcR were essential for ERK activation by EPO in endothelial cells.

Conclusions: Administration of EPO and D-EPO increased oxidative stress and impaired endothelial function in normal rats and in human endothelial cells.

IL-6 Increases Production of Galactose-Deficient IgA1 by IgA1-Secreting Cells from IgA Nephropathy Patients through STAT3 Signaling Pathways

Koshi Yamada,[1,2] Zhi Qiang Huang,[1] Hitoshi Suzuki,[2] Milan Raska,[1,3] Zina Moldoveanu,[1] Yusuke Suzuki,[2] Bruce A. Julian,[1] Robert J. Wyatt,[4] Yasuhiko Tomino,[2] Jiri F. Mestecky,[1] Ali G. Gharavi,[5] Jan Novak.[1] *[1]University of Alabama at Birmingham, Birmingham, AL; [2]Juntendo University, Tokyo, Japan; [3]Palacky University, Olomouc, Czech Republic; [4]University of Tennessee, Memphis, TN; [5]Columbia University, New York, NY.*

Background: IL-6 is a B-cell differentiation factor that regulates IgA1 production through STAT3 and STAT1. We have shown that IL-6 increases production of galactose-deficient IgA1 (Gd-IgA1) in IgA1-secreting cells from IgA nephropathy (IgAN) patients but not in those from healthy controls (HC). Here, we analyzed the regulatory pathways involved in IL-6-induced production of Gd-IgA1 in IgAN.

Methods: EBV-immortalized IgA1-secreting cells derived from the circulation of IgAN patients and HC were stimulated with IL-6. Levels of IgA1 and Gd-IgA1 were determined by ELISA. STAT3 and STAT1 phosphorylation was analyzed using SDS-PAGE and Western blotting and confirmed by using specific inhibitors of signaling.

Results: IL-6 increased production of IgA1 by 45% in cells from HC and by 15% in cells from IgAN. Moreover, IL-6 increased the production of Gd-IgA1 in the cells only from IgAN patients, by 33%. Phospho-STAT3 was up-regulated by IL-6 in a dose-dependent manner, and to a higher degree (2.5 fold) in the cells from IgAN patients compared to those from HC. Phospho-STAT1 was down-regulated by IL-6 in IgAN and HC cells. Inhibitors of STAT signaling prevented IL-6-induced increase in production of IgA1 and Gd-IgA1 in a dose-dependent manner. One of the inhibitors of STAT signaling blocked IL-6-induced increase of IgA1 by up to 112% in HC cells and up to 68% in IgAN cells, and reduced production of Gd-IgA1 in IgAN cells by up to 93%. This blockade was associated with down-regulation of STAT3 phosphorylation.

Conclusions: IL-6 increased production of Gd-IgA1 in IgAN through STAT3 activation. Thus, blockade of STAT3 signaling may be considered as a possible future therapeutical approach in IgAN.

Signaling Pathways that Stimulate Production of Galactose-Deficient IgA1 in Tonsillar Cells from Patients with IgA Nephropathy

Koshi Yamada,[1,2] Hitoshi Suzuki,[2] Yusuke Suzuki,[2] Zhi Qiang Huang,[1] Milan Raska,[1,3] Zina Moldoveanu,[1] Bruce A. Julian,[1] Yasuhiko Tomino,[2] Jan Novak.[1] *[1]University of Alabama at Birmingham, Birmingham, AL; [2]Juntendo University, Tokyo, Japan; [3]Palacky University, Olomouc, Czech Republic.*

Background: IgA1-producing cells from tonsils of IgA nephropathy (IgAN) patients secrete galactose-deficient IgA1 (Gd-IgA1), one of the key factors in the pathogenesis of this disease. The pathways involved in the production of Gd-IgA1 are not well understood. Here, we characterized cytokine-induced signaling pathways leading to overproduction of Gd-IgA1 in tonsillar cells.

Methods: We assessed the effects IL-6 on IgA1 production and *O*-glycosylation using EBV-immortalized IgA1-secreting cell lines derived from tonsils (IgAN-TC) and the peripheral blood (IgAN-PB) of IgAN patients, tonsils of controls with sleep apnea syndrome (HC-TC), and the peripheral blood (HC-PB) of healthy controls. STAT3 and STAT1 phosphorylation was determined by SDS-PAGE and Western blotting and validated by using specific inhibitors of signaling.

