Naohiko Fujii,[1] Takayuki Hamano,[2] Masaya Katayama.[4] *[1]Nephrology, Hyogo Prefectural Nishinomiya Hospital, Hyogo, Japan; [2]Department of Comprehensive Kidney Disease Research, Osaka University Graduate School of Medicine, Osaka, Japan; [3]Nephrology, Osaka University Graduate School of Medicine, Osaka, Japan; [4]Dialysis, Second Rokushima Clinic, Hyogo, Japan.*

Background: Alkaline phosphatase (ALP) is a biomarker which is associated well with cardiovascular (CV) and all-cause mortality in both maintenance hemodialysis (MHD) and predialysis patients. It is, however, inconclusive whether bone turnover markers such as bone-specific ALP (BSAP), serum N-terminal telopeptide of type I collagen (NTX), and tartrate-resistant acid phosphatase 5b (TRAP5b) can predict prognosis of MHD patients.

Methods: In this single-centred prospective observational study, we enrolled 128 MHD patients in May 2006 and followed-up until May 2012. We measured 1-84 PTH, NTX, TRAP5b and BSAP at baseline. We used Cox proportional hazards model employing each of the four parameters (BSAP, NTX, TRAP5b, and PTH) to evaluate the predictors of CV and all-cause death, respectively. Adjustment was performed for age, sex, diabetic status, and dialysis vintage.

Results: The subjects were aged 67+/-13 with a median vintage of 5.0 (IQR 3.0-8.6) years. During a median follow-up of 6.1 (2.5-6.1) years, 40 patients died, 18 of whom died of CV diseases. When the third quartile (Q3) was set to the reference, the hazard ratios (HRs) for all-cause mortality in the quartiles (Q1-Q4) of the four parameters were (2.0, 2.4, 1, 2.9*) for PTH, (1.3, 0.9, 1, 2.2) for NTX, (1.9, 2.6, 1, 3.5*) for TRAP5b, (0.7, 0.7, 1, 0.5) for BSAP, respectively. The HRs for CV death were (3.0, 2.7, 1, 6.1*) for PTH, (1.2, 1.0, 1, 2.5) for NTX, (2.1, 2.4, 1, 5.0*) for TRAP5b, (0.9, 0.2, 1, 0.6) for BSAP, respectively. (* P<0.05).

Conclusions: The associations between all-cause mortality and PTH or bone resorption markers were J-shaped with highest HR in the highest quartiles (Q4). The association with CV death was also J-shaped but the effect sizes of all these biomarkers were higher for CV mortality than all-cause mortality. This may imply the validity of the concept of chronic kidney disease-mineral bone disorders (MBD).

SA-PO625

Association of Geriatric Nutritional Risk Index and C-Reactive Protein with Cardiovascular Morbidity in End-Stage Renal Disease Patients Who Just Began Hemodialysis Therapy

Chieko Matsubara,[1] Hirotake Kasuga,[1] Ryo Takahashi,[1] Keiko Kimura,[1] Kyoko Kikuchi,[1] Yasuhiko Ito.[2] *[1]Nephrology, Nagoya Kyoritsu Hospital, Nagoya, Japan; [2]Nephrology, Nagoya University Graduated School of Medicine, Nagoya, Japan.*

Background: Protein-energy wasting (PEW), commonly observed in patients with end-stage renal disease (ESRD), is currently considered to be due to not only nutritional disorder but also inflammatory process. Recently, geriatric nutritional risk index (GNRI) has been developed as a simplified screening tool for PEW. We investigated the association of GNRI and C-reactive protein (CRP) with future cardiovascular (CV) morbidity in ESRD patients who just began hemodialysis (HD) therapy.

Methods: A total of 1548 ESRD patients who stably started HD therapy were examined. The GNRI was calculated from medical records at starting of HD, as follows; GNRI = (14.89 × albumin) + [41.7 × (body weight / body weight at BMI of 22)]. Patients were divided into quartiles according to GNRI levels; quartile 1 (Q1): <85.2, Q2: 85.2-91.2, Q3: 91.2-97.0 and Q4: >97.0. They were also divided into quartiles of CRP; Q1: <0.7mg/l, Q2: 0.7-1.8 mg/l, Q3: 1.8-6.1 mg/l and Q4: >6.1 mg/l, and were followed up to 10-year.

Results: Elevated CRP was independently associated with severe PEW defined as Q1 of GNRI (odds ratio 1.04, 95%CI 1.02-1.06, p=0.0001). At the 10-year follow-up, event-free survival rates for CV morbidity were 37.1%, 43.3%, 54.7% and 58.9% in Q1, Q2, Q3 and Q4 of GNRI, and were 63.6%, 55.3%, 47.8% and 32.2% in Q1, Q2, Q3 and Q4 of CRP, respectively (p<0.0001 in both). In the combined setting of GNRI and CRP, the risk of CV morbidity was 8.27-fold (95%CI 3.47-19.7) higher in Q1 of GNRI with Q4 of CRP compared to Q4 of GNRI with Q1 of CRP. Similar results were also obtained for mortality.

Conclusions: Lower GNRI, might reflect PEW state, and elevated CRP were closely linked, and were interactively associated with increasing risk of CV morbidity and mortality in ESRD patients just beginning HD therapy.

SA-PO626

Mortality Rate and Left Ventricular Systolic Function Associated with Interleukin-18 Level among Hemodialysis Patients

Chi-Ting Su,[1,2] Jenq-wen Huang,[2] Chih-Kang Chiang,[2] Kuan-Yu Hung.[2] *[1]Nephrology, National Taiwan University Hospital, Yun-Lin, Douliou, Taiwan; [2]Nephrology, Nation Taiwan University Hospital, Taipei, Taiwan.*

Background: The impact of persistent inflammation on cardiac function is not well illustrated among patients on maintenance hemodialysis. The study explores the prognostic value of interleukin (IL)-18 as an indicator of inflammation status for LV systolic function among asymptomatic ESRD patients.

Methods: Adult ESRD patients undergoing maintenance hemodialysis were enrolled prospectively. The exclusion criteria included LVEF <50%, severe valvular heart disease, chronic atrial fibrillation, acute decompensated heart failure, and acute coronary syndrome. Participants received 2-dimensional (2D) echocardiography with tissue Doppler imaging (TDI) and myocardial deformation analysis (2D strain analysis). Inflammatory cytokines, i.e. high-sensitivity C-reactive protein (hsCRP), IL-6 and IL-18, were measured.

Results: There were 90 patients who were 64.6±9.5 years of age and 40% of them are male. Patients were stratified into 2 groups by the threshold of an IL-8 value of 667 pg/ml, the median of IL-8 values. Compared to the low IL-18 group, the high IL-18 group showed increased hsCRP levels, but not IL-6 concentration. Using the 2D strain analysis, the high IL-18 group had worse LV systolic function: reduced global LV peak systolic longitudinal strain (GLS; high IL-18 group *vs.* low IL-18 group: -16.9 ± 3.6% *vs*. -19.2 ± 3.7%, p=0.01). In a multivariate regression analysis, GLS was the only independent factor of the IL-18 level (odds ratio= 1.25, p =0.03, 95% C.I. 1.02-1.52). Seventeen (24%) patients died during follow-up.Underthe Kaplan-Meier model, the high IL-18 group had higher all-cause mortality (p =0.05).

Conclusions: The study demonstrated LV systolic dysfunction and worse outcome among ESRD patients with increased IL-18 levels. GLS was the only independent correlate of IL-18 level. Thus, subtle LV systolic dysfunction may contribute to poor prognosis of ESRD patients with an elevated IL-18 level.

SA-PO627

Effect of Circulating Soluble Receptor for AGE (sRAGE) and the Proinflammatory RAGE Ligand (S100A12) on Mortality in Chronic Kidney Disease (CKD) Patients Stages 3-5

Marcelo M. Nascimento,[1] Shirley Yumi Hayashi,[1] Astrid Seeberger,[1] Tae Yamamoto,[1] Britta Lind,[2] Björn Anderstam,[2] Miguel C. Riella,[3] Bengt Lindholm.[1] *[1]Divisions of Renal Medicine and Baxter Novum, Department of Clinical Science, Intervention and Technology, Karolinska Institutet, Stockholm, Sweden; [2]Department of Medical Engineering, School of Technology and Health, Royal Institute of Technology, Stockholm, Sweden; [3]Centro de Ciências Médicas e Biológicas, Pontifícia Universidade Católica do Paraná, Curitiba, Parana.*

Background: Activation of the soluble receptor for AGE (sRAGE) is implicated in the progression of vascular complications. We investigated if increased circulating concentrations of sRAGE, and the RAGE ligand S100A12, predicted mortality in ESRD patients (pts).

Methods: A total of 145 pts (median age 61 y, 61% males; 36 hemodialysis (HD), 55 peritoneal dialysis (PD) and 54 CKD stages 3-5) were studied. All survivors completed 36 months of follow-up. Clinical characteristics were documented, and markers of mineral metabolism including fibroblast growth factor-23 (FGF-23), inflammation (high-sensitivity C-reactive protein, hsCRP; and interleukin-6, IL-6) were analyzed as well as plasma concentrations of S100A12 and sRAGE. The myocardial systolic (peak systolic velocity, PSV) and diastolic (early diastolic velocities, E') velocities were assessed by Tissue Doppler Imaging.

Results: After 36-months follow-up, mortality rate (Kaplan–Meier analysis) was associated with increased plasma levels of S100A12 (χ^2 = 3.58; P <0.05) and sRAGE(χ^2 = 5.95; P = 0.01). S100A12 was positively associated with IL-6 (r= 0.26, p<0.001), FGF-23 (r= 0.18, p<0.001), hsCRP (r= 0.25, p=0.02), TNFα (r=0.16;p=0.03) and OPG (r= 0.44, p<0.0001). sRAGE was negatively associated with E' (r=0.22, p<0.01). In Cox analysis, only sRAGE (hazard ratio, HR=1.91((95% confidence interval, CI) 1.03-1.61) and IL-6 (HR= 1.59(95% CI 1.20-2.15) were independently associated with increased risk of death.

Conclusions: Increased concentrations of sRAGE and S100A12 were associated with increased all-cause mortality in CKD stages 3-5 pts possibly reflecting increased activation and production of RAGE in the context of accelerated vascular disease.

The Significance of Interleukin-33 and Soluble ST2 in Coronary Artery Disease Associated with End-Stage Renal Disease

Amal Hasan,[1] Ebaa Alozairi,[2] Ali Hussein Ali,[3] Bassam A. Alhelal,[3] Said Dermime,[1] Reem A. Asad.[2] *[1]Immunology & Innovative Cell Therapy Unit, Department of Biomedical Research, Dasman Diabetes Institute, Kuwait, Kuwait; [2]Clinical Department, Dasman Diabetes Institute, Kuwait, Kuwait; [3]Nephrology Department, Aladan Hospital, Alahmadi, Kuwait.*

Background: End-stage renal disease (ESRD) is associated with coronary artery disease (CAD). The IL-33/ST2 pathway is thought to be protective against atherosclerosis due to its important role in Th2 immune responses and its ability to block the differentiation of macrophage-derived foam cells. No studies investigated the role of IL-33 and soluble ST2 (sST2) in CAD associated with ESRD patients.

Methods: To determine whether IL-33 and/or sST2 levels are altered in CAD/ESRD patients, and whether the level of these markers can be used to predict the risk of CAD development. A total of 46 adult ESRD patients, with and without CAD were recruited. The levels of serum IL-33 and sST2 were quantified, using enzyme-linked immunosorbent assays, and compared between CAD and non-CAD patients. The levels were also correlated with triglycerides (TGL), total cholesterol (Tchol), low-density lipids (LDL) and high density lipids (HDL). Statistical analyses was performed using the unpaired two tailed t-test and a P-value of less than 0.05 was considered significant. For correlation analysis, the pearson test was performed.

Results: In ESRD patients, higher levels of IL-33 and sST2 were associated with optimal levels of TGL (< 1.7) and LDL (< 3.3),and the level of IL-33 was negatively correlated with Tchol(P = 0.02). When diabetic and non-diabetic ESRD patients were compared, a negative correlation between IL-33 and Tchol (P = 0.002) and LDL (P = 0.04) was only found in the non-diabetic ESRD group. There was no difference in the level of IL-33 or sST2 between CAD and non-CAD patients, the level of IL-33 was negatively correlated with Tchol (P = 0.025) and positively correlated with sST2 (P = 0.006) in the non-CAD patients only.

Conclusions: IL-33 may act protective against CAD development in ESRD patients; further tests of more patients are currently underway.

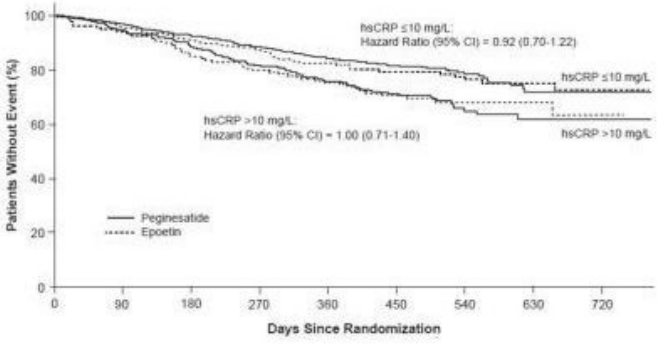
Relationship between Baseline Inflammatory Status and Cardiovascular (CV) Events in Hemodialysis (HD) Patients (Pts) on Peginesatide or Epoetin

Francesco Locatelli,[1] Anatole Besarab,[1] Amit Sharma,[1] Helen Tang,[2] Vandana S. Mathur,[2] Steven Fishbane,[1] Krishna R. Polu.[2] *[1]AFX01-12 and -14 Peginesatide Study Groups; [2]Affymax, Inc., Palo Alto, CA.*

Background: Analysis of a blinded, independently-adjudicated CV composite safety endpoint (CSE) using data pooled from two Phase 3 randomized, active-controlled, open-label trials (EMERALD 1, 2) comparing (2:1) peginesatide once every four weeks vs epoetin 1-3x weekly in HD pts showed similar CSE event rates for peginesatide (22.8%) and epoetin (24.4%; HR for time to first event [95% CI], 0.95 [0.77, 1.17]). High-sensitivity C-reactive protein (hsCRP) is a known predictor of CV outcomes. To evaluate the association between baseline hsCRP and CV events, we performed a prespecified subgroup analysis.

Methods: EMERALD 1 and 2 enrolled HD pts on stable epoetin doses ≥4 weeks. Pooled data from both studies (peginesatide [n=1066]; epoetin [n=542]) were examined for CSEs (all-cause death, stroke, myocardial infarction, and serious adverse events of congestive heart failure, unstable angina, and arrhythmia) by predefined baseline hsCRP level (≤10, >10 mg/L).

Results: Median baseline hsCRP was 5.4 mg/L for peginesatide (n=1051) and 5.8 mg/L for epoetin (n=526). The percent of pts with baseline hsCRP ≤10 and >10 mg/L was similar for peginesatide and epoetin (≤10 mg/L: 68.7% and 67.5%; >10 mg/L: 31.3% and 32.5%, respectively). Compared with the hsCRP ≤10 mg/L subgroup, the CSE event rate in the hsCRP >10 mg/L subgroup was higher for both treatment arms: peginesatide 30.4%, epoetin 29.8% vs peginesatide 19.1%, epoetin 21.1%, respectively. CSE events over time did not differ between treatments in either hsCRP subgroup (Figure).



Conclusions: In HD pts receiving peginesatide or epoetin, baseline hsCRP >10 mg/L was associated with worse CV outcomes. No differences in CV outcomes between treatments were evident in either hsCRP subgroup.

Mortality and Cardiovascular (CV) Events Are Associated with Low Hemoglobin (Hb): Results of Analyses in the MIRCERA Trials Database

Francesco Locatelli. *A. Manzoni Hospital, Lecco, Italy.*

Background: Several randomized controlled trials (RCTs) have raised concerns about potential harm with use of erythropoiesis-stimulating agents (ESAs), especially at high Hb. To explore the relation between Hb and mortality/CV events, we analyzed data from all patients in the MIRCERA RCT program.

Methods: We analyzed the relationship between Hb (last value within 4 weeks before an event; mean over time; deviation from target) and a composite endpoint (fatal adverse event, non-fatal myocardial infarction or stroke) and its components in pooled data from 9 RCTs (3405 CKD patients; 2826 patient exposure years) with both MIRCERA and reference ESAs.

In an analysis of the last value before an event, rate ratios (RRs) and bootstrap 95% BCa confidence intervals (CIs) were calculated from the distribution of all Hb values in comparison to the distribution of Hb values associated with events. Mean Hb over time and deviation from target (baseline ±1 g/dL) were analyzed using a Cox regression model, and hazard ratios (HRs) and 95% CIs were calculated.

Results: Comparison of percentage of Hb values within each Hb category to the percentage of events associated with each category showed the highest RR in the Hb category <10 g/dL and the lowest RR in the category 12 to <13 g/dL (CIs of the estimates excluding unity). Findings for individual components of the composite were similar.

In an analysis of time-adjusted average Hb, HRs >1 with CIs excluding unity were in the lowest Hb categories.

HR >1 with CI excluding unity was found in patients whose Hb fell below the target.

Hb level (g/dL)	< 10	10 to <11	11 to < 12	12 to <13	≥13
RR (95% BCaCI)	**2.44 (1.96-2.98)***	0.96 (0.75-1.19)	0.88 (0.74-1.02)	**0.77 (0.63-0.93)***	0.96 (0.72-1.22)
Hb over time (g/dL)	< 10	10 to <11	11 to < 12	12 to <13	≥13
HR (95% CI)	**4.39 (2.53-7.63)***	**2.10 (1.58-2.78)***	1.00 (ref)	0.85 (0.65-1.13)	1.42 (0.79-2.56)
Deviation from target Hb	Hb decrease by > 1 g/dL		Hb ±1 g/dL of baseline	Hb increase by > 1 g/dL	
HR (95% CI)	**3.00 (2.24-4.01)***		1.00 (ref)	1.43 (0.82-2.52)	

* CIs excluding unity

Conclusions: In multiple analyses from a large program of ESA treatment, risk of mortality and CV events was consistently higher at low Hb and in patients whose Hb fell below target.

Funding: Pharmaceutical Company Support - F. Hoffmann-La Roche Ltd.

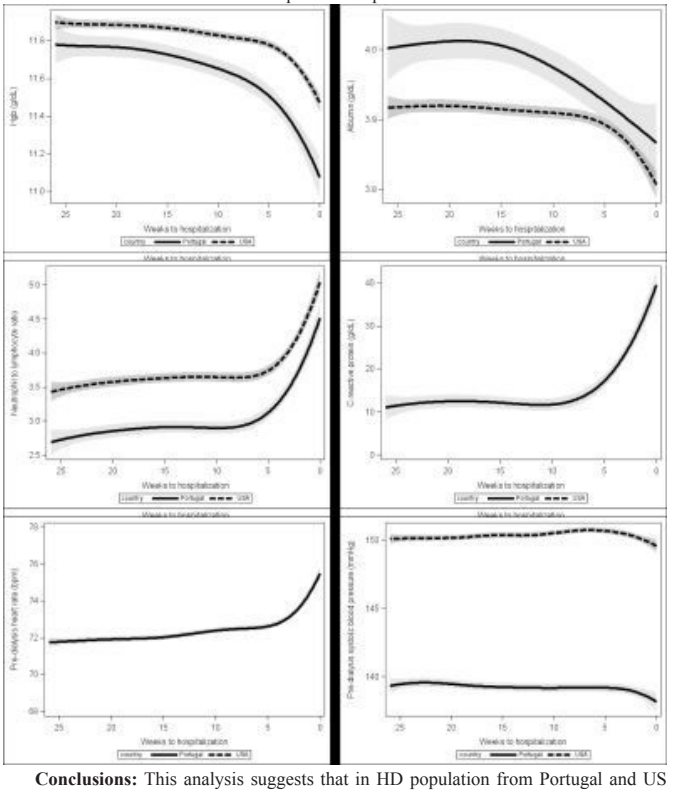
Changes in Key Clinical and Laboratory Parameters Identify Patients at Increased Risk of Future Hospitalization: Results from an International Study

Daniele Marcelli,[3] Adrian Marcos Guinsburg,[4] Aileen Grassmann,[3] Adam Tashman,[1] Cristina Marelli,[4] Eric Liu,[2] Frank van der Sande,[6] Inga Bayh,[3] Jeroen Kooman,[6] Laura Scatizzi,[3] Michael Etter,[2] Stephan Thijssen,[1] Edwin B. Toffelmire,[5] Yuedong Wang,[7] Len A. Usvyat,[1] Nathan W. Levin,[1] Peter Kotanko.[1] *[1]Renal Research Institute, NY, NY; [2]Fresenius Asia Pacific Ltd, Hong Kong, Hong Kong; [3]Fresenius Medicare Care, Bad Homburg, Germany; [4]Fresenius Medical Care, Buenos Aires, Argentina; [5]Fresenius Medical Care Canada, Toronto, Canada; [6]Maastricht University Hospital, Maastricht, Netherlands; [7]University of California, Santa Barbara, CA.*

Background: Recent studies in HD indicate a change in several parameters before death. We aimed to understand whether clinical parameters also change before hospitalization in international dialysis patient (pt) population.

Methods: The MONitoring Dialysis Outcomes (MONDO) consortium consists of HD databases from RRI clinics (USA), FMC clinics in Europe, Asia, Latin America and Canada, Maastricht University (Netherlands) and KfH clinics (Germany). Only databases from US and Portugal were queried to obtain data prior to first hospitalization in all HD pts bn 1/2007 and 12/2011. We computed weekly averages for several key parameters up to 26 weeks prior to first hospitalization.

Results: We studied 6458 pts (US, 4789; Portugal, 1669). In both countries hgb and albumin levels started to decline 7 to 12 weeks prior to hospitalization. NLR and CRP started to increase about 7 weeks prior to hospitalization. SBP started to decrease and heart rate started to increase about 5 weeks prior to hospitalization.



Conclusions: This analysis suggests that in HD population from Portugal and US clinical and laboratory indicators change as early as weeks before the hospitalization. Delineating these characteristics may aid the development of alert systems.

SA-PO632

Pre-Procedural Serum Albumin and C-Reactive Protein Levels Predict Long-Term Clinical Outcome after Percutaneous Coronary Intervention in Hemodialysis Patients

Hirotake Kasuga,[1] Ryo Takahashi,[1] Chieko Matsubara,[1] Keiko Kimura,[1] Kyoko Kikuchi,[1] Yasuhiko Ito.[2] *[1]Nephrology, Nagoya Kyoritsu Hospital, Nagoya, Japan; [2]Nephrology, Nagoya University Graduated School of Medicine, Nagoya, Japan.*

Background: Although percutaneous coronary intervention (PCI) has been widely performed in hemodialysis (HD) patients with coronary artery disease, poor outcome such as higher restenosis or poorer survival after PCI remains clinical problems in such population. On the other hand, lower albumin levels and chronic inflammation state are highly prevalent, and linked to poor cardiovascular outcome in HD patients. We evaluated the possible prognostic values of serum albumin and C-reactive protein (CRP) levels for clinical outcomes after PCI in HD patients.

Methods: A total of 549 HD patients successfully undergoing PCI for stable angina were enrolled. They were followed-up for up to 10 years. Serum albumin and CRP levels were measured prior to PCI. They were divided into the lowest, the middle and the highest tertile (T1, T2 and T3) according to serum albumin and CRP levels, respectively. We analyzed the incidence of major adverse cardiovascular events (MACE) as a composite endpoint of target lesion revascularization (TLR), non-fatal myocardial infarction (MI) and death.

Results: Kaplan-Meier analysis showed that 10-year event-free survival rates from MACE were 14.7%, 21.1%, and 32.1% in T1, T2 and T3 of albumin (p=0.0006), and were 34.2%, 23.9% and 6.5% in T1, T2 and T3 of CRP (p<0.0001), respectively. After adjustment, lower albumin (HR 1.43, 95%CI 1.03-1.99, p=0.045 for T1 vs. T3) and elevated CRP (HR 1.68, 95%CI 1.19-2.36, p=0.011 for T3 vs. T1) were independent predictors for MACE, respectively. In the combined setting of albumin and CRP, the risk of MACE was 3.43-fold (95%CI 1.78-6.59, p=0.0070) higher in the T1 of albumin with T3 of CRP compared to the T3 of albumin with T1 of CRP even after adjustment. Similar results were obtained for TLR and death.

Conclusions: Lower albumin and elevated CRP levels could predict MACE after PCI in HD patients. Furthermore, the combination of these variables is more markedly related to increased MACE than either variable alone.

SA-PO633

The Association of Low Triiodothyronine with Sudden Cardiac Death and Infectious Death in a Cohort of Incident Peritoneal Dialysis Patients

Ea Wha Kang,[1] Yong Kyu Lee,[1] Tae Ik Chang,[1] Soo Young Yoon,[2] Sug Kyun Shin.[1] *[1]Internal Medicine, NHIC Ilsan Hospital, Goyang, Gyeonggi-do, Republic of Korea; [2]Internal Medicine, Kwandong University College of Medicine, Goyang, Gyeonggi-do, Republic of Korea.*

Background: A direct association between low triodothyronine (T3) and all-cause and cardiovascular mortality have been reported in hemodialysis patients. However, the implication of this syndrome in peritoneal dialysis (PD) patients has not been described even though small studies suggested its association with all-cause mortality. To address this existing gap in knowledge, we examine the association between low T3 and cause-specific and all cause-mortality in a large cohort of incident PD patients.

Methods: After exclusion of 52 patients with thyroidstimulating hormone (TSH) values outside the normal range, 475 clinically and biochemically euthyroid incident PD patients were followed for a median of 46 months. Measurements of thyroid hormones, albumin, CRP, Urea kinetics were performed at baseline. All cause and cause-specific deaths were registered during follow-up. Low T3 was defined as a serum T3 level below the lowest tertile of T3 in the study patients.

Results: Patients with low T3 at baseline were significantly older and have lower BMI, hemoglobin, serum albumin, urine volume and residual renal function (RRF) compared to patients with non-low T3. In multivariable analysis, T3 levels at baseline were independently associated with hemoglobin (p=0.006) and RRF (p=0.03). Patients who died had significantly lower T3 at baseline than those who survived (P<0.001). In Cox analyses, Low T3 at baseline was a significant predictor of all-cause mortality independent of well known risk factors (Adjusted HR 2.05, CI;1.36-3.09) in incident PD patients. Low T3 at baseline was also significantly associated with sudden cardiac death (Adjusted HR 1.97, CI;1.13-3.40) and infectious death (Adjusted HR 3.04, CI;1.49-6.21).

Conclusions: Low T3 at baseline was independent predictor of mortality after adjusting well-known risk factors in incident PD patients. We need to turn attention to low T3 as prognostic marker on mortality, frequently observed in the peritoneal dialysis population.

SA-PO634

Elevated Troponin I Levels and Cardiac-Specific Mortality in Asymptomatic Hemodialysis Patients

Andrea Palumbo,[1] Paul E. Barre,[1] Ahsan Alam,[1] Allan Sniderman.[2] *[1]Division of Nephrology, McGill University Health Centre, Montreal, Canada; [2]Division of Cardiology, McGill University Health Centre, Montreal, Canada.*

Background: Elevated troponin I (TnI) levels are associated with all-cause mortality in stable hemodialysis patients. However, the relationship to cardiac-specific death has been inconsistent. We hypothesized that elevated TnI levels in chronic stable hemodialysis patients would track best with cardiac-specific mortality.

Methods: Single-centre, cohort study of prevalent hemodialysis patients at a tertiary care hospital. Plasma TnI levels were measured with routine pre-dialysis monthly blood tests in clinically stable patients for 2 consecutive months. Plasma TnI was measured by immunoassay (Beckman Coulter, Inc.) and a value above the laboratory reference range (0.06 µg/L) was considered elevated. The primary outcomes were all-cause and cardiac mortality. Cox proportional hazard models were used to examine the association of TnI with the outcomes of interest.

Results: Of 133 patients (mean age 59.6 ± 27.5; 56% male; 40% diabetic; 40% with prior CAD, 91% hypertensive, and a median dialysis vintage 2.8 years) followed for a median of 1.7 years, there were 38 deaths (58% non-cardiac, 39% cardiac, 3% unknown). A mean TnI >0.06 was found in 27% (N=36) of patients. Elevated TnI was associated with all-cause mortality [HR 2.44 (95% CI 1.16-5.11)] and cardiac death [HR 6.04 (1.77-20.7). After adjusting for age, gender, dialysis vintage, diabetes status, and prior CAD history, only cardiac mortality remained significantly associated with elevated TnI [HR 4.32 (1.16-16.1)].

Conclusions: Elevated TnI was independently associated with cardiac mortality, but not all-cause mortality, in asymptomatic hemodialysis patients. Chronic myocardial injury may explain this increased risk. TnI may reflect recurrent subclinical ischemia-reperfusion injury in otherwise stable patients with underlying atherosclerotic heart disease. Whether patients with an elevated TnI would benefit from targeted investigations and strategies to manage cardiovascular risk remains to be determined.

SA-PO635

High Sensitivity Troponin as a Predictive Marker for Cardiovascular Events and Mortality in the Stable Dialysis Population

Hicham I. Cheikh Hassan,[1,2] Andrew D. Jefferys,[1] Kenneth J. Howlin,[1] Michael G. Suranyi,[1] Ananthakrishnapuram N. Aravindan,[1] Govindarajan Suryanarayanan,[1] Angela Makris.[1,2,3] *[1]Renal Unit, Liverpool Hospital, Sydney, Australia; [2]Univeristy of New South Wales, Sydney, Australia; [3]University of Western Sydney, Sydney, Australia.*

Background: High Sensitivity Troponin (hsTnT) is a cardiac biomarker used in diagnosing myocardial injury and predicting outcome. Its interpretation and application in the haemodialysis (HD) and peritoneal dialysis (PD) population remains unclear. Our aim is to determine if hsTnT is effective in predicting cardiac events and death in the stable dialysis population.

Methods: A prospective observational study of prevalent nonacute HD and PD patients from July 2011. hsTnT was obtained with routine blood tests and baseline characteristics. Patients were followed up for one year (outcomes; death/new cardiac event). SPSS v.20 used and appropriate tests employed based on data distribution.

Results: 393 patients, 275 HD(70%) and 118 PD(30%) were included. Median hsTnT was 57.5ng/L IQR [36.0,101.1] with no difference between HD and PD patients. There was a statistically significant reduction in hsTnT postHD (p<0.0001). However the amount and rate of change was not clinically significant. Patients who developed a cardiac event had higher hsTnT (102.0ng/L vs 56.0ng/L, p<0.0001) and increased mortality (33.3% vs 6.9%, Likelihood ratio (LHR) 15.8,p<0.0001). This was valid in both HD patients (p=0.003, LHR 8.89 p=0.003) and PD patients (p=0.002, LHR 8.5 p=0.004) for cardiac events and mortality respectively. All cause mortality (but not cardiac mortality) was associated with higher hsTnT (91.0ng/L vs 56.0ng/L p= 0.007). This was only valid in PD patients (p=0.035) and not HD patients (p=0.075). Dividing the study group into quartiles (Q) by hsTnT revealed incremental rise in LHR of developing cardiac events;Q1-Q2 (LHR 10.1,p=0.001), Q1-Q3 (LHR 11.4,p=0.004), Q1-Q4 (LHR 11.5,p=0.001). Mortality similarly increased across quartiles reaching significance between Q1-Q4 (LHR 9.8,p= 0.002).

Conclusions: A higher hsTnT may have a role in predicting cardiac events and death in stable dialysis patients.

SA-PO636

Interaction of B-Type Natriuretic Peptide and Cardiac Troponin T Improves the Prediction of Mortality in Patients on Hemodialysis Kaoru

Kaoru Yasuda,[1] Shoichi Maruyama,[1] Hirotake Kasuga,[2] Yoshinari Yasuda,[1] Tomoki Kosugi,[1] Waichi Sato,[1] Naotake Tsuboi,[1] Yasuhiko Ito,[1] Enyu Imai,[1] Seiichi Matsuo.[1] *[1]Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Aichi, Japan; [2]Nephrology, Nagoya Kyoritsu Hospital, Nagoya, Aichi, Japan.*

Background: Patients on hemodialysis (HD) are regarded as the highest risk group for cardiovascular disease (CVD). Thus, the risk stratification for future events is clinically important. Elevated plasma B-type natriuretic peptide (BNP) and serum cardiac troponin T (TnT) levels were highly prevalent in HD patients. We investigated whether combination of BNP and TnT could improve predictive values for mortality in HD patients.

Methods: A total of 516 stable HD patients were enrolled and were followed up for 10 years. They were divided into tertiles according to plasma BNP levels; tertile 1 (T1): <184ng/l, T2: 184-463ng/l and T3: >463ng/l. They were also divided into tertiles of serum TnT levels; T1: <0.05µg/l, T2: 0.05-0.10µg/l and T3: >0.10µg/l, and were followed-up for 10-year.

Results: At the 10-year follow-up, Kaplan-Meier survival rates were 73.8%, 60.6% and 40.1% in T1, T2 and T3 of BNP, and were 82.7%, 54.6% and 36.2% in T1, T2 and T3 of TnT, respectively (p<0.0001 in both). In the combined setting of BNP and TnT, the risk of mortality was 5.04-fold (95%CI 2.61-9.74) higher in T3 of both BNP and TnT compared to T1 of both (p<0.0001). Similar results were also obtained from CVD mortality. C-index also showed that adding both BNP and TnT significantly increased prognostic values for all-cause mortality and CVD mortality.

C-index by combination of BNP and TnT

	All-cause mortality		CVD mortality	
	C-index(95%CI)	P	C-index(95%CI)	P
Basic model	0.745(0.702-0.788)	Ref.	0.692(0.631-0.753)	Ref.
Basic model+BNP	0.785(0.745-0.825)	0.0011	0.712(0.653-0.771)	0.048
Basic model+TnT	0.786(0.746-0.826)	0.0006	0.722(0.664-0.780)	0.028
Basic model+BNP and TnT	0.806(0.767-0.845)	<0.0001	0.733(0.676-0.790)	0.0075

Established risks include male, age, duration of HD, traditional risk factors, BMI, hemoglobin, albumin and CRP.

Conclusions: The combination of BNP and TnT could more accurately predict mortality than either variable alone in C-statistics.

SA-PO637

Prognostic Value of N-Terminal Pro-B-Type Natriuretic Peptide (NT-proBNP) Concentrations in Patients with End Stage Renal Disease Frank Dellanna,[1] Michael Dickenmann,[2] Valeriy Y. Shilo,[3] Werner Kleophas.[1]
[1]Dialysezentrum Karlstrasse, Düsseldorf, Germany; [2]University Hospital Basel, Basel, Switzerland; [3]Moscow University of Medicine and Dentistry, Moscow, Russian Federation.

Background: NT-proBNP is a powerful diagnostic tool in chronic kidney disease (CKD) patients not on dialysis receiving erythropoiesis stimulating agents (ESAs). Although the predictive value of NT-proBNP in end stage renal disease (ESRD) patients is not known, a strong association of NT-proBNP levels >10,000 ng/mL with increased mortality has been reported. This analysis explored the prediction of clinical outcomes by NT-proBNP in ESRD patients treated with long-acting continuous erythropoietin receptor activator (C.E.R.A.).

Methods: Data from 10 international multicenter open-label trials including 1597 patients on dialysis who switched to treatment with once-monthly C.E.R.A. were analyzed. Predictive NT-proBNP cut-offs were searched for each parameter leading to an odds ratio (OR) for binary outcomes; pertaining p-values were corrected for optimization bias.

Results: NT-proBNP significantly predicted the safety endpoints cardiac adverse events (AEs; OR 2.9, p<0.0001), vascular disorders (OR 3.6, p=0.022), and hypertensive AEs (OR 3.6, p=0.056). No association to thromboembolic and dialysis-related disorders was observed. Likewise, NT-proBNP predicted the occurrence of serious cardiovascular AEs (OR 2.2, p=0.016). It did not predict ESA maintenance parameters such as Hb stability, Hb fluctuation, or response probability in these 10 trials. However, high NT-proBNP correlated with a higher maintenance dose (OR 1.4, p=0.007), and low dose/Hb effect (OR 1.4, p=0.014).

Conclusions: This pooled analysis confirmed the strong predictive value of baseline NT-proBNP levels for cardiovascular AEs in patients with ESRD. NT-proBNP does not predict thromboembolic effects. Association with Hb maintenance performance parameters in terms of stability was not found, while elevated NT-proBNP was associated with a higher dose requirement and a diminished Hb response.

SA-PO638

NT-proBNP in Hemodialyzed Patients: Marker for Overhydration or Cardiovascular Complications? Krzysztof Schwermer, Krzysztof Hoppe, Jolanta Kaczmarek, Peter Sawatiuk, Marcin Czyzewski, Malgorzata Szkudlarek, Bartlomiej Posnik, Dorota Sikorska, Krzysztof Pawlaczyk, Andrzej P. Oko.
Nephrology, Transplantology and Internal Diseases, Poznan University of Medical Sciences, Poznan, Poland.

Background: Proper volume control is one of the chief goals in the care for patients undergoing maintenance hemodialysis (HD). An overhydration state (OH) in the inter-dialytic period directly correlates with the risk of cardiovascular complications. NT-proBNP is one of the most popular indicators of heart failure, particularly during overload.

Methods: The study was performed on 136 HD patients (male n=89, female n=47). OH, serum NT-proBNP, cardiac troponin T (cTnT), hemoglobin (Hgb), osteocalcin (Osc), and pre- and post-dialytic blood pressure (BP) were assessed during a 6 month period (at time 0 and 6 months). OH was evaluated using both clinical methods and bioimpedance (BIA - Fresenius Body Composition Monitor). The study group was divided into 3 subgroups according to initial NT-proBNP levels (A: <500pg/ml, n=9; B: 500-5000pg/ml, n=50; C: >5000pg/ml, n=77).

Results: No difference was observed regarding age and gender among subgroups. Most interestingly, at time 0, the clinical determination of OH within subgroups did not show differences compared to the same measurements using BIA (1.13 vs. 2.01 vs. 4.53, p<0.00001), the same relation was observed at 6 months (0.74 vs. 2.08 vs. 4.11, p<0.0001). At time 0 an evident difference was observed in serum Hgb and Osc concentrations (12.1 vs. 11.7 vs. 10.8, p<0.0005; 169.8 vs. 147.7 vs. 211.8, p<0.02 respectively), and after 6 months a continued significance was seen in Osc concentrations (163.2 vs. 171.4 vs. 229.0, p<0.005). cTnT levels differed significantly both at time 0 and after 6 months (0.028 vs. 0.051 vs. 0.115, p<0.00001; 0.037 vs. 0.057 vs. 0.098, p<0.0005). At both time points there were statistical differences in post-HD systolic BP (p<0.05).

Conclusions: The use of NT-proBNP as a measure of intravascular volume is limited due to the intricate relations of pathophysiologic mechanisms. However, according to our results, NT-proBNP seems to be a significant marker of overhydration and heart muscle damage among HD patients.

SA-PO639

Biological Variation of N-Terminal B-Type Natriuretic Peptide (NT-proBNP) in the Stable Dialysis Population Magid Fahim,[1,3] Andrew Hayen,[4] Amanda Coburn,[3] Goce Dimeski,[2,3] Andrea R. Horvath,[4,6,7] David W. Johnson,[1,3] Jonathan C. Craig,[5,6] Scott Campbell,[1,3] Carmel M. Hawley.[1,3]
[1]University of Queensland; [2]Pathology Queensland; [3]Princess Alexandra Hospital; [4]University of New South Wales; [5]Westmead Children's Hospital; [6]University of Sydney; [7]Prince of Wales Hospital, Australia.

Background: Change in NT-proBNP levels correlates with the risk of cardiovascular events on dialysis and may be useful for monitoring cardiac-risk but the biological variation of NT-proBNP in this setting is unknown. The aim of our multi-centre, prospective cohort study was to determine the within- & between-person variation of NT-proBNP in stable dialysis patients.

Methods: 55 prevalent HD and PD patients were assessed 10-times over 5 months, weekly for 5-weeks then monthly for 4-months. Assessments were conducted in a standardised manner between 6-10AM, at the same point in the dialysis cycle. At each visit, subjects underwent clinical review, whole body multifrequency bioimpedance, EKG and NT-proBNP testing. Plasma was frozen within an hour of collection, batched and analysed in duplicate in a single run. Subjects were deemed unstable if they underwent a change in cardiac medication, dialysis prescription, ischaemic symptomatology, extracellular volume > 1L, new arrhythmia or hospital admission between visits. Data from the intervals preceding and following such events were excluded from analysis. Analytical (CV_A), between-person (CV_G) and within-person biological variation (CV_I) were calculated. The difference in serial levels needed to detect a clinically significant change with 90% certainty (RCV) & index of individuality (IOI) were derived.

Results: 41 subjects, 147 weekly & 142 monthly intervals were analysed. Median NT-proBNP= 1974 pg/mL (IQR 711 - 3967 pg/mL). CV_A= 1.9%, CV_G= 189%, weekly CV_I= 27% & monthly CV_I= 35%. The 90% weekly & monthly RCV= -46% – +84% & -54% – +120% respectively. IOI= 0.14.

Conclusions: A large change in serial NT-proBNP levels is needed to confidently exclude change due to analytical & biological variation alone. The best strategy for applying NT-proBNP in dialysis is relative change monitoring rather than comparing results to reference intervals.

Elevation in Endothelial Progenitor Cells Are Associated with Worse Survival in African-American Hemodialysis Patients Francesca Cardarelli,[1] Qi Long,[3] Monnie Wasse.[1]
[1]Renal Division, Emory University, Atlanta, GA; [2]Cardiology Division, Emory University, Atlanta, GA; [3]Department of Biostatistics and Bioinformatics, Rollins School of Public Health, Emory University, Atlanta, GA.

Background: Circulating endothelial progenitor cells (EPC) have been correlated to endothelial function and cardiovascular disease risk. In this study we wanted to evaluate the association between circulating EPC and mortality in patients receiving hemodialysis.

Methods: We measured circulating EPC in 58 African American patients undergoing regular hemodialysis at one of the Emory University-affiliated Davita dialysis centers. We collected all-cause mortality data at a mean follow-up of 1182.53 days (SD=442.3). Cox proportional hazards models were used to analyze the association between EPC and patient survival time.

Results: At follow up 38% of patients died and 62% survived. Higher circulating EPC were associated with increased mortality. After controlling for gender, age, diabetes mellitus, dialysis vintage, and erythropoetin weekly dose, the association remained significant.

Estimated hazard ratio (95% confidence interval) for one unit increase in each EPC type, after controlling for gender, age, diabetes, dialysis vintage, and erythropoetin weekly dose. The outcome variable is the survival time.

EPC type	HR (95% CI)	P value
CD34+	1.74 (1.16,2.59)	0.007
CD34+/CD45 med	1.76 (1.17,2.64)	0.007
CD34+/CD133+	2.19 (1.22,3.94)	0.009
CD34+/CD133+/ CD45 med	2.20 (1.21,4.02)	0.010
CD34+/VEGF2R+/CD45 med	1.00 (0.34,2.97)	0.999
CD34+/CD133+/ VEGF2R+/ CD45 med	0.84 (0.15,4.85)	0.851

Conclusions: In a limited sample of African-American dialysis patients, elevated EPC were associated with increased mortality. Unlike in cardiovascular studies, where elevated EPC are associated with better survival, it is possible that in dialysis patients there is a stimulation of EPC, with subsequent increased circulating level, but the EPC are dysfunctional and are therefore associated with increased mortality. More studies are needed to examine possible correlation between EPC function and outcome.

SA-PO641

Circulating Endothelial Cells Predict Long-Term Cardiovascular Events and Survival in Hemodialysis Patients Rajesh Mohandas,[1] Mehmet Koc,[2] Xuerong Wen,[1] Mark S. Segal.[1] *[1]Division of Nephrology, Hypertension & Transplantation, University of Florida, Gainesville, FL; [2]Division of Nephrology, Marmara University School of Medicine, Istanbul, Turkey.*

Background: Circulating endothelial cells (CEC) are thought to be markers of endothelial injury and dysfunction. We hypothesized that the numbers of CEC may provide a novel means for predicting long-term cardiovascular events and survival in hemodialysis subjects who are known to be at markedly increased risk for cardiovascular disease.

Methods: Twenty-nine hemodialysis patients underwent a single enumeration of their CEC number. Patients were separated into two groups, a low CEC group (≤19 CEC/mL) and high CEC group (>19 CEC/ml). We retrospectively analyzed the survival and incidence of adverse cardiovascular events in these two populations. Survival was compared using Kaplan-Meier curves and the risk of adverse cardiac events using Multivariate Poisson Regression analysis.

Results: Baseline characteristics in both groups were not significantly different. In over 9 years of follow up, only 2 of the patients in the low CEC group had died of cardiovascular causes, as compared with 6 in the high CEC group. When controlled for diabetes and pre-existing CAD each 10 CEC/ml increase was associated with an 18% increased risk of adverse cardiovascular events during follow-up (P= 0.05).

Conclusions: In this hemodialysis population, a single measurement of CEC was an independent predictor of long term future adverse cardiovascular events and survival. CEC number at baseline had better predictive value than diabetes, hyperphosphatemia, low albumin and other known risk factors. CEC may be a novel and relatively inexpensive biomarker to assess endothelial health and cardiovascular risk. Further studies in a larger cohort are needed to investigate the utility of CEC in predicting cardiovascular isk.

SA-PO642

Effect of Membrane Permeability on Cardiovascular Risk Factors and B2m Plasma Levels in Patients on Long Hemodialysis: A Randomized Cross-Over Trial Charles Chazot,[1] Judith Kirchgessner,[2] Tieu Duyen Chung,[2] Cyril Vo-van,[1] Jean-marc Hurot,[1] Christie Lorriaux,[1] Guillaume Jean,[1] Daniele Marcelli.[2] *[1]NephroCare Tassin-Charcot, Sainte Foy Les Lyon, Rhone Alpes, France; [2]Fresenius Medical Care, Bad Homburg, Germany.*

Background: Mortality of HD patients is mainly of cardiovascular origin related to traditional and non traditional risk factors. Also, long-hour dialysis and Beta2-microglobulin (B2m) are related to patient survival. We have evaluated the effects of both session length and membrane flux on CV risk factors and B2m plasma levels.

Methods: One hundred and sixty-eight patients were included in a randomized cross-over trial. Patients were split in 2 groups (5-6 hours - Group 1 - and 7-8 hours -Group 2). The 2 groups were assigned randomly and consequently to a low-flux and a high-flux 9-months period (Period 1 and 2).

Results: 155 patients started the study after the run-in phase. Age, gender, BMI and vintage were not different according to the flux periods. 83 patients ended the whole study. No difference was found regarding Lpa, homocystein, LDL and HDL cholesterol between groups and periods of treatment. B2M was in average 39.0±11.8 and 46.5±10 mg/L respectively in Group 1 and 2 at the end of the low flux period. Independently of treatment time and sequence, B2m was significantly lower at the end of the high flux phase (respectively at 26.9±7.8 and 27.8±4.3 mg/L in Group 1 and 2, p<0.0001). Phosphate and the CaxP product were significantly lower at the end of the high-flux period (respectively p=0.045 and p=0.009), but nPCR decreased under high flux filter (p=0.0025). Triglycerides levels presented a trend to decrease under high flux filter (p=0.067). There was a statistical trend for more deaths during low flux treatment (13 versus 5, p=0.071).

Conclusions: Hence there was no influence of high-flux filters on several traditional CV risk factors in a HD patients treated with extensive treatment time. Treatment time is not enough to reach the targets of B2m and high flux filters are necessary to optimize the middle molecules clearance.

SA-PO643

Impact of Frequent Hemoglobin Measurement and ESA Dose Titration on Hemoglobin Stability in Dialysis Lynda A. Szczech,[1] William G. Harrison,[2] Alex Yang.[3] *[1]PPD, RTP, NC; [2]ZS Associates, San Francisco, CA; [3]Affymax, Inc., Palo Alto, CA.*

Background: Recent changes in the clinical landscape in ESRD have highlighted a lack of evidence surrounding the frequency of Hb monitoring and ESA dose changes. Using patient (pt) data from a large US dialysis provider, we evaluated the relationship between frequency of Hb measurement, epoetin dose titrations and use, and Hb stability.

Methods: Dialysis facilities were split into cohorts based on 1) Hb measurement frequency (<2, ≥2 to <3, or ≥3 measurements/pt-month), or 2) titration frequency (<0.8, ≥0.8 to <1.2, or ≥1.2 titrations/pt-month). Proportion of dose changes across cohorts (up/down titration or dose hold) was compared.

Results: Across 1630 dialysis facilities (N=141,631 pts) in 2010, 5.8%, 58.5%, and 35.7% averaged <2, 2 to <3, and ≥3 Hb measurements/pt-month, respectively. Demographics, comorbidities, hospital admission/duration, albumin, and ferritin were similar across all groups. Proportion of changes in ESA dose and Hb stability is described.

	Hb Measurements				Titration Frequency		
	<2	≥2 to <3	≥3		<0.8	≥0.8 to <1.2	≥1.2
No. facilities, n	94	954	582		170	1030	430
Mean Hb measurements/pt-month	1.8	2.5	3.6		NA	NA	NA
Mean dose titrations/pt-month[1]	0.8	1.0	1.2		0.6	1.0	1.4
- Up, %	42	44	41		42	41	43
- Down, %	40	39	41		41	41	35
- Holds[2], %	18	17	18		17	18	23
Mean epoetin use, U/pt-month	58K	69K	72K		54K	69K	75K
Hb stability (pts w/Hb 10-12 g/dL), %	59.9	59.9	61.8		61.6	61.0	62.1
Hb variability (mean SD), g/dL	0.72	0.72	0.73		0.73	0.73	0.71

[1] ≥10% change in consecutive doses; [2] ≥3 consecutive sessions with zero dose

Evaluation of a subset of facilities (n=19 facilities, 1461 pts) with the least variability in twice-monthly Hb measurements per pt (avg 2 Hb measurements/pt-month; SD ±0.5) demonstrated a similar trend in association of titration frequency with epoetin use, with no effect on Hb stability or variability.

Conclusions: Across facilities, increased Hb measurement frequency was associated with greater frequency of ESA dose titration, which was, in turn, associated with higher rate of dose holds. Increased frequency of Hb measurements and titrations were both associated with greater epoetin use, but neither was associated with a greater percentage of pts in goal Hb range.

Time-Dependent Modeling of Mortality Benefits of Statins in Dialysis Patients Theresa I. Shireman,[1] Milind A. Phadnis,[1] James B. Wetmore,[1] Sally K. Rigler,[1] Qingjiang Hou,[1] John Spertus,[2] Jonathan D. Mahnken.[1] *[1]University of Kansas Medical Center, Kansas City, KS; [2]Mid-America Heart Institute, Kansas City, MO.*

Background: Cardiovascular disease is a leading cause of death in patients with end-stage renal disease (ESRD). The role of HMG-CoA reductase inhibitors (statins) in the prevention of cardiovascular events in ESRD patients on dialysis is uncertain. Despite the completion of three randomized clinical trials (RCTs) in dialysis patients, the efficacy of statins in reducing mortality or cardiovascular events has not been definitively established. This was unexpected, given two earlier observational studies that had suggested a survival benefit of statins in this population.

Methods: We developed a novel time-dependent model of statin exposure to determine whether they confer survival benefits in dually eligible Medicare-Medicaid ESRD patients. We linked Medicaid pharmacy claims with data from the USRDS core files and Medicare institutional and physician/supplier service claims and selected a cohort of ESRD patients initiating dialysis between 1/1/2000 to 9/30/2005. We followed the cohort until their date of death, loss of eligibility, or 12/31/2005. Medication exposure was defined with three time-dependent covariates: current weekly drug availability (per days supply from claims), cumulative percentage of weeks with a medication available (compliance), and cumulative number of weeks where drug availability switched (available vs not available). Models were adjusted for demographic, functional status, and comorbidity covariates. We used a Cox proportion hazards model with time-dependent covariates including a three-way interaction between the medication exposure measures.

Results: The final sample included 76,372 ESRD patients. Statin compliance and switches were not significant in the final models. The adjusted hazard ratio (AHR) for time-dependent statin use = 0.547 (99% confidence interval, 0.526-0.569).

Conclusions: In this cohort study of new dialysis patients, weekly statin availability was associated with a substantial decline (45.3%) in mortality, suggesting that current statin use is more important than cumulative use.

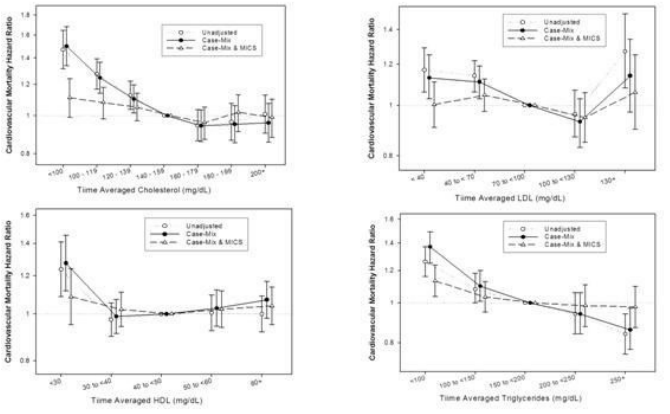
Hypercholesterolemia and Hypertriglyceridemia Are Associated with Better Survival in Hemodialysis Patients Hamid Moradi,[1] Elani Streja,[2] Hamid M. Said,[1] Madeleine V. Pahl,[1] Nosratola D. Vaziri,[1] Kamyar Kalantar-Zadeh.[2,3] *[1]Medicine, University of California, Irvine, Orange, CA; [2]Harold Simmons Center, LA BioMed, Harbor-UCLA, Torrance, CA; [3]Medicine, University of California, Los Angeles, Los Angeles, CA.*

Background: Lipid levels are inversely associated with mortality in maintenance hemodialysis (MHD) patients, a group at high risk for cardiovascular (CV) mortality. We hypothesized that this association would persist despite adjustment for malnutrition-inflammation complex (MIC), body mass index (BMI), serum calcium and phosphorus.

Methods: A 2 year cohort (July 2004 through June 2006) of 32,278 MHD patients was studied in the United States from DaVita dialysis clinics where lipid profiles were measured in at least 50% of all outpatients during a given calendar quarter. Cox proportional hazard models were adjusted for case mix and surrogates of MIC, BMI, calcium and phophorus.

Results: The 32,278 patients were 60 ± 15 years old and included 46% women. Increases in both total cholesterol and triglycerides were associated with an improvement

in survival. LDL level <100 > 130 mg/dL were associated with increased CV mortality therefore indicating a U shaped association. While serum HDL cholesterol <30 mg/dL was associated with an increased risk of death, HDL level greater than 60 mg/dL did not have any clear association with better survival.



Conclusions: The inverse association of total cholesterol and triglyceride levels with mortality in MHD patients persists despite adjustment for MIC, BMI, plasma calcium and phosphorus. While low LDL levels are associated with an increased risk of CV mortality, high LDL levels (>130 mg/dL) also increased risk of death in MHD patients. Furthermore, low HDL levels are associated with an increased risk of death however higher plasma HDL levels (>60 mg/dL) are not associated with improved survival.

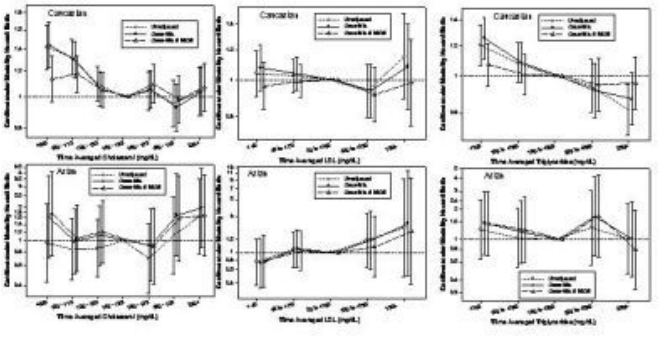
SA-PO646

Impact of Race and Ethnicity on the Association of Lipids with Mortality in Dialysis Patients Hamid Moradi,[1] Elani Streja,[2] Madeleine V. Pahl,[1] Keith C. Norris,[3] Nosratola D. Vaziri,[1] Kamyar Kalantar-Zadeh.[2,3] *[1]Medicine, University of California, Irvine; [2]Harold Simmons Center, Harbor-UCLA; [3]Medicine, University of California, Los Angeles.*

Background: Lipid levels are inversely associated with cardiovascular mortality (CV) in maintenance hemodialysis (MHD) patients. We examined the association of lipids with cardiovascular (CV) mortality in African American (AA), Hispanic and Asian MHD patients.

Methods: A 2 year cohort (July 2004 - June 2006) of 32,278 MHD patients was studied in U.S. DaVita dialysis clinics where lipid profiles were measured in at least 50% of all patients during a given calendar quarter. Cox proportional hazard models were adjusted for case mix and surrogates of malnutrition-inflammation complex.

Results: The 32,278 patients were 60±15 years old with 46% women. Increases in both total cholesterol (TC) and triglyceride levels were associated with improved survival in all groups except Asians in whom TC <140 and >200 mg/dL was associated with increased CV mortality. LDL level <70 and > 130 mg/dL was associated with increased mortality in all groups except Asians in whom CV mortality increased with higher LDL levels. In Caucasian patients, serum HDL cholesterol <30 mg/dL was associated with increased CV mortality, while in AA and Hispanic patients there was no clear association with reduced HDL. In Asians both HDL <30 and > 60 mg/dL were associated with increased CV mortality.



Conclusions: There is an inverse association between total cholesterol and triglyceride levels and CV mortality in all MHD patients except for Asians. Also, elevated LDL cholesterol is associated with increased CV mortality in the Asian MHD population. While low HDL levels are associated with an increased risk of death in the Caucasian and Asian population, higher HDL levels (>60 mg/dL) are not associated with improved survival regardless of race or ethnicity.

SA-PO647

Long Chain n-3 Fatty Acids and Risk of Sudden Cardiac Death in Patients Starting Hemodialysis Allon N. Friedman,[1] Zhangsheng Yu,[1] Rebeka Tabbey,[1] Cheryl Denski,[1] Hector Tamez,[2] Julia Beth Wenger,[2] Ravi I. Thadhani,[2] Yong Li,[3] Bruce A. Watkins.[3] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Massachusetts General Hospital, Boston, MA; [3]University of Connecticutt, Storrs, CT.*

Background: Sudden cardiac death is the single leading cause of mortality in hemodialysis patients and occurs at an exceptionally high rate. No treatment for this problem currently exists. Experimental and clinical evidence suggests that long chain n-3 fatty acids are protective against sudden cardiac death. It is unclear whether such a protective relationship exists in the hemodialysis population, and if so, whether it applies to the early high-risk period after initiating hemodialysis.

Methods: We conducted a nested case-control study using 100 patients who died of sudden cardiac death during the first year of hemodialysis and 300 patients who survived that period. Groups were frequency matched by age, sex, and race. Baseline serum phospholipid fatty acids were measured in stored samples by gas chromatography.

Results: Long chain n-3 fatty acids were inversely related to the risk of sudden cardiac death even after adjusting for relevant co-morbid conditions, biochemical values, and dietary fats (P<0.003). As compared to the lowest quartile of long chain n-3 fatty acids, the 1-year hazard of sudden cardiac death was 50% (95% confidence interval: 0.28 to 0.90%), 70% (0.15 to 0.62%), and 71% (0.13 to 0.69%)) lower for the third, second, and highest quartiles, respectively. Moreover, the inverse relationship between long chain n-3 fatty acids and sudden cardiac death was maintained even during the highest-risk first few months after starting hemodialysis.

Conclusions: Blood long chain n-3 fatty acid levels, which are easily modifiable by dietary supplementation, are strongly associated with a reduced risk of sudden cardiac death in hemodialysis patients throughout the first year after starting hemodialysis.

SA-PO648

Uremic Dyslipidemia and Arterial Stiffness in Hemodialysis Patients R. Filipowicz,[1] Alfred K. Cheung,[1,2] T. Alp Ikizler,[3] Y. Zhang,[1] Tom Greene,[1] T. S. Bjordahl,[1] A. N. Habib,[1] G. Wei,[1] S. Beddhu.[1,2] *[1]U of Utah, Salt Lake City, UT; [2]SLCVHA, Salt Lake City, UT; [3]Vanderbilt Univ, Nashville, TN.*

Background: Uremic dyslipidemia is characterized by ↓ plasma high density-lipoprotein cholesterol (HDL-C) and increased triglycerides (TG) levels, which are potentially atherogenic and increased arterial disease in hemodialysis (HD) patients (pts). We examined the associations of fasting plasma TG, HDL-C, total cholesterol (TC) and low density-lipoprotein cholesterol (LDL-C) levels with arterial stiffness as assessed by aortic pulse wave velocity (PWV) in the ongoing Protein Intake, CVD and Nutrition In CKD stage V (PICNIC) Study.

Methods: Fasting lipids were measured in non-HD day plasma samples. PWV was measured using carotid and femoral pulses with a Sphygmacor PVX. Baseline and 12-month follow-up PWV were related to baseline lipids in separate linear regression models. Average of baseline, 6 and 12 month PWV values were also related to baseline lipids using generalized estimating equations.

Results: 116 participants with baseline lipids collected were included in the analysis. Mean age was 52 ± 16 yrs; 41% were women, 20% were Black, 48% had DM, 27% had CAD, 23% had PVD, and 22% had CHF. Mean baseline TG, HDL-C,TC and LDL-C levels were 144 ± 75, 43 ± 15, 149 ± 35 and 77 ± 30 mg/dL, respectively. Mean PWV were 9.8 ± 3.4, 10.3 ± 3.8 and 10.2 ± 3.4 m/s at baseline, 6 and 12 months, respectively.

Associations * of fasting plasma lipid levels with aortic PWV

	Baseline PWV (m/s)	12 mo PWV (m/s)	Baseline, 6 and 12 mo PWV (m/s)
	β (95%, CI)	β (95%, CI)	β (95%, CI)
Model 1			
For each ↑ SD TC (mg/dL)	-0.10 (-0.65, 0.46)	0.05 (-0.81, 0.91)	-0.13 (-0.56, 0.30)
Model 2			
For each ↑ SD HDL-C (mg/dL)	-0.30 (-1.06, 0.45)	-0.25 (-1.26, -0.76)	-0.17 (-0.72, 0.38)
For each ↑ SD TG (mg/dL)	-0.02 (-0.67, 0.63)	0.03(-0.97, 1.03)	-0.08 (-0.41, 0.57)
For each ↑ SD LDL-C (mg/dL)	-0.03 (-0.60, 0.53)	0.12 (-0.79, 1.03)	- 0.12 (-0.56, 0.31)

*Adjusted for demographics, vascular access, vintage, smoking, DM, BP, serum Ca and P and study site.

Conclusions: In 12 month this study, uremic dyslipidemia was not appear to be associated with arterial stiffness. Further studies are warranted to determine whether Rx of uremic dyslipidemia will impact CV events or mortality in HD pts.

Regulation of CD36 Expression on Monocytes of Dyslipidemic Hemodialysis Patients Alicja E. Grzegorzewska,[1] Leszek Niepolski,[2] Jan Sikora,[3] Pawel P. Jagodzinski,[4] Dominik Pajzderski.[1] *[1]Dpt. of Nephrology, Poznan University of Medical Sciences (UMP); [2]B.Braun Avitum Dialysis Centre, Nowy Tomysl; [3]Dpt. of Clinical Immunology, UMP; [4]Dpt. of Biochemistry and Molecular Biology, UMP, Poland.*

Background: Role of CD36 receptor in the development of atherosclerosis and atorvastatin effect on CD36 are not clear. Our aim was to check how amelioration of serum lipids with therapeutic lifestyle changes (TLC) or atorvastatin influences monocyte CD36 expression in dyslipidemic hemodialysis (HD) patients.

Methods: HD patients (n=49), dyslipidemic according to KDOQI (2003) and not taking lipid lowering drugs, were enrolled into the prospective study started with 4 week education in low-fat diet and physical activity. In 34 persons, still dyslipidemic after 21 TLC weeks, atorvastatin (10 mg/d) was added for 4 weeks. Patients' evaluation was done after 4, 8, 18, 25, and 29 weeks from the study beginning. CD36 expression was measured as mean fluorescence intensity by flow cytometric analysis, serum salusin-alpha - by RIA.

Results: LDL-Ch decreased (141±56 vs 116±27 mg/dL, p=0.009), HDL-Ch (38.6±9.9 vs 44.2±10.3 mg/dL, p=0.001) and CD36 expression increased (1,387±899 vs 2,064±1,256, p<0.001) during TLC. CD36 correlated with total Ch (r= -0.359, p=0.020), LDL-Ch (r= -0.354, p=0.022), non-HDL-Ch (r= -0.345, p=0.025), anti-atherogenic salusin-alpha (r=0.392, p=0.007), arm circumference (r= -0.312, p=0.044), and triceps skinfold (TSF) thickness (r= -0.477, p=0.001). Patients with CD36 expression >1,000 showed higher chance for total Ch <200 mg/dL and non-HDL-Ch <160 mg/dL (for both OR 10.6, 95% CI 2.51–45.0). Patients with TSF thickness <12 mm had higher probability for CD36 >1,000 (OR 5.20, 95% CI 1.37–19.8). CD36 expression, lower than in controls before atorvastatin (1,152±631 vs 1,650±840, p=0.015), increased with the drug-induced amelioration in serum lipids to 1,365±870, p=0.028.

Conclusions: In dyslipidemic HD patients CD36 expression upregulates in response to changes in serum cholesterols induced by TLC or atorvastatin, and depends on fat depot. Our results support the concept designated monocyte CD36 expression as an anti-atherogenic factor. ClinicalTrials.gov ID NCT01448174.

Whole-Genome Expression Levels Associated with Cardiovascular Disease in End-Stage Renal Disease Patients Martin Schalling,[1] Karin Luttropp,[1] Bengt Lindholm,[2] Peter Stenvinkel,[2] Olivier Devuyst,[3] Louise Nordfors.[1,2] *[1]Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden; [2]Renal Medicine and Baxter Novum, Karolinska Institutet, Stockholm, Sweden; [3]Division of Nephrology, UCL Medical School, Brussels, Belgium.*

Background: Patients (pts) with end-stage renal disease (ESRD) are at increased risk of developing cardiovascular disease (CVD). Although the exact mechanisms responsible are unknown, persistent inflammation and oxidative stress may increase the vascular risk. Increased apoptosis in smooth muscle cells (SMC) has been associated with vascular calcification (VC), and the dialysis process itself may induce SMC apoptosis.

Methods: The material consisted of iliac artery (IA) and abdominal subcutaneous fat (ASCF) from 10 pts with ESRD. The pts were divided into matched pairs of 5 pts suffering from CVD (coronary artery calcification, CAC) and 5 pts without known CVD. Pts were matched for age, gender, diabetes, treatment modality, hypertension and previous history of CVD. Samples were collected during renal transplantation. Degree of VC was defined by Agatston score.RNA was prepared using Bio-Rad RNA preparation kit for fibrous tissue. Microarray analysis was performed using Illumina® HumanWG-6 v3.0 arrays. Statistical analysis was performed using limma and samr packages in BioConductor® software.

Results: The statistical analysis resulted in 378 and 252 significant genes for ASCF and IA respectively. Changes in ASCF ranged from 4.6-fold up-regulated, to 2.7-fold down regulated in patients with CVD compared to those without CVD. In IA, fold changes ranged from 2.4-fold upregulated, to 2.4-fold down-regulated in pts with CVD. False discovery ratios (FDR) were below 13 % in ASCF, and below 10 % in IA. The expression of genes involved in pathways regulating apoptosis was up-regulated in ESRD pts with CVD; these candidate genes are now the focus of further studies.

Conclusions: We identified genes whose expression levels differed between ESRD patients with and without VC. These genes may indicate pathways and molecular mechanisms associated with CVD in ESRD. Interestingly, our results indicate that the process of apoptosis is important in the development of VC in ESRD.

The Impact of Different Comorbidity for Survival Analyses in Dialysis Patients: A Long-Term Population-Based Study Wei-Chih Kan,[1] Chih-Chiang Chien,[1] Yi-hua Lu.[1] *[1]Nephrology, Chi-Mei Medical Center, Tainan, Taiwan; [2]Chi-Mei Medical Center; [3]Chi-Mei Medical Center.*

Background: The global prevalence and incidence of end-stage renal disease has been rapid-increasing annually. However, the risk factors for mortality and long-term survival between hemodialysis (HD) and peritoneal dialysis (PD) appear to be inconclusive. This study aims to investigate the risk factors that impact on mortality among dialysis patients.

Methods: We conducted an observational cohort study to investigate the impact of underlying comorbidities on long-term outcome of dialysis patients in Taiwan. Several risk factors possibly affecting mortality were analyzed. Survival rates of different groups were also compared.

Results: In all, 5683 HD patients and 302 PD patients were enrolled for analysis. Patients who selected PD tended to be younger and less likely to have baseline comobidities compared to those on HD. The percentage of diabetes mellitus (DM) is much lower in PD patients (36.8%) than in HD patients (53.1%). The prevalence of hypertension (HTN) was 75.5% in HD patients and 64.2% in PD patients. In HD patients, mortality risk increased with older age, DM, HF, CAD, stroke, peripheral vascular disease (PVD) and liver cirrhosis (LC). In PD patients, mortality risk increased with older age and DM. The cumulative survival rate among HD patients was 95.7% at one year, 66.2% at five years and 44.3% at nine years; that among PD patients was 95.8% at one year, 66% at five years and 50.4% at nine years. There was no statistically difference between HD and PD patients (log-rank: P = 0.398). However, the survival became different after stratification by DM/non-DM. For non-DM patients, the survival rate was higher on PD than HD group; in contrary, higher survival rate was found in HD group among DM patients (log-rank: P<0.001).

Conclusions: Our findings show that each comorbidity had different impact on long-term survival among dialysis patients. Older age and DM were strong predictors for mortality whether in HD or PD patients. There was no statistically difference in long-term survival between HD and PD patients from our study.

SA-PO652

Trade-Offs in Claims-Based Comorbidity Identification with Early Loss of ESRD Patients: Adaptation of the Liu Comorbidity Index James B. Wetmore,[1] Sally K. Rigler,[4] Jonathan D. Mahnken,[2] Qingjiang Hou,[2] Theresa I. Shireman.[3] *[1]Division of Nephrology, University of Kansas Medical Center, Kansas City, KS; [2]Department of Biostatistics, University of Kansas Medical Center, Kansas City, KS; [3]Preventive Medicine & Public Health, University of Kansas Medical Center, Kansas City, KS; [4]Medicine, University of Kansas Medical Center, Kansas City, KS.*

Background: Claims-based comorbidity indices are widely used in observational studies. In 2010, Liu et al. published a new comorbidity index for use in USRDS studies which combines information from the baseline Medical Evidence Form (CMS 2728) with Medicare claims incurred during six months of chronic dialysis. Given the high mortality rate in incident dialysis patients, Liu's six month claim capture period, while resulting in high sensitivity for comorbidities, could lead to a survivor bias as well as smaller samples with reduced generalizability.

Methods: We examined potential trade-offs between the original 180-day versus a 90-day claim capture period. We selected persons initiating dialysis with continuous Medicare and Medicaid eligibility during the first 90 days. We computed a Liu original index using 180 days of Medicare claims (starting with 90-day survivors, and continuing on to day 270) and compared it to a modified Liu Index which used only the initial 90 days after initiating dialysis with continuous Medicare coverage.

Results: There were 70,114 persons with complete data. The original Liu Index could be computed for only 52,937, demonstrating a 25% reduction in sample size resulting from the stipulation that patients survive a full 270 days. The Modified Liu score using only the first 90 days of dialysis was 7.3 ± 4.0, but when limited to only those who would have survived the full 270 days required of the original Liu Index, the mean score on the modified index was 6.4 ± 3.6 points. This mean difference of 0.98 ± 2.8 points represents only a 12% reduction from the original score.

Conclusions: This modified approach allows inclusion of 25% more subjects and permits initiation of outcome measure ascertainment from day 91, thereby reducing survivor bias.

SA-PO653

The Impact of Advancing Age on Coronary Disease Prevalence and Associated Mortality in End Stage Kidney Disease Liam F. Casserly,[1] Cornelius John Cronin,[1] Ailish Hannigan,[2] Austin G. Stack.[1,2] *[1]Nephrology and Medicine, University Hospital Limerick, Ireland; [2]Graduate Entry Medical School, University of Limerick, Ireland.*

Background: Coronary disease and advancing age are both independent risk factors for death on dialysis. The impact of age on coronary disease prevalence and associated mortality is unclear although it is postulated that the mortality risks increase with advancing age. The purpose of this study was to determine the contribution of age to disease prevalence and associated mortality in national cohort.

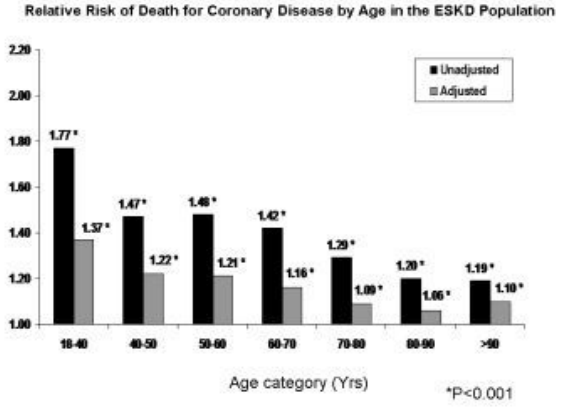
Methods: National incidence data on all new dialysis patients (N=823, 753), between May 1995 and December 2004 and followed until October 2006, were analysed from the U.S. Renal Data System. Age specific prevalence and 1-year mortality rates were determined for each of 7 age groups (18-40, 40-50, 50-60, 60-70, 70-80, 80-90 and > 90) and relative hazard ratios (RR) were calculated for those with and without coronary disease using multivariable Cox regression. All analyses were adjusted for 21 demographic, clinical, socioeconomic and laboratory indicators.

Results:

Prevalence of Coronary Disease by Age Group and Age-specific Death Rates

Age Group Category (Years)	18-40	40-50	50-60	60-70	70-80	80-90	90
Coronary disease (%) *	1.2	4.6	14.2	27.3	35.5	16.3	1.0
Age specific death rates (per 1000 person years)							
Coronary disease (n=222,221) *	158	178	229	338	496	701	1074
No coronary disease (n=601,532) *	89	121	155	237	383	582	893

*P<0.001



The hazard of death for coronary disease was modelled separately in each age category *P<0.001.

Conclusions: The prevalence of coronary disease increased with advancing age up to the seventh decade and declined thereafter. Mortality impact was greatest for younger compared to older patients. Whether this reflects age differences in rates of disease detection and/or severity; patient compliance or use of interventional strategies needs further evaluation.

SA-PO654

Impaired Chronotropic Response Limits Exercise Tolerance in Peritoneal Dialysis and Renal Transplant Patients Maggie Kam Man Ma,[1] David Chung Wah Siu,[1] Wai Kei Lo,[2] Desmond Y.H. Yap,[1] Daniel Tak Mao Chan.[1] *[1]Department of Medicine, Queen Mary Hospital, Hong Kong; [2]Department of Medicine, Tung Wah Hospital, Hong Kong.*

Background: Chronotropic incompetence (CI), defined as blunted increase in heart rate (HR) during exercise, has been accepted as an independent predictor of cardiovascular mortality. Little is known about its prevalence in peritoneal dialysis (PD) and renal transplant (RT) patients. This study aimed to investigate the prevalence of CI and its relationships with exercise intolerance in these patients.

Methods: Ambulatory PD and RT patients were recruited for treadmill stress test using modified Bruce protocol. Exercise duration and HR response was recorded. Maximum age-predicted HR was defined as (220-age). Heart rate reserve was defined as difference between peak heart rate achieved during exercise and resting heart rate. Chronotropic response (CR) to exercise was evaluated by the percentage of heart rate reserve ([peak HR-resting HR/maximal age predicted HR-resting HR]x100%).

Results: 86 patients (mean age 51.72±8.78 years, male 53.5%) were included in this study. RT patients had significantly longer exercise duration than PD patients (10.01±3.59 min Vs 6.26±3.16 min, P=0.000). Both PD and RT patients demonstrated blunted HR response to exercise. PD patients had significantly lower maximum heart rate than RT patients (75.34±13.67% Vs 86.57±23.56% of age-predicted HR respectively, p=0.009). CR was also significantly lower in PD than RT patients (58.64±24.11% Vs 79.73±43.54%, p=0.008). CI (i.e. CR<80%) was noted in 28 (64%) PD and 15 (36%) RT patients respectively.

Exercise Testing Measurements in PD and RT Patients

	RT(n=42)	PD(n=44)	P
Baseline HR	70.90±10.18	71.48±14.41	0.83
Peak HR	146.76±36.73	128.93±23.98	0.009
Rest sBP	137.62±20.38	143.86±20.54	0.163
Rest dBP	85.50±10.15	73.00±11.57	0.000
Treadmill time (min)	10.01±3.59	6.26±3.16	0.000
% maximum age predicted HR	86.57±23.56	75.34±13.67	0.009
HR reserve	75.85±34.34	57.09±26.84	0.007
CR (%)	79.73±43.54	58.64±24.11	0.008
CI(CR<80%), n(%)	15(36)	28(64)	0.01

Conclusions: Chronotropic incompetence was more prevalent in PD than RT patients and such difference might account for the discrepancy in their exercise tolerance.

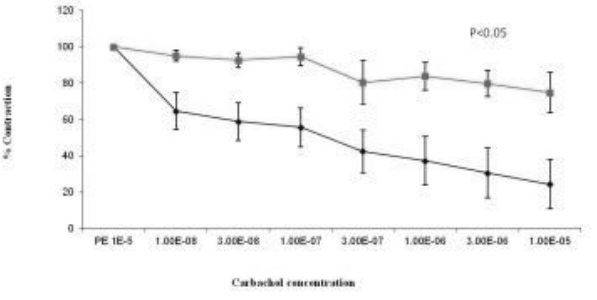
Phosphate Has Deleterious Effects on Vascular Function Kathryn K. Stevens,[1,2] Rajan K. Patel,[1,2] Sarah Kettlewell,[1] Marc J. Clancy,[2] Christian Delles,[1] Godfrey L. Smith,[1] Alan G. Jardine.[1,2] *[1]ICAMS, University of Glasgow, Glasgow, United Kingdom; [2]Renal Unit, Western Infirmary, Glasgow, United Kingdom.*

Background: Elevated serum phosphate is a risk factor for cardiovascular disease. Whether this is a direct effect of phosphate is unknown. We examined the effects of phosphate in human resistance vessels and human umbilical vein endothelial cells (HUVECs).

Methods: Adipose tissue was removed from CKD patients undergoing live donor transplantation and their normal donors. Resistance vessels were dissected and incubated in normal (1.18mM) or high phosphate concentration (2.5mM) solution for 16 hours, then mounted on a myograph. Vasoconstrictor response to phenylepherine (PE) and vasorelaxation responses to carbachol and sodium nitroprusside (SNP) were measured. Concentration-response curves were constructed. HUVECs were grown in normal (0.5mM) and high (3mM) phosphate medium. We measured superoxide production (electron paramagnetic resonance spectroscopy), eNOS and nitrotyrosine expression (Western blot) and intracellular calcium concentration (epifluorescence).

Results: Vessels from patients with and without CKD incubated in high phosphate relax less well to carbachol (p<0.05).

Figure 1: Relaxation of human vessels from patients with CKD to increasing concentrations of carbachol. Vessels incubated in high (pink) and normal (blue) phosphate concentration media.



Vessels from patients without CKD also relax less well to SNP (p<0.05). HUVECs grown in high phosphate produce more superoxide (p<0.05), have reduced expression of eNOS and increased expression of nitrotyrosine. Calcium concentration was similar between HUVECs in high and normal phosphate.

Conclusions: Elevated phosphate decreases endothelium dependent vasodilatation in patients with and without CKD. This may be a marker of endothelial dysfunction, (reduced eNOS and increased nitrotyrosine expression and increased suproxide production in HUVECs). Endothelial independent relaxation is also impaired in patients without CKD. These experiments support the notion that phosphate has direct effects in uremia.

SA-PO656

Directly Toxic Effect of Phosphate on the Vasculature Can Be Reversed by Zaprinast Kathryn K. Stevens,[1,2] Rajan K. Patel,[1,2] Sarah Kettlewell,[1] Christian Delles,[1] Godfrey L. Smith,[1] Alan G. Jardine.[1,2] *[1]ICAMS, University of Glasgow, Glasgow, United Kingdom; [2]Renal Unit, Western Infirmary, Glasgow, United Kingdom.*

Background: Hyperphosphataemia is a risk factor for cardiovascular disease; whether this is a direct effect of phosphate is unknown. This study looks at the effect of phosphate on vessels and smooth muscle cells (SMCs) and endothelial cells (ECs).

Methods: Mesenteric resistance vessels were dissected from WKY rats and incubated in physiological saline solution (PSS) with normal (1.18mM) or high phosphate concentration (2.5mM) for 16 hours. Vessels were mounted on a myograph and vasoconstriction response to phenylepherine (PE) and vasorelaxation response to carbachol and sodium nitroprusside (SNP) were measured ± phosphodiesterase 5 inhibitor (zaprinast). Concentration-response curves were constructed for PE, carbachol and SNP ±zaprinast. Area under the curve was calculated. SMCs and ECs were grown in normal (0.5mM) and high (3mM) phosphate medium. Western blot was performed for eNOS and protein kinase G (PKG) expression. Calcium concentration was measured by epifluorescence.

Results: Vessels incubated in high phosphate relax less well to carbachol and SNP (max relaxation 95.7% vs 61.6% and 85% vs 43%, $p<0.05$). The addition of zaprinast improved relaxation response to carbachol and SNP in both high and normal phosphate PSS. This was most marked in vessels in high phosphate (improvement of 22.9% (carbachol) $p<0.05$) resulting in no difference in relaxation response to carbachol and SNP between vessels in normal and high phosphate. Expression of eNOS was unchanged in SMCs but reduced in ECs grown in high phosphate. PKG expression was lower in SMCs grown in high phosphate. Calcium concentration was not significantly different between either SMCs or ECs grown in high and normal phosphate.

Conclusions: Elevated phosphate impairs endothelium dependent and independent vasorelaxation. The mechanism may relate to reduced available nitric oxide (reduced eNOS) and reduced cGMP production/guanylate cyclase expression (reduced PKG) in vascular SMCs. Zaprinast reduces cGMP breakdown and corrects the impaired vasorelaxation. Elevated phosphate, one aspect of the uraemic environment, has direct effects on vascular cells and function.

GYY4137 Inhibit the Transdifferentiation of Human Vascular Smooth Muscle Cell Induced by Phosphorus

Ping Wen, Junwei Yang. *Center for Kidney Disease, 2nd Affiliated Hospital, Nanjing Medical University.*

Background: Vascular calcification is one of the major pathogenic factors for cardiovascular complication in patients with chronic kidney diseases (CKD). Accumulated evidences suggested that vessel smooth muscle cells (VSMC) to osteoblast-like cells transdifferentiation (VOT) plays a crucial role in promoting vascular calcification. Therefore, Targeting VSMA VOT may ameliorate vascular calcification and reduce the incidence of cardiovascular event in CKD patients. H_2S is now recognized as a gas playing an important role in ameliorating vascular calcification induced by vitamin D_3 plus nicotine in rats. However, the clinical usage of H_2S is limited due to its gas feature. that GYY4137 was recently reported to releases H_2S slowly both *in vitro* and *in vivo,* which may mimic the biological effect of H_2S. Thus, the protective role of GYY4137 on inhibiting VSMC VOT and vascular calcification was investigate in this study.

Methods: The human VSMCs were treated with phosphorus (3.0mM, 4.5mM), bmM, 100mM, 150ma and Cbfa-1, known as marker of VSMCs and osteoblasts respectively, bone morphogenetic protein (BMP)-2 and OC were tested by Western Blotting. mRNA expression of Cbfa-1, BMP-2, osteoponin (OPN) and collagen I were detected by RT-PCR.

Results: 1) Both mRNA and protein expressions of Cbfa-1, BMP-2 and OC were markedly induced in VSMC treated with phosphorus or b-glycerophosphoric acid, while protein level of SM-22a was diminished. 2) GYY4137 inhibited the expression of BMP-2 and OC induced by phosphorus, but exhibited no effect on Cbfa-1 expression. The down-regulation of SM-22a induced by phosphorus could be partially restored by GYY4137.

Conclusions: Our study confirmed that both inorganic phosphorus and donor of phosphorus stimulated VSMC transdifferentiating to osteoblast-like cells, represented by *de novo* synthesis markers of osteoblast and losing markers of VSMC. GYY4137, a donor of H_2S, provided beneficial effects against VSMC phenotypic modulation induced by phosphorus but the precise mechanisms need to be explored in depth.

Magnesium Reduces Vascular Calcification in Uremic Rats

Alan Peralta-Ramírez,[1] Juan R. Muñoz-castañeda,[2] Maria Encarnacion Rodriguez Ortiz,[2] Carmen Herencia,[2] Carmen Pineda,[3] Julio Manuel Martínez Moreno,[2] Fatima Guerrero,[3] Sayda Perez Delgado,[1] Mirjam Peter,[5] Sonja Steppan,[5] Jutta Passlick-Deetjen,[6] Ignacio Lopez,[3] Escolastico Aguilera-tejero,[3] Yolanda Almaden Peña,[2] Mariano Rodriguez.[2] *[1]Veterinary School UNAN-León, Nicaragua; [2]Univ Hospital Cordoba, Spain; [3]Veterinary School Univ Cordoba, Spain; [4]Dpt Anatomy Univ Cordoba, Spain; [5]Fresenius Medical Care Deutschland GmbH; [6]Univ Düsseldorf, Germany.*

Background: Phosphate (P) binder containing magnesium (Mg) are used to reduce P absorption in chronic renal disease patients. However, the role of Mg in secondary hyperparathyroidism and vascular calcification (VC) is not completely known.

Methods: To evaluate Mg effects on VC, Wistar rats 5/6 nephrectomized (Nx) were fed with a high P diet (1.2%) and received calcitriol (CTR) i.p. on alternate days. Rats were randomly assigned to groups with different Mg diet content: 0.1%, 0.3%, 0.6% and 0.9%. Control healthy rats were fed normal P diet (0.6%) and 0.1% Mg. Urine was collected on 3 consecutive days to determine the excretion of P (UP/UCr). After 15 days animals were euthanized and plasma levels of ionized Ca (selective electrode), Mg, P, aortic Ca content (spectrophotometry) and PTH (ELISA) were measured.

Results: The results expressed as mean ± standard error are shown in the table.

	Plasma Mg (mg/dL)	Plasma iCa (mM/L)	Plasma P (mg/dL)	PTH (pg/mL)	Aortic Ca (mg/g tissue)	UP/UCr
Control	2.14 ± 0.06	1.17 ± 0.01	6.5 ± 0.29	21.36 ± 6.78	0.42 ± 0.03	0.68 ± 0.06
Nx+CTR+P+Mg 0.1%	2.66 ± 0.23	1.07 ± 0.03 (a)	10.65 ± 1.53 (a)	355.29± 146.42 (a)	33.39 ± 7.57 (a)	8.27 ± 2.38 (a)
Nx+CTR+P+Mg 0.3%	2.97 ± 0.19	1.19 ± 0.02 (a, b)	7.99 ± 0.81 (b)	267.62 ± 129.828 (a)	2.44 ± 0.80 (b)	6.69 ± 0.85 (a)
Nx+CTR+P+Mg 0.6%	3.31 ± 0.36 (a)	1.13 ± 0.03 (a)	7.95 ± 0.92 (b)	79.20 ± 45.65 (b)	1.07 ± 0.41 (b)	2.61 ± 0.66 (b)
Nx+CTR+P+Mg 0.9%	4.43 ± 0.36 (a, b)	1.11 ± 0.03 (a)	7.93 ± 0.55 (b)	22.64 ± 17.32 (b)	0.60 ± 0.17 (b)	1.97 ± 0.30 (b)

a: $P<0.05$ vs. control. b: $P<0.05$ vs. Nx+CTR+P+Mg 0.1%

Increased plasma Mg levels were accompanied by decreased levels of plasma P, PTH, aortic Ca and UP/Ucr.

Conclusions: An increase in diet Mg content decreased P, plasma PTH and also significantly reduced VC in uremic rats.

Association of Proton-Pump Inhibitor Use and Serum Magnesium

Jeffrey H. William, Kenneth J. Mukamal, John Danziger. *Department of Medicine, Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Despite the staggering number of U.S. prescriptions for proton-pump inhibitors (PPIs) and their numerous known adverse effects, only case reports that describe the association of hypomagnesemia and PPI use have been published. The FDA released a statement in March 2011 outlining the risk of low magnesium levels for long-term PPI users.

Methods: The MIMIC-II database, consisting of ICU patients from a large, urban academic medical center, was used. Pre-admission medications were determined using a Natural Language Processing (NLP) algorithm on discharge summaries. Sequential multivariate linear and logistic regressions were developed to assess whether acid-suppressive medications were related to serum magnesium.

Results: 2629 (23%) patients were on a PPI prior to admission. PPI use was associated with a 0.012 (±0.004) mg/dL lower serum magnesium concentration compared to users of no acid-suppressive medications ($p=0.003$). Among concurrent diuretic users, PPI use was associated with a 55% increase in the odds of hypomagnesemia (95% CI, 1.21-1.98) and a 0.030 (±0.008) mg/dL lower serum magnesium concentration ($p<0.001$). There was no association between PPI use and magnesium concentrations in those not on diuretics.

Abbreviations: Ref, reference category.
Reference category is those on no acid-suppressive medications.

*Hypomagnesemia was defined as a serum magnesium level <1.6 mg/dL.
‡A multiplicative interaction term between PPI and diuretic use was significant ($p<0.001$). A multiplicative interaction term between H2RA and diuretic use was also significant ($p=0.002$).

Conclusions: This is the first study to provide an analysis of PPI use and serum magnesium concentrations in a large population. Magnesium levels on admission were lower among PPI users, especially those concurrently on diuretics. The mechanism of PPI-induced hypomagnesemia may be related to compensatory upregulation of renal tubular magnesium reclamation in response to a negative total body balance. This net loss of magnesium could also explain the increased risk of hip fractures in PPI users described in the literature. Our findings verify initial case reports of hypomagnesemia in long-term PPI users and confirm another adverse effect of PPI use.

SA-PO660

The Relationship between Proton Pump Inhibitor Use and Serum Magnesium Concentration among Hemodialysis Patients

Sharon Nessim,[1] Catalina Hernandez,[3] Mark L. Lipman,[1] Ahsan Alam.[2] *[1]Division of Nephrology, Jewish General Hospital, McGill University, Montreal, QC, Canada; [2]Division of Nephrology, Royal Victoria Hospital, McGill University, Montreal, QC, Canada; [3]McGill University, Montreal, QC, Canada.*

Background: It is known that serum magnesium (Mg) concentration is inversely related to vascular calcification and hyperparathyroidism among patients with end-stage renal disease (ESRD). In recent years, there have been several case reports of hypomagnesemia due to the use of proton-pump inhibitors (PPI), attributed to inappropriate gastrointestinal (GI) Mg loss. We hypothesized that the tendency to GI Mg loss among PPI users is more common than is currently reported. Since patients on dialysis have little to no renal Mg loss to alter Mg balance, they are an interesting population in whom to study the relationship between PPI use and serum Mg levels.

Methods: Using a single-center cross-sectional design, we studied 155 prevalent hemodialysis (HD) patients. Serum Mg concentration for each patient was determined based on the mean of 3 consecutive serum Mg levels drawn at 6 week intervals. PPI use was documented. The relationship between PPI use and serum Mg was determined in unadjusted analyses, as well as after adjustment for age, gender, cause of ESRD, diabetes, time on HD and dialysate Mg concentration.

Results: 55% of patients were on PPIs at the time of the study. The majority of patients (62%) used a dialysate Mg (in mmol/L) of 0.5, and the remainder (38%) used a dialysate Mg of 0.375. Serum Mg levels were significantly lower among PPI users vs. non-users (0.93

vs. 1.02 mmol/L, p<0.0001). In addition, more PPI users vs. non-users had a Mg level < 1 mmol/L (79% vs. 43%) and a Mg level < 0.8 mmol/L (16% vs. 4%). On multivariate analysis, PPI use remained an independent predictor of a lower serum Mg concentration (p<0.0001).

Conclusions: Among HD patients, PPI users have lower serum Mg levels as compared with non-users, supporting the hypothesis that PPI-induced GI Mg loss is more common than is currently recognized. Further research is required to determine whether the magnitude of change in Mg levels among PPI users with ESRD is associated with adverse outcomes.

Postprandial Mineral Metabolism in Hemodialysis Patients Mark Reinhard,[1] Jan Frystyk,[2] Bente Jespersen,[1] Per R. Ivarsen.[1] *[1]Department of Renal Medicine, Aarhus University Hospital, Aarhus N, Denmark; [2]Department of Endocrinology and Internal Medicine & Medical Research Laboratories, Department of Clinical Medicine, Aarhus University Hospital, Aarhus C, Denmark.*

Background: Abnormal mineral metabolism in hemodialysis (HD) patients is associated with cardiovascular death. The aim was to characterize postprandial mineral ion handling in HD patients compared with healthy volunteers.

Methods: On a non-HD day, 12 HD patients (M/F: 8/4; median age 61 years, range 39-74) and 12 healthy individually matched volunteers consumed a weight-adjusted standardized meal containing between 292-372 mg of calcium and between 441-818 mg of phosphorus. Following an overnight fast, blood samples were collected at baseline and until 9 h after the meal. Urine samples were collected from healthy volunteers to measure fractional excretion of calcium and phosphate.

Results: After the standardized meal, HD patients and healthy volunteers differed significantly in terms of changes in plasma phosphate (p=0.001) and parathyroid hormone (PTH) (p=0.02) levels, but not in ionized calcium levels (p=0.17). Plasma phosphate, ionized calcium, and PTH levels did not significantly deviate from baseline at any time in the healthy volunteers; however, all three parameters showed significant postprandial changes in the HD patients. Phosphate levels decreased at 60 to 240 min (maximum of 9% at 120 min, p<0.001) and then rose slightly by a maximum of 4% before returning to baseline at 540 min. Similarly, ionized calcium decreased slightly after the meal (maximum of 2% at 240 min, p=0.003). PTH levels increased at 240 min to the end of the study (maximum of 14% at 540 min, p<0.001). The healthy volunteers demonstrated an immediate increase in fractional excretion of calcium (maximum of 154% at 120 min, p<0.001) and of phosphate (maximum of 47% at 360 min, p<0.001).

Conclusions: After a dietary calcium and phosphorus load, both plasma phosphate and ionized calcium levels decreased, while PTH levels increased in HD patients. The mechanisms governing the extrarenal phosphate clearance in HD patients are unclear, but may involve both skeletal and extraskeletal soft tissue deposition.

SA-PO662

A New Equation to Predict 24-Hour Urinary Phosphorus Cassianne Robinson-Cohen,[1] Geoffrey A. Block,[2] Martha S. Persky,[2] Glenn M. Chertow,[3] Bryan R. Kestenbaum.[1] *[1]Kidney Research Institute, University of Washington; [2]Denver Nephrology; [3]Nephrology, Stanford University Medical Center.*

Background: Traditional management of stage III-V chronic kidney disease includes dietary phosphate restriction and/or the use of phosphorus binders. Monitoring dietary phosphorus is key for assessing compliance to and effectiveness of therapeutic interventions. The 24-hour urine collection is the gold standard method for estimating dietary phosphorus; however, it is cumbersome and prone to timing errors. The precision and accuracy of spot urine phosphorus (s-UP) measurement have never been thoroughly investigated.

Methods: We studied 143 participants from the Phosphate Normalization Trial, a randomized trial of phosphorus binders *versus* placebo among patients with eGFR 20-45 mL/min/1.73m^2. We evaluated multiple simultaneous spot and 24-hour urine phosphorus (24h-UP) measurements per participant. We used forward stepwise linear regression to model 24h-UP as a function of s-UP plus the following covariates: spot urine creatinine, treatment assignment, age, sex, height, weight, time of urine collection, and time since last meal. We validated our results using leave-one-out cross-validation.

Results: In addition to s-UP, the following covariates improved the 24hUP model: spot urine creatinine, age, gender and weight. Treatment assignment did not significantly add to the predicted 24hUP concentration. Compared to a model containing only the s-UP to creatinine ratio (r^2=0.12, RMSE=0.45, p<0.001), the novel regression equation correlated more strongly with 24hUP (validation r^2=0.49, RMSE=0.35, p<0.001).

Linear regression coefficients of significant predictors of ln(24-hour urine phosphorus excretion)

Variable	Estimate	Standard error
Intercept	6.39	0.16
ln(Spot Urine Phosphorus, µg/dl)	0.47	0.06
(Spot urine creatinine, µg/dl)^-2	0.02	0.01
sqrt(Spot urine creatinine, µg/dl)	-0.68	0.12
Male gender	0.31	0.05
Age, years	-0.007	0.002
Body weight, kg	0.005	0.001

Conclusions: We describe a new equation that incorporates s-UP and creatinine, age, sex, and weight to predict 24hUP. The equation is more accurate than the s-UP to spot creatinine ratio and provides a simple method for estimating this important characteristic in CKD patients.

VS-501: A Novel Phosphate Binder Derived from Natural Plant Polymer J. Ruth Wu-Wong, Yung-wu Chen, Jerry Wessale. *Vidasym, Chicago, IL.*

Background: Inadequate control of serum phosphate in chronic kidney disease (CKD) can lead to pathologies of clinical importance including cardiovascular complications, renal osteodystrophy, and increased mortality. On-market phosphate binders are mainly used in dialysis patients but effectiveness is limited by safety concerns and low compliance due to high pill burden and gastrointestinal (GI) discomfort.

Methods: VS-501 is a chemically-modified, plant-derived natural polymer that absorbs phosphate in the GI tract, and doesn't have many of the shortcomings of the current phosphate binders.

Results: When male Sprague–Dawley rats on normal diet containing 0.7% phosphorus and 1% calcium were treated with 3% (by dry weight) VS-501 or Sevelamer in the food for 6 days, serum phosphate was not significantly altered, but urinary phosphate levels decreased from 135 ± 22 µmol/24 hr (no treatment) to 7.2 ± 0.6 and 5.5 ± 1.4 µmol/24 hr in the VS-501 and Sevelamer treatment groups, respectively. VS-501 had no effect on serum Ca or PTH, while Sevelamer increased serum Ca from 10.0 ± 0.1 mg/dL to 12.3 ± 0.5 mg/dL and reduced serum PTH from 138 ± 15 pg/ml to 35 ± 12 pg/ml. Increasing dietary phosphate (KH_2PO_4 at 0.67% and K_2HPO_4 at 0.33% by dry weight in food) led to an increase in serum phosphate from 3.33 ± 0.11 mmol/L (the pre-dosing level) to 4.67 ± 0.65 mmol/L in the vehicle-treated group, but no significant changes in serum phosphate were observed in rats treated with 1%, 5% or 10% (by dry weight) VS-501 in the food for 5 days. Water and food consumptions were not significantly changed (vs. vehicle alone) in the VS-501 treatment groups. Furthermore, in vitro studies demonstrated that, upon adding 5 ml water to 0.1 g of VS-501 or Sevelamer (dry powder), the volume of Sevelamer increased from 0.1 cm^3 to 2 cm^3 (20-fold) within 20 min at 37°C, while the volume of VS-501 increased from 0.09 cm^3 to 0.25 cm^3 (3-fold) after 6 hours at 37°C.

Conclusions: The results strongly support the conclusion that VS-501 effectively controls serum phosphate levels via absorbing phosphate in GI with minimal swelling volume and without affecting serum Ca and PTH levels, indicating a compelling product profile for clinical development as a prescription drug or medical food.

Dietary Phosphate Restriction Prevents Renal Anemia in Chronic Kidney Disease Model Rats Mari Nakao, Hironori Yamamoto, Otoki Nakahashi, Mina Kozai, Yutaka Taketani, Eiji Takeda. *Department of Clinical Nutrition, University of Tokushima, Institute of Health Biosciences, Tokushima, Japan.*

Background: The restriction of dietary phosphate (Pi) has been known as a critical nutritional therapy to prevent hyperphosphatemia and development of cardiovascular disease in chronic kidney disease (CKD) patients. However, the effects of dietary Pi restriction on the renal anemia in CKD is still unclear. In order to understand the beneficial effects of multiple associated with improvement of hyperphosphatemia in CKD patients, we examined whether the dietary Pi restriction affects on the development of renal anemia in CKD model rats.

Methods: 8 weeks aged male wister rats were received either a AIN93G based diet containing adenine, or a control diet for about 5 weeks. Then, CKD rats were divided into two groups, the control diet group (CKD-CP; Pi:1.06%) and restricted Pi diet group (CKD-RP; Pi:0.2%). was administered for 7 or 16 days. For histology using paraffin sections of liver tissues, ferric iron was detected by berlin blue staining. Gene expression analysis were performed using western blots and real-time PCR methods.

Results: In blood biochemical data, CKD-CP rats exhibited anemia with hyperphosphatemia, hypocalcemia, high plasma levels of parathyroid hormone (PTH) and FGF-23, low plasma levels of 1,25-dihydroxyvitamin D ($1,25(OH)_2D$) when compared with control rats. Interestingly, we observed that dietary Pi restriction for 7 days prevented renal anemia in the levels of hemoglobin, red blood cells, iron and erythropoietin in blood. In the other hand, plasma levels of creatinine, BUN, $1,25(OH)_2D$ and hepcidin had no difference between CKD-CP and CKD-RP. In addition, dietary Pi restriction for 7 days also reduced the CKD-induced hepatic iron accumulation. Moreover, we found dietary Pi restriction also could regulate the expression of iron metabolism related genes including hepcidin, DMT-1 and Cybrd1 in liver and intestine of CKD rats.

Conclusions: These results suggest that the dietary Pi restriction in CKD rats improves the metabolic abnormalities of Pi, calcium, PTH and FGF-23 but also prevent renal anemia through the maintain of plasma erythropoietin levels.

Self-Reported Non-Adherence with Phosphate Binder Prescription Is Associated with High Serum Phosphorus and PTH: Results from the DOPPS

Francesca Tentori,[1,2] Angelo Karaboyas,[1] Brian Bieber,[1] Ananda Sen,[1,3] Takashi Akiba,[4] Juergen Bommer,[5] Jean Ethier,[6] Yun Li,[1,3] Michel Y. Jadoul,[7] Ronald L. Pisoni,[1] Bruce M. Robinson.[1,3] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]Vanderbilt U Medical Center, Nashville, TN; [3]U of Michigan, Ann Arbor, MI; [4]Tokyo Women's Medical Univ, Japan; [5]Dialysezentrum Heidelberg, Germany; [6]Center Hospital de U of Montreal, Canada; [7]Cliniques Univ. St Luc, Univ Catholique de Louvain, Belgium.*

Background: Most patients on maintenance hemodialysis are prescribed phosphate binders (PB). However, practitioners report that patient adherence to PB regimens is less than optimal. The impact of non-adherence on serum phosphorus (P) and PTH levels has not been well reported.

Methods: Self-reported non-adherence to PB prescription (# of times a patient reported skipping PBs in the previous month) was obtained from 5,089 participants in DOPPS phase 4 (2009-2011). Labs, including P and PTH, and PB data were also collected that month. Adjusted logistic regression was used to model high P (> 5.5 mg/dL) and PTH (>600 pg/mL).

Results: PB prescription varied across DOPPS countries (median = 5 PB pills/day, IQR: 3-9). 55% of patients reported taking all prescribed PBs in the past month; 27% skipped 1-3 times; 10% skipped 3-6 times; 8% skipped >6 times. Non-adherence was lowest among patients prescribed 1-2 PB pills/day, but did not vary among patients prescribed more pills (even ≥12/day). Non-adherence showed a strong linear association with elevated serum P and PTH levels (Figure), both with and without adjustment for PB pills/day.

Conclusions: Non-adherence to PB regimens is common and is associated with high P and PTH levels. As high P and PTH may be risk factors for adverse clinical outcomes including cardiovascular events, interventions and patient support activities aimed at improving adherence to PB therapies should be investigated.

Reasons for Phosphate Binder Discontinuation Vary by Binder Type

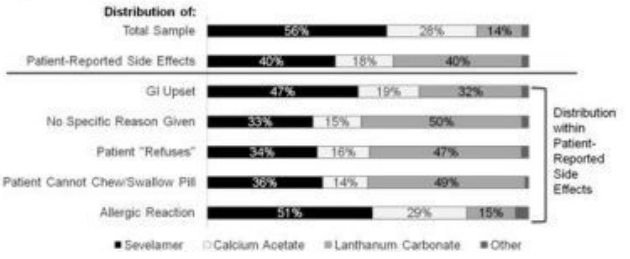
Thomas Alfieri,[1] Steven Wang,[1] Peter G. Braunhofer,[2] Britt B. Newsome.[3] *[1]DaVita Inc., Denver, CO; [2]Vifor Pharma, Glattbrugg, Switzerland; [3]Denver Nephrology, Denver, CO.*

Background: Non-adherence with phosphate binders (PB) is common in ESRD patients (pts) which contributes to elevated phosphorus levels. Pill burden, side-effects, complex regimens, and cost all contribute to the non-adherence seen. With recent reports of PB non-adherence in ESRD pts at 62%, there is an unmet need for new PBs that can overcome these barriers to adherence. We assessed the reasons for PB discontinuation to better understand the drivers of non-adherence for particular PBs.

Methods: PB prescriptions and reasons for discontinuation, either switched or ceased medication entirely, were analyzed for Medicare pts receiving hemodialysis treatment at a large dialysis organization from their electronic medical records. Two independent coders classified each reason for discontinuation from 7/1/2009–6/30/2011 into 6 categories which were subsequently divided into 40 subcategories. The percent of pts on each type of PB was calculated within each category.

Results: 30,933 reasons were classified for this study; 50.1% of records cited the pt discontinued the PB but contained no additional information. "Lab Results", cited for 27.4% of the reasons for discontinuation, and "Patient-Reported Side Effects", cited for 10.8% of the reasons, were the 2nd and 3rd largest categories. While pts on lanthanum carbonate accounted for 14% of the total sample, they comprised 40% of the "Patient-Reported Side Effects" category and were similarly over-represented in 4 of the 5 subcategories.

Figure. Distribution of Binders Within Reasons for Discontinuation



Conclusions: The high percentage of reported side effects (>10%) resulting in discontinuation identifies an unmet need for improved PBs. Although a disproportionate percentage of pts prescribed lanthanum reported side effects, further work is needed to identify the relative tolerability of PBs and potential explanations, such as prescription bias.

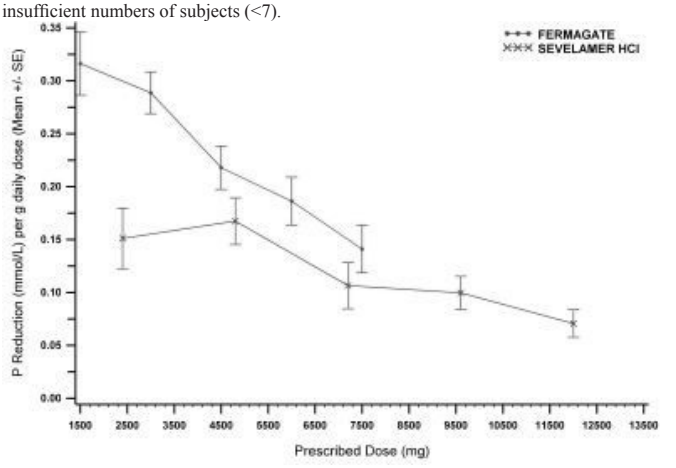
Fermagate Is a More Potent Binder Compared to Sevelamer HCl in ESRD Patients on Hemodialysis

Martin E. Wilkie,[1] Marializa Bernardo,[2] Vinod K. Bansal,[3] Joel Z. Melnick,[4] Alan Chapman.[5] *[1]Northern General Hospital, United Kingdom; [2]SouthWest Houston Research Ltd., TX; [3]Loyola University Medical Center, IL; [4]Cytochroma, IL; [5]INEOS Healthcare Ltd, United Kingdom.*

Background: Fermagate (F) is a magnesium iron hydroxy carbonate phosphate (P) binder. In vitro studies have shown that F binds 2.5x more P /g than sevelamer HCl (S). In this phase 3 study, we compared F to S in the management of hyperphosphatemia in hemodialysis (HD) patients.

Methods: After screening, subjects completed a 2-week course of current P binder therapy, followed by a 1- to 4-week washout period, and then were randomized to receive F (1.5 or 3.0 g/d) or S (2.4 or 4.8 g/d). The starting doses were titrated up to 9.0 g/d (F) or 12.8 g/d (S) to reduce serum P to the target range of 0.8-1.78 mM (2.5-5.5 mg/dL) then maintened for up to 5 months. Potency was calculated using each subject's highest dose during titration.

Results: F and S (284 and 138 subjects, respectively) reduced serum P by a mean of 0.71 and 0.61 mM (2.2 and 1.9 mg/dL), respectively (p<0.001). No difference between groups was noted for serum P or Ca x P. Intact parathyroid hormone decreased after 3 months in the F group (p<0.01) and trended downward in the S group. Mean potency of F was greater at all doses and ~2x greater at the lower doses. The potency of both drugs decreased as dose increased. The highest doses in both groups were not plotted because of insufficient numbers of subjects (<7).



Serum magnesium levels increased with F treatment and serum total 25-hydroxyvitamin D levels decreased more with S. The most common related adverse events for F were discoloured faeces (12.7%) and diarrhoea (11.6%) and for S were nausea (3.6%) and dyspepsia (2.2%).

Conclusions: F was generally well-tolerated. Subjects taking F achieved similar serum P reductions compared to S using approximately half the dose.

Mechanisms of Hyperphsphaturia in the Osteocyte-Abelated Mice

Sawako Tatsumi, Tatsuya Kamatani, Kengo Nomura, Ayako Yoshimi, Yuji Shiozaki, Shohei Sasaki, Mai Manabe, Shinsuke Kido, Hiroko Segawa, Ken-ichi Miyamoto. *Molecular Nutrition, Health Biosciences, University of Tokushima Graduate School, Tokushima, Japan.*

Background: Recent studies have shown that alterations in osteocyte metabolism occur in very early stages of chronic renal disease (CKD) and likely mediate altered bone and mineral metabolism in patients even with very mild degree of renal dysfunction. Fibroblast

growth factor 23 (FGF23) is a phosphaturic factor secreted by the osteocytes involved in the control of phosphate homeostasis. FGF23 is elevated from the early stage of CKD. We have established a transgenic mouse model, based on the diphtheria toxin (DT) receptor-mediated cell knockout (TRECK) system, in which inducible and specific ablation of osteocytes is achieved in vivo (Tatsumi S. et al. Cell Metab. 2007). To understand the role of osteocytes in Pi homeostasis, we investigated renal Pi handling in the osteocyte-ablated mice.

Methods: Ten-week old wild-type (WT) and transgenic (Tg) mice were injected i.p. with vehicle or 15-50 μg/kg body weight DT. After 8 days, we investigated Pi metabolism in Tg and WT mice.

Results: Within 48 hours of DT administration, 60–80% osteocytes were killed. The number of ablated osteocytes was dependent on DT concentration. After 8 days, osteocyte-ablated mice exhibited excessive bone resorption, impaired mineralization and adipose tissue proliferation in marrow space. These are hallmarks of the ageing skeleton. Moreover, the osteocyte-ablated mice demonstrated a marked increase of urinary Pi excretion and a significant decrease of renal sodium dependent Pi co-transporters, NaPi-IIa and NaPi-IIc at protein level, whereas no alteration in both plasma Pi and calcium concentration. Further, in this model, plasma FGF23 levels were significantly decreased, while PTH levels were conversely increased. In addition, dietary Pi manipulation was not affected Pi excretion in the osteocyte-ablated mice.

Conclusions: The reduction of osteocyte number appears to be induced urinary Pi excretion through PTH action. On the basis of the present results, we will discuss the role of osteocytes on Pi homeostasis.

Role of Estrogen Receptors ERα and ERβ in Estrogen-Induced Downregulation of NaPi-IIa and Phosphaturia in Ovariectomized Rats

Hassane Amlal,[1] Dara Burris,[1] Moshe Levi,[2] Faraaz Siddiqui.[1] *[1]Internal Medicine, University of Cincinnati, Cincinnati, OH; [2]Internal Medicine, University of Colorado, Cincinnati, CO.*

Background: We have previously demonstrated that estrogen (EST) downregulates NaPi-IIa and causes phosphaturia and hypophosphatemia in ovariectomized (OVX) rats. However, the effects of EST on other renal Pi transporters and the respective roles of estrogen receptor isoforms (ERa and ERb) in this effect remain unknown.

Methods: OVX rats were placed in metabolic cages with access to food and water and treated with EST or estrogen receptors (ER) agonists or their vehicle. The expression of ERα and ERβ was examined by RT-PCR. The expression of phosphate (Pi) transporters was examined with Northern hybridization and immunoblotting and correlated with urinary Pi excretion.

Results: RT-PCR data indicate that both ERα and ERβ are expressed in the proximal tubule (PT) cells of rat kidney. Molecular studies demonstrated that NaPi-IIa mRNA and protein were significantly reduced by EST in a dose-dependent manner, whereas the expression levels of NaPi-IIc and Pit2 were unchanged. Phosphaturia and decreased NaPi-IIa expression were also observed in pelletized slow-release EST experiments, were not hampered by the presence of progesterone and were reproduced by tamoxifen. Using specific agonists of either ERα(PPT) or ERβ (DPN) or both (PPT+DPN), we demonstrated that food intake was decreased in PPT- and PPT+DPN- but not in DPN-treated rats. PPT and DPN alone did not affect NaPi-IIa protein abundance and did not cause phosphaturia despite a decrease in the expression of its mRNA levels. However, PPT+DPN caused a sharp downregulation of NaPi-IIa along with significant urinary Pi wasting.

Conclusions: The phosphaturic effect of EST results from a specific downregulation of NaPi-IIa in the proximal tubule. This effect is not altered by progesterone and is mimicked by tamoxifen, indicating that the latter acts as estrogen agonist in the kidney. The effect of estrogen on NaPi-IIa is mediated via a complex mechanism involving the activation and likely heterodimerization of ERα and ERβ. Lastly, we propose that tamoxifen could be used as a phosphaturic agent to treat hyperphosphatemia.

Klotho and Na+/Pi Cotransporter on High Phosphorous Induced Vascular Calcification and Early Intervention by Sodium Thiosulfate in Remnant Kidney Rat

Yi Yu. *Department of Hemodialysis, Dongfang Hospital of Fujian Province, Fuzhou, Fujian, China.*

Background: To investigate the expression of Klotho and Na+/Pi cotranspoter involved in high phosphorous induced vascular calcification and effect of sodium thiosulfate (STS) on vascular calcification in remnant kidney rats.

Methods: SD rats (n=35) underwent 5/6 nephrectomy (n=21) or sham operation (n=14). Rats were fed with high phosphorus (HP) or normal phosphorus (NP) diet for 16 weeks. They were divided into 5 groups: (1) remnant kidney rats receiving HP diet (NHP, n=7) (2) remnant kidney rats receiving NP diet (NNP, n=7), (3) sham operation rats receiving NP diet (SNP, n=7), (4) sham operation rats receiving HP diet (SHP, n=7). (5) remnant kidney rats receiving HP diet with STS (THP, n=7). The treatment group was given STS intraperitoneally three times a week for 16 weeks. Aortic calcification was confirmed by Von kossa staining. Klotho, Cbfα1 and Pit-1 expression in aorta were determined by immunohistochemistry, while Klotho and NaPi2a mRNA in kidney were determined by Real-time PCR.

Results: After 16 weeks, Scr, P^{3+} and iPTH were higher in NHP than those in SNP group ($P<0.05$). THP group showed significant decrease in Scr, P^{3}+ and iPTH and its pathological changes and aortic calcification alleviated compared with NHP group ($P<0.05$). Von kossa showed significant vascular calcification in NHP, occasional calcification in NNP and SHP, none in SNP group. The aorta expression of Klotho decreased while Pit-1 and Cbfα1 increased in NHP compared with SNP group ($P<0.01$). The aorta expression of Klotho increased and Pit-1 and Cbfα1 decreased ($P<0.01$) in THP compared with NHP group($P<0.01$). The kidney expression of Klotho mRNA decreased, while kidney NaPi2a mRNA increased in NHP compared with SNP group ($P<0.01$). After treatment, the kidney expression of Klotho mRNA increased while NaPi2a mRNA decreased in THP compared with NHP group ($P<0.05$).

Conclusions: The regulation of Klotho and Na+/Pi cotranspoter in both aorta and kidney may contribute to high phosphorous induced vascular calcification in remnant kidney rat. The effect of sodium thiosulfate is encouraging in decreasing serum phosphate and delaying the progression of vascular calcification.

Uromodulin Upregulates TRPV5 by Impairing Caveolin-Mediated Endocytosis

Matthias Tilmann Florian Wolf,[1] Chou-Long Huang.[2] *[1]Pediatrics, UTSW Medical Center, Dallas, TX; [2]Internal Medicine, UTSW Medical Center, Dallas, TX.*

Background: Uromodulin (UMOD), also known as Tamm Horsfall protein, is synthesized in the thick ascending limb of Henle's loop and secreted into urine as the most abundant protein. Association studies in humans suggest protective effects of UMOD against calcium-containing kidney stones. Mice carrying mutations of Umod found in human uromodulin-associated kidney disease (UAKD) exhibit hypercalciuria, but the potential mechanism for UMOD regulation of urinary Ca^{2+} excretion is incompletely understood. This study examined the hypothesis that UMOD regulates TRPV5 and TRPV6, channels critical for renal transcellular Ca^{2+} reabsorption.

Methods: HEK293 cells were cotransfected with TRPV5 and secreted or transmembrane KL. Whole-cell current was analyzed by patch-clamp recording.

Results: We found that coexpression with UMOD increased whole-cell TRPV5 current density in cultured human embryonic kidney (HEK) cells. Biotinylation studies showed that UMOD increased TRPV5 cell-surface abundance. Extracellular application of purified UMOD or supernatant of media harvested from UMOD-expressing cells upregulated TRPV5 current density and cell-surface abundance within physiological relevant concentration ranges. UMOD exerted a similar effect on TRPV6. It has been reported that TRPV5 undergoes constitutive caveolin-mediated endocytosis. We further showed that UMOD had no effect on TRPV5 in a caveolin-1 deficient cell line and expression of recombinant caveolin-1 in the cells restored the ability of UMOD to upregulate TRPV5. Finally, secretion of UAKD-mutant UMOD was markedly reduced and coexpression of mutant UMOD with TRPV5 failed to increase its current.

Conclusions: Thus, UMOD upregulates TRPV5 by acting from the extracellular side and by decreasing endocytosis of TRPV5. The stimulation of Ca^{2+} reabsorption via TRPV5 by UMOD may contribute to protection against kidney stone formation.

Loss of Insulin-Induced Activation of TRPM6 Channels Results in Impaired Glucose Tolerance during Pregnancy

Joost G. Hoenderop,[1] Anil V. Nair,[1] Berthold Hocher,[2] Karl P. Schlingmann,[3] Martin Konrad,[3] René J. Bindels.[1] *[1]Physiology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [2]Institute of Nutritional Science, University of Potsdam, Potsdam, Germany; [3]Department of General Pediatrics, University Children's Hospital Münster, Münster, Germany.*

Background: Gestational Diabetes Mellitus (GDM) is a condition in which women without previously diagnosed diabetes exhibit high blood glucose levels during pregnancy. Women with GDM are at a higher risk for pre-eclampsia and as well as developing Diabetes Mellitus type 2 (DM2). Hypomagnesemia affects insulin resistance and is a risk factor for DM2 and GDM. Two single nucleotide polymorphisms in the epithelial magnesium channel TRPM6 were predicted to confer susceptibility for DM2.

Methods: Using HEK293 cells expressing TRPM6, immunoblotting and patch clamp analysis the mechanism of insulin-stimulated channel activity was investigated. Dynamic regulation of TRPM6 at the plasmamembrane was determined by Total Internal Reflection Fluorescent (TIRF) microscopy. A total of 997 pregnant women described as the Berlin Birth Cohort were included in the study.

Results: Using patch clamp analysis and TIRF microscopy, we demonstrated that insulin stimulates TRPM6 activity via a phosphoinositide 3-kinase and Rac1-mediated elevation of cell surface expression of TRPM6. Interestingly, insulin failed to activate the genetic variants TRPM6(V^{1393}I) and TRPM6(K^{1584}E) which is due to the inability of the insulin signaling pathway to phosphorylate TRPM6(T^{1391})and TRPM6(S^{1583}). Moreover, by measuring Total Glycosylated Hemoglobin in 997 pregnant women as a measure of glucose control, we demonstrated that TRPM6(V^{1393}I) and TRPM6(K^{1584}E) are associated with higher TGH and confer a higher likelihood of developing GDM. The impaired response of TRPM6(V^{1393}I) and TRPM6(K^{1584}E) to insulin represents a pathway leading to GDM where the defect is located in TRPM6.

Conclusions: Pregnant women carrying TRPM6(V^{1393}I) and TRPM6(K^{1584}E) possibly lack the physiological regulation of TRPM6 by insulin. These genetic variants of TRPM6 could be used as potential biomarkers to improve diagnosis and identify those at risk for developing GDM/DM2-induced hypomagnesemia.

Osteoblast-Specific Calcium-Sensing Receptor (Casr) Deficient Mice Display Temporary Growth Delay with Decreased Trabecular Bone

Hakan R. Toka,[1,2] Salvatore Dibartolo,[2] Yingben Xue,[3] David B. Mount,[1] Gary C. Curhan,[1] David Goltzman,[3] Edward M. Brown,[4] Martin R. Pollak.[2] *[1]Nephrology, Brigham and Women's Hospital, Boston, MA; [2]Nephrology, Beth Israel Deaconess Medical Center, Boston, MA; [3]Endocrinology & Metabolism, Royal Victoria Hospital McGill University, Montreal, QC, Canada; [4]Endocrinology, Brigham and Women's Hospital, Boston, MA.*

Background: Casr has an important role in regulating calcium homeostasis within several tissues including bone. *In vivo* and *in vitro* data strongly suggest that Casr regulates osteoblast (Ob) proliferation, differentiation and mineralization, and thereby skeletal growth. Ob Casr-deficient mice under the Osterix (Osx) promoter have been reported to have severe growth retardation and decreased life expectancy.

Methods: We generated a conditional Casr-deficient mouse model targeting exon 3 using the Cre/Lox system. We obtained Cre transgenic mice driven by the Ob-specific Osx promoter and developed Ob Casr-deficient mice (Ob $Casr^{-/-}$).

Results: Immunohistochemistry in Ob $Casr^{-/-}$ shows absence of Casr in Obs, which are born at the expected Mendelian ratio. Ob $Casr^{-/-}$ develop significant growth delay, which is evident between the ages of 2 to 6 weeks compared to control mice (n=10 vs. 10, p=0.0002). DEXA studies show decreased BMC and BMD at age 3 weeks (p=0.002 and p=0.02) that is no longer evident at 3 months of age. Micro CT studies show decreased trabecular bone parameters in experimental mice (BV/TV, p=0.0001; Tb.Th, p=0.03; Tb.N, p=0.0001; Tb.Sp, p=0.0001). Bone histomorphometry displays increased osteoclast (Oc) cell numbers in Ob $Casr^{-/-}$ (N.Oc/BP, p=0.0001). Preliminary qPCR studies show decreased expression of several markers of Ob proliferation (e.g. IGF1R) or differentiation (e.g. Osx).

Conclusions: Our studies show that conditional Ob $Casr^{-/-}$ mice display temporary growth delay. The likely mechanism in our model is a temporary decrease in trabecular bone growth mediated by Ob Casr deficiency until skeletal growth plateaus in the adult mouse. Studies with primary Ob cultures addressing the effects of Casr deficiency on Obs and indirectly Ocs during bone growth are being pursued.

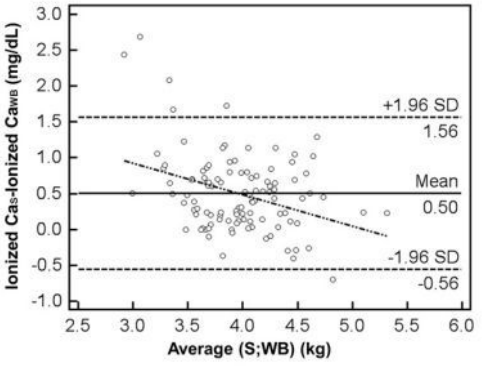
Effect of Heparin on Level of Ionized Calcium in Dialysis Patients

Seokhui Kang, Jun-Young Do, Kyu-hyang Cho, Jong-Won Park, Kyung Woo Yoon. *Department of Internal Medicine, Yeungnam University Hospital, Daegu, Korea.*

Background: Heparin as anticoagulant is especially associated with lower ionized calcium level in whole blood than that in serum. The aim of this study is to evaluate the bias of ionized calcium between whole blood containing heparin and serum.

Methods: We included 107 patients under maintenance hemodialysis in out hospital hemodialysis (HD) unit. The clinical and laboratory data were collected and were measured simultaneously. Non-heparinized, dry, and vacutainer tube was used to determine serum ionized calcium. Whole blood ionized calcium was obtained using sodium heparin-coated 3-ml syringe.

Results: Total calcium was 8.3 (7.1–11.6) mg/dL in non-corrected and 8.28 (6.93–11.53) in corrected. Ionized calcium was 3.76 (1.70–5.20) mg/dL in whole blood and 4.15 (3.25–5.43) mg/dL in serum. Level of ionized calcium in serum was higher than that in whole blood (P < 0.001). Serum ionized calcium was correlated with whole blood ionized calcium, total calcium, and corrected total calcium (P < 0.001). Bland-Altman analysis showed that a bias for ionized calcium was 0.5027. Most of ionized calcium in serum – ionized calcium in whole blood was within ±1.96 SD of 0.5027.



For bias, non-standardized β was –0.4389 (P < 0.001) and intercept was 2.2418 (P < 0.001). There was a significant difference in distribution of categories according to ionized calcium level between two methods (Kappa, 0.279; P < 0.001). When ionized calcium in whole blood was measured, forty three patients with normocalcemia were miscategorized to hypocalcemia.

Conclusions: This study demonstrate that whole blood ionized calcium is underestimated comparing with serum ionized calcium. Measuring bias will be increased along with the decrement of whole blood ionized calcium. Therefore, significant hypocalcemia in whole blood ionized calcium may be verified by serum ionized calcium.

SA-PO675

Phosphate Is a Key Factor for Chronic Kidney Disease Progression

Irene F. Duayer, Flavia G. Machado, Marina A. Fanelli, Denise M.A.C. Malheiros, Roberto Zatz, Clarice K. Fujihara, Fabiana G. Graciolli, Luciene M. dos Reis, Vanda Jorgetti, Rosa M.A. Moyses. *University of Sao Paulo, Brazil.*

Background: Although experimental studies showed that protein (Prot) restriction slows CKD progression, this was not confirmed by clinical studies, suggesting that other factors could offset the benefits of such regimen. Since phosphate (Pi) has been recently recognized as a nontraditional risk factor for CKD progression, we sought to discern the possible deleterious effects of Pi from those of Prot intake. For this purpose, we studied the effect of two different dietary Pi contents in rats subjected to 5/6 nephrectomy (Nx) that received a low-Prot diet.

Methods: Nx rats were divided in 2 groups according to Pi content (0.2 and 0.9%), while all were maintained on a 12% Prot diet. After 2 months, biochemical, histological and imunohistochemical analyses were performed.

Results: Both groups showed low-level interstitial (INT) expansion and glomerulosclerosis (GS), consistent with dietary Prot restriction. Nx animals fed 0.9% Pi exhibited lower hematocrit (Ht) and creatinine clearance (ClCreat), as well as higher fractional excretion of Pi (Fe%Pi) and serum FGF-23, than those receiving 0.2% Pi. Despite Prot restriction, Pi overload was associated with worsening of renal function, and with an increase in the INT area and staining for α-actin (α-ACT). Moreover, FGF-23 correlated with Ht, Fe%Pi and α-ACT (r = -0.6, 0.8 and 0.6, respectively; p< 0.05 for all), consistent with the hypothesis that FGF-23 not only governs Pi homeostasis but may also contribute to the pathogenesis of renal fibrosis.

	0.2Pi	0.9Pi
Ht(%)	44±1	38±1*
Pi(mg/dl)	6±1	7.5±1
Cl_{creat}(ml/min)	0.6±0.04	0.4±0.07*
FePi(%)	0.15±0.07	10±0.7*
FGF-23(pg/ml)	153±16	767±60*
GS%	1.0±0.6	1.15±1
INT%	0.2±0.08	1.2±0.3*
α-ACT%	0.7±0.07	3.7±0.6*

*p<0.05

Conclusions: Pi overload plays a role in CKD progression through an increase in interstitial fibrosis, even in the presence of Prot restriction, suggesting that both Pi and Prot intake should be limited in CKD. These preliminary data may help us to understand the negative findings of some clinical studies of Prot restriction on CKD progression, in which little attention was paid to dietary Pi.

Association of Vitamin D (D25) Deficiency and Low Serum Phosphorus (Phos) with Obesity in a Large Ethnically Diverse Non-CKD Population

John J. Sim,[1] In-lu Amy Liu,[1] Antoine C. Abcar,[1] Dean A. Kujubu,[1] Samuel Meguerditchian,[1] Scott A. Rasgon,[1] Kamyar Kalantar-Zadeh.[2] *[1]Nephrology & Hypertension, Kaiser Permanente Los Angeles Medical Center, Los Angeles, CA; [2]Nephrology & Hypertension, Harbor UCLA Medical Center, Torrance, CA.*

Background: Higher overall dairy intake has been associated with lower obesity rates but serum Phos levels relation to obesity are unknown. Higher dietary Phos and low D25 have been described more in obese populations which suggests the hypothesis that obesity is associated with higher serum Phos particularly in those without CKD. To this end, we sought to determine the risk for obesity in those with D25 deficiency and across differing Phos levels within a large ethnically diverse population of subjects without CKD.

Methods: Subjects age ≥ 18 yrs with measured 25-hydroxyvitamin D (D25), serum Phos, documented eGFR≥60ml/min, and body mass index (BMI) in 1/1/2007-12/31/31. Obesity defined as BMI ≥ 30 and D25 deficiency <30mg/dl. Serum Phos was analyzed as both continuous & categorical quartile variables. Demographic and comorbidity data were extracted from the electronic medical records. Logistic regressions were performed to determine odds ratio (OR) for risk of obesity.

Results: A total of 35,280 subjects met the inclusion criteria for analysis. 44% had BMI ≥ 30 and 65% had D25 deficiency. The lower Phos group (1.9-3.1mg/dl) had the greatest proportion with D25 deficiency (67%). Multivariable logistic regressions obesity OR (95% CI) was 1.84 (1.67-2.03) in those with D25 deficiency after adjusting for age, gender, race, diabetes, hypertension, calcium, and PTH. Conversely, obesity OR were 10% lower for every 1 mg/dl Phos increase [OR = 0.90 (95% CI 0.83-0.97)].

OR for Obesity

Phosphorus	OR	95% CI
1.9-3.1	-	-
3.1-3.5	0.97	0.85-1.11
3.5-3.9	0.96	0.84-1.1
3.9-5.7	0.80	0.70-0.91
D25<30	1.84	1.67-2.03

Conclusions: We found greater risk for obesity with D25 deficiency and lower serum Phos levels. This is consistent with the mechanism of D25 on calcium and Phos balance but contrary to the high Phos diets observed in the obese population. D25 and Phos levels may reflect risk factors for the metabolic syndrome in the non CKD population.

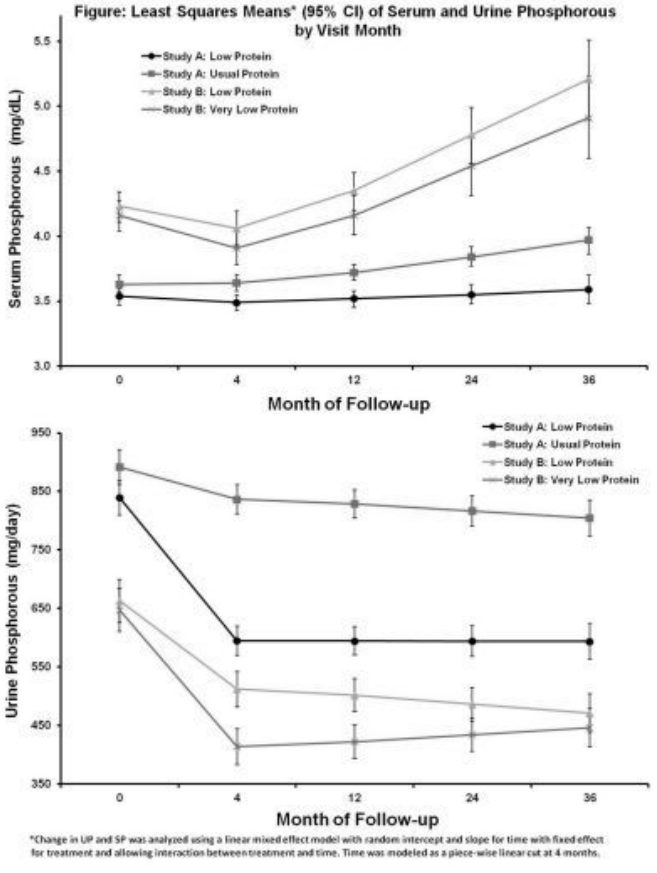
SA-PO677

Diet Modification Effects on Serum and Urine Phosphorous Levels: The Modification of Diet in Renal Disease Study Britt B. Newsome,[1] Joachim H. Ix,[2] Hocine Tighiouart,[3] Mark J. Sarnak,[3] Andrew S. Levey,[3] Gerald J. Beck,[4] Geoffrey A. Block.[1] *[1]Denver Nephrology; [2]UC San Diego; [3]Tufts Medical Center; [4]Cleveland Clinic.*

Background: We examined the relationship between dietary phosphorous (P) and protein modification on serum (SP) and urine (UP) phosphorous levels in chronic kidney disease (CKD).

Methods: Analysis of the Modification of Diet in Renal Disease (MDRD) Study, a randomized trial of dietary protein restriction and blood pressure control on CKD progression. Study A: 585 patients with a glomerular filtration rate (GFR) 25-55ml/min/1.73m^2 assigned to a usual-protein (1.3 g/kg/day) or a low-protein diet (0.58 g/kg/day). Study B: 255 patients with a GFR 13-24ml/min/1.73m^2 assigned to the low-protein or a very-low-protein diet (0.28 g/kg/day) supplemented with ketoacid-amino acids. Dietary P targets (mg/kg/day): usual protein 16-20; low protein 5-10; very low protein 4-9. We used a linear mixed effect model to assess UP and SP change.

Results: All 3 lower protein groups achieved dietary P restriction. Baseline SP was higher for Study B vs. A (Figure). The mean SP (mg/dL) change from 0-4 months was 0.01(Study A, usual protein), -0.05(Study A, low protein), -0.17(Study B, low protein) and -0.25(Study B, very low protein). Follow-up SP was similar among Study B groups while the Study A low protein group remained lower than the usual diet group. Baseline UP was lower for Study B vs. Study A. The mean UP (mg/day) change from 0-4 months was -55(Study A, usual protein), -244(Study A, low protein), -151(Study B, low protein) and -233(Study B, very low protein). UP levels at ≥4 months were different between Study A groups while Study B groups were different only at 4 and 12 months.



Conclusions: Dietary P restriction resulted in significant UP reductions despite minimal SP reductions. Effective SP reduction strategies will require more than diet modification.

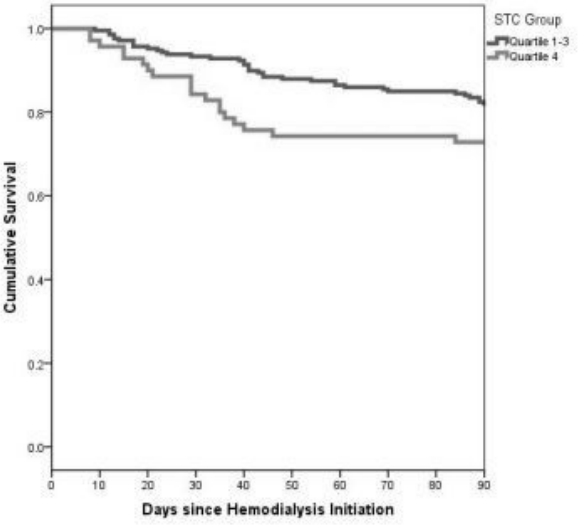
Serum Stanniocalcin-1 Associates with Mineral Bone Disease, and Mortality in Hemodialysis Sagar U. Nigwekar,[1] Ishir Bhan,[1] Julia Beth Wenger,[1] S. Ananth Karumanchi,[2] Ravi I. Thadhani.[1] *[1]Massachusetts General Hospital; [2]Beth Israel Deaconess Medical Center.*

Background: Disordered mineral metabolism has been implicated in decreased survival among hemodialysis (HD) patients. Stanniocalcin-1, an intracellular and secreted glycoprotein known to regulate calcium and phosphorous balance in bony fish, is also produced in many human tissues. We investigated how stanniocalcin-1 associates with traditional markers of mineral bone disease (MBD) and mortality in HD patients.

Methods: Serum stanniocalcin-1 levels at the time of HD initiation were measured in 280 subjects enrolled prospectively in the Accelerated Mortality on Renal Replacement (ArMORR) cohort. Associations between stanniocalcin-1 levels and traditional serum markers of MBD were assessed. Hazard ratios (HR) and 95% confidence intervals (CI) for 90-day mortality were calculated by comparing quartiles of stanniocalcin-1 using Cox proportional hazard models.

Results: The mean age was 65 years and 53% of subjects were males. Median stanniocalcin-1 level was 11,431 pg/mL (IQR 8,295-14,512). Serum stanniocalcin-1 correlated positively with phosphorous (r= 0.21, p= 0.0004) and negatively with calcium (r= -0.13, p= 0.031). No significant correlations were observed with parathyroid hormone, alkaline phosphatase, and 25-hydroxyvitamin D. In multivariate analyses, patients with serum stanniocalcin-1 levels in the highest quartile had significantly higher 90-day mortality (HR 2.76, 95% CI 1.35-5.67) compared with the remaining subjects.



This relationship was observed across all quartiles of phosphorous and calcium.

Conclusions: Elevated stanniocalcin-1 independently predicts mortality and is associated with higher phosphorous and lower calcium levels in HD. Future studies are needed to identify stanniocalcin-1's mechanism of action and to determine if these associations are causative.

SA-PO679

Non-Invasively Assessed Bone Loss Is a Stronger Predictor than Traditional Risk Factors for Coronary Artery Calcification Progression in Patients with CKD-5D Hartmut H. Malluche,[1] Gustav A. Blomquist,[2] Daniel Davenport,[3] Paul Anaya,[4] Vincent L. Sorrell,[2,4] Marie-Claude M. Faugere.[1] *[1]Div of Nephrology, University of Kentucky; [2]Dept of Radiology, University of Kentucky; [3]Dept of Surgery, University of Kentucky; [4]Div of Cardiology, University of Kentucky, Lexington, KY.*

Background: Coronary artery calcifications (CAC), commonly found in patients with CKD-5, are associated with high morbidity and mortality. Risk factors for elevated CAC in this patient population are not well established. This prospective study evaluated the impact of bone loss, as well as traditional and non-traditional predictors, on CAC.

Methods: At baseline and after one year, bone mineral density was measured at L1-L2 vertebrae and total hip using dual-energy x-ray absorptiometry (DXA) and quantitative computed tomography (QCT). CAC was concurrently quantified by Agatston scores using CT.

Results: 148 subjects (age 53±13) with CKD-5D were enrolled. Eighty-four had CAC<400 and 64 had CAC≥400. Those with CAC≥400 were older, had lower QCT scores of the hip and spine and lower DXA scores of the hip (all p<.05). Gender, race, diabetes, dialysis vintage, BMI, hypertension, smoking, exercise, HDL/LDL, serum phosphorus, calcium and iPTH, use of vitamin D or calcium-based phosphate binders did not differ significantly between the CAC groups. In prospective analysis of one year follow-up (at this time n=44), only bone loss at the spine and age correlated with CAC progression.

Predictors of CAC Progression in Patients with CKD-5D

	Spearman's Rho Correlation with CAC Progression after 1 year	P-value
Δ L1-L2 QCT	-.450	.003
Δ L1-L2 DXA	-.300	.048
Age at baseline	.373	.013

Conclusions: The profile of risk factors for CAC in CKD-5D differs from the general population. In cross-sectional analysis the strongest predictors are age followed closely by non-invasively assessed bone mass at both the hip and spine. Serum phosphorus, calcium and iPTH are not predictive. Prospectively, after one year the strongest predictors of CAC progression are bone loss of the spine followed by age. Due to lower bone turnover of the hip, longer observation may be required to identify bone loss at the hip in addition to spine as a predictor.

Funding: NIDDK Support

SA-PO680

Bone Mineral Density 5 Years after Parathyroidectomy in Hemodialysis Patients with Secondary Hyperparathyroidism Masayuki Yamanouchi, Yoshifumi Ubara, Keiichi Sumida, Koki Mise, Kenmei Takaichi. *Nephrology Center, Toranomon Hospital, Minato-ku, Tokyo, Japan.*

Background: Whether bone mineral density (BMD) improves 5 years after parathyroidectomy (PTx) for secondary hyperparathyroidism (SHPT) remains unknown.

Methods: To investigate BMD after PTx using dual energy X-ray absorptiometry (DXA).BMD was examined at the distal one third of the radius (non-shunt side) and at the lumbar supine (L2-L4, lateral view) before and five years after PTx in 35 hemodialysis patients who underwent surgery from April 1994 to May 2004. Their data were analyzed retrospectively.

Results: Intact PTH decreased significantly from 1100±530 (range, 446 to 2300) pg/mL before PTx to 75±68 (2 to 251) pg/mL at 5 years after PTx (P<0.01). The radial BMD and the lumbar BMD before PTx showed a decrease of -3.3±1.9 SD below and -1.3±2.4 SD below the corresponding normal mean T-score, respectively. The radial BMD (T-score) before PTx was 0.522±0.113 g/cm^2(-3.3±1.9), and increased significantly to 0.545±0.114 g/cm^2 (-2.8±2.0)(*P*=0.01) five years after PTx. While the lumbar BMD (T-score) showed no significant changes by 0.734±0.202 g/cm^2 and 0.746±0.199 g/cm^2 (-1.3±2.4 to -1.1±2.3) between before and five years after PTx. The patients did not suffer any fractures during the follow-up period.

Conclusions: These findings indicate that maintenance of iPTH at a level under 300 pg/mL for five years after PTx can increase radial BMD in patients with SHPT showing a marked preoperative decrease to the osteoporosis range (less than –2.5 SD of the T score) according to the WHO classification, and can be stabilization or no further significant loss of lumbar BMD.

SA-PO681

Evaluation of Bone Mineral Density, Kidney Function and Arterial Stiffness in 371 Long-Standing Type 1 Diabetic Patients with or without Diabetic Nephropathy Maria Lajer,[1] Simone Theilade,[1] Christel Joergensen,[1] Frederik I. Persson,[1] Lise Tarnow,[1,4] Hans-Henrik Parving,[2,4] Peter S. Lacy,[3] Bryan Williams,[3] Peter Rossing.[1,4] *[1]Steno Diabetes Center, Denmark; [2]Rigshospitalet, Denmark; [3]University of Leicester, United Kingdom; [4]University of Aarhus, Denmark.*

Background: Patients with chronic kidney disease may have lower bone mineral density (BMD).

Methods: Prospective cohort of 141 patients with diabetic nephropathy (DN) (55% men; age [mean±SD] 53±9 years, 42±8 years of diabetes, DN duration 22±6 years) and 230 with normoalbuminuria (50% men, 58±10 years, 40±10 years of diabetes). Femoral and lumbar spine BMD (g/cm^2) was measured by DXA. Osteopenia and osteoporosis were defined by any T-score of -2.5 to -1.0 and <-2.5, respectively. Glomerular filtration rate (GFR) by ^{51}Cr-EDTA was determined in DN and estimated (MDRD) in normoalbuminuric patients. Pulse wave velocity (PWV) was measured by SphygmoCor and 24h blood pressure by BPro watch.

Results: Among patients with DN, 73 (52%) and 36 (26%) had osteopenia or osteoporosis, respectively compared to 124 (54%) and 32 (14%) of normoalbuminuric patients (p=0.013). In males, 34% with DN vs. 14% with normoalbuminuria had osteoporosis (p<0.001). Among women, femoral BMD were different after adjustment for sex and age. Baseline eGFR levels were not associated with declining BMD. Among patients with DN, 24h central PP were higher (p= 0.014) while 24h central systolic dip were lower in osteoporotic compared with osteopenic patients and patients with normal BMD (p<0.001). PWV also tended to be elevated and GFR lower in osteoporotic patients although not significantly (p=0.12 and 0.14). Among normoalbuminuric patients, 24h central BP and PWV were elevated in osteoporotic patients (p=0.005 and 0.028, respectively) while 24h central systolic dip were not significantly different (p>0.05).

Conclusions: The risk of osteoporosis was highest among male type 1 diabetes patients and long-standing DN and femoral BMD was associated with albuminuria status, pulse pressure and dipping. Hence, screening and treatment of osteoporosis in patients with albuminuria or arterial stiffness should be considered.

Funding: Private Foundation Support

SA-PO682

Fibroblast Growth Factor 23, Bone Mineral Density and Risk of Hip Fracture among Older Adults: The Cardiovascular Health Study Anna Jeanette Jovanovich,[1] M. Chonchol,[1] John A. Robbins,[3] Howard Fink,[4] Ian H. de Boer,[2] Bryan R. Kestenbaum,[2] Ronit Katz,[2] Laura Carbone,[5] Gail A. Laughlin,[6] Michael Shlipak,[7] Linda F. Fried,[8] Kenneth J. Mukamal,[9] Joachim H. Ix.[6] *[1]University of Colorado; [2]University of Washington; [3]University of California Davis; [4]VA Minneapolis HCS; [5]VA Memphis HCS; [6]University of California San Diego; [7]University of California San Francisco; [8]VA Pittsburgh HCS; [9]Beth Israel Deaconess Medical Center.*

Background: Fibroblast growth factor 23 (FGF23) regulates renal phosphorus excretion and inhibits calcitriol synthesis. The association of high FGF23 levels with bone loss and fracture in the general population is uncertain.

Methods: We evaluated 3337 ambulatory participants ≥65 years. Total hip (TH) and lumbar spine (LS) bone mineral density (BMD) was measured by dual x-ray absorptiometry in a subset (n=1291). In all participants, hip fracture incidence was assessed prospectively by hospital records review.Associations of plasma FGF23 levels with BMD and incident hip fracture were examined with linear regression and Cox proportional hazard models, respectively. We tested whether associations differ by chronic kidney disease (CKD) status.

Results: Mean age was 78 ± 5 years, 60% were women, and 16% were black. Men had a lower median plasma FGF23 level than women (66 [IQR 52- 92] vs. 75 [56-107] RU/mL; p< 0.001). In models adjusted for important confounders, higher FGF23 levels associated with greater TH BMD and LS BMD in men only (ß per doubling of FGF23: 0.02 [95% CI 0.001, 0.04] g/cm^2 and 0.03 [95% CI 0.006, 0.06] g/cm^2, respectively). During a mean follow-up of 11 years, 328 hip fractures hospitalizations occurred. Higher FGF23 levels did not associate with hip fracture risk in women or men (adjusted HR: 0.95 [95% CI 0.78, 1.15] and 1.09 [95% CI 0.82, 1.46] per doubling of FGF23, respectively). Results were similar irrespective of CKD status (p >0.4 for interaction).

Conclusions: In this large cohort of older adults, higher FGF23 levels were associated with greater BMD in men only, and had no statistically significant association with hip fracture risk in either sex.

SA-PO683

Rapid Cortical Bone Loss in Patients with Chronic Kidney Disease Thomas L. Nickolas,[1] Stephanie Boutroy,[1] Serge Cremers,[1] Donald J. Mcmahon,[1] Mary B. Leonard,[2] Elizabeth Shane.[1] *[1]Columbia University, NY, NY; [2]CHOP, Philadelphia, PA.*

Background: Fracture risk is elevated in chronic kidney disease (CKD) patients. We reported that CKD patients with prevalent fractures have lower areal BMD (aBMD) by DXA at the ultradistal radius (UDR) and lower cortical (Ct) and trabecular (Tb) volumetric BMD (vBMD), thinner cortices and abnormal Tb microarchitecture of the distal radius (RAD) and tibia (TIB) by high resolution peripheral computed tomography (HRpQCT).

Methods: To ascertain if microarchitectural abnormalities associated with CKD are progressive, we enrolled 54 patients in a longitudinal study and measured aBMD by DXA at the lumbar spine (LS), total hip (TH), femoral neck (FN), 1/3 and ultradistal radius (1/3R; UDR), and Ct and Tb vBMD, geometry and microarchitecture of the distal RAD and TIB by HRpQCT (voxel size 82µm). Median (interquartile range) followup was 1.8 (1.3-2.1) years. Serum was archived for batch analysis at study completion. Changes in bone measures were annualized and compared by mixed models adjusted for age, sex, race, dialysis status and baseline bone measures.

Results: At baseline, mean±SD age was 69±10 yrs, 52% were female, 33% had prevalent fractures and 17% were on dialysis. Mean eGFR in nondialyzed patients (37±17 mL/min) did not change (-0.3±7 mL/min, p=1.0). There were significant declines in aBMD at the TH (1.2±2.6%, p<0.01) and UDR (2.4±5.6%, p<0.01) but not the LS, FN or 1/3R. By HRpQCT, there were significant declines in RAD Ct area (2.9±3.8%, p<0.0001), density (1.2±1.6%, p<0.0001) and thickness (1.2±1.6%, p<0.0001). In contrast, Tb vBMD and microarchitecture did not change, excepting a small, significant increase in Tb area (0.4±0.9%, p<0.0001). The pattern and significance of changes were mirrored at the TIB.

Conclusions: CKD is associated with progressive Ct bone loss at the RAD and TIB. Declines in Ct density, thickness and area, coupled with increases in Tb area suggest endocortical cancellization is the primary mechanism of Ct loss. Pharmacologic interventions to decrease Ct loss could represent a strategic therapeutic target to prevent deterioration of bone microarchitecture and lower fracture risk in this vulnerable population.

Association of Bone Density and Mass with Coronary Artery Calcification in Incident Dialysis Patients Laura H. Mariani, Anne K. Tsampalieros, Mary B. Leonard, Sylvia E. Rosas. *Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA.*

Background: Vascular calcification has been associated with low bone mineral density (BMD) in the general population and pre-dialysis CKD. In dialysis patients, it has been associated with low trabecular bone volume and low bone turnover. Little is known about the association at the time of dialysis initiation.

Methods: 96 patients were enrolled within 4 months of dialysis initiation and underwent both tibia quantitative CT (QCT) and ECG-triggered multi-slice CT scans. QCT provides measures of trabecular and cortical volumetric BMD and bone mineral content (BMC). Multivariable ordinal logistic regression was used to assess the relationship between coronary artery calcification (CAC) Agatston score and bone density and mass.

Results: Mean (SD) age was 50 (13) yr, BMI was 29 (5.8) kg/m² and dialysis vintage was 66 (31) days. 67% were male, 62% black and 49% diabetic. Total Agatston score was 0 in 36%, >0 to 100 in 25%, >100 to 400 in 17% and >400 in 22%. The mean (SD) z-score for trabecular BMD was -0.28 (1.32), cortical BMD was -0.41 (1.22) and cortical BMC was 0.34 (1.21). There was no statistical difference in bone parameters across the four CAC categories. In univariate models, greater trabecular BMC was associated with a greater odds of elevated CAC. In fully adjusted models, greater cortical BMC was associated with greater CAC (Table 1).

Association of Bone Parameters with CAC using Ordinal Logistic Regression

Bone Parameter	Unadjusted		Adjusted for Age,Sex,Race		Fully Adjusted*	
	OR per SD	p-value	OR per SD	p-value	OR per SD	p-value
Cortical Bone						
BMC(mg)	1.01	0.97	1.30	0.35	1.83	0.05
BMD(mg/cm³)	0.70	0.07	1.00	0.99	1.09	0.71
Trabecular Bone						
BMC(mg)	1.54	0.03	1.45	0.09	1.56	0.08
BMD(mg/cm³)	0.73	0.13	0.80	0.32	1.04	0.88

*Adjusted for age, sex, race, diabetes, smoking and hyperlipidemia

Conclusions: We found that cortical content by QCT was positively associated with CAC after multivariable adjustment in these incident dialysis patients. The relationship between bone and vascular calcification may vary depending on the bone imaging modality used and longitudinal studies are needed to further explore the interplay between bone and vascular calcifcation.

SA-PO685

Changes in DXA Measures of Bone Mineral Density after Pediatric Renal Transplantation Anne K. Tsampalieros,[1] Lindsay M. Griffin,[1] Babette Zemel,[1] Heidi Kalkwarf,[2] Justine Shults,[1] Mary B. Leonard.[1] *[1]Pediatrics, Children's Hospital of Philadelphia, Philadelphia, PA; [2]Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: We recently reported (JASN 2012) that trabecular volumetric bone mineral density (vBMD) decreases, cortical vBMD increases and cortical thickness did not improve following pediatric renal transplantation (Txp), as measured by quantitative CT (QCT). Changes in DXA measures of areal BMD (aBMD) in pediatric Txp have not been well characterized.

Methods: DXA scans were obtained in 56 Txp recipients (age 6 -21 yr) at Txp, and 3, 6, and 12 months later. Sex- and race- specific Z-scores were generated for DXA whole body bone mineral content (WB-BMC-Z) and lumbar spine BMD (LS-BMD-Z) relative to age and adjusted for height-Z based on >900 healthy reference participants. Changes in Z-scores were assessed using quasi-least squared regression models.

Results: At baseline, LS-BMD-Z was significantly elevated in younger Txp recipients only (Table). In all Txp recipients combined, LS-BMD-Z decreased significantly and decreases were independently associated with greater mean glucocorticoid (GC) dose (p=0.001) and greater declines in PTH levels (p=0.002). Although WB-BMC-Z scores on average did not change significantly over the year, greater GC doses (p<0.001) and lesser decreases in PTH levels (p=0.03) were independently associated with declines in WB-BMC-Z scores.

Height-Z Adjusted DXA Z-scores at Txp and 12 Month Follow-up

	0	12	p value of change
LS-BMD <13 yrs	1.36 ± 1.48*	0.68 ± 1.17*	0.006
LS-BMD ≥13 yrs	0.21 ± 0.80	-0.01 ± 0.76	0.06
WB-BMC	-0.33 ± 1.10	-0.38 ± 1.03*	0.43

* p<0.05 compared to reference participants

Conclusions: These data demonstrated that greater GC exposure following Txp was associated with decreases in LS-BMD-Z and WB-BMC-Z scores. The association with declines in WB-BMC-Z may reflect impaired expansion of cortical dimensions with growth, consistent with our prior QCT analysis. The differential effect of changes in PTH is consistent with PTH effects to increase and decrease trabecular and cortical vBMD, respectively. These data suggest that DXA captures GC and PTH effects on trabecular and cortical bone following Txp.

SA-PO686

Low Fracture Rrates with Normal DXA Scans in Hemodialysis(HD) Patients Scott A. Rasgon,[1] Richard M. Dell,[1] John J. Sim.[1] *[1]Nephrology, Kaiser Permanente, Los Angeles, CA; [2]Nephrology, Kaiser Permanente, Los Angeles, CA; [3]Nephrology, Kaiser Permanente, Los Angeles, CA.*

Background: KDIGO makes the following recommendations for DXA scans in dialysis patients. " **3.2.2 In patients with CKD stages 3-5D with evidence of CKD-MBD, we suggest that BMD testing not be performed routinely, because BMD does not predict fracture risk as it does in the general population, and BMD does not predict the type of renal osteodystrophy (2B)."**This is based on 13 studies with the most subjects in any of the studies was 242. 5 studies showed no correlation with fracture rates and 8 showed some correlation with low BMD and increased fracture rate. Last year we presented data on 1883 patients who had DXA scans. We saw a correlation between a low fracture rate in patients who had a normal DXA. We now have 1954 HD patients with DXA scans and one more year of follow up on our existing patients to identify the predictive value of DXA in HD patients.

Methods: We reviewed the BMD data from DXA scans in a population of HD patients at Kaiser Permanente to see if any correlation exist between BMD testing and hip fracture rates in HD patients greater than 60 years of age. In our 60+ population there was 940,153 DXA done of which 1954 scans were done on HD patients during the time period of 01/01/1998-05/09/12.

Results: We found the following results. 325 HD patients had a normal DXA and only 4 had hip fracture with a 1.2 % rate of fracture.

Hemodialysis DXA and Hip Factures

	No DXA	Normal	Osteopenia	Osteoporosis	Unknown	Total
Hemodialysis Hip Fx	27	4	42	93	0	166
Hemodialysis	954	321	791	689	14	2769
Hemodialysisi Total	981	325	833	782	14	2935

Comparing the risk of hip fracture in a normal DXA vs osteoporosis/osteopenia result showed an unadjusted relative risk of 6.8 with a p=.0001.

Conclusions: Our findings demonstrate that normal DXA scans predict a low fracture risk even in HD patients. This has continued to be supported in our large updated data base with more DXA scans and one more year of observation. We have more subjects in our study than previous studies combined.This data supports the use of DXA scans in HD patients to identify those at highest risk to concentrate on fall prevention and treatment options.

SA-PO687

Mineral Metabolism and Cortical Volumetric Bone Mineral Density in Childhood Chronic Kidney Disease Michelle Denburg,[1] Anne K. Tsampalieros,[1] Ian H. de Boer,[2] Justine Shults,[1] Heidi Kalkwarf,[3] Babette Zemel,[1] Mary B. Leonard.[1] *[1]The Children's Hospital of Philadelphia, Philadelphia, PA; [2]University of Washington, Seattle, WA; [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: The objective of this study was to determine the relations among measures of mineral metabolism and cortical volumetric bone mineral density (CortBMD) in children with CKD.

Methods: Cross-sectional study of 172 children (ages 5-21 yr) with CKD stages 2-5D. Serum measures included 25-hydroxyvitamin D (25[OH]D), $1,25(OH)_2D$, $24,25(OH)_2D$, PTH, fibroblast growth factor 23 (FGF23), calcium (Ca, corrected for albumin), and phosphorus (Pi). Free and bioavailable 25(OH)D were calculated using total 25(OH)D, albumin and vitamin D-binding protein levels. Tibia quantitative CT scans were used to measure CortBMD and results expressed as sex-, race- and age-specific Z-scores based on 675 controls. Multivariate linear regression was used to identify independent correlates of CortBMD-Z.

Results: Median CortBMD-Z was lower in CKD stages 4-5D compared with stages 2-3 (-0.47 vs. +0.14; p < 0.01). Median PTH was 182 pg/ml in stages 4-5D and 44.5 pg/ml in stages 2-3 (p <0.0001). In multivariate analysis (Table), Ca and 25(OH)D were positively associated, and PTH and $1,25(OH)_2D$ levels were inversely associated with CortBMD-Z. The positive association between 25(OH)D levels and CortBMD-Z was comparable using total, free or bioavailable levels. CKD severity and Pi were not associated with CortBMD-Z, independent of PTH level. Sex, race, underlying disease, FGF23 level, and vitamin D sterol therapy were not associated with CortBMD-Z.

Multivariate Model of Determinants of CortBMD-Z

Covariate	Change in CortBMD-Z	p
Age (per yr)	-0.048	0.07
PTH (per 10%)	-0.024	0.002
Ca (per 1 mg/dl)	0.37	0.02
25(OH)D (per 10 ng/ml)	0.19	0.03
1,25(OH)2D (per 10%)	-0.075	<0.001

PTH and 1,25(OH)2D log transformed

Conclusions: Greater PTH and $1,25(OH)_2D$ levels and lower calcium and 25(OH)D levels were independently associated with cortical deficits in childhood CKD, as measured by quantitative CT. Bone biopsy studies are needed to determine if these deficits represent increased porosity and/or a mineralization defect.

Bisphosphonate Use in Chronic Kidney Disease Meghan J. Elliott,[1] Matthew T. James,[1] Luz Palacios-derflingher,[1] Marcello Tonelli,[2] Braden J. Manns,[1] Robert R. Quinn,[1] Pietro Ravani,[1] Gregory Kline,[1] Brenda Hemmelgarn.[1] *[1]Medicine, University of Calgary, Calgary, AB, Canada; [2]Medicine, University of Alberta, Edmonton, AB, Canada.*

Background: While bisphosphonates are commonly used in the general population, their use in patients with eGFR < 30 mL/min/1.73 m^2 is not recommended due to lack of data regarding safety and efficacy. We aimed to investigate the association between CKD stage and bisphosphonate use in a community-based cohort.

Methods: Participants aged ≥ 66 years were identified from a province-wide lab database, Alberta, Canada between 2002 and 2008. We included patients who had at least 1 outpatient creatinine measurement and did not require renal replacement therapy at baseline. GFR was estimated using the CKD-EPI equation, categorized as ≥ 60, 45-59, 30-44, 15-29 and < 15 mL/min/1.73 m^2 (index date was the date of the first eGFR). Bisphosphonate use was defined as at least 2 prescriptions in the year after their index eGFR. Logistic regression models (adjusted for demographics, comorbidities, steroid use and prior fractures) were used to determine the likelihood of bisphosphonate use by stage of CKD (reference eGFR ≥ 60).

Results: Among the 304,601 participants (median age 74.7 years; 55.7% female), 33% had eGFR < 60. Prevalence of bisphosphonate use declined with decreasing eGFR, however their use remained substantial even among patients with eGFR < 30. Compared to patients with eGFR > 60, patients with eGFR 15-29 were only 30% less likely to use bisphosphonates (OR 0.70; 95% CI 0.65, 0.76) after adjusting for demographics, comorbidities, steroid use and prior fracture.

Prevalence and adjusted likelihood of bisphosphonate use

eGFR (mL/min/1.73 m²)	Crude prevalence of bisphosphonate use (95% CI)	Adjusted* OR (95% CI)
≥ 60	13.7% (13.6, 13.9)	Reference
45-59	13.3% (13.0, 13.6)	0.89 (0.86, 0.91)
30-44	12.0% (11.7, 12.4)	0.80 (0.77, 0.84)
15-29	9.8% (9.2, 10.5)	0.70 (0.65, 0.76)
<15	4.0% (3.0, 5.5)	0.32 (0.23, 0.44)

*Adjusted for age, sex, comorbidities, steroid use and prior fracture

Conclusions: Despite a lack of data on efficacy and safety, the prevalence of bisphosphonate use among patients with severe CKD (eGFR < 30) was only slightly lower than in people with normal kidney function.

SA-PO689

Zoledronic Acid Improves Bone Volume but Not Arterial Calcification in CKD-Mineral Bone Disorder Neal X. Chen,[1] Matthew R. Allen,[1] Vincent H. Gattone,[1] Xianming Chen,[1] Drew M. Brown,[1] Alexander J. Carr,[1] Mohammad Walid Aref,[1] Sharon M. Moe.[1,2] *[1]Indiana Univ School of Medicine, Indpls, IN; [2]Roudebush VAMC, Indpls, IN.*

Background: Bisphosphosphonates have not been directly tested in CKD patients. Zoledronic acid (ZOL) is a potent bisphosphonate that could improve bone properties in CKD. It also has anti-VEGF properties and thus may be effective in the vascular disease of CKD-MBD.

