Background: Serum uric acid (UA) is commonly elevated in hemodialysis (HD) patients but the implications of high UA in HD pts are unclear. Therefore, we examined whether UA is associated with arterial stiffness (a known predictor of cardiovascular events and mortality in HD patients) using the data from the ongoing Protein intake, Cardiovascular disease and Nutrition in CKD stage V (PICNIC) Study.

Methods: Carotid and femoral pulses were used to measure aortic pulse wave velocity (PWV) with a Sphygmacor PVX device. Measurements were conducted at baseline. PWV at baseline was related to baseline serum UA concentration with linear regressions. Adjustments were made for age, gender, race, vascular access, ESRD duration, intra abdominal fat area (IAFA), fasting insulin, hsCRP and study center.

Results: 119 HD patients who had non-missing data at baseline were included in the analysis. The mean age was 52 ±16 years, 59% were men, 82% were Caucasians and 47% had diabetes. Mean UA was 5.5 ± 1.8 mg/dL. The associations of baseline serum UA with baseline PWV are summarized in the table.

Association of uric acid with pulse wave velocity

	Baseline model, beta[95% CI], p-value
Model 1	
Each SD ↑ in Uric acid (mg/dL)	0.84 [0.27, 1.40], p=0.004
Model 2	
Each SD ↑ in Uric acid (mg/dL)	0.77 [0.17,1.38], p=0.013
Model 3	
Each SD ↑ in Uric acid (mg/dL)	0.84 [0.21, 1.47], p=0.009

Model 1: adjusted for age, gender, race, duration of ESRD, vascular access, and study site. Model 2: adjusted for IAFA in addition to model 1. Model 3: adjusted for fasting insulin and hsCRP in addition to model 2.

Conclusions: Serum uric acid is associated with arterial stiffness in hemodialysis patients. Interventions that target UA might decrease arterial stiffness in dialysis patients.

PUB377

All Cause and Cardiovascular Mortality in Dentate and Edentulous Patients in Hemodialysis: A Prospective Multinational Cohort Study
Suetonia Palmer,[1] Marinella Ruospo,[2] Fabio Pellegrini,[3] Jonathan C. Craig,[4] Jorgen B.A. Hegbrant,[2] Giovanni F.M. Strippoli.[2,3,4] *[1]University of Otago; [2]Diaverum Medical Scientific Office; [3]Mario Negri Sud Consortium; [4]University of Sydney.*

Background: People who require hemodialysis experience high rates of mortality. Dental disease may be associated with death due to inflammation or as an indicator of general health status. We explored whether total teeth loss predicted 12 month mortality (total and cause-specific) mortality in patients on hemodialysis.

Methods: ORAL-D is an ongoing multinational prospective cohort study of consecutive adults receiving hemodialysis in 75 outpatient clinics selected randomly from a collaborative dialysis network in Italy, Hungary, Poland, Argentina, Portugal, France and Spain. A dental surgeon evaluated the presence or absence of teeth during a standardized oral examination. We assessed survival at 12 months using centralized mortality data. We conducted analysis using a Cox regression controlling for age, gender, previous cardiovascular events, income status, clinical performance measures, dialysis prescription and performance indicators, and depressive symptoms.

Results: 4720 hemodialysis patients in participating clinics received a complete dental evaluation and completed follow up. Median follow up was 19.9 (17.0 to 28.0) months. 922 patients were edentulous (20%) and 492 (11%) died during follow up. Complete loss of teeth had uncertain associations with risks of all-cause (HR 1.06 [95% CI, 0.86-1.31]) and cardiovascular mortality (HR 0.90 [95% CI 0.66-1.22]) when adjusted for potentially confounding variables.

Conclusions: Dentate status has uncertain associations with all-cause or cardiovascular mortality in patients on hemodialysis. ORALD will be completed by end of 2013.

PUB378

The Impact of Dialysis Treatment Modality in the Progression of Left Ventricular Hypertrophy in Patients with Chronic Kidney Disease
Maria Eugenia F. Canziani,[1] Jean Carlo Rodriguez Pegas,[2] Adriano Luiz Ammirati.[2] *[1]Nephrology, Federal University of San Paulo, San Paulo, Brazil; [2]Nephrology, Albert Einstein Hospital, San Paulo, Brazil.*

Background: Left ventricular hypertrophy(LVH)is highly prevalent in Chronic Kidney Disease(CKD) and has important clinical impact in this population. Patients on hemodialysis(HD) and peritoneal dialysis(PD) have different cardiovascular risk factors which may influence differently the progression of LVH.

Methods: A retrospective study in which we reviewed the medical records of patients followed in chronic HD and DP programs of the Osvaldo Ramos Foundation, which had at least 2 echocardiograms(*E)* registered from Jan 2006 to Jan 2010. We evaluated demographic, clinical and laboratory. The index of left ventricular mass(LVMI) was calculated by dividing LV mass by height. LVH was defined when LVMI was higher than 50g/m^2(men) and 47g/m^2 (women). The progression of LVH was assessed by LVMI difference between the 2nd and 1st *E* corrected by the time interval between the *E*.

Results: At 79 HD and 43 PD were included. HD patients were more hypertensive, received higher doses of erythropoietin, had lower total cholesterol, phosphorus, iPTH and potassium levels. These patients also had higher albumin and ferritin levels. At baseline *E*, HD patients showed higher diastolic(49,13 ± 5,15 x 46,19 ± 5,02 mm; p= 0,003), systolic diameter(32,76 ± 5,43 x30, 14 ± 4,02 mm; p= 0,006) and LV mass(234 ± 84,49 x 204,51 ± 57,98 g; p= 0,04). The progression of LVH[0,94 (0,07; 5,64) in HD vs. 0,97 (0,03; 3,41) in DP patients, g/m^2/months; p= 0,183], as well as the percentage of patients with LVH progression(49,3 vs. 41,8 % HD vs DP respectively; p= 0,307) were similar in both groups. In HD patients, the progression of LVH was positively related with the dose of erythropoietin(r= 0,452; p= 0,004) and negatively with hemoglobin level(r= -0,321; p= 0,046). In PD was positively associated with ionized calcium(r= 0,484; p= 0,042) and negatively with hemoglobin(r= -0,574; p= 0,013). The multivariate analysis, no variable was asociated with the progression of LVH, both groups.

Conclusions: The treatment modality has not influence the progression of LVH in CKD patients on dialysis.

PUB379

VAP-1 and Renalase in Regard to Diabetes and Cardiovascular Status in Hemodialyzed Patients
Jolanta Malyszko, Jacek S. Malyszko, Ewa Koc-Zorawska, Edyta Zbroch, Michal Mysliwiec. *Nephrology, Medical University, Bialystok, Poland.*

Background: VAP-1 is a copper-containing SSAO (semi-carbazide sensitive amine oxidase) secreted by vascular smooth muscle cells, adipocytes, and endothelial cells with functional monoamine oxidase activity. Renalase, with possible monoamine oxidase activity, which breaks down catecholamines like SSAO, is also expressed in the endothelium as well as in the kidney

The aim of the study was to assess VAP-1 levels and its correlations renalase in 60 hemodialyzed patients.

Methods: VAP-1 and renalase were assessed with commercially available assays.

Results: The mean VAP-1 was significantly higher in HD when compared to the control group (291.01±94.91 ng/mL vs 158.34±56.89 ng/mL, p<0.01) as well as renalase. Diabetic patients had higher serum VAP-1 than non-diabetic. Patients with blood pressure over 140/90 mm Hg had higher VAP-1 levels when compared to patients with lower blood pressure values. Patients with hemoglobin over 10 g/dL had lower VAP-1 than patients with anemia define as hemoglobin less than 10g/dL. No difference in VAP-1 was found between patients with and without coronary artery disease as well as with and without residual renal function. Males had higher VAP-1 levels when compared to females. Patients treated with beta-blockers or calcium channel blockers had higher VAP-1 than non treated.

In univariate analysis, VAP-1 correlated with presence of diabetes (r=0.27, p<0.05), presence of hypertension (r=0.32, p<0.05), use of calcium channel blockers (r=0.30, p<0.05), use of betablockers (r=0.25, p<0.05), ejection fraction (r=-0.38, p<0.01), systolic blood pressure before (r=0.52, p<0.001) and after hemodialysis (r=0.30, p<0.01), weight gain (r=0.41, p<0.01), MCV (r=-0.29, p<0.05). VAP-1 tended to correlate with fibrinogen (r=0.22, p=0.09) and white blood cell count (r=-0.24, p=0.06).In multiple regression analysis VAP-1 was predicted 77% by serum ejection fraction (beta value -0.66, p=0.000668), and fibrinogen (beta value 0.59, p=0.007).

Conclusions: VAP-1, elevated in patients on renal replacement therapy, is predominantly dependent on blood pressure and diabetes, both factors associated with endothelial damage and promoting cardiovascular complications.

PUB380

Better Phosphorus Control May Delay the Need for Heart Valve Replacement in ESRD Patients
Ada Emerenini, Maria Coco. *Renal Division, Montefiore Medical Center, Bronx, NY.*

Background: Chronic Kidney Disease alters metabolism of calcium and phosphate leading to extraosseous calcifications. High phosphorus has been associated with increased mortality in dialysis patients. There is great emphasis on stringent control of mineral metabolism with cinacalcet and phosphate binders, but it is not known whether better control impacts on survival. Reports indicate that as many as 30% of dialysis patients may develop calcified valvular heart disease necessitating valvular replacement surgery. Previous studies report a one year survival approaching 50%.

Methods: Using electronic medical records, we looked at the survival pattern at Montefiore Medical Center during the years 2000 to 2009 of ESRD patients undergoing isolated valvular replacement surgery. We evaluated results pre and post 2005, corresponding to the introduction of cinacalcet and lanthanum in the management of mineral metabolism.

Results: 104 patients underwent isolated valve surgery. They had been on dialysis for 3±1 years. 61% were male; 40% were African American, 32% Hispanic, 18% Caucasian and 10% other. 40% had diabetes, 27% had endocarditis. There were 53 aortic valve replacements (AVR) and 51 mitral valve replacements (MVR). 61% were bioprosthetic.The median survival for AVR was 336 days and 483 days for MVR. There was no difference in survival for sex, mechanical vs bioprosthetic valve, diabetes or dialysis access in the entire cohort. We compared pre-2005 with post-2005 cohorts. There was no difference in survival post valve replacement in pre (763±933 days) vs post (727±600 days) 2005. Phosphorus was significantly lower in the post-2005 cohort (5.9±2.2 v 4.8±1.5 mg/dl, p=0.01, pre vs post 2005). Patients had been on dialysis significantly shorter in the pre-2005 cohort (2±.7 vs 3.7±.5 yrs, p=.0001).

Conclusions: We postulate that mineral metabolism has improved since 2005. The patients undergoing valvular surgery have survived a longer time on dialysis with improved phosphorus control. However, it remains unclear why survival has not improved following heart valve replacement surgery.

Carotid Arterial Strain (CAS) Using Speckle Tracking (ST) in Pediatric (ped) Patients (pts) Receiving Maintenance Dialysis (MD)
Poyyapakkam Srivaths,[1] Rajesh Krishnamurthy,[1] Eric Y. Yang,[1] Stuart Goldstein,[2] Gerd Brunner,[1] Vijay Nambi.[1] *[1]Sections of Pediatric Nephrology, Pediatric Radiology, Cardiovascular Research and Nephrology, Baylor College of Medicine, Houston, TX; [2]Center for Acute Care Nephrology, Cincinnati Children's Hospital, Cincinnati, OH.*

Background: Children and young adults receiving MD have very high cardiovascular (CV) mortality. Although arterial stiffness is a potential consequence of end stage renal disease only limited data exist related to the effect of MD on arterial properties in ped pts. Speckle Tracking (ST) tracks the arterial wall, through acoustic fingerprints and gives direct wall information

Aim: We evaluated carotid arterial strain (CAS) using a novel ST approach in ped pts receiving MD and compared them to healthy ped controls (con).

Methods: Bilateral ECG gated ultrasound of the distal common carotid were performed in 3 con and 12 ped pts receiving MD (4 HD, 8PD, vintage 36 ±23 mo). All scans in MD pts performed post dialysis. Peak CAS measured in six equal segments; average of three far wall segments (FWCAS) and global average (GCAS) were used as primary outcome measures based on prior experience in other disease states.

Results: GCAS and FWCAS were significantly lower in pts when compared to controls (see table). There was no correlation of CAS with age or ethinicity in pts or con; there was no difference in CAS between HD and PD, or correlation of CAS with dialysis vintage, Ca, P or PTH in pts.

Table

	Age y *	Ethnicity N	GCAS (%)1 *	FCAS (%)2 *
Cases (n=12)	17 (14.3-18.5)	2 Black, 8 Hispanic, 2 White	5.09 (3.25-5.73)	5.09 (3.06-5.72)
Controls(n=3)	11 (6-14)	2 Hispanic, 1 Asian	7.93 (7.35-9.31)	8.4 (7.85-10.13)

1 p=0.02, 2 p=0.01; * values expressed median (IQR)

Conclusions: CAS measurement with ST is feasible in ped pts. Ped pts receiving maintenance dialysis have lower GCAS and FWCAS implying stiffer arterial wall. More pt and control recruitment is underway to study this novel method in a larger population.

PUB382

Heart Rate as a Predictor for Adverse Outcomes in Chronic Hemodialysis Patients Arkom Nongnuch, Arisara Khaosabai, Montira Assanatham, Vasant Sumethkul, Prin Vathesatogkit. *Department of Internal Medicine, Ramathibodi Hospital, Mahidol University, Bangkok, Thailand.*

Background: Elevated heart rate was related to poor cardiovascular outcomes in general population and coronary heart disease (CHD) patients, however information for chronic hemodialysis (HD) patients were limited. This study explored the relationship between heart rate and cardiovascular outcomes and all-cause mortality in chronic hemodialysis patients.

Methods: Data of all chronic hemodialysis patients at Ramathibodi Hospital were retrospectively reviewed from January 2004 to December 2010. Patients with arrhythmia and previous CHD were excluded. Baseline characteristic and heart rate were recorded at the first HD visit of each month for 10 consecutive months and the means were used. These included resting heart rate pre, post HD and the highest value during HD. Primary outcome was combined major adverse cardiovascular events (MACE) and all-cause mortality.

Results: Fifty seven patients were eligible for this study (mean age 53 years, 49% women). Median follow up period was 53 months. Mean dialysis vintage was 66 months. Age, diabetes and hemodialysis vintage were associated with adverse outcomes in univariable models (all $P<0.05$). Average heart rates pre-, post- and during HD were higher in those who developed outcomes compared to who did not (74 vs. 71, 77 vs. 70, and 80 vs. 74 beats per minute (bpm) respectively). In age-adjusted models, every 10 bpm increment in heart rate at pre-, post- and during HD significantly raised the risk of outcome (HR 1.82, 1.76 and 1.51 respectively, all $P<0.05$). In multivariable adjusted model, post hemodialysis heart rate remained an independent predictor for outcome (HR 1.65, 95% confidence interval (CI) 1.03-2.66, P 0.04).

Conclusions: Elevated post hemodialysis heart rate is an independent predictor for adverse outcomes in hemodialysis patient after adjusting for multiple risk factors. Higher heart rate pre- and during hemodialysis also show a trend toward a higher risk in age-adjusted models. This may imply the use of heart rate as a simple and low cost tool for predicting adverse events in chronic hemodialysis patients.

PUB383

Design and Characterization of a Study in Small Dialysis Organizations: STEPPS Steven M. Brunelli,[1] Grace S. Park,[2] Peter J. Neumann,[3] Matthew Gitlin,[2] Brian D. Bradbury,[2] Robert J. Rubin.[4] *[1]Brigham and Women's Hospital, Boston, MA; [2]Amgen, Inc., Thousand Oaks, CA; [3]Tufts Medical Center, Boston, MA; [4]Georgetown University School of Medicine, Washington DC.*

Background: In 2011 the Prospective Payment System (PPS) for ESRD was launched and payment bundling expanded to include independently-reimbursed services. Small dialysis organizations (SDOs) may be particularly susceptible to the financial implications of the PPS. The ongoing prospective observational Study to Evaluate the PPS Impact on SDOs (STEPPS) was designed to describe trends in dialysis treatment and patient outcomes over the PPS implementation period. Herein we report basic study design elements and characterize the STEPPS sample.

Methods: Independents and facilities associated with a chain of ≤50 (n=1020) were contacted to assess interest. 100 expressed interest, 51 were enrolled. A random ~50% of patients within each facility were enrolled. Facility-level data are collected quarterly; patient-level data on demographics, comorbidities, labs, medications and outcomes (death, hospitalization, transfusion, transplantation, withdrawal from dialysis, facility transfer-out) are collected monthly or quarterly.

Results: 1873 hemodialysis and peritoneal dialysis ESRD patients were enrolled during the baseline period (Oct-Dec 2010); total enrollment was 2186 as of May 2012. STEPPS SDOs are representative of the US SDO population circa 2011 although slightly more urban and larger, and over-representative of the Western US. STEPPS patients are generally representative of the US dialysis population but tend to be slightly older, more Hispanic, and with fewer black patients (table).

Mean ± SD; n (%)	STEPPS baseline (N=1873)	US Medicare Dialysis population (%)*
Age (years)	61.2 ± 15.2	58.7
Female	791 (42.2%)	44.7
Race		
White	1021 (54.5%)	55.9%
Black	477 (25.5%)	37.0%
Other/unknown	375 (20.0%)	7.1%
Hispanic ethnicity	551 (29.4%)	16.3%
Dialysis vintage (years)	3.2 ± 3.3	4.1
Primary cause of ESRD		
Diabetes	846 (45.1%)	44.0%
Hypertension	487 (26.0%)	28.4%
Other	451 (24.1%)	23.7%
Unknown	89 (4.8%)	3.9%
Dialysis modality		
Hemodialysis (in center)	1791 (95.6%)	91.9%
Home hemodialysis	11 (0.6%)	1.1%
Peritoneal dialysis	68 (3.6%)	6.9%
Vascular access type		
Arteriovenous fistula	1093 (60.7%)	55.1%
Arteriovenous graft	296 (16.4%)	27.2%
Venous catheter	413 (22.9%)	17.7%

*From USRDS 2011 Annual Data Report (representing 2009 population)

Conclusions: STEPPS captures relevant facility and patient-level data for a representative sample of dialysis patients in US SDOs and will enable timely investigations into the effects of the PPS on patient outcomes in this setting.

Role of Mineral Disorders in Uremic Pruritis Steven Fishbane,[1] Shayan Shirazian,[2] Mary Schanler,[2] Shubha Shastry.[2] *[1]Division of Nephrology, Hofstra North Shore-LIJ School of Medicine; [2]Division of Nephrology, Winthrop-University Hospital.*

Background: Pruritis is a common problem among hemodialysis patients. There is widespread belief that disorders of phosphate or calcium balance may be an important cause. We sought to explore the relationship.

Methods: This is a post hoc analysis of data from a randomized controlled trial of 3 months of ergocalciferol vs. placebo treatment in 51 hemodialysis patients with uremic pruritis. Ergocalciferol was found not to be superior to placebo. A pruritis survey was administered every two weeks for 3 months. In the current study we have examined changes in pruritis over time, and the relationship between calcium and phosphate to concurrent pruritis scores.

Results: There was significant variation in pruritis survey results, less for calcium (Ca) and phosphate (Phos) for patients during the study, with CV 0.48, 0.03 and 0.15, respectively. For the entire study population we found no correlation between pruritis survey scores and concurrent serum Phos, Ca or Ca/Phos product. Similarly, when subdivided by treatment allocation (ergocalciferol vs. placebo) there were no correlations. When analyzed by quartiles of serum Phos, Ca and Ca/Phos product, there were no significant related differences in pruritis scores. In a sensitivity analysis of weeks when serum phosphate was > 6.5 mg/dL, serum calcium was > 10 mg/dL or Ca/Phos > 65 there was no significant change in concurrent pruritis scores.

Conclusions: We found no relationship between serum calcium, serum phosphate or calcium phosphate product with survey scores for pruritis.

PUB385

Factors Influencing Regional Differences in the Survival of New Dialysis Patients Satoshi Ogata, Norio Hanafusa, Kunitoshi Iseki, Yoshiharu Tsubakihara. *Committee of the Renal Data Registry, The Japanese Society for Dialysis Therapy, Tokyo, Japan.*

Background: There are regional differences in the survival of new dialysis patients, but few studies have investigated the reasons.

Methods: We investigated 37 clinical factors stratified by gender for patients from 47 prefectures in Japan using the Japanese Society for Dialysis Therapy database (JRDR-09105) of 102,011 patients who commenced dialysis during 2004-06, and 20 institutional factors from data on 3,958 institutions of the 47 prefectures in 2005.

Results: A total of 16 factors were significantly correlated with 1-year survival according to univariate analysis. All of these significant factors were subjected to analysis by the Kaplan-Meier method to compare survival between the upper 23 and lower 23 prefectures (the 24th prefecture from the top/bottom was deleted). As a result, 11 factors (a history of cerebral hemorrhage, protein catabolic rate, creatinine production rate, Kt/V, dialysis time, fluid removal, Ministry of Welfare clinical score at initiation of dialysis, nighttime centers/total dialysis centers ratio, number of full-time dialysis nurses, number of full-time dialysis dieticians (males only), and blood urea nitrogen after dialysis) were significant by the log-rank test.

Conclusions: Various clinical and institutional factors influence the survival of chronic dialysis patients and are associated with regional differences of their outcome.

PUB386

Effects of Intradialysis Resistance Exercise in Patients with Chronic Kidney Disease Elisa M.S. Higa,[1,2] Bruna Lourenco,[1] Marcos A. Nascimento,[1] Thiago S. Rosa,[1] Anderson Sola de Haro,[1] Marco T. Mello,[3] Vicente N. Siqueira,[4] Maria Eugenia F. Canziani.[1] *[1]Medicine, UNIFESP; [2]Emergency Division, UNIFESP; [3]Psychobiology, UNIFESP; [4]Cardiology, UNIFESP.*

Background: The loss of body mass is common in chronic kidney disease (CKD) patients, and it is a predictor of mortality. In Brazil the number of patients utilizing the hemodialysis (HD) in 2010 was 92.091. The decrease the life quality in this population can be attributed for factors as psychological alterations, comorbidities, biological aging, malnutrition, oxidative stress, use of corticosteroids and the HD process itself. Studies show that resistance training (RT) can be efficient on power gain and improvement of life quality in CKD patients analyzed by functional capacity tests. Evaluate the strength values before and after intradialysis RT in CKD patients.

Methods: There were recruited 10 patients in HD clinic Oswaldo Ramos (UNIFESP); we included both male and female patients with age between 20 and 76 yrs and dialysis treatment ≥ 3 months. The average body mass index (BMI) was 25.2± 5.2 characterizing overweight. Previous to RT, the patients were submitted to ergometric test, echocardiography and physical evaluation. Then, it was realized the 1 maximum repetition test (1MR), during the HD, before and after the training, in order to obtain strength values and exercise load estimative for each exercise. The RT was constituted for seven exercises, being: 3 to upper limb and 4 to lower limb, realized on 6 weeks period, 3 times/week during the HD session, with exercise intensity of 40% of 1MR on the first 3 weeks and 60% of 1MR in the other weeks. Each session was composed for 3 series of 12 repetitions with two minutes resting intervals between the exercises. For data analysis (mean ± standard error) it was utilized the t student test with value of $P<0.05$.

Results: On the 1MR tests we found strength increase (kg) after training, on the following exercises: shoulder press 8±0.55 vs 7±0.51; biceps 8±0.47 vs 7±0.61, triceps 5±0.56 vs 4±0.82 and leg extension 10±1.32 vs 7±0.70, $P<0.05$ for all.

Conclusions: Intradialysis resistance exercise promotes power increase in CKD patients which may improve their daily life activities.

PUB388

The Effect of Vitamin D Insufficiency on Uremic Pruritis Shayan Shirazian,[1] Mary Schanler,[1] James Drakakis,[1] Nobuyuki (Bill) Miyawaki,[1] Steven Fishbane.[2] *[1]Division of Nephrology, Winthrop University Hospital, Mineola, NY; [2]Division of Nephrology, Hofstra North Shore-LIJ School of Medicine, Great Neck, NY.*

Background: Vitamin D insufficiency is highly prevalent in patients on hemodialysis (HD). In addition, uremic pruritis is a common and troubling symptom in HD patients. The objective of this study was determine whether vitamin D insufficiency was more prevalent in patients with uremic pruritis and whether repletion with ergocalceriferol improved itching severity in HD patients with vitamin D insufficiency.

Methods: This is a post hoc analysis of a randomized controlled trial of 3 months of ergocalciferol vs. placebo treatment in 50 HD with uremic pruritis. Ergocalciferol 50,000 IU was given weekly for 12 weeks and was found to be equivalent to placebo for treating uremic pruritis. In the current study we tested vitamin D 25OH levels in a control population of 50 HD patients without uremic itching and compared them to levels in our original study population. We also tested the effect of ergocalciferol supplementation in a subgroup of HD patients with uremic pruritis that were vitamin D insufficient.

Results: Baseline vitamin D 25OH levels were lower in HD patients with uremic pruritis compared to HD patients without uremic pruritis, however this difference did not reach statistical significance (17.4 ng/mL vs. 19.4 ng/mL, p=0.40). 19 out of 25 HD patients from our original study who were randomized to ergocalciferol treatment were vitamin D 25OH insufficient (levels<30ng/mL) at study initiation. In these patients, there was a mean increase in vitamin D 25OH levels of 20.6ng/mL. When compared to placebo, our subgroup had a larger decrease in itching severity scores from the start to end of study, however this did not reach statistical significance (5.6 vs. 4.7, p=0.58).

Conclusions: Ergocalciferol repletion in HD patients with vitamin D insufficiency and uremic pruritis did not lead to a significant improvement in itching when compared to placebo in this small subgroup analysis. Further, larger studies are needed to determine whether ergocalciferol repletion is an effective treatment for uremic pruritis in HD patients with vitamin D insufficiency.

PUB389

Interactions (Age by Race; Age by Vitamin D Analog) Modify the Relationships between Vitamin D, and Hospitalization in Hemodialysis Patients K. Servilla, O. Myers, E. Bedrick, S. Paine, P. Zager. *Medicine, UNM, Albuquerque, NM.*

Background: The Institute of Medicine has questioned the benefits of vitamin D beyond improving bone health. The present study explores the hypothesis that active vitamin D is associated with decreased hospitalization in hemodialysis (HD) patients.

Methods: We studied black (n=5301), Hispanic (n=633) and non-Hispanic whites (NHW)(n=8727) who began HD between 1/1/99 and 12/31/04 in Dialysis Clinic Inc. facilities. Patients were followed for 3 years or until 12/31/07. Hospitalization was analyzed using Prentice, Williams, Peterson (PWP) gap-time models for recurrent events. Models contained baseline (age, sex, race, ESRD cause, vintage, Ca, PO_4) and time varying (albumin, Hgb, Kt/V, BP, BMI, clinic SMR) covariates. We fitted models with main effects for vitamin D use or type. We added interaction terms to see if relationships with hospitalization were modified by race and age.

Results: PWP (HR1.00, 95%CI 0.98-1.02) and marginal structural models (HR 0.96, 95%CI 0.90-1.01) did not detect an overall association between vitamin D and hospitalization. There was not a significant race x vitamin D interaction (p=0.84). Thus, the relationship of vitamin D to hospitalization was similar across races. There were significant age x vitamin D ($p<0.001$) and age x race ($p<0.01$) interactions. Vitamin D was associated with reduced ($p<0.01$) and increased ($p<0.05$) hospitalization in patients 20 to 39 and 60 to 69, respectively. Among patients over 50, blacks had lower hospitalization than NHW. In PWP models including vitamin D type, paricalcitol (HR 0.94; 95%CI 0.91-0.97) but not calcitriol (HR HR 1.01; 95%CI 0.98-1.04) or doxercalciferol (HR 0.99; 95%CI 0.96-1.02) was associated with an overall decrease in hospitalization. In these models there were significant age x vitamin D (p=0.004) and age x race (p=0.004) interactions. Paricalcitol and doxercalciferol were associated with decreased hospitalization in patients 20 to 39.

Conclusions: Overall, there was no association between vitamin D and hospitalization but results differed across subgroups. It is necessary to test for interactions when assessing relationships of vitamin D to outcomes among HD patients.

PUB390

Endogenous Testosterone Deficiency in Dialysis Patients: Influence of Dialysis Modality Secundino Cigarran,[1] Francisco Coronel,[2] Juan Villa Rincon,[1] Enrique Antonio Florit,[2] Jose A. Herrero,[2] Juan Jesus Carrero.[3] *[1]Nephrology, Hospital Da Costa, Burela, Lugo, Spain; [2]Nephrology, Hospital Clinico Universitario San Carlos, Madrid, Spain; [3]Nephrology, Karolinska Institute, Stockholm, Sweden.*

Background: Testosterone deficiency (TD)is common in men with chronic kidney disease (CKD). Age-related decline in testosterone levels in healthy men is associated with decreased muscle mass, muscle strength and lower extremity strength, decreasing exercise capacity. However, it is unknown if reduced endogenous testosterone associates with dialysis modality and changes in body composition.

Methods: Cross-sectional study of 43 men in dialysis (24 HD & 19 PD) mean age 66.44 ± 13.22 yrs, 41.1% diabetic status.Both groups were compared. Endogenous testosterone was measured by immunolumiscence method (Male normal range 3-11 ng/ml), and anemia, inflammation and nutricional markers as well. Body composition was assessed by bioelectrical impedance (Vectorial in HD and Spectroscopy in PD). Parameters derived from bioelectrical impedance were : lean body and fat mass. Data were processed with software package for windows SPPS 18 (Chicago IL, USA). Variables were processed as appropiate.A p value <0.05 was considered statistically significant.

Results: 17 HD pt (70.4%) and 1 on PD (5.3%) had TD. and was associated significntly with older, higher PCR, anaemia and poor nutritional status by serum markers and BIA, and lower Vit D.

T-Paired test Testosterone levels.

variable	Deficiency (n=18)	Normal (N=25)	P
Age (yr)	71.94±10.9	62.48±13.4	.05
Fat Free Mass (%)	59.64±5.12	57.88±14	.05
Fat mass (%)	33.33±5.3	38.81±12.28	.05
nPNA(gr/kg/d)	1.11±0.48	1.47±0.25	NS
%Hypocromes	8.71±13	3.07± 87	.001
SCr	6.68±2.25	10.1± 4.10	.001
Prealbumin (mg/dl)	29.7±2.25	37.06±10.8	.05
CRP (mg/dl)	1.15±1.7	1.52± .58	.001
Phosphorous (mg/dl)	4.43±1.32	5.0±1.43	.05
25OHD	9.94±4.43	12.96±6.59	.001
iPTH (pg/ml)	272.8±197.5	234.9±141.9	.05

Conclusions: In conclusion, TD in dialysis patients are associated to dialysis modality (HD) and body composition in an independent way. TD is associated to inflammatory, nutritional status associated to age effect, and increased cardiovascular risk. More studies are required to compare TD in both techniques.

A Single Center UK Experience of Pregnancy in Women Receiving Dialysis
Arvind Ponnusamy, Maharajan Raman, Hayley L. Mcmanus, Daniel J. Hall, Philip A. Kalra, Teresa Kelly, David I. New. *Renal, Salford Royal Hospital, Salford, United Kingdom.*

Background: Patients with end stage renal disease rarely conceive due to anovulatory menstrual cycle.

Methods: We undertook a retrospective review of pregnancy in women on renal replacement therapy from 2007 to 2011. All patients are cared in a multidisciplinary team involving comprising nephrologists, obstetricians, midwives, dietician and dialysis nurses from the antenatal period to delivery and beyond.

Results: There were 4 pregnancies during this period all of which resulted in a live newborn giving an incidence rate of 2 per 1000 dialysis patients/year. They were no reported case unsuccessful pregnancy. However, one of the cases was a twin pregnancy whereby one of twins died. The mean age was 34 years (range 29-42). Three patients were Asian and 1 was Caucasian. All patients were on aspirin and some form of anti-hypertensive medication. All pts were on daily dialysis – or at least 6 times/week with a mean frequency was 5.5 times/week. Our patients tolerated daily dialysis. Average urea levels were less than 17 mmol/L. Mean UF during the dialysis was 1.4 ± 1 litres. Average gestational age at delivery was 32.3 ± 3.3 weeks. The average birth weight was 1827 ± 750 g. Table below shows the laboratory features of these patients during pregnancy.

	1st trimester	2nd trimester	3rd trimester
Hb	104+ 11	99 + 14	93.2 + 19
Uric Acid	0.27 + 0.1	0.31 + 0.1	0.31 + 0.02
Systolic BP	127	122	128

Conclusions: Evidence on pregnancy in dialysis patients is scattered and heterogeneous. Our cohort of patients had good maternal and foetal outcome. This is due to combination of daily dialysis, optimum BP control, dietary input for PO4/fluid gains/essential vitamins(avoiding vitamin A), aspirin as pre eclampsia prophylaxis and careful monitoring foetus.

PUB392

Impact of Late Nephrology Consultation on Mortality in End Stage Renal Disease: A Single Center Experience in Korea
Seon Ha Baek,[1] Sejoong Kim,[2] Ho Jun Chin,[2] Ki Young Na,[2] Dong Wan Chae,[2] Suhnggwon Kim.[1] *[1]Department of Internal Medicine, Seoul National University Hospital; [2]Department of Internal Medicine, Seoul National University Bundang Hospital.*

Background: Late encounter of nephrologists before dialysis initiation on maintenance hemodialysis (HD) or peritoneal dialysis (PD) has been reported to be associated with increased mortality. However, the benefits of timely consultation in patients receiving renal replacement therapy (RRT) including HD, PD, and transplantation are rarely described. We therefore investigated the relationship between timing of nephrology consultation and mortality in those patients. The effect of emergent dialysis including emergent HD, PD, and continuous RRT on mortality was also evaluated.

Methods: Based on end stage renal disease registry (ESRD) databases in a tertiary university hospital from 1995 to 2010, 3499 subjects were identified. Early (EC) and late (LC) consultation were defined by the time of first nephrologists encounter more than or less than 3 month before first ESRD diagnosis, respectively.

Results: Of 3499 subjects (mean age 56.5±15.3 year, male to female ratio 2084:1415), 2237 (63.9%) were qualified for EC group and 1262 (36.1%) were for LC group. The mean baseline creatinine of the subjects was 7.49±3.65 mg/dL and emergent RRT patients were 403 (11.5%). During the periods, 984 patients were reported dead. LR was significantly associated with increased all-cause mortality with a hazard ratio of 1.23 (95% CI 1.05 to 1.44, P=0.011) in cox proportional hazard model adjusted for age at diagnosis, gender, presence of hypertension, diabetes, and baseline glomerular filtration rate. Compared to planned RRT, emergent RRT patients had significantly higher mortality rate adjusted for relevant factors (Hazard ratio 2.39, 95% CI 2.03 to 2.82, P<0.0001).

Conclusions: A comprehensive analysis of RRT subjects demonstrated the significant relationship between late encounter of nephrologists and all-cause mortality. Patients with emergent RRT revealed increased mortality compared to planned RRT. These analytic results suggest that the timely consultation to nephrologists before first RRT is important in determining long term prognosis in ESRD.

PUB393

Association of Pruritus and Quality of Life (QOL) among Patients at a Large Dialysis Provider
T. Christopher Bond, Richard Mutell, Helen M. Wilfehrt, Mahesh Krishnan, Tracy Jack Mayne. *DaVita Clinical Research, Minneapolis, MN.*

Background: Patients on dialysis frequently report pruritus, ie, itchy skin. The Kidney Disease Quality of Life 36 (KDQOL) assesses dialysis-specific, patient-reported health-related QOL for individuals with end-stage renal disease (ESRD) who are undergoing dialysis; it includes the SF-12 physical and mental component scores (PCS and MCS, respectively), subscales for burden of disease, symptoms and problems (including skin itch), and effects on daily life. This survey is administered to all dialysis patients yearly. We hypothesized that patient-reported itch would be associated with other items of the KDQOL.

Methods: We analyzed the association between itchiness score on the KDQOL and component scores and subscales reported on the same test for 71,012 patients who completed the SF-12 portion of the survey (Jan 2009-May 2012). ANOVAs were performed to compare scores on the 4 scales not including the skin itch question by level of itchiness.

Results: Thirty percent of patients reported that they were moderately to extremely bothered by itching; 61% reported any complaint of itching. A significant association was observed between itchiness and both PCS and MCS scores and between itchiness and the burden and effects subscales (not shown). Itchiness was also correlated with other questions in the symptoms subscale.

Table. Association Between Itchiness and KDQOL SF-12 MCS and PCS Scores.

Itchiness score	PCS Score			MCS Score		
	Mean	SD	Median	Mean	SD	Median
Not bothered at all (N=28360)	39.28	10.66	39.22	52.06	10.00	54.59
Somewhat bothered (N=21481)	36.97	10.15	36.39	49.73	10.40	51.60
Moderately bothered (N=10912)	34.91	9.66	33.91	47.68	10.75	48.63
Very much bothered (N=6556)	33.14	9.26	32.28	44.79	11.06	44.42
Extremely bothered (N=3703)	32.18	9.53	30.51	43.42	11.87	42.77
ANOVA p-value	<0.0001			<0.0001		

Conclusions: Self-reported skin itch is highly correlated with validated component and subscale scores on the KDQOL. Skin itch is an independent predictor of other aspects of the quality of life of dialysis patients, suggesting that it is an important condition to address. Risk Factors for Bacteremia in Incident Hemodialysis Patients
Sara Atwater,[1] Rhonda E. Colombo,[1] Stephanie L. Baer,[1,2] Mufaddal F. Kheda,[1] Puja Chebrolu,[1] Earnest J. Baulkmon,[1] Kristina W. Kintziger,[1] N. Stanley Nahman.[1,2] *[1]Georgia Health Sciences University, Augusta, GA; [2]Charlie Norwood VAMC, Augusta, GA.*

Background: Infection is the second leading cause of mortality in incident hemodialysis (HD) patients. We recently showed that bacteremia (BAC) occurred in ~ 22% of incident HD patients from the USRDS (Cherbrolu, IDSA, submitted). BAC may be access-related or be associated with other co-morbidities. To address this question, we queried the United States Renal Data System (USRDS) for potential access-dependent and access-independent risk factors for BAC in these patients.

Methods: All incident HD cases from the USRDS for calendar years 2005-2008 were queried for a diagnosis of bacteremia and several potential clinical covariates using ICD-9 diagnosis codes submitted for Medicare billing. Descriptive statistics and log-binomial regression analysis were performed. Covariates were stratified by time of occurrence (before BAC, and/or before starting HD) and grouped according to access-related or access-independent factors.

Results: For the 4 year period of study, 362,799 patients were available for analysis. The median age was 65 years. BAC was identified in 79,725 (22%) patients. Among bacteremic patients, vascular access type included AVF in 47,936 (13%), AVG in 14,226 (3.9%) or vascular catheter in 295,688 (82%) patients. When compared to AVF, the relative risk (RR) of catheter access-related BAC was 1.91, 95% confidence interval (CI) 1.86-1.96, and for grafts, RR 1.57, 95% CI 1.51-1.64. Access-independent co-morbidities included other infectious events (candidemia, MRSA colonization and HIV, [RR 3.69, CI 3.55-3.84; RR 3.32, 95% CI 3.26-3.38 and RR 2.12, 95% 2.04-2.21, respectively]), diabetes (RR 2.27, 95% CI 2.24-2.30), and lupus(RR 1.75, 95% CI 1.67-1.83). A decreased risk of BAC was associated with normal and increased BMI, female sex and previous kidney transplant.

Conclusions: BAC occurs in nearly one fourth of incident HD patients. Access type, infectious co-morbidities, diabetes and lupus represent high risk conditions for BAC in incident HD patients and may contribute to mortality in the first year of dialysis.

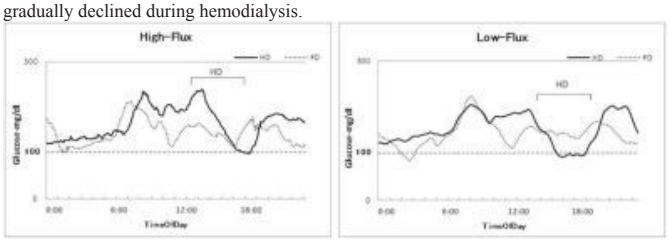
Assessment of Hemodialysis Membranes in Glycemic Control on Diabetic Hemodialysis Patients Using Continuous Glucose Monitoring (CGM)
Jyunichiro Hashiguchi,[1] Satoshi Funakoshi,[1] Yoshiaki Lee,[1] Tomoya Nishino,[2] Yoko Obata,[2] Jyunichiro Hashiguchi,[1] Kenichi Miyazaki,[1] Takashi Harada,[1] Kazunori Utsunomiya,[3] Shigeru Kohno.[2] *[1]Nagasaki Renal Center, Japan; [2]Nagasaki University Graduate School of Medicine, Japan; [3]Jikei University, Japan.*

Background: Although the glycemic control in diabetic hemodialysis patients is considered to be affected by the type of dialyzer used, it is still controversial which membranes to choose. We hereby compared higher and lower flux dialyzers on the glycemic control in diabetic hemodialysis patients monitored by CGM.

Methods: Five relatively well-controlled (HbA1c<7.0) diabetic hemodialysis outpatients were enrolled in this study, then monitored overall 48-hours glycemic control,

on both hemodialysis day (HD) and non- hemodialysis days (free day: FD), by CGM. Polyester-polymer membrane dialyzers with higher insulin-clearance (high-flux) were replaced with EVAL membrane with lower insulin-clearance (low-flux) for a week, and glycemic controls were compared in each patient.

Results: As shown in Figure 1, the average plasma glucose curve in high-flux on HD gradually declined during hemodialysis.



On the other hand, that in low-flux on HD steeply declined followed by relatively hyperglycemic state thereafter. More importantly, the mean amplitude of glycemic excursions (MAGE) in low-flux on HD was significantly higher than in high-flux (64.0±19.5 mg/dL vs 47.9±20.1 mg/dL, p=0.042).

Conclusions: Glycemic variability plays a major role in the development and progression of cardiovascular diseases in diabetic hemodialysis patients. Dialyzers with high performance membrane like polyester-polymer are recommended for glycemic control in relatively well-controlled diabetic hemodialysis patients.

Prevalence of Bacterial Catheter Colonisation Using Different Catheter Lock Strategies in Longterm Hemodialysis Patients Philipp Grosse,[1] Michael Dickenmann,[1] Stefan Erb.[2] *[1]University Hospital Basel, Clinic for Nephrology and Transplantation Immunology, Basel, Switzerland; [2]University Hospital Basel, Division of Infectious Diseases and Hospital Epidemiology, Basel, Switzerland.*

Background: Catheter related bloodstream infections (CRBSI) in longterm hemodialysis patients with permanent venous catheters have been attributed to adverse outcomes in terms of mortality, morbidity and excess costs. To minimize the danger of CRBSI by manipulation of dialysis catheters the needleless luer-lock device TEGO® connector has been FDA-approved in 2006 as an alternative to standard catheter caps (SCC).

Methods: Our prospective, interventional study investigated the prevalence of asymptomatic catheter contamination as a risk factor for CRBSI in three different catheter lock techniques in 39 patients with permanent venous dialysis catheters: (i) TEGO® system with saline locking solution, (ii) SCC with 46.7% citrate locking solution and (iii) SCC with 30% citrate locking solution plus intensive training of dialysis staff in aseptic catheter manipulation technique.

Results: We could demonstrate significantly higher catheter colonisation rates using the TEGO® system with saline locking solution as compared to SCC with 46.7% citrate solution (OR 0.22, p=0.011) or 30% citrate solution (OR 0.07, p=0.001).

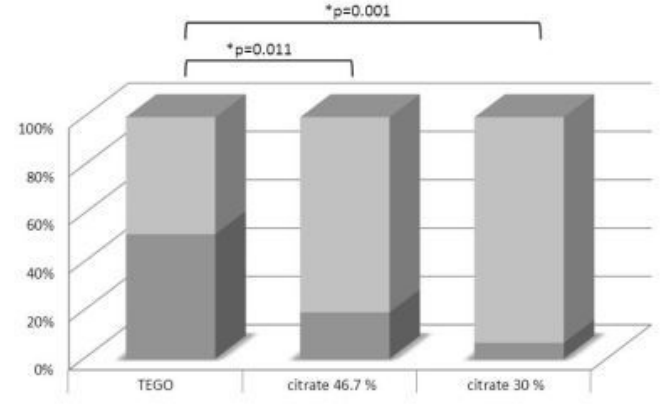

Figure 1: Prevalence of catheter colonisation using different catheter lock strategies. Percentages of sterile and contaminated catheters are indicated. Light green: sterile catheters. Dark green: contaminated catheters. Statistical analysis was performed using the Generalised Estimation Equation GEE. P-values <0.05 are considered statistically significant*.

Conclusions: We recommend cautious use of needlefree connectors for dialysis venous accesses since they might bear the danger of increased rates of CRBSI.

PUB397

QUALITY in Crisis Time: The Value of the Synergies Maria Eva Baro-Salvador, Raul Noguera. *Nephrology, Hospital de Torrevieja/Hospital de Vinalopo, Torrevieja/Elche, Alicante, Spain.*

Background: Though the quality for years is evaluated systematicly in the majority of dialysis units (DU),the quality accreditations in the same ones are long and costly processes that requires time and implication of the whole team.The synergy between two services in protocols, quality, clinical electronic history..can optimize the work,minimize the costs and benefit, later,the improvement of both centers.

Methods: Aim: Take advantage of a common headquarters in the nephrology service of two hospitals from the same company to accredit the welfare quality in both UD.In Valencian Community,DU can realize a quality accreditation with a specific institution for dependent on the Qualit Agency of the government.This is a long process that begins with an autoevaluation from which there is issued a situation-report that will be the base for the preparation of the accreditation visit and his later analysis.All this process it needs a time and dedication from professionals who,in addition, generally are profane to this knowledge area.The same headquarters and identical organization of service improves the performance of the above mentioned process shortening it in time,costs and improving the results of the same one.

Results: In December, 2010 we request to initiate the process of autoevaluation for the qualit accreditation of our DU of Torrevieja's Hospital. In November, 2011 we had the above mentioned accreditation with EXCELLENT qualification and immediately it was requested date evaluation for the UD of the Hospital of the Vinalopó without realizing the previous autoevaluation since the whole documentation, processes, protocols, qualit tools,.. are common. His evaluation is foreseen in June, 2012. The majority of the accreditations are realized with auditors that they were not specifics of the sanitary area.This process needs an implication in whole team, a documentation reaodering, an analysis of the weak points for his modification and, definitively, a new vision of the key processes.

Conclusions: In our experience the effort realized to accredit two related DU, not only optimize efforts but also reduce direct and indirect costs.

PUB398

Comprehensive and Personalized Care of the Hemodialysis Patient in Tassin, France: A Model for the Patient-Centered Medical Home for Subspecialty Patients Evamaria Anvari,[1] Charles Chazot.[2] *[1]Nephrology, University of Arizona, Tucson, AZ; [2]Nephrology, Nephro Care, Tassin-Charcot, Sainte Foy Les Lyon, France.*

Background: End-stage renal disease (ESRD) continues to increase in prevalence and incidence in developed countries. According to the International Study of Health Care Organization and Financing (ISHCOF) the United States has the second highest death rate per year among patients on hemodialysis even though it had the highest annual expenditure. Patient-centered medical homes (PCMH) are being studied as models for health care delivery. Their aim is to have the primary care physician provide all the patient's health care needs and arrange care with other qualified professionals in order to maximize health outcomes.

Methods: ESRD patients may represent the ideal patient population for PCMH for subspecialty patients. The American Society of Nephrology (ASN) appointed a taskforce to assess how nephrologists would interact with PCMH.

Results: The Centre de Rein Artificiel in Tassin, France provides a model for PCMH for patients with chronic renal disease and ESRD. This center is completely dedicated to kidney disease patients. It consists of a hospital, an operating room, a radiology suite, an outpatient clinic, outpatient HD rooms, and a next door Chateau where patients do self-dialysis overnight. Patients are seen by a nephrologist during every dialysis. They have frequent visits to the radiologist, dietitian, social worker, and psychologist if needed. Fistula creations are done by the interventional nephrologist and access dysfunction is also managed by them and their interventional radiologist. Hospitalized patients are also managed by the nephrologist and occasional outside specialist are called for consults. These patients have lower mortality rates and fewer complications.

Conclusions: Patient-centered medical homes based in dialysis centers have the potential to improve the overall quality-of-care, provide a more specific focus on the management of chronic diseases. The Tassin experience in France indicates that this approach is possible and has desirable outcomes.

PUB399

Application of Novel Methicillin-Resistant S. aureus (MRSA) Reduction Practices in Outpatient Dialysis Ioan Cosma,[1] Dottie Lagasse,[3] Lori Travis,[2] Brad M. Schimelman,[1] Mark G. Parker.[1] *[1]Maine Medical Center; [2]Maine Medical Center Research Institute, Portland, ME; [3]Fresenius Medical Care North America, Westbrook, ME.*

Background: MRSA infections are highly prevalent in outpatient hemodialysis units, partly due to high utilization of central vein catheter access, raising healthcare costs and exposing dialysis patients to a 2.5 fold increased risk for all-cause mortality. Systems improvement and positive deviance have been shown to reduce MRSA infections in hospital settings. We studied the use of these techniques in an outpatient dialysis unit.

Methods: Staff from a FMCNA dialysis unit introduced lean methods and social/behavioral change dialogues derived from positive deviance methods to identify effective practice changes for prevention of MRSA transmission. They developed hand hygiene education tools, standardized communication tools, and optimized strategies for information dissemination. Historical infection rates were compared to rates after application of new

strategies. Implementation occurred from July, 2010 through September, 2011, and data collection continued through March, 2012. Outcomes included rates of MRSA bacteremia, all-type MRSA infections, and all-cause bacteremia, and were analyzed with descriptive statistics including t-tests.

Results: The average patient census was 97/month. There was no statistically significant change in Quarterly Average Rates/1000-patient-months of MRSA bacteremia (4.51 vs 3.96, average difference 0.56, 95% CI [-3.45, 4.57], p-value 0.78), all-type of MRSA infections (5.40 vs 7.80, average difference - 2.4, 95% CI [-6.35, 1.55], p-value 0.22), or all-cause bacteremia (12.95 vs 7.45, average difference 5.5, 95% CI [-0.69, 11.68], p-value 0.08).

Conclusions: After implementation of lean and positive deviance interventions in an outpatient dialysis unit, no significant difference was noted in rates of MRSA bacteremia, all-type MRSA infections, or all-cause bacteremia. These results may reflect barriers to effective use of these organizational change strategies in outpatient dialysis, as compared to hospital settings. Study limitations included low baseline event rates and short duration of post-intervention observation.

PUB403

A Randomized Control Trial for Prescribing the Best Dialyzer Choice for Elderly Dialysis Patients

Ikuto Masakane,[1] Jun Minakuchi.[2] *[1]Nephrology, Yabuki Shima Clinic, Yamagata, Japan; [2]Nephrology, Kawashima Hospital, Tokushima, Japan.*

Background: Several recent reports warned that high efficient hemodialysis with polysulfone (PS) membrane occasionally led to the deterioration of nutritional status in elder patients. Ethylene vinyl alcohol (EVAL) membrane has high biocompatibility and a broad solute removal property. In the prior studies, EVAL membrane improved the deteriolated nutritional status caused by PS membrane. The E-HOPOED-Study Group was established in 2010 to determine the best dialyzer choice for elder dialysis patients.

Methods: The E-HOPED-Study is a randomized control trial registered in UMIN-CTR system (UMIN 000003730) and being performed in 278 dialysis facilities in Japan. The patients who accept the enrollment to the study will be randomly divided into the next two groups; the Group A, treated by EVAL membrane; the Group B, treated by several high flux membrane such as PS. The entry criteria of the patients are the age more than 70 years old, the dialysis vintage less than 180 days. The target number of the entry is 800 in each Group. The 5 year-survival, changes in the nutritional status, occurrence of complications and others are the end points.By the end of April 2012, 362 patients have recruited to the study, and 88 questionarreis about the patients information at 0 and 6month were collected. Interim analysis for the first 88 data set was conducted.

Results: Interim analysis showed that the mean age of the patients was 77.4 years old, 58 (66 %) were male, and 38 (43 %) were diabetes. The mean serum creatinine was 6.67 mg/dL, the mean estimated GFR was 6.97 ml/min. There were no differences in all parameters in cluding outcome parameters between Group A and B at 0 month and 6 months after. In the comparison between 0 and 6 months, the mean level of serum creatinine was increased and the mean level of intact PTH was decreased siginificantly in Group A. The post-dialytic serum UN was siginificantly decreased in Group B.

Conclusions: Based on this preliminary analysis there are no clinically noteworthy differences between EVAL and PS for elder dialysis patients. However, we believe that further data collection can propose a suitable dialyzer choice for elder dialysis patients.

PUB405

Clinical Sexology and Quality of Life in Clinical Renal Insufficiency Patients: A Quality Evaluation of Training Program

Franca Giacchino,[1] Vilma Duretto,[2] Serafina Lo Piccolo,[1] Rosaria Rita Patti.[1] *[1]Nephrology and Dialysis Unit, Civil Hospital, Ivrea, Turin, Italy; [2]Psicology, Civil Hospital, Turin, Italy.*

Background: Chronic renal insufficiency negatively impacts on patients' affective and relational experiences, thus compromising their quality of life.

The aim of this study was to evaluate the effects of training program to provide a correct sexological background to health professionals in order to prevent the onset of pathological relationships in renal insufficiency patients. The course focuses on counseling and active-selective listening tools to deal with any sexual issue that may be brought up and ensure a comprehensive care of patients.

Methods: 67 members of the dialysis staff participated in the course and gave a qualitative evaluation by answering a series of question. The Sternberg triangle test and a body perception test on " sensitive body zone" were submitted and completed. Besides frontal lessons, the didactical method included interactive discussion after slide presentation, movies or readings. Didactic brochures were provided.

Results: 84% of the staff felt better informed on how to deal with sexual in dialysis patients; 86% appreciated the course design and didactical method.; 82% found the course useful and relevant for their profession; 69% found the duration of the course appropriate and 31% felt the need for more sessions.

Conclusions: Our findings provide evidence that gaining awareness of one's own behaviors and rigidities often greatly improves relationships with patients, ensuring a better quality of life for patients and a better professional life for caregivers.

PUB406

Relationship between Initial Serum Uric Acid Level and One-Year All-Cause Mortality in Incident Hemodialysis Patients: A Single Center Experience over Five Years

Manabu Asano,[1] Masahiro Shimoyama,[1] Tokuya Nakahara,[1] Machiko Okamoto,[1] Hitoshi Iwabuchi,[1] Kenichi Oguchi,[1] Hachiro Yamanishi.[2] *[1]Renal Unit, Ikegami General Hospital, Tokyo, Japan; [2]Tenri Health Care University, Tenri, Nara, Japan.*

Background: Serum uric acid level is known as a risk factor for death in chronic hemodialysis patients. However, there are conflicting reports regarding the association of hyperuricemia with mortality. We examined whether the initial serum uric acid level might affect all-cause mortality in incident hemodialysis patients.

Methods: One-year all-cause mortality in which 150 patients initiated chronic hemodialysis in our facility between 2006 and 2010 were retrospectively assessed. The incident hemodialysis patients were assigned to two groups, 32 patients to the fetal group and 118 patients to the survival group. A multiple logistic regression model was used to compare the predictive factors of two groups. The model included known risk factors (e.g. age, gender, diabetes, physician type, serum uric acid, albumin, total cholesterol, creatinine, hemoglobin, C-reactive protein, calcium, phosphate).

Results: The number and causes of death were 11 for infection, 9 for heart failure, 3 for malignant tumor and 9 for others. Initial serum uric acid levels were 8.4±1.9 mg/dl and 9.3±3.3 mg/dl for the survival group and fetal group, respectively. Linear regression analysis showed that serum uric acid correlated with creatinine ($r=0.37$, $p<0.05$) and phosphate ($r=0.44$, $p<0.01$). The odds ratios (95% confidence interval, p-value) for these risk factors were 1.087 (1.031-1.166, 0.003), 5.713 (1.757-18.57, 0.004), 1.150 (1.031-1.284, 0.012) and 1.253 (1.008-1.559, 0.042) for age, whether attended by a nephrologist, C-reactive protein and uric acid.

Conclusions: The present study suggests that a higher level of initial serum uric acid is a risk factor for one-year death in incident hemodialysis patients. Uric acid management before starting hemodialysis therapy may help to improve one-year mortality. Interventional study should be conducted to confirm an association between the serum uric acid level and mortality in prevalent hemodialysis patients.

PUB407

Reliability of the 2014 Quality Incentive Program (QIP) Total Performance Score

John Kalbfleisch,[1] Alissa Kapke,[2] Jeffrey Pearson,[2] Erik Roys,[1] Matthew Paul,[1] Emily E. Messersmith,[2] Marc Turenne,[2] Yi Li.[1] *[1]University of Michigan Kidney Epidemiology and Cost Center, Ann Arbor, MI; [2]Arbor Research Collaborative for Health, Ann Arbor, MI.*

Background: The reliability of the 2014 CMS ESRD QIP total performance score (TPS) for dialysis facilities was evaluated using CMS ESRD claims data. The TPS, which is a composite measure based on three clinical measure scores (hemoglobin>12 g/dL, URR≥65, and the average of fistula use and catheter use) and three reporting measures, was estimated using only the clinical measures due to data availability. The reliability of a facility level measure reflects the extent to which it measures the performance of the facility as opposed to random variation of patient outcomes within the facility. The variance of a measure is the sum of a between-facility variance (Sb) and within-facility variance (Sw). The ratio of Sb to the sum of Sw and Sb is commonly referred to as the inter-unit reliability (IUR).

Methods: The IUR for simple measures can often be calculated using an analysis of variance (ANOVA). A complex composite measure like the TPS cannot be expressed as an average of responses at the patient level and another approach is needed. We present a bootstrap methodology whereby Sw is estimated by selecting a large number of bootstrap samples of individuals from each facility and the TPS is calculated for these samples.

Results: Since the reliability of the TPS may vary with facility size, we divided facilities into deciles based on dialysis patient counts. The IUR ranged from 0.61 in the lowest decile to 0.80 in the highest decile and generally increased as facility size increased.

Reliability of 2014 QIP TPS stratified by facility size

Decile (patient count)	# Facilities	Average facility size	IUR
1 (11-21)	491	16.8	0.61
2 (22-29)	497	25.4	0.65
3 (30-37)	531	33.5	0.66
4 (38-44)	472	41.1	0.64
5 (45-52)	515	48.5	0.64
6 (53-61)	512	57.0	0.68
7 (62-72)	511	66.8	0.68
8 (73-85)	532	78.5	0.69
9 (86-106)	512	94.8	0.68
10 (>=107)	512	137.7	0.80

Conclusions: These results indicate that most of the variation in the TPS is due to differences between facilities as opposed to random variation in patient outcomes within facilities.

PUB408

Risk of Calciphylaxis with Commonly Used Medications in Hemodialysis Patients

Sagar U. Nigwekar, David J.R. Steele, Ishir Bhan, Ravi I. Thadhani. *Massachusetts General Hospital.*

Background: Calciphylaxis, a rare but highly fatal condition seen in hemodialysis (HD) patients, is reportedly on the rise. We investigated the risk of calciphylaxis in relation to commonly used medications that have a potential role in vascular calcification (active vitamin D analogues, erythropoietin, iron, calcium-based phosphate binders and warfarin).

Methods: Cases (n=62) comprised HD subjects with skin-biopsy confirmed calciphylaxis diagnosed between 2000 and 2011. Controls (n=124) were HD subjects without calciphylaxis matched to cases by gender and calendar year. Medications and other covariates were compared between cases and controls. Association with calciphylaxis was determined using unadjusted and adjusted logistic regression models for each medication category.

Results: Utilization of calcitriol (21% vs. 7%, p=0.01) and warfarin (43% vs. 19%, p<0.001) was more common in cases compared to controls. Utilization of paricalcitol (29% vs. 26%, p=0.64), doxerecalciferol (6.5% vs. 6.6%, p=0.99), erythropoietin (42% vs. 34%, p=0.28), iron (7% vs. 11%, p=0.37), and calcium-based phosphate binders (32% vs. 33%, p=0.91) was similar. In unadjusted analyses, calcitriol (OR 5.77, 95% CI 1.75-18.46) and warfarin (OR 9.72, 95% CI 3.00-31.40) were associated with increased odds of calciphylaxis but other medications were not. In analyses adjusted for age, race, diabetes, macrovascular disease, obesity, and laboratory values (serum calcium, phosphorous, alkaline phosphatase, parathyroid hormone, 25-hydroxyvitamin D, and albumin), calcitriol and warfarin continued to confer higher risk for calciphylaxis.

Adjusted odds of calciphylaxis

Medication	OR	95% CI	P
Calcitriol	4.56	1.19-17.48	0.03
Selective vitamin D analogues (paricalcitol and doxerecalciferol)	1.89	0.72-4.99	0.20
Erythropoietin	1.51	0.57-4.05	0.41
Iron	0.45	0.13-1.51	0.20
Calcium-based phosphate binder	0.81	0.30-2.18	0.68
Warfarin	5.66	1.91-16.76	<0.001

Conclusions: Calcitriol and warfarin use are associated with greater calciphylaxis risk. Future studies are needed to establish if these relationships are causal. Considering significant morbidity and mortality of calciphylaxis, HD providers should take these potential risks into account while prescribing medications.

PUB409

Outcome of Chronic Dialysis Patients Admitted to the ICU over a 5-Year Period in a Single Center Hugues Bouchard,[1] Georges Ouellet,[1] Jean-Philippe Lafrance,[1] Lynne Senecal,[1] Denis Ouimet,[1] Martine Leblanc.[1,2] *[1]Nephrology, Maisonneuve-Rosemont Hospital, Montreal, QC, Canada; [2]Critical Care, Maisonneuve-Rosemont Hospital, Montreal, QC, Canada.*

Background: Critical illness in chronic dialysis pts may further increase their high mortality rates. The aim of our study was to describe outcomes of chronic dialysis pts when admitted to ICU.

Methods: By chart review, we identified all pts admitted to ICU (medico-surgical or coronary care) among our chronic dialysis (>90d) cohort from March 2006 to March 2011 (672 on HD, 79 on PD).

Results: 175 pts were admitted 231 times to ICU (mean age 67.4y, 44% women, 44% HD with a catheter, 40.6% HD with an AVF, 15.4% PD, median vintage 37m). For the 35 pts admitted more than once, only the first admission was considered for survival analysis.

Causes of ESRD were DM 36%, HTN 27%, and GN 11%. Main comorbidities were HTN (158 pts), DM (94), CAD (118) and peripheral vascular disease (76). Cardiac insufficiency was previously diagnosed in 45%.

At ICU admission, the median APACHE II and SOFA scores were 23 and 7; main reasons for transfer to the ICU were acute coronary syndrome (32.2%), severe infection (13.9%), urgent surgery (11.3%), cardiorespiratory arrest (9.6%), arrhythmia with hemodynamic instability (8.3%), neurologic cause (5.2%), pulmonary edema (4.8%), and "other" including GI bleeding (10.9%). During the ICU stay, 23% were mechanically ventilated for >24h, over a median time of 55h. Renal replacement therapy was usually performed with intermittent HD (72.2%); CRRT was used in 7.4% of the admissions, much less frequently than for AKI in our center.

The mean delay between hospital admission and transfer to the ICUs was 3.7d, while the mean ICU stay was 4.3±3.3d. During the same hospitalization, readmission rate to ICU was 6.9%. Mean hospital stay was 23.6±27.9d (median 14). Mortality rates were 16.6% and 29.1%, during the first ICU stay and hospital stay, respectively Survival at 30d, 6ths, 1 y and 2 y were 69.1%, 59.4%, 51.1% and 35.6%.

Conclusions: In conclusion, our chronic dialysis pts are admitted relatively often in the ICU for relatively short stays. Although their global mortality rate is high, most were discharged alive from the ICU.

PUB410

Inpatient Hepatitis B Vaccination for Non Immune Hemodialysis Patients: A Critical Need Prabhat Singh, Maureen Lawlor, Raghavesh Pullalarevu, Saba Akhtar, Amit Ladani, Mohamed Hamdy Yassin. *Internal Medicine, UPMC Mercy, Pittsburgh, PA.*

Background: It is the standard of care to confirm that all patients with end stage renal disease (ESRD) are vaccinated for the hepatitis B virus (HBV). A hepatitis B antibody titer (HBsAb) above 10 is considered protective. Despite efforts to vaccinate HD patients, the response to the HBV vaccine is lower and less sustained than healthy individuals. Due to a greater percentage of acute HD patients treated within inpatient units, there is an increased risk of a HBV outbreak if a newly presenting HBV positive patient is introduced into the HD unit.

Methods: A prospective quality improvement initiative conducted over 2 months (10-2011 till 12-2011) that was designed to improve protection against HBV in the HD population treated at UPMC Mercy. All patients treated within the UPMC Mercy inpatient HD unit were included. The following HBV serologies were monitored; HBsAg, HBsAb titer, and HBc Ab. Vaccination with Engerix 40 mcg was offered to all HD with HBsAb titers < 10 IU/L.

Results: Sixty HD inpatients were enrolled in the study over two months period. Among these 60 patients, only 25 (42%) were immune with HBs Ab titer ≥10. Forty five patients had received prior vaccinations and 15 patients had no history of prior vaccination. Out of 45 vaccinated, only 32 patients had completed series of vaccination prior. All vulnerable patients 35 (58%) were offered vaccination.

Conclusions: HBV poses a great risk as a bloodborne pathogen particularly in inpatient HD units. Monitoring HBV serology (HBs Ag, HBs Ab, HBc Ab) on a routine basis is essential to prevent HBV outbreaks within HD units. Monitoring HBs Ag alone is insufficient and should be coupled with additional serology to ensure adequate protection for this particularly vulnerable population. Focus on vaccination especially in the inpatient facilities is a great opportunity to control HBV spread.

PUB411

Thirst and Oral Symptoms in People on Hemodialysis: A Multinational Prospective Cohort Study (Oral-D) Suetonia Palmer,[1] Marinella Ruospo,[2] Michela Sciancalepore,[2] Mariacristina Vecchio,[3] Letizia Gargano,[2] Patrizia Natale,[2] Valeria Maria Saglimbene,[3] Paul Stroumza,[2] Jorgen B.A. Hegbrant,[2] Fabio Pellegrini,[3] Eduardo Jorge Celia,[2] Jonathan C. Craig,[4] Giovanni F.M. Strippoli.[2,3,4] *[1]University of Otago; [2]Diaverum Medical Scientific Office; [3]Mario Negri Sud Consortium; [4]University of Sydney.*

Background: Thirst and xerostomia, the subjective complaint of dry mouth, may be increased in people on hemodialysis due to reduced salivary and lacrimal secretion, intravascular volume changes, fluid-restriction, endocrine hormone abnormalities, and medication use. Existing data for the prevalence of thirst and xerostomia are limited. We evaluated the prevalence of thirst and oral symptoms in adults on hemodialysis.

Methods: ORAL-D is a multinational cohort study of oral diseases in consecutive adults on hemodialysis in 75 outpatient clinics selected randomly from a collaborative dialysis network in Europe and South America. We administered xerostomia and thirst inventories based upon validated methodology. We analyzed prevalence data using descriptive analyses.

Results: 4720 hemodialysis patients in the participating clinics completed a self-administered questionnaire on oral symptoms. 1773 (38%) patients reported occasional use of candies for dry mouth sensation, 1095 (34%) had difficulties swallowing and 2437 (53%) needed to sip to aid swallowing. 2112 (45%) reported waking up during the night to drink, 1700 (36%) reported dry mouth sensation and 2309 (50%) had dry lips. The mean xerostomia inventory score was 21.14 (SD 5.56). Thirst was a reported problem for 2895 (62%) patients (62%); 3585 (78%) were thirsty during the day and 2173 (47%) during the night. Overall, 1169 (26%) patients reported that thirst influenced their social life. The mean dialysis thirst inventory score was 17.64 (SD 5.41).

Conclusions: Oral symptoms are highly prevalent in hemodialysis, with marked interference with daily life. Additional study of the predictors of thirst and xerostomia are now needed.

Assessing Overall Dialysis Center Efficiency among Free Standing Dialysis Centers Sanatan Shreay,[1] Mark Stephens,[2] Jill Mccluskey,[3] Matthew Gitlin.[1] *[1]Health Economics, Amgen, Thousand Oaks, CA; [2]Prima Health Analytics, South Weymouth, MA; [3]School of Economics, Washington State University, Pullman, WA.*

Background: Assessment of dialysis center (DC) efficiency has been limited, although research suggests efficiency is affected by multiple factors. Due to the limited research available, the purpose of this study was to assess overall DC efficiency as well as the impact of anemia drug choice on efficiency.

Methods: A data envelopment analysis (DEA) was performed using Medicare Renal Cost Reports 2010 data to model the efficiency of 4343 free-standing DCs relative to one another. Using a linear programming technique, DEA converts multiple inputs (costs, staffing levels) and an output measure (number of dialysis sessions) to a single score between 0 and 1 (low to high efficiency) for each DC. Simulations were conducted to assess changes in score distribution related to using a longer acting anemia drug by adjusting supply costs and staffing levels.

Results: Most DCs were located in the South (47%), 78% were affiliated with a large organization (2 largest chains) and 93% were for-profit. Annual supply costs per DC represented 14% (mean: $270,519; median: $202,287; SD: $230,627) of operating costs and nursing staff levels averaged 4.2 per DC (median: 3; SD: 3.6). The average number of treatments per year was 11,444 (median: 9893; SD: 7078). The DEA indicated 33% of the DCs were most efficient (score 0.9 to 1) followed by 11% (score 0.8 to 0.9); 19% (score 0.7 to 0.8); 22% (score 0.6 to 0.7); 11% (score 0.5 to 0.6) and 4% (scored <0.5). Overall, 26% (n=1055) of the for-profit DCs scored between 0.9 and 1. About 42% (n=104) of small organizations (< 50 DCs) and 23% (n=773) of large organization centers were most efficient. The simulated model when adjusting for longer acting anemia drug administration did not reveal any changes in the distribution of efficiency scores (32% of facilities were most efficient).

Conclusions: About 33% of DCs were deemed most efficient and simulated changes to supply costs and staff time by switching to longer acting anemia drug did not impact the distribution of overall DC efficiency scores.

PUB413

Randomizing Study Group Labels to Estimate Valid P-Values in Complex Data Sets John Rogus, Shu-Fang Lin, Franklin W. Maddux, Eduardo K. Lacson. *Fresenius Medical Care North America, Waltham, MA.*

Background: Maintenance hemodialysis (HD) allows for collection of repeatedly measured clinical, laboratory, and anthropometric values. Such correlated data complicates statistical analyses, particularly with assignment of valid p-values. Aggregating data into a single summary value per patient offers one option to circumvent the issue, albeit highly inefficient. Other methods such as generalized least squares or linear mixed models can be used, but with large national data sets, become too computationally intensive. We describe an efficient, non-parametric approach to assign valid p-values to effects estimated using ordinary linear regression.

Methods: For a continuous outcome and variable of interest with two labels (e.g., "case" or "control"), we derive regression statistics in terms of sums and sums of squares of the outcome. From these, we can calculate true parameter estimates (by preserving label designations) and also resample under the null (by randomizing label designations). We demonstrated this Monte Carlo procedure with an example based on 629,452 measurements of systolic blood pressure (SBP) in 39,313 patients undergoing HD at Fresenius Medical Care, North America. Cases had dialysate Na+ decreased by 3 mEq/L while controls had no change. The transition period was from Jan-June 2009. We compared the two groups during a 6-month baseline and 24-month follow-up period (excluding transition).

Results: Using the Monte Carlo procedure, we found a significant decrease in SBP for patients with a decrease in dialysate Na+ (p=0.04). Other computationally feasible, but inefficient, approaches such as data aggregation and year-over-year comparisons were unable to demonstrate this significant association.

Conclusions: Monte Carlo simulation is a simple way to assign valid p-values to the complex data sets common in HD studies. This method can accommodate covariates with a 2-step procedure involving an initial regression analysis. Future work is needed to characterize power relative to other methods and to study whether weighting strategies are useful when subjects have varying counts of data points.

PUB414

Routine Monthly ACTs Not Associated with Lower Clotting Events in Hemodialysis Adults on Heparin M. Khaled Shamseddin,[1,2] Sean W. Murphy,[1] Bryan M. Curtis,[1] Brendan J. Barrett.[1] *[1]Nephrology, Memorial University, St. John's, NF, Canada; [2]Nephrology, Queen's University, Kingston, ON, Canada.*

Background: Anticoagulant effect of heparin used during hemodialysis (HD) is usually measured by activated clotting time (ACT) to achieve a specific target.

Methods: A prospective study in 109 HD patients was designed to evaluatewhether a change in practice from monthly ACTs to one in which ACTs are only measured if clotting occurred will lead to any significant increase in clotting. All clotting events on heparin during phase I (4 months with monthly ACTs) were compared with phase II (4 months with ACTs if clotting occurred), using Poisson and Logistic Regression. Clotting event was classified as type 1 (Clot in the dialyzer bottom), 2 (Clotted filter), or 3 (Circuit changed).

Results: Routine ACTs were <150 in more than 50% of cases regardless of clotting occurrence in phase I. Heparin dose was changed in <10% of low ACTs, and dose change was effective (new ACT ≥150) only in 50% of cases. Surprisingly, 87 clotting events occurred in phase I (Type 1 (62), 2 (23), 3 (2)) compared with 58 events in phase II (Type 1 (41), 2 (16), 3 (1)). The incident rate for all clotting events in phase I was 1.5x higher than phase II (Exp (B) 1.5, 95% CI: 1.1-2.1, *P* 0.02). The incident rates for clotting events type 1, 2, and 3 were also higher during phase I compared with phase II, 1.5x (*P* 0.04), 1.4x (*P* 0.27), and 2x (*P* 0.57), respectively. To evaluate intrapersonal effects on clotting, since some patients had more than one event, we compared if any clotting event occurred in phase I vs. II, using binary logistic regression. The Odd Ratio of any clotting event to occur in phase I vs. II was 1.87, 95% CI: 1-3.4, *P* 0.04. Furthermore, the rate of effective heparin dose change, achieving ACT ≥150, was higher in phase I compared with phase II (*P* 0.00). If clotting type 2 or 3 occurred in phase I, the incident rate for heparin dose change was significantly higher (*P* 0.04), but was not more effective compared with phase II (*P* 0.4).

Conclusions: Routine monthly ACTs are not associated with lower clotting events in HD adults on heparin, as heparin dose was not changed or dose change was not effective.

PUB415

Chylous Ascites: Delayed Transient Cloudy Peritoneal Fluid after Laparoscopic Placement of Peritoneal Dialysis Catheter Alvaro A. Ryes. *St. Elizabeth Physicians, Cincinnati, OH.*

Background: Chylous ascites after laparoscopic implantation of a peritoneal dialysis cateheter (PDC) may be a less rare event than previously recognized. We describe the transient nature of this complication in one of our patients.

Methods: A 76 year-old man with end stage renal disease after complications of cholecystitis started hemodialysis via tunneled catheter (TC). After 6 months, he agreed to switch to peritoneal dialysis (PD) to allow TC removal. He underwent uncomplicated laparoscopic placement of a PDC which was flushed weekly with NS over the next 2 weeks. He began trainnig for chronic ambulatory PD and had 4-5 clinic visits with uneventful exhanges, each time obtainng clear PD fluid. He was scheduled to have his TC removed but he presented to the ER for an unrelated injury after falling on a parking lot. He was otherwise asymptomatic. In the ER he had his PDC flushed as per protocol and it was noticed that the PD fluid was cloudy. Vanc was given IP, PD fluid samples were obtained and he was discharged. On follow up his PD cell count was 10 WBC/mm3, RBCs were 43/mm3. No more antibiotics were given. On the following day he came to the PD clinic and had a PD exchange which was cloudy (see photograph). Samples were obtained: cholesterol was 22 mg/dL, amylase was 22 U/L and lipase was 62 U/L. The lab did not run triglycerides. A CT of the abdomen identified a previously noted paraceliac adenopathy but was otherwise negative. After another less cloudy PD exchange the chylous ascites resolved spontaneously without further episodes. There was no time to implement dietary modifications (low fat diet). He will have a follow up CT in 6 months to monitor paraceliac adenopathy.

Conclusions: Chylous ascites may have been the result of unavoidable trauma to the lympathic flow on the abdominal wall during laparoscopic insertion of the PDC. However, the trauma did not result in immediate development of chylous fluid; instead, it was a complication first evident as late as 10-14 days after laparocopic surgery and lasted only a couple of days making the detection more difficult. The development of chylous ascites could have benn missed altogether if the exchanges had not coincide with its transient nature.

PUB416

Icodextrin Preserved Renal Residual Function, Phosphate Clearance and Improved Atherosclerosis Takeyuki Hiramatsu, Takahiro Hayasaki, Akinori Hobo, Shinji Furuta, Yoshiyasu Iida. *Department of Nephrology, Konan Kosei Hospital, Konan, Aichi, Japan.*

Background: We reported that use of icodextrin ameliorates the progression of cardiac hypertrophy and valve calcification in incident peritoneal dialysis patients. Since icodextrin removed more phosphorus than glucose does, this study was aimed to examine whether removal of phosphorus affect the cardiac hypertrophy or not.

Methods: A retrospective analysis was conducted on 20 only glucose patients (Group A) and 20 icodextrin patients (Group B). Data on laboratory and cardiovascular ultrasound examination at the start of PD and every 6 months for 2 years were retrieved and analyzed.

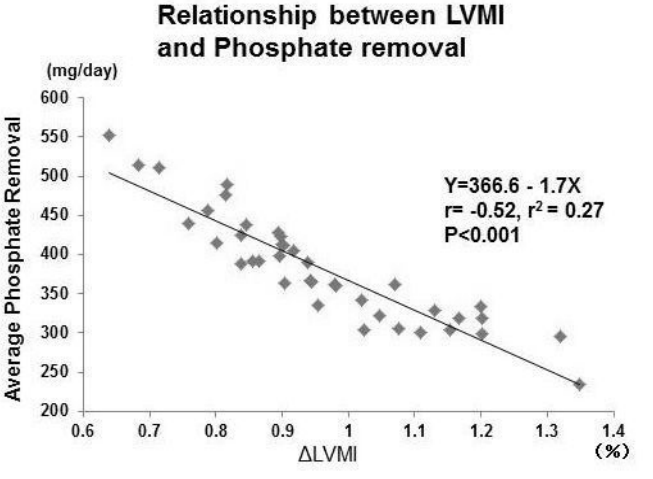
Results: At the start of PD, group B showed significantly higher value in PET, BNP left ventricular mass index(LVMI) and aortic valve calcification score(AVC) and lower urinary volume(UV) than those of group A. During 2 years on PD, phosphate removal and UV were preserved. And improvement of PET, LVMI, and decreased value of BNP were also observed.

Change in laboratory findings

	baseline		after 2 years	
	group A (Glucose)	group B (Icodextrin)	group A (Glucose)	group B (Icodextrin)
phosphate removal(mg/day)	406.7±17.0	369.4±21.8	305.8±16.4	422.4±14.1
urinary volume(ml/day)	1210.0±99.0	762.5±53.5	712.5±109.1	625.5±70.1
LVMI(g/m2)	139.3±7.0	161.9±9.5	155.2±8.5	130.0±8.0

Table 1

The correlation between phosphate removal and progression of LVMI showed statistical significance.



And in the cases with AVC improvement, phosphate removal were more than those without improvement.

Conclusions: These results indicate icodextrin preserved UV and peritoneal membrane function and ameliorated the progression of cardiac hypertrophy and valve calcification. And phosphate clearance by icodextrin was better than that by glucose. More phosphate removal ameliorates the progression of atherosclerosis. So the phosphorus was thought to be the factor of atherosclerosis.

PUB417

Mycobacterium Fortuitum: A Rare Exit Site Infection in a Peritoneal Dialysis Patient James E. Novak,[1] David R. White.[2] *[1]Henry Ford Hospital; [2]Nephron Associates.*

Background: Exit-site infections (ESI) are common in patients undergoing peritoneal dialysis (PD), but < 1% of causative pathogens are mycobacterial.

Methods: We report a case of *Mycobacterium fortuitum* ESI in which aggressive treatment was required for technique salvage.

Results: A 63-year-old man with end-stage renal disease status post recently failed kidney transplant initiated PD. His immunosuppressive regimen of rapamycin,

mycophenolic acid, and prednisone was gradually tapered. One month after starting PD, he noted pain, erythema, and purulent discharge from the PD catheter exit site. He denied fever, chills, abdominal pain, or cloudy dialysate, and did not show signs of peritonitis. He was prescribed trimethoprim-sulfamethoxazole (TMP-SMX) for 2 weeks with complete resolution of signs and symptoms. Discharge from the exit site subsequently grew *M. fortuitum*. After 2 months, purulent discharge recurred. TMP-SMX was resumed and cultures again grew *M. fortuitum*. TMP-SMX was changed to intravenous cefoxitin for 2 weeks and oral clarithromycin for 6 weeks. The patient underwent laparoscopic removal of the infected catheter with simultaneous placement of a new catheter at a different site. His dialysis prescription was temporarily adjusted to low-volume exchanges to allow the new catheter site to heal. The patient has remained on PD with no recurrence of infection. In this case, the tapering immunosuppression from his failed kidney transplant may have predisposed him to ESI with *M. fortuitum*.

Conclusions: *M. fortuitum* is a Gram-positive, acid-fast, rapidly growing, nontuberculous mycobacterium (NTM) with global distribution. It can be found in natural and processed water, sewage, and dirt. It has been associated with nosocomial infection of implanted devices, including catheters. Of the NTM, *M. fortuitum* is the most common pathogen giving rise to ESI, tunnel infections, or peritonitis in patients undergoing PD. In cases of peritonitis with any organism, 30–50% result from inadequately treated ESI, and rates of catheter loss in this setting are as high as 15–57%. In summary, *M. fortuitum* ESI requires aggressive treatment, including prolonged antibiotic treatment and frequently catheter exchange, to allow continuation of PD.

PUB418

Clinical Outcomes of Uncommon Bacterial Peritonitis in Peritoneal Dialysis Patients Omkar U. Vaidya, Ramesh Saxena. *Nephrology, University of Texas Southwestern, Dallas, TX.*

Background: Peritoneal dialysis (PD) patients occasionally get uncommon bacterial peritonitis (UBP).Not much data on prevalence of UBP and their clinical outcomes is available.That led us to perform a retrospective analysis of outcomes of UBP in our PD patients.

Methods: We performed a retrospective evaluation of all the patients initiated on PD between 2001 and 2012 and developed UBP.Patients who developed peritonitis from common bacteria and fungi were excluded.Primary outcomes were defined as resolution of UBP, PD technique failure or death due to peritonitis.

Results: We initiated 421patients on PD between 2001 and 2012. Of these, 31 patients developed 41 episodes of UBP.All patients received appropriate intraperitoneal antibiotics for 14– 21 days as per their sensitivities & response to treatment. Of the 31 patients with UBP, 7 had PD technique failure leading to transition to hemodialysis. Of these 7 patients, one had 2 recurrent Acenetobacter infections, one had three recurrent Corynebacterium infections and 2 had single episodes of Acinetobacter Peritonitis.Additionally one each has UBP from Campylobacter, Acid fast bacilli (AFB) and Neisseria species. All other UBP resolved. All cases of UBP from Acinetobacter, Corynebacterium, Campylobacter, AFB and Neisseria species led to PD failure.No death resulted from UBP.

Patient characteristics of PD techinque failure from UBP

Sr no	Age/Race	Sex	Etiology of End stage renal disease	Medical and Sugical history	Organism
1	44 yr African American	Male	IgA nephropathy	Hypertension(HTN)	Acinteobacter baumanni
2	29 yr Caucasian	Male	Failed living related kidney transplant	HTN	Neisseria species
3	32 yr Hispanic	Male	HTN/DM	Diabetes Mellitus(DM)/HTN	Recurrent Acinetobacter baumannii
4	54 yr Caucasian	Female	HTN	HTN/ Oopherectomy	Acid fast Bacilli
5	32 yr African American	Male	HIV/HTN	HIV/HTN	Recurrent Corynebacterium species
6	46yr Caucasian	Male	DM/HTN	DM/HTN	Campylobater species
7	42 yr Hispanic	Female	Lupus	Cesarean section, Hysterectomy	Acinetobacter baumannii

Table 1

Conclusions: We observed that overall UBP has good outcome. However, UBP from Acinetobacter, Corynebacterium, AFB, Neisseria species and Campylobacter is associated with PD technique failure.

PUB419

Aggravation of Peritoneal Permeability during Long-Term Peritoneal Dialysis Therapy Related to Increase in PD Dropout Yasufumi Takahashi,[1] Mamoru Kobayashi,[1] Koji Hashimoto,[2] Yuji Kamijo,[2] Makoto Higuchi.[2] *[1]Nephrology Internal Medicine, Nagano Red Cross Hospital, Nagano, Japan; [2]Nephrology Internal Medicine, Shinshu University School of Medicine, Matsumoto, Japan.*

Background: Insufficient bodily fluid removal is the most serious problem causing dropout from peritoneal dialysis (PD) therapy and in these cases, a transfer to hemodialysis or a combination therapy of PD and hemodialysis is crucial. Therefore, control of the fluid volume is very important for management of PD. The fluid removal capacity in PD is known to be related to peritoneal permeability; however, it is still unclear whether peritoneal permeability status has an influence on the PD dropout rate.

Methods: We investigated 74 patients undergoing PD, retrospectively. Throughout the observation period, we regularly carried out a peritoneal equilibration test (PET) to evaluate their peritoneal permeability status. Using this PET data -- as well as other parameters, including various laboratory examinations, the incidence rate of peritonitis, existence of diabetes, and medication history -- we statistically analyzed prognostic factors responsible for PD dropout. Patients who withdrew premeditatedly from PD to prevent encapsulating peritoneal sclerosis were excluded as dropouts.

Results: During the observation period (average: 49 months), 30 patients (41%) dropped out of PD and 12 patients (16%) died. The dialysate/plasma creatinine (D/P Cr) ratio at the PD starting point for each patient was unrelated to the dropout and mortality rates. The Cox proportional hazards model revealed that an increase in the D/P Cr ratio during long-term PD, the existence of diabetes, and the incidence rate of peritonitis were all significant independent predictors of dropout from PD (HR and 95% CI, 4.83 (1.3-17.6) vs. 4.31 (1.0-23.2) vs. 4.89 (1.7-14.1), respectively).

Conclusions: These findings suggest that the detection of peritoneal permeability aggravation during long-term PD is more important for predicting dropout than a one-point evaluation of PET. Careful monitoring of peritoneal permeability status would be very important for preventing PD dropout.

PUB420

Risk Factors for Recurrent Peritoneal Dialysis Peritonitis in CAPD Patients Sug Kyun Shin,[2] Youngeun Kwon,[1] Kyoung Sook Park,[1] Jae-kyoung Kim,[1] Yong Kyu Lee,[2] Tae Ik Chang,[2] Ea Wha Kang,[2] Seung Hyeok Han,[1] Tae-hyun Yoo,[1] Beom Seok Kim.[1] *[1]Internal Medicine, Yonsei University Medical School, Seoul, Korea; [2]Inernal Medicine, NHIC Ilsan Hospital, Goyang-shi, Kyunggi-do, Korea.*

Background: Recurrent peritoneal dialysis peritonitis(RPDP) is a serious cause in PD patients' drop out. In spite of the advancement of connectology and biocompatibility in peritoneal dialysate, the incidence of RPDP does not seems to be reduced. Assessment of risk factors for RPDP can be helpful to prevent PD complication.

Methods: Total 498 PD peritonitis episodes(PDPE) were included that were developed from Mar. 2000 to Dec. 2011 at NHIC Ilsan hospital, Korea. We conducted the analysis of PDPE that was devided to simple PD peritonitis(SPDP) and RPDP. RPDP was defined as a developed peritonitis within 4 weeks after antibiotic therapy or a peritonitis needed antimicrobial therapy of more than 6 weeks. We compared the basic data, hematologic, biochemical parameters and the results of culture study between RPDP and SPDP.

Results: Total 498 PDPE were measured in 389 PD patients. Univariate analysis showed that Hb., albumin and residual renal function(RRF) were lower, and age, the proportion of diabetes was higher in RPDP than SPDP group. Bicarbonate dialysate and no growth in culture were significantly frequent in RPDP compared to SPDP group. Multivariate analysis showed that RRF, bicarbonate dialysate, plastic bag and fungal peritonitis were significant.

Multivariate Analysis on Risk Factors of Recurrent PD Peritonitis

Factors	O.R.	95% C.I.	p-value
Time to peritonitis	1.027	0.97-1.51	0.387
Serum albumin (g/dL)	0.831	0.45-1.48	0.457
Initial dialysate WBC count on peritonitis (/mm^3)	0.954	0.57-1.58	0.098
RRF on peritonitis (ml/min/1.73mm^2)	1.142	0.95-2.89	0.038
Kinds of dialysates	1.254	0.91-2.88	0.049
Kinds of PD bag's materials	1.313	0.79-1.57	0.045
Fungal peritonitis	8.791	3.69-21.24	0.000

PD: peritoneal dialysis, OR: odds ratio, C.I.: confidence interval, RRF: residual renal function

Conclusions: In this study, not only RRF and fungal peritonitis, but also bicarbonate dialysate and plastic bags were revealed as independent risk factors for RPDP. To verify our results may be needed multi-center analysis with larger size.

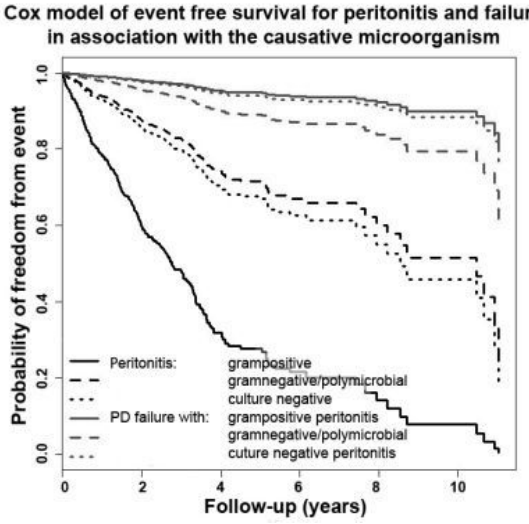
PUB421

Infectious Peritonitis in Peritoneal Dialysis: Germ Spectrum and Its Impact on PD Failure Claudia Praehauser,[1] Bernard Descoeudres,[2] Andreas Schötzau,[3] Michael Mayr.[1,4] *[1]Medical Outpatient Department, University Hospital Basel, Basel, Switzerland; [2]Department of Nephrology, Hôpital du Jura, Porrentruy, Switzerland; [3]Schötzau & Simmen, Basel, Switzerland; [4]Clinic for Transplantation Immunology and Nephrology, University Hospital Basel, Basel, Switzerland.*

Background: Infectious peritonitis (IP) is a major reason for peritoneal dialysis (PD) failure. Aim of the study was to analyze the importance of specific pathogenic microorganisms for clinical outcome.

Methods: Retrospective single centre study of all patients admitted for PD from 1983 to 2011. Combined endpoint was IP related PD failure consisting of technique failure (defined as the inevitable definitive stop of PD) and death in association with the causative microorganism.

Results: 139 of 321 patients (43%) experienced 268 IP episodes. 226 (84%) episodes were culture positive, of them 68% were gram-positive, 19% gram-negative and 13% polymicrobial. Compared to the risk for gram-positive IP, the risk for gram-negative or polymicrobial (HR 0.26, CI 0.20-0.35) and culture negative IP (HR 0.31, CI 0.21-0.44) was significantly lower (figure).



39 patients experienced IP associated PD failure (12 deaths and 27 technique failures). The percentage of fatal episodes and technique failures was 1% (2/154) and 3% (4/154) in gram-positive, 7% (3/42) and 21% (9/42) in gram-negative, 13% (4/30) and 33% (10/30) in polymicrobial and 7% (3/42) and 10% (4/42) in culture negative IP episodes, respectively. The risk of IP associated PD failure was significantly higher for gram-negative/ polymicrobial (HR 8.33, CI 3.62-19.19) and culture negative (HR 3.82, CI 1.36-10.79) IP than for gram-positive IP.

Conclusions: Grampositive bacteria are the most frequent cause of IP in PD. However, the risk of IP associated PD failure is much higher in gram-negative, polymicrobial and culture-negative IP than in gram-positive IP.

PUB422

Serum Response Factor Expedites Epithelial-to-Mesenchymal Transition by Modulating the Expression of Snail in Peritoneal Mesothelial Cells

Shiren Sun,[1] Lijie He,[1] Hanmin Wang.[1] *[1]Department of Nephrology, Xijing Hospital, FMMU, Xi'an, Shaan Xi, China.*

Background: Treatment of primary human peritoneal mesothelial cells (HPMCs) with high glucose (HG) induced EMT, characterized by downregulating E-cadherin, upregulating of α-SMA and cell spindle-like morphology. Serum response factor (SRF), a transcription factor activated when translocation in nucleus, can regulate cell metastasis by expediting EMT. However, the mechanism of SRF in PD process hasn't to be elucidated.

Methods: We isolated HPMCs from PD effluents from CAPD patients. All these cells were characterized by phenotype markers and tested the location of SRF by immunofluorescence. We also tested these in immortal HPMCs and PD animal model, and explored the possible pathway regulated by SRF.

Results: With the dialysis time, HPMCs undergo a transition from an epithelial to a mesenchymal phenotype with a loss of epithelial morphology, a decrease E-cadherin, an increase α-SMA and the translocation of SRF from cytoplasm into nucleus. Moreover, blockade of SRF expression could reverse EMT in transdifferentiated HPMCs isolated from PD effluents. In vitro analyses, HG-induced HPMCs were change into fibroblast-like cells, down-regulation of E-cadherin, up-regulation of α-SMA and translocation into nucleus of SRF. Overexpression of SRF demonstrated that active SRF is required in EMT process marking for down-regulation E-cadherin and up-regulation α-SMA. Obtained with SRF inhibitor or infection with SRF-siRNA vectors could reverse EMT by upregulation E-cadherin and downregulation α-SMA. HG-mediated induction of mRNA and protein expression of the transcription factor Snail1, a repressor of E-cadherin expression and a potent inducer of EMT, was inhibited by blockade of SRF. Furthermore, ChIP and reporter assay showed SRF could directly promote the transcription of snail by binding serum responding element 2 (SER2).

Conclusions: The findings suggest that modulation of the SRF/Snail1 pathway may provide a means of enhancing the progressive structural and functional deterioration of the peritoneal membrane during PD.

PUB423

Analyses for Peritoneal Dialysis Withdrawal: Twenty-Seven Years of Experience in a Single PD Center in China

Huiling Wang. *Division of Nephrology, Jimin Hospital, Shanghai, China.*

Background: The number of peritoneal dialysis (PD) withdrawal is increasing last ten years. The study investigated causes of PD withdrawal and assessed risk factors of death in 27 years of experience in a single PD center.

Methods: All the Patients undergoing PD at lest 1 months, enrolled this retrospective observational study from January 1985 to December 2011. We investigated causes of PD withdrawal, analyzed demographic characteristics, laboratory data, dialysis adequacy parameters, residual renal function, peritoneal transport characteristics, and nutritional status according their medical records.

Results: A total of 595 patients were enrolled, of whom 292 were females (49.1%). The mean age at the start of PD was 59.9 ± 16.8 years. The primary diseases of ESRD were glomerulonephritis (52.3%), hypertension (16.6%), diabetes (15.3%) respectively. The mean PD duration was 14.7 ± 16.8 months. Until December 2011, 296 (49.8%) died, 152 (25.5%) transferred to hemodialysis, 64 (10.8%) received kidney transplant, and 83 (13.9%) lost in follow up. The first cause of death was cardiovascular events (41.6%); the second was infection (33.0%) in which pulmonary infection (23.2%) and peritonitis (9.8%) was the severe events directly related to death. The cerebral vascular accident (9.5%) was the third cause for death. PD associated infection was first reason for transfer to hemodialysis (59.2%), the followed reason was technique failures (occlusion, drift, leakage, etc. 25.7%) and insufficient PD (7.2%). In the Cox proportional hazards model analysis, the risk factors related to mortality were gender which means female PD patients had a higher risk (RR:1.33, p = 0.014); age (RR: 1.04, p < 0.001), diabetes (RR: 1.65, p = 0.001), hemodialysis transfer to PD (RR: 1.33, p = 0.015), and low serum albumin level (RR: 1.27, p = 0.015).

Conclusions: In our PD center, the major cause of PD withdrawal was death, and then was transferred to hemodialysis. The cardiovascular events was the first cause of death. PD associated infection was the major reason for transferred to hemodialysis. Female, older age, diabetes, malnutrion condition or hemodialysis transfer to PD, predict higher risk for all cause-death.

Multicultural Dialisys Unit New Opening: Three Years Experience

Maria Eva Baro-Salvador. *Nephrology, Hospital de Torrevieja/Hospital de Vinalopo, Torrevieja/Elche, Alicante, Spain.*

Background: New Peritoneal Dialysis Unit opening always represents a challenge for a Nephrology Service.Initial inexperience´s team, sluggish growth in patients number,new tests implementation in other servicies(laboratory,radiology), understanding with the surgical unit,.are reasons of constant effort and learning.If patients have diverse nationalities this is impeded furthermore.In the unit openning besides the previous one, we had to bear in mind a cultural and idiomatic differential fact and that, in addition, was very dispersed.It was worrying us that this idiomatic and cultural barrier can cause implementation and maintenance problems of the technique.For this reason we analyze the three years experience information of prevalence,incidence,complications and cessations of technique,TT and age to reject that the differential(cultural/idiomatic)fact had effect in the above mentioned information.

Methods: Annalisis of three years data of prevalence, incidence,complications and cessations/changes of technique, time of training and age.

Results: Program entries 23 patients(13W/10M),ages from 30 to 80 years (total ages:59; ages spanish:52. 8; ages other languages:69.1);14 Spanish and 9 foreigners (61 and 29 % respectively. Time of training (TT),total: 7.6,TT spanish:7.25,TT others: 8.7, TT <65 years (total): 7.2, TT> 65 y (total): 9.8. Exits of program 5 patients.Complications: peritonitis 6 in 4 patients (2 episodes/year); placements of catheter 28 in 23 patients (5 refills, 2 peritonitis and 3 dysfunction);cuff extrussion 4;escapes of liquid 2; exit site infection 23; tunelitis 1. Results: we have not found any relation between nationality/language and complications or technique maintenance,we found differences in TT between age and idiom, our results shows that TT is higher in the 65-year-old major patients not only in the foreign but also in the spanish speak group.

Conclusions: Putting in march a new unit of peritoneal dialysis is costly but an idiomatic difference in the patients does not imply more complications or diferences on technique maintenance in this group; nevertheless the training time in this group is more difficult and take us more time as it happens also in the most aged patients of our unit.

PUB425

Peritoneal Balances of Mg in Peritoneal Dialysis Patients Treated and Not Treated with Oral Mg Salts Binders

Jesus Montenegro, José Ignacio Cornago, Maria Isabel Gallardo, Paula García, Ainhoa Hernando, Rosa Ines Munoz. *Nephrology, Hospital de Galdakao-Usansolo, Galdacano, Spain.*

Background: Optimun concentration of Mg in Peritoneal Dialysis solutions remains in controversy.With the objective of finding out the peritoneal balances of Mg, a randomized cross over study was done in prevalent CAPD patients.

Methods: The patients were divided into 2 randomized groups. Group 1: the 23 patients started taking Mg salts (Mg carbonate and Ca acetate, Osvaren®, Fresenius Medical Care) during 2 months; after these two months they took Lanthane Carbonate (Fosrenol®, Shire) during two months and at the end they changed to Osvaren during 2 months. In group 2 there were 22 patients and the design: Fosrenol→Osvaren→Fosrenol, changing every 2 months. The peritoneal fluid contained 1,2 mg/dL (0,50 mmol/L) of Mg. Every period lasted 2 months and at the end of this period the following values were measured: Mg, Ca, P, in blood, peritoneal fluid and 24 hours urine. PTH levels were measured as well. The residual renal function was calculated as well ultrafiltration (UF) and peritoneal balances of Mg.

Results: Serum Mg increases signiphicantly during the period they took Mg salts. The peritoneal balances of Mg were negative in every patient and in all periods and the peritoneal losses of Mg were greater significantly during the intake periods with Mg salts, related with the UF and the serum levels of Mg, see.

Peritoneal Balances of Mg

Groups: daily peritoneal losses	Basal	2 months	4 months	6 months
G1: Mg.mg/day	-22.7±20.3	-48.8±22.1	-17.9±9.9	-33.3±13.0
G2: Mg.mg/day	-23.7±17.4	-28.5±28.9	-38.0±13.2	-18.6±10.7
p	0.87	0.003	0.001	0.0002

UF influences peritoneal balances of Mg (p= 0, 02), in other words, the greater the UF the greater the peritoneal loss of Mg. The serum levels of Mg contributed much more (p=0,001), for every increase of 1 mg of serum Mg, the peritoneal losses of Mg increased in 32, 8 mg/day. There was no case of clinic hypermagnesemia.

Conclusions: Therefore Mg salts are safe in patients treated with PD solutions containing a concentration of 0, 50 mmol/L of Mg. After this study, we recommend an increase in the concentration of Mg in the PD fluids, at least in patients that are not taking Mg salts.

PUB426

Peritoneal Dialysis Associated Achromobacter Xylosoxidans Peritonitis, a Rare but Virulent Organism Seyyar Khan,[1] Ashish Kataria,[1] Elvedin Lukovic,[2] Mala Sachdeva.[1] *[1]Department of Medicine-Division of Nephrology, Hofstra North Shore-LIJ School of Medicine, Great Neck, NY; [2]Downstate Medical Center.*

Background: Peritonitis is a well known complication in patients on peritoneal dialysis (PD). Staphylococcus species and gram negative organisms such as Escherichia Coli and Pseudomonas Aeruginosa remain the most common causative organisms, although fungal, mycobacterial, and polymicrobial peritonitis do occur. Achromobacter Xylosoxidans causing peritonitis has rarely been reported. We report a complicated case of Achromobacter Xylosoxidans associated peritonitis requiring catheter removal.

Methods: A sixty-eight year old Korean female with a history of diabetes mellitus, hypertension, and end stage renal disease on Continuous Ambulatory Peritoneal Dialysis (CAPD) for four years presented with abdominal pain, fever, and cloudy dialysate for two weeks. Intraperitoneal (IP) vancomycin and ceftazidime were empirically begun for suspected peritonitis. Initial peritoneal fluid cell count and culture revealed 3500 WBC's with 73% granulocytes and coagulase negative Staphylococcus and bacillus species, not anthrax. Day two peritoneal fluid culture revealed coagulase negative Staphylococcus and Achromobacter Xylosoxidans. Achromobacter Xylosoxidans was initially sensitive to ceftazidime and ciprofloxacin. Thus, she was maintained on vancomycin IP, ceftazidime IP, and oral ciprofloxacin. Sensitivities five days post treatment revealed that Achromobacter Xylosoxidans was resistant to ceftazidime. Day six culture continued to grow out Achromobacter Xylosoxidans. Multiple CT abdomen and pelvis were negative for abdominal pathology. Given persistent culture positivity despite aggressive antibiotic treatment, a decision was made for catheter removal and hemodialysis was initiated.

Conclusions: Despite breakthroughs in treating PD associated peritonitis, clinicians must keep in mind all organisms responsible. When Achromobacter Xylosoxidans is the causative agent careful monitoring and quick removal of peritoneal catheter should be implemented. This avoids the high morbidity and mortality that has been associated with this organism as it is a highly virulent and resistant organism.

PUB427

Residual Renal Function Is a Crucial Determinant of Blood Pressure of Patients with Peritoneal Dialysis Hideki Yamahara, Takanobu Imada, Hiroko Ueda, Mitsutaka Nakahigashi, Chikara Nakano, Kazunori Someya, Makiko Kusabe, Sanae Kikuchi, Hiroyasu Tsukaguchi, Hiroya Masaki, Mitsushige Nishikawa, Ichiro Shiojima. *Department of Medicine II, Kansai Medical University, Osaka, Japan.*

Background: Continuous ambulatory peritoneal dialysis (CAPD) is an important renal replacement therapy. However, continuous exposure of the peritoneal membrane to unphysiologic PD fluid results in injury of the peritoneum.

Methods: We performed a peritoneal equilibration test every 6 months to 18 outpatients. We checked weekly Kt/V urea as a dose of small-solute clearance. On the same day, we checked their human atrial natriuretic peptide (hANP), brain natriuretic peptide (BNP) and blood pressure.

Results: Total small-solute clearance (weekly Kt/V urea) was suitable (2.31 ± 0.573 (mean ± SD)). However, some CAPD patients had increased hANP (74.1 ± 65.7 pg/ml) and, BNP (166 ± 164 pg/ml), and blood pressure (153 ± 21.2 / 90 ± 12.7 mmHg) than standard value. Blood pressure was negatively correlated with residual renal small-solute clearance (r=-0.319, p=0.009), and urine volume (r=-0.318, p=0.008), but was not significantly associated with dialysis small-solute clearance (r=0.157, p=0.206). BNP and hANP were also negatively correlated with residual renal small-solute clearance and urine volume, but was not associated with dialysis small-solute clearance.

Conclusions: The main finding of this study is that residual renal function contributes to blood pressures of CAPD patients. CAPD patients with low residual renal function tends to cause volume expansion. Thus, combination therapy of hemodialysis and peritoneal dialysis or discontinuation of CAPD is desirable for CAPD patients with low residual renal function and high blood pressure.

PUB428

Peritoneal Balances of Calcium in Peritoneal Dialysis Patients Treated with and without Oral Calcium Salts Binders Jesus Montenegro, José Ignacio Cornago, Maria Isabel Gallardo, Paula García, Ainhoa Hernando, Rosa Ines Munoz. *Nephrology, Hospital Galdakao-Usansolo, Galdacano, Vizcaya, Spain.*

Background: The concentration of Ca 7 mg/dL or 5 mg/dL in Peritoneal Dialysis Solutions (PDS), can induce positive and negative peritoneal balances of Ca (PBCa).

Methods: A randomized cross-over study was designed in prevalent CAPD patients to find out if the BPCa were related with the intake of phosphate Ca binders (Ca acetate and Mg carbonate, Osvaren®, Fresenius Medical Care) or binders without Ca (Lanthanum Carbonate, Fosrenol® ,Shire). After 15 days of wash-out the patients were randonmized into two groups: group 1: Osvaren-Fosrenol-Osvaren, changing every 2 months the phosphate binder. Sequence in group 2: Fosrenol-Osvaren-Fosrenol, changing the phosphate binder every 2 months as well. The P contained 7 mg/dL of Calcium in both groups. At the end of each period, the following values were determined: Ca, Mg, P, in blood, in peritoneal fluid (LP) and in 24 hour urine. PTH levels were measured. The dose of phosphate binders, the proteins intake, the ultrafiltration and the BPCa were calculated.

Results: The BPCa was positive in all patients of both groups and in all periods, independently of the intake of salts with Ca salts or without Ca, see **Table 1**.

Outline of peritoneal balance of calcium in both groups

Groups	Basal	2 months	4 months	6 months
G1 (BPCa, mg/día)	+50.7±27.8	+26.2±38.3	+35.1±25.2	+ 34.2±27.0
G2 (BPCa, mg/día)	+43.4±30.8	+37.6±26.8	+26.5±28.5	+40.7±29.3
p	0.41	0.26	0.29	0.44

The degree of UF influences on the BPCa, p<0,001, therefore, the greater the UF, the greater the peritoneal emoval of Ca. The serum Ca increased with the intake of Ca salts and had a greater contribution in the Calcium peritoneal removal, p<0,001, for every increase of 1 mg of serum Ca, the peritoneal removal of Calcium raised 24,5 mg per day.

Conclusions: All patients gains Ca with this PDS, independently of type of binders, UF and serum Ca. The standard concentration of 7 mg/dL of Ca in PDS is excessive for every patient. We should consider that the concentration of 6 mg/dL of Ca could be the standard SDP. The concentration of Ca of 5 mg/dL in PDS is recommended in patients who take Ca salts in great amounts.

PUB429

Glucose Profile Assessment of Continuous Glucose Monitoring System and Use of Insulin Pumps in Patients with End-Stage Diabetic Nephropathy on Maintenance Continuous Ambulatory Peritoneal Dialysis Shuangxin Liu, Wei Shi, Xinling Liang, Zhiming Ye, Wenjian Wang, Jianchao Ma, Lixia Xu. *Division of Nephrology, Guangdong General Hospital, Guangzhou, Guangdong, China.*

Background: The glycemic control is known to be an important determinant of the rate of progression of patients with diabetic continuous ambulatory peritoneal dialysis (CAPD) patients. Good glycemic control is often difficult to maintain in diabetic patients with CAPD, because they are continuously exposed to high concentrations of glucose in peritoneal dialysate. However, recent studies have suggested that diabetic patients who use insulin pump has been shown to reduce glycated hemoglobin levels without an increased risk of hypoglycemia, as compared with a regimen of multiple daily insulin injections. The continuous blood glucose monitor (CGMS) has recently offered an opportunity to monitor blood glucose at 5-minute intervals for 72 continuous hours in diabetic patients.

Methods: There were 12 diabetic patients on CAPD using conventional 1.36% or 2.27% glucose PDFs examined in the study. All participants underwent 72-hour CGMS and HbA1c evaluation. Continuous subcutaneous insulin pump insulin intensive therapy group for the ultra-short effect of human insulin analogues - insulin lispro, conventional subcutaneous insulin Humalog before meals program for the Addition 21:00 Novolin N treatment. There was the whole area under the curve (AUC) of each 24-hour glucose profile. Glucoes area above high limit is 10 mmol/L, and glucose area below low limit is 3.9mmol/L.

Results: Diabetic CAPD patients 12 cases with first use of continuous subcutaneous insulin pump therapy to strengthen, then the routine use of subcutaneous insulin program. Duration above high glucose limits are 65% ± 22%, duration within limits are 35 ± 15% in continuous subcutaneous insulin pump therapy group, while duration above high glucose limits are 81% ± 32%, duration within limits are 19% ± 8% in the conventional subcutaneous insulin program, p< 0.05.

Conclusions: In diabetic peritoneal dialysis patients with insulin pump therapy compared with conventional subcutaneous insulin solution, blood glucoes are more stable standard.

PUB430

Surgical Complications of Peritoneal Dialysis Catheters Surabhi B. Thakar, Timothy A. Pflederer, Beverley L. Ketel, Timothy P. O'Connor. *Renal Care Associates.*

Background: Peritoneal dialysis catheters (PDC) are associated with complications requiring surgical treatment, including malposition, inflow or outflow occlusion, refractory peritonitis, and ineffective dialysis leading to removal and change of modality. The rate of these events in North American practices is not widely reported.

Methods: We conducted a retrospective review of initial PDC placements over a 4 year period in an ESRD practice with 14% prevalence of PD. PDC's were inserted by 2 surgeons and 1 nephrologist. Data fields collected were prior abdominal surgery, technique used, types and timing of subsequent surgery, PDC complication noted, other dialysis modalities used, reasons for multiple PDC procedures. PDC removals due to kidney transplant were excluded.

Results: Out of 179 PD insertions, 157 (87.7%) were open procedures and 22 (12.2%) laparoscopic. 79 (44.1%) had a subsequent procedure at a median time of 106 days. 33 (18.4%) of insertions had a second procedure within 60 days. 26 (32.9%) of subsequent procedures were repositioning for malposition/adhesions/flow problems, (18 in first 60 days) and 53 were removals (13 in 1st 60 days). 23 removals (43.3%) were for refractory peritonitis, 7 (13.2%) for malfunction, 4 (7.5%) for tunnel/exit site infection, 13 (24.5%) for elective convertion to hemodialysis, 5 (9.4%) for other reasons and 1 for diaphragmatic fistula. 9 (40.9%) of the laparoscopic and 70 (44.3%) of open insertions needed a subsequent procedure. 114 (63.3%) patients had a history of prior abdominal surgery before PDC placement, 55 (44.5%) of these had a subsequent procedure while 59 (51.7%) did not.

5 (22.7%)laparoscopic insertions and 28 (17.7%) open insertions needed a subsequent procedure in 1st 60 days. 9 (5%) PDC insertions underwent >1 subsequent procedure.

Conclusions: PDC insertions are associated with a reasonable number of surgical complications, needing more removals than repositioning, the most common indication for removal being recurrent peritonitis. Prior abdominal surgery or particular method of insertion did not increase the risk of subsequent procedure. Open PDC insertion when compared to laparoscopic placement was not associated with more subsequent procedures in the first 60 days.

PUB431

Study of Long-Term Peritoneal Dialysis Hiroyuki Tamura. *Nephrology, Toshima Central Hospital, Toshima-ku, Tokyo, Japan.*

Background: In Japan, in order to prevent serious complicating disorder such as encapsulating peritoneal sclerosis, at the beginning of treatment, the available period of peritoneal dialysis (PD) has been set, and combination therapy of PD and hemodialysis has been giving priority rather than solo PD treatment in many cases.

Although we have been providing solo PD treatment since 1986 without the available period, the case of encapsulating peritoneal sclerosis has been zero for now, many PD-patients have continued for long periods.

Here we examined the continuation rates of PD at our hospital and factors affecting long-term PD.

Methods: In patients who started PD at our hospital between 1986 and 2012, we examined continuation rates, patient characteristics at the introduction of PD, the peritoneal equilibration test (PET), and reasons for withdrawal of PD.

Results: This study included 113 patients (66men, 47women). The mean age at introduction was 57.94 years (range: 13-90). The mean PD duration was 5.4years (range: 0.1-19). The 5- and 10-year continuous PD rates were 60%, and 38%, respectively. The factors affecting continuation of PD were the presence or absence of diabetes and ischemic heart disease among patient characteristics, as well as ultrafiltration failure among reasons for withdrawal of PD.

Conclusions: In many cases, as the PD-patients accept the available period and combination treatment, it may be difficult to examine the possibility of PD treatment.

Throughout solo PD treatment, we have achieved certain guidelines (routine performance of PET and assessment of dialysis doses, early detection, early treatment, etc. of peritonitis, catheter dysfunction, etc.; and prevention and treatment of complications), allowing examination of long-term ongoing PD. The factors affecting the long-term continuation were diabetes, ischemic heart disease, and ultrafiltration failure. No influence of peritonitis morbidity was observed. PD is a therapeutic approach using biological membranes, and caution is necessary with the continuation of this approach. However, long-term continuation of better PD may be achieved by periodic screening of PD itself and appropriate treatment of complications specific to this form of dialysis.

PUB432

Anuria: A Villain in Quality of Life and Sexual Dysfunction in Peritoneal Dialysis Pedro Francisco Azevedo,[1] Ricardo Santos,[2] Jose Duraes,[1] Olivia Santos,[1] Maria João Carvalho,[1] António Manuel Nunes Cabrita,[1] Anabela S. Rodrigues.[1] *[1]Nephrology, Hospital Santo António, Porto, Portugal; [2]Gynecology and Obstetrics, Centro Hospitalar do Alto Ave, Guimarães, Portugal.*

Background: There are several studies that address the quality of life of patients on peritoneal dialysis (PD). Sexual dysfunction, anxiety and depression are highly prevalent in patients undergoing PD, but studies focusing these particular issues are scarce, especially, in an integrated approach to the patient with anuria.

This study aims to evaluate sexual dysfunction and its predictors among PD patients, particularly in patients without residual renal function.

Methods: In this observational, cross-sectional study, all chronic PD patients in one Center were asked to complete a self-reported questionnaire: the International Index of Erectile Function (IIEF) for men and the Index of Female Sexual Function (IFSF) for women. Both groups answered the Hospital Anxiety and Depression Scale (HADS) to evaluate the prevalence of depression and anxiety and the EuroQol (EQ5D) to measure quality of life (QoL).

Mann Whitney U and Chi-square tests were used for group comparisons. We assessed confounding variables with multivariate regression analysis.

Results: We evaluated 57 PD patients (50,9% males, mean age 53,9±15,7 years, 27,6% diabetes, 24.6% anuric). Anuric patients had higher CRP (P=0,011), lower serum uric acid (P=0,034) and lower nPCR (P=0,002). The prevalence of sexual dysfunction was higher in anuric patients (78,6 vs. 46.5%, P=0,036). Anuric males had worse QoL (P=0,014) and erectile function (P=0,04). On multivariate analysis, anuria, diabetes and smoking were independent predictors of worse IIEF score (P<0.001), in a model that accounts for 56% of sample variation (adjusted R square). The same was not true with the FSFI score in anuric women. Anuria did not have a significant impact in HADS score.

Conclusions: Sexual function and QoL assessment should be part of the integrated care of PD patients. Male patients with anuria, diabetes and smoking habits deserve closer attention in these issues.

PUB433

Our Experience with Encapsulating Peritoneal Sclerosis (EPS) Erzsebet Ladanyi,[1] Otto Arkossy.[2] *[1]Nephrology Center, Fresenius Medical Care, Miskolc, Hungary; [2]Dialysis Center, Fresenius Medical Care, Budapest, Hungary.*

Background: EPS is a rare but serious complication of mainly long-term peritoneal dialysis (PD). The number of long-term PD patients is increasing in our center. The clinical assessment of EPS is difficult due to the insidious development and broad clinical spectrum. The aim of this study was to evaluate the clinical features of our EPS cases and to identify possible risk factors.

Methods: Retrospective review of patients with diagnosis of EPS and the long-term patients (>60 months) over the last 11 years in our center. Demographic data, peritoneal equilibration test (PET), clinical outcomes were collected.

Results: 239 patients were treated with PD between 2000-2011. The mean duration of PD treatment was 36 months. There were 41 long-term patients (17%) with the average of 95 months PD treatment. The average D/P and the peritonitis rate at PD withdrawal were 0,68 and 1,9 /treatment. We identified 4 EPS cases (0,01%). Their mean duration of peritoneal treatment was 121 months. Their mean peritonitis rate was 5/treatment. The reasons of finishing PD were I type UF failure and inadequate dialysis. Their avarage D/P at PD cessation was 0,85 (0,82-0,88). All of EPS cases had been diagnosed after withdrawal from PD and being on HD treatment. Mean time from stopping PD to time of symtomps and diagnosis of EPS was 5-6 months in all cases! The typical symtomps of EPS were abdominal pain, vomiting, bloody ascites, fever, elevated CRP. The diagnosis was confirmed by CT scan and laparoscopy. Three patients had laparatomy, enterolysis and succesful treatment with temporary parenteral nutrition and immunosuppessive regime (prednisolon, azathioprin) for 6 months. One of them needed a second operation after 8 months.

Conclusions: The first 6 months HD treatment of previously long-term PD patient could be critical of development of EPS based our experience. Along with other published cases it can suggest that cessation in itself maybe a risk factor beside of long term PD (>5 ys), high permeabile peritoneal membran (D/P>0,8), and high peritonitis rate (>4-6). To know more about EPS we have already registered our cases in the European EPS Registry.

PUB434

Predictors of Cardiovascular Events in Peritoneal Dialysis Patients and Impact on Kt/V Adequacy Ana Pinho, André Fragoso, Anabela Malho, Pedro Neves. *Nephrology, Faro, Portugal.*

Background: The emerging evidence linking uremia to an increase in oxidative stress and endothelial injury will necessarily lead to new therapies designed to improve the devastating consequences of vascular diseases in renal failure. The aim of this study was to evaluate the predictive factors of cardiovascular events (CVE) in relation to peritoneal dialysis (PD) adequacy.

Methods: 105 consective PD patients were included; Charlson Comorbidity Index adjusted for age (CCI-age score), sCRP and biochemical data (Kt/V,Hb,Albumin,Ca,P,PTH,lipid profile) at baseline were calculated from the average of repeated evaluations on the first three months of stable PD.Time-averaged values of laboratory and dialysis parameters (Kt/V,transporter type,RRF) during PD period were determined, excluding data from acute states. CVE and death were recorded. The 3rd percentile sCRP level at baseline was defined as the high-risk sCRP group.

Results: 36.2% patients had a CVE(1.4 ep/pt-yr). After adjusting for potential confounders (CCI-age score>=5,gender,diabetes,hypertension,pulse pressure,peritonitis), low levels of albumin (HR= 2.7), high levels of sCRP (HR=1.04) and high levels of PTH (≥400pg/ml) (HR=9.8) remained as significant predictors for CVE. There were no differences between high-risk and low-risk sCRP groups regarding follow-up period, as for other laboratory data and dialysis parameters.The high-risk sCRP group showed a significant rise of sCRP during DP period (median high-risk vs low-risk sCRP groups, 7.7 vs 45mg/L;p<0.001). Each mg/L of the time-averaged sCRP value, adjusted for CCI-age score, was associated with a 0.8% increased risk for death (p=0.018) and 0.6% for CVE (p=0.02). There are no significant differences related to other dialysis parameters and biochemical data, with exception to lower time-averaged Kt/V in high-risk sCRP group (2.1 vs 2.8mg/L;p<0.02).

Conclusions: Higher baseline sCRP, PTH and lower levels of albumin appeared as independent predictors for CVE. The higher baseline sCRP values were associated with higher time-averaged sCRP during DP stage and lower time average Kt/V. These results suggest that more intensive dialysis could be indicated for patients with increased inflammation activity.

PUB435

Assessment of Hydration Status in Patients' Undergoing Peritoneal Dialysis in Relation to Gender Dorota Sikorska, Jolanta Kaczmarek, Maria Wanic-Kossowska, Bartlomiej Posnik, Krzysztof Hoppe, Krzysztof Schwermer, Pawel Samborski, Krzysztof Pawlaczyk, Andrzej P. Oko. *Department of Nephrology, Transplantology and Internal Diseases, Poznan University of Medical Sciences, Poznan, Poland.*

Background: Continuous overhydration is a common problem in patients undergoing peritoneal dialysis (PD). Multi-frequency bioimpedance analysis (BIA) offers the potential to accurately determine a patient's dry body weight. The purpose of the study was to use BIA to assess the level of hydration in PD patients with regard to gender. Secondarily, the results were compared with clinical assessment.

Methods: The examination involved 24 PD patients (female-F n=12, age 49.3±17.4; male-M n=12, age 64.8±17.2). The patients were divided according to gender, the level of hydration was evaluated twice (6 months interval) by means of clinical criteria and the use of BIA. The values of BP, nutritional status using Subjective Global Assessment (SGA), and concentration of NT-proBNP in serum were also analysed.

Results: Considerable differences were demonstrated in regard to the level of hydration and BP with BIA as compared to clinical assessment alone. Comparable values of systolic (F 140.33±22.13 vs. M 146.45±24.92 mmHg) and diastolic (F 83.17±13.43 vs. M 81.36±13.45 mmHg) BP were observed, but after 6 months there was a significant difference between genders in systolic (F 129.88±13.09 vs. M 145.36±16.76) but not in diastolic (F 78.00±8.76 vs. M 78.91±12.36) BP. Comparable SGA (F 8.8±3.13 vs. M 8.8±1.14) were observed in both groups, without a significant difference after 6 months. Initially no statistically significant difference between genders was found in NT-proBNP (F 3020.8 vs. M 2736.3 pg/mL) with increased values observed at 6 months (F 6746.6 vs. M 5811.1). The overhydration level was correlated to the concentration of NT-proBNP ($p<0.02$). Clinically observed overhydration was confirmed using BIA, which revealed physically undetectable overhydration.

Conclusions: BIA seems to be a better criterion of assessing hydration in reference to PD patients as compared to clinical assessment alone. The male gender may be a potential factor determining a higher tendency for continuous overhydration.

PUB436

Advance Care Plans: Haemodialysis Patient View Maria Da Silva-gane,[1] David Wellsted,[2] Ken Farrington.[1] *[1]Renal, Lister Hospital, Stevenage, Hertfordshire, United Kingdom; [2]Centre for Lifespan & Chronic Illness Research, University of Hertfordshire, Hatfield, Hertfordshire, United Kingdom.*

Background: Many patients on dialysis are elderly and have multiple co-morbidities. Whilst mortality is high the needs of patients who are approaching the end of their life often go unaddressed. We undertook a study to define attitudes and perceptions of haemodialysis (HD) patients regarding future care including end of life (EoL) care planning.

Methods: We administered a self-completion questionnaire to determine levels of concern and willingness to discuss end of life planning amongst our HD population. The questionnaire used a likert scale (1-9). We classified patients who responded positively to each item (response of 7 or more), response was equivocal (4-6), and negative (3 or less).

Results: 240 (75%) agreed to participate. Participation rates were comparable across age, gender, ethnicity and co-morbidity groups. Mean age of respondents was 63 years (range 17-89); 20% were from non-white ethnic groups. 104 (43%) were considered to have severe co-morbidity.

Less than 45% had thought about future options in face of deteriorating health. 58% thought they should have a personal EoL care plan. In the event of deteriorating health 88% wanted involvement in discussing future options. Those with higher symptom burden were more likely to want this ($p = 0.01$). The majority would wish 'everything done' should their health suddenly deteriorate, 82% would wish ITU and 75% were positive towards resuscitation. Patients >75 years had a more negative view in regard to resuscitation ($p=0.001$). There was a significant association between attitudes on the benefits of a personal EoL care plan and the wish for resuscitation ($p=0.012$). Overall, there was little evidence that attitudes towards future treatment options or EoL care planning were significantly influenced by current physical or mental health states.

Conclusions: Patients on HD are not averse to discussing EoL care planning, perhaps to ensure respect for their wishes about treatment escalation in a crisis. Further qualitative research is needed to enable us to have a more in depth understanding of the views of this patient group.

PUB437

Attitudes and Perceptions of Renal Staff to Advance Care Planning Maria Da Silva-gane,[1] David Wellsted,[2] Ken Farrington.[1] *[1]Renal, Lister Hospital, Stevenage, Hertfordshire, United Kingdom; [2]Centre for Lifespan & Chronic Illness Research, University of Hertfordshire, Hatfield, Hertfordshire, United Kingdom.*

Background: It is generally acknowledged by clinicians working in the renal field that there is a need for a supportive care approach for dialysis patients as they face difficult decisions towards the end of their life. The aim of this study was to explore the attitudes and perceptions of clinicians involved in the care of haemodialysis patients regarding advance care planning.

Methods: We conducted private one to one interviews using a semi-structured interview schedule. Interviews were audio taped and transcribed verbatim, before Grounded Theory analysis was undertaken.

Results: 12 members of staff; 3 consultant nephrologists, 6 HD nurses and 1 Social Worker were interviewed, time working in renal & haemodialysis ranged from 1.5 – 21 years (mean 13.4). The majority expressed discomfort regarding discussions around future end of life care planning or ACP. Some felt that they avoided the discussions and that even in the face of deteriorating health of the patient dialysis treatment would often continue. Underpinning apprehension were issues of; lack of time, the environment, sensitivity of the subject, lack of communication skills and support network. Many felt other members of the renal team (counsellors) as having the time, training and experience to develop these conversations. Also cited was concern of upsetting patients or destroying hope. Whilst in general ACP was felt to be useful, they were seen to be about withdrawal of dialysis rather than a holistic care plan.

Conclusions: Nursing staff, in particular, expressed discomfort in relation to discussions in regard to ACP. Some of this was centred on the misconception that the focus would be withdrawal of dialysis. This leads us to consider that the focus on 'Advance' introduces, for some, apprehension and pre-conceived ideas. An alternative is to consider a shared care plan and focus discussions on realistic options in the context of current health status and likely future prognosis. If this is accomplished in an unambiguous way it could mean more open and realistic communications between the renal team and patients.

PUB438

Dialysis Staff Attitudes toward Deceased Organ Donation among End Stage Renal Disease Patients Allyce L. Haney,[1] Ann Andrews,[1] Holly Jenkins Riley,[4] Remonia Chapman,[3] Kenneth A. Resnicow,[5] Jerry Yee.[2] *[1]National Kidney Foundation of Michigan, Ann Arbor, MI; [2]Henry Ford Hospital, Detroit, MI; [3]Gift of Life Michigan/MOTTEP, Ann Arbor, MI; [4]Greenfield Health Systems, Bingham Farms, MI; [5]School of Public Health, University of Michigan, Ann Arbor, Mi.*

Background: The organ donor waiting list continues to expand. Patients with end-stage renal disease (ESRD) are typically not viewed, by themselves or their health care team, as potential donors after death. However, ESRD patients are eligible to donate organs. We examine the attitudes of renal team members, excluding physicians, about the potential of ESRD patients to donate organs after death, as part of a larger study that evaluates if peer mentoring increases ESRD patients enrolled in the Michigan Organ Donor Registry (MODR).

Methods: The cluster randomized design, controlled intervention study is conducted in collaboration with the National Kidney Foundation of Michigan (NKFM), Greenfield Health Systems (GHS), Henry Ford Health System, Gift of Life Michigan, and the University of Michigan. Staff at 12 GHS hemodialysis units in Southeast Michigan will receive training in donation. Hemodialysis units are then randomized to an intervention or control group. ESRD patients in intervention units are assigned peer mentors and will meet 7 times during a 4-month interval, utilizing a mix of in-person and phone contacts. Peer mentor-patient meetings teach coping mechanisms for chronic illnesses and discuss leaving a legacy by MODR enrollment. Patients in comparison units receive mailings about donation and the MODR. Renal team staff were surveyed regarding attitudes toward organ donation and the ability of ESRD patients to donate organs after death.

Results: 87 Greenfield staff were surveyed in 4 hemodialysis units. We expect to survey 10 more staff in 2 more units in the next 3 months.

Conclusions: Peer mentoring of ESRD patients is a potential alternative for augmenting the organ donor pool. Evaluations of organ donation knowledge and attitudes and self-reported donation status will be conducted to determine the success of this novel initiative.

Metabolic Acidosis in Hemodiafiltration: The Stewart-Figge Approach Sara Mohrbacher, Maria Julia C.L.N. Araujo, Hugo Abensur, Rosa M.A. Moyses, Manuel C. Castro, Rosilene M. Elias. *Nephrology, Universidade de São Paulo, Brazil.*

Background: On-line hemodiafiltration (HDF) represents the most advanced and clinically appropriate renal replacement therapy available. We hypothesized that HDF and high-flux conventional hemodialysis (HD) would be similar regarding metabolic acidosis correction, given that, in HD, there is mass transfer of HCO_3^- into the blood due to diffusion, whereas in HDF, there is a loss of HCO_3^- by convection, which is compensated for by diffusion and fluid replacement. To test that hypothesis, we used the Stewart-Figge approach to compare HDF and HD in the same patients.

Methods: We performed blood gas and biochemical analyses in 7 dialysis patients before and after the midweek dialysis session, collecting blood samples during 1 regular HD session and during 1 post-dilution on-line HDF session, using the same dialysis fluid. The effective strong ion difference (SIDe) was calculated by Figge's formula and the strong ion gap (SIG) was determined by the difference between the apparent SID (SIDa) and SIDe.

Results: Overall, HD and HDF both improved acidosis; reduced K and Cl; and increased HCO_3^- and SIDe. However, the ΔpH, ΔK, ΔHCO_3^-, Δbase excess and ΔSIDe were significantly higher in HDF than in HD. The ΔSIG correlated with Δbase excess in HD and HDF ($r=-0.859$ and $r=-0.755$; $p<0.05$ for both).

	HDF		HD	
Variable	pre	post	pre	post
pH	7.40±0.04	7.46±0.04*†	7.39±0.04	7.43±0.05
K, mEq/L	6.0±0.9	4.0±0.6*	5.1±0.6	3.6±0.3*
Cl, mEq/L	99.1±2.9	95.0±3.8*	99.7±5.3	96.1±3.5*
HCO_3^-, mmol/L	25.6±2.6	30.5±2.0*†	23.7±1.4	28.5±1.9*
Base excess, mmol/L	1.1±2.5	6.5±2.2*†	-0.4±1.9	4.2±2.1*
SIG	9.8± 3.9	4.7± 1.9*	10.1± 1.9	4.6±2.4*
SIDa	47.8±1.6	48.7±1.8*	47.0±2.2	46.7± 2.5
SIDe	37.9±4.8	45.0 ±3.1*†	36.9±1.7	42.1±2.0*

*p<0.05 pre vs. post dialysis; †p<0.05 vs. HD (Δ)

Conclusions: Uremic acidosis was well corrected in HD and HDF, decreasing SIDe and increasing SIG. The Stewart-Figge approach does not improve the characterization of acid-base status in patients on HDF. However, the HCO_3^- gain was much greater in patients on HDF, indicating the potential risk of alkalosis in this modality.

PUB440

Increased Plasma AVP Levels during Severe Hyponatremia: Paradoxical Secretion? Naoko Iwata,[1] Miho Sasaki,[1] Ryo Horibe,[1] Makoto Ikeniwa,[1] Masako Yamauchi,[1] Takashi Murase,[1,2] Ikuo Yamamori.[1] *[1]Endocrinology and Metabolism, Japanese Red Cross Nagoya Daiichi Hospital, Naogya, Aichi, Japan; [2]Endocrinology and Diabetes, Nagoya Medical Center, Nagoya, Aichi, Japan.*

Background: The regulatory mechanisms controlling arginine vasopressin (AVP) secretion remain to be elucidated in patients with the Syndrome of Inappropriate Antidiuretic Hormone secretion (SIADH). Here we examined the relation between serum [Na^+] and plasma AVP levels in patients with hyponatremia.

Methods: Analysis of plasma AVP levels in 264 samples from 171 patients measured in our hospital during 2010.

Results: There were 64 cases of hyponatremia due to various etiologies: SIADH (26), diuretic use (14), hypovolemia (13), and other causes (11). There were no significant differences between serum [Na^+] and plasma AVP levels among the groups. A U-shaped curve best fit the relationship between serum [Na^+] and plasma AVP in the SIADH group, with the nadir of the curve at a serum [Na^+] of approximately 120 mmol/L. For serum [Na^+] ≤120 mmol/L, there was a significant negative linear correlation (R^2=0.6519, p=0.028) between serum [Na^+] and plasma AVP. There were no significant correlations between plasma AVP levels and BUN, uric acid, or percent change in circulating blood volume calculated from the change in hematocrit. No apparent correlations were observed bewtween plasma AVP levels and neurologic symptoms. In contrast, there was a positive correlation between serum [Na^+] and plasma AVP levels with serum [Na^+] levels >120 mmol/L. For serum [Na^+] ≤120 mmol/L, the reglession lines representing the relation between [Na^+] and AVP were almost identical in the SIADH and the diuretic-treated groups, but the slope of the regression line was steeper in the hypovolemic group.

Conclusions: There was an apparently paradoxical increase in AVP secretion associated with the decline in serum [Na^+] during severe hyponatremia. It is possible that higher plasma AVP levels caused more water retention and resulted in further decreases in serum [Na^+], but there were no apparent correlations between plasma AVP levels and measures of volume status. Also, it would be difficult to explain this finding simply by neurologic symptoms such as nausea.

PUB441

Traumatic Encephalopathy Leading to Cerebral Salt Wasting and Hyponatremia with Permanent Brain Damage Allen I. Arieff. *UCSF.*

Background: 1.5 to 2 million USA civilians per year suffer traumatic brain injury. 4.5% of these sustain a chronic and severe disabling condition. It has not been previously noted that cerebral salt wasting could lead to hyponatremia which might result in severe brain damage or death. I was consulted on 14 individuals who suffered acute traumatic encephalopathy {(motor vehicle accident (10), falls (7)}. All patients were admitted via the ER and had closed head injury by neuroimaging studies. Brain lesions consisted of: subdural hematoma (6), diffuse cerebral edema (5), cerebral infarct (2), subarachnoid bleed (1). After admission, all were receiving isotonic fluids and becoming progressively more alert.. All developed hyponatremia after 57±32 hours, with plasma Na falling from 138±4 to 119±7 mmol/L. All 14 patients were initially diagnosed as having SIADH on the basis of urine osmolality > 400 mOsm/kg. All were initially treated with fluid restriction (below 1000 ml/day). Over 24 hours of fluid restriction, the mean BP declined from 135/63 mm Hg to a systolic BP below 100 mm Hg (92/48 mm Hg). Urine Na (184±66 mmol/day) was significantly above control (113±65 mmol/day, p <0.01). The systolic BP was restored to above 100 mm Hg by IV infusion of 0.9% NaCl. Two patients suffered hypoxic brain damage while the other 12 recovered. The 12 surviving patients were eventually maintained on oral NaCl tablets (mean 2.5 gm/day). Conclusions: a) closed head trauma can lead to hyponatremia secondary to a cerebral Na wasting syndrome; b) fluid restriction can lead to shock, worsening of hyponatremia and hypoxic brain damage; c) the Na wasting could eventually be controlled with oral NaCl tablets.

PUB442

Ultrafiltration Does Not Improve Neurohormonal Activation in Acute Decompensated Heart Failure Natallia Maroz, Amir Kazory. *Division of Nephrology, Hypertension, and Renal Transplantation, University of Florida, Gainesville, FL.*

Background: Blood urea nitrogen (BUN) has recently emerged as a marker of neurohormonal activation, which is considered the central pathophysiologic mechanism of acute decompensated heart failure (ADHF). Compared with conventional therapies, extracorporeal ultrafiltration represents a therapeutic strategy that is superior in symptomatic improvement of ADHF. However, there is no data on the impact of ultrafiltration on the underlying pathophysiologic mechanisms of ADHF and its potential effects on outcomes.

Methods: We searched articles cited in PubMed database from 1970 to 2012 using key words: "ultrafiltration" and "heart failure". All types of publications written in English language journals including case reports and case series were identified and relevant articles were selected. We then reviewed and compared the results of those studies which used the novel portable device approved by the Food and Drug Administration (FDA) exclusively for management of volume-overloaded patients with ADHF.

Results: A total of 60 relevant articles were identified on the use of ultrafiltration in the setting of ADHF. Nine studies using the FDA-approved ultrafiltration device were selected; 4 were randomized controlled trials and 5 without a control group. BUN levels were not reported in 2 studies. Four studies reported no significant change in BUN, while 3 studies found an increase in BUN levels following ultrafiltration therapy. None of these studies directly evaluated the impact of ultrafiltration on neurohormonal status (e.g. serum arginine vasopressin levels) or long-term survival of patients with ADHF.

Conclusions: While the higher efficacy of ultrafiltration for rapid decongestion and improvement in symptoms has been demonstrated in patients with ADHF, currently available data does not support its beneficial impact on BUN which is considered a marker of neurohormonal activation in this setting. Further studies are needed to assess whether this observation translates into lack of improvement in long-term outcomes due to inability to modify underlying pathophysiologic mechanisms in this population.

PUB443

Is Sodium Polystyrene Sulfonate (SPS) Effective in Treating Hyperkalemia in Acute Setting? Manoj Bhattarai,[1] Douglas G. Shemin.[2] *[1]Internal Medicine, Memorial Hospital, Pawtucket, RI; [2]Renal, Rhode Island Hospital, Providence, RI.*

Background: With conflicting reports regarding effectiveness and adverse effects of SPS, it is still used as an initial treatment in majority of hyperkalemia cases in emergent conditions. We sought to evaluate its effectiveness.

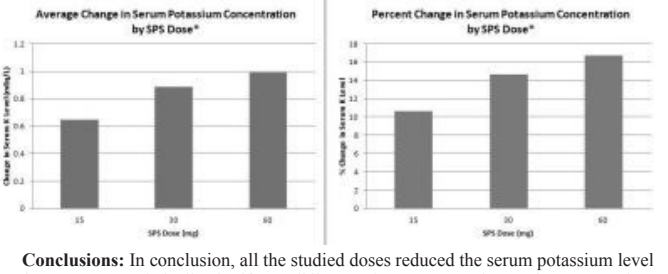
Methods: We carried out a retrospective study of patients who were admitted to Rhode Island Hospital in a six month period and received a single dose of SPS as an initial sole agent for the treatment of hyperkalemia. There were 559 cases of hyperkalemia treated with SPS alone. Patients received one of the three different doses of SPS (15 gms, 30 gms, or 60 gms) orally. Outcomes examined were change in serum potassium level and percent change in serum potassium level while accounting for the potential of repeated observations of the same patient. Outcomes were adjusted for pre-treatment serum potassium concentrations and for creatinine level.

Results: Out of 559 SPS cases that were examined, 179 cases received 15 gms, 295 cases received 30 gms, and 85 cases received 60 gms of SPS. Table 1 depicts the unadjusted mean serum potassium levels before and after SPS for the true dosage groups.

Table 1

SPS dose (Grams)	Number of cases (n)	Mean Potassium level before SPS	Mean Potassium level after SPS	K change
15	179	5.79	5.16	0.62
30	295	5.83	4.97	0.87
60	85	6.25	5.07	1.19

The mean adjusted change in potassium after 15 gms, 30 gms, and 60 gms of SPS are illustrated in figure below. The reductions in serum potassium level between 30 and 60 gms groups were no different (p=0.179). None of the subjects in any group developed symptomatic hypokalemia during the study.



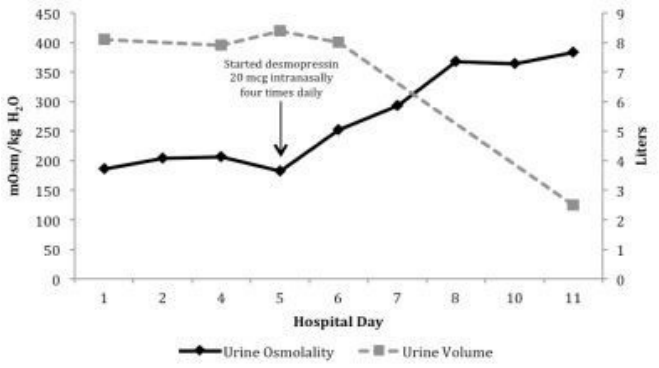
Conclusions: In conclusion, all the studied doses reduced the serum potassium level but there was no statistically significant difference between SPS doses of 30 gms and 60 gms. Thus, cautious use of higher doses is warranted to prevent potential complications.

PUB444

Ifosfamide-Induced Fanconi Syndrome and Concomitant Desmopressin-Responsive Nephrogenic Diabetes Insipidus Sophia C. Kamran,[1] William Franklin Pendergraft,[2] David Harmon,[2] Mario F. Rubin.[2] *[1]Harvard Medical School, Boston, MA; [2]Massachusetts General Hospital, Boston, MA.*

Background: Ifosfamide, an alkylating chemotherapeutic agent, has been reported to cause Fanconi syndrome in cancer patients and can also cause nephrogenic diabetes insipidus (NDI), although this latter complication is rare. The most commonly proposed risk factors for nephrotoxicity include a high cumulative ifosfamide dose, young age at treatment, prior exposure to cisplatin, and a prior reduction in kidney mass.

Methods: We report here a case of a young adult patient who developed Fanconi syndrome and concomitant NDI after only receiving a cumulative dose of 23.4 g/m^2 of ifosfamide for recurrent rhabdomyosarcoma. Remarkably, her concentrating tubular defect responded to repetitive administration of intranasal desmopressin as evidenced by a normalization of urine osmolality.



Conclusions: The pathophysiologic mechanisms responsible for ifosfamide mediated tubular toxicity (proximal and distal) remain elusive. Despite cessation of ifosfamide, our patient has continued to require treatment for the Fanconi syndrome (suggesting irreversible proximal tubular damage) while her polyuric state has resolved. This pattern of residual injury suggests that the distal tubular dysfunction appears to be partial and reversible. Therefore, clinicians should consider repetitive doses of desmopressin as treatment for ifosfamide-induced NDI in order to prevent severe volume depletion.

PUB445

Body Temperature, and Not Disease Specificity, Is the Major Factor Responsible for Hyponatremia in Children with Common Febrile Diseases Hideki Matsumura,[1] Akira Ashida,[2] Akihiko Shirasu,[2] Hyogo Nkakura,[2] Motoshi Hattori,[3] Hiroshi Tamai.[2] *[1]Pediatrics, Hirakata City Hospital, Osaka, Japan; [2]Pediatrics, Osaka Medical College, Osaka, Japan; [3]Pediatric Nephrology, Tokyo Women's Medical University, Tokyo, Japan.*

Background: Hyponatremia is a common electrolyte abnormality in hospitalized patients. We previously reported that the serum sodium level is inversely correlated with body temperature in children with common febrile diseases (ASN 2011, FR-PO1741). However some reports that have pointed out the relationship between clinical diagnosis and hyponatremia, have paid little attention to body temperature. Here we examined pediatric patients with hyponatremia in relation to their clinical diagnoses, excluding the effect of body temperature.

Methods: In this retrospective case study based on chart review, 1,973 children presenting with acute illnesses at Hirakata City Hospital between November 2008 and October 2009, and for whom blood test data were available, were enrolled. The median age of this cohort was 2.7 years. The patients were classified into four groups on the basis of body temperature: <37°C, 37°C, 38°C and ≥39°C. Within each temperature group, serum sodium levels in patients with different clinical diagnoses were compared.

Results: The mean serum sodium levels in the temperature groups were, in ascending order, 138.6 mEq/L, 137.3 mEq/L, 136.1 mEq/L and 134.6 mEq/L, respectively. The mean sodium level in patients with febrile seizure in the 38°C group was 134.9 mEq/L, and that in patients with Kawasaki disease in the ≥39°C group was 132.3 mE1/L, both being significantly lower than the levels in the patients with other clinical diagnoses. However, there were no significant differences in sodium levels between patients with different diagnoses except for these two diseases only at the particular febrile conditions.

Conclusions: There is no specific disease that leads to hyponatremia, regardless of body temperature. Body temperature, rather than disease specificity, appears to be a major factor contributing to the development of hyponatremia in children with common febrile diseases.

PUB446

Association between Extracellular Fluid Status and Autonomic Function in Hemodialysis Patients Yi Shin Chen,[1] Ming-Ju Wu.[2] *[1]Division of Nephrology, Department of Medicine, Taichung Tzu Chi General Hospital, Taichung, Taiwan; [2]Division of Nephrology, Department of Medicine, Taichung Veterans General Hospital, Taichung, Taiwan.*

Background: Autonomic dysfunction is common in hemodialysis patients and associated with sudden cardiac death. Fluid control affects the outcome especially for cardiovascular mortality and morbidity. Little is known for the association between extracellular fluid status(ECF) and autonomic function.

Methods: In this prospective study, autonomic function was measured by frequency domain analysis of heart rate variability (HRV) from 5 minutes ECGs in 24 hemodialysis patients(DM/non-DM, 9/15). Bioelectrical impedance analysis (BIA) was conducted on all patients and ECF was acquired via BIA. Correlation between ECF and HRV was investigated.

Results: ECF was significantly correlated to variance of RR interval values (r=-0.442, P=0.031) and total power (r=-0.406, P=0.049) both of which represent summation of sympathetic and parasympathetic tone. No significant correlation between gender and ECF. No difference of ECF between DM and non-DM patients.

Conclusions: ECF was negatively related to autonomic function. Poor fluid status control may worsen the autonomic function. Further investigation is needed.

PUB447

Chronic Outpatient Hyponatremia: Reduced Mortality with Thiazide Diuretic Associated Hyponatremia Greg Nieckula,[1] Brittany J. Hale,[2] James A. Tumlin.[3] *[1]Internal Medicine, University of Tennessee College of Medicine, Chattanooga, TN; [2]Clinical Research, Southeast Renal Research Institute, Chattanooga, TN; [3]Internal Medicine Division Nephrology, University of Tennessee College of Medicine, Chattanooga, TN.*

Background: Hyponatremia is a signifcant cause of morbidity and mortality among patients with chronic kidney disease (CKD). While multiple risk factors including heart failure, advanced cirrhosis and other disorders contribute to hyponatremia in hospitalized patients, few studies have investigated hyponatremia in outpatient CKD patients. Moreover, it is unknown whether thiazide diuretics worsen patient mortality in the out patient setting. To investigate this, we evaluated the effect of thiazides on patients with three different levels of hyponatremia.

Methods: We retrospectively reviewed 7287 patient records from an outpatient CKD clinic and found a 14.1% incidence of hyponatremia. Of the 1026 patients with hyponatremia, 898 had mild (126-130), 178 moderate (121-125), and 50 severe (115-120) hyponatremia. The annulaized mortality rate was calculated for each group using date of death. Non-parametric analysis was performed using a Chi-squared test when appropriate.

Results: Mean Na+ for the mild, moderate and severe groups were 128+0.04, 123+0.1, and 118+0.2 meq/L respectively. The annualized mortality was 17.8%, 22.4%, and 19.4%/year for each group respectively. There was no difference in mortality between groups. For patients with severe hyponatremia, there was a trend toward worse mortality but this was not signfican.

Hyponatremia	Severe	Moderate	Mild
	Na+ (115-120) Pt#-50	Na+ (121-125) Pt#-178	Na+ (126-130) Pt#-898
Mean Na+	118.4	123.4	128.4
Total Mortality	19.4%/year	22.4%/year	17.8%/year
Mortality Thiazide	13.5%/year	32.2%/year	16.7%/year
Mortality Non- Thiazide	31.3%/year	18.7%/year	18.4%/year

Conclusions: In conclusion, we find that that out-patient hyponatremia is common and associated with significant mortality. A serum Na+ below 130 meq/l was associated with a 17% annual mortality, but did not worsen with falling sodium. These data suggests that out-patient hyponatremia is common and contributes to the mortality of CKD patients.

PUB448

Risk Factors for Developing Significant Hyponatremia in Thyroid Cancer Patients Undergoing Low Iodine Diet and Radioactive Iodine Therapy Hyeong Cheon Park, Seung Kyu Kim, Seung Kyo Park, Kihyun Kim, Gi Young Yun, Jung Eun Lee, Hoon Young Choi, Sung-Kyu Ha. *Internal Medicine, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Korea.*

Background: Postoperative management of high risk thyroid carcinoma patients consists of radioactive iodine (RAI) therapy. These high risk patients are given low-iodine diet along with levothyroxine withdrawal to optimize RAI uptake by thyroid tissues and patients experience mild hyponatremia during this short-term hypothyroid status. However, some patients develop life threatening severe hyponatremia. This study aimed to assess risk factors for developing siginificant hyponatremia during low iodine diet and RAI therapy.

Methods: Data for patients with thyroid carcinoma who underwent total thyroidectomy and RAI therapy from July 2009 to February 2012 at Gangnam Severance hospital was retrospectively collected. Clinical and biochemical parameters including serum sodium and thyroid function tests were assessed along with medication history.

Results: Total 2223 patients [female: 1679 (76.3%)] were enrolled and the mean age was 47±11 yrs. The number of patients with serum sodium level less than 130 mEq/L (significant hyponatremia), 131 to 135 mEq/L, and above 136 mEq/L (normonatremia) were 44 (2.0%), 263 (11.8%), and 1916 (86.2%), respectively. Three hundred fifty patients (15.7%) were older than 60 years of age, 44 patients (2.0%) used thiazide agents, and 23 patients (1.0%) had lung metastasis. Patients who developed significant hyponatremia were older (46±11 vs. 61±11, p<0.001) and showed lower mean TSH level (82.8±19.7mcIU/mL vs. 71.3±24.6mcIU/mL, p<0.001) and lower mean serum sodium level measured at the start of RAI therapy (139±2mEq/L vs. 137±4mEq/L, p<0.001). Logistic regression analysis showed that thiazide use (OR 5.4), lung metastasis (OR 5.1), older age (≥ 60 yrs, OR 7.9) were independent risk factors for occurrence of significant hyponatremia in patients undergoing RAI therapy after total thyroidectomy.

Conclusions: Our data suggest that old age, thiazide medication use or presence of lung metastasis are risk factors for developing significant hyponatremia during RAI therapy after total thyroidectomy.