Results: IL-6 increased production of Gd-IgA1 in IgAN-TC and IgAN-PB, but not in HC-PB or HC-TC. This effect was mediated by STAT3 signaling. STAT3 phosphorylation was up-regulated and that of STAT1 down-regulated by IL-6 in a dose-dependent manner, and to a higher degree in IgAN-TC compared to HC-TC and HC-PB. Inhibitors of STAT3 signaling prevented, in a dose-dependent manner, IL-6-induced increase in production of IgA1 in all cell lines and that of Gd-IgA1 in IgAN-TC and IgAN-PB. One inhibitor that blocked IL-6-induced phosphorylation of STAT3 in all cell lines up-regulated phosphorylation of STAT1 in cells from the circulation but not in cells from tonsils, suggesting differences between IgAN-TC and IgAN-PB.

Conclusions: IL-6 enhances production of Gd-IgA1 in IgA1-secreting cells from tonsils and the circulation of patients with IgAN. This process is mediated by STAT3/STAT1 signaling and inhibitors of the signaling pathways may be considered for future therapeutic approaches. These findings may be relevant to the consideration of tonsillectomy in some patients with IgAN.

Paricalcitol Attenuates 4-Hydroxy-2-Hexenal-Induced Inflammation and Fibrosis in Human Renal Proximal Tubular Epithelial Cells

Chang Seong Kim,[1] Joon Seok Choi,[1] Eun Hui Bae,[1] Seong Kwon Ma,[1] Soo Wan Kim.[1] *[1]Department of Internal Medicine, Chonnam National University Hospital, Gwnagju, Republic of Korea; [2]Department of Physiology, Chonnam National University Hospital, Gwnagju, Republic of Korea.*

Background: 4-hydroxy-2-hexenal (HHE), which is the aldehyde product of lipid peroxidation, might be responsible for the pathogenesis of renal mitochondrial dysfunction and apoptosis. Recently, paricalcitol (19-nor-1, 25-dihydroxyvitamin D2) is renoprotective in various experimental nephropathy models through its anti-inflammatory and anti-fibrotic

actions. We investigated the effects of paricalcitol on inflammation and fibrosis after HHE-induced renal tubular epithelial cell injury.

Methods: To investigate the underlying molecular mechanisms of HHE-induced tubule cell injury, we examined the nuclear factor-κB, mitogen-activated protein kinase (MAPK), β-catenin signaling, and the expression of the iNOS, COX-2, CTGF and fibronectin in human proximal tubular epithelial (HK-2) cells by semiquantitative immunoblotting.

Results: In HHE-treated HK-2 cells, paricalcitol attenuated the increases of the expression of p38 MAPK, extracellular signal-regulated kinase (ERK) and c-Jun N-terminal kinase (JNK), and also prevented the activation of nuclear factor-κB. The expression of the inflammatory protein iNOS and COX-2 were attenuated by paricalcitol treatment. In addition, HHE increased the expression of the TGF-β1 and fibrotic protein such as fibronectin and CTGF, which were attenuated by the treatment of paricalcitol. Treatment of HHE results in the activation of β-catenin signaling, whereas paricalcitol reduced the expression of β-catenin in HHE-treated cells. Inhibitor of β-catenin (ICG-001) decreased the expression of TGF-β1 and attenuated HHE-induced fibrosis.

Conclusions: Paricalcitol appears to attenuate HHE-induced renal tubular cell injury by suppression of inflammation and fibrosis through inhibition of the nuclear factor-κB, MAPK and β-catenin signaling pathways.

Regulation of Fibronectin in Diabetes: Phosphorylation of CREB Induces mRNA Expression and Promoter Activity of Fibronectin in Renal Proximal Tubular Cells Samy L. Habib,[1,2] Sitai Liang,[2] Shaza Tizani,[2] Anthony J. Valente.[3] *[1]Geriatric Research, Education, and Clinical Center, South Texas Veterans Healthcare System, San Antonio, TX; [2]Cellular and Structural Biology, University of Texas Health Science Center, San Antonio, TX; [3]Medicine, University of Texas Health Science Center, San Antonio, TX.*

Background: Diabetic nephropathy is characterized by excessive deposition of extracellular matrix in the kidney, leading to tubulointerstitial fibrosis. The rate of deterioration of kidney function is highly correlated with the degree of tubular fibrosis and accumulation of cell matrix proteins. The mechanisms of renal cell matrix expansion in the diabetic milieu are incompletely characterized.