Methods: Cy/+ male rats (CKD) or their normal littermates (NL) were treated with a normal (0.6%) phosphorus casein diet, and given a single SQ injection of zoledronic acid (ZOL) or vehicle at 25 wks (~30% NL GFR) of age. Serum biochemistries were followed for 10 wks; blood pressure, heart mass, aorta calcification, and bone were assessed at 35 wks of age (~15% NL GFR).

Results: The CKD rats developed CKD-MBD with a progressive increase in phosph, PTH, FGF23 and BUN. The aorta calcium content in CKD rats was 2x that of NL animals and was correlated with PTH (r=0.65), FGF23 (r=0.73), phosph (r=0.70) and heart wt (r=0.81); all $p < 0.001$. ZOL had no effect on biochemistries of CKD-MBD, arch calcification, or heart wt. CKD animals treated with ZOL had significantly higher proximal tibia trabecular bone volume compared to vehicle ($23.0 \pm 7.5\%$ vs $9.7 \pm 4.4\%$, $p < 0.001$). These effects were similar to those observed in NL animals. ZOL treatment resulted in higher trabecular number, but not thickness in both CKD and NL rats. There was no relationship between arch calcification and bone volume. FGF23, PTH, calcium and phosph did not correlate with trabecular bone volume nor trabecular number, but were strongly correlated with trabecular thickness. The effect of ZOL on bone strength and cortical bone is being evaluated. There were no adverse effects on kidney function.

Conclusions: In a slowly progressive rat model of CKD fed a normal phosphorus diet, there was a substantial positive effect of ZOL on trabecular bone volume. In contrast to studies from other bisphosphonates, ZOL had no effect on aorta calcification, heart size, calcium, phosph, PTH or FGF23. These studies suggest that ZOL may provide an effective therapy for bone preservation in the setting of CKD-MBD.

SA-PO690

Pharmacokinetic Effect of Cinacalcet on Patients with Secondary Hyperparathyroidism (SHPT): Useful Data in Clinical Practice Dolores Arenas,[1] Vanesa De la Fuente,[1] Pablo Delgado,[1] Patricia Gutiérrez,[1] Jorge Ribero,[1] Mariano Rodriguez,[2] Victor Lorenzo,[3] Yolanda Almaden Peña.[2] *[1]H.Perpetuo Socorro, Alicante, Spain; [2]H.Reina Sofía, Córdoba, Spain; [3]H.U.Canary Islands, La Laguna, Spain.*

Background: The pharmacokinetic (PK) effect on patients (pts) controlled and treated chronically with cinacalcet is unknown. Our objective was to describe the PK effect over 48 hours (h) after a single dose of cinacalcet in pts on hemodialysis (HD) with controlled iPTH (100–400 pg/ml).

Methods: Single-center, open, exploratory and uncontrolled PK clinical trial with a single dose of cinacalcet based on clinical practice (30–90 mg) and a 48h follow-up. The treatment the pts received before the start of the study was maintained. iPTH, ionic Ca, P, and calcitonin were determined at baseline (24h after the last cinacalcet dose, trough level in daily dosing regimen), and at 1, 3, 6, 12, 24 and 48h. PTH was determined with the Duo PTH kit (Scantibodies Laboratory,Santee,CA,USA).

Results: We included 10 pts (8 men) with SHPT (median diagnostic age of 4.5 years (y), range 2–31), with a mean age 66 y (39–82), receiving HD for a median of 5 y (2–31). Table 1 shows the mean levels (SD) during the study. Pts received the dose that they were due to receive: 6 pts received 30 mg of cinacalcet, 3 received 60 mg and 1 received 90 mg. They were all treated with hidroferol for 2 months before the study. 25OHD3: 52.6±13.5; 1.25OH2D3: 18.8±14.4.

Table 1. Mean levels (SD) at baseline and after cinacalcet administration, and percentage of patients in range. Repeated measures ANOVA P

Time	Previous 2 months	0 hours	1 hour	3 hours	6 hours	12 hours	24 hours	48 hours	P-Value
Intact PTH (pg/ml)	252.9 (80.5)	140.1 (96.7)	74.6 (42.5)	78.4 (35.1)	131.4 (94.6)	204.2 (147.9)	175.5 (118.2)	250.0 (141.7)	0.007
% pat. with PTH < 100	0	40	70	80	50	30	30	10	-
% pat. with PTH 100-400	100	60	30	20	50	50	70	70	-
% pat. with PTH >400	0	0	0	0	0	20	0	20	-
Ionic calcium (mg/dl)	8.7* (0.6)	4.96 (0.39)	5.05 (0.23)	5.05 (0.25)	5.11 (0.51)	4.87 (0.25)	5.11 (0.30)	5.03 (0.40)	NS
Phosphorus (mg/dl)	4.9 (0.9)	4.51 (0.6)	4.15 (0.52)	4.01 (0.68)	4.02 (0.64)	3.98 (0.76)	4.78 (0.94)	5.32 (1.27)	0.04
Calcitonin (pg/ml)	—	15.0 (14.1)	19.5 (18.2)	33.8 (32.9)	29.5 (32.4)	20.6 (21.3)	14.4 (14.5)	11.0 (10.1)	0.01

*Serum calcium; SD = standard deviation, NS = not significant

Conclusions: In HD pts with SHPT controlled by cinacalcet, a similar PK effect to *de novo* pts is produced, with a predictable response (reduction in PTH and P, and increase in calcitonin in the subsequent 6h with no change in Ca) and a significant increase at 48h in PTH and P and reduction in calcitonin. In pts with excessively suppressed PTH at minimum doses of cinacalcet, it could be suggested that spacing the doses might be useful.

SA-PO691

Effect of Sevelamer Treatment on Fibroblast Growth Factor 23 and Pulse Wave Velocity in CKD Stage 3 Patients Annet Bouma-de Krijger, Frans J. van Ittersum, Pieter M. Ter Wee, Marc G. Vervloet. *Nephrology, VU University Medical Center, Amsterdam, Netherlands.*

Background: FGF23 is independently associated with cardiovascular outcome. In this pilot study we investigated the effect of phosphorus binding therapy on FGF23 and subsequent change in pulse wave velocity.

Methods: 24 normophosphatemic CKD stage 3 patients were treated with a fixed dose of sevelamer-carbonate 2,4 gram twice daily with their meal. Patients remained on their usual diet. Measurement of pulse wave velocity (PWV) was performed and blood samples were obtained 2 weeks prior to baseline, at start of sevelamer treatment, at 8 weeks sevelamer treatment and after a wash-out of 2 weeks. We measured 3 times PWV at each time point with the Sphygmocor® device. Measurements were valid with a SD < 10%. General Estimated Equations (SPSS) was used to evaluate the effect of phosphorus binding on the mean PWV.

Results: Of 24 patients, 2 withdrew because of hypophosphatemia (<0.7 mmol/l) and 4 because of side effects. Analysis was performed in the remaining 18 patients. In these, phosphate levels decreased not significantly during treatment from a mean of 1.12 (± 0.17) to 1.07 mmol/l (± 0.21). During treatment period phosphate excretion decreased from a median of 26,3 to 17,5 mmol/24 h (p 0.02), but not paralleled with a decline in FGF23. FGF23 decreased not significantly from a median of 169 (IQR 123-215) to 155 RU/l (IQR 113-214).

	regression coefficient (B)	p-value	explained variance (model)
PWV (m/s)			0.47
Treatment compared to baseline	-0.27	0.15	
Wash-out compared to treatment	0.27	0.32	
Female compared to male	-1.02	0.02	
Diabetes	0.42	0.34	
Age (years)	0.10	<0.001	
MAP (mmHg)	0.02	0.38	
FGF23 (RU/ml, log transformed values)	0.60	0.04	

Phosphorus binding with sevelamer showed a non-significant trend towards a decline in PWV. In additon to this finding 24 hour phosphate excretion did not influence PWV. lnFGF23 is significantly associated with PWV.

Conclusions: Phosphorus binding therapy by sevelamer leads to a decline in phosphate excretion but not to a decline in FGF23 or improved PWV. For the latter our study was most likely underpowered. However, overall FGF23 was independently associated with increased PWV, suggesting a direct effect on vascular function.

Funding: Pharmaceutical Company Support - Sanofi, the Netherlands

SA-PO692

Effect of Eldecalcitol, a New Active Vitamin D Analog, on Bone Metabolism in Postmenopausal Women Undergoing Maintenance Hemodialysis Naomi Sasaki,[1] Ryota Ikee,[2] Megumi Sato,[3] Masataka Tsunoda,[4] Nobuo Hashimoto.[1] *[1]Department of Nephrology and Dialysis, H. N. Medic, Atsubetsuchuo, Atsubetsu-ku, Sapporo, Japan; [2]H. N. Medic Kitahiroshima; [3]Jinzonaika Megumi Clinic; [4]H. N. Medic Sapporo-Higashi.*

Background: Eldecalcitol (ED) is a new agent that was developed to improve the effects on bone status while maintaining the positive effects of the conventional active vitamin D on Ca metabolism.In cases of primary osteoporosis, ED is known to dose-dependently increases bone density in the lumbar vertebrae while reducing the frequency of new vertebral fractures, and has attracted attention as new therapeutic drug for the

treatment of osteoporosis.However, there has been no report examining the effects of ED treatment on bone metabolism in patients with ESRD to date. We examined the safety and effects on bone metabolism of ED treatment in postmenopausal female patients undergoing maintenance dialysis.

Methods: Forty postmenopausal women who had received maintenance dialysis for at 6 months at our institution were enrolled. Patients with an average Ca(Alb) level of more than 9.5mg/dL prior to ED treatment were excluded. ED (0.5μg/day) was added to the existing treatment regiment, and patients were followed for 6 months after the onset of treatment.

Results: 1) Excluding 4 subjects who changed hospital and 4 subjects removed from the study, 32 subjects were followed-up for 6 months after ED treatment. The reason for removal of the 4 subjects was hypercalcemia (≥11.0), constipation, diarrhea and skin irritation, respectively.

2) A comparison of mean values for the 6 months before treatment and 6 months after ED treatment.

Effects on Bone Metabolism

	Pre-treatment	Post-treatment	
Ca(Alb)	9.0±0.3	9.5±0.5	0.001*
intPTH	108±57	80±56	0.004*
BSAP	133±79	88±45	0.006*
TRACP-5b	659±346	485±266	0.02*
LV-BMD	0.501±0.108	0.525±0.015	0.06
LV-Tscore	66.1±14.3	69.5±16.0	0.04*

LV; Lumber vertebrae, mean±SD

Conclusions: We followed-up postmenopausal woman undergoing maintenance dialysis for 6 months after the onset of ED treatment. ED treatment did not result in severe hypercalcemia and was continued. In addition a significant reduction in a bone metabolism marker and increase in lumbar vertebrae bone density were observed.

SA-PO693

PA21, a Novel Iron-Based Phosphate Binder, Has High Phosphate Binding Capacity and Low Iron Release In Vitro across a Physiological pH Range

Maria Wilhelm,[1] Felix W. Funk,[1] Sylvain Gaillard.[2] *[1]Vifor (International) Inc., St. Gallen, Switzerland; [2]Vifor Pharma, Glattbrugg, Switzerland.*

Background: Management of hyperphosphatemia in chronic kidney disease can be challenging due to limitations of current treatments, e.g., high pill burden and poor tolerability. The novel iron-based phosphate binder PA21 is being developed and may provide an alternative treatment for hyperphosphatemia. This *in vitro* study investigated phosphate binding capacity and iron release of PA21 at pH values found in the gastrointestinal (GI) tract.

Methods: PA21 (90mM Fe) was incubated with phosphate buffer (36mM) in an aqueous solution at pH 1.2 for 1 hr. The solution was subsequently adjusted to pH 2.5 for 1 hr, 4.5 for 1.5 hrs, 7.0 for 2 hrs, and 7.5 for 2.5 hrs. After each timepoint, phosphate adsorption (difference between amount of phosphate added and the amount not adsorbed) and final pH of samples were measured. Phosphorus concentration was determined photometrically as molybdenum blue at 740nm. Additionally, iron release was determined by inductively-coupled plasma optical emission spectrometry in samples prepared at pH 1.2, 1.7 and 2.1.

Results: Phosphate adsorption was lowest (0.184 mg P/mg Fe) at pH 1.3, peaked (0.214 mg P/mg Fe) at pH 2.5, then declined slightly with increasing pH (Figure 1). Iron release peaked (6.2%) at a final pH of 1.2 (initial pH: 1.2). Iron release was 1.3% at a final pH of 2.5 (initial pH: 1.7) and was not detectable at a final pH of 5.6 (initial pH: 2.1).

Conclusions: PA21 showed a high phosphate binding capacity even at low pH, and robust phosphate binding capacity at higher pHs. Iron release was negligible except at the lowest pH (1.2), representative of the fasting state of the stomach. These characteristics of PA21, observed *in vitro*, indicate that it could be a potent phosphate binder that minimizes the risk of systemic effects in patients with hyperphosphatemia.

Indoxyl Sulfate Induces Oxidative Stress and Apoptosis in Cultured Osteoblast Cells

Hyo-Wook Gil,[1] Soon Hyo Kwon.[2] *[1]Department of Internal Medicine, Soonchunhyang University Cheonan Hospital, Cheonan, Chungnam, Korea; [2]Department of Internal Medicine, Soonchunhyang University Hospital, Seoul, Korea.*

Background: Indoxyl sulfate (IS) is an organic anion uremic toxin. IS accumulates in the blood and promotes the progression of renal dysfunction. Recently, a few reports have suggested that IS inhibits osteoblastic cell function, suppresses parathyroid hormone (PTH)-stimulated intracellular cAMP production, and decreases PTH receptor expression. However, whether IS suppresses osteoblastic cell differentiation and induces apoptosis is still unclear. In the present study, we investigated whether IS induces apoptosis and inhibits differentiation in cultured osteoblast cells.

Methods: We examined the cytotoxicity of IS in MC3T3-E1 cell line (newborn mouse calvaria-derived preosteoblast cell line) by MTT assay. To determine whether IS inhibits the differentiation of MC3T3-E1, real time PCR (type I collagen, osteonectin) was performed and alkaline phosphatase (ALP) activity was measured. Generation of reactive oxygen species (ROS) was measured using 5-(and-6)-Carboxy-2',7'-dichlorodihydrofluorescein diacetate (DCF-DA). To investigate IS-induced apoptosis, we performed fluorescence-activated cell sorting (FACS) and measured caspase 3/7 activity.

Results: IS showed cell toxicity in a dose-dependent pattern (0.1, 0.5, 1, 1.5 mM, 72 h) and suppressed ALP activity in dose- and time-dependant patterns in the differentiated osteoblast cells. Real time PCR for collagen I and osteonectin showed that IS suppressed the expression of these genes at doses above 0.5 mM at day 5. The expression of these genes was not supressed at days 1 and 3 in the presence of IS. These findings suggest that IS inhibits the differentiation of osteoblast cells. Further, IS provoked ROS in a dose-dependent pattern as found using DCF-DA. Caspase 3/7 activity peaked at 6 h (IS: 1mM). Antioxidant (n-acetylcysteine) attenuated caspase 3/7 activity that was induced by IS. IS caused apoptosis at doses above 0.1 mM during 24 h (0.1 mM, 63.02%), as observed by FACS.

Conclusions: IS induces ROS and apoptosis in cultured osteoblast cells. In addition, IS inhibits differentiation of osteoblast cells.

p-Cresyl Sulfate Deteriorates Osteoblast Function through Up-Regulating MAPK Cascade

Hisae Tanaka,[1] Yoshiko Iwasaki,[2] Yoshitaka Mori,[1] Hirotaka Komaba,[1] Hiroshi Watanabe,[3] Hideyuki Yamato,[4] Toru Maruyama,[3] Masafumi Fukagawa.[1] *[1]Division of Nephrology, Endocrinology, and Metabolism, Tokai University School of Medicine, Isehara, Japan; [2]Department of Health Sciences, Oita University of Nursing and Health Sciences, Oita, Japan; [3]Department of Biopharmaceutics, Graduate School of Pharmaceutical Sciences, Kumamoto University, Kumamoto, Japan; [4]Kureha Special Laboratory Co., Ltd, Fukushima, Japan.*

Background: Accumulation of uremic toxins (UTx) such as Indoxyl sulfate (IS) is not only a key player in progression of kidney dysfunction, but also a leading cause of various complications in chronic kidney disease (CKD). p-Cresyl sulfate (PCS), the main metabolite of p-cresol, predicts the risk of cardiovascular and all-cause mortality in patients with CKD through mechanism not fully understood yet. In order to prove possible contribution of PCS on bone metabolism in CKD, we analyzed the toxic effects of PCS on osteoblasts in comparison with IS.

Methods: Primary osteoblastic cells from mouse calvariae were exposed with PCS (0 to 0.5mmol/L) for 24hr, and stimulated by 10^{-8}mmol/L parathyroid hormone (PTH) for 10min. We evaluated intracellular cAMP production, reactive oxygen species (ROS) production, cell viability, and amount of DNA fragmentation. MAPK signaling pathways were also determined.

Results: PTH-induced intracellular cAMP production of osteoblasts decreased in the presence of 0.125-0.5mmol/L PCS. Increased DNA fragmentation and decreased cell viability were observed with PCS treatment above 0.125mmol/L. On the other hand, IS did not suppress the PTH response of osteoblasts until at a dose of 2mmol/L and decreased cell viability at the concentration range of 0.5-2mmol/L. IS demonstrated significant increase in ROS production at 0.25mmol/L, while PCS demonstrated that only at 0.5mmol/L. We also observed that PCS induced phosphorylated JNK, a MAP kinase protein.

Conclusions: PCS deteriorated osteoblast function through the activation of MAPK cascade in addition to ROS production. These findings suggest that PCS plays significant roles in abnormal bone metabolism in CKD through mechanisms different from those of IS.

SA-PO696

Falsely Low Parathyroid Hormone Levels in Dialysis Patients Receiving Biotin Supplements

Anuradha Wadhwa, Vinod K. Bansal, Earle W. Holmes. *Loyola University, IL.*

Background: Biotin has been identified as a potential cause of falsely suppressed parathyroid hormone (PTH) levels in samples measured using "classic" Siemens Advia Centaur PTH assay (CLPTH). We compared PTH results measured by CLPTH with the manufacturer's new enhanced PTH assay that is free from biotin interference (ENPTH) and also evaluated the clinical significance of inter-assay differences in PTH results.

Methods: Samples from 128 dialysis subjects taking standard doses of renal vitamin supplements were tested by CLPTH and ENPTH methods. Four patients that showed the largest inter-method differences were further evaluated for potential analytical interference by heterophile antibodies to goat IgG, and by substances that bind to streptavidin (e.g.

biotin). Each patient's PTH results were interpreted relative to KDOQI 2002 Guideline (target: 150-298 pg/mL) and Commentary 2010 (target: 2-9 times ULN of the assay).

Results: 37 of 128 (29%) patients had PTH values that were decreased by > 10% when assayed by CLPTH as compared to ENPTH (median decrease: 20 %; range: 11% -98%). Four samples with largest inter-method differences were free from interference by heterophile antibodies. Pretreatment of these specimens with streptavidin prior to re-assay by the CLPTH method resulted in an increase in the PTH values, suggesting that the interfering substance inhibited the binding of the biotinylated capture antibody to streptavidin. Evaluation of the inter-assay differences relative to the PTH targets in the KDOQI guidelines and the commentary 2010 showed that the negative interference in the CLPTH would have affected the clinical interpretation of results in as many as 8 (6 %) and 7 (5 %) cases, respectively. The prevalence of biotin interference in our patients greatly exceeded the expected 0.5% rate that was reported by the manufacturer.

Conclusions: An interfering substance (presumably biotin) is present in the plasma of dialysis patients taking standard doses of commonly used vitamins at levels sufficient to cause significant negative interference in the CLPTH assay. The resulting false decreases in PTH results had the potential to adversely affect the management of Secondary hyperparathyroidism.

SA-PO697

The Influence of Different Heparins and Sulodexide on Concentration and Gene Expression of OPG/RANK/RANKL Pathway in Human Umbilical Vein Endothelial Cells (HUVECs) Beata Naumnik, Katarzyna Gasowska, Michal Mysliwiec. *Dept. of Nephrology and Transplantation with Dialysis Unit, Medical University of Bialystok, Bialystok, Poland.*

Background: OPG/RANK/RANKL (Osteoprotegerin/Receptor Activator of Nuclear Factor κB/Receptor Activator of Nuclear Factor κB Ligand) system plays an important role in vascular calcification. Heparins and others glycosaminoglycans, interact with OPG, may influence the process of atherogenesis. Von Willebrand Factor (vWF) functionally connected with OPG in Weibel-Palade bodies, presents as well-known endothelial dysfunction marker.

Methods: HUVECs were obtained as described by Jaffa. The cultures were supplemented with unfractionated heparin (UFH), enoxaparin and sulodexide. The concentrations of OPG, sRANKL and vWF were determined (ELISA) in supernatant from the culture before and after drugs' stimulation. To determine the genes expression of all examined factors in endothelial cells, the Real Time-PCR reaction was carried out.

Results: We found 1.5 fold increase in OPG gene expression after 1 hour of incubation ($p=0.027$) with 4 μg/ml of UFH, followed by increase of OPG concentration after 6 hours of incubation. UFH and sulodexide provoked fast increase of sRANKL concentration, but only UFH increased RANKL gene expression after 1 h of incubation ($p=0.042$). vWF level raised accordingly with UFH concentration ($p<10^{-3}$) as well as the duration of incubation ($p=0.006$) and was positively correlated with OPG increase. Sulodexide induced the 2.5 fold increase of vWF gene expression during the second hour of incubation ($p<10^{-3}$).

Conclusions: UFH occurred to be the most potent in releasing OPG, sRANKL and vWF from HUVECs. Similarly, the increase of OPG and RANKL genes expression was observed only with UFH supplementation. The positive correlation between the increase in vWF and OPG after UFH administration reinforces the presumption of the pathophysiological linkage between OPG/RANK/RANKL axis and vascular calcification.

Two Novel Vitamin D Receptor Modulators of Similar Structures Exhibit Distinctly Different Hypercalcemic and Cardiovascular Effects in 5/6 Nephrectomized Uremic Rats J. Ruth Wu-Wong, Megumi Kawai, Yung-wu Chen, Masaki Nakane. *Vidasym, Chicago, IL.*

Background: Vitamin D receptor modulators (VDRMs) such as calcitriol, paricalcitol and doxercalciferol are commonly used to manage secondary hyperparathyroidism in chronic kidney disease (CKD). Clinical observations demonstrate that VDRM therapy may provide cardiovascular benefit in CKD. Current on-market VDRMs have a narrow therapeutic index (TI) at 1-4-fold (estimated from the hypercalcemic toxicity and PTH suppressing efficacy). Hypercalcemia is a serious concern, leading to the need for frequent drug dose titration and serum calcium monitoring. A VDRM with expanded TI and cardiovascular benefit will be desirable. However, it is not well understood why structurally similar VDRMs exhibit different hypercalcemic profile and how hypercalcemia affects VDRM's cardiovascular effect.

Methods: We studied two novel VDRMs with similar structures (one difference in the A-ring) in the 5/6 nephrectomized (NX) male Sprague–Dawley rats with established uremia, elevated parathyroid hormone (PTH), endothelial dysfunction and left ventricular (LV) hypertrophy.

Results: VS-110 and VS-411 at 0.01-1 μg/kg (i.p. 3x/week for two weeks) suppressed serum PTH in the 5/6 NX rats effectively. VS-411 potently raised serum calcium in a dose-dependent manner with 11% increase in serum calcium at 0.01 μg/kg (TI = ~1-fold), while VS-110 didn't raise serum calcium even at 1 μg/kg (TI > 50-fold). When the 5/6 NX uremic rats were treated with VS-110 or VS-411 (0.01- 0.1 μg/kg) for two weeks, VS-110 improved endothelium-dependent aortic relaxation and reduced LV hypertrophy in a dose-dependent manner without affecting serum calcium. VS-411 also exhibited effects on the cardiovascular parameters, but was less potent. VS-110 and VS-411 induced HL-60 differentiation with EC_{50} at 0.8 and 0.3 nM (vs. calcitriol at 13.9 nM), respectively. Both VS-110 and VS-411 inhibited the proliferation of primary human keratinocytes with IC_{50} at 1.40 and 0.04 nM (vs. calcitriol at 10 nM), respectively.

Conclusions: These studies demonstrate that structurally similar VDRMs can exhibit distinctly different hypercalcemic and cardiovascular effects in 5/6 NX uremic rats.

SA-PO699

Fibroblast Growth Factor 23, Parathyroid Hormone and Phosphate Excretion in CKD Stage 3 Maarten W. Taal,[1] Victoria Thurston,[1] Natasha J. Mcintyre,[2] Nigel Lawson,[1] Richard J. Fluck,[1] Chris W. McIntyre.[2] *[1]Department of Nephrology, Royal Derby Hospital, Derby, United Kingdom; [2]School of Graduate Entry Medicine, University of Nottingham, Derby, United Kingdom.*

Background: Fibroblast growth factor (FGF)23 has been identified as an important regulator of phosphaturia that becomes elevated early in CKD to increase urinary fractional excretion of phosphate (FePhos) and maintain phosphate balance. We aimed to investigate FGF23 and PTH levels in relation to GFR and FePhos in persons with predominantly early CKD stage 3.

Methods: Serum intact FGF23 (Kainos ELISA) and PTH (Roche E170) were measured in 1667 persons with estimated GFR 59-30ml/min/1.73m^2 recruited from 32 Primary Care Practices. Detailed medical history and clinical assessment were peformed as well as urine and serum biochemistry tests.

Results: Median values for key variables were: age 74(IQR 67 to 79)y, eGFR 53(46 to 60)ml/min/1.73m^2, PTH 46(34 to 66)pg/ml, FGF23 42(33 to 53)pg/ml, FePhos 23(19 to 29)%. PTH and FGF23 were elevated in similar proportions of participants at all levels of GFR (Table). Multivariable analysis identified GFR, serum calcium, phosphate, logPTH, uric acid concentrations as well as log urine PCR and BMI as independent determinants of serum FGF23 concentration (adjusted R^2=0.22). Both log serum PTH and FGF23 concentration were independent determinants of FePhos, as well as age, gender, diabetes, current smoking status, BMI, eGFR, Hb, HDL cholesterol and log hsCRP (adjusted R^2=0.33).

GFR bands	Both normal	FGF23 ⇑	PTH ⇑	Both ⇑	Totals
20-29ml/min	4 (15%)	9 (35%)	2 (8%)	11 (42%)	26
30-39ml/min	43 (24%)	51 (28%)	32 (18%)	54 (30%)	180
40-49ml/min	198 (46%)	92 (21%)	84 (19%)	57 (13%)	431
50-59ml/min	380 (61%)	113 (18%)	89 (14%)	39 (6%)	621
60-69ml/min	260 (76%)	34 (10%)	38 (11%)	9 (3%)	341
70-79ml/min	49 (79%)	6 (10%)	6 (10%)	1 (2%)	62
80-89ml/min	4 (67%)	1 (17%)	1 (17%)	0	6

Conclusions: FGF23 and PTH become elevated in CKD stage 3 and together mediate an increase in FePhos. Multiple factors in addition to GFR and serum phosphate are independent determinants of FGF23 concentration. Further research is required to identify factors that provoke a rise in FGF23 as well the relative importance of FGF23 and PTH in increasing FePhos.

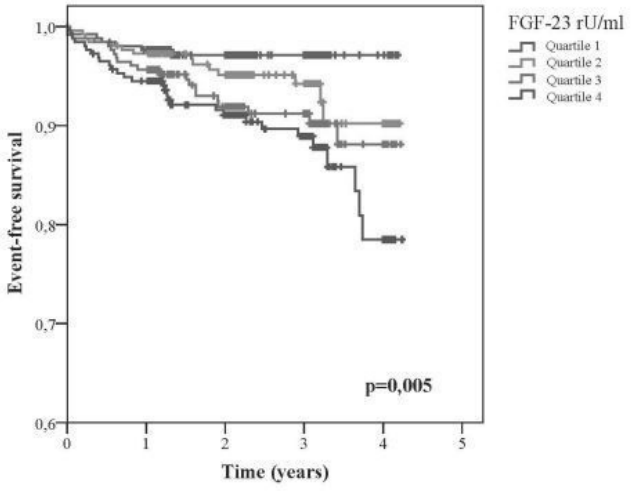
Increased FGF-23 Levels Are Predictors of Cardiovascular Morbidity and Mortality in Subjects with Intact Renal Function-The HOM SWEET HOMe Study Sarah Seiler,[1] Bodo Cremers,[2] Philipp Ege,[1] Michael Fehrenz,[1] Gunnar Max Große-dunker,[1] Florian Hornof,[1] Niko Rebling,[1] Kyrill S. Rogacev,[1] Bruno Scheller,[2] Michael Böhm,[2] Danilo Fliser,[1] Gunnar H. Heine.[1] *[1]Internal Medicine IV, Saarland University Medical Center, Homburg, Saar, Germany; [2]Internal Medicine III, Saarland University Medical Center, Homburg, Saar, Germany.*

Background: Our HOM SWEET HOMe study aimed to investigate cardiovascular (CV) implications of elevated FGF-23 in subjects with intact renal function. We now report first data on the predictive value of FGF-23 levels on CV morbidity and mortality in HOM SWEET HOMe participants.

Methods: We recruited 1309 subjects admitted at Saarland University Hospital for elective coronary angiography between May 2007 and January 2010. At baseline, we recorded classical cardiovascular risk factors and comorbidity; blood samples were obtained for the measurement of C-terminal FGF-23 levels. Patients with eGFR < 60 ml/min/1.73 m² were excluded from this analysis. We assessed the occurrence of the predefined primary endpoint (acute myocardial infarction, CV death and non-hemorrhagic stroke) and of secondary endpoints (CV events; death from any cause) by yearly follow-up interviews.

Results: 1026 from 1309 patients had an eGFR > 60 ml/min/1.73 m², their mean age was 63 ± 10 years, and 513 patients had coronary artery disease at baseline. During a follow-up period of 2.4 ± 1.0 years, patients in the highest FGF-23 quartile reached the predefined primary ($p = 0.005$) and secondary (CV events $p = 0.041$; death from any cause $p = 0.008$) endpoints more often than patients in lower quartiles.



Conclusions: In line with recent data on a direct cardiotoxic effect of FGF-23, our study found a prognostic impact of elevated FGF-23 levels in subjects with intact renal function. These results suggest that FGF-23 might become a new therapeutical target even in the absence of CKD.

SA-PO701

FGF-23: The New HbA1C of Phosphate Homeostasis? Sarah Seiler, Gaetano Lucisano, Philipp Ege, Matthias Klingele, Anne Lerner-Gräber, Danilo Fliser, Gunnar H. Heine. *Internal Medicine IV, Saarland University Medical Center, Homburg, Saar, Germany.*

Background: It has recently been claimed that the phosphaturic hormone FGF-23 better mirrors long-term systemic phosphate burden than a single phosphate measurement, similar to glycosylated haemoglobin (HbA1c) which reflects average blood glucose levels.

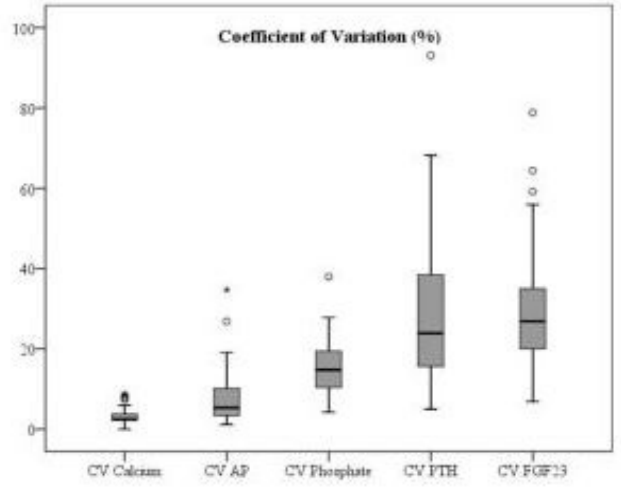
Against this background, we conducted the DIAL HOMe (Dialysis in Homburg Evaluation) study to test the following hypotheses:

1) Plasma FGF-23 values are more strongly associated with average phosphate value over the previous four weeks than with a single random plasma phosphate measurement.

2) Compared to conventional parameters of calcium phosphate metabolism, repeated measurements of plasma FGF-23 have a lower coefficient of variation.

Methods: We included 40 hemodialysis patients into a prospective cohort study. During the study period of four weeks, dialysis dosage, dialysate calcium concentration and co-medication (phosphate binder, calcimimetics, vitamin D, iron) was kept stable. Plasma calcium and phosphate levels were measured at the beginning of each dialysis session, and FGF-23, alkaline phosphatase and parathyroid hormone levels were measured once weekly.

Results: Expectedly FGF-23 correlated with the average phosphate value of the previous four weeks ($r=0.586$; $p<0.01$). However, in contradiction to our hypothesis, this correlation did not significantly differ from the correlation of FGF-23 with a single random phosphate value ($r=0.551$; $p<0.01$). Furthermore, intraindividual stability of FGF-23 was not superior to stability of conventional markers of calcium phosphate metabolism (phosphate, calcium, parathyroid hormone, alkaline phosphatase; [Figure 1]).



Conclusions: In our DIAL HOMe study FGF-23 was neither a specific marker for long term phosphate burden of our patients, nor did it display a higher intraindividual stability than other markers of calcium phosphate metabolism.

SA-PO702

Fibroblast Growth Factor Receptor 1 and Fibroblast Growth Factor Receptor 4 Are the Predominant Receptors for Fibroblast Growth Factor 23 Jyothsna Gattineni,[1] Carlton M. Bates,[2] Michel G. Baum.[1] *[1]Pediatric Nephrology, UT Southwestern Medical Center, Dallas, TX; [2]Pediatric Nephrology, Childrens Hospital of Pittsburgh, Pittsburgh, PA.*

Background: FGF23 is a phosphaturic hormone that is implicated in many hypophosphatemic and hyperphosphatemic disorders. We have previously shown that at baseline individual FGFR1(kidney conditional), FGFR3 and FGFR4 mice had serum phosphorus levels comparable to wild type mice indicating that there is more than one receptor regulating the phosphaturic actions of FGF23. FGFR1 and FGFR4 null mice had ~1.4 times higher serum FGF23 levels suggesting that these receptors are important for the phosphaturic actions of FGF23. Therefore, we studied FGFR1 (kidney conditional) FGFR4 double mutant mice (DKO).

Methods: DKO mice were generating by using the lox-p cre technique. Mice were placed on a phosphate depleted diet for 5 days to study the role of phosphate in the regulation of FGF23.

Results:

Baseline Parameters of Wild Type and DKO Mice

	Wild Type	DKO
Serum FGF23 (pg/ml)	121.3± 6.7	3762 ± 523.5*
Serum Phosphorus (mg/dl)	7.1 ± 0.2	9.2 ± 0.3*
FePhos	6.9 ± 1.5	5.6 ± 0.5
BBM NaPi-2a/β-actin expression	0.6 ± 0.1	0.6 ± 0.2
BBM NaPi-2c/β-actin expression	0.5 ± 0.1	0.7 ± 0.1
Serum PTH (pg/ml)	143.0 ± 26.7	66.4 ± 20.7#
Serum 1,25 Vitamin D (pmol/L)	132.8 ± 9.2	182.5 ± 22.4#

*$p<0.001$; #$p<0.05$

Conclusions: Basal serum phosphorus levels were higher in DKO mice despite a 30 fold higher FGF23 levels in DKO mice compared to wild type mice. Basal BBM NaPi-2a, NaPi-2c expression and FePhos was comparable in DKO and wild type mice showing a resistance to the phosphaturic actions of FGF23. DKO mice have elevated 1,25 vitamin D levels indicating that FGFR1 and R4 also play a role in vitamin D homeostasis. To study the role of serum phosphorus in regulating FGF23 levels, DKO and wild type mice were placed on a LP diet. On an LP diet, serum phosphorus decreased and was comparable in both sets of mice {WT 3.6 ± 0.4 vs 4.0 ± 0.4} but FGF23 levels remained significantly elevated in DKO mice {8.2 ± 3.6 vs 510.1 ± 215.7*, $p<0.05$}. Despite being hypophosphatemic on LP diet, DKO have elevated FGF23 levels. We conclude that FGFR1 and FGFR4 are the principal receptors regulating the phosphaturic actions of FGF23.

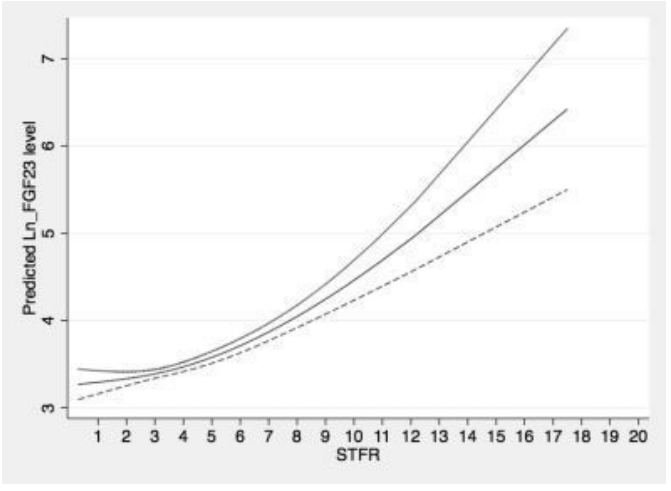
Serum FGF-23 Levels Are Independently Associated with Markers of Iron Metabolism in Kidney Transplant Recipients Istvan Mucsi,[1,2] Miklos Zsolt Molnar,[2,3] Akos Ujszaszi,[2] Myles S. Wolf.[4] *[1]McGill University Health Centre, Montreal, QC, Canada; [2]Semmelweis University, Budapest, Hungary; [3]Harbor-UCLA Medical Center, Torrance, CA; [4]University of Miami Miller School of Medicine, Miami, FL.*

Background: Recent reports suggested a mechanistic link between iron metabolism and circulating levels of FGF-23. We analyzed the association between markers of iron metabolism versus FGF23 levels in kidney transplant recipients.

Methods: Data from 984 Tx recipients (mean age 51±13 years, 57% males, mean eGFR 51±21 ml/min/1.73m2, median Tx vintage 72 months) were analyzed. Serum FGF-23 was measured using a C-terminal enzyme-linked immunosorbent assay (Immutopics, San Clemente, CA, USA). Iron metabolism was characterized by serum iron, transferrin saturation, serum ferritin and also serum soluble transferrin receptor (STFR) levels. eGFR was calculated using the 4-variable MDRD equation.

Results: Age, gender and eGFR adjusted FGF23 levels were weakly and negatively correlated with serum iron and transferrin saturation ($r=-0.079$ and $r=-0.083$, respectively; $p<0.05$). Serum ferritin was negatively ($r=-0.170$, $p<0.001$), STFR positively correlated ($r=0.262$, $p<0.001$) with serum FGF23. In a multivariable linear regression model STFR remained significantly associated with logarithmically transformed serum FGF23 levels (beta=0.200, $p<0.001$), after adjusting for age, gender, eGFR, comorbidity, BMI, Hb, serum albumin, Ca, PO4, PTH, CRP, interleukin 6, TNF-alpha, erythropoietin levels and erythropoietin treatment).



Association between STFR and ln_FGF23 levels (cubic spline model).

Conclusions: Lower levels of iron stores or iron availability are associated with higher serum C-terminal FGF23 levels. These results are compatible with the hypothesis that iron deficiency may modulate FGF23 metabolism in kidney transplant recipients.

Funding: Private Foundation Support, Government Support - Non-U.S.

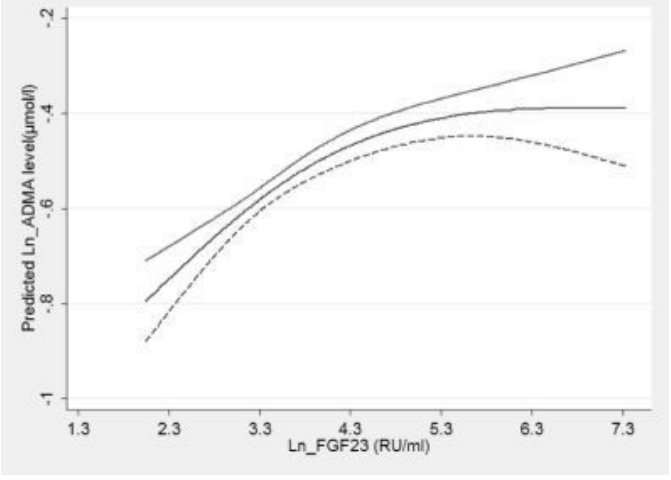
Serum FGF23 Levels Are Indepently Associated with Serum Asymmetric Dimethylarginine (ADMA) Levels in Kidney Transplant Recipients

Istvan Mucsi,[1,2] Akos Ujszaszi,[2] Myles S. Wolf,[3] Jan T. Kielstein,[4] Miklos Zsolt Molnar.[2,5] *[1]McGill University Health Centre, Montreal, QC, Canada; [2]Semmelweis University, Budapest, Hungary; [3]University of Miami Miller School of Medicine, Miami, FL; [4]University of Hannover, Hannover, Germany; [5]Harbor-UCLA Medical Center, Torrance, CA.*

Background: FGF23 may interfere with vascular reactivity induced by the nitric oxide (NO) system. We assessed if serum FGF23 is associated with serum ADMA in stable kidney transplant recipients.

Methods: Data from 258 kidney transplant recipients (age 54+12, mean eGFR 42+21 ml/min/1.73m2) followed at a single transplant center were analyzed. Serum FGF23 was measured using a C-terminal enzyme-linked immunosorbent assay (Immutopics, San Clemente, CA, USA). ADMA was determined using liquid chromatography-mass spectrometry. Variables with non-normal distribution were natural log-transformed for the analyses.

Results: Serum FGF23 levels positively correlated with serum ADMA in bivariate Pearson correlation analysis (r=0.385, p<0.001). In a multivariable linear regression model serum FGF23 remained independently associated with serum ADMA levels (beta=0.157, p=0.013) (adjusted for age, gender, serum albumin, eGFR, Charlson Comorbidity Index, systolic blood pressure, serum phosphate, BMI, total cholesterol and serum PO4).



Association between ln_FGF23 levels and ln_ADMA (cubic spline model)

Similar independent association was seen in a model using L-arginin/ADMA as the dependent variable.

Conclusions: Higher serum FGF23 is independently associated with higher serum ADMA levels in stable kidney transplant recipients. These results are compatible with the hypothesis that higher serum FGF23 levels may be associated with endothelial dysfunction in this patient population.

High Serum Phosphate and Vitamin D Deficiency Enhance TACE Activation and TNFα Release in Vascular Smooth Muscle Cells

Petya Valcheva,[1,2] Yolanda Almaden Peña,[3] Mariano Rodriguez,[2] Adriana S. Dusso.[1] *[1]Experimental Nephrology, IRBLleida, Lleida, Spain; [2]Nephrology Service Research Unit, Hospital Reina Sofia, Cordoba, Spain; [3]Lipid and Atheroesclerosis Unit IMIBIC, Hospital Reina Sofia, Cordoba, Spain.*

Background: High serum phosphate (HP) and vitamin D (VitD) deficiency are associated with a higher risk of cardiovascular (CV) mortality. Increases in serum TNFα, a main cause of systemic inflammation and CV lesions, require enhanced activation of TNFα converting enzyme (TACE). Because parathyroid TACE activity is strongly induced by HP and suppressed by VitD receptor (VDR) activation, we examined whether HP could initiate CV lesions through a distinct up-regulation of TACE activation and TNFαrelease in aortic vascular smooth muscle cells (VSMC) from wild type (wt) and VDR-null mice.

Methods: Changes in TACE expression, subcellular location, and activity were measured in primary cultures of VSMC exposed for 8h to: a) Normal (0.9 mmol/L) or high (3.3 mmol/L) P; b) Lipopolysaccharide (LPS, 100 μg/ml), a known inducer of TACE/TNFα signals, or c) HP with 25-hydroxyvitaminD (10^{-10}M), paricalcitol (10^{-8}M) or both.

Results: In VSMC from wt mice, HP increased cytosolic levels of pro-TACE, inactive TACE, and activated TACE. HP also increased by 2.2±0.2 fold the translocation of active TACE to the cell membrane to release TNFα, as strongly as LPS (2.1±0.19).In VSMC from the VDR-null mice, basal TACE content and activity at the cell surface was 1.8±0.2 fold higher than in wt cells, and was more robustly enhanced by HP and LPS. Accordingly, VDR activation effectively attenuated HP-induced TACE/TNFα signals only in wt cells. Importantly, the 25-hydroxyvitaminD+paricalcitol combination was more potent than either monotherapy.

Conclusions: A cause-effect link between HP and CV damage is that HP enhances TACE/TNFα signals in VSMC as strongly as LPS. Similarly, the CV protective actions of VDR activators could be partially accounted for by their efficacy to attenuate TACE/TNFα signals in VSMC.

SA-PO706

Arterial Klotho Is Regulated via a HSP72-SRF-Dependent Pathway and Is an Obligate Transducer of HSP72 Anti-Calcific Effects

Kenneth Lim,[1,2] Tzong-Shi Lu,[1] Daniel Zehnder,[2] Li-Li Hsiao.[1] *[1]Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [2]Warwick Medical School, Coventry, United Kingdom.*

Background: Klotho is a 130kDa transmembrane protein that is expressed in arterial smooth muscle cells. We previously showed that arterial Klotho deficiency under pro-calcific environments in CKD results in accelerated calcification and causes resistance to anti-calcific effects of the circulating phosphatonin, FGF-23. Heat shock protein (HSP)-72 is an inducible chaperone that can inhibit the development of arterial calcification. Here, we postulate that regulation of vascular health involves cross-talk between Klotho and HSP72.

Methods: *In vitro* model: Human aortic smooth muscle cells (HA-SMCs) +/- Klotho, HSP72 or SRF siRNA. Induction of HSP72 was achieved by heat shock treatment (HST) at 42°C for 30 minutes. Assessment of calcification was achieved by Alizarin red and Arsenazo III method.

Results: We show for the first time that suppression of vascular Klotho under pro-calcific stress (2.7mM CaCl2 and 2mM β-glycerophosphate) can be reversed by induction of HSP72 by HST. These effects were mitigated by HSP72 siRNA. Suppression of vascular Klotho by pro-calcific stress was associated with osteogenic transformation as demonstrated by upregulation of bone phenotypic regulators Runx2 and ALP and dedifferentiation of SMC phenotype as shown by downregulation of serum response factor (SRF), myocardin and α-SMA. Since SRF is a master regulator of SMC contractile genes, we next investigated whether SRF could regulate vascular Klotho expression. SRF suppression by the chemical inhibitor CCG-1423 and SRF siRNA, resulted in loss of Klotho expression. Furthermore, we found HSP72-SRF and SRF-Klotho protein-protein interaction following induction of HSP72 by HST. Finally, induction of HSP72 inhibited the development of HA-SMC calcification and these effects were mitigated by both HSP72 siRNA and Klotho siRNA.

Conclusions: Arterial Klotho is regulated by HSP72 and SRF. Cross-talk between Klotho and HSP72 was mediated by protein-protein interaction with SRF. Arterial Klotho functions as an obligate transducer of HSP72 calcification inhibitory effects.

Erythropoietin Enhances 25-Hydroxy-Vitamin D in Rats with Renal Mass Reduction

Tsuneo Takenaka, Tsutomu Inoue, Yusuke Watanabe, Takashi Miyazaki, Hiromichi Suzuki. *Saitama Medical University, Iruma, Saitama, Japan.*

Background: We showed that erythropoietin (EPO) doses correlated to 1,25-dihydroxy-vitamin D (1,25VD) in hemodialysis patients (Int Urol Nephrol 2003;35:407-13). An activation of EPO receptors stimulates JAK/STAT system to induce erythropoiesis. Enzymatic conversion from vitamin D to 25-hydroxy-vitamin D (25VD) occurs in the liver. To date, 6 cytochromes (CYP2J3, 3A2, 27A1, 2C11, 2R1 and 2D25) are known to be involved in conversion to 25VD. In uremia, CYPs including CYP27A1 and CYP2C11 are reduced in liver. Growth hormone transduces its signal through JAK/STAT pathway

to up-regulate hepatic CYP2C11. However, the influences of EPO on 25-hydroxy-vitamin D and CYPs have not been examined.

Methods: In the present study, the influence of human recombinant EPO (300 units/kg/week for 8 weeks) on CYPs and 25VD were assessed in control Wister (n=5) and 5/6 nephrectomized rats treated with (n=5) and without EPO (n=5). Real time RT-PCR was used to evaluate CYPs with GAPDH as a house keeper.

Results: Hematocrit was decreased in uremic rats (48±1 vs 22±1%, p<0.01), and EPO reversed renal anemia (to 30±2%, p<0.05). Furthermore, 25VD (75±2 vs 17±3 ng/ml, p<0.01), 1,25VD (140±34 vs 26±7 pg/ml, p<0.05), hepatic CYP2C11 (0.42 fold, p<0.05) and CYP27A1 (0.43 fold, p<0.05) were lower in rats with reduced renal mass than the control. The administration of EPO reversed the decrements of 25VD (to 29±4 ng/ml, p<0.01) and 1,25VD (to 68±14 pg/ml, p<0.05) in rats with renal insufficiency. In addition, EPO restored CYP2C11 expression to the control level, but CYP27A1 remained reduced. However, EPO altered serum levels of neither parathyroid hormone nor insulin-like growth factor. Although hepatic JAK2 was increased by 2.8 fold (p<0.05) in uremic animals, EPO reduced JAK2 (0.03 fold, p<0.01). Surprisingly, EPO receptors were detectable in uremic liver.

Conclusions: Our data indicate that the administration of EPO increased 25VD in 5/6 nephrectomized rats. In addition, the present results implicate that EPO elicited an induction of CYP2C11 independently of JAK/STAT pathway. Finally, our findings suggest that EPO may have direct action on hepatic cells in uremia.

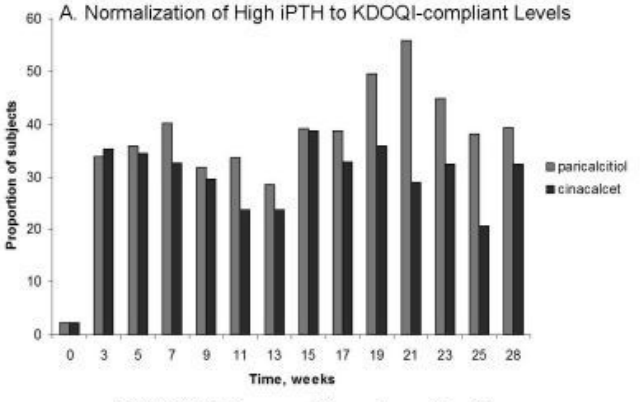
Paricalcitol Compared to Cinacalcet for Treatment of Secondary Hyperparathyroidism (SHPT): Analyses of the IMPACT Study

Markus Ketteler,[1] Kevin J. Martin,[2] Michael Amdahl,[3] Mario Cozzolino,[4] David Goldsmith,[5] Amit Sharma,[6] Samina Khan.[3] *[1]Klinikum Coburg, Coburg, Germany; [2]St. Louis Univ, St. Louis, MO; [3]Abbott, Abbott Park, IL; [4]Univ of Milan, Milan, Italy; [5]Guy's Hospital, London, United Kingdom; [6]Pacific Renal Research Inst, Meridian.*

Background: KDIGO and KDOQI guidelines define target iPTH levels and advise measuring calcium (Ca), phosphorus (P), alkaline phosphatase (AP) and bone-specific AP (BSAP). AP and BSAP are markers of bone turnover; elevated levels are linked to increased mortality. Vitamin D receptor activator (VDRA) therapy is linked to reduced mortality; however, use of non-selective VDRAs leads to an increase serum Ca. Paricalcitol, a selective VDRA, lowers iPTH with minimal impact on Ca and P.

Methods: The IMPACT study compared IV or oral paricalcitol to cinacalcet with low-dose vitamin D. Subjects were initially analyzed by oral and IV randomization strata; for these post-hoc analyses strata were combined to compare overall efficacy of paricalcitol to cinacalcet. iPTH, Ca and P were measured bi-weekly from weeks 3-25 and at week 28.

Results: There were 134 subjects in each treatment group. A greater proportion of paricalcitol subjects had KDOQI-compliant iPTH (upper threshold 300 pg/mL) at every visit except week 3 than cinacalcet (A). Of subjects with baseline iPTH above KDIGO-compliant levels (upper threshold 585 pg/mL), a greater proportion normalized with paricalcitol than cinacalcet at every visit except week 3. Mean iPTH, calcium, and P over time are shown (B). Mean changes from baseline to final were -15.9, +15.2 in AP (IU/L) and -10.3, +9.6 BSAP (U/L) for paricalcitol and cinacalcet, respectively.



Conclusions: Paricalcitol was more effective than cinacalcet at normalizing high iPTH levels, with minimal impact on Ca and P. Paricalcitol treatment reduced, while cinacalcet increased AP and BSAP.

Fibroblast Growth Factor 23 and Cardiovascular Events in Patients with Chronic Kidney Disease: Findings from the CRIC Study

Julia J. Scialla,[1] Tamara Isakova,[1] Amanda Hyre Anderson,[2] Alan S. Go,[3] Juan E. Grunwald,[2] Takayuki Hamano,[2] Jiang He,[4] John W. Kusek,[5] James P. Lash,[6] Lisa C. Nessel,[2] Akinlolu O. Ojo,[7] Mahboob Rahman,[8] Dominic S. Raj,[9] Huiliang Xie,[1] Wei (Peter) Yang,[2] Xiaoming Zhang,[2] Harold I. Feldman,[2] Myles S. Wolf.[1] *[1]University of Miami; [2]University of Pennsylvania; [3]Kaiser Permanente; [4]Tulane University; [5]NIDDK; [6]University of Illinois; [7]University of Michigan; [8]Case Western Reserve; [9]George Washington University.*

Background: Fibroblast growth factor 23 (FGF23) is a phosphaturic hormone that is elevated in CKD and associates with mortality. FGF23 induces myocyte hypertrophy in animal models. We hypothesized that higher FGF23 is associated with all cardiovascular (CV) events, and particularly congestive heart failure (CHF).

Methods: We measured baseline FGF23 in 3860 CRIC participants with CKD followed up to 6 years for pre-ESRD atherosclerotic cardiovascular disease (ASCVD; myocardial infarction, stroke or peripheral vascular disease procedure) or CHF hospitalizations. We assessed the association between FGF23 and events using Cox models adjusted for demographics, kidney function, traditional/nontraditional CV risk factors, and CV drugs.

Results: Mean eGFR was 44 ± 15 ml/min/1.73m^2. A prior history of ASCVD was present in 1,179 participants (31%), and 373 (10%) had a history of CHF. Median FGF23 was 145 (IQR 96 to 239) RU/ml. Higher log-FGF23 was associated with a linear increase in risk of ASCVD and CHF. Results were similar if death was included in the endpoint or if analyses were not censored at ESRD. For each, results were similar among those without prevalent disease (ASCVD or CHF, respectively) and by level of eGFR (≥45, 30-44, or <30 ml/min/1.73m^2).

	Hazard Ratio (95% CI) per doubling of FGF23	
	ASCVD Outcomes N=287 events 22/1000 person years	CHF Hospitalization N=360 events 27/1000 person years
Unadjusted†	1.37 (1.25-1.50)	1.75 (1.64-1.88)
Fully adjusted†‡	1.23 (1.04-1.45)	1.38 (1.21-1.58)
Event or death‡	1.31 (1.19-1.46)	1.42 (1.31-1.54)

†Censored for death and ESRD
‡Adjusted for demographics, kidney function, proteinuria, comorbidity, traditional cardiovascular risk factors, cardiovascular medications, other mineral metabolites, hemoglobin, C-reactive protein and serum albumin

Conclusions: Higher FGF23 is associated with ASCVD and CHF in patients with CKD, but the association with CHF is stronger.

SA-PO710

Direct In Vivo Effects of Vitamin D Sterol Therapy on Wnt Signaling in End Stage Kidney Disease

R.C. Pereira,[1] Harald Jüppner,[2] Isidro B. Salusky,[1] Katherine Wesseling-Perry.[1] *[1]Pediatrics, David Geffen School of Medicine at UCLA, Los Angeles, CA; [2]Endocrine Unit, Harvard Medical School and Massachusetts General Hospital, Boston, MA.*

Background: Wnt signaling is suppressed in early CKD resulting in decreased bone turnover, a phenomenon that is overcome by 2^{o}HPT in late CKD (Sabbagh et al JBMR 2012). It has been postulated that PTH stimulates FGF23 expression through increases in Wnt signaling (Rhee et al JBMR 2011). While vitamin D sterols suppress PTH and increase FGF23, the effect of these agents on osteocytic Wnt signaling remains unknown.

Methods: Protein expression of sclerostin (SOST), a known inhibitor of Wnt signaling, and of FGF23 were assessed by immunohistochemistry in the iliac crest of 11 dialysis patients (6M, 5F), age 16 ± 1 years, before and after 8 months of therapy with vitamin D sterols and phosphate binders.

Results: Biochemical values, bone histomorphometry, and bone SOST and FGF23 protein expression are displayed below.

	Pre	Post
Biochemicals		
Calcium (mg/dL)	8.6 ± 0.2	8.8 ± 0.2
Phosphorus (mg/dL)	6.3 ± 0.4	6.0 ± 0.4
Alkaline Phosphatase (IU/L)	298 (146, 488)	175 (124, 414)
PTH (pg/mL)	517 (378, 1048)	559 (375, 922)
FGF23 (RU/mL)	705 (318, 1196)	1696 (565, 3973)
Plasma SOST (pmol/L)	47 ± 9	50 ± 12
Bone Histomorphometry and SOST Expression		
BFR/BS (μm³/mm²/d)	50.0 ± 10.4	30.4 ± 7.5
OV/BV (%)	7.0 ± 1.1	4.4 ± 0.8*
O.Th (μm)	12.7 ± 0.9	10.2 ± 0.6*
OS/BS (%)	41.1 ± 3.9	31.7 ± 3.8*
OMT (d)	15.3 ± 1.4	14.6 ± 2.1
MLT (d)	29 (24, 47)	36 (30, 46)
BV/TV (%)	37.2 ± 3.7	36.1 ± 2.7
Tb.Th (μm)	173 ± 19	159 ± 6
Bone SOST (pixels/mm²)	0 (0, 21)	208 (11, 961)*
Bone FGF23 (pixels/mm²)	216 (136, 465)	469 (328, 1165)*

PTH values did not change with therapy. Bone SOST was expressed almost exclusively in cortical bone while FGF23 was found in both trabecular and cortical bone. At baseline, bone SOST expression was very low and increased with therapy. Bone FGF23 also increased with vitamin D sterol therapy.

Conclusions: Vitamin D sterol therapy may suppress Wnt signaling in cortical bone, independent of any changes in PTH. Increasing bone FGF23, occurring in conjunction with increasing SOST expression, calls into question current theories regarding Wnt-mediated regulation of FGF23 in CKD.

Fibroblast Growth Factor 23 Increases Rapidly after Acute Kidney Injury

Marta Christov,[1,2] Sushrut S. Waikar,[4] R.C. Pereira,[6] Andrea Havasi,[3] David E. Leaf,[4] David Goltzman,[7] Paola Divieti Pajevic,[1] Myles S. Wolf,[5] Harald Jüppner.[1]
[1]Endocrine Unit, Massachusetts General Hospital, Boston, MA; [2]Nephrology, Beth Israel Deaconess Medical Center, Boston, MA; [3]Nephrology, Boston Medical Center, Boston, MA; [4]Nephrology, Brigham and Women's Hospital, Boston, MA; [5]Nephrology, University of Miami School of Medicine, Miami, FL; [6]Pediatric Nephrology, UCLA School of Medicine, Los Angeles, CA; [7]Endocrinology, McGill University, Montreal, PQ, Canada.

Background: FGF23 is a bone-derived phosphate-regulating hormone, which acts on the kidney to increase urinary phosphate excretion. Circulating FGF23 levels are elevated in chronic kidney disease but little is known about FGF23 levels in acute kidney injury (AKI).

Methods: We investigated changes in FGF23 levels during AKI using folic acid nephropathy in WT as well as genetically modified mice. We also measured FGF23 levels in 14 patients peri- and post-cardiac surgery and compared levels in patients who developed AKI (n=4) versus those who did not (n=10).

Results: FGF23 levels increase within hours after AKI in mice, similar to NGAL, an established AKI marker. Circulating FGF23 levels also increased more than 10-fold 24 hours after AKI in all genetically modified animals, including mice bearing osteocyte-specific PTH/PTHrP deletion, or PTH deletion, or global VDR deletion, similar to the changes observed in WT animals. In phosphate restricted animals we found that despite reduced baseline serum phosphate levels, circulating FGF23 levels increased similar to animals maintained on a phosphate-replete diet. The increase in circulating FGF23 was associated with (or was induced by) an increase in bone FGF23 production. Finally, FGF23 levels increased in post-surgical patients with AKI within 24 hours post-operatively.

Conclusions: In conclusion, FGF23 is rapidly up-regulated during AKI, both in rodents and humans and it can be used as a novel marker of renal injury. This elevation of serum FGF-23 appears to be independent of serum phosphate, PTH, or $1,25(OH)_2$ vitamin D signaling.

SA-PO712

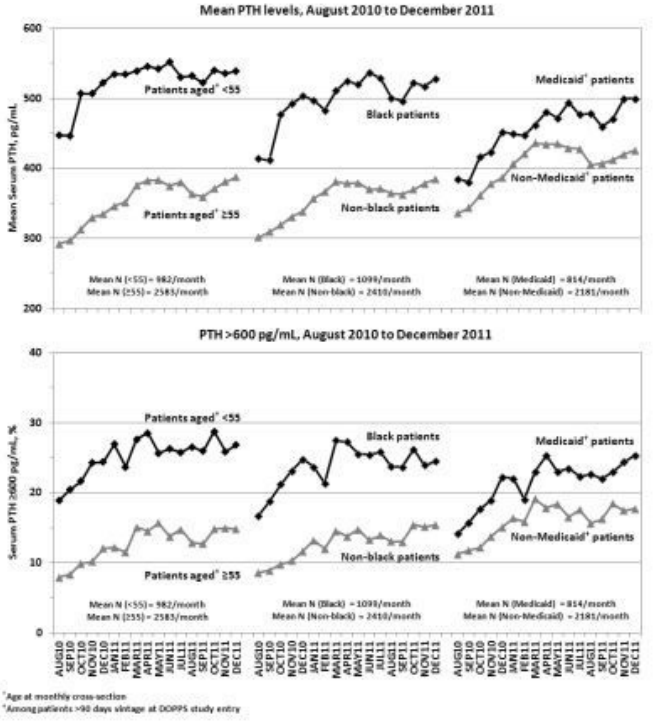
Very High PTH Levels in Hemodialysis (HD) Patients (pts) Who Are Black, on Medicaid, or Aged <55 after Implementation of the Prospective Payment System (PPS): Results from the DOPPS Practice Monitor

Francesca Tentori,[1,2] Douglas S. Fuller,[1] Ronald L. Pisoni,[1] Brenda W. Gillespie,[3] Brian Bieber,[1] Bruce M. Robinson.[1,3] *[1]Arb Res Collab Hlth, Ann Arbor, MI; [2]Vanderbilt Univ Med Ctr, Nashville, TN; [3]Univ of MI, Ann Arbor, MI.*

Background: The 2009 KDIGO guidelines and the 2011 implementation of the PPS may both have contributed to the rise in serum PTH in US HD pts. Due to higher medication use, Blacks, Medicaid pts, and pts aged <55 were identified in a 2010 GAO report as being at higher risk of developing very high PTH levels with the PPS.

Methods: We report trends in mean PTH levels and prevalence of PTH ≥600 pg/mL from Aug 10 to Dec 11 among ~3500 US pts/mo in the nationally representative DOPPS Practice Monitor (DPM; www.dopps.org/dpm). Survey-weighted regressions were used to test group differences.

Results: 48% of US DOPPS medical directors reported higher PTH targets in 2011 vs 2010. Mean PTH levels increased 28% from Aug 10 to Apr 11 and then stabilized. Trends did not differ by race (Black/non-Black, p=0.92), Medicaid status (p=0.16), or age <55 (p=0.05). As at prior time points, the prevalence of PTH ≥600 pg/mL in Dec 11 was higher among Blacks (27%, p<0.001 vs non-Blacks), Medicaid pts (26%, p=0.04 vs non-Medicaid), and pts aged <55 (28%, p<0.001 vs ≥55). Notable changes in secondary hyperparathyroidism therapies were higher oral vitamin D use (3% in Aug 10; 7% in Dec 11) and switch of vitamin D analog type in many facilities (paricalcitol to doxercalciferol). No difference in PTH trend by analog type was seen (p=0.14).



*Age at monthly cross-section
*Among patients >90 days vintage at DOPPS study entry

Conclusions: Following recent guidelines and payment changes, higher PTH targets have been adopted, leading to even higher prevalence of very high PTH levels in certain pt groups. Given the strong association of PTH ≥600 pg/ml with adverse outcomes, clinicians may need to reconsider treatment strategies in these patient groups.

Association of Vitamin D Status and Secondary Hyperparathyroidism in CKD

Jennifer L. Ennis,[1] Elaine M. Worcester,[2] Stuart M. Sprague,[3] Fredric L. Coe.[2] *[1]Litholink Corporation, Chicago, IL; [2]Dept of Medicine, University of Chicago, Chicago, IL; [3]Dept of Medicine, Northshore University Health System, Evanston, IL.*

Background: Vitamin D deficiency is prevalent in CKD patients and contributes to secondary hyperparathyroidism. Current guidelines recommend achieving vitamin D levels above 30 ng/ml, but this target is based upon expert opinion rather than quantitative evidence. We asked if PTH falls progressively with higher 25-hydroxyvitamin D (25-D) levels, and specifically if values above 30 ng/ml are associated with additional reduction in parathyroid hormone (PTH) across all stages of CKD.

Methods: We performed a cross-sectional analysis of initial laboratory data collected on 14289 stage 1-5 US CKD patients enrolled in the Litholink CKD program. Serum calcium (Ca), phosphorus (P), 25-D and plasma PTH levels were compared within a given CKD stage and across CKD stages.

Results: Within CKD stages 3-5, ascending 25-D pentiles (<17.8, 17.8-24.9, 25-31, 31.1-39, >39 ng/ml) were associated with progressively lower unadjusted PTH values. Higher serum Ca values associated with higher 25-D pentiles in stages 4 and 5. Results were similar when PTH was adjusted for serum Ca. Serum P values did not differ significantly between 25-D pentiles within CKD stage. Individual scatter plots of unadjusted PTH vs 25-D showed progressively greater negative slope values from stages 1 through 5; slopes were significant in all 5 CKD stages.

Conclusions: Serum PTH values are progressively lower at higher ranges of 25-D in CKD stages 3-5, including 25-D values above 30 ng/ml. Though observational, these findings support dosing to achieve vitamin D levels above 30 to lower PTH.

SA-PO714

Fibroblast Growth Factor 23 (FGF23) Plasma Levels Are Elevated with Early Chronic Kidney Disease (CKD) and Positively Associated with Steroid Based (SB) versus Steroid Free (SF) Immunosuppression in Pediatric (ped) Renal Transplant (Tx) Patients (pts) Rachana Srivastava, Poyyapakkam Srivaths, Scott E. Wenderfer, Eileen D. Brewer. *Pediatrics, Renal Section, Baylor College of Medicine, Houston, TX.*

Background: FGF23 is a phosphaturic hormone that also suppresses renal 1α-hydroxylase activity. In adult CKD pts FGF23 increases in early stages. Few studies have focused on FGF23 & CKD in ped Tx pts. **Aim:** Determine plasma FGF23 & evaluate potential associations with renal function & mineral metabolism parameters in ped Tx pts.

Methods: Cross-sectional study of 53 ped Tx pts (33M; median age 15.2y, range 3.9-21.8y; 23 Hispanic/16 white/13 black/1 Asian) with CKD stages 1-3 (mean±SD Schwartz eGFR 102±27 ml/min/1.73m2); median time since Tx 1.18y (range 0.15-11y). Immunosuppression was 43 pts steroid free (SF) & 10 steroid based (SB). Serum Cr, Ca, P, iPTH, 1,25vitD; plasma C-terminal FGF23 by ELISA; & urine Ca, P, Cr were measured. 10/53 pts (19%) were on P supplements for hypophosphatemia for age. 13/53 pts (25%) were prescribed calciferol, & 4/53 pts (7.5%), calcitriol.

Results: 14/53 pts (26%) had plasma FGF23>130 RU/ml (normal±2SD=69±39 in healthy controls in 2 ped studies). Plasma FGF 23 levels were not associated with gender, age, ethnicity, time since Tx, tubular reabsorption P (TRP), or serum P, iPTH or 1,25vitD. Elevation of plasma FGF23 was the only mineral metabolism abnormality associated with lower eGFR to CKD stage 2-3 (Table). Plasma FGF23 was higher in pts receiving SB vs. SF (206±207 RU/mL vs. 95±67 RU/ml, p=0.004).

eGFR Schwartz (ml/min/1.73m2)	Serum Ca (mg/dl)	Serum P (mg/dl)	iPTH (pg/ml)	1,25vitD (pg/ml)	TRP (%)	FGF23 (RU/ml)
eGFR ≥90; n=37	9.8 (9.5-10.2)	4.4 (3.6-4.8)	62 (45-153)	57 (46-82)	85 (81-89)	79 (55-95)
eGFR 30-89; n=16	9.8 (9.5-10.1)	4.4 (3.6-4.7)	45 (19-77)	48 (28-55)	84 (80-88)	115* (85-131)

Values as median (interquartile range); *p=0.013, CKD 1 vs CKD 2-3

Conclusions: In ped Tx pts with CKD stages 1-3: 1) elevated plasma FGF23 is the only mineral metabolism parameter associated with early decrease in GFR; 2) elevated FGF23 is strongly associated with SB immunosuppression, suggesting an effect of steroids on FGF23 metabolism in ped Tx.

Funding: Clinical Revenue Support

SA-PO715

Hypovitaminosis D Is Associated with Elevated Parathyroid Hormone (iPTH) in Pediatric (ped) Renal Transplant (Tx) Patients (pts) with Good Function (fx) Rachana Srivastava, Eileen D. Brewer, Tian Tian, Lorrie J. Moreno, Poyyapakkam Srivaths. *Pediatrics, Renal Section, Baylor College of Medicine, Houston, TX.*

Background: Vitamin D (vitD) deficiency (def) is widespread in adult Tx & CKD pts. Prevalence & risk factors associated with vit D def are not well described for ped Tx pts. **Aim:** Assess prevalence of vitD def assessed by serum 25-OH vit D (25OHD) & associations with other mineral parameters or renal fx in ped Tx pts.

Methods: Cross-sectional study of 54 ped Tx pts (34M; median age 15.2y, range 3.9-21.8y; 23 Hispanic/17 white/13 black/1 Asian) with mild CKD stages 1-3 (mean±SD eGFR Schwartz 102±27 ml/min/1.73m2); median time since Tx 1.19y (range 0.15-11 y). Immunosuppression was 44 pts steroid free (SF), 10 pts steroid based (SB). Serum 25OHD, 1,25vitD, Ca, P, iPTH, Cr & plasma C-terminal fibroblastic growth factor (FGF) 23 by ELISA were measured. 13/54 pts (24%) were prescribed calciferol supplements (sup), & 4/54 pts (7%), calcitriol. Average sun exposure (questionaire) was ≥4h/wk (range 4-14) in 14/54 pts (26%).

Results: 45/54 pts (83%) had hypovitaminosis D (25OHD<30ng/ml); 16/45 pts (36%) had vit D def (<15ng/ml); 29/45 pts (64%) had vit D insufficiency (16-29ng/ml). Serum 25OHD levels were not associated with gender, ethnicity, age, eGFR, time since Tx, SF or SB. Serum iPTH but not Ca, P or 1,25vitD were significantly greater in pts with vit D def (table). Serum 25OHD was positively correlated with average weekly sun exposure (r=0.34, p=0.01), but not prescirbed calciferol sup.

25OHD (ng/ml)	Ca (mg/dl)	P (mg/dl)	iPTH (pg/ml)	1,25vitD (pg/ml)	FGF23 (RU/ml)
vitD def <30; n=45	9.8 (9.5-10.2)	4.4 (3.6-4.8)	62* (45-153)	57 (46-82)	86.4 (56-142)
vitD replete≥30; n=9	9.8 (9.5-10.1)	4.4 (3.6-4.7)	45 (19-77)	48 (28-55)	80.7 (55-104)

Serum/plasma values as median (interquartile range); *p=0.049, vitD def vs replete

Conclusions: In ped Tx pts with good graft fx: 1) vitD def is highly prevalent; 2) low serum 25OHD is associated with elevated iPTH, but not other demographic or biochemical parameters; 3) sun exposure was <4h/wk in most pts (74%) and likely contributed to vitD def. Further studies are in progress to evaluate efficacy of calciferol sup to treat vitD def.

SA-PO716

Spak Regulates FGF23 Formation, Phosphate Homeostasis and Bone Mineralization Michael Föller,[1,2] Ganesh Pathare,[2] Diana Michael,[2] Bernd Pichler,[3] Florian C. Lang.[2] *[1]Campbell Family Institute for Breast Cancer Research, University Health Network, Toronto, ON, Canada; [2]Institute of Physiology, University of Tübingen, Tübingen, Germany; [3]Department of Radiology, University of Tübingen, Tübingen.*

Background: The WNK-dependent STE20/SPS1-related proline/alanine-rich kinase (Spak) regulates the thiazide-sensitive sodium, chloride cotransporter (NCC) and the sodium, potassium, chloride cotransporter (NKCC2) in the distal tubule of the kidney thereby maintaining extracellular fluid volume and blood pressure. NCC is also expressed in osteoblasts where it is implicated in bone mineralization. Osteoblasts control phosphate homeostasis by forming the phosphaturic factor FGF23. Here, we tested *in vivo* whether Spak participates in the regulation of FGF23 formation and of phosphate homeostasis.

Methods: FGF23 serum levels and phosphate homeostasis were analyzed in mice expressing transgenic Spak resistant to WNK-dependent activation ($spak^{tg/tg}$) and in wild type mice ($spak^{wt/wt}$) as well as in wild type mice following NCC inhibition with hydrochlorothiazide (HCT).

Results: As a result, HCT treatment of $spak^{wt/wt}$ mice significantly increased the serum FGF23 level and renal phosphate excretion. Moreover, the serum FGF23 level was significantly higher in $spak^{tg/tg}$ mice than in $spak^{wt/wt}$ mice. Urinary phosphate excretion was significantly larger in $spak^{tg/tg}$ mice compared to $spak^{wt/wt}$ mice despite a lower serum phosphate concentration in $spak^{tg/tg}$ mice. The urinary calcium excretion was significantly reduced in $spak^{tg/tg}$ mice. Serum levels of calcitriol and PTH were not significantly different between the genotypes. Bone density was significantly increased in $spak^{tg/tg}$ mice compared to $spak^{wt/wt}$ mice.

Conclusions: In conclusion, Spak is a strong regulator of FGF23 formation, bone mineralization and phosphate homeostasis.

SA-PO717

High Dose Intravenous Iron and Intact FGF23 in Normal Rats Eva Gravesen,[1] Jacob Hofman-Bang,[1] Ewa Lewin,[1,2] Klaus Olgaard.[1] *[1]Nephrological Department P, Rigshospitalet, Copenhagen, Denmark; [2]Nephrological Department B, Herlev Hospital, Copenhagen, Denmark.*

Background: Administration of intravenous iron has been proposed to induce elevation of fibroblast growth factor 23 (FGF23), hypophosphatemia and osteomalacia. High levels of FGF23 are associated with increased mortality in the CKD population. CKD patients often develop iron deficiency, anemia and the need for intravenous iron therapy. As such it is important to obtain further knowledge on the possible effects of iron on FGF23. Therefore, the effect on FGF23 levels of two different iron preparations, iron (III) isomaltoside 1000 and ferric carboxymaltose was examined in rats.

Methods: A single high dose of 60 mg/kg b.w of iron (III) isomaltoside 1000, or ferric carboxymaltose, or vehicle, was given intravenously and the effects on plasma levels of FGF23, phosphate, Ca^{2+}, PTH, transferrin, ferritin and iron was examined. Normal Wistar rats kept on a standard diet (0.9% calcium and 0,7% phosphorus), weighing 250 g, were used (n=8 in each group). Samples for determination of FGF23 were obtained at time 0, 30, 60, 120, 180 minutes and after 48 hours. FGF23 was measured by the intact FGF23 assay from Kainos lab. Japan.

Results: FGF23 levels at baseline were 91± 9 pg/mL in all 3 groups. In the vehicle group 93±16 pg/mL at 30 minutes, 92±13 pg/mL at 180 minutes, and 148±22 pg/mL at 48 hours. In the iron (III) isomaltoside 1000 group 111±26 at 30 minutes, 124 ±32 pg/mL at 180 minutes and 194±59 pg/mL at 48 hours. In the ferric carboxymaltose group 97±16 at 30 minutes, 86±13 pg/mL at 180 minutes and 156±35 pg/mL at 48 hours. No significant differences in FGF23 levels were observed at any time point between the groups.

Conclusions: A single high dose of either iron (III) isomaltoside 1000 or ferric carboxymaltose had no effect on intact FGF23 levels for up to 48 hours after intravenous injection in normal rats.

Ergocalciferol Treatment and Aspects of Mineral Homeostasis in Patients with Chronic Kidney Disease, Stage 4-5 Eva Gravesen,[1] Jacob Hofman-Bang,[1] Ewa Lewin,[2,1] Klaus Olgaard.[1] *[1]Department of Nephrology, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark; [2]Department of Nephrology, Herlev Hospital, University of Copenhagen, Copenhagen, Denmark.*

Background: Plasma levels of FGF23 are elevated in patients with CKD. FGF23 is correlated to adverse outcome and cardiovascular mortality in both CKD and non-CKD subjects. Treatment with active vitamin D induces elevated FGF23, while epidemiological studies have found positive effects of active vitamin D on mortality in CKD. In normal subjects an increase in 1,25(OH)2D and FGF23 has been observed after nutritive vitamin D treatment. Focus on non-classical effects and possible less side effects of treatment with nutritional vitamin D, raises the expectation of possible benefits of treating CKD patients with nutritional vitamin D. It is not known if nutritional vitamin D alters FGF23 levels in CKD patients. The objective was to examine the possible effects of treatment with high doses of ergocalciferol on FGF23 levels and other parameters of mineral homeostasis in predialysis CKD patients.

Methods: 43 adult patients with CKD stage 4-5, not receiving vitamin D supplementation, were studied, and allocated by simple randomization to either an intervention (n=26) or a control group (n=17). The intervention group received ergocalciferol, 50.000 IU/week for 6 weeks. Plasma FGF23, creatinine, PTH, phosphate and Ca^{2+} were obtained at baseline and after the six weeks. Data are Mean±SEM.

Results: The intervention group had a significant increase in p-25(OH)D_2 levels from <10 to 90±4 nmol/L, while plasma 1,25(OH)$_2$D (62±6 at baseline and 67±6 at 6 weeks) remained stable. No changes were seen in circulating vitamin D levels in the control group. After the six weeks of treatment no significant changes were seen in plasma FGF23 levels 35±4 to 37±5 control group and 48±6 to 58±11 and the levels of plasma creatinine, phosphate, Ca^{2+} and PTH remained stable in both groups.

Conclusions: No stimulatory effect of treatment with high dose of ergocalciferol was found on FGF23 levels in CKD patients, stage 4-5 and as such no harmful effects of ergocalciferol treatment were observed.

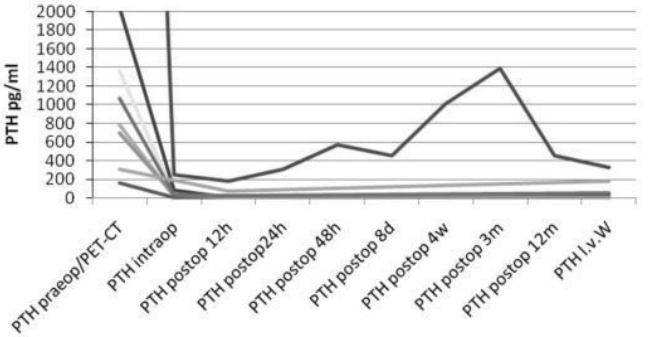
SA-PO719

The Role of Preoperative Positron Emission Tomography/Computed Tomography PET/CT for Localization Diagnostics of Parathyroid Glands Frieder Keller. *Nephrology, Internal Medicine, University Hospital, Ulm, Germany.*

Background: Surgical removal of the parathyroid tissue becomes necessary in many cases. An accurate preoperative localization and identification of the number of epithelial glands is very important, especially in case of recurrent hyperparathyroidism and to identify ectopic epithelial tissue.

Methods: In our retrospective study we investigated the role of positron emission tomography/ computed tomography (PET/CT) as an additional imaging technique. Between January 2001 and March 2011, a total of 12 patients underwent PET/CT because of severe hyperparathyroidism or recurrence after a previous operation. Eight patients underwent ultrasound as well. In nine patients PET/CT was positive and they received surgical treatment. Three patients were not operated because of the negative results of the PET/CT. The analysis was followed by an assessment of the sensitivity, the specificity, the accuracy as well as the positive and negative predictive value of the PET/CT. As the reference the combined scoring was selected based on the last follow-up values for parathyroid hormone, serum calcium and phosphate concentrations.

Results: The sensitivity of PET/CT was superior (87 % vs 66 %) and the specificity was comparable (50 % vs 50 %) to that of standard ultrasound. The positive predictive value in PET/CT and ultrasound was almost equal (77 % vs 80 %) whereas the negative predictive value (66 % vs 33 %) as well as the accuracy (75 % vs 62 %) were more precise in PET/CT than in ultrasound. Two atypical localizations of parathyroid glands were detected by PET/CT none of them by ultrasound. Subnormal, normal and even slightly elevated parathyroid hormone levels were measured after total parathyroidectomy.



Conclusions: Sensitivity, accuracy and negative predictive values for PET/CT are superior to ultrasound. PET/CT may provide valuable topographic information before parathyroidectomy.

SA-PO720

Renal Phosphate Clearance Is an Important Determinant of Serum FGF23 Level in Peritoneal Dialysis Patients Shunsuke Yamada,[1] Hisako Yoshida,[2] Kazuhiko Tsuruya,[2] Masatomo Taniguchi,[1] Takanari Kitazono.[1] *[1]Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; [2]Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan.*

Background: Fibroblast growth factor 23 (FGF23) is a bone-derived phosphaturic hormone that regulates phosphate (P) homeostasis. Recent clinical studies have revealed that serum FGF23 is regulated by various factors including P load, and is closely associated with high morbidity in dialysis patients. However, the clinical characteristics that determine serum FGF23 level remain unclear in peritoneal dialysis (PD) patients.

Methods: The present cross-sectional study was performed to indentify the clinical factors that regulate serum FGF23 level in PD patients. We enrolled 56 prevalent outpatients receiving PD treatment with various dialysis vintages at Kyushu University Hospital on April 1st in 2012. We determined demographic, clinical, and biochemical parameters including serum intact FGF23 (Kainos laboratories Inc., Japan) level, and collected urine and PD fluid for 24-hours. The dependent variable was serum log FGF23 level, and the independent variables were renal P clearance and other clinical parameters. Linear regression analysis and trend analysis were used to determine the effect of renal P clearance on serum FGF23 level.

Results: Patients were 54 ± 13 years old, 64% man, and 42% diabetes. Dialysis vintage was 615 ± 526 days. Serum FGF23 level was 5920 ± 6789 pg/mL. Univariate analysis revealed that dialysis vintage, serum P, renal P clearance, and peritoneal P clearance were significantly associated with serum FGF23 level (p<0.05). In the multivariate analysis, renal P clearance was negatively associated with serum FGF23 level (p<0.05) even after adjusted for age, sex, underlying kidney disease, dialysis vintage, serum P, and peritoneal P clearance.

Conclusions: Renal P clearance is a negative determinant of serum FGF23 level in PD patients. Preserving residual renal function can maintain serum FGF23 level within the appropriate range, leading to the prevention of future cardiovascular events.

SA-PO721

The Type IIa Sodium-Phosphate Cotransporter (NpT2a) Is Transcriptionally Regulated by Parathyroid Hormone (PTH) Rebecca Murray,[1] Nina W. Lesousky,[2] Syed J. Khundmiri,[1,2] Barbara Clark,[3] Eleanor D. Lederer.[1,2,4] *[1]Physiology & Biophysics, University of Louisville, Louisville, KY; [2]Medicine, University of Louisville, Louisville, KY; [3]Biochemistry & Molecular Biology, University of Louisville, Louisville, KY; [4]Robley Rex VAMC, Louisville, KY.*

Background: Primary hyperparathyroidism manifests in patients as high PTH, high serum calcium, and low serum phosphate levels. PTH exerts multiple effects in the proximal tubule, including reduced phosphate reabsorption. While much is known about acute inhibition of NpT2a by PTH, little is known about the mechanisms responsible for chronic hypophosphatemia under conditions of primary hyperparathyroidism. We hypothesize that PTH chronically regulates NpT2a at the transcriptional level either by affecting NpT2a mRNA stability or by decreasing promoter function.

Methods: We used two models to explore this hypothesis: a transgenic mouse that displays a parathyroid-specific Cyclin D1 overexpression (PTH-D1), leading to gradual development of primary hyperparathyroidism; and opossum kidney (OK) WT cells exposed to long-term PTH stimulation.

Results: Chronic PTH exposure (100 nM) suppressed NpT2a mRNA and protein expression in both models. Quantitative RT-PCR revealed that NpT2a mRNA levels were decreased 50% in kidney cortex of PTH-D1 mice versus control. PTH treatment of OK cells decreased NpT2a mRNA levels by 40% within 1 hour, with a maximal 75% decrease within 24 hours. NpT2a mRNA half-life in PTH-treated OK cells was 1.5 hours, in contrast to a 7-hour half-life when transcription was inhibited by actinomycin D (1 µg/mL). When OK cells were treated with PTH in the presence of actinomycin D, the effect of PTH on NpT2a mRNA half-life was blocked.

Conclusions: We conclude that (1) chronic PTH decreases NpT2a mRNA expression, and (2) PTH induces the transcription of an unknown protein that results in enhanced NpT2a mRNA degradation.

Sclerostin and DKK-1 Levels in Pre-Dialyisis CKD Patients Geert J. Behets,[1] Liesbeth Viaene,[2] Bjorn Meijers,[2] Patrick C. D'Haese,[1] Pieter Evenepoel.[2] *[1]Laboratory of Pathophysiology, University of Antwerp, Antwerp, Belgium; [2]Laboratory of Nephrology, Catholic University Leuven, Leuven, Belgium.*

Background: Sclerostin and Dickkopf-1 (DKK-1) are inhibitors of the canonical Wnt pathway, known to suppress bone formation. In dialysis patients, serum levels of sclerostin are elevated and correlate positively with bone mineral density and bone volume and negatively with bone turnover. Little is known about serum levels of sclerostin and DKK-1 in predialysis CKD patients.

Methods: We performed a cross-sectional observational study in 149 patients (CKD stage 1-5, 81 men, 60 ± 16 years, 22 diabetic). Serum sclerostin and DKK-1 were measured using ELISA kits (Biomedica). Other parameters of mineral metabolism included 1-84 PTH, calcitriol, calcidiol (all DiaSorin), FGF-23 (Kainos) and bone specific alkaline phosphatase (BsAP – electrophoretic method). Glomerular filtration rate was estimated using the 4-variable MDRD method.

Results: Mean eGFR was 43 ± 27 ml/min/1.72 m² (range 4.1 – 139.2). Overall mean serum sclerostin and DKK-1 levels were 68 ± 45 pmol/l and 38 ± 15 pmol/l respectively. Overall, sclerostin correlated positively with 1-84PTH ($r = 0.312$, $p < 0.001$), FGF-23 ($r = 0.320$, $p < 0.001$) and age ($r = 0.474$, $p < 0.001$), and negatively with calcitriol ($r = -0.393$, $p < 0.001$) and eGFR ($r = -0.616$, $p < 0.001$). Multivariate analysis indicated older age, lower eGFR, and gender (male) to be independently associated with higher sclerostin levels. No correlation was found between sclerostin and bone alkaline phosphatase. DKK-1 levels, conversely, showed a positive correlation with eGFR ($r = 0.212$, $p < 0.01$).

Conclusions: Serum sclerostin levels but not DKK-1 levels increase along the progression of renal disease. The finding of positive association between PTH and sclerostin is opposite to what has been observed in other populations (dialysis, primary hyperparathyroidism, general population) and conflicts with experimental data. Whether the increasing sclerostin levels in progressive renal failure protects the bone against the deleterious consequences of high PTH levels or merely reflects decreased clearance of sclerostin remains to be clarified.

25-Hydroxyvitamin D, Parathyroid Hormone, and Coronary Artery Calcification in Pre-Dialysis Chronic Kidney Disease Amrita Kaur Sukhi,[1] Rachel M. Holden,[1] Alexander R. Morton,[1] Robert Louis Nolan,[2] Wilma M. Hopman,[3] Jocelyn S. Garland.[1] *[1]Department of Medicine, Queen's University, Kingston, ON, Canada; [2]Department of Radiology, Queen's University, Kingston, ON, Canada; [3]Clinical Research Centre, Kingston General Hospital, Kingston, ON, Canada.*

Background: The role of Vitamin D in contributing to coronary artery calcification (CAC) in chronic kidney disease (CKD) is challenging to ascertain. Studies evaluating whether 25-Hydroxyvitamin D (25(OH)D) is a risk factor for CAC have mainly considered 25(OH)D as a separate variable. The majority has shown no correlation between 25(OH)D and CAC. However, pre-clinical studies have suggested parathyroid hormone (PTH) may impact on 25(OH)D synthesis, by down-regulating hepatic production of 25(OH)D. In fact, a negative correlation has been demonstrated between 25(OH)D and PTH in uremic animal models. The purpose of our study was (1) to translate the reported negative association between 25(OH)D and PTH *in vivo* in CKD patients, and (2) to evaluate whether 25(OH) D and PTH, when considered as separate variables versus together, are associated with CAC cross-sectionally, and in prospective follow-up.

Methods: 88 stage 3 to 5 pre-dialysis CKD patients underwent multi-slice computed tomography for the evaluation of CAC in 2005 and 2009. 25(OH)D and PTH levels were obtained at the original visit and at four year follow-up.

Results: 25(OH)D and PTH were negatively correlated ($r=-0.32$; $P=0.002$). By multivariable logistic regression adjusted for age, season of blood-work and kidney function, 25(OH)D and PTH as separate co-variates did not reveal an association with CAC. However, when considered as an interaction term, (25(OH)D*logPTH), there was a statistically significant association bewteen 25(OH)D*logPTH with prevalent CAC >100 Agatston units (AU) (OR=0.97; 95% confidence interval (CI) 0.949 to 1.00; P=0.047), and CAC progression >100 AU over 4 years (OR=0.98; 95% CI 0.959 to 1.00; P=0.05).

Conclusions: Similar to the findings in pre-clinical studies, 25(OH)D levels decreased as PTH levels rose. Moreover. the interaction of low 25(OH)D and elevated PTH predicted CAC, suggesting an inter-dependence of 25(OH)D and PTH in contributing to CAC development.

SA-PO724

Proximal Tubular Resistance to the Action of Fibroblast Growth Factor-23 in Sickle Cell Disease Vimal Master Sankar Raj,[1] Dima Hamideh,[2] Wacharee Seeherunvong,[1] Ofelia A. Alvarez,[2] Carolyn L. Abitbol,[1] Jayanthi Chandar,[1] Michael Freundlich,[1] Gaston E. Zilleruelo.[1] *[1]Pediatric Nephrology, University of Miami, Miami, FL; [2]Pediatric Hematology, University of Miami, Miami, FL.*

Background: Proximal tubular supra-normal function in patients with sickle cell (SS) disease has been described with increased proximal tubular re-absorption of phosphorus(P) and secretion of creatinine. Since the mechanisms remain elusive and Fibroblast Growth Factor-23 (FGF23) is an important modulator of P homeostasis, measurements of serum FGF23 and renal P handling were evaluated in SS patients with normal GFR.

Methods: We conducted a cross-sectional study evaluating renal handling of phosphorus in 14 subjects (mean age 16.6± 4.3 yr) with SS disease and normal or elevated GFR.Serum creatinine, cystatin C, mineral biochemical data including 25-(OH)vitamin D and FGF23 were measured. Intact FGF23 was measured by ELISA kit (Millipore, MA; normal range 22-91pg/mL). The tubular re-absorption of phosphorus (TRP) and maximum re-absorption of phosphorus (TMP/GFR) were calculated. GFR was estimated by serum creatinine using modified Schwartz or MDRD per age and by cystatin C.

Results: Of the 14 patients,12 were African Americans (5M,9F).Mean GFR by serum creatinine was 159.5±32.4 and by cystatin C 137.6±34.2 ml/min/1.73m²,respectively. Most had Vitamin D deficiency (13±8ng/ml), normal serum calcium and alkaline phosphatase, but increased serum P for age(5.2±0.7mg/dl). TRP was elevated in most patients for serum P with average 95.6±2.4%(normal >80%) and TMP/GFR at 5.0±0.4mg/dl(normal 2.6-4.4). Intact FGF23 concentrations were elevated at 106.2±28.7pg/ml. Linear regression analysis showed significant correlations of serum FGF23 with TRP ($r=0.6$,$p=0.03$) and urine phosphorus excretion ($r=-0.5$,$p=0.04$).

Conclusions: These preliminary cross-sectional data demonstrate elevated serum FGF23 levels in SS patients with normal GFR. The elevated serum P with concomitant high TRP and TMP/GFR indicates proximal tubular resistance to the phosphaturic action of FGF23. Further studies are needed to better understand the role of FGF23 and its co-factor, Klotho in the proximal tubular function in SS patients.

Vascular Calcification and Tumoral Calcinosis in a Family with Hyperphosphatemia and an FGF-23 Mutation Anuja P. Shah,[1] Clinton Miller,[2] Cynthia C. Nast,[1] Mark D. Adams,[2] Barbara J. Truitt,[2] John Tayek,[1] Lili Tong,[1] Parag Mehtani,[1] John R. Sedor,[3] Kenneth E. White,[4] Rajnish Mehrotra,[1] Janine A. La Page,[1] Francisco J. Monteon,[5] Patricia Dickson,[1] Sharon G. Adler,[1] Sudha K. Iyengar.[2] *[1]Nephrology, LABiomed Research Institute, Torrance, CA; [2]Genetics, Case Western Reserve University, Cleveland, OH; [3]Nephrology, Case Western Metro Health Center, Cleveland, OH; [4]Medical & Molecular Genetics, University of Indiana, Indianapolis, IN; [5]Nephrology, Instituto Mexicano del Seguro Social, Guadalajara, Mexico.*

Background: We studied a kindred with vascular calcification (VC) requiring limb/digit amputations unlike most cases of tumoral calcinosis. The only metabolic abnormality was hyperphosphatemia (hi P). We conducted genetic/pathobiological assessments to evaluate the cause of their VC.

Methods: High dimensional genetic analysis of 13 family members, and exome analysis of 6 members was performed. To characterize osteogenic features of the patient's vessels in the vicinity of VC, we evaluated amputation tissue with medium to small size vessels from our proband.

Results: Severe VC occurred almost ubiquitously, associated with hi P, but without diabetes, CKD, hypertension, hyperlipidemia, hypercalcemia, hyperparathyroidism, or hypervitaminosis D. There was a novel Q67K FGF-23 mutation and a null (deletion) allele on the other FGF-23 homologue in all 3 affecteds. Affecteds had high plasma C-terminal FGF-23, but little or no circulating intact FGF-23. Endothelial and vascular smooth muscle cells, and few interstitial monocyte/marcophages and spindle cells expressed the osteoblast marker osteonectin, often associated with segmental or, circumferential internal elastic lamina calcification in all size vessels, and focal medial calcification mostly in larger arteries without arteriosclerosis or lipid deposition.

Conclusions: This FGF-23 mutation segregates with hi P and is a plausible causes of the osteogenic changes in intima, media, and capillaries without typical atherosclerosis. This family's novel phenotype differentiates it from reported FGF-23 mutation cases and suggests that FGF-23 fragments may regulate VC, or that other genes, which the affected members share, may modify this process.

Maxacalcitol Ameliorates Tubulointerstitial Fibrosis in Obstructed Kidneys by Recruiting PPM1A/VDR Complex to pSmad3 Kazunori Inoue,[1] Isao Matsui,[1] Takayuki Hamano,[2] Akihiro Shimomura,[1] Chikako Nakano,[1] Yasuo Kusunoki,[1] Yoshitsugu Obi,[1] Yoshiharu Tsubakihara,[2] Hiromi Rakugi,[1] Yoshitaka Isaka.[1] *[1]Geriatric Medicine and Nephrology, Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [2]Comprehensive Kidney Disease Research, Osaka University Graduate School of Medicine, Suita, Osaka, Japan.*

Background: Tubulointerstitial fibrosis (TIF) remains unresolved in nephrology because satisfactory therapies have not been established. One of the candidates protecting the kidney from TIF is active vitamin D (aVD) because aVD negatively regulates renin. We examined if maxacalcitol (22-oxacalcitriol (OCT)) suppressed TIF in unilateral ureteral obstructed (UUO) kidney.

Methods: Six-week-old male Sprague-Dawley rats were randomly divided into four groups; sham + vehicle (S+V), sham + OCT (S+O), UUO + vehicle (U+V), or UUO + OCT (U+O). Vehicle or OCT at a dose of 0.5 μg/kg BW was administrated subcutaneously twice a day. To elucidate the anti-fibrotic mechanism of OCT, *in vitro* experiments were performed using NRK52E cells.

Results: In UUO rats, OCT ameliorated all fibrotic parameters, such as tubular injury index, interstitial volume index, collagen I positive area, and mRNA levels of extracellular matrix genes. We found that TGF-β1 itself induced its expression in a phosphor-Smad3 (pSmad3)-dependent manner, and that OCT ameliorated TIF by abrogating this autoinduction.TGF-β1 increased both the nuclear levels of protein phosphatase Mg^{2+}/Mn^{2+} dependent 1A (PPM1A), a pSmad3 phosphatase, and the interaction levels between the vitamin D receptor (VDR) and PPM1A. Under the presence of OCT, PPM1A/VDR complex was recruited to pSmad3, and pSmad3 was dephosphorylated. Consequently, autoinduction of TGF-β1 was suppressed.

Conclusions: Our findings provide a novel approach to inhibit TGF-β1 signaling pathway in fibrotic diseases.

Mineral and Bone Disorder among Participants in the Saudi Arabia Dialysis Outcomes and Practice Patterns Study (DOPPS): Serum Biomarkers and Therapeutic Regimens

Jamal S. Alwakeel,[2] Brian Bieber,[1] Mohammed A. Al-Ghonaim,[2] Ayman Karkar,[2] Fayez F. Alhejaili,[2] Faissal A. Shaheen,[2] Saad Alghamdi,[2] Haroun Zakaria Ahmed,[2] Sylvia Paz B. Ramirez,[1] Bruce M. Robinson,[1] Ronald L. Pisoni.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]Saudi Arabia DOPPS Country Investigators.*

Background: The DOPPS has recently conducted a pilot study in Saudi Arabia (SA). Abnormalities in markers of mineral and bone disorder (MBD) have been recognized as potential risk factors for cardiovascular disease in the hemodialysis (HD) population and associated with poor clinical outcomes. We report findings related to management of MBD in the SA DOPPS study cohort with comparisons to other DOPPS regions.

Methods: 20 HD facilities treating at least 23 HD pts were randomly selected from a comprehensive roster of dialysis units to be representative of >95% of SA HD pts. Descriptive results for SA, based upon a random sample of 20-25 HD pts in each study facility, are compared to other DOPPS regions. Preliminary results for SA are from 315 HD pts treated at 16 dialysis facilities. Results are presented as weighted estimates, accounting for the sampling fraction in each unit.

Results: Mean s. calcium was similar in the SA DOPPS sample (9.2 mg/dL) compared to other DOPPS regions. Mean s. phosphorus was higher in SA (5.4 mg/dL) compared to Eur/ANZ (5.0), but similar to Japan (5.5) and North America (5.2). Mean PTH in SA (479) was higher than other DOPPS regions(range 168-376), with 32% of SA pts having a serum PTH>600 pg/mL. Mean dialysate calcium in SA (3.1 mEq/L) was also higher than other DOPPS regions(range 2.5-2.8). The % of pts prescribed IV Vit. D, oral Vit. D, a phosphate binder, and cinacalcet were 27, 46, 92, and 24%.

Acute Changes in Plasma Ca^{2+} and Regulation of Plasma FGF23 Levels

Ewa Lewin,[1,2] Eva Gravesen,[1] Jacob Hofman-Bang,[1] Klaus Olgaard.[1] *[1]Nephrological Department P, Rigshospitalet, Copenhagen, Denmark; [2]Nephrological Department B, Herlev Hospital, Copenhagen, Denmark.*

Background: Fibroblast Growth Factor 23 (FGF23) has an essential physiological role in phosphate and vitamin D homeostasis. Calciotropic hormones are the potent regulators of FGF23. How phosphate and calcium influence FGF23 secretion is less clarified. Dietary phosphate load has been shown to increase FGF23 levels. In parallel, manipulation of plasma calcium levels by dietary means has been shown to regulate FGF23 levels, suppressing FGF23 in hypocalcemia and increasing FGF23 in hypercalcemia. The aim of the present investigation was to study whether plasma Ca^{2+} might participate in the acute regulation of plasma FGF23 and therefore the response of FGF23 to acute changes in plasma Ca^{2+} levels was examined in the rat.

Methods: Acute hypercalcemia was induced by intravenous (iv) infusion of 25 mM calcium for 60 minutes and hypocalcemia by iv infusion of 30 mM EGTA. Control rats had an iv saline infusion. Samples for plasma Ca^{2+}, phosphate, PTH and FGF23 were obtained at time 0, 5, 10, 20, 30, 40, 50 and 60 minutes. FGF23 was measured as intact FGF23 by the Kainos Lab assay.

Results: Significant hypercalcemia was induced with an increase in plasma Ca^{2+} from 1.33±0.03 to 1.65±0.02 mmol/L. The levels of FGF23 remained stable, 90±22 to 86±23 pg/mL. In EGTA infused rats plasma Ca^{2+} decreased from 1.33±0.04 to 1.01±0.04 mmol/L, while FGF23 levels remained stable, 51±6 to 69±12 pg/mL. Control rats has stable Ca^{2+} 1.34±0.01 to 1.30±0.01 mmol/L and again stable FGF23 levels were obtained from 77±9 to 92±10 pg/mL.

Conclusions: Acute induction of hypocalcemia or hypercalcemia did not induce any significant changes in plasma levels of intact FGF23 in normal rats.

SA-PO729

Oxidation Matters when Measuring Parathyroid Hormone in Patients on Dialysis

Martin Tepel,[1] Franz Paul Armbruster,[2] Hans Jürgen Grön,[2] Alexandra Scholze,[1] Christoph Reichetzeder,[3] Heinz Juergen Roth,[4] Berthold Hocher.[3] *[1]Nephrology, Odense University Hospital, Odense, Denmark; [2]Immundiagnostik AG, Bensheim, Germany; [3]Institute of Nutritional Science, University of Potsdam, Potsdam-Rehbrücke, Germany; [4]Department of Endocrinology/ Oncology, Limbach Laboratory, Heidelberg, Germany.*

Background: Only non-oxidized parathyroid hormone (PTH) has bioactive function. We evaluated the hypothesis that determination of biological active parathyroid hormone (BA-PTH) more accurately predicts mortality in hemodialysis patients.

Methods: PTH was measured by means of the third generation intact-PTH electrochemiluminescence immunoassay system, either directly (iPTH) and after prior removal of oxidized PTH molecules using specific monoclonal antibodies raised against the oxidized human PTH (BA-PTH) in 340 prevalent hemodialysis patients (224 men/116 women; median age, 66 years).

Results: 170 patients (50%) died during a follow up of 5 years. Median BA-PTH levels were higher in survivors (7.2 ng/L; IQR 3.1 to 16.5 ng/L) compared to deceased patients (5.0 ng/L; IQR, 1.9 to 11.1 ng/L; p=0.002). Survival analysis showed increased survival in the highest BA-PTH tertile compared to the lowest BA-PTH tertile (Chi square 14.3; p=0.0008 by log-rank test). Median survival was 1702 days in the highest BA-PTH tertile, whereas it was only 453 days in the lowest BA-PTH tertile. We *a priori* stratified iPTH levels into five categories representing very low (<20ng/L), low (20 to 65ng/L), medium (65 to 150ng/L), target (150 to 300ng/L), and high (>300ng/L). Survival analysis showed that patients with target iPTH levels had longer median survival compared to the other categories. However, the BA-PTH to PTH ratio was significantly different among these five categories, ranging from 9 to 17% (p<0.0001). This finding indicates that the amount of BA-PTH but not iPTH predicted patients' survival.

Conclusions: Biologically active PTH (BA-PTH) is directly associated with all-cause mortality in patients on dialysis. Further larger studies are needed to provide evidence whether current PTH guidelines for target PTH levels (based on currently available assay systems) needs to be revised or BA-PTH measured instead.

Renoprotective Effects of Vitamin D Receptor Agonist during Low but Not during High Dietary Sodium in Adriamycin Nephrosis

Katarina Mirkovic,[1] Anne-Roos Sophie Frenay,[2] Jacob van den Born,[1] Harry Van Goor,[2] Gerjan Navis,[1] Martin H. De Borst.[1] *[1]Nephrology; [2]Pathology and Medical Biology, University Medical Center Groningen, University of Groningen, Netherlands.*

Background: Renin-angiotensin-aldosterone system (RAAS) blockade is the standard renoprotective therapy and dietary sodium restriction potentiates its efficacy. Add-on vitamin D receptor agonist (VDRA) may provide additional renoprotection but whether its efficacy depends on sodium intake is unknown. We studied the effect of the VDRA paricalcitol, alone and combined with RAAS blockade during low and high sodium intake in adriamycin (ADR)-induced proteinuric nephropathy.

Methods: Six weeks after ADR injection, male Wistar rats (n=64) were randomized into 8 groups stratified for proteinuria (UP). Four groups received low sodium chow (LS, 0.05% NaCl), with vehicle (LS+V) or lisinopril (75mg/l in drinking water; LS+LIS), paricalcitol (3x/wk 160 ng/kg p.o.; LS+P) or both (LS+LIS+P). The other groups received high sodium chow (HS, 2% NaCl) and the same regimens. Blood pressure (BP) and UP were measured 2-weekly. After 6 wks rats were sacrificed; interstitial macrophage accumulation (mø) and α-smooth muscle actin (α-SMA) protein were determined.

Results: At start of treatment, nephrotic range UP was present (mean±SD 212±196 mg/d) and progressed to 335±214 mg/d at wk 12 in LS+V. UP was reduced in LS+P (160±107, p<0.05) and more prominently in LS+LIS (25±15) and LS+LIS+P (30±46, both p<0.05). Systolic BP was elevated in LS+V (164±23 mmHg) and in LS+P (160±12), with lower BP in LS+LIS (108±18) and LS+LIS+P (112±32, both p<0.05). During LS all treatments reduced renal mø (LS+V 29±6 vs. LS+LIS 14±9, LS+P 17±7, LS+LIS+P 12±9, all p<0.05). α-SMA expression was reduced in LS+P (1.1±0.3%) and LS+LIS+P (1.1±0.4%) compared to LS+V (2.2±1.0%, both p<0.05), whereas in LS+LIS (1.4±0.6%) the decrease was non-significant. None of the treatments reduced UP, α-SMA or mø during HS intake.

Conclusions: VDRA has renoprotective effects independent of BP alone and in combination with RAAS-blockade, reducing UP, renal inflammation and pre-fibrotic changes. The renoprotective effects of VDRA require dietary sodium restriction.

SA-PO731

Stronger Association of Fibroblast Growth Factor 23 (FGF-23) with Neutrophil Gelatinase-Associated Lipocalin (NGAL) than with C-Reactive Protein (CRP) in Mexican Americans with Type 2 Diabetes and Chronic Kidney Disease Shweta Bansal,[1,2] Khaled Khazim,[1,2] Nagarjun Kasaraneni,[1,2] Nedal H. Arar,[1,2] Hanna E. Abboud,[1,2] Paolo Fanti.[1,2] *[1]Division of Nephrology, University of Texas Health Sciences Center at San Antonio, San Antonio, TX; [2]Renal Section, Audie L. Murphy VA Hospital, San Antonio, TX.*

Background: In addition to abnormal phosphorus homeostasis, FGF-23 may be regulated by systemic inflammation in chronic kidney disease (CKD). The aim of this study was to evaluate the association of plasma FGF-23 with NGAL, a novel marker of inflammation, in Mexican Americans with different stages of CKD.

Methods: FGF-23, NGAL, CRP and other parameters were assessed in a cross-sectional analysis of stored plasma samples from 115 Mexican Americans who participated in the Family Investigation of Nephropathy and Diabetes (FIND) study from 2001 to 2004. The enrolled population consisted of type 2 diabetic (T2DM) patients with variable kidney functions and their family members.

Results: Of 115 people, 22% were healthy, 26% had T2DM, 8% had microalbuminuria, 20% had macroalbuminuria and 24% were on hemodialysis. In bivariate correlation analysis, $\log_{10}$ transformed FGF-23 and NGAL levels increased progressively with worsening estimated glomerular filtration rate (eGFR) (r=-0.75, p<0.001), and (r=-0.75, p<0.001), respectively and significantly associated with $\log_{10}$CRP (r=0.4, p<0.001), and (r=0.38, p<0.001), respectively. Serum albumin and phosphate were other parameters associated significantly with $\log_{10}$FGF-23 and $\log_{10}$NGAL. On further analysis, Log_{10}FGF-23 levels associated with plasma $\log_{10}$NGAL (r=0.75, p<0.001) and remained significant after adjustment for age, BMI, eGFR, phosphorus, albumin, and CRP in partial correlation analysis (r=0.32, p=0.004), much more pronounced in advanced CKD (r=0.61, p<0.001). The association between FGF-23 and CRP was lost after adjustment for NGAL (r=0.1, p=0.41).

Conclusions: Higher FGF-23 levels are associated with markers of inflammation in Mexican Americans with different stages of diabetic kidney disease. FGF-23 associates better with NGAL than CRP, suggesting NGAL to be a better marker to evaluate the relationship between FGF-23 and inflammation.

SA-PO732

Serum Soluble α-Klotho Is Associated with Coronary Calcification and Insulin Sensitivity Ana L.E. Cancela,[1] Silvia M. Titan,[1] Alexandre Costa Pereira,[2] Luciene M. dos Reis,[1] Fabiana G. Graciolli,[1] Susan Schiavi,[3] Raul D. Santos Filho,[2] Vanda Jorgetti,[1] Rosa M.A. Moyses.[1] *[1]Nephrology, Universidade de São Paulo, Brazil; [2]Heart Institute, Universidade de São Paulo, Brazil; [3]Genzyme Co.*

Background: Klotho is a protein related to mineral metabolism homeostasis. In addition, it seems to be involved in aging, atherosclerosis and insulin sensitivity. However, little is known about serum soluble α-Klotho and its association with CAD or other biochemical markers of mineral metabolism, since these assays have just recently become available. In this study, we have analysed these relationships in patients with normal kidney function and suspected CAD.

Methods: Data on 290 patients (167 males) with suspected CAD and a median GFR of 92 ml/min undergoing elective coronary angiography was collected. Serum soluble α-klotho, FGF-23 and other mineral metabolism biomarkers were ascertained. Patients were genotyped for the KL-VS allele. Coronary obstruction was quantified using the Friesinger score (FS). Coronary calcification was assessed by MSCT and quantified using the Agatston score (AS).

Results: Median serum soluble α-klotho was 489 (361- 665) pg/ml. In the univariate and multivariate linear regression analysis, log serum α-klotho was negatively correlated with total calcium (p = 0.02) and positively related to glycemia (p = 0.04). There was no correlation between serum α-klotho and phosphorus, FGF23 or lipid profile. KL-VS polymorphism was not associated with serum klotho, AS or FS. In calcified patients, a positive association between serum α-klotho and AS was found (p=0.04), even after adjustments for other mineral metabolism variables and cardiovascular risk factors.

Conclusions: In patients with suspected CAD and preserved renal function, serum soluble α-klotho levels correlated positively with coronary calcification and glycemia. Prospective studies are needed to confirm its role as a new marker of calcification and insulin sensitivity.

SA-PO733

Is Insulin Resistance Associated with Disrupted Renal Phosphorus Homeostasis in Stage 3-5 Chronic Kidney Disease? Jocelyn S. Garland,[1] Rachel M. Holden,[1] Robert Louis Nolan,[2] Wilma M. Hopman,[3] Alexander R. Morton.[1] *[1]Medicine, Queen's University, Kingston, ON, Canada; [2]Radiology, Queen's University, Kingston, ON, Canada; [3]Clinical Research Center, Kingston General Hosptial, Kingston, ON, Canada.*

Background: Insulin is directly involved in renal phosphorus (PO_4) handling, increasing renal PO_4 re-absorption at the proximal tubule sodium-phosphate co-transporter type II (NaPi-2). In insulin resistance, insulin receptor number remains preserved in the kidney,which we hypothesize could maintain, or increase, renal PO_4 re-absorption. Our primary hypothesis was insulin resistant CKD patients would demonstrate greater disruption in renal PO_4 homeostasis, detected by greater fibroblast growth factor-23 (FGF-23) levels.

Methods: 72 stage 3-5 pre-dialysis CKD patients were enrolled to evaluate associations between insulin resistance (homeostasis model assessment of insulin resistance (HOMA-IR)) and disrupted renal PO_4 homeostasis (FGF-23). Coronary artery calcification (CAC), FGF-23, and mineral metabolism parameters were compared based on median HOMA-IR. Patients with diabetes treated with insulin were excluded.

Results: Patients with HOMA-IR > 2.2 had 30% higher log FGF-23, and 40% higher CAC. FGF-23 correlated with HOMA-IR (r=0.25; P=0.04), waist circumference (r=0.29, P=0.02), and body mass index (r=0.33; P=0.004). Linear regression: insulin resistance was a risk factor for greater log FGF-23 levels, (HOMA-IR, ß = 0.37; 95% CI 0.14 to 0.6; P=0.002), adjusted for age, 1,25 Dihydroxyvitamin D, kidney function, and parathyroid hormone (PTH).

Clinical Characteristics Based on HOMA-IR

Variable	HOMA-IR >2.2	HOMA -IR < 2.2	P
Age	63 ± 13	65 ±1 5	0.64
eGFR	26.8 ± 12.1	24.9 ± 13.5	0.5
iPTH	9.85 (5.8 – 21.4)	8.05 (5.6 – 18.5)	0.7
1,25(OH)2 Vit D	49.9 (33-70)	50.7 (35 – 80)	0.1
phosphorus	1.26 ± 0.21	1.27± 0.27	0.8
calcium	2.35 ± 0.27	2.26 ± 0.2	0.15
BMI	35.1 ± 7.5	25.3 ± 4.3	<0.0001
Log FGF-23	2.32 ±0.02	2.04 ± 0.42	0.01
Log CAC score	2.09 ± 0.87	1.58 ± 1.26	0.05

Conclusions: Insulin resistant CKD patients demonstrated greater disruption in renal PO_4 homeostasis (↑ FGF-23) and CAC, while PO_4 levels remained normal. These findings suggest insulin resistance may modify renal PO_4 handling in CKD, and studies are needed to explore this relationship.

SA-PO734

Serum Soluble α-Klotho Levels in Patients with Chronic Kidney Disease Noriyuki Okada,[1] Kodo Tomida,[2] Akira Suzuki,[2] Terumasa Hayashi,[2] Tatsuya Shoji,[2] Yoshiharu Tsubakihara.[3] *[1]Clinical Labratory, Osaka General Medical Center, Osaka, Japan; [2]Kidney Disease and Hypertension, Osaka General Medical Center, Osaka, Japan; [3]Comprehensive Kidney Disease Reserch, Osaka University Graduate School of Medicine, Suita, Japan.*

Background: Membrane-bound Klotho is known a cofactor for fibroblast growth factor 23(FGF-23) to regulate phosphorus and vitamin D homeostasis. Soluble Klotho in circulation is known to act a humoral factor such as regulating insulin and IGF-1 receptor binding, calcium and phosphorus homeostasis. Klotho deficiency is associated with progression and complications in chronic kidny disease(CKD). A few investigators reported that soluble Klotho level were decreased in patients with CKD from early stage, but other investigator reported no change of soluble Klotho in CKD.

Methods: Fourty eight patients (30 males and 18 females, 34-86 yrs of age) with CKD stage 2-5 were enrolled in this study. We measured serum soluble α-Klotho(sαKl), FGF-23, intact PTH, and 1,25$(OH)_2$D3. SαKl were measured by using human soluble α-Kloth kit(Immuno-Biological Laboratories Co.,Ltd. Gunma, Japan). We calculated eGFR using the Japanese equation for estimating GFR.

Results: 1,25$(OH)_2$D3 levels progressively declined from Stage 2 to Stage 5. Intact PTH and FGF-23 levels begun to rise in Stage 3A, and thereafter drastically elevated. Whereas serum calcium and phosphate levels were within normal range in this group. We couldn't observe significant relationship between eGFR and sαKl level(P=0.78), a few patients revealed low sαKl levels in Stage 4-5. SαKl levels in various CKD stage were as follows (mean±SD) : Stage 2 (n=5) 457.0±68.8pg/ml, Stage 3A (n=9) 540.2±117.5pg/ml, Stage 3B (n=15) 513.3±69.3pg/ml, Stage 4 (n=14) 517.1±144.9pg/ml, Stage 5 (n=5) 438.7±202.8pg/ml. SαKl levels in these stages showed no significant difference each other. SαKl levels had no significant relationship to intact PTH, FGF-23, 1,25$(OH)_2$D3, calcium and phosphate levels, respectively.

Conclusions: In our small group study, we observed progressive decline of 1,25$(OH)_2$D3 levels and elevation of intact PTH and FGF-23 levels with deterioration of renal function, but sαKl levels were not associated with renal function.

SA-PO735

Bone Disease Is an Early Event in Lupus Nephritis Patients Aline Lázara Resende, Cristiane Bitencourt Dias, Luciene M. dos Reis, Vanda Jorgetti, Viktoria Woronik. *University of Sao Paulo, Sao Paulo, Brazil.*

Background: The role of glucocorticoid as the major factor for bone loss in lupus nephritis patients (LN) has been questioned. Our aim was to evaluate bone disease in newly diagnosed LN patients.

Methods: Pre-menopausal female patients with ≤2months of diagnosed LN and GFR>30 ml/min/1.73m^2 were submitted to bone biopsy and histomorphometry analysis. Controls for static parameters were female age-matched healthy subjects (1:2) from a Brazilian database (Dos Reis et al. Bone 1998;23)[1]. Dinamic parameters were compared to female subjects from Melsen et al. (Calcif Tiss Res 1978;26)[2].

Results: Patients presented a mean age of 30.5±9.7years and were on glucocorticoids for 35.3±11.5days. Seven patients presented proliferative LN. Mean proteinuria was 6.0±1.9g/day and estimated GFR was 65.1±34.5ml/min/1.73m^2. All patients presented vitamin D deficiency (25OHD=8.8±2.7ng/ml). Structure parameters of patients and controls were not different. LN patients presented a reduced OV/BV, O.Th, MS/BS and BFR/BS, suggesting an impaired bone formation and mineralization These patients also presented higher ES/BS and Oc.S/BS, revealing an increased bone resorption.

Histomorphometric parameters of LN patients and controls.

	LN Patients (n=8)	Controls (n=16)[1] (n=29)[2]	p
Formation			
OS/BS (%)	2.13 (0.98-12.61)	8.6 (6.6-16.1)	0.06

Newly Diagnosed Lupus Nephritis Patients: Bone Disease beyond Glucocorticoid Use and Proteinuria Aline Lázara Resende, Cristiane Bitencourt Dias, Luciene M. dos Reis, Vanda Jorgetti, Viktoria Woronik. *University of Sao Paulo, Sao Paulo, Brazil.*

Background: The etiology of bone loss in lupus nephritis patients (LN) is multifactorial. Our aim was to evaluate bone disease in newly diagnosed LN patients.

Methods: Pre-menopausal female patients with ≤2 months of diagnosed LN and GFR>30 ml/min/1.73m^2 were submitted to bone biopsy and histomorphometry analysis. Controls were primary glomerulopathies (PG) female patients with similar estimated GFR and proteinuria (Dias et al. Kidney Int 2007;71).

Results: Mean period of glucocorticoid use was 35.3±11.5days. LN patients presented significantly lower vitamin D levels, possibly contributing to higher iPTH levels. Structure parameters were not different. LN patients presented a reduced O.Th, suggesting a reduced bone formation, and a higher ES/BS, revealing an increased bone resorption.

Clinical and histomorphometric parameters of LN patients and controls

FGF-23 Inhibits Hyperphosphatemia-Induced Apoptosis and Stabilizes Tight Junction Protein ZO-1 Expression in Human Brain Microvascular Endothelial Cells in CKD, In Vitro Chih-ping Chung,[1,2] Tzong-Shi Lu,[1] Kenneth Lim,[1,3] Christina Lee,[1] Daniel Zehnder,[3] Li-Li Hsiao.[1] *[1]Renal Division, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [2]Department of Neurology, Taipei Veterans General Hospital, Taipei, Taiwan; [3]Clinical Sciences Research Institute, Warwick Medical School, United Kingdom.*

Background: CKD patients exhibit cerebral small-vessel diseases among other cardiovascular consequences. Fibroblast growth factor 23 (FGF23) levels rise in CKD and functions to counteract hyperphosphatemia. We postulate that hyperphosphatemia is a major contributor of brain microvascular endothelial dysfunction in CKD, whilst rising FGF-23 levels may inhibit this process.

Methods: *In vitro*: Human brain microvascular endothelial cells (HBMECs). CKD conditions: borderline-high (2mM) and high (5mM) phosphate for 72 hours. Cell viability: XTT assay. Apoptosis: caspase-3 fluorometric assay.

Results: We show that treatment of HBMECs with 5mM but not 2mM phosphate decreased cell viability and increased caspase-3 mediated apoptosis. FGF-23 inhibited phosphate-induced caspase-3 mediated apoptosis at the concentrations ranging from 0.5 – 10ng/ml with significance at 5 and 10ng/ml. We next treated HBMECs with recombinant soluble Klotho (0.2 nM) and showed that it also inhibited phosphate-induced caspase-3 mediated apoptosis. Furthermore, we show that 5mM but not 2mM phosphate decreased the tight junction protein, ZO-1 expression in HBMECs and FGF-23 reversed phosphate-induced ZO-1 suppression at the concentration of 5 and 10ng/ml. However, HBMECs treated with soluble Klotho did not modulate phosphate-induced suppression of ZO-1.

Conclusions: Our study is the first to describe hyperphosphatemia as a significant contributor of cerebral microvascular dysfunction. Furthermore, we show that FGF-23 can reverse HBMEC apoptosis and stabilize tight junction protein ZO-1 induced by hyperphosphatemia. We therefore speculate that hyperphosphatemia may be involved in the development of cerebral small vessel disease and propose rising FGF-23 levels as a mediator of a bone-kidney-brain axis in CKD.

SA-PO738

CSF-1 Dependent Defective Kidney Repair Triggers Nephritis in Lupus-Susceptible Mice Yasunori Iwata,[1,3] Elisabeth A. Boström,[3] Julia Menke,[2] Takashi Wada,[1] Vicki R. Kelley.[3] *[1]Kanazawa University; [2]Johannes Gutenberg-University of Mainz; [3]Brigham and Women's Hospital.*

Background: Inflammation is meant to promote healing. Macrophages (Mø) are central to inflammation and require colony stimulating factor (CSF)-1 for survival, proliferation and activation. Our prior studies indicate that CSF-1 is upregulated in tubular epithelial cells and hastens renal tubular repair following transient injury, ischemia/reperfusion (I/R) in normal (B6 and BALB/c) mice. Paradoxically, CSF-1 drives lupus nephritis in genetically-susceptible mice. We hypothesized that CSF-1 dependent Mø-mediated inflammation after I/R leads to non-resolving inflammation that triggers lupus nephritis in lupus-susceptible mice.

Methods: Using MRL-*Fas^{lpr}* mice genetically constructed to express differing levels of CSF-1 in the kidney and circulation: TgC/+ (high), wildtype (moderate), and op/op (none), we compared parameters of kidney repair (tubular pathology, proliferation/apoptosis and KIM expression, magnitude of Mø and fibrosis) and lupus nephritis (glomerular pathology and IgG/C3 deposits, and serum IgG) after I/R. Normal (B6 and BALB/c) mice served as controls.

Results: We detected defective renal tubular repair and non-resolving inflammation (accumulation of Mø) in MRL-*Fas^{lpr}* mice compared to normal mice after I/R. Moreover, I/R triggered early-onset lupus nephritis (glomerulonephritis, IgG/C3 glomerular deposits and elevated serum IgG) in MRL-*Fas^{lpr}* mice, and not in normal mice. Defective renal repair and early-onset lupus nephritis was most pronounced in MRL-*Fas^{lpr}* mice expressing the highest level of CSF-1 in the kidney and circulation. Moreover, we did not detect tubular pathology, an increase in Mø and early-onset lupus nephritis in MRL-*Fas^{lpr}* mice deficient in CSF-1.

Conclusions: CSF-1 released from injury tubules mediates defective Mø mediated renal repair and non-resolving inflammation, that hastens the onset of lupus nephritis in genetically susceptible mice. This suggests that CSF-1 expands Mø in lupus-susceptible individuals that are responsible for triggering lupus nephritis.

TWEAK Transactivates Epidermal Growth Factor Receptor to Modulate Renal Inflammation in the Kidney Sandra Rayego-Mateos,[1] Jose Morgado,[2] Ana Belen Sanz,[2] Daniel Batlle,[3] Janos Pato,[4] Gyorgy Keri,[4] Jesus Egido,[2] Alberto Ortiz,[2] Marta Ruiz-Ortega.[1] *[1]Nephrology, Universidad Autónoma, Madrid, Spain; [2]Nephrology, IIS-Fundacion Jimenez Diaz, Madrid, Spain; [3]Northwestern University Feinberg Medical School, Northwestern University, Chicago, IL; [4]Vichem, Budapest, Hungary.*

Background: The cytokine tumor necrosis factor-like weak inducer of apoptosis (TWEAK), binds to its receptor Fn14 to elicit multiple biological activities, including stimulation of cell growth/apoptosis, angiogenesis and induction of inflammatory cytokines. TNF-α induced transactivation of the EGF receptor (EGFR) in a variety of cells, a process involved in renal disease progression. EGFR transactivation involves the release of EGFR ligands by metalloproteinases of the ADAM family, of which ADAM-17 is the best characterised member. Our aim was to investigate whether TWEAK could transactivate EGFR in the kidney and the involvement of this molecular pathway in TWEAK mediated-renal responses.

Methods: The in vivo effect of Tweak was evaluated by intraperitoneal injection of recombinant human Tweak (0.5 µg/per mouse) into C57BL6 mice and in vitro in tubular epithelial cells.

Results: TWEAK in vivo increased renal EGFR phosphorylation levels, mainly located in tubular epithelial cells. In vitro, TWEAK by binding to Fn14, induced EGFR phosphorylation in tubular epithelial cells. This procces is mediated by ADAM17, as demonstrated by pharmacological inhibition with TAPI-2, or by ADAM17 gene silencing. In Tweak-injected mice treatment of with the EGFR kinase inhibitor erlotinib markedly diminished renal EGFR activation and inhibited TWEAK-induced renal changes observed at 24 hours, including ERK activation (a downstream EGFR signalling), up-regulation of proinflammatory factors and interstitial inflammatory cell infiltration. Moreover, in tubular epithelial cells EGFR transactivation blockade, by TAPI and ADAM17 gene silencing, diminished TWEAK-induced ERK activation and upregulation of proinflammatory factors.

Conclusions: TWEAK transactivates EGFR signalling pathway leading to modulation of downstream mechanisms, such as ERK activation, and cellular responses, including renal inflammatory cell infiltration.

Expression of Tumor Necrosis Factor-Like Weak Inducer of Apoptosis (TWEAK) & TWEAK Receptor, Fibroblast Growth Factor-Inducible 14 (Fn 14) in IgA Nephropathy Jungkook Wi, Hong Joo Lee, Joo Hee Cho, Wha-young Suk, Eun Young Kim, Ju-Young Moon, Sang-Ho Lee, Kyung-hwan Jeong, Tae-won Lee, Chun-Gyoo Ihm. *Department of Nephrology, College of Medicine, Kyung Hee University, Seoul, Republic of Korea.*

Background: Recently,it was reported that TWEAK might play an important role in the pathogenesis of kidney damage. In present study, we investigated the correlation between clinical parameters and urinary TWEAK levels and the degree of TWEAK-Fn14 interaction expressed by immunohistochemistry (IHC) in IgA nephropathy (IgAN).

Methods: We investigated urinary TWEAK and serum TWEAK levels in 21 patients with biopsy proven IgAN and in 15 healthy volunteers. We also examined the renal TWEAK-Fn14 expression by IHC. As a control, we used nonpathological kidney tissues obtained from nephrectomized surgical specimen. The expressions of TWEAK and Fn14 were assessed using Allred scoring system by one pathologist and one nephrologist.

Results: The mean age was 36.1 ± 9.5 years in IgAN group and 36.0±8.3 years in healthy control group. The level of uTWEAK in IgAN was significantly higher compared to healthy controls ($p<0.01$). While the TWEAK and Fn14 interaction was not observed in control human kidney tissues, it was, in contrast, clearly observed in tubular cells of IgAN patients.There was no correlation between the levels of sTWEAK or uTWEAK and score of immunostaining with TWEAK ($p=0.496$) or Fn 14 ($p=0.440$) or other clinical parameters. The score of immunostaining did not correlate with the proteinuria or the degree of histological change. There is, however, the significant correlation between the immunostaining of TWEAK and Fn14 and eGFR of IgAN patients ($P= 0.02$ and 0.03, respectively).

Conclusions: This study shows that the degree of TWEAK & Fn 14 interaction in IgAN has a significant correlation with renal function, suggesting the role in the pathogenesis of IgAN.

Involvement of Endoplasmic Reticulum Stress in Bovine Serum Albumin Induced NLRP3 Inflammasome Activation Li Fang, Ping Wen, Lei Jiang, Chunsun Dai, Junwei Yang. *Center for Kidney Disease, 2nd Affiliated Hospital of Nanjing Medical University, Nanjing, Jiangsu, China.*

Background: Albuminuria, an universal feature of chronic kidney disease, contribute to the progression of tubulointerstitial fibrosis. Although it seems that ongoing albuminuria can lead to tubular injury, the molecular machnism remains mostly unknown. Here we show that endoplasmic reticulum (ER) stress is involved in the inflammasome activation of tubular epithelial cells induced by bovine serum albumin.

Methods: Both the renal biopsies samples from patients with albuminuria and the cultured NRK-52E were investigated. The association between the severity of albuminuria or the injury of NRK-52E and the inflammasome activation was estimated. The resting NLRP3 inflammasome was located on ER of kidney epithelial cells according to our results of immunofluorescence staining of renal tissues or cultured cells. To further evaluate the role of ER stress on activation of the NLRP3 inflammasome induced by albumin, NRK-52E were exposed to bovine serum albumin (BSA) with or without the chemical chaperone taurine-conjugated ursodeoxycholic acid (TUDCA) and the inflammasome activation was assessed.

Results: In the biopsies samples, we provide the inflammasome activation characterized by the caspase-1 activation and maturation of IL-1b and IL-18 is associated with the severity of albuminuria. In vitro, BSA can also induce the activation of NLRP3 inflammasome. Because there is a significant overlap of NLRP3 with the ER marker calreticulin, the *ER* stress provoked by BSA seems to play a crucial role in the activation of the NLRP3 inflammasome. For exploration of the functional roles of ER stress, we demonstrated that TUDCA which was proved to be an enhancer for the adaptive capacity of ER could attenuate NLRP3 inflammasome activation induced by albumin not only in vitro but also in diabetic nephropathy.

Conclusions: These findings suggest that ER stress seems to play an important role in BSA-induced NLRP3 inflammasome activation, and elimination of ER stress via TUDCA may hold promise as an novel avenue for preventing NLRP3 inflammasome activation and ameliorating tubular injury induced by albuminuria.

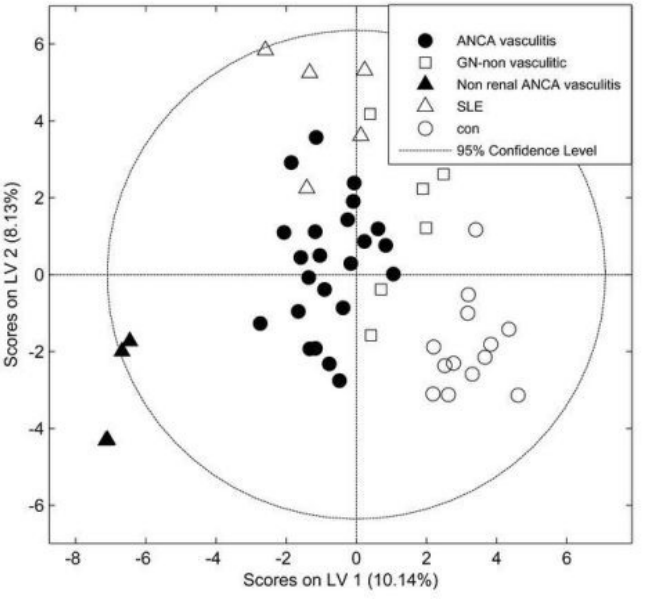
Urinary Metabolomic Biomarkers in Remitting and Relapsing Vasculitic Glomerulonephritis Bahjat Al-ani,[4] Hamad Al Nuaimi,[4] Martin A. Fitzpatrick,[3] Stuart W. Smith,[4] Caroline O.S. Savage,[4] Yasmeen Ghani,[2] Alan D. Salama,[2] Stephen P. Young,[3] Mark A. Little.[1] *[1]Trinity Health Kidney Centre, TCD, Ireland; [2]UCL Centre for Nephrology Royal Free, UCL, United Kingdom; [3]Dept of Rheumatology, University of Birmingham, United Kingdom; [4]Renal Immunobiology, University of Birmingham, United Kingdom.*

Background: Current vasculitis biomarkers lack predictive value and are insensitive to early vasculitic injury. To address this, we analysed the longitudinal urinary metabolomic profile in a rat model of anti-MPO vasculitis (Experimental Autoimmune Vasculitis, EAV).

Methods: We obtained urine at regular intervals over 6 months after EAV induction after which we induced relapse with MPO and endotoxin. Urine metabolites were assessed using NMR, partial least squares discriminant analysis (PLSDA) and partial least squares regression (PLS-R). To validate findings in humans, we analysed the urine of patients with renal anti-MPO vasculitis (varying disease activity), non-renal vasculitis, non-vasculitic glomerulonephritis (GN) and healthy controls.

Results: In EAV, peak haematuria and anti-MPO titre occurred 8 wks post immunisation and declined steadily thereafter. Four weeks after relapse, histological markers of GN and lung iron staining (lung haemorrhage) increased compared to non-relapsed animals. Rats with acute vasculitis (8 wks) had a significantly different metabolite profile compared to controls; the observed PLSDA clusters dissipated between 8 and 26 weeks and re-emerged after relapse. The most raised metabolites in rats with active vasculitis were betaine, trimethylamine and dimethylglycine, which correlated well with the GN score. In patients with renal vasculitis, we observed similar clustering and some of the same metabolites were elevated in the urine.



Conclusions: Vasculitic GN results in a distinct urinary metabolite profile, forming a basis for novel biomarker development.

Evidence for a Pro-Inflammatory Role of P2X7 in Anti-Podocyte Nephritis

Jan Hendrik Knop,[1] Marlies Sachs,[1] Welbeck Danquah,[2] Björn Rissiek,[2] Friedrich Koch-nolte,[2] Catherine Meyer-Schwesinger.[1] *[1]Nephrology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]Institute of Immunology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany.*

Background: The P2X7 receptor is a ligand-gated cation channel that is expressed by a variety of immune cells, including macrophages and lymphocytes. Activation of P2X7 leads to influx of Ca^{2+} ions and the efflux of K^+ ions. Calcium influx is linked with the activation of the pro-inflammatory metalloprotease ADAM17 in T cells. Moreover, P2X7 activation induces the assembly of the NALP3 inflammasome complex resulting in the release of IL-1β. Sustained activation of P2X7 leads to cell death. Increased expression of both P2X7 mRNA and protein was reported in mesangial cells and macrophages infiltrating the glomeruli in animal models of antibody-mediated glomerulonephritis. Cultured podocytes express mRNA of P2X7and react to benzoyl ATP, a selective agonist of P2X7. P2X7 could therefore mediate podocyte injury and be a potential therapeutic target for podocyte disease.

Methods: In this study, we used P2X7-knockout mice in the experimental model of anti-podocyte nephritis. In addition we investigated the role of P2X7 with pharmacological modulation in wild-type mice.

Results: P2X7 deficiency was significantly renoprotective compared with wild-type controls, evidenced by better renal function, a striking reduction in proteinuria, and decreased histologic glomerular and podocyte injury. In addition, the selective blockade of P2X7 attenuated, while the selective activation of P2X7 accelerated and exacerbated the course of anti-podocyte nephritis.

Conclusions: These results support a pro-inflammatory role for P2X7 in podocyte injury and suggest that the P2X7 receptor is a potential therapeutic target in podocyte damage.

SA-PO744

Alternative Pathwayactivation of Complement by Shiga Toxin Induces Podocyte Damage in Experimental HUS

Marina Morigi,[1] Simona Buelli,[1] Monica Locatelli,[1] Anna Pezzotta,[1] Daniela Rottoli,[1] Daniela Corna,[1] Giuseppe Remuzzi,[1,2] Carlamaria Zoja.[1] *[1]Mario Negri Institute, Italy; [2]Unit of Nephrology and Dialysis, Ospedali Riuniti di Bergamo, Italy.*

Background: Shiga toxin (Stx)-producing *E.coli* O157:H7 is the offending agent of diarrhea-associated hemolytic uremic syndrome (HUS), a disorder characterized by microvascular thrombosis and glomerular ischemic changes. We recently found that Stx induced complement (C) alternative pathway-mediated C3b deposition and C3a generation at glomerular level, responsible for endothelial P-selectin expression and thrombus formation in experimental HUS. In search for mechanisms linking C activation and glomerular capillary wall damage, we explored in a murine HUS model whether early glomerular C activation/deposition caused podocyte injury.

Methods: Mice i.p. injected with Stx2 plus LPS were sacrified at 24 and 48h and kidneys used for immunohistochemistry.

Results: In Stx2/LPS mice, exuberant glomerular C3b deposits preceded a substantial decrease in podocyte number (Stx/LPS 24h, 92±10 and 48h, 54±1 vs saline, 138±10podo /glom, $p<0.05$ and $p<0.01$)**.** By contrast, factor B deficient mice challenged with Stx/LPS were protected from C deposition and showed limited podocyte loss (Stx/LPS 24h, 82±6 and 48h, 90±8 vs saline,102±8 podo/glom), indicating that the alternative pathway of C triggers podocyte injury. C3a receptor antagonist given to Stx/LPS mice also lessened podocyte loss to a significant extent as compared to untreated mice (11 vs 44 %, $p<0.05$). Relevance for integrin-linked kinase (ILK) regulation and related proteins on podocyte dysfunction was also addressed. In Stx/LPS mice, increased ILK expression was followed by upregulation of Snail, a transcription factor that promotes podocyte dedifferentiation and motility. In parallel, alpha actinin-4, a podocyte protein associated to F-actin and integrin signals, was markedly reduced (score: Stx/LPS 24h, 2.09±0.1 and 48h, 1.62±0.1 vs saline 2.9±0.1, $p<0.01$). Factor B deficiency limited glomerular changes in ILK, Snail and alphaactinin-4.

Conclusions: These results identify Stx-induced C activation as a key mechanism of C3a-dependent podocyte damage in experimental model of human typical HUS.

NF-κB Inhibition Strongly Attenuates Interstitial Inflammation and Renal Functional Loss Induced by Excess Dietary Adenine

Cristiene Okabe, Raquel L. Borges, Denise M.A.C. Malheiros, Camilla Fanelli, Flavia G. Machado, Simone C.A. Arias, Grasiela P. Barlette, Thales de Brito, Niels O.S. Camara, Roberto Zatz, Clarice K. Fujihara. *Univ of Sao Paulo, Brazil.*

Background: Dietary adenine (ADE) excess promotes severe interstitial (INT) inflammation and fibrosis, leading to progressive INT nephritis and renal insufficiency. We showed previously [PONE, 2011;6:e29004] that, on excess ADE, KO mice for TLR-2, -4, MyD88, ASC or Caspase-1 exhibit less renal injury than WT mice, suggesting a pathogenic role for TLR activation and inflammasome assembly in this model. Here we investigated whether a distinct pathway of innate immunity – the NF-κB system – also participates in the chain of reactions triggered by intratubular crystal (Crys) precipitation.

Methods: Forty-two adult male Munich-Wistar rats were divided in 3 groups. **C:** given standard chow; **ADE:** given ADE in chow, 0,75% during 1 week and 0.53% for 2 weeks; **ADE+PDTC**, given ADE as described and the NF-κB inhibitor pyrrolidine dithiocarbamate (PDTC), 120 mg/kg/day in drinking water. At the end of this 3-week period, blood pressure (BP, mmHg), serum creatinine (S_{Cr}, mg/dL), glomerular volume (V_G, $10^6\mu m^3$), % cortical interstitium (%INT), the rate of tubulointerstitial (TI) cell proliferation ($PCNA^+$ cells/mm^2), the intensity of Crys deposition/mm^2 and the number of renal granulomas (Gran)/mm^2 were measured.

Results:

	BP	Scr	V_G	%INT	$PCNA^+$	Crys	Gran
C	121±2	0.6±0.1	0.85±0.03	0.2±0.1	35±2	0±0	0±0
ADE	130±4[a]	2.8±0.1[a]	0.58±0.02[a]	20.0±1.1[a]	1187±112[a]	114±7[a]	26±2[a]
ADE+PDTC	132±3[a]	1.5±0.2[ab]	0.68±0.02[a]	9.0±1.2[ab]	725±62[ab]	100±7[a]	4±1[ab]

Mean±SE, [a]$p<0.05$ vs. C, [b]$p<0.05$ vs. ADE+V.

Conclusions: As expected, ADE promoted Crys deposition and Gran formation, in association with slight hypertension, glomerular shrinkage, TI proliferation, severe INT damage and marked creatinine retention. PDTC strongly attenuated ADE-induced renal injury/inflammation/hyperplasia and functional decline, without changing Crys. These findings are consistent with the concept that the NF-κB system is activated by intratubular Crys precipitation and contributes, along with other pathways of innate immunity, to initiate the severe inflammatory response associated with this model. SA-PO746

TLR-2/-4 TREM-1 Pathway Is Activated but Dispensable in Inflammatory Macrophages in Sterile Kidney Injury

Gabriela Campanholle, Jeremy Stuart Duffield. *Renal Division and Center for Lung Biology - Department of Medicine, Institute of Stem Cell & Regenerative Medicine, University of Washington, Seattle, WA.*

Background: Inflammatory macrophages (MΦ) are abundant in kidney disease, stimulating repair, or driving fibrosis by excessive or inappropriate activation. Damage associated molecules (DAMPs), released from injured cells, engage pattern recognition receptors (PRRs) on MΦ, contributing to activation. Triggering Receptor Expressed in Myeloid cells (TREM-1) and Toll-Like Receptors (TLRs) are important activators in MΦ. Understanding mechanisms of MΦ activation during kidney injury would help to prevent fibrosis.

Methods: Kidney MΦ were isolated 5d after Unilateral Ureteral Obstruction (UUO) and Microarray was performed. Crude DAMPS were purified from UUO kidney to stimulate cells *in vitro*. Mice were subjected to UUO and unilateral ischemia and reperfusion injury (IRI), and treated with soluble TREM1-fc and analyzed for responses to injury. TLR2-4-/-, Myd88-/- or Csf1Rcre;Myd88fl/fl mice were subjected to UUO or IRI and analyzed for rsponses to injury.

Results: TREM-1 is highly upregulated in kidney MΦ after injury and is a marker of M1 cells. DAMPs from UUO kidney activated bone marrow MΦ *in vitro* independently of TREM-1, but partially dependent on TLR-2/-4, MyD88 pathway. In UUO and IRI, TREM-1 blockade by TREM1-Fc treatment had no impact on disease progression or MΦ activation *in vivo*. In the IRI model, TLR-2/-4 or MyD88 deficiency was anti-inflammatory. However, deletion of MyD88 only in myeloid cell lineage had no effect on MΦ activation or disease progression. Instead TLR-2/-4 or MyD88 deficiency reduced activation of mesenchymal lineage of cells (pericytes and myofibroblasts) resulting in less fibrosis.

Conclusions: TREM-1 and TLR2/4 pathways are dispensable in MΦ activation in sterile kidney injury but TLRs play a role in mesenchymal cell activation.

Integrin Linked Kinase Plays a Key Role in the Regulation of the Renal Inflammatory Response

Matilde Alique,[1] Esther Civantos,[1] Elsa Sanchez-lopez,[1] Sandra Rayego-Mateos,[1] Carolina Lavoz,[1] Raquel Rodrigues-Diez,[1] Isabel Serrano,[2] Jesus Egido,[3] Alberto Ortiz,[3] Maria P. Ruiz-torres,[2] Diego Rodriguez-Puyol,[2] Marta Ruiz-Ortega.[1] *[1]Nephrology, Universidad Autónoma, Madrid, Spain; [2]Physiology, UAH, Madrid, Spain; [3]Nephrology, ISS-Fundación Jimenez.*

Background: Inflammation plays a key role in the progression of renal diseases. Integrin-linked kinase (ILK) is involved in cell-matrix interactions and regulates many processes, including proliferation, migration, and angiogenesis, while its role in the inflammatory process is unknown. We therefore investigated whether ILK-signaling system regulates renal inflammatory response.

Methods: The role of ILK in renal inflammation was studied using the model of systemic infusion of Angiotensin II (AngII) in conditionally ILK deficient mice (cKO). I*n vitro* the blockade of endogenous ILK was done by small interfering RNA in cultured tubular epithelial cells (HK-2).

Results: AngII-infused mice presented an inflammatory response in the kidney, characterized by interstitial infiltration of monocytes/macrophages (F4/80+ cells) and T lymphocytes (CD3+) and upregulation of proinflammatory molecules and adhesion factors (MCP-1, IL-6, RANTES and ICAM-1). In AngII-infused ILK-deficient mice, the number of interstitial inflammatory cells and the renal levels of proinflammatory factors were similar to controls (saline-infused cKO). Moreover, AngII-induced renal Akt and NF-kB activation was abolished in ILK deficient mice, suggesting a downstream mechanism of ILK. To further investigate molecular mechanism in vitro studies were done. In HK2 cells, ILK gene silencing inhibited the activation of Akt/GSK3 induced by AngII, demonstrating that GSK3 and Akt are downstream signals in ILK pathway. The activation of NF-kB pathway is regulated by ILK, as observed by downregulation of NF-kB activation and related gene upregulation by silencing ILK and, its downstream signalling GSK3α/β.

Conclusions: Our data demonstrated a key role of ILK in renal inflammation, by regulation of GSK3α/β/Akt signaling and activation of NF-kB pathway, and suggest a potential therapeutic target for AngII-mediated renal diaseses.

Phenotypic Shift of Activated Glomerular Cells towards Redifferentiation by the Unfolded Protein Response Hisashi Johno, Shotaro Nakajima, Hironori Kato, Jian Yao, Masanori Kitamura. *Department of Molecular Signaling, University of Yamanashi, Chuo, Yamanashi, Japan.*

Background: During recovery from acute glomerulonephritis, cell proliferation, matrix expansion and expression of a-smooth muscle actin (a-SMA; dedifferentiation marker) subside spontaneously. However, molecular mechanisms underlying this recovery process remain elusive. In mesangioproliferative glomerulonephritis, the unfolded protein response (UPR) is induced in activated, dedifferentiated mesangial cells. In the present report, we investigated a role of UPR in mesangial cell deactivation and redifferentiation.

Methods: Mesangioproliferative glomerulonephritis was induced in rats by intravenous administration with anti-Thy 1 antibody. To induce UPR, tunicamycin was injected intraperitoneally at day 3. At day 7, kidneys and isolated glomeruli were subjected to immunohistochemistry and Western/Northern blot analyses. In vitro, activated rat mesangial cells were treated with UPR inducers, and phenotypic shift of mesangial cells was evaluated using Western/Northern blot analyses, reporter assays and assessment of mitogenesis.

Results: We found that, during experimental glomerulonephritis in rats, reinforcement of UPR significantly attenuated mesangial cell proliferation, matrix expansion and expression of a-SMA. Consistent with this in vivo result, induction of UPR suppressed cell proliferation and transcriptional expression of type IV collagen (ColIV) and a-SMA in activated mesangial cells. UPR reduced phosphorylation of Akt selectively, and it was responsible for attenuation of cell proliferation. UPR also preferentially depressed levels of total and phosphorylated Smads without affecting their transcriptional levels. It was responsible for the suppression of ColIV and a-SMA. Translational suppression via the eIF2a pathway, but not proteasome-mediated protein degradation, was responsible for the down-regulation of Smads.

Conclusions: These results suggest the novel potential of UPR to facilitate a phenotypic shift of activated glomerular cells towards deactivation and redifferentiation. UPR may serve as endogenous machinery that supports recovery of glomeruli from acute inflammation.

SA-PO749

A Novel Role for the Cytochrome P450 System in Modulating Immune-Associated Inflammation Gabriela E. Garcia,[1] Richard J. Johnson,[1] Luan D. Truong,[2] Lili Feng.[2] *[1]Medicine, University of Colorado Denver, Aurora, CO; [2]Medicine, Baylor College of Medicine, Houston, TX.*

Background: Very little is known about the role of the cytochrome P450 system in modulating glomerular injury and inflammation. Previously, we found that vagus nerve stimulation could attenuate inflammation in anti-glomerular basement membrane (GBM) glomerulonephritis (GN) in association with the induction of cytochrome P4501A1 (CYP1A1) in the kidney. We hypothesized that induction of CYP1A1 might be responsible for the anti-inflammatory effects.

Methods: To test this hypothesis, we used 3-methylcholanthrene (3MC) which is known to increase CYP1A1 expression. Rats received 3MC every other day, starting either before or after the induction of the disease with sacrifice at day 14.

Results: Rats given 3MC showed marked increased expression of kidney CYP1A1 with a 60% and 50% reduction in proteinuria in rats treated before and after the injection of anti-GBM antibody, respectively, compared with control rats. In addition, prominent macrophage (Mø) infiltration was observed in the control group and was reduced significantly by 3MC treatment (44% and 38% in rats treated before and after induction of GN, respectively). Consequently, the severity of glomerular hypercellularity, necrotizing lesion, and crescent formation were significantly reduced in the 3MC treated groups. In addition, sclerotic glomeruli were reduced in the 3MC pretreated group compared to the control group. In control and 3MC treated rats, induction of anti-GBM GN led to a prominent kidney expression of fractalkine/CX_3CL1, MPC-1/CCL2, MIP-1β/CCL4, and MIP-3β/CCL19. The expression of adhesion molecule VCAM-1 was decreased in the 3MC treated groups compared with the control group. Notably, decreased $PCNA^+$ Mø were found in 3MC treated rats compared to control rats.

Conclusions: These findings suggest that vagus nerve stimulation attenuates inflammation in part by CYP1A1-linked inhibition of Mø infiltration through reduction of adhesion molecule expression and Mø proliferation. In addition, these studies demonstrate the novel role for cytochrome P4501A1 as an anti-inflammatory system in GN, and offers insights into novel treatment strategies.

Renoprotective Effect of Direct Renin Inhibitor in Gentamicin-Induced Kidney Injury in Rats Eun Hui Bae, Joon Seok Choi, Chang Seong Kim, Soo Wan Kim. *Internal Medicine, Chonnam National University Medical School, Gwangju, Korea.*

Background: Inhibition of the renin-angiotensin system (RAS) is a key therapeutic strategy in slowing progression of kidney injury. Recently, renin inhibition has also emerged as a potential therapy to block the RAS. The protective effect of aliskiren, a direct renin inhibitor, against tubulointerstitial renal injury remains to be defined. This study aimed to examine the protective effects of the aliskiren on gentamicin (GM)-induced kidney injury.

Methods: Male Sprague-Dawley rats (180-200g) were intramuscularly injected with GM (100 mg/kg per day) for 14 days. Aliskiren was infused for two weeks using osmotic minipumps. Human proximal tubular epithelial (HK-2) cells, were cultured with GM in the absence or presence of aliskiren. Inflammatory and profibrotic markers were evaluated *in vivo* and *in vitro.*

Results: GM increased plasma creatinine level, fractional excretion of sodium and urine output, while aliskiren treatment ameliorated these functional changes. Inflammatory cytokines such as tumor necrosis factor (TNF)-α, interleukin (IL)-1β, interferon (IFN)-γ and inducible nitric oxide synthase (iNOS) were increased in the GM-treated kidneys. GM treatment also induced chemokines and adhesion molecules such as monocyte chemoattractant protein (MCP)-1, intercellular adhesion molecule (ICAM)-1 and vascular cell adhesion molecule (VCAM)-1. These changes were counteracted by aliskiren co-treatment. The accumulation of ED-1 expressing macrophages in GM-treated kidneys was reduced by aliskiren. Masson's trichrome stain demonstrated increased collagen deposition and fibrosis in GM-treated rats, which was ameliorated by aliakiren treatment. Aliskiren also effectively reversed increased expression of TGF-b and α-SMA in GM-treated rat kidney. Along with these changes, aliskiren also attenuated the increased expression of nuclear factor κB and phosphorylated extracellular signal-regulated kinase in HK-2 cells cultured with GM.

Conclusions: These findings suggest that aliskiren prevents GM-induced kidney injury by inhibiting renal inflammation and fibrosis, the mechanism of which was the interruption of NF-κB and/or ERK signaling pathways.

SA-PO751

A Transcriptional Regulator, Inhibitor of Differentiation 3 (ID3), Is a Novel Risk Factor for Kidney Disease Harini Bagavant,[1] Paromita Dey,[1] Barbara M. Szczerba,[1] Agnieszka M. Szymula,[1] Ani W. Manichaikul,[3] Coleen Mcnamara,[2] Umesh Deshmukh.[1] *[1]Division of Nephrology; [2]Cardiovascular Medicine, Department of Medicine; [3]Department of Public Health Sciences, University of Virginia, Charlottesville, VA.*

Background: The deficiency of a transcriptional regulator, inhibitor of differentiation 3 (*Id3*), in hyperlipidemic Apolipoprotein E deficient mice induces severe glomerulonephritis and proteinuria (Am J Pathol 2011;179:651). ID3 regulates the helix-loop-helix family of transcription factors and a functional deficiency in Id3 is linked to increased atherosclerosis in mice and humans. We postulated that *Id3* deficiency facilitates kidney disease by influencing glomerular cell responses to inflammatory lipids.

Methods: Primary mesangial cell lines were generated from $Id3^{+/+}$and $Id3^{-/-}$ mice and stimulated with oxidized phospholipids (oxPL). Cytokines produced were analyzed by multiplex bead array assays. $Id3^{+/+}$and $Id3^{-/-}$ female mice were fed an atherogenic Western diet (TD.88137; 42% calories from fat) or a chow diet (TD.7012; 17% calories from fat) for 15wks. Mice were evaluated for proteinuria, renal histopathology and inflammatory cell infiltrates. Gene expression analyses were carried out by qPCR.

Results: Compared to $Id3^{+/+}$cells, $Id3^{-/-}$ mesangial cells incubated with oxPL produce higher amounts of CXCL1, an important macrophage and neutrophil chemoattractant. In vivo, both $Id3^{+/+}$ and $Id3^{-/-}$mice fed a Western diet showed increased weight gain and elevated cholesterol levels compared to mice on chow diets. Blood glucose levels were not different between groups. However, only $Id3^{-/-}$ mice fed a Western diet developed severe proteinuria and glomerulonephritis. Glomerulonephritis was accompanied by increased macrophage infiltration and glomerular CXCL1 deposition. A preliminary analysis in humans showed a significant association between *ID3* single nucleotide polymorphisms and albuminuria.

Conclusions: Exacerbated inflammatory responses to lipids in $Id3^{-/-}$ mice facilitate kidney disease in hyperlipidemia. Thus, a functional Id3 regulates chemokine production and is reno-protective. Id3 may provide a critical link between hyperlipidemia, atherosclerosis, and kidney disease.

SA-PO752

Effect of a Serine Protease Inhibitor on the Progression of Renal Injury in Metabolic Syndrome Teruhiko Mizumoto,[1] Kohei Uchimura,[1] Yutaka Kakizoe,[1] Manabu Hayata,[1] Tomoaki Onoue,[1] Miki Ueda,[1] Rika Yamazoe,[1] Jun Morinaga,[1] Sakai Yoshiki,[2] Kimio Tomita,[1] Kenichiro Kitamura.[1] *[1]Department of Nephrology, Kumamoto University Graduate School of Medical Sciences, Kumamoto, Japan; [2]Research Headquarters, Ono Pharmaceutical Co., Ltd., Osaka, Japan.*

Background: It is well known that metabolic syndrome (Mets) contributes to the development and progression of CKD. Previously we reported the involvement of serine proteases in the pathogenesis of salt-sensitive hypertension and renal fibrosis. Therefore, we

hypothesized that a synthetic serine protease inhibitor camostat mesilate (CM) attenuates the progression of renal injury induced by metabolic syndrome.

Methods: Thirteen week-old SHR/ND mcr-cp rats, a rat model of Mets, were divided into four groups: 1) normal salt (NS) group, 2) high salt (HS) group, 3) HS+CM group, and 4) HS+hydralazine (hyd) group. NS rats were fed normal diet (0.8% NaCl), and HS rats were fed high salt diet (8% NaCl). The HS+CM rats were subcutaneously implanted with slow-releasing pellets containing CM. Blood pressure (BP) measurements and 24 hr urine collections were made every week, and rats were sacrificed following 4 weeks treatment period.

Results: Severe hypertension and proteinuriawere observed in HS group (proteinuria, NS 54±6.4, HS 345±20.4mg/day), and both were substantially attenuated by CM (28±4.3mg/day). Although reduction in BP levels were comparable between HS+CM and HS+Hyd, the anti-proteinuric effect of CM was much greater than Hyd (110±27.3mg/day), indicating that CM has an ameliorating effect on proteinuria besides its BP lowering effect. Immunohistochemical analysis revealed that CM markedly attenuated the reduced glomerular expression of nephrin induced by HS. Fasting blood sugar and insulin levels as well as insulin resistance index were not affected by CM treatment.

Conclusions: Here we demonstrated that a serine protease inhibitor CM significantly ameliorated the development and the progression of Mets-induced kidney injury by reducing blood pressure and proteinuria. These findings strongly suggest the possibility that CM could be a new class of therapeutic strategy against CKD with Mets.

SA-PO753

Role of Plasmacytoid Dendritic Cells (pDCs) and Interferon-alpha (IFN-α) in the Activation of Tubular Epithelial Cells (RPTEC) in Lupus Nephritis (LN) G. Castellano,[1] Cesira Cafiero,[1] C. Divella,[1] Fabio Sallustio,[2] Margherita Gigante,[3] Loreto Gesualdo.[1] *[1]Renal Dialysis and Transplant Unit, University of Bari, Italy; [2]CARSO Consortium, Valenzano-Casamassima, Italy; [3]Department of Biomedical Science, University of Foggia, Italy.*

Background: PDCs, the major producer of IFN-alpha, play a key role in autoimmune response in SLE. However, the involvement of pDCs in LN is unclear.The aim of this study was to investigate the effects of IFN-alpha in vitro and in biopsies from LN patients.

Methods: Confocal microscopy showed peritubular infiltrating pDC in LN patients, expressing the MXA protein, a specific marker of IFN-alpha local production. We then performed microarray analyses (Illumina), on IFN-alpha activated RPTEC (100U/ml for 48h).

Results: Following stimulation, we found 108 significantly up-regulated genes and 7 down-regulated genes (fold-change >2; false discovery rate, FDR<.05). Gene set enrichment analysis identified 123 processes differentially regulated in IFN-alpha activated RPTEC: the interferon response, the antigen presentation and inflammatory pathways. Among over-expressed genes, we identified the HLA-I, the ubiquitin (FBXO6; DTX3L) and the immunoproteasome subunits LMP7. After validation by RT-PCR, flow citometry experiments on IFN-activated RPTEC confirmed a significant increase of antigen presentation molecules (HLA-I: 75%±2/MnI 7.8±3 basal vs 90%±3/MnI 11±2 IFN-alpha) and inflammatory signalling (LMP7: 49.75%±2 basal vs 72.4%±2 IFN-alpha). Immunohistochemical analysis on renal biopsies of patients with class IV LN showed a significant increase of tubular LMP7 expression (LMP7: 5% ± 2 NL class I vs 16 ± 5% class IV, p<.0001) and MXA expression compared to class I LN (MXA: 0±1.0% class I vs 4.5±1.2% class IV, p<.0001). Confocal analysis in LN patients confirmed the colocalization of IFN-signalling with the immunoproteasome induction (LMP7+/MXA+) and the activation of inflammatory signaling (NF-kB-p65+/MXA+) in renal tubuli.

Conclusions: Our data demonstrate a critical role of pDC-derived INF-alpha in the activation of RPTEC. Therefore we hypothesize that inhibition of IFN-alpha pathway may be a novel therapeutic strategy to reduce renal damage in patients with LN.

Identification of Urine Biomarkers of Lupus Nephritis: CKD Biomarkers Consortium Jon B. Klein,[1] Michael Merchant,[1] Huijuan Song,[2] Xiaolan Zhang,[2] Alison Marie Mckinley Neal,[2] Brad H. Rovin.[2] *[1]Kidney Disease Program, University of Louisville School of Medicine, Louisville, KY; [2]Internal Medicine/Nephrology, Ohio State University Medical Center, Columbus, OH.*

Background: The current treatment of lupus nephritis is unsatisfactory in terms of both outcome and toxicity. Predictive biomarkers of the course and pathology of lupus nephritis (LN) would lead to less immunosuppression and decrease its associated toxicity. However, no such biomarkers have been discovered with sufficient sensitivity and specificity. We addressed the hypothesis that urine biomarkers would correlate with the presence and extent of inflammation or fibrosis in the tubulointerstitial compartment during LN.