PUB449

Randomized, Double-Blind, Placebo-Controlled Trial of Tolvaptan in Cancer Patients with Hyponatremia: Preliminary Report Najeeba Ali, Shana Palla, Marina George, Amit Lahoti, Abdulla K. Salahudeen. *General Internal Medicine and Biostatistics, University of Texas MD Anderson Cancer Center, Houston, TX.*

Background: Hyponatremia is the most common electrolyte abnormality, yet it is often underdiagnosed and untreated. We recently reported a high rate of hyponatremia in hospitalized cancer patients (Am J Kidney Dis. 2012;59:222-8). Therapy with V2 receptor antagonists that allow renal water excretion is a major breakthrough. Tolvaptan is a newer

orally active antagonist, but data is limited whether it can ameliorate hyponatremia in cancer patients. The objective is to compare the rate of hyponatremia correction between tolvaptan and placebo treated cancer patients over a 14-day period, along with comparision of length of hospital stay and mental test score change.

Methods: This study, based on adaptive randomization, is designed to accrue a minimum of 30 and a maximum of 120 patients. Inclusion criteria: Euvolemic or hypervolemic adult patients with cancer admitted to hospital with serum sodium of 125-130 mEq/L. Exclusion criteria: Critical illness, renal failure, volume depletion- or hormonal deficiecy-related hyponatremia or taking strong Cyp-3A4 modulators.

Results: Over the last 12 months we have identified 8670 patients with hyponatremia, 104 were screened and 45 eligible patients were randomized to receive either tolvaptan 15 mg daily or matching placebo. The dose was titrated aiming for a serum sodium correction of 6-12 mEq/L daily to a target of 136-145 mEq/L. Of the 45 patients randomized, 3 discontinued the study due to polydipsia, 3 were moved to ICU for worsening cancer, 3 were transferred to hospice care, 6 withdrew consent and 5 lost to follow up. Of the 25 subjects completed this ongoing blinded study, 15 were males and the age was 63±12 yr (mean±SD). Serum sodium and urine osmolality (mOsm/kg) on D_0 and D_{14} were 128±1 and 136±5 mEq/L and 400±169 and 351±127 respectively.

Conclusions: Our preliminary review supports the feasibility of the study in hospitalized cancer patients. A higher dropout rates mostly due to advanced illness and poor cancer outcomes is noted. A larger patient sample size than initially estimated may be required to complete the study.

PUB450

Hyperkalemia of Angiotensin-Converting Enzyme Inhibitors or Angiotensin Receptor Blockers in Hemodialysis: A Meta-Analysis Qian Zhang, Yan Chen, Lili Liu, Yongman Lv, Zufu Ma. *Tongji Hospital.*

Background: Agiotensin-converting enzyme inhibitors (ACEIs) and angiotensin receptor blockers (ABRs) are well accepted for the cardiorenal-protective benefits added to antihypertensive effects in patients with chronic renal insufficiency, but associated with an increased risk of hyperkalemia. However, the effect of ACEIs or ARBs on serum potassium in hemodialysis (HD) patients is unclear. So we conducted a meta-analysis to evaluate the safety of ACEIs or ARBs use on the hyperkalemia in HD patients.

Methods: We searched Medline, Embase, the Cochrane Library, as well as reference lists of eligible and review articles for the randomized clinical trials (RCTs) on comparison of ACEIs/ARBs or placebo in HD patients. 224 citations were identified. Eight met the eligibility criteria and were subjected to Meta analysis by employing the Cochrane Collaboration's RevMan 4.2 software package.

Results: The results showed that there was no difference on hyperkalemia in HD patients between ACEIs or ARBs group and control group (ACEIs vs Control: RD: 0.03; 95% CI: -0.13-0.18; Z=0.34; P=0.73; ARBs vs Control: RD: -0.02; 95% CI: -0.07-0.03; Z=0.75; P=0.45). However, the serum potassium between ACEIs or ARBs group and control group in HD patients has significant difference (ACEIs vs Control: WMD: 0.10; 95% CI: 0.06-0.15; Z=4.64; P<0.00001; ARBs vs Control: WMD: -0.24; 95% CI: -0.37--0.11; Z=3.58; P=0.0003).

Conclusions: It is concluded that the use of ACEIs or ARBs will not cause an increased risk of developing hyperkalemia in HD patients. But the serum potassium will be increased with use of ACEIs in HD patients. So the serum potassium concentration should still be closely monitored when the medication of ACEIs is taken during the maintenance hemodialysis.

PUB451

Blood and Urinary Physicochemical Alterations in the Course of Acute Kidney Injury in Critically Ill Patients Etienne Macedo, Alexandre Toledo Maciel, Marcelo Park. *University of Sao Paulo.*

Background: Metabolic acidosis in acute kidney injury (AKI) is generally attributed to increases in serum unmeasured anions and phosphate. The combination of urinary electrolyte composition and urinary strong ion difference can be a parameter to assess adequate renal handling of metabolic acidosis. The aim of our study was to assess sequential blood and urinary physicochemical parameters and evaluate the potential differences between transient and persistent AKI.

Methods: Blood labs and spot urine sample were daily collected from patients with urinary catheters in a mixed ICU. Serum creatinine, strong ion difference, strong ion gap (SIG), phosphate levels, urinary sodium (NaU), chloride (ClU) and 2-h creatinine clearance were measured daily. AKIN sCr criterion was used to determine AKI diagnosis with daily sCr adjusted for fluid balance. Transient AKI was defined as AKI resolution within 72 hours.

Results: 113 out of 168 patients (67.3%) developed AKI during the follow up period. Of these, 50.4% had a transient AKI, and 49.6% a persistent AKI. AKI development was characterized by increases in SIG and phosphate levels and decreases in both NaU and ClU values. SID value remained stable. In transient AKI, these alterations were also transient, reaching values similar to those of non-AKI patients 2 days after the AKI diagnosis.

Blood and urinary physicochemical parameters in the course of acute kidney injury.

		Day of AKI diagnosis by sCr (n=168)	Day +1 (n=164)	Day +2 (n=117)
SIG (mEq/L)	No-AKI	4.8 [2.9,7.3]	4.8 [3.3,6.4]	5.2 [4.1,7.1]
	transient	5.9 [4.1,7.3]	5.1 [3.5,7.1]	4.3 [2.0,6.6]
	persistent	7.1 [4.7,9.7]	8.7 [5.8,10.8]	7.6 [5.2,10.3]
	P	.198	<.000	<.000
Phosphate (mEq/L)	No-AKI	1.9 [1.3,2.3]	1.4 [1.2,1.9]	1.4 [1.1,1.9]
	transient	2.2 [1.6,2.8]	1.7 [1.3,2.0]	1.3 [1.1,2.0]
	persistent	2.4 [1.7,3.1]	2.2 [1.6,2.8]	2.2 [1.6,2.7]
	P	.122	.007	<.000
Urinary Cl (mEq/L)	No-AKI	113 [39,173]	109 [52,163]	125 [95,184]
	transient	56 [23,101]	68 [31,135]	135 [80,191]
	persistent	39 [17,84]	42 [15,97]	60 [22,103]
	P	.221	.001	<.000

P for difference between transient and persistent AKI.

Conclusions: Though transient and persistent AKI have the same blood and urinary physicochemical characteristics, they differ in severity and duration.

PUB452

Does Bio-Impedance Analysis Predict Volume Overload States and Clinically Relevant Outcomes in Septic Intensive Care Unit Patients? Bram Rochwerg, Jason H. Cheung, Peter Margetts, Scott K. Brimble, Catherine M. Clase, Christine M. Ribic, Deborah Cook, Azim S. Gangji. *Department of Medicine, St. Joseph's Healthcare, Hamilton, ON, Canada.*

Background: The mortality rate in patients with septic shock is as high as 40%. The initial management of sepsis has been well-established through early-goal directed therapy. Beyond the acute setting, persistent hypervolemia results in prolonged mechanical ventilation, the need for renal replacement therapy, and increased mortality.

Clinical assessment of volume status is limited by the absence of a feasible, continuous, non-invasive methods. Bio-impedance analysis (BIA) devices are compact, portable and can be used to make repeated measurements. BIA vector length has been previously shown to correlate with volume status in hemodialysis populations. We hypothesized that the change in BIA measurements is predictive of extubation status in patients who have SIRS due to infection and require mechanical ventilation.

Methods: We conducted a prospective observational study targeting 52 ICU patients. BIA is was measured on ICU admission and then every 4 days until discharge. Patients were followed for 30 days. Secondary outcomes included mortality, rates of acute kidney injury requiring dialysis, and length of stay in the ICU. A correlation between BIA with known measures of volume status was completed.

Results: The baseline vector length correlated significantly with the clinical edema score, proBNP serum level & CVP ($p<0.05$ for all). As far as our primary outcome of ventilator requirement during the first 30 days after enrolment, we did see that for every 50 unit increase in VL (ohms/m), there was a 22% increase in having a "status of extubation" (p=0.126). This makes sense based on our hypothesis that longer vector lengths should be correlated with improved outcomes.

Conclusions: The significant correlation between vector lengths with known clinical measures of volume status strengthens the construct validity of the BIA method in assessing volume status in ICU patients. This pilot study has proved to be feasible and may identify BIA as a safe and easy bedside measure to assess ICU patients' volume status.

Value of Determining Fractional Excretion of Urate in Nonedematous Hyponatremia James Drakakis,[1] Louis J. Imbriano,[1] Shayan Shirazian,[1] Dympna Gallagher,[2] Maria Marotta-kollarus,[1] Maanvi Kumar,[1] John K. Maesaka.[1] [1]*Department of Medicine, Winthrop University Hospital, Mineola, NY;* [2]*Department of Body Composition, St Lukes Hospital.*

Background: FEurate is increased in SIADH and cerebral/renal salt wasting (RSW), but normalizes in SIADH and remains persistently increased in RSW after correction of hyponatremia. We recently reported a normal FEurate to be highly suggestive of reset osmostat (RO) in patients with nonedematous hyponatremia.

Methods: We conducted a prospective study to determine the diagnostic value of determining FEurate in nonedematous hyponatremic patients.

Results: Of 25 consented patients, 13 were found to have increased FEurate > 12%. SIADH could be confidently differentiated from RSW in only 4 patients. Two had SIADH based on an increase in total body (TBW) and extracellular (ECW) water as determined by deuterium and sodium bromide, respectively. Two had RSW; 1 patient with pneumonia without cerebral disease had decreased TBW and ECW and 1 had subarachnoid hemorrhage with increased FEurate and normonatremia. The remaining Twelve patients had normal FEurate of 4-11% that was consistent with RO; TBW and ECW were increased in the one patient studied and 3 had dilute urines on random urine samples. Determinations of plasma renin, aldosterone and BNP, and urine sodium concentrations were generally not helpful and all 25 patients had diverse comorbid conditions.

Conclusions: These studies demonstrate how difficult it is to differentiate SIADH from RSW; RSW was again noted in a patient without cerebral disease, supporting our previous proposal to change cerebral salt wasting to RSW because RSW is being noted in increasing number of patients without cerebral disease. RO is common in hospitalized patients with nonedematous hyponatremia. RO can be readily identified by a normal FEurate and should be considered a separate clinical entity and not designated as type C SIADH, because it is patho-physiologically different from SIADH by virtue of the normal FEurate and predictable ADH response to changes in plasma osmolality.

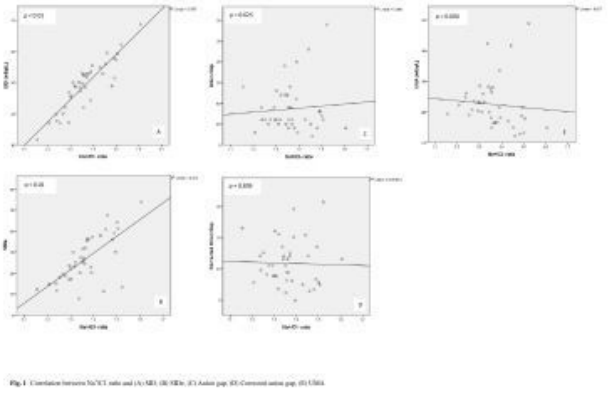
The Use of Sodium-Chloride Ratio and Sodium-Chloride Difference in Evaluating the Etiology of Metabolic Acidosis in Critically Ill Patients
Preetika Rao, Prachi Aggarwal, Devjit Roy, Thara Basavaiah, Frantz M. Duffoo, Shitij Arora. *Internal Medicine, Wyckoff Heights Medical Center, Brooklyn, NY.*

Background: Acid-base disorders are a common problem in critically ill patients. Stewart's physiochemical approach is an accurate, reliable method to analyze base deficits, but involves complex mathematical equations. Previous studies suggest using the sodium-chloride ratio (Na:Cl), where a high or low ratio indicates hypochloremia or hyperchloremia respectively as a cause of metabolic acidosis. Our study aims to assess the use of Na:Cl as a simple bedside diagnostic tool and compares it to other existing base deficit equations.

Methods: This retrospective study included 41 ICU patients with evident metabolic acidosis, defined as pH <7.25 and sHCO3 concentration <22 mEq/l. Henderson-Hasselbach and Stewart's physiochemical approach were used to calculate Na:Cl ratio, sodium-chloride difference (DiffNaCl), anion gap (AG), albumin-corrected anion gap (AGcorr), strong ion difference (SID), effective strong ion difference (SIDe), unmeasured anions (UMA), and tissue acids (TA) at each episode of metabolic acidosis. Patients were grouped according to the Na:Cl ratio; group I, Na:Cl< 1.3; group II, Na:Cl 1.3-1.5; group III, Na:Cl> 1.5.

Results: The study shows that both DiffNaCl and the Na:Cl ratio have correlations with SID and SIDe but none with AGcorr, UMA, and TA. This suggests that the chloride ion plays a more important role in metabolic acidosis than an elevation of UMA or TA. We also demonstrate the Na:Cl ratio as the two strongest cations and anions showing a positive correlation with coeffecients of Stewarts theory (SID, SIDe).



Conclusions: Our study suggests that the Na:Cl ratio and DiffNaCl may be a simple, fast alternative method to Stewart's physiochemical approach in identifying raised UMA and TA in critically ill and otherwise acidotic patients.

PUB455

High Rates of Hyperkalemia in Patients with Chronic Kidney Disease Stage 3 or 4, Diabetes, and Hypertension
Jamie Cope,[1] David A. Bushinsky,[2] Lance Berman.[1] *[1]Relypsa, Santa Clara, CA; [2]University of Rochester Medical Center, Rochester, NY.*

Background: Hyperkalemia can cause life-threatening arrhythmias and is associated with increased mortality. The reported incidence of hyperkalemia varies widely, depending on the population studied and the definition of high potassium. Renal impairment, diabetes, advanced age and the use of RAAS blockading agents all increase the risk of hyperkalemia. Hyperkalemia is a barrier to the use of renoprotective and cardioprotective RAAS blockers. Here, we report the rates of hyperkalemia observed during enrollment for AMETHYST-DN (ID: NCT01371747), a Phase-2 study to investigate in >300 patients with CKD, type 2 diabetes mellitus (T2DM) and hypertension (HTN) the effect of RLY5016 (patiromer), a new polymer-based treatment for hyperkalemia.

Methods: Qualifying subjects were 30-80 y.o., with CKD [eGFR 15-60ml/min/m^2), T2DM, HTN, urine albumin to creatinine ratio > 30mg/g and on RAAS blockers. Those with pre-existing hyperkalemia (serum K^+ 5.1-6.0mEq/L) at screening were randomized to the treatment phase directly. Those who were normokalemic (serum K^+ 4.3-5.0mEq/L) at screening discontinued their current RAAS blockers and were run in for up to 4 weeks on maximum-labeled doses of RAAS blocker for additional BP control [100mg losartan, and/or up to 50mg spironolactone].

Results: Thirty-nine percent of screened subjects (225/572) had pre-existing hyperkalemia (central K^+ ≥5.1 mEq/L) and 14% (80/572) had a serum K^+ ≥5.5 mEq/L (table). Of the 72 subjects who entered run-in (average serum K^+: 4.8mEq/L) at the beginning of maximum-dose RAAS blockade, 69% (50/72) became hyperkalemic within an average of two weeks and 25% (18/72) had a serum K^+ ≥5.5 mEq/L. The average serum K^+ increase was 0.4mEq/L.

Hyperkalemia	≥5.1mEq/L	≥5.5mEq/L
Pre-existing	39%	14%
After maximum-dose RAAS blockade	69%	25%

Conclusions: Hyperkalemia is common in patients with compromised renal function (CKD Stages 3/4), hypertension and diabetes, even without the use of maximum-labeled doses of RAAS blockers. Most patients placed on maximum-labeled doses of RAAS blockers develop hyperkalemia rapidly.

Combination of ARB with an L/N-Type CCB Achieves an Excellent Outcome Compared with L-Type CCB on Adriamycin-Induced Cardiomyopathy and Nephropathy in SHRs
Shizuka Aritomi, Kazumi Niinuma, Mai Kawakami, Eri Harada. *Research Center, Ajinomoto Pharmaceuticals Co., Ltd., Kawasaki, Kanagawa, Japan.*

Background: In this study, we investigated the effect of L/N-type CCB cilnidipine on the adriamycin (ADR)-induced cardiomyopathy and nephropathy in SHR comparing with that of L-type CCB when given concomitantly with ARB.

Methods: ADR (1.5 mg/kg) was administered intravenously to SHR once a week for 3 weeks. Control rats were administered saline (unaffected group). One week after the last administration of ADR, rats were divided into 3 groups and administered either the vehicle (untreated group), valsartan (Valgroup), cilnidipine+valsartan (CV group), or amlodipine+valsartan (AV group) for 4 weeks.

Results: There was no difference in antihypertensive effect between CV group and AV group throughout the experimental period. ADR caused an increase in the urinary albumin excretion (UAE). Although CV group showed same antihypertensive effect as AV group, only CV suppressed the increase of UAE. In addition, ADR induced cardiac contractile dysfunction assessed by echocardiography. CV group also showed an improvement of contractile dysfunction, but AV group did not. Furthermore, CV group showed a lower level of plasma aldosterone than untreted group.

Conclusions: The results of the present study indicate that, when given concomitantly with ARB, cilnidipine suppresses the progression of renal and cardiac dysfunction induced by ADR. Since such effect was not observed by L-type CCB amlodipine treatment, blockade of N-type calcium channel might play an important role for protection of both renal and cardiac function. And the mechanism of cilnidipine's effect can be partly explained by its suppressive action in aldosterone through N-type calcium channel.

Fractalkine and Its Receptor, CX3CR1, Contribute to Hypertensive Kidney Fibrosis
Kazuaki Shimizu,[1] Kiyoki Kitagawa,[1] Yasunori Iwata,[1] Takashi Wada.[2] *[1]Department of Disease Control and Homeostasis, Institute of Medical, Pharmaceutical and Health Sciences, Kanazawa University, Kanazawa, Japan; [2]Department of Laboratory Medicine, Institute of Medical, Pharmaceutical and Health Sciences, Kanazawa University, Kanazawa, Japan.*

Background: Fractalkine/CX3CL1 is a unique chemokine, which works as a leukocyte chemoattractant as well as an adhesion molecule. Fractalkine/CX3CL1 was reported to be involved in the progression of human glomerulopathy. The involvement of the fractalkine-CX3CR1 axis in the pathogenesis of hypertensive kidney fibrosis remains unclear.

Methods: The impacts of the fractalkine-CX3CR1 axis on hypertensive kidney fibrosis were investigated in a deoxycorticosterone acetate (DOCA)-salt hypertensive model in CX3CR1deficient mice and wild type mice, which were sacrificed on day 28.

Results: Systolic blood pressure was elevated in all mice 14days and 21days after DOCA treatment. Levels of blood pressure were similarly elevated in both CX3CR1-/-C57BL/6 (119.3mmHg) and wild-type C57BL/6 mice (119.7mmHg). Fractalkine and CX3CR1 were upregulated in damaged kidneys by hypertension in wild-type C57BL/6 mice, expressed in tubular epithelial cells and vascular endothelial cells. The mean interstitial fibrosis was reduced in DOCA administered CX3CR1-/- (2.9%) compared with DOCA administered C57BL/6 mice (8.7%). CX3CR1 deficient mice had been showed downregulation of type I collagen protein and type I procollagen mRNA expression in damaged kidneys. Kidney transforming growth factor (TGF)-β_1 expression was decreased by CX3CR1 deficiency. The number of infiltrating F4/80-positive macrophages in damaged kidneys was also decreased in CX3CR1 deficient mice.

Conclusions: These results suggest that fractalkine-CX3CR1 axis contributes to kidney fibrosis in a hypertensive mouse model.

PUB458

The Bufodienolide, Cinobufatalin, Produces a Preeclampsia-Like Syndrome in a Rat Model
Daad Abi-Ghanem, Cindy J. Balog-alvarez, Luc R. Berghman, Darijana Horvat, Biresh Kumar, Mohammad Nasir Uddin, Jules B. Puschett. *Texas A&M University, College Station, TX.*

Background: The bufodienolides are a group of agents found in the skin and venom of the common toad *Bufo marinus* and in plants. They are members of a family of substances called cardiotonic steroids. Previous studies from this laboratory have demonstrated that one of these substances, marinobufagenin (MBG) causes a syndrome in the rat which includes many of the characteristics of human preeclampsia (PE): hypertension, proteinuria and intrauterine growth restriction (IUGR).

Methods: To determine if the administration of another bufodienolide, cinobufatalin (CINO) could cause a similar disorder, we gave normal pregnant (NP) rats CINO (30 µg/kg/day) daily from early pregnancy by intraperitoneal injection. IUGR was estimated by analyzing the number of pups/litter (#pups) and the percentage of abnormal pups (%abn). Final blood pressure (FBP) data, protein excretion (UVPr), #pups, and %abn were compared to the values obtained in NP rats.

Results: Mean FBP +/- SD in CINO rats of 128+/-6 mmHg exceeded that of NP (90 +/- 6 mmHG), P< 0.05. UVPr in CINO rats was 5.8 +/- 1.8 mg/24hr which exceeded that in NP (2.4 +/-1.2), P< 0.05. The #pups in CINO rats (12.2 +/- 1.8) were less than those in NP (15.0 +/- 1.9), P< 0.05. Furthermore, there were 11% abn pups in CINO but none in NP.

Conclusions: CINO produces a PE-like syndrome in rats similar to that induced by MBG.

Increases in ACE Aggravates the Preeclampsia-Like Phenotype in Mice

Feng Li,[1] Oliver Smithies,[1] Nobuyuki Takahashi.[2] *[1]Pathology and Laboratory Medicine, University of North Carolina at CH, Chapel Hill, NC; [2]Graduate Schools of Pharmaceutical Sciences and Medicine, Tohoku University, Sendai, Japan.*

Background: Preeclampsia (PE) is pregnancy-induced hypertension with proteinuria. Excess sFlt-1, an endogenous VEGF inhibitor of placental origin has been implicated to play an important role in hypertension, proteinuria and glomerular endotheliosis, hallmarks of PE. sFlt-1 induces endothelial dysfunction via several pathways including decreased eNOS. We have proven that mice lacking eNOS have aggravated PE-like phenotype. (JASN 2012) ACE inactivates bradykinin, then its down-stream factor, eNOS. Human *ACE* polymorphisms leading to elevated activity of ACE are associated with PE.

Methods: We tested whether an increase in ACE aggravates PE using mice having 4 copies of *Ace* gene.

Results: Their basal levels of blood pressure (BP) do not differ from those of WT mice. Adenoviral mediated sFlt-1 overexpression to the non-pregnant female mice increased BP more in mutant mice than WT mice (from 118.4 ± 6.7 mmHg to 162.4 ± 10.1 mmHg in the mutant mice, from 120.1 ± 3.9 mmHg to 142.4 ± 3.9 mmHg in WT mice). Mutant sFlt-1 mice showed higher daily urinary albumin excretion (288 ± 42 vs. 150 ± 60 mg/day in WT sFlt-1) and lower GFR (170 ± 55 vs. 493 ± 109 ml/min in WT sFlt-1). Mutant sFlt-1 mice had less glomerular open capillary volume (20.5 ± 3.8 vs. 34.7 ± 10.5 % in WT sFlt-1 mice), and lost fenestration of glomerular capillary endothelial cells, suggesting mutant sFlt-1 mice have more severe endotheliosis than WT sFlt-1 mice. Mutant mice also show podocyte foot process effacement in some glomeruli.

Conclusions: We conclude that mice having 4 copies of *Ace* gene develop more severe PE-like phenotype than WT mice. The mechanism underlying this phenomenon is under investigation.

Down-Regulation of Integrin β1 Associated with Focal Adhesion Kinase Signaling Pathway in Renal Glumoruli under Various Hemodynamic Conditions

Zilong Li, Juan Wang, Xiaoli Yuan, Xiaohui Yin, Kai Li, Hua Zhou, Lining Wang. *Department of Nephrology, The First Affiliated Hospital of China Medical University, Shenyang, Liaoning, China.*

Background: The study focuses on the changes of β1 integrin and the associated signal molecular focal adhesion kinase (FAK) under various hemodynamic conditions in podocytes using novel "In vivo cryotechnique". [1, 2]

Methods: "In vivo cryotechnique"group: The "In vivo cryotechnique" was performed on left kidneys of anesthetized C57BL/6 mice, as reported before. [3]. Control group: the kidney tissues were fixed with the conventional immersion and perfusion preparation methods. Their serial sections were stained and observed by light, confocal laser scanning microscopy and immunoelectron microscopy. The expression levels of β1 and FAK proteins and mRNA were measured by western blot and Real Time PCR.

Results: By the "In vivo cryotechnique", the β1 integrin was significantly decreased under the acute hypertensive and cardiac arrest conditions, compared with the control group. Being a potential regulator, the expression of FAK was increased, and it was translocated and accumulated in nuclei of the podocytes under abnomal hemodynamic conditions.

Conclusions: These results indicate that the decreased expression of β1 integrin and associated FAK pathway my play an important role in regulating the functions of podocytes under abnormal hemodynamic conditions. "In vivo cryotechnique" followed by freeze-substitution should be a reliable tool to observe the proteins in situ and capture transient dynamic images of functioning glomeruli in living mice.

World Kidney Day (WKD): Four Year Analysis of Health Events in UK

Sohan Shah,[1] Bhavna Pandya.[2] *[1]Medical Student, University of Liverpool, Liverpool, United Kingdom; [2]Nephrology, Aintree University Hospital and University of Liverpool, Liverpool, United Kingdom.*

Background: WKD is an annual kidney awareness event. For the past 4 years, health clinics have been held for the staff and shoppers in Liverpool. The aim was to determine the general health: blood pressure, blood glucose, urine abnormality, heart rate and cholesterol.

Methods: Individuals who attended annual WKD events from 2009-2012 came forward for blood pressure (electronic blood pressure monitor), capillary blood glucose monitoring (CBGM), urinalysis (automated urinalysis machine), heart rate (manual radial pulse) and cholesterol readings.

Results: A total of 871 patients were included in the analysis. The median age was 54 (range 12-102) with a M:F ratio of 1:3. The median systolic and diastolic blood pressure was 137 mmHg (range 83-217; SD 22) and 81 mmHg (range 40-128; SD 12) respectively. Defining hypertension as blood pressure >140/90, 361 (51%) patients were identified to be hypertensive. A systolic BP >180 was found in 37 patients. Median heart rate from 395 patients was 76 bpm (SD 13). Of the 585 patients who had a random CBGM test, 5 patients had blood glucose of over 10 mmol/L (mean 5.5; SD 1.5). There were 675 patients who had a urinalysis test. Of these, 125 and 201 showed some degree of haematuria and proteinuria respectively. A combination of at least moderate (++) haematuria and proteinuria was found in 22 patients. There were signs of leucocyturia in 246 patients and 11 patients were found to have glycosuria. Two of these had severe glycosuria (+++). Twelve patients showed mild positive (+) nitrate results suggesting infection. Random cholesterol was measured in 174 patients (median 5.00 mmol/L; range 3.00-7.76; SD 0.87). Twelve patients had high cholesterol >6.5.

Conclusions: The above analysis shows that hypertension, urine abnormalities and hypercholesterolaemia are prevalent throughout the community. Regular events like this help to discover undiagnosed patients and increase confidence in the community thus improving health check-up attendances. It also helps identify and prevent severe consequences of undiagnosed and prevalent risk factors in the community.

PUB463

Telmisartan Increase the Nitric Oxide Production in 5/6 Nephrectomy Rats: Partly Dependent of PPARγ/nNOS Activation

Ying Yao,[1] Rong Zou,[1,2] Yong He,[1,3] Min Han,[1] Zufu Ma,[1] Xiaocheng Liu,[1] Rui Zeng,[1] Gang Xu.[1] *[1]Tongji Hospital; [2]Wuhan Integrated TCM & Western Medicine Hospital; [3]Wuhan No.5 Hospital.*

Background: To study the nitric oxide synthesis and probable mechanisms influenced by telmisartan in 5/6 nephrectomized rats.

Methods: male Wistar rats were randomly divided into sham-operation group, untreated 5/6 Nx rats, telmisartan group, telmisartan + GW9662 group, and troglitazone group. The 12th week rats were killed with decapitation method, and detected in serum urea nitrogen, creatinine, 24h urinary protein, NOx. Remnant kidney tissue were taken pathological examination and immunohistochemistry to observe the PPARγ, nNOS distribution. RT-PCR and Western Blot were used to detect the expression of PPARγ and nNOS.

Results: The degree of glomerular sclerosis and tubulointerstitial damage in the telmisartan group was markedly reduced, compared with untreated 5/6 Nx rats. But the protection effects of telmisartan were markedly abolished by GW9662 (P<0.05). Immunohistochemistry showed that the distribution of PPARγ protein in the glomerulus and renal tubules decreased obviously in 5/6 Nx group, which was recovered by telmisartan or troglitazone. The NO production could be increased by telmisartan, with the abolishment of GW9662. nNOS in renal cortex was mainly localized in dense patches and renal tubular epithelial cells. The expression of PPARγ and nNOS were downregulated in 5/6 Nx group compared to sham group, which were recovered by treatment with Telmisartan and Troglitazone.

Conclusions: 5/6 nephrectomy causes a significant downregulation of intrarenal nNOS and NO. Telmisartan exert a stimulatory effect on nNOS and NO levels via PPARγ activation in the 5/6 nephrectomized rats. The renal protection effects of telmisartan partly due to the regulation of nNOS and NO system.

PUB464

Role of (Pro)renin Receptor in Angiotensin II-Dependent and -Independent EGF Receptor Transactivation

Akira Nishiyama,[1] Hiroyuki Kobori,[1] Atsuhiro Ichihara.[2] *[1]Department of Pharmacology, Kagawa University Medical School; [2]Department of Hypertension and Endocrinology, Tokyo Women's Medical University.*

Background: Prorenin-induced intracellular signaling pathway is not fully elucidated. We investigated whether the (pro)renin receptor mediates epidermal growth factor (EGF) receptor transactivation throughangiotensin (Ang) II-dependent and -independent pathways in human embryo kidney 293 cells.

Results: Prorenin(2 nmol/L) caused biphasic phosphorylation of EGF receptor (Tyr992) and extracellular signal-regulated kinase (ERK) 1/2, peaking at 5 minutes followed by a decrease and a second peak at 60–120 minutes, whereas EGF receptor (Tyr1068) and Src were phosphorylated at only 120 minutes. These prorenin-induced phosphorylation processes were inhibited by (pro)renin receptor siRNA. Similarly, Ang II type 1 (AT_1) receptor blocker (ARB) or AT_1 receptor siRNA completely inhibited prorenin-induced phosphorylation of EGF receptor (Tyr1068) and Src, as well as the late peaks of EGF receptor (Tyr992) and ERK 1/2. However, early peaks of EGF receptor (Tyr992) and ERK 1/2 at 5 minutes were not effectively blocked byARB or AT_1 receptor siRNA. Incubation with prorenin (120 minutes) significantly increased Ang II levels of cell lysate.

Conclusions: These data indicate that the (pro)renin receptor mediates EGF receptor transactivation in both Ang II-dependent and-independent pathways.

Aldosterone Breakthrough during Aliskiren, Valsartan, and Combination (Aliskiren + Valsartan) Therapy for Proteinuric Kidney Disease Andrew S. Bomback,[1] Yelena Rekhtman,[1] Philip J. Klemmer,[2] Pietro A. Canetta,[1] Jai Radhakrishnan,[1] Gerald B. Appel.[1] *[1]Columbia University; [2]UNC Kidney Center.*

Background: Aldosterone levels increase in 30-40% of patients on ACE-inhibitors and/or ARBs over the long-term. Aldosterone breakthrough may carry important clinical consequences given aldosterone's non-epithelial, pro-fibrotic actions. The renin inhibitor, aliskiren, by suppressing the RAAS proximally, may limit breakthrough compared to conventional RAAS blockade.

Methods: This open-label study (NCT01129557) randomized subjects to aliskiren 300 mg daily, valsartan 320 mg daily, or valsartan 160 mg daily + aliskiren 150 mg daily for 9 months. Eligible subjects had proteinuria >300 mg/day, eGFR>45 ml/min/1.73m2, and SBP>130 or DBP>80 mm Hg. Serum and 24-hr urine aldosterone (indexed to 24-hr urine Na) were checked prior to initiation of therapy and at 3, 6, and 9 months. Aldosterone breakthrough was defined as a sustained increase from baseline aldosterone by study end. The study was intended to enroll 120 subjects but was terminated early by the sponsor. We present here the results of subjects who completed the protocol.

Results: This analysis includes 33 subjects randomized to aliskiren(n=12), valsartan(n=11), or valsartan+aliskiren(n=10). Twenty-five(76%) were male; 20(61%) were white; mean age was 44.7(±14.7) years. Mean baseline eGFR was 75.5(±23.3) ml/min/1.73m^2; baseline proteinuria was 3104(±2943) mg/day; and baseline BP was 134.7(±10.5)/84.8(±8.4) mm Hg. Three(27%) subjects on valsartan, three(25%) subjects on aliskiren, and three(30%) subjects on aliskiren + valsartan had aldosterone breakthrough. Mean proteinuria reduction was 31% from baseline in all subjects – in subgroup analysis, proteinuria reduction was 30% in subjects with breakthrough vs. 32% in subjects without breakthrough. Mean BP reduction was 11.0/8.8 mm Hg in all subjects – in subgroup analysis, BP reduction was 8.4/6.1 in subjects with breakthrough vs. 12.0/9.8 in subjects without breakthrough.

Conclusions: Aliskiren, alone or in combination with valsartan, did not reduce the incidence of aldosterone breakthrough in subjects with hypertension and proteinuria compared to conventional RAAS blockade.

PUB466

An Analysis of Blood Pressure Management of Patients with Chronic Kidney Disease and Hypertension Steven Arikian,[1,3] Frank A. Corvino,[1,2] David Oliveri,[1] Marko Zivkovic,[1,2] Michael Hagan.[4] *[1]Genesis Life Sciences, Hoboken, NJ; [2]Stevens Institute of Technology, Hoboken, NJ; [3]Columbia University, New York, NY; [4]Takeda Pharmaceuticals International, Inc., Deerfield, IL.*

Background: Hypertensive (HTN) patients with chronic kidney disease (CKD) are at greater risk of hypertension complications, require lower blood pressure (BP) levels, and may have non-standard response to therapy. Since outcomes depend on the treated population, a better understanding of population characteristics, BP management and goal attainment (BP<130/80 mmHg), and adverse event occurrences is important for successful treatment of CKD and HTN patients.

Methods: We performed a retrospective analysis of the General Electric Electronic Medical Records database of 3,348 CKD and HTN patients (January 2007 to May 2011). Patients had 1+ year of database activity prior/post the start of the most recent therapy, and ≥1 quarterly BP reading for the first year of therapy.

Results: The population was 56.7% female and 38.3% white, with a mean age of 68.6 years. Stage 2 hypertension was observed in 69.5% of the population. Mean BP was reduced from baseline 155.5/80.5 mmHg to 134.8/72.8 mmHg after 1 year (p<0.01). The most common therapeutic classes added were angiotensin-converting-enzyme inhibitors (ACEi, 39.2%) and angiotensin receptor blockers (ARB, 18.9%). 7.1% of the population was treated with ARB+thiazide (ARB+HCTZ) and 5.05% with ACEi+thiazide combinations (ACEi+HCTZ). The most common ARB and ARB+HCTZ was valsartan (6.0%) and valsartan+HCTZ (4.2%). ACEi+HCTZ exhibited the greatest systolic BP reduction after 1 year (15.4%). After 1 year of treatment, 43.4% of patients reached BP goal regardless of administered therapy, with the highest goal attainment observed for ACEi+HCTZ (51.5%). In the 1-year follow-up, 16.9% of the population had a CVD event, most often in patients treated with centrally acting antiandrenergics (18.9%).

Conclusions: CKD and HTN patients have a high risk of CVD events. Monotherapies are more broadly administered. BP goal attainments of 40-50% suggest a possible unmet need for more effective therapies in this population.

PUB467

Aliskiren Suppresses Renin-Angiotensin-Aldosterone System Leading to Reduced Blood Pressure and Albuminuria in Elderly Chronic Kidney Disease Patients with Hypertension Akihiko Numata,[1] Yoshiyuki Morishita,[1] Toshihiro Yasui,[2] Akira Onishi,[1] Eiji Kusano.[1] *[1]Division of Nephrology, Department of Internal Medicine, Jichi Medical University, Shimotsuke-city, Tochigi, Japan; [2]Internal Medicine, National Health Insurance Yukawa Clinic, Niimi-city, Okayama, Japan.*

Background: The effects of blockade of the renin-angiotensin-aldosterone system (RAAS) by aliskiren in elderly chronic kidney disease (CKD) patients have not been established. In the present study, we investigated the effects of aliskiren on the suppression of RAAS as well as blood pressure (BP) and renoprotection and cardioprotection in elderly CKD patients with hypertension.

Methods: This study was a 28-week, multicenter study consisting of a 4-week observation period to fix any drugs, including existing antihypertensives, and an 24-week treatment period with 150mg/ day of aliskiren. Twenty three elderly CKD patients were enrolled. Nineteen patients (9 males, 10 females, aged 74±7, estimated glomerular filtration rate (eGFR) 52±29 mL/min/1.73 m^2) completed the study period and analyzed. The changes of plasma renin activity (PRA), plasma renin level, plasma angiotensin I (Ang I) level, plasma angiotensin II (Ang II) level, plasma aldosterone (Ald) level, BP, eGFR and urine albumin/creatinine ratio (UACR) with aliskiren treatment were measured. The echocardiography with aliskiren treatment was also performed.

Results: Aliskiren treatment suppressed RAAS as follows: PRA (1.3±1.0 to 0.3±0.3 ng/ml/h, P<0.05), Ang I (59±32 to 26±17 pg/ml, P<0.05), Ang II (58±62 to 14±9 pg/ml, P<0.05) and Ald (86±38 to 80±53 pg/ml, NS), whereas plasma renin level was increased (4.9±5.0 to 30.9±26.4 pg/ml, P<0.05) by negative feedback. Aliskiren treatment reduced systolic BP (154±15 to 131±16 mmHg, P<0.05) and diastolic BP (77±10 to 72±10 mmHg, P<0.05). It also reduced UACRs (747±112 to 409±146 mg/g, P<0.05), whereas it did not change eGFR (52±29 to 51±29 mL/min/1.73 m^2, NS) and ejection fraction measured by echocardiography (66.8 ±7.9 to 66.5±6.8 %, NS).

Conclusions: Aliskiren suppressed RAAS leading to reduced BP and UACR, whereas it maintained eGFR and ejection fraction in elderly CKD patients with hypertension.

PUB468

Combination Therapy of Angiotensin II Receptor Blocker and Calcium Channel Blocker Exerts Pleiotropic Therapeutic Effects in Addition to Blood Pressure Lowering: Amlodipine and Candesartan Trial in Yokohama (ACTY) Akinobu Maeda, Kouichi Tamura, Yoshiyuki Toya, Satoshi Umemura. *Department of Medical Science and Cardiorenal Medicine, Yokohama City University Graduate School of Medicine, Yokohama, Japan.*

Background: Accumulated evidence showed that strict blood pressure (BP) control is essential to prevent target organ damage and to reduce cardiovascular mortality in hypertensive patients. Although angiotensin II receptor blocker (ARB) and calcium channel blocker (CCB) are the first-line antihypertensive drugs, monotherapy either by ARB or CCB achieves the target BP in only a limited number. Thus, we conducted the ACTY trial to examine effects of combination therapy with ARB and CCB on BP profile and several target organ functions in essential hypertensive patients.

Methods: We recruited the participants aged 26-76 years, who did not achieve the target BP level during the monotherapy period either by candesartan or amlodipine. After the monotherapy period, for the patients already being treated with amlodipine, a once-daily 8 mg dose of candesartan was added-on during the combination therapy period (ARB add-on group), and a once-daily 5 mg dose of amlodipine was added-on for those already being treated with candesartan (CCB add-on group), followed for 12 weeks.

Results: Participants were characterized as middle-aged, obese, mild-to-moderate hypertensive patients with impaired renal function and insulin resistance. Combination therapy with ARB and CCB significantly decreased clinic and home SBP and DBP. In addition, urine albumin excretion was significantly reduced (374±124 vs 105±34mg/g-Cr, *P<0.01)* without decrease in estimated glomerular filtration ratio (73.3±4.6 vs 71.8±4.8ml/min/1.73m^2, N.S.), and resulted in improvements in vascular function, such as baPWV and cSBP, and insulin sensitivity. Furthermore, the CCB add-on group showed a significantly greater decrease in clinic and home DBP than the ARB add-on group, and also exhibited better improvements in vascular functional parameters.

Conclusions: These results suggest that combination therapy with candesartan and amlodipine is an efficient therapeutic strategy for hypertension with pleiotropic benefits.

PUB469

Home Blood Pressure Control after the Great East Japan Earthquake Is Associated with Renin-Angiotensin System Inhibitor Medications in Hemodialysis Patients Makoto Kanno,[1] Kenichi Tanaka,[1,2] Kimio Watanabe,[1] Yoshihiro Tani,[1] Yoshimitsu Hayashi,[1] Koichi Asahi,[1,2] Masaaki Nakayama,[1] Kazuhiro Suzuki,[3] Tsuyoshi Watanabe.[1] *[1]Nephrology and Hypertension, Fukushima Medical University, Fukushima, Japan; [2]Chronic Kidney Disease Initiatives, Fukushima, Japan; [3]En-jin-kai Suzuki Clinic, Koriyama, Japan.*

Background: At 14:46 on March 11, 2011, northeastern Japan was struck by a major earthquake measuring 9.0 on the Richter scale. We recently reported poor BP control after the Great East Japan Earthquake in patients with stage 3-4 CKD (Tanaka et al. *Am J Hypertens. in press*). The present study evaluated deteriorations in BP control after this earthquake and clarified factors associated with these changes in patients on chronic hemodialysis.

Methods: Changes in self-measured BPs in the morning at home following the earthquake were investigated in 25 patients on chronic hemodialysis who were residents of Koriyama City (mean age, 65.7 years; median dialysis duration, 27.0 months).

Results: Steep elevations in home BP were observed the day after the earthquake (March 12) compared with baseline (systolic 161±18 vs. 151±13 mmHg, *P*=0.02; diastolic 81±13 vs. 78±11 mmHg, *P*=0.08). Mean home systolic and diastolic BPs were significantly elevated 1 week after the earthquake compared with at baseline (systolic 158±16 vs. 151±13, *P*<0.01; diastolic 81±13 vs. 78±11, *P*=0.01), but these values had returned to baseline by 4 weeks after the earthquake (systolic 151±16, *P*=0.8; diastolic 79±13, *P*=0.5). Mean BP was not significantly changed 1 week after the earthquake compared with at baseline in patients treated with RAS inhibitors (104±9 vs. 102±9, *P*=0.5), but was significantly higher than pre-earthquake levels in patients not treated with RAS inhibitors (112±13 vs. 105±12, *P*=0.01). Moreover, changes in mean BP were significantly greater even 6 weeks after the earthquake in patients who were not treated with RAS inhibitors than in those treated with RAS inhibitors (+4.4±5.6 vs. -2.3±3.9 mmHg, *P*<0.01).

Conclusions: Home BP was significantly increased after a major earthquake, and RAS inhibitor medication was associated with earthquake-induced poor BP control in patients on chronic hemodialysis.

PUB470

Effects of Eplerenone Add-On Therapy on BP and Sodium Excretion in Patients Taking Renin-Angiotensin System Blockers Noritaka Kawada,[1] Toshiki Moriyama,[1] Tomonori Kimura,[2] Harumi Kitamura,[2] Hiromi Rakugi,[2] Yoshitaka Isaka.[2] *[1]Health Care Center, Osaka University, Toyonaka, Osaka, Japan; [2]Division of Nephrology, Osaka University Gradutae School of Medicine, Suita, Osaka, Japan.*

Background: This study determined whether addition of anti-aldosterone agent, eplerenone (Ep) could result in clinical benefits in patients already taking angiotensin-converting enzyme inhibitors (ACEis) or angiotensin receptor blockers (ARBs).

Methods: During the course of the study, patients were treated with a gradual increase of Ep to a final dose of 50 mg/day. Last year, we have reported the data obtained by sitting position (Group A, n=25), and this year, additional data obtained by supine position (Group B, n=12) were included to this study. In Group B, we have also assessed central BP measured by HEM-9000AI, PWI, and 24hours urine analysis.

Results: At baseline, plasma Na, K, and serum osmolarity at sitting position (Group A) were higher than that of supine position (Group B). In the total thirty-seven patients, the administration of 50 mg of Ep significantly reduced SBP and DBP measured by sitting position, but had no significant effects on TTKG or proteinuria measured by spot urine analysis. Ep reduced serum osmolarity at sitting position (Group A), but had no effect on supine position (Group B). Therefore, osmolarity gap between sitting and supine position were minimized by Ep. In Group B, Ep reduced central BP (-8.5%, p<0.05) and baPWV (left: -4.4%, p<0.05. right: -4.5%, p<0.05), and increased FENa, but failed to show effects on proteinuria or albuminuria in 24hours urine analysis.

Conclusions: The Ep add-on therapy in CKD or HT patients taking renin-angiotensin system blockers may have cardioprotective effects by lowering central BP and moderating serum osmolarity gap between sitting and supine position.

PUB471

Anti-Hypertensive Therapy Reverses Microalbuminuria in Children M. Khurram Faizan,[1] Maman Mansoor,[2] Jason M. Kurland.[3] *[1]Pediatrics, Hasbro Children's Hospital, Providence, RI; [2]Aga Khan University, Karachi, Pakistan; [3]Medicine, UMass Memorial Medical Group, Worcester, MA.*

Background: An association between microalbuminuria (MA) and hypertension (HTN) has recently been described in adults. We have previously reported that this important relationship also exists in the pediatric hypertensive population [ASN 2010, PAS 2008, 2012 (abstracts)]. We now studied whether microalbuminuria can be reversed after treatment of hypertension in children.

Methods: Retrospective cohort study from Dec 2006 to Apr 2010, on *non-diabetic* pts between the ages of 0-21 years. All pts had a diagnostic study with 24-hour ambulatory blood pressure monitoring (ABPM) in an urban pediatric nephrology clinic. HTN was defined as ≥ 95th percentile of systolic and/or diastolic blood pressure for age, gender and height. MA was assessed on a morning clinic sample and defined as urine albumin-creatinine ratio of ≥20 mg/g. Pts with HTN were treated with standard anti-hypertensive medications. A follow-up urine was assessed for the presence of MA after treatment.

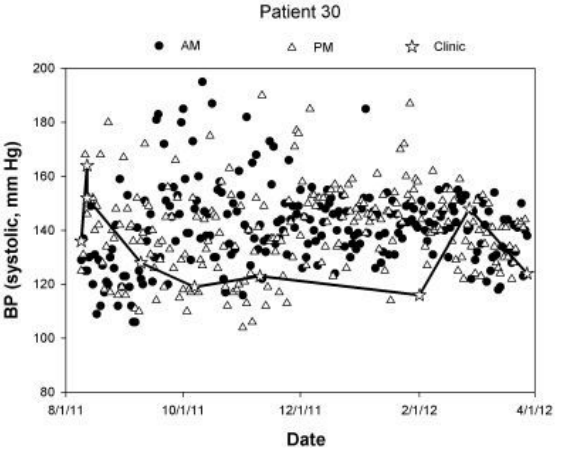
Results: 10 pts were included. Mean age was 12.6 yrs. 4 (40%) were male. Mean BMI was 24.3 kg/m^2 and 50% of pts were obese or overweight. 5 pts received ACEi, 3 β blockers, 1 calcium channel blocker, and 1 diuretic. **MA decreased in *all* pts on anti-hypertensive therapy, and normalized (<20 mg/g) in 9/10 pts on last clinic follow-up.** Mean pre- and post-treatment MA was **65 mg/g** and **19 mg/g**, respectively (***p* = 0.002**). Mean BP decreased from **140/88 mmHg** at baseline to **115/71 mmHg** after treatment. Mean time between performance of ABPM and final MA collection was 11.5 mths. Mean time between start of anti-hypertensive treatment and final MA collection was 10 mths.

Conclusions: Our study shows for the first time in children that MA is readily reversible with treatment of HTN, irrespective of the choice of agent. Recent studies have shown an association between MA and cardiovascular and renal disease in the adult hypertensive population. Microalbuminuria likely represents an important injury marker and risk factor in patients with clinically significant hypertension. This evolving relationship needs to be further explored in large scale prospective trials.

PUB472

Masked Hypertension (MH) Is a Chronic Condition that Is Seen in Both CKD and Non-CKD Patients Christopher Valentine, Ravish Shah, Daniel J. Birmingham, Lee A. Hebert. *Division of Nephrology, The Ohio State Univeristy Medical Center, Columbus, OH.*

Background: MH is defined as normal blood pressure in the office (clinic) but hypertension out of office determined by either ambulatory blood pressure monitoring (ABPM), or home blood pressure monitoring (HPBM). MH is associated with increased cardiovascular (CV) risk. The risk is comparable to that of sustained hypertension (SH, hypertension both in and out of the office). These associations of MH with increased CV risk were found by cross sectional testing, or longitudinal testing in which the status of the MH patients was tested 3-10 years after the diagnosis of MH was made. The patients' blood pressure during this interval was not studied. The mechanism of CV risk of MH is unknown. We tested the hypothesis that MH is chronic condition.



Methods: 33 patients with treated hypertension followed by our Resistant Hypertension Program were selected for study because they agreed to daily HBPM both AM and PM, and they had calibrated HBPM equipment and proper technique.

Results: Follow up was 4-15 months, median 10 months. The number of daily HPBM measurements per patient during follow-up ranged from 103 to 767, median 301. MH was present in 8/33 (24%), White Coat Hypertension (WCH) in 4/33 (12%), neither MH or WCH (NMW) in 64%. The figure is a representative MH patient. In the MH cohort, mean systolic BP (SBP) during follow up was: Clinic 128 +/- 8, HBPM PM, 143 +/- 4.2, P=0.003. In the NMW cohort, mean SBP during follow up was: clinic 125+/-5, HBPM PM 124+/-6, P=0.48. CKD was present was present in 50% of MH and 64% NMW (NS).

Conclusions: HBPM is needed to identify and appropriately treat the chronic hypertension of MH. This might be especially important in CKD and in order to minimize both CV disease and CKD progression.

Funding: NIDDK Support

PUB473

Resistant Hypertension and Vitamin D Deficiency Alexis Payette, Jean-Philippe Lafrance, Vincent Pichette, Michel Vallee. *University of Montreal - HMR, Canada.*

Background: Vitamin D deficiency is thought to play a significant role in cardiovascular disease and hypertension. In animal models, vitamin D regulates the renin-angiotensin system. Several observational studies have reported an association between vitamin D deficiency and hypertension in humans. This study evaluates the association between vitamin D status and BP in patients with resistant or difficult-to-control hypertension. We measured BP levels using 24-hour ambulatory blood pressure monitoring (ABPM) which correlates more closely with cardiovascular complications. We hypothesized that patients with resistant hypertension could have a significant vitamin D deficiency.

Methods: We conducted a retrospective study among patients referred in a tertiary hypertension clinic in Montreal, Canada. Through chart review, we collected clinical and laboratory data from 113 patients. Association between vitamin D and BP was evaluated with linear regression. We performed a subgroup analysis among patients requiring ≥3 antihypertensive drugs.

Results: The average initial BP was 139/79mmHg on ABPM. The mean age was 59.3y and 49.6% of patients were females. On their initial visit, 53.1% required ≥3 antihypertensive drugs and were classified as having resistant hypertension. The most prevalent comorbidity was diabetes (24.8%). Less than 10% of patients had a history of stroke or myocardial infarction. The mean circulating level of 25(OH)D was 27.8 ng/mL. This mean value is similar to that of the general Canadian population (27.1 ng/mL). We did not observe a significant relationship between 25(OH)D circulating level and systolic or diastolic 24-hour mean BP in this population [beta regression coefficient 0.07 (95%CI:-0.03-0.17) for systolic BP and -0.02 (95%CI:-0.11-0.06) for diastolic BP]. This absence of relationship was also observed in patients requiring ≥3 antihypertensive drugs.

Conclusions: We did not observe a significant relationship between circulating levels of 25(OH)D and BP levels in our population of patients with resistant or difficult-to-control hypertension, as measured with ABPM. These results suggest that vitamin D deficiency is not a clinically important risk factor in resistant or difficult-to-control hypertension.

PUB474

Evidence for the Need to Screen Patients before Treatment with Renal Denervation Eva Vink,[1] Willemien Verloop,[2] Evert-jan Vonken,[4] Michiel Voskuil,[2] Wilko Spiering,[3] Peter J. Blankestijn.[1] *[1]Nephrology, UMC Utrecht, Utrecht, Netherlands; [2]Cardiology, UMC Utrecht, Utrecht, Netherlands; [3]Vascular Medicine, UMC Utrecht, Utrecht, Netherlands; [4]Radiology, UMC Utrecht, Utrecht, Netherlands.*

Background: Currently renal denervation(RDN) is only advised for patients with resistant hypertension. We have implemented a standardized stepwise screening protocol to screen patients before treatment with RDN. The aims of this protocol are: confirmation of the diagnosis of hypertension(HT), exclusion of secondary forms of HT and obtaining imaging of the renal arteries. The aim of this study is to evaluate the results of our screening protocol. We hypothesize that the use of a standardised screening protocol allows exclusion of a considerable number of patients from treatment with RDN.

Methods: We have evaluated screening results from all patients referred to the UMC Utrecht for RDN in the period of August 2010 and April 2012. All patients underwent a stepwise protocol, including 24-h ambulatory blood pressure monitoring(ABPM), 24-h urine collection, collection of serum and saliva, tests of the RAAS and MRI/MRA of the renal arteries. Central in our protocol is a multidisciplinary approach.

Results: 126 patients were referred to the UMC Utrecht for treatment with RDN. 79 patients(63%) were excluded from treatment. Excluded patients were slightly younger compared to the eligible patients and had a lower BP. The most important reason for exclusion was a BP-related factor in 38(48%) patients: 18 patients(23%) had an office systolic BP <160mmHg, 19 patients(25%) did have an ABPM below the threshold. This last category of patients did have a clear white coat effect. We have found 8 cases(11%) of secondary HT, the majority being primary hyperaldosteronism(5 patients: 6%).

Conclusions: We have found relevant percentages of patients with a secondary cause of HT or a severe white coat effect, evidenced by the 24-h ABPM. Therefore all patients should be screened before treatment with RDN with the use of a standardized screening protocol. Because of the high percentage of patients with a severe white coat effect, the first step in screening should be 24-h ABPM. Finally a multidisciplinary approach is advised.

PUB475

Haptoglobin Phenotype and Antihypertensive Treatment Response Charlotte Strandhave,[1] My Svensson,[3] Henrik B. Krarup,[2] Jeppe Hagstrup Christensen.[1] *[1]Department of Nephrology, Aalborg Hospital, Aarhus University Hospital, Aalborg, Denmark; [2]Department of Clinical Biochemistry, Aalborg Hospital, Aarhus University Hospital, Aalborg, Denmark; [3]Department of Nephrology, Aarhus University Hospital, Aarhus, Denmark.*

Background: Many hypertensive patients fail to reach blood pressure (BP) goals of 135/85 mmHg despite treatment. Genetic markers may be important in resistant hypertension (RH), among these haptoglobin phenotypes (Hp) (1-1, 2-1, and 2-2). Hp 2-2 has been associated with RH and a need for several drugs to achieve BP goals. The aim was to examine if Hp 2-2 may predict poor response to treatment regarding both BP lowering effect and response to antihypertensive drugs.

Methods: Patients with incident hypertension (n=127) were examined at baseline and one year. We performed 24h ambulatory BP measurements and estimated the difference in daytime systolic BP (SBP) between visits. Hp phenotype was determined by high-performance liquid chromatography.

Results: Patients were divided in two groups: 1-1+2-1 (n=87) and 2-2 (n=40). Baseline characteristics and response to treatment are shown in the table.

	Hp 1-1+2-1	Hp 1-1	p
Age (yrs)	50±11	50±13	ns
Female (n)	49(56%)	20(50%)	ns

Diuretics (n)	26(37%)	16(46%)	ns
ΔSBP, diuretics (mmHg)	29±16	21±10	ns

Mean±SD or numbers(%)

SBP goals was reached in 61% of Hp 1-1+2-1 patients versus 69% in Hp 2-2 patients (p=0.3). Adjusted regression analysis also showed that Hp 2-2 patients reached BP goal to same extend as Hp 1-1+2-1 patients (β- coeff.=-0.04, p=0.7).

Conclusions: In hypertensive patients Hp 2-2 did not predict poor response to antihypertensive treatment. Hp 2-2 patients did not need more intensive treatment to achieve BP goals, nor did BP decrease less sufficient in response to different antihypertensive drugs.

Incidence of Hypokalemia and Acute Kidney Injury with the Use of Triamterene/Hydrochlorothiazide versus Hydrochlorothiazide Amy J. Zwettler, Kevin C. Abbott, David K. Oliver, Robert Nee. *Nephrology Department, Walter Reed National Military Medical Center, Bethesda, MD.*

Background: Triamterene/Hydrochlorothiazide (Maxzide) was introduced with the goal of reducing the potential for hypokalemia. This study aims to look at the incidence of hypokalemia comparing use of Maxzide with the separate use of hydrochlorothiazide (HCTZ).

Methods: We queried the institutional electronic medical record for all adults (>18 years of age) with new prescriptions for Maxzide or HCTZ between September 1, 2002 to October 31, 2010. Serum potassium, magnesium, and creatinine values were obtained both prior to initiation and subsequent to therapy. The primary outcomes were: incidence of hypokalemia (serum potassium level <3.5 mEq/L) and acute kidney injury (AKI, defined as a >= 50% increase in serum creatinine from baseline) within one year of prescription. Logistic regression was used to calculate adjusted outcomes.

Results: We identified 940 patients with new Maxzide prescriptions and 3525 patients with new HCTZ prescriptions. Maxzide users were significantly younger and more likely female, compared to HCTZ users. The majority of the study population was also prescribed either an angiotensin converting enzyme-inhibitor or angiotensin-receptor blocker. Overall hypokalemia was significantly more common in the Maxzide group at one year (16.17% compared to 13.23% in HCTZ group, p=0.024 by Chi square). When evaluating potassium at both 30 and 60 days after initial prescription, however, there was no difference in the incidence of hypokalemia. Furthermore, after adjusting for baseline demographics, comorbid conditions, and concomitant medication use, there was no difference in the incidence of hypokalemia at 60 or 90 days. There was also no difference in the incidence of AKI, hyperkalemia, or hypomagnesemia.

Conclusions: These results suggest that Maxzide use, when compared to HCTZ, is not associated with a significantly reduced incidence of hypokalemia. *"The views expressed in this abstract are those of the authors and do not necessarily reflect the official policy or position of the Department of the Army, the department of the Navy, the Department of Defense, or the United States government."*

Can We Stop Using Mercury in Pregnancy? Patrick Lan, Adrian G. Gillin. *Renal Medicine, Royal Prince Alfred Hospital, Sydney, NSW, Australia.*

Background: Mercury sphygmomanomtery remains the gold-standard in measuring blood pressure (BP) in hypertension in pregnancy. However it has a number of limitations and exposure risks that may be overcome by automated BP measuring devices. We sought to determine if such devices are a reliable alternative to mercury sphygmomanometry in an outpatient setting.

Methods: Patients were recruited from the hypertension in pregnancy clinic at Royal Prince Alfred Hospital. Three sequential BP measurements were taken by mercury sphygmomanometry and by an automated device (Omron HEM-7200). The order of the two methods was randomly allocated. Paired t-test was used to determine the presence of a difference between the two methods. The level of intra-observer variability for each method was determined by random effects regression. The number of different clinical decisions that would have been made with the automated reading compared to the manual reading was determined based on our management guidelines.

Results: The study included 51 patients for a total of 110 sets of measurements. 73% of the readings were performed in patients with either pre-eclampsia or gestational hypertension, and 70% were performed in post-partum patients. There was a difference between the automated and manual methods for both systolic BP (mean 2.6mmHg, SD 6.8mmHg, 95%CI 1.3 to 3.9mmHg, p<0.01) and diastolic BP (mean -2.3mmHg, SD 6.2mmHg, 95%CI -3.5 to -1.1mmHg, p<0.01). This difference was similar both antenatally and postnatally. In regards to intra-observer variability, the standard deviation for the manual readings were 4.0mmHg (p<0.01) for systolic BP and 3.1mmHg (p<0.01) for diastolic BP. The corresponding standard deviations for the automated readings were 4.6mmHg (p<0.01) and 3.1mmHg (p<0.01), respectively. Additionally, the automated measurements would have resulted in 4 (3.6%) different clinical decisions being made.

Conclusions: There was a difference between the two methods of BP measurement. However, this was of little clinical significance. In addition, intra-observer variability within either method was comparable. As such, automated BP measuring devices are a reliable alternative to mercury sphygmomanometers in outpatients with hypertension in pregnancy.

PUB478

Combination Antihypertensive Drugs Could Improve Blood Pressure Control and Adherence to Medications Hideki Kato, Masayuki Tanemoto, Shunya Uchida. *Nephrology, Teikyo University, Itabashi, Tokyo, Japan.*

Background: Hypertension constitutes a major risk factor for cardiovascular and chronic kidney disease. Blood pressure control, however, are sometimes difficult to achieve. Recently several combination antihypertensive drugs of angiotensin-receptor blocker (ARB) and calcium-channel blocker (CCB) have become available in clinical medicine. In this study, we examined whether combination antihypertensive drugs could improve blood pressure control and patients' satisfaction using questionnaire forms.

Methods: We retrospectively examined 97 outpatients in our hospital to whom anti-hypertensive treatment was switched from individual drug to combination drugs. Blood pressures (BPs) in clinics were measured and costs for the drugs were calculated. We also asked these patients to fill in a questionnaire about the alteration of home BPs, skip

medications, copayments for the drugs, and satisfaction levels. We assigned titer to each anti-hypertensive drug, and calculated the total titers in each patient.

Results: The average BPs of 97 patients were significantly decreased after the switch (SBP from 143.2 ± 19.1 to 135.7 ± 17.7, p<0.01). We divided patients into three groups according to the changes of the titers (decreased, not changed and increased). The group with the increased-titers had significantly higher BPs before the switch as compared to other groups and this group exhibited the most significant improvement of BPs after the switch. Costs for the anti-hypertensive drugs were decreased by 23% and copayments were also reduced. Adherence to medications was improved and home BPs were decreased. 79 % of patients preferred combination drugs.

Conclusions: Switching to combination drugs exhibit several advantages of BP control, cost reduction, adherence to medications and patients' satisfaction levels.

Micro RNA Profile Distinguishes Subjects with Cardiovascular Risk Factors from Healthy Individuals

Berenice Y. Gitomer,[1] Kristen L. Jablonski,[1] Aik Choon Tan,[2] Wei Wang,[1] Eric Lader,[3] Jonathan Michael Shaffer,[3] M. Chonchol.[1] *[1]Department of Medicine, University of Colorado Denver, Aurora, CO; [2]Medical Oncology, University of Colorado Denver, Aurora, CO; [3]Sample and Assay Technologies, Qiagen, Frederick, MD.*

Background: Recent studies reported that miRNAs can be detected in the blood and may play a key role in cardiovascular development. Thus, we hypothesize that it may be possible to differentiate patients with cardiovascular disease (CVD) risk factors from healthy participants based on a distinct set of serum miRNAs.

Methods: We performed miRNA profiles on 10 healthy non-Hispanic Caucasian volunteers (controls) and 9 race matched subjects (cases) with cardiovascular risk factors. Subjects were free from clinical CVD and other chronic diseases and not using prescription medication. miRNA profiles was analyzed using a custom PCR array containing 372 miRNAs previously determined to be readily detectable in serum.

Results: Characteristics of the study population are shown in Table 1

Characteristics of study subjects

	cases (n=9)	controls (n=10)
Gender (M/F)	6/3	7/3
Age (y)	58±2	58±2
BMI (kg/m²)	36.3±1.3*	21.5±0.6
Regular aerobic exercise (%)	0*	100
Total cholesterol (mg/ml)	219±10*	174±9
SBP>120 or DBP>80	89*	0
Fasting glucose>100mg/dl (%)	56*	10
CRP (mg/ml)	6.2±1.0*	0.5±0.1

Data are mean±SEM. * p<0.05 vs.control. Regular aerobic exercise is defined as ≥1 hours of vigorous activity≥5days/week

For the arrays cases and controls were analyzed as 3 respective pools. 12 miRNAs were significantly downregulated and 23 miRNAs were upregulated (≥ 2.5 fold) in the cases compared to the controls. Among these 3 miRNAs were downregulated and 5 miRNAs upregulated ≥ 4 fold. These included miR-365 which has been associated with cardiac hypertrophy.

Conclusions: Subjects with CVD risk factors can be distinguished from healthy subjects without CVD risk factors based on a miRNA profile. The utility of this profile for prediction of future cardiovascular events will need validation in a larger population.

Ultrasound-Guided Trans-Hepatic Embolization of Renal Artery Pseudoaneurysm

Emiliana Ferramosca,[1] Carla Serra,[2] Antonio Di Felice,[1] Marcora Mandreoli,[1] Antonio Santoro.[1] *[1]Nephrology, Dialysis, Hypertension, S.Orsola-Malpighi Univ Hosp, Bologna, Italy; [2]Diagnostic and Interventional US, Dpt. Internal Med and Gastroenterology, S. Orsola-Malpighi Univ Hosp, Bologna, Italy.*

Background: The standard treatment of pseudoaneurysm is selective angiographic coil embolization. We report a case of an alternative renal artery pseudoaneurysm (RAP) repair in a high-risk pt.

Methods: Female, 67 ys, chronic renal failure (CRF) from phenacetin abuse, sCreat 4 mg/dl, previous left nephrectomy for cancer, prone to develop pseudoaneurysms, mainly after endovascular procedures. After a diagnosis of a RAP, she underwent a selective angiographic stent insertion, via right brachial artery, with the RAP exclusion. The procedure was complicated by a right brachial artery pseudoaneurysm, then surgically corrected. One month later, a ColorDoppler US (CDUS) and Contrast-enhanced US (CEUS) of the treated RAP showed its diameter increase (from 2.5 to 3.6 cm) and a turbulent flow in the site of RAP. Due to CRF and previous pseudoaneurysm development, a novel percutaneous trans-hepatic US guided approach for coil embolization was proposed. The procedure was planned and guided by CEUS and 3D-CEUS.

A iU22 US machine (2007, Philips, WA), with a 5-2 MHz curved-array probe and contrast-specific software, was used. A 2nd generation echo-contrast agent SonoVue(Bracco, IT) was employed.

With the pt in supine position, with a trans-hepatic approach, by US guidance a 18 gauge needle was advanced into the RAP. Through the needle, a fluoroscopy control was performed. When the needle was in the flow lumen, numerous coils (Balt, Montmorency, France) of 6, 8 e 12 mm of diameter were inserted. The flow in the lumen was assessed by CDUS and CEUS for monitoring the development of occlusion. Once the aneurysm was thrombosed, the needle was removed. The characteristics of the main renal artery and intrarenal flow were documented before, during and after the procedure using CDUS and CEUS. The procedure was well tolerated and no worsening in sCreat occurred.

Conclusions: The reported procedure may be an attractive alternative to surgery or traditional percutaneous trans-catheter approach in RAP management in selected high-risk pts.

PUB481

Causes of Hypertension and Prevalence of Target Organ Damage in a Population-Based Sample of 9- to 10-Year-Old Icelandic Children

Sigridur Birna Eliasdottir,[1] Sandra Dis Steinthorsdottir,[1] Olafur S. Indridason,[2] Hrodmar Helgason,[2] Inger Maria Agustsdottir,[2] Runolfur Palsson,[1,2] Vidar O. Edvardsson.[1,2] *[1]University of Iceland, Reykjavik, Iceland; [2]Landspitali – the National University Hospital of Iceland, Reykjavik, Iceland.*

Background: The aim of the study was to investigate the causes of hypertension and the prevalence of target organ damage (TOD) in a population-based sample of hypertensive Icelandic children.

Methods: Thirty 9- to 10-year-old children found to have hypertension in a population–based study conducted by our group were invited to participate. Blood and urine biochemical studies were performed for the evaluation of secondary causes of hypertension and TOD. All study subjects underwent ambulatory blood pressure monitoring (ABPM), echocardiography, ultrasound evaluation of carotid intima-media thickness (cIMT) and an ultrasound examination of the kidneys. Controls, one for each study subject, were matched for gender, height and weight underwent echocardiography and cIMT evaluation.

Results: Of the 30 hypertensive children, sustained hypertension was confirmed in 24 children with ABPM. Six children with white-coat hypertension were excluded from further study. The 24 hypertensive subjects were found to have essential hypertension. Eight of these (33%) had signs of TOD, of whom 6 had left ventricular hypertrophy (LVH) defined as LV mass >51 g/m² vs. only one in the control group (p=0.041), 2 had isolated mild microalbuminuria and 1 of the study subjects with LVH did also have microalbuminuria. The hypertensive group had greater septal (p=0.001) and posterior wall (p=0.009) thickness than controls. When controlled for body surface area and height, a significant difference was noted in LV mass between study subjects and controls, 84 vs. 71 g/m² (p=0.044) and 72 vs. 62 g/m(p=0.047). There was no significant difference in the cIMT between the 2 groups.

Conclusions: All children in our population-based study cohort had essential hypertension. Manifestations of TOD, primarily LVH, were observed in a substantial number of study subjects.

PUB482

Thrombotic Microangiopathy Complicating Malignant Hypertension

Linda C. Esuzor, Taopheeq A. Mustapha. *Internal Medicine, Meharry Medical College, Nashville, TN.*

Background: TMA is an uncommon complication of malignant hypertension. Though the prognosis for patients with TMA occurring with malignant hypertension has improved over the past decade, the clinical and prognostic features are poorly understood. We describe two cases of severe hypertension complicated by TMA and also highlight the disparate renal outcomes and time for resolution of hemolysis and correlation with BP control.

Methods: Case 1

A 36yr old AAM with h/o HTN and CKD who presented with a 2day h/o of abdominal pain, nausea, vomiting. He stopped taking his BP meds 3 days prior. Admission BP was 225/158.

P/E revealed mildly tender abdomen, neuro exam was normal.

Labs: creatinine of 9.51, plt 42,000, Hb 14.3, LDH 1352, haptoglobin 8, Coags normal, Tbil 2.4.

Working diagnosis were hypertension complicated by acute on chronic kidney failure and/or TMA, Scleroderma renal crisis and TTP/HUS. ADAMTS13 level was normal.

See table 1.

table1

1	42	28
2	29	24
3	37	38
4	78	40
5	82	54
6	151	
7	220	
8	278	
9	299	
10	283	
11	274	

Case 2

A 39yr old AAM with pmhx of HTN and type 2 DM presented with 1wk h/o of abdominal pain, nausea with jaundice but no pruritus. He had no other c/o. On presentation, his BP was 179/116.

P/E was significant for sclera icterus, pallor and epigatric tenderness.

Labs showed Hb 10, plt 28000, LDH 1718, haptoglobin 3, PT 16.7s, INR 1.3 and creatinine 1.05, Tbil was 8.4. CT Abd and renal US were normal. ADAMTS13 levels was not done.

Results: Thrombocytopenia and Creatinine improved with BP control. Kidney biopsy revealed findings consistent with TMA and peripheral smear revealed schistocytes.

Conclusions: Malignant hypertension can be complicated by TMA but severe hypertension is also associated with HUS/TTP. The clinical features of these two entities overlap significantly hence it is sometimes difficult to distinguish them. In our patients, their response to BP control, normal ADAMTS13 levels and resolution of thrombocytopenia

excluded TTP. Renal failure was irreversible in case 1 as repeat renal biopsy 3 months after dialysis initiation showed persistent TMA which highlights that persistent renal TMA may account for the irreversibility of renal failure in cases of malignant HTN.

PUB483

Standing Blood Pressure: A Useful Tool for Risk Stratification in Healthy Young Adults? Hsiao L. Lai, Caitlin Thys, Courtland Winborne, Cynthia R. Christiano. *IM, ECU, Greenville, NC.*

Background: Primary prevention of risk factors for cardiovascular disease (CV) has become an important focus in the past 10 years. A preliminary study conducted between Jun and Oct 2010 in NC undergraduate students demonstrated high prevalence of multiple CV risk factors: 30% had two or more risk factors, 12% had three or more risk factors. Risk factors were defined as hypertension, obese body mass index, dyslipidemia, abnormal fasting blood glucose, smoking and sedentary activity level. This study demonstrated the feasibility of screening young adults utilizing the college setting, existing college forums, and Health curricula. Because of limited space and time use of standing, at rest blood pressure (BP) were taken instead of the standard seated BP.

Methods: Nov 2011 to Dec 2011, 209 undergraduate students participated in CV screening. Standing BP was obtained at rest with arm at heart level using manual aneuroid sphymanometry followed by seated resting BP obtained at rest under standard conditions. Hypertension, a systolic blood pressure (SBP) > 139 mmHg or diastolic blood pressure (DBP) > 89 mmHg.

Results: The mean age was 19 yo with 51% female, 79% white, and 11% Black. There was no difference between average standing and sitting SBP: 115.7 mmHg versus 116 mmHg, (p=0.85); or in the average DBP: 73.9 mmHg versus 73.8 mmHg, (p=0.91). The proportion of participants classified as hypertensive: 5.2% versus 3.8%; prehypertensive: 27.7% versus 27.6%; and normotensive: 67.9% versus 69.3%; based on standing or seating BP did not significantly change.

Conclusions: Young adults without established CVD the standing BP at rest does not significantly differ from seated BP taken under standardized setting. We did not perceive any significant trend towards higher or lower measurements in standing versus seated BP. Use of standing at rest BP taken by experienced clinicians may suffice as well as standard, seated, at rest BP measurement for initial BP screening in settings where space limitations. This single center study of a limited population and cannot be generalized to all young adults. Multicenter studies with larger number and increased proportion of Black and other demographic groups are needed.

PUB484

Changes to Renal Perfusion and Oxygen Bioavailability in Swine when Exposed to Propofol and Isoflurane Anesthesia Zaheer Akhtar,[1,3] Andrew Wentland,[1] Nathan Artz,[1] Sean Fain,[1] Arjang Djamali,[3] Elizabeth Sadowski.[1] *[1]Department of Radiology, University of Wisconsin Madison, Madison, WI; [2]Department of Nephrology, University of Wisconsin - Madison, Madison, WI.*

Background: In this study, we evaluated total renal blood flow, renal perfusion and oxygen bioavailability in swine anesthetized with either propofol or isoflurane.

Methods: Seven swine were evaluated at two time points: (1) under two hours of propofol anesthesia and (2) under two hours of isoflurane anesthesia. For each time point, mean arterial pressure (MAP), mean heart rate (MHR), total renal blood flow (via phase contrast MRI), perfusion (via arterial spin labeling MRI), and oxygen bioavailability (via BOLD MRI) were evaluated. Differences in these measures between the two time points were evaluated with paired Student's t-tests.

Results: MAP (87 versus 57 mmHg; p<0.001) was significantly higher and MHR (68 versus 86 bpm; p<0.04) was significantly lower under propofol anesthesia than under isoflurane anesthesia respectively. Total renal blood flow was significantly higher under propofol than under isoflurane anesthesia (263.7 versus 96.5 mL/min; p<0.0014). Cortical perfusion and oxygen bioavailability were significantly greater with propofol than with isoflurane (ASL perfusion: 208- versus 78 mL/100g/min; p<0.00001; R2*: 9.9 versus 11.9 s^{-1}; p<0.009). Medullary perfusion and oxygen bioavailability were not significantly different between the two time points.

Conclusions: There are significant hemodynamic differences between isoflurane and propofol, which likely affect total renal blood flow, cortical perfusion and oxygenation. Medullary perfusion and oxygenation are not significantly different between the two anesthetics, likely due the kidney's autoregulatory mechanisms which maintain stable medullary oxygenation over a broad range of blood pressures and varying levels of renal blood flow. When conducting studies aimed at assessing the effects of disease or pharmacologic maneuvers on renal blood flow, perfusion, or oxygenation bioavailability, it is important to recognize the baseline effects commonly used anesthetic agents have on the kidney.

PUB485

What Is the Significant Cut-Off Level of Albuminuria for Diagnosis of Subclinical Atherosclerosis in General Population? Ja Seon Kim, Soon Bae Kim. *Division of Nephrology, Department of Internal Medicine, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea.*

Background: The aim of this study was to estimate the cut-off level of microalbuminuria diagnostic for subclinical atherosclerosis. To do this, we evaluated the carotid, coronary and peripheral arteries in subjects recruited from the general population.

Methods: Study population included a total of 1,692 persons (1,069 males and 623 females), who participated in health screening at Asan Medical Center. The study involved performing coronary CT and carotid Doppler ultrasound on all patients, as well as determining their ankle-brachial index, pulse wave velocity and urinary albumin-to-creatinine ratio (UACR). Subjects with at least one of the following were classified as members of atherosclerosis group: 1) a coronary CT: coronary calcium score >400; 2) sonographically visible plaque or intimal thickening detected using carotid Doppler ultrasound; 3) an ankle-brachial index <0.9; or 4) a pulse wave velocity >8.5 m/s.

Results: Among 1,692 participants, 510 persons were assigned to the atherosclerosis group. The respective mean ages in the atherosclerosis and non-atherosclerosis groups were 59.2 ± 8.6 years and 52.6 ± 8.9 years (p < 0.001). The median UACR in the atherosclerosis group was 8.50 mg/g (95% CI: 7.60–9.55 mg/g), which was significantly higher (p = 0.017) than that in the non-atherosclerosis group, where it was 7.05 mg/g (95% CI: 6.60–7.55 mg/g). The use of receiver operating characteristic (ROC) curves for UACR to identify atherosclerosis indicated that the optimal cutoff value of UACR was 7.75 mg/g (47.5% sensitivity; 69% specificity). The gender-specific cutoff points were 6.45 mg/g (50.0% sensitivity; 70.1% specificity) in men and 8.45mg/g (62.7% sensitivity; 63.0% specificity) in women. Using multivariate analysis, male gender was the most powerful independent predictor for atherosclerosis. Smoking, hypertension, HbA1c, age, and body mass index were all independently associated with atherosclerosis, although microalbuminuria was not.

Conclusions: We have shown that the cut-off value of albuminuria for atherosclerosis using ROC curve analysis is much lower than the traditional level of microalbuminuria.

PUB486

Alterations in Cardiac Autonomic Tone in IgA Nephropathy: Baseline and Responses to Angiotensin II Challenge Michelle C. Mann, Derek Exner, Brenda Hemmelgarn, Tanvir Chowdhury Turin, Darlene Y. Sola, Sofia B. Ahmed. *Faculty of Medicine, University of Calgary, Calgary, AB, Canada.*

Background: Cardiac autonomic tone (CAT) dysfunction, particularly loss of cardioprotective vagal activity, and renin-angiotensin sysmte (RAS) upregulation increase cardiovascular disease (CVD) risk in chronic kidney disease (CKD), though whether this applies to those with early kidney disease and normal glomerular filtration rate (GFR) is unknown. We examined the CAT response, as measured by the balance of sympathetic to vagal activity, in response to angiotensin II (AngII) challenge in subjects with IgA nephropathy (IgAN) and normal GFR compared to healthy controls.

Methods: Eight male IgAN subjects (39±4y) and 26 healthy controls (34±2y, 27% male) were studied in high-salt balance during AngII challenge (3ng/kg/min x30min, 6ng/kg/minx30min). Sympathetic (LF), vagal (HF), and total sympathovagal (LF:HF) CAT were measured by heart rate variability (HRV) power analysis at baseline and in response to AngII. Baseline and response variables were adjusted for gender, BMI, and baseline HRV using ANCOVA.

Results: Compared to healthy controls, IgAN subjects demonstrated similar baseline sympathetic activity (LF nu, p=0.4 vs. controls) but significantly decreased vagal tone (HF nu, 26.2±4 vs. 35.8±7, p=0.02 vs. controls), though total sympathovagal CAT did not differ between groups (LF:HF, 1.86±0.3 vs. 1.94±0.6 p=0.8 vs. controls). In response to each AngII dose, both groups maintained similar sympathetic activity (ΔLF nu 30min, p=0.3; ΔLF nu 60min, p=0.4 vs. controls) but IgAN subjects demonstrated an exaggerated vagal response (ΔHF nu 30min, 10.4±3 vs. -2.8±2 nu, p=0.002; ΔHF nu 60min, 5.8±2 vs. -7.0±3 nu, p=0.07 vs. controls). Overall sympathovagal CAT did not differ between the two groups (ΔLF:HF 30min, p=0.4; ΔLF:HF 60min, p=0.2 vs. controls).

Conclusions: Compared to healthy controls, individuals with IgAN and normal GFR demonstrate withdrawal of cardioprotective vagal tone at rest and an augmented vagal response to AngII challenge, suggesting that alterations in CAT, which may influence CVD risk, occur even in patients with the earliest stages of CKD.

PUB487

Vitamin D Supplementation Improves Cardiac Autonomic Tone in IgA Nephropathy Michelle C. Mann, Derek Exner, Brenda Hemmelgarn, Tanvir Chowdhury Turin, Darlene Y. Sola, Sofia B. Ahmed. *Faculty of Medicine, University of Calgary, Calgary, AB, Canada.*

Background: Vitamin D (VD) deficiency, increased renin-angiotensin system (RAS) activity, and poor cardiac autonomic tone (CAT) are common in chronic kidney disease (CKD) and are risk factors for cardiovascular disease (CVD). We examined the impact of VD supplementation on CAT in subjects with IgA nephropathy (IgAN) at baseline and in response to angiotensin II (AngII) challenge.

Methods: Eight male IgAN subjects (39±4 yrs, eGFR 91±11 ml/min/1.73m2) with VD-insufficiency (<75nmol/L 25OH VD) were studied in high-salt balance before and after 4 weeks of VD therapy (10,000 IU cholecalciferol/day). Sympathetic (LF), vagal (HF), and overall sympathovagal (LF:HF) CAT was measured by heart rate variability (HRV) power spectral analysis both at baseline and in response to AngII (3ng/kg/minx30min, 6ng/kg/minx30min). Pre- and post-supplementation measures were compared by non-parametric paired analysis.

Results: Both 25OH and 1,25OH VD levels increased in all subjects post-supplementation (25OH 59±9 vs. 137±19nmol/L, p=0.02; 1,25OH 111±12 vs. 139±15pmol/L, p=0.08, all values pre- vs. post-supplementation). VD supplementation did not result in a significant change in baseline CAT (LF nu, 68±7 vs. 70±8, p=0.4; HF nu, 19±6 vs. 27±9, p=0.1; LF:HF, 1.7±0.3 vs. 1.9±0.4, p=0.4), though the increase in 25OH VD with supplementation was positively correlated with baseline vagal tone (r=0.78, p=0.02) while the increase in 1,25OH VD with supplementation was positively correlated

with the change in baseline sympathovagal CAT (r=0.84, p=0.04). Overall sympathovagal CAT response to AngII challenge was improved post-supplementation (ΔLF:HF time 60, -0.02±0.3 vs. -0.43±0.3, p=0.04), which shifted more dramatically post-supplementation due to increased cardioprotective vagal contribution (ΔHF nu, 6±3 vs. 12±6, p=0.07) and an unchanged sympathetic response (ΔLF nu, p=0.5).

Conclusions: VD supplementation in VD-insufficient individuals with IgAN and normal kidney function appears to improve CAT, mainly through enhancing cardioprotective vagal resistance, both at rest and in response to acute RAS upregulation through AngII challenge.

Funding: Government Support - Non-U.S.

PUB488

Effect of Vitamin D Supplementation on the Arterial Response to Angiotensin II Challenge in Individuals with IgA Nephropathy

Ahmed Abdi Ali, Michelle C. Mann, Brenda Hemmelgarn, Jennifer M. MacRae, Tanvir Chowdhury Turin, Darlene Y. Sola, Sofia B. Ahmed. *Department of Medicine, University of Calgary, Calgary, AB, Canada.*

Background: IgA nephropathy (IgAN) is associated with increased cardiovascular (CV) risk. Arterial response to angiotensin II (AngII), a measure of endothelial health and intrinsic RAS tone, is an intermediate measure of CV risk. Low vitamin D (VD), a negative endocrine regulator of the RAS, status is common in kidney disease patients and is associated with increased CV risk. We sought to clarify the influence of vitamin D (VD) supplementation in modulating arterial response to angiotensin (Ang) II challenge in individuals with IgAN.

Methods: Ten normotensive, non-diabetic, non-obese subjects with IgAN (age 43±5, 90% men, eGFR 77.4±9.7 ml/min, 25OH VD 62±8 nmol/l), were studied before and after ingestion of 10000U of cholecalciferol daily x 28 days. All subjects were studied in high salt balance and women were studied in the same phase of their menstrual cycle. Blood pressure and arterial stiffness (aortic augmentation index (AIx)) were measured manually and by tonometry respectively, at baseline and in response to AngII infusion (3ng/kg/min x 30 min then 6ng/kg/min x 30 min). The primary outcome was the effect of VD supplementation on the BP and arterial response to AngII challenge.

Results: Baseline serum 25(OH)-VD levels increased from 628 to 14521 nmol/l after VD supplementation (p=0.04). VD supplementation had no effect on baseline BP (MAP:94±3 vs. 96±6 mmHg, p=0.3) or arterial stiffness (AIx:12±2.7 vs. 13±4 %, p=0.7) (all values pre- vs. post- VD supplementation). However, post-VD supplementation, a decreased in BP sensitivity to the vasoconstrictor effects of AngII challenge was observed (pre- vs. post- supplementation ΔMAP:21±2 vs. 17±3 mmHg, p=0.005). Post-VD supplementation, there was a trend towards decreased arterial sensitivity to AngII challenge (pre- vs. post-supplementation ΔAIx:12±2 vs. 9±5 %, p=0.2).

Conclusions: VD supplementation alters both the hemodynamic and arterial sensitivity to AngII in humans with IgAN. Further studies are needed to determine if VD supplementation ultimately decreases CV disease in individuals with IgAN.

PUB489

A Rare Case of Renal Infarction in a 35 Year Old Female: A Puzzle Unsolved

Dhavalkumar Sureja, Haider Shamsulddin, Arash Pasha, Robert N. Pursell. *Medicine, Easton Hospital, Easton, PA.*

Background: Renal infarction is rare and easily missed diagnosis due to its non-specific symptoms. The exact incidence is not known. Hematuria, leukocytosis, and an elevated serum lactate dehydrogenase (LDH) are associated with renal infarction. Delay in the diagnosis is associated with higher morbidity and mortality. A computed tomography (CT) scan is the initial test of choice but angiography is still the gold standard. Some of the common etiologies are hypercoagulable state, and thromboembolic diseases, while fibromuscular dysplasia (FMD), vasculitis, spontaneous artery dissection, and segmental arterial mediolysis (SAM) are less common.

Methods: A 35 year old non-pregnant female without significant history presented with left flank pain for 3 days. On examination, she was afebrile, normotensive, in normal sinus rhythm, and had left flank tenderness. Her serum creatinine, amylase, lipase and electrolytes were normal. LDH and WBC were mildly elevated. The urinalysis was negative for any hematuria, pyuria or proteinuria. The CT scan of abdomen showed a left renal segmental infarct.

Her autoimmune, vasculitis, and hypercoagulable work-up were negative. The renal angiogram showed mild irregularity and short segment narrowing of the second and third order branches of the left renal artery, respectively, suggestive of questionable FMD versus SAM. These diagnoses are frequently associated with aneurysm, dissection, occlusion or stenosis, which were absent in our case. The normal transesophageal echocardiogram made thromboembolic cause unlikely. In view of inconclusive workup, idiopathic etiology remains a possibility.

Conclusions: This case provided a diagnostic and therapeutic challenge. The renal infarction should be suspected in all patients with flank pain even in the absence of risk factors. Once the diagnosis is made, FMD or SAM should also be considered as etiology.

PUB490

The Administration of Pitavastatin Augments Creatinine Clearance Associated with the Reduction in Oxidative Stress Parameters: Acute and Early Effects

Keizo Kanasaki,[1] Daisuke Koya,[1] Hirokazu Kakuda.[2] *[1]Diabetology and Endocrinology, Kanazawa Medical University, Kahoku, Ishikawa, Japan; [2]Medicine, Kakuda Clinic, Kahoku, Ishikawa, Japan.*

Background: Chronic kidney disease (CKD) is a serious health problem worldwide. Therapies that can halt the progression of CKD are limited, and the identification of new strategies for CKD treatment is therefore important. Pitavastatin, one of the newest statins introduced to the market, has been shown to exhibit some beneficial effects on renal and endothelial function.

Methods: We enrolled 12 health volunteers for our study. With or without pitavastatin administration, creatinine clearance (Ccr), urine albumin excretion, lipid status and oxidative stress markers are evaluated in acute and early phase after the administration of drug.

Results: A single pitavastatin administration increased Ccr and reduced oxidative stress parameters, such as 8-OHdG levels and isoprostane production, within 6 hours, without altering lipid status in healthy participants. A two-week treatment with pitavastatin lowered total- and LDL-cholesterol and triglycerides but not HDL-cholesterol at 7 and 14 days. This change in lipid profile is associated with enhanced Ccr and the suppression of oxidative stress parameters. Urine albumin excretion was reduced after either acute or chronic administration of pitavastatin, although this effect was not significant yet.

Conclusions: Here, we found that pitavastatin augmented Ccr and reduced oxidative stress parameters in healthy subjects. These data suggest that pitavastatin affects renal outcomes in both lipid status-dependent and -independent manners. Pitavastatin could be potential therapeutic options for CKD patients regardless of lipid status.

Uremia-Induced Inflammation Preceeds Myocardiac Fibrosis in an Animal Model of Uremia

Aline Borsato Hauser,[1] Viviane Carvalho,[2] Caroline Gribner,[1] Mateus Justi Luvizotto,[2] Danielle De Paula e Silva Carneiro,[2] Melani Custodio,[3] Lúcia Noronha,[2] Roberto Pecoits-Filho.[2] *[1]Department of Medical Pathology, Universidade Federal do Paraná, Curitiba, Parana, Brazil; [2]School of Medicine, Pontificia Universidade Catolica, Curitiba, Parana, Brazil; [3]School of Medicine, Universidade de Sao Paulo, Sao Paulo, Brazil.*

Background: Chronic kidney disease is a multiplier of cardiovascular disease, through the induction of accelerated vascular disease and myocardiopathy. Uremia-induced inflammation leading to fibrosis may play an important role. It was analyzed the myocardial inflammation and fibrosis in an animal model ofuremia.

Methods: The uremicgroup underwent subtotalnephrectomy and the Control manipulation ofrenal pedicles. Euthanasiawas performed 4 and 8 weeksafter surgery. Histological sections were prepared from the myocardium to detect fibrosis and Tissue Micro Array was performed to detect expression of αTNF.

Results: In Uremic group, the weight of thecardiac masswas higher (p=0.043) andmyocardiac fibrosis increased over time (Fig1). In the 4 week the differences between uremic and control were not that pronounced (p=0.15); however fibrosis was significantly more intense in the Uremic group compared to controls at the 8 week (p=0.042). Regarding the αTNF expression, the highest levels occurred at 4 weeks, declining in the 8 week evaluation (Fig2). The increase in αTNF expression in uremic animals compared to controls was statistically significant at 4 weeks (p=0.001).

Conclusions: The αTNF expression suggesting that the uremia-induced inflammation of the heart decreases over time, unlike the fibrosis that seems to increase linearly until 8 weeks. Our study provides indirect evidence that uremia-induced inflammation preceeds myocardiac fibrosis in animal model.

PUB492

Are Kidney Volume and Renal Vascular Resistance Associated with Augmentation Index in Early ADPKD? Ankit Chothani,[1] Nitender Goyal,[2] Kevin Heffernan,[3] Mark J. Sarnak,[1] Vandana Menon,[1] D. Miskulin.[1] *[1]Tufts Medical Center; [2]Steward Carney Hospital; [3]Syracuse University.*

Background: Augmentation Index (AIx) is elevated in Autosomal Dominant Polycystic Kidney Disease (ADPKD) before the onset of hypertension or reduced kidney function. Cysts impinging on arteries and arterioles create reflection points that may increase the amplitude of the reflected wave that is produced at bifurcation of resistance vessels. We sought to explore the association of AIx with Total Kidney Volume and Total Liver Volume (TKV+TLV), and Renal Vascular Resistance (RVR), in a subset of HALT PKD Study A Subjects (GFR>60 mls/min/1.73m^{2}).

Methods: Peripheral AIx was measured by pulse wave analysis from finger plethysmography in 44 subjects. TKV, TLV and renal blood flow (RBF) were measured via MRI. RVR was calculated as (MAP/RBF)*80000. Relationships of TKV+TLV and RVR with height adjusted AIx were determined through linear regression.

Results: The mean ±SD age was 43±7 years and the mean eGFR 71±27 mls/min/173 m^2. Factors significantly associated with AIX in unadjusted and multivariable models without RVR (Model 1) and with RVR (Model 2) are shown in the table.

Factors Associated with Augmentation Index

	UNIVARIATE	MULTIVARIATE without RVR	MULTIVARIATE with RVR
	B[95% CI]	B[95% CI]	B[95% CI]
AGE year	0.74[0.38 -1.11]	1.22[0.35 - 2.08]	2.66[1.10 - 4.23]
GLOMERULAR FILTRATION RATE ml/min/1.73m2	-0.21[-0.36 - -0.06]	ns	ns
MEAN ARTERIAL PRESSURE (MAP) mmHg	0.38[0.01 - 0.75]	ns	ns
URINARY ALBUMIN CREATININE RATIO mg/g	0.02[-0.05 - 0.09]	0.13[-0.02 - 0.27]	0.55[0.17 - 0.93]
TKV+TLV ml (per 50% increase in TKV+TLV)	5.9[-4.79 - 16.59]	11.85[2.01 - 21.7]	ns
RVR 1000 dynes second/cm-5	0.50[-0.17- 1.17]	-	-2.24[-4.85 - 0.36]

ns=non significant

Conclusions: AIx is significantly associated with TKV+ TLV after age, height and UACR are accounted for. When RVR is added to the model, TKV +TLV is no longer significant. Contrary to our hypothesis, RVR and AIx are inversely related. RVR measured in the main renal arteries may not capture vascular resistance at smaller arterial beds. An alternate explanation is that the relationship of TKV+TLV with AIx is not mediated through effects of cyst growth on vascular resistance.

PUB493

Efficacy of Cinacalcet for the Treatment of Secondary Hyperparathyroidism in CKD Patients on Peritoneal or Hemo Dialysis: The Middle-East Experience Krishan L. Gupta, Abdullah Al Hwiesh, Ibrahim Saeed, Fahd Muhanna. *Department of Internal Medicine, Nephrology Division, University of Dammam, KFHU, Al-Kobar, Eastern Province, Saudi Arabia.*

Background: Management of secondary hyperparathyroidism (SHPT) is challenging with traditional therapy. Calcimimetics lower parathyroid hormone levels without increasing calcium and phosphorus levels. Our study was aimed at evaluatating effectiveness of calcimimetic, cinacalcet hydrochloride in reducing serum intact PTH (iPTH) levels in patients with end stage renal diseases and SHPT.

Methods: The study included patients who were receiving regular dialysis and had inadequately controlled SHPT despite standard treatment (calcium based phosphorus binders and/or sevlamer carbonate at ceiling doses with or without vitamin D sterols - 1,25(OH)2-vitamin D). They were assigned to receive cinacalcet (Group I, n= 69; 45 on hemodialysis and 24 on automated peritoneal dialysis) or their usual drugs without cinacalcet (Group II, n= 40; 20 each on hemodialysis and peritoneal dialysis) for 12 months. Once-daily doses of cinacalcet hydrochloride was increased from 30 mg to 180 mg to achieve iPTH levels of < 300 pg/ml. Serum calcium, phosphorous and iPTH were monitored before starting cinacalcet, at 3 months, 6 months and 12 months.

Results: Overall the mean iPTH before start of therapy was 1086 ± 84.52 pg/ml in cinacalcet-group I and 644.9 ± 86.58 pg/ml in no-cinacalcet group II [p= 0.60]. At the end of the study these levels changed to 465.1± 46.51 pg/ml and 914± 173.6 pg/ ml respectively [p=0.01]. Serum calcium at 12 months was higher in the cinacalcet group compared to controls. Serum phosphorus was higher in the cinacalcet group at the start of therapy and persisted to remain so till end of study at 12 months.

Conclusions: Cinacalcet effectively lowers parathyroid hormone levels in patients receiving dialysis and having uncontrolled secondary hyperparathyroidism. Frequent monitoring and adequate replacement with calcium and vitamin D sterols prevent hypocalcemia with cinacalcet therapy. Thus, cinacalcet is a goad therapeutic option for controlling SHPT in end-stage renal disease patients on both hemo and peritoneal dialysis.

PUB494

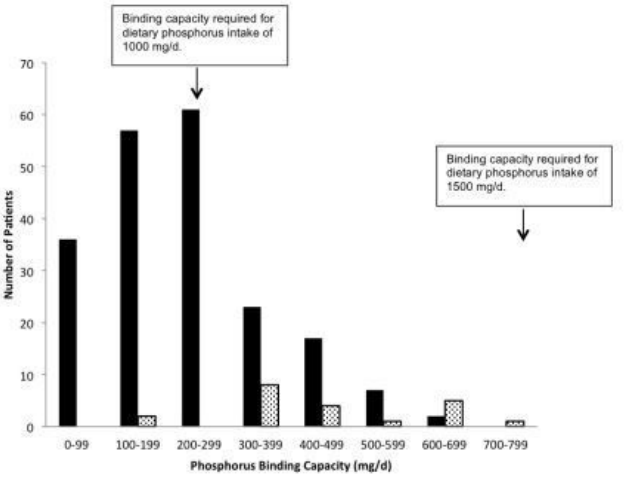
The Adequacy of Phosphorus Binder Prescriptions among Hemodialysis Patients Anne M. Huml, Catherine M. Sullivan, Janeen B. Leon, Ashwini R. Sehgal. *Department of Medicine, Division of Nephrology, MetroHealth Medical Center, Cleveland, OH.*

Background: Because hemodialysis treatment has a limited ability to remove phosphorus, dialysis patients must both restrict dietary phosphorus intake and use phosphorus binding medication. Among patients with restricted dietary phosphorus intake, binders must bind about 250 mg/d of phosphorus to maintain balance. Among patients with more typical phosphorus intake, binders must bind about 750 mg/d. We sought to determine the phosphorus binding capacity of binder prescriptions among hemodialysis patients.

Methods: We randomly selected 300 chronic hemodialysis facilities from *Dialysis Facility Compare.* Study personnel called each facility's dietitian and obtained the following data for one randomly selected patient: phosphorus binder prescription, most recent serum phosphorus level, post-dialysis weight, height, age, gender, race/ethnicity, and years on dialysis. We calculated the phosphorus binding capacity for each binder prescription. To determine the adequacy of binder prescriptions, we used standard estimates of phosphorus intake, gut absorption, and dialytic removal.

Results: Among the 224 patients prescribed binders, the mean phosphorus binding capacity was 256 mg/d (SD 143). 59% of prescriptions had insufficient binding capacity for restricted dietary phosphorus intake, and 100% had insufficient binding capacity for typical dietary phosphorus intake. Patients using two binders had a higher binding capacity than patients using one binder (451 vs. 236 mg/d, p <0.001).

Figure 1: Distribution of PBC. Dark bars represent 203 patients on single binder. Light bars represent 21 patients on two binders.



Conclusions: A majority of binder prescriptions have insufficient binding capacity to maintain phosphorus balance. Use of two binders results in higher binder capacity. Further work is needed to understand the impact of binder prescriptions on mineral balance and metabolism and to determine the value of substantially increasing binder prescriptions.

PUB495

Efficacy of PA21, a New Iron-Based Phosphate Binder, as Compared to Lanthanum Carbonate and Sevelamer Carbonate on Mineral Metabolism Disorders and Vascular Calcifications in Uremic Rats Olivier Phan,[1] Marc P. Maillard,[1] Felix W. Funk,[2] Bruno Vogt,[1] Michel Burnier.[1] *[1]University of Lausanne CHUV; [2]Vifor (International) Inc.*

Background: The present study compared the efficacy of PA21 with lanthanum carbonate (La) and sevelamer carbonate (Se) on hyperphosphatemia, secondary hyperparathyroidism and vascular calcification in rats with chronic renal failure (CRF).

Methods: CRF was induced by feeding a 0.75% adenine-enriched high phosphorus (P 1.3 %) diet for 4 weeks. Rats were randomized to one of 3 binder treatment groups (PA21, La and Se) or to CRF and non-CRF controls for another 4 week period. The concentration of each binder (% of binder added to the diet) was chosen to deliver approximately the same amount of active pharmaceutical ingredient to each rat: PA21 5% (corresponding to 1% iron), La 2% (1% lanthanum), Se 1.5% (1% sevelamer). A computer-assisted automated quantitative measurement was used to assess the degree of calcification from von Kossa stained vessel sections. Data were expressed as the relative proportion (%) of calcified area to total surface area of each vascular ring.

Results:

	N	Creat (micromol/l)	P (mmol/l)	iPTH (pg/ml)	Abdominal aorta (%)	Inferior Thoracic Aorta (%)	Superior Thoracic Aorta (%)
Non-CRF control	4	48±3	2.09±0.05	275±38[b]	0	0	0
CRF control	20	144±11[a]	3.30±0.29	3567±593	1.25±0.66	3.22±1.31	8.05±2.01
CRF PA21	19	141±10	2.06±0.06[b]	1459±242[b]	0.10±0.06[b]	0.34±0.21[b]	0.14±0.13[b,c]
CRF Se	20	147±11	2.51±0.12[b]	1569±238[b]	0.53±0.40	0.55±0.38[b]	1.59±0.91[b]
CRF La	18	140±8	2.24±0.07[b]	1360±170[b]	0.20±0.15	0.39±0.27[b]	3.93±1.13[b]

Values are shown as mean±SD, [a]p<0.05 vs non-CRF control, [b]p<0.05 vs CRF control, [c]p<0.05 vs CRF La

Conclusions: PA21 is as effective as La and Se to control hyperphosphatemia and secondary hyperparathyroidism. The extent of vascular calcifications in all phosphate binder treated animals was significantly lower than in the CRF control animals. In the upper part of the thoracic aorta, PA21 was even more efficient than Lanthanum carbonate to prevent calcifications.

PUB496

Comparison of Efficacy and Equivalent Dose between Osvaren and Fosrenol for the Control of Serum Phosphate in CAPD Patients Jesus Montenegro, José Ignacio Cornago, Maria Isabel Gallardo, Paula García, Ainhoa Hernando, Rosa Ines Munoz. *Nephrology, Hospital de Galdakao, Bilbao, Vizcaya, Spain.*

Background: To find out the capacity and the equivalent dose between two phosphate binders, Mg Carbonate and Ca Acetate (Osvaren®, Fresenius Medical Care) and Lantanum Carbonate (Fosrenol®, Shire) for the control of serum P, a randomized cross over study was done (Fosvaren Study) in CAPD patients.

Methods: After two weeks of wash-out, they were randonmized into 2 groups. Group 1, 23 patients: Osvaren→Fosrenol→Osvaren; in group 2, 22 patients: Fosrenol→Osvaren→Fosrenol. The patients changed the binder every 2 months. By protocol, the equivalent dose was: one pill of Osvaren (435 mg of Ca acetate and 235 mg of Mg carbonate) to 1 pill of Fosrenol 500 mg. It was also established by protocol that for every increase of 1 mg/dL of serum P two pills per day of binder. Every two months before changing the binder the following values were determined in blood: P, total Cal, Ca++, Mg, PTH, alkaline phosphatase and bicarbonate. Daily urinary excretion of P, Ca and Mg were calculated. Daily peritoneal phosphate removal and protein intake were calculated.

Results: The binder dose, vitamin D dose and the protein intake varied very little. The urinary phosphate and the peritoneal phosphate removal were similar in both groups all time. The serum P at the beginning, basal, was similar in both groups, but the serum P decreased significantly with both phosphate binders, as we can observe throughout the study in the table.

Outline of serum phosphate in both groups

Groups and serum P	Basal	2 months	4 months	6 months
G1: P (mg/dL)	6.38 (0.71)	4.85 (0.78)*	4.90 (0.80)	4.76 (0.83)
G2: P (mg/dL)	6.18 (0.64)	4.86 (0.72)*	4.92 (0.81)	4.79 (0.73)

*p<0.05

The serum Ca and Mg increased significantly during the intake periods of Calcium and Magnesium salts and the PTH had a greater descent reaching in some periods a significant decrease.

Conclusions: We can conclude that both phosphate binders, Osvaren and Fosrenol, return to normal the levels of serum phosphate in the majority of PD patients. According to these results, an equivalent dose of 1 tablet of Osvaren/1 tablet of Fosrenol 500 mg has been established for serum phosphate control.

PUB497

Extracorporeal Phosphate Removal with a Packed Bed Adsorber Rebecca J. Desch,[1] Juliann K. Leny,[1] Stephen W. Thiel,[1] Vadim Guliants,[1] Heather Duncan,[2] Kotagal Shashi Kant.[2] *[1]School of Energy, Environmental, Biological and Medical Engineering, University of Cincinnati, Cincinnati, OH; [2]School of Energy, Internal Medicine, University of Cincinnati, Cincinnati, OH.*

Background: Phosphorous (PO4) control continues to be a complex and vexing problem for dialysis patients. PO4 dialysance with conventional dialysis is suboptimal largely because of the multicompartment distribution of phosphate. Effectiveness of oral PO4 binders is limited by issues of cost, efficacy and adherence. We are exploring an alternative approach that incorporates a packed bed for PO4 adsorption into the dialysis circuit to remove excess PO4 during regular dialysis treatments. This will address the multicompartment nature of PO4 distribution and increase total PO4 removal.

Methods: The efficacy of adsorbents incorporating aluminum, lanthanum, and zirconium were evaluated with batch equilibrium (0-25 mg/dL PO4) and kinetic studies (10 mg/dL PO4) in water at pH 8.2 at 37°C.

Results: PO4 adsorption to resin-based adsorbants was slow. Lanthanum activated carbon and aluminum oxide combined relatively fast adsorption with PO4 capacity of 30mg/g adsorbent, at a PO4 concentration of 5mg/dL. The interference of blood components, including salts and proteins, was tested on the adsorption of 20mg/dL PO4. Most of the tested salts and biomolecules enhanced or minimally impacted PO4 loadings, but bovine serum albumin (BSA) reduced the PO4 loading significantly.

Interference effects on PO_4 adsorption onto lanthanum activated carbon

Blood Component	Concentration (mg/dL)	%Phosphate Loading
Water	-	100
NaCl	900	95
$NaHCO_3$	233	88
Urea	50	96
BSA	4300	71
γ-Globulin	2400	92

Finally, the PO4 desorption in the presence of potential regeneration solutions was measured. PO4 was effectively desorbed using concentrated acid or base; however these strong regeneration solutions damaged the adsorbents.

Conclusions: Lanthanum activated carbon and aluminum oxide show promise as selective, high capacity, and cost effective materials for phosphate adsorption. The insights from this research will guide the design of packed bed adsorption units to safely and effectively control PO4 concentrations in dialysis patients.

Magnesium Retards the Progress of the Artery Calcifications in Hemodialysis Patients: A Controlled Prospective Study Ioannis P. Tzanakis, Elisavet E. Stamataki, Antonia N. Papadaki, Vlasios V. Spantidakis, Stella N. Kagia, Styliani-rafaella Poulidaki. *Nephrological, General Hospital of Chania, Chania, Krete, Greece.*

Background: Results from observational studies provide enough evidence that high serum magnesium is related with less calcifications in hemodialysis patients. The aim of the study was to evaluate the impact of magnesium (Mg), dosing as a phosphate binder, on the evolution of artery calcifications in hemodialysis patients.

Methods: Seventy-two stable hemodialysis patients were randomly allocated to two groups: 36 administered the regimen OSVAREN containing Magnesium carbonate plus Calcium acetate as a phosphate binder (Mg group), while the rest 36 received Calcium acetate alone (Ca group). The presence and the progression of artery calcifications were evaluated in plain X-ray of pelvis, femur, abdomen and hands at the begging and at the end of the study using a simple vascular calcification score (SVCS). The duration of the follow up period was 12 months.

Results: Fifty-nine patients completed the sudy: 32 of Mg group and 27 of Ca group. The mean time average values of Calcium, Phospate, Calcium X Phosphate product and parathyroid hormone did not differ between the two groups, whereas there was a significant difference in serum Mg: 2.83±0.38 in Mg group vs 2.52±0.27 mg/dl in Ca group, p=0,001. In 9/32 (28.12%) patients of the Mg group and in 12/27 (44.44%) patients of the Ca group the artery calcifications were worsened within the 1 year period, p=0.276. Moreover in 4/32 (15.6%) patients of Mg group and in 0/27 (0%) patients of Ca group the artery calcifications were improved, p=0.040 Figures 1-4.The multivariate logistic regression analysis revealed that serum magnesium was the only independed predictor for no progression (improvement and stable) of the artery calcifications, p=0.47.

Conclusions: The hemodialysis patients who received the magnesium containing regimen manifested less progression or regression of artery calcifications. Serum magnesium was found to be an independed factor of no progression of the calcifications. Magnesium probably retards or even improves the evolution of the artery calcifications in hemodialysis patients.

PUB499

Association of Serum Magnesium and Mortality in Incident Dialysis Patients Johanna Van den Broek,[1] Christiane Drechsler,[2] Vincent Brandenburg,[3] Friedo W. Dekker,[4] Marc G. Vervloet.[1] *[1]Nephrology, VU Medical Center, Amsterdam, Netherlands; [2]Internal Medicine 1, Division of Nephrology, University of Würzburg, Würzburg, Germany; [3]Cardiology, University Hospital of the RWTH, Aachen, Germany; [4]Clinical Epidemiology, Leiden University Medical Center, Leiden, Netherlands.*

Background: Although several biomarkers of the chronic kidney disease-mineral and bone disorder (CKD-MBD) syndrome are associated with clinical endpoints, the potential role of magnesium is underexposed. Magnesium appears to have beneficial effects on the process of vascular calcification. We therefore searched for epidemiological evidence to support the assumption of a favorable effect of magnesium on mortality in CKD.

Methods: Magnesium levels were determined in 766 incident hemodialysis and peritoneal dialysis patients from the NECOSAD cohort. Association with all-cause mortality at months 36 from start of dialysis was studied for tertiles of magnesium levels. Multivariate adjustments were made for age, dialysis modality, primary kidney disease and presence of diabetes mellitus.

Results: 766 patients were studied (63 ± 14 years, 59% male, 91% hemodialysis, 93% Caucasian). Diabetes was present in 25%. Magnesium levels were 1.05 ± 0.19 mmol/l. All-cause mortality at month 36 after start of dialysis was 30%. Using univariate analysis mortality was associated with age (B 0.049, p <0.005), dialysis modality (B -1.002, p 0.005), primary kidney disease and diabetes (B 0.673, p <0.005). Using multivariate analysis dialysis modality was no longer significant. The lower magnesium tertile was associated with a non-significant trend with higher mortality in the full-adjusted model (B 0.167, p 0.31 compared with the highest, and B 0.194, p 0.23 compared with intermediate tertile).

Conclusions: Low magnesium levels show a non-significant trend to be associated with higher mortality at month 36 for incident dialysis patients. The inference of a causal relation cannot be made from our data. However, our results do reassure the relative safety of magnesium levels in high-normal range in these subjects.

PUB500

Predicting Serum Phosphate Concentrations in Patients Undergoing Chronic Hemodialysis Using a Dynamic Model Derrick J. Stobaugh, Parakkal Deepak, Eli D. Ehrenpreis, Stuart M. Sprague. *NorthShore University HealthSystem.*

Background: Managing phosphate overload is a significant clinical problem in patients with End Stage Renal Disease (ESRD). A dynamic model to predict serum phosphate concentrations in ESRD subjects was developed by simulating phosphate intake, absorption and elimination and the effects of diet, phosphate binders and dialysis.

Methods: Using published data, a computer model with STELLA software (ISEE, Hanover, NH) and advanced simulations with the Berkeley Madonna program (Berkeley Madonna Inc., Berkeley, CA) was developed. Simulations of a variety of conditions were performed using multiple adjustable parameters. To test model function, serum phosphate concentrations following standardized thrice weekly chronic hemodialysis (CHD), nocturnal hemodialysis (NHD) for 8 hours daily, short daily (SHD; 2 hours/day, 5 days/week) and peritoneal dialysis (PD) were compared. This simulation included NHD (no phosphate binders, average dietary phosphate intake of 1.4g a day), and CHD, SHD, and PD with the highest recommended doses of lanthanum (4.5g) or sevelamer (4.8g), (average phosphate consumption 0.9 g/ day. Lanthanum or sevelamer were ingested with meals, thrice daily. Graphic display of phosphate concentrations over ninety 24 hour cycles (3 months) were produced.

Results: Simulations demonstrated that patients on NHD had the lowest mean phosphate level (3.53 mg/dl), followed by SHD, PD, and then CHD (mean phosphate 5.06 mg/dl, 5.28 mg/dl, and 6.07 mg/dl respectively). PD had the lowest variability of phosphate levels. Table 1 shows phosphate levels simulated in patients receiving either sevelamer or lanthanum.

Serum phosphate levels with binder and/or dialysis

	NHD	SHD		CHD		PD	
		Sev	Lan	Sev	Lan	Sev	Lan
Mean phos	3.53	4.62	3.93	5.62	4.43	4.86	4.44
SD	2.03	1.23	1.12	0.92	0.70	0.41	0.20
Max phos	7.49	7.15	5.91	8.29	5.71	6.10	5.13

Sevelamer Sev; Lanthanum Lan.

Conclusions: A model has been developed to simulate intake and removal of phosphate in ESRD patients. Inputs are adjustable to develop predictive data. Further validation will require real time patient testing. Potential applications of this model include individualization of patient care and new drug development.

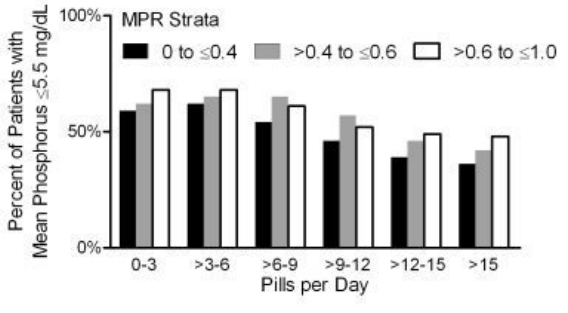
PUB501

Serum Phosphorus Levels Are Inversely Associated with Medication Possession Ratio among Hemodialysis Patients Steven Wang,[1] Thomas Alfieri,[1] Peter G. Braunhofer,[2] Britt B. Newsome.[3] *[1]Davita Inc., Denver, CO; [2]Vifor Pharma, Glattbrugg, Switzerland; [3]Denver Nephrology, Denver, CO.*

Background: Phosphate binders (PB) account for ~1/2 of the high daily pill burden (median=19) for US hemodialysis (HD) patients (pts), which may reduce adherence. Effective adherence is best estimated using the medication possession ratio (MPR) which reflects the proportion of time the pt had sufficient supply to have taken the medication as prescribed. The longer the gaps between fills, the lower the MPR. Using data from a dialysis provider's pharmacy management program, we assessed the effect of PB pill burden and compliance (MPR) on phosphorus goal attainment.

Methods: Monotherapy HD pts were tracked from first PB fill from 1/1/2007–6/30/2011 for 1 year, or until they switched PBs or were censored (at automatic refill program enrollment, 180 day gap between medication fills, 2 consecutive phosphorus levels < 3.0 mg/dL, discontinuation of HD, or death). MPR was calculated as (prescription days filled in period – excess days) / (days in period), where excess days is the days of pills left at the end of the period. Mean MPR scores were weighted by pt-time contributed. Associations were assessed by GLM.

Results: After exclusion of dual therapy pts (28%), 9346 pts were included. Lower mean phosphorus levels and higher % of pts with ≤ 5.5 mg/dL phosphorus were associated with higher MPR; effects were accentuated in higher pill burden strata ($p<0.001$ across strata for both). However, the 6-9 and 9-12 pills/day strata were U-shaped.



Conclusions: MPR was negatively related to phosphorus level and positively related to % of pts in phosphorus range. Within pill burden strata, phosphorus decreased and % of pts in phosphorus range generally increased with increasing MPR suggesting that pts prescribed more PB pills are more likely to have treatment gaps and poorer outcomes.

Improved Patient Survival with Sevelamer Compared to Calcium-Based Phosphate Binders: A Meta-Analysis of Long-Term Randomized Controlled Trials Nashila AbdulRahim,[1] Donald A. Molony,[1] Shradha Kulkarni,[1] Antonio Bellasi.[2] *[1]Renal Dis & Hypertension, Univ Tx Houston Med Sch, Houston, TX; [2]U.O.C. di Nefrologia, Dialisi, Ospedale Sant'Anna, Como, Italy.*

Background: Epidemiologic studies support the hypothesis that excess oral intake of calcium results in increased cardiovascular events in chronic kidney disease (CKD) and ESRD patients. Conversely, by reducing calcium and PO_4 exposures in CKD patient, sevelamer could potentially improve survival. Demonstrating a survival benefit with sevelamer has been difficult, mainly because of the small size, short duration, or incomplete follow-up of the RCTs conducted to date. Meta-analyses have reported mixed results. The purpose of the current study is to perform a standard meta-analysis comparing the survival benefits of sevelamer versus calcium-based phosphate binders in CKD patients, antecedent to a network meta-analysis.

Methods: A systematic review of the literature was performed using PubMed, EmBase, Trip and the Cochrane trials registry through 6/01/2012. We included only those studies with follow-up of 1 year or greater and transformed the number of deaths reported into a rate expressed in terms of subjects years at risk to account for the variation in drop-out rates and duration of follow-up.

Results: Eleven RCTs (9 for ESRD and 2 pre-dialysis CKD cohorts) were included in the final analysis. For the 9 ESRD studies the combined odds ratio (OR) using a random effects model was 0.498 (95% CI 0.274 – 0.889, I^2 79%) favoring a survival benefit with sevelamer. The survival benefit with sevelamer was no-longer observed when RCTs of less than 1 year duration were included or when incident dialysis patient RCTs were excluded (OR 0.753, 95% CI 0.51-1.119) but was observed when only studies of moderate or higher grade were analyzed. A survival benefit with sevelamer was observed when the incident patients were analyzed separately (OR 0.296 95%CI 0.154 – 0.57, I^2 26%). The pre-dialysis studies demonstrated a relative risk similar to that in incident ESRD patients.

Conclusions: The current meta-analysis demonstrates a survival advantage with sevelamer which can be attributed, in part, to inclusion of higher quality or incident dialysis studies.

Regulation of Type II Sodium Phosphate Cotransporter Trafficking Eleanor D. Lederer,[1,2,3] Rachel Grisham,[2] Syed J. Khundmiri,[2,3] Edward J. Weinman.[4,5] *[1]Medicine, Robley Rex VA Medical Center, Louisville, KY; [2]Medicine, University of Louisville School of Medicine, Louisville, KY; [3]Physiology and Biophysics, University of Louisville School of Medicine, Louisville, KY; [4]Medicine, Baltimore VA Medical Center, Baltimore, MD; [5]Medicine, University of Maryland School of Medicine, Baltimore, MD.*

Background: We have previously shown that the type II sodium phosphate cotransporter Npt2a exists in a multi-protein complex in the brush border membrane (BBM) of proximal tubule cells. The molecular mechanisms responsible for the assembly and trafficking of the complex are unknown. We hypothesized that the complex assembles in intracellular compartments and traffics to the apical membrane by vesicular transport.

Methods: We compared compartment protein expression at 37C and 16°C, to arrest protein trafficking, in opossum kidney (OK) cells in the presence of low phosphate, a stimulus for Npt2a exocytosis. Cell lysates were separated by sucrose gradient centrifugation and analyzed by western blot. To determine if Npt2a trafficked through vesicular transport, we compared low phosphate stimulated Npt2a plasma membrane expression in OK cells where the SNARE protein SNAP 23 was knocked down and in cells transduced with a competitive SNAP23 inhibitory peptide.

Results: Incubation at 16°C resulted in a parallel increase in expression of Npt2a and NHERF1 in Golgi fractions (GM58+) and a comparable decrease in plasma membrane fractions. Western blot of Npt2a in BBM derived from OK cells, vector-transfected (VF), and knockdown (E9) cells showed a 25 kD decrease in the molecular size of Npt2a in E9 cells. F-glycosidase digestion of BBM resulted in the appearance of a band at 75 kDa for all three cell types. PTH decreased Npt2a expression by 50% in VF and 75% in E9. Low phosphate stimulated 25% increase in Npt2a expression in VF and a 75% increase in E9.

Conclusions: We conclude that NHERF and Npt2a traffic in the same temporal pattern, suggesting association prior to apical membrane insertion and that SNAP 23 does not play a role in Npt2a apical membrane trafficking, but may play a role in post-translational modification.

Comparison of Dose Holds for Paricalcitol and Cinacalcet during Treatment of Secondary Hyperparathyroidism (SHPT): Secondary Analysis of the IMPACT Study Markus Ketteler,[1] Kevin J. Martin,[2] Michael Amdahl,[3] Mario Cozzolino,[4] David Goldsmith,[5] Amit Sharma,[6] Samina Khan.[3] *[1]Klinikum Coburg, Coburg, Germany; [2]St. Louis University, St. Louis, MO; [3]Abbott, Abbott Park, IL; [4]University of Milan, Milan, Italy; [5]Guy's Hospital, London, United Kingdom; [6]Pacific Renal Research Institute, Meridian, ID.*

Background: Secondary hyperparathyroidism (SHPT) is a complication of chronic kidney disease (CKD), typified by elevated intact parathyroid hormone (iPTH) and altered mineral metabolism. Most guidelines require dose holds when SHPT medications disrupt calcium (Ca) or phosphorus (P) metabolism beyond specified levels. Such recurrent interruption may jeopardize treatment optimization and possibly lead to non-compliance. Here we report a secondary endpoint examining dose holds during the IMPACT-SHPT study.

Methods: IMPACT-SHPT was a study of hemodialysis subjects receiving IV (IV Stratum) or oral paricalcitol (Oral Stratum) compared with subjects receiving cinacalcet with low-dose vitamin D. Doses of study drugs were adjusted or held based on pre-defined iPTH, Ca and Ca x P product thresholds. A negative binomial regression analysis was used to compare the number of doses held between paricalcitol and cinacalcet groups in each stratum.

Results: There were a total of 126 subjects in the IV Stratum and 142 in the Oral Stratum. There were 268.4% (P=0.003) and 171.6% (P<0.001) more doses held for cinacalcet than paricalcitol in the IV Stratum and Oral Stratum, respectively. Lab results (Table) showed that dose holds in paricalcitol subjects mostly followed high Ca, CaxP and/or low iPTH and dose holds for cinacalcet subjects mostly followed low Ca, CaxP and iPTH.

	IV Stratum		Oral Stratum	
	Paricalcitol	**Cinacalcet**	**Paricalcitol**	**Cinacalcet**
Subject lab results prior to dose hold, n (%)	**(16 total dose holds)**	**(43 total dose holds)**	**(39 total dose holds)**	**(86 total dose holds)**
Ca>11mg/dL, CaxP>75mg²/dL², iPTH<150pg/mL	2 (13)	0	4 (10)	0
Ca>11mg/dL, CaxP>75mg²/dL²	0	0	1 (3)	0
Ca>11mg/dL, iPTH<150pg/mL	5 (31)	0	10 (26)	0
Ca>11mg/dL	1 (6)	0	3 (8)	0
CaxP>75mg²/dL², iPTH<150pg/mL	0	0	2 (5)	0
CaxP>75mg²/dL²	0	0	1 (3)	0
Ca<7.5mg/dL, iPTH<150pg/mL	0	7 (16)	0	0
Ca<7.5mg/dL	0	13 (30)	0	30 (35)
iPTH<150pg/mL	4 (25)	15 (35)	11 (28)	27 (31)
Other	4 (25)	8 (19)	7 (18)	6 (7)

Conclusions: In the IMPACT study, subjects given paricalcitol required fewer dose holds than those given cinacalcet.

PUB505

Acetazolamide-Induced Remission in Severe Tumoral Calcinosis Despite Persistent Hyperphosphatemia Gal Finer,[1] Heather E. Price,[1] Richard M. Shore,[1] Kenneth E. White,[2] Craig B. Langman.[1] *[1]Kidney Diseases, Northwestern University, Chicago, IL; [2]IUPUI, Indianapolis, IN.*

Background: Idiopathic tumoral calcinosis (TC) is an AR disorder characterized by ↑ tubular phosphate (P) resorption, hyperphosphatemia (hiP) and tumor-like extraosseous periarticular calcifications. Despite the hiP, patients have ↑ serum 1,25-dihydroxyvitamin D. TC results from an inactivating mutation in *FGF23*, *GALNT3* or *KLOTHO*. In addition to tumor removal by surgery, medical Rx of low P diet and P-binders aims to prevent new ones but is not effective uniformly. Sporadic reports of alternative medical Rx include acetazolamide (ACTZ).

Results: We describe a 7yo AA boy with severe and protracted TC (multiloculated calcified masses of buttock & elbow), who responded to ACTZ-induced metabolic acidosis despite ↑ serum P (Table). Histopathology of the masses confirmed TC. FGF23 assays revealed ↑c-terminal but ↓intact FGF23 levels for the degree of hiP (Table). DNA sequencing showed compound heterozygosity in *GALNT3*. Rx with sevelamer was initiated, but the patient had recurrence of para-articular mineral deposits in the hip & elbow and progression of bone disease involving tibia, ulna, mandible & maxilla that required surgeries. At 9.5y, ACTZ(40 mg/kg/day) was begun, & resulted in complete cessation of new tumor eruption for 2 years. ACTZ induced mild acidosis but no change in hiP or TRP (Table). Patient had no side effects related to Rx, had normal eGFR and improved linear growth to the 40th%ile for age.

	At presentation	On P Binder Mean (range)	On ACTZ Mean (range)
P (mg/dL)	6.8	6.7 (5.3-7.9)	6.9 (4.9-8.8)
CO2 (mEq/L)	24	25.6 (25.2-27.4)	21.2 (19-25.3)
serum pH	7.42	7.38 ((7.32-7.42)	7.31 (7.29-7.4)
TRP (%)	96.6	97.4 (96.9-97.9)	95.6 (91.7-98.2)
25(OH)D (ng/mL)	22	20.7	20
1,25-D3 (pg/mL)	52	42.4	48
iCa (mM)	1.27	1.30 (1.25-1.4)	1.32 (1.21-1.43)
Total Ca (mg/dL)	9.7	9.8	10.2
PTH (pg/mL)	15	10	9
FGF23 C-terminus RU/mL	759		1584
FGF23 intact pg/mL	26		7

Conclusions: In TC, ACTZ halted disease progression despite no changes in serum P and TRP. This suggests that ACTZ increased the calcium-phosphate complex solubility, likely through pH modifications, and not by promoting phosphaturia as previously thought.

PUB506

25OHVitD Levels and His Association with Demographic, Biochemical and Cardiovascular Factors and Survival in Hemodialysis Patients Yanet Parodis López,[1] Beatriz Quintana Viñau,[1] Francisco Alonso Alman,[1] Juan Francisco Betancor Jiménez,[1] Miguel Angel García Bello,[2] Jose C. Rodriguez-Perez.[1] *[1]Nephrology, Baxter; [2]Investigation Unit Department, Dr Negrín Hospital, Las Palmas, Spain.*

Background: Low vitamin D levels are common in hemodialysis patients and its deficit has been associated with cardiovascular complications and mortality. We conduct this study to know the 25OHVitD levels and correlate these levels with the biochemical, demographic and cardiovascular state as well as assess its impact on survival.

Methods: This is a cross sectional study in the first half of 2011 in 232 hemodialysis patients. Demographic and clinical data including echocardiographic, ankle/brachial index (ABI) and Charlson index were recorded. We correlate these variables with each other as with 25OHVitD levels. Survival (Kaplan-Meier) is assessed by levels of vitamin D at one year of follow up.

Results: The 88.79% of patients had some degree of hypovitaminosis D. Diabetes Mellitus (p=0.003) and older age (p=0.017) were associated with more 25OHVitD deficiency. Female sex (OR:4.78: 95% CI 2.53 to 9.03) and Charlson Index ≥5 (OR 3.84: 95% CI 1.68 to 8.76) were considered independent risk factors for 25OHVitD deficiency. No relationship was found between 25OHVitD and echocardiographic parameters. Those with ABI ≤0.9 (26/73), only 1 patient had normal 25OHVitD levels, the remaining 25 (96.1%) had 25OHVitD hypovitaminosis (p=0,02). Significant differences were seen between the ABI mean levels comparing 25OHVitD deficient patients vs others (p=0.036). There was significant association between Diabetes Mellitus and Charlson ≥5 with ABI ≤0.9 (p=0.01 and p=0.003 respectively). We found worse survival in 25OHVitD deficient patients when compared with others (p=0,03).

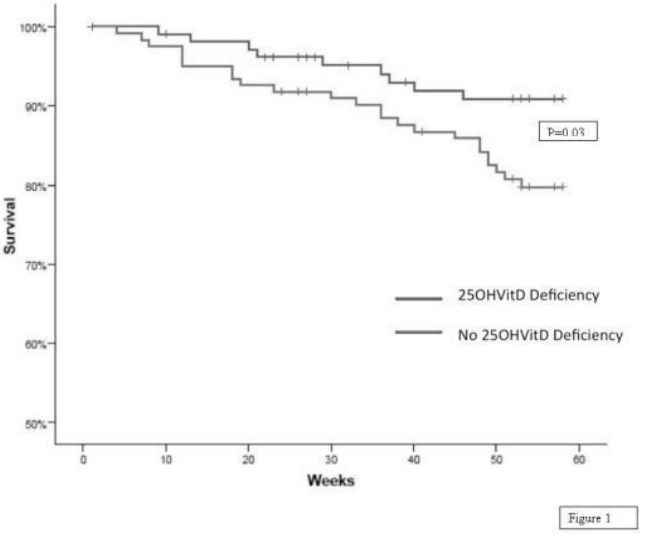

Figure 1

Conclusions: Vitamin D deficiency is common in hemodialysis patients. The higher vitamin D deficiency increased mortality.

PUB507

25 OH Vitamin D Therapeutic Response in the Two Fist Weeks after Calcidiol Administration Emilio E. Gonzalez-parra, Maria Vanessa Perez Gomez, Laura Rodríguez-osorio, Valeria Sainz, Alberto Ortiz, Jesus Egido. *Nephrology, Fundación Jiménez Díaz, Madrid, Spain.*

Background: Recommendations of guidelines, CKD patients must maintain values of 25OHD> 30 ng / ml. In Spain, the most used is Calcidiol supplementation, although other groups advocate the use of Cholecalciferol to avoid adverse effects such as hypercalcemia.

However, there is a lot of factors that can alter the effectiveness or toxicity of treatment. Objectives: 1) Observe 25OHD levels after administration of 16000 u. Calcidiol in patients on hemodialysis (HD) 2) determine whether treatment with Calcidiol affects to calcium (Ca), phosphorus (P) and PTH 3) Detect whether FGF23 affect baseline calcidiol response.

Methods: In 27 HD patients (10 m and 17 w, mean age 72.3 ± 13.58 years) was administered 16000 units Calcidiol in the first HD session of the week (HDb) messurements of 25OHD, Ca, P and PTH before administration and before the following sessions a week (HD1, HD2, HD3). There was also a baseline measurement of FGF23.

Results: 25OHD of 16.49 ± HDb 7.29 ng / dl, HD1 and HD3 18.68± 7.5 vs 16.07 ± 6.71 (ns). 10%, 59% increased levels of 250HD> 10%, 41% had no increased or decreased. The Cab 9.15 ± 0.69, Ca1 = 8.8 ± 0.56 and Ca3 = 8.6 ± 0.63, down 4% from baseline (p = 0.0001). Percentage of patients with Ca> 9.5, HDb = 22.2% = 12% HD1, HD3 = 14.8%. Pb = 3.66 ± 1.55, P1 = 4.36 ± 1.73 and P3 = 4.34 ± 1.92. 4.5, HDb=22,2%, HD1=44%, HD3=40,7. The P increased by 36% (p = 0.0047). Patients with P> 4.5, HDb = 22.2% = 44% HD1, HD3 = 40.7%. The PTHb = 417.19 ± 572.95, PTH1 = 448.41 ± 497.23, PTH3 = 449.05 ± 474.64 (ns). The FGF23b= 3292.59 ± 5101.32. Patients with increased 250HD1> 10% FGF23b = 2375 ± 3550, in which 250HD1 <10%, FGF23b= 5127 ± 6619.77 (ns).

Conclusions: 1) There is a high heterogeneity in the values of 25OHD Calcidiol after supplementation. 2) We found no differences between baseline and 48 hours after treatment 3) Appreciate the decrease in Ca and P increased 4) One week no change in PTH levels 5) FGF23 values have not been shown to significantly influence the response to Calcidiol, although a trend towards better response to supplementation with lower levels of FGF23.

PUB508

Differentiation of 1-84 Parathyroid Hormone (PTH) and 1-84 Fragments in CKD-BMD Emilio E. Gonzalez-parra, Laura Rodríguez-osorio, Valeria Sainz, Maria Vanessa Perez Gomez, Alberto Ortiz, Jesus Egido. *Nephrology, Fundación Jiménez Díaz, Madrid, Spain.*

Background: PTH is one of the molecules used in the management of CKD-BMD. The methods currently used determine both, whole molecule 1-84, and their degradation fragments not 1-84 (PTH). Both molecules have different and sometimes opposite effects. This ratio is used to determine if the patient has or not low bone remodeling. Will be marketed automated methods 3rd generation, that these measured PTH 1-84 (PTHbio). This change will rethink many of the current approaches. OBJECTIVES: 1. - To determine the values of 1-84, 7-84 and PTH1-84/7-84PTH ratio in HD patients. 2. - To determine the correlations between the ratio 1-84/PTH 7-84 with other clinical and biochemical parameters.

Methods: In 147 hemodialysis patients has made the determination of iPTH, PTHbio, PTH ratio (PTHbio / PTH-PTHbio), Ca, P, FGF23, 25 OH vitamin D, before hemodialysis. IPTH, and PTHbio ratio was determined by the method of Roche Elecsys, the FGF23 (Inmunotopics).

Results: The average age was 66.1 ± 14.59 years, 76 men and 71 women, with a stay at 5.2 ± 4.79 HD years. 13 in online HDF, 134 conventional. Mean values were studied: Ca 9.21 ± 0.74 mg / dl, P 5.34 ± 2.3 mg / dl, PTH 298.04 ± 306.53 pg/ ml, PTH bio 174.94 ± 172.18 pg / ml, PTH1-84/PTH7-84 ratio: 1,723 ± 3285, FGF23: 2855.0 ± 4246.8 RU / ml, 25 OH VitD 35.55 ng / ml. Correlation between FGF23 and PTH i, PTHbio and PTH1-84/ PTH7-84 ratio, but not with the 25-OH-VitD. In the univariate model PTH1-84/PTH7-84 ratio positively correlated with FGF23 (p 0.04) so that a 1% increase in the ratio of an increase of 1.6% of FGF23. PTHbio and iPTH also correlated with FGF23. The ratio does not correlate with either the Ca or P, or years in HD or age.

Conclusions: 1. - We must know the values of 1-84, and 1-84 fragments not of our patients. 2. - 1-84 PTH values are significantly lower than those used now. 3. - All forms of measuring PTH correlate well between them even indicate different aspects. 4. - The ratio of our sample expressed hyperdynamic bone and is correlated with FGF23.

PUB509

Association between Estrogen Use, Mineral Metabolism Markers and Bone Mineral Density in Women: The MESA Study Nisha Bansal,[1] Ronit Katz,[2] Bryan R. Kestenbaum,[2] Ian H. de Boer,[2] Gail A. Laughlin,[3] Matthew Jay Budoff,[4] Joachim H. Ix.[3] *[1]UCSF; [2]UW; [3]UCSD; [4]UCLA.*

Background: Markers of mineral metabolism (MMM) vary by hormonal status and may be associated with bone mineral density (BMD). We evaluated associations of estrogen therapy (ET) with MMM, as well as associations of ET and MMM with lumbar BMD, in a community-based population of women.

Methods: We studied 3,422 post-menopausal women in the Multi-Ethnic Study of Atherosclerosis (MESA), 946 of whom were on ET. Serum phosphorus (phos), 25(OH) vitamin D (vit D), FGF-23, PTH, serum calcium (Ca), and fractional excretion of phosphorus (FEphos) were measured at baseline. A subset of 894 women had lumbar BMD measured by CT scans. We explored the association between ET and MMM as well as MMM and BMD, adjusting for age, race, education, clinical site, season, tobacco use, physical activity, BMI, eGFRcys, urine ACR, and diuretic use. We examined associations between ET and BMD, adjusting for MMM.

Results: Compared to women not on ET, women on ET were similar in age (62±9 vs 62±11 years), however more likely to be White (55% vs 32%), have lower BMI (28 vs 29 kg/m^2), higher eGFRcys (97 vs 92 ml/min/1.73 m^2) and higher BMD (110 vs 107 mg/cm^3) (all P<.05). In multivariate models, ET was associated with lower phos, higher FEphos, higher vit D, and lower Ca (all P<.05). There was no significant association between ET and PTH or FGF-23. Every 1mg/dL higher Ca was associated with 0.106 (0.033, 0.180) mg/cm^3 higher BMD; there was no significant association between other MMM and BMD. ET was associated with higher BMD, and adjustment for MMM did not change this association.

Table 1. Association between estrogen use (ET) and BMD (mg/cm3)

	Univariate	Multivariate*
ET	0.153 (0.084, 0.222)	0.097 (0.024, 0.170)
ET + mineral metabolism markers†	0.176 (0.104, 0.249)	0.120 (0.043, 0.197)

*adjusted for age, race, education, site, season, tobacco use, physical activity, BMI, eGFRcys, ACR, diuretic use; † phos, vit D, FGF-23, PTH, Ca, FEphos

Conclusions: ET is associated with lower phos, higher FEphos, and higher vit D. Except for serum Ca, we did not observe an association between MMM and BMD, and MMM do not explain the association of ET with lumbar BMD.

PUB510

Linear Functions Relate [PTH]7-84 to [PTH]1-84 in Normal Subjects and Patients with Chronic Kidney Disease Kenneth R. Phelps,[1,2] Roy Mathew,[1,2] Kim Stote,[1,3] Lisa M. Hewson,[1] Deborah A. Hallenbeck.[1] *[1]Stratton VAMC, Albany, NY; [2]Albany Medical College, Albany, NY; [3]SUNY Empire State College, Saratoga Springs, NY.*

Background: Parathyroid cells secrete intact PTH 1-84 and a fragment thought to be PTH 7-84. The fragment may interfere with end-organ effects of the hormone, and that interference is sometimes quantified with the ratio [PTH]1-84/[PTH]7-84. We present evidence that linear functions relate [PTH]7-84 to [PTH]1-84 in normal subjects and patients with CKD. These functions determine the ratio [PTH]1-84/[PTH]7-84 at a given [PTH]1-84.

Methods: We submitted plasma specimens to Scantibodies Laboratories from 30 patients with CKD (eGFR 14-49) and 14 normal subjects (eGFR > 60). Assays for combined [PTH]1-84 and [PTH]7-84 and for [PTH]1-84 ("x") alone were performed on each specimen. [PTH]7-84 ("y") was estimated as the difference between the two results. In each group, we sought linear regressions of y on x and additionally plotted x/y against x. Having found linear relationships between y and x, we employed the equations to derive "ideal" values of y for each x. We calculated x/y from these values of y and plotted the resulting ratios against x to yield idealized curves.

Results: In each group, we found a highly significant linear relationship between [PTH]7-84 (y) and [PTH]1-84 (x) (see Table 1).

Table 1. Linear Regressions*

Group	Equation	R2	p
CKD (n = 30)	y = 0.63x + 7.76	0.71	< 0.001
Controls (n = 14)	y = 0.92x - 9.37	0.78	< 0.001

*y = [PTH]7-84; x = [PTH]1-84

Slopes and y-intercepts of the two equations were dissimilar. Plots of x/y against x suggested curvilinear relationships in which x/y was between 1 and 2 for most values of x. As x increased, idealized curves showed a gradual increase in x/y in the CKD group and a gradual decrease in x/y in controls.

Conclusions: Linear relationships between [PTH]7-84 and [PTH]1-84 suggest that a regulated process links secretion of the fragment to secretion of the intact hormone. The slope and y-intercept of each linear function determine the shape of the curve relating [PTH]1-84/[PTH]7-84 to [PTH]1-84. The ratio changes gradually over the range of [PTH]1-84 in normal subjects and patients with CKD.

Serum Vitamin D Concentration and Estimated Glomerular Filtration Rate (eGFR) in the Polish Elderly Population Andrzej Wiecek,[1] Magdalena Szotowska,[1] Marcin Adamczak,[1] Jerzy Chudek,[1,2] Edward Franek.[3,4] *[1]Department of Nephrology, Endocrinology and Metabolic Diseases, Medical University of Silesia, Katowice, Poland; [2]Department of Pathophysiology, Medical University of Silesia, Katowice, Poland; [3]Department of Internal Diseases, Endocrinology and Diabetology, Central Clinical Hospital MSWiA, Warsaw, Poland; [4]Medical Research Center, Polish Academy of Sciences, Warsaw, Poland.*

Background: Maintaining an appropriate vitamin D levels seems to be one of the crucial public health issues. The aim of this study was to estimate serum 25-hydroxyvitamin D concentration (25-OHD) and its relationship with eGFR in representative samples of the elderly population in Poland.

Methods: In 4054 subjects (2117 males; 1937 females) aged over 65 years (mean age 79 ± 9 years) and 715 subjects with age 55-64 years (332 males; 383 females) from the "PolSenior" study serum 25-OHD was measured by ELISA method.

Results: Serum 25-OHD concentration was significantly lower and vitamin D deficiency (<30 ng/ml) was found significantly more frequent in the subjects with age over 65 years than in subjects with age 55-64 years (respectively, 39.3±22.4 vs 50.5±24.7 p<0.001 and 39.0 % vs 17.7 % p<0.001). Serum 25-OHD concentration in the elderly subjects was significantly higher in subjects with normal (eGFR>60 ml/min; n=3371) comparing with impaired kidney function (eGFR<60 ml/min n=1186) (42.0±23.4 vs 36.5±20.9; p<0.001). Serum 25-OHD concentration in the females with age over 65 years was significantly lower comparing to males (36.3±20.8 vs 42.0±23.4; p<0.001). Significant, negative correlation was found between serum 25-OHD concentration and age (R=-0.286; p<0.001) and positive correlation between serum 25-OHD concentration and eGFR (R=0.143; p<0.001). Multiple regression analysis with gender, age and eGFR as independent factors showed that only age and gender have significant influence on serum 25-OHD concentration in the elderly Polish population (p<0.001).

Conclusions: 1. 25-OHD concentration decrease with growing age of subjects from the Polish population study. 2. Moderate kidney impairment does not independently influence vitamin D status.

PUB512

Prevalence and Determinants of 25-Hydroxyvitamin D Deficiency in the Chronic Kidney Disease in Children (CKiD) Cohort Juhi Kumar,[1,2] Lisa Aronson Friedman,[2] Alison G. Abraham,[2] Valerie L. Johnson,[1] Frederick J. Kaskel,[2] Bradley A. Warady,[2] Susan L. Furth,[2] Michal L. Melamed,[3] Anthony A. Portale.[2] *[1]Pediatrics, Weill Cornell Medical College, New York, NY; [2]CKiD Investigators; [3]Medicine, Albert Einstein College of Medicine, Bronx, NY.*

Background: Deficiency of 25-hydroxyvitamin D (25OHD) is highly prevalent in healthy children. Children with chronic kidney disease (CKD) are at higher risk for 25OHD deficiency.

Methods: We analyzed baseline data of 414 children, with CKD stages 2-4 enrolled in the observational Chronic Kidney Disease in Children (CKiD) study, to determine the associations of demographic, nutritional and behavioral factors with 25OHD deficiency. 25OHD deficiency was defined as levels ≤20 ng/ml and sufficiency defined as levels ≥30 ng/ml. We used multivariate logistic analysis to determine significant predictors of 25OHD deficiency.

Results: 43% of the children had sufficient 25OHD levels and 28% had deficient levels. 53% of African-American children had deficient levels compared to 21% of other races. Unadjusted analyses showed that African-American race, older children, lower maternal education, lower income, higher body mass index (BMI), more time spent watching TV, infrequent milk consumption, nephrotic range proteinuria, lower serum calcium, and lower serum albumin were associated with 25OHD deficiency. Multivariate analysis showed that African-American race (OR 4.4, 95% CI 2.1-9.1, p <0.001), higher BMI (OR 1.1, 95% CI 1.0-1.2, p <0.01), nephrotic range proteinuria (OR 4.3, 95% 1.8-10.2, p<0.01) and less than daily milk intake (OR 2.9, 95% CI 1.6-5.4, p <0.001) were significant predictors of 25OHD deficiency. Season, gender, fish intake and GFR were not significantly associated with 25OHD deficiency. Only 1% of subjects were taking inactive vitamin D supplements. Plasma FGF 23 and iPTH levels were not associated with 25OHD deficiency in the multivariate models.

Conclusions: Deficiency of 25OHD in the CKiD cohort is associated with race and the potentially modifiable risk factors of lower milk intake, higher BMI and proteinuria.

PUB513

Paricalcitol and Left Ventricular Hypertrophy in Young Hemodialysis Patients with Elevated FGF23 Levels Wacharee Seeherunvong, Chryso P. Katsoufis, Carolyn L. Abitbol, Jayanthi Chandar, Gaston E. Zilleruelo, Michael Freundlich. *Pediatric Nephrology, University of Miami, Miami, FL.*

Background: Left ventricular hypertrophy (LVH) in uremia is multifactorial including calcitriol deficiency and ↑FGF23 levels. Studies have demonstrated improved LVH with vitamin D analogs although the recent PRIMO trial in predialysis CKD adults given the analog paricalcitol (Pc) failed to demonstrate regression of the left ventricular mass index (LVMI) (JAMA, 2012). Therefore LVMI changes in hemodialysis (HD) patients on Pc were evaluated.

Methods: In 27 young patients (age 16.8±3.1 yr) on hemodialysis (HD) vintage 23.1±23 months receiving Pc for hyper-PTH and with↑FGF23 levels [381± 1,285 fold>upper limit of normal (ULN)], we studied mineral metabolism markers and cardiac function by echocardiograms (echo) including 14 studied longitudinally after 17±6.8 months.

Results: Baseline LVH (LVMI>95%tile) was observed in 15/27(55%). LVMI correlated with log-C-terminal FGF23(r=0.52, p=0.03), systolic(S) (r=0.58, p=0.01) and diastolic Z-score blood pressure (BP) (r=0.63, p=0.006) but not with phosphorus (P), PTH, proBNP, or Pc dose (6 month time-average 20.4±16.3 mcg/week). Longitudinally, while on Pc treatment (17.8±10 mcg/week), hyper-PTH improved (↓70% to 379 ± 158 pg/ml). On sequential echos LVMI was 45±11g/m$^{2.7}$ with LVH in 9/14 (64%; 7 concentric, 2 eccentric) including 5 with original LVH and 4 de-novo LVH. In 5 remaining patients, 4 had LVMI progression without reaching LVH, and only 1 had LVH regression >30%. In patients with progressive LVMI, intact FGF23 fold-levels > ULN correlated with %change LVMI (r= 0.9, $P < 0.05$). LVMI correlated with SBP Z-score (r=0.65, p=0.01) but not with calcidiol, logFGF23, P, PTH, proBNP or HD vintage. Pc dose was similar in those with or without LVMI progression, and did not correlate with PTH, logFGF23, or LVMI.

Conclusions: In young HD patients with hyperPTH and ↑FGF23 levels, LVMI and LVH continued to progress. Treatment with Pc improved hyper-PTH but did not significantly regress LVMI or improve LVH in most. Longer treatment and higher doses of Pc in a larger cohort may be required to further evaluate the potential salutary effects of Pc on LVH.

Vitamin D Status and Its Association with Mineral and Bone Disorders in a Multi-Ethnic Chronic Kidney Disease Population in Southeast Asia Melissa Ngai,[1] Valerie Lin,[2] Hung Chew Wong,[3] Vathsala Anantharaman,[4] Priscilla P. How.[2,4] *[1]Department of Pharmacy, National University Hospital, Singapore; [2]Department of Pharmacy, Faculty of Science, National University of Singapore; [3]Yong Loo Lin School of Medicine, National University of Singapore; [4]Department of Medicine (Nephrology), National University Hospital, Singapore.*

Background: Vitamin D insufficiency/deficiency is associated with elevated parathyroid hormone (PTH) concentration and mineral and bone disorder (MBD) in chronic kidney disease (CKD). Suboptimal vitamin D concentrations have been reported globally.However, the vitamin D status of CKD patients in Singapore has not been well-described. As such, the objectives of this study were to determine the prevalence of vitamin D insufficiency/deficiency, and the association between vitamin D status and MBD in our multiethnic CKD population.

Methods: Predialysis CKD patients from an outpatient renal clinic were included in this single-center cross-sectional study. Patient demographics, medical/medication histories and laboratory parameters [serum 25(OH)D, creatinine, phosphorus, calcium, albumin and intact-PTH (i-PTH) concentrations] were collected and compared among patients in various stages of CKD. Multiple linear regression was used to determine the association between 25(OH)D and these parameters.

Results: A total of 204 patients with a mean(SD) eGFR of 28(13.7)ml/min/1.73m^2 were included. Vitamin D deficiency and insufficiency was found in 28.9% and 57.8% of the patients, respectively. Mean serum 25(OH)D was 20.9(9.3)µg/L. Female patients had significantly lower vitamin D concentrations (17.2µg/L vs 24µg/L; p<0.001). Serum 25(OH)D concentrations were also significantly higher in Chinese (22.4 µg/L) than Malay (17.4 µg/L) and Indian (13.1µg/L) patients (p<0.05). i-PTH was found to be inversely associated with 25(OH)D (p=0.05).

Conclusions: Despite being a sun-rich country with abundant sunshine all year round, majority (86.7%) of predialysis CKD patients in Singapore have suboptimal vitamin D status. Lower vitamin D concentrations were found in females and patients with darker skin tone. Patients with lower serum 25(OH)D concentrations tended to have higher i-PTH values.

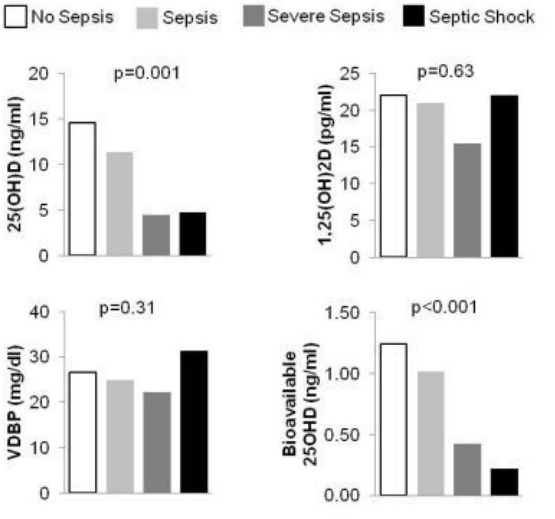
PUB515

Vitamin D and Outcomes in Acute Kidney Injury David E. Leaf,[1] Sushrut S. Waikar,[1] Leonard Stern.[2] *[1]Renal Medicine, Brigham and Women's Hospital, Boston, MA; [2]Renal Division, Columbia University Medical Center, New York, NY.*

Background: Vitamin D deficiency is common among critically ill patients and is associated with adverse outcomes. In contrast, little is known about vitamin D deficiency among patients with acute kidney injury (AKI) and whether lower levels are associated with adverse outcomes.