Methods: Mouse proximal tubular cells were grown in normal glucose (NG, 5mM) or treated with high glucose (HG, 25mM) for 24h. Nuclear and cytoplasmic proteins, and RNA from cells treated with HG or HG+rapamycin were extracted. Cells were infected with *Ad-CREB* or transfected with siRNA against CREB then treated with HG or HG+rapamycin.

Results: HG induced CREB phosphorylation and led to increased expression of fibronectin mRNA, suggesting transcriptional regulation. We have cloned a section of the fibronectin promoter region and identified two potential putative CREB binding sites. Using EMSA assay, we found that HG significantly enhanced the binding of CREB in the cell nuclear extracts to the putative fibronectin-CREB sites. Further, HG significantly increased the promoter activity of fibronectin while rapamycin reversed HG effects to NG levels. In addition, down-regulation of CREB by siRNA or expression of dominant negative CREB in HG-treated cells significantly reduced fibronectin mRNA and promoter activity to the NG levels.

Conclusions: We have identified novel putative CREB binding sites in the fibronectin promoter that regulate the transcriptional activity of fibronectin. Downregulation of CREB by siRNA or Ad-CREB resulted in a significant decrease in cell matrix protein accumulation in cells exposed to HG. These data identify CREB, as a major transcription factor involved in the regulation of cell matrix protein in diabetic patients, and a potential therapeutic target.

Angiotensin II (AngII) Activation of NF-kB Is Mediated by beta-Arrestin Dependent AT1a Receptor (AT1aR) Internalization in Rat Aorta Vascular Smooth Muscle Cells (RASMC) Thomas Morinelli,[1] Mi-hye Lee,[1] Ryan T. Kendall,[1] Louis Luttrell,[1,2] Linda Walker,[1] Michael E. Ullian.[1,2] *[1]Medical University of South Carolina, Charleston, SC; [2]Ralph H. Johnson VA Hospital, Charleston, SC; [3]Medical University of South Carolina.*

Background: AngII, a key hormone in reno-vascular homeostasis, also contributes to renal and blood vessel inflammation and fibrosis. Activation of the AngII $AT_{1A}R$ in RASMC increases synthesis of the pro-inflammatory enzyme cyclooxygenase 2 (COX-2). We have previously shown that nuclear localization of internalized $AT_{1A}R$ activates transcription of the gene for COX-2, PTGS-2. Others have suggested that AngII stimulation of COX-2 protein synthesis is mediated by NF-κB. The purpose of the present study was to examine the interrelationship between $AT_{1A}R$, β-arrestin and NF-κB in the ability of AngII to increase COX-2 protein synthesis in RASMC.

Methods: We utilized RASMC, inhibitors of the NF-κB pathway, β-arrestin knockdown, radioligand binding, immunoblotting and immunofluorescence to characterize the roles of $AT_{1A}R$ internalization, NF-κB activation and β-arrestins in AngII-induced COX-2 synthesis.

Results: The NF-κB inhibitors Ro 106-9920 or parthenolide, agents that inhibit the initial steps of NF-κB activation, blocked AngII-induced p65 NF-κB nuclear localization, COX-2 protein expression, β-arrestin recruitment to the $AT_{1a}R$ and $AT_{1A}R$ internalization, without inhibiting AngII-induced p42/44 ERK activation. The AT1R biased (non-G protein-mediated) agonist SII-AngII, also promoted p65 NF-κB nuclear localization. Curcumin, an inhibitor of NF-κB induced transcription, blocked AngII-induced COX-2 protein expression but without altering $AT_{1A}R$ internalization, AngII-induced p65 NF-κB nuclear localization or p42/44 ERK activation. SiRNA-induced knockdown of β-arrestin 1 and 2 inhibited AngII-induced p65 NF-κB nuclear localization.

Conclusions: Therefore, in vascular smooth muscle cells, internalization of the activated $AT_{1A}R$ mediated by β-arrestins activates the NF-κB pathway, producing nuclear localization of the transcription factor and initiation of COX-2 protein synthesis; thereby linking the internalization of the receptor with the NF-κB pathway.