Methods: Urine samples were obtained immediately prior to renal biopsy in patients with LN. Three urine groups (Control, Inflamed, Fibrotic) were defined based on blinded scoring of tubulointerstitial inflammation or fibrosis. Urine samples (n=5 in each group) were depleted of 12 abundant proteins using a ProteomeLab IgY-12 LC-2 column and analyzed using 2D-LC-MS/MS combined with a label-free quantitative strategy to define protein expression differences in urine samples.

Results: Using rigorous standards, 587 proteins across 15 samples were identified. By ANOVA 26 urinary proteins were significantly, differentially abundant (p≤0.05) between C, I, and/or F groups. Of the group of 26 proteins, osteopontin (OPN), hemopexin (HPX) and the endothelial protein c receptor (EPCR) urine levels were examined by ELISA. OPN levels were different in I versus F urine (n= 8 and 18, respectively, p<0.002). HPX levels discriminated between C versus I and F groups (p<0.05). EPCR levels did not differ between groups.

Conclusions: In summary, our results suggest the type and extent of renal tubulointerstitial damage in patients with LN correlates with the abundance of specific urinary proteins. With confirmation, the quantitative assessment of these proteins in individuals may be valuable to guide individualization of lupus treatment. This work was partially supported by the Chronic Kidney Disease Biomarker Consortium funded by NIDDK U01DK085673.

Understanding the Molecular Mechanisms of LN Progression and Remission in NZB/W Mice Celine C. Berthier,[1] Ramalingam Bethunaickan,[2] Matthias Kretzler,[1] Anne Davidson.[2] *[1]University of Michigan; [2]Feinstein Institute for Medical Research.*

Background: Systems biology technologies allow integration of current knowledge with large scale experimental data to generate insight into the regulatory events occurring in lupus nephritis (LN). We analyzed the time dynamics of renal molecular changes during LN progression and remission in the NZB/W mouse model.

Methods: Affymetrix based expression profiles at sequential times during LN progression and early or late remission induced by co-stimulatory blockade or BAFF-inhibition respectively, were analyzed for dynamic transcriptional changes using Genomatix Pathway Systems and Ingenuity Pathway Analysis softwares.

Results: Proteinuria onset was characterized by renal inflammatory cell infiltration. STAT-1/-3, EGR1, HIF1A were the top transcription factors (TF) having a binding site (BS) in the regulated gene promoter. Complete remission 3 weeks after co-stimulatory blockade showed a return to baseline expression, reflecting reduction in infiltrating cells. A 654 biomarker dataset (q<0.05) was extracted from the regulated genes overlapping between the proteinuria onset and either age matched non-proteinuric or the remission mice. 17% of these biomarkers had a STAT-1 TF BS in their promoter. STAT-1 was also a major regulated node in human LN kidneys, compared to living donors. LN disease progression to established proteinuria (36 weeks) showed a mitochondrial dysfunction signature, which overlapped significantly with the 403 transcripts that differed between mice in the early and late stages of remission.

Conclusions: NZB/W LN onset is associated with inflammatory cell infiltration of the kidneys but LN disease progression is linked to mitochondrial dysfunction, most probably secondary to hypoxia and tubular damage. A similar mitochondrial dysfunction profile is seen during impending relapse and in human LN. Therapies addressing this intrarenal response to inflammation may synergize with immune modulation in human LN treatment. Many of the inflammatory, metabolic and hypoxia-responsive transcripts appear downstream of STAT-1 dependent regulation, implicating Type I/II IFNs as possible regulators of nephritis onset and remission.

Laminin α5 Overexpression Accelerates Glomerular Disease Progression in Alport Mice Brooke M. Steenhard, Patricia St. John, Adrian T. Zelenchuk, Larysa Stroganova, Dale R. Abrahamson. *Anatomy and Cell Biology and the Kidney Institute, University of Kansas Medical Center, Kansas City, KS.*

Background: Extracellular matrix expansion in mesangial and glomerular basement membrane (GBM) compartments occurs in many glomerular diseases. Mice on the 129X1/SvJ background harboring a deletion of *Col4a3*, which encodes the collagen α3(IV) chain, are a faithful model of human Alport syndrome. In the absence of collagen α3(IV), a GBM collagen α3α4α5(IV) network fails to form, and ~2 weeks of age, there is upregulation of several laminin isoforms, including laminin α5. These mice develop proteinuria at ~5 weeks and die of renal failure at ~9 weeks. We hypothesized that laminin dysregulation also contributes to the pathogenesis of Alport, and crossed Alport mice with a human (hu) *LAMA5* transgenic line we created that overexpresses hu laminin α5.

Methods: To minimize strain variations known to affect progression of Alport disease in mice, male hu *LAMA5*+/- hemizygotes were mated to female, 129-derived, *Col4a3*+/- heterozygotes. F1 *LAMA5*+/-, *Col4a3*+/- males were backcrossed to 129 *Col4a3* females, and male offspring were analyzed at 2 weeks of age.

Results: Confocal microscope quantification showed that all Alport GBMs (with or without hu laminin α5) contained more mouse laminin α5 than wildtype. Alport mice with hu *LAMA5* expressed 2 fold more hu laminin α5 protein in the GBM than non-Alport, hu *LAMA5* controls, with co-localization of both mouse and human protein to the subepithelial GBM nodules characteristic of Alport. Additionally, an enzyme-linked immunosorbent assay showed that 2 week-old Alport mice with the hu *LAMA5* transgene had urinary albumin levels averaging >300 µg/ml (N=6), which was >11 fold greater than Alport mice without *LAMA5* (N=5). There were no statistical differences in albumin levels between Alport mice without *LAMA5*, non-Alport *LAMA5* mice, or wildtypes.

Conclusions: We conclude that, in the absence of collagen α3α4α5(IV), excess GBM laminin α5 accelerates progression of glomerular structural and functional deficits in Alport *LAMA5* mice. This genetic cross may help uncover mechanisms causing matrix overproduction and proteinuria in glomerular disease.

Expression of a Novel Stress-Inducible Protein, Sestrin 2, in Rat Glomerular Parietal Epithelial Cells (PECs) Hiroko Hamatani,[1] Keiju Hiromura,[1] Toru Sakairi,[1] Satoshi Takahashi,[1] Akito Maeshima,[1] Takamoto Ohse,[2] Jeffrey W. Pippin,[3] Stuart J. Shankland,[3] Yoshihisa Nojima.[1] *[1]Department of Medicine and Clinical Science, Gunma University Graduate School of Medicine, Maebashi, Japan; [2]Division of Nephrology and Endocrinology, University of Tokyo School of Medicine, Tokyo, Japan; [3]Division of Nephrology, University of Washington, Seattle, WA.*

Background: Sestrin2, firstly identified as a p53-target hypoxia-inducible gene, accumulates in cells exposed to stress and inhibit mammalian target of rapamycin (mTOR). In this study, we examined the expression of sestrin2 in the kidney.

Methods: Immunohistochemical staining was performed on rat developing and adult kidneys and kidneys with adriamycin-induced (ADR) nephropathy. Immortalized mouse cultured PECs were used for in vitro study.

Results: In embryonic and newborn kidney, immunohistochemical stainings revealed that sestrin2 was moderately expressed in metanephric mesenchyme and comma- and S-shaped body. Increased expression of sestrin2 was observed in PECs of capillary-stage. However, in adult kidney, sestrin2 was selectively expressed in PECs (Figure), similar to claudin-1, the marker of PECs. In ADR nephropathy, sestrin2 expression was markedly decreased in PECs at 8 weeks, when glomerulosclerosis and periglomerular fibrosis were observed. In contrast, increased expression of sestrin2 was detected in some tubular cells (Figure). We then examined the role of sestrin2 using cultured PECs. By western blotting and real time PCR, PECs showed strong sestrin2 expression. Downregulation of sestrin2 by shRNA increased apoptosis of PECs (5.0% vs 2.3%, shRNA vs control, P<0.05), together with increased phosphorylation of p70S6K and 4E-BP1 which are the downstream targets of mTOR.

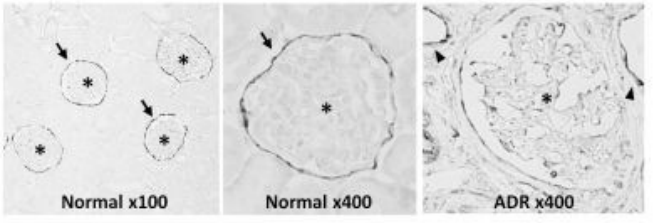

Figure. Sestrin2 expression in rat adult normal kidney and ADR nephropathy

* glomerulus; arrows, sestrin2 in PECs; arrowheads, sestrin2 in tubular cells

Conclusions: These data suggest that increased sestrin2 expression is required for PEC homeostasis.

SA-PO758

Cyclin I and p35 Modulate the Subcellular Localization of Cyclin-Dependent Kinase 5 (Cdk5) Yoshinori Taniguchi,[1] Jeffrey W. Pippin,[1] Henning Hagmann,[2] Ronald D. Krofft,[1] Jiong Zhang,[1] Shokichi Naito,[1] Peter J. Nelson,[1] Yoshio Terada,[3] Paul T. Brinkkoetter,[2] Stuart J. Shankland.[1] *[1]University of Washington, Seattle, WA; [2]University of Cologne, Germany; [3]Kochi University, Japan.*

Background: Cdk5 and its activators, cyclin I and non-cyclin p35, have critical survival functions in terminally differentiated podocytes (podo) and neurons.

Methods: To test hypothesis that subcellular localization for Cdk5 is determined by cyclin I and p35, subcellular distribution of Cdk5 was studied in podo and neurons of wild-type ($^{+/+}$), cyclin $I^{-/-}$ ($I^{-/-}$) and $p35^{-/-}$ mice.

Results: In quiescent podo, cyclin I is predominantly nuclear (nucl), whereas p35 cytoplasmic (cyto). In $^{+/+}$ podo and neurons in vivo, Cdk5 stained in nucl and cyto. This was confirmed in cultured $^{+/+}$ podo by western analysis (WB) of subcellular protein fractions, using TATA-box binding protein (TBP) and α-tubulin (tub) as nucl and cyto control proteins for loading. In contrast, $I^{-/-}$ podo and neurons in vivo showed predominantly cyto staining of Cdk5 ($p<0.05$ vs. $^{+/+}$). Transfecting $I^{-/-}$ podo with myc-cyclin I resulted in Cdk5 localizing to both nucl and cyto, similar to $^{+/+}$ cells. In $p35^{-/-}$ podo and neurons in vivo, Cdk5 staining was predominantly nucl ($p<0.05$ vs. $^{+/+}$). When $p35^{-/-}$ podo were transfected with p35-vector, Cdk5 localized to both nucl and cyto, indistinguishable from $^{+/+}$ cells. The subcellular localization for Cdk5 was not altered in either null cells transfected with control GFP-vectors. These were confirmed in null podo using the ratio's of Cdk5/TBP and Cdk5/tub on isolated subcellular fractions ($p<0.05$ vs. $^{+/+}$). To better define the mechanisms of the nucl-cyto localization of Cdk5, the nucl export inhibitor Leptomycin (LM) was used. LM prevented nucl-to-cyto translocation of Cdk5 in $^{+/+}$, $I^{-/-}$ and $p35^{-/-}$ podo.

Conclusions: In summary, these results support that cyclin I anchors Cdk5 to the nucl, while p35 anchors Cdk5 to the cyto, corresponding to primary subcellular localization of each activator. Any movement of Cdk5 from the nucl to cyto is via classical CRM1-dependent mechanism. We conclude that nucl-cyto distribution for Cdk5 is critical for normal survival functions in terminally differentiated podo.

Cyclin-Dependent Kinase 5 Maintains Podocyte Survival during Experimental Glomerular Disease Yoshinori Taniguchi,[1] Jeffrey W. Pippin,[1] Henning Hagmann,[2] Ronald D. Krofft,[1] Jiong Zhang,[1] Shokichi Naito,[1] Peter J. Nelson,[1] Yoshio Terada,[3] Paul T. Brinkkoetter,[2] Stuart J. Shankland.[1] *[1]University of Washington, Seattle, WA; [2]University of Cologne, Germany; [3]Kochi University, Japan.*

Background: Cdk5 is expressed constitutively in podocytes (podo). Because biological role for Cdk5 in podo health and disease is poorly understood, we generated transgenic mice to selectively and inducibly delete Cdk5 from podo.

Methods: Mice with podocin promoter driven reverse tetracycline transactivator driven cre (NPHS2rtTA/TetO-cre) were crossed with Cdk5 floxed mice (Cdk5-lox/p). When the resultant $TetOCdk5^{-/-}$ mice are given doxycycline (Dox), Dox binds tetracycline receptor present only on podo, resulting in cre recombinase expression (confirmed by immunostaining) which excises the lox/p sites flanking Cdk5, preventing Cdk5 expression in podo (confirmed by immunostaining). Under non-stressed conditions, kidneys from $TetOCdk5^{-/-}$ mice given Dox or control water were normal, as was renal function. To test hypothesis that Cdk5 is required for podo survival during disease, $TetOCdk5^{-/-}$ mice given either Dox or water for 14 days were then injected with anti-podo antibody, which induced podo apoptosis, leading to glomerulosclerosis. Several disease parameters were assessed by immunostaining.

Results: The result of staining showed podo apoptosis was increased compared to diseased control mice (0.3±0.0 vs. 0.1±0.0; $p<0.05$). This resulted in more pronounced decrease in podo number (4.6±0.6 vs. 6.4±1.1; $p<0.05$), proteinuria (Upro/cre 62.4±15.3 vs. 22.1±5.1; $p<0.05$) and glomerulosclerosis (1.7±0.1 vs. 1.4±0.1; $p<0.05$).

Conclusions: In summary, when Cdk5 is reduced, podo are susceptible to increased apoptosis following injury which results in reduced podo number, increased proteinuria and glomerulosclerosis. We conclude that Cdk5 is an important podo survival protein during disease.

SA-PO760

Tissue Transglutaminase: A Novel Enzymatic Pathway Modulating Podocyte Phenotype, Autophagy and Survival Cécile Fligny,[1] Carole Hénique-Gréciet,[1] Marine Milon,[1] Sandra Schordan,[2] Laurent Mesnard,[3] Patrick Bruneval,[1,4] Martin Flamant,[5] Nicole Endlich,[2] Pierre-Louis F. Tharaux.[1] *[1]Paris Cardiovascular Centre - PARCC, INSERM & Université Paris Descartes, Paris, France; [2]Institut für Anatomie und Zellbiologie, Universitätsmedizin Greifswald, Greifswald, Germany; [3]UMR 702, Hôpital Tenon, INSERM & Université Pierre et Marie Curie, Paris, France; [4]Dept of Pathology, Hôpital Européen Georges Pompidou, Assistance Publique-Hôpitaux de Paris, Paris, France; [5]Service de Physiologie–Explorations Fonctionnelles, Hôpital Bichat, Assistance Publique–Hôpitaux de Paris, Paris, France.*

Background: We found marked podocyte expression of the protein cross-linking enzyme, tissue transglutaminase (TG2) in mice and human kidneys with Rapidly Progressive Glomerulonephritis (RPGN).

Methods: Impact on glomerular phenotype of global and podocyte selective Tgm2 (Tg2) gene invalidation was evaluated. The nephrotoxic serum (NTS) model of RPGN was applied to these strains.

Results: In the NTS-induced RPGN, Tg2 invalidation was associated with marked alleviation of glomerular injury. Albuminuria was 25 fold lower in Tg2 null mice at day 11 ($p<0.001$) that displayed much fewer crescent formation (2 ± 2% of the glomeruli at day 4 and 30 *vs.* 25 ± 6% at day 4 and 45 ± 6% at day 30, $p<0.001$). Accordingly, BUN levels remained within normal ranges at day 30 ($p<0.001$).

Podocin-Cre x Tg2 lox/lox mice also displayed significant protection against the development of RPGN with inhibition of podocyte migration. In addition, TG2 deficiency enhances constitutive autophagy in podocytes. Autophagy is protective in RPGN as selective deficiency in Atg5 in podocyte profoundly altered autophagy and accentuated glomerular damage. Furthermore, we found enhanced anti-oxidant Nrf2 pathway in TG2 deficient podocytes. In fact, TG2 appeared to be essential for normal degradation of p62 by autophagy, a master regulator of Nrf2 transcriptional activity.

Conclusions: Full TG2 activity is essential for severe RPGN, in part through promotion of migration of podocytes and alteration of autophagy. This study unravels a novel enzymatic pathway in podocytes and suggests that targeting TG2 would be clinically beneficial for treatment of severe RPGNs.

Molecular Changes in Kidney Cortex Precede Proteinuria in Aging Mice Magali Araujo,[1,2] Marcela Ururahy,[1,3] Nancy L. Koles,[1] Sonia Q. Doi.[1] *[1]Medicine, Uniformed Services University, Bethesda, MD; [2]Nephrology & Hypertension, Georgetown University, Washington DC; [3]Clinical Analysis & Toxicology, Federal University of Rio Grande do Norte, Brazil.*

Background: Aging is associated with renal structural changes and decline of renal function. The progressive decrease in glomerular filtration rate (GFR) and renal blood flow in aging individuals varies widely, and the distinction between age-related loss of GFR and the presence of chronic kidney disease (CKD) in the elderly is yet undefined. This study

was designed to evaluate age-dependent molecular alterations in kidney cortex compared to the onset of albuminuria in mice.

Methods: C57Bl6 male mice were studied at ages 3, 6, 12 and 21 months (m). RNA expression of IL-6, IL-1β, TNF-α, CD68, class A scavenger receptor (SRA), collagen I, fibronectin, TLR2 and TLR4 was measured (normalized to β-actin) in kidney cortex using real time RT-PCR. Urinary albumin and creatinine were measured using commercial kits. Double-staining immunofluorescence (IF) for CD68 (macrophage marker) and Will's Tumor (WT1, podocyte marker) was performed in kidney frozen sections.

Results: Compared to 3m, expression of target genes at older ages showed that IL-6, TNF-α, TLR2 and CD68 increased significantly by 12m, while IL-1β and collagen I increased significantly only at 21m, and TLR4, SRA, collagen IV and fibronectin remained unchanged. Urinary albumin/creatinine ratio increased significantly only at 21m compared to 3m (871±302 vs. 165±40 mg/g creatinine, respectively). IF analysis revealed that CD68 positive signal was predominantly localized in glomeruli overlapping WT1 cytoplasmic staining. Positive staining appeared weakly in approximately 25% of glomeruli at 6m and intensified with age reaching approximately 50% of glomeruli/section.

Conclusions: Our data is consistent with an inflammatory process mediated by TLR2 that begins early at 12m preceding renal fibrosis and proteinuria, and that progresses as the animals age. The co-localization of CD68 with WT1 together with the unchanged SRA expression suggest that the increased renal CD68 in aging mice is due primarily to an aberrant expression by injured podocytes rather than macrophage infiltration.

SA-PO762

Relative Podocyte Depletion in Obese Caucasian American Men without Renal Disease Victor G. Puelles,[1] Rebecca N. Douglas-Denton,[1] Jinhua Li,[1] Wendy E. Hoy,[2] Jens R. Nyengaard,[3] John F. Bertram.[1] *[1]Anatomy and Developmental Biology, Monash University, Melbourne, VIC, Australia; [2]Center for Chronic Diseases, University of Queensland, Brisbane, Queensland, Australia; [3]Stereology and EM Laboratory, Aarhus University Hospital, Aarhus, Denmark.*

Background: Obesity is a worldwide epidemic and a risk factor for CKD. Glomerular hypertrophy and podocyte dysfunction have been described in both obesity and obesity-related glomerulopathy. The aim of this study was to quantify features of podocyte depletion in obese male Caucasian Americans without overt renal pathology.

Methods: Renal tissue obtained at autopsy from Caucasian American men was selected based on Body Mass Index (BMI): 4 obese (BMI ≥30.0 kg/m^2) and 4 lean (BMI ≤24.9 kg/m^2). Individual Glomerular Volume (IGV) was measured using the Cavalieri estimator - 30 glomeruli per subject. A combination of immunohistochemistry, laser confocal microscopy and design-based stereology was used to quantify numbers of podocytes and parietal epithelial cells (PECs) in 6 glomeruli per subject (10th and 90th IGV percentiles). Podocyte number per IGV (Pod/IGV) and percentage of podocytes per glomerulus (podocyte number divided by the total number of tuft cells per glomerulus) were also calculated.

Results: Median IGV was significantly higher (P<0.0001) and IGV variance was three times greater in obese subjects than their lean counterparts. The absolute numbers of podocytes and PECs per glomerulus also varied greatly between subjects in both groups: podocyte number ranged from 263 to 983 (3.7-fold) and PEC number from 124 to 1,279 (10.3-fold). While glomeruli from obese subjects contained more podocytes and more PECs (P<0.01), large glomeruli from obese subjects had lower Pod/IGV (P<0.05) and lower percentage of podocytes per glomerulus (P<0.01) than large glomeruli from lean subjects.

Conclusions: Obese subjects showed evidence of glomerular hypertrophy and relative podocyte depletion. We hypothesize that podocyte depletion predisposes hypertrophied glomeruli to proteinuria and segmental sclerosis.

Podocyte-Specific Deletion of Signal Transducer and Activator of Transcription 3 Attenuates Nephropathy in a Murine Model of Human Immunodeficiency Virus Associated Nephropathy Leyi Gu,[3] Yan Dai,[2] John C. He,[1] Peter Y. Chuang.[1] *[1]Div of Nephrology, Mount Sinai School of Medicine, New York, NY; [2]Div of Nephrology, Shanghai First Affiliated Hospital, Shanghai, China; [3]Renal Division, Renji Hospital, Shanghai Jiatong University School of Medicine, Shanghai, China.*

Background: Human immunodeficiency virus associated nephropathy (HIVAN) is characterized by collapsing glomerulosclerosis, glomerular epithelial cell proliferation, and reduction of podocyte-specific markers. We previously showed that reduction of signal transducer and activator of transcription (STAT) 3 activity attenuates renal injury in a murine model of HIVAN (Tg26). The role of podocyte STAT3 in the pathogenesis of glomerular pathology of HIVAN has not been confirmed.

Methods: Tg26 mice on the FVBN background with and without podocyte-specific deletion of STAT3 were generated. Podocyte-specific deletion of STAT3 was achieved by crossing the podocin-Cre mice to mice with *loxp* sequences flanking exons 18 to 20 of *STAT3*. Renal function was assessed by serum urea nitrogen. Albuminuria was quantified by ELISA and then normalized to urine creatinine concentration. Glomerulosclerosis and tubular atrophy/dilation was scored using periodic acid-Schiff stained kidney sections. Expression of cell markers were quantified by western blotting, real-time PCR or immunolabeling.

Results: The expression and phosphorylation of STAT3 in the glomeruli of Tg26 mice with podocyte-specific STAT3 deletion (Tg26-STAT3$^-$) were less than that of Tg26 mice without STAT3 deletion (Tg26-STAT3$^+$). Tg26-STAT3$^-$ mice had significantly less proteinuria, serum urea nitrogen, glomerulosclerosis, and tubular dilation/atrophy at 4w and 7w of age compared to Tg26-STAT3$^+$. The expression of podocyte markers (synaptopodin, nephrin, and WT-1) was reduced and the expression of pro-inflammatory STAT3 target genes (MCP-1 and IL-6) was higher in Tg26-STAT3$^+$ mice compared to Tg26-STAT3$^-$ mice.

Conclusions: Activation of podocyte STAT3 is necessary to drive glomerular cell proliferation, loss of podocyte marker expression, loss of kidney function, tubular atrophy/dilation, and glomerulosclerosis in the Tg26 murine model of HIVAN.

SA-PO764

Structure of Endothelial Surface Glycocalyx, Measured In Vivo by Confocal Microscopy, Is Altered in Mesenteric Microvessels of Proteinuric Rats Kai Brodie Betteridge, Kenton P. Arkill, Chris R. Neal, Andy Salmon. *Physiology & Pharmacology, University of Bristol, United Kingdom.*

Background: The luminal surface of blood vessels is coated with a size limiting, specialised, composite endothelial glycocalyx-surface layer (EG-SL) which has a fundamental role in microvessel permeability. Systemic loss of this EG-SL and increased vascular permeability coincides with the onset of albuminuria in diabetic patients (Nieuwdorp *et al.*, 2006), and depletion of the EG-SL in coronary arteries is accompanied by an accelerated development of atherosclerosis in apolipoprotein E deficient mice (Nagy *et al.*, 2010). We hypothesised that albuminuria, independent of diabetes, would result in a reduction of EG-SL in systemic blood vessels, such as mesenteric microvessels. Our aim was to compare measurements of EG-SL depth by Confocal Microscopy (CM) *in vivo* in mesenteric microvessels of albuminuric and control animals.

Methods: Male Sprague Dawley rats were injected with either Puromycin Aminonucleoside (PA) to cause PA induced Nephrosis (PAN) or PBS sham controls. Nine days following injection PAN rats reached maximal proteinuria. Mesenteric microvessels of PAN and sham rats were exposed, cannulated, and perfused with octadecyl rhodamine B chloride (R18: Plasma membrane label) and Fluorescein Isothiocyanate conjugated Wheat Germ Agglutinin (FITC-WGA lectin: EG-SL label) for comparison. EG-SL depth (CM) was estimated based on either: Full Width Half Maximum (FWHM) fluorescence intensity of FITC-WGA; or the anatomical distance between peak fluorescence of FITC-WGA and R18 signals (P-P).

Results: EG-SL depth by the peak to peak method resulted in a value of 242±29nm in sham rats, and this value was significantly reduced to 149±23nm (p=0.0426) in PAN rats. In comparison using the FWHM method resulted in a value of 1557±185nm in the sham rats with no significant change in PAN induced rats (1465±140nm-p=0.7614).

Conclusions: We have shown that EG-SL can be visualised, and depth quantified, *in vivo* using CM, and this depth is significantly reduced in PAN rats compared to control (P-P). Future work will focus on both Electron Microscopy and permeability measurements of EG-SL in the same mesenteric vessels.

HIV-Induced Dedifferentiation in Human Podocytes Is Mediated by Epigenetic Factors through Epithelial Mesenchymal Transition Tejinder Singh, Nirupama Chandel, Partab Rai, Gautam Kishore Valecha, Mohammad Husain, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Hofstra Norh Shore LIJ Medical School, Great Neck, NY.*

Background: HIVAN patients have been demonstrated to display proliferation of podocytes and the activation of the renin angiotensin system (RAS). We hypothesize that HIV-induced epigenetic factors stimulate epithelial mesenchymal transition (EMT) in podocytes.

Methods: Immortalized and differentiated human podocytes (IDHPs) were transduced with either empty vector (EV) or HIV (NL4-3) constructs. Both EV/IDHPs and HIV/CIDHPs were de-differentiated at 33°C for 48 hours. Cells were lysed; proteins and RNAs were extracted and probed for VDR, renin, transforming growth factor (TGF)-ß, "-SMA, vimentin, and FSP-1. Ang II contents were measured in cellular lysates of control and experimental cells. EV/IDHP and HIV/IDHPs were assayed for Cytosine-hosphate-Guanosine (CpG) methylatoin and expression of DNA methyltransferase (Dnmt)-1-3. To determine the role of epigenetic factor and the RAS, EV/IDHPs and HIV/IDHPs were incubated in media containing buffer, 5-azacytidine (AZAC, a demethylating agent, 5μM), or losartan (10^{-7}M) for 48 hours. Subsequently, immunoblots were probed for VDR, renin, Snail, "-SMA, vimentin, and and FSP-1. Renal tissues of four weeks old Tg26 (HIV transgenic mice, n=4) were treated with saline or losartan for two weeks and then evaluated for expression (both protein and mRNA) of VDR, renin, Snail, vimentin, and FSP-1.

Results: HIV/IDHPs displayed enhanced (3-fold) expression of Dnmt-3. HIV stimulated CpG methylation of VDR in podocytes. HIV/IDHPs displayed downregulation (2-fold) of VDR and activation of the RAS. HIV/IDHPs displayed enhanced (2-3-folds) expression of TGF-ß, Snail, "-SMA, vimentin, and FSP-1. AZAC inhibited HIV-induced podocyte down regulation of VDR, up regulation of the RAS and expression of podocyte EMT markers. Tg26 mice displayed enhanced renal tissue expression of EMT markers; however, losartan attenuated expression of EMT markers in HIV/IDHPs as well as in renal tissues of Tg26 mice.

Conclusions: These findings suggest that HIV stimulates dedifferentiation of podocyte through the induction of EMT via epigenetic factors.

PTP1B Inhibition Protects against Podocyte Injury and Proteinuria
Takanori Kumagai, Cindy Baldwin, Lamine Aoudjit, Lei Zhu, Tomoko Takano. *Department of Medicine, McGill University, Montreal, QC, Canada.*

Background: Protein tyrosine phosphatase 1B (PTP1B) is an ubiquitously expressed nonreceptor protein-tyrosine phosphatase, which regulates various cellular functions including migration. Recent studies suggest that increased migratory phenotype of podocytes may be responsible for foot process effacement *in vivo*. The current study addresses the role of PTP1B in podocyte injury and proteinuria.

Methods: Expression of PTP1B in the kidney was studied by immunohistochemistry. Podocyte-specific deletion of the PTP1B gene was done by crossing $ptp1b^{flox/flox}$ mice with $ptp1b^{flox/+}$; podocin-Cre/+ mice. Podocyte injury was induced by puromycin aminonucleoside (50 mg/kg, i.v.) in rats, adriamycin (12.5 mg/kg, i.v.) in mice or by lipopolysaccharide (LPS, 200 μg each, i.p.) in mice. Urine albumin-to-creatinine ratio (ACR) was determined by enzyme-linked immunosorbent assay. Cell migration was quantified by wound healing assay.

Results: PTP1B was markedly upregulated in the glomerulus, notably in podocytes, in rats with puromycin aminonucleoside nephrosis and in mice treated with adriamycin or LPS. Podocyte-specific PTP1B knockout mice showed normal urine ACR up to 7.5 months of age, while showing increased nephrin tyrosine phosphorylation, as compared with wild-type. LPS-induced albuminuria and foot process effacement were ameliorated in knockout mice (ACR: wild-type: 6255±944 vs knockout: 3274±939 μg/mg, $p<0.05$, n=8-9). Knockout mice also showed ameliorated albuminuria in adriamycin-injected mice. Similarly, PTP1B inhibitor (Calbiochem, #539741, 10mg/kg) reduced LPS-induced albuminuria and foot process effacement in wild-type mice (ACR: LPS alone: 9284±2905 vs LPS + PTP1B inhibitor: 2339±857 μg/mg, $p<0.05$, n=4-5). In cultured mouse podocytes, PTP1B knockdown and the PTP1B inhibitor both reduced LPS-stimulated cell migration and FAK phosphorylation at Y397, which plays a critical role in cell migration.

Conclusions: PTP1B upregulation in podocytes contributes to podocyte injury and proteinuria likely via FAK-mediated migratory response of podocytes. PTP1B may be a promising therapeutic target in proteinuric diseases.

NFKB Protects Human Mesangial Cells against Apoptosis Induced by Changes in Extracellular Matrix Composition: Implication in Renal Physiopathology
Alicia Luengo, Ines Mora, Sergio De Frutos Garcia, Maria Del Nogal, Paloma Martín-sánchez, Manuel Rodriguez-Puyol, Gemma Olmos, Laura Calleros. *Department of Physiology, Universidad de Alcalá, Alcalá de Henares, Madrid, Spain.*

Background: Renal fibrosis leads to chronic renal failure, characterized by a progressive substitution of extracellular matrix (ECM) proteins such as collagen type I (COL I) that may induce significant changes in growth patterns through the interaction with integrins. The aim of this study was to identify the mechanisms responsible for human mesangial cell (HMC) survival, conditioned by changes in extracellular matrix composition.

Methods: HMC where incubated with soluble COL I or collagen type IV, and pretreated with or without selective AKT inhibitor, AKT small interfering RNA (siRNA), PDTC and superrepressor IκBα. HMC apoptosis was determined by Anexin-V and flow cytometric analysis. The NFκB transcriptional activity was analyzed by 3xNFκB-TK-Luc reporter plasmid assay. The protein levels of p65, IκB, P-AKT and Bcl-xL was determined by western blot.

Results: Our results indicate that COL I induce apoptosis in HMC but only after inactivation of nuclear factor NFκB by expression of superrepressor IκBα or PDTC inhibitor. We show that COL I-treated HMC significantly increased NFκB-dependent transcription, IκBα degradation and p65/NFκB translocation to the nucleus. Since AKT activity was increased in this proecess, we wonder the role of AKT and Bcl-xL in the NFκB-mediated apoptosis regulation by COL I. The AKT inhibition by using a specific inhibitor or siRNA blocked the NFκB activity increase leading a sustained cell death by COL I.NFκB mediated the HMC survival by the transcriptional activation of the antiapoptotic Bcl-2 family member Bcl-xL, since the expression of this protein was abrogated by superrepressor IκBα, PDTC or AKT inhibitor.

Conclusions: Our data suggest that HMC exposed to COL I are protected against apoptosis by a mechanism involving AKT-dependent NFκB activation with a consequent Bcl-xL activation and this mechanism may block renal fibrosis.

Puromycin Aminonucleoside, a Model of Nephrotic Syndrome, Induces the Nuclear Translocation of IQGAP1 Protein in Human Podocytes through the Involvement of ERK Signaling Pathway
Claire Rigothier,[1,2,3] Moin Saleem,[2] Jean Ripoche,[1] Christian Combe,[1,3] Gavin Iain Welsh.[2] *[1]INSERM U1026, Université Bordeaux Segalen, Bordeaux, France; [2]Academic Renal Unit, University of Bristol, Bristol, United Kingdom; [3]Service de Néphrologie, CHU Bordeaux, Bordeaux, France.*

Background: IQGAP1, a protein which links the actin cytoskeleton to slit diaphragm proteins, is involved in podocyte motility and permeability. We have treated human podocytes with puromycin aminonucleoside (PAN), inducer of nephrotic syndrome in rat, and studied its effects on IQGAP1 biology and podocyte signaling pathways.

Methods: In human podocytes exposed to PAN, Western blot (WB), immunocytolocalization (IC), quantitative PCR and immunoprecipitation were performed to determine the subcellular expression and localization, the transcription and the interacting partners of IQGAP1. Activation of different signaling pathways, IQGAP2 expression and the degree of IQGAP1 phosphorylation were evaluated.

Results: PAN induced the nuclear translocation of IQGAP1 protein from the cell membrane, a phenomenon observed by IC ($p<0.05$) and confirmed by WB after selective extraction ($p<0.01$). IQGAP2 expression remained cytoplasmic. IQGAP1 nuclear translocation was associated with significant decrease of its interaction with nephrin and podocalyxin and a significant increase of its phosphorylation. Activation of the ERK pathway was observed in PAN treated podocytes with a nuclear translocation of the phosphorylated form of ERK (P-ERK) ($p<0.02$). The ERK signaling pathway was involved in IQGAP1 nuclear translocation: inhibitors of ERK pathway blocked IQGAP1 nuclear translocation ($p<0.02$). IQGAP1 interaction with P-ERK increased upon podocyte exposure to PAN ($p<0.05$) and this was inhibited by inhibitors ($p<0.05$). Chromatin interaction protein assays demonstrated the interaction of IQGAP1 with the chromatin.

Conclusions: PAN induced the translocation of IQGAP1 into the nuclei in human podocytes. IQGAP1 nuclear trafficking required ERK signaling pathway and led to IQGAP1 interaction with the chromatin. Given its implication in podocyte motility, IQGAP1 protein may have a role in the gene regulation of proteins involved in migration or microtubules remodelling.

Ret Is Critical for Podocyte Survival Following Glomerular Injury In Vivo
Cynthia C. Tsui,[1] Victoria Wu,[1] Lawrence B. Holzman,[2] Brian A. Pierchala.[3] *[1]Internal Medicine-Nephrology, University of Michigan, Ann Arbor, MI; [2]Internal Medicine-Renal Electrolyte and Hypertension, University of Pennsylvania, Philadelphia, PA; [3]Biologic and Materials Sciences, University of Michigan, Ann Arbor, MI.*

Background: Podocyte injury and loss directly cause proteinuria and progression to glomerulosclerosis. Elucidation of the mechanisms of podocyte survival and recovery from injury is critical for designing strategies to prevent the progression of glomerular diseases. Previously Ret and its ligand, glial cell line-derived neurotrophic factor (GDNF), were demonstrated to be upregulated both in non-immune and immune mediated models of glomerular diseases *in vitro* and *in vivo*. Ret is a receptor tyrosine kinase that is critical for the growth, maintenance, and survival of several populations of neurons in the CNS and PNS. Currently, we are investigating whether Ret is necessary to maintain podocyte function and survival *in vivo*.

Methods: Since deletion of Ret results in perinatal lethality due to renal agenesis, we examined the role of Ret in glomeruli *in vivo* by generating BALB/c mice with a conditional deletion of Ret in podocytes (Nphs2-CRE $Ret^{flox/flox}$). We utilized light microscopy and PAS staining to determine severity of glomerular injury. TUNEL+ cells were imaged by immunofluorescence microsopy. At least 80-100 glomeruli were scored from each animal from a minimum of 4 mice per genotype. Two independent, blinded observers and imagers were used for each experiment.

Results: There were no developmental deficits in $Ret^{-/-}$ podocytes. In contrast to the lack of any developmental and early maintenance phenotype, these Nphs2-CRE $Ret^{f/f}$ mice showed a significantly enhanced susceptibility to adriamycin nephropathy, a rodent model of focal segmental glomerulosclerosis (FSGS). We observed a statistically significant increase in apoptosis between Nphs2-CRE $Ret^{+/+}$ vs Nphs2-CRE $Ret^{f/f}$ mice (10.5±1.05 vs 50.9±4.85; P=0.0002.) We also observed increased glomerular injury between Nphs2-CRE $Ret^{f/f}$ vs Nphs2-CRE $Ret^{+/+}$ mice (1.6±0.22 vs 0.54±0.09; P=0.004.)

Conclusions: Therefore, Ret appears to be critical specifically for podocyte survival and recovery from injury *in vivo*.

SA-PO770

Albumin Uptake in Podocytes Occurs in a Polarized, Caveolin-Dependent Manner
Evgenia Dobrinskikh,[1] Kayo Okamura,[1] Jeffrey B. Kopp,[2] R. Brian Doctor,[1] Judith Blaine.[1] *[1]Medicine, University of Colorado Denver, Aurora, CO; [2]NIDDK, National Institutes of Health, Bethesda, MD.*

Background: Albuminuria is strongly associated with an increased risk of chronic kidney disease progression and albumin-containing endosomes have been found in podocytes from patients with nephrotic syndrome. Albumin uptake into cultured podocytes also occurs but the underlying endocytic mechanisms in podocytes remain to be determined.

Methods: We studied previously characterized human podocytes isolated from urine (Sakairi et al., Am J Physiol Renal, 2010). Uptake kinetics of fluorescein isothiocyanate (FITC)-labeled albumin were measured by spectrofluorometry and Western blotting. Colocalization of albumin and endocytic proteins was studied using confocal microscopy. Total internal reflection fluorescence microscopy (TIRF) examined the polarity of albumin uptake. Intensity correlation coefficient (ICQ) analysis measured the temporal distribution of albumin with components of endocytic pathways.

Results: Albumin uptake by podocytes was minimal at 4 °C, readily observed at 37 °C and plateaued by 1 hour. Although albumin was more freely accessible to the apical cell surface, live-cell imaging showed that albumin was preferentially endocytosed along the basal membrane. FITC-albumin containing endosomes co-localized with megalin and the neonatal Fc receptor, both proteins shown to be involved in albumin uptake in the renal proximal tubule. In contrast to the proximal tubule, albumin endocytosis in podocytes was a caveolin- and not a clathrin-dependent process. FITC-albumin containing endosomes

colocalized with caveolin but not with clathrin and inhibition of caveolin-dependent but not clathrin-mediated endocytosis inhibited albumin uptake. Once in the cell interior, albumin transited through the early endosome and lysosome compartments.

Conclusions: This study demonstrates that podocytes endocytose albumin in a polarized, caveolin-dependent manner. The findings may contribute to the understanding of the pathogenic mechanisms that underlie the chronic kidney disease associated with albuminuria.

SA-PO771

Low Concentration Cadmium Exposure Causes Albuminuria by Inducing Endoplasmic Reticulum Stress and Apoptosis in Podocytes Hsiang-Hao Hsu,[1,2] Kuan-hsing Chen,[1] Cheng-chieh Hung,[1] Hermann Pavenstaedt.[2] *[1]Kidney Research Center, Department of Nephrology, Linkou Chang Gung Memorial Hospital; [2]Medizinische Klinik und Poliklinik D, Universitätsklinikum Münster.*

Background: Proteinuria, especially albuminuria, mainly caused by podocyte injury and ensuing filtration barrier failure, predicts progression and renal outcomes in human glomerular diseases. Cadmium (Cd) is an important industrial and environmental heavy metal pollutant that with chronic, low-level patterns of exposure the kidney is the primary target of toxicity. It is not known if low-level exposure to Cd induces an irreversible dysfunction in glomerular podocytes, which have a significant role in establishing the selective permeability of the kidney filtration barrier.

Methods: In this study, we analyzed the association between blood and urinary Cd levels and kidney abnormalities (serum creatinine level, urine creatinine clearance and albuminuria) in a rodent model. Adult male Sprague-Dawley rats were daily subcutaneous infused with 0.3 mg/kg $CdCl_2$ for up to 12 weeks. In vitro toxic effects and cellular mechanisms of Cd were examined on cultured murine podocytes.

Results: The results showed that significant elevated serum creatinine level and raise of albuminuria were associated with increased serum and urine Cd concentration by continuous infusion in rats. Histological confirmation of podocyte injuries was done by transmission electron microscopy (showing Cd-induced podocyte foot process effacement) and immunohistochemistry exam of augmented cleaved caspase 3 staining. This study further examined in vitro toxic effects and cellular mechanisms of Cd on cultured murine podocytes. We showed that treatment with low concentration $CdCl_2$ (500nM, 48hrs) markedly increases intracellular Cd concentration in cultured podocytes. Accumulation of Cd in podocytes resulted in increased reactive oxygen species production, endoplasmic reticulum stress, inhibition of the survival pathway Akt and Erk, and finally led to cellular apoptosis.

Conclusions: This observation suggests that low concentration Cd exposure causes kidney injuries by inducing endoplasmic reticulum stress and apoptosis in glomerular podocytes.

SA-PO772

Fibrates May Protect Glomerular Filtration Barrier by Increasing Synthesis of EETs Ellen T. McCarthy,[1] Virginia J. Savin,[2] Tarak Srivastava,[3] Shuhua Wang,[1] Ram Sharma,[2] Mukut Sharma.[2] *[1]Kidney Institute, University of Kansas Medical Center, Kansas City, KS; [2]Kansas City VA Medical Center, Kansas City, MO; [3]Children's Mercy Hospital, Kansas City, MO.*

Background: We have shown that 20-hydroxyeicosatetraenoic acid (20-HETE) and 8,9-epoxyeicosatrienoic acid (8,9-EET) and the drugs clofibrate and cyclosporine A (CSA) each protect the glomerular protein permeability barrier from injury. We hypothesize that clofibrate and CSA increase synthesis of one or more protective eicosanoids by podocytes.

Methods: Cultured immortalized podocytes were incubated with vehicle, clofibrate 100 μM or CSA 1 μM X 6 hr, clofibrate 100 μM or CSA 1 μM X 6 hr + arachidonic acid (AA) 30 μM X 10 min or AA 30 μM X 10 min. Cells were then incubated with a calcium ionophore to activate phospholipase A_2, and lipids extracted, identified and measured using liquid chromatography-mass spectrometry (LC-MS). In a separate study, mesangial cells were incubated with calcium ionophore and lipids extracted and analyzed.

Results: Both podocytes and mesangial cells can synthesize cytochrome P450 eicosanoids, including 19- and 20-HETE; 5,6-, 8,9-, 11,12- and 14,15-EET; and 5-, 12-, and 15-HETE. Podocytes produced significantly more of each of these eicosanoids that did mesangial cells ($P<0.001$ for each eicosanoid). Clofibrate significantly increased podocyte synthesis of 8,9-, 11,12- and 14,15-EET ($P<0.001$); synthesis of all four EETs was significantly amplified by exogenous AA. Clofibrate did not increase 19- or 20-HETE synthesis even in the presence of exogenous AA. CSA increased synthesis of HETEs and EETs only with the addition of exogenous AA.

Conclusions: We conclude that protection of the glomerular protein permeability barrier by fibrates or CSA does not depend on mesangial cell eicosanoid synthesis or on increased synthesis of 20-HETE. CSA appears to protect the filtration barrier through mechanisms that are independent of eicosanoids. In contrast, fibrate-induced increase in podocyte synthesis of 8,9-EET may protect the glomerular filtration barrier. Studies of fibrates and of anaolgs of 8,9-EET may permit development of novel agents to treat glomerular disease.

The Uremic Toxin Indoxyl Sulfate Causes Podocyte Injury *In Vivo* and *In Vitro* Osamu Ichii,[1,2] Huiyan Lu,[1] Hideko Takahashi,[3] Patricia M. Zerfas,[4] Jeffrey B. Kopp.[1] *[1]NIDDK, NIH, Besethda, MD; [2]Graduate School of Veterinary Medicine, Hokkaido University, Sapporo, Hokkaido, Japan; [3]NEI, NIH, Besethda, MD; [4]Office of the Director, NIH, Besethda, MD.*

Background: Indoxyl sulfate (IS) accumulates in chronic kidney disease (CKD), with serum levels 0.1-1 mM. IS is a ligand of the aryl-hydrocarbon receptor (Ahr), a transcription factor, activating detoxification pathways and other cell functions. Exogenous IS causes tubulo-interstitial injury; we examined whether IS induces podocyte injury.

Results: In FVB/N mouse kidney, Ahr was expressed in podocytes and tubular epithelial cells, most strongly in the former where it was present in the nucleus. In isolated glomeruli from acutely exposed mice (800mg/kg IP, at 2 h), *Cyp1a1,* a sensitive reporter gene for Ahr activation, was induced 470-fold. With chronic exposure (600-800 mg/kg IP daily for 4 wk), renal cortical podocyte mRNA expression (*Nphs1*, *Nphs2*, *Cd2ap, Podxl*, *Synpo*, *Myh9*, *Actn4*, *Wt1*) were reduced to 52-76 % of control mice. Mice undergoing uninephrectomy followed by IS 600-800 mg/kg IP daily for 4 wk manifested microalbuminuria (7-fold over control), while glomeruli showed mild mesangial expansion, capillary loop thickening, and decreased podocyte staining for synaptopodin and non-muscle myosin IIA. Immortalized, differentiated murine podocytes were exposed to 1 mM IS for 30-60 min and manifested Ahr nuclear translocation. At 2 hr cell mRNA expression of *Wt1*, *Podxl*, *Synpo*, *Myh9*, *Cd2ap*, and *Actn4* decreased in a dose-dependent fashion, reaching 33-47 % of baseline. At 24 hr, certain cytokine RNAs increased, in particular *Tnfa* (6-fold), and podocytes showed reduced cell size, loss of actin stress fibers and decreased viability. In normal human kidney, Ahr localized to podocytes and tubular epithelial cells. In immortalized human podocytes, 1 mM IS exposure caused Ahr nuclear translocation and reduced cell viability.

Conclusions: IS caused podocyte injury with altered differentiation markers and cytokine RNA expression. In patients with CKD, accumulation of IS may drive a feed-forward process that contributes to progressive glomerular injury and further deterioration in renal function.

SA-PO774

ApolipoproteinL1-B Splice Variant Is Expressed by Podocytes In Vitro and In Vivo and Shows Both Nuclear and Cytoplasmic Distribution Hidefumi Wakashin, Jeffrey B. Kopp. *NIDDK, NIH, Bethesda, MD.*

Background: Apolipoprotein L1 (ApoL1) is a minor component of HDL particles, although its function there is unknown. ApoL1 promotes lysis of *Trypanosoma brucei brucei,* via enhanced chloride ion channel activity in the parasite lysosome. *APOL1* variants, exclusively present in individuals of recent African descent, are associated with substantially increased risk for glomerular disease. The mechanisms by which *APOL1* variants induce glomerular injury are unknown. ApoL1 has several RNA splice variants. The A isoform consists of 398 amino acid (aa) residues, with a predicted molecular mass (Mw) of 43.9 kDa, and is encoded by exons 1, 3-7. The B isoform consists of 414 aa, having a 16 aa extension at the N-terminus, and is encoded by exon 1-7, with a predicted Mw of 45.9 kDa. The C isoform consists of 381 aa residues, with a predicted Mw of 42.2kD, and is encoded by exons 1, 3, 5-7.

Results: Using the 16 aa sequence unique to ApoL1-B, we raised an rabbit anti-peptide antibody. On western blot, this antibody recognized 4 bands in immortalized human podocyte lysates, at 80, 65, 55, 42 kDa; all 4 bands were eliminated by pre-incubation with the immunizing peptide. The identities of these bands remain to be fully determined. Western blots using normal human kidney tissue showed a single band at 55 kDa. Using immunofluorescence staining, we found that ApoL1-B was expressed by podocytes and proximal tubular epithelial cells in normal human kidney and by cultured human podocytes. Interestingly, ApoL1-B was present in the nuclei of podocytes (in vitro) and tubular epithelial cells (in vivo) in a speckled pattern. In cultured podocytes, ApoL1-B showed partial co-localization with the splicesome marker SC35. ApoL1-B was also present in a filamentous cytoplasmic pattern (in vivo and in vitro), which co-localized with F-actin and myosin heavy chain IIA.

Conclusions: ApoL1-B is expressed in the nucleus and cytoplasm. On-going studies are examining sub-nuclear and sub-cytoplasmic localization, using a GFP-ApoL1-B vector and are seeking to identify nuclear and cytoplasmic binding partners, using flag-tagged ApoL1-B.

Protein Overload Induced Proteinuria in the Munich Wistar Frömter Rat Does Not Correlate with an Increase in GSC of Surface Glomeruli Measured Using Intravital 2-Photon Microscopy Mark C. Wagner,[1,2] Ruben M. Sandoval,[1] Silvia B. Campos-bilderback,[1] Sarah E. Wean,[1] George Rhodes,[1] Bruce A. Molitoris.[1,2] *[1]Medicine/ Division of Nephrology, IU School of Medicine, Indianapolis, IN; [2]Roudebush VAMC, Indianapolis, IN.*

Background: Injection of large doses of albumin are known to cause nephrotic range proteinuria in rats. Multiple glomerular changes including foot process effacement and cytoplasmic swelling have been documented.

Methods: To ask the fundamental question whether a change in the glomerular sieving coefficient (GSC) occurs during this protein insult event eight Female Munich Wistar Fromter rats were injected IP with either bovine or rat serum albumin at a dose of 1.25g in 5ml of saline on 2 successive days.

Results: Twenty four hour urine collections documented the presence of markedly increased protein which ranged up to 780mg/24 hours. 24 or 48 hrs after the 2nd injection the animals had their GSC measured using intravital 2-photon microscopy using Texas Red-rat albumin as the marker. If the increased in urine protein is simply the result of a glomerular injury than an increase in GSC would be expected. However, if other events i.e. change in albumin uptake or release from tubule segments participate than an altered GSC may not be observed thus implicating non-glomerular processes in the resultant proteinurea. GSC ranged from a low of 0.0073 to a high of 0.0144.

Conclusions: The lack of correlation between an increase in urine protein and GSC supports involvement of non-glomerular processes. We are presently evaluating Texas Red-rat albumin uptake by the tubules and the role of FcRn and will report these results.

Podocytes Produce Microparticles in Response to Diabetic Stress Factors: Implications in Diabetic Kidney Disease Dylan Burger, Jean-Francois Thibodeau, Chet E. Holterman, Chris R. Kennedy. *Kidney Research Centre, Ottawa Hospital Research Institute, Ottawa, ON, Canada.*

Background: Microparticles (MPs) are submicron (0.1-1.0 µm), anuclear fragments shed from cell membranes and released into the extracellular space. MPs are formed from multiple cell populations in response to stress/injury. However, whether podocytes produce MPs, and whether podocyte MP formation reflects glomerular injury is unknown. We examined MP formation from podocytes in a conditionally immortalized human podocyte cell line (HPOD) and in two mouse models of progressive diabetic kidney disease: streptozotocin (STZ, 50 mg/kg x 5 days) and OVE26 mice.

Methods: HPODs were either exposed to 10% equibiaxial cyclical stretch, high glucose conditions (HG, 25 mM), or treated with angiotensin II (Ang II, 500 nM) or transforming growth factor beta (TGF-β, 5 ng/mL). Additionally, to determine the in vivo significance of podocyte MP formation, we probed whether podocytes release MPs into urine in diabetic mice. MPs were isolated from media/urine by differential centrifugation and quantified by Annexin V (total MPs) or podocalyxin (podocyte MPs) labeling and flow cytometry.

Results: Cyclic stretch was associated with a 3-fold increase in MP release after 5 hours ($P<0.01$). Similarly, HG increased MP release 2-fold after 24 hours ($P<0.05$). Neither Ang II, nor TGF-β had any effect on podocyte MP formation over 24 hours. Both mouse models displayed evidence of glomerular injury (mesangial expansion) and frank proteinuria as evidenced by increased urinary albumin/creatinine levels compared with untreated or wild-type controls (STZ: 1312±224 µg/mg vs 264±130 at 8 weeks, $P<0.001$; OVE26: 391±130 µg/mg vs. 29±6 at 16 weeks, $P<0.05$). STZ-treated mice displayed increased urinary podocyte MPs as compared with untreated mice (17478±8329 MPs/mg Creatinine vs. 7 ±7, $P<0.05$). Similarly, OVE26 mice displayed increased urinary podocyte MPs compared with their wild-type littermates (6956±2386 vs. 9±9, $P<0.01$).

Conclusions: Taken together our results suggest that podocytes produce MPs which are released into urine and may be indicative of glomerular injury. Such processes may be mediated by mechanical stretch and high glucose conditions.

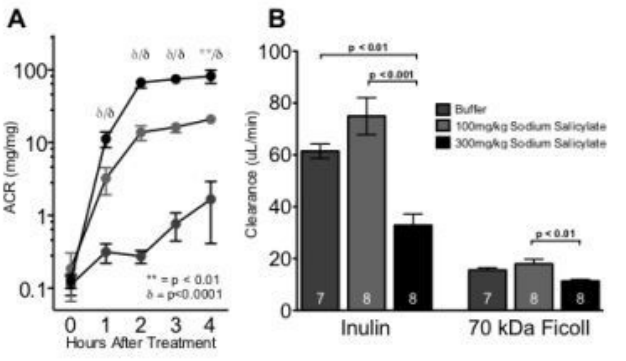
SA-PO777

Rapid and Massive Albuminuria with Undetectable Glomerular Damage Following Sodium Salicylate in Mouse Ryan B. Sanford,[1] John R. Hagaman,[2] Longquan Xu,[2] Jennifer C. Wilder,[2] Mike Kelly Altenburg,[2] J. Charles Jennette,[2] Oliver Smithies.[2] *[1]Division of Nephrology and Hypertension, University of North Carolina Chapel Hill, Chapel Hill, NC; [2]Department of Pathology and Laboratory Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: The mechanism of renal albumin handling remains debated. Opposed to the dominant theory of a low sieving coefficient with a tight glomerular filter, another model proposes a high sieving coefficient with extensive proximal tubule reclamation. Here we tested these models using salicylate-induced proteinuria.

Methods: We measured urinary albumin, glucose, and gamma-glutamyl transferase (GGT); GFR; ficoll clearance; and renal histology in male CD1 mice after sodium salicylate or buffer IP injections.

Results:



Mice receiving salicylate developed albuminuria peaking between 2-4 hours following injection (A). In addition, glucosuria and increased urinary GGT occurred in treatment groups (data not shown). GFR was decreased compared to buffer in the high dose treatment, but not in the low dose treatment. Clearance of a 70 kDa polydisperse TRITC-Ficoll was unchanged compared to buffer treatment (B). Histology revealed coagulative necrosis of proximal tubular cells; the glomeruli were normal in appearance. By electron microscopy, the glomerular capillary wall was normal in appearance without changes to podocyte architecture.

Conclusions: Within 2 hours of IP sodium salicylate, massive albuminuria occurred accompanied by proximal tubule damage and necrosis. Correspondingly, glomerular damage was undetectable by both structural and functional methods. These findings are consistent with a high glomerular sieving coefficient for albumin with proximal tubular reclamation. Back-leak of albumin from peritubular capillaries into the tubular lumen is also possible.

EphB Receptors Modulate the Nephrintyrosine Phosphorylation: A Potential Mechanism for Adhesion and Repulsion at the Slit Membrane Eva Koenigshausen, Nils Tim Haep, Magdalena Woznowski, Ivo Quack, Lars C. Rump, Lorenz Sellin. *Nephrology, Heinrich Heine University, Duesseldorf, Germany.*

Background: Proteinuria is the strongest predictor for cardiovascular events. Glomerular proteinuria arises from a damaged glomerular filter. The glomerular slit membrane is a specilized cell cell contact with nephrin being its major component. Nephrin is endocytosed after its binding to β-arrestin2, which finally destabelizes the glomerular filter. Eph receptors and their ligands, the ephrins, mediate adhesion and repulsion in specific cell cell contacts. Recently, ephrinb1 was detected at the glomerular slit. The molecular function of the EphB-ephrin family for the podocyte is unknown.

Methods: Podocyte RNA the samples are subjected to qPCR to detect ephrinb1, b2, Eph1 and 2. Furthermore, nephrin, β-arrestin2, Nck1/2 and FAK expressing cells are used. After cell lysis co-immunoprecipitations are done and lysates are subjected to western blot analysis. Serum straved podocytes were stimulated with preclustered ephrinb1-Fc or IgG-Fc for the indicated time. Thereafter nephrin was precipitated from podocyte lysates are analysed by western blotting.

Results: EphB1, B2, ephrinb1 and b2 are expressed in podocytes. EphB1 and EphB2 interact with the extracellular domain of Nephrin and also with podocin, β-arrestin2 and FAK. The expression of EphB1 and EphB2 induces a marked nephrin tyrosine phosphorylation especially at the Nck1/2 binding sites. The stimulation with ephrinb1 decreases tyrosine phosphorylation of nephrin Y1217. EphB1 and B2 expression leads to an enhanced interaction of nephrin with Nck2 and mediates a strong attenuation of the nephrin binding to β-arrestin2. The tyrosine phosphorylation is reproduced in podocytes.

Conclusions: EphB receptors stabelize the glomerular slit membrane thru enhanced nephrin tyrosine phosphorylation at Nck-binding sites. By binding ephrinb1 to EphB receptors a tyrosine desphosphorylation of nephrin is induced. This might cause a destabelization of the slit membrane. The EphB rezeptor mediated cell adhesion and repulsion could contribute to a better understandig of the glomerular pathobiology and open novel therapeutic avenues for glomerular diseases.

SA-PO779

Role of Protein-Tyrosine Phosphatase 1B (PTP1B) in Complement-Mediated Glomerular Injury Lisa Nezvitsky, Michel L. Tremblay, Tomoko Takano, Andrey V. Cybulsky. *Medicine, McGill University, Montreal, QC, Canada.*

Background: Glomerular diseases may be associated with activation of endoplasmic reticulum (ER) stress, notably the unfolded protein response (UPR) and ER-associated degradation (ERAD). PTP1B enhances activation of the inositol requiring-1α (IRE1α) branch of the UPR. IRE1α may regulate ERAD, in part, via induction of ER-associated degradation enhancing α-mannosidase-like protein (EDEM). We propose that PTP1B is an important modulator of ERAD in cells undergoing complement attack.

Methods: Complement was activated in PTP1B wild type (WT) and knockout (KO) mouse embryonic fibroblasts (MEF), and rat glomerular epithelial cells (GEC) by incubation with antibody and normal serum (decomplemented serum in control). To specifically activate the UPR, cells were treated with tunicamycin. Degradation of the T cell receptor subunit, CD3δ, fused to yellow fluorescent protein (CD3δ-YFP) was employed as an ERAD reporter.

Results: Deletion of PTP1B in MEFs impaired tunicamycin-induced activation of c-Jun N-terminal kinase, which is dependent on IRE1α. Complement-mediated cytotoxicity (lactate dehydrogenase release) was reduced in PTP1B KO MEFs, compared to WT, implying that PTP1B enhanced cytotoxicity. After incubation with complement, CD3δ-YFP degradation was decreased in KO MEFs, compared to WT, suggesting that deletion of PTP1B impaired ERAD, possibly via reduced IRE1α-dependent induction of EDEM. In GECs treated with kifunensine (an inhibitor of α1,2-mannosidase and ERAD), degradation of CD3δ-YFP was decreased after exposure to complement, compared to untreated GECs. Similarly to the MEFs, in GECs treated with a chemical inhibitor of PTP1B or transfected with a PTP1B dominant negative cDNA, complement decreased degradation of CD3δ-YFP, compared to control GECs. Surprisingly, in GECs overexpressing PTP1B WT, complement also decreased degradation of CD3δ-YFP, compared to control cells.

Conclusions: After exposure of cells to complement, ERAD and cytotoxicity were reduced upon inhibition of PTP1B. Overexpression of PTP1B also reduced ERAD, suggesting that ERAD is dependent on tight regulation of PTP1B expression. PTP1B is potentially a novel target for modulation of complement-mediated injury.

Role of IL-17 Signaling in the Experimental Crescentic Glomerulonephritis Su Mi Lee, Seung Hee Yang, Do Hyoung Kim, Yun Jung Oh, Jung Pyo Lee, Yon Su Kim. *Seoul National University Hospital, Seoul, Republic of Korea.*

Background: T cells play a major role in the pathogenesis of crescentic glomerulonephritis (GN), which is the most severe form of GN and progresses to end-stage renal disease unless treated adequately. Th17 cells have been reported to contribute to renal injury in crescentic GN. In the present study, we examined the notion that the modulation of Th17 response could reduce the renal injury utilizing a murine cresentic GN model.

Methods: IL-17 deficient and STAT-3β deficient mice were used because IL-17 is the major cytokine of Th17 cells and STAT-3 is the essential transcriptional factor of Th17 cell differentiation. Experimental crescentic GN was induced by the injection of anti-glomerular basement membrane (GBM) antibodies into Balb/c, C57BL/6, IL-17 deficient Balb/c, and STAT-3β deficient C57BL/6 mice.

Results: After 7 days of disease induction, the elevated BUN and urine protein/creatinine ratio in wild type mice were significantly reduced in IL-17 deficient (BUN 55 ± 22.7 vs 154 ± 17.5mg/dl, $p<0.01$; U prot/cr 114 ± 10. 6 vs 143 ± 16.6 mg/mg, $p<0.05$) and STAT-3β deficient mice (BUN 116 ± 25.0 vs 156 ± 8.0 mg/dl, $p<0.05$; U prot/cr 53 ± 6.8 vs 99 ± 6.8, $p<0.05$). In addition, the glomerular injury and crescent formation by anti-GBM antibody were attenuated in IL-17 deficient and STAT-3β deficient mice compared to those of wild type mice. Accordingly, intrarenal mRNA expression of IL-1β, TGF-β, MCP-1, IL-12p19 and STAT-3 were elevated in wild type mice, but these changes were attenuated in IL-17 and STAT-3β deficient mice. Treatment of CD3 in co-cultured mesanigal cells and NKT cells induced mRNA expression of IL-17 receptor and secretion of IL-17 and IL-12p70 as well as inflammatory cytokines such as IL-2, TNF-α and IL-6. Blocking of IL-17 receptor reduced these inflammatory reactions.

Conclusions: Taken together, these data suggest that Th17 cells play an important role in the pathogenesis of experimental cresecentic GN. IL-17 and STAT-3 might be a feasible target in protecting renal injury in the disease.

HIV Related Kidney Disease: A Shift in the Paradigm Sandeep K. Mallipattu,[1] Ruijie Liu,[1] Vivette D. D'Agati,[3] Ali G. Gharavi,[2] Peter Y. Chuang,[1] John C. He.[1] *[1]Nephrology, Mount Sinai School of Medicine, New York, NY; [2]Nephrology, Columbia University, New York, NY; [3]Pathology, Columbia University, New York, NY.*

Background: HIV-associated nephropathy (HIVAN), an aggressive form of focal segmental glomerulosclerosis, has historically been considered the typical presentation of kidney disease in patients with Acquired Immunodeficiency Syndrome. However, with the widespread use of antiretroviral therapy in the United States, the incidence of HIVAN has decreased and the spectrum of HIV-related kidney disease has dramatically changed.

Methods: Although epidemiological studies suggest that HIV infection may accelerate the progression of diabetic nephropathy or age related nephrosclerosis in this population, the mechanism behind this association has yet to be described. To study this, HIV-1 transgenic mice (Tg26) were initially backcrossed to C57BL/6 background; a strain that is typically resistant to classical HIVAN. Next, Tg26 and wild-type mice were treated with low-dose streptozotocin (STZ) to induce diabetes mellitus. Proteinuria was assessed monthly and all mice were sacrificed at 12 months of age.

Results: STZ-treated Tg26 mice exhibited a significant increase in proteinuria, mesangial expansion, glomerular basement membrane thickening, and podocyte effacement compared to untreated age-matched Tg26 mice or STZ-treated wild-type mice. Additionally, Tg26 mice demonstrated a significant increase in proteinuria, podocyte effacement, and GBM thickening at 12 months of age as compared to age-matched wild-type mice. Next, microarray gene expression studies were performed on isolated glomerular extracts from mice revealing a significant upregulation of pro-inflammatory and pro-fibrotic signaling pathways. The upregulation of genes downstream of these pathways was confirmed by real-time PCR and immunostaining.

Conclusions: To date, this is the first study to provide a novel insight into the mechanism of non-HIVAN related glomerular disease progression in the presence of HIV-1 infection and concurrent comorbidities such as diabetes and aging. Finally, we have also confirmed an upregulation of pro-inflammatory and pro-fibrotic pathways.

1,25-Dihydroxyvitamin D(3) Reduces Proteinurea via Inhibiting uPAR Expression Jianchao Ma, Wei Shi, Shuangxin Liu, Wenjian Wang, Bin Zhang. *Department of Nephrology, Guangdong General Hospital, Guangzhou, Guangdong, China.*

Background: Accumulating studies have demonstrated that 1,25-Dihydroxyvitamin D(3) reduces podocytes loss and slows the decline of kidney function in chronic kidney disease. Recent evidences showed that urokinase receptor (uPAR) and its soluble form carry a key role in the pathogenesis of focal segmental glomerulosclerosis. In this study, we hypothesized that vitamin D protects podocytes via modulating uPAR expression.

Methods: 24 C57BL/6 male mice were randomly divided into three groups: control group(Con), LPS group (LPS) and 1,25(OH)2D3 treated group(LPS+1,25(OH)2D3). We injected C57BL/6 mice intraperitoneally with 300 μg LPS. In 1,25(OH)2D3 treatment ,we gavage mice with 1,25(OH)2D3 2.5μg·kg-1·d-1 2 days before LPS injection. We collected the mouse urine for 24 hours after LPS injection. All were executed at the third day. In vitro, immortalized mouse podocytes were cultured and randomized into three groups: control group,LPS ($50mg\cdot L^{-1}$) group, LPS ($50mg\cdot L^{-1}$)+$1,25(OH)_2D_3$ ($1nmol\cdot L^{-1}$) group. The podocytes motility was checked by transwell migration assay .The expression of uPAR in podocytes were detected by immunofluorence method, flow cytometry method and real-time PCR.

Results: The proteinuria were 72.0±35.6mg/gCr,(732.9±233.2)mg/g Cr,(412.3±82.7 mg/g Cr)in control group, LPS group and LPS plus 1,25(OH)2D3 group, respectively. Meanwhile the uPAR expression was increased in LPS group, and was inhibited by 1,25(OH)2D3 in both protein level and mRNA level. The number of podocytes in the transwell migration assay were 8.4±3.8, 31.3±7.9, 19.2±6.8 in the control group, LPS group and LPS+1,25(OH)2D3 group, respectively.

Conclusions: Our findings provided new insights of the renopretection role of 1,25-Dihydroxyvitamin D(3) in podocytes injury, and offer a potential target in reduces proteinurea by inhibiting uPAR expression.

TGF-β Antagonism Is Reno-Protective by Blunting Podocyte Injury in a Novel T2D Model of Diabetic Nephropathy (DN) Mandy M. Smith, Stephen O'Brien, John N. Vassiliadis, Stefan Wawersik, Steven R. Ledbetter, Cynthia M. Arbeeny, Hong Ling. *Sanofi-Genzyme R&D Center, MA.*

Background: Transforming growth factor β (TGF-β) plays a central role in the pathogenesis of DN and TGF-β antagonism has positive effects on renal pathophysiology in diabetic models. However, the impact of treatment on podocyte integrity is less clear and was the goal of this study utilizing 1D11 (a TGF-β antagonist antibody) in a novel T2DN model.

Results: We have reported that female uni-nephrectomized (Unx) KK-A^y mice fed a moderate fat diet develop progressive renal impairment, albuminuria, decline in GFR and pathology characteristic of human DN. Unx-KK-A^y mice were dosed for 12 wk with 1D11 at 2 and 5 mg/kg or 13C4 (control antibody) at 5 mg/kg. The 13C4 group showed glomerular hypertrophy, glomerulosclerosis and tubulointerstitial fibrosis. Serum BUN was increased to >40 mg/dl in the 13C4 group, and the 1D11 group had a 17% reduction at 12 wk. The 13C4 group had marked albuminuria which was ~10 fold above non-diabetic (KK-aa) controls. Albuminuria was attenuated in the 1D11 groups at all timepoints, with a 35% reduction at 12 wk. Urine nephrin proteion (ELISA) increased progressively in the 13C4 group and was correlated with albuminuria; while 1D11 (5mpk) significantly decreased nephrin loss at week 8 post dosing. Nephrin gene expression in kidney homogenates was down-regulated with 13C4, but was upregulated with 1D11, indicating a podocyte protective effect. Western blotting showed that PAI-1 was elevated in the 13C4 group vs non-diabetics and was normalized with 1D11. A similar pattern for activated TGF-β1 was observed. Using immunostaining, PAI-1 was localized in peri-tubular capillaries and glomerular tufts, a pattern similar to TGF-β1 localization observed in other renal disease models. PAI-1 immunostaining was reduced in mice dosed with 1D11 supporting the changes detected by western blotting.

Conclusions: The data indicates that TGF-β neutralization is reno-protective, possibly by maintaining podocyte integrity and reducing endothelial localized PAI-1. It is plausible that a maximal treatment effect requires RAS inhibition and combination studies are planned.

SA-PO784

Investigations Into the Mechanism of Action of the Splice Isoform Vascular Endothelial Growth Factor 165^b on Glomerular Water Permeability In Vivo Megan Stevens, Andy Salmon, David O. Bates, Steve Harper, Sebastian Oltean. *Microvascular Research Laboratories, University of Bristol.*

Background: Several glomerular diseases are associated with increased expression of the pro-permeability, pro-angiogenic vascular endothelial growth factor (VEGF-A, main isoform $VEGF_{165}$). The functionally different splice isoform, $VEGF_{165}b$, has been shown to decrease glomerular water permeability (L_pA/V_i) in kidneys of transgenic mice over-expressing $VEGF_{165}b$ under a nephrin promoter (Qiu et al. JASN 2010;). However,

the molecular mechanisms of this inhibition are unknown. We analyzed the expression and phosphorylation of VEGFR2 in two mouse models.

Methods: Glomeruli isolated from nephrin-$VEGF_{165}$b over-expressing mice and wild-type controls. Western blots used to determine expression and phosphorylation levels of VEGFR2. Isolated glomeruli were incubated with saline or PTK787 (inhibitor of VEGF receptors) and L_pA/V_i measured (Salmon et al. JPhys 2006).Immunofluorescence for expression levels and phosphorylation of VEGFR2 on kidneys from diabetic DBA2J mice treated with i.p. injection of $VEGF_{165}$b, compared to diabetic WT controls.

Results: Western blots show increased phosphorylation of VEGFR2 in the glomeruli of neph-$VEGF_{165}$b over-expressing mice compared to WT littermates (n=3). Western blot for nephrin-$VEGF_{165}$b glomeruli show reduced phosphorylation of VEGFR2 when incubated for 1 hour in 100nM PTK 787 compared to saline (n=1). In WT littermates, phosphorylation of VEGFR2 is blocked by incubation of glomeruli with 100nM PTK 787 (n=3). Incubation of glomeruli from neph-$VEGF_{165}$b mice with PTK leads to a further reduction in L_pA/V_i compared to those incubated with saline ($p<0.05$; mice n=5, glomeruli n=18).In glomeruli from diabetic DBA2J mice treated i.p.with $VEGF_{165}$b (n=3) immunofluorescence revealed increased expression and phosphorylation of VEGFR2.

Conclusions: $VEGF_{165}$b increases phosphorylation of VEGFR2 in glomeruli in both models. However, inhibition of VEGF receptors in neph-$VEGF_{165}$b over-expressing mice further decreases L_pA/V_i, suggesting that although $VEGF_{165}$b is acting through VEGFR2, it is likely that it does not block all VEGFR2 sites, possiblysignaling through other VEGF receptors.

Systems Analysis of MYH9 Protein-Protein Interactions Reveals Multiple Possible Functions within the Podocyte Thomas Hays,[1] Deborah P. Hyink,[2] Paul E. Klotman.[2] *[1]Medicine, Mount Sinai School of Medicine, New York, NY; [2]Medicine, Baylor College of Medicine, Houston, TX.*

Background: MYH9 encodes the predominant force-generating ATPase in non-muscle cells. Rare nonsynonymous mutations in MYH9 cause a Mendelian disease, which includes a variably penetrant glomerulopathy leading to renal failure. Additionally, work by our group has recently identified reduced MYH9 expression in the setting of HIV-associated nephropathy. MYH9's function in generating tension across the actin cytoskeleton, and in stress fibers has been well characterized in multiple models. However, its precise functions in podocytes remain unknown. Podocytes are highly differentiated cells which maintain the selectively permeable glomerular filtration barrier of the kidney. This function relies upon a mechanically dynamic actin cytoskeleton supporting the podocyte-specific proteins which make up the slit diaphragm apparatus.

Methods: To better understand MYH9's role within the podocyte, we performed an immunoprecipitation mass-spectrometry screen and identified MYH9-interacting proteins within murine and human conditionally immortalized podocytes. Using immunohistochemistry, we characterized the subcellular localization of MYH9 within podocytes in vivo. Finally, we tested the effect of loss of MYH9 expression on podocytes in vitro.

Results: Systems biological analyses revealed that MYH9-interacting proteins belonged to signaling networks known to regulate cytoskeletal actin organization, including the RhoA pathway. Immunohistochemistry revealed MYH9 to be expressed within the podocyte processes overlying glomerular capillary tufts. Knockdown of MYH9 demonstrated that its function was necessary for cytoskeletal organization.

Conclusions: Our results provide the first detailed survey of MYH9 interactions within the podocyte, and demonstrate the important role of this protein in organization the elaborate cytoskeleton of podocytes.

Transgenic Rats Overexpressing a Constitutively Active TGF-ß1 Receptor in Podocytes Develop Podocyte Injury and Albuminuria Sigrid C. Hoffmann, Rebecca Walz, Sabine Neudecker, Carsten Sticht, Norbert Gretz, Wilhelm Kriz. *Medical Faculty Mannheim, University of Heidelberg, Mannheim, Germany.*

Background: Glomerular TGF-ß1 is increased early in the course of FSGS and diabetic nephropathy. The podocytes are source and targets of TGF-ß1. This study addressed the hypothesis that increased TGF-ß1 induces podocytes damage leading to glomerular disease.

Methods: Transgenic rats were generated by pronuclear microinjection of a constitutively active TGF-ß1 type 1 receptor [hTßRI$_{(T204-D)}$] cDNA driven by the podocin promoter into fertilized Sprague Dawley oocytes. The transgene expression was verified by Northern blotting, Real-Time RT-PCR, In-situ hybridization and Western blotting. Glomerular expression of 93 genes either specific to the podocyte or implicated in cell survival and TGF-ß signalling, respectively, were examined by Real time RT-PCR, Western blotting and immunohistochemistry. Kidney function was evaluated by urinary albumin excretion in the 24h urine and by creatinine clearance in a monthly interval. Structural changes in the kidney were explored by light and electron microscopy.

Results: hTßRI$_{(T204-D)}$ overexpression in podocytes caused in 83% of male rats a significant slowly progressing albuminuria with at maximum 21mg albumin/24hr excretion in individuals. Morphological alterations correlated with the degree of albuminuria and comprised podocytes injury such as pseudocysts, foot process effacement and decay of podocytes in addition to mesangial expansion, matrix accumulation leading focally to capillary loss and occasionally adhesion of glomerular tuft to Bowman's capsule. Expression profiling revealed that 24 out of 93 tested genes were significantly different regulated resulting in increased glomerular PAI-1/PA and bax/blc-1 ratios, altered collagen composition and down-regulated synaptopodin, podocin and nephrin expression in glomeruli of transgenic rats.

Conclusions: TGF-β regulates the podocyte fate *in vivo* and contributes to the leakage of the glomerular filter. Down-regulation of nephrin, synaptopodin and podocin as well as altered pathways affecting ECM turnover and survival seems to be mechanisms leading to the observed structural and pathophysiological changes.

Dynamin Activation Rescues PKCε Deficiency Induced Actin Dysregulation in Podocytes Beina Teng,[1] Changkyu Gu,[2] Hermann G. Haller,[1] Sanja Sever,[2] Mario Schiffer.[1] *[1]Division of Nephrology, Department of Medicine, Medical School Hannover, Hannover, Germany; [2]Nephrology Division, Department of Medicine, Massachusetts General Hospital, Charlestown, MA.*

Background: We have previously demonstrated that the novel PKC isoform (PKCε) participated in signalling pathways controlling actin filament dynamics. PKCε deficiency in podocytes resulted in defective actin arrangement which led to a progressive reduction of podocytes and a spontaneous glomerulosclerosis phenotype in PKCε-/- mice *in vivo*.

Methods: PKCε-/- podocytes were infected with adenoviruses expressing wild type and dominant negative PKCε, as well as wild type and different dynamin mutants.

Results: Re-expression of wild type PKCε, but not the enzymatically impaired mutant, resulted in increased formation of stress fibres, focal adhesion complexes, lamellipodia and filopodia in PKCε-/- podocytes. Overexpression of PKCε in PKCε-/- podocytes also resulted in alteration of the signalling pathways, which play a central role in the control of actin-cytoskeletal rearrangement. Loss of PKCε in podocytes dramatically reduced the activity of Rho family small GTPases that are key upstream regulators of actin-cytoskeleton rearrangement, which could be reversed by re-expression of wild type PKCε.

Dynamin is a large GTPase known to regulate actin cytoskeleton through direct dynamin-actin interactions. Overexpression of dynamin mutant with increased affinity for actin (dynE/K) but not the mutants with impaired ability to bind F-actin, significantly enhanced the formation of stress fibres, number of focal adhesions and lamellipodia. All the disordered actin-cytoskeletal phenotypes due to PKCε deficiency could be partially rescued by overexpression of 'gain of function' dynamin.

Conclusions: The ability of dynamin mutant with increased affinity for F-actin to partially rescue organization of the actin cytoskeleton in podocytes lacking PKCε suggests that actin cytoskeleton in podocytes is regulated by two distinct signalling pathways; one regulated the RhoA family small GTPases, and the second one regulated by large GTPase dynamin. In addition, our study demonstrates that activity of dynamin in podocytes is not regulated by PKCε.

SA-PO788

Toll-Like Receptor 9 Signaling Is Activated in Podocytes of Purimycin Aminonucleoside (PAN) Injury Models Yaojun Liang, Chun-xia Zheng, Zhao-hong Chen, Cai-hong Zeng, Zhi-Hong Liu. *Research Institute of Nephrology, Jinling Hospital, Nanjing University School of Medicine, Nanjing, Jiangsu, China.*

Background: Several recent studies have implicated Toll-like receptor 9 (TLR9) signaling in podocyte injury as TLR9 was found upregulated in podocytes of the patients with lupus nephritis and its expression correlated with treatment outcome (Papadimitraki ED, 2009; Machida H, 2010.); in addition, TLR9 upregulation was also found in podocytes of some patients with polyoma nephropathy, haemolytic uraemic syndrome (Batsford S, 2011), and FSGS (our unpublished observation). To determine if TLR9 signaling mediates podocyte injury, we developed in vitro and in vivo experimental models at first.

Methods: Conditionally-immortalized human podocytes and rats were treated with PAN in vitro and in vivo. Expressions of TLR9, the components and downstream targets of TLR9 pathway, were examined by quantitative RT-PCR, western blotting, and immunohistochemistry. Podocyte injury was evaluated by Annexin V flowcytometry and cytoskeletal alteration.

Results: We show TLR9 and two components of the pathway, IRAK1 and TRAF6, were upregulated at both mRNA and protein levels in the podocytes treated with PAN. Immunohistochemical staining revealed significant upregulations of TLR9, IRAK1 and TRAF6 in the podocytes of PAN-treated rats. To determine if TLR9 signaling is activated in the podocytes treated with PAN, we performed qRT-PCR and found the downstream targets of TLR9 signaling, IL-12, IFN-alpha, and MMP9 were upregulated, suggesting a TLR9 signaling activation. Consistent with previous studies, we also observed that PAN induced both apoptosis and cytoskeletal damage of podocytes, two common consequences found in many podocyte injury models.

Conclusions: PAN-treated podocytes and rats may serve as appropriate in vitro and in vivo models for elucidating the role of TLR9 signaling in podocyte injury. We are examining the role of TLR9 signaling in podocyte injury induced by PAN and seeking the possible CpG ligands and their origins.

SA-PO789

Calcium/Wnt/beta-Catenin Signaling Cascade Mediates Angiotensin II-Induced Podocyte Injury and Albuminuria Lei Jiang, Junwei Yang, Chunsun Dai. *Center of Kidney Disease, 2nd Affiliated Hospital, Nanjing Medical University, Nanjing, Jiangsu, China.*

Background: Angiotensin II (Ang II) plays a pivotal role in promoting podocyte dysfunction and albuminuria, however, the underline mechanisms is not fully delineated yet.

Methods: Four weeks of continuous osmotic pump administration of Ang II and two weeks of administration of exogenous Ang II by vein injection in Balb/c mice were use for in vivo study. cyclosporine A (CsA) or exogenous Dkk1 were administrated in Ang II treated mice.Cultured mouse podocytes(MPC5) were used in vitro.Dkk1 or beta-catenin siRNA were used to block Wnt/beta-catenin signaling activation. CsA or CK59 were used to block calcium signaling.

Results: In this study, we found that Ang II induced Wnt1 expression and b-catenin nuclear translocation in cultured mouse podocytes. Blocking canonical Wnt signaling with *Dickkopf1* (Dkk1) or beta-catenin siRNA attenuated Ang II induced podocyte injury. Ang II could also activate calcium and its two downstream signaling pathways, including calcineurin/NFAT and Camk II, in cultured podocytes. Blockade of the calcium signaling pathways with cyclosporine A (CsA) or CK59 respectively could significantly inhibit Ang II induced Wnt mRNA expression, b-catenin accumulation and podocyte injury. In *in vivo* studies, administration of Ang II promoted glomerular Wnt/b-catenin signaling activation, podocyte damage and albuminuria in mice. CsA could remarkably ameliorate Ang II induced podocyte damage and albuminuria in mice, which is in parallel with the inhibition of glomerular Wnt1 expression. Indeed, administration of exogenous Dkk1 also attenuated Ang II induced podocyte damage and albuminuria in mice.

Conclusions: Taken together, this study demonstrates that Calcium/Wnt/beta-catenin signaling cascade mediates Angiotensin II-induced podocyte injury and albuminuria, targeting this signaling may offer renal protection against the development and progression of proteinuric kidney diseases.

Zonulin, a Novel Regulator of Podocyte Function and Mediator of the Intestinal-Renal Syndrome? Britta Sylvia Walter, Alexis J. Sloan, Saurav Singh, Christian Faul. *Division of Nephrology, Department of Medicine, University of Miami Miller School of Medicine, Miami, FL.*

Background: Zonulin is a 47kDa protein that is secreted by enterocytes, and serves as a paracrine regulator of small intestine permeability. While the physiological function of this reversible process is not well understood, it has been shown that in patients with Celiac Disease (CD) zonulin levels are elevated in responses to a gluten-rich diet, leading to abnormal paracellular transport and diarrhea. Mechanistically, zonulin binds to protease-activated receptor (PAR) 2 on enterocytes leading to the phosphorylation of zonula occludens (ZO)-1 and the transient disassembly of tight junctions (TJ). Since zonulin has also been described to be elevated in the serum of patients with CD as well as other autoimmune diseases, zonulin could function as a potential circulating modulator of TJs in other tissues.

Methods: In order to analyze if zonulin can directly affect the podocyte slit diaphragm, a specialized cell-cell junction that contains TJ-proteins, we used the AT1002 peptide, which resembles zonulin's active PAR2 binding domain.

Results: AT1002 treatment of cultured podocytes caused a rearrangement of the actin cytoskeleton accompanied by decreased cell migration, as well as an increase in tyrosine-phosphorylation of ZO-1. Furthermore, in paracellular flux assays, movement of 70kDa dextran particles across podocyte layers was increased in the presence of AT1002. When isolated rat glomeruli where treated with AT1002, albumin permeability was increased. Interestingly, when glomeruli where incubated with serum from patients with FSGS, the elevation of albumin permeability was significantly reduced in the presence of a zonulin blocking antibody or blocking peptide. Finally, when gluten was delivered repetitively by gavage, mice developed mild proteinuria.

Conclusions: Taken together, our preliminary data indicate that zonulin increases paracellular transport across podocytes and modulates the selectivity of glomerular filtration. Future studies aim to determine serum zonulin levels in FSGS patients, and urine albumin levels in patients with CD.

SA-PO791

Mifepristone Is as Effective as Methylprednisolone as Therapy for Experimental Nephrotic Syndrome Danica Petrovic-djergovic, Milan Popovic, Seetharamaiah Chittiprol, Tad Eichler, Phylip Chen, Richard F. Ransom. *Center for Clinical and Translational Research, The Research Institute at Nationwide Children's Hospital, Columbus, OH.*

Background: Glucocorticoids (GC) are the primary therapy for nephrotic syndrome (NS), and patient response to GC largely defines their prognosis. Experimental NS induced in rats by puromycin aminonucleoside (PAN-NS) is a well-established model of GC-responsive NS. The elegant transplantation experiments of Hoyer *et al*. demonstrated that the kidney is the site of action of PAN, and, by extension, of GC therapy in PAN-NS.

Methods: Injection of 50 mg/kg PAN in Wistar and nude (*Foxn1*$^{rnu/rnu}$) rats was used to induced PAN-NS, daily injections of 5 mg mifepristone (RU486) or 15 mg methylprednisolone (MP)/kg were used for therapy. Protein assay, qRT-PCR, and EM were by standard methods.

Results: Both Wistar and immunodeficient nude rats responded equally to methylprednisolone therapy by a >60% reduction in proteinuria and podocyte foot process effacement. To our surprise, and in contrast to our previous results in cultured podocytes, the GC receptor (GR) antagonist, RU486, and RU486+MP were as effective as MP at reducing PAN-induced proteinuria and podocyte foot process effacement, and were also effective therapy after development of proteinuria. The efficacy of RU486 and MP was associated with modulationi of mRNA expression of specific genes induced by PAN (*Angptl4*, *Trpc6*, *Cxcl10*), but not of typical GC-induced genes (*Dusp1*, *Tsc22d3*).

Conclusions: Our results demonstrated that mature T-cells were unnecessary for either the development of PAN-NS or the therapeutic effect of GC. The common efficacy of RU486, MP, and RU486+MP in PAN-NS strongly support a common mechanism, and highlight the relevance of specific molecules whose expression is altered during nephrosis and modulated by both MP and RU486. Together, our results support the hypothesis that the kidney is a major site of action of GC therapy in NS, and that RU486 is a specific agonist of the GR for the molecular mechanism(s) responsible for the therapeutic effect of GC in NS. Our findings also raise the novel prospect of the use of RU486 as an alternative or supplement to GC in the therapy of NS.

SA-PO792

Secretion of CXCL10 by Podocytes Coordinates Trafficking of Interferon-γ-Activated Macrophages in Puromycin Aminonucleoside Nephrosis in Rats Danica Petrovic-djergovic, Milan Popovic, Seetharamaiah Chittiprol, Santiago Partida-Sanchez, Richard F. Ransom. *The Research Institute at Nationwide Children's Hospital, Columbus, OH.*

Background: The mechanism responsible for trafficking of activated macrophages into kidney tissue in the puromycin aminonucleoside model of nephrotic syndrome in rats (PAN-NS), and the significance of this infiltration, remain largely unknown. Interferon gamma (IFN-γ) inducible protein 10 (IP-10, CXCL10) is a small chemokine secreted in many Th1-type inflammatory diseases, where it plays an important role in trafficking of monocytes and activated T-cells into sites of tissue inflammation. We hypothesized that induction of circulating IFN-γ and glomerular TNF-α during PAN-NS would stimulate release of CXCL10 by glomerular podocytes, leading to infiltration of activated immune cells and greater glomerular injury.

Methods: PAN-NS was by single injection of 50 mg/kg PAN in Wistar and nude (*Foxn1*$^{rnn/rnu}$) rats, macrophage depletion by clodronate liposomes. Cytokine ELISA, protein assay, qRT-PCR, and monocyte (THP-1) migration were by standard methods.

Results: We found that serum INF-γ, glomerular *Cxcl10* mRNA, and intra- and peri-glomerular infiltration of macrophages, but not T-lymphocytes, were strongly induced during the late acute phase of PAN-NS (12 d after injection) in Wistar rats, but not in nude rats lacking functional effector T-lymphocytes. Wistar rats also developed significantly greater proteinuria than nude rats in the late acute phase of PAN-NS, and this greater proteinuria was abolished by macrophage depletion. Stimulation of cultured podocytes with both IFN-γ and TNF-α markedly induced the expression of *Cxcl10* mRNA and the release of a monocyte chemoattractant identified as CXCL10.

Conclusions: Together, these data provide strong support for our hypothesis that increased circulating IFN-γ and glomerular TNF-α synergistically induce the production and secretion of CXCL10 by podocytes, attracting activated macrophages into kidney tissue. The study also suggests that INF-γ, secreted from Th1 lymphocytes, has an important role in priming of pro-inflammatory macrophages whose presence consequently aggravates renal injury.

Roles of Na^+/H^+ Exchanger Type 1 and Intracellular pH in Angiotensin II-Induced Reactive Oxygen Species Generation and Podocyte Apoptosis Akira Nishiyama, Hiroyuki Kobori. *Department of Pharmacology, Kagawa University Medical School, Japan.*

Background: A growing body of evidence suggests that podocyte apoptosis is a major cause of decreased podocyte number, which leads to albuminuria and glomerular injury. The aim of this study was to clarify the molecular mechanisms of angiotensin II (Ang II)-induced apoptosis in cultured mouse podocytes.

Methods: We examined the effects of Ang II (100 nmol/L) on apoptosis, superoxide anions, and cytosol pH in podocytes. For intracellular pH measurements, image analysis was conducted using confocal laser microscopy after incubation with carboxy-seminaphthorhodafluor-1.

Results: Superoxide anions and intracellular pH were elevated with Ang II treatment. Apoptotic cell numbers, as measured by TUNEL staining and caspase 3 activity, were also augmented in the Ang II-treated group. Pre-treatment with olmesartan (100 nmol/L, an Ang II type 1 receptor blocker), apocynin (50 μmol/L, NADPH oxidase inhibitor), or 5-N,N hexamethylene amiloride (30 μmol/L, Na^+/H^+ exchanger type 1 [NHE-1] inhibitor) abolished Ang II-induced podocyte apoptosis, whereas *NHE-1* mRNA expression was not affected by Ang II treatment.

Conclusions: These results suggest that superoxide production, NHE-1 activation, and intracellular alkalization were early features prior to apoptosisin Ang II-treated mouse podocytes, and may offer new insights into the mechanisms responsible for Ang II-induced podocyte injury.

Cross-Talk between GR, PPARγ and MAPK Signaling Links COX-2 to Injury and Protection in Podocytes Shipra Agrawal,[1] Adam J. Guess,[1] Ruma Pengal,[1] William E. Smoyer.[1,2] *[1]Clinical & Translational Research, The Research Institute at Nationwide Childrens Hospital, Columbus, OH; [2]Department of Pediatrics, The Ohio State University, Columbus, OH.*

Background: γProteinuria is a common feature of glomerular disease as well as a critical determinant of disease progression. Serum albumin (SA) exposure is known to cause podocyte injury both in vitro and in vivo. Moreover, renal injury has been shown to induce COX-2 in podocytes. However, podocyte protection and signaling are now known to be regulated by nuclear receptors [glucocorticoid receptor (GR) and peroxisome proliferator-activated receptor γ (PPARγ)] and MAPK pathways, and cross-talk among them. We thus hypothesized that COX-2 serves as a molecular link between SA-induced podocyte injury and protection, via cross-talk among the GR-, PPARγ- and MAPK-mediated signaling pathways.

Methods: Podocytes treated with SA were analyzed for COX-2 mRNA and protein expression. In addition, the abilities of glucocorticoids (GCs), thiazolidinediones (TZDs), GR and PPARγ antagonists, as well as MAPK and NFκB inhibitors, to regulate SA-induced COX-2 were also analyzed.

Results: SA was endocytosed by podocytes and induced COX-2 mRNA and protein in a dose- and time-dependent manner. SA-induced COX-2 expression was inhibited by both GCs and TZDs. However, pre-treatment with antagonists for GR (RU486 and CORT108297) and PPARγ (GW9662) prevented the GC-mediated inhibition. Surprisingly, some of these antagonists alone enhanced SA-induced COX-2 expression, suggesting a possible role for basal GR and PPARγ activity in podocyte pathophysiology. Additionally, SA activated the kinases ERK1/2, p38 MAPK, MK2, JNK and NFκB, while NFκB inhibition and inhibitors for these kinases (with the exception of JNK) reduced SA-induced COX-2 expression.

Conclusions: Physiologic concentrations of SA induce podocyte COX-2 expression, which can be inhibited by GCs, TZDs, and select MAPK and NFκB inhibitors. Since proteinuria exposes podocytes to increased concentrations of SA, and GCs, TZDs and MAPK inhibitors are all known to directly protect podocytes, our results suggest that COX-2 may serve as a molecular link between injury and protection of podocytes.

Genetic Alterations in α-Actinins Modulate Effectors of Podocyte Adhesion and Cytoskeletal Dynamics Fangfang He,[1,3] Hui Chen,[1] Philip A. Bondzie,[1] Julie A. Tomolonis,[1] Martin R. Pollak,[2] Joel M. Henderson.[1] *[1]Department of Pathology and Laboratory Medicine, Boston University School of Medicine, Boston, MA; [2]Division of Nephrology, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA; [3]Department of Nephrology, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China.*

Background: We previously demonstrated that genetic alterations in α-actinins are associated with changes in traction force generation and cell motility. The aim of this study is to define the mechanisms by which these genetic alterations contribute to podocyte motility.

Methods: α-actinin-1 and α-actinin-4were ablated in cultured murine podocytes using lentiviral RNA interference. Real time PCR was used to detect vinculin mRNA expression, and Western blot and immunohistochemistry were used to characterize vinculin protein expression and distribution in cultured cells. Small GTPase activities were measured by G-LISA RhoA, Rac1 and Cdc42 activity assays.

Results: Ablation of α-actinin-4 resulted in significant increases in vinculin expression at the mRNA and protein levels, larger focal adhesions, decreased RhoA activity and increased Cdc42 activity. No significant changes in vinculin expression, focal adhesions, or GTPase activities were detected in α-actinin-1-ablated cells.

Conclusions: These findings suggest that alterations in podocyte motility in α-actinin-4-ablated cells are associated with changes in focal adhesions and small GTPase activities. Therefore, changes in podocyte adhesion and small GTPase-mediated cytoskeletal dynamics may play a role in glomerular damage and glomerular barrier dysfunction developing secondary to mutations in α-actinin-4.

Characterization of Signaling Pathways in Cultured Human Mesangial Cells Induced by IgA1-Containing Immune Complexes from Patients with IgA Nephropathy Zhi Qiang Huang, Joshua Anderson, Timothy D. Rohrbach, Stacy D. Hall, Rhubell T. Brown, Bruce A. Julian, Christopher D. Willey, Jan Novak. *University of Alabama at Birmingham, Birmingham, AL.*

Background: In patients with IgA nephropathy (IgAN), galactose-deficient IgA1 (Gd-IgA1) and anti-glycan antibodies form immune complexes (IC) that activate mesangial cells (MC) and induce cellular proliferation. MC activation includes changes in tyrosine kinase (TK) activity, but the specific pathways induced by the Gd-IgA1-containing IC are unknown.

Methods: Cultured human primary kidney MC were stimulated with native IC isolated from sera of IgAN patients or stimulated with *in vi*tro-formed IC using recombinant IgG antibody specific for Gd-IgA1. Cell lysates were preliminarily analyzed by SDS-PAGE/Western blotting using anti-phospho-tyrosine antibody. Specific TK activities in the samples were then determined with a PamStation® 12 high-content peptide substrate microarray. Data were analyzed using BioNavigator to identify peptides significantly altered in phosphorylation, and GeneGo Metacore to identify altered signal-transduction pathways important in IC-mediated activation of MC. MC proliferation was also assessed.

Results: MC proliferation was induced by both native and *in vitro*-formed IgA1-containing ICs. Kinomic profiling showed that phosphorylation of fourteen peptides was significantly altered in the ICs-stimulated MC. Further analysis using a Drug Targeting Network identified ICs-altered TK-inhibitor targetable signaling pathways, including PDGF/PDGFR, c-Kit, and c-Raf pathways. Direct Interaction mapping identified altered signaling in the JAK1, JAK2, FAK, PYK2, PLC-g as well. Enhanced phosphorylation and cell proliferation were blocked by kinase inhibitors targeting some of these pathways.

Conclusions: Gd-IgA1-containing ICs activated multiple signaling pathways in MC and led to cellular proliferation. Inhibition of TK signaling using small molecule inhibitors prevented these changes. Thus, IC-mediated TK pathways in MC represent targets for developing new disease-specific treatment.

Klotho Is a Target of PPAR-γ and Protective against Cellular Hypertrophy and Apoptosis in High Glucose-Stimulated Glomerular Cells Hye-young Kang,[1] Seong Hun Kim,[1] Dae-Suk Han,[2] Shin-Wook Kang,[1,2] Seung Hyeok Han.[2] *[1]Brain Korea 21, Yonsei University; [2]Department of Internal Medicine, College of Medicine, Yonsei University, Seoul, Republic of Korea.*

Background: Klotho is known as an anti-aging hormone that has anti-oxidative and anti-senescence effects. In this study, we investigated whether klotho can play a protective role in high glucose (HG)-stimulated glomerular cells.

Methods: The mRNA and protein expression of klotho and PPAR-γ were examined in mouse mesangial cells and podocytes exposed to 5 mM (NG) and 30 mM glucose (HG) by real-time PCR (RT-PCR) and Western blot, respectively. To explore whether klotho expression was determined by PPAR-γ, we evaluated klotho expression in glomerular cells treated with PPAR-γ agonist (pioglitazone, 50 μM) or antagonist (GW9662, 20 μM), and performed a chromatin-immunoprecipitation (ChiP) assay. The effects of klotho on cell cycle regulation and apoptosis were also elucidated in these cells.

Results: The presence of klotho gene was confirmed in glomerular cells using RT-PCR. Immunofluorescence staining revealed that klotho was mainly expressed in cytoplasm of these cells. The protein expression of klotho was concordant with that of PPAR-γ, which was increased up to 24 hours and decreased at 48 hours in HG-stimulated glomerular cells. In addition, klotho protein expression was increased by PPAR-γ agonist and decreased by PPAR-γ antagonist. The ChiP assay found PPAR-γ responsive element in the 5'-flanking region of the klotho gene. Administration of recombinant klotho (rKL, 1 μg/ml) induced a decrease in G0/G1 phase cells and increases in S and G2 phases cells in HG-stimulated glomerular cells. The expression of $p21^{Clip1}$, $p27^{Kip1}$, cleaved caspase-3, and the ratio of Bax/Bcl-2 was also significantly increased in these cells. rKL significantly attenuated the increased expression of these proteins, whereas klotho siRNA further increased these expression.

Conclusions: Klotho was a target of PPAR-γ in glomerular cells and ameliorated cellular hypertrophy and apoptosis in HG-stimulated glomerular cells, suggesting that klotho may exert a protective effect in glomerular cells under diabetic conditions.

SA-PO798

Inhibition of Notch Pathway Protects the Mice from Human Immunodeficiency Virus Associated Nephropathy Madhulika Sharma,[1] Lynn Magenheimer,[1] Carol G. Carlton,[1] Deborah P. Hyink,[2] Pravin C. Singhal,[3] Paul E. Klotman,[2] Timothy A. Fields,[1] Gregory B. Vanden Heuvel.[1] *[1]University of Kansas Medical Center, Kansas, KS; [2]Baylor College of Medicine, Houston, TX; [3]Hofstra North Shore-LIJ School of Medicine, Great Neck, NY.*

Background: Notch signaling is activated when Notch receptors (Notch 1-4) bind Jagged and Delta ligands and induce cleavage of Notch intracellular (IC) domain. The Notch IC then translocates to the nucleus, binds to RBP-jk protein and activates transcription of *Hes* and *Hey* genes. Human Immunodeficiency Virus Associated Nephropathy (HIVAN) is characterized by podocyte hyperplasia and glomerular collapse. Here we show that Notch pathway is activated in Tg26 mouse model of HIVAN and Notch inhibition protects these mice from disease progression.

Methods: Notch pathway expression analysis was performed in Tg26 mice. These mice were treated with GSIXX (Notch inhibitor) and disease progression was evaluated. Immortal differentiated podocytes were treated with HIV proteins/ GSIXX and effects on cell proliferation were evaluated.

Results: Notch1 IC, Notch4 IC and Hes1 were all upregulated in the glomeruli. Of these, Notch4 IC expression was most robust and co-localized with the podocyte marker synaptopodin and the proliferation marker (Ki-67). Among ligands, glomeruli showed expression of Jagged2 only. However, tubules showed elevated expression of Jagged1, Jagged2, Delta-like1, and Delta-like4. We treated six week-old Tg26 mice with GSIXX for nine days, and evaluated disease severity. Strikingly, GSIXX treatment resulted in significant improvement in both histologic kidney injury scores and renal function. GSIXX-treated Tg26 mice showed diminished podocyte proliferation and dedifferentiation. Moreover, *in vitro* studies revealed that Notch inhibitors can block podocyte proliferation induced by HIV proteins Nef and Tat.

Conclusions: These studies suggest that Notch signaling, particularly Notch4 IC, may promote collapsing glomerulopathy and HIVAN progression. Thus, Notch inhibition may be a viable treatment strategy for HIVAN.

SA-PO799

Retinoids Augment the Number of Glomerular Epithelial Transition Cells in Experimental Glomerular Diseases Jiong Zhang,[1] Jeffrey W. Pippin,[1] Ronald D. Krofft,[1] Yoshinori Taniguchi,[1] Paola Romagnani,[2] Peter J. Nelson,[1] Zhi-Hong Liu,[3] Stuart J. Shankland.[1] *[1]University of Washington, Seattle, WA; [2]University of Florence, Italy; [3]Nanjing University School of Medicine, China.*

Background: Reduced podocyte number underlies glomerulosclerosis in membranous nephropathy (MN) and FSGS. Parietal epithelial cells (PEC) that begin to express proteins considered unique to podocytes, called glomerular epithelial transition cells (GETC), might serve as podocyte progenitors. We tested the hypothesis that retinoids improve outcomes in glomerular diseases characterized by reduced podocyte number in part by increasing the number GETC.

Methods: Rats with experimental MN (PHN model) and mice with experimental FSGS (anti-glomerular antibody model) were given all-trans retinoic acid (ATRA) or DMSO (control) following the onset of proteinuria. GETC were defined as cells co-staining for both PAX2 (PEC marker) and WT-1 (podocyte marker).

Results: In MN rats given ATRA (5mg/kg IP, 5x a week until sacrifice), there was a significant increase in the number of GETC lining Bowman's basement membrane (BBM) compared to DMSO at d13 (9.1±0.9/mm of BBM *vs.* 4.0±0.5/mm of BBM, $p<0.01$), d35 (8.7±0.9/mm *vs.* 5.5±0.6/mm, $p<0.01$), and d110 (6.1±0.7/mm *vs.* 0.4±0.1/mm, $p<0.01$). In MN rats, ATRA also increased the number of GETC lining the GBM at d13 (185±36.8/mm^2 of tuft *vs.* 26.4±7.9/mm^2 of tuft, $p<0.01$), and d35 (367±62.8/mm^2 *vs.* 75.2±16.7/mm^2, $p<0.01$). These changes were accompanied by increased podocyte number at d110 in ATRA treated MN rats (1592±84.5/mm^2 *vs.* 962±54.8/mm^2, $p<0.01$ *vs.* DMSO). In FSGS mice, ATRA (16mg/kg IP daily until sacrifice) increased the number of GETC lining Bowman's capsule at d14 (7.5±0.8/mm of BBM *vs.* 1.3±0.5/mm of BBM, $p<0.01$), and along the GBM at d7 (44.1±20.4/mm^2 of tuft *vs.* 11.8±11.8/mm^2 of tuft, $p<0.05$), and d14 (48.8±23.3/mm^2 *vs.* 13.5±13.5/mm^2, $p<0.05$).

Conclusions: In summary, these data show that the normalization of podocyte number by retinoids in experimental MN and FSGS is accompanied by an increase the number GETC. The latter might serve as a podocyte progenitor population to enhance overall glomerular repair in diseases characterized by reduced podocyte number.

SA-PO800

Podocyte-Specific Constitutive Activation of CaMKII in Mice Results in Reversible Proteinuria and Foot Process Effacement Saurav Singh,[1] Britta Sylvia Walter,[1] Alexis J. Sloan,[1] Ansel P. Amaral,[1] Christian Faul.[2] *[1]Molecular Cell and Developmental Biology, University of Miami Miller School of Medicine, Miami, FL; [2]Department of Medicine, University of Miami Miller School of Medicine, Miami, FL.*

Background: Ca2+ is an important second messenger in podocyte foot processes (FP), and mounting evidence has revealed alterations in Ca2+-mediated signal transduction in podocyte pathophysiology. For example, gain-of-function mutations in TRCP6 calcium channels can cause changes in proper podocyte morphology and glomerular filteration leading to the development of proteinuria. Additionally, elevations of intracellular calcium levels in podocytes can occur under other non-genetic insults such as increases in blood pressure, bacterial infection, and trauma. Calcium/calmodulin dependent kinase II (CaMKII) is key mediator of Ca2+ signaling in various cell types. CaMKII can directly modulate actin fibers, as reported for hippocampal neurons and the regulation of synaptic plasticity, as well as control gene expression via the regulation of histone acetylation as shown in cardiac myocytes. This dual role of CaMKII in the regulation of actin dynamics and epigenetic changes makes it an interesting candidate to function as a key regulator of podocyte morphology and function in health and disease.

Methods: In order to study CaMKII function in vivo, we have generated an inducible transgenic mouse model for the podocyte-specific expression of a constitutive active CaMKII-alpha mutant form.

Results: Podocytes express various isoforms of CaMKII, and the pharmacological inhibition of CaMKII in cultured podocytes induces the degradation of the actin-binding protein synaptopodin, and a loss of actin stress fibers. Transgenic CaMKII mice develop profound proteinuria and podocyte FP effacement, and the proteinuria regresses within 3 months, indicating the activation of compensatory processes.

Conclusions: Our novel data indicate that CaMKII is an important signal mediator in podocytes, and that its inhibition or overactivation can have pathological effects. Future studies aim to determine the precise molecular events underlying CaMKII function in podocytes.

SA-PO801

Active Proteases in Nephrotic Plasma Lead to a Podocin Dependent Phosphorylation of VASP in Podocytes via Protease Activated Receptor-1 Hugh J. McCarthy, Gavin Iain Welsh, Moin Saleem, Jessica Harris. *Academic Renal Unit, University of Bristol, Bristol, United Kingdom.*

Background: Focal Segmental Glomerulosclerosis (FSGS) is known to result in dramatic changes in actin cytoskeleton and injury to the podocyte cell. Post-transplant recurrence of FSGS exemplifies disease due to prescence or absence of a plasma factor(s). There is increasing indication that plasma protease activity may be key.

Methods: Utilising plasma exchange material collected from patients with active post-transplant recurrence of FSGS paired with samples from the same patients in remission the effect on human conditionally immortalized podocytes (ciPods) was analysed.

Results: We show that vasodilator stimulated phosphoprotein (VASP) is phosphorylated in response to relapse plasma from 12 consecutively tested patients, and not in response to paired remission plasma or non-FSGS controls. The phosphorylation signal is absent in human podocytes carrying a pathological podocin mutation. To test for a plasma ligand, inhibition of proteases in relapse plasma leads to the loss of VASP phosphorylation. By the use of siRNA technology we show that proteases in the plasma signal predominantly via protease activated receptor 1 (PAR1) to VASP. Mechanistically FSGS plasma increases podocyte motility, which is dependent on VASP phosphorylation.

Conclusions: These data suggest a specific biomarker for disease activity, as well as revealing a novel and highly specific receptor mediated signaling pathway to the actin cytoskeleton.

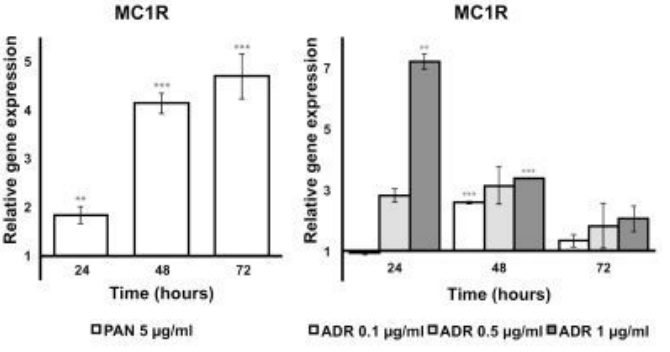
SA-PO802

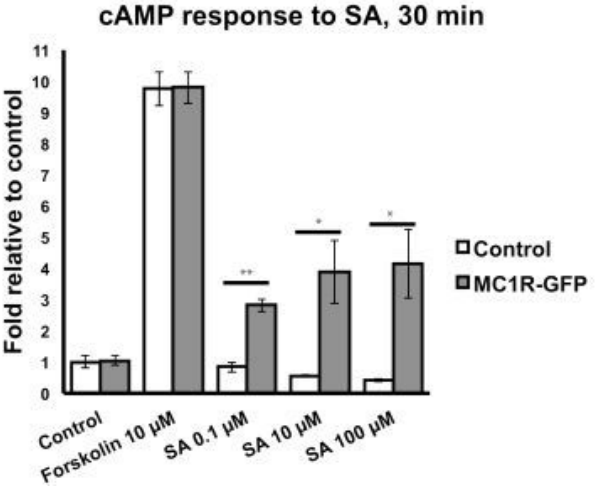
The Melanocortin Receptor 1: A Potential Target for Therapeutical Drugs in Nephrotic Syndrome Johannes Elvin,[1] Annika Lindskog Jonsson,[1] Lisa Maria Buvall,[2] Anna Granqvist,[1] Jenny C. Nystrom,[3] Borje Haraldsson.[1] *[1]Department of Molecular and Clinical Medicine, The Sahlgrenska Academy, University of Gothenburg, Sweden; [2]Department of Nephrology, Massachusetts General Hospital & Harvard Medical School, Boston, MA; [3]Department of Physiology, The Sahlgrenska Academy, University of Gothenburg, Sweden.*

Background: Previously, we have shown that treatment with adrenocorticotropic hormone (ACTH) and agonists targeting the melanocortin receptor 1 (MC1R) reduce proteinuria, improve glomerular morphology and reduce oxidative stress. We propose that MC1R is a potential therapeutic target in renal disease and our aim with this study was to further explore the mechanisms behind MC1R stimulation in vitro.

Methods: In these experiments, we used conditionally immortalized mouse podocytes. The cells were subjected to puromycin aminonucleoside (PAN) or adriamycin (ADR) at different time points. The cDNA was analysed with qPCR and the MC1R gene expression levels were examined. Human MC1R was over-expressed in the podocytes, a novel and Selective Agonist (SA) for MC1R was added and the intracellular cAMP was analysed at different time points in a functional assay.

Results: The native MC1R gene expression is low but stable in podocytes, and we found that both PAN and ADR treatment significantly increased the expression in a dose dependent manner. The effect of the SA against podocytes over-expressing human MC1R was confirmed by a significant increase in intracellular cAMP. MC1R exhibited a high cAMP response to the SA.





Conclusions: The MC1R expression level in mouse podocytes is low, but the up-regulation observed suggests that MC1R is involved in the response to pathological stress. Adding to earlier findings with ACTH, MC1R is proposed to be protective against podocyte-specific renal injury when stimulated with an agonist in a cAMP dependent pathway.

EPLIN (Epithelial Protein Lost in Neoplasm) Interacts with Paxillin and Regulates Mesangial Migration

Haruko Tsurumi,[1] Yutaka Harita,[1] Hidetake Kurihara,[2] Yuko Kajiho,[1] Shoichiro Kanda,[1] Ken-ichiro Miura,[1] Takashi Sekine,[1] Motoshi Hattori,[3] Takashi Igarashi.[1] *[1]Pediatrics, University of Tokyo, Tokyo, Japan; [2]Anatomy, Juntendo University School of Medicine, Tokyo, Japan; [3]Pediatric Nephrology, Tokyo Women's Medical School of Medicine, Tokyo, Japan.*

Background: Migration of mesangial cells is crucial during glomerular injury or glomerular development. Directional migration requires coordinated actin dynamics and turnover of focal adhesion proteins. The mechanisms how mesangial migration is regulated in mesangial proliferative diseases are still unknown.

The objective was to determine regulatory mechanisms underlying cytoskeletal alteration in migration of mesangial cells.

Methods: During the search for actin regulatory proteins expressed in mesangial cells, we found that EPLIN was highly expre--ssed in rodent and human mesangial cells. We analyzed expression of EPLIN in cultured mesangial cells and in experimental glomerulonephritis. We also investigated its role in mesangial cell proliferation and migration by siRNA-mediated depletion of EPLIN.

Results: By immunoelectron microscopy, EPLIN was localized at the edge of mesangial processes and mesangial angles where they are attached to the GBM. In cultured mesangial cells, EPLIN was colocalized with peripheral actin bundles and paxillin, focal adhesion protein. Immunoprecipiation experiments revealed the interaction between EPLIN and paxillin. By PDGF treatment, localization of EPLIN at focal adhesion was reduced and translocated to peripheral ruffles. Expression of EPLIN was dramatically decreased in Thy-1.1 nephritic rat model. Knockdown of EPLIN facilitated PDGF-induced focal adhesion disassembly and promoted PDGF-induced mesangial cell migration.

Conclusions: We found EPLIN inhibits the migration of mesangial cells possibly by stabilizing focal adhesion complex. These observations shed light on coordinated actin remodeling in the mesangial cells in restorative remodeling processes. Alteration of expression and localization of cytoskeletal regulators underlies phenotypical change of mesangial cells during mesangial injury.

SA-PO804

COL4A3$^{+/-}$/Nphs2$^{+/R140Q}$ Mice: Glomerular Basement Membrane and Slit Diaphragm Interactions with Impact on Podocyte Pathology and Kidney Fibrosis

Jenny Kruegel,[1] Diana Rubel,[1] Rainer Girgert,[1] Gerhard-anton Mueller,[1] Corinne Antignac,[2] Oliver Gross.[1] *[1]Nephrology & Rheumatology, University Medicine Goettingen, Goettingen, Germany; [2]Faculté de Médecine Paris Descartes, Université Paris Descartes, Paris, France.*

Background: Homozygous mutations of the glomerular basement membrane (GBM) collagen IV alpha 3/4/5 (Col4), as well as the slit diaphragm protein podocin have a strong impact on podocyte pathology and renal failure. However, heterozygous patients develop late, if any, changes. Interestingly, patients with double-heterozygous mutations for Col4 and podocin developed early ESRF. Therefore, we hypothesized that an interaction exists between the podocytes, slit diaphragm and GBM-matrix, which is important for maintenance of podocyte structure and function and development of kidney fibrosis.

Methods: COL4A3$^{+/-}$/Nphs2$^{+/R140Q}$ (mutant), respective heterozygous single knockouts (sKO) and wildtype (WT) mice were investigated at different ages using light and electron microscopy, as well as immunohistological and western blot technique.

Results: No difference in lifespan was revealed between mutants, sKO and WT. In mutants, urine analysis showed an age-dependent increased loss of high molecular weight proteins. Profibrotic markers were elevated as well. Light microscopically, laminin-staining did not reveal strong matrix deposition. However, podocyte effacement and moderate tubulointerstitial fibrosis could be detected in mutants using electron microscopy.

Conclusions: We here introduce a new mouse model, to study GBM–podocyte–slit diaphragm-interactions. Compared to the healthy phenotype of heterozygous single knockout mice, the double heterozygous mice showed moderate changes of kidney pathology, like effacement of podocytes, tubulointerstitial fibrosis and proteinuria. We assume a link between GBM and slit diaphragm that might influence podocyte structure. Consequently, patients with heterozygous Col4 mutations who usually present with late changes in kidney function, aggravate earlier due to additional heterozygous podocin mutations. Finding the key players in these interactions could lead to a better understanding of fibrogenesis and new therapeutic targets for common glomerular diseases.

SA-PO805

Small Dense Low-Density Lipoprotein Cholesterol, and Its Clinical Features in Patients with Nephrotic Syndrome

Mayumi Miyamoto,[1] Hidenori Yamazaki,[1] Fumihiro Tomoda,[1] Tsutomu Koike,[1] Satoshi Kagitani,[1] Taizo Nakagawa,[1] Hiroshi Inoue,[1] Masataka Takiwaki,[2] Yoshinori Uji,[2] Isao Kitajima.[2] *[1]The Second Department of Internal Medicine, University of Toyama, Toyama, Japan; [2]The Department of Clinical Laboratory and Molecular Pathology, University of Toyama, Toyama, Japan.*

Background: Nephrotic syndrome (NS) is commonly complicated with hyperlipidemia. Recently, small dense low-density lipoprotein cholesterol (sdLDL-C) has been highlighted as the most harmful lipoprotein on the cardiovascular system. In this study, the associations of sdLDL-C and other lipid parameters to urinary proteinuria and oxidative stress were investigated in patients with NS.

Methods: Fourteen patients with NS (NS group) and 28 age-matched healthy subjects (control group) were enrolled into the study. NS was due to minimal change disease (MCD) in 7 patients and membranous nephropathy (MN) in the remainders. Plasma levels of sdLDL-C (using assay kit supplied by Denka Seiken Co., Ltd., Niigata, Japan), low-density lipoprotein cholesterol (LDL-C), triglycerides (TG), high-density lipoprotein cholesterol (HDL-C) were measured. Urinary protein excretion, eGFR and plasma 8-hydroxy-2'-deoxyguanosine (8-OHdG, i.e. a marker for oxidative stress) were also evaluated.

Results: sdLDL-C as well as LDL-C and TG were significantly greater in NS than in control group (69±12, 198±21, 219±37 mg/dL in NS vs 18±1, 63±4, 76±6 mg/dL in control) despite no difference of HDL-C among both groups. In NS group, LDL-C positively correlated with urinary protein excretion ($r= 0.623$, $p< 0.05$), but not with eGFR. Additionally, ratio of sdLDL-C to LDL correlated positively with plasma 8-OHdG ($r= 0.152$, $p< 0.05$), although LDL and sdLDL-C did not associate with it. In contrast, TG and HDL-C did not relate with urinary protein excretion or plasma 8-OHdG in NS group. There was no difference of eGFR, proteinuria and lipid profiles between the patients with MCD and MN.

Conclusions: These results indicated that in NS group, (1) sdLDL-C elevates together with the other lipids and (2) Increased LDL and elevated fraction of sdLDL-C within LDL-C could lead to the aggravations of proteinuria and oxidative stress, respectively.

SA-PO806

Analysis of Gene *SOCS3* and *SOCS5* Sequencing in Children with Steroid-Resistant Nephrotic Syndrome

Danuta Ostalska-Nowicka,[1] Katarzyna Zaorska,[2] Jacek Zachwieja,[1] Michal Janusz Nowicki.[2] *[1]Poznan University of Medical Sciences, Department of Pediatric Cardiology and Nephrology, Poznan, Poland; [2]Poznan University of Medical Sciences, Department of Histology and Embryology, Poznan, Poland.*

Background: The strong evidence of the immunologic factors in the pathogenesis of idiopathic nephrotic syndrome (INS) is known. Glucocorticoids (GCs) are generally applied and highly effective drugs in most cases of INS and steroid responsiveness is the major determinant of prognosis of the disease. Approximately 85-90% of patients with INS respond to glucocorticoid treatment, but 10-15% have partial or no response to GC. Children with SRNS (steroid resistant nephrotic syndrome) progress to end-stage renal failure. There is evidence that either in SSNS or SRNS group of patients, regardless of histological diagnosis, several elements of the Jak/Stat signaling pathway are being excited. After 6-week glucocorticoid treatment expression of all analyzed elements in the SSNS group is back to the level compared to the control group, whereas in the SRNS group there are still high levels of only two elements – *SOCS3* and *SOCS5* transcripts, coding for suppressor proteins of the Jak/Stat pathway. Normal and increased transcription of these genes correlated with absence or presence of proteinuria.

Methods: Sequencing analysis of coding regions of genes *SOCS3* and *SOCS5* was conducted in three groups: *study group 1* counting 40 SRNS patients, *study group 2* counting 30 SSNS patients and *control group* of 30 healthy individuals. All results were establish in terms of Hardy-Weinberg Equilibrium. Odds ratio value (OR) was based on frequencies of alleles and genotypes and SNP (single nucleotide polymorphism) analysis was provided with gene structure based on Haploview software.

Results: We found eight SNP within *SOCS1*, 6 SNP in *SOCS3* and 18 SNP in *SOCS5* (heterozygotic: 2, 1 and 6).

Conclusions: The results showed no significant differences in OR value among the three groups, although *SOCS5* gene structure showed weaker linkage between heterozygous SNPs in SRNS group than in SSNS and control group.

SA-PO807

Urinary Proteins Can Be Reliably Measured after Five Years of Frozen Storage

Rutger J. Maas,[1] Ruben L. Smeets,[2] Hans J.L. Willems,[2] Jeroen Deegens,[1] Jack F. Wetzels.[1] *[1]Nephrology, Radboud University Nijmegen Medical Centre, Netherlands; [2]Laboratory Medicine, Radboud University Nijmegen Medical Centre, Netherlands.*

Background: Little is known about the effects of prolonged frozen storage (>1 year) on the stability of urinary biomarkers. We investigated the recovery of various urinary proteins after prolonged storage at -80°C.

Methods: We used urine samples from a mixed population of 30 adult patients with glomerular diseases or tubulo-interstitial nephritis. All urine samples had a pH >6.0 after premedication with sodium bicarbonate, and bovine serum albumin was added prior to

storage. The fresh measurements were performed on the same day as collection. Analyses of urine biomarkers were performed after a median storage of 5.0 years (range 2.1 - 9.0 years) at -80°C in the same samples.

Results: Median proteinuria in fresh urine samples was 4.5 g/10 mmol creatinine (IQR 2.2 – 9.6 g/10 mmol). Sodium quantification was highly reproducible, indicating that the storage procedures were adequate and not affected by evaporation (Table). There was a strong correlation between repeated measurements. After correction for interassay variation from quality control pools, the large majority of measured protein concentrations were within 99% confidence limits.

Conclusions: The current set of urinary protein concentrations were stable after prolonged storage at -80°C.

Urinary markers at fresh measurement and after frozen storage

	Fresh	After storage at -80°C	Coefficient of determination	Overall (inter)-assay variation (CV%)	Samples with difference within 3 CV (%)
Sodium (mmol/l)	60 (40-74)	60 (41-74)	0.99	0.7	68
IgG (mg/l)	69 (19-121)	67 (20-120)	0.99	4.5	93
Transferrin (mg/l)	72 (24-190)	63 (29-187)	0.98	4.7	93
Alpha 1-microglobulin (mg/l)	37 (16-70)	36 (16-71)	0.98	3.4	83
Beta 2-microglobulin (mg/l)	1.3 (0.3-7.4)	1.5 (0.4-6.2)	0.98	5.8	85

Concentration expressed as median (IQR)

Higher Precision of Urinary Protein/Creatinine Ratio Compared with 24 Hours Protein Excretion in Kidney Diseases Gianluigi Ardissino, Sara Testa, Francesca Tel, Stefani Rotondo, Luciano Sangaletti, Paolo Vercelloni, Luisa Napolitano, Marieclaire Allaz, Nora Bettinardi. *Center for HUS Control, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy.*

Background: Proteinuria, an important biomarker in all nephropathies, is commonly measured as urinary protein excretion on 24-hour timed collection (PE24hrC) a time consuming, burdensome, often unreliable method. In the pediatric setting, the urinary protein-over-creatinine ratio (uPr/uCr) on spot samples is widely employed as surrogate marker of PE24hrC but, to the best of our knowledge, the reliability of uPr/uCr has only been compared with PE24hrC assuming the latter as a gold standard rather then analysing respective precision and accuracy. The present study compares the precision (degree to which repeated measurements under unchanged conditions show the same results) of the two methods of assessing proteinuria (PE24hrC vs uPr/uCr) in a selected group of patients with stable renal disease with the working hypothesis that the most precise method is the one with lowest coefficient of variation (CV).

Methods: Ten patients with longstanding and well documented stable renal disease (hypodisplasia, FSGS and HUS in remission) were provided written instruction on how to perform 4 sets of urine sampling within a short period of time. Each set included a 24hrC and 4 urine samples collected any time during the day in different days across the urine collection (total of 120 determinations). The mean CV of proteinuria was calculated for the PE24hrC and for uPr/uCr as single sample as well as for the mean of 2, 3 and 4 samples assuming that, in patients with stable disease, the CV of proteinuria, with any method, should approach 0, by definition.

Results: The mean CV for PE24hrC was 31.1 while for uPr/uCr it was 29.4, 29.4, 25.5 and 22.7% for 1, 2, 3 and 4 sampling, respectively.

Conclusions: The best method for assessing proteinuria in patients with kidney diseases, as to precision, is uPr/uCr and, even on a single sample it has a higher precision than PE24hrC. However the mean of 4 samples has the lowest CV and therefore the highest precision.

The Importance of Screening for Proteinuria in Women of Childbearing Age Jwa-kyung Kim, Jisuk Han, Myung Jin Choi, Sung Gyun Kim. *Internal Medicine, Hallym University Sacred Heart Hospital, Kidney Research Institute, Republic of Korea.*

Background: Detection of protein in the urine, even relatively small amount, can be early sign of kidney damage and often precede a detectable decline in glomerular filtration rate (GFR). Particularly, proteinuria in young-aged women has greater significance because of the possibility for pregnancy. The purpose of this study is to evaluate the prevalence and diagnosis of proteinuria in childbearing-aged women.

Methods: A total of 10,385 Korean women between 20 and 39 years of age, who received health examination from January 2011 to December 2011 were surveyed. Patient were tested for proteinuria with dipstick (-,±,1+,2+,or 3+) and abnormal level of proteinuria was defined as 1+ or greater. Persistent proteinuria was established by confirming proteinuria on subsequent test a week or two after the initial test. In addition, the histopathologic types of kidney diseases in the young-aged women were also evaluated using the renal biopsy data in the ProgressiveREnal disease and Medical Informatics and gEnomics Research (PREMIER) program supported by the Korean Society of Nephrology.

Results: At initial test, abnormal proteinuria was detected in 227 (2.2%) patients: 1+ (184,1.8%), 2+ (40,0.4%) and 3+ (3,0.03%). Among these, 59 (26.0%) patients had repeated testing, and 33 (55.9%) of them showed positive results. Therefore, about 1.2% of patients showed persistent proteinuria. Patients with persistent proteinuria had higher body mass index, lower GFR, and elevated fasting glucose than those with transient proteinuria. However, further diagnostic work-up was performed only about half of the patients with persistent proteinuria (18/33,54.5%). According to the PREMIER data, definite difference in the histopathologic lesions was observed between young-aged women (20–40years) and old-aged women (>40years): the incidence of IgA nephropathy and lupus nephritis was significantly higher, but that of crescentric glomerulonephritis, membranous nephropathy, and diabetic nephropathy was significantly lower.

Conclusions: Approximately 1.2% of women in childbearing age have persistent proteinuria. Specific attention and consultation for further diagnostic work-up is needed.

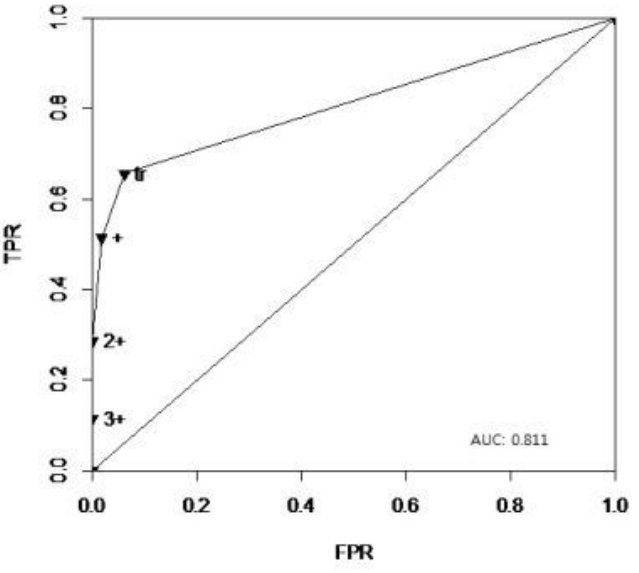
SA-PO810

How to Interpret Trace Result in Urine Dipstick Test for Proteinuria? Beom Kim, Dongyoung Lee, Hye Won Kim, Joong Il Park, Kyoung Hyoub Moon, Soohyun Yang. *Internal Medicine, Veterans Health Service Medical Center, Seoul, Kuwait.*

Background: Urine dipstick test(DIP) is often used for screening for proteinuria owing to simplicity. But it is uncertain we should regard trace result as positive for overt proteinuria. We compared urine dipstick test to spot urine protein to creatinine ratio(PCR) to investigate how to interpret trace result.

Methods: We extracted DIP and PCR results from medical record of Korean Vietnam war veterans who applied for medical check checkup for agent orange poisoning. Regarding PCR as true value, we calculated sensitivity(SN) and specificity(SP) for DIP(cutoff: trace, 1+, 2+). We used KDIGO guideline for PCR result interpretation.

Results: Two hundred sixteen laboratory results were available from as many patients(M: 215). Their median age was 65(61~80). Positive PCR was shown in 6.6%(12/182) of negative DIP, 38.5%(5/13) in trace DIP, 72.7%(8/11) in 1+ DIP and 100%(10/10) in 2+ and 3+ DIP. SN and SP for trace cutoff were 65.7, 93.9%, for 1+ cutoff were 51.4, 98.3%, for 2+ cutoff 28.6, 100%. Area under the curve in ROC curve was 0.811.



Conclusions: To increase SN for proteinuria, it is advisable to regard trace results as positive for proteinuria in mass screening.

SA-PO811

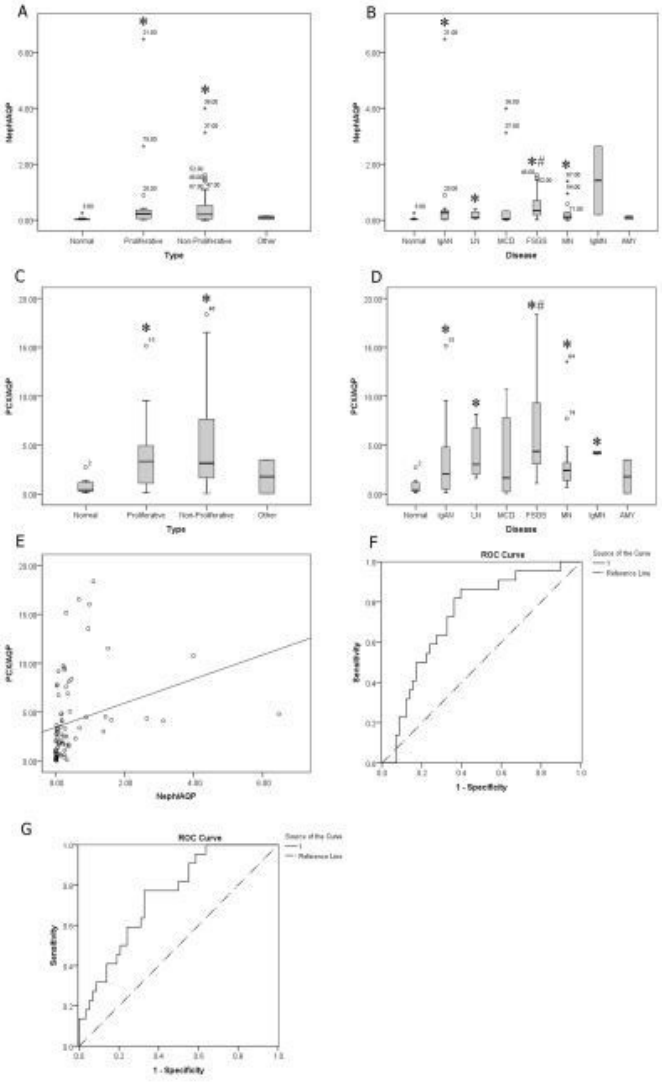
ELISA Analysis of Urinary Nephrin and Podocalyxin Standardized by Aquaporin-2 in the Adult Patients with Nephrotic Syndrome Bin Zhu, Xiaoling Zhu, Yi Lin, Caifeng Zhu, Xiao-xia Cheng, Hongyu Chen, Yongjun Wang. *Department of Nephrology, Hangzhou Hospital of Traditional Chinese Medicine, China.*

Background: To investigate the urinary nephrin and podocalyxin excretion standardized by AQP-2 with ELISA method in the adult nephrotic syndrome patients.

Methods: 71 adult nephrotic syndrome patients including 20 proliferative nephritis patients(13 IgAN, five lupus nephritis, two IgMN), 49 non-proliferative patients(11 MCD, 22 FSGS, 16 MN) and the other two amyloidosis patients. Ten healthy persons were enrolled as the control group. Urinary nephrin, podocalyxin and AQP-2 were measured using the ELISA method. Urinary nephrin and podocalyxin were standardized by AQP-2 (neph/AQP and PCX/AQP).

Results: Urinary neph/AQP correlated positively to PCX/AQP ($r=0.616$, $P<0.001$,Figure 1 E.). Urinary neph/AQP and PCX/AQP were lowest in the normal persons as compared with the nephrotic syndrome patients(Figure 1 A-D). Both proliferative and non-proliferative nephrotic syndrome patients excreted more urinary neph/AQP and PCX/AQP without a significant difference between them ($P>0.05$, Figure 1 A,C). FSGS patients excreted higher neph/AQP and PCX/AQP in the urine than those in the other patients ($P<0.05$,Figure 1 B,D). For the diagnosis of FSGS, a ROC curve analysis indicated that

the sensitivity value is 0.864 while the specificity value is 0.603 when the urinary neph/AQP borderline value was 0.165, and the sensitivity value is 0.773 while the specificity value is 0.672 when the urinary PCX/AQP borderline value was 3.056(Figure 1 F,G).



A.Urinary neph/AQP among proliferative, non-proliferative and renal amyloidosis patients.*: P<0.05, vs. Normal.
B. Urinary neph/AQP among different nephrotic syndrome patients. *: P<0.05, vs. Normal; #: P<0.05, VS MN patients.
C.Urinary PCX/AQP among proliferative, non-proliferative and renal amyloidosis patients.*: P <0.05, vs. Normal.
D. Urinary PCX/AQP among different nephrotic syndrome patients. *: P <0.05, vs. Normal; #: P <0.05, VS MN patients.
E. Urinary neph/AQP correlated positively to urinary PCX/AQP.
F. ROC curve analysis of neph/AQP for the diagnosis of FSGS.
G. ROC curve analysis of PCX/AQP for the diagnosis of FSGS.

Conclusions: Urinary neph/AQP and PCX/AQP by an ELISA method were both significantly increased in the proliferative and the non-proliferative glomerulonephritis patients. FSGS patients excreted higher neph/AQP and PCX/AQP. It is also possible to distinguish FSGS patients from other nephrotic syndrome patients using this method.

Validation of AcSDKP-NH2 as a Non Radioactive Peptidic Marker of Glomerular Filtration Rate in Humans

Anne Blanchard,[1] Matthieu Monge,[1] Cedric Gauci,[2] Cedric Mesmin,[3] Dominique Prie,[2] Eric Ezan,[3] Michel Azizi.[1]
[1]Clinical Investigation Center, Assistance Publique - Hôpitaux de Paris, Paris, France; [2]Renal Physiology, Assistance Publique - Hôpitaux de Paris, Paris, France; [3]CEA, CEA Valrho, Bagnols Sur Ceze.

Background: The natural hemoregulatory peptide AcSDKP is degraded by angiotensin I converting enzyme (ACE) and eliminated in the urine by glomerular filtration in humans. We have shown that 1) the amidated form of AcSDKP (AcSDKP-NH_2) is not hydrolysed by murine or human ACE *in vitro* and, 2) measurements of the urinary clearance of AcSDKP-NH_2 and of tritiated inulin in rats give identical results, suggesting that AcSDKP-NH_2 could be used as a new GFR marker (patent N°: WO2004/096292 ;US2008/0199397A1). The objective is to validate AcSDKP-NH_2 as a GFR marker in humans.

Methods: We performed an open label equivalence phase I study where AcSDKP-NH_2 (bolus 0.4 µg/kg, 0.2 µgmin/100 mL eGFR) and inulin (bolus 30 mg/Kg, 15 mg/min/100 mL eGFR) were simultaneously infused during 4h15 to 25 healthy normotensive male subjects (aged 18-35 yrs) with a normal eGFR (MDRD). AcSDKP-NH_2 was measured by an original chromatography/tandem mass spectrometry (LC/MS/MS) assay. Urinary clearance of each marker was calculated. Results are expressed as median [IQR]. The primary end-point is the equivalence between the urinary AcSDKP-NH_2 and inulin clearances.

Results: eGFR (MDRD) was 121 [112 ; 130] ml/min/1,73 m^2. Inulin and AcSDKP-NH_2 urinary clearances were 102 [94 ; 124] and 112 [102 ; 121] ml/min/1,73 m^2, respectively. In the Bland Altman plot, the bias between the two methods was 5 (95%CI: -1; 15) ml/min/1,73 m^2 (p=0.0499). The AcSDKP-NH2 injection was well-tolerated.

Conclusions: This study validate for the first time that AcSDKP-NH_2 is a new and peptidic marker for GFR measurement in humans. Measurements in CKD patients are ongoing.

Funding: Government Support - Non-U.S.

SA-PO813

Diagnostic Cut-Off Values of Creatinine and Cystatin C for Severely Impaired Renal Function in Chinese Children with Kidney Injuries

Mengchun Gong, Xuemei Li. *Dept. of Nephrology, PUMC Hospital, Beijing, China.*

Background: There is no data about the normal range of serum creatinine, either measured by the Jaffe method (CrCA) or the enzymatic method (CrE), or cystatin C (CysC) in the Chinese children.

Methods: We determined GFR with plasma clearance of ^{99m}Tc-DTPA in 92 hospitalized children with renal injury and analyze the cutoff value of CrCA, CrE and CysC for diagnosing GFR lower than 60mL/min/1.73m^2, using the Receiver Operating Curve (ROC) analysis. The serum were sampled and divided on morning of the day of GFR measurement, stored at -80 degrees centigrade and measured in the central lab with standard quality control.

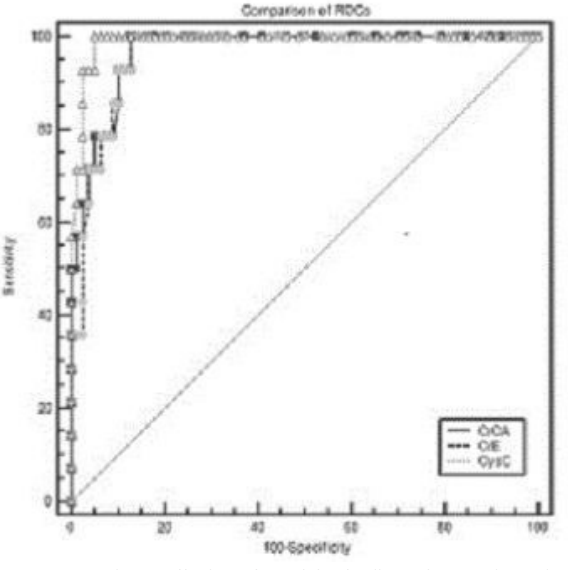
Results: In the 92 children, 49% were male and the mean age was 13 (IQR [10,15]) years old. Their mean GFR was 99.8 (IQR [73.5, 117.7]) mL/min/1.73m^2. The results of ROC analysis, divided by Age=14, are shown in Table 1. The AUC were close to 1 and indicated satisfactory diagnostic power of CrCA, CrE and CysC.

Results of ROC Analysis

	Age	AUC	Cut-Off Value	Se %	Sp %
CrE (µmol/L)	≥14	0.964*	84	100	90
	<14	0.983*	47	100	94
CrCA (µmol/L)	≥14	0.984*	102	100	94
	<14	0.986*	62	100	94
CysC (mg/L)	≥14	0.992*	1.29	100	97
	<14	0.987*	1.46	100	94

*all with p<0.0001; AUC, area under curve; Se, sensitivity; Sp, Specificity; +LR, positive likelihood ratio; -LR, negative likelihood ratio

Paired ROC comparison between CrCA, CrE and CysC showed that in the whole group, not divided by age of 14, the area under the ROC of CysC is significantly greater than the other two (both P<0.05).



Conclusions: The cut-off values of Creatinine for diagnosing GFR lower than 60 mL/min/1.73m^2, measured either by Jaffe method (CrCA) or enzymatic method (CrE), differ a lot between different age groups. The cut-off value of CystatinC, on the other side, remains stable between the two age groups and a CysC level over 1.4mg/L should be highly suspected as an indicator for severely impaired renal function.

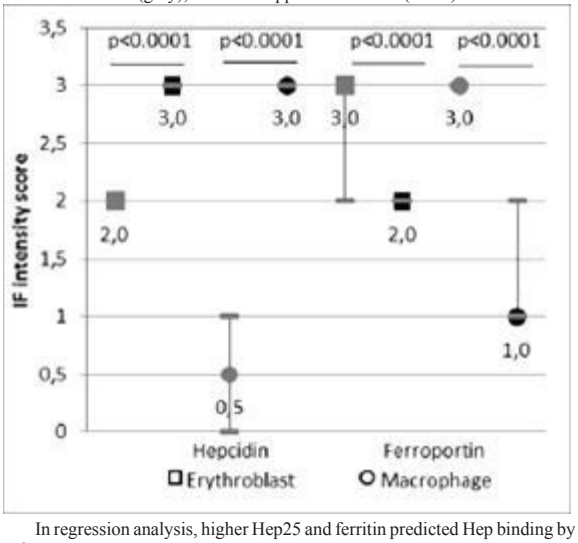
SA-PO814

Bone Marrow Iron Distribution, Hepcidin and Ferroportin Expression in Renal Anemia Liliana Barsan,[2] Simona Stancu,[1] Ana Stanciu,[2] Cristina Capusa,[1] Gabriel Mircescu.[1] *[1]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania; [2]"Dr Carol Davila" Hospital of Nephrology, Bucharest, Romania.*

Background: The hepcidin-ferroportin system is involved in both conditions associated with iron-restricted erythropoiesis in renal anemia: iron deficiency anemia (IDA) and anemia of chronic disorders (ACD). As serum hepcidin could have diagnostic utility, we investigated its relationships with iron distribution, hepcidin (Hep) and ferroportin (Fpn) expression in bone marrow (BM) cells, and peripheral iron indices (ferritin; transferrin saturation) in non-dialysis chronic kidney disease (CKD) patients.

Methods: Prospective observational single center study on 54 CKD patients, epoetin and iron naïve, classified according to BM iron distribution (Perls' stanin) as IDA (n=26), ACD (n=21) or normal iron stores (n=7). Hep and Fpn expression by erythroblast and macrophage was evaluated by immunofluorescence on semiquantitative scales. Serum hepcidin (Hep25) was measured by ELISA (Bachem, UK).

Results: Low Hep and high Fpn expression by erythroblast and macrophage (Figure) were seen in IDA (grey), while the opposites in ACD (black).



In regression analysis, higher Hep25 and ferritin predicted Hep binding by erythroblast (R^2= 0.48; p<0.0001), while lower ferritin and Hep25 predicted erythroblast Fpn expression (R^2=0.29; p=0.003). Inflammation had no contribution. In ROC analysis, Hep25 and ferritin had similar moderate utility in differentiating IDA from ADC (AUC 0.63 95%CI 0.47–0.79 and 0.76 95%CI 0.61-0.90, respectively).

Conclusions: In anemic CKD patients, hepcidin and ferroportin expression by erythroblast and macrophage are correlated and closely related to BM iron distribution. Although the hepcidin-ferroportin system reaction seems to be regulated by the ferritin-driven Hep25, serum hepcidin and peripheral iron indices are of little help in describing bone marrow iron status.

SA-PO815

Hematuria Following Exercise Prem P. Varma,[1] Prashant Sengupta,[1] Ranjith K. Nair.[1] *[1]Department of Nephrology, Army Hospital (Research & Referral) Delhi Cantt-10, New Delhi, Delhi, India; [2]Department of Pathology, Army Hospital (Research & Referral) Delhi Cantt-10, New Delhi, Delhi, India; [3]Department of Nephrology, Army Hospital (Research & Referral) Delhi Cantt-10, New Delhi, Delhi, India.*

Background: Incidence of Exercise induced hematuria has been reported to be between 5-30%. Available literature suggests that it lasts for few hours to a maximum of 3 days. *Aim:* We planned to study incidence and duration of hematuria after a 5 km run in soldiers who are accustomed to 1.5-2 km run 5 days a week.

Methods: All fit and healthy soldiers without any co-morbidities, who volunteered to participate in the study were the subjects. They ran for 5 km at 0630 h. There was no water intake permitted during the run. Timings for the successful completion of run was 25 minutes for those below 30yrs and it was 26.5 and 28 mts for those between the age of 30-40yrs and 40-50 yrs respectively. Urine sediment of soldiers was examined before and after the run. Anyone with an abnormal pre-exercise sediment was excluded from the study. All those who had post exercise hematuria were followed with daily urine examination and those who continued to have hematuria beyond 14 days were thoroughly evaluated and subjected to renal biopsy also.

Results: 491 participants completed the run successfully and fifty nine of them (12%) developed post exercise hematuria. We found that the younger participants (age < 30 yrs) had a significantly higher incidence of hematuria as compared to their older compatriots (p=0.019). Mean duration of hematuria was 1.98 +/- 1.89 days. Hematuria cleared in 81% of the participants within 3 days and in other 19% it persisted. Of these in 12% hematuria lasted between 3-7 days and in another 7% it continued beyond 7 days. Three individuals had persistence of hematuria beyond day 14 and all of them were found to have primary glomerular diseases on kidney biopsy (two had IgA nephropathy and one had FSGS).

Conclusions: Exercise induced hematuria can last upto a fortnight and if it persists beyond a fortnight an underlying cause is likely. We feel hematuria is possibly related to intensity of exercise as in our study younger participants who had lesser time to complete the run had higher incidence of hematuria.

SA-PO816

Hepatitis C Virus P22 Antigen Test: Serological Response, Diagnostic Advantages and Cost Effectiveness in a Tertiary Care Haemodialysis Centre Subash Somalanka, Lennard Lee, David Makanjuola, John Clark. *Epsom & St Helier University Hospitals NHS Trust, London, United Kingdom.*

Background: p22 ELISA stains for a part of the nucleocapsid of Hepatitis C Virus (HCV) genome & has recently become commercially available. The current recommendation is to use ELISA to check for antibodies against HCV. We present a case of acute HCV infection in a tertiary renal unit with subsequent screening, source identification & follow up of all the Haemodialysis [HD] patients & staff who might have had contact with the index case. Serological response, alanine transaminase[ALT], HCV antibody[Ab], HCV p22 antigen[Ag], HCV RNA PCR test, advantages of p22 Ag test & financial implications are discussed.

Methods: Blood samples were obtained from the index patient. ALT, p22 Ag, HCV Ab & RNA PCR were performed retrospectively. 165 patients were investigated. p22 HCV Ag test was used as a screening test which being less sensitive than PCR required a week of additional screening.

Serological tests of the index case

Time[Weeks]	ALT[5-40 IU/L]	HCV Ab	p22 Ag[<3 fmol/L]	RNA PCR[<50 IU/ml]
0	26	-	-	-
2	22	-	3474	140,000
8	394	-	>20,000	2,100,000
11	474	+	2399	106,000
16	181	+	6573	558000

Results: Following screening, 1 patient previously known to have HCV was found to have the same HCV genotype as the index case. Gene sequencing showed only 2 different base pairs, suggesting that this individual was the source of transmission. Additional cost implications to the renal unit were minimised by the use of p22 Ag test in comparison to RNA PCR (£12 Vs £40 per test). p22 Ag test was run on an existing automated serological testing platform [ARCHITECT i2000 SR]. It was cheaper, easy to run & had a rapid result turnover.

Conclusions: p22 Ag ELISA is a robust, cheap & reliable test that allows for earlier detection of HCV viraemia. This would be of crucial importance in patient subgroups that need early treatment or where early detection is required to reduce risk of cross-transmission. Even though the HCV PCR was more specific & sensitive, p22 Ag ELISA can be used as a cost effective way of early serological diagnosis. It would also be useful in patients who fail to mount an adequate Ab response.

SA-PO817

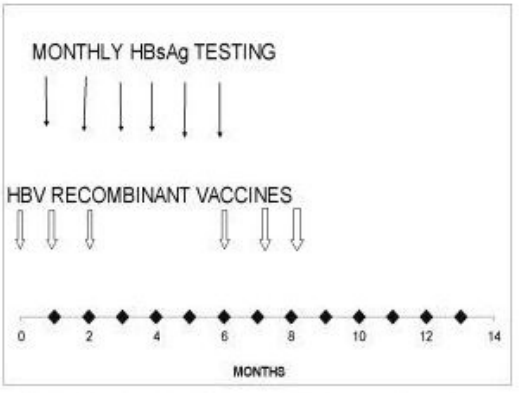
Transient Post-Vaccination Recombinant HBsAgenemia among ESRD Patients: How Common Is This Phenomenon? What Implications for Dialysis Care? Macaulay A. Onuigbo,[1] Nnonyelum T. Onuigbo.[2] *[1]College of Medicine, Mayo Clinic; [2]Information Technology, NTEC Solutions.*

Background: Hepatitis B Virus (HBV) infection affects millions worldwide, and constitutes a serious public health scourge; complications including heptaocellular carcinoma, liver failure and death. Hemodialysis (HD) exposes ESRD patients to significantly higher risks of de novo HBV infection. Therefore, current US CDC guidelines call for monthly HBsAg testing for all HD patients, perpetuated indefinitely. Furthermore, US CDC guidelines stipulate 100% coverage of all ESRD patients with Recombinant HB vaccinations, usually administered in a series of 3-4 scheduled booster doses. The phenomenon of transient post-vaccination Recombinant HBsAgenemia soon following HB vaccinations, which could be easily mistaken for de novo HBV infection, with dire consequences to the patient, has been rarely reported. The incidence in a routine HD Unit over 10 years has rarely bee studied.

Methods: We retrospectively analyzed our Mayo Clinic Renal Database for all patients seen in Northwestern Wisconsin, July 2000-July 2010, to ascertain the frequency of such phenomenon.

Results: The electronic databases and paper records of 965 HD patients were analyzed. One case of falsely positive HBsAg was detected. We described this rare phenomenon in an 81-year old HD patient in 2010, two days after the first of three planned Engerix B vaccines.

Conclusions: This scenario of indefinitely repeated monthly HBsAg screening tests among all HD patients, superimposed on often repeated series of Recombinant HB vaccination booster doses, lends itself to the potential of errors of false positive HBsAg test from vaccine-related Recombinant HBsAgenemia (Fig 1). It appears rare in routine ESRD care. We however re-echo previous recommendations that HD patients must not be screened for HBsAg for at least 4 weeks following a Recombinant HB vaccination.



The scenario of increasing potential for falsely positive post-vaccination Recombinant HBsAgenemia resulting from repeated monthly HBsAg testing among ESRD patients who receive multiple doses of HB Recombinant vaccinations in series together with sometimes the need for repeated booster HB vaccine doses.

SA-PO818

Imbalance of CCN2/CCN3 as a Marker for Detecting Glomerular Matrix Expansion Long Chen, Min Zheng, Dan Liu, Linli Lv, Bi-Cheng Liu, Jiandong Zhang. *Institute of Nephrology, Southest University, Nanjing, China.*

Background: Accumulating evidence suggests that members of CCN family proteins such as connective tissue growth factor (CCN2) and nephroblastoma overexpressed (CCN3) play important role in remodeling extracellular matrix.

Methods: We initially examined CCN2, CCN3 expression in a dynamic period of anti-Thy1 glomerulonephritis. Next, we asked whether the imbalance of CCN2/CCN3 seen in our animal experiments has its clinical implication as a biomarker in detecting glomerular histological changes. Our previous study suggested that urinary mRNA measurement is a powerful tool to monitor renal damages in patients with chronic kidney diseases (CKD). We investigated whether urinary mRNA of CCN2 and CCN3, can provide some clinical insight into the management of patients with CKD with a total of 35 patients with CKD and 12 healthy volunteers.

Results: Our results indicated that both mRNA expression of CCN2 and CCN3 was increased in nephritic glomeruli isolated from rats 4 days after injection of OX-7 Ab (16.85±1.36 au; 4.4±0.52 au,), as well as their protein level (1.14±0.1 vs. 0.68±0.04au, $p<0.01$; 0.6±0.05 vs. 0.33±0.04au,$p<0.01$). Intriguingly, enhanced mRNA expression of CCN3 was shown to decline by 40.3% in d6 nephritic glomeruli (3.03±0.18 au), by contrasting to steadily exaggerated expression of CCN2 (29.3±6.88 au). Of note, this imbalance of CCN2/CCN3 in glomeruli was in coincidence with massive glomerular matrix accumulation as indicated by PAS score (65.2±3.1vs. 53.2±3.2, $p<0.05$).In CKD patients compared to healthy controls the results indicated that urinary mRNA of both CCN2 and CCN3 were distinctively greater. Urinary mRNA of CCN3 was shown to inversely correlate to the degree of glomerular histological changes(r=-0.615, p=0.009). Furthermore, the ratio of urinary mRNA of CCN2 to CCN3 had an even stronger correlation efficient with glomerulosclerosis(r=0.647, p=0.005).

Conclusions: Our study demonstrates that the ratio of CCN2/CCN3 urinary mRNA correlates to the degree of glomerular histological changes in CKD patients, suggesting that imbalance of CCN2/3 may be a useful marker for evaluating CKD.

Gas Chromatography: A New Opportunity of Renal Diseases Diagnostics P. Miarka,[1] B. Grabowska-Polanowska,[2] J. Faber,[2] M. Skowron,[2] A. Pietrzycka,[3] P. Zagrodzki,[2] I. Sliwka,[2] Wladyslaw Sulowicz.[1] *[1]Dept. of Nephrology, UJ-CM, Poland; [2]Institute of Nuclear Physics of Polish Academy of Sciences, Poland; [3]Faculty of Pharmacy, UJ-CM, Poland.*

Background: During last decade, number of patients suffering from chronic kidney disease (CKD) has significantly increased. The physicians' efforts are focused on early CKD diagnosis and reduction of the end-stage renal diseases incidence. The breath test seems to be promising diagnostic device offering early noninvasive diseases detection. Trimethylamine (TMA) ismentioned in literature as potential marker of chronic kidney diseases. The aim of presented study was the determination of breath composition in persons suffering from CKD.

Methods: Exhaled air samples were enriched using solid phase microextraction (SPME) and analyzed by gas chromatography equipped with mass spectrometer (GC–MS).

Results: Breath samples were collected from 14 patients with CKD and 7 healthy volunteers. In the whole group of CKD patients the mean creatinine values were 171.2±74.2umol/l, urea 11.9±4.0mmol/l and eGFR 37.4±18.9ml/min/1/73m2. Trimethylamine was detected in 11 CKD patients and in none of control group. TMA mean values in exhaled air were 21.49±19.68ppb in CKD. Among breath components were also detected sulfur compounds such as dimethyl sulfide (DMS), carbon disulfide (CS_2) and also potential markers of oxidative stress. The presence of DMS in breath was confirmed in all participants. In CKD patients DMS concentrations ranged from 0.01 to 1.02nmol /l in control group from 0.05 to 0.39nmol/l $CS_2$was detected in all patients, and its concentration ranged from 0.009 to 0.15nmol/l. In the control group, in 4 out of 7 cases we detected CS_2 in the concentration range from 0.01 to 0.02nmol/l.TMA significantly correlated with eGFR ($r=-0.18$ $p<0.05$) and creatinine ($p<0.05$). Interestingly a significant correlation between DMS and eGFR ($r=-0.44$ $p<0.05$) was found. In addition, CS_2 correlated with creatinine ($r=0.44$ $p<0.05$) and uric acid concentration ($r=0.73$ $p<0.05$).

Conclusions: In the future, current diagnostic procedures (blood and urine tests, kidney biopsy) may be supplemented by detection of TMA concentration in human breath in early stages of chronic kidney diseases.

SA-PO820

Immunochemical Determination of Monomer, Homodimer and Total Neutrophil Gelatinase-Associated Lipocalin Kristian Bangert, Niels Rosenkilde, Jakob Ploug Jørgensen, Alexandra Baer, Lars O. Uttenthal. *BioPorto Diagnostics A/S.*

Background: NGAL (neutrophil gelatinase-associated lipocalin) released from the kidney in early acute kidney injury is reported to be chiefly in the monomer form, whereas NGAL released from neutrophils in inflammation contains a substantial amount of homodimer in addition to monomer. Immunochemical assays that can specifically measure monomer and homodimer forms of NGAL without the need for molecular size separation are therefore of interest for the rapid measurement of NGAL in different pathological conditions, as well as a total NGAL assay that measures monomer and homodimer forms identically.

Methods: By pairwise testing of a large series of mouse monoclonal antibodies raised against recombinant human NGAL in sandwich ELISA, we have developed immunochemical assays specific for monomer and homodimer NGAL, as well as an assay for total NGAL. The specificities of the assays were verified by means of recombinant human NGAL monomer and homodimer standards and peaks of native NGAL obtained by molecular exclusion chromatography of urine and plasma.

Results: The monomer NGAL assay cross-reacted <1% with homodimer NGAL and the homodimer NGAL assay cross-reacted <0.1% with monomer NGAL, while the total NGAL assay reacted equally with NGAL monomer and homodimer on a mass basis.

Conclusions: These assays are more convenient for the rapid analysis of different molecular forms of NGAL than methods involving molecular size separation and may aid in distinguishing between NGAL responses due to different pathological processes and of different cellular origin.

Plasma Basigin/CD147 as a Biomarker of the Kidney Diseases Mayuko Maeda, Tomoki Kosugi, Waichi Sato, Tomohiro Masuda, Hiroshi Nagaya, Kayaho Maeda, Yuka Sato, Hiroshi Kojima, Shoichi Maruyama, Seiichi Matsuo. *Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Japan.*

Background: Basigin (Bsg)/CD147 is a transmembrane glycoprotein, and contributes to cell survival, invasion and metastasis. Recently, we documented in the experimental studies that Bsg is involved in the pathogenesis of renal inflammation caused by ischemia and renal fibrosis. Regardless of the primary disease process, these are the key determinant of diseased kidney and the prognostic predictors of renal function. We therefore investigated whether Bsg could serve as a novel biomarker for a differential diagnosis and prognosis in kidney diseases.

Methods: Plasma and spot urine samples were collected from the 261 patients, who underwent renal biopsy in our affiliated hospitals between 2008 and 2011. They included minor glomerular abnormality (MGA) as a pathological control (n=13), lupus nephritis (LN; n=64), minimal change nephrotic syndrome (MCNS; n=45), diabetic nephropathy (DM; n=24), IgA nephropathy (IgAN; n=43), focal segmental glomerulosclerosis (FSGS; n=32), and membranous nephropathy (MN; n=40). Plasma and urine Bsg values were measured by ELISA. Bsg expression in kidneys was examined by immunohistochemistry staining. Particularly in lupus nephritis, we verified the benefit of Bsg, using histopathological index.

Results: In normal kidney, Bsg is mainly distributed in tubular epithelial cells, but not glomeruli. Its expression was extremely lower in atrophic tubules. In kidney diseases with active injury, Bsg was more detected in macrophages and fibroblasts around damaged tubules and blood vessels. Positive but weak staining for Bsg was observed in injured glomeruli. Indeed, there was the strong relationship between plasma Bsg and serum creatinine. Bsg values in plasma and urine were significantly higher in LN, MCNS, DM, FSGS and MN patients compared with MGA, but not IgAN. Particularly, Bsg values with LN showed strong correlation with histological index. These data indicate that Bsg may be one of reliable biomarkers for renal injuries.

Conclusions: Plasma Bsg may be a prime candidate for developing a new procedure for the evaluation of renal injury and the prognostic predictor.

SA-PO822

Urine Exosomal Ceruloplasmin: A Potential Biomarker of Early Kidney Disease Krishnamurthy P. Gudehithlu,[1] Amit J. Joshi,[1] Mark A. Kraus,[1] Peter D. Hart,[1] Jose A.L. Arruda,[2,3] George Dunea,[1,3] Ashok K. Singh.[1,2,3] *[1]Division of Nephrology, John H. Stroger, Jr., Hospital of Cook County, Chicago, IL; [2]Section of Nephrology, University of Illinois at Chicago and VAMC, West Side Division, Chicago, IL; [3]The Hektoen Institute of Medicine, Chicago, IL.*

Background: Urine exosomal proteins could act as fingerprints of glomerular and tubular cells and as such may offer new biomarkers for diagnosing early kidney disease. We investigated this by identifying in the urinary exosomes of renal disease patients abundant proteins that were present in low concentrations in control urine.

Methods: We isolated urine exosomes from biopsy-proven patients of membranous nephropathy (n=9), IgA nephropathy (n=7), lupus nephritis (n=10), focal segmental glomerulosclerosis (n=10) and normal controls (n=5) by differential centrifugation. Proteins were extracted from the exosomes and subjected to SDS-PAGE fractionation followed by liquid chromatography / tandem mass spectrometry (LC-MS/MS) analysis. A total of 88 proteins (probability score of 95% or more) were identified that were abundant in urinary exosomes of patients and present at low concentrations in controls. Among them, we selected three proteins, ceruloplasmin, nephrilysin and alpha-1-antitrypsin, for further investigation. The three selected proteins were quantified in the urine exosomal extracts by ELISA.

Results: Quantitative results showed that of the three proteins ceruloplasmin was the most promising; it was 30-60 fold higher in the exosomal extracts of renal disease patients (expressed as ug ceruloplasmin/mg exosomal protein) and approximately 300 fold higher (expressed as ug exosomal ceruloplasmin/mg of urinary creatinine) than in controls. Increased ceruloplasmin levels correlated poorly with the degree of proteinuria in these patients suggesting that increased urine exosomal ceruloplasmin was specific to the underlying kidney disease rather than to increased leakage of systemic proteins.