Methods: We recruited 30 patients with AKI and 30 patients without AKI from the intensive care units and general hospital wards. The following vitamin D metabolites were measured at study enrollment: 25-hydroxyvitamin D (25(OH)D), 1,25-dihydroxyvitamin D (1,25$(OH)_2$D), 24R,25-dihydroxyvitamin D_3 (24R,25$(OH)_2D_3$), and Vitamin D Binding Protein (VDBP). In addition, using previously developed equations, we estimated levels of bioavailable 25(OH)D, defined as the sum of free- and albumin-bound hormone.

Results: Participants with AKI, compared to controls, had a trend toward lower levels of 25(OH)D (p=0.057); significantly lower levels of 1,25$(OH)_2$D (p=0.01), 24R,25$(OH)_2D_3$ (p=0.01), and VDBP (p<0.01); and no difference in levels of bioavailable 25(OH)D. Among the vitamin D metabolites, bioavailable 25(OH)D showed the strongest dose-response relation with severity of sepsis (figure).



In analyses adjusted for age and enrollment creatinine, levels of bioavailable 25(OH) D, but not other vitamin D metabolites, were inversely associated with higher risk of in-hospital mortality (odds ratio 0.16 per SD of natural log-transformed bioavailable 25(OH) D, 95% C.I. 0.03 to 0.85, p=0.032).

Conclusions: Patients with AKI, compared to controls, have lower levels of most vitamin D metabolites. Although bioavailable 25(OH)D was similar between groups, levels were inversely associated with severity of sepsis and mortality, suggesting a potential role as a biomarker or even a mediator of adverse outcomes among patients with AKI.

PUB516

FGF-23 in Acute Sarcoidosis with Normal Kidney Function Donal John Sexton, Anthony O'Regan. *Department of Respiratory Medicine, University College Hospital Galway, Galway, Ireland.*

Background: Fibroblast growth factor (FGF) 23 regulates serum phosphate and calcitriol. It is a marker of abnormal renal phosphate handling. Sarcoidosis is characterised by granulomatous inflammation, which is associated with extrarenal calcitriol production. This results in increased intestinal calcium and phosphate absorption with hypercalciuria in 30-50% and hypercalcaemia in 10-20% of patients. Little is known about the role of FGF-23 in the adaptation to increased intestinal phosphate absorption.

Methods: We conducted a cross sectional study of 43 patients with a diagnosis of acute sarcoidosis. Ethical committee approval was obtained to conduct this study. We measured serum levels of FGF-23 as well as calcium, phosphate, 24 hour urinary calcium, iPTH and 25-OH vitamin D_3.

Results: 26 patients were male. Mean (st dev) age was 33 (9.6) yrs, iPTH 25.35(12) pmol/L, serum calcium 2.32(0.16)mmol/L, phosphate 1.07(0.21)mmol/L,25-OH Vitamin D_3 38(18.5) nmol/L, and eGFR 117 (4)ml/min/1.73m^2. Median (25th-75th centile) FGF23 levels were 0 (0-129.5)pg/ml and 24 hour urinary calcium excretion was 4.8(2.8, 7.5) mmol/L. FGF-23 was detectable only in those patients with hypercalciuria (14%). On univariate linear regression, FGF-23 was independently associated with serum calcium (β=99 P<0.001), and inversely with iPTH (β =-1.3, P=0.001), but not with 24 hour urinary calcium, serum phosphate or 25-OH Vitamin D_3 (all P>0.05). Using stepwise multivariate linear regression iPTH was no longer independently associated with FGF-23 levels (P=0.09), however serum calcium (β=91, P=0.02), serum phosphate (β=54, P=0.02)and 24 hour urinary calcium (β=3.4 P=0.01)were all independently associated with FGF-23 levels. The final model had an R^2 adjusted of 59.2%.

Conclusions: FGF-23 is detectible in patients with acute Sarcoidosis with normal kidney function, these levels are independently associated with serum calcium, serum phosphate and 24 hour urinary calcium levels but not with eGFR. Whether serum FGF-23 is associated with adverse events in patients with chronic Sarcoidosis warrants further investigation. 1,25 OH_2Vitamin D_3 levels and TmP/GFR phosphate measurements were not available which is a limitation in our study.

PUB517

25-Hydroxy Vitamin D Insufficiency in CKD Stage 3 Maarten W. Taal,[1] Victoria Thurston,[1] Natasha J. Mcintyre,[2] Nigel Lawson,[1] Chris W. McIntyre,[2] Richard J. Fluck.[1] *[1]Department of Nephrology, Royal Derby Hospital, Derby, United Kingdom; [2]School of Graduate Entry Medicine, University of Nottingham, Derby, United Kingdom.*

Background: Deficiency or insufficiency of 25-hydroxy Vitamin D ($25OHD_3$) is common in CKD and is associated with increased mortality in the general population. Uncertainty remains, however, regarding the optimal strategy for screening or treatment. Most previous studies have been conducted in Secondary Care. We aimed to investigate serum $25OHD_3$ concentration and factors related to $25OHD_3$ insufficiency in CKD stage 3 in Primary Care.

Methods: Serum $25OHD_3$ was measured by tandem mass spectometry in 1664 persons with estimated GFR 59-30ml/min/1.73m^2 recruited from 32 Primary Care practices. Detailed medical history and clinical assessment were performed as well as urine and serum biochemistry. $25OHD_3$ deficiency was defined as <25nmol/L (<10pg/L) and insufficiency as 25-49nmol/L (10-20pg/L).

Results: Median values for key variables were: age 74(IQR 67 to 79)y, eGFR 53(46 to 60)ml/min/1.73m^2, PTH 46(34 to 66)pg/ml, $25OHD_3$ 53(38 to 71)nmol/L. Overall 104 (6.2%) persons had $25OHD_3$ deficiency and 648 (38.9%) insufficiency. $25OHD_3$ deficiency or insufficiency was more prevalent in several clinically relevant subgroups (Table). $25OHD_3$ concentration showed no correlation with serum phosphate and only weak correlation with serum calcium (r=0.09; p<0.001) but was more strongly correlated with logPTH (r=-0.35; p<0.001). $25OHD_3$ concentration showed no correlation with arterial pulsewave velocity.

Factor	Present	Absent	p-value
Asian ethnicity	22/28(79%)	730/1636(45%)	<0.001
Female	480/1010(48%)	272/654(42%)	0.02
Age≥75y	382/791(48%)	370/873(42%)	0.02
Socially deprived	80/146(55%)	845/671(44%)	0.02
Diabetes	151/275(55%)	601/1389(43%)	<0.001
Obesity	325/620(52%)	427/1043(41%)	<0.001
CKD 3B	193/388(50%)	559/1276(44%)	0.04
Albuminuria	145/275(53%)	607/1388(44%)	0.006

Conclusions: Whereas $25OHD_3$ deficiency was uncommon, insufficiency was relatively common, though values are similar to those reported for the general population in the UK. These data provide support for measuring $25OHD_3$ in all persons with CKD stage 3 but further randomised studies are required to evaluate the benefit of $25OHD_3$ replacement in this group.

Up-Regulation of Fibroblast Growth Factor 23 in Prostate Cancer and Bone Metastatic Lesions of Prostate Cancer-Induced Oncogenic Hypophosphatemic Osteomalacia Akira Iguchi,[1] Hajime Yamazaki,[1] Junichiro J. Kazama,[2] Ichiei Narita.[2] *[1]Nagaoka Red Cross Hospital, Nagaoka, Niigata, Japan; [2]Nephrology and Rheumatology, Niigata University, Niigata, Japan.*

Background: Fibroblast growth factor 23 (FGF23) secreted by mesenchymal benign tumor has been known to induce hypophosphatemic osteomalacia, as a kind of paraneoplastic syndrome. In previous reports, a part of prostate cancer, which is an endodermal origin, with bone matastasis have resulted in oncogenic hypophosphatemic osteomalacia, although FGF23 was secreted from osteocyte of mesenchymal origin. Moreover, patients of prostate cancer with hypophosphatemic osteomalacia have a poor prognosis compared to patients without it. However, whether prostate cancer cells or osteocytes in bone metastatic lesion secrete FGF23 has been unclear to date.

Methods: We investigated the serum level and expression of FGF23 in the tissues in two cases of prostate cancer with bone metastasis accompanied by hypophosphatemia with elevated fractional excretion of phosphate. Immunohistochemical staining for FGF23 was performed in prostate cancer and bone metastatic lesion.

Results: The serum level of FGF23 was elevated and that of 1,25-hydroxyvitamin D was low. In both prostate cancer cells and tumor cells of bone metastatic lesion, immunohistochemical stainings were positive for FGF23, but not in normal prostate cells.

Conclusions: Although, it is well known that almost cases of prostate cancer-induced oncogenic hypophosphatemia had bone metastasis, we have for the first time confirmed that FGF23 was expressed by not only osteocytes in bone metastatic lesions, but also by prostate cancer cells which were an endodermal origin in patients with prostate cancer-induced oncogenic hypophosphatemic osteomalacia.

PUB519

PTH Regulates FGF23 Gene Transcription via Multiple Signaling Pathways Maria Encarnacion Rodriguez Ortiz,[2] Zhousheng Xiao,[1] Leigh Darryl Quarles.[1] *[1]UTHSC, Memphis, TN; [2]University Hospital Reina Sofia, Spain.*

Background: Whether PTH directly stimulates FGF23 gene transcription in osteoblasts (Obs) is uncertain.

Methods: PTH regulation of FGF23 gene expression was assessed by quantitative RT-PCR measurement of endogenous mRNA levels and activity of previously characterized FGF23 promoter/reporter constructs (pFGF23-luc) in UMR-106 Obs.

Results: We observed a dose-dependent stimulation of FGF23 mRNA levels by both PTH and forskolin (FK), achieving a 3 to 6-fold increase at 100 nM PTH and 10 μM FK, respectively. The effect of FK on FGF23 mRNA was detected by 8 hr and was sustained for 48 hrs, whereas PTH transiently stimulated FGF23 expression at 8 but not 24 hrs. IBMX (0.5 mM) significantly augmented the stimulatory effects of PTH, treatment with actinomycin D blocked both PTH and FK stimulation. but cycloheximide (CHX) partially blocked FK- without affecting PTH-stimulated FGF23 mRNA levels in UMR-106 obs. Surprisingly, CHX alone increased FGF23 mRNA levels 3-fold, suggesting suppression of basal FGF23 mRNA levels by a synthesized protein. FK equally but weakly (2-fold) stimulated FGF23 promoter activity in UMR-106 obs transfected with p8Kb-FGF23-luc, p3.5Kb-Fgf23-luc, and p0.6Kb-Fgf23-luc, compared to a 6-fold stimulation of pCRE-luc expressing cells. PTH, in the presence of IBMX, also weakly stimulated luciferase activity by ~2.5 fold in UMR-106 obs transfected with p0.6Kb-FGF23-luc, compared to a 40-fold stimulation in pCRE-luc transfected obs. The PKA inhibitor H89 (1 μM) inhibited both FK and PTH effects on FGF23 gene transcription in UMR-106 cells. In contrast, staurosporine (100 nM), a broadly selective protein kinase inhibitor, augmented PTH stimulation of both FGF23 mRNA and p0.6Kb-FGF23-luc promoter activity, but had no effect on FK stimulation of FGF23 gene transcription in UMR-106 obs.

Conclusions: PTH, especially in the presence of IBMX and staurosporine, stimulates FGF23 gene transcription in UMR-106 obs *in vitro*. Inhibition of protein synthesis increases basal FGF23 gene transcription in these cells. The net effect of positive and negative regulators of FGF23 gene transcription may explain the variable effects of PTH to regulate FGF23 expression *in vivo*.

PUB520

Long-Term Treatment of Cinacalcet with Maxacalcitol Has Limitations to Control Mild to Severe Secondary Hyperparathyroidism with Enlarged Parathyroid Glands Tatsuo Tsukamoto,[1] Motoko Yanagita,[1] Eri Muso.[2] *[1]Nephrology, Graduate School of Medicine, Kyoto University, Kyoto, Japan; [2]Nephrology & Dialysis, Kitano Hospital, the Tazuke Kofukai Medical Research Institute, Osaka, Japan.*

Background: We demonstrated the suppressive effect of the protocol therapy of cinacalcet with maxacalcitol, an active vitamin D derivative, on the secondary hyperparathyroidism (SHPT) in chronic hemodialysis patients whose intact parathyroid hormones (iPTH) ranged from 300 to 1000pg/ml in the last ASN meeting (SA-PO2298). In addition, we showed the decrease of the enlarged parathyroid gland volume after one year. However, long-term use of cinacalcet with vitamin D treatment may bring lower turnover of bone leading to hypercalcemia. Here, we show exacerbation of SHPT after the reduction of maxacalcitol, together with the regrowth of parathyroid glands in our extensive cohort study (UMIN 000001793).

Methods: Fifty-three hemodialysis patients with 159 enlarged parathyroid glands were enrolled and treated with the combination therapy for 3 years.

Results: The dose of cinacalcet increased every 2 to 4 weeks until intolerance, and predicted hypocalcemia was dealt with increase of maxacalcitol. The maximum dose of cinacalcet and maxacalcitol were 40mg daily and 18mg per week in the first year, respectively. PTH was successfully controlled from 565.5±32.0pg/mL (mean±SE) to 164.1±2.5pg/mL after one year (n=51), 159.6±3.1pg/mL after 2 years (n=39), and 207.2±6.5pg/mL after 3 years of the treatment (n=28). Calcium increased within normal range along with the decrease of ALP from 323.2±3.3U/L to 224.6±2.6U/L after 2 years. Phosphate did not change significantly. Thus, we eventually reduced maxacalcitol to 10mg per week after 3 years. 85 enlarged parathyroid glands showed significant volume reduction after the one-year treatment, however, 21 of the shrunk glands displayed regrowth by a high-resolution color Doppler ultrasonography.

Conclusions: The combination of cinacalcet with maxacalcitol could be a powerful strategy to suppress SHPT, however, this therapy failed by hypercalcemia along the decrease of ALP in some patients with regrowth of the parathyroid glands, suggesting that those might be the limitation of this therapy.

PUB521

A Better Response to 48-Month Cholecalciferol Supplementation Is Associated with Improvement of Cardiovascular Risk Markers in Hemodialysis Patients Patrícia Matias,[1,2,3] Cristina Jorge,[1,2,3] Marco Mendes,[1,2,3] Carina Ferreira,[1,2,3] Inês Aires,[1,2,3] Tiago Amaral,[1,2,3] Marília Borges,[4] Célia Gil,[1,2,3] José Cortez,[4] Manuel A. Ferreira.[1,2,3] *[1]Nephrocare, Vila Franca de Xira, Portugal; [2]Dialverca, Forte da Casa, Portugal; [3]NIDAN, Lisboa, Portugal; [4]Laboratório Dr. Fernando Teixeira, Lisboa, Portugal.*

Background: There is a wide variation in the response of serum 25-hydroxyvitamin D [25(OH)D] levels to native vitamin D supplementation.

The aim of this prospective study was to evaluate if a better response to cholecalciferol supplementation was associated with improvement of cardiovascular (CV) risk factors in chronic hemodialysis (HD) patients.

Methods: Serum 25(OH)D levels were measured before and 48-months after cholecalciferol supplementation with 7992 units per week (divided in 3 doses given during the HD session). Patients were distributed in tertiles according to their supplementation response. Parameters of inflammation, pulse pressure (PP), left ventricular mass index (LVMI), vascular calcifications (VC) and serum markers of bone metabolism were evaluated before and after supplementation, in 96 HD patients with mean age (± SD) of 61.8±14.2 years, 46% female, 27% diabetics, and mean HD time of 39.8±34.3 months.

Results: At baseline 79.3% of the patients were insufficient/deficient in [25(OH)D] and a significant increase of 25(OH)D levels was observed after 48 months of supplementation, from 23.4±13.3 to 44.5±18.6 ng/mL, ($p<0.001$). Older patients ($p=0.02$), diabetics ($p=0.01$) and females ($p=0.03$) had a worse response to supplementation. Patients with higher C-reactive protein ($p=0.01$) and lower albumin ($p=0.03$) levels were also worse responders. Patients from the third tertile (with the best response to supplementation) had a higher decrease of PP ($p=0.02$), LVMI ($p<0.001$) and less progression of VC ($p=0.03$). This supplementation was well tolerated without adverse effects.

Conclusions: In conclusion, a better response to 48-month cholecalciferol supplementation was associated with improvement of CV risk markers like inflammation, PP, LVMI and VC, in prevalent HD patients.

PUB523

Calcifediol Intoxication Isabel Martínez,[1] Ramon M. Saracho,[2] Adriana S. Dusso.[3] *[1]Nephrology, Hospital de Galdakao, Usansolo, Vizcaya, Spain; [2]Nephrology, Hospital Universitario de Alava, Vitoria, Alava, Spain; [3]Experimental Nephrology Lab, IRBLleida, Lleida, Spain.*

Background: Patients with CKD frequently present vitamin D (VitD) deficiency, and Guidelines recommend VitD supplementation. Correction of VitD deficiency in individuals with no renal disease is well established. However, the extrapolation of VitD supplementation strategies from other pathologies fails in CKD.

Usually, the correction of VitD deficiency is achieved with daily low doses of cholecalciferol, an inactive compound, or with intermittent doses of calcifediol every 1 or 2 weeks. Calcifediol can directly activate the VitD receptor with a

potency much lower (200 times) than calcitriol, but it circulates in concentrations 1,000 times higher than calcitriol. Furthermore, calcifediol has a half life of 18 days vs. 5-7 days for cholecalciferol. In Spain, calcifediol exists in two oral formulations of 0.266 and 3 mg. In order to assess the risk of toxicity using oral calcifediol formulations, we performed a retrospective study.

Methods: We search for all patients receiving oral calcifediol with serum 25(OH) vitaminD levels ≥100 ng/ml. We identified 55 positive subjects from a sample of 469 patients. Complete information for analysis was available in 28 patients. The characteristics were: male/female 11/17; Average age 74 (12)yrs, CrCl adjusted by 1.73m2, Median 43: range 20-78ml/min. Patients were receiving calcifediol at doses of 3mg, 0.266mg or 0.1 mg/ml. Some patients took different doses sequentially.

Results: Serum chemistries during the period of the highest 25(OH)vitaminD levels showed: Increases in plasma total and ionic calcium of 0.6 mg/dl, $p<0.0001$, and 0.5 mg/dl, $p=0.0009$, respectively, with no increase in phosphatemia. Significant

reduction in PTH from 130 to 71pg/ml, $p<0.0001$. An striking increase in urinary calcium from 43 to 76 mg/24, $p=0.001$, with no changes in phosphaturia. Average increases in serum creatinine of 17%, $p=0.0012$, which reached a maximum of 97%, suggesting ARF.

Conclusions: Supplementation therapies with high doses of oral Calcifediol in patients with CKD should be replaced by small dosage and higher frequency and subjected to a strict analytical control to avoid VitD intoxication and ARF.

PUB524

Differential Contribution of 25-Hydroxyvitamin D Status to Insulin Resistance According to Degree of Renal Function in Non-Diabetic Korean Population Seong Woo Lee, Kook-Hwan Oh, Kwon Wook Joo, Yon Su Kim, Suhnggwon Kim, Dong Ki Kim. *Department of Internal Medicine, Seoul National University Hospital, Seoul, Korea.*

Background: There have been only few literatures on the interaction between kidney function and 25-hydroxyvitamin D (25OHD) status on insulin resistance (IR).

Methods: Data from the Korea National Health and Nutrition Examination Survey in 2008-2010 were analyzed. The study subjects comprised 16,379 non-diabetic participants aged ≥ 20 years whose glomerular filtration rate (GFR) were ≥ 30 ml/min/1.73m^2. GFR and IR were estimated by Chronic Kidney Disease Epidemiology Collaboration equation and Homeostatic model assessment (HOMA), respectively. The evaluations of unit-change effect and threshold were done by generalized linear model and generalized additive model (GAM), respectively.

Results: No specific relation between HOMA-IR and estimated GFR (eGFR) was observed until eGFR decreased to 90-99.9 ml/min/1.73m^2; thereafter, HOMA-IR increased constantly with decreasing eGFR. With GAM, the threshold value of eGFR for HOMA-IR was 97.2 ml/min/1.73m^2. As for 25OHD, HOMA-IR increased constantly with decreasing 25OHD. Since 25OHD was not fitted to HOMA-IR with GAM, we could not identify the threshold value. The unit-change of 25OHD was associated with 0.005 decrease of HOMA-IR. The unit-change effect of 25OHD tended to decrease from -0.005 in ≥ 120 ml/min/1.73m^2 to -0.008 in 90-99.9 ml/min/1.73m^2; thereafter it increased as eGFR decreased. The statistical significance of unit-change effect was evident in eGFR ≥ 80 ml/min/1.73m^2.

Conclusions: The threshold value of eGFR for HOMA-IR was 97.2 ml/min/1.73m^2. The effect of 25OHD on IR was significant only in eGFR ≥ 80 ml/min/1.73m^2 and the maximum effect was observed in eGFR 90-99.9 ml/min/1.73m^2. Future study needs to be followed.

PUB525

1,25/25D Ratio as an Indirect Tool to Evaluate the Activity of Vitamin D Hydroxylases (D-OHase) Sandro Mazzaferro,[1] Lida Tartaglione,[1] Silverio Rotondi,[1] Cristiana Leonangeli,[1] Martino Marangella,[2] Marzia Pasquali.[1] *[1]Department of Cardiovascular, Respiratory, Nephrologic and Geriatric Sciences, Sapienza University of Rome, Rome, Italy; [2]Nephrology and Dialysis Unit, ASO Ordine Mauriziano, Turin, Italy.*

Background: Differently regulated anabolic and/or catabolic D-OH-ases are responsible for variable 1,25D levels in different clinical conditions. The overall balance could also affect sensitivity to replacement therapies: cases with more efficient activity are, predictably, less dependent from vitamin D stores, and more sensitive to storage replacement therapies. We hypothesized that the ratio between the active hormone, 1,25D, and its precursor, 25D, could represent an indirect tool to estimate the overall balance of D-OH-ases activity.

Methods: We considered that two CKD populations, CRF on conservative therapy and renal TX pts, who are developing or, respectively, recovering from secondary hyperparathyroidism, should have different overall D-OH-ase activity. 70 CRF and 80 TX, naïve to vitamin D therapy, were selected to be comparable for age (58±15vs54±10y), renal function (eGRF 45±22vs46±15ml/min) and 25D levels (23±11vs26±11ng/ml);300 normal subjects (N;45±14y;eGFR113±14ml/min;25D 25±13ng/ml) as controls.

Results: 1,25D levels were 24±13, 42±15 and 50±16 pg/ml respectively in CRF, TX and N($p<.001$). The ratio 1,25D/25D was 1,4±1,0 in CRF,2.0±1,4 in TX,and 3.0±2,4 in N($p<.0001$). In cases with 25D≥20 ng/ml the ratio was 0.9±0.5 in CRF; 1.4±0.6 in TX and 2.0±0.5 in N;$p<.0001$; and in cases with 25D<20 ng/ml was 2.2±1.2 in CRF;3.4±1.6 in TX and 4.0±3.3 in N($p<.001$). The ratio was different between the two storage conditions ($p<.001$), in CRF, TX and N. The ratio correlated negatively with 25D in each population ($p<.0001$), with r values definitely increasing (from linear to non-linear models) in N (from 0.556 to 0.774) and in TX (from 0.692 to 0.812), but not in CRF (from 0.648 to 0.692).

Conclusions: As expected in feed-back systems, the ratio 1,25D/25D, is negatively correlated with the substrate, has higher values in case of deficiency, with an exponential increment in N. CRF patients with the lowest values, are presumably less sensitive to storage replacement therapies, as compared to TX.

PUB526

Evolution over 48 h in Levels of 1-84 ("whole") and Non-1-84 Parathyroid Hormone (PTH) after a Single Administration of Cinacalcet in Patients with Secondary Hyperparathyroidism (SHPT) Dolores Arenas,[1] Vanesa De la Fuente,[1] Pablo Delgado,[1] Patricia Gutiérrez,[1] Jorge Ribero,[1] Mariano Rodriguez,[2] Victor Lorenzo,[3] Yolanda Almaden Peña.[2] *[1]H.Perpetuo Socorro, Alicante, Spain; [2]H.Reina Sofía, Córdoba, Spain; [3]H.Canary Islands, La Laguna, Spain.*

Background: "Intact" PTH(iPTH) measures not only PTH 1-84(whole(W)-PTH) but also non-1-84 fragments(non-whole(NW)-PTH), including PTH 7-84, which can cause skeletal resistance to W-PTH. We evaluated whether cinacalcet(CIN) modifies the relative proportion of PTH fragments in hemodialysis(HD) pts with controlled SHPT.

Methods: Single-center, open, exploratory, uncontrolled trial with administration of a single dose of CIN(30–90 mg) and 48-hour(h) follow-up. iPTH, W-PTH and ionic Ca(iCa) were measured at baseline (24h after last CIN dose, trough level in daily regimen), and at 1,3,6,12,24 and 48h. PTHs were determined with the Duo PTH kit (Scantibodies).

Results: 10 pts with SHPT were included (8 men, median diagnostic age 4.5 years(y) (range 2–31), mean age 66 y(39–82), on HD for a median of 5 y(2–31). 6 pts received 30mg of CIN, 3 pts 60mg and 1 pt 90 mg. Mean(SD) baseline levels of iPTH and W-PTH (pre-CIN) were 164(98) and 90(58)pg/ml, respectively. Following CIN, there was a significant and comparable reduction in iPTH and W-PTH at 1h and a return to baseline values at 24h. At 48h(24h after the absence of the daily dose), a significant increase was observed in both iPTH and W-PTH vs baseline. The relative proportion of W-PTH/iPTH was constant between 1-48h. No significant changes were observed in iCa within the dosing intervals of 24h or 48h (intra-patient variability 4.9–18.6%,range 4.3–5.9mg/dl).

Table 1.

	0 hours	1 hour	3 hours	6 hours	12 hours	24 hours	48 hours
iPTH (pg/ml), *average (SD)*	140.1 (96.7)	74.6 (42.5)*	78.4 (35.1)*	131.4 (94.6)*	204.2 (147.9)*	175.5 (118.2)	250.0 (141.7)*
Whole PTH (1-84 PTH) (pg/ml), *average (SD)*	80.8 (54.2)	43.3 (25.6)*	39.5 (16.7)*	64.6 (36.0)*	99.9 (71.0)*	98.0 (59.5)	127.8 (61.9)*
W-PTH/iPTH, % (CI 95%)	61% (48 to 74)	63% (50 to 75)	52% (44 to 56)	55% (41 to 69)	53% (42 to 63)	60% (50 to 70)	54% (44 to 63)
Average percentage change over baseline for iPTH, % (CI 95%)		−42%* (−19 to −64)	−30%* (−34 to −66)	−17%* (−2 to −33)	+26%* (1 to 50)	+14% (−5 to 32)	+51%* (26 to 76)
Average percentage change over baseline for W-PTH, % (CI 95%)		−44%* (−26 to −61)	−51%* (−37 to −66)	−22%* (−11 to −33)	+21%* (3 to 38)	+14%* (−2 to 31)	+53%* (10 to 97).
Ionic calcium (mg/dl), *average (SD)*	4.95 (0.40)	5.05 (0.23)	5.05 (0.25)	5.11 (0.50)	4.87 (0.25)	5.11 (0.30)	5.05 (0.40)
Ratio wholemon-whole PTH, *median*	1.35	1.64	1.13	1.17	1.30	1.37	1.10
Ratio wholeintact iPTH, *median*	0.57	0.61	0.53	0.54	0.57	0.58	0.52

*p<0.05 compared to baseline; SD = standard deviation, CI = confidence interval

Conclusions: In HD pts with controlled SHPT assessed in this study, the chronic administration of cinacalcet seems not to change the relative proportion of 1-84 and non-1-84 fragments(W:NW PTH ratio).

PUB527

Vitamin D: A Marker of Metabolism Mineral or Something More in Type 2 Diabetic? Ana Paula Silva, Ana Pinho, André Fragoso, Cláudia Silva, Nelson Almeida Tavares, Pedro Neves. *Nefrologia, Hospital Faro, Portugal.*

Background: A recent study in type 2 diabetic patients, investigating the mechanism by which vitamin D (25 (OH)D) deficiency mediates increased risk of cardiovascular disease. Found that low vitamin D levels, causing an increased oxidative stress, inflammation, activation of the renin-angiotensin-aldosteren system, speed up the onset of cardiovascular disease in type 2 diabetic compared with non diabetic.

The aim of our study was to evaluate the relationship of 25 (OH) D and cardiovascular mortality in type 2 diabetics with mild to moderate kidney disease.

Methods: In this prospective study, we included 92 type 2 diabetic patients (f=38 m=54), mean age 63 years, mean eTGF 42, 1 ml/min.

At baseline, the patients underwent a complete clinical history and physical examination and several laboratory parameters were analyzed: insulin resistance (HOMA-IR), inflammation (TNF α), mineral metabolism (phosphorus (P), PTH, FGF-23), and oxidative stress (oxLDL), adiponectin, eTGF. We evaluated the systolic and diastolic blood pressure, the mean arterial pressure (MAP), the pulse pressure (PP) and the left ventricular mass index (LVMI) was calculated using the Penn convention criteria.

We divided the population in 3 groups, according to the 25 (OH)D tertiles. GI (n=30) 25(OH)D <12.5 ng/mL; GII (n= 30) – 25(OH)D >12.6 and < 24.9 ng/mL; GIII (n=32) 25(OH)D ≥ 25 ng/mL.

Results: We found the G=I are older (p=0.015) and showed higher levels of FGF-23 (p=0.0001), PTH (p=0.0001), P (p= 0.0001), TNFα (p=0.0001), oxLDL (p=0.0001), HOMA-IR (p=0.0001), LVMI (p= 0.0001), systolic blood pressure (p=0.0001), PP (p=0.0001)and lower levels of adiponectin (p=0.0001) and eTGF (p=0.0001) when compared with other groups.

Using the Kaplan Meier analysis we found that the survival of the GI, GII, and GIII at 43 months was respectively: 23.3%, 44.6 %, 100% (Log –rank = 43.8 p=0.0001).

Conclusions: In our study, we observed a relationship between low levels of vitamin D with non-traditional factors of cardiovascular risk in a population at high cardiovascular risk.

Low levels of vitamin D is a factor of cardiovascular mortality in type 2 diabetic patients in stage 3 and 4 of chronic kidney disease.

Vitamin D Deficiency in Post Transplant South Asian Patients Priyanka Govindan,[1] Arjun V. Sharma,[1] Georgi Abraham.[2] *[1]Internal Medicine, University of Connecticut, Farmington, CT; [2]Nephrology, PIMS, Pondicherry, India.*

Background: Vitamin D deficiency is prevalent in CKD patients but there is limited data available in vitamin D levels in renal transplant recipients in India. CKD MBD is influenced by multiple factors including pre transplant supplementation, immunospressants, age, gender and Vitamin D. Presence of the type 5 skin predisposes South Asians to vitamin D deficiency compared to Caucasians. This is an ongoing prospective study to study the vitamin D levels in the first month after renal transplant in a tertiary care centre in South India. This would allow us to intervene and follow up these patients.

Methods: The 25-(OH) vitamin D levels were measured in all renal transplant patients in their first month, irrespective of their age, gender, renal parameters and other co morbid conditions. We studied 60 renal transplant patients between 2009 to 2011, and monitored their 25(OH) vitamin D levels in the first month after transplant. Males- 46, females-14, age-30 to 62 yrs, DM-18,HTN -50, The vitamin D level is sufficient if it is > 30 ng /ml. All the patients were on pretransplant 1 alpha or 1, 25 Dihydroxyvitamin D3 therapy.

Results: Vitamin D levels - no of patients.

>30ng/ml – 17
15 -29 ng/ml-25
7 -14 ng/ml-15
1-7 ng/ml- 3.

Conclusions: Vitamin D insufficiency and deficiency is highly prevalent in South Asian Patients. In the studied population it was seen inspite of pre transplant supplementation with 1 alpha or 1,25 dihydroxy vitamin D3. Appropriate replacement therapy has been instituted using oral cholecalciferol. Close surveillance of Vitamin D levels is necessary for the management of these patients.

PUB530

Demographic Factors and Practice Patterns Associated with Facility Level Parathyroid Hormone Control Jamie Heise,[1] David M. Spiegel,[2] J. Brian Copley,[1] Moshe Fridman.[3] *[1]Shire Pharmaceuticals; [2]University of Colorado Denver; [3]AMF Consulting.*

Background: Management of mineral and bone disorders in chronic kidney disease remains difficult and optimal therapeutic targets are controversial due to a lack of randomized outcome trials. It is common to consider hyperparathyroidism as a risk factor for cardiovascular and bone diseases.

Methods: Hemodialysis patients (n=116,489) treated in a large dialysis organization during August 2011, were grouped and assessed by facility. Facilities with ≥ 50 patients (N=972) were ranked according to the proportion of patients with serum parathyroid hormone (PTH) in the range 150–600 pg/mL. The top and bottom 5% of facilities were compared for demographic factors and achievement of targets for other laboratory measures (calcium, Ca; phosphate, P; and albumin), use of vitamin D, vitamin D analogues, P-binders and calcimimetics.

Results: The top (n=48) and bottom (n=58) 5% of facilities treated 4035 and 4949 patients, respectively. Target PTH range was achieved by 88% and 51% of patients, respectively (p<0.0001), and overall 70% of patients had serum PTH in range. Compared with the bottom-ranked facilities, patients in the top facilities were older (63 vs 60 years; p=0.0001), a higher percentage were Hispanic (25% vs 12%; p=0.007) or white/other (42% vs 26%; p=0.001), and a lower percentage were African American (28% vs. 57%; p<0.0001). There were no significant differences in the proportions with serum albumin ≥ 3.5g/dL (89% vs 87%), Ca 8.8–10.2 mg/dL (99% vs 98%), or P ≤ 5.5 mg/dL (79% vs 77%). Patients in top-performing facilities were more likely to use IV paricalcitol (13% vs 3%; p=0.038), lanthanum carbonate (16% vs 10%; p=0.001) or sevelamer (68% vs 62%; p=0.044) and were less likely to use calcium acetate (28% vs 37%; p=0.006) or calcium carbonate (1% vs 3%; p=0.001). There were no other significant differences.

Conclusions: With respect to PTH control, demographic factors were different between the top and bottom facilities and top performing facilities used more non Ca-based P-binders. Causality of these factors and PTH control needs to be investigated.

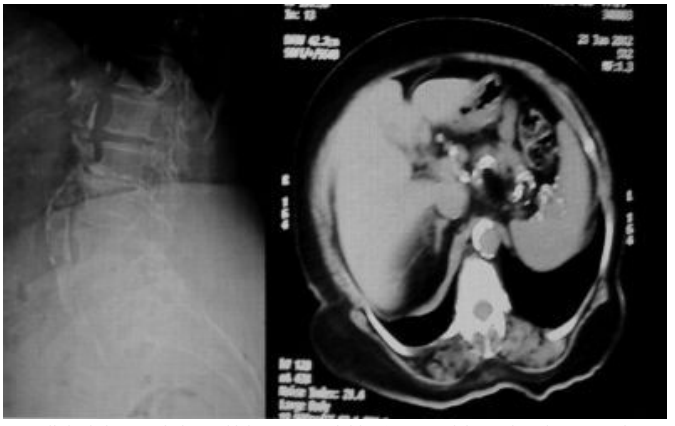
PUB531

Screening for the Prevalence of Vascular Calcification in Pre-ESRD (CKD Stage 4 & 5) Indian Patients: A Single Center Experience Sham Sunder, Himanshu Verma, Venkataramanan K. *Nephrology, PGIMER & Dr. Ram Manohar Lohia Hospital, New Delhi, Delhi, India.*

Background: Vascular calcification (particularly coronary artery and aortic calcification) is a common complication and a predictor of cardiovascular morbidity and mortality in dialysis patients. However, the prevalence of vascular calcification in pre-dialysis chronic kidney disease (CKD) is poorly understood.Currently in India, we do not have epidemiological data on the extent of vascular calcification existing in pre-ESRD (stage 4 and 5 CKD) patients. Abdominal aortic calcification (AAC) can be recorded using plain radiographs (digital X-Ray lumbar spine), multi-slice CT scan and EBCT-scan.

Methods: A total of 90 CKD patients were screened for AAC in the study. Inclusion criteria were age ≥18 years, CKD stage 4 & 5 not on dialysis ,hyperphosphatemia (serum phosphate > 5.5mg/dL).Digital X-Ray lumbar spine (lateral view) and non contrast 40-slice CT scan of the abdominal aorta was used to determine abdominal aortic calcification.



Clinical characteristics and laboratory variables (serum calcium, phosphate, ALP, iPTH, 25,OH,vit D_3) were also assessed. The duration of study was 1 year.

Results: 90 patients (mean age 56.13 ± 11.9 years old, 46 male and 44 female) with pre – dialysis CKD in stage 4 and 5 (66 and 24 in stages 4 and 5, respectively) participated in the study.The primary kidney diseases were diabetic nephropathy (34), chronic interstitial nephritis (35), chronic glomerulonephritis (9), hypertensive nephropathy (7), chronic pyelonephritis (5). Among the patients,75% had abdominal aortic calcification (73.6% and 81.8% for CKD stages 4 and 5, respectively).

Conclusions: The prevalence of vascular calcification (AAC) in pre – ESRD (CKD stage 4 and 5) Indian patients is 75%.Decreased GFR and serum CaxPo4 product correlates with the extent of abdominal aortic calcification in pre-dialysis CKD stages 4 & 5.

PUB532

Introduction of a Protocol for Management of Hungry Bone Syndrome Following Parathyroidectomy Sandesh Parajuli, Jacob Moalem, David A. Bushinsky, Scott E. Liebman, Byron T. Slaton, Rebeca D. Monk. *University of Rochester Medical Center, Rochester, NY.*

Background: There is no standard approach to treating patients with secondary hyperpara-thyroidism (SPT) who require parathyroidectomy (PTX) and then develop hungry bone syndrome (HBS). In January 2010 we established a protocol to manage HBS in post-PTX dialysis pts with the goal of standardizing care, providing adequate calcium repletion and reducing complications.

Methods: Retrospective chart review of patients with SPT who underwent PTX in the last five years. Pts treated on or after 1/1/ 2010 were treated by protocol (Prot) and those treated previously were not (No Prot). Prot pts were transferred to the Nephrology service on POD1. Pre- and post-op PTH, serum ionized calcium (iCa), total calcium (Ca) and phosphorus (P) levels were monitored until discharge. Rate of Ca infusion, P repletion and other medications were adjusted according to Prot. Ca infusion was started at ~1 amp/ hr with goal iCa of 4.5 – 5.1 mg/dl. Oral calcitriol and Ca were started on day 1. IV Vit D was started at dialysis. Complications, demographics, length of hospital stay (LOS), year of PTX, and readmission data were reviewed. Ca drip was tapered off as the iCa remained > 4.5. Pts were discharged when iCa remained ≥4.5 x 24 hours off iv Ca.

Results: There were 10 pts in Prot and 10 in No Prot group. Pts on Prot had a trend toward higher PTH (2010 vs. 1400), higher mean iCa during admission and less readmission (1 vs. 3). LOS was mean 24 (9 – 49) days in prot vs 13 (2 – 44) with No Prot. 2 pts in No Prot group had seizure/arrhythmia vs.0 in protocol group.

Conclusions: Use of a protocol for management of HBS simplified care despite a trend toward extended LOS. Results of Prot use suggest that very high dose parenteral infusion is needed to achieve pt safety and adequate Ca repletion. This is often only permissible in the inpatient setting. Higher PTH levels by the time pts are referred for PTX may contribute to worse HBS, greater Ca deficit and longer LOS. Pts referred for PTX with very high PTH levels should anticipate a long LOS. Protocols may assist in increasing safety in the management of these complex pts.

PUB533

Relationship of Activated Vitamin D and Parathyorid Hormone Levels in Hemodialysis Patients Gregor Paronian,[1] Ming Yuan,[2] K. Edmund Tse.[2] *[1]Huntington Hospital, Pasadena, CA; [2]Pasadena Nephrology, Pasadena, CA.*

Background: The SEEK study revealed that as kidney function declined, parathyroid levels (PTH) increased while 1,25 dihydroxyvitamin D (1,25D) levels decreased. Often, esculating dose of activated vitamin D is used for this treatment. However, overuse of activated vitamin D can induce many side effects. Our goal of this study is examine the relationship of iPTH and 1,25D levels in ESRD patients on hemodialysis (HD).

Methods: This is a retrospective review of 67 ESRD patients treated with HD from April 2008 to March 2010. Patients on cinacalcet or paricalcitol were excluded. Calcium bath on dialysis was constant at 2.5mEq/L. 23 patients had iPTH levels measured by both the Nichols and Scantibodies assays. CAP (1-84 PTH) to CIP (7-84 PTH) ratio was calculated from the Scantibodies method. High and low iPTH was defined as iPTH > 300 and < 150 pg/mL, respectively. Normal 1,25D levels was 15-75 ng/mL.

Results: 52% patients' iPTH levels were found to be at 150-300 pg/mL in which 26% had normal 1,25D levels. Only 7% of patients were found to have both high iPTH and low 1,25D. 76% patients with high iPTH had normal 1,25D levels instead of low; and yet, 44% patients had both low iPTH and low 1,25D levels. The mean serum calcium, phosphate, and 25D levels were 8.3 ± 0.7 mg/dL, 5.3 ± 0.6 mg/dL, and 31.2 ± 4.2 ng/mL respectively. No patient was found to have high phosphate levels (>5.5 mg/dL), high iPTH, and low 1,25D togather. 29% of patients with normal 1,25D had both high phosphate levels and high iPTH. No difference in the iPTH levels between the Nichols and Scantibodies assays (p=0.49) was found. There was no difference between the number of low 1,25D patients with low CAP/CIP ratio (<1.4) by the Scantibodies method and that with low iPTH by the Nichols assay (p=0.29).

Conclusions: iPTH levels correlate poorly with 1,25D levels in ESRD patients. Caution should be made to avoid excessive amount of activated vitamin D to be given to patients who may not have low 1,25D. Low CAP/CIP was found in patients with low 1,25D making Scantibodies assay confusing in determinating appropiate vitamin D therapy.

PUB534

Parathyroidectomy: Good for the Bones and Good for the Heart? Maria Julia C.L.N. Araujo, Sara Mohrbacher, Vivian Lumi Onusic, Patricia T. Goldenstein, Hugo Abensur, Fabiana G. Graciolli, Luciene M. dos Reis, Rosilene M. Elias, Rosa M.A. Moyses. *Nephrology, Universidade de Sao Paulo, Brazil.*

Background: Parathyroidectomy (PTX) has been associated with better outcomes in chronic kidney disease (CKD) patients, who usually present an improvement in their clinical status, as well as a decrease in mortality risk, after PTX. However, little is known about the effects of PTX on cardiac function.

Methods: We prospectively studied 10 patients who underwent PTX, evaluating weight, body mass index (BMI), blood pressure (BP), and use of antihypertensive drugs, as well as serum parathyroid hormone (PTH), calcium (Ca), phosphate (P), alkaline phosphatase (AP), fibroblast growth factor 23 (FGF23), potassium (K), aldosterone and pro-brain natriuretic peptide (proBNP).

Results: During one year of follow-up, no symptoms or signs of cardiac failure were observed. As expected, a significant decrease was seen in Ca, P, AP, PTH, and FGF23 (10.1 ± 0.9 vs. 8.8 ± 1.0 mg/dl; 6.8 ± 1.8 vs. 4.8 ± 1.6 mg/dl; 442 ± 324 vs. 89 ± 35 U/L; 1,590 ± 517 vs. 66 ± 71 pg/ml; and 16,341 vs. 850 pg/ml, respectively; $p < 0.05$ for all). There was also a reduction in the need for hypertensive drugs, with no change in BP, accompanied by a consistent increase in BMI. No significant differences were seen in aldosterone or K. However, a significant increase in proBNP was observed (1,070 vs. 1,322 pg/ml; $p < 0.05$). Higher serum proBNP was seen in patients with hypocalcemia (2,861 vs. 1,219 pg/ml; $p< 0.05$). Log proBNP correlated negatively with BMI and Ca ($r = -0.56$ and -0.47, respectively; $p < 0.05$). Stepwise multiple regression analysis revealed that log proBNP was dependent on both BMI and Ca (adjusted $R^2 = 0.4$; $p < 0.05$).

Conclusions: Despite improving clinical status, PTX is associated with myocardial dysfunction or hypervolemia, as indicated by elevated proBNP, either of which could be related to hypocalcemia. Better control of BP, initially interpreted only as a consequence of an improvement in nutritional status, can also be an indicator of such impairment. This information should be taken into account mainly in patients with a history of cardiac disease who are to be submitted to PTX.

PUB535

No Interaction of PA21 with Micro- and Macronutrients under Physiologically Relevant Conditions Michael Löpfe,[1] Maria Wilhelm,[1] Sylvain Gaillard,[2] Felix W. Funk.[1] *[1]Vifor (International) Inc., St. Gallen, Switzerland; [2]Vifor Pharma, Glattbrugg, Switzerland.*

Background: Hyperphosphatemia, a common and serious complication of chronic kidney disease, often necessitates the use of phosphate binders. A possible undesirable effect of phosphate binders is adsorption or degradation of micro- or macronutrients, requiring supplementation of these elements. This *in vitro* study investigated the interaction of the novel iron-based phosphate binder PA21 with physiologically relevant concentrations of water-soluble B vitamins, amino acids, fluoride, sulphate and oxalate.

Methods: *Method 1:* Each nutrient was incubated with PA21 active pharmaceutical ingredient at pH 3.0, 5.5 and 8.0 for 2 hrs at 37°C. The supernatant was filtered and the nutrient concentration assessed using high-performance liquid chromatography with diode array and mass spectroscopy detectors, and ion chromatography. A recovery range of 80–125% was defined as bioequivalence limits. *Method 2:* As Method 1, but with addition of phosphate buffer. *Method 3 (simulated gastrointestinal [GI] tract conditions):* As Method 2, but for each nutrient, pH was increased stepwise from 3.0 to 5.5 to 8.0 after each incubation (total incubation time: 6 hrs).

Results: In the absence of phosphate (Method 1; Figure 1), only amino acids and sulphate showed a recovery rate of >80% across pH 3.0–8.0. In the presence of phosphate (Method 2), the vitamins B3, B5 and B7 were recovered at >80% at pH 3.0–8.0, B9 and oxalate at pH 8.0, B9 and fluoride at pH 5.5 and B6 at pH 3.0. Under simulated GI conditions (Method 3), vitamins B6, B9 and fluoride were recovered at >80%. The minor interaction of oxalate did not affect the binding capacity of PA21.

Conclusions: PA21 did not show a biologically relevant interaction with the investigated nutrients under physiologically relevant conditions.

Figure 1: Nutrient recovery rate

	pH	Vitamins	Amino acids	Fluoride	Sulphate	Oxalate
Method 1	3.0 and 5.5	<80%	>92%	<80%	>91%	<80%
	8.0	B3: 97.9% B5: 91.9% B7: 93.7%		83.7%		
Method 2	3.0–8.0	>94.1% for B3, B5, B7				
	3.0	B6: 95.9% B9: <80%		<80%		<80%

PUB536

A Prospective Audit of Dietician-Led Management of Chronic Kidney Disease-Mineral Bone Disorder Parameters in Haemodialysis Patients

Jan Flint,[1] John Cunningham.[2] *[1]Nutrition & Dietetics, Royal Free London NHS Foundation Trust, London, United Kingdom; [2]Dept of Nephrology, UCL Medical School, London, United Kingdom.*

Background: Haemodialysis(HD) patients with chronically elevated serum inorganic phosphate(Pi) are at increased risk of vascular calcification, a marker for adverse events. An expanded role for dieticians(RD), to include adjustment of phosphate binder therapy, and its integration with dietary support, may improve Pi management in HD patients.

Methods: The aim was to prospectively audit the difference between RD vs physician(PL) management of serum Pi, corrected calcium(Ca) and parathyroid hormone(PTH), use of binders, active vitamin D(alfacalcidol), calcimimetics and patient experience in HD patients. The PL group(n=131) had the medications adjusted by the nephrologist and RD input bi-annually. The RD group(n=144) were seen monthly for dietary counselling & review of these medications which were adjusted as required following agreed protocol. Data were collected at baseline and 12 months with an experience questionnaire distributed.

Results: There was no statistically significant difference in the adjusted mean serum Pi, Ca or PTH between baseline and 12 months (Adjusted means for Pi were:PL 1.57mmol/l & 1.56mmol/l, RD 1.45mmol/l & 1.44mmol/l baseline and 12 months respectively). There was NS difference in alfacalcidol dose, % taking a calcimimetic, or in dose or type of binder used (calcium vs.non-calcium) at baseline or 12 months between groups. There was a trend towards using fewer binders in the RD group although this was NS (4.92 & 4.95 PL and 4.13 & 3.91 RD). 85 individuals (n=42 RD,n=43 PL) responded to the questionnaire. Individuals in the RD group self reported to be more confident in managing diet and bone medications and felt more involved in making changes vs those in the PL group.

Conclusions: In regard to biochemical control of bone & mineral parameters, there is no difference in the quality of care delivered by dieticians or nephrologists. Despite their greater experience in the management of CKD-MBD, nephrologists may be disadvantaged by poorer knowledge of the dietetic issues. RD's may be a more cost effective strategy for CKD-MBD management.

PUB537

Serum C-Reactive Protein and K/DOQI Guidelines for Bone Metabolism and Disease in Predialysis Patients: Can We Achieve Them?

Eleni Chelioti,[1] Dimitrios Athanasopoulos,[2] Maria Sotiraki,[1] Evdokia Efthimiou,[1] Ekaterini Garopoulou,[3] Maria Tsilivigou,[1] Gabriel Papadakis.[1] *[1]Dept of Nephrology, General Hospital of Piraeus "Tzaneio", Athens, Greece; [2]Health Centre of Dimitsana, General Hospital of Tripoli, Tripoli, Greece; [3]Dept of Pediatric, Hospital "Aglaia Kyriakou", Athens, Greece.*

Background: Mineral metabolism abnormalities and several inflammatory parameters, mainly C-reactive protein (CRP) and IL-6 are concerns in chronic kidney disease (CKD). In spite of the important prevalence and relevance of alterations of mineral metabolism and inflammation in CKD patients, the achieving K/DOQI guidelines have been scarcely analyzed, especially in predialysis patients. The **aim** of this study was to examine the achieving among the main parameters of mineral metabolism (Ca, P, CaxP, and PTH) in the presence/absence of an inflammatory state in predialysis patients.

Methods: A cross sectional study was carried out. The study included patients with CKD not on dialysis and not receiving calcium supplements, phosphorus binders, or vitamin D. The following parameters were determined and analyzed: calcium (Ca), phosphorus (P), Ca-P product, parathyroid hormone (PTH) and CRP. The presence of an inflammatory state defined as CRP>3mg/l and the absence as CRP<3mg/l. Continuous data are presented as mean± standard deviation and categorical data as absolute and relative frequencies.

Results: In the study participated 144 patients (86 males / 58 females, mean age 63±14yearsand mean estimated GFR 34.6±9.5 ml/min/1.73m^2). The percentage of the patients who met the criteria for Ca, P, CaxP, PTH and CRP<3mg/l were 45.1% (n=65), 61.1% (n=88), 88.9% (n=128) 32.6% (n=47) and 36.8% (n=53) respectively. Only 3.5% (n=5) of the patients met all four criteria simultaneously. The percentage of the patients who met the criteria for Ca, P, CaxP, PTH and CRP>3mg/l were 5.6% (n=8). The correlation between P and CRP was not statistically significant (r=0.149, p=0.07).

Conclusions: These data indicate that current practice for the management of mineral metabolism in patients with CKD not on dialysis falls far short of meeting the K/DOQI guidelines both in the presence and in the absence of an inflammatory state.

PUB538

Racial Impact on Bone Metabolism Parameters: Retrospective Review

Sajeet S. Sawhney, Yelena Mushiyakh, Farhanah Yousaf, Haroon Rashid, Chaim Charytan, Bruce S. Spinowitz. *Division of Nephrology, New York Hospital Queens, Flushing, NY.*

Background: Bone metabolism is deranged in end stage renal disease. Race may contribute to the differences observed in the bone metabolism profiles. We explored the impact of Asian race versus other races on the bone metabolism parameters at the initiation of chronic dialysis.

Methods: Medical records of new admissions at Trude Weishaupt Dialysis Center from 2009-2011 were reviewed. Race and parameters of bone metabolism were extracted for every new admission.

Results: There were 181 new admissions between 2009 and 2011. Fifty seven patients did not have lab data from within 14 days of initiation of chronic dialysis, 5 had failed renal transplant before initiation of chronic dialysis, 2 had parathyroidectomy before initiation of chronic dialysis, and 3 were on cinacalcet at the time of chronic dialysis initiation leaving 114 patients for analysis.

Table 1: Demographics

	Asians n=38	Other Races n=76
Age (years)	70±13	67±16
Gender (M / F)	20 (53%) / 18 (47%)	52 (68%) / 24 (32%)
HD / PD	31 (82%) / 7 (18%)	65 (86%) / 11 (14%)
Diabetes	28 (74%)	35 (46%)
Not Taking Phosphate Binder or Vitamin D[¥]	23 (61%)	40 (53%)

[¥] at chronic dialysis initiation or within 14 days

Table 2: Parameters of Bone Metabolism

	Asians (n=38)	Other Races (n=76)
Albumin (g/dL)	2.8 ± 0.6	2.8 ± 0.7
Calcium (mg/dL)	8.1 ± 0.9	8.1 ± 0.9
Phosphorus (mg/dL)	6.2 ± 2.4	6.3 ± 2.4
Alkaline Phosphatase (U/L)	70 ± 25	92 ± 99
PTH [intact] (pg/mL)	306 ± 169*	417 ± 369*

*p<0.05

PTH levels were significantly lower in the Asian population compared to other races even when adjusted for diabetes. There were no significant differences in other parameters of bone metabolism in Asian versus other races group.

Conclusions: Our study shows that PTH levels in the Asian population at chronic dialysis initiation were significantly lower compared to other races. There were no significant differences in albumin, calcium, phosphorus, and alkaline phosphatase, Vitamin D or binder prescription between the two groups. Difference in dietary intake in different racial groups could explain these findings and should be studied to better understand the impact of race/diet on the parameters of bone metabolism.

PUB539

Low-Grade Inflammation and Achieving Laboratory Target Values for Bone and Mineral Metabolism in Hemodialysis Patients

Eleni Chelioti,[1] Kaiti Tselenti,[2] Evdokia Efthimiou,[1] Maria Sotiraki,[1] Stathi Maria,[2] Maria Albanoudi,[2] Katena Digalaki,[3] Gabriel Papadakis.[1] *[1]Dept of Nephrology, General Hospital of Piraeus, Athens, Greece; [2]Biochemical Laboratory, General Hospital of Piraeus, Athens, Greece; [3]Dept of Biopathology, General Hospital of Piraeus, Athens, Greece.*

Background: Inflammation is recognized in up to 50% of Chronic Kidney Disease patients being a common feature of advanced renal disease. Serum C-reactive protein (CRP) had been found to be significantly elevated in hemodialysis (HD) patients and reflects chronic inflammation. Most studies have been performed in hemodialysis on the achievement of more recent and stringent guidelines. The K/DOQI guidelines for HD patients define therapeutic targets for renal osteodystrophy: iPTH: 150-300 pg/ml P=3,5-5,5mg/dl Ca=8,4-9,5mg/dl and product Ca x P ≤ 55mg^2/dl^2. **Aim**: To evaluate our ability to meet the laboratory target values for bone and mineral metabolism in HD patients and the status of inflammation (CRP<3mg/l or CRP>3mg/l).

Methods: We have retrospectively investigated the laboratory parameters for bone and mineral metabolism and the serum levels of CRP of 52 HD patients over a 12 months period in our Hemodialysis Unit. Serum calcium (Ca) and phosphorus (P) levels were determined using standard assay, PTH and CRP levels were determined using chemiluminescence and nephelometry immune assay respectively.

Results: A total of 52 patients (32M/20F, mean age 65±15 years, mean period on dialysis 8±5years, mean Kt/V 1,5±0,3)were included in the study. A total of 104 determinations for CRP and each bone metabolism parameters assessed. Percentage of laboratory determinations that were within the recommended range: 82% for Ca and 71% for CaxP product. Regarding the P and PTH, only 46 (44%) and 35 (33,6%) of the values met the target range respectively. Notably, only 13 determinations (12, 5%) met all four requirements simultaneously. However, 73% of the values for CRP were above 3mg/l and only 27% were below 3mg/l.

Conclusions: Our data suggest that while achieving laboratory values within the target range for bone and mineral metabolism is difficult, it is even more difficult to sustain low-grade inflammation in HD patients.

PUB540

Reversibility of Medial Vascular Calcification in Renal Failure: A Case of Osteoclast Deficiency? Na'Da Abouhassan,[1] W. Charles O'Neill.[2] *[1]Medical University of South Carolina, SC; [2]Nephrology, Emory University, Atlanta, GA.*

Background: Dissolution of hydroxyapatite requires a low pH which, in bone, is achieved by binding of osteoclasts and secretion of protons. Whether this process is active in the arterial wall and can reverse vascular calcifications is unknown.

Methods: Calcified arteries in breast tissue from 19 patients with chronic kidney disease (10 with ESRD) and in amputated lower limbs of 10 additional ESRD patients were examined histologically for osteoclasts. To determine reversibility of medial calcification, breast artery calcification was compared in a blinded fashion by two observers in sequential mammograms at least one year apart from 15 women with end-stage renal disease (ESRD) after successful renal transplantation (mean serum creatinine 1.04 ± 0.05 mg/dl, range 0.7 – 1.29 mg/dl).

Results: Arterial calcification was present in breast tissue from 18 of 19 women but no osteoclasts were observed. Occasional osteoclasts were observed in 3 of 22 heavily calcified arteries from amputated lower limbs of 10 ESRD patients. Of the 8 women with arterial calcification on the earliest mammogram after transplantation (age 58 ± 4 y; 4 with diabetes), 1 showed slight regression on the second mammogram while 2 showed no change and 4 showed progression (mean interval: 3.4 ± 0.65 y; range: 1.0-5.2 y). Of the 7 patients with no arterial calcification on the first mammogram (age 54.5 ± 3.9 y; 4 with diabetes), none had calcification on the second mammogram (mean interval: 3.4 ± 0.5 y; range: 2-6 y).

Conclusions: Osteoclasts are rare in medial arterial calcification and this is reflected by the lack of regression of calcification in most of the patients after successful renal transplantation. In addition to impeding the resolution of vascular calcification, this failure to mobilize osteoclasts may also exacerbate ongoing vascular calcification.

Diastolic Dysfunction Is Common in CKD-5D Patients with Coronary Artery Calcifications Paul Anaya,[1] Hartmut H. Malluche,[2] Anas Al Rifai,[3] Gustav A. Blomquist,[4] Daniel Davenport,[5] Marie-Claude M. Faugere,[2] Vincent L. Sorrell.[1,4] *[1]Division of Cardiology, University of Kentucky; [2]Division of Nephrology, University of Kentucky; [3]Department of Internal Medicine, University of Kentucky; [4]Department of Radiology, University of Kentucky; [5]Department of Surgery, University of Kentucky, Lexington, KY.*

Background: In CKD 5D patients, coronary artery calcification (CAC) is common and cardiovascular disease is the leading cause of death. This study was designed to investigate cardiac morphologic and functional implications of CAC in patients with CKD-5D who are often excluded from cardiovascular clinical trials.

Methods: As part of an ongoing IRB approved study, echocardiograms were performed in 37 subjects (54±15yrs) with CKD-5D. Concurrently, CAC was measured by 64-slice multidetector computed tomography (MDCT) and quantified by Agatston scores. Echocardiograms adhered to American Society of Echocardiography guidelines and comprehensive measures were analyzed by expert cardiologists blinded to CAC results.

Results: The median CAC score was 518, a value conferring high risk for cardiovascular events. The range of CAC scores was wide (0 to 4628). Left ventricular (LV) global systolic function was normal (LV ejection fraction [LVEF] = 60±9%), however, sensitive markers of LV myocardial performance (LVMP index 0.80±0.25) and diastolic function (left atrial volume index=39±14) were abnormal. LV elastance and ventricular-arterial coupling were also abnormal. CAC was associated with concentric LV hypertrophy (p=0.06) even in the small cohort enrolled to date. Additionally, cardiac calcification was positively associated with CAC score.

Conclusions: CAC is associated with structural and functional cardiac abnormalities in patients with CKD-5D. These findings imply a link between CKD, subclinical atherosclerosis, adverse cardiac remodeling, and myocardial stiffness (diastolic dysfunction) emphasizing the need for continued investigation.

PUB542

Usefulness of Radiologic Evaluation to Predict the Response of Cinacalcet Treatment in Secondary Hyperparathyroidism of Hemodialysis Patients Gang Jee Ko,[1] Yoo Sun Cho,[1] Mi-yeon Jung,[1] Soo Young Oh,[1] Jae Hee Seo,[1] Heui Jung Pyo,[1] Sangil Suh,[2] Young-Joo Kwon.[1] *[1]Department of Internal Medicine, Korea University College of Medicine, Seoul, Korea; [2]Department of Radiology, Korea University College of Medicine, Seoul, Korea.*

Background: Cinacalcet, a currently available calcimimetics was supposed to have a role in treatment of secondary hyperparathyroidism (SHPT) refractory to previous medical treatment. However, although resistance to cinacalcet therapy was reported in advanced nodular hyperplasia, the method elucidating cinacalcet response was not established yet. We aimed to investigate whether radiologic examinations would be helpful to determine the response of cinacalcet treatment.

Methods: Twenty six patients who received hemodialysis more than 3 months were treated with cinacalcet for 20 weeks. Before administration of cinacalcet, radiologic evaluations for parathyroid glands were done with sonographic measurement for diameter and volume of each gland by 3 dimentional reconstruction by one expert. Computed tomography (CT) was also taken to measure the diameters of glands by one expert. Patients with median PTH <300 pg/mL during the period of therapy and follow-up were considered responders.

Results: Among 26 patients, 17 patients were responders. Serum calcium and PTH before treatment, and ALP and PTH in follow-up period were lower in responder group. Diameter in sonography and CT, and gland volume were tended to be lower in responder, though it was not significant (responder vs nonresponder: 10.3±5.6 vs 12.5±6.3 mm, 14.0±4.0 vs 17.3±5.0 mm, 700.0±726.8 vs 1015.6±1331.6 mm^3, p>0.05). When cutoff value for each radiologic parameter was calculated to maximize sensitivity and specificity with ROC curve, the number of glands bigger than the cutoff in CT scan (>11.2mm) was significantly more in non-responder group (p=0.021).

Conclusions: Measurement of parathyroid gland diameters with CT scan was useful to predict the response of cinacalcet therapy. Further studies with larger population should be needed.

PUB543

The Predictors of Progression of Vascular Calcification in Hemodialysis Patients Sun Ryoung Choi, Youngki Lee, Min-Gang Kim, Myung Jin Choi, Jwa-kyung Kim, Soo Jin Kim, Taejin Park, Young Rim Song, Sung Gyun Kim, Ja-Ryong Koo, Hyung Jik Kim, Jung-woo Noh. *Internal Medicine, College of Medicine, Hallym University, Seoul, Korea.*

Background: Vascular calcification is thought to be associated with a significant mortality and morbidity in patients with chronic kidney disease (CKD). Although the KDIGO recommended that a lateral abdominal radiograph be used to detect the presence or absence of vascular calcification, the risk factors for progression of calcification are not clearly elucidated. Therefore, we investigate the predictors of progression in vascular calcification.

Methods: This study was prospective observational study. Lateral lumbar radiography of the abdominal aorta was used to evaluate the overall abdominal aorta calcification (AAC) score, which is related to the severity of calcific deposits at lumbar vertebral segments L1–L4. Lumbar radiography was performed at baseline and after 1 year, respectively. The progression of AAC score was defined by any increase in Δcalcification (the change of AAC score).

Results: The subjects were 124 patients on maintenance hemodialysis. 68 (58.1%) were female. The mean age was 57.2±10.9 years. The vintage of dialysis was 56.7 ± 53.8 months. The underlying renal diseases were DM in 66(56.4%) patients. The mean baseline AAC score of the study population was 6.2±6. The risk factors of AAC were age, presence of cardiovascular diseases, and dialysis vintage. 65 patients (53%) showed AAC progression, and 59 patients (47%) showed no change of AAC score after 1 year. In a multivariate analysis, the presence of AAC at baseline (p = 0.017) were independent risk factors for AAC progression. No significant association with AAC progression was found between the baseline and follow up clinical parameters, including gender, obesity, diabetes, hypertension, and dialysis vintage.

Conclusions: This study identified that the risk factor related with AAC progression in hemodialysis patients was the presence of AAC at baseline. Furthermore, considerable number of patients had progression in AAC even after 1 year. Patients should be carefully evaluated and managed from early stage to prevent development and progression of AAC.

PUB544

Differences of CKD-MBD Characteristics and Treatment Practices among Dialyzed Patient's Groups in Hungary Istvan Kiss, Zoltan Kiss, Andras Szabo, Dr.szegedi János, Jozsef Balla, Erzsebet Ladanyi, Botond Csiky, Otto Arkossy, Marietta Török, Sándor Túri, Imre Kulcsar. *Working Group of CKD-MBD, Hungarian Society of Nephrology, Budapest, Hungary.*

Background: Different age groups have different health conditions demanding different treatment approches. Our aim was to survey epidemiology, disease characteristics and treatment practice of CKD-MBD in Hungarian dyalized patients according to age groups.

Methods: It is a multicentre, non-interventional, retrospective, cross-sectional study. We collected CKD-MBD related data: gender, age, BMI, cause of ESRD, se-PTH, se-Ca, se-P, comorbidities and treatment practice. 5008 dialized patient were enrolled into the study. The patients were allocated by their ages (years) into three groups (I:<55; II: 55-74; III: 74+).

Results: Mean age: 63,4±14,2 years old, male proportion: (n=2644) 52,8% (I: 60 %, II: 53,6 %, II: 43,8 %), hemodialysis: 88,6% (I: 85 %, II: 88,6 %, III: 92,4 %). The most frequent cause of ESRD were in 22,9 % hypertension, in 22,1 % diabetes mellitus, in 16,2 % glomerulonephritis. Serum median iPTH level was 178,0 pg/ml (IR: 75,8-361,5). iPTH level was in group I: 223,5 pg/ml (IR: 93,5-514,0), in group II: 181,9 pg/ml (IR: 78,0-348,8), in group III: 141,0 pg/ml (62,2-280,5) (p<0,001). The higher the age was the lower the PTH level was found (p<0,001). Significant differences were among the age-groups in use of calcimimetics (I: 11,3 %, II: 4,1 %, III: 1,3 %), non-Ca-based phosphate binder (I: 29,6 %, II: 18,4 %, III: 8,2%). Among older patients there were significantly higher prevalence of bone disease (BD / I: 30,4 %, II: 39,7 %, III: 44,9 %) and soft tissue calcification (STC / I: 37,1 %, II: 53,6 %, III: 58,5 %).

Conclusions: There are significant differences in epidemiology, laboratory, treatment practice, BD and STC related data in groups divided by ages. Serum iPTH level significantly decreased as the patients ages increased. Further research of this topics and incorporation of current age speciifc findings into clinical practice and also guidelines are needed in the near future.

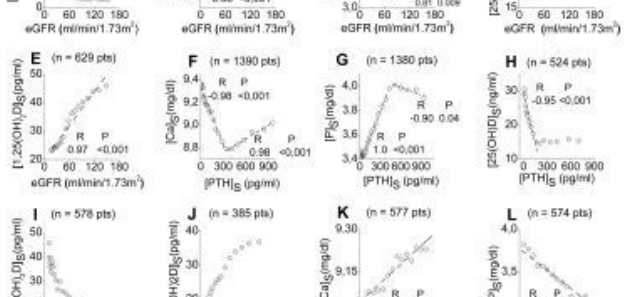
PUB545

Chronic Kidney Disease: Development of Secondary Hyperparathyroidism in 3 Phases Ana Pires,[1] Hugo G. Ferreira.[2] *[1]Nephrology, Professor Doutor Fernando Fonseca Hospital, Portugal; [2]REQUIMTE, Chemistry, New University of Lisbon, Portugal.*

Background: Regulation of the phosphorus-calcium metabolism changes in the course of chronic kidney disease (CKD) but always relying on well known physiological mechanisms.

Methods: Retrospective data from 2507 CKD patients (pts) not on vitamin D therapy, dialysis or submitted to a renal transplant. Each pt was represented by a set of serum concentrations of creatinine, calcium ($[Ca]_S$), phosphorus ($[P]_S$), $[PTH]_S$, $[25(OH)D]_S$ and $[1,25(OH)_2D]_S$. Glomerular filtration rate (eGFR) was estimated by MDRD formula. Functional relations were obtained by pairing variables measured, filtering with a moving average of 3 to 5 points, followed by binning into frequency classes represented by their means and respective standard errors.

Results: Pts were 64±17 years old, 52% male, 97% caucasian. Mean eGFR was 57±34 [15-160ml/min/1,73m^2].



eGFR was negatively correlated with $[PTH]_S$ (Panel A) and $[Ca]_S$ for eGFR above 60 ml/min/1.73m^2 (Panel B) and $[P]_S$ for eGFR under 60 ml/min/1.73m^2 (Panel C) and was positively correlated with $[25(OH)D]_S$ (Panel D), $[1,25(OH)_2D]_S$ (Panel E), $[Ca]_S$ for eGFR under 60 ml/min/1.73m^2 (Panel B) and $[P]_S$ for eGFR above 60 ml/min/1.73m^2 (Panel C). $[PTH]_S$ was negatively correlated with $[Ca]_S$ for PTH > 300 pg/ml (Panel F), $[P]_S$ for PTH < 460 pg/ml (Panel G), $[25(OH)D]_S$ for PTH < 200 pg/ml (Panel H) and $1,25(OH)_2D$ (Panel I) and positively correlated with $[Ca]_S$ for PTH > 300 pg/ml (Panel F) and $[P]_S$ for PTH < 460 pg/ml (Panel G).

Conclusions: For eGFR above 60ml/min/1.73m^2 there was a decline of $[1,25(OH)_2D]_S$ and $[P]_S$ and an increase of $[Ca]_S$ (First Phase). As eGFR reduces $[1,25(OH)_2D]_S$ continues to decrease and $[25(OH)D]_S$ and $[Ca]_S$ diminish and $[P]_S$ increases, suggesting that parathyroid glands are driven by their regulatory actions (Second Phase). In a later phase the parathyroid cells become partially or totally insensitive (Third Phase).

PUB546

The Italian Multicentric Study on the Prevalence of Vascular Calcifications and Vertebral Fractures in Parathyroidectomised (PTX) Dialysis Patients (Cave PTX Study): Phase I Results Sandro Mazzaferro. *Cardiovacular, Respiratory, Nephrology and Geriatric Sciences, Sapienza University, Rome, Italy.*

Background: With a low prevalence of cases, data of clinical outcomes of PTX are limited. The CAVE PTX study of dialysis patients who received PTX, aims to evaluate the control of divalent ions and pertinent medical therapies (phase I), and the prevalence of aortic calcifications and vertebral fractures (phase II).

Methods: Biochemistries (Ca, P, PTH) and therapies of PTX patients were collected by means of an electronic data sheet from 149 Italian dialysis Units. With a computerized procedure, a control group ©, comparable for age, sex and dialysis duration, was selected from the whole cohort. We report on the preliminary data of biochemistries and therapies.

Results: From a total of 12515 patients (HD = 87.7%; PD = 12.3%), 528 (4.22%) received PTX. Prevalence of PTX was definitely higher in HD (4.5%) compared to PD (1.9%). Cases and C (n=320) characteristics are compared in table 1.

TABLE 1	Age, y	M/F, %	Dialysis, y	Ca, mg/dl	P, mg/dl	PTH, pg/ml
PTX	58±13	56/44	15±8	8,8±0,8	4,9±1,3	182±292
C	60±14♦	56/44	12±13♣	9,0±0,6♣	5,1±1,3♦	335±300♣
♦p<.05, ♣p<.001 vs PTX						

TABLE 2	PTH < 150		PTH 150 - 300		PTH > 300	
Ca, mg/dl	8,6±0,8	9,0±0,8♠	8,9±0,7	9,0±0,3	9,2±0,8	8,9±0,3♠
P, mg/dl	4,8±1,3	4,7±1,5	4,9±1,3	4,5±0,6♠	5,1±1,3	4,6±0,6♠
PTH, ng/ml	40±30	87±40♠	216±40	217±41	630±417	567±337
♠p<.0001 PTX vs C						

Ca, P and PTH values in the three K/DOQI PTH range groups are in table 2. Respectively in PTX and C, PTH was low (<150) in 64% vs 20%; optimal (150-300) in 17% vs 40%; and high (>300) in 19% vs 40%. Prescribed drugs, respectively in PTX and C, were: Vitamin D (61 vs 69%); Phosphate binders (88 vs 80%) and Calcimimetic (13 and 37%). Notably, Calcitriol and Ca based binders, and Paricalcitol and Sevelamer were the most frequently prescribed drugs respectively in PTX and C.

Conclusions: PTX has a low prevalence in Italy, and is confirmed to mainly involve relatively young, females and long-term haemodialysis patients. In these patients PTH values are mostly low or high while therapeutic choices may be challenging.

PUB547

Cinacalcet and Paricalcitol Flexible Doses Combination in the Treatment of Moderate to Severe Secondary Hyperparathyroidism in Hemodialysis Patients German Perez Suarez,[1] Bilal El Hayek,[1] Elvira Bosch,[1] Ignacio Ramirez,[1] Eduardo Baamonde,[1] Cesar Garcia-canton,[2] Maria Dolores Checa.[2] *[1]Nephrology, AVERICUM, Las Palmas, Spain; [2]Nephrology, Hospital Universitario Insular de Gran Canaria, Las Palmas, Spain.*

Background: Combined therapy with Cinacalcet and low doses of Paricalcitol has shown improved achievement of the biochemical targets for bone and mineral disorder (MBD) in dialysis patients with moderate to severe secondary hyperparathyroidism (HPTMS). Aim: Determine the long time effect of flexible doses of Paricalcitol and Cinacalcet combination in the parathyroid hormone (iPTH) and calcium-phosphorus product (CaxP) in hemodialysis patients with HPTMS.

Methods: Forty eight patients (male 60%, mean age:58±16 years) with HPTMS(mean iPTH (727± 352pg/mL) and CaxP<55, received combined treatment with flexible dose of Paricalcitol (mean dose: 9.4 mg/week) and Cinacalcet (mean dose of 38.5 mg/day). Clinical and demographic data and biochemical parameters of MBD were recorded (iPTH, calcium, phosphorus and Ca x P). In addition, we recorded all attached medication at the beginning and during the follow-up (mean 17±11month).

Results: Three months after treatment started a reduction in iPTH level were observed (727±352pg/mL to 509±281pg/mL, P<0.000) and this decline persisted at first year of combined treatment, being the reduction of 40.7% (727 ± 352pg/mL to 431±144pg/mL, P <0,000). Also, at 1 year Phosphorus decreased (-9%, 5.2±1.2mg/dl to 4.7±0.9 mg/dl, P=0,048), Calcium (-1%, 9.1±0.7mg/dl to 9.0 ± 0.6mg/dl, P=0.270) and Ca x P (-3%, 47.1±10 mg/dl to 45.9±13mg/dl, P=0.600). Non calcium-containing phosphate-binding doses increased (Sevelamer hydrochloride (P=0.550), lanthanum carbonate (P=0.621), while calcium-containing phosphate-binding doses decreased, (P=0.188). Finally, we observed a reduction of erythropoiesis stimulating agents doses (P=0.08). One patient need a parathyroidectomy and an episode of symptomatic hypocalcemia was recorded.

Conclusions: Combined therapy with flexible doses of Paricalcitol and Cinacalcet in dialysis patients with HPTMS is capable of producing a sustained decline in iPTH and serum phosphorus without increasing others biochemical parameters of MBD.

PUB548

Hip DXA and QCT Scans Are Useful Screening Tests for Low Bone Volume in CKD-5D Patients Gustav A. Blomquist,[1] Hanna W. Mawad,[2] Daniel Davenport,[3] Marie-Claude M. Faugere,[2] Hartmut H. Malluche.[2] *[1]Department of Radiology, University of Kentucky; [2]Division of Nephrology, University of Kentucky; [3]Department of Surgery, University of Kentucky, Lexington, KY.*

Background: Non-invasive radiologic techniques for the measurement of bone mass by dual-energy x-ray absorptiometry (DXA) and quantitative computed tomography (QCT) are used to screen patients for osteoporosis, defined as t-scores ≤ -2.5. However, in CKD-5D patients, previous reports have shown that osteoporosis by DXA and QCT does not accurately identify patients with low bone volume as determined by bone biopsy. Low bone volume, the invasive measurement of low bone mass, is a risk factor for fractures and vascular calcifications.

Methods: In this study, 20 men (mean age 52) and 19 women (mean age 50) with a mean dialysis vintage of 51 months underwent DXA and QCT measurement of bone mass. Concurrently, iliac crest bone biopsies were done for assessment of cancellous bone volume, cortical thickness and porosity to identify low bone volume.

Results: Low bone volume was detected by histology in 33/39 patients (85%). Sensitivity and specificity of t-scores from QCT and DXA at hip and spine for prediction

of low bone volume are shown (Table). A t-score cutoff of ≤-2.5 at the hip missed ¾ of CKD-5D patients with low bone volume (sensitivity 23-25%). A hip t-score cutoff value of ≤0 increased the sensitivity of DXA and QCT for identifying low bone volume to 81-94%. This cutoff level did not reach clinically acceptable specificity (67% vs. the required >80%). Spine sensitivity and specificity were insufficient for screening.

	Spine		Hip	
t-score	QCT	DXA	QCT	DXA
	Sensitivity			
≤0	58%	61%	81%	94%
≤-2.5	18%	12%	25%	23%
	Specificity			
≤;0	67%	67%	67%	67%
≤-2.5	83%	100%	100%	100%

Conclusions: DXA or QCT should be used to screen for low bone volume. The recommended cutoff of t-score ≤ -2.5 for treatment of osteoporosis in the general population should be extended to ≤ 0 in CKD-5D patients.

Dietary Zinc Intake and Kidney Stone Disease: The National Health and Nutrition Examination Survey III, 1988-1994 Jie Tang, Kim Mcfann, M. Chonchol. *Medicine/Nephrology, University of Colorado Sch of Med, Aurora, CO.*

Background: Trace elements are thought to affect calcium-based crystal formation. However, role of zinc intake on kidney stone formation is unclear, as existing studies have shown inconsistent results.

Methods: We used The Third National Health and Nutrition Examination Survey, to determine the independent association between dietary zinc intake, obtained from 24h dietary recall, with kidney stone disease defined as self-report of any previous episode of kidney stone.

Results: A total of 762 among 16456 eligible participants reported a history of kidney stone.

Table 1. Characteristics of the study population

	Stone formers (N = 762)	Non-stone formers (N = 15694)	P value
Age (years)	53.65 ± 0.79	43.12 ± 0.19	< 0.0001
Men	453 (59%)	7211 (46%)	< 0.0001
Race: white	649 (85%)	10433 (66%)	< 0.0001
Hypertension	302 (40%)	4091 (26%)	< 0.0001
Diabetes	86 (11%)	1225 (8%)	< 0.0001
BMI (kg/m2)	27.90 ± 0.30	26.33 ± 0.07	< 0.0001
Zinc use (mg per day)	13.28 ± 0.83	11.91 ± 0.11	0.1
HCTZ use	22 (3%)	266 (2%)	<0.01
Serum calcium (mg/dl)	414.81 ± 73.17	452.29 ± 22.67	0.6

Table 1 shows the characteristics of the study population. Among stone formers, dietary zinc intake increased with advancing age in both men and women, though did not reach statistical significance (p = 0.95). Men had a significantly higher dietary zinc intake than women, regardless of kidney stone history (p<0.0001). After adjustment for age, sex, race, histories of diabetes and hypertension, BMI, dietary protein, water and salt intake, total calorie intake, usage of HCTZ and serum calcium concentration, higher dietary zinc intake was significantly associated with prevalent kidney stone disease when zinc intake (log transformed) was modeled as a continuous variable, OR=1.36, 95% CI 1.07-1.75, p=0.01. In addition, we divided daily zinc intake into three categories using clinically significant cut-offs (< 7 mg, 7-15 mg, > 15 mg). The adjusted odds for stone formation was 1.63 (95% CI 1.08-2.46, p=0.02) when comparing zinc consumption >15 mg/day to <7mg/day.

Conclusions: Our study suggests that higher dietary zinc intake is associated with increased risk of kidney stone disease. Future prospective studies are needed to clarify the causal relationship.

Determination of Ureter Stent Appearance on Dual-Energy Computed Tomography Scan Maria Jepperson,[2] William E. Haley,[1] Joseph Cernigliaro,[2] David D. Thiel.[3] *[1]Nephrology and Hypertension, Mayo Clinic, Jacksonville, FL; [2]Department of Radiology, Mayo Clinic, Jacksonville, FL; [3]Department of Urology, Mayo Clinic, Jacksonville, FL.*

Background: Dual-enery computed tomography (DECT) is useful to evaluate renal and ureteral calculi. DECT assigns a color based on density and chemical composition and accurately distinguishes uric acid (UA) calculi from other types. Some ureteral stents are characterized as more closely resembling the dual-energy characteristics (DEC) of UA calculi (red); others the DEC of non-UA calculi (blue). This study examined the DECT properties of commonly used ureteral stents to optimize stent selection for calculi being followed by DECT imaging.

Methods: Seven stents were individually placed in a phantom and imaged by a Siemans SOMATOM Definition Flash CT scanner. DECT peak tube potentials (kVp) of 80/140 and 100/140 were used to reflect our current protocols. These were compared to 31 in-vivo ureteral stents in 27 patients. The data were reconstructed on a Multimodality Work Place (Siemans) using CT Syngo Post Processing Suite Software, version VE 36A.

Results: Average patient age 64 years (range 27-90). Four patients were being treated for UA stones, 22 for calcium-based stones. There was no difference in the DEC of stents from the same manufacturer. All imaged Cook and Bard stents had DEC that approached those of calcium stones (blue). All Boston Scientific and Gyrus ACMI stents had DEC resembling UA stones (red). Patient age, BMI, gender, type of stone disease, time duration since stent placement, and stent location had no effect. There was no discrepancy between in vivo and in vitro findings. Varying kVp had no effect on stent characterization.

Conclusions: Stents from different manufacturers are characterized by the dual-energy algorithm on DECT imaging and, therefore have color appearances that mimic UA or non-UA calculi. This study provides, to our knowledge, the first data on DECT stent characterization for various stent manufacturers. This information will aid in optimal stent selection for stent/calculi color contrasting and improved visualization of stone material in patients being treated for obstructing ureteral calculi and followed with DECT imaging.

Are Healthy Subjects at Risk to Become Stone Formers? Oriane Dohein,[1] Inmaculada Buendia,[1] Ivan A. Tack,[2] Michel Daudon,[3] Picard Pascaline.[1] *[1]Danone Research RD128, Palaiseau, France; [2]Dpt of Clinical Physiology, Université Paul Sabatier, Toulouse, France; [3]Dpt of Clinical Physiology, Tenon Hospital, APHP, Paris, France.*

Background: Nephrolithiasis is a common disease often related to dietary habits and low diuresis. Several urinary markers, including urine osmolality, calculated risk index such as Tiselius index (TI), and crystalluria have been proposed to assess the risk of stone recurrence in patients. The relevance of these markers to predict first stone occurrence in general population have not yet been assessed. The aim of this study was to describe the status of normal subjects as regard to the risk of nephrolithiasis.

Methods: We enrolled 144 healthy volunteers (96 males and 48 females) aged 37.9 years (16-67 years) who provided a first or second fasting morning urine sample for urine biochemistry and research of crystalluria. The presence of crystals was compared to urine biochemistry and theorical risk of stone formation assessed by TI.

Results: We enrolled 144 healthy volunteers (96 males and 48 females) aged 37.9 years (16-67 years) who provided a first or second fasting morning urine sample for urine biochemistry and research of crystalluria. The presence of crystals was compared to urine biochemistry and theorical risk of stone formation assessed by TI.

Table

	Q1 (TI<0.6)	Q4 (TI>2)	p
Presence of crystals (% yes)	3.4	48.6	<0.001
Osmolality (mean mOsm/kg±SD)	366±156	827±145	<0.001

Conclusions: In stone formers, we previously found that TI > 2.1 was related to a high occurrence of crystals (> 50% of urine samples) and a high occurrence of stone formation. Our data suggest that this relationship applies also in general population, with more than 50% of subjects with TI > 2 presenting crystals in urine and a higher osmolality. As TI or crystalluria are not often assessed in general population, it would be of interest to determine if urine osmolality can identify subjects at risk in further studies.

Based on crystalluria studies, we suggest that a significant part of the general population who exhibit high Tiselius index and osmolality values could be at risk to form urinary stones.

PUB552

Nephrolithiasis, Obesity, and Dietary Factors Laura Soldati,[1] Simona Bertoli,[2] Annalisa Terranegra,[1] Alessandra Mingione,[1] Elena Dogliotti,[1] Francesca Frau,[1] Alessandro Leone,[2] Laila Vignati,[2] Daniele Cusi,[1] Alberto Battezzati.[2] *[1]Department of Health Sciences, University of Milan, Italy; [2]International Center for the Assessment of Nutritional Status (ICANS), Dep. DEFENS, University of Milan, Italy.*

Background: This study investigated the nephrolithiasis (NL) frequency in 621 Caucasian subjects recruited from ICANS outpatient facility and divided in: normal weight (NW; BMI 20-25, n=125), overweight (OW; BMI 25-30, n=235) and obese (OB; BMI >30, n=261).

Methods: Nutritional assessment included: Mediterranean diet questionnaire, anthropometry and biochemistry. The presence of NL, osteoporosis, hypertension, diabetes mellitus and metabolic syndrome (MS) were noted.

Results: The frequency of NL was 9.91%. NSF were younger than SF (47.8±10.1 yrs. vs 51.9±11 yrs [p=0.001]. In particular, in the decade 60-70 yrs the frequency of NL doubled in comparison with the decade 50-60 yrs (18.2% vs 8.97%), in parallel with the increase up of subjects with a BMI > 25 (40% vs 20%).The percentage of subjects with osteoporosis was higher in SF than in NSF (16.9% vs 6.7%, p=0.007). SF had higher hepatic GGT (51.9±124.5 vs 27.9±30.4 U/I, p=0.0006), AST (24.3±12.3 vs 20.3±7.8 U/I, p=0.0008), ALT (29.7±20.4 vs 24.4±15.0 U/I, p=0.0186), triglycerides (147.8±150.6 vs 111.5±68.8 mg/dl, p=0.0016) and higher fasting serum glucose (100.1±20.7 vs 94.4±14.2 mg/dL, p=0.0078). Moreover, SF with a BMI>25 had higher transaminases, serum glucose level, waist circumference and umbilical visceral adipose tissue than SF with a BMI < 25. Not differences were found about the adherence to the Mediterranean diet between SF and NSF.

Conclusions: In conclusion, SF had an increased risk of osteoporosis, altered glucose metabolism and MS than NSF. OW and OB subjects with NL had higher risk of MS than NW subjects with NL. The cohort of OW and OB subjects presented an increase of prevalence in NL mainly in the decade 60-70 yrs linked to a BMI >25 in comparison with general Italian population (18% vs 5%). This increase does not seem linked to dietary habits, but probably to metabolic disorders developed in the long term.

PUB553

Descriptive Analysis of Clinical and Nutritional Status of Patients with Nephrolithiasis Carmen B. Tzanno-martins,[1] Bárbara Margareth Menardi Biavo,[2] Camila Machado de Barros,[2] Jacqueline Santos,[2] Elzo R. Junior.[1] *[1]Director, CINE-HDC-RENALCLASS Group, Sao Paulo, Brazil; [2]Nutritionist, CINE-HDC-RENALCLASS Group, Sao Paulo, Brazil.*

Background: Nephrolithiasis is a high incidence and high recurrence condition and, if untreated, it progresses with high rate of complications. The objective of this study is to describe the nutritional and feeding status in patients with diagnostic imaging of Nephrolithiasis.

Methods: 30 adult patients in regular follow-up outpatient clinic. Data evaluated were gender, age, anthropometry and dietary survey (Food Frequency Questionnaire - FFQ adapted to highlight food sources of oxalate, calcium, sodium and purines).

Results: Mean age was 46.6 ± 13 years, predominantly female (51.7%). About 41.4% of the patients underwent metabolic investigation, main disorders detected were hypercalciuria, hypocitraturia, hyperoxaluria and hyperuricosuria. Most patients showed overweight (25.9%) and obesity (41.8%). According to the FFQ, 35% of patients ingested foods with excessive oxalate content (> 99mg oxalate per serving),while 59.4% consumed foods with high oxalate content (26 to 99 mg). Regarding purines, 20% of patients consumed food with excessive (150-1000 mg of purines in 100 g of food) while 75.8% ingested foods with high amount (75-100 mg of purines per 100 g of food). Daily consumption of high sodium content foods proved to be elevated in 70%. 96.7% consumed food which were calcium sources, while fluid intake was inadequate (<2.5 L / day) in 93.3% of them.

Conclusions: Most patients were overweight or obese. In spite of calcium intake proved to be appropriate, there were factors that contribute to bladder stone formation such as alarming frequency of foods with high levels of oxalate, purine and sodium in the diet, associated with an inadequate fluid intake.

Systematic Review of Dietary and Pharmacological Treatment to Prevent Recurrent Kidney Stones Keith E. Eidman,[1] Manoj Monga,[2] Timothy J. Wilt,[4] Pranav S. Garimella,[3] Roderick Macdonald,[4] Indulis R. Rutks,[4] Michelle Brasure,[4] Robert Kane,[4] Jeannine Marie Ouellette,[4] Howard Fink.[4] *[1]Hennepin County Medical Center, Minneapolis, MN; [2]Cleveland Clinic; [3]John H. Stroger, Jr. Hospital of Cook County; [4]Minneapolis Evidence Based Practice Center.*

Background: Optimal treatment to prevent recurrent kidney stones in adults is uncertain. We systematically reviewed the evidence on benefits and harms of dietary and pharmacological treatment to prevent recurrent kidney stones and on whether baseline or follow up biochemistries predicted treatment outcomes.

Methods: We searched MEDLINE®, Cochrane and other databases through November 2011 and reference lists from systematic reviews and eligible randomized controlled trials (RCT's). Eligible studies must have been English-language RCT's of dietary or pharmacological treatment to prevent recurrent kidney stones in adults that reported stone outcomes and/or adverse events. Two reviewers assessed study design, participant characteristics, efficacy outcomes and adverse events and rated quality and strength of evidence.

Results: There were 28 eligible RCT's. We found low strenth of evidence (SOE) that compared to no treatment, both increased fluid intake (RR=0.45 95% CI=0.24-0.84) and reducing high soft drink consumption (RR=0.83 CI=0.71-0.98) cut risk of recurrent stones. Other dietary interventions had mixed results. In patients with past calcium stones, we found moderate SOE that thiazides (RR=0.59 CI=0.41-0.68), citrates (RR=0.25 CI=0.14-0.44) and allopurinol (RR=0.59 CI=0.42-0.84) reduced risk of recurrence versus control. We found low SOE that addition of citrate or allopurinol to thiazides added no further benefit. Allopurinol benefit appeared limited to individuals with hyperuricemia or hyperuricosuria. Other baseline biochemistries did not predict treatment outcomes. Adverse event reporting was poor. Withdrawals were low with fluid intake trials, high for other dietary interventions, and increased for thiazide and citrate therapy.

Conclusions: Increased fluid intake and reducing high soft drink consumption (low SOE); and thiazides, citrates and allopurinol (moderate SOE) reduce risk of recurrent kidney stones.

Urinary Citrate Protects Rats from Oxalate-Dependent Whewellite Nephrolithiasis Françoise Praddaude,[1] Marie Buleon,[1] Julien Allard,[1] Acil Jaafar,[1] Michel Daudon,[2] Ivan A. Tack.[1] *[1]INSERM UMR1048, CHU Toulouse, Toulouse, France; [2]Dpt of Clinical Physiology, Tenon Hospital, APHP, Paris, France.*

Background: Whewellite (Wh), the oxalate-dependent form of calcium oxalate (CaOx) lithiasis, is difficult to prevent otherwise than by diet. Relevance of the experimental models of CaOx lithiasis in rodents is controversial since they use either a tubulotoxic precursor of oxalate (Ethylene Glycol) and L-Hydroxyproline (HP) or oxalate alone do not induce lithiasis. We assumed that rodents do not develop urinary stone spontaneously because their high urinary oxalate excretion and concentration are balanced by a high excretion of citrate, a powerful inhibitor of crystallization. Therefore, a new model of lithiasis based on citraturia reduction was developed.

Methods: Adult, 20 male Sprague-Dawley rats were divided in two groups: group I received a lithogenic diet containing 3% of HP and 3% sodium oxalate and 0.21M NH4Cl in drinking water for 10 weeks whereas group II (controls) received standard diet and tap water. Urinary parameters (osmolality, citrate, oxalate, urinary acidification and dipstick) were analyzed weekly and creatinin clearance was performed every 3 weeks. After 10 weeks, arterial blood was collected, X-ray and photographs of uro-genital apparatus were performed. Stone composition was analysed using infrared spectrometry (IRS).

Results: All rats from group I developed millimetric calculi and four had migrating stones in the ureter (no lithiasis in group II). IRS analysis was typical of Wh.

Despite a lower body weight, lithiasic rats developed neither renal failure nor metabolic acidosis. Treatment resulted in a marked hypocitraturia whereas oxaluria was increased. Calciuria remained unchanged. Urine and blood osmolality were unaffected. Finally in group I, urine pH was decreased, titrable acidity and ammonuria were increased and haematuria was present since the third week ($p<0.05$ for all data).

Conclusions: In conclusion, hypocitraturia in rats that excrete a large amount of oxalate induces bilateral nephrolithiasis closely mimicking human Wh kidney stones. This model sustains the critical role of citrate for the protection of Wh kidney stones in rat, but also possibly in human.

PUB556

Genome-Wide Analysis of Differentially Expressed Genes in Human Kidney Epithelial Cells (HK-2 Cells) in Response to Elevated Oxalate Sweaty Koul, Lakshmipathi Khandrika, Hari K. Koul. *Urology, University of Colorado School of Medicine, Aurora, CO.*

Background: Nephrolithiasis is a multi-factorial disease, which in majority of cases involves renal deposition calcium oxalate. Oxalate a metabolic end product excreted primarily by the kidney and is the driving force for renal damage and nephrolithiasis in subsets of patients suffering from hyperoxaluria. In previous studies others and we have shown that oxalate is injurious to the renal epithelial cells, however oxalate renal epithelial cell interactions are not completely understood.

Methods: In this study, we utilized an unbiased approach of gene expression profiling using Affymetrix HG_U133_plus2 gene chip to understand global gene expression changes in human renal epithelial cells (HK-2) after exposure to oxalate. We analyzed the expression of 47000 transcripts and variant including 38,500 well characterized human genes in the HK2 cells after 4h and 24h of oxalate exposure. Gene expression was statistically compared among replicates as per the Affymetrix statistical program. Gene expression among various groups was compared using various analytical tools and differentially expressed genes wereclassified according to the Gene Ontology Functional Category.

Results: Results from this study show that oxalate exposure induces significant expression changes in many genes. We show for the first time that, oxalate exposure induced as well as shuts off genes differentially. During this time course, we found 750 up-regulated and 2276 down-regulated genes, which have not been reported before. Our results also show for the first time that oxalate exposure to the renal cells results in regulation of genes that are associated with specific molecular function, biological processes as well as cellular components. In addition we have identified for the first time a set of 20 transcripts that is differentially regulated by oxalate irrespective of duration of exposure and may be useful in monitoring oxalate nephrotoxicity.

Conclusions: Taken together our studies profile for the first time genome wide gene expression changes in response to oxalate and provides a unique insight in oxalate renal cell interactions and oxalate nephrotoxicity.

PUB557

Novel Report on Practice Patterns among Pediatric Nephrologists Managing Nephrolithiasis David J. Sas, Kimberly L. Hays. *Pediatrics, Medical University of South Carolina, Charleston, SC.*

Background: Pediatric kidney stones are increasing in incidence and are a significant burden for affected children and their families. Little is documented regarding practice patterns of pediatric nephrologists caring for these patients. Recent studies suggest examination of different practice patterns may be beneficial in developing more consistent and effective standards of care. In this study, we surveyed pediatric nephrologists in an effort to describe practice characteristics and identify areas for future research.

Methods: We conducted a survey using an online pediatric nephrology list serve (pedneph@lists.uchicago.edu) to collect data regarding practice characteristics of pediatric nephrologists caring for patients with nephrolithiasis.

Results: Responses were received from 52 institutions across the United States and Canada. Results revealed 57% of responders see >15 pediatric stone patients per year, 96% have access to a full-time pediatric urologist and 22% have a dedicated stone clinic, of which 70% are jointly managed by nephrology and urology. Of the responders, 45% have >20 years of experience. In regards to evaluation, 58% use Litholink exclusively for 24-hour urine profiles, while 17% utilize their home lab, 2% use Urorisk (or Stonerisk) and 23% use a combination of Litholink, their home lab, and/or another lab. In reference to imaging, 71% choose ultrasound for initial imaging while 29% use CT. For calcium phosphate stone formers who are hypocitraturic, responders differ regarding urine pH values at which it is appropriate to start citrate supplementation (for example, 50% supplement at pH 5.8, 42% at 6.5 and 25% at 7.0). Only 8% of respondents supplement citrate if urine citrate is normal.

Conclusions: Our results reveal significant differences in the way pediatric nephrologists care for their nephrolithiasis patients. It is clear from the results there is no consensus regarding optimal practice setting, evaluation, and treatment. The number of responses to this survey is encouraging and suggests a multicenter registry for the prospective collection of data on nephrolithiasis patients would provide critical information for improving future standards of care.

PUB558

Increasing Trends in Uric Acid Stone Formation in the Setting of the Growing Obesity Epidemic Cindy T. Pynadath, Xiaobo Liu, Surafel K. Gebreselassie. *Glickman Urological and Kidney Institute, Cleveland Clinic Foundation, Cleveland, OH.*

Background: Kidney stone occurrences are increasing in the United States with a lifetime prevalence of 10% in men and 5% in women. Calcium stones predominate, followed by uric acid and struvite. The purpose of this study was to evaluate the effects of BMI and urine pH on recent patterns in uric acid stone formation.

Methods: Our retrospective analysis included 1905 adult subjects seen in the Cleveland Clinic between January 2006 and December 2010 who had kidney stone analysis and corresponding 24 hour urinalysis including volume, creatinine, citrate, calcium, sodium, oxalate, uric acid and pH.

Results: Ninety-one percent of our patients were Caucasian, 58.6% were male, and the mean age was 53.2 years. Similar to other reports, calcium stones predominated (70.7%) followed by uric acid (both mixed 17.1% & pure 6.4%), struvite (4.2%) and cystine stones (0.42%). A two sample T test to compare BMI between calcium and uric acid stone formers found a significantly higher mean BMI of 35.53 among the pure uric acid group when compared with a mean BMI of 28.88 among the calcium stone group ($p<0.001$), while mixed stones showed a mean BMI of 30, as depicted in Table 1. Using the Wilcoxon rank sum, urine pH was found to be lower among uric acid stone formers when compared to those with calcium stones, with the mean urine pH 5.5 and 6.0 respectively ($p<0.001$), as depicted in Table 1.

Table 1: Comparison of Mean BMI & Mean Urine pH Among Calcium, Mixed (Calcium + Uric Acid), & Pure Uric Acid Stone Formers

Stone Type	Calcium	Mixed (Calcium + Uric Acid)	Uric Acid
Mean BMI	28.88	30.8	35.53
Mean Urine pH	6	5.5	5.5
p-value	<0.001	<0.001	<0.001

Conclusions: In conclusion, our study shows that higher BMI and lower urine pH is prevalent among uric acid stone formers when compared with calcium stone formers, which is consistent with previous studies. However, it is notable that our study found an increase in uric acid (both pure and mixed) stones when compared with previous reports. This increasing trend may be explained by the worsening obesity epidemic. Further studies can evaluate whether lowering BMI will decrease the occurrences of uric acid stone formation.

PUB559

Electrolyte Club: A Proposal for a Novel Curriculum to Enhance Understanding of Fluid, Electrolyte, and Acid-Base Disorders Helbert Rondon-Berrios. *Nephrology, University of New Mexico Health Sciences Center, Albuquerque, NM.*

Background: In an internet-based survey between 2004 and 2008 among US nephrology fellows, 1.5% of them indicated that their fellowship program offered little or no training in electrolyte disorders and 13.5% indicated that they received some training but not enough to feel competent. This has reflected in the ASN-In Training exam scores. In 2009, the overall mean percent correct scores in the areas of sodium/water and acid-base/potassium were 76% and 59% respectively. Delivery of content in this area is usually in the way of a lecture that do not favor either learning acquisition or long-term retention. Multiple RCTs have shown that spaced education is an effective way to increase the amount and durability of learning. Will the implementation of a novel curriculum in fluid, electrolytes and acid-base disorders that utilizes spaced education for a group of nephrology fellows lead to improvement in MCQ examination scores compared to usual training opportunities?

Methods: The electrolyte club features a curriculum across 5 modules: solution stoichiometry, sodium, water, potassium, and acid-base. A 40-item validated test will be administered before the course. Nephrology fellows will be block randomized to 2 cohorts: Cohort 1 receives instruction in solution stoichiometry, sodium and water. Cohort 2 receives instruction in potassium and acid-base. The method of instruction will consist of prior reading, case discussions and adaptive spaced education. Each module consists of two 1-hour sessions per week for 8 weeks. Fellows will be given review articles and 2 clinical cases prior to every session. Sessions will consists of case discussions facilitated by a tutor. After completion of each module, adaptive spaced education items will be distributed via email. Based on a validated curriculum, an spaced education course was structured for each module so fellows will be sent 2 items via email every other day. At the completion of all modules, fellows will be asked to take the same validated test and fill a survey to assess satisfaction. Fellows will be asked to take the validated test again after 3 months to assess durability of learning.

PUB560

Changing Needs for Information and Support in an Online System for Parents of Children with Kidney Disease Maury N. Pinsk,[1] David B. Nicholas.[2] *[1]Department of Pediatrics, Division of Nephrology, University of Alberta, Edmonton, AB, Canada; [2]Department of Social Work, University of Calgary, Calgary, AB, Canada.*

Background: Paediatric chronic kidney disease is psychologically, financially and physically demanding on parents providing care. Many parents feel isolated because of the rarity of the condition; geographic isolation confounds this perception in Canada. Many parents seek assistance online for both information and social support. This study examines an online portal "Ability Online" that provides these functions to a diverse group of parents.

Methods: Transcripts were reviewed from participants in the online system to generate semi-structured interviews focused on technology and social support. Telephone interviews were then conducted with an experienced user group. Participant experiences were evaluated using Descriptive Interpretation as a qualitative methodology, enriched with assessments of demography, social support quality, stress and satisfaction as a caregiver.

Results: Many parents experience a progression through which their needs for knowledge and support change over time. Technology parallels to provide those resources are discussed.

Conclusions: Web developers should account for the changing needs of participants in designing such online support networks, and minimize the reasons that participants fail to adopt, or terminate their online experiences.

Funding: Government Support - Non-U.S.

Hemodialysis Nurses' Knowledge of Dietary Control of Potassium and Phosphorus Is Insufficient and Can Be Improved by Education Margo Laute, Renee Bultynck, Marijn M. Speeckaert, Annemieke Dhondt, Raymond C. Vanholder. *Nephrology, Ghent University Hospital, Ghent, Belgium.*

Background: Dietary non-adherence is a common and serious problem among patients on hemodialysis. Patient coaching and support by trained nurses improves their adherence and quality of life. This study evaluates nurses' knowledge on dietary control measures influencing serum levels of potassium (K) and phosphorus (P) before and after a 2h theoretical educational program given by a dietician.

Methods: This prospective self-controlled study was organized in a dialysis unit with a full-time dietician linked to the unit (A) and in a unit without a dietician (B). Initial knowledge was assessed using a questionnaire consisting of 17 dietary control questions (DCQ) and 10 medical questions (MQ), assessing K/P-content of food, use of K/P-binders and complications associated with hyperkalemia and hypophosphatemia. Subsequently, a nephrology dietician conducted a 2h educational program, herewith instructing 25 dialysis nurses (11 of unit A, 14 of unit B). To evaluate the change of knowledge associated with the program, the same questionnaire was applied 3 weeks after the program. A correct answer was attributed 1 point, an incorrect answer 0. The mean percentage of correct answers was calculated (mean score) and the ANOVA repeated measures test was used for comparing change of knowledge, with a significance level of <0.05.

Results: At baseline the mean DCQ score was significantly different between both units ($p = 0.017$). Overall, the DCQ score was only 52% in unit A and even lower in unit B (42%). No significant difference was observed in mean MQ score (71% vs. 61%, $p = 0.8$). Three weeks after the program, the mean score for both units combined had significantly improved for both DCQ and MQ (DCQ: 44% vs. 56%, $p = 0.009$ and MQ: 69% vs. 79%, $p < 0.001$). There was no longer a significant difference observed after the program between both units concerning DCQ and MQ scores.

Conclusions: A short educational program significantly improves nurses' knowledge on dietary control measures and its medical importance. The presence of a full-time dietician in a dialysis unit positively impacts nurses' basic dietary knowledge.

PUB562

Information Needs of Patients with Early Stage Chronic Kidney Disease: Focus Group Study Pamela Andrea Lopez-Vargas,[1,2] Allison Tong,[1,2] Richard K.S. Phoon,[3] Steven J. Chadban,[4] Yvonne Shen,[5] Jonathan C. Craig.[1,2] *[1]Centre for Kidney Research, the Children's Hospital at Westmead, NSW, Australia; [2]Sydney School of Public Health, University of Sydney, NSW, Australia; [3]Department of Renal Medicine, Centre for Transplant and Renal Research, Westmead Hospital, NSW, Australia; [4]Royal Prince Alfred Hospital, University of Sydney, NSW, Australia; [5]Royal North Shore Hospital, University of Sydney, NSW, Australia.*

Background: The key risks of early-stage chronic kidney disease (CKD) are premature cardiovascular mortality and progression to end-stage kidney disease. Education for prevention of CKD progression in patients with early stage kidney disease may be fragmented and inadequate. The aim of this study was to identify the information and education needs of patients with CKD.

Methods: Patients with CKD Stages 1-3 were purposively sampled from three major hospitals in Sydney, Australia to participate in focus groups. Transcripts were thematically analysed.

Results: From nine focus groups including 38 participants, seven major themes were identified: disease management (medication safety, treatment options, pathology results); lifestyle changes (dietary advice, alcohol consumption, physical activity, smoking cessation); understanding causes and risk factors of CKD (diabetes, high blood pressure,

medication); hopelessness (no cure, genetic predisposition, unknown future); motivation (avoid dialysis, find a cure, prevent progression); lack of medical support (education, follow up); and access to multi-modal education (pamphlets, booklets, DVDs, internet, health care professionals).

Conclusions: Patients believe that their capacity to slow the progression of CKD is limited by the lack of knowledge of risk factors, treatment, lifestyle modifications and poor access to education. Development of multi-modal educational resources including practical lifestyle recommendations, such as adequate diet according to CKD stage and types of appropriate physical activities, combined with active physician engagement in prevention, are likely to promote patients' ability and motivation to make lifestyle modifications for prevention of CKD progression.

PUB563

Conservative Management of Sever Hyperkalemia due to Oral Potassium Overdose

Meteb M. AlBugami, David J. Hirsch. *Internal Medicine, Division of Nephrology, Dalhousie University, Halifax, NS, Canada.*

Background: Elevated serum potassium (K) is a common problem. However, hyperkalemia due to oral potassium overdose is rarely encountered. The management of severe hyperkalemia with normal renal function is controversial, with no evidence based guidelines. We report a case of intentional oral potassium overdose resulting in severe hyperkalemia with normal kidney function and minor electrocardiogram (ECG) changes, that was managed without hemodialysis (HD).

Methods: A 48-year-old female presented to our Emergency Department after ingesting 30 tablets of 20 mg sustained release potassium chloride. Her main symptoms were peripheral paraesthesia and mild distal weakness. She was hemodynamically stable, with peaked T waves seen on her initial ECG. The maximum K level was 10.1 mEq/L. She was treated initially with calcium gluconate, insulin, salbutamol, and calcium resonium. later on, she was started on insulin drip, and furosemide drip along with intravenous fluids, and small dose PEG to enhance K excretion via the renal and GI routes were added. She was kept in ICU for close monitoring with no significant arrhythmia. K level went to normal level in 10 hours, during which she was hemodynamically stable. her urine output was more than 3 L during the first 24 hours, and she was transferred to psychiatry floor.

Conclusions: This patient with severe hyperkalemia on suicide attempt was managed successfully without HD. The main reasons to go conservatively were absence of significant ECG changes and having normal renal function, otherwise HD was to be utilized for prompt removal of K. We highlighted the importance of volume expansion and forced diuresis as rapid K excretion is expected with normal kidney function. Using PEG as whole bowel irrigation was reported before in such case but needs to be given early. In the literature, cases of severe hyperkalemia (K >8), some of them had significant arrhythmia, were managed without HD and few cases had bad outcomes including death.

Severe hyperkalemia with normal renal function could be managed successfully with forced diuresis as long as there is no hemodynamic instability due to arrhythmia.

PUB564

Acute Relapse of MELAS Syndrome in Dialysis Patient Induced by Infection

Pietro Claudio Dattolo, Stefano Michelassi, Giulia Sansavini, Alma Mehmetaj, Marco Amidone, Giuseppe Ferro, Francesco Pizzarelli. *Nephrology, S M Annunziata Hospital, Florence, Italy.*

Background: MELAS syndrome is a maternally inherited multisystemic disorder caused by mutations of mitochondrial DNA. Frequently it is associated with hypertrophic cardiomyopathy and diabetes, while association with nephropathies is less common. We describe the first case of MELAS relapse following an acute infectious disease in a hemodialysis patient.

Methods: A 42-years-old Caucasian man was admitted to our hospital because of progressive weakness and lethargy. The patient was on hemodialisys since 2008. At the age of 30 he was diagnosticated with MELAS (besides characteristic clinical features, muscular biopsy presented ragged red fibers and DNA analysis showed C3243A>G mutation); he presented congenital bilateral hypoacusia, recurring generalized seizures and encephalopathy,progressive bradyphrenia and bradykinesia, restrictive cardiomyopathy, diabetes and CKD due to FSGS. At the time of hospitalization, he was febrile and drowsy and he was suffering from malaise, anorexia, vomiting, dyspnea, and lower limbs paresthesias. Laboratory tests showed severe lactic acidosys, systemic cytolysis and increased inflammation markers.

table1

Laboratory Tests	Admission	Nadir	Discharge
Lactic Acyd (mg/dL)	9	22	2
AST (U/L)	735	1628	29
ALT (U/L)	1331	2384	40
Ammonemia (µg/dL)	63	108	
PT ratio (%)	46	31	94
CK (U/L)	507	507	64
LDH (U/L)	1236	1420	285
Troponin-I (ng/mL)	2.84	3.53	0.24
CRP (mg/L)	12.94	16	0.17
Procalcitonin (pg/mL)	6.78	14.93	2.5
White blood count /µL)	12000	18500	7300

Abdominal US showed hepatomegaly and gallbladder wall edema, while EEG, cranial TC, and echocardiography had no significant variations. He was treated with intensive dialysis (CVHDF), broad-spectrum antibiotics and supporting medical therapy, which produced an improvement of his conditions. When discharged, the patient's clinical picture was completely solved.

Conclusions: We are not aware of any case of relapsing MELAS syndrome in HD patients. Our patient had been stable during the previous 4 years of dialysis. Following an acute infectious episode, he ostensibly suffered from a relapse of MELAS, with appearance of several of the disease's archetypal symptoms.

PUB565

Splenic Laceration in a Peritoneal Dialysis Patient with Recurrent Peritonitis

Sandesh Parajuli, Scott E. Liebman, Sai Subhodhini Reddy. *Department of Medicine, Div of Nephrology, University of Rochester Medical Center, Rochester, NY.*

Background: Introduction: Hemoperitoneum is not an uncommon occurrence in peritoneal dialysis (PD) patients. Rarely hemoperitoneum may signify serious intra-abdominal pathology. Here we report a case of hemoperitoneum related to a splenic laceration.

Methods: Case: A 28 year old woman with diabetes mellitus, hypertension, and ESRD on PD for 23 months presented to an outside hospital with pneumonia and *Enterobacter cloacae* peritonitis (her third episode of peritonitis). At that time, her PD fluid had >90,000 WBC and <3,000 RBC / milliliter (ml) and frank blood clots. She was treated with oral moxifoxacin and intra-peritoneal (IP) cefepime. Two days after discharge she presented to our hospital with nausea, vomiting and severe abdominal pain. On exam, she was hypertensive to 231/149. Her exit site was benign. She had left lower quadrant abdominal tenderness and rebound. Laboratory evaluation showed hemoglobin of 11.8. The PD fluid was clear, with 59 nucleated cells and 20 RBC / ml. She was treated with antihypertensive, antiemetic and analgesics. CCPD with IP cefepime was continued. Despite antibiotics and a negative cell count, her severe abdominal pain persisted and her hemoglobin dropped to 7.1. A CT scan showed a splenic laceration, mesenteric edema and colitis. She denied any trauma, and was managed non-operatively. PD was discontinued, the hemoglobin stabilized, her abdominal pain gradually improved and she was discharged after one week on hemodialysis.

Conclusions: A potential explanation of the splenic laceration is that adhesions from multiple episodes of peritonitis resulted in decreased splenic mobility with traction related injury due to fluctuating abdominal pressures. A similar mechanism has been postulated for splenic injury in inflammatory bowel disease patients undergoing colonoscopy. In this case, inflammatory adhesions render the spleen less mobile with traction injury induced by the increased intra-abdominal pressure during the procedure. Splenic injury in PD patients is uncommon, but should be considered in those with recurrent peritonitis, hemoperitoneum and unremitting abdominal pain.

PUB566

Antineutrophil Cytoplasmic Antibody Associated Vasculitis Following Interferon Treatment for Hepatitis C

Reginald Ifeanyi Obi, Karlene O. Hewan-Lowe, Courtland Winborne. *Internal Medicine/Nephrology, East Carolina Brody School of Medicine, Greenville, NC.*

Background: ANCA associated vasculitis is a multisystem autoimmune syndrome characterized by vasculitis predominantly affecting microscopic vessels and circulating autoantibodies to neutrophil cytoplasmic antigens. Renal involvement occurs in 70% of affected patients and is manifested as rapidly progressive glomerulonephritis (GN) with pauci-immune necrotizing, crescentic GN on biopsy. This case study illustrates the rare occurrence of ANCA vasculitis following interferon therapy for treatment of Hepatitis C.

Methods: 49 yo African American male with history of stage 2 Chronic Kidney Disease due to hypertension and Hepatitis C associated with positive cryoglobulins, completed a 24-week course for Hepatitis C with triple therapy of Pegylated Interferon, Ribavirin and Telaprevir. He responded with an undetectable viral load at the end of treatment. In the final week of therapy, he developed generalized malaise, muscle aches, joint pain, stiffness, swelling and episodic mild hemoptysis. He was seen 2 weeks later and found to have an elevated creatinine at 5.26 mg/dL up from his baseline of 1 mg/dL. He also had significant anemia with hemoglobin of 6.4 g/dL. His chest X-ray was normal. The workup revealed normal complement levels, a positive P–ANCA at 1:160 titer, and renal biopsy confirmed pauci-immune GN. Patient was treated with pulse steroids and prednisone taper. He responded well with a decline in creatinine to 2 mg/dL and complete resolution of symptoms. His Hepatitis C viral load remains undetectable.

Conclusions: Pauci-immune GN arising from interferon therapy is a rare complication. This should be suspected if a rapidly progressive renal failure occurs while receiving this medication. Interferon should be included in the list of drugs inducing ANCA vasculitides. Treatment of ANCA vasculitis traditionally involves cyclophosphamide in conjunction with steroids. We opted to treat conservatively with steroids due to concerns of Hepatitis C reactivation. The patient's creatinine stabilized at 2 mg/dL and his Hepatitis C viral load remains undetectable post steroid treatment.

PUB567

Pet Ownership and Automated Peritoneal Dialysis, Can They Coexist?

Sasan Raeissi,[1] Chebel Khalil,[2] Antoine L. Samaha.[2] [1]*Internal Medicine, Good Samaritan Hospital, Cincinnati, OH;* [2]*Nephrology, Good Samaritan Hospital, Cincinnati, OH.*

Background: Automated peritoneal dialysis (APD) is more popular option than continuous ambulatory peritoneal dialysis (CAPD) since it offers more flexibility for patients during the daytime. However, in either option, aseptic technique including proper

handling of the dialysis tubing and connector in a safe and clean environment are the key to prevent infectious complication such as peritonitis.

Methods: A 65-year-old Caucasian male with end stage renal disease (ESRD) who started hemodialysis at age 62 and later switched to APD 7 months prior to his presentation with abdominal cramping and discomfort associated with cloudy peritoneal fluid. He was hemodynamically stable and afebrile. His abdominal examination revealed a soft, non-distended abdomen with diffuse tenderness but no guarding. His peritoneal fluid cell count showed: WBC 11480 /uL with 93% Neutrophils. Peritoneal fluid culture revealed Pasteurella Multocida. The patient admitted there are two cats at home. He also admitted that they have chewed on the tubing system. He was started on intra-peritoneal Ceftazidime (1.5 grams daily) and oral Ciprofloxacin (500 mg daily) for a total duration of 3 weeks. His symptoms improved significantly and his peritoneal fluid cell count and differential normalized. The patient was discharged after 5 days of hospital stay.

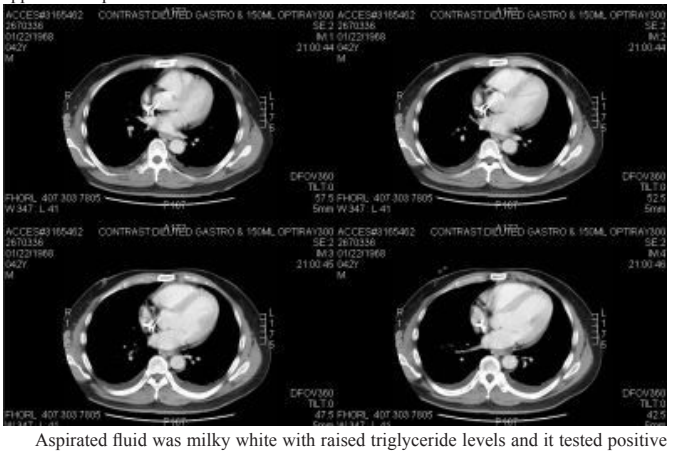
Conclusions: Pasteurella Multocida is a rare form of PD-related peritonitis and is closely associated with pets namely cats. Patients on APD are more affected than those on CAPD since the patient performing the CAPD fluid exchange is in control of his or her surrounding as opposite to the patient on APD where the exposure to hazards such as a pet chewing on dialysis tubing may not be controlled. Our patient's wife refused to remove the cats from her household regardless the consequences. The patient himself refused to go on CAPD or in-center hemodialysis as an alternative. His wife then arranged for building gates in their house. Hence, the issue of safety and prevention should be discussed thoroughly with patients before their discharge with follow up home visit to assure the application of these measures.

PUB568

An Unusual Presentation of Abdominal Pain Pran M. Kar,[1] Shaan E. Alam.[2] *[1]Nephrology, Florida Hospital, Orlando, FL; [2]University College of Medical Sciences, New Delhi, India.*

Background: Chylous ascites consists of chyle accumulation in the peritoneal cavity. It rarely develops following unrecognized iatrogenic injury to lymphatic vessel. We present a patient with chylous ascites following bilateral nephrectomy for polycystic kidney disease (PKD).

Methods: A 42-year-old Filipino man with PKD presented with left flank pain, vomiting and hematuria. On examination he had costo-vertebral angle tenderness and trace bilateral pedal edema. CT scan of abdomen revealed multiple cysts in both kidneys consistent of PKD. He underwent bilateral open nephrectomy. The post operative period was uneventful except mild abdominal discomfort and he was discharged on antibiotics and a repeat CT scan was advised in a week. After 10 days, he presented with vomiting, abdominal pain and poor appetite. A repeat CT scan of abdomen revealed fluid collection in bilateral renal fossae.



Aspirated fluid was milky white with raised triglyceride levels and it tested positive for Sudan III. A diagnosis of chylous ascitis was made with likelihood of iatrogenic lymphatic duct injury. He was managed conservatively with dietary modifications to which he responded poorly. Oral diet was then with held and the patient was managed with total parenteral nutrition, anti secretory drugs and supportive treatment with repeated aspiration of ascites fluid. To this he improved significantly with complete resolution of ascites.

Conclusions: Although rare, chylous ascites is a possibility in patients with nephrectomy. This must be ruled out when such patients present with abdominal pain and intra abdominal fluid collection in the post operative period.

PUB569

Hypercalcemia and Acute Kidney Injury due to Panhypopituitarism and Adrenal Insufficiency Julia Lichtnekert, Hans J. Anders, Wolfgang Neuhofer. *Division of Nephrology, Medizinische Klinik und Poliklinik IV, Munich, Germany.*

Background: Uncontrolled hypercalcemia is a frequent cause of AKI. In the present report we describe a rare case of hypercalcemia-induced AKI associated with hypopituitarism following brain injury with severe lesions in the hypothalamic-pituitary area.

Methods: We report a 24-year old man with a known history of traumatic brain injury 7 months ago. Due to AKI the patient was referred. He reported a 4-month history of increasing fatigue, depression, absence of libido, nausea and emesis, increased thirst (5l/d), polyuria and loss of weight. The medical history before the accident was unremarkable. The medication consisted of thyroxine. In the physical examination an anorectic body habitus, left incomplete hemiparesis and amaurosis of the right eye was noted. Blood and urinary parameters showed elevated levels of creatinine, severe hypercalcemia and hypercalciuria, low urine osmolality with normal serum osmolality, elevated alpha1-microglobulin excretion, and normochrome anemia. TSH was suppressed. Renal sonography was unremarkable. There was no evidence of malignancy, hyperparathyroidism, vitamin D intoxication and sarcoidosis. However, in endocrinological tests, panhypopituitarism was detected: Secondary adrenal insufficiency, hypogonadotropic hypogonadism, secondary hypothyroidism, growth hormone deficiency, and central diabetes insipidus. The MRI revealed traumatic ischemic lesions in the hypothalamic-pituitary region. Initial treatment consisted of bisphosphonates and forced diuresis. After correction of serum calcium, renal function improved, suggesting AKI was associated with hypercalcemia. Further treatment included substitution of hydrocortisone, testosterone, thyroxine and desmopressin. Under this medication, the patients' general condition improved within a week: Polydipsia and polyuria ceased, fatigue disappeared and the mental status stabilized. At discharge from the hospital, serum calcium had returned to normal levels and renal function was completely restored.

Conclusions: Therefore, in the absence of usual conditions associated with hypercalcemia, endocrinological abnormalities should be considered in cases of otherwise unexplained AKI.

PUB570

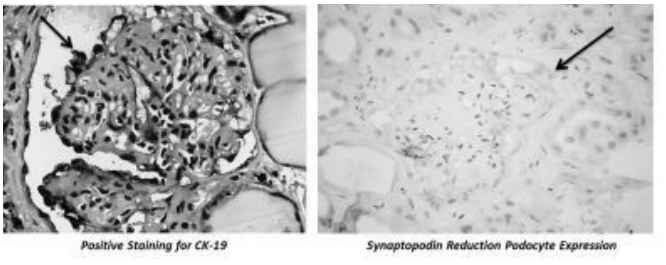
Collapsing Glomerulopathy Associated with Pamidronate: Case Report and Immunohistochemical Analysis Maria Carolina N.R. Neves,[1] Andrea C.E.P. Valenca,[1] Luis H.B.C. Sette,[1] Maria Alina G.M. Cavalcante,[1] Denise M.A.C. Malheiros,[2] Lucila Maria Valente.[1] *[1]Nefrologia, Hospital das Clinicas-UFPE, Recife, Pernambuco, Brazil; [2]Patologia, Universidade de Sao Paulo, Sao Paulo, Brazil.*

Background: Pamidronate has been described as a cause of Collapsing Glomerulopathy (CG). This is a distinct clinicopathologic entity seen in patients with HIV infection and has its main feature as renal insufficiency and nephrotic syndrome (NS).

Methods: A 60 years old woman with multiple myeloma (MM), diagnosed in 2004, was submitted to autologous stem cell transplantation. Pamidronate therapy was initiated in 2007, at a dose of 90mg IV monthly. In 2011, she presented with impairment of renal function and NS (Proteinuria 3.8g/d, albumin 1.7g/dl and edema). MM was in remission (urinary immunoelectrophoresis and bone marrow examination were without abnormalities). Pamidronate therapy was stopped and a renal biopsy was performed, which was consistent with CG with moderate interstitial fibrosis and tubular atrophy with microcystic degeneration. The immunohistochemical (IHC) analysis showed positive staining for CD-10, WT-1 and CK-19 (arrow) and negative staining for Ki67 and synaptopodin (arrow).

Immunohistochemical Markers

Markers of Podocyte Differentiation	Markers of Podocyte Dedifferentiation
WT-1 (+)	CK19 (+)
CD10 (+)	Ki67 (-)
Synaptopodin (-)	



Two months later, she started hemodialysis.

Conclusions: We described a case of CG associated with the use of pamidronate and its IHC profile.

PUB571

Purpuric Rash: A Benign Pediatric Disease Can Be Extremely Rare and Critical in an Adult Subhasish Bose, Joseph Benjamin. *Department of Nephrology, Temple University Hospital, Philadelphia, PA.*

Background: We present a 30 year old previously healthy Caucasian female with a purpuric rash. The final diagnosis represents a primarily childhood vasculitis which is extremely rare in adults.

Methods: Our patient presented with limb swelling, polyarthralgia and crampy diffuse abdominal pain with loose stool for 4 days. One week prior to this, patient had URI symptoms. On admission, patient was noted be afebrile, distressed with abdominal pain and had purpuric rash on her lower extremities. Lab data included a normal chemistry panel (serum creatinine 0.69 mg/dl) and normal CBC except total WCC of 19.4 X 10*3/uL with no bandemia. Pregnancy test was negative. CT scan of abdomen and pelvis revealed small bowel wall thickening with mesenteric lymphadenopathy. Colonoscopy showed scarring of the ileocecal valve and ulcerations in transverse colon. ANA, Anti-ds DNA, ANCA, Anti-Smith, Anti-RNP, RF, C3&C4, Hepatitis serologies, respiratory viral panel, Monospot, blood & stool culture, hemolysis screen were all normal. Echocardiogram showed normal EF, no endocarditis. Over next 5 days, patient's renal function rapidly deteriorated with significant proteinuria and microscopic hematuria. Her purpuric rash spread to all extremeties. Biopsy

samples from skin and kidney were obtained and patient was started on high dose steroid. At this point, patient developed dyspnea and seizure needing intubation. Subsequently, patient was started on hemodialysis(HD) and plasmapharesis. Patient's ASO titre came back as high. Colonic and skin biopsies were inconclusive. Kidney biopsy was consistent with IgA mediated glomerular disease strongly suggestive of Henoch-Schonlein Purpura(HSP). Patient's clinical condition progressively improved, she was extubated successfully but needed routine HD with hope of regaining significant kidney function.

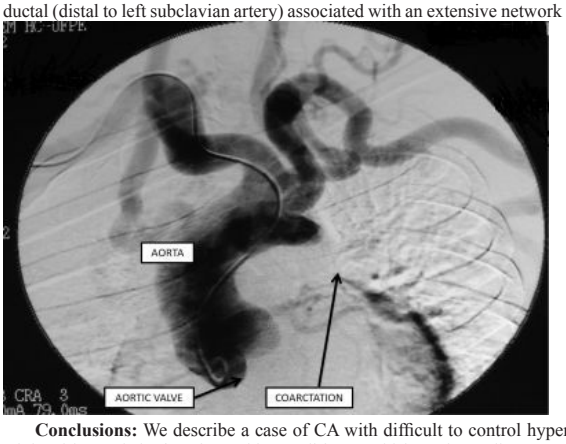
Conclusions: HSP is a systemic disease where antigen-antibody (IgA) complexes activate the alternate complement pathway, causing small vessel vasculitis. It is often triggered by streptococcal URI. Early recognition and appropriate timely intervention is extremely crucial to manage the disease and limit organ damage.

PUB572

Coarctation of the Aorta in a 46 Years-Old Man as a Cause of Severe Hypertension and Renal Dysfunction: The Importance of Physical Examination in Nephrology Marclebio M.C. Dourado, Camila B.l. Oliveira, Edmir R.B. Dias, Maria Carolina N.R. Neves, Andrea C.E.P. Valenca, Luis H.B.C. Sette, Maria Alina G.M. Cavalcante, Lucila Maria Valente. *Nefrologia, Hospital das Clinicas-UFPE, Recife, Pernambuco, Brazil.*

Background: Coarctation of the aorta (CA) is a rare cause of secondary hypertension in adults and leads to a poor cardiovascular prognosis.

Methods: A 46-years old patient presented to consultation with difficult to control hypertension and renal dysfunction (CrCl 48mL/min/1.73m^2). He has been using his medications irregularly for the last 25 years, until 4 years ago, when he had an episode of pulmonary edema requiring hospitalization. At that time, brachial access coronary angiography showed mild coronary atherosclerosis. Echocardiography revealed moderate concentric left ventricular hypertrophy, slight enlargement of the aortic root and ascending aorta, without valvular abnormalities. Physical examination revealed asymmetric pulse in upper and lower limbs and asymmetric blood pressure (BP) in all four limbs. BP (mmHg) in the left and right upper limbs were 240x120 and 230x110; left and right lower limbs were 120x80, 130x80. There was no bruit over subclavian arteries or abdominal aorta. Patient reported no history of claudication. CT angiography showed severe stenosis of the descending aorta after the left subclavian artery branch and hypertrophy of the intercostal, mammary and epigastric arteries. Angiography showed arterial occlusion after aortic ductal (distal to left subclavian artery) associated with an extensive network of collaterals.



Conclusions: We describe a case of CA with difficult to control hypertension in an adult with renal dysfunction. This condition could have been discovered earlier with physical examination and prevent kidney and heart failure. The patient is now awaiting surgical procedure.

PUB573

Extreme Pseudohyperkalemia in a Patient with Acute Myelogenous Leukemia Nadear A. Elmahi, Kenneth E. Kokko. *Department of Medicine, Division of Nephrology, University of Mississippi Medical Center, Jackson, MS.*

Background: Pseudohyperkalemia occurs in some patients with extreme leukocytosis and the diagnosis is often difficult to establish. We describe a challenging case of possible pseudohyperkalemia associated with extreme leukocytosis.

Methods: 55 year old African American male was seen in the oncology clinic on 07/28/11 for follow up of acute myelogenous leukemia for which he refused chemotherapy. During that visit his potassium (K) was normal and WBC was moderately elevated. Subsequent visits revealed progressive hyperkalemia and worsening leukocytosis. On August 18, he refused hospital admission for K of 8.8 mmol/l with normal ECG. On August 22 he came to the hospital for evaluation of shortness of breath. Initial work up was significant for K of 15.3 mmol/l, WBC of 403 th/cmm and Creatinine of 1.6 mg/dl. Repeat K the next day was 15.5 mmol/l.

Lab Results

Date	WBC (th/cmm)	Potassium (mmol/l)
7/28/11	23	Normal
08/04/11	139	5.6
08/18/11	240	8.8
08/22/11	403	15.3

Potassium and WBC count

Initial and repeat ECGs showed atrial flutter with no findings suggestive of hyperkalemia. Careful handling of the sample, measurement of plasma potassium and measurement of potassium in arterial blood gas (ABG) were not helpful in establishing the diagnosis of possible pseudohyperkalemia. The patient and family refused aggressive interventions (dialysis and leukophresis) and chose comfort care. Diagnosis of pseudohyperkalemia was assumed and no further treatment was offered. The patient expired 48 hours later after major stroke due to leukocytosis.

Conclusions: The lessons learned from the case include: 1) Pseudohyperkalemia should be considered as cause of elevated potassium in patients with substantial leucocytosis who do not have clinical or ECG changes suggestive of hyperkalemia, 2) Comparison of serum and plasma potassium and measurement of potassium in ABG may help in establishing the diagnosis of pseudohyperkalemia. However, the diagnosis should not fully ruled out based on negative results 3) The diagnosis should be considered in the right clinical setting even in the absence of confirmatory tests since aggressive treatment can lead to life-threatening hypokalemia.

PUB574

Acute Renal Failure Complicating Preeclampsia/HELLP Khin S. Yee. *Renal Department, SUNY Downstate Medical Center, Brooklyn, NY.*

Background: Acute renal failure complicating preeclampsia is rare but serious. It is often a diagnostic challenge as it carries overlapped manifestations with TTP where plasma exchange is the mainstay of treatment. This case demonstrates a rare presentation of acute renal failure secondary to preeclampisa/HELLP.

Methods: Medical record review of a a previously healthy woman for clinical course, diagnostic studies, treatment strategies and overall outcome.

Results: 34 year old female G1P0 with gestational hypertension presented to ER @ 40 weeks. On admission, patient's BPs were 130-150/70-80, asymptomatic except labor pain with normal lab values. She was treated with cytotec for induction of labor followed by epidural four hour later. At that time her BPs were significantly increased with sign of fetal distress. Patient started complaining of epigastric discomfort. Repeat labs showed elevated liver enzymes, coagulopathy, thrombocytopenia and hemolytic anemia consistent with HELLP/preeclampsia. Primary cesarean section was performed. Patient received 2 units FFP, 1 unit platelet and magnesium. Creatinine started to rise post op day 1 and peaked to 6.14 over 6 days. Due to relentlessly rising creatinine while LFT and coagulation profile were improving, question of whether renal biopsy should be pursued arose. Peripheral smear showed occasional schistocytes seen average 1 per 3-5 hpf. Given patient's asymptomatic nature, decision was made to defer renal biopsy. Renal function improved after 2 sessions of dialysis and back to baseline in a week.

Conclusions: Preeclampsia/HELLP complicated with acute renal failure is a rare entity with only few cases reported in literature. Vasoconstriction that characterizes preeclampsia,leads to mild functional renal impairment and improves completely after delivery of the fetus. Early prophylactic dialysis of acute renal failure is associated with rapid renal recovery. However, no data are available on long-term renal outcome due to paucity of such cases. Bilateral renal cortical necrosis seen most commonly in women with underlying chronic hypertension and superimposed preeclampsia is associated with more severe adverse maternal and fetal outcomes.

PUB575

Pseudoacidosis due to the Presence of a Plasma Inhibitor Naveen S. Sandhu,[1] Michael Shoemaker-Moyle,[1] Son G. Lam,[2] Vikram R. Beemidi,[1] Luis A. Juncos.[1] *[1]Division of Nephrology, University of Mississippi Medical Center, Jackson, MS; [2]Oxford Nephrology Associates, LLC, Oxford, MS.*

Background: A patient presented to an outside hospital with a low serum bicarbonate (HCO3-) and high anion gap (AG). She had no signs or symptoms of acidosis despite a HCO3- level of 1.6 mmol/L with an AG of 33. She received a HCO3- infusion, but her serum HCO3- remained low and her AG persisted. A workup for a high AG acidosis was negative. She was then referred to our hospital where our lab confirmed the low measured HCO3- level using Cobas bicarbonate liquid test. Her blood gas showed a pH of 7.39 and pCO2 of 41. With the normal blood gas and the negative work up for acidosis the validity of the lab measurement for serum HCO3- came into question.

Methods: To assess for a substance interfering with the lab test, we performed serial dilutions of the sample. The HCO3- level measured by the Cobas assay increased with dilution but remained below the predicted HCO3- level which is consistent with the presence of an interfering substance. An alternative method to measure serum HCO3- is the Vitros ECO2 slide method. In this test a drop of serum is placed on a multilayered slide where it diffuses from the initial spreading layer to the gel layer where the same enzymatic reactions occur as in Cobas assay. Theoretically a large enough interfering substance would not be able to diffuse through the spreading layer and interfere with the enzymatic reactions. When the patient's serum was analyzed using this method her HCO3- was 27. This implies that an interfering compound was too large to diffuse through the spreading layer and her serum HCO3- could undergo the requisite enzymatic reactions to yield an accurate result.

Conclusions: The spuriously low HCO3- value in this case results in a high AG without a detectable endogenous or exogenous acid. A similar case was reported in NDT (Navaneethan, et al) in 2008. To our knowledge no other examples of this phenomena have been reported. Reduction in the serum HCO3- due to an interfering substance should be considered in an asymptomatic patient presenting with a high AG acidosis without detectable exogenous or endogenous acids.

PUB576

Use of Citrasate Dialysate in Extended Dialysis Kunal Malhotra, Venkatesh Kumar Ariyamuthu, Vibhu Dhawan, Preethi Yerram. *Department of Nephrology, University of Missouri, Columbia, MO.*

Background: Anticoagulation for continuous renal replacement therapy(CRRT) can be challenging in acutely ill patients due to the risk of bleeding with heparin, and the risk of citrate toxicity with regional citrate anticoagulation, especially in patients with decompensated liver failure. We describe our experience in an acutely ill patient who successfully underwent extended dialysis with citrasate dialysate.

Methods: 53-year-old male with end stage renal disease on chronic hemodialysis three times a week via arterio-venous fistula presented with delirium, abdominal pain, jaundice and septic shock, and was initiated on broad-spectrum antibiotics, vasopressors and intubated for respiratory failure. He was found to have pancytopenia, ischemic liver injury, metabolic acidosis and worsened rapidly to develop disseminated intravascular coagulation (DIC) and bleeding from IV lines and other orifices. He received multiple transfusions of red blood cells and fresh frozen plasma and developed abdominal compartment syndrome and anasarca. He required CRRT for acidosis and attempted fluid removal. However, heparin couldn't be used because of ongoing bleeding, while citrate use was undesirable given the risk of citrate toxicity. The patient was started on CRRT with citrasate dialysate (CD) that continued for 20 hours before clotting.

Relevant labs

	Serum bicarbonate meq/L	Serum sodium meq/L	Anion gap	Ionized Calcium
pre CRRT	15	141	30	1.09
post CRRT	28	138	14	1.04

Conclusions: CD contains a low concentration of citric acid (2.4meq/L) that can provide anti-coagulation in the extra-corporeal circuit, without any systemic anticoagulant effects. When faced with a therapeutic dilemma of choosing an anticoagulant to prevent clotting of the CRRT circuit in patients with bleeding diatheses, dialysis with CD is a viable option that seems to be safe and effective.

PUB577

Pregnancy & Renopancreas Transplant: Is Patient Satisfaction Enough? Amelia Rita Bernasconi,[1] Ricardo M. Heguilen,[1] Rosa Alejandra Waisman,[1] Jorgelina Petroni,[3] Roland C. Blantz.[2] *[1]Medicine, Hospital J.A.Fernandez, Bs As, Caba, Argentina; [2]Medicine, University of California, San Diego, CA; [3]Nephrology, Instituto de Nefrología de Bs As, Bs As, Caba, Argentina.*

Background: The major benefit of a pancreas-kidney graft (KPT) is an improvement of QOL due to freedom from both insulin & dialysis, along with the prevention of progressive DBT-associated organ damage. Better organ preservation and immunosuppressive therapies improved graft-survival. Prenatal counselling must address maternal & fetal complications. We communicate the outcome of pregnancy in a (DKPT) recipient.

Methods: A 30 year-old, DKPT recipient in 2008, underwent successful pregnancy after a complex medical history of diabetes in her childhood with retinopathy & polyneuropathy, hypothyroidism, and ESRD afterwards. She became pregnant in 2011, MMF was withdrew and switched into a pregnancy-friendly schedule (AZA, TAC, prednisone). Scr was 1.7 mg/dl and remained initially stable; increased near delivery (36.2 wks) and remained at 2.5 mg /dl postpartum. Her BP increased near term without need of medication, serum uric acid rose to 6.52 mg/dl and proteinuria developed. She was normoglycemic, with normal pancreatic and hepatic function throughout pregnancy and postpartum. Epo and iron (H^{to} 24.7%, HB 8.2 g/dl) were prescribed. Betamethasone was given for fetal lung maturity. She developed preterm premature rupture of membranes, with clear amniotic fluid; methylprednisone pulse was given peripartum to avoid intra and postpartum stress. She delivered vaginally a healthy baby (BW: 2100 g., intrauterine growth retardation) with no congenital anomalies & Apgar 9/10. Both were discharged home 3 days later without complications. Breastfeeding was inhibited. There was no postpartum hypertension and she continued with increased but stable renal parameters. Three months later her Scr returned to baseline.

Conclusions: Pts should be advised of the high risk of graft loss, and adverse pregnancy outcome. CIN should be used with caution; adequate levels of immunosuppressive drugs must be maintained to avoid acute rejection. Preterm delivery, IUGR and low birth weight are common probably due to adverse effects of drugs.

PUB578

Hyponatremia due to Reset Osmoreceptor in HIV Positive Patient Devang V. Lodhavia, Zohreh S. Soltani. *Nephrology, LSUHSC, New Orleans, LA.*

Background: Hyponatremia is a common manifestation in HIV infection and AIDS. Most of this patients have SIADH but in some cases may be due to intravascular volume depletion, adrenal insufficiency and CNS infection. Here we present a case of SIADH variant of reset osmoreceptor in a patient with HIV and CNS infection.

Methods: A 31 year old African American male with past medical history of HIV presented with altered mental status. Initial serum work up was normal. CT Head showed a brain mass with midline shift. The patient was underwent an open brain biopsy with final diagnosis of toxoplasmosis. However the patient had his sodium dropped from 136 to 127 mEq/L after his cranial surgery. At this point, he was started on 3% normal saline (NS) by primary team but sodium remained stable at 131mmol/l after 3 days. Nephrology was consulted due to persistent hyponatremia. Further workup revealed urine osmolality of 751 moms/kg (while he was on hypertonic fluid), urine sodium of 204 mol/l, serum osmolality of 264 mosm/l, uric acid of 3.9 mg/dl and normal cortisol and TSH level. Despite continuous 3% NS for two more days sodium level remained in range of 128-131 meq/L. Based on the available clinical and laboratory data, we made a presumptive diagnosis of the syndrome of inappropriate antidiuretic hormone (SIADH). After 5 days of fluid restriction and tolivaptan therapy, his sodium levels failed to rise above a high of 131 mEq/L. As patient remained persistently hyponatremic, the diagnosis of reset osmostat secondary to neurological infection and surgery was implied. In our patient we confirmed the reset osmostat variation of SIADH by giving a free-water challenge. He was discharged home with follow-up upon which his sodium level continued to be stable at 131 mEq/L.

Conclusions: Hyponatremia due to downward resetting of osmostat is one form of the SIADH. Because it has been suggested that one third of the SIADH might be due to the reset osmostat, we recommend that physicians consider investigating this possibility when appropriate. Identification of a reset osmostat is important because the therapeutic recommendations for the SIADH may not apply for this variant.

PUB579

Renal Cell Carcinoma in the Transplanted Kidney Sayed Husain, Noori Al-Waili, Anita K. Patel, Mariella Goggins, K.K. Venkat. *Nephrology/Transplant, Henry Ford Health System, Detroit, MI.*

Background: Immunosuppression increases the risk of malignancies. Renal cell carcinoma (RCC) develops mainly in native kidneys and it is rare in the allograft. We report 3 recipients who developed RCC in their allograft.

Methods: The first patient was a 57 year old female with end stage renal disease (ESRD) secondary to lupus nephritis who received a living related kidney transplant (LRKT) with zero haplotype match in 1994. She was treated with azathioprine (AZA), cyclosporine (CyA). MRI in 2011 due to chronic abdominal pain showed a new 1.3 cm mass in the allograft and biopsy showed conventional clear cell RCC. The second case was a 45 year old female with ESRD due to unknown eiology and underwent a LRKT with one haplotype match in 2001. Her regimen was CyA and MMF. Ultrasonography in 2011 for microscopic hematuria, showed a complex cyst and mass of 1.3 cm in the allograft. Biopsy revealed papillary RCC. The third patient was 46 year old male with ESRD associated with IgA nephropathy that underwent LRKT with zero haplotype match in 1997 and was given CyA and MMF**.** In 2011, due to increasing serum creatinine ultrasound and CT scan showed a solid and vascular lesion 3.1 cm the allograft. Nephrectomy specimen showed RCC. Total allograft nephrectomy was performed and dialysis was reinstituted in all of them.

Conclusions: The uniqueness of this case series is that in all 3 patients RCC developed in the allograft following LRKT suggesting the possibility of an inherited susceptibility aggravated by immunosuppression. Also of interest is the development of RCC after a span of many years suggesting that the tumor was not transplanted with the allograft. The donors have been advised regular monitoring for the development RCC in their remnant native kidney**.** Allograft RCC cases have been reported to be very rare (0.32% to 0.45% incidence). Genetic analysis using fluorescence in situ hybridization (FISH) and DNA microsatellite analysis of the tumor have generally revealed donor-cell origin of the tumor. Partial nephrectomy and percutaneuos ablation of the tumor to preserve renal function has been performed though our patients were treated by total allograft nephrectomy.

PUB580

IgA Nephropathy and Amyloidosis Associated with Ankylosing Spondylitis Ikuyo Narita, Michiko Shimada, Takeshi Fujita, Yuko Shimaya, Reiichi Murakami, Norio Nakamura, Hideaki Yamabe, Ken Okumura. *Nephrology, Hirosaki University, Hirosaki, Japan.*

Background: Ankylosing spondylitis (AS) is a chronic inflammatory disease of the vertebral joints and soft tissues. Although the kidneys can be affected sometimes, the precise etiology and causal relationship remain to be elucidated. A patient with IgA nephropathy and amyloidosis associated with AS is presented.

Methods: A 58-year-old male with a three-year history of hypertension, anemia and micro-hematuria was admitted with fever, rapid onset of edema, weight gain, gross hematuria, proteinuria and pleural effusion. Last doctor's visit was 3 years ago. Blood pressure was 170/85mmHg, physical examination was compatible with presenting symptoms. Laboratory data were as follows: Hb 9.1 g/dl, total protein 6.0 g/dl, albumin 3.0 g/dl, BUN 18 mg/dl, serum creatinine (s-Cre) 0.96 mg/dl, CRP 13 mg/dl, IgA 573 mg/dl, serum protein electrophoresis: negative, antinuclear antibody:negative, C3/C4 :normal, urinary protein 1.1 g/24hr. Renal biopsy revealed mild mesangial proliferation in Periodic acid-Schiff staining, Congo Red negative on light microscopy (LM), IgA positive staining on immunofluorescence microscopy (IF) and electron dense mesangial deposits were seen on electron microscopy (EM), compatible with diagnosis of IgA nephropathy. After exclusion of other etiologies, treatment with corticosteroid resulted in normalization of CRP and resolution of fever. The patient was re-admitted a year later with low back pain, massive lower extremity edema, low grade fever, s-Cre 1.35 mg/dL, CRP 13.6 mg/dL and urinary protein 4.0 g/24hr. Skeletal x-rays showed typical bamboo-spine which is diagnostic feature for AS. Repeat renal biopsy now revealed disappearance of IgA deposition on IF and EM, but with appearance of Congo Red positive deposits on LM, and amyloid fibrils on EM, compatible with amyloidosis.

Conclusions: We experienced a case of AS complicated with IgA and renal amyloidosis. One year steroid therapy was effective for his IgA nephropathy, whereas it was not effective to prevent the progression to amyloidosis.

PUB581

Tolvaptan Is a New Therapeutic Tool for Patients with Congestive Heart Failure Who Underwent Peritoneal Dialysis Noriaki Iino, Ichiei Narita. *Division of Nephrology and Rheumatology, Niigata University, Niigata, Japan.*

Background: Peritoneal dialysis is one of the blood purification therapies for end-stage renal diseases. Some PD patients occasionally developed congestive heart failure due to ultrafiltration failure of peritoneal dialysis. Patients suffered from congestive heart failure; they received some medical interventions such as prescription of increased doses of diuretics or modification of peritoneal dialysis regimens. Patients did not respond to these therapies; they required more intensive interventions such as ultrafiltration using extracorporeal circulation. Recently, we can use vasopressin V2 receptor antagonist, tolvaptan for the treatment of loop-diuretics resistant congestive heart failure in Japan. We tried to verify the capability of tolvaptan for the PD patients with congestive heart failure.

Methods: Case was 59 years old male. He developed end-stage renal disease because of progression of diabetic nephropathy. Peritoneal dialysis started since August 2010. His peritoneal equilibrium test was high. Thus, It was difficult to maintain optimal extracellular body fluid by conventional peritoneal dialysis. In September 2011, he felt dyspnea on exertion. The chest x-ray reveled moderate cardiomegaly and lung congestion. He had diagnosed congestive heart failure. On laboratory tests, a value of B-type natriuretic peptide elevated at 1778 pg/ml. After he had admitted a hospital, he prescribed tolvaptan 15mg once daily. One day after admission, his body weight decreased by 3kg. Tolvaptan effectively increased his urine output. Moreover, tolvaptan also increased his peritoneal drain volume. Thus, his symptom of congestive heart failure gradually improved. Six days after admission, a value of B-type natriuretic peptide decreased to 380 pg/ml.

Conclusions: According to this experience, we believe tolvaptan is a promising drug for patients with congestive heart failure who received peritoneal dialysis. Futhermore,if tolvaptan can substitute for ultrafiltration therapy using extracorporeal circulation, patients with severe congestive heart failure will receive safety benefits because of not requiring central venous catheter insertion.

PUB582

An Unusual Case of Membranous Nephropathy Antoine Azar, Apurv Khanna. *Nephrology, Suny Upstate Medical University, Syracuse, NY.*

Background: Currently accepted treatment for high risk idiopathic membranous nephropathy is combined immunosuppressive treatment. Here we present an unusual case in which patient responded to steroids alone.

Methods: A 52 year old man with DM 2,previous history of cocaine abuse,and a normal serum creatinine,presented with shortness of breath,and anasarca,he denied any non-steroidal anti-inflammatory drugs use.A spot urine protein creatinine ratio of >20 gram protein per gram creatinine.Subsequently he rapidly developed worsening kidney function and hyperkalemia necessitating dialysis,serologic work up was negative,Kidney biopsy showed subepithelial deposits(IgG and C3),thickening of glomerular basement membrane,secondary focal segmental glomerulosclerosis with foot process effacement,and tubulitis,consistent with membranous nephropathy. Due to a history of irregular adherence to treatment he was started on Prednisone alone(Dose mg/kg)with the intent to initiate further immunosuppression on outpatient followup.His kidney function improved within 10 days after starting steroids,he did not require further dialysis any more,his serum creatinine improved to 1.5 mg/dl,a follow-up spot urine protein creatinine ratio showed a decreased proteinuria to 3 gram protein per gram creatinine,patient was discharged home. He was then lost to follow up and presented months later with a similar presentation.During this hospitalization,kidney function again deteriorated significantly necessitating dialysis;He was restarted on prednisone,within 7 days his serum creatinine normalized;his proteinuria improved to 3 from 10 in a spot urine sample.