Blockade of Smad Signaling by 3'-Deoxyadenosine: A Mechanism for the Anti-Fibrotic Potential Liubao Gu, Hisashi Johno, Shotaro Nakajima, Hironori Kato, Masanori Kitamura. *Department of Molecular Signaling, University of Yamanashi, Chuo, Yamanashi, Japan.*

Background: *Cordyceps militaris* has been used in Eastern countries for the treatment of various diseases including chronic kidney diseases (renal fibrosis). However, there are no reports that identified its active entities and molecular mechanisms underlying its therapeutic usefulness. 3'-Deoxyadenosine is a major nucleoside isolated from *Cordyceps militaris*. In the present report, we investigated whether and how 3'-deoxyadenosine interferes with fibrogenic processes in the kidney.

Methods: Effects of 3'-deoxyadenosine on the expression of collagens and activity of Smad signaling were tested *in vitro* and *in vivo*. Northern and Western blot analyses, reporter assays and immunohistochemical analyses were utilized for this purpose. Unilateral ureteral obstruction (UUO) in mice was used as a model of renal fibrosis.

Results: 3'-Deoxyadenosine suppressed expression of collagens induced by TGF-β1 and BMP-4 in renal tubular cells. This suppression occurred at the transcriptional level and was correlated with blunted activation of the CAGA box and the BMP-responsive element. The suppressive effects were mediated by adenosine transporter and A_3 adenosine receptor, but not A_1/A_2 adenosine receptor. 3'-Deoxyadenosine reduced levels of both phosphorylated and total Smad proteins (Smad1, 2, 3). It was mainly ascribed to transcriptional suppression, but not enhanced protein degradation or eIF2α-mediated translational suppression. Consistently, *in vivo* administration with 3'-deoxyadenosine reduced the levels of phosphorylated and total Smad proteins as well as the levels of Smad mRNAs in the kidney subjected to UUO. It was associated with blunted induction of type I collagen and α-smooth muscle actin, the markers for fibrogenesis and downstream targets of Smad pathways.

Conclusions: Our data suggest that 3'-deoxyadenosine interferes with the TGF-β and BMP signaling via down-regulation of Smads, which may underlie the anti-fibrotic effect of this agent. 3'-Deoxyadenosine may be useful for therapeutic intervention in TGF-β-related fibrotic disorders.

The miRNA Landscape of a Murine Inner Medullary Collecting Duct Cell Mollie E. Jacobs,[1] Amanda Welch,[2,3] Charles S. Wingo,[2,3] Brian D. Cain.[1] *[1]Biochemistry and Molecular Biology, University of Florida, Gainesville, FL; [2]Medicine, University of Florida, Gainesville, FL; [3]North Florida/South Georgia VA Medical Center, Gainesville, FL.*

Background: MicroRNAs (miRNAs) are a family of small (~22 nt) noncoding RNAs. They have been shown to play a crucial role in post-transcriptional gene regulation by blocking protein translation or inducing degradation of specifically targeted messenger RNAs. Dysregulation of miRNA levels has been shown to be involved in the pathogenesis of many diseases including renal fibrosis, diabetic nephropathy, and hypertension-related renal disease. However, miRNAs also play important roles in the regulation of metabolism in the healthy cell. Aldosterone is the major known steroid hormone responsible for sodium retention in the kidney collecting duct. To date, the role of aldosterone to modulate miRNA expression in a clonal cell line has not been examined. Our working hypothesis is that aldosterone alters the miRNA content in the inner medullary collecting duct which results in increased translation of mRNAs that are involved in sodium reabsorption and urinary acidification.

Methods: To look for miRNAs subject to aldosterone regulation, an miRNA microarray analysis was performed. Murine inner medullary collecting duct cells (mIMCD-3) were plated in transwell inserts to induce polarity. Cells were treated with either 100nM aldosterone or vehicle for 24 hours. Total RNA was extracted using Trizol, and RNA integrity was determined using the Agilent 2100 Bioanalyzer. Ten independently prepared RNA samples, five aldosterone treated samples and five vehicle treated samples, were used in a Toray 3D-Gene miRNA microarray analysis. The microarray chip contained probes for 1080 mature miRNAs.

Results: We identified five miRNAs whose abundance increased significantly with aldosterone treatment and several miRNAs that were down regulated by aldosterone.