Conclusions: We conclude that urinary exosomal ceruloplasmin is up-regulated in renal disease patients and may be a biomarker of early kidney disease.

Urinary Exosomes: A Novel Means to Non-Invasively Assess Changes in Renal Gene Expression Anja Susanne Muhlfeld,[1] Silvia Spanu,[2] Claudia R.C. van Roeyen,[1] Bernd Denecke,[3] Jürgen Floege.[1] *[1]Department of Nephrology and Clinical Immunologie, RWTH Aachen University, Aachen, Germany; [2]Department of Nephrology, University of Medicine and Pharmacy, Cluj-Napoca, Romania; [3]IZKF, RWTH Aachen University, Aachen, Germany.*

Background: In clinical practice there is a lack of markers for the non-invasive diagnosis and follow up of kidney disease. This study was designed as a proof-of-concept-study to evaluate urinary exosomes as diagnostic markers for kidney disease. Exosomes are membrane vesicles, which are secreted from their cells of origin into surrounding body fluids and contain proteins and mRNA which are protected from digesting enzymes by a cell membrane.

Methods: Toxic podocyte damage was induced by puromycin aminonucleoside in rats (PAN). Urinary exosomes were isolated by ultracentrifugation at different time points during the disease (day 0: prior to disease induction, day 5: at the beginning of proteinuria, day 10: at maximal kidney damage). Exosomal mRNA was isolated, amplified, and the mRNA species were globally assessed by gene array analysis. Tissue specific gene and protein expression was assessed by RT-qPCR-analysis and immunohistochemistry.

Results: Gene array analysis of mRNA isolated from urinary exosomes revealed cystatin C mRNA as one of the most highly regulated genes during the course of PAN. Its gene expression in urinary exosomes increased 7-fold by day 5 and remained high at a 2-fold increase until day 10. This was paralleled by a 2-fold increase in cystatin C-mRNA expression in the renal cortex. Protein expression in the kidneys also dramatically increased with *de novo* expression of cystatin C in glomerular podocytes, in parts of the proximal tubule and the renal medulla. Urinary excretion of cystatin C increased about 2-fold after the induction of podocyte damage.

Conclusions: In this proof-of-concept-study we could demonstrate that changes in urinary exosomal cystatin c mRNA expression are representative of changes in renal mRNA and protein expression during the course of PAN. Because cells lining the urinary tract produce urinary exosomal Cystatin C mRNA, it might be a more specific marker of renal damage than glomerular filtered free cystatin C.

Divergent Time-Dependent Prediction of the Severity of Mouse Folic Acid-Induced Kidney Fibrosis by Urinary Exosomal microRNA-27b Taro Horino,[1] Xuzhen Hu,[1] Takayuki Tsuji,[1,2] Alejandro Alvarez-Prats,[1] Ana Carolina Souza,[1] Robert A. Star,[1] Peter S.T. Yuen.[1] *[1]NIDDK, NIH, Bethesda, MD; [2]1st Department of Medicine, Hamamatsu University, Hamamatsu, Japan.*

Background: Epidemiological studies indicate that renal fibrosis is a predictor of rapidly declining kidney function during CKD, but more accessible biomarkers are needed. Urinary exosomes contain proteins, mRNAs, and miRNAs that can serve as biomarkers of renal injury. We tested how well urinary exosomal miRNAs, collected at different times post-injury, correlate with the degree of kidney fibrosis.

Methods: Outbred CD-1 mice (n = 7) were administered folic acid (FA) (250 mg/kg, i.p.) then urine was collected for 24 h in metabolic cages ending on days 2, 6, 10, and 14. Urinary exosomal fraction was isolated by 2-step centrifugation (17,000 x g for 15 min, and 200,000 x g for 1 hr). We measured 4 kidney-enriched miRNAs (miR21, miR27b, miR192 and miR200b) by RT-qPCR (Taqman). We scored the degree of kidney fibrosis at 14 days and compared it with urine concentrations of exosomal miRNAs.

Results: All 4 urine exosomal miRNA levels were elevated on day 2 post-FA; miR27b and miR200b were nearly maximum on day 2. Urinary miRNAs displayed a time-dependent correlation with fibrosis score. At day 6, all 4 urinary exosomal miRNAs were negatively correlated to fibrosis score; miR27b had the strongest negative correlation (r^2=0.793). At day 10, miRNAs were not correlated with fibrosis. At day 14, urine exosomal miR27b was again correlated to fibrosis score, but this time positively correlated (r^2=0.854).

Conclusions: We found that urinary exosomal miR27b predicted kidney fibrosis in the FA mouse model. Interestingly, the association was time-dependent: the correlation was negative early on (day 6) but changed to a positive correlation later (day 14). This switching could be explained by multiple roles for miR27b in renal tubule cells. This time dependence complicates the use of miR27b as a potential biomarker or therapeutic target for renal fibrosis, as time-dependent staging would be required to determine whether to inhibit or stimulate miR27b in order to treat the progression of kidney disease.

SA-PO825

Endogenous Human Inhibitor Interferes with Detecting microRNA-27b in Urine and Non-Exosomal Urine Fractions Taro Horino, Robert A. Star, Peter S.T. Yuen. *NIDDK, NIH, Bethesda, MD.*

Background: Urinary exosomal and non-exosomal miRNAs are potential biomarkers for acute and chronic kidney diseases, but we found that human urine contains an inhibitor of miRNA purification/detection. Therefore, we developed a more sensitive purification/assay system, then measured and validated the distribution of miR27b in different fractions of normal urine.

Methods: We separated healthy human or rat urine into 4 subfractions: 17K pellet, 17K supernatant, 200K supernatant, and 200K pellet (Exosomes). We compared 3 methods to purify miRNA [TRIzol, miRNeasy, or TRIzol/miRNeasy]. We measured [RNA] by NanoDrop, and [miR27b] by Taqman (RT-PCR) using synthetic, pure, mature miRNA standards. We validated assays by the Standard Addition Method (SAM; parallel addition of 4 known increasing amounts of pure miRNA to an unknown sample, then extrapolate to 0 addition).

Results: TRIzol/miRNeasy had the highest recovery of miR-27b. miR-27b was undetectable in supernatant fractions from 2 ml of human urine. Pure miR-27b recovery was inhibited by <5 µl of urine, with as much as 63% inhibition by 50 µl of urine. Inhibitory activity was not in mouse or rat urine, but was in human supernatant fractions. The urine inhibitor prevented miR-27b from binding to the purification column. We could reduce inhibitory activity by capturing the inhibitor on a first column then purifying the the flow-through on a second column. However, a simpler solution was to use 0.1 ml of urine, as all fractions were almost completely unaffected by inhibitory activity, which we validated by SAM. We found that in human urine 60% of mi-R27b was found in the 200K sup, 27% in the 17K pellet, and 13% in the 200K (exosomal) pellet.

Conclusions: We validated a sensitive assay for urinary miRNAs from 0.1 ml of urine, using a combined method (TRIzol/miRNeasy). In larger volumes of human urine or supernatant fractions, miR-27b could not be accurately assayed due to endogenous inhibitory activity. We postulate that inhibitor(s) could compete with miRNA binding to the purification column, lowering assay results (yield). Now that technical issues have been resolved, we can test miRNAs from each urine fraction as potential biomarkers for renal diseases.

SA-PO826

Urinary Expression of miR-21, miR-29 Family, miR-93 and TGF-β_1/SMAD Signaling Pathway Associated Molecules in Patients with IgA Nephropathy Gang Wang,[1] Yongcheng He,[2] Bc Kwan,[1] Kai-ming Chow,[1] Fm Lai,[1] Philip K.T. Li,[1] Cheuk-Chun Szeto.[1] *[1]Medicine & Therapeutics, The Chinese University of Hong Kong, Hong Kong, China; [2]Nephrology, Shenzhen University, Shenzhen, China.*

Background: MicroRNAs play important roles in the development and progression of renal fibrosis. We studied the expression of miR-21, miR-29 family, miR-93, miR-377 and miR-216a, together with messenger RNA of TGF-β_1, SMAD2, SMAD3, SMAD4 and SMAD7 in the urinary sediment of patients with IgA nephropathy.

Methods: We studied 43 patients with biopsy-proven IgAN. Urinary expression of miRNAs and mRNAs was determined and compared to that from 13 healthy controls.

Results: The urinary expression levels of miR-29b and miR-29c were significantly lower and the urinary expression levels of miR-93 was higher in patients with IgA nephropathy than normal controls. Proteinuria significantly correlated with urinary expression levels of miR-29b (r = -0.388, P = 0.003) and miR-29c (r = -0.409, P = 0.002). GFR significantly correlated with urinary expression levels of miR-21 (r = 0.338, P = 0.028), miR-29b (r = 0.333, P = 0.031) and miR-29c(r = 0.304, P = 0.050). Urinary expression level of miR-93 significantly correlated with glomerular scarring (r = -0.392, P = 0.010). There was significant correlation between the levels of urinary SMAD3 and miR-21 (r = 0.624, P < 0.001), miR-29b (r = 0.566, P < 0.001), miR-29c (r = 0.619, P < 0.001) and miR-93 (r = 0.332, P = 0.032). The level of urinary SMAD4 negatively correlated with the level of urinary miR-29c (r = - 0.325, P = 0.036).

Conclusions: We find the urinary expression of miR-29b and miR-29c is downregulated and miR-93 is upregulated in patients with IgA nephropathy. The expression of miR-29b and miR-29c significantly correlates with proteinuria and renal function and the expression of miR-93 significantly correlates with glomerular scarring. Our results suggest these miRNAs might play an important role in the pathophysiology of IgA nephropathy and the levels of urinary miR-29b, miR-29c and miR-93 have the potential to be developed as non-invasive markers for IgA nephropathy.

Evaluation of Disease State of Various Glomerulonephritis by the Levels of Claudin1 and CD68 mRNA in Urine Kojiro Yamamoto,[1] Takashi Oda,[1] Takahiro Uchida,[1] Atsushi Watanabe,[1] Hanako Takechi,[1] Naoki Oshima,[1] Yutaka Sakurai,[2] Hiroo Kumagai.[1] *[1]Nephrology, National Defense Medical Collage, Tokorozawa, Saitama, Japan; [2]Preventive Medicine and Public Health, National Defense Medical Collage, Tokorozawa, Saitama, Japan.*

Background: Urine test is non-invasive and can reflect more general condition of the whole kidney than findings of renal biopsy. We reported at the last ASN that the immunostaining for claudin1 (CLDN1) and CD68 of urinary sediment was useful for the evaluation of the activity of glomerular diseases. In order to confirm the finding at the mRNA level, we measured CLDN1 and CD68 mRNA using real-time RT-PCR.

Methods: We collected morning urine samples from 196 patients who had been hospitalized for kidney biopsy from '08 to '11. Total RNA isolated from sediments of collected urines was subjected to real-time RT-PCR. We used TaqMan Probes for CLDN1, CD68, and Aquaporin2 (AQP2) (all from Applied Biosystems). AQP2 was used as a kidney-derived reference gene. The relationship between relative levels of target mRNAs divided by AQP2 mRNA levels and the histological changes such as existence of crescent formation (CF) (with or without) or global sclerosis rate (under 30% global sclerosis is low and over 30% global sclerosis is high) was evaluated. We also evaluated the relationship of mRNA results with the state of glomerular crescents (cellular crescent (CC), fibro-cellular crescent (FCC), fibrous crescent (FC), and no crescent (NC)).

Results: The relative levels of the CLDN1 and CD68 mRNA were significantly increased in those patients with CF ($p<0.01$ and $p<0.01$, respectively). On the other hand, no significant differences in the relative levels of the CLDN1 and CD68 mRNA were found in relation to the global sclerosis rate. Interestingly, the relative levels of the CLDN1 mRNA was significantly increased in the patients with FC but was unchanged in those with CC or FCC. The relative levels of the CD68 mRNA was significantly increased in patients with CC but was unchanged in those with FC or FCC.

Conclusions: These data suggest that the quantification of the CLDN1 and CD68 mRNA (adjusted by AQP2 mRNA) of urinary sediment is useful for the evaluation of the state of the glomerular disease.

SA-PO828

Next-Generation Sequencing of Urinary microRNA in Human Lupus Nephritis Beatrice Goilav,[1] Iddo Z. Ben-Dov,[2] Irene Blanco,[3] Olivier Loudig,[4] Dawn Wahezi,[5] Chaim Putterman.[3] *[1]Nephrology, Children's Hospital at Montefiore, Bronx, NY; [2]Laboratory of RNA Molecular Biology, Rockefeller University, New York, NY; [3]Rheumatology, Albert Einstein College of Medicine, Bronx, NY; [4]Epidemiology, Albert Einstein College of Medicine, Bronx, NY; [5]Rheumatology, CHAM, Bronx, NY.*

Background: Lupus nephritis (LN) is associated with significant morbidity and mortality. microRNAs (miRs) are small non-coding RNAs that regulate translation. Previous studies report changes in miR expression in kidney tissue, urine and PBMC that correlate with LN disease activity. However, use of RNA deep-sequencing methods has not been previously described. We aimed at identifying miR expression patterns in LN by RNA sequencing.

Methods: Cell-free urine from adult (n=9) and pediatric (n=4) female patients with LN were obtained at time of active disease and in remission. Total RNA was used to prepare small RNA cDNA libraries for sequencing. Multiplexing through sample-specific 3' adapters was applied to limit batch effects and cost. Sequence reads were mapped to the human genome and small RNA databases. miRs were quantified by relative read abundance. qRT-PCR was used for quantitative validation.

Results: We obtained reproducible profiles of miRNA from cell-free urine. In a paired-sample analysis comparing miR abundance in urine of active vs inactive LN, we found significant changes in 19 miRs, including upregulation of miR-185, -328, and -423 by 400-1,000x during active disease. Differential read abundance was confirmed by qRT-PCR.

Conclusions: We detected miRs (most of which had not been previously linked to LN) with significantly higher presence in the urine during active LN. These miRs may be biomarkers of disease activity or indicators of specific histology. Several of the miRs we detected in the urine were previously found to be differentially expressed in PBMCs during active disease. This may imply that their presence in urine originates from infiltrating rather than kidney cells. Finally, upregulated miRs during active LN could point towards "protective" target genes that are repressed in relapse and identifying the latter may reveal new therapies.

Clinical Investigation of Galectin-1 in SLE Patients Yinghong Liu, Wenzhen Xie, Guochun Chen, Fuyou Liu. *Department of Nephrology, The Second Xiangya Hospital, Changsha, Hunan Province, China.*

Background: Galectin-1(Gal-1) is an endogenous glycan-binding protein which controls a diversity of immune cell processes and involved in immunoregulation. **Objectives** To analyze the expression of Gal-1 in the serum, urine and kidney tissues that derived from SLE patients with the aim of establishing a correlation between these parameters and the clinical profile.

Methods: 50 SLE patients were selected. Serum and urine were collected and the expression of Gal-1 was examined by ELISA .Kidney tissues were obtained from 36 LN patients. The expression of Gal-1 in the kidney tissues were analyzed by immunofluorescent or immunohistochemical staining.

Results: We found significantly enhanced level of Gal-1 in urine from SLE patients compared to controls. The urine levels of Gal-1 were significantly higher in SLE patients with active disease than inactive individuals.But no difference were observed between the urine Gal-1 level of inactive group and that of control group. We detected a significant positive association between the urine Gal-1 level and SLEDAI scores. Similarly, a positive correlation were observed between urine Gal-1 level and anti ds-DNA antibody titers, ESR, urine protein. And a negative correlation between the urine Gal-1 level and the serum total protein,seralbumin,complement C 3 were observed.Galectin-1 immunoreactivity was found in renal of LN cases, while control glomeruli were negative. The expression of Gal-1 in renal whose AI(acute indexes) were above 4 were significantly higher compare to that were less than 4.And a positive correlations were observed between the expression of Gal-1 and the AI,AI+CI(chronic indexes) and SLEDAI scores .However, no significant differences were found between the serum Gal-1 level of control group and that of SLE patients.

Conclusions: Our data suggest that urine Gal-1 could serve as a novel biomarker to predict the disease activity of SLE and involvement of kidney. As Gal-1 participates in modulating the immune system, we suggest that the presence of Gal-1 in the kidney may contribute to the immune deregulation observed in LN.

SA-PO830

Severe Lupus Nephritis: The Predicitve Value of a ≥50% Reduction in Proteinuria at 6 Months Stephen M. Korbet, Edmund J. Lewis, The Collaborative Study Group. *Nephrology, Rush University Medical Center, Chicago, IL.*

Background: In severe lupus nephritis (SLN), attainment of a complete remission (CR) in proteinuria (UPro) with treatment is associated with a favorable outcome. While the initial course of therapy can be up to 6 mo, the time to remission in the majority of patients is >6 mo and many don't attain a CR until after 12 mo. We assess the value of a ≥50% reduction in UPro at 6 months in predicting outcome in SLN pts.

Methods: We studied 86 adult pts in the prospective, controlled trial of plasmapheresis (PP) in SLN (NEJM 1992). All pts had ISN/RPS class IV ± class V (25 pts) lesions. All pts received pred and oral CYC and 40 pts received PP. Pts were categorized based their status at 6 months: (a) CR ≤6 mo, (b) ≥50% reduction in UPro, (c) <50% reduction in UPro, (d) ESRD/ death. The outcomes were compared between pts with ≥50% or <50% reduction in UPro at 6 mo. A CR was defined by a SCr of ≤ 1.4 mg/dL and UPro of ≤0.33 g/day and partial remission (PR) by a ≤25% increase in baseline SCr and ≥50% reduction in UPro to ≤1.5 g/d.

Results: The 86 pts were 32±12 yrs old, 84% were female, 63% white and 24% were AA. At 6 mo. 13 pts (15%) had died or reached ESRD and 12 pts (14%) had attained a CR while 34 pts (40%) had a ≥50% reduction and 27 pts (31%) a <50% reduction in UPro. Comparing pts with ≥50% and <50% reduction in UPro at 6 mo there was no difference in baseline age (31±12 v. 29±12 yrs), gender (76% v. 85% female), race (68% v. 63% white), SCr (1.8±0.9 v. 1.9±0.9), histology or treatment. However, the baseline UPro was higher in pts with ≥50% reduction in UPro at 6 mo (7.1±3.6 v. 4.6±3.2, P 0.002). At follow-up (120±65 mo), pts that had a ≥50% reduction in UPro at 6 mo attained a CR in 56% and PR in 35% of cases compared to pts that had a <50% reduction in UPro at 6 mo who had a CR in 22% (P 0.009) and PR in 33% (P- NS). The 15-yr renal survival (71% v. 25%, P 0.003) and 15-yr pt survival without ESRD (66% v. 18%, P 0.002) was greatest in pts with a ≥50% reduction in UPro at 6 mo compared to pts with <50% reduction and similar to that of pts with CR at ≤6 mo (82% and 82%).

Conclusions: A ≥50% reduction in UPro at 6 mo is predictive of a favorable outcome in pts with SLN.

SA-PO831

Does H Ficolin Contribute to the Pathogenesis of Lupus Nephritis? Zofia I. Niemir,[1] Anna Swierzko,[2] Maciej Cedzynski,[2] Anna Maciejewska,[3] Jolanta Lukasiewicz,[3] Magdalena Polcyn-adamczak.[1] *[1]Department of Nephrology, University of Medical Sciences, Poznan, Poland; [2]Institute of Medical Biology, Polish Academy of Sciences, Lodz, Poland; [3]Ludwik Hirszfeld Institute of Immunology and Experimental Therapy, Polish Academy of Sciences, Wroclaw, Poland.*

Background: Recently, increased levels of H-ficolin in sera of patients with systemic lupus erythematosus (SLE) have been reported. Given the potential importance of this protein in autoimmunity, we compared its serum levels in patients with different morphological forms of primary glomerulonephritides (PGN), active and inactive lupus nephritis (LN) and healthy controls (C).

Methods: The study involved 120 patients with PGN (43 with IgA-mesangial proliferative GN, 36 with non-IgA-mesangial proliferative GN, 6 with membranoproliferative GN, 19 with idiopathic membranous GN, and 16 with focal-segmental glomerulosclerosis), 55 with LN (40 with active and 15 with inactive phase of the disease) and 65 C. The activity of LN was assessed by scoring the symptoms of SLE according to the systemic lupus erythematosus disease activity index. The serum level of H-ficolin (s-H-ficolin) was determined using the NUNC Maxisorp plates coated with *H. alvei* 1200 LPS, monoclonal anti-H-ficolin antibodies and HRP-labeled anti-mouse IgG.

Results: Median s-H-ficolin concentration was 23.9 mg/ml (range 1.6 to 59) in patients with LN, 16.8 mg/ml (range 2.6 to 53.5) in those with PGN and 18.9 mg/ml (range 6.4 to 35.9) in C (LN vs. PGN and C, $p<0.0001$). We compared the number of subjects that could be allocated to the fourth quartile obtained in C. This resulted in 24.6% of those from the C group, 29.1% of patients with PGN and 63.6% of patients with LN (LN vs. PGN and C; $p<0.0001$) In LN, s-H-ficolin levels tended to be higher in patients with active lupus flare than in those with inactive disease, but the difference did not reach the statistical significance. No statistically significant differences could be found between patients with various morphological forms of PGN.

Conclusions: Our results indicate that H-ficolin may be involved in the pathogenesis of LN. Further studies are required to resolve this issue.

Development of a Novel High Throughput Assay of Hydroxychloroquine in Whole Blood Samples Enables Identification of Medication Non-Adherence in Patients with Lupus Nephritis

Gary Chusney, Tom Cairns, Janet Lee, Liz Lightstone. *Leslie Brent Laboratory, Imperial College Healthcare NHS Trust, London, United Kingdom.*

Background: Use of hydroxychloroquine (HCQ) in lupus patients is associated with improved long term outcomes. It has a long half life & recent data suggest low levels identify non adherence with therapy – a major cause of poor outcomes in lupus. Our aim was to develop & validate a liquid chromatography with tandem mass-spectrometric detection (LCTMS) method for the routine monitoring of HCQ in whole blood from patients treated for lupus.

Methods: The LCTMS method used a sample of 25µL whole blood with a simple protein crash treatment using deuterated (d4)-HCQ as the internal standard. The compounds were detected in the column effluent by monitoring specific m/z transitions of HCQ (336.1>247.1) & d4-HCQ (340.1>251.1). Throughput was 15 samples per hour. Calibrators (range 0 – 3.80mg/L) & quality controls, at 3 concentrations, were prepared in-house.

Results: The LCTMS assay was linear up to a concentration of at least 4.00mg/L. The LOQ was 25µg/L. The intra-assay imprecision was 8.7% @ 0.23mg/L, 4.8% @ 0.82mg/L & 6.8% @ 1.82mg/L & total imprecision was 8.7% @ 0.23mg/L, 6.9% @ 0.82mg/L and 6.8% @ 1.82mg/L (n=36). Absolute recovery was (mean±SD, n=5) 70.0±5.3% @ 0.5mg/L & - 73.7±3.6% @ 1.0mg/L.

In an initial cohort of 52 patients taking 200mg bd, 44 had levels >0.2mg/L. In these patients the median HCQ concentration was 0.87mg/L (range 0.23-1.89mg/L) – slightly lower than the suggested optimum of 1mg/L. Importantly, these preliminary data suggest 15% were not taking their prescribed medication.

Conclusions: The LCTMS method described is simple, precise, requires small sample volumes and therefore effective for routine therapeutic monitoring of HCQ. Identifying non adherent patients may well improve future adherence and therefore outcomes. To our knowledge it is the first LCTMS method described for measuring this drug in a clinical environment.

SA-PO833

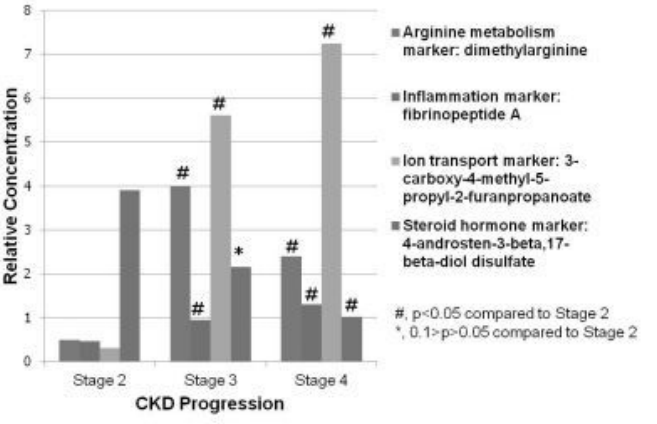
Metabolomics Profiles in Different Stages of Chronic Kidney Disease (CKD)

Vallabh O. Shah,[1] Raymond R. Townsend,[2] Harold I. Feldman,[2] Kirk L. Pappan,[3] Elizabeth Kensicki,[3] David L. Vander Jagt.[1] *[1]UNMHSC, Albuquerque, NM; [2]Uni of Pennsylvania, Philadelphia, PA; [3]Metabolon Inc, Durham, NC.*

Background: CKD is a common public health problem. Identifying biomarkers adds prognostic / diagnostic value by contributing to an understanding of CKD at the molecular level possibly defining new drug targets. Metabolomics provides a snapshot of biochemical events at a particular time in the progression of CKD. In this pilot study we ascertained whether metabolite profiles are significantly different in CKD stages 2, 3 and 4.

Methods: An analysis of plasma metabolites, using GC/MS and LC/MS platforms, was conducted on thirty participants comprised of non-diabetic males ages 40-52 with ten each in stage CKD-2, CKD-3 and CKD-4 based on eGFR.

Results: Comparison of CKD-3/CKD-2 identified 62 metabolites that differed ($p\leq0.05$), with 39 higher and 23 lower in CKD-3 compared to CKD-2; comparison of CKD-4/CKD-2 identified 111 metabolites, with 66 higher and 45 lower; and comparison of CKD-4/CKD-3 identified 11 metabolites, with 7 higher and 4 lower. Major changes in metabolic profiles with increasing stage of CKD were observed, including altered arginine metabolism, elevated coagulation/ inflammation, impaired carboxylate anion transport, and decreased adrenal steroid hormone production.



Conclusions: Global metabolic profiling uncovered potential biomarkers of stages of CKD offering insight into pathophysiological processes. This pilot study suggests metabolomics can be used to formulate testable hypotheses of the usefulness of measuring specific metabolite patterns as indicators of kidney disease in diverse populations.

Elevated Plasma Levels of Vasohibin-1 Predict Renal Dysfunction and Renal Levels of Vasohibinb-1 Are Associated with Histological Alterations in CKD Patients

Norikazu Hinamoto,[1] Yohei Maeshima,[1] Daisuke Saito,[1] Hiroko Yamasaki,[1] Hiroyuki Watatani,[1] Haruyo Ujike,[1] Shinji Kitamura,[1] Hitoshi Sugiyama,[1] Naoki Kanomata,[2] Hikaru Sonoda,[3] Yasufumi Sato,[4] Hirofumi Makino.[1] *[1]Medicine and Clinical Science, Okayama University, Okayama, Japan; [2]Pathology, Kawasaki Medical School, Kurashiki, Okayama, Japan; [3]Discovery Research Laboratories, Shionogi, Settsu, Osaka, Japan; [4]Vascular Biology, Tohoku University, Sendai, Miyagi, Japan.*

Background: Vasohibin-1 serves as a negative feedback regulator of angiogenesis and we reported the therapeutic efficacy of Vasohibin-1 in mouse diabetic nephropathy models. The aim of the current study is to examine the plasma, urinary and renal levels of Vasohibin-1 in patients with renal disorders and to evaluate its clinical usefulness.

Methods: We studied 78 Japanese CKD patients with (n=54) or without renal biopsies and 6 control subjects. The levels of plasma, urinary Vasohibin-1 were determined by ELISA and immunohistochemistry for Vasohibin-1 was conducted. Correlation among clinical, histological parameters, the plasma, urinary levels of Vasohibin-1 and the number of renal Vasohibin-1^+ cells were examined.

Results: The plasma levels of Vasohibin-1 inversely correlated with age and systolic blood pressure and positively correlated with the number of renal Vasohibin-1^+ cells. Vasohibin-1 was observed in renal endothelia of normal subjects and additionally in mesangial cells, crescent and interstitial inflammatory cells in CKD patients. Double immunostaining showed partial co-localization of Vasohibin-1 and αSMA/CD31 in glomeruli. Significant positive correlation was observed between [1)]crescent formation and the number of Vasohibin-1^+ cells in glomerulus or cortex, and [2)]interstitial cell infiltration and the number of Vasohibin-1^+ cells in cortex. The plasma levels of Vasohibin-1 and the number of glomerular Vasohibin-1^+ cells correlated with glomerular VEGFR-2^+ area. Baseline plasma levels of Vasohibin-1 inversely correlated with the annual alteration of eGFR (r=-0.36, *P=0.03).*

Conclusions: Elevated plasma levels of vasohibin-1 predicts renal dysfunction and renal expression of vasihibin-1 is associated with histological alterations in CKD patients.

SA-PO835

The Association of Complement 3 (C3) and Proteinuria in Non-Nephrotic Chronic Kidney Disease

Kentaro Kohagura,[1] Tsuyoshi Miyagi,[1] Yusuke Ohya,[1] Kunitoshi Iseki.[2] *[1]Cardiovascular Medicine, Nephrology and Neurology, University of the Ryukyus, Nishihara-cho, Okinawa, Japan; [2]Dialysis Unit, University of the Ryukyus, Nishihara-cho, Okinawa, Japan.*

Background: Obesity and hypertriglyceridemia (hTG) are risk factors for progression of chronic kidney disease (CKD). Adipocytokine such as Complement 3 (C3) is associated with metabolic abnormality and vascular damage. However, the roles of C3 on the association with the metabolic marker, renal arteriolopathy, and proteinuria are not clear. The clinical significance has not been investigated among CKD patients.

Methods: In the present study, we examined 145 non-nephrotic (serum albumin ≥3 g/dl) CKD patients excluding lupus, who had undergone renal biopsy (54% male). Arteriolar-wall thickening was assessed semi-quantitatively. We further investigated the variables based on the median level of serum C3.

Results: The mean (SD) age was 42 (17) years, urine protein (UP) 1.2 (1.2) g/gCr, and eGFR 80 (25) ml/min/1.73 m^2, C3 level 80 (26) mg/dl. Although the mean age, eGFR and blood pressure was comparable between higher and lower C3 groups, UP was significantly higher in the higher C3 group than those in the lower C3 group. Patients with higher C3

level were significantly larger in body mass index, grade of arteriolar-wall thickening and higher prevalence of diabetes mellitus (DM) and hTG. Logistic analysis adjusted for age showed higher C3 was significantly associated with higher risk for the presence of above the mean value of UP (higher UP) as well as hypertension, DM and hTG. Higher C3 level was a significant factor for higher UP after adjustment with age, sex and other significant factors. The adjusted odds ratios (95% CI) of higher C3 level was 2.6 (1.2 to 5.8). Coexistence of higher C3 level and hTG was significantly associated with higher UP and the odds ratio (95% CI) was 3.4 (1.2 to 9.9) compared to the lower C3 level and hTG(-).

Conclusions: Increased level of C3 was related to metabolic abnormalities and associated with higher UP in non-nephrotic CKD patients, especially when complicated with hTG. The present study suggests the clinical significance of C3 among patients with CKD. However, the causal role of C3 on proteinuria remained to be studied.

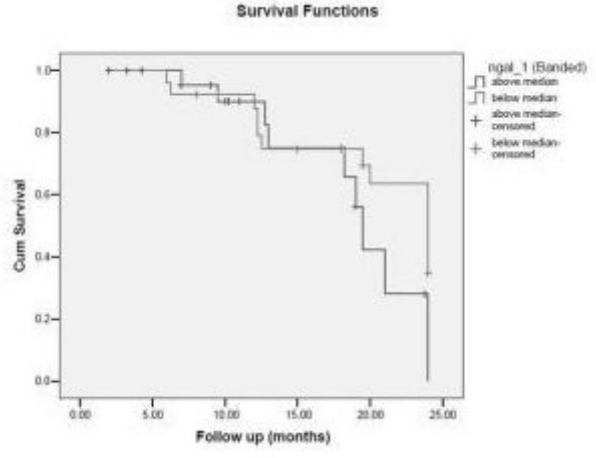
SA-PO836

Plasma NGAL Does Not Predict ADPKD Progression Grazia Maria Virzì,[1,2] Dinna N. Cruz,[1,2] Fiorella Gastaldon,[1] Valentina Corradi,[1,2] Maurizio Clementi,[3] Claudio Ronco.[1,2] *[1]Nephrology, St Bortolo Hosp, Italy; [2]International Renal Research Institute Vicenza; [3]Clinical Genetics, Univ of Padua, Italy.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is a genetic disease with variable rate of progression. Neutrophil gelatinase-associated lipocalin (NGAL) has been implicated in pathological conditions and it is proposed as a biomarker for CKD progression in kidney diseases. We hypothesized that NGAL could also be a good marker for progression of ADPKD. Our aim was to evaluate if NGAL could predict loss of function in ADPKD patients.

Methods: ADPKD patients with confirmed mutations (PKD1, n=33; PKD2, n=17) were enrolled and followed prospectively. Creatinine (sCr) and NGAL values were measured at baseline and on follow-up (median 18 mos, IQR 11-28). Plasma NGAL was measured by Triage point of care test. CKD progression was defined as 15% decrease in eGFR from baseline to follow-up. Patients were divided into 2 groups based on median baseline NGAL and compared by the Kaplan-Meier curve.

Results: We enrolled 50 ADPKD pts (60%M age 41yrs); mean sCr 1.3±0.7mg/dl and median eGFR was 62 mL/min/1.73m². NGAL values are inversely correlated with baseline eGFR (r=-0.64, p<0.001). There was weak correlation between baseline NGAL and subsequent change in eGFR (r=0.28, p=0.05) 9/50 patients had NGAL below limits of detection (60pg/ml); median NGAL level was 79pg/ml. On follow-up, 12 patients (24%) had progression as defined. No statistically significant relationship between higher NGAL and ADPKD progression was observed.



Conclusions: We did not observe a relationship between NGAL and CKD progression in patients with genetically confirmed ADPKD; however 18% of patients had undetectable plasma NGAL levels. This raises doubt about the utility of the current NGAL assay as a biomarker for CKD progression in this population. The new extended range NGAL assay may prove more useful.

SA-PO837

Urinary Vitamin D Binding Protein: A Potential Novel Marker of Interstitial Inflammation and Fibrosis Katarina Mirkovic,[1] Carolina R.C. Doorenbos,[1] Wendy Dam,[1] Hiddo Jan Lambers Heerspink,[2] Ferdau L. Nauta,[1] Maartje C.J. Slagman,[1] Andrea B. Kramer,[1] Ron T. Gansevoort,[1] Jacob van den Born,[1] Gerjan Navis,[1] Martin H. De Borst.[1] *[1]Nephrology; [2]Clinical Pharmacology, University Medical Center Groningen, University of Groningen, Netherlands.*

Background: The severity of interstitial fibrosis strongly predicts progression of renal function loss. We explored the role of urinary vitamin D binding protein (uVDBP), a low-molecular-weight protein reabsorbed by receptor-mediated uptake in tubular cells, as a marker of tubulointerstitial inflammation and fibrosis in rats and tested if uVDBP responds to therapy intensification in humans.

Methods: Wistar rats were sacrificed at 6, 12, 18, 24, and 30 wks after unilateral adriamycin proteinuric (UAP) nephropathy (n=60). Saline-treated rats (n=30) served as controls. uVDBP was measured by ELISA and related to interstitial α-smooth muscle actin (α-SMA) and collagen III staining and macrophage accumulation. uVDBP was also measured in subjects with normoalbuminuria or microalbuminuria (both n=100), and in 47 stage I-III non-diabetic CKD patients after two 6-wk treatment periods: ACE inhibitor (ACEi) under normal sodium (NS) or ACEi+ARB under low sodium (LS) diet (intensified therapy).

Results: In rats, uVDBP was increased at 6 wks after UAP induction (523 [236-1235] ug/d vs controls 6 [3-13], p<0.01) and increased over time (30 wks: 940 [656-2107] vs 168 [105-342] ug/d, p<0.01). uVDBP was associated with interstitial α-SMA (standardized β 0.43, p=0.01), collagen III (st.β 0.44, p=0.02) and macrophage accumulation (st.β 0.47, p=0.01) independently of albuminuria.

In humans, uVDPB was increased in microalbuminurics (15 [8-38] ug/d) and in CKD patients (ACEi+NS: 4446 [712-14214] ug/d) compared to normoalbuminurics (7 [3-18] ug/d, p<0.001). uVDBP responded to therapy intensification in CKD patients (ACEi+ARB+LS: 987 [200-3498], p<0.001 vs ACEi+NS), but remained >100-fold higher than in normoalbuminurics (p<0.001).

Conclusions: uVDBP may be a novel urinary biomarker of tubulointerstitial inflammation and fibrosis. Persistently elevated uVDBP suggests ongoing interstitial damage despite optimal renoprotective therapy in CKD patients.

SA-PO838

The Atlas Database of Kidney Tubular Proteins Is Refined with the Gene Expression Information for New Urinary Biomarkers Discovery Hidehiko Fujinaka,[1] Tadashi Yamamoto.[2] *[1]Institute for Clinical Research, Niigata National Hospital, Kashiwazaki, Niigata, Japan; [2]Structural Pathology, Institute of Nephrology, Niigata University, Niigata, Japan.*

Background: Recently, several proteins have been proposed as new urinary biomarkers of kidney injury. But they do not always identify the injured sites of kidney nephron segments, especially in case the biomarker may be also derived from plasma. An ideal biomarker must originate from injured cells. Discovery of new urinary biomarkers originated from the specific nephron segments or cells may be difficult in patients with massive proteinuria since most of proteins arederived from plasma. We compared the immunohistochemistry atlas database of kidney tubular proteins (http://www.proteinatlas.org/) with our microarray database of kidney genes expression for new biomarkers discovery.

Methods: Kidney tubule-predominant proteins were defined that the antibody staining intensity level in tubular cells was strong (weak or negative in glomerular cells) or moderate (negative in glomerular cells). The microarray analysis was done by preparation of Cy5-labeled cRNA from human glomeruli and Cy3-labeled cRNA from human cortices. The genes of positive Cy3/Cy5 ratio were defined as kidney tubule-predominant genes.

Results: From the atlas database of immunohisotochemistry, 468 proteins were determined as kidney tubule-predominant proteins. Among genes of these 468 proteins, 268-gene-derived proteins were confirmed kidney tubule-predominant genes, some of which were established tubule-predominant proteins such as SLC12A1 and FABP1. Among the 268 kidney tubule-predominant proteins, 62 proteins were listed in the urinary proteome database (http://141.61.102.16/urine/). In the listed 62 proteins, the expressions of CALB1 (in distal tubule cells) and ALDOB (in proximal tubule cells) were reduced in kidney sections with tubulointerstitial injury, and urinary CALB1 and ALDOB were shown reduced in some patients with tubulointerstitial injury by Western blotting.

Conclusions: The atlas database of kidney tubular proteins can be refined by combination with the gene expression information, which may be a good tool for new urinary biomarkers discovery.

Renal miRNA-mRNA Expression Signatures in Progressive Chronic Kidney Disease Michael Rudnicki,[1] Paul Perco,[2] Barbara D'Haene,[3] Judith Sunzenauer,[1] Pieter Mestdagh,[3] Jo Vandesompele,[3] Bernd Mayer,[2] Gert J. Mayer.[1] *[1]Dept. of Internal Medicine IV - Nephrology and Hypertension, Medical University Innsbruck, Innsbruck, Austria; [2]Emergentec Biodevelopment GmbH, Vienna, Austria; [3]Biogazelle, Zwijnaarde, Belgium.*

Background: MicroRNAs (miRNAs) significantly contribute to the pathophysiology of chronic kidney disease (CKD) progression but their association with clinical outcome remains poorly understood.

Methods: Large scale miRNA and mRNA expression profiling was performed on 45 renal biopsies from patients with proteinuric kidney diseases. Patients were defined as progressive (doubling of serum-creatinine or end-stage renal disease during follow up) or stable. Median follow-up time was 44 months. Differentially expressed miRNAs between stable and progressive patients were determined, and inversely correlated to global mRNA expression. These miRNA-mRNA pairs were further characterized.

Results: In progressive subjects 12 miRNAs (miR-140-3p, miR-148a, miR-190, miR-192, miR-192*, miR-194, miR-204, miR-206, miR-216b, miR-30d, miR-30e*, miR-532-3p) were downregulated, which correlated with upregulated mRNAs involved in inflammatory response, cell-cell-interaction, metabolism, apoptosis, and intracellular signalling. While we also observed upregulation of 9 miRNAs (miR-142-3p, miR-143-5p, miR-150, miR-223, miR-223*, miR-31, miR-31*, miR-511, miR-629*) in progressive cases, these did not correlate to a significant extent with downregulated mRNAs. Eight of the 12 downregulated miRNAs were associated with creatinine at biopsy and creatinine at follow-up, proteinuria at follow-up, and the degree of pathohistological injury. Bioinformatics analysis of predicted targets of these 12 miRNAs revealed 2 groups of upregulated genes (CCR7, CCL19, CXCL1, S1PR4, PLCB2, and RASGRP2, RASGRP1, ITPR3), which positively correlated with arterial hyalinosis, tubular atrophy/interstitial fibrosis and histological diagnosis.

Conclusions: We identified renal miRNA- and mRNA-profiles being differentially expressed in progressive chronic kidney disease. These miRNAs and mRNAs were mainly associated with inflammatory pathways, and the degree of expression correlated with renal disease severity.

SA-PO840

Mass Spectrometry- and Antibody-Based Proteomics of Human Kidney Tissues for Clinical Application Tadashi Yamamoto, Hidehiko Fujinaka. *Department of Structural Pathology, Institute of Nephrology, Niigata University, Niigata, Japan.*

Background: The glomerulus and other compartments of the human kidney are aimed to analyze by proteomics using mass spectrometry (MS) and antibody (Ab)-based immunohistochemistry (IHC).

Methods: Proximal tubules, distal tubules and collecting ducts were differentiated in formalin-fixed paraffin-embedded (FFPE) human kidney sections by IHC using anti-AQP1, calbindin and AQP2 antibodies, respectively and a laser-capture microdissection (LCMD) method. To apply proteomics to clinic, a new method, On-Site Direct Digestion (OSDD) method was developed to prepare peptides efficiently from FFPE tissues since conventional methods were not satisfactory for MS sample preparation from tiny FFPE tissue samples such as 1 mm^2 area-tissue section, which corresponds roughly to 50 human glomerular sections. To elucidate difference in glomerular proteome, 50 glomerular sections were collected from each FFPE kidney biopsy specimens and peptides were prepared by the OSDD method.

Results: Approximately 500-3000 proteins were identified in each FFPE 1 mm^2 area-section of the kidney compartments. The numbers of identified proteins were significantly higher (about ten-times) than the conventional methods. The results were summarized into proteome databases, which provide MS-based information and protein localization in the kidney. Proteomes of the glomerulus were compared between normal controls and glomerular sclerosis or other glomerular diseases, which confirmed glomerular expression of already-known proteins but also elucidated not-known disease-unique proteins. These studies also proposed protein enrichment and interactions in glomerular disease conditions.

Conclusions: Human kidney compartments, such as the glomerulus and other nephron segments were analyzed by MS and Ab-based proteomics. The OSDD method was successfully developed for analysis of proteomes of small compartments in FFPE human biopsy samples, which provided new significant information for understanding physiology and pathology.

SA-PO841

Massively Parallel Sequencing of Human Urinary Exosome/Microvesicle Nucleic Acids Reveals a Predominance of Non-Coding RNA Leileata M. Russo,[1] Kevin Miranda,[2] Anna Scott.[1] *[1]Exosome Diagnostics, Inc., New York, NY; [2]Program in Membrane Biology, Massachusetts General Hospital, Boston, MA.*

Background: The recent demonstration that exosomes/microvesicles (collectively referred to as microvesicles) contain RNA and DNA has sparked much interest in their use as nucleic-acid based biomarkers for the non-invasive analysis of disease. We have previously shown that high integrity RNA can be isolated from micorvesicles and here we determine the complete nucleic acid content of urinary microvesicles using massively parallel sequencing.

Methods: Extraneous nucleic acids were digested using RNase and DNase treatment and the microvesicle inner nucleic acid cargo was analyzed without DNase digestion (to examine both DNA and RNA based sequences) and with DNase to examine only RNA sequences using the Illumina Genome Analyzer.

Results: Approximately 18 million reads were found to map to the human genome. A substantial proportion (~88%) of reads aligned to ribosomal RNA sequences. Of the remaining sequences, ~35% aligned to protein coding genes and splice sites encompassing approximately 16,000 of the known ~23,000 protein coding genes of the human genome. Analysis of protein coding genes specific to the renal and genitourinary tract revealed that complete segments of the renal nephron and collecting duct as well as genes indicative of the bladder and prostate could be identified. Surprisingly, the remaining ~65% of sequences aligned to non-coding and repeat sequences which were shown to be RNA based (ncRNA).

Conclusions: This data supports the use of deep sequencing of microvesicles to analyze both coding and non-coding RNA which is thought to play an emerging role in cell regulation broadening the potential of microvesicles as a unique source of non-invasive biomarkers for disease monitoring without the need for invasive biopsy. Deep sequencing may be used to identify novel ncRNA sequences (beyond miRNA) that may be useful in the identification of much needed renal disease biomarkers.

SA-PO842

Distribution of Nucleic Acids in Urinary Exosomes/Microvesicles Sub-Fractionated via Percoll Gradient Leileata M. Russo, Guillermo Salazar, Anna Scott, Kendall Bate. *Exosome Diagnostics, Inc., New York, NY.*

Background: Urinary exosomes/microvesicles (collectively referred to as microvesicles) may be used to non-invasively examine the transcriptional profile of the kidney without the need for biopsy. However, before this powerful technology can be utilized, it is important to understand the distribution of mRNA, rRNA, small RNA (including miRNA) and DNA within microvesicles. Here we examine the nucleic acid content of urinary microvesicles fractionated on a Percoll gradient to better understand their utility as a potential non-invasive source of nucleic acid biomarkers for acquired renal disease diagnosis and monitoring.

Methods: Microvesicles were isolated via differential centrifugation to remove whole cells and cellular debris and the microvesicle pellet was then fractionated on a Percoll gradient and the nucleic acid composition of each fraction determined. RT-qPCR was used to examine transcript expression in each Percoll fraction.

Results: Analysis of various renal mRNA transcripts including H+/Cl- exchange transporter 5 (CLCN5), cubilin (CUBN), megalin (LRP2) as well as bladder markers including uroplakin (UPK2) were shown to have a strong correlation with the presence of rRNA detected via RT-qPCR of 18S rRNA and via the correlation of 18S / 28S rRNA peaks analyzed via the Agilent Bioanalyzer. Small RNA and high integrity RNA (with 18S / 28S rRNA peaks) was present in similar fractions. Genomic DNA was not contained within microvesicles and could be removed via DNase digestion of the microvesicles prior to their lysis.

Conclusions: Protein coding transcripts detected at the mRNA level correlated strongly with the amount of rRNA (R^2=0.78 to 0.94) suggesting that rRNA is packaged together with mRNA and that the two are not present in separate microvesicle populations. Genomic DNA may co-isolate with microvesicles thus it is important that DNA is removed or mRNA specific primers and probes are used for transcriptional analysis in microvesicles. Overall, these findings support the use of rRNA integrity as a quality control of general RNA integrity which is critical when using microvesicles as a source of non-invasive transcriptional biomarkers for renal disease diagnosis.

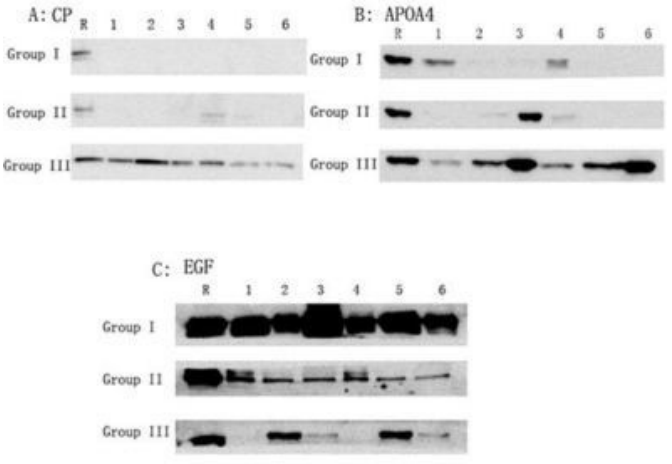
Establishment of Urinary Proteome and Identification of Protein Biomarkers of Metabolic Syndrome with Early Renal Injury Xuejiao Liu,[1] Mingxi Li,[1] Bixia Gao,[1] Jianfang Cai,[1] Youhe Gao,[2] Xuemei Li,[1] Xuewang Li.[1] *[1]Nephrology, Peking Union Medical College Hospital, Beijing, China; [2]Physiology and Pathophysiology, Institute of Basic Medical Sciences Chinese Academy of Medical Sciences, Beijing, China.*

Background: To identify potential urinary biomarkers of metabolic syndrome (MetS) with early renal injury by spectral counting and iTRAQ quantitative proteomic approaches.

Methods: 1. Participants were divided into three groups: group I health control, group II MetS patients (IDF 2005 criteria) without MAU and group III MetS patients with early renal injury (20μg/min≤UAE<200μg/min and eGFR≥60mL/min.1.73m2). 2. Overnight urine were collected. After intra-group mixture, proteins were digested by trypsin. 3. Peptides of intra control, group I, II and III were labeled by iTRAQ reagents 114, 115, 116 and 117, and were mixed together. 4. Proteins of three groups were analyzed by LC-MS/MS for spectral counting, and the mixture of labeled proteins were identified by LC-MS/MS for iTRAQ. 5. Differential proteins were determined by ANOVA by both quantitative approaches. 6. Western Blot was applied to validate differentially expressed proteins.

Results: 1. Total of 807, 630 and 456 proteins were identified respectively in group I, II and III, and 566 proteins were identified in iTRAQ labeled sample. 2. Totally, 47 proteinsbetween group III and II, 35 proteins between group III and II were identified differentially by two quantitative approaches. 3. CP and APOA4 in group III was higher expressed than that in group I and II by western blot, and EGF in group II and III was lower than that in group I.



Conclusions: 1. The urinary proteome of MetS with early renal injury is established. 2 Differential proteins between MetS and MetS with early renal injury are identified 3. CP and APOA4 may be biomarkers of MetS with early renal injury, and EGF is a potential biomarker of MetS.

A Novel Approach for Discovering Chronic Kidney Disease Associated Human Podocyte-Enriched Genes Wenjun Ju,[1] Casey Greene,[2] Felix H. Eichinger,[1] Viji Nair,[1] Jeffrey B. Hodgin,[1] Markus Bitzer,[1] Young-suk Lee,[2] Qian Zhu,[2] Min Li,[3] Masami Ikehata,[3] Maria Pia Rastaldi,[3] Clemens D. Cohen,[4] Olga Troyanskaya,[2] Matthias Kretzler.[1] *[1]Internal Medicine, University of Michigan, Ann Arbor, MI; [2]Department of Computer Science, Princeton University, Princeton, NJ; [3]Renal Research Laboratory, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy; [4]Institute of Physiology, University of Zurich, Zurich, Switzerland.*

Background: Cell-lineage-specific transcripts are essential for differentiated tissue function in metazoan organisms. They are frequently found to be the cause of hereditary disease and mediate end organ specific damage in acquired chronic diseases.

Methods: We developed a genome-scale method to identify genes with novel cell-lineage-specific expression, referred to as "in silico nano-dissection", leveraging high-throughput functional genomics data from tissue homogenates using a machine learning framework. This approach was tested in chronic kidney disease (CKD) to predict proteins enriched in renal visceral epithelial cells (podocytes), whose dysfunction is responsible for hereditary proteinuric syndromes and acquired glomerular diseases.

Results: In silico nano-dissection identified transcripts with cell-lineage enrichment for podocytes. Podocyte-enriched expression was validated using the human protein atlas and compared to expression profiles derived from fluorescence tagged podocytes in murine models. Our result indicates that the prediction accuracy exceeds predictions from transcriptional profiles of the murine models. The relevance for human monogenetic glomerular disease was demonstrated by prediction of the recently reported association of MYO1E with autosomal-recessive glucocorticoid resistant nephrotic syndrome. In acquired human glomerular disease, the podocyte gene set correlated significantly and positively with the level of renal impairment in 139 biopsies of CKD patients.

Conclusions: In summary, nano-dissection can define cell-lineage-enriched transcriptome that can serve as highly specific markers of disease stage and provide a starting point for the development of targeted, organ specific therapeutics.

Urinary Proteomics for Diagnosis and Prognosis of Chronic Kidney Disease Marius A. Øvrehus, Petra Zürbig, Knut Aasarod, Bjorn Egil Vikse, Stein I. Hallan. *St Olav University Hospital, Norway.*

Background: CKD markers beyond eGFR and proteinuria are needed, and urine proteomic analyses have shown promising promising results in some primary kidney diseases. However, few data from unselected CKD patient series have been published.

Methods: 19 consecutive out-patients with CKD stage 4-5 and 17 healthy volunteers were included in a single-blinded proof-of-concept study. Mid-stream morning urinary samples were stored at –80°C. Specific patterns of 273 urinary biomarker peptides (from a total of >5000 peptides measured with CE-MS analysis from Mosaiques Diagnostics) were used to predict classification scores (previously validated cut-off value ≥0.343 indicating CKD). Annual eGFR decline over 2-11 years, proteinuria and other relevant data for characterizing phenotype were recorded.

Results: The CE-MS method diagnosed CKD with a sensitivity/specificity of 0.89/1.00, and ROC analysis estimated an AUC value of 0.972 (95% CI 0.924-1.020). Corresponding data for proteinuria were 0.74/0.82 and 0.70 (95% CI 0.494-0.905). Regression analyses showed that the CE-MS score were strongly associated with both proteinuria and loss of GFR (p<0.001 and p=0.002, respectively) independent of age, sex, BP, and other relevant risk factors. Table 1 exemplifies that patients with a wide range of diagnosis, including nephrosclerosis, were correctly classified.

Exemplary participants illustrating subject characteristics and urine proteomics results

Subject characteristics					Urine Proteomic	
Age (y)	Cause of CKD	GFR (ml/min/1.73m2)	Proteinuria	GFR decline/y	Score	CKD
48	Glomerulonephritis	23	+	-23	0.942	Y
70	Nephrosclerosis	26	+++	-15	0.672	Y
19	Alport syndrome	13	+++	-12	0.468	Y
81	Nephrosclerosis	20	0	-11	0.933	Y
77	Nephrosclerosis, DM	30	++	-11	0.934	Y
47	Glomerulonephritis	9	+++	-10	0.782	Y
77	Nephrosclerosis	30	+	-7	0.451	Y
61	Healthy volunteer	78	0	-1	-0.100	N
33	Healthy volunteer	>90	0	-1	-0.725	N

Conclusions: Although based on small numbers and patients with advanced disease, our data show that urine proteomics have a high diagnostic accuracy for CKD over a wide range of kidney diseases. Strong associations with the rate of eGFR decline and degree of proteinuria indicate a potential for CKD risk staging as well.

Integrated Epigenetic Analysis of Chronic Kidney Disease Yi-An Ko,[1] Davoud Mohtat,[3] Ae Seo Deok Park,[1] Maria Concepción Izquierdo,[3] James M. Pullman,[4] Thomas H. Hostetter,[3] Katalin Susztak.[1] *[1]Renal Electrolyte and Hypertension Division, University of Pennsylvania, Philadelphia, PA; [2]Department of Genetics, Albert Einstein College of Medicine, Bronx, NY; [3]Department of Pathology, Montefiore Medical Center, Bronx, NY; [4]Department of Medicine/Nephrology, Albert Einstein College of Medicine, Bronx, NY.*

Background: Epidemiological data indicate the adverse intrauterine and postnatal environment have long lasting roles in chronic kidney disease (CKD) development, epigenetic information can be a plausible carrier for mediating the effects. However, as of yet epigenetic differences have not been shown between control and CKD kidneys, we performed genome wide analysis for cytosine methylation (CM) and histone modification (HM) in normal and CKD human kidney tissue samples.

Methods: The DNA methylation profiles in micro-dissected human kidney tubule samples of patients with moderately advanced CKD are used for a genome-wide restriction enzyme based CM assay. In addition, the ChIP-seq data were generated with a panel of histone marks (H3K4me1, H3K3me3, H3K9ac, H3K36me3, H3K27me3) using human kidney lysate. The chromatin annotation with CM data and gene expression data are integrated in a genome wide manner.

Results: We observed differences both in CM and HM when comparing CKD to healthy human kidney tissues. Most differentially methylated regions (DMR) (51%) localized to gene body and were relatively rare on promoters. The difference in CM level was modest (<20%) and more loci showed loss of CM in CKD samples. Gene ontology showed enrichment for regions/genes involved in cell adhesion, development and immune processes (key pathways in CKD progression) influenced both by CM and the gene expression level. The DMRs showed the most overlap with H3K4me1 modification and computationally these regions were annotated as enhancers.

Conclusions: Our report is the first to demonstrate epigenetic differences in tubule epithelial cells obtained from patients with CKD, raising the possibility that epigenetic deregulation could play a critical role in CKD development via influencing core profibrotic pathways.

Propensity-Matched Mortality Comparison of Peritoneal Dialysis Patients with Technique Failure Jinn-Yang Chen. *Division of Nephrology, Taipei Veterans General Hospital, Taipei, Taiwan.*

Background: Comparisons of mortality in peritoneal dialysis patients with technique failure and matched hemodialysis patients are lacking. We aimed to compare survival of peritoneal dialysis patients with technique failure and hemodialysis by intention-to-treat analysis in a matched-pair cohort.

Methods: We estimated the propensity score for peritoneal dialysis prescription at the start of follow-up with a logistic regression model that included all listed covariates as predictors. We constructed matched pairs with a greedy matching 5→1 algorithm by randomly selecting for each peritoneal dialysis patient with score p a corresponding hemodialysis patient with score between p + 0.1 and p - 0.1. The degree of matching was checked by standard difference. The hazzard of survival was estimated by Cox model robust standard errors.

Results: During this period, 973 patients experienced technique failure. We matched 952 patient pairs from a retrospective cohort of who initiated dialysis from 2005~2008 in Taiwan. In the primary intention-to-treat analysis of survival from day 0, mortality hazzard was higher for peritoneal dialysis patients with technique faioure than for hemodialysis patients (PD vs. HD, HR= 2.95, 95% CI: 2.54~3.41, p<0.001).

The hazzard was especially high at the second year. When stratified by age group (>= or< 65 years), with/without diabetes and with/without cardiovascular disease, PD patients all have higher hazzard compared to matched HD patients.

Conclusions: Peritoneal dialysis patients with technique failure have excess mortality risk comared to their matched hemodialysis patients.

The Detrimental Effects of Comorbidity Burden and Baseline Characteristics on Peritoneal Dialysis Technique Failure in Taiwan: A National Cohort Study 2005~2009 Jinn-Yang Chen. *Division of Nephrology, Taipei Veterans General Hospital, Taipei, Taiwan.*

Background: The comorbidity burdens were different between hemodialysis (HD) and peritoneal dialysis (PD) patients. This study aimed to compare comorbidity burdens and to identify baseline and time-dependent risk factors for PD technique failure.

Methods: Those who have survived for the first 90 days among patients initiated dialysis between July 1, 2005 and December 31, 2008 were analyzed. A novel comorbidity index developed for Taiwan dialysis patients was used to quantify comorbidity burden. PD technique failure was defined as shifting to HD for more than 30 days or death. The outcome was censored by transplantation, recovery of renal function and loss of follow-up. An extended Cox's proportional hazard model was used to estimate hazard ratios.

Results: HD patients have higher comorbidity score than that of PD patients (median score, HD vs. PD= 6 vs. 4). Among 3308 PD patients, 439 patients (13.3 %) died, 534 patients (16.2%) were transferred to haemodialysis, 105 patients (3.2%) received renal transplantation and 126 patients (3.8 %) loss follow up. Age, male gender (HR=1.24, 95% CI: 1.09~ 1.42, p <0.001), and peritonitis-free survival as time-dependent variable (HR=2.15, 95% CI: 1.75~ 2.65, p=0.006) affected PD technique survival independently. Icodextrin use before the attack of peritonitis did not improve PD technique survival. Diabetic patients had poorer PD technique survival (HR=1.91, 95% CI: 1.65~2.20, p<0.001). SLE (HR=1.68, 95% CI: 1.11~2.54, p=0.013) affect PD survival, while polycystic kidney disease (HR=0.88, 95% CI: 0.53~1.44, p=0.603) did not affect PD technique survival. The chance of PD technique survival for those who had comorbidity score > 10 were only 25% after 3 years.

Conclusions: High comorbidity burden affected the technique survival of PD patients in Taiwan.

SA-PO849

A Retrospective Analysis of Patient Outcomes on Peritoneal Dialysis: Technique and Patient Survival and the Impact of Switching to Haemodialysis Shiv Bhutani, Jernej Pajek, Angela M. Summers, Helen Hurst, Paul E. Brenchley, Anand Vardhan, Alastair J. Hutchison. *Manchester Institute of Nephrology & Transplantation, Manchester Royal Infirmary, Manchester, United Kingdom.*

Background: PD remains an integral form of renal replacement therapy and has witnessed changes in the last decade including increase in automated PD, assisted PD, use of icodextrin and biocompatible solutions. To establish the impact of prevailing PD practice at our centre we carried out a retrospective outcome analysis.

Methods: Medical records of all patients commencing PD over a 7 year period between 2004 and 2010 to the end of the observation period in March 2011 were reviewed. Data collected included demographic, clinical, PET and adequacy. Outcome was analysed in terms of patient and technique survival using Cox's proportional hazards model.

Results: 286 patients commenced PD in the seven year period. Mean age was 55.2y (SD 17.6), 39% were female and median follow-up was 24 months (Range 0.8-84). 76 patients (27%) were transplanted and 102 (36%) died in the observation period. Patient survival probabilities at 3 and 5 years were 0.69 and 0.53, technique survival 0.67 and 0.58, transplantation 0.23 and 0.32 respectively. Peritonitis was the main cause for technique failure (42%) while ultrafiltration failure 6.3%. High Davies comorbidity grade, creatinine and BMI were independent predictors of technique failure. Sudden cardiovascular events were the predominant mode of death (31%), followed by debilitation (19%) and peritonitis (13%). PD failure was an independent predictor of death. When successful switch to HD was analysed, haemodialysis via catheter presented an elevated death hazard compared to staying on PD or HD through fistula.

Conclusions: Technique and patient survival of our cohort is comparable to published reports. However, the incidence of ultrafiltration failure and predictive value of residual renal function in technique survival are less so. Cardiovascular mortality and morbidity from peritonitis are predominant adverse events despite achieving recommended peritonitis targets. Nature of vascular access has serious impact on outcome when switching from PD to HD.

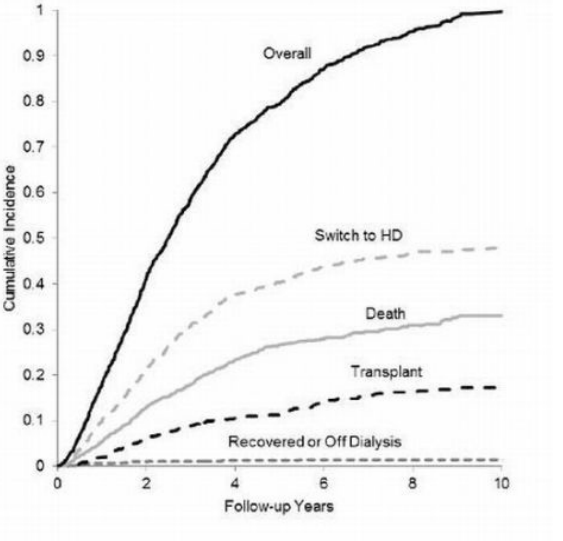
Technique Survival for Incident Peritoneal Dialysis (PD) Patients: The Kaiser Permanente Experience Wan-ting Yang,[1] Margo A. Sidell,[2] Jason Jones,[2] Victoria A. Kumar.[1] *[1]Nephrology, Kaiser Permanente, Los Angeles, CA; [2]Research and Evaluation, Kaiser Permanente, Pasadena, CA.*

Background: Few large studies have focused on outcomes for peritoneal dialysis (PD) patients in the United States (US). Our aim was to examine technique survival among patients who initiated PD at our institution over the past decade.

Methods: We used an internal ESRD registry to identify all patients who initiated PD between January 1, 2001 and December 31, 2010. Inclusion criteria included age > 18 years and 1 year of prior KP membership at initiation of PD. Patients were censored from the technique survival analyses at the earliest of any of the following: transplantation, recovered GFR, study end, loss of KP coverage or death. Patients who transitioned to HD temporarily were allowed up to 120 days off PD, after which they were deemed technique failures.

Results: A total of 1,710 patients initiated PD during the study period and 1,378 patients met inclusion criteria. Mean patient age was 56.5±14.0 years. Approximately 54% of patients were male and 63% were diabetic. The median size of individual PD programs was 42 patients/year (range 15-115). One and two year technique survival was 83% and 63%, respectively. Technique failure by competing risks is plotted below.



Two year technique survival for patients with ESRD due to cystic kidney disease, diabetes mellitus, glomerulonephritis, hypertension and other was 50%, 59%, 65%, 68% and 73% respectively, p=.004. For every ten year increase in age at initiation of PD, the RR of technique failure was 1.06, p=0.02. Vintage, sex and race were not associated with technique survival in our study.

Conclusions: Cause of ESRD and baseline age were associated with technique survival in our patients, while baseline vintage, sex and race were not. Technique survival in our study may reflect center size and experience.

Combination Therapy with Peritoneal Dialysis and Hemodialysis from the Initiation of Dialysis Preserve the Residual Renal Function and Serum Albumin-Retrospective Cohort Study for 30 Months- Atsushi Ueda,[1,3] Aki Hirayama,[2] Chie Saito,[3] Kunihiro Yamagata.[3] *[1]Kidney & Dialysis Center, Namegata District General Hospital, Namegata, Ibaraki, Japan; [2]Tsukuba University of Technology, Tsukuba, Ibaraki, Japan; [3]University of Tsukuba, Tsukuba, Ibaraki, Japan.*

Background: In ASN 2011, we reported advantages of the combination of peritoneal and hemodialysis (PD+HD) from the initiation of dialysis therapy on the patients' survival rate compared to PD or HD groups. In this study, we investigated the impact of PD+HD on the residual renal function (RRF), and the relation between RRF and oxidative stress.

Methods: We employed 86 end-stage renal disease patients received an adequate explanation about the three modalities and selected by our criteria (HD=52, PD=21 and PD+HD=21). Daily urine volume as a marker of RRF, blood analysis data, peritoneal permeability and serum beta-2-microglobulin (β_2MG) from the start of dialysis until 30 month in every 6 month were measured. Pentosidine were measured in the 35 patients at the start of dialysis and 12 month later.

Results: Urine volume at the start in HD group was 991±500mL/day, and decreased rapidly from 6 to 30 months (136±260 mL/day). Urine volume in PD group gradually declined from 6 month and maintained until 30 month (1077±813 mL/day). However, that in the PD+HD group was kept during 30 months (1234±684 mL/day). The peritoneal permeability was not different between PD and PD+HD group. Albumin level in PD group was significantly lower than that of the other groups from 6 to 30 months. β_2MG levels in PD+HD group in 0 and 6 months were lower, but there were no significant differences among the three groups in 12, 18 and 24 months. There was no correlation between pentosidine level and urine volume at start of dialysis, however, there was a negative correlation in 12 month.

Conclusions: It is considered that RRF is the most important factor, and serum albumin level is also meaningful for dialysis patients' prognosis. Our study demonstrated that the PD+HD therapy showed both advantages to preserve RRF and serum albumin. Moreover, the patients with preserved RRF indicated lower oxidative stress. Therefore, these beneficial effects may bring an excellent prognosis.

SA-PO852

Is Peritoneal Dialysis Better than Hemodaialysis for ESRD Patients with End-Stage Liver Disease? Chih-Chiang Chien. *Chi-Mei Medical Center.*

Background: Patients with end-stage renal disease (ESRD) are at a higher risk for chronic hepatitis, liver cirrhosis (LC) and death than the general population. Optimal renal replacement therapy for ESRD patients concomitant end-stage liver disease remains controversial. We investigated the long-term outcome among dialysis patients in an endemic area for chronic liver disease.

Methods: We did a longitudinal cohort study and selected all adult ESRD patients (≥18 years old) on maintenance dialysis who began renal replacement therapy between January 1st, 1999, and December 31st, 2000 (n = 12902). For 11293 incident hemodialysis (HD) and 761 peritoneal dialysis (PD) patients, follow-up was from the start of dialysis until the date of death or the end of database (December 31, 2008). A Cox proportional hazards model identified the risk factors for all-cause mortality.

Results: Patients on PD were predominantly younger than those on HD. There were many more HD than PD patients who had DM and cardiovascular diseases. However, there were no significant differences between these 2 groups based on HTN, PAD, LC, cancer, dementia, and hemiplegia or paraplegia. The percentage of LC was 6.2% in HD patients and 5.3% in PD patients. After adjustment, male patients had a higher mortality rate than female patients. Other than well-known risk factors, LC (hazard ratio [HR] 1.473, 95% CI: 1.329-1.634) and dementia (HR 1.376, 95% CI: 1.083-1.750) were also independent predictors of mortality. With all-cause mortality as the outcome, there were only 3 significant factors that interacted with dialysis mortality: (1) DM, (2) chronic lung disease, and (3) dementia.

Conclusions: In conclusion, 3 baseline comorbidities—DM, chronic lung disease, and dementia—had different effects on long-term outcomes in HD and PD patients. This nationally representative study of incident dialysis patients in an endemic area for chronic hepatitis shows that LC was an important predictor of mortality; however, the effect on mortality was not different between HD and PD patients.

SA-PO853

N-Terminal Pro-Brain Natriuretic Peptide as Useful Predictor for Decline of Residual Kidney Function in Peritoneal Dialysis Patients Takeshi Yokoyama,[1] Katsuomi Matsui,[2] Tsutomu Sakurada,[2] Yusuke Konno,[1] Kenjiro Kimura.[2] *[1]Nephrology and Hypertension, Kawasaki Municipal Tama Hospital, Kawasaki, Kanagawa, Japan; [2]Nephrology and Hypertension, St. Marianna University School of Medicine, Kawasaki, Kanagawa, Japan.*

Background: Preservation of residual kidney function (RKF) has been recognized as an independent predictor of survival in peritoneal dialysis (PD) patients. Although heart failure is known to associate with decline of RKF, little is known which neurohumoral factorsare helpful to predict decline of RKF. The aim of present study is to determine which neurohumoral factors are helpful to predict decline of RKF.

Methods: Neurohumoral factors such as N-terminal pro-brain natriuretic peptide (NT-pro-BNP), BNP, atrial natriuretic peptide (ANP) were measured in 28 PD patients at the initiation of PD. We calculated RKF as the half of the sum of weekly urea and creatinine clearances normalized to 1.73m^2 BSA, and defined the rate of decline of RKF as [(latest RKF - intial RKF) / duration of PD]. We examined the correlations between the rate of decline of RKF and the neurohumoral factors. Furthermore, the patients were divided into 2 groups based on NT-pro-BNP value and we compared the initial parameters between 2 groups.

Results: Average RKF at the initiation of PD was 40.7 24.5 L/week/1.73m^2 and average rate of decline of RKF was -1.10 0.97 L/week/1.73m^2/month. Rate of decline of RKF was significant correlated with NT-pro-BNP (r = -0.43, p > 0.05), but not correlated with BNP and ANP. In high NT-pro-BNP group, proportion of diabetic nephropathy and daily consumption of peritoneal dialysate were singificantly higher than low NT-pro-BNP group. BNP and ANP were also significantly higher in high NT-pro-BNP group.

Conclusions: Among the neurohumoral factors, NT-pro-BNP was the most useful predictor for decline of RKF in PD patients.

SA-PO854

Prospective Multicenter Cohort Study of the Effect of Residual Renal Function on Clinical Parameters in Patients with Peritoneal Dialysis: PDR-CS Hitoshi Sugiyama,[1] Yasuhiko Ito,[2] Kazuhiko Tsuruya,[3] Hisako Yoshida,[3] Hiroki Maruyama,[4] Shin Goto,[4] Masaaki Nakayama,[5] Hidetomo Nakamoto,[6] Hiroshi Morinaga,[1] Seiichi Matsuo,[2] Hirofumi Makino.[1] *[1]Okayama University, Japan; [2]Nagoya University, Japan; [3]Kyushu University, Japan; [4]Niigata University, Japan; [5]Fukushima Medical University, Japan; [6]Saitama Medical University, Japan.*

Background: Previous literatures and the guidelines for PD in the 2009 Japanese Society for Dialysis Therapy document the importance of the residual renal function (RRF) in PD patients.

Methods: A prospective multicenter observational study, known as the Peritoneal Dialysis Registry and Cohort Study (PDR-CS), began enrolling patients in December 2009 (UMIN000003659). This investigation analyzed the clinical parameters significantly associated with RRF as evaluated based on the daily urine volume (UV).

Results: Four national university hospitals participated in the PDR-CS and 178 patients were enrolled as of December 2010 (mean age, 58.8 years; male, 68.0%; diabetic nephropathy (DM), 30.3%). The analysis showed that 86.4% and 68.5% of the maintenance PD patients (n=140) exhibited a daily UV of at least 100 ml and at least 400 ml, respectively. The group with a daily UV of 100 ml or over (n=121) showed significant differences in the duration of PD and serum beta 2-microglobulin (B2M, p<0.01) in comparison to the group with a daily UV under 100 ml (n=19). Dividing the patients based on a daily UV of 400 ml or over (n=87) or under 400 ml (n=40) revealed dramatic differences in the 8 clinical parameters, including PD duration (30 vs. 42 months, p<0.01), PD drain volume (391 vs. 1000 mL, p<0.01), cause of ESRD (DM, 21.8 vs. 42.5%, p<0.05), PD Kt/V (1.10 vs. 1.53, p<0.01), residual renal Kt/V (0.74 vs. 0.06, p<0.01), total Kt/V (1.83 vs. 1.65, p<0.01), serum phosphate (5.00 vs. 5.53 mg/dL, p<0.05), and B2M (21.1 vs. 35.4 mg/L, p<0.01).

Conclusions: The current study suggested that PD patients with a daily UV of 400 mL or over exhibited better demographic and clinical data. Further studies are necessary to clarify the daily UV of 400 mL or over as being an adequate marker of RRF and to elucidate its association with the patient prognosis in PD.

SA-PO855

The Glomerular Filtration Rate Estimated from Serum Creatinine Predicts Residual Renal Function in Peritoneal Dialysis Patients Seokhui Kang, Kyu-hyang Cho, Kyung Woo Yoon, Jong-Won Park, Jun-Young Do. *Department of Internal Medicine, Yeungnam University Hospital.*

Background: The aim of this study was to evaluate the clinical relevance of estimated GFR (eGFR) equations in predicting residual renal function (RRF) in peritoneal dialysis (PD) patients.

Methods: We reviewed the medical records to identify all adults who underwent PD between April 2001 and March 2012. We identified 515 patients whose creatinine clearances were measured by both eGFR and 24-hr urine, dialysate collections one or more times, for a total of 3141 pairs of measurements. The eGFRs were calculated using Cockcroft-Gault's formula (CG), four variable MDRD formula (MDRD4), six variable MDRD formula (MDRD6), and CKD-EPI formula.

Results: In anuric patients, there was no significant correlation between the eGFRs and peritoneal clearance. In non-anuria patients, significant correlations were noted between the eGFR and residual renal function, total creatinine clearance, but not peritoneal clearance. (male, r = 0.7830 for CG, r = 0.7804 for MDRD4, r = 0.8097 for MDRD6, r = 0.7782 for CKD-EPI; female, r = 0.6717 for CG, r = 0.6610 for MDRD4, r = 0.6584 for MDRD6, r = 0.6624 for CKD-EPI; $P < 0.0001$ for all variables). In males, simple linear regression analyses using eGFRs for the prediction of residual renal function showed that non-standardized-βs of eGFR were 0.783 for CG, 0.780 for MDRD4, 0.810 for MDRD6, and 0.778 for CKD-EPI ($P < 0.0001$ for all variables). In females, non-standardized-βs of eGFR were similar to those in males (0.672 for CG, 0.661 for MDRD4, 0.658 for MDRD6, and 0.662 for CKD-EPI).

Conclusions: The present study demonstrates that residual renal function is associated with eGFR using serum creatinine. The eGFR using serum creatinine may be an alternative method for predicting residual renal function without 24-hr urine collection.

SA-PO856

The Role of Residual Renal Function in Plasma and Dialysate Clearances of Icodextrin in APD Patients Talerngsak Kanjanabuch, Somchai Eiam-Ong. *Chulalongkorn University.*

Background: To investigate the role of residual renal function (RRF) over pharmacokinetics (PK) of icodextrin and its metabolites in APD patients.

Methods: A prospective non-randomized PK study was conducted. Each patients was administered 1.5 L of solution containing 7.5% icodextrin for 12 hours (8:00-20:00). Afterwards the solution was drained and the patients resumed NIPD (1.8-2L/cycle x 5cycles during 20:00-8:00) using glucose-based solution. Icodextrin and its metabolites (DP2-DP7) were measured in blood, urine, and dialysate by HPAE-PAD with Carbopac PA-1 detector and enzymatic methods. After 24 hours, patients were requested to return on days 3,7,14, and 28 for collections of blood, dialysate, and urine samples. The total carbohydrate (CHO) levels were assessed by enzymatic amyloglucosidase method.

Results: Twelve patients (7 with RRF, 5 without RRF) on APD were included. All patients had been used icodextrin during the 12-hour long dwell for at least 28 days. Approximately two thirds of both groups had diabetes. At baseline both groups were similar in baseline demographics, laboratory measurements, and dialysis parameters besides urine volume and renal clearance. Plasma AUC as well as peak and trough levels of icodextrin were significant higher in the no-RRF group. However, differences between the peak and trough concentrations of icodextrin in both groups were <20%. Peak plasma levels of icodextrin metabolites (DP2-DP7) were observed at 12 and 14 hours after icodextrin administration in the group with RRF and without, respectively. There were trends of lower individual and total plasma DP2-7 levels in the group without RRF. However, the levels seemed to be stable during 1-month period of observation. Of interest, the total CHO concentration faster disappeared from the dwelt dialysate (t0-t12) in the group with RRF but seemingly not differed between groups with or without DM.

Conclusions: RRF plays a significant role in clearance of icodextrin from the plasma and dialysate. Hence administration of icodextrin solution in patients without RRF should warrant for accumulation effects in the long-term usage.

SA-PO857

Skin Autofluorescence, a Measure of Cumulative Advanced Glycation End Products, Is a Strong Predictor of Cardiovascular Events in Patients with Peritoneal Dialysis

Masahiro Koizumi,[1] Noriko Yoshikawa,[2] Hirotaka Komaba,[1] Takatoshi Kakuta,[1] Masafumi Fukagawa.[1] *[1]Division of Nephrology, Endocrinology and Metabolism, Tokai University School of Medicine, Isehara, Kanagawa, Japan; [2]Division of Nephrology, Tokyo Medical University Hachioji Medical Center, Hachioji, Tokyo, Japan.*

Background: Advanced glycation end products (AGEs) are biomarkers of metabolic stress and are thought to play a role in the pathogenesis of chronic complications of chronic kidney disease. Tissue autofluorescence (AF) is related to the accumulation of AGEs. Evaluation of accumulative AGEs by skin AF predicts cardiovascular outcomes in patients with predialysis CKD and hemodialysis. However, little is known whether skin AF is associated with cardiovascular outcomes in patients with peritoneal dialysis (PD).

Methods: This multicenter, prospective cohort study enrolled 105 PD patients, aged 20-80 years, between April 2007 and March 2009. Skin AF and clinical parameters concerning residual kidney function were measured at baseline and study months 6, 12, and 24. The primary outcome was the occurrence of major cardiovascular events.

Results: There was a progressive and significant increment in skin AF levels from 2.89 ± 0.97 A.U. at baseline to 3.89 ± 1.13 A.U. at months 24. Changes in skin AF levels were significantly associated with changes in serum beta-2 microglobulin (< 0.01) and renal Kt/V (< 0.05). During the follow-up periods (3.46 ± 1.2 years), 32 patients had a major cardiovascular event, of which 7 died from cardiovascular causes. Cox proportional hazards analysis showed that skin AF was a significant predictor of cardiovascular events (hazard ratio, 0.28; 95% CI, 0.12 to 0.66), independently of serum beta-2 microglobulin (hazard ratio, 0.21; 95% CI, 0.12 to 0.67), and renal Kt/V (hazard ratio, 0.19; 95% CI, 0.11 to 0.58).

Conclusions: Skin AF level is associated with residual kidney function, and a strong and independent predictor of cardiovascular events in PD patients.

SA-PO858

The Effect of Residual Renal Function and Other Patient Factors on Gram Positive Peritonitis Outcomes

Rachel Whitty,[1] Philip Lui,[1,2] Alex Kiss,[3] Linda Dresser,[1,2] Joanne M. Bargman.[1] *[1]University Health Network, Toronto, Canada; [2]Faculty of Pharmacy, University of Toronto, Toronto, Canada; [3]Sunnybrook Research Institute, Toronto, Canada.*

Background: Gram positive organisms are the most common cause of peritonitis in patients treated with peritoneal dialysis. Pharmacokinetic studies have indicated that clearance of antibiotics is higher with Continuous Cyclic Peritoneal Dialysis (CCPD) than Continuous Ambulatory Peritoneal Dialysis (CAPD), and that patients who are non-anuric have lower cefazolin concentrations compared to patients who are anuric. Few studies have examined how these and other factors affect peritonitis treatment outcomes.

Methods: Between 2003 and 2010, all gram positive peritonitis episodes treated with cefazolin at a large tertiary care hospital were included. A Cox proportional hazards model was used to examine the relationship between the primary outcome, time to resolution of the intraperitoneal (IP) white blood cell (WBC) count, and the following factors: PD modality, renal creatinine clearance (CrCL), PD vintage, hospitalization during peritonitis treatment, age, change in antibiotic during peritonitis treatment, and cefazolin dose per kilogram of body weight. Polymicrobial infections were excluded.

Results: There were 119 patients with 177 peritonitis episodes in this study. Lower CrCLwas associated with a greater likelihood of resolution of the IP WBC count (p=0.0002). Shorter duration of PD was associated with a greater likelihood of resolution (p=0.005). Interestingly, age was also statistically significant (p=0.03) with older age associated with greater resolution.

Conclusions: Longer PD vintage may be associated with changes to the peritoneal membrane that leads to decreased resolution. The association between greater renal function and non-resolution suggests renal cefazolin clearance contributing to lower cefazolin concentrations and treatment failure. The unexpected association of younger age with non-resolution warrants further investigation.

SA-PO859

Factors Affecting Treatment Outcomes of Peritonitis in Peritoneal Dialysis Patients

Rachel Whitty,[1] Philip Lui,[1,2] Alex Kiss,[3] Linda Dresser,[1,2] Joanne M. Bargman.[1] *[1]University Health Network, Toronto, Canada; [2]Faculty of Pharmacy, University of Toronto, Toronto, Canada; [3]Sunnybrook Research Institute, Toronto, Canada.*

Background: Peritonitis associated with peritoneal dialysis is usually treated successfully. However, failed treatment can lead to relapse, catheter removal, change to hemodialysis, and even death. Few studies have examined factors that affect outcomes of peritonitis treatment.

Methods: Data from all peritonitis episodes at a large tertiary care hospital was collected prospectively from 2003-2010. A Cox proportional hazards model was used to examine the relationship between the primary outcome, time to resolution of the intraperitoneal (IP) white blood cell (WBC) count, and the following factors: PD modality, renal creatinine clearance (CrCL), PD vintage, hospitalization during peritonitis treatment, age, and change to an alternative antibiotic during peritonitis treatment. CrCL was analyzed in three groups: 0 mL/min (group 0), >0 to 5 mL/min (group 1), and >5 mL/min (group 2). Polymicrobial, fungal, and mycobacterial infections were excluded.

Results: There were 215 patients with 393 episodes of peritonitis in the study. Lower CrCL was associated with a greater likelihood of resolution of the IP WBC count (HR 1.52, p=0.0076 for group 1 vs. 2). Treatment at home was associated with a greater likelihood of resolution of the IP WBC count compared to hospitalization (HR 1.59, p=0.0005).

Conclusions: Greater residual kidney function and hospitalization during peritonitis treatment were associated with a decreased likelihood of resolution of peritonitis. PD modality, PD vintage, age, and change to an alternative antibiotic during peritonitis treatment did not significantly affect the primary outcome. Hospitalization was likely a surrogate for more severe peritonitis. However, the surprising association of better renal function with non-resolution suggests that current antibiotic regimens may lead to underdosing and may not account for renal antibiotic clearance.

SA-PO860

Peritoneal Dialysis as Rescue Therapy for Patients with No Vascular Access: A Prospective Study

Viviane Felis Pinheiro,[1] Cristiane C. Cavalcante,[1] Eliane Gloria Xavier,[1] Ana C.D. Faita,[1] Soraia S. Drumond,[1] Rosa M.A. Moyses,[1,2] Zita Maria Leme Britto.[1] *[1]Cetene - Centro de Terapia Nefrológica, São Paulo, Brazil; [2]Nephrology, Universidade de São Paulo, Brazil.*

Background: The choice between peritoneal dialysis (PD) and hemodialysis (HD) is usually based on clinical criteria and on patient preference. However, some patients are referred to PD because of difficulties in obtaining vascular access for HD and are commonly considered "negative selection" (NEG) patients, who will probably have a worse prognosis than will those who are incident dialysis patients and choose to start PD (POS patients). However, there have been few prospective studies comparing outcomes in such patients.

Methods: We compared POS patients (n=72) and NEG patients (n=14) referred to our PD clinic between Jan. 2009 and Sep. 2011, following them until May 2012.

Results: NEG patients tended to be younger (56 ± 12 vs. 64 ± 16 yrs; p = 0.09), had been on HD for 32 months and had a median of 5 previous vascular access failures. No differences were seen regarding gender, race or prevalence of diabetes (55.6 vs. 35.7%; ns). After 475 ± 240 days of follow-up, 41 episodes of peritonitis had occurred in 29 patients, although there was no difference between POS and NEG patients (33 vs. 36%; ns). All deaths (n = 14) occurred among POS patients. A composite analysis of survival and return to HD showed no significant differences between POS and NEG patients. Analysis of patients that present a failure in PD modality identified peritonitis as a positive risk factor (RR=3.94; p<0.0001), independent of status (POS or NEG).

Conclusions: Our data show that patients referred to PD as a last recourse for dialysis do not present a worse prognosis than do those choosing PD as a first option. However, the occurrence of peritonitis can lead to modality failure, HD no longer being an alternative for some. Therefore, such patients should be closely monitored to avoid this common complication of PD.

Peritoneal Dialysis-Associated Peritonitis in Austria: Epidemiology, Risk Factors, and the Role of Oral Active Vitamin D

Julia Kerschbaum,[1] Andreas Vychytil,[2] Karl Lhotta,[3] Friedrich C. Prischl,[4] Martin Wiesholzer,[5] Veronika Machold-fabrizii,[6] Gertrude Kopriva-altfahrt,[6] Christoph Schwarz,[7] Peter Balcke,[5] Rainer Oberbauer,[2,7,8] Reinhard Kramar,[8] Michael Rudnicki,[1] Paul Koenig.[1] *[1]Medical University Innsbruck, Austria; [2]Medical University Vienna, Austria; [3]Landeskrankenhaus Feldkirch, Austria; [4]Klinikum Wels-Grieskirchen, Austria; [5]A.ö. Krankenhaus St. Pölten, Austria; [6]Wilhelminenspital, Austria; [7]Krankenhaus der Elisabethinen, Austria; [8]Austrian Dialysis and Transplant Registry, Austria.*

Background: Peritonitis is a major complication of peritoneal dialysis being associated with hospitalization, technique failure, and increased mortality. Data on incidence and risk factors for peritonitis are scarce.

Methods: Patients who performed PD between January 2000 and December 2009 in seven Austrian PD-units were included (n=720). Date and culture result for peritonitis, concomitant medication and comorbidities were identified from the patients records.

Results: We collected data from 720 patients representing 1703 patient years and 44.3 % of the PD population treated in Austria in this time period. The median peritonitis incidence rate was 0.34 episodes/patient–year (interquartile range: 0.32-0.39). In a multivariate analysis the risk for peritonitis was decreased by 57 % in patients treated with oral active vitamin D (HR 0.43; 95 % CI 0.28-0.64). Furthermore, renal diagnosis and decreased albumin levels were associated with an increased risk for peritonitis. Detailed analysis revealed that vitamin D especially reduced the risk for gram-positive and -negative episodes of peritonitis, whereas in sterile episodes no significant association could be shown. Beside decreased levels of albumin, higher age, and cardiomyopathy which increased the risk for all-cause mortality, treatment with oral active vitamin D was also associated with a significantly lower risk of death (HR 0.46; 95% CI 0.27-0.81).

Conclusions: In this nationwide retrospective cohort study we identified several factors related to increased risk for peritonitis. Oral active vitamin D was independently associated with decreased risk for peritonitis and all-cause mortality in PD-patients.

SA-PO862

Pets-Related Peritonitis and Its Prevention in Peritoneal Dialysis: A Case Study Mekdess Abebe,[1] Cheryl Laveglia,[2] Nand K. Wadhwa.[1] *[1]Division of Nephrology, Stony Brook University, Stony Brook, NY; [2]Dialysis Clinic, Inc, East Setuaket, NY.*

Background: Many peritoneal dialysis (PD) patients keep animals/pets as life time companion for their social support. However, the interaction with pets can increase the risk for peritonitis. We encountered a patient who kept pets and had recurrent peritonitis due to Pasteurella multocida. This prompted us to evaluate the prevalence of animals/pets in PD patients and to incorporate a training session about pets when the patient initiates PD. Thus we evaluated the prevalence of pets and associated peritonitis before and after the training.

Methods: All PD patients in our dialysis unit were included. A training session was instituted for PD patients who have kept domestic animals as pets. The training included interventions including patient education, counseling on hygiene and placement of barriers limiting the pets' access to the dialysis equipment. Questionnaires related to the interactions of the patients with the pets during treatment and/or set up were distributed to all PD patients before and after the training. The prevalence of pets and peritonitis rates were analyzed.

Results: The patient population included 17 males and 11 females with a mean age of 55 years. The PD patients who kept companion animals were 21% (6/28) compared with 23% (6/26) two years ago. Only 50% (3/6) of patients allowed pets in the room during set up and/or treatment as compared to 83% (5/6) before our intervention. Only one patient reported that pets are allowed in the room during set up and treatment. Two patients don't allow pets in the room during set up but occasionally pets enter the room during treatment. Three patients never allowed their pets to interact during setup, exit site care or treatment. Subsequently we have no episode of peritonitis related to pets in our unit. Our patient with recurrent peritonitis due to Pasteurella multocida has been free of peritonitis for three years after the training on handling of pets during PD treatment.

Conclusions: We recommend a periodic questionnaire and an educational session for all PD patients who have or intend to have pets for their social support to prevent pets-related peritonitis.

SA-PO863

Low Serum Cultured Adipose-Derived Mesenchymal Stromal Cells Ameliorate Rat Model with Zymosan Induced Severe Peritonitis Hangsoo Kim, Masashi Mizuno, Kazuhiro Furuhashi, Takayuki Katsuno, Takenori Ozaki, Kaoru Yasuda, Waichi Sato, Naotake Tsuboi, Yasuhiko Ito, Enyu Imai, Shoichi Maruyama, Seiichi Matsuo. *Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Japan.*

Background: In peritoneal dialysis,fungal peritonitis is a major problem as the fibrosis can progress rapidly and it may evolve into encapsulating peritoneal sclerosis even after the peritoneal dialysis catheter has been removed.

In this study, we used rat peritonitis model induced by zymosan administration after peritoneal scrape accompanied complement activation and attempted to treat the model by low serum cultured adipose-derived mesenchymal stromal cell(LASC).

Methods: The fungal peritonitis was induced in the rat model by administrating zymosan daily for 5 days after scraping the peritoneum mechanically. The rats were divided into two groups; LASC (L group) or vehicle (V group) administration intraperitoneally with PD solution every day. On day 5, rats were euthanized and the peritoneums were harvested, then the thickness of the peritoneum, the infiltration of inflammatory cells, and the deposition of the complement were compared between the groups.To trace LASCs,CFSE labeled LASCs were administered, then assessed by immunofluorescent staining.For the in vitro study, we obsereved the interaction between mesothelial cells(MCs) and LASCs.

Results: On day 5, microscopic findings in L group had less plaques and less edematous. Histologically, the thickness of the peritoneum, the infiltration of inflammatory cells and the deposition of complements in L group was significantly more reduced than those in V group. In addition, the mesothelial cell layer on the peritoneal surface in L group recovered more quickly compared with that in V group. Also, the layer in L group showed complement regulatory factors clearly. In the tracing study, LASCs were laid mainly on the surface of peritoneum along with the recovered MCs.In vitro study, the supernatant of LASCs stimulated the growth of MCs.

Conclusions: The results suggest that LASCs have the multiple effects on peritoneal damage. In the future, LASC therapy may be useful for treating peritoneal injury during fungal infection of the peritoneum.

SA-PO864

Probiotics Decrease the Incidence of Gram Negative Peritonitis in Patients on Peritoneal Dialysis An-Bang Wu, Ming-cheng Wang, Yu-tzu Chang, Chin Chung Tseng. *Division of Nephrology, Department of Internal Medicine, National Cheng Kung University Hospital, Tainan, Taiwan.*

Background: Peritonitis may cause catheter removal in uremia patients. Gram negative bacteria (GNB), most coming from intestinal tract, may cause worse result. The probiotics may decrease pathogens in intestinal tract. So we use probiotics to prevent peritonitis, and improve the gastrointestinal function.

Methods: This was a randomized double blind study. The inclusion criteria were 1. Uremia patients on peritoneal dialysis (PD) more than 3 months. 2. Age between 16 and 75 years. The exclusion criteria were 1. Patients had advanced malignance. 2. Patients had more than two episodes of G(+) peritonitis within one year. 3. Patients had expected life less than one year. 4. Patients had drug abuse. 5. Poor compliant patients. 6. Patients had active infection. 7. Patients had uncontrolled autoimmune disease. Fifty patients received probiotics one pack per day (Lactobacillus acidophilus, Bifidobacterium, Enterococcus faecium, Bifidobacterium longum and prebiotics (Fructo Oligo Saccharides)) and the other fifty patients received placebo (prebiotics only). The primary end point was time to the first episode of peritonitis. The secondary outcome was SGA score and serum albumin change.

Results: The first patient was recruited on March 16, 2010 and the last on April 26, 2010. Total 100 patients were included. The baseline characteristics were similar.Eight patients drop out. Two received renal transplantation, two expired, and four shifted to hemodialysis (due to refractory peritonitis, colon perforation, tunnel infection and patient's request). There were 12 episodes of peritonitis including 3 GNB peritonitis. No difference was found in peritonitis incidence between two groups. However, no GNB peritonitis developed since four months of study in two groups. There was no significant difference in the nutrition marker.

Conclusions: There was no significant difference in peritonitis incidence between the two groups. But no GNB peritonitis developed since four months of the study. Both probiotics and prebiotics may prevent the GNB peritonitis in patients receiving PD.

SA-PO865

The Improvement of Peritoneal Dialysis (PD) Device and Biocompatible Dialysate Might Decrease the Frequency of PD-Associated Peritonitis, and Result in Reducing the Risk for Encapsulating Peritoneal Sclerosis Masatsugu Nakao, Keitaro Yokoyama, Izumi Yamamoto, Yudo Tanno, Ichiro Ohkido, Hiroshi Hayakawa, Masato Ikeda, Hiroyasu Yamamoto, Tatsuo Hosoya. *Division of Nephrology & Hypertension Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan.*

Background: Peritoneal dialysis (PD)-associated peritonitis is a serious complication in patients undergoing PD that results in discontinuation of PD and encapsulating peritoneal sclerosis (EPS). It is therefore important to elucidate the prevalence of PD-associated peritonitis and the causative pathogens. Particularly in Japan, changes to PD devices and fluid pH, from acidic to neutral, are expected to affect the prevalence of PD-associated peritonitis and associated pathogens, and thus the prevalence EPS.

Methods: This study assessed patients who had undergone PD at our hospital between January 1990 and May 2012. For each PD device, patients were divided according to the following: single-bag and acidic PD fluid (S+A group); twin-bag and acidic PD fluid (T+A group); and twin-bag and neutral PD fluid (T+N group). The prevalence of PD-associated peritonitis, pathogens, and the incidence of EPS were then compared between groups.

Results: The T+A group had fewer cases of peritonitis (76.0±11.7 patient-months vs. 114.8±61.3 patient-months P=0.001) and a lower percentage of *Staphylococcus sp.* (43.5% vs. 26.1%, P=0.001) and *Pseudomonas aeruginosa* (25.8% vs. 5.6%, P=0.0003) than the S+A group. Although the number of peritonitis cases was similar in the T+A and T+N groups (114.8±61.3 patient-months vs. 122.3±60.7 patient- months, NS), the T+N group had a higher percentage of *Streptococcus sp.* (4.9% vs. 27.4%, P=0.001) and Gram-negative rods, excluding *Pseudomonas aeruginosa*, (4.9% vs. 13.9%, P=0.03) than the T+A group. The rate of EPS was 25.2% (24/95 patients) in the S+A group, 6.3% (10/158 patients) in the T+A group, and 0% in the T+N group, showing that the incidence was extremely low or zero with the use of twin bags (P<0.0001).

Conclusions: Changes in PD devices and fluids resulted in a different prevalence of peritonitis, type of pathogen, and incidence of EPS.

SA-PO866

Lack of Patient Free Choice of Technique Predicts Peritonitis in Peritoneal Dialysis Clara Santos, Joao Carlos Fernandes, Ana Marta Gomes, Joaquim Seabra. *Nephrology, CHVNG/E, Portugal.*

Background: Peritonitis is a major complication of peritoneal dialysis (PD) and its occurrence is associated with significant morbidity and mortality. Determining factors that are associated with PD peritonitis might have an important role in its prevention.

Methods: Retrospective longitudinal cohort study of all patients on PD program between 1998 and 2011. Demographic and clinical variables were evaluated and compared between patients who had at least one episode of peritonitis and patients who never had peritonitis. In statistical analysis, we used the chi-square, Student's t test and Mann-Whitney test. In univariate and multivariate longitudinal analysis we used log-rank test and Cox regression model, respectively. A p-value less than 0.05 was considered statistically significant.

Results: We studied 122 patients with mean age 53±15years, 61%male, 16%diabetic, with an average length of stay in PD for 23 months. 140 episodes of peritonitis were identified in 58 patients, yielding a total rate of 1 episode per 20.6 months. 35% of first peritonitis episodes were observed during the first 6 months of treatment. The occurrence of peritonitis was not correlated with gender, age, diabetes, first renal replacement therapy, PD modality, loss residual renal function and D/P creatinine at the time of PD start. In multivariate analysis, obligatory inclusion on PD, compared to patient free choice, was the only predictive factor of the development of peritonitis (HR = 2.05; 95% CI 1.10 to 3.84; p=0.025).

Conclusions: The principal finding of the study was that obligatory inclusion on PD, usually for lack of vascular access for hemodialysis, was the only significant predictive factor of the development of peritonitis. These patients may benefit from a more intense and closely supervised PD training. The fact that 35% of first peritonitis episodes occur during the first 6 months of technique also stresses the importance of more intensive training and attention during the initial period of treatment. The occurrence of peritonitis is higher in patients who start PD without other choice than those who freely choose this technique. Those patients may benefit from more intense training programs and more attention.

SA-PO867

The Long Term Observation of Conservative Therapy for Encapsulating Peritoneal Sclerosis (EPS) Kyoko Kishida,[1] Keitaro Yokoyama,[1] Nanae Matsuo,[1] Masatsugu Nakao,[1] Yudo Tanno,[1] Ichiro Ohkido,[1] Hiroshi Hayakawa,[1] Kenji Kasai,[2] Hiroyasu Yamamoto,[1] Tatsuo Hosoya.[1] *[1]Division of Kidney, Hypertension, The Jikei University School of Medicine, Tokyo, Japan; [2]Division of Internal Medicine, Fuji City General Hospital, Shizuoka, Japan.*

Background: Encapsulating peritoneal sclerosis (EPS) is a severe complication of peritoneal dialysis (PD). For reason that surgical treatment for EPS is technically difficult; in patients who have relieved symptoms of the intestinal obstruction without surgery, the operation for EPS is hesitated even if the risk for the recurrence of intestinal obstruction is not necessarily low. In fact some patients with EPS died due to the recurrence of intestinal obstruction. So it is required to evaluate the validity of this conservative treatment.

Methods: In order to investigate long-termoutcome in patients with EPS, in this historical cohort study, we recruited 50 EPS cases admitted to our Hospital from 1989 November to 2011 May. Patients were divided into two groups, the conservative therapy group and the surgical treatment group, and their outcomes were compared.

Results: Twenty nine of the 50 EPS cases have relieved symptoms of the intestinal obstruction conservatively such as IVH, NPO and so on, but 7 of the 29 cases underwent emergency surgery within a few years because of bowel perforation, and 3 of them died after surgery. For death cases of the conservative therapy group, 8 of them were EPS related-death. The survival rate was higher in the surgical treatment group.

Conclusions: During long-term observation, the prognosis of EPS patients with conservative therapy was poor depend on developing bowel perforation. Accordingly, surgical treatment for EPS should not be hesitated for the reason why it is technically difficult. The indications and timing of surgery for EPS should be reconsidered based on the results of this study.

SA-PO868

Laparoscopic Approach for Evaluation of Encapsulating Peritoneal Sclerosis in Peritoneal Dialysis Patients Yudo Tanno, Masatsugu Nakao, Izumi Yamamoto, Nanae Matsuo, Ichiro Ohkido, Hiroyasu Yamamoto, Keitaro Yokoyama, Tatsuo Hosoya. *Division of Kidney and Hypertension, Jikei University School of Medicine, Tokyo, Japan.*

Background: Encapsulating peritoneal sclerosis (EPS) is a serious complication of peritoneal dialysis (PD). Therefore, assessment of peritoneal injury in patients undergoing PD is important in preventing EPS. Clinical significance of assessing peritoneal permeability with peritoneal equilibration test (PET) and of measuring biomarkers in PD effluent is not established. Furthermore, since examination of peritoneal tissue samples only assesses pathology of parietal peritoneum around the catheter insertion site, it is difficult to predict any existing visceral peritoneal injury from this result. We reported that it was possible to detect early changes observed in the development of EPS by using laparoscopy (Kidney International 2012 in press). Therefore, we studied laparoscopic findings in patients who had undergone PD for more than 4 years.

Methods: 14 patients underwent laparoscopy at the time of PD catheter removal. Duration of PD in these patients was 7.8±4.8 years. Clinically, none of these patients had developed EPS by the time of the investigation. The findings of both parietal and visceral peritoneal tissues were categorized according to color changes, presence of neovascularizations and adhesions.

Results: It was found that longer the duration of PD, the worse the peritoneal injury. Changes in the parietal and visceral peritoneum had heterogeneous distributions. Moreover, with regard to adhesions in the visceral peritoneum, they were dominant in the right lower abdomen. There was discrepancy in the findings between the parietal and visceral tissues, as shown in the table below.

Percentages of macroscopic changes observed in the peritoneum

	color changes	neovascularizations	adhesions
parietal peritoneum	85%	64%	42%
visceral peritoneum	39%	35%	28%

Conclusions: These findings suggest that EPS can occur focally in isolation therefore, blind biopsies of the peritoneum may not be sufficient to detect EPS. For this reason, evaluation of the entire peritoneum by laparoscopy provides more accurate and extensive information about the peritoneal injury.

SA-PO869

Influence of Peritoneal Membrane Phosphate Transport Characteristics on Choice of Peritoneal Dialysis Modality Asmaa Y. Mohammed Al- Chidadi, Andrew Davenport. *UCL Center for Nephrology, Royal Free Hospital, London, United Kingdom.*

Background: Hyperphosphatemia is associated with an increased risk of mortality in dialysis populations. There is little data on peritoneal phosphate clearance (PPiCl) in PD patients, and we set out to review its determining factors.

Methods: In a cross sectional observational prospective study, measurements of D/P Pi and D/P Cr were made during a standard PET, and PPiCl with 24 hour PD effluent in 327 consecutive adult PD patients, 161 female (49.2%). Patients were stratified according to their D/PCr and D/PPi and modality (CAPD or APD).

Results: D/PPi correlated with D/PCr together with peritoneal Cr Clearance (PCrCl) and PPiCl. Among anuric patients with Pi≥1.7 there was no significant difference between total PiCl compared to those with Pi<1.7 (47.9 ±37.5 vs 60 ±27.9 l/wk). Similar results were found in those with RRF (44.8 ±42 vs 43 ±28 l/wk). There was no significant difference in dietary protein intake (nPNA) according to Pi level (0.94 ±0.3 vs 0.96 ±0.2). In both anuric patients and those with RRF, high Pi transporters had significantly lower serum Pi, indicating D/PPi as an independent factor predicting hyperphosphatemia (0.86 ±0.3 vs 1.2 ±0.3, p<0.05). There was a significant difference between D/P Pi groups in regard to PPiCl and PCrCl (p<0.05) but not in peritoneal KT/V (p<0.09). PCrCl and PPiCl were significantly higher in CAPD vs APD (36 ±24 vs 24.9 ±27, p<0.001 and 31.7 ±20.7 vs 22 ±24.6, respectively p<0.001). D/PCr was significantly higher in CAPD patients(0.7 ±0.1 vs 0.7 ±0.1, p=0.04). D/PPi did not achieve significance in CAPD.

Among fast average and slow average Pi transporters, PCrCl and PPiCl were significantly higher in CAPD patients (36 ±24 vs 24.9± 27, p< 0.001 in fast average transporters and 32.6 ±17.9 vs 15.9 ±18.9, P 0.03 in slow average transporters and 31.7 ±20.8 vs 22 ±24, P 0.001 in fast average transporters and 33 ±17 vs 12.9 ±16.5 in slow average transporters respectively).

Conclusions: Peritoneal Pi transport characteristics should be considered when optimizing PD modality in hyperphosphatemic patients. Increasing APD dwell times and switching to CAPD can improve PPiCl in patients with inadequate phosphate control on APD.

Funding: Government Support - Non-U.S.

SA-PO870

Influence of Dialysis Modality on Chronic Kidney Disease-Mineral Bone Disorder: Hemodialysis x Peritoneal Dialysis Rodrigo Azevedo de Oliveira,[1] Fellype Carvalho Barreto,[1,2] Zita Maria Leme Britto,[3] Viviane Felis Pinheiro,[3] Luciene M. dos Reis,[1] Rosa M.A. Moyses,[1] Vanda Jorgetti.[1] *[1]Universidade de São Paulo, São Paulo, SP, Brazil; [2]Uninove, São Paulo, SP, Brazil; [3]Cetene, São Paulo, SP, Brazil.*

Background: Few studies have evaluated Chronic Kidney Disease - Mineral Bone disorder (CKD-MBD) with bone biopsy in peritoneal dialysis patients. They suggest a higher prevalence of low turnover bone disease in comparison to hemodialysis population. However, there is not any study with homogeneous compared groups. The aim of our research was to compare CKD-MBD profile (laboratorial abnormalities and renal osteodysthrophy) between peritoneal dialysis (PD) and hemodialysis (HD) patients matched to age, sex and length on dialysis.

Methods: Thirty-two HD patients (68.7% male; 48.8± 12.3 years old; length on HD: 23.0 ± 15.3 months) were comparedto 32 PD patients (50% male; 49.0 ± 10.4 years old; length on PD: 18.8 ± 17.5 months). Both groups were submitted to laboratorial evaluation and iliac crest bone biopsy. Bone tissue was evaluated according to TMV classification (Turnover, Mineralization and Volume).

Results: Concerning the laboratorial evaluation, in general, HD patients presented higher levels of biochemical markers of mineral metabolism than PD patients: alkaline phosphatase: 229.6 ± 93 x 107.7 ± 36 U/L; p <0.00i; iPTH: 207.5 (88.7 – 656.0) x 359.0 (242.0 – 483.5); p = 0.04; FGF-23: 11826 (3369 – 28763) x 497 (411 – 1186) pg/ml; p < 0.001; 25(OH)vitaminD: 35.9 ± 15.6 vs 12.1±7.0; p<0.001; and albumin: 3.8 ± 0.2 vs 3.5 ± 0.5; p<0.001. According to TMV classification, peritoneal dialysis was associated to low bone turnover (p=0.04), low bone mineralization (p=0.04) and to a normal/high trabecular bone volume (p = 0.005) compared to HD patients.

Conclusions: Our bone-biopsy based study confirmed that PD is associated to low bone turnover in comparison to HD treatment, probably due to lower PTH and vitamin D levels. Interestingly, PD treatment seems to preserve trabecular bone volume.

Funding: Government Support - Non-U.S.

SA-PO871

Oral Sodium Bicarbonate May Ameliorate Hyperphosphatemia in Peritoneal Dialysis Patients with Metabolic Acidosis Subir K. Paul, Narasimha R. Boorgu, Rajesh Boorgu, Shejuti Paul. *Shoals Kidney & Hypertension Center, Florence, AL.*

Background: Despite achievement of adequate solute clearance with peritoneal dialysis (PD), metabolic acidosis (MA) remains a frequent problem in PD patients and is associated with adverse outcome. Similarly, despite implementation of current therapeutic approaches, hyperphosphatemia (HP) management remains sub-optimal in many PD patients. HP and high calcium phosphorus product (CaPP) are known causes of vascular, cardiac, and soft tissue calcifications. We have found a strong inverse correlation (r=-0.56) between serum bicarbonate concentration and phosphate level in patients on chronic PD. This study tests the hypothesis that correction of MA in chronic PD patients with oral $NaHCO_3$ will be beneficial for control of HP.

Methods: 13 patients on chronic PD with MA (serum HCO_3 < 22 meq/L) with mean age of 52.5 were included. 9 were male, and 4 were female. Serum HCO_3, phosphate, and Ca levels were measured in DaVita laboratory 4 weeks prior to initiation of therapy, at baseline, and 2-4 weeks following start of therapy. $NaHCO_3$ was given orally with total dose of 3900 mg daily for one month. No change was made in dietary phosphate restriction, phosphate binders, or in vitamin D dosages. Data was analyzed by student's paired t-test and linear regression.

Results: During pre-treatment phase, serum HCO_3 worsened from 21.4 meq/L to 19 meq/L in 4 weeks (p <0.0001). With oral $NaHCO_3$ therapy, serum HCO_3 improved from 19 meq/L to 24.9 meq/L (p < 0.0001). In pretreatment phase serum phosphate increased from 5.9 mg/dl to 7.3 mg/dl. (p<0.0001) With treatment, serum phosphate decreased from 7.3 mg/dl to 5.4 mg/dl (p <0.0001). In pretreatment phase CaPP increased from 54.4 to 63.7 (p<0.0001) but decreased from 67.7 to 50.4 (p<0.0001) following treatment. 69% of treated patients met K/DOQI guidelines of phosphate <5.5 and 77% met recommended value of CaPP < 55.

Conclusions: We conclude that oral sodium bicarbonate therapy corrects metabolic acidosis in chronic PD patients and may be therapeutically beneficial in the management of HP. Double blind, large, randomized, placebo controlled studies are warranted.

SA-PO872

Effects of Paricalcitol on Peritoneal Membrane in a Rat Peritoneal Dialysis Model Arzu Velioglu,[1] Zeynep Bozkurt,[1] Halil Tugtepe,[2] Deniz Filinte,[3] Ebru Asicioglu,[1] Izzet Hakki Arikan,[1] Serhan Tuglular,[1] Ishak Cetin Ozener.[1] *[1]Nephrology; [2]Pediatric Surgery; [3]Pathology, Marmara University, School of Medicine, Istanbul, Turkey.*

Background: Experimental studies showed activation of vitamin D receptor reduced the fibrotic lesions in kidney and heart. Effects of vitamin D and its analogs on peritoneal function and morphology in peritoneal dialysis (PD) were not suggested previously. In this study, we aim to examine the effects of paricalcitol on peritoneal membrane.

Methods: We use 30 rat to 4 groups: Group N, Sham operated rats as control group (n=6); Group U, Ureamic rats (5/6 nephrectomy, 2weeks) (n=8); Group PD, Ureamic rats (2 weeks) + PD (4 weeks) (n=8); Group PD-P, Ureamic rats (2 weeks) + [PD + paricalcitol (0.24 mcg/kg/day, IP)] (4 weeks) (n=8). For PD, a silicone catheter was introduced into the abdominal cavity after development uremia. At the end of study, 24-hour urine samples were collected and 1-h peritoneal equilibration test was performed. Blood pressure (BP) was measured using tail-cuff system. Peritoneal thickness was measured, and inflammation, fibrosis, and vascularization were evaluated semi-quantitatively score.

Results: PDF instillation, resulted in obvious alterations in peritoneal transport (increased D/P urea, decreased D1/D0 glucose) and peritoneal morphology (increased neovascularization, inflammation and fibrosis) compared to control and ureamic groups. Paricalcitol administration significantly improved UF capacity of peritoneum decreasing peritoneal thickness, neovascularization and inflammation compared to the group PD (42,5±16,6 vs. 25,6±4,9 µm, p=0,038; 72,7±19,1 vs. 14,6±5,4, p=0,02; 2,63±0,51 vs. 1,38±0.51, p<0,0001;respectively). 24-h urine output was not decreased in group PD-P. Increased BP was observed in uremic rats (group U, PD, PD-P). Paricalcitol administration was decreased BP levels in PD-P group compared to PD group (173,2±3,2 mmHg vs. 163,7±4,6 mmHg, p=0,005).

Conclusions: Paricalcitol ameliorated peritoneal function and morphology in subtotally nephrectomized rats who were receiving peritoneal dialysis.

Prevalence of Chronic Kidney Disease: Mineral and Bone Disorder in Incident Peritoneal Dialysis Patients and Its Impact on Short Term Morbidity and Mortality Shen Hui Chuang,[1,2] Hung Chew Wong,[3] Vathsala Anantharaman,[4] Priscilla P. How.[1,4] *[1]Pharmacy, National University of Singapore (NUS), Singapore; [2]Pharmacy, Tan Tock Seng Hospital, Singapore; [3]Biostatistics Unit, Yong Loo Lin School of Medicine, NUS, Singapore; [4]Medicine (Nephrology), National University Hospital, Singapore.*

Background: A complex relationship exists between chronic kidney disease-mineral and bone disorder (CKD-MBD) and adverse clinical outcomes in incident peritoneal dialysis (PD) patients. The objectives of this study were to report the prevalence of CKD-MBD and examine the impact of attaining target CKD-MBD parameters on one-year morbidity and mortality in incident PD patients in Singapore.

Methods: In this retrospective cohort study, patients electively initiated on PD from June 2006 to August 2010 were followed up for one year from date of PD initiation. CKD-MBD parameters were collected and the prevalence of CKD–MBD at 4 to 6 months after PD initiation was determined based on KDOQI and KDIGO guidelines. Linear regression and Cox proportional hazards model were used to evaluate the effects of attaining target CKD-MBD parameters at 4 to 6 months post-PD initiation on hospitalization, peritonitis or exit-site infections and mortality at one year.

Results: Eighty-six patients were included in this study. The prevalence of CKD-MBD was 86.0% (KDOQI) and 54.7% (KDIGO). Duration of hospitalization was similar in patients who met CKD-MBD goals and those who did not. In the adjusted analyses, patients who failed to meet all of KDIGO's CKD-MBD goals [regression coefficient (RC): 1.24, p= 0.01] or calcium (Ca) targets [RC: 1.18, p= 0.02] had a significantly higher incidence of peritonitis or exit-site infections. Additionally, there was a trend towards shorter time to death in patients who failed to meet KDIGO's phosphorus (P) targets [adjusted hazard ratio: 9.54, 95% CI: 0.98 - 92.86, p=0.05].

Conclusions: Prevalence of CKD-MBD in our patient population was moderate (KDIGO) to high (KDOQI). Achievement of all of KDIGO's CKD-MBD goals or individual Ca targets was associated with reduced peritonitis and exit-site infections. There was a trend towards improved survival in patients who met KDIGO's P goals.

SA-PO874

Short Term Impact of the Peritoneal Dialysate Switch from Low Calcium to Standard Calcium Concentration Minoru Ito. *Division of Nephrology, Yabuki Hospital, Yamagata, Japan.*

Background: In patients on peritoneal dialysis (PD) therapy, calcium (Ca) concentration of peritoneal dialysate is an important factor influencing serum Ca concentration and parathyroid hormone (PTH) levels. In Japan, low Ca (2.5 mEq/L) dialysate and standard Ca (3.25 - 4.0 mEq/L) dialysate are available. Actually, low Ca dialysate is commonly used compared with standard Ca dialysate in Japan. However, there is a no guideline about the choice of Ca concentration. The adequate Ca concentration of PD solution is still unclear. The aims of this study are to assess the influence of the change from low Ca solution to standard Ca solution and to consider the optimal Ca concentration of peritoneal dialysate.

Methods: 9 patients (male 4, female 5) on PD with hyperparathyroidism were included in this study. A mean age was 70.4 ± 16.9 years and mean PD duration was 26.6 ± 7.8months. They were treated with low calcium dialysate from initiation to the time of this study. We analyzed their clinical data before and after the switch of peritoneal dialysate from low Ca to standard Ca.

Results: Three months after the switch of dialysate, the average PTH level was decreased significantly, from 527.1 ± 526.8 to 189.3 ± 92.6 pg/ml ($p < 0.01$). However, effects to serum Ca and phosphate (P) level were not found. The prescribed doses of vitamin D analogs and P binders had to be reduced in some patients.

Conclusions: Low Ca dialysate is commonly used, since favorable effects were expected in terms of good control of serum Ca, P and PTH levels with high dose of vitamin D analogs and Ca containing P binders. However, low Ca calcium dialysate could not maintain PTH levels within the target range in this study. And we could control secondary parathyroidism better after the change to the standard Ca dialysate without hypercalcemia. In this study, we couldn't estimate the calcification effect of the Ca concentration of peritoneal dyalaysate. Therefore, Further investigations must be needed to consider the optimal Ca concentration of peritoneal dialysate. At this point, the Ca concentration of dialysate should be determined on an individual basis with a deliberate consideration.

SA-PO875

Total Alkaline Phosphatase Is Related to Parathyroid Hormone Increases in Patients with Peritoneal Dialysis Juan Carlos Ramirez-Sandoval, Jorge Jesus-silva, Olynka Vega, Luis E. Morales-Buenrostro, Ricardo Correa-Rotter. *Nephrology, Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico DF, Mexico.*

Background: Total alkaline phosphatase (tAP) in conjunction with intact parathyroid hormone (iPTH) can be useful as a surrogate of bone turnover. However, there is no consensus about the interpretation of tAP's concentration in patient follow-up as most studies are cross-sectional. The aim of this study was to determine the ability of routine measurement of tAP to mirror a change in serial measurements of iPTH concentration of patients treated with peritoneal dialysis.

Methods: We examined 179 collected data from 54 stable peritoneal dialysis patients in a 3-year cohort. We included those with more than three serial routine measurements of tAP and iPTH taken simultaneously, all negative for hepatitis B and hepatitis C virus and with normal LFTs. The value of each tAP and iPTH were assessed by comparing changes in each measurement to obtain a ratio of recent tAP/previous tAP (rtAP/ptAP) and recent iPTH/previous iPTH (riPTH/piPTH-) for every patient. Indeed, patients were assigned to one of two groups according to iPTH behavior: (group A, n=13) patients with initial stable iPTH who subsequently showed an increase of at least nine times the upper normal value, and (group B n=41) patients with stable iPTH who did not show a meaningful increase. Furthermore, we compared tAP´s increase between both groups.

Results: The Spearman correlation coefficient between rtAP/ptAP and riPTH/pPTH was 0.67 (P: 0.001).Correlation between tAP and iPTH was 0.47 (P: 0.001). Group A had significantly different tAP respect group B (median tAP group A: 214.9 IU/L, 94-503; group B: 107.6 IU/L, 22-473, P <0.0001). The rtAP/ptAP was different between both groups aswell (median rtAP/ptAP group A: 1.87, 1.30-4.04, and group B: 1.01, 0.38-1.60, P=0.0004).

Conclusions: In this study we found that a 60% or greater tAP rise is a good marker of a clinically important iPTH increase. tAP may be an alternative surrogate of mineral metabolism status, applicable in the routine monitoring of dialysis patients in low income countries when iPTH is not available or limited due financial constraints.

Pleiotropic Effects of Sevelamer in Peritoneal Dialysis Patients with Type II Diabetes Mellitus Sudha P. Chennasamudram, Tetyana L. Vasylyeva. *Pediatrics, Texas Tech University Health Sciences Center, Amarillo, Tx.*

Background: In chronic kidney disease (CKD) patients, hyperphosphatemia promotes vascular calcification and is a strong risk factor for cardiovascular mortality. Sevelamer, a phosphate binder used to treat hyperphosphatemia, may act as an anti-inflammatory agent in hemodialysis patients. The pleiotropic properties of sevelamer have not been studied in peritoneal dialysis (PD) patients with diabetes. This study compared the effects of sevelamer and calcium carbonate on endothelial function (EF) and inflammation in patients with type II diabetes mellitus (T2DM) on PD.

Methods: This open-labeled, randomized, cross-over study with 15 subjects (average age: 54±9 years) whose serum phosphate levels were ≥ 5.5 mg/dL was approved by TTUHSC Institution Review Board. After consent, subjects discontinued all phosphate binders to undergo a 2-week washout period. Subjects were then randomly assigned to receive either sevelamer or calcium carbonate for 8 weeks. Subjects underwent a second 2-week washout period to cross-over to either the alternate treatment for another 8 weeks. At the beginning and end of each treatment phase, EF was evaluated by reactive hyperemia index (RHI). Serum levels of EF biomarkers (endothelin-1 [ET-1], plasminogen activator inhibitor-1 [PAI-1], soluble vascular adhesion molecule [sVCAM] and soluble intercellular adhesion molecule [sICAM]) and pro-inflammatory cytokines (interleukin 6 [IL6], interleukin 1 [IL1], tumor necrosis factor alpha [TNF-α] and C reactive protein [CRP]) were measured. Serum calcium, phosphate, and lipids were also measured.

Results: As expected, both phosphate binders decreased phosphorus levels, and when treated with calcium carbonate serum calcium levels were elevated. There was a significant improvement in lipid profile with sevelamer treatment compared to calcium carbonate

treatment. There was no difference in RHI with both the treatments, but serum levels of ET-1, PAI-1, CRP and IL6 were significantly lower with sevelamer treatment compared to calcium carbonate treatment.

Conclusions: Treatment with sevelamer has beneficial effects compared to calcium carbonate in decreasing inflammation and improving EF in patients with T2DM on PD.

The Relationship between Apelin and Cardiac Parameters in Patients on Peritoneal Dialysis: Is There a New Cardiac Marker? Serhat Karadag,[1] Savas Ozturk,[1] Meltem Gursu,[1] Zeki Aydin,[1] Sami Uzun,[1] Abdullah Sumnu,[1] Huseyin Oflaz,[3] Rumeyza Kazancioglu,[2] Egemen Cebeci.[1] *[1]Nephrology, Haseki Training and Research Hospital, Istanbul, Turkey; [2]Nephrology, Bezmialem Vakif University, Medical Faculty, Istanbul, Turkey; [3]Cardiology, Istanbul University Istanbul Medical Faculty, Istanbul, Turkey.*

Background: Many markers have been proposed for CVD risk assessment in dialysis population. Apelin is a peptide that has roles in cardiovascular functions and volume regulation namely vasodilation, decreased blood pressure(BP), positive inotropic effect and inhibition of antidiuretic hormone release. The aim of this study was to examine relationship of apelin levels with echocardiographic findings and laboratory parameters related with cardiovascular function and bone mineral metabolism among peritoneal dialysis(PD) patients.

Methods: This is a cross-sectional study in which chronic PD patients aged between 18 and 80 without active cardiac, infectious or malignant diseases and hypervolemia have been included. Apelin levels and echocardiographic findings were recorded as well as clinical and laboratory data.

Results: Of the 53 patients, the mean age and female/male ratio was 52.8±15.3years and 30/23, respectively. Mean apelin level was 1.45±0.37ng/ml. Gender, drugs (renin-angiotensin-aldosteron inhibitors, statins), presence of left ventricular hypertrophy, diabetes mellitus, hypertension, hyperlipidemia and residual renal function did not affect apelin levels. Apelin was correlated negatively with age and left atrium diameter; and positively with diastolic BP, ejection fraction (EF), total cholesterol, LDL-cholesterol, HDL-cholesterol, parathyroid hormone and alkaline phosphatase levels. Diastolic BP, LDL-cholesterol, ALP and EF were found to be the independent determinants of apelin levels with linear regression analysis. In patients with hypertension; diastolic BP, LDL-cholesterol and EF remained as the determinants of apelin level.

Conclusions: Apelinergic system has important roles in volume regulation, cardiovascular functions, lipid metabolism and bone mineral disorders in PD patients. It may be a treatment alternative for these disorders in the future.

SA-PO878

Cholecalciferol Therapy: LongTermEffectin Peritoneal Dialysis Patients Francesca K. Martino,[1,2] Elisa Scalzotto,[1,2] Manish Kaushik,[1,2] Jeong Chul Kim,[1,2] Maria Pia Rodighiero,[1,2] Claudio Ronco.[1,2] *[1]Department of Nephrology, Dialysis & Transplantation, San Bortolo Hospital, Vicenza, Italy; [2]International Renal Research Institute, Italy.*

Background: The deficiency of vitamin D is a widespread problem in general population and in patients with chronic kidney disease (CKD).Moreover, in such patients vitamin D plays a central role in the pathogenesis and treatment of mineral bone disorder (MBD). A recent metanalysis showed that Cholecalciferol may improve MBD in CKD patients. However, there is no evidence on its long term effect. The purpose of the study is to evaluate the long term effect of Cholecalciferol in PD patients.

Methods: We studied on 65 patients on peritoneal dialysis treated with Cholecalciferol for at least 6 months. We measured calcium before and after the treatment with vitamin D. The following characteristics of patients were evaluated: age, primary renal disease, duration of RRT, history of CVD, other drug therapy with Calcitriol and calcium based binders. Finally, we evaluated every 3 months Albumin, phosphorus and PTH and every 6 weeks calcium levels. Continuous non-normally distributed variables were presented as median values and interquartile range (IQR). Friedman's test was used to evaluate the differences before and after the treatment with Cholecalciferol. Multivariable logistic regression models were used to evaluate the variable related with hypercalcemia.

Results: The median period of follow-up was 10 month (IQR 8-12). 56.9% were male. 58.5% in the period of observation received therapy with Calcitriol with maximal dosage 0.5 mcg, while 29.2% received calcium carbonate with maximal dosage 2g. Finally, the dosage of chelecalciferol was between 625 and 8750 U per week. During the follow-up, 35.6% had at least one hypercalcemia episode. There was no difference in calcium values from baseline (median 9.4 mg/dl IQR 9.2-10.7) to study end (median 9.8 IQR 9.3-10.2) with p=0.25. In multivariable analyses, we found that only additionalCalcitriol therapy was independent predictor of hypercalcemia episode.

Conclusions: In this analysis, we conclude that hypercalemia episode in PD patients is not related with Cholecalciferol.

SA-PO879

Clinical and Laboratory Features in Uremic Patients on Continuous Ambulatory Peritoneal Dialysis before and after Parathyroidectomy Ying-tang Wang, Yu-Juei Hsu, Sung-Sen Yang, Shih-Hua P. Lin. *Division of Nephrology, Department of Medicine, Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan.*

Background: Although parathyroidectomy (PTX) in indicated for severe hyperparathyroidism (HPT) refractory to medical control, a detailed pre- and post-PTX assessment in uremic patients on continuous ambulatory peritoneal dialysis (CAPD) is rarely reported.

Methods: Uremic patients on CAPD who received PTX for severe HPT defined as serum PTH greater than 800 pg/ml were enrolled for analysis. Pre-PTX clinical and biochemical findings, and post-PTX predictors for "hungry bone syndrome" (HBS) and management were evaluated.

Results: There were 22 patients (M:F = 8:14, age 49.1 ± 10.3 years) with serum PTH concentrations 1619.6 ± 473.1 pg/ml. The most common clinical manifestations associated with severe HPT were pruritus (59.1%), fatigue (40.9%), bone pain (40.9%) and multiple uremic tumoral calcinosis (UTC) (22.7%). Despite calcium and vitamin D supplements, thirteen patients developed HBS (serum total $[Ca^{2+}] < 8.5$ mg/dl with neuromuscular symptoms). These patients had significantly higher pre-PTX serum i-PTH and alkaline phosphotase (ALP), and lower post-PTX serum calcium at 4th hour than 9 patients without HBS. Six patients with more severe HBS needed the addition of intraperitoneal calcium supplement (360~1080 mg elemental calcium) for 1 to 4 months to correct hypocalcemia and symptoms. Of note, UTC completely resolved over 4 to 8 months in 4 patients with severe HBS.

Conclusions: UTC is also not uncommon in CAPD patients with severe HPT and has a favorable response to PTX. A higher pre-PTX serum ALP, iPTH and lower post-PTX calcium are the indicators of post-PTX HBS. Intraperitoneal calcium supplementation is an alternative effective treatment for severe HBS in CAPD patients after PTX.

SA-PO880

Serum Alkaline Phosphatase Is an Independent Predictor of Mortality in Peritoneal Dialysis Patients Paul A. Fein, Oluwatoyin Akinrinade, Jyotiprakas Chattopadhyay, Morrell M. Avram. *Avram Division of Nephrology, S.U.N.Y. Downstate Medical Center UHB at Long Island College Hospital, Brooklyn, NY.*

Background: Elevated levels of serum alkaline phosphatase (AlkP) have been reported to be associated with increased mortality risk in hemodialysis (HD) patients (pts). We have examined the association of serum AlkP with all-cause mortality in our PD pts.

Methods: Ninety PD pts were enrolled in this study beginning in 1995. On enrollment, demographics, clinical and biochemical data were recorded. Pts were followed up to September 2011.

Results: The mean age was 62 years. Sixty-one percent were female and majority (81%) were African descent. Mean and median AlkP were 135 U/L and 113 U/L, respectively. Fifty-six percent of the pts had elevated levels (greater than 104 U/l) of AlkP. Mean and maximum follow-up were 2.61 and 16.2 years, respectively. As expected, AlkP correlated directly with serum intact parathyroid hormone (PTH) (r=0.36 p=0.003). In Cox's multivariate regression analysis, adjusting for confounding variables (Table 1 footnotes), AlkP remained a significant independent predictor of mortality (Relative Risk=1.016, p=0.004). For each unit increase in enrollment AlkP, there was a 1.6% increase in relative risk of death. Albumin corrected calcium (Relative Risk: 2.20, p=0.035) and PTH (Relative Risk: 0.998, p=0.02) were also significant predictors of mortality in this model (Table 1).

Table 1. Multivariate Cox's Regression Analysis

Variables	Relative risk	p
AlkP (U/L)	1.016	0.004
PTH (pg/ml)	0.998	0.02
Albumin corrected calcium (mg/dl)	2.20	0.035

Other variables included in the model, but were not significant: age, race, gender, diabetes, hypertension, dialysis vintage at enrollment, albumin, creatinine, blood urea nitrogen, glutamic oxaloacetic transaminase (SGOT), hemoglobin, iron, and white blood cell (WBC) count.

Conclusions: Higher levels of serum AlkP is a strong independent predictor of increased risk of mortality in our PD pts followed up to 16 years. Further studies are needed to elucidate the mechanism underlying the association between AlkP and mortality in PD pts.

SA-PO881

Differences in Coagulation Protein Concentrations between Dialysis Modalities Daniel E. Carl,[1] Erika Martin,[2] Todd W. Gehr,[1] Donald F. Brophy.[2] *[1]Internal Medicine, Nephrology, Virginia Commonwealth University, Richmond, VA; [2]Pharmacotherapy, Virginia Commonwealth University, Richmond, VA.*

Background: It is widely accepted that ESRD patients are predisposed to increased cardiac and thrombotic events; and that differences likely exist between hemodialysis (HD) and peritoneal dialysis (PD). We evaluated coagulation protein concentrations in HD and PD patients, including tissue factor (TF), tissue factor pathway inhibitor (TFPI), prothrombin fragment 1+2 (F1+2), von Willebrand's factor (vWf), and fibrinogen. The goal was to determine whether significant differences in these protein concentrations exist between dialysis modalities.

Methods: 47 patients were enrolled: 20 HD, 20 PD, and 7 healthy volunteers. Patients on anti-platelets or chronic anticoagulation were excluded. In the HD patients, labs were drawn pre-treatment and heparinase was added to counteract any potential heparin effect.

Results: Both HD and PD groups had significantly greater coagulation protein concentrations compared to healthy controls. PD patients had significantly higher plasma concentrations of fibrinogen, TF, and TFPI compared to HD and controls. HD and PD patients had similar levels of vWf and F1+2.

	Normal values	Controls	HD	PD	P value
vWF	0.52-1.54 U/mL	0.8±0.3	2.3±1.5	2.2±1.2	<0.05
TF	23-130 pg/mL	102.0±22.6	375.0±124.8	521.6±153.7	<0.0001
TFPI	75-120 ng/mL	45.7±11.8	86.1±21.8	114.5±34.3	<0.0001
F1+2	66-229 pmol/L	136.9±55.8	379.6±152.6	348.5±162.4	0.002
Fibrinogen	200-400 mg/dL	297.1±87.1	445.2±132.4	560.0±142.9	<0.0001

Conclusions: ESRD patients have elevated coagulation protein concentrations compared to healthy controls, which likely contributes to the increased prevalence of thrombotic disease in ESRD. While fibrinogen is also an inflammatory marker, it further contributes to hypercoagulability. PD patients appear to have higher plasma levels of coagulation proteins relative to HD. The relationship between increased coagulation protein levels and thrombotic events in these patients needs to be addressed.

SA-PO882

Peritoneal Dialysis Patients Exhibit Pro-Thrombotic Platelet Function and Blood Viscoelasticity Compared to Hemodialysis Patients

Daniel E. Carl,[1] Erika Martin,[2] Todd W. Gehr,[1] Donald F. Brophy.[2] *[1]Internal Medicine, Nephrology, Virginia Commonwealth University, Richmond, VA; [2]Pharmacotherapy, VCU, Richmond, VA.*

Background: ESRD patients have pro-inflammatory disease states that pre-dispose them to increased cardiac and thrombotic events. The goal of this study was to assess for differences in platelet function and viscoelasticity between patients receiving hemodialysis (HD) and peritoneal dialysis (PD).

Methods: 47 patients were enrolled: 20 HD, 20 PD, and 7 controls. Patients on anti-platelets or chronic anticoagulation were excluded. HD patient labs were drawn pre-treatment with added heparinase. The time to clot onset and was measured by Force Onset Time (FOT) and the Reaction time (R). K represents the time from clot initiation until final clot firmness. Platelet contractile force (PCF) measured the force produced by platelets during clot retraction, while clot rigidity was measured as clot elastic modulus (CEM) and maximum amplitude (MA). FOT, CEM and PCF were measured by Hemodyne; R, K and MA were measured by TEG.

Results: PD and HD patients had high fibrinogen levels, with PD patients being statistically greater than HD. The PCF, CEM and FOT in the HD group was similar to the controls, while the PD group was significantly greater than both groups. PD patients also had shorter K times and made firmer clots (MA) compared to HD and controls.

	Normal Range	Controls	HD	PD	P value
PCF	4.0-9.5 Kdyne	7.51±0.97	8.46±3.94	11.88±4.26	<0.01
CEM	14.0-35.0 kdyn/cm2	26.0±4.7	30.0±14.0	40.7±16.0	0.02
FOT	3.0-8.0 min	5.3±1.6	7.1±2.4	5.6±1.8	NS
R	3.0-8.0 min	7.2±2.0	7.9±2.0	6.9±1.9	NS
K	1.0-3.0 min	2.1±0.6	1.6±0.3	1.3±0.3	<0.001
MA	51-69 mm	65.4±3.6	65.8±6.0	72.7±5.5	<0.001
Fibrinogen	200-400 mg/dL	297.1±87.1	445.2±132.4	560.0±142.9	<0.0001

Conclusions: This study suggests PD patients exhibit a more pro-thrombotic profile compared to HD. PD PCF,CEM and MA values were markedly greater than the HD and control patients. Time to clot onset (FOT and R) however was not different compared to controls. These data may help explain the observational findings of greater thrombotic events in PD patients compared to HD. Further study is needed to study the links between coagulation proteins, platelet function and clinical outcomes.

SA-PO883

Coronary Artery Calcification Score as a Predictor of All-Cause Mortality and Cardiovascular Morbidity in Peritoneal Dialysis Patients

Tongying Zhu, Qionghong Xie, Xiaoling Ge, Chuanming Hao. *Renal Department, Huashan Hospital of Fudan University, Shanghai, China.*

Background: This study aimed to examine whether coronary artery calcification is associated with all-cause mortality and cardiovascular events in peritoneal dialysis (PD) patients.

Methods: Adult PD patients who were clinically stable for at least 2 months were recruited to this prospective observational cohort study. Coronary artery calcification was assessed using multislice spiral computed tomography (MSCT) and recorded according to Agatston score (CaCS). The primary endpoint was all-cause mortality and secondary endpoint was cardiovascular events including acute coronary syndrome (ACS), acute ischemic stroke, acute cerebral hemorrhage and peripheral vascular occlusion. The clinical data including general information, adequacy of PD and laboratory data were collected. Multivariate Cox regression was used to identify predictor of all-cause mortality and cardiovascular events in these patients.

Results: 179 PD patients (86 men) with a median age of 67 years were recruited to this study. CaCS ranging 0 to 5257 was stratified as follow: low (CaCS = 0, n = 54, age 52.2±15.8), moderate (0 < CaCS < 400, n = 72, age 65.8±11.7), high (CaCS ≥ 400, n = 53, age 71.9±9.6). The follow-up duration was 30.6±16.2 (24 to 63) months. Univariate analysis revealed that serum Ca, P, iPTH, cholesterol, triglyceride, LDL and dialysis duration were not significantly different, while age ($p<0.001$), diabetes mellitus (DM, $p=0.012$), BMI ($p=0.02$), renal GFR ($p=0.037$), serum albumin ($p=0.003$) and HDL ($p=0.024$) were significantly different among the 3 groups. Multivariate analysis (Cox regression) revealed that CaCS had a positive correlation with all-cause mortality ($p = 0.001$) and cardiovascular events($p = 0.011$) in these PD patients after adjustment for age, sex, DM, albumin, HDL, BMI, residual renal GFR and dialysis duration.

Conclusions: CaCS is an independent predictor of all-cause mortality and cardiovascular morbidity in PD patients.

SA-PO884

Comparison of Indices of Insulin Resistance in Peritoneal Dialysis Patients

Kelli R. King-Morris,[1] Adriana Hung,[1,2] Phyllis Ann Egbert,[1] Charles D. Ellis,[1] Aihua Bian,[1] Ayumi Shintani,[1] T. Alp Ikizler.[1,2] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]CSR&D, VA TVHS, TN.*

Background: Insulin resistance (IR) is common in chronic dialysis patients and is associated with excess mortality. Previous studies using indirect measures show that IR is prevalent in those receiving peritoneal dialysis (PD). There are limited studies using the gold standard hyperinsulinemic euglycemic glucose clamp (HEGC) in this patient population. Also, the comparison of indirect and practical indices of IR to HEGC has not been adequately performed in PD patients.

Methods: This is a cross-sectional, single center study performed in 7 prevalent PD patients (median age 50 years (interquartile range [IQR] 42.0, 55.5), 43% men, median body mass index (BMI) of 26.6 kg/m2 (IQR 25.1, 36.2) who were studied three consecutive times. IR was assessed by HEGC (glucose disposal rate [GDR]), homeostatic model assessment of IR (HOMA-IR), HOMA-IR corrected by adiponectin (HOMA-AD), leptin adiponectin ratio (LAR), QUICKI, McAuley's index, and oral glucose tolerance Test (OGTT) at each time point. Fasting state was ensured by withholding PD for 8 hours prior to and during study times.

Results: Seventy-one percent of the subjects displayed abnormal glucose tolerance by HGEC (GDR median 6.42; IQR 6.1, 7.3); 1 of which was overtly insulin resistant (GDR 3.5 mg/kg/min) and not previously known to be diabetic. HOMA-AD and McAuley's index were correlated with IR measured by HGEC ($p = 0.038$ and $p < 0.001$, respectively). HOMA-IR, LAR, QUICKI were not correlated. All 7 patients had at least 1 abnormal OGTT demonstrating impaired glucose tolerance.

Conclusions: Insulin resistance is highly prevalent in chronic peritoneal dialysis patients, which might be related to continuous, hypertonic glucose exposure. McAuley's index performed well in PD patients despite performing poorly in chronic hemodialysis patients. This potentially could be explained by PD patients showing more pronounced hypertriglyceridemia than prior reports in the HD population. Other indirect indices of IR such HOMA-AD also perform well in PD patients and may be used in large epidemiological outcome studies.

SA-PO885

Usefulness of the Brachial-Ankle Pulse Wave Velocity in Assessment of Earlier Atherosclerosis Risks in Peritoneal Dialysis Patients

Mitsutaka Nakahigashi,[1] Hiroyasu Tsukaguchi,[1] Takanobu Imada,[1] Chikara Nakano,[1] Hiroko Ueda,[1] Sanae Kikuchi,[1] Hideki Yamahara,[1] Hiroya Masaki.[2] *[1]2nd Department Internal Medicine, Kansai Medical Univeristy, Moriguchi, Osaka, Japan; [2]Clinical Sciences and Laboratory Medicine, Kansai Medical Univeristy, Moriguchi, Osaka, Japan.*

Background: Cardiovascular disease is a major cause of morbidity and mortality in patients with end-stage renal diseases. Management of risk factors for the atherosclerosis is therefore crucial to improve the prognosis. This study aimed to define the clinical factors that accelerate earlier atherosclerotic changes in peritoneal dialysis (PD) patients.

Methods: A total 42 PD patients (average age 55.4, male/female ratio 1.2, follow-up 26 months) were studied. We evaluated the vascular stiffening by measuring brachial-ankle pulse wave velocity (baPWV, n=41), which relies not only on pathologically visible sclerosis but also on functional resistance in peripheral muscular arteries of lower limbs. Carotid intima-media thickness (cIMT), which reflects the stiffening in central elastic arteries, was also examined (n=26).

Results: In multivariate models, cIMT correlated only with reduced diastolic pressure ($\beta=-0.45$, $p<0.02$), likely resulting from the stiffened central arteries. In contrast, baPWV, was independently associated with urinary protein excretion ($\beta=0.58$, $p<0.001$), elevated systolic blood pressure ($\beta=0.28$, $p<0.001$) and hemoglobin A1c ($\beta=0.27$, $p<0.002$). Both cIMT and baPWV did not significantly correlate with other parameters including serum calcium, phosphorus, lipids, residual renal functions, C-reactive protein and dialysis duration.

Conclusions: Our observations suggest that (1) baPWV could predict the ongoing endothelial injuries and/or stress with much higher sensitivity than cIMT, thereby represents a useful, non-invasive modality to grasp earlier treatable atherosclerotic risks and (2) blood pressure and glycemic levels should be rigorously controlled in PD patients who are prone to hyperglycemia and/or hypervolemia.

SA-PO886

Adipokines and Coronary Artery Calcification in Uremic Patients Undergoing Peritoneal Dialysis Kuo-hsiung Shu, Chi-Hung Cheng, Ming-Ju Wu, Cheng-Hsu Chen, Tung-min Yu, Ya-Wen Chuang. *Internal Medicine, Taichung Veterans General Hospital, Taichung, Taiwan.*

Background: Uremic patients are associated with various cardiovascular complications. Coronary artery calcification (CAC) may serve as a surrogate marker of atherosclerotic coronary artery disease. Adipokines have been linked to atherosclerotic diseases. The aim of our study is to investigate the prevalence of CAC and alteration of adipokines in uremic patients undergoing peritoneal dialysis (PD).

Methods: Newly diagnosed uremic patients undergoing PD as their mode of renal replacement therapy at our hospital were recruited for the study. A multislice detector computer tomography (MDCT) heart scan were performed at the initiation of PD. Fasting venous blood samples were collected for routine biochemistry, blood routine and adipokines, including adiponectin (APN), leptin, visfatin and resistin. Univariate and multivariate logistic regression were used to identify factors that were associated with CAC and serum levels of adipokines.

Results: A total of 21 PD patients were recruited for the study. The mean age was 52.3±12.3 years. Six (26.1%) had diabetes mellitus (DM) as their underlying chronic kidney diseases. CAC was found in 14 (66.7%) patients, of which 3 (14.3%) had severe calcification (calcification score >1000). No significant risk factor for CAC was identified in this study. A high serum APN level (51.5±35.8 mg/ml) and leptin level (17.6±18.8 mg/ml) were found. Univariate logistic regression revealed female was associated with a higher APN level while DM, fasting blood sugar and serum uric acid level were negatively correlated with APN level. Total serum protein and albumin were positively correlated with leptin level, while serum uric acid was negatively correlated with visfatin level. On multivariate study, only female gender and DM were associated with APN level.

Conclusions: The current study revealed a high prevalence of CAC and alteration of adipokines in PD patients and provided potential treatment targets for the prevention of cardiovascular diseases.

SA-PO887

Prevalence and Risk Factors of Vascular Calcification in Coninuous Ambulatory Peritoneal Dialysis Patients Dhavee Sirivongs,[1] Jinvibha Anusri,[1] Sajja Tatiyanupangwong.[2] *[1]Medicine/Nephrology, Faculty of Medicine, Khon Kaen University, Khon Kaen, Thailand; [2]Medicine/Nephrology, Northeast Kidney Physician Network of Thailand, Khon Kaen, Thailand.*

Background: Cardiovascular disease is a major cause of death in chronic dialysis patients, resulting from their mineral abnormalities. Vascular calcification (VC) is associated with many cardiac events, currently used as an index of cardiac mortality. This study aimed to determine the prevalence and risk factors of VC in continuous ambulatory peritoneal dialysis (CAPD) patients.

Methods: The multicenter cross-sectional study of CAPD patients under Thai PD first policy from 7 hospitals was conducted during January-December 2011. Plain radiographs of lumbar spine and pelvis were performed to detect the calcification of aorta, iliac and femoral arteries, read by a radiologist. VC score was assessed by diagnostic criteria of Bellasi and NKF.

Results: Total 557 CAPD patients were enrolled, female in 50.09% and DM in 33.57%. Mean age was 52±13.74 years. Average of CaxP level and dialysis vintage were 36.58±14.45 mg/dL and 21.64±12.53 months, respectively. There were 144 patients (25.85%) had aortic calcification, male in 43.75%, and DM in 53.47%. Regarding the VC group, average age was 58±11.90 years, mean VC score>0 was 6.43±5.47, rates of iliac and femoral VC were 14.13% and 18.29% respectively. Mean CaxP, PTH and calcium-based phosphate binder dosage were 36.55±14.41 mg/dL, 225.17±333.75ng/ml and 1,164.84±795.61 mg/day, respectively. CaxP > 55 was seen in 10.53% of VC group. Mean dialysis vintage was 22.02±12.96 months. By multivariate analysis, only diabetes (OR =2.82, p=0.000) and age>30 years (OR =5.93, p=0.015) were risk factors for VC.

Conclusions: Prevalence of VC in CAPD patients of our series is quite low compared to that of hemodialysis patients, may be due to shorter in dialysis vintage.Age>30 years and DM are risk factors for VC, so every patient who has one of them may need to be monitored for VC and should be treated properly to prevent cardiac mortality.

SA-PO888

Risk Factors Associated with Development of Peripheral Artery Occlusive Disease in Patients on Maintenance Peritoneal Dialysis Chin Chung Tseng, An-Bang Wu, Yu-tzu Chang, Meng-Fu Cheng, Ming-cheng Wang. *Division of Nephrology, Department of Internal Medicine, National Cheng Kung University Hospital, Tainan, Taiwan.*

Background: The prevalence and risk factors for peripheral artery occlusive diseases (PAD) have been widely studied in patients with end-stage renal disease. However, the risk factors for development of PAD after starting of dialysis therapy in peritoneal dialysis (PD) patients have rarely been evaluated.

Methods: Between 1 October 2006 and 31 December 2009, our PD unit provided chronic renal replacement therapy for 194 patients. Among these patients, 167 patients, from whom informed consent was obtained, were included for study. Diagnosis of PAD was made by measurement of ankle–brachial blood pressure index (ABI) and clinical manifestations. PAD was defined in the patients with an ABI value less than 0.90 in either extremity or having the typical signs and symptoms of intermittent claudication. ABI was performed and clinical manifiestations of PAD were re-evaluated every year for each patient during the study course. Baseline characteristics, comorbid conditions, and history of dialysis were obtained. Patients' clinical and laboratory data after initiation of PD were collected.

Results: 141 patients were initially negative in PAD. Among these patients, 22 % (31/141) developed PAD during the follow-up course. Preexisting diabetes mellitus (DM) was the patient characteristic associated with development of PAD. Longer PD duration, lower residual renal function (urine amount, kidney Kt/V urea and weekly CrCl) were associated with development of PAD. Higher ALK-P, history of parathyroidectomy, and lower serum potassium levels were significant risks, but serum triglyceride and cholesterol levels were not. Among these factors, DM, Lower residual renal function, and higher serum ALK-P level were independently associated with PAD.

Conclusions: DM, PD duration, lower residual kidney function, history of parathyroidectomy, higher serum ALK-P level, and lower serum potassium level were associated with new development of PAD. Among these factors, DM, Lower residual renal function, and higher serum ALK-P level were independent risk factors.

SA-PO889

The Relationship of Plasma ADMA Levels with Cardiac Functions and Metabolic Parameters in Peritoneal Dialysis Patients Savas Ozturk,[1] Serhat Karadag,[1] Meltem Gursu,[1] Zeki Aydin,[1] Sami Uzun,[1] Abdullah Sumnu,[1] Egemen Cebeci,[1] Rumeyza Kazancioglu.[2] *[1]Department of Nephrology, Haseki Training and Research Hospital, Istanbul, Turkey; [2]Department of Nephrology, Bezmialem Vakif University, Medical Faculty, Istanbul, Turkey; [3]Cardiology, Istanbul University Istanbul Medical Faculty, Istanbul, Turkey.*

Background: Asymmetric dimethylarginine(ADMA) is accepted as a risk factor for coronary artery disease by causing endothelial dysfunction and vasospasm. We aimed in the present study to investigate the relationship between ADMA levels and echocardiographic parameters in PD patients; and to determine its utility as a cardiovascular risk determinant in this population.

Methods: This is a cross-sectional study in which PD patients aged 18-80; with at least three month duration of dialysis and without active cardiac, infectious or malignant diseases, and clinically evident hypervolemia were included. ADMA levels and echocardiographic parameters were recorded.

Results: Of the 55 patients included, the mean age was 53±15years. Mean ADMA level was 81.9±48.0µmol/L. The variables found to be positively correlated with ADMA levels were weight, body surface area, BMI, glucose, uric acid, sodium, ultrafiltration volume, left atrium diameter, intraventricular end-systolic diameter and intraventricular end-diastolic diameter. PTH, Kt/V and EF were found to be negatively correlated with ADMA levels. Male gender, use of acetyl salicylic acid and the presence of hypertension were found to increase plasma ADMA levels; while presence of ischemic heart disease, DM, hyperlipidemia, and use of statins, ACEi, ARB, beta blockers, erythropoiesis stimulating agents, vitamin D and nitrate did not change plasma ADMA levels. Although ADMA levels in patients with IHD had higher levels of ADMA; the difference was not statistically significance. ADMA levels were similar in patients with or without significant daily urine volume. With multivariate analysis; gender, BMI and use of ASA were found to be the independent variables determining ADMA levels.

Conclusions: The correlation of ADMA with BMI, gender and hypertension leads to the idea that ADMA may be used as a CVD risk determinant in PD patients.

SA-PO890

Increased Peritoneal Permeability at Peritoneal Dialysis Initiation Is a Possible Cardiovascular Risk in Patients Using Biocompatible Peritoneal Dialysis Solution Yoshifumi Hamasaki,[1] Yoshitaka Ishibashi,[2] Kent Doi,[1,3] Masaomi Nangaku,[1] Eisei Noiri.[1] *[1]Nephrology and Endocrinology, University of Tokyo, Japan; [2]Nephrology, Japanese Red Cross Medical Center, Japan; [3]Emergency and Critical Care Medicine, University of Tokyo, Japan.*

Background: Peritoneal dialysis (PD) patients suffer from cardiovascular disease (CVD) partly because of malnutrition-inflammation-atherosclerosis syndrome. It is still unclear what factors increase CVD risk even when patients are treated using biocompatible PD solution (BPDS). We investigated the relationship between clinical parameters at PD initiation and CVD occurred during PD therapy using BPDS.

Methods: The data from patients who started PD from 2001 to 2009 at University of Tokyo Hospital were collected retrospectively. To identify contributing factors for CVD events (cerebrovascular disease, ischemic heart disease or heart failure, and peripheral arterial disease) occurred until March 2012, we analyzed data including clinical parameters measured within 6 months after starting PD using BPDS.

Results: 116 patients were included; 98 patients were started PD as the first renal replacement therapy (RRT) and 18 patients were switched from HD to PD. New CVD events occurred in 31 patients. Age (66.2 vs 57.6 y.o.), history of CVD before starting PD (50 vs 17%), systolic BP (139 vs 127 mmHg), CRP (0.73 vs 0.38 mg/dl), and D/P(4h) creatinine values of peritoneal equilibration test (D/Pcre) (0.64 vs 0.57) were significantly higher in the new onset CVD group than the non-CVD group ($p < 0.05$ in each). Serum albumin (Alb) was significantly lower in the new onset CVD group than the non-CVD group (3.3 vs 3.6 g/dl, $p < 0.01$). In patients starting PD as the first RRT, D/Pcre was significantly correlated with Alb and serum iP ($r = -0.37$ and -0.24). When patients were split down the middle based on the D/Pcre, CVD morbidity was higher and duration of PD monotherapy was shorter in the high D/Pcre subgroup than the low D/Pcre subgroup.

Conclusions: Peritoneal permeability at PD initiation was associated with new onset of CVD events. Increased peritoneal permeability at PD initiation may contribute to progress atherosclerosis through malnutrition even in PD patients using BPDS.

SA-PO891

Hepatocyte Growth Factor (HGF) as a Long Term Predictor Factor for Total and Cardiovascular Mortality in Peritoneal Dialysis (PD) Patients

Katarzyna Janda,[1] Marcin Krzanowski,[1] Wladyslaw Sulowicz.[1] *[1]Nephrology, Jagiellonian Univeristy, Cracow, Poland; [2]Medical Diagnostics, Jagiellonian Univeristy, Cracow, Poland.*

Background: The aim of the study was to access the influence of increased HGF levels on total and cardiovascular mortality (CV) in PD patients on the basis of a 6 year observation period.

Methods: The study group consisted of 67 patients (31 W, 36 M) with a mean age of 53 +/- 13 years, treated with PD for a median period of 24 months. We assessed the following parameters: HGF, IL-6, hsTNF-α, hsCRP, albumin concentration, WBC count and ejection fraction (EF) %. Calcium scoring (CaSc) was measured using multirow spiral computed tomography (MSCT).

Results: During the 6 year observation period, 22 patients died, where 17 patients died due to CV causes. Survival was 1-72 months (median 20 months). Significant influence of HGF and proinflammatory cytokines on total and CV mortality in dialysis patients were shown using univariate Cox regression:

Total mortality:

Albumin (HR-0.89; p=0.026); hsTNF-α (HR-1.57; p=0.006); hsCRP (HR-1.06; p=0.0002); IL-6 (HR-1.05; p=0.0003); HGF (HR-2.39; p=0.004); EF% (HR-0.96; p=0.033); CaSc (HR-1.0003; p=0.024)

CV mortality:

Albumin (HR-0.96; p=0.5); hsTNF-α (HR-1.7; p=0.004); hsCRP (HR-1.06; p=0.0005); IL-6 (HR-1.05; p=0.001); HGF (HR-2.51; p=0.007); EF% (HR-0.98; p=0.3); CaSc (HR-1.0005; p=0.003)

Multiple regression analysis model was shown in table 1.

Table 1. Multiple Cox regression models to predict total and CV mortality.

independent variables	total mortality	total mortality	CV mortality	CV mortality
	HR (95% CI)	p	HR (95% CI)	p
HGF	3.64 (1.74-7.60)	**0.0006**	3.84 (1.70-8.66)	**0.001**
PD duration	1.00 (0.98-1.02)	0.8	0.99 (0.96-1.01)	0.2
Age	0.95 (0.90-0.99)	**0.03**	0.94 (0.89-1.00)	0.06
EF%	0.97 (0.93-1.01)	0.2	0.98 (0.93-1.04)	0.5
CaSc	1.0007 (1.0004-1.001)	**0.0001**	1.0008 (1.0004-1.001)	**0.0001**
Albumin	0.87 (0.78-0.97)	**0.01**	0.89 (0.78-1.02)	0.1

Conclusions: HGF is an independent risk factor for total, as well as for CV mortality in the PD patients.

Multiple Factors Affect Sleep Quality in Peritoneal Dialysis Patients

Yan-ru Chen, Hui Peng, Hai-xia Xiong, Hong-li Shang, Hui-qun Li, Tan-qi Lou. *Department of Nephrology, The Third Affiliated Hospital, Sun Yat-sen University, Guangzhou, Guangdong, China.*

Background: Studies have shown that sleep disorders are prevalent in dialysis patients, and poor sleep quality impacts the life quality of those patients. However, few studies investigate the influence factors of sleep quality in dialysis patients. The objectives of the present study were to evaluate influence factors of sleep quality in peritoneal dialysis patients.

Methods: 77 patients (61 male, 16 female) were included in the study, who were treated with CAPD from 3 months to 63 months (mean 10months).The mean age was 47 years(from 16 to 82 years). Pittsburg Sleep Quality Index(PSQI) was used to assess sleep quality. Quality of life parameters were assessed by Kidney Disease Quality of Life Questionnaire(KDQOL- SF™1.3).We also evaluated depressive state with Beck Depression Inventory (BDI) as well as anxiety with Self-rating Anxiety Scale(SAS)in those patients.

Results: The average of overall PSQI scores was 7.9±3.8. Positive correlation was found among PSQI scores and age (R = 0.41), BDI scores (R = 0.31), and SAS scores(R = 0.35). However, negative correlation was found between PSQI scores and serum albumin (R = - 0.36). Subjective sleep quality was positively related to general health scores (R = 0.34), social function scores (R = 0.39), physical fitness scores (R = 0.36), physical symptoms scores (R = 0.38) as well as disease burden scores (R = 0.39) of KDQOL-SF ™-1.3. Multivariate regression analysis showed somatic symptom was the independent risk factor of PSQI scores *(P=0.0002) and subjective sleep quality (P=0.007).*

Conclusions: Our study shows that many factors come together to induce poor sleep quality, especially somatic symptom. Medical staffs should attach importance to comprehensive evaluation of each patient, and then develop the individual therapy and nursing intervention.

SA-PO893

The Perspectives of Adults Living with Peritoneal Dialysis: Systematic Review and Thematic Synthesis of Qualitative Studies

Allison Tong,[1,2] Brian Lesmana,[1,2] David W. Johnson,[3] Germaine Wong,[1,2,4] Denise Campbell,[1,2] Jonathan C. Craig.[1,2] *[1]Sydney School of Public Health, University of Sydney, Sydney, NSW, Australia; [2]Centre for Kidney Research, The Children's Hospital at Westmead, Sydney, NSW, Australia; [3]Department of Nephrology, University of Queensland at Princess Alexandra Hospital, Brisbane, QLD, Australia; [4]Centre for Transplant and Renal Research, Westmead Hospital, Sydney, NSW, Australia.*

Background: Most patients with end-stage kidney disease require dialysis to survive, unable to access kidney transplantation. Peritoneal dialysis (PD) is generally recommended as the first choice of dialysis modality for adults without significant comorbidities or those with residual kidney function. This study aims to synthesize qualitative studies on patients' experiences and beliefs about PD.

Methods: We conducted a systematic review and thematic synthesis of qualitative studies on adult perspectives of living with PD. MEDLINE, Embase, PsycINFO, CINAHL, theses databases and reference lists were searched to November 2011.

Results: Thirty-nine studies involving 387 participants were included. We identified seven themes: resilience and confidence (determination, overcoming vicissitudes); support structures (strong family relationship, peer support, professional dedication, social abandonment, desire for holistic care); overwhelming responsibility (disruptive intrusion, family burden, onerous treatment regimen); control (gaining bodily awareness, achieving independence and self-efficacy, information seeking); freedom (flexibility and autonomy, retaining social functioning, ability to travel); sick identity (damage to self-esteem, invisible suffering); and disablement (physical incapacitation, social loss and devaluation).

Conclusions: PD can offer patients a sense of control, independence, self-efficacy and freedom. However, holistic and multidisciplinary care is needed to mitigate the risks of impaired self-esteem, physical incapacitation, reduced social functioning, and poor sense of self-worth. Strategies that aim to strengthen social support, and promote resilience and confidence in patients are integral to achieving positive adjustment, improved psychosocial outcomes and treatment satisfaction.

SA-PO894

Sexual Dysfunction in Men and Women in Peritoneal Dialysis: Differential Link with Metabolic Factors and Quality of Life Perception

Pedro Francisco Azevedo,[1] Ricardo Santos,[2] Jose Duraes,[1] Olivia Santos,[1] Maria João Carvalho,[1] António Manuel Nunes Cabrita,[1] Anabela Rodrigues.[1] *[1]Nephrology Department, Hospital Santo Antonio, Oporto, Portugal; [2]Gynecology and Obstetrics Departement, Centro Hospitalar do Alto Ave, Portugal.*

Background: Peritoneal dialysis (PD) patients face a demanding challenge in all aspects of their lives: physical, psychological and social. Although several conditions affect the sexual function of patients on PD, there are few studies that have been dedicated to these issues in PD. This cross-sectional study aims to evaluate sexual dysfunction (SD) and the determinants among PD patients.

Methods: All chronic PD patients in one Center were asked to complete the International Index of Erectile Function (IIEF) for men and the Index of Female Sexual Function (IFSF) for women. Both groups answered the Hospital Anxiety and Depression Scale (HADS) and the Euroqol (EQ5D) to measure the quality of life (QoL).

Results: We evaluated 57 PD patients (50,9% males), aged 53,9±15,7 years, 27,6% diabetics.

SD was diagnosed in 54,4% of the patients. These were older (P=0,029), had lower albumin (P=0,042), lower PTH (P=0.015)and lower EQ5D scores (P=0,012) without significant differences in HADS score.