Conclusions: UK research Council studied 52 patients with idiopathic membranous nephropathy with heavy proteinuria (10 g/day) and normal renal function treated with steroids,and compared them with 51 patients with same characteristics treated conservatively,study showed steroids alone did NOT show better results. High risk patient are those with proteinuria of >8 grams/day,renal function that is either below normal or declines over three months despite maximum conservative therapy. Our case is unique because it represents a high risk membranous nephropathy patient who responded to steroids alone on two occasions.

PUB583

An Unusual Case of Hyponatremia Varun Malhotra,[1] Medha Joshi,[2] Pooja Singh,[1] Rakesh Gulati.[1] *[1]Nephrology, Thomas Jefferson University, Philadelphia, PA; [2]Internal Medicine, Mercy Catholic Medical Center, PA.*

Background: Differentiating Syndrome of inappropriate antidiuretic hormone hypersecretion (SIADH) from renal salt wasting (RSW) rests on evaluation of the patient's "effective arterial blood volume (EABV)." We present a case which illustrates that EABV assessment based solely on clinical exam can often be misleading.

Methods: 68-year old woman with past history of breast cancer and failure to thrive; presented with productive cough. Physical examination was remarkable for a cachectic female, afebrile, pulse of 70/min, BP 118/74, with no orthostasis, respiratory rate of 16/min, crackles over the left lung base but no jugular venous distention or peripheral edema. CXR showed a left lower lobe infiltrate. Initial labs were impressive for a serum osmolality of 260 mosm/L, serum sodium of 122 meq/L, creatinine of 0.5 mg/dL, Uosm of 426 mosm/kg, urine sodium (Una) of 101 mmol/L and urate of 0.9 mg/dL. TSH and cortisol were normal. A diagnosis of SIADH secondary to the lung process (pneumonia) was made. Over the next two days, her serum sodium dropped to 112 meq/L despite strict fluid restriction and protein supplementation. Symptoms of nausea and headache prompted treatment with hypertonic saline. While repeated clinical and laboratory evaluations showed no evidence of volume depletion, echocardiogram revealed a small LV cavity and collapsed IVC consistent with low central venous pressure. Una and Uosm were persistently elevated. Further questioning revealed a history of nocturia for several years in the setting of chronic analgesic use and past cisplatin use for breast cancer. Possibility of RSW was entertained. Her serum sodium improved slowly to >130 meq/l over the next 4 days with IV normal saline, salt tablets and fludrocortisone. We concluded that her hyponatremia was a result of RSW from chronic tubulointerstitial disease.

Conclusions: A valid diagnosis of "salt wasting" requires evidence of inappropriate urinary salt losses and a reduced "EABV." The clinical assessment of EABV, is fraught with errors unless invasive procedures, like determination of blood volume by radioisotope dilution methodology, pulmonary wedge, or central venous pressures are used.

PUB584

Adult Minimal Change Disease with Acute Kidney Injury Elise J. Barney, James Wilson. *Nephrology, Olive View-UCLA Medical Center, Sylmar, CA.*

Background: Introduction: Minimal change disease (MCD) is responsible for 10-15% of primary nephrotic syndrome in adults. Acute kidney injury (AKI) in the setting of MCD is uncommon; pathology shows foot process effacement and focal proximal tubular epithelial flattening. The following is a case in which the severe tubular injury led to a pathological misclassification as ATN rather than MCD.

Methods: Case: A 43 year-old Hispanic man was admitted for lower extremity edema following recent discharge from an outside hospital, where he had kidney biopsy done for nephrotic syndrome. At the time of initial presentation, labs noted serum creatinine of 5.5 mg/dL, urea nitrogen of 54 mg/dL, serum albumin of 1.1 g/dL, and 6.7% eosinophilia. Proteinuria workup was unremarkable. Renal ultrasound noted normal echogenicity and minimal fluid anterior to right kidney. History was significant for food-associated urticaria 2 months prior and NSAID use over the past 6 weeks. Physical exam noted blood pressure 125/81 mm Hg and anarsaca; 24-hour urine revealed 66 gm of protein. Biopsy pathology reported severe diffuse ATN. However, given significant proteinuria, a pathology second opinion was obtained. Light microscopy review noted irregular flattening of many tubular cells, debris and granular casts in tubules with mild diffuse edema of interstitium. Immunofluorescence demonstrated IgG pseudolinear staining; electron microscopy revealed effacement of foot processes and no electron dense deposits. The patient was diagnosed with MCD. After 9 weeks of prednisone, the serum creatinine was 0.95 mg/dL and urine protein/creatinine ratio was less than 0.140.

Conclusions: Discussion: This case illustrates the importance of obtaining a second opinion if the initial biopsy read is not consistent with the clinical picture. In this case, the biopsy was incorrectly read as ATN, but upon second opinion, was correctly diagnosed as MCD. Potential mechanisms for ATN coexisting with MCD may be secondary to renal interstitial edema and/or ischemic tubular injury. Associated risk factors are older age, hypertension, vascular disease, high protein excretion, and very low serum albumin. The AKI is usually reversible with complete recovery of function.

PUB585

Tenofovir (TDF) Induced Acute Kidney Injury Joseph Zhao, Louis A. Carrera, Maria V. DeVita, Michael F. Michelis. *Division of Nephrology, Lenox Hill Hospital, New York City, NY.*

Background: Tenofovir (TDF) is a commonly used to treat human immunodeficiency virus infection and has been only rarely reported to cause acute renal injury. Since its use in 2001, less than 40 cases have been reported with last series done in 2010. We report a case of TDF nephrotoxicity in a woman on the medication for 18 months.

Methods: A 57 year old Hispanic woman with CKD 3 (creatinine 1.7mg/dL and proteinuria 500mg); DMII and HTN, with HIV since 1996, on anti-retroviral therapy. To reduce pill burden, she was changed to Atripla (efavirenz, emtricitabine, and tenofovir) in 2010. She developed AKI with an increase in creatinine to 3.5 mg/dL and proteinuria of 2195 mg/g creatinine. Her viral load was undetectable; CD4 count 828; urinalysis revealed blood, 4-20 rbc, no wbc, 1+ protein, no glucose or casts. Since Nexium and alendronate were possible nephrotoxic agents, both were discontinued; despite this, her creatinine continue to increase.BP 138/68 mmHg; she was clinically euvolemic without edema or localizing findings. HbSAg, Hep C AB, anti-ds DNA, myeloperoxidase AB, proteinase-3, and immunofixation were all negative. C3 and C4 were normal. With worsening in her condition, a kidney biopsy was performed which revealed a distinctive pattern of proximal tubular injury characterized by severe mitochondrial damage due to TDF induced renal injury. Her medication was changed to Combivir and Efavirenz in May 2012 with a decrease in her creatinine to 2.4 mg/dL within 4 weeks.

Conclusions: AKI is a known adverse effect of TDF, however, empiric discontinuation of her anti-retroviral therapy was fraught with concern since her HIV was controlled. Most cases occur within a median of 8 months after initiating therapy. In addition, most cases also display Fanconi's Syndrome. Despite the presence of severe renal failure, our patient showed significant improvement after TDF cessation. It is important to emphasize that TDF nephrotoxicity does not occur immediately and has been reported as late as 2 years after initiation. Kidney biopsies are critical to establish a diagnosis prior to empiric change in anti-retroviral treatment in this rare but potentially serious complication.

PUB586

43-Year-Old Woman with Systemic Lupus, Abdominal Pain, New-Onset Severe Hypertension, and Bilateral Perinephric Hemorrhage Ivan E. Porter, William E. Haley. *Internal Medicine, Mayo Clinic, Jacksonville, FL.*

Background: Connective tissue disease can manifest with the onset of renal failure suggesting lupus nephritis. Definitive diagnosis requires biopsy as well as broad differential and consideration of associated conditions as illustrated in this case.

Methods: A 43-year-old female with history of systemic lupus and no renal involvement presented with 5 days of worsening bilateral lower abdominal pain radiating to the back. There was history of treatment for chronic refractory autoimmune thrombocytopenia with low dose prednisone, danazol, eltrombopag and intermittent IVIG. On PE, BP 164/108, HR 105; she was in acute distress. Abd was soft, nondistended, with no organomegaly, but tenderness to palpation diffusely. Tests revealed Hbg 10.6 g/dL, WBC count 24,700, plts 134,000, INR 2.1, creatinine 2.1 mg/dL, and UA positive for moderate occult blood and microhematuria. Complement levels normal, negative c-ANCA, PR3, MPO, anti-DNA and cryoglobulins, positive p-ANCA and IgG phospholipid antibody, and high titer ANA and SS-A. Abd CT scan showed bilateral renal subcapsular hematoma and retroperitoneal hemorrhage. Angiogram showed innumerable areas of well-contained extravasation (pseudoaneurysms) throughout the renal parenchyma. Renal biopsy showed focal medium artery transmural disruption with perivascular fibrin extravasation, zonal cortical necrosis with ATN and GBM ischemic corrugation but no evidence of immune complex processes on IF or EM. Renal failure worsened requiring dialysis and she also required coil embolization of branch arteries on two separate occasions to control hemorrhage. She was treated with glucocorticoid and cyclophosphamide. Three months following presentation she experienced sudden death following acute onset abdominal pain.

Conclusions: This patient had polyarteritis nodosa (PAN) associated with systemic lupus and autoimmune thrombocytopenia, and manifesting severe new-onset hypertension, renal failure, intrarenal and perinephric hemorrhage. Poor prognosis despite aggressive treatment was demonstrated with death occurring within 3 months of presentation.

PUB587

Reversible Fanconi Syndrome Associated with Human Immunodeficiency Virus Alex J. Hernandez, Zohreh S. Soltani. *Department of Medicine/Section of Nephrology, LSUHSC-NO, New Orleans, LA.*

Background: Renal disease is a common complication of patients infected with the human immunodeficiency virus (HIV); it can be directly related to the virus, or associated to the highly active antiretroviral therapy (HAART). Since the introduction of HAART, a variety of renal side effects have been recognized and vary from proteinuria to acute renal failure.

Methods: A 45-year-old Caucasian man with HIV infection for five years, was referred to the renal clinic for proteinuria work-up. He noticed increase thirst, polyuria, as well as fatigue for the last six weeks. He was taking lisinopril, ritonavir, atazanavir, and emtricitabine/tenofovir. He was compliant with his medications, does not use tobacco, alcohol or drugs. He denied use of NSAIDs or herbal supplements. Physical examination was unremarkable, except for trace edema. The laboratory data was normal except creatinine 1.54 mg/dL, and phosphorus 1.8 mg/dL. A urine analysis showed a pH of 5.0, protein of 150 mg/dL, glucose of 1000mg/dL and blood of 25/uL. protein creatinine ratio 1719 mg/g. Hemoglobin A1c was 5.1%. Renal ultrasound was normal. Serum and urine protein electrophoresis did not reveal gammopathy.

Conclusions: Fanconi syndrome was suspected secondary to antiretroviral tenofovir. Therapy was changed to darunavir and lamivudine/zidovudine. Phosphorus was replaced orally. A follow-up appointment showed a decreased proteinuria of 654 mg/day, MACR 85 mcg/mg, phosphorus within normal limits and no glucosuria on urine dipstick. Fanconi syndrome consists of a generalized defect of membrane transporters in the proximal tubule, leading to renal loss of glucose, as well as a loss of phosphate, calcium, uric acid, amino acids, bicarbonate and tubular proteins. This case confirms the previously reported association of tenofovir with Fanconi syndrome. It is recommended that patients on this drug should be followed closely after initiation of therapy and should have a urinalysis, serum creatinine, and electrolytes performed on a regular basis. It is important for clinicians to recognize this potential side effect, so that patients with similar scenarios may be discovered early and be switched to an alternate antiretroviral therapy.

PUB588

Membranous Lupus Nephritis in the Absence of Serum Anti-Nuclear Auto-Antibodies Hanni Menn-Josephy, Ramon G. Bonegio, Jean M. Francis, Ian R. Rifkin. *Nephrology, Boston University Medical Center, Boston, MA.*

Background: Membranous lupus nephritis and nephrotic syndrome can occasionally present in patients with negative ANA. Most of these patients will become ANA positive later in the course of the disease.

Methods: A 36 year old Hispanic female presented with a 4 month history of weight loss, diffuse lymphadenopathy and intermittent fever. Two months later she developed acute pulmonary emboli from a left leg DVT. One month thereafter, she was hospitalized for abdominal pain. She had cervical and axillary lymphadenopathy but no other abnormalities on exam. Serum creatinine and electrolytes were normal but she had hypoalbuminemia, microcytic anemia and lymphopenia. Urinalysis revealed 3+ protein with a protein: creatinine ratio of 11.3 but no cellular casts. Chest and abdominal CT revealed lymphadenopathy and hepatosplenomegaly with a large spleen infarct. Comprehensive infectious disease work-up was negative. ANA, anti-dsDNA and cryoglobulins were not detected. Serum complement levels were normal. Coagulopathy work-up was negative, with no anti-cardiolipin antibody or lupus anti coagulant detected. Free light chains were not increased and no monoclonal bands were seen on serum or urine immunoelectrophoresis. Bone marrow, lymph node and small bowel biopsies all showed reactive follicular hyperplasia. Kidney biopsy showed many subepithelial, subendothelial and mesangial immune complex deposits on EM, and strong immunofluorescence staining for IgG, C3, kappa and lambda with weaker staining for IgM, IgA and C1q. Notably, immune deposits were also seen in the tubular basement membrane. The patient subsequently developed alopecia and autoimmune hemolytic anemia. The clinical and pathological presentation was highly suggestive of lupus and membranous lupus nephritis, despite the repeatedly negative ANA. Treatment with prednisone and mycophenolate was started with reduction in lymphadenopathy and proteinuria and resolution of constitutional symptoms.

Conclusions: Membranous lupus nephritis should be considered in the differential diagnosis of patients with nephrotic range proteinuria even in the absence of systemic or serologic features diagnostic of lupus.

PUB589

Rapid Progressive Glomerulonephritis in Diabetic Patient Presenting with Urinary Tract Infection and Acute Kidney Injury Arksarapuk Jittirat,[1] Natthavat Tanphaichitr.[2] *[1]Olive View Medical Center- UCLA; [2]Northeast Ohio Medical University.*

Background: Diabetic nephropathy occurs in approximately 40% of diabetic patients. Renal biopsy is not routinely performed in diabetic patients with proteinuria. However, non-diabetic renal disease(NDRD) may coexist in up to one third of diabetic patients. It is important that NDRD is diagnosed early since its treatment and outcome are different from diabetic renal disease. The delay in treatment can cause worsening renal function and may progress to ESRD.

Methods: A 56 year old woman with DM, HTN, CKD with baseline creatinine(Cr) 1.2 presented to the hospital with fever, nausea, vomiting, dysuria and flank pain for 3 days. Urine culture grew ESBL E.coli. She was also found to have acute kidney injury(AKI) with Cr of 2.8 and urine protein to creatinine(UPC) ratio of 3.1.Work up revealed positive myeloperoxidase ANCA. Renal biopsy showed an active crescentic glomerulonephritis(GN) in 80% of glomeruli with a mild degree of interstitial fibrosis and tubular atrophy consistent with pauci-immune GN. Treatment was initiated with cyclophosphamide and steroid. The renal function and proteinuria continued to improve during subsequent follow up. Her Cr 4 months after therapy was 1.2 and UPC ratio was 0.8.

Conclusions: Many studies have been done to determine the role of renal biopsy in diabetic patients with renal involvement. Chong et al. reviewed the clinical predictors of NDRD from 2004-2008 and concluded that the useful clinical markers are AKI and microscopic hematuria. The prevalence of NDRD is high in patients with short duration of DM, absence of diabetic retinopathy and nephrotic range proteinuria.

In this case, the patient had DM, AKI and UTI which are associated with proteinuria. Treatment of symptomatic UTI reduces proteinuria. Many experts recommend repeating UPC two weeks after the treatment of UTI. However, early proteinuria work up in this patient led to the diagnosis of rapidly progressive GN. The treatment was started immediately and the renal function had recovered. It is important to make a diagnosis of NDRD in diabetic patients with variable presentations and initiate the treatment in a timely manner.

PUB590

Mitochondrial Disease and Renal Transplant Matthew Miller,[1] Mohan Cooray,[2] Catherine M. Clase,[1] Chidam Yegappan,[3] Azim S. Gangji.[1] *[1]Div. of Nephrology, McMaster University, Hamilton, ON, Canada; [2]Dept. of Medicine, McMaster University, Hamilton, ON, Canada; [3]Div. of Neurology, McMaster University, Hamilton, ON, Canada.*

Background: Mitochondria are responsible for ATP generation and have their own DNA (mtDNA) that is maternally inherited and present in multiple copies per cell. Prevalence of mitochondrial disease is 1-2:10000 and usually presents in childhood but diagnosis can occur in adulthood.

Mitochondrial Encephalopathy with Lactic Acidosis and Stroke-like episodes (MELAS) is the most common mitochondrial disease. It can be accompanied by seizures, diabetes, deafness, and weakness. 80% of MELAS is associated with mtDNA A3243G mutation; 5% have nephropathy. Tubular dysfunction and proteinuria are the most common manifestations. Pathology shows FSGS or interstitial nephritis with proliferation of large, dysmorphic mitochondria. 50% develop ESRD.

Six transplants in mitochondrial disease have been described. One had pre-existing cognitive impairment and stroke. Three others developed strokes within two years of transplant. Two had pre-existing diabetes, whereas three developed it post-transplant. Transplant function remained normal in all.

It is difficult to determine if transplant worsens mitochondrial disease or if these represent natural disease progression. Nephropathy does not recur after transplant. Given the development of complications shortly after transplant, nephrologists should be cautious about increased risks of complications when considering transplant for patients with mitochondrial disease.

Methods: GW was a 58-year-old male with ESRD from chronic interstitial nephritis, interstitial fibrosis, and tubular atrophy. Other history included deafness, ataxia, and chronic fatigue. He received a transplant in August 2010. Post-transplant he developed severe weakness, a CK of 1700, and NODAT. In May 2011, he developed progressively worsening multifocal strokes and seizures.

He had elevated lactates throughout his final admission. A muscle biopsy was consistent with MELAS. Despite therapy, he suffered further cognitive decline and died in September 2011. His transplant functioned well until death.

PUB591

Non-Cryoglobulinemic Hepatitis C with Renal Thrombotic Microangiopathy Sara Husain, Dilip Samarapungavan, Raviprasenna K. Parasuraman, Gampala Harish Reddy. *Internal Medicine, Wiliam Beaumont Hospital, Royal Oak, MI.*

Background: Hepatitis C (**HepC**) associated renal disease manifests typically as MPGN, often with mixed cryoglobulinemia(**Cryo**), membranous nephropathy and rarely fibrillary glomerulonephritis. We present an unusual case of HepC associated isolated renal thrombotic microangiopathy (**r-TMA**).

Methods: A 57 year-old male with untreated HepC presented with worsening dyspnea. He had no diarrhea. Examination showed 3+ leg edema, but no fever, skin rash or neurological deficits.

Laboratory tests: platelets 75 bil/L, hemoglobin 8.2 g/dL, BUN 22 mg/dL, creatinine 1.1 mg/dL (rising to 2.0 mg/dL, with a baseline of 0.45 mg/dL), 24 hour urine protein 2530 mg, LDH 612 U/L; haptoglobin < 8 mg/dL. Peripheral smear showed schistocytes. Bone marrow biopsy, C3, C4, and ADAMTS 13 activity were normal. ADAMTS inhibitor, ANA, anti-dsDNA, anticardiolipin antibodies (**aCL**), RF, Cryo and drug screen were negative.

Renal biopsy showed several small arteries with thrombi formation on light microscopy. By electron microscopy the glomerular basement membrane had scattered subendothelial electron-lucent areas with fibrin material mixed with lucent ischemic changes characteristic of r-TMA. There were no features of MPGN or immune-complex disease.

Conclusions: TMA is associated with several causes. Endothelial injury is the common primary event in its pathogenesis. HepC associated r-TMA has been described. There are a few cases in renal transplant recipients with HepC in association with aCL. It has also been occasionally reported in native kidneys in combination with MPGN and Cryo, aCL, as well as in conjunction with interferon therapy. The mechanism is yet to be established. If present, aCL may initiate endothelial damage. Cacoub et al have demonstrated that HepC with mixed Cryo may induce r-TMA by the developement of anti-endothelial cell antibodies. Our patient had no detectable aCL or Cryo and the only renal lesion was the TMA. It is possible that current laboratory assays do not detect all possible aCL antibodies that exist. It is also unclear if HepC may cause direct endothelial injury. We are awaiting results of immunohistochemical staining for HepC in the biopsy sample.

PUB592

Calciphylaxis and Leukocytoclastic Vasculitis in End Stage Renal Disease Patient on Warfarin: Is There a Synergy? Karthik Karanam. *Indiana University Hospital, Indianapolis, IN.*

Background: Calciphylaxis is a well-known complication in end stage renal disease (ESRD) patients and warfarin puts them at increased risk of it. Warfarin is also known very rarely to cause leukocytoclastic vasculitis. We report a first case of calciphylaxis and leukocytoclastic vasculitis in an ESRD patient probably exacerbated by warfarin.

Methods: A 41 year old female with past medical history of blindness secondary to retinitis pigmentosa, ESRD on hemodialysis, hypertension, cardiomyopathy, and history of thrombosis on warfarin was referred to the hospital for painful lesions on the buttocks and thighs. Patient was also on calcium containing phosphate binders and calcitriol. She apparently was seen by dermatology at an outside clinic and received a biopsy of the lesion before she presented here. The lesions on the buttocks showed diffuse erythema and black eschar in the middle. The lesion on the left thigh was also similar and the one on the right was erythematous. The skin biopsy showed perivascular and interstitial neutrophilic infiltrate. Microcalcification was present in the wall of the small blood vessels. These changes were consistent with leukocytoclastic vasculitis and calciphylaxis with early epidermal necrosis. All the potentiating factors such as calcium containing binders and calcitriol were stopped. Patient was optimized on dialysis and sodium thiosulfate was started. Warfarin was stopped as there was no proper indication for it after appropriate work up was done. As vasculitis was noted on the biopsy, appropriate serology was sent for analysis. Antiphospholipid antibodies were negative, C3 and C4 were normal and ANA was negative. Patient later underwent total parathyroidectomy during the hospitalization. Patient had a good recovery later.

Conclusions: Warfarin is known to potentiate calciphylaxis by inhibiting the vitamin K dependent carboxylation of matrix G-1a protein, which inhibits calcification locally. Warfarin is also known to cause leukocytoclastic vasculitis, but is there a synergistic effect between its ability to potentiate calciphylaxis and cause vasculitis needs to be ascertained more at the histological and molecular level.

PUB593

Haemolysis, Elevated Liver Enzymes and Low Platelets (HELLP) Syndrome Complicated by Acute Kidney Injury: Is Therapeutic Plasma Exchange the Answer? Konstantinos Koutroutsos,[1] Louise E. Ross,[1] Aris Papageorghiou,[2] Roberto Stasi,[3] Debasish Banerjee.[1] *[1]Renal Unit, St George's Healthcare NHS Trust, London, United Kingdom; [2]Obstetrics Unit, St George's Healthcare NHS Trust, United Kingdom; [3]Haematology Department, St George's Healthcare NHS Trust, London, United Kingdom.*

Background: Differential diagnosis of microangiopathic disorders in pregnancy is difficult, due to overlapping clinical and laboratory findings.Limited case series suggest that plasma exchange may be successful in patients with HELLP syndrome complicated by organ failure.

Methods: A 38 year old pregnant woman (Gestational age:39+6 weeks) presented to the obstetric unit following a tonic-clonic seizure. She had an uncomplicated pregnancy and no past medical history. On arrival, she was hypertensive (BP: 177/125mmHg) with proteinuria. The seizure was considered an eclamptic fit and the patient was started on MgSO4 and Hydralazine infusion. She underwent emergency caesarean section and delivered a healthy baby girl(Weight: 3190g, Apgar score 9). Postpartum, the patient was found to have microangiopathic haemolytic anaemia (Hb:7.7g/dl,PLT:42000/ml,LDH:1647u/l), elevated liver function tests (ALT:1538U/L) and acute kidney injury (AKI, cr:286umol/L).She was transferred to the Intensive Care Unit, received blood transfusions and underwent haemofiltration. On the 2nd day postpartum and in view of persistent haemolysis, she was started on daily Plasma Exchange with fresh frozen plasma (1,5x plasma volume). The patient had 10 Plasma Exchange sessions in total. Complement factors B(293,reference range(ref):295-400) H(517,ref:345-590) I(66,ref:38-58) and ADAMTS13 activity (61%,ref:60-123) were found to be normal and a diagnosis of HELLP was established.The patient was discharged 10 days after admission and recovered completely from HELLP and AKI.

Conclusions: This case underlines the complexity in the diagnosis and management of pregnancy-related thrombotic microangiopathies. In our case plasma exchange was initiated early, based on a mixed clinical presentation of severe HELLP and atypical Haemolytic-Uremic syndrome. It appears that plasma exchange may be a successful treatment in persistent, life-threatening HELLP syndrome.

PUB594

Solitary Kidney Autotransplantation: An Alternative to Dialysis Commitment in a Patient with Significant Vascular Disease Nadear A. Elmahi, Kenneth E. Kokko, Tibor Fulop, Mehrdad Hamrahian. *Department of Medicine, Division of Nephrology, University of Mississippi Medical Center, Jackson, MS.*

Background: Renal autotransplantation (RAT) refers to the relocation of the kidney within the body. Although RAT is indicated in a variety of renal and ureteral diseases, it remains underutilized procedure. We describe a unique case of solitary RAT in a patient with significant vascular disease (VD) and hypercoagulable state.

Methods: 41 yr old African American female presented to the hospital with bilateral lower extremities and mesenteric ischemia due to extensive VD and thrombosis of the abdominal aorta (AA). Computer topographic angiography showed an isolated patent segment of the AA at the level of renal arteries. She underwent a complex thoraco-abdominal bypass surgery with a four-limb graft; 1st limb to the superior mesenteric artery, 2nd limb to the isolated patent segment of AA, and 3rd and 4th limbs to femoral arteries. Further work up revealed low levels of protein C, protein S and antithrombin III. Patient was discharged on long-term anticoagulation, but unfortunately she lost the follow up and stopped her anticoagulation. Two years later she presented to the hospital with acute kidney injury (AKI) and volume overload that required intermittent hemodialysis (HD). Her blood pressure (BP) remained elevated despite ultrafiltration and multiple antihypertensive medication use. Extensive work up without use of contrast revealed inoperable occluded graft limb to AA and a non-functional atrophic left kidney with inadequate blood flow to the right kidney. Renal biopsy of the right kidney showed severe tubular necrosis and viable tissue. Based on the tissue viability, she underwent RAT of the right kidney after which she recovered from her AKI and had BP well controlled on a single agent. Her creatinine was 0.75 mg/dl 3 months post RAT.

Conclusions: RAT is an alternative therapeutic approach to lifelong HD commitment and to resistant hypertension in a patient with solitary kidney and inoperable renal vascular perfusion disorder. Multidisciplinary team approach is the key factor for such a challenging surgery.

PUB595

Should Nephrologists Be Aware of Posterior Reversible Encephalopathy Syndrome? Javier A. Neyra,[1] Carlos Calle-muller,[2] James E. Novak.[3] *[1]Division of Nephrology, UT Southwestern Medical Center, Dallas, TX; [2]Department of Internal Medicine, Henry Ford Health System, Detroit, MI; [3]Division of Nephrology, Henry Ford Health System, Detroit, MI.*

Background: Posterior Reversible Encephalopathy Syndrome (PRES) is a clinicoradiologic entity characterized by altered mental status, headache, visual disturbances, or seizures in combination with classic neuroimaging changes that are frequently reversible. Patients with kidney disease are uniquely at risk for developing this syndrome, since they may be uremic, hypertensive, and exposed to immunosuppressants.

Methods: A 25 year-old man with history of heroin abuse presented to the emergency department with 1 week of diffuse abdominal pain, myalgias, nausea, and vomiting. The patient was afebrile with blood pressure 160/100 mmHg. Evaluation revealed acute kidney injury (AKI) with creatinine 7.1 mg/dL, blood urea nitrogen 58 mg/dL, phosphorus 5.1 mg/dL, and creatine phosphokinase 1,642 IU/L. After a few hours, the patient became anuric and developed tonic-clonic seizures, for which he required emergent hemodialysis and antiepileptic drugs. Brain MRI revealed extensive bilateral cortical and subcortical white matter hyperintensity involving the cerebral and cerebellar hemispheres. Following hemodialysis, the patient's seizure activity ceased, as confirmed by continuous electroencephalography. The patient was initially dialysis-dependent but achieved adequate solute control and remained seizure-free without the need for additional antiepileptic drugs. Subsequent neuroimaging revealed interval improvement in brain white matter signal abnormalities.

Conclusions: Our patient represents the first known case of PRES secondary to severe AKI attributed to heroin-induced rhabdomyolysis. Additionally, our patient exhibited the classic clinical and radiographic interval improvement and remission of seizure activity without the need for continued antiepileptic therapy. Therapeutic intervention in PRES should be targeted to symptom control and identification of the underlying cause. PRES may result in significant long-term neurologic deficits or death, and prompt recognition may be life-saving.

PUB596

Acute IgG4 Interstitial Nephritis and Cholestatic Jaundice: Metformin as a Possible Trigger Swati Arora, Katherine M. Jasnosz, Barbara A. Clark. *Nephrology and Pathology, Allegheny General Hospital, Pittsburgh, PA.*

Background: Acute interstitial nephritis (AIN) with IgG4 positive plasma cell infiltrates is a recently recognized entity most often associated with inflammation in the pancreas or intrahepatic bile ducts. Though etiology is unclear, autoimmunity, allergen or drug induced triggers remain a possibility. Metformin has been rarely associated with cholestatic hepatitis and post marketing analysis suggests a 0.07% incidence of AIN.

Methods: We report a case of a 75 y/o male with a history of DM-II, hypertension and hyperlipidemia maintained on metformin, lantus, quinapril, metoprolol, asa, rosuvastatin presenting with jaundice and AKI. MRCP and ERCP were negative. CRP was 21.8. Total IgG was 1959 mg/dl (nl 70-1600) but IgG4 wnl. Hep B and C; ANA, ANCA; anti smooth muscle ab all negative; SPEP, kappa/lambda ratio wnl. Enlarged kidneys on renal US (14.8; 15.4cm); liver bx with small bile duct cholangitis (IgG4 negative); no active infectious process; kidney bx with diffuse plasma cell infiltrate in interstitium (up to 20 IgG4 positive cells/hpf) suggesting IgG4 AIN. Upon admission, all meds except insulin were held. Despite this, liver and kidney disease progressed (peak cr 9.35mg/dl; bili 7.2mg/dl; AP 673 u/L). Following the kidney bx, he received solumedrol 250mg IV x 1 and prednisone 60 mg daily was started. Within a few days both the liver and kidney function began improving. Within 3 weeks, his creatinine returned to his prior baseline of 1.1 mg/dl and LFTs normalized. Prednisone was tapered to zero over the next ten weeks. His metoprolol had been resumed prior to discharge from the hospital but the metformin, quinapril and rosuvastatin were held. Quinapril was resumed after 6 weeks because of persistent HTN and statin was resumed after 12 weeks for hyperlipidemia, without any adverse effects on kidney or liver function. Metformin remained a possible suspect inciting medication and was not resumed.

Conclusions: While this case has some features of IgG4 nephritis, it did not meet all the criteria. We postulate that some cases with IgG4 positive AIN may be drug induced and implicate metformin as a possible trigger in this case of cholestatic jaundice and AIN.

PUB597

N-Acetyl Cysteine in Management of Methotrexate Induced Kidney Damage Rikin Kartikbhai Shah, Osvaldo Regueira, Curtis W. Turner, Tetyana L. Vasylyeva. *Department of Pediatrics, Texas Tech University Health Science Center, Amarillo, TX.*

Background: High Dose Methotrexate (HD MTX) /Leucovorin Rescue (LCV) alternating with Doxorubicin/Cisplatinum is the current therapy for Osteosarcoma in the Pediatric Population. NAC has been demonstrated to decrease MTX induced oxidative renal damage in preclinical models (Cetinkaya, 2007). We describe the use of NAC to reverse MTX induced nephrotoxicity in an adolescent treated with MTX/LCV for osteosarcoma.

Methods: 18-year old women initiated chemotherapy for osteogenic sarcoma of the left proximal humerus with alternating cycles of Doxorubicin/Cisplatinum (Doxo/CDDP) and High Dose Methotrexate (HD MTX) /Leucovorin Rescue (LCV). Pretreatment serum creatinine level was 0.57 mg/dl and received prehydration with IV fluids at 3000 cc/m^2. The patient was admitted for a sixth overall systemic chemotherapy encounter (Doxo/CDDP - cycles 1 and 3) and specifically the fourth admission for intravenous HD MTX which was administered at a dose of 12 grams/m^2 over 4 hours. She received post hydration intravenous fluids and LCV 15mg/ m^2 IV /PO every 6 hours beginning at hour 0. Serum MTX levels at 24, 48 and 72 hours after MTX infusion demonstrated toxic range. Serial serum creatinine levels increased from baseline 0.57 mg/dl to 0.87 and 1.43 mg/dl at 24 and 48 hours respectively.

Sixty hours after the MTX infusion, we began NAC 600 mg orally every 8 hours. Subsequent creatinine levels decreased to 1.01 and 0.80 mg/dl on day 4 and day 5 respectively. For subsequent admissions for HD MTX/LCV therapy, we coadministered prophylactic NAC and creatinine level remained between 0.65 to 0.95 mg/dl. MTX levels have remained in therapeutic levels.

Conclusions: NAC may have ameliorated the MTX induced nephrotoxicity in our patient. NAC may act as an antioxidant and reverse free-radical mediated cell damage and mitochondrial injury in the renal cells.

Further prospective clinical trials for oncology patients receiving nephrotoxic drugs may be warranted. Additional preclinical studies may clarify the mechanisms of action.

PUB598

Non-Dilated Urinary Tract Obstruction and Oliguric as Well as Non-Oliguric Acute Kidney Injury Layla Kamal,[2] Ilya Glezerman,[1] Carlos D. Flombaum.[1] *[1]Nephrology, Memorial Sloan Kettering Centre; [2]Nephrology, New York Presbyterian Hospital, Weill Cornell Medical College.*

Background: Urinary tract obstruction is a significant cause of acute kidney injury (AKI), accounting for about 9.5% of causes of AKI. In approximately 4% of patients with obstructive uropathy imaging studies do not reveal any evidence of dilatation of the collecting system. We report one patient who developed AKI as a result of non-dilated obstructive uropathy.

Methods: Patient is a 66 year old female with a large pelvic mass secondary to endometrial cancer who is being evaluated for a SCr of 3.8 mg/dl from a baseline of 1.0 mg/dl, confusion and fever secondary to Serratia Marcescens in blood and urine. A renal ultrasound (US) was negative for hydroureteronephrosis. The next day, Scr was 5, with daily UOP of 1.2l and persistent bacteremia. The patient underwent a left sided antegrade pyelogram that demonstrated a minimally dilated left collecting system with a moderately to severely dilated proximal and mid ureter. She underwent bilateral percutaneous nephrostomy which resulted in increase in UOP and decrease in SCr to 0.9 mg/dl.

Conclusions: Conventional imaging techniques such as CT and US are not diagnostic in non dilated obstructive uropathy. In a case series of 166 patients with obstructive uropathy requiring antegrade percutaneous nephrostomy placement, 7 patients had no dilatation on either CT or US. 6 of these patients had intrapelvic neoplasm. Other causes include retroperitoneal fibrosis, urolithiasis and pelvic surgery. Encasement of ureters in neoplastic or fibrous tissue, defect of ureteral peristalsis and intraureteral debris as well as edema have been proposed as possible mechanisms of this phenomenon. In our case, obstruction was secondary to the large intrapelvic malignant mass likely causing encasement of the ureters. What was unusual is the lack of oliguria that is typical of non dilated obstructive uropathy, which could be explained by the partial nature of the obstruction and the associated concentrating defect. The recognition of non dilated obstructive uropathy requires a high index of clinical suspicion as radiologic studies are non diagnostic in these cases.

PUB599

End Stage Renal Disease due to Fibrillary Glomerulonephritis in a Four Year Old Child M. Mandava, Senthilkumar Sankararaman, Sabeen Y. Habib. *Pediatrics, LSU Health Sciences Center, Shreveport, LA.*

Background: Fibrillary glomerulonephritis (FGN) is a very rare disease and only few pediatric cases have been reported so far. Most of the patients had persistent proteinuria and hematuria without progression to renal failure. This is an atypical case of FGN with rapid progression to ESRD with a coincidental family history of IgA nephropathy.

Methods: Four-year-old African-American male with no significant past medical history presented with a two weeks history of cold symptoms and cola colored urine. He has a strong family history of IgA nephropathy. On evaluation, he had macroscopic hematuria, severe proteinuria and a serum creatinine of 1.2mg/dl. Two days later his renal functions worsened with a serum creatinine of 3.3mg/dl and serum potassium of 6meq/L. Further labs showed ASO 1659, low C3, normal C4, normal ADAMTS 13, normal Factor H, negative serology and urine protein of 1.6gm/day. Renal biopsy showed coarsely granular capillary loops and mesangial deposits with IgG, C3 and fibrin in all glomeruli. Electron microscopy showed proliferative glomerulonephritis with fibrillary deposits. He did not improve with steroids and required peritoneal dialysis. Patient was then started on cytoxan. He demonstrated transient improvement in renal function and despite treatment he developed end stage renal disease within a month. He developed membrane failure and switched to hemodialysis.

PUB600

A Case of Fibrosing Cholestatic Hepatitis Following Renal Transplant Umbar Ghaffar, Nitin Relia, Mandeep Singh, Sundararaman Swaminathan. *Nephrology, University of Arkansas for Medical Sciences, Little Rock, AR.*

Background: This case describes a novel diagnosis for acute hepatic failure in renal transplant population.

Methods: 64 year old male with history of IgA nephropathy s/p living donor kidney transplant, Gout, HTN, and CAD was admitted for jaundice and altered sensorium.His medications included Tacrolimus, Mycophenolate, Prednisone, Valganciclovir and Bactrim. Vitals were Temp: 97°F, HR: 48/min, BP: 131/77 mm Hg. Examination was significant for somnolence, scleral icterus, absence of asterixis and spider nevi. Abdomen: non-tender with good bowel sounds. Significant labs :Total bilirubin:12mg/dl, Direct bilirubin:7.4 mg/dl, AST:447 IU, ALT:548 IU, ALP:220 IU,Calcium:10.8 mg/dl, Albumin: 2.6 g/dl, PT:14.7 seconds, INR:1.2, serum amylase and lipase: normal, serum creatinine:0.9 mg/dl. All infectious and autoimmune workup was negative. No recent change in medications was reported. Hepatitis panel and HIV antibody were negative. Serum acetaminophen level was normal. Ultrasound showed fatty infiltration of the liver. Liver biopsy showed cholestatic hepatitis with neutrophilic cholangitis with negative CMV immunostain and no viral inclusions. Patient was discharged with improvement in liver functions. He was readmitted 5 months later with similar complaints. HIDA scan showed acute cholecystits leading to cholecystectomy. Repeat liver biopsy showed cholestatic injury, now with bridging fibrosis and early nodularity. Repeat hepatitis panel for Hep B and C and autoimmune work up was negative.CMV, EBV, HSV, Parvo and BK virus PCRs were also negative. Literature search revealed similar reported cases of cholestatic injury with fibrosis described in transplant population, an entity called Fibrosing Cholestatic hepatitis (FCH), attributable to overwhelming Hepatitis B or C virus infection following solid-organ transplantation,c hemotherapy,and immunocompromised states like HIV. Our patient's HCV PCR returned positive at >69 million copies.The donor tested negative for HCV. It is possible that patient had acquired Hepatitis C infection prior to transplant, but demonstrated a negative HCV antibody. He is currently awaiting liver transplant.

PUB601

Uretero-Colonic Diversion Causing Colonic Cancer and Obstructive Nephropathy in a 38 Year Old Man Ricardo Salas, Arksarapuk Jittirat, Ramy Magdy Hanna, Eduardo A. Lopez, Rajendra P. Niraula. *Olive View - UCLA Medical Center.*

Background: There are several complications associated with utero-colic diversions(UCD). Approximately 10% of patients with congenital bladder exstrophy(CBE) status post UCD develop renal failure and death. The most common complication is obstructive nephropathy secondary to anastomotic site stenosis. However, malignant tumors at the anastomosis have also been reported. The risk of malignancy is increased

by 100–200 times after 20-30 years of prolonged exposure to urine. Strict follow up and screening with sigmoidoscopy is important in early recognition of tumor and treatment to prevent further renal complications.

Methods: A 38 year old man with CBE who had a reconstruction surgery and UCD at 13 month old presented to the hospital with acute kidney injury(AKI) and bilateral hydronephrosis secondary to obstruction, requiring hemodialysis. He never had screening sigmoidoscopy in the past. Further evaluation revealed a mass at the site of UCD anastomosis. Biopsy showed poorly differentiated epithelial mesenchymal neoplasm–carcino sarcoma.

Three months later the patient was readmitted for severe anemia secondary to bleeding from the tumor. CT indicated an interval increase in the size of the mass with mesenteric lymphadenopathy. He was submitted to surgery, followed by chemotherapy. His hospitalization was complicated by infection, respiratory failure leading to his death.

Conclusions: Malignancies near the site of UCD anastamosis have been reported to be as high as 24% with half of these being adenocarcinomas. The pathogenesis of the tumor is thought to be secondary to the production of nitrosamines from nitrates and endogenous amines in the urine by bacteria in the colon and due to increased expression of CYP 450 isoenzyme 2E1. Complications of the tumor include obstructive nephropathy, AKI, nephrolithiasis and pyelonephritis.

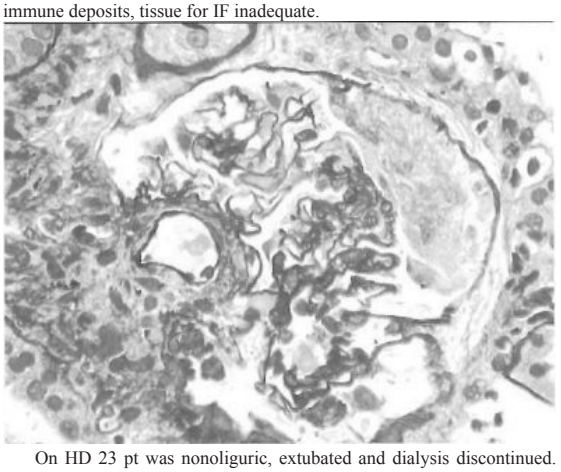
However, tumors at UCD anastomotic site are often overlooked and screening is not routinely done. Studies have shown that time of surgical diversion to the onset of tumor has a mean of 20 years. Screening with flexible sigmoidoscopy should begin 10 years after the initial operation and yearly thereafter.

PUB602

A Case of Dual Anti-Glomerular Basement Membrane Antibody and Myeloperoxidase-ANCA Crescentic Glomerulonephritis Hilda E. Fernandez, Brenda B. Hoffman, Raphael M. Cohen. *Univ of Pennsylvania, Philadelphia, PA.*

Background: Rapidly progressive glomerulonephritis (RPGN) in pts with both anti-glomerular basement membrane (GBM) antibodies and antineutrophil cytoplasmic antibodies (ANCAs) specific for myeloperoxidase (MPO-ANCA) have a better prognosis than anti-GBM glomerulonephritis.

Methods: 76 yo AAF with a h/o hypertension presented w/ acute shortness of breath. Given bloody secretions from ET tube and white-out of R side on CXR, emergent bronchoscopy performed, w/ no acute bleed or lesion. CT Chest consistent with diffuse alveolar hemorrhage. Acute kidney injury (AKI) was also noted w/ a Cr of 6.2 (baseline Cr 1.5) w/ gross hematuria, no dysmorphic RBCs. Pt on maximal ventilatory support and anuric within 48 hours. Due to concern for RPGN with pulmonary hemorrhage, pt was pulsed steroids and plasmapheresis initiated. Dialysis required for anuric AKI, volume overload, hyperkalemia. Serologic testing showed positive anti-GBM antibody, ANA, and pANCA/MPO. Plasmapharesis was continued daily for 7 days, then every other day for 7 more days. Repeat anti-GBM antibody negative after plasmapharesis. Cytoxan given on hospital day (HD) 7. Renal biopsy demonstrated a necrotizing crescentic RPGN, no EM immune deposits, tissue for IF inadequate.



On HD 23 pt was nonoliguric, extubated and dialysis discontinued. On HD 30 pt discharged w/ Cr of 3.7. Five days after discharge pt had further decrease in Cr to 3.2 w/ plan to continue prednisone taper and IV cytoxan therapy monthly for 6 months.

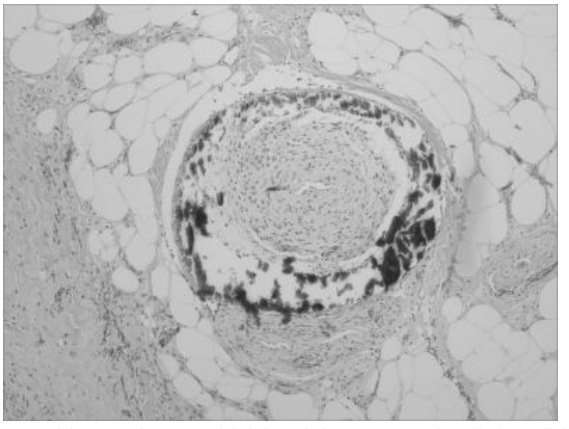
Conclusions: The literature suggests that pts w/ anti-GBM RPGN requiring dialysis do not recover renal function, but pts with dual positive anti-GBM and ANCA positive RPGN tend to have a better prognosis than w/ anti-GBM RPGN, though worse than w/ ANCA positive RPGN. The rapid initiation of therapy prior to diagnosis w/ serologic testing may have had a significant impact on this outcome.

PUB603

Between the Devil and the Deep Blue Sea Evamaria Anvari, Bijin Thajudeen, Preethi William, Mordecai M. Popovtzer. *Nephrology, Southern Arizona VA Health Care System, Tucson, AZ.*

Background: Calciphylaxis is a poorly understood disease with high mortality causing vascular calcification and skin necrosis.It occurs 1-4% of ESRD patients annually.

Methods: 63 yr old male evaluated for ulcerated, infected skin lesions of extremities .He was diagnosed with atherosclerotic disease one year ago and underwent angiography and endovascular intervention.Despite intervention skin lesions progressively worsened. Warfarin was initiated 10 months back for DVT.Past medical history include type 2 DM,hypertension and ESRD on PD.Medications include calcium acetate,calcitriol.Physcial exam showed dry gangrene of fingers and toes,multiple ulcers coated with dark eschar on hands, forearm, knee ,dorsum of foot and heel with feeble peripheral pulses in upper and lower extremities .Labs showed calcium 10.5 mg/dL, phosphorus 6.4 mg/dL,PTH 390pg/ml.CTA left upper extremity showed diffuse atherosclerotic calcifications and stensosis of brachial ,ulnar and radail arteries.He underwent ulnar artery exploration, patch angioplasty and finger amputations. Due to predisposing factors and distribution of ulcers, possibility of calciphylaxis was considered.A skin biopsy showed gangrenous necrosis of soft tissue with calcification of the subcutaneous arterioles.



Calcium supplements,calcitriol,warfarin were stopped .Daily hemodialysis with low calcium bath,non calcium based phosphate binders and thrice weekly intravenous sodium thiosulphate were initiated with some improvement in the skin lesions.Eventually he died of sepsis.

Conclusions: Diagnosis of calciphylaxis could be missed in presence of atherosclerotic peripheral vascular disease. A high index of suspicion is required especially in the back ground of predisposing factors.Simultanous management of calciphylaxis and peripheral vascular disease is essential.Initiation of warfarin could have precipitated the calciphylaxis.

PUB604

Fluid Removal in Hypertensive Pregnant Female on Dialysis Avoided Early Termination of Pregnancy Hiral V. Desai, Alekhya Potluri, Jacques Abi Rached, Ziauddin Ahmed. *Nephrology, Hahnemann Hospital, Philadelphia, PA.*

Background: Hypertension is a common complication in pregnant dialysis females leading to a high percentage of early termination of pregnancy due to possible preeclampsia. One of the reasons could be gradual fluid accumulation as fluid removal is done judiciously during pregnancy to avoid maternal hypotension for the fear of fetal compromise and to allow for the 1 lb weight gain a week. Here, we present case of a difficult to treat hypertension in a pregnant dialysis patient which was managed by aggressive fluid removal.

Methods: A 22 year old female with h/o of HTN, ESRD on HD was admitted at 26 wks gestation with complaints of shortness of breath and hypertensive urgency with BP of 170/90. Her outpatient dialysis prescription was 6 days/wk, 3 hrs each .She was allowed to gain 1 lb/wk in her 2nd trimester to account for the normal pregnancy weight gain. During the hospitalization she remained hypertensive with systolic BP ranging in the 150's-160 despite 2 maximally titrated BP medications. She had no edema and was at her dry weight. Lab studies were normal. Chest x-ray showed bilateral pulmonary congestion. Emergent control of her BP was necessary at this point to avoid early termination of pregnancy due to suspected preeclampsia. At this point a key decision was made to dialyze her with aggressive fluid removal challenging her dry weight. A fetal monitor was placed during HD to monitor for fetal distress and she was dialyzed daily with 3-4 liters ultrafiltrate per session. Her BP improved after 3 dialysis sessions and she was 6 kg below her dry weight. During aggressive fluid removal no sign of fetal distress was observed. She continued to be dialyzed throughout her pregnancy with fluid removal to target a systolic BP of 130's. She delivered a healthy baby at term.

Conclusions: We believe that fluid removal in this hypertensive pregnant woman to control BP even in the absence of edema did not harm the fetus. This may be due to effective auto regulation by the placenta. Aggressive volume removal to improve hypertension may have prevented early termination of pregnancy improving fetal outcome. A pilot study is required to substantiate this finding.

PUB605

Rhabdomyolysis Post Streptococcal Pharyngitis Neelima Chilukuri. *Nephrology, Richmond University Medical Center, Staten Island, NY.*

Background: We describe here the case of a severe rhabdomyolysis post streptococcal pharyngitis which has been reported as only two case reports in the past with group C streptococcal infection.

Methods: This is a case of a 23year old male who presented with generalized body pain and brown urine, he reported to have taken amoxicillin for five days for streptococcal infection as outpatient and started to feel body pains since then and so came to ER, only past

medical history was left shoulder surgery for recurrent dislocation two weeks ago, no h/o trauma,denies any illicit drug use, physical exam was essentially normal, his labs were wbc 17.3, Hgb/Hct 14.6/44, Na 136,K 6.0,BUN 12.6, Cr 1.0, Total CPK 843535.00,AST,2925, ALT 806, Urine analysis showed specific gravity 1.026, urine ph 5.5 protein >300,large blood,positive nitrate,large bilirubin,moderate leukocyte esterase, RBC 2-4, WBC 12-14, sediments moderate,C ANCA negative, P ANCA negative,C3-114, C4-31, ASO 261, LDH 18480, CRP 3.1,Hepatitis B and C non reactive, HIV non reactive, Urine drug screen Negative, Renal ultrasound was normal, patient was hemodynamically stable, patient was treated with normal saline @250cc/hr and 150meq of sodium bicarbonate and 20mg of furosemide, during the hospital course the total CK trended down to 13863 over 9 days and his creatinine remained stable at 0.7 to 0.8.

Conclusions: It is rare and interesting to see rhabdomyolysis after a streptoccoal pharyngitis with a very high total CK of 843535, in literature only few cases were reported with streptococcal C infection and the total CK was 35506.

PUB606

HIV Nephropathy: A Minimal Change Disease Perspective, and Glucocorticoid Treatment Dilemma in Immunocompromised States

Leonard Gyebi, Zohreh S. Soltani. *Nephrology, Lousiana State University, New Orleans, LA.*

Background: A 20-year-old transgender male with a one year history human immunodeficiency virus (HIV) was seen by the Nephrology consult for acute renal failure, proteinuria, and edema.

Methods: The patient was in his usual state of health up until 2 weeks prior to his admission, when he suddenly developed nausea, vomiting and abdominal pain. His review of symptoms was noted for penile and rectal cultures positive for human herpes simplex 2 (HSV2). RPR was negative. A day prior to admission Gonorrhea and Chlamydia cultures were positive in urine and rectum so, he had been treated with Rocephin IM and azithromycin and asked to follow up the next day. On follow up his creatinine had increased to 5.34 mg/dL from baseline 0.5mg/dl. At the time of consult his blood pressure was 148/86 with a heart rate of 100. He weighed 72kg and 173cm. He had generalized edema. Additional laboratory data included a creatinine of 11mg/dL and BUN 125 mg/dL, positive hepatitis B core and surface antibodies, negative surface antigen, CD4 count of 27 per cubic millimeter, and the viral load of 3,980,000 copies per cubic millimeter. His urine microscopy revealed hematuria, along with muddy brown cast. Urine protein to creatinine ratio was 10,000 mg/g. Renal ultrasound showed right kidney 12 cm and left kidney 12.4 cm. Serum electrophoresis and urine protein electrophoresis was unrevealing. Serum levels of IgA, IgM, complement levels of C3 and C4 were all within normal limits. Test for antinuclear antibodies, c-ANCA, p-ANCA and anti- GBM antibodies was negative. A renal biopsy demonstrated complete foot process effacement with microvillous transformation of the epithelial cells. Final diagnosis of minimal change disease, and acute tubular necrosis was made. Dialysis was initiated and tentative use of steroids after initiation of HAART out patient was favored.

Conclusions: While the most common HIV associated glomerular injury is focal segmental glomerular sclerosis this case is a reminder that the differential diagnosis related to common comorbid conditions is broad. This case also exposes some of the treatment dilemmas in use of steroids in the immunocompromised patients.

PUB607

Colchicine Induced Nephrogenic Diabetes Insipidus

Keith R. Bartolomei,[1] Abraham Cohen-Bucay,[2] Suzanne Saindon,[3] Geetha Narayan.[4] *[1]Nephrology, Tufts Medical Center, Boston, MA; [2]Medicine, St. Elizabeth's Medical Center, Boston, MA; [3]Medicine, St. Elizabeth's Medical Center, Boston, MA; [4]Nephrology, St. Elizabeth's Medical Center, Boston, MA.*

Background: Nephrogenic diabetes insipidus (NDI) is the resistance to antidiuretic hormone (ADH) resulting in a urinary concentrating defect. We present a case of NDI induced by colchicine.

Methods: 65-year-old male admitted for drainage of an idiopathic pericardial effusion. His medical history included a traumatic brain injury, bipolar disorder and seizures. He was on valproic acid, olanzapine, metoprolol and doxepin. He was started on colchicine 0.6 mg twice daily to prevent re-accumulation of pericardial fluid. Five days after starting colchicine he abruptly developed polyuria of 5-6 L/day. Initial serum creatinine (SCr), glucose and electrolytes were normal and obstruction was ruled out by ultrasound. Over 36 hours, his serum sodium (SNa) rose from 138 to 151 mEq/L. While hypernatremic, urine osmolality (Uosm) was 164 mOsm/Kg and plasma ADH was 0.9 pg/ml (normal <0.7 pg/ml). Administration of DDAVP did not change the Uosm or output. Simultaneously, SCr rose from 1.0 to 2.1 mg/dl as he became volume depleted. Repletion with hypotonic fluids resulted in normalization of SNa and SCr. Colchicine was stopped and within days his urine output decreased to 2 L/day, Uosm increased to 406 mOsm/Kg and SNa remained normal.

Conclusions: A diagnosis of NDI was made based on a low Uosm despite hypernatremia, a high plasma ADH and a dose of DDAVP. Acquired NDI is caused by infiltrating diseases, obstruction, metabolic disturbances and drugs. In our patient, all well-known causes of NDI were ruled out. Colchicine has been linked to NDI in two case reports. One case was reported after ingestion of a large dose of colchicine in a suicide attempt. A second case was seen in a patient taking colchicine for gout. Both patients improved after cessation of the drug. Colchicine has been found to inhibit ADH- and cAMP-mediated water reabsorption in the distal nephron in *in situ* studies, possibly leading to increased free water losses. Despite the absence of other causes, a chance association cannot be excluded.

PUB608

Progression towards End Stage Renal Disease in Primary Sjogren's Syndrome Complicated by Thrombotic Microangiopathy

Karthik Karanam. *Indiana University Hospital, Indianapolis, IN.*

Background: Kidney involvement in Sjogren's syndrome is characterized by interstitial nephritis, mild elevation in creatinine, distal RTA type I or nephrogenic diabetes insipidus. We present a case of primary Sjogren's syndrome presenting at CKD stage III and progressing towards ESRD secondary to the development of thrombotic microangiopathy not explained by other causes.

Methods: A 54 year old female with past medical history of Sjogren's syndrome (ANA +, SSA +, SSB +), B cell lymphoma 11 years back status post parotidectomy and radiotherapy, GERD, migraines, hypothyroidism and hypertension presented to the hospital with complaints of intractable nausea and emesis, associated with non blanchable purpuric spots on the hands and thighs. She was in oliguric acute renal failure, thrombocytopenia and had hemolytic anemia. Blood pressure was also high initially. Plasmapheresis was initiated as the initial thought was TTP/HUS. Later the ADAMTS 13 came back as normal, platelet counts were stabilized and the hemolytic picture resolved. The purpuric lesions were still present and the skin biopsy showed leucocytoclastic vasculitis. The patient's kidney function continued to deteriorate as she became more uremic and urine output was low. A kidney biopsy was done as the possibility of vasculitis was high. The biopsy showed acute and chronic thrombotic microangiopathy with mesangial sclerosis, moderately severe chronic tubulointerstitial nephritis, acute tubular necrosis and arteriosclerosis. High dose of furosemide was used to improve the urine output but in vain. Patient was started on hemodialysis because of uremia and increasing confusion. After 3 sessions of hemodialysis patient's condition improved and creatinine was back to the baseline. Other laboratory tests showed normal C3, low C4 which was chronic, negative ANCA, negative dsDNA and negative Smith antibodies. Cryoglobulins and SPEP were negative. After a year the patient again presented with same symptoms and high creatinine. This time she was started on hemodialysis and being presently continued on that.

Conclusions: This represents a rare case of thrombotic microangiopathy complicating the course of kidney involvement in a patient with Sjogren's syndrome.

PUB609

Beta Blocker Use in End Stage Renal Disease: Time to Consider One Agent over Another

Karthik Karanam. *Indiana University Hospital, Indianapolis, IN.*

Background: Many patients with ESRD on hemodialysis are on beta blocker therapy either to control hypertension or as a treatment for other co-morbid conditions such as congestive heart failure and myocardial infarction. The choice of the agent to use has not been extensively studied before. We report an ESRD case on hemodialysis about that particular choice and discussion about the further consideration.

Methods: A 67 year old white male with past medical history of hypertension, diabetes mellitus, ESRD secondary to diabetic nephropathy, diabetic neuropathy, stroke, depression and GERD came in with lower extremity redness and pain associated with diabetic ulcers. Patient was diagnosed with cellulitis and started on IV antibiotics. During the hospitalization it was found that his heart rate was in 50 – 60's at the time of admission and started to drop further. Patient got symptomatic with dizziness when his heart rate finally went to low 40's and reached 35 during the night. Review of his medications showed that he was on atenolol at 75 mg daily. The recommended dose of atenolol in ESRD patients on hemodialysis is 50 mg every other day with dose being given post dialysis. Because of the prolonged effects seen with atenolol and patient's blood pressure being normal and well managed with HD, the atenolol was stopped with gradual tapering. Patient was finally discharged to the extended care facility after his cellulitis started clearing. A week after discharge, patient again got readmitted for new onset atrial fibrillation. Patient was stabilized on cardizem drip and then anti coagulated. Later he was started on metoprolol twice a day and finally discharged. Patient to this day has been stable on metoprolol.

Conclusions: Atenolol is moderately dialyzable and has to be used cautiously in ESRD patients as its half-life is significantly prolonged in them from 6 hours to nearly 35 hours. Metoprolol on the other hand does not need to be adjusted according to renal function and undergoes significant hepatic metabolism with half-life being the same irrespective of kidney functions. Large size studies may be needed to exclusively study these both drugs in ESRD patients but theoretically at least metoprolol may have an edge over atenolol here.

PUB610

Unusual Facial Swelling as an Early Manifestation of Lupus Nephritis: Case Report

Abubakar Ibrahim. *Medicine, Nephrology Unit, Ahmadu Bello University Teaching Hospital, Zaria, Kaduna, Nigeria.*

Background: Systemic lupus erythematosis is easily recognizable when it manifests classically. Nevertheless, confusion may arise when it presents atypically which can delay diagnosis. To highlight this issue, a young Nigerian woman was referred by her family practitioner with massive facial puffiness which was considered to be due to angioneurotic oedema or nephrotic syndrome.

Methods: A 23 year-old unmarried nigerian woman presented with isolated massive facial puffiness with no urinary or uremic symptoms. Her Family Practitioner had treated her for angioneurotic oedema to no avail and referred her with suspected nephrotic syndrome. Aside experiencing fatigue and joint pains, she offered no other relevant symptoms.

Pertinent findings on examination included facial swelling involving the lips and periorbital areas and mild 'malar' rash. Laboratory results revealed numerous dysmorphic red blood cells and red cell casts in her urine sediments, with no proteinuria. Full blood count showed ESR, 122 mm/hour (W-G method), positive 'LE cells', serum creatinine

98 umol/L. She commenced prednisolone therapy; within a few days there was complete disappearance of the facial swelling leaving behind exuberant malar rash. Kidney biopsy showed a histological pattern consistent with diffuse proliferative glomerulonephritis. She received azathioprine and prednisolone and Neoral. She developed neuropsychiatric symptoms, episodes of convulsions with progressive kidney dysfunction and died within 3 years of diagnosis.

Conclusions: Practitioners in the West African sub region should familiarize with varied features of lupus to facilitate early intervention.

This case typifies the challenges of evaluation and management of SLE in a resource-poor setting and highlights the implications on patients survival. Athough several studies indicate high prevalence of lupus in Blacks in USA and UK, data on the native populations of West Africa are inconsistent, with some studies reporting rarity of lupus while others showing high prevalence. It is conceivable that complementary tests for diagnosis and therapy of SLE are lacking due to their cost-intensive nature (human and material) and may have impacted on the disease course.

PUB611

Acute Membranoproliferative Glomerulonephritis in a Patient with Hepatitis B and Autoimmune Hemolytic Anemia Katharine Cheung,[1] Alan C. Pao.[1,2] *[1]Nephrology, Stanford University, Stanford, CA; [2]Nephrology, Palo Alto Veterans Hospital, Palo Alto, CA.*

Background: 57 year old male with a history of chronic hepatitis B infection, and schizophrenia presented with two weeks of fevers, nausea, emesis, abdominal pain, arthralgias and dark colored urine.

Methods: Six months prior he was diagnosed with autoimmune hemolytic anemia and treated with steroids and rituximab, which resulted in a partial response. Two years prior he had a lower leg skin biopsy that demonstrated leukocytoclastic vasculitis. Physical exam revealed hypertension, somnolence, abdominal distention, asterixis and sacral edema. Laboratory exam demonstrated a rise in serum creatinine to 3.26mg/dL from 1-1.5mg/dL and blood urea nitrogen 132g/dL. Urinalysis showed 2+ proteinuria and 3+ blood with red blood cell casts on microscopy. A spot urine protein/creatinine ratio was 2.37. Serologies were negative for ANA, ANCA, Anti-GBM, HCV and HIV. Hepatitis B viral load was greater than 110 million, complements were low, rheumatoid factor was greater than 100U/mL and cryoglobulin positive with 4% cryocrit. A renal biopsy revealed membranoproliferative glomerulonephritis. The patient was started on hemodialysis and tenofovir. He received high dose steroids and two weeks of plasmapheresis for the cryoglobulinemia, with subsequent decrease in his cryocrit percent to 1%, although without effect on his rheumatoid factor. His renal function recovered to a point where he no longer required dialysis.

Conclusions: Although this case illustrates a classic presentation of cryoglobulinemia, it is unique in that chronic hepatitis B infection was the underlying cause for the MPGN and cryoglobulinemia. Most viral cases of MPGN are related to hepatitis C, and there is limited published literature on the treatment of hepatitis B associated MPGN. It is notable that our patient presented with acute glomerulonephritis just a few months after steroids and rituximab. While rituximab is a treatment option for cryoglobulinemia, it has also been reported to accelerate immune complex deposition. We present a case of hepatitis B associated MPGN and cryoglobulinemia that was successfully treated with high dose steroids and plasmapheresis.

PUB612

Desmopressin, an Effective Adjunct Treatment, for Reversing Rapid Correction of Hyponatremia and Prevention of Osmotic Demyelination Syndrome Nadear A. Elmahi, Mehrdad Hamrahian, Bereket Alemu, Tibor Fulop. *Division of Nephrology, University of Mississippi Medical Center, Jackson, MS.*

Background: Osmotic demyelination syndrome (ODS) is a devastating consequence of rapid correction of chronic hyponatremia. Hypokalemia at presentation increases the risk of ODS further. Uncontrolled large free water diuresis could complicate correction of hyponatremia, once underlying etiology (e.g. nausea) is controlled. We present a unique case illustrating the added value of ADH analog in eliminating erratic polyuria and simplifying management of these patients.

Methods: A 50-year-old male was admitted to the intensive care unit after 3 episodes of seizure. He had nausea and vomiting for two weeks prior to admission and was drinking large amount of water and carbonated beverages in an attempt to control his chronic hiccups. Laboratory results on admission showed sodium 107 mmolL, potassium < 1.5 mmol/L, chloride < 60 mmol/L, bicarbonate 38 mmol/L, PH of 7.60 and a serum osmolality 217 mOsm/kg. He was treated with 3% saline and then maintained on 0.9% saline. After successful medical management of his nausea, he developed polyuria of 6 L over 8 hours with low urine osmolality of 60 mOsm/kg. His serum Na^+ increased to 126 mmol/L within 12 hours after admission. His free water deficit was replaced over 10 hours with target Na^+ of 120 mmol/L. Desmopressin was initiated at 1 mcg IV and then increased to 2 mcg IV twice daily. Few hours after initiation of desmopressin, his Na^+ dropped to 118 mmol/L and his urine output decreased to around 2 L/day. His sodium was then corrected by 2-3 mmol/L/day. His potassium was then corrected slowly, which helped in the correction of his metabolic alkalosis. At the time of discharge, the serum Na^+ was 128-130 mmol/L, hypokalemia was corrected and he had fully recovered without neurologic sequelae.

Conclusions: Overcorrection of hyponatremia is often blamed on overzealous correction with hypertonic IV fluid. The condition is often complicated by uncontrolled large free water diuresis. Use of ADH analog could provide a controlled correction of hyponatremia by limiting urine output and control unpredictable free water losses.

PUB613

Sporadic Gitelman Syndrome Complicated by Severe Vitamin D Deficiency and Hypocalcemia Noori Al-Waili, Mark D. Faber. *Nephrology, Henry Ford Hospital, Detroit, MI.*

Background: Gitelman syndrome is a rare autosomal recessive kidney disease. We report a case of sporadic Gitelman Syndrome. This 42 year old African American woman demonstrated all of the classical diagnostic criteria (recurrent severe hypomagnesemia, hypokalemia, hypocalciuria, volume depletion, and chondrocalcinosis) but without any family history. She also had severe hypocalcemia likely related to superimposed vitamin D deficiency.

Methods: The patient was admitted for syncope, generalized weakness and muscle cramps. BP was 130/80, and HR 116 bpm. Extremities were spastic with cog wheeling. She had carpopedal spasm. Lab showed severe hypomagnesemia (<0.4 mg/dl), hypocalcemia (4.6 mg/dl) and hypokalemia (2.2 mEq/L). EKG showed SVT. Serum creatinine was 1.85 mg/dl. Uric acid and CPK were normal. PMH was remarkable for frequent episodes of severe symptomatic hypomagnesemia since age 12 despite taking Mg supplements. FH in parents, sibling, and children (ages 16 and 22) was negative. Hypomagnesemia was often accompanied by hypokalemia and hypocalcemia. She experienced multiple episodes of volume depletion and hypotension. She developed stage 3 CKD (creatinine baseline 1.3-1.6 mg/dL) following an episode of NSAID related AKI, and had been diagnosed with gout and normocytic anemia. Hospital Course- Vitamin D was 5 ng/ml. Intact PTH was 409 pg/ml. Urinary calcium excretion was < 100 mg/day. She responded to electrolyte replacement, vitamin D, calcitriol, lisinopril, and amiloride. Wrist pain and swelling developed and responded to oral prednisone. X- ray showed chondrocalcinosis. At discharge she was asymptomatic and serum Ca, Mg, and K were normal.

Conclusions: Gitelman syndrome is a clinical diagnosis typically established by history and supporting laboratory findings. Genetic testing is not usually available. Establishing the correct diagnosis is important for proper management of various complications (e.g. CPP crystal arthropathy or pseudogout would not respond to xanthine oxidase inhibition), recognition of co-morbid conditions and possibly for genetic counseling. Hypocalcemia is not a hallmark of this disorder but was likely a manifestation of severe vitamin D deficiency.

PUB614

Membranous Nephropathy Associated with Sjögren's Syndrome Sabine Karam, Kevin A. Sterling. *Medicine, George Washington University Hospital, Washington, DC.*

Background: Tubulointerstitial nephritis with defects in tubular function is the most common renal manifestation of Sjögren's syndrome. However, glomerular disease can be rarely seen in this condition.

Methods: We present the case of a 34-year-old woman with history of allergic rhinitis who presented with increased weight gain, fatigue and lower extremity edema which worsened over a three month period. She also complained of both oral and vaginal dryness. She was found to have nephrotic range proteinuria with serological tests positive for ANA, RNP, and SS-A antibodies. Subsequent renal biopsy showed thickened capillary loops with moderately expanded mesangium on light microscopy (LM). Foamy histiocytes and a moderate lymphoplasmacytic infiltrate were also seen in the interstitium on LM. On immunofluorescence, capillary loop and possible mesangial granular staining patterns were seen with antisera specific for IgG (3+), IgA (2+), IgM (3+), C1q (1+), C3 (3+), kappa and lambda light chains (both 3+). Electron microscopy showed superficial subepithelial and large mesangial deposits with severe visceral epithelial cell foot process effacement. The patient was given the diagnosis of Sjögren's syndrome associated membranous glomerulonephritis. She was managed in collaboration with the Rheumatology service and was treated with steroids with reduction in her proteinuria.

Conclusions: Therefore, as is the case for other auto-immune conditions characterized by B cell hyperactivity and subsequent production of autoantibodies and immune complexes, glomerular involvement rarely occurs in Sjögren's syndrome. Routine screening of patients with Sjögren's syndrome for proteinuria might be appropriate.

PUB615

Treatment of Fatal Pulmonary Embolism in Hepatitis B Virus-Associated Membranous Nephropathy Guochun Chen, Yinghong Liu, You-ming Peng, Lin Sun, Fu-You Liu. *Renal Division, Kidney Research Institute of Central South University, Changsha, Hunan, China.*

Background: Patients with nephrotic syndrome (NS) are at increased risk of developing venous thrombosis. Embolism occurs when all or a portion of the thrombus breaks free and flows downstream in the circulation, blocking flow to vital organs. Although modern anticoagulant and thrombolytic therapies have been widely developed since 1960s, thromboembolism remains a life-threatening complication in NS. Here we report a case of NS with severe pulmonary embolism (PE) that was completely resolved by urokinase (UK) thrombolytic therapy.

Methods: A 39-year-old man presented with 2-day chest pain, hemoptysis and progressive dyspnea. He has been diagnosed 2 months earlier with nephrotic syndrome following intermittent generalized edema. Hepatitis B virus-associated membranous nephropathy was subsequently confirmed by renal biopsy. Ultrasonography revealed diffuse thrombi in his left superficial femoral vein and popliteal vein. On admission, the patient had marked respiratory difficulty, with a respiratory rate of 30 breaths per minute. Urgent chest X-ray showed decreased lung markings in the right lung hilum. CT angiogram confirmed the diagnosis of PE, showing filling defect in both left and right inferior pulmonary artery. Intravenous infusion of UK (20,000U/kg) for 2 hours was administered to the patient right

after the diagnosis of PE. The patient's respiratory status dramatically improved and his respiratory rate normalized to 20 breaths per min 24 hours after thrombolytic treatment. Repeated chest X-ray and computed tomography demonstrated resolution of PE 10 days later. The patient was discharged in good clinical condition 4 weeks later followed with continuous warfarin treatment. Prednisolone combined with tacrolimus was administered for nephrotic syndrome. A 3-month follow-up visit showed remission of nephrotic syndrome and no recurrence of PE.

Conclusions: Our case suggests that body weight adjusted UK-2 h regimen could be safe and effective for acute PE in NS. Further studies of randomised controlled trials are required to evaluate the short and long-term outcomes of UK thrombolytic regimens in NS.

Funding: Clinical Revenue Support

PUB616

Normokalemic, Normotensive Primary Aldosteronism Associated with Supra Physiologic Aldosterone Levels and Nephrocalcinosis Neha Garg, Jiwan K. Thapa, Surafel K. Gebreselassie, Emmanuel L. Bravo. *Nephrology and Hypertension, Cleveland Clinic Foundation, Cleveland, OH.*

Background: Primary Aldosteronism is an important cause of secondary hypertension and usually associated with hypokalemia, metabolic alkalosis and often times with resistant hypertension.

Methods: We report a case of 61 year old Caucasian woman with long standing history of medullary sponge kidney, bilateral nephrolithiasis and osteopenia who was found to have a 2.5 cm left adrenal mass on CT imaging in 2003. Three years later she developed new onset hypertension that was well controlled with triamterene and hydrochlorothiazide. More recently she had worsening diastolic blood pressure that prompted workup for secondary causes and subsequent referral to our center when found to have serum aldosterone > 400 ng/dl. Her initial serum studies showed: potassium 3.9 mmol/L, HCO3 28 mmol/L, creatinine 1.28 mg/dl and eGFR 48 ml/min. After an oral salt load, the 24 hour urine collection showed a urine sodium level of 296 mmol/24 hours with a blunted kaliuretic response (potassium 93 mmol/24 hours) despite high urine aldosterone level (231 ug/24 hours). Plasma renin activity was 5.7 ng/dl and plasma aldosterone 475.5 ng/dl. We evaluated the renal tubular function with 80 mg intravenous lasix challenge which showed only a 2 fold increase in fractional excretion of potassium despite a 7 fold increase in fractional excretion of sodium. Serum potassium before (3.9 mmol/L) and after (3.7 mmol/L) lasix were similar.

Conclusions: Regardless of high aldosterone levels, this patient had normokalemia and normotension at the time of initial diagnosis. Given her age and underlying kidney disease it is possible that subsequent onset of hypertension could have been from essential hypertension and possibly exacerbated by aldosteronism. We concluded that resistance to aldosterone action was at the level of distal tubules secondary to tubulointerstitial disease from nephrocalcinosis. This was supported by lack of adequate kaliuresis after salt load and lasix challenge. This illustrates that patients with primary hyperaldosteronism can have normal blood pressure and normal potassium if there is an underlying renal tubular disease.

PUB617

Merkel Cell Carcinoma and Squamous Cell Carcinoma in a Kidney Transplant Recipient Neil D. Ybanez,[1] Pamela C. Gibson,[2] Shirley Shwu-Shiow Chang.[1] *[1]Nephrology, University of Vermont, Burlington, VT; [2]Pathology, University of Vermont, Burlington, VT; [3]Hematology, University of Vermont, Burlington, VT; [4]Surgery, University of Vermont, Burlington, VT.*

Background: Merkel cell carcinoma (MCC) is a rare & aggressive neuroendocrine (NE) skin cancer. It occurs in 0.9% of transplant (tx) recipients with denovo skin cancers. MCC occurs from 5-286 months after the tx, affects older adults, usually involves the head & neck, and may be associated with other skin cancers. Risk of MCC is increased in kidney(K) tx recipients in whom it occurs at a younger age with a more aggressive clinical course.

Methods: A 56 yo man had living unrelated kidney tx in 1/2011 from ADPCKD. Patient (pt) was induced with thymoglobulin and maintained on Mycophenolic acid & Tacrolimus. BK viruria was dectected three months (mo)after his tx, progressed to BK viremia 10 mo post-tx, leflunomide was started and mycophenolic acid reduced. Pt noted a golf-sized lump in his left axilla 12 months post-tx, reported to tx center 2 mo later. 14 mo post-tx, left axillary mass bx showed mixed NE carcinoma (stained postively for CK20 conisistent with MCC), squamous cell carcinoma (SCC); tx k bx showed BK/polyoma tubulointerstitial nephritis. Work-up for MCC included CT of the chest, abdomen & pelvis without a primary neoplasm source. Mycophenolic acid was discontinued and renal function remained stable. Left axillary node dissection at 16 mo post-tx showed all 15 nodes + for metastatic MCC & SCC. Initial PET scan 15 mo post-tx showed left axilla lymph nodes uptake, numerous skeletal lesions; repeated PET scan 2 months later showed bone marrow metastatic disease progression. Pt received 15 radiation treatments, with plans for Imatinib instead of the usual regimen for high-grade NE tumors (platin & etoposide) due to potential toxicity to K allograft and CD117 + (c-kit expression). Pt was started on carboplatin & etoposide at 17 mo post-tx, died 11 days later.

Conclusions: MCC tends to be more aggressive in tx recipients, majority of whom have lymph node metastases, and about half die of their malignancy. MCC occurs in association with SCC or basal cell skin cancers or malignant melanoma.

PUB618

Complication after Embolization of a Renal Vascular Malformation Myung Hyun Lee, Hyun Chul Whang, Gun Hee An, Jeong Gwan Kim, Yul Hee Cho, Yong-Soo Kim, Chul Woo Yang. *Nephrology, St. Mary Hospital, Seoul, Korea.*

Background: A renal artery aneurysm (RAA) combined with arteriovenous fistula(AVF) in native kidney is so rare. Here, we present a case of left RAA with AVF, in which massive thrombosis developed after transarterial embolization(TAE) for the treatment of RAA with AVF, and therefore left nephrectomy was done.

Methods: A 60-year-old woman was referred for management of a left renal artery aneurysm diagnosed incidentally in regular medical checkups. She was asymptomatic and didn't have any concomitant morbidities and chronic diseases. Her physical examination and laboratory analysis were unremarkable except cardiomegaly on chest x-ray. Contrast-enhanced computer tomography(CT) showed a 2.4 cm diameter arterial aneurysm with AVF in upper pole of the left kidney and an associated 4.4 cm diameter aneurysm of the renal vein. We performed an embolization of renal vascular malformation.The next day, the patient had syncope and was pulseless. Her echocardiography showed right ventricular dilation and D-shaped left ventricle. Chest and abdomen enhanced CT showed a pulmonary thromboembolism(PTE) in right pulmonary artery and thrombosis in left renal artery and vein near embolization site. We planned a heparinization with IVC filter but we could not use an IVC filter because of mega IVC (3.2 cm). For the prevention of the development of recurrent thrombosis around embolized site in left kidney, we performed a left nephrectomy and started an anticoagulation with enoxaparine and warfarin. Three weeks after anticoagulation, she didn't complain of any chest discomfort and improved cardiomegaly compared to previous study was detected on follow-up chest x-ray and echocardiography. In follow-up chest CT performed after 3 weeks from the start of anti-coagulation, PTE was not observed any more.

Conclusions: In case of RAA combined with AVF, performance of TAE needs caution, because it can induce massive thrombosis around embolized site due to the development of venous stasis after procedure.

PUB619

Vancomycin Resistant Staph Aureus Niama Huda, Adepeju A. Jinadu, Sayed Husain, Vivek Soi. *Nephrology Department, Henry Ford Hospital, Detroit, MI.*

Background: Only a few cases of infection by *Staphylococcus aureus* with reduced susceptibility to vancomycin (vancomycin-intermediate *S. aureus* (VISA) or glycopeptideintermediate *S. aureus* (GISA) have been reported in the United States. We report a case of VISA infection.

Methods: The patient is an 83 year old female who presented after her hemodialysis session with fevers. Blood cultures were checked. Vancomycin and gentamycin were started empirically. The blood cultures were positive for Staphylococcus Aureus and endocarditis was diagnosed on echocardiogram. The source of the patients bacteremia was an infected arterio-venous graft (AVG).The patient was discharged per infectious diseases recommendations on intravenous vancomycin for two weeks after resection of the AVG.

Two months later, the patient presented with chills and back pain. Imaging revealed that the patient had L1-L2 discitis and osteomyelitis. Repeat blood cultures were drawn yielding VISA. Diagnosis of VISA infection was based on vancomycin breakpoints (vancomycin minimum inhibitory concentration 4–8 μg/ml) established by the Clinical and Laboratory Standards Institute (CLSI). The patient was then started on Ceftaroline and Bactrim for a total of 6 weeks.

Conclusions: VISA or/and VRSA (vancomycin resistant S.aureus) isolates remain rare and represent less than 0.3% of >300 000 *S. aureus* isolates in the United States.In the first four cases of VISA documented world wide three patients were dialysis patients. The three had poor clinical response to vancomycin therapy. These findings suggest that monitoring for colonization or infection with *S. aureus* with intermediate glycopeptide resistance may be warranted among patients who are often treated with vancomycin, such as patients on dialysis.

The widespread use of vancomycin resulted in the dramatic increase in the prevalence of vancomycin-resistant enterococci in U.S. hospitals may cause a similar increase in the prevalence VISA and GISA. VISA infection should be suspected in MRSA-infected patients who fail to respond to vancomycin therapy.

Infection-control and laboratory personnel should implement active surveillance for VISA and GISA in populations at high risk, such as patients on hemodialysis.

PUB620

Intractable Pain in Loin Pain Hematuria Syndrome from Thin Basement Membrane Disease Karthik Karanam, Richard N. Hellman. *Indiana University Hospital, Indianapolis, IN.*

Background: Loin pain hematuria syndrome is a poorly characterized disorder seen as a primary or secondary disorder. It is considered primary when it is associated with abnormally thin or thick glomerular basement disorder and secondary when it is associated with acquired glomerular disorders such as IgA nephropathy. We report a case of debilitating flank pain in primary loin pain hematuria syndrome.

Methods: A 40 year old female with past medical history of thin GBM disorder, chronic flank pain, CKD stage 2, hypertension and asthma was referred to the nephrology clinic for further management. Patient has chronic flank pain bilaterally with exacerbations of the pain on the left side more than the right. She is incapacitated with pain and cannot sit at work in her job as secretary. Significant family history included her son, diagnosed with the same disorder of thin GBM disorder. Physical exam was remarkable for hyperalgesia in her left

flank area. Work up in the past for recurrent pain was unrevealing for any musculoskeletal etiology or sciatica. Urine analysis showed microscopic hematuria with dysmorphic RBC. Ultrasound showed a 3 cm Bosniak class 2 cyst which has been stable for several years. Her kidney functions were stable for the past 10 years. She was on opiod, non –opiod analgesics, lidocaine patch, pregabalin and amitriptyline over many outpatient visits without improvement. She was on Lisinopril. She was followed at pain clinic; had a nerve block with partial improvement in pain and recurrence again. Later she was considered for a spine stimulator. She did not notice any improvement and had worsening of pain over the next couple of days. Work up for UTI was negative. Patient continues to stay in severe pain even to this day without effect from medications and interventions, significantly affecting her quality of life and work.

Conclusions: Thin GBM disorder has been rarely associated with loin pain hematuria syndrome and the intractable nature of the pain is rarely reported. The hypothesis is thought to be the occlusion of renal tubules with RBC's and back leak of filtrate causing stretching of the kidney and its capsule. Further treatment strategies for pain needs to be defined in this condition.

PUB621

A Case of Membranous Nephropathy Secondary to a Small Mucinous Cystic Neoplasm of the Pancreas Daniel J. Soberon,[1] Fernando E. Pedraza,[1] Ivonne Hernandez Schulman.[2] *[1]Division of Nephrology, University of Miami Miller School of Medicine, Miami, FL; [2]Division of Nephrology, Miami Veterans Administration Medical Center, Miami, FL.*

Background: A 73 year old male with hypertension and benign prostatic hypertrophy presented with worsening lower extremity edema, hypoalbuminemia, and intermittent hemoptysis.

Methods: CT scan incidentally found left renal vein thrombosis, right lower lobe pulmonary embolus, and pancreatic mass. MRI described a 1.6 cm T2 hyperintense nonenhancing cystic structure in the uncinate process of the pancreas. Laboratory studies revealed a serum creatinine of 1.3 mg/dL, and proteinuria of 5.8g per gram creatinine. Serum complements, serum and urine protein electrophoreses were normal. ANA, anti-dsDNA, ANCA, hepatitis B, hepatitis C and HIV serologies were negative. A CT guided kidney biopsy was performed. Light microscopy showed glomerular capillary wall thickening. Immunofluorecense was positive for +3 IgG, +1 IgA, +3 IgM, +3 C3, +1 C4, +2 C1q. Electron microscopy showed severe effacement of glomerular visceral epithelial cell foot processes and numerous subepithelial deposits. A diagnosis of secondary Membranous Nephropathy was made. Whipple procedure was performed and the uncinate lesion was resected with clean margins. The mass was a 2 x 2 x 1.5 cm mucinous cystic neoplasm consisting of predominantly pancreatic intraepithelial neoplasia with focal areas of micropapillary architecture (IPMN).

Conclusions: In this case of secondary membranous nephropathy, the patient endured a prolonged hospital course including refractory volume overload, acute on chronic kidney injury due to hemorrhagic shock, and eventual dialysis dependence. The patient has now been on dialysis for greater than 6 months. This is a dramatic disease course ultimately due to such a small tumor.

PUB622

Acute Renal Failure Associated with Hemophagocytic Lymphohistiocytosis Julie Ann T. Linatoc, Todd W. Gehr. *Virginia Commonwealth University.*

Background: Hemophagocytic Lymphohistiocytosis (HLH) is a rare but distinct condition caused by dysregulated activation of the immune system with infiltration of bone marrow and various organs by activated T-lymphocytes and histiocytes (macrophages). HLH could be due to inherited immune dysregulation, or secondary to infectious, neoplastic disease or immune deficiency state such as post transplantation.

Methods: A previously healthy 38-year-old woman was admitted to the hospital because of fever. On physical examination, blood pressure was 110/60 and febrile at 39.2. Heart and lung exam were normal. She had hepatosplenomegaly. There were no rashes. Laboratory studies showed white cell count 3,100 mcL, hemoglobin 8.2g/dL, platelet 32, 000/mcL, BUN 54 mg/dL, creatinine 3.4 mg/dL, AST 778 u/L, ALT 135 u/L. Urinalysis showed granular cast. Coagulation profile showed a prothrombin time (PT) of 27 s (normal: 9-11) and activated partial thromboplastin time (APTT) of 41 s (normal: 24–35). Fibrinogen level was <60 mg/dL.There was no evidence of hemolysis on peripheral smear. Cultures and serologic tests for infectious and autoimmune diseases failed to reveal any obvious source of fever. Both kidneys appeared normal and no hydronephrosis on ultrasound. She became anuric and was started on intermittent hemodialysis. Renal biopsy was not performed due to coagulopathy. Further evaluation showed elevated ferritin of 107,323 ng/mL. Bone marrow biopsy revealed frequent histiocytes with leukophagocytosis and erythrophagocytosis. She was initially treated with corticosteroids and cyclosporine which was later switched to IL-1 blockade with anakinra after she developed leukopenia from cyclosporine. Her kidney function recovered and has been on remission.

Conclusions: Our patient had fever, liver dysfunction, hepatosplenomegaly, pancytopenia, hypofibrinogenemia, hyperferritinemia and bone marrow morphology suggestive of HLH. Multi-organ failure can complicate this life-threatening condition and renal involvement has been reported with acute kidney injury due to tubular necrosis as common renal presentation. The possibility of HLH should be considered in febrile pancytopenia accompanied by acute kidney in the setting of malignancy, infection or immunosuppression.

PUB623

No Clear Consensus Regarding the Timing for Renal Biopsies Post Pre-Eclamptic Pregnancy Oyije S. Iheagwara, Kevin A. Sterling. *Division of Nephrology, George Washington University Hospital, Washington, DC.*

Background: Introduction: Persistent proteinuria after delivery in a preeclamptic patient is not uncommon. Watchful waiting for resolution is typical. Unfortunately, underlying renal disease may be present. Evidence based guidelines about the timing of biopsies for the evaluation of proteinuria post pre-eclampsia are lacking. Some argue that renal biopsies should be performed if proteinuria persists for more than 6 weeks to 3 months post-partum to allow for complete resolution of the renal lesions associated with preeclampsia. **Clinical Case:** We present a 42 year old Hispanic female with no known history of renal disease who was evaluated for persistent nephrotic range proteinuria 6 weeks after a pre-eclamptic pregnancy. A renal biopsy was performed at 4 months post-partum. Laboratory Studies: sCrt was 0.6mg/dl, hemoglobin of 12.1g/dl and a platelet count of 330,000.Serum albumin was 2.5g/dl, AST and ALT was 25 IU/L and 22 IU/L respectively. Urinalysis showed 3+ proteinuria but no blood. The urine sediment had no dysmorphic RBC or casts. UPC ratio was 16.1. HBsAg and HCV antibodies were negative. ANA was positive, but dsDNA antibodies were absent. Anti-centromere and anti-SSA antibodies were positive. C4 was normal, but C3 low. **Renal Biopsy:** Light microscopy revealed moderately thickened capillary loops. Tubular atrophy and interstitial fibrosis was absent. Immunofluorescence showed capillary loop staining for IgG(3+), IgA(2+), IgM(2+), kappa (2+) and lambda(3+). Staining was equivocal for c3 but absent for C1q. EM revealed numerous capillary loop deposits. Mesangial deposits were present with tubulo-reticular inclusions(TRI). Near full house staining, TRI and positive anti-centromere and SSA antibodies suggested Lupus Nephritis class 5 though other features suggestive of SLE were absent. Management: She initially received an ACEi with no improvement in proteinuria, then Prednisone and MMF were started.

PUB624

Successful Remission of Dense Deposit Disease with Plasmapheresis Sheena Sharma, Katarina Supe-Markovina. *Department of Pediatrics, Stony Brook Long Island Children's Hospital, Stony Brook, NY.*

Background: Dense Deposit Disease (DDD) is an extremely rare condition affecting 2-3 persons per million in the general population. The most common etiology is due to C3 nephritic factor (C3NF), an IgG autoantibody which stabilizes C3 convertase, resulting in uncontrolled activation of the alternative complement pathway. Remnants of C3 are deposited in the glomerular basement membrane causing injury and approximately 50% of patients develop end-stage renal disease within 10 years. Due to its rarity, there are no evidence based guidelines for the treatment of DDD. We present the case of a 15 year old Caucasian male with DDD secondary to C3NF who achieved remission with short-term plasmapheresis therapy.

Methods: Our patient presented with gross hematuria and proteinuria. A native kidney biopsy revealed DDD. Components of the complement cascade were measured. C3 was found to be low and C3NF was elevated. In order to remove the pathologic antibody, pheresis treatments were initiated. Treatments were performed with the Cobe Spectra Collect Flow Path using citrate dextrose containing heparin for anticoagulation and 5% albumin as replacement fluid. Our patient had a total of 18 treatments over 6 months; weekly for 3 months then bimonthly for an additional 3 months. C3 levels and proteinuria were monitored bimonthly, and C3NF was monitored prior to the initiation of treatments, mid-way through treatments, and following cessation of treatments.

Results: C3 levels and proteinuria normalized after 6 months of plasmapheresis. C3NF initially decreased while receiving treatments, but increased once stopped. Despite this, he remains in clinical remission defined as urine protein/creatinine <0.5 on first morning void, normal estimated GFR, normotensive, and normal serum C3.

Conclusions: We have shown that plasmapheresis is a safe and effective method for inducing remission in patients with DDD secondary to C3NF. The efficacy may be due to removal of the pathologic antibody. The persistent elevation of C3NF after pheresis could possibly be explained by change in epitope or anti-idiotypic antibodies which should be explored in the future.

PUB625

Temporary Depletion of Regulatory T Cells Exacerbates Cytokine Release and Progression of Spontaneous Autoimmune Nephritis in BIM Knockout Mice Yuan Min Wang,[1] Geoff Yu Zhang,[1] Ya Wang,[2] Min Hu,[2] Jimmy Jianheng Zhou,[1] Andrew Sawyer,[1] Mitsuru Saito,[1] Tania Polhill,[1] Qi Cao,[2] Yiping Wang,[2] Guoping Zheng,[2] Vincent W.S. Lee,[2] David C. Harris,[2] Stephen Alexander.[1] *[1]Centre for Kidney Research, Children's Hospital at Westmead, University of Sydney, Sydney, NSW, Australia; [2]Centre for Transplant and Renal Research, University of Sydney at Westmead Millennium Institute, Sydney, NSW, Australia.*

Background: Bim is a pro-apoptotic member of the B-cell lymphoma 2 (Bcl-2) family, and is an inducer of programmed cell death and stress-induced apoptosis. Bim knockout (Bim-/-) mice fail to delete autoreactive T cells in the thymus, leading to spontaneous autoimmune renal disease. The aim of the study is to evaluate the role of regulatory T cells (Tregs) in spontaneous immune nephritis.

Methods: We evaluated the role of Tregs in glomerulonephritis in Bim-/- mice by depleting Tregs in two month old mice using PC61, an anti-CD25 monoclonal antibody. At six months of age, renal function, histologic injury, serum cytokines and in vitro Treg functional assessment were performed.

Results: Treg depletion was associated with increased proteinuria, worse renal function, weight loss and worse histological injury characterised by glomerular scarring, antibody deposition and tubular damage. There was a marked increase in interstitial infiltrate comprising T cells and macrophages. Serum cytokines IL-2, IL-4, IL-6, IL-10, IL-17a, IFN-γ and TNF were significantly increased after Treg depletion in Bim-/- mice. Tregs from Bim-/- mice demonstrated less suppressive function than C57BL/6 wild-type Tregs in vitro.

Conclusions: Temporary loss of Tregs allows effector T cell activation of all classes leading to worsening of nephritis in this spontaneous model.

Activation of Innate Immunity in Children with Henoch-Shoenlein Purpura: Toll-Like Receptors in Circulating Mononuclear Cells

Roberta Camilla,[1] Elisa Loiacono,[1] Maria Elena Donadio,[1] Margherita Conrieri,[2] Manuela Bianciotto,[2] Francesca Maria Bosetti,[2] Licia Peruzzi,[1] Giovanni Conti,[3] Laura Morando,[1] Alessandro Amore,[1] Rosanna Coppo.[1] *[1]Nephrology, Dialysis, Transplantation, R. Margherita Hospital, Turin, Italy; [2]Pediatric Emergency, R. Margherita Hospital, Turin, Italy; [3]Pediatric Nephrology, G. Martino Hospital, Messina, Italy.*

Background: Henoch-Schoenlein purpura (HSP) in children is often triggered by mucosal infections and presents with a benign course with rapid resolution of purpura and transient hematuria and proteinuria. We aimed at investigating the activation of innate immunity and the relationships with the regulatory T (Treg) cells and proinflammatory Th17 cells.

Methods: In 42 children with HPS (aged 3-14 years) and 35 healthy controls peripheral mononuclear cells (PBMC) were isolated by centrifugation gradients. Real time PRC (Taqman) was used to to measure in PBMC mRNA expression of Toll-like receptors (TLR) TLR2, TLR3, TLR4, TLR9 and of regulation-associated genes of Treg including forkhead box P3 (Foxp3), Th17-related factors (IL-17), retinoid orphan nuclear receptor (RORc), and TFG-β1 which modulates the differentiation of Th17. Values were normalized using Abelson housekeeping gene mRNA and expressed as fold changes.

Results: PBMC ofchildren with HSP had, in comparison to healthy controls (HC), significantly increased expression of mRNA encoding for TLR 2 (2.83 ± 2.57 vs 1.42± 0.77 in HC, P=0.042) and TLR4 (2.17 ± 1.63 vs 1.37± 0.73 in HC, P= 0.011), while showed a significantly decreased expression of mRNA encoding for TGFβ1 (0.89 ± 0.58 vs 1.44 ± 0.5 in HC, <0.0001). A significant correlation was found between TLR4 and TGFβ1 mRNAs (p=0.033) and between TLR4 and foxp3 mRNAs (P< 0.05). No differences were observed in cases with systemic purpura with or without renal involvement.

Conclusions: In children with HSPwe observed a significant activation of innate immunity, with particular engagement of TLR4, which was correlated with down modulation of factors favouring the differentiation of Th17. This changes are coincident with the benign course of HSP in the children investigated.

PUB627

Regulatory T Cells (TREG) and Tryptophan/Kynurenine Pathway in IgA Nephropathy

Elisa Loiacono,[1] Davide Defedele,[2] Maria Paola Puccinelli,[2] Roberta Camilla,[1] Rachele Gallo,[1] Licia Peruzzi,[1] Cristiana Rollino,[3] Michela Ferro,[3] Alessandro Amore,[1] Rosanna Coppo.[1] *[1]Nephrology, Dialysis, Transplantation, R. Margherita Hospital, Turin, Italy; [2]Diagnostic Department, R. Margherita Hospital, Turin, Italy; [3]Nephrology, G. Bosco Hospital, Turin, Italy.*

Background: In IgA nephropathy (IgAN) a dysregulation of the immune system is likely to lead to persistent T cell response after exposure to common mucosally encountered antigens. In these patients we aimed at investigating regulatory T-cells (Treg), which pay an essential role in the negative regulation of immune response. We assessed also the activity of the ancestral metabolic enzyme indoleamine 2,-dioxygenase (IDO), an inducer and amplifier of Treg functions.

Methods: PBMC were isolated from 54 patients with IgAN (28.4±21 y.o.), with e-GFR 96.8±42 ml/min and proteinuria 0.62 ±1.19 g/day, and from 30 healthy controls (HC). We measured by Taqman the mRNA expression of the Treg regulation-associated gene forkhead box P3 (Foxp3) and we assessed IDO activity effects as change in the ratio between tryptophan (Trp) and its catabolic product kynurenine (Kyn) (isocratic RP HPLC with UV detection).

Results: The transcriptional level of Foxp3 was significantly lower in patients with IgAN versus HC (0.90±0.51 vs 1.26±0.65, P= 0.0014). Trp levels were similar in IgAN patients and HC, but Kyn, its catabolic product, resulted significantly increased (2.47 ± 0.60 vs 2.02 ± 0.32, P= 0.0012) and so was the Kyn/Trp ratio (5.03±1.65 vs 3.72±0.55 in HC, P= 0.0016). No correlation was found with proteinuria levels, nor with eGFR values. No correlation was found with possible TReg modulator factors, including Toll-Like Receptors (TLR 3,4 and 9).

Conclusions: In patients with IgAN there is a defective transcription of mRNA encoding for Foxp3 hence a likely defective Treg activity, in spite of hyperactivity of the IDO enzyme which is expected to trigger Tregs. Environmental cues have been reported to induce Foxp3 Treg to undergo phenotypic changes, including conversion, plasticity or reprogramming to rapidly adopt a pro-inflammatory phenotype. The mechanisms inhibiting Tregs in IgAN in spite of IDO activation deserve further investigation.

PUB628

Renal Cell Snail Expression Determines Vitamin D Receptor Status in HIV Milieu

Nirupama Chandel, Tejinder Singh, Partab Rai, Xiqian Lan, Rivka Lederman, Mohammad Husain, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY.*

Background: HIV transgenic mice have been demonstrated down regulation of renal tissue vitamin D receptor (VDR) and activation of the renin angiotensin system (RAS). However, the involved mechanism of down regulation of VDR is not clear. Since VDR is a negative regulator of the RAS it may be playing an important role in the development and progression of HIV-associated nephropathy (HIVAN). Therefore, it may be important to explore the involved mechanism of HIV-induced down regulation of VDR. We hypothesized that Snail family of proteins could be down regulating renal cell VDR in HIVAN.

Methods: Renal tissues of four weeks old, age and sex matched control and Tg26 (HIV transgenic mice) in groups of six were evaluated for protein and mRNA expression of Snail, VDR, renin and angiotensinogen. Renal cortical sections of control and Tg26 mice were labeled for Snail and VDR and examined under an immunofluorescence microscope. In *in vitro* studies, human podocytes (HPs) and human proximal tubular cells (HPTCs) were transduced with either empty vector or NL4-3 (HIV) constructs and assayed for expressions (protein and mRNA) of Snail and VDR. Both HPs and HPTCs were also transfected with siRNA-Snail and scrambled siRNA and then probed for Snail and VDR expression.

Results: Renal tissues of control mice showed only minimal expression of Snail, whereas, renal tissues of Tg26 mice displayed moderate expression of Snail. In renal cortical sections of Tg26 both podocytes and tubular cells displayed expression of Snail but attenuated expression of VDR. Renal cells in control mice displayed robust expression of VDR but attenuated expression of Snail. Renal cortical sections of Tg26 mice also displayed enhanced expression of renin. In *in vitro* studies, both HIV/HPs and HIV/HPTCs displayed higher expression of Snail and attenuated expression of VDR when compared to EV/HPs and EV/HPTCs. HIV/HPs and HIV/HPTC silenced for Snail displaced enhanced expression of VDR.

Conclusions: These findings indicate that HIV may be downregulating VDR expression in HIVAN mice by upregulating renal cell expression of Snail.

PUB629

Hyperglycemia Up Regulates Snail and Epithelial Mesenchymal Transition in HIV-Associated Nephropathy

Partab Rai, Dileep Kumar, Andrei Plagov, Rivka Lederman, Guohua Ding, Mohammad Husain, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY.*

Background: Epithelial mesenchymal transition (EMT) has been reported to contribute to the progression of renal lesions in HIV-associated nephropathy (HIVAN) as well as in diabetic nephropathy. We hypothesized that HIVAN patients with hyperglycemia are likely to have accelerated EMT. We further hypothesized that hyperglycemia may be inducing EMT in kidney cells of HIVAN patients by enhancing renal cell expression of Snail, a repressor of E-cadherin transcriptor and negative regulator of vitamin D receptor (VDR). Conversely, VDR being a negative regulator of renin-angiotensin system (RAS), would further enhance EMT in HIVAN patients.

Methods: Four weeks old control (C) and Tg26 (HIV) mice (n=4) were either administered vehicle or streptozotocin (STZ, 150 mg/Kg, intraperitoneal, single dose). At the end of two weeks, mice were sacrificed. Kidneys were harvested for renal histology, imunohistochemical, and immunoblotting studies for Snail, proliferating cell nuclear antigen (PCNA), a-SMA, fibroblast specific protein (FSP1), and E/P-cadherin, and VDR. In *in vitro* studies, empty vector (EV) and HIV (NL4-3) constructs transduced human podocytes (EV/HP and HIV/HP) and tubular cells (EV/HPTC and HIV/HPTC) were incubated in media containing either 5 mM or 30 mM glucose for 24 hours. Immunoblots were probed for Snail, PCNA, a-SMA, FSP1 and E/P-cadherin and VDR.

Results: Renal cells in HIV alone displayed enhanced expression of Snail, PCNA, a-SMA, and FSP1 and down regulation of E/P-cadherin; Interestingly, renal cells of HIV-STZ displayed higher expression of Snail, PCNA, "-SMA, and FSP1 and more down regulation of E/P-cadherin and VDR when compared to HIV alone. Western Blot studies and real time PCR studies further confirmed these findings. HIV/HPs and HIV/HPTCs treated with high glucose also displayed enhanced EMT markers and downregulation of VDR when compared to HIV/HPs and HIV/HPTCs treated with normal glucose.

Conclusions: These findings indicate that hypeglycemia accelerates the progression of HIVAN by enhancing EMT via upregulation of Snail and down regulation of VDR.

PUB630

The Accumulated VH Replacement Products Contribute to the Generation of Auto/Polyreactive Antibodies in Systemic Lupus Erythematosus

Zhixin (Jason) Zhang. *Pathology and Microbiology, University of Nebraska Medical Center, Omaha, NE.*

Background: Systemic lupus erythematosus (SLE) is characterized by the over-production of high affinity autoantibodies. However, it is not clear how these autoantibodies are generated and selected in SLE patients. V_H replacement is originally considered as a receptor editing process to change unwanted non-functional immunoglobulin heavy chain (IgH) genes or IgH genes encoding self reactive BCRs. Our sequence analysis show that V_H replacement products are highly enriched in IgH genes derived from different autoimmune diseases, including SLE.

Methods: To gain insight into the mechanisms responsible for autoantibody generation in SLE, we performed single cell RT-PCR analysis to study the functional antibody repertoires in active SLE patients.

Results: Analysis of 180 recombinant antibodies derived from SLE patients showed that 19.0% of the antibodies derived from naïve B cells and 56.9% of the antibodies derived from plasmablasts are autoreactive. In contrast, only 7.7% of the antibodies derived from naïve B cells and 17.4% of the antibodies from plasmablast B cells are autoreactive in healthy donors. Detailed sequence analysis revealed that V_H replacement products are significantly increased in IgH genes obtained from SLE patients (20%) compared to that in healthy controls. Importantly, the accumulated V_H replacement products in SLE patients have long CDR3 regions enriched with positively charged amino acids; 74% of them directly encode anti-nuclear antigen or polyreactive antibodies.

Conclusions: Based on these results, we conclude that the accumulated V_H replacement products in SLE patients contribute to the generation of auto/polyreactive antibodies in SLE.

PUB631

Combined C3b and Factor B Autoantibodies and MPGN II Peter F. Zipfel,[1] Qian Chen,[1] Christine Skerka,[1] Dominik Müller.[2] *[1]Infection Biology, Leibniz Institute for Natural Product Research and Infection Biology, Jena, Thueringen, Germany; [2]Pediatric Nephrology, Charite Berlin, Berlin, Germany.*

Background: Membranoproliferative glomerulonephritis type II, dense deposit disease is a rare glomerular disease. MPGN II is complement-associated, due to systemic C3 activation and C3 deposition along the GBM. Genetic causes include mutations in the *factor H* and *C3* genes, which cause C3 convertase deregulation. Also autoantibodies, such as C3 nephritic factor (C3Nef), which stabilize C3 convertase have been identified in 50-80% of MPGN2 patients. Single cases with autoantibodies to Factor B and Factor H were described. There is currently no effective treatment for MPGN II, and the prognosis for survival of a kidney transplant is poor.

Methods: We now report combined C3b and Factor B autoantibodies in two unrelated patients, an eight-year-old girl with MPGNII and ESRD and a 20-year-old man with MPGN. Both patients lacked C3Nef but presented autoantibodies to the two individual components of the C3 convertase, i.e. C3b and Factor B. These autoantibodies enhance C3 convertase activity.

Results: Based on the diagnosis of autoimmune MPGN2 weekly plasma exchanges and immunosuppressive therapy (rituximab (375 mg), tacrolimus (10 ng/l), mycophenolate mofetil (2.0 ng/l) and glucocorticoids (1 mg/kg)) was administered to the 8-year-old patient, and her C3b autoantibody levels declined (0.8 to 0.4 arbitrary units (AU)), and her Factor B autoantibody levels decreased Her Ba activation fragment dropped to background levels, and C3 plasma levels increased to normal values. She was transplanted and plasma-exchange was performed every other day prior to and for three weeks after transplantation, then was continued weekly for eight weeks after transplantation (week 4-12), and then every other week for four more weeks (week 13-16). Serum-creatinine was 0.7 mg/dl, and proteinuria was absent one week after transplantation.

Conclusions: 30 months after transplant, she is stable and without disease recurrence. This autoimmune form of MPGN shows that in addition to C3Nef further autoantibodies develop in MPGN2 that lead to complement deregulation that requires targeted treatment.

PUB632

The CCL1-CCR8 Axis Drives the Recruitment of Inflammatory Mononuclear Phagocytes and Tissue Injury in Murine Experimental Glomerulonephritis Erik M. Disteldorf,[1] Hans-Joachim Paust,[1] Oliver M. Steinmetz,[1] Anett Peters,[1] Sabrina Bianca Bennstein,[1] Hans-willi Mittrücker,[2] Rolf A. Stahl,[1] Ulf Panzer.[1] *[1]Nephrology, Universitätsklinikum Hamburg Eppendorf, Hamburg, Germany; [2]Immunology, Universitätsklinikum Hamburg Eppendorf, Hamburg, Germany.*

Background: Human and experimental forms of crescentic glomerulonephritis are characterized by the recruitment of leukocyte subsets that cause renal tissue damage. Infiltration of leukocytes upon renal injury is substantially affected by chemokines. CCR8 is expressed on T cells and mononuclear phagocytes, which are found to accumulate within the inflamed tissue in large amounts. However the functional role of CCR8 and its ligand CCL1 during crescentic glomerulonephritis remains currently unclear.

Methods: Experimental crescentic glomerulonephritis (nephrotoxic nephritis - NTN) was induced in CCR8-deficient and WT mice.

Results: Induction of nephritis resulted in an up-regulation of renal CCL1 and CCR8 mRNA expression. CCR8-deficient mice developed an ameliorated course of disease in terms of lower BUN levels and significantly reduced glomerular and tubulointerstitial damage. Analysis of cellular infiltrates by flow-cytometry revealed a markedly reduced number of mononuclear phagocytes ($CD11b^+F4/80^+$) to be present in the inflamed tissue compared to WT nephritic mice. In line, immunohistochemical examination clearly showed less $F4/80^+$ mononuclear cells within the renal cortex of nephritic CCR8 deficient mice. Intracellular staining showed a considerable positivity for TNF-α, underscoring a proinflammatory phenotype of the renal $CD11b^+F4/80^+$ mononuclear phagocytes. Moreover, renal damage and infiltration of mononuclear phagocytes could be restored by adoptivley transferring CCR8 expressing, bone-marrow derived CD115+ monocytes during experimental injury.

Conclusions: In conclusion, our study shows that the CCL1- CCR8 orchestrates renal recruitment of pro-inflammatory mononuclear phagocytes and tissue injury during experimental glomerulonephritis. Thus, CCR8 might be a promising new therapeutic target in human proliferative and crescentic glomerulonephritis.

PUB633

LPS-Contamination May Contribute to FGF-23 Induced *In Vitro* Monocyte Activation Adam M. Zawada, Aurelia Luthe, Sarah Seiler, Kyrill S. Rogacev, Danilo Fliser, Gunnar H. Heine. *Dept. of Internal Medicine IV, Saarland University Medical Center, Homburg, Saarland, Germany.*

Background: CKD patients display proinflammatory activation of monocytic cells. Moreover, monocyte subset distribution is skewed towards proinflammatory subsets (CD14++CD16+ and CD14+CD16++ monocytes). This phenomenon is unexplained so far. Recently, FGF-23 has been reported to influence monocyte function, e.g. their anti-microbial capacity; however the effect on monocyte subsets has not previously been reported.

Methods: Human monocyte subsets were stimulated for 5 h *in vitro* with rFGF-23 (0; 0.25; 0.5; 1; 10; 50 ng/ml) which was either derived from *E.coli* (Alexis Biochemicals), or from mouse-myeloma-(NS0)-cells (R&D). Formation of proinflammatory CD14++CD16+ and CD14+CD16++ monocytes and their activation status – i.e. CD86 expression – was analysed flow-cytometrically; the production of ROS was measured by electron-spin-resonance.

Results: Stimulation of monocytes with rFGF-23 from *E.coli* significantly activated proinflammatory monocyte subsets and increased their CD86 expression ($p < 0.001$), whereas rFGF-23 from NS0-cells did not. LPS-stimulation of monocytes had a comparable effect as rFGF-23 from *E.coli*.

Conclusions: Activation of monocytes after short-term (≤ 5 h) *E.coli*-rFGF-23 stimulation is likely to be an artifact due to LPS-contamination. Since CKD-patients are chronically subjected to elevated FGF-23 levels, future studies should evaluate potential long-term effects. For such studies, we advocate the use of non-*E.coli*-rFGF-23 as monocytes are extremely sensitive to LPS-contamination.

PUB634

Human Factor H-Related Protein 2 (CFHR2) Regulates Complement and Is Affected in a Patient with MPGN I Hannes Uwe Eberhardt,[1] Qian Chen,[1] Markus J. Kemper,[2] Teresia Hallström,[1] Peter F. Zipfel,[1] Christine Skerka.[1] *[1]Infection Biology, Leibniz Institue for Natural Product Research and Infection Biology, Jena, Germany; [2]University Hospital Hamburg, University Hospital, Hamburg, Germany.*

Background: Membranoproliferative glomerulonephritis type I (MPGN) is a severe kidney disease characterized by subendothelial and glomerular basement membrane deposits containing immune complexes and complement activation products. Previous studies in knock out mice demonstrated a critical role of iC3b, a C3 cleavage product, for MPGN development.

Results: Here we describe a MPGN I patient with a stop mutation in exon 4 of the *CFHR2* gene and severely reduced CFHR2 plasma levels. This CFHR2 deficiency suggests to be linked to disease pathology as we identify CFHR2 as novel human complement regulator, that inhibits C3 convertase activity, which is continuously activated in this patient.

Conclusions: Thus deficiency of the novel human regulator CFHR2 under conditions of enhanced complement activation likely leads to accumulation of inflammatory iC3b at the glomerular basement membrane and pathology. These results shed light on the underlying pathomechanism of MPGN I and may have implications for therapy.

PUB635

Effects of L-Carnitine on Interstitial Fibrosis and Inflammation in Chronic Cyclosporine Nephrotoxicity in Rats Can Li,[1] Ying Xiang,[1] Jing Hao Cui,[2] Hong Bin Zou,[3] Ying Shun Jin,[1] Shang Guo Piao,[4] Bi Hu Gao,[5] Chul Woo Yang.[4] *[1]Nephrology, YanBian University Hospital, YanJi, JiLin, China; [2]Control Release of Drug Delivery System, SuZhou University, SuZhou, China; [3]Nephrology, The First Affiliated Hospital of JiLin University, ChangChun, JiLin, China; [4]Nephrology, The Catholic University of Korea, Seoul, Korea; [5]Nephrology, The Affiliated Zhong-Shan Hospital of DaLian University, DaLian, China.*

Background: L-carnitine has been shown to prevent allograft dysfunction and cyclosporine induced lipid peroxidation; however, its effects on the kidney with chronic cyclosporine nephrotoxicity are undetermined. The aim of this study was to investigate whether concomitant treatment with l-carnitine attenuates interstitial inflammation and fibrosis in an animal model of chronic cyclosporine nephrotoxicity.

Methods: Male adult Sprague-Dawley rats kept on a slat-depleted diet (0.05% sodium) were treated daily for 28 days with vehicle (olive oil 1 mL/kg s.c), cyclosporine (15 mg/kg s.c), l-carnitine (50 mg/kg or 200 mg/kg i.v), and both cyclosporine and l-carnitine. Body weight, renal function, histomorphology (tubulointerstitial fibrosis and ED-1-positive cells), and the expression of transforming growth factor (TGF)-β1 and apoptotic cell death were compared for different treatment groups.

Results: CsA-treated rats showed decreased renal function and increased histomorphological parameters compared with VH-treated rats. Concomitant administration of l-carnitine significantly improved renal function and histomorphological parameters (all $P < 0.05$). At the molecular level, the increased TGF-β1 expression and TUNEL-positive cells seen in CsA-treated rat kidneys were markedly decreased after l-carnitine treatment in a dose-dependent manner.

Conclusions: These findings suggest that concomitant treatment with l-carnitine prevents CsA-induced renal interstitial inflammation and fibrosis through suppressing apoptotic cell death and TGF-β1 expression in chronic cyclosporine nephrotoxicity.

PUB636

Abelmoschus Manihot (L.) Medic, a Compound of Chinese Herbal Medicine, Ameliorates Adriamycin-Induced Glomerular Inflammatory Damage via Down-Regulating p38MAPK Expression in Rats Yue Tu, Wei Sun, Yigang Wan. *[1]Department of Graduate School, Nanjing University of Chinese Medicine, Nanjing, China; [2]Jiangsu Provincial Hospital of Chinese Medicine, Affiliated Hospital of Nanjing University of Chinese Medicine, Nanjing, China; [3]Nanjing Drum Tower Hospital, the Affiliated Hospital of Nanjing University Medical School, Nanjing, China.*

Background: *Abelmoschus manihot (L.) Medic* (AM) is widely used for chronic kidney disease (CKD) in China. Increasing evidence suggests that AM can significantly reduce proteinuria and improve glomerulosclerosis. Given a rich literature identifying glomerular inflammatory injury as an important step in the pathophysiological progression to glomerulosclerosis, we hypothesized that AM ameliorates glomerular lesions from undergoing inflammatory injury.

Methods: A rat model of glomerulosclerosis created by unilateral nephrectomy and twice intravenous injections of adriamycin. Rats in sham-operation and vehicle group received distilled water, while the ones in AM-treated group received AM for 4 weeks. Proteinuria, immunofluorescence (IF) staining of macrophages (ED1+ and ED3+ cells), α-smooth muscle actin (α-SMA) and collagen type I, glomerular morphological changes, and the protein expressions of TGF-beta1, p38MAPK and phosphorylated-p38MAPK (p-p38MAPK) were evaluated, respectively.

Results: ADR induced massive proteinuria, intense staining of α-SMA and collagen type I elevation, as well as glomerulosclerosis in ADR-nephropathy (ADRN) rats, which were associated with up-regulation of TGF-beta1, an essential molecule for glomerulosclerosis. Moreover, ADR induced glomerular inflammatory damage, as a result of infiltrated ED1+ and ED3+ cells, which was correlated with activation of p-p38MAPK, a key molecule in the inflammation-related p38MAPK-signaling pathway. Compared with ADRN rats, AM significantly prevented proteinuria elevation, alleviated glomerulosclerosis and glomerular inflammatory damage via down-regulating the expressions of TGF-beta1 and p-p38MAPK.

Conclusions: AM ameliorates ADR-induced glomerular inflammatory damage in ADRN model. The anti-inflammatory action of AM may be partly attributable to the depression of TGF-beta1 and p-p38MAPK protein expression.

Increased Maternal IL-6 during Gestation Alters Fetal Kidney Development Mukut Sharma,[1] Jianping Zhou,[1] Junming Luo,[1] Pramod B. Mahajan,[2] Tarak Srivastava,[3] Ram Sharma,[1] Thomas Wiegmann,[1] Ellen T. McCarthy,[4] Virginia J. Savin,[1] Jean-francois Gauchat.[5] *[1]Research, KC VA Medical Center, Kansas City, MO; [2]PBA Sciences, Drake University, Des Moines, IA; [3]Nephrology, CMH, UMKC, Kansas City, MO; [4]Kidney Institute, KU Medical Center, Kansas City, KS; [5]Pharmacology, Université de Montréal, Montreal, QC, Canada.*

Background: The effect of increased interleukin 6 (IL6) in obese pregnant women on fetal development and on the susceptibility to chronic disease in the offspring is not known. Recently, we showed that podocytes express IL6 receptor-alpha (IL6Ra) and that exogenous IL6 causes derangement of the podocyte actin cytoskeleton and increases *in vitro* glomerular albumin permeability. We hypothesize that maternal IL6 adversely affects fetal renal development.

Methods: We injected recombinant IL6 to timed pregnant C57BL6 mice (10 pg/g body weight, i.p.) on embryonic days (E) 13.5, 15.5 and 17.5 and observed its effect on E19.5 fetal renal histology using light microscopy and morphometry, components of JAK/STAT, SHP2-MAPK/ERK and PI3K/Akt pathways using Western blotting. Methylation of genomic DNA was determined by measuring 5-methylcytosine (5mC) levels using LC-MS.

Results: Midgestation injection of IL6 to pregnant mice altered fetal renal structure. Light microscopy showed glomerulopenia, poorly defined corticomedullary junction and approximately 35% increase in tubular lumen diameter ($P<0.01$) in fetal kidneys from IL6-injected mothers. IL6 injection resulted in increased phosphorylation of JAK2 and STAT3 in fetal kidney tissue confirming activated JAK/STAT pathway ($P<0.001$). We also noted significantly down-regulated phosphorylation of STAT5, ERK1/2 and Akt ($P<0.001$). Levels of 5mC were significantly increased ($P<0.05$). In summary, midgestational increase in maternal IL6 altered the renal development, key signaling pathways and DNA methylation in the fetal kidney by late gestation.

Conclusions: Elevated maternal IL6 may have trans-generational effect on renal function and cause increased susceptibility to chronic kidney disease in the offspring through epigenetic mechanisms.

PUB638

NTS Is Aggravated in CD73/Ecto-5'-Nucleotidase Deficient Mice by Increased Leucocyte Invasion into the Renal Tissue Nelli Shushakova,[1] Kathrin Eller,[3] Alexander R. Rosenkranz,[3] Hermann G. Haller,[1] Christine S. Falk,[4] Jurgen Schrader,[2] Cornelia Anneliese Blume.[1] *[1]Nephrology and Hypertensiology, Medical School Hannover, Hannover, Germany; [2]Molecular Cardiology, Heinrich Heine University Düsseldorf, Düsseldorf, Germany; [3]Internal Med., Nephrology, Graz Medical University, Graz, Austria; [4]Transplant Immunology, Medical School Hannover, Hannover, Germany.*

Background: We previously have shown that a lack of extracellular adenosine formed by the ectoenzyme CD73 leads to an autoimmune phenotype with proteinuria and renal injury in older animals. These mutant mice exhibit glomerular endotheliosis with elevated levels of the chemoattractant IL-18 and fibrosis [Plos One2012].

Methods: Now we induced a nephrotoxic serum nephritis (NTS) in 6-10 CD73-deficient ($CD73^{-/-}$)mice and wild-type (WT) controls and monitored proteinuria and renla function over 2 weeks, before kidneys were harvested for further histological analysis. Histomorphometry, immune staining of the kidneys, analysis of cytokines and chemokines in the plasma and a 19 F magnet resonance imaging method to track the monocytes were performed.

Results: In NTS, proteinuria was elevated in the $CD73^{-/-}$ mutant (13.8 mg/24 h ± 0.5 vs. 5.5 mg/24h ± 0.4 or 0.31 ± 0.01g/g creatinine versus 0.19 ± 0.03 g/g creatinine), and this phenotype was not abrogated by a continuous i.p. application of the A2A-agonist CGS-21680 twice a day. Histomorphometry revealed accelerated tubule-interstitial injury as well as vaso-occlusion in $CD73^{-/-}$mice with more crescents and perivascular fibrosis. Using a 19F MRI for noninvasive inflammation imaging, we observed a significant shift of monocytes into renal tissue in mutant mice compared to WT-controls (figure 1), which is likely to be mediated by the adenosine A2B-receptor as it was previously shown for ischemia. The increased plasma levels of IL-18 were down-regulated in CD73-/-mice in NTS.

Conclusions: Due to the disturbed barrier function of the endothelium together with immune cells without adenosinergic feedback, lack of CD73-derived extracellular adenosine aggravates the course of NTS. Analysis of immune cell subtypes and cytokine levels in the renal tissues is in support of this interpretation.

PUB639

1,25$(OH)_2$- Vitamin D3 Prevents Interleukin-6 Induced Muscle Atrophy by Stimulating Differentiation and Inhibiting Myostatin Expression in C2C12 Muscle Cells Huiling Wang. *Division of Nephrology, Jimin Hospital, Shanghai, China.*

Background: The 1,25-dihydroxyvitamin D (1,25-D3) deficiency is highly prevalent among patients with chronic kidney disease (CKD). Although 1,25-D3 was administrated wildly for bone mineral disorder in CKD, and the mechanism or the role of 1,25-D3 regulation of calcium and phosphate homeostasis is well known, there is little information about vitamin D in muscle wasting, a main aspect in CKD with protein energy wasting.

Methods: Cultured mouse C2C12 myogenous cells, treated with interleukin-6(IL-6 20ng/ml) and 1,25-D3 (100nM). We observed myotube's morphology by light microscopy, measured the expression of myogenic and proliferation molecular by quantitative RT-PCR and Western blotting.

Results: After chronic exposure to IL-6(20ng/ml) from day 1 to day 8, the size of muscle myotube which differentiated from cultured C2C12 myoblast was reduced markedly, the mRNA expressions of Atrogin-1 and myostatin are elevated 3-6 folds, the myoD and myogenin down-regulated 3-5 folds. After treated with 1,25-D3(100nM/day), there resulted in an increase in the diameters in muscle size, indicating that the muscle atrophic responses stimulating by IL-6 were inhibited. As expected, with the myotubes expressing VDR, the expression of Atrogin-1 and myostatin significantly blocked, and the expression of myoD and myogenin were increased. In addition, we found the VDR activated enhanced the Insulin growth factor-II (IGF2) expression.

Conclusions: 1,25-dihydroxyvitamin D prevents interleukin-6 induced muscle atrophy by promoting myogenic differentiation, up-regulating the expression of myoD and myogenin, and inhibits the expression of atrogin1 and myostatin.

PUB640

HIV-Induced Down Regulation of Tubular Cell Vitamin D Receptor Is Mediated through Tumor Necrosis Factor-α Divya Salhan, Nirupama Chandel, Tejinder Singh, Gautam Kishore Valecha, Mohammad Husain, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY.*

Background: Tumor necrosis factor (TNF)-α is an important mediator of inflammation. Recently, we demonstrated that HIV-induced down regulation of vitamin D receptor (VDR) contributed to the activation of the tubular cell renin angiotensin system (RAS) in HIV transgenic (Tg26) mice. We hypothesize that HIV down regulates tubular cell VDR expression through the generation of TNF-α in Tg26 mice.

Methods: Renal tissues of four weeks old, age and sex matched control and Tg26 mice in groups of six were prepared for Western blotting and real time PCR studies for the expression of TNF-α, VDR, and renin. The immunoblots were stripped and probed for actin. Renal cortical sections of control and Tg26 mice were immunolabeled for TNF-α, VDR, and renin and scored for intensity of staining. To determine temporo-spatial relationship

between VDR and renin, renal cortical sections of control and Tg26 mice were co-labeled for VDR and renin and examined under an immunofluorescence microscope. Human renal proximal tubular cells (HRPTC) were transduced with either empty vector or HIV (NL4-3) constructs. EV/HRPTC and HIV/HRPTCs were incubated in media containing either buffer, neutralizing anti-TN-α antibody (5mM) or mouse IgG (5mM) for 24 hours, followed by probing of immunoblots for VDR and actin. Cellular lysates and supernatants of EV/HRPTCs and HIV/HRPTCs were also assayed for TNF- α by Western blotting and ELISA respectively. HRPTCs were treated with variable concentration of TNF- α. Subsequently, immunoblots were probed for VDR and actin.

Results: Renal cortical sections of Tg26 mice displayed higher expression of TNF-α-and renin but diminished expression of VDR. HIV/HRPTCs displayed down regulation of VDR, however, anti-TNF-α antibody enhanced VDR expression by HRPTCs both under basal and HIV-stimulated states. HIV also stimulated two-fold increase in TNF-α production by HRPTCs. Moreover, TNF- α directly attenuated tubular cell VDR expression.

Conclusions: These findings indicate that HIV-induced down regulated VDR expression is mediated though tubular cell TNF-α generation.

PUB641

Impact of Fructose on Markers of Kidney Injury in Animal Model

Mariusz Flisinski,[1] Andrzej Brymora,[2] Pawel Strozecki,[1] Anna Stefanska,[3] Jacek Manitius.[1] *[1]Dept Nephrology, Nicolaus Copernicus University, Bydgoszcz, Poland; [2]Dialysis Unit, Nowy Szpital, Swiecie, Poland; [3]Laboratory Medicine, Nicolaus Copernicus University, Bydgoszcz, Poland.*

Background: It is has been shown that fructose (FR) induces pro-inflammatory mediators as MCP-1 in proximal tubules, which lead to macrophage infiltration of tubulointersitial tissue. FR elevates uric acid which decreases NO and then alters renal autoregulation and results in glomerular hypertension [1]. This study was designed to evaluate the impact of 60% FR diet on markers of kidney injury and inflammation in subtotally nephrectomized and control rats.

Methods: Male Wistar rats (386±40 g) underwent sham operation (CON=10) or 5/6 nephrectomy (SNx=12). Animals were further assigned to 2 diets protocol: regular – RD or 60% FR – F60. After 8 weeks serum concentration of creatinine (Cr), uric acid (UA), soluble intercellular adhesion molecule (sICAM) and homocysteine (HCY) was measured. On the basis of a 24-hour urine collection protein to creatinine ratio (PCR), N-Acetyl-Glucosaminidase (NAG) to urinary creatinine (NAG/Cr), MCP-1 to urinary creatinine (MCP-1/Cr), and urinary uric acid excretion (UAE) were done. Creatinine clearance (CrCl) was calculated upon Cockroft-Gault formula.

Results:

Table 1

	CON+RD (I)	CON+F60 (II)	p (I vs II)	SNx+RD (III)	SNx+F60 (IV)	p (III vs IV)
Fructose [mg/dl]	0,59±0,05	0,94±0,47	=0,08	0,87±0,39	1,15±0,51	NS
CrCl [ml/min]	3,11±0,42	2,58±0,66	NS	1,61±0,64*	1,14±0,58*	=0,08
UA [mg/dl]	1,7±0,4	1,6±0,1	NS	1,59±0,3	2,04±1,3	NS
UAE [mg/24]	4,1±2,1	2,2±0,5	=0,08	1,1±0,4*	0,9±0,4*	NS
HCY [µmol/l]	4,5±0,2	6,4±1,5	<0,05	5,2±1,3	10,1±2,8*	<0,01
sICAM [ng/ml]	15,1±2,4	16,7±4,5	NS	37,8±16,8*	23,9±8,3*	<0,05
PCR [mg/mg creatinine]	3±1,6	13,5±1,3	<0,01	34,5±1,8*	49±2,2*	<0,01
MCP-1 / Cr [ng/mg creatinine]	3,5±0,5	11,9±2,3	<0,01	8,7±6,4*	7,6±8,3	NS
NAG/Cr [U/g creatinine]	7,9±5,4	21,4±5,5	<0,05	43,9±28,3*	28,4±17,5*	NS

* p<0,05 SNx vs CON

Conclusions: In CON animals F60 diet is associated with induction of a local (MCP-1) and systemic (HCY) inflammatory response which leads to proximal tubular injury (NAG) and proteinuria. In SNx rats F60 diet, through these factors, contribute to deterioration of renal function.

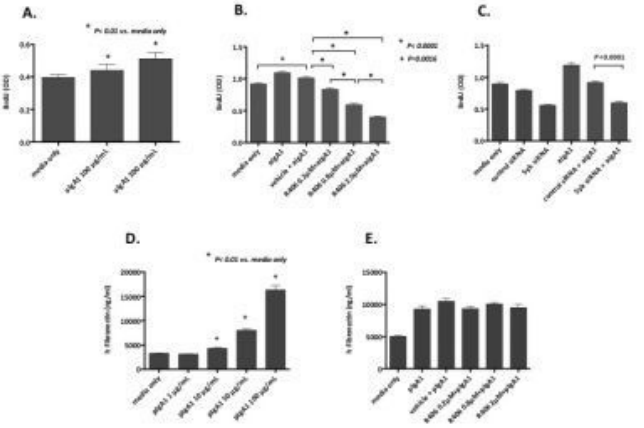
Spleen Tyrosine Kinase (Syk) Is Involved in the Mesangial Cell Proliferation Following Stimulation with IgA1 Isolated from IgA Nephropathy (IgAN) Patients

Min Jeong Kim,[1] Jonathan Barratt,[3] Karen Molyneux,[3] John P. McDaid,[2] Charles D. Pusey,[2] Frederick W.K. Tam.[2] *[1]Clinic for Nephrology, Univ. Hosp. Basel, Switzerland; [2]Kidney and Transplant Institute, Imperial College London; [3]Dept of Infection, Immunity & Inflammation, Univ. of Leicester, United Kingdom.*

Background: We previously reported that the inhibition of Syk by Syk inhibitor, R406 or Syk siRNA reduces the synthesis of various cytokines by human mesangial cells (HMC) upon stimulation with IgA1 isolated from serum of IgAN patients (pIgA1). We examined if Syk is involved in the HMC proliferation and the production of fibronectin following stimulation with pIgA1.

Methods: IgA1, purified from serum of IgAN patients, was aggregated at 63°C for 150 min (aIgA1). HMC were incubated with aIgA1 for 24h and cell proliferation assay with BrdU was performed. We incubated HMC with R406, 1h before stimulation with aIgA1 (200µg/mL). HMC were transfected with Syk- or control siRNA, 72h before stimulation. Human fibronectin produced by HMC upon stimulation with pIgA1 for 24h was examined in culture supernatants by ELISA. HMC were incubated with R406, 1h before stimulation with pIgA1 (50µg/mL).

Results: HMC proliferation increased upon stimulation with aIgA1 and was inhibited by R406 in a dose dependent manner. HMC transfected with Syk siRNA proliferated significantly less than the cells transfected with negative control siRNA (A-C). The concentration of human fibronectin increased significantly following stimulation with pIgA1. The preincubation with R406 did not reduce fibronectin (D-E).



Conclusions: Our data suggest the involvement of Syk in HMC in the production of various cytokines and HMC proliferation, but not in the synthesis of fibronectin, upon stimulation with pIgA1. Syk may be considered as a potential target in the treatment of IgAN.

PUB643

Activation of Protease-Activated Receptor 4 (PAR-4) in Tubular Epithelial Cells Contributes to Diabetic Nephropathy

Wai Han Yiu,[1] Joseph C.K. Leung,[1] Loretta Y.Y. Chan,[1] Kwok Wah Chan,[2] Hui Y. Lan,[3] Kar Neng Lai,[1] Sydney C.W. Tang.[1] *[1]Department of Medicine, University of Hong Kong, Queen Mary Hospital, Hong Kong; [2]Department of Pathology, University of Hong Kong, Queen Mary Hospital, Hong Kong; [3]Department of Medicine and Therapeutics, and Li Ka Shing Institute of Health Sciences, The Chinese University of Hong Kong, Hong Kong.*

Background: Protease-Activated Receptors (PARs) have been implicated in the pathogenesis of many inflammation-associated disorders, however their roles in diabetic nephropathy (DN) have not yet been explored. Further to our findings on the up-regulation of PAR-4 expression in human renal proximal tubular epithelial cells (PTEC) in response to high glucose stimulation, herein we investigated the pro-inflammatory potential of this receptor in tubular cells and examined its expression in renal tissues of DN.

Methods: Renal biopsies from patients with proven DN were immunohistochemically examined for the expression of PAR-4. To elucidate the role of PAR-4, human PTEC were cultured with 1) selective PAR-4 activating peptide or 2) high glucose medium in the presence of PAR-4 antagonist, and the effects on the expression of pro-inflammatory genes were studied.

Results: High PAR-4 expression was detected in tubular cells of all DN biopsies whereas very low expression was found in normal control subjects. *In vitro*, PAR-4 activating peptide induced chemokine (C-C motif) ligand 2 (CCL-2) expression and to a lesser extent, interleukin 6 (IL-6) expression in PTEC in a time- and dose-dependent manner. Inhibition of PAR-4 by a specific antagonist partially suppressed high glucose-induced mitogen-activated protein kinase (MAPK) p42/p44 signaling and the subsequent CCL-2 and IL-6 production.

Conclusions: Our data demonstrated an increased expression of tubular PAR-4 in human DN biopsies and an enhanced secretion of PAR-4 stimulated inflammatory cytokines from PTEC. These findings suggest a novel role for PAR-4 in mediating diabetic tubular injury. This study is supported by the General Research Fund of the Research Grants Council of Hong Kong (project number 7796/11M).

Increased Granulocyte Heparanase Activity: The New Specific Marker of Neutrophils Activation in Patients with Lupus Nephritis and Idiopathic Membranous Nephropathy

Maciej Szymczak,[1] Jakub Kuzniar,[1] Waclaw Kopec,[1] Agnieszka Halon,[2] Zofia Marchewka,[3] Marian Klinger.[1] *[1]Department of Nephrology and Transplantation Medicine, Wroclaw Medical University, Wroclaw, Poland; [2]Department of Patomorphology, Wroclaw Medical University, Wroclaw, Poland; [3]Department of Toxicology, Wroclaw Medical University.*

Background: Heparanase is a beta-glucuronidase, that cleaves sugar chains of heparan sulfate proteoglycans. It is supposed that heparanase may be involved in proteinuria pathogenesis. The aim of the study was to assess the heparanase activity in the proteinuric pts with different glomerulonephritis types.

Methods: The evaluation of heparanase activity in serum, urine, granulocytes and superoxide dismutase activity in granulocytes of patients with: lupus nephritis (n=17), membranous nephropathy (n=11), IgA nephropathy (n=12), focal and segmental glomerulosclerosis (n=18), mesangiocapillary glomerulonephritis (n=12) and in 19 healthy

volunteers was processed. Immunohistochemical heparanase staining of kidney biopsy specimens from 6 patients with lupus nephritis was also processed.

Results: The heparanase activity in granulocytes of patients with lupus nephritis and membranous nephropathy was higher than heparanase activity in granulocytes in control group (p=0,02 in both cases). There was no difference between superoxide dismutase activity in granulocytes of patients with all investigated types of glomerulonephritis and control group. Correlations between heparanase activity in urine and the dsDNA titer r=0,51 (p=0,04), and between heparanase in urine and hemolytic activity of the complement r=-0,57 (p=0,03) in the lupus nephritis group, and between heparanase activity in granulocytes and serum total protein level r=-0,69 (p=0,02) in membranous nephropathy was observed. Evaluation of biopsy specimens from lupus pts revealed the correlation between the heparanase intensity staining in loop Henle's tubule and percent of the glomeruli with sclerosis r=0,92 (p=0,009).

Conclusions: In active lupus nephritis and in the nephritic phase of idiopathic membranous nephropathy heparanase appears as the novel marker of granulocyte activation.

PUB645

The Role of Macrophage Stimulating Protein and Its Receptor, Recepteur d'Origine Nantais, RON in Gentamicin Induced Nephropathy

Koeun Lee, Chang Seong Kim, Joon Seok Choi, Eun Hui Bae, Seong Kwon Ma, Soo Wan Kim. *Internal Medicine, Chonnam National University Medical School, Gwangju, Korea.*

Background: Macrophage stimulating protein (MSP) was reported to mediate inhibition of apoptosis and inflammation responses, suggesting that it may play a role in tubular regeneration in acute kidney injury. We investigated whether MSP ameliorates tubular dysfunction and inflammation in gentamicin (GM) induced kidney injury.

Methods: Human renal proximal tubular (HK-2) cells were incubated with 2mg/mL GM for 24h at different concentrations of MSP, and cell viability was measured by MTT assay. The protein expressions of RON, COX-2, Bcl2, Bax, caspase3, nuclear factor-kappa B (NF-κB), IκB-α, Akt and mitogen-activated protein kinases (MAPKs) were analyzed by immunoblotting. To examine the changes of MSP and RON in GM-induced kidney injury, rats were injected with GM (150mg/kg, i.m.) for 7 days.

Results: GM (2 mg/ml) treatment decreased the cell viability in HK-2 cells which was counteracted by MSP treatment (30 ng/ml). GM decreased the expression of Bcl-2, while it increased that of Bax and cleaved-caspase 3, which were attenuated by the treatment of MSP. Additionally, MSP attenuated GM-induced increased expression of COX-2 and phosphorylated Akt. GM treatment increased phosphorylation of ERK, JNK and P38, however, MSP attenuated expression of p-P38, but not that of p-ERK and p-JNK. In GM-induced nephropathy rats, the expression of MSP and RON was markedly upregulated compared with controls.

Conclusions: In conclusion, MSP attenuates GM-induced nephropathy by suppression of inflammatory and apoptotic factors through the inhibition of Akt/P38/NF-κB signaling pathways.

PUB646

The Effect of Statin on Epithelial-Mesenchymal Transition in Peritoneal Mesothelial Cells

Seong Hun Kim,[1] Hye-young Kang,[1] Dae-Suk Han,[2] Shin-Wook Kang,[1,2] Seung Hyeok Han.[2] *[1]Brain Korea 21, Yonsei University, Seoul, Republic of Korea; [2]Department of Internal Medicine, College of Medicine, Yonsei University, Seoul, Republic of Korea.*

Background: Statin has recently been highlighted due to its pleiotropic actions besides cholesterol-lowering effect. However, it is currently unknown whether statin therapy may inhibit peritoneal dialysis-related epithelial-mesenchymal transition (EMT).

Methods: *In vitro*, human peritoneal mesothelial cells (HPMCs) were exposed to 5.6 mM glucose (NG), NG+1 μM simvastatin (SV), or 4.25% peritoneal dialysis fluid (PDF) with or without SV. *In vivo*, PD catheters were inserted into 32 Sprague-Dawley rats, and saline (C, n=16) or PDF (PD, n=16) was infused for 4 weeks. Eight rats from each group were treated with 5 mg/kg/day of simvastatin intraperitoneally. EMT markers in HPMCs and the peritoneum were evaluated by Western blot analysis. We also examined the protein expression of RhoGTPases in HMPCs exposed to PDF with or without SV.

Results: Compared to the NG group, E-cadherin expression was significantly decreased, while α-SMA and fibronectin expression were significantly increased in HPMCs exposed to PDF, and these changes were significantly abrogated by SV ($p<0.05$). In addition, the cobblestone-like appearance of HPMCs was converted into a fibroblast-like morphology after PDF treatment, which was reversed by SV. This EMT-like change was also observed in HPMCs treated with 5 μM geranyl-geranyl pyrophosphate. Moreover, PDF significantly increased the protein expression of RhoA and Rac1 in the membrane fractions, and these changes were ameliorated by SV ($p<0.05$). In PD rats, E-cadherin/α-SMA ratios in the peritoneum were significantly decreased, whereas fibronectin expression was significantly increased compared to C rats ($p<0.05$). Furthermore, the thickness of the submesothelial layer was significantly greater and the intensity of Masson's trichrome staining was significantly higher in PD rats than in C rats ($p<0.05$). These changes in PD rats were significantly attenuated by SV ($p<0.05$).

Conclusions: PD-related EMT was mediated through the activation of mevalonate pathway and statin treatment inhibited EMT changes in PDF-stimulated HPMCs and PD rats.

PUB647

Renal Infiltration of T Lymphocytes in Radiation Nephropathy

Nathan Rudemiller,[1] Eric P. Cohen,[1,2] Brian L. Fish,[1] David L. Mattson.[1] *[1]Medical College of Wisconsin, Milwaukee, WI; [2]Froedtert Hosptial, Milwaukee, WI.*

Background: The role of renal inflammation in the pathogenesis of hypertension and renal disease is intensely studied. Prevention of infiltration of T lymphocytes into the kidneys attenuates hypertension and renal damage (Am J Physiol 298:R1136-42, 2010). The role of the immune system in the kidney damage associated with radiation treatment is uncertain.

Methods: We tested for T cells ($CD3^+$), B cells ($CD45R^+$), and macrophages ($CD11b^+$) in a radiation nephropathy model. Rats underwent 10 Gy total body irradiation (TBI), without or with captopril treatment (300 mg/L in drinking water starting on day 9 after TBI), and were sacrificed 22 weeks after TBI. Peripheral blood samples and kidneys were extracted from three groups (non-irradiated, irradiated, and irradiated + captopril). The mononuclear cell populations were isolated from the peripheral blood and the kidneys of each rat as described (Am J Physiol 298:R1136-42, 2010). Flow cytometry was performed for T cells (CD3), B cells (CD45R), and macrophages (CD11b).

Results: There were no significant differences between groups in the total number of mononuclear cells or any of the cells assessed via flow cytometry in the peripheral blood samples. The total kidney cell counts for T cells, B cells, and macrophages were:

Rat Group	BUN (mg/dL)	Total CD3+ cells/2 kidneys (10^6)	Total CD45R+ cells/2 kidneys (10^6)	total CD11b+ cells/2kidneys (10^6)
Control (non-irradiated) (n=4)	17.0±1.7	1.06±0.32	0.06±0.02	1.00±0.37
Irradiated (n=4)	96.3±17.5*‡	4.47±1.3*	0.52±0.25	6.15±1.98
Irradiated + captopril (n=4)	34.5±0.6	4.07±0.48*	0.33±0.07	4.47±0.93

*significant compared to control; ‡significant compared to iraddiated + captopril

Conclusions: Both irradiated groups had significantly increased renal infiltration of CD3+ cells. There is a trend for an increase of CD11b+ in the kidneys of the irradiated rats. These results indicate a role for T cells and macrophages in radiation nephropathy. This may clarify the hypertension and salt sensitivity in this model, and may be relevant for development of new mitigators of radiation injury.

PUB648

Specific Deletion of the IL-6 Cytokine Family Receptor gp130 in Podocytes

Yoshikuni Nagayama, Gerald S. Braun, Luigi Villa, Peter Boor, Tammo Ostendorf, Jürgen Floege. *Division of Nephrology, RWTH University of Aachen, Aachen, Germany.*

Background: Gp130 is a ubiquitously expressed co-receptor for cytokines of the IL-6 family. So far, the role of gp130 or IL-6 signaling in podocytes has not been defined.

Methods: Podocyte-specific gp130 knockout (KO) animals were generated by breeding mice expressing cre-recombinase under the control of the podocin promotor (pod-cre+) with mice bearing loxP sites surrounding exon 16 of gp130, yielding pod-gp130 KO mice. Pod-cre-, gp130 f/f animals served as controls (WT). In these mice lipopolysaccharide (LPS)-induced nephritis (1x LPS 10mg/kg body weight) was studied in age-matched 15~22 week old female animals. Additionally, nephrotoxic nephritis was induced in 12 week old male mice.

Results: Successful generation of pod-gp130-KO was confirmed by RT-PCR, Western blot, and immunofluorescence. As expected, gp130 downstream signaling was also abrogated in the KO mice: the number of phospho-STAT3-positive glomerular cells following LPS injection was significantly reduced (WT 5.3±0.13 vs KO 0.84±0.11 cells/glom cross section, means±SEM, $p<0.01$). Pod-gp130-KO mice exhibited no spontaneous functional or histological renal phenotype at 10, 20, and 40 weeks of age. Following LPS injection no significant difference in albuminuria was found between WT and KO at 24h (mean urinary albumin/creatinine ratio: WT 0.232±0.049 vs KO 0.210±0.040 mg/mg, $p=0.73$). Following the induction of nephrotoxic nephritis KO animals tended to exhibit milder disease but all differences at day 14 remained non-significant: crescents WT 15.6±4.2 vs KO 11.8±3.1 %, $p=0.47$; fibrinoid necrosis score (0~4/glom) WT 1.0±0.23 vs KO 0.86±0.17, $p=0.75$. Day 3 urinary albumin/creatinine ratio was WT 45±6.5 vs KO 34±2.8 mg/mg, $p=0.14$.

Conclusions: Our data suggest that gp130 is not a critical component of the podocyte in the normal or ageing kidney. Similarly, in two inflammatory models no statistically significant effects of podocytic gp130 deletion could be identified.

C3a/C3ar Was Involved in the Recruitment of Renal Mast Cells in Patients with Renal Diseases

Jingmin Zheng, Rong Wang, Zhi-Hong Liu. *Research Institute of Nephrology, Jinling Hospital, Nanjing University School of Medicine, Nanjing, Jiangsu.*

Background: Increased renal mast cells (MCs) have been reported and thought to contribute to renal injury. However, mechanisms about the recruitment of renal MCs are still unclear. The aim of the present study was to evaluate the possible role of C3a/C3aR in the recruitment of renal MCs.

Methods: 100 patients with renal diseases (including diabetic nephropathy, IgA nephropathy, membranous nephropathy, lupus nephritis, acute interstitial nephritis and chronic interstitial nephritis) and 10 normal controls (kidney donors) were recruited. Immunohistochemical staining for tryptase, C3aR and C3c was done on the sections of

renal biopsy. For each specimen, the number of MCs was counted, the immuno-staining intensity of C3c was measured by using Image Plus 2 software, and the correlations between MCs number and C3c level was analyzed in each disease.

Results: C3aR was found highly expressed by renal MCs. Increased C3c was found in the renal tubular interstitium and correlated with the increases of MCs number in patients with renal diseases. MCs were found distributed in the areas where increased C3c was found.

Conclusions: These findings suggested that C3a/C3aR was involved in the recruitment of MCs in patients with renal diseases. As it has been reported that C3 can also be activated through a MCs dependent way, a vicious cycle between complement activation and renal MCs recruitment might exist and contribute to renal injury.

Evaluation of High-Density Lipoprotein-Associated Proteins as Novel Biomarkers in Chronic Kidney Disease Chantal Maureen Kopecky,[1] Georg Michlits,[1] Philipp Eller,[2] Walter Hoerl,[1] Marcus Saemann.[1] *[1]Dept. of Internal Medicine III, Clinical Division of Nephrology and Dialysis, Medical University of Vienna, Vienna, Austria; [2]Dept. of Angiology, Medical University of Graz, Graz, Austria.*

Background: Cardiovascular events are the main cause of death in individuals with chronic kidney disease (CKD) and end-stage renal disease (ESRD).Patients are further characterized by increased atherosclerosis and dyslipidemia affecting quantity and quality of high-density lipoproteins (HDL). By proteomic analysis, we identified disease-specific proteins including serum amyloid A (SAA), surfactant protein B (SP-B) and Apo-CII enriched in ESRD-HDL compared to healthy HDL and found that the altered protein composition of HDL influenced its anti-inflammatory function and reversed the molecule's atheroprotective action.

Methods: Blood samples were drawn from a total of 20 ESRD patients and 16 healthy controls and immediately centrifuged to obtain plasma.

HDL-bound proteins were detected by enzyme-linked immunosorbent assay. We used an HDL catching antibody to capture HDL directly from plasma samples. Detection antibodies were directed against SAA, SP-B and Apo-CII. Protein amount was measured by a colorimetric reaction using a biotinylated secondary antibody and streptavidin-HRP.

Results: We developed an easy applicable assay using plasma samples for quantitative detection of HDL-bound proteins without the requirement of a preliminary extensive isolation of HDL from plasma. HDL-associated SAA, SP-B and Apo-CII can be measured individually for ESRD patients in considerably higher levels than controls. Consistent results with high reproducibility and low inter-assay variation are obtained for different patient-control groups which were recruited at different time points. We are currently testing biobank samples for subsequent correlation of HDL-bound proteins with several laboratory parameters, disease progression and mortality.

Conclusions: We demonstrate a defective anti-inflammatory function of ESRD-HDL caused by specific protein alterations that may provide a molecular explanation for the cardiovascular mortality in ESRD and can be used as novel cardiovascular biomarkers.

PUB651

S100A12 Induces the Proliferation and the Osteochondrogenic Differentiation in Vascular Smooth Muscle Cells(VSMCs) Eiko Matsuoka,[1] Yasukiyo Mori,[1] Yayoi Shiotsu,[1] Atsushi Kosaki.[2] *[1]Division of Nephrology, Department of Medicine, Kyoto Prefectual University of Medicine, Kyoto, Japan; [2]Faculty of Nursing, Setsunan University, Osaka, Japan.*

Background: S100A12 is an endogenous ligand for the receptor for advanced glycation end products (RAGE). We have reported that plasma S100A12 level was an independent factor associated with the prevalence of cardiovascular disease(CVD)in the patients with end-stage renal disease (ESRD)(Shiotsu Y and Mori Y et al. Clin J Am SocNephrol 2011; 6: 718-723). However, the detailed mechanism of the association of S100A12 in ESRDwith CVD remains uncertain.In this study,we evaluate the effect of S100A12 on the phenotypical changes in VSMCs.

Methods: Because the mice lacks the S100A12 expression, we have generated the human S100A12 overexpressing mice (C57BL6/J) using serum amyloid P promoter (S100A12Tg mice) to maintain the plasma levels of circulating S100A12. Subtotal nephrectomy (5/6NTx) followed by AngiotensinII (AngII) infusion (1000ng/kg/min) for 3 weeks was performed.We evaluated the histological changes of VSMCs in the thoracic aorta. As the *in vitro* experiment, we prepared cultured VSMCs from WT mice. First, we determined the proliferation of VSMCs using the Ki-67 staining. Authentic S100A12 (1μg/mL; Circulex, Japan) was added to serum-free culture medium, and the changes in Ki-67 positivity was observed. Furthermore, we determined the mRNA expression of osteochondrogenic marker (Runx2) and smooth muscle markers (SM22α) by real-time PCR.