Conclusions: These results demonstrate a novel and heretofore unknown mechanism for aldosterone to modulate gene expression. In addition, the results provide a database of those miRNAs that are expressed in mIMCD-3 cells and potential pathways that may be coordinately regulated by aldosterone.

Altered Mitochondrial Homeostasis, p62, and PPARγ and α Contribute to Oxidative Stress-Induced Kidney Injury David M. Small,[1] Nigel C. Bennett,[1] Jeff S. Coombes,[1,2] David W. Johnson,[1,3] Glenda C. Gobe.[1] *[1]Centre for Kidney Disease Research, Sch of Medicine, Univ Queensland; [2]Sch of Human Movement Studies, Univ Queensland; [3]Dpt of Nephrology, PA Hospital, Brisbane, Queensland, Australia.*

Background: Oxidative stress deregulates mitochondrial genes and has a key role in the development of many kidney diseases. Balancing degradation of defective mitochondria with renewal of healthy mitochondria is vital for renal cell health. p62 (indicates faulty mitochondria) and nuclear transcription factors peroxisome proliferator-activated receptor (PPAR) γ and α (oxidative stress-responsive, mitochondrial biogenesis) need investigation. The aim was to investigate mitochondrial homeostasis, p62 and PPARγ and α expression and activation in oxidative stress-induced renal proximal tubular (PT) epithelial injury.

Methods: HK-2 PT cells were treated with hydrogen peroxide (H_2O_2; 0.2, 0.4, 0.6, 0.8, 1.0mM) for 2h and 18h. p62, phospho-PPARγ/PPARγ, PPARα and LC3-II (autophagy) (Western blot; densitometry), and cellular ATP (luciferase-based assay) were analyzed. Mitochondrial biogenesis was quantified (MitoTracker Red; analysis software). PPARγ agonists and antagonists were used to determine protective or cytotoxic effects.

Results: Following 2h H_2O_2 exposure, p-PPARγ/PPARγ, p62 and PPARα decreased ($p<0.05$), along with ATP and MitoTracker Red ($p<0.001$, $p<0.05$, respectively). These results indicate early mitochondrial dysfunction and degradation. PPARγ modulation had no effect. Following 18h H_2O_2 exposure, p62 and LC3-II expression increased ($p<0.05$), p-PPARγ/PPARγ was normal, and ATP and MitoTracker Red remained low ($p<0.001$, $p<0.05$, respectively). Apoptosis increased progressively with H_2O_2 in a concentration and temporal manner. Results suggest mitochondrial biogenesis is impeded by degradation and autophagy resulting in progressive loss of renal cells after oxidative stress.

Conclusions: Oxidative stress promotes mitochondrial destabilisation in HK-2 cells by increasing p62, and perhaps by early loss of PPARγ activation. Failure to remove damaged mitochondria via autophagy, or defective p62, may lead to a spiralling cycle of oxidative stress, with progressive deterioration of tubular function in kidney disease.

Stanniocalcin-1-Mediated Endothelium-to-Epithelium Cross Talk Promotes Kidney Epithelial Cell Survival Luping Huang,[1] Tatiana Belousova,[1] Jie Du,[3] Pumin Zhang,[2] David Sheikh-Hamad.[1] *[1]Medicine, Baylor College of Medicine, Houston, TX; [2]Molecular Physiology and Biophysics, Baylor College of Medicine, Houston, TX; [3]Laboratory of Remodeling-Related Cardiovascular Diseases, Institute of Heart Lung and Blood Vessel Diseases, Beijing, China.*

Background: Stanniocalcin-1 (STC1) is an extracellular signaling protein; it binds to the cell surface, internalized to the mitochondria and diminishes superoxide generation through induction of uncoupling proteins (intracrine signaling). The cellular distribution of STC1 mRNA and protein in the kidney does not parallel; the mRNA is observed in blood vessels, cortical and medullary collecting ducts, and is absent in PT cells; but the protein is detected in blood vessels and along the entire nephron (albeit, at varying levels), suggesting that STC1 is produced by one cell and is picked up by neighboring cells. STC1 Tg mice which display preferential expression of the transgene in endothelial cells are resistant to ischemia/reperfusion kidney injury (KI, 2012); kidney epithelial cells express high levels of UCP2 and produce less superoxide. Therefore, we hypothesized that endothelium-derived STC1 is picked up by neighboring epithelial cells, where it promotes cell survival.