In male patients, metabolic factors such as diabetes (P=0,005), hypercalcemia (P=0,038), lower PTH levels (P=0,014) and lower testosterone (P=0,002), were associated with SD. EQ5D score was not significantly corrrelated with reported IIEF score in this group. In female patients, a worse SD score was associated with lower QoL index (P=0,003) as well as with worse nutricional parameters, such as albumin (P=0,007), nPCR (P=0,008) and phosphorous (P=0,0014). Time in peritoneal dialysis, previous hospitalization and peritonitis episodes were not associated with erectile or female sexual dysfunction.

Conclusions: Sexual dysfunction is highly prevalent in PD patients, with impact on quality of life. Differences in male and female were highlighted, pointing to distinct modifiable risk factors for this complication. A comprehensive PD approach should address these issues for a better patient rehabilitation.

SA-PO895

Economic Burden of Incident Unplanned Starts on Peritoneal Dialysis in a High Specialty Health Care Facility in Mexico City

Sergio O. Hernandez-Ordonez,[1] Surrey Walton,[2] Alfonso Ramos,[3] Angela S. Rivera,[3] Frank Xiaoqing Liu.[3] *[1]National Institute of Cardiology "Ignacio Chavez", Mexico D.F., Tlalpan, Mexico; [2]University of Illinois at Chicago, Chicago, IL; [3]Baxter Healtcare Corporation, Deerfield, IL.*

Background: Few studies have examined unplanned initiation of peritoneal dialysis (PD). This study used detailed 2010 data from a Health Care Facility in Mexico to examine patient demographics, hospitalization costs, and outcomes associated with unplanned PD and tested differences for those requiring urgent hemodialysis (HD) while initiating PD.

Methods: Highly detailed data were collected to characterize patients. Descriptive analyses were conducted with a focus on costs and differences for patients requiring urgent HD were measured and tested using Stata 11.

Results: Of 195 hospitalized patients in 2010 for PD placement, 51 incident patients met criteria for unplanned PD initiation. Among them, 25 required urgent HD prior to PD initiation and 26 did not. Overall, for a Mexican population with kidney disease, this was a relatively young population with relatively low cardiovascular comorbidities, similar diabetes presence. 92% of the patients received a 90% or greater government subsidy for hospital costs. Average total costs associated with hospitalization for unplanned start of dialysis were 72,123.23 MXN ($5,233.91 US) with most of the costs associated with hospital bed rates and procedures. Costs were 88,078.03 MXN ($6,391.73) per patient for those requiring urgent HD and 56,782.16 MXN ($4,120.62) for those not requiring urgent HD, a difference (P<0.05) of over 30,000 MXN ($2,200). These results are from a single site and may not generalize, although they may apply to Public Health institutions providing acute renal replacement therapy to uninsured ESRD patients with low socio-economic status.

Conclusions: The results highlight the potential cost savings to payers for developing a well structured PD program in order to improve the handling of resources related to PD starts, and should help inform policy regarding oversight and coverage of low income patients at risk of dialysis.

Funding: Pharmaceutical Company Support - Baxter Healtcare Corporation

SA-PO896

Survival of Patients with Heart and Lung Transplants on Peritoneal Dialysis and Hemodialysis Pramod Kumar Guru, Heena S. Sheth, Rachita Prakash, Renee A. Burr, Filitsa H. Bender, Beth M. Piraino. *Renal-Electrolyte Division, University of Pittsburgh Medical Center, Pittsburgh, PA.*

Background: ESRD, mostly due to calcineurin inhibitor toxicity, impacts negatively on survival of those with heart and lung transplants. Outcomes in relation to dialysis modalities, PD vs HD, are sparsely reported. The purpose of the study is to compare the survival of patients with heart and lung transplants on PD and HD.

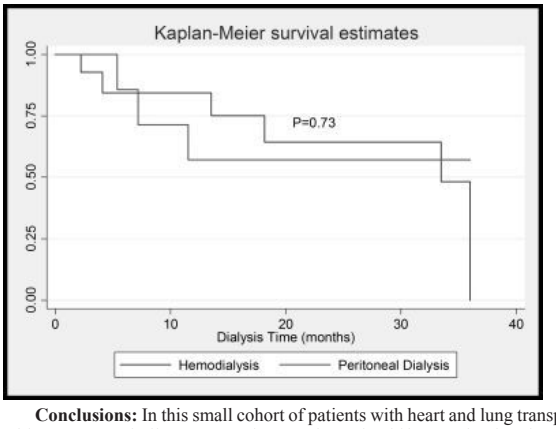
Methods: A single-center, retrospective review of prospective IRB approved registry was performed including patients with heart, lung and both transplants between 1992-2011 on dialysis at our outpatient dialysis center. Patients with kidney and abdominal organ transplants were excluded as were 2 heart/lung transplant patients who switched modalities.

Results: Cohort consists of 26 patients: heart (17), lung (8), heart & lung (1); 10 on PD and 16 on HD. Demographics are shown below.

Table 1

Demographics	PD	HD	P value
Women (%)	2 (20)	3 (19)	0.93
African American (%)	0	5 (31)	0.05
Mean age, years(SD)	55.9 (12.7)	54.0 (13.0)	0.67
Diabetes mellitus (%)	3 (30)	8 (50)	0.31
Charlson Comorbidity Index (median)	5	5	0.8
Initial serum albumin (median) gm/dl	3.8	3.05	0.03
Transplant (%)			0.43
Lung	2 (20)	6 (37.5)	
Heart	8 (80)	9 (56.2)	
Both	0	1 (6.2)	

There were 3 deaths in PD (30%) and 8 on HD (50%). From start of outpatient dialysis, survival at 6 month was 90% & 87.5%, and at 1 year was 80% & 81.2% for PD and HD patients respectively. Multivariate analysis controlling for initial albumin showed no difference in survival on PD and HD (HR 1.37, P=0.7). Kaplan-Meier survival curves are shown below.



Conclusions: In this small cohort of patients with heart and lung transplants, survival with ESRD was similar on HD and PD. Patients should be permitted to choose the modality best suited to their life-style.

SA-PO897

Ultrafiltration, Free Water and Solute Transport in Cirrhotic and Non Cirrhotic High Transport Patients on Peritoneal Dialysis Javier De Arteaga, Fabian Ledesma, Walter Guillermo Douthat, Carlos R. Chiurchiu. *Nephrology, Hospital Privado, Postgraduate Nephrology, Catholic University Cordoba, Cordoba, Argentina.*

Background: Besides being mostly high transporters (HT), cirrhotic pts have an unusually high UF volume on PD. Objective: to compare fluid and solute transport parameters between cirrhotic and non cirrhotic HT pts. Pts: We evaluated all of our HT pts (n= 17) since 2001 5 pts are cirrhotic.

Methods: Modified (4.25%) PET tests are done yearly since 2001.Minipets are done since 2006 for free water transport and NA removal data. Peritoneal ultrafiltration is measured manually hourly. HT is defined as a D/P creatinine ≥ 0.80 at 4 hs. We have not corrected NA sieving for NA difussion from the circulation for any pt from both groups. table 1 shows the comparative results between both HT groups: cirrhotic (Gr 1) vs non cirrhotic (Gr2).

Results:

	Gr1	G2	P
N	5	12	-
Age	58,2 ± 9,23±	46,8 ± 15,74	0,1
KTV(wk)	2,15 ± 0,89	1,9 ± 0,46	0,71
Prot (gr)	6,12 ± 2,87	9,8 ± 3,34	0,04
Time on PD (ms)	43,75 ± 23,37	25 ± 20,60	0,14
Time to Pet (ms)	19,00 ± 23,44	9,25 ± 17,27	0,35
D/P Creat 4 hs	0,80 ± 0,03	0,84 ± 0,03	0,03
DNa T 0 (meq/lt)	132,80 ± 4,76	129,54 ± 2,23	0,12
DNa 60 (meq/lt)	129,78 ± 2,99	124,54 ± 3,5	0,02
Plasma Na (meq/lt)	141,2 ± 2,86	137,61 ± 3,81	0,03
DIP Na	-3,0 ± 3,8	-5 ± 2,49	0,14
NAR final (meq/lt)	132,45 ± 32,95	87,96 ± 17,90	0,02
% FWT	15,60 ± 6,50	35,67 ± 21,24	0.01
UF 1 h (ml)	636 ± 132,21	373,33 ± 172,56	0,01
UF final (ml)	950 ± 265,59	665 ± 139,62	0,08

Conclusions: Cirrhotic pts have a higher drainage volume (UF) and peritoneal sodium removal (P=0.02). As expected for a HT state, NA sieving is blunted in both groups (Na difussion correction not done for neither) and this reflects a lower free water transport mostly for cirrhotic pts (p=0.01). The fact that peritoneal drainage volume is significantly higher in cirrhotics despite a HT state is probably due to the ascitic fluid generated" per se" more than true osmotic ultrafiltration and this might explain a lower free water transport in this group.(p<001) Daily loss of protein is slightly higher in non cirrhotics (p=0.04). HT cirrhotic pts have peritoneal physiologic parameters that allow to differentiate them from non cirrhotic HT pts.

SA-PO898

Randomized Cross-Over Study to Analize the Degree of Hydratation, Mesured by BCM with the Use of Conventional and Biocompatible Peritoneal Dialysis Solutions Jesus Montenegro, José Ignacio Cornago, Maria Isabel Gallardo, Paula García, Ainhoa Hernando, Rosa Ines Munoz. *Nephrology, Hospital Galdakao-Usansolo, Bilbao, Spain.*

Background: The Ultrafiltration(UF) is less with biocompatible Peritoneal Dialysis Solutions (PDS) than conventional PDS, but those preserved better the residual renal function (RRF), although a few studies don´t find these differences.

Methods: We designed a randomized cross over study to compare the hydration in stable CAPD patients treated with biocompatible and conventional PDS, measuring the RRF and the UF. The degree of hydration was measured by bioimpedance with the equipment Body Composition Monitor (BCM, Fresenius Medical Care). Patients with some RRF were randomized into two groups. Group 1: the patients started with a pure bicarbonate PDS (bicaVera®, FMC) bicaVera-standard-bicaVera. Group 2: standard-bicaVera-standard. The patients changed the type of PDS every month. In the last day of each period of study the RRF was calculated and a peritoneal equilibrium test (PET) with the solution in study was done.

Results: Results of BCM of 16 patients in each arm are shown in the table.

Degree of hydratation in liters with both PDS

Results BCM	1 month	2 months	3 months
Group 1:Liters	1.22±1.5	0.84±1.2	0.77±1.1
Group 2: Liters	1.16±1.6	1.19±1.6	0.85±1.8
p	0.93	0.57	0.81

A tendency of increase in diuresis and GFR is observed when dialyzed with bicaVera®, however, the daily UF as the UF of the PET increases significantly when dialyzed with a standard PDS (p< 0.05) but the daily loss of liquids (Diuresis+UF) was similar with both PDS. According to the measurement with BCM, there were no significant differences between the degree of hydration of the patients when dialyzed with biocompatible PDS and the degree of hydration in patients dialyzed with conventional PDS (p>0.05).

Conclusions: This decrease of the UF is statistically significant, but clinically isn´t important due to the fact that a lower UF is compensated by a greater diuresis. Measuring hydration with BCM is recommended in clinical practice and the BCM helps to know the degree of overhydration more precisely. The study will need to be continued with more patients to reach major statistic strength.

SA-PO899

Effluent Cancer Antigen 125: A Predictor of Technique Survival in Peritoneal Dialysis Deirisa Lopes Barreto,[1] Nynke Halbesma,[2] Martijn Leegte,[3] Raymond T. Krediet.[1] *[1]Internal Medicine, Division of Nephrology, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands; [2]Clinical Epidemiology, Leiden University Medical Center, Leiden, Netherlands; [3]Hans Mak Instituut, Naarden, Netherlands.*

Background: Cancer antigen (CA) 125 is the best known effluent marker in peritoneal dialysis (PD). It reflects the mesothelial cell mass of the peritoneal membrane. A decline is observed with duration on PD. In this study we aimed to investigate effluent CA125 as a predictor of technique survival.

Methods: Adult patients with a PD duration of at least 24 months were eligible for this study. Technique failure was defined as switch from PD to hemodialysis (HD). To determine the predictive value of CA125 a Kaplan-Meier analysis was performed, where the difference between low (<6.5 kU/L) versus high (>6.5 kU/L) CA125 levels was determined by means of a log-rank test. Censored observations consisted of death, transplantation, lost to follow-up and end of study period.

Results: One hundred and six incident PD patients were included in this prospective study with a maximum follow-up of 60 months after commencing PD. The Kaplan-Meier curve showed a borderline significance, where technique failure was more often observed in patients with low CA125 levels as compared to patients with high CA125 levels. After a longer follow-up this difference became more pronounced. Technique survival rates were 83% in patients with high levels of CA125 and 38% for those with low CA125 levels. The two CA125 groups were comparable according to their characteristics. Only the group with low levels of CA125 had a longer PD duration and utilized more automated PD.

Conclusions: Patients with high CA125 levels tend to have a better technique survival as compared to patients with low CA125 levels. These results support the importance of membrane failure as cause of drop-out in long term PD.

SA-PO900

Root Cause Analysis of Low KT/V in Peritoneal Dialysis Farsad Afshinnia, Ziad S. Zaky, Jonathan H. Segal. *University of Michigan.*

Background: A target total weekly KT/V of 1.7 may not be achieved in all peritoneal dialysis (PD) patients. This study identifies risk factors for a KT/V < 1.7 and assesses the response to intervention in a single center out-patient dialysis unit.

Methods: Clinical information including demographic, duration of PD, details on prescription, prior abdominal surgery, catheter dysfunction, hernia, leak, and peritonitis were collected. Primary endpoint is defined as the first KT/V below 1.7 after initiation of PD. Time to event analysis was performed with Cox regression analysis. McNemar test was used to test the change in KT/V category after intervention.

Results: 13 of 35 patients (37.1%) were found to have at least one KT/V of < 1.7 during the study period. Mean (SD) age was 49.2 (15) years. Mean age, weight and fill volume were not statistically different between the low and acceptable KT/V groups, but total volume was 14.3 (2.8) vs 11.6 (3.8) L (p=0.033), and residual KT/V was 0.2 (0.4) vs 0.6 (0.5) (p = 0.041), respectively. History of prior surgery was 76.9% (10) vs 72.7% (16), catheter dysfunction 46.2% (6) vs 27.3% (6), hernia 38.5 (5) vs 22.7% (5), leak 23.1% (3) vs 9.1% (2) and peritonitis was 36.4% (8) vs 46.2% (6) in patients with low and acceptable KT/V, respectively. Relative risk of low KT/V was 3.6 times higher (95% CI: 1.5-8.7) with each additional risk factor. Incorporation of time-varying covariates showed that every 1 kg increase in weight without a change in PD prescription was associated with a 5% (95%CI: 1%-10%) increased risk of low a KT/V. After appropriate interventions including adjusting total volume in PD prescription 11 patients (84.6%) with low KT/V increased to acceptable range (p = 0.001).

Conclusions: Number of risk factors and loss of residual renal function are significant predictors of poor clearance. Correcting modifiable risk factors and increasing total therapy volume may improve Kt/V and can be used as targeting intervention for quality improvement.

SA-PO901

Intercalated Cells Maintain Sterility of the Urinary Tract John David Spencer, Andrew L. Schwaderer, David S. Hains. *Pediatrics, Nationwide Children's Hospital, Columbus, OH.*

Background: Although urine is sterile, little is known how the kidney maintains sterility. We have shown that the renal collecting duct produces several antimicrobial peptides (AMP) that help maintain sterility. Intercalated cells (IC) produce one of the most potent human AMPs – Ribonuclease 7 (RNase7). When RNase7 is neutralized in the urinary tract, bacterial growth increases. This study was designed to further characterize the biological relevance of RNase7 and Ribonuclease Inhibitor (RI) in the human kidney during infection.

Methods: *Gene expression*: RNA from non-infected and pyelonephritic human kidney tissue was used to quantify RNASE7 and RI using real-time PCR. *Protein expression*: IF localized RNase7 and RI production. Western blot (WB) and ELISA quantified RNase7 and RI production in non-infected/infected kidney and urine samples. RNase7 function: Live/Dead kill assays assessed the antimicrobial function of RNase7 on uropathogens in the presence and absence of RI.

Results: *Gene expression:* With pyelonephritis, RNASE7 mRNA expression increased from 1028 ng to 2927 ng/10ng total RNA (p<0.04) while RI mRNA expression decreased from 806 ng to 549 ng/10ng total RNA (p<0.05). Protein expression:IF localized RNase7 production to the apical surfaces of IC and RI to the basolateral surfaces of IC. Extracellular staining showed that IC secrete RNase7 into the urinary space. ELISA showed kidney and urinary RNase7 peptide production increase with infection. WB showed concurrent decreases in kidney RI production with pyelonephritis. RI was not detected in sterile urine. Degraded RI was identified in infected urine. RNase7 function: Recombinant RNase7 rapidly kills Gram-positive/negative uropathogens at micromolar concentrations (0.1-2.5μM). In the presence of equal concentrations of RI, the antimicrobial effects of RNase7 significantly decreased.

Conclusions: ICs are important in maintaining sterility of the urinary tract as they produce potent AMPs like RNase7. IC also produce regulatory proteins like RI, which abrogates the antimicrobial effects of RNase7. Further elucidation of the IC factors that regulate production and function of AMPs like RNase7 may lend insight into the pathogenesis of UTIs.

The Crucial Role of Th2 Lymphocytes in Renal Fibrosis Lili Liu,[1] Qiao Zeng,[1] Sheng Chen,[2] Gang Xu.[1] *[1]Tongji Hospital, Wuhan, Hubei, China; [2]The Cancer Center, Union Hospital, Wuhan, Hubei, China.*

Background: Renal tubulointerstitial fibrosis is the final common stage of renal failure. $CD4^+$ T lymphocytes recruitment and activation after injury could be the very important early event that mediates the onset of renal fibrogenesis. But the role of $CD4^+$ T lymphocytes in renal fibrosis is controversial and its cellular mechanism needs to be further investigated.

Methods: Biopsy specimens were from patients with minimal change or IgA nephropathy. Mouse renal fibrosis was induced by unilateral ureteral obstruction. $CD4^+$ T lymphocytes of wild BALB/c mice were deleted with anti-CD4 monoclonal antibody. Flow cytometry analyzed the ratios of subtypes of $CD4^+$ T lymphocytes. $CD4^+$ T lymphocytes were isolated by magnetic-activated cell sorting (MACS). BALB/c Nu/Nu mice were reconstituted with polarized Th1 or Th2 cells by tail vein injection which were labeled and tracking with DiI. Kidney sections were examined for HE, Masson's trichrome's staining and immnohistochemistry of α-SMA and vimentin. ELISA quantified the levels of cytokines. RT-PCR detected the mRNA expression of collagen I, fibronectin and TGF-β1 and specific transcriptional factors.

Results: Our study demonstrated that the depletion of $CD4^+$ T lymphocytes inhibited the process of UUO-induced mouse renal fibrosis.In the process of UUO-induced renal fibrosis, Th1 cells were predominant on day 3 after UUO, the ratios of Th2/Th1 increased with time gone and Th2 cells were predominant on day 14 after UUO. Results also have shown that Th2-reconstituted mice developed renal fibrosis easier than Th1-reconstituted mice manifested by interstitial expansion and collagen deposition, higher expression of α-SMA and Vimentin and increased expression of fibronectin, TGF-β and collagen I. We also found that $CD4^+$ T cells from Th1-reconstitued mice tended to secret IL-4 and IL-13 Th2-like cytokines.

Conclusions: In conclusion, our study demonstrated the importance of $CD4^+$ T lymphocytes in renal fibrosis and gave the first direct evidence that Th2 cells play the pivotal role in UUO-induced renal fibrosis. Deletion of Th2 cells or inhibition of $CD4^+$ T lymphocytes differentiation to Th2 would be a potential therapeutic intervention to prevent renal fibrosis.

SA-PO903

The Uremic Toxicity Affects the Oxidative Burst and Antigen Presentation on Monocyte-Derived Macrophages: Potential Link between Uremia and Adaptive Immune Dysfunction Andrea Novais Moreno-Amaral,[1] Marina Luise Viola de Azevedo,[1] Natalia Borges Bonan,[1] Bruna Bortolini,[1] Elis Fernanda Demenech,[1] Wesley M. Souza,[2] Andréa Marques Stinghen,[2] Roberto Pecoits-Filho.[1] *[1]Pontifícia Universidade Católica do Paraná, Curitiba, Parana, Brazil; [2]Federal University of Parana, Curitiba, Parana, Brazil.*

Background: The immune system of CKD is characterized by disorders on innate immune activation that leads to a deficiency in the adaptive immune response, established by an increased susceptibility to infections and poor response to vaccination. To understand the mechanisms behind these events, we investigated the role of uremic serum (US) and isolated uremic toxins on burst oxidative production and antigen presentation markers expression on U937 monocyte derived-macrophage (MDM).

Methods: MDM was incubated with p-cresol (pC), p-cresyl sulphate (pCS) or US obtained from CKD patients in stage II/III and superoxide anion production was evaluated through NBT assay. Cell surface markers expression related to antigen presentation were evaluated using mAb anti-HLA-ABC-FITC, -HLA-DR-PE, and to co-stimulatory molecules using -CD80-FITC and -CD86-PE and analyzed by flow cytometry.

Results: Our results showed that both uremic toxins and US were able to induce an increase in oxidative stress in MDM, assessed by superoxide anion production, and were able to increase HLA-ABC and CD80 expression in the same level when compared to the LPS. Interestingly, we observed that US was not able to modulate HLA-DR expression and the isolated toxins showed slight effect on this expression. Equally results were observed for CD86, where basal expression was expressed after MDM incubation with US and with both toxins pC and pCS.

Conclusions: It is know that CD86 has higher affinity to CD28 and this binding induce T cell proliferation while CD80 is the preferred CTLA-4 ligand, which promote the cell-cycle arrest. Our results suggest that the uremic toxins can induce macrophage dysfunction causing increase oxidative stress and also an important factor for the increased incidence of infections in uremia, since no modulation on HLA-DR and CD86 expression, suggesting a possible negative signal to T cells during antigen presentation.

SA-PO904

Receptor-Mediated Extravasation of IgG Auto-Antibodies: A Novel Role of FcRn in Autoimmune Pathology Florina Olaru,[1] Wentian Luo,[1] Linna Ge,[1] Yoshikazu Sado,[2] Dorin-Bogdan Borza.[1] *[1]Vanderbilt University School of Medicine, Nashville, TN; [2]Shigei Medical Research Institute, Okayama, Japan.*

Background: In most capillary beds, endothelial cells restrict the passage of macromolecules from plasma to the interstitial space. IgG autoAbs targeting extravascular autoAgs, such as α3(IV) collagen, can only induce inflammation and tissue injury after crossing this barrier. How this occurs is not known. We hypothesized that IgG extravasation is mediated by FcRn, a key regulator of IgG homeostasis expressed in endothelial cells.

Methods: We determined how genetic and pharmacologic targeting of FcRn affects in vivo binding of IgG autoAbs to mouse tissues at 18-24h after passive immunization with IgG mAbs to α3/α5(IV) collagen NC1 domains (a model for Goodpasture autoAbs). The duration of the experiments was chosen to minimize the impact of accelerated IgG catabolism in the absence of FcRn.

Results: In vivo binding of IgG autoAbs to α3/α5(IV) collagen in the basement membranes (BMs) of alveoli, skin, and neuromuscular junction (NMJ) was strongly inhibited by genetic ablation of FcRn. Binding of IgG autoAbs to extra-renal BMs was also reduced by treatment with high dose intravenous immunoglobulin (IVIG) and effectively prevented by treatment with a blocking anti-FcRn mAb. Ablation of FcRn function did not affect the binding of IgG autoAbs to the GBM and tubular BMs, and only slightly reduced the titers of circulating IgG autoAbs.

Conclusions: The mechanisms of IgG extravasation are tissue-specific. Our results indicate that FcRn mediates this process in microvascular beds with continuous but not fenestrated endothelia (e.g. in lungs, skin and skeletal muscle but not kidneys). In these tissues, FcRn acts as a "Trojan horse" that transports IgG autoAbs for binding to autoAgs in the extracellular matrix (e.g. collagen IV), thereby promoting autoimmune pathology. Competitive inhibition of FcRn-mediated IgG extravasation may be a novel mechanism for the beneficial activity of high-dose IVIG in autoimmune diseases. Targeted FcRn inhibitors more specifically and effectively blocking this process may provide a novel approach for treating IgG-mediated diseases affecting lungs, skin, NMJ and other sites.

C-Reactive Protein Exacerbates Renal Ischemia Reperfusion Injury Melissa A. Pegues, Mark Mccrory, Alexander J. Szalai. *Medicine, University of Alabama at Birmingham, Birmingham, AL.*

Background: Acute kidney injury (AKI) is a serious complication of hypertensive crisis, cardiovascular surgery, and ischemia reperfusion injury (IRI). Mortality from AKI is as high as 80% due to incomplete knowledge of the mechanisms leading to AKI. It is known that a systemic inflammatory response always accompanies AKI and that increasing levels of the acute phase protein C-reactive protein (CRP) associate with worsening of AKI. These studies were undertaken to determine if CRP is actively involved in AKI-and not just marking its occurrence.

Methods: Wild-type, human CRP transgenic (CRPtg), and mouse CRP deficient ($CRP^{-/-}$) mice were subjected to bilateral renal IRI for 30 minutes and outcomes measured after 24 hours of reperfusion.

Results: Serum levels of human CRP increased in CRPtg mice subjected to IRI (14.81±3.00 μg/ml at baseline, 59.76±7.86 μg/ml 24 hours post-surgery), but did not increase in CRPtg mice subjected to sham surgery without IRI (23.54±1.16 μg/ml at baseline, 14.51±5.06 μg/ml 24 hours post-surgery). Mouse CRP was minimally elevated by IRI (2.41±0.42 μg/ml at baseline, 12.77±4.71 μg/ml 24 hours post-surgery). Compared to their wild-type and $CRP^{-/-}$ counterparts, CRPtg mice subjected to IRI had increased serum creatinine and urinary albumin and more histological evidence of kidney damage (increased necrosis, brush border loss, and cast formation). $CRP^{-/-}$ mice showed improvement in all measured markers of renal damage compared to wild-type mice. RT-PCR analysis revealed decreased expression of FcγRIIb mRNA in injured kidneys of CRPtg mice compared to wild-type mice subjected to IRI. Also, kidneys of $CRP^{-/-}$ mice subjected to IRI had increased expression of markers of alternatively activated macrophages (arginase 1 and mannose receptor) compared to controls.

Conclusions: Taken together these data indicate that CRP plays an active role in renal IRI induced AKI, perhaps by depressing expression of the inhibitory FcγRIIb receptor and promoting classically activated macrophage polarization.A better understanding of this damaging sequence in AKI will allow for the development of interventions to shorten the course of AKI, prevent the need for hemodialysis, and improve survival.

In Fabry Disease the Storage of Globosides but Not of Isoglobosides Impacts the Development of Invariant Natural Killer T Cells and Their Interaction with Dendritic Cells Hermann-Josef Groene, Stefan Porubsky, Mahnaz Bonrouhi. *Cellular and Molecular Pathology, German Cancer Research Center, Heidelberg, Germany.*

Background: Invariant natural killer T cells (iNKT) are important players at the crossroad between innate and adaptive immunity with implications also in kidney diseases such as FSGS or lupus erythematodes. Recognition of endogenous lipid antigen(s) on CD1d molecules is required for iNKT cell development. Isoglobotrihexosylceramide (iGb3) has been implicated as this endogenous selecting ligand and recently suggested to control over-stimulation of iNKT cells in α-galactosidase A-deficient mice ($\alpha GalA^{-/-}$, human Fabry disease). A higher incidence of autoantibodies in Fabry patients has been also reported. In addition, iGb3 bears a terminal Galα3Gal epitope which is recognized by xeno-antibodies mediating hyperacute rejection in pig-to-human transplantation. However the presence and function of iGb3 in murine tissues remained controversial.

Methods: Here we generate a Gb3-synthase deficient mouse ($Gb3S^{-/-}$).

Results: We show that in $\alpha GalA^{-/-}/Gb3S^{-/-}$ double knockout mice, which store isoglobosides but no globosides, minute amounts of iGb3 (1619±380 molecules of iGb3 per thymocyte (mean±SEM, n=3)) can be detected by high performance liquid chromatography. Analyzing multiple gene targeted mouse strains, we demonstrate that globoside, rather than iGb3, storage is the major cause for the 50% reduced iNKT cell frequencies and the 80% less efficient antigen presentation in $\alpha GalA^{-/-}$ mice. Finally, we show that correction of globoside storage in $\alpha GalA^{-/-}$ mice by crossing them with $Gb3S^{-/-}$ normalizes iNKT cell frequencies and DC function.

Conclusions: We conclude that - although detectable in murine thymus in $\alpha GalA^{-/-}/Gb3S^{-/-}$ mice - iGb3 does not influence either the development of iNKT cells or their interaction with peripheral DCs. Moreover in $\alpha GalA^{-/-}$ mice it is the Gb3-storage that is responsible for the decreased iNKT cell numbers and impeded antigen presentation on DCs.

SA-PO908

Paricalcitol and Mesenchymal Stem Cells Additively Suppress Primary T-Helper 17 Differentiation via Distinct Mechanisms Michelle M. Duffy, Bairbre A. McNicholas, Matthew D. Griffin. *Regenerative Medicine Institute, College of Medicine, National University of Ireland, Galway, Ireland.*

Background: T-helper 17 (Th17) cells play a pathogenic role in acute kidney injury (AKI), glomerulonephritis and transplant rejection. We previously reported that mesenchymal stem cells (MSCs) suppress primary Th17 induction via PGE2 production induced by direct contact with activated $CD4^+$ T-cells. Vitamin D receptor agonists (VDRa) also have direct and indirect suppressive effects on T-helper differentiation. The current study aimed to investigate the combined effects of MSCs and the VDRa paricalcitol on Th17-mediated responses in vitro and in unilateral ureteral obstruction (UUO).

Methods: Th17 differentiation was induced by 3-day activation of total $CD4^+$ T-cells or FACS-purified naive and memory $CD4^+$ T-cells with anti-CD3 + APCs in the presence of IL-6, TGFβ1, anti-IFNγ and anti-IL-4. Paricalcitol or vehicle was added in graded concentrations (10^{-12}-10^{-7}). MSCs were added at 1:400 MSC:T-cell ratio. Analyses included ELISA, surface and intracellular flow cytometry and immunoblotting. UUO was carried out for 72 hours in adult mice. Kidney cells suspensions were enriched for $CD45^+$ cells by magnetic separation and stimulated with anti-CD3ε followed by IL-17A ELISA in the presence or absence of paricalcitol and/or MSCs.

Results: Paricalcitol suppressed IL-17A production in dose-dependent fashion in Th17 cells *in vitro*. At its optimal concentration (10^{-8}M) paricalcitol mildly inhibited T-cell proliferation but strongly reduced the frequency of $IL\text{-}17A^+$ cells. Combined MSCs and paricalcitol further inhibited Th17 induction from both naive and memory responders to a greater degree than either intervention alone. MSCs reduced expression of the Th17-associated transcription factors RORγt, RORα, Runx1 and IRF4. MSC-mediated Th17 suppression was reversed by selective COX 2 inhibition while paricalcitol-mediated suppression was not. MSCs and paricalcitol also suppressed IL-17A secretion by effector memory Th17 cells from obstruced kidney.

Conclusions: MSCs and paricalcitol additively suppress primary Th17 differentiation via distinct mechanisms and inhibit re-activation of Th17 cells from obstructed kidney.

microRNA-155 Deficiency in Peripheral Lymphocyte Is Related to IgA Nephropathy Ping Fu, Wei Qin. *Division of Nephrology, Department of Medicine, West China Hospital of Sichuan University, Chengdu, Sichuan, China.*

Background: MicroRNA-155 (miR-155) involves in lymphocyte homeostasis and adjusts multiple immune genes. Lymphocytes dysfunctions and impaired homeostasis are key pathogenesis of IgA nephropathy (IgAN). miR-155 level in peripheral lymphocytes of IgAN patient was studied to clarify potential pathogenic relationship.

Methods: Forty biopsy-proven IgAN patients and 15 unrelated healthy controls were included. Expression of miRNAs in peripheral lymphocyte was first determined using Exiqon microRNA microarray. Realtime RT-PCR of miR-155 was performed. The expression level of Foxp3, a regulator of miR-155, was also measured. Correlation between miR-155 and Foxp3 expression level as well as clinical indexes, such as proteinuria, hematuria, renal function and albumin level was analyzed.

Results: Microarray results indicated that in the 1035 microRNAs successfully analyzed, 533 are upregulated and 499 are downregulated compared with normal controls. The expression level of miR-155 in IgAN patients was dramatically lower than that in normal control (fold change: -0.61), which was further confirmed by realtime RT-PCR (IgAN 0.197±0.07 vs Control 0.796±0.13, $p<0.01$). Further study showed that baseline proteinuria (24 hour quantification) and hematuria (RBC per high power view) level was significantly correlated to the miR-155 expression level (proteinuria: $r=-0.594$, $p<0.001$, hematuria: $r=-0.590$, $p<0.001$). However, no apparent correlation was observed in baseline serum creatinine level, serum albumin level, serum albumin concentration. Significantly

correlation between miR-155 and Foxp3 expression level was also noticed(R=0.681, p<0.001). Moreover, it is noticed that the peripheral lymphocytes miR-155 level is higher in patients with mild pathological changes (Lee's grade) as well as IgA1 glycosylation level.

Conclusions: Remarkable lower expression of miR-155 in peripheral lymphocytes was observed in IgA nephropathy patients, which was correlated with proteinuria, hematuria, kidney lesion scores and IgA glycosylation level. These results suggested that miR-155 might play important roles in the pathogenesis of IgAN and might be a potential biomarker of the disease.

Differential Effect of High-Density Lipoprotein from Healthy Subjects and from Chronic Kidney Disease Patients on Polymorphonuclear Leukocytes

Gerald Cohen,[1] Jana Raupachova,[1] Chantal Maureen Kopecky,[1] Georg Michlits,[1] Philipp Eller,[2] Marcus Saemann,[1] Walter Hoerl.[1] *[1]Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria; [2]Department of Internal Medicine I, Graz Medical University, Graz, Austria.*

Background: Cardiovascular disease (CVD) and infections of chronic kidney disease (CKD) patients are related to disturbed functions of immune cells such as polymorphonuclear leukocytes (PMNLs). Gradual changes in the protein composition of high-density lipoprotein (HDL) with decreasing renal function may lead to a loss of its anti-atherosclerotic properties. While the effect of unmodified HDL and HDL modified by the uremic milieu on monocytes has already been investigated, no such experiments with PMNLs have been conducted so far.

Methods: HDL was isolated from plasma of healthy subjects (HS-HDL; n=7), patients with CKD stage 3 (CKD3-HDL; n=8) and hemodialysis patients (HD-HDL; n=8). Final HDL concentrations were 10 and 100 µg/ml. PMNLs were isolated from HS. The oxidative burst was stimulated with phorbol-12-myristate-13-acetate (PMA) or E. coli and measured via cytochrome c reduction. The surface expression of CD14, a pattern recognition receptor, was quantified by flow cytometry. Apoptosis was assessed by evaluating morphological features under the fluorescence microscope and by measuring the DNA content by flow cytometry.

Results: HS-HDL, CKD3-HDL and HD-HDL significantly increased the basal surface expression of CD14 at a final concentration of 100µg/ml. Only HD-HDL showed this effect already at 10µg/ml. The formyl-methyl-leucyl-phenylalanine stimulated CD14 expression was increased by all isolates tested. CKD3-HDL and HD-HDL strongly reduced the PMA stimulation of the oxidative burst already at 10µg/ml whereas HS-HDL had a much lesser effect at 100µg/ml. The activation of the oxidative burst by E. coli was diminished only by HD-HDL. While HS-HDL and CKD3-HDL had no significant effect on PMNL apoptosis, HD-HDL significantly decreased PMNL apoptosis, an effect characteristic for pro-inflammatory mediators.

Conclusions: The different effect of HDL modified by the uremic milieu on PMNLs may contribute to the deranged immune response in CKD3 and HD patients.

CD4+CD25+Nrp1+ Regulatory T Cells Induce the Renal Protect Effect of Ischemic Preconditioning

Fan He, Gang Xu, Ying Yao, Yongman Lv, Lili Liu, Qian Zhang, Yanhua Wang. *Department of Nephrology, Tongji Hospital, Wuhan, Hubei, China.*

Background: Ischemic reperfusion is one of important causes of acute kidney injury. T cell mediated inflammatory is the major mechanism of kidney ischemic reperfusion injury (IRI). A short-time preconditioning ischemia(PI) spurs kidney tolerance to following ischemic dysfunction. And the underlying mechanisms of IP are thought to involve adaptive changes within the injured tissue. Because regulatory T cells play a key role in inflammatory suppressing and tolerance maintenance, we hypothesized that CD4+CD25+Nrp1+ regulatory T cells induce the protect effect of ischemic preconditioning in kidney.

Methods: C57BL/6 mice underwent 25 min of bilateral renal clamping or sham operation. CD4+CD25+Nrp1+ T cells were analyzed by flow cytometry. At 5 days after IP (or sham operation), purified leukocytes from spleen were adoptively transferred into T cell-deficient (nu/nu) mice. After 1 week, these mice underwent 35 min of renal IRI, the renal functioan and pathology were detected. We used anti-CD25 monoclonal antibody to deplete regulatory T cells, and evaluated the renal protect effect of ischemic preconditioning. And we transfered CD4+CD25+Nrp1+ T cells isolated from PI mouse to assess whether thus can reverse the renal protection.

Results: 7 days after operation(bilateral renal clamping or sham operation), the proportion of CD4+CD25+Nrp1+ regulatory T cells was 4-folder higher in IP group than in sham operation group. In vitro analysis the CD4+CD25+Nrp1+ T cells isolated from PI mice, the Foxp3 expressing rate was 96.7%±1.3%. The nu/nu mice receiving leukocytes from ischemic wild-type mice had significantly reduced renal injury and inflammatory compared with nu/nu mice receiving leukocytes from sham-operated, wild-type mice. Depletion of regulatory T cells deprived the adoptive protect effect of PI. Adoptive transfer the CD4+CD25+Nrp1+ T cells protect the kidney from subsequent ischemic reperfusion injury and inflammation.

Conclusions: These results demonstrated that immune cells primed after renal IRI with an increasing proportion of CD4+CD25+Nrp1+ regulatory T cells and thereby suppressed the inflammatory and injury during a second episode of IRI.

SA-PO912

HLA-DQB1*05:02 Allele and DPB1*05:01-DQB1*03:02 Haplotype Are Associated with Susceptibility to Chronic Glomerulonephritis (CGN)

Qin Zhou, Jianghua Chen. *Kidney Disease Center, The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, Zhejiang, China.*

Background: Association of HLA loci with specific diseases has been widely studied. However, such an association is not well documented about Chronic Glomerulonephritis (CGN). The objective of this study was to examine the association between the susceptibility to conventional CGN with HLA-C,-DPB1,-DQB1 loci in Zhejiang Han population.

Methods: Genotyping for HLA-C, -DPB1 and -DQB1 loci was performed in 112 patients with CGN and 115 control individuals. Frequencies of the allele and haplotype were analyzed to clarity the association of HLA-C,-DPB1,-DQB1 loci with CGN.

Results: The results were showed that the frequency of DQB1*05:02 allele (2.23%) was significantly lower in patients than that in controls (10.0%). Linkage disequilibrium were confirmed for C-DPB1,C-DQB1,DPB1-DQB1 and C-DPB1-DQB1 haplotypes in patients and controls. The frequency of DPB1*05:01-DQB1*05:02 haplotype in patients (0%) was significantly lower than that in controls (5.50%).

Conclusions: It was concluded that the decreased expression of DQB1*05:02 allele and DPB1*05:01-DQB1*03:02 haplotype are strong predisposing factor for conventional CGN in Chinese Han population.

Highly Significant Association of HLA Serotypes with Autoimmune End-Stage Renal Diseases

John Farrell, Gyungah Jun, Laurence H. Beck, David J. Salant. *Biomedical Genetics and Medicine, Boston University Medical Center.*

Background: Autoimmune kidney diseases may cause end stage renal disease (ESRD). The UNOS Kidney Registry routinely collects HLA serotypes to help match registrants with kidney donors. We mined this large dataset and evaluated association of HLA serotypes with primary diagnoses of ESRD.

Methods: A total of 346,317 subjects registered on the UNOS Kidney Registry waitlist (1987-2011) were available with complete gender, primary diagnosis and HLA serotyping data. We performed association analyses with 107 HLA A, B, DR serotypes for 43 primary renal diagnoses in four ethnic groups (N=316,369). The control group consisted of 29,948 patients registered with a diagnosis of polycystic kidney disease (PKD), which has established genetic risk variants outside of the MHC region. A step-wise logistic regression was applied in the ethnicity-matched case-control groups after adjusting for sex. We excluded diagnoses with small sample size (N < 200). After correction for multiple testing, a significance threshold of $1.1x10^{-5}$ was applied.

Results: We found significant associations with HLA serotypes for 23 primary diagnoses of European (EA), African (AA), Hispanic (HSP) and Asian (ASN) ancestry. Novel associations were found for membranous nephropathy (MN) with DR5 (EA: OR=1.47, $P=2.66x10^{-21}$; AA: OR=1.57, $P=6.61x10^{-14}$) and with DR6 (EA: OR=1.28, $P=7.28x10^{-10}$). For the first time, we discovered significant HLA associations in AA for systemic lupus erythematosus (SLE) with DR2 (OR= 1.76, $P=4.81x10^{-33}$) and B8 (OR=1.84 $P=1.32x10^{-12}$) and chronic glomerulonephritis A68 (OR=0.57, $P= 6.67x10^{-14}$). We also observed significant association for IgA nephropathy with DR2 (EA: OR=0.71, $P=1.87x10^{-32}$; AA: OR=0.68, $P=1.39x10^{-05}$) and Wegeners granulomatosis for DR4 (EA: OR=1.4 $P=1.14x10^{-12}$) and DR6 (EA: OR=0.62,$P=2.59x10^{-11}$), which have not been reported. We confirmed known associations for Type 1 diabetes with DR3, DR4, DR2, B39, Goodpasture syndrome with DR2, SLE with DR2 and DR3 and MN with DR3.

Conclusions: This data mining approach revealed several novel HLA serotypes primarily from the MHC II region (HLA-DR) that are significantly associated with autoimmune kidney diseases.

SA-PO914

The Role of γδ T Cells in Pyelonephritis

Simon Teteris, Christian Kurts. *Institute for Experimental Immunology, Rheinische Friedrich Wilhelms University, Bonn, North Rhein Westphalia, Germany.*

Background: Cells of the innate immune system are the first responders to, and are responsible for, the clearance of bacterial infections. IL-17 has been established as one of the key cytokines in pathways of Polymorphonuclear neutrophilic granulocyte (PMN) recruitment and activation. Recent studies also point to a role for this cytokine in various forms of glomerulonephritis. In addition to the well-known Th17 cells, another major producer of IL-17 are gamma delta (γδ) T cells. Here we investigate the role played by γδ T cells in pyelonephritis.

Methods: The clinical uropathogenic *E. coli* isolate 536 (UPEC 536) was instilled into the bladder of anaesthetised C57Bl/6 mice using a catheter. Mice were infected again three hours later to induce an ascending renal infection. Kidneys were excised enzymatically digested and the inflammatory infiltrate analysed by flow cytometry. The level of kidney infection was determined by plating dilutions of the renal digest onto CPS ID plates.

Results: Renal infection with *E. coli* was maximal 3 hours after the second infection, with the numbers of *E. coli* present dropping 1000 fold over the following 72 hours. Infiltration of the renal tissue by PMNs peaked at day 2 post-infection and decreased sharply as the bacteria were cleared. However, PMN numbers rose again if the bacteria were not cleared and a chronic infection was established. Notably although γδ T cells were extremely rare in the normal kidney, their numbers increased significantly, from 4 fold at

72 hours post-infection up to 12 fold at day 7 post-infection. When the cytokine profile of the γδ T cells was investigated they produced IL-17 rather than IFNγ (27.3% versus 2.4% respectively). Additionally γδ T cells predominately produced IL-17A alone (17.6%) rather than a combination of IL-17A and IL-17F (3.9%) or IL-17F alone (4.4%).

Conclusions: Pyelonephritis induces the infiltration of γδ T cells into the renal parenchyma where they express IL-17A. The expression of IL-17 by γδ T cells later in renal infection may be responsible for amplification of the innate immune response, enabling optimal recruitment and activation of PMNs and clearance of persistent renal infections.

Role of CCR2 and CX_3CR1 in Homeostatic and Inflammatory Recruitment of Kidney Mononuclear Phagocytes Daniel Engel,[1] Torsten Urzynicok,[1] A. Richard Kitching,[2] Christian Kurts.[1] *[1]Institute for Experimental Immunology, Bonn, Germany; [2]Medicine, Monash University Clayton, Melbourne, Australia.*

Background: The kidney harbors a dense network of mononuclear cells, including macrophages and dendritic cells (DC), which directly contribute to both innate and adaptive immunity and can originate from blood monocytes. Nevertheless, the mechanisms that regulate migration of macrophage and DC- progenitors in homeostasis and inflammation are currently unclear.

Methods: The abundance of macrophages (CX3CR1+, F4/80+, CD11c-) and DCs (CX3CR1+, CD11c+) within the healthy and the inflamed kidney of $CCR2^{-/-}$x $CX3CR1^{GFP/+}$, $CCR2^{+/+}$x $CX3CR1^{GFP/+}$ and $CCR2^{+/+}$x $CX3CR1^{GFP/GFP}$ mice were analysed by flow cytometry. Renal inflammation was induced by unilateral ureteral obstruction or by instillation of uropathogenic *E.coli* into the urinary bladder. Injected BM-derived monocyte-progenitors (BMMP) were isolated out of $CCR2^{-/-}$x $CX3CR1^{GFP/+}$, $CCR2^{+/+}$x $CX3CR1^{GFP/+}$ and $CCR2^{+/+}$x $CX3CR1^{GFP/GFP}$ mice by sorting or by negative MACS enrichment. The number of CX3CR1-expressing donor macrophages and DCs within the kidney was defined as mentioned above.

Results: We found that homeostatic migration of macrophages and DCs into the kidney depends on the chemokine receptor CCR2, but that renal DCs additionally depend on CX3CR1. In Homeostasis, BMMP did not efficiently migrate into the kidney. In contrast, migration of donor BMMP into the kidney was significantly increased by inflammation, for example by unilateral ureteral obstruction and bacterial pyelonephritis. Of note, such BMMP that infiltrated into the kidney were able to differentiate into both renal macrophages and DCs. Consistent with the findings under homeostatic conditions, migration of BMMP and the subsequent generation of macrophages within the inflamed kidney was dependent on CCR2, whereas generation of DCs mainly required CX3CR1.

Conclusions: These findings suggest a non-redundant role for CCR2 and CX3CR1 in the migration of macrophages and DC-progenitors into the kidney, with DCs having a greater dependence on CX3CR1. This differential dependency might allow to therapeutically modulating renal inflammatory processes in which either DCs or macrophages are involved.

SA-PO916

Immune Complexes Enhance Dendritic Cell Migration to Lymph Nodes Menna R. Clatworthy,[1,2] Caren Petrie-aronin,[2] Rebeccah J. Mathews,[1] Ken Smith,[1] Ronald N. Germain.[2] *[1]CIMR/Department of Medicine, University of Cambridge, Cambridge, United Kingdom; [2]LSB, NIAID, NIH, Bethesda, MD.*

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease characterised by immune complex (IC) deposition in tissues, including the kidneys, causing inflammation and disease. Many deleterious effects of IC are mediated via Fcγ receptors (FcγR), which are found on most immune cells, including dendritic cells (DCs). DCs are important antigen presenting cells. Following antigen acquisition in tissues, DCs migrate to lymph nodes and activate T cells. We sought to determine how FcγR cross-linking with IgG IC might affect DC migration.

Methods: Bone marrow DCs (BMDCs) were generated from wild type (WT) & FcγRIIB-/- mice & stimulated with IC. *In vivo* migration assay: BMDCs were injected subcutaneously (S/C), lymph nodes harvested and DCs enumerated histologically and by flow cytometry. *In vitro*, 3D chemotaxis assay: Murine BMDCs & human monocyte-derived DCs were placed in a CCL19 gradient in a collagen matrix and time-lapse confocal imaging performed.

Intravital two-photon microscopy: Dermal DCs from WT & FcγRIIB-/- CD11cEYFP mice were imaged following stimulation with IC or lupus serum.

Results: FcγR-crosslinking with ICs increased BMDC migration from peripheral tissues to draining lymph nodes; In a 3D collagen matrix, IC-stimulated murine and human DCs showed enhanced directional migration in a CCL19 gradient;· FcγR-crosslinking with IgG ICs increased CCR7 expression on BMDC and on human monocyte-derived DCs; Intravital, two-photon imaging demonstrated that S/C administration of IC resulted in dermal DC mobilisation *in vivo*. S/C application of autoantibody-containing serum from mice (NZB/WF1) and humans with SLE increased dermal DC mobilisation *in vivo.*

Conclusions: Our study demonstrates a novel effect of IC in increasing DC migration to lymph nodes. Furthermore, we show that DC mobilisation *in vivo* is increased following S/C administration of IC or autoantibody-containing lupus serum. Together, these data suggest an additional mechanism by which ICs might drive autoimmunity in SLE via the inappropriate localisation of autoantigen-bearing DC.

SA-PO917

Expression of Toll-Like Receptors and Cathelicidin in Hemodialysis Patients with Vitamin D Deficiency Caren Cristina Grabulosa,[1] Edgar Ferreira Cruz,[1] Silvia Regina Manfredi,[1] Silvia Regina Moreira,[1] Lilian Cuppari,[1] Beata Marie Redublo Quinto,[1] Marcelo Costa Batista,[1,2,3] Miguel Cendoroglo-Neto,[1,2,3] Maria Dalboni.[1] *[1]Nephrology, Universidade Federal de São Paulo, Sao Paulo, Brazil; [2]Nephrology, Hospital Israelita Albert Einstein, Sao Paulo, Brazil; [3]Nephrology, Tufts-New England Medical Center, Boston, MA.*

Background: Patients in hemodialysis (HD) may have vitamin D (vit D) deficiency which is associated with inflammation, impaired immunity and increased susceptibility to infections. Besides, vit D regulates toll-like receptors (TLR) and antimicrobial peptides, such cathelicidin. However, data on expression of TLR and cathelicidin in HD patients with deficiency of vit D are limited.

Objective: To evaluate the expression of TLR-2 and TLR-4 on PMN and MN and serum levels of cathelicidin from HD patients with deficiency of vit D.

Methods: Blood samples from 38 HD patients and 31 age-and gender-matched controls were analyzed for TLR2 and TLR4 expression on PMN (CD66+) and MN (CD14+) by flow cytometry. We measured serum levels of cathelicidin, CRP and vit D.

Results: The HD patients had low vit D ($p = 0.008$), high CRP ($p = 0.04$), high cathelicidin ($p = 0.01$) and exhibited significant upregulation of CD66TLR2 (313±168 vs. 249±56; $p = 0.04$), CD66TLR4 (212±157 vs. 121±35; $p = 0.02$) and CD14TLR2 (369±210 vs. 269±144; $p = 0.03$) expression. Vit D correlated negatively with age ($r = - 0.31$; $p = 0.01$) and CRP correlated positively with cathelicidin ($r = 0.50$; $p < 0.0001$). We did no observe any correlations between vit D and TLR2, TLR4 and cathelicidin expressions.

Conclusions: CD66TLR2, TLR4 and CD14 TLR2 and cathelicidin expressions are increased in hemodialysis patients. This suggests that these results are associated with a priming inflammatory state in this population. Besides, it is possible that there are other molecules enrolled in vit D regulation of TLR and antimicrobial peptide in HD patients. Futures studies are necessary to investigate the mechanisms between vitamin D and impaired immunity associated with increased susceptibility to infections in hemodialysis patients.

Identification of Candidate Target Antigens for Membranous Lupus Nephritis Dawn J. Caster,[1] Erik Korte,[1] Michael Merchant,[1] Brad H. Rovin,[2] John Barker Harley,[3] Bahram Namjou,[3] Jon B. Klein,[1] Kenneth R. McLeish,[1] David W. Powell.[1] *[1]Medicine, University of Louisville School of Medicine, Louisville, KY; [2]Medicine, Ohio State University College of Medicine, Columbus, OH; [3]Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Membranous lupus nephritis (MLN) is described in 15%-40% of LN renal biopsies, but the mechanism of immune complex deposition is unknown. An autoantibody to the ~ 145kDa M-type phospholipase A2 receptor (PLA2R) on podocytes was shown to be present in 70%-80% of patients with idiopathic membranous nephropathy (iMN). However, this antibody is rarely present in patients with MLN. This study tested the hypothesis that patients with MLN develop unique autoantibodies against a protein expressed on podocyte plasma membranes.

Methods: Human podocyte membrane and cytosol proteins were separated by SDS-PAGE and immunoblotted with 1:200 dilution of pooled human sera from 5 patients with biopsy confirmed MLN, 10 patients with Class III/IV LN, 4 SLE patients with no kidney involvement, or 4 normal individuals. Proteins in the MW region corresponding to a band reactive only with MLN sera were characterized by LC-MS/MS.

Results: Sera from patients with SLE with or without class III/IV or class V LN had multiple reactive bands against cytosol proteins. MLN sera specifically reacted with one prominent ~ 50kDa band in membrane proteins that was not present in cytosol proteins. Several promising candidate proteins were identified in the ~ 50kDa region including a recognized lupus-associated auto-antigen (Sjögren Syndrome auto-antigen, lupus La protein), proteins implicated in LN (Annexin A2 and the PDGF receptor), antigens associated with other autoimmune diseases (SLC9A3R1, snRNP70, LEPREL4), and auto-immune signaling proteins (TRAF2, TRIP6).

Conclusions: Our findings support a hypothesis that MLN patients express unique auto-antibodies against a ~ 50kDa endogenous podocyte plasma membrane protein. These findings support the hypothesis that iMN and MLN have a similar pathophysiology, in that they result from auto-antibodies binding to podocyte membrane proteins.

SA-PO919

Regulation of Glomerular DAF by Heme: Role of HO-1 Maria Detsika,[1] Pu Duann,[2] Elias A. Lianos.[1] *[1]Medicine, University of Athens, Greece; [2]Nephrology, UMDNJ, NJ.*

Background: In systemic hemolysis and in hematuric forms of glomerulopathy, glomeruli are exposed to high heme concentrations. Although cytotoxic, heme can have cytoprotective effects by inducing heme oxygenase (HO). It also attenuates complement (C)-mediated cell injury by up regulating endothelial cell Decay-accelerating factor (DAF). Rat glomeruli express DAF exclusively in glomerular epithelial cells (GEC). The effect of heme on glomerular DAF expression is unknown and highly significant in C-mediated forms of injury.

Methods: Glomeruli were isolated from wild type (WT) and *hmox1*+/-, Sprague-Dawley rats. The latter were obtained by Zinc Finger Nuclease (ZFN) technology designed to target a specific exon 3 HO-1 sequence. Glomeruli were treated with Heme (Hemin) or

Cobalt Protoporphyrin (CoPP) (HO inducers) or Zinc (ZnPP) or Tin (SnPP) Protoporphyrins (HO enzyme activity inhibitors) for 18 h. HO-1 and DAF expression was assessed by real-time PCR and western blot analysis.

Results: Constitutive HO-1 and DAF expression was observed in WT and *hmox1*+/- glomeruli. In the latter, there was 60-70% HO-1 protein depletion while DAF protein decreased by 3-fold. Heme and CoPP increased both HO-1 and DAF expression. However, their effect on HO-1 synthesis was biphasic: a dose-dependent increase at low concentrations (6-200 μM) followed by reduction to constitutive or sub-constitutive HO-1 levels at high concentrations (400 and 800 μM, respectively). In contrast to HO-1, high heme or CoPP concentrations (≥400 μM) failed to reduce DAF expression; it further increased by 2-3 fold in both WT and *hmox1*+/- glomeruli. ZnPP and SnPP (12.5, 25, 50 and 100 μM) also increased DAF protein levels dose-dependently. This was independent of changes in HO-1 synthesis, which was increased by ZnPP but reduced by SnPP. In the presence of hemin (200 μM and 400 μM), ZnPP and SnPP (50 μM) had an additive effect on DAF induction.

Conclusions: HO-1 regulates glomerular DAF expression. Heme and non-Fe metalloporhyrins upregulate DAF independently of effects on HO-1 expression/activity and may thus have a dual protective effect on C-dependent glomerular injury.

SA-PO920

VEGF Splicing in the Normal Kidney and in Diabetic Nephropathy Rosanne Jane Turner, Jan A. Bruijn, Hans J. Baelde. *Pathology, Leiden University Medical Center, Leiden, Netherlands.*

Background: The cytokine vascular endothelial growth factor (VEGF) is a key regulator in the development and maintenance of the glomerular filtration barrier. VEGF plays an important role in the development of diabetic nephropathy. There are seven proangiogenic VEGF splicing variants. Important differences between these isoforms are the in- or exclusion of exon 6 and 7 of the VEGF gene, on which the neurophilin- and heparin binding sites are encoded. Longer isoforms containing these binding sites, such as the common variants VEGF 165 and 189, have a prolonged and more effective mode of action in comparison to shorter isoforms, such as the common variant VEGF 121. In rodents the dominant isoform in the kidney and glomeruli is the 165 variant. In this study, we set out to investigate the splicing pattern of VEGF in isolated glomeruli and whole tissue in the normal kidney and in the kidneys of patients with diabetic nephropathy.

Methods: The relative expression of each individual splice variant was measured in samples of glomeruli isolated by laser captured microdissection and whole kidneys from 23 controls and 28 patients with diabetic nephropathy with the use of RT-PCR followed by quantitative fragment analysis with capillary electrophoresis.

Results: VEGF 121 was the dominant isoform with a relative expression of 69% and 74% in the glomeruli and kidneys respectively. The expression of VEGF 165 was 23% and 24% and the expression of VEGF 189 was 2.6% and 5.6% in the glomeruli and kidneys. In a few samples the VEGF 181 isoform was detected with a relative expression of less than 1%. Overall, splicing patterns in diabetic patients were similar to those in controls.

Conclusions: In conclusion, this is the first report to show VEGF 121 to be the dominant isoform in both the human kidney and the glomerulus. This is in contrast with findings in rodents, in which the 165 variant is the most common. VEGF splicing patterns were the same in patients with diabetic nephropathy and controls.

SA-PO921

VEGF-A Regulates Glomerular Endothelial Cell Expression of Protective Complement Regulators Lindsay S. Keir,[1] Gavin Iain Welsh,[1] Richard Coward,[1] Simon C. Satchell,[1] Anna Richards,[2] Moin Saleem.[1] *[1]Academic Renal Unit, University of Bristol, Bristol, United Kingdom; [2]Queens Medical Research Institute, University of Edinburgh, Edinburgh, United Kingdom.*

Background: Glomerular thrombotic microangiopathy (TMA) is the pathological feature of hemolytic uremic syndrome (HUS). The rare atypical HUS is predominantly caused by mutations in regulatory proteins of the alternative complement pathway. While Shiga toxin (Stx)-HUS is more common, it has a poorly defined pathogenesis. Recently, Stx-treated human podocytes were found to secrete less VEGF-A. A proportion of patients treated with VEGF-inhibitor drugs and adult mice with a specific podocyte VEGF-A knock down also develop TMA. We hypothesised that reduced podocyte VEGF-A decreases glomerular endothelial cell (GEnC) expression of complement regulators making them vulnerable to complement injury and development of TMA.

Methods: VEGF-A treated conditionally immortalised human GEnC were analysed for expression of complement regulators using immunofluorescence, western blot and qPCR. GEnC viability, C3d and C4d deposition was assessed using a complement-mediated cytotoxicity assay with or without preceding VEGF-A treatment.

Results: VEGF-A increased GEnC surface expression of CD46, CD59 and factor H. CD55 expression was not altered by VEGF-A. Factor H was also secreted by GEnC but complement factor H related protein 5 (CFHR5) and factor I were not. Functionally, VEGF-A treated GEnC had significantly improved viability and showed 30% less C3d and C4d compared to untreated cells. Kidneys from adult mice with a podocyte specific VEGF-A knock down and TMA are now being examined to explore this in vivo.

Conclusions: This work identifies a link between podocyte VEGF-A and the up-regulation of protective complement regulator expression on glomerular endothelium which in vitro, protects GEnC from complement activation. Preliminary in vivo work supports this but further analysis is required.

SA-PO922

Analysis of Germline VH Sequences of IgG Autoantibodies Specific for Galactose-Deficient IgA1 in Patient with IgA Nephropathy Zhi Qiang Huang,[1] Milan Raska,[1] Zhixin (Jason) Zhang,[2] Hitoshi Suzuki,[3] Stacy D. Hall,[1] Robert J. Wyatt,[4] Bruce A. Julian,[1] Ali G. Gharavi,[5] Jan Novak.[1] *[1]University of Alabama at Birmingham, Birmingham, AL; [2]University of Nebraska Medical Center, Omaha, NE; [3]Juntendo University, Tokyo, Japan; [4]University of Tennessee, Memphis, TN; [5]Columbia University, New York, NY.*

Background: In IgA nephropathy (IgAN), glomerular deposits of immune complexes (IC) with galactose-deficient IgA1 (Gd-IgA1) likely originate from circulating IC wherein Gd-IgA1 (autoantigen) is bound by anti-glycan autoantibodies of IgG or IgA1 isotype. Variable region of the heavy chains (VH) of IgG autoantibodies from IgAN patients have a unique sequence at the N-terminal part of CDR3, YCSR/K, whereas antibodies from healthy controls have a YCAR/K sequence. However, it is unknown whether the unique VH sequences are of germline origin, *i.e.*, rare VH alleles, or from somatic mutations or other processes.

Methods: Using genomic DNA of three IgAN patients and two healthy controls, we PCR-amplified, cloned, and sequenced VH CDR3 coding regions with primers designed according to the corresponding VH gene of each IgG specific for Gd-IgA1 (J. Clin. Invest. 119, 1668-1677, 2009).

Results: Analyses of VH genomic DNA revealed that the unique CDR3 of IgG anti-Gd-IgA1 antibodies in IgAN patients did not originate from rare alleles of germline VH sequences. Using recombinant IgG antibodies and site-directed mutagenesis, we showed that the S residue in CDR3 is required for binding to Gd-IgA1. These data indicate that a complex process of abnormal immune responses is involved in production of pathogenic antibodies specific for Gd-IgA1. Our recent GWAS data associated three loci on chromosome 6 in the HLA region with IgAN, whichis consistent with this hypothesis.

Conclusions: Unique VH CDR3 regions of Gd-IgA1-specific antibodies in IgAN patients are not encoded by rare alleles of germline VH sequences but may be generated through somatic mutation upon antigenic stimulation. Removal or blockade of Gd-IgA1 antigen or anti-Gd-IgA1 antibodies would prevent IC formation and such strategies may lead to future disease-specific treatment of IgAN.

SA-PO923

Aberrant *O*-Glycosylation of IgA1 in IgA Nephropathy (IgAN) and the Role of Initiating Enzymes Tyler J. Stewart, Kazuo Takahashi, Koshi Yamada, Milan Raska, Milada Stuchlova-Horynova, Matthew B. Renfrow, Jan Novak. *University of Alabama Birmingham, Birmingham, AL.*

Background: IgAN is associated with aberrant glycosylation of IgA1 hinge-region (HR). Circulatory IgA1 has 3 to 6 of the 9 potential HR sites *O*-glycosylated and in patients with IgAN some of these sites are galactose deficient, *i.e.,* contain terminal or sialylated *N*-acetylgalactosamine (GalNAc). HR glycopeptides with 5 or 6 *O*-glycansare more abundant on IgA1 from IgAN patients, whereas those with 3 or 4 *O*-glycans predominate on IgA1 from healthy controls. These data suggest that the postulated primary initiating enzyme, GalNAc-transferase 2 (GalNAc-T2), or other GalNAc-Ts contribute to the glycosylation abnormality in IgAN.

Methods: *In vitro* time-course reactions of purified recombinant GalNAc-T2 and -T14 with IgA1 HR synthetic peptides were characterized using high-resolution mass spectrometry. Homology models of GalNAc-T14 to crystal structure of GalNAc-T2 were created and aligned with HR peptides. GalNAc-T2 co-crystalized with a mucin peptide was compared to IgA1 HR peptide models.

Results: We showed that GalNAc-T2 is expressed in IgA1-secreting cells from IgAN patients and controls, but GalNAc-T14 was the only initiating enzyme that was overexpressed in the cells from IgAN patients. To understand better the biochemical mechanisms of IgA1 *O*-glycosylation, we performed comparative structural analysis and modeling of GalNAc-T2 and -T14. The first and second preferred glycosylation site of IgA1 HR, as observed in *in vitro* reactions, contained the amino-acid motif TPSP where the first threonine is glycosylated. The first glycosylated site of IgA1 HR localized to the GalNAc-T2 catalytic site. Modeled GalNAc-T14 varied from GalNAc-T2 crystal structure in the lectin domain and a variable loop involved in the catalytic site of GalNAc-Ts, thus underscoring differences between the two enzymes.

Conclusions: These results suggest a structure function relationship between GalNAc-Ts that could help to explain how upregulation of GalNAc-T14 in IgAN patients could lead to aberrant *O*-glycosylation of IgA1 HR. We postulate that the lectin domain and the variable loop in GalNAc-Ts affect *O*-glycosylation.

SA-PO924

Molecular Characterization of IgA1 Secreted by IgA1-Producing Cell Lines from Patients with IgA Nephropathy Kazuo Takahashi,[2,1] Hitoshi Suzuki,[3,1] Koshi Yamada,[1] Stacy D. Hall,[1] Zina Moldoveanu,[1] Knud Poulsen,[4] Jiri F. Mestecky,[1] Bruce A. Julian,[1] Matthew B. Renfrow,[1] Jan Novak.[1] *[1]University of Alabama at Birmingham, Birmingham, AL; [2]Fujita Health University School of Medicine, Toyoake, Japan; [3]Juntendo University Faculty of Medicine, Tokyo, Japan; [4]Aarhus University, Aarhus, Denmark.*

Background: IgA1 with galactose (Gal)-deficient hinge-region (HR) *O*-glycans plays a key role in the pathogenesis of IgA nephropathy (IgAN). We established IgA1-producing cells derived from the circulation of IgAN patients and healthy controls (HC). IgA1 secreted by cells from IgAN patients has more Gal-deficient *O*-glycans compared to IgA1 from HC cells. To characterize IgA1 involved with IgAN, *O*-glycan microheterogeneity and attachment sites should be analyzed, as each HR has nine potential sites for *O*-glycosylation.

Methods: In this study, IgA1 secreted by cells from IgAN patients (IgAN-IgA1; n=6) and HC (HC-IgA1; n=7) was individually analyzed to define the HR glycosylation patterns and glycosylation sites using high-resolution mass spectrometry (MS).

Results: High-resolution MS analyses revealed that the total content of *N*-acetylgalactosamine (GalNAc) in IgA1 from IgAN-IgA1 was higher that in HC-IgA1 (4.73 *vs*. 4.37 mol/HR peptide, *P*=0.003). Moreover, the amount of Gal-deficient *O*-glycans in IgAN-IgA1 was greater than that in IgA1 from HC-IgA1 (0.28 *vs*. 0.21 mol GalNAc/ HR peptide, *P*=0.004). HR glycopeptides with 5 or 6 *O*-glycan chains were more abundant in IgAN-IgA1, whereas those with 3 or 4 *O*-glycan chains predominated on HC-IgA1. Four HR glycoforms, including three glycoforms with Gal-deficient *O*-glycans, predominated in IgAN-IgA1. Tandem MS revealed that the sites with Gal-deficient *O*-glycans or nonglycosylated sites included mainly S230, T233 and T236, whereas T225, T228 and S232 were glycosylated predominantly by GalNAc-Gal disaccharide.

Conclusions: This study shows first definitive identification of HR *O*-glycosylation microheterogeneity on IgA1 from IgAN-IgA1 and HC-IgA1. The glycoforms predominating in IgAN-IgA1 may be candidates for biomarkers specific for IgAN.

SA-PO925

Synthesis of Galactose-Deficient IgA1 *O*-Glycans by GalNAc-Transferases Expressed in IgA1-Producing Cells: Implications for the Pathogenesis of IgA Nephropathy Kazuo Takahashi,[2,1] Milan Raska,[3,1] Milada Stuchlova-Horynova,[3,1] Alena Kasperova,[3,1] Stacy D. Hall,[1] Yoshiyuki Hiki,[2] Yukio Yuzawa,[2] Bruce A. Julian,[1] Zina Moldoveanu,[1] Matthew B. Renfrow,[1] Jan Novak.[1] *[1]University of Alabama at Birmingham, Birmingham, AL; [2]Fujita Health University, Toyoake, Japan; [3]Palacky University in Olomouc, Olomouc, Czech Republic.*

Background: IgA1 with galactose (Gal)-deficient hinge-region (HR) *O*-glycans (Gd-IgA1) plays a pivotal role in IgA nephropathy (IgAN). IgA1 HR has up to 6 of the 9 potential *O*-glycosylation sites occupied; some Gal-deficient glycans consist of terminal *N*-acetylgalactosamine (GalNAc). IgA1 HR *O*-glycosylation was reported to be initiated by GalNAc-T2. However, the expression of GalNAc-T2 did not differ between cells from patients and those from healthy controls (HC). In contrast, expression of GalNAc-T14, the enzyme with highest similarity to GalNAc-T2, was 5-fold greater in IgA1-producing cells derived from IgAN patients than in those from HC. Here, we analyzed kinetics and site-specificities of GalNAc-T2 and -T14 on HR using high-resolution mass spectrometry (MS).

Methods: We produced recombinant soluble GalNAc-T2 and -T14 enzymes. A synthetic HR (sHR) and a panel of synthetic HR glycopeptides (sGP) with a single GalNAc residue at different sites were used as enzyme acceptors.

Results: GalNAc-T2 showed higher activity *i.e.*, faster rate of glycosylation of sHR, than GalNAc-T14. GalNAc-T14 can add GalNAc to up to 5 sites in HR of IgA1. Distinct sHR *O*-glycoforms generated by GalNAc-T2 and -T14 were subjected to tandem MS to localize glycosylated sites. The sites of glycosylation on sHR catalyzed by GalNAc-T2 and -T14 were the same and appeared in an ordered fashion: GalNAc was attached to T7 first and then to T15, followed by S11 and T4. GalNAc-T14 ineffectively glycosylated the sGP with a GalNAc at S9, the site that corresponds to S230 on IgA1 HR, which is the dominant site with terminal GalNAc in Gd-IgA1 proteins.

Conclusions: GalNAc-T2 and -T14 have similar site-specificity on IgA1 HR, but differ in kinetics and how they are affected by preexisting glycosylation. Elevated expression of a specific GalNAc-T is a possible mechanism for production of Gd-IgA1 in IgAN.

MAPK/ERK Signaling Pathway Activation in Mesangial Cells Is Predictive of Renin Angiotensin System Blockers Efficiency in IgA Nephropathy Jonathan M. Chemouny,[1,2,3] Houda Tamouza,[1,2] Leona Raskova-Kafkova,[4] Laureline Berthelot,[1,2] Martin Flamant,[1,2,5] Meetu Kaushik Tiwari,[1,2] Marie Demion,[1,2] Laurent Mesnard,[6,7,8] Bruce A. Julian,[4,9] Emilie Tissandie,[1,2] Marc Benhamou,[1,2] Niels O.S. Camara,[10] Jan Novak,[4] Francois Vrtovsnik,[1,2,3] Renato C. Monteiro,[1,2] Ivan Cruz Moura.[1,2] *[1]INSERM U699, Paris, France; [2]UPDiderot, Paris, France; [3]Néphrologie, Bichat, Paris, France; [4]Microbiology, UAB, Birmingham, AL; [5]Physiologie–Explorations Fonctionnelles, Bichat, Paris, France; [6]Urgences Néphrologiques et Transplantation Rénale, Tenon, Paris, France; [7]INSERM U702, Paris, France; [8]UPMC, Paris, France; [9]Medicine, UAB, Birmingham, AL; [10]Laboratory of Transplantation Immunobiology, Department of Immunology, IBS IV, USP, São Paulo, Brazil.*

Background: IgA nephropathy (IgAN) has a significant morbidity as 20-40% of patients progress to ESRD within 20 years after disease onset. We aimed to gain insight into the molecular mechanisms involved in IgAN progression.

Methods: We evaluated renal biopsy specimens from IgAN patients (n=31) for the activation of MAPK/ERK signaling pathway. We tested the association between p-ERK1/2 staining and clinical and histological data.

Results: MAPK/ERK signaling pathway was activated in the mesangium of patients presenting with over 1 g/day proteinuria and elevated blood pressure, but absent in biopsy specimens of patients with IgAN and modest proteinuria (1 g/day). In human mesangial cells in vitro, MAPK/ERK activation through mesangial IgA1 receptor (CD71) controlled cytokines secretion and was induced by large-molecular-mass IgA1-containing circulating immune complexes purified from patient sera. Moreover, IgA1-dependent ERK activation required renin–angiotensin system (RAS) as its blockade was efficient in reducing proteinuria in those patients exhibiting substantial mesangial activation of ERK.

Conclusions: These results suggest a major role of MAPK/ERK activation in mesangial cells in glomerular injury in IgAN. We hypothesize a new mechanism sustaining anti-proteinuric properties of RAS blockers. ERK1/2 phosphorylation in mesangial cells on diagnostic biopsy may have a pronostic value concerning RAS blockers efficiency in decreasing proteinuria.

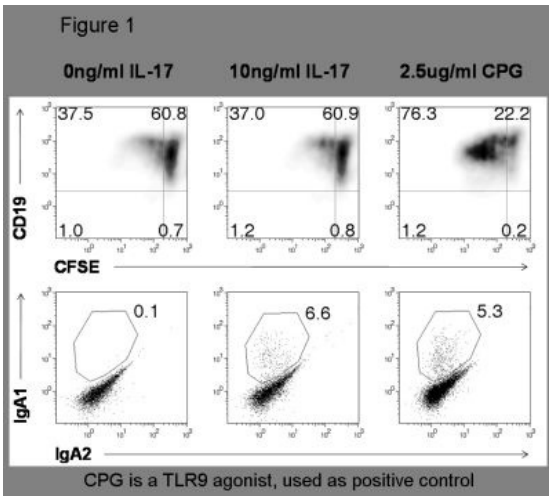
IL-17-Producing CD4 T-Cells Induce B Cells Secreting IgA1 in IgA Nephropathy Patients Wei Chen, Xumin Chen, Mengjun Liang, Wang Zhang, Xueqing Tang, Xueqing Yu. *Department of Nephrology, The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China.*

Background: Immune complexes containing aberrantly glycosylated IgA1 are the features of IgA Nephropathy (IgAN). IL-17-Producing CD4 T-Cell cells can induce B cells proliferation, and trigger antibody production. We aimed to elucidate the role of Th17 in the pathogenesis of IgAN through promoting B cell response.

Methods: Expression of cell surface markers and intracellular cytokines was assessed by flow-cytometer, data were analyzed using FlowJo software. In vitro study, circulating B cells were enriched from healthy donors and cultured with 10ug/ml anti-IgM and 100ng/ml sCD40L, with or without 10ng/ml IL-17. B cell proliferation was monitored by measuring CFSE dilution by FACS.

Results: $IgA1^+$ B cell was found to be increased in IgAN patients as compared with healthy controls (4.97%±2.58% vs. 2.76%±1.96%, P =0.009). No significant difference in the total B cells between two groups (P =0.98). IgAN patients had more Th17 (1.88%±0.95% vs. 1.08%±0.46%, P =0.003) and Th2 cells (2.67%±1.12% vs. 1.59%±0.84%, P =0.005) compared with controls. Th17 was found to be significantly positive correlation with Th2 cells (r=0.555, P<0.001),and no significant association was observed between the frequency of Th2 cells and B cells in IgAN patients (r=0.049, P =0.760). Moreover, in vitro, induced $IgA1^+$B cells were significantly increased with IL-17 (6.6% vs. 0.1%, P =0.025), there was no change of proliferation rate of total B cells (37.5% vs. 37.0%, P=0.513).



Conclusions: Our data support the hypothesis that Th17 and Th2 participate in inducing IgA1 secreting B cells in IgAN, and IL-17 may contribute to the pathogenesis of IgAN by promoting IgA1 production.

DNA Vaccination with Plasmids Encoding Different Human Glycosyltransferases Induces High Titers of Specific Serum Antibodies in Mice Milada Stuchlova-Horynova,[1,2] Kazuo Takahashi,[2,3] Katerina Zachova,[1] Alena Kasperova,[1,2] Jiri F. Mestecky,[2] Jan Novak,[2] Milan Raska.[1,2] *[1]Palacky University, Olomouc, Czech Republic; [2]University of Alabama at Birmingham, Birmingham, AL; [3]Fujita Health University School of Medicine, Toyoake, Japan.*

Background: Galactose (Gal)-deficient *O*-glycans on IgA1 molecules play a key role in pathogenesis of IgA nephropathy (IgAN). *O*-glycosylation is initiated by attachment of *N*-acetylgalactosamine (GalNAc) to Ser/Thr residues of the hinge region by *N*-acetylgalactosaminyltransferases (GalNAc-T2 and GalNAc-T14) followed by addition of Gal to the GalNAc catalyzed by β1,3-galactosyltransferase 1 (C1GalT1). This structure can be modified by attachment of sialic acid to the Gal residues in a reaction catalyzed by a α2,3-sialyltransferase (ST3Gal) and/or to the GalNAc residues catalyzed by α2,6-sialyltransferase II (ST6GalNAcII). We explored DNA vaccination approach for the generation of hyperimmune sera for detection of individual glycosyltransferases.

Methods: The cDNAs coding for human GalNAc-T2, -T14, C1GalT1, ST6GalNAc II, and ST6GalNAcI were cloned into mammalian expression plasmids hydrodynamically administered to BALB/c mice. In parallel, the secretory versions of above glycosyltransferases were expressed in HEK 293T cells for Western blotting. Hyperimmune sera as well as commercially available monoclonal antibodies specific to cis- and trans-Golgi markers were used for colocalization of target glycosyltransferases by fluorescence microscopy.

Results: Purified recombinant glycosyltransferases were identified by MALDI-TOF mass spectrometry and used for Western blot evaluation of specific serum antibodies elicited in mice by DNA immunization. Hyperimmune sera allowed localization of respective glycosyltransferases into cis- or trans-Golgi subcompartments of tested B cell lines.

Conclusions: We used hydrodynamic DNA vaccination for successful preparation of hyperimmune mouse sera specific for glycosyltransferases involved in generation of *O*-glycans on IgA1 molecules as a tool for detection of potential abnormalities in glycosyltransferases localization, a mechanism potentially contributing to IgA pathogenesis.

SA-PO929

Increased Levels of Indoleamine 2,3-Dioxygenase (IDO) Activity and Regulatory T-Cells in Henoch Schoenlein Purpura Roberta Camilla,[1] Elisa Loiacono,[1] Maria Elena Donadio,[1] Margherita Conrieri,[2] Manuela Bianciotto,[2] Francesca Maria Bosetti,[2] Licia Peruzzi,[1] Davide Defedele,[3] Maria Paola Puccinelli,[3] Giovanni Conti,[4] Laura Morando,[1] Alessandro Amore,[1] Rosanna Coppo.[1] *[1]Nephrology, Dialysis, Transplantation, R. Margherita Hospital, Turin, Italy; [2]Pediatric Emergency, R. Margherita Hospital, Turin, Italy; [3]Diagnostic Department, R. Margherita Hospital, Turin, Italy; [4]Pediatric Nephrology, G. Martino Hospital, Messina, Italy.*

Background: Indoleamine 2,3-dioxygenase (IDO) catabolizes tryptophan (Trp) producing kynurenine (Kyn). IDO-expressing dendritic cells possess T cell regulatory properties that block T responses to antigenic stimulation leaded by interleukin 17 producing T cells (Th17). We aimed at investigating IDO metabolites and Th-17 cells activity in children with Henoch-Schoenlein purpura (HSP) presenting with acute onset followed by complete resolution.

Methods: 23 children (3-14 y.o) with HSP - with or without renal involvement - were studied in different phases of systemic vasculitic activity with multiple sampling. IDO activity was assessed in sera as change in Trp and Kyn determined using isocratic RP HPLC with UV detection. The Kyn/Trp ratio was also calculated. In mononuclear cells real time PRC (Taqman) detected mRNA levels of TFG-β1, which modulates the differentiation of Th17.

Results: Children with HSP had increased Kyn levels (2.31±0.54 vs 2.02±0.32 μmol/l; P= 0.048), while Trp levels were similar to controls. TGFβ1mRNA transcriptional levels were significantly depressed (0.89±0.57 vs 1.43±0.51; P<0.0001). There was a significant inverse correlation between Kyn levels and TGFβ1mRNA values (P= 0.023). In phases of clinically active purpuric rash with or without renal involvement, children presented with a Kyn/Trp ratio - indicating IDO activity - similar to controls, while it increased during healing phase and inactive disease (3.82±0.76 vs 4.58±0.77, P<0.05).

Conclusions: We report for the first time a modulation of IDO in children with HSP: the activation of this pathway, known to regulate tolerogenic immune mechanisms, is associated with remission of signs of systemic vasculitis. IDO may play a role in regression/progression of disease activity in HSP.

SA-PO930

Chemokines Usage by Tubular Epithelial Cells in IgA Nephropathy: Role of TNF-α and Angiotensin II Ai Ing Lim, Sydney C.W. Tang, Loretta Y.Y. Chan, Kar Neng Lai, Joseph C.K. Leung. *Department of Medicine, University of Hong Kong, Hong Kong.*

Background: Tubulointerstitial infiltration of immunocompetent cells is associated with a rapid progression in IgA nephropathy (IgAN). We examined the role of tumor necrosis factor-α (TNF-α) and angiotensin II (AngII) in tubular chemokines usage in IgAN.

Methods: Using a transwell co-culture system, we studied the chemokines usage and chemotactic responses of peripheral blood mononuclear cells (PBMC) towards proximal tubular epithelial cells (PTEC) following activation by conditioned medium prepared from mesangial cells cultured with IgA from IgAN patients (IgA-medium; n=45) and healthy subjects (n=30).

Results: Increased expression of chemokines, including CXCL1, CXCL2, CXCL8, CCL2, CCL5 and CCL11, was observed in PTEC cultured with IgA-medium. In response to IgA-medium, chemotaxis of CD45+ PBMC, and in particular, the activated GMP-17+, CD3+ lymphocytes and CD14+ monocytes towards PTEC were increased. The transmigrated subsets exhibited differential up-regulated expression of CXCR2, CCR2 and CCR5. Chemotactic response of activated CD3+ cells was attenuated by anti-CCL5, followed by anti-CCL2 but not by anti-CXCL1 or anti-CXCL2. Transmigrated activated CD14+ cells was reduced by anti-CCL2, anti-CCL5 and anti-CXCL2. Transmigrated activated GMP-17+ was inhibited by anti-CCL5. Under all circumstances, anti-CCL11 have no effect on the cellular transmigration. PTEC activated by IgA-medium had elevated expression of AngII, transforming growth factor-β (TGF-β) and TNF-α. The release of CXCL1, CXCL2, CXCL8, CCL2, CCL5 and CCL11, was increased by TNF-α, but not by TGF-β. AngII priming further increase all chemokines examined. Synthesis of chemokines and transmigration after activation of PTEC with IgA-medium was blocked by anti-TNF-α or losartan, but not by anti-TGF-β or PD123319 (AT2R blocker). Interestingly, TGF-β blockage enhanced the apoptosis of transmigrated GMP17+ subset.

Conclusions: Our data show the differential chemotactic responses of PBMC subsets towards PTEC in IgAN. These events utilize different chemokine-chemokine receptor axes and are tightly regulated through the interaction of IgA-medium induced TNF-α and AngII.

Cytokine-Mediated Dysregulation of Specific Glycosyltransferases Contributes to Aberrant Glycosylation of IgA1 in Patients with IgA Nephropathy Hitoshi Suzuki,[1,2] Milan Raska,[3] Koshi Yamada,[1] Zina Moldoveanu,[1] Bruce A. Julian,[1] Robert J. Wyatt,[4] Yasuhiko Tomino,[2] Ali G. Gharavi,[5] Jan Novak.[1] *[1]University of Alabama at Birmingham, Birmingham, AL; [2]Juntendo University Faculty of Medicine, Tokyo, Japan; [3]Palacky University in Olomouc, Olomouc, Czech Republic; [4]University of Tennessee Health Science Center, Memphis, TN; [5]Columbia University, New York, NY.*

Background: IgA1-producing cell lines from patients with IgAN (IgAN cells), but not those from healthy controls (HC cells), secrete galactose (Gal)-deficient IgA1 (Gd-IgA1), with *O*-glycans with terminal or sialylated N-acetylgalactosamine (GalNAc). The aberrant glycans constitute the neoantigen that leads to formation of nephritogenic immune complexes. This aberrancy has been associated with decreased activity of β1,3-galactosyltransferase (C1GalT1) and elevated activity of α2,6-GalNAc-sialyltransferase II (ST6GalNAcII) in IgAN cells, but the regulation of these enzymes is not well understood.

Methods: To confirm the roles of these glycosyltransferases in the production of Gd-IgA1, we used knocked-down of *C1GalT1* and *ST6GalNAcII* genes by siRNA using Amaxa electroporation.

Results: Expression of *C1GalT1* decreased by 70% after siRNA knock-down in all cells,resulting in the increase of Gd-IgA1 by 50% in HC cells ($P<0.01$) and 20% in IgAN cells ($P<0.05$). Conversely, galactosylation of IgA1 *O*-glycans in IgAN cells increased after knock-down of *ST6GalNAcII*($P<0.01$). Expression of these glycosyltransferases was regulated by several cytokines, including IL-6 that decreased enzyme activity of C1GalT1

and elevated activity of ST6GalNAcII in IgAN cells. Moreover, serum levels of IL-6 were elevated in patients with IgAN compared to those in healthy control ($P<0.05$).

Conclusions: Our results confirmed the roles of C1GalT1and ST6GalNAcII in the synthesis of Gd-IgA1. Furthermore, increased levels of IL-6 contributed to the dysregulation of these enzymes. These cell lines are a valuable tool for studies of pathways leading to production of Gd-IgA1 and development of new therapeutic strategies for IgAN.

Dietary Zn Condition May Determine the Susceptibility of IgA Nephropathy

Masayuki Maiguma, Yusuke Suzuki, Hitoshi Suzuki, Keiko Okazaki, Yasuhiko Tomino. *Division of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan.*

Background: Many etiologic factors including mucosal infections, genetic predisposition, diet and environmental agents are associated with the onset of IgA nephropathy (IgAN). Some experimental data have shown the relationship between IgAN and innate-immunity particularly via toll-like receptors (TLR). It has recently been revealed that Zn may play an important role in various immune-related diseases. Zn homeostasis is thus critically involved in dendritic cell (DC) maturation and affects the magnitude of immune-responses via TLR, such as TLR4. It is recently discussed that chronic Zn insufficiency by excess intake of instant food may influence the susceptibility of atopic or autoimmune diseases.

Methods: IgAN-prone mice which we recently established (Okazaki K, JASN 2012) were divided into three groups given with low, normal and high Zn diets. To assess exogenous pathogen-mediated immune responses, lipopolysaccharide (LPS) was nasally administered to each group. The activity of IgAN was biochemically and pathologically evaluated during the disease course. To approach detailed mechanisms, we cultured whole spleen cells or B cells with T cells or DCs under various Zn conditions with/without LPS, and then measured IgA production.

Results: Levels of urinary albumin and serum IgA-IgG immune-complex were increased in low Zn group. In high Zn group, serum IgA concentration and mesangial IgA depositions were significantly lower than those in other groups. IgA production by spleen cells was increased in low Zn condition and decreased in high Zn condition. In normal and low Zn condition, IgA production tended to be higher in presence of LPS. However, only in high Zn condition, IgA concentration remained at a low level despite of LPS stimulation. Furthermore, these influences of Zn concentration on IgA production by B cells were enhanced in the presence of DCs.

Conclusions: Dietary Zn may affect the amplitude of immune-responses to exogenous antigens including nephritogenic IgA production and thus play important roles in the susceptibility of IgAN.

SA-PO933

Effects of Long-Acting Erythropoiesis Stimulating Agents on Glomerulosclerosis in Acute or Chronic Model with Mesangial Proliferative Nephritis

Michinori Hirata, Ken Aizawa, Yoshihito Tashiro, Satoshi Takeda, Koichi Endo. *Product Research Department, Chugai Pharmaceutical Co., Ltd., Gotemba, Shizuoka, Japan.*

Background: It has been reported that darbepoetin-α (DA) prevents proteinuria in a reversible model, anti-Thy1 antibody-induced glomerulonephritis (Thy-1-GN) rats. However, it has not been elucidated whether long-acting erythropoiesis stimulating agents (ESAs) can also protect against glomerulosclerosis in chronic state. This study aimed to assess whether continuous erythropoietin receptor activator (C.E.R.A.), a newly developed long-acting ESA, could exert renoprotective effects 1) in Thy-1-GN rats (acute model) and 2) in chronic Thy-1-GN (an irreversible chronic model) rats.

Methods: Thy-1-GN rats (F344, male, 6 weeks old) were produced by the injection of anti-Thy1.1 monoclonal antibody (OX-7). At the induction of nephritis (day 0) C.E.R.A. or DA (25 mcg/kg, n=10, respectively) was intravenously injected. Chronic Thy-1-GN rats (F344, male, 7 weeks old) were produced by the injection of OX-7 and uninephrectomy. C.E.R.A. was intravenously injected 4 hour before or 24 hour after of the injection of OX-7.

Results: Both of them significantly inhibited proteinuria and cystatin C at day 6 and day 8 but not at day 4 compared to vehicle-treated Thy-1-GN rats (n=10). In addition, C.E.R.A. significantly suppressed glomerulosclerosis as well as DA at day 8. Simultaneously, the significant inhibition of C.E.R.A. on α-SMA and type I collagen expressions were observed by immunostaining method. In separated glomeruli, C.E.R.A. significantly prevented mRNA levels of fibronectin and type I collagen at day 6 and day 8 but not at day 4. In irreversible chronic model rats, both pre- and post-treatment of C.E.R.A. (25 mcg/kg, n=12) significantly inhibited proteinuria at day14. Furthermore, the effect was maintained until day 28 ($p<0.01$).

Conclusions: C.E.R.A. significantly inhibited mesangial proliferative glomerulonephritis partly due to preventing the production of matrix proteins in glomeruli. This beneficial effect of C.E.R.A. was exerted both in acute and chronic state. The renoprotective effect of post-treatment of C.E.R.A. could be of advantage in clinical conditions.

SA-PO934

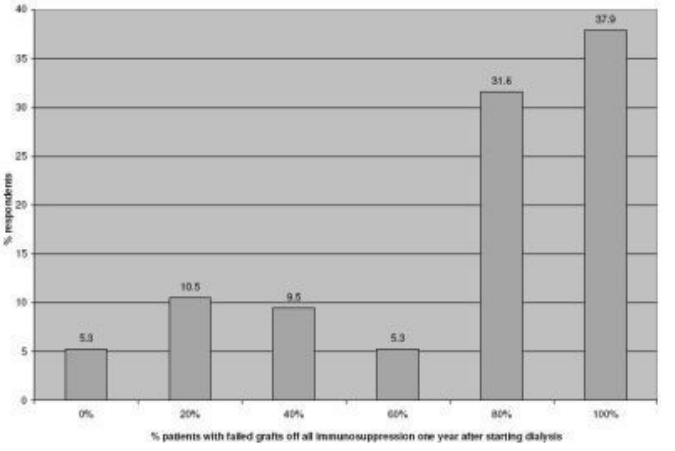
A Survey of US Transplant Center Practices on Immunosuppression after an Allograft Fails

George P. Bayliss,[1] Reginald Y. Gohh,[1] Didier A. Mandelbrot.[2] *[1]Medicine, Rhode Island Hospital, Providence, RI; [2]Medicine, Beth Israel Deaconess Medical Center, Boston, MA.*

Background: The decision to continue or stop immunosuppression medication in the patient who has returned to dialysis after failure of a transplanted kidney is complex. Continuing immunosuppression increases infection risk. Stopping immunosuppression may increase risk of sensitization, reducing the chance of retransplant, or of rejection of a subsequent renal transplant. Drug cessation also increases risk of acute rejection from a failed transplant, possibly necessitating allograft nephrectomy. There is no clear standard of care. We surveyed US transplant centers to define current practices.

Methods: Using the REDCap survey program, we emailed a 19-question survey to medical and surgical transplant directors as identified by the United Network for Organ Sharing.

Results: Emails were sent to 231 programs; 97 (42%) responded. 25% of respondents reported adjusting immunosuppression according to a standard protocol; 73% said practices are physician-dependent. The majority said that 80% or 100% of patients are off all immunosuppression 1 year after returning to dialysis.



Only 5% of respondents have no patients off immunosuppression at 1 year, and 1% continued full immunosuppression without a taper. The most important factors cited in deciding whether to stop immunosuppression were plans to retransplant (38%) and signs and symptoms of rejection (36%). Respondents most commonly said they performed graft nephrectomy only if there are signs and symptoms of rejection (45%) or if signs and symptoms of rejection fail to respond to steroids (33%).

Conclusions: We lack good data to guide decisions on immunosuppression in patients with failed allografts. More study is needed to determine which policies lead to the best outcomes in terms of infection rates, success of retransplantation and overall survival.

Immunosuppression and Outcomes in African-American (AA) Kidney Transplant Recipients: A 4-Year Analysis from the Mycophenolic Acid Observational Renal Transplant (MORE) Registry

Mohanram Narayanan,[1] Oleh Pankewycz,[2] Fuad S. Shihab,[3] A. Wiland,[4] Kevin M. Mccague,[4] L. Chan.[5] *[1]Scott and White Healthcare, Temple, TX; [2]Buffalo General Hospital, Buffalo, NY; [3]University of Utah School of Medicine, Salt Lake City, UT; [4]Novartis, East Hanover, NJ; [5]University of Colorado Medical Center, Denver, CO.*

Background: AA kidney transplant patients are at increased immunological risk. Tacrolimus absorption is reduced in AAs, and they may have a higher risk of rejection following mycophenolic acid (MPA) dose reductions vs non-AAs. Data on outcomes using modern immunosuppressive regimens in AAs, or comparing enteric-coated mycophenolate sodium (EC-MPS) vs mycophenolate mofetil (MMF), are lacking.

Methods: The MORE registry is a prospective, observational study of *de novo* adult kidney transplant patients receiving MPA at 40 US centers. 4-year data from tacrolimus-treated patients were analyzed.

Results: 218 AA (149 EC-MPS, 69 MMF) and 686 non-AA (467 EC-MPS, 219 MMF) patients were analyzed. The groups were similar other than living donors (24% AAs, 48% non-AAs; $p<0.01$). Mean tacrolimus trough level was similar in AAs and non-AAs at all time points. More AA vs non-AA patients received steroids, but mean steroid dose was similar in steroid-treated AA and non-AA patients. Within the AA group, more patients received the full recommended MPA dose (1.44g EC-MPS, 2.0g MMF) with EC-MPS vs MMF at month 6 (56% vs 36%, $p=0.02$) and month 36 (47% vs 17%, $p=0.03$). Graft survival at 4 years was 89% in AAs vs 96% in non-AAs (log rank $p<0.01$, Kaplan Meier); patient survival was 96% and 94% ($p=0.99$). Biopsy-proven acute rejection (BPAR) occurred in 19% AAs and 11% non-AAs ($p<0.01$). Efficacy endpoints were similar with EC-MPS or MMF in AAs and in non-AAs. Adverse events were similar in AAs vs non-AAs other than diabetes (17% vs 11%, $p=0.02$), cardiovascular events (11% vs 6%, $p=0.03$) and bone-related events (8% vs 14%, $p=0.02$).

Conclusions: BPAR and graft loss were more frequent in AAs vs non-AAs despite similar tacrolimus exposure and more frequent steroid therapy. In AAs, full MPA dose was maintained more frequently with EC-MPS than MMF at months 6 and 36, but immunosuppression may still have been inadequate.

SA-PO936

Effect of HLA DR Matching on Renal Transplant Outcomes Using Contemporary Immunosuppression

Vaqar Ahmed,[1] Anita Sultan,[1] David J. Taber,[2] Bethany Wolf,[3] Martin C. Bunke.[1] *[1]Nephrology, MUSC, Charleston, SC; [2]Pharmacy, MUSC, Charleston, SC; [3]Biostatistics, MUSC, Charleston, SC.*

Background: Does HLA DR matching has an impact on graft outcomes using contemporary immunosuppression (IS).

Methods: Retrospective analysis of 555 patients receiving a kidney transplant at MUSC from 1/2005-6/2008 was performed. Patients received an IL-2 receptor antagonist(IL-2A) as induction unless they were a re-transplant, had PRA>20%, or if the kidney had a cold ischemia time >24 hours, in these cases they received Thymoglobulin(Thymo). Maintenance IS consisted of a calcineurin inhibitor, mycophenolate, and prednisone. Kaplan–Meier analyses were used to examine associations between graft failure and variables using a log rank test to determine differences. Cox regression model was used to determine graft survival by HLA DR matching after adjusting for demographic & clinical characteristics.

Results: 62% were male, mean age 49+/-15 yrs, median f/u 1324 days, 54% were African American(AA), 68% received IL-2A induction and 32% received Thymo. 85.6% subjects had either 1 or 2 DR mismatch(DRMM). AA had an increased number of at least 1 DRMM compared to Caucasians. Patients with increasing numbers of DRMM had higher numbers of HLA A and B MM(p<.001 for both). DRMM were also associated with an increased incidence of acute rejection in the first 6 months; 0 DRMM 5%, 1 DRMM 14%, 2DRMM 19%(p=.015). Cox regression model that examined DRMM and graft survival revealed that AA had a 2.5 fold higher risk of graft failure relative to Caucasians(p=.006). Subjects with 1 DRMM had a 6.6 fold increased hazard of graft failure (p=.010) and 2 DRMM had an 8.2 fold increased hazard(p=.006) when compared to 0 DRMM. If the data is examined based on induction therapy type, the IL-2A group had a decrease in graft survival in 2 DRMM compared to O DRMM(p=.016). Thymo group did not show a decrease in survival in 2 DRMM compared to 0 DRMM.

Conclusions: DRMM is associated with increased early acute rejection even with use of contemporary immunosuppression. DRMM increases the risk of graft failure. Small subset of patients with DRMM with Thymoglobulin induction did not show increased incidence of graft failure.

SA-PO937

Early Corticosteroid Withdrawal after Kidney Transplantation: Paradoxical Effects on the Central and Peripheral Skeleton

Sapna Iyer,[1] Lucas Nikkel,[2] Chiyuan Amy Zhang,[1] Donald J. Mcmahon,[1] Stephanie Boutroy,[1] David J. Cohen,[1] Elizabeth Shane,[1] Thomas L. Nickolas.[1] *[1]Columbia University; [2]Penn State College of Medicine.*

Background: In the first year after kidney transplantation (KTx), patients on corticosteroid-based immunosuppression experience significant loss of areal bone mineral density (aBMD) and high fracture rates. In some studies, early corticosteroid withdrawal (ECSW) is associated with lower rates of bone loss; its effects on bone quality are unclear.

Methods: We enrolled 48 adult KTx recipients, mean age 50±14 yrs, in a prospective study to quantify effects of ECSW on bone quality. We measured aBMD by dual energy X-ray absorptiometry (DXA) of the lumbar spine (LS), total hip (TH), femoral neck (FN), 1/3 radius (1/3R) and ultradistal radius (UDR) at baseline, 3, 6 and 12 months (m) after KTx. We used high resolution peripheral quantitative computed tomography (HRpQCT) to assess volumetric BMD (vBMD), bone geometry and microstructure at the radius and tibia. Comparisons were made using mixed models adjusted for age, BMI, sex, diabetes, race and pretransplant dialysis and diabetes; results are expressed as Means±SD.

Results: 39, 40 and 41 patients completed 3-, 6- and 12m follow-up, respectively. At KTx, BMI was 28±6 Kg/m^2; 29% were women and 71% were white. Over 12m, TH and FN aBMD declined at 3m (-1.2±4.1%, p<0.01 and -1.3±5.9%, p<0.05, respectively), but recovered to levels not significantly different from baseline by 12m. In contrast, 1/3R and UDR aBMD declined linearly over 12m (-1.9±6.3%, p<0.001 and -2.9±8.7%, p<0.01, respectively). LS aBMD did not change. By HRpQCT at the radius, cortical (Ct) and trabecular (Tb) vBMD declined over 12m (-2.1±4.9% and -4.7±7.1%, p<0.001, respectively). Tb microstructure did not change. These changes were mirrored at the tibia, though the amount of loss was smaller. Older age and female gender were associated with Ct bone loss. Older age was associated with Tb bone gain.

Conclusions: Over the first year of KTx, ECSW is associated with bone loss at the peripheral but not the central skeleton. Future studies will elucidate biochemical mechanisms of these bone changes and their effects on bone strength and fracture risk.

Prolonged-Release Tacrolimus (QD) Is Non-Inferior to Immediate-Release (BD) Tacrolimus Using Different Measures of Clinical Efficacy: A Combined Analysis

Bernhard K. Krämer,[1] Nassim Kamar.[2] *[1]University of Heidelberg, Mannheim; [2]CHU Rangueil, Toulouse.*

Background: Non-inferiority of tacrolimus QD vs BD was assessed in two large prospective studies in *de novo* kidney transplantation. Study 12-03 was a double-blind, double-dummy, randomized trial; OSAKA was an open-label, parallel-group, randomized trial. Efficacy was assessed at Week 24 by biopsy-proven acute rejection (BPAR) in Study 12-03, and a composite endpoint based on EMA guidelines (graft loss, BPAR, renal dysfunction (eGFR; MDRD4) at the end-of-study visit) in OSAKA. These combined analyses investigate a number of different efficacy parameters.

Methods: The analyses (n=1278) included 633 patients receiving tacrolimus QD (12-03: 331 patients; OSAKA: 302) and 645 receiving tacrolimus BD (12-03: 336; OSAKA: 309). Only patients receiving a starting dose of tacrolimus 0.2mg/kg/day (QD or BD) with MMF and low-dose corticosteroids are included in these analyses. Data were collected up to the end-of-study/follow-up visit for BPAR, the US FDA composite endpoint (graft loss, BPAR, loss to follow-up), and the EMA composite endpoint. Renal dysfunction was defined as eGFR <40mL/min/1.73m^2. 95% CIs were calculated using a 10% margin for non-inferiority.

Results: Baseline demographics were balanced between groups. In both groups, 49% of kidneys were from deceased male donors. BPAR incidence was comparable between groups (13.9% vs 14.1% tacrolimus QD vs BD, respectively) (table). Of the patients who received a kidney from a deceased donor, 9.6% vs 9.9% experienced BPAR, respectively. The US FDA composite endpoint was reached by 21.5% of tacrolimus QD- and 19.8% of BD-treated patients, and the EMA composite endpoint was reached by 40.3% vs 38.3%, respectively (table). The incidence of graft dysfunction was comparable between groups.

	BPAR	FDA composite EP	EMA composite EP
Tacrolimus QD	13.9%	21.5%	40.3%
Tacrolimus BD	14.1%	19.8%	38.3%
Difference (QD–BD)	–0.2%	+1.7%	+2.0%
95% CI	–4.0%, 3.6%	–2.7%, 6.1%	–3.4%, 7.4%

Conclusions: Non-inferiority of tacrolimus QD vs tacrolimus BD, measured by standard efficacy endpoints (BPAR, US FDA and EMA composite endpoints), was demonstrated in a large combined database of kidney transplant recipients.

Efficacy and Safety of Anti-Thythymocyte (ATG) Induction for Highly Sensitized Kidney Recipients with Hepatitis C Virus (HCV) Infection

Qing Ren, Martha Behnke, Julie Ann T. Linatoc, Todd W. Gehr, Anne L. King. *Nephrology, Virginia Commonwealth University, Richomond, VA.*

Background: ATG induction has been reported to improve graft outcomes in highly sensitized (panel reactive antibody (PRA) >80%) kidney recipients, but its efficacy and safety is still uncertain in HCV + patients.

Methods: From 2003 to 2009, 509 deceased donor kidney recipients who received ATG induction, followed by tacrolimus, mycophenolate mofetil and steroid maintenance were retrospectively studied and divided into 6 groups based on PRA and HCV status. HCV progression as reflected by Alanine Aminotransferase (ALT), aspartate aminotransferase (AST) and HCV titers was monitored. Infection, malignancy, rejection, graft and patient survival rates were compared among these groups.

Results: Acute humeral rejection (AHR) rate was higher in highly sensitized groups, but no difference between the HCV+ and HCV-groups. Acute cellular rejection (ACR) at 1 year and late rejection at 3 and 5 year were similar among all groups. Compared to the other groups, HCV+/PRA>80% group had equivalent patient and graft survival rates at 1, 3 and 5 year. There was no increased incidence of infection and malignancy in HCV+/PRA>80% group. AST, ALT and HCV titers were also found stable among HCV+ groups.

Results

	HCV+/PRA>80	HCV-/PRA>80	HCV+/PRA 79-21	HCV-/PRA 79-21	HCV+/PRA<20	HCV-/PRA<20	P
N	23	164	14	91	40	177	
AHR 1 yr	8.7%†	8.5%†	0	4.4%	0	1%	0.0002 (0.99†)
ACR 1yr	21.7%	10.4%	6.7%	7.7%	7.5%	8.5%	NS
Rejection 5yr	0	4%	0	3%	0	4.4%	NS
Patient survival 1yr	91.7%	97%	100%	98.9%	90%	96%	NS
Patient survival 5yr	82.5%	82.7%	100%	91.9%	70.4%	84.5%	NS
Graft survival 1yr	83.3%	90.2%	100%	94.5%	84%	93.2%	NS
Graft survival 5yr	64.8%	72.7%	93.3%	79.8%	60%	74.6%	NS
Infection 1yr	47.8%	37.8%	29%	48.4%	50%	39.5%	NS
Infection 5yr	16.7%	27.3%	14.3%	17.5%	15%	32.4%	NS
Malignacy	4.5%	6.6%	0	2.2%	0	2.3%	NS

Conclusions: By using ATG induction, HCV+ highly sensitized kidney recipients did not have higher rates of rejection. They could have comparable short and long-term graft and patient survival outcomes. ATG induction was well tolerated by HCV+ patients. Our data suggested ATG induction can be efficaciously and safely used in highly sensitized patients with HCV infection.

SA-PO940

Low Dose Schemes of Thymoglobulin as Induction Therapy in High Risk Kidney Transplant Recipients Daniel Perez-Vega, Jorge Andrade-Sierra, Francisco Molina-Ruiz. *Nephrology and Transplant Uit, Hospital de Especialidades CMNO, IMSS, Guadalajara, Jalisco, Mexico.*

Background: The use of Thymoglobulin (rATG) as induction therapy in high risk kidney trasplant recipients(HKR) to prevent acute rejection (AR) is a common practice, however the evidence is scarce respecting low dose schemes. Aim: To show the AR incidence and renal function 1 year after transplantation in HKR according to two different low dose schemes.

Methods: KR were classified as high risk when: they had a previous trasplant or a cadaveric donor, and if they had a crossmatch test or PRA>10%. 93 HKR were prospectively analyzed according to total rATG dose (4mg/kg vs 4.1-6mg/kg). The primary endpoint was the rate of AR and graft failure at 1 year. The secondary endpoints were serum creatinine, hematological adverse effects and infections. All patients received inmunosupression with a calineurine inhibitor, mycophenolate mophetil and steroids.

Results: In group 1 the mean accumulated dose was 3.7 mg/kg vs 5.4mg/kg in group 2. There were no significant differences in AR(biopsy proved) rates at 1 year as shown in Table 1. Infection was significantly more frequent in the higher dose group (62.1 vs 33.9%; p=0.045).

Table 1. One year outcomes according to total rATG dose

Variable	**All (93)**	**≤4mg/kg(56)**	**>4mg/kg(37)**
Acute rejection n(%)	10 (10.7%)	4 (7.1%)	6(16.2%)
Graft failure n(%)	1 (1.1%)	1 (1.7%)	0 (0%)
Infections n(%)	42(45.1%)	19(33.9%)	23(62.1%)**
Urinary Tract Infections n(%)	40(43%)	19(33.9%)	21(56.7%)
Cytomegalovirus n(%)	1(1.1%)	1(1.8%)	0 (0%)
BK virus n(%)	1 (1.1%)	1(1.8%)	0 (0%)
Death n(%)	5 (5.3%)	3 (5.2%)	2 (5.4%)
Serum Creatinine (mg/dl)	1.13 ±0.47	1.18±0.45	1.07±0.28
Creatinine Clearence (ml/min)	81.1 ±16.7	78.7±16.2	84.6±17.1
Lymphocyte count(cels/mm3)	1005±426	1026±423	975±435
Platlet count (1000 cels/mm3)	205±58	203±62	209±52
Hemoglobin (g/dl)	13.9 ±2.1	13.8±2.1	14.2±2.0

* *p= <0.05

Conclusions: Lower dose of rATG was not associated to more AR or graft failure and it was associated to lower infection frequency compared to those with higher dose in HKR.

SA-PO941

Systematic Review and Meta-Analysis of Alemtuzumab versus Anti-Thymocyte Globulin in Induction Therapy for Kidney Transplants Kevin C. Roe, Ridhmi P. Rajapakse, Nasrollah Ghahramani. *Nephrology, Penn State College of Medicine - Hershey Medical Center, Hershey, PA.*

Background: In renal transplant recipients, induction therapy with lymphocyte depleting agents is effective at decreasing incidence of acute rejection (AR). This review compares reported outcomes of several randomized controlled trials (RCTs) using anti-thymocyte globulin (ATG) versus alemtuzumab.

Methods: We conducted a systematic review and meta-analysis to compare outcomes from induction therapy using ATG and alemtuzumab in renal transplant. Two of the authors independently conducted literature searches and data extraction from the PUBMED and Cochrane Central databases to identify RCTs comparing outcomes in adult kidney-alone transplants using alemtuzumab versus ATG induction therapy.

Results: We identified 6 RCTs (447 patients). The studies were published from 2007-2011. Four studies (n= 244) reported on AR at 1 year. For these studies, the odds ratio (OR) of AR with alemtuzumab compared with ATG induction was 0.80 (95% CI: 0.38 to 1.70; p=0.57). Among the three studies (n= 379) that reported on Cytomegalovirus (CMV) disease, the OR of CMV disease with alemtuzumab compared with ATG induction was 0.71 (95% CI: 0.37 to 1.36; p=0.30). Among the three studies (n= 379) that reported on polyoma BK-virus nephropathy(BKVN), the OR of BKVN with alemtuzumab compared with ATG induction was 0.58 (95% CI: 0.23 to 1.47; p=0.25). Four studies (n=405) reported on delayed graft function (DGF). For these studies, the OR of DGF with alemtuzumab compared with ATG induction was 0.84 (95% CI: 0.47 to 1.52; p=0.57).

Conclusions: Meta-analysis of results of RCTs of the two induction regimens showed no significant difference in the incidence of: a) AR at 1 year; b) DGF; c) BKVN; d) and CMV. Therefore, although there are multiple analyses and some conflicting data on outcomes from the use of alemtuzumab versus ATG for induction therapy, our review does not confirm a difference in the incidence of the outcomes studied.

SA-PO942

Influence of a Long-Term Immunosuppression with Everolimus on the Aortic Pulse Wave Velocity in Renal Transplant Recipients Joerg Seckinger, Anna K. Schlenker-Bø, Lars Kihm, Claudia Sommerer, Martin G. Zeier, Vedat Schwenger. *Department of Nephrology, University Hospital Heidelberg, Heidelberg, Germany.*

Background: In renal allograft recipients cardiovascular disease is the leading cause of death. The aortic pulse wave velocity (PWV) is an established cardiovascular risk factor and easy to assess in a daily clinical routine. While the therapy with calcineurin inhibitors (CNI) is suspected to promote aortic stiffness the effect of a long-term therapy with mTOR-inhibitors remains unclear.

Methods: In a clinical trial we examined the effect of a long-term immunosuppressive therapy with everolimus (EVR) compared to the standard immunosuppression with CNI on the aortic PWV in renal transplant recipients.

Results: A total of 24 renal allograft recipients were investigated (EVR: n=12, CNI: n=12). The demographic data of both patient groups (EVR vs. CNI) was comparable (age: 44.5±15.2 vs. 47.1±11.4 years, p=0.39; time on dialysis: 55.4±32.6 vs. 60.5±39.2 months, p=0.33; 75% males in both groups). The therapy switch from CNI to EVR occurred at an average of 7.5 months post transplant. While the PWV in the two patient groups was similar at the time of the therapy switch (9.74 vs. 9.68 m/s, p=0.42) a significant difference was noted at the time of the follow-up approximately 5 years (59.1±14.4 vs. 60.3±11.1 months, p=0.44) after the transplantation: 10.9±2.45 vs. 12.3±2.28 m/s (p=0.04).

Conclusions: In renal transplant recipients a long-term immunosuppressive therapy with everolimus was associated with less aortic stiffening compared to the standard treatment with calcineurin-inhibitors. The routine assessment of pulse wave velocity may aid the clinician in the decision process to switch patients at an increased risk for cardiovascular disease to an mTOR based regimen.

SA-PO943

Influence of a Switch from a Cyclosporine A to an Everolimus Based Immunosuppression on the Diabetic Status in Renal Transplant Recipients Joerg Seckinger, Florian Kälble, Christian Morath, Matthias Schaier, Vedat Schwenger, Martin G. Zeier, Claudia Sommerer. *Department of Nephrology, University Hospital Heidelberg, Heidelberg, Germany.*

Background: The choice of the primary immunosuppressive drug has a significant influence on the glucose metabolism in transplant recipients. While a calcineurin inhibitor or steroid therapy is associated with an increased risk for the development of an impaired glucose tolerance or a new onset diabetes mellitus after transplantation (NODAT) the role of mTOR-inhibitors remains unclear to date.

Methods: In a case-control study we examined renal transplant recipients that were switched from a cyclosporine A (CyA) and mycophenolate based immunosuppression to an everolimus (EVR) based therapy within the first year after transplantation with regard to the development of impaired glucose tolerance (fasting blood glucose values 110-125 mg/dl) and NODAT (>=126 mg/dl). Follow-up data was collected at 12 and 24 months after the therapy switch.

Results: A total of 146 patients (54 female, 92 male) at the age of 45.8±14.8 years were enrolled in the study (BMI 25.3±4.1 kg/m²). The demographic data in both patient groups was comparable. The switch to EVR (n=73) occurred at a median of 3.4 months post transplant. The average trough levels 12 and 24 months after the therapy switch were 6.0±2.2 mg/l and 6.4±2.9 mg/l for EVR, and 148±65 µg/l and 134±47 µg/l for CyA, respectively. The steroid doses in both groups (EVR versus CyA) at the time of the therapy switch (8.7±6.7 mg vs. 7.1±4.3 mg, p=0.78) and during the follow-up at 12 months (4.2±2.5 mg vs. 4.3±2.8 mg, p=0.15) and 24 months (3.6±0.9 mg vs. 3.8±0.9 mg, p=0.22) were comparable. The cumulative incidence of impaired glucose tolerance and NODAT 12 and 24 months after the switch of the primary immunosuppression was significantly lower for patients in the EVR group: 8.2% vs. 24.7% (p=0.007) and 1.4% vs. 12.3% (p=0.009), respectively.

Conclusions: In this retrospective study a therapy switch from a cyclosporine A to an everolimus based immunosuppression was associated with a significantly lower rate of impaired glucose tolerance and NODAT.

SA-PO944

Variation of Tacrolimus Blood Levels and Transition Readiness in Adolescent Renal Transplant Recipients Edward Iglesia,[1] Maria E. Ferris.[2] *[1]Robert Wood Johnson Medical School; [2]UNC Kidney Center.*

Background: Medication nonadherence is a major cause of rejection and graft failure in adolescents. The transition from pediatric to adult services is a particularly vulnerable period. We examined the relationship of the variation of tacrolimus blood levels with transition readiness.

Methods: We performed a retrospective study of renal transplant recipients ≥12 years old followed at the UNC Kidney Center pediatric nephrology clinic who are on tacrolimus and had a transition readiness assessment (UNC TR$_x$ANSITION Scale). Using tacrolimus (TAC) trough levels, we calculated medication adherence based on standard deviation (SD) and percent coefficient of variation (%CV). The TR$_x$ANSITION Scale was used to assess self-reported adherence (higher score = greater adherence) and overall transition readiness (higher score = greater adherence). TAC SD and %CV were calculated for 52 weeks prior to the transition readiness assessment. Spearman's correlation was performed to examine the relationships among TAC SD, %CV, self-reported adherence, and overall transition readiness. Patients with a SD>2 or a %CV>30 were considered nonadherent.

Results: Of 14 patients, 36% were female and 57.1% white. Mean age at transition assessment was 15.5±2.4 years and mean number of weeks post-transplantation was 221.6±135 (range 68-485). Mean number of TAC trough levels was 9.3±3.5 (range 3-14). Mean TAC SD was 1.7±.80, mean %CV was 25±9, mean TR$_x$ANSITION adherence subscale score was .86 ±.19 (max 1.0), and mean overall TRANSITION Scale score was 6.3±2.0 (max 10). Twenty-nine percent were considered nonadherent by TAC SD>2 and 36% by %CV>30. TR$_x$ANSITION adherence subscale score had a significant negative correlation with %CV (rho= -.62, p=.02) and trended towards significance with TAC SD (rho= -.52, p=.06). Overall TR$_x$ANSITION score (rho= -.56, p=.03) was negatively correlated with %CV (rho= -.58, p=.03).

Conclusions: Adherence based on %CV of tacrolimus blood levels significantly correlated with self-reported adherence and overall transition readiness. This supports that the acquisition of transition-related knowledge and skills may play an important role in decreasing morbidity related to medication adherence.

The Relationship between Hemorheological Factors and Vascular Endothelial Dysfunction in Cyclosporine A or Tacrolimus Treated Renal Transplant Recipients

Mustafa Arici,[1] Hadim Akoglu,[1] Tolga Yildirim,[1] Nurten Seringec,[2] Ercan Turkmen,[1] Ergun Baris Kaya,[3] Rahmi Yilmaz,[1] Neslihan Dikmenoglu,[2] Yunus Erdem.[1] *[1]Nephrology, Hacettepe University Medical Faculty, Ankara, Turkey; [2]Physiology, Hacettepe University Medical Faculty, Ankara, Turkey; [3]Cardiology, Hacettepe University Medical Faculty, Ankara, Turkey.*

Background: Calcineurin inhibitors, mainly cyclosporine A (CsA), are associated with endothelial dysfunction in renal transplant recipients (RTR). Hemorheological disturbances including decreased erythrocyte deformability (ED), increased plasma viscosity and erythrocyte aggregation (EA) have also been reported in CsA treated RTR. We aimed to investigate the relationship between hemorheological factors and endothelial dysfunction in CsA and tacrolimus (Tc) treated RTR.

Methods: Thirty one RTR and sixteen healthy subjects were recruited. The RTR group included patients receiving CsA (n=16) or Tc (n=15). Endothelial function was evaluated by flow-mediated dilation (FMD) of the brachial artery.ED and EA were measured with laser-assisted optical rotational cell analyzer and plasma viscosity by a cone-plate viscometer. Transthoracic echocardiography was performed to assess left ventricular mass index (LVMI).

Results: FMD of CsA group was significantly lower than the controls (6.3±5.1vs 11.9±5.6 %, P=0.024), whereas, there was no significant difference between Tc group (8.8±5.4%) and controls. Both CsA and Tc groups had significantly higher LVMI than the controls (104.1±31.8 and 90.5±17.1 vs 72.0±16.7 g/m^2, P=0.003). At shear stresses ranging between 0.95 and 30 Pa, ED of CsA group were significantly lower compared with the controls. In Tc group, the decrease in ED was significant at shear stresses ranging between 0.53 and 5.33 Pa. ED indices did not correlate with FMD or LVMI in any of the groups.

Conclusions: The degree of endothelial dysfunction and reduction in ED were significant in patients on CsA therapy. Hemorheological factors were not likely to be associated with endothelial dysfunction in RTR.

SA-PO946

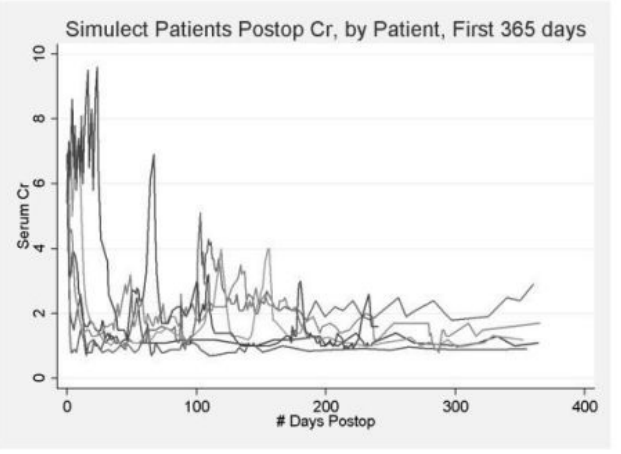
Novel Substitution of Basiliximab for FK506 in Renal Transplant Patients

John R. Montgomery, Andrew Lawrence Singer, Robert Avery Montgomery, Nada Alachkar. *Johns Hopkins University.*

Background: Kidney transplant recipients with calcineurin inhibitor (CNI) toxicity and contraindication to sirolimus have limited maintenance immunosuppressant options. Replacement of CNI/sirolimus with Basiliximab (anti-CD25) provides a novel substitution for long-term maintenance therapy. We present 6 such cases at our institution between 2007 and 2011.

Methods: Four patients received living donor transplants (LDKT) and two received deceased donor transplants (DDKT). All LDKT recipients were highly sensitized; 3 had a positive flow crossmatch (XM+) with their donors before desensitization and one was ABO incompatible (XM+/ABOi). Besides delayed graft function experienced by DDKT recipients, all transplants were uncomplicated. Patients were discharged on MMF, Prednisone, and FK506 (n=5) or sirolimus (n=1). At mean time of 0.9 year (range 0.2-4.1 years), five patients switched to Basiliximab due to CNI toxicity and 1 patient due to non-healing wounds on serolimus. A monthly dose of 20 mg IV was administered in our infusion center. Mean follow-up time was 2.3 years (range: 0.7-5.3 years).

Results: One death was reported 13 months after DDKT due to sepsis and one graft was lost 2 years after transplantation due to recurrent hemolytic uremic syndrome. Figure 1 shows the allograft function in the survived patients. Three patients were hospitalized with diarrhea due to C. difficile colitis or CMV; one of them had urinary tract infection (UTI) as well. One patient developed BK viremia and 1 had UTI and CMV viremia but did not require hospitalization. One case of acute cell-mediated rejection was noted (Banff 2A) that resolved with therapy.



Conclusions: Basiliximab provides a novel substitution for CNI/sirolimus as maintenance immunosuppression therapy. In spite of the small size of our study, patient and allograft survival seemed comparable with our overall kidney transplant recipients.

SA-PO947

Concomitant Use of Proton Pump Inhibitors and Mycophenolate Mofetil Is Associated with an Increased Risk of Rejection in Kidney Transplant Recipients

John P. Knorr,[1] Mariel Sjeime,[1] Radi Zaki,[2] Jorge Ortiz.[2] *[1]Pharmacy, Einstein Medical Center, Philadelphia, PA; [2]Transplant Surgery, Einstein Medical Center, Philadelphia, PA.*

Background: Recent pharmacokinetic studies have demonstrated that proton pump inhibitors (PPI) reduce exposure of mycophenolic acid (MPA); however the clinical significance of this drug-drug interaction on transplantation outcomes has not been determined.

Methods: This was a retrospective cohort study to evaluate the impact of PPI use on the one-year rates of biopsy-proven acute rejection (BPAR) in kidney transplant recipients who were prescribed rabbit anti-thymocyte globulin (rATG), calcineurin inhibitor, mycophenolate mofetil (MMF) and steroids.

Results: 225 patients that were prescribed PPI were compared to 390 patients who were on standard acid-suppressive therapy with ranitidine. BPAR occurred more frequently in the PPI group (20.9% vs. 16.4%, RR=1.5, p=0.03). More black patients had BPAR (28.5% vs. 11.7%, RR=2.1, p<0.001) but were less likely to receive PPIs (46.2% vs. 53.7%, p=0.03). Age, gender, HLA mismatch, cold-ischemic time, donor age, CMV status, rATG dose and MMF dose at discharge were similar between groups. Although the PPI group had more patients with prior transplantation (21.7% vs. 13.8%) and with PRA >20% (28.8% vs. 16.7%), neither variable was associated with BPAR (both p>0.35). At one year, BPAR type, BPAR grade, patient and graft survival, graft function and time to BPAR were unaffected by PPI exposure.

Conclusions: In this retrospective study, PPI use in the first transplant year was associated with an increased risk for BPAR. It is possible that a reduction in MPA exposure contributed to the increased risk. In kidney transplant recipients on MMF, PPIs should be judiciously prescribed.

SA-PO948

Influence of the Type of Calcineurin Inhibitor and Severity of Metabolic Alterations Following Fructose Consumption in Renal Transplant Recipients

Michal P. Nowicki, Anna Zawiasa. *Department of Nephrology, Hypertension and Kidney Transplantation, Medical University of Lodz, Lodz, Poland.*

Background: Metabolic disturbances are common in renal transplant recipients (RTR). Alterations in lipid and uric acid (UA) metabolism that have been linked to adverse graft outcome may be a consequence of impaired graft function, a choice of immunosuppressive therapy and other factors including excessive fructose consumption. The aim of the study was to examine influence of short-term fructose load on serum UA, plasma lipids and blood pressure (BP) among RTR treated with cyclosporine-based or tacrolimus-based standard triple immunosuppressive therapy.

Methods: 55 cadaveric RTR were enrolled. 26 RTR were treated with cyclosporine A (CsA), age 42.8±12.9 years, GFR$_{C\text{-}G}$ 54.4±13.8 mL/min/1.73 m^2 and 29 with tacrolimus (Tac), age 46.1±10.8 years, GFR$_{C\text{-}G}$ 55.3±14.2 mL/min/1.73 m^2. An oral fructose tolerance test (OFTT) was based on consumption of 70 g of fructose. Blood samples for UA, total cholesterol (TC), triglycerides (TG), LDL and HDL cholesterol were obtained at baseline and 60, 120, 180, and 240 min. thereafter.

Results: There was a significant increase of serum UA during OFTT in both groups from 416.6 ± 84.6 to 452.2±89.4 µmol/L after 240 min. in CsA group and from 420.4±102.4 to 449.9±101.9 µmol/L in Tac group; p <.001 in both groups. The peak increase of UA to 459.0±89.8 µmol/L and 464.1±102.8µmol/L, respectively was noticed 120 min. after fructose intake. Serum TG increased during OFTT from 2.31±1.74 mmol/L at baseline to

2.59±1.68 mmol/l after 240 min. in CsA (p <.001), and from 1.89±1.28 to 2.05±1.34 mmol/L in Tac-treated patients (p <.01). In both groups TC, LDL and HDL cholesterol significantly decreased during OFTT. No significant changes in BP were noticed.

Conclusions: RTR treated with CsA when compared to Tac patients, show similar predisposition to purine metabolic disturbances following fructose consumption. Use of immunosuppressive protocols including CsA is associated with less favorable, as compared to Tac profile of lipid changes induced by fructose.

SA-PO949

High Intrapatient Tacrolimus Variability and Early Sub-Therapeutic Tacrolimus Levels Predict Worse Renal Transplant Function at 1 Year

Henry Whalen, Julie Glen, Marc J. Clancy. *Transplant Unit, Western Infirmary, Glasgow, United Kingdom.*

Background: High intrapatient tacrolimus variability (ITV) is associated with worse clinical outcomes post-renal transplant. High tacrolimus levels cause toxicity, whilst sub-therapeutic tacrolimus (STT) levels predispose to acute rejection (AR) and graft loss. We investigated the effects of ITV and STT on renal transplant outcomes at 1 year.

Methods: Data was collected from the prospectively-compiled electronic patient record for 239 adult kidney transplants performed between 01/01/07 and 01/03/09. Patients received Basiliximab induction and triple therapy immunosuppression with prednisolone and mycophenolate. Target tacrolimus trough levels were 5-8ng/dL.

Median ITV 6–12 months post transplant was calculated, with high variability (HV) defined as variability > observed median and low variability (LV) as </= observed median.

For STT analysis, the % of STT levels in the post transplant year were calculated. Patients > observed median were considered High Frequency (HF) and those </= the median were low frequency (LF).

Groups were compared for AR, graft survival and eGFR at 1 year.

Results: Median ITV was 16%. AR in HV patients was 21% (25/119), compared with 8% (9/120) for LV patients. (p=0.0049). eGFR at 1 year was worse in the HV group (mean 54 µMol/L, SD 21.2) compared to the LV group. (mean 64 µMol/L, SD 20.0) p=0.0008.

Median STT was 14%. AR in HF patients was 21.7% (25/115) compared with 7.3% (9/124) for LF patients. (p= 0.0015). eGFR at 1 year in the HF group (mean 52.5 µMol/L, SD 22.4) was lower compared to the LF group (mean 65.0 µMol/L, SD 17.8). p=0.0001.

Conclusions: Our findings support the hypothesis that high levels of ITV and STT are associated with worse clinical outcomes. This may represent covariation with patient's compliance but the importance of achieving target tacrolimus levels is confirmed.

Our follow up may be insufficient to show an association between shorter graft survival and high ITV or STT levels. However, we find a reduced eGFR in both HV and HF groups that may predict shorter graft survival in the long term.

SA-PO950

Steroid Resumption after Early Withdrawal Predicts New Onset Diabetes and Morbid Obesity after Kidney Transplantation

Christopher A. Carlos, Donald E. Hricik, Joshua J. Augustine. *Medicine, University Hospitals Case Medical Center, Cleveland, OH.*

Background: New onset diabetes (NODAT) and morbid obesity (BMI ≥ 35 kg/m^2) are associated with poor outcomes after kidney transplantation. Randomized studies have shown modest improvements in weight gain and diabetic severity with steroid avoidance. We hypothesized that resumption of steroids after early withdrawal may lead to an increased risk of NODAT and morbid obesity and thus attenuate the metabolic benefits of steroid withdrawal.

Methods: We analyzed outcomes in 228 consecutive patients from 1/2006 to 12/2010 who all underwent steroid withdrawal at 4 days post-transplantation. NODAT was defined by outpatient fasting glucose levels of ≥ 126 mg/dl, a random glucose ≥ 200 mg/dl, or a HbA1c of ≥ 6.5% in 157 patients with no pretransplant diabetes. BMI values were calculated at 24 months in 189 patients and compared to baseline and 12 month values.

Results: Within a year of transplantation, 49 (21%) patients resumed steroid therapy (SR). There were no differences in recipient age, gender, ethnicity, or donor source between steroid-free (SF) and SR patients. SR patients had less HLA matching at transplantation, more rejection, and a lower GFR at one year. NODAT was subsequently diagnosed in 29% of the SR patients vs. 15% of the SF patients (p=0.05). At the time of transplantation, there were no differences in the rates of morbid obesity between SR and SF groups (14% vs. 10%, p=ns). However, by 24 months post-transplantation, the rates were 28% in the SR group vs. 15% in the SF group (p=0.05). Between 12 and 24 months post-transplantation, SR patients had an increase in BMI of 1.3±3.1 kg/m^2, vs. 0.5±1.5 kg/m^2 in SF patients (p=0.02). SR remained a predictor of weight gain during this time period after controlling for baseline BMI, age and ethnicity (p=0.02).

Conclusions: Resumption of corticosteroid therapy in the first year following early withdrawal in kidney transplant recipients was associated with a near doubling of NODAT and a near doubling in the rate of morbid obesity at two years post-transplantation. Steroid resumption was an independent predictor of weight gain after the first year of transplantation.

SA-PO951

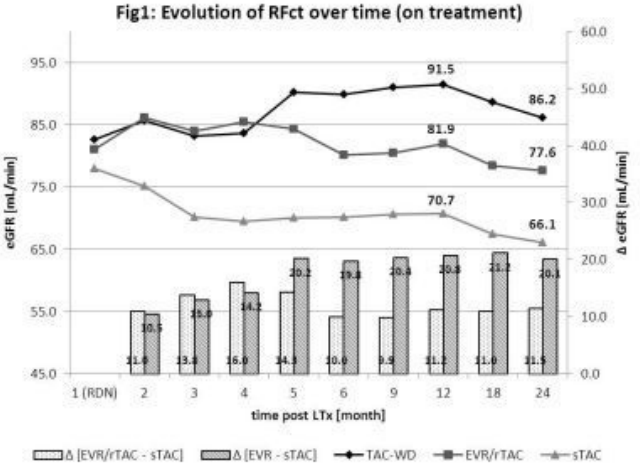
Evolution of Renal Function after Liver Transplantation: Do Patients Benefit from mTOR Treatment? 2-Year Follow-Up of 719 De Novo LTx Recipients from Study H2304

G. Junge, Patricia M. Lopez, Sven Kohler, Heike Schwende, J. Fung. *H2304 Study Group.*

Background: mTOR inhibitor facilitated CNI reduction and/or elimination may reduce CNI-associated nephrotoxicity in de novo liver transplant recipients (LTxR). Little is known about long-term treatment with everolimus(EVR) in LTx LTxR. Maintained efficacy, development and amount of proteinuria as well as evolution of renal function represent open questions to be addressed in this abstract.

Methods: H2304 (NCT00622869) is a 24-month(M) multinational RCT that randomized n=719 de novo LTxR 1:1:1 into (1) EVR (3-8ng/mL) + reduced tacrolimus (3-5ng/mL; EVR+rTAC; N=245), (2) EVR (6-10ng/mL) + TAC withdrawal (TAC-WD; N=231) at M4, and (3) standard TAC (6-10ng/mL; TAC-C; N=243). Main endpoints at M12 and 24M include composite efficacy failure rate of treated BPAR, graft loss or death and evolution of renal function(RF) from randomization to M12 and M24.

Results: BPAR rates at M12/24 were 4.1/6.1% for EVR+rTAC vs 10.7/13.3% with TAC-C demonstrating significantly lower rates with EVR/rTAC at M12 p= 0.0052 and M24 p=0.010. Enrollment in TAC-WD arm was stopped early due to higher AR rate. ITT and on-treatment analysis of evolution of renal function showed significantly better results for EVR/rTAC over TAC-C (Fig1). Urinary protein excretion was highest at M6 (290 mg/g) and further decreased in the EVR/rTAC arm from 245 mg/g at M12 to 194 mg/g at M24, clearly below the proteinuria threshold (300 mg/g).



Conclusions: H2304 24-month data confirm numerically better efficacy with significant fewer BPAR events and superior renal function with EVR/rTAC over TAC-Control. The overall safety profile was not distinct from previous experiences with everolimus and expectations in a *de novo* liver transplant population.

SA-PO952

Hepatitis C Related Renal Disease: Do HCV Patients Benefit from mTOR Treatment after LTx?

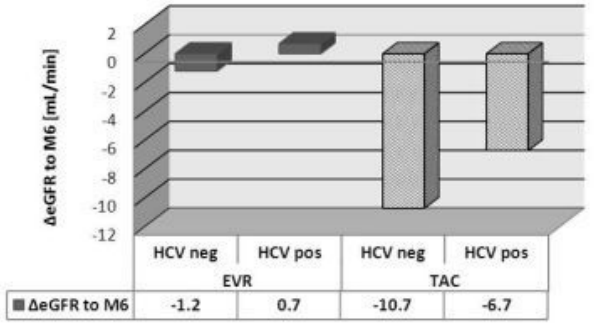
G. Junge, Patricia M. Lopez, Sven Kohler, Heike Schwende, J. Fung. *H2304 Study Group.*

Background: Tx recipients treated with CNI are at high risk of developing renal injury. CNI nephrotoxicity is manifested as acute azotemia often responsive to dose reduction, or as progressive CKD which is usually irreversible. In addition to symptomatic CKD, clinically silent glomerular disease has been described in HCV patients, primarily in those who underwent LTx due to chronic HCV. Here, the impact of an everolimus(EVR) facilitated CNI-sparing regimen on the evolution of renal function(RFct) in HCV patients post LTx is presented.

Methods: H2304 (NCT00622869) is a 24-month(M) international RCT. 719 de novo LTx recipients were 1:1:1 randomized to EVR(3-8ng/mL)+Reduced TAC(3-5ng/mL; EVR+rTAC, N=245) or EVR(6-10ng/mL)+TAC withdrawal (TAC-WD; N=231) at M4 or TAC-C(6-10ng/mL; N=243). Composite efficacy failure(tBPAR, graft loss or death) and RFct(eGFR) were assessed in the ITT and HCV population.

Results: Comparison of EVR+rTAC vs TAC-C is presented. Enrollment into TAC-WD arm was prematurely stopped due to higher tBPAR (16.5%). Patients were stratified for HCV viral status and eGFR leading to homogenous distribution of HCV patients (31.8/31.3%) and RFct at RDN. In the ITT population, composite efficacy failure at M12: 6.7 vs 9.7% (p=0.230) and BPAR: 4.1 vs 10.7% (p=0.005) for EVR+rTAC vs TAC-C. In HCV patients, efficacy failure was comparable for both arms, but fewer EVR patients had fibrosis progression. Mean eGFR in HCV patients at M6: 78.8 vs 69.9 mL/min and change in eGFR to M6: +0.7 vs -6.7 mL/min for EVR+rTAC vs TAC-C (Fig1). Complete M12/24 data will be presented.

Fig1: ΔeGFR to M6 in HCV patients post LTx



Conclusions: Early EVR-facilitated TAC reduction demonstrated comparable efficacy and superior renal function in HCV patients indicating that patients with HCV related nephropathy significantly benefit from treatment with mTOR inhibition, also suggesting lower rates of HCV related fibrosis compared to standard CNI treatment.

SA-PO953

Current Reduction in the Toxicity of Calcineurin Inhibitor on Protocol Allograft Biopsy during the Period of Two Decades (1990-2010) Ken Sakai, Yasushi Ohashi, Kentaro Tanaka, Sonoo Mizuiri, Atsushi Aikawa. *Nephrology, Toho University, Tokyo, Japan.*

Background: Calcineurin inhibitors (CNIs); the cornerstone of most immunosuppressive regimens in the past 20 years, have undesirable chronic effects. According to the improvement of therapeutic drug monitoring, we re-examined the frequency of CNI toxicity.

Methods: 1hour, 1year, 3year and 5year protocol biopsy was performed after kidney transplant (KTx) for all recipients in this institution. From 1990 to 1995, a total of 30 recipients underwent protocol biopsies up to 5years after KTx (1990's group). From 2000 to 2003, another 56 recipients underwent protocol biopsies up to 5 years after KTx (2000's group). Both of two groups took protocol biopsy completely and analyzed in this retrospective study. Anti CD25 antibody was used as an initial immunosuppressant only for 2000's group. Biopsy tissue was evaluated by Banff classification 1997. Newly appearance of Ah (arteriolar hyalinosis) score is defined as CNI toxicity.

Results: In 1990's group (13% for ABO incompatible KTx, 13% for secondary KTx, mean age 30.4±14.1yrs, donor 47.8±14.1yrs at KTx), Cv (intimal thickening) increased sequentially (0.22±0.44, 0.85±0.69, 0.83±0.75, 1.25±0.5 at 1hour, 1y, 3y, 5y respectively). Ah also increased sequentially (0, 0, 0.71±0.95, 1.0±0.81). In 2000's group (21% for ABO incompatible KTx, 7% for secondary KTx, mean age 32.8±18.4yrs, donor 52.1±12.6yrs), Cv remained constant (0.25±0.59, 0.22±0.48, 0.09±0.39, 0.16±0.25 at 1hour, 1y, 3y, 5y respectively) and Ah also remained constant (0, 0.08±0.28, 0.31±0.54, 0.17±0.31 at 1hour, 1y, 3y, 5y respectively). Serum creatinine (mg/dl) elevated more in 1990's group (1.15±0.35 to 1.31±0.62, P=0.02) during 5 years than in 2000's group (1.04±0.33 to 1.18±0.52, P=NS). Ah score was significantly higher at 5yrs after KTx in 1990's group than in 2000's group (P=0.03).

Conclusions: Contemporary use of CNI with CD25 antibody significantly reduced the CNI toxicity and improved graft function in this era.

SA-PO954

Cytomegalovirus Infection Rates Post Renal Transplant: 5 Years Single Centre Experience in United Kingdom Riaz Bavakunji, Jeetendra Ramesh Rathod, Linda Evans, Amanda J. Knight, Catherine Byrne. *Renal Transplant Unit, Nottingham University Hospitals NHS Trust, Nottingham, Nottinghamshire, United Kingdom.*

Background: To evaluate the overall incidence, severity and outcome of CMV infection after 100 days of prophylactic Valganciclovir. We also estimated cost and clinical effectiveness of 200 days prophylaxis.

Methods: Retrospective data of all incident lone-kidney transplant recipients and infections between 1.1.2006 to 30.6.2011.

Results: 290 lone-kidney transplants were performed in 285 recipients. Fifty six (19%) recipients were high risk CMV Donor+/Recipient–. All appropriate recipients received prophylaxis. Forty six recipients (16%) had CMV infection, regardless of sero-status. The mean age was 46 years. Nineteen of the 46 (41.3%) had late onset (>200days) CMV infection. Of these 11 (23.17%) recipients in this group were high risk. In the late onset high risk group (11 recipients) there were two episodes of biopsy proven acute rejection, both preceding CMV infection by several months. One patient had gastrointestinal haemorrhage. All except two, patients were treated with Valganciclovir. The average dose of valganciclovir was 900mg/day. The median treatment duration 51days. The average out-patient treatment cost with Valganciclovir was £2200 ($3451) In our high risk late onset there were no proven tissue invasive disease. There was one graft failure unrelated to CMV infection or no CMV related deaths. Renal function remained unchanged after treatment up to 3 yrs. If we were to extend our prophylaxis by a further 100 days for the 56 high risk recipients our estimated additional costs would be £ 121,072($189968) when the actual treatment cost was £32620 ($51182).

Treatment Cost Analysis

	Outpatient days	Inpatient days	Cost of treatment
Valganciclovir £43.24 ($66)	417	-	£18030 ($29289)
IV Ganciclovir £35.71 ($ 56)	107	20	£4535 ($7115)
IV Foscarnet £41.39 ($65)	-	40	£1655 ($2596)
Average Bed Tariff £210 ($329)	-	60	£8400 ($13180)
Total	549	35	£32620 ($51182)

Conclusions: Pre-emptive therapy and prompt immunosuppression reduction, as opposed to longer prophylaxis, is cost effective in our population and does not seem to cause any significant mortality or rejection.

SA-PO955

Outcome of Hepatitis B and C Virus Associated Hepatocellular Carcinomas Occurring after Renal Transplantation Nada Kanaan,[1] Claudia Raggi,[1] Eric Goffin,[1] Ziad Hassoun.[2] *[1]Nephrology, Cliniques Universitaires Saint Luc, Brussels, Belgium; [2]Gastroenterology, Cliniques Universitaires Saint Luc, Brussels, Belgium.*

Background: Chronic hepatitis B (HBV) and C (HCV) virus infections are causes of morbidity and mortality in kidney transplant recipients (KTR). Immunosuppressive agents enhance HBV and HCV replication, leading to decreased patient survival due to progressive liver disease, including cirrhosis and hepatocellular carcinoma (HCC). The aim of this study was to assess the incidence and outcome of HCC in KTR.

Methods: We performed a case-control study in patients with chronic HBV and/or HCV infection who underwent kidney transplantation (KT) between 1976 and 2011 and subsequently developed HCC. Patients' characteristics and outcomes were compared to a control group of HBV and/or HCV positive patients with HCC matched for age and gender who did not have KT.

Results: Among 2944 KTR, 330 had hepatitis B and/or C. Fourteen developed HCC, an incidence of 4.24%. All patients were Caucasian, and 86% were male. Mean age at HCC diagnosis was 52.6 ± 2 years (53.2 ± 1.5 in controls, p = ns). Mean time between transplantation and HCC diagnosis was 16.7 ± 2.7 years. Six HCCs were related to HBV, 6 to HCV, and 2 to co-infection with HBV and HCV. Immunosuppressive therapy was comparable in HBV, HCV and HBV+HCV patients. All patients had corticosteroids. Sixty-four percent of patients received induction treatment and were on triple therapy. At diagnosis, 71% of patients met Milan criteria (65% in the control group, p = ns). Tumour characteristics and treatment modalities including surgical resection, chemoembolization, radiofrequency ablation, or liver transplantation were comparable between the two groups. Patient survival 2 years after HCC diagnosis was 43% in KTR, compared to 76% in the control group (p=0.03). There was no significant difference in overall survival between HBV- and HCV-infected KTR with HCC.

Conclusions: HCC occurs with an incidence of 4.24% in HBV and/or HCV infected patients after KT. Survival after HCC diagnosis is significantly worse compared to a control group of non-transplanted patients with HBV and/or HCV, matched for age and gender, and with similar tumour characteristics.

SA-PO956

Renal Allograft Outcomes in Recipients with BKVN Diagnosis Using Combination IVIG and Leflunomide Therapy Jun B. Lee,[1] Surya Seshan,[3] Lisa Walters,[1] Choli Hartono,[1] Thangamani Muthukumar,[2] David Serur,[1] Manikkam Suthanthiran,[2] Darshana Dadhania.[2] *[1]Nephrology, Rogosin Institute, New York, NY; [2]Nephrology, Weill Medical College of Cornell University, New York, NY; [3]Pathology, Weill Medical College of Cornell University, New York, NY.*

Background: BKV Nephropathy (BKVN) is associated with greater than 50% risk of graft loss. The cornerstone of management is reduction in immunosuppression. In 2005, we initiated a standard treatment protocol using IVIG and leflunomide with discontinuation of MMF and reduction of tacrolimus to troughs of 3-5ng/dL (ILTR). Here we evaluated the impact of this therapy on one of the largest cohort with biopsy proven BKVN diagnosis.

Methods: We performed a retrospective review of individuals with biopsy proven BKVN transplanted at our center between 5/1998 and 5/2010 and evaluated the impact of ILTR therapy and other risk factors on graft outcomes.

Results:

Table 1

	No ILTR Rx (N=16)	ILTR Rx (N=31)	P value
Age (mean±SD)	46 ±14	55 ±14	0.05
Gender (% Female)	8/16 (50.0%)	6/31 (19.4%)	0.03
Post Tx Month (mean±SD)	17 ±14	14 ±14	0.8
Living Donor Tx (%)	6/16 (37.5%)	14/31 (45.2%)	0.6
ATG Induction (%)	4/16 (25.0%)	27/31 (87.1%)	<0.001
Steroids Maintenance (%)	12/16 (75.0%)	14/31 (45.2%)	0.05
Baseline Creatinine (mean±SD, mg/dL)	1.5 ±0.5	1.6 ±0.5	0.5
Creatinine at Time of BKVN (mean±SD, mg/dL)	2.5 ± 0.8	2.5 ±1.1	0.4
Steroids Rx (%)	4/16 (25.0%)	4/31 (12.9%)	0.3
IVIG Rx (%)	7/16 (43.8%)	31/31 (100%)	n/a
Leflunomide Rx (%)	3/16 (18.8%)	31/31 (100%)	n/a
Graft Loss (%)	10/16 (62.5%)	11/31 (35.5%)	0.08
Median Time to Graft Loss (months)	33	37	0.5

We found a trend towards lower graft loss in those treated with ILTR therapy. A multivariate logistic regression model with stepwise backward elimination found treatment with ILTR therapy (P=0.08) and lower serum creatinine at time of BKVN diagnosis to be protective against graft loss (P=0.03) independent of age, gender, induction and steroid therapy. However, time to graft loss was not different between the ILTR group and the No ILTR group.

Conclusions: Combination therapy with IVIG and leflunomide may be associated with decreased risk of graft loss. Prospective randomized study using this combination therapy and stratification by serum creatinine level at time of biopsy is warranted.

SA-PO957

Assessment of Anti-HLA Antibody Production in Pediatric Renal Transplant and Dialysis Patients with the H1N1/Influenza A Combination Vaccine Vaishali Bansilal,[1] Gail Prado,[1] Morris J. Schoeneman,[1] Anil K. Mongia,[1] Bandana Paudyal,[1] Valeriya M. Feygina,[1] David Hochman,[2] Allen J. Norin,[2] Hanan K. Tawadrous.[1] *[1]Div. of Pediatric Nephrology, Dept. of Pediatrics, SUNY Downstate Medical Center, Brooklyn, NY; [2]Transplant Immunology and Immunogenetics, Dept. of Cell Biology, SUNY Downstate Medical Center, Brooklyn, NY.*

Background: Pediatric patients (pts) with ESRD who are on dialysis and awaiting for transplant, and transplanted kidney pts are immunosuppressed. It is recommended that such pts receive yearly vaccinations with the influenza A/H1N1 preparation. The immunogenicity, safety and tolerability among pediatric transplant pts for influenza A vaccines have been previously reported. Similar data is not available for dialysis pts, especially those who have been lost their renal allograft.

Methods: The aim of this study is to investigate the immunogenicity of influenza A/H1N1 given to pediatric pts with ESRD on dialysis (D) and with kidney transplant (T), and whether there is an increase in anti-HLA antibodies secondary to vaccination. 21 pediatric pts were enrolled. Mean age was 15.5 years old, 29% female, 71% male, 57% African American, 29% Hispanic. They were divided into 2 groups;12 pts with ESRD on dialysis, 4/12 with previous history of kidney transplant (D), and 9 kidney transplant recipients with good graft function (T). All subjects were tested for anti-HLA antibody 1 month prior to vaccination, and 1 month and 6 months afterwards.

Results: Among the T group, no pt tested positive for either anti-HLA class I or class II before or after Flu A/ H1N1 vaccine. In the D group, 4 pts with a previous history of graft failure were mildly sensitized before immunization; 2 showed no change in class I & II, one patient had mild increase in class I after vaccination, and one patient had an increase in class I by 24%.

Conclusions: None of the the T pts had either cell mediated or humoral rejection secondary to Flu A/H1N1 vaccine. In the D group, no pt had evidence of anti–HLA antibody following vaccination. Our study suggests that influenza A/H1N1 vaccination may be immunogenic, safe and tolerable in pediatric dialysis pts with or without a failed kidney allograft.

SA-PO958

Use of Tenofovir Did Not Negatively Impact Long-Term Graft Function in HIV (+) Kidney Transplant Recipients Gregory Malat, Dwight M. Matthew, Karthik M. Ranganna, Alden Michael Doyle. *Department of Nephrology, Drexel Medicine, Philadelphia, PA.*

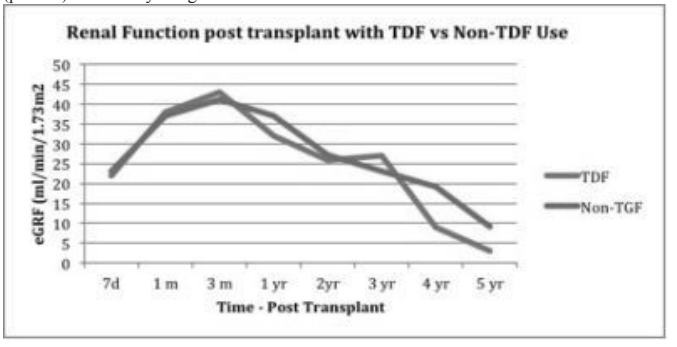
Background: Dosing calcineurin inhibitors in HIV(+) kidney transplant recipients (KTR) is difficult secondary to the drug interactions noted with concurrent HAART medications. Tenofovir (TDF) is not metabolized through the same CYP3A enzyme, but has been reported to cause nephrotoxicity in non-transplant patients. Whether TDF would have similar deleterious effects on kidney allograft function is not known. Herein, we report the first long-term experience with HAART regimens including TDF in HIV(+) KTR.

Methods: Drexel has performed 98 HIV(+) KTR since 2001. We divided the patients into 2 groups, HAART +TDF (TDF) vs. HAART without TDF (nonTDF), and analyzed long-term kidney function (~5 years).

Results: The demographics were generally comparable in both groups.

Demographic	TDF (n=21)	nonTDF (n=77)	p-value
Recipient			
Male	81%	87%	0.49
African American	62%	92%	0.00
Age, years	48 (28-62)	48 (22-71)	0.23
Donor			
Male	62%	58%	0.81
African American	19%	23%	0.78
Age, years	27 (7-60)	42 (2-76)	0.05
CVA	10%	45%	0.00
Hypertension	14%	33%	0.11
Deceased Donor	90%	91%	1.0
Terminal creatinine>1.5mg/dL	33%	32%	1.0
Cold Ischemia Time	15 (0-29)	15 (0-33)	0.59
Post-operative Characteristics			
Delayed Function	62%	60%	1.0
ACR (cumulative)	48%	77%	0.02
ACR (< 1 year)	42%	62%	0.20

The incidence of delayed function was similar in both groups. The nonTDF group had a statistically higher incidence of cellular rejection (ACR). This result was cumulative, and was not seen early post-transplant (< 1 year). Both groups had comparable graft survival (p=0.41) and kidney allograft function.



Conclusions: When HIV(+) KTR who received TDF as part of their HAART were compared with those who did not, we found that both groups had similar long-term kidney survival/function. We therefore suggest that use of TDF in HIV(+) KTR is safe when dosed appropriately.

SA-PO959

Characterization of EBV Infections in Children and Adolescents Post-Renal Transplant Nilka deJesus-Gonzalez, Isa F. Ashoor, Deborah R. Stein, Michael J. Somers. *Nephrology, Boston Children's Hospital and Harvard Medical School, Boston, MA.*

Background: EBV infections(infx) are common after pediatric renal transplants(Tx). Whether the impact and complications are different in asymptomatic vs. symptomatic EBV infx is uncertain.

Methods: We characterized the spectrum of EBV infx in pts <18yo who underwent Tx at our center over a 9-yr period. Post-Tx EBV infx was defined as >25K EBV DNA copies/ml by PCR. We ascertained post-Tx primary EBV infx or EBV reactivation incidences, episodes of acute rejection(AR) and PTLD, modifications in immunosuppression and eGFR changes during EBV viremia.

Results: In 158 pts evaluated, median age was 11yo(IQR,4-16yo), 52% boys, 48% LD recipient. 41% of recipients were EBV seropositive(+) at Tx while 92% of donors were EBV+. 97% of EBV+ recipients received an EBV+ donor graft. 57/158 pts had an EBV infx at a median of 8mo after Tx(4-19mo); 42/57 manifested a primary EBV infx with 44% having clinical symptoms. Median peak EBV copies was 178,500/ml(55,500-500K). 45/57 pts who developed EBV post-Tx were on antiviral prophylaxis. Immunosuppression was reduced in 21/57 pts who developed EBV infx. In 52/57 pts, EBV amplification turned negative in 28days(11-87days). In the 5 pts with persistent EBV viremia, median EBV copies of 80K/ml (14K-244,500 copies/ml) were found at last f/u of median 52days of EBV+ (8–648days). Children <5yo had a lower EBV+ at the time of Tx and higher incidence of EBV infx postTx compared to older children. During EBV viremia, mean eGFR was 83ml/min/1.73m2 (±43) and decreased to 66ml/min/1.73m2 (±45) on their last

f/u(p<0.0001). There were also 6 cases of AR during EBV viremia compared to 0 cases in EBV- pts(p=0.007). 10 of 57 EBV viremic pts developed PTLD vs. 1 of 101 EBV-pts(p=0.009). PTLD developed in 0-7.5mo post-infx with median EBV copies of 55,200/ml at diagnosis(40,500-292Kcopies/ml).

Conclusions: 1. 1/3 of pts developed EBV infx, despite the majority being on prophylaxis. 2.Post-tx EBV infx was more likely in younger pts, most of them having a primary infx rather than EBV reactivation. 3.Immunosuppression reduction led to EBV infx remission in most pts. 4.Pts with post-Tx EBV infx had higher incidence of PTLD and AR.

SA-PO960

Risk Factors and Outcomes of Acute Graft Pyelonephritis Prem P. Varma, Ashok Kumar Hooda, Sonia Badwal. *Department of Nephrology, Army Hospital (Research & Referral) Delhi Cantt-10, New Delhi, Delhi, India.*

Background: Acute graft pyelonephritis (AGPN) is a common post transplant complication which can result in acute graft dysfunction. Since the diagnosis is largely clinical, there is conflicting data on short and long term graft outcomes. Aim: To prospectively follow biopsy proven cases of AGPN for graft outcome.

Methods: All patients transplanted between 2002 and 2007 at our centre were followed for graft dysfunction. Anyone with graft dysfunction underwent an allograft biopsy, even if the diagnosis was apparent clinically. Diagnosis of AGPN was made by presence of neutrophilic infiltrate in the interstitium/ and/or neutrophilic casts in the tubules. AGPN was classified as "Early" if it occurred within 6 months post transplant and "late" if it occurred after that. Risk factors for AGPN were analysed. Each episode of AGPN was treated with 4-6 weeks of antibiotics. Individuals with concomitant acute rejection were given anti rejection therapy with steroids after 3-7 days of antibiotics if the graft dysfunction persisted. All patients with AGPN were given prophylactic antibiotic cover for the next 6 months and were followed for graft outcomes. SPSS 11 was used for statistical analysis.

Results: Over a mean follow up period of 30.9 months, 110 of 265 patients developed graft dysfunction. 26 (10%) had evidence of graft pyelonephritis; 9 "early" and 19 "late" AGPN. Seven had evidence of concomitant acute rejection. HCV infection was the only significant risk factor for AGPN (p= 0.03), while immunosuppression, rejection, stent placement etc did not show any significance. After a median follow up 14.6 months both early and late AGPN had poor outcomes with significantly higher Creatinine values (p=0.02 for early and p<0.01 for late AGPN) as compared to the immediate post treatment value. Those with concomitant acute rejection did not fare any better despite anti rejection therapy. 75% of patients relapsed requiring repeat courses of antibiotics.

Conclusions: AGPN is an important cause of graft dysfunction, which frequently precipitates acute rejection. The presence of HCV infection was found to be a risk factor for development of AGPN. Outcome of both early and late AGPN was observed to be poor.

SA-PO961

Long-Term Outcome of HCV-Associated *Versus* Non-HCV-Associated Glomerulonephritis after Renal Transplantation Laura Garcia-puente Suarez, Esther Gonzalez Monte, Natalia I. Polanco Fernandez, Manuel Praga, Amado Andres, J. Morales. *Nephrology Department, Hospital 12 de Octubre, Madrid, Spain.*

Background: Many studies have described the worse progression over time of hepatitis C virus (HCV) associated nephropathies, however there isn't much information available on the evolution of HCV-associated glomerulopathies in the renal transplant on subjects with active HCV infection. We collected a series of membranous and membranoproliferative glomerulopathies (MGN and MPGN respectively) which either recurred or appeared *de novo* in our transplant population and tried to define whether HCV influenced progression towards end-stage renal failure.

Methods: Single-center, observational study of subjects with biopsy proven MPGN or MGN which either recurred or appeared *de novo* after renal transplantation. Two groups were designed according to the coexistence of HCV infection.

Results: 44 patients were collected with the following demographic characteristics: 9 female *vs* 35 male, mean age 50.2 ± 13.8 years, 45.4% presenting MGN and 54.5% MPGN, and 50% being HCV positive. We analysed the evolution of renal function over time measured as serum creatinine in mg/dl (sCr), the amount of 24-hour proteinuria developed over time (24-h Prot), the long-term allograft survival, censored graft survival and patient survival.

Characteristics of study group

	HCV positive	HCV negative
Number of patients	22	22
Mean age (years)	48.09 ± 11.1	52.32 ± 16
Gender (M/F)	18/4	17/5
Mean basal sCr (mg/dL)	1.45 ± 0.43	1.47 ± 0.37
Mean final sCr (mg/dL)	4.18 ± 2.09	3.9 ± 2.55
Median basal 24-h proteinuria (g/L)	0.4 (0-1.8)	0.52 (0-2.5)
Median final 24-h proteinuria (g/dL)	2.9 (0.10-17)	3.9(0.1-12)
Mean allograft survival (months)	39.11 (3-125)	42.04 (3-144)

p<0.05 for all demographic characteristics analysed

There were no differences between the mean final sCr or the median final proteinuria of both groups. Kaplan-Meier overall survival analysis was the same for both groups.

Conclusions: In our group of patients the diagnosis of MGN or MPGN in the kidney allograft led to rapid worsening of the real function, and end-stage renal disease in most subjects although the presence of HCV infection did not result in a worse evolution over time.

SA-PO962

Urinary Tract Infections in Renal Transplant Recipients: Does Prophylaxis Prevent? Fatima Khalid, Syed Hassan, Hasan Zahid, Sarim Rashid, Tamim Hamdi, Waqas Qureshi. *Henry Ford Hospital.*

Background: Symptomatic urinary tract infections(UTI)are common in renal transplant(RT)patients. Scarce data is available about the risk factors and outcomes of symptomatic UTI in patients on antibiotic prophylaxis. The aim of this study is to analyze these features in renal transplant patients during first year post–transplant.

Methods: Consecutive patients(n=490)that underwent RT at our institute from 2008-2011 were evaluated retrospectively.227 patients were placed on prophylactic antibiotics which were included in the final analysis. Symptomatic Urinary tract infection(UTI) was defined as:presence of signs and symptoms of infection with≥10^5CFU/ml of bacteria. Urinary frequency,urgency,dysuria, suprapubic pain,flank pain,fever,chills and pain over the graft site were considered symptoms. Primary outcomes were graft failure and death within 1 year. Results were computed using univariate and multiple logisitic regression analysis.

Results: Out of 227-RT patients on antibiotic prophylaxis,102 patients developed asymptomatic and 27 developed symptomatic UTIs in the first year. Symptomatic UTI was associated with ESBL positive bacteria in 14 patients(51.8%) and E. coli in24(88.8%). Polymicrobial infections were frequently associated with symptoms17(62.9%). Symptomatic UTI was associated with diabetes,female gender,deceased kidney donors,CMV infection,longer cold ischemia time(16.7±6.8hours)and early graft loss(OR1.7;95% CI 1.1-2.9,p=0.02)but not with acute rejection or death. Previous hospitalization within 30 days with UTI was not a predictor of symptomatic UTI(p=0.319).Most common symptoms were fever in19(70.3%)patients,dysuria in16(59.2%),frequency and urgency in6(22.2%), while only 2(7%)had graft tenderness. Most of the patients had imaging characteristics of pyelonephritis25(92.5%).

Conclusions: In patients on antibiotic prophylaxis, it seems that there is still a significant incidence of symptomatic UTI and prophylactic antibiotics do not improve outcomes regarding graft loss. A recent UTI is not a predictor of recurrent UTI in these patients so there is less role of nosocomial infections in this group of patients but more of community acquired infections.