Results: In 5/6NTx-S100A12Tg mice with AngII, the density of VSMCs in thoracic aorta was higher than that in WT mice. In cultured VSMCs, the treatment with S100A12 for 24hr increased the positivity of Ki67 significantly (1.6-fold vs no-additives, P<0.01). The stimulating effect was abolished by the pretreatment with RAGE neutralizing antibody. Furthermore, the addition of S100A12increased the Runx2 mRNA level for 24hr (1.9-fold). In contrast, the accumulation of SM22α mRNA was decreased for 4days (0.5-fold).

Conclusions: These findings suggest that S100A12 induce the cell proliferation via the RAGE pathway and the osteochondrogenic differentiation in VSMCs.

PUB652

1,25-Dihydroxyvitamin D3 Suppresses High Glucose Activated Macrophage Driven Tubular Epithelial to Mesenchymal Transition in Proximal Tubular Epithelial Cells Xiaoliang Zhang, Yansheng Jin, Bi-Cheng Liu. *Nephrology, Zhong Da Hospital, Southeast University, Nanjing, Jiangsu, China.*

Background: 1,25-dihydroxyvitamin associates with amelioration of renal fibrotic lesions in patients of diabetic nephropathy (DN). Classically activated macrophage may promote fibrosis process, while alternatively activated macrophage play a role in repairing process. The aim of this study is to investigate the effect of $1,25(OH)_2D_3$ on glucose induced macrophage activation and subsequent influence to EMT.

Methods: U937 cells were incubated with high glucose. Activity of intracellular iNOS and cytokines of IL-6, IL-12 and TNF-α in supernatant were measured. The high glucose incubated U937 cells were removed from supernatant and put into HK2 cells followed by co-culturing for 24 hours. α-SMA, fibronectin and E-cadherin in HK2 cells were examined. $1,25(OH)_2D_3$. pre-treatment with macrophages was done before high glucose treated macrophage being put into HK2 cells for co-culture. EMT Markers and pro-inflammatory cytokines in macrophages were examined.

Results: After high glucose stimulation, iNOS activity was increased as same as in the IFNγ/LPS group. Meanwhile, IL-6, IL-12 and TNF-α were increased. After co-culture with high glucose incubated U937 cells, HK-2 cells developed an EMT phenomena and protein and mRNA levels of E-cadherin decreased, while a-SMA and fibronectin increased. In subsequent experiments, $1,25(OH)_2D_3$ caused fibronectin and mannose receptor C increased and cytokines of IL-6, IL-12, TNF-a and iNOS decreased. In co-culture experiment, $1,25(OH)_2D_3$ reversed the phenotype changes of HK-2 cells and also revealed an inversion changes in the expression of E-cadherin, a-SMA, and fibronectin expression.

Conclusions: High glucose inducedclassically activated macrophage facilitates the process of EMT in renal proximal tubular epithelial cell. 1,25-Dihydroxyvitamin D3 suppresses high glucose-induced classically activated macrophage and may contribute to blocking EMT process.

PUB653

Gene Expression of *Pattern Recognition Receptor* Signaling in Patients of Chronic Kidney Disease Yasutaka Kamikawa, Shinji Kitajima, Tadashi Toyama, Kiyoki Kitagawa, Kengo Furuichi, Takashi Wada. *Nephrology, Kanazawa University Hospital, Kanazawa, Ishikawa, Japan.*

Background: Pattern recognition receptors (PRRs) play a critical role in innate immunity. However, few studies have been revealed on PRR expression in chronic kidney disease (CKD) patients. In this study, we evaluated the gene expression of PRRs in CKD patients, by analyses using RNA microarray of peripheral blood leukocyte.

Methods: Nineteen gender- and age-matched hypertension patients without diabetes were evaluated in this study.The patients were divided into three groups: HT group (8 hypertension patients with eGFR > 60 mL/min/1.73m2), CKD group (7 patients with eGFR < 60 mL/min/1.73m2), and HD group (4 patients on hemodialysis). All CKD and HD patients were clinically diagnosed benign nephrosclerosis. Blood samples were collected in PaxGene RNA collection tubes, and genesof innate immunitywas evaluated by RNA microarray.

Results: The ratio of neutrophils in peripheral blood was higher in HD group than HT group (HT ; 55.2±12.5%, HD ; 68.4±4.4%, p<0.05). Reversely, the lymphocytes ration in peripheral blood was lower in HD group than HT group (HT ; 35.4±12.1%, HD ; 21.1±4.9%, p<0.05). Gene array data indicated that some PRR genes of Toll like receptor (*TLR) signaling pathway and Nod like receptor (NLR)* signaling pathway were varied in CKD and HD group. Among the gene expression of PRRs, TLR4 expression was down-regulated in accordance with decline of eGFR. Moreover, some genes in NLR signaling pathway, including IPAF, RICK, and cardinal, were also down-regulated in the similar way to that of TLR4.

Conclusions: Some genes of PRR signaling pathways were affected by kidney function. These results suggested that these genes might play a role in innate immunity involved in the progressing of CKD.

PUB655

Crude *Cecropia pachystachya* Extract Effect in the Development of Renal Lesions in 5/6 Nephrectomized Rats Claudia Maquiaveli,[1] Heloisa Francescato,[1] Cleonice G. Da Silva,[1] Edson Roberto Da Silva,[2] Terezila Machado Coimbra.[1] *[1]Physiology, University of Sao Paulo, Ribeirão Preto, Sao Paulo, Brazil; [2]Basic Sciences, University of Sao Paulo, Pirassununga, Sao Paulo, Brazil.*

Background: Angiotensin II has an important role in the renal lesions observed in 5/6 nephrectomized rats. Recent studies showed that molecules present in the *Cecropia pachystachya* (CP) extract can inhibit the angiotensin converting enzyme (ACE) *in vitro*. This study evaluated the effect of this extract in the renal lesions in 5/6 nephrectomized rats.

Methods: Male Wistar 5/6 nephrectomized rats were treated (NE, n=10) or not (NW, n=7) with CP extract (6 g/kg/day), from 15 to 90 days after the surgery. The control groups were subjected to a sham operation and treated (SE, n=7) or not (SW, n=8) with the extract. Albuminuria and systolic blood pressure (SBP) were evaluated during the treatment. The glomerular filtration rate (GFR) was determined 75 days after starting treatment. The animals were killed and the kidneys removed for histological and imunohistochemical studies.

Results: The results showed that nefrectomized animals presented progressive albuminuria (mg/24h) [96.1 (64.9;238.5) and 194.0 (104.0;264.9)], 60 and 90 days

after surgery, respectively, that was less intense in NE group [16.8 (7.5;83.0) and 113.7 (31.1;226.2)], respectively, p<0.05. SBP (mmHg) was lower at the end of treatment in NE (180.5±11.0) than in NW group (217.0±12.7), p<0.05. Nefrectomized animals also showed reduction of GFR (mL/min/100g) (0.12±0.03), compared to SW group (0.44±0.04), which was attenuated by treatment with CP extract (0.27±0.04). Nephrectomized rats presented glomerulosclerosis and tubulointerstitial lesions, associated with increased ED1+ cells (macrophages/monocytes) in renal cortex. All these alterations were less intense in the NE group (p<0.05).

Conclusions: Treatment with CP extract attenuated the functional and structural changes, as well as SBP increase and inflammatory process in the renal cortex of 5/6 nephrectomized rats. The inhibitory effect of the components present in the CP extract on ACE might be contributing to the renal protective effect of this extract. Financial support: CAPES, FAPESP.

PUB656

Erlotinib Preserves Renal Function and Prevents Salt Retention in Doxorubicin Treated Nephrotic Rats Raed Bou Matar,[2] Janet D. Klein,[1] Jeff M. Sands.[1] *[1]Department of Medicine, Renal Division, Emory University, Atlanta, GA; [2]Department of Pediatrics, Emory University, Atlanta, GA.*

Background: Nephrotic syndrome is associated with an up-regulation of the heparin-binding epidermal growth factor-like growth factor (HB-EGF). Erlotinib blocks the activation the epidermal growth factor receptor (EGFR) in response to HB-EGF. This study investigates the effect of Erlotinib on the progression of proteinuria, renal dysfunction and salt retention in doxorubicin treated nephrotic rats.

Methods: Male Sprague Dawley rats were divided into 3 weight matched groups (n = 13/group) as follows: Controls (Ctrl), IV doxorubicin 7.5 mg/kg once (Dox), IV doxorubicin followed by oral Erlotinib 10 mg/kg daily starting at day 6 (Erl). The animals were pair fed throughout the observation period. Weight, urine output and urine protein excretion were serially monitored. Upon establishment of high grade proteinuria (defined as a 4 fold increase in urine protein), urine sodium and creatinine clearance were measured. Kidney tissue was dissected and analyzed for the abundances of γ-ENaC, NKCC2, NCC and AQP2 using western blot.

Results: Creatinine clearance was preserved in rats treated with Erlotinib as compared to untreated nephrotic animals (in ml/min: Ctrl: 5.2 ± 0.5, Dox: 1.9 ± 0.3, Erl: 3.6 ± 0.5, p < 0.01). Despite a minimal effect on the degree of proteinuria (in mg/d: Ctrl: 240 ± 35, Dox: 1177 ± 229, Erl: 1082 ± 252), Erlotinib prevented salt retention (Urinary Na in mEq/d: Ctrl: 2.2 ± 0.2, Dox: 1.8 ± 2.3, Erl: 2.2 ± 0.2, p < 0.05). Cortex tissue abundance of uncleaved γ-ENaC was reduced by 40 ± 7% in the Dox group when compared to controls but unchanged in the Erl group. Cleaved γ-ENaC was unchanged in the groups tested. NKCC2 in the outer medulla was reduced by 76 ± 5% in the Dox group and by 59 ± 7 % in the Erl group when compared to control levels. Inner medullary AQP2 was reduced by 68 ± 12% in the Dox group but was unchanged in the Erl group compared with controls.

Conclusions: Erlotinib therapy, started 6 days following IV doxorubicin, preserves renal function and prevents salt retention in nephrotic rats. The observed effects are likely mediated by a reversible blockade of EGFR.

PUB657

Dose-Dependent and Temporal Effects Enalapril in ZSF1 Model of Diabetic Nephropathy: Insights from Renal Functional and Histopathological Endpoints and Metabolomics Assessment Ryan M. Fryer, Xiaomei Zhang, Suzanne Nodop Mazurek, Akalushi C. Muthukumarana, Kathleen A. Lincoln, Paul Harrison, Glenn A. Reinhart, Hu Sheng Qian, Steven M. Weldon. *Cardiometabolic Disease Research, Boehringer-Ingelheim Pharmaceuticals Inc., Ridgefield, CT.*

Background: The effects of enalapril were characterized temporally on multiple renal functional and histopathological endpoints, including metabolomic profile, in a pre-clinical model of diabetic nephropathy.

Methods: Enalapril was tested in telemetered ZSF1 rats over 15-wks of treatment. Metabolic profiling was used to assess biochemical components in urine for identification of disease and treatment biomarkers.

Results: Enalapril had no effect on glucose or HbA1C and no effect on urine or plasma creatinine and electrolytes. Enalapril (1, 3, 10, 30 mg/kg/d in water) produced dose-dependent and sustained reductions in blood pressure compared to vehicle (mean study values = -7, -16, -17, and -31 mmHg below baseline, respectively). In the 30 mg/kg group decreases in MAP were accompanied by an increase in BUN suggestive of renal hypoperfusion. Enalapril also elicited dose-dependent reductions in urinary protein excretion in the 3, 10, and 30 mg/kg dose groups beginning at weeks 8-9 of treatment that were sustained throughout the study. After 15-weeks of treatment and based on semi-quantitative scoring, enalapril produced dose-dependent decreases in the incidence and severity of glomerulosclerosis in all treatment groups (-75% and -41% below vehicle controls, respectively, in the 30 mg/kg dose group). Enalapril also elicited reductions in the severity of interstitial lesions, KIM-1, and a-SMA expression in the 3, 10, and 30 mg/kg dose groups. Samples for metabolomic analysis were assayed at baseline, 5, 10 and 15 weeks of treatment. Several metabolites were identified from a variety of biochemical classes (fatty acids, acetylated amino acids, uremic toxins and sugars) that correlated to disease progression.

Conclusions: The dose-responsive effects of enalapril in ZSF1 rats were characterized. Temporal changes in urinary metabolites were able to successfully classify treatment groups with up to 80% accuracy over the 15 week study.

PUB658

P-Cresyl Glucuronide-Induced Cell Stress Affects Xenobiotic Elimination Pathways in Human Renal Proximal Tubule Cells Henricus A.M. Mutsaers,[1,2] Anita C.A. Dankers,[1] Andries Seegers,[1] Martijn J. Wilmer,[1] Lambertus Vd Heuvel,[3] Joost G. Hoenderop,[2] Rosalinde Masereeuw.[1] *[1]Pharmacology and Toxicology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [2]Physiology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [3]Pediatrics, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.*

Background: During chronic kidney disease (CKD), toxic solutes accumulate due to inadequate renal clearance. Here, the impact of p-cresyl glucuronide (pCG), on the phenotype and functionality of conditionally immortalized renal proximal tubule epithelial cells (ciPTEC) was studied.

Methods: HPLC was used to determine plasma pCG concentration and to study cellular metabolic activity (7-hydroxycoumarin and p-cresol glucuronidation). ciPTEC phenotype was analyzed by flow cytometry and qPCR. Membrane vesicles isolated from multidrug resistance protein 4 (MRP4) or breast cancer resistance protein (BCRP) overexpressing cells were used to study the impact of pCG on substrate specific uptake.

Results: Plasma of end-stage CKD patients showed 160-fold accumulation of pCG (mean concentration: 46 ± 30 μM), compared to controls. Moreover, ciPTEC actively metabolized p-cresol into pCG (Km: 33 ± 13 μM, Vmax: 266 ± 25 pmol/min.mg). Exposure of ciPTEC to 2 mM pCG for 48h caused a 1.6 ± 0.3 fold increased expression of the mesenchymal marker vimentin, compared to untreated cells, suggesting epithelial-to-mesenchymal transition (EMT). Also, mRNA levels of BCRP, Bcl-2 and iNOS were elevated by pCG with a fold change of 2.2 ± 0.3, 1.5 ± 0.3 and 2.0 ± 1.5, respectively. In contrast, MRP4 expression was unaltered. Furthermore, pCG decreased 7-OHC glucuronidation with 23 ± 7% in ciPTEC. In addition, pCG inhibited MRP4-mediated [^{3}H]-methotrexate uptake in concentrations ranging from 10 μM to 1 mM, whereas transport by BCRP was unaffected.

Conclusions: Thus, pCG induces a stress-response in ciPTEC. Consequently, cellular phenotype and functioning are influenced, as shown by the inhibition of glucuronidation and altered efflux transporter function and expression. Together with the increased pCG levels in CKD patients, this indicates that this solute could contribute to the progression of CKD.

PUB659

Proximal Tubular Expression of Megalin Is Down-Regulated in Human Proteinuriic Nephropathies Mohamed Hussein Chunara,[1] Richard J. Baines,[2] Nigel J. Brunskill.[1,2] *[1]Infection, Immunity and Inflammation, University of Leicester, Leicester, United Kingdom; [2]John Walls Renal Unit, Leicester General Hospital, Leicester, United Kingdom.*

Background: Proteinuria is a hallmark of progressive renal disease. Filtered macromolecules including albumin activate proximal tubule cell (PTC) signalling pathways to induce an aberrant PTC phenotype characterised by inflammation, fibrosis and apoptosis. Low-density lipoprotein receptor-type megalin is an important PTC receptor for albumin. Whilst the megalin-albumin interaction is a recognised PTC albumin retrieval pathway, it may also activate intracellular signalling cascades and have gene regulatory capacity via the megalin cytoplasmic tail. Cellular abundance of megalin is crucial in this regard. In vitro, PTC expression of megalin is down-regulated by high concentrations of albumin and in people with diabetes urinary losses of megalin are increased possibly as a consequence of cell shedding. However whether PTC expression of megalin is altered in human proteinuric disease is unknown.

Methods: Patients with nephrotic syndrome as a result of minimal change disease (MCD, n=9), membranous nephropathy (MN, n=10) and focal segmental glomerulosclerosis (FSGS, n=9) were identified from the renal tissue biobank. Normal renal tissues taken from the unaffected pole of renal cell cancer nephrectomy specimens were used as healthy controls (HC, n=11). Immunostaining using a primary antibody directed against the megalin cytoplasmic tail was performed. 6 blinded scorers studied 6 fields of view along the length of a stained biopsy section and scored each slide on a scale of 0 to 5, where 0 represented minimum staining of megalin and 5 - maximum staining.

Results: PTC staining for megalin was substantial in healthy renal tissue with a significant reduction of megalin expression in proteinuric renal disease (HC 4.56±0.032 vs MCD 2.29±0.074, MN 3.14±0.064 and FSGS 2.31±0.060, p<0.0001).

Conclusions: In health there is substantial PTC staining of megalin. Proteinuria associates with a reduction in such expression, the pattern of which relates to the underlying glomerular lesion. For the first time, these date report changes in megalin PTC expression in human disease.

PUB660

C4d Staining Impact on Renal Outcome in Lupus Nephritis Mamdouh N. Albaqumi, Lutfi Alkorbi. *Medicine, KFSHRC.*

Background: A recent study has shown a strong association of C4d staining and the presence of micro thrombi in lupus nephritis renal biopsies, suggesting a role for complement activation.

Whether activating lectin complement pathway and subsequent C4d deposition play a role in lupus nephritis remains unclear. Herein, we study a population of lupus nephritis (Class IV and V) to look at C4d staining impact on renal and patient outcome.

Methods: We retrospectively reviewed all renal biopsies with lupus nephritis and reclassified them according to ISN/RPS 2003 classifications. Medical records reviewed to include their demographics, co-morbidities, laboratory, and patient and renal survival.

Results: A total of 86 patients included in this analysis. 24 (28%) patients stained positive for C4d while 42 (72%) stained negative. Both groups were similar in terms of co-morbidities.

Majority of patients in the C4d+ group were class V (58.3%) while C4d – group had more patients with IV global (51.6%). Estimated GFR and proteinuria at baseline showed no statistical difference between the two groups. More patients in the C4d – group were treated with cyclophosphomide as induction therapy in comparison to more patients in the C4d + group who were treated with CsA as an induction therapy. Complete remission, partial remission, and treatment failure were not significantly different among the two groups. Probability of renal survival and patient survival showed no statistical difference between the two groups.

Conclusions: C4d staining might not have an impact on clinical outcome in lupus nephritis.

PUB661

Disruption of Gastric, Jejunal, and Ileal Epithelial Tight Junction in Uremi

Nosratola D. Vaziri, Nisa Goshtasbi, Mahyar Khazaeli, Jun Yuan. *Department of Medicine, Division of Nephrology and Hypertension, University of California, Irvine, Irvine, CA.*

Background: Inflammation is a constant feature and a major mediator of progression of chronic kidney disease (CKD) and its numerous complications. There is increasing evidence pointing to the intestinal barrier dysfunction and its contribution to the prevailing inflammation in advanced CKD. In a recent study we found marked depletion of the key trans-cellular [claudin-1 and occludin) and intracellular [ZO1] constituents of colonic epithelial tight junction (TJ) in animals with chronic renal disease induced by either subtotal nephrectomy or adenine-induced tubulo-interstitial nephropathy [Vaziri et al, NDT, 2012]. The present study was designed to determine whether uremia-induced disruption of epithelial TJ is confined to colon or extends to other segments of the gastrointestinal tract.

Methods: Sprague–Dawley rats were randomized to undergo 5/6 nephrectomy (CKD) or sham-operation (control) and observed for 12 weeks at which point they were euthanized, ileum, jejunum, and stomach were removed and processed for expression of the TJ proteins by Western blot and immunohistological analysis.

Results: The CKD group showed hypertension, proteinuria, azotemia, and reduced GFR. As can be seen in the table below the TJ proteins were significantly reduced in stomach, jejunum and ileum in the CKD animals when compared with the control group.

Protein abundance of ZO-1, Occludin and Claudin-1measured by Western blot and expressed as relative optical densities normalized against beta actin in the given tissues of CKD and control rats

Tissues	Stomach		Jejunum		Ileum	
Groupss	CTL	CRF	CTL	CRF	CTL	CRF
ZO-1	100 ±4	69 ±2*	100 ±6	75 ±3*	100 ±5	61 ±5*
Occludin	100 ±1	34 ±4*	100 ±5	60 ±2*	100 ±3	59 ±2*
Claudin-1	100 ±2	58 ±4*	100 ±3	70 ±4*	100 ±2	81 ±1*

*P< 0.05

Conclusions: The results of the present study revealed that uremia-induced depletion of the epithelial TJ is not confined to the colon as shown in our earlier study and extends throughout the gastrointestinal tract.

PUB662

Red Propolis Reduces Proteinuria and Glomerular Damage in the Remnant Kidney Model

Flavio Teles,[1] Tarcilo Machado,[1] Francisco Pessoa da Cruz Júnior,[1] Vítor Hugo Honorato Pereira,[1] Camilla Fanelli.[2] *[1]Clinical Medicine, State University of Health Sciences of Alagoas (UNCISAL), Maceió, Alagoas, Brazil; [2]Clinical Medicine, University of São Paulo, São Paulo, Brazil.*

Background: The pathogenic role of inflammation and oxidative stress in chronic kidney disease (CKD) is well established and pharmacological inhibition of these pathways has shown potential renoprotection in experimental CKD models. Brazilian Red Propolis (RP), resinous glue produced by honeybees through the collection of plant exudates, has been demonstrated to possess antioxidant and anti-inflammatory effects.The present study was designed to evaluate the renal effects of RP on remnant kidney model (Nx).

Methods: In order to obtain the Nx model, adult male Wistar rats underwent a surgical procedure performed in two steps: Removal of the left kidney poles, followed by right nephrectomy (performed 7 days after polectomy). The animals were distributed among 4 groups: Sham-operated rats (S, n=6), Sham rats treated orally with RP, 150mg/kg/day (S+RP, n=6), untreated Nx rats (Nx, n=6) and Nx rats treated orally with RP, 150mg/kg/day (Nx+RP, n=6). All groups were followed for 3 months. At this time, body weight, BW (g), tail-cuff pressure (TCP, mmHg), serum creatinine (SCr, mg/dL), urinary protein excretion (Uprot, mg/dL), percent glomerular esclerosis (%GS), percent renal cortical interstitial area (%INT) and renal macrophage infiltration (MØ, cells/mm^2) were determined.

Results: (Mean ± SD, one-way ANOVA, †p <0.05 vs CN, §p <0.05 vs CN+PV, *p <0.05 vs Nx+PV).

Table 1

GROUPS	TCP	SCr	Uprot	%GS	%INT	Mø

Treatment with RP reduced Uprot levels, glomerular damage, interstitial expansion and macrophage infiltration in Nx rats; independently of blood pressure lowering.

Conclusions: These partial results suggest that RP treatment attenuates renal damage in the remnant kidney model.

PUB663

Angiotensin II/DOCA Salt Model of Chronic Kidney Disease in the C57BL/6 Mouse

Zahraa Mohammed-ali, Gaile L. Cruz, Baqer Jafar, Richard Austin, Jeffrey G. Dickhout. *Medicine, Division of Nephrology, McMaster University and St. Joseph's Healthcare Hamilton.*

Background: C57BL/6 mice are resistant to Chronic Kidney Disease (CKD) by standard techniques such as reduced renal mass and angiotensin II (Ang II) infusion, thereby limiting the use of knockout mice to study the progression of CKD. We developed a model of CKD in the C57BL/6 mouse using Ang II infusion and DOCA treatment with high sodium intake. Our study characterizes the model.

Methods: All the mice underwent a uninephrectomy (Unx) or a sham operation 2-weeks before the start of the experiment. The Unx mice were placed on 1% sodium chloride in the drinking water and received a 50 mg 21-day release deoxycorticosterone acetate (DOCA) pellet implant and Ang II infusion (1.5 ng Ang II/minute/g) using osmotic mini pumps. Blood pressure was measured using tail cuff plethysmography and 24 h urine was collected for protein analysis. On day 21, the animals were sacrificed. Cardiac and renal tissues were weighed and evaluated by periodic acid-schiff (PAS), α-smooth muscle actin and TUNEL staining to assess kidney injury.

Results: This model of CKD involves various physiological changes in Unx versus sham operated animals. A significant increase in systolic and diastolic blood pressure and total protein in 24 h urine was observed post-CKD development. Kidney sections from Unx animals exhibited an increase in PAS-positive intratubular protein casts indicative of renal pathology. Proteinuria was highly predictive of total protein cast area (R^2=73%). *De novo* α-smooth muscle actin staining showed renal interstitial fibrosis and T cell infiltration further confirmed a neo-antigen mediated immune response in CKD. A significantly higher level of apoptosis occurred in the tubular epithelium of Unx animals. Electron microscopy showed glomerular capillary dilation and disruption of the podocyte filtration barrier.

Conclusions: The Ang II/DOCA salt model of CKD developed in the C57BL/6 mouse resembles the pathological features found in many patients with late stage CKD, including proteinuria, hypertension, cardiac hypertrophy and renal pathology. This model is highly applicable to the study of various genetic knockouts in CKD development.

Establishment of New High Functional Culture System for Renal Cells and In Vitro Model of Diabetic Nephropathy Using Radial Flow Bioreactor

Toru Iwahori,[1,2] Akira Shimizu.[2] *[1]Nephrology & Immunology, Koyukai Memorial Hospital, Chiba, Japan; [2]Analytic Human Pathology, Nippon Medical School, Bunkyo-ku, Tokyo, Japan.*

Background: It is not possible that we could apply monolayer culture system as in vivo three dimensional condition. A radial-flow bioreactor (RFB) can be characterized as a system in which high perfusion rate at the center would allow adequate supply of oxygen and nutrients to the cells at the center. We have established three dimensional and high functional renal cell culture system by using RFB in order to create in vivo condition on in vitro. We also carried out experiments to make sure how renal cells characterize in the conditions of several glucose and oxygen concentration by using culture control system in closed culture system of RFB.

Methods: Two to 5 ×10^7 renal cells (LLC-PK1 or human mesangial cell) were injected in the RFB. Isolated cells were loaded in the RFB column and became trapped and adhered to the porous culture beads under the condition of several glucose and oxygen concentration. For each data point, RNA was obtained from the cells cultured in the RFB or monolayer dish and we performed real-time quantitative PCR. Furthermore, we stained the cells with antibodies to connective tissue growth factor (CTGF) and fibronectin (FN) so as to investigate of renal fibrosis.

Results: Renal cells were able to be cultured in the RFB. Especially, we could culture LLC-PK1 for longer than 100 days without passage. Then the mRNA expression of the 1-alpha-hydroxylase (CYP27B1) in LLC-PK1 cells were higher than those in a monolayer culture. Furthermore, FN expression of LLC-PK1 cells under high glucose and low oxygen were higher than those another condition. In terms of CTGF, the condition of high glucose and low oxygen led to the opposite results.

Conclusions: RFB system composed of proximal tubular cells could be useful as high functional culture system similar to in vivo, and we can detect CYP27B1 mRNA anytime as their function. We also observed the expression of FN and CTGF associated with renal fibrosis under high glucose and hypoxic condition in this system were changed. Based on these results, it could be useful for the in vitro model of diabetic nephropathy.

PUB665

Epidermal Growth Factor Inhibits Basal and Transforming Growth Factor Beta-Induced Collagen and Smooth Muscle Alpha-Actin Expression in Renal Tubular Epithelial Cells

Xiaoying Liu, H. William Schnaper. *Department of Pediatrics, Northwestern University, Chicago, IL.*

Background: Transforming growth factor beta (TGFβ) signaling plays an important and complex role in renal fibrogenesis. The seemingly simple TGFβ/Smad cascade is intensively regulated at different levels including crosstalk with other signaling pathways. Epidermal growth factor (EGF) is a potent mitogen for epithelial cells and is elevated in

diseased kidneys, but its effect on TGFβ-induced fibrotic changes is unclear and will be examined in this study.

Methods: Human proximal tubular epithelial cells (HKCs) were treated with TGFβ (1 ng/ml) and/or EGF (25 ng/ml) for different time periods. EGFR inhibitor AG1478 (10 uM), JNK inhibitor SP600125 (20 uM), PI3K inhibitor wortmannin (10 uM) or MEK inhibitor PD0325901 (100 nM) were added 1 hour prior to TGFβ or EGF treatment. Actinomycin D (10 ug/ml) was used to determine mRNA half-life. qPCR and western blotting were used to examine mRNA and protein level, respectively.

Results: EGF specifically inhibited basal and TGFβ-induced type-I collagen and smooth muscle α-actin (αSMA) expression at both the mRNA and the protein level. Inhibitors AG1478 and PD0325901 prevented the inhibition by EGF, but SP600125 or wortmannin did not. Further, EGF did not block Smad2 or Smad3 phosphorylation by TGFβ, or Smad2/3 nuclear import. However EGF reduced the activation of ARE-luc (Smad2 readout) and SBE-luc (Smad3 readout). Both reductions were prevented by PD0325901. EGF also diminished TGFβ induction of both collagen I and αSMA promoters. Collagen I mRNA had a half-life of ~4 hr whereas the half-life for αSMA mRNA was longer than 24 hr. EGF had little effect on collagen mRNA stability, suggesting that regulation was solely transcriptional, whereas EGF accelerated degradation of αSMA mRNA.

Conclusions: These results suggest EGF inhibits two markers of EMT through EGF receptor tyrosine kinase and downstream ERK activation, but not through PI3K or JNK. The inhibition results from both reduced basal mRNA expression and effector mechanisms downstream of Smads. Thus EGF stimulates multiple, complementary systems to regulate TGFβ/Smad signals mediating renal fibrogenesis.

PUB666

Thromboxane A_2 Receptor Stimulation Suppresses ICAM-1 Expression on Renal Tubular Epithelial Cells that Results in Inhibition of Leukocyte Adhesion Yoshiyuki Morishita, Minami Watanabe, Hiromichi Yoshizawa, Akira Onishi, Eiji Kusano. *Division of Nephrology, Department of Internal Medicine, Jichi Medical University, Shimotsuke, Tochigi, Japan.*

Background: Thromboxane A_2 receptor signaling was reported to increase ICAM-1 expression on vascular endothelial cells; however, little is known about its effects on renal tubular cells. In the present study, we investigated the effects of TXA_2 receptor stimulation on ICAM-1 expression and adhesion with leukocytes for renal tubular epithelial cells.

Methods: The subcellular localization of TXA_2 receptor on HK-2 cells (immortalized human renal proximal tubular epithelial cells) was investigated by immunohistochemistry. HK-2 cells were stimulated with U46619 (9,11-dideoxy-9α,11α-methano-epoxyprostaglandin F2α) (10^{-6}-10^{-10} M), an agonist of TXA_2 receptor, with or without pretreatment with SQ29548 ([1S-[1α,2α(Z),3α,4α]]-7-[3-[[2-[(phenylamino) carbonyl]hydrazino]methyl]-7-oxabicyclo[2.2.1]hept-2-yl]-5-heptenoic acid) (10^{-5} M), an antagonist of TXA_2 receptor, for 24 hrs. Then, the change of ICAM-1 expression on HK-2 cells was analyzed by qRT-PCR and flow cytometry at 24, 48, 72, 96 and 120 hr after stimulation with U46619. HK-2 cells stimulated with U46619 (10^{-6} M) for 72 hrs were co-cultured with peripheral blood mononuclear cells (PBMCs) obtained from healthy donors for a further 2 hrs to investigate the change of their adhesion by cell adhesion assay.

Results: TXA_2 receptor was a localized intracellular structure on HK-2 cells. U46619 decreased ICAM-1 expression on HK-2 after 72 hrs in a dose-dependent manner. This decrease of ICAM-1 expression on HK-2 cells was inhibited by pretreatment with SQ29548. The adhesion between PBMCs and HK-2 cells was significantly decreased to 60% ($p<0.05$) by stimulation of HK-2 cells with U46619 (10^{-6} M) compared with that of HK-2 cells without stimulation. Pretreatment of HK-2 cells with SQ29548 (10^{-5} M) inhibited this decreased adhesion between PBMCs and HK-2 cells.

Conclusions: The results of the present study suggested that TXA_2 receptor stimulation suppresses ICAM-1 expression on renal tubular epithelial cells, which results in inhibition of leukocyte adhesion.

PUB667

Cordyceps Sinensis Ameliorates Renal Fibrosis in the Remnant Kidney Model by Down-Regulating Mitochondrial Oxidative Stress Ming-hui Zhang, Haifeng Ni, Junfeng Chen, Bi-Cheng Liu. *Institute of Nephrology, Zhong Da Hospital, Southeast University, Nanjing, Jiangsu, China.*

Background: Cordyceps sinensis(CS) is widely used in traditional Chinese medicine for nearly 2,000 years, and it has potential renoprotective effects. but the mechanisms by which CS improves renal function and fibrosis still not be fully ascertained. Our study is aimed to investigate the effects of CS on the mitochondrial oxidative stress level and find the mechanisms of the Chinese herbal as a nephroprotective agent in the remnant kidney model.

Methods: Male SD rats were allocated to the following groups: Sham surgery+vehicle (S) group, 5⁄6 nephrectomy+vehicle (N) group, and 5⁄6 nephrectomy+CS(2g/kg bw·d)(C) group. Rats were killed on week 12 after surgery. Pathological and ultrastructural changes of the renal tissues were observed. Activity of MnSOD, GSH-Px,and MDA in the kidney cortex, and the level of mitochondrial membrane potential(MMP), ROS by chromatometry. And the expression of CytoC and Prohibitin in both mitochondria and cytoplasm were tested by western blot.

Results: Compared with the S group, BW, SBP, 24hUTPro, NAG, SCr and BUN were significantly increased ($P<0.01$) in the N group, while they all appeared significantly decrease in C group compared with the N group ($P<0.01$); Glomerular sclerosis, tubulointerstitial fibrosis, the infiltration of inflammatory cells and the mitochondrial swelling and the diminution of cristae were observed in the N group. The changes described above were obviously improved in the C group; The activities of MnSOD, GSH-Px and MMP were significantly reduced in the renal cortex of the N group. ($P<0.01$), and there were significantly elevated in the C group. While the MDA and ROS levels appeared crosscurrent; the expression of CytoC and Prohibitin in mitochondria were significantly reduced ($P<0.01$) in the N group. And there were significantly elevated in the C group.

Conclusions: Our findings indicate that the CS exerts effective antioxidation and plays a protective role against the development of renal fibrosis in experimental animal model, which might be related with its down-regulating mitochondrial oxidative stress.

PUB668

Cross Talk between Cardiotonic Steroids (CTS) and 20-HETE in Cardiac Fibroblasts Vinai Kumar Katragadda,[1] Imad Hariri,[1] Steven T. Haller,[1] Yanling Yan,[1] Deepak K. Malhotra,[1] Zi-jian Xie,[2,1] Michal L. Schwartzman,[3] Nader Abraham,[2] Joseph I. Shapiro,[1,2,4] Jiang Liu.[1,4] *[1]Medicine, University of Toledo College of Medicine, Toledo, OH; [2]Physiology and Pharmacology, University of Toledo College of Medicine, Toledo, OH; [3]Pharmacology, New York Medical College, Valhalla, NY; [4]Pharmacology and Physiology, Marshall University JCE School of Medicine, Huntington, WV.*

Background: 20-HETE has been characterized as a second messenger in signal transduction pathways participating in the regulation of vascular tone, sodium excretion, cell proliferation, and angiogenesis. 20-HETE has been shown to inhibit Na/K-ATPase but its effect on fibrosis is unclear. We investigate if 20-HETE can interact with cardiotonic steroids to stimulate collagen production in isolated rat cardiac fibroblasts.

Methods: Primary culture of rat cardiac fibroblast, c-Src phosphorylation, collagen production.

Results: We have reported that cardiotonic steroid marinobufegenin (MBG) stimulates collagen (type 1) production and cardiac fibrosis both *in vitro* and *in vivo*, through Na/K-ATPase signaling. In primary culture of rat cardiac fibroblasts isolated from Sprague Dawley rats, both MBG (1 and 10nM, 24 h) and 20-HETE (10 and 100nM, 24h) stimulated collagen production. Interestingly, the selective inhibitor of 20-HETE biosynthesis HET-0016 significantly attenuated the stimulatory effect of MBG, whereas anti-MBG antibody has no significant effect on 20-HETE-induced collagen production. It appears that 20-HETE production may interplay with MBG and enhance the effect of MBG in collagen production. While low dose of MBG (0.1nM) and 20-HETE (0.1 and 1nM) alone did not stimulated collagen production, co-administration of MBG (0.1nM) and 20-HETE (0.1 and 1nM) had synergistic effect and significantly stimulated collagen production. Furthermore, both MBG and 20-HETE (10nM, 15min) activated c-Src.

Conclusions: Like MBG, 20-HETE stimulated collagen (type 1) production in cardiac fibroblasts. Inhibition of 20-HETE might attenuate MBG-induced collagen production. The data also suggest that MBG and 20-HETE might have substantial cross-talk.

PUB669

The Role of the Urokinase Plasminogen Activator Receptor and Complement Factor H in Neutrophil Adhesion: Relevance for the Atypical Hemolytic Uremic Syndrome? Judith Gras,[1] Fred G. Pluthero,[1] Christoph Licht.[1,2] *[1]Program for Cell Biology, The Hospital for Sick Children, Toronto, ON, Canada; [2]Division of Nephrology, The Hospital for Sick Children, Toronto, ON, Canada.*

Background: In the pathogenesis of the atypical haemolytic uremic syndrome (aHUS), an interplay of complement and coagulation can be observed: Through dysfunctional regulation of the alternative complement pathway (e.g. mutations in complement factor H (CFH)) on the surface of the glomerular basement membrane endothelial cells are damaged, which leads to an activation of the coagulation system. Many aspects of the disease also suggest an involvement of polymorphonuclear leucocytes (PMN). As PMNs are known to interact with CFH through complement receptor 3 (CR3) during adhesion and CR3-mediated adhesion in general is positively regulated by the coagulation protein urokinase plasminogen activator receptor (uPAR), this project focused on the investigation of a putative connection between CFH and uPAR in neutrophil adhesion.

Methods: The potential consequence of an interaction between CFH and uPAR was investigated with a microfluidic flowchamber system (BioFlux). Human PMNs were preincubated with αuPAR, αCR3 antibodies or nonspecific IgG as a control. Cells were then under constant flow introduced into BioFlux channels that were covered with a monolayer of Human umbilical vein endothelial cells (HUVECs), HUVECs bound with additional CFH or CFH alone. PMN adhesion was then quantified and compared with the control.

Results: Whereas PMNs incubated with αCR3 in all approaches adhered less to the surface, the use of αuPAR lead to different results: As expected, neutrophils blocked with αuPAR compared to the control adhered less to a surface covered with a HUVEC monolayer. However, if the surface was coated with additional CFH, the effect of αuPAR could partly be reversed. If the surface was coated solely with CFH, PMNs incubated with uPAR adhered more.

Conclusions: With uPAR we have been able to identify a protein of the coagulation pathway that is able to negatively regulate the interaction of PMNs with CFH. Whether these findings have consequences for the pathogenesis of aHUS has to be established in further experiments.

17β-Estradiol Attenuates Renal Fibrosis in Mice with Obstructive Uropathy Min Hyun Cho,[1] Youngju Hwang,[1] Hee-Seong Jang,[2] Kwon Moo Park.[2] *[1]Pediatrics, Kyungpook National University; [2]Anatomy, Kyungpook National University.*

Background: Men are generally more prone to chronic kidney disease and to progress to end stage renal disease than are women. The purpose of this study is to prove the effect of gender and sex hormone on the renal fibrosis in mice with unilateral ureteral obstruction (UUO) and to elucidate the specific mechanisms.

Methods: We compared the expression of α-smooth muscle actin (α-SMA) in female and male mice with complete UUO (day 7). After this, we estimated the changes of renal fibrosis in the female mice with ovariectomy and in the female mice with ovariectomy and replacement of 17β-estradiol, respectively.

Results: The level of α-SMA in the female kidney with UUO was significantly lower than that in the male kidney with UUO. Ovariectomy and replacement of 17β-estradiol did not change the expression of angiotensin II type 1 (AT_1) receptor in the female kidney with UUO, whereas the expression of angiotensin II type 2 (AT_2) receptor was significantly more elevated in the intact female (IF) and the ovariectomized female with estrogen (OF+E) than that in the ovariectomized female (OF). The expressions of inducible nitric oxide synthase (iNOS) in the IF and OF+E mice were significantly more elevated than that in the OF mice, which was similar to the expression of AT_2 receptor.

Conclusions: The female gender is associated with resistance to renal fibrosis in obstructive uropathy and this gender difference may originate from the existence of 17β-estradiol, which has an anti-fibrotic effect via upregulation of the AT_2 receptor and iNOS.

PUB671

Effect of Notoginseng on Renal ICAM-1 Expression in Unilateral Ureteral Obstruction Rats Xia Liu, Yanjie Huang, Xiaoqing Yang. *Pediatrics, The First Affiliated Hospital of Henan University of Traditional Chinese Medicine, China.*

Background: Notoginseng is a anti-coagulant drug of traditional chinese medicine (TCM). The effect of Notoginseng on the expression of P-selectin, intercellular cell adhesion molecule-1 (ICAM-1), transforming growth factor-1 (TGF-β1), and the infiltration of macrophage were observed in kidney of unilateral ureteral obstruction (UUO) rats.

Methods: 52 male SD rats were randomly divided into: 1) sham group (n=12); 2) UUO model group (n=20); 3) notoginseng group (n=20). Half rats in each group were sacrificed respectively on day 7 and day 14. Renal P-selectin, ICAM-1, CD68, TGF-β1 expression and localization were detected by immmunohistochemical analysis. Rat kidney tissue sections were stained with Masson's trichrome and periodic-acid Schiff for histopathological analysis.

Results: Compared with the sham group, the levels of renal tissue ICAM-1, P-selectin, CD68, TGF-β1 expression were significantly upregulated in UUO model group on day 7 and day 14 ($P<0.05$). Notoginseng decreased tubulointerstitial injury score and the renal interstitial inflammatory cell count, and suppressed significantly the levels of renal ICAM-1, CD68, TGF-β1 expression on day 7 and day 14, compared with the UUO model group ($P<0.05$).

Conclusions: Notoginseng meliorates development of tubulointerstitial fibrosis via decreased ICAM-1-mediated inflammatory cell infiltration, then lowed TGF-β1 level in UUO rats.

PUB672

The Impact of Reversible Unilateral Ureter Obstruction on Epithelial-Myofibroblast Transdifferentiation Hong Li Lin, Shen Nan, Yan Ling Sun. *The First Affiliated Hospital of Dalian Medical University.*

Background: The aim of this present study is to investigate the process of epithelial-myofibroblast transdifferentiation or myofibroblast-epithelial transdifferentiation in reversible unilateral ureter obstruction rats.

Methods: Ninety male Sprague-Dawley rats(20 to 25 g) were randomly divided into four groups, i.e, normal control group (CON, n = 10), sham operation group (SOR, n = 10), unilateral ureteral obstruction group (UUO, n = 24) and reversible unilateral ureteral obstruction group (RUUO, n = 36). RUUO was induced by clamping the left ureter using a hemostatic ligating clip. The obstruction was reversed three days after the operation by removing the clip. Six animals in each group were killed at weeks 1, 2, 4, 8 and 12. Firstly, we used Real time-PCR Arrays to detect the mRNAs expressions of TGF-β1 and α-SMA among the above-mentioned groups, then we further detected and confirmed the expression changes of N-cadherin, collogen-1, FSP-1, TGF-β1 and α-SMA by Western blot or immunofluorescence. Serum creatine (Scr) and blood urea nitrogen (BUN) was used to assess renal function. Interstitial fibrosis and renal morphology were assessed by examination of PAS and PASM staining.

Results: Untreated obstructed rats showed marked tubular atrophy and apoptosis, tubulointerstitial macrophage infiltration and fibrosis. Following the relief of obstruction, however, there was a significant restoration. Compared with CON and SHAM groups, the mRNA levels of TGF-β1 and α-SMA were significantly increased in UUO rats detected by Real time-PCR ($P<0.05$). They were significantly higher than baseline from 3 to 7 days after relief of UUO, and then gradually reduced to normal. Western blot showed that the expression of TGF-β1 and α-SMA significantly increased in UUO group compared with CON group($P<0.05$), whereas, the expressions were obviously decreased after the release of ureter.

Conclusions: Our study described a model of renal injury and repair in the adult mouse after RUUO. Following the relief of obstruction, the indicators of inflammation, EMT and fibrosis were attenuated significantly.

PUB673

Cobalt Chloride Deteriorates Renal Fibrosis after Ischemia Reperfusion Injury Associated with Decreased Hypoxic Renal Tubular Cells Yoichiro Ikeda, Tetsuhiro Tanaka, Reiko Inagi, Masaomi Nangaku. *Division of Nephrology and Endocrinology, University of Tokyo, School of Medicine, Tokyo, Japan.*

Background: Chronic hypoxia exists in chronic kidney disease in general. Renal ischemia reperfusion injury (IRI) devastates renal architecture especially in tubules with maximal magnitude in one day and within some days, kidney restores histologically and functionally with some traces of the insult, namely tubulointerstitial fibroses according to the magnitude of the insult. Cobalt chloride (Co), hypoxia mimetics, upregulates hypoxia inducible factors (HIFs) and its administration before IRI ameliorate IRI, but its effect on chronic kidney diseases is controversial and may be dependent on cases. HIF-1a is predominant in tubules. Pimonidazole is a chemical indicating the histological low oxigen tension. Here we demonstrate Co administered at recovering phase of IRI deteriorates renal function and fibrosis.

Methods: Wistar male rats were subjected to IRI by clamping bilateral renal arteries for 45min. After 24h, BUN and Cre were measured to confirm the same insult, and Co was injected intraperitoneally (30mg/kg) once and continuously administered by osmotic pump (80mg/rat). Pimonidazole was injected (60mg/kg) and 1h later they were sacrificed 15days after IRI with PFA perfusion fixation.

Results: Renal function and fibrosis were deteriorated by Co administration at restoring phases of IRI for 14days (BUN 23±1.5 vs 39±2.2 mg/dL, Cre 0.71 ± 0.08 vs 1.0±0.08 mg/dL; IR-Co(-) vs IR+Co(+), mean±SEM). Immunohistochemical staining of pimonidazole revealed sustained hypoxia especially in cortical tubules even weeks after IRI, and Co decreased the area of hypoxic tubules in cortex due to dropout of tubules. Elevation of HIF1a protein level sustained elevated after IRI for weeks, which was enhanced by Co administration.

Conclusions: Hypoxia sustained in cortical tubules long after IRI with enhancement of HIF. Cobalt chloride administered at the restoring phase of IRI deteriorated renal function and fibrosis. HIF activation by cobalt chloride during the development of renal fibrosis is dependent on the timing of the administration.

PUB674

Protein Loading Mediates Epithelial-to-Mesenchymal Transition in Biomimetic Proximal Tubular Microenvironment Hong Li Lin. *Tthe First Affiliated Hospital of Dalian Medical University.*

Background: Leaked protein-loading has been implicated in the development of tubulointerstitial injury in the clinical and basic researches when glomerulonephritis existed. Yet we lack an in vitro model that would allow exploration which type of the leaked proteins damaged renal interstitial and further our ability to elucidate the underlying mechanisms that govern the progression of tubulointerstitial fibrosis.

Methods: Here, we introduced a simple microfluidic and compartmental cell-culture system in which simulate proximal tubular microenvironment and recapitulated the process of epithelial to mesanchymal transition (EMT) in vitro. The system consisted of two micro scale devices, one for exploration of EMT inductors of multiple protein loading, the other for assay of the behavior of cells migration directional trans-tubular basement membrane (TBM) the process of EMT.

Results: The results showed that, on the microfluidic rapid evaluating of multi-inductors device, tubular epithelial cells exposed to normal serum proteins presented phenotypic and functional characteristics of mesenchymal cells. The expression of E-cadherin was reduced and the expression ofα-SMA and FSP-1 was increased. Exposure of the cells to the complement anaphylotoxin C3a induced similar features. On the compartmental microscale decice, cells migrated significantly, mediated by TGF-β1 and C3a, along with the matrix around destroyed during the process of EMT. And cells migrated accompanied with morphological changing from typical "flagstone" to obvious spindle shape.

Conclusions: In summary, this microscale model enables control of both spatial and temporal aspects within the microenvironment, allowing recapitulation of the environment *in vivo* in ways not practical with existing experimental models. We found that lower concentration of active serum proteins can induce EMT on proximal tubular epithelia cells (PTECs) on the microfluidic devices, and the complement anaphylotoxin C3a is an important mediator of proximal tubular injury and can induce tubular EMT. Meanwhile, we proved PTECs through EMT migrate trans-TBM directionally *in vitro.*

PUB675

Targeting Kirsten Ras Antisense in the Murine Chronic Folic Acid Nephropathy Model Lucy Jade Newbury, Bruce M. Hendry, Claire C. Sharpe. *Department of Renal Medicine, Kings College London, London, United Kingdom.*

Background: Renal fibrosis is thought to occur via different signaling pathways, many of which converge on Ras GTPases. We used antisense oligonucleotides (ASO) to silence Kras expression to observe its effect on interstitial fibrosis in a novel chronic folic acid nephropathy (CFAN) model.

Methods: ASO were screened in CD1 mice. 20mg/kg ASO were injected SC on alternate days for 6 days. The animals were killed on day 7.

The CFAN model: Male CD1 mice were given folic acid (FA) 125mg/kg IV in $NaHCO_3$ at day 0 and at day 21 (n=24). Controls received $NaHC0_3$ alone(n=8). FA-treated animals were divided into three equal groups. Each group received 3x SC injections/week from day 35 reducing to 2/week from day 49 of saline, ASO166 or ASO143 (20mg/kg). Animals were killed on day 85. Control groups were killed on day 0 (n=4) and day 85 (n=4).

Kras mRNA knockdown was analyzed by RT-QPCR. Fibrosis was analyzed by quantifying total collagen using picrosirius red staining (PSR).

Results: In normal mice we achieved 43% and 44% knockdown of Kras with ASO166 and 143, respectively. FA-treated mice gained weight more slowly than vehicle controls, demonstrating acute weight loss post FA injections ($p> 0.05$). The FA placebo group showed a trend increase in Kras expression when compared with aged controls. The FA-ASO143 group showed a significant Kras mean knockdown, of 43% when compared with placebo-treated animals ($p<0.05$). The FA-ASO166 demonstrated a non-significant mean knockdown of 29%.

FA-treated animals demonstrated a 3.4 fold increase in collagen deposition at day 85 when compared with vehicle. ASO-166 did not appear to affect fibrosis. ASO-143 was associated with a 27.5% reduction in fibrosis compared to placebo-treated animals. Although this was not statistically significant, the fibrosis score of each animal showed a positive correlation with Kras mRNA expression.

Conclusions: This novel chronic folic acid model achieved a 3.4 fold increase in collagen deposition (PSR) compared with controls. Expression of Kras mRNA positively correlates with amount of collagen deposition in the kidneys - This highlights Kras as a potential therapeutic target.

PUB676

Immunization against Marinobufagenin Inhibits Renal Fibrosis in Experimental Uremic Cardiomyopathy Steven T. Haller,[1] Jiang Liu,[1,2] Yanling Yan,[1,2] Anna P. Shapiro,[1] Olga Fedorova,[4] Alexei Bagrov,[4] Joseph I. Shapiro,[1,3] Deepak K. Malhotra.[1] *[1]Medicine, University of Toledo, Toledo, OH; [2]Pharmacology, Marshal University, Huntington, WV; [3]Medicine, Marshal University, Huntington, WV; [4]National Institute on Aging, Baltimore, MD.*

Background: Experimental uremic cardiomyopathy causes cardiac fibrosis and is associated with increased levels of the cardiotonic steroid marinobufagenin (MBG), a ligand of the Na/K-ATPase. We have shown that treatment with a monoclonal antibody against MBG (3E9 mAb), and Digibind (the Fab fragments of ovine digoxin antibody), which binds to endogenous cardiotonic steroids, attenuated cardiac fibrosis and improved creatinine clearance in experimental renal failure. In the present study, we tested the effects of the 3E9 mAb and Digibind treatment on the development of renal fibrosis.

Methods: Male Sprague Dawley rats weighing between 250-300 gms were used for these studies. At four weeks following partial nephrectomy (PNx,) these rats were administered vehicle (n=6), 10 mg/kg of Digibind (n=6), or 50 µg/kg of the 3E9 anti-MBG mAb (n=6). One week following treatment (five weeks post PNx), animals were sacrificed and tissues were harvested for biochemical and histological analysis.

Results: The 3E9 mAb treatment group demonstrated a substantial decrease in renal fibrosis (assessed by trichrome staining, sirius red/fast green staining, and Western blot) compared to PNx. Digibind treatment had a similar, yet less pronounced effect.

Conclusions: Our results suggest that immunization against MBG may offer a potential therapy for uremic cardiomyopathy by inhibiting the development of renal fibrosis.

Mesenchymal Stromal Cells and Lisinopril in Combination Therapy Reduce Renal Fibrosis Inhibiting Renin Angiotensin System in Unilateral Ureteral Obstruction Model Giulia Bedino, Marilena Gregorini, Teresa Valsania, Chiara Rocca, Valeria Corradetti, Francesca Bosio, Eleonora Francesca Pattonieri, Pasquale Esposito, Carmelo Libetta, Teresa Rampino, Antonio Dal Canton. *Unit of Nephrology, Dialysis & Transplantation, Fondazione IRCCS Policlinico San Matteo & University, Pavia, Italy.*

Background: Renin-angiotensin system plays a pivotal role in renal fibrosis and angiotensin-converting enzyme inhibitors(ACEi)are the most effective therapy to reduce progression of chronic kidney disease.It is known that ACEi induce a compensatory increase in plasma renin levels and renin promotes renal injury by stimulating angiotensinII(ANG II) generation and up-regulating pro-fibrotic genes.We have proved that ACEi and mesenchymal stromal cells(MSC)reduce renal fibrosis in unilateral ureteral obstruction model(UUO). Aim of this study was to understand the mechanism underlying the protective effects of ACEi and MSC inUUO.

Methods: We studied 5 groups of SD rats.MSC were isolated by bone marrow.A:5 rats sham operated.B:8 rats UUO received saline solution d0.C:8 rats UUO received MSC d0 via tail vein.D:8 rats UUO received lisinopril(ACEi),d1-21.E:8 rats UUO received MSC d0, and ACEi d1-21.Rats were sacrified on d7 and 21.Serum ANGII levels,renin mRNA expression,ED1 positive cells,interstitial fibrosis(Masson's trichrome staining),%of broken tubules/HPF were evaluated.

Results: Serum ANGII levels increased in B compared to A,monotherapy with MSC reduced ANGII levels, but ACEi and combination therapy determined a further suppression effect($p<0.05$)on d7.On d21 serum ANGII levels were lower in all rats.Renin mRNA expression did not increase in B and C, compared to A,while increased in D.Rats receiving combination therapy showed lower renin mRNA levels compared to D.ED1 positive cells number in B was greater than in C and D.In E it was further reduced.The fibrosis was less severe in C,D and even more inE than inB($p<0.05$).% of broken tubules/HPF was reduced in D compared to B and C($p<0.05$),but further in E.

Conclusions: Our results show that MSC in UUO model prevent renin increase,reduce angiotensinII generation but combination therapy suppress further ANGII block leading to a synergistic effect.

PUB679

Mesenchymal Stromal Cells and Lisinopril in Combination Therapy Modulate Scatter Factors in Unilateral Ureteral Obstruction Model Valeria Corradetti, Marilena Gregorini, Teresa Valsania, Chiara Rocca, Francesca Bosio, Eleonora Francesca Pattonieri, Giulia Bedino, Pasquale Esposito, Carmelo Libetta, Teresa Rampino, Antonio Dal Canton. *Nephrology, IRCCS Policlinico S.Matteo and University of Pavia, Pavia, Italy.*

Background: Hepatocyte Growth Factor (HGF)/Met and Macrophage Stimulating Protein (MSP)/Ron systems are Scatter Factors that regulate tissue remodelling and inflammatory cells response in renal diseases, including unilateral ureteral obstruction (UUO). We have proved that angiotensin-converting enzyme inhibitors (lisinopril, ACEi) and MSC accelerate renal repair in UUO. The aim of this study was to evaluate whether ACE and MSC in mono and combination therapy induce renoprotective effect modulating Scatter Factors.

Methods: We studied 5 groups of Sprague-Dawley rats. MSC were isolated from bone marrow. Group A: 5 sham-operated rats. Group B: 8 rats undergone UUO received saline solution on day 0, Group C: 8 rats UUO received MSC ($3x10^6$) on day 0 via tail vein. Group D: 8 rats UUO received ACEi in water, days 1-21. Group E: 8 rats UUO received MSC on day 0 and ACEi, days 1- 21. Rats were sacrified on days 7 and 21. HGF and MSP mRNA (RT- PCR), HGF, Met, MSP, Ron proteins (Western blot) were analysed in renal tissue. Ron and Met expression were evaluated by immunohistochemistry.

Results: HGF and MSP mRNA were not significantly different in all rats. HGF and Met proteins were similar in A and B, increased in rats treated respectively with MSC (C) and ACEi (D)($p<0.001$ vs A and B), and rose further in E ($p<0.0001$vs A and B). MSP and Ron proteins were similar in A and B, but increased significantly only in C ($p<0.005$ vs A, B, D, E). Compared to sham operated rats (A) and controls (B) monotherapy with ACEi (D) and MSC (C) increased the extent of tubular Met staining ($p<0.005$), but combination therapy induced additional increase of positive tubular area ($p<0.001$). The combination therapy induced an increase of Ron tubular expression in E ($p<0.001$ vs B, C, D).

Conclusions: Our results showed that both ACEi and MSC may promote renal repair modulating Scatter Factors in UUO, yet the combination therapy lead to additive upregulation of HGF/Met and MSP/Ron signalling.

PUB680

A Short Isoform of Podocin Is Expressed in Human Kidney Linus A. Völker,[1] Eva-maria Schurek,[1] Tobias Lamkemeyer,[2] Denise Ungrue,[2] Christine E. Kurschat,[1,2] Bernhard Schermer,[1,2,3] Thomas Benzing,[1,2,3] Martin Höhne.[1,3] *[1]Renal Division, Department of Medicine and Center for Molecular Medicine, University of Cologne, Cologne, NRW, Germany; [2]Cologne Excellence Cluster on Cellular Stress Responses in Aging-Associated Diseases, University of Cologne, Cologne, NRW, Germany; [3]Sybacol - Systems Biology of Ageing Cologne, University of Cologne, Cologne, NRW, Germany.*

Background: Podocin, the protein encoded by the NPHS2 gene, is an essential and integral part of a functional kidney filtration barrier. Database searches and recent publications suggest the presence of a short 315 amino acid isoform of human podocin that lacks exon 5 and a central part of the PHB-domain. Given the importance of a functional PHB-domain in recruiting a specialized lipid microenvironment, we sought to elucidate the effect of this structural alteration on protein function and localization. Additionally, as all evidence of expression hitherto has been based on antibody-mediated detection or RT-PCR, conclusive proof of expression was required. We employed a bottom-up mass spectrometric approach to identify a peptide unique to the short isoform in human glomerular lysates. After tryptic digestion, the presence of a peptide bridging the gap between exon 4 and 6 was indicated by nanoLC-ESI-MS/MS. Upon biochemical analysis by sucrose gradient density centrifugation, we found this short isoform still to be associated with detergent-resistant membrane fractions. In overexpression, the short isoform was mainly retained in the endoplasmic reticulum while the full-length protein localized to the plasma membrane, indicative of divergent functions. An additional band of higher molecular weight in western blot could be attributed to post-translational modification: Removal of N-glycosylation by PNGase F treatment consistently abrogated the formation of the additional band, and site-directed mutagenesis of a potentially N-glycosylated residue mapped this effect to an asparagin at position 287 (355 in the full length protein). We present for the first time proof of presence of an additional human isoform of podocin on protein level, which adds new aspects to the molecular function of podocin in human podocytes.

PUB681

Albumin Exposure Induces an Inflammatory Response In Vitro and In Vivo
Judith Blaine,[1] Kayo Okamura,[1] Patrick Daniel Dummer,[2] Jeffrey B. Kopp.[2]
[1]Medicine, University of Colorado Denver, Aurora, CO; [2]NIDDK, National Institutes of Health, Bethesda, MD.

Background: Albuminuria is associated with an increased risk of kidney disease progression. While the injurious effects of albumin on renal proximal tubule cells are well documented, the effects of albumin on podocytes are less well studied.

Methods: We studied previously characterized human podocytes isolated from urine (Sakairi et al., 2010). Podocytes were exposed to medium supplemented with fetal bovine serum plus either 5 mg/ml low endotoxin recombinant human albumin or dextran of a similar molecular mass as an oncotic control. Cell death as measured using the trypan blue exclusion assay. The inflammatory response to albumin was assessed by measuring cytokine mRNA levels using quantitative RT-PCR and cytokine release by ELISA. To examine the effects of albuminuria *in vivo* we used the murine albumin overload nephropathy model.

Results: After 24 hrs the percentage of dead cells was 23 +/- 5% in podocytes exposed to albumin versus 11 +/- 3 % in dextran treated cells (P<0.0001) and after 48 hrs the percentage of dead cells was 25 +/- 5 % versus 10 +/- 1 % for controls, P = 0.0009. Albumin exposure significantly increased caspase 3 and 7 activity (P<0.0001) and increased the number of apoptotic cells as measured by the TUNEL assay. Albumin exposure increased expression of interleukin-1beta (IL-β) expression (peak mRNA increase ~ 8 fold at 3 hours, peak protein increase, P=0.005 compared to control), increased tumor necrosis factor (TNF) expression (peak mRNA increase ~3 fold at 3 hours, peak protein increase ~15 fold at 6 hours, P=0.003 compared to control), increased interleukin-6 expression (peak mRNA increase ~ 7 fold and peak protein increase ~8 fold at 48 hours, P<0.0001 compared to control). After 6 sequential bovine serum albumin (BSA) injections glomeruli isolated from BSA-injected mice had a 2-fold increase in IL-1β and TNF expression compared to saline injected animals (P=0.02).

Conclusions: These results suggest that podocyte exposure to albumin induces a pro-inflammatory response and increases apoptosis. Thus albumin exposure may contribute to podocyte loss in proteinuric states.

Cholesterol Loading Activates Intracellular Renin-Angiotensin Systemin Human Renal Mesangial Cells: A Potential Mechanism for Glomerulosclerosis
Jie Ni,[1] Kun Ling Ma,[1] Chang Xian Wang,[2] Jing Liu,[1] Yang Zhang,[1] Bi-Cheng Liu.[1] *[1]Institute of Nephrology, Zhong Da Hospital, Southeast University School of Medicine, Nanjing, Jiang Su Province, China; [2]Infection Management Department, Zhong Da Hospital, Southeast University School of Medicine, Nanjing, Jiang Su Province, China.*

Background: Dyslipidemia and local activation of renin-angiotensin system (RAS) play crucial roles in the progression of chronic kidney disease (CKD). The present study was undertaken to investigate possible effects of dyslipidemia on intracellular RAS activation and its underlying mechanism in glomerulosclerosis using human renal mesangial cells (HMCs).

Methods: HMCs were cultured and divided into Control group (treated with serum free medium) and cholesterol loading group (treated with serum free medium plus 30 μg/ml cholesterol and 1μg/ml 25-hydroxycholesterol). The lipid accumulation in HMCs was examined by Oil red O staining. The production of extracellular matrix in HMCs was examined by immunohistochemical staining and immunofluorescent staining. The gene and protein expressions of molecules involved in RAS components and the pathway of mammalian target of rapamycin (mTOR) were examined by real-time PCR and Western blot.

Results: Cholesterol and 25-hydroxycholesterol loading increased lipid accumulation in HMCs, and inhibited protein expression of α-SMA and collagen IV. Further analysis showed that cholesterol loading upregulated mRNA and protein expression of RAS components (angiotensinogen, angiotensin II, rennin, angiotensin-converting enzyme, agiotensin II type 1 receptor and type 2 receptor) in HMCs. Interestingly, lipid accumulation activated mTOR pathway, characterized by increased mRNA and protein expression, and protein phosphorylation level of mTOR, eukaryotic translation initiation factor 4E binding protein 1(4EBP1), ribosomal protein S6 kinase 1(S6K1), which were closely correlated with intracellular RAS activation.

Conclusions: Cholesterol loading affected mesangial cell functions and stimulated extracellular matrix excretion through intracellular RAS activation, which was correlated with the upregulation of mTOR pathway, suggesting a potential mechanism in the progression of glomerulosclerosis.

Podocytes Are Detached by PAI-1 Coupling with uPA and uPAR through the Internalization Mechanism
Namiko Kobayashi,[1] Toshiharu Ueno,[1] Yasutoshi Takashima,[1] Hanako Yamashita,[1] Taiji Matsusaka,[2] Michio Nagata.[1] *[1]Renal Pathology, University of Tsukuba, Tsukuba, Ibaraki, Japan; [2]Internal Medicine, Tokai University School of Medicine, Isehara, Kanagawa, Japan.*

Background: Mouse model of collapsing FSGS (NEP25 mice) with podocyte specific injury revealed thrombotic microangiopathy (TMA) with PAI-1 gene activation, and PAI-1 inhibitor ameliorates both proteinuria and disease progression with preservation of podocyte number (ASN 2011). Furthermore, in vivo, elevation of mRNA uPAR, which triggers internalization and degradation of PAI-1 with uPA, was observed in kidney from NEP mice. We hypothesized PAI-1 binding to uPA coupling with uPAR was associated with detachment of podocyte through the internalization mechanism.

To elucidate the mechanism whereby PAI-1 inhibition reserved podocyte number, we tested the role of PAI-1 on podocyte detachment *in vitro*.

Methods: Immortalized cultured podocytes were incubated either by uPA or PAI-1 alone (Group P, Group U), uPA+PAI-1 (Group U+P), uPA+PAI-1 with uPAR antibody or PAI-1 inhibitor (Group R, Group I), and remnant cell number was counted after incubation to assess cell detachment by effect of PAI-1. Immunofluorescent staining of uPAR on podocytes incubated by PAI-1 with uPA at 4°C (to prevent endocytosis and keep the protein at the cell surface)and 37°C (to promote endocytosis) were performed to analyze the localization.

Results: Most cells remained attached in Group U (100 ± 0.1%) and Group P (93.4 ± 1.5%).

Notably, when incubated with uPA+PAI-1, significant cells were detached, resulting in decreased attachment (60.6 ± 4.4%, $p < 0.05$ vs Group U). Furthermore, addition of uPAR antibody or PAI-1 inhibitor to uPA+PAI-1 restored attachment of podocytes (92.7 ±7.2, 110.9 ± 1.9%, respectively).

Confocal microscopy revealed that mostly uPAR with PAI-1 and uPA were on cell membrane at 4°C. However, after the incubation at 37°C for 5min, uPAR was decreasing from the cell membrane, and internalized in cell cytoplasm.

Conclusions: This suggests that PAI-1 involved in podocyte detachment by coupling with uPA and uPAR through the internalization mechanism, and potential role of PAI-1 inhibition to prevent podocyte from detachment.

PUB684

Mice Lacking Expression of the PI3K-C2β Enzyme Develop Mild Hyperglycaemia and Glomerular Abnormalities
Jan Domin,[1,3] Sanjeevi Balakrishnan,[1] Alan D. Salama,[1,2] Charles D. Pusey.[1] *[1]Renal Section, Imperial College London, London, United Kingdom; [2]UCL Centre for Nephrology, University College London, London, United Kingdom; [3]Division of Science, University of Bedfordshire, Luton, United Kingdom.*

Background: In mammals phosphoinositide 3-Kinase (PI3K) enzymes form a family of 8 intracellular signalling molecules that regulate a wide spectrum of cellular processes. Class I PI3K isoforms (p110α, p110β, p110γ and p110δ) have been implicated in cancer, autoimmunity, chronic inflammation, allergy, cardiovascular and metabolic disease. We have recently shown that mice null for the class II PI3K enzyme PI3K-C2α develop focal segmental glomerulosclerosis, affecting podocyte morphology and function (Harris et al 2011). In contrast, the precise physiological role of the class II PI3K enzyme PI3K-C2β remains unclear. In this study, we investigate whether the PI3K-C2β enzyme is also required for maintaining normal renal architecture and function.

Methods: Mice null for PI3K-C2β (PI3K-C2β$^{-/-}$) were re-derived as previously described (Harada et al 2005). All experiments were performed using sex and age matched controls, and animals of both sexes were used in this study. Assessment of basal level parameters was performed in control and PI3K-C2β$^{-/-}$ mice. 50 glomeruli were counted/measured in each section for histological analysis. Renal histology was performed to quantify glomerular volume, number of nuclei inside glomerulus and mesangial matrix deposition using morphometric analysis.

Results: PI3K-C2β$^{-/-}$ mice developed mild proteinuria (24 hours urine) compared to WT mice. The lack of PI3K-C2β expression also resulted in elevated blood glucose concentrations compared to control animals. Histological examination of PAS stained kidney sections from PI3K-C2β$^{-/-}$ mice revealed an increased number of nuclei inside the glomerulus, mesangial matrix deposition and a greater glomerular volume.

Conclusions: Mice deficient in PI3K-C2β expression exhibit renal abnormalities demonstrating that the PI3K-C2β enzyme plays a critical role in the maintenance of normal kidney function. PI3K-C2β$^{-/-}$ mice also have mild hyperglycaemia and show glomerular abnormalities, supporting its role in insulin signalling.

PUB685

Extraglomerular C3 Deposition and Metabolic Impacts in Patients with IgA Nephropathy
Isao Ohsawa,[1] Gaku Kusaba,[1] Hiroyuki Inoshita,[1] Seiji Nagamachi,[1] Hiyori Suzuki,[1] Hiroyuki Ohi,[2] Yasuhiko Tomino.[1] *[1]Division of Nephrology, Department of Internal Medicine, Juntendo University Faculty of Medicine, Bunkyo-ku, Tokyo, Japan; [2]Department of Medicine, Tsurumi-Nisiguchi Hospital, Tsurumi-ku, Yokohama City, Kanagawa, Japan.*

Background: Although extraglomerular (Bowman's capsule and/or arteriole) deposition of C3 is encountered in the results of routine histological studies in IgA nephropathy (IgAN), these findings have received little attention. The objective of the present study then was to explore the clinical significance of extraglomerular C3 (ex-C3) deposits in IgAN patients.

Methods: 170 patients with IgAN were divided into two groups: Group A (n = 79), patients who did not have ex-C3 deposits and Group B (n = 91), patients who had ex-C3 deposits. Anthropometric, histological and laboratory data were evaluated in a cross-sectional as well as in a prospective manner.

Results: At the time of renal biopsy, Group B was characterized by a significant increase in diastolic blood pressure, as well as total cholesterol, triglyceride and lower density lipoprotein-cholesterol levels. After 4 years, the estimated glomerular filtration rate (eGFR) in Group B was significantly decreased compared with that in Group A. In electron microscopy, arteriolar dense deposits in Group B were significantly higher than those in Group A. 134 patients underwent a 3 years follow-up study after the intervention and were re-divided into the following 2 therapeutic factors: "conventional therapy", i.e.

treatment with anti-hypertensive drugs and/or anti-platelet drugs, and "aggressive therapy", i.e. additional treatment with either tonsillectomy and/or corticosteroid. Patients treated with conventional therapy in Group B showed significantly higher levels of body mass index, C3 and CH50 compared with other groups. Aggressive therapy was significantly effective in urinary protein reduction in both groups A and B. Except for the patients who received aggressive therapy in Group A, the levels of eGFR gradually declined.

Conclusions: It is necessary to pay particular attention to IgAN patients who have ex-C3 deposits and to develop a new therapeutic approach.

PUB686

Long-Term Observation of Prognostic Factors and Outcomes of Japanese Patients with Pauci-Immune Crescentic Glomerulonephritis

Kiyoki Kitagawa, Shinji Kitajima, Tadashi Toyama, Yasunori Iwata, Kengo Furuichi, Takashi Wada. *Division of Nephrology, Kanazawa University Hospital, Kanazawa, Japan.*

Background: Prognostic factor and outcome of patients with pauci-immune crescentic glomerulonephriris (CreGN) are presumed to vary among periods. We examined characteristics and prognostic factors of Japanese patients with CreGN according to the periods.

Methods: From 1968 to 2011, a total of 102 patients diagnosed as CreGN by renal biopsy in Kanazawa University Hospital and collaborative group was examined in this study. The patients were divided into three groups by the treated periods: Group I (1968-1988, 18 cases), group II (1989-2001, 37 cases) and group III (2002-2011, 47 cases). Mean follow-up period was 1625±1387 (mean ± SD) days. To evaluate prognostic factors at the diagnosis of RPGN, we selected age, sex, levels of proteinuria, serum creatinine (Cr), C-reactive protein and MPO-ANCA for clinical features, and degree of crescentic formation, interstitial inflammatory cell infiltration, interstitial fibrosis, vasculitis and atherosclerosis for pathological features. The Hazard ratios (HR) for renal and life outcome were estimated using a Cox regression model.

Results: The serum Cr (<3.0, 3.0-6.0, >6.0 mg/dl) and crescentic formation (<30, 30-50, 50-80, >80%) were a significant renal prognostic factor in group III (Serum Cr : HR 5.37, CI 1.84 – 15.6, $p < 0.01$. Crescentic formation : HR 2.86, CI 1.06 – 7.73, $p = 0.04$). Furthermore, renal survival rate of patients with less than 50% of crescentic formation and patient survival rate of patients with less than 3.0mg/dl of serum Cr improved in group III. On the other hand, neither renal nor patient survival rate of cases with more than 3.0mg/dl of serum Cr and 50% of crescentic formation improved in group III.

Conclusions: In conclusion, outcomes of the patients diagnosed with less than 3.0mg/dl of serum Cr associated with less than 50% of crescentic formationwas improved in recent years. However, prognosis of the cases diagnosed with serum Cr ≥ 3 mg/dL and rate of crescentic formation ≥ 50% was not improved.

PUB687

Immunoenzymatic and Biochip Array Profiling of the Biomarkers of Inflammation and Hemostatic Activation Processes

Vinod K. Bansal,[2] Jjais Richards,[1] Joesphine Cunanan,[1] Jawed Fareed.[1] *[1]Pathology, Loyola University Medical Center; [2]Nephrology, Loyola University Medical Center.*

Background: Considerably higher cardiovascular events occur in ESRD patients on hemodialysis. The objective of this study was to utilize newly introduced cardiac biomarker chips and immunoenzymatic methods, profiling various biomarkers of inflammation and thrombogenesis.

Methods: Seventy-two patients on maintenance hemodialysis were recruited for this study. The normal group comprised of 25 to 50 healthy male and female adults. Blood samples from the ESRD patients were drawn prior to maintenance hemodialysis. ELISA methods were used for Tissue Plasminogen Activator – Plasminogen Activator Inhibitor Type-1 complex (tPA-PAI-1 complex), Plasminogen Activator Inhibitor Type-1 (PAI-1), Myeloperoxidase, (MPO), Thrombomodulin, (TM), Interleukin-1 beta (IL-1β), Anti-Annexin V, human sL-selectin, and Inter-Cellular Adhesion Molecule 1 (ICAM-1). Functional methods were used for measuring Antithrombin and Von Willebrand factor (vWF) activity. The biochip arrays (Randox, Evidence System, United Kingdom)for cardiac markers, included creatine kinase-MB (CK-MB), Myoglobin (Myo), Heart-type fatty acid binding protein (hFABP) and cardiac troponin I (cTn1). The cerebral array included C-reactive protein (CRP), D-Dimer (DDMER), Neuron Specific Enolase (NSE), Neutrophil Gelatinase-Associated Lipocalin (NGAL), soluble Tumor Necrosis Factor Receptor 1 (TNFRI) and Thrombodulin (TM).

Results: ESRD patients showed assay dependent decrease in markers such as tPA-PAI-1, Anti-Annexin V, L-selectin and Antithrombin activity (ranging from 18 to 46%). The levels for MPO, TM, CK-MB, MYO, FABP, CRP, DDMER, NSE, NGAL, TNFR1, and vWF activity all showed elevation in the ESRD patients (ranging from 25%-5587%). No changes were observed in the IL-1B, ICAM1, or cTn1 in ESRD patients.

Conclusions: The cardiac biochip array revealed a remarkable elevation of the FABP and as well as a notable increase in MYO. The cerebral array revealed a remarkable elevation of the TNFR1. Taken together these results indicate that ESRD represents a complex pathophysiologic syndrome resulting in the generation of various prognostic biomarkers.

PUB688

Urinary Dipstick pH Accuracy: Better than You Thought

Jian Li,[1] Clare C. Hassett,[1] Thomas D. DuBose,[2] Jerry Yee.[1] *[1]Division of Nephrology, Henry Ford Hospital, Detroit, MI; [2]Internal Medicine, Wake Forest University School of Medicine, Winston-Salem, NC.*

Background: Urine pH measurement is a basic step to assess distal urinary acidification. The "gold standard" measurement is by pH meter determination in a morning sample collected under oil or in a sealed syringe. Dipstick urine pH measurement is utilized in multiple clinical circumstances such as urinary alkalinization, but its accuracy has been questioned. To determine dipstick pH accuracy, we compared it to the "gold standard."

Methods: pH of 87 urine specimens was determined by Ames Multistix and a pH meter. Dipstick accuracy was defined as the percentage of time the dipstick value was consistent with the metered value of each specimen. The dipstick pH was reported in 0.5 pH unit increments and was considered accurate if within ± 0.5 pH units of the metered value. The dipstick pH was accurate at pH 7.0 if the metered level was 7.00 to 7.50.

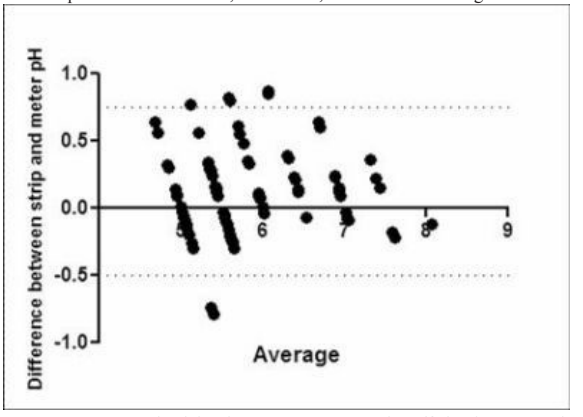
Results:

Patient's demographic

Age	18 – 94 (60.14 ±16.26)
Gender (M/F)	46/41
Urinalysis	69/87 (79.31%)
Proteinuria	
Microscopic Hematuria	59/87 (66.67%)
Blood chemistry panel (* mMol/L)	
Sodium*	127 – 145 (140.56 ± 4.24)
Potassium*	3.1 – 6.2 (4.38 ± 0.42)
Bicarbonate*	17 – 34 (29.09 ± 0.71)
Chloride*	93 – 117 (103.76 ± 7.07)
SCr (mg/dL)	0.5 – 6.28 (2.21 ± 1.81)

1. Dipstick pH accuracy was 88.50% in all specimens; 91.83%, 81.82%, 87.50% in urine pH of 5.0–5.5; 6.0–6.5; 7.0–8.0, respectively.

2. Bland-Altman plot demonstrated significant correlation between dipstick and metered pH values: bias 0.122, SD 0.3190, and 95% limits of agreement -0.503 to 0.747.



Conclusions: Dipstick urine pH measurement is sufficiently accurate in the clinical, diagnostic setting. It may be applicable to evaluate type I RTA, obviating cumbersome metered pH measurement; or function as a monitoring tool for specific therapies. Urine dipstick pH accuracy must be confirmed at each laboratory before utilization in this manner.

PUB689

Baseline Cohort Description of the Randomized Intervention in Children with Vesicoureteral Reflux (RIVUR) Trial

Tej K. Mattoo,[1] Myra A. Carpenter,[2] Ranjiv I. Mathews,[3] Ziya Kirkali,[4] Ron Keren,[5] Alejandro Hoberman,[6] Russell W. Chesney,[7] Marva M. Moxey-Mims.[4] *[1]Department of Pediatrics, Children's Hospital of Michigan, Detroit, Mi; [2]University of North Carolina at Chapel Hill, NC.*

Background: Vesicoureteral reflux (VUR) is a common congenital urological abnormality in children, which is believed to predispose to UTI and renal scarring.

Methods: RIVUR is a double-blind placebo-controlled trial of TMP/SMZ prophylaxis in children < 6 years old with grade I-IV vesicoureteral reflux (VUR) diagnosed following a 1st or 2nd UTI. The study involved central reading of renal imaging by expert radiologists, two each for VCUGs and dimercaptosuccinic acid (DMSA) renal scans. Patient enrollment started in June 2007 and was completed in May 2011. A total of 607 children were randomized at 19 participating sites. Primary referral sources for patient enrollment were urology, radiology, primary care practices, emergency departments, laboratories and inpatient.

Results: 49% of the randomized patients are aged 2-11 months (300), 92% (558) are females, 81% (482) are white and 5% (27) black; 87% (527) participants have non-Hispanic and 13% (77) have Hispanic ethnicity. Male participants (49) were younger (median age 5 mo) than female participants (median age 12 mo), p<0.0001. The distribution of VUR grades in randomized children is 61 (10%) grade I, 254 (42%) grade II, 230 (38%) grade III, 49 (8%) grade IV, and 5 (< 1%) missing grade, and did not differ by sex. Seven participants have grade 0 VUR and one has grade V VUR; these children were included

in the study because eligibility was based on local readings that were interpreted as grade I-IV. Baseline DMSA was done in 582 (96%) patients, and showed a variable degree of renal scarring in 21 (4%) of assessments.

Conclusions: Majority of the patients included in the study are caucasian females with grade II and III VUR and the number of patietns with renal scarring on baseline DMSA is lower than anticipated.

PUB690

Plasma CystatinC and Monocyte Chemotactic Protein-1 in ADPKD Progression Grazia Maria Virzi,[1,2] Fiorella Gastaldon,[1] Valentina Corradi,[1,2] Dinna N. Cruz,[1,2] Massimo de Cal,[1,2] Maurizio Clementi,[3] Claudio Ronco.[1,2] *[1]Nephrology Dep., St Bortolo Hospital, Vicenza, Italy; [2]International Renal Research Institute Vicenza, IRRIV, Italy; [3]Clinical Genetics, Univ. of Padua, Italy.*

Background: Autosomal polycystic kidney disease (ADPKD) is a hereditary cause of end-stage renal disease in the world. It is a genetically heterogeneous condition with a variable rate of progression and it is typically characterized by renal cystic changes paralleled by interstitial inflammation and gradual fibrotic changes. The aim of the study was to evaluate whether CystatinC (CystC) and Monocyte Chemotactic Protein-1 (MCP-1) could predict the progression of the kidney failure in ADPKD patients in stage II-III CKD, as defined in NKF-K/DOQI CKD Guidelines.

Methods: Patients with ADPKD, based on ultrasound criteria and genetic diagnosis, were enrolled and followed prospectively. Creatinine (sCr), CystC and MCP-1 levels were measured at baseline and followed up in plasma. eGFR was calculated with 4-variable standardized-MDRD formula. CystC and MCP-1 were measured by ELISA tests. Survival data were analyzed by the Kaplan-Meier curve using the median values as a cut-off value (CystC: 0,842 mg/L; MCP-1: 203,73 pg/ml).

Results: We enrolled 24 ADPKD pts (18M/6F; mean age 41±9 yrs); mean sCr was 1,3±0,7mg/dl and median eGFR was 62 mL/min/1.73m^2(range:36-75.5). After a median follow-up of 19months (range:12-27.5), 4 patients (17%) progressed to a worse stage of CKD and 83% were stable. No statistically significant relationship between higher levels of CysC and MCP-1 and ADPKD progression was observed by Kaplan-Meier survival curves. Although, CysC and MCP-1 levels were inversely correlated with eGFR (CysC r= -0,706; MCP-1 r= -0,472, both for p<.005). eGFR was higher in subjects with these values below medians.

Conclusions: We did not observe a relationship between CystC/MCP-1 and progression of CKD in ADPKD patients in stage II-III CKD. The present study has some limitations: it was a single-center study and the cohort of patients was very small. It is necessary to increase the sample size of ADPKD subjects enrolled to validate our hypothesis and to examine the relationship between proinflammatory cytokines and ADPKD.

PUB691

Effect of Paricalcitol on Renin and Albuminuria in Non-Diabetic Stage III-IV Chronic Kidney Disease: A Randomized Placebo-Controlled Trial Thomas Larsen, Frank H. Mose, Jesper N. Bech, Erling B. Pedersen. *Department of Medical Research, Holstebro Hospital, Holstebro, Denmark.*

Background: Vitamin D receptor activators reduce albuminuria and may improve survival in chronic kidney disease (CKD). Animal studies suggest that the reno-protection associated with vitamin D treatment is mediated by suppression of renin. However, randomized trials in humans remain to establish this relationship.

Methods: In a randomized, placebo-controlled, double-blinded crossover study, the effect of oral paricalcitol (2μg/day) was investigated in 26 patients with non-diabetic, albuminuric stage III-IV CKD. At the end of each six-week treatment period we determined plasma concentrations of renin (PRC), angiotensin II, aldosterone, brain natriuretic peptide, vasopressin and FGF23. BP was assessed by 24-h ambulatory BP monitoring, GFR by ^{51}Cr-EDTA clearance and assessment of renal NO dependency was performed by infusion of NG-monomethyl-L-arginine (L-NMMA). Albumin excretion was analyzed in both in 24-h urine and during the clearance experiment.

Results: Paricalcitol did not alter PRC, other hormones measured, 24-h BP or sodium and potassium excretion. FGF23 increased by 46% (p=0.001) without any major changes in plasma levels of calcium and phosphate. Paricalcitol reduced albumin excretion rate by 19% (p=0.003) and the albuminuric response to L-NMMA seemed abrogated by paricalcitol.

Conclusions: The assumption that paricalcitol reduces albuminuria by suppressing renin release was not confirmed in this study. The abrogation of the rise in albumin excretion during NOS blockade by paricalcitol may indicate that a novel pathway involving a favourable modulation of renal NO dependency could be involved in mediating reno-protection and survival benefits in CKD.

Normotensive and Hypertensive Scleroderma Renal Crisis Cases Compared by Renal Biopsy Yasunori Suzuki,[1] Fae Kim,[1] Ichiro Mizushima,[1] Hiroshi Fujii,[1] Masami Matsumura,[2] Mitsuhiro Kawano,[1] Kazunori Yamada.[1] *[1]Division of Rheumatology, Department of Internal Medicine, Kanazawa University Graduate School of Medicine, Kanazawa, Japan; [2]Research Center of Medical Education, Kanazawa University Graduate School of Medicine, Japan.*

Background: Scleroderma renal crisis (SRC) is characterized by acute kidney injury, malignant hypertension and hyperreninemia. About 10% of SRC patients are normotensive, but its pathogenesis has not been well documented. The purpose of this study is to assess clinicopathological differences between hypertensive and normotensive SRC by renal biopsy.

Methods: We evaluated 4 patients with SRC, excluding ANCA positive cases, between 2007 and 2011. Three female and one male, mean age 60 years. All cases had diffuse cutaneous type and two were normotensive. Mean duration from onset of systemic sclerosis to SRC was 24 months. Three cases had taken steroid at the diagnosis of SRC. Anti RNA polymerase I/III was positive in 3 cases. All patients were treated with ACE inhibitors, 2 normotensive cases with plasma exchange, 2 with temporary dialysis and 1 with permanent dialysis. Renal biopsy was performed in all patients when the platelet count became normal.

Results: One of two normotensive patient had heart failure and might not be able to raise blood pressure. Another normotensive patient showed severe hemolytic anemia, thrombocytopenia and relatively low plasma renin activity (4.0 ng/ml/hr vs 11.8, 15.0 and 70.8). Renal biopsy of this patient showed mesangiolysis, subendothelial expansion and thrombi in glomeruli which were compatible with thrombotic microangiopathy (TMA). Glomerular lesions other than collapse of capillary tufts were shown only in this case. In this case, smaller arteries were affected than in the other 3 cases (mean size of arteries: 28.9 μm vs 67.5, 51.6 and 89.5).

Conclusions: In normotensive SRC, endothelial cell injury in relatively small artery may cause TMA.

PUB693

Immunohistochemical Evaluation of Collapsing Glomerulopathy in Non-HIV Patients: Series of Cases Andrea C.E.P. Valenca, Maria Carolina N.R. Neves, Luis H.B.C. Sette, Maria Alina G.M. Cavalcante, Gisele Vajgel Fernandes, Lucila Maria Valente. *Nefrologia, Hospital das Clinicas-UFPE, Recife, Pernambuco, Brazil.*

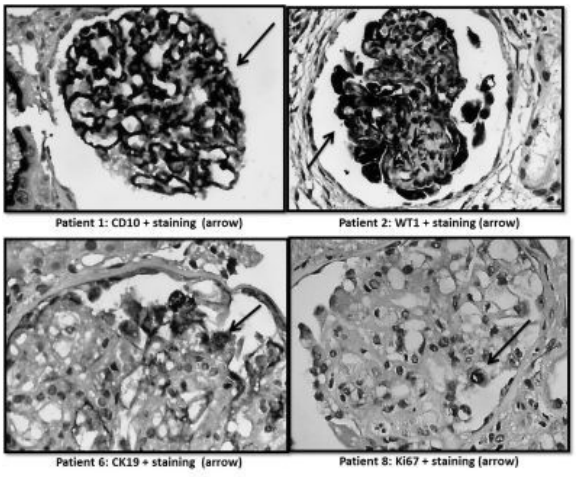
Background: Collapsing Glomerulopathy (CG) is characterized by severe podocyte injury and glomerular epithelial cell proliferation. It is clinically marked by proteinuria and renal insufficiency. First described as associated with HIV infection, it is now related with various etiologic factors. Collapsing variant of FSGS presents molecular changes that differs from others and can be demonstrated by immunohistochemistry (IHC).

Methods: We reviewed files of 11 patients wtih CG, according to Columbia classification, from 2005-2012. Renal biopsy specimens were submitted to IHC reactions with the following antibodies: CD10, WT-1, Ki67 and CK19.

Results: Patients characteristics were: mean age, 38.7 yrs; female, 54.5%; non-white, 54.5%. Nephrotic syndrome (NS) was the clinical presentation in 54.5% of the patients followed by rapidly progressive glomerulonephritis (RPGN) with 45.5%. None cause were associated in 72.7%, classified as idiopathic. Associated factors were pamidronate, tacrolimus (FK) and lymphangioleiomyomatosis (LAM). Laboratory revealed: mean proteinuria, 12.4g/day; albumin, 1.75g/dL; sCr, 3.18mg/dL. IHC did not show the lost of the expression of podocyte differentiation's markers (WT-1, CD10). Staining for CK19 was positive only in FK, LAM and pamidronate associated CG. Ki67 was positive in 2 other patients. Both are podocyte dedifferentiation's markers.

Epidemiological, Clinical and IHC Characteristics

Patient	Age	Gender	Clinical Presentation	WT-1	CD10	CK19	Ki67
1	49	M	RPGN	+	+	-	-
2	19	M	NS	+	+	-	-
3	69	F	RPGN	+	+	-	-
4	60	F	NS	+	+	+	-
5	27	F	NS	+	+	+	-
6	55	F	RPGN	+	+	+	-
7	14	M	NS	+	+	-	-
8	21	M	RPGN	+	+	-	+
9	33	F	NS	+	+	-	+
10	34	M	RPGN	+	+	-	-
11	45	F	NS	+	+	-	-



Conclusions: We described a serie of cases of 11 patients with non-HIV CG and its IHC analysis.

Morphological Characteristics of Kidney Involvement in Plasma Cell Dyscrasias and Lymphoproliferative Disorders: One Center Experience
Elena Zakharova,[1] Ekaterina Stolyarevich.[2] *[1]Nephrology, Clinical Hospital n.a. Botkin, Moscow, Russian Federation; [2]Patology, Nephrology Center, Moscow, Russian Federation.*

Background: Kidney damage in plasma cell dyscrasias and lymphoproliferative disorders (PCD/LPD) include specific infiltration, organized and non-organized paraprotein deposition, paraneoplastic glomerulonephritis, treatment complications and others. We aimed to evaluate incidence of different kidney lesions in patients, admitted to nephrology unit and diagnosed with (PCD/LPD).

Methods: Using electronic database for 1994-1012 we searched 204 patients with "primary" amyloidosis, multiple myeloma (MM), Waldenström's macroglobulinemia (WM), non-Hodgkin lymphoma/leukemia (NHL/CLL), Hodgkin's lymphoma (HL) and monoclonal gammapathy of undetermined significance (MGUS). Work-up included serum and urine immunochemistry, kidney biopsy with light microscopy and immunofluorescent study, and occasionally electron microscopy, bone marrow aspiration and/or biopsy with immunohistochemistry and lymph node biopsy. Patients with non-verified morphologicaly kidney damage were excluded from analysis.

Results: 89 patients, 50 (56.2%) male/39 (43.8%) female, median age 56 [17; 78] had biopsy-proven kidney damage. Pathology and clinical correlations shown in table.

Paraprotein deposition and non-paraproteinemic lesions

Organized paraprotein deposits (N 66)				Non-organized paraprotein deposits (N 5)			
AL-amyloidosis	**AH-amyloidosis**	**Cryoglobulinemic GN**	**Cast-nephropathy**	**Light Chain Deposition Disease**	**IgM deposition GN**	**Monoclonal proliferative IgG/IgA GN**	
46							Primary amyloidosis
15			1	1			MM
1		1			2		WM
1							Castleman disease
	1						Franklin disease
						1	NHL/CLL
						1	MGUS
63 (70.7%)	**1**	**1**	**1**	**1**	**2**	**2**	**Total**
Non-paraproteinemic damage (N 11)				**Complications of treatment (N7)**			
Lymphoid infiltration	**Membranous nephropathy**	**Minimal changes**	**Focal segmental glomerulosclerosis**	**Tubulointerstitial nephritis**		**AA-amyloidosis**	
4	1			3		1	NHL/CLL
		2	1			2	HL
			1				WM
	1		1	1			MGUS
4 (4.5%)	**2**	**2**	**3**	**4 (4.5%)**		**3**	**Total**

Conclusions: In our cohort dominated AL-amyloidosis, constituting 71% of all biopsy-proven cases with more than 2/3 of "primary" amyloidosis. Specific lymphoid infiltration and drug-induced tubulo-interstitial nephritis were rare, about 4.5% each, other variants - miscellaneous.

PUB695

Detection of Urinary Trefoil Factor Family Peptides in Association with Renal Dysfunction and Proteinuria in Patients with Chronic Kidney Disease
Hiroshi Morinaga,[1] Hitoshi Sugiyama,[1] Masashi Kitagawa,[1] Ayu Ogawa,[1] Toshio Yamanari,[1] Keiichi Takiue,[1] Yoko Kikumoto,[1] Tatsuyuki Inoue,[1] Shinji Kitamura,[1] Yohei Maeshima,[1] Yasukazu Ohmoto,[2] Daisuke Ogawa,[1] Kenichi Shikata,[3] Hirofumi Makino.[1] *[1]Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Japan; [2]Otsuka Pharmaceutical Co., Ltd., Japan; [3]Center for Innovative Clinical Medicine, Okayama University Hospital, Japan.*

Background: The Trefoil factor family (TFF) peptides 1, 2 and 3 are small peptide hormones secreted by mucus-producing cells, and by epithelial cells from multiple tissues. TFF3 plays essential functions in both mucosal surface maintenance and restitution in the intestines, colon and kidney. A decrease in the urinary levels of TFF3 is associated with acute kidney injury in animal models. However, whether or not the urinary levels are associated with proteinuria and renal dysfunction in patients with chronic kidney disease (CKD) remains to be elucidated.

Methods: This study determined urinary TFF levels by peptide-specific ELISAs and investigated their association with clinical parameters in 219 CKD patients (mean age 53.6 years, female 47.9%, chronic glomerulonephritis 46.6%, nephrosclerosis 10.5%, mean eGFR 57.5 ml/min/1.73m^2).

Results: All TFF peptides were detectable in the urine of CKD patients (Concentration, TFF2 > TFF3 > TFF1). Significant correlations were identified between the urinary levels of TFF1 and TFF2 ($p < 0.0001$) or TFF3 ($p < 0.0001$), but not between urinary TFF2 and TFF3. The urinary TFF1 and TFF3 levels inversely correlated with eGFR, but TFF3 alone positively correlated with the excretion of urinary protein ($p = 0.0051$). The levels of urinary TFF2 decreased along with the degree of renal dysfunction and also inversely correlated with daily proteinuria ($p = 0.0165$).

Conclusions: These data suggested that the urinary excretion of TFF peptides are differentially regulated in CKD patients. TFF3 may be associated with renal dysfunction and proteinuria. Further examination is therefore required to elucidate the role of urinary TFF in CKD patients.

PUB696

Altered Vitamin D Receptor Expression in the Renal Tissues with IgA Nephropathy
Huiling Wang. *Division of Nephrology, Jimin Hospital, Shanghai, China.*

Background: Local inflammation is thought to contribute to the progression of IgA nephropathy (IgAN). Recently, vitamin D receptor (VDR) activated has reported ameliorate proteinuria and kidney injury with inhibited expression of proinflammatory cytokines, reduced renal infiltration of monocytes/macrophages, and suppressed expression of the fibrogenic factor. But these effects still need confirm in patients renal biopsy. The aim of study was to investigate the change of VDR in renal tissues of patients withIgAN, cooperative expression of Transforming growth factor-β(TGF-β1),Monocyte chemoattractant factor (MCP-1), endo-Nitric oxide synthase (eNOS) and Angiotensin II (AngII) and its association with changes of renal injury.

Methods: Fifty patients diagnosed as having IgAN by renal biopsy were enrolled as IgAN group(IgAN), and 5 normal renal biopsy specimens were used as controls(CTL). Expression of VDR,TGF-β1,MCP-1,eNOS and AngII in renal tissues was observed by immunohistostaining. The relationships between these factors and degree of renal pathological lesions in IgAN were assessed by Spearman correlation.

Results: Immunohistostaining analysis showed that VDR protein was present in epithelial cells of renal tubules, mesangial cell, andin normal and IgAN renal tissues. With more severe renal pathological lesions, the expression of VDR in IgAN was decreased(21.5±6.63 IgAN vs 36.8±18.71CTL, $p<0.05$);and the inflammatory cytokines increased respectively, TGF-β1(35.7±19.57 IgAN vs 18.3±10.34 CTL, $p<0.05$), MCP-1(19.7±13.08 IgAN vs 10.1±5.25 CTL, $p<0.05$), eNOS(17.2±8.78 IgAN vs 8.8±10.95 CTL, $p<0.05$);AngII(8.5±3.62 IgAN vs 4.4±3.73 CTL, $p<0.05$). The expression of VDR was negatively correlated with the degree of pathological lesions, including of mesenchymal cell proliferation, tubular atrophy, interstitial fibrosis, and inflammatory cell filtration. A single factor analysis showed that VDR was negatively correlated to the expression of TGF-β, MCP-1, and AngII, but no relationship with eNOS.

Conclusions: The expression of VDR showed down-regulation in renal tissue of patients with IgA nephropathy, and negatively correlated with the severity of pathological lesions and inflammatory factors.

PUB698

Minimal Change Disease with IgA Deposition Might Not Be a Phenotype of IgA Nephropathy
Yu Yan, Wei Chen, Bao Dong, Mei Wang. *Renal Division, Peking University People's Hospital, Beijing, China.*

Background: Some IgAN patients with nephrotic syndrome (NS), who mostly have no hematuria, no hypertension and normal renal function were named MCD with IgA deposition (MCD-IgA). Whether it is a special phenotype of IgAN or MCD was in debate. The current study was to investigate the relationship among MCD-IgA, MCD and typical IgAN through clinical and pathological analysis.

Methods: Patients diagnosed as IgAN presenting NS without hematuria, hypertension and renal dysfunction were enrolled in the study. Those with NS and hematuria but without

hypertension and renal dysfunction (NS-IgAN) and those with nephrotic proteinuria without hypoalbuminemia (HP-IgAN) were used as controls. Clinical features were collected. Pathological slides were studied using two scoring systems (Katafuchi's IgAN scoring and OXFORD-MEST). Numbers of glomerular inherent cells were counted using image acquisition. Percentages of each cell were calculated.

Results: Clinically, comparing with HP-IgAN and NS-IgAN, patients with MCD-IgA and MCD had lower SBP, albumin, serum IgG, less urine RBC, TCHO and LDL-C ($P<0.05$). No significant differences were found between MCD-IgA and MCD. No significant differences were seen comparing with HP-IgAN. There were only less urine RBC and lower UP in NS-IgAN group than in HP-IgAN ($P<0.05$). In pathological analysis, MCD-IgA had lower scores in every item and total score except vascular hyaline score according to Katafuchi's IgAN scoring system. The same profile was obtained using OXFORT-MEST scoring system ($P<0.01$). 38 patients who had at least one glomerulus with both urinary pole and vascular pole in the slides were used for cells counting. Similar with MCD, MCD-IgA had more podocytes but less mesangial cells than HP-IgAN and NS-IgAN. All inherent cells percentages were similar between HP-IgAN and NS-IgAN ($P<0.05$).

Conclusions: MCD-IgA may be MCD with non-specific deposition rather than a phenotype of IgAN. More podocytes with less mesangial proliferation might help to differentiate MCD-IgA from typical IgAN.

PUB699

Proximal Tubule Expression of Klotho in Healthy Kidney Transplant Donors Eileen W. Tsai,[1] Sharon E. Joo,[1] R.C. Pereira,[1] Miguel Fernando Palma Diaz,[2] Robert B. Ettenger,[1] Isidro B. Salusky,[1] Katherine Wesseling-Perry.[1] *[1]Pediatrics, Division of Nephrology, Mattel Children's Hospital UCLA, Los Angeles, CA; [2]Pathology and Laboratory Medicine, UCLA, Los Angeles, CA.*

Background: FGF23 requires the presence of Klotho to induce renal phosphate wasting; however, membrane-bound Klotho has not previously been identified in human proximal tubular cells.

Methods: Immunohistochemical staining using a monoclonal anti-goat antibody against human Klotho (Immuotopics) was performed in wedge biopsies from 16 healthy adult kidney transplant donors. Protein expression was classified as present or absent by two blinded observers and demographic data were compared between groups.

Results: Klotho expression was detected exclusively in proximal tubular cells in 10 biopsy specimens (63%). Specimens with Klotho staining were derived exclusively from deceased donors who, as a group, were younger than their living donor counterparts. Additionally, living donor kidneys were preserved with heparinized solution.

Donor Kidney Characteristics	Klotho positive (n=10)	Klotho negative (n=6)
Age (years)	22 ±3.9*	38 ±8.9*
White	3 (30%)	4 (66.7%)
Male	5 (50%)	3 (50%)
Deceased Donor	6 (100%)	0 (0%)*
Heparinized Preservation Solution	0 (0%)	6 (100%)*
Cold Ischemia Time (hours)	15.8 ±5	1.3 ±0.7*

*p<0.05 between groups

Conclusions: Klotho protein expression localizes to the proximal renal tubule in kidneys from deceased donors. The absence of Klotho in living donor kidneys may be secondary to the use of heparinized solution and/or increased donor age.

Validation of Point of Care Module (Nitto Denko Portable Urinalysis Device) for Detection of Urinary Microalbuminuria Vijay K. Kher,[1] Manish Jain,[1] Puneet Sodhi.[1] *[1]Medanta-The Medicity, Gurgaon, India; [2]Nitto Denko Asia Technical Centre, Singapore.*

Background: Microalbuminuria (MAU) is an early marker for detection of renal and cardiovascular disease.Current urine analysis for MAU is restricted to laboratories. Measuring MAU at the point of care helps to screen large population in countries like India.

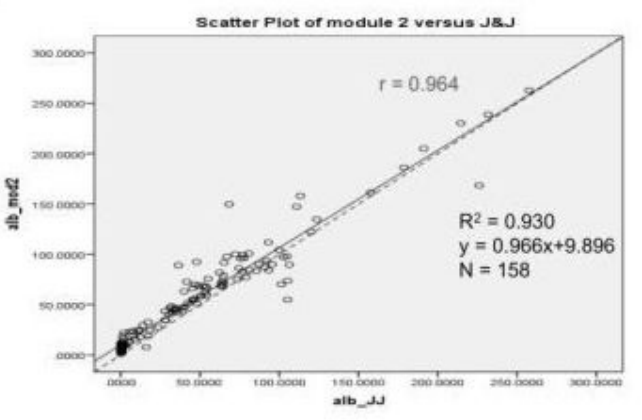
Nitto Denko Asia Technical Center,Singapore has devised a portable hand held device (150mm x 75mm x 25mm) by which urine ACR could be rapidly detected bed side.

The preliminary study was to test the efficacy of the device with urine of patients as well as normal subjects and comparing it with the standard laboratory test (Johnson and Johnson Vitros 5.1-Turbidometric immunoassay) at Medanta.

Methods: A total of 164 urine samples were collected and analysed for albumin and creatinine by Nitto Denko Device in comparison with standard test performed in Medanta Laboratary.

Results: The concentration correlation for urine albumin between both the methods is 0.964.

Figure 1 shows the scatter plot of urine albumin obtained by Nitto Device(Module 2) vs Medanta Laboratory (J&J).R2 value of0.930 suggests 93% of variability of data could be explained by linear regression.



The concentration correlation for urine creatinine is 0.981.The R2 is 0.962 suggesting 96.2% of variability of data could be explained by linear regression.

Conclusions: The Nitto Urinalysis Device was found to be comparable with the standard laboratory method in terms of the determination of urine albumin and creatinine concentrations.

This is a preliminary study to validate the Point of Care module to measure Microalbuminuria.We plan to confirm the results across a larger set of samples across multiple centres.

The authors acknowledges the members from Nitto Denko Asia Technical Centre (Visit Thaveeprungsriporn, Yingsong Wang, Hui Yee Sin, Juliana Chua) and Drs.A.Raizada,Deepti Gupta & K.Vinayak for their contributions.

PUB701

Analysis of Relative Expression Level of VEGF, HIF-1alpha, and CTGF Genes in Renal Tissue from Renal Biopsies of Chronic Glomerulonephritis Patients Rafal Donderski,[1] Ilona Miskowiec-wisniewska,[1,2] Jacek Manitius,[1] Andrzej Marszalek,[3] Andrzej Tretyn.[4] *[1]Dept. of Nephrology, Hypertension and Internal Diseases, CM UMK; [2]Dept. of Hygiene and Epidemiology, CM UMK; [3]Dept. of Clinical Pathology, CM UMK; [4]Dept. of Biotechnology, Nicolaus Copernicus University, Torun, Poland.*

Background: Gene expression analysis of renal tissue is a valuable diagnostic tool in renal diseases. We wanted to evaluate a relative gene expression level of VEGF, CTGF and HIF-1α and to evaluate relationship with eGFR and daily proteinuria (DP) in chronic glomerulonephritis (CGN) patients (pts).

Methods: 28 pts with CGN. Type of CGN confirmed by kidney biopsy: MCD-3pts, IgA nephropathy-5pts, FSGS-3pts, MN-4pts, MPGN-4pts, lupus nephritis-6pts, Wegener's Granulomatosis-2 pts; hypertensive nephropathy-3pts. Control-renal tissue from 3 pts with normal eGFR and histology. eGFR and DP were assessed at the time of biopsy and at 6months intervals. RT-PCR was used to determine relative gene expression. The *GAPDH* gene served as normalization control.

Results: At the time of the biopsy relative expression of 3 genes were diminished in comparison to control.

Table 1. Results of relative gene expression level

GENE	TYPE	Reaction efficiency	Expression	Std.Error	95% C.I.	P(H1)
VEGF	TRG	1,06	0,300	0,163-0,485	0,107-1,445	0,003
GAPDH	REF	0,99	1,000			
CTGF	TRG	1,06	0,571	0,271-1,474	0,133-2,005	0,211
GAPGH	REF	0,99	1,000			
HIF1alfa	TGR	0,95	0,614	0,106-1,559	0,048-22,535	0,542
GAPDH	REF	0,99	1,000			

Legend: P(H1)- Probability of alternate hypothesis that difference between sample and control is due only to chance, TRG - Target, REF – Reference.

Pts with GFR≤60ml/min (at the onset of study) showed significantly lower VEGF relative expression in compare to pts with GFR≥60ml/min ($p<0,022$), we found higher VEGF expression in pts with DPE≥3,5g in compare to subjects with DPE≤3,5g ($p<0,034$) at the onset of study. There were no statistically significant relationship between VEGF, CTGF and HIF-1α relative gene expression and ΔeGFR and ΔDP.

Conclusions: Overexpression of VEGF gene in pts with DP≥3,5g may indicate oxygen supply deficiency in renal tissue which may result in tubulointerstitial fibrosis with further renal function impairment and eGFR decline.

PUB702

Sarcoidosis: Atypical Renal Presentation Fernando Caeiro Pereira, Fernanda Carvalho, Dulce Carvalho, Manuel A. Ferreira, Fernando Barbosa Nolasco. *Nephrology, Hospital Curry Cabral, Lisbon, Portugal.*

Background: Sarcoidosis is a systemic disease associated with derangement of the immune system, with upregulation of the TH1 response. Renal involvement is albeit rare (5-10% of cases) and is usually manifested has nephrocalcinosis and nephrolitisis, however some cases of acute kidney injury (AKI) due to acute interstitial nephritis with or without granulomas have been described.

Methods: We retrospectively analyzed all the biopsies performed at our institution between January 1992 and Septembre 2011, and identified five patients with the diagnosis of acute kidney injury due to sacoidosis. We performed imunohistochemistry analysis of these specimens.

Results: Median age at time of presentation was 53,4 years and median creatinine was 5,54mg/dL. All patients were started on prednisolone (40-60mg/day). Two patients required hemodialyis but only one recovered. All other patients had a remarkable recovery of GFR (average 55ml/min) and normalization of calcium levels. Median follow-up is 8,6 months (2 to 16).

Morphological analysis of all biopsies and identification of the cells present by imunohistochemistry reveled interstitial infiltrate has the predominating feature with no glomerular involvement whatsoever. Only one biopsy had granulomas. The infiltrate was characterized by lymphocytes, particularly CD4.

Kidney biopsies morphological analysis

Patient	Glomerulus	Cellular Infiltrate	Tubular atrophy	Interstitial fibrosis	Sarcoid angiitis	Granuloma	Asteroid bodies
1	0	+++	+++	++	0	0	0
2	0	+++	ATN	0	0	0	0
3	0	++	++	+++	0	+	+
4	0	++	+++	+++	+	+	+
5	0	++	++	+	0	0	0

ATN: acute tubular necrosis

Conclusions: Even if sarcoidosis is a rare cause of AKI its timely diagnosis is important since it seems to respond fairly well to treatment, however because diagnostic criteria have not been firmly established a large amount of clinical suspicion associated with all available data are required. Finally, granulomas may not be present in the biopsy specimen, as they are rare and sparse, but fibroedema with a large cellular infiltrate of lymphocytes is highly characteristic.

PUB703

Lectin-Based Flow Cytometry for Glycoprofiling of Urinary Extracellular Vesicles and Tamm-Horsfall Protein Anja Krüger,[1,2] Jared Q. Gerlach,[2] Shirley Hanley,[1] Christopher James Ward,[3] Marie C. Hogan,[3] Lokesh Joshi,[2] Matthew D. Griffin.[1] *[1]Regenerative Medicine Institute, National University of Ireland, Galway, Ireland; [2]Glycosciences Group, National University of Ireland, Galway, Ireland; [3]Dept of Medicine, Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Background: Detection of alterations to urinary extracellular vesicles (uEVs) may be a novel, non-invasive means to diagnose and monitor kidney health. In this study, flow cytometry (FCM)-based analysis of lectin binding was adapted to profile glycosylation of uEVs as well as purified Tamm-Horsfall protein (THP).

Methods: uEVs were isolated by ultracentrifugation (UC) or by centrifugal filter concentration (CON) from multiple healthy volunteers and were labelled with PKH26. For FCM analysis, 5 µg of uEVs or purified THP were attached to 4 µm aldehyde/sulfate beads and were incubated with 6 distinct biotinylated lectins followed by streptavidin-PE-Cy7 or -APC. A FACSCanto cytometer and FlowJo software were used for detection and analysis of lectin binding. uEV proteins and THP were also immunoblotted on PVDF membranes with biotinylated lectins followed by Avidin-AP.

Results: Binding of PKH26-labelled uEVs prepared by UC and CON methods to latex beads was confirmed by FCM. uEV- and THP-coated beads produced distinct patterns of lectin binding. PNA (Galβ(1,3)GalNAc) bound selectively to uEV- but not to THP-coated beads. Other lectins - AAA (α-Fuc), SNA-I (NeuAcα2,6Gal/GalNAc) and MAA (NeuAcα2,3Gal) – also bound consistently to uEVs from multiple donors, albeit with lower intensity, indicating a complex profile of surface glycosylation. In contrast, PHA-E (biantennary N-glycans) and WFA (sulfated GalNAc/GalNAc) bound at high to medium intensity to THP but only weakly or variably to uEVs. Immunoblots of uEV-derived protein lysates with PNA, AAA and SNA-1 demonstrated distinctive band patterns consistent with a broad repertoire of differentially-glycosylated proteins.

Conclusions: uEVs contain differentially-glycosylated surface proteins which are detectable by lectin-based FCM. Lectin-binding profiles of uEVs are distinct from THP and may serve as diagnostic/prognostic markers of renal diseases.

PUB704

Glomerulonephritis Combined with Nutcracker Syndrome in Children with Isolated Proteinuria Jin-soon Suh,[1] Yumi Choi,[2] Byoung-Soo Cho.[2] *[1]Department of Pediatrics, Bucheon St. Mary's Hospital, Catholic University, Bucheon-si, Gyeonggi-do, Korea; [2]Department of Pediatrics, School of Medicine, Kyung Hee University, Seoul.*

Background: Nutcracker syndrome (NS) refers to the compression of the left renal vein between the aorta and the superior mesenteric artery, resulting in renal venous hypertension. It is known that NS is the frequent cause of hematuria and/or low-grade proteinuria and is a benign condition. However, some reports have suggested that NS can be combined with glomerulonephritis (GN) such as IgA nephropathy (IgAN). In this study, we evaluated the characteristics of patients with GN in combination with NS in children.

Methods: This study included 8 children with isolated proteinruria who were diagnosed of NS by renal Doppler sonogram and evaluated for GN by renal biopsy between 2002 and 2012. The indication of renal biopsy were based on the following criteria: persistent and increasing proteinuria (spot urine protein to creatinine ratio more than 1) during follow up period or persistent proteinuria (spot urine P/Cr more than 0.5) after disappearance of NS in follow-up Doppler sonogram.

Results: Subjects included male 4 and female 4, and their age ranged between 9 and 15 years. The mean spot urine protein to creatinine ratio at initial diagnosis of NS and renal biopsy were 0.60 and 1.16, respectively. Mean period between the point of time for diagnosis of NS and the time for renal biopsy was 25 months. The renal biopsy findings were as follows; IgAN 1, focal segmental glomerulosclerosis 1, minor glomerular abnormalities such as focal GBM thinning or focal foot process effacement and/or mild mesangial proliferation 5 and no abnormality 1.

Conclusions: Renal biopsy findings were almost mild as previous studies reported. However, some patients had significant abnormalities such as FSGS and IgAN. Therefore, long term follow-up are needed for proteinuria with NS and renal biopsy is indicated when they show persistent proteinuria and/or newly developed hematuria.

PUB705

Failure of Soluble CD30 Decent at Day 3 to 5 after Renal Transplantation Rather than Its Absolute Level Is a Predictor of Increased Risk of Rejection Ahmed G. Adam,[1] Rasha Shaefi,[1] Nahed Baddour,[2] Wesam Gendy.[3] *[1]Renal, Dialysis & Transplantation Unit, Faculty of Medicine; [2]Pathology Department, Faculty of Medicine; [3]Clinical Pathology Department, Faculty of Medicine, University of Alexandria.*

Background: The impact of sCD30 on renal graft survival in renal transplant patients with the follow up and its serial measurement over a period of one year in comparison to CKD & normal.

Methods: sCD30 by ELISA – for at least 9 times during follow up, urine albumin creatinine ratio, resistive index (RI) & histo pathological study were done.

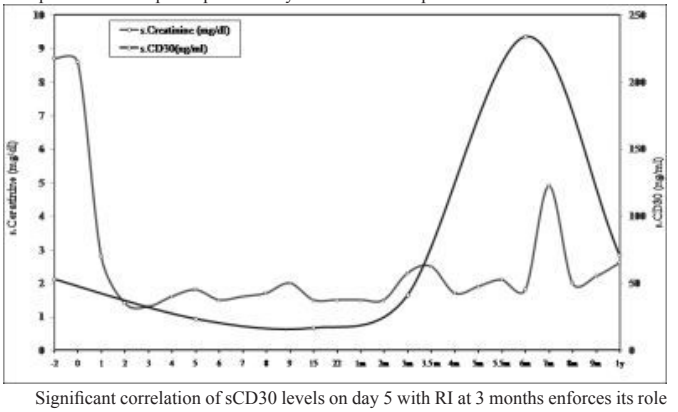
Results: sCD30 level was found normal within normal population increased in CKD patients, return to normal level post transplant at day 5/ day 15/ 1m.

Significant correlation between cyclosporine trough at 3m with sCD30 on the same day adds a benefit for use of sCD30 in adjustment of immunosuppressant dose.

Correlations between urine albumin creatinine ratios at 6m and the degree of HLA mismatch with sCD30 on the same day, at 3m respectively suggesting its role in long term renal graft survival.

As predictive value of sCD30 in renal graft survival a significant correlation was found with ischemia time on day 0 & levels at 3 months contributes to its role in detection of renal graft survival.

Relationship between s.creatinine (mg/dl) & sCD30 (ng/ml) from day -2 up to 1y post transplant as an exmple of predicitivity value of sCD30 prior to s-creatinine.



Significant correlation of sCD30 levels on day 5 with RI at 3 months enforces its role as prognostic marker to aid risk stratification for future transplant dysfunction.

Correlation between soluble CD30 levels on day 5 with RI on 5d and RI at 3m

	Soluble CD30	Soluble CD30
	r (Pearson coefficient)	p
On Day 5	-0.101	0.767
At 3 months	0.719	0.029

Conclusions: Pre transplant levels of sCD30 over 100 U/mL and a failure of soluble CD30 to decrease at day 3 to 5 predicts increased risk of rejection.

PUB706

Corticosteroids Significantly Improve Renal Dysfunction and the Clinical Prognosis in Patients with Tubulointerstitial Nephritis Yoko Kikumoto,[1] Hitoshi Sugiyama,[2] Toshio Yamanari,[1] Ayu Ogawa,[1] Masashi Kitagawa,[1] Keiichi Takiue,[1] Hiroshi Morinaga,[2] Shinji Kitamura,[1] Yohei Maeshima,[1] Hirofumi Makino.[1] *[1]Department of Medicine and Clinical Science, Okayama University; [2]Department of CKD and Peritoneal Dialysis, Okayama University.*

Background: The etiological and clinicopathologic features and prognosis of tubulointerstitial nephritis (TIN) tend to vary greatly. Controversy persists regarding the role of corticosteroids in the treatment of TIN.

Methods: We retrospectively analyzed 16 patients with TIN identified by reviewing the records of 411 renal biopsy specimens received at our hospital during the period from 2007-2011. TIN was classified as acute or chronic based on the clinicopathologic features. The clinical, laboratory and histological parameters at the start of the study were analyzed. The degree of cell infiltration ranged from 0 and 3 (absent, mild, moderate, severe). The endpoint of the study was the recovery of the renal function expressed by a more than 30% increase in the estimated GFR (eGFR), and the effectiveness of corticosteroid/conservative therapy for improving the renal function were evaluated.

Results: The baseline serum creatinine level and the interstitial cell infiltration grade were significantly higher in the patients showing a greater recovery of the renal function as expressed by a >30% increase in eGFR (group 1, n=9) than the remaining patients (group 2, n=7). A ratio of steroid-treated patients was significantly higher in group 1 (p=0.048). Steroid treatment improved the recovery of the renal function, which was shown by an increase in eGFR, at 3 months following the initial diagnosis (p=0.047) and the effect continued during the follow-up period (mean follow-up period was 27.2± 4.9 months, p=0.036). However, no beneficial effect of ACE inhibitor/ARB administration was seen regarding the rate of renal recovery during the follow-up period.

Conclusions: In conclusion, these results suggest that corticosteroid treatment could significantly improve both renal dysfunction and the clinical prognosis of TIN, particularly in cases exhibiting a higher grade of interstitial cell infiltration.

PUB707

Lifting the Veil on Complementary and Alternative Medicine: Prevalence in the Vasculitis Population Elisabeth Berg, JulieAnne G. McGregor, Madelyn Burkart, Caroline Jennette Poulton, Ronald J. Falk, Susan L. Hogan. *Internal Medicine, UNC Kidney Center, Chapel Hill, NC.*

Background: Complementary and alternative medicine (CAM) has been explored in managing various chronic diseases. This study aimed to discern the prevalence of CAM use in a cohort of small vessel vasculitis (SVV) patients. Included patients participate in the Glomerular Disease Collaborative Network (GDCN).

Methods: Structured CAM questionnaires were administered at UNC medical appointments (7/11-4/12). CAM treatments (acupuncture, massage, reflexology, etc.) and self-help practices (meditation, yoga, qigong, etc.) were reported separately.

Results: Of 102 patients surveyed, 85% were Caucasian and 62% were female. Within the last year, 81% received CAM treatments or used self-help practices. Further, 46% received ≥1 CAM treatments while 74% (33% excluding prayer) indicated use of ≥1 self-help practices. The highest reported treatments were exercise promotion (22%), nutritional supplements (20%) and massage (15%). Top self-help practices included prayer (65%), relaxation techniques (20%) and meditation (13%). Among specified treatment and self-help users, perceived CAM helpfulness was ascertained. Exercise promotion was helpful to 64%, nutritional supplements (55%), and massage (87%). Helpful self-help practices included prayer (67%), relaxation techniques (60%) and meditation (69%). Among CAM users, 23% used CAM to manage symptoms, 11% to tolerate treatment side effects or 9% for both. Overall, 67% of patients were comfortable sharing CAM practices with their physician, while only 21% stated their physician has talked about CAM. The primary reason for not using CAM was due to not receiving information (49%).

Conclusions: SVV patients commonly report some form of CAM treatment and/or self-help practices, but discussion surrounding CAM usage with their physician is limited.

Amyloidosis Secondary to Hidradenitis Suppurativa: Exceptional Response to Infliximab Adoración Martin,[1] Francisco Javier Gonzalez,[2] Secundino Cigarran,[3] Eugenia Palacios.[1] *[1]Nephrology, Poniente Hospital, Almeria, Spain; [2]Nephrology, Poniente Hospital, Almeria, Spain; [3]Nephrology, Costa Hospital, Burela, Lugo, Spain; [4]Nephrology, Poniente Hospital, Almeria, Spain.*

Background: Secondary (AA) amyloidosis (SAAA) seldom complicates the course of hidradenitis suppurativa (HS), a chronic skin condition which is notoriously difficult to treat.Both conditions have been reported independently to respond to anti-TNF agents.The course of renal amyloidosis may lead to chronic renal failure.Therefore,management must be focused on ensuring a strict control of the underlying disease to prevent amyloid deposits.

Methods: A 39-year-old male with a 9-year history of relapsing HS.No sustained response could be yielded from medical measures (antiandrogenic agents,antibiotics,isotretinoin), having multiple surgical interventions. He was assessed due multiple scars inaxillae, groins and perineum. There were no oedema.Proteinuria (3.7 g/24 h) and microhematuria were detected.Plasma creatinine was 0.83 mg/dl;albumin 2.9 g/dl;cholesterol 245 mg/dl;triglycerides 156 mg/dl.Abdominal ultrasound showed no abnormalities.kidney biopsy revealed abundant type AA amyloid deposits.Echocardiography yielded no further abnormal findings.Treatment with infliximab infusions (5 mg/kg) at weeks 0,2, 6 and 14 was then started.Significant reduction in HS activity and gradual decrease in proteinuria, without any adverse reactions was seen.From week 10 onwards, proteinuria has been undetectable on follow-up. This favourable response has been sustained throughout the 24 months of follow-up.

Results: SAAA is due to amyloid formed from serum amyloid A, produced in response to inflammation.The use of anti-TNF therapies in the latter may reduce the development of SAAA, as well as stabilise or revert established one, since they seem to interfere with fibril formation.To our knowledge, this is the first report of both entities concurring on the same patient ever being successfully treated with an anti-TNF agent.

Conclusions: We´d like to emphasise the possible role of anti-TNF therapy in the treatment of both SAAA and HS. Prospective, controlled trials are needed to assess the actual role and security profile of these agents in both entities.

PUB709

Higher Incidence of AKI Contributed to Longer Time to Remission in Older Patients with Adult-Onset Minimal Change Nephrotic Syndrome, Compared with Younger Patients Daisuke Mori,[1] Maki Shinzawa,[2] Tomoko Namba,[2] Ikue Nagayama,[1] Yoshito Yamaguchi,[1] Seiji Itano,[1] Natsuko Imakita,[1] Masanobu Takeji,[1] Ryohei Yamamoto,[2] Yoshitaka Isaka,[2] Atsushi Yamauchi.[1] *[1]Division of Nephrology, Osaka Rosai Hospital, Osaka, Japan; [2]Geriatric Medicineand Nephrology, Osaka University Graduate School of Medicine, Osaka, Japan.*

Background: Little information is available about the predictor of the time to remission in patients with adult-onset minimal change nephrotic syndrome (MCNS), including acute kidney injury (AKI). The aim of the present study was to identify these predictors in younger and older patients with adult-onset MCNS.

Methods: The present retrospective cohort study included 40 patients aged at least 18 years who were diagnosed as idiopathic MCNS at Osaka Rosai hospital between 1994 and 2009. All except 1 patient received steroid pulse therapy. The outcomes was time to remission defined as urinary protein <0.3 g/day. Associations of age (younger group (18-50 years) vs. older group (>50 years)) and AKI during follow-up period, defined as 50% increase in serum creatinine level according to the RIFLE, with remission were assessed using Log-rank test.

Results: Baseline characteristics of the 40 patients were as follows; age median 42 (interquartile range 28-63) years, male 70%, serum creatinine 0.9 (0.7-1.0) mg/dL and urinary protein 7.8 (3.9-10.4) g/day. The time to remission is 12 (8-21) days. Compared with younger patients, 3-week cumulative probability of remission of older patients were significantly lower (0.50 vs. 0.91, P = 0.014 in log-rank test). AKI during follow-up was observed in 11 (61%) and 3 (14%) patients in 18 older and 22 younger patients, respectively. Interestingly, 11 older patients with AKI significantly had higher 3-week probability of remission, compared with 22 younger patients (0.27 vs. 0.91, P = 0.003), whereas 7 older patients without AKI did not (0.86 vs. 0.91, P = 0.88).

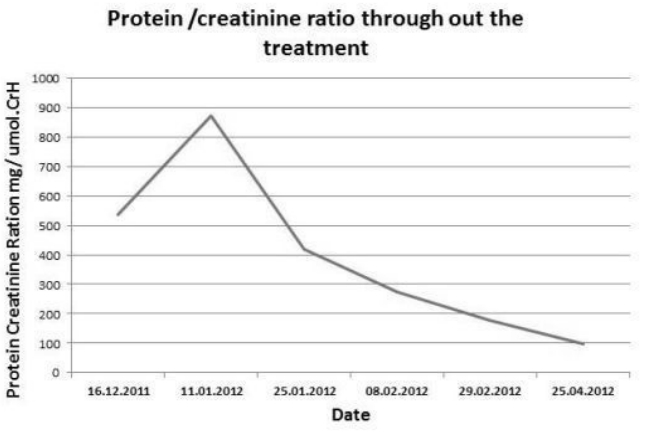
Conclusions: Higher incidence rate of AKI contributed to longer time to remission in older patients with MCNS, compared with younger patients.

PUB710

Successful Use of Angiotensin Converting Enzyme Inhibitor, and Angiotensin Receptor Blocker for Nephrotic Syndrome in Patient with Solitary Kidney Ihab El Madhoun. *Renal Unit, Al Wakra Hospital- HMC, Qatar.*

Background: Hypertension and proteinuria if not treated are associated with long term morbidity and mortality. The management of patients with solitary kidney can be challenging.

Methods: 41 years old female referred because of hypertension for 12 years and proteinuria from late childhood. She also has congenital solitary kidney. Her past history includes preeclampsia required caesarean section twice about 20 and 10 years ago and bronchial asthma. She was maintained on Losartan 50 mg once a day and Amlodipine 5 mg once a day. BP 166/103 mmHg, had pedal oedema and otherwise unremarkable. Serum creatinine 64 umol/l, Urea 4.5 mmol/l, Albumin 31 g/l, total protein 61g/l, potassium 4.4 umol/l and total cholesterol 6.53 mmol/l. Immunology screen was negative. 24 hour urine collection for protein was 5.3 gram. There was 1+ of microscopic haematuria on urine dipstick. Ultrasound scan confirmed normal size solitary right kidney. She declined renal biopsy and was started on Atorvastatin 20mg once daily, ACE-I Lisinopril 2.5 mg/ day and gradually increased to 30mg/ day. The ARB Losartan dose was increased to 100mg/ day with careful and regular monitoring of serum creatinine. The BP came down to 113/75 mmHg. Proteinuria improved to 1.1gram/24 hour urine, Serum Albumin 36 g/l and serum cholesterol lowered to 4.6 mmol/l.

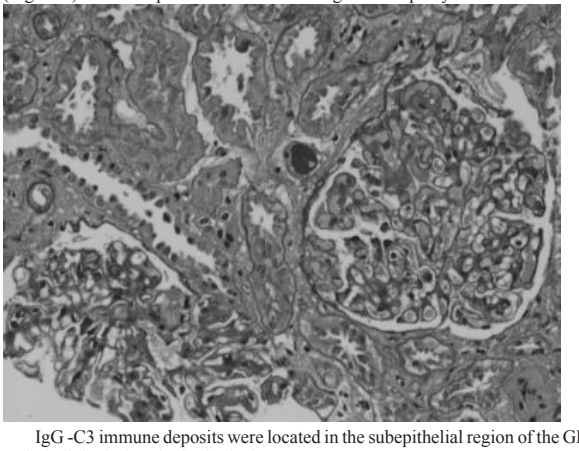


Conclusions: A previously published systematic review and meta-analysis showed that combination use of ACE-I and ARB in treating proteinuric kidney disease is safe and efficacious. In patient with single kidney, the use of high doses of dual blockers could be challenging. This case, shows that carefully introduced and monitored ACE-I and ARB proven to be highly successful in controlling the blood pressure and also massively reducing the proteinuria form nephrotic range down to almost 1 gram/day.

PUB711

Mixed Membranous and Focal Proliferative Crescentic Glomerulopathy in a Patient with Past Hepatitis B Exposure Heino R. Anto, Catalin Mihai Perju, Robenson Jean Marie. *Nephrology, St. John's Episcopal Hospital, Far Rockaway, NY.*

Background: A 64 y/o female presented with nephrotic syndrome (urine protein of 8.3 gms/24 hrs.,serum albumin 1.6 g/L, serum cholesterol 261 mg/dL), BUN 14 mg/dL, and serum creatinine 1.34 mg/dL. ANA, double stranded DNA antibody, and ENA antibodies were all negative. Serum C3, C4, ANCA and anti-GBM antibodies were all normal or negative.Hepatitis B surface, core and e antigens were all negative; however hepatitis B surface, core, and e antibodies were all positive. Renal biopsy revealed a membranous (Figure 1) and focal proliferative crescentic glomerulopathy.



IgG -C3 immune deposits were located in the subepithelial region of the GBM,without endothelial tubuloreticular inclusions on EM.

Conclusions: The rare association of membranous and crescentic gn has been reported in patients who are ANCA or anti-GBM antibody positive and who are carriers of hepatitis B antigens. While our patient had exposure to hepatitis B she was no longer a carrier of the viral antigens. In the abscence of any observable cause of crescentic gn it is concievable that prior exposure to hepatitis B may have primed the glomerulus, leading to a mixed membranous and crescentic gn.

PUB712

Adrenocorticotropic Hormone Therapy for Idiopathic Glomerulonephritis: 6-Week Interim Data from an Ongoing, 6-Month Trial Robert A. Welik. *12502 Willow Brook Rd, Suite 450, Cumberland, MD.*

Background: Previous research has shown treatment with adrenocorticotropic hormone (ACTH) can provide benefits for patients with idiopathic glomerulonephritis, but as of yet no long-term or prospective studies have evaluated whether natural source ACTH gel (H.P. Acthar Gel®; Questcor Pharmaceuticals, Inc.) can offer a complete or partial remission of nephropathy. This prospective study examines ACTH treatment in 7 patients, all of whom have previously been treated with standard immunosuppressive therapies according to their etiologies, including IgA nephropathy, idiopathic membranous glomerulonephritis, acute interstitial nephritis, and focal segmental glomerulosclerosis, without adequate response.

Methods: This is an ongoing, 6-month study in which patients are receiving deep intramuscular injections of ACTH 80 units (1 ml) twice weekly. The data presented here are the comparisons of glomerular filtration rate (GFR) calculated by using the Modification of Diet in Renal Disease formula at baseline and Week 6.

Results: Mean GFR of the patients (n=7) at baseline was 38.0 mL/min per 1.73 m^2. After 6 weeks of treatment with ACTH, mean GFR improved to 44.1 mL/min per 1.73 m^2, and those increases approached significance (P<0.0526). The GFR for one patient who has completed 8 weeks of treatment increased from 15.0 to 27.0 mL/min per 1.73 m^2, and creatinine decreased from 3.2 to 2.3 mg/dL. Once this 6-month study is complete (expected shortly), analyses will reveal the effects of ACTH therapy on other outcomes, including creatinine clearance, serum chemistries, 24-hr urine samples to assess protein, lipid levels, glucose concentrations, and blood urea nitrogen.

Conclusions: Although this study is still ongoing, the data obtained thus far at 6 weeks (as well as 8 weeks for one patient) and presented in this interim analysis indicate that ACTH therapy may be effective for improving GFR and creatinine, is well tolerated, and may be preferable in terms of administration and side effect profile. Therefore, ACTH may provide several benefits for patients with nephropathy that have not responded adequately to other types of treatment.

PUB713

Collapsing Glomerulopathy Occurring in a Patient with Pheochromocytoma: Chance Occurrence or a New Pathogenic Association? Joseph P. DeJonckheere,[1] Hammad Arshad.[2] *[1]Three Rivers Nephrology and Hypertension Associates, Pittsburgh, PA; [2]Internal Medicine, Mercy Hospital, University of Pittsburgh Medical Center, Pittsburgh, PA.*

Background: Collapsing glomerulopathy (CG) involves podocyte transformation to a more immature and proliferative phenotype. Pheochromocytomas (PHEOs) are rare tumors that are known to secrete a number of biologically active peptides and, based on variations in hormones the tumor releases, present with a wide variety of signs and symptoms. Case reports have shown CG to occur in association with Parvovirus B19, Pamidronate, and interferon gamma. Here, we report a case of CG occurring in association with PHEO and explore whether this is a chance occurrence or if a pathogenic mechanism of PHEO induced CG exists.

Methods: 53-year-African American female presenting with nausea and fatigue was found to have nephrotic range proteinuria and a PHEO found incidentally. Kidney biopsy revealed CG. HIV, Parvovirus B19, and other serologic tests were negative. Prednisone was started with improvement in proteinuria and this was followed by a sustained steroid free remission after tumor removal.

Conclusions: Secretory products from PHEOs are well established to have effects on the proliferation, structure, or function of various cell types, including podocytes. This report and other published cases suggest that biologically active products from PHEOs have direct effects on glomerular permeability resulting in proteinuria that is not due to hypertension and which resolves upon removal of the tumor. Our case is the first demonstrating biopsy proven CG in association with PHEO. The patient's response to steroids suggests a potential moderating effect on an unspecified factor released by the tumor which caused CG and allowed for steroid withdrawal shortly after tumor removal. Based on the clinical evidence presented and the unlikely occurrence of CG and PHEO occurring together as isolated events, it is likely that this case is the first description of a new pathogenic association.

PUB714

Human Immunodeficiency Virus-Associated Nephropathy with Undetectable Viral Load: A Departure from the Usual Shweta Punj,[1] Mark A. Kraus.[2] *[1]Medicine, John H Stroger Hospital, Cook County, Chicago, IL; [2]Nephrology, John H Stroger Hospital/ Rush Univ, Chicago, IL.*

Background: HIV infection is a widespread infectious disease with progressive immunosuppression mediated by lysis of CD4 T helper cells. It's most common renal manifestation, HIV-associated nephropathy (HIVAN), is an AIDS-defining illness typically a consequence of advanced untreated HIV/AIDS with reduced CD4 count and detectible viremia. The current standard of care of HIVAN is immune reconstitution by administration of highly active antiretroviral therapy (HAART) with a clinical goal of increase in CD4 count and undetectable viral load. We describe a patient who developed the clinical syndrome of HIVAN despite ongoing HAART administration, undetectable viral load and an intact CD4 count.

Methods: The patient, a 55 year old African American male with hypertension, type 2 diabetes, hepatitis C, and HIV, presented to his provider with anasarca for 2 weeks. He was noted to have a blood pressure of 119/81 mmHg, to be alert and oriented and in no distress. There was 2+ edema in the legs and 1+ edema up to the shoulders. Systemic exam was otherwise unremarkable. Laboratory analysis revealed AKI with a serum creatinine of 2.9 mg/dL, a urinalysis with 3+ proteinuria, glucosuria, and bland sediment, and a spot urine protein to creatinine ratio of 16 g/g. His serum albumin was 1.8g/dL and total cholesterol was 329mg/dl. CD4 count was 629 cells/uL and serum HIV RNA level was undetectable. The renal biopsy revealed focal (10 of 23 glomeruli) and segmental scars with collapsing features and proliferation and hypertrophy of overlying podocytes. Immunofluorescence revealed nonspecific staining of a segmental scar for IgM and C3. Tubular casts were positive for IgA, IgM, and light chains. A rapid loss of renal function resulted in ESRD over 3 months despite the addition of steroids and ACE inhibitor therapy.

Conclusions: This case is unique in that HIVAN developed despite clinically effective HAART for over 2 years previously. It suggests that the occurrence of HIVAN may not depend wholly on viral mediated immunosuppression and highlights the need for continued vigilance for diagnosing this potentially reversible glomerulopathy.

PUB715

Epidemiologic and Clinical Presentation of 215 Cases of Lupus Nephritis: A Single Center Experience Maria Carolina N.R. Neves, Andrea C.E.P. Valenca, Marclebio M.C. Dourado, Edmir R.B. Dias, Luis H.B.C. Sette, Gisele Vajgel Fernandes, Maria Alina G.M. Cavalcante, Lucila Maria Valente. *Nefrologia, Hospital das Clinicas-UFPE, Recife, Pernambuco, Brazil.*

Background: Lupus nephritis (LN) is a common and is the most important predictor of morbidity and mortality in patients with systemic lupus erythematous. Clinical presentation of LN is variable, ranging from asymptomatic proteinuria to rapidly progressive glomerulonephritis. We describe a case series of 215 patients attended in our center.

Methods: We conducted a retrospective study evaluating medical records of patient at initial presentation. We evaluated ambulatory patients in a tertiary hospital at the northeast of Brazil, from 1989-2012. Epidemiological, clinical and laboratory data were analyzed.

Results: The table below describes epidemiological, clinical and laboratory data.

Epidemiologic, Laboratory and Clinical Characteristics

	N=215 (100%)
Age (range)	32.4 (14-60)
Female, n (%)	97.6 (210)
Race	
White, n (%)	86 (40)
Non-white, n (%)	129 (60)
Presentation, n (%)	207 (96.2)
Acute renal failure	47 (22.7)
Nephrotic syndrome	39 (18.9)
Nephritic and Nephrotic syndrome	23 (11.1)
Hematuria and/or non-nephrotic proteinuria	98 (47.3)
Renal Biopsy according to WHO class, n (%)	137 (63.7)
II	4 (3.0)
III	17 (12.4)
IV	34 (61.3)
V	14 (10.2)
Mixed membranoproliferative	15 (13.1)
Laboratory	
Serum creatinine (mg/dl) (mean/±SD)	1.54 ± 1.56
CrCl (mean/±SD)	77.5 ± 40.6
CrCl < 30ml/min/1.73m² (%)	14.5
Serum albumin (g/dl) (mean/±SD)	3.0 ± 2.9
Hematuria (%)	62.6
Proteinuria (g/day) (mean/±SD)	3.48 ± 3.7
ANA positive (%)	94

ANA= anti-nuclear antibody; CrCl=Creatinine Clearance

Conclusions: We reported a large series of LN cases attended in our center. Like other reports in the literature, there was a high prevalence of women and non-white patients. The most prevalent clinical presentation was hematuria and/or non-nephrotic proteinuria. Histological classification revealed a predominance of Class IV.

PUB716

Induction Therapy in Proliferative Lupus Nephritis: Single Center Retrospective Cohort Analysis Andrea C.E.P. Valenca, Maria Carolina N.R. Neves, Marclebio M.C. Dourado, Edmir R.B. Dias, Luis H.B.C. Sette, Gisele Vajgel Fernandes, Maria Alina G.M. Cavalcante, Lucila Maria Valente. *Nefrology, Hospital das Clínicas - UFPE, Recife, Pernambuco, Brazil.*

Background: Lupus Nephritis (LN) is common in patients with systemic lupus erythematosus and is the most important predictor of morbimortality in these patients. The aim of this study was to evaluate the treatment success in patients followed in our center.

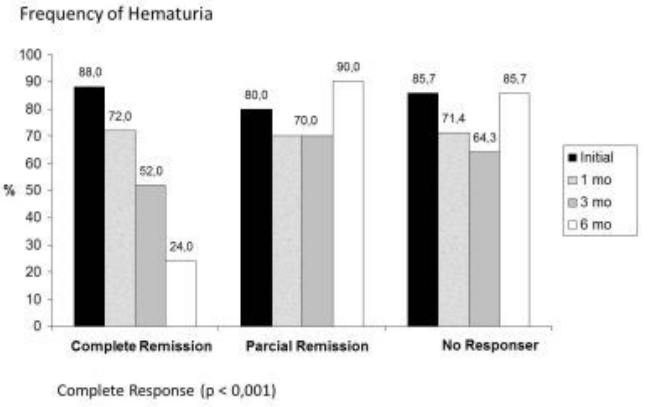
Methods: We included patients that underwent renal biopsy that had proliferative LN. They were classified as complete remission (CR), defined as 2 or more of the following: proteinuria <0.5g; absence of hematuria (HT) or cellular casts; stability or decrease in 25% of sCr. Partial response (PR), defined as improvement of 50% of all CR criteria, and non-responders (NR) neither CR or PR.

Results: Main findings are detailed in table below.

General Characteristics

Characteristics	All (N = 49)	CR	PR	NR	p-value
Total Patients (%)	49 (100)	25 (51.0)	10 (20.4)	14 (28.6)	-
Age: mean ± SD	31.7 ± 9.9	33.8 ± 10.1	27.9 ±9.4	30.7 ±9.4	0.257
Induction Therapy (%)					
CYC	47 (96)	24 (96)	10 (100)	13 (92.9)	0.683
MMF	02 (4)	01 (4)	00	01 (7)	
Biopsy (WHO class) (%)					
III	08 (16.3)	07 (87.5)	01 (12.5)	00	0.152
IV	33 (67.3)	14 (42)	07 (21)	12 (36)	

Class III LN had a higher CR rate while PR and NR were mostly observed in class IV. Albumin significantly increased in CR, PR and NR. In the group that reached CR or PR this increase was observed in the first month (CR: p = 0,01; PR: p = 0,026) while in the NR the albumin raised only in the third month (p = 0,006). In patients with CR the percentage of HT significantly reduced after 6 months of treatment (p < 0,001), while in the groups with PR and NR this did not occur.



Conclusions: This study suggests that first month serum albumin could be an early surrogate marker of therapeutic response. HT is also a relevant parameter during induction therapy regarding complete remission.

PUB717

Clinical Follow-Up of 45 Patients Treated for Proliferative Lupus Nephritis: Retrospective Cohort Maria Carolina N.R. Neves, Andrea C.E.P. Valenca, Luis H.B.C. Sette, Marclebio M.C. Dourado, Edmir R.B. Dias, Gisele Vajgel Fernandes, Maria Alina G.M. Cavalcante, Lucila Maria Valente. *Nefrologia, Hospital das Clinicas - UFPE, Recife, Pernambuco, Brazil.*

Background: Lupus Nephritis (LN) is a major contributor to morbimortality in patients with systemic lupus erythematosus (SLE) and impacts in clinical outcomes. We performed a retrospective cohort study with 45 patients with proliferative LN.

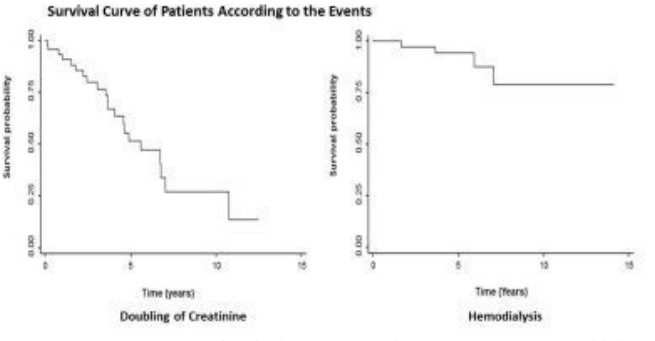
Methods: We reviewed files of patients with SLE who had underwent kidney biopsy and had proliferative lupus nephritis. Exclusion criteria were prior immunosuppressive treatment within the past 10 months. Patients were evaluated separately in creatinine (sCr) and hemodialysis (HD) cohorts.

Results: Forty five patients were included. Mean age was 31.6 yrs, sCr 2.7 mg/dL and proteinuria 4.6g/d. Most common presentation was rapidly progressive glomerulonephritis (RPGN). Analysis showed class III in 17% and class IV in 70.3% of patients. Nephritis flare was seen in 29.3%. Cyclophosphamide (CYC) was the only induction therapy. Maintenance therapy was: azathioprine 76.7%; CYC 14%;MMF 9.3%; non available 8.5%. Mean follow-up time was 3.8 yrs and 5.3 yrs in the HD and sCr cohort, respectively.

Descriptive Analysis and Hazard Ratio According to Doubling sCr and ESRD

Description of Cohort	Doubling sCr	ESRD
No of Events	21	4
Incidence (100 persons/yr)	12 (7.9-18.6)	1.6 (0.6-4.4)
Occurrence of events (%)		
1 yr	7	0.0
3 yrs	20.5	2.6
5 yrs	48.3	5.9
10 yrs	72.6	20.9
Maintenance Therapy		
Yes	1.0	1.0
No	2.16 (0.28 - 17)	¥
Flare		
No	1.0	1.0
Yes	1.93 (0.78 - 4.8)	3.71 (0.37 - 36.7)
Therapeutic Evaluation		
NR	1,0	1,0
CR/PR	1.22 (0.43 - 3.44)	¥

¥ No ESRD in this group



Conclusions: We reported a single center experience on LN treatment with long term follow up. After ten years, most patients doubled creatinine and 20% were in ESRD. These data are similar to those found in literature and shows a poor overall renal outcome.

PUB718

The Renal Pathological Characteristics and Clinical Features in Elder Patients with Kidney Disease Huiling Wang.[4] [1]*Division of Nephrology, Jimin Hospital, Shanghai, China;* [2]*Division of Nephrology, Jimin Hospital, Shanghai, China.*

Background: With the elderly population increased to more than 20% in Shanghai and other district of China, the composition of elder patients with kidney disease was increased too. The number of renal biopsy in elderly patients goes up to more than 10% recent years. This study was to investigate the clinical features and renal pathological characteristics in elder patients in our division.

Methods: It was a retrospective study, 56 patients over age 60 were enrolled, and we investigated the original causes of renal biopsy, analyzed clinic feature including blood pressure, GFR, proteinuria, biochemistry meters, and renal pathological change. We compared the results with 280 patients under age 60.

Results: In the elderly patients, the original causes of renal biopsy were nephrotic syndrome, hypertension, acute Kidney Injury, renal function insufficiency, which accounts for 32.1%, 28.6%, 14.3%, and 14.3% respectively; the incidence of anemia was increased(32.1% vs 18.2%,P<0.05), but the plasma albumin and glomerular filtration rate were decreased compared with the young patients(p<0.05).The Systolic blood pressure, cholesterol, triglyceride were significant higher in elder patients than that in young patients(P<0.05). The renal pathology showed Membranous nephropathy (27.5%) and IgA nephropathy (25.0%) was the major primary glomerulonephritis(71.4%), the arteriolonephrosclerosis was the major secondary kidney disease (41.7%). We also found that the acute tubular necrosis (37.5%) and crescentic glomerulonephritis(37.5%) were the mostly histopathologic features in the elderly patients undergoing renal disease with acute kidney injury. However, the lupus nephritis was the major secondary kidney disease in non-elderly patients (54.8%).

Conclusions: The original causes of renal biopsy and pathologic feature were difference in the elderly patients from that of the non-elderly patients. Membranous nephropathy and IgA nephropathy were two major primary glomerulonephritis; and the arteriolonephrosclerosis was the major secondary kidney disease. We should confirm these data in a large number of elderly patients.

Primary Gastrointestinal Involvement in ANCA-Associated Vasculitis: Poor Outcome and Possible Alternative Treatment Targets Joerg Latus,[1] Peter Fritz,[2] Martin Kimmel,[1] Dagmar Biegger,[3] German Ott,[4] Kerstin U. Amann,[5] Mark Dominik Alscher,[1] Niko Braun.[1] [1]*Nephrology, Robert-Bosch Hospital, Stuttgart, Germany;* [2]*Division of Pathology, Diagnostic Medicine, Stuttgart, Germany;* [3]*Margarete Fischer-Bosch Institute, Clinical Pharmacology, Stuttgart;* [4]*Department of Diagnostic Medicine, Devision of Pathology, Robert-Bosch Hospital, Stuttgart;* [5]*Nephropathology, University Erlangen, Erlangen.*

Background: Patients with granulomatosis with polyangiitis (GPA) or microscopic polyangiitis (MPA) often present with ear, nose and throat manifestations, pulmonary disease and renal disease. Primary gastrointestinal involvement is rare, however it is associated with poor outcome and high mortality.

Methods: We retrospectively reviewed the medical charts of 7 patients with (ANCA)-associated vasculitis (AAV) and primary GI involvement regarding clinical presentation, outcome, diagnostic tools and therapy. Second, we studied the cellular composition of the inflammatory infiltrate associated with the vascular lesions to detect possible treatment targets using antibodies against CD20, CD3 and CD34 and compared them with a healthy control group.

Results: Mean age at onset of the first symptoms of vasculitis was 48 ± 21.3 year. All patients suffered from abdominal pain, 4 of 7 (57%) had an acute kidney injury and 3 patients required hemodialysis. At the time of diagnosis 5 of 7 patients (71%) required surgery, mean Birmingham Vasculitis Activity Score (BVAS) on admission was high (26.3 ± 7.7) and remained high after induction therapy. All patients were treated with i.v. steroids, i.v. cyclophosphamide. The expression of CD3 was significantly higher in patients with AAV with GI involvement compared to the control group (p=0.02). The analysis of the expression of CD20 and CD34 showed no statistically significant differences between patients with AAV with GI involvement compared to the control group.

Conclusions: Primary GI involvement in AAV is associated with poor outcome and treatment response to established therapies is insufficient. Target related therapy with CD20 antibodies might be a treatment option. Other targets like CD3 need further evaluation.