Methods: We generated STC1 shRNA Tg mice that express STC1 siRNA upon removal of floxed reporter stuffer (PGK-driven EGFP), bringing the H1 promoter ahead of the siRNA cassette. Using ultrasound microbubble-mediated delivery of Tie2-Cre to the kidney we knocked down the expression of STC1 in kidney endothelial cells in STC1 shRNA Tg mice (within 4-5 days), but not in scrambled shRNA Tg mice.

Results: This reveled diminished staining for STC1 in epithelial cells of STC1 shRNA Tg kidneys, accompanied by tubular epithelial cell injury [vacuolization, cell sloughing, lower expression of UCP2 and greater generation of superoxide (MitoSox fluorescence)].

Conclusions: These novel observations suggest STC1-mediated endothelium-to-epithelium cross-talk. Endothelium-derived STC1 is picked up by neighboring epithelial cells; where, it drives the expression of UCP2, diminishing superoxide generation - promoting epithelial cell survival.

FR-PO101

Bidirectional Regulation of miR-29c on Inhibiting Renal Fibrosis Chen Yu,[1] Ying Yu,[1] Lunjun Fu,[1] Eugene Chin.[2] *[1]Division of Nephrology, Tongji Hospital, School of Medicine, Tongji University, Shanghai, China; [2]Institute of Health Sciences, Shanghai Institutes for Biological Sciences, Chinese Academy of Sciences& Shanghai Jiao Tong University School of Medicine, Shanghai, China.*

Background: Strong antifibrotic effects of miR-29s have been demonstrated in heart, kidney, and other organs. Leukemia inhibitory factor (LIF) is a pleiotropic glycoprotein belonging to the interleukin-6 family of cytokines. We previously showed that LIF ameliorated the progression of heart and renal fibrosis. The databases of TargetScan, miRBase and miRNA.Org show there is binding site for STAT3, the downstream transcription factor of LIF signaling pathway, in miR-29c promoter region and it is highly conserved among different species. The aim of this study was to explore the role of miR-29cc in LIF anti-renal fibrosis processes.

Methods: Rat renal fibroblast cells (NRK-49F) were used for in vitro study and unilateral ureter obstruction(UUO) rats for in vivo study.

Results: Our results showed that: **1)** LIF inhibited TGF-β and AngII-induced expressions of type 1 collagen (col1) and type 3 collagen (col3) protein and mRNA, in a dose dependent manner, in NRK-49F cells and mice UUO model. **2)** MiR-29c enhanced the expression of LIF and LIFR protein and mRNA, and slightly increased the expression of gp130 (the homo-receptor of LIF) protein and mRNA. **3)** MiR-29c increased phosphorylation of STAT3 on Tyr705 and on Ser727, especially on the former. **4)** Using luciferase assay tests, it was seen that miR-29c down-regulated fluorescence intensities of luciferase reporter containing col1- and col3-3'UTR. **5)** Over-expression miR-29c decreased col1 and col3 expressions in NRK-49F cells, in a dose-dependent manner.

Conclusions: Our data uncovered firstly that miR-29c exerted anti-renal fibrosis effects via bidirectional regulation: on one hand, miR-29c down-played directly the production of collagen; on the other hand, miR-29c enhanced the expression LIF and LIFR, which in turn inhibited TGF-β and AngII-induced production of collagen.

FR-PO102

Connexin43 Hemichannel-Mediated Release of ATP Suppresses AMPK Activation in Renal Tubular Epithelial Cells Yuan Chi, Kun Gao, Hironori Kato, Shotaro Nakajima, Masanori Kitamura, Jian Yao. *Department of Molecular Signaling, University of Yamanashi, Chuo, Yamanashi, Japan.*

Background: ATP/P2 receptor system regulates multiple renal functions. However, the molecular mechanisms underlying ATP release and its actions are still poorly understood. Here we tested the possible involvement of connexin (Cx) hemichannels in ATP release and explored the potential influence of the released ATP on AMP-activated kinase (AMPK), a key regulator of multiple channel activities.

Methods: AMPK activation was evaluated by phosphorylation levels of AMPK at Thr-172. ATP was measured using a luciferin/luciferase bioluminescence assay kit. Cx43 channels was interrupted with various blockers or through specific siRNA. Cell membrane permeability was detected by measurement of the fluorescent intensity of the preloaded calcein.