SA-PO963

Dapsone Induced Methemoglobinemia: Increased Prevalence in a Cohort of Renal Transplant Recipients Nicos Mitsides, Darren Green, Rachel Middleton, David I. New, Elizabeth H. Lamerton, Jude Allen, Jane Redshaw, Paul Chadwick, Chinari Pradeep Kumar Subudhi, Grahame Wood. *Salford Royal Hospital, United Kingdom.*

Background: Dapsone is the commonest cause of drug-induced methemoglobinemia (MHb). The prevalence of MHb in patients on dapsone is reported to be up to 20%. Following an outbreak of pneumocystis pneumonia (PJP) in our tertiary nephrology unit, dapsone 50-100mg daily was used as second line chemoprophylactic agent. Because dapsone is renally excreted, we hypothesized that the rate of MHb would be even higher in this CKD population. We also aimed to describe the demographics, risk factors and presenting features of MHb in these patients.

Methods: This was a case series of 26 consecutive transplant recipients commenced on dapsone for chemoprophylaxis against PJP from February to September 2011. All patients had negative Glucose-6-phosphate dehydrogenase levels prior to treatment. Measurement of MHb level was triggered either by symptoms or drop in serum hemoglobin (Hb) and cases were diagnosed based on elevated levels (>1.5%). MHb patient characteristics were compared against the rest of the cohort to determine potential risk factors.

Results: Of the 26 patients, 46% developed MHb (MHb levels 6.4±4.1%). 50% of cases were symptomatic on presentation, with breathlessness most common (33.3%). Cases had a mean drop in Hb of 19±7.0%. Hb drop was associated with low serum albumin (correlation coefficient [cc] -0.805, p=0.002) and baseline Hb (cc -0.715, p<0.001). MHb led to 5 admissions (median length of stay, 5 days, range 1-10 days) with MHb level showing a strong correlation with length of stay (cc 0.762, p=0.002). 17% of cases required blood transfusion, 17% had computed tomography of the Chest and 8% had bronchoscopy. Following the high number of adverse reactions, the use of dapsone as chemoprophylaxis was stopped.

Conclusions: This is the highest reported prevalence of MHb in patients receiving dapsone and its use led to significant morbidity in this renal transplant population. This study raises concerns to its use as chemoprophylaxis in this setting. As half the cases were asymptomatic on diagnosis, we recommend MHb levels be measured routinely in all patients.

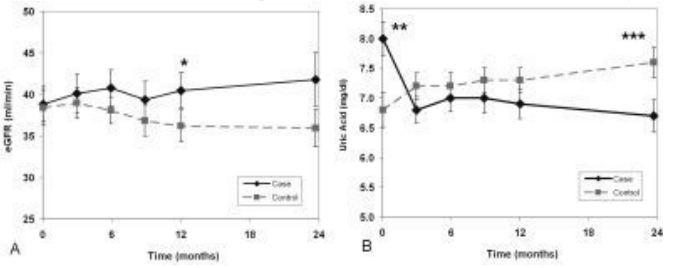
SA-PO965

Effect of Allopurinol in Slowing Allograft Functional Decline in Kidney Transplant Recipients Bhargavi Tangirala, Liliana Osadchuk, Muhammad H. Bashir, Richard J. Marcus, Sabiha M. Hussain, Khaled Nashar, Kalathil K. Sureshkumar. *Division of Nephrology and Hypertension, Allegheny General Hospital, Pittsburgh, PA.*

Background: There is some evidence that hyperuricemia may increase risk for allograft functional decline and the development of chronic allograft nephropathy in kidney transplant recipients (KTR). We aimed to explore any potential beneficial effects of allopurinol in KTR.

Methods: A retrospective chart review of KTR at our institution from 2003-2008 was performed to identify patients on allopurinol (cases), who were then matched with controls based on the time of transplant (±3 months) and estimated GFR (eGFR; ±10 ml/min). Serum uric acid (UA) levels, eGFR, blood pressures (BP), dipstick proteinuria (grade 0-4) and graft loss were compared between the groups.

Results: Out of 428 KTR,54 cases and 54 controls were identified. At the start of allopurinol, mean serum UA level (mg/dl) was 8.0±2.0 vs. 6.8±2.1 (p=0.001) and eGFR was 38.8±15.5 vs. 38.4±15.5 (p=0.64) for cases vs. control groups. Serum UA level was significantly lower at 2 years (6.7±1.7 vs. 7.6±1.6, p=0.02) and eGFR significantly higher at 1 year (40.5±15.2 vs. 36.2±13.4, p=0.04) for cases vs. controls as observed in the figure.



*p=0.04,**0.001,***0.02.

Proportion of patients on cyclosporine A (CsA), BP, proteinuria at 1 year, graft loss at 3 years were similar in both groups as shown in the table.

outcome	Case(n=54)	Control(n=54)	p-value
Graft loss(n)	3	8	0.11
% on CsA	39	42	0.51
Proteinuria(0-4)	0.23±0.77	0.23±0.60	1.00
SBP(mm Hg)	136±20	134±16	0.76
DBP(mm Hg)	75±11	73±10	0.67

Conclusions: Our study showed a potential beneficial effect of allopurinol in preserving eGFR in KTR. This could be related to allopurinol's ability to ameliorate the harmful effects of hyperuricemia such as oxidative stress, endothelial dysfunction, proinflammatory and proliferative actions.

SA-PO966

Osteoporosis after Renal Transplantation Siren Sezer,[1] Emre Tutal Tutal,[1] Mehtap Erkmen Uyar,[1] Zeynep Bal,[1] Bahar Gurlekdemirci,[1] Firdevs Tugba Bozkurt.[2] *[1]Nephrology, Baskent University, Ankara, Turkey; [2]Internal Medicine, Baskent University, Ankara, Turkey.*

Background: By the improvement of long-term patient and graft survival after renal transplantation,post transplantation complications gained importance. The restoration of vitamin D synthesis, clearance of phosphate, and reduction of parathyroid hormone (PTH) levels decreases bone loss but on the other hand, osteoporosis still remains as an important problem due to steroid use, persistent hyperparathyroidism in some cases and other disturbances. In this present study, we investigated the effects of renal function and antropometric measurements on bone mineral density in renal transplant recipients.

Methods: 103 renal transplant recipients (34 female, age, 35.9 ± 9.3 years) with bone mineral densitometer (BMD) analysis at the end of post-transplant 1 year were included in the study. BMD (femoral neck) were measured by dual-energy X-ray absorptiometry (DEXA).Body compositions were analyzed by using the Body Composition Analyzer (Tanita BC-420MA). Laboratory tests including creatinine, GFR, albumin, CRP, calcium, phosphorus, PTH, hemoglobin levels at the end of first post transplantation year were retrospectively collected. Patients were grouped according to femoral neck t scores as osteoporotic (n: 34, t score < -2) and normal (n: 69) BMD patients.

Results: Female gender was more common in osteoporosis group (%52 vs %23, p: 0.003). Glomerular filtration rate of osteoporotic patients were significantly lower (65.4 ± 28.2 vs 79.4 ± 22.8 ml/min, p: 0.03). We found that osteoporotic patients had lower waist-hip ratios, sagittal abdominal diameters, body mass index, fat mass, visceral fat ratio, muscle mass and degree of obesity (p: 0.0001). A correlation analysis revealed that femur t score was positively correlated with glomerular filtration rate (r:401, p: 0.002), body mass index (r:.427, p: 0.001), fat mass and visceral fat ratio (r:.361, 446 respectively, p: 0.001), and negatively correlated with PTH level (r: -.370, p: 0.008).

Conclusions: Our results indicate that better graft function improves bone mineral disease and prevents post transplantation osteoporosis despite of corticosteroid usage in renal recipients.

SA-PO967

Delays as an Indicator of Dysfunctional Systems and Processes in Kidney Transplantation Daniela Ladner, Olivia A. Ross, Pamela H. Sharaf, Kathleen R. Hoke, Krutika Lakhoo, Anton I. Skaro, Elisa J. Gordon, Amna Daud, Donna Woods, Michael Abecassis, Jane Holl. *NU Transplant Outcomes Research Collaborative, Northwestern University, Chicago, IL.*

Background: Kidney transplantation is a complex procedure involving multidisciplinary teams, which can unveil OR system and process failures. To assess safety vulnerabilities, a proactive Failure Modes Effects Analysis (FMEA) was performed.

Methods: FMEA participants included transplant nurses, anesthesiologists, surgeons, technicians, and students. A process map was created by observation and FMEA. System and process failures and causes were identified. Frequencies and potential consequences were assigned. Failure causes were coded applying Joint Commission root cause categories.

Results: 10 FMEA sessions (17 participants) and 12 observations identified 82 steps, beginning with OR set up and ending with patient transfer from OR. 155 system and process failures were identified, with 203 total potential consequences grouped into 7 types (Table 1).

Failure Mode Consequences

Consequence Type	n (%)	Examples
Delay	49%	Waiting for lab results, OR supplies not available
Wasted resources	19%	Incorrect supplies opened, Contamination of central line kit
Injury to patient	14%	Incorrect positioning leading to neuropraxia, Omitted antibiotics leading to infection
Poor teamwork	8%	Telephones/pagers interrupting care, Unprofessional behavior leading to frustration
Risk to personnel	4%	Uncovered cords leading to falls, Inappropriate disposal of sharps leading to injury
Suboptimal care	4%	Oversedation, Critical information missed during timeout
Incomplete/Inaccurate Documentation	2%	EMR not available, incomplete recording of urine output

Nearly half of process failures result in delay. Types of causes leading to delays were: Human Factors (57%), Leadership (20%), Physical Environment (18%), and Communication (5%).

Conclusions: Despite their frequency, delays are often ignored as an accepted part of patient care. Causes of delays offer insight into existing systems and process vulnerabilities. FMEA findings can support proactive systems and process re-designs to reduce human error and improve and standardize communication, care planning, and leadership.

SA-PO968

Effect of a Multifactorial Intervention with the Aid of Nursepractitioners on Cardiovascular Outcome in Kidney Transplant Recipients Arjan D. Van Zuilen,[1] Michiel Bots,[2] Peter J. Blankestijn,[1] Jack F. Wetzels.[3] *[1]Nephrology, UMC Utrecht, Netherlands; [2]Julius Center, UMC Utrecht, Netherlands; [3]Nephrology, Radboud University Medical Center Nijmegen, Netherlands.*

Background: The MASTERPLAN study evaluated if implementation of current guidelines with aid of a nurse practitioner improved cardiovascular outcome in patients with chronic kidney disease(CKD). Despite small but significant improvements of blood pressure(BP), LDL-cholesterol(LDLc) and proteinuria in the intervention group(IG), no differences in the primary outcome were observed. We performed a post hoc analysis in prevalent transplant recipients that participated in the study.

Methods: MASTERPLAN is a randomized controlled clinical trial, performed in nine Dutch hospitals. 788 patients with CKD (eGFR 20-70 ml/min/1.73m2) were randomised to either receive care by the nephrologist (CG) or intensified care with nurse practitioner support(IG). At baseline stratification on transplantstatus was performed. Both groups were subject to identical guidelines. Patients were followed for a median of 4.8 yrs. The primary endpoint was a composite of myocardial infarction, stroke and cardiovascular death. Also changes in quality of care of cardiovascular risk factors were evaluated.

Results: We analysed 110 transplant recipients (66M), age 51 (12) yrs, eGFR 40(13) ml/min/1.73m^2. Mean follow-up after transplantation 7.5 (5.4) years. The intervention resulted in significantly lower diastolic BP 77 vs 81 mmHg (p=0.006), no significant differences were noted for systolic BP, LDLc, proteinuria, smoking cessation, body weight, physical activity or sodium excretion. The primary outcome occurred in 33.1/1000py in IG and in 25.2/1000py in CG (HR 1.33; 95%CI 0.46 to 3.84). Incidence of ESRD was 39.1 vs 38.6/1000py (HR 0.99; 95%CI 0.39 to 2.49). There were no adverse consequences associated with the intervention.

Conclusions: In this subgroup of 110 patients only diastolic BP is significantly better in IG than in CG. For all other factors direction of difference was similar to the main study, however no statistical significant changes were found. The intensified treatment did not significantly reduce the rate of the composite endpoint or the rate of ESRD.

SA-PO969

Vitamin D Deficiency in Renal Transplantation Is Not Associated with Graft Fibrosis Kristin Vibeke Veighey,[1] David C. Wheeler,[1] Anne B. Dawnay,[2] Francis Lam,[2] Martyn Egerton,[3] Alexander J. Howie,[1] Mark Harber,[1] Aliyye Karasu,[1] Cono A. Ariti,[4] John Cunningham.[1] *[1]UCL Centre for Nephrology; [2]UCLH; [3]Epsom General Hospital; [4]LSHTM.*

Background: Vitamin D deficiency is endemic in CKD patients undergoing kidney transplantation and may contribute to increased ischaemia-reperfusion injury and graft fibrosis. We postulated that patients deficient in 25-hydroxyvitamin D (25OHD) and/or 1,25-dihydroxyvitamin D (1,25OH_2D) would therefore have increased fibrosis on subsequent protocol biopsies.

Methods: 103 patients (53% White, 22% Black, 15% Asian, 3% Mixed, 7% other) transplanted between 2008-11 had protocol biopsies at 6 (t6) and 52 weeks (t52) and had stored pretransplant serum available. None received supplemental vitamin D at transplantation, 47% were supplemented thereafter. Serum 25OH D2/D3 and total 1,25OH_2D levels were quantified by mass spectrometry and enzyme immunoassay respectively. Fibrosis was quantified using a validated index of chronic damage (ICD) measurement (%). Linear regression was used to assess associations between 25OHD/1,25OH_2D and: 1). ICD at t6 and t52, 2). MDRD eGFR at 1 year.

Results: At transplantation, 80% were 25OH vitamin D deficient (<75nmol/l), including 60% of Asian patients. In 94%, 25OHD2 was below the assay range. 1,25OH_2D levels were subnormal in 60% (80% Asians) and normal (40-150pmol/l) in the remainder. 25OHD levels did not predict 1,25OH_2D levels (r =-0.04 p=0.689). 68% of those replete in the former were deficient in the latter. 1,25OH_2D was not significantly higher in those receiving 1alphacalcidol (45 vs 38pmol/l). At t52 sera were available from 37 patients. Of those

supplemented, (cholecalciferol 20,000iU/wk) 92% became vitamin D replete (>75nmol/l). Despite adjustment for cold ischemic time, donor age, and recipient diabetes, there was no association between vitamin D metabolites and ICD at either t6/t52, or eGFR at 1 year.

Conclusions: Only 20% of CKD patients were vitamin D replete at transplantation. 25OHD2 status had little bearing on overall D status. Oral supplementation effectively repleted 25OHD. There was no association between vitamin D status and chronic damage on protocol biopsies or eGFR.

Funding: Pharmaceutical Company Support - Abbott

SA-PO970

Assessment and Management of Chronic Pain InRenal Transplant Patients
Rosa Sanchez, Juan Pablo Leiva, María José Fernández-reyes, Manuel M. Heras, Alvaro Molina Ordas, Maria Astrid Rodriguez Gomez, Fernando Alvarez-Ude, Carmen Centeno. *Nephrology, General Hospital Segovia, Segovia, Spain.*

Background: Little is known about chronic pain and long-term impact on renal transplantation (RT). We studied the prevalence of pain, clinical and psychological risk factors associated, treatment and analgesic response in recipients of RT.

Methods: Prospective, transversal in 101 TR. Variables were analyzed clinical, laboratory and radiological weapons. We used the following scales: Brief Pain Inventory-Short Form (BPI-sf), Hospital Anxiety and Depression Scale (HADS), Short Portable Mental Status Questionnaire (SPMSQ) and Palliative Performance Scale (PPS). Statistical analysis SPSS 18.0.

Results: Mean age of 59.3 years. 65.3% men and 46% (N = 47) of the population had pain. Of these, 74% (N = 35) noted pain in more than two locations, the average of the highest intensity of pain is 7/10 points, the lowest average intensity 4/10. 25% (N=12) had previously prescribed analgesia and reported relief an average only 30%. Anxiety was found 14% (N= 7) and 8% depression (N= 4). 88% of patients had between 90-100 points in the PPS. 96% of the population had no cognitive impairment. Pain patients show a higher incidence of bone loss (BL), digestive disease and greater use of steroids. In the study univarientes confirm a correlation between pain and: use of steroids and calcineurin inhibitors ($p<0.0001$ and $p=0.027$ respectively), BL ($p=0.000$) gastrointestinal disease ($p=0.032$). In multivariate analysis with correction for age, sex, and years of transplantation the only factors that independently correlated with pain were quantified steroids (ExpB: 9.171, CI: 2.602 to 32.328, $p=0.001$) and osteoporosis (ExpB: 6.527, CI: 2.049 to 20.788, $p=0.002$). Importantly, pain occurred in patients regardless of stage of disease. No relationship was found between pain and laboratory parameters examined, duration of hemodialysis years, and transplant years evolution.

Conclusions: About half of patients with RT have chronic pain, mainly associated with steroids and BL. The transplant patient's functional capacity is excellent despite the pain. Analgesic treatment in this population is underutilized.

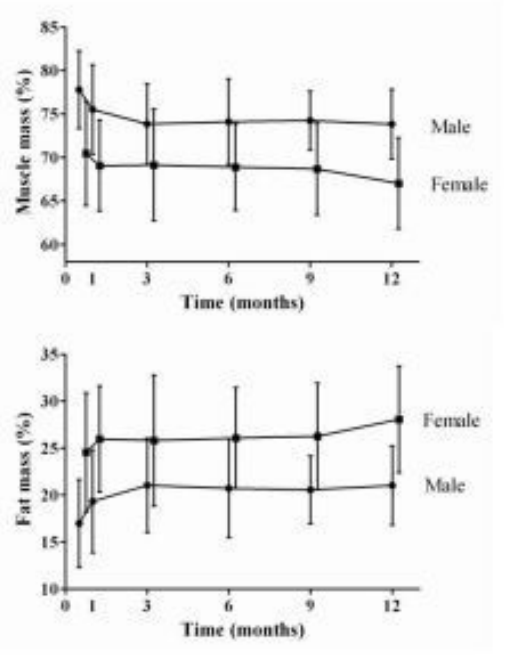
SA-PO971

Change in Body Compositions of Asian Recipients after Kidney Transplantation
Seung Seok Han, Curie Ahn, Yon Su Kim. *Internal Medicine, Seoul National University College of Medicine, Seoul, Korea.*

Background: Kidney transplantation and accompanying medical conditions may result in changes in body composition. Such changes have been evaluated in Caucasian recipients, but not in Asian recipients. Herein, we conducted a study on Asian recipients because Asians have a different body composition from Caucasians.

Methods: A total of 50 Asian recipients (M : F, 24 : 26; body mass index, 21.8 ± 2.6 kg/m^2) were enrolled as a prospective cohort. Using bioelectrical impedance analysis, body composition (muscle and fat mass) was assessed after 2 weeks (baseline), and at 1, 3, 6, 9, and 12 months following kidney transplantation. To find predictors related to changes, the data were analyzed by multivariate analysis using forward selection.

Results: All of the patients had good graft function during the study period (last serum creatinine, 1.16 ± 0.28 mg/dL). Patients gained approximately 3 kg within 1 year of kidney transplantation. The proportion of muscle mass significantly decreased (P trend = 0.001) and the proportion of fat mass significantly increased over time (P trend = 0.002).



The multivariate results revealed that male recipients, deceased donor type, and low protein intake were associated with an increase in fat mass and a decrease in muscle mass.

Conclusions: The results from this study may help to investigate differences in body composition changes between races, as well as the factors related to these changes.

SA-PO972

Cholecalciferol Supplementation Reduces Proteinuria and Parathormone in Kidney Transplant Patients
Ines Aires, Manuel A. Ferreira, Fernando Barbosa Nolasco. *Nephrology and Transplantation, HCC, Lisbon, Portugal.*

Background: Native vitamin D (25-OH vitD) levels are frequently reduced in chronic renal failure patients (pts). Less is known in the kidney transplant (KTx) population. Chronic kidney disease-mineral and bone disorder (CKD-MBD) is common in KTx pts but frequently underlooked.

Methods: We prospectively evaluated the effects of 1 year cholecalciferol supplementation, in 133 KTx pts, 84 men, mean age 54.4±13 years, 34 diabetic, mean post KTx follow up 80.6±64.9 months. All pts were naïve to 25-OH vitD therapy. Immunosuppression was based in calcineurin inhibitors in 79% and sirolimus in 21% pts.

Pts were supplemented accordingly to basal (T0) calcidiol serum levels (SerL): deficiency (<15), insufficiency (15 to 30) and normal (>30 ng/mL). Paired t and Anova tests were used.

Results: At T0, 25-OH vitD levels were 15.4±8.1 ng/mL. 54.9% pts were deficient and 38.4% insufficient. Mean PTH levels were 134.8±90.9 (pcg/mL). 25-OH vitD deficient pts showed higher PTH levels (153±107 vs 97±45 in calcidiol sufficient pts).

All pts completed 6 months (T6), cholecalciferol supplementation (median dose 2664 UI) and 78 pts completed 1year (T12). At T6 mean calcidiol SerL increased to 29,7±11 and at T12 to 30,8±10,2. At T6 4,5% pts remained in deficiency, and 45,8% achieved normal SerL (vs 6.7% T0).At T12, 55% pts attained normal calcidiol levels.

Proteinuria was significantly reduced from 0.99±1.6g/day to 0.64±0.9 g/day (T6), and to 0.56±1 g/day ($p<0.001$) (T12). Pts under sirolimus had the higher proteinuria at T0 and in his group the reduction was higher. PTH levels were significantly reduced to 113±92 pg/mL (T6) and to 107±79,4 ($p<0.001$) at T12. No differences were observed in calcium, phosphorous and creatinine SerL. 25-OH vit.D supplementation was well tolerated, and no adverse events were reported.

Conclusions: Our results shows that vitamin D deficiency is highly prevalent in KTx pts. Oral supplementation with cholecalciferol is efficient, cheap and safe in the correction of calcidiol SerL, leading to significant reduction in proteinuria and improvement in CKD-MBD.

Larger and longer randomized controlled studies are needed to confirm these results in this particular population.

SA-PO973

Vitamin K Intake and Vascular Vitamin K Status in Kidney Transplant Recipients Paul Boxma,[1] Else van den Berg,[1] Johanna M. Geleijnse,[2] Gozewijn Dirk Laverman,[3] Leon J. Schurgers,[4] Cees Vermeer,[5] Gerjan Navis,[1] Stephan J.L. Bakker,[1] Martin H. De Borst.[1] *[1]Dept of Nephrology, University Medical Center Groningen; [2]Dept of Nutrition, Wageningen University; [3]Dept of Medicine, ZGT Almelo, Netherlands; [4]Dept of Biochemistry, Maastricht University, Netherlands; [5]VitaK BV, Maastricht.*

Background: Vitamin K insufficiency is associated with an increased risk of cardiovascular morbidity and mortality. Vitamin K is essential for activation of vascular calcification inhibitor proteins such as matrix Gla-protein (MGP). Insufficient vitamin K intake results in accumulation of uncarboxylated MGP, contributing to an increased risk of vascular calcification. In kidney transplant recipients, cardiovascular risk is high but vitamin K intake and status have not been defined.

Methods: We investigated dietary vitamin K intake, vascular vitamin K status and its determinants in a cohort of kidney transplant recipients (n=60) with stable renal function (creatinine clearance 61 [42-77] (median [interquartile range]) ml/min), 75 [35-188] months after transplantation). Vitamin K intake was estimated by 3-day food records and food frequency questionnaires, and vascular vitamin K status was measured as plasma desphospho-uncarboxylated MGP (dp-ucMGP) by ELISA.

Results: Total vitamin K intake was below recommendations (<120 mg/d for men or <90 mg/d for women) in 50% of patients, probably due to less consumption of green vegetables. Patients below the median of vitamin K intake had higher dp-ucMGP levels (621 (481-927) vs 753 (543-1091), p<0.05). Accordingly, the majority of patients (80%) had elevated dp-ucMGP levels (>500 pmol/L), suggesting vitamin K insufficiency. Multivariate regression revealed CrCl (standardized β -0.51, p<0.001), coumarin use (st. β 0.31, p=0.005), body mass index (st. β 0.35, p=0.001) and sodium excretion (st. β 0.22, p=0.05) as independent determinants of vascular vitamin K status.

Conclusions: A considerable part of the kidney transplant population has increased plasma dp-ucMGP levels, which may contribute to arterial calcification. Improving vitamin K status may have health benefits for kidney transplant recipients.

Funding: Government Support - Non-U.S.

SA-PO974

Elevated Circulating Desphospho-Uncarboxylated Matrix Gla Protein Is an Independent Risk Factor for Mortality and Graft Failure after Kidney Transplantation Paul Boxma,[1] Elke Magdeleyns,[2] Cees Vermeer,[2] Gerjan Navis,[1] Stephan J.L. Bakker,[1] Martin H. De Borst.[1] *[1]Department of Nephrology, University Medical Center Groningen; [2]VitaK BV, Maastricht, Netherlands.*

Background: An increased circulating level of desphospho-uncarboxylated matrix Gla-protein (dp-ucMGP) species, indicating vitamin K insufficiency, has been associated with cardiovascular morbidity and mortality and with progression of chronic kidney disease. Its role in allograft and patient survival after kidney transplantation is unknown. We hypothesized that plasma dp-ucMGP is an independent risk factor of mortality and graft failure in kidney transplant recipients (KTR).

Methods: Baseline plasma dp-ucMGP levels were measured by a conformation-specific sandwich ELISA in a cohort of stable outpatient KTR (n=528) at 7.8 ± 6.4 (mean ± SD) years after transplantation. Associations between dp-ucMGP levels and the composite outcome of all-cause mortality and graft failure were analyzed by multivariable Cox regression analysis adjusting for age, gender, eGFR (CKD-EPI), proteinuria, hemoglobin, use of ACEi/ARB, waist circumference, smoking, diabetes, total cholesterol, HDL cholesterol and systolic blood pressure. Sensitivity analyses were performed in a subgroup with eGFR >30 and <90 mL/min.

Results: At baseline, patients (55% male, age [mean±SD] 52±12 yrs, eGFR 62±23 ml/min) had plasma dp-ucMGP levels of median [interquartile range] 1039 [733-1542] pmol/L; 91% of the population was above the upper-normal limit of 500 pmol/L, indicating vitamin K insufficiency. After 6.4±1.7 years of follow-up, 133 (22%) patients had died and 53 (9%) had developed graft failure. Plasma dp-ucMGP levels were associated with an increased risk of all-cause mortality or graft failure (full model hazard ratio 1.86 per 1 SD increase [95% CI 1.23-2.82], p=0.004). Analyses per tertile of dp-ucMGP and sensitivity analyses provided similar results.

Conclusions: Elevated plasma dp-ucMGP, indicating vitamin K deficiency, is an independent risk factor for mortality and graft failure after kidney transplantation. Future studies should address whether vitamin K supplementation improves outcome after kidney transplantation.

SA-PO975

Long-Term Management of Severe Recurrent Focal Segmental Glomerulosclerosis by Soluble Urokinase Receptor Modification Changli Wei,[1] Jochen Reiser,[1] Martin G. Zeier,[2] Christian Morath.[2] *[1]University of Miami; [2]University of Heidelberg, Germany.*

Background: Soluble urokinase receptor (suPAR) is a cause of native and recurrent focal segmental glomerulosclerosis (FSGS) through pathological activation of podocyte β3 integrin. Lowering of suPAR to ranges whereby podocyte β3 integrin is turned off, can lead to clinical remission.

Methods: We report the effects of suPAR modification in long-term management of severe recurrent FSGS accompanied by renal failure.

Results: A 59-year old female patient with primary FSGS had elevated pretransplantation serum suPAR level (5,782 pg/mL), suggesting high risk for FSGS recurrence, which was later confirmed by graft biopsies and by proteinuria of 9.7 g/d. As serum suPAR remained high post-transplantation, intensive plasmapheresis (PP) treatments were initiated with significant improvement of proteinruia. Attempts to wean the patient from PP failed due to severe oliguria following suPAR rebound, suggesting dependence of improved podocyte foot process structure and hydraulic permeability on sufficient circulating suPAR reduction. Since PP was not well tolerated, the patient was instead treated with immunoadsorption (IA), which showed equal efficacy in producing a 42% suPAR reduction rate per session. Overall, the serum suPAR was maintained at a median level of 3,878 pg/mL through PP or IA treatments. Using cellular podocyte integrin activation assay, we found that PP reduced podocyte β3integrin activation gradually, which was associated with a parallel decrease in proteinuria. Reducing PP to twice a week however led to a reversible increase in podocyte β3 integrin activation and rising proteinuria to 10.8 g/d. Both proteinuria and β3 integrin activity was lowered significantly again with IA. More than 15 months after transplantation, the patient is now successfully managed with one IA treatment on alternate weeks with a serum creatinine of 1.5 mg/dL and proteinuria of 2.6 g/d. Electron microscopy shows partial recovery of podocyte foot process pathology on postoperative day 437.

Conclusions: This study suggests that circulating suPAR reduction is critical for renal output, foot process recovery and management of severe recurrent FSGS.

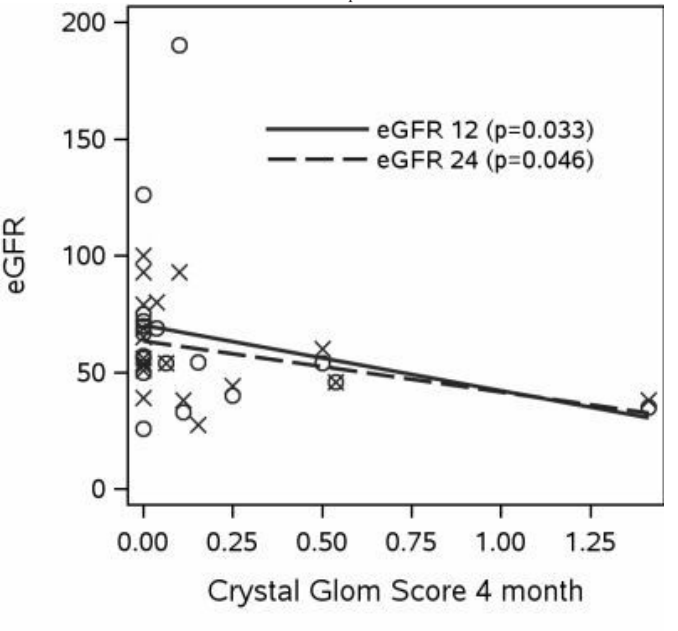
SA-PO976

Post Transplant Recurrence of Oxalosis in Primary Hyperoxaluria Type 1: A Study of Protocol Biopsies Nageswara Pamidi,[1] Lynn D. Cornell,[2] Eric J. Bergstralh,[3] Ramila A. Mehta,[3] Julie Heimbach,[4] Dawn S. Milliner.[1] *[1]Nephrology, Mayo Clinic; [2]Pathology, Mayo Clinic; [3]Biostatistics, Mayo Clinic; [4]Transplantation Surgery, Mayo Clinic.*

Background: Primary hyperoxaluria (PH) accounts for 1% of pediatric ESRD in US and European registries. After transplant (Tp) recurrent oxalosis in the allograft remains a problem. Protocol biopsies were studied to assess the frequency of recurrence and its effect on renal allograft function.

Methods: Of 330 patients enrolled in Rare Kidney Stone Consortium PH Registry 26 patients who received 27 transplants[8 kidney alone (K),19 simultaneous liver and kidney(L/K)] and had at least one protocol biopsy(4, 12, 24 or 60 months)were included. Median age at Tp was 33 years.Crystal score in kidney tissue was estimated as number of crystals /total glomeruli.Spearman's correlation was used to test associations.

Results: 73 protocol biopsies were done in 27 allografts.Calcium oxalate(CaOx)crystals were found in atleast one biopsy in 55%(15/27)of allografts. No associations were found between CaOx crystals and donor age, time on dialysis before Tp & Tp type (K or L/K). Crystals were more often seen in 4 month biopsy (45%) than at 12 and 24 months (15% & 31% respectively).15% of implantation biopsies showed crystals 20 min after graft placement.The crystal/glomerulus score (mean 0.08, range:0-1.41) correlated with 24 hour urine oxalate (r=0.41,p=.0007),calcium(r=-0.42,p=.003),magnesium(r=-0.48,p=.006)and with plasma oxalate at time of biopsy(r=0.44,p=.0008).Crystal score at 4 months(n=19) correlated with eGFR at 12 and 24 mos after Tp



After 24 months 87.5% grafts survived with mean eGFR of 63.2 ml/min/1.73m².2 grafts were lost to oxalosis & 1 to rejection.

Conclusions: Recurrence of Caox crystals was seen in 55% of allografts.Intensity of crystal deposition correlates with concurrent urine analytes and has a negative impact on 2yr graft function.

SA-PO977

Desensitization Protocols for Highly Sensitized Patients on the Waiting List for Deceased Donor Kidney Transplant Hyuk Yong Kwon,[1] Yoonjung Kim,[1] Myung-gyu Kim,[1] Tai Yeon Koo,[1] Curie Ahn,[1,2] Jaeseok Yang.[1] *[1]Transplantation Center, Seoul National University Hospital, Seoul, Korea; [2]Department of Nephrology, Seoul National University Hospital, Seoul, Korea.*

Background: Along with decreased organ availability, HLA sensitization is the most important barrier to deceased donor kidney transplantation (DDKT). Here, we present our experiences of desensitization (DST) for wait-listed patients for DDKT.

Methods: Highly sensitized adult Korean patients with peak panel reactive antibody (PRA) level above 50% that had waited for DDKT for longer than 4 years from 2010 to 2011 in Seoul National University Hospital were enrolled. High dose intravenous immunoglobulin (IVIg, 2 g/kg) and rituximab (375mg/m^2) were administered at day 0. Another dose of IVIg (2 g/kg) and a cycle of bortezomib (1.3mg/m^2) were administered at day 30.

Results: A total of 8 patients were enrolled. Mean age was 53.0±7.6 years, and 6 patients were male. Initial peak PRA level was 98.1±2.2% and sum of mean fluorescent intensity (sMFI) of class I and II antibodies was 26549.8±9036.7. Six cases were retransplants and 2 patients had a history of multiple transfusion. A mean waiting time was 7.8±4.2 years. The mean follow up PRAs were 88.8±19.4% (sMFI 23984.1± 14849.5), 83.5±23.8% (sMFI 20814.6±11488.0), and 85.0±15.6% (sMFI 22554.1±13624.6) at 3, 6, and 12 months after DST, respectively.

4 among 8 patients (50%) had succeeded in getting KT at 2.5±1.4 months after DST with mean reduction of PRA by 17% (sMFI by 30%) just before KT. Donor sepcific antibody (DSA) was converted to negative or titer of DSA decreased at time of KT compared with that before DST. Patient and graft survival were 100%, with 3 patients having at least 12 months of follow up. Their mean serum creatinine at 12months after KT was 1.23±0.31 mg/dl. Acute rejection or infection did not occur.

The other 4 patients are still on the waiting list. Their mean PRAs were 97.3±2.2% (sMFI 28529.8 ±6450.8) before DST and 93.3±5.6% (sMFI 32311.8.0±5623.5) 1 year after DST with a tendency of less reduction compared with the KT group.

Conclusions: DST using high dose IVIg with rituximab/bortezomib could be a promising strategy for the highly sensitized, long-waiting patients for DDKT.

SA-PO978

Incidental Finding of IgA Deposits in Deceased Donor Kidneys in Zero-Hour Biopsies and Impact on Allograft Function Rachelle V. Dyquiangco,[1] Chalit Wanthakawikran,[1] Lillian W. Gaber,[2] Venkataraman Ramanathan.[1] *[1]Nephrology, Baylor College of Medicine, Houston, TX; [2]Pathology, The Methodist Hospital, Houston, TX.*

Background: Given that IgA nephropathy is the most common primary glomerulonephritis worldwide, it is not uncommon to see incidental IgA deposits in kidney biopsies performed in donors without overt renal disease. We studied the prevalence of such deposits among our deceased donors and the impact on allograft function.

Methods: During the 2-year study period, 186 patients underwent deceased donor (DD) kidney transplantation at The Methodist Hospital, Houston, and zero hour biopsy was performed in 156 DD kidneys. We identified biopsies with significant IgA deposits and compared renal outcomes in recipients of those kidneys with matched controls. Microscopic exam of urine, random protein-creatinine ratio (expressed in gm/gm of creatinine) and serum creatinine were obtained at 12 and 18 months post-transplant for both groups. Microscopic hematuria was defined as >3 RBC/HPF. Student t-test or Fisher Exact test was used as appropriate.

Results: IgA mesangial deposits were seen in 22 donor kidney biopsies (14%) and we compared the recipients of these kidneys with controls (n=22). Donor (age, gender, race, cold ischemia time, ECD kidney, and history of HTN) and recipient characteristics (race, etiology of ESRD, number of kidney transplants and high PRA, defined as >20%) were similar in both groups. As shown in table, patients with IgA deposits had similar allograft function, hematuria incidence and proteinuria at 12 and 18 months, compared to patients without these deposits.

	IgA deposits in Donor kidneys (n=22)	Controls (n=22)
Serum creatinine @ 12 months (mg/dL)	1.6±1.5	1.3±0.4 *
Serum creatinine @ 18 months	1.4±0.5	1.5±0.6 *
Microscopic Hematuria at 12 months	1 (5%)	1 (5%) *
Microscopic Hematuria at 18 months	0	1 (5%) *
Proteinuria at 12 months	0.25±0.63	0.17±0.28 *
Proteinuria at 18 months	0.06±0.16	0.18±0.2 *

Conclusions: IgA deposits noted during zero-hour biopsy do not have significant impact on allograft function during short-term follow up. Incidental finding of these deposits should not preclude donation.

SA-PO979

Renal Transplantation in Patients with Atypical Hemolytic Uremic Syndrome Jacobien Verhave,[1] Henk W. Van Hamersvelt,[1] Maria J. Van Helden,[1] Nicole Van De Kar,[2] Jack F. Wetzels.[1] *[1]Nephrology, University Medical Center, Nijmegen, Netherlands; [2]Pediatric Nephrology, University Medical Center, Nijmegen, Netherlands.*

Background: Atypical hemolytic uremic syndrome (aHUS) is mostly caused by complement dysregulation. After renal transplantation, 50% of patients with aHUS develop disease recurrence. Risk factors of recurrence include use of calcineurin inhibitors, rejection, cold ischemia, recurrence of aHUS in a previous graft. It is proposed that all patients should receive prophylactic therapy with plasma exchange or eculizumab.

Methods: We have used an adapted transplantation protocol in patients with aHUS who received a living donor kidney.

Results: Four patients were transplanted. Two patients had lost a previous graft due to recurrent aHUS (patient 3 and 4). In three patients genetic abnormalities in complement regulation were found (Table). Immunosuppression consisted of basiliximab induction and low doses of tacrolimus (0.03 mg/kg BID), prednisone and mycophenolate mofetil (AUC 40-60 mg*h/ml) with the possibility of eculizumab rescue treatment. All patients received a statin, and were targeted to a low blood pressure (CCB, ACEi) to prevent endothelial damage. Follow-up is now 6 – 11 months. No patient developed a rejection or needed eculizumab for recurrent aHUS. Outcome is given in table.

Conclusions: Our data indicate that renal transplantation in aHUS patients, using a protocol that minimizes endothelial damage, seems to have a high success rate without plasma exchange or eculizumab prophylactic therapy. Although long term outcome is unknown, our data suggest that in adult patients controlled trials are needed to demonstrate cost efficacy of prophylactic therapy compared to rescue treatment with eculizumab. Our data are not (yet) applicable to recipients of cadaveric donor grafts.

Patient and outcome data

Patient	Sex	Age	Compl	Follow up (months)	Creatinine (umol/l)/ Uprot	LDH	Thrombocytes
1	F	35	Lower C3	11	115/ neg	177	274
2	F	54	polyCFH	9	113/ neg	233	285
3	F	29	CFH	9	73/ neg	214	317
4	M	46	C3	6	118/ neg	169	170

Reversibility of Calcineurin Inhibitor Related Thrombotic Microangiopathy with Short Course Eculizumab Miriam R. Berry, Andrew Butler, Meryl Griffiths, Nicholas Torpey. *Addenbrooke's Hospital, Cambridge, United Kingdom.*

Background: Thrombotic microangiopathy (TMA) affects up to 10% of patients with renal dysfunction following solid organ and hematopoietic stem cell transplantation. The etiology is multi-factorial, but calcineurin inhibitors (CNIs) are likely to play a major role. Eculizumab, a monoclonal antibody against the complement component C5, has been used in a number of clinical settings including paroxysmal nocturnal hemoglobinuria and atypical hemolytic uremic syndrome. It may have a potential role in the treatment of post-transplant TMA.

Methods: We report 4 patients (aged 28-51 yrs) treated with eculizumab for de novo post-transplant TMA; 2 following multi-visceral transplantation, one renal and one stem cell allograft. All 3 solid organ recipients had previously been treated for acute rejection but none had detectable donor specific antibodies nor evidence of humoral rejection. No complement mutations were detected.

Results: TMA was diagnosed at a mean of 20.5 (range 4-48) weeks post transplant; 2 patients had biopsy proven renal TMA and 2 had diagnostic peripheral blood films and acute kidney injury. The mean peak creatinine was 425 (range 180-600) µmol/l and one patient was hemodialysis dependent. All were taking CNIs which were discontinued at the time of diagnosis. 3 patients were treated with plasma exchange without improvement in renal parameters. All patients received 900 mg eculizumab weekly for 4 weeks, and one patient received maintenance therapy for 4 months. No major adverse events were observed, and in particular there were no infective episodes attributable to this treatment. Mean creatinine improved to 200 (range 70-400) µmol/l (p=0.025) and no patients required ongoing hemodialysis. In 3 patients there was no evidence of ongoing or recurrent TMA following completion of eculizumab therapy with mean follow up time of 20 (range 4-36) weeks.

Conclusions: Short course eculizumab therapy is a safe and effective therapy which completely or partially reversed TMA and significantly improved renal function in 4 patients with refractory post-transplant TMA.

SA-PO981

Renal Transplantation and Alports's Syndrome in Ireland: A National Retrospective Review of Outcomes Kai Ching Peter Leung, Carol A. Traynor, Frank J. O'Brien, Catherine M. Brown, Peter J. Conlon. *Department of Nephrology, Beaumont Hospital, Dublin, Ireland.*

Background: Alport's syndrome is a progressive hereditary nephritis caused by abnormal alpha IV collagen chains of the basement membrane. Patients with renal failure from Alport's syndrome account for 1.6% of all transplants in Ireland. We present one of the largest series of transplanted patients with Alport's syndrome.

Methods: Data was collected from patients who underwent renal transplantation in Ireland between 1980 and 2011. Transplanted Alport's syndrome patients were identified based on biopsy and compared to a matched non- Alport's transplanted population which comprised of non diabetic living and deceased donor transplants with recipients greater than 16 years of age. Incidence of anti-GBM antibody disease post- transplant was also recorded.

Results: 51 renal transplants were identified in 42 Alport's syndrome patients. The mean age at transplant was 32.7 years (SD 11.2 years) and 85.7% were male. There was a known family history in 23 patients. There were 47 cadaveric transplants and 4 living related transplants. 2 patients had preemptive transplants. Of the 42 patients transplanted the 1, 5 and 10 years patient survival rate was 97.4%, 97.4% and 72.9% respectively compared to 95.8%, 86.6% and 72.9% for non Alport's (p=0.021). Overall graft survival was 94.1% at 1 year, 80.6% at 5 years and 60.8% at 10 years. This is compared to 88.3%, 73.2% and 53.8% graft survival in the non- Alport's population (p=0.131). Median graft survival was 15.6 years, compared to 11.3 years in the control group. 20 patients failed their first graft and 9 of these patients went on to receive a second transplant Graft loss was due to chronic allograft nephropathy in 57.9% of cases and acute rejection occurred in 38.8% of transplants. There was no evidence of anti-GBM antibody disease recorded in the Alport patient cohort.

Conclusions: Renal transplantation was successful in patients with Alport's syndrome. Chronic allograft nephropathy accounted for almost half of graft loss. Acute rejection was high in our cohort. Second transplant is effective and safe. In our series, there were no cases of post-transplant anti-GBM antibody disease.

SA-PO982

The Decline in GFR in Children Following Renal Transplant Khurrum Siddique,[1,2] Leisa Borders,[2] Mouin Seikaly.[1,2] *[1]Pediatric Nephrology, UT Southwestern Medical Center, Dallas, TX; [2]Pediatric Nephrology, Children's Medical Center, Dallas, TX.*

Background: Measured Glomerular Filtration Rate (mGFR) remains the gold standard for evaluating renal function. Our primary end point is to: 1) evaluate the mGFR at 1, 2 and 3 years post renal transplant in our pediatric patients, 2) estimate an annual rate of decline of mGFR following kidney transplant, and 3) evaluate factors that may affect mGFR over time.

Methods: Plasma disappearance of ^{125}I-iothalamate (C_{IO}) was used as a marker to mGFR. C_{IO} was performed on patients who received renal transplant between June 1987 – Sept. 2011. The average follow-up time post renal transplant was 4.9 years (range 0.8-16.2 years). Mixed linear regression analysis of log mGFR after renal transplant was performed to evaluate 220 C_{IO} studies, and mGFR was estimated at 1, 2 and 3 years post-transplant. Variables tested for association with decline in renal function were: age at the time of transplant, sex, ethnicity, primary renal disease as glomerular (G) versus non-glomerular (NG), source of allograft (deceased versus living donor), and length of hospital stay (LOS) following renal transplant.

Results: A total of 220 C_{IO} studies were performed on 123 renal post-transplant patients. Mean age at transplant was 9.7±4.7 years (age range: 1.1-18.8 years). 48% of our cohort had more than one C_{IO} test performed. mGFR at 1, 2 and 3 years post-renal transplant was 68.2, 62.4 and 57.2 ml/min/1.73m^2 respectively. The overall rate of mGFR decline following transplant was 8.8%/yr. Patient's age, sex, ethnicity, primary renal disease, source of allograft, and LOS were not associated with the rate of decline of renal function. Higher mGFR at baseline was associated with younger age at transplant (2.7% higher per year of age below the mean) and G disease (29% higher than NG disease).

Conclusions: In our cohort of transplanted children the rate of decline of mGFR following renal transplant was 8.8% per year. Younger age at transplant and glomerular diseases were associated with higher mGFR at baseline but were not associated with variation in the rate of decline of mGFR.

SA-PO983

Efficacy and Safety of Enzyme Replacement Therapy in a Cohort of Kidney Transplant Recipients with Fabry Disease Markus Cybulla,[1] Sandro Feriozzi,[5] Michael L. West,[2] Joan Torras,[6] Kathleen M. Nicholls,[3] Gere Sunder-plassmann.[4] *[1]Nephrology and Rheumatology, FGM, Center of Internal Medicine, Muellheim, Germany; [2]Nephrology, Dalhousie University, Halifax, Canada; [3]Nephrology, Royal Melbourne Hospital, Melbourne, Australia; [4]Nephrology, Medical University, Vienna, Austria; [5]Belcolle Hospital, Viterbo, Italy; [6]Hospital of Bellvitge IDIBELL, Barcelona, Spain.*

Background: Enzyme replacement treatment (ERT) was introduced in 2001 as a new treatment option for patients with Fabry disease. The Fabry Outcome Survey (FOS, sponsored by Shire HGT) is a worldwide outcome database which was established to monitor the long-term efficacy and safety of ERT with agalsidase alfa. The study presents the clinical data of a follow up analysis in kidney transplant recipients (KTRs) with Fabry disease.

Methods: The effects of long term ERT with agalsidase alfa (Replagal®; Shire HGT) on renal outcome were analyzed.

Results: Renal function was analysed in 77 patients (male 70 (90.9%), female 7 (9.1%), 62 (80.5%) received ERT at any time, mean time since transplantation to start of ERT 25,7 (77.3) months, mean time on ERT until last visit, 3.7 (2.9) years; mean time on dialysis before transplantation 4.2 (5.4) years). During the observation time (start of ERT and last visit) the average slope per year in eGFR was -0.03 (-1.66, 1.61; 95%CI) mL/min/1.73 m2 in men and -0.25 (-7.08, 6.59) mL/min/1.73 m2 in women. Patients with proteinuria had poorer graft function at follow-up compared with patients without proteinuria. Arterial hypertension (RR > 120/80 mmHg) has no negative impact on values of proteinuria and renal function respectively. Additionally dialysis treatment before transplantion has also no negative impact on the later graft function. Only minor side effects or infusion related reactions are reported.

Conclusions: This study showed, that graft function in KTR Fabry patients remains stable under enzyme replacement therapy and that the treatment seems to be well tolerated.

SA-PO984

Role of Monocyte in the Development of Chronic Kidney Disease in Kidney Transplant Recipient Elena Guillen-gomez,[1] Lluis Guirado Penit,[2] Carme Facundo,[2] Jose Ballarin,[2] Montserrat M. Diaz Encarnacion.[2] *[1]Laboratory Medicine, Fundación Puigvert, Barcelona, Spain; [2]Nephrology, Fundación Puigvert, Barcelona, Spain.*

Background: Chronic allograft tubular atrophy/interstitial fibrosis (TA/IF) occurs early after transplantation. Interstitial fibroblasts seem to be one of the principal sources of kidney fibrosis. There are several studies that show a close association between macrophage infiltrate and excessive extracellular matrix protein accumulation. In addition, the number of infiltrating macrophages has been shown to correlate with the number of myofibroblasts. The aim of this study is to determine the role of the activated circulating monocytes in kidney allograft recipients pre-and post-transplant, as an initial response to tissue damage and a chronic inflammatory stimulus that could be related to early onset of chronic kidney allograft dysfunction.

Methods: Whole blood samples from 24 kidney recipients and 17 living donors were collected at different time points. Monocytes were analyzed by flow cytometry and levels of IL-10 and soluble CD163 were determined by ELISA. Clinical dates were get it from clinical database.

Results: Classical monocytes (CD14+/CD16-) difference between month 4 and baseline correlated positively with creatinine levels (p=0.0018) and negatively with MDRD (p=0.006) at month 12, and with creatinine at month 18-24 (p=0.02). As described, at 24 hours there is a pick of surface CD163 (p=0.0001), after one week post-transplant surface CD163 and IL-10 levels remain higher than baseline (p=0.0003 and p=0.0463, respectively), while the concentration of soluble CD163 decreased (p=0.0107). Monocytes CD163+ difference between 1/2 weeks and baseline correlated positively with creatinine levels (p=0.04) at 4 month.

Conclusions: These results of CD163 could be initially associated with an early onset of healing, but the persistence of higher levels than baseline could be associated with mechanisms that have been related to fibrosis.

Increasing total amount of classical monocytes (CD14+/CD16-) correlation with serum creatinine and MDRD confers on these cells a new and promising prognostic value on the development of chronic kidney disease in renal transplant patients.

FOXP3 Expression in Peripheral Blood Lymphocytes of Kidney Transplant Recipients under Different Induction Antibody Therapies Mark L. Lipman,[1] Yan Zhang,[1] Minh-tri Nguyen,[2,3] Michel Marcil,[1] Jean Tchervenkov,[3] Steven Paraskevas.[2,3] *[1]Lady Davis Institute for Medical Research, Jewish General Hospital, Montreal, QC, Canada; [2]Human Islet Transplantation Laboratory, McGill University Health Centre, Montreal, QC, Canada; [3]Department of Surgery, McGill University, Montreal, QC, Canada.*

Background: Regulatory T cells (Treg) have been recognized as a mechanism to promote tolerance in organ transplantation. Forkhead box P3 (Foxp3) is an important transcription factor for the development and function of Treg. Here, we describe FOXP3 expression in peripheral blood lymphocytes of 35 renal transplant recipients treated with either one of the three common induction therapies: rabbit antithymocyte globulin (rATG) or alemtuzumab (ALTZ), which are both lymphocyte-depleting agents (LDA), and basiliximab (BSLX), a nondepleting agent.

Methods: FOXP3 was determined by qPCR on Day 0 prior to transplantation and then on Day 1, 7, 14, 30, and 180 post-transplantation.

Results: Both rATG and ALTZ resulted in immediate and dramatic suppression of FOXP3 expression to less than 10% of baseline at Day 1 and 7 post-transplantation. Subsequently, with LDA, FOXP3 levels recovered modestly to 40% of baseline by Day 14 and to 50% and 70% at 1 and 6-months post-transplantation, respectively. Early results, based on a limited number of cases treated to date with BSLX, demonstrated a much more modest reduction in FOXP3 expression to only 40% at Day 1 and 7 and a full recovery to baseline by Day 14.

Conclusions: It appears that FOXP3 expression varies considerably between lymphocyte-depleting rATG/ALTZ treatment vs. non-depleting BSLX treatment with a more profound and prolonged suppression of FOXP3 expression with the former. These findings do not support a determining role for absolute levels of FOXP3 transcripts in the lower rejection rates reported with LDA compared to BSLX. However, since the lower FOXP3 levels with rATG/ALTZ are likely a function of the lymphopenia, it does not rule out the possibility of a relative shift in T cell subsets (within an overall reduced T cell population), in favor of a higher Treg/Teffector ratio with rATG/ALTZ, as mechanistically implicated in the lower rejection rates described with LDA.

SA-PO986

Metallothioneins as Functionally Relevant Markers for Biological Organ Age in Preimplantation Kidney Biopsies Johannes Leierer,[1] Michael Rudnicki,[1] Paul Perco,[2] Irmgard Muehlberger,[2] Christian Koppelstaetter,[1] Wolfgang Steurer,[4] Robert Öllinger,[3] Gert J. Mayer.[1] *[1]Dept. of Nephrology and Hypertension, Medical University Innsbruck, Innsbruck, Austria; [2]Emergentec Biodevelopment GmbH, Vienna, Austria; [3]Dept. of General and Transplant Surgery, Medical University Innsbruck, Austria; [4]Dept. of Surgery, Robert-Bosch-Krankenhaus, Stuttgart, Germany.*

Background: Renal transplantation is the treatment of choice for patients with end stage renal failure. Despite overall inferior outcome kidneys from elderly donors are used more frequently due to organ shortage. However chronological donor age considerably lacks sensitivity and specificity for prediction of individual short and long term outcome and hence biomarkers for biological age are an urgent clinical need.

Methods: Age-regulated gene expression changes in 77 zero hour donor kidney biopsies were determined using microarray technology followed by ANOVA and SAM analysis. Expression changes of selected genes were confirmed by quantitative real-time PCR. *In situ* hybridization was used to localize mRNA expression in zero hour biopsies. Functional aspects were examined comparing cell lines (HK-2, htert-RPTEC) grown in normoxic and hypoxic conditions.

Results: Donors were classified into 3 age groups (<40, 40-59, >60 years). 349 genes with altered expression associated with age were identified. These genes were mostly related to Gene Ontology classes of immunity, apoptosis, cell structure and motility and stress response. Three predominant patterns of gene expression were: (1) increasing expression across the age groups, (2) decreasing with age and (3) increasing with age but reduced expression in donors >70 years. Group 3 was dominated by genes encoding for metallothionein (MT) isoforms. *In situ* hybridization demonstrated localization of MT mRNA in renal proximal tubular cells. Cell lines overexpressing MT2A were less sensitive towards hypoxia-induced apoptosis.

Conclusions: Metallothionein expression might serve as a marker for biological age in zero hour biopsies from elderly donors. Furthermore our data support the idea that a reduced expression of MT isoforms predisposes to a reduced anti stress response capacity.

Funding: Government Support - Non-U.S.

SA-PO987

Level of Virus-Specific T Cells (Tvis) as an Indicator of Overimmunosuppression after Pediatric Kidney Transplantation Thurid Ahlenstiel,[1,3] Urban Sester,[2] Lars Pape.[1,3] *[1]Pediatric Nephrology, Hannover Medical School, Hannover, Germany; [2]Nephrology, University Saarland, Homburg, Germany; [3]IFBTx, Hannover, Germany.*

Background: After transplantation (Tx) immunosuppression leads to impaired cellular immune defense resulting in increased risk of viral complications. Post-Tx follow-up of virus-specific T cells (Tvis) may serve as an indicator of viral diseases and overimmunosuppression.

Methods: Within a prospective longitudinal study we monitored Cytomegalovirus (CMV)- and Adenovirus (ADV)-Tvis in 37 children (1-17 years, median 13 years) during the first year after kidney Tx. Based on specific cellular activation and induction of intracellular cytokine production, CMV- and ADV-CD4+ and CD8+Tvis were determined by flow cytometry.

Results: CMV- and ADV-CD4+Tvis were permanently detectable and fluctuated depending on the grade of immunosuppression: Under the intensified immunosuppression during the initial post-Tx period we found temporary decrease of CD4+Tvis. When immunosuppression was reduced, Tvis were increasing. In the presence of sufficient numbers of ADV- or CMV-CD4+Tvis (>2 cells/µl) we did not detect any relevant viral infections or reactivations. Patients with low CD4+Tvis were susceptible for various symptomatic viral infections (e.g. CMV, EBV): The absence of CMV- and ADV-CD4+Tvis (<2 cells/µl) was correlated with a high risk of EBV-infections/-reactivations with persistence of EBV-DNA (Spearman r= -0.68 and -0.49, p<0.0001). In case of high EBV-DNA load (>2500 cop/ml) CMV- and ADV-CD4+Tvis were significantly lower than without relevant EBV-DNA-detection (CMV-CD4+Tvis: 1.6±1.3/µl versus 18.8±13.3/µl; p<0.0001). In contrast to CD4+Tvis, CD8+Tvis were only temporarily detectable.

Conclusions: After kidney Tx CMV- and ADV-CD4+Tvis represent not only virus-specific, but also general cellular immune defense: Sufficient levels of CD4+Tvis (>2 cells/µl) prevent from symptomatic viral infections whereas a decrease is associated with an elevated risk of viral complications. Serving as an indicator of overimmunosuppression, monitoring of CD4+Tvis may improve post-Tx management and optimize individual timing of antiviral therapy and dosing of immunosuppression (effect-related drug-monitoring).

SA-PO988

Minimal Peritubular C4d Staining Is Associated with Clinical and Molecular Features of Antibody-Mediated Rejection Nicole A. Hayde,[1] James M. Pullman,[2] Enver Akalin.[3] *[1]Pediatric Nephrology; [2]Department of Pathology; [3]Adult Nephrology, Transplant Center, Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY.*

Background: Diffuse (>50%) and focal (11-50%) peritubular (PTC) C4d positive staining is accepted as a footprint of antibody-mediated rejection (AMR) and is strongly associated with donor-specific antibodies (DSA). The significance of minimal (1-10%) PTC C4d staining by immunoperoxidase is unclear. We investigated the clinical and molecular significance of minimal PTC C4d staining in kidney transplant biopsies.

Methods: We analyzed 255 clinically indicated transplant biopsies. C4d staining was performed on paraffin sections using a polyclonal rabbit anti-C4d antibody. Gene expression profiles in a subset of patients were studied using Affymetrix HuGene 1.0ST arrays.

Results: Of the 255 biopsies, 130 (51%) were C4d negative, 78 (31%) had isolated glomerular C4d, 38 (15%) had focal/diffuse PTC C4d and 9 (3%) had minimal PTC C4d+ staining. Minimal and focal/diffuse PTC C4d+ staining were associated with a higher frequency of donor-specific anti-HLA antibodies (DSA) (67% vs. 82% vs. 25%), histopathologic findings of acute or chronic AMR (66% vs. 89% vs. 19%), glomerulitis (0.88 vs. 0.65 vs. 0.25, p=0.003), interstitial inflammation (1.25 vs. 1.41 vs. 0.79; p=0.003) and peritubular capillaritis scores (1.5 vs. 1.5 vs. 0.34; p < 0.001), compared to the C4d negative group, respectively. Using gene ontology, both minimal and focal/diffuse C4d+ biopsies showed increased expression of genes related to activation of the immune response when compared to native pre-implantation biopsies. There was no significant differential gene expression profile between minimal and focal/diffuse PTC C4d+ biopsies. Using the Pathogenesis Based Transcripts, both groups showed enrichment of the gamma-IFN and rejection induced (GRIT), quantitative cytotoxic T cell-associated (QCAT) and quantitative constitutive macrophage-associated transcripts (QMAT) compared to C4d negative controls.

Conclusions: Minimal PTC C4d positive staining is associated with AMR and DSA and demonstrates similar clinical and molecular features compared to diffuse/focal PTC C4d+ biopsies.

SA-PO989

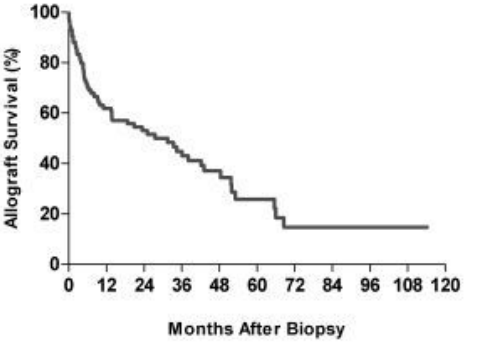
Independent Risk Factors for Allograft Failure Following the Diagnosis of Transplant Glomerulopathy Pallavi Patri, Thangamani Muthukumar, Choli Hartono, Darshana Dadhania, Manikkam Suthanthiran, Surya Seshan. *Weill Medical College of Cornell University.*

Background: Transplant glomerulopathy (TG) is a pattern of glomerular injury characterized by duplication of glomerular basement membrane. Chronic antibody-mediated injury is a major cause for its development. While TG portends a poor prognosis, risk factors of allograft failure following TG have not been well defined.

Methods: We reviewed 1523 consecutive for-cause kidney allograft biopsies at our center (1/2000-12/2010) and identified 84 recipients with TG. We performed Cox proportional hazard regression to identify independent risk factors for graft failure.

Results: TG was diagnosed 41 mo (median) after transplant. eGFR-23ml/min; proteinuria >1g/day-56 (67%); glomerulitis-57 (69%); peritubular capillary inflammation-51 (61%); tubulitis/interstitial inflammation-40 (48%); severe interstitial fibrosis (IF/TA)-19 (23%), severe vascular fibrous intimal thickening-16 (19%) and positive C4d staining-33 (40%). Donor specific antibody: available-28 (34%); positive-22 (79%). Forty-two (51%) patients received combination of pulse steroids, intravenous immunoglobulin, plasmapharesis, rituximab (Ritux) or antithymocyte globulin (Thymo). Median follow up after biopsy-46 mo. There were 31 allograft failures within 1 year of biopsy. One-year post-biopsy allograft survival-63% (Panel-A). By Cox regression, eGFR, proteinuria, IF/TA and additional therapy with Ritux or Thymo were independent predictors of allograft failure (Panel-B).

A) Allograft Survival Following the Diagnosis of TG (N=84)



B) Independent Risk Factors of Allograft Failure Following the Diagnosis of TG (N=84)

Variable	Reference	Hazard Ratio	95%CI	P Value
Time to biopsy	months	0.99	0.99-1.00	0.21
eGFR at biopsy	**10 ml/min**	**0.53**	**0.41-0.69**	**0.000**
Proteinuria >1 g/day	**<1 g/day**	**3.92**	**1.59-9.68**	**0.003**
Glomerulitis, yes	no	0.83	0.39-1.77	0.64
Peritubular capillary inflammation, yes	no	0.50	0.23-1.04	0.07
Tubulitis/interstitial inflammation, yes	no	1.49	0.75-2.94	0.24
Interstitial fibrosis, severe	**nil / mild-moderate**	**2.65**	**1.36-5.16**	**0.004**
Vascular fibrosis intimal thickening, severe	nil / mild-moderate	0.83	0.40-1.71	0.62
Peritubular capillary C4d, positive	negative	1.07	0.54-2.13	0.83
Treatment with pulse steroids, IVIG or PP	no treatment	0.56	0.25-1.24	0.15
Additional therapy with Ritux or Thymo	no additional therapy	2.77	1.03-7.46	0.04

Conclusions: In our single-center analysis of 1523 renal allograft biopsies, we identified 84 transplant recipients with TG. One-year post-biopsy allograft survival was 63%. Level of graft function and proteinuria at the time of biopsy as well as IF/TA were independent risk factors of allograft failure. Unexpectedly, additional therapy with Ritux or Thymo was associated with allograft failure.

SA-PO990

Natural Killer Cells Were Involved in Human Renal Allograft Rejection

Ping L. Zhang, Dilip Samarapungavan, Francis Dumler, Raviprasenna K. Parasuraman. *Departments of Anatomic Pathology, Nephrology and Transplantation, William Beaumont Hospital, Royal Oak, MI.*

Background: Natural killer (NK) cells play an important role in xenograft rejection by way of "natural" antibody mediated acute humoral xenograft rejection. Expression of NK cells in human renal allograft rejection has not been described. We have evaluated for presence of NK cells by screening CD56 expression, a major receptor of NK cells, in human renal allograft biopsies (Study 1) and explant specimens (Study 2) from patients with cellular and humoral rejection.

Methods: In Study 1, we compared the cytoplasmic CD56 expression in 3 groups of renal transplant biopsies including 1) acute tubular injury as controls, 2) acute cellular rejection (ACR), and 3) antibody mediated rejection (AMR, also called humoral rejection) with or without ACR. In Study 2, we evaluated CD56 expression in 1) control kidney sections (removed for renal tumors), 2) renal allograft explants with ACR only, and 3) renal allograft explants with ACR and AMR. All kidney sections were stained for CD56 (monoclonal antibody from Dako) and their presence in cellular infiltration (CI) area of ACR and peritubular capillaries (PTC) were counted per high power filed (x400) for comparison using ANOVA.

Results: Control cases stained entirely negative for CD56. In rejection cases, CD56 positive NK cells represented less than 5% of inflammatory cells in cellular infiltration. Their presence in peritubular capillaries was also scattered in general (see table below, *p< 0.05 vs control; #p< 0.05 vs ACR only). There were no differences in the presence of CD56 positive NK cells between ACR and AMR in two clinical settings evaluated.

		Biopsy	Biopsy		Explant	Explant
	n	CI	PTC	n	CI	PTC
Controls	12	0.00±0.00	0.00±0.00	10	0.00±0.00	0.00±0.00
ACR only	13	3.54±1.36*	0.31±0.18	6	7.33±3.61*	6.17±5.03*
AMR	11	0.64±0.31#	1.28±0.69	12	5.25±1.81*	3.92±0.76

Conclusions: According to our knowledge, it is the first human study to show that CD56 positive NK cells were present in both ACR and AMR, although their amount in both cellular infiltration areas and peritubular capillaries were relatively small. Further study is needed to determine the significance of NK cells involved in human allograft rejection.

Integrin β3 Expression May Contribute to Kidney Allograft Failure

Jianguo Chen,[1] Anna Zmjewska,[1] Deidra Sanders,[2] Roslyn B. Mannon.[1] *[1]Nephrology, University of Alabama at Birmingham, Birmingham, AL; [2]Meharry Medical College, Nashville, TN.*

Background: Late allograft failure is a considerable problem in kidney transplantation. Expression of integrin $\alpha v\beta_3$ ($ITG\beta_3$) has been detected in rejecting kidney allografts. However, the role of $ITG\beta_3$ in the late kidney allograft failure is unknown. We hypothesize that $ITG\beta_3$ mediates interstitial fibrosis (IF) and tubular atrophy (TA), the hallmarks of late kidney graft failure.

Methods: Expression of $ITG\beta_3$ and its ligand vitronectin (VN) were evaluated in a well-characterized mouse kidney allograft model of IF/TA, in serum, urine and kidney allografts from human recipients, and in mouse collecting duct epithelial cells (mIMCD) by real-time PCR, immunofluorescence staining, Elisa, and western blot.

Results: Compared to isografts, gene expression of $ITG\beta_3$ was substantially elevated in mouse kidney allografts at 1w and 2w (6.6 and 5.3-fold, p<0.05) prior to development of IF/TA and remained elevated at 6w and 12w after IF/TA was established (1.6 and 2.5-fold; p<0.05). Moreover, $ITG\beta_3$ staining was localized in the renal collecting ducts and increased in allografts compared to isografts. To begin to explore the relationship between this expression and allograft failure, mIMCD cells were exposed to 5ng/ml $TGF\beta_1$ for 24h. Compared to vehicle, $TGF\beta_1$ markedly induced $ITG\beta_3$ mRNA expression (5.9-fold) and was associated with up-regulation of col1A1 (8.6-fold) and fibronectin1 (3.2-fold) (p<0.05). Finally, we evaluated the expression of $ITG\beta_3$ in human kidney transplant recipients. Compared to stable function recipients, $ITG\beta_3$ was elevated by 5.2-fold in graft biopsies with IF/TA (p=0.02). Accompanying these changes were marked elevations in ITGβ3 ligand VN in recipient urine with IF/TA (6.85 ± 1.66 ng/mg creat) compared to recipients with stable allograft function (1.89 ± 0.89 ng/mg creat; p<0.05). Moreover, the extent of elevation was associated with the severity of IF/TA.

Conclusions: Increased expression of $ITG\beta_3$ in kidney allografts within renal collecting duct cells and the ligand VN are associated with the development of IF/TA. Further investigation into this pathway may provide new insights into the development of allograft fibrosis in kidney transplants.

SA-PO992

Obesity Impairs Foxp3+ Treg Cell Function in Clinical Allograft Recipients

Wayne W. Hancock,[1] Matthew H. Levine,[2] Ulf H. Beier,[1] Liqing Wang,[1] Rebecca A. Simmons,[2] Isaac Sasson,[2] Tatiana Akimova.[1] *[1]Children's Hosp of Philadelphia, Philadelphia, PA; [2]U Penn, Philadelphia, PA.*

Background: Being overweight or obese (ow/ob) increases risk of hypertension, diabetes and other illnesses, including in transplant recipients, but has been little studied with regard to its immune effects. We have undertaken clinical, translational and basic studies of this link.

Methods: We assessed if CNI or rapamycin (RPM) affected metabolic events in children (n = 62) with stable, long-term kidney or liver allografts (32 M, 30 F), and if being overweight or obese (Ow/Ob) was associated with impaired Treg phenotype or function.

Results: Most patients received CNI (39) or RPM (9) monotherapy, though 12 had CNI (8) or Rapa (4) plus MMF, Aza or steroids. 45 children were normal weight, 7 were overweight and 10 were obese. The CNI-group had more Ow/Ob patients (p=0.045) and higher BMI-for age percentile than RPM-group (61.7 vs. 42.9, p=0.047). CNI dose correlated with BMI (0.521, p=0.013), while RPM use negatively correlated with BMI (-0.888, p=0.044). Ow/Ob patients on CNI therapy had reduced Treg suppressive function compared to patients with normal weight (p=0.045). Hence, CNI use is associated with ow/ob post-Tx, and both CNI and ow/ob are independently associated with impaired Treg function and phenotype, favoring a pro-inflammatory phenotype. In mice, administration of a high fat diet for 5 weeks markedly impaired Treg function, and we are now assessing the effects of leptin on both inflammation and Treg function. Lastly, we are currently testing whether the decreased Treg function caused by a high fat diet can be reversed by HDAC inhibitor therapy in vivo (experimental mice) or in vitro (clinical transplant recipients).

Conclusions: Obesity has typically not been considered when assessing risk factors negatively impacting to long-term graft outcomes. However, the current studies suggest that obesity, like CNI therapy, has a negative effect on Treg function. Efforts to understand these interactions and to find ways to reverse these effects may have important clinical applications for all transplant recipients, as well as for an increasing proportion of the US population who are ow/ob.

Sirolimus (SRL) Induces $ILT3^{high}ILT4^{high}$Dendritic Cells (DC) Promoting a New Immunoregolatory Pathway

Giovanni Stallone,[1] Paola Pontrelli,[3] Barbara Infante,[1] Margherita Gigante,[2] Giuseppe Stefano Netti,[2] E. Ranieri,[2] Loreto Gesualdo,[3] Giuseppe Grandaliano.[1] *[1]Dept of Medical and Surgical Sciences-Nephrology Unit, University of Foggia, Italy; [2]Dept of Medical and Surgical Sciences-Clinical Pathology Unit, University of Foggia, Italy; [3]Dept. of Emergency and Organ Transplant, University of Bari, Italy.*

Background: $ILT3^{high}ILT4^{high}$DCs may cause anergy in $CD4^+$ effector T cells converting them into regulatory-type T cells (Treg). The aim of the present study was to investigate in renal transplant recipients whether chronic exposure to SRL may modulate this immunoregulatory pathway.

Methods: Fortyrenal transplant recipients on calcineurin-inhibitor (CNI)-based therapy with biopsy-proven chronic allograft nephropathy were randomly assigned to either CNI dose reduction or CNI withdrawal/SRL introduction. At conversion and 2 years thereafter, we evaluated the SRL effects on circulating DCs (BDCA1+/BDCA2+ and ILT3/ILT4 expression), $CD4^+/CD25^{hi}/Foxp3^+$Tregs and $CD8^+/CD28^-$T cells as well as on ILT3/ILT4 expression and the Th1/Th2 balance in graft biopsies.

Results: In SRL-treated patients, peripheral $BDCA2^+$ cells were significantly increased (p=.0001) along with $ILT3/ILT4^+$DC (p=.0002). In the SRL group we observed an increase in the number of circulating $CD4^+/CD25^{high}/Foxp3^+/CTLA4^+$Tregs (p=.0001) and $CD8^+CD28^-$T cells (p=.002). $ILT3/ILT4^+BDCA2^+$DCs number was directly and significantly correlated with circulating Tregs (z=3.392; p=.0007) and $CD8^+CD28^-$T cells (z=2.016; p=.04). Finally, ILT3/ILT4 expression was increased in kidney biopsies at the end of the study period (p=.001) along with a significant bias toward a Th2 response (evaluated by GATA3 protein expression) within the graft only in the SRL-treated patients (p=.0001).

Conclusions: In conclusion, our data demonstrate that SRL induces the up-regulation of ILT3and ILT4on DC surface and this effect is associated with an increase in the number of Tregs and with the expansion of the $CD8^+CD28^-$ T cell population. This observation would suggest that mTOR inhibition may promote a novel immunoregulatory pathway.

Immunologic Monitoring of T-Lymphocyte Subsets and HLA-DR Positive Monocyte in Kidney Transplant Recipients

Jang-Hee Cho,[1,2] Jun-Seop Kim,[1,2] Yunjeong Kang,[1,2] Ga-young Park,[1,2] Owen Kwon,[1,2] Ji-Young Choi,[1,2] Sun-Hee Park,[1,2] Yong-Lim Kim,[1,2] Chan-Duck Kim.[1,2] *[1]Kyungpook National University Hospital, Republic of Korea; [2]CRC for ESRD in Korea.*

Background: T-lymphocyte and HLA-DR positive monocyte play immunomodulatory roles in kidney transplantation. However, the clinical significance of circulating T-lymphocyte subsets and HLA-DR positive monocyte in the peripheral blood remains unclear. We examined the efficacy of the measurement of these cells for immunologic monitoring in kidney transplant recipients (KTR).

Methods: Blood samples were obtained before transplantation, 2 weeks after transplantation, at the diagnosis of biopsy-proven acute rejection, and at the diagnosis of cytomegalovirus infection. $HLA\text{-}DR^+$, $CD3^+$, $CD4^+$, $CD8^+$, $CD25^+$ T lymphocytes and HLA-DR positive monocyte in the peripheral blood were analyzed by flow cytometry.

Results: Seventy-seven specimens were included in this study (64 before and after transplantation, 8 acute cellular rejection, 5 cytomegalovirus infection). The frequencies of $CD4^+CD25^+$ T cells, $CD8^+CD25^+$ T cells, and HLA-DR positive monocyte were significantly decreased at 2 weeks after transplantation compared with those before transplantation (8.75±4.19% vs. 4.34±3.14%, 14.14±5.99% vs. 7.45±5.96%, and 97.96±3.36% vs. 96.85±3.18%, respectively; all P < 0.005). When comparing the frequency at 2 week after transplantation, the frequency of $CD4^+CD25^+$ T cell was significantly increased in KTR with acute rejection (7.45±5.96% vs. 11.79±6.53%; p = 0.019). However, no significant differences were found between stable KTR and KTR with cytomegalovirus infection.

Analysis involving the receiver-operating-characteristic curve demonstrated that acute rejection could be predicted with a sensitivity of 87.5% and a specificity of 68.7% using cutoff value of 7.7% frequency of the $CD4^+CD25^+$ T cells.

Conclusions: The measurement of circulating $CD4^+CD25^+$ T cells might be used as a useful noninvasive immunologic monitoring tool by which acute rejection can be identified after transplantation.

In Situ Genetic Analysis of Cellular Chimerism in Gender Independent Kidney Transplantation Maristela L. Onozato, Ladan Fazlollahi, Rex Neal Smith, A. Bernard Collins, A. John Iafrate. *Department of Pathology, Massachusetts General Hospital, Boston, MA.*

Background: Intragraft chimerism has generated much interest for its immunological implications and to elucidate the origin of the regenerating cells. Recently our laboratory developed highly specific fluorescence *in situ* hybridization (FISH) probes termed polymorphic deletion probes (PDP) that target a highly polymorphic subclass copy number variation loci that result in true deletions of genomic content. The deletion loci on chromosomes 2p, 4q and 8p were identified from single nucleotide polymorphism null genotype database or by array comparative genomic hybridization. Individuals can have homozygous, heterozygous or null genotype at each of these loci and population frequency data predicts that PDP analysis for these 3 loci can distinguishing two individuals at nuclear level *in situ* 95% of times. Importantly these probes are not on the sex chromosomes so can be used in same-sex transplants.

Methods: PDP-FISH combined with immunofluorescence (IF) for common leukocyte antigen (CD45) and the endothelial marker, CD34 were used to identify the frequency and distribution of chimeric cells in 14 renal explant cases. Only cells with two copies of a non-polymorphic control probe were scored.

Results: We performed CD45-IF and FISH with the 3 PDP probes separately in order to differentiate the genotype of transplanted tissue (from the donor) from genotype of CD45 stained leukocytes within the tissue (mainly from the recipient). All cases were informative with at least one of the three applied probes different between donor and recipient. Next, we combined CD34-IF with PDP-FISH to observe the genotype of the endothelial cells. Chimerism was observed in tubular epithelial, transitional cell and endothelial cells. In order to confirm findings with PDP-FISH, XY-FISH was also done on 3 sex mismatched cases.

Conclusions: We found that chimerism is a common event in transplanted kidneys using a highly specific method of PDF-FISH. Epithelial lineage cells tended to present higher frequency of chimerism than vascular endothelial cells raising the question of the role of non-blood stream seeded origin of these cells.

Tacrolimus Can Not Increase Serum Cystatin C Concentration of Adult Recipients in the Early Postoperative Stage of Renal Transplant Fei Liu. *Nephrology, West China Hospital of Sichuan University, Chengdu, Sichuan, China.*

Background: Assesment of renal function is of vital importance for patients with renal transplants. The glomerular filtration rate (GFR) is generally considered the best measure of renal function. Previous reports have suggested benefits of serum cystatin C measurements in patients with renal transplants. However, increased levels of serum cystatin C in adult renal transplant recipients associated with administration of tacrolimus compared with administration of cyclosporine A has been reported recently. The purpose of the present study was to evaluate possible different levels of serum cystatin C between tacrolimus and cyclosporine A-treated renal transplant recipientsunder steady-state in the early postoperative stage.

Methods: One hundred and nine patients with renal transplants under steady-state in the early postoperative stage were included in the study. Steady-state was defined as lack of acute rejection and estimated GFR >60 ml/min/1.73m^2 calculated by the MDRD formulas. The early postoperative stage was defined as between 2 and 6 weeks after renal transplantation. The patients were divided into two groups according to their different Immunosuppression. Serum cystatin C was measured using latex particle enhanced turbidimetric immunoassay(PETIA).

Results: Thirty seven renal transplant recipients treated with cyclosporine A and seventy two recipients treated withtacrolimus under steady-state in the early postoperative stage were included in the study in our hospital between March 2010 and October 2011. Serum cystatin C concentration (reference: 0.51–1.09 mg/L) was 1.41±0.15mg/L in cyclosporine A group and 1.44±0.27mg/L (reference 0.51–1.09 mg/L) in tacrolimus group. There was no statistically significant difference between two groups for serum cystatin C concentration (P=0.71). No correlation was obtained between serum cystatin C and cyclosporine A or tacrolimus blood concentration .

Conclusions: We concluded that there is no significant difference for serum cystatin C between two groups. Tacrolimus can not increase serum cystatin C concentration of adult recipients in the early postoperative stage of renal transplant.

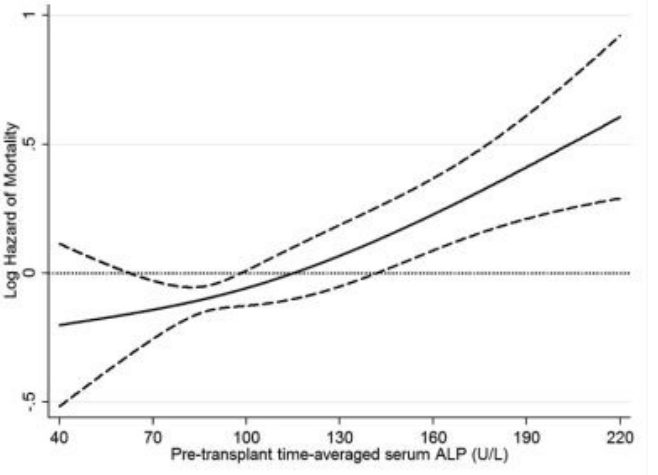
SA-PO997

Impact of Pre-Kidney-Transplant Serum Alkaline Phosphatase Level on Post-Transplant Outcomes Csaba P. Kovesdy,[1] Miklos Zsolt Molnar,[2] Istvan Mucsi,[3] Isidro B. Salusky,[4] Kamyar Kalantar-Zadeh.[1,4] *[1]University of Tennessee; [2]Harold Simmons Center, LABioMed at Harbor-UCLA; [3]McGill University Health Centre; [4]David Geffen School of Medicine at UCLA.*

Background: Mineral-and-bone disorders (MBD) are common in long-term dialysis patients and are risk factors for unfavorable outcomes. The associations between pre-transplant levels of alkaline phosphatase (ALP) and outcomes after kidney transplantation are not well defined.

Methods: Data of the Scientific Registry of Transplant Recipients (SRTR) up to 6/2007 were linked to the 5-year (7/2001-6/2006) cohort of a large dialysis organization in the United States. We identified all dialysis patients who received a kidney transplant during this period and divided them into groups according to increments of pre-transplant ALP. Unadjusted and multivariate adjusted predictors of transplant outcomes were examined.

Results: The 11,776 patients were 47±14 years old and included 39% women. There was linear increasing association between serum ALP level and risk of mortality. Compared to recipients with pre-transplant time-averaged serum ALP 80-<120 U/L, recipients with pre-transplant serum ALP 120<-160 and ≥160 U/L had 49% (HR: 1.49, 95% CI: 1.14-1.93) and 64% (HR:1.64, 95% CI:1.21-2.23) higher graft failure censored all-cause mortality in fully adjusted models.



Compared to recipients with pre-transplant serum ALP 80-<120 U/L, recipients with pre-transplant time-averaged serum ALP of 120<-160 and ≥160 U/L had 111% (HR:2.11, 95% CI:1.26-3.52) and 100% (HR:2.00, 95% CI:1.10-3.65) higher graft failure censored cardiovascular mortality. There was no significant association between time-averaged serum ALP categories and risk of death censored graft failure, delayed graft function or acute rejection.

Conclusions: Hemodialysis patients with pre-transplant serum alkaline phosphatase >120 U/L have unfavorable post-transplant mortality.

SA-PO998

Long-Term Improvement of Oxidative Stress via Kidney Transplantation Ameliorates Serum Sulfatide Levels, a Novel Candidate Inhibitory Factor of Cardiovascular Diseases Yuji Kamijo, Makoto Harada, Taro Kanno, Yasufumi Takahashi, Koji Hashimoto, Makoto Higuchi. *Department of Nephrology, Shinshu University School of Medicine, Matsumoto, Nagano, Japan.*

Background: Oxidative stress is a strong risk factor for cardiovascular diseases (CVD). The incidence of CVD is lower among kidney transplant recipients than hemodialysis patients, and the reduction in oxidative stress may be one reason for this difference. Recently, serum sulfatides were recognized as a candidate inhibitory factor of CVD affected by oxidative stress. However, the long-term changes in oxidative stress and serum sulfatide levels in kidney transplant recipients are unknown.

Methods: We investigated the long-term changes in a serum oxidative stress marker, malondialdehyde (MDA), and the serum sulfatide levels in 17 kidney transplant recipients. Multiple regression analysis was used to analyze the factors correlated with serum sulfatide levels.

Results: The high serum levels of MDA in the kidney transplant recipients decreased dramatically but were still high 1 year after kidney transplant surgery. MDA levels decreased further and reached near-normal levels more than 3 years after the surgery. Similarly, over the same 3 years, the low serum sulfatide levels increased to near-normal levels, reaching saturation. Multiple regression analysis showed that the most significant factors influencing serum sulfatide levels were MDA and total cholesterol content.

Conclusions: The current results show that over the long term, the internal improvement brought about by successful kidney transplantation can normalize oxidative stress. Oxidative normalization was significantly correlated with the restoration of serum sulfatide levels, which were also influenced by lipoprotein metabolism. The amelioration of serum sulfatide levels might contribute to the low incidence of CVD in kidney transplant recipients.

SA-PO999

GDF-15 Is Related to Anemia and Hepcidin in Kidney Allograft Recipients Jolanta Malyszko,[1] Jacek S. Malyszko,[1] Ewa Koc-Zorawska,[1] Iain C. Macdougall,[2] Michal Mysliwiec.[1] *[1]Nephrology, Medical University, Bialystok, Poland; [2]Renal Unit, King's College of London, United Kingdom.*

Background: Anemia is more prevalent in transplant recipients than in GFR matched CKD-patients, as a series of additional reasons come into play in the transplant situation. Hepcidin is a small defensin-like peptide whose production by hepatocytes is modulated in response to anemia, hypoxia or inflammation. Growth differentiation factor 15 (GDF-15) was identified as hepcidin-suppression factor that is expressed at high levels in patients with ineffective erythropoiesis.

The aim of the study was to assess GDF-15 levels and its correlations with iron parameters, including hepcidin in 60 stable kidney allograft recipients maintained on triple immunosuppressive therapy. Healthy volunteers were studied to obtain the normal ranges for the studied parameters.

Methods: Complete blood count, urea, serum lipids, fasting glucose, creatinine, iron status, were studied by standard laboratory method in the hospital central laboratory. We assessed GDF-15, hepcidin, sTfR, hemojuvelin, IL-6 and NGAL with commercially available assays.

Results: The mean GDF-15, NGAL, hepcidin and hemojuvelin were significantly higher in kidney allograft recipients when compared to the control group ($p<0.001$). GDF 15 was significantly higher in patients with anemia according to WHO definition when compared to non-anemic counterparts ($p<0,05$). GDF 15 levels were not dependent on the type of immunosuppressive therapy (MMF, azathioprine, CNI). In univariate analysis GDF-15 was related to the kidney function (creatinine $r=0.39$, $p<0.01$, eGFR by MDRD $r=-0.37$, $p<0.01$), urea ($r=0.39$, $p<0.01$), uric acid ($r=0.42$, $p<0.01$), hepcidin ($r=-0.32$, $p<0,01$), IL-6 ($r=0.28$, $p<0.,05$), hemoglobin ($r=-0.32$, $p<0.05$), hematocrit ($r=-0.31$, $p<0.05$), erythrocyte count ($r=-0.38$, $p<0.01$), NGAL ($r=-0.35$, $p<0.01$). GDF-15 was not related to serum iron, ferritin, sTfR. In multivariate analysis predictor of GDF-15 was hepcidin (beta value 0.32, $p=0.03$). explaining 38% of the variation of the hepcidin levels.

Conclusions: GDF 15 by affecting hepcidin expression might be involved on the pathogenesis of anemia in kidney allograft recipients.

Renal Allograft Calcification: Prevalence, Associated Clinical Conditions and Implications for the Long-Term Transplant Outcome Wilfried Gwinner,[1] Irina Scheffner,[1] Johan M. Lorenzen,[1] Verena Broecker,[3] Bernhard Vaske,[1] Michael Mengel,[2] Hermann G. Haller,[1] Anke Schwarz.[1] *[1]Hannover Medical School, Germany; [2]University of Alberta, Canada; [3]University of Cambridge, United Kingdom.*

Background: We have previously reported that renal allograft calcification is frequent in the first months after transplantation (Tx) and is associated with a deterioration of the graft function at one year (Am J Transplant 5:1934,2005). In this study, a large cohort of renal Tx recipients is examined for allograft calcification, with emphasis on factors associated with the calcifications and the long-term graft outcome.

Methods: 420 patients with protocol biosies (6 weeks, 3 & 6 months) were included. Clinical and lab data were recorded at the biopsy time points and then yearly. Allograft outcome was assessed over a period of up to ten years post-Tx.

Results: Of 420 patients, 106 (25%) had calcifications in the tubular lumen and interstitium in one or repeated protocol biopsies. In univariate analyses, pre-Tx hyperparathyroidism, duration of dialysis treatment, post-Tx serum levels of calcium and parathormone and acute tubular injury were related to the calcifications. Calcifications were not related to rejection episodes, calcineurin inhibitor toxicity, or tubulointerstitial fibrosis and tubular atrophy. By regression analysis, serum levels of calcium and parathormone were confirmed as significant factors. Long-term outcome over a period of up to 10 years was assessed by patient and graft survival and renal function. Patient and graft survival was similar in patients with and without allograft calcification. A progressive decline in allograft function was observed in patients with severe or repeated findings of calcification in the biopsies, compared to patients without calcification (eGFR -4.3 vs. -2.3 ml/min*year; $p=0.006$). Parathyroidectomy was associated with a stabilization of allograft function in these patients.

Conclusions: Renal allograft calcification is a relevant complication after renal Tx leading to an inferior long-term function. Decision for parathyroidectomy and its timing or use of potential medical alternatives like calcimimetics need further study.

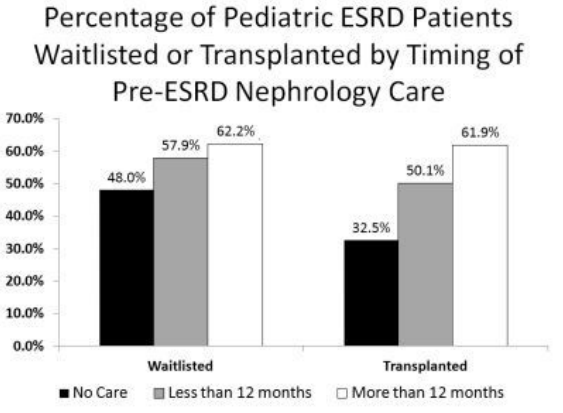
Access to Pre-ESRD Nephrology Care Is Associated with Improved Transplant Access for Children with ESRD Rachel E. Patzer,[1,2] Nancy G. Kutner,[3] William M. McClellan,[2,4] Sandra Amaral.[5] *[1]Emory Transplant Center, Emory University, Atlanta, GA; [2]Department of Epidemiology, Rollins School of Public Health, Atlanta, GA; [3]USRDS Rehabilitation/QoL Special Studies Center, Emory University, Atlanta, GA; [4]Division of Nephrology, Emory University, Atlanta, GA; [5]Department of Pediatrics, The Children's Hospital of Philadelphia, Philadelphia, PA.*

Background: In 2005, the United States Renal Data System (USRDS) began collecting information about receipt of nephrologist care prior to ESRD. We examined whether pre-ESRD nephrology care was associated with transplant access for children with ESRD.

Methods: We examined all pediatric (< 21 yrs) ESRD patients in USRDS from 2005-2009 who had complete data on pre-ESRD nephrology care. Multivariable Cox models were used to examine the impact of pre-ESRD nephrology care on waitlisting and transplantation.

Results: Among 5,776 children with incident ESRD between 2005-2009, the median age was 15 years, 40.4% were white, 27% Hispanic, and 24% black. 66.2% of patients received nephrology care prior to ESRD. Public or no health insurance, African American race, cystic/hereditary renal disease, and younger age were associated with lower likelihood of receiving any nephrology care prior to ESRD (all $p<0.0001$). A greater proportion of patients who had < 12 months and ≥ 12 months vs. no pre-ESRD nephrology care were waitlisted (57.9% and 62.2% vs. 48%, $p<0.0001$) and transplanted (50.1% and 61.9% vs. 32.5%, $p<0.0001$), respectively.



In multivariable analyses, pre-ESRD nephrology care was associated with an increased rate of waitlisting (HR=1.68; 95% CI: 1.54-1.82) and transplant (HR=1.85; 95% CI: 1.69-2.04) compared with no preceding specialty care.

Conclusions: Access to nephrology care prior to ESRD is associated with a higher rate of waitlisting and transplantation among children with ESRD.

SA-PO1002

Clinical Features of Tuberculosis in Kidney Transplant Recipients in Brazil Igor Marques,[1] Bernadete M.C. Ferreira,[2] Luiz Sergio Azevedo,[1] Ligia C. Pierrotti,[3] Victor Sato,[2] Renato Antunes Caires,[2] Elias David-Neto.[1] *[1]Renal Transplant Service, Hospital das Clínicas, University of Sao Paulo School of Medicine, São Paulo, SP, Brazil; [2]Nephrology Division, Hospital das Clínicas, University of Sao Paulo School of Medicine, São Paulo, SP, Brazil; [3]Department of Infectious Disease, Hospital das Clínicas, University of Sao Paulo School of Medicine, São Paulo, SP, Brazil.*

Background: Most studies about post-transplant tuberculosis (TB) describes small patient samples, not comparing kidney transplant recipients (KTRs) with and without TB. The aim of this study was to identify risk factors and to describe the incidence and clinical features of *Mycobacterium tuberculosis* infection after kidney transplantation in Brazil.

Methods: A retrospective case-control single center study with total of 47 cases (2.9%) in Brazil (2000 to 2010) comparing it with 94 KTRs without TB.

Results: The incidence was 945 cases/100,000 patients/year, much higher than the general population of Brazil. Ten-year death-censored graft survival and patient survival were similar between KTRs with TB and those without (62% vs. 72%; p=0.33 and 65% vs. 72%; p= 0.73, respectively). The groups were compared regarding age, gender, re-transplants, cause of end-stage renal disease, renal replacement therapy prior to the transplantation, hepatitis C virus infection, diabetes, type of donor, cytomegalovirus infection and immunosuppressive protocol, but no statistical difference was found between them. Among the cases, 19 (40,4%) had prior acute rejection against 34 (36%) controls ($p=45$). Of the KTRs with TB, 81% were diagnosed within the first 2 years post-transplant and 83% had pulmonary TB, 11% had previous history. The commonest symptoms were fever (81%) and cough (32%). The median time for the diagnosis was 32 days.Mortality during treatment was 13% (6 cases) and 5 deaths were attributed to TB.

Conclusions: This study didn't identify risk factors for TB post-transplant, but there is the necessity of more studies. It is imperative to know and understand the behavior and presentation of TB in KTRs and determinate the possible risk factors for its occurrence to delineate possible interventions to decrease the incidence of TB post-transplant.

SA-PO1003

Inflammatory Infiltrates and Renal Outcome in BKVAN and Acute Renal Allograft Rejection Ünsal Yapici,[1] Jesper Kers,[1] Frederike J. Bemelman,[2] Joris J. Roelofs,[1] Nike Claessen,[1] Ineke Ten Berge,[2] Sandrine Florquin.[1] *[1]Pathology, Academic Medical Center, Amsterdam, Netherlands; [2]Nephrology, Academic Medical Center, Amsterdam, Netherlands.*

Background: Cellular infiltrates in renal biopsies are the hallmark of acute rejection and viral infections, particularly BK-virus nephropathy (BKVAN). Characterization of the heterogeneous interstitial infiltrate might have the potential to discriminate between specific/harmful and non-specific/harmless infiltrates and perhaps between viral infections and acute rejection.

Methods: Using immunohistochemistry, we quantified T- and B-lymphocytes, plasma cells and macrophages in two cohorts comprising of 50 patients with an episode of acute rejection and 30 patients with BKVAN. In addition, the expression of MHC class II, C4d and C3c in tubular epithelial cells was investigated in both cohorts. All biopsies were scored according to Banff 2007. The BKVAN cohort was also scored for viral load (immunohistochemistry) and viral stage (histology). Late renal allograft dysfunction was defined as an eGFR < 30 mL/min/1,73m² or return to dialysis.

Results: No differences in the number of T-lymphocytes, B-lymphocytes and macrophages were observed between the two cohorts. In both cohorts variable expression of MHC class II was found, without significant differences between the groups. We could not detect C4D or C3C staining along the tubular basement membrane. In BKVAN, a significantly higher number of plasma cells was found ($P = 0.03$) and interstitial fibrosis and tubular atrophy was more pronounced ($P < 0.01$). There were no significant differences in outcome between acute rejection and BKVAN. In the BKVAN cohort, the viral load score was not associated with a detrimental outcome. However, stage B was associated with worse outcome, even compared to stage C.

Conclusions: These findings indicate that the composition of the inflammatory infiltrate is comparable in acute rejection and BKVAN, except for higher amount of plasma cells in BKVAN. There is no difference in tubular expression of HLA class II, C4d or C3c and both groups show a comparable renal outcome. However, in the BKVAN cohort a stage B at histological examination is related to late renal allograft dysfunction.

SA-PO1004

Increased Renal Tubular Cell Apoptosis in Donation after Cardiac Death (DCD) Kidneys Compared with Standard Criteria Donor (SCD) Kidneys Swati Jain, Danica Galesic Ljubanovic, Charles L. Edelstein, Alkesh Jani. *UC Denver, Aurora, CO.*

Background: DCD kidneys suffer increased DGF due to warm and cold ischemia (CI). The effect of pulsatile perfusion (PP) vs. static preservation (SP) on apoptotic pathways is unknown. In a porcine model of DCD, we hypothesized that DCD kidneys have increased apoptosis and caspase-3, and reduced X-linked inhibitor of apoptosis (XIAP) protein compared with SCD kidneys. We also sought to determine whether PP protected DCD kidneys by reducing apoptosis and increasing XIAP expression.

Methods: Male Yorkshire pigs subjected to cardiac death were perfused with cold UW solution and subjected to SP or PP for 24 hrs. Kidney biopsies were obtained at 0 and 24 hrs of CI. Apoptotic renal tubular cells (RTE) were quantitated by a renal pathologist. SCD kidneys not subjected to cardiac death were used as controls. Immunoblot was used to assess active caspase-3 (17kDa) and XIAP(53kDa).

Results: Apoptotic RTEs and caspase-3 expression were significantly increased in DCD vs SCD kidneys whereas XIAP and BCL-XL expression were not detected in DCD kidneys.

Table 1

	SCD		DCD	
CI Time (hrs.)	0	24	0	24
Apoptotic RTEs/ hpf	1.3±0.6	2.2±0.5	0.2±0.1	9.8±2.3*
Caspase-3 expression	ND	ND	++	+++
XIAP expression	+++	+++	ND	ND
BCL-XL expression	+++	+++	ND	ND

n=4; *P < 0.005 vs SCD 0 and 24 hr CI

Next we hypothesized that DCD kidneys subjected to PP would have less apoptosis and increased XIAP expression vs. DCD kidneys stored by SP. PP significantly reduced RTE apoptosis in DCD kidneys but was not associated with increased XIAP expression. Table 2.

	SP		PP	
CI Time (hrs.)	**0**	**24**	**0**	**24**
Apoptotic RTE/hpf	**0.2± 0.1**	**9.8± 2.3***	**0.1± 0.1**	**2.5± 1.4****
Caspase 3/7 activity nmol/min/mg	**84.3 ± 20.5**	**453.3 ±307.7**	**88.5 ±33.8**	**466.3± 234.1**
XIAP protein expression	**ND**	**ND**	**ND**	**ND**

n=4; *P < 0.005 vs. SP 0 hr CI; ** P<0.005 vs. SP 0 and 24 hr CI; ND = not detected

Conclusions: These findings suggest that DCD kidneys experience more RTE apoptosis vs. SCD kidneys associated with loss of anti-apoptotic XIAP and BCL-XL protein expression. DCD kidneys subjected to PP had significantly decreased apoptosis that was independent of caspase-3 and XIAP protein expression.

SA-PO1005

Assessment of Beta Cell Function Following Renal Transplantation David Langsford,[1] Varuni Obeyesekere,[2] Robyn G. Langham,[1] Glenn Ward,[2] Karen M. Dwyer.[1] *[1]Department of Nephrology, St Vincent's Hospital, Melbourne, Australia; [2]Department of Endocrinology, St Vincent's Hospital, Melbourne, Australia.*

Background: Up to fifty percent of non-diabetic patients on the renal transplant waiting list have unrecognised hyperglycemia and are at risk for new onset diabetes after transplantation (NODAT). We aimed to assess the risk of developing NODAT by measuring peri-transplant β cell function in patients with end stage renal failure (ESRF) and following transplantation.

Methods: The recruited patients all had ESRF and had received a transplanted kidney from a living donor. All patients received induction therapy with basiliximab and standard triple therapy with a calcineurin inhibitor, mycophenolate mofetil and steroids. A modified oral glucose tolerance test (oGTT: 0, 30, 60 and 120 minutes) was performed pre-, 3 and 12 months post transplantation. A shortened intravenous glucose tolerance test (IV GTT) was performed pre-, day 7, 3 and 12 months post transplantation. The oral disposition (DIo) and IV disposition indices (DIiv) were calculated. Baseline, post-transplant metabolic and renal specific data were collected.

Results: Thirty percent (3/9) of patients with ESRF had unrecognised hyperglycemia pre-transplant. Fifty percent (5/10) patients developed hyperglycemia post transplant within three months of transplantation, which resolved in three patients within one year. Changes in DIo and DIiv were detected as early as day seven post transplant, however the changes in DIo and DIiv are not necessarily concordant.

Conclusions: Unrecognised hyperglycemia is common in patients with ESRF. β cell function is dynamic and changes rapidly following renal transplantation. Such changes can be measured by calculation of the DI and reflect the impact of surgery and high dose immunosuppression and changes in pre-existing insulin resistance. DIo and DIiv do not necessarily change in parallel, which together with transient hyperglycemia may reflect inhibition of the incretin effect in the setting of the high dose steroids given in the early post transplantation period.

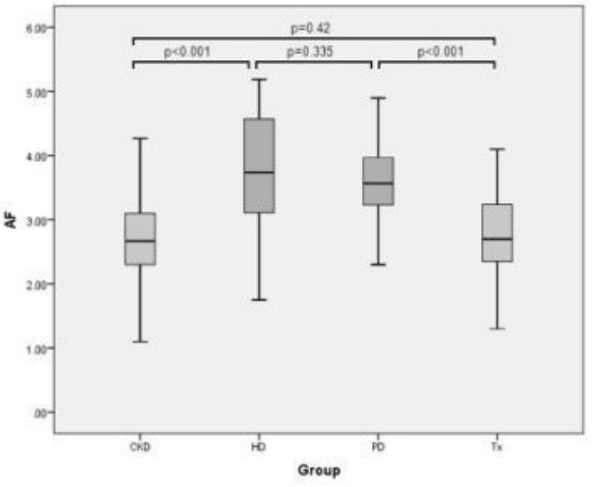
SA-PO1006

Transplantation Is Associated with Reduced Tissue-Advanced Glycation End Product Deposition Lisa E. Crowley,[1] Catherine Johnson,[1] Richard J. Fluck,[1] Maarten W. Taal,[1] Chris W. McIntyre,[1,2] Janson Leung.[1] *[1]Department of Renal Medicine, Royal Derby Hospital, Derby, United Kingdom; [2]School of Graduate Entry Medicine and Health, University of Nottingham, Nottingham, United Kingdom.*

Background: Tissue-Advanced glycation end products (AGEs) are a measure of cumulative metabolic stress. Measurement of tissue AGEs by skin autoflourescence (SAF) correlates well with cardiovascular outcomes in diabetic and dialysis patients and is independently associated with cardiovascular risk factors in chronic kidney disease stage 3. This study aimed to evaluate tissue AGEs in a population of renal transplant patients.

Methods: We studied 66 transplant patients (31 female, 35 male). Tissue AGEs were measured in transplant recipients using a SAF reader (AGE reader, DiagnOptics). Values were compared with a matched cohort of CKD 3 patients (on a 2:1 basis) and 115 dialysis patients (62 HD, 53 PD).

Results: Mean value of measured SAF in the transplant patients was 2.79±0.63. SAF correlated most strongly with age (r=0.31) but there was no correlation between SAF and eGFR, transplant age or renal replacement therapy vintage. There was a significant difference between values in dialysis patients and those found in transplant recipients but no difference between transplant and CKD stage 3. In the small number of patients with results recorded both on dialysis and following transplantation SAF decreased by around 25% (mean post transplant time of 20 months).



Conclusions: Tissue AGE values in transplant patients are elevated compared to non CKD control values. However they were similar to patients with established CKD 3 and significantly lower than patients still receiving dialysis. Our data suggest that transplantation may be associated with a reduction in accumulated tissue AGE products and this might be an important component of the observed reduction in cardiovascular risk compared to dialysis patients.

SA-PO1007

Dietary Omega-3 Fatty Acids Intake Is Independently Associated with Lower Serum FGF23 in Renal Transplant Recipients Leandro Cunha Baia,[1] Else Van den Berg,[1] Marc G. Vervloet,[2] Ita Pfeferman Heilberg,[3] Gerjan Navis,[1] Stephan J.L. Bakker,[1] Martin H. De Borst.[1] *[1]Nephrology, University of Groningen (UMCG), Groningen, Netherlands; [2]Nephrology, VU-MC, Amsterdam, Netherlands; [3]Nephrology, Universidade Federal de Sao Paulo, Sao Paulo, Brazil.*

Background: Fibroblast growth factor 23 (FGF23) has been identified as an independent risk factor for cardiovascular morbidity and mortality in patients with chronic kidney disease and renal transplant recipients (RTR). Little is known about determinants of FGF23. We aimed to identify dietary factors as independent modifiable determinants of FGF23 after kidney transplantation.

Methods: In this cross-sectional study, the diet of 707 RTR was assessed with a food frequency questionnaire, inquiring about intake of macro- and micronutrients. Serum intact FGF23 levels were determined by ELISA and values were log-transformed for analyses. We assessed known determinants of FGF23 including intake of protein and phosphate, BMI, serum hsCRP, phosphate and PTH, eGFR and proteinuria as potential confounders. Urinary calcium and phosphate excretions were measured in 24h urine samples. We applied uni- and multivariate regression analyses to identify independent determinants of FGF23 levels.

Results: Mean age was 53±12.8 years; 57% of patients were male. Median time after transplantation was 5.4 [1.9-12.2] years and mean eGFR was 52.3 ± 20.2 ml/min. Multivariate regression analyses revealed significant independent associations of eGFR (standardized $\beta = -0.49$ $p<0.001$), serum phosphate (st. $\beta = 0.21$, $p<0.001$) and BMI (st. $\beta = 0.14$, $p=0.004$) with FGF23. Of the dietary factors, the omega-3 fatty acids docosahexaenoic acid (DHA) (st. $\beta = -0.14$, $p=0.004$) and eicosapentaenoic (EPA) (st. $\beta= -0.15$, $p=0.001$) were inversely associated with FGF23, independent of eGFR, serum phosphate and BMI. No association was found between protein or phosphate intake and FGF23.

Conclusions: Dietary intake of DHA and EPA emerged as novel factors inversely associated with serum FGF23, independent of known determinants of FGF23 in RTR. Accordingly, an increase in dietary DHA and EPA intake might reduce serum FGF23 levels and help lowering cardiovascular morbidity and mortality in RTR.

SA-PO1008

Altered Gene Expression in Transplant Kidneys in the Early Stage of New Onset Diabetes after Transplantation Zoltan G. Laszik,[1] Sindhu Chandran,[2] F. Vincenti.[2] *[1]Pathology, UCSF, San Francisco, CA; [2]Transplant Service, UCSF, San Francisco, CA.*

Background: New-onset diabetes after transplantation (NODAT) is an independent risk factor for graft loss of unclear etiology. The aim of our study was to determine global gene expression differences in transplant kidney surveillance biopsies of patients with NODAT at 6 months post transplantation.

Methods: Renal transplant recipients with NODAT who underwent a 6-month surveillance biopsy at UCSF between July 1, 2009 and October 31, 2010 were identified. Controls included 6-months surveillance biopsies with no NODAT and no pre-existing diabetes mellitus. Only biopsies with normal morphology and with at least 3 months duration of diabetes in the NODAT group were included in the study. Agilent whole human genome 4x44K ink-jet arrays were used to determine global gene expression in 5 biopsies with and in 16 biopsies without NODAT. A one-way ANOVA linear model was fit to the comparison to estimate the mean M values, B statistic, false discovery rate (FDR) and p-value for each gene for the comparison of interest.

Results: With a stringent FDR of < 0.01 there were 25 differentially expressed transcripts identified in NODAT versus control kidneys. The average difference in gene expression level was 1.51-fold with 19 genes being up-regulated and 6 genes being down-regulated. Some of the differentially expressed genes code for structural proteins such as elastin while others play a role in mediating growth and repair (GDF7), apoptosis (SLC39A4), acquired podocyte diseases (CMIP), inflammation (chemokine receptor CCR1), metabolism (NADH dehydrogenase), protein trafficking (RAB2A), vascular homeostasis (HSPG2) and signal transduction (PRR5, GDF7). Most of these genes have no known function in the kidney. Possible therapeutic targets in the dataset include CCR1 and HSPG2.

Conclusions: Defining altered molecular phenotype in transplanted kidneys with recent onset NODAT may help to understand the pathogenetic pathways during the early preclinical stages of progressive renal injury. This approach may also help to identify therapeutic targets for further analysis aimed to prevent disease progression.

SA-PO1009

Urinary Polyomavirus-Haufen Shedding Marks Polyomavirus Nephropathy: A Proof-of-Concept Study for a Novel Diagnostic Non-Invasive Urine Biomarker Volker Nickeleit, Bruna Brylawski, Harsharan Singh. *Pathology, Division of Nephropathology, University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: Polyomavirus Nephropathy (PVN) is the most significant viral renal allograft infection with 4% incidence. Currently a definitive diagnosis is only established by renal biopsy. Recently we described a novel, non-invasive urinary assay to diagnose PVN, i.e. the "polyomavirus (PV)-Haufen-test", with positive and negative predictive values of > 95%. This test has great diagnostic potential. Hypothesis: PV-aggregation and Haufen formation depend on a high concentration of Tamm-Horsfall protein (THP) that is only present in injured renal tubules and not in voided urine. Thus the presence of PV-Haufen in voided urines is specific for intrarenal disease.

Methods: Part-A- association of PV-Haufen and THP: A1) Immunohistochemistry of PVN cases (n=3) with double labeling to detect PV and THP in renal tubules. A2) Immunogold electron microscopy of urinary PV-Haufen to detect Haufen-bound THP (n=3). A3) Immunoprecipitation studies on urinary PV-Haufen (n=6). A4) Dilution curves altering THP concentrations in fluids mimicking primary and secondary urines and evaluating for PV-aggregation and Haufen formation (n=5). Part-B – THP concentrations in voided urine samples (with concurrent kidney biopsies; n=20).

Results: Part-A. A1) In PVN intratubular PV aggregates show abundant THP. A2) Urinary PV-Haufen are intimately admixed with THP. A3) Immunoprecipitation of urinary PV-Haufen shows abundant coprecipitation of PV and THP. A4) PV aggregation and PV-Haufen formation is THP dose dependent and only occurs with high THP concentrations of > 1mg THP/ml fluid mimicking primary urine in injured tubules. Part-B. THP concentrations in voided urine samples are low, median THP 4.5 microgram/ml urine, range: 0.7-19.5.

Conclusions: PV-Haufen are closely associated with THP. PV-Haufen formation occurs in the setting of very high THP concentrations found in injured renal tubules exceeding voided urine THP concentrations 50 fold. The genesis of PV-Haufen is similar to the formation of intratubular red- or white blood cell casts. Urinary PV-Haufen are novel biomarkers for intrarenal PVN.

SA-PO1010

Prevanlence of Donor Specific HLA-Antibodies (DSA) after Pediatric Kidney Transplantation and Follow Up after Therapeutic Intervention Lars Pape, Nele K. Kanzelmeyer. *Pediatric Nephrology, MHH, Hannover, Germany.*

Background: DSA can lead to deterioration of graft function, associated with chronic humeral rejection after ped. KTx. Until now, no data about prevalence and treatment protocols for children with early detection of DSA are available.

Methods: We retrospectively analyzed 256 routine-measurements of HLA ab-class I and II on a yearly basis in 88 children after KTx (mean age 15 ± 4 years, 30 girls) from 2008-2012 with Luminex xMAP technology. In case of positive HLA ab, donor-specificity was evaluated. The clinical course, therapeutic interventions and kidney biopsy results were analyzed.

Results: In 48% of patients no DSA were found. 52 % patients showed HLA antibodies, donor specifity was confirmed in 12,5% of patients. 4/11 patients (mean DSA MFI 7964) received no treatment because of normal renal function. Transplant function was stable and DSA-MFI increased to 9105. 3/11 were treated with Rituximab because of an increase in s-creatinine > 10% and one child was treated with immuneglobulins. In these children kidney function stayed stable, mean DSA MFI was stable 6820 to 7717). In 3 patients with an increase of s-creatinine > 25%, kidney biopsies showed chronic humeral rejection, in 2 cases associated with transplant glomerulopathy. One patient was treated only with Prednisolon-pulses and Rituximab. No further increase in s-creatinine could be detected and mean DSA MFI increased from 8997 to 17180. In the other three children DSA (mean MFI 7231) were associated with the most severe increase in s-creatinine. They were treated with Prednisolone-pulses, plasmapheresis, rituximab and immuneglobulins. Kidney function and DSA-MFI stayed stable (mean MFI 7300).

Conclusions: In an unselected population after ped KTx, the prevalence of DSA is approximately 12,5 %. It remains unclear, if treatment with Rituximab will help to avoid later humoral rejection in children with DSA who experience no graft dysfunction. Intensive therapy with Prednisolon-pulses, Rituximab and immuneglobulins ± Plasmapheresis seems to be a good option for treatment of DSA-associated chronic rejection with deterioration of graft function. Effect of treatment can be seen on graft function but not on DSA-MFI values.

SA-PO1011

Cytokines and Chemokines as Markers of Tolerance and Rejection after Kidney Transplantation Cornelia Anneliese Blume,[1] Hermann G. Haller,[1] Christine S. Falk.[2] *[1]Nephrology and Hypertensiology, Medical School Hannover, Hannover, Germany; [2]Institute for Transplant Immunology, Medical School Hannover, Hannover, Germany.*

Background: Defining biomarkers suitable for prediction of operational tolerance or rejection is of central interest in future transplantation medicine in order be able to classify patients for individualized immunsuppression.

Methods: Using multiplex protein arrays with 60 different parameters (cytokines. chemokines and growth factors), we analyzed the microenvironment in 32 renal biopsies of 131 renal transplant recipients with histological definition of transplant condition. The patient group comprised 30 patients with T cell mediated rejection (TCMR) according to borderline changes (group 1). 5 of 15 patients with TCMR (group 2). 5 of 18 patients with chronic humoral rejection (group 3) and 16 of 68 patients with unsuspicious biopsies and stable transplant function (tolerant patients, group 0). Levels of three biopsy compartments (capsule, subcapsule and cortex region, re-evaluated by pathological analysis) were compared to plasma levels of these soluble factors (T-test).

Results: 1. We found characteristic gradients for SCF as well as HGF, M-CSF and CXCL9 in the biopsy of group 0 that were mostly abrogated in case of rejection. 2. The plasma level of CXCL9 was indicative for chronic humoral rejection (group 3) and the plasma level of CCL2 for acute rejection (group 2) (table 1). 3. The cortex levels of SCF, CXCL9, the chemokine CCL5 (Rantes), M-CSF, HGF and CCL2 were generally elevated in rejection (Table 2-6) as compared to unsuspicious biopsies (group 0).

Conclusions: SCF should be tested as a marker of tolerance. CXCL9–already described as a urine marker of rejection – may also serve as a plasma marker of rejection. During rejection, HGF may reflect tissue repair, M-CSF may indicate a shift of macrophages towards the graft. With this protein-based technique, novel biomarkers in kidney biopsies and plasma may be verified by ROC- analysis in order to classify patients by the microenvironment in addition to the pathological staging which may substantially improve the reliability of the classification.

Utility of ImmuKnow Assay in BK Infection after Kidney Transplantation Nashat Burhan Imran,[1] Vikyath Prakash,[1] Rachelle V. Dyquiangco,[1] Medha Airy,[1] Charles G. Minard,[1] Richard J. Knight,[2] Venkataraman Ramanathan.[1] *[1]Nephrology, Baylor College of Medicine, Houston, TX; [2]Methodist Hospital, Houston, TX.*

Background: By quantifying cellular ATP production, ImmuKnow® assay provides an estimate of immune function. We studied the utility of this assay in kidney transplant (KT) patients with BK infection.

Methods: We identified KT recipients who had BK viremia (BKV) during 2-year study period. ATP level and blood BK PCR was obtained at 1 month post-transplant and then quarterly for a year. BKV was defined as PCR >1000 copies and first detection was defined as incident viremia. We compared ATP values in BK negative patients to patients with varying levels of BKV (1-10K, 10-100K and >100K). ATP values were subdivided into recommended "low" (≤225), "moderate" (226-524) and "strong" immune response categories. A general linear mixed model with an unstructured residual covariance matrix was used to model ATP values as a function of BK infection status and time. Bonferroni correction was used.

Results: We had 261 paired ATP/BK PCR observations and 72 patients developed BKV during the study period. After adjusting for time, BK infection was significantly associated with low ATP (P=0.01). Mean ATP levels were in "moderate" immune response category in all groups. But ATP was significantly lower in patients in BK >100k compared with the BK negative (359vs.468, P=0.03) and BK 1k-10k groups (359vs.493, P=0.007).

	No BK (n=124)	1K-10K (n=60)	10K-100K (n=43)	>100K (n=34)
ATP	468±21	493±26	420±30	359±35
ATP≥525	51(41%)	25(42%)	7(16%)	5(15%)
ATP≤225	13(10%)	10(17%)	10(23%)	15(44%)

When subdivided into immune response categories, high viral load patients had "low" immune response (Fisher Exact test P=0.0001). Compared to their baseline ATP values, incident viremia patients had 32% decline in ATP values (541±272 vs. 366±204, p 0.0001) at time of first BK positivity. Even though, every 100 value drop in ATP had a 6.6% greater hazard for BK infection, it was not statistically significant.

Conclusions: Even though ATP level is significantly low when BK PCR >100K copies, most BK patients are in "moderate" immune category. Incident viremia patients have a significant decline in ATP value compared to baseline values.

Renal and Urinary Levels of EPCR Correlate with Acute Renal Allograft Rejection Lionel Lattenist,[1] Jesper Kers,[1] Nike Claessen,[1] Ineke Ten Berge,[2] Frederike J. Bemelman,[2] Sandrine Florquin,[1] Joris J. Roelofs.[1] *[1]Pathology, Academic Medical Center, Amsterdam, Netherlands; [2]Nephrology, Academic Medical Center, Amsterdam, Netherlands.*

Background: The Endothelial protein C receptor (EPCR) is expressed on endothelial cells of large blood vessels and to a lesser extent on capillaries. Through cleavage by a metalloprotease soluble EPCR (sEPCR) is formed. EPCR increases activation of proteinC. Active protein C has anticoagulant, anti-inflammatory and cytoprotective effects.

Acute rejection of kidney allograft can be divided in acute T-cell and antibody-mediated rejection (respectively TCMR and ABMR). Especially ABMR is characterized by activation of coagulation. Currently no reliable non-invasive biomarkers are available to monitor rejection.

In this study we investigate the EPCR expression pattern in kidney transplants and correlate plasma and urine sEPCR levels to acute renal allograft rejection.

Methods: Renal biopsies were available from 87 renal transplant patients (39 without rejection, 29 TCMR and 19 ABMR), we had access to matched plasma and urine samples for a portion of this cohort. Renal EPCR expression was assessed by RT-PCR and immunostaining. Plasma and urine sEPCR levels were measured by ELISA. Staining intensity was scored semiquantitatively on a scale from 0 to 3.

Results: ABMR patients showed higher levels of EPCR mRNA than TCMR patients.

EPCR expression in venules did not differ whereas EPCR expression on glomeruli and peritubular capillaries was significantly elevated in ABMR patients than in TCMR or control patients. EPCR expression was higher in tubules and arteries of rejection patients than in control patients.

Plasma sEPCR levels did not differ. Urine sEPCR levels were elevated in the ABMR group than in patients with TCMR or without rejection. ROC analysis demonstrated that urinary sEPCR is appropriate to discriminate between ABMR patients and TCMR or control patients.

Conclusions: We conclude that urinary sEPCR could be a novel non-invasive biomarker of antibody mediated rejection in renal transplantation.

SA-PO1014

Angiopoietin-2: A Prognostic Marker in Kidney Transplantation Welmoet H. Westendorp,[1] Harry Van Goor,[2] Lyan G. Koudstaal,[1] Jeffrey Damman,[1] Hans Burgerhof,[3] Rutger J. Ploeg,[5] Marc Seelen,[4] Henri G.D. Leuvenink.[1] *[1]Surgery, University Medical Center Groningen, Groningen, Netherlands; [2]Pathology, University Medical Center Groningen, Groningen, Netherlands; [3]Epidemiology, University Medical Center Groningen, Groningen, Netherlands; [4]Nephrology, University Medical Center Groningen, Groningen, Netherlands; [5]Nuffield Dept. of Surgical Sciences, University of Oxford, Oxford, United Kingdom.*

Background: Organs derived from deceased brain dead (DBD) donors show worse organ function and more acute rejection episodes than organs derived from living donors. Human studies have provided evidence that DBD donors suffer from bacterial translocation and higher endotoxin load. A link between endotoxemia and Angiopoietin 2 (Ang2) is established. In humans, LPS triggers Ang2 release, which binds to the Tie2 receptor. Use of Ang2 as biomarker of endothelial integrity has gained much attention since Ang2 reflects the immunogenic state of an organ and could therefore be used as a predictor of organ quality and survival.

Methods: We measured serum Ang2 by ELISA in 100 DBD and 220 living donors (LD). Serum was obtained immediately after the declaration of brain death (T0) and just before organ retrieval (T1). Serum from living kidney donors retrieved after start of the operation (T0) and just prior to organ retrieval (T1) was used as control.

Results: Serum Ang2 levels in DBD donors are higher at T0 and T1 (T0: 1925 ± 198.9 pg/ml and T1: 2418 ± 305.2 pg/ml) compared to living donors (T0: 690.7 ± 47.60 pg/ml and T1: 1384 ± 102.9 pg/ml). In LD, Ang2 levels increased at T1 compared to T0 ($p<0.05$). In LD, T1 Ang2 levels are associated with glomerular filtration rate (GFR) at 12 months after transplantation (Spearman's ρ -0.193 p=0.019). In DBD donors, T0 Ang2 levels are associated with serum creatinin 14 days after transplantation (Spearman's ρ -0.333 p=0.017).

Conclusions: These results show elevated Ang2 levels in DBD compared to LD, which is illustrative of an inflammatory response. A clinical validated Ang2 test and therapeutic interventions that modulate the Ang2 response in the DBD donor might be novel tools to improve organ quality.

Reduced Urinary NOx-Excretion Is Associated with Increased Cardiovascular Risk Factors in Renal Transplant Recipients

Else van den Berg,[1,2] Gerjan Navis,[2] Elizabeth Brink,[1] Lisette Den Boef,[3] Henri G.D. Leuvenink,[4] Reinold O.B. Gans,[5] Stephan J.L. Bakker,[1,5] Harry Van Goor.[3] *[1]TI Food&Nutrition, Wageningen; [2]Dept of Nephrology, University Medical Center Groningen (UMCG); [3]Dept of Pathology, UMCG; [4]Dept of Surgery, UMCG; [5]Dept of Internal Medicine, UMCG, the Netherlands.*

Background: Cardiovascular (CV) risk is high in renal transplant recipients (RTR) and a leading cause for graft loss and mortality. Since endothelial dysfunction is common in RTR, reduced NO production might relate to increased CV risk in RTR. We studied 1) NO production in RTR vs controls; 2) its determinants in RTR; 3) its association with CV risk factors in RTR.

Methods: We included 707 outpatient RTR (age 53±13 yrs, 57% male, ≥1yr post-transplantation (Rtx), time since Rtx 5.4 [1.9-12.2] yrs) and 107 healthy controls (53±10 yrs, 47% male). Systemic NO production was assessed by measurement of 24h urinary excretion of its stable end products NO_2/NO_3 (UNO_x). Detailed data on diet (questionnaires) and drugs were obtained to assess exogenous NO-sources (mainly vegetables). CV risk factors (blood pressure, pulse pressure, heart rate, plasma sodium, Nt-pro-BNP, hs-CRP, HbA1c, proteinuria) were measured.

Results: UNO_x was markedly decreased in RTR (588 [400-812] vs. 1020 [796-1285] nmol/24h in controls, p<0.001), while vegetable intake was similar (92±57 vs. 93±58 g/d, ns) and approximately half of the WHO-recommended intake. Gender, vegetable intake and renal function were independent determinants of UNO_x in RTR. SBP and DBP were 136±18 and 83±11 mmHg resp; creatinine clearance was 66±26 ml/min. On linear regression analyses, UNO_x was inversely associated with SBP (β=-0.29; p=0.005), pulse pressure (β=-0.16; p=0.02) heart rate (β=-0.19 p=0.008), plasma sodium (β=-0.03 p=0.04), hs-CRP (β=-0.02 p=0.008), HbA1c (β=-0.01 p=0.05) and positively with CrCl (β=0.51, p=0.002), independent of age, sex, BSA, drug use and vegetable intake. No association was observed with proteinuria.

Conclusions: The pronounced reduction in UNO_x in RTR compared to controls, and its robust, independent association with CRP and functional characteristics of CV risk points to a role for endogenous NO in CV risk in RTR.

SA-PO1016

Urinary Excretion of Sulfate and Thiosulfate in Renal Transplant Recipients

Else van den Berg,[1,3] Andreas Pasch,[2] Gerjan Navis,[3] Elizabeth Brink,[1] Reinold O.B. Gans,[3] Harry Van Goor,[3] Stephan J.L. Bakker.[3] *[1]TI Food&Nutrition, Wageningen; [2]Dept of Nephrology and Hypertension, University Hospital and University of Bern; [3]University Medical Center Groningen (UMCG), the Netherlands.*

Background: Sulfuric acid is the main degradation endproduct of the sulfur-containing amino acids (SAA) methionine and cysteine. This sulfur metabolism is allegedly adverse by its contribution to metabolic acid load, particularly in renal patients. However, sulfur-containing compounds may have protective effects by intermediated conversion to hydrogen sulfide (H_2S). The major metabolite of SAA excreted in urine is sulfate (SO_4^{2-}). A smaller portion is excreted as thiosulfate ($S_2O_3^{2-}$), reflecting endogenous H_2S-production.

Methods: Urinary SO_4^{2-} and $S_2O_3^{2-}$ excretion was studied in 707 renal transplant recipients (RTR) (age 53±13y, 57% male, time since Rtx 5.4y) and 107 healthy controls (53±10y, 47% male). Diet was assessed for SAA content. Blood pressure, pulse pressure, blood gases, metabolic acid load (NAE), hs-CRP, NT-pro-BNP and renal function were measured and related to urinary SO_4^{2-} and $S_2O_3^{2-}$ excretion.

Results: Urinary $S_2O_3^{2-}$was higher in RTR (7.0 [3.9-11.9] vs 2.1 [0.3-10.1] µmol/24h in controls, p<0.001), whereas $SO_4^{2-}$was similar (both 18±6 mmol/24h; p=0.3). Correlations with intake of SAA were 0.10; p=0.01 for $S_2O_3^{2-}$and 0.32; p<0.001 for SO_4^{2-}. $S_2O_3^{2-}$correlated with renal function (r=0.28), serum HCO3- (r=0.20), serum pH (r=0.20), NAE (r=0.14) and was inversely related with hs-CRP (r=-0.18) and NT-Pro-BNP (r=-0.28), all p<0.001. SO_4^{2-}correlated positively with renal function (r=016; p<0.001), NAE (r=0.51; P<0.001) and serum pH (r=0.08; p=0.05) and inversely with hs-CRP (r=-0.15; p=0.003) and Nt-Pro-BNP (r=-0.24; p<0.001).

Conclusions: In line with the classic view, urinary SO_4^{2-} excretion is associated with NAE, but is not adversely associated with acidosis. The associations of urinary SO_4^{2-} and $S_2O_3^{2-}$ with a favorable risk profile suggests a larger role for H_2S-production as an intermediate pathway than appreciable from the relatively small amount of $S_2O_3^{2-}$ excretion compared to SO_4^{2-}. Exogenous sulfur might serve as therapeutic agent in RTR.

SA-PO1017

Increased Urinary CCL2: Cr Ratio at 6 Months Is Associated with Late Renal Allograft Loss

Julie Ho,[1] Chris J. Wiebe,[1] David N. Rush,[1] Claudio Rigatto,[1] Leroy J. Storsley,[1] Martin Karpinski,[1] Ang Gao,[1] Ian W. Gibson,[2] Peter W. Nickerson.[1] *[1]Nephrology, University of Manitoba, Winnipeg, MB, Canada; [2]Pathology, University of Manitoba, Winnipeg, MB, Canada.*

Background: Early non-invasive markers that identify patients at risk of renal allograft loss may stratify patients for more intensive monitoring or therapy. CCL2 is a CCR2 receptor chemokine that is a chemoattractant protein for monocytes/macrophages, T cells and natural killer cells. We have previously demonstrated in a multi-centre cohort that urinary CCL2 at six months is an independent predictor for the development of IFTA at 24 months. The goal of this study was to determine if early urinary CCL2 is a predictor of graft loss in an independent patient cohort.

Methods: A prospective, observational cohort study was conducted in the Transplant Manitoba Adult Kidney Program (n=231 patients) from 1997-2008. Six-month urinary CCL2 was measured by ELISA, corrected for urinary creatinine and correlated with long-term graft outcomes.

Results: Urine CCL2: Cr at six months was significantly associated with death-censored graft loss [OR 1.01, 95% CI 1.003-1.020, AUC 0.78, p=0.004]. On multivariate analysis, urinary CCL2: Cr at six months remained an independent predictor of death-censored graft loss [OR 1.01, 95% CI 1.005-1.021, p=0.0015] after adjustment for donor specific antibody and delayed graft function. For each 10ng CCL2/mmol Cr incremental increase in 6-month urinary CCL2 there was a 1.13-fold increased risk of graft loss. The combined model of CCL2, donor specific antibody and delayed graft function yielded an AUC 0.87 for prediction of death-censored graft loss.

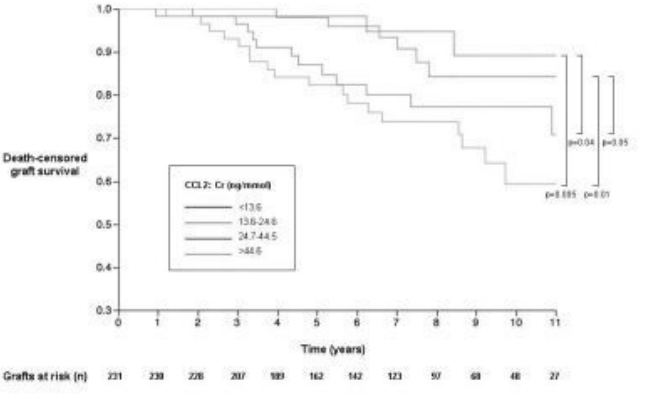

Figure 1. Death-censored graft survival by 6-month urinary CCL2: Cr quartiles, p=0.006

Conclusions: This study confirms in an independent prospective cohort that early urinary CCL2 at six months is a non-invasive independent predictor for late renal allograft loss.

Three Month Protocol Biopsies Show Clinically Significant Diseases and Correlate with Graft Dysfunction at One Year: Genomics of Chronic Allograft Rejection Cohort

Ivy A. Rosales,[1] Rex Neal Smith,[1] Evan A. Farkash,[1] Philip O'Connell,[2] Lorenzo G. Gallon,[3] Bernd Schroppel,[4] Caixia Xi,[4] Barbara T. Murphy,[4] Robert B. Colvin.[1] *[1]Pathology, Massachusetts Gen. Hosp., Boston, MA; [2]Nephrology, Sydney Medical School, Sydney; [3]Nephrology, Northwestern Univ., Chicago, IL; [4]Nephrology, Mt. Sinai Hosp., New York, NY.*

Background: Protocol biopsies provide the opportunity to determine graft histologic status and to identify potential subclinical events. The Genomics of Chronic Allograft Rejection (GoCAR) study is an ongoing, prospective multicenter study using differential gene expression and pathology to predict development of chronic rejection using 0,3,12 and 24-month protocol biopsies. We report pathologic features in 3mo biopsies and the correlates with dysfunction at 12 mos.

Methods: All 3mo protocol biopsies with microarray studies presently available (n=100) were scored by 2 pathologists for 55 variables including Banff categories and analyzed for correlations with 3 and 12mo eGFR.

Results: 12% of biopsies had pathology diagnoses with clinical implications: 8 had evidence of rejection, 2 had polyoma virus infection and 2 had C4d+ with no evidence of rejection. 3 lost their graft during the 1st year (2 due to polyoma, 1 death with function). Histologic variables differing most between patients with 3mo eGFR<50mL/min (n=36) vs >50mL/min (n=64) were % tubular atrophy (p<0.025) and Banff scores for interstitial fibrosis (ci, p<0.02) and tubulitis (t, p<0.05, 2-tailed t test). Features that correlated to the greatest degree with function at 12 mos (eGFR/graft loss) were % fibrosis (p<0.05), % tubular atrophy (p<0.001) and their sum (p<0.001), and Banff ci (p<0.02) and t (p<0.05) scores, and scores for tubular atrophy (ct, p<0.05), and total inflammation (ti, p<0.025). The Chronic Allograft Damage Index (p<0.02) and 3mo eGFR (p<0.001) were both associated with 12mo function.

Conclusions: A substantial fraction of 3mo protocol biopsies reveal diseases that warrant a change in therapy. Extent of tubular atrophy and fibrosis in 3mo protocol biopsies, and active lesions like tubulitis and cortical inflammation, indicate graft status relative to eGFR in this cohort and correlate with later function.

SA-PO1019

A Novel Approach for Detection of Renal Allograft Rejection Mark J. Lerman,[1] Sandra Hinton,[1] Judson M. Hunt,[1] Brandt Moore,[2] Cindy L. Corpier,[1] Richard Dickerman,[1] Tina Worley,[1] Karen Roush,[3] Afzal Nikaein.[2] *[1]Transplant Services, Medical City Hospital, Dallas, TX; [2]Texas Medical Speciality, Medical City Hospital, Dallas, TX; [3]Transplant Immunology, Methodist Medical Center, Dallas, TX.*

Background: Diagnosis of renal transplant (tx) rejection is based on serum creatinine (Cr) and invasive biopsies. However, quality of biopsies are not always adequate to show graft injuries. Urine produced and excreted by the kidney, has the potential to reflect injuries to the renal allograft. We have investigated the presence of biomarkers in urine of patients with or without rejection. The biomarkers included osteoprotegerin (OPG), monokine induced by interferon- γ (MIG) and interferon-γ induced protein of kDa (IP-10). These three biomarkers were increased in 100% of patients with cellular and >80% with humoral rejection.

Methods: 52 renal tx recipients with possible rejection were included. Biopsies were evaluated for rejection, tubular injury, glomerulonephritis, BK virus, and C4d staining. Patient's sera and urine were obtained at the time of biopsies for presence of HLA antibodies and biomarker respectively. Tests were performed by solid phase immunoassays.

Results: According to the following table, all patients with cellular rejection had high level of biomarkers in urine. Only one had lower level of MIG, but close to cut-off value. In addition, 4/6 patients with humoral rejection had high level of all 3 markers. One had lower IP-10 and 2 had lower MIG level, but still elevated. In contrast, only 6/30 (20%) of patients with no rejection had high level of all 3 markers. One patient had BK virus.

# patients	Sr. Cr.	IP-10 > 25pg/ml	MIG>25 pg/ml	OPG >75 pg/ml
Cellular Rejection (12)	1.1-9.9	12 (100%)	11 (91.6%)	12 (100%)
Humoral Rejection (6)	1.2-4.5	5 (83%)	4 (66.6%)	6 (100%)
Glomerulonephritis (3)	1.8-2.8	1 (33%)	1 (33%)	1 (33%)
No Rejection (30)	1.03-8.9	6 (20%)	6 (20%)	7 (23%)

Conclusions: This noninvasive test has potential to be used for diagnosis of rejection and in some cases would eliminate an invasive test which may cause complications with bleeding and infection.

SA-PO1020

Identification of miRNA Pathways Discriminating Acute Cellular and Humoral Renal Allograft Rejection by Using a Newly Developed miRNA Pathway Tool Sara Ivcevic,[1,2] Andreas Heinzel,[1,2] Julia Wilflingseder,[1,3] Rainer Oberbauer.[1,3] *[1]Nephrology, KH der Elisabethinen, Linz, Austria; [2]Bioinformatics, University of Applied Sciences Upper Austria, Austria; [3]Nephrology, Medical University of Vienna, Austria.*

Background: Aim of this project was to develop a miRNA pathway tool for providing fast and reliable information about miRNAs and their affected pathways. We elucidated the test characteristics of our algorithm in miRNAs discriminating acute vascular, interstitial and anti-body mediated rejection after renal transplantation.

Methods: The core of this tool is a relational database for systematic collection and management of information on miRNA target prediction and pathways. Ten algorithms have been selected to predict target genes of miRNAs in-silico. To reduce the high false-positive rate of these predictions we focused on genes predicted as targets by more than one method as well as information on experimentally verified miRNA targets. The obtained targets were used to find pathways which are regulated by those genes to get a global miRNA pathway landscape. For this purpose several statistical methods were applied and the calculation performed for each miRNA as well as for the whole set of miRNAs combined. The tool is available at www.meduniwien.ac.at/nephrogene.

Results: Results from miRNA profiling experiments covering 15 cases with acute vascular rejection, 15 cases with acute interstitial rejection, 11 cases showing antibody-mediated rejection and 10 protocol biopsies (control group) were used for verification of the tool. miRNAs discriminating the different forms of acute renal allograft rejection have been linked to several pathways. A detailed analysis of the identified pathways and involved target genes will be presented at the meeting.

Conclusions: The miRNA pathway tool produces fast and biologically relevant results. The application on acute rejection provides novel insights in the molecular regulation of this complication after renal transplantation and paves the way for new diagnostic and therapeutic targets.

Funding: Government Support - Non-U.S.

SA-PO1021

The Banff Fibrosis Trial of Visual Assessment of Interstitial Fibrosis in Kidney Biopsies Michael Mengel,[3] Robert B. Colvin,[2] Alton B. Farris.[1] *[1]Emory; [2]MGH; [3]UAlberta.*

Background: Interstitial fibrosis (IF) in renal biopsies is a valuable correlate for organ function, provides prognostic information and is a potential end point in trials.

Methods: In a multi-centre trial using 15 allograft and 15 native kidney biopsies with a full range of IF, sections were stained with trichrome, PAS, Collagen III, and virtual microscopy scans (Aperio) were prepared for scoring. Slides were assessed by 27 pathologists following two different definitions of IF shown in figure 1. Reproducibility was assessed by kappa statistics. Results were correlated with collagen III IHC slides after computer based image analysis (reference standard) and GFR at time of biopsy.

Results: Using the trichrome stain better correlations with image analysis were obtained compared to the PAS stain. Approach B, i.e. estimating the % abnormal cortex, was superior to approach A (Table 1). A stronger inverse association between IF and GFR was seen with the trichrome stain. Tubular atrophy and the Banff total i-score correlated less well with the collagen III stain and GFR. Independent of the approach and the stain, reproducibility between observers for assessing IF was weak (kappa <0.25). We then ask the participants to score the Collagen III stained slides. This revealed similar correlations as observed with the trichrome stain: approach A r=0.66 with image analysis and r= -0.37 with GFR; approach B r=0.68 with image analysis and r= -0.4 with GFR.

Figure 1

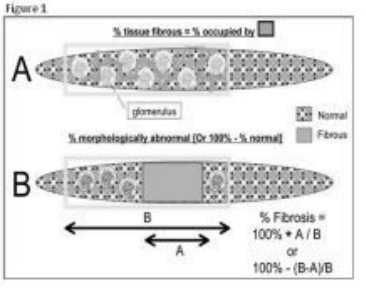

Table 1: Spearman correlations: mean r-values derived from the 27 participant scores are given for the listed associations between the two stains and the two scoring approaches with Collagen IHC and GFR.

	Approach A PAS Stain	Approach A Trichrome Stain	Approach B PAS Stain	Approach B Trichrome Stain	Tubular Atrophy PAS stain	Total I-Score	Collagen III immunohistochemistry
Collagen III immunohistochemistry	0.50	0.61	0.57	0.66	0.57	0.18	
GFR-Cockroft - Gault	-0.36	-0.42	-0.39	-0.43	-0.40	-0.22	-0.44

Conclusions: Trichrome and collagen III stains are similar but superior to the PAS stain in assessing IF. Pathologists are better capable of assessing the extent of abnormal cortex than the extent of interstitial space occupied by fibrous tissue. Visual assessment of IF correlates with organ function as well as computer-based image analysis. However, significant variability between observers argues for more precise consensus criteria for measuring IF visually.

SA-PO1022

Pre-Transplant Plasma Levels of PRA and Soluble CD30 in Kidney Graft Recipients as Predictors of Acute Allograft Rejection: Single Centre Experience Lilija Supranaviciene,[1] Tadas Daugela,[2] Marius Miglinas.[1] *[1]Nephrology Department, Vilnius University Hospital Santariskiu Klinikos, Vilnius, Lithuania; [2]Vilnius University Faculty of Medicine, Vilnius, Lithuania.*

Background: Our aim is to evaluate the influence of panel reactive antibodies (PRA) and plasma pre-transplant levels of soluble CD30 (sCD30) on the incidence of acute rejection episodes (ARE) following 2 years after renal transplantation.

Methods: We retrospectively analyzed medical records from renal transplant recipients >17 years old who received kidney graft between November 2008 and December 2011. Patients have been followed for 2 years and the incidence of the first ARE was verified both on histological and clinical findings. Patients had their plasma sCD30 levels measured on the day of the transplantation. By this finding they were divided into high and low risk groups: sCD30 levels >115 U/ml were considered as high risk group and <115 U/ml – low risk group. Maximum percentage of historical PRA was considered positive when > 5%. Other analysed variables were: age, gender, re-transplants and serum creatinine levels at 1, 3, 6, 12 and 24 months after transplantation.

Results: Among 70 transplants, 35 (50%) had ARE episode. Univariate analysis showed, that positive PRA was more frequent in the ARE patients (p = 0,015). In the low sCD30 group there were 53 (75.7%) patients and 25 of them experienced an ARE episode vs high group – 17 (24.3%) patients with 10 rejection episodes (p = 0.41). Kaplan - Meier estimate showed that in the high risk group (with sCD30 > 115 U/ml) there were more ARE after the first year, but results were not significant (p = 0,776). There was no significant correlation between sCD30 levels and recipients creatinine levels measured at 1, 3, 6, 12 and 24 months after transplantation (p > 0.05).

Conclusions: In this single centre study, the positive pre-transplant PRA was a predictive factor of developing ARE. Pre-transplant sCD30 levels did not show any significant difference between rejection and non rejection group in our transplant population and had no influence on graft function after transplantation.

SA-PO1023

Kidney Allograft SHROOM3 Predicts Fibrosis Madhav C. Menon,[1] Peter Y. Chuang,[1] Yi Luan,[1] Zhengzhe Li,[1] Weijia Zhang,[1] Philip O'Connell,[4] Lorenzo G. Gallon,[2] Robert B. Colvin,[3] Bernd Schroppel,[1] John C. He,[1] Barbara T. Murphy.[1] *[1]Nephrology, Mount Sinai Hospital, New York, NY; [2]Nephrology, Northwestern University, Chicago, IL; [3]Pathology, Harvard Medical School, Boston, MA; [4]Nephrology, University of Sydney, Sydney, Australia.*

Background: The Genomics of Chronic Allograft Rejection (GoCAR) is a multicenter study investigating the ability of differential gene expression to predict the development of Chronic allograft nephropathy.

Methods: 589 patients have been enrolled. Allograft biopsies were obtained were obtained at 0, 3, 12, and 24 months post-transplant with Chronic allograft dysfunction index score (CADI) reported from a core lab. Gene expression microarray analysis was performed on 3 month biopsies (Affymetrix: human exon-1chip) and correlation to 12-month CADI and eGFR analysed (n=160). Overexpression studies were performed on human primary tubular cells (RPTE).

Results: Expression of the SHROOM3 gene was found to correlate linearly with fibrosis and negatively with eGFR at 1 year (n=101; $p<0.05$). This was confirmed by RTPCR independently (n=32) No correlation was seen between SHROOM3 expression and 3 month CADI (n=100). A SNP in SHROOM3 has been linked to CKD in genome-wide association studies. We found that homozygosity for this risk allele (A/A) in donors was associated with higher intragraft SHROOM3 expression at 3 mths (n=134;p=0.03). The risk allele was more prevalent in white vs. non-white donors. While in white donors SHROOM3 expression was predictive of CADI at 12 mths, this was not true for non-whites. In vitro, overexpression of SHROOM3 in human primary tubular cells (RPTE) significantly increased type-1 collagen and fibronectin-1 transcripts, and accentuated TGF-β mediated production of mesenchymal markers (Collagen-1, matrix metalloproteinase-2, SNAIL) and phosphorylation of Smad-3.

Conclusions: These novel findings demonstrate that SHROOM3 expression in kidney allografts is predictive of the development of fibrosis. Initial mechanistic studies suggest that it potentiates the effects of TGF-b. These data support the further investigation of SHROOM3 as a potential therapeutic target for the prevention of renal fibrosis.

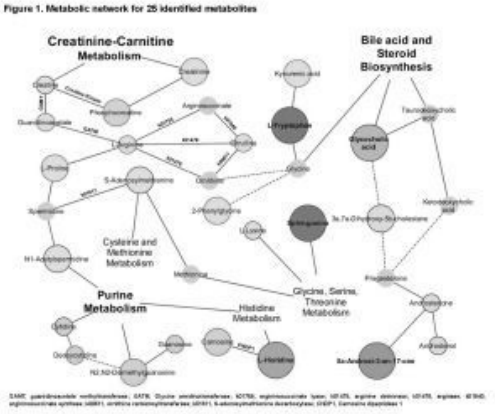
Impact of Urinary Metablolic Profiles in Predicting Graft Function after Renal Transplantation Jung-Ju Seo,[1] Prasad B. Phapale,[2] Sun-Hee Park,[1] Chan-Duck Kim,[1] Young-ran Yoon,[2] Yong-Lim Kim.[1] *[1]Division of Nephrology, Department of Internal Medicine, Kyungpook National University Hospital, Daegu, Republic of Korea; [2]Clinical Trial Center and Department of Molecular Medicine, Kyungpook National University School of Medicine and Hospital, Daegu, Republic of Korea.*

Background: Metabolomics can yield markers with improved precision and accuracy for monitoring clinical outcomes. We evaluated clinical applicability of metabolomics to predict GFR after kidney transplantation(KT) using liquid chromatography–mass spectrometry (LC/MS)-based global metabolic profiling along with integrative data analysis and metabolic network analysis.

Methods: In this prospective and exploratory study, LC/MS-based analysis was performed to analyze global metabolic profiles of urine collected from 12 recipients before(-2 days) and after(5, 30, and 90 days) KT. We applied partial least squares(PLS) model and variable influence on projection(VIP) to find metabolite correlated with GFR(VIP>1.3) and identified metabolites by matching MS/MS spectrum to metabolite database, such as HMDB. After metabolic network analysis, we selected most significant metabolites to predict GFR using integrative approach and drew new prediction equation for GFR.



Results: We selected five representative metabolites based on statistical and biological significance in predicting GFR; 5a-androst-3-en-17-one(AS), glycocholic acid(GC), sphingosine(SG), tryptophan(TR), and histidine(HT). We built clinically applicable prediction equation using these metabolites; $GFR_{Predicted}$=0.45HT+0.46AS+0.39TR+0.54SG+0.38GC. The predicted GFR showed strong correlation with observed GFR(R^2=0.71) and could predict long-term GFR at 2 years after KT(R^2=0.50).

Conclusions: In conclusion, we confirmed that urine metabolic phenotype would be more comprehensive biomarker for predicting early and long-term GFR after KT up to 2 years.

Surveillance Biopsies: The Imapact on Immunosuppression Management in Kidney Transplant Recipients Nadia N. Chaudhri, Emilio Ramos, Joseph M. Nogueira, David K. Klassen, Matthew R. Weir, Abdolreza Haririan. *Medicine, University of Maryland Medical Center, Baltimore, MD.*

Background: The utility of surveillance biopsies in management of immunosuppression(IS) in kidney transplant recipients in the modern era remains unclear. The purpose of our study was to assess whether histological findings on surveillance biopsies help guide changes IS regimen.

Methods: We examined 320 protocol biopsies: 205 at 3.7±0.97 and 115 at 13.1±1.7 mos, scored according to Banff 97 criteria. Tacrolimus, MMF/MPA and early steroid withdrawal were used for maintenance IS. For cause biopsies were excluded.

Results: Patient characteristics are summarized below.

Baseline Characteristics

Age(mean±SD)	50.1±22.9yrs
African American(%)	122 (51.9)
Male(%)	141 (60)
DM(%)	101 (43)
HTN(%)	228 (97)
Hemodialysis (%)	143 (64.7)
DDRT(%)	183 (78.1)
Alemtuzumab induction(%)	138 (59.5)
Basiliximab(%)	70 (30.2)
Thymoglobulin(%)	23 (9.9)
HLA mismatch	4.8±1.5

Mean cr at 3 and 12 mo was 1.62±0.57 and 1.68±0.64 mg/dl, and the incidence of subclinical acute cellular rejection(ACR) was 8.8% (n=18) and 15.7 % (n=16), respectively. In pts with and without ACR, the mean cr at 3 and 12mos was not statistically different (1.78 and 1.62, p=0.16; 1.83 and 1.60, p=0.2, respectively). Progression of IF/TA from 3 to 12mo was seen in 29.2% of ps. A change in IS was made in 31.5% of pts at 3mos and 49.3% of pts at 12 mos. 4.2% and 5.6% of pts were treated for ACR and 1.4 % and 1.4% for antibody mediated rejection at 3 and 12 mos, respectively. Maintenace IS was modified in 26.4% of pts at 3 mos and 40.6% at 12 mos. These changes included increasing or decreasing CNI/MPA/MMF, adding steroids, or changing to mTORi. Progression of IF/TA was observed in 31.7% with no IS adjustment versus in 14.3% with treatment adjustment (p=0.16).

Conclusions: Surveillance biopsies reveal significant subclinical histological changes that could guide adjustment in IS regimen. The biopsy guided IS modification may decrease risk of progression of IF/TA post transplant. Larger prospective studies are needed to examine the impact of surveillance biopsies on long term renal allograft survival.

SA-PO1026

Systems Biology Analyses of Renal Allograft Injury Julia Wilflingseder,[1,2] Andreas Heinzel,[3] Alexander Kainz,[1,2] Bernd Mayer,[4] Rainer Oberbauer.[1,2] *[1]Nephrology, Medical University of Vienna, Austria; [2]KH der Elisabethinen, Linz, Austria; [3]Bioinformatics, University of Applied Science Upper Austria; [4]Emergentec Biodevelopment, Vienna, Austria.*

Background: Large scale molecular characterization of renal allograft pathology is essentially based on transcriptomics data. However, the test characteristics of diagnostic or predictive markers derived on this basis proved as being rather low.

Methods: Thus we set out to study this enigma using a considerable wider approach by incorporating a broad range of publicly available omics data (genetic background, protein coding as well as non-coding transcripts, as well as proteomics and metabolomics signatures) into the analysis of the prediction of DGF, ABMR, TCMR and early IFTA. We complemented this molecular feature set with our transcriptomics data (mRNA and miRNA) derived from a clinical biopsy repository holding tissue and clinical information of renal allograft recipients at baseline, together with management and indication biopsies (n=170).

We use a hybrid molecular interaction network covering about 15,000 molecular features from the human protein coding gene set, and holding about 800,000 molecular relations for integrating the given cross-omics data sets. This renal allograft-specific network is then segmented into distinct molecular processes relevant in the pathology, in their totality providing us with a molecular model of the different clinical phenotypes.

Results: The workflow for generating the molecular model and characteristics of the identified molecular processes will be presented at the meeting. Preliminary results suggest molecular units being specific for the distinct clinical entities. Such molecular units serve as basis for selection of biomarkers being specific for the individual clinical presentations, and their functional analysis may further serve as basis for better understanding of relevant molecular pathophysiology, in turn being the prerequisite for improving therapeutic measures.

Conclusions: We will present the first results of this cross-omics, Systems Biology-motivated approach in identifying prognostic and diagnostic as well as potential therapeutic molecular candidates for clinico-pathological entities.

Age as an Effect Modifier for Renal Transplantation in Canada's Aboriginal Peoples Manish M. Sood,[1] Brenda Hemmelgarn,[2] Claudio Rigatto,[1] Paul Komenda,[1] Karen E. Yeates,[3] Julie Mojica,[1] Navdeep Tangri.[1] *[1]Medicine, Section of Nephrology, University of Manitoba, Winnipeg, MB, Canada; [2]Medicine, Section of Nephrology, University of Calgary, Calgary, AB, Canada; [3]Medicine, Section of Nephrology, Queen's University, Kingston, ON, Canada.*

Background: Previous studies have demonstrated Aboriginals are less likely to receive a renal transplant in comparison to Caucasians however whether this applies to the entire population or specific subsets remains unclear. We examined age as an effect modifier on the outcome of transplantation in Aboriginals.

Methods: Data on 30,688 dialysis (Aboriginal 2,361, Caucasian 28, 327) patients obtained between Jan. 2000 and Dec. 2009 were included in the final analysis. Racial status was self-reported. Cox proportional hazards and the Fine and Grey sub-distribution method to account for competing events were used to determine the association between race, age and transplantation.

Results: In comparison to Caucasians, Aboriginals were less likely to receive a renal transplant (Adjusted HR 0.66 95% CI 0.57-0.77, P<0.0001) however after stratification by age and treating death as a competing outcome, the effect was more predominant in younger Aboriginals (Age 18-40: 20.6% aboriginals vs. 48.3% Caucasians transplanted; aHR 0.50(0.39-0.61), p<0.0001, Age 41-50: 10.2% aboriginals vs. 33.9% Caucasians transplanted; aHR 0.46(0.32-0.64), p=0.005, Age 51-60: 8.2% aboriginals vs. 19.5% Caucasians transplanted; aHR0.65(0.49-0.88), p=0.01, Age >60: 2.7% aboriginals vs. 2.6% Caucasians transplanted; aHR 1.21(0.76-1.91), P=0.4, Age X race interaction p<0.0001). Both living and deceased donor transplants were lower in Aboriginals under the age of 60 compared to Caucasians.

Conclusions: Younger Aboriginals are less likely to receive a renal transplant compared to their Caucasian counterparts, even after adjustment for comorbidity. Determination of the reasons behind these discrepancies and targeted interventions are urgently required.

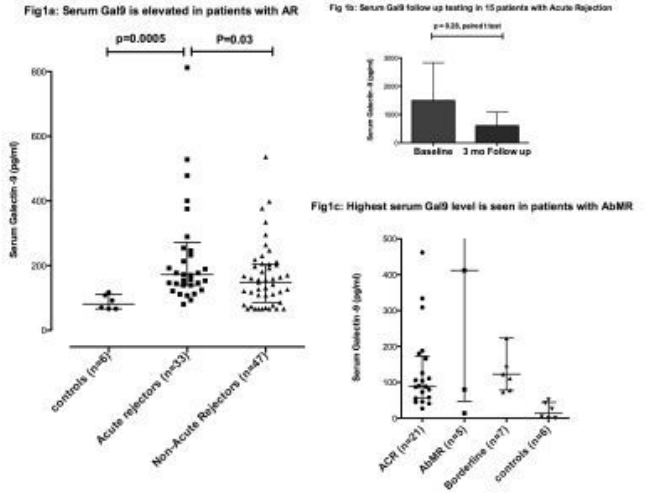
SA-PO1028

Galectin-9: A Novel Serum Biomarker of Acute Rejection in Renal Transplant Recipients with Allograft Dysfunction Isa F. Ashoor,[1] Usaila Ahmad,[1] Sacha A. De Serres,[1] Monica Grafals,[2] Toshiro Niki,[3] Nader Najafian.[1] *[1]Nephrology, Transplantation Research Center, Brigham and Women's Hospital and Children's Hospital Boston, Boston, MA; [2]Nephrology, Lahey Clinic, Burlington, MA; [3]Kagawa University, Kagawa, Japan.*

Background: Acute renal allograft rejection remains a significant problem. A non-invasive test to predict rejection would be greatly beneficial. Galectin-9 (Gal9) is a lectin that binds to TIM3+ effector Th1/Th17 cells inducing apoptosis. We previously demonstrated accelerated rejection in a murine vascularized cardiac transplant model with Gal9 blockade suggesting a protective role for Gal9. We hypothesize that human serum Gal9 (sGal9) is elevated as a compensatory response and may serve as a biomarker of acute rejection.

Methods: Blood was collected from 6 healthy controls, and 80 renal transplant recipients admitted for allograft biopsy due to an acute rise in serum Cr. Pts were classified by histology as acute rejectors (AR) or non-acute rejectors (NAR). sGal9 was measured using a sandwich ELISA assay.

Results: 33 pts were classified as AR (21 ACR, 5 AbMR, 7 borderline cellular rejection) and 47 as NAR (32 chronic changes,10 GN, 5 ATN). There were no significant differences in terms of age, gender, donor type or immunosuppressive regimen. Median sGal9 levels in AR was 106 pg/ml (IQR 73-205) significantly higher than HCs (15 pg/ml (IQR 0-44), p=0.0005) and NAR (82 pg/ml (IQR 20-138), p=0.03). In 15 AR pts who underwent f/u testing, sGal9 decreased at 3 mo. Within AR, sGal9 was highest in AbMR group.



Conclusions: 1) sGal9 is a novel biomarker elevated in acute rejection at the time of biopsy 2) This elevation is transient suggesting an acute involvement of the TIM-3:Gal9 pathway as a compensatory response 3) Moderate elevation of sGal9 with chronic allograft changes likely reflects an attempt to curtail an ongoing low-grade alloimmune injury.

SA-PO1029

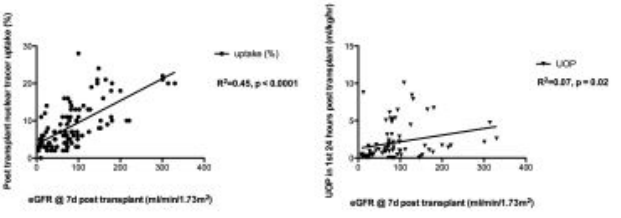
Immediate Post-Renal Transplant Nuclear Scans in Children Correlate with Transplant Function at One Week Isa F. Ashoor, Nilka deJesus-Gonzalez, Michael J. Somers. *Nephrology, Boston Children's Hospital and Harvard Medical School, Boston, MA.*

Background: Delayed graft function (DGF) impacts long term renal graft survival. We assessed if immediate post transplant (tx) Mag3 nuclear tracer uptake correlates with 1 week graft function. This could allow early DGF risk assessment with targeted intervention to improve outcome.

Methods: We reviewed 100 consecutive renal tx pts ≤ 21 yo. Ischemia times, urine output in 1st 24hr post tx (UOP) and POD7 eGFR were calculated. Mag3 was performed by protocol within hrs of tx. DGF was defined as dialysis by POD7.

Results: 47 children were LD recipients (55% boys, median age 8 yo (IQR 2-15), cold ischemia time (CIT) 0.95hr (0.78-1.13), warm ischemia time (WIT) 28min (22-36), UOP 2.1 ml/kg/hr (0.9-5.3), POD7 eGFR 88 ml/min/1.73m^2 (63-145); 2 developed DGF. 53 were DD recipients (60% boys, median age 10 yo (3-16), CIT 9.4hr (7-12.9), WIT 31min (24.5-38.5), UOP 0.9 ml/kg/hr (0.3-1.5), POD7 eGFR 64 (22-92)); 5 developed DGF. DGF pts had lower Mag3 tracer uptake (4% vs 7%,p=0.048), longer WIT (38 vs 29min,p=0.02), and lower POD7 eGFR (10 vs 78,p<0.0001). Age, CIT and UOP were not different. Using POD7 eGFR >60 ml/min/1.73m^2 as surrogate for good early graft function, those pts had both higher UOP (1.7 vs 0.4 ml/kg/hr) and Mag3 tracer uptake (10% vs. 4%,p<0.0001). Times to peak Mag3 activity and 20 min residual were lower in the good eGFR group. POD7 eGFR correlated with Mag3 tracer uptake (R^2=0.45, p<0.0001) but not with UOP (R^2=0.07, p=0.02).

Fig 1:
Post transplant nuclear tracer uptake correlates well with POD7 eGFR while UOP in the 1st 24 hours does not



Conclusions: 1) Patients who develop DGF show reduced Mag3 tracer uptake within hrs of tx.

2) Early Mag3 tracer uptake correlates with POD7 eGFR.

3) Early Mag3 tracer uptake predicts DGF and POD7 eGFR better than early UOP.

4) Mag3 parameters (tracer uptake, time to peak, residual) can be used to develop predictive models for DGF/POD7 tx function, allowing early intervention to improve graft outcomes.

SA-PO1030

Efficacy of Rituximab Compare to Conventional Treatment for Recurrent Idiopathic Membranous Nephropathy after Kidney Transplantation Damien Ambrosetti,[1] Laetitia Albano,[2] Elisabeth Cassuto.[1,2] *[1]Anatomopathologie, CHU de Nice, Nice, France; [2]Transplantation Rénale, CHU de Nice, Nice, France.*

Background: Recurrence rate of membranous nephropathy (MN) after kidney transplantation (KT) varies between 7 to 42% depending on whether biopsies are performed according to protocol or based on symptoms The possibility that AntiPLA2R1 antibody could be a biomarker for IMN recurrence after KT is still debated. The therapy for IMN is challenging. Rituximab has been shown to reduce proteinuria and prevent MN progression.

Methods: We report two male kidney recipients developing recurrent IMN with nephrotic syndrome after KT, treated with or without rituximab, and we analyze clinical, histological and immunological outcome. Patient #1 was treated with high-dose cyclosporin, pulse corticosteroid therapy and ACE inhibitors. Proteinuria decreased drastically and persisted at 0.2 g/dL. Thirteen years later, while serum creatinine was moderately increased, an allograft biopsy was performed. The histologic analysis found a recurrent stage 3 IMN associated with interstitial fibrosis and tubular atrophy. Anti PLA2R1 Ab in serum of patient #1 were detected before KT, at the initial recurrence of IMN and at the time of the last biopsy.Patient #2 was treated and cured with 4 weekly rituximab infusions. Currently, 5 years later, the patient is still asymptomatic. In view of the case of patient #1, a kidney graft biopsy was performed showing no recurrence of MN, but a moderate interstitial fibrosis and tubular atrophy. Anti PLA2R1 Ab were detected in the serum of the patient #2 before KT and at the time of recurrence but were undetectable at the time of the last biopsy.