PUB720

Long Term Follow Up of Once Daily Dose versus Twice Daily Dose Cyclosporine in Primary Membranous Glomerulopathy with the Nephrotic Syndrome Frieder Keller. *Internal Medicine I, Nephrology, University Hospital, Ulm, Germany.*

Background: Cyclosporine (CsA) in combination with corticosteroids has shown efficacy in primary membranous glomerulopathy in achieving remission of the nephrotic syndrome. Our hypothesis was that cyclosporine-associated nephrotoxicity could be avoided by monitoring trough concentrations (Co) and by reducing the total daily dose using single daily dose regimes (Clin Nephrol. 2007 May;67(5):285-92.). In this retrospective long-term analysis we compared patients with the nephrotic syndrome and membranous nephropathy treated with once daily dose (ODD) or twice daily dose (TDD) cyclosporine regimes.

Methods: Twelve patients (6 in each group, mean age 65 SD 15 years) were treated with CsA (target through level 50-100 ng/ml) and an average total dose of 200 mg per day (150-300) that is 2.74 mg/kg body weight (1.69-4.44) over more than 60 months.

Results: After 60 months, a complete remission of the nephrotic syndrome was achieved in both groups. With ODD proteinuria decreased from 8.6 g/l (4.2-10.9) to 0.4 g/l (0.1-0.7), p=0.008, and with TDD from 3.3 g/l (1.2-2.5) to 0.3 g/l (0.1- 3.2), p = 0.029, Friedman-test. There was no difference in final proteinuria between ODD 0.43 g/l (0.06-0.07) and TDD 0.27 g/l (0.0-3.19); Mann-Whitney-U-Test p=0.394. Serum protein was significantly increased in both groups after two years. The increase of serum creatinine was significant in both groups: ODD from 84 µmol/l (62-106) to 147 µmol/l (92-182), p = 0.002, and TDD from 93 µmol/l (70-103) to 105 µmol/l (71-138), p = 0.045, Friedman-test. However and contrasting to our hypothesis, after60 months the MDRD-2 GFR was significantly less in the ODD as compared to the TDD group (39 ml/min (25-77) versus 69 ml/min (47-105), p = 0.026 Mann-Whitney-U-test).

Conclusions: ODD and TDD CsA is an effective treatment of the nephrotic syndrome in patients with membranous glomerulopathy. However, for long term therapy twice daily CsA dosing (TDD) should be preferred due to less nephrotoxicity.

Prospective Therapy with Adequate Steroids Inducement in Adult Minimal Change like Iga Nephropathy Jinquan Wang, Chenxia Juan, Qian Huang, Cai-hong Zeng, Zhi-Hong Liu. *Research Institute of Nephrology, Jinling Hospital, Nanjing University School of Medicine, Nanjing, Jiangsu.*

Background: There is no high-quality evidence to recommend using adequate steroids in patients with minimal change like-IgA nephropathy (MCD-IgAN). This study is to prospectively evaluate its efficacy and safety.

Methods: Thirty biopsy-proved adult MCD-IgAN patients volunteered in the prospective treatment. Daily single doses of 1mg/kg (maximum 60mg) prednisone were given until complete remission (CR). Then the doses were tapered slowly. The clinical data were collected from baseline up to 12 weeks.

Results: (1). General situation: The patients consisted of 18 males and 12 females, aged 28.4±11.3y (18-60y) at renal biopsy. The baseline data were seen in table 1. (2). Efficacy and duration of remission: One (3.03%), 12 (40%), 14 (46.7%) and 8 (10%) patients achieved CR (proteinuria< 0.4g /24h) at 1, 2, 4 and 8 weeks after the treatment, respectively. (3) Relapse: Two cases relapsed at the 6th and 8th week respectively, one for rapid withdrawing of steroids, the other for upper respiratory infection.(4) Side effect: Infection, alanine aminotransferase elevation (>twice the normal value), fasting blood sugar elevation (> 6.2mmol/L) and hypokalemia (< 3.5mmol/L) occurred in 2, 5, 2 and 5 cases respectively. All recovered after treatment modulation.

The main laboratory parameters at renal biopsy

Parameter		n	%	χ±S
Blood	Albumin (g/L)	30	100	23.0±3.44
	Serum creatinine (mg/dl)	30	100	0.817±0.45
	Hightercholesterolemia (>6mmol/L)	30	100	10.0±2.22
	Hypertriglyceridemia (>2.2mmol/L)	17	56.7	2.93±1.62
Urine	Proteiuria(g/24h)	30	100	8.03±3.64
	Red blood cells of urinary sediment (million /ml)	13	43.3	23.7±66.52
	Ascending of NAG (>17 u/g.cr)	19	63.3	38.0±11.2
	Ascending of RBP (>0.5mg/L)	10	33.3	1.47±1.02
	Ascending of lysozyme (>0.5mg/L)	5	16.7	0.77±0.32
	Ascending of C3 (>2.76mg/L)	11	36.7	3.69±1.46
	Ascending of α2 macroglobulin (>2.87mg/L)	16	53.3	3.25±0.78

Note:NAG- N-acetyl-β-D-gluco Saminidase, RBP- retinol binding protein

Conclusions: Adequate steroids induction therapy is effective and safe for adult MCD-IgAN patients.

Funding: Government Support - Non-U.S.

Clinical Observation of Low-Dose Mycophenolate Mofetil in the Treatment of IgA Nephropathy Ping Fu, Tao Ye, Jin Qiaoling, Xiao Xiao Yu, Mian Wei. *Division of Nephrology, Department of Medicine, Chengdu, Sichuan, China.*

Background: IgA nephropathy (IgAN) is the most common form of glomerulonephritis worldwide.Up to 40% progress to end-stage renal disease (ESRD) over 10–20 years. Currently, treatment is limited. We investigate the efficacy and safety of steroid and low-dose mycophenolate mofetil (MMF) in the treatment of IgA nephropathy retrospectively.

Methods: 23 patients with IgA nephropathy from may 2009 to may 2011 in our hospital were treated with steroid and low-dose mycophenolate mofetil (MMF). The initial dose of prednisone was 0.6 mg/kg/d,after 4 to 8 weeks,gradually reduced to 10mg/d maintenance. MMF was started at 0.5-1.5g/d and target blood concentration was 30-60mg.h/L. Clinical parameters such as serum creatinine,urine protein,serum albumin and side-effect were recorded and analyzed each follow up. Induction course of the treatment was initially set to 6 months,if subjects did not achieve complete remission (PR) within 6 months,it would be extended to 9 months. The primary end point was complete and part remission(CR) during induction therapy.

Results: All of the 23 patients had been observed for 6 months or above. Among the 23 cases, CR 4 cases, PR 16 cases, NR 3 cases, the totel effective rate was 87.0%.2 patients experienced respiratory infection, one of them was hospitalized;2 patients suffered from urinary tract infection,1 patient had diarrhea.

Conclusions: Low-dose MMF therapy was an effective and safety therapy with low medical cost for IgA.

PUB723

Antineutrophil Cytoplasmic Autoantibody-Negative Small Vessel Vasculitis with Renal Involvement: A 24-Year Retrospective Study Helena Marco,[1] Emilia Corica,[2] Montserrat Picazo,[1] Yolanda Arce,[3] Silvia Gracia,[4] Jm Llobet,[2] Montserrat M. Diaz Encarnacion,[1] Jose Ballarin.[1] *[1]Nephrology, Fundacio Puigvert, Spain; [2]Rheumatology, Hospital de Sant Pau, Spain; [3]Pathological Anatomy, Fundacio Puigvert, Spain; [4]Haematology, Fundacio Puigvert, Spain.*

Background: Pauci-immune renal vasculitis with focal glomerular necrosis and crescent formation is usually associated with antineutrophil cytoplasmic antibodies (ANCAs). However, ANCA´s are absent in 10 to 33% of cases. Prevalence, clinical manifestations, histopathology and outcomes of ANCA-negative SVV remain controversial.

Methods: We performed a single center retrospective review of 105 cases of SVV with renal involvement (1985-2009). We evaluated clinical and laboratory variables, presence and type of ANCA, kidney biopsy, immunosuppression therapy and renal/patient survival.

Proportions of patients were compared using Chi-Squared tests and serum creatinine by a t-student test.

Results: 13/105(12%) patients diagnosed with renal vasculitis were ANCA-negative. The median age was 69(57-89) years in ANCA-negative and 68(12-84) years in ANCA-positive. Creatinine at diagnosis was 453(71-1668) µmol/L in ANCA-negative and 386(49-1101) µmol/L in ANCA-positive (p=0.044). There was not a statistically significant difference regarding clinical variables at diagnosis except for the presence of oliguria, 4/13(31%) in the ANCA-negative and 6/86(7%) in the ANCA-positive (p=0.02). 10/12(83%) of the ANCA-negative received immunosuppressive therapy and 89/90(99%) of the ANCA-positive (p=0.03). The amount of patients that received dialysis at diagnosis was 8/12(67%) of the ANCA-negative and 34/91(37%) of the ANCA-positive (p=0.06). Mortality within 6 months of diagnosis was 6/11(54%) of the ANCA-negative and 12/88(14%) of the ANCA-positive (p = 0.004).

Conclusions: 12% of the patients were ANCA-negative, they had higher creatinine levels with higher tendency to be dialyzed at diagnosis. A greater number of patients did not receive immunosuppressive therapy.

This increased mortality highlights the importance of early diagnosis and treatment of this disease despite the ANCA-negative to improve renal and patient survival.

Nation-Wide Consciousness Investigation on the Clinical Remission of IgA Nephropathy in Japan Keiichi Matsuzaki,[1,5] Yusuke Suzuki,[1,5] Tetsuya Kawamura,[2,5] Hitoshi Suzuki,[1,5] Naoko Sakamoto,[3,5] Hiroyuki Yanagawa,[1,5] Satoshi Horikoshi,[1,5] Seiichi Matsuo,[4,5] Yasuhiko Tomino.[1,5] *[1]Division of Nephrology, Department of Internal Medicine, Juntendo University Faculty of Medicine, Tokyo, Japan; [2]Jikei University School of Medicine, Tokyo, Japan; [3]National Research Institute for Child Health & Development, Tokyo, Japan; [4]Nagoya University Graduate School of Medicine, Aichi, Japan; [5]Progressive Renal Diseases Research, Research on Intractable Disease, from the Ministry of Health, Labour and Welfare of Japan.*

Background: Since annual check-ups with urinalysis are routine in Japan, various stages of IgA nephropathy (IgAN) are diagnosed and managed. Because of recent disease specific therapies, we frequently experience the clinical remission. However, the clinical remission has not been clearly defined, and thus the definitions are largely different among the Japanese nephrologists. The present study aimed to investigate the consciousness on the clinical remission for IgAN in Japan.

Methods: The Special IgAN Study Group of the Progressive Renal Diseases Study Committee organized by the Minister of Health, Labor and Welfare conducted the questionnaire survey to nephrologists in 312 teaching hospitals in Japan.

Results: Valid answers were returned from 193 hospitals (59.2%). 95 hospitals (50.2%) had an original criteria. 126 respondents (65.3%) answered that the clinical remission is defined as complete disappearance of urinary abnormalities. 43 (22.3%) and 10 (5.2%) respondents choose proteinuria alone or hematuria alone as critical definition criteria, respectively. Most common answer of clinical remission criteria was as below; hematuria; (-) in dipstick (59.0%) or less than 5 erythrocytes/HPF in urinary sediment (77.2%) and proteinuria; (-) in dipstick (50.2%) or less than 0.2g/day (73.6%). More than half respondents needed three consecutive times in 6 months to determine the clinical remission.

Conclusions: Although there were various definitions of clinical remission for IgAN in Japan, we may find the consensus criteria for the definition of the clinical remission.

PUB725

Secondary Amyloidosis in the Setting of Periodic Fever Syndromes: Two Mutations in the Same Patient Anna Clementi,[1] Dinna N. Cruz,[2] Giovanni Giorgio Battaglia.[1] *[1]Nephrology and Dialysis, SS Marta-Venera, Acireale, Italy; [2]Nephrology, Dialysis and Transplantation, San Bortolo Hospital, Vicenza, Italy.*

Background: Secondary amyloidosis (AA) may complicate inflammatory diseases, neoplasms and several periodic fever syndromes, such as familial Mediterranean fever (FMF) and tumor necrosis factor receptor-1 syndrome (TRAPS), where specific genetic mutations correlates with the severity of amyloidosis. We report the first case in literature of AA amyloidosis where mutations involving the gene of FMF and the gene of TRAPS coexist.

Methods: A 21-year-old Romanian woman at the 35th week of gestation developed acute abdominal pain, nausea, vomiting and inability to pass flatus. Pitting edema was present in the lower limbs. Past medical history was significant for hepatitis C(HCV). Laboratory workup performed after delivery showed heavy proteinuria (3.6g/24h) and increased serum amyloid A protein (591.3ng/ml). ANA,ENA,ANCA,C3,C4 and Ig levels were normal. No monoclonal band was present on serum protein electrophoresis. Hepatitis B virus infection markers were negative, and apart from a slight increase in HCV antibody titre, there were no signs of active hepatitis. Kidney ultrasound showed hyperechogenic cortex. Echocardiography revealed only mild mitral regurgitation. Electromyography detected initial signs of lower limb sensory neuropathy. Kidney biopsy revealed diffuse glomerular and tubular deposition of amorphous hyaline material which stained weakly with PAS and bound Congo red and thioflavine T. Rectal biopsy showed the presence of A protein and the absence of immunoglobulin light chains. Genetic testing for AA amyloidosis detected two mutations; the first involved the FMF gene (MEFV), and it was p.M694I on chromosome 16. The second involved the tumor necrosis factor receptor-1 gene (TNFRSF1A), and it was p.R92Q on chromosome 12p13.2.

Results: The diagnosis of AA amyloidosis secondary to periodic fever syndromes was then confirmed.

Conclusions: Although the two mutations identified in our patient are not usually associated with amyloidosis, the presence of both together might have been determinant for the development of the disease.

PUB726

Mycophenolate Mofetil or Combined Corticosteroids in Progressive Immunoglobulin A Nephropathy Suya Wang, Heng Li, Jianghua Chen. *Kidney Disease Center, The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, Zhejiang, China.*

Background: Progressive IgA nephropathy (IgAN) is a common cause of ESRD. Whether mycophenolate mofetil (MMF) or combined corticosteroidsis necessary and effective in progressive IgAN has not been clarified.

Methods: Twenty-two Chinese patients (male 12, mean years 46.32±13.9, range 27-78)with hematuria (434.48red cells per high-power microscopic field, range 5-2455.8), and proteinuria (mean 3.23±1.81g/day, range 0.27- 6.45)were enrolled. All patients have biopsy-proven IgAN, 20 patients (90.91%) had diffuse mesangial proliferation with 2.63-42.61% florid crescents, 21 patients (95.45%) had mild to moderate degrees of glomerular sclerosis (4.17- 76.6%) and interstitial changes. Seven patients accepted MMF (1.0/d)monotherapy, ten patients adopted MMF(1.0/d)combined prednisone (0.5mg/kg/d) withtapered maintain until discontinuation. Five of 12 patients with florid crescents more than 10% treated with 3 pulses of methylprednisolone (MP)(10mg/kg) followed by MMF/ prednisone (MP-MMF/prednisone).

Results: Two patients stop using MMF at 2 and 3 months due to pulmonary infection (one with MMF/prednisone, and another one with MP-MMF/prednisone schedule). Six of 20 patients treated with MMF up to 6 months, and 8 of 20 patients were up to 12 months. The mean serum creatinine level significantly decreased from 209.82±113.47 (range 124-660) µmol/L before therapy to 126.5±34.85 (range 58-206)µmol/L at 6 months, p =0.002, and to 117.9±27.99 (range 87-188)µmol/L at 12 months, p = 0.001. The mean values of eGFR had improved significantly from 33.6±10.39 (range 6.32-51.88)mL/min/1.73m^2 before therapy to 54.77±16.35 (range 29.37–102.29) mL/min/1.73m^2 at 6 months, p< 0.001, and to 58.1±14.88 (range 39.04-77.26)mL/min/1.73m^2 at 12 months, p=0.001. The mean proteinuria excretion decreased from 3.23±1.81 (range: 0.27-6.45) g/day at baseline to 1.29±1.26 (range 0.1-4.88) g/day at 6 months(p=0.002), and to 0.59±0.7(range 0.1-3.1) g/dayat 12 months(p=0.001).

Conclusions: MMF or MMF/corticosteroids therapies may be an effective proposal for reversal renal function lesion in progressive IgAN patients with acute inflammatory histologic changes.

C3 Glomerulonephrtis in Children: Presentation as Atypical Post-Infectious Glomerulonephritis(PIGN) Sang Taek Lee,[1] Yo Han Ahn,[2] Su Jung Park,[1] Hye Jin Chang,[1] Jiwon L. Lee,[1] Hyewon Park,[3] Hee Gyung Kang,[1] IL-Soo Ha,[1] Hae Il Cheong.[1] *[1]Departs of Pediatrics, Seoul National University Children's Hospital; [2]Center for Pediatric Oncology, National Cancer Center; [3]Health Promotion Center, Seoul National University Bundang Hospital, Republic of Korea.*

Background: C3 glomerulonephropathy (C3GN) is characterized by mesangial (± subendothelial) C3 deposition without other immnunoglobulin or complement. Pathogenesis is assumed to be related to disregulation of alternative complement pathway (ACP). Clinical manifestaions have not been clarified yet; we reviewed our previous renal biopsy reports to investigate characteristics of C3GN.

Methods: Among more than two thousand biopsy cases performed in our center, five cases were compatible to C3GN. Initial pathologic diagnoses were postinfectious glomerulonephritis (PIGN); Renal function was normal. Serum complement 3 (C3) levels were within normal range in four cases but decreased in case 1. Case 1 and 5 had fluctuation of C3 level but others had normal range.

Results: One patient presented with gross hematuria and proteinuria (case 1), two patients with nephrotic syndrome (case 2, 4), and two patients with asymptomatic proteinuria and hematuria (case 3, 5). Case 1 and 5 showed fluctuation of their hematuria, proteinuria and hypocomplementemia despite treatment. Follow-up biopsy of case 5 revealed membranoproliferative glomerulonephritis (MPGN) pattern. Case 2 and 4 were resistant to steroid and calcineurin-inhibitor and persistent for seven and two years without deterioration of renal function, respectively. Re-biopsy revealed MPGN pattern in case 4 and disappearance of C3 deposit with focal segmental glomerulosclerosis in case 2. In case 3, C3 deposit was lost in 2 years with newly found mesangial IgA deposition. She lost her renal function in five years and got kidney transplantation.

Conclusions: While the entity of C3GN is relatively new and not universally applied yet, our cases showed diverse presentation and outcome, which were quite distinctive from typical PIGN. For better understanding this entity, further study on regulatory system of ACP is required, as well as other markers which can predict clinical course of C3GN.

PUB728

Tachyphylaxis to Cyclosporin A in Children with Refractory Nephrotic Syndrome

Yoshitsugu Kaku. *Nephrology, Fukuoka Children's Hospital, Fukuoka, Japan.*

Background: Cyclosporin A (CYA) is an essential drug for children with steroid dependent (SD) or steroid resistant (SR) nephritic syndrome (NS). CYA has excellent effects to prevent the relapse of SDNS and to introduce the remission of SRNS. However, these patients often have considerable dependency to CYA. Recently, as long-term use of CYA increases, the tachyphylaxis to CYA is becoming the considerable problem. Tachyphylaxis often makes the disease return to steroid dependent or frequent relapser again.

Methods: 134 idiopathic NS patients had been treated in our department from 2004 to 2010. They had various clinical courses and 31 were SRNS. CYA was used in 70, and combined with or without other immunosuppressants. In almost of them, CYA was effective initially.

Results: 4 of 70 patients, however, showed the tachyphylaxis to CYA subsequently.

[Case 1] At the age of 2 years old, her SRNS developed. mPSL pulse therapy and CYA could introduced the remission. CYA and small dose PSL could maintain the remission for 18 months, however NS became SD and SR thereafter.

[Case 2] His NS developed at 8 years old and relapsed frequently. Between 15 to 30 months from the onset, relapse was infrequent by CYA. However, the relapse became frequent again in spite of using CYA.

[Case 3] Her NS developed at 8 years old and was SR. We could obtain the remission with chlorambucil. After 4 years, relapse was found and became frequent. From 15 years old, CYA could maintain the remission and after 3 years CYA was discontinued. However, NS shows secondary resistance to CYA now.

[Case 4] His FRNS developed at 4 years old. Although various therapies were performed, he suffered relapses. At the age of 21 years old, CYA was started and the relapse did not develop for 15 months. However relapse became frequent again subsequently.

Conclusions: CYA is very useful and essential for refractory NS. However, since many patients have the dependency to CYA, the duration of treatment tends to be prolonged. It is necessary to hurry measures to the tachyphylaxis.

PUB729

The Effects and Safety of Tacrolimus for the Rescue Therapy of Refractory Lupus Nephritis

Lan Lan, Fei Han, Jianghua Chen. *Kidney Disease Center, The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, Zhejiang, China.*

Background: Systemic lupus erythematosus (systemic lupus erythematosus, SLE) is a multisystem autoimmune disease. The kidney is a common systemic lupus erythematosus involving parts. Tacrolimus may be a promising alternative for the patients with refractory lupus nephrits (LN). It was used as a conversion alternative or combined therapy with mycophenolate mofetil (MMF) as reported.

Methods: Twelve LN patients did not respond to prednisone (1.0 mg/kg/d)combined with MMF(1.5-2.0g/d)therapy were retrospectively analyzed. Oral tacrolimus was administered as conversion alternative for MMF (n =6) or combined therapy with MMF (n=6). The initial dose of tacrolimus was 0.05 mg/kg/d ,the target trough levels was 3 to 8 ng/mL for 24 weeks, then reduced to 3 to 6 ng/mL for another 24 weeks. Outcome variables included mean remission rate, average remission time.

Results: Eight of 12 patients (66.7%) experienced remission (either complete or partial), and 4 of 12 patients (25%) experienced complete remission. There were no significant difference in remission rate between the two groups (remission rate:66.6% vs 83.3%, p=0.221;remission time:38.0±16.49 weeks vs 33.8±17.6 weeks, p=0.71). The decrease of proteinuria in 24 weeks and 48 weeks were all statistically significant (p=0.04, p=0.00, respectively). The increase of serum albumin in 24weeks and 48 weeks were all also statistically significant (p=0.003, p=0.001, respectively). There were no difference between the two groups in proteinuria (24w, 48w), but the tacrolimus combined group indicated higher serum albumin than the alterntive therapy group, it was significantly in 24 weeks, and in 48 weeks (41.52±4.70mg/dL vs 32.43±10.96mg/dL p=0.003, 46.9±2.37mg/dL vs 39.88±9.32 mg/ dL, p=0.001). The renal function during observe was stable. No patient experienced renal flair in 1 year.

Conclusions: Tacrolimus may be an effective and safety rescue therapy for refractory lupus nephritis. Tacrlimus combined with MMF therapy probably had better result than tacrolimus monotherapy.

Dense Deposit Disease: What Can We Learn with Long Term Follow-Up of Three Atypical Cases?

Marie-lucile Figuères,[1] Veronique Fremeaux-bacchi,[2] Marion Rabant,[1] Louise Galmiche,[1] Philippe H. Lesavre,[1] Laure-Helene Noel,[1] Aude Servais.[1] *[1]Necker, Paris, France; [2]HEGP.*

Background: Dense deposit disease (DDD) is a severe nephropathy, associated with uncontrolled activation of the complement alternative pathway. We report 3 atypical cases with long term evolution and various histological patterns on iterative biopsies.

Methods: Clinical, biological, immunological and histological data of the 3 patients (P1, P2 and P3) were collected between 1976 and 2012.

Results: Ages at the first manifestations were respectively 6 (P1), 11 (P2) and 23 (P3) years. These manifestations were different in the 3 cases: mild proteinuria with macroscopic hematuria (P1) or nephrotic syndrome (P2 and P3). Estimated GFR was initially normal in all cases. P1 and P2 had a low C3 level and the three patients had a C3Nef. Genetic analysis found a rare variant of factor I in P1. P1 had 3 biopsies during a 34 years follow-up. They showed a thickening of glomerular (GBM) and tubular basement membranes with a stable mild mesangial proliferation, but a progressive accumulation of mesangial deposits and " humps " (C3 and C5b-9 positive). However, eGFR remained normal and proteinuria disappeared. P2 had also three biopsies (22 years of follow-up). There was a constant thickening of GBM but mesangial proliferation and C3 deposits decreased. However, he developed a mild kidney failure (eGFR 54 mL/min/1.73 m2) and proteinuria increased (2.4g/day).The 2 biopsies of P3 were peculiar with GBM thickening, without mesangial proliferation, but rare C3 and C5b-9 epimembranous deposits. Renal function remained normal despite of persisting proteinuria (2.7g/L) after 5 years of follow-up.

Conclusions: These three observations of DDD show heterogeneous histological patterns: C3 deposits accumulation (P1), decreasing C3 deposits and proliferation (P2), or isolated dense deposits with few C3 deposits (P3). Despite of the detection of a C3Nef in all patients, one did not have any C3 peripheral consumption and had only few C3 deposits (P3). The relation between the activation of the complement alternative pathway and dense deposits remains partially unknown. The factors involved in clinical progression are not yet elucidated.

Outcomes in Patients with Acute Interstitial Nephritis: A Large Single-Center Experience

Siddiq Anwar, Rachael Pocock, Savas Hadjiphilippou, Usha Gurung, Sohail Ahmad. *Renal Unit, East Kent Hospitals University NHS FoundationTrust, Canterbury, United Kingdom.*

Background: Acute interstitial nephritis (AIN) is a common cause of acute kidney injury. However the evidence for treatment with steroids is anecdotal. In our centre decision to treat with steroids is based on the renal biopsy.

Methods: We performed retrospective analysis of all biopsy proven AIN's between 2007 and 2012. We identified 50 patients with mean age of 64.7±1.6 years. Demographic data and clinical outcomes at one year were collected from electronic records. Patients with disease associated AIN like sarcoid, vasculitis, SLE and transplants were excluded from analysis. These patients had a baseline eGFR of 58.7±3.1 ml/min more than 3 months prior to biopsy.

Results: 39 patients were treated with steroids for a mean duration of 20.6±2.6 months. 11 patients were not given steroids due to minimal inflammation and/or spontaneous improvement in creatinine. Patients in the steroid group had a 3 fold decline in eGFR to 15.1±1.5 ml/min from baseline compared to only a one fold decline to 26.4±4.7 ml/min in the un-treated group. Not surprisingly patients in the treatment group failed to reach their baseline creatinine at one year (43.5±3.6 vs 60.5±3.5 ml/min). However the un-treated group was at its baseline within one year (53.6±3.7 vs 52.4±6.4 ml/min). In 13 patients the cause of interstitial nephritis was not clear; 12 received steroids, 4 were on steroids at one year and 3 patients required Azathioprine. In this series the steroid group appears to have florid interstitial infiltrate compared to the un-treated group.

Conclusions: Our retrospective analysis suggests that treatment with steroids is beneficial in the presence of florid inflammatory infiltrate on renal biopsy. Despite treatment these patients fail to reach their baseline creatinine. This emphasizes the importance of early renal biopsy in suspected cases. Patients with unknown offending agents are more likely to need long term steroids or immunosuppressants. A randomized control trial is needed to evaluate treatment in varying severity of inflammation on biopsy. An AIN grading system based on clinical and biopsy findings may help to evaluate treatment strategies.

PUB732

CD147 Is a Prognostic Predictor of Renal Survival in Patients with IgA Nephropathy

Huang Chen. *Nephrology, Xijing Hospital, Xi'an, China.*

Background: Renal fibrosis is a final common process that leads to the progression of various types of kidney disease. CD147, a multifunctional molecule, plays a key role in the development and progression of several tumor tissues. Previous study indicated that CD147 promotes renal fibrosis after unilateral ureteral obstruction(UUO). However, the relationship between CD147 expression and clinical significance in patients with IgA nephropathy(IgAN) is not known. We examined whether the degree of expression of CD147 in renal biopsies could be a novel marker for predicting IgAN progression.

Methods: We obtained the renal biopsy samples from IgAN patients who had received renal biopsy and evaluated the correlation between immunohistochemical staining scores and clinical parameters. We also studied whether the expression of CD147 in the renal samples was correlated with renal survival in IgAN patients.

Results: Increased CD147 expression was found in tubular epithelial cell from the kidneys of patients with IgAN, however, in normal kidneys, little positive staining for CD147 was found. Our data showed a negative association between CD147 protein and estimated glomerular filtration rate (eGFR) and a positive association with serum creatinine and the percentage of tubulointerstitial fibrosis. Kaplan-Meier survival curves showed that the CD147 overexpression was relevant with decreased renal survival.

Conclusions: Our results demonstrated the involvement of CD147 in the pathophysiology of IgAN and suggested its potential role as a surrogate marker for renal survival in IgAN patients.

PUB733

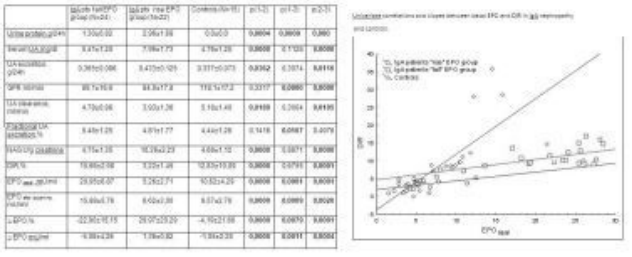
Variation in EPO Response to Dopamine Identifies Differences in Tubulointerstitial Function in Patients with IgA Nephropathy

Beata Sulikowska, Magdalena Grajewska, Rafal Donderski, Jacek Manitius. *Dept. of Nephrology, Hypertension and Internal Disease, Collegium Medicum, Nicolaus Copernikus University in Torun, Bydgoszcz, Poland.*

Background: Clinical course of IgA nephropathy depends on progression and irreversibility of tubulointerstitial renal changes. Hypoxia is one of the mechanisms leading to irreversible interstitial changes. A number of interdependencies between the marker of renal tubular dysfunction (NAG), progression of changes in biopsied kidneys, and EPO plasma levels was observed in patients with IgA nephropathy. The aim of study: to establish the relationship between EPO plasma level changes, and intrarenal vascular function in pts with IgA nephropathy.

Methods: 46 non-nephrotic IgA pts, 15 controls with GFR 86.7±17.4 and 118.1±17.2 ml/min respectively, renal vascular function estimation based on DIR. DIR was measured using two 120-min creatinine clearances (before and after i.v. administration 2µg/kg/min dopamine) and at the same points EPO was measured. UA, urinary UA, urine protein and NAG were measured.

Results: Dopamine-induced changes in EPO plasma levels using dose of dopamine in all pts, were different for different patients.



Conclusions: In IgA nephropathy with relatively preserved glomerular filtration and proteinuria, patients with the same GFR present different vascular and interstitial functional status. Vascular functional status expressed by blunted response to vasodilating effect of dopamine accompanies higher proteinuria and lower uric acid clearance and lower EPO levels.

PUB734

Cyclophosphamide for Nephrotic Associated Idiopathic Membranous Nephropathy (IMN)

Abdulfattah Alejmi, Rajiva Guddappa Ibakkanavar, Gareth Roberts. *Directorate of Nephrology and Transplant, University Hospital of Wales, Cardiff, South Glamorgan, United Kingdom.*

Background: Idiopathic Membranous nephropathy (IMN) is a common cause of nephrotic syndrome in adults. There is a paucity of data regarding the role of cyclophosphamide in IMN. We report our centre's experience of treating IMN with cyclophosphamide.

Methods: A single centre retrospective 5-year study of nephrotic associated IMN. Patients included in the study had biopsy proven MN and clinical evidence of nephrotic syndrome. Patients were treated with either pulsed IV or oral cyclophosphamide (1-2mg/kg/day) along with oral prednisolone 1mg/kg tapered over 6 months. The primary outcome was remission of nephrotic syndrome (defined as normalisation of serum albumin). Untreated matched patients served as controls. Chi squared and unpaired T test were used.

Results: 39 patients with IMN met study inclusion criteria. 21 were treated with Cyclophosphamide (n=16 IV, n=5 oral) and 18 patients had no immunosuppressive treatment (control). Median time from biopsy to treatment was 5.39 months. Use of ACE inhibitors/ARBs/diuretics were similar between both groups. There was no statistical difference in treated and untreated groups in terms of age (P=0.76), gender (p=0.3), proteinuria (p=0.28) and serum albumin (p=0.71) at baseline. There was a significant difference in eGFR at the time of diagnosis in treated and untreated groups (mean eGFR 45ml/min,eGFR 79ml/min, respectively, P=0.007). In the treated group 38% of patients achieved remission by 6 months, 61% by 12 months and 75% by 24 months. Remission rates were similar in the oral and IV therapy groups. Only 6% of untreated patients achieved remission by 12 months and 25% by 24 months. Mean increase in eGFR at 12 months was similar in both groups 6ml/min (treated) vs. 5ml/min (untreated). Leucopenia, infection and hospital admission rates were higher in oral as compared to IV cyclophosphamide group.

Conclusions: Cyclophosphamide is an effective therapy for nephrotic associated IMN. Complete remission rates and time to remission are significantly improved following therapy. Given the lower rate of treatment related side effects, we would advocate an IV pulsed Cyclophosphamide regimen.

PUB735

Prognostic Factors and Treatment Outcomes in Idiopathic Membranous Nephropathy: A Single Center Experience

Ga-young Park,[1,2] Jang-Hee Cho,[1,2] Jun-Seop Kim,[1,2] Owen Kwon,[1,2] Ji-Young Choi,[1,2] Chan-Duck Kim,[1,2] Yong-Lim Kim,[1,2] Sun-Hee Park.[1,2] *[1]Kyungpook National University Hospital, Republic of Korea; [2]CRC for ESRD in Korea.*

Background: This study was aimed to investigate the prognostic factors and outcomes in patients with idiopathic membranous nephropathy (IMN).

Methods: Data from a total of 76 patients with biopsy-proven IMN (male=37, median age=39 yrs [range 19-84 yrs]) between January 2002 to June 2011 were analyzed. Outcomes included remission (complete and partial) (complete remission [CR], proteinuria <0.02g/day and serum albumin >3.5g/dl; partial remission [PR], decrease of proteinuria >50% between baseline and last follow-up) and progression (increase of serum creatinine [s-Cr] >50% vs. initial s-Cr). Multivariate logistic regression analysis was used.

Results: At presentation, 41 patients (53.9%) had a nephrotic range of proteinuria. Mean protein excretion was 4.6 g/day and s-Cr was 0.84±0.36 mg/dl. Thirty-nine patients (51.3%) were treated only with ACEi and/or ARBs, whereas 35 patients (46.1%) with immunosuppressants. Remission occurred in 57 (75.0%) patients (CR 26 [34.2%] and PR 31 [40.8%]) during mean follow-up of 52±33 months. On multivariate logistic regression, uric acid level (OR 1.367, CI 1.014-1.844, p=0.041) was an independent risk factor for persistent proteinuria. Twenty-two patients (28.9%) were progressed and 4 of them (5.3%) needed renal replacement therapy. On univariate analysis, age (OR 1.067, CI 1.019-1.117, p=0.005), hypercholesterolemia (OR 7.857, CI 1.656-37.283 p=0.009), proteinuria >6g/day (OR 2.974, CI 1.181-10.371, p=0.024), use of immunosuppressants (OR 0.227, CI 0.078-0.659, p=0.006) and remission induction (OR 0.218 CI 0.071-0.674, p=0.008) were associated with progression. Multivariate logistic regression showed age (OR 1.095, CI 1.029-1.166, p=0.004) and remission induction (OR 0.190, CI 0.042-0.854, p=0.030) were independent prognostic factors for progression.

Conclusions: Uric acid level at presentation was an independent risk factor for persistent proteinuria in IMN. In addition, old age and persistent proteinuria without remission were independent risk factors for deterioration of renal function in IMN.

PUB736

Rituximab in Idiopathic Membranous Glomerulonephritis

Marco Fiorentino, Vincenzo Montinaro, Marica Strippoli, Carlo Manno, Loreto Gesualdo. *DETO, University of Bari, Bari, Italy.*

Background: Rituximab represents a new therapeutic option in idiopathic membranous GN (IMGN). Although several studies have proven its efficacy in improving outcomes of this disease, its role in treatment regimens is still unclear. The purpose of this study was to evaluate the clinical course of IMGN patients treated with Rituximab.

Methods: We retrospectively studied 13 IMGN patients with frequent relapses of nephrotic syndrome despite standard immunosuppression therapy. Median age was 65 years (IQR 46-76); all patients had nephrotic proteinuria (median 5.78 g/24h, IQR 4.6–9,93). Median eGFR was 56 ml/min/m² (IQR 41.9-95). Median CD20+ B lymphocytes count before treatment was 9% (IQR 7-10). Rituximab was administered at a dose of 375 mg/m² for a total of 4 weekly cycles. A quarterly follow-up for an average observation period of 12 months was performed by monitoring proteinuria, renal function and lymphocyte subpopulations.

Results: Five patients (38%) achieved a complete remission of nephrotic syndrome, with significant reduction in proteinuria (<0.5 g/24h) in the first 3 months and maintained stable values of proteinuria and renal function during the observation period. Five patients (38%) achieved a partial remission, with reduction of proteinuria from 52 to 76% compared to baseline values. Three patients (24%) did not respond to therapy, with persistence of high levels of proteinuria and, in two cases, a reduction of eGFR(from 75 to 56 and from 61 to 25 ml/min/m²). In 11 patients, eGFR remained stable in the period of observation. Median eGFR and proteinuria at last follow-up were 54 ml/min/m² (IQR 33.2-64.2) and 1.04 g/24h (IQR 0.71-3.65; p<0.45, Wilcoxon test). CD20+ B lymphocytes remained cleared in the first six post-treatment months; four patients had an increase of CD20+ lymphocytes in the seventh month (median percentage of CD20+: 0.2 %,IQR 0-5). Treatment with Rituximab was well tolerated by all patients.

Conclusions: In conclusion, our experience suggests that Rituximab may represent a therapeutic option for patients with membranous nephropathy, resistent to conventional immunosuppressive therapies. The drug is well tolerated and may have a role in slowing the progression to ESKD.

PUB737

Clinicopathologic Correlates for Activity and Damage of Lupus Nephritis in Childhood-Onset Systemic Lupus Erythematosus Michael R. Bennett, Rina Mina, Shannen Nelson, Jessica Hummel, David P. Witte, Prasad Devarajan, Hermine Brunner. *Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: High AI activity (AI), tubulointerstitial (TI), and chronicity index (CI) scores from renal biopsy may predict poor renal outcomes in lupus nephritis (LN) in childhood-onset systemic lupus erythematosus (cSLE). Our aim is to evaluate the relationship between histologic evidence of renal disease activity and damage of LN with conventionally used biomarkers in cSLE.

Methods: Biopsy specimens of 18 cSLE patients were rated by a single nephropathologist for the AI, TI, and CI. Using logistic regression, the relationships between the biomarkers and high scores for AI (≥ 4), high CI (≥ 7), and high TI (≥ 4) were evaluated. Biomarkers evaluated include serum creatinine, creatinine clearance, urine sediment, proteinuria, albumin, blood pressure, anti-ds DNA antibody, C3, C4, sedimentation rate, and blood urea nitrogen (BUN); these were obtained on the day of renal biopsy to 30 days after.

Results: Patient's mean age ± SD was 14.1 ± 2.7 years. LN class distribution was as follows: II (28%), III (17%), IV (50%), and III plus IV (6%). All were positive for anti-ds DNA antibody. Only elevated BUN (odds ratio=14, 95% CI=1.2-156, p-value=0.04) was significantly associated with high TI score. None of the biomarkers were significantly associated with high AI and high CI scores.

Conclusions: Commonly used biomarkers are poorly associated with histological features for activity and damage of LN in cSLE highlighting the need for better biomarkers that can be used in clinical care.

Increased Risk for Type 2 Diabetes Mellitus and Renal Injury in a Low Level Cadmium Exposure Population Ernesto Sabath,[1,2] Ma. Ludivina Robles-osorio.[2] *[1]Unidad Estatal de Hemodialisis, SESEQ, Queretaro, Mexico; [2]Endocrinologia y Enfermedades Metabolicas, Universidad Autonoma de Queretaro, Queretaro, Mexico.*

Background: Environmental pollution by heavy metals has been recognized as major risk factor for chronic diseases in developed and non-developed countries and is likely that cadmium may play a role in the high prevalence of renal disease and type 2 diabetes mellitus seen in low-income areas. The aim of this study was to know the association between Cd urinary excretion (Cd U), renal injury and T2DM in an open population in Central Mexico.

Methods: Cross-sectional study done in 7 communities of Central Mexico with diabetic and non-diabetic people. Pregnant women and those patients with uncontrolled blood pressure were excluded. Urine was collected in cadmium-free flasks for albumin, α1-microglobulin (α1M) and cadmium measurements; α1-microglobulin was measured by ELISA and cadmium by cell-mass spectrometry.

Results: We enrolled 185 participants with a mean age of 46.9 years old. Non diabetic participants with Cd levels higher than 0.7 µg/grCr had a higher urinary α1M excretion (12.9 vs 2.1 µg/gCr p=0.002), and albuminuria (0.03 vs 0.08 gr/gCr p=0.04) than those with with Cd < 0.7 µg/grCr. Multivariate analysis showed that Cd was the most important factor associated with α1M urinary excretion (p=0.03) and albuminuria (p=0.001).

In patients with T2DM, CdU excretion higher than 0.7 µg/grCr was associated with decrease in GFR (71.6 vs 88.4 ml/min p=0.003) but not differences in α1M or albuminuria were found.

Median Cd U excretion was higher in patients with T2DM (0.48 vs 0.37 µg/gCr p=0.01) and the OR associated with a higher risk for T2DM for patients with Cd ≥1.0 µg/grCr) was 5.6 (IC95% 1.2-26.3 p=0.03).

Conclusions: In this study we found in non-diabetic people an association between Cd U levels with albuminuria and α1-microglobulin excretion. In T2DM patients, Cd was associated with less GFR but not with proteinuria. Also, this study suggest a role of Cd in the physiopathology T2DM.

Observational Pilot Study to Assess the Efficacy and Safety of Mannitol in Reducing Severe Edema in Children with Nephrotic Syndrome Indira Agarwal, Nalini Aswathaman, Leni Kumar Joseph, Rajiv Sinha. *Pediatric Nephrology Divison, Christian Medical College, Vellore, India.*

Background: The potent diuretic effect of Mannitol in management of severe edema in children with nephrotic syndrome has not been adequately studied though literature reports it to be safe, effective and a possible inexpensive alternative to 20%Albumin.

Methods: Aims: To study the efficacy and safety of mannitol in reducing severe edema in childhood onset nephrotic syndrome.

Methodology: A prospective pilot study was conducted in the Pediatric nephrology division of Christian Medical College, Vellore,from March - November 2011. Children between 1-15yrs old with proven nephrotic syndrome and persistent edema despite 3 days of frusemide, with none of the exclusion criteria (secondary nephrotic syndrome, low GFR,abnormal blood pressure, cardiac failure, coexisting severe infection) were recruited. Mannitol (20%) 1gm/kg infusion with frusemide 2mg/kg/dose midway was given twice daily for 3 days. Children were uniformly assessed for edema based on a devised grading scale, weight changes, abdominal girth, urine output and adverse events. Results were compared with similar data while on frusemide. Statistical analysis using SPSS and Epidata was done and Student t test was applied.

Results: 20 children were recruited.Reduction in edema by 2.1 grades after mannitol and 0.2 grades after frusemide was statistically significant (p=0.00). At 72 hours, mean percentage weight loss was higher after mannitol compared to frusemide (9.3% vs. 4.83%- p=0.07).Mean abdominal girth reduction by 3.8cms after mannitol was statistically significant when compared to 0.9cms after frusemide(p=0.05). Mean increase in urine output was higher after frusemide(0.9 vs. 0.5 ml/kg/hour-p=0.5). Side effects of mannitol noted were hyponatremia, hypokalemia and hyperkalemia in 3/20, reduced creatinine clearance (2/20) and hypernatremia and hypotension in 1/20 each. Four children with these effects needed withdrawal.

Conclusions: Mannitol shows promise as a diuretic in reducing edema in Nephrotic Syndrome. A Randomised control trial comparing its efficacy against the more expensive albumin may be helpful in promoting its use in resource poor countries.

PUB740

MCP-1 Tissue Expression in Renal Biopsy of Patients with Proliferative Lupus Nephritis Correlates with Chronicity Index Cristiane Bitencourt Dias,[1] Patrícia Malafronte,[1] Aline Lázara Resende,[1] Cilene Carlos Pinheiro,[1] Denise M.A.C. Malheiros,[2] Rui Toledo Barros,[1] Viktoria Woronik.[1] *[1]Nephrology, Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil; [2]Pathology, Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil.*

Background: The aim of this study was to describe correlations of renal outcomes with tecidual MCP-1 expressed in renal biopsy specimens obtained on the diagnosis of proliferative lupus nephritis.

Methods: Thirty four female newly diagnosed patients with proliferative LN were prospectively followed-up during 3.5 (3.2 - 4.0) years. Conventional laboratory tests were collected on diagnosis and on last follow-up. Renal biopsy was done on diagnosis and immunohistochemical study was performed with monoclonal antibody anti-MCP-1, and results expressed as cells/microscopic fields. Patients were stratified in two groups according to renal outcome: GFR ≤ 60 mL/min/1.73m^2 (n=15) and GFR > 60mL/min/1.73m^2 (n=19). Considering treatment, all patients received prednisone and 6 pulses of cyclophosphamide (CYA) on induction. Maintenance treatment was conventional.

Results: There were no difference between group with GFR > 60mL/min/1.73m^2 and GFR ≤ 60 mL/min/1.73m^2 in relation to age 24.0 ± 7.0 vs 28.8 ± 11.7 years, activity index 5.0 ± 1.6 vs 4.3 ± 2.5, initial MDRD 49.4 ± 28.0 vs 32.0 ± 23.2, initial proteinuria 3.8 ± 2.2 vs 5.4 ± 2.7 g/day, systemic SLEDAI 25.3 ± 5.6 vs 25.0 ± 6.6, glomerular MCP-1 expression 0.5 ± 0.5 vs 0.8 ± 0.9 cells/field, interstitial MCP-1 expression 5.2 ± 4.9 vs 7.4 ± 7.6 cells/field and tubule MCP-1 expression 0.2 ± 0.3 vs 0.5 ± 0.7 cells/field. The only difference was in the chronicity index that was higher in GFR ≤ 60 mL/min/1.73m^2 group, 3.6 ± 1.8 vs 1.8 ± 2.1.

Considering all patients (n=34) there was positive correlation between interstitial MCP-1 and chronicity index (r=0.56, p=0.001) and negative correlation between tubule MCP-1 and final MDRD (r= -0.3, p=0.04).

Conclusions: Interstitial MCP-1 showed significant correlation with chronicity index. Chronicity index was the only parameter correlated with worse renal function on follow up.

PUB741

A Rare Case of Idiopathic Collapsing Focal Segmental Glomerulosclerosis that Responded to Treatment Alaa Abu-sayf, Sulaiman Alhassan, Omid Bakhtar, David R. White. *Department of Medicine, Detroit Medical Center, Detroit, MI.*

Background: Out of the five histological types of FSGS, the Collapsing variant is characterized with the worst prognosis, frequent association with HIV infection, predominance of blacks, massive proteinuria (>10g/day), resistance to treatment and rapid progression to End Stage Renal Disease. We report a case of idiopathic collapsing FSGS successfully treated with steroids despite advanced renal failure and lack of evidence-based guidance.

Methods: A 51-year-old Jamaican-American woman with a history of hypertension, presented with fever and flu-like symptoms for one month. She denied any recent usage of NSAIDS, interferon, bisphosphonates or intravenous drugs. She had a temperature of 38.5 Celsius, tachycardia and bilateral lower extremity pitting edema. Initial creatinine (Cr) was as high as 5.4 mg/dl with no known baseline kidney function. She was diagnosed with nephrotic syndrome with 17 grams/day of proteinuria. Our workup ruled out SLE, ANCA-vasculitis, multiple myeloma, HIV (nuclear amplification test also done), viral hepatitis and other infections associated with this diagnosis. The renal biopsy demonstrated collapsing variant FSGS, with tubuloreticular inclusions (TRIs) identified in 2 out of 13 glomeruli. Treatment was started with pulsed methylprednisolone of 1 gram for 3 days followed by 40 mg of prednisone daily. The constitutional symptoms resolved after one week. Six weeks into treatment, Cr fell to 2.6 mg/dl and proteinuria was down to 4.7 grams. Biopsy was repeated and confirmed the initial diagnosis. Partial remission was achieved after 20 weeks with a Cr of 1.8 mg/dl and proteinuria of 1.7 grams. The prednisone is currently being tapered down to complete a six month course.

Conclusions: This case provides organization of evidence of a rare case of idiopathic collapsing FSGS, diagnosed despite the presence of TRIs. The rare response to steroids was dramatic and we are now contemplating the next course of treatment. It is important to consider this therapeutic intervention as we move forward to potentially conduct controlled studies to coagulate its significance.

PUB742

Quantitative Assessment of Serum Free Light Chains in Patients with Immunoglobulin A Nephropathy Byeong Yun Yang,[1] Sang Heon Song,[1] Min Ji Shin,[1] Harin Rhee,[1] Il Young Kim,[2] Eun Young Seong,[1] Dong Won Lee,[2] Soo Bong Lee,[2] Ihm Soo Kwak.[1] *[1]Division of Nephrology, Pusan National University Hospital, Busan, Republic of Korea; [2]Division of Nephrology, Pusan National University Yangsan Hospital.*

Background: Polyclonal free light chains have recently been assessed in chronic kidney disease (CKD), diabetic nephropathy, and renal transplantation patients. Serum free light chain (sFLC) is suspected as a novel biomarker reflecting renal function of these patients. So we evaluated sFLCs in patients with Immunoglobulin A nephropathy (IgAN), the most common primary glomerulonephritis.

Methods: We studied 56 patients with primary IgAN. sFLCs were assessed with the immunoassay Freelite.

Results: sFLC κ and λ levels increased progressively with KDOQI stages (both $p<0.001$) and significantly correlated with estimated glomerular filtration rate (eGFR), cystatin C, and β2-micoglobulin (Table 1). Mean arterial pressure and urine protein to creatinine ratio (UPCR) had significant associations with λ level, not κ level (Table 1). In multivariate regression analysis, independently contributing factors to eGFR were log cystatin C (standardized $\beta=-0.588$, $p<0.001$) and log κ (standardized $\beta=-0.197$, $p=0.003$). Gradual increments in the variables according to UPCR grades (0: < 0.5 g/g, 1: 0.5 to 1.0 g/g, 2: 1.0 to 2.0 g/g, 3: > 2.0 g/g) were observed in eGFR ($p=0.009$) and λ level ($p=0.043$). In UPCR grade 0 group, eGFR was 107.1±29.0 ml/min/1.73m^2, while λ level was 21.0±6.6 mg/L, higher than the reference (reference average: 13.4 mg/L).

Conclusions: sFLCs accounts for renal function in patients with IgAN. sFLC λ may be a new biomarker of isolated hematuria originated from renal parenchymal disease such as IgAN, which should be validated in further studies.

Table 1: Spearman correlation coefficients among the variables

Epidemiologic Study on the Relations between HBV Infection and Proteinuria in South China Yimin Zhang. *Division of Nephrology, The 6th Affiliated Hospital, Sun Yatsen University, Guangzhou, Guangdong, China.*

Background: Hepatitis B virus(HBV) infection is a serious threat in Chinese population, it is estimated that about 170 million Chinese are chronically infected with HBV, about 20 million of whom are chronic hepatitis B patients. Although a major target organ of HBV infection is the liver, extrahepatic manifestations are also frequently observed in patients with HBV infection. Glomerulonephritis is an important extrahepatic manifestation of chronic HBV infection, which are clinically characterized by hematuria and proteinuria. In the present study, we investigated whether HBV infection, diagnosed by HBsAg and HBeAg positivity,, were associated with CKD components in South China individuals who underwent general health screening.

Methods: Between March 2007 and June 2010, 6816 people (3199 women and 3617 men) underwent a general health screen at Sun Yatsen Memorial Hospital, including an estimation of urinary excretion of albumin, haematuria, various markers of HBV, and were enrolled in the study. Blood and urine samples were taken from the subjects after an overnight fast. The levels of HBsAg and HBeAg in the sera were determined using commercially enzyme immunoassay kits. The data in this study were analyzed by χ^2 test and Mann-Whitney U test using the computer software SPSS 15.0.

Results: 903(13.25%)of the 6816 subjects were HBV carriers and 390(5.72%) had abnormal proteinuria. The frequency of abnormal proteinuria was not significantly different in those with[57 of 903 cases(6.31%)] or without[333 of 5913 cases(5.63%)] HBV carriage($P>0.05$). This lack of association remained when carriers were classified into those who were HBsAg positive and those with active viral replication (HBeAg positive)($P>0.05$). Haematuria was not significantly different either in those with [199 of 903(22.04%)] or without [1419 of 5913(23.30%)]HBV carriage($P>0.05$).

Conclusions: In conclusion, HBV infection does not uniformly lead to development of renal disease. There was no association between HBV infenction and CKD components (haematuria and albuminuria) in south China. Further studies will need to identify the incidence, risk factors and the natural history of renal involvement among patients with HBV infection.

"How Well Is RPGN Doing?" Rapidly Progressive Glomerulonephritis, an Institutional Experience in Disease Outcome Kamal Shemisa, Lavinia A. Negrea. *Nephrology, University Hospitals Case Medical Center, Cleveland, OH.*

Background: Rapidly Progressive Glomerulonephritis, RPGN, is characterized by the development of renal insufficiency within a short period, of weeks to months, and left untreated progresses to ESRD and death. RPGN is characterized by >50% crescents on renal biopsy. The known etiologies for RPGN vary form PAN, Wegeners', Churg Strauss, micro-PAN, Good-Pasture's, Lupus, and HSP. The majority are pauci-immune types (55%), ANCA associated. Despite the numerous causes, the prevalence is rare 7/1,000,000; and constitutes 1% of renal biopsy diagnoses. RPGN reports describe rapid progression to uremia and death. Outcomes for RPGN however are improving with combined treatment of corticosteroids, cyclophosphamide, or rituximab. We sought to assess clinical outcomes at UHCMC to verify this claim.

Methods: Standard computations for statistical analysis calculated mean, standard deviation and range were reported for mortality, hospital length of stay, ICU admission, rehospitalization, and rates of remission.

Results: In biopsy proven RPGN, the overall patient mortality at 18 months was (0%± 0). The mean age was 44 years ± 27 with equal gender representation. In our series, pauci-immune RPGN was diagnosed in 50% of patients. Treatments consisted of corticosteroid and cyclophosphamide 87% or rituximab 13%. Remission was characterized as being hemodialysis free or without renal transplant after treatment. The mean rate for remission was 56%. Patients with pauci-immune RPGN who received rituximab achieved a 100% remission rate. The time for remission ranged from 3 to 8 months. The most common reason for hospital readmission was renal replacement therapy, 38% and treatment for symptomatic anemia, 13%. Adverse side affects of therapy were neutropenia 19%.

Conclusions: The results are similar to prior estimates of prevalence and rates of remission. Higher rates of remission were achieved in pauci-immune RPGN with rituximab. Time to remission may be as long as 8 months. Consideration for long-term hemodialysis or renal transplantation should be reserved in patients who do not remit beyond this time. Awareness of potential adverse hemotologic side effects including neutropenia is crucial.

PUB745

Patterns of Glomerular Diseases from a Tertiary Care Center in Pakistan Nauman Tarif,[1] Omer Sabir,[1] Imrana Tanvir,[2] Rizwan Akhtar,[2] Haroon Younas,[1] Noman Hameed.[1] *[1]Medicine, Division of Nephrology, Fatima Memorial Hospital, Lahore, Pakistan; [2]Medicine, Division of Nephrology, Fatima Memorial Hospital, Lahore, Pakistan; [3]Pathology, Fatima Memorial Hospital, Lahore, Pakistan; [4]Pathology, Fatima Memorial Hospital, Lahore, Pakistan.*

Background: The data regarding the patterns of glomerular disease in Pakistan remains scanty. We present data from two years of our recently established nephrology unit.

Methods: Renal biopsies performed under real time ultrasound guidance using semiautomatic biopsy needle. The samples were routinely stained with: H&E, PAS, Silver and congo red. Immunoperoxidase staining for IgG, IgA, IgM, C3, C1q and C4 were initiated after one year. Electron microscopy is not available in Pakistan except a single center that is not accessible to everyone. The final diagnosis was approved in the nephropathology conference held every week. Retrospective review and descriptive data is presented.

Results: 148 biopsies were performed from March 2010 till May 2012. 73 were males (49.32%,) and 75 were females (50.67%). The mean age was: males 34.09±13.6 years and females 30.18 ±10.98. Missed or non-informative biopsies were 9 (6.0%). Being a referral centre for Rheumatology, we had 49 cases of Lupus Nephritis (33.1%). Among the idiopathic glomerular diseases, Focal Segmental Glomerulosclerosis was the most common diagnosis in 29 patients (19.59%). The other diagnoses included Membranous Nephropathy 6(4.0%), Membranoproliferative GN 6 (4.0%), Mesangioproliferative GN 4 (2.7%) Minimal Change Disease 5 (3.37%), secondary Amyloidosis 6 (4.0%), primary amyloidosis 2 (1.35%), Diabetic Nephropathy 5 (3.37%), Rapidly Progressive GN 12 (8.1%), Post infectious GN 2 (1.35%), Acute interstitial Nephritis/Tubulointerstitial Nephritis 2 (1.35%), IgA Nephropathy 2 (1.35%) were the other common biopsy findings. One patient had Chronic Kidney Disease (0.67%). 6 patients had biopsy of transplanted kidney (4.0%). One patient had vasculitis (0.67%) and other patient had scleroderma renal crises (0.67%).

Conclusions: Pattern of glomerular disease in our patients is consistent with the international data revealing FSGS as the commonest finding for idiopathic glomerular diseases.

PUB746

Increased Body Mass Index May Be a Risk Factor for the Development of Lupus Nephritis Abhijeet S. Danve, Nripesh Pradhan, Supriya Kulkarni, Donald I. Baumstein. *Nephrology, Metropolitan Hospital/New York Medical College, New York, NY.*

Background: Increased body mass index (BMI) is a risk factor for development of Chronic Kidney Disease (CKD). Obesity is low grade inflammatory state which leads to CKD by lipotoxicity, increased leptin levels, cytokine mediated glomerular injury and fibrosis. Systemic Lupus Erythematosus (SLE) is autoimmune inflammatory disease associated with high leptin levels and dyslipidemia. This study was designed to assess whether BMI is a predictor for development of lupus nephritis in SLE.

Methods: A retrospective cross sectional case control study was conducted at a municipal hospital serving mostly Hispanics and Blacks in East Harlem, New York. Data for 172 SLE patients identified by ICD code and further confirmed by American College of Rheumatology criteria was retrieved from electronic medical records for years 2002-2011. All 22 cases of biopsy proven lupus nephritis were included. We then randomly selected 25 controls who had SLE without nephritis. Age, sex, and race were compared between the two groups. To avoid treatment related alterations, BMI was calculated for all patients at diagnosis of SLE or first clinic contact. Cases and controls were grouped into normal weight (0-24.9), over weight (25-29.9) and obese (>30) based on their BMI. Mean BMI was compared between the two groups using independent-samples *t test.* BMI subgroups were compared in cases and controls by chi square test.

Results: There is no significant difference between both groups across age, sex and race. Mean BMI was significantly higher in lupus nephritis cases compared to SLE controls. There are significantly more overweight and obese patients in cases than in controls.

Results

	Lupus Nephritis (Cases) N=22	SLE without nephritis (Controls) N=25	p
Mean Age +/- SD (years)	34.5 ±10	40.9±14	0.10
Female	91%	96%	0.51
Race: Hispanic/ black	81% / 9%	60% / 40%	0.1
Mean BMI (kg/m²)	27.4	24.3	0.032
BMI (0-24.9)	18%	56%	0.029
BMI (25-29.9)	36%	24%	0.029
BMI (>30)	46%	20%	0.029

Conclusions: Increased BMI may be associated with increased risk for developing lupus nephritis in patients with SLE. Prospective studies involving broader population samples are required to substantiate this finding.

PUB747

Incidence of Lupus Nephropathy in the Colombian Caribbean Region during the Years 2008 to 2012 Using Data from NEFRORED Gustavo Jose Aroca Martinez, Andres A. Cadena. *Atlantico, Clinica de la Costa, Barranquilla, Atlantico, Colombia.*

Background: There is no reliable information in Colombia about the incidence of SLE and Lupus Nephritis, using date derived from NEFRORED we evaluated the incidence of biopsy diagnosed lupus nephropathy in the caribbean region of Colombia. All the biopsies were performed at the Clinica de la Costa in Barranquilla Colombia, this is a referral center for kidney biopsies in all the region.

Methods: Using data collected from NEFRORED, 805 kidney biopsies were documented in the database from Jan 2008 to April 2012, 194 biopsies were lupus nephritis,28 biopsies were insufficient for a proper diagnosis, 166 biopsies were studied under light microscopy and immunofluoresence.

Number of biopsies per region.

Results: Lupus Nephritis was the diagnosis in 20,6% of all the biopsies performed in this time period. 81% of the patients were female with a female to male ratio of 4:1, the race was latino in 95% of the cases with a high school education in 66,2% of the cases. Family history of SLE was found in 5.6% of the patients and 50% of the patients had a preexisting diagnosis of lupus at least for the past 3 years before the biopsy was performed.

The most common clinical finding was nephrotic syndrome in 58% of cases followed by asymptomatic non nephrotic range proteiniuria + microscopic hematuria in 33% of the cases.

The most common age group was 30 to 39 y/o. Class IV LN was the most common histologic type (69,5%), class III (16,2%), Class II (8,6%), Class V (4,8%) and type I (0,9%) and Class VI (0%).

Conclusions: This is the first attempt to describe the demographics and pathology findings of patients diagnosed with lupus nephritis in the Caribbean region of Colombia. Lupus nephritis is more commong in young women with class IV being the most common finding on biopsy.

Data on the long term progression to worsening kidney disease and ESRD is not yet available.

PUB748

A 3 Years Prospective Comparison of Safety of Bedside Insertion of Permanent Hemodialysis Catheter by Nephrologist and the Hemodialysis Permanent Catheters Inserted by Vascular Surgeons, and Interventional Radiologist in Riyadh Military Hospital Ebadur Rahman,[1] Habib Rahman,[2] Raees Farhan Mushtaq.[1] *[1]Nephrology, Riyadh Military Hospital, Saudi Arabia; [2]Nephrology, King Khaled University, Riyadh, Saudi Arabia.*

Background: This is a prospective comparative study on the safety and cost effectiveness of bedside Permanent catheters insertion. Comparison was between nephrologist inserting Permanent catheters (PC) using vascular ultra sound(USG) at bed side and PC inserted by vascular surgeons in theater.

Methods: 441 procedures were included from October 2009 to October 2011. Catheter related bacteremia within 2 weeks was defined as acute infection in this study. Nephrologist inserted bed side PC using USG or in fluoroscopy using both (USG) and fluoroscopy. Vascular surgeons used both ultrasound and fluoroscopy for their procedure. All of them had utilized Bird precurved PC. SPSS software version 19 was used for the data analysis. Blood flow rate (BFR), morbidity; cost of procedure, minimum number of consultations needed for the insertion of PC were analyzed. BFR was measured by same type of HD machine. Cost of procedure was derived from the number of days in hospital multiplying with cost of stay per day in hospital.

Results: Total number of procedure included in this study was 441. Gender distribution and mean average age was not significant among the different groups. The average costs per procedure in Saudi Riyals (S.R.) were:

I.) 1525.42 SR for Bedside insertion by nephrologist: and ii). 9653.63 S.R.for Vascular Surgeons. The mean BFR in the two groups were:

i). Bedside 457.29ml/min, ii).Vascular Surgeons: 380.22 ml/min;

BFR was significantly ($p < 0.0001$) better in PC inserted by nephrologist at bedside than those inserted by vascular surgeon. Nephrologist needed significantly low number of consultations when compared with vascular surgeons ($p < 0.0001$). Infection rates and morbidity among the groups did not show any significant difference (p value 0.06 and 0.164 respectively).There was no difference in BFR of PC inserted bedside or in flouroscopy by nephrologist or PC inserted by intervention radiologist during this observation period.

Conclusions: Bed side PC insertion by trained nephrologist using (USG) is safe and cost effective.

PUB749

Delayed Catheter Removal and Fatal Outcome in Catheter Dependent Hemodialysis Patients with Candida Parapsilosis Infection Ebadur Rahman,[1] Habib Rahman,[2] Raees Farhan Mushtaq.[1] *[1]Nephrology, Riyadh Military Hospital, Saudi Arabia; [2]Nephrology, King Khaled University Hospital, Saudi Arabia.*

Background: This is the largest series of CP infection in Hemodialysis in Saudiarabia dueto out break of Candida parapsilosis infection occurred due to colonization of distribution tubings of treated water in Hemodialysis unit of Riyadh Military Hospital in October 2009. This lead to infection of 15 patients dialyzing with permanetcathter (permcath).

Methods: The diagnosis was made either by positive culture from 2 separate peripheral Intravenous (IV) sites, or one peripheral IV site and perm cath or 2 positive cultures from permcath where samples were taken 15 minutes apart. Trans thoracic Echocardiography was done in all patients to rule out infective endocarditis. Trans esophageal echocardiogram was performed in selected patients with high clinical suspicion of infective endocarditis. Fundoscopy examination was made in all cases. All patients were initially treated with imperic IV Fluconazole. Antifungal therapy was upgraded to IV Caspofungin despite having sensitivity to Fluconazole in patients with infective endocarditis.

Results: The observation revealed that all the cases were sensitive to Fluconazole. Fatality was seen in 4 out 15 (26.7%) patients. These 4 patients refused to remove the infected perm cath early on. Moreover, 50% (2 out of 4) of the fatal cases developed Infective Endocarditis. These patients antifungal therapy was upgraded to IV Caspofungin despite having sensitivity to Fluconazole. The other 11 infected (73.3%) patients had their perm catheter removed within 72 hours of detection of the infection. They received Fluconazole for additional 2 weeks. These patients did not have re-infection after discontinuation of the drug. Survelence Echo in this patients were negetive for infectine endocarditis. Fundoscopic examinations were negetive in all cases.

Conclusions: Candida Parapsilosis is potentially fatal infection if infected catheter removal is delayed.Fluconazole is an effective treatment if catheter is removed early.

PUB750

A Challenge of Safety in Hemodialysis Practice: Advancing Anticoagulation Therapy in Saudi Arabia Ali Mohammed Allehbi,[1] Ayesha Noor,[2] Archie Dumdum Bunani.[3] *[1]Medicine - Nephrology, DaVita Lehbi Care - Saudi Arabia, Riyadh, Saudi Arabia; [2]Pharmacy, DaVita Lehbi Care - Saudi Arabia, Riyadh, Saudi Arabia; [3]Clinical Services, DaVita Lehbi Care, Riyadh, Central Province, Saudi Arabia.*

Background: Effective heparinization during dialysis is vital since it allows blood to flow into the extracorporeal circuit. This study aimed to develop a relationship between errors in Heparin administration and the study of Partial Thromboplastin Time (PTT), Hemoglobin (Hgb), Hematocrit (Hct), and Platelet (Plt) levels of hemodialysis (HD) patients.

Methods: 255 HD patient records were examined for compliance and errors in heparin administration practices. With multiple tendencies, cox regression was used to analyze trends whilst Pearson rho moment correlation determined relationships.

Results: The results indicated that heparin was administered via three routes namely bolus (90.47%), maintenance (100% via machine, 19.04% via manual approach) preparation and administration. It was significant that only 8% of nurses followed the *Independent Double Check* method of heparin preparation and administration which was a required standard within the unit through Clinical Pharmacist's and Nurse's protocol. Data showing both medication administration practices and extent of errors versus the mean scores of the PTT, Hct, Hgb and Plt were analyzed individually showing a significant regression of PTT (r=1.38, 1.50), Hgb (r=0.80, 1.03), Hct (r=1.11, 1.07), and Plt (r=1.22, 1.27). Results were summed and revealed strong correlation between the errors versus the mean values of the PTT (p=+0.77), Hct (p==0.55), Plt (p=+0.67) with the exception of Hgb which did not show any correlation at all p=(+0.04).

Conclusions: The results of this study led to the development of a standardized protocol minimizing errors relating to heparin administration during dialysis. Additionally, the study provided a *Process Map* when untoward incidences relating to use of Low Molecular Weight Heparins occurred. Further, the study has led to a significant decline in errors in medication administration practices in general within the unit.

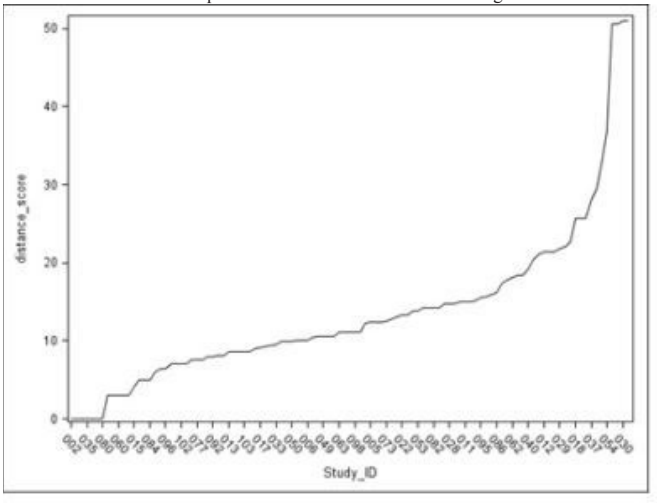
PUB751

A Composite Measure of Medication Hazard in Pre-Dialysis Chronic Kidney Disease (CKD) Min Zhan,[1] Clarissa Jonas Diamantidis,[3] Corinne Woods,[2] Jeffrey C. Fink.[3] *[1]Department of Epidemiology and Preventive Medicine, University of Maryland, Baltimore, MD; [2]Pharmaceutical Research Computing, School of Pharmacy, University of Maryland, Baltimore, MD; [3]Department of Medicine, University of Maryland, Baltimore, MD; [4]University of Maryland, Baltimore, MD.*

Background: Many medications require dosing modifications/special considerations in CKD. FDA guidance on medication precautions with low GFR vary and CKD patients have poly-pharmacy making it difficult to quantify the extent of their ***medication hazard***. We recorded the frequency of medications with precautions in the Safe Kidney Care (SKC) cohort, developed a composite measure of medication hazard, and identified factors associated with this measure.

Methods: SKC phase 1 participants (n=107) had baseline medications (prescribed and OTC) and last eGFR recorded. The SKC drug cross-walk flagged medications with dose precautions based on GFR and established FDA/literature-based recommendations. Unique flags included: excessive dose/frequency, avoid use, use with caution, reduce dose, individualize dose, and NSAID use. A distance procedure input the type and frequency of each precaution flag into a hazard measure using a Euclidian distance matrix of flags weighted by severity (SAS 9.2 User's Guide). Multiple regression identified factors associated with the hazard score.

Results: 1293 medications were recorded at baseline SKC visit. 94 (88%) participants had at least one hazard flag, and 684 (52%) medications were flagged with a precaution. The distribution of the composite hazard measure are shown in Figure 1.



Key factors predicting a higher hazard score (after adjusting for age, GFR, and race) included gender, diabetes, and cancer.

Conclusions: Medication precautions are common and diverse in CKD patients and single score can be used to characterize the burden of their medication hazard.

PUB752

Delayed Removal of of Chronic Candida Parapsilosis Infected Hemodialysis Permanent Catheter and Subsequent Adhesion of Catheter to the Vascular Tree and Atrium in a Noncompliant Patient Ebadur Rahman,[1] Raees Farhan Mushtaq,[1] Habib Rahman.[2] *[1]Nephrology, Riyadh Military Hospital, Riyadh, Saudi Arabia; [2]Nephrology, King Khaled University Hospital, Riyadh, Saudi Arabia.*

Background: To the best of our knowledge this is the first case of chronic candida parapsilosis fungemia complicated by catheter adhesion to the vascular tree and with grave outcome.

Methods: This is a case report of a 29-year-old Saudi male patient on maintenance Hemodialysis with history of poor compliance who was offered fistula creation several times but insisted on remaining in catheter for dialysis and had several hospital admissions for treatment of line related sepsis. During the last one year with the exposure of multiple antibiotics and the outbreak of candida parapsilosis (CP) infection in Hemodialysis unit, he acquired CP infection. Immediate removal of the infected line and anti fungal treatment was offered, but he refused. The blood culture remained positive for CP for one year although he was asymptomatic and he persistently refused to remove the catheter. Finally he agreed to remove the catheter as it was thrombosed. The vascular surgeons tried to remove but unfortunately they failed. Urgent CT Angio was done, which showed calcification in right atrium and the catheter tip was seen adherent to atrial wall. Patient was offered high-risk cardiac surgery for removal of adherent Permanentcatheter, but he declined any sort of intervention. A right jugular permanent catheter was inserted for hemodialysis as he refused femoral route. The patient left the hospital without any medical advice and was dialysing in other hospital. After 3-months he was admitted in ICU with massive left middle cerebral artery territory stroke and found to have vegetations in both aortic and mitral valves. Patient remained intubated and the treating consultants decided to only continue supportive management for him.

Conclusions: Chronic CP infection in hemodialysis catheter can cause catheter ahesion to the vascular tree with grave consequences.

PUB753

Chronic Kidney Disease Awareness in Primary Care: A Cross-Sectional Study in a Central European Country Yuki Tomonaga,[1] Thomas D. Szucs,[2] Lorenz Risch,[3] Patrice M. Ambuehl.[4] *[1]Institute of Social and Preventive Medicine, University of Zurich, Zurich, Switzerland; [2]European Center of Pharmaceutical Medicine, University of Basel, Basel, Switzerland; [3]Labormedizinisches Zentrum Dr. Risch, Schaan, Liechtenstein; [4]Renal Division, Stadtspital Waid, Zurich, Switzerland.*

Background: As severe chronic kidney disease (CKD) is usually identified based to typical symptoms, mild to moderate CKD in primary care remains mostly underdiagnosed. Our aim was to investigate the CKD-awareness in a primary care setting in Switzerland.

Methods: A multicenter, cross-sectional study with randomly selected general practitioners (GP) was performed. Adults visiting the GPs during defined periods were asked to participate. Demographic and social variables were collected. Urine and blood samples were analyzed in a central laboratory. Renal status was assessed calculating the estimated glomerular filtration rate (eGFR) and albumin-to-creatinine ratio (ACR), as suggested in the KDIGO classification [1]. For each patient, the GP had to indicate, based on the subject's personal clinical history and demographics, which laboratory analyses he deemed appropriate.

Results: 1000 individuals with mean age of 57±17 years were included. For subjects with either a substantial reduction in renal function (eGFR<60 ml/min/1.73m^2) or high levels of proteinuria (ACR>30 mg/g creatinine), plasma creatinine (PCr) or urinary albumin (UAlb) tests were considered appropriate for 39% and 22% of the cases, respectively. For patients without CKD, both analyses were considered significantly less useful (PCr: 29%, p=0.003; UAlb: 10%, p<0.001).

		eGFR<60 and/or ACR>30	
Test	Test appropriate?	Yes	No
Serum creatinine	Yes	9%	22%
	No	14%	55%
Urinary albumin	Yes	5%	8%
	No	18%	69%

Conclusions: Although GPs performed more analyses for patients with abnormal renal status, creatinine or albumin tests were considered necessary for less than 40% of the CKD patients. This indicates that the majority of the CKD patients may remain undetected due to a lack of CKD awareness in primary care.

PUB754

Baking Soda Pica in ESRD Patient with Severe Metabolic Alkalosis and Recurrent Hospitalizations Neha Garg, Isaiarasi Gnanasekaran. *Internal Medicine, Lincoln Medical and Mental Health Center, Bronx, NY.*

Background: Pica has been frequently reported in ESRD patients. Pica of alkali/ alkali precursors can lead to severe metabolic alkalosis with increased risk for cardiac arrhythmia, seizures, hypercapnia, hypoxemia, and cardio-pulmonary arrest. A pH >7.65 carries a high risk of mortality (up to 80%). Prompt recognition of pica is critical for patient safety. To our knowledge, this is the first reported case of life threatening metabolic alkalosis with peak pH of 7.71 in an ESRD patient secondary to pica.

Methods: 41 year old black male patient on maintenance hemodialysis for 17 months, requiring >4hrs of dialysis, 4-5 days a week for severe fluid overload with usual interdialytic weight gain of > 10kgs and weekly hospitalization. Patient was admitted to our hospital for acute respiratory failure due to fluid overload and severe metabolic alkalosis. Medical history was significant for diabetes mellitus, hypertension, right parietal skull fracture with subdural hematoma and subarachnoid hemorrhage. Patient was extubated after 5days of daily dialysis. Hospital course was significant for unexplained severe metabolic alkalosis with peak pH of 7.71, peak pCO2 of 77 mmHg, hypoxemia (pO2 of 54 mmHg), peak serum sodium and bicarbonate of 153 mEq/L and 56 mEq/L respectively, nadir serum chloride of 85 mEq/L and interdialytic weight gain of 12kgs (post-extubation). Patient denied GI symptoms. Hemoglobin was low (7.7gm/dL) with normal iron indices. Severe metabolic alkalosis and hypernatremia with excessive weight gain raised the concern for pica. On repeated questioning, patient acknowledged chewing rubber and plastic only. Later patient was witnessed to be consuming baking soda brought from home. Patient admits hiding this information for fear of criticism. Patient was evaluated by psychiatry service and extensive counseling was done with improvement in metabolic alkalosis and weight gain.

Conclusions: Though pica is highly prevalent in ESRD patients, it is under recognized. Besides GI acid loss, high bicarbonate dialysate use and regional citrate dialysis, pica should be suspected as a cause of metabolic alkalosis in ESRD. Failure to recognize pica may jeopardize patient safety.

PUB755

Causative Organisms and Antibiotics Susceptibility in Patients with Community Acquired Acute Pyelonephritis Who Adimitted to Emergency Room Dae-hong Jeon,[1] Dong Jun Park,[2] Se-Ho Chang,[2] Yeojin Kang,[2] Hyejung Ha.[3] *[1]Internal Medicine, Republic of Korea Airforce Eduction & Training Command Aerospace Medical Group; [2]Division of Nephrology, Gyeongsang National University Hospital; [3]Division of Nephrology, Jinju Korea Hospital.*

Background: Over the 10 years, ciprofloxacin has been used as one of antibiotics of choice for the empirical treatment of community-acquired acute pyelonephritis (APN), of which *Escherichia coli (E. coli)* is the main causative bacterium. Recently, however, some studies show that ciprofloxacin-resistant *E. coli* is increasing in APN. This study aimed to re-evaluate ciprofloxacin as one of initial antibiotics for APN according to the survey of the patients' clinical and microbiologic characteristics.

Methods: The records of 356 patients who visited Gyeongsang National University Hospital emergency room from Jan 01, 2000 to Dec 31, 2009 and diagnosed as APN were reviewed retrospectively. This study investigated the clinical characteristics of patients, causative organisms and annual change of antibiotics susceptibility to each antibiotics, associated factors that influence the ciprofloxacin resistance.

Results: According to the urine or blood cultures, the patients with isolated microorganism reached up to 60.4% (215/356) and *E. coli* occupied 84.2% (181/215) out of the isolates. Among the antibiotics chosen initially, ciprofloxacin was most common (75.0%, 267/356) and the third generation cephalosporin was next (23.0%, 82/356). The analysis of antibiotics sensitivity among 181 *E. coli* isolates, demonstrated that ciprofloxacin susceptibility was 81.8%. And in the recent 3 years, from 2007 to 2009, ciprofloxacin susceptibility was 87.7% and this was higher than the years before 2007 (77.8%). When the ciprofloxacin-resistant bacterium was isolated, the APNs had high tendency to be complicated by diabetes mellitus or urinary anatomical abnormalities.

Conclusions: For the community acquired APNs, among the *E. coli* isolates, there were no significant change in ciprofloxacin resistance by years. However, ciprofloxacin should be carefully used as initial antibiotics especially in case of the patients having diabetes mellitus or urinary anatomical abnormalities.

PUB756

Preclinical Safety of Baxter's Anti-MIF Antibody Barbara Dietrich, Frank Horling, Michael Thiele, Margit Spatzenegger, Randolf J. Kerschbaumer, Hans Peter Schwarz, Friedrich Scheiflinger, Eva-Maria Muchitsch. *Baxter Innovations GmbH, Vienna, Austria.*

Background: Baxter developed a fully human monoclonal antibody (BAX B01) directed against the human proinflammatory cytokine macrophage migration inhibitory factor (MIF). The antibody was expressed in a Chinese Hamster Ovary cell line using a plasma protein-free production process including two virus inactivation steps. BAX B01 exerts significant anti-inflammatory properties by neutralizing MIF. BAX B01 is currently being studied in patients with lupus nephritis.

Methods: The in-vivo safety evaluation of the anti-MIF antibody consisted of a safety pharmacology study in telemetered macaques and repeated doses toxicity studies in rats and macaques. In addition, tissue cross reactivity, cytokine release and compatibility with human blood was assessed in vitro.

Results: Treatment with BAX B01 did not result in any toxicologically relevant adverse effect on the cardiovascular or respiratory system at doses up to 200 mg/kg. The anti-MIF antibody was well tolerated in rats at weekly doses up to 250 mg/kg over a period of one month. No adverse effects could be detected in this species. Repeated administration of the anti-MIF antibody to macaques was well tolerated after weekly doses up to 200 mg/kg and no signs indicative of severe toxicity were observed. Dose-dependent, inflammatory signs in knee joints were evident at doses ≥50 mg/kg with partial recovery after a 4-week treatment-free period while similar findings were observed in elbow joints after a single dose of 25 mg/kg. In-vitro tissue cross reactivity on human and macaque tissues showed that the staining pattern was very much comparable. Furthermore, cross-reactivity to other antigenic sites was evaluated as unlikely. The anti-MIF antibody was very well compatible with human blood.

Conclusions: In summary, the results obtained from preclinical studies were basis for a safety profile which supported the initiation of human trials.

PUB757

CTP-499, a Novel Drug for the Potential Treatment of Chronic Kidney Disease, Possesses a Unique Metabolite Profile Lijun Wu, Kristine Hogan, Gary W. Bridson, Julie Fields Liu, Sophia Nguyen, Vinita Uttamsingh, Ara Aslanian. *Concert Pharmaceuticals, Lexington, MA.*

Background: CTP-499 is a novel agent in phase II clinical development for the treatment of diabetic nephropathy, a common cause of chronic kidney disease (CKD). It is structurally identical to the primary active metabolite M1 from pentoxifylline (PTX), except that several key deuterium atoms are present in place of hydrogen. Both M1 and PTX form common metabolites M2-M5 and share the pharmacological properties of inhibiting inflammation and oxidation. Their common downstream metabolites M5, and possibly M4, possess hemorrheologic effects. To date, CTP-499 (deuterated M1) has demonstrated anti-inflammatory, anti-oxidative, anti-fibrotic and reno-protective activities pre-clinically.

Results: In this study, CTP-499, PTX, and the metabolites M2-M5 were characterized for their activity in inhibiting the release of pro-inflammatory cytokines from stimulated human blood as well as inhibiting the formation of reactive oxygen species (ROS) from stimulated human neutrophils. Besides PTX and CTP-499, M2 was found to be the most active species, achieving 70% and 89% of the activity of PTX for TNF-α and ROS inhibition, respectively. In CTP-499-dosed rats, CTP-499 and M2 showed preferential distribution to the kidney, with a kidney to plasma exposure ratio of 2.3- and 8.3-fold (N=4), respectively, 4 hours post dosing.

In a human phase I study, CTP-499-dosed subjects had a significantly higher plasma exposure of M2 (increase of 138%, p= 0.00015) compared to PTX-dosed subjects, whereas similar exposures were found for CTP-499 vs. M1 formed from PTX, as well as for PTX vs. deuterated PTX formed from CTP-499 (D-PTX).

Conclusions: These data suggest that the M2 metabolite of CTP-499 and PTX is biologically active in inhibiting pro-inflammatory cytokines and ROS generation. Its preferential distribution to kidney in rats makes it a potentially very important contributor to the efficacy of CTP-499 in CKD. Since CTP-499-dosed subjects had higher exposures to M2 in comparison to PTX-dosed subjects, CTP-499 may offer potential advantages over PTX in treating CKD.

Assessment of Cyclohexanone Levels in Hemodialysis and Continuous Renal Replacement Therapy Systems and Patients: A Pilot Study Joshua D. King, Derek M. Fine. *Division of Nephrology, Johns Hopkins University, Baltimore, MD.*

Background: Hemodialysis (HD) is known to depress cardiac output, although the mechanisms behind this effect are somewhat unclear. Cyclohexanone (CHX), a solvent used in the synthesis of polyvinyl chloride medical devices such as intravenous (IV) fluid bags and tubing used in HD, has been shown to depress cardiac output and cause hypotension, and has been suggested as a possible mediator of these effects in dialysis. Previous studies have revealed the presence of CHX in IV medications and dialysate used for continuous renal replacement therapy (CRRT) in our hospital. We performed a pilot study to see if CHX is removed by several modalities of dialysis in dialysis circuits with and without patients.

Methods: We measured CHX levels via gas chromatography in saline samples and whole blood samples from HD patients. We also measured CHX levels in dialysate and saline used in sham models of HD and CRRT systems, as well as CHX levels in peritoneal dialysate.

Results: CHX was found to be present at detectable levels in saline and dialysate used for CRRT. CHX was undetectable in HD patients' blood before and after initiation of HD.

Cyclohexanone levels in hemodialysis patients

Patient	Saline	Initial blood	1.5 hr into HD	3 hr into HD
1	1.02	0	0	0
2	1.88	0	0	0
3	1.66	0		
4	1.42	0	0	0
5	3.2	0	0	0
6	1.72	0	0	0

All levels in mg/L

In sham models using saline run through dialysis systems, CHX was decreased in saline samples post-HD, but not in saline samples post-CRRT.

Cyclohexanone levels in sham hemodialysis systems (mg/L)

Sample	Saline	Pre-dialyzer	Post-dialyzer
1	4.4	5.0	1.08
2	2.6	2.4	1.74

Cyclohexanone levels in sham CRRT systems (mg/L)

Sample	Saline	Pre-dialyzer	Post-dialyzer	Dialysate
CVVHD	5.2	6.2	5.6	3.0
CVVH	3.4	5.6	4.2	

Further data regarding CHX levels in HD, CRRT and peritoneal dialysate are pending at this time.

Conclusions: Cyclohexanone is effectively removed by HD; however, it does not appear to be significantly removed by CRRT, possibly due to the presence of CHX in dialysate used for CRRT. Further human studies are needed to assess the clinical significance of this finding in patients undergoing CRRT.

Differential Expressions of miRNAs in Kidney in Puromycin Aminonucleoside Nephropathy Model and Intervened Effects of Leizhi Capsule Wei Sun. *Nephrology, Jiangsu Provincial Hospital of Chinese Medicine, Affiliated Hospital of Nanjing University of Chinese Medicine, Nanjing, Jiangsu, China.*

Background: Leizhi capsule (LZC) is widely used for reducing proteinuria. The aim of this study was to investigate the mechanism of LZC for reducing proteinuria and ameliorating podocyte in puromycin aminonucleoside (PAN) nephropathy rat.

Methods: Fifty male Wistar rats were randomly subdivided into five groups, control group (A), model group (B), LZC-treated group(C), multi-glycoside of *Tripterygium wilfordii* Hook. f. (GTW)-treated group (D), and valsartan-treated group (E). Except the rats in A group, PAN nephropathy model was induced by a single jugular vein injection of PAN at the dose of 100 mg/kg in B, C, D, and E groups. At the 2nd day after PAN nephropathy model was established, daily oral administration of LZC in C group, GTW in D group, valsartan in E group, and physiological saline in A and B groups as a control was started and lasted for 10 days. Proteinuria, glomerular ultrastructure, and glomerular immunofluorescence staining of dicer enayme, nephrin, podocin and synaptopodin were examined. The differential expressional characteristics of miRNAs in renal cortex were analyzed through biochip assay. Moreover, the differential expressional volumes of no-miR-23a, rno-miR-300-3p, rno-miR-24, and rno-miR-30c were measured by real-time PCR, respectively.

Results: In PAN-induced rats, proteinuria and podocyte foot processes effacement were investigated, as well as the expressions of nephrin, podocin, and synodopotodin were affected by dicer enayme. The differential expressional miRNAs in kidney included rno-miR-24, rno-miR-30c, rno-miR-23a, and rno-miR-300-3p. LZC could improve proteinuria, alleviate podocyte foot processes effacement, reduce the expression of dicer enayme, increase the expressions of nephrin, podocin, and synodopotodin, and regulate the differential expressional miRNAs as well in PAN nephropathy model.

Conclusions: In PAN nephropathy rat, with the treatment of LZC, proteinuria can be reduced and the expressions of nephrin, podocin, and synaptopodin can be regulated, the mechanism of which is probably due to intervening dicer enayme and differential expressions of miRNAs in kidney.

The Role of Rosuvastatin in the Cyclosporine Induced Nephropathy in Rats Young Ki Son,[1] Hyun Kyung Nam,[2] Won Suk An,[1] Ki Hyun Kim,[1] Seong Eun Kim.[1] *[1]Division of Nephrology, Dong-A University Hospital, Busan, Korea; [2]Divisin of Nephrology, Busan Medical Center, Busan, Korea.*

Background: Cyclosporine (CsA) – induced kidney injury is characterized by renal dysfunction with interstitial fibrosis, inflammatory cell infiltrations and glomerular sclerosis. Pleiotropic effects of statins may exert anti-inflammatory and anti-arteriosclerotic actions beyond lipid control. The aim of this study was to investigate the effect of rosuvastatin (RUS), which has anti-inflammatory and anti-fibrotic effects, on chronic CsA-induced nephropathy in a rat model.

Methods: Male Sprague Dawley rats fed with low sodium diet were divided into four treatment groups: control (0.9% saline injection), CsA (15mg/kg/day by s.c.), CsA + rosuvastatin (CsA plus rosuvastatin 10mg/kg/day by p.o.). Renal function, cyclosporine level and lipid level were measured at the end of 4 weeks. The expression of ED-1, transforming growth factor (TGF-β1) and α-smooth muscle actin (α-SMA) were examined by western blot analysis. The expression levels of apoptosis-associated factors were examined by western blot analysis. Apoptosis was detected using TUNEL method.

Results: Kidney function was decreased in CsA-treated rats compared with controls, which was attenuated by RUS. RUS did not affect lipid level and blood CsA level. Tubular atrophy, interstitial fibrosis, and glomerular change in CsA-treated rats were attenuated by RUS supplementation. The expression of ED-1, α-SMA, fibronectin, TGF-β1, Smad2/3, and Smad4 was increased in the CsA-treated rats, which was attenuated by RUS. In addition, RUS prevented CsA-induced increased expression of Bax/Bcl-2 ratio. TUNEL staining showed that RUS inhibits CsA-induced tubular apoptosis.

Conclusions: RUS supplementation can reduce or reverse CsA-induced nephropathy through suppression of proinflammatory pathways, profibrotic pathways and apoptotic factors.

PUB761

The Study of the Induction of AGEs on Transdifferentiation of Rat Aortic Smooth Muscle Cells Ruoyun Tan, Min Gu, Chao Liu, Pei Lu. *Department of Urology, The First Affiliated Hospital Nanjing Medical University, Nanjing, Jiangsu, China.*

Background: Objective To investigate the mechanism of advanced glycosylation end products(AGEs) involved in the progression of artherosclerosis after kidney transplantion.

Methods: The fifth SD rat aortic VSMCs was an *in vitro* culture system. The VSMCs were incubated with 200mg/L AGEs or BSA for 12h~12d, then the cells were collected and detected the expressions of alpha-smooth muscle actin(a-SMA), RUNX2 and Osteopontin(OPN) by Western blot and indirect immunofluorescence staining assays.

Results: The abundance of a-SMA was very high in the second to fifth SD rat aortic VSMCs. Compared with normal control or the cells treated with BSA, AGEs can reduce a-SMA protein expression (P<0.05) and the percent of a-SMA positive cells in rat aortic VSMCs in a time-dependent manner(P<0.05). Meanwhile, the expression of RUNX2 protein was rapidly induced after AGEs treatment for 12h(P<0.05), and followed up, the expression of OPN was also increased in rat aortic VSMCs cells(P<0.05).

Conclusions: These results suggest that AGEs maybe act as a key role in the procession of artherosclerosis after kidney transplantion through inducing transdifferentiation of VSMCs to osteoblast-like cells by upregulation of RUNX2.

PUB762

Tacrolimus Induces Glomerular Injury via Endothelial Dysfunction Caused by Reactive Oxygen Species and Inflammatory Change Kengo Kidokoro, Minoru Satoh, Hajime Nagasu, Yuko Nishi, Tamaki Sasaki, Naoki Kashihara. *Nephrology and Hypertension, Kawasaki Medical School, Kurashiki, Okayama, Japan.*

Background: The calcineurin inhibitor (CNI) tacrolimus (FK506) is used clinically to reduce the rejection rate in patients with kidney transplantation; however, the resultant nephrotoxicity remains a serious problem. Multiple factors have been reported to mediate the pathogenic mechanisms underlying CNI nephrotoxicity including activation of the renin angiotensin system. In the present study we have attempted to elucidate the mechanisms of glomerular injury induced by FK506 and the renoprotective effects of the angiotensin II receptor blocker telmisartan.

Methods: Seven-week-old male Wistar rats were divided into three groups: vehicle group, FK506 group, and FK506 + telmisartan group. After 8 weeks, we assessed kidney function and renal morphological changes including oxidative stress. We also assessed the effect of FK506 in human glomerular endothelial cells (hGECs) with regard to reactive oxygen species (ROS).

Results: Systolic blood pressure did not differ between groups. Serum creatinine and urinary protein excretion were significantly higher in the FK506 group compared with the other two groups. FK506 induced ROS production via activation of NAD(P)H oxidase in the glomeruli. Expressions of p47*phox* and p67*phox* mRNA were significantly increased in isolated glomeruli from the FK506 group. Expression of ICAM mRNA was increased in glomeruli from the FK506 group. These effects resulted in macrophage infiltration into the glomeruli. FK506 directly promoted NAD(P)H oxidase activity and accelerated production of ROS in hGECs. Conversely, co-treatment with telmisartan inhibited both NAD(P)H oxidase activity and production of ROS.

Conclusions: The present findings indicate that oxidative stress induced by FK506 in glomerular endothelial cells is involved mainly in NAD(P)H oxidase activity and subsequently induces inflammatory changes. This action could play a role in vascular injury and in complications associated with the long term use of FK506.

PUB763

Increased HLA Mismatches Promote Clinically Significant De Novo Donor-Specific Antibody Formation Rajat Joshi, Danielle Ladie, Kristina Krecko, Robert Scott, Kenneth Bogdanovich, Harold Yang, Mary Waybill, Seth Narins. *Transplantation, PinnacleHealth.*

Background: Antibody formation against human leukocyte antigens(HLA) is associated with graft dysfunction and loss in renal transplant recipients. We have shown that recipients with positive leukocyte antibody panel(LABB) tests demonstrate higher total numbers of HLA mismatches as compared to patients with negative LABB, and that positive-LABB recipients demonstrate donor and class-specific antibody against mismatched HLA loci with increased serum creatinine levels. It is unknown if differences exist in class identity of HLA mismatches observed.

Methods: This is a retrospective analysis of 106 renal transplant patients undergoing LABB testing October 2010-June 2011. LABB was positive in 49 patients and negative in 57 patients. There were no significant demographic differences between the two groups. Two LABB-negative patients were excluded due to insufficient HLA documentation(*n*=55). Recipient and donor HLA were compared for mismatches at A,B,DR and DQ loci. Student's T-Test was used to compare the differences in mean total, class-specific, and loci-specific HLA mismatches.

Results: LABB-positive patients demonstrated significantly more total HLA mismatches and mismatches in both Class I & Class II HLA than LABB-negative patients. Increasingly significant differences were seen at the A(p=0.0315), B(p=0.0025) and DR loci(p<0.0001), respectively.

HLA Mismatches	Negative LABB(Mean+/-SEM)	Positive LABB(Mean+/-SEM)	p-Value
Total	3.07+/-0.29	4.49+/-0.31	0.0013
Class I	1.87+/-0.18	2.51+/-0.18	0.0141
Class II	1.20+/-0.15	1.98+/-0.18	0.0013
HLA-A	0.82+/-0.11	1.15+/-0.10	0.0315
HLA-B	1.05+/-0.10	1.52+/-0.10	0.0025
HLA-DR	0.69+/-0.10	1.31+/-0.10	<0.0001
HLA-DQ	0.67+/-0.10	0.88+/-0.11	0.1520

Conclusions: Significantly more HLA mismatches were observed in LABB-positive kidney transplant recipients at both Class I & II HLA loci and may promote donor-specific antibody production and subsequent renal dysfunction. The greater statistical significance that exists for HLA-DR and HLA-B mismatches supports previous data demonstrating increased risk for graft loss with mismatches at these loci, and may warrant more rigorous antibody monitoring in post-transplant HLA-mismatched patients.

Zinc-N-Acetylcysteine Inhibits Cell Death during Cold Storage of Kidneys
Mandeep Singh, Eugene Apostolov, Alexei G. Basnakian. *[1]Nephrology, University of Arkanasas for Medical Sciences, Little Rock, AR; [2]Nephrology and Pharmacology, University of Arkansas for Medical Sciences, Little Rock, AR; [3]Pharmacology and Nephrology, University of Arkansas for Medical Sciences, Little Rock, AR.*

Background: Cold storage of the kidneys is a major problem in USA. Of all the donated kidneys 16% are discarded due to limited viability because of the cold storage induced cell death.

Methods: Zinc-N-acetylcysteine (ZnNAC) was synthesized in our laboratory. Its antioxidant and anti-endonuclease activities were tested by Trolox equivalent antioxidant capacity assay and plasmid incision assay respectively. The pattern of DNA degradation in male rat kidneys stored in the University of Wisconsin solution (UWS) at 0ºC, 22ºC and 37ºC was studied. To study the effects of ZnNAC on cell death, rat kidney cells were stored at 0 degree Celsius in UWS or ZnNAC (0.3-30 mM in UWS) for 24 hours (in vitro) and the rat kidneys were flushed with pre-cooled UWS or ZnNAC (0.3-30 mM in UWS), and then stored in the same solutions for 24 hours (ex vivo). Propidium iodide assay was used to assess the rat kidney cell death in vitro. TUNEL assay was used to quantify DNA fragmentation indicating irreversible cell death ex vivo. The quantification of cleaved caspase-3 and endonuclease G was done by immunohistostaining of the rat kidney tissue section slides from the 10 mM ZnNAC experiment and control groups. Rat kidney cells stored in 10 mM ZnNAC group were stained with flourophobe, TFL ZN to stain intracellular zinc.

Results: DNA fragmentation (cell death) was significantly inhibited but at 0ºC as compared to 22ºC and 37ºC. Tubules were affected more than glomeruli. The cell death was significantly inhibited both in the cortex and medulla by ZnNAC at concentrations 1-30 mM, with the maximum effect reaching at 10 mM. Immunohistostaining showed that the expression of cleaved caspase 3 and endonucleases were also markedly inhibited by ZnNAC at 10 mM. TFL Zn stain showed that NAC delivers zinc inside the cells.

Conclusions: ZnNAC in UWS can inhibit caspase 3 and endonucleases, and cell death in kidneys during cold storage.

The Nature of Cylcosporine Induce Tubular Vacuolization
Chi-Hung Cheng, Kuo-hsiung Shu. *Nephrology Section, Taichung Veterans General Hospital, Taichung, Taiwan.*

Background: Cyclosporine (CsA) induce characteristic tubular vacuolization (TV) in renal tubular cell. Previous study showed tha TV was endoplasmic reticulum (ER) in orgin. However the nature CsA induced TV and the relationship between CsA induce ER stress remain unknwon.

Methods: Proximal tubule NRK52E cells was used as an in vitro model and acute CsA nephrotoxicity in Sprague Dawley rats was used as an in vivo study.

Results: In our in vitro study of NRK52 cell line, we showed that CsA-induced TV was ER in origin and was a reversible process. CsA-induced nephrotoxicity overexpressed chaperones mainly within the endoplasmic reticulum of the integrated stress response (ISR) related proteins -Bip/Grp78, ATF6, IRE1 and CHOP. Cytoplasmic ER stress related chaperones-HSP70, HSP 40, HSP27, HSP90 and HSP60 was not overexpressed after CsA treatment. Among the ISR chaperones, Bip/Grp78 was overexpressed on the membrane of TV. Blocking Bip/Grp78 by shRNA inhibited CsA induced TV formation and enhanced CsA induced cell death.

In our in vivo study of acute CsA nephrotoxicity in rat, we found that CsA induced TV had characteristic striped pattern in tubular interstitial. Moreover Bip/Grp78 was overexpressed within TV which was similar to our obervation in our in vitro study.

Conclusions: In summary, we demonstrated that CsA induced TV was a reversible process in which Bip/Grp78 over-expression is essential for TV formation. Inhibition of Bip/Grp78 inhibit TV formation and enhanced CsA toxicity. It is possible that Bip/Grp78 expression and TV formation may be involved in cellular defense mechanism against CsA nephrotoxicity.

PUB766

Outcome of the Kidney Transplantation (KT) in Patients with Liver Cirrhosis (LC)
Kyeong Woo Nho, Su-Kil Park, Soon Bae Kim. *Nephrology, Division of Nephrology, Department of Internal Medicine, College of Medicine, University of Ulsan, Asan Medical Center, Seoul, Korea.*

Background: Patients with established LC on biopsy are at risk for frank hepatic decompensation after transplantation, and KT alone without simultaneous liver transplantation is contraindicated [Textbook of KT, 5th ed.]. We retrospectively reviewed outcome of the KT in patients with liver cirrhosis.

Methods: We performed 13 KT (10 males, age 43±10year) in patients with LC during 1995~2011 and followed-up for median 55 months (range 13-202). The causes of LC are hepatitis B virus in 10, hepatitis C virus in 1, alcohol in 1 and unknown in 1. Diagnosis of LC was based on liver biopsy in 9, on imaging study in 4. One patient biopsied after 16 months after KT, because of the elevation of liver enzymes, AST increased to 144 and ALT to 238. Liver enzymes returned to normal at 6 months after biopsy.

Results: Serum creatinine increased by 2 fold in 3 patients (23%) during follow-up. Two patients received hemodialysis (HD). One patient who started HD at 196 months after KT showed recurrent IgA nephropathy on biopsy. The other patient received HD 56 months after KT. Child class before KT was A in 8 and B in 5. There was no class C. HCC was found in 2 patients (15%) at 31 and 58 months after KT, respectively. When HCC was found, liver enzymes were within normal limit. In 1 patient, who was diagnosed as HCC at 58 months after KT, radiofrequency ablation (RFA) was done 4 times and trans arterial chemo embolization (TACE) was done 3 times. He started HD at 58 months after KT. His Child class was A before KT, however, he died of hepatic decompensation at 33 months after HCC. He was the only mortality. Other patient was diagnosed HCC 31 months after KT. TACE was done 4 times. Pulmonary metastatic nodules were found 21 months after HCC was confirmed. He received Sorafenib chemotherapy. At last follow up, this April, there was no recurred HCC, however, pulmonary metastatic nodules were increased. His kidney function did not change 59 months after KT. His CPS was B before KT and didn't change.

Conclusions: In conclusion, KT may be performed in patients with LC.

PUB767

No Association between Day One Renal Allograft Resistive and Perfusion Indices and Twelve Month Glomerular Filteration Rate
Sajan Thomas,[1] Wai Hon Lim,[1] Gursharan K. Dogra.[1] *[1]Nephrology, Sir Charles Gardner Hospital, Nedlands, WA, Australia; [2]Nephrology, Sir Charles Gardner Hospital, Nedlands, WA, Australia; [3]Nephrology, Sir Charles Gardner Hospital, Nedlands, WA, Australia.*

Background: Renal function within the first year after transplantation has been reported to be an important factor affecting graft survival.However there is no reliable method to predict 1 year allograft function in stable renal transplant recipients. Doppler ultrasonography and MAG3 scan has been the corner stone for assessing immediate graft function post renal transplant.The present study aims to explore the association between early post renal transplant parameters and 12 month graft function.

Methods: We performed a retrospective, observational study and included both live and deceased donor renal transplant recipients between 2008 and 2009 at Sir Charles Gardner Hospital,WA. Early post transplant parameters measured were day 7 GFR, Day 1 Resistive Index and Day 1 Perfusion Index. The outcome assessed was 12 month MDRD-derived glomerular filtration rate (GFR).

Results: In this transplant cohort OF 68 patients, 13% and 21% had abnormal resistive (>0.8) and perfusion (>250) indices respectively. In patients with RI>0.8, the mean Day 7 and Year 1 GFR were 38.2 and 39.8 respectively. However, in patients with RI 250, the mean Day 7 and year 1 GFR were 32.6 and 45.6 respectively while those with perfusion index<150 the mean Day 7 and year 1 GFR were 55.2 and 56.8 respectively attaining statistical significance(p=0.002 and 0.10 respectively).On the univariate regression analysis, Day 7 GFR was closely associated with Year 1 GFR (P<0.001) which was maintained on the multivariate regression analysis after adjusting for the confounding variables.(P=0.01) .The Resistivity index had no association with year 1 GFR in the univariate regression analysis.

Conclusions: There was no association between Day 1 resistive and perfusion indices in the transplant cohort and Day 7 graft function however we found a strong correlation between Day 7 GFR and year 1 graft function.

PUB768

Prevention and Treatment of Polyomavirus-Associated Nephropathy: Clinical Approach Including the Association of Sirolimus and Leflunomide
Caroline Lamarche,[1] Anne Boucher,[2] Raymond Dandavino,[2] Lynne Senecal,[2] Suzon Collette,[2] Duy Tran,[2] Michel Vallee.[2] *[1]Internal Medicine, Hopital Maisonneuve-Rosemont, Université de Montréal, Montreal, QC, Canada; [2]Nephrology, Hopital Maisonneuve-Rosemont, Université de Montréal, Montreal, QC, Canada.*

Background: Polyomavirus-associated nephropathy (PVAN) is an important cause of graft failure, affecting 1-10% of renal transplant patients. Systematic screening and diminution of immunosuppression is now a standard of care, but no specific protocol has been proven superior. Sirolimus and leflunomide are two potential therapeutic agents, but they have never been evaluated in combination.

Methods: In this retrospective cohort study, we reviewed the clinical data of 173 renal allograft recipients transplanted from June 2006 toDecember 2010. We routinely screened for BK viremia (BKV) by real time PCR and performed graft biopsy if viremia was significant ($\geq 10^4$ copies/mL) and sustained or if there was renal dysfunction.

Results: 43 patients (24,9%) developed a BKV-viremia of more the 100 copies/mL. Patients were separated into three groups: (i) definitive PVAN defined by biopsy (n=17), (ii) presumptive PVAN defined by plasma BKV-viremia of $\geq 10^4$ (n = 8) and (iii) low BKV-load defined by BK-viremia $< 10^4$(n = 18). MMF dose has been decreased by 50% in 31 patients, 12 patients have been switched to sirolimus and 9 received leflunomide. 11/43 patients (25.6%) have not cleared viremia and 3/43 (7,0%) had a clinical rejection, all in the PVAN group. In the PVAN group, 8/17 received the combination of sirolimus and leflunomide;7/8 (87.5%) have persistent positive viremia after an average of 23 months of follow-up, but 6/8 have stable renal function.

Conclusions: MMF reduction alone is effective to treat most of low BKV-viremia or presumptive PVAN. Acombination of sirolimus and leflunomide for PVAN patients is not an effective therapy to clear viremia.

PUB769

Minimizing Exposure to Calcineurin Inhibitors in Kidney Transplant: Should We Use Only Tacrolimus Raquel Vaz, Maria Francisca Barros, Ana Teresa Nunes, Isabel Tavares. *Serviço Nefrologia, HSJ, Porto, Portugal.*

Background: Protocols to minimize exposure to calcineurin inhibitors (CNI) intend to be a safe way to maintain graft function and avoid some risks of excessive immunosuppression, without increasing rejection. Our aim was to evaluate the impact of minimizing exposure to CNI in acute rejection rate and graft function after 1 year of follow-up; and to identify differences between two CNI used in minimization protocols.

Methods: Retrospective evaluation of 52 consecutive deceased kidney transplants performed at our institution in 2010 and followed for 1 year. 14 patients received induction with basiliximab and maintenance with mycophenolate mofetil(MMF), prednisolone(PDN) and low-dose tacrolimus (TAC)(trough levels 3-7ng/mL) or cyclosporine (CSA)(trough levels 50-100ng/mL). 29 patients were subjected to basiliximab, MMF, PDN and standard dose TAC or CSA. 9 patients receive MMF, PDN and standard dose TAC or CSA, without basiliximab. Graft function was evaluated by serial serum creatinine and renal biopsy was performed if dysfunction.

Results: Patients of low-dose protocol were older (p=0.002) and more frequently received kidneys from expanded criteria donors (ECD) (p=0.019), but didn't had differences in PRA or number of mismatchs. Initial graft function and serum creatinine at discharge were similar between groups (p=0,893). At 1-year 28,6% of CNI minimization patients had acute rejection versus 17,2% in basiliximab+standard dose CNI and 22.2% in standard dose CNI patients, but it wasn't statistically significant (p=0,427). This high rejection rate in minimization group stemmed mainly from patients taking CSA, who had 42,8% of rejection compared to 14,3% in TAC (but not statistically significant, p=0.559). Renal function at 1-year was similar, regardless the type of CNI used(p=0,233).

Conclusions: Minimization protocol with TAC allowed good graft function and rejection rates similar to standard protocols. However, we found a prohibitive incidence of rejection in low-dose CSA which, even not being statistically significant (probably because of the low number of patients enrolled), shows a trend and must compel us to revise the strategy of immunosuppression at our unit.

PUB770

Sympathetic Overactivity after Renal Transplantation and Calcineurin Antagonists Administration Dan Sapoznikov, Michal Elhalel, Dvora Rubinger. *Nephrology and Hypertension Services, Hadassah University Medical Center, Jerusalem, Israel.*

Background: The arterial blood pressure is believed to be controlled by both baroreflex and feedforward centrally activated sympathetic (non-baroreflex) mechanisms. The latter are characterized by an inverse relationship between systolic blood pressure (SBP) and the interbeat interval (IBI).This study was undertaken to define non-baroreflex episodes in patients with end stage renal disease on chronic hemodialysis (HD) and after renal transplantation (TX).

Methods: Continuous IBI and SBP were monitored in chronic HD (n=73), in TX patients with normal renal function (n=53) treated with calcineurin antagonists (CAN) and in control (C) individuals (n=50).Overlapping one minute time windows at one beat steps were selected for analysis of beat-to-beat IBI-SBP relationship.

Results: The percentage (%) of epochs (*Ep*) with inverse SBP-IBI relationship (median and interquartile range) was 20 (57) in C, 13(52) in HD and 73(72) in TX (p< 0.01 vs. C and HD). The SBP-IBI regression coefficients (*b*) were correlated with age, the variability of interbeat intervals (IBI) in the low frequency (LF) range (LF IBI, LF SBP), LF α (square root of LF IBI and LF SBP ratio) and baroreceptor slope (Table 1). LF oscillations are believed to be representative of sympathetic nervous system activation.

Table 1.

	C		HD		TX	
	r	p	r	p	r	p
Age	-0.524	0.001	-0.337	0.005	-0.379	0.007
LF IBI	0.577	0.001	0.679	0.001	0.598	0.001
LFα	0.772	0.001	0.757	0.001	0.858	0.001
sd IBI	0.528	0.001	0.680	0.001	0.634	0.001
Slope	0.733	0.001	0.671	0.001	0.685	0.001

b was enhanced in TX patients treated with cyclosporine as compared with those treated with tacrolimus. % *Ep* and *b* were not affected by antihypertensive drugs administration.

Conclusions: Our data show: 1.In all patients, *b*, representative of the magnitude of SBP-IBI relationship, is significantly correlated to markers of sympathetic activation and baroreflex slope, but decreases with age ;2. % *Ep* is markedly increased in transplanted patients as compared with both C and HD; 3. *b* is increased in patients treated with cyclosporine. Our results support the hypothesis that non-baroreflex episodes are representative of sympathetic overactivity, which is significantly enhanced after renal TX and chronic CAN exposure.

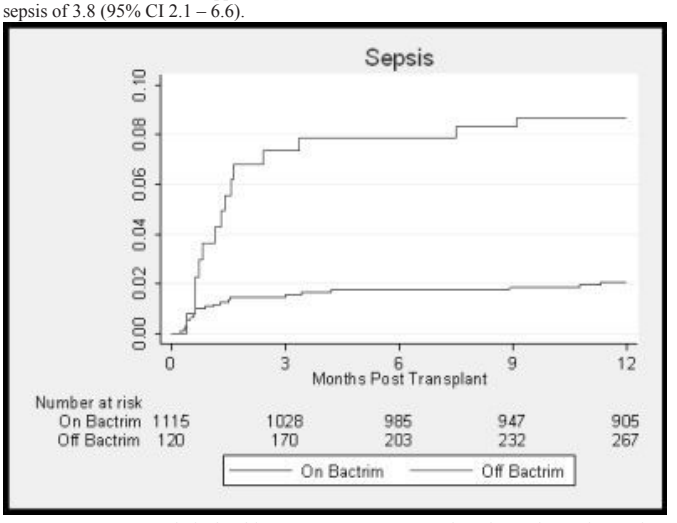
PUB771

Sulfamethoxazole-Trimethoprim Reduces the Rate of Sepsis after Kidney Transplan Timothy A. Horwedel,[1] Lyndsey Bowman,[1] Daniel C. Brennan,[2] Georges Saab.[2] *[1]Pharmacy, Barnes-Jewish Hospital, St. Louis, MO; [2]Nephrology, Washington University in St. Louis, St. Louis, MO.*

Background: Sepsis is associated with significant costs, morbidity, and mortality in renal transplant recipients. SMX-TMP is used for prophylaxis of *Pneumocyctis jirovecii* Pneumonia. SMX-TMP may prevent other infectious complications, such as urinary tract infections (UTI), post-transplant and thus prevent sepsis.

Methods: We included renal transplant recipients who were transplanted between 1/2002 – 12/2010, allowing for >1 year of follow-up. Data were extracted from electronic patient records. The primary outcome was time to first septic episode. Secondary outcomes included UTI and pneumonia. Time to sepsis was analyzed using Cox-regression with time-dependent covariates.

Results: Data were collected on 1235 patients: 61% were male; 76.7% where Caucasian; and mean age was 50.2 years. Overall, 5.2% of patients experienced sepsis which occurred earlier (within 3 months) and was more frequent among those not receiving SMX-TMP (16.2 vs. 4.2%, p <0.001). More UTIs occurred in the non- SMX-TMP group (44.4 vs 23.7%, p <0.001). A genitourinary source was found in 61.9% of sepsis cases. There was a higher rate of SMX-TMP resistant infection in the patients who received SMX-TMP (74.1 vs 21.4%, p = 0.002). After multivariate adjustment for age, induction, and maintenance immunosuppression, lack of SMX-TMP was associated with a HR for sepsis of 3.8 (95% CI 2.1 – 6.6).



Conclusions: Prophylaxis with SMX-TMP prevents sepsis and UTIs in renal transplant recipients, but is associated with SMX-TMP resistance. Alternative UTI prophylaxis during the first three months after transplant should be considered in those intolerant of SMX-TMP.

PUB772

Immunosuppression and Outcomes for Expanded Criteria Donor (ECD) Kidney Transplants: Four-Year Data from the Mycophenolic Acid Observational Renal Transplant (MORE) Registry Kimi Ueda Stevenson,[1] Cataldo Doria,[2] A. Wiland,[3] Kevin M. Mccague,[3] V. Ram Peddi.[1] *[1]California Pacific Medical Center, CA; [2]Thomas Jefferson University Hospital, PA; [3]Novartis, NJ.*

Background: The literature indicates a higher rate of failure with ECD than standard criteria donor (SCD) grafts, with a demonstrable survival difference as early as one year post-transplant.

Methods: MORE is a prospective, observational registry of *de novo* kidney transplant recipients receiving mycophenolic acid (MPA) as mycophenolate mofetil (MMF) or enteric-coated mycophenolate sodium (EC-MPS), managed according to local practice. Data were analyzed for ECD vs SCD grafts. ECD was defined as donor ≥60 years, or 50-59 years with two of the following: hypertension, serum creatinine >1.5mg/dL, or cerebrovascular accident death.

Results: 103 ECD (29 MMF/74 EC-MPS) and 838 SCD (277 MMF/561 EC-MPS) patients were analyzed. ECD vs SCD transplants had older donors (mean 61 vs 39 years, p<0.01) and older recipients (62 vs 50 years, p=0.02). Other characteristics did not differ significantly. ECD and SCD groups were similar regarding use of induction (100% and 99%), tacrolimus (97% and 95%) and steroids (74% and 74%). Compared to the SCD group, fewer ECD patients received full MPA dose (2.0g MMF, 1.44g EC-MPS) at months 3, 24 and 36 (all p<0.03). At 4 years, biopsy-proven acute rejection (BPAR) (11% vs 13%, p=0.66) and all-cause graft survival (91 vs 94%, p=0.12) were similar for ECD vs SCD transplants; patient survival was 85% vs 96% (p<0.01). Efficacy was similar in both groups for MMF- vs EC-MPS-treated patients, except for patient survival in the SCD group (93% vs 97%, p=0.01). Mean (SD) serum creatinine was 1.9 (1.0)mg/dL vs 1.5 (1.3)mg/dL for ECD vs SCD patients, respectively (p=0.05). Reported adverse events were similar (i) between ECD and SCD groups except cardiovascular events (15% vs 7%, p=0.01) and (ii) for MMF vs EC-MPS groups except for infections among ECD patients (45% vs 22%, p=0.03).

Conclusions: In contrast to published data, graft survival was similar in recipients of ECD or SCD kidneys at four years post-transplant. Additionally, despite receiving less MPA, the incidence of BPAR was similar in ECD and SCD patients.

PUB773

Corticosteroid Withdrawal (CSW) Following Kidney Transplantation: 4-Year Data from the Mycophenolic Acid Observational Renal Transplant (MORE) Registry Kimi Ueda Stevenson,[1] A. Wiland,[2] Kevin M. Mccague,[2] V. Ram Peddi.[1] *[1]California Pacific Medical Center, CA; [2]Novartis, NJ.*

Background: CSW may reduce steroid-related complications but results are conflicting. Long-term evidence from real-life practice is sparse.

Methods: The MORE registry is a prospective, observational study of *de novo* adult kidney transplant patients receiving mycophenolic acid (MPA) at 40 US centers, managed according to local practice. Four-year data from tacrolimus-treated patients were analyzed. CSW was defined as steroid withdrawal by month 3.

Results: The CSW (n=363) and steroid continuation (CSC, n=509) groups were similar except more CSW patients had panel reactive antibodies <30% (90% vs CSC 77%, p<0.01) with a trend to more living donors (46% vs CSC 41%, p=0.09). More CSW vs CSC patients received induction with rabbit ATG (62% vs 59%, p=0.02) or alemtuzumab (24% vs 55%, p<0.01). Tacrolimus trough levels were similar. Fewer CSW patients received the full daily MPA dose (1.44g EC-MPS, 2.0g MMF) vs CSC patients at all timepoints (all p<0.01). In the CSC group, but not the CSW group, more patients were maintained on full MPA dose in year 1 with EC-MPS vs MMF (month 1 p=0.05; month 3, p=0.03; month 6, p=0.03; month 12, p=0.03). Biopsy-proven acute rejection was similar with CSW vs CSC (10% vs 14%, p=0.12) but graft survival was higher (97% vs 94%, p=0.03); patient survival was similar (96% vs 95%, p=0.65). Final mean serum creatinine was 1.6g/dL with CSW vs 1.5g/dL with CSC (p=0.38). Adverse events were similar except for neutropenia (CSW 17%, CSC 11%; p=0.01) and leukopenia (CSW 61%, CSC 30%; p<0.01), with a trend to fewer infections in the CSW group (25% vs CSC 31%, p=0.06).

Conclusions: In this real-life population of patients receiving tacrolimus and MPA, CSW patients received more aggressive induction therapy and were less likely to receive the full dose of MPA than CSC patients. Greater use of lymphocyte-depleting induction may have led to lower MPA tolerability and higher hematological toxicity in CSW patients. Despite a similar rate of BPAR, long-term graft survival was superior with CSW than CSC, possibly due to lower immunological risk and numerically more living donors.

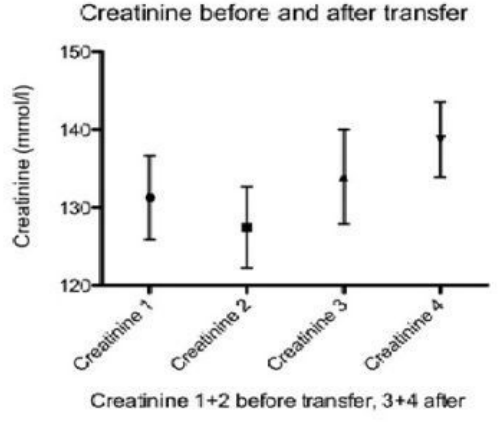
PUB774

Creatinine in Renal Transplant Recipients Following Transfer Back to Referring Centre Adarsh Babu. *Department of Nephrology, Gloucestershire Royal Hospitals NHS Trust, Gloucester, United Kingdom.*

Background: Renal transplant recipients are followed up at transplant centres for six months, before being transferred back to referral centres. In paediatrics transition to adult care is associated with an increase in creatinine, reduced compliance with immunosuppression and increased graft loss. There is limited data on changes in renal function following change of follow-up centre in adults prompting us to this study.

Methods: All patients who were transferred back to the referring centre following renal transplant in the time period between 2004 to 2010. Demographics, transplant and referral back dates were collected.Creatinine values were collected prior to and after transfer using the electronic patient records. Creatinine values were corrected to IDMS standardisation at both centres.Last two creatinine values prior to transferand first two creatinine results after transfer, were analysed using repeated measure ANOVA.

Results: 38 patients were transferred back to the referring centre during the period studied. We compared the last two creatinine values in transplanting centre prior to transfer (labelled as creatinine 1 and 2) and first two creatinine values post transfer (labelled as creatinine 3 and 4). The mean creatinine values were: creatinine 1 131.3mmol/l, creatinine 2 127.4mmol/l, creatinine 3 133.99mmol/l, creatinine 4 138.76mmol/l.



Repeated measure ANOVA shows a significant difference between the mean creatinine before and after transfer (P=0.0064).

Conclusions: The reasons for rise in creatinine are complex and not made clear in this study. It could be related to expertise, reduced intensity of follow-up and review. Non-compliance and psychological factors may also play a role. In our opinion, a useful next step would be replication of these results in a larger group of patients from multiple centres, and comparison with controls remaining at transplanting centres.

PUB775

Effects of Calcineurin Inhibitor Reduction/Withdrawal on Renal Allograft Function and Lipid Control: A Retrospective Analysis Husham Rasheed, Mark J. Andrews, Mahzuz Karim. *Renal Medicine, Norfolk and Norwich University Hospital, Norwich, Norfolk, United Kingdom.*

Background: Calcineurin inhibitors (CNI) have played a central role in immunosuppressive protocols. However, their long term use can contribute to progressive chronic allograft dysfunction and eventual graft failure. The aim was to establish whether CNI reduction or elimination had any effect on progressive graft dysfunction or lipid control in patients in a single centre experience.

Methods: All renal transplant patients in our centre who had undergone immunosuppressive drug substitution (to reduce ongoing CNI exposure) were retrospectively identified. For each patient the serum creatinine at the time of switch and time points closest to one year before and one year after were collated, and the rates of change of creatinine over time pre- and post-switch were compared, together with changes in requirements for lipid-lowering therapy.

Results: 39 patients were identified: 21 switched from CNI to sirolimus and 18 switched from azathioprine to MMF with reduction in CNI dose. Indications for switches were: biopsy-proven CNI toxicity (11/21 in sirolimus group, 6/18 in MMF group), progressive chronic allograft dysfunction without biopsy (8/21, 7/18), and other indications (2/21, 5/8). Adverse events included 1 patient in the MMF group and 5 patients who had to stop sirolimus (2 excluded from further analysis). In the sirolimus group the median rise in creatinine was 28 mmol/L/year pre-switch and -24.8 mmol/L/year post switch, with 17/19 patients showing a reduction in the rate of rise in creatinine; in the MMF group the median rise was 13.2 mmol/L/year pre-switch and -4.3 mmol/L/year post-switch, with 11/18 patients showing a reduction in the rate of rise. 7/19 patients in the sirolimus group required an increase in lipid-lowering therapy post-switch compared to 3/18 in the MMF group.

Conclusions: Outside the setting of a tight protocol of a clinical trial, reduction in long term CNI exposure in renal transplant patients selected on clinical and / or pathological grounds can have a significant beneficial effect on graft function. However, this may be at the expense of worsening hyperlipidaemia, particularly with the use of sirolimus.

PUB776

Urinary Monocyte Chemoattractant Protein-1 Levels and Their Relationship with Interstitial Alterations in the Renal Cortex and Loss of Renal Function in Post-Renal Transplantation Miguel Moyses-Neto, Elen A. Romao, Gyl E.B. Silva, Roberto S. Costa, Marcio Dantas, Silvio Tucci, Terezila Machado Coimbra. *Faculty of Medicine-USP, Ribeirao Preto, SP, Brazil.*

Background: Monocyte chemoattractant protein-1 (MCP-1) is a potent proinflammatory chemokine that has a strong chemotactic action on macrophages. The aim of this study was to determine the urinary MCP-1(uMCP-1) levels and their possible correlation with the relative cortical interstitial area (RCIA), macrophage renal infiltration and the outcome of the graft in post kidney transplantation patients.

Methods: Twenty two patients submitted to cadaveric transplantation were followed up for one year and had their renal function evaluated by plasma creatinine levels. A total of 55 biopsies were examined with a median of 2.5 for each patient. The glomeruli number of each biopsy was 14.3±9.0.

Results: Light microscopy showed morphological features characteristic of acute tubular necrosis in 22 biopsies from 9 patients and chronic nephropathy of the graft in 18 biopsies from 14 patients. The RCIA from renal cortex was 7.1% (6.4; 9.2) in the control and 37.1% (28.1; 43.7) in patients with kidney transplantation (p<0.0003).There was also a significant increase in uMCP-1 of transplanted patients (p<0.0001) compared to controls. Patients who presented in the first biopsy higher RCIA showed higher levels of plasma creatinine one year after transplantation (r=0.44; p<0.05). There was also a correlation between the RCIA and the number of macrophages in the interstitial area (r=0.49; p<0.0002). However, there was no correlation between uMCP-1 and creatinine plasma levels one year after the transplant (p=0.26). The number of macrophages per grid field of 0.245 mm^2 was higher [19.4 (9.0;47.1)] in the TI area from renal cortex of transplanted patients compared to control [2.5 (1.8;3.4)] (p<0.001) and correlated with the creatinine plasma level at one year after transplantation.

Conclusions: In conclusion, our results demonstrated increased levels of uMCP-1 in the transplanted patients and that macrophages interstitial infiltration and RCIA could predict the outcome of renal function in these patients.

PUB777

Outcomes of Thrimethoprim-Sulphamethoxazole Use as Chemoprophylaxis Following an Outbreak of Pneumocystis Pneumonia in a Renal Transplant Population Nicos Mitsides,[1] Darren Green,[1] Rachel Middleton,[1] Kerry Greenan,[2] Elizabeth H. Lamerton,[1] Jude Allen,[1] Jane Redshaw,[1] Paul Chadwick,[1] Chinari Pradeep Kumar Subudhi,[1] Grahame Wood.[1] *[1]Salford Royal Hospital, Salford, United Kingdom; [2]University of Manchester, Manchester, United Kingdom.*

Background: An increase in Pneumocystis pneumonia (PJP) clusters has been reported in renal transplant recipients. In response to such an outbreak affecting 19 patients in our tertiary nephrology unit, all transplant patients were offered chemoprophylaxis, except for females of child-bearing potential. Trimethoprim-sulphamethoxazole (T-S) 480mg daily was used as first line agent but a high rate of complications was noted. The aim of this study was to quantify the adverse events associated with T-S, and whether the prophylactic benefit outweighed the complications.

Methods: This was an observational study of outcomes in 300 transplant recipients commenced on T-S prophylaxis in the 12 months from February 2011. End-points were adverse events due to the T-S, the additional medical burden as a result of these events, and diagnoses of PJP.

Results: Of 300 patients commenced on T-S, 121 (40%) developed compilations. Of these, the most common were: rise in serum creatinine >15% from baseline (79%), gastrointestinal symptoms (11%), leukopenia (6%). 24 (20%) complications led to hospital admission (median time in hospital 4 nights, range 1-13 nights). Because most patients with intolerance required unplanned medical review, a dedicated review clinic had to be set up. Many patients required extra investigations to rule out other causes of allograft dysfunction including renal ultrasound imaging (18%) and renal biopsy (6%). Few patients responded to desensitisation (3%) or dose reduction (5%). The remainder had to stop the T-S. Despite this PJP incidence fell. Prior to use of prophylaxis there were 19 cases in 19 months. During the study period there were 2 cases in 12 months.

Conclusions: Although use of chemoprophylaxis reduced the incidence of PJP we faced an unexpectedly high number of intolerant patients. The fact that this was mainly in the form of raised serum creatinine caused significant anxiety and let to a significant increase in investigations.

PUB778

Risk Factors and Outcomes of Asymptomatic Bacteriuria in the First Year after Renal Transplantation Syed Hassan,[1] Fatima Khalid,[1] Sarim Rashid,[1] Hasan Zahid,[1] Chetan Mittal,[1] Anita K. Patel,[2] Mayur S. Ramesh,[3] George J. Alangaden.[3] *[1]Internal Medicine, Henry Ford Hospital; [2]Nephrology, Henry Ford Hospital; [3]Infectious Disease, Henry Ford Hospital.*

Background: The optimal management of asymptomatic bacteriuria (ASB) in renal transplant (RT) patients is poorly defined. We examined the risk factors and outcomes of ASB in 436 RT patients in the first year after RT.

Methods: All patients who underwent RT at Henry Ford Hospital,detroit from 2008-2011 were enrolled in this retrospective study. A total of 490 patients underwent RT,436 had complete follow up data for 1 yr and were included in the analysis. Patient demographics, clinical and laboratory data were collected. ASB was defined as: isolation of $\geq 10^5$ cfu/ml of bacteria in an appropriately collected urine specimen in the absence of symptoms or signs of urinary infection (UTI). UTI was defined as: presence of signs and symptoms of infection with $\geq 10^5$ cfu/ml of bacteria. Results were computed using univariate and multiple logisitic regression analysis.

Results: 102/436 (23%) of patients developed ASB in the first year post-RT. Median time to ASB was 78 days.Significant factors associated with ASB were female gender, UTI prior to RT, prior hospitalization less than 30 days of ASB (all p value <0.001),and CMV seropositive recipient (p =0.019). On multivariate logistic regression, female gender OR 2.2 (CI 1.8-2.6),CMV seropositive recipient OR 2.32 (CI 1.22-4.64), prior hospitalization OR 6.0 (CI 3.22-11.51) were independent risk factors for ASB. Of the 102 RT patients with ASB, 93 (91%) were treated with antibiotics, in those patients 65 (70%) had recurrent ASB and 8 (9%) developed UTI during follow up. Out of the 9 patients who were not treated, 3 cleared ASB, 4 had recurrence of ASB and 2 developed UTI. 1-year graft and patient survival in patients with ASB was 100% and 98.1% respectively.

Conclusions: ASB occurs in about a quarter of RT patients.Female gender, CMV seropositivity, and prior hospitalization appear to be significant risk factors for ASB. Antibiotic therapy of ASB does not appear to significantly impact outcomes. Prospective studies on the natural history and optimal therapy of ASB in the RT patients are warranted.

PUB779

Evaluation of Irbesartan and Losartan on Renal Protection in Renal Transplant Recipients (I-LORD Study) Hitoshi Yokoyama, Hideki Yamaya, Hiroshi Okuyama. *Division of Nephrology, Kanazawa Medical University School of Medicine, Uchinada-Kanazawa, Ishikawa, Japan.*

Background: The beneficial effect of angiotensin II receptor blockers (ARB), especially the differential effects of its subclasses of drugs, in renal transplant recipients is not yet well established. Our objective was to investigate the impact of the use of irbesartan and losartan on graft function and urinary surrogate markers in a single center cohort.

Methods: Sixty-seven Japanese recipients with hypertension were enrolled in this study. Patients were randomly divided into two groups based on demographic factors and were given either irbesartan (Group I, n=35) or losartan (Group L, n=32). During the study period, the dosage was adjusted to control blood pressure levels (BP, <=130/80 mmHg). Physiological and biochemical parameters including urinary albumin and MCP-1 were measured before and after the 12-month study period.

Results: We successfully continued administration of ARB on 28 patients of Group I (80%) and 32 patients of Group L (86.4%) over the one-year study period Mean BP was significantly decreased from 94.69 to 91.24 mmHg in Group I and from 96.60 to 91.25mmHg in Group L (p=0.047 and p=0.003 by paired t-test, respectively). Changes inestimated glomerular filtration rate (ΔeGFR)were observed in both groups (-2.8 and -1.7 mL/min/1.73m^2/year, respectively). No significant differences in albuminuria, serum creatinine, and urinary MCP-1 levels among the groups were detected. In multivariate regression analysis, urinary albumin and MCP-1 levels were correlated with ΔeGFR (beta index, -0.358, p=0.007; -0.283, p=0.03, respectively). Higher urinary albumin levels and body mass index before study, and decreased BP during study, were selected as predictive factors for the reduction of albuminuria by ARB (beta index, -0.542, p=0.001; -0.235, p=0.024; 0.289, p=0.004, respectively). Improvement of urinary MCP-1 level by ARB was positively correlated with the changes in albuminuria (beta index, 0.251, p=0.047).

Conclusions: Both irbesartan and losartan improved BP in Japanese renal transplant recipients with hypertension. However, no significant differences in ΔeGFR, urinary albumin and MCP-1 levels were detected between the groups.

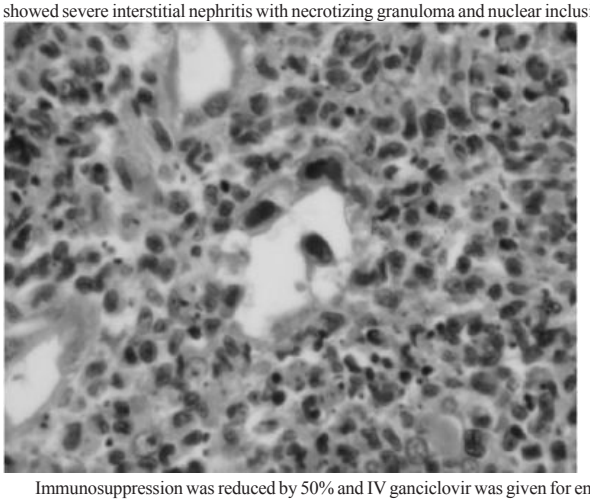
Severe Necrotizing Adenovirus Nephritis in a Renal Transplant Recipient: A Case Report and Literature Review Steven Schmidt,[1] Ping L. Zhang,[2] Dilip Samarapungavan,[2] Gampala Harish Reddy,[2] Francis Dumler,[2] Leslie L. Rocher,[2] Alan Koffron,[2] Raviprasenna K. Parasuraman.[2] *[1]Internal Medicine, William Beaumont Hospital, Royal Oak, MI; [2]Division of Transplant, William Beaumont Hospital, Royal Oak, MI.*

Background: Viral pathogens remain one of the principal causes of mobidity and mortality in transplant recipients. Vigilance for emerging pathogens is important in the modern era of potent immunosuppression. We present a case of severe adenovirus (ADV) necrotizing granulomatous tubulo-interstitial nephritis.

Methods: A 44-year-old male with ESRD secondary to hypertension underwent a deceased donor renal transplantation with basiliximab for induction and tacrolimus, mycophenalate mofetil and prednisone for maintenance therapy. Post transplant he developed slow graft function with a serum creatinine (SCr) level decreasing to 2.3 mg/dL on day 19. SCr increased to 2.8 mg/dL on day 22 resulting in an allograft biopsy which showed severe interstitial nephritis with necrotizing granuloma and nuclear inclusion bodies.



Immunosuppression was reduced by 50% and IV ganciclovir was given for empiric viral nephritis pending further evaluation. Subsequently, the patient developed fever, hematuria and mild interstitial pneumonitis. Results of urine and serum quantitative PCR for ADV returned with >2,000,000 and 649,000 copies/mL respectively. Subsequently the patient received 3 doses of 240 mg of cidofovir every other week in addition to IVIG 500 mg/kg. The patient had an excellent response with complete clinical and virological resolution. SCr decreased from 2.85 mg/dL to 1.54 mg/dL 3 weeks after initiation of therapy.

Conclusions: ADV induced tubulo-interstitial nephritis is extremely rare with approximately 20 reported cases in the literature. Our case highlights the need for vigilance of emerging infections such as ADV in renal allograft recipients.

PUB781

BK-Viremia and Polyomavirus Nephropathy (PyVAN) Following Kidney Transplantation: Single Center Experience in 352 Transplant Recipients

Johannes Jacobi,[1] Antonina Prignitz,[2] Alexander Weidemann,[1] Klaus Korn,[3] Maike Julia Buettner,[4] Karl F. Hilgers,[1] Kai-Uwe Eckardt,[1] Kerstin U. Amann.[4] *[1]Nephrology & Hypertension, University of Erlangen-Nuremberg, Erlangen, Bavaria, Germany; [2]Gemeinschaftspraxis Nuremberg, Nuremberg, Bavaria, Germany; [3]Clinical & Molecular Virology, University of Erlangen-Nuremberg, Erlangen, Bavaria, Germany; [4]Nephropathology, University of Erlangen-Nuremberg, Erlangen, Bavaria, Germany.*

Background: To evaluate the incidence and outcome of BK-viremia and PyVAN in n=352 kidney transplants performed between 2008-2011.

Methods: Retrospective analysis of all kidney transplants performed between 2008-2011. Screening for BK-viremia was recommended 3,6,9 and 12 months post transplantation. Protocol biopsies were offered at 3 and 12 months, in addition all patients with BK-viremia underwent transplant biopsies. In patients with PyVAN switch of immunosuppression to mTORi + low dose cyclosporine (CyA) was implemented whenever possible.

Results: The overall incidence of BK-viremia was 12.8%. Transplant recipients >65 years of age (ESP) showed a significantly higher incidence (26.8%). In logistic regression analyses the following risk factors for BK-viremia were determined: ESP-recipient, recipient age, BPAR, previous transplantation, mode of renal replacement therapy, recipient CMV-status (IgG+) and 25-hydroxyvitamin D3 levels. In two-third of the patients viremia occurred between 2-6 months following transplantation. A second peak was noted one year after transplantation in patients with missed screening intervals. In 21 patients (46.7%) BK-viremia was associated with biopsy proven PyVAN. Initial and peak viral load were 1-log scale higher in patients with PyVAN. While renal function remained stable in patients without PyVAN, it significantly deteriorated in patients with PyVAN. Switch of immunosuppression to mTORi + low dose CyA was safe and well tolerated.

Conclusions: Our data highlight the importance of screening for BK-viremia, especially in aged transplant recipients. Without specific antiviral strategies the mainstay of therapy remains reduction of immunosuppression. In patients with PyVAN combination therapy with mTORi + low dose CyA appears to be safe and well tolerated.

The Early Reduction of Mycophenolate Mofetil Is Safe in Kidney Transplant Recipients Who Need Desensitization by Rituximab

Ja Seon Kim,[1] Won Seok Yang,[1] Duck Jong Han,[2] Su-Kil Park.[1] *[1]Division of Nephrology, Department of Internal Medicine, Asan Medical Center, University of Ulsan College of Medicine; [2]Department of Surgery, Asan Medical Center.*

Background: For ABO incompatible (ABOi) and/or T cell flow cytometry crossmatch positive (TFCP) kidney transplantation (KT), desensitization is necessary for successful outcome of transplantation under the therapy with rituximab, plasmapheresis, or IVIG. Some people reported increased risk of infection, and others reported no increased risk of infection after rituximab therapy. Our study is aimed to prospectively evaluate the outcome of 1.0g use of mycophenolate mofetil (MMF) in kidney recipients who need desensitization by rituximab at postoperative 1 week.

Methods: We evaluated the outcome of 28 patients who underwent HLA-sensitized or ABOi living donor KT after one dose of rituximab (200mg ABOi, 500mg TFCP) (group 1). Fifty-three living kidney transplant recipients who did not require rituximab served as a control (group 2). The desensitization was performed by plasmapheresis and ritixumab ± IVIG. Maintenance immunosuppression was tacrolimus, MMF (1.5g/day) and methylprednisolone, which was initiated 7 days (group 1) or 3 days (group 2) prior to operation. Basiliximab was administered in both. MMF was reduced to 1.0g/day from 7 days after surgery in group 1.

Results: There was no difference in demographic data. Postoperative infections occurred in 6 patients (21.4 %) of group 1 and 11 patients (20.8 %) of group 2 during the follow-up period (4.3±1.2 mo), which was not different (p=0.579). Renal function was same during follow-up; serum creatinine (mg/dl): 1mo, 1.06±0.32 vs.1.22±0.47, p=0.368; 3 mo, 1.12±0.30 vs. 1.21±0.32, p=0.198. Acute rejection developed in 2 patients (7.1%) of group 1 and 4 patients (7.5%) of group 2, which was not different (p=0.659). The dose of MMF (g/day) at the following times postoperatively was lower in group 1 than group 2: 7 days, 1.02±0.09 vs. 1.46±0.45, p<0.001; 1mo, 0.98±0.09 vs. 1.46±0.45, p<0.001; 3mo, 1.00±0.22 vs. 1.24±0.35, p=0.001.

Conclusions: The early reduction of MMF regimen was safe and might be acceptable in rituximab-treated kidney transplant recipients.

PUB783

Factors Affecting eGFR 5 Year Post Deceased Donor Renal Transplant: Analysis and Predictive Model

Abdalla Elbadri, John T. Veitch, Carol A. Traynor, Patrick O'Kelly, Colm Magee, Mark D. Denton, Peter J. Conlon. *Nephrology, Beaumont Hospital, Dublin, Ireland.*

Background: Long-term survival of renal allografts has improved consistently over the last twenty years. However, less is known about factors which accurately predict long-term allograft function as determined by eGFR. The aim of this study was to investigate factors which affect allograft function (eGFR) at 5 years after renal transplantation. The statistically relevant factors were then used to construct a predictive model for expected eGFR at five years post transplant.

Methods: We retrospectively reviewed all adult patients who received a renal transplant in Beaumont Hospital between 1990 and 2004 (Beaumont Hospital is the national renal transplant centre for the Republic of Ireland).Data collected included era of transplantation (1990-1994, 1995-1999, 2000-2004), donor and recipient age and gender, number of HLA mismatches, cold ischaemic time, number of prior renal transplants, immunosuppressive regimen used and acute rejection episodes. eGFR was calculated at 5 years after transplantation using the MDRD equation. This population was then divided into two equal unbiased groups of 489 patients, the first group (hypothesis cohort) being used to construct a predictive model for eGFR five years post transplantation, the second (validation cohort) to test this model.

Results: Nine hundred and seventy eight patients were analysed. The mean age at transplantation was 42.7 years; 620 (63.4%) were male. Factors found to have a statistically relevant (P value <0.05) effect on eGFR in the hypothesis cohort at 5 years were donor age, recipient sex, CMV disease, acute rejection and exposure to tacrolimus. The derived equation was then tested in the validation cohort with results in the Table below.

table:1

Median eGFR after 5 years	Era 1 (1990-1994)	Era 2 (1995-1999)	Era 3 (2000 - 2004)
Predicted	45.1	44.7	50.6
Actual	42.6	47.4	55.3

Conclusions: The predictive model we have developed shows good correllation between predicted and actual median eGFR at five years. Applications of this model include comparison of current and future therapy options.

PUB784

Ureteral Stent Placement and the Risk for Development BK Viruria and Viremia in Kidney Transplant Recipients

Faris Q. Hashim,[1] Vikas R. Dharnidharka.[2] *[1]Pediatric Nephrology, UF/College of Medicine, Gainesville, FL; [2]Pediatric Nephrology, Department of Pediatrics/Washington University School of Medicine, St Louis, MO.*

Background: Polyomavirus (BKV) infection is one of the causes of allograft dysfunction following kidney transplant. Placement of a ureteral stent (US) at time of surgery was associated with 4-fold increase in the risk for developing BKV nephropathy (BKVN).

Methods: Retrospective secondary data base analysis of all kidney transplants that performed from July 1, 2007 and December 31, 2010 at the University of Florida with at least 6 months follow up.

Results: From 640 recipients, 621 were eligible for the study. BK viruria was seen in 137/529 (26%) and BK viremia 115/606 (19%). A ureteral stent (US) was placed in 295 (46%) of recipients. BK viruria was seen in 75/250 (30%) of stented patients. In contrast, only 62/279 (22%) of the recipients with BK viruria were without US, p = 0.04. BK viremia was seen in 63/289 (22 %) if stented versus 52/317(16%) without stent, p = 0.05. Patient age, gender, ethnicity and type of induction therapy were not statistically significant factors in the development of BK infection. However BK viremia was significant in recipients with immediate graft function. In a multivariate logistic regression model that included an interaction term between graft function and US placement, graft function fell out and only US placement remained significant for BK viruria (p = 0.03, odds 1.83 with 95% CI 1.29–2.61) and BK viremia (P=0.04, odds 1.65, CI 1.23-1.74).

Univariate and Multivariate analyses

BK virus status	Stent 295 (46%)	No Stent 326 (54%)	P Value
BK Viruria 26 %	30%	22%	0.04
BK Viremia 19%	22%	16%	0.05
Predictor Variable	BKVU P value	BKVM P value	
Stent	0.03	0.04	
Age Group	0.18	0.11	
Gender	0.49	0.43	
Cold Ischemia	0.41	0.42	
Induction Medication	0.91	0.82	
Graft Function	0.41	0.76	

Conclusions: Ureteral stent placement significantly increased the risk for BK viruria in univariate model and both BK viruria and viremia in multivariate model. Future studies should asses the risks and benefits of US placement, including consideration of the cost of BK testing as well as the potential for a nephritis that can affect the long time graft survival.

PUB785

Switching Study of Kidney Transplant Patients with Tremor to LCP-Tacro (STRATO): An Exploratory Study

Anthony J. Langone,[1] Christine Culkin,[2] John C. Morgan,[3] Vincenza Nigro.[4] *[1]Vanderbilt University, TN; [2]Hahnemann University Hospital, PA; [3]Georgia Health Sciences University, GA; [4]Veloxis Pharmaceuticals, NJ.*

Background: Neurotoxicity occurs in up to 50% of renal transplant recipients (RTR). Tremor is the most common manifestation of neurotoxicity. Tacrolimus (TAC) is implicated as the cause of tremor with 2 hour (peak) serum concentrations correlated with toxicity. Reduction or cessation of TAC may reduce tremor symptoms but increases the risk for rejection, especially in patients that are symptomatic despite goal TAC serum concentrations.

Methods: This study is designed to determine if conversion of RTR who have tremor with a standard TAC formulation to LCP-Tacro (extended-release once-daily MeltDose formulation, Veloxis Pharma) leads to measurable improvement in tremor. The LCP-Tacro formulation has smaller and more homogenous molecular components that result in consistent and predictable absorption across the gastrointestinal tract. Peak concentration is reduced but total AUC exposure is comparable to standard dose TAC. We hypothesize that a reduction in peak concentration with preservation of AUC will ameliorate symptoms while maintaining clinical efficacy. The Fahn-Tolosa-Marin (FTM) tremor rating scale is used

to enroll and assess RTR with TAC-related tremors. Eligible subjects have TAC-induced moderate to severe hand tremor and ≥1 complaint of tremor with postural or action tremor on finger-to-nose. Subjects remain on their pre-enrollment Prograf/generic TAC twice-daily treatment for the first week of the study before switching to LCP-Tacro once-daily for a week. The primary analysis is mean change of FTM score from Day 7 to Day 14. The FTM scale is administered 2 hours postdose and evaluated by independent blinded neurologists. Additional endpoints include tremorometer, quality of life, and safety.

Conclusions: We believe this is the first trial in RTR to utilize a sophisticated and reproducible measurement of tremor. This study will determine if RTR who currently experience a minimal threshold of tremor by FTM measurements have a significant reduction in symptoms after conversion to a novel (LCP-Tacro) formulation while maintaining comparable drug exposure.

A Single Center UK Experience of Pregnancy in Women with Kidney Transplant Maharajan Raman, Arvind Ponnusamy, Daniel J. Hall, Hayley L. Mcmanus, Teresa Kelly, Philip A. Kalra, David I. New. *Renal, Salford Royal NHS Trust Foundation, Salfoird, United Kingdom.*

Background: Renal transplantation improves fertility. Studies report that pregnancy is common in 12 % of women of childbearing age.

Methods: We undertook a retrospective review of pregnancy in women with renal transplant from 2007 to 2011. All patients are cared in a multidisciplinary team involving comprising nephrologists, obstetricians, midwives, dietician and transplant nurses from the antenatal period to delivery and beyond.

Results: There were 5 patients with confirmed pregnancy during this period. Average age of patients were 28.4 years. 3 had live donor and 2 had cadaveric transplants. Average time to pregnancy post transplantation was 24 months (range (25-36) and Two patients were on ACE and ARB at time conception which was subsequently stopped. Average creatinine was 118 ± 30 and proteinuria was 0.28 gm (range 0.6-0.88).

	Medication	Renal function(Pre-Pregancy	Renal function(3 months Post pregnancy)	Outcome
1	Tac/Aza	126	102	Miscarriage at 17 weeks
2	Ciclo/Aza	165	155	Birth at 33 weeks
3	Tac/MMF	85	99	Birth at 38 weeks
4	Tac	106	99	Birth at 38 weeks
5	Tac/Pred	108	88	Birth at 33 weeks

Average tacrolimus level was 1st trimester was 6.7, 2nd was 5.1 and 3rd was 3.9. MMF was stopped and replaced with azathioprine. Average booking BP was 131± 10.1 and 3rd trimester BP was 128 ± 11. There was no statistically significant reduction in creatinine in at 3 months post pregnancy. Average proteinuria was post 3 months was 0.55 gms. Although, one patient had miscarriage at 17 weeks but she is pregnant again. Average birth weight was 2854 gm.

Conclusions: Pregnancy in transplants is associated better foetal and maternal outcome due to careful monitoring of BP, urine protein, renal function and drug therapy.

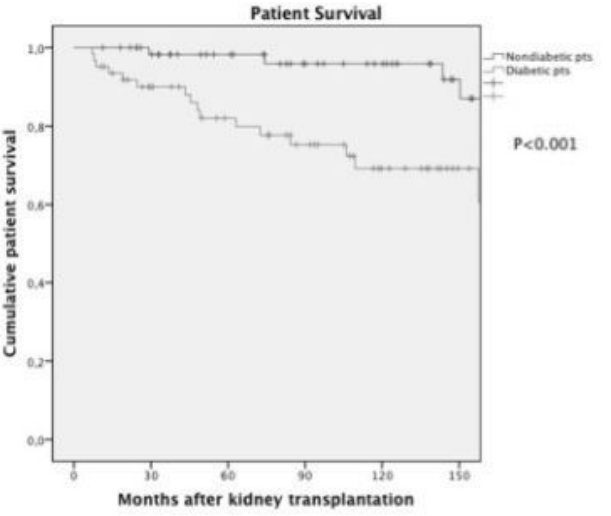
PUB787

Kidney Transplantation in Type 2 Diabetic Patients: A Matched Survival Analysis Ana Rocha, Jorge Malheiro, Isabel Fonseca, La Salete Martins, Antonio Andresen Henriques. *Centro Hospitalar do Porto.*

Background: Diabetes mellitus (DM) is the most prevalent cause of kidney failure. Some concerns have been raised about the kidney transplantation (KT) results in diabetic patients. Therefore we compared outcomes between diabetic and non-diabetic patients after KT.