Conclusions: So, both patients have a similar history of early recurrent IMN after KT, with favorable long-term clinical outcome after treatment. It's remarkable that the presence of histological recurrence is associated with AntiPLA2R1 Ab in the serum of the patient treated without rituximab. In conclusion, no proteinuria doesn't mean no recurrence of IMN after KT. The presence of serum antiPLA2R1 Ab could incite to look at a histological recurrence. In our case, rituximab seems more efficient than cycloporin to avoid IMN recurrence.

SA-PO1031

Reemergence of Adrenocorticotropin Hormone as Novel Therapy for Focal Segmental Glomerulosclerosis Sireesha Koppula, Barry R. Gorlitsky, Amy Nicole Sussman. *Nephrology, University of Arizona, Tucson, AZ.*

Background: Focal segmental glomerulosclerosis (FSGS) accounts for nearly one-third of all nephrotic syndrome (NS) cases in the adult population. Unresponsive patients progress to ESRD 50% of the time. Patients who experience partial or complete remission have up to 90% 10-year kidney survival rates. Many patients remain refractory to standard treatments. Adrenocorticotropin hormone has been used as primary and secondary therapy for nephrotic syndrome but there is no published experience for its use in the treatment of FSGS.

Methods: We report a case of a 28-year-old Filipina female with history of NS, biopsy proven in 2004 consistent with minimal change disease. After multiple treatment failures utilizing cyclosporine and prednisone, a repeat biopsy in 2008 showed FSGS (>50% podocyte effacement in both affected and unaffected capillary loops). Most recently she relapsed with NS, characterized by hypoalbuminemia (1.5g/dl), volume overload, dyslipidemia, and >10 grams of proteinuria quantified by spot protein to creatinine ratio. She was initiated on prednisone 1mg/kg daily; however, by week 8 she continued to have high-grade proteinuria and persistent NS. She subsequently underwent treatment with repository corticotropin injection (H.P. Acthar® Gel, repository corticotropin injection; Questcor), a long-acting formulation of the full sequence ACTH [1-39] that includes other pro-opiomelanocortin [POMC] peptides) at a dose of 80IU twice weekly SC for 6 months. By month 2, she demonstrated >50% reduction of proteinuria and by month 6 she demonstrated a near complete remission and normalization of her serum albumin and lipid panel.

Conclusions: In FSGS, ACTH may work through its melanotropic effect apart from steroidogenesis. There is considerable debate on the ideal treatment regimens for FSGS, particularly in poorly responsive cases. ACTH can be an effective treatment in NS due to FSGS and should be considered in patients who are recalcitrant to standard therapy. Further studies are ongoing to determine efficacy of ACTH as treatment for NS due to FSGS.

SA-PO1032

Hepatitis C-Associated Thrombotic Microangiopathy (TMA) without Cryoglobulinemia Reem Daloul, Francis Dumler, Gampala Harish Reddy, Ping L. Zhang. *Division of Nephrology, William Beaumont Hospital, Royal Oak, MI.*

Background: We report a case of hepatitis C associated TMA in a patient who presented with nephrotic syndrome and progressive renal failure.

Methods: 57 y/o male with a history of hepatitis C and hypertension was admitted with progressive shortness of breath, edema, and easy bruising. Hemoglobin was 8.2 g/dL and platelets 60,000 bil/L. Baseline BUN and serum creatinine where 6 and 0.4 mg/dL. Urinalysis: 1+ blood, 3+ protein, 5 rbc/hpf, 3 wbc/hpf, and no casts. Urine protein creatinine ratio was 5.03. Schistocytes were present in the peripheral blood and haptoglobin was undetectable, Cryoglobulins were negative on several occasions. ADAMTS 13 activity was 86% and ADAMTS13 inhibitor was not detected. Combs ANA, ANCA, Rheumatoid factor, C3, C4, and total complement were normal. Renal biopsy showed thickened glomerular capillary loops, a membranoproliferative pattern but no diffuse proliferation, necrosis or crescent formation. Several small arteries exhibited thrombi formation. Mild interstitial fibrosis and tubular atrophy were also present. Stains for IgM and fibrinogen were positive but others were negative. On electron microscopy glomerular basement membranes were thickened, and mesangial interposition and scattered subendothelial lucent areas were seen. Fibrin material was identified in the subendothelial areas mixed with lucent ischemic changes. No immune complex deposits were identified in the mesangial, subendothelial, or subepithelial areas. No paired tubular structures consistent with cryoglobulins were found. Blood counts stabilized after five cycles of apheresis but renal function continued to deteriorate. Hemodialysis was initiated six weeks later. The patient continues to be dialysis dependent at present.

Conclusions: TTP is known to occur in hepatitis C patients with cryoglobulinemia and/or treatment with pegylated- interferon alpha 2a, in the presence of ADAMTS13 inhibitor and/or a low ADAMTS13 activity. Our patient developed TTP and renal TMA lesions in the absence of these risk factors suggesting that other pathogenetic factors may be involved in the development of TMA in hepatitis C patients.

SA-PO1033

IgA Nephropathy in Sarcoidosis: A Consequence or Just a Coincidence? Nripesh Pradhan, Rochak Varma, Roger F. Carbajal Mendoza, Ashok P. Chaudhari, Donald I. Baumstein. *Nephrology, New York Medical College/Metropolitan Hospital Center, New York, NY.*

Background: Renal involvement in sarcoidosis is largely due to hypercalcemia. Granulomas in interstitium are found in 40% cases. Glomerular diseases due to sarcoidosis are very rare and Ig A nephropathy has been reported in very limited case reports. The association may be more than just a coincidence. We describe a case of sarcoidosis with renal impairment and Ig A nephropathy on kidney biopsy.

Methods: A 38 year old Hispanic male presented with a generalized nodular skin eruption for 2 months. He had a past medical history of kidney stones two years ago. Physical examination showed multiple erythrematous non-tender nodules in arms, flanks and thighs. Routine laboratory test revealed elevated creatinine of 2.6 mg/dl and calcium of 10.7 mg/dl. Mild proteinuria (Spot urine protein creatinine ratio- 0.4) was noted on urine analysis with no cells and bilateral hilar enlargement on chest roentogram. Further work up was noteworthy for elevated 1, 25 OH Vitamin D, suppressed Parathyroid hormone, elevated serum Angiotensin converting enzyme level of 294 (9-67 U/l) ,24 hour urine calcium of 733 mg while serological markers were all negative. Diagnosis of sarcoidosis was confirmed with skin biopsy of the nodular lesions. Renal ultrasound was normal. A Renal biopsy to confirm renal sarcoidosis surprisingly revealed mesangial proliferative glomerulonephritis with immunoflurorescence staining consistent with Ig A nephropathy. Patient was discharged on oral prednisone with close outpatient follow up.

Conclusions: Murray FE et al and Chung Park M et al have in past described simultaneous occurrence of sarcoidosis and Ig A nephropathy in 1987 and 1990 respectively. Sarcoidosis is a state of heightened immune response manifested by polyclonal increase in immunoglobulins. Whether such state is responsible for Ig A deposition in mesangium of glomerulus is not clear. Besides this, familial clustering has also been reported in both Ig A nephropathy and sarcoidosis. So in our case, we think Ig A nephropathy is more likely to be a consequence of sarcoidosis rather than just a coincidence.

SA-PO1034

Proliferative Glomerulonephritis with Monoclonal IgG Deposits Associated with Immune Disorder by Parvovirus B19 or Hepatitis C Virus Infection Emiko Fujita,[1] Akiko Mii,[1] Yukinari Masuda,[2] Megumi Fukui,[1] Shinya Nagasaka,[2] Akira Shimizu.[2] *[1]Department of Internal Medicine, Nippon Medical School, Bunkyo-ku, Tokyo, Japan; [2]Department of Analytic Human Pathology, Nippon Medical School, Bunkyo-ku, Tokyo, Japan.*

Background: Proliferative glomerulonephritis (PGN) with monoclonal immunoglobulin G (IgG) deposits (PGNMID) is a recently described disease entity, characterized by non-organized electron-dense deposits in glomeruli and immunofluorescence findings indicating monoclonal IgG deposits. The pathogenesis of many cases of PGNMID remains unknown. We herein report three cases of monoclonal IgG deposition disease associated with viral infection.

Methods: Two cases are with human parvovirus B19 (HPV) who developed nephritic syndrome with hypocomplementemia (case 1) or persistent proteinuria and congestive heart failure (case 2). Other one case with hepatitis C virus (HCV) infection showed severe nephrotic syndrome (case 3). All 3 cases, however, neither patients had detectable levels of serum and urine monoclonal IgG. Renal biopsy in both case1 and case2 showed diffuse endocapillary PGN with monoclonal IgG3-κappa deposits, whereas membranous nephropathy in case 3 with monoclonal IgG1-lamda deposits. Deposits have no organization by electron microscopy in all cases. Clinical symptoms, abnormal laboratory findings, and urinary abnormalities recovered spontaneously in both case 1 and case 2 within 4 weeks. In case3, combined therapy with steroid and an immunosuppressive agent are needed to recover.

Conclusions: Our cases may be the first reported PGNMID patients possibly associated with viral infection. Immune disorders including cryoglobulinemia and monoclonal gammopathies can result from HPV and HCV that may be associated with PGNMID in our cases. Viral infection-associated immune disorders could be implicated in the pathogenesis of PGNMID.

SA-PO1035

Anti-Glomerular Basement Membrane Disease Superimposed on IgA Nephropathy Lin Liu, Lijun Mou, Yubing Wen, Wenling Ye, Jianling Tao, Mingxi Li, Yang Yu, Xuemei Li, Xuewang Li, Limeng Chen. *Department of Nephrology, Peking Union Medical College Hospital, Beijing, China.*

Background: Anti-GBM disease with concurrent IgA nephropathy is rare. We try to observe the clinicalpathologic features of 3 such cases with crescents and to identify the other 21 anti-GBM disease patients without IgA deposition.

Results: 3 cases, including 1 male and 2 female, were identified as anti-GBM disease superimposed on IgA nephropathy in PUMCH, during the past 11 years. Two of them had recent history of infection or fever. Hematuria, oliguria, hemoptysis was not seen in any of them. No one was hemodialysis dependent. Lab results revealed a mean serum creatinine (SCr) level of 283±221μmol/L at diagnosis, anti-GBM antibody maximum titer of 260±35 EU/ml, and negative ANCA. In kidney biopsy, glomerular crescents were observed in all 3 cases with a cellular/fibro-cellular proportion of 72±49%. With treatment of pulse methylprednisolone and cyclophosphamide in all and plasmapheresis in 2 of them, they showed improvement in renal function with SCr decreasing to 120±60μmol/L. Further, compared with data of 21 IgA-free anti-GBM disease patients with crescents, the 3 cases showed lower SCr than those without IgA nephropathy at diagnosis (819±606μmol/L, p=0.020), with better outcome that 100% had their SCr≤300μmol/L after similar treatment (vs. 29% of those without IgA nephropathy, p=0.042). But no significant differences showed in age, sex, and other clinicalpathological features.

Conclusions: The 3 cases with anti-GBM disease superimposed on IgA nephropathy showed milder kidney damage and better prognosis. The more which may indicate some different mechanism involved requires further research.

Funding: Government Support - Non-U.S.

SA-PO1036

Crescentic Glomerulonephritis (GN) in a Child with X-Linked Agammaglobulinemia (XLA) Sabahat Afshan,[1] Theodore Matthew Eison,[1] Margaret Colleen Hastings,[1,2] Christie Michael,[1] Karen Maltby,[1] Patrick D. Walker,[3] Bettina H. Ault.[1] *[1]Pediatrics, University of Tennessee Health Science Center, Memphis, TN; [2]Medicine, University of Tennessee Health Science Center, Memphis, TN; [3]Nephropath, Little Rock, AR.*

Background: XLA is caused by a mutation in Bruton's tyrosine kinase gene resulting in absent or marked reduction in antibody synthesis.

Methods: A five year-old Caucasian male with XLA received gammaglobulin from age three months. Two weeks prior to presentation, he had sore throat and fever; four days prior to presentation he developed cola-colored urine. On presentation blood pressure was 152/112 mm Hg and he had periorbital edema and ascites. Laboratory studies revealed blood urea nitrogen 24 mg/dL, creatinine 0.98 mg/dL, albumin 2.4 g/L, C3 16.6 mg/dL and C4 3.3 mg/dL. Urinalysis showed 3+ blood, 3+ albumin, 316 RBC, 112 WBC, and 1-2 RBC casts/hpf. Plasma IgG (316 mg/dL, normal 470-1400) and IgM (28.1 mg/dL, normal 37-117) were obtained one day after a gammaglobulin dose. Blood culture grew *Streptococcus pneumoniae*. Kidney biopsy showed crescentic GN with diffuse mesangial expansion of intact glomeruli on light microscopy (LM); 3 of 9 glomeruli were globally sclerotic. Plasmacytoid cells were noted in the interstitium. Immunofluorescence showed 3+ IgG, trace IgA, 3+ C3, 3+ kappa and 3+ lambda. Electron microscopy showed subendothelial and mesangial immune complex type electron dense deposits and rare intramembranous deposits. Six doses of 30 mg/kg intravenous methylprednisolone (MP) and then oral prednisone 2 mg/kg/day was given. Serum creatinine fell to 0.58 mg/dl after the fourth dose of MP.

Conclusions: Two cases of GN in XLA are reported, one with membranous and one with membranoproliferative GN. Presence of immune complexes would seem unusual in XLA. Measurable plasma IgM and interstitial plasmacytoid cells on LM and trace IgA on IF suggest that the antibody in the immune complexes could be endogenous. Immune dysregulation resulting from patient's immunodeficiency likely contributed to his severe immune complex GN.

SA-PO1037

Successful of Humanized Anti-Interleukin-6 Receptor Antibody (Tocilizumab) Therapy for a Case of AA Amyloidosis Complicated by Familial Mediterranean Fever Satoshi Hamanoue, Yoshifumi Ubara, Tatsuya Suwabe, Koki Mise, Keiichi Sumida, Masayuki Yamanouchi, Junichi Hoshino, Kenmei Takaichi. *Nephrology Center, Toranomon Hospital, Tokyo, Japan.*

Background: Familial Mediterranean fever (FMF) is a cause of AA amyloidosis and is the most frequent type of familial amyloidosis. Colchicine has proved to be an effective treatment for FMF. However, treatment for patients who are refractory to colchicine remains controversial.

Methods: We encountered 4 patients who were diagnosed as having FMF by detection of the specific gene for MEFV. Although 3 patients were negative for AA-amyloidosis, one was shown to have AA-amyloidosis by biopsy of the kidney and stomach. Treatment for this disease was investigated.

Results: Three patients were successfully treated by conservative therapy including colchicine. Colchicine was also administered first to a 51-year-old man with AA-amyloidosis. However, his arthralgia and nephropathy showed progression. Therefore, a humanized anti–interleukin-6 receptor antibody (tocilizumab) was administered at a dose of 8 mg/kg monthly. After 2 years, his serum creatinine decreased from 2.3 mg/dL to 1.5 mg/dL, CRP decreased from 2.5 mg/dL to 0.0 mg/dL, and proteinuria improved from 2.5 g daily to 0.2 g daily. His arthralgia also subsided. Repeat biopsy of the stomach showed the disappearance of AA-amyloidosis.

Conclusions: This case suggests that treatment with tocilizumab can achieve significant improvement and represents a new therapeutic option for patients with FMF and AA amyloidosis if colchicine is not effective.

SA-PO1038

Unusual Presentation of Anti-Glomerular Basement Disease with Linear IgA Staining Gaurav Agarwal,[1] Olatokunbo O. Shobande,[1] Jose R. Torrealba,[2] Weixiong Zhong,[2] Micah R. Chan.[1] *[1]Department of Medicine, Division of Nephrology, University of Wisconsin School of Medicine and Public Health, Madison, WI; [2]Department of Pathology, University of Wisconsin School of Medicine and Public Health, Madison, WI.*

Background: Anti-GBM disease is an aggressive form of glomerulonephritis usually mediated by circulating IgG autoantibodies to the non-collagenous (NC1) domain of alpha3 subunit of Type IV collagen. There have been few case reports about an IgA variant of anti-GBM disease.

Methods: A 72-year-old white male presented with complaints of one episode of gross hematuria. He was found to have acute kidney injury (AKI) with a creatinine of 2.7 mg/dL, which rapidly increased to 5.6 mg/dL over 3 days. His baseline creatinine was 1.0 mg/dL.

His urinalysis was significant for 1+ protein and 2+hematuria. Complement levels were normal. Serologic studies were negative for anti-nuclear antibodies, anti-neutrophil cytoplasm antibodies, cryoglobulins, hepatitis B and C panels, anti-GBM ab.

Due to concern for a rapidly progressive glomerulonephritis, a renal biopsy was performed.

Renal biopsy yielded 3 glomeruli with cellular crescents and fibrin deposits. Immunofluorescence revealed +3 capillary wall linear staining for IgA and segmental +3 staining for fibrin. Electron microscopy reveals mild increase in mesangial matrix and normal cellularity. Glomerular basement membrane is of normal thickness with segmental, severe ischemic wrinkling. No electron-dense immune-like deposits.

The patient was treated with methylprednisolone 1 g IV daily for 3 days, then transitioned to oral prednisone (1 mg/kg/day), oral cyclophosphamide (1.5 mg/kg/day), and received a 6-week course of plasmapheresis. His renal function improved gradually from 5.6 mg/dL to 3.2 mg/dL by 3 weeks of treatment.

Conclusions: We report a case of IgA anti-GBM disease suggesting a possibility of a novel GBM antigen. The antigenic heterogeneity of anti-GBM IgA antibody disease demonstrates the necessity of renal biopsy for reliable diagnosis of this atypical presentation, as serological assays are likely to give false negative results. Further studies are needed to identify these novel antigen targets.

SA-PO1039

Eculizumab Therapy in an Atypical Haemolytic Uraemic Syndrome (aHUS) Patient (pt) with Long-Term Renal Failure and Posterior Reversible Encephalopathy Syndrome (PRES) Hannah Povey, Rahul Vundru, Mahdi Jibani. *Ysbyty Gwynedd, Bangor, United Kingdom.*

Background: aHUS is a rare, life-threatening, genetic disease of chronic, uncontrolled complement activation. Eculizumab, a monoclonal antibody that selectively inhibits terminal complement activation, is approved in all pts with aHUS.

Methods: 21-year-old female with a late diagnosis of aHUS (STEC-HUS diagnosed at age 3, kidney impairment at age 14, iron deficiency and anaemia). Medical records are summarized.

Results: The pt presented with malaise, headache and easy bruising. Thrombotic microangiopathy (TMA) was shown by decreasing platelets (90×10^9U/L), increasing creatinine (166µmol/L), elevated lactate dehydrogenase (LDH; 1175U/L) and presence of schistocytes. ADAMTS13 activity, levels of C3 and C4 were normal (77%, 0.91g/L and 0.28g/L respectively). No complement mutations were identified (factor H, I and MCP activity was normal; CFH auto-antibodies were negative). Despite intensive plasma exchange (PE) she became anuric and required haemodialysis (HD). During the 8th week on HD, the pt lost vision in both eyes, followed by 3 grand mal seizures. A cerebral MRI showed parietaloccipital lobe edema consistent with PRES. The pt received labetalol infusions and eyesight was regained in 3 days. Support with HD and PE continued (36 sessions over 10 weeks total), however, thrombocytopenia continued and LDH remained elevated (Table). Eculizumab administration (900mg/wk for 4 wk, 1200mg wk 5 and 1200mg/2wk thereafter) improved platelet count, reduced LDH and decreased creatinine (Table). After the second eculizumab dose, renal function recovered and HD was discontinued (2.5 months on HD). The patient is currently on chronic eculizumab treatment.

Conclusions: Eculizumab, in contrast to intensive PE, inhibited complement-mediated TMA, improved renal function and eliminated the need for HD in a pt with life-threatening aHUS.

Day	Creatinine (µmol/L)	LDH (U/L)	Platelets (x10^9 U/L)	Management Since Previous Measure

Eculizumab in Genetic Form of Atypical Hemolytic Uremic Syndrome Associated with Cocaine Consumption Carola Arcal Cunillera, Josep Miquel Blasco Pelicano, Nestor Yesid Rodriguez, Luis F. Quintana, Federico Oppenheimer, Francisco Maduell, Josep Maria Campistol Plana. *Nephrology and Kidney Transplant Division, Hospital Clínic, Barcelona, Spain.*

Background: We present the case of two brothers with Atypical Hemolytic Uremic syndrome (aHUS) associated to factor H (FH) gene mutation and triggered by cocaine, with completely different renal outcome related to treatment.

Methods: A 27-year-old man presented with acute kidney failure, non-immune hemolytic anemia and thrombocytopenia. Complementary blood test showed raised lactate dehydrogenase, presence of schistocytes and low haptoglobin and C3 levels. A renal biopsy was performed showing thrombotic microangiopathy. After ruling out other causes, he was diagnosed with aHUS. Despite plasma exchange (PE) was administered every-other-day for 6 weeks (20 sessions), mild signs of hemolysis persisted (20 red-cell bags were

transfused) with no improvement on kidney function, hence the patient started chronic hemodyalisis. Genetic analysis revealed a mutation on complement FH gene (c.3514G>T; Glu1172Stop) with low concentration levels of protein 14.7 mg/dl (normal 12-56 mg/dl). Cocaine consumption was documented, considering it a potential trigger.

Six years later his younger brother (30 years old at that time) presented with severe kidney failure (creatinine 12 mg/dl), non-immune hemolytic anemia and thrombocytopenia. ADAMTS 13 activity was normal (85%) and test for cocaine was positive again. With the suspicion of aHUS and considering the poor outcome of PE on his brother, early treatment with eculizumab was started on day 4 (900 mg weekly during four weeks, then mantainance therapy with 1200 mg every two weeks). The hemolysis was reverted in a few days and kidney function progressively improved, currently mantaining a serum creatinine of 1.5 mg/dl after 11 months of treatment. Genetic analysis showed the same mutation on FH as his brother.

Conclusions: The opposite evolution of the brothers according to the treatment performed suggests that early treatment with eculizumab may prevent progression to end stage renal disease. These cases also suggest that cocaine could be acting as an enviromental trigger over a genetical succeptibility.

Efficacy of Rituximab in Adult Patients with Multirelapsing, Steroid-Dependent and Steroid-Resistant Nephrotic Syndrome: Report of 4 Cases and a Meta-Analysis Andreas Kronbichler,[1] Julia Kerschbaum,[1] Martin Busch,[2] Gert J. Mayer,[1] Michael Rudnicki.[1] *[1]Department of Internal Medicine IV - Nephrology and Hypertension, Medical University Innsbruck, Innsbruck, Austria; [2]Department of Internal Medicine III – Nephrology, Endocrinology and Rheumatology, Medical University Jena, Jena, Germany.*

Background: Rituximab (RTX) has shown efficacy in adult patients with nephrotic syndrome due to minimal-change disease (MCD) and focal segmental glomerulosclerosis (FSGS). Here we report 4 cases, and we analyzed the efficacy of RTX in multirelapsing (MR), steroid-dependent (SD) and steroid-resistant (SR) nephrotic syndrome from published reports treated with RTX, thereby identifying factors predicting a favorable therapeutic response.

Methods: Studies were identified through Pubmed. Studies on children were excluded. Four patients with MCD and FSGS treated with RTX in our centers were included. Clinical characteristics, laboratory data, treatment modalities, and data on outcome parameters were collected. Primary outcome parameters were complete/partial remission.

Results: We analyzed data from 30 patients from the literature, and we included 5 patients from our cohort (22 SD patients, 13 SR patients). In total, 26 patients received complete or partial remission, while 9 patients were non-responsive to RTX treatment. All seventeen patients with MCD were responsive to RTX therapy, whereas only half of the patients with FSGS received complete or partial remission ($p=0.001$). SR patients were non-responsive in 8 out of 13 cases, whereas SD patients received remission in 21 out of 22 patients ($p<0.001$). In univariate binary regression steroid-dependency as compared to steroid-resistance was associated with a 21-fold increased chance of remission. Furthermore, serum albumin at time of referral (per unit increase) and a low sum score of immunosuppressive agents before treatment with RTX were associated with a favorable outcome ($p=0.007$ and $p=.017$, respectively).

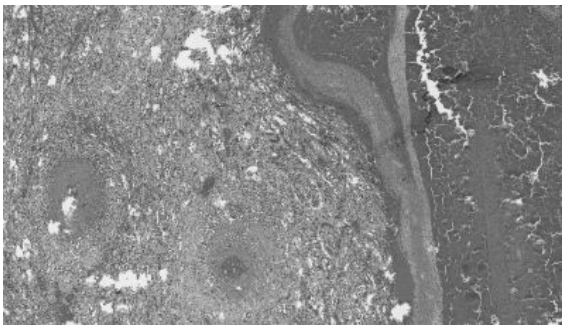
Conclusions: In multirelapsing, steroid-dependent and steroid-resistant nephrotic syndrome due to MCD or FSGS in adult patients we identified several factors associated with treatment response to RTX. These results need to be validated in a prospective study.

SA-PO1042

Acute Peri-Renal Hemorrhage as a Complication of Necrotizing Granulomatous Vasculitis Kiran B. Mandya Chikkalingaiah,[1] Hieu Q. Vo,[1] Arif Showkat,[1] Cuong Tan Nguyen,[1] Barry M. Wall.[1,2] *[1]UTHSC, Memphis, TN; [2]VAMC.*

Background: Multifocal necrotizing gramulomatous arteritis with no pulmonary involvement.

Methods: 66-yr old Asian female with hypertension and osteoarthritis on meloxicam 15 mg/d with serum creatinine (SCr) of 0.8 mg/dL was admitted for non-oliguric acute kidney injury. She had recently received Ciprofloxacin for presumed urinary tract infection. She denied fever or respiratory symptoms. Physical examination was unremarkable with normal vital signs and no skin lesions. Urinalysis: 25 RBC/hpf, 2-3 WBC/hpf, and granular casts, no eosinophiluria. Urine protein:creatinine ratio was 2.0, BUN 44 mg/dL, SCr 5.5 mg/dL, serum albumin 2.7 g/dL, WBC 17,200/m, hemoglobin 8.5 g/dL, platelet 442. Serologies for HIV, Hepatitis B and C, ANA, cANCA and pANCA were negative. C3,C4, CPK, LDH, CXR, and renal ultrasound were normal. Urine and blood cultures were negative. Ciprofloxacin was discontinued as a possible source for allergic interstitial nephritis, but SCr continued to rise, peaking at 7.3 mg/dL on day 4 and 6.8 mg/dl on day 6. Kidney biopsy was planned, but on day 6 she reported lower abdominal and back pain. She collapsed 6 hr later with hypotension and subsequently expired. Hemoglobin had dropped from 11 g/dL to 3.2 g/dL. Autopsy revealed multifocal necrotizing granulomatous vasculitis involving small arteries of kidneys (no glomerular crescents or proliferative changes (figure 1), esophagus, bladder, and ovaries. There were bilateral sub capsular renal hematomas and massive retroperitoneal hemorrhage with normal lung pathology.



Conclusions: This case illustrates several unusual features of granulomatous polyangiitis: ANCA negativity, non-pulmonary involvement and catastrophic spontaneous peri-renal hemorrhage. Vasculitides require tissue diagnosis such that a high index of suspicion should lead to prompt biopsy of involved organs, including the kidney.

SA-PO1043

Favorable Response to Rituximab in Diffuse Sclerosing Variant of Fibrillary Glomerulonephritis Asad J. Chaudhary,[1] Geeta G. Gyamlani,[1,2] Barry M. Wall.[1,2] *[1]University of Tennessee Health Science Center, Memphis, TN; [2]VAMC.*

Background: Fibrillary GN with sclerosing features has been associated with rapidly deteriorating renal function. We present 2 cases with favorable responses to Rituximab with 1 yr follow up.

Methods: Case 1: 62 yr old Caucasian male with type II diabetes mellitus developed rapidly worsening nephrotic range proteinuria despite lisinopril (80mg/day) and losartan (50 mg/day). HIV, hepatitis B and C serologies, serum and urine IFE, and ANA were negative. Renal biopsy showed diabetic nodular glomerulosclerosis. Congo red negative. Immunofluoresence (IF) positive for IgG,IgM, IgA, C3,C4, κ and λ light chains. Electron microscopy (EM) showed frequent intramembranous nonbranching, randomly arranged fibrils segmentally extending into subepithelial areas forming feather-like spikes. Biopsy results were consistent with Fibrillary Glomerulonephritis with extensive scarring and diabetic changes. He received 4 weekly doses (700 mg) of rituximab. Nephrotic range proteinuria has persisted, likely due to underlying diabetic nephropathy, however, SCr remains 1.4 mg/dl after 12 mos of follow-up.

Case 2. 55 year old Caucasian male presented with proteinuria and microscopic hematuria with SCr of 1.5 mg/dl and spot protein creatinine ratio (PCR) 8. C3 and C4, hepatitis B,C,and HIV serologies, and ANCA panel were normal or negative. Renal biopsy showed global and focal glomerulosclerosis. Congo red negative. IF positive for IgG, C3, C4. κ and λ light chains. EM revealed markedly thickened basement membranes. The mesangium was expanded with presence of randomly oriented fibrils which extend into the basement membranes. SCr had increased to 2.15 mg/dl with random PCR of 12. He received rituximab, 2 doses of 750mg, one week apart. Over the course of one year follow up his most recent spot PCR is 1 gram and SCr is 2.5 mg/dl.

Conclusions: Both patients with idiopathic sclerosing forms of fibrillary GN treated with rituximab demonstrated stable renal function with stable or declining proteinuria, suggesting that rituximab may be effective therapy for this variant of fibrillary GN, which typically progressees rapidly to end stage renal disease.

SA-PO1044

Combined Kidney and Auxiliary Liver Transplantation in a Patient with Primary Hyperoxaluria Type I: A Case Report Bojana Maksimovic,[1] Branislav Kocman,[2] Karlo M. Mihovilovic,[1] Mladen Knotek.[1] *[1]Renal Division, University Hospital Merkur, Zagreb, Croatia; [2]Surgery Division, University Hospital Merkur, Zagreb, Croatia.*

Background: Primary hyperoxalurias (PH) are rare inborn errors characterized by the overproduction of oxalate, which is deposited as calcium oxalate in various organs. PH type 1 is due to the defects in the gene that encodes the hepatic peroxisomal enzyme alanine:glyoxylate aminotransferase (AGT). Kidney is the prime target of oxalate deposition. Combined liver and kidney transplantation is treatment of choice in patients with ESKD due to PH1. Kidney transplantation alone results in early graft loss, due to recurrent disease.

Methods: Case Description: Here we present the case of a 21 year old Caucasian male who was diagnosed with PH1, and who developed ESKD subsequent to recalcitrant renal stone formation. In February 2012 the patient received simultaneous deceased-donor auxiliary liver and kidney transplantation. The patient underwent left hepatectomy with cholecystectomy, which was followed by the orthotopic transplantation of the second and third liver segment and a kidney transplantation. Immediate function of both grafts was established with substantial drop in serum creatinine and liver enzymes level. However, in the early post transplantation period dialysis was continued five days for the enhanced oxalate removal. Renal biopsy performed one month post transplantation showed normal renal parenchyma and 5-10% of renal tubules containing oxalate crystals. This is similar to 1-month protocol biopsy findings in our two previous patients who received combined whole liver and kidney transplant for PH1. Three months following transplant, the patient maintains good liver and kidney function.

Conclusions: Discussion: Combined auxiliary liver and kidney transplantation is a good treatment option for patients with PH1 and ESKD. It is also a safer treatment option, because whole liver transplantation requires removal of native liver which is functional in all other aspects, but AGT enzyme defect. With this approach life-threatening risk of potential liver graft failure is avoided, with maintenance of sufficient AGT enzyme level to prevent recurrent kidney disease.

SA-PO1045

Acute Kidney Injury Post Transplant: Broadening the Differential Diagnosis Lindsay Kruska, Jason M. Kidd, Karin A. True. *UNC Kidney Center, Chapel Hill, NC.*

Background: Annually, approximately 18,000 patients undergo renal transplantation. Often the etiology of their native disease is unknown. This case illustrates the importance of keeping a broad differential diagnosis for graft dysfunction.

Methods: A 74 yo Caucasian man underwent living unrelated donor renal transplant 9 months after reaching ESRD. His underlying renal insufficiency was thought to be related to acute tubular necrosis related to a prolonged hospital stay several years before, but had never had a diagnostic biopsy. Immunosuppression consisted of alemtuzimab 30mg IV, methylprednisolone 500mg IV followed by mychophenolate mofetil, tacrolimus and steroid taper. Renal function improved rapidly in first 5 days after transplant, but in the setting of Pseudomonas bacteremia he developed acute kidney injury requiring dialysis. Urine sediment showed monomorphic RBC and granular casts. Biopsy was performed and showed pauci-immune necrotizing and crescentric glomerulonephritis. He had a positive ANCA with MPO titer of 115 u/mL. Pretransplant banked serum sample was checked for ANCA and showed MPO titer of 137.6 u/mL. An unexpected diagnosis of recurrent ANCA vasculitis was made and the patient was treated with methylprednisolone 500mg IV daily for 3 days followed by prednisone 60mg daily and plasmapheresis. He has recovered enough renal function to be dialysis independent.

Conclusions: ANCA associated vasculitis (AAV) is the most common cause of rapidly progressive glomerulonephritis, though still rare with an estimated incidence of 20 cases per million. Approximately 30% of those diagnosed with progress to ESRD. Transplantation is a good option with 5 year graft survival rates comparable to all transplant recipients. The risk of relapse has been estimated between 11 – 50%, though in more recent series estimates range 9 – 17% with some relapses extrarenal. Though mean time to relapse is 31 months, reports of relapse range 5 days to 13 years. This case illustrates the importance in establishing an etiology of ESRD prior to transplant, but if impossible, maintaining a broad differential diagnosis for graft dysfunction.

SA-PO1046

Biopsy Proven Polyomavirus JC-Associated Nephropathy, Eleven Years after a Kidney Transplantation Marie-christine Guilbert,[1] Mathieu Latour,[1] Marie-chantal Fortin,[2] Harsharan Singh,[3] Volker Nickeleit,[3] Marie-Josee Hebert,[2] Edith A. Renoult.[2] *[1]Pathology Department, Centre Hospitalier de l'Université de Montréal, Canada; [2]Internal Medecine, Nephrology Service, Centre Hospitalier de l'Université de Montréal, Canada; [3]Nephropathology Laboratory, University of North Carolina at Chapel Hill.*

Background: Polyomavirus-associated nephropathy (PVAN) is a severe complication in renal transplant recipients. It is attributed to BK virus (BKV) and, more rarely, to JC virus (JCV), typically associated with progressive multifocal leukoencephalopathy. We describe a case of PVAN caused by JCV, in a 59-year-old male presenting with progressive kidney failure, 11 years after kidney transplantation.

Methods: This patient underwent cadaveric renal transplantation in 2001. Over the last 4 years, he was regularly lost to follow-up and serum creatinine rose from 139 to 241µmol/l, prompting a transplant biopsy. The biopsy specimen showed interstitial inflammation, slight tubulitis with viral inclusions and atypical enlarged nuclei, in a background of interstitial fibrosis and tubular atrophy, as well as severe arteriolar hyalinosis, consistent with calcineurin inhibitor toxicity. Immunohistochemical staining for SV40 large T antigen was positive. Decoy cells were present in the urine and cast-like polyomavirus aggregates (Haufen) were also detected by negative electron microscopy. Quantitative PCR in blood was negative for BKV and positive for JCV (7.38×10^4 copies/ml). Finally, JCV specific large T antigen was detected in the atypical tubular nuclei seen in the biopsy specimen. In order to improve JCV-specific immunity, immunosuppressive treatment has been reduced. Neurological evaluation is ongoing.

Conclusions: In contrast to the accumulating data of PVAN due to BKV, there are limited data reported on PVAN due to JCV. These two infectious nephropathies share some clinical and pathological signs but they may have different pathophysiological mechanisms. It is important that clinicians are aware that JCV as well as BKV should be considered a possible cause of PVAN. With wider clinical recognition and experience with this feature, we will better understand its prognostic significance.

SA-PO1047

Oxalosis after Kidney Transplantation in Bariatric Surgery Patients: A Retrospective Analysis Bhavna Chopra, Hatem Amer, Emilio Rodrigo, John C. Lieske. *Division of Nephrology, Mayo Clinic, Rochester, MN.*

Background: Obesity is a growing epidemic. We increasingly encounter candidates for transplantation who have had bariatric surgery. Roux en Y gastric bypass (RYGB) has been associated with enteric hyperoxaluria and renal failure from oxalosis, raising concern for early graft loss after kidney transplant (KTx). The objective of this study was to review our KTx experience in patients after RYGB.

Methods: All KTx recipients at our center with greater than 1 year follow-up who had undergone previous RYGB for obesity were retrospectively reviewed. Results were expressed mean±SD [range].

Results: Nine patients, all female and primarily Caucasian (7/9) were identified. Majority (8/9) were on dialysis prior to KTx, for 2.8±2.6yr. Causes of renal failure were diabetes (4), nephrectomy (2), oxalate nephropathy (1), ADPKD (1), and unknown (1). Age at transplant was 61.5±7.0 yrs. Time from RYGB to KTx was 6.9±4.4 yrs and 7/9 received a living KTx. All grafts were functioning during a study follow-up of 3.2±1.8 yrs [1.4-6.6] yrs. BMI at RYGB was 51.7±7.7 kg/m^2 and 32.4±8 kg/m^2 at KTx. Length of small intestinal common channel was 141.6±17.6 cm. Kidney stones pre-KTx occured in 4/9 pts. The peak plasma oxalate (PlOx) pre-KTx was 29.1±27.4 [5.2-88.7] µmol/L (normal < 3; with risk of oxalosis at > 25-30). Therapy for enteric hyperoxaluria (low oxalate diet + calcium binders) lowered immediate pre-KTx PlOx to 18.4±9.5 [6.6-28.0] µmol/L. PlOx at 3 wk post KTx was 3.7±1.7, and then 9.1±6.7µmol/L at last follow up. The 24 hr urine oxalate at last follow-up post KTx was elevated at 0.64±0.24 mmol/24hr (nl < 0.45). eGFR (MDRD) at 1, 3, 6, 12 months was 46.2, 48.3, 51.5, 46.5 ml/min/1.73 m^2, respectively. Two patients had oxalate crystals in biopsy at 8 months and 2 yrs post-KTx respectively.

Conclusions: This experience suggests that short term KTx graft survival is reasonable after RYGB. Patients in our group were treated to reduce PlOx to an accepted limit for systemic CaOx supersaturation (highest PlOx 28µmol/L). Long term graft outcomes need to be determined. Urine and plasma oxalate should be measured and promptly treated as indicated. A standardized approach to this high risk group is advisable.

SA-PO1048

Two Cases of Passenger Lymphocyte Syndrome Following Renal Transplantation Luxme Nadarajah,[1] Neil Ashman,[1] Raj Thuraisingham,[1] Colin Barber,[2] Shubha Allard,[2] Laura Green.[2] *[1]Nephrology Department, Barts Health NHS Trust, London, United Kingdom; [2]NHS Blood and Transplant, Barts Health NHS Trust, London, United Kingdom.*

Background: Passenger lymphocyte syndrome (PLS) is an immune-mediated red blood cell (RBC) haemolysis which occurs following ABO-mismatch solid organ and/or bone marrow transplantation. Passive transfer of viable donor B-lymphocytes occurs during transplantation and when these are stimulated, they cause the production of antibodies which are capable of reacting towards recipient RBC antigens, leading thus to haemolysis.

Methods: We report 2 cases of PLS occurring after renal transplantation. Both recipients were young males who had biopsy proven end-stage renal failure secondary to hypertension. They received live-related kidney transplants; one from his mother (case-1) and the other from his brother (case-2). The direction of blood group transfer, from donor to recipient, was O Rh + to A Rh + in both cases. Approximately 12 days after transplantation both recipients showed a rapid fall in their haemoglobin levels with no identifiable bleeding source. Their haemolytic screens were consistent with DAT positive haemolysis and anti-A antibody was detected in their sera, thus confirming the PLS-induced haemolysis. Treatment with blood transfusion and alteration of immunosuppressive therapy led to the recovery of haemoglobin and subsequent renal graft function.

Conclusions: In the literature we have identified 82 PLS cases related to renal transplants. Previous ABO sensitisation, group O donor to group A recipient transplant, cyclosporine treatment and patient secretor status, have all been identified as risk factors. Clinical outcomes in general are good; nonetheless, cases of graft failure and deaths have been reported. Therefore, it is imperative that clinicians are made aware of this condition so as to enable early diagnosis and appropriate treatment. It should also be highlighted that good communication between haematologists and nephrologists is key to managing PLS-induced haemolysis following ABO-mismatched renal transplants.

SA-PO1049

Aeromonas Caviae Infection in a Renal Transplant Recipient: More than Just an Innocent Bystander Amy J. Zwettler, Kevin C. Abbott, Robert Nee. *Nephrology Department, Walter Reed National Military Medical Center, Bethesda, MD.*

Background: Aeromonas species are gram-negative anaerobic rods that are ubiquitous in water and soil. Aeromonas has been considered a colonizer in asymptomatic hosts or a contaminant in cultures; however, more recent data suggests that certain strains are emerging enteropathogens. Transplant patients may be at increased risk of infection given their immunosuppressed state.

Methods: A 54-year old male with history of end-stage renal disease secondary to hypertension, underwent a living unrelated donor transplant. Transplantation was from a 35-year old male donor, with 5 antigen mismatches, and Thymoglobulin was used for induction. The donor was cytomegalovirus (CMV)-negative and the recipient positive. His postoperative course was unremarkable until day 14 when he developed abdominal pain and diarrhea. Stool studies were negative for CMV and Clostridium difficile PCRs. However, stool culture grew Aeromonas caviae for which the patient received a 5-day course of levofloxacin, followed by resolution of his symptoms.

Conclusions: Aeromonas is becoming an increasingly recognized cause of diarrhea. While patients with immunosuppression may be at increased risk, this is to our knowledge the first reported case in a renal transplant patient. Interestingly, this patient was a prior undersea medical officer, and therefore may have had occupational exposure and colonization to Aeromonas that was then allowed to cause diarrheal illness in the setting of immunosuppresion. A growing body of evidence supports the pathogenicity of Aeromonas, and our case suggests that Aeromonas infection should be considered in kidney transplant patients with diarrhea, as treatment may lead to relief of symptoms and prevention of

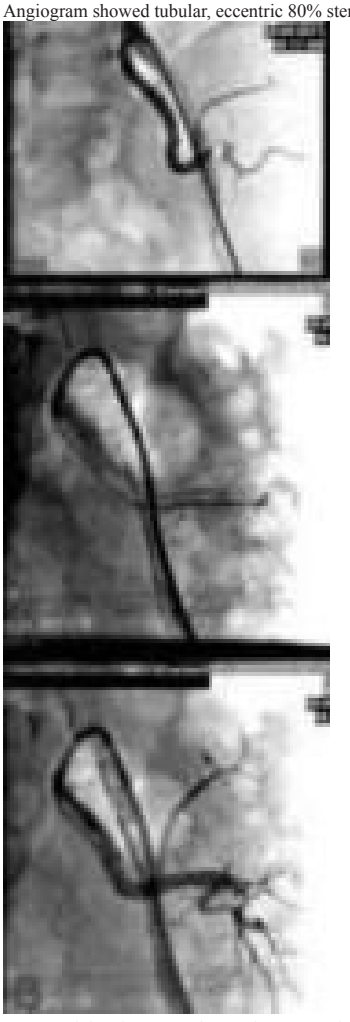
poor outcomes. "The views expressed in this abstract are those of the authors and do not necessarily reflect the official policy or position of the Department of the Army, the department of the Navy, the Department of Defense, or the United States government."

SA-PO1050

Distal Stenosis of the Transplanted Renal Artery Masquerading as Acute Rejection: Improvement in Renal Function after Percutaneous Transluminal Angioplasty Brian Michael I. Cabral, Ma Czarlota M. Acelajado-valdenor. *Center for Renal Diseases, St. Luke's Medical Center, Global City, Philippines.*

Background: A case of renal failure in a kidney transplant recipient. History was suspicious for acute rejection. Workup showed Doppler findings of distal TRAS. Renal function improved after angioplasty.

Methods: A 33 y/o male cadaveric kidney recipient sought 2nd opinion for azotemia. 2mos post-transplant, crea increased (2.8 from baseline 2mg/dL). Biopsy showed CNI toxicity. Immunosuppressants were adjusted with temporary improvement. However, azotemia recurred, accompanied by proteinuria, HPN & anemia. Upon presentation, crea was 6.8mg/dL, BP was high despite 5 anti-hypertensive drugs. Biopsy showed borderline changes suspicious for acute rejection: mild tubulitis,focal c4d, interstitial fibrosis & tubular atrophy. Duplex scan: increased peak systolic velocity in the distal segment of the allograft artery with RIR>3.5, suggestive of stenosis. Methylprednisolone 1500 mg was given. Angiogram showed tubular, eccentric 80% stenosis of the distal segment.



A peripheral stent was inserted. Post-stenting angiogram showed a patent, well apposed distal stent. Renal function & BP improved post-angioplasty. After a month, crea stabilized at 2mg/dL, BP controlled w/ 2 drugs.

Conclusions: We present a case of transplant renal artery stenosis arising early post-transplant in a cadaveric allograft recipient, accompanied by HPN, graft failure, biopsy findings consistent with borderline rejection, &stenosis occurring at an unusual location distal to anastomotic site. Here we see the value of conducting a thorough workup in patients with allograft dysfunction: while a rejection episode might have adequately explained the azotemia, the biopsy showed borderline rejection not consistent with the increase in crea nor the presence of refractory HPN prompting workup for vascular complications.

SA-PO1051

Mycoplasma Hominis Infection in Three Pediatric En-Bloc Kidney Transplant Patients: Is the Recipient the Source? Janet Y. Young, Deborah B. Adey. *Internal Medicine, Univ. of Calif, Davis, Sacramento, CA.*

Background: M. hominis is an organism that colonizes GU tract, posterior pharynx, and lower GI tract. It is of low pathogenicity but can cause severe infections in immunosuppressed patients. We report three cases of M.hominis infection in pedi-en-bloc kidney transplant recipients.

Methods: Case 1: 41yo female with ESRD from IgA nephropathy received pedi-en-bloc kidney transplant from 4mo male. On POD 7, she developed a retroperitoneal hematoma. Subsequent fever and leukocytosis triggered empiric antibiotics and surgical evacuation on POD 14. Peritoneal fluid cultures were initially negative and later grew M.hominis. She was switched to doxycycline/azithromycin and later to ciprofloxacin. She received 14 weeks of antibiotics.

Case 2: 28yo male with ESRD from reflux nephropathy received pedi-en-bloc kidney transplant from 2mo female. Readmitted POD 11 for fever and leukocytosis. Abdominal CT showed 4cm perinephric fluid collection with air. The incision appeared erythematous and the wound was surgically explored. Initial cultures were negative but grew M.hominis at 10 days. He received 6 weeks of doxycycline/ciprofloxacin.

Case 3: 28yo female with ESRD from unknown etiology received pedi-en-bloc kidney transplant from 1mo male. On POD 8, she had fever and leukocytosis. CT abdomen showed 4.4cm peritoneal abscess and 2.7cm perinephric hematoma. Abscess was drained, cultures grew M.hominis at 10 days. She received 6 weeks of ciprofloxacin/doxycycline.

Conclusions: M.hominis is undetectable by gram stain and grows slowly. Risk factors for infection are immunosuppression, tissue trauma, GU manipulation. Optimal treatment regimen and duration is unclear. Antibiotics effective against M.hominis include tetracyclines, clindamycin, fluoroquinolones, though resistance is emerging.

In kidney transplantation, it has led to perinephric abscesses/hematomas, perihepatitis, peritonitis, graft loss, death. For the 3 patients above, source of infection is likely the recipient given donor age. M.hominis must be considered when transplant patients present early with signs of infection. Early suspicion for the organism will hasten diagnosis and treatment, given difficulty in organism isolation.

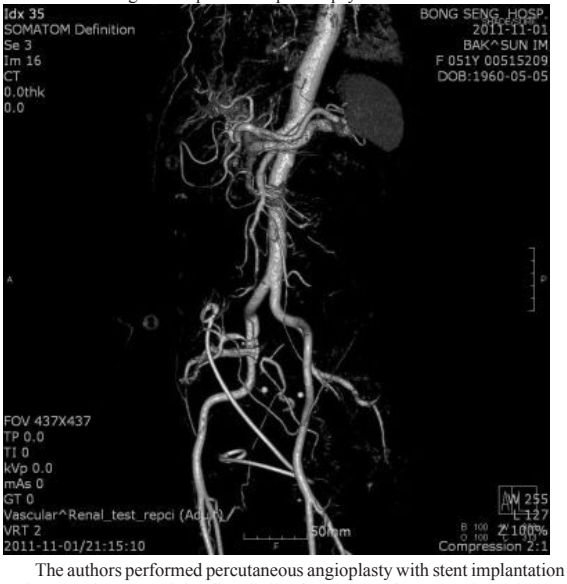
SA-PO1052

A Case of Acute Renal Failure in a Renal Allograft Recipient Caused by a Post-Biopsy Renal Arteriovenous Fistula Superimposed on the Onset of Renal Artery Stenosis Seong Min Kim, Joon Seok Oh, Joong Kyung Kim. *Internal Medicine, Bong Seng Memorial Hospital, Busan, Korea.*

Background: Renal biopsy of the transplanted kidney is an essential diagnostic tool of acute and chronic rejection as well as recurrent and de novo nephropathies in renal allograft recipients. Arteriovenous fistula(AVF) is an uncommon but well-known complication of percutaneous renal biopsy. Most postbiopsy AVFs are asymptomatic and regress spontaneously ; however, some AVFs result in hypertension, hematuria and renal insufficiency. Whether postbiopsy AVF superimposed on transplant renal artery stenosis(TRAS) also regress spontaneously is unknown.

Methods: The authors present a case of acute renal insufficiency in a 51-year-old female renal allograft recipient with postbiopsy AVF and TRAS.



The authors performed percutaneous angioplasty with stent implantation for the TRAS and transcatheter arterial coil embolization therapy for AVF. The patient's renal function returned to baseline level and is being followed up for 6 months.

Conclusions: What is noteworthy from our case is that before renal biopsy, our patient had arterial hypertension and showed mild elevated serum creatinine. This frasgile equilibrium was broken by postbiopsy arteriovenous fistula superimposed with arterial

stenosis. This patient showd abnormal lab finding on post-trasnplantation 3 months. This combination caused acute renal hypoperfusion, and indeed oliguria and pre-renal azotemia. After embolization of the AVF and stent implantation on TRAS, renal function parameters returned to basal levels. Of course, the findings of allograft biopsy was normal.

SA-PO1053

Two Cases of Successful Renal Transplantation in MYH9-Related Disorder

Byoung-Soo Cho,[1] Jin-soon Suh.[2] *[1]Department of Pediatrics, School of Medicine, Kyung Hee University, Seoul, Korea; [2]Bucheon St. Mary's Hospital, Catholic University, Bucheon, Korea.*

Background: MYH9-related disorders (MYH9-RD) is a group of autosomal dominantly inherited disorders caused by mutations of the MYH9 gene, which encodes the non-muscle myosin heavy chain IIA. Renal transplantation (RT) has been rarely reported in patients with MYH9-RD.

Methods: A 17-year-old-girl was admitted for living-related RT. She was diagnosed at 2 years old as having idiopathic thrombocytopenic purpura (ITP) which proved refractory to medications. At age 9, she developed hematuria and proteinuria and two years later, she was diagnosed of mesangial proliferative glomerulonephritis. Subsequently, her renal function progressed to end-stage renal disease (ESRD) at age of 17 years. On admission for RT, her platelet count was 44,000/mm^3. To prevent and control bleeding, she received IVIG and platelets perioperatively. The operation was performed without excessive bleeding and the platelet count was 126,000/mm3. However, large hematoma developed and after removing hematoma, her graft function was improved. She performed genetic study and a mutation was detected in MYH9 exon 16 (p.Arg702Cys), compatible with Fechtner syndrome. This mutation was a de novo mutation. An audiogram revealed bilateral high-frequency hearing deficit and she needs a hearing aid. The peripheral blood smear showed giant platelets, but no apparent inclusion bodies. On ophthalmic examination, cataracts were found in both eyes. An one year follow-up of the patient showed a favorable clinical course.

Second case is of 23 year-old-man diagnosed as ITP. Proteinuria was found on his school screening test and he was diagnosed with mesangial proliferative GN. He underwent genetic study which showed a mutation in MYH9 gene motor domain exon 1 suggesting MYH9-RD. This mutation was also a de novo mutation. He also performed renal transplantation successfully and his graft function is well maintained.

Conclusions: Our case suggests that renal transplantation is also the treatment of choice for ESRD in patients with MYH9-RD and the macrothrombocytopenia is not a contraindiation to aggressive management of ESRD.

SA-PO1054

Retroperitoneal Fibrosis in Context of Diffuse Large B Cell Lymphoma Presenting as Pseudoobstructive Uropathy

Buthayna Dinary, Khaldoon Shaheen, Ismail Hader, Keyvan Ravakhah. *Internal Medicine, St. Vincent Medical Center, Cleveland, OH.*

Background: Retroperitoneal fibrosis (RPF) encompasses a range of diseases characterized by the presence of a fibro-inflammatory tissue, which usually surrounds the abdominal aorta and the iliac arteries and extends into the retroperitoneal to envelop neighboring structures—eg, ureters. RF is generally idiopathic, but can also be secondary to certain drugs, malignancy, infections, and surgery. Here we describe a case of sudden onset of acute renal failure (ARF), hydronephrosis, in association with diffuse large B cell lymphoma and RPF.

Methods: A 71 year-old previously healthy man was admitted with two days history of fever, dull abdominal pain, decreased urine output, left leg and scrotal swellings. Examination was significant for scrotal and left leg pitting edema. Laboratory studies showed potassium (6.4mmol/l), creatinine (3.1 mg/dl), BUN (70 mg/dl), Hg (10.9 gm/dl), LDH 1240 u/l and proteinuria. US showed bilateral hydronephrosis. CT abdomen revealed retroperitoneal LAP and a solid retroperitoneal mass consistent with RPF. Duplex US of renal veins revealed left RVT. Retrograde pyelogram showed patency of the calyceal system. Lymph node biopsy confirmed B Cell Lymphoma. He was hydrated, anticoagulated and treated with IV dexamethasone. Patient creatinine improved to 2.5 mg/dl. He was discharged on prednisone, Lovenox, and Rituximab with plan to start CHOP.

Conclusions: Retroperitoneal Fibrosis should be suspected in any patient presenting with unexplained ARF and enlarged kidneys, especially in the setting of widespread lymphoma. It remains a mystery whether B cell lymphoma triggered the symptoms of a latent RPF or whether the two diseases merely coincided. Prompt diagnosis of RF improves chances of preserving renal function. Steroids are typically used to treat RPF, although other options—eg, tamoxifen-available. The outlook is usually good, but, if not appropriately diagnosed or treated, the disease can cause severe complications, such as ESRD.

SA-PO1055

Metastatic Breast Cancer Causing Type B Lactic Acidosis

Hala Yamout, Cybele Ghossein. *Nephrology, Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: To report an unusual case of type B lactic acidosis caused by metastic breast cancer.

Methods: A 24 year old woman with breast cancer complicated by metastasis to the bone, liver, and lung, presented with new right facial nerve palsy. Work up showed new brain metastasis and treatment included dexamethasone and radiation. Labs showed an anion gap metabolic acidosis with elevated lactate levels despite hemodynamic stability.

Date	pH	CO2 (mmHg)	HCO3 (mEq/L)	Lactate (mMol/L)	Metabolic Acid
1/12: 10:49	7.02	44	11	>20	18
1/12: 18:45	7.11	22	7	>20	33
1/13: 1:00	7.38	33	20	>20	34
1/14: 5:00am	7.34	30	9	>20	
1/17: 4:00	7.20	27	11	>20	42

Metabolic acidosis was treated with a bicarbonate drip. Lactate levels remained elevated. The patient's family eventually withdrew care.

Conclusions: There are different types of lactic acidosis: type A caused by tissue hypoperfusion; type B caused by to malignancy, medications, or hereditary disorders; or type D found in short bowel syndrome or a history of jejuno-ileal bypass surgery. Type B lactic acidosis is mainly described with hematological malignancies. The mechanism of disease is partially secondary to liver and kidney dysfunction with impaired clearance of lactate. Tumor overproduction of lactate likely contributes through overexpression of glycolytic enzymes, mitochondrial dysfunction, and use of anaerobic metabolism.

Treatment of lactic acidosis depends on treating the underlying cause, with no randomized controlled trials comparing the treatments of type B lactic acidosis. Chemotherapy is effective in a small group by reducing lactate production. Bicarbonate use is controversial as it may increase mortality and cause intracellular acidosis by CO2 generation. The role of thiamine remains unclear as it may either shunt away production of lactate by pyruvate yet may be a cofactor in tumor DNA production. Dialysis has been used to medically stabilize the patients and possibly clear excess lactate.

We present an unusual case of metabolic acidosis caused by type B lactic acidosis from a solid malignancy. Type B lactic acidosis should be considered in the differential diagnosis of patients with both solid and hematological malignancies who present with an anion gap acidosis.

SA-PO1056

Severe and Prolonged Hypocalcemia Following a Single Subcutaneous Dose of Denosumab in a Patient with Metastatic Prostate Cancer

James Drakakis, Karl Ziermann, Nobuyuki (Bill) Miyawaki, Shayan Shirazian. *Division of Nephrology and Hypertension, Winthrop University Hospital, Mineola, NY.*

Background: This case describes the onset of life-threatening hypocalcemia following a standard dose of denosumab (AMG-162), a full human monoclonal antibody with high affinity for the receptor activator of NF-kappaB (RANK) ligand. While prior studies involving denosumab have made mention of hypocalcemia as a mostly transient and asymptomatic adverse effect, this is the first reported case of clinically significant hypocalcemia, requiring a prolonged course of an intravenous calcium drip.

Methods: A 73 year old male with a history of prostate cancer with diffuse osseous metastatic disease, presented to the emergency department for evaluation of weight loss and low back pain. His prostate cancer had been diagnosed several days prior, after a biopsy was performed. He was admitted to the hospital and received sporadic treatment with androgen deprivation therapy. Admission serum calcium was 9.0 mg/dL. On hospital day five, he received one dose of 120mg of denosumab subcutaneously. In the days that followed, the serum calcium decreased to a range of 6.5 to 7.1 mg/dL and within one week, the level reached a nadir of 4.6 mg/dL. This prompted the initiation of an intravenous calcium drip. The patient required this calcium infusion of 148grams of elemental calcium over a total of eighty consecutive days, as well as aggressive oral supplementation with 375grams of elemental calcium, in order to sustain acceptable serum calcium levels.

Conclusions: Denosumab has proven to be effective at preventing bone loss due to several medical conditions, including postmenopausal osteoporosis and metastatic disease, with a relatively innocuous safety profile. The causation of hypocalcemia has previously been looked at as an occasionally expected but temporary and slight occurrence, manageable with oral supplementation. This case has brought to light the potential for severe hypocalcemia; one that is more difficult to manage and is of longer duration than first thought. As the use of denosumab becomes more widespread, clinicians in all fields need to be aware of potential severe, refractory hypocalcemia.

SA-PO1057

56 Year Old African American Female with Stage IV Metastatic Colon Cancer Was Given Oxaliplatin Causing Immune-Related Intravascular Hemolysis and Acute Tubular Necrosis

Ishwinder Sidhu, Zulqarnain Abro, Kenneth D. Abreo. *Department of Nephrology and Hypertension, Louisiana State University Health Sciences Center, Shreveport, LA.*

Background: Oxaliplatin (OXP) is a third-generation diaminocyclohexane platinum analogue. OXP compared to cisplatinis characterized by low-plasma accumulation and renal eliminationvia simple glomerular filtration without tubular metabolism.OXP is used for extended periods in advanced colorectal cancer causing unexpected nephrotoxicities; acute interstitial nephritis, thrombotic microangiopathy, and immune-related intravascular hemolysis causing ATN.Reported cases of OXP-induced ATN are rare.

Methods: A 56 y/o African American female with a history of type II diabetes, hypertension, Stage II Colon Cancer s/p resection on 11/04. The patient relapsed to Stage IV with mets to the lung on 07/05. The patient received chemotherapy with OXP/5-fluorouracil/leucovorin with bevacizumab. Oxaliplatin was restarted due to progression of cancer. During the second cycle, patient developed chest tightness/rash/itchiness/fever and chills immediately after OXP infusion. The patient's symptoms improved after the infusion was stopped. Two hours later patient's urine turned dark brown. Patient's physical exam was unremarkable. Urine analysis was strongly dipstick positive for blood with no RBCs/HPF. Hemoglobin decreased from a baseline of 10.3 to 8.2 g/dl. The serum increased to Cr 2.6 mg/dl from baseline of 0.7 mg/dl. The BUN was 42 mg/dl, LDH 396 U/dl, and haptoglobin 62 L. The patient received IV fluids and OXP was held. The serum Cr returned to baseline.

Conclusions: ARF occurs rarely during OXP treatment. OXP most likely causes the formation of a drug-antibody immune complex that binds via Fab to a 110 kDa protein on the RBC membrane leading to acute hemolysis. The latent period of several cycles before the development of overt hemolytic anemia is probably secondary to a gradual buildup of the immune response to OXP. After OXPtreatment, hematological abnormalities may occurduring ARFand mimic TMA. Nephrologists should be aware of thispossibility,since in addition to the supportive therapy ofARF, the treatmentof acute episodes of TMA requires plasma exchanges.

SA-PO1058

Mycophenolate Mofetil as a Steroid Sparing Agent in Renal Sarcoidosis
Anita A. Zaidi, Jordan L. Rosenstock, Maria V. DeVita. *Department of Nephrology, Lenox Hill Hospital, New York, NY.*

Background: Steroids are the mainstay of treatment for renal sarcoidosis. Many patients with sarcoidosis are chronically dependent on steroids and there is limited data on the use of steroid sparing agents. This is a case of a patient that has remained in remission using mycophenolate mofetil (MMF).

Methods: This is a 56 year old female with a history of sarcoidosis who developed acute renal failure when weaned from steroids. Her baseline creatinine ranged from 1.5-2.0 mg/dl on chronic prednisone and plaquenil. The patient had 3 relapses in 2 years while being weaned from steroids. Her most recent relapse occurred when the prednisone dose was lowered to 7.5 mg/day. On exam, she was an African American woman in no distress. Blood pressure was 110/80 with pitting edema in the lower extremities. Labs revealed a serum creatinine of 3.5 mg/dl (prior 2.0), ACE level was 147 (prior 38) and calcium 10.6. It was decided not to perform a kidney biopsy due to her being a Jehovah's Witness, but it was felt she had interstitial nephritis related to sarcoidosis. The patient was started on prednisone 40mg with improvement in creatinine to 2. Due to possible lifelong need for prednisone, MMF was started as a steroid sparing treatment. MMF was started and titrated to 1gm BID which she tolerated and the prednisone was decreased to 10mg daily. The serum creatinine improved to 1.6. Prednisone was decreased to 5mg and than tapered off after 3 months. The patient's most recent creatinine was 1.7 after being off prednisone for 14 months and on MMF for 22 months.

Conclusions: There have been only a few case reports about the use of MMF as a steroid sparing agent in renal sarcoidosis in which patients could be successfully weaned off steroids. The cases included a 56 year old patient who remained in remission on MMF after 18 months. Another case was of a 15 year old male that remained in remission for one year and a third case mentions a 57 year old female that has remained in remission after 28 months. Although renal failure from sarcoidosis is treatable by steroids, MMF should be studied further as a potential steroid sparing agent in the treatment of renal sarcoidosis.

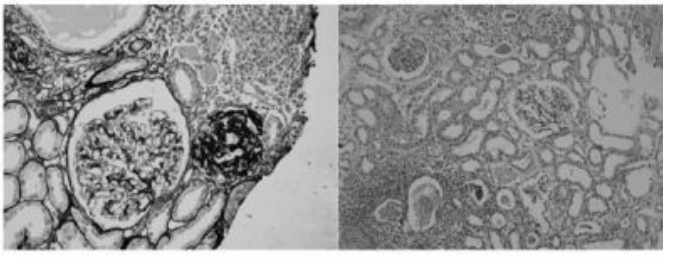
SA-PO1059

14-Year Follow-Up of a Chinese Boy with Lowe' Syndrome
Li Lin, Hong Ren, Jingyuan Xie, Nan Chen. *Nephrology Department, Ruijin Hospital, Shanghai Jiaotong University, Shanghai, China.*

Background: Oculocerebrorenal (Lowe) syndrome is a rare X-linked recessive disorder characterized by congenital cataracts, mental retardation, and renal tubular dysfunction.

Methods: An eight-month-boy first admitted to our hospital 14 years ago because of proteinuria. We followed up him for 14 years, all laboratory tests were recorded and renal biopsy was performed.

Results: The patient had congenital cataract and mental retardation. He was admitted to our hospital for mild to moderate proteinuria at 14-month-old. The patient was given glucocorticoid treatment (prednisone 2.5mg/kg/d at initiation then decreased) for 2 years but proteinuria persisted. At the age of 14, he came to our hospital for hypermicrosoma and obvious proteinuria (2-3 g/d). Physical examination showed facial edema, mild X-type legs and short-waisted(Height:120cm,Weight:30kg). Blood test showed creatinine was 59umol/L, phosphorus was 1.14mmol/L and HCO_3 was 22mmol/L. The increase of urine PH to 7.2 as well as over secretion of all kinds of amino acid and calcium in urine indicated proximal tubular injury(5.14mmol/24h).Urinary glucose and UA were normal (1.08 mmol / 24 h and 2.43mmol/l).Renal biopsy was conducted consequently, which showed interstitial infiltration of inflammatory cells and deposit of both IgM and C3 in mesangial region. Electron microscope was normal.The pathogenesis of proteinuria in Lowe syndrome remains unknown and further study needs to be done.The patient was given cyclosporine (125mg/d) and prednisone(15mg/d) therapy but the proteinuria persisted after 4 months.



Conclusions: Lowe syndrome not only presents defects in eyes, brain and renal tubule but also in glomeruli. This case indicated lack of response to immunosuppressive therapy in patients with Lowe syndrome.

SA-PO1060

Variation in Presentation and Presence of DNA Adducts and p53 Mutations in a Patients with Endemic Nephropathy: An Environmental Form of the Aristolochic Acid Nephropathy
Sandra Karanovic,[1] Ivana Vukovic-Lela,[1] Bojan Jelakovic,[1] Kathleen G. Dickman,[2] Anamarija Kovac Peic,[3] Damir Dittrich,[3] Andrea Fernandes.[2] *[1]Department of Nephrology, Arterial Hypertension and Dialysis, UHC Zagreb, School of Medicine, University of Zagreb, Zagreb, Croatia; [2]Departments of Pharmacological Sciences & Medicine/Nephrology, State University of New York at Stony Brook; [3]General Hospital "Dr. Josip Bencevic", Slavonski Brod, Croatia.*

Background: Endemic nephropathy (EN) and associated upper urothelial cancers (UUC) are a form of aristolochic acid nephropathy (AAN), in which ingestion of bread contaminated with Aristolochia leads to chronic dietary intoxication.

Methods: This abstract presents the cases of 3 members of the same family who showed different EN clinical courses and pathological spectra. Although they shared the same household and familiar environment for 18 years and were therefore similarly exposed to aristolochic acid (AA), they exhibited different clinical courses. EN can present as renal insufficiency or UUC alone, or in combination, regardless of which develops first. Moreover, UUC commonly affects both the right and the left sides, and our study clearly showed this. The patient in Case 1 had UUC with typical EN histopathological signs, whereas that in Case 2 had right UUC without EN followed by left UUC with typical EN histopathological signs. In contrast, the patient in Case 3 initially showed renal insufficiency, complicated afterwards by right UUC, and later on by left UUC with histopathological end-stage chronic changes but without typical EN changes. AA-DNA adducts and specific p53 mutational spectra (A:T→ T:A transversion) were found in tissues of cases 1 and 2. For Case 3, the appropriate tissue sample to detect adducts couldn't have been obtained. This patient possibly had specific p53 mutations in exons that were not examined.

Conclusions: The diverse clinical courses reported herein could be attributed to differences in metabolic activation or detoxification of AA and/or DNA repair resulting from different genetic polymorphisms.

Funding: Other NIH Support - NIH Fogarty Center, NIEHS (ES-04068)

SA-PO1061

Tubulointerstitial Nephritis in Behcet's Disease Sumi Sukumaran Nair, Shuchi Anand, Neiha Arora. *Stanford University.*

Background: Behcet's Disease[BD] is a rare disease with multisystem involvement, with a prevalence of about 1 in 300,000 persons per year in the US. Renal involvement is known to occur with BD, with AA amyloidosis being the most common manifestation. We report a case of tubulo-interstitial nephritis in a patient with BD.

Methods: A 26-year-old Brazilian man with a history of treated *Helicobacter pylori* gastritis and recurrent oral ulcers presented with severe abdominal pain. He also reported fatigue, weight loss and night sweats that began 1-month prior. His initial labs were significant for a SCr of 2.7mg/dl and ESR 136mm/hr. Abdominal imaging showed thrombus in the inferior vena cava, with extension into the bilateral renal veins. Urine analysis was bland without any proteinuria. An extensive workup for coagulopathy (including ANA, antiphospholipid antibody, factor V leiden, Prothrombin A mutation, JAK 2 mutation, ß2 glycoprotein), malignancy (SPEP/UPEP, colonoscopy, testicular ultrasound, PET scan, biopsy of the IVC lesion and lymph node), infection and autoimmune disease was unrevealing. His renal function rapidly improved with hydration (SCr decreased from 2.7 to 1.2 mg/dL), supporting a prerenal etiology. Given the history of recurrent oral ulcers, two previous episodes of painless red-eye, and severe thrombosis with a negative workup, he was given a presumptive diagnosis of BD.

He was started on azathioprine and prednisone therapy. Roughly 7 months after the initial episode, he noted recurrent oral ulcers while tapering the prednisone; at this time, he was found to have an increase in SCr (from a baseline of 1.2 mg/dL up to 1.6 mg/dL), with significant proteinuria (spot urine protein/creatinine 3.2 g/g). Renal biopsy showed tubulo-interstitial nephritis (TIN). He was continued on prednisone and azathioprine and lisinopril was added, with subsequent improvement in his SCr (1.2mg/dl) and proteinuria (1.2g/g).

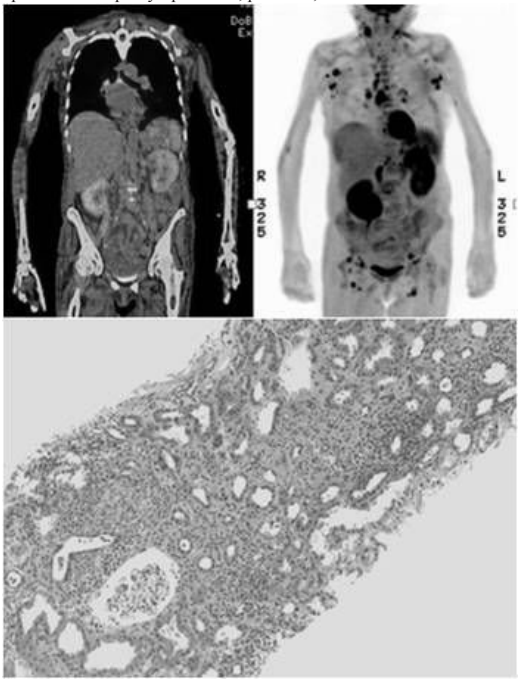
Conclusions: Although renal manifestations of BD including AA amyloidosis, glomerulonephritis, and renal vascular disease have been well described, BD- associated TIN has not been widely reported- a review of the literature showed only 6 reported cases to date. This case adds to our understanding of the spectrum of renal pathology in patients with BD.

SA-PO1062

DRESS due to Vancomycin Mandana Rastegar, Mark A. Perazella. *Section of Nephrology, Yale School of Medicine, New Haven, CT.*

Background: Drug Rash with Eosinophilia and Systemic Symptoms (DRESS) syndrome is a severe, multi-system drug reaction characterized by three of the following: fever, skin rash, peripheral eosinophilia, atypical circulating lymphocytes, lymphadenopathy, and hepatitis. These features are common to many systemic disorders, often delaying prompt diagnosis.

Methods: A 54-year old female with history of chronic pancreatitis complicated by pancreatic pseudocyst and duodenal artery pseudoaneurysm required coil embolization 3 months prior to presentation. Two months later, she developed fever, vomiting and abdominal pain, found to have *Staphylococcus* bacteremia and candidemia. IV vancomycin and fluconazole were administered for 14 days. Two weeks later, she presented with similar complaints. Vancomycin, fluconazole, ciprofloxacin and flagyl were administered, but discontinued as cultures remained negative. Two days later, patient developed fever, hypotension, cervical lymphadenopathy, hepatomegaly, and worsening morbilliform rash. Serum creatinine was 2.6mg/dL (baseline 0.6 mg/dL) and WBC was 37.4K/mm^3 with 31% eosinophils. CT Scan showed diffuse lymphadenopathy. PET scan demonstrated extensive uptake in multiple lymph nodes, pancreas, and renal cortices.



Kidney biopsy revealed granulomatous AIN with numerous eosinophils. This patient had classic features of DRESS syndrome secondary to vancomycin. She received IV steroids followed by oral prednisone taper with complete resolution of the systemic illness and AKI.

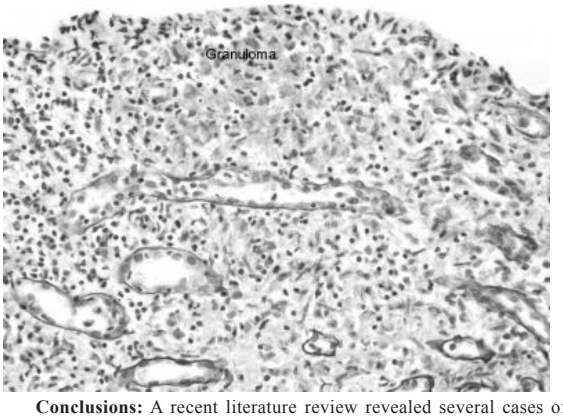
Conclusions: Early recognition and prompt removal of causative agents are critical in managing DRESS syndrome. PET-CT is used to detect tumors and inflammatory processes; it has potential as a non-invasive diagnostic tool for AIN. The etiology of AKI often rests between ATN or AIN. When biopsy is risky, PET scan offers a diagnostic alternative to distinguish the cause of AKI. This test may provide same day results for timely treatment.

SA-PO1063

Etanercept Induced Acute Granulomatous Interstitial Nephritis in a Rheumatoid Arthritis Patient Case Report Amr Yafi,[1] Laurie Matt,[1] Nairmeen Haller,[1] Natthavat Tanphaichitr.[2] *[1]Internal Medicine, Akron General Medical Center, Akron, OH; [2]Nephrology, Akron Nephrology Associates, INC, Akron, OH.*

Background: Acute interstitial nephritis (AIN) is a common cause of acute kidney injury in adults. The majority of cases are associated with drug-induced AIN. Tumor necrosis factor (TNF)-α inhibitor is a frequently used medication in advanced autoimmune diseases. Granuloma formation has been associated with AIN, however it is a rare occurrence.

Methods: This is a 55 year old female patient with a several-year history of rheumatoid arthritis (RA). She presented to the hospital with deterioration in renal function and hypertension. Approximately seven years prior to her presentation, etanercept therapy was started and her symptoms have been under control since. The initial laboratory tests were consistent with acute kidney injury, with no active urine sediments. A kidney biopsy revealed acute granulomatous interstitial nephritis. Her acute renal injury improved following withdrawal of etanercept and initiation of steroid therapy.



Conclusions: A recent literature review revealed several cases of sarcoid-like reaction secondary to initiation of TNF-α inhibitors, but none of these cases showed granulomatous interstitial nephritis formation. To our knowledge, this is the first case of etanercept-induced acute granulomatous interstitial nephritis in an adult RA patient. This case underscores the importance of having a high index of suspicion for AIN with the use of TNF-α inhibitor therapy.

SA-PO1064

Hemodialysis Improved CO2 Narcosis in Mixed Respiratory Acidosis and Metabolic Alkalosis Shamik Bhadra, Ziauddin Ahmed. *Nephrology, Drexel University College of Medicine, Philadelphia, PA.*

Background: Acute on chronic respiratory acidosis with metabolic alkalosis commonly cause CO2 narcosis in patients with a combination of COPD, CHF, and OSA .Since ventilator dependency can be a huge problem in such patients, any innovative treatment of Metabolic Alkalosis can be extremely helpful. We present a case where we used Hemodialysis as rescue therapy.

Methods: A 49 y/o AAM with h/o DM2, CKD stage 2, with baseline creatinine b/w 1.13-1.3 with nephrotic syndrome, diastolic heart failure and OSA who presented to the hospital with complaints of dyspnea of exertion and orthopnea of one month duration. Clinical exam showed pulmonary edema and hypercapnic respiratory failure. He was started on a bumex drip at 2 mg/hr. P/E revealed, an obese male, drowsy with BP of 140/90, bilateral +3 pedal edema, with O2 sat of 94% on BIPAP. His serum bicarb was 35, chloride 101, and Scr -1.33. ABG of 7.25/86/73/37/92%. Patient diuresed well with urine output of 1.4 L in the first 24 hrs and 6 L on the 2nd day. His PCO2 rose from 86 to 94, and subsequently to 108 but his pH remained at 7.25. He became obtunded but was not intubated because of concern for difficulty weaning. Serum creatinine increased from 1.33 at admission to 1.41 and serum bicarb rose from 35 to 43, with chloride decreasing to 94. Potassium remained 4.2 after 4 days of diuresis and PCO2 rose to 95. The diuretic was discontinued and patient was dialyzed once with a HCO3 bath of 25 and 3k potassium bath for 3 hours and given 500 ml of NSS. At 2 hours post HD his ABG was 7.28/78/131/36.7/98% and bicarb improved to 31. Ten hours post HD the ABG was 7.32/75/115/38/98% with HCO3 31, chloride 101 and potassium 4.8. His urine pH was 5.0. Patient clinically improved and was taken off the BIPAP. Two days after HD he was discharged with ABG of 7.40/60/84/36/96%, HCO3 of 31, Scr of 1.14 and with normal mental and respiratory status.

Conclusions: Hemodialysis with low bicarbonate bath may have a role in improving the metabolic alkalosis component of the CO2 narcosis and avoid ventilator dependence.

SA-PO1065

Demyelinating Neuropathy and Rhabdomyolysis Induced by Simvastatin in a CAPD Patients Somchai Yongsiri,[2] Jiranuch Thammakumpee.[1] [1]*Internal Medicine, Chonburi Hospital, Mueng, Chonburi, Thailand;* [2]*Internal Medicine, Burapha University, Mueng, Chonburi, Thailand.*

Background: Statin is a well-known drug causing rhabdomyolysis. Demyelinating neuropathy is another serious side effect that reported less frequently. This current case illustrate a CAPD patients who suffered from both rhabdomyolysis and demyelinating neuropathy induced by simvastatin.

Methods: Case description. A 37 year-old female had been on CAPD for 10 months because of hypertensive renal disease presented at the outpatient clinic with generalized muscle weakness and muscle pain for 2 days. Medical history showed an episode of peritonitis 4 months after started CAPD. Her medications included simvastatin, amlodipine, losartan and furosemide. On physical examination, she had muscle tenderness, motor power grade 1 all extremities with reduced deep tendon reflex and decreased pinprick sensation all extremities. Cranial nerves were intact. Serum creatinine phosphokinase level was elevated at 1208 U/L (normal 24-170 U/L). MRI of C-spine found no spinal cord or nerve root lesion. Lumbar puncture showed clear, colorless fluid without cell, normal glucose and protein level. Electromyography and nerve conduction velocity studied revealed sub-acute demyelinating neuropathy. Diagnosis. Demyelinating neuropathy and rhabdomyolysis secondary to simvastatin. Clinical course. She had been treated conservatively with temporary hemodialysis and physical rehabilitation. Her conditions were progressively improved over 3 months after simvastatin withdrawal and regain muscle power to grade 4/5.

Conclusions: Discussion. The incidence of peripheral neuropathy and rhabdomyolysis associated with the use of statins are about 1 in 14,000 and 1 in 10,000 person-years respectively. It can occur many months or years after starting the drug. A possible mechanism of neuropathy and rhabdomyolysis from statin is the inhibition of mitochondrial respiratory chain and an intracellular deficiency of ubiquinone. Risk factors include statin characteristic and higher dose, pre-existing neuromuscular disease, concurrent drug use, and renal dysfunction. Nephrologist should be aware of these serious side effects in ESRD patients taking statins.

SA-PO1066

Peritoneal Drainage of Chronic Ascites Secondary to Right Ventricular Failure and Endstage Renal Disease Siddiq Anwar, Aman Gupta, Merajul Haq Khan, Sohail Ahmad. *Renal Unit, East Kent University Hospitals NHS Foundation Trust, Canterbury, United Kingdom.*

Background: We report two cases of haemodialysis (HD) patients where severe right ventricular failure and resultant chronic ascites was successfully managed using peritoneal drainage.

Methods: The first case is a 63 year old female on HD via arteriovenous fistula (AVF) secondary to polycystic kidneys and congestive cardiac failure (CCF). She had a tenchkoff catheter inserted for drainage of chronic ascites. Her pulmonary artery pressure (PAP) was 50mmHg + right atrial pressure (RAP) and had an ejection fraction of 10-15%. Ultrafiltration (UF) on HD proved futile due to severe symptomatic hypotension. Her dialysis adequacy could not be met via peritoneal dialysis alone due to large polycystic kidneys. We simulated UF by removing fluid thrice per week via the tenchkoff catheter before HD sessions. This enabled effective dialysis and fluid balance without compromising hemodynamic stability. Over two months her exercise tolerance improved (NYHA IV to NYHA II) and serum albumin increased by 73% (11 to 19 g/l). This might have been related to alleviating the compressive effect of chronic ascites. Our second case is a 72 year old male also on HD via AVF. He has a background of chronic glomerulonephritis and CCF. His PAP was 44mmHg + RAP. Like the previous case, cardiovascular fragility made UF difficult on HD. His ascites was drained just before his HD session thrice per week via tenchkoff catheter. It was his choice to stay on HD. His albumin improved 48% (23 to 34 g/l) and exercise tolerance (NYHA IV to NYHA II) over a 3 month period.

Conclusions: Peritoneal Dialysis alone has been described in patients with ESRF and severe CCF. These cases are unique and demonstrate that intermittent peritoneal drainage via tenchkoff catheter can be used to successfully drain chronic ascites in patients with heart failure. We feel that intermittent peritoneal drainage via tenchkoff is an underused therapeutic measure. We believe that this has a role in patients with severe right heart failure with chronic fluid overload. This can be a palliative measure, as in our case or in patients waiting for a heart transplant even without severe renal impairment.

SA-PO1067

Recurrent Catastrophic Anti-Phospholipid Antibody Syndrome Triggered by Peritoneal Dialysis Peritonitis Ahsan Ahmed Syed, Vinod Mathrani, Mangalakumar Veerasamy. *Renal, Hull Royal Infirmary, Hull, United Kingdom.*

Background: Catastrophic antiphospholipid syndrome (CAPS)is a rare and life threatening variant of antiphospholipid syndrome. It is characterized by microvascular thrombosis leading to involvement of 3 or more organs, developing over short period of time (less than one week), and the presence of antiphospholipid antibodies (aPL) in high tires. Infection acts as a trigger to increase aPL by molecular mimicry.

Methods: We present a patient who reached ESRD due to CAPS developed recurrence of CAPS following PD peritonitis. PD peritonitis was treated appropriately along with consideration of PD catheter change. Due to poor venous access, temporary replacement of warfarin to unfractionated heparin (UH) was challenging, therefore commenced on low molecular weight heparin at reduced dose. Over the next 10 days she developed pyrexia of unknown origin and a full septic screen was negative. She rapidly developed respiratory insufficiency with pulmonary infiltrates, acute coronary event, abdominal pain and lactic acidosis, suggesting rapidly evolving microvascular thrombosis affecting above organs. This was associated with high aPL titres and low anti-Xa activity. In spite of optimising the anti-coagulation, she developed generalised seizure & CT brain showed bilateral subdural haemorrhages. All above features suggested recurrence of CAPS. She was treated with plasma exchange, UH along with multi-organ support. Since she had prolonged activated prothrombin time (aPTT) at the baseline we needed to monitor anti-Xa activity whilst receiving UH which is not the standard practice. She made a good recovery and discharged on warfarin.

Conclusions: Patients with CAPS can develop thrombotic events due to increase in aPL titre after infection. Since infection is a common occurrence in ESRD patients with indwelling catheters, close monitoring and optimisation of anti-coagulation is essential to prevent thrombotic events during episodes of infection. Since these patients could have prolonged aPTT due to the presence of lupus anti-coagulant, aPTT measurement alone might result in under-anticoagulation hence we suggest factor Xa activity rather than aPTT monitoring while on UH.

SA-PO1068

Successful Long-Term Intermittent Haemodialysis in a Patient with Left Ventricular Assist Device Haridian Sosa Barrios,[1] Andrew Palmer,[1] Nick Banner,[2] Neill D. Duncan.[1] [1]*Renal Medicine, Hammersmith Hospital, London, United Kingdom;* [2]*Cardiac Surgery, Harefield Hospital, London, United Kingdom.*

Background: Left ventricular assist devices (LVAD) in patients with refractory heart failure are bridging treatment to cardiac transplantation. With coexistent end-stage renal failure (ESRF) continuous veno venous haemofiltration (CVVHF) is employed, but ESRF is an ineligibility criterion for cardiac transplantation and the LVAD becomes the destination treatment. CVVHF cannot be provided in the long-term or outside of an intensive care. Uncommonly LVAD-supported patients are treated with intermittent haemodialysis (HD), we present a 48yr male treated in this way.

Methods: Despite cardiac resynchronisation and a pacemaker defibrillator his cardiac function worsened, a Heartware LVAD was inserted. Following CVVHF, intermittent HD four times a week treatment was delivered via a cuffed central venous catheter.

He was ultimately discharged to independent living in the community. He was pulseless and dialysis nurses measured mean arterial pressure using a Doppler ultrasound device. In the event of circulatory collapse fluid replacement was the advised but not required. He had three access-related bacteraemias treated with line salvage - 2.26 episodes per year. Other medical complications were two episodes of epistaxis resulting from nasal septal perforation and obligatory anticoagulation for the LVAD and a gastrointestinal bleed from a duodenal ulcer. He describes good quality of life 17 months after starting HD.

Conclusions: 14% of patients required renal replacement therapy in a recent study of patients who received a LVAD as bridging treatment, and ESRF was associated with 80% mortality. Our novel report of outpatient HD in a LVAD recipient demonstrates this should be considered and can provide long-term quality of life in those without prospects for cardiac transplant.

SA-PO1069

Successful Pregnancy after Intracytoplasmic Sperm Injection in a 36 Year Old Hemodialysis Patient Daniel Zickler, Achim Joerres, Ralf Schindler, Andreas Kahl. *Nephrology and Intensive Care, Universitatsmedizin Berlin, Berlin, Germany.*

Background: Fertility is markedly reduced in the dialysis patient population. Causes are multifactorial and include hormonal imbalances. Here we report a case of successful intracytoplasmic sperm injection (ICSI) in a 36 year old hemodialysis patient.

Methods: The patient was diagnosed with end stage renal disease at age 28 caused by interstitial nephritis secondary to sulfasalazine intake for ulcerative colitis. After 4 years of regular sexual intercourse without contraception and a complete infertility workup

of the patient's spouse the diagnosis of infertility was made. The patient and treating gynecologist decided to move to ICSI. After two implantation failures a third embryo could be successfully implanted. During pregnancy hemodialysis was intensified (6 times/week 5 hours). Adequate substitution of erythropoeitin, vitamines, trace elements and iron was given on the basis of monthly measurements.

Results: During pregnancy an exarcerbation of the ulcerative colitis was successfully treated with steroids. Furthermore hypertension had to be treated with alpha-methyl-Dopa and metoprolol. Moreover, an impairment of regurgitation of the mitral valve occurred. Despite these problems the pregnancy proceeded without further complications. At week 34 a healthy male infant (1750g) was delivered spontaneously. 5 weeks after delivery the resection of a small segment of the child´s colon was necessary due to necrotizing enterocolitis, requiring neonatology care for two months. At present, the physical and mental development of the 18 month old boy is normal. Shortly after delivery the mother showed signs of progressive cardiac insufficiency which resolved spontaneously. It remains unclear if the cardiac impairment was associated with pregnancy or fluid overload. One year after the delivery the mother underwent successful kidney transplantation.

Conclusions: To our knowledge this is the first reported case of a successful pregnancy induced by ICSI in a patient on longterm dialysis treatment (>7 years). Successful outcome was achieved by close monitoring of mother and child during and after the pregnancy, as well as intensified hemodialysis treatment.

SA-PO1070

Intraperitoneal Oxacillin in Methicillin Sensitive Staph Aureus (MSSA) Infective Endocarditis: A Case Report Priyanka Singh, Paul A. Fein, Morrell M. Avram. *Avram Division of Nephrology, SUNY Downstate University Hospital at LICH, Brooklyn, NY.*

Background: The treatment of local infection (peritonitis) in patients maintained on continuous ambulatory peritoneal dialysis (CAPD) typically includes repeated administration of intraperitoneal (IP) antibiotics, which are systemically absorbed to varying degrees, but sufficient to reach measurable serum levels. Factors influencing systemic absorption include molecule size, dialysate drug concentration, dwell period, protein binding, distribution volume, and presence or absence of peritonitis. There is limited data available, however, regarding the use of IP antibiotics for systemic infections.

Methods: Case Report: A 42 y/o African-American woman with aortic valve replacement and mitral valve repair receiving hemodialysis via left upper arm arteriovenous (AV) graft developed MSSA endocarditis with aortic root abscess. She was initially treated with intravenous (IV) nafcillin using a Hickman catheter. Cardiac surgery was deferred due to severe anemia (6.8Gm/dL) and religious transfusion objection. The clinical course was complicated by vascular access failure and catheter-related infections, so she was switched to CAPD. Nafcillin-related liver enzyme elevations necessitated a switch to oxacillin. Due to line/catheter infection, we switched IV to IP oxacillin added to each PD exchange using the following conversion: 2Gm IV every 4 hours to 3Gm IP every 6 hours (each totaling 12Gm/day). The serum oxacillin level after 8 PD exchanges was 50 mcg/ml (reference range: peak serum level after 500mg IV oxacillin is 43 mcg/ml). We continued this regimen while the patient was optimized for cardiac surgery using high dose epoetin and iron sucrose, and she remained afebrile, non-toxic, and non-bacteremic for the following month.

Conclusions: Intraperitoneal antibiotics can be considered for systemic infection as long as therapeutic drug levels are achieved in serum. Given the very limited data available, varied antibiotic kinetics and peritoneal absorption rates, therapy must be individualized, and modified as clinically warranted.

SA-PO1071

Ischemic Monomelic Neuropathy Associated with HeRO Vascular Access Device: A Case Report Jagannath H. Saikumar, Sandeep S. Soman, Lalathaksha Murthy Kumbar. *Nephrology, Henry Ford Hospital, Detroit, MI.*

Background: Complications arising from vascular access for hemodialysis are not uncommon. Ischemic Monomelic Neuropathy (IMN) is one the most serious non-vascular complication resulting in irreversible neuronal damage. Here we present an interesting case of a patient who underwent a HeRO (Hemodialysis Reliable Outflow)™ graft implantation resulting in the onset of symptoms suggestive of IMN requiring emergent ligation of the vascular access.

Methods: A 51 y.o woman with ESRD presented to our hospital emergency room with onset of altered mental status shortly after hemodialysis at an outside facility. An acute cerebro-vascular event was ruled out. Her mental status improved with supportive care over two days. She then complained of numbness in her left hand and inability to extend her left middle 3 fingers and elbow. Her husband informed us that she had a left upper extremity HeRO™ graft implantation 3 days earlier at another facility as she was found to have bilateral subclavian vein occlusion. Adequate radial pulsation was noted on Doppler study in the left arm. Due to the possibility of IMN, the patient underwent an emergent graft ligation and placement of a temporary tunneled cuffed catheter. Electromyogram performed post-ligation showed decreased nerve conduction velocity in the left median nerve and in sensory and motor nerve amplitudes in the left arm and forearm suggestive of an acute pan-brachial plexopathy involving primarily the lower trunk. No significant improvement was seen in symptoms and motor function in her left hand at the time of discharge,3 days post ligation. She was lost to follow-up.

Conclusions: IMN is a serious but uncommon complication of hemodialysis access that can result in permanent neurological sequelae.Clinical manifestations of IMN can be misinterpreted as post surgical changes.Previous experience has shown that even with timely intervention, the axonal damage done may be permanent with residual loss of function as in our patient.This case underlines the importance of a high index of suspicion for IMN in the appropriate setting.To the best of our knowledge,this is the first report of IMN in a patient who received a HeRO™ graft.

SA-PO1072

Successful Treatment of Diltiazem Sustained Release (SR) Overdose with Charcoal Hemoperfusion Sreedhar R. Adapa, Tarun Chugh, Rajan Kapoor, Savneek S. Chugh, Maureen E. Brogan. *Department of Nephrology, New York Medical College, Valhalla, NY.*

Background: Hemoperfusion is an extracorporeal technique that works on the principle of adsorption and is used to remove protein-bound and lipid-soluble drugs more efficiently than hemodialysis.

Methods: 50 yo male with PMH of HTN, schizophrenia admitted after being found unconscious in prison cell. Vitals signs: HR of 40/min, BP of 70/40 mm Hg, and RR of 12/min. Physical examination revealed unconscious patient with bradycardia and hypotension. EKG showed sinus arrest with a ventricular escape rhythm at 45 bpm. Significant labs: BUN 31 mg/dl, creatinine 2.2 mg/dl, bicarbonate 16 mEq/L and blood glucose 39 mg/dl. The patient was intubated in the ER. Initial treatment comprised of gastric lavage, IV calcium chloride, IV atropine, insulin and dextrose drip and glucagon for presumptive diltiazem overdose (as few tablets of diltiazem SR were found with the patient). Patient required maximal doses of three pressors, transvenous pacing for symptomatic bradycardia and sustained anuric acute kidney injury (AKI). With no improvement in his hemodynamic status and refractory diltiazem overdose, he got charcoal hemoperfusion for three hours. After a few hours, his cardiorespiratory status improved, transvenous pacer and pressor support was weaned off. Patient required three treatments of intermittent hemodialysis for his AKI. Diltiazem levels were subsequently confirmed to be 5900ng/ml (reference range 50-200 ng/ml) on admission, and 990ng/mlafter hemoperfusion. Transient thrombocytopenia and hypocalcemia were seen with hemoperfusion that were self-limiting.

Conclusions: Hemoperfusion was used with success in standard formulation diltiazem overdose, which didn't respond to intense medical management in few case reports previously. Diltiazem SR formulations cause prolonged toxicity and potentially life threatening. The efficacy of hemoperfusion in treating diltiazem SR overdose was debated recently. We successfully treated diltiazem SR overdose with one of the highest serum concentrations reported in a patient who survived, with hemoperfusion which was refractory to intense medical management.

SA-PO1073

A Surviving Patient with Record High Creatinine Naing L. Htike,[1] Andrew C. Storm,[3] David A. Cohen,[2] Robert L. Benz.[1] *[1]Internal Medicine, Nephrology, Lankenau Medical Center and Lanenau Institute of Medical Research, Wynnewood, PA; [2]Internal Medicine, Lankenau Medical Center, Wynnewood, PA; [3]Internal Medicine, The Johns Hopkins Hospital, Baltimore, MD.*

Background: Creatinine is a product of muscle protein breakdown cleared by the kidneys at a constant rate. The glomerular filtration rate is estimated based on serum creatinine. Higher serum creatinine concentration is associated with either a reduced renal excretion of creatinine or increased production by the body during myositis or rhabdomyolysis. There is no definitive level of serum creatinine which is itself incompatible with human survival. We present the highest serum creatinine level associated with survival based on a thorough review of the literature.

Methods: We report a 34 year old male patient with baseline serum creatinine 1.2 mg/dl who presented to Lankenau Medical Center's emergency department with a six week history of new onset of uremic symptoms including nausea, vomiting, ankle swelling and 30 lb weight loss. His past medical history was unremarkable and was on no prescribed medication. On exam, he had no acute distress. His BMI was 28. His exam was significant only for an elevated blood pressure of 184/93 and asterixis. His oxygen saturation was 100% on room air. His peak serum creatinine of 53.9 mg/dl with an estimated GFR of 1ml/min. There was no hydronephrosis on renal ultrasound. The patient subsequently required maintenance hemodialysis and later changed to long term peritoneal dialysis.

Conclusions: To our knowledge, based on a thorough review of the literature using PubMed, Cochrane Data Base and USRDS, this is the highest level of serum creatinine ever reported. The USRDS records show that over the past 15 years, less than 1.3% of all new ESRD patients have a reported initial creatinine over 20 mg/dl. The USRDS data-base also includes no value over 30 mg/dl. We conclude that serum creatinine itself is non-lethal. It is more likely that other electrolyte and retained metabolic product abnormalities of renal failure frequently cause symptoms or death before lethal toxicity, if such a level exists, of creatinine has been reached.

SA-PO1074

The Treatment Dilemma of Hypodipsic Hypernatremia Ghassan Bandak,[1] John Manllo,[1] Javier A. Neyra,[1] Jerry Yee.[2] *[1]Internal Medicine, Henry Ford Hospital; [2]Nephrology, Henry Ford Hospital.*

Background: Serum osmolality, serum sodium and water homeostasis are hypothalamically regulated via thirst sensation of AVP secretion in response to tonicity and ECF volume changes. Hypothalamic pathology may alter this homeostatic balance, producing disorders of serum sodium.

Methods: A 50 y.o. previously healthy male presented with acutely altered mental status and severe hypernatremia of 188 mEq/L. Laboratory evaluation revealed acute kidney injury with SCr 2.4 mg/dL, Sosm 394 mOsm/kg, UNa 16 mEq/L, Uosm 483

mOsm/kg, measured after IV fluid administration, and inappropriately low serum AVP levels. A brain MRI was consistent with diffuse encephalomyelitis. The patient received DDAVP and isotonic IV fluids with improvements of kidney function, hypernatremia and mental status that approached his baseline by time of discharge. However, symptomatic hypernatremia recurred and required repeated hospitalization. Inpatient evaluation demonstrated increased Uosm to 924 mOsm/kg and reduced 24-h urine volume of 900 mL during water restriction. Urine volume increased to 1750 mL at Uosm of 609 mOsm/kg after isotonic fluid infusion. On a fixed water intake of 2 L per day, the patient currently maintains a SNa at approximately 144 mEq/L.

Conclusions: Hypodipsic hypernatremia represents an infrequently reported, rare, hypothalamic disorder of impaired osmoregulation. In this case, cerebral inflammation impaired thirst function with consequent symptomatic hypernatremia, but the urinary concentration mechanism remained intact, characteristic of patients with hypodipsic hypernatremia. A therapeutic regimen of scheduled water intake is challenging, but was salutary in this case. Lastly, the role of desmopression as thirst stimulant in this uncommon problem is controversial.

A Simple Screening Test for the Detection of Anti-Erythropoietin Antibodies

Soma Meran, Alexa Wonnacott, Mat Davies, Aled O. Phillips. *Institute of Nephrology, Cardiff University, Cardiff, United Kingdom.*

Background: Antibody mediated Pure Red Cell Aplasia is a rare complication of erythropoietin (EPO) therapy. Identification and demonstration of functional activity of EPO antibodies required to diagnose this condition is difficult and only performed in select laboratories worldwide. **Objectives:** We report three recent cases of of antibody mediated PRCA associated with subcutaneous Epoetin Alfa (EPREX) use and describe the use of a simple inhibitor assay that can be used to diagnose PRCA in local laboratories.

Methods: Assay Description: A sample of patient serum is incubated for 1h at 37 degrees with an equal volume of serum of known concentration (e.g 50 mIU/ml). By measuring the EPO in the patient sample in conjunction with the level in the incubated mixture, the percentage recovery can be calculated. If the recovery is found to be less than 80% of the expected value, the presence of EPO inhibitor activity is suspected. The assay has been validated by running the test for 6 patients with known EPO antibodies, and compared to 10 CKD patients without PRCA.

3 patients with CKD 4, all on subcutaneous EPREX, developed a sudden onset profound anaemia after 17, 7 and 21 months on EPO therapy. All patients had absolute reticulocyte counts below 7x109/mL. 2 patients had diabetic nephropathy and 1 patient had CKD of unknown cause. The in-house inhibitor assay was performed for all three patients and demonstrated EPO recovery of 0, 11 and 62 percent. Subsequently frozen serum samples were sent to USA for investigation and found to contain neutralising EPO antibodies at titres of 1/1000, 1/10000 and 1/100 respectively. EPO therapy was discontinued for all the patients. Immunosuppressive therapy was discounted for all the patients and all patients are now on unit Haemodialysis and remain transfusion dependent.

Conclusions: These 3 recent cases identifies that the risk with subcutaneous EPO still requires careful observation, and diagnosis and monitoring of new cases of EPO-mediated PRCA remains mandatory. We propose that our novel and simple in-house assay could have widespread use in local laboratories to guide clinical suspicion in suspected cases.

SA-PO1076

Plasmapheresis in a Triad of Hypertriglyceridemia, Acute Pancreatitis, and Diabetic Ketoacidosis

Yin L. Win, Farhanah Yousaf, Sheng F. Kuo, Chaim Charytan, Bruce S. Spinowitz, Marilyn Galler. *Division of Nephrology, New York Hospital Queens, Flushing, NY.*

Background: Severe hypertriglyceridemia induced acute pancreatitis has been well described. This condition may be debilitating and fatal. Currently accepted therapeutic options are limited. We report a case of acute pancreatitis associated with hypertriglyceridemia that was safely and effectively managed with plasma exchange.

Methods: A 38-year-old female with history of gestational diabetes presented with acute onset of nausea and abdominal pain. She denied alcohol use and was on oral contraceptive pills. On physical exam, she was afebrile, normotensive, and tachycardic with mild abdominal distension and diffuse tenderness. Diagnostic tests revealed a serum glucose of 414 mg/dL, triglycerides >816 ng/dL, amylase of 106 U/L, lipase of 272 U/L, anion gap of 23, BUN of 13 mg/dL, creatinine of 0.3 mg/dL, sodium of 120 mmol/L, HCO3 of 14 mmol/L, and positive urine ketones. Computed tomography of the abdomen showed severe acute pancreatitis without evidence of pseudocyst, abscess formation, or cholelithiasis.

The patient was aggressively hydrated and treated with gemfibrozil, insulin, heparin, and morphine on Day 1. Due to persistence of symptoms, plasma exchange using NxStage system with plasmaflo OP-5W dialyzer was performed on Day 2 and 3, which resulted in significant reduction of the triglyceride level and resolution of abdominal pain. Patient was discharged home with gemfibrozil and glyburide as maintenance therapy.

Conclusions: The exact mechanism of hypertriglyceridemia-induced pancreatitis is not clear. It has been postulated that hyperviscosity of blood due to lipid particles cause ischemia in the pancreas, releasing inflammatory mediators and leading to pancreatic necrosis and inflammation. The advantage of plasma exchange over conservative management is the removal of lipid particles in a relatively short period of time and clearance of triglyceridemia associated pro-inflammatory agents. To our knowledge, this is the first adult case of hypertriglyceridemia-induced acute pancreatitis with diabetic ketoacidosis that was successfully treated with plasma exchange.

SA-PO1077

Severe Hyperkalemia Caused by a Commonly-Used Antibiotic in the Outpatient Setting

Otto Ostolaza, Jose David Ortiz, Hector R. Cordova. *Renal Section-Medical Service, VA Caribbean Healthcare System, San Juan, PR.*

Background: Six patients with severe symptomatic hyperkalemia arrived to the emergency department of our institution. The severity of hyperkalemia was out of proportion to the degree of renal dysfunction. All patients were recently prescribed Trimethoprim/Sulfamethoxazole (TMP/SMX) in the outpatient clinics. Trimethoprim reduces renal potassium excretion through the competitive inhibition of epithelial sodium channels in the distal nephron principal cells. We retrospectively identified several risk factors for the development of hyperkalemia in these patients. Failure to recognize them before considering use of TMP/SMX might result in a life-threatening complication.

Methods:

Summary of clinical characteristics

Patient #	1	2	3	4	5	6
Age (yrs)	71	83	68	80	78	72
Base Creat (mg/dl)	1.9	4.5	N/A	N/A	2.4	1.7
Peak Creat (mg/dl)	5.9	8.8	5.0	4.5	4.7	2.6
Peak [K+] (meq/l)	7.5	8.3	7.7	7.3	7.6	8.8
Hx of Diabetes	Yes	N/A	Yes	Yes	Yes	Yes
ACEI use	Yes	Yes	No	No	Yes	Yes
ARB use	No	No	No	Yes	No	Yes
Beta-blocker	Yes	No	No	No	No	Yes
TMP160/SMX800 (# tabs bid)	2	1	N/A	2	1	1

All patients had an acute increase in serum creatinine levels. Five out of the six patients had changes on ECG consistent with hyperkalemia. Of these, three required acute dialysis. Cardiac pacing was necessary in two patients and one required mechanical ventilation. Most patients were on drugs that block the Renin-Angiotensin-Aldosterone System (RAAS). The patients were discharged home without the need of chronic dialysis.

Conclusions: The liberal use of TMP/SMX in the primary care setting could lead to a rise in the incidence of severe hyperkalemia in patients with chronic kidney disease (CKD), particularly those taking medications that impair renal potassium excretion. Although the previously reported incidence of serum potassium level greater than 5.5 meq/l in healthy subjects treated with TMP/SMX was 6%, our report suggests that the incidence is much higher in patients with CKD with RAAS inhibition. This complication can be avoided with the careful identification of clinical risk factors, proper antibiotic dose adjustment, and close monitoring of serum electrolytes.

Funding: Veterans Administration Support

Mind the Gap, but Do Not Be Fooled by Its Absence

Hanni Menn-Josephy, Jasvinder S. Bhatia. *Nephrology, Boston University Medical Center, Boston, MA.*

Background: Chronic ingestion of ethylene glycol is a challenging diagnosis that can present as AKI with subtle physical findings and without the classical metabolic derangements.

Methods: 41 year old male with a past history of hypertension and depression was admitted for 5 days of abdominal pain, nausea and vomiting. He was found to have oliguric AKI with creatinine up to 7.4 mg/dL from a baseline of 0.9. On presentation he was hemodynamically stable with an unremarkable physical exam. Lab tests were notable for mild anion gap metabolic acidosis, but no other electrolyte abnormalities. Urine sediment showed non pigmented granular casts, but no cellular casts or crystals. Despite aggressive fluids and resolution of his anion gap within 48 hours, his Cr continued to rise to a peak of 15.5. Radiologic evaluation with abdominal MRA/CT and renal US were unremarkable. Serologies for hepatitis B, C, HIV, ANA, ANCA and immunofixation were unrevealing. A kidney biopsy revealed extensive oxalate crystal deposition in the tubules with associated signs of acute tubular injury and mild focal interstitial inflammation. The patient had no evidence of primary hyperoxaluria or enteric hyperoxaluria and he repeatedly denied ethylene glycol ingestion. His kidney function gradually improved with supportive care and recovered 3 months post admission. Seven months later, he represented with altered mental status post suicidal attempt and was found to have acute kidney injury, severe metabolic acidosis with an anion gap of 25 and osmolar gap of 43. His ethylene glycol level was 94mg/dl, and he required urgent dialysis. The patient later confessed to ingesting small amounts of ethylene glycol over the past year. He had mild improvement of kidney function but Cr remained elevated at 4.9 on discharge.

Conclusions: Ethylene glycol metabolizes to oxalic acid within 24-72 hours, with the resolution of both anion and osmolar gap. This resolution may lead to a delay in diagnosis leading to CKD. This case illustrates the need to consider chronic ingestion despite the lack of exposure history or presence of a significant anion gap or urinary crystals, particularly in high risk patients with a history of depression and an unexplained AKI.

SA-PO1079

Inversion Posture of Standing Head Down Precipitating Acute Kidney Injury: Report of Two Cases

Abubakar Ibrahim. *Medicine, Ahmadu Bello University Teaching Hospital, Zaria, Kaduna, Nigeria.*

Background: Although reports of acute kidney injury (AKI) occurring in the setting of physical exercises are numerous in publications none has addressed the impact of change in body posture on kidney function. Therefore, we report 2 cases of young nigerian men

who developed AKI after engaging in physical exercise involving inversion posture of standing head down. This is very unusual, in view of the acclaimed benefits of this posture to practitioners of yoga.

Methods: Two young men, aged 27 and 29 years respectively, were referred to our centre with strikingly similar presentations; they developed severe kidney dysfunction within one week of undergoing military training in a camp. Both had no prior history predisposing to kidney disease and data regarding their pre-recruitment records confirmed their medical fitness. Their camp daily routines included participation in physical exercises entailing inversion posture of standing head down for several minutes.

At presentation, both patients had pressure ulcers on their scalps consistent with prior assumption of this unusual posture. They were hypertensive (150/90, 144/100 mm Hg), had markedly impaired kidney function (urea 73 mmol, and 90.3 mmol, creatinine 1890umol and 2305 umol). Daily urine outputs were normal which showed bland sediments with no pigments or proteinuria. These abnormalities reversed completely with conservative management in one (urea 2.9 mmol, creatinine 102 umol) and hemodialysis in the other (urea 3.8 and creatinine 122 umol). Computerized angiography revealed diffuse bilateral renal ischaemia despite normal renal arteries.

Conclusions: Inversion posture of standing head down may trigger kidney injury. Predisposing factors for this unusual cause of AKI in persons with seemingly intact renal arteries remain to be ascertained.

Since man assumed the erect posture billions of years ago, the position of both native and transplant kidneys, below the heart, offers peculiar advantage to glomerular hemodynamics. Reversal of this position places the heart above the kidneys and diverts greater than usual cardiac output to organs and tissues above the heart in the inverted posture, thus creating a 'steal' syndrome in the kidneys.

SA-PO1080

Hyperparathyroid Lung Disease in a Chronic Hemodialysis Patient Adepeju A. Jinadu, Niama Huda, Sayed Husain, Sandeep S. Soman. *Nephrology, Henry Ford Hospital.*

Background: Hyper parathyroid lung disease is usually a subclinical entity diagnosed at autopsy. Only a few cases have been reported in which it lead to significant clinical symptoms. We report a case leading to respiratory symptoms.

Methods: The patient is a 70 years old male with history of end stage renal disease on hemodialysis for 7 years. He presented with a complaint of dyspnea. His Chest X-ray revealed a right lower lobe infiltrate he was treated with antibiotics for pneumonia and discharged.

He presented a month later with persistent dyspnea. Repeat Chest X-ray showed persistent right sided infiltrate, CT scan was done which showed a mass like airspace opacity in the right lower lobe with adjacent small airspace nodularity and non-specific visceral pleural thickening. Differential diagnosis included a neoplastic or Fibrotic process.

He underwent a CT guided trans-thoracic lung biopsy which revealed Metastatic calcification in the airspace with foreign body giant cell response. His Calcium phosphorus product was 48, iPTH level; 595. 25OH-vitamin D level was 8. Sevelamer was continued and calcitriol 0.5mcg daily was initiated.

Conclusions: Hyperparathyroid lung disease is usually an indolent disease, it is found on autopsy in 60 to 70 % of Hemodialysis patient. Clinical manifestations are minimal but can lead to dyspnea and respiratory failure. Chest radiography is insensitive for the diagnosis, and may show only diffuse airspace abnormality or nodular infiltrate. CT scan may show infiltrate, ground-glass infiltrate, consolidation, calcified nodules, HRCT Scan and Technetium scans are sensitive for diagnosis of this condition. The progression and management of the disease is poorly understood, with aim of treatment including correction of elevated calcium phosphorus product and treatment of hyperparathyroidism. Our patients, symptoms and radiographs were initially misinterpreted, and only after a lung biopsy was diagnosis made. We present this case history to heighten awareness of this condition, which should be kept in mind when dialysis patients develop unexplained radiographic changes or pulmonary symptoms, to avoid patient undergoing an invasive procedure like lung biopsy which is not required for diagnosis.

SA-PO1081

A Case Report: Renal Failure in a Cutaneous T-Cell Lymphoma/Sezary Syndrome Patient Sujay Dutta Paudel, Hui Peng, Yuanqing Li, Meirong Zhong, Tan-qi Lou. *Division of Nephrology, Department of Medicine, The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, Guangdong, China.*

Background: Sezary syndrome (SS) is a rare form of cutaneous T-cell lymphoma and the renal failure due to sezary cells infiltration is even rare. Till date only one similar case has been reported in the literature. Here we report a case of SS and its involvement in renal failure (RF).

Methods: A 39 years old Chinese male was presented to our hospital with high fever, diffuse skin rash and renal failure with a family history of congenital ichthyosis. He gives history of ingestion of prescribed antibiotics (streptomycin), and therefore the skin rash due to drug reaction was presumed.His urinary output did decrease. During admission, he had fever (38^0C), peripheral edema, lymphadenopathy of supraclavicular, axillary and inguinal region. Scaly, erythematous and desquamated skin rash and murmur on auscultation. Initial laboratory parameters revealed; Serum creatinine-907µmol/L, BUN- 23.92mmol/L, Hb-91gm/L, Albumin-29gm/L. Ultrasonography abdomen showed both kidneys enlarged and enlargement of hilar lymph nodes. Cervical lymph node biopsy revealed peripheral T-cell lymphoma and skin biopsy revealed the presence of sezary cells. Hemodialysis started and patient kept on oral steroids, antibiotics. Fever gradually subsided and there was improvement in his skin rash. But on the 9th day of admission, patient complained of sudden severe pain in the right inguinal region. His HGB dropped to 29gm/L and CT-scan showed right retroperitoneal bleeding. He was then referred to intervention radiology for embolization and patient stabilized. Next day his Serum amylase increased to 428U/L and therefore was further managed in the line of acute pancreatitis. He was discharged on request from his family members citing financial problem. Few weeks after the discharge, the patient died.

Conclusions: Literature addressing SS and renal failure are very few. In this patient, the bigger size of the kidney, persistent proteinuria, no oliguria and the presence of sezary cells in skin biopsy indicate that RF is a result of leukemic infiltration of the sezary cells.

SA-PO1082

IgG4 Related Tubulointerstitial Nephritis Associated with Chronic Lymphocytic Leukemia Andrew F. Malone,[1] David Howell,[2] John Paul Middleton,[1] Stephen R. Smith,[1] Ruediger W. Lehrich.[1] *[1]Division of Nephrology, Duke University Medical Center, Durham, NC; [2]Department of Pathology, Duke University Medical Center, Durham, NC.*

Background: IgG4 related systemic diseases are characterized by plasma cell infiltrates positive for IgG4 staining. The extent of involvement of the kidney is unknown. Here we describe a case of IgG4 related tubulointerstitial nephritis (IgG4-TIN) associated with chronic lymphocytic leukemia (CLL).

Methods: A 72yo African American man was referred with proteinuria and recently normal renal function. Patient was easily fatigued and had frothy urine. He had no family history of kidney disease. BP was 135/80 mmHg. The rest of his exam was normal. On admission his creatinine was 6.8 mg/dl, dipstick trace positive for blood, 1 rbc/hpf and 10 wbc/hpf and no casts. He had 0.9 g/day of proteinuria. The rest of his renal failure work up was normal except ANA of 1:40. Hemoglobin was 8.9 g/dl; white cell count 18,000/ml with 79% lymphocytes. Marrow aspirate showed abnormal monoclonal B cells. Total serum IgG was 3150mg/dl with normal IgG4. Kidneys were 12.9cm bilaterally. The patient did not require dialysis. Renal histology revealed an interstitial plasma cell infiltrate with scattered eosinophils and extensive fibrosis and tubular atrophy. Plasma cells stained heavily for IgG4 by immunohistochemistry. There was mesangial matrix expansion. Therapy with prednisone 60mg daily was started and creatinine improved to 2.7mg/dl.

Conclusions: To our knowledge this is the first reported case of IgG4-TIN and CLL. Obtaining a kidney biopsy and specifically staining for IgG4 was crucial in obtaining a diagnosis. Diagnosis and treatment was guided by a recent report by Raisson et al (J Am Soc Nephrol, 22: 1343-52, 2011). The fact that CLL was diagnosed simultanously with IgG4-TIN suggests that there is a causal relationship. IgG4-TIN needs to be considered in a patient with CLL and abnormal renal function. Our case demonstrates the importance of making a diagnosis of IgG4-TIN because it responds readily to corticosteroids.

SA-PO1083

Treating One Disease Causes Another: Renal Sarcoidosis Anila P. Sankar,[1] Alex J. Hernandez,[1] Shalini Barlapudi.[1] *[1]Department of Nephrology, The Ochsner Clinic Foundation, New Orleans, LA.*

Background: Renal sarcodosis (RS) is a multisystem granulomatous disorder of unknown etiology characterized pathologically by nonceasating granulomas. Common renal manifestations are nephrocalcinosis and nephrolithiasis. We present a rare case of Etanercept (tumor necrosis factor inhibitor) induced RS.

Methods: Case: 42 year old female with psoriasis treated with subcutaneous injections of etanercept 50 mcg twice weekly for three years presents to renal clinic with weakness and acute kidney injury. Current medications were prednisone10 mg, etanercept ,and multivitamin. Recent gastric biopsy for reflux gastropathy revealed multiple nonceasating granulomas. No pertinent family history or use of herbal medications ,NSAIDS, or IV drugs. Physical examination: vitals :BP 100/72, HR 89,100% O2,with multiple healing erythematous plaques on joints. Laboratory data creatinine of 3.8 mg/dL (10/2011) increased from 1.3 mg/dL,BUN 29 mg/dl,Hb 9.3 gm/dl, calcium 8.6 ,ace level 53 U/L and no eosinophilia. Urine analysis negative. Serological evaluationand renal ultrasound were normal. With worsening creatinine of 6.2 mg/dL a renal biopsy was done which reported subacute and chronic granulomatous interstitial nephritis. Etanercept was discontinued and high dose steroid treatment was started. Creatinine has improved to 2.4 mg/dl with steroid taper.

Conclusions: Discussion: The possibility of Etanercept induced sarcoid was considered given previous cases reported by Gifre et el(J ClinRheumato April 2011). With this in mind we attributed etanercept to cause RS. This case highlights importance for monitoring renal function and discontinuation of drug if suspicious for RS.

SA-PO1084

Pregnancy and Kidney Disease in a Patient with Sjogren's Syndrome and Tubulointerstitial Nephritis Abhishek Joshi,[1] Keelin O'Donoghue,[2] Uzma Mahmood,[2] Debasish Banerjee,[3] Anita Banerjee.[1] *[1]Directorate of Medicine, Princess Royal University Hospital, Orpington, Kent, United Kingdom; [2]Department of Obstetrics and Gynaecology, Cork University Maternity Hospital, University College Cork, Cork, Ireland; [3]Cardiovascular Research Centre, St. George's Hospital, London, United Kingdom.*

Background: Maternal and fetal outcome in pregnancy with renal failure is unpredictable, where each condition can adversely affect the other. We present a case of steroid sensitive Sjogren's nephritis worsened by pregnancy, demonstrated over the course of multiple pregnancies and investigated the aetiology.

Methods: A 28-year-old nullipara with a diagnosis of primary Sjogren's syndrome (SS) presented with a deterioration of renal function. A diagnosis of secondary tubulo-interstitial nephritis was made on renal biopsy.

Her first pregnancy ended in the second trimester with a decision to deliver a female infant at 27 weeks due to worsening maternal renal function. Renal function improved immediately. A second pregnancy ended in a 1st trimester miscarriage. The 3rd and 4th pregnancies delivered male infants at 35 and 34 weeks, with worsening renal function in each pregnancy, reaching end-stage. Repeat biopsy showed extensive glomerulosclerosis and male cells were identified.

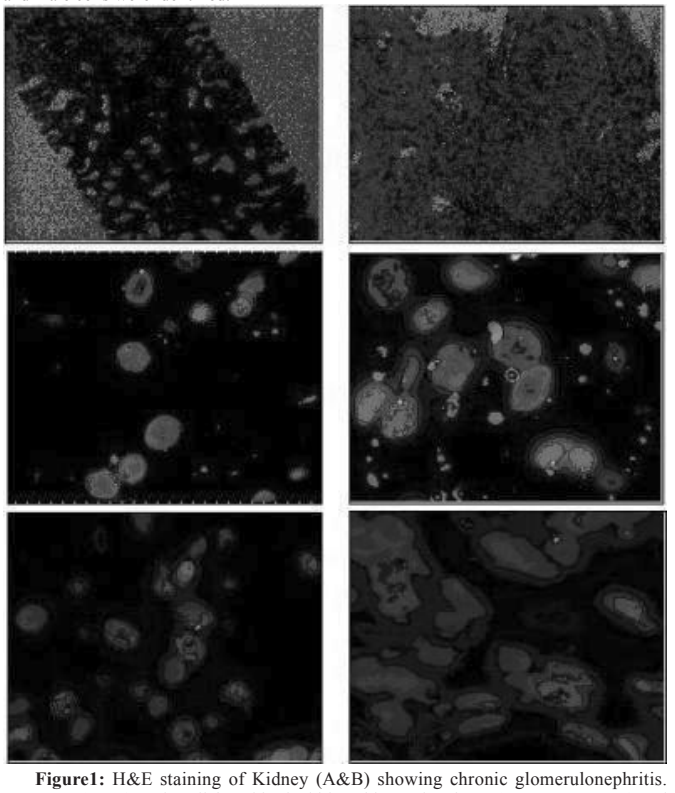

Figure1: H&E staining of Kidney (A&B) showing chronic glomerulonephritis. XY-FISH (C&D) Male cell found in the kidney biopsy, bearing X(SpectrumOrange) and Y(SpectrumGreen) chromosomes. Adjacent are female cells with (XX) genotype. Y-FISH (E&F) confirms presence of male cells.

Conclusions: This case of SS with renal disease demonstrated the increased risk of fetal and maternal adverse pregnancy outcomes. Renal function worsened in each pregnancy and progressed to end-stage renal disease. Fetal microchimerism offers an interesting mechanism for our patient's renal failure and its apparent relationship to her pregnancies.

SA-PO1085

Bacterial Peritonitis Following Esophagogastroduodenoscopy in a Patient on Peritoneal Dialysis Manmeet Brar, Tibor Fulop. *Nephrology, University of Mississippi, Jackson, MS.*

Background: We report the case of a 54 year old African American female with end stage renal disease on CAPD presenting with generalized abdominal pain along with nausea and vomiting. Two days earlier, she has undergone an esophagogastroduodenoscopy (EGD) with biopsy. Surgical exploration revealed murky peritoneal fluid and stain showed mixed flora (both Gram negative and Gram positive rods); blood and peritoneal fluid culture grew only *Streptococcus pneumoniae*. An occult perforation, not obvious to naked eye and without contrast extravasation, can occur after EGD and may lead to peritonitis, especially in the high risk setting of a patient with end stage renal disease on PD. To our knowledge, this is the first reported case of mixed peritonitis attributable to suspected microperforation after EGD. It is important to recognize the importance of antibiotic prophylaxis to decrease the occurrence of infectious complications in PD patients undergoing upper gastrointestinal procedures. In addition, prompt recognition of possible mixed bacterial infection is essential in this setting.

SA-PO1086

Role of Dialysis in a Patient with Intracranial Hemorrhage due to Dabigatran *Pradaxa*®) Muhammad W. Khattak, Hasan Arif, Ami Patel. *Nephrology, Drexel School of Medicine, Philadelphia, PA.*

Background: Dabigatran is a new direct thrombin inhibitor which is mainly used to prevent stroke in patients with atrial fibrillation. There is no antidote for this medication. The primary clearance of dabigatran is through kidneys with the half-life around 12-18 hours. This drug is 30% protein bound and its clearance with dialysis is around 60 % in 2-3 hours. There is very limited data available regarding the role of dialysis treatment in case of toxicity related to dabigatran. We report a case of using dialysis in reversing the anticoagulation effects from dabigatran in the setting of intracranial bleed.

Methods: We report a case of an 83 year old white male with a history of CAD with cardiac bypass surgery and chronic atrial fibrillation who was discovered to have a spontaneous subdural hematoma after presenting with altered mental status. His home medications included asprin 81 mg, dabigatran 150 mg twice daily. The last dose of dabigatran was at the morning of admission. His vitals were stable and had right sided weakness with aphasia. His admission creatinine was 0.93 mg/dl, INR was 1.17, and partial thromboplastin time (PTT) was 47.9 seconds. On the second day of admission he had worsening intra cerebral bleed with midline shift and the repeat PTT was 48.1 sec. The thrombin time (TT) was not available. As a last effort in reversing coagulopathy, the patient underwent 4 hours of HD using Optiflux® F160 dialyzer with blood flow of 350 ml/min. The PTT normalized after dialysis and since the thrombin time remained elevated on the third admission day, our patient underwent a second hemodialysis treatment to possibly aid in the clearance of dabigatran. TT improved to 27.7 sec. Repeat imaging of the brain showed stability of the bleeding. Although his coagulopathy was reversed, the patient expired the following day due to respiratory complications.

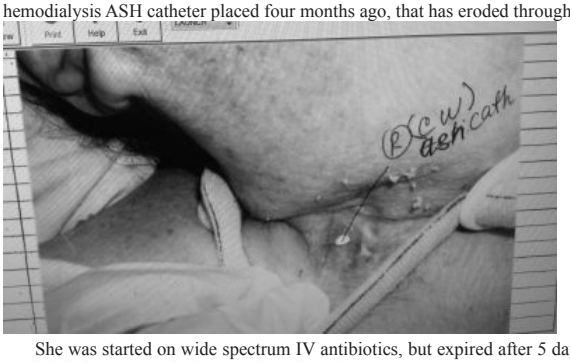
Conclusions: This case illustrates the possible role of hemodialysis in reversing the coagulopathy due to dabigatran-related bleeding in which there is no clear antidote available. Although, it is difficult to determine the degree of renal clearance of the drug in this patient, we believe that hemodialysis enhanced it.

SA-PO1087

Erosion of the Skin by the Hemodialysis Catheter: An Infrequent Complication Chadi Saifan, Rabih Nasr, Elie El-Charabaty, Suzanne E. El Sayegh. *Nephrology, Staten Island University Hospital, Staten Island, NY.*

Background: The use of chronic hemodialysis tunneled catheters has been increasing. The two major complications seen are infections and thrombosis. We report a case of an elderly woman who presented from nursing home secondary to altered mental status and found to have an erosion of the skin by an ASH catheter.

Methods: A 74 year old female was transferred from the nursing home because of hypotension and worsening confusion. She is known to have ESRD secondary to hypertension, metabolic encephalopathy, CVA, chronic respiratory failure vent dependent. On admission her vitals showed a BP of 104/70 mmHg, temperature of 97. Her physical exam was remarkable for decreased breath sounds bilaterally, decubitus ulcer on her back and sacrum, and lower extremities edema. She was noted by the nurse as well to have on the upper right chest wall, a 1 cm white silicone catheter exposed to the air. It was the tunneled hemodialysis ASH catheter placed four months ago, that has eroded through the skin.



She was started on wide spectrum IV antibiotics, but expired after 5 days secondary to Klebsiella pneumonia bacteremia and sepsis.

Conclusions: Chronic tunneled dialysis catheters have been increasingly used for patients with comorbidities and with a life span less than one year. They can be a useful bridge for patients waiting on the transplant list and those refusing a permanent access such as graft or fistula. They are the preferred vascular access for about 10% of patients on dialysis. The main disadvantages of the tunneled catheters are infections and thrombosis. While erosion of the catheter through the skin is not a very frequent complication, it requires a prompt intervention and removal to avoid subsequent infections and blood stream bacteremia.

SA-PO1088

Arteriovenous Graft VS Tunneled-Cuffed Hemodialysis Catheter: A Hidden Focus of a Hemodialysis Access-Related MSSA Bacteremia Ekamol Tantisattamo, Royden S. Young, Chuong Dinh. *Medicine, University of Hawaii John A. Burns School of Medicine, Honolulu, HI.*

Background: Vascular access-related blood stream infection is a common complication leading to high morbidity and mortality. Arteriovenous graft (AVG) thrombosis is a common complication which not only indicates a possible infection, but also needs invasive therapeutic procedures. We report a case of ESRD presenting with bacteremia and AVG thrombosis. Signs of infection were persistent even after tunneled-cuffed hemodialysis catheter (TCHDC) removal. AVG removal revealed pus around the graft.

Methods: A 56 year-old ESRD woman started hemodialysis via right internal jugular TCHDC 1 month ago when the left arm AVG was placed. The last two hemodialysis treatments werepreformed via the AVG. One day after the last hemodialysis, she developed fever and chills. There was no discharge from the exit site or tenderness along the TCHDC area. On the AVG, there was no thrill, bruit, or tenderness. CBC revealed WBC of 17,100/mm^3. Blood culture grew methicillin-sensitive *Staphylococcus aureus* (MSSA).

Transesophageal echocardiography showed mitral valve endocarditis. Nafcillin was started, and the TCHDC was removed. The catheter tip culture was negative. Repeated blood cultures showed no growth. However, she still had persistent leukocytosis and developed bandemia 2 days later when the AVG thrombolectomy was scheduled. Intraoperatively, copious pus was found surrounding the AVG. The graft was removed, and culture grew MSSA. Nafcillin was continued for 4 weeks with resolution of her symptoms.

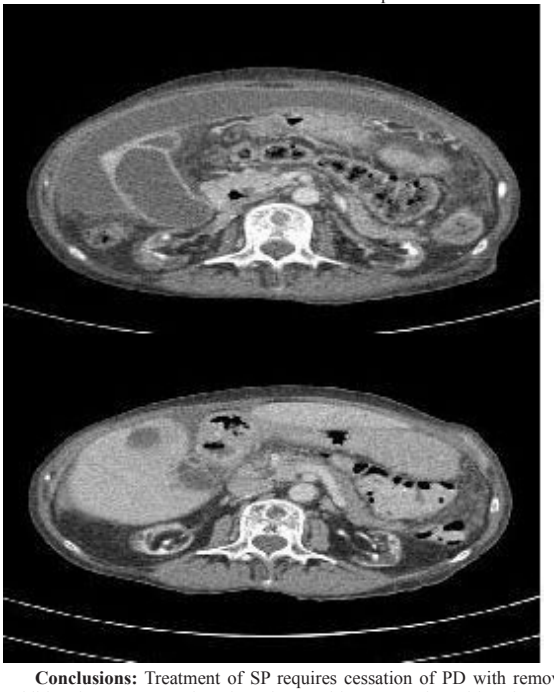
Conclusions: Our patient with TCHDC and AVG presented with MSSA bacteremia. Statically, the most likely cause of vascular access dialysis is from TCHDC. However, given AVG thrombosis and bacteremia, our patient's AVG appears to have been the source of sepsis despite a clinically benign appearance externally. Our case should serve as a reminder to consider all intravascular foreign material as a potential source of infection. Moreover, AVG thrombosis with bacteremia should raise a suspicion for the graft infection and prompt surgical removal should be highly considered.

SA-PO1089

Steroid Responsive Sclerosing Peritonitis: A Case Report and Review of Literature Srinivasa Iskapalli,[1] Deepthi Panjam,[2] Kavitha Kesari,[2] Raviprasenna K. Parasuraman.[3] *[1]Internal Medicine, Beaumont Health System, Royal Oak, MI; [2]Internal Medicine, McLaren Regional Medical Center; [3]Nephrology and Transplantation, Beaumonth Health System.*

Background: Sclerosing Peritonitis (SP) is a rare complication seen in ESRD patients on long-term peritoneal dialysis (PD) and/or in patients with recurrent bacterial peritonitis. SP is associated with high morbidity and mortality and a mortality rate of 56% was reported by Rigby et al.

Methods: A 72y-old female on PD for 16 years presented with vomiting and abdominal pain of 1 week duration. Two months prior to this presentation, she was treated for staphylococcus aureus peritonitis with antibiotics and Tenckhoff catheter removal. Patient evaluation showed distended tender abdomen with significant ascites and leukocytosis (WBC, 15,000/mL). CT of the abdomen showed significant peritoneal enhancement with large loculated ascites and mass effect on bowel loops. Ascitic fluid showed lymphocytic pleocytosis and was negative for bacterial infection. A diagnosis of SP was made based on duration of PD, recent peritonitis and CT findings and was initiated on low dose prednisone 15mg/day immunosuppression. Patient responded well with significant resolution of symptoms and loculated ascitic fluid on follow-up CT scan. Below is the picture showing CT scans before and after treatment over 6months period.



Conclusions: Treatment of SP requires cessation of PD with removal of catheter. Additional treatment such as bowel rest with parenteral nutrition, immunosuppression, tamoxifen and surgical viscerolysis depends on severity and duration. Kawanishi et al. reported 38.5% recovery for those receiving steroids. Commonly oral prednisone is initiated at 0.5-1mg/kg/day and tapered over 6 months depending up on the response and side effects. Early diagnosis and treatment is important to reduce SP related morbidities as demonstrated in this case.

SA-PO1090

Acute Bleeding and Dabigatran: Is Hemodialysis an Option? Tripti Singh,[1] Thin Maw,[1] Mark L. Unruh,[1] Kenneth R. Hallows,[1] Thomas D. Nolin.[2] *[1]Renal-Electrolyte Division, University of Pittsburgh, Pittsburgh, PA; [2]Department of Pharmacy and Therapeutics, University of PIttsburgh, Pittsburgh, PA.*

Background: Dabigatran (DB) is an oral, reversible-direct thrombin inhibitor for anticoagulation. It is FDA-approved for prevention of stroke in patients with atrial fibrillation. DB has predictable pharmacodynamics and is 80% renally excreted, so it does not require monitoring routinely. The half-life of the drug is prolonged in CKD as well as AKI. The rate of major bleeding in patients on DB is similar to the rate of major bleeding associated with warfarin. However, no specific antidote is currently available for reversal of the anticoagulant effect of DB. We hypothesized that hemodialysis (HD) could be an effective measure to eliminate DB and thus potentially life-saving in cases of acute bleeding with renal dysfunction.

Methods: Four patients on DB 150 mg po bid were admitted for acute bleeding in setting of renal dysfunction causing high DB levels. Factor VII was given to all patients to reverse the anticoagulant effect of DB. HD was performed to remove dabigatran.

Results: HD was effective in removing 55-65% of DB from blood with one HD session. However, there was a substantial rebound in the blood levels of DB >6 h after completion of HD.

Age (yrs)	Serum creatinine (mg/dl)	Reason for admission	HD Duration	Pre-HD DB Conc (ng/mL)	Post-HD DB Conc (ng/mL)	% Δ in DB Conc	Rebound DB Conc (ng/mL) / Time post-HD
77	1.2	Acute Abdomen	3 h	875	382	56% ↓	538/48 h
86	3.1	*SAH	4 h	318	115	64% ↓	437/12 h
65	1.4	GI Bleeding	2 h	1200	420	65% ↓	626/6 h
81	1.2	*SAH	4 h	269	118	56% ↓	44/24 h

* Sub Arachnoid Hemorrhage

Conclusions: DB is clinically dialyzable and HD can be effective in accelerating plasma clearance of DB, especially in patients with renal impairment. However, the benefits of HD should be carefully weighed against the risk of bleeding with HD catheter insertion in these patients with severely deranged coagulation profile. Further work is needed to better characterize the role of renal replacement therapy in the treatment of acute bleeding in the setting of DB use.

SA-PO1091

Impact of Diagnosing and Treating Primary Hyperparathyroidism in Chronic Kidney Disease Surju Patel,[1] Samer S. Nasser.[2] *[1]The Kidney Center, Johnston, PA; [2]Internal Medicine, Conemaugh Memorial Hospital, Johnstown, PA.*

Background: Intact parathyroid hormone (iPTH) levels are checked once every 3-6 months in stage 3 and 4 chronic kidney disease (CKD) patients. Vitamin D analogues (VDA) are used to treat renal osteodystrophy by targeting certain PTH level depending on the CKD stage. Few CKD patients present with hyperparathyroidism with mild hypercalcemia. Assumption of secondary hyperparathyroidism in patients with mild hypercalcemia or high normal calcium levels may preclude the use of VDA to prevent worsening of the hypercalcemia. There is limited data on primary hyperparathyroidism in the setting of CKD.

Methods: Two CKD patients present with hyperparathyroidism and hypercalcemia that worsened overtime. All VDA were discontinued. During the hypercalcemia work-up, a Sestamibi scan revealed solitary parathyroid adenomas in both patients. Parathyroidectomies on the 2 patients led to lowering of the iPTH levels with correction of the hypercalcemia. At least 6 months later, the 2 patients had iPTH levels that were off target with normal or low calcium, and were treated with VDA without ensuing hypercalcemia. One patient had improvement in the kidney function, after the correction of the hypercalcemia.

PTH level, Calcium levels, and Glomerular Filtration rate (GFR) pre- and post- parathyroidectomy

	Patient 1			Patient 2		
	iPTH (pg/ml)	iCa (mg/dL)	GFR (ml/min)	iPTH	Ca	GFR
preparathyroidectomy	961	12.3	25	193	11.3	22
postparathyroidectomy	171	8.8	28	152	9.1	36
3 months follow up after adding Vitamin D analogue	117	8.8	29	129	8.8	45

Conclusions: Some patients with hyperparathyroidism and hypercalcemia may remain misdiagnosed as secondary hyperparathyroidism especially if they are started on VDA and then develop hypercalcemia. Secondary Hyperparathyroidism may coincide with primary hyperparathyroidism and manifest later after the parathyroidectomy. After the correction of the hypercalcemia with parathyroidectomy, it is safe to target iPTH levels with VDA. Further guidelines for work-up and management may be warranted especially with the advent of new medical therapy for primary hyperparathyroidism.

SA-PO1092

Calciphylaxis in a Patient on Hemodialysis, Pathological Clinical Study Carmen H. Sckell de Duarte. *Department of Nephrology, Facultad de Ciencias Médicas - UNA, Asuncion, Central, Paraguay.*

Background: Calciphylaxis is a condition that is increasing with the onset of CRF and HD in diabetics.

Methods: This clinical and pathological case that was studied, diagnosed and certified by skin biopsy.

Results: 47 years old white female patient with a with a HX of T2DM for 18 years at TX with crystalline insulin and obesity (BMI> 40 kg/m2), deadly CKD, regular HD periodic 2 years, presented thrombosis of the superior vena cava a year before, coagulated later with warfarin. Secondary anemia TX with erythropoietin.Secondary hyperparathyroidism TX with CaCO3 until a month ago. Previously hypertensive patient once the HD Tx, is prone to severe hypotension. 5 months beginning with lump in abdomen (umbilicus), indurated, very painful purplish erythematous about 10cm in dia.

The lesion grew covering the entire lower abdomen, becoming a crusty ulcer, necrotic, much more painful,not calmed by painkillers, including opioids. 2 months ago another similar lesion appeared in right breast. Ultrasound of soft parts: thrombosis in this region. Lesion interpreted as calciphylaxis. ECHO: mitral annular calcification, aortic valve opening and slightly calcified with preserved motility. Pelvis RX: shows little air density radiopaque calcium in soft tissues. CXR: mild calcification of the aortic knob. Lesion biopsy is performed, the results: calcific uremic arteriopathy (calciphylaxis) disseminated thrombophlebitis with perivascular inflammatory changes (panniculitis associated with vasculitis of medium caliber of the hypodermis). Hyaline arteriosclerosis.

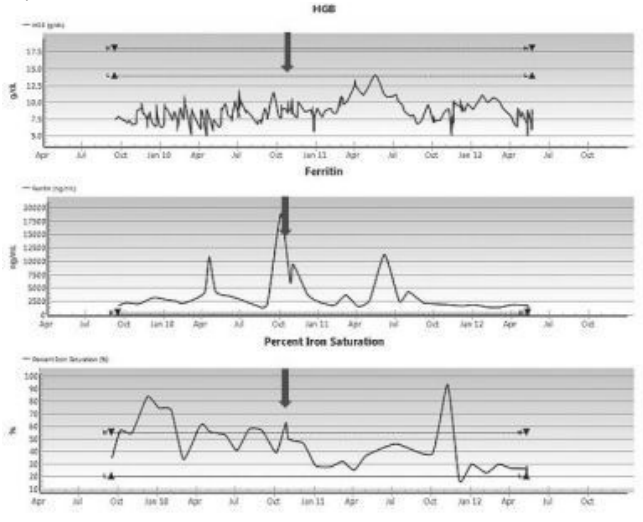
Conclusions: Through this study we characterized the group of sensitive patients to develop calciphylaxis and identify potential risk factors for the emergence of this disease, and thus facilitate prevention.

SA-PO1093

A Case of a 72 Year Old Man with ESRD and MDS with Anemia Which Improved with Desferrioxamine Therapy Ankita B. Patel, Ahmad Waseef, Subodh J. Saggi. *Nephrology, SUNY Downstate, Brooklyn, NY.*

Background: Management of anemia in patients with ESRD and MDS is a unique challenge as EPO requirements are huge.Also, they require multiple PRBC transfusions causing iron overload.

Methods: A 72 year old man with history of ESRD and MDS on HD since Sept '09 was severely anemic requiring massive doses of Epo in excess of 90,000 units/week.Fe sat was consistently >60%; ferritin was >2500. Desferrioxamine (DFO) 125 mg IV/wk was begun in Nov '10. His PRBC transfusion and Epo requirements declined after that. He had 33 ER visits for PRBC transfusions (1-3 transfusions/visit) from Sept '09 to Nov '10 (avg:2.35/mo) which decreased to 18 visits for in 20 months after getting DFO (avg:0.9/mo).His Hb and iron indices are as shown.



Conclusions: Iron excess increases oxidative stress:Excess non-tranferrin bound labile iron is a source of reactive oxygen species. It also causes a decrease in reduced glutathione(antioxidant) and increases membrane lipid peroxidation. Furthermore, iron overload itself has an *in vitro* suppressive effect on erythroid progenitors and seems to increase transfusion requirement.

Epo is regulated by hypoxia via HIF-α. At normal o2 tension the HIF-α undergoes post-translational modification by proline hydroxylation causing it to rapidly degrade. At low o2 tension, HIF-α escapes degradation and translocates into the nucleus stimulating Epo production.DFO has been shown to activate HIF-α in vitro, with kinetics similar to those associated with hypoxia, and to increase expression of HIF-1 target genes, including EPO.

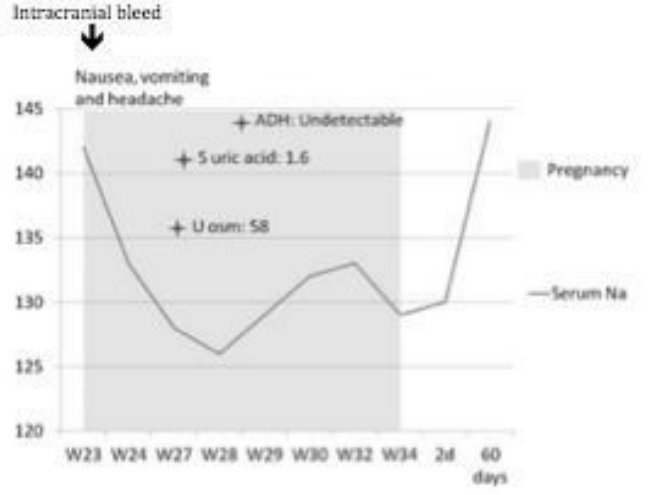
DFO promotes iron release from storage sites and seems to upregulate Epo response. It improves anemia and decreases transfusion requirements. Larger studies are required to validate it as a treatment option.

SA-PO1094

Hyponatremia: Does Intracerebral Bleeding Cause Thirst? Ashish Kataria,[1] Hitesh Patni,[1] Deepa Malieckal,[2] Kenar D. Jhaveri.[1] *[1]Division of Nephrology, Hoffstra North Shore LIJ School of Medicine, Great Neck, NY; [2]Department of Internal Medicine, Hoffstra North Shore LIJ School of Medicine, Manhasset, NY.*

Background: Hyponatremia is a common electrolyte derangement during pregnancy,but hyponatremia secondary to intense thirst after intracranial bleeding from arteriovenous malformation(AVM) has not been described.

Methods: We report a previously healthy,25-year-old woman who had sudden onset severe headache and nausea, 23 weeks into her first pregnancy. A MRI scan showed an AVM with intracranial bleeding in the lateral, third and fourth ventricles with mild hydrocephalus. She developed intense thirst and started drinking 8-10 liters of water each day. She was in no acute distress, euvolemic and her psychiatric evaluation was unremarkable. She developed persistent hyponatremia, with serum sodium ranging between 122-126 mmol/L



Her urine sodium and chloride were low and urine osmolarity ranged between 50-60 mosm/L. Upon water restriction, she retained the urinary concentrating ability and serum sodium increased, suggesting the etiology to be water intoxication. Her ADH level was undetectable (<0.6 pg/ml). She was managed with fluid restriction, and had a caesarean section at 34 weeks of pregnancy. Thirteen weeks after the bleeding in the brain, her serum sodium levels normalized with improvement in her thirst impulses.

Conclusions: Although hyponatremia has been reported with intracerebral bleeding, the etiology implicated mostly is anti diuretic hormone excess. We report a case of hyponatremia after intracerebral bleeding with suppressed ADH hormone, with intense thirst leading to excessive water ingestion. Our patient had a midline brain AVM, which could have contributed to the thirst. However, since the symptoms resolved with conservative management, it suggests the contribution of intracerebral bleed or possibly pregnancy related changes in AVM.

SA-PO1095

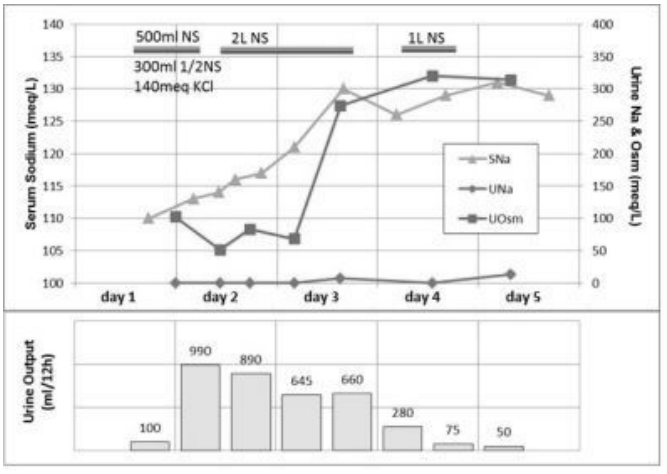
Hyponatremia: Don't Forget the Gut Matthew J. Volk. *Nephrology, University of North Carolina.*

Background: Evaluation of urinary indices is needed for analysis of most electrolyte derangements. In a nephrologist's enthusiasm to marshal related equations, stool and gut function can be missed as contributing factors.

Methods: A 29-year-old female with ulcerative colitis status post total colectomy and ileostomy was admitted with a sodium of 110 meq/L. Since surgery she had suffered high ostomy output and partial bowel obstruction. She had had poor intake aside from clear fluid and recently had developed oliguria and dizziness. On exam she had a pressure of 99/70 and a pulse of 118. She was alert with flat neck veins, clear lungs, and no peripheral edema. Labs appear below. Urine sodium was <5, so saline was infused. Ostomy output increased to over 2L per day of 89 meq Na/L solution, nearly equal to infusion sodium content. Though serum sodium corrected, urine sodium remained <5. Urine briefly became more dilute and plentiful with sodium exposure. It then became much more concentrated as the hyponatremic stimulus resolved. Urine sodium and output did not normalize until 3 weeks later, after completion of ileoanal anastomosis and initiation of TPN. At that point urine sodium was 146 meq/L.

Serum Electrolytes

	Admission	3 Weeks	6 Months
Na meq/L	110	131	141
K meq/L	2.0	4.5	4.3
BUN mg/dl	<2	5	7
Cr mg/dl	0.32	0.37	0.62



Conclusions: Three gut-related mechanisms contributed to the hypotonic hyponatremia. Sodium losses from the ileostomy resulted in volume depletion and low urine sodium, a complication discussed in the surgical literature. Partial obstruction limited the patient's protein intake over a long period resulting in low obligate solute excretion, consistently just 160 mosm/day (1.5L/day free water excretion). This effect has been reported with beer potomania and ovolactovegetarianism. Finally, the low free-water content of this patient's stool (424ml/day), also typical of end-ileostomies, limited the protective effect against hyponatremia typically conferred by diarrhea.

SA-PO1096

Clinical Features of Patients with Stress-Induced Cardiomyopathy Associated with Renal Dysfunction: 7 Cases Series Min Ji Shin, Eun Young Seong, Harin Rhee, Byeong Yun Yang, Sang Heon Song, Ihm Soo Kwak, Soo Bong Lee, Il Young Kim. *Department of Internal Medicine, Pusan National University School of Medicine, Republic of Korea.*

Background: Stress-induced cardiomyopathy(sCMP) is characterized by transient wall-motion abnormalities involving the left ventricular apex,precipitated by emotional or physical stress.As the heart and kidneys influence each other's function by bidirectional pathways,sCMP can induce renal dysfunction or be induced by renal dysfunction.These case series examined the clinical characteristics and outcomes of patients with confirmed sCMP associated with renal dysfunction.

Methods: Patients who met the following criteria of sCMP were included:(1) development of takotsubo on transthoracic echocardiography(TTE) after emotional or physical stress;(2)no evidence of obstructive coronary artery disease on coronary angiography(CAG);for those patients who could not undergo CAG,follow-up TTE showed improvement of LV function were used;(3)new ECG abnormalities or elevation in troponin.Acute kidney injury(AKI) was diagnosed on the RIFLE classification.There were 30 patients with sCMP From 2010 to 2012,and 7 patients were associated with renal dysfunction.3 patients were under prevalent hemodialysis(HD) and 4 patients had AKI(injury in 1,failure in 2 and ESRD in 1).3 of the 7 patients were women.The triggering events were pneumonia in 4 patients,infectious colitis in 2 patients,and RPGN in 1 patient. The mean ejection fraction(EF) in initial TTE was 36%,and in follow-up TTE,mean EF was 56%.Pericardial effusion was detected in all HD patients in initial TTE and 2 of them had uremic encephalopathy,and these patients were treated with intensive HD as suspected under-dialysis status.In AKI patients,mean of maximum level of serum creatinine(SCr) was 4.17 mg/dL and 2 patients were treated with CRRT.SCr restored to normal at 7 and 14 days,respectively in 2 patients.1 patient was required maintenance HD and 1 patient died because of recurrent ventricular tachycardia.

Conclusions: sCMP can be occurred in patient with renal dysfunction including ESRD or AKI.Additionally,as sCMP can induce renal dysfunction,renal function must be closely monitored.

PUB001

Epicatechin Prevents Renal Injury by Targeting Mitochondria in Mouse Cisplatin Nephropathy Katsuyuki Tanabe, Yoshifuru Tamura, Miguel A. Lanaspa, Richard J. Johnson, Takahiko Nakagawa. *Division of Renal Diseases and Hypertension, University of Colorado Denver, Aurora, CO.*

Background: Cisplatin nephropathy is one of the common causes of hospital-acquired acute kidney injury, and it can be regarded as a mitochondrial disease. However, intervention to prevent such deleterious injury has not been established. Recently, epicatechin, a derivative from cocoa, emerges as a novel compound to protect mitochondria in cardiovascular and other organ systems. Here, we examined if epicatechin could prevent the kidney injury by protecting mitochondria in the mouse cisplatin nephropathy.

Methods: Kidney Injury was induced by intraperitoneal single injection of 30mg/kg cisplatin to 8-week old C57BL/6 mice, and epicatechin injection at dosage of 1mg/kg twice a day intraperitoneally was started 8 hours after cisplatin injection. Blood samples were collected and kidneys were harvested on day 3. Immortalized mouse proximal tubular cells (TKPTS) were stimulated by 100μM cisplatin for 1 hour, followed by treatment with or without 10^{-7}-10^{-6}M epicatechin for 4-24 hours.

Results: Cisplatin caused increase in serum creatinine while such elevation was significantly prevented by epicatechin (3.85±1.00 vs 1.86±0.86). This compound also ameliorated renal tubular injury (ATN score 3.7±0.7 vs 2.3±0.8) in association with a decrease in number of apoptotic cells. An increase in oxidative stress in cisplatin group was demonstrated by higher levels of nitrotyrosine in the renal cortex as well as isolated mitochondria while such oxidative stress was significantly reduced by epicatechin. Likewise, levels of the mitochondrial DNA amount and the mitochondrial proteins were also reduced by cisplatin yet epicatechin blocked such alterations. In in vitro study using mouse proximal tubular cells, epicatechin was shown to prevent the cisplatin-induced mitochondrial injury (dysfunction, decreased COX-IV level and fragmentation). Importantly, we confirmed that epicatechin did not disturb anticancer effect of cisplatin in the HeLa cells.

Conclusions: These results suggest that epicatechin prevents the progression of kidney injury in mouse cisplatin nephropathy. A mechanism is likely its mitochondrial protection.

PUB002

Alteration of the Gut Microbiome by Vancomycin: Impact on Renal Ischemia Tolerance Kieran Mccafferty, Conor J. Byrne, Julius Edward Kieswich, Magdi Yaqoob. *William Harvey Research Institute, Queen Mary University London, London, United Kingdom.*

Background: The importance of the intestinal microbiome in the pathogenesis of human disease is becoming increasingly recognized. Alteration of intestinal microbiota is associated with multiple disease states including obesity, diabetes and cardiovascular disease. A recent study[1] in rats demonstrated that alteration of gut microbiota using oral vancomycin, increased myocardial ischemia tolerance, which was mediated by a reduction in serum leptin. The role of leptin in ischemia reperfusion injury is controversial: leptin has been shown by different groups to both increase and reduce myocardial ischemia tolerance. The effects of vancomycin induced alteration in gut microbiota on renal ischemia reperfusion injury is unknown.

Methods: 24 male Wistar Rats were split into 2 groups. Group 1 were treated with Vancomycin 0.5mg/ml added to their drinking water for 7 days, Group 2 were given water with no additive. After 7 days both groups underwent a right nephrectomy followed by 45 minutes of left renal artery occlusion. The rats were then left to recover for 48 hours before being sacrificed with blood taken for markers of renal dysfunction and serum leptin.

Results:

	Control	Vancomycin	p
Creatinine (umol/l)	327 (203)	395 (200)	NS
Urea (mmol/l)	48 (28)	55 (21)	NS
Potassium (mmol/l)	4.7 (2.3)	4.7 (1.3)	NS
Sodium (mmol/l)	142 (6)	145 (5)	NS
Phosphate (mmol/l)	4.4 (1.9)	5.1 (2.1)	NS
AST (U/l)	82 (32)	67 (19)	NS
Leptin (ng/ml)	13.0 (6.4)	8.1 (3.2)	0.04

Values diaplayed as Mean (SD), with p value results of 2 tailed t test

Conclusions: In this study we confirm that treatment with vancomycin leads to a reduction in serum leptin levels. However, in contrast to the heart, this does not result in improved renal ischemia tolerance. 1. Lam V et al. Intestinal microbiota determine severity of myocardial infarction in rats. *FASEB J*. 2012;26:1727-1735.

PUB003

The Effect of Dietary Supplementation with Alpha Lipoic Acid in Young Rats on Reduced Glutathione Levels in Mitochondria from Kidney Cortex and Medulla Marianna J. Zamlauski-Tucker, Halah Albar, Robert J. Faulkner, Bingwei Ye. *Physiology & Health Science, Ball State University, Muncie, IN.*

Background: A previous study reported that mitochondrial reduced glutathione (GSH) levels in kidneys from young rats did not increase when the rats were given dietary antioxidant supplementation. GSH is the principal antioxidant inside cells and its level is maintained to protect cells against oxidative injury. The present study investigated whether dietary supplementation with alpha lipoic acid affects mitochondrial GSH levels in kidney cortex and medulla from young rats.

Methods: Young (i.e., 3 months of age) female Lewis rats were given D,L-alpha lipoic acid (100 mg/Kg body wt) via intraperitoneal injection for one week. Age-matched control rats were not given any exogenous supplementation. The kidneys were harvested at the end of the treatment period and separated into cortical and medullary sections. The sections were further separated into cytosolic and mitochondrial fractions by differential centrifugation. GSH levels in the fractions were measured using a spectrophotometric assay. Statistical comparisons were done using a Student's t test.

Results: There were significant increases in both mitochondrial and cytosolic GSH levels in kidney cortex and medulla from young rats receiving dietary supplementation with alpha lipoic acid.

Kidney GSH Levels

		Control (n = 8)	Experimental (n = 6)
GSH - Cytosol	Cortex	5.5 ± 0.4	9.9 ± 0.2 *
μmol/g kid wet wt	Medulla	3.07 ± 0.2	6.3 ± 0.3 *
GSH - Mitochondria	Cortex	100 ± 6	157 ± 11 *
nmol/g kid wet wt	Medulla	92 ± 7	174 ± 8 *

All data expressed as X ± SEM. * Significantly different ($p < .05$) from Control

Conclusions: Dietary antioxidant supplementation in young rats is effective in increasing both mitochondrial and cytosolic GSH levels in kidney cortex and medulla.

PUB004

Shortening of Primary Cilium in Cisplatin-Induced Tubular Cell Apoptosis Shixuan Wang, Zheng Dong. *Cellular Biology and Anatomy, Georgia Health Sciences University and Charlie Norwood VA Medical Center.*

Background: Cilium is an organelle protruding from the apical surface of the cell. Most of the cells in human body have cilia. In the kidney, each tubular epithelial cell contains only one cilium, termed primary cilium or mono-cilium. It has been proposed that primary cilia of kidney tubular cells are mechanosensors to fluid flow. Interestingly, ciliary dysfunction in polycystic models sensitizes animals to acute kidney injury (AKI) induced by renal ischemia-reperfusion, although the underlying mechanism is unknown.

Methods: This study examined the change of primary cilium and is role in tubular cell apoptosis induced by cisplatin, a chemotherapy agent with notable nephrotoxicity.

Results: In cultured human proximal tubular epithelial cells (HK-2), cilium became shorter during cisplatin treatment, followed by apoptosis. To determine if ciliary shortening affects apoptosis, HK-2 cells were transfected with shRNAs targeting KIF3A and TG737, respectively. Ciliary length and frequency were reduced in the knockdown cells. Cisplatin induced higher apoptosis rate and caspase activity in KIF3A/TG737 knockdown cells than that in the non-target sequence transfected cells. We further subcloned HK-2 cells and derived cell clones with long or short cilia. HK-2 clones with shorter cilia were more sensitive to cisplatin-induced apoptosis.

Conclusions: Taken together, the results suggest a role of ciliary regulation in tubular apoptosis during AKI.

PUB005

EPO Intervention on Controlling of Acute Kidney Injury Repair by Bone Marrow Mesenchymal Stem Cells Transplantation for Mice and Its Possible Mechanism Huiling Wang. *Division of Nephrology, Jimin Hospital, Shanghai, China.*

Background: To construct Acute Kidney Injury (AKI) mouse model which is induced by ischemia/reperfusion (I/R). Bone marrow mesenchymal stem cells (BM-MSCs) transplantation has been taken through tail vein injection, observing controlling of exogenous EPO on AKI repair by BM-MSCs transplantation, the role of SDF-1/CXCR4 axle in the controlling effect has also been discussed.

Methods: Altogether 100 C57BL/6 mice had been randomly divided into normal group, model group (AKI group), BM-MSCs transplantation group, EPO intervention group, EPO intervention + BM-MSCs transplantation group, transplanted BM-MSCs were marked by BrdU. Some mice had been sacrificed after the model been constructed 1d, 3d, 7d, and 14d respectively; arterial blood was reserved for testing blood BUN and Scr level; pathological changes for nephridial tissue have been observed and the injury degree for renal tubular has been scored; BM-MSCs distributed in nephridial tissue for recipient mice were observed with immunohistochemistry method and SDF-1 level in injured nephridial tissue was tested by Western Blot.

Results: Contrasted with BM-MSCs transplantation group and EPO intervention group, in EPO internvention + BM-MSCs transplantation group, BUN, Scr and ATN scores were declined sharply; on the 14th day after the transplantation, BUN, Scr degrees for the mice were even close to that of normal group. IHC shown that $BrdU^+$ cells distribution could be detected in the mice kidneys for BM-MSCs transplantation group, and the value reached to the peak on the 7th day after the surgery [(11.32±1.38)%]; EPO intervention combined with BM-MSCs transplantation could increase the number of $BrdU^+$ positive cells in nephridial tissue. SDF-1 level was raised for nephridial tissue after AKI model been constructed, which went to the peak on the 7th day after the model been constructed, and EPO intervention could obviously increase SDF-1 expression.

Conclusions: EPO intervention could increase the number of transplanted cells after BM-MSCs transplantation, enhance AKI repair effect. The high level of SDF-1 expression, which could promote stem cells homing to kidneys, may be one of possible mechanisms.

JNK Signalling Is Required for LPS-Induced Albuminuria in Mice

David J. Nikolic-Paterson,[1] Julie Ho,[1] Elyce Ozols,[1] Brydon Bennett,[2] Frank Yuanfang Ma.[1] *[1]Nephrology and Medicine, Monash University and Monash Medical Centre, Clayton, Victoria, Australia; [2]Celgene, San Diego, CA.*

Background: Activation of c-Jun amino terminal kinase (JNK) signalling has been shown to promote leukocyte-dependent proteinuria in rat models of nephrotoxic serum nephritis. However, recent studies have reported that blockade of JNK signalling exacerbates podocyte injury and albuminuria in models of diabetic nephropathy. We sought to examine the role of JNK signalling in other models of proteinuria kidney injury. Systemic administration of lipopolysaccharide (LPS) to mice induces podocyte damage and transient induction of albuminuria. *In vitro* studies have shown that LPS-induced signalling via its receptor (TLR4) operates, in part, via JNK. Therefore, the aim of this study was to determine whether JNK signalling is required for LPS-induced albuminuria *in vivo*.

Methods: Male C57Bl/6J mice were given an intraperitoneal injection of 5mg/kg LPS and 24hr later a 6hr urine collection was performed. Mice were treated with the selective JNK inhibitor CC-930 (60mg/kg/BID) or vehicle, beginning 1hr before LPS and then killed at 4hr (n=2) or 30hr (n=10).

Results: At 4hr after LPS administration, vehicle treated mice showed a dramatic activation of JNK signalling (immunostaining for phospho-c-Jun Ser63) in glomerular cells, including podocytes, and in tubular epithelial cells. This was associated with a 300-fold and 30-fold increase in NOS2 and TNF-α mRNA levels in the kidney, respectively. At 30hr, vehicle treated mice exhibited a 10-fold increase in the urine albumin to creatinine ratio (ACR) and a 67% reduction in nephrin mRNA levels. CC-930 treatment prevented JNK activation and abrogated the up-regulation of NOS2 and TNF-α mRNA levels at 4hr after LPS administration. Furthermore, CC-930 treatment reduced urine ACR by 75% compared to vehicle controls and prevented the down-regulation of nephrin mRNA levels at 30hr after LPS administration.

Conclusions: LPS-induced podocyte damage and albuminuria is dependent upon JNK signalling. These data suggest that blockade of JNK signalling may be a novel therapeutic strategy for sepsis-induced acute renal failure.