Methods: All kidney transplants performed in type 2 diabetic patients, from July 1983 to December 2009 in our centre, with a graft survival over 3 months, were included. Non-diabetic controls were individually matched with diabetic patients with respect to gender, age, year of transplantation, number of donor HLA mismatches and dialysis vintage. The two groups were compared concerning patient and graft survival, delayed graft function (DGF) and prevalence of acute rejection (AR).

Results: We included 62 type 2 diabetics and 62 non-diabetic patients who were followed for a mean period of 102±64 months after KT. Diabetic patients and controls were similar for the matched variables. Graft survival censored for patient death for diabetics and non-diabetics was 70 and 83% at 5 years and 54 and 71% at 10 years, respectively (log rank test p=0.13). Patient survival at 5 and 10 years was 69 and 50% for diabetic patients and 96 and 84% for non-diabetic patients, respectively (log rank test p<0.001).



The prevalence of AR was 24.2% in diabetic and 17.7% in non-diabetic patients (X^2 test p=0.38). Occurrence of DGF did not differ (X^2 test p=0.12). Using multivariate Cox's proportional hazards analysis, DM (HR=7.72; p=0.001) and hepatitis (HR=4.18; p=0.02) correlated with reduced patient survival.

Conclusions: Diabetic patients' survival after KT was reduced when compared with non-diabetic matched patients. However, censored graft failure was similar between the two groups. Concerns about graft survival should not prevent KT in diabetic patients with kidney failure.

PUB788

Changes of Serum Bilirubin after Kidney Transplantation and UGT1A1*28 Polymorphism Affect the Graft Survival in Kidney Transplantation Do Hyoung Kim,[1] Jung Pyo Lee,[2,3] Seung Hee Yang,[3] Jeonghwan Lee,[1] Yun Jung Oh,[1] Ho Jun Chin,[4] Dong Ki Kim,[1] Yun Kyu Oh,[2] Chun Soo Lim,[2] Yon Su Kim.[1,3] *[1]Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Korea; [2]Department of Internal Medicine, Seoul National University Boramaen Medical Center, Seoul, Korea; [3]Kidney Research Institute, Seoul National University College of Medicine, Seoul, Korea; [4]Department of Internal Medicine, Seoul National University Bundang Hospital, Seong Nam, Korea.*

Background: In kidney transplantation patients, oxidative stress is a major mediator of adverse outcome including acute rejection, and is balanced by various anti-oxidants such as bilirubin. Bilirubin degradation is mainly determined by the activity of hepatic bilirubin uridine diphosphate-glucuronosyltransferase (UGT1A1), which is significantly influenced by a TA-repeat polymorphism in the gene's promoter, an allele designated UGT1A1*28. In this study, we evaluated the role of bilirubin in kidney transplantation patients, and the relationship between serum bilirubin levels and UGT1A1*28 polymorphism related with bilirubin degradation.

Methods: We collected clinical data from 229 Korean kidney transplantation patients from 1999 to 2008. Serum bilirubin levels and biopsy proven acute rejection were traced. Genotyping of the UGT1A1 TA-repeat polymorphism was performed. The endpoints were acute rejection and graft survival.

Results: The UGT1A1*28 genotype frequencies were 79.0%, 18.8%, 1.3%, and 0.9% for 6/6, 6/7, 7/7, and 6/8 for kidney transplantation patients. Post-transplant 1 year bilirubin levels of the 6/6 genotypes were significantly lower than those of the 6/7, 7/7, and 6/8 genotypes (0.73±0.29 versus 0.91±0.50 mg/dL, P=0.043). In a Kaplan-Meier model, the 6/6 genotypes showed poor graft survival compared to the 6/7, 7/7, and 6/8 genotypes (P=0.039). The acute rejection incidence in the 6/6 genotypes was higher compared to the 6/7, 7/7, and 6/8 genotypes (19.9% versus 8.3%, P=0.085).

Conclusions: Elevation of serum bilirubin after kidney transplantation was associated with UGT1A1*28 polymorphism. Lower serum bilirubin level and the 6/6 UGT1A1*28 genotype might have a negative effect on graft survival.

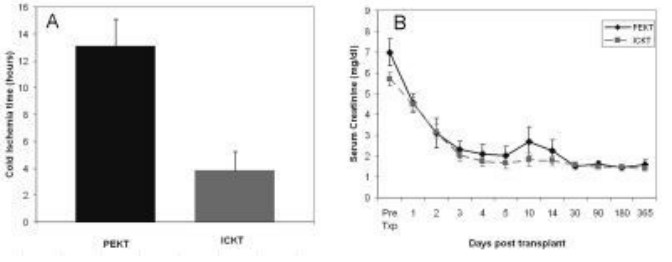
PUB789

Paired Exchange versus In-Center Living Donor Kidney Transplantation: A Single Center Experience Arpit Bhargava, Swati Arora, Richard J. Marcus, Kalathil K. Sureshkumar. *Nephrology and Hypertension, Allegheny General Hospital, Pittsburgh, PA.*

Background: Paired exchange kidney transplantation (PEKT) is one of the newer strategies aimed at expanding the living donor pool. Recent practices involve transporting the kidneys (with resultant increase in cold ischemia time [CIT]) rather than have the donors travel. It would be interesting to know the outcomes of PEKT vs. the traditional in-center live-donor kidney transplants (ICKT).

Methods: Retrospective chart review of adult patients who undewent PEKT and ICKT from 01/2009 to 02/2012 at our institution was done. CIT, delayed graft function (DGF) incidence, rates of acute rejection (AR), trend of serum creatinine (S.Cr), proteinuria, patient and graft survival were compared between the groups.

Results: The demographics of PEKT (n=15) vs. ICKT (n=30) were similar: recipient age 51±15 vs.52±10 years; donor age 46±13 vs. 43±12 years, pre-transplant dialysis duration 23±15 vs. 17±14 months and HLA mismatch 4±2 vs. 4±2. CIT was 13.1 hours in PEKT group and 3.8 hours in ICKT group ((p <0.001). (Fig 1A). None of the patients in either group developed DGF. At a median follow- up of 12.4 months (range 2-27.5 months), graft and patient survival rates were 100% in both groups. Serial S.Cr levels were similar between the groups (Fig 1B). AR rates (3/15 vs. 3/30, p=0.35) and prevelance of proteinuria post-transplantation (8/15 vs. 22/30, p=0.18) did not show any significant differences for PEKT vs. ICKT groups.



Conclusions: Our study showed similar allograft function, AR as well as graft and patient survivals between PEKT and ICKT groups despite involving organ transportation and higher CIT in the PEKT group. These findings support the current practice of PEKT, which should be encouraged in patients with incompatible living donors in order to increase the chances of a successful living donor kidney transplantation.

PUB790

Urinary Tract Infections during First Year after Cadaveric Renal Transplantation Justyna E. Golebiewska, Alicja Debska-Slizien, Boleslaw Rutkowski. *Department of Nephrology, Transplantology and Internal Medicine, Medical University of Gdansk, Gdansk, Poland.*

Background: Urinary tract infections (UTIs) are most common infections in renal transplant recipients and are considered a potential risk factor for poorer graft outcomes. There are conflicting data on risk factors and the influence of UTIs on long-term kidney allograft function in RTx recipients.

Methods: We analyzed urine cultures performed within first 12 months after RTx with reference to clinical data of patients who received a cadaveric RTx at Gdansk Transplantation Centre between January 2007 and December 2009. Renal function assessed by creatinine concentration and eGFR was recorded 24 months after RTx.

Results: We studied 206 cadaveric renal transplant recipients, including 59% of male gender, with mean age of 46,6±14 years. We observed 320 episodes in 109 patients, consisting of asymptomatic bacteriuria (53%, n=169), lower UTIs (25%, n=81) and upper UTIs (22%, n=57) including 13 cases of bacteremia. Over 38% of UTIs were diagnosed during the first month posttransplant and the most frequently isolated uropathogen was *Enterococcus faecium* (36%, n=44). Beginning from the second month *Escherichia coli* predominated (57%, n=113). Risk factors for posttransplant UTIs were: female gender, induction, a history of acute rejection (AR) and/or cytomegalovirus (CMV) infection, recurrent UTIs before RTx, comorbidity measured by Charlson Comorbidity Index. All patients with confirmed vesico-ureteral reflux or strictures (n=19) suffered from recurrent UTIs. eGFRwas significantly worse in patients suffering from UTIs from baseline. However the evolution of renal graft function did not differ significantly between patients with and without UTIs.

Conclusions: UTIs are a frequent problem after RTx, with asymptomatic bacteriuria as most common form. *Escherichia coli* and *Enterococcus faecium* are predominant pathogens. Exposition to greater immunosuppression due to induction, episodes of AR or as a result of CMV infection is a risk factor for UTIs. Recurrent UTIs may be considered either an effect or a marker of underlying dysfunction of urinary tract or comorbid conditions. UTIs do not impair graft function in 24month observation.

PUB791

Prevalence and Predictor Factors of Graft Dysfunction (GD) a Year Postransplant Gerardo Gilberto Azúa Díaz,[1] Jorge Andrade-Sierra.[1] *[1]Nefrologia, IMSS, Guadalajara, Jalisco, Mexico; [2]Nefrologia, IMSS, Guadalajara, Jalisco, Mexico; [3]Nefrologia, IMSS, Guadalajara, Jalisco, Mexico.*

Background: In renal transplant (RT) minimal changes in serum creatinine (SCr) since 6 months predicts worse graft outcomes, an increase of 0.5 to 1.0 mg/dl from 6-12 months increase the risk of GD 2.26 times. On the other hand SCr> 1.5 mg/dl, at one year of RT predict graft loss at 3 years in almost 20%. To determine the prevalence of GD at 1 yr post-RT and associated factors in a RT Mexican population.

Methods: This is a retrospective cohort study performed between Jan-Dec/2010 in 209 RT receptors; GD was defined as SCr≥1.5mg/dl at 1 year.

Results: Main results are show in table.

Comparison of variables in patients with and without graft dysfunction.

Variables	GD (≥8805;1.5 mg/dl)	No-GD (< 1.5 mg/dl)	p value
Receptor age (years)	28.7 ± 13.8	27.2 ± 10.7	0.44
Donor age (years)	40.0 ± 11.5	35.2 ± 10.4	0.01
Time on dyalisis (months)	24.2 ± 18.6	27.9 ± 25.9	0.29
HLA antigens matched N(%)	3.1 ± 1.2	2.8 ± 1.7	0.20
Cold ischemia (min)	70 ± 154	113 ± 232	0.15
Immunosupression (%)	98%	99%	ns
Acute Rejection (%)	64%	25%	<0.0001
Baseline Creatinine	1.30 ± 0.30	1.00 ± 0.26	<0.0001
7 days creatinine	1.30 ± 0.34	1.07 ± 0.43	0.002
1 m creatinine	1.34 ± 0.47	1.04 ± 0.33	<0.0001
3 m creatinine	1.35 ± 0.45	1.07 ± 0.27	<0.0001
6 m creatinine	1.64 ± 0.95	1.07 ± 0.27	<0.0001
9 m creatinine	2.96 ± 2.67	1.04 ± 0.21	<0.0001
12 m creatinine	3.05 ± 2.6	1.04 ± 0.21	<0.0001

Conclusions: Donor age, baseline and 6 month serum creatinine significanty predicts GD at 1 year. (X^2 62.4; p < 0.0001).

PUB792

Body Mass Index of Donor or Recipient Are Not Associated with Delayed Graft Function in Deceased Donor Kidney Transplantation Mahendra V. Govani, Alvin Wee, Islam A. Ghoneim. *Kidney Transplantation, St. Vincent Hospital, Indianapolis, IN.*

Background: Recent reports suggest that high donor and recipient body mass index (BMI) are significantly associated with increased incidence of delayed graft function (DGF), defined as need of dialysis within a week of kidney transplantation. We conducted a retrospective review of our deceased donor (DD) kidney transplant records to confirm this association.

Methods: Records of all 112 DD kidney transplants performed at our center between 1/1/2009 and 4/30/2009 were reviewed for parameters including DGF, demographics and BMI of donor and recipient, SCD/ECD/DCD status, cold ischemia time (CIT), diabetes, PRA, retransplant status, patient and graft survival. and serum creatinine. Four patients were excluded from analysis: 1 with simultaneous heart and kidney transplant, 1 with vascular thrombosis, 1 with primary non-function, and 1 patient who died within a few days of transplant due to presumed pulmonary embolis with normal graft function. Median follow-up at 5/31/2012 was 18.9±11.4 (range 1.4-41.3) months.

Demographics and Outcomes

Variable	N=108
Age in yrs, mean ± SD	55.7 ± 13.4
Male, n (%)	72 (66.7)
AA, n (%)	44 (40.7)
SCD/ECD/DCD	60/23/26*
Recipient BMI, mean ± SD	30.7 ± 6.2
Donor BMI, mean ± SD	28.8 ± 6.3
CIT, hrs mean ± SD	13.7 ± 5.0
PS, n (%)	106 (98.1)
GS, n (%)	103 (95.4)
DGF, n (%)	6 (5.6)
ARR, n (%)	13 (12)

*1 DCD donor was ECD as well.

Thymoglobulin induction was used at standard dosage in all patients, and tacrolimus was introduced after renal function was well established. Mycophenolate and prednisone were used as adjuvant agents.

Results: Six of 108 (5.6%) patients developed DGF. Patient and graft survival (PS & GS) at 1 year (71 patients) were 100% and 99.1% respectively. Overall, PS and GS were 98.1% and 95.4% at follow-up; both patients who died had functioning grafts leading to actual GS 97.2%. Acute rejection rate (ARR) was 12%. No significant association was found between DGF and Donor BMI (p=0.86) or between DGF and recipient BMI (p=0.38).

Conclusions: DGF was not associated with donor or recipient BMI. However, DGF rate in our study was low reducing power of our study. Further studies are necessary.

Successful Withdrawal of Antiviral Treatment in Kidney Transplant Recipients with Chronic Hepatitis B Virus Infection Jang-Hee Cho,[1,2] Jun-Seop Kim,[1,2] Yunjeong Kang,[1,2] Ji-Young Choi,[1,2] Sun-Hee Park,[1,2] Yong-Lim Kim,[1,2] Chan-Duck Kim.[1,2] *[1]Kyungpook National University Hospital, Republic of Korea; [2]CRC for ESRD in Korea.*

Background: The optimal duration of antiviral therapy for kidney transplant recipients (KTRs) with chronic hepatitis B virus (HBV) infection remains unclear. We examined the results of withdrawals of antiviral treatment and the factors associated with successful withdrawal in KTRs with chronic HBV infection.

Methods: We investigated the hepatitis B surface antigen (HBsAg)-positive KTRs with antiviral agents between January 2000 and January 2012. Antiviral treatments were withdrawn in patients who met all of the following criteria: (1) normal liver biochemistry, (2) negative for both HBV DNA and hepatitis B e antigen (HBeAg), (3) immunosuppressants at maintenance dosage for more than 3 months, (4) duration of antiviral therapy at least 9 months, and (5) no resistance to antiviral agent.

Results: Fourteen HBsAg-positive patients among a total of 424 KTRs were included in this study (mean follow up period: 4.0±2.5 years). Antiviral agents were used in 11 patients with lamivudine and 3 patients with adefovir, telbivudine and entecavir respectively.

Discontinuation of antiviral agent was attempted in 6 patients (42.9%) who satisfied the criteria, except 8 patients (positive HBV DNA in 2 patients, lamivudine resistance in 2 patients, short duration of therapy in 2 patients, and unwillingness in 2 patients). The duration of antiviral therapy before withdrawal was 1.3±0.5 years. Four (66.7%) of 6 patients were successfully withdrawn and remained negative for HBV DNA for 5.1±1.2 years. The baseline HBV DNA titer and HBeAg status was not related to maintenance of remission after withdrawal. However, the duration of antiviral therapy before withdrawal showed longer tendency in patients maintaining remission compared to relapsed patients after withdrawal (485.0±193.9 and 283.5±91.2 days, P=0.165). During the follow up, patient death and graft failure were not reported for all HBsAg-positive KTRs.

Conclusions: Antiviral treatment can be successfully discontinued in selected KTRs with chronic HBV infection after complete suppression of HBV and sufficient duration of antiviral therapy.

PUB794

Mycophenolic Acid Withdrawal in the First 12 Months Predicts Graft Outcome at 24 Months in Renal Transplant Recipients Natalie L. Borman,[1] Scott Harris,[2] Gopalakrishnan Venkat-Raman.[1] *[1]Wessex Renal and Transplantation Service, Portsmouth Hospitals NHS Trust, Portsmouth, United Kingdom; [2]Department of Medical Statistics, University of Southampton, Southampton, United Kingdom.*

Background: Mycophenolic acid precursors (MPAP) are widely used in transplantation. Many patients cannot tolerate MPAP, with reduction or cessation usually reversing side effects. Long term graft survival has not significantly improved despite these drugs and early graft factors influence this. Despite increasing knowledge about MPAP it is unclear if dose alteration independently affects graft function. **AIM:** To establish whether alteration/cessation of MPAP in the first 12 months post transplantation is an independent predictor of graft function at 24 months.

Methods: A retrospective analysis of 153 renal transplant recipients looking at graft function, MPAP dose alteration, clinical and graft factors in the first 24 months post transplantation. Primary outcome measure was change in creatinine from 12 to 24 months.

Results: All participants received CNI (76.5% Cyclosporine A, 23.5% Tacrolimus) and MPAP at the time of transplant. 60.8% were male, 93.5% Caucasian, mean age at transplantation 47 years (range 17-76). Participants were categorized into 3 groups: those remaining on full dose MPAP, those with a dose-reduction and those who discontinued MPAP in the first 12 months. Groups were analysed according to the primary outcome measure. Statistical analysis used ANOVA with $P<0.05$ as significant. Stopping MPAP was found to be significantly associated with a deterioration in creatinine from 12 to 24 months when compared to dose reduction or no change [P= 0.015 (95% CI 6.82 to 63.06) and 0.01 (95% CI 8.83 to 65.08) respectively]. Data was analysed for multiple potential confounding variables including biopsy proven rejection, type of transplant and CNI agent. None were significantly different between the groups and combined adjustment for all the variables made no difference to the significance observed.

Conclusions: Early MPAP withdrawal post renal transplantation is an independent predictor of graft function at 24 months. This may result from chronic / subclinical rejection due to under immunosuppression in these individuals.

PUB795

Eculizumab Rescue and Bridging in Severe Antibody Mediated Rejection in Kidney Transplantation Martina Guthoff,[1] Barbara Schmid-Horch,[2] Silvio Nadalin,[3] Hans-Ulrich Haering,[1] Nils Heyne.[1] *[1]Dept. of Endocrinology and Diabetology, Angiology, Nephrology and Clinical Chemistry, University of Tuebingen, Tuebingen, Germany; [2]University of Tuebingen, Center of Clinical Transfusion Medicine, Tuebingen, Germany; [3]Dept. of General, Visceral and Transplantation Surgery, University of Tuebingen, Tuebingen, Germany.*

Background: Acute antibody mediated rejection (AMR) is a severe complication following kidney transplantation with profound impact on allograft survival. Human leukocyte antigen (HLA) antibody mediated cytotoxicity involves terminal complement activation and subsequent cell lysis. The humanized C5b-antibody eculizumab is a novel therapeutic option, blocking terminal complement activation. We report eculizumab to effectively interrupt AMR in kidney transplantation.

Methods: A 48-year old sensitized patient underwent HLA-incompatible living donor kidney transplantation from his brother. Preconditioning included rituximab, bortezomib and immunoadsorption, alemtuzumab was used for induction. After excellent primary function, a rise in serum creatinine occurred after two weeks and *de novo* donor-specific antibodies (DSA) were highly detectable. Histopathology revealed C4d-positive AMR.

Results: Despite continued plasma cell therapy and immunoadsorption, renal function deteriorated and DSA remained high with profound rebound after extracorporeal therapy. In consideration of therapeutic options, eculizumab was administered. Urinary output normalized rapidly and renal function stabilized despite unchanged DSA titres. Eculizumab was continued bi-weekly, with subsequent prolongation of intervals. 9 months after transplantation, continued plasma cell therapy effectively decreased DSA levels and eculizumab was tapered. Renal function is stable with a serum creatinine of 1.9 mg/dl and an eGFR of 38 ml/min/1.73 m².

Conclusions: Complement C5b blockade by eculizumab is highly effective in interrupting HLA antibody mediated cell injury in AMR. Eculizumab bridging creates a therapeutic window for antibody-directed B- or plasma cell therapy to become effective, allowing subsequent taper of eculizumab. As novel concept and treatment option, eculizumab may improve outcome of AMR in kidney transplantation.

PUB796

Looking Into the Crystal Ball: Can We Foresee Late-Onset Cytomegalovirus Infection or Disease in Kidney Transplant Recipients? Alainna Jamal, Shahid Husain, Yanhong Li, Olusegun Famure, Joseph Kim. *Multi-Organ Transplant Program, Toronto General Hospital, University Health Network, Toronto, ON, Canada.*

Background: Risk factors for late-onset CMV, apart from D+/R- serostatus, have not been clearly defined. This study aimed to explore other potential risk factors for late-onset CMV infection/disease in kidney transplant recipients.

Methods: A retrospective cohort study was conducted with 641 patients who underwent kidney transplants from 1 Jan 2003 to 31 Dec 2010 at a single Canadian center. A Cox proportional hazards model was used for risk factor analysis. American Society of Transplantation definitions were used for late-onset CMV infection/disease.

Results: This cohort included 110 D+/R- and 531 R+ patients. D+/R- patients were younger (47.4 vs. 52.7 years), more likely White (85.5% vs. 52.7%), had larger BMI (26.8 vs. 25.1 kg/m^2), and more likely living donor transplants (57.3% vs. 41.2%). They also had a shorter dialysis vintage (2.3 vs. 3.7 years), a longer period of prophylaxis (97 vs. 91 days), and a lower neutrophil count at prophylaxis cessation (3.4 vs. 4.0 x 10^3 cells/L). Cumulative incidence estimates for late-onset CMV infection/disease after prophylaxis cessation in D+/R- vs. R+ patients were 27.2% vs. 5.5% at 6-months and 31.3% vs. 5.9% at 1-year, respectively. The Cox model showed that D+/R- serostatus (HR 4.0 [95% CI, 2.4-6.8]) and estimated glomerular filtration rate (eGFR) by the CKD-EPI formula (HR 2.1 [95% CI, 1.1-4.1], for < 45 ml/min and 1.5 [95% CI, 0.8-2.9], for 45 to 60 ml/min) were the most important predictors of late-onset CMV infection/disease. Similar results were observed when the cohort was restricted to patients receiving ≤ 6 months of prophylaxis (HR 2.3 [95% CI, 1.1-4.3]) and those only receiving valganciclovir (HR 2.0 [95% CI, 0.9-4.1]).

Conclusions: In this cohort, D+/R- serostatus and low eGFR at the cessation of prophylaxis were most predictive of late-onset CMV infection/disease. Patients with lower eGFR at prophylaxis cessation should be considered for more intensive CMV surveillance, particularly within the first-year after prophylaxis cessation.

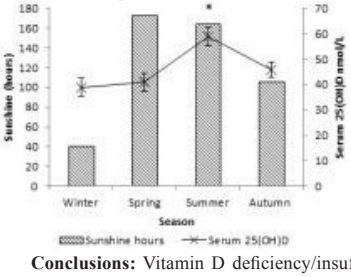
PUB797

Are We Inducing Harmful Vitamin D Deficiency in Our Renal Transplant Patients by Promoting Sun Avoidance? Hugo Penny, Sharon Frame, Francis L.F. Dickinson, Giorgia Louise Garrett, Antony R. Young, Robert Sarkany, Nihil Chitalia, Geeta Hampson, David Goldsmith. *Guy's &St Thomas' NHS Trust.*

Background: Renal transplant (RTx) patients are advised to avoid direct sunlight due to their increased risk of developing non-melanoma skin cancer (NMSC) with cumulative UV light exposure, and immunosuppression. However, sun-avoidance puts these patients at particular risk of vitamin D (25(OH)D) deficiency, which is linked to fractures, cardiovascular disease, and solid-organ cancer risk. In this study, we aimed to characterise the degree of vitamin D deficiency/insufficiency in a cohort of ambulant long-term RTx patients who were all well-educated about sun-avoidance.

Methods: We analysed the serum 25(OH)D and PTH concentrations from 266 RTx patients presenting to our clinic over the period of a year.

Results: The mean age of the cohort was 54±13years, 82% were Caucasian, mean eGFR was 50±19, median allograft age was 194 (149-277) months. 45 (17%) patients had NMSC. During the Winter, 9% of patients were vitamin D sufficient (>75nmol/L), 31% insufficient (75-37.5nmol/L) and 58% deficient (<37.5nmol/L). In Summer, 32% were vitamin D sufficient, 37% insufficient and 31% deficient. Serum 25(OH)D concentrations followed the recorded sunlight hours (figure 1). Patients reporting no/mild activity (72%) had lower 25(OH)D concentrations ($p<0.05$) than patients reporting moderate/vigorous activity (28%). There was an inverse correlation between serum 25(OH)D and PTH concentrations ($p<0.05$).



*[Figure 1. Serum 25(OH)D concentrations in patients presenting in Winter (n=54), Spring (n=59), Summer (n=67), Autumn (n=86). Error bars represent standard error of the mean. Bar charts represent mean seasonal sunshine hours falling on the South of England. *Denotes that Summer 25(OH)D concentration is significantly higher than 25(OH)D concentrations during the other seasons ($p<0.001$; all other values $p>0.05$).]*

Conclusions: Vitamin D deficiency/insufficiency was common (83%). This was particularly marked during the Winter and in patients who had low activity levels. Sun-avoidance is important, but leaves these patients susceptible to the secquelae of chronic vitamin D deficiency. Oral vitamin D supplementation may be the ideal treatment approach, but this needs a randomised controlled trial to confirm.

PUB798

Clinical Outcome of BK Virus Associated Nephropathy in Renal Transplant Recipients: Single Center Experience Hae Min Lee, Keunsuk Yang, Bumsoon Choi, Cheol Whee Park, Yong-Soo Kim, Chul Woo Yang, Byung Ha Chung. *Division of Nephrology, Department of Internal Medicine, Seoul St. Mary's Hospital, Seoul, Korea.*

Background: BK polyomavirus nephropathy (BKVN) is an important cause of allograft dysfunction in kidney transplant recipients. Once develop, its clinical course is known to be unfavorable and definite treatment guideline has not been established. In this study, we reported our center's experience of biopsy proven BKVN and their clinical course.

Methods: From Jan 2004 to Mar 2012, 17 cases of biopsy proven BKVN developed in Seoul St. Mary's hospital. Eight cases were deceased donor transplantation and nine were living donor transplantation. Two cases were retransplantation. Main immune suppressant was cyclosporine in five patients and tacrolimus in twelve patients.

Results: BKVN was observed at a mean duration 27.3±24.8 months after transplantation and serum creatinine at biopsy was 2.6±1.9 mg/dL. In five patients, BKVN was combined with acute rejection, and in one patient, it was combined with calcineurine inhibitor toxicity. In ten patients, monitoring for BKV replication using BKV real time PCR was available and the DNA copy number was 1.2 x 10^7 / mL (1.6 x 10^4 / mL -5.0 x 10^7/mL) in plasma and 1.1 x 10^{11} / mL (1.7 x 10^9/mL – 3.9 x 10^{11}/mL) in urine. Immunosuppression modification or reduction were done in fifteen patients. One of two patients who did not reduce immunosuppressant, were treated with steroid pulse due to combined acute cellular rejection. In addition, leflunomide was applied in seven, intravenous immunoglobulin in two out of fifteen patients had immunosuppression modification. Allograft loss developed in 23.5% (4 / 17) during follow up period (median 38.1 months (0.7 – 93.9)). Allograft loss developed at 0.7, 17.1, 21.8, 93.9 months from the diagnosis of BKVN respectively. The serum creatinine at diagnosis was higher in patients who suffered allograft loss compared to patients who did not.

Conclusions: As shown in this report, the clinical outcome of biopsy-proven BKVN is unfavorable, especially in cases diagnosed at later stage. Therefore, surveillance of BKV replication for earlier diagnosis of BKVN is recommended to prevent allograft loss due to BKVN.

PUB799

Optimizing Oral Glucose Tolerance Test for the Prediction of Prediabetes in Renal Transplantation Esteban Porrini,[1] Joan Manuel Diaz,[2] Irene Silva,[2] Meritxell Ibernon,[3] Patricia Delgado Mallen,[1] Francesc J. Moreso,[3] Benitez Rocio,[4] Jose Manuel Osorio,[5] Armando Torres.[1] *[1]Hospital Universitario de Canarias; [2]Fundación Puigvert; [3]Hospital Vall d´Hebron; [4]Hospital de Cruces; [5]Hospital Virgen de las Nieves.*

Background: Prediabetes: impaired fasting glucose (IFG: ≥100<126mg/dL) or impaired glucose tolerance (IGT: 2-h glucose ≥140<200mg/dL), is frequent in renal transplantation (RT), with IGT being more common. Diagnosis is made by oral glucose tolerance test (OGTT), a time-consuming non-standard practice.

Methods: We wished to optimize the use of OGTT by identifying patients with prediabetes. Eight Spanish centers each contributed 50-100 non-diabetics patients. After RT, OGTT was done at 3months and annually for 5 years. Stable patients beyond 12 months without new-onset diabetes were studied. ROC curves were used to analyze the goodness of fit of markers: fasting glucose (FG), HbA1c, triglycerides (TG), BMI or their combination to predict prediabetes.

Results: A total of 427 (144 prediabetic) patients were studied. Areas under the curve (AUC) were 0.713 (FG), 0.694 (HbA1c), 0.557 (TG) and 0.599 (BMI). With FG >or< 90 mg/dL, AUC was 0.657 and 0.493. With TG >or<150 mg/dL AUC was 0.574 and 0.511. The best predictor of prediabetes was a combination of both; **group A:** FG >90 mg/dL and **group B:** TG>150 mg/dL in patients with FG < 90 mg/dL. This strategy yielded overall AUC 0.61 (95%CI: 0.58-0.65), p<0.001, sensitivity 79.17 (71.6-85.5), specificity 42.66 (37.9-47.5), +likelihood ratio 1.38 (1.2-1.6) and-likelihood ratio 0.49 (0.4-0.7). Other analyses with HbA1c or BMI did not improve the prediction. This strategy detected 114 of 144 (79.16%) prediabetic patients.

Figure 1

		PREDIABETES	Cases
Fasting Glucose	Triglycerides		
< 90 mg/dL	< 150 mg/dL	YES	30
		NO	183
	> 150 mg/dL	YES	8*
		NO	49
> 90 mg/dL	-----	YES	106*
		NO	151

* cases detected, 114 of 144 (79.16%), OGTT done to detect these patients in grey

Conclusions: The use of OGTT to detect prediabetes in stable RT patients can be optimized by using the thresholds of FG >90 mg/dL and of TG >150 mg/dL.

PUB800

Serum Aldosterone in Prednisolone-Treated Renal Transplant Recipients Laura V. de Vries, Michiel N. Kerstens, Anna Muller Kobold, Ido P. Kema, Jan-Stephan Sanders, Gerjan Navis, Stephan J.L. Bakker. *Department of Medicine, UMCG, Netherlands.*

Background: Short-term outcome after kidney transplantation is excellent, but long-term survival is limited by chronic transplant dysfunction. The mineralocorticoid (MC) aldosterone is essential for sodium and potassium homeostasis, but it is also known for its adverse profibrotic and pro-inflammatory effects on the kidney. We aimed to investigate the associations of serum aldosterone with graft function and graft survival in prednisolone-treated renal transplant recipients (RTR).

Methods: Baseline measurements were performed between 2001 and 2003 in outpatient RTR with a functioning graft >1 yr. Follow-up was recorded until May 2009. Graft failure was defined as return to dialysis or re-transplantation. Serum aldosterone concentration was measured by Siemens Coat-A-Count® Radioimmunoassay, which has no cross-reactivity with prednisolone.

Results: A total of 566 RTR (age 51±12 yrs, 55% men) were studied. Median [IQR] aldosterone concentration was 0.28 [0.16-0.44] nmol/l. Aldosterone was higher in females than in males (P<0.001). It was positively associated with proteinuria (r=0.16, P=0.002) and use of antihypertensive drugs (r=0.13, P=0.002), and inversely associated with serum sodium (r=-0.08, p=0.04), 24h sodium excretion (r=-0.12, P=0.005), and creatinine clearance (r=-0.22, P<0.001). No association with blood pressure, serum potassium, or prednisolone dose was found. During follow-up for 6.9 [6.1-7.4] years, 51 (9.2%) RTR experienced graft failure. In univariate Cox-regression analysis, serum aldosterone was positively associated with graft failure (HR=1.76 [95%CI 1.32-2.35], P=0.001). This association remained significant after adjustment for age, sex, CV risk factors, and sodium status (HR=1.48 [95%CI 1.08-2.03], P=0.01).

Conclusions: In this prospective cohort of RTR, despite MC effects of prednisolone treatment, serum aldosterone was associated with sodium and blood pressure homeostasis, and renal function. Findings are consistent with suppression by high sodium availability, and adverse effects on blood pressure and graft function on the long-term. Intervention with aldosterone blockade might be beneficial in prednisolone-treated RTR.

PUB801

Indoleamine 2,3-Dioxygenase Activity Following Renal Transplantation Rashmi Karanth,[1] Rachel Harbarger,[2] Rokshana R. Thanadar,[1] Julie J. Kim,[1] Todd D. Merchen,[3] Calpurnia Jayakumar,[1] Ganesan Ramesh,[1] Andrew L. Mellor,[2] John White,[1] N. Stanley Nahman.[1,4] *[1]Medicine, Georgia Health Sciences University, Augusta, GA; [2]Immunotherapy Center, Georgia Health Sciences University, Augusta, GA; [3]Surgery, Georgia Health Sciences University, Augusta, GA; [4]Medicine, Charlie Norwood VAMC, Augusta, GA.*

Background: Indoleamine 2,3-dioxygenase (IDO) degrades tryptophan (Trp) to kynurenine (Kyn). Through depletion of lymphocyte Trp, IDO may contribute to the development of host tolerance to alloantigens and thus be of clinical use in kidney transplantation (KTx). Harnessing the immunomodulatory effects of IDO requires the ability to non-invasively monitor its activity in vivo. To address this question, we assessed serum and urine Trp and Kyn levels from individuals with normal renal function (NL), hemodialysis patients (HD), and following KTx.

Methods: NL (N=8) or HD (N=10) had a single sampling of blood and urine (NL only). KTx (N=4) were sampled pre- (blood only), and post-transplant (blood and urine). Serum and urine Kyn and Trp levels were measured using HPLC. The ratio of Kyn/Trp is an accepted marker for IDO enzyme activity. All Kyn/Trp ratios were corrected for level of renal function by dividing by the respective serum or urine creatinine concentration.

Results: KTx patients had 4.3±1.7 (mean±SD) samples obtained on post-operative days ranging from 6 to 58. Serum creatinine was higher in HD (N=10 samples) when compared to NL (N=8 samples) and KTx (N=15 samples) (5.44±2.1 vs 0.8±0.17 and 1.14±0.48 mg/dl, p<0.001, respectively). Serum Kyn/Trp ratios were not different between NL, HD and KTx (0.05±0.007, 0.03±0.015 and 0.04±0.028, respectively). When corrected urinary Kyn/Trp values were compared between NL (N=7 samples) and KTx (N=13 samples), there was a trend toward higher levels in KTx (0.04±0.02 and 0.35±0.44 for NL vs KTx, respectively).

Conclusions: These data indicate a trend toward higher corrected urinary Kyn/Trp ratios following KTx and suggest that allograft IDO activity is increased in these patients. We would theorize that corrected urinary Kyn/Trp activity may be a useful biomarker of kidney IDO activity following KTx.

Multimodal Tacrolimus Adherence Measurement: The Role of Depression Daniel Cukor,[1] Nisha Ver Halen,[1] Ankita B. Patel.[2] *[1]Psychiatry, SUNY Downstate Medical Center, Brooklyn, NY; [2]Medicine, SUNY Downstate Medical Center, Brooklyn, NY.*

Background: Non-adherence to immunosuppressant medication following kidney transplant is associated with graft loss, increased hospitalization and death, yet is quite prevalent. Accurate assessment of medication adherence is essential to clinical care and

predicting rejection. Despite the importance placed on medication adherence there is little data on the reliability or validity of the various assessment strategies.

Methods: Thirty kidney transplant recipients who were more than 6 months post transplant were followed for their Tacrolimus adherence over a 3 month assessment window. Adherence to Tacrolimus was assessed through 3 different modalities: self-report questionnaire (Immunosuppressant Therapy Adherence Scale - ITAS), pill count (both phone and in-office), and serum Tacrolimus levels.

Results: Over the course of the three-month assessment window, average serum Tacrolimus levels were within target (5-15) range for 62% of the sample. Pill count data indicated 68% of the sample took at least 95% of their pills, and 79% of the sample indicated perfect adherence through the self-report questionnaire. While there was reasonable internal consistency for each of the measurement styles (the monthly values were each highly correlated with one another (Cronbach's alpha -ITAS=.66, lab test=.63, pill count = .60) there was low levels of agreement across the different modalities (.34). Interestingly, subjects self reporting substantial non adherence reported significantly higher depression scores (t=3.3,p<.01) but no difference in actual pill counts (p>.05) or serum Tacrolimus levels (p>.05).

Conclusions: Immunosuppressant non-adherence is common in the kidney transplant community and more rigorous exploration into the methodologies utilized for assessment is an essential first step in improving the quality of the science in this area.

PUB803

Effect of Early Corticosteroid Minimization versus Early Corticosteroid Withdrawal on Graft Function and Cardiovascular Risks in Simultaneous Kidney Pancreas Transplantation Carolyne J. Jepkorir, Basma Sadaka, Jaime A. Pineda, R. Alloway, E. Steve Woodle, Amit Govil. *Nephrology/Transplant Division, Univ of Cincinnati, Cincinnati, OH.*

Background: Early corticosteroid (CS) withdrawal (ECSWD) and early CS minimization (ECSM) in SKP transplantation have been evaluated at single centers with no direct comparison. We report a sequential comparison of graft function and cardiovascular (CV) risks/events between ECSWD and ECSM.

Methods: 110 consecutive SKP transplants receiving rATG induction, FK, MMF and sequential regimens of chronic corticosteroids (CCS) (n=23), ECSWD(n=42), and ECSM with a rapid taper to 5mg/day (n=45) were retrospectively reviewed. CV risk factors were assessed along with graft function. Stats were performed using ANOVA and KM.

Results: Patient characteristics, FK level/MMF dose, SrCr, MDRD and fasting glucose were similar. ECSWD had greater improvement in BP with less meds while CCS had significantly high total cholesterol and LDL levels with no significant difference in TG, HDL and lipid therapy. CV events to date are similar between groups with no significant differences in rejection, patient, allograft function/survival.

	CCS (n=23)	ECSWD (n=42)	ECSM (n=45)	p-value
Median Follow-up (days)	3355	2261	802	
Steroid doses (mg/day) (mean ± SD)

Year 1	66.59 ± 30.54	68.89 ±20.83	65.6 ± 18.75	NS
Year 2	65.52 ± 22.42	65.72 ± 22.24	74.79 ±47.78	NS
Fasting Blood glucose				
Year 1	95 ± 18	93 ± 11	100 ± 41	0.53
Year 2	94 ± 37	93 ± 11	100 ± 36	0.65
Post-transplant LDL (mean ± SD)				
Year 1	108 ± 45.5	77.9 ± 27.6	68.3 ± 19.1	<0.0009
Year 2	97.9 ± 26.4	73.8 ± 24.4	83.6 ± 29.6	0.02
Kidney Graft Survival n (%)				
Year 1	21 (91.3)	41 (97.6)	43 (95.6)	NS
Year 3	19 (82.6	39 (92.9)	43 (95.6	NS
Pancreas Graft Survival n (%)				
Year 1	22 (96.6)	39 (92.9)	41 (91.1)	NS
Year 3	20 (87)	38 (90.5)	38 (84.4)	NS

Conclusions: Long-term follow up is required to better delineate differences in CV events, rejection, patient and graft survival in ECSWD vs. ECSM vs. CCS.

PUB804

Efficacy and Safety of Administering Renin-Angiotensin-Aldosteron System Blockers Very Early after Renal Transplantation Christos D. Chatzikyrkou,[1] Jenny Eichler,[1] Christian Clajus,[1] Jan Menne,[1] F. Lehner,[2] Fabian A. Helfritz,[2] Lampros Kousoulas,[2] Wolf Ramackers,[2] Hermann G. Haller,[1] Mario Schiffer.[1] *[1]Department of Nephrology and Hypertension, Hannover Medical School, Hannover, Germany; [2]Clinic for General, Abdominal and Transplant Surgery, Hannover Medical School, Hannover, Germany.*

Background: Renal transplant physicians are reluctant to use renin-angiotensin-aldosteron system (RAAS) blockers, due to the risk of renal function decline and hyperkalemia. The aim of this study was to investigate the safety and antihypertensive efficacy of RAAS blocker in the very early postoperative period after renal transplantation.

Methods: We analyzed the charts of 130 kidney transplant recipients, who received a RAAS blocker in the very early postoperative period 130 kidney transplant patients who did not receive a RAAS blocker served as controls. Cases and controls were matched by age, sex, year of transplantation and serum creatinine at the time of administration of the RAAS blocker. Clinical and laboratory variables, which were monitored closely before and after initiation of therapy, were compared between the two groups. Paired t-test was performed to compare blood pressure, serum creatinine, eGFR and serum potassium levels at therapy initiation and discharge.

Results: 105 (80.8%) patients were treated with an ACE inhibitor, and 25 (19.2%) with an ARB. Most patients received the RAAS blocker at postoperative day 8 and were discharged from hospital at postoperative day 13. Systolic, diastolic and mean arterial blood pressure were significantly reduced from 148 ± 17, 87 ± 11 and 108 ± 11mmHg at treatment initiation to 136 ± 17, 81 ± 10 and 99 ± 11 mmHg at discharge (p<0.001 for all variables). Transplant function was not affected. Serum creatinine decreased and eGFR increased (from 162 ± 79 µmol/l to 132 ± 40 µmol/l and from 48 ml/min ± 21 to 55 ± 18 ml/min). Serum potassium levels increased significantly (4.35 ± 0.46 mmol/l to 4.63 ± 0.58 mmol/l), but remained within the normal range.

Conclusions: RAAS blockers can effectively reduce blood pressure in the early postoperative period after kidney transplantation, without jeopardizing graft function and without increasing the risk of hyperkalemia.

PUB807

The Role of Pre-Dialysis Education on the Choice of Kidney Transplantation among Dialysis Patients Tarek Alhamad, Bruck Yemenu, Nasrollah Ghahramani. *Internal Medicine, Penn State College of Medicine, Hershey, PA.*

Background: End-stage renal disease (ESRD) is associated with significant morbidity and mortality. Among various therapies for ESRD, kidney transplantation (KT) is associated with the greatest longevity and the highest quality of life. The patient's understanding of the process of transplantation is a major determinant of preference for KT.

Objective: To investigate the impact of pre-dialysis education about transplantation on the preference for KT among dialysis patients.

Methods: We conducted a cross sectional self-administered survey among a potential pool of 80 dialysis patients. Participants were recruited during in-center hemodialysis (HD) session, or at home dialysis clinic.

Results: Fifty five dialysis patients (36 male; 38 white) provided informed consent to participate in the study (in-center HD: 43; peritoneal dialysis: 10; home HD: 2). Mean age was 59.27 ± 16.92, time since initiation of dialysis was more than a year for 68% of the patients and 29% had seen a nephrologist for the first time within 3 months of dialysis initiation. Twenty-four patients (44%) believed they had received adequate information about KT prior to dialysis initiation, while 19 patients (35%) considered the information about KT to have been adequate only after dialysis initiation. Ten patients (18%) acknowledged inadequate information about KT. When asked if they were offered the option of continuing current dialysis, switching the dialysis modality or opting for KT, 24 patients (44%) indicated that they would select KT. Using a stepwise logistic regression model which included demographic and treatment-related covariates (age, gender, race, employment status, education, income, current modality of therapy, time since initiation of dialysis), the perceived adequacy of information about KT received prior to initiation of dialysis was an independent predictor of selecting KT as the therapy of choice (OR=4.07; 95% CI: 1.31 to 12.65; p=0.015).

Conclusions: This pilot study highlights the importance of providing chronic kidney disease patients with adequate information about transplantation and other available treatment options before initiation of dialysis.

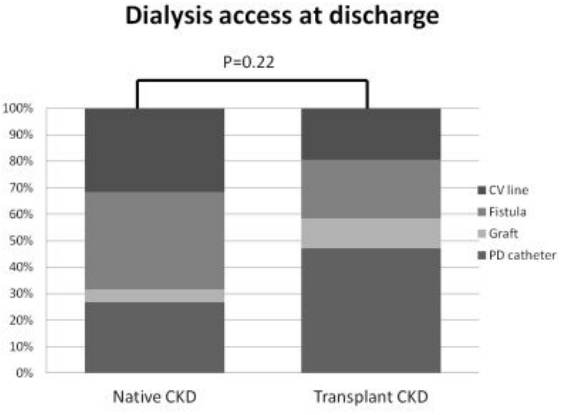
PUB808

Impact of Multidisciplinary Predialysis Care on Outcomes after Kidney Transplant Failure Brendan Boyd,[1,2] Mimi Cheng,[1] Niki Dacouris,[1] G.V. Ramesh Prasad,[1] Jeffrey Perl.[1] *[1]St. Michael's Hospital; [2]University of Toronto.*

Background: Reduced survival of kidney transplant failure (TF) patients relative to native kidney function decline (NKFD) patients initiating dialysis may relate to poor quality and fragmentation of predialysis care. Multidisciplinary predialysis care (MPC) has been associated with improved dialysis initiation outcomes for NKFD patients. We compared dialysis initiation outcomes, as well as the rate of kidney function decline, for TF and NFKD patients attending our MPC clinic.

Methods: Demographic, comorbidity and laboratory data were extracted retrospectively for patients discharged from the MPC clinic, using medical records. Continuous variables were compared via t-test or Mann-Whitney analysis where appropriate. Categorical variables were compared using chi-square analysis.

Results: 54 TF and 66 NKFD patients were identified. TF patients were younger (53.0±11.0 vs. 66.6±16.3, p <0.001), with a lower Davies comorbidity index (0(0-1) vs. 1(0-2), p=0.002), and a lower eGFR (15.0(12.9-18.7) vs. 18.6(14.2-23.0), p=0.002) at MPC referral. At the time of discharge, rates of optimal dialysis initiation (permanent surgical vascular access or the initiation of peritoneal dialysis) were similar between the groups(**Figure**). TF patients also experienced more rapid decline of eGFR(**table**) over the course of follow-up.



Temporal mean eGFRs (±SD)

Days attending MPC	TF eGFR (mL/min/1.73m2)	NKFD eGFR (mL/min/1.73m2)	P-value
0-99	14.8±4.17	18.3±7.32	<0.001
100-199	14.6±5.47	22.4±11.2	<0.001
200-299	12.4±4.56	20.4±10.9	<0.001

Conclusions: Although TF patients are referred at a lower eGFR, they initiate dialysis optimally at a similar rate to NKFD patients. This preliminary data indicates that MPC may confer similar benefits to both NKFD and TF patient highlighting its potential impact on improving the survival of TF patients, which warrants further prospective study.

PUB810

Operative Time and Outcome after Kidney Transplantation: Does the Time of Day or the Day of Week Matter? Seema Baid-Agrawal,[1] Holly J. Kramer,[2] Harold I. Feldman.[3] *[1]Department of Nephrology and Medical Intensive Care, Campus Virchow Clinic, Charite Medical University, Berlin, Germany; [2]Department of Preventive Medicine, Loyola Medical Center, Maywood, IL; [3]Center for Clinical Epidemiology and Biostatistics, University of Pennsylvania Medical Center, Philadelphia, PA.*

Background: Medical care during off-hours i.e. at night-time or during weekends has been associated with increased morbidity and mortality compared with care delivered in regular hours among patients with multiple medical and surgical conditions. We compared outcomes of off-hour kidney transplantation (KTx) to those performed during regular hours.

Methods: Using the United Network for Organ Sharing database, we analzyed 181,925 adults aged >20 years who received a deceased donor KTx between January 1, 1990 and September 1, 2010 and who had complete information on time and date of surgery. Cox proportional hazards models were fit to evaluate the association between KTx during daytime (6 AM -9:59 PM) vs. night-time (10 PM -5:59 AM) and weekend (Saturday/Sunday) vs. weekday (Monday-Friday), and patient and graft survival at 1, 3, 5 and 10 years post-Tx, while adjusting for multiple covariates. All models were adjusted for both time of day and weekend vs. weekday.

Results: The average age was 47.8 years ± 12.7; 60.3% were male, 42.3% and 27.3% received Tx at night-time, and on the weekend, respectively. No significant association was noted between time of day or day of week and allograft failure including death or patient mortality at 1, 3, 5 and 10 years (Table 1).

Table 1: Outcome

10-y	1.01 (1.00-1.02)	1.07 (0.98-1.16)	1.01 (0.99-1.03)	1.00 (0.98-1.16)

HR, hazard ratio; CI, confidence interval; y, year

Conclusions: The relatively stable condition of KTx recipients before Tx and protocolized nature of care may make this group less susceptible to adverse factors associated with off-hour care.

PUB811

Bone and Mineral Metabolism (BMM) in a Representative Sample of Spanish TR Patents (EMITRAL Study) Armando Torres, Daniel Dorado, Manuel Arias, Josep Maria Campistol Plana. *ICNU, Hospital Clinic, Barcelona, Spain.*

Background: The prevalence and treatment of bone and mineral metabolism disorders in renal transplantation (RT) are little known. The present cross-over study involved 729 recipients from 29 Units, with over one year from RT (69.2±30.6 months).

Methods: The estimated GFR was < 40 and ≥ 40 ml/min/1.73m2 in 55% and 45% of the cases. Centralized biochemical and radiological studies were made (Genant score for dorsolumbar vertebral fracture, and Kauppila score for abdominal aortic calcification). The proportion of patients with values within range for each stage of chronic kidney disease according to the guides (KDOQI and SEN) was 49.7% for Ca (only 6.5% with hypercalcemia), 86.2% for PO4, and 99.3% for Ca x PO4. The PTH levels were inversely correlated to estimated GFR (r=-0.33; p<0.001), and in 71.9% of the cases were above the established range for the corresponding chronic kidney disease stage.

Results: 39.8% of the cases with PTH above the range for the corresponding disease stage had elevated bone alkaline phosphatase. The 25OHD3 levels were insufficient (10-30 ng/ml) in 69.4% of the cases, and deficient (<10 ng/ml) in 13.85%. However, most of the patients presented adequate 1,25(OH)2D3 levels (>25 ng/ml). The 25OHD3 levels were inversely correlated to PTH (r=-0.23; p<0.001). 10% of the patients were receiving calcimimetic treatment, and 37.2% were administered vitamin D metabolites (nutritional, calcitriol, or paricalcitol). Although only 3% had known fracture antecedents following RT, 27% presented some prevalent vertebral fracture (FxV). A total of 67.3% showed aortic calcifications and the patients with FxV had a higher pulse pressure and CaAo score. Only 58% of the known fractures had received treatment.

Conclusions: Among stable RT recipients:a) hypercalcemia is infrequent, and the PO4 levels stay in the recommended range until stage V is reached; b) in most subjects PTH is above and 25OHD3 below the recommended range for the corresponding chronic kidney disease stage; c) asymptomatic FxV and CaAo are frequent in this population and are inter-related; and d) there is room for improvement in the management of BMM disorders after RT.

Possible Predictors for Rituximab Responsiveness in Patients with Standard-Therapy Resistant Kidney Allograft Rejection Maximilian Ernst Daemmrich,[1] Verena Broecker,[2] Clemens L. Bockmeyer,[1] Wilfried Gwinner,[3] Anke Schwarz,[3] Hermann G. Haller,[3] Hans H. Kreipe,[1] Cornelia Anneliese Blume.[3] *[1]Pathology, Medical School Hannover, Hannover, Germany; [2]Histopathology, University Hospital Cambridge, Cambridge, United Kingdom; [3]Nephrology and Hypertensiology, Medical School Hannover, Hannover, Germany.*

Background: Rituximab serves as immunosuppressive rescue to treat standard therapy resistant rejections. Due to possible severe side effects, criteria to predict Rituximab responsiveness are most desirable. In this retrospective analysis, we compared Rituximab responders and non-responders (R and NR).

Methods: 20 renal transplant recipients were analysed with their last biopsy previous to rituximab therapy (375 g/qm2 b.s., 1-2 courses, 15 x combined with plasmapheresis). 10 patients were identified as NR returning to dialysis 5.7 ± 1.5 months after therapy. In 10 patients (R), kidney graft function was preserved after therapy (20.7±7.3 months; eGFR: 28.3 ± 2.6 ml/min; p<0.0001). Clinical, serological and histomorphological parameters were compared between both cohorts by Wilcoxon-or chi-square tests.

Results: NR had a significant lower eGFR (MDRD) at the time of biopsy, higher max. proteinuria and significant more biopsies with acute cellular rejections in their history. Immunohistochemical analysis of CD3, 20, 68 was not different between both groups, but interestingly the infiltrate of CD138 positive plasma cells was higher in the R-group. Histomorphological Banff parameters for acute cellular, acute and chronic humoral as well as glomerular, vascular and tubulointerstitial lesions in the last biopsy before rituximab and serological findings (HLA-mismatches, HLA-antibodies class I and II, DSA) or clinical parameters (recipients' age, sex, deaths, infections, living or cadaveric donor, previous renal transplants, time after transplantation) were not different between groups.

Conclusions: Transplant function, max. proteinuria and the number of historic rejections were predictive for therapy outcome. These criteria and particulary the infiltrate of plasma cells in biopsies of rituximab treated patients need validation in future prospective randomized studies.

Endothelial Dysfunction Assessment in Kidney Transplant Recipients Converted from Calcineurin Inhibitors to Everolimus: Preliminary Analysis Ruben O. Schiavelli,[1] Fernando Margulis,[1] Carlos E. Cuevas,[1] Esteban Alvarenga,[1] Alcira B. Otero,[2] Marcelo Ponte.[1] *[1]Nephrology and Transplantation, Hospital Argerich, Buenos Aires, Argentina; [2]Novartis Arg SA, Buenos Aires, Argentina.*

Background: Pulse wave velocity is considered an independent predictor of cardiovascular mortality. Stiffness index (SI) and reflection index (RI) reflect the stiffness of large arteries and vascular tone (endothelial function) of small-size arteries. The objective

of this study has been to assess the effect of the conversion from calcineurin inhibitor (CNI) to everolimus (EVR) on endothelial dysfunction and arterial wall stiffness.

Methods: Open, prospective, one year study with a control arm in kidney transplant patients (KTP). Twenty KTP (3 to 12 months after transplant) were converted from a CNI to EVR. Ten patients remained on CNI (control arm). To assess endothelium dependent arterial vasodilation, 400 ug of salbutamol (Salb) were given by inhalation.The vasodilation, dependent on endothelial function, was defined as the maximum difference in ΔRI between baseline and the post-Salb. SI and ΔRIb/RIs, 24 ambulatory MAP (mean arterial pressure); LVMI (Left Ventricular Mass index) were performed baseline and post conversion. We report a descriptive analysis of the 6 months after conversion period.

Results: At month six 5 patients discontinued: one control and 4 EVR. 95% CI values for main variables: Baseline: 1- 24 Amb MAP Control (90.7,101.3); EVR (97,113); 2-SI Control (6.6,10.6), EVR (9,11); 3- ΔRIb/RIs Control (-0.9,7.1); EVR: (1.5,15.5) and LVMI Control (124,166); EVR (158,190). At month six: 1- 24 Amb MAP Control (94,102); EVR (91,106); 2-SI Control (8.3,10.3), EVR (8.4,10.4); 3- ΔRIb/RIs Control (2.2,8.2); EVR: (0.7,6.7) and LVMI Control (102,152); EVR (144,182). P values were non statistically significant in any case. No changes were registered in endothelial function as per ΔRIb/RIs. A numerical trend to improve figures in variables representing arterial wall stiffness was observed in EVR arm.

Conclusions: In this group of stable KTP and in this time frame, conversion to EVR appears to produce a numerical improvement in arterial wall stiffness markers. No valid changes in endothelial function have been observed.

PUB814

Association between One-Year Serum Albumin and Patient Outcomes after Kidney Transplantation Il Hwan Oh, Joon-sung Park, Gheun-Ho Kim. *Department of Internal Medicine, Hanyang University College of Medicine, Seoul, Republic of Korea.*

Background: Hypoalbuminemia are associated with increased risk of mortality in patients with kidney failure. There are limited data evaluating the relationship between serum albumin and patient outcomes in kidney transplantation (KT). We investigated whether serum albumin level is associated with patient outcomes after KT.

Methods: All recipients were divided into two groups according to serum albumin level at 1yr posttransplant: Group I (n = 188), >4.5 and 5.0 g/dL; Group II (n = 191), ≥ 4.0 and 4.5g/dL. Multiple linear regression analysis was used to find contributing factors to serum albumin level at 1yr posttransplant, and Kaplan-Meier (KM) analysis was used to compare patient outcomes between the Groups. The relationship between patient outcomes and factors including serum albumin was evaluated by Cox proportional hazard model.

Results: Three hundred and seventy-nine allograft recipients were followed for 121 ± 55 months. At 1 yr posttransplant, Group I had younger age (36.4 ± 9.7 vs. 41.9 ± 10.1 years, P<0.01), shorter dialysis vintage (27.6 ± 31.7 vs. 40.8 ± 46.6 months, P<0.01), higher serum hemoglobin level (13.3 ± 2.2 vs. 12.5 ± 2.0 mg/dL, P<0.01), and higher serum protein level (7.3 ± 0.4 vs.7.0 ± 0.4 g/dL, P<0.01) compared with Group II. Multiple linear regression revealed that serum albumin level at 1yr posttransplnat was significantly associated with age and serum protein level. KM analysis revealed that Group II had a worse patient survival, graft survival, and cardiovascular (CV) event-free survival as compared with Group I (P's<0.05 by the log-rank test). In Cox proportional hazard model, the serum albumin level was significantly associated with patient survival (HR = 0.222; 95% CI = 0.081-0.608), graft survival (HR = 0.403; 95% CI = 0.211-0.773), and CV event-free survival (HR = 0.321; 95% CI = 0.151-0.682).

Conclusions: These results suggest that the one-year serum albumin level may predict patient outcomes after KT. Such finding may have implications for early identification of vulnerable patients and for the development for targeted interventions to reduce the risk of mortality in this patient population.

PUB815

The Impact of Type 2 Diabetes on the Outcome of Patients on the Kidney Transplant Waiting List in France Frank Géoffroy Azimafoussé Assogba, Cécile Couchoud, Christian Jacquelinet. *Agence de la Biomédecine, Saint Denis la Plaine, France.*

Background: End stage of renal disease (ESRD) patients with diabetes have been shown to be less likely wait-listed or transplanted and more likely to have a longer waiting time. We aim to evaluate the proper effect of type 2 diabetes (T2D) on dead or too sick patients delisting (DTSPD) among kidney transplant (KTx) candidates.

Methods: The cohort of all 2785 ESRD adult patients (type 1 diabetes excluded) registered on the French national waiting list between January 2006 and December 2008 for first kidney transplantation was enrolled in the study and followed until 13 July 2011. DTSPD defined the event of interest and KTx a competing event. We used competing risks regression analyses with sequential adjustment to identify factors associated with DTSPD and evaluate the proper effect of T2D.

Results: Mean age was 51±12 years. The 3-year cumulative incidence was 4% for DTSPD and 76% for KTx. In univariate analysis, patients with T2D had an increased risk of DTSPD (Hazard ratio, HR, 1.85; 95% CI, 1.19-2.88) and lower access to KTx (HR, 0.87; 95% CI, 0.76–0.99) when compared to non diabetic. After adjusting for potential confounders such as age and sex, matched donor potential, immunisation status and number of cardiovascular disease the proper effect of T2D on both DTSPD (p=0.7) and KTx (p=0.3) was no more observed. Furthermore, increased age (HR, 2.40; 95% CI, 1.10-5.24 for 50-59 years; HR, 3.91;1.78-8.59 for 60 years) was independently associated with DTSPD and has no influence on KTx. Patients with two and more cardiovascular comorbidities have 30% less likely to access to KTx and 3.49 times to dead or be delisted compared to those with none.

Conclusions: T2D per se is not associated with both DTSPD and KTx when the other factors are taken into account for patients registered on the waiting list. Despite a higher selection of patients before registration on the waiting list, cardiovascular comorbidities are an important barrier to access to KTx and remain with older age the factors leading to either death or delisting from waiting list in France. Should we be more selective before registration on waiting list or need to transplant them faster?

PUB816

Hypertension in Post Renal Transplant Patients: A Pilot Study Anita Saxena, Raj K. Sharma, Amit Gupta. *Nephrology, SGPGIMS, Lucknow, Uttar Pradesh, India.*

Background: Hypertension following renal transplantation being a major risk factor for graft loss and patient survival, must be aggressively treated. Objective: Relationship of body water and body composition with hypertension in renal transplant patients.

Methods: 45 post transplant patients were divided into two groups. Group 1: patients on one antihypertensive drug and Group 2: patients on more than one antihypertensive drug. Nutritional status of the patients was assessed using subjective global assessment. Blood pressure (BP) was labeled controlled if BP was ≤120/80 mmHg and not under good control if BP was ≥ 120/80 mmHg. Body composition (water compartments, body fat and lean mass) was assessed using bioelectrical impedance analysis. Controls were 30 healthy volunteers. All the biochemical parameters were tested.

Results: Patients had normal nutritional status. In patients, systolic blood pressure was associated with TBW (p=0.016), extracellular water (ECW Lt; r =0.99), ECW% (r = 0.78) and diastolic BP with TBW% (p=0.003), dry weight (r= 0.76) ECW% (r= 0.95), and ICW% (r=0.79). Compared to controls, ECW and ECW% was higher in patients and ICW% was less in patients. There was significant difference in the actual weight of the patients and BIA derived dry weight although patients were clinically not edematous. Study shows significant increase in diastolic BP with increase in dry weight. Significant difference in the total body water (TBW) was observed when the patients were grouped on the basis antihypertensive medication patient was taking (1 antihypertensive drug versus more than 1 antihypertensive drug).

Conclusions: Study shows association between hypertension and overhydration. BIA may be a useful tool for clinical assessment of overhydration in nonedematous post transplant patients.

PUB817

Provider–Patient Visit Frequency on Hemodialysis and Kidney Transplantation Yelena Slinin,[1] Haifeng Guo,[2] Suying Li,[2] Jiannong Liu,[2] David T. Gilbertson,[2] Allan J. Collins,[2] Areef Ishani.[1,2] *[1]Veterans Administration Health Care System, Minneapolis, MN; [2]Chronic Disease Research Group, Minneapolis, MN.*

Background: Centers for Medicare & Medicaid Services tied provider reimbursement for outpatient hemodialysis services to a number of times per month providers see their patients on hemodialysis, resulting in increased frequency of provider-patient visits on dialysis. We aimed to determine whether greater provider-patient visit frequency is associated with a greater hazards of transplant waiting list placement and transplantation compared to fewer visits among incident hemodialysis patients.

Methods: Using United States Renal Data System data for patients who initiated in-center hemodialysis between 10/1/2003, and 9/30/2006, we defined patient characteristics and provider visit frequency on dialysis during months 4-6 of hemodialysis. Patients (N=87931) who were not on the kidney transplant waiting list and patients (N=3345) who were on the transplant waiting list at the start of follow-up were followed for 1 year for placement on the transplant waiting list and transplantation, respectively. We used Cox proportional hazards modeling to determine the association between provider-patient visit frequency and the outcomes.

Results: Of the 87,931 patients not on the waiting list and of the 3,345 patients on the waiting list at the start of follow-up, 60.8% and 58.5%, respectively, were seen by their providers at least 4 times a month. After multivariate adjustment for patient characteristics, greater provider visit frequency (4+ times/month compared to <4) was not associated with shorter time to placement on the kidney transplant waiting list: Adjusted Hazards Ratios (AHR) (95% Confidence Interval (CI)) 1.02 (0.96-1.08), or to kidney transplantation AHR (95% CI) 1.05 (0.91-1.22).

Conclusions: Greater frequency of provider visits to hemodialysis patients is not independently associated with either a greater rate of placement on the kidney transplant waiting list or kidney transplantation in hemodialysis patients.

PUB818

Burden of Kidney Disease Post Transplantation Jeanne Dreier, Sridhar K. Reddy, Avrum Gillespie. *Nephrology, Temple University Hospital, Philadelphia, PA.*

Background: Allograft dysfunction, common in an inner city population, may erode both patient satisfaction with transplantation and self-reported health. The purpose of this study is to examine the association between self-reported health, disease burden, treatment satisfaction and clinical markers in an inner city population of kidney transplant recipients.

Methods: Fifty-four patients completed a survey specifically designed for this study. The survey data was merged with common laboratory test data and analyzed in SPSS, version 18. The mean age of participants was 56.7 years, males and females were equally represented and mean serum creatinine was 1.65 mg/dl. Respondents were 64.1% African American, 18.9% Hispanic and 17% Caucasian.

Results: Most patients (77.4%) were satisfied with their transplantation experience. Yet, only 49.1% reported that they were not at all burdened by their current kidney disease. Serum creatinine was not correlated with disease burden, self-reported health or satisfaction with treatment. Patients indicating some level of disease burden were more likely to report poorer health (Pearson .395, p=.003), less likely to be satisfied with their current treatment (Pearson .475, p<.001), and they also had lower serum albumin (Pearson -.304, p=.027) compared to those who reported no burden. Patients who reported more disease burden had shorter allograft vintage (Pearson -.468, p=.001). Interestingly, burden-free patients were more likely to be African American or Hispanic (Chi-Square 7.711, p=0.021).

Conclusions: In conclusion, post-kidney transplantation self-reported health, disease burden, and satisfaction with treatment are not correlated with allograft function. Patients who reported any kidney disease burden have poorer self-reported general health, less satisfaction with current treatment, shorter allograft vintage, and lower serum albumin. Lastly, African Americans and Hispanics are more likely to be burden-free from their kidney disease.

Adult Preemptive Kidney Transplantation: A Paired Kidney Analysis
Boleslaw Rutkowski,[1] Alicja Debska-Slizien,[1] Beata Bzoma,[1] Andrzej Chamienia,[2] Grazyna Moszkowska,[3] Dariusz Zadrozny,[4] Anna Milecka.[4] *[1]Department of Nephrology, Transplantology and Internal Diseases, Gdansk Medical University, Gdansk, Poland; [2]Department of Nursing Science, Gdansk Medical University, Gdansk, Poland; [3]Department of Immunology, Gdansk Medical University, Gdansk, Poland; [4]Department of General, Endocrine and Transplant Surgery, Gdansk Medical University, Gdansk, Poland.*

Background: From November 2003 to December 2012, in GdanskCenter, 58 patients received preemptive transplantation (PET). PET consisted 8% of all 703 kidney transplantations performed during this time. The benefits for individual patients and for the health care system are discussed.

Methods: The present study compares the outcomes of these PET patients who had their kidney donor pairs transplanted after variable duration of dialysis (PTD).

The mean age was 41.8 and 45.9 years in 45 PET and 45 PTD, respectively. PTD patients remained on dialysis for 3.5-180 (mean 37,08) months before transplantation.

Results: Mean transplantation waiting time was 3.7 *vs.* 24,3 months (U Test, $p<0.05$) and the mean Charlson co-morbidity index was 2.49 *vs.* 2.96 (U Test, $p>0.05$) for the PET and PTD groups, respectively. Both groups did not differ significantly with respect to one-year patient and graft survival and incidences of acute rejection. Four (9%) PET patients and 14 (35%) PTD patients experienced delayed graft function (U Test, $p<0.05$). The graft function (GFR) one year after transplantation was similar in both groups. A comparison of serum creatinine concentration indicated significantly lower levels in the PET group and this difference was stable throughout our observation (ANCOVA Test, $p<0.05$). More PET patients led normal professional activities or continued education before and after transplantation (Fisher test, $p<0.05$).

Conclusions: Our single-center results confirmed that PET is an optimal mode of renal replacement therapy for both medical and socioeconomic reasons. Long-lasting medical care allows appropriate and optimal treatment of end stage renal disease.

PUB820

Permanent Vascular Access and Mortality among Failed Kidney Transplant Patients Who Initiate Maintenance Hemodialysis (MHD)
Saugar Maripuri, T. Alp Ikizler, Kerri L. Cavanaugh. *Division of Nephrology and Hypertension, Vanderbilt University Medical Center, Nashville, TN.*

Background: In the US, 1,700 patients return to MHD each year after kidney transplant failure. Several studies suggest these patients have higher mortality compared to wait-listed dialysis patients. It is unknown if this observation is related to differences in hemodialysis access attainment.

Methods: A retrospective USRDS cohort was generated of adult patients who initiated MHD between 2005-2007 after failure of their first kidney transplant. Baseline characteristics and vascular access type were determined from the core files and medical evidence report. Mortality risk was examined using multivariable Cox models.

Results: A total of 4,624 patients with primary kidney transplant failure returned to MHD. Median transplant survival was 7.6 years. Pre-transplant dialysis exposure occurred in 88% (HD only 66%, PD only 10%, mixture HD and PD 12%). Permanent hemodialysis access (AVF or AVG) was present in 36% at re-initiation, but only 16% of those treated with pre-transplant PD. The unadjusted mortality rate after initiation of MHD was 16.7 events per 100 person-years. Pre-transplant PD associated with increased hemodialysis mortality (HR 1.18 CI 1.04-1.34) when compared to pre-transplant HD. After adjustment for permanent dialysis access (HR 0.73 CI 0.65-0.82), pre-transplant PD was no longer independently associated with hemodialysis mortality (HR 1.11 CI 0.97-1.26).

Conclusions: Pre-transplant PD associated with higher mortality after transplant failure and re-initiation of hemodialysis, but is largely attributable to differences in vascular access attainment. Greater attention should be placed at improving fistula rates prior to allograft failure.

Renal Transplatation Outcomes in C3 Glomerulopathy: The Irish Experience
Limy Wong,[1] Michelle M. O'Shaughnessy,[1] John O'Regan,[1] Carol A. Traynor,[1] Michael James Flanagan,[1] Chia Wei Teoh,[2] Nicholas R. Medjeral-Thomas,[3] Anthony M. Dorman,[1] Matthew C. Pickering,[3] H. Terence Cook,[3] Peter J. Conlon.[1] *[1]Department of Nephrology, Beaumont Hospital, Dublin 9, Dublin, Ireland; [2]Department of Nephrology, The Children's University Hospital Temple Street, Dublin 1, Dublin, Ireland; [3]Centre for Complement and Inflammation Research, Imperial College London, South Kensington Campus, London, United Kingdom.*

Background: "C3 glomerulopathy" (C3G) describes a heterogenous group of glomerular disorders defined by the presence of glomerular deposits of complement C3, in the absence of significant amounts of immunoglobulin, on immunofluorescence microscopy. Outcomes following renal transplantation in C3G are not well described and therefore we reviewed the experience of renal transplantation in C3G patients.

Methods: All renal biopsies reported between January 1995 and December 2011 were reviewed for evidence of C3G and confirmed by a second renal pathologist with expertise in this field. Patients within this cohort who received at least one renal transplant are described. Clinical data were obtained through retrospective review of medical records.

Results: Ten patients with a pathological diagnosis of C3G were identified (6 dense deposit disease [DDD], 4 non-DDD). Eight patients (80%) developed biopsy-proven C3G recurrence in their allograft (mean time to recurrence 46.5mths, range 2-124mths). Of these, 3 experienced allograft loss due purely to C3G (all DDD, mean allograft survival 84.3mths), 3 experienced allograft loss due to C3G combined with other factors (1 DDD, allograft survival 60.0mths; 2 non-DDD, mean allograft survival 53.5mths), and 2 continue to have a functioning allograft (1 DDD, follow-up 176.0mths; 1 non-DDD, follow-up 41.0mths). Two patients had no evidence of disease recurrence at time of last follow-up (1 DDD, follow-up 65.0mths; 1 non-DDD, follow-up 6.0mths).

Conclusions: This is the largest series describing outcomes following renal transplantation in patients with C3G (with or without features of DDD). The majority of patients in this cohort developed biopsy-proven C3G recurrence in the allograft but this did not universally lead to allograft loss.

PUB822

Transmission of HTLV-1 by Kidney Transplantation and Post-Transplant Manifestation of Cutaneous T-Cell Lymphoma
Sebastian Alexander Potthoff,[1] Ilona Glowacka,[2] Ivo Quack,[1] Lars C. Rump,[1] Katrin Ivens.[1] *[1]Department of Internal Medicine / Nephrology, Heinrich-Heine University - Medical Faculty, Düsseldorf, Germany; [2]Department of Virology, University Hannover - Medical Faculty, Hannover, Germany.*

Background: Kidney transplant recipients are at risk of post-transplant lymphoproliferative disease (PTLD). PTLD commonly occurs as B-cell non-Hodgkin-lymphoma. Primary cutaneous lymphomas are uncommon. Human T-lymphotropic virus type 1 (HTLV-1) is the first retrovirus discovered in humans (prevalence <1% in most western countries). HTLV-1 infects CD4+ T-cells and persists during life time. Two HTLV-1 associated diseases are known: adult T-cell lymphoma and HTLV-1-associated myelopathy. 1-2 % of infected individuals develop a HTLV-1 associated disease.

Methods: Case report:

Results: A male (born 1984) received a kidney transplant in 2006 (standard immunosuppression: tacrolimus, MMF and low dose steroids). In 2009 the patient developed painful skin lesions (hands/feet). Cutaneous T-cell lymphoma was diagnosed with predominant infiltration of T-cells in biopsies. Systemic evaluation of an extra cutaneous manifestation was negative. The patient was set on high dose steroid therapy (prednisolone 250mg/day for 5 days, tapering during follow up), on which skin lesions healed quickly without residues. In 2011, we became aware of the HTLV-1 positive status of the donor and a possible HTLV-1 transmission during transplantation in 2006. It was confirmed that our patient was HTLV-1 positive and pre-transplant serum of him was HTLV-1 negative. A liver recipient from the same donor developed similar skin lesions with T-cell infiltration. Skin biopsies from this liver recipient showed increased HTLV-1 viral load compared to non-infiltrated tissue controls. Evaluation of viral load in our patient's skin biopsies showed similar results.

Conclusions: Our patient developed a HTLV-1 associated cutaneous T-cell lymphoma after transmission of HTLV-1 during kidney transplantation. An exclusive cutaneous manifestation of HTLV-1 associated T-cell lymphoma has not been described previously. Continuous immunosuppression might be a reason for this uncommon and early manifestation of this HTLV-1 associated disease.

PUB823

Role of Plasmapheresis, Intraveinous Immunoglobulin and Rituximab in Renal Allografts Manifesting Antibody Mediated Change
Salim Baghli,[1] Christin M. Spatz,[1] Osun Kwon,[1] Bishal B. Rawal,[1] Tarek Alhamad,[1] Haresh Mani,[2] Hiroko Shike,[2] Bruck Yemenu.[3] *[1]Nephrology, Penn State University, Hershey, PA; [2]Pathology, Penn State University, Hershey, PA; [3]Internal Medicine, Penn State University, Hershey, PA.*

Background: Antibody-mediated rejection (AMR) has been increasingly recognized as a poor prognosticator of kidney transplant outcome. It is reported that antibody mediated changes (AMC) such as circulating donor specific anti-HLA antibodies (DSA) and C4d

positivity in graft tissues are associated with shortening of renal graft survival; however, no standard therapeutic modality is established yet.

Methods: Twenty five adult renal transplant recipients who received PPIGR for DSA and/or positive C4d after kidney transplant were followed for 6 months to 3 years. Subjects were analyzed for change in graft function as well as circulating DSA and C4d in graft tissues. The control group included 13 kidney transplant recipients with positive DSA who did not receive PPIGR. DSA was monitored by Luminex assay, C4d by immunohistochemistry and graft function by change in serum creatinine concentration.

Results: DSA disappeared in 6 out of 14 DSA positive subjects during follow-up compared to only 2 of 13 controls. Disappearance of DSA was noted within 5 days after PPIGR for 4 out of 6 subjects. Among 5 controls with newly formed DSA, spontaneous disappearance occurred in 2 cases at 84 and 353 days after transplantation. Positive C4d staining in graft tissues disappeared in 94% (17/18) of subjects within one week after PPIGR. No subject nor control developed acute AMR during follow up. Acute cellular rejection coexisted with antibody mediated change in 13 subjects and 2 controls. No significant change in graft function was detected in subjects compared to controls during follow-up even after adjustment for acute cellular rejection. Four subjects and one control had graft failure within one year.

Conclusions: Our findings suggest that PPIGR modulates AMC, but does not have a beneficial effect on long term kidney graft function.

PUB824

Factors Associated with Transplant Glomerulopathy Emma Romo,[IMSS] Jorge Andrade-Sierra.[IMSS] *[1]Nefrología, IMSS, Guadalajara, Jalisco, Mexico; [2]Nefrologia, IMSS, Guadalajara, Jalisco, Mexico; [3]Nefrologia, IMSS, Guadalajara, Jalisco, Mexico; [4]Nefrologia, IMSS, Guadalajara, Jalisco, Mexico.*

Background: Transplant glomerulopathy (TG) is a disease of poor prognosis for graft survival. The general characteristics and factors associated with this entity have not been described in our population.

Methods: We included 35 patients diagnosed with TG from 2008 to 2011. We collected demographic data, clinical and biochemical one month prior to diagnosis and the time of diagnosis. In all cases histopathological report was obtained through allograft biopsy.

Results: 63% male, 54% had a history of cellular rejection and / or humoral confirmed by biopsy. The average TG was introduced 75 months after transplantation. At diagnosis 80% were with sirolimus and 20% calcineurin inhibitor. The average creatinine was 1.8 mg / dl one month prior and at diagnosis 2.3 mg / dl. Proteinuria in 24 hours urine was of 4.45 gr. We compared groups according to C4d positivity with immunohistochemistry in renal biopsy.

Factors associated with transplant glomerulopathy

Characteristic	All cases (n=35)	C4d + (n=13)	C4d - (n=6)
Age	28	30	25
Months of diagnosis of TG	75	69	98
Number of antigens	3	3	3
CD25 induction (n) (%)	31 (88)	9 (67)	6 (100)
Severe glomerulitis (n) (%)	21 (60(	8 (61)	5 (83)
Fibrosis more 25% (n) (%)	30 (85)	10 (77)	5 (83)
Capilaritis (n) (%)	16 (45)	6 (50)	0 (0)
GFR before TG (ml/min)	53.71	52.8	39.2
GFR al diagnosis TG (ml/min)	48.31	46.6	30.2
Loss of GFR (ml/min)	-21.5	-19.1	-13.02
Sirolimus (n) (%)	28 (80)	8 (61)	6 (100)

TG = Transplant glomerulopathy, GFR = Rate filtration glomerular

Conclusions: The TG was presented at 6 years after transplantation, no clinical or histopathological baseline characteristic was associated with the presentation of this entity, but 80% of patients receiving sirolimus at diagnosis. C4d + was associated with the presence of capillaritis and greater loss of glomerular filtration at the end of the study. The outcome in this group of patients confirms the poor prognosis of this disease reported a loss of glomerular filtration rate of 21.5 ml / ml.

PUB825

Cardiovascular Risk in Non-Dipper Pediatric Renal Transplant Recipients Christine Sethna,[1] Cathy H. Laney,[2] Nina Laney,[2] Howard Trachtman,[3] Rachel Frank,[1] Lulette Infante,[1] Kevin E.C. Meyers,[2] Nandita Patnaik.[1] *[1]Pediatric Nephrology, Cohen Children's Medical Center of New York, New Hyde Park, NY; [2]Pediatric Nephrology, The Children's Hospital of Philadelphia, Philadelphia, PA; [3]Pediatric Nephrology, NYU Langone Medical Center, NY, NY.*

Background: An abnormal decline in nocturnal blood pressure (non-dipping) is commonly found during ambulatory blood pressure monitoring (ABPM) in pediatric renal transplant recipients (Txp). Non-dipping is independently associated with increased cardiovascular risk in the adult population. The objective was to examine aortic stiffness, left ventricular dimensions and lipids in non-dipper vs. dipper Txp.

Methods: 24-h ABPM, echocardiography for left ventricular mass index (LVMI), and carotid-radial pulse wave velocity (PWV) were performed in 53 Txp at two tertiary centers. Non-dipping was defined as a decline of <10% in blood pressure (BP) from day to night. Differences between non-dipper and dipper groups were assessed by Student's t-test and linear regression.

Results: Non-dipper subjects included 9 F/11 M (38%), age 12.8 ± 4.6 yr. Dipper subjects consisted of 13 F/20 M (62%), age 14±4.7 yr. The two groups showed no difference in age, gender, BMI z-score and GFR as well as cholesterol, HDL, LDL, triglycerides and uric acid levels. The nocturnal dip was 3.7%/7.6% (systolic/diastolic) in the non-dippers and 11.1%/19.5% in the dippers. Non-dippers had significantly higher nocturnal BP compared to dippers (116/70 vs. 105/60 mmHg, p<0.001). Clinic, average 24-h, and daytime 24-h BP were similar between groups. PWV did not significantly differ between non-dippers and dippers (8.27±1.94 vs. 8.34±4.1 ms, p=0.96) with no alteration after adjustment for age, gender and BMI (p = 0.98). LVMI did not significantly differ between non-dippers and dippers (54.4±20.3 vs. 55.2±20.8 $g/m^{2.7}$, p=0.88) with no alteration after adjustment for age, gender and BMI (p=0.67).

Conclusions: The non-dipping pattern in pediatric renal transplant recipients does not appear to be associated with measures of arterial stiffness, left ventricular mass and lipids. Future studies are needed to delineate the effect of non-dipping in these subjects at risk for cardiovascular disease.

PUB826

Impact of Pre-Transplant Dialysis Modality on Clinical Outcome in Kidney Transplant Recipients Hyun Gyung Kim,[1] Byung Soo Kim,[1] Chul Woo Yang.[2] *[1]Internal Medicine, The Catholic University of Korea, St. Paul's Hospital, Seoul, Korea; [2]Internal Medicine, The Catholic University of Korea, Seoul St. Mary's Hospital, Seoul, Korea.*

Background: We performed this study to evaluate the effect of pre-transplant dialysis modality on graft and patient survival in living donor kidney transplant recipients (KTR).

Methods: This study included 365 living donor KTR receiving dialysis treatment for at least three months prior to KT. We compared the baseline characteristics including age at KT, gender, primary renal disease, and the number of HLA mismatch and clinical outcomes such as graft and patient survival according to the pre-transplant dialysis modality. The mean age at KT was 40.1±10.7 (16-73) years and 60.5% (n=221) were men. The mean duration of follow-up was 92.3±53.7 months. Seventy five percent (n=274) of patients were followed pre-transplant hemodialysis (HD) and 25% (n=91) peritoneal dialysis (PD).

Results: The mean dialysis duration was 26.2±32.5 (3-225) months and it was shorter in the PD group compared to the HD group (24.9±25.0 vs. 26.6±34.7 months, p=0.026). DM was more common in the PD group (8.4% vs. 15.5%, p=0.045). However, there were no significant differences in baseline clinical parameters such as gender (male 62.7% vs. 53.8%, p=NS), age at renal transplantation (40.5±10.8 vs. 39.0±10.4, p=NS), HLA mismatch number (3.0±1.5 vs. 3.0±1.4, p=NS), donor age (37.4±10.7 vs. 38.4±11.1 years, p=NS) and donor gender (male 57.6% vs. 53.8%, p=NS) between HD and PD groups. The 5-year graft survival rate was not significantly different between two groups (90.7% in the HD group vs. 82.9% in the PD group, p=NS). A subanalysis of our data showed no difference in the frequency of rejection (63.4% in the HD group vs. 60% in the PD group, p=NS) or patient death (19.5% in the HD group vs. 25% in the PD group, p=NS) as a cause of graft failure. The 5-year patient survival rate of 96.9% in the HD group was similar to that of the PD group (93.4%, p=NS). There was no association between pre-transplant dialysis modality and cardiovascular mortality rate.

Conclusions: Pre-transplant dialysis modality had no significant influence on graft and patient survival in living donor kidney transplant recipients.

PUB827

Clinical Features of Simultaneous Pancreas-Kidney Transplantation Hee Jung Jeon,[1] Yoonjung Kim,[2] Hyuk Yong Kwon,[2] Myung-gyu Kim,[2,3] Tai Yeon Koo,[4] Jong Cheol Jeong,[1] Jaeseok Yang,[2,4] Curie Ahn.[1,2,4] *[1]Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea; [2]Transplantation Center, Seoul National University Hospital, Seoul, Republic of Korea; [3]Department of Internal Medicine, Korea University Medical Center, Seoul, Republic of Korea; [4]Transplantation Research Institute, Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: This study examined the clinical features of simultaneous pancreas-kidney (SPK) transplantation in diabetic end stage renal disease and evaluated the results.

Methods: We retrospectively reviewed SPK transplantation from 2002 to 2010 in Seoul National University Hospital in Korea. 20 patients (11 males and 9 females) underwent SPK transplantation from deceased donors. 8 patients suffered type 1, whereas 12 patients suffered type 2 diabetes mellitus.

Results: The mean recipient age was 42.9 years (range, 29.6-70.7) in SPK. The mean donor age was 28.5 years (range, 16.5-41.9). Immunosuppressive treatment consisted of basiliximab induction followed by tacrolimus, mycophenolate mofetil, and prednisone. Pancreas graft management for the exocrine drainage involved enteric drainage in all cases. The mean duration of hospital stay was 43.5 days (range, 15-121 days). After a mean follow-up of 45.2 months (range, 15-121), patient survival rate, kidney allograft survival rate, and pancreas allograft survival rate were 95%, 90%, and 80%, respectively. One patient died of cerebral infarction and small bowel perforation. Two pancreas allografts were lost due to CMV pancreatitis and small bowel perforation. Other early complications associated with the pancreas transplantation included 4 cases of perigraft fluid collection, 4 of hematoma in abdomen, 3 of small bowel perforation, and 2 of venous thrombosis in pancreas allograft; Beyond the early postoperative period, allograft loss of pancreas and kidney was limited to 1 case of noncompliance to the immunosuppressive medications.

Conclusions: SPK is a well-established therapeutic option with tolerable outcomes for patients with multiple organ failure. However, we should be careful about the complications in the immediate postoperative period of SPK.

PUB828

Trough to Target Immunosuppression Is the Risk Factor for Polyoma Virus Infection in Renal Transplantation Ahmed G. Adam,[1] Nagwa Farouk,[1] Mona Salem,[2] Doaa Hashad,[3] Hala S. Elwakil.[1] *[1]Kidney, Dialysis and Transplantation Unit, Internal Medicine Department, Faculty of Medicine; [2]Pathology Department, Faculty of Medicine; [3]Clincial Pathology Department, Faculty of Medicine, University of Alexandria, Egypt.*

Background: BK virus infection after kidney transplantation is common but usually asymptomatic; however may be life threatening. More potent immunosuppression poses threat to improving transplant graft survival by reactivating BK.

Methods: All kidney transplant recipients in our university clinic were included. Urine decoy cells, PCR for BKV in blood and Transplant biopsy were done. Studied population was divided: Group I: was negative for decoy cells in urine and undetectable BKV load in blood. Group II (reactivation group): was positive for decoy cells and /or viremia and /or nephropathy. Follow up for 6 months.

Results: Among the 75 kidney transplant recipients who consented, 8 were positive for decoy cells (11%), 3 viremia (4%), 2 nephropathy proved by biopsy as intranuclear inclusions in tubular cells. A significant difference as regards acute rejection episodes (p =0.012); more than one methylprednisolone pulse (p =0.012). No difference regarding the immunosuppressive protocol, drug, or the anti-metabolite drug used. However a significant difference in the percentage of patients with immunosuppressive level above the target (p =0.004). Logistic regression analysis revealed that high trough to target ratio was significantly associated with polyoma virus reactivation and increase risk by 12.71 times.

Factors associated with polyoma virus reactivation, results of multivariate logistic regression analysis.

	Regression Coefficient	p	Odds Ratio	95.0 % CI - Lower	95.0 % CI - Upper level
Number of transplantation 1 vs. 2	0.320	0.841	1.377	0.061	31.207
Duration of Transplantation	0.015	0.256	1.015	0.989	1.041
Number of rejections espisodes 0 vs >1	0.575	0.498	1.778	0.336	9.405
Trough above Target vs. within Target	2.542	0.008*	12.710	1.963	82.289

Kaplan- Meier analysis showed 77.8% recovered spontaneously with a mean time 120.8 ±31.302 days.

Conclusions: The Trough to Target immune suppression is a main factor influencing Polyoma. Incomplete response to anti-rejection raises the suspicion of PVAN.

PUB829

Usefulness of Liver Biopsy in Anti-Hepatitis C Virus Antibody (Anti-HCV Ab) Positive and HCV RNA Negative Kidney Transplantation (KT) Recipient Kyeong Woo Nho,[1] So Mi Kim,[2] Su-Kil Park,[1] Soon Bae Kim.[1] *[1]Nephrology, Department of Internal Medicine, College of Medicine, University of Ulsan, Asan Medical Center, Seoul, Korea; [2]Nephrology, Department of Internal Medicine, College of Medicine, University of Jeju, Jeju, Korea.*

Background: Liver biopsy is recommended to all Anti-HCV Ab(+) KT recipients [Textbook of KT, 5th ed.]. However, the benefit of liver biopsy is unclear in HCV RNA(-) KT recipients. We investigated usefulness of liver biopsy in Anti-HCV Ab(+) and HCV RNA(-) patients.

Methods: A total of 30 Anti-HCV Ab(+) patients underwent liver biopsy before KT in the Asan Medical Center during 1995-2011 were reviewed. The patients were divided into two groups based on HCV RNA positivity; seventeen patients were positive and thirteen negative. Hepatic histological findings, inflammation, and fibrosis were analyzed by using the METAVIR scoring system, and clinical outcomes including mortality, graft loss, progression of advanced liver disease of the two groups were compared.

Results: Age, gender, DM, duration of dialysis, duration of HCV infection, AST and Child-Pugh score were not different between the two groups. Only ALT was higher in HCV RNA(+) group. Ultrasound of liver showed abnormal findings in three HCV RNA(+) patients [one cirrhotic change, two chronic parenchymal change]. Both activity and fibrosis scores were higher in HCV RNA(+) group [Activity score : 1.11±0.85 vs 0.46±0.51, p=0.01, Fibrosis score : 1.05±1.24 vs 0.15±0.37, p=0.01]. Four patients in HCV RNA(+) group received antiviral therapy and 3 showed sustained viral response. One patient in HCV RNA(+) group with fibrosis 4 received liver and kidney co-transplantation. Two patients died of sepsis in HCV RNA(+) group and one patient died due to sudden cardiac arrest in HCV RNA(-) group [p=0.65]. The loss of graft was one patient in both RNA(+) and RNA(-), respectively [p=0.68]. Advanced liver disease was found in 3 patients in the RNA(+) group only [p=0.16].

Conclusions: There was no case of changing management by histological finding before KT or showing advanced liver disease after KT in HCV RNA(-) group. Therefore, we concluded that liver biopsy is not necessary in anti HCV Ab(+) and HCV RNA(-) KT recipient.

PUB830

Incidence of Infection in Patients Continued on Immunosuppression after Allograft Failure Claire T. Kassakian, George P. Bayliss. *Medicine, Rhode Island Hospital, Providence, RI.*

Background: There is little data to guide decisions on whether to continue immunosuppression medications in renal transplant patients whose grafts have failed. Continuation of such regimens can leave patients open to infection, one of the most common causes of mortality in this population. We sought to evaluate the risk of infection from continuing immunosuppression (IS) or stopping it (no IS) in renal transplant patients from a single center whose allografts have failed as well as the types of infections that occurred.

Methods: We reviewed the electronic medical record of 100 renal transplant recipients between 1999 to the present. We included patients described as either on hemodialysis or deceased after restarting dialysis. Patients were excluded if no allograft failure was present prior to death. The primary outcome is the incidence of infections requiring hospitalization.

Results: We identified 18 patients in the IS group and 11 patients in the no IS group. Age at transplant was similar in both groups; there were more men than women in the IS group than in the no IS group. The incidence of any infection was greater in the IS group (72%) than in the no IS group (45%), although not significantly (p=0.24). The incidence of line infections was greater in the IS group than in the no IS group (14% vs 0%, p=0.13), as were incidences of Clostridium difficile infection (7% vs 0%) infectious endocarditis (3% vs 0%), pyelonephritis (7% vs 0%), aspirgilloma (3% vs 0%) and septic arthritis (3% vs 0%). There was no difference in the incidence of urinary tract infections or pneumonia between the two groups.

Conclusions: We found a greater incidence of infections, particularly line infections, in renal allograft failure patients who are continued on immunosuppression after graft failure versus those who are not. Our data also demonstrates that these patients have a higher incidence of other infections as well, although the incidence of pneumonia and urinary tract infections were similar. While not reaching statistical significance, our data point to the need for further study to help define risks and the optimal regimen for discontinuing immunosuppression in patients with failed allografts.

PUB831

Effect of Mycophenolate Mofetil (MMF) on Progression of Chronic Allograft Dysfunction Karlo Mihovilovic,[1] Bojana Maksimovic,[1] Branislav Kocman,[2] Zeljko Vidas,[2] Danica Galesic Ljubanovic,[3] Mladen Knotek.[1] *[1]Division of Nephrology, University Hospital Merkur, Zagreb, Croatia; [2]Division of Surgery, University Hospital Merkur, Zagreb, Croatia; [3]Division of Pathology, University Hospital Dubrava, Zagreb, Croatia.*

Background: Main histological changes that determine chronic transplant dysfunction are interstitial fibrosis and tubular atrophy (IF/TA). Evidence from animal models suggests that MMF may exert a positive effect on renal damage by direct antifibrotic properties due to antiproliferative action on both immune and nonimmune cells. The aim of our study was to investigate role of MMF dose on progression of chronic allograft dysfunction.

Methods: A cohort of 80 patients included patients with kidney, kidney-pancreas and kidney-liver transplantation.Protocol kidney biopsies were scored according to the Banff 07 classification. Interstitial fibrosis (ci) and tubular atrophy (ct) progression was determined by calculating Δci and Δct after subtracting 0 biopsy scores from 1 year chronic scores. Estimated GFR (eGFR) was calculated using Cockroft Gault formula. MMF exposure was determined as average MMF dose over 1 year post transplant, calculated from dose at month 1, 3, 6 and 12. Univariate and multiple regression analyses were done to test relationship between independent variables and eGFR, Δci and Δct.

Results: Average MMF dose during 1 year posttransplant was 2151mg ± 610 (range 1062.5 – 4000). eGFR at 1 year post transplant positively correlated with average MMF dose (p=0.046) while donor and recipient age(p<0.05) negatively correlated with eGFR. Allograft function was also negatively correlated with Δci and Δct (p<0.05). In multivariate analysis average MMF dose remained significant for eGFR at 1 year post transplant (b=0.27±0.1, p=0.01). In univariate analyses both Δci and Δct significantly negatively correlated with average MMF dose (p <0.01). In a multiple regression analyses Δci (b=-0,36 ± 0.11, p<0.01) and Δct (b=-0,40 ± 0,11, p<0.01) were independently only associated with MMF dose.

Conclusions: Higher MMF dose over 1 year is associated with better renal function and slower progression of IF/TA.

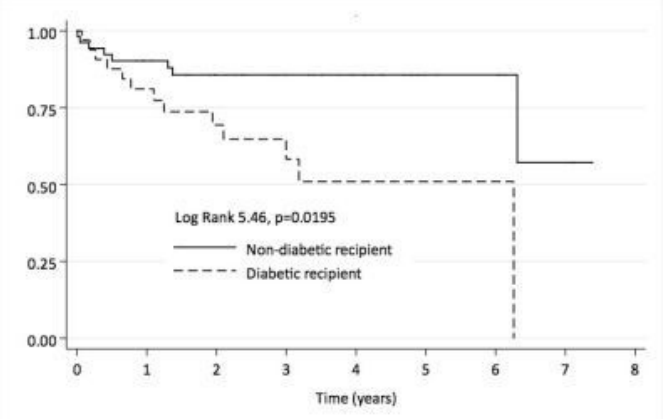
PUB832

Mild Diabetic Changes in Reperfusion Biopsies Do Not Influence Graft Outcomes Eric J. Lai, Heather K. Morris, Sumit Mohan, Michael B. Stokes, Jai Radhakrishnan. *Internal Medicine, Columbia University Medical Center, New York, NY.*

Background: The increasing prevalence of obesity and diabetes mellitus and the greater incentive to expand the donor pool has led to more frequent use of organs from patients with these co-morbidities. We evaluated outcomes in patients who received renal allografts from diabetic donors (DMD).

Methods: We examined 90 patients who received kidney transplants from DMD at Columbia University Medical Center from 2004 onwards. All post-reperfusion biopsies from a DMD were scored and assigned a diabetic nephropathy class. Recipients were then followed to determine whether the findings on the initial post-reperfusion biopsy were predictive of graft outcome.

Results: 86/90 patients in our cohort had adequate follow-up data in which the status of patient and graft survival was known. Among these, 75.6% were alive with a functioning graft at time of last follow-up. Outcomes in diabetic recipients were significantly worse than those in non-diabetic recipients.



The majority of donor kidneys had relatively minor diabetic changes (class I-IIa glomerular lesions and zero or < 25% interstitial fibrosis/tubular atrophy) on the post-reperfusion biopsy. The pathology findings on these biopsies did not influence graft survival.

Conclusions: Our recipients of deceased DMD kidneys fared well with respect to graft and patient survival, although diabetic recipients had significantly worse graft survival than non-diabetic recipients. Pathology findings on the post-reperfusion kidney biopsies did not influence graft survival – probably due to the relatively minor diabetic changes in both the glomerular and tubulointerstitial compartments in the majority of cases. Our data indicate that good outcomes can be achieved with DMD kidneys in non-diabetic recipients, particularly when the glomerular and tubulointerstitial lesions are not advanced.

PUB833

Timely Listing for Kidney Transplantation in England: A Quality Improvement Programme Partha Das,[1] Donal O'Donoghue,[2] Beverley Matthews.[1] *[1]NHS Kidney Care, London, United Kingdom; [2]National Clinical Director for Kidney Care, Department of Health, London, United Kingdom.*

Background: Renal transplantation is the "Gold Standard" modality of renal replacement therapy (RRT). Barriers exist within the National Health Service (NHS) preventing patient access to transplantation and pre-emptive transplantation is only performed in a minority of incident patients. NHS Kidney Care present here the results of a nationally funded and locally led program to improve access to renal transplantation across England.

Methods: All renal units in England were invited to submit a project work profile detailing strategies to overcome barriers to transplantation and measure quality improvement. The successful bids were provided with a grant to assist their projects and for the recruitment of a specialist nurse to act as project lead. Projects began in September 2011 and completed in April 2012.

Results: 20 transplant units in England successfully applied for funding for their projects. Common themes in all projects included a need to refine data collection, formalise care pathways, streamline investigation requesting, educate frontline staff and engage with patients more effectively. NHS Kidney Care supported the projects by providing a regular e-seminar programme, quality improvement workshops and disseminating information on strategies to improve listing for transplantation. An online discussion forum enabled units to share ideas. Most units had difficulties recruiting staff into post due to the fiscal climate. All noted improvements in their transplantation pathways including formation of dedicated multiprofessional assessment clinics, increased numbers of patients with a documented transplant decision, faster completion of investigations and better patient/prospective donor education materials.

Conclusions: This national programme has enabled renal units to improve access to transplantation. The locally led/centrally co-ordinated approach has been successful in terms of implementing change. Though the project period is too short to assess whether there has been an increase in the number of transplants performed, all centres will be followed up in 1 year's time to assess the long term impact of this programme.

PUB834

Safe and Effective Treatment of Persistent Hypercalcemia and Hyperparathyroidism with Cinacalcet in Renal Transplant Recipients Prasad Madhavan Nair, Narayanan Nampoory, Torki Al Otaibi, Osama Gheith, Medhat Abdul Halim, Tarek Said. *Department of Nephrology, Organ Transplant Centre, Hamad Al Essa, Kuwait, Kuwait.*

Background: The calcimimetic, cinacalcet offers an attractive alternative to parathyroidectomy for treating hypercalcemia with persistent hyperparathyroidism in renal transplant recipients (RTR). The objective of this study is to evaluate the efficacy of cinacalcet in RTR with hypercalcemia and persistent hyperparathyroidism and its safety after long term use.

Methods: Cinacalcet at a dose of 30 to 90 mg was prescribed to 15 RTR (8 women, 7 men) with a mean age of of 46.6 years (range = 23 to 68) and hypercalcemia with hyperparathyroidism. Cinacalcet therapy was started at a mean of 35.4 (range=4 to 153) months post transplant and period of follow up after treatment was 20.5 (range = 6 to 54) months.

Results: Treatment with cinnacalcet effectively reduced levels of, serum calcium from 2.70 ± 0.07 to 2.33 ± 0.22 mmol/L in 6 months (P< 0.001) and 2.31 ±0.17 mmol/L in 12 months (P< 0.001); intact parathyroid hormone (iPTH) from 74.8 ± 34.82 to 22.2 ± 12.34 pmol/L in 6 months (P< 0.001) and 19.28 ± 8.08 pmol/L in 12 months (P< 0.001) and raised levels of serum phosphate from 0.92 ± 0.22 to 1.14 ± 0.29 mmol/L in 6 months (P<0.001) and to 1.11 ± 0.26 mmol/L in 12 months (P= 0.001). Renal function remained stable with pretreatment, 6 month and 12 month post treatment serum creatinine levels of 127 ± 72.4, 130 ± 80.45 (P= 0.381), 131.2 ± 95.75 (P= 0.331) umol/L and estimated glomerular filtration rates (eGFR) of 72.6 ± 29.23, 74.6 ± 32.39 (P = 0.406) and 75.82 ± 36.34 (P = 0.816) ml/mt. Immunosuppressant drug levels remained unchanged and there were no rejection episodes or any significant adverse effects described.

Conclusions: Cinacalcet was safe and effective in renal transplant recipients with hypercalcemia secondary to hyperparathyroidism with no evidence of declining renal function or limiting side effects.

PUB835

Impact of the Determination of HLA Antibodies in Kidney Transplant over Ten Years of Monitoring Jacqueline Apaza, Esther Gonzalez Monte, Enrique Morales, Natalia I. Polanco Fernandez, Julie Hinostroza Yanahuaya, Laura Garcia-puente Suarez, Ignacio Bengoa, Amado Andres, J. Morales. *Nephrology, Hospital Universitario 12 de Octubre, Madrid, Spain.*

Background: The goal of this study was to determine the prevalence of anti-HLA antibodies and the clinical outcome in patients with functioning renal graft over ten years.

Methods: We measured the presence and the levels of class I and II anti-HLA antibodies by microbead technology (Luminex) in 120 patients with functioning renal graft over 10 years.

Results: The average time of transplantation was 15, 4±3, 7 years. 25% of the patients studied, had anti-HLA antibodies. The presence of anti-HLA antibodies was associated with worse serum creatinine levels (p 0,03), lower glomerular filtration rate (p 0,02) and increased proteinuria (p 0,00). Antibodies were measured one year after the first determination in patients with positive anti- HLA antibodies. The elevation of these antibodies did not influence the evolution of renal function or degree of proteinuria. (Cr in patients with increased antibody titers compared with those who remained stable was 1, 53 mg/dl vs. 1, 9 mg/dl - p 0.33).

Conclusions: Our study show that in patients with functioning renal graft over ten years, the presence of anti-HLA antibodies was 25%, and this was associated with the development of chronic rejection, worse renal function and greater proteinuria levels, regardless of the evolution of antibody titers at one year. The determination of HLA antibodies could be useful in the management of transplant patients.

PUB836

Effects of Donor-Recipient Gender Mismatch on Intact Parathyroid Hormone (iPTH) Level, Urine Protein/Creatinine Ratio (UPr/Cr) and Kidney Function Sima Terebelo, Ajibola Monsur Adedayo, Ankita B. Patel, Mariana S. Markell. *Medicine/Neprhology, SUNY Downstate Medical Center, Brooklyn, NY.*

Background: Size mismatch between kidney donor and recipient has been variously implicated in causing poorer allograft outcome, or having no effect due to post-transplant adaptation, however studies have looked primarily at size disparities and gender effects have not been carefully studied.

Methods: A retrospective chart review was performed in a random cross-sectional sample of 59 deceased donor kidney transplant recipients attending transplant clinic for whom donor characteristics were available.

Results: Of the recipients 86.4% (51) were black vs 13.6% (8) donors, 64.4% (38) donors were male vs 55.9% (33) recipients. Donor/recipient gender was both male 39% (23), both female 16.9% (10), male donor/female recipient 16.9% (10) female donor/male recipient 24.9% (15). Mean months since transplant was 35 ± 29.5 (range 3 to 183), eGFR by MDRD was 53.87 ml/min ± 19.2 (range 20 to 105). By Kruskal-Wallis test, comparing 3 categories of donor vs. recipient gender, differences were found for creatinine (MM-1.91±0.81 mg/dl, FF-1.32+0.30, MF-1.12+0.22 mg/dl**,** FM-1.80+0.46 mg/dl, p=0.001), iPTH (MM-301.9+215.4, FF-181.7+99.6, MF-114.5+50.3, FM-209.8+151.6, p=0.025) and UPr/Cr (MM-0.80+1.13, FF-0.25+0.12, MF-0.12+0.07 FM-0.26+0.13, p=0.007). There was no significant difference for eGFR by MDRD estimate, recipient age, BUN, albumin, dosage of prograf, hemoglobin level, serum calcium, magnesium, phosphorus, total cholesterol, tacrolimus levels, 25-OH vit D, or donor age. There was no impact of donor race on any of the findings.

Conclusions: In our population, 1. Although males with either gender donor had higher creat values, when calculated as eGFR, which corrects for gender, kidney function did not differ 2. Male to Male recipients had the highest creat, iPTH and UPr/Cr, while male to female had the lowest. 3. The observation that female to male recipients had better values than male to male, suggests that donor/recipient size mismatch does not explain the findings 4. As gender mismatched kidneys had the lowest values for creat, future investigation of the impact of donor gender should be performed.

PUB837

Early Graft Function Is Associated with Long-Term Graft Survival of Kidneys from Expanded Criteria Donors Nassima Smail,[1] Jean Tchervenkov,[2] Steven Paraskevas,[2] Prosanto Chaudhury,[2] Istvan Mucsi,[1] Mazen Hassanain,[2] Dana Baran,[1] Marcelo Cantarovich.[1] *[1]Medicine, McGill University Health Center, Montreal, QC, Canada; [2]Surgery, McGill University Health Center, Montreal, QC, Canada.*

Background: The use of kidneys from expanded criteria donors (ECD) has increased over the past decade. However, ECD transplants are associated with an increased risk of graft loss.

Methods: We studied 280 recipients of KTx from standard criteria donors (SCD), and 243 from ECD, transplanted between January 1990 and December 2006. We analyzed donor and recipient variables.

Results: 10-yr patient survival was similar in recipients of KTx from SCD (81.8%) and ECD (80.8%, p=0.54) with immediate graft function (IGF, defined as a decline in serum creatinine ≥20% on day 1 post-KTx). As well, 10-yr DCGS did not significantly differ in recipients of KTx from SCD (83%) and ECD (76.3%, p=0.17) with IGF. Multivariate analyses showed that predictors of DCGS were serum creatinine at 1 yr (HR: 1.027, CI: 1.02-1.36, p<0.0001), and estimated glomerular filtration rate (eGFR) drop >30% between 1 and 12 months post-KTx (HR: 2.165, CI: 1.12-4.24, p=0.02). There was no difference in 10-yr DCGS in recipients of KTx from SCD or ECD when stratified by IGF (SCD: 87%, ECD: 83.4%, P=0.69) vs. delayed graft function (DGF, defined as the need for dialysis during the first week post-KTx) (SCD: 72.9%, ECD: 74.1%, p=0.61), and by eGFR drop ≤30% between 1 and 12 months post-KTx.

Conclusions: Recipients of KTx from SCD or ECD with IGF have similar long-term patient and DCGS. In addition to serum creatinine, eGFR drop between 1 and 12 months post-KTx is a strong predictor of DCGS. Recipients of KTx from ECD with IGF or DGF whose eGFR decreased ≤30% between 1 and 12 months post-KTx have similar 10-yr DCGS compared to recipients of KTx from SCD.

PUB838

Modelling the Allocation of Deceased Donor Kidneys in Australia Philip A. Clayton,[1] Blair S. Grace,[1] Keith McCullough,[2] Robert Merion,[2] Alan B. Leichtman,[2] Scott Campbell,[3] Jenni Wright,[4] Jeremy Chapman,[4] Stephen P. McDonald,[1] Steven J. Chadban.[1] *[1]Australia and New Zealand Dialysis and Transplant (ANZDATA) Registry, Adelaide, SA, Australia; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Princess Alexandra Hospital, Brisbane, QLD, Australia; [4]National Organ Matching System, Sydney, NSW, Australia.*

Background: Donors, their families and the general community expect that scarce deceased donor (DD) kidneys will be allocated fairly and to the best advantage of patients awaiting transplantation. Generation of a model able to simulate current allocation outcomes is an essential first step in exploring alternative allocation systems.

Methods: Data were sourced from the Australia and New Zealand Dialysis and Transplant (ANZDATA) and Organ Donor (ANZOD) Registries and Australia's National Organ Matching System. We adapted the US Scientific Registry of Transplant Recipients Kidney-Pancreas Simulated Allocation Model (KPSAM) software to simulate the allocation of deceased donor kidneys based on current Australian allocation rules which primarily consider waiting time, HLA match and peak PRA.

Results: The simulation included 4146 wait-listed patients and 1882 kidneys from 1043 donors over 06/28/06-12/31/10. There was excellent agreement with actual allocation with no significant differences in recipient age (simulated mean 51.9 vs actual 51.8 years), sex (62% vs 64% male), race, co-morbidity, waiting time (42.0 vs 42.7 months), HLA mismatch or peak PRA. The proportions of kidneys shipped interstate (12.8% vs 14.1%) and allocated to patients previously transplanted (16.1% vs 15.6%) were also well matched. Of the wait-listed patients not allocated a DD kidney the proportion who received a living donor transplant, died or remained alive on dialysis were similar, and the characteristics of those patients at the time of the outcome were very well matched between the simulation and the actual outcomes.

Conclusions: Although KPSAM was developed in the United States it can be adapted to simulate DD kidney allocation in a different country. This provides a valuable tool to explore the potential effects of any changes in allocation rules.

Screening for Inherited and Acquired Thrombophilia Prior to Renal Transplantation Raquel Melo Silva, Igor Marques, Cinthia Esbrile Moraes, Flavio De Paula, Elias David-Neto. *Renal Transplant Service, University of Sao Paulo - School of Medicine, Sao Paulo, Brazil.*

Background: Renal allograft recipients with thrombophilia are at higher risk for early allograft loss, microvascular occlusion and acute rejection with major consequences for allograft survival.The aim of the present study was to evaluate the prevalence of prothrombotic risk factors in patients awaiting renal transplantation and its contribution to patient and transplant outcomes.

Methods: All patients with a history of a thromboembolic event underwent laboratory screening for thrombophilia.

Results: Since the introduction of the screening for hypercoagulable risk factors, 156 candidates for renal transplantation underwent laboratory evaluation. Eighty-eight patients (56%) exhibited at least one prothrombotic laboratory parameter, besides of isolated hyperhomocysteinemia, which confirmed a thrombophilic state.Among the 156 patients, 30 underwent renal transplantation and were followed for a median of 199 days (range, 9 – 418). Thrombophilia was identified in 16 (53%). Seventeen (57%) received perioperative anticoagulation with unfractionated heparin (9 patients with thrombophilia and 8 without laboratory confirmed thrombophilia). Five (30%) of these patients developed perinephric hematomas. Three patients with thrombophilia developed thrombotic complications (2 upper limbs deep-vein thrombosis and 1 allograft artery thrombosis) and 1 patient without thrombophilia developed allograft vein thrombosis, p=0.35. Nine patients developed acute rejection (5 in the group with thrombophilia and 4 in the group without thrombophilia, p=0.87). Mean glomerular filtration rate was similar between thrombophilic and non-thrombophilic patients in the last follow-up (54±27 vs. 47±22 mL/min/1.73m², p=0.35). One graft loss and 1 patient death were observed in each group.

Conclusions: Prothrombotic risk factors, are highly prevalent in patients awaiting renal transplantation with a clinical or familial history suggestive of thrombophilia. Despite pre-transplant screening and perioperative treatment and/or monitoring, thrombotic and bleeding complications are still frequent and severe.

Preemptive Living Donor Kidney Transplantation: An Opportunity for the Elderly Amna Daud, Raymond Kang, Anton I. Skaro, Pamela H. Sharaf, John Joseph, Kathleen R. Hoke, Ed Wang, Lee A. Lindquist, Michael Abecassis, Daniela Ladner. *Northwestern University, Chicago, IL.*

Background: Living donor kidney transplantation (LDKT) and especially preemptive kidney transplantation, which is kidney transplantation prior to initiation of dialysis, leads to improved outcomes, better quality of life and greater cost savings. Despite proven benefit of kidney transplantation for elderly who meets operative clearance, surveys have shown that there is reluctance to pursue transplantation and especially LDKT.

Methods: Single center data were analyzed between January 2006 and May 2009. Demographics and donor information were extracted from the electronic medical records.

Results: Between January 2006 – May 2009, 731 kidney transplantations were performed, 451 (62%) were LDKT and 159 (35%) were preemptive. Fifty three recipients were >65 years of age, 40 (75%) received a LDKT and 18 (45%) received it preemptively. Only 14 recipients were > 70 years of age, all but one (93%) received a LDKT and 7 (53%) were preemptive. For preemptive transplants, median days between the first encounter at the center and transplant date was 203 for age >65 vs. 256 days for younger recipients (<65).

Among patients > 65 years of age vs. < 65 years, recipients were predominantly male (72%) vs. (59%), on Medicare (72%) vs. (40%), and non-Hispanic white (55%) vs. (50%). The living donors for elderly recipients (>65 yrs) were predominately children of recipient (35%) vs. sibling (25%) and other non-related donors (30%), while younger recipients primarily received their organs from non-related donors (30%). The most prevalent cause for chronic kidney disease in elderly was hypertension (45%) compared to diabetes (33%) for younger patients.

Conclusions: At our center LDKT rates are high compared to the national average. Our analysis shows that the likelihood of receiving a LDKT and a preemptive kidney transplant increases with age. This suggests timely referral of nephrologists and expeditious work-up at transplant center after referral. LDKT and particularly preemptive kidney transplantation offer an expeditious path to kidney transplant for the elderly sparing them morbid sequelae of prolonged waiting.

PUB841

Intermediate Early Graft Function Is Associated with Increased Incidence of Graft Loss and Worse Long-Term Graft Function in Kidney Transplantation Mário Raimundo, José Guerra, Catarina Teixeira, Alice Santana, Antonio Gomes da Costa. *Nephrology and Kidney Transplantation, Hospital de Santa Maria, Lisbon, Portugal.*

Background: Delayed graft function (DGF) is associated with undesired outcomes in kidney transplantation. Regarding early intermediate graft function (IGF) these prognostic observations have not been clearly made. Our objective was to investigate the impact of IGF, as compared to excellent graft function (EGF), on relevant renal allograft outcomes.

Methods: Retrospective observational study. Definitions: DGF-need for dialysis in the first 7 days post-transplantation; EGF-serum creatinine (sCr)<3 mg/dl at 5 days post transplantation; IGF-absence of dialysis need but with a sCr>3 mg/dl at 5 days post-transplantation. Univariate analysis was performed with the Student's t-test, the Mann-Whitney test or the Chi-square test, as appropriate. Kaplan-Meier method was used to determine survival curves and log-rank test for comparison. Multivariate logistic regression analysis was used to determine independent predictors of IGF and of graft survival.

Results: 570 patients were included in the analysis: 69.0% had EGF, 22.6% IGF and 8.4% DGF. Patients with IGF had worse graft survival at 5 and 10 years post-transplantation (75%vs92% and 69%vs85%, respectively;p<0.001 for both comparisons) and higher incidence of acute rejections (AR) (27% vs 41%;p=0.001), compared to patients with EGF. In multivariate analysis, IGF was independently associated with an increased risk of graft loss [Odds ratio (OR) compared to EGF: 2.40;95%CI 1.32–4.35;p=0.004] after adjustment for the occurrence of AR and other covariates. Donor age (OR 1.03 per year; 95%CI 1.02–1.05;p<0.001) was the strongest predictor of the occurrence of IGF. IGF was associated with worse long-term graft function until 7 years post-transplantation (mean GFR 48.3 ± 18.9 vs 57.4 ± 20.4 ml/min/1.73m²;p=0.008).

Conclusions: IGF, as DGF, is associated with increased rate of graft loss and AR and worse long-term graft function. Efforts should be undertaken to minimize the incidence of IGF. Donor age was the strongest risk factor for the occurrence of IGF. This is especially relevant regarding the increasing use of extended donor criteria.

PUB842

Are There Real Advantages of Induction Therapy with Basiliximab in Kidney Transplantation? Catarina Teixeira, Mário Raimundo, José Guerra, Alice Santana, Antonio Gomes da Costa. *Nephrology and Kidney Transplantation, Hospital de Santa Maria, Lisbon, Portugal.*

Background: Randomized clinical trials (RCT) have supported the use of interleukin-2 receptor (IL-2R) antagonists as induction therapy in patients with low-moderate immunologic risk. Despite reducing the incidence of acute rejections (AR) this advantage has not been translated into improved graft survival, maybe due to the limited follow-up time of RCT. Our objective was to investigate the impact of induction therapy with basiliximab, as compared to no induction therapy, on relevant clinical outcomes – initial length of stay, incidence of AR, long term graft function and graft survival – in a "real life" clinical setting.

Methods: Retrospective observational study of a 15-year period. Patients who received triple immunosuppression with cyclosporine, mycophenolate mofetil and prednisolone were selected for analysis (n=334) and classified into two groups: G1-no induction therapy (n=131); G2-induction with basiliximab (n=203). Univariate analysis was performed with the Student's t-test, the Mann-Whitney or the Chi-square test, as appropriate. Kaplan-Meier method was used to determine survival curves and log-rank test for comparison.

Results: Mean follow-up time was 72.7±35.4 months. Baseline characteristics were similar between groups. Group 2 had a shorter hospital stay (19.2vs22.5 days;p=0.02), lower incidence of AR (10.8%vs23.7%;p=0.02) and better graft function at 12 months (mean eGFR 59.4±18.4vs54.8±18.7 ml/min/1.73m^2; p=0.015) and 5 years (mean eGFR 64.1±21.5vs55.4±19.6 ml/min/1.73m^2; p=0.009) post-transplantation. There was no difference in graft survival (log-rank: p=0.54).

Conclusions: This study confirms that induction therapy with basiliximab is associated with a reduced incidence of AR and a better long-term graft function. Despite the relatively long follow-up, these advantages have not translated into improved graft survival maybe due to the increasing effectiveness of rescue therapies for AR and the influence of non-immunologic factors. Considering the substantial difference in eGFR at 5 years post-transplantation, a longer follow-up would eventually entail considerable difference in graft survival.

PUB843

Lower Serum Magnesium 1-Year Posttranplantation Is Associated with Decreased Graft Survival in Non-Diabetic Renal Transplant Recipients Camila Hitomi Nihei,[1] Igor Marques,[2] Loyana Teresa Teofilo Lima Silva,[1] Raquel Maria Maia,[1] Bernadete M.C. Ferreira,[1] Elias David-Neto.[2] *[1]Renal Transplant Service, University of Sao Paulo School of Medicine, Sao Paulo, Brazil; [2]Nephrology Division, University of Sao Paulo School of Medicine, Sao Paulo, Brazil.*

Background: Hypomagnesaemia is a known side effect of immunosuppressive regimen, especially calcineurin inhibitors, and has been associated with new onset diabetes after transplantation (NODAT) and decreased graft survival in chronic cyclosporine nephrotoxicity. Proton pump inhibitors-induced hypomagnesaemia has been described recently, although its relevance in renal transplant recipients is still unknown.

Methods: We conducted a single center cross-sectional retrospective study of renal transplantations performed between 2006 and 2011 in order to evaluate the impact of low serum magnesium (Mg) levels in patient and graft outcomes. Serum Mg levels 1-year after transplantation were available for 227 patients. Those with previous diabetes were excluded in order to evaluate the association of hypomagnesaemia and NODAT.

Results: The median follow-up was 1149 days (range, 524–2347). Patients were divided into four groups, based in quartiles of serum Mg levels, and no significant differences were found regarding sex, age, pretransplantation cholesterol, albumin, triglycerides, body mass index, donor age and type, immunosuppressive regimen, calcineurin inhibitors and mTOR-inhibitors trough levels, use of Mg supplements, delayed graft function, acute rejection, HCV infection or NODAT development. Patients with Mg < 1.6 mg/dL (n=56) had a higher frequency of prolonged (> 1 year) PPI use (91% vs. 80%, p=0,05) and a higher glomerular filtration rate in the last follow-up (60±22 vs. 48±22 mL/min/1.73m², p=0.007), when compared to patients with Mg > 2 mg/dL (n=57). Using Cox proportional hazards analyses, the adjusted graft survival was significantly reduced in the low Mg group after 3.4 years posttransplant (50% vs. 55% in the higher Mg group, HR 3.3; p=0.008).

Conclusions: Hypomagnesaemia 1-year posttransplantation, possibly related to prolonged use of PPI, is associated with decreased graft survival independently of the development of NODAT.

PUB844

Evaluating Changes in Kidney Transplantation and Geographic Inequity Since the Final Rule Ashley E. Davis, Sanjay Mehrotra, John J. Friedewald, Anton I. Skaro, Michael Abecassis, Daniela Ladner. *NU Transplant Outcomes Research Collaborative, Northwestern University, Chicago, IL.*

Background: In 1998, the Department of Health and Human Services' Final Rule mandated organ allocation to be geographically equitable. Despite this mandate, geographic inequity persists in kidney allocation. This study assesses the predictive factors of geographic inequity, by examining the kidney transplant system during 2000-2009.

Methods: Retrospective study of US adult End-Stage Renal Disease (ESRD) patients, kidney transplant candidates, and transplant recipients was performed and analyzed by Donor Service Area (DSA) during 2000-2009. Multivariate regression was used to determine significant predictive factors of long waiting times.

Results: During 2000-2009 1,158,928 adults suffered from ESRD, 331,270 listed for kidney transplantation, and 142,549 received a kidney transplant.

58 DSAs were divided into three groups of 19 short (1.3 years), 20 medium (1.7 years) and 19 long (2.5 years) median waiting times. Significant predictors ($p < 0.05$) of long-waiting times were high: ESRD prevalence, waitlisting rates within DSA of residence, and ESRD patient ethnic diversity.

Consequently, long-waiting time DSAs conducted more marginal DDKTs, more living donor kidney transplants, and used more non-locally procured kidneys. These DSAs have higher waitlist mortality and DDKT recipients are at increased risk for graft failure and mortality.

Long waiting time DSAs often (50%) geographically neighbor short waiting time DSAs. In fact, long-waiting time DSAs more frequently educate patients about transplantation and list a higher percentage of ESRD patients. Further, ESRD patients living in long-waiting time DSAs regularly list within their home DSA (94%) while ESRD patients living in short waiting time DSAs tend to list in long-waiting time DSAs (12%).

Conclusions: Geographic inequity continues to exist and affects all regions of the country. Most prominent predictors of long-waiting time were high: ESRD prevalence, waitlisting rates within DSA of residence, and ESRD patient ethnic diversity. Number of transplant centers was not a predictor of long-waiting time.

PUB845

High-Dose I.V. Immunoglobulin (i.v.-Ig) Treatment of Severe Anemia due to Parvovirus Infection in Renal Transplant (R-Tx): Case Report Antonio Di Felice,[1] Emiliana Ferramosca,[1] Giorgio Gallinella,[2] Antonio Santoro.[1] *[1]Nephrology Diaysis Hypertension, S.Orsola-Malpighi University Hospital, Bologna, Italy; [2]Dept of Haematology and Oncological Sciences, University of Bologna, Bologna, Italy.*

Background: Parvovirus is a rare infection, which occasionally involves renal transplantation causing severe anaemia. Few cases are still reported in literature.

Methods: CASE REPORT. A 51 y/o male, with ESRD for polycystic kidney disease, underwent living donor R-Tx in July 7, 2010. No rejection occurred after surgery; immunosuppressive treatment included steroid, Tacrolimus (FK), and Mycophenolic Acid (MPA). Serum creatinine (S-Cr) was stable around 1,3-1,6 mg/dl; Hb (12,5 gr/dl), was normal; FK-levels were 8,0-10,0 ng/ml, with peaks up to 13 ng/ml. After 1 year, the patient was admitted to our hospital for weakness and severe anemia (Hb 5.4 gr/dl). S-Cr at the admission was around 1,2 mg/dl. Haemorrhage was excluded. Viral study showed a rise of Parvovirus-B19 DNA up to 1*10^11 UI/ml, with normal viral IgG/IgM. Bone-Marrow Biopsy was suggestive for Parvovirus infection. The treatment was: RBC-transfusion, erythropoietin (rHu-EPO), MPA withdrawal and Tacrolimus dose reduction. After 2 weeks, persisted anaemia (Hb 5,7) and B19 DNA was still elevated, 3*10^11 UI/ml, with no significant rise of B19-IgM. The patient then started treatment with high-dose i.v.-Ig, 400 mg/Kg/day for 4 days. Few side-effects were recorded: mild fever only for few hours, and a transient slight rise of S-Cr. Afterwards, a slow progressive improvement of anaemia and reduction of rHu-EPO dose, up to complete withdrawal after 5 months, while B19 DNA persisted elevated. Only after 6 months we recorded a significant reduction of B19-DNA (2*10^5 UI/ml) and the appearance of anti-Parvovirus IgM (5.5). To date, after 8 months, Hb is 11.9 gr/dl, S-Cr 1.44 mg/dl, FK-level 6.9 ng/ml, Parvovirus B19 DNA 4*10^4 UI/ml.

Conclusions: B19 infection must be suspected when a R-Tx patient presents an otherwise inexplicable anaemia. High-dose i.v.-Ig can be useful and safe in the treatment of this infection, but virus disappearance is slow. More cases and a longer follow-up are needed to clarify viral transmission, and outcome.

PUB846

Urine Neutrophil Gelatinase-Associated Lipocalin as a Predictor of Recovery from Delayed Graft Function after Kidney Transplantation Kazuhide Saito,[1] Noriko Saito.[2] *[1]Division of Urology, Graduate School of Medical and Dental Sciences, Niigata University, Niigata, Japan; [2]Department of Nephrology, Shinraku-en Hospital, Niigata, Japan.*

Background: Urine neutrophil gelatinase-associated lipocalin(UNGAL) is reported to be a sensitive and useful biomarker for acute kidney injury. We have tested its advantage for perioperative management both in living and deceased kidney transplantation.

Methods: 26 living kidney transplant recipient(LKR) and 26 living kidney donor(LKD), 5 deceased kidney transplant recipient(DKR) and 2 deceased donor(DKD) were enrolled in this study. Urine samples were collected and UNGAL level was measured

by chemiluminescence immunoassay(CLIA) using ARCHITECT Urine NGAL (Abbot Japan). Other standard clinical parameters were also evaluated.

Results: Preoperative UNGAL(ng/ml) in LTD was 9.8±14.6, it increased to 19.0±25.0 on POD 1 and 16.5±25.0 on POD7. Postoperative UNGAL in LKR without acute rejection or surgical/urological complication was 59.3±43.8 on POD2, 39.1±26.0 on POD3 and remain stable during 4 weeks. UNGAL in cases with urological complication or acute rejection was elevated than that of other patients. Elevated UNGAL was also observed in patients with residual urine secretion from native kidney within a few days after transplantation.

In 4 of 5 DKR, DGF occurred. 3 were from non-heart beating donors(NHBD) and one from brain dead donor. UNGAL of DGF patients were significantly elevated with maximum level over 10,000, however, they all could leave HD from 11 to 18 POD, when UNGAL decreased less than 1,000. In the patient with immediate function in DKR, UNGAL level achieved less than 100 ng/ml within a few days after transplantation. ROC decision plot curve analysis showed cut off value of 60.3ng/ml was the point that both sensitivity and specificity achieved 100%.

Conclusions: UNGAL is an effective biomarker for DGF and AKI after kidney transplantation. It is useful not only to predict recovery from DGF in DKR, but also to evaluate postoperative renal function in LKD as well as in LKR.

PUB847

Incidence of Metabolic Syndrome in the Second Year of Kidney Transplant and Its Effect on Graft Function Alejandro Concepcion Orozco Jimenez, Jorge Andrade-Sierra. *Nephrology and Transplant, IMSS, Gudalajara, Jalisco, Mexico.*

Background: Metabolic Syndrome (MS) is a risk factor to kidney disease. The MS during the second year of kidney transplant (KT) has not been completely evaluated and the possible impacts on graft function.**Objective:** Describe the incidence of MS in three different groups (MS free, One evaluation and Persistent), 24 months after KT and its impact on graft function according to time of development.

Methods: Prospective cohorts (Mar/2009-Apr/2011) of 197 kidney recipients, diabetic patients before transplant were excluded. MS was defined using the ATP III criteria adjusted to Hispanic population.

Results: The accumulated incidence of MS at 6, 12, 24 months were 20, 22, 34% repectively. Abdominal size, CRP and tryglicerides were significantly different among groups. 121 (61%) were MS free during the follow up; 10 patients had MS during the follow. Other results are shown in table.

Comparison of clinical and biochemical variables at 24 months post-KT according to exposure to MS

Variable	MS Free	One Evaluation	Persistent
MS N(%)	39 (61)	25 (39)	133 (68)
Mean age (yr)	38.4 ± 10.2	36 ± 11.3	39.5 ± 9.8
Size (cm)	163.44 ± 8.9 <<	165.07 ± 8.9 *	175.1 ± 9.9*<<
BMI	22.61 ± 3.4	29.71 ± 4.9	27.77 ± 2.96
Waist (cm)	81.37 ± 10.39 << >>	91.8 ± 10.5>>	101.55 ± 9.2 <<
Sistolic blood pressure (mmHG)	125.75 ± 15.03<<	133.15 ± 15.75	149.3 ± 20.21<<
Diastolic blood pressure (mmHG)	78.44 ± 11.89	81.58 ± 11.37	88.6 ± 9.38
Medium blood pressure (mmHG	51.09 ± 47.98<< >>	79.27 ± 40.90>>	108.9 ± 11.69<<
Triglycerides (mg/dl)	123.19 ± 70.05 << >>	184.63 ±99.22>>	189.72 ± 98.38<<
HDL (mg/dl)	52.43 ±12.82 <<	42.53 ± 9.25<<	35.5 ± 5.6<< >>
CRP (mg/l)	5.3 ± 8 <<	8 ± 13 <<	6.2 ± 7.6 <<>>
GFR (ml/min/ 1.73m2)	73.3 ± 27.5	81.2 ± 19.6	68.8 ± 11.7

P<0.05, p significant when compared with an assessment against persistent SM; << p significant when comparing never against persistent; >>p significant when compared against an evaluation never.

Conclusions: 5% of our patients persisted with MS and 61% were MS free at 2 year follow up, the latter is similar with the current literature in MS. Time of exposure to MS could affect the result in renal function.

PUB848

Predictors of Donor Kidney Discard: A Single DSA Experience Edward Wang, Anton I. Skaro. *Comprehensive Transplant Center, Northwestern University, Chicago, IL.*

Background: There is a severe donor organ shortage in the US resulting in high kidney transplant waitlist mortality. Augmentation of the donor pool should entail minimizing kidney discards. However there are limited data on kidneys that are discarded prior to transplant. We sought to examine risk factors for kidney discard in a single donor service area (DSA).

Methods: We examined data prospectively collected by the Gift of Hope from 1996-2011 on all donors considered for kidney procurement (n=7,933). We conducted a comparative analysis of donor characteristics for kidneys that were discarded and those that were transplanted. Data were analyzed using univariate and multivariate logistic regressions in SAS 9.2.

Results: A total of 1,090 kidneys (13.7%) were discarded during the time period studied. The leading reason for organ discard was biopsy findings (66.0%) at the time of procurement. Compared to organs that were not discarded, the donors of kidneys discarded were older (54.4 ±15.8 vs. 37.1 ± 18.3; p<0.001), more likely to be female (48.9% vs. 38.4%, p<.001), had a greater BMI (19.8 ±5.3 vs. 18.6 ± 4.9; p<0.001) and consisted of a higher proportion of African-American (26.9% vs. 23.6%; p<0.001) and Asian race (2.2% vs. 1.3%, p<.05). Moreover, a higher proportion of donors with organ discards had cerebrovascular/stroke (64.1% vs. 35.3%; p<0.001) as a cause of death and DCD (13.2% vs. 9.5%; p<0.001). In the univariate analysis, older age (≥65) (OR=5.39, 95% CI 4.56-6.36), higher BMI (OR=1.04, 95% CI 1.03-1.06), female (OR=1.53, 95% CI 1.35-1.74), Asian or African-American (OR=1.45, 95% CI 1.02-2.88) donors, DCD (OR=1.45, 95% CI 1.19-1.76), and stroke (OR=5.03, 95%CI 4.22-5.98) were associated with greater odds of discard. In the multivariate model, all remained significant predictors of kidney discard.

Conclusions: Donor age, BMI, gender, race, and circulatory status all appear to influence kidney utilization. Despite perceived lower organ quality, broader sharing of rare kidney resources with competitive DSAs might reduce kidney discard. These data may have implications on organ availability for kidney transplantation as the US population increases in age and accumulates associated comorbidity.

PUB849

Is Living Donor Nephrectomy an Acute Kidney Injury? José Guerra, Mário Raimundo, Catarina Teixeira, Alice Santana, Antonio Gomes da Costa. *Nephrology and Renal Transplantation, Hospital de Santa Maria, Lisbon, Portugal.*

Background: Acute Kidney Injury (AKI), defined and stratified by the Risk, Injury, Failure, Loss and End-Stage (RIFLE) criteria, has been associated with increased risk of cardiovascular disease, development of chronic kidney disease and short and long-term mortality. Living donor nephrectomy results in an "acute" loss of about 50% of the functional renal mass. We applied the concept of AKI to the living donor nephrectomy in order to quantify its incidence and impact on long-term kidney function.

Methods: We evaluated sequential renal function in 50 living donors without perioperative complications. Serum creatinine (sCr) was collected at three time points: before nephrectomy (T0), early post-nephrectomy (T1) - the highest value in the first 7 days - and one year after nephrectomy (T2). Glomerular Filtration Rate (GFR) was estimated by the CKD-EPI equation. AKI was defined and stratified by the RIFLE criteria.

Results: The 50 living donors had a mean age of 46.42 ± 11.1 years, 90% were Caucasian and 70% female. Mean length-of-stay was 7.1 ±1.6 days. Using the GFR criteria 76% of patients developed AKI Risk, 14% AKI Injury and none developed AKI Failure. eGFR was significantly lower 1 year after transplantation compared to pre-nephrectomy eGFR.

Serum creatinine and eGFR at T0, T1 and T2

	T0	T1	T2	p value*
sCr (mg/dl)	0.75±0.14	1.13±0.24	1.08±0.22	<0.001
eGFR (ml/min/1.73m2)	110.9±18.3	67.4±13.2	71.6±15.9	<0.001

* Friedman Test

Conclusions: Living donor nephrectomy leads to an early deterioration of renal function that fits the currently accepted AKI criteria. Kidney function improves during the first year post-nephrectomy but does not return to baseline values, representing, approximately, an average loss of 30 ml/min/1.73m^2. This may eventually lead to a progressive loss of function on the long-term and the criteria for living donor transplantation should be revised in a more restricted perspective.

The Pathological Role of FGF23 in the Cardiorenal Syndrome Is Mediated by the Activation of Calcineurin/NFAT Signaling in the Heart Ansel P. Amaral,[1] Alexis J. Sloan,[1] Saurav Singh,[1] Ming Chang Hu,[2] Orson W. Moe,[2] Makoto Kuroo,[2] Giovana S. Di Marco,[3] Marcus Brand,[3] Myles S. Wolf,[1] Christian Faul.[1] *[1]Nephrology and Hypertension, Medicine, University of Miami Miller School of Medicine, Miami, FL; [2]Internal Medicine and Pathology, University of Texas Southwestern Medical Center, Dallas, TX; [3]Internal Medicine, University of Münster, Münster, Germany.*

Background: Cardiovascular disease is the primary cause of death in chronic kidney disease (CKD), and left ventricular hypertrophy (LVH) is an important mechanism in this context. Patients with CKD develop marked elevations in circulating levels of the phosphorus-regulating hormone, fibroblast growth factor (FGF) 23, and work from our group has shown that rates of LVH are elevated in CKD, and that elevated FGF23 is independently associated with LVH.

Methods: In a recent experimental study, we demonstrated a direct causal role for elevated FGF23 in the pathogenesis of LVH. We show that FGF23 directly induces pathological hypertrophy of isolated cardiac myocytes, and that multiple mouse models for elevated serum FGF23 levels develop LVH. Most importantly, administering an FGF receptor blocker to the 5/6 nephrectomy rat model of CKD attenuated the severity of LVH without reducing the animals' markedly elevated blood pressure. This data suggests a novel mechanism to explain the high rates of LVH in patients with CKD.

Results: Our ongoing experiments aim to identify the precise signal transduction pathways in the heart that are activated by FGF23, in order to screen for novel drug targets to interfere with LVH in the Cardiorenal Syndrome. Our novel data indicate, that FGF23 activates nuclear factor of activated T-cells (NFAT) in isolated cardiac myocytes as well as in the mouse heart upon i.v. injection. In contrast, FGF23 does not cause an activation of Ca^{2+}/calmodulin dependent kinase II or protein kinase C, two other major branches of Ca^{2+}-mediated pro-hypertrophic signaling.

Conclusions: Since cyclosporine A treatment of 5/6 nephrectomized rats inhibits the development of LVH, the calcineurin/NFAT signaling axis appears to function as the major mediator of FGF23's cardiac effects.

Molecular Mechanisms of Cadmium (Cd) Dependent Fibroblast Growth Factor 23 Secretion in Bone Shinsuke Kido, Marina Fujihara, Kengo Nomura, Shohei Sasaki, Yuji Shiozaki, Hiroko Segawa, Sawako Tatsumi, Ken-ichi Miyamoto. *Department of Mocular Nutrition, Institute of Health Biosciences, the University of Tokushima Graduate School, Tokushima, Japan.*

Background: Fibroblast growth factor 23 (FGF23) is a bone-derived phosphaturic factor and is known to regulate blood inorganic phosphate (Pi). Medication such as infusion of select iron-containing compounds increases serum FGF23 concentrations, with patients developing hypophosphartemia. In autosomal dominant hypophosphatemic rickets (ADHR) patients, low serum iron was correlated with elevated serum FGF23 concentration. In animal study, cadmium (Cd) administration increases serum FGF23 concentration. Thus, a relationship between metal ion and FGF23 metabolic pathway has been proposed.

Methods: In this study, we investigated the molecular mechanism of FGF23 production by Cd.

Results: Cd injection to mice increased plasma FGF23 concentrations, but FGF23 mRNA expression in bone was not changed. Further studies indicate that increased plasma FGF23 levels in the Cd-injected mice are caused by the post-translational events of the FGF23 protein. GalNAc-T3 is known to be involved in secretion of intact FGF23. To determine potential roles of GalNAc-T3 in Cd-induced FGF23 production, we examined the effect of Cd on the GalNAc-T3 mRNA expression in vivo and in vitro. In Cd-injected mice, GalNAc-T3 gene expression was significantly increased in bone. Cd also enhanced the expression of GalNAc-T3 to cultured osteosarcoma UMR106 cells. Interestingly, we found that Cd activates aryl hydrocarbon receptor (AhR), suggesting the requirement of AhR for the induction of the GalNAc-T3 gene expression by Cd. In addition, Cd enhanced the transcriptional activity of the GalNAc-T3 gene through AhR. AhR siRNA markedly suppressed the stimulation of transcriptional activity by Cd. Moreover, Cd-dependent FGF23 production was inhibited by AhR antagonist. Thus, Cd stimulates GalNAc-T3 gene transcription via an enhanced AhR binding to the GalNAc-T3 promoter.

Conclusions: The present study suggests that the elevation GalNAc-T3 by Cd suppress proteolytic processing of FGF23 and stimulates the elevation of serum FGF23 concentrations.

HS-OR03

T-Cell Autophagy Is Required for Transplantation Tolerance Divya Anna Verghese, Peyman Bizargity, Anju Yadav, Barbara T. Murphy, Bernd Schroppel. *Nephrology, Mount Sinai School of Medicine, New York, NY.*

Background: In order to be effective, tolerance induction regimens require the removal by cell death of potentially destructive alloreactive T cell clones. We investigated the role of autophagy, a pathway utilized by cells during nutrient or growth factor deprivation that can also contribute to cell death, in the induction of transplant tolerance.

Methods: Peripheral transplant tolerance was induced using costimulation blockade with anti-CD154 (MR1) and donor specific transfusion (DST). Chemical and genetic strategies were used to inhibit autophagy.

Results: We found that autophagy is required for peripheral transplantation tolerance induced by costimulation blockade with DST-MR1. Additionally, we observed that tolerance induction with DST-MR1 led to the induction of autophagy in graft infiltrating immune cells. Upon chemical inhibition of autophagy using the phosphoinositide 3-kinase (PI3K) inhibitor 3-methyladenine (3-MA), transplant tolerance was abrogated. The administration of 3-MA at a later time after transplant had no effect, indicating that autophagy was important in the induction of tolerance but not in its maintenance. We confirmed the importance of autophagy in the induction of tolerance using a mouse model with the genetic disruption of the autophagy-related gene (Atg) *beclin*1. We found that *beclin*$1^{+/-}$ recipients displayed high anti-donor immune responses reflected by increased intragraft $CD4^+$ T-cell infiltration and elevated IFNγ production. Adoptive transfer of $Rag^{-/-}$ bone marrow into *beclin*$1^{+/-}$ recipients demonstrated that immune cell-derived autophagy was required to induce tolerance. Furthermore, activated T cells with *beclin*1 deficiency had enhanced survival. Using conditional knockout models where Atg7, a critical protein for autophagy, was specifically deleted in T or B cells, we found that autophagy-sufficiency in T cells but not in B cells was required to achieve peripheral tolerance.

Conclusions: These findings highlight the importance of autophagy as a key mechanism to reduce the allospecific T-cell pool. We postulate that autophagy presents a putative target to facilitate transplant tolerance.

HS-OR04

Absence of Adenylyl Cyclase 6 Is Markedly Protective in Polycystic Kidney Disease in Mice Donald E. Kohan, Karl P. Roos, Kevin A. Strait, Sara Rees. *Division of Nephrology, University of Utah, Salt Lake City, UT.*

Background: Cyclic AMP is an important mediator of renal cyst formation and fluid secretion in autosomal dominant polycystic kidney disease (PKD), however it is unknown which adenylyl cyclase (AC) isoforms are involved in PKD.

Methods: Mice were generated with collecting duct-specific knockout (CD KO) of either the *KD1* gene, the Adcy6 gene, or both using mice with loxP-flanked target alleles bred with mice transgenic for the aquaporin-2 promoter driving Cre recombinase expression.

Results: CD PKD1 KO results in polycystic kidneys that are first evident at 1-2 weeks postnatal. Mice with CD PKD1 KO lived an average of 48 ± 6 days (N=42). Coincident heterozygous deletion of AC6 increased life span to 94 ± 11 days (N=24), while coincident homozygous deletion of AC6 (double CD PKD1 and AC6 KO) further increased life span to at least 147 ± 20 days (N=21) (18 double KO mice remain alive beyond 200 days of age). As compared to PKD1 KO, double PKD1/AC6 KO mice had reduced renal cyst size, cyst number, renal cell proliferation and apoptosis, kidney size and weight, and BUN when all mice were analyzed at 4 weeks of age. Coincident AC6 KO mice had increased urine volumes. Interestingly, double PKD1/AC6 KO did not reduce 24-hr urinary cAMP excretion as compared to PKD1 KO alone. Western analysis of whole kidneys revealed that phosphorylated B-Raf and MEK1/2 protein levels were reduced by coincident AC6/PKD1 KO as compared to PKD1 KO alone.

Conclusions: AC6 is an important mediator of renal disease progression in a mouse model of PKD. This pathogenic effect of AC6 may relate more to AC isoform activation of specific signaling pathways rather than simply a reduction in renal cell cAMP production.

Wnt Signaling Is Required for Kidney Regeneration from Adult Zebrafish Nephron Progenitor Cells Caramai Nanae Kamei,[1,2] Yan Liu,[1,2] Iain A. Drummond.[1,2] *[1]Nephrology, Massachusetts General Hospital, Charlestown, MA; [2]Genetics, Harvard Medical School, Boston, MA.*

Background: In contrast to mammalian kidney regeneration, zebrafish can not only repair existing nephrons but are also capable of de novo generation of new nephrons from adult organ progenitor cells. Activation of both repair mechanisms is likely to be signaled by positive and negative growth regulators that ultimately restore normal kidney function. We report here that Wnt signaling plays a role in adult zebrafish kidney regeneration.

Methods: In situ hybridization as well as a transgenic reporter line expressing gfp in regenerating lhx1a-positive nephron progenitors was used to visualize regeneration in response to acute gentamicin injury. Wnt signaling was perturbed using the chemical activator BIO and the inhibitor XAV939.

Results: Both individual lhx1a-positive adult kidney progenitor cells and differentiating cell condensates are specifically marked by expression of the Wnt receptor frizzled9b (fzd9b). Active Wnt signaling was detected in differentiating nephron progenitors by expression of the canonical Wnt target lef1. Acute injury to the adult zebrafish kidney by gentamicin injection expanded the population of fzd9b-positive nephron progenitors. Pharmacological blockade of Wnt signaling reduced progenitor cell expansion after injury while activation of Wnt signaling was sufficient to expand fzd9b/lhx1a-positive progenitors in the absence of injury.

Conclusions: Our results demonstrate a role for Wnt signaling in adult zebrafish kidney regeneration and identify fzd9b as a new marker of adult kidney progenitor cells. Our results open new avenues to investigate the developmental origins and regenerative potential of nephrogenic stem cells.

Missense Mutation in Cell Cycle Gene FSGS7 Is a Cause of Autosomal Dominant FSGS Rasheed A. Gbadegesin,[1] Gentzon Hall,[2] Guanghong Wu,[2] David Howell,[5] Mario Schiffer,[3] Michelle P. Winn.[2] *[1]Pediatrics, Duke University, Durham, NC; [2]Medicine, Duke University, Durham, NC; [3]Nephrology, Hannover Medical School, Hannover, Germany; [4]Pathology, Duke University, Durham, NC.*

Background: Focal and segmental glomerulosclerosis, a condition that is characterized by segmental scarring of the kidney, is a leading cause of kidney failure. Identification of genes causing familial FSGS has improved our understanding of the disease mechanisms and points to defects in the glomerular epithelial cell, the podocyte, as a major factor in the pathogenesis of the disease.

Methods: We identified a family with autosomal dominant FSGS with nine affected individuals and carried out genome-wide linkage analysis (GWLA) using the Illumina Infinum II HumanLinkage-24 beadchip genotyping assay, performed whole-exome sequencing and confirmed all identified novel variants by Sanger sequencing.

Results: We identified a missense mutation *R431C* in *FSGS7* an F-actin binding cell cycle gene as a new cause of FSGS. The mutation segregates with the disease in the family and we did not find the change in 1600 control chromosomes. The change is conserved in evolution and it is predicted to be deleterious by *in-silico simulation*. *FSGS7* is upregulated in proliferating podocytes in kidney biopsies from individuals with collapsing FSGS. Knockdown of *FSGS7* in zebrafish recapitulated the human phenotype. Additionally, *FSGS7* gene deficiency in a human immortalized podocyte cell line resulted in reduced podocyte motility.

Conclusions: Collectively, these findings suggest that *FSGS7* is important in maintaining the podocyte actin cytoskeleton and emphasizes the importance of cell proliferation, cell migration and filopodia formation in the pathogenesis of FSGS. Molecular dissection of the pathways by which *FSGS7* cause FSGS will provide insight into the mechanisms of podocyte renewal in health and disease.

Endophilin, a Functional Partner of Dynamin and Synaptojanin 1 at Synapses, Is Required for Podocyte Function in the Kidney Keita Soda, Xuefei Tian, Sung Hyun Son, Shuta Ishibe. *Internal Medicine, Section of Nephrology, Yale University, New Haven, CT.*

Background: The importance of clathrin-coated pits and vesicles that are observed in podocyte foot processes, is currently unknown. We have initially identified synaptic proteins, dynamin and synpatojanin1, which when lost in mice, result in severe proteinuria and foot process effacement. These two proteins also interact with Myo1e, CD2AP, and Nck, which have been shown to be causal for nephrotic syndrome in humans and or mice. Here, we identified endophilin, an interacting protein of dynamin, synaptojanin1, and CD2AP, that is recruited to the necks of endocytic clathrin-coated pits, and is necessary for podocyte function in the kidney.

Methods: Wild type and constitutive *endophilin 1,2,3* triple knock out (TKO) mice were analyzed to deteremine the role of endophilin *in vivo*. To assess the temporal and spatial dynamics in podocytes, fluorescently tagged endophilin in relation to clathrin or actin was visualized, using time lapsed spinning disc confocal microscopy.

Results: Immunofluorescence staining of kidney sections from mice revealed endophilin expression in podocytes, which colocalized with nephrin. Histological examination of the *endophilin* TKO kidney cortex demonstrated mesangial matrix accumulation in the glomeruli and dilated tubules with proteinaceous casts. Urine obtained from these mice revealed robust proteinuria (Albumin/creatinine ratio (μg/mg); control 15±7 vs. TKO 1045±220, n=5, p<0.001). Severe foot process effacement with a thickened glomerular basement membrane was also observed by EM at birth. *In vitro*, we observed endophilin arriving at late stage clathrin-coated pits along with CD2AP in podocytes. Moreover, endophilin, as well as dynamin and synaptojanin1, colocalized with F-actin at clathrin-coated pits in podocytes.

Conclusions: Our results emphasize a striking recapitulation of a fundamentally conserved mechanism linking a protein network at neuronal synapses that operates at the interface of the endocytic machinery and the actin cytoskleleton, to also form and maintain the kidney glomerular filtration barrier.

HS-OR08

Feasibility of Repairing GBM Defects in Alport Syndrome Jeffrey H. Miner, Xiaobo Lin. *Renal Division, Washington University Sch. of Medicine, St. Louis, MO.*

Background: The glomerular basement membrane (GBM) is a crucial component of the glomerular filtration barrier (GFB). The GBM's major components are the collagen IV α3/4/5 network, laminin-521, nidogen-1 and -2, and agrin. Of these 9 components, mutations that affect 4 of them cause human kidney disease: *COL4A3*/*A4*/*A5* mutations cause Alport syndrome, and *LAMB2* mutations cause Pierson syndrome/congenital nephrotic syndrome. The existence of well-characterized mouse models make these diseases especially attractive for investigating therapies. Several groups have explored the potential for cell-based therapies aimed at replacing the missing collagen IV network in Alport mice. Although the positive effects of bone marrow and other cell transplants or infusions on progression of kidney disease are promising, the fate of the infused cells and the reported effects of these procedures on the GBM's collagen IV network have been disparate, difficult to interpret, and controversial.

Methods: We have used podocyte-specific and ubiquitously expressed reverse tetracycline transactivator (rtTA) transgenic mice and a novel $(tetO)_7$-regulated collagen IV α3 transgene in *Col4a3*$^{-/-}$ Alport mice to attempt to induce collagen IV network restoration either before or after GBM maturation. We have generated novel nephrin-rtTA-3G transgenic mice with improved podocyte-specific doxycycline-induced gene activation.

Results: Prenatal induction of Col4a3 expression by doxycycline in *Col4a3*$^{-/-}$ Alport mice decreased proteinuria and BUN and greatly extended life span by promoting collagen α3/4/5(IV) deposition and assembly in the GBM. Postnatal induction of Col4a3 expression at P14 also promoted collagen α3/4/5(IV) network assembly, with significant improvements in proteinuria, BUN, and life span. Even induction starting as late as P18 improved kidney function by reducing BUN.

Conclusions: 1) Postnatal incorporation of collagen α3/4/5(IV) into the mutant Alport GBM is feasible. 2) Even partial restoration of the collagen IV network slows progression to ESRD. The results of these feasibility studies have implications not only for treating human kidney disease, but also for our basic understanding of BM biology, GBM plasticity, and cell/matrix interactions.

HS-OR09

Disruption of PHD2 in the Kidney Results in HIF-2 Dependent Polycythemia Pinelopi P. Kapitsinou, Volker H. Haase. *Nephrology, Vanderbilt University Medical Center, Nashville, TN.*

Background: Polycythemia is often associated with increased erythropoietin (EPO) synthesis and defective oxygen sensing. Among the three prolyl hydroxylase domain containing proteins (PHD1-3), which serve as oxygen sensors and regulate Hypoxia Inducible Factors (HIFs), PHD2 has been identified as the critical enzyme controlling renal EPO production. We have previously demonstrated that the induction of renal Epo under low oxygen conditions is mediated by Hif-2. To what degree Hif-2 mediates the effects of PHD2 on Epo synthesis remains to be defined however. Here, we used a genetic approach to dissect the contribution of HIF-2 in a novel model of renal Epo-driven erythrocytosis that results from PHD2 inactivation in renal Epo producing (REPO) cells.

Methods: To delete Phd2 and/or Hif-2 in the kidney, P3ProCre transgenics were crossed to mice carrying conditional Phd2 and/or Hif-2 alleles (P3-Phd2$^{-/-}$, P3-Phd2$^{-/-}$Hif2$^{-/-}$).

Results: While mice lacking one copy of Phd2 (P3-Phd2$^{+/-}$) appeared normal, deletion of both Phd2 alleles (P3-Phd2$^{-/-}$) resulted in a) premature mortality (60% mortality at 10wks, P=0.001), b) decreased body weight (14g vs 24g, n=6-7, P<0.001) and c) excessive erythrocytosis (Hct; 75±1.6% vs 50±1.2 %, n=11-12, P<0.0001). Serum Epo levels were increased by ~60-fold in P3-Phd2$^{-/-}$ mutants compared to controls (36332±6853pg/ml vs 573±136pg/ml, n=11-12, P<0.0001), which associated with a ~60-fold increase in renal *Epo* mRNA (n=3-5, P=0.04). FACS analysis revealed a significant increase of CD71+TER119+ erythroid progenitors specifically in the spleen (4.6-fold, P<0.001) but not bone marrow. Furthermore, kidneys of P3-Phd2$^{-/-}$ mutants showed stabilization of Hif-1 and Hif-2 proteins and increased expression of Hif target genes such as *Glut1*. Simultaneous inactivation of Hif-2 (P3-Phd2$^{-/-}$Hif2$^{-/-}$) resulted in anemia associated with deficient Epo production and augmented Hif-1 signaling as previously described for P3-Hif2$^{-/-}$ (*Kapitsinou, Blood 2010*).

Conclusions: Our data establish HIF-2 as the critical HIF isoform regulating EPO synthesis in Phd2 deficient REPO cells. Our findings identify the PHD2/HIF-2 axis as a specific target for therapy aiming at increasing endogenous renal EPO production.

Insights into ANCA-Associated Vasculitis Provided by the First Genome-Wide Association Study Kenneth G.C. Smith. *Cambridge Institute for Medical Research and the Department of Medicine, University of Cambridge, Cambridge, United Kingdom.*

Background: Presented on behalf of the European Vasculitis Genetics Consortium.

Anti-neutrophil cytoplasm antibody (ANCA)-associated vasculitis (AAV) encompasses two major syndromes – Granulomatosis with Polyangiitis (Wegener's) (GPA) and Microscopic Polyangiitis (MPA) – both of which are significant causes of renal failure. We examined their genetic underpinning by performing the first genome-wide association study (GWAS) in AAV.

Methods: Discovery cohort 1,233 UK AAV patients, 5,884 controls. Replication cohort 1,454 Northern European cases, 1,666 controls. Quality control, population stratification and statistical analysis used standard criteria. Further analysis of the discovery cohort used the Immunochip (Cortes A, Brown MA. Arth Res Ther. 2011;13:101).

Results: MHC and non-MHC associations with AAV were found, and GPA and MPA were genetically distinct. The strongest genetic associations were not with clinical syndrome but with the antigenic specificity of ANCA. Anti-proteinase 3 (PR3) AAV associated with *HLA-DP, SERPINA1 and PRTN3*. Anti-myeloperoxidase AAV associated with HLA-DQ (Lyons PA et al. NEJM 2012;367:214-223). We used the Immunochip to analyse the discovery cohort, allowing the imputation of classical MHC alleles. 3 independent alleles contribute to the risk of anti-PR3 AAV at the HLA-DP locus, one conferring susceptibility and two resistance. Two alleles contribute to the risk of anti-MPO AAV at HLA-DQ, one conferring susceptibility and one resistance. Novel SNP associations outside the MHC were also identified by the Immunochip, and are being replicated.

Conclusions: This study has confirmed a genetic component to AAV , demonstrated that GPA and MPA are genetically distinct diseases better defined by ANCA specificity than clinical syndrome, and shown that the response to the autoantigen PR3 (encoded by

Underline represents presenting author/disclosure.

PRTN3) is a central aetiological feature of PR3-AAV. Further detailed analysis of the MHC association of both PR3- and MPO-AAV has been possible using the Immunochip, which has also uncovered further susceptibility loci. Thus, from a genetic standpoint, PR3- and MPO-AAV must be considered as distinct autoimmune syndromes.

The Aliskiren Trial in Type 2 Diabetes Using Cardio-Renal Endpoints (ALTITUDE) Hans-Henrik Parving,[1] Barry M. Brenner,[2] John Mcmurray,[3] Dick de Zeeuw,[4] Steven Mark' Haffner,[5] Scott D. Solomon,[2] Nish Chaturvedi,[6] Frederik I. Persson,[7] Akshay Suvas Desai,[2] Maria Nicolaides,[8] Marc A. Pfeffer.[2] *[1]Rigshospitalet, University of Copenhagen, Denmark; [2]Harvard Medical School; [3]University of Glasgow, United Kingdom; [4]University of Groningen, Netherlands; [5]University of Texas, TX; [6]Imperial College London, United Kingdom; [7]Steno Diabetes Center, Denmark; [8]Novartis Pharma AG, Switzerland.*

Background: The macro- and microvascular complications of type 2 diabetes are augmented in those with concomitant kidney and/or cardiovascular disease. ALTITUDE was undertaken to determine whether use of the direct renin inhibitor aliskiren would improve prognosis by reducing fatal and non-fatal cardiovascular and renal events in type 2 diabetic patients at high risk for these complications.

Methods: ALTITUDE was an international randomized double-blind study in 8561 subjects randomized to aliskiren (A) 300 mg once daily or placebo (P) on top of single RAAS blockade. The primary outcome measure was time to first event for the composite endpoint of CV death, resuscitated death, MI, stroke, unplanned hospitalization for HF, onset of ESRD or doubling of baseline creatinine.

Results: Baseline characteristics of the two groups were similar, eGFR 56.9 mL/min/1.73m^2 in both groups and albuminuria (mg/g) 200 vs. 201. Time averaged mean BP was lower in the A group (1.3/0.6 mmHg). At a median follow-up of 32.9 months the primary composite endpoint had occurred in 767 patients (17.9%) assigned to A and 721 (16.8%) assigned to P, HR for A vs. P 1.08 (95% CI 0.98, 1.20) p=0.14. Stroke occurred in 146 (3.4%) of the A and 118 (2.7%) in P, HR 1.25 (0.98, 1.60) p=0.070. Doubling of serum creatinine or ESRD was similar in the two groups and the mean reduction in albuminuria was 14% (CI 11-17) lower in A. Patients on A experienced significantly increased serum potassium ≥6 mmol/L (8.8% vs. 5.6%), and reported hypotension (12.1% vs. 8.0%).

Conclusions: The trial does not support administration of aliskiren on top of standard therapy with RAAS blockade in type 2 diabetic patients at high risk for cardiovascular and renal events, and may even be harmful.

Tolvaptan in Patients with Autosomal Dominant Polycystic Kidney Disease: The TEMPO 3:4 Trial Vicente E. Torres,[1] Arlene B. Chapman,[2] Olivier Devuyst,[3,4] Ron T. Gansevoort,[5] Jared J. Grantham,[6] Eiji Higashihara,[7] Ronald D. Perrone,[8] Holly B. Krasa,[9] John Ouyang,[9] Osamu Sato,[10] Frank S. Czerwiec.[9,11] *[1]Mayo Clinic; [2]Emory Univ.; [3]Univ. Catholique de Louvain; [4]Univ. of Zurich; [5]Univ. of Groningen; [6]Kansas Univ.; [7]Kyorin Univ., Mitaka; [8]Tufts Univ.; [9]Otsuka Pharmaceutical Development & Commercialization, Inc., Rockville; [10]Otsuka Pharmaceutical Co., Ltd., Tokyo; [11]for the TEMPO 3:4 Trial Investigators.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) causes kidney cysts often associated with pain, hypertension, and kidney failure. Preclinical studies justify testing vasopressin V_2 receptor antagonists to inhibit cyst growth and slow kidney function decline.

Methods: In a phase 3, multi-center, double-blind, placebo-controlled, 3-year trial, 1445 ADPKD subjects, 18-50 year-old, with total kidney volume (TKV) ≥750 ml and estimated creatinine clearance ≥60 ml/min, were randomized 2:1 to split dose tolvaptan (45/15, 60/30 or 90/30 mg daily as tolerated) or placebo. Primary outcome was annual rate of TKV change. Sequential secondary endpoints included composite of time to clinical progression events (worsening kidney function, kidney pain requiring intervention, hypertension or albuminuria) and rate of kidney function decline.

Results: TKV increase over 3 years was halved in subjects treated with tolvaptan compared to placebo (2.80%/year versus 5.51%/year, P <0.001). The composite endpoint favored tolvaptan (hazard ratio [HR] 0.87, P <0.01) with fewer events of worsening kidney function (HR 0.39, P <0.001) and kidney pain requiring intervention (HR 0.64, P=0.007). Tolvaptan reduced the slope of kidney function decline (reciprocal serum creatinine, -2.61 versus -3.81 (mg/ml)$^{-1}$/year, P <0.001). ADPKD-related adverse events were less common in tolvaptan treated subjects. Aquaretic- and non-ADPKD hepatic-related adverse events were more common in tolvaptan treated subjects contributing to higher rates of discontinuation, 23% with tolvaptan versus 14% with placebo.

Conclusions: Tolvaptan demonstrated clinically meaningful disease-specific benefits for ADPKD patients.

Evaluation of Cinacalcet Therapy To Lower Cardiovascular Events (EVOLVE) Trial Glenn M. Chertow,[1] Geoffrey A. Block,[2] Ricardo Correa-Rotter,[3] Tilman B. Drueke,[4] Jürgen Floege,[5] William G. Goodman,[6] Christian Mix,[6] Marie-Louise Trotman,[6] Yumi Kubo,[6] Charles A. Herzog,[7] Gerard M. London,[8] Kenneth Mahaffey,[9] Sharon M. Moe,[10] David C. Wheeler,[11] Patrick S. Parfrey.[12] *[1]Stanford Univ SOM; [2]Denver Neph; [3]Instituto Nacional de Ciencias Méd y Nutrición, Mexico; [4]Picardie Univ SOMP, France; [5]RWTH Aachen, Germany; [6]Amgen; [7]Univ of Minnesota; [8]Hôpital Manhès, France; [9]Duke Univ Med Ctr; [10]Indiana University SOM, United States; [11]Univ College London, United Kingdom; [12]Health Sciences Ctr, Canada.*

Background: Secondary HPT (sHPT) and other abnormalities associated with chronic kidney disease – mineral bone disorder (CKD-MBD) may contribute to increased cardiovascular (CV) mortality and morbidity. Dietary modification and a variety of medications are used to attenuate the severity of sHPT.

Methods: EVOLVE was designed to test the hypothesis that tx with cinacalcet compared with placebo (on a background of PB +/- vit D sterols) reduces the risk of death or non-fatal CV events among pts on hemodialysis (HD) with sHPT. Sample size was calculated based on these assumptions: primary composite event rate of 23.2%/yr in the placebo group, 20% effect size, 1.5-yr enrollment period, 4-yr total study duration, lost to follow up rate 1%/yr, drop-out rate 10%/yr in the cinacalcet and drop-in rate 10% in the placebo group. With an overall α=0.05, we calculated that 1882 primary composite endpoints are needed to get a power of 90%.

Results: 3883 pts were randomized from 22 countries. The burden of overt CV disease at baseline (BL) was high (e.g. MI 12.4%, HF 23.3%). The median PTH at BL was 693 pg/mL (10%, 90% range, 363 to 1694 pg/mL). 87.2% of patients were prescribed PB and 57.5% were prescribed vit D derivatives at BL.

Conclusions: Using an unadjusted intent-to-treat (ITT) analysis, cinacalcet did not significantly reduce the risk of death or major CV events in patients on HD with moderate to severe sHPT. Results from ITT analyses using multivariable adjustment and censoring data 6 months after cessation of study drug will be presented along with safety data. NCT00345839

Funding: Pharmaceutical Company Support - Amgen

A Randomised Trial of Mycophenolate Mofetil Versus Cyclophosphamide for Remission Induction in ANCA-Associated Vasculitis: MYCYC. On Behalf of the European Vasculitis Study Group Rachel B. Jones,[1] Michael Walsh.[2] *[1]Department of Medicine, University of Cambridge, United Kingdom; [2]Department of Clinical Epidemiology & Biostatistics, McMaster University, Canada.*

Background: Cyclophosphamide (CYC) induction regimens are standard therapy for ANCA-associated vasculitis (AAV) with major organ involvement. However CYC is associated with considerable toxicity. Mycophenolate mofetil (MMF) is a potential alternative to CYC. We performed an international, multi-centre non-inferiority randomised controlled trial comparing MMF to CYC for remission induction of AAV.

Methods: Eligible patients had newly diagnosed AAV and were randomised to receive up to 6 months induction with either MMF 2-3mg/day (n=70) or 6-10 pulses of IV CYC 15mg/kg (n=70). Both groups received the same tapering oral prednisolone regimen and azathioprine maintenance therapy. The primary outcome was remission (absence of disease activity for ≥4 weeks while adhering to the glucocorticoid regimen). We hypothesized that MMF treatment would result in no more than 12% fewer remissions.

Results: The groups were similar at trial entry. The primary remission endpoint occurred in 46/70 (66%) MMF vs 48/70 (69%) CYC (risk difference -3%, 90% CI -16 to 10%; p=0.06 for non-inferiority). Remission induction irrespective of steroid compliance occurred in 61/70 (87%) MMF vs 54/70 (77%) CYC (risk difference 10%, 90% CI -1 to 21%; p=0.01 for non-inferiority). However, glucocorticoid dosing did not differ significantly between groups overall (p=0.96). Key safety outcomes did not differ significantly (Table 1).

Conclusions: In the primary analysis we were unable to demonstrate that MMF is non-inferior to IV CYC for remission induction at six months in newly diagnosed AAV. How, glucocorticoid treatment affects remission induction with MMF requires further study. **Longer term safety outcomes and relapse data are required to fully understand the role of MMF as induction therapy for AAV.**

Table 1. Key safety outcomes

Safety Outcome	MMF	CYC	Risk Difference (95% CI)	p-value
Any SAE	32 (46%)	27 (39%)	7% (-9 to 23%)	0.39
Serious Infection	18 (26%)	11 (16%)	10% (-3 to 23%)	0.14
Dialysis	2 (3%)	3 (4%)	-1% (-8% to 5%)	0.99
Death	5 (7%)	4 (6%)	1% (-7 to 10%)	0.99

Survival of Dialysis Patients in the US after Surgical Versus Percutaneous Coronary Intervention Charles A. Herzog,[1,2] Craig Solid.[1] *[1]CVSSC, United States Renal Data System, MMRF, Minneapolis, MN; [2]University of Minnesota, Minneapolis.*

Background: There are few published data on the comparative survival of dialysis pts undergoing surgical versus percutaneous coronary revascularization in the era of drug-eluting stents (DES). Preliminary data have suggested superior long-term outcomes after coronary artery bypass surgery (CAB) vs percutaneous coronary intervention (PCI).

Methods: We searched the records of the United States Renal Data System database to identify 23,038 dialysis pts having CAB, bare-metal stent (BMS) or DES in 2004-2009. Long-term survival was estimated by Kaplan-Meier method and independent predictors of death were examined in a comorbidity-adjusted Cox model.

Results: There were 6,178 CAB pts, 5,013 BMS pts and 11,847 DES patients. The tables show survival and predictors of death, (age < 65, male, white, hemodialysis, time on dialysis < 2 years, no comorbidity, CAB is reference) with hazard ratio (HR). DES patients have the best survival at 12 months, but after 18 months CAB patients have the best survival. CAB pts receiving internal mammary grafts (IMG) (75% of CAB pts) do significantly better than those without (Log-Rank p-value = 0.0005).

Conclusions: Our data suggest that DES provide the best short term survival, but unadjusted long-term survival is best in CAB patients. In the most recent treatment era, CAB and DES have similar overall outcomes in US dialysis pts, but the best survival is associated with CAB utilizing IMG.

SURVIVAL %				
2004-2009 PTS				
Months	CAB(IMG+)	CAB(IMG-)	DES	BMS
1	90	87	94	90
6	79	72	83	75

Ten-Year Safety of Prediabetic Living Kidney Donors Sindhu Chandran, Umesh Masharani, Allison B. Webber, David Wojciechowski. *Medicine, UCSF, San Francisco, CA.*

Background: Potential living kidney donors with prediabetes are often excluded due to concerns about the development of diabetes and progression to ESRD in the setting of a solitary kidney. This strategy may be unnecessarily restrictive.

Methods: An electronic database of all living kidney donors at UCSF was queried to identify donors from 1996-2005 with serum glucose >100 mg/dl (impaired fasting glucose or IFG). A medical history questionnaire was administered and blood and urine specimens obtained from donors who were successfully contacted and agreed to participate.

Results: 35 donors were enrolled. At the time of donation, mean fasting glucose was 108.6 mg/dl (SD 6.9) and a 2-hour glucose tolerance test was negative (<140 mg/dl) in all tested (n=10). HgA1c was checked in 15 patients with a mean value of 5.5% (SD 0.4). Other pre-donation characteristics are listed in table 1. At study enrollment, mean time from donation was 10.2 years (SD 3.1). Medical history and laboratory data are listed in table 1. 4 donors had developed diabetes. Except for 2 donors with known diabetes, none had albuminuria >30 mg/g.

PRE-DONATION	N=35
Male (%)	14 (40)
Age yrs (SD)	48.3 (11)
Race (%)	
-Caucasian	26 (74.3)
-African-American	1 (2.9)
-Other	7 (20)
BMI kg/m2	28.1 (3.9)
Related to recipient (%)	19 (54.3)
Urine Pr:Cr mg/g	0.04 (0 to 0.13)
Blood pressure mm Hg, N=21	
-Systolic	131 (12.2)
-Diastolic	76.6 (8.6)
MDRD eGFR 30 d post-donation	59.4 (9.9)
AT ENROLLMENT	N=35
Age yrs (SD)	58.4 (12)
BMI kg/m2 (SD)	27.9 (4.9)
History	
(1) High blood sugar (%) yes	11 (31.4)
(2) Diabetes (%) yes	4 (11.4)
(3) Diet controlled vs. oral meds	1 vs. 3
(4) High BP (%) yes	15 (42.9)
-On BP meds?	12 (34.3)
Mean fasting glucose mg/dl (SD)	102.7 (29.9)
<100 mg/dl	24 (68.6)
100-125 mg/dl	10 (28.6)
>125 mg/dl	1 (2.8)
HgbA1C % (SD)	5.9 (1.3)
<5.7	13 (37.1)
5.7-6.4	19 (54.3)
>6.4	3 (8.6)
MDRD eGFR (SD)	68.9 (14.3)
Urine Alb:Cr mg/g (SD)	9.14 (26.1)
>30 mg/g	N=2
Triglycerides mg/dl	123.4 (64.8)

Conclusions: Only a minority (11.4%) of living donors with IFG had developed diabetes 10 years post-donation. Kidney function remained well-preserved in all. Modest albuminuria was present in only 2 patients, both diabetic. Renal outcomes appear to be excellent in kidney donors with IFG.

Amplification of Albuminuria in Remote-Living Australian Aboriginal Adults by Early Life Risk Factors: The Multideterminant or Multihit Model of Renal Disease Wendy E. Hoy,[1] Andrew V. White,[2] Gurmeet R. Singh,[3] David A. Mccredie.[4] *[1]School of Medicine, Univ Queensland; [2]James Cook Univ; [3]Menzies School of Health Research; [4]Royal Children's Hosp and Univ Melbourne, Australia.*

Background: Albuminuria marks renal disease in remote-living Aboriginal people and predicts renal failure and nonrenal deaths. Levels increase markedly with age and over modest ranges of BMI and are higher in females. We describe albuminuria in the context of birthweight (Bwt) and episodes of childhood poststreptococcal glomerulonephritis (PSGN), singly and together.

Methods: 800 members of one tribal group were 10-39 yr during community health screens (>80% participation), and had satisfactory chart reviews for histories of PSGN and recorded Bwt. Urine ACR was the outcome of interest.

Results: Bwts were <2.5 kg in 28% of females & 22% of males, while 23% & 20% had "remote" episodes of PSGN (≥3 years prior). Bwt (inversely), a PSGN history, BMI and age all correlated independently with ACR. ACR levels were lowest in those with Bwts ≥2.81kg (the group median) and no PSGN history, intermediate in those with either lower Bwts or past PSGN, and highest in those with both, and with significant interaction terms between Bwt and PSGN. ACR levels were higher in females, and more sensitive to a single risk factor. ACR ≥3.4 (microalbuminuria threshold) was increased 1.9-fold and 2.7-fold in females with 1 and 2 risk factors respectively; rates were not higher in males with one risk factor, but were increased 3.7-fold with two risk factors.

Conclusions: A "multideterminant" model of renal disease is evident in relation to early life risk factors. Nephron deficiency established in early life, through underendowment (lower Bwts) and/or childhood loss (PSGN) establishes susceptibility and propagates higher ACRs with increasing age or BMI. Greater susceptibility in females is probably due to their lower nephron endowment, a feature of females generally, exacerbated by their lower Bwts, while slightly higher BMIs propagate their adult ACR levels. Potential for primary prevention is excellent.

Prolonged Use of Sulfamethoxazole-Trimethoprim at DS Dose Decreases Post-Transplant Urinary Tract Infection Timothy A. Horwedel,[1] Lyndsey Bowman,[1] Daniel C. Brennan.[2] *[1]Pharmacy, Barnes-Jewish Hospital; [2]Medicine, Washington University, St. Louis, MO.*

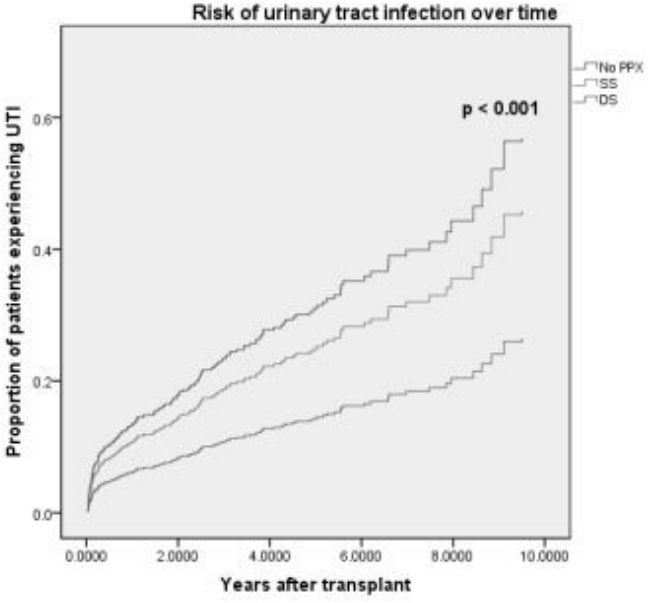
Background: Urinary tract infections (UTI) are common after renal transplant (RT), and guidelines do not address standardized UTI prophylaxis. We sought to examine our policy of indefinite use of sulfamethoxazole-trimethoprim (SMX/TMP) on the rates of UTI after RT.

Methods: We included RT recipients transplanted 1/2002 – 12/2010, allowing for >1 year of follow-up. Demographics and transplant characteristics were extracted from medical

Underline represents presenting author/disclosure.

records, and all outcome data were manually reviewed. The primary outcome was time to first UTI. Secondary outcomes included culture data. Time to UTI was analyzed using Cox-regression with time-dependent covariates.

Results: 1235 RT recipients were included, 130 received no SMX-TMP (no PPX), 300 on 400/80 mg (SS) daily and 805 on 800/160 mg (DS) daily. There were more females in the no PPX group; other characteristics were well matched. 198 (16%) experienced a UTI. UTI was associated with a >60% increased risk of graft failure (HR 1.62, 95% CI 1.16 – 2.28). By multivariate analysis, lower SMX/TMP dose ($p < 0.001$), increased age (p 0.03), and female sex ($p < 0.001$) predicted UTI. For each dosing increment there was a 32.8% relative risk reduction.



The benefit for females was particularly robust ($p < 0.001$). The time to UTI was 10 months in the no PPX group, 9 months in SS, and 28 months in DS. There were no differences in pathogens between groups, with coliforms cultured in 65.6% of UTI. There was 76.4% SMX/TMP resistance rate in the groups receiving drug, and 26.9% resistance with no PPX ($p < 0.001$). There was an increase in penicillin resistant organisms ($p < 0.001$), but susceptibility to other drugs was not different.

Conclusions: Prolonged SMX-TMP at the DS level should be used for indefinite UTI prophylaxis after RT to prevent UTIs, which are associated with graft loss.

SA-PO1099

Cardiovascular Risk in Diabetic Kidney and Kidney-Pancreas Transplant Recipients with Persistent Hyperparathyroidism

Francesco Rainone,[1] Lino Merlino,[1] Annalisa Terranegra,[2] Alessandra Mingione,[2] Laura Soldati,[2] Giuseppe Vezzoli.[1] *[1]Ospedale San Raffaele, Milan; [2]Università degli Studi, Milan.*

Background: Hyperparathyroidism (HPT) has been associated with cardiovascular mortality and morbidity in patients with chronic kidney disease. HPT may persist in kidney transplant recipients. Kidney transplantation may disclose the severity of a functional alteration in the parathyroid glands. Therefore we studied the association between major cardiovascular events (CVEs) and HPT in kidney transplant recipients (KTR) and kidney-pancreas transplant recipients (KPTR).

Methods: We analyzed the association of major CVEs with HPT in 63 diabetic KPTR, 25 diabetic KTR and 61 non-diabetic KTR.

Results: 117 patients (78.5%) had persistent HPT (iPTH > 63 pg/ml, one year after transplantation): 100 of them (67.1%) had HPT and normal serum calcium; 17 (11.4%) had HPT and high serum calcium. The proportion of patients with persistent HPT was lower in diabetic than in non-diabetic transplanted patients (n=64 vs 53, OR=0.4, 95%CI 0.2-1, p=0.039), but not different in diabetic KTR (n=16) or KPTR (n=48).

Considering together pre and posttransplantation CVEs in diabetic KTR or KPTR, a Cox proportional regression model showed that the risk of major CVEs was significantly increased in patients with hypercalcemic (OR=11, 95%CI 1.6-64, p=0.014) and normocalcemic (OR=6, 95%CI 1.5-24, p=0.013) HPT and in patients in the lowest (OR=8.2, 95%CI 2-35, p=0.004) and the highest (OR=3.8, 95%CI 1.1-13, p=0.037) tertiles of pretransplantation serum phosphate or kidney-pancreas transplantation (OR=4.0, p=0.006). Similar findings were obtained considering tertiles of serum iPTH and calcium in the Cox regression model. CVEs were not associated with HPT in non-diabetic KTR. The risk of postransplantation major events was increased in diabetic KTR (n=9, OR=2.5, 95%CI 1-6, p=0.05), but not KPTR (n=12). It was associated with HPT (OR=8.6, 95%CI 1.4-51, p=0.018) in diabetic patients.

Conclusions: Persistent HPT increases cardiovascular risk in diabetic transplanted patients already predisposed to CVEs. The association with cardiovascular risk is proportional to the severity of parathyroid alterations in diabetic CKD patients.

Prolonged Hemodialysis and Low-Salt Diet Reduce Skin Sodium Content

Anke Dahlmann,[1] Kathrin Dörfelt,[1] Peter Linz,[2] Charles Chazot,[3] Stephan Horn,[6] Patrick Deleaval,[3] Peter Wabel,[4] Joerg H. Vienken,[4] Kai-Uwe Eckardt,[1] Friedrich C. Luft,[5] Jens Titze.[7] *[1]Nephrology and Hypertension, University Hospital Erlangen, Germany; [2]Interdisciplinary Center for Clinical Research, University Erlangen-Nuremberg, Germany; [3]NephroCare Tassin-Charcot, France; [4]FMC, Bad Homburg, Germany; [5]ECRC, MDC Berlin, Germany; [6]KfH Dialysis center, Erlangen, Germany; [7]Clinical Pharmacology, Vanderbilt University, Nashville, United States.*

Background: In Tassin, France, the dialysis center is renowned for its prolonged, slow 8 h thrice-weekly dialysis treatments and rigorous attention to diet. We have developed sodium magnetic resonance imaging (Na-MRI) to measure sodium proteoglycan skin storage. We had occasion to study dialysis patients from Tassin and to compare them with matched dialysis patients undergoing trice-weekly 4 h treatments in Erlangen, Germany.

Methods: We used ^{23}Na magnetic resonance imaging at 3Tesla (T) to quantify sodium and water content in skeletal muscle and skin of the left lower leg. Nine men and 2 women from Tassin (aged 56±13 years), were compared to 9 men and 2 women of similar age from Erlangen. Blood sample were drawn before dialysis and BCM measurements were performed before Na MRI.

Results: Tassin and Erlangen patients had similar muscle sodium contents (18.62±3.29 vs. 17.34±3.21 mmol/l), but Tassin patients had lower skin sodium values (18.13±4.49 vs. 21.76±4.76 mmol/l, $p<0.05$). Water content values were not significantly different. Changes in interdialytic weight gain (2.6±1,2 vs. 1.5±0.8 kg, $p<0,05$) were not reflected by changes in estimated total muscle sodium content or total body water.

Conclusions: We have developed a non-invasive MRI technique to reflect sodium and water content in tissues. The method allowed us to detect differences in two dialysis populations managed with divergent treatment philosophies. We suggest that this method could have utility in predicting outcomes and reflecting treatment quality of dialysis patients.

SA-PO1101

Sustained Improvement of Hemoglobin A1c Reduces Risk of End-Stage Renal Disease in Patients with Type 1 Diabetes and Proteinuria

Jan Skupien,[1] James Warram,[1] Adam Smiles,[1] Andrzej Galecki,[2] Robert C. Stanton,[1] Andrzej S. Krolewski.[1] *[1]Joslin Diabetes Center, Boston, MA, United States; [2]University of Michigan, Ann Arbor, MI.*

Background: No strong evidence exists that in patients with type 1 diabetes (T1D) and proteinuria improved glycemic control can reduce the risk of end-stage renal disease (ESRD).

Methods: 350 patients with T1D and proteinuria were followed for 5-18 years to ascertain ESRD (n=112, incidence rate 3.9/100 person-years) or death (n=25). HbA1c before study entry (5-year pre-baseline period) was compared with follow-up values (median 3.4 years after baseline), and changes were examined for effects on risk of ESRD during follow-up. We used follow-up serum creatinines to assess trajectories of estimated glomerular filtration rate (eGFR).

Results: Median HbA1c was 9.3% in pre-baseline period and decreased during follow-up to 8.8%. HbA1c was categorized into good, fair and poor (≤8, >8-≤9.5, and >9.5%, respectively). 220 patients (63%) remained in the same category (Table diagonal, bold), in 35 (10%) post-baseline HbA1c category worsened (below diagonal) and in 95 (27%) it improved (above diagonal). The incidence rate of ESRD decreased dramatically with improving HbA1c (Table; for example, with improvement from poor pre-baseline to fair post-baseline HbA1c, the incidence of ESRD dropped from 7.5 to 3.3/100 patient-years).

Incidence rates of ESRD (per 100 patient-years) according to pre- and post-baseline category of HbA1c

	Pre-baseline HbA1c		
Post-baseline HbA1c	good	fair	poor
good	1.8 (n=59)	3.0 (n=35)	0.0 (n=14)
fair	1.9 (n=12)	3.7 (n=78)	3.3 (n=46)
poor	(n=0)	5.7 (n=23)	7.5 (n=83)

In Cox regression relative hazard of ESRD per 1% post-baseline HbA1c improvement was 0.72 (95% CI: 0.61, 0.89; $p<0.001$). This effect was independent from pre-baseline HbA1c and anti-hypertensive treatment. It was not confounded by sex, age, albumin/creatinine ratio, eGFR or blood pressure. Improvement in post-baseline Hb1Ac was strongly associated with decelerating eGFR decline ($p=0.002$), while trajectories were linear if HbA1c was constant.

Conclusions: In T1D patients with proteinuria sustained improvement of glycemic control is an effective treatment that reduces long-term risk of ESRD.

SA-PO1102

Multicenter Double-Blind, Randomized, Placebo-Controlled Trial of Rituximab for the Treatment of Childhood-Onset Refractory Nephrotic Syndrome

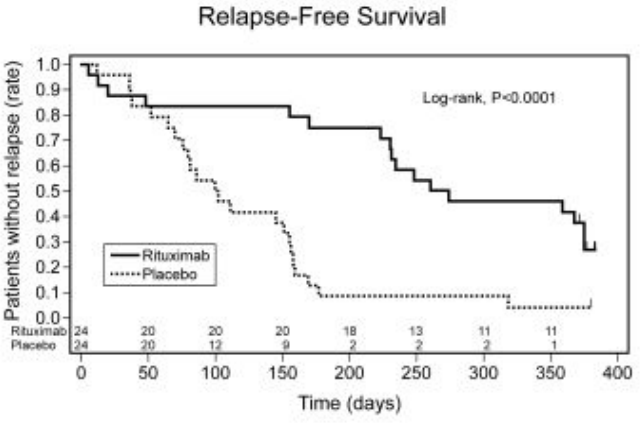
Kazumoto Iijima,[1] Mayumi Sako,[2] Nao Tsuchida,[2] Yasuo Ohashi.[3] *[1]Kobe Univ. Graduate School of Medicine, Kobe, Japan; [2]National Center for Child Health and Development, Tokyo, Japan; [3]University of Tokyo, Japan.*

Background: Some studies reported the efficacy of rituximab for the refractory frequent–relapsing nephrotic syndrome/steroid–dependent nephrotic syndrome (refractory FRNS/SDNS); however, the efficacy and the safety of the therapy have not been established.

Underline represents presenting author/disclosure.

Methods: We conducted a multicenter double-blind, randomized, placebo-controlled trial to investigate the efficacy and the safety of rituximab for refractory FRNS/SDNS. Eligible patients were over 2 years old, and diagnosed as refractory FRNS/SDNS at one to 18 years. They received standard steroid therapy at the relapse, and enrolled after confirming remission. Twenty-four patients each were randomized to rituximab group (375 mg/m^2, once a week for four weeks) and placebo group. Both group stopped immunosuppressive agents such as cyclosporine before Day 169, and followed for one year. Primary endpoint is the duration of relapse-free period. Treatment failure is defined as relapse within Day 85, frequent relapse during follow-up, or develops steroid dependence or steroid-resistant nephrotic syndrome.

Results: Relapse-free period of rituximab group was significantly longer compared to the placebo group (50% relapse-free period: 267 vs. 101; HR=0.27, 95%CI: 0.14-0.53; log-rank test, p<0.0001).



Rituximab group had significantly lower rate of treatment failure (log-rank test, p=0.0010) and relapse rate taking multiple recurrences into account (person-year method; 1.09 vs. 3.77; permutation test, p<0.0001). No difference in adverse events, including frequency and severity of infection, was observed between the groups.

Conclusions: Rituximab is effective and safe for the treatment of refractory FRNS/SDNS.

Funding: Government Support - Non-U.S.

SA-PO1103

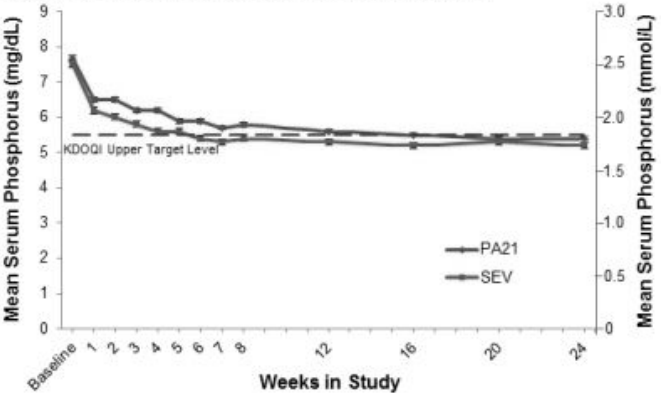
Efficacy and Safety of PA21 in Hyperphosphatemic CKD Patients on Dialysis Jürgen Floege,[1] Markus Ketteler,[2] Anjay Rastogi,[3] Adrian Covic,[4] Edward M.F. Chong,[5] Laura J. Lisk,[5] Sylvain Gaillard,[5] Stuart M. Sprague.[6] *[1]RWTH Univ Hosp Aachen; [2]Coburg Clinic and KfH-Dialysis Center; [3]Univ of California; [4]Gr.T. Popa Univ of Med and Pharm; [5]Vifor Pharma; [6]NorthShore Univ HealthSystem.*

Background: A randomized, open-label, active-controlled, two-stage, phase 3 study investigated efficacy and safety of a new, iron-based phosphate binder (PA21) in lowering and maintaining serum phosphorus (sP) levels, and non-inferiority (NI) vs sevelamer carbonate (SEV).

Methods: 1,059 patients with hyperphosphatemia were randomized 2:1 to PA21 (1.0–3.0 g/day; starting dose 1.0 g/day; n=710) or SEV (2.4–14.4 g/day; starting dose 4.8 g/day; n=349) for 24 weeks. During the first 8 weeks, doses were titrated to reach predefined sP levels (2.5–5.5 mg/dL). Doses were unchanged in weeks 8–12. NI (2° endpoint) was assessed after 12 weeks. In the subsequent maintenance phase, the aim was to maintain sP in the predefined range. Of patients receiving PA21, 99 were re-randomized after 24 weeks of treatment and entered a 3-week superiority assessment of maintenance-dose (n=50) vs low-dose (250 mg/day; n=49) PA21 (1° endpoint).

Results: 1° and 2° endpoints were met. PA21 maintenance dose was superior to low-dose PA21 in maintaining sP levels within the predefined range. NI of PA21 vs SEV was established (Fig.1), with a lower pill burden than SEV (3.1 [SD: 1.14] vs 8.1 [SD: 3.15] pills/day).

Figure 1: Effect of PA21 and SEV on sP over 24 weeks



No differences were observed between PA21 (83%) and SEV (76%) in the frequency of treatment-emergent adverse events (TEAEs) and serious TEAEs. Incidence of gastrointestinal TEAEs was higher with PA21 vs SEV (45% vs 34%), mainly due to discolored feces (15.4% vs 0.3%) and diarrhea (20.1% vs 7.5%). Diarrhea was mostly mild, occurred in the first week of PA21 treatment and abated with continued dosing.

Conclusions: PA21 is efficacious and well tolerated, with a lower pill burden vs SEV.

SA-PO1104

Use of Everolimus as Rescue Therapy in Kidney Transplant Recipients Anil Bhalla,[1] Anshul Bhalla.[2] *[1]Institute of Renal Sciences, Sir Ganga Ram Hospital, New Delhi, Delhi, India; [2]Department of Critical Care Medicine, Sir Ganga Ram Hospital, New Delhi, Delhi, India.*

Background: With the availability of newer immunosuppressive agents, there are various innovative strategies that reduce exposure to Calcineurin Inhibitors(CNI) to help preserve long term renal functions. Chronic Allograft Nephropathy(CAN) is also a major cause of progressive renal failure in kidney transplant recipients. Most of the time patient presents with creeping creatinine. As a rescue therapy, conversion from CNI to Tac based regimen has been tried. Recently, interest has generated over Everolimus as a Proliferative Signal Inhibitor(PSI) and as a rescue therapy to prevent further rejection and avoid nephrotoxicity. The objective of this study is to evaluate the effect of reduction of CNI doses in kidney transplant patients with CAN and at the onset of acute rejection.

Methods: 490 kidney transplants were performed in the last two years. All were on triple drug immunosuppresion. In 30 patients with creeping creatinine and those who developed acute rejection, therapy was changed to an Everolimus based regime. Biopsy proven acute rejection was treated with IV Solumedrol for 3 days. Cyclosporine(CsA) or Tacrolimus doses were reduced by 50-80% in 24 patients(Group 1) and discontinued in 6 patients(Group 2). Mycophenolate or Azathiprine were withdrawn in 5 patients in group 1. All patients received prednisolone.

Results: 30 renal allograft recipients were switched to Everolimus based regimen and were followed up for a mean period of 12 months (range 1-24 months). Mean(SD) baseline serum creatinine was 2.6 mg/dl(0.4) and mean serum creatinine at the end of study was 1.8 mg/dl(0.3) (p value<0.01). Graft biopsy showed 23 patients with CAN. 7 patients had acute rejection(Banff grade 2A and 2B). Patient and graft survival was 100%. Mean trough level of Everolimus was 5.2 +- 1.5 ng/ml.

Conclusions: Use of Everolimus as rescue therapy for CAN and after onset, of acute rejection and synchronised with reduction of CNI doses or discontinuance was associated with good patient and graft survival in kidney transplant recipients. This intervention can lead to 80% reduction in CsA and Tac dosage and thus, preservation of GFR.

Extended Treatment with RP103 (Procysbi) in Patients with Nephropathic Cystinosis Craig B. Langman,[1] Laurence A. Greenbaum,[3] Georges Deschenes,[4] Heather E. Price,[1] Patrice Rioux.[2] *[1]Kidney Diseases, Lurie Childrens Hosp of Chicago, Chicago, IL; [2]Raptor Pharmaceuticals, Novato, CA; [3]Peds Kidney, Emory Univ, Atlanta, GA; [4]Kidney, Hopital Robert Debre, Paris, France.*

Background: Cystinosis is a ultra-orphan disease for which Rx with Cystagon® is effective but difficult to use long-term. RP103 (Procysbi) is used q12h, & offers better long-term adherence strategy.

Methods: After we showed short term non-inferiority for optimal control of WBC [cystine] < 1 nmol ½ cystine/mg protein with RP103 vs Cystagon® in a randominzed X-over study of 41 patients (CJASN, 2012), we enrolled 40 of these patients in a prospective, ongoing study with RP103 of up to 20mos (m) to determine control of WBC[cystine], its relationship to plasma[cysteamine], eGFR, quality of Life (QOL), and use of antacids.

Results: At study onset on RP103, WBC[cystine]=0.58±0.70 (mean±SD) and remained at this optimal level for up to 19m in all. The dose of RP103 at study onset = 83% of total daily (TD) Cystagon® dose. TD dose for 13(33.3%) subjects has been unchanged; ↑ for 15(38.4%); ↓ for 11(28.2%). We modeled the relation for plasma[cysteamine] and WBC[cystine] using an inhibitory E_{max} PD model, and found that, 0.5h after RP103 dose,91.0 % of WBC[cystine] with blood [cysteamine] > 0.1 mg/L was ≤1;94.8% had WBC[cystine] ≤1 when [cysteamine] was >0.2 mg/L . For 16 patients with >12m follow-up, eGFR at

Underline represents presenting author/disclosure.

study onset = 65±28 ml/min/1.73m^2 and 15m later was unchanged, 61±21, p=NS. From the study onset, the PedsQL4.0 scores improved in all patients, p<10^{-3}, especially in social performance, p<10^{-3}. 9/40 patients began this study on PPI+H2 blockers, and 31/40 did not use them during the entire study. WBC[cystine] on these 9 did not differ for up to 20m from the non-users, & RP103 dose ↓ in 5/9; ↑ in only 1/9.

Conclusions: Optimal WBC[cystine] can be achieved safely and effectively long-term in patients with nephropathic cystinosis using twice daily RP103, with preservation of eGFR and improved QOL. Plasma [cysteamine] post-dose provides an index for optimal WBC[cystine] and represents a new way to monitor patients. RP103, unlike Cystagon®, does not require use of concomitant antacid medications in most.

SA-PO1106

EPPIC (Evaluating Prevention of Progression In Chronic Kidney Disease): Results from 2 Phase III, Randomized, Placebo-Controlled, Double-Blind Trials of AST-120 in Adults with CKD Gerald Schulman,[1] Tomas Berl,[2] Gerald J. Beck,[3] Giuseppe Remuzzi,[4] Eberhard Ritz.[5] *[1]Vanderbilt Univ., Nashville, TN, United States; [2]Univ. of Colorado, Denver, CO, United States; [3]Cleveland Clinic, Cleveland, OH, United States; [4]Mario Negri Institute, Bergamo, Italy; [5]Univ. of Heidelberg, Heidelberg, Germany.*

Background: To evaluate the efficacy of AST-120, spherical carbon adsorbent, when administered orally with standard therapy for slowing CKD progression.

Methods: The 2 similar EPPIC trials enrolled pts with CKD III-V (mean eGFR 21-22 mL/min). The primary (1°) endpoint (endpt) was time to initiation of dialysis, transplant, or 2x baseline sCr. The secondary (2°) endpt was the 1° endpt + death. Pooled placebo data were used to identify baseline factors associated with fast CKD progression based on median eGFR decline (-0.292 mL/min/month). Fast progressors exhibited UP:UCr≥1.0 and hematuria+ at baseline.

Results: 2035 pts were randomized in the 2 trials. AST-120 did not show a benefit (Table) in pts with or without use of ACEs/ARBs. The post-hoc subgroup with baseline UP:UCr≥1.0, hematuria+, and AST-120 compliance≥80% had a reduction in CKD progression with AST-120.

	AST-120		Placebo		AST-120 vs Placebo	
	N	n (%)	N	n (%)	HR (95% CI)	P value
EPPIC-1						
1° endpt	500	178 (35.6)	502	177 (35.3)	1.03 (0.84-1.27)	0.777
2° endpt	500	213 (42.6)	502	201 (40.0)	1.08 (0.89-1.31)	0.418
EPPIC-2						
1° endpt	500	172 (34.4)	497	183 (36.8)	0.91 (0.74-1.12)	0.371
2° endpt	500	204 (40.8)	497	217 (43.7)	0.90 (0.74-1.09)	0.281
Pooled Analysis						
1° endpt	1000	350 (35.0)	999	360 (36.0)	0.97 (0.83-1.12)	0.639
2° endpt	1000	417 (41.7)	999	418 (41.8)	0.99 (0.86-1.13)	0.860
Pooled Analysis – UP:UCr≥1.0/hematuria+/compliance≥80%						
1° endpt	239	101 (42.3)	223	116 (52.0)	0.74 (0.56-0.98)	0.035

Conclusions: Results from the 2 EPPIC trials do not support the efficacy of AST-120 for slowing CKD progression; however, the variables used to enrich the population with pts likely to progress did not result in the expected degree of progression in this population. A subgroup analysis indicated a trend that AST-120 may reduce CKD progression in compliant pts with factors associated with fast progressing CKD. Further trials are needed to ascertain whether AST-120 is of benefit in fast progressing CKD pts.

SA-PO1107

Urine Exosome mRNA as Biomarkers of Diabetic Nephropathy Natalie Sweiss,[1] Masato Mitsuhashi,[2] Loki Natarajan,[3] Kumar Sharma.[1] *[1]Center for Renal Translational Medicine, University of California, San Diego, San Diego, CA; [2]Hitachi Chemical Research Center, Inc, Irvine, CA; [3]Division of Biostatistics & Bioinformatics, University of California, San Diego, San Diego, CA.*

Background: Current tests to assess diabetic kidney disease are limited to evaluation of the degree of kidney dysfunction and are not specific to the disease state. In order to develop a non-invasive diagnostic system to evaluate diabetic kidney disease, urine exosome mRNA was analyzed in patients with diabetic kidney disease and healthy controls.

Methods: Urine samples were obtained from healthy donors (CTL) (n=23) and patients with diabetic nephropathy (DM) (n=23) at the University of California, San Diego Medical Center. Each urine sample was centrifuged at 1,000 x*g* for 15 min, and 10 mL supernatant was applied to 96-well exosome-capture filterplate (Hitachi Chemical Research Center (HCR)). The captured exosome was lysed on the filterplate, and the resultant lysates were transferred to oligo(dT)-immobilized microplate (HCR) for mRNA purification, followed by cDNA synthesis and real time SYBR green PCR. A total of 21 candidate mRNAs were quantified.

Results: Using the Benjamini Hochberg method to control for the false discovery rate, a 2-sample (unequal variance) t-test revealed statistically significant differences between DM and CTL in mean values of PGC1alpha (*P*=0.002), Uromodulin (*P*=0.002), and SMAD1 (*P*=0.002). Patients with DM and CKD Stage 3 (eGFR 30-59 ml/min) compared to controls also had a statistically significant difference in cycle threshold of PGC1alpha (*P*=0.004), Uromodulin (*P*=0.001), and SMAD1 (*P*=0.005).

Conclusions: These results indicate that mRNA is preserved in the encapsulated urine exosomes from normal and diabetic individuals. Use of urine exosomal mRNA gene expression using this method may provide new insight into kidney tissue gene expression. Urine exosomal mRNA levels of PGC1 alpha, Uromodulin and SMAD1 are significantly different in patients with diabetic kidney disease vs healthy controls. Using this technology, these three biomarkers may aid in diagnosis of diabetic nephropathy.

TLR9 Gene Polymorphism (rs187084, rs352140): Association with Acute Rejection and Estimated Glomerular Filtration Rate in Renal Transplant Recipients Tae hee Kim,[1] Ho seok Koo,[2] Sunwoo Kang,[1] Yang Wook Kim.[1] *[1]Internal medicine, Inje University, Busan, Republic of Korea; [2]Internal Medicine, Inje University, Seoul, Republic of Korea.*

Background: The Toll-like receptors (TLRs) are related to innate immunity. *TLR9*, a member of TLRs, is expressed in immune cell rich tissues and mediates cellular response. We investigated the association between *TLR9* polymorphisms and kidney allograft outcomes.

Methods: To investigate whether *TLR9* polymorphisms are associated with acute rejection after renal transplantation, two single nucleotide polymorphisms (SNPs) of *TLR9* gene (rs187084, -1486; rs352140, G2848A) were selected and genotyped by direct sequencing in 342 renal transplant recipients. SNPStats, SNPAnalyzer, Helixtree, and Haploview version 4.2 were used to analyze genetic data. Multiple logistic regression models (codominant, dominant, recessive, and log-additive) were used to evaluate odds ratios (ORs), 95% confidence intervals (CIs), and p values.

Results: Both SNPs, *TLR9* rs187084 -1486 and rs352140 G2848A, of recipients were associated with the risk of acute rejection in renal transplantation. C allele of rs187084 -1486 and A allele of rs352140 G2848A were protective genotype for acute rejection (OR 0.6, 95% CI 0.40-0.92; P=0.018, OR 0.64, 95% CI 0.42-0.98; P=0.04, respectively). rs187084 -1486 CT and rs352140 G2848A GA genotype were associated with a lower eGFR after a year of renal transplantation.

Conclusions: *TLR9* polymorphisms, rs187084 and rs352140, of recipients were associated with the risk of acute rejection in renal transplantation. The patients with rs187084 -1486 CT and rs352140 G2848A GA genotype showed a lower eGFR after a year of renal transplantation.

Long-Term Outcomes for Vitamin D Treatment on Patients with Chronic Kidney Disease Hector Tamez. *Massachusetts General Hospital. On Behalf of the PRIMO Steering Committee, Boston, MA.*

Background: Paricalcitol did not reduce left ventricular mass in the PRIMO randomized trial (NCT00497146), but it decreased cardiovascular (CV) hospitalizations, left atrial volume and attenuated the rise of brain natriuretic peptide compared to placebo in patients with chronic kidney disease (CKD).

Methods: Patients who completed study were offered to enroll in an 18-month follow up study. Laboratory values are summarized in medians (interquartile range [IQR]) and compared with Wilcoxon Rank Sum test. Frequency data was compared using χ^2-tests.

Results: 64/88 patients in the paricalcitol group and 66/91 in the placebo group enrolled in the follow up study. At baseline patients in the paricalcitol group had lower diastolic blood pressure (74±9 mmHg vs. 78±10 mmHg; P=0.03), parathyroid hormone ([PTH]; 27 pg/mL [IQR: 10, 70 pg/mL] vs. 92 pg/mL [IQR: 65, 149 pg/mL]; P<0.001), estimated glomerular filtration rate (26 mL/min [IQR: 18, 37 mL/min] vs. 34 mL/min [IQR: 23, 46 mL/min]; P=0.01) and higher calcium (9.8 mg/dL [IQR: 9.3, 10.2 mg/dL] vs. 9.2 mg/dL [IQR: 9, 9.6 mg/dL]; P<0.0001) compared to placebo. At the end of the follow up period PTH increased (paricalcitol 95 pg/mL [IQR: 62, 127 pg/mL]; placebo 23 pg/mL [IQR: -5, 52 pg/mL]; P=0.01). Similarly, calcium decreased in paricalcitol compared to placebo (-0.38 mg/dL [IQR: -0.54, -0.22 mg/dL] vs. -0.13 mg/dL [IQR: -0.26, 0.01]; P=0.01) as well as eGFR (-0.1 mL/min [IQR: -1.9, 1.7 mL/min] vs. -3.3 mL/min[IQR: -4.9, -1.8 mL/min]; P=0.002). The percentage of patients with all-cause hospitalizations was similar between groups (27.7% in paricalcitol vs. 15.3% in placebo; P=0.08) with similar findings for CV hospitalizations (1.5% in paricalcitol vs. 4.2% in placebo; P=0.36). Similarly, 1.5% of patients in the paricalcitol group and 2.8% of patients in the placebo group were hospitalized for renal failure or dialysis initiation (P=0.62). One patient died in the paricalcitol group compared to 3 in the placebo group (P=0.36).

Conclusions: All-cause, CV and renal failure hospitalizations did not differ after 18 months in patients with CKD who had received either paricalcitol or placebo for 48 weeks as part of the PRIMO randomized trial.

Patiromer Safely and Predictably Lowers Serum Potassium in Subjects with Chronic Kidney Disease and Type 2 Diabetes: Results of the AMETHYST-DN Study

George L. Bakris,[1] Bertram Pitt,[2] Jamie Cope,[3] Yuri Stasiv,[3] Patricia A Feeney,[4] Alicia Y Toledano,[4] Lance Berman.[3] *[1]University of Chicago, Chicago, IL; [2]University of Michigan, Ann Arbor, MI; [3]Relypsa, Inc., Santa Clara, CA; [4]Statistics Collaborative, Inc., Washington, DC.*

Background: Patients with advanced CKD are at high risk of hyperkalemia (HK), especially when guideline-recommended renin angiotensin system inhibitors (RASi) are used. HK limits appropriate dosing of RASi, thus attenuating cardio-renal protective benefits. In the PEARL-HF study, patiromer, a non-absorbed potassium-binding polymer, prevented HK after 4 weeks of increased spironolactone dosing in a placebo-controlled heart failure trial.

Methods: AMETHYST-DN tests the ability of patiromer to reduce potassium (K) in HK subjects (K>5.0 mEq/L). Due to the inherent risks of HK and treatment daily for up to 1 year in the long-term maintenance phase, an active polymer control or placebo was unethical. The study enrolled 306 CKD subjects with T2DM into two K strata (S1 and S2). Mean eGFR was 42ml/min/m^2, 49% of subjects had ACR>300 mg/g and 34% had heart failure.

Results: The primary outcome, mean change from baseline in serum K (mEq/L) at week 4 or first patiromer dose titration analyzed using a parallel lines ANCOVA model, was -0.47±0.038 (p<0.001) in S1 and -0.90±0.076 (p<0.001) in S2. Mean K reduction after a median 2 days of treatment was -0.29±0.03 (S1) and -0.55±0.05 mEq/L (S2). Table 1 summarizes the means and changes from baseline, allowing titration. No treatment-related SAEs occurred and a low incidence of hypokalemia was observed (2% during the 8 weeks).

	Stratum 1 ([S1], BL K >5.0-5.5 mEq/L)			Stratum 2 ([S2], BL K >5.5-<6.0 mEq/L)		
	Baseline (n=217)	Week 4 (n=197)	Week 8 (n=185)	Baseline (N=84)	Week 4 (n=70)	Week 8 (n=70)
Mean K (SE) (mEq/L)	5.15 (0.02)	4.54 (0.03)	4.59 (0.03)	5.64 (0.04)	4.65 (0.06)	4.52 (0.06)
LS Mean change (SE) (mEq/L)	-	-0.61 (0.03)	-0.55 (0.03)	-	-0.97 (0.06)	-1.10 (0.06)

BL=Baseline; K=serum potassium; SE=Standard Error; LS=Least Squares Pub #: SA-PO1112 Edit_id:

Conclusions: Patiromer reduced serum K within days of treatment initiation, an effect sustained over two months without significant adverse effects, including hypokalemia.

Sevelamer is Cost-Effective Versus Calcium Carbonate for the Treatment of Hyperphosphatemia in Chronic Kidney Disease Patients Not on Dialysis in the UK

Melissa Thompson,[1] Susan Bartko-Winters,[1] Andrew Mackay Fenton,[2] Biagio Raffaele Di Iorio.[3] *[1]Cornerstone Research Group Inc., Burlington, ON, Canada; [2]Genzyme Therapeutics, Oxford, United Kingdom; [3]Department of Nephrology, Ospedale A. Landolfi di Solofra, Solofra, Avellino, Italy.*

Background: The randomized, controlled INDEPENDENT study (Di Iorio et al., 2012) is the first study to show that sevelamer (SV) significantly increases overall survival (OS) (p<0.01) versus calcium carbonate (CC) in CKD patients not on dialysis (CKD-ND). The objective of this study was to conduct a cost-effectiveness analysis (CEA) of SV versus CC from the perspective of the NHS in the UK.

Methods: A Markov model was developed to estimate life years (LYs), incremental cost/LY gained and incremental cost/quality-adjusted LY (QALY) gained. Health states were 'Alive without Dialysis', 'Alive with Dialysis', and 'Dead' and transitions between health states were captured as survival curves. Three-year treatment-specific OS and time to dialysis curves from the INDEPENDENT study were extrapolated to lifetime using Weibull regression analysis. Phosphate binder doses were also from the INDEPENDENT study. Health utilities and unit costs were derived from the literature. Costs (in £2011) and outcomes were discounted at 3.5%. A probabilistic sensitivity analysis (PSA) was performed to characterize the uncertainty around the cost-effectiveness of SV given the variability around all key input variables.

Results: Over a lifetime horizon, treatment with SV resulted in incremental LYs (2.0493), QALYs (1.5613), and costs (£37,282) per patient versus CC.Incremental cost/QALY gained was £23,878; incremental cost/LY gained was £18,193. Results were most sensitive to daily dose of SV, utility, and cost of dialysis; results were not sensitive to a 20% increase/decrease in the cost of SV. At a willingness-to-pay threshold of £30,000/QALY gained, the PSA revealed that SV was cost-effective compared with CC in ~93% of simulations.

Conclusions: SV represents a cost-effective alternative to CC for the treatment of hyperphosphatemia in CKD-ND patients in the UK.

SA-PO1112

Relationship between Baseline Serum Uric Acid Levels and CKD Progression in Patients Attending Tertiary Care Centers in Italy

Elena Sestigiani,[1] Dario Tedesco,[2] Leopoldo Baldrati,[3] Marcora Mandreoli,[1] Fabio Olmeda,[4] Paola Rucci,[2] Antonio Santoro.[1] *[1]Nephrology, Dialysis, Hypertension Unit, Policlinico S.Orsola-Malpighi, Bologna, Italy; [2]Dept of Medicine and Public Health, University of Bologna, Bologna, Italy; [3]Nephrology and Dialysis Unit, Ospedale M. Bufalini, Cesena, Italy; [4]Nephrology and Dialysis Unit, Ospedale Policlinico, Modena, Italy.*

Background: Evidence from the literature suggests that levels of serum uric acid (SUA) are associated with cardiovascular events and Chronic Kidney Disease (CKD). This study aims to analyze the relationship between baseline levels of SUA and progression of CKD in a population of 2,222 outpatients followed in Prevention of Progressive Renal Insufficiency program (PIRP). Data are drawm from PIRP registry. CKD progression was defined as all-cause mortality+dialysis, dialysis alone, estimated annual decrease in GFR.

Methods: The mean age was 71.3±12.8 years, 65.1% males and 34.9% females, with a mean SUA of 6.46±1.79 mg/dl and 6.27±1.79 mg/dl respectively. Baseline GFR was 29.1±12.4 ml/min per 1.73 m^2. The percentage of patients in CKD stages were: 2 (2%), 3A (7.2%), 3B (32.2%), 4 (49.4%), 5 (9.2%). Linear and logistic regression models were carried out to examine the relationship between baseline SUA levels and each of the three outcomes. All the analyses were adjusted for sex, age and baseline serum creatinine levels.

Results: All-cause mortality+dialysis and dialysis alone were unrelated to baseline SUA levels in logistic regression models after adjusting for covariates. On the contrary, the estimated annual decrease in GFR was significantly associated (p=0.021) with SUA levels. Specifically, the decrease in GFR was 0.123 ml/min per 1.73 m^2 for a 1 mg/dl increase in baseline SUA after adjusting for covariates.

Table1. SUA levels and annual progression in CKD

	b	SE (b)	beta	t	P
Age (yrs)	0.054	0.07	0.153	7.311	< 0.001
Gender (M vs F)	-0.642	0.201	-0.068	-3.198	0.001
S-Creatinine (mg/dl)	0.292	0.104	0.159	2.819	0.005
S-Uric acid (mg/dl)	0.123	0.053	0.048	2.313	0.021
costant	-6.478	0.680		-9.519	< 0.001

Conclusions: In conclusion, this study suggests that SUA levels are associated with the estimated annual decrease in GFR but not with the renal failure and mortality.

SA-PO1113

Minor Elevations of Postoperative Serum Creatinine Are Independently Associated with Higher Mortality and Longer Hospital Length of Stay in Patients Undergoing Non-Cardiac Surgery

Felix Kork,[1] Felix Balzer,[1] Claudia Spies,[1] Almut Grenz,[2] Holger Eltzschig.[2] *[1]Anesthesiology and Intensive Care Medicine, Charité - University Medicine Berlin, Campus Virchow Klinikum and Campus Charité Mitte, Berlin, Germany; [2]Anesthesiology, University of Colorado Denver, Anschutz Medical Campus, Denver, CO.*

Background: Acute kidney injury (AKI) is a serious complication in hospitalized patients with impact on morbidity and mortality. Here, we hypothesized that already minor elevations of serum creatinine (Scr) levels have profound consequences on postoperative outcomes in patients undergoing non-cardiac surgery.

Methods: The local ethics committee of the Charité – University Medicine Berlin approved the study (EA1/303/11) and waived the requirement of informed consent; the study has been registered at ClinicalTrials.org (NCT01522313). In this retrospective analysis, all patients undergoing non-cardiac surgery at a single tertiary care center between 2006 and 2012 were included. Perioperative renal function was evaluated by Scr level.

Results: The data of 27,616 patients were analyzed. After multivariate adjustment for age, comorbidities, renal function, high-risk surgery, and postoperative ICU admission, we found that already minor changes in Scr (0.25–0.50mg/dl) were independently associated with a prolonged HLOS (hazard ratio for early discharge 0.79 [95%CI 0.71 – 0.88], p<0.01). Furthermore, this increase of serum creatinine was associated with a 2-fold increase in the risk of death during the postoperative hospital stay (odds ratio for all-cause in-hospital death OR 2.17 [95CI% 1.36 – 3.47], p<0.01). Increases in postoperative Scr greater than 0.50mg/dl were independently associated with longer HLOS and higher mortality.

Conclusions: This study demonstrates for the first time, that even minor elevations of Scr in patients undergoing non-cardiac surgery are independently associated with dramatic increases of severe adverse outcomes. These findings implicate that therapeutic approaches to prevent mild postoperative AKI would have a major impact on overall outcomes in surgical patients.

Underline represents presenting author/disclosure.

SA-PO1114

Randomized Trial of Short Prehydration with Sodium Bicarbonate Versus Pre- and Posthydration with Sodium Chloride To Prevent Contrast Induced Acute Kidney Injury: The Salina Trial

Judith Kooiman,[1] Yvo W.J. Sijpkens,[2] Harald Brulez,[3] Jean-Paul P.M. De Vries,[4] Jaap Hamming,[1] Aart J. Van der Molen,[1] Nicolas J.M. Aarts,[2] Suzanne Cannegieter,[1] Renata Swarts,[1] Wilbert Van den Hout,[1] Ton J. Rabelink,[1] Menno V. Huisman.[1] *[1]Leiden University Medical Center, Netherlands; [2]Bronovo Hospital, Netherlands; [3]St. Lucas Andreas Hospital; [4]St. Antonius Hospital.*

Background: Yearly, millions of patients with renal failure worldwide receive intravascular contrast media, requiring hospitalization for hydration.

Aim: To analyze whether 1 hour (hr) prehydration with 250ml 1.4% sodium bicarbonate (Na-bic) is non-inferior to 4-12 hrs pre- and posthydration with 1000ml 0.9% sodium chloride (NaCl) in preventing contrast induced acute kidney injury (CI-AKI) in patients with a GFR<60ml/min undergoing intravenous contrast-enhanced CT.

Methods: From 2010-2012, 571 patients were randomized. Primary outcome was the relative increase in serum creatinine 48-96 hrs post CT. Secondary outcomes were the incidence of CI-AKI (serum creatinine increase>25%/>0.5mg/dl), recovery of renal function in CI-AKI patients, the need for dialysis, and 2-month hospital costs. Na-bic was considered non-inferior if the mean relative serum creatinine increase was at most 15% higher compared with NaCl.

Results: Patient characteristics were comparable in both groups (mean GFR 45ml/min, range 14-59). Mean relative increase in serum creatinine for Na-bic was 1.2%(SD13.2) and 1.5%(SD14.1) for NaCl (mean difference -0.33%; 95%CI-2.7-2.0). CI-AKI occurred in 22 patients (4.1%); 8 (3%) were treated with Na-bic, 14 (5.1%) with NaCl (P=0.23). Renal function recovered after 2 months in 75% and 70% of CI-AKI patients, respectively (p=0.81). No patient developed a need for dialysis. Mean hydration costs per patient were €224 ($266) for Na-bic and €683 ($811) for NaCl (p<0.001). Other costs were comparable.

Conclusions: Prehydration with Na-bic was non-inferior to pre- and posthydration with NaCl. Incidences of CI-AKI were similar in both groups. Thus, 1 hr Na-bic prehydration can be safely used, and may lead to substantial reductions in healthcare costs. This study is important for efficiently protecting patients from CI-AKI.

Effects of Aleglitazar on Renal Function in Patients with Stage 3 Chronic Kidney Disease and Type 2 Diabetes

Luis M. Ruilope,[1] Markolf Hanefeld,[2] A. Michael Lincoff,[3] G. Viberti,[4] Sylvie C. Meyer Reigner,[5] Dietmar Volz,[5] Dominika Anna Wieczorek Kirk,[5] Klas A. Malmberg,[6] Matthias Herz.[5] *[1]Hospital 12 de Octubre, Madrid, Spain; [2]Center for Clinical Studies, Technical University, Dresden, Germany; [3]Cleveland Clinic, OH; [4]King's College London, United Kingdom; [5]F. Hoffmann-La Roche, Basel, Switzerland; [6]Karolinska Institute, Stockholm, Sweden.*

Background: Aleglitazar (ALE) is a balanced PPAR-α/γ agonist in Phase 3 for CV risk reduction in patients following an acute coronary syndrome who have T2D. This phase 2b study (AleNephro) evaluated renal effects of ALE in stage 3 CKD patients with T2D.

Methods: Patients with stage 3 CKD and T2D were randomized to 52 weeks double-blind treatment with ALE 150µg/d or pioglitazone (PIO) 45mg/d, followed by an 8 week off-treatment period. The primary endpoint was non-inferiority for the difference between ALE and PIO in % change in eGFR from baseline (BL) to end of follow-up (EOF; 8 weeks after end of treatment [EOT]). A pre-specified exploratory analysis evaluated change in UACR in a subgroup with BL macroalbuminuria.

Results: The trial included 302 patients (ALE n=150; PIO n=152) with mean eGFR 47 mL/min/1.73m^2 and 81% on ACEi/ARB at BL. Mean eGFR change at EOT with ALE was –15% (95% CI: –19, –11) vs –5.4% (95% CI: –9.6, –1.2) with PIO and was non-progressive for both. Mean eGFR change from BL to EOF was –2.7% (95% CI: –7.7, 2.7) with ALE vs –3.5% (95% CI: –8.5, 1.8) with PIO, establishing non-inferiority (0.77%; 95% CI: –4.5, 6.0). In patients (N=48) with BL macroalbuminuria (>90% on ACEi/ARB), change in UACR at EOT was –59% (95% CI:–76, –29) with ALE and -51% with PIO (95% CI: –70, –20). The change in UACR at EOF was –54% (95% CI: –74, –20) with ALE and –33% (95%CI: –59, 9) with PIO. No major safety concerns or new toxicities were identified.

Conclusions: The primary endpoint in AleNephro was met, indicating that in stage 3 CKD patients with T2D, the eGFR decrease after 52 weeks treatment with ALE plus 8 weeks off-treatment was comparable (non-inferior) to PIO, implying reversibility. Mean on-treatment decrease in eGFR was mild, not progressive and accompanied by significant UACR reduction in patients with BL macroalbuminuria.

Prevention of Contrast Induced Acute Kidney Injury – A Systemic Review and Network Meta-Analysis

Tao-Min Huang,[1,2,3] Guang-Huar Young.[4] *[1]Department of Internal Medicine, National Taiwan University Hospital Yun-Lin Branch, Dou-Liou, Taiwan; [2]Institute of Epidemiology and Preventive Medicine, Taipei, Taiwan; [3]Department of Internal Medicine, National Taiwan University Hospital and College of Medicine, Taipei, Taiwan; [4]Department of Surgery, National Taiwan University Hospital and College of Medicine, Taipei, Taiwan.*

Background: Contrast induced acute kidney injury (CI-AKI) is among the most severe adverse outcome in patients undergoing coronary angiography. Treatments have been proposed to prevent this potential devastating complication, but relative preventive efficacy was not clear. Therefore, we conducted a systemic review and meta-analysis to assess the current evidence of treatments to prevent renal injury, including N-acetylcysteine, statins, isotonic sodium bicarbonate, ascorbic acid, fenoldopam, and theophylline.

Methods: We performed traditional meta-analyses for head-to-head comparisons with placebos. Furthermore, a network meta-analysis was performed by applying Bayesian mixed treatment comparisons to estimate the odds ratio (OR) and 95% credible intervals (CrI) for the relative effects.

Results: We identified a total of 90 RCTs including 90 with 15676 participants, of which 5684 (36%) developed CI-AKI. Traditional meta-analyses reported that N-acetylcysteine (OR = 0.69, 95% confidence interval [CI] = 0.53 – 0.82), statins (OR = 0.43, 95% CI = 0.19 – 0.98), and Sodium bicarbonate (OR = 0.46, 95% CI = 0.28 - 0.75) were significantly protective; while ascorbic acid (OR = 0.59, 95% CI = 0.28 - 1.23), fenoldopam (OR = 1.01, 95% CI = 0.60 - 1.70), and theophylline (OR = 0.58, 95% CI = 0.23 - 1.47) did not prove their efficacies over placebo. Network meta-analysis identified sodium bicarbonate to be the most effective one to prevent CI-AKI (OR = 0.39, 95% CrI = 0.07 - 6.29). Both high dose (OR = 0.52, 95% CrI = 0.28 - 0.86) and low dose (OR = 0.63, 95% CrI = 0.45 - 0.84) were protective. No specific adverse events were noted.

Conclusions: Our findings suggested the use of Sodium bicarbonate to prevent CI-AKI. in patients undergoing coronary angiography. N-acetylcysteine is protective in this setting and higher dose (more than 1000mg/dose) seems protective for developing CI-AKI.

Sevelamer Dominates Calcium Carbonate in a Patient-Level Cost-Effectiveness Analysis of the Randomized, Open-Label INDEPENDENT-HD Study

Matteo Ruggeri,[1] Biagio Raffaele Di Iorio,[2] Antonio Bellasi,[3] Domenico Russo.[4] *[1]Faculty of Economics, Università Cattolica del Sacro Cuore, Roma, Italy; [2]Department of Nephrology, Ospedale A. Landolfi di Solofra, Solofra, Avellino, Italy; [3]Department of Nephrology, Ospedale Sant'Orsola-Malpighi, Bologna, Italy; [4]Department of Nephrology, School of Medicine, Federico II University, Napoli, Italy.*

Background: In the randomized, open-label INDEPENDENT-HD study sevelamer (SV) significantly increased overall survival (OS) (p<0.001) versus calcium salts (CS) in incident dialysis patients. A patient-level cost-effectiveness analysis (CEA) was conducted to determine if improved OS with SV translates into good value for money from an NHS perspective.

Methods: The CEA used OS and concomitant medication use data from 199 (SV) and 198 (CS) completer patients of the INDEPENDENT-HD study. Hospitalizations and length of stay (LOS) were collected retrospectively from medical charts. A clinician (BDI) estimated the frequency of use and dosage of concomitant medications. DRG tariffs and hospital acquisition costs informed hospitalization and drug costs, respectively. CEA outcomes were reported as incremental cost/life year gained (LYG) over 36 months. A probabilistic sensitivity analysis (PSA) was performed by bootstrapping.

Results: SV patients lived 4.75 months (95% CI 3.27–6.23) longer on average than CS patients. SV patients also had 76% fewer hospital admissions and shorter LOS (-0.06 d, p>0.05) than CS patients, resulting in reduced total hospitalization costs (-€455,704 vs. CS). Considering drug acquisition and concomitant medication costs, both higher for SV, SV patients had higher total average costs (€35,280) vs. CS patients (€29,235), resulting in an incremental cost/LYG of €15,272 (without dialysis costs) and €44,078 (with dialysis costs). The PSA revealed that 1) SV provides more life years in 99.4% of simulations, 2) SV dominates CS (i.e., more effective and less costly) in 17% of simulations, and 3) SV is cost effective in >90% of remaining simulations at the €50,000 willingness-to-pay threshold.

Conclusions: SV is cost effective versus CS for the treatment of hyperphosphatemia in incident dialysis patients.

Clinical Characterization of Medullary Cystic Kidney Disease Type 1 (MCKD1) Families with *MUC-1* Gene Mutations Anthony J. Bleyer,[1] Corinne Antignac,[2] Steven J. Scheinman,[3] Stephen J. Knohl,[4] Gerald A. Hladik,[5] Philip J. Klemmer,[5] Stanislav Kmoch.[6] *[1]Wake Forest Medical School, NC; [2]Hopital Necker Enfants Malades, Paris, France; [3]Commonwealth Medical College, Scranton, PA; [4]State University of NY Upstate, Syracuse, NY; [5]Univ North Carolina, NC; [6]First Faculty of Medicine, Charles University, Praga, Czech Republic.*

Background: The very recent identification of mutations in the MUC1 gene as a cause of medullary cystic kidney disease type 1 (MCKD1) allowed us to perform the first clinical characterization of affected individuals and families and perform immunostaining of kidney biopsy material.

Methods: MCKD1 was found to result from a heterozygous mutation resulting in an extra cytosine within a run of seven cytosines in the variable number tandem repeat (VNTR) sequence of the mucin 1 (MUC1) gene in 6 families. Mutational analysis and clinical characterization was carried out in an additional 21 families without UMOD mutations.

Results: 13 of the 21 additional families had the MUC1 mutation. The Figure shows the latest estimated GFR for 114 affected individuals. Marked heterogeneity in GFR decline was seen within and between families, with age of ESRD ranging from 23 to over 70. While MUC1 is expressed in many tissues, there was no evidence of organ pathology in any other tissues besides the kidney. Immunostaining with antibodies to the mutant MUC1 protein revealed intracellular accumulation in affected individuals. The presence of medullary cysts on renal ultrasound was uncommon. While gout is common in kidney disease from UMOD mutations, there was not a significant family history of gout prior to kidney failure in any of the 19 identified families.

Conclusions: MUC1 mutations are common in hereditary interstitial kidney disease families that do not have UMOD mutations. Age of onset of ESRD is highly variable within and between families.

Long Term Pathologic Changes in Kidney Allografts of Highly Sensitized Recipients Serena M. Bagnasco,[1] Andrea A. Zachary,[2] Lorraine C. Racusen,[1] Lois J. Arend,[1] Robert Avery Montgomery,[3] Edward S. Kraus.[2] *[1]Pathology, Johns Hopkins University, Baltimore, MD; [2]Medicine, Johns Hopkins University, Baltimore, MD; [3]Surgery, Johns Hopkins University, Baltimore, MD.*

Background: We studied the development of kidney graft injury over 1-9 years post-transplant follow up (FU) in 218 patients transplanted with an HLA-incompatible kidney between 2000 and 2010.

Results: Protocol and "for cause" biopsies were available in 120 pts: 38 M, 82 F; 98 whites, 16 blacks, 6 of other race; median age 45 years; median FU 3.2 years. Median PRA was 95. DSA at transplant were present in 81 pts: 31 class I only, 27 class II only, 23 both. Five pts died (4 with functioning graft), 14 lost their graft. Biopsy proven rejections were detected in 83 pts: antibody mediated rejection (AMR) in 19%, cell mediated rejection (CMR) in 31%, both in 18%, none in 38 pts, 9 pts had BK nephropathy. Rejections were most frequent in the first month (20% CMR, 16% AMR). The average eGFR (ml/min/1.73 m^2) declined significantly (P<0.001) from 63 at 3 months to 54 at 1 year, and was 48 at 4 year.

After the first year, 56 pts required graft biopsies, revealing CMR in 9 pts, AMR in 11 pts, both CMR and AMR in 3 pts, mixed CMR and AMR in 2 pts, glomerulitis (g≥1) and capillaritis (ptc≥1) but negative C4d in 8 pts, borderline inflammation in 5 pts. There was progressively higher average tubulointerstitial scarring (ci+ct) from 3 to 6 to 12 months (P<0.001), and from 1 to 2 to 3 years (P<0.05) post transplant. Transplant glomerulopathy (cg ≥1) developed in 54 pts, 14 by 6 months, and 23 by year 1, with proteinuria in 31, and was preceded by capillaritis (g≥1, ptc≥1) with positive C4d in 38%, and with negative C4d in 29%. Capillaritis (g≥1 and ptc≥1) with negative C4d was detected in the biopsies of 25 pts, of which at least 8 had moderate to high strength DSA, potentially indicating episodes of C4d-negative AMR.

Conclusions: Our observations support a role for capillaritis, even with negative C4d, in the development of transplant glomerulopathy. Despite good graft survival, acute and chronic allograft injury due to both AMR and CMR develop over time in incompatible allografts.

The Effect of Cinacalcet on Mineral and Bone Disorder in Hemodialysis Patrick S. Parfrey,[1] Geoffrey A. Block,[2] Ricardo Correa-Rotter,[3] Tilman B. Drueke,[4] Jürgen Floege,[5] Christian Mix,[6] Bastian Dehmel,[6] Marie-Louise Trotman,[6] Dennis Modafferi,[6] Yumi Kubo,[6] Charles A. Herzog,[7] Gerard M. London,[8] Kenneth Mahaffey,[9] Sharon M. Moe,[10] David C. Wheeler,[11] Glenn M. Chertow.[12] *[1]Health Sciences Ctr, Canada; [2]Denver Neph; [3]Inst Nacional de Ciencias Méd y Nutrición, Mexico; [4]Picardie Univ SOMP, France; [5]RWTH Aachen, Germany; [6]Amgen; [7]Univ of Minnesota; [8]Hôpital Manhès, France; [9]Duke Univ Med Ctr; [10]Indiana Univ SOM; [11]Univ College London, United Kingdom; [12]Stanford Univ SOM.*

Background: Treatment of secondary hyperparathyroidism (sHPT) in patients on dialysis with cinacalcet may reduce parathyroidectomy (PTX) and fracture (Fx) rates, but the extent of this benefit is uncertain.

Methods: We designed the EVOLVE trial to primarily test the hypothesis that treatment with cinacalcet reduces the risk of death or non-fatal cardiovascular events among patients on hemodialysis with sHPT. Adjudicated secondary endpoints included PTX and clinical Fx. 3883 patients on hemodialysis with moderate to severe sHPT (median PTH concentration 693 pg/mL [10%, 90% range, 363 to 1694 pg/mL]) were randomized to cinacalcet versus placebo on a background of conventional therapy and followed for up to 64 months. 4.6% and 19.8% of the study population at baseline presented with a history of PTX and Fx, respectively. We defined an endpoint of 'severe unremitting HPT' as time to first of any of the following three criteria: 1) plasma PTH >1000 pg/mL with serum total calcium >10.5 mg/dL (2.6 mmol/L) on two consecutive occasions; or 2) plasma PTH >1000 pg/mL and total calcium >10.5 mg/L (2.6 mmol/L) on one occasion with prescription of commercial cinacalcet within 2 months, or 3) surgical PTX.

Results:

Conclusions: We will present the treatment effect of cinacalcet on mineral and bone disease, with a focus on PTX, severe unremitting HPT and Fx rates, using the pre-specified intent-to–treat analysis, multivariate adjustment for baseline imbalances and censoring of data 6 months after study drug cessation. (NCT00345839)

SA-PO1121

Arteriovenous Fistula Survival and Needling Technique: Results from a Randomized Buttonhole Trial. Jennifer M. MacRae, Sofia B. Ahmed, Brenda Hemmelgarn. *Medicine, University of Calgary, Calgary, Alberta, Canada.*

Background: We have previously shown in a randomized trial that buttonhole (BN) vs standard needling (SN), was associated with significant reduction in the hematoma rate. Given that hematoma is associated with increased risk of thrombosis, BN may increase survival of arteriovenous fistula (AVF). The purpose of this study was to compare AVF survival and AVF complications in BN and SN pts.

Methods: 140 conventional HD pts were randomized to BN or SN to explore the impact of needling on pain score at 8 weeks. Patients were followed until they transferred modality (peritoneal dialysis, transplant) or died. Their AVF was followed until abandonment, removal or thrombosis or until July 30 2011. Complications of infection and stenosis requiring a fistuloplasty (FP) were tracked. In BN pts time to first infection, time to abandonment of buttonholes and reason for abandonment was determined.

Results: Baseline characteristics were similar. The median follow up time was 521(360 – 1149) and 584 days (381-1245) for SN and BN; p=0.24. The median time to abandonment or loss of AVF from study start (censored for death, transplant, PD) was 397 (151- 687) in SN and 674 days (300 – 1216) in BN; p=0.04. AVF thrombosis were similar: 7 SN (20.6%) and 6 BN (17.4%).

Over the follow-up period the majority of pts abandoned their buttonhole (46/70); median time to abandonment 345 days (15 – 554). The time to first infection for BN from study start is 338 days (150 – 912). There are no infections to date in SN.

Conclusions: AVF needled with BN appeared to have longer survival although this is not explained by a reduced thrombotic or F/P rate. The possible increased survival must be weighed against the higher risk of infection.

Rates of secondary outcomes, for standard and buttonhole needling. Rate expressed as time to first event

Outcomes	Standard Needling Rate per 10, 000 patient days at risk	Buttonhole needling Rate per 10, 000 patient days at risk	p value
Infection requiring antibiotics	0	0.029 (0.013 - 0.0.046)	0.99
Thrombosis	0.021 (0.007 - 0.035)	0.014 (0.004-0.025)	0.6
Fistulogram/plasty	0.31 (0.21 - 0.41)	0.37 (0.26 - 0.47)	0.16
Surgical intervention	0.046 (0.018 - 0.075)	0.032 (0.012 - 0.051)	0.59

Values expressed as median (25th - 75th percentile)

SA-PO1122

A Randomized 5-Year Trial of Angiotensin II Blockade vs. Placebo in Kidney Transplant Recipients Hassan N. Ibrahim,[1] Bertram L. Kasiske,[2] Michael Mauer.[3] *[1]Department of Medicine, University of Minnesota, Minneapolis, MN; [2]Department of Medicine, Hennepin County Medical Center, Minneapolis, MN; [3]Department of Pediatrics and Medicine, University of Minnesota, Minneapolis, MN.*

Background: Interstitial fibrosis/tubular atrophy, not otherwise specified, (IF/TA) is a major cause of kidney transplant loss that lacks treatment or preventive options.

Methods: We conducted a 5-year, double-blind, randomized placebo controlled trial in 153 kidney transplant recipients who were randomly assigned to receive losartan 100mg/d (n=77), or matching placebo (n=76). The main outcome measure was a composite of doubling of the fraction of renal cortical volume occupied by interstitium from baseline to 5 year biopsies or ESRD from IF/TA at any time during the trial.

Results: Both systolic and diastolic blood pressures were highly comparable between the two groups and consistently <130mmHg and <80mmHg, respectively. Annual measured GFR and urine protein were also similar. Twelve participants ended follow-up early by developing ESRD from IF/TA, 4 by developing non IF/TA related ESRD, 12 by death and 16 by withdrawal. In the intention to treat analysis, using only those with complete structured data, the primary endpoint occurred in 6/47 subjects receiving losartan and 12/44 receiving placebo (OR 0.39, 95% CI 0.13-1.15, p =0.08). For doubling of interstitial volume and all cause ESRD, losartan was protective; O.R. 0.36 (95% C.I. 0.13-0.99), p=.049. An increase of 10% in interstitial volume over the 5-year period was associated with a 3 ml/min decline in GFR in the losartan group and 18 ml/min in the placebo group. Losartan treated patients had, on average, serum potassium that was 0.2-0.3 mEq/L higher than placebo treated subjects. Uric acid and hemoglobin, on the other hand, were lower in the losartan group.

Conclusions: These results suggest that losartan, when used preemptively before the development of proteinuria or allograft dysfunction, is not associated with a statistically significant benefit in prevention of cortical interstitial volume. Whether its use in established allograft dysfunction would be beneficial remains to be studied.

SA-PO1123

Tubulointerstitial Inflammation in Lupus Nephritis Gia J. Oh,[1] Paul C. Grimm,[1] Neeraja Kambham.[2] *[1]Pediatrics, Stanford University Medical Center, Stanford, CA; [2]Pathology, Stanford University Medical Center, Stanford, CA.*

Background: The renal biopsy diagnosis including the RPS/ISN class, activity (AI) and chronicity (CI) indices determine the management of lupus nephritis (LN). The glomerular disease may be largely antibody-dependent, while the tubulointerstitial (TI) disease may be antibody-independent and influenced by T cells. Recent studies have suggested that TI inflammation and scarring, rather than glomerular inflammation are better predictors of outcome.

Methods: Our Pathology database was searched for adequate renal biopsies with active lupus nephritis (criteria: class III/IV; AI>3) from 2004-08. 41 biopsies from 41 adult and pediatric subjects with at least one follow-up creatinine value were identified and we perfomed histological and immunophenotypic analysis. Of these, 7 were lost to follow up and hence excluded In addition to determining T cell subsets (CD3, CD4, CD8, GATA3, T-bet, ROR γt, Foxp3, IL-17), B cell (CD20) and monocyte (CD14) infiltrates were evaluated in both glomeruli and TI. On follow-up, the adverse endpoint was a composite outcome of dialysis, transplant or 50% decrease in GFR or proteinuria by ANOVA method.

Results: The mean follow-up time of the study subjects was 3.8 years +/- 750 days. In addition to chronicity index, the individual histological parameters of TI inflammation, tubular atrophy, interstitial fibrosis, glomerulosclerosis and crescents predicted adverse outcome. On immunophenotypic analysis, the density of TI T lymphocytes (CD3; p=0.042), glomerular and TI monocytes (CD14; both p=0.02) and TI IL-17 (p=0.04) were significantly correlated with the endpoints.

Conclusions: The TI infiltrates, especially T lymphocytes and monocytes influence the progression of the renal disease in LN. IL-17 producing cells such as Th17 subset of T cells may be an important driver of kidney disease in systemic lupus erythematosus.

SA-PO1124

A Randomized Controlled Trial To Evaluate the Effect of Ages 3 - 5 Chronic Kidney Disease: The OPERA Study Angela Yee Moon Wang,[1] Fang Fang,[2] John Chan,[3] Qing Shang,[2] Gladys G. Lo,[3] Iris Chan,[5] Kar Neng Lai,[1] Christopher W. Lam,[6] Cheuk-man Yu.[2] *[1]Medicine, Queen Mary Hospital, University of Hong Kong, Hong Kong; [2]Medicine & Therapeutics, Prince of Wales Hospital, Chinese University of Hong Kong, Hong Kong; [3]Diagnostic Radiology, Hong Kong Sanatorium Hospital, Hong Kong, Hong Kong; [4]Medicine, Tung Wah Hospital, Hong Kong, Hong Kong; [5]Pathology, United Christian Hospital, Hong Kong, Hong Kong; [6]Macau Institute for Applied Research in Medicine and Health, Macau.*

Background: Vitamin D has been suggested to play a role in cardiovascular disease through interaction with vitamin D receptor.

Methods: We conducted a prospective double-blind randomized placebo-controlled trial in 60 stages 3-5 chronic kidney disease (CKD) subjects with echocardiographic evidence of left ventricular (LV) hypertrophy who were randomly assigned to receive either oral paricalcitol, 1μg/d (N=30) or matching placebo (n=30). Primary endpoint was change in LV mass index over 52 weeks by cardiac magnetic resonance imaging. Secondary endpoints included echocardiographic changes in LV volumes, systolic & diastolic function, biochemical parameters of CKD-mineral bone disease (MBD), arterial stiffness, 24-hour urine protein & estimated GFR.

Results: After 52-week, the change in LV mass index did not differ significantly between treatment [-2.97 ± 6.97g/m^2] and placebo group [-3.73 ±10.04g/m^2]. Changes in LV end-systolic, end-diastolic volumes, ejection fraction, tissue doppler derived measure of diastolic mitral annular velocity (E'), systolic mitral annular velocity (S') & early mitral inflow velocity to diastolic mitral annular velocity (E/E') did not differ between the two groups. Paricalcitrol treatment significantly lowered intact PTH [-10.31 ± 10.76 vs 6.33 ± 12.41 pmol/L; P<0.0001] and alkaline phosphatase [-14 ± 21.66 vs 2.13 ± 17.95 U/L; P=0.001] in treatment vs placebo group.

Conclusions: Fifty-two weeks treatment with oral paricalcitol significantly improved biochemical parameters of CKD-MBD but did not alter LV mass, volumes and function in stage 3-5 CKD patients.

SA-PO1125

The Soluble Triggering Receptor Expresed on Myeloid Cells-1 (STREM-1) as Inflammation Marker in Hemodialysis Patients Montañez F. Joseluis,[1] Enrique Rojas-Campos,[2] Alfonso M. Cueto-Manzano.[2] *[1]Nefrologia-Hemodialisis, Hospital General Regional No.110. I.M.S.S, Guadalajara, Jalisco, Mexico; [2]Unidad de Investigaciones Medicas en Enfermedades Renales, Hospital de Especialidades, CMNO, Guadalajara, Jalisco, Mexico.*

Background: Inflammation predicts lower survival in ESRD patients with/without dialysis. sTREM-1 is a new inflammation marker associated to worse prognosis in the intensive care and surgery settings. Aim: To determine the serum sTREM-1 concentrations and compare them with other inflammation markers in hemodialysis (HD) patients.

Methods: In a cross-sectional evaluation, 264 chronic HD patients and 148 healthy subjects were evaluated. Age, gender, cause of ESRD, time on dialysis, type of vascular access, presence of DM and/or hypertension, serum glucose, urea, creatinine, total, HDL- and LDL-cholesterol, triglycerides, albumin, electrolytes, and inflammation markers [interleukin 6 (IL-6), C-reactive protein (CRP), tumor necrosis factor alpha receptor (TNFaR) and sTREM-1] were measured/recorded.

Results: Main results are shown in Table. Serum sTREM-1 concentrations were correlated with IL-6 (r=0.56; p<0.05), TNFαR (r=0.76; p<0.05), and CRP (r= 0.56; p<0.05).

Variable	Hemodialysis N = 264	Healthy subjects N=148
Age (yrs)	47 ± 17*	39 ± 12
Weigth (Kg)	65 ± 16*	73 ± 15
SBP (mmHg)	152 ± 26*	119 ± 15
DBP (mmHg)	86 ± 14*	73 ± 11
Time on HD (months)	10.3 ± 18.2	
Vascular access, N (%)	45% 8% 47%	
Hemoglobin (g/dl) *	9.7 ± 3.1	14.4 ± 2.0
Leucocytes (mm/μL) *	6650 ± 2660	7750 ± 1826
Glucose (mg/dl) *	111 ± 50	87 ± 19
Albumin (g/dl) *	3.7 ± 0.6	4.5 ± 6.4
Creatinine (mg/dl) *	8.7 ± 3.3	0.8 ± 0.2
Uric acid (mg/dl)	5.8 ± 1.8	5.2 ± 1.41
sTREM-1 (pg/mL) *	1006 (613-1650)	0
IL-6 (pg/mL) *	7.9 ± 4.8	1.7 ± 1.0
TNFα (pg/mL) *	35.3 ± 21.7	1.7 ± 1.0
CRP (mg/L) *	6.8 (2.4-16.4)	1.9 (0.9-5.2)

*P<0.05 vs healthy subjects

Conclusions: This is the first study that evaluate sTREM-1 in ESRD. HD patients had higher serum concentrations of sTREM-1, IL-6, TNFαR and CRP than healthy subjects. sTREM-1 was also positively correlated with IL-6, TNFα and CRP.

It is possible that sTREM-1 may have a relevant role as an earlier marker of inflammation than traditional ones.

Funding: Government Support - Non-U.S.

SA-PO1126

COUP-TFII Is Essential for Metanephric Mesenchyme Formation and Kidney Progenitor Cell Renewal Chengtai Yu,[1] Akio Kobayashi,[3] Sophia Y. Tsai,[1,2] Ming-jer Tsai.[1,2] *[1]Molecular and Cellular Biology, Baylor College of Medicine, Houston, TX; [2]Program in Developmental Biology, Baylor College of Medicine, Houston, TX; [3]Department of Medicine, Harvard Medical School and Harvard Stem Cell Institute, Boston, MA.*

Background: Development of the metanephric kidney in mammals requires complex reciprocal interactions between the ureteric epithelium and the mesenchyme. Previous studies indicated that loss of *Osr1*, *Eya1*, *Pax2* or *Wt1* gene function in the metanephric mesenchyme compromises the formation of the kidney. Moreover, it has been shown that the Hox11-Eya1-Pax2 complex activates the expression of *Six2* and *Gdnf* in the metanephric mesenchyme to drive nephrogenesis.

Methods: We using the inducible knockout mice to delete COUP-TFII at E7.5 and collect embryos at E10.5 to study COUP-TFII functions in metanephric mesenchyme formation. At later stages of kidney development, the kidney specific Six2-Cre was used to ablate COUP-TFII in kidney progenitor cells.

Results: Here, we demonstrate that the COUP-TFII is required for the specification of the metanephric mesenchyme. Deletion of *COUP-TFII* at E7.5 results in improper

Underline represents presenting author/disclosure.

differentiation of the metanephric mesenchyme. COUP-TFII lies upstream of essential developmental regulators, such as *Eya1*, *Six2,* Pax2 and *Gdnf* to exert its function. Importantly, COUP-TFII directly regulates the transcription of both *Eya1* and *Wt1* in the metanephric mesenchyme. We also observed that the *Six2*$^{Cre/+}$*:COUP-TFII*$^{flox/flox}$ mutant mice kidney showed severe hypoplastic phenotypes and loss of the nephrogenic zone at P0 and cause neonatal death. We also found that Six2 expression in the cap mesenchyme is lost in the E13.5 mutant embryo, resulting in an increase of ectopic pretubule aggregates. Our results shows COUP-TFII is the key factor to regulate Six2 and maintaining kidney progenitor cell renewal.

Conclusions: Our findings reveal that COUP-TFII plays a central role in the specification of metanephric fate and in the maintenance of metanephric mesenchyme proliferation and survival through regulating the expression of *Eya1* and *Wt1*. In the later stage COUP-TFII is also indispensible for kidney progenitor cell renewal by regulate *Six2* expression.

Inhibition of Hyaluronan Synthesis Protects from Renal Function Impairment and Inflammation in a Mouse Model of Renal Ischemia-Reperfusion Injury Vanessa Colombaro,[1] Inès Jadot,[1] Virginie Voisin,[1] Laetitia Giordano,[1] Anne-Emilie Decleves,[2] Isabelle Habsch,[1] Bruno Flamion,[1] Nathalie Caron.[1] *[1]Molecular Physiology Research Unit - URPHYM, University of Namur - FUNDP, Namur, Belgium; [2]Experimental Nephrology Unit, Université Libre de Bruxelles - ULB, Brussels, Belgium.*

Background: Ischemia-reperfusion (IR) injury (IRI) to the kidney is a complex patho-physiological process that may lead to acute renal failure and chronic dysfunction in renal allografts. It was previously demonstrated that during IRI, hyaluronan (HA) accumulates in the cortical and external medullary interstitium together with an increased expression of its main receptor, CD44, on inflammatory and tubular cells. In mice, CD44 deficiency protects against short term IRI. The HA-CD44 pair may be involved in persistent postischemic inflammation.

Methods: Male C57BL/6 mice received a Western diet containing 4-methylumbelliferone (4-MU; 10 mg/g body weight/day), a potent HA synthesis inhibitor, for 14 weeks beginning at 4 weeks of age. At the end of the treatment, unilateral renal IR was performed by clamping the left artery for 28 min before removing the right kidney. Mice were euthanized 48 h post-IR, blood was collected and the kidney was harvested for analytical purposes.

Results: 4-MU treatment for 14 weeks reduced plasma HA level but was otherwise well tolerated. Forty-eight hours after IR in 4-MU treated mice, intrarenal HA content significantly decreased in the cortex (from 75.7 ± 14.8 to 20.6 ± 5.2 ng/mg, P< 0,05 ; n=8) and in the inner medulla (from 167,2 ± 37 to 41,5 ± 9,5 ng/mg, P< 0,05 ; n=8), as were also CD44 expression, creatininemia and histopathological lesions, as demonstrated by semi-quantitative methods. Moreover, inflammation was significantly attenuated as attested by markedly reduced macrophages and lymphocytes infiltration. Finally, proliferation, assessed by immunohistochemical staining, was reduced in animals treated with 4-MU.

Conclusions: Our results demonstrate that HA plays a significant role in the pathogenesis of renal IR injury, at least in part through reduced expression of CD44. Suppression of HA synthesis and/or accumulation during IR injury may protect renal function against ischemic insults.

Phosphate Binder Comparison: Sevelamer Carbonate & CaSuccinate/MgLipoate Deanna J. Nelson,[1] Keith A. Hruska.[2] *[1]BioLink Life Sciences, Inc., Cary, NC, United States; [2]Washington University, St. Louis, MO.*

Background: Hyperphosphatemia is causally related to atherosclerotic cardiovascular disease, the most important cause of death in all stages of renal failure and the single greatest threat to survival among ESRD patients undergoing dialysis. Patients use cationic binders to bind phosphate (Pi) in the GI tract and prevent its uptake. FDA-approved phosphate binders include calcium acetate or carbonate, lanthanum salts, or sevelamer, a cationic polymer. The combination of calcium succinate (CS) and magnesium lipoate (ML) has the potential both for phosphate binding with reduced calcium load and for reduction in oxidative stress, vascular calcification, and bone dysfunction.

Methods: LDLR -/- mice were fed high fat/high cholesterol diets supplemented with 1% or 3% (w/w) sevelamer carbonate (SC) or 1% or 3% (w/w) CS/ML. The actions of CS/ML were compared with those of SC using multiple criteria, including: (1) Pi binding; (2) effects on vascular calcification; and (3) effects on bone remodeling disorder as described in Hruska et al., *J Am Soc Nephrol 2007;18:122-30.*

Results: The untreated CKD mice were hyperphosphatemic, and significantly, CS/ML treatment dose-dependently decreased the serum Pi at least as effectively as SC treatment, if not more effectively. Similar effects on vascular calcification and bone remodeling were observed after treatment with SC or CS/ML. Four unexpected results related to CS/ML were obtained: (i) A significant reduction in serum glucose was observed in animals treated with 1% and 3% CS/ML in the diet. (ii) A 30% reduction in serum cholesterol, comparable to the reductions typically caused by SC treatment of CKD patients, was observed in animals treated with 1% CS/ML. (iii) Animals treated with 1% and 3% CS/ML in the diet showed an absence of weight gain. (iv) Animals in the 1% and 3% CS/ML treatment groups exhibited high BUN, hair loss, and skin disorders that were likely related to treatment.

Conclusions: These preliminary data suggest that CS/ML has the potential to provide pleiotropic benefits similar to those provided by SC. Additional preclinical studies are underway to confirm that CS/ML can be effectively and safely administered to ESRD patients.

Recombinant Human Erythropoietin Improves Rhabdomyolysis-Induced Acute Kidney Injury in Rats Regardless of Dose Yang Wook Kim,[1] Bongsoo Park,[1] Tae Hee Kim,[2] Kyu-Bok Jin,[1] Mi Seon Kang.[3] *[1]Nephrology, Internal Medicine, Haeundae Paik Hospital, Inje University; [2]Nephrology, Internal Medicine, Pusan Paik Hospital, Inje University; [3]Pathology, Pusan Paik Hospital, Inje University, Busan, Republic of Korea.*

Background: Rhabdomyolysis is one of the causes of acute kidney injury. Erythropoietin has cytoprotective effects on various non-erythroid cell as well as erythroid cells.

We studied he preventive and therapeutic effects of recombinant human EPO(rhEPO) on glycerol-induced rhabdomyolysis with acute kidney injury in rats.

Methods: Sprague-Dawley rats were divided into 6 groups of Control(C) , Glycerol(G1), EPO+Glycerol[(G2:1000U/kg(G2-L) or 5000U/kg(G2-H)], Glycerol+EPO(1000U/kg: G3-L), and Glycerol+EPO(5000U/kg:G3-H). Rhabdomyolysis was induced by intramuscular injectionof 50% glycerol (10 ml/ kg) in rats. For EPO+Glycerol group, the rats received intraperitoneal injection (IP) of rhEPO 24 hours prior to Glycerol injection. On the other hand, Glycerol+EPO group received rhEPO daily 24 hours after the injection of Glycerol. Hemoglobin, blood urea nitrogen (BUN), creatinine (Cr), and creatine phosphokinase(CPK) were measured at 0, 24, 48, 72, hr. When rats were sacrificed 5 days later, the same parameter was measure, and the kidneys were removed immediately for pathology and immunohistochemistry.

Results: Intramuscular injection of glycerol increased blood BUN, Cr, and CPK level significantly and induced severe histopathologic damages in the kidneys. In G2, Cr level was not different compared to G1 regardless of the rhEPO dosage . In G3, Cr level decreased subsequently after EPO injections. However, the Cr levels between two groups(G3-L vs G3-H) were not different. Histologic findings revealed that tubular necroses were resolved progressively in G3. The serum concentration of TGF-β increased in G1 & G2, but decreased in G3. The immunohistochemical expressions of TGF-β were correlated with the serum TGF- β level.

Conclusions: This study suggests that rhEPO improved the acute renal injury caused by rhabdomyolysis . It, however, did not have the preventive effect. It may also ameliorate the rhabdomyolysis-induced acute kidney injury through TGF-β suppression regardless of dose.

SOCS3-Independent Src Signaling Is Enhanced by cAMP and PC1 p30 in ADPKD Jeffrey Talbot,[1] Xuewen Song,[2] York P. Pei,[2] Thomas Weimbs.[1] *[1]Molecular Cellular & Developmental Biology, University of California Santa Barbara, Santa Barbara, CA; [2]Divisions of Nephrology & Genomic Medicine, University Health Network & University of Toronto, Toronto, ON, Canada.*

Background: Elevated levels of activated STAT3 are present in cyst-lining renal epithelial cells in ADPKD patients. Increased cAMP and decreased HNF1-b induce SOCS3 expression, and are present in ADPKD. Here we look at SOCS3 and its effect on STAT3 signaling in ADPKD.

Methods: SOCS3 mRNA from micro-dissected human cyst-lining renal epithelial cells was quantified by microarray & qPCR. Total/phospho- JAK2, STAT3 & Src were determined by western blot from whole cell lysates of cultured cells or PKD mouse models. Luciferase transcriptional reporter assays were run in HEK293T cells transfected w/a STAT1/3 lucif. reporter & the genes of interest.Forskolin stimulated cAMP levels.

Results: SOCS3 transcripts were significantly elevated in cyst-lining renal epithelial cells of human patient kidney samples at all stages of cystic progression.

JAK2 is a regulatory target of SOCS3, we found slight up-regulation of total protein levels in cystic animals, but no disease-related activation of JAK2.

Luciferase assays revealed that the disease-associated PC1 p30 cleavage product enhances STAT3 signaling by Src in a SOCS3-independent manner. This Src/p30 complex enhances EGFR-STAT3 signaling. Forskolin increased cAMP levels, and enhanced all Src-dependent signaling while inhibiting all JAK2-dependent signaling.

The ability of SOCS3 to regulate JAK2-dependent pathways was tested using Polycystin-1 and IL6. Both were unable to activate STAT3 in the presence of SOCS3.

Conclusions: We investigated the newly discovered paradox of high phospho-STAT3 and high SOCS3 in cyst-lining epithelial cells in ADPKD.

Src/p30 activates STAT3 in a SOCS3- and JAK2-independent manner. In vitro and possibly in ADPKD, the cAMP-induced expression of SOCS3 prevents JAK2-dependent signaling, preventing activation of STAT3 by PC1 and IL6.

High cAMP levels activate Src signaling and in doing so enhance the Src/EGFR positive feedback loop. The PC1 p30 fragment further enhances this feedback loop, creating an environment of high STAT3 activity while in the presence of high SOCS3.

The Function and Mechanism Study of Curcumin:Loaded Nanoparticles Against Renal Ischemia:Reperfusion Injury Yong Xu,[1] Donghui Zheng.[1] *[1]Nephrology Department, Huai'an Second Hospital, Huai'an, JiangSu, China.*

Background: To study the effects of curcumin-loaded nanoparticles against ischemia-reperfusion renal injury, and to investigate its mechanism.

Methods: Synthetize controlled releasing curcumin-loaded nanoparticles by amphilic mPEG-PCL block copolymers, and cultivated renal tubular epithelial cells (cells line HK-2) in vitro. HK-2 cells were divided into four groups: Control group; Ischenmia reperfusion injurygroup (IRI group); Curcumin group(Cur group); Curcumin nanoparticle group(CurNP group). In each group, HK-2 cells viability was assessed by dimethylthiazol-diphenyltetrazoliumbromide (MTT) tests. Apoptotic Cells were measured by Flow Cytometry. H2DCF-DA was used to detect intracellular generation of ROS. BCA was used to detect SOD activation and the Concentration of MDA. Protein levels of procaspase-3 were analyzed by Western Blot.

Results: We successfully constructed curcumin-loaded nanoparticles by amphilic mPEG-PCL block copolymers. In IRI group, cell viability gradually decreased, cell apoptosis had an obvious increased, SOD activity declined, the level of ROS and MDA activation significantly increased , the expression of Caspase-3 increased. In Cur group and CurNP group, cell viability and SOD activity significantly increased. A great reduction in the level of cells apoptosis was observed. The level of ROS and MDA activation were inhibited, the expression of Caspase-3 decreased. Compared with Cur group, showed marked changes in CurNP group($P<0.05$).

Conclusions: 1.Efficiently produce controlled releasing Curcumin-loaded nanoparticles by amphilicmPEG-PCL block copolymers.Drug loading content(DLS) and encapsulation efficiency(EE) were more than other reports.Data indicated that incorporated Curcould be slow released from the core–shellstructureof polymericnanoparticles. 2.CurNP can ameliorate ischemia-reperfusionrenal injury in vitro. 3.The protective effects of Cur-NP against ischemia-reperfusion renal injury were involved in the suppression of oxidative stress reaction.

Tweak Levels Are elevated in Diabetic Nephropathy and Stimulate Cytokine, Chemokine and Fibrotic Genes in Renal Cells Priya S Chockalingam, Michael Luong, Gregory J. Carven, Stephane Olland, Edward R. Lavallie, Nick Pullen, Lih-ling Lin. *Pfizer, Cambridge, MA.*

Background: Tumor necrosis factor-like weak inducer of apoptosis (Tweak, Apo3L, TNFSF12), a member of the TNF super family, activates the Fn14 receptor, regulates cell proliferation, death, differentiation, and inflammation, and plays a role in acute and chronic renal injury. We analyzed expression levels of Tweak and Fn14 in human diabetic nephropathy (DN) kidneys and correlated with animal and in-vitro models of DN/fibrosis. We also studied the effect of Tweak on primary human renal cells.

Methods: Snap frozen human DN (n=17) and non-DN (n=11) kidneys were obtained from various sources. Kidneys were harvested from C57BL6 mice (Taconic; 8-9 weeks old) that underwent a unilateral urethral obstruction (UUO) procedure and sacrificed at different times post-surgery (3, 7, or 10 days; n=6 per group). Human primary renal mesangial (HRMes, Lonza) and proximal tubuloepithelial cells (HRPTec, ScienCell) were treated with 100mM D-glucose or 0.2-2nM recombinant Tweak for 24-72 hrs followed by mRNA analysis and/or assays for cytokine and chemokine release.

Results: Tweak mRNA was elevated 4-fold in human DN kidneys compared with non-DN kidneys ($p=0.00008$); Fn14 mRNA showed a trend towards up-regulation but did not reach significance. Tweak and Fn14 mRNA showed a significant 2-3 and 5-16 fold increase, respectively, in the mouse UUO kidneys as compared with sham and naïve kidneys. Induction of HRMes with Tweak resulted in a dose-dependent increase in chemokine/cytokine release (CCL2, CCL5, CXCL1, IL6 and IL8). Tweak stimulation of HRPTec showed mRNA up-regulation of the same set of cytokines and chemokines as observed for HRMes, and in addition, fibrotic genes such as Col1A1, Col4A1, CTGF, ACTA2, TIMP1, and MMP9. High glucose treatment of HRMes cells induced mRNA expression of Tweak and fibrotic markers (Col4A1, CTGF, FN1, and TIMP1).

Conclusions: Our findings add further evidence for involvement of Tweak-Fn14 in human renal diseases and suggest a novel role for this pathway in diabetic nephropathy. These data provide new insights into potentially preventing pathological remodeling in chronic renal indications including DN.

SA-PO1133

CCL5 Protects from Chronic Hypertensive Kidney Injury Via Blood Pressure-Independent Mechanisms Mehul B. Patel,[1] Jiandong Zhang,[1] Bob Griffiths,[1] Phillip Ruiz,[2] Steven D. Crowley.[1] *[1]Duke University, Durham, NC; [2]Jackson Memorial Hospital, Miami, FL.*

Background: T lymphocytes are critically involved in the pathogenesis of hypertensive kidney disease. In chronic hypertension, the chemokine CCL5 is highly expressed in the kidney and is thought to recruit T cells to peri-vascular tissues. However, the precise role of this chemokine in the progression of hypertensive kidney damage is unknown. Here we study the influence of CCL5 on blood pressure (BP) and kidney injury during angiotensin II (Ang II) induced hypertension.

Methods: We subjected uni-nephrectomized, 129SVE wild-type (WT) and $CCL5^{-/-}$ (KO) mice to chronic Ang II infusion (1000ng/kg/min) for four weeks while measuring BP by radiotelemetry. To gauge the extent of kidney injury, we measured urinary albumin excretion, kidney pathology, and renal gene expression after four weeks of Ang II.

Results: Ang II caused a robust and similar BP elevation in the WT and KO groups (average MAP during third week of Ang II 192±4 vs.190±3 mm Hg). Despite these similar blood pressures, KO mice had significantly increased albuminuria compared to WT controls (21.1±1.9 vs 13.9±2.2 mg albumin/mg Cr; $p=0.02$). Furthermore, compared to WTs, KOs had significantly greater renal gene expression of the injury markers NGAL [0.38±0.06 vs. 1.69±0.37 arbitrary units (au); $p=0.002$], PAI-1 (0.58±0.11 vs. 1.42±0.20 au; $p=0.002$), and TNF-alpha (0.57±0.12 vs. 1.48±0.27 au; $p=0.006$). In examining differences in the immune response to explain the dissimilarities in kidney damage, we found that compared to WT mice, KOs had dramatically increased dense peri-vascular T cell infiltrates in the kidney (28 vs. 57% of vessels surrounded by > 50 T cells; $p<0.03$). To ascertain a possible mechanism of increased renal T cell infiltration in the KO group, we measured gene expression of the other known ligands to CCR5, CCL3 and CCL4; however, renal levels of these chemokines were similar in the two groups.

Conclusions: In chronic hypertension, the T cell chemokine CCL5 mitigates the progression of renal damage by paradoxically suppressing the infiltration of T cells into the kidney.

Anti-miR21 Protects Collagen 4A3 Deficient Mice from Progression of Alport Disease Ivan G. Gomez,[2] Deidre Mackenna,[1] Geoffrey Richard Linn,[2] Bryce Gordon Johnson,[2] Xinqiang Huang,[1] Dorin-Bogdan Borza,[3] Jie Zhang,[4] Philip Janiak,[5] B. Nelson Chau,[1] Jeremy Stuart Duffield.[2] *[1]Regulus Therapeutics, San Diego, CA; [2]Division of Nephrology, and Lung Biology Institute for Stem Cell & Regenerative Medicine, University of Washington, Seattle, WA; [3]Vanderbilt University, Nashville, TE; [4]R&D Center, Sanofi-Genzyme, Framingham, MA; [5]R&D Center, Sanofi-Genzyme, Chilly-Mazarin, France.*

Background: Alport syndrome in humans is an inherited form of kidney disease caused by a mutation in the gene coding the capillary basement membrane collagen IV. The disorder is characterized by progressive glomerulonephritis, leading to glomerulosclerosis, tubulo-interstitial disease and organ failure. $Col4a3^{-/-}$ mice also spontaneously develop severe kidney disease highly similar to human disease. Recent studies have shown that miR-21 promotes interstitial kidney disease with fibrosis by silencing metabolic pathways, particularly fatty acid metabolism, and by promoting ROS formation. We hypothesized that treating $Col4a3^{-/-}$ mice with silencing anti-miR21 oligonucleotides would prevent progression of disease.

Methods: $Col4a3^{-/-}$ mice were given anti-miR21 (25mg/kg q4d) or control from wk3 to wk9. Urine, plasma and kidneys were harvested at the end of wk9. All samples were analyzed to determine changes in kidney function and fibrosis.

Results: Anti-miR-21 treatment attenuated the loss of kidney function and development of albuminuria. Glomerulosclerosis and interstitial fibrosis were markedly attenuated and proximal tubules were preserved. Furthermore, anti-miR21 reduced infiltrating macrophages, and myofibroblast appearance. Ppara activity and fatty acid metabolism were preserved by anti-miR21 and cell activation signal transduction pathways including P42/P44 MAPK were inhibited by anti-miR21.

Conclusions: Anti-miR21 prevents progressive loss of kidney function in the $Col4a3^{-/-}$ mouse, attenuates both glomerular and tubulo-interstitial disease. Anti-miR21 is a potential new therapy for human kidney disease.

Activation of Soluble Guanylate Cyclase Ameliorates Renal Extracellular Matrix Overproduction in Experimental Diabetes Gabor Kokeny,[1,3] Lilla Fang,[1,3] Sina Abhari,[1] Arash Samarghandi,[1] Laszlo Rosivall,[1,3] Tamas Radovits,[2] Miklos M. Mozes.[1,3] *[1]Dept. of Pathophysiology, Semmelweis University; [2]Heart Center, Semmelweis University; [3]International Nephrology Research and Training Center, Semmelweis University, Budapest, Hungary.*

Background: The pathogenesis of diabetic nephropathy is associated with abnormalities of the NO-cGMP axis and functional imbalance of matrix metalloproteinases (MMPs) and their inhibitors (TIMPs). The PDE-5 inhibitor sildenafil has been reported to reduce extracellular matrix (ECM) production in type-2 diabetic rats. We investigated whether restoring cGMP levels by soluble guanylate cyclase (sGC) activator cinaciguat may attenuate renal ECM overproduction in type-1 diabetic rats.

Methods: Diabetes was induced in male Sprague-Dawley rats with single dose of streptozotocin (60 mg/kg). Experimental groups were (n=8/group): 1) Non-treated diabetic (DM); 2) Diabetic + cinaciguat (treated with 10 mg/kg/day per os for 8 weeks, DM-Cin); 3) Non diabetic controls (Co). Kidneys were analyzed after 8 weeks of treatment for histology and mRNA expression levels.

Results: In diabetic rats, cinaciguat treatment elevated serum cGMP levels (Co: 18±2, DM: 15±3, DM-Cin: 36±19 pmol/ml, $p<0.05$), reduced glomerulosclerosis (score: Co: 0.1±0.1, DM: 0.6±0.2, DM-Cin: 0.2±0.1, $p<0.05$) and collagen-IV expression (score: Co: 2.0±0.3, DM: 3.6±0.2, DM-Cin: 2.6±0.2, $p<0.05$). CTGF mRNA expression was also reduced in DM-Cin rats (relative expression, Co: 0.9±0.1, DM: 1.9±0.5, DM-Cin: 0.8±0.3, $p<0.05$). MMP2 expression was reduced in DM rats but restored in DM-Cin rats (Co: 0.7±0.2, DM: 0.3±0.1, DM-Cin: 0.8±0.4, $p<0.05$). TIMP-1 was markedly elevated in DM rats but almost normalized in DM-Cin rats (Co: 1.0±0.1, DM: 4.6±2.4, DM-Cin: 1.4±0.6,

Underline represents presenting author/disclosure.

p<0.05). In contrast, MMP9 expression was reduced in both diabetic (DM and in DM-Cin) rats, regardless of treatment (Co: 1.0±0.1, DM: 0.2±0.1, DM-Cin: 0.2±0.2, p<0.05).

Conclusions: We conclude that NO-independent activation of sGC might attenuate the progression of renal ECM accumulation in type-1 diabetic rats by direct effects on MMP2 and TIMP-1 expression, indicating the potential clinical use of cinaciguat in diabetic nephropathy.

SA-PO1136

Role of EGFR, p53 and ROS Mediated Signaling Networks in Renal Fibrosis and Induction of Fibrotic Effectors by TGF-ß1 Rohan Samarakoon,[1] Amy D. Dobberfuhl,[2] Jessica Overstreet,[1] Paul J. Higgins.[1] *[1]Center for Cell Biology and Cancer Research, Albany Medical College, Albany, NY; [2]Division of Urology, Albany Medical Colllege, Albany, NY.*

Background: TGF-β1 is one of the most potent inducers of kidney fibrosis regardless of etiology (e.g., renal obstruction, diabetes and hypertension). While SMAD3 initiated signaling networks downstream of TGF-ß1 have been extensively studied, the role of non-SMAD mechanisms in the kidney disease progression and orchestration of profibrotic gene changes remains largely unexplored.

Methods: We utilized unilateral ureteral obstruction (UUO) in mice and renal cell lines to investigate the role of non-SMAD signaling in kidney fibrosis.

Results: SMAD3 activation in the obstructed kidney correlated with EGFR and p53 phosphorylation suggestive of potential crosstalk among EGFR, p53 and SMAD3 transduction networks. TGF-ß1 stimulated EGFR activation and p53 signaling were required for induced expression of profibrotic PAI-1 and CTGF genes. Both PAI-1 and CTGF are causatively linked to the progression of obstructive and diabetic renal disease. ROS dependent mechanisms initiated by TGF-ß1 are crucial for both $p53^{Ser15}$ and $EGFR^{Y845}$ phosphorylation and subsequent PAI-1 and CTGF expression. EGFR, p53 and SMAD3 induction, readily evident in the dilated tubules of the fibrotic kidney, correlated with PAI-1 and CTGF induction suggestive of interplay among these transcription factors in profibrotic gene induction.

Conclusions: Our studies establish interplay between non-SMAD (e.g., EGFR, p53 and ROS) elements and SMAD3 in the induction of profibrotic genes by TGF-ß1 suggesting the potential benefit of combinational therapeutic targeting of non-SMAD and SMAD3 pathways to suppress fibrotic gene induction associated with renal fibrosis and CKD.

SA-PO1137

Soluble Hemojuvelin – An Early Biomarker Promotes Iron Deposition during Acute Kidney Injury Guang-Huar Young,[1] Tao-Min Huang.[2,3] *[1]Department of Surgery, National Taiwan University Hospital, Taipei, Taiwan; [2]Department of Internal Medicine, National Taiwan University Hospital and College of Medicine, Taipei, Taiwan; [3]Department of Internal Medicine, National Taiwan University Hospital Yun-Lin Branch, Dou-Liou, Taiwan.*

Background: Free iron plays an important role in the pathogenesis of acute kidney injury (AKI) via the formation of hydroxyl radicals. Systemic iron homeostasis is controlled by the hemojuvelin/hepcidin axis ratio in the liver, but less is known about this process in AKI.

Methods: Proteomic method is used to identify a 42 kDa soluble hemojuvelin (sHJV) from urine during post cardiac surgery AKI. We use several animal models including renal ischemia/reperfusion (I/R) injury, glycerol-induced rhabdomyolysis and folic acid-induced acute tubular necrosisin order to assess the changes of HJV and to identify potential factors associated with iron homeostasis during AKI. Further, we evaluate the effect of iron deposition on cultured renal tubular epithelial cells (HK2).

Results: The biopsies from human and mouse specimens with AKI confirm that extensive HJV ispredominant induced in the proximal renal tubules after I/R injury. Urinary HJV levels could be used to specifically predict AKI compare to healthy volunteers (265.8±109.6 vs. 41.5±36.7ng/ml, P<0.01). In the human renal proximal tubule cells (HK-2), iron overload induces the expression of sHJV and results in iron deposition. Pretreatment of HK2 cells with furin inhibitor significantly decreases the generation of sHJVunder iron overload, induces the expression of ferroportin and prevent iron deposition. Furin inhibitorcould also reduce the degradation of membrane bound HJV, prevent the accumulation of iron in the kidney compare to vehicle group (43.2±17.2vs. 76.1±15.1 mg/kg at 24 hours, P=0.03) and further ameliorate I/R injury during AKI.

Conclusions: Our findings link HJV inextricably with renal iron homeostasis for the first time, add new significance to early predict AKI, and identify novel therapeutic targets to reduce the severity of AKI by furin inhibitor.

SA-PO1138

Redox Control of p53 in the Transcriptional Regulation of TGF-β Target Genes through SMAD Cooperativity Jessica Overstreet, Rohan Samarakoon, Paul J. Higgins. *Center for Cell Biology and Cancer Research, Albany Medical College, Albany, NY.*

Background: SMADs cooperate with non-SMAD co-factors to achieve optimal TGF-β1 target gene expression. TGF-β1/SMAD3 and p53 promote insulin resistance, diabetic nephropathy and renal fibrosis. Our identification of SMAD3 and p53 activation in the obstructed kidney prompted us to investigate the potential cooperation of these transcription factors in TGF-β1-orchestrated pro-fibrotic gene changes, focusing on a major target gene PAI-1 given its causative role in renal diabetic and obstructive fibrosis.

Methods: Molecular approaches (i.e., RNA interference, genetic ablation, pharmacological inhibition) implicate p53 and SMADs as mediators of TGF-β1 signaling in multiple cell lines. Transcriptional cooperation between SMADs and p53 in renal cells were established using immunoprecipitation (IP), chromatin immunoprecipitation (ChIP), and immunohistochemistry.

Results: p53 genetic ablation and gene silencing suppressed, while expression of p53 in $p53^{-/-}$ MEFs rescued TGF-β1-stimulated PAI-1 induction. Furthermore, pifithrin-α, a p53 inhibitor eliminated TGF-β1-mediated expression of pro-fibrotic genes (i.e., PAI-1, CTGF) in HK-2 human tubular epithelial cells. TGF-β1-stimulated p53 and SMAD interactions occurred prior to promoter occupancy of these transcription factors to the PAI-1 gene confirmed by ChIP analysis. Consistent with the emerging role of oxidative stress as a causative element in fibrosis, TGF-β1-initiated phosphorylation of $p53^{Ser15}$ was ROS-dependent. Prominent co-expression of SMAD3, p53 and PAI-1 in the tubular epithelium of the obstructed kidney compared to the contralateral controls highlighted *in vivo* correlation of p53 and SMADs in TGF-β1-driven renal fibrosis.

Conclusions: TGF-β1 regulates the transcriptional activity of p53 promoting interactions with SMADs and subsequent binding of both molecules to the PAI-1 promoter establishing a multi-transcriptional complex involving p300. Collectively, TGF-β1-mediated pro-fibrotic gene expression involves p53, SMAD, and ROS providing attractive targets downstream of aberrant TGF-β1 signaling leading to renal failure.

SA-PO1139

KP-2326, a Peptide Agonist of the Calcium Sensing Receptor, Prevents Vascular Calcification in a Rodent Model of Uremia Sarah Walter, Jin Dong, Shawn T. Alexander, James Tomlinson, Qun K. Yin, Tom Hunter, Derek Maclean, Randolph M. Johnson. *Research, Amgen, South San Francisco, CA.*

Background: Chronic Kidney Disease (CKD) is linked to an increased risk for vascular calcification and deaths from cardiovascular disease. KP-2326 is a novel agonist peptide of the calcium sensing receptor (CaSR) that was evaluated in the adenine model for its ability to prevent vascular calcification.

Methods: Male Wistar rats were fed a low protein (2.5%), high phosphorus (0.92%) diet containing 0.75% adenine and randomly assigned to receive daily subcutaneous doses of placebo or KP-2326 (0.3 or 1 mg/kg) for 4 weeks (15 animals/group). A control group (9 animals) was fed the identical diet without adenine. 24 hours following the last dose, animals were sacrificed, blood samples taken for biochemical determinations and tissues removed for analysis. Aortic tissue was processed and stained both by Alizarin Red and von Kossa methods to visualize vascular mineralization.

Results: Using a scoring system from 0-5, identical sections of von Kossa-stained aorta from all animals were scored in a blinded fashion. 10/15 animals in the vehicle group showed evidence of some calcification; 9 of these animals had evidence of at least 40-60% calcification based upon the intensity and extent of the staining. In contrast, 0/15 rats in the 1 mg/kg group and 1/15 in the 0.3 mg/kg groups had detectable mineralization. One animal in the 0.3 mg/kg group received a score of 1 (0-20% calcification). Plasma PTH and serum creatinine were dose-dependently reduced in the KP-2326 groups, compared with the vehicle control animals (PTH: 295, 492, 1656 pg/mL for 1, 0.3 mg/kg and vehicle, respectively). Parathyroid glands in the KP-2326 groups were also significantly reduced in size compared with controls, normalized to body weight (group means of 3.38 and 7.52 mg/kg for the 1 mg/kg and vehicle groups, respectively).

Conclusions: KP-2326 is an agonist peptide of the CaSR, prevents vascular calcification, reduces PTH and prevents increases in parathyroid gland weight in a rodent model of uremia.

Production of Erythropoietin by Renal Human $CD133^+$ Progenitors under Hypoxia and Prolyl Hydroxylase Inhibition Benedetta Bussolati,[1] Massimiliano Mazzone,[2] Giovanni Camussi.[1] *[1]Internal Medicine, University of Torino, Torino, Italy; [2]VIB Vesalius Research Center, University of Leuven, Leuven, Belgium.*

Background: A peritubular population of cells with mesenchymal phenotype is considered to be responsible for the production of erythropoietin. However, in the human tissue, their precise identification is unclear. Using CD133 as marker, a population of renal resident progenitor has been localized in different segments of the nephron. In the present study, we investigated whether $CD133^+$ renal progenitors could be a source of EPO, and its modulation by HIF stabilization through prolyl hydroxylases (PHD) inhibitors.

Methods: CD133+ were isolated from human specimens, cultured and characterized as renal progenitors expressing mesenchymal markers by FACS analysis and real time quantitative PCR. Epithelial differentiation was induced by culture with 10% serum, 10 ng/ml Hepatocyte Growth Factor and 10 ng/ml Fibroblast Growth Factor-4. When cultured in hypoxic conditions, cells were placed in hypoxic chambers with 1% O_2. EPO mRNA was detected by real time quantitative PCR and EPO release into the supernatant using an ELISA. Generation of negative progenitors for HIF-2a or for PHD2 was obtained by infection with specific shRNA lentiviruses.

Results: CD133+ progenitor cells released EPO under hypoxia at levels comparable with those previously reported in EPO releasing human cells in vitro (18 ±3 mU/ml after 24 hours hypoxia). Erythropoietin synthesis was lost when CD133+ progenitors differentiated and acquired an epithelial phenotype. Inhibition of PHD2 induced EPO transcription, but not its release. Indeed, hypoxic conditions were required for the release of the intracellular pool of EPO after PHD2 knock down. Finally, blockade of HIF-2alpha impaired EPO synthesis.

Conclusions: These results indicate that human renal CD133+ progenitor cells via the PHD2-HIF2 alpha axis synthesize and release EPO under hypoxia and provide a new

Underline represents presenting author/disclosure.

rationale for the use of PHD inhibitors in clinical setting of acute or chronic renal injury. In addition, renal CD133+ progenitor cells represent a model for the study of the mechanisms of EPO synthesis and release.

Effects of Preterm Birth and Ventilation on Glomerular Capillary Growth in the Neonatal Lamb Kidney Megan R. Sutherland,[1] Danica Vojisavljevic,[1] Mar Janna Dahl,[2] Kurt Albertine,[2] Mary Jane Black.[1] *[1]Anatomy and Developmental Biology, Monash University, Clayton, Victoria, Australia; [2]Pediatrics, University of Utah, Salt Lake City, UT.*

Background: Preterm neonates are born with developmentally immature kidneys, with vascularisation of the glomeruli likely ongoing after birth. Preterm birth, and the related increase in blood oxygen concentration, leads to impaired vascular development in a number of diseases of prematurity (such as bronchopulmonary dysplasia). Hence, it is likely that glomerular capillary development will also be impaired. The aim of this study was to determine the effects of preterm birth and ventilation on glomerular capillary growth in a neonatal lamb model.

Methods: Four experimental groups were analysed: Lambs delivered preterm at 130d gestation (term=147d), and ventilated +3 days after birth (Preterm: n=7); 133d gestational controls (Fetal Control: n=5); Term controls born naturally, unassisted breathing +3 days after birth (Term Control: n=8); Term lambs ventilated +3 days after birth (Term Ventilated: n=8). Epon-araldite sections of inner, mid, and outer renal cortex from perfusion-fixed kidneys were assessed using stereological techniques to calculate total capillary length and surface area per renal corpuscle. Nephron number was assessed in glycolmethacrylate sections using the physical disector/fractionator approach, and total renal filtration surface area (TRFSA) calculated for each kidney.

Results: Preterm birth resulted in significantly increased capillary length, capillary surface area, and TRFSA compared to fetal controls. In comparison to term controls, however, preterm lambs had significantly reduced capillary length and TRFSA, but equivalent capillary surface area which may be indicative of capillary dilation. Importantly, term lambs ventilated for 3 days after birth exhibited significantly reduced capillary length, surface area and TRFSA compared to term controls.

Conclusions: The findings demonstrate that ventilation impairs glomerular capillary growth independently of preterm birth; capillary dilation in the preterm kidney may predispose to the development of glomerulosclerosis, and thus pose an additional risk to long-term renal health.

Pathomechanisms of Vascular Calcification: Urokinase Receptor Directs Osteogenic Differentiation of Mesenchymal Stem Cells Via Regulation of Complement Anaphylatoxin 5a Receptor Expression Margret Patecki, Parnian Kalbasianaraki, Hermann G. Haller, Inna Dumler. *Nephrology, Medical School Hannover, Hannover, Germany.*

Background: The vascular calcification process follows developmental programs that recapitulate embryonic ossification, with modulations by inflammatory and metabolic phenomena; mesenchymal stem cells (MSCs) contribute to this process. In our study we aimed to reveal the role of the multifunctional fibrinolytic urokinase (uPA) / uPA receptor (uPAR) system in induction and propagation of osteogenic differentiation of MSCs and a probable connection to the complement system.

Methods: Osteogenic differentiation of human bone marrow derived MSCs was induced by dexamethason, ß-glycerophosphate and ascorbic acid. Alkaline phosphatase activity and calcium deposition were monitored. Upregulation and silencing of uPAR were achieved by means of lentiviral transfection methods. Changes in expression levels were analyzed by RT-PCR, western blotting and flow cytometry.

Results: We examined the effect of uPAR silencing (uPARsi) and upregulation (uPARup) on osteogenic differentiation of MSCs. The osteogenic differentiation was impaired in uPARsi-MSCs and upregulated in uPARup-MSCs. Interestingly, we detected an increased expression of the complement anaphylatoxin C5a receptor (C5aR) mRNA in MSCs during osteogenic differentiation, whereas no change in C5aR level could be seen in uPARsi-MSCs. Furthermore, use of a specific C5aR antagonist blocked osteogenic differentiation of MSCs. These findings are in agreement with our previous data pointing to uPAR as an important mediator of the C5aR expression and of related signaling and functional effects in other cell types. They further suggest a general role for uPAR in C5aR regulation.

Conclusions: These results clearly show that the fibrinolytic and the complement systems functionally interfere during osteogenic differentiation. uPAR seems to play a regulatory role in this process leading to C5aR expression changes. To clarify the relevance of these findings in vivo, we use a mouse model with uPAR$^{-/-}$/ LDL-R$^{-/-}$ double knockout and LDL-R$^{-/-}$ mice on a fatty diet. Analyzing differences of arterial calcification and C5aR levels is in progress.

Effect of Recombinant Human Erythropoietin on Iron Metabolism Gene Expression João Fernandes,[1] Patricia Garrido,[2] Sandra Ribeiro,[3] José Sereno,[2] Joanna Sajkowska,[3] Henrique Nascimento,[3] Susana Rocha,[3] Luis Belo,[3] Elísio Costa,[3] Alice Santos-Silva,[3] Flávio Reis.[2] *[1]IBILI, UC and IBMC, UP; [2]IBILI, UC; [3]FF and IBMC, UP.*

Background: In vitro studies have shown that rhEPO has an inhibitory effect upon hepcidin gene expression. Therefore, rhEPO may interfere with iron metabolism through hepcidin. Our aim was to evaluate the effect of high rhEPO in the expression of hepcidin and other iron metabolism associated genes.

Methods: Three groups of Wistar rats were studied: i) control, ii) rats administrated with 50 IU/kg/week, iii) rats administrated with 200 IU/kg/week, during a 12 weeks period. Several putatively relevant genes involved in iron metabolism (hepcidin- Hamp, ferroportin – Slc40A1; transferrin – TFR; transferrin receptor 1 and 2 – TRFr1 and TRFr2; erythropoietin and erythropoietin receptor – EPO and EPOr; bone morphogenic proteins – BMP2, BMP4 and BMP6; hemojuvelin and hemochromatosis factor – HJV and HFE1; matriptase2 – TMPRSS6; and divalent metal transporter 1 – DMT1) and IL-6 gene expression were studied in the liver; iron serum levels were also evaluated.

Results: We found a down-regulation in EPO gene for both groups under rhEPO administration, suggesting a negative feedback mechanism. No other changes were found for rats under 50 IU/kg/week, when compared to control group. Concerning rats under 200 IU/kg/week we found over-expression of Hamp, TRFr2, Hfe, TRF, EPOr and IL-6 genes in liver, as compared with rats under 50 IU/kg/week. In accordance, iron levels were significantly increased in this group.

Conclusions: Our data suggest that an inflammatory environment might have developed, Hamp and IL-6 genes were overexpressed. Strengthening this hypothesis, we found an overexpression of BMP2 and BMP6, known to trigger the overexpression of Hamp gene. Moreover, due to the high rhEPO levels several iron metabolism associated genes were overexpressed. These results could explain the changes in iron metabolism described for hemodialysis patients requiring high rhEPO doses. Furthermore, Hamp expression seems to be primarily regulated by iron levels and inflammation than by rhEPO administration.

Deletion of the Proton-Sensing Receptor GPR4 Leads to Glomerulosclerosis in Old Mice Xuming Sun,[1] Doris P. Molina,[1] Lois J. Arend,[3] Juan Codina,[2] Thomas D. DuBose,[2] Snezana Petrovic.[1,2] *[1]Department of Physiology&Pharmacology, Wake Forest School of Medicine, Winston-Salem, NC; [2]Department of Internal Medicine, Wake Forest School of Medicine, Winston-Salem, NC; [3]Department of Pathology, Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: Proton-sensing receptors are members of a unique family of G protein-coupled receptors that function as pH sensors in the blood vessels, bone, kidney, airway smooth muscle, lung cancer, and possibly brain. Of the three receptors characterized so far, GPR4, is the one most abundant in kidney. We have characterized the phenotype of GPR4-/- to include a non-gap metabolic acidosis with features similar to classical distal renal tubular acidosis (RTA).

Methods: Since chronic metabolic acidosis affects progression of chronic kidney disease, the presence of chronic low grade metabolic acidosis in GPR4-/- prompted comparison of kidney histology of GPR4-/- and +/+ at different ages, using both light and electron microscopy.

Results: We analyzed young (<6 months; n=8 of each) and old mice (12 months; GPR4 +/+, n= 18 and GPR4-/-, n= 30). As we reported previously, kidney histology was unremarkable in young animals, but in contrast, ~30% of GPR4-/- developed severe glomerulolerosis by 12 months. Older GPR4-/- glomeruli showed expanded mesangium and excessive deposition of extracellular matrix and distended capillary loops. Mesangial deposits were confirmed by electron microscopy. Glomerular changes in GPR4-/- were accompanied by mild to moderate proteinuria. Interestingly, histological analysis did not reveal significant interstitial infiltration or fibrosis in the affected GPR4-/-. Histologic changes or proteinuria were not apparent in younger GPR4-/- or GPR4+/+, regardless of age.

Conclusions: In conclusion, we report that deletion of the pH sensor GPR4, accompanied by low grade chronic metabolic acidosis, is also associated with the development of glomerulosclerosis with advancing age. Since spontaneous, chronic acidosis in GPR4-/- precedes the development of kidney disease, GPR4-/- may be a useful experimental model in which to investigate the interaction of metabolic acidosis and kidney disease.

BRP39 Expression in Cystic Kidney Disease Mouse Models of PC1 and PC2 Deficient Background Seung H. Lee,[1] Chang-Min Lee,[2] Xin Tian,[1] Sohan Lal,[1] Sung Hyun Son,[3] Stefan Somlo.[1] *[1]Internal Medicine, Section of Nephrolgy, Yale School of Medicine, New Haven, CT; [2]Internal Medicine, Section of Pulmonology, Yale School of Medicine, New Haven, CT; [3]Internal Medicine, Section of Nephrolgy, BHS Han Seo Hospital, Busan, Korea.*

Background: Cystic kidney disease carries an inflammatory component, but the contribution of macrophage to cell proliferation is not clear. *As a chitinase-like protein, BRP-39 (Breast regression protein 39) is strongly induced in the macrophages in a number of inflammatory conditions*. In addition, recent studies indicated that BRP39 induces cellular

Underline represents presenting author/disclosure.

proliferation which contributes to the development and progression of tissue-remodeling responses such as pulmonary or renal fibrosis. To determine BRP39 contribution in the proliferation of cyst-lining cells in kidney, we evaluated the expression of BRP39 in cystic kidney mouse model of polycystin1 (PC1) and polycystin 2(PC2) deficient background.

Methods: Western blot and qPCR were used to evaluate the expression of BRP-39 in the kidney samples from p10, p16, p24, and p35of the mice with early onset cystic kidney model with PC1 deficient background and wild type controls. We also evaluated the levels of BRP39 expressions in the mice of adult onset cystic kidney model with PC2 deficient background by qPCR. Immunofluorescent stain of macrophage and BRP were performed in p10, p16, p24, and p35of the mice with early onset cystic kidney model with PC1 and PC2 deficient background.

Results: We found BRP39 expression was markedly increased along with cystic cell proliferations in early onset cystic kidney model. BRP-39 expression was more than 10 folds higher induced in the mice with PC1 and PC2 null mutation compared to controls (P=0.022) by qPCR. Immunofluorescent stain showed macrophages and BRP expressions are markedly increased in early onset cystic kidney disease models compared to control animals.

Conclusions: These data suggest that BRP39 may play a certain role in cystic cell proliferation through macrophage infiltrations in early and adult onset cystic kidney disease mouse models of PC1 and PC2 deficient background.

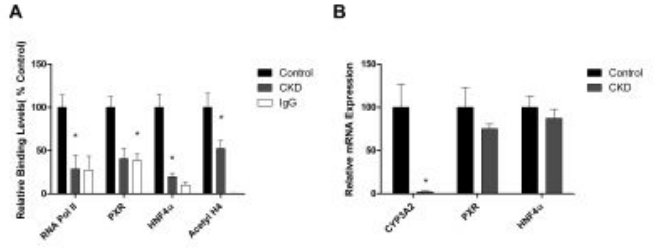
Decreased Nuclear Receptor Activity Mediates Down-Regulation of Drug Metabolizing Enzymes in Chronic Kidney Disease. Thomas Velenosi,[1] David A. Feere,[1] Gurjeev Sohi,[1] Daniel B. Hardy,[1] Angel Yi Nam Fu,[1] Brad Urquhart.[1,2] *[1]Physiology and Pharmacology, University of Western Ontario, London, ON, Canada; [2]Medicine - Division of Nephrology, University of Western Ontario, London, ON, Canada.*

Background: Patients with Chronic Kidney Disease (CKD) require many medications, the majority of which are metabolized by the drug metabolizing enzyme, CYP3A. Drug metabolizing enzymes are regulated by nuclear receptors and expression of these enzymes is decreased in CKD; however the mechanism by which this occurs is unknown.

Methods: CKD in rats was surgically induced by 5/6 nephrectomy. Rats were sacrificed on day 42 and hepatic CYP3A1, CYP3A2 and CYP2C11 mRNA expression were determined. Chromatin Immunoprecipitation (ChIP) was performed on the pregnane X receptor (PXR) and hepatocyte nuclear factor 4α (HNF4α) to determine nuclear receptor mediated differences in the transcriptional activation of these enzymes. Epigenetic modifications were also assessed by ChIP.

Results: Hepatic CYP3A and CYP2C11 mRNA expression was significantly decreased in CKD rats compared to controls ($P<0.05$). RNA polymerase II binding to the CYP3A and CYP2C11 promoter regions was decreased in CKD rats ($P<0.05$)(Figure 1). ChIP also revealed a decreased PXR binding to the CYP3A2 promoter in CKD rats ($P<0.05$). HNF4α binding to the CYP3A and CYP2C11 promoter regions was also decreased compared to controls ($P<0.05$); however, no change in nuclear receptor expression occurred (Figure 1). The decrease in PXR and HNF4α binding was concurrent with diminished histone 4 acetylation in the CYP3A2 promoter locus for nuclear receptor activation.



Conclusions: We demonstrate a novel mechanism of drug metabolizing enzyme regulation in CKD. Our results show that decreased CYP3A and CYP2C11 mRNA expression is secondary to decreased PXR and HNF4α binding as a result of histone modulation in CKD.

A Protective Role of Indoleamine 2, 3-Dioxygenase in Antibody Mediated Nephritis Kapil Chaudhary,[1] Lei Huang,[2] Michael P. Madaio,[3] Tracy L .McGaha.[4] *[1]Molecular Medicine, Georgia Health Sciences University, Augusta, GA; [2]Immunotherapy Center, Georgia Health Sciences University, Augusta, GA; [3]Medicine, Georgia Health Sciences Center, Augusta, GA; [4]Immunotherapy Center, Georgia Health Sciences Center, Augusta, GA.*

Background: Antibody mediated glomerulonephritis is a significant cause of chronic, progressive kidney disease; however, effective therapy remains elusive. Indoleamine 2,3-dioxygenase (IDO) drives immunologic tolerance and restricts inflammation by Trp depletion and generation of Trp catabolities. The aim of the present study is to determine the mechanism(s) by which IDO activity protects the kidney from antibody mediated nephritis.

Methods: Nephritis was induced by i.p. 12µl/g sheep anti-mouse nephrotoxic serum (NTS) to IDO1-KO, GCN2-KO (Trp depletion-responsive pathway), aryl hydrocarbon receptor (AHR) deficient (AHRd, tryptophan catabolite-responsive pathway) and WT (C57BL/6) mice. Renal function was monitored from day 3 to 21. Co-staining of IDO was preformed with markers for endothelial cells, podocytes, macrophages and dendritic cells on frozen sections 3 days after nephritis induction. To induce IDO prior to nephritis, DNA nano-particles (DNPs) were administered i.v.

Results: While IDO1-KO and AHRd mice developed severe form of nephritis with significant increase in BUN, albuminuria, body weight and kidney NGAL expression on day 15, GCN2-KO mice had no change in disease characteristics compared to WT mice. Moreover, lack of IDO1 or AHR enhanced pathologic alteration of the glomerular architecture with increased basement membrane thickening, glomerular and interstitial infiltrates, tubular cell necrosis and crescent formation. IDO expression was primarily in podocytes with some expression in macrophages and interstitial cells. Finally, IDO induction by DNPs prior to NTS administration did not prevent nephritis in IDO1-KO mice.

Conclusions: The data suggests that IDO limits renal pathology by a mechanism dependent on Trp catabolite driven activation of AHR transduction pathway. Moreover, results indicate methodologies to induce IDO expression that may have utility in the treatment of kidney inflammation.

SA-PO1148

Dual Regulation of Cadmium-Induced Apoptosis by mTORC1 through Induction of Selective Unfolded Protein Response Hironori Kato, Shotaro Nakajima, Masanori Kitamura. *Department of Molecular Signaling, University of Yamanashi, Chuo, Japan.*

Background: Cadmium (Cd) causes generation of reactive oxygen species (ROS) and consequent ER stress that triggers renal tubular injury. We found that rapamycin, an inhibitor of mTORC1, attenuated Cd-induced apoptosis in renal tubular cells. In this report, we investigated the link between mTORC1 and individual branches of the unfolded protein response (UPR) in Cd-triggered apoptosis of tubular cells.

Methods: Roles of mTORC1 in the induction of apoptosis and regulation of the UPR were tested using rapamycin, siRaptor and siTSC2. Involvement of IRE1a pathways in the Cd-triggered, mTORC1-mediated apoptosis was investigated using dominant-negative inhibition of IRE1a (kinase or endonuclease domain), XBP1 and JNK. Activity of mTORC1 and UPR pathways was evaluated by Western blot analysis of relevant indicators.

Results: Rapamycin, an inhibitor of mTORC1, attenuated Cd-induced apoptosis in renal tubular cells. Knockdown of Raptor, a positive regulator of mTORC1, also had the similar effect. Rapamycin did not alter generation of ROS, suggesting that mTORC1 is a target downstream of ROS. Indeed, ROS caused activation of mTORC1, and it contributed to activation of the selective UPR; i.e., the IRE1apathway. Although Cd triggered three major UPR pathways, activation of mTORC1 by Cd did not contribute to induction of the PERK–eIF2a and ATF6 pathways.Consistently, knockdown of Raptor caused suppression of JNK without affecting the PERK–eIF2a pathway in Cd-exposed cells. Knockdown of TSC2, a negative regulator of mTORC1, caused activation of mTORC1 and enhanced induction of the IRE1a–JNK pathway and apoptosis by Cd without affecting other UPR branches. Inhibition of IRE1akinase led to suppression of JNK activity and apoptosis in Cd-exposed cells. Dominant-negative inhibition of JNK also suppressed Cd-induced apoptosis. In contrast, inhibition of IRE1aendonuclease activity or downstream XBP1 modestly enhanced Cd-induced apoptosis.

Conclusions: These results disclosed dual regulation of Cd-induced apoptosis in renal tubular cells by mTORC1 through selective induction of the IRE1a kinase and endonuclease signaling.

SA-PO1149

APOL1 Is an Innate Immunity Effector That Induces Stress Autophagy by Interacting with the SNARE Protein, VAMP8 Sethu M. Madhavan,[1] John F. O'Toole,[1] Martha Konieczkowski,[1] Santhi Ganesan,[1] David B. Thomas,[2] Laura M.C. Barisoni,[2] Leslie A. Bruggeman,[1] John R. Sedor.[1] *[1]Case Western Reserve University; [2]University of Miami.*

Background: Apolipoprotein L1 (APOL1) prevents African Sleeping Sickness unless it is bound by a trypanosomal SRA resistance protein. Genetic variants in the *APOL1* SRA-binding domain circumvent parasitic resistance, but associate with non-diabetic kidney diseases through unknown mechanisms. We hypothesized that the SRA-binding domain of APOL1 would have human binding partners, which would highlight candidate pathways in disease pathogenesis.

Methods: APOL1:VAMP8 interaction was evaluated with immunoblotting, immunoprecipitation (IP) and pull-downs. Confocal microscopy evaluated colocalization of APOL1 and VAMP8 *in vitro* and *in vivo*.

Results: A BLAST search with amino acids 31-79 of SRA protein sequence yielded no mammalian ortholog. Since structural homology may exist with divergent primary sequences, we performed a secondary structure search with a Hidden Markov Model algorithm. A SNARE protein, Vesicle Associated Membrane Protein 8 (VAMP8) was identified as a structural ortholog of the SRA domain that binds APOL1. VAMP8 mediates membrane fusion required for vesicular trafficking and has been associated with selective autophagy pathways. By IP and pulldowns, VAMP8 bound wild type APOL1 but this interaction was decreased with disease-associated APOL1 variants. Transfected APOL1 and VAMP8 colocalized in HeLa cells. In normal kidney sections, VAMP8 and APOL1 colocalized in podocytes but not in proximal tubules. In FSGS and HIVAN biopsies with *APOL1* risk alleles, APOL1 and VAMP8 partially dissociated. Using immuno-EM, APOL1 was rarely associated with double membranes vesicles in normal kidney, but in diseased kidney, APOL1 was near podocyte vacuoles and in cytoskeleton abutting the GBM. WT APOL1 expression stimulated autophagy, as demonstrated by LC3-II. Autophagy induction by variant APOL1 was attenuated.

Underline represents presenting author/disclosure.

Conclusions: APOL1 interacts with VAMP8, a structural homolog of trypanosomal SRA protein. We propose that variant APOL1 proteins reduce VAMP8 binding and attenuate stress-induced autophagy that leads to kidney injury with relevant environmental challenges.