Oxidative and Carbonyl Stress: Hemoglobin Modification in Snakebite Mediated Acute Kidney Injury: A Pathogenesis Link

Pinaki Mukhopadhyay, Raghwendra Mishra, Debarati Mukherjee, Gautam Mukherjee, Piyali Banerjee, Monoj Kar. *[1]Department of Nephrology, NRS Medical College & Hospital, Kolkatta, West Bengal, India; [2]Department of Biochemistry, NRS Medical College & Hospital, Kolkatta, West Bengal, India; [3]Department of Biochemistry, NRS Medical College & Hospital, Kolkatta, West Bengal, India; [4]Department of Gynaecology, North Bengal Medical College, Siliguri, West Bengal, India; [5]Department of Gynaecology, Bagnan Rural Hospital, Howrah, West Bengal, India.*

Background: The aims of the study were to evaluate structural modification of hemoglobin, oxidative and carbonyl stress in snakebite mediated acute kidney injury (SAKI) patients and established a pathogenesis link.

Methods: Demographical, clinical and biochemical data was recorded in 175 SAKI patient prospectively.Various biophysical characterization of purified Hb including tryptophan quenching, surface hydrophobicity, synchronous fluorimetric study were carried out with the blood sample of SAKI patients. Non-heme iron (NHI) and heme degradation product (HDP) were measured from hemolysate. Advance oxidation protein product (AOPP), Pentosidine, Dityrosine, Thioberbituric acid reactive substance and methyl glyoxate (MG) measured as oxidative and carbonyl stress marker.All data were analyzed with appropriate statistical methods.

Results: Hb degradation and modification increases in SAKI patients. Elevated HDP, PFA and NHI level indicate denaturation and oxidative damage of heme moiety. Increased intrinsic fluorescence of Hb, elevated hydrophobicity of the globin chain and FRET changes indicate a alteration in the secondary and tertiary structure of Hb in SAKI patients. Synchronous studies indicate alteration in tryptophan and tyrosine micro environment of Hb as well as unstable quarternary structure in SAKI patients. These alterations may leads to increased ROS generation. AOPP and MG was also increased linearly suggesting oxidative stress.This is the initiator of inflammatory cascade leading to acute kidney injury.

Conclusions: Structural modification of Hb in SAKI associated with increased non-heme iron and heme degradation product which may lead to functional alteration and profound oxidative and carbonyl stress leading to kidney injury.

PUB009

A Porcine Model of Acute Kidney Injury to Investigate Putative Renoprotective Factors

Mark A.J. Devonald,[1,2] Simon J. Welham,[2] Louise J. Lloyd,[2] Thomas A. Mcculloch,[1] Zsolt Hodi,[1] David S. Gardner.[2] *[1]Nottingham University Hospitals NHS Trust, United Kingdom; [2]University of Nottingham, United Kingdom.*

Background: Ischemia-Reperfusion Injury (IRI) has been studied extensively in rodents but the pig is a better model for human disease. We developed a porcine IRI model that produces mild histological acute tubular injury (ATI). We characterised blood and urine biochemistry and investigated 2 putative renoprotective interventions: erythropoietin (EPO) and remote ischemic preconditioning (RIPC). Primary outcomes were plasma creatinine and histological scoring of ATI. Secondary outcomes included urine electrolytes, plasma and urine biomarkers (NGAL, KIM-1), apoptosis and histology of distant organs (lung, liver, brain).

Methods: 30 pigs were anaesthetised and both renal arteries clamped (40min) or sham operated via abdominal incision. Reperfusion followed for 48h with blood and urine sampled at intervals. Design was 2 (sham/IR) × 3 (saline/EPO/RIPC) factorial, n=5 pigs/group (30 total) with 90% power to observe moderate AKI in 4/5 untreated IR pigs and 0/5 sham control pigs. EPO (1000 iu/kg) was given as i.v. bolus 30min before sham/IR. RIPC was conducted 30min before sham/IR and comprised 3×cycles of 5min inflation/deflation (200mmHg) of cuff around hind-leg followed by 3×cycles of 5min deflation.

Results: IRI elicited a significant (P<.001) increase in kidney mass. This was accompanied by early (<2h) pronounced (from baseline 140 to 250 umol/L at 8-24h after IR) increments in plasma creatinine. Plasma alanine aminotransferase increased significantly in controls but more so after IR, suggesting further liver injury. Urine albumin:creatinine ratio peaked +2h after IR, declining to baseline by 24h. Plasma osmolality did not deviate from baseline but urine osmolality declined significantly. From plasma and urine biochemistry, EPO or RIPC appeared to offer no significant renoprotection.

Conclusions: We have established a large animal model of AKI and have conducted preliminary analyses of plasma and urinary biochemistry to characterise moderate renal and distant organ injury. Histological assessment of injury in kidney at +24 and 48h and in liver and lung at +48h are continuing and will be presented.

PUB010

Renal Treg Recruitment by DMS Is Not due to De Novo Conversion

Li-Wen Lai,[1] Kim-Chong Yong,[1] Michael Lien,[1] Yeong-Hau Howard Lien.[2,3] *[1]Biochemistry and Chemistry, University of Arizona, Tucson, AZ; [2]Medicine, University of Arizona, Tucson, AZ; [3]Arizona Kidney Diseases and Hypertension Center, Tucson, AZ.*

Background: Regulatory T cells (Tregs) have become an immunotherapeutic agent for treating inflammatory processes. Previously, we reported that pretreatment of mice with a sphingosine derivative N, N-dimethylsphingosine (DMS) increases both tissue infiltrating T effectors (Teff) and Tregs in the early phase of renal ischemia/reperfusion injury (IRI), and protects mice from IRI. This Treg recruitment plays a key role in DMS-induced renoprotection because depleting or disabling Treg abolishes renal protection. The peripheral Tregs can be induced by homing and/or de novo conversion. In this study, we used adoptive transfer to determine if DMS causes homing or de novo conversion using $Foxp3^{EGFP}$ mice as a donor, which express EGFP/Foxp3 fusion protein via an endogenous Foxp3 promoter.

Methods: We isolated CD4+EGFP- (Teff) and CD4+EGFP+ (Treg) cells respectively from splenocytes which were first subjected to a negative selection to enrich for CD4+ cell then the flow cytometry sorting to separate EGFP+ cells from EGFP- cells. The EGFP- cells (10^6 cells, > 98% purity) were transfused to wild type BALB/c mice via tail vein injection. On day 4, the recipients were treated with either vehicle or DMS (0.43 mg/kg) for 1 h then kidney, spleen, thymus, bone marrow, and peripheral blood were obtained. Cell suspensions were subjected to CD4 staining and flow cytometry analysis to quantify the CD4+EGFP+ cells. If DMS induces de novo conversion, we expect to see the EGFP+ cells in organs of mice that received EGFP- cells.

Results: We found no EGFP+ cells in any of the organs we tested in either group, suggesting that de novo conversion is not the mechanism of DMS-induced Treg recruitment. In addition, DMS was found to up-regulate the renal expression of chemokines CXCL9 and CXCL10, which are ligands for CXCR3, a key receptor for Treg migration signaling.

Conclusions: Collectively, our findings suggest that DMS may induce renal expression of chemokines, which attract Tregs into the inflamed site and offer the protection against IRI.

The Effects of Extracorporeal Shock Wave for Renal Ischemia Reperfusion Injury in Rats

Mai Yoshida,[1] Takashi Nakamichi,[1] Takefumi Mori,[1] Kenta Ito,[2] Hiroaki Shimokawa,[2] Sadayoshi Ito.[1] *[1]Division of Nephrology, Endocrinology and Vascular Medicine, Tohoku University Graduate School of Medicine, Sendai, Miyagi, Japan; [2]Department of Cardiovascular Medicine, Tohoku University Graduate School of Medicine, Sendai, Miyagi, Japan.*

Background: Extracorporeal shock wave (ESW) is a novel potential and safe treatment for ischemic disorders such as angina pectoris and peripheral artery diseases by mediating angiogenesis. We designed this study to investigate whether ESW ameliorated ischemic AKI.

Methods: We created renal ischemia reperfusion (I/R) models on male 8-week-old Sprague-Dawley rats. Under general anesthesia, the left renal pedicles were clamped for 45 min, and then declamped. The operated rats were divided into ESW group (ESW, n=8) and control group (CON, n=8). Both kidneys of only ESW group were treated with ESW (200 shocks/day for each kidney, 0.09 mJ/mm^2) just after I/R operation, and 24, 48 hours after the operation. Immediately after the third ESW treatment, the rats of both groups were sacrificed to analyze kidney weights, renal histological changes, and renal function.

Results: Among CON group, the left, I/R operated, kidney weight was significantly increased compared with the right kidney (Lt 0.52 ± 0.02 vs. Rt 0.39 ± 0.01 g/100 g body weight). The left kidney weight of ESW group was light compared with that of CON group (ESW 0.45 ± 0.02 vs. CON 0.52 ± 0.02 g/100 g body weight). Plasma creatinine of ESW group was significantly lower than CON group (ESW 0.32 ± 0.03 vs. CON 0.43 ± 0.03 mg/dl). Elastica-Masson stain revealed that tubular injury scores in the outer medulla of ESW group were significantly lower than CON group (ESW 1.6 ± 0.2 vs. CON 2.0 ± 0.1).

Conclusions: ESW ameliorates tubular injury and recovers renal function in a rodent I/R model. ESW may be an effective, safe, and noninvasive therapy for ischemic AKI, although a further investigation is required to solve the underlying mechanisms.

PUB012

Egr-1 Mediates Hypoxia-Induced Epithelial-Mesenchymal Transition via PKC/ERK Pathway in Tubular Epithelial Cells Shiren Sun,[1] Lijie He,[2] Hanmin Wang.[3] *[1]Xijing Hospital, FMMU; [2]Xijing Hospital, FMMU; [3]Xijing Hospital, FMMU.*

Background: Tubular epithelial cells under hypoxia can undergo Epithelial-mesenchymal transition (EMT), and finally lead to renal fibrosis. Egr-1, as a transcription factor, is proven to be important in promoting EMT and be induced by hypoxia in different cell lines. However, the role and underlying mechanisms of Egr-1 in hypoxia-induced renal tubular cells EMT are not well known.

Methods: Western blot (WB)and quantitative reverse transcriptase PCR was performed to detect the protein and mRNA level of Egr-1 under low oxygen. Tubular epithelial cells (HKC and HK-2 cells) were treated Calphostin C or PD98059 under low oxygen to explore the underlying mechanisms of hypoxia-induced Egr-1. Sense and siRNA vector of Egr-1 was transfected in HK-2 and HKC cells to investigate the role Egr-1in hypoxia-induced EMT. SiRNA against snail was done to elucidate the downstream pathway of Egr-1. The expressions of HIF-1α, Egr-1 and Snail in kidney tissues from 5/6- nephrectomized rat model and CKD patients were detected by immunohistochemistry and WB.

Results: Hypoxia enhanced the expression of Egr-1 in tubular epithelial cells, which started at 0.5h and reached to peak at 4h and persists to 72h in HK-2cells. Overexpression of Egr-1 in both HKC and HK-2 cells promoted a mesenchymal phenotype accompanied by reduced expression of the epithelial marker E-cadherin and increased expression of the mesenchymal markers FSP-1, while Egr-1 knockdown by siRNA effectively reversed hypoxia-induced EMT. Calphostin C or PD98059, specific inhibitors to PKC or MAPK/ERK could abolish hypoxia-induced Egr-1, indicating hypoxia induced Egr-1 through PKC/ERK pathway. Egr-1 promoted the expression of snail under hypoxic conditions through transactivation of the snail promoter, which in turn upregulated FSP-1 and downregulated E-cadherin. In 5/6-nephrectomized rats and CKD patients' kidney tissues, Egr-1 and Snail were overexpressed in tubular epithelial cells showing EMT.

Conclusions: Our results indicate that hypoxia induced Egr-1 expression through PKC/ERK pathway and Egr-1 mediates hypoxia-induced renal tubular epithelial cells EMT and renal fibrosis through the activation of the snail pathway.

PUB013

Gender Differences Control Susceptibility to ER-Stress Induced Acute Kidney Injury Rawad Hodeify,[1] Judit Megyesi,[1] Adel Tarcsafalvi,[1] Nang San Hti Lar Seng,[1] Peter M. Price.[1,2] *[1]UAMS; [2]VA Med Ctr.*

Background: ER stress contributes to acute kidney injury induced by several causes.

Methods: Mice were injected intraperitoneally (1 mg/kg body weight) with tunicamycin, an agent known to cause ER stress. Renal function and histology were assessed 3 or 5 days after injection. In addition, a group of female mice was treated with testosterone (5 mg pellet) before tunicamycin.

Results: We observed differences in the severity of kidney injury between male and female mice in response to tunicamycin. Treated male mice showed a severe decline in kidney function (BUN and creatinine), and extensive damage in the outer cortex of the kidney (S1 and S2 segments). Kidney function in female mice did not decline, although their kidneys showed damage of the inner cortex (S3 segment). Protein markers of ER stress were also more elevated in male mice compared with females. Specifically, levels of glucose-regulated protein (GRP-78/Bip), and CHOP/GADD153 were significantly higher in tunicamycin-treated male mice, and was localized primarily to nuclei of proximal tubule cells that showed signs of injury. RT-PCR analysis showed that the splicing of XBP1 (X-box binding protein 1) to its active form (XBP1S), was higher in male than female mice after tunicamycin. Furthermore, staining for active XBP1 was significantly increased in proximal tubules in the deep cortex in male mice, while female mice showed very few active-XBP1-stained nuclei, that mainly localized to the outer cortex. Apoptosis induction, (Bax and caspase-3 activation), was also higher in tunicamycin-treated male mice. Testosterone pretreatment of female mice before tunicamycin exposure resulted in a phenotype similar to male mice with a comparable decline in renal function, and similar kidney damage and induction of ER stress markers.

Conclusions: Male mice are much more susceptible to ER stress-induced AKI than females, and this sexual dimorphism is due to testosterone. ER stress and gender could play a major role in promoting kidney injury. The effect of this sexual dimorphism could provide further insight to understand the relationship between segment-specific damage and kidney function.

PUB014

Pretreatment with Paricalcitol Attenuates Inflammation from Ischemia-Reperfusion Injury in Mice Hyeonseok Hwang,[1] Yoon-Kyung Chang,[1] Cheol Whee Park,[2] Suk Young Kim,[1] Sangju Lee,[1] Chul Woo Yang.[2] *[1]Division of Nephrology, Department of Internal Medicine, The Catholic University of Korea, Seoul, Daejeon, Korea; [2]Division of Nephrology, Department of Internal Medicine, The Catholic University of Korea, Seoul, Seoul, Korea.*

Background: The effect of paricalcitol on renal ischemia–reperfusion injury (IRI) has not been investigated. We examined whether paricalcitol is effective in preventing inflammation in a mouse model of IRI, and evaluated the prostaglandin E2 (PGE2) pathway as a potential protective mechanism of paricalcitol.

Methods: Paricalcitol (0.3 mg/Kg) was administered to male C57BL/6 mice 24 h before IRI. Bilateral kidneys were subjected to 23 min of ischemia, and mice were killed 72 h after IRI. The effects of paricalcitol on renal IRI were evaluated in terms of renal function, tubular necrosis, apoptotic cell death inflammatory cell infiltration and inflammatory cytokines. The effects of paricalcitol on PGE2, its synthetic enzymes and receptors were also investigated.

Results: Paricalcitol pretreatment improved renal function (decreased blood urea nitrogen and serum creatinine levels), and renal pathology (decreased tubular necrosis and apoptotic cell death) in IRI-mice kidneys. The infiltration of inflammatory cells (T cells and macrophages), and production of proinflammatory cytokine (RANTES, tumor necrosis factor-a, interleukin-1b and interferon-g) were reduced in paricalcitol-treated mice with IRI. Paricalcitol upregulated cyclooxygenase-2 expression and PGE2 synthesis in postischemic renal tissue. EP4 mRNA expression increased in paricalcitol-treated mice with IRI, whereas it did not affect EP2 mRNA expression.

Conclusions: Our study demonstrates that paricalcitol pretreatment prevents renal IRI via inhibition of renal inflammation, and we propose upregulation of PGE2 and EP4 as protective mechanisms of paricalcitol in IRI.

PUB015

Renoprotection Derived from Regulatory Changes of OAT1/3 in Ischemic Acute Kidney Injury (iAKI) Marcus Meusel,[1] Michael Kersten,[1] Christopher Held,[1] Boris Betz,[1] Kerstin Möller-Ehrlich,[2] Christoph Wanner,[1] Reinhard Schneider.[1] *[1]Dept. Nephrology, University Hospital Wuerzburg; [2]Center of Experimental Molecular Medicine (ZEMM), Wuerzburg; [3]Clinic of Anaesthesiology, University Hospital Halle, Germany.*

Background: Prostaglandin E_2 (PGE_2) diminishes expression organic anion transporters (OAT1, OAT3) in proximal tubules (PT). In iAKI, OAT down regulation is induced by the COX inhibitor (indomethacin [INDO]) in low doses, and correlates with improvment of renal function. INDO accumulates in proximal tubular cells (PCTs) when internalized by OAT1/3. Thus, we applied a competetive inhibitor of OAT (probenecid [PBC]) to block INDO uptake into PTs with the aim to abolish the effect on OAT1/3 and renal function.

Methods: iAKI was induced in rats by bilateral clamping of renal arteries for 45 min. INDO (1mg/kg) +/- PBC (50mg/kg) was applied i.p. before reperfusion. 24h after ischemic injury the clearance of inulin (C_{IN}, resp. GFR) and para-aminohippuric acid (C_{PAH}, resp. RPF) were measured. PAH net secretion (NS_{PAH}) was determined to elucidate transporter capacities and respective expressions (OAT1/3). Protein- and mRNA-expression were analyzed in renal cortical, and ED1+ infiltration was depicted by immunohistology.

Results: In iAKI INDO restored OAT1/3 expression as well as NS_{PAH} net secretion and PGE_2 clearance. Additionally, INDO substantially improved renal function as measured by C_{IN} and C_{PAH} clearance. Besides, renal cortical apoptosis and iNOS expression was diminished. Notably, low-dose INDO did not affect inflammatory parameters in the renal cortex (e.g. MCP-1, ED1+-cells). In addition, PBC blocked the restoration of OAT1/3 expression induced by INDO. Actually, PBC moreover abrogated all the beneficial effects of INDO on renal outcome described above.

Conclusions: (I) Beneficial effect of low dose INDO is not due to its anti-inflammatory potency, but (II) due to its effects on regulation of OAT expression. PBC competitively inhibits INDO uptake into the PCT, thereby (III) restoring PGE_2 induced down regulation of OAT after iAKI and re-establishing renal damage. This is (IV) evidence for a mechanistic role of OAT1/3 in renoprotection in iAKI.

PUB016

Aging Enhances Renal Tubular Cell Apoptosis Following Renal Ischemia-Reperfusion Injury Zygimantas C. Alsauskas, Madhavi J. Rane, Kenneth R. McLeish. *Kidney Disease Program, University of Louisville, Louisville, KY.*

Background: Aging is associated with an increased risk of acute kidney injury following renal ischemia-reperfusion (IRI). Apoptosis of renal tubular cells contributes significantly to renal dysfunction in IRI. The effect of age on development of tubular cell apoptosis following IRI is unclear. This study tested the hypothesis that advanced age enhances tubular cell apoptosis and renal dysfunction in mice with IRI.

Methods: Young (7-20 weeks, n=6) and old (84 weeks, n=3) male C57B6 mice underwent renal ischemia-reperfusion via bilateral renal pedicle clamping for 20 minutes at 37C, followed by sacrifice after 24 hours of reperfusion. Plasma creatinine was measured at sacrifice, and TUNEL+ cells in sections of fixed kidney were counted in outer medulla (at least 10 HPF in at least 2 sections).

Results: Creatinine was routinely less than 0.5 mg/dL after 24 hr in mice following sham-surgery. Creatinine elevation after 24 hr did not differ between younger mice (2.22±0.35 mg/dL) and older mice (2.13±0.18 mg/dL) with IRI, p=0.86. Older mice

exhibited lethargy and hypothermia at 24 hours that was not observed in younger mice. The mean number of TUNEL+ cells per HPF was significantly increased in older mice (23.2±2 cells/HPF) compared to younger mice (11.9±1.1 cells/HPF), p=0.01.

Conclusions: Renal tubular epithelial cells in older mice are more susceptible to apoptotic cell death following ischemia-reperfusion, which may explain increased susceptibility to ischemic kidney injury observed in aged animals. Despite an increase in apoptosis, no differences in the early loss of renal function were observed.

PUB017

Role of Estrogen Receptor α and β in Ischemia/Reperfusion-Induced Acute Kidney Injury Rodrigo Maranon,[1] Arnaldo F. Lopez-Ruiz,[2] Andrea P. Soljancic,[2] Kiran B. Chandrashekar,[2] Ruisheng Liu,[1] Luis A. Juncos.[1,2] *[1]Physiology and Biophysics, University of Mississippi Medical Center, Jackson, MS; [2]Medicine/ Nephrology, University of Mississippi Medical Center, Jackson, MS.*

Background: Premenopausal females are less susceptible to I/R-AKI than males. We previously found that this protective effect is eliminated by blocking the ERα with fulvestrant (FVT). In the present study, we examined whether ovariectomizing female rats (OVX) mimics the effects of FVT, and then examined the role of each of the two estrogen receptors (ERα and ERβ) and their interactions with the cytoprotectant HO in mediating the protective effects of estrogens on I/R-AKI.

Methods: We induced I/R-AKI (40min of bilateral clamping) in intact and OVX female Sprague-Dawley rats. In addition, subsets of OVX rats received either PPT (an ERα agonist) or DPN (ERβ agonist). Renal function (plasma creatinine), injury (KIM-1), inflammation (TNFα) and HO-1 expression were determined 24 hours after ischemia.

Results: OVX and FVT-treated rats had more severe I/R-AKI than intact rats. Administration of either PPT or DPN to OVX rats ameliorated I/R-AKI.

	PL. Creat	TNFα	HO-1	Urine KIM-1
Sham-intact	0.4 ±0.03	0.3±0.04	0.2±0.07	9351±3
I/R-AKI	1.7±0.2	1±0.1	1.2±0.1	148980±1
I/R-AKI + FVT	2.4±0.4	2±0.2	0.79±0.1	183532±1
Sham-Ovx	0.7±0.3	0.3±0.02	0.73±0.3	51409±2
I/R-AKI-Ovx	3±0.1	0.6±0.1	1.6±0.1	676554±4
I/R-AKI -Ovx +PPT	1.8±0.1	0.3±0.02#	2.3±0.1	411578±3
I/R-AKI -Ovx +DPN	2±0.1	0.3±0.01#	2.05±0.1	479708±2

Data: Mean±SEM: *p<0.05vs Sham; # p<0.05vs AKI

Conclusions: The decreased susceptibility to I/R-AKI in females appears to be due to activation of both estrogen receptors; OVX exacerbated injury, whereas administering agonists of either ER ameliorated injury. Activation of the estrogen receptors facilitates AKI-mediated induction of HO-1, which may be responsible for their protective effects against I/R-AKI.

PUB018

Increased Endogenous Hydrogen Sulfide Formation Exacerbates Renal Damage Induced by Cisplatin Injection Heloisa Francescato, Cleonice G. Da Silva, Terezila Machado Coimbra. *Physiology, University of Sao Paulo, Ribeirão Preto, Sao Paulo, Brazil.*

Background: Cisplatin (CP)-induced renal damage is associated with an inflammatory process. Hydrogen sulfide (H_2S) is an important signaling molecule involved in inflammation. The inflammatory process is more intense five days after CP injection.This study evaluated the effect of *Lawesson* reagent (LR), a donor for endogenous H_2S formation, on the renal damage induced by CP in rats.

Methods: Twelve rats were injected with CP (5 mg/kg, i.p.), 6 of them received LR (30 µmol/kg/once a day, s.c.), for four days, starting 1 hour before CP injection. Six control rats were injected with 0.15 M NaCl. Blood and urine samples were collected 5 days after saline or CP injections to evaluate plasma urea levels, and sodium and potassium fractional excretions. The kidneys were removed for determination of renal H_2S formation and histological analysis. Immunohistochemistry for vimentin expression in renal tissue, a marker of recent tubular cell lesion, was also performed.

Results: CP-treated rats presented increases in plasma urea levels and in sodium and potassium fractional excretions. Treatment with LR exacerbated all these functional alterations. Plasma ureia levels [mg/dl; expressed as median and interquartile range (25;75%)] were 173.8 (140.0;227.1) in CP-injected rats, 287.1 (83.0;317.4) in the rats treated with LR+CP and 43.4 (34.1;48.8) in control rats (p<0.05). The score for tubulointerstitial lesions (tubular necrosis, interstitial inflammatory infiltrate, tubular lumen dilation) were increased in the renal outer medulla in both groups injected with CP. A greater immunostaining for vimentin on outer medulla tubular cells, evaluated by scores, was observed on LR+CP-group [2.2 (1.8;2.6)], compared to CP [1.4 (1.2;1.8)] and control [0.2 (0.1;0.2)] groups. These alterations were associated with increased H_2S formation in LR+CP group (79.5±10.5 µg/mg prot/h), compared to CP (60.3±5.8) and control (32.4±4.2) animals (p<0.05).

Conclusions: In conclusion, treatment with a donor for H_2S formation aggravates the renal lesion induced by CP. Research Support: CNPq.

Protein Kinase C-α Regulates Mitochondrial Function and Cell Survival by Associating with Heat Shock Proteins Grazyna Nowak, Sridharan Soundararajan. *Pharmaceutical Sciences, University of Arkansas for Medical Sciences, Little Rock, AR.*

Background: Primary cultures of renal proximal tubular cells (RPTC) respond to stress by synthesizing different heat shock proteins (HSP), including HSP70, which prevents cell death following ATP depletion. HSP70 interacts with PKC-α to protect ventricular myocytes against ischemia. The goal of this study was to determine whether PKC-α associates with HSP70 in RPTC mitochondria and if this complex plays a role in mitochondrial and cellular repair following oxidant injury.

Methods: Wild-type PKC-α (wtPKC-α) and inactive PKC-α (dnPKC-α) were overexpressed in primary cultures of RPTC and mitochondrial PKC-α and iHSP70 levels, mitochondrial function, ATP content, and monolayer regeneration were assessed following exposure to the model oxidant, *tert*-butylhydroperoxide (TBHP).

Results: TBHP exposure decreased active PKC-α levels in mitochondria, mitochondrial function, and ATP content, and induced 40% cell loss. Overexpressing wtPKC-α promoted, whereas overexpressing dnPKC-α blocked, recovery of mitochondrial function, ATP content, proliferation, and cell survival. Co-immunoprecipitation and proteomic analysis revealed an association between the inducible HSP70 (iHSP70) and the inactive PKC-α in RPTC mitochondria. Mitochondrial iHSP70 levels increased as the levels of active PKC-α decreased after TBHP exposure. Overexpressing wtPKC-α abrogated whereas overexpressing dnPKC-α augmented TBHP-induced increases in mitochondrial iHSP70. Overexpressing iHSP70: 1) maintained active PKC-α levels in mitochondria, 2) improved recovery of state 3 respiration and ATP content, 3) decreased RPTC death, and 4) accelerated proliferation following oxidant injury. In contrast, iHSP70 inhibition decreased mitochondrial levels of PKC-α, blocked recovery of ATP content, and exacerbated cell death after injury.

Conclusions: We conclude that inactive PKC-α and iHSP70 form nonfunctional complex in mitochondria, which inhibits iHSP70 and blocks recovery of mitochondrial function and ATP content, and regeneration of oxidant-injured RPTC. Active PKC-α maintains iHSP70 functional and improves mitochondrial functions, ATP content, and RPTC regeneration following oxidant injury.

Effect of Erythropoietin on Short-Term I/R Injury in Rats Ciro Esposito,[1] Massimo Torreggiani,[1] Francesca Castoldi,[2] Clara Migotto,[2] Nicoletta Serpieri,[2] Fabrizio Grosjean,[1] Alessandra Manini,[2] Enrico Pertile,[2] Antonino Dal Canton.[2] *[1]Nephrology, Fondazione IRCCS S. Maugeri, University of Pavia, Pavia, Italy; [2]Nephrology, Fondazione San Matteo, University of Pavia, Pavia, Italy.*

Background: Oxidative stress, apoptosis, necrosis and inflammation contribute to the pathogenesis of ischemia/reperfusion (I/R) injury. Bone marrow progenitor cells (BMC) are thought to participate in tissue repairing. We tested the efficacy of erythropoietin (EPO) to recruit BMC and ameliorate renal damage at 48 hours in a I/R rat model.

Methods: Female Sprague-Dawley rats were irradiated with a single dose of ^{137}Cs (10 Cy) and transplanted with 10^7 BMC from male donors of the same strain. After 4 weeks, animals were anesthetized and, through a bilateral subcostal incision, renal arteries were clamped for 45 minutes. Reperfusion of the kidneys was visually confirmed. 8 rats were randomized to receive EPO (5000UI/Kg of body weight, i.p.) 30 minutes before I/R while 8 rats received an equal volume of saline. Animals were sacrificed 48 hours later.

Results: There was no difference between the two groups in serum creatinine (3.2±0.8 vs. 2.4±0.8mg/dl), creatinine clearance (0.44±0.20 vs. 0.45±0.16ml/min), diuresis (24.75±7.90 vs. 16.00±3.29ml/24h), proteinuria (0.59±0.25 vs. 0.45±0.18g/24h) and hemoglobin (9.39±0.67 vs. 11.63±0.34g/dl). The FISH technique did not show any difference in the number of Y+ cells in the kidney, mostly of inflammatory origin. Histologically, we observed foci of tubular necrosis, a mild inflammatory infiltrate and leucocyte margination along peritubular capillaries in both groups. However, EPO-treated rats had less apoptotic cells than controls, as shown by TUNEL (7.27±1.73 vs. 19.61±4.56%, p<0.05) and less oxidative stress, as demonstrated by the extent of protein oxidation.

Conclusions: EPO does not ameliorate renal function through BMC recruitment, confirming the results from our previous study that prolonged the observation at 4 weeks after injury. However, EPO seems to act blunting the oxidative burden and preserving cells from apoptosis. The short follow-up time could have masked a faster renal function recovery in the EPO group, as suggested by their higher diuresis.

Early Postoperative Serum Uric Acid May Be Associated with Early Acute Kidney Injury A. Ahsan Ejaz,[1] Noel I. Ejaz,[2] Ganesh Kambhampati,[1] Bhagwan Dass,[1] Vijay Lapsia,[3] Michiko Shimada,[4] Rajesh Mohandas,[1] Negiin Pourafshar,[1] Richard J. Johnson.[5] *[1]Division of Nephrology, Hypertension and Transplantation, University of Florida, Gainesville, FL; [2]University of Chicago; [3]Mount Sinai School of Medicine; [4]Hirosaki University; [5]University of Colorado Health Sciences Center.*

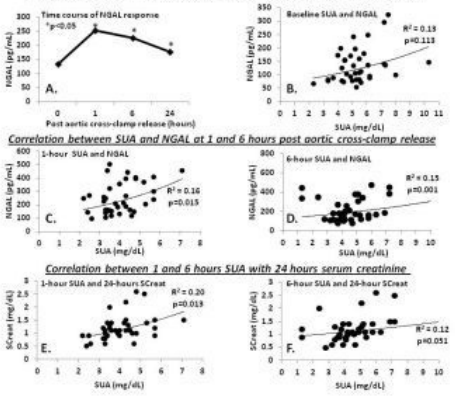
Background: We have reported that pre- and postoperative serum uric acid (SUA) is associated with an increased risk factor for acute kidney (AKI) as measured by serum creatinine (SCr) criteria (AJM, J Nephrol 2012). Based on our previous studies, we

hypothesized that SUA measured in the early, post aortic cross-clamp (ACC) release period may be associated with renal parenchymal damage as measured by serum neutrophilgelatinase-associated lipocalin (NGAL), a reliable predictor of early kidney injury.

Methods: Samples for SUAandNGAL were prospectively collected at 0, 1, 6 and 24 hours post ACC release and stored at -70C in a previously reported study (JTCVS). The relationship of SUA, NGAL and SCr were investigated. We only compared absolute values for each variable in the time period specified to minimize the effects of dilution.

Results: 37 patients were included for analyses. As expected, NGAL peaked between 1 and 6 hours following ACC release (Fig. 1A). There were no significant correlation between SUA and NGAL measured at baseline (Figure 1B). However, there were significant correlation between SUA and NGAL measured at 1 hour (Fig. 1C) and at 6 hours post ACC release (Fig. 1D). Similarly, there were significant correlation between SUA measured at 1 hour (Fig. 1E) and and at 6 hours post ACC release with SCreat measured at 24 hours (Fig. 1F).

Figure 1. Association of postoperative SUA with early and late markers of AKI



Conclusions: The data suggests that early postoperative SUA may be associated with early renal parenchymal injury as evidenced by elevated NGAL and subsequent 24-hour SCr concentrations.

PUB023

Exploring Factors Determine Prognosis of Patients Need Continuous Renal Replacement Therapy (CRRT) due to Acute Kidney Injury (AKI) after Major Cardiovascular Surgery Hiromichi Suzuki, Tsutomu Inoue, Hirokazu Okada, Tsuneo Takenaka. *Department of Nephrology, Saitama Medical University, Iruma Gun, Saitama, Japan.*

Background: Acute kidney injury is a common and major complication of cardiovascular surgery with a high mortality rate. Although multiple recent clinical trials have prospectively evaluated the impact of dose and modality of RRT, the literature on examining the factors to start CRRT in AKI is far less robust.

Methods: In a retrospective observational cohort study from April 2009 to March 2012, we linked electronically stored intra and perioperative clinical data with prognosis of patients who needed CRRT due to AKI after major cardiac surgery. We excluded patients presenting with pre-operative end-stage kidney disease requiring dialysis, AKI preceding surgery and patients having received contrast media within 3 days pre-operatively. All patients were cared for by the same team of cardiologist, surgeons, anesthetists and nephrologists.

Results: One hundred sixty eight patients were recruited. Thirty one patients (18%) did not survive to hospital discharge. There were no significant differences in age, gender and serum levels of creatinine between the survival and non survival groups. However, co-morbidity diseases such as diabetes, hypertension and dyslipidemia were more frequently recorded in non survival group. Among 137 patients survived to hospital discharge, twent-four patients needed CRRT. The pre-operative levels of serum creatinine in patients free from RRT at discharge were lower than those of patients needed RRT at discharge, however, no significant differences in urinve bolume between the two groups at the start of CRRT. Receiver operation curve of preoperative eGFR for prediction of RRT at discharge in AKI patients after cardiac surgery revealed 27ml/min/1.73m^2.

Conclusions: Prognosis of severely ill patients suffering AKI after cardiac surgery who needed CRRT depends on pre-operative levels of eGFR and co-morbid diseases.

PUB024

Urinary RANTES May Predict Long-Term Renal Recovery among Acute Kidney Injury Survivors Osun Kwon, William Brian Reeves. *Medicine/Nephrology, Penn State College of Medicine, Hershey, PA.*

Background: Acute Kidney Injury (AKI) is a common disorder associated with a high morbidity and mortality. Noninvasive parameters which reflect the ongoing pathology in the kidney and predict outcomes are needed to facilitate improved management and decrease morbidity and mortality. AKI is often multifactorial and its pathogenetic mechanism involves inflammation and regeneration. Recently we reported that urinary IP-10, IL-8, VEGF, TGF-α and EGF may predict renal functional outcome within the first week of ischemic AKI and urinary IL-8, MCP-1, IP-10, RANTES, EGF and VEGF may predict 3 month mortality. We questioned whether the urinary markers have predictability for long-term renal outcome and mortality in those patients.

Methods: The subjects were 82 adult patients with AKI referred for renal consultation who had a known baseline serum creatinine concentration (b-s-Cr). Urinary cytokine levels were measured on the day of consultation by microsphere based immunofluorescence multiplex assay and their ability to predict renal functional and patient survival outcome was evaluated at 3 year follow-up.

Results: Among the 82 subjects, 27 (33%) had b-s-Cr > 1.3 mg/dl, suggesting baseline CKD and 48 (59%) had died by 3 year follow-up. Among 9 survivors in the CKD group, 6 recovered renal function (67%), whereas among 25 survivors in normal b-s-Cr group, 21 showed recovery of renal function (84%). A receiver operating characteristic curve was used to determine the cutoff point of each urinary cytokine level with respect to distinguishing subjects with different outcomes at 3 years. Among cytokines examined (IL-1β, IL-6, IL-8, MCP-1, IP-10, RANTES, EGF, TGF-α, and VEGF), no urinary cytokine predicted mortality or survival at 3 years. Interestingly, among survivors at 3 years, high urinary RANTES levels tended to predict renal recovery; AUC 0.735, cutoff value 9.71 pg/mg urine creatinine (U-Cr), sensitivity 0.741, specificity 0.714, P=0.058, especially in patients with normal b-s-Cr; AUC 0.810, cutoff value 9.71 pg/mg (U-Cr), sensitivity 0.762, specificity 0.750, P=0.054.

Conclusions: This finding suggests that high urinary RANTES might predict renal recovery within 3 years among survivors of AKI.

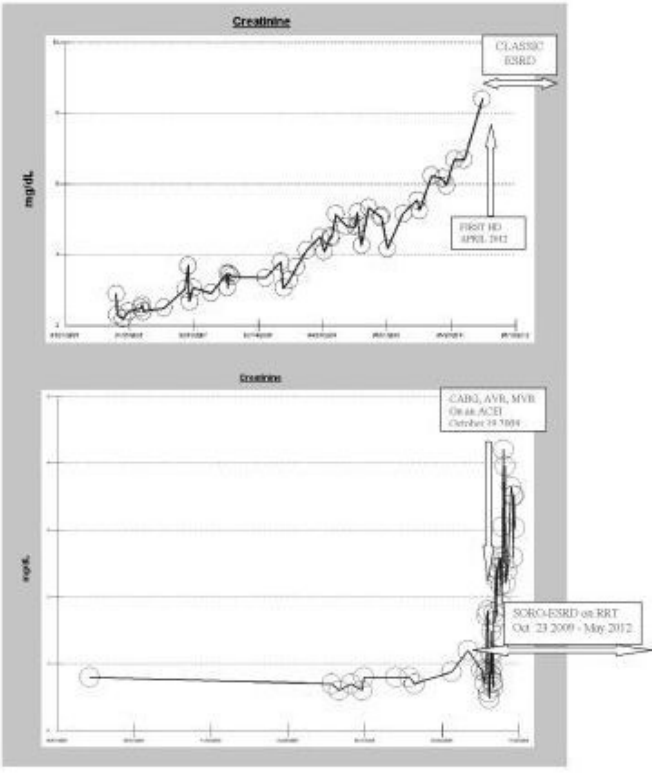
Syndrome of Rapid Onset ESRD versus Classic ESRD: A Tale of Two Different Cities: A New Unrecognized Syndrome and Implications for Improved Dialysis Care Macaulay A. Onuigbo. *Nephrology, Mayo Clinic Health System, Eau Claire, WI.*

Background: Classic CKD-ESRD progression is a predictable, linear, progressive and time-dependent decline in renal function, leading inexorably to ESRD and need for RRT (Fig 1). The syndrome of rapid onset end-stage renal disease (SORO-ESRD), which we first described in 2010, is irreversible ESRD rapidly following AKI superimposed on apriori stable CKD (Fig 1). SORO-ESRD demands study.

Methods: In June 2011, we retrospectively analyzed serum creatinine trajectories of the last 100 ESRD patients on RRT for >90 days. Any patient with an eGFR of >/= 30 ml/min/1.73 sq m BSA on or before 90 days antedating the first RRT was categorized as SORO-ESRD.



Results: Excluding 9 patients (incomplete data), of 91 ESRD patients, 57M:34F, age 39-93 years, 31 (34%) including two RTR had SORO-ESRD – 18M:13F, age 72 (50-92) years. AKI precipitating SORO-ESRD followed pneumonia (8), ADHF (7), pyelonephritis (4), post-operative (5), general sepsis (3), contrast-induced nephropathy (2), and others (2). Time between AKI and initiation of RRT was less than one week following cardiac surgery. Incidentally, 7 of 31 (23%) SORO-ESRD patients were concurrently on RAAS blockade at the time of initiation of first hemodialysis.

Conclusions: SORO-ESRD, after the fact, on maintenance RRT, appears similar to ESRD. However, SORO-ESRD and Classic ESRD are so very different – a tale of two different cities. With the former, there is no time for patient education, AVF planning and counseling. Furthermore, there are often huge communication and information gaps between

the nephrologist, the nurses, social workers and the patients/families as to the expectations of renal recovery or otherwise, at the outset, before irreversible ESRD is confirmed, so many months later. This new syndrome must be further studied to unravel these significant unanswered questions.

PUB026

Sodium Bicarbonate versus Ascorbic Acid in the Prevention of Contrast-Induced Nephropathy Bernardo Fargier,[1] Dulce M. Winterdaal,[1] Aristarco Diaz,[1] Abdel J. Fuenmayor.[2] *[1]Unidad de Nefrologia, University Hospital of the Andes, Merida, Venezuela; [2]Instituto Investigaciones Cardiovasculares, Universidad de Los Andes, Mérida, Venezuela.*

Background: Renal injury caused by contrast media is the third leading cause of in -hospital acute renal failure (ARF). Special attention is currently being directed at developing strategies for the prevention of contrast media nephropathy (CMN). The aim of this study is to determine the effectiveness of ascorbic acid vs. sodium bicarbonate in the prevention of CMN.

Methods: This is a prospective, experimental, single-blind, randomized study that was conducted between June 2010 and April 2011. We included 31 patients randomly assigned to 4 groups as follows: Group 1 (n = 8) received 0.9% saline at a rate of 1ml/kgr/hr during twelve hours before the beginning of the study and twelve hours after its completion; Group 2 (n = 8) was administered sodium bicarbonate 5% at a dose of 3ml/Kg before the beginning of the study followed by a dose of 1ml/Kg 6 hours after completion of the study; Group 3 (n = 8) was administered 3 grams of ascorbic acid endovenously before the beginning of the study and 2 grams every 12 hours in 3 additional doses upon completion of the study; Group 4 (n = 7) was given sodium bicarbonate, ascorbic acid at the same doses as those administered to the three previous groups. Groups 2, 3 and 4 received 0.9% saline at the same dose as that given to Group 1. The end point of follow-up was a relative increase ≥ 25% or an absolute increase of 0.5 mgrs / dl of serum creatinine, above baseline, 24 or 48 hours after exposure to a contrast medium. The results were expressed as absolute values , standard deviation and percentages. The ANOVA test was applied to assess between-group differences with a p value < 0,05.

Results: No significant differences were found among the groups. The serum creatinine and glomerular filtration rate 24 and 48 hours following the administration of contrast media did not increase in relation to the baseline levels.

Conclusions: Saline hydration is the ideal protective measure to prevent the occurrence of CMN, and the association of bicarbonate, ascorbic acid or both does not increase its protective effect.

PUB027

Is Intravesicular Pressure a Better Tool to Predict Renal Failure in Critically Ill Patients Compared with Routine Hemodynamic Parameters? Elie El-Charabaty, Chadi Saifan, Morton J. Kleiner, Suzanne E. El Sayegh. *Nephrology, Staten Island University Hospital, Staten Island, NY.*

Background: Acute renal failure is a frequent complication in patients admitted to the ICU. Several studies have tried to find a correlation between hemodynamic parameters and worsening of renal function in acute CHF and were unsuccesful. The aim of the study is to find if there is a linear relationship between worsening of renal function, bladder pressure (bp), hemodynamics (CVP) and blood values.

Methods: We analyzed patients admitted to the ICU with evidence of acute CHF. bp was measured using the transvesical method. Parameters measured were: weight, MAP, urine output, Cr, the use of a diuretic or pressor.

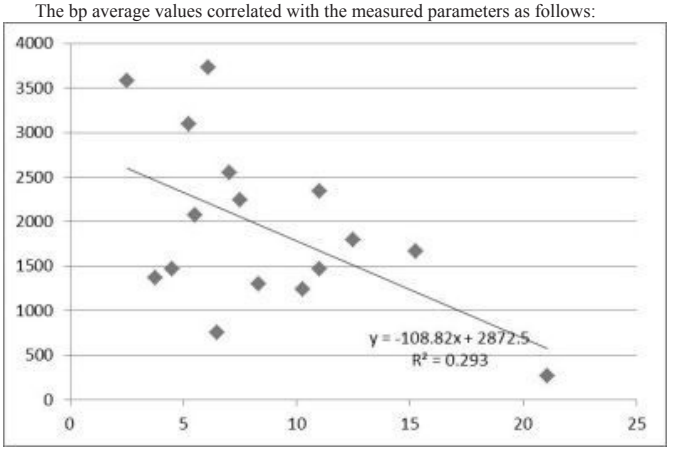
Results: 16 patients were included (5 M, 11 F) with a mean age of 72.9 y, and a mean EF of 37.14 %, 50% were on pressors and 75 % on diuretics. The mean bp measured on admission and within the hospital stay was 9.7 and 7.45 mmHg respectively. The averages of the bp, weight, creatinine level, MAP and urine output were calculated.

Patients characteristics

	Average	SD
Weight admission, Kg	80.44	18.79
Weight later, Kg	80.35	20.32
Cr admission	1.71	1.1
Cr later	1.63	1.03
MAP admission	75.99	8.25
MAP later	83.16	15.85
UO admission	2011	954
UO later	1856	982
bp admission	9.7	5.75
bp later	7.45	1.07

UO: urine output

The bp average values correlated with the measured parameters as follows:



1) For the urine output: y= -108.82 x + 2872.5; r= 0.54
2) For the MAP: y= -0.6555 x + 85.232; r=0.27
3) For the creatinine: y= 0.0246 x + 1.4613; r= 0.11
4) For the weight: y= 1.8277 x+ 64.634; r= 0.43.

Conclusions: Our study showed that bladder pressure measurements correlated better with urine output and weight change than with serum creatinine or mean arterial pressure. It is considered an easy non invasive method to monitor patients volume status and should be used more often during hospitalizations.

PUB028

Association of Left Ventricular End Diastolic Pressure with Acute Kidney Injury in Patients Undergoing Cardiac Catheterization Rebekah Adia Neal, K. Edmund Tse. *Huntington Hospital, Pasadena, CA.*

Background: The use of contrast for computed tomography scans, cardiac catheterizations, and other procedures is a well-known risk factor for the development of acute kidney injury (AKI). Proposed mechanisms include renal ischemia due to reduction of blood flow or increase in oxygen demand and, possibly, by direct toxicity to the renal tubular epithelial cells. It is unclear if volume status at the time of cardiac catheterization, as indicated by the subject's left ventricular end diastolic pressure (LVEDP), has any significant impact on the development of AKI. The primary purpose of the study is to assess for a correlation between LVEDP and the risk for AKI after cardiac catheterization. The secondary purpose of the study is to assess for other risk factors which may contribute to the development of AKI.

Methods: This is a retrospective review of 200 subjects who underwent cardiac catheterization at Huntington Memorial Hospital, Pasadena, California from 2010-2012. Inclusion criteria were documented LVEDP and pre- and post-procedural creatinine levels. AKI definition was based on the critieria from the Acute Kidney Injury Network. LVEDP was assessed in relationship to AKI. Other variables, which included patient age, gender, creatinine levels, amount of contrast, amount of peri-procedural intravenous fluids, ejection fraction (EF), and the use of bicarbonate, N-acetylcysteine, and RAAS inhibitors, were also assessed. Variables were analyzed using the student's t test and ANOVA.

Results: Of the 200 subjects, 39 were found to meet the criteria of AKI. Elevated LVEDP was associated with increased risk of AKI (27mmHg vs. 31 mmHg, p-=0.0313). Only one of variable, EF < 40%, showed a statistically significantly increased risk for the development of AKI in patients with elevated LVEDP > 19 mmHg compared to LVEDP <19 mmHg (p=0.0299).

Conclusions: Elevated LVEDP in subjects with reduced left ventricular ejection fraction is a predictor of AKI in subjects who have undergone cardiac catheterization. Caution should be made to avoid excessive amount of fluid to be given to patients with LVEDP > 19mmHg and EF < 40%.

PUB029

Overload of Either Monoclonal or Polyclonal Light Chains in Proximal Tubules Is Associated with Renal Dysfunction Ping L. Zhang. *Department of Anatomic Pathology, William Beaumont Hospital, Royal Oak, MI.*

Background: Free light chains are small molecules passing through glomerular barriers freely and reabsorbed via their receptors in proximal tubules under normal circumstances, but overload of free light chains, either monoclonal or polyclonal, to proximal tubules may cause acute tubular injury. This study was to investigate expression of monoclonal and polyclonal light chains in proximal tubules in human renal biopsies, and to correlat light chain expression with both renal functional index and tubular injury index in renal biopsies.

Methods: A sensitive immunohistochemical staining (IHC) method (polymer technique) was used to stain unremarkable renal parenchyma from tumor associated nephrectomy (control group 1, n = 39), renal biopsies with history of renal failure and proteinuria (polyclonal group 2, n = 33) and renal biopsies with diagnosis of variants of monoclonal light chain associated nephropathy (monoclonal group 3, n = 36). Diminished brushed borders of proximal tubules on PAS stained sections were scored 0 to 3+ for indicating acute tubular injury. The highest light chain stain from each case was scored from 0 to 3+. Serum creatinine levels were obtained from each patient based on the clinical record.

Results: Both polyclonal and monoclonal groups had significantly stronger staining scores for light chains in proximal tubules (2.33 ± 0.12 and 2.79 ± 0.08 arbitrary units [AU], higher serum creatinine levels (2.56 ± 0.21 and 4.47 ± 0.56 mg/dL) and higher tubular injury scores (PAS scores 1.52 ± 0.16 and 2.06 ± 0.16 AU), when compared to those in control group (0.97 ± 0.10 AU, 1.00 ± 0.05 mg/dL and 0.39 ± 0.12 AU, respectively) (ANOVA, $p<0.05$). There was a significantly linear correlation with between light chain scores or tubular injury scores and serum creatinine levels when three groups were taken together for analysis, although the correlation with polyclonal group alone was not as strong as that with the monoclonal group alone.

Conclusions: Our current data suggest that the overload of free light chains, being either monoclonal or polyclonal type, in the proximal tubules can all be associated with the acute tubular injury thus renal dysfunction.

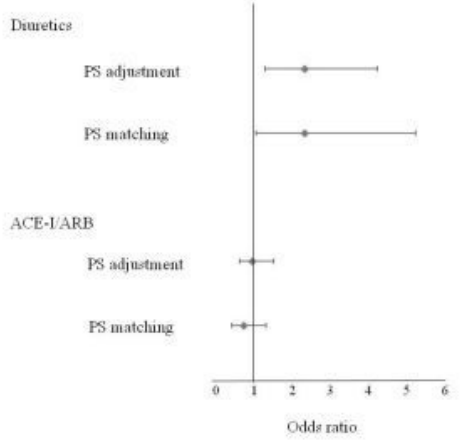
Study of Which Antihypertensives Are Predictors of Acute Kidney Injury in What Kind of Patients after Non-Cardiac Surgery Using Propensity Score

Miho Tagawa,[1] Takayuki Hamano.[2] *[1]Kyoto Katsura Hospital; [2]Osaka University.*

Background: Most of the studies on predictors of postoperative acute kidney injury (AKI) have been performed in cardiac surgery. No study has evaluated which kind of preoperative prescription of antihypertensives are risk factors of AKI after non-cardiac surgery.

Methods: This is a retrospective observational study. Inclusion criteria were adult (age ≥ 18) patients who underwent non-cardiac surgery under general anesthesia from 2007-2009 at our institute. Exclusion criteria were urological surgery, those without creatinine (Cre) values, and who had underwent dialysis preoperatively. Exposure of interests were preoperative use of diuretics and angiotensin converting enzyme inhibitors (ACE-I)/ angiotensin receptor blockers (ARB). Outcome variable was postoperative AKI defined by AKI network (increase in Cre ≥ 0.3 mg/dL or 150 %, or urine output < 0.5 ml/kg/hour for > 6 hours). A propensity score (PS) of receiving diuretics or ACE-I/ARB therapy preoperatively was estimated and adjusting for PS quintiles in multiple logistic regression analyses and matching on log(PS) were performed (user: non-user = 1:2).

Results: There were 137 AKI (5.0 %) among 2,725 subjects. Diuretics but not ACE-I/ ARB were significant predictors of postoperative AKI.



In the patients with the lower quintiles of PS, the greater effect sizes of diuretics were observed.

Odds ratio of AKI according to diuretics PS quintile comparing users with non-users

	Odds Ratio	95% CI	p
Q1+Q2	7.99	1.69-37.82	0.009
Q3	6.92	1.39-34.37	0.018
Q4	1.30	0.16-10.31	0.804
Q5	1.87	0.92-3.82	0.086

Conclusions: Diuretics but not ACE-I/ARB were significant predictors of postoperative AKI. Diuretics were predictors of postoperative AKI in patients to whom physicians were not likely to prescribe diuretics.

PUB031

Neutrophil Gelatinase Associated Lipocalin (NGAL) and Renal Impairment after Non-Cardiac Surgery

John F. Mooney,[1,2] Clara K. Chow,[1,2] Siddharth Trivedi,[3] Federica Barzi,[1] Jagnoor Jagnoor,[1] Stephanie Wilson,[1] Stephen C.H. Li,[4] Michael Clough,[4] Graham Hillis,[1,5] Richard Halliwell,[6] Vincent W.S. Lee.[3] *[1]The George Institute for Global Health, Sydney, NSW, Australia; [2]Dept of Cardiology, Westmead Hospital, Sydney, NSW, Australia; [3]Centre for Transplant and Renal Research, Westmead Millenium Institute, University of Sydney, Sydney, NSW, Australia; [4]Institute for Clinical Pathology and Medical Research, Westmead Hospital, Sydney, NSW, Australia; [5]Dept. of Cardiology, Concord Repatriation and General Hospital, Sydney, NSW, Australia; [6]Dept. of Anaesthesia, Westmead Hospital, Sydney, NSW, Australia.*

Background: Acute kidney injury (AKI) is a known complication of surgery. Neutrophil gelatinase associated lipocalin (NGAL) is a potentially novel means of detecting AKI early.

Methods: A representative sample of patients ≥45 years undergoing elective major non-cardiac surgery were followed with daily creatinine measurement. Patients with dialysis dependence or undergoing nephrological procedures were excluded. Urinary NGAL was collected 4-6 hours after commencement of surgery (Abbott diagnostics). We conducted an interim analysis of the first 101 patients enrolled. We used a linear regression model to assess relationship of NGAL to change in peak creatinine measured in the first 3 days after surgery.

Results: Patients underwent vascular, gastrointestinal, neurosurgical, orthopaedic, urological and gynaecological procedures. Mean age was 65, 52% were female, 51% had hypertension and 14.3% diabetes, 8.3% had baseline serum creatinine > 105 mmol/L and 26% had baseline proteinuria detected on urinalysis. Six patients had AKI determined by the AKIN criteria. Three of these patients had a NGAL > 100 mmol/L, compared with 7 of 95 patients without AKI. NGAL remained an independent predictor of post operative creatinine change after adjusting for age, gender, hypertension, diabetes, higher risk surgery and pre-operative creatinine levels (coefficient 3.17; CI 0.65-5.67, *p > 0.01).*

Conclusions: Urinary NGAL is associated with postoperative creatinine independent of some known predictors of AKI and potentially may have utility in early identification of patients that develop AKI after non-cardiac surgery.

PUB032

Is Angiotensin-Converting Enzyme Inhibitors/Angiotensin Receptor Blockers Associated with Acute Kidney Injury Post Coronary Artery Bypass Grafting in a Mixed Ethnicity Population in a Community-Based Hospital in Hawaii?

Ekamol Tantisattamo, Ma Clarisse M. Toledo, Dorothy M. Shigaki, Roland C.K. Ng. *Medicine, University of Hawaii.*

Background: Acute kidney injury (AKI) after coronary artery bypass grafting (CABG) is common, and preoperative risk factors are well-established. Angiotensin-converting enzyme inhibitors/Angiotensin receptor blockers (ACEI/ARB) therapy have shown cardio-protective effects in coronary artery disease patients; however, there were concerns that preoperative use of ACEI/ARB poses patients at risk for the development of AKI post-surgery. We aim to determine whether preoperative use of ACEI/ARB is associated with AKI post CABG in a mixed ethnicity population in Hawaii.

Methods: This was a retrospective study of 101 adult patients undergoing CABG between January 2009 and December 2011 in one community hospital in Hawaii. Baseline data collection included patients' characteristics, perioperative variables, and postoperative complications. The incidence of AKI was likewise obtained.

Results: Of the 101 patients, AKI defined by AKIN criteria occurred in 35 patients (35%). The incidence of stage 1 and 2 AKI was 94% and 6%, respectively. There was no incidence of stage 3 AKI. From all of the variables, only advanced age (≥65 years old) was significantly associated with an increased incidence of AKI ($p = 0.022$); otherwise, there were no significantly increased incidence of AKI with the following variables: gender ($p = 0.308$), insulin-dependent diabetes mellitus ($p = 0.716$), hypertension ($p = 0.251$), hyperlipidemia ($p = 1$), COPD ($p = 0.608$), preoperative use of ACEI/ARB ($p = 0.527$) / furosemide (0.072), postoperative use of aspirin ($p = 0.269$), and postoperative atrial fibrillation ($p = 0.593$). With a mixed ethnicity in our population, Japanese was account for the main population (51%) followed by Filipino (18%), mixed ethnicity (8%), and others (23%).

Conclusions: Incidence of AKI post CABG in Hawaii is not different from that of available data. In addition to cardiovascular benefit, ACEI/ARB therapy is not associated with an increased risk of AKI post CABG. Since the outcome of CABG is correlated with AKI, preoperative discontinuation of ACEI/ARB may not be warranted.

PUB033

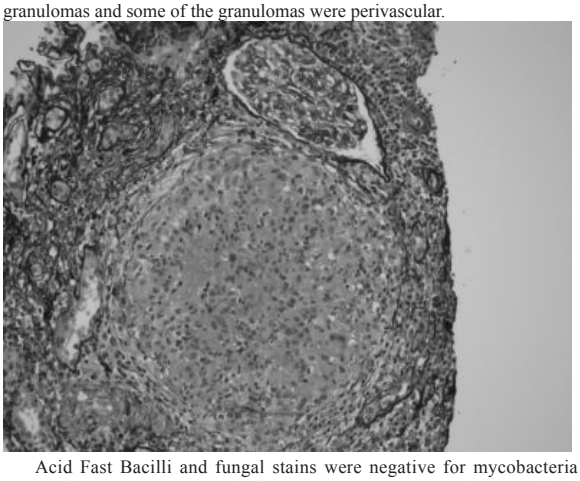
A Rare Case of Drug Induced Interstitial Nephritis with Granuloma Formation in Kidney Biopsy

Rohan Garje,[1] Arash Rashidi.[2] *[1]Internal Medicine, Fairview Hospital; [2]Nephrology, Fairview Hospital, A Cleveland Clinic Hospital.*

Background: Interstitial nephritis (IN) is associated with multiple etiologies but granulomatous IN is a rare finding. Here we report a 48 years old white female with granulomatous IN secondary to Allopurinol.

Methods: A 48 y/o Caucasian female was evaluated for weakness, fatigue and nocturia. She had history of hypertension controlled with Valsartan and was recently diagnosed with gout for which she was started on Colchicine, Allopurinol and Ibuprofen about two

weeks prior to the presentation. She did not have any significant drug allergies. Physical examination was normal and vitals were stable. Renal function testing revealed a serum creatinine of 3.24 mg/dl from the baseline which was 1.0 mg/dl. Urinalysis was negative for red blood cells and eosinophils. Spot urine protein to Cr ratio did not show significant proteinuria. Complete blood count did not reveal eosinophilia. Serology tests including hepatitis B and C, Anti-Nuclear antibody, cytoplasmic-ANCA and peripheral-ANCA were negative and C3 and C4 were normal. Kidney biopsy revealed tubulointerstitial inflammation composed of lymphocytes, eosinophils, epithelioid histiocytes and giant cells forming granulomas and some of the granulomas were perivascular.



Acid Fast Bacilli and fungal stains were negative for mycobacteria and fungi. Immunofluorescence was negative for IgG, IgA, IgM, C3c, C1q, kappa and lambda. Electron microscopy revealed thickened glomerular basement membranes and extensive epithelial foot process effacement. Patient was treated with steroids over a course of 2 months and Allopurinol was stopped. Her renal function significantly improved and her present serum creatinine level is 1.38mg/dl.

Conclusions: Granulomatous IN is an uncommon form of drug induced IN. Our patient had AKI because of granulomatous IN, most likely secondary to Allopurinol.

PUB034

Incidence and Mortality in Critical Units Patients Associated to Acute Kidney Injury: 30-Days and One-Year of Evolution Andres Boltansky,[1] Gabriel Cavada,[2] Guillermo Eugenio Villamizar,[1] Carlos E. Irarrazabal,[2] Antonio Vukusich.[1] *[1]Nefrología, Clinica Davila, Santiago, Chile; [2]Medicina, Universidad de los Andes.*

Background: The aim of this work was determine incidence and risk of mortality in Intensive Care Unit (ICU), Coronary Care Unit (CCU) and Intermediate Critical Care Unit (ICCU) patients associated to Acute kidney injury (AKI), considering intra hospital and 1-year evolution since discharge.

Methods: This is a historic cohort analysis of clinical data from patients admitted in the Critical Units (CU): ICU, CCU and ICCU, which belong to a tertiary health center in Santiago-Chile. Serum creatinine (SCr) variations in 48 hours were used for AKI classification (AKIN criteria). Information from each patient included demographics (age, sex), SCr measurements (estimated baseline and observed creatinine), and 30-days and one-year mortality. We enrolled 2703 patients discharged in 2010. A group of patients (969) were excluded, leaving 1734 patients for analysis (ICU: 366; CU: 347; IU: 981).

Results: The median age was 60.88 ± 19.65 (15 - 99) years, 53.23% were male. The incidence of AKI was 27.69% in CU (30.05; 33.72 and 27.69 % for ICU; CU; and ICCU, respectively). The mortality at before 30 days for no AKI patients was 6.38% (8.76; 2.63 and 3.52 % for ICU; CU; and IU, respectively) and increased for AKI patients: AKI-I 10.00% (Odds ratio [OR]: 1.63; Confidence interval [CI]: 1.02-2.58); AKI-II 15.38% (OR: 2.669, CI: 1.38-5.15); and AKI-III: 28.18% (OR: 5.762; CI: 3.57-9.27). The relationship between intra-hospital mortality and AKI III in the distinct CU was: ICU 35.29%, CCU 21.43% and, ICCU 16.33%. The mortality at before 1 year for no AKI patients was 16.05% and increased for AKI patients: AKI-I: 21.85% (OR: 1.42, CI: 1.02-1.96); AKI-II: 35.06% (OR: 2.73, CI: 1.67-4.47); and AKI-III: 43.60% (OR:3.918; CI: 2.60-5.88).

Conclusions: This data shows that an episode of AKI during a stay in critical units was associated to an increased general mortality before 30-days and one-year of evolution. Also, it shows that the general mortality was elevated in patients with higher AKI stages.

PUB035

Perfusion Pressure during Cardiac Surgery and Its Relation to Acute Kidney Injury Kristian Kandler,[1] Jens C. Nilsson,[2] Daniel Steinbrüchel.[1] *[1]Cardiothoracic Surgery, Rigshospitalet, Copenhagen, Denmark; [2]Cardiothoracic Anaesthesia, Rigshospitalet, Copenhagen, Denmark.*

Background: The aim was to investigate if a higher-than-standard mean arterial pressure (MAP) during cardiopulmonary bypass (CPB) could lower the incidence of acute kidney injury (AKI) after cardiac surgery.

Methods: Preliminary data from the first 16 patients (5 women and 11 men) in a randomized controlled trial was collected. Inclusion criteria are high preoperative risk of AKI (age > 70 years, coronary artery bypass plus valve surgery). The patients were randomized to a MAP > 60 mmHg (HG) or a control group (CG). Norepinephrine infusion was used to maintain a higher MAP. The outcome was measured by glomerular filtration rate (GFR) using Cr-EDTA clearance and urine neutrophil gelatinase associated lipocalin (NGAL) levels. The incidence of AKI was assessed using the AKIN criteria. The study is planned to include 100 patients.

Results: MAP during CPB was 63.4 ± 3.0 mmHg and 48.8 ± 1.7 mmHg ($p<0.0001$) in the HG and CG respectively. Comparing baseline GFR with 5 days postoperative measurements no differences were found between the groups, -4 vs. -15 ml/min ($p=0.49$) in the HG and CG. Urine NGAL levels increased by 33.5 [2.5–1386] ng/ml in the HG and by 163 [-73–1128] ng/ml in the CG ($p = 0.86$), comparing baseline values with postoperative values just prior to admission to the ICU. Five patients in the HG and 7 patients in the CG developed AKI ($p=0.57$).

Conclusions: No significant advantage were found in regard to the incidence of AKI using a higher-than-standard MAP during cardiac surgery.

Tacrolimus-Induced Thrombotic Microangiopathy Post Allogeneic Stem Cell Transplant Laith F. Al-rabadi,[1] Rawan T. Al-odat,[2] Christopher D. Blosser.[1] *[1]University of Iowa; [2]Jordan Hospital.*

Background: Calcineurin inhibitors (CNI), Tacrolimus and Cyclosporine, are key immunosuppression medications in this era of transplant. Graft versus host disease (GVHD) remains a major complication after allogeneic stem cell transplant (allo-SCT) with incidence of 5-20 %. Immunosuppression therapy is the standard response to GVHD, and Tacrolimus is preferred immunoprophylaxis for patients at high risk of GvHD. However, Tacrolimus has known systemic and nephrotoxic clinical and histopathologic features, including the rare, but clinically devastating thrombotic microangioathy (TMA). Renal injury is one of the most serious consequences of TMA, and hence nephrologists play an integral role in diagnosis and treatment.

Methods: Two Case reports and literature review.

Results: We describe two cases of Tacrolimus-induced TMA associated with renal injury. Both patients had high FK levels on presentation and experienced renal recovery after discontinuation of Tacrolimus. Interestingly, despite reintroduction of a CNI, both patients did not experience recurrent clinical or pathologic disease.

Conclusions: Members of the bone marrow transplant community posit that transplantation-associated TMA (TA-TMA) is distinct from de novo thrombotic thrombocytopenic purpura (TTP), and is associated with GVHD, infections, and medications. Others believe TMA is a form of TTP, and tacrolimus as one medication associated with the disorder. High FK levels have been associated with greater systemic disease, including kidney injury. Nasesen et al. suggested that the local effects are more essential than systemic factors in determining the toxicity of Tacrolimus, thereby arguing against the importance of dose-dependent toxicity. The treatment of Tacrolimus-induced TMA differs from idiopathic TTP, and portends a poor prognosis (mortality 60-90%). Medication discontinuation is the mainstay of treatment, as plasmapheresis is not indicated in Tacrolimus-induced TMA. Recent introduction of Rituxmab, and Daclizumab show promise in inducing remission. Here we discuss the potential mechanisms of the disease, compare and contrast dose related effect and local effect-hypotheses and modalities of treatment for Tacrolimus-induced TMA.

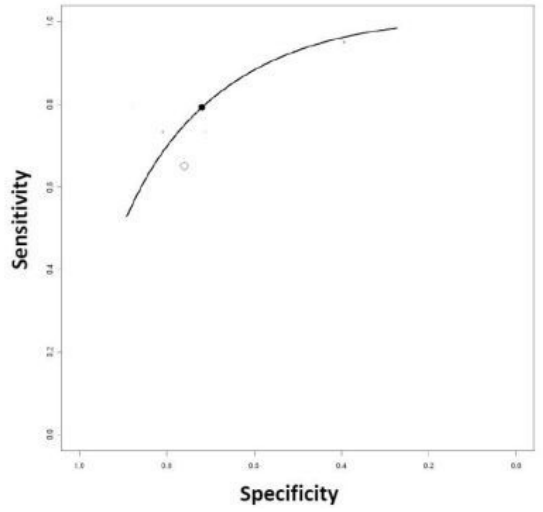
PUB037

Urinary Liver-Type Fatty Acid Binding Protein (L-FABP) for Detection and Prognostication of Acute Kidney Injury (AKI): A Systematic Review Paweena Susantitaphong,[1,2] Kent Doi,[3] Eisei Noiri,[3] Norma Terrin,[4] Bertrand L. Jaber.[1] *[1]Medicine, St. Elizabeth's Medical Center, Boston, MA; [2]Medicine, Chulalongkorn University, Bangkok, Thailand; [3]Department of Nephrology and Endocrinology, University of Tokyo, Tokyo, Japan; [4]Institute for Clinical Research and Health Policy Studies, Tufts University, Boston, MA.*

Background: Urinary L-FABP is a proximal tubular epithelial cell biomarker for early detection of AKI, with variable performance characteristics according to clinical settings. We performed a meta-analysis of all observational studies that have tested this biomarker in AKI.

Methods: We performed a literature search using MEDLINE, Cochrane Central Register of Controlled Trials, ClinicalTrials.gov, American Society of Nephrology scientific abstracts, and bibliographies of retrieved articles. Human studies investigating the performance characteristics of urinary L-FABP for diagnosis and prognosis of AKI were included.

Results: 13 prospective cohort studies and 2 case-control studies were identified. Only 5 cohort studies could be meta-analyzed. The estimated sensitivity of urinary L-FABP for the diagnosis of AKI was 78.6% (95% CI 63.1, 88.7) and the specificity 70.7% (95% CI 53.8, 83.3). The hierarchical summary receiver-operator-characteristic (HSROC) curve is displayed in figure 1. The estimated sensitivity of urinary L-FABP for predicting dialysis requirement was 69.1% (95% CI 34.6, 90.5) and the specificity 42.7% (95% CI 3.1, 94.5), and for predicting in-hospital mortality, 93.2% (95% CI 66.2, 99.0) and 78.8% (95% CI 27.0, 97.4), respectively.



Conclusions: Urinary L-FABP is a promising biomarker for diagnosing AKI and predicting adverse outcomes. However, the potential value of this biomarker in AKI needs to be further validated in large cohort studies and across a broader spectrum of clinical settings.

PUB038

Acute Kidney Injury (AKI) by Following Pulmonary Thromboendarterectomy (PTE) in Patients with Chronic Thromboembolic Pulmonary Hypertension (CTEPH) Jang Won Seo,[1] Soo Young Yoon,[1] Kim Kerr,[2] William Auger,[2] Michael M. Madani,[3] Stuart Jamieson,[3] Ravindra L. Mehta.[1] *[1]Department of Medicine, UCSD, San Diego, CA; [2]Division of Pulmonary and Critical Care Medicine, UCSD, San Diego, CA; [3]Division of Cardiothoracic Surgery, UCSD, San Diego, CA.*

Background: PTE is an established technique to improve pulmonary and cardiovascular (CV) function in CTEPH, however its effect on renal function is not known. Since PTE surgery requires complete circulatory arrest, we hypothesized that it would be associated with development of AKI. In addition, we postulated that the enhancement in CV performance would result in an improvement in renal function at hospital discharge.

Methods: We reviewed data from 123 adult pts. with CTEPH undergoing PTE enrolled in a prospective trial of a lung protective ventilation strategy to prevent acute lung injury. AKI was determined by the AKIN/KDIGO AKI criteria [sCr change ≥0.3 mg/dl or ≥50% within 48 hrs or urine output (UO) <0.5 ml/kg/hr >6 hrs]. Outcomes included duration of mechanical ventilation, ICU and hospital stay, and renal function at discharge.

Results: Fifty-one (41%) pts. developed AKI following PTE surgery; 25 (20%) met the sCr and 26 (21%) the UO criteria. Underlying CKD (CKD-EPI GFR < 60 ml/min per 1.73 m^2) was present in 10% and was more frequent in pts. with AKI (AKI 19.6% vs no-AKI 2.8%, p=0.003). The mean time to development and duration of AKI were 2.7 and 2.3 days, respectively. AKI and no-AKI pts. had a similar duration of ventilator requirement (median of 1.0 day, p=0.77) and significantly longer median lengths of stay in the ICU (AKI 4.0 vs no-AKI 3.0 days, p=0.02) and hospital (AKI 13 vs no-AKI 11 days, p=0.05). At discharge, renal function had improved in 40.6%, was unchanged in 56.1%, and had worsened in 3.3%. A similar trend was seen in pts. with pre-existing CKD (n=13) with over 76% showing improvement to an eGFR >60 ml/min.

Conclusions: We observed a high incidence of AKI following PTE which was associated with worse outcomes. Renal function improved following PTE and was similar in AKI and no-AKI pts. These findings highlight the importance of measuring renal function changes in CTEPH pts. undergoing PTE.

PUB039

Urinary Neutrophil Gelatinase-Associated Lipocalin (uNGAL) as a Biomarker for Early Identifying Acute Kidney Injury in Critically Ill Patients Maria De Fatima Vattimo,[1] Gabriela Fulan-silva,[2] Cassiane Dezoti Fonseca,[1] Mirian Watanabe.[1] *[1]School of Nursing, University of Sao Paulo, Sao Paulo, SP, Brazil; [2]Heart Institute, University of Sao Paulo, Sao Paulo, SP, Brazil.*

Background: Acute kidney injury (AKI) in intensive care unit (ICU) is frequent and is associated with increased mortality. Levels of uNGAL are correlated with the degree of tubular injury and it has been confirmed as the novel biomarker for early identification of AKI, renal replacement therapy (RRT) and death in critically ill patients. The aim of this study was to evaluate the utility of uNGAL compared with other renal parameters for the early detection of AKI.

Methods: Eighty three (n=83) critically ill patients were enrolled in this study. Urinary output, serum creatinine and uNGAL were evaluated. Urine and serum samples were collected 24 and 48 hours after intensive care unit (ICU) admission. AKI patients were stratified based on AKIN (stages I, II and III). The study was approved by Ethical Committee.

Results: Prevalence of AKI was 78.3%; being 44.6% patients admitted with AKI and 33.7% acquired ICU AKI. Among AKI patients, 50.8% were AKIN I, 20.0% AKIN II and 29.2% AKIN III. Highest levels of uNGAL were observed in the AKIN III group ($p<0.05$). uNGAL in the 24 and 48 hours were significantly higher in ICU AKI patients ($p<0.05$), with an area under the curve (AUC) 0.70. Non survivors and RRT patients, at every time point, presented higher uNGAL levels, while serum creatinine and urinary output did not show such tendency.

Conclusions: Our study concludes that uNGAL is a useful biomarker of AKI and is an early good predictor of the onset of ICU AKI.

PUB040

Relationship between Urinary Fractional Excretion of Sodium and Life Prognosis in Liver Cirrhosis Patients Naro Ohashi,[1] Yukitoshi Sakao,[2] Tomoyuki Fujikura,[1] Hideo Yasuda,[1] Akihiko Kato,[2] Yoshihide Fujigaki.[1] *[1]First Department of Medicine, Hamamatsu University School of Medicine, Hamamatsu, Shizuoka, Japan; [2]Blood Purification Unit, Hamamatsu University School of Medicine, Hamamatsu, Shizuoka, Japan.*

Background: Severe renal vasoconstriction in the setting of generalized vasodilatation with blood pooling in areas of vasodilatation and consequent reduction of effective arterial volume is the pathophysiologic basis in liver cirrhosis patients. Low levels of fractional excretion of sodium (FENa) are one of the effective markers to determine hypoperfusion of renal artery. However, the relationship between FENa and life prognosis in liver cirrhosis patients has not been elucidated yet.

Methods: We examined 19 liver cirrhosis patients (14 men and 5 women; mean age: 66.0±11.1 years; underlying liver cirrhosis: type B hepatitis in 2 patients, type C hepatitis in 11, alcoholic hepatitis in 5 and autoimmune hepatitis in 1) with renal damage (estimated glomerular filtration rate (eGFR) < 60 ml/min) that admitted to our hospital to treat complications of liver cirrhosis. Some parameters were compared between patients who survived and those who died during hospitalization.

Results: Eight of 19 patients were died because of uremia in 3 patients, liver failure in 3, and gastrointestinal bleeding in 2, respectively, and 11 patients had survived. Diuretics were administered to all of the patients. There were no differences in patient background, and the levels of serum creatinine and eGFR. However, in addition to total-bilirubin (T-Bil), glutamic oxaloacetate transaminase (GOT), prothrombin time (PT) (%), and Child-Pugh score, dead patients had significant difference about FENa (dead patients: 0.44±0.51% and alive patients: 1.08±0.45%, respectively, p=0.010). FENa levels were significantly and inversely correlated with T-Bil, GOT, and Child-Pugh score, and were significantly and positively correlated with PT (%). Moreover, the sensitivity (75%) and the specificity (100%) of FENa<0.5% about the death were extremely high.

Conclusions: In conclusion, it is possible that FENa in liver cirrhosis patients reflects the severity of disease condition and that it is associated with life prognosis.

PUB041

Urinary NGAL, L-FABP, and KIM-1 Trends in Pediatric Patients after Living-Donor Kidney Transplantation Akihiko Shirasu,[1] Akira Ashida,[1] Hyogo Nkakura,[1] Hideki Matsumura,[2] Motoshi Hattori,[3] Hiroshi Tamai.[1] *[1]Pediatrics, Osaka Medical College, Takatsuki, Osaka, Japan; [2]Pediatrics, Hirakata City Hospital, Hirakata, Osaka, Japan; [3]Pediatric Nephrology, Tokyo Women's Medical University, Tokyo, Japan.*

Background: Neutrophil gelatinase-associated lipocalin (NGAL), L-type fatty acid binding protein (L-FABP), and kidney injury molecule 1 (KIM-1) have emerged as early marker proteins that are predictive of acute kidney injury (AKI) in various clinical settings, including transplantation. However, the patterns of these marker proteins in pediatric patients after renal transplantation have not been studied in depth. Therefore, we examined the levels of these proteins in pediatric patients undergoing living-donor kidney transplantation. Additionally, we examined the relationship between these marker proteins and eGFR at discharge, in order to clarify whether they would be predictive of the graft function.

Methods: NGAL, L-FABP and KIM-1 in urine samples from seven pediatric patients on days 0, 1, 2, and 7 after transplantation, and at discharge, were examined. Urinary NGAL, L-FABP and KIM-1 were measured using an ELISA kit. eGFR was estimated using the Schwartz formula at discharge.

Results: Seven patients (5 males and 2 females, age 11.6 ± 4.3 years, range 5 to 17 years) were enrolled. All underwent living-donor kidney transplantation without any delay in graft function. The levels of NGAL and L-FABP were highest on day 0, and decreased rapidly to the normal range by day 2. The level of KIM-1 was increased on day 2 and then decreased gradually to the normal range. The eGFR at discharge ranged from 82.8 to 102.3 ml/min/1.73 m^2, and showed a tendency to be negatively correlated with the level of NGAL at day 0 (p=0.06).

Conclusions: In pediatric recipients, the levels of urinary NGAL and L-FABP decreased rapidly and normalized within 2 days after transplantation. This trend is similar to the adult. The level of NGAL on day 0 after transplantation appeared to be potential predictor of renal graft function.

PUB042

Renal Recovery Induced by Eculizumab in a Peritoneal Dialysis Dependent Child with Atypical HUS Omar Nihad Al Masri, Zubaida Al-Ismaili, Eslam Tawfik. *Pediatric Nephrology, Sheikh Khalifa Medical City Managed by Cleveland Clinic, Abu Dhabi, United Arab Emirates.*

Background: Atypical hemolytic uremic syndrome is an ultra-rare disease resulting from defective regulation of the alternative complement pathway. Kidney involvement can be severe resulting in renal failure or death despite therapy with plasma exchange or plasma infusion. Eculizumab (Soliris, Alexion), a monoclonal antibody directed against the complement protein C5, has shown success in inducing and maintaining remission in patients with atypical HUS. Only few cases of dialysis dependent patients that benefited from eculizumab have been reported.

Methods: We report a 2 y/o male who presented 3 months earlier to another hospital with severe acute renal failure associated with hemolytic anemia, thrombocytopenia, low C3 level and biopsy evidence of thrombotic microangiopathy. There was no history of diarrhea and ADAMTS 13 activity was normal .He remained on peritoneal dialysis since presentation despite treatment with daily plasma infusion for 1 week then thrice weekly for 3 months. He was transferred to our hospital where repeat kidney biopsy confirmed the presence of thrombotic microangiopathy with ischemic looking glomeruli and less than 50% chronic interstitial fibrosis. Eculizumab was initiated at dose 600mg then 1 week later 300 mg. Urine output slowly improved and plasma creatinine level continues to fall. 12 days after first dose of Eculizumab infusion the patient is currently dialysis free with creatinine level of 161µmol/L.

Conclusions: This case supports the role of Eculizumab in atypical HUS even if a patient has been dialysis dependent and oliguric for several months. The role of the repeat kidney biopsy prior to commencing Eculizumab was important in both confirming the diagnosis and degree of chronic damage thereby justifying its use.

PUB043

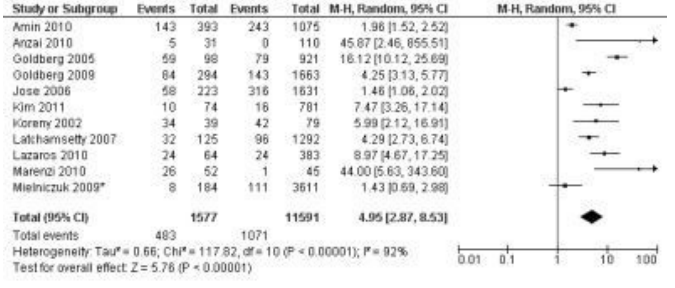
Cardio-Renal Syndrome Typre 1 in Acute Coronary Syndrome: A Systematic Review Dinna N. Cruz,[1] Manish Kaushik,[1] Claudio Ronco,[1] Sean M. Bagshaw.[2] *[1]St Bortolo Hospital, Italy; [2]University of Alberta, Canada.*

Background: Acute kidney injury (AKI) or worsening renal function (WRF) is an important complication of acute cardiac conditions, including acute heart failure and acute coronary syndrome (ACS). This was recently classified as Cardio-Renal Syndrome Type 1 (CRST1). The aim of this systematic review was to establish the incidence of CRST1 in patients hospitalized with ACS and describe its impact on mortality.

Methods: We searched Medline, EMBASE and CENTRAL for studies with original data on AKI and its associated mortality in ACS. Literature search, study selection and data extraction were performed in duplicate. Primary outcome was all-cause mortality. Pooled analysis was performed using a random-effects model. Adjusted odds/hazard ratios were extracted when available, and used in a secondary analysis.

Results: We identified 15 studies from 10 countries (n=249,482 patients). Sample size ranged from 76 to 147,007; follow-up ranged from duration of hospitalization to 48 mos; 2 large studies had 10-yr follow-up. AKI was variably defined using change in serum creatinine (ΔsCr) only (n=11 studies), ΔeGFR, either ΔsCr and/or ΔeGFR, either ΔsCr and/or urine output, or by Δblood urea nitrogen only (n=1 for all). CRST1 occurred in 67,978 (27.2%) subjects. CRST1 was associated with significantly higher odds for death (Fig.1, Odds Ratio 4.95; 95% CI 2.87-8.53, p<0.001; 11 studies, n=11,591). There was statistical heterogeneity across studies (I^2 92%, p<0.001). Using adjusted-OR (n=10 studies, n=10,522), CRST1 remained associated with a significantly higher odds of death (OR 1.99; 95% CI, 1.76-2.25, p<0.001; I^2 87%, p<0.001). The 2 largest studies reported mortality by AKI severity; in both, worse AKI was significantly associated with higher mortality.

Conclusions: In patients presenting with ACS, 1 in 4 develop clinically important CRS Type 1 that portends a higher risk of death.



PUB044

Weight Loss by Bariatric Surgery May Permit Patients with Significant Residual Renal Function to Come Off Dialysis Jack Rubin. *Medicine, Los Alamitos Medical Center, Los Alamitos, CA.*

Background: Many years ago a wise nephrologist was heard to say; "Patients shrink to the amount of dialysis provided them." But what if patients were shrunk to the amount of residual kidney function to support their body mass? Could they then be removed from dialysis? A BMI > 35 is present in almost 14% of Network 18 patients and of these 14% almost 22% have Diabetes. The average GFR of patients starting dialysis approximates 10 ml/min.

We report two patients who underwent bariatric surgery and after substantial weight loss came off dialysis. Patient 1, age 60, had chronic interstitial nephritis from repeated urinary tract infections and recurrent stone disease as well as type 2 diabetes as the major etiologies of renal failure. She was on dialysis 1208 days of which 508 days occurred after banding and gastric bypass surgery. She weighed 312 pounds at the start of dialysis and 142 at the end. Her residual renal function was 6 ml/min at the start and 13 ml/min at the end. She has been off dialysis over 2 years. Her residual renal function remains 13 ml/min. Patient 2, age 55, had type 2 diabetes and acute renal failure culminating in dialysis (possible cortical necrosis) as the cause of renal failure. He was on dialysis 828 days of which 469 were after gastric banding. His residual renal function at the start of dialysis was 15 ml/min and 20 ml/min when removed from dialysis. He weighed 292 pounds at the start of dialysis and 200 pounds when removed from dialysis. He has been of dialysis 3 months and his residual renal function remains 20 ml/min.

It seems sensible to consider offering bariatric surgery to patients with adequate residual renal function, especially since it may convert a dialysis patient to a non dialysis office patient with "just" chronic renal failure. Removing these potentially many selected patients from dialysis by bariatric surgery seems a better and perhaps less expensive option then a long wait on dialysis for an expensive transplant that may never to come because they are too big.

PUB045

Acute Renal Failure due to Anaplasmosis or Thrombotic Thrombocytopenic Purpura? Manish K. Saha,[1] Tarek Hamieh,[1] Vishal Sagar.[1] *[1]Internal Medicine, Health Partners; [2]Internal Medicine, Health Partners; [3]Nephrology, Health Partners.*

Background: Patients who present with fever, confusion, in the setting of acute renal failure and thrombocytopenia almost always begin with a presumptive diagnosis of TTP/HUS. We present a case series of 3 patients who had similar presentations. Peripheral blood smear (PBS) did not reveal schistocytes, but rather, anaplasmosis/ehrlichiosis.

Results: All patients presented in the summer months, from Midwest, with fever, confusion, and diarrhea. Relevant clinical and laboratory data as noted in the table.

Table 1

Case	Creatinine(mg/dl)	Post Rx creatinine	FENA	HGB(g/dl)	Platelet(K/UL)	ALT	CPK
1	4	1.4	<1	13	27	40	451
2	11	1.5	3	12	22	252	3648
3	6.5	1.6	2	12	44	40	235

Urinalysis showed active sediments with minimal proteinuria.

Conclusions: The combination of fever, confusion, renal failure, and thrombocytopenia in our patients initially directed us to entertain TTP/HUS as the main differential diagnosis. However, there was no evidence of hemolysis on PBS. Given the prevalence of tick-borne illnesses in the summer, a PBS of Buffy coat was done. All patients were found to have anaplasmosis/ehrlichiosis. Two patients initially required hemodialysis on presentation. Treatment with doxycylcine resulted in rapid improvements in renal function. Anaplasmosis-Ehrlichosis are tick born bacterial illnesses most prevalent in Midwestern and Northeastern region. Our case series highlights the need to consider anaplasmosis in the work up of patients presenting with TTP/HUS like picture. A high index of suspicion leads to early diagnosis and initiation of therapy. Although one case report had suggested rhabdomyolysis causing renal failure with anaplasmosis, our patients had minimally elevated creatine kinase. The presence of active sediment on urinalysis and improvement in renal function with doxycycline suggest infectious interstitial nephritis as a possible mechanism of renal failure. Acute tubular necrosis or hypovolemia due to diarrhea can also play a role. Renal biopsy may assist in understanding the pathogenesis; however, given the profound thrombocytopenia in our patients and rapid improvement with initiation of antibiotics, biopsy was not preformed.

PUB046

Urine Sediment Contains Acute Kidney Injury-Specific Proteins Nithin Karakala, Benjamin Neely, Alison Bland, Joseph Alge, Michael G. Janech, Juan Carlos Q. Velez, John M. Arthur. *Department of Medicine, Nephrology, Medical University of South Carolina, Charleston, SC.*

Background: Urine sediment(SED) is an important source of information in the diagnosis of acute kidney injury (AKI). While urine supernatant (SUP) has been investigated for identifying diagnostic and prognostic biomarkers of AKI, no studies have attempted to identify candidate markers in SED. We hypothesized that urine SED may contain proteins of diagnostic value for AKI.

Methods: Urine was collected from 4 patients in the medical ICU without AKI and 4 with AKIN stage 3 AKI. Liquid chromatography/tandem mass spectrometry was used to identify proteins that are different between SUP and SED.

Results: We identified 666 proteins (327 SUP no AKI, 459 SED no AKI, 413 SUP AKI and 420 SED AKI). 16 and 36 proteins were unique to the SED AKI and SED no AKI groups respectively. 26 proteins were statistically (p<0.5) more abundant and 15 less abundant in SED AKI compared to the other groups. Analysis of Gene Ontology (GO) terms showed that SED AKI is enriched in proteins derived from mitochondria. These differences could be related to mitochondrial injury or to biogenesis. No other differences in GO term frequencies were seen between groups. Tsukushin and Xaa-Pro dipeptidase were present in 3 out of 4 AKI SED samples and none of the other 12 samples. These proteins are predominantly present in the cytoplasm of renal tubular cells. Tsukushin is a

small leucine-rich repeat proteoglycan that forms a coat on the fibril surface that impedes access to collagenolytic proteinases. It could be playing a role in tubular cell regeneration after AKI. Xaa-Pro dipeptidase splits dipeptides with a prolyl or hydroxyprolyl residue in the C-terminal position. It plays a role in collagen metabolism and may be important in the regulation of basement membrane deposition or degradation.

Unique Proteins

	Supernatant	Sediment
AKI 3	49	15
Without AKI	16	36

Conclusions: Urine sediment contains proteins present in different abundances than the supernatant in AKI. Analysis of the sediment could be a gateway to identifying novel biomarkers and understanding mechanisms of injury and repair.

PUB047

Predictors of Acute Kidney Injury Following on Pump Cardiac Surgery Keren Grynberg,[1,3] Kevan Polkinghorne,[1,2] Jonathan Barrett,[3] Shaun A. Summers.[1,2] *[1]Department of Nephrology Monash Medical Centre, Southern Health, Melbourne, Victoria, Australia; [2]Department of Medicine, Monash University, Melbourne, Victoria, Australia; [3]Intensive Care Unit, Cabrini Health, Melbourne, Victoria, Australia.*

Background: Acute kidney Injury (AKI) post cardiac surgery is a poor prognostic indicator, which independently predicts mortality. Newer published biomarkers are expensive and are not routinely available in clinical practice. We aimed to define the incidence of AKI post cardiac surgery, to identify pre-morbid and operative risk factors for developing AKI, and to accurately predict patients at risk of AKI using routine biochemical tests.

Methods: We prospectively studied 93 consecutive patients undergoing elective (on pump) cardiac surgery. Baseline patient characteristics, including presence of medical co-morbidities, proteinuria, procedural data and kidney function (serum creatinine (sCr) were collected. Internationally standardised criteria for AKI was used, (sCr >1.5 times baseline, elevation in sCr >26.4 µmmol/L (0.3mg/dl), or urine output< 0.5ml/kg/hr for >6 hours within 48 hours). Measurements were collected pre-operatively, within 2 hours of surgical completion and daily for two days. Logistic regression was used to assess predictive factors for AKI including immediate post operative (OPsCr). Model discrimination was assessed using ROC AUC curves.

Results: 18 (19%) patients developed AKI in the post operative period. Inotrope use (OR 3.90, p<0.026), preoperative eGFR (OR 0.96, p=0.013), but not proteinuria (OR 2.58, p=0.11) were associated with AKI in univariate analysis. A multivariate logistic model with preoperative and surgical factors (age, gender, eGFR, proteinuria, cardiac bypass time & inotropes) demonstrated moderate discrimination for AKI (ROC AUC 0.76). The addition of OPsCr improved model discrimination for AKI (AUC 0.83) independently associated with AKI (OR 1.39/µmol increase, 95% CI 1.05-1.82, p=0.018).

Conclusions: 1 in 5 patients developed AKI post cardiac surgery. The development of AKI post cardiac surgery is strongly linked to patient morbidity and mortality. OPsCr accurately predicts the development of AKI, providing a cheap readily available prognostic marker.

PUB048

Comparison of Interstitial Inflammatory Pattern of Acute Interstitial Nephritis with Various Etiologies Cui Li, Tao Su, Rong Chu, Xiaomei Li, Li Yang. *Renal Division, Peking University First Hospital, Beijing, China.*

Background: Acute interstitial nephritis (AIN) accounts for 10% of biopsied acute kidney injury, and is pathologically characterized by dramatic interstitial inflammation with intact glomeruli. Drug hypersensitivity and autoimmune diseases are the major causes of AIN. This study aimed to investigate the difference of inflammatory infiltrate in AIN patients with various etiologies.

Methods: One hundred patients, 21 men and 79 women, aged 47±13y, were clinical-pathologically diagnosed as AIN from 2001 to 2011 and enrolled in the study. More than one year follow-up was performed to ascertain the etiology of AIN. Inflammatory cells were determined on the renal biopsy specimens through immunofluorescence staining of anti-CD3 (T lymphocyte), CD20 (B lymphocyte), CD68 (Monocyte/Macrophage), CD38 (Plasma cell) and neutrophil elastase (Neutrophil). Eosinophil was detected with H&E staining. The number of positive cells was counted and the difference among the AIN cases with various etiologies was tested.

Results: Sixty-three patients had drug hypersensitivity AIN (DAIN), 22 developed Tubulointerstitial Nephritis and Uveitis syndrome (TINU, 13 had later onset uveitis) and 15 were of Sjogren's syndrome (SS). Patients of DAIN and TINU exhibited comparable amount of interstitial infiltrates (402±120 vs 436±122 /400xHP) with similar inflammatory cell proportion, T lymphocyte (46±8% vs 48±8%), Monocyte/Macrophage (26±7% vs 24±6%), B lymphocyte (12±6% vs 13±3%) and Plasma cell (11±5% vs 10±4%). Neutrophil and Eosinohil were common in both groups. Patients with SS had fewer infiltrates (323±107, p=0.02), more plasma cells (30±14%, p=0.000) and less percentage of the rest kinds of inflammatory cells (p<0.001). Neutrophil or eosinohil was rarely seen in SS kidneys (p=0.000).

Conclusions: DAIN and TINU exhibit the same pattern of renal inflammatory infiltration, making the differential diagnosis rather difficult in those who develop uveitis later on. Cellular immunity is the major immune response while the pathogenic role of the 20% humoral immune infiltrates needs further investigation. The SS related AIN lacks acute inflammatory response, and the humoral immunity plays a key role.

PUB049

Kidney Injury Molecule-1 Is More Sensitive Biomarker on Contrast-Induced Nephropathy in Children Min Hyun Cho, Youngju Hwang. *Pediatrics, Kyungpook National University Hospital, Korea.*

Background: Contrast-induced nephropathy (CIN) is an important cause of acute kidney injury (AKI) in hospitalized patients. The aim of this study was to discover the reliable and sensitive biomarkers on AKI caused by the contrast material used for cardiac catheterization in pediatric patients with congenital heart disease.

Methods: A variety of clinical findings were analyzed in 26 children that received cardiac catheterization for congenital heart disease; including the amount of contrast agent used and the level of serum creatinine before and after the catheterization. No patient had a prior history of renal disease. The level of urine KIM-1, NGAL, IL-18, L-FABP as candidate biomarkers for AKI were evaluated before and 6, 24, 48 hours later after catheterization by ELISA and compared with each other.

Results: The mean age of the patients was 7.1 years and the male: female ratio was 12:14. Although only one patient had cyanosis caused by pulmonary atresia (oxygen saturation 89%), the others had no cyanosis or congestive heart failure. Ultravist®, a low osmolar dye, was used as the contrast media in all 26 cases; the amount of contrast agent used was on average 31.2±16.7 mL (2.5±2.8 mL/kg of weight). The levels of serum creatinine were checked before, 6h, and 24h after catheterization and showed little change within the normal range as: 0.4±0.19, 0.41±0.19, 0.41±0.22 mg/dL, respectively. The level of urine IL-18, NGAL and L-FABP also showed no significant change to the infusion of contrast. However, the average levels of the urine KIM-1 evaluated before, at 6h, 24h and 48h (N=11) after catheterization were: 70.94±80.83, 78.33±52.5, 107.98±94.2 and 133.21±136.86 pg/mL respectively, showing a progressive increase after catheterization. There was significant difference between the level of KIM-1 before and at 24h after catheterization.

Conclusions: KIM-1 is more sensitive biomarker on contrast-induced AKI in children than other biomarkers including NGAL, IL-18 and L-FABP. Further prospective research is needed.

PUB050

Three Demensions of Hospital-Acquired Acute Kidney Injury ImpactLong-Term Outcome Jinyoung Yoo, Jiyeon Lee, Jin Seok Jeon, Hyunjin Noh, Dong-Cheol Han, Soon Hyo Kwon. *Internal Medicine, Soon Chun Hyang University Hospital, Seoul, Korea.*

Background: Acute kidney injury (AKI) has 3 dimensions; severity, reversibility and duration. We investigated whether these dimensions of AKI impact long-term survivals in hospital-acquired AKI patients.

Methods: We monitored serum creatinine everyday for all patients admitted in Soon Chun Hyang Hospital using a hospital data survey system from Sep. 2007 to August 2008. One hundred twenty three hospital-acquired AKI patients were followed up until 2011. Duration of AKI was categorized as AKI for 1 to 2, 3 to 6, at least 7 days and persistent AKI on the basis of renal recovery back to baseline at the time of discharge. And the severity of AKI was classified by AKIN staging criteria. Kaplan-Meier techiniques were used to conduct the survival analysis.

Results: Duration of AKI: 1 to 2 days (32; 26%), 3 to 6 days (23; 18.7%), at least 7 days (27; 22%), persistent AKI (41; 33.3%) were categorized. AKI stage was classified as stage 1, 28.5%, stage 2, 30.9%, and stage 3, 40.7%. The median follow-up duration was 240 days (53 - 1428 days). Our data showed that persistent AKI and AKIN stage 3 were associated with high mortality (p<0.001, p=0.023). There was no difference in long-term outcome between each duration group (p=0.365).

Conclusions: Severity and reversibility of AKI impact mortality in hospitalized patients. Even short duration of AKI has same effects in long-term outcome compared to long duration group.

PUB051

Carpediem: Cardio-Renal Pediatric Dialysis Emergency Machine: A New Hope for Infant Francesco Garzotto,[1] Anna Clementi,[1] Jeong Chul Kim,[1] Roberto Cena,[2] Monica Zanella,[1] Claudio Ronco.[1] *[1]Dep of Nephrology and IRRIV, St. Bortolo, Vicenza, Italy; [2]Bellco, Mirandola, Italy.*

Background: Although acute kidney injury is a well known independent risk factor for increased morbidity and mortality in critically ill paediatric patients, a safe and specific renal replacement therapy does not still exist.The Cardio-Renal Pediatric Dialysis Emergency Machine (CARPEDIEM) was designed for newborns and infants.The aim of our study was to evaluate their performance respect to some of the design constraints.

Methods: Arterial and venous line pressures were evaluated with a 5FR (3L,11cm) and a 5FR(2L,13cm) catheters, using bovine blood (hct 35%) at increasing values of blood flows.The filtration fraction was kept constant at 20%.The UF vs TMP characteristics was assessed using the 0.147m^2 dialyzer and a 4 FR catheter(2L, 5cm) varying UF from 0 to 4 ml/min at 4 different Qb(10–30mL/min) recording the corresponding stabilized TMPs. The m-hemolysis was evaluated by measuring the normalized (by hematocrit) index of hemolysis (NIH).We tested, with 1L of bovine blood hct 45% circulated for 10 hours,3 different kits with 3 tests each:1st with the 0.075m^2 dialyzer and a Qb of 40 ml/min,2nd with the 0.245m^2 and a Qb of 50mL/min,3rd without the dialyzer.

Results: As shown in Figure 1, arterial and venous blood pressures,varied within a safe range up to 30mL/min of Qb. Figure2 reports the UF vs TMP relationships which are non linear at low Qb (10-15) with a plateau at 80 mmHg,while are linear at higher Qb in the range of allowed UF.As expected,an increase of Qb was associated to a decrease of TMP. Figure3 reports the mean of NIH.The µ-hemolysis index which is always lower than 10,7x10^-4,no difference were observed.

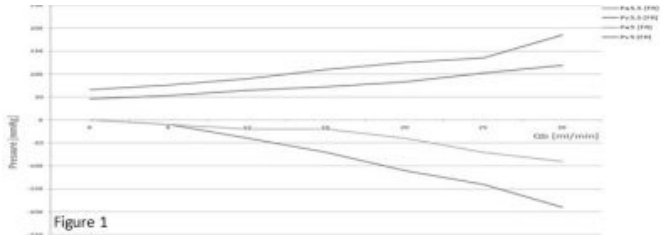

Figure 1

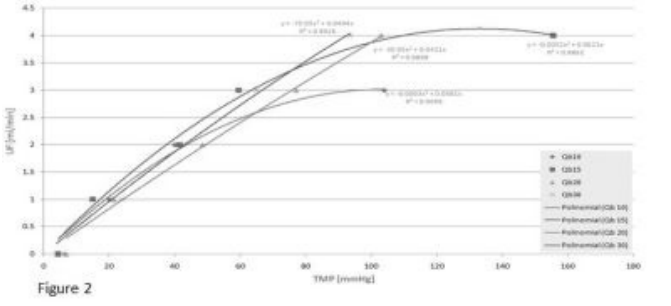

Figure 2

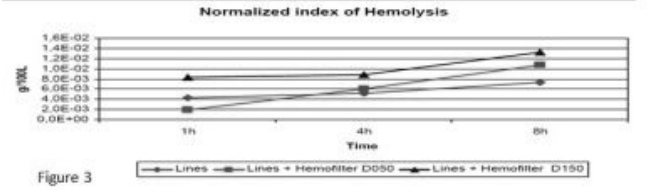

Figure 3

Conclusions: The CARPEDIEM performance connected to different small catheters seems to be adequate to treat paediatric patients safely.Pressure values were stable during all the phases of the test.

PUB052

Caucasian Race as Risk Factor for Vancomycin Nephrotoxicity Srujana Polsani,[1] Jolina Pamela C. Santos,[1] Kisra Anis,[1] Andi Qipo,[1] Belinda Bun Jim.[1] *[1]Jacobi Medical Center; [2]Albert Einstein College of Medicine, Bronx, NY.*

Background: The incidence of vancomycin nephrotoxicity ranges from 14.6 to 29.6%. Risk factors include high trough levels, duration of therapy, concomitant nephrotoxins, obesity and advanced age. Here we confirm well known risk factors, as well as describe novel features of vancomycin nephrotoxicity from an inner city hospital that serves predominantly a minority population.

Methods: We report on 7 cases of vancomycin nephrotoxicity encountered between July 2011 and June 2012. Clinical data such as age, sex, race and ethnicity, comorbidities, dose and duration of vancomycin therapy, vancomycin levels, BUN and serum creatinine were collected.

Results: We found that the median (interquartile range) age was 87 years (63, 90), vancomycin level 40.7 (30.1, 50.8), and peak BUN-to-serum creatinine ratio 11.5 (10.6, 16.9) for all cases. Administration of vancomycin ranged from 4 to 14 days, all via intermittent dosing. There was a predominance of females (71%) vs males (29%) affected. All of the patients were on piperacillin-tazobactam (100%). Forty-two percent of patients had BMI of less than 18 kg/m^2, while 58% had BMI of greater than 20 kg/m^2. Unexpectedly, there was a high percentage of Caucasians affected (43%) vs. African Americans (29%), Hispanics (14%) and Asian Americans (14%). Given that racial mixture of our hospital consists of only 6.5% Caucasians, with African American making up 31.5% and Hispanics 48.5%, this suggests the Caucasian race is an additional risk factor. We also note that the BUN-to-serum creatinine ratio is relatively low (<20), helping to discriminate from a pre-renal state.

Conclusions: We conclude that though our series of patients exhibited traditional risk factors, we also discovered unique features such as the Caucasian race as a new risk factor, a stronger than usual association with piperacillin-tazobactam, and a notable "low" BUN-to-serum creatinine ratio. Given that novel risk factors still being discerned, we recommend to initially follow vancomycin levels until proper dosing can be established. These findings are being confirmed in a larger cohort.

PUB053

The Risk Stratification for the Development of Acute Kidney Injury after Orthopedic Surgery: Preliminary Report Tae Hee Kim,[1] Mi Seon Kang,[2] Sunwoo Kang,[1] Yang Wook Kim.[3] *[1]Internal Medicine, Busan Paik Hospital, University of InJe, Busan, Republic of Korea; [2]Pathology, Busan Paik Hospital, University of InJe, Busan, Republic of Korea; [3]Internal Medicine, Heaundae Paik Hospital, University of InJe, Busan.*

Background: Acute kidney injury (AKI) following operation is associated with increased morbidity and mortality. Specific risk stratification and prognostic scores for the development of AKI has been reported well after cardiac surgery. Recently orthopedic surgery was increased due to aging, trauma, and accident. But, there is little known about postoperative AKI risk after orthopedic surgery. We could easily and accurately identify high-risk patients for the development of AKI following orthopedic surgery.

Methods: From January 2007 to November 2011, 488 patients undergoing orthopedic surgery at Busan Paik Hospital, University of InJe were evaluated. Inclusion criteria were the following: male and female: above 18 years of age: using general anesthesia: femur surgery. Univariate and multivariate analyses were used to evaluate pre-, intra-, and postoperative parameters associated with AKI (underlying disease, serum creatinine, albumin, hemoglobin, bicarbonate, transfusion or not, and pre-op cardiac function). The definition of AKI used an increase of 50% above baseline serum creatinine.

Results: The incidence of AKI was 2.7% (n=13), there was no one who required dialysis.

58 patients had already chronic kidney disease or AKI. 96.6% (n=56) among 58 patients after surgery improved or didn't change their baseline serum creatinine. We suggest that preoperative hydration, short operation time, and postoperative intensive care.

The limitation of this preliminary report is that the incidence of AKI is very low (2.7%), and the reliability of statistical analyses is not confident.

Conclusions: We extended and reevaluated patients including knee orthopedic surgery.

PUB054

Acute Kidney Injury with Normal Urinalysis Alon Antebi, Daniel Kushnir, Victor Frajewicki. *Department of Nephrology and Hypertension, Carmel Medical Center, Haifa, Israel.*

Background: Acute kidney injury (AKI) is associated with increased risk for development of CKD or death. Urine examination is the oldest and one of the most commonly used tests for differential diagnosis of AKI.

Methods: We reviewed complete electronic records for all patients who were admitted to the our service due to AKI, during a 3 year period (2004-2007). Patients with normal urinalysis were selected.The cause of AKI was recorded from the final diagnosis. Urinary ultrasound was performed in all patients before admission to the Nephrology ward.

Results: Of 227 patients (266 admissions) who met inclusion criteria of AKI, 19 cases (7%) were found with normal urinalysis, aged 71±14 years.

Cause of AKI

Clinical Diagnosis	Incidence (%)
Prerenal Azotemia	68.0
Cardio-renal Syndrome	10.5
Obstruction	5.2
Sepsis	5.2
CKD	5.2
Unknown	5.2

In 6 cases AKI was considered drug related, mostly ACEI. Serum creatinine at admission was 3.2 ± 1.5 mg/dl (range 1.5-6.5) with a concomitant urea level of 162 ±93 mg/dl (range 33-380). Admission blood pressure was 127±26/69±16 mmHg. No kidney biopsy was performed in these patients. Two (10%) needed temporary dialysis treatment, but no patient required permanent dialysis. All patients were discharged alive with improvement of their kidney function. Hospitalization length was 5.9±2.4 days.

Conclusions: AKI with normal urine examination is related to prerenal azotemia in most cases if urinary tree obstruction is rouled out before admission. Drug related renal dysfunction should be considered in the differential diagnosis. Short term prognosis was excellent, which allowed to discharge 100% of patients.

PUB055

Path Batch Hemodialysis (PBH): A Safe and Efficient Method for Acute Kidney Injury (AKI) Cancer Patients in the Intensive Care Unit (ICU) Veronica T. Costa e Silva,[1] Ana Paula Leandro Oliveira,[1] Elerson Costalonga,[1] Henrique Palomba,[1] Ludhmila Abrahão Hajjar,[2] James Hung,[1] Cilene Muniz Soares,[1] Juliana Silva Bezerra,[1] Luciane Oikawa,[1] Luis Yu,[1] Emmanuel A. Burdmann.[1] *[1]Nephrology Division, Sao Paulo State Cancer Institute - University of Sao Paulo School of Medicine, Sao Paulo, Brazil; [2]Intensive Care Unit Department, Sao Paulo State Cancer Institute - University of Sao Paulo School of Medicine, Sao Paulo, Brazil.*

Background: The adequacy and safety of PBH have not been evaluated in AKI ICU cancer patients (pcts).

Methods: We prospectively analyzed all PBH performed in AKI adult cancer pcts in the Sao Paulo State Cancer Institute ICU from June 2010 to February 2012.

Results: A total of 373 PBH were performed in 116 AKI cancer pcts. Their characteristics were age 61 14 y, 62.1% male, 18.5% on vasopressors and 10.2% on mechanical ventilation. Most pcts (81%) had solid cancer (urinary tract 41.4%,

gastrointestinal tract 13.8% and gynecologic system 12.1%). The most important AKI etiologies were sepsis (55.2%), obstructive uropathy (27.6%) and surgeries (25.0%). Hospital mortality was 59.5%. Venous access was temporary catheter in 97.9% (58% femoral and 44% internal jugular veins), high-flux polysulphone membrane filters (FS80 in 67%) were utilized and median blood and dialysate flows were 250 (200 300) mL/min. They received 2.97 1.1 hemodialysis (HD) during 4.9 +/- 2.1 days of therapy. Median received Kt/V per session was 0.95 (0.80 – 1.10) and an adequate metabolic control was achieved (post dialysis tests results): Cr 2.70 (1.96 – 3.59) mg/dL; urea 71 (49 – 102) mg/dL; bic 24.2 (22.5 – 25.5) mEq/l; K 3.8 (3.5 – 4.1) mEq/l. The prescribed ultrafiltration was 1500ml (500 2000) which was obtained in 66% of the procedures. The prescribed dialysis time was 240 (240 360) min which was attained in 75% of HDs. The main complications were: hypotension (mean blood pressure <70 mmHg) in 24.9% of HDs, but only 6.3% required dialysis interruption; prescribed blood flow reduction in 6.7%; lines reversion in 19.8% and lines clotting with dialysis interruption in 16.9%.

Conclusions: PBH was as a safe and adequate alternative for HD in this group of AKI ICU cancer pcts.

PUB056

Acute Kidney Injury in a London District General Hospital: Retrospective Audit Data from the North Central London Acute Kidney Injury Network
Arunraj Navaratnarajah,[1] Peter Simon West,[2] Chris Laing,[3] Shyama Dakshina Jayasena.[2] *[1]Kings College London Hospital, London; [2]North Middlesex University Hospital, London; [3]Royal Free Hospital, London.*

Background: The NCEPOD audit 'Adding Insult to Injury' highlighted deficiencies of care in AKI management. The North Central London Acute Kidney Injury Network was established to address these deficiencies at a local level. We present baseline audit data from a London District General Hospital prior to network implementation.

Methods: Patients aged >16 admitted with AKI to North Middlesex University Hospital, London, between March 1st 2009 and March 1st 2010, were reviewed. Cases were included if criteria for AKI stage 3 (AKIN classification) were fulfilled.

Results: 40 patients with AKI3 were audited. No risk assessment was documented in any patient, though co-morbidity scores were high on review. Risk factors included dehydration (65%), sepsis (55%) and ACE-i / ARB / NSAID therapy (53%). 98% of patients had appropriate admission observations. 63% of patients had timely consultant review. 93% received appropriate fluid resuscitation. Cessation of potential nephrotoxins occurred in 83%. 50% were imaged either by US (40%) or CT (10%) within 12 hours. Of septic patients (63%), 84% were given timely administration of antibiotics. 50% of patients were referred to nephrology. 1 patient required transfer to the local tertiary centre for renal replacement therapy (RRT). 5 patients (13%) were admitted to ITU, 2 for RRT alone. In 35%, renal function returned to baseline pre-discharge. Of those that did not (40%, excluding deaths), 38% had nephrology follow-up, 31% primary care follow-up and 25% no follow-up. 20% died during admission due to renal failure. Subsequent follow-up revealed a further 13% mortality.

Conclusions: Problems were highlighted at individual, local and regional level. Local factors include i) delays in access to imaging ii) use of critical care beds due to lack of specialist renal beds iii) limitations of coding in identifying serious AKI. Regional issues include lack of co-ordination of care between district general and tertiary centres for specialist renal care. We hope the network initiative will improve all aspects of AKI care.

PUB057

Factors Associated with Acute Kidney Injury in Patients with Post Hepatic Resection
Mary Muoneke, Bruce E. Berger. *[1]Case Western Reserve University/ St Vincent Charity Medical Center; [2]Nephrology, University Hospitals Case Medical Center.*

Background: We looked at the development of Acute Kidney Injury(AKI) following hepatic resection. We defined AKI as an absolute increase in the serum creatinine level of 0.3mg/dl or above from baseline within 48hours. In this study, we explored the relationship between AKI post resection & co-morbidities like Diabetes, Hypertension, Chronic Kidney Disease (CKD)& use of medications such as Angiotensin converting enzyme inhibitors(ACEI) or non steroidal anti-inflammatory drugs(NSAIDS).

Methods: To understand the distribution of important variables in the study, a univariate analysis was conducted. Between Dec, 2010 & Dec 2011, 69 consecutive patients underwent hepatic resection. 31 for primary malignancy& 38 for metastatic malignancy.8 patients developed AKI post hepatic resection& were compared to 8 randomly selected patients from a pool of 61 patients who had hepatic resection but no AKI.

Results: 75% of the participants in both groups were males. Mean age in the AKI group was 60yrs & 62yrs in non AKI group.

The odds of Hypertension among the individuals with AKI was 80% higher compared to the odds among those without AKI.

The odds of Diabetes among individuals with AKI was 57% lower compared to the odds among those without AKI

The odds of CKD among those with post hepatic resection AKI was similar to the odds among those without AKI.(OR=1.00)

Prior use of NSAIDS and/ or ACEI showed a remarkable association with AKI post resection.There was a 21 fold increase in the odds of regular use of NSAIDS and/or ACEI among those with AKI compared to those without AKI.

There was no observed changes in liver function tests among those with AKI compared to those without AKI.

Conclusions: AKI post hepatic resection was found to be significantly associated with prior use of NSAIDS and/or ACEI & hypertension and inversely associated with diabetes. There may be a need to investigate these variables as collective factors in AKI as well as replicate this study in a larger population.

Limitation:This study has a relatively small sample size although the findings may help direct future investigations into the cause of AKI in post resection patients.

PUB058

Factors Related to Coagulation in Non Continuous Hemodialysis (NCHD) for Acute Kidney Injury (AKI) Cancer Patients in the Intensive Care Unit (ICU)
Veronica T. Costa e Silva,[1] Cilene Muniz Soares,[1] Henrique Palomba,[1] Elerson Costalonga,[1] Ludhmila Abrahão Hajjar,[2] James Hung,[1] Ana Paula Leandro Oliveira,[1] Luciane Oikawa,[1] Juliana Silva Bezerra,[1] Luis Yu,[1] Emmanuel A. Burdmann.[1] *[1]Nephrology Division, Sao Paulo State Cancer Institute - University of Sao Paulo School of Medicine, Sao Paulo, Brazil; [2]Intensive Care Unite Department, Sao Paulo State Cancer Institute - University of Sao Paulo School of Medicine, Sao Paulo, Brazil.*

Background: Factors which could lead to dialysis inefficiency or interruption have not been well studied in AKI ICU cancer patients (pcts).

Methods: We prospectively analyzed all NCHD performed in AKI adult cancer pcts in the Sao Paulo State Cancer Institute ICU from June 2010 to February 2012.

Results: A total of 373 NCHD sessions were performed in 116 AKI pcts. Pcts' characteristics were age 61 +/- 14 y, 62.1% male, 18.5% on vasopressors. Most (81%) pcts had solid cancer, 35.7% with metastatic disease (MD) and 16.4% with previous chemotherapy (CT). Sepsis was the most important AKI etiology factor (55.2%). Hospital mortality was 59.5%. Venous access was temporary catheter (11 Fr) in 97.9% (58% femoral and 44% internal jugular veins). Catheter malfunctioning (CM), defined as prescribed blood flow reduction or lines reversion was observed in 6.7% and 19.8% of hemodialysis (HD), respectively. High-flux polysulphone membrane filters were utilized (FS80 in 67%). Median blood and dialysate flows were 250 (200 300) mL/min, achieved ultrafiltration was 1000 (500 2000) ml and dialysis time was 240 (180 300) min (18.5% of HD > 6 h). Heparin was not used in 66% of the procedures due to contra-indications. Lines clotting causing dialysis interruption was observed in 16.9% of the sessions and was related to CM (OR: 3.01/CI:1.72 - 5.22) and heparin use (OR: 0.33/0.79 – 0.93). The following factors were not related to clotting: catheter site (P: 0.105 and 0.100, for femoral and jugular sites, respectively); HD > 6 h (P: 0.209); MD (P: 0.332); previous CT (P: 0.293); thrombocytopenia (P: 0.265); coagulopathy (P: 0.090) and hypotension (P: 0.103).

Conclusions: Factors related to clotting in NCHD AKI ICU cancer pcts were mostly related to CM and heparin use.

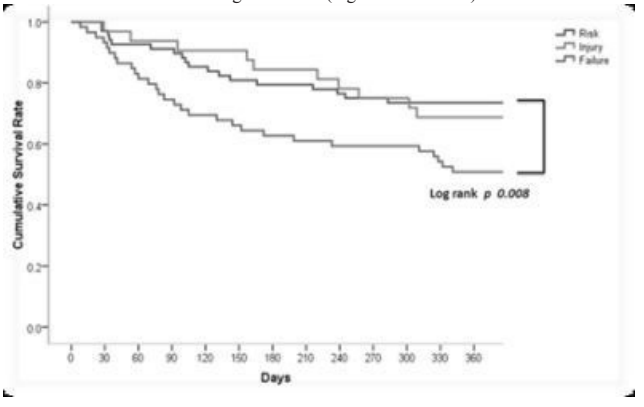
PUB059

One Year Clinical Outcome of Acute Kidney Injury Admitted to Medicine Service: Single Tertiary Care Center Experience
Nuttasith Larpparisuth, Nongnuch Lawattanatrakul, Thawee Chanchairujira, Somkiat Vasuvattakul. *Department of Medicine, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand.*

Background: Acute kidney injury (AKI) is the considerable problem which associated with higher in-hospital mortality and subsequent development of chronic kidney disease (CKD). Study of long-term outcome of AKI patients admitted to medicine service which have more complex entities is sparse.

Methods: We retrospectively reviewed all consecutive 5,570 patients admitted to medicine service, including ICU, in a single tertiary hospital between 1 January and 30 June 2010. AKI occurred in 870 patients (15.6%) with in-hospital mortality rate of 43% (374 patients). The retrieved data included demographic data,severity of AKI stratified by RIFLE criteria and mode of renal replacement therapy (RRT). 496 AKI patients who survived at discharge had been followed up for 1 year. The crucial factors for mortality and development of CKD stage V were analyzed by the Kaplan-Meier method.

Results: One-year mortality rate of surviving AKI patients was 33.9% (168 patients). Pre-existing CKD stage III and IV, lack of renal recovery at discharge, sepsis, cirrhosis and malignancy were independent determinants of one year survival. In aspect of change in renal function, the lowest one year survival was observed in patients with prior CKD who suffered from 'Failure' degree of AKI (log rank P = 0.008).



All patients with CKD stage 5 required RRT at one year follow-up (3.4%) had baseline eGFR < 60 ml/min. Pre-existing CKD was the most important risk factor for development of CKD stage 4 and 5 after AKI event.

Conclusions: AKI not only affects on short-term but also on long-term outcome in both mortality and renal survival especially in patients with CKD. Surviving AKI patients should be closely monitored in the months for potential development or progression of CKD and death.

PUB060

Testing of a Multi-Platform IT Medication Inquiry System (MIS) in Chronic Kidney Disease (CKD) Clarissa Jonas Diamantidis,[1] Marni Zuckerman,[1] Jeffrey C. Fink.[1] *[1]Department of Medicine, University of Maryland, Baltimore, MD; [2]Tech Moksha Consulting, Herndon, VA; [3]Novel Health Strategies, Columbia, MD.*

Background: Patients with CKD are at high risk for medication errors. Establishing a simple health information technology (IT) application designed to guide the safe use of medications in CKD, and making it available on various technology platforms may reduce medication errors in patients with CKD who have a range in familiarity and comfort with IT tools.

Methods: Participants with CKD underwent formal usability testing of a medication inquiry search system (MIS) on three technology platforms: 1) mobile device with SMS text, 2) Personal Digital Assistant (PDA; e.g., iPod Touch), and 3) Internet website. A single interviewer (and 2nd recording observer) conducted all usability test with participants randomized to a predetermined testing sequence. The interviewer provided each participant with a list of 19 tasks on the mobile device and website, and 22 tasks on the PDA. Example tasks include entering a medication name in the MIS, and interpreting the safety response. Tasks were rated as either "completed", "non-critical error", or "critical error" (user cannot complete a task without significant interviewer intervention).

Results: 20 participants representative of the CKD population completed formal usability testing.

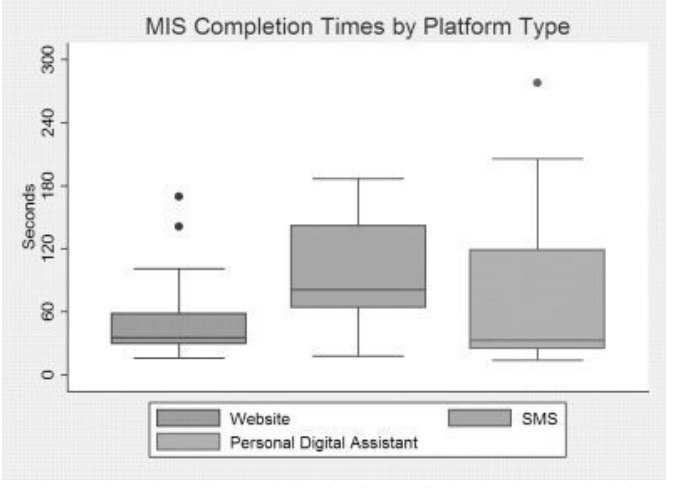

Figure 1 shows the median completion time for a medication inquiry on each platform. Total number of critical errors in the SMS, PDA, and Website group were 28 (7.36%), 23 (5.22%), and 28 (7.36%), respectively. After usability testing, 50% preferred to use the website-based MIS application, 30% favored the PDA, and 20% preferred the SMS application.

Conclusions: Understanding patient preference in technology use and adapting applications to a variety of technology portals will ensure most effective use of targeted interventions to improve patient safety in CKD.

PUB061

Assessing Computer Literacy in Chronic Kidney Disease (CKD): Results from Safe Kidney Care Clarissa Jonas Diamantidis, Marni Zuckerman, Wanda Fink, Jeffrey C. Fink. *Medicine, University of Maryland School of Medicine, Baltimore, MD.*

Background: Several reports have shown that health outcomes of patients with chronic disease can improve when they are empowered with information technology (IT) tools, however there are few such applications employed in CKD and it is not well-known how often CKD patients' use such technologies. As part of Safe Kidney Care (SKC), a study of patient safety in CKD which employs an educational Web site, we report here on computer and Internet usage characteristics of participants.

Methods: The SKC study (R01DK084017) is conducting two sequentially enrolled cohort studies in pre-dialysis CKD to assess patient safety among individuals with Stage III or greater CKD. The first cohort evaluates an alert system using a medical alert bracelet (or necklace) linked to an informational Web site to evaluate the effect of increased recognition of CKD on unsafe medical practices and errors. As part of baseline visits, SKC participants were asked about their computer access, and Internet usage and preferences. The results from Phase 1 baseline visits are presented here.

Results: Of 108 participants completing baseline visits, 85% (n=92) reported available computer access. 67% (n=72) reported using the Internet, with 55% of participants (n=59) reporting weekly to daily Internet use. Of those using the Internet, devices used to access the Internet were computer (97%, n=70), mobile device (21%, n=15), and entertainment device (6%, n=4). The majority of Internet users claimed use of the Internet without assistance (85%, n=61). 51 Internet users (71%) reported using the Internet to search for health information. Factors associated with regular Internet use are shown below.

Table 1. Adjusted odds of regular internet use among CKD patients in SKC

Baseline Characteristic*	Odds Ratio (OR)	P-Value
> High school diploma (ref. ≤ high school)	3.70	0.01
Adequate health literacy (ref. inadequate)	1.66	0.03

*age, gender, marital status, race, or GFR were not significant

Conclusions: Patients with CKD have variable access to a computer and the Internet. Distribution of health information in CKD should target a wide range of IT ability.

PUB062

Effects of Flow Configurations on Flow Dynamics and Solute Transport in a Helmofilter during Continuous Renal Replacement Therapy Jeong Chul Kim,[1,2] Francesco Garzotto,[1,2] Manish Kaushik,[1,2] Dinna N. Cruz,[1,2] Federico Nalesso,[1,2] Alessandra Brendolan,[1,2] Claudio Ronco.[1,2] *[1]Department of Nephrology, Dialysis & Transplantation, San Bortolo Hospital, Vicenza, Italy; [2]International Renal Research Institute, Vicenza, Italy.*

Background: In hemodialysis for CKD patients flow configurations between blood and dialysate are countercurrent to facilitate maximum diffusion of solutes. In contrast, in CRRT dialysate flow is less than 35 ml/min and flow configuration and blood flow direction are random depending on nurses' preference or machine design. Therefore, for a best practice of CRRT in ICU, it is necessary to evaluate the effects of flow configurations (cocurrent vs. countercurrent) and blood flow direction (upward vs. downward) on solute transport and flow dynamics in a hemofilter.

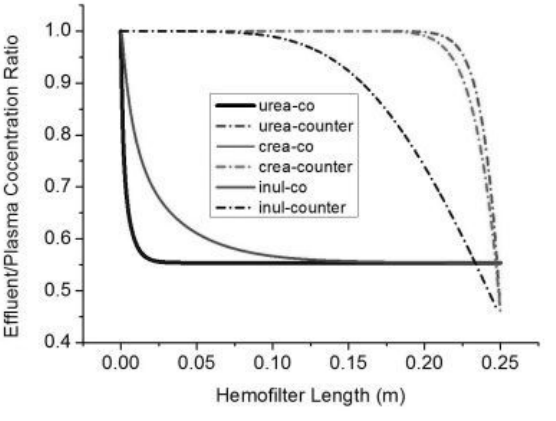
Methods: We analyzed flow dynamics and solute transport (urea, creatinine and inulin) in a hemofilter using computational fluid dynamic modeling according to 4 types of extracorporeal circuit setup during CVVH with blood flow rate of 200 ml/min and dialysate of 2 liters/h.

Results: Pressure profiles in a hemofilter are different depending on flow configuration and blood flow direction.

Pressure profiles in a hemofilter according to flow configuration and blood flow direction

Configuration	Cocurrent Flow		Countercurrent Flow	
Blood Flow Direction	Up	Down	Up	Down
ΔPB (mmHg)	29	5	23	1
ΔPD (mmHg)	24	10	8	20

For downward blood flow, pressure drops in the blood compartment were lower than upward because blood flow was assisted by gravity. Solute extraction ratio in countercurrent configuration is higher than that of cocurrent by 9.8% for urea. As molecular weight increased, the extraction ratio difference increased (9.9% for creatinine and 10.5% for inulin).



Conclusions: Countercurrent flow configuration and downward blood flow direction setting of CRRT could enhance solute removal in a stable flow dynamic condition.

PUB063

NEFRORED Developing a Registry of Patients with Lupus Nephritis and Primary Glomerulonephritis in the Caribbean Region of Colombia Gustavo Jose Aroca Martinez, Andres A. Cadena. *Nephrology, Clinica de la Costa, Barranquilla, Atlantico, Colombia.*

Background: In Colombia there is no reliable information about the local incidence, prevalence and outcomes of patients with lupus nephritis and other glomerular diseases. The Colombian healthcare system is limited in coverage and resources, the patients have

barriers to reach appropriate evaluations and there is insufficient availability of nephrologists for the diagnosis and management of glomerular diseases.

The Objective of NEFRORED is to establish a local network of early detection and attention of patients with lupus nephropathy and other glomerular diseases using a web-based platform.

Methods: NEFRORED was developed in 2008 under a web based protocol (MySQL), the project is shared by all the nephrologist of the northern region of Colombia (Caribbean) and has provided information on the epidemiology of the disease, outcomes, incidence and prevalence of cases. Figure 1

There are two groups of patients: children and adults, and the categories are lupus nephritis and all the other glomerular diseases are grouped in a second category. The university Simon Bolivar (http://www.unisimon.edu.co) has provided assistance with software development and also provides the hosting for the webpage www.nefrored.com.co, under all the standards of information safety and retrieval.

Results: As of 2012 NEFRORED includes data entry for 7 different states in the north of Colombia: Total of Lupus Nephritis 175 cases

LN in adults 166 cases LN in children 9 cases. Other Glomerular diseases 287 Total 486 cases reported.

Conclusions: NEFRORED is the first organized attempt of a group of nephrologists in Colombia to establish a local network for the identification, treatment, prevention and follow up evaluation of patients with lupus nephritis and other glomerular diseases in the Caribbean region of Colombia under a very simple and intuitive web base platform.

VEGF Production by Intracellular Prostatglandin-E_2: Role of Retinoic Acid Response Element (Rare) and EGF Receptor (EGFR) Javier Lucio, Ana Belen Fernandez. *Physiology, Alcala University, Alcala de Henares, Madrid, Spain.*

Background: In HK2 cells PGE_2 increases the production of renal protector VEGF through up-regulation of transcription factor retinoic acid receptor-ß (RARß) by intracellular PGE_2. Our aim here was to study the regulation of RARß expression and VEGF production by PGE_2.

Methods: Cells: HK2 (human proximal tubular) Treatment: 16,16-dymethyl-PGE_2 (analogue of PGE_2). Pre-incubations: transcriptional inhibitor actinomycin D (AMD), antagonists of EP receptors (EPR) AH6809/GW627368X, inhibitor of prostaglandin transporter bromocresol green (BG) or inhibitor of EGFR activation AG1478. Transfections: luciferase reporter construct containing RARE (RARE-Luc) from the RARß promoter. Quantifications: mRNA, Q-RT-PCR protein, WB, IF or ELISA. Statistical Analysis: nonparametric Bonferroni test.

Results: i) PGE_2 increased RARß mRNA and protein, the latter being prevented by AMD ii) AH6809, GW627368X or BG prevented PGE_2-induced RARß mRNA up-regulation. Therefore, PGE_2-induced RARß up-regulation is likely due to increased RARß mRNA transcription upon activation of intracellular EPR by intracellular PGE_2. iii) PGE_2 determined an AH6809-, GW627368X- and BG-sensitive increase in RARE-Luc activity (RARE sequences in the RARß promoter are the key for RARß mRNA up-regulation), iv) PGE_2 increased phosphorylated EGFR (a potential consequence of intracellular EPR activation) and VEGF, these effects being inhibited by AH6809, GW627368X or BG. v) AG1478 prevented the activation of RARE, the increase in RARß mRNA/protein expression and in VEGF production induced by PGE_2.

Conclusions: PGE_2-induced VEGF production is due to the sequential activation of EPR and EGFR by intracellular PGE_2, which results in activation of RARE in the RARß promoter leading to transcriptional up-regulation of RARß expression.

PUB065

Identification of Translocated Promoter Region and α-Actinin-4 as Two Novel Ste20-Like Kinase, SLK-Interacting Proteins Aala Jaberi, Erika Hooker, Julie Guillemette, Joan Papillon, Andrey V. Cybulsky. *Medicine, McGill University, Montreal, QC, Canada.*

Background: Expression and activity of the Ste20-like kinase, SLK, are increased during kidney development and recovery from ischemic injury. SLK mediates apoptosis in renal tubular and glomerular epithelial cells (GEC). SLK can also regulate cell cycle progression and cytoskeletal remodeling. In cells, SLK is present as a high molecular mass complex, suggesting that SLK is a dimer/oligomer, or is in tight association with other proteins. To better understand the regulation, localization and function of SLK, we sought to identify proteins in this high molecular mass complex.

Methods: Proteins eluted from a SLK affinity column were analyzed by mass spectrometry. Two putative interacting proteins were then tested for interactions with SLK by co-immunoprecipitation and pull-down techniques. Interactions were further validated by immunofluorescence microscopy in GEC, COS-1 and HeLa cells.

Results: Analysis by mass spectrometry identified the nucleoporin, Tpr (translocated promoter region), and the cytoskeletal protein, α-actinin-4, as potential SLK-interacting proteins. The interaction of SLK with Tpr and α-actinin-4 was confirmed by co-immunoprecipitation with full-length SLK, and by pull-down with the 350 amino acid C-terminal, coiled-coil domain of SLK. The region of α-actinin-4 that interacted with SLK was within amino acids 1-300. Tpr and a portion of SLK colocalized in the perinuclear regions of cells, and there was cytoplasmic colocalization of SLK and α-actinin-4. Co-expression of SLK and Tpr in COS-1 cells resulted in reduced autophosphorylation of serine-189 in SLK, in keeping with reduced kinase activation; however, serine-189 phosphorylation was not affected by α-actinin-4.

Conclusions: Interactions of SLK with Tpr and α-actinin-4 are at least in part responsible for the high molecular mass complex of SLK that is present in cells. These protein-protein interactions may control the subcellular localization of SLK. Moreover, the interaction between SLK and Tpr reduces SLK activity. The interacting proteins may impact on the functions of SLK, including regulation of apoptosis, cell cycle, or cytoskeleton.

PUB066

Role of Human ß Defensins in Patients with Chronic Kidney Disease Youn-su Park,[1] Min-jee Han,[1] Jung-ho Shin,[1] Su Hyun Kim,[1] Hye Ryoun Kim,[2] Suk-hee Yu.[1] *[1]Internal Medicine, Chung-Ang University College of Medicine, Seoul, Korea; [2]Laboratory Medicine, Chung-Ang University College of Medicine, Seoul, Korea.*

Background: DN was known as the main cause of chronic kidney disease (CKD), which was associated with alterations in the two major branches of the immune system, innate and adaptive immunity. Taken together, our aim was to determine whether HBD, pro-inflammatory cytokines including interleukin (IL)-6 and tumor necrotic factor (TNF)-α could be relevant factors of the development and aggravation of patients with CKD, especially from DN.

Methods: Serum samples were obtained from 338 patients who visited the department of nephrologic clinic between February and November 2011 and 88 sex, age-matched healthy controls (61.1±14.3 vs. 57.9±5.96 yrs, p>0.05). The concentration of HBD-1 were assayed using radio immunoassay kit. The concentration of HBD-2 ,IL-6 and TNF-α were assayed using enzyme-linked immunosorbent assay kit. And we reviewed the medical records of the patients.

Results: Serum concentrations of HBD-1, HBD-2, IL-6 and TNF-α were higher in CKD patients over healthy controls (2282.8±792.6 vs. 1605.7±331.7, p=0.000, 1535.9±420.1 vs. 1349.4±775.3, p=0.003, 3.91±3.14 vs. 2.49±2.45, p=0.000, 1.62±2.52 vs. 1.00±0.62, p=0.000, respectively). Serum concentration of HBD-1 was negatively correlated with hemoglobin (Hb)(β=-0.264, p=0.000), estimated GFR (β=-0.586, p=0.000) and positively correlated with fasting blood glucose level (β=0.226, p=0.000) in patients with CKD. Serum concentration of HBD-2 was correlated with WBC count (β=0.158, p=0.003) in patients with CKD and duration of hemodialysis period (β=-0.258, p=0.003). Serum concentration of HBD-1, IL-6 and TNF-αin patients with CKD from DN was increased compared to patients with CKD from non-DN and healthy controls. In contrast, there was no significant statistical difference of serum HBD-2 concentration among above groups.

Conclusions: These data suggest that HBD-1 could affect on both kidney function and Hb level in patients with CKD. In addition, increase of HBD-1, IL-6 and TNF-α may be causative factors of reduction of renal function in DN.

PUB067

c-Abl Mediates Angiotensin II-Induced Apoptosis in Podocytes Xinghua Chen,[1] Tean Ma,[1] Wei Liang,[1] Dongqing Zha,[1] Zhilong Ren,[1] Yipeng Liu,[1] Pravin C. Singhal,[2] Guohua Ding.[1] *[1]Division of Nephrology, Renmin Hospital of Wuhan University, Wuhan, Hubei, China; [2]Medicine, North Shore LIJ Hofstra Medical School, Great Neck, NY.*

Background: Our previous studies have demonstrated that angiotensin II(Ang II) induces podocyte apoptosis. c-Abl, the nonreceptor tyrosine kinase has been implicated in the regulation of cell proliferation, survival, cell adhesion and migration. A recent study has demonstrated c-Abl expression in rat kidney. The present study investigates whether c-Abl is involved in Ang II-induced podocyte apoptosis.

Methods: (1) 24 male Sprague-Dawley rats (Group C, D, E and F) were assigned to receive Ang II (400 kg-1min-1) by osmotic minipump and of which 12 rats (Group D and

F) were assigned to receive Telmisartan (3 mg·kg-1d-1) together, 6 rats received normal saline (Group B), and 6 rats used as normal contro1 (Group A). Expression of podocyte c-Abl was examined by immunohistochemistry, and podocyte apoptosis was examined by TUNEL staining. (2) Conditionally immortalized mouse podocytes were used in vitro. The cultured podocytes were treated with Ang II10-9M to 10-6M for various periods with or without c-Abl inhibitor Src-I1, or specific c-Abl siRNA, c-Abl plasmid alone. Expression of podocyte c-Abl, c-Abl-phospho Y245 and Y412 were examined by Real-time PCR, Western blot and immunofluorescence staining. c-Abl and p53 in the nucleus were examined by co-immunoprecipitation and western blot. Podocyte apoptosis was examined by flow cytometry and Hoechst-33342 staining.

Results: Ang II induced podocyte apoptosis in vivo and in vitro, and podocyte c-Abl expression was increased by Ang II both in vivo and in vitro. Y245 and Y412 phosphorylation of c-Abl was also upregulated. Ang II induced an increase in nuclear p53 protein and nuclear c-Abl-p53 complex in podocytes. Down-regulated c-Abl expression by c-Abl inhibitor (Src-I1) or specific siRNA inhibited Ang II-induced podocyte apoptosis. Up-regulated c-Abl expression by plasmid transfection increased Ang II-induced podocyte apoptosis.

Conclusions: c-Abl mediates Ang II-induced podocyte apoptosis, and inhibition of c-Abl could protect podocyte injury induced by Ang II.

PUB068

Role of Smad2/3 Acetylation in Angiotensin II-Induced Extracellular Matrix Synthesis Chen Yu,[1] Lunjun Fu,[1] Ying Yu,[1] Limin Lu.[2] *[1]Division of Nephrology, Tongji Hospital, School of Medicine, Tongji University, Shanghai, China; [2]Department of Physiology and Pathophysiology, Fudan University, Shanghai Medical College, Shanghai, China.*

Background: Angiotensin II (AngII) has long been recognized in stimulating extracellular matrix (ECM) synthesis and plays a critical role in renal fibrosis. The phosphorylation and nucleus translocation of Smad proteins have been demonstrated to be involved in AngII- induced ECM synthesis. Acetylation was recently noticed as another way of Smads modification. The aim of this study is to investigate the role of acetylaiton of Smad2/3 on AngII-induced ECM synthesis and the related mechanism.

Methods: Cultured rat renal interstitial fibroblast cells (NRK-49F) were used in the experiment. The collagenIV and fibronectin protein levels, phosphorylation of Smad2/3 were measured by Western blot. Acetylation of Smad2/3 was measured by co-immunoprecipitation. The siRNA interfering was used to knockdown p300 or CBP expression.

Results: 1) AngII increased the expressions of ECM proteins, including collagenIV and fibronectin, in a concentration dependent manner. 2) AngII stimulated both the acetylation and phosphorylation of Smad2/3. 3) Transfection of siRNA-p300, but not siRNA-CBP, blocked AngII-induced acetylation of Smad2/3, and reduced the expressions of collagenIV and fibronectin.4) The inhibitor of p38 (SB203580) reversed AngII-induced phosphorylation of smad2/3 as well as the expressions of collagenIV and fibronectin. 5) SB203580 abrogated AngII-induced increase in Smad2/3 acetylation; however, neither C646 (p300 inhibitor) nor siRNA-p300 had obvious effects on the increase of Smad2/3 phosphorylation, which was induced by AngII.

Conclusions: AngII stimulates Smad2/3 acetylation and phosphorylation in cultured NRK-49F. Both Smad2/3 phosphorylation and acetylation participate in AngII-induced ECM synthesis. P300 is the key acetyltransferase which responsible for the AngII-induced Smad2/3 acetylation, while p38 plays the crucial role in Ang II-induced Smad2/3 phosphorylation. The phosphorylation of Smad2/3 seems prior and nessecary for the acetylation.

Dyslipidemia Activates Intracellular Renin-Angiotensin System and Accelerates the Progression of Renal Tubular Interstitial Fibrosis Jie Ni,[1] Kun Ling Ma,[1] Chang Xian Wang,[2] Yang Zhang,[1] Bi-Cheng Liu.[1] *[1]Institute of Nephrology, Zhong Da Hospital, Southeast University School of Medicine, Nanjing, Jiang Su Province, China; [2]Infection Management Department, Zhong Da Hospital, Southeast University School of Medicine, Nanjing, Jiang Su Province, China.*

Background: Dyslipidemia and activation of the intracellular renin-angiotensin system (RAS) are risk factors in the progression of tubular interstitial fibrosis (TIF). This study was to investigate potential synergistic effects of dyslipidemia with RAS using human tubular epithelial cell line (HK-2) and explore its underlying mechanisms.

Methods: HK-2 cells were cultured and divided into Control group (serum free medium) and cholesterol loading group (serum free medium containing 30 μg/ml cholesterol plus 1μg/ml 25-hydroxycholesterol). Lipid accumulation in cells was evaluated by Oil red O staining. The gene and protein expressions of molecules involved in Epithelial-mesenchymal transition (EMT), RAS components and mammalian target of Rapamycin (mTOR) pathway were examined by real-time PCR and Western blot.

Results: Cholesterol loading increased intracellular lipid accumulation. Further analysis demonstrated that there were decreased mRNA and protein expression of E-cadherin and increased mRNA and protein expression of α-smooth muscle actin (α-SMA) in cholesterol loading group compared to the control, suggesting that lipid accumulation contributes to EMT. These were closely associated with increased mRNA and protein expression of angiotensinogen, angiotensin II, rennin, angiotensin-converting enzyme, agiotensin II type 1 and type 2 receptors in HK-2 cells. Interestingly, lipid accumulation increased mRNA and protein expression, and protein phosphorylation level of mTOR, eukaryotic translation initiation factor 4E binding protein 1(4EBP1), ribosomal protein S6 kinase 1(S6K1), which was closely correlated with intracellular RAS activation.

Conclusions: Dyslipidemia contributed to the progression of TIF through intracellular RAS activation. It suggests a possible synergistic effect existed in the pathogenesis of TIF. These effects mediated by intracellular RAS activation could be correlated with the up-regulation of mTOR pathway.

PUB070

Identification of Two Direct Carbonylation Sites in the Na/K-ATPase α1 Subunit Stimulated by Ouabain and Glucose Oxidase in LLC-PK1 Cells Yanling Yan,[1,3] Anna P. Shapiro,[1] Vinai Kumar Katragadda,[1] Deepak K. Malhotra,[1] Zi-jian Xie,[2,1] Joseph I. Shapiro,[1,2,3] Jiang Liu.[1,3] *[1]Medicine, University of Toledo College of Medicine, Toledo, OH; [2]Physiology and Pharmacology, University of Toledo College of Medicine, Toledo, OH; [3]Pharmacology and Physiology, Marshall University JCE School of Medicine, Huntington, WV.*

Background: We recently found that protein carbonylation regulated renal proximal tubular Na/K-ATPase/c-Src signaling and sodium reabsorption. We reported here that both ouabain and glucose oxidase stimulated direct carbonylation of two amino acid residues in the Na/K-ATPase α1 subunit.

Methods: Immunoprecipitation, LC-MS/MS.

Results: LLC-PK1 cells were treated with ouabain (100nM) or GO (3mU/ml) for 1 hr. The Na/K-ATPase α1 subunit was immunoprecipitated with anti-α1 antibody and separated with SDS-PAGE. The α1 bands were processed for in-gel trypsin digestion and LC-MS/MS analysis. Direct carbonylation modification of two amino acid residues, Pro^{234} (mass 113.0477 with mass diff 15.9949) and Thr^{237} (mass 99.0320 with mass diff -2.0156), in peptide ^{226}SPDFTNENPLETR^{238} (*UniProtKB/Swiss-Prot No P05024 (AT1A1_PIG)*) were present in control, ouabain- and GO- treated cells. Furthermore, direct carbonylation of both Pro^{222} and Thr^{224} in peptide ^{211}VDNSSLTGESEPQTR^{225} were shown only in response to ouabain and GO treatments. Peptide ^{211}VDNSSLTGESEPQTR^{225} is highly conserved in Na/K-ATPase α1/α2/α3/α4 isoforms. These two peptides are linked and located in the actuator (A) domain of the α1 subunit, and Pro^{222}/Thr^{224} locate on the surface facing the nucleotide binding (N) domain. It was indicated that the conformation changes favor high affinity ouabain binding and affect binding of signaling molecules such as c-Src, PI3K and IP3R (Yatime, L., et al., J Struct Biol. **174**(2): p. 296-306), which are critical in the Na/K-ATPase signaling. The highly conserved ^{217}TGES^{220} motif has been shown to affect conformation change and stabilize the Na/K-ATPase in E2P:Ouabain state.

Conclusions: Ouabain and glucose oxidase stimulated direct carbonylation of two amino acid residues (Pro and Thr) in the A domain of the Na/K-ATPase α1 subunit.

PUB071

Calcitriol Decreased TNF-α Induced TGF-β1 Production in Aortic Smooth Muscle Cells via Rac1/Syk Pathway Su-Kil Park, Won Seok Yang. *Internal Medicine, Asan Medical Center University of Ulsan, Seoul, Republic of Korea.*

Background: Interestingly, TGF-β1 is known to have interwoven atherogenic and atheroprotective properties. The various studies depending on animal studies or human studies show conflicting results as well as dependent on damaging insults. Recently, the interest in vitamin D is increasing because it is known to have cardiovascular protective effects. Therefore, we investigated the effect of calcitriol on the production of TGF-β1 and its intracellular signaling pathways after stimulation of cultured aortic smooth muscle cells by TNF-α.

Methods: We performed western blot, EMSA and Rac1 pull down assay. Intracellular reactive oxygen species(ROS) production was evaluated with the probe 5-(and 6)-chloromethyl-2',7'-dichlorodihydrofluorescein diacetate by confocal microscopy.

Results: TNF-α (10ng/ml) increased TGF-β1 expression after 8hr, which was decreased by calcitriol (120nM, 240nM) in western blot assay. Calcitriol (120nM) decreased intracellular ROS production after 30min stimulation of TNF-α, which was evaluated by confocal microscopy. TNF-α increased p-Syk after 30min stimulation, which was decreased by calcitriol, however there was no change in TNF-α induced p38 activation, p65 nuclear translocation or IkBα degradation by calcitriol in western blot assay. In EMSA, TNF-α-increased DNA-binding activities of AP-1 and NF-κB, whereas calctriol (120nM) downregulated TNF-α-induced DNA-binding activities of both AP-1 and NF-κB. In Rac1 pull-down assay, active Rac1 increased by TNF-α in 15 min incubation, which was decreased by calcitriol.

Conclusions: In conclusion, calcitriol could decrease TNF-α induced Rac1/ROS/Syk/TGF-β1 production which means that calcitriol might have antioxidant activity by itself. This pathway may explain the mechanism of cardiovascular protective activity of calcitriol.

PUB072

Mechanisms of Renoprotective Effects of Cordyceps Sinensis in 5/6 Nephrectomy Rats Shanmai Guo, Fang Zhong, Qiao Zhou, Ying Lu, Xu Hao, Weiming Wang, Nan Chen. *Ruijin Hospital, Shanghai Jiao Tong University.*

Background: To explore the mechanism of C. sinensis on chronic renal insufficiency and renal fibrosis.

Methods: The CKD rat model was established by performing 5/6 subtotal nephrectomy. Male SD rats were divided into three groups: sham-operated group (SO group); untreated nephrectomized group(OP group); and administration of C.sinensis-treated nephrectomized group (CS group). Kidneys, sera and urine were collected for analysis.

Results: Scr, BUN and UACR were significantly increased in OP groups than in SO groups ($p<0.05$), and the Alb significantly decreased ($p<0.05$). Obvious pathological changes were detected in OP groups, which including focal or diffused glomerulosclerosis, tubular interstitial changes such as infiltration of inflammatory cells, more deposition of ECM and thickening of arterial wall. The lesion was more serious at 8 weeks after operation. Number of CD68, FSP1 positive cells and the expression area of FN, Col-I, Col-III, and α-SMA in the OP groups were increased compared with SO groups($p<0.05$). However, these changes were partly reversed after C. sinensis treatment. Pathological changes were improved and the mitochondrial damage was alleviated in CS groups. Glomerulosclerosis and interstitial fibrosis were also significantly relieved. Besides Alb were significantly increased, and UACR were significantly decreased in CS groups ($p<0.05$). The number of CD68 and FSP1 positive cells declined ($p<0.05$), and the protein and mRNA level of FN, Col-I, Col-III and α-SMA were obviously decreased($p<0.05$) in CS groups. Compared with SO groups, the protein levels of GRP78, p-eIF2α, ATF4, CHOP, caspase12 and c-caspase 3 in OP groups were significantly increased ($p <0.05$). But they were significantly reduced after treatment with C. sinensis preparations ($p <0.05$). Expression of oxidative stress indicators, such as SOD and MDA were disturbed in OP groups, and they were significantly improved by C. sinensis.

Conclusions: C. sinensis could improve renal dysfunction, alleviate glomerulosclerosis, inflammation and tubular interstitial fibrosis through inhibiting the ERS, alleviating oxidative stress damage, renal tubular cell apoptosis and mitochondrial damage.

PUB073

Nicotine-Induced ERK1/2 Phosphorylation in Rat Mesangial Cells: Role of PKC, PKA, EGFR and CaMKII Ping Hua,[1] Wenguang Feng,[1] Gabriel Rezonzew,[1] Phillip H. Chumley,[1] Edgar A. Jaimes.[1,2] *[1]University of Alabama at Birmingham; [2]Birmingham VA Medical Center, Birmingham, AL.*

Background: Tobacco smoking is associated with accelerated progression of chronic kidney disease of different etiologies including diabetes and hypertension. The mechanisms involved are however not well understood. We have previously reported that nicotine, a biologically active compound present in high concentrations in tobacco, induces cell proliferation and fibronectin production in human mesangial cells (MC) which are prevented by ERK1/2 inhibition (AJP'05). In these studies we determined whether rat MC express nicotine receptors and characterize the signaling pathways that lead to ERK1/2 phosphorylation in response to nicotine.

Methods: Rat MC were grown in DMEM and several nicotinic Ach receptor (nAChR) subunits (α1-7 and β1-4) assessed by western blot (WB). In separate experiments MC were first pre-treated with inhibitors for PKC, PKA, EGFR and CaMKII for 30 min and then the cells were treated with nicotine (10^{-7}M). In other experiments MC were pre-treated with the calcium channel blocker Verapamil (10^{-9} M) before nicotine. Cells were then harvested and ERK1/2 phosphorylation detected by WB.

Results: We first demonstrated that MC are endowed with several nAChR subunits (α2-7 and β1-4). Treatment with nicotine at 10^{-7}M caused a time-dependent ERK1/2 phosphorylation which peaked after 10 min of stimulation (N=3). The calcium/calmodulin-dependent protein kinase II (CaMKII) inhibitor KN93 (10^{-7}M) decreased the ERK1/2 phosphorylation level by ~57% as compared to nicotine. The PKC inhibitor Go6983 at 10^{-9}M, the PKA inhibitor H89 (10^{-8} M) and the EGFR inhibitor AG 1478 (10^{-7} M) also inhibited ERK1/2 phosphorylation by 60%, 48% and 68% respectively as compared to nicotine. Treatment of MC with Verapamil resulted in 33% inhibition of ERK1/2 phosphorylation as compared to nicotine alone.

Conclusions: In these studies we have demonstrated that rat MC are endowed with several nAChR subunits and that ERK1/2 phosphorylation in response to nicotine requires CaMK II, PKA, PKC and EGFR. In addition we have shown that these effects require Ca^{2+} consistent with the role of the nAChRs as agonist-regulated Ca^{2+} channels in MC.

PUB074

Differential Ubiquitylation of the Mineralocorticoid Receptor Is Regulated by Phosphorylation Nourdine Faresse, Olivier Staub. *Pharmacology &Toxicology, University of Lausanne, Lausanne, Switzerland.*

Background: Aldosterone stimulation of the mineralocorticoid receptor (MR) is involved in numerous physiological responses, including Na^+ homeostasis, blood pressure control, as well as heart failure. Aldosterone binding to MR promotes different post-translational modifications (PTMs) that regulate MR nuclear translocation, gene expression and finally receptor degradation.

Methods: Here we studied by different biochemical experiments, the effects of aldosterone stimulation (from 0.1 to 10 nM) on MR PTMs in renal epithelial cells.

Results: We found that aldosterone stimulates rapid phosphorylation of MR via ERK1/2 in a dose dependent manner in renal epithelial cells. This phosphorylation induces an increase of MR apparent molecular weight, with a maximal upward shift of 30 kDa. Strikingly, these modifications are critical for the regulation of the MR ubiquitylation state. Indeed, we find that MR is monoubiquitylated in its basal state and this status is sustained by the tumor suppressor gene 101 (Tsg101). Phosphorylation leads to disruption of MR/Tsg101 association, and monoubiquitin removal. These events prompt polyubiquitin-dependent destabilization of MR and degradation. Preventing MR phosphorylation by ERK1/2 inhibition or mutation of target serines affects the sequential mechanisms of MR ubiquitylation and inhibits the aldosterone mediated degradation.

Conclusions: Our data provide a novel model of negative feedback of aldosterone signaling, involving sequential phosphorylation, monoubiquitin removal and subsequent polyubiquitylation/degradation of MR.

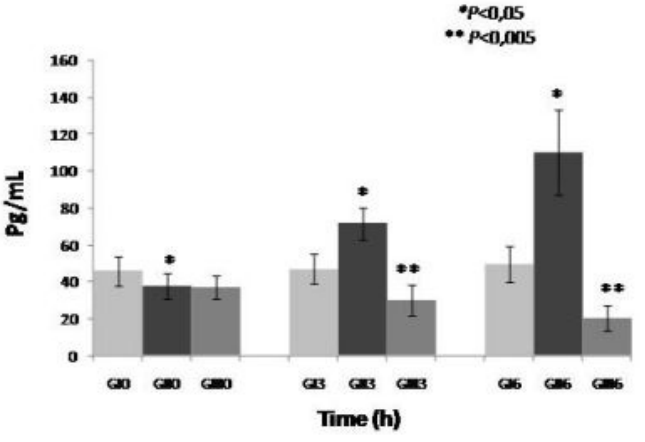
PUB075

Advanced Glycation End Products and MCP-1 Expression by Endothelial Cells through PKC-β Pathway Lisienny Campoli Tono Rempel,[1] Rayana Ariane Pereira Maciel,[1] Bruna Bosquetti,[1] Andrea Novais Moreno-Amaral,[2] Rodrigo B. Oliveira,[3] Roberto Pecoits-Filho,[2] Andréa Marques Stinghen.[1] *[1]Basic Pathology Department, Universidade Federal do Paraná, Curitiba, Paraná, Brazil; [2]Center for Health and Biological Sciences, Pontifícia Universidade Católica do Paraná, Curitiba, Paraná, Brazil; [3]Nephrology Department, Universidade de São Paulo, São Paulo, Brazil.*

Background: Studies have demonstrated the role of uremic toxins in the development of cardiovascular disease, the first cause of mortality in CKD patients. However, its mechanisms are not fully understood. We investigated the expression of MCP-1 triggered by advanced glycation end products (AGES), targeting PKC-β pathway in human umbilical vein endothelial cells (HUVECs).

Methods: HUVECs were cultured in MEM-199, FBS and pen/strepto. AGES were prepared with BSA and glucose. The cells were treated according to the following groups: GI-control (HUVECs + BSA), GII (HUVECs + AGES), and GIII (HUVECs + AGES + PKC-β inhibitor, Gö-6983). All groups were incubated in a kinetics of 0 (baseline), 3 and 6h, and the supernatants were collected to evaluate MCP-1 levels (ELISA).

Results: HUVECs exposed to AGES (GII) showed an important increase of MCP-1 levels after 3 and 6h respectively (72 ± 9; 110 ± 25 pg/mL) in comparison to baseline (38 ± 7 pg/mL), $P<0.05$. In the opposite, in the control group (GI), the MCP-1 expression in 0, 3 and 6h was respectively 46 ± 8; 47 ± 8 and 50 ± 10 pg/mL. HUVECs exposed to AGES + PKC-β inhibitor (GIII) demonstrated a significant decrease in MCP-1 expression after 3 and 6h respectively (30 ± 8; 20 ± 7 pg/mL), $P<0.005$, when compared to AGES (GII).



Conclusions: We demonstrated an increase in MCP-1 production by HUVECs when exposed to AGEs in a time-dependent way. In addition, PKC-β blockade reduced MCP-1 expression, suggesting a potential antiinflammatory action by the inhibition of this pathway.

PUB076

Advanced Glycation End-Products Reduced Podocyte Adhesion via Upregulation Integrin Linked Kinase Expression and Cytoskeleton Reorganization Cailian Cheng,[1] Zhenda Zheng,[1] Xun Liu,[1] Ying Tang,[2] Tan-qi Lou.[1] *[1]Department of Nephrology, The 3rd Affiliated Hospital of Sun Yat-Sen University, Guangzhou, Guangdong, China; [2]Department of Nephrology, The 2rd Affiliated Hospital of Sun Yat-Sen University, Guangzhou, Guangdong, China.*

Background: Recent studies showed podocyte detached from the glomerular basement membrane played an important role in the pathogenesis ofpodocytopenia in diabetic kidney disease. Advanced glycation end-products (AGEs) increase at an accelerated rate in diabetes and associate with the severity of diabetic complications. Little is known about the effects of AGEs on podocyte adhesion and the roles of integrin linked kinase (ILK) and actin cytoskeleton in the process.

Methods: Podocyte adhesion was measured by cytometry and hexosaminidase assay. The levels of receptor for AGEs (RAGE), ILK, α-actinin-4, and synaptopodin were evaluated by western blotting and the distribution of F-actin, α-actinin-4, and synaptopodin were observed by immunofluorescence and confocal fluorescence microscope.

Results: AGEs caused an increase in the expression of RAGE and ILK by 70% and 100%, respectively ($P<0.05$). The expression levels of α-actinin-4 and synaptopodin decreased by 50% and 60%, respectively ($P<0.05$). And AGEs also caused rearrangement of F-actin, redistribution of α-actinin-4 from the membrane to the cytoplasm. AGEs (80 μg/ml) decreased podocyte adhesion by 60% ($P<0.05$). However, pretreatment with anti-RAGE antibody (50μg/ml) inhibited the effects induced by AGEs.

Conclusions: AGEs reduced podocyte adhesion via upregulation of both ILK and RAGE, downregulation of both α-actinin-4 and synaptopodin and reorganization of actin cytoskeleton.

PUB077

Advanced Glycation End-Products Activate the Renin-Angiotensin System through the RAGE-PI3-K /Akt Signaling Pathway in Podocytes

Cailian Cheng,[1] Xun Liu,[1] Zhenda Zheng,[1] Ying Tang,[2] Tan-qi Lou.[1] *[1]Department of Nephrology, The 3rd Affiliated Hospital of Sun Yat-Sen University, Guangzhou, Guangdong, China; [2]Department of Nephrology, The 2rd Affiliated Hospital of Sun Yat-Sen University, Guangzhou, Guangdong, China.*

Background: Renin-angiotensin system (RAS) play an important role in the pathogenesis of chronic kidney disease. Advanced glycation end-products (AGEs) were involved in the progression of diabetic kidney disease. However, little is known about the effects of AGEs on RAS in podocytes and the mechanism of these effects.

Methods: Immortalized mouse podocytes were exposed to various concentrations of AGEs (0, 20, 40, 80, 160 μg/ml) for different time intervals(12h, 24h, 48h. The expression levels of angiotensinogen (AGT), renin, and angiotensin II (Ang II) type 1 and 2 receptors (AT1R and AT2R), receptor for AGEs (RAGE) and both Akt and phosphorylated Akt were examined by western blotting. Ang II levels were assayed by ELISA, and angiotensin converting enzyme (ACE) activity was evaluated by ultra violet spectrophotometry.

Results: Treatment with AGEs resulted in significant increase in the expression of AGT (62%, P<0.05) and AT1R (59%, P<0.05). Moreover, Ang II levels increased significantly in both cell lysates and conditioned media (70% and 65%, P<0.05); ACE activity was also significantly higher in cell lysates and conditioned media (68% and 65%, P<0.05). However, there were no changes in renin or AT2R expression (P>0.05). AGEs did increase the expression of RAGE by 50% (P<0.05) and the phosphorylation of Akt by 100% (P<0.05). When podocytes were pretreated with anti-RAGE antibody (50 μg/ml) or the phosphoinositide 3-kinase (PI3K) inhibitor LY294002 (10 μM), the AGEs-induced increase in AGT and AT1R expression was reduced significantly. Likewise, Ang II levels and ACE activity decreased significantly.

Conclusions: AGEs activated the RAS in podocytes through the RAGE-PI3K/Akt-dependent pathway, which may provide a new therapeutic for diabetic kidney disease.

Acidosis Attenuates Leucine Induced Signal Transduction and Protein Synthesis in Rat Skeletal Muscle

Sumita Sood,[1,2] Yu Chen,[1,2] Kevin L. Mcintire,[1,2] Ralph Rabkin.[1,2] *[1]Research Service, Veterans Affairs Health Care Palo Alto, Palo Alto, CA; [2]Medicine Dept/ Renal Division, Stanford University, Stanford, CA.*

Background: Metabolic acidosis is a common cause of skeletal muscle wasting which occurs mainly due to increased proteolysis, though protein synthesis (PS) may also be impaired. Since leucine (LEU) comprises ~20% of daily essential amino acid requirements and is a known stimulator of PS, we set out to evaluate the impact of acidosis on LEU induced anabolic signaling and PS. LEU apart from serving as a substrate, stimulates PS largely by directly activating the nutrient sensitive mTOR signaling complex, with downstream phosphorylation of eukaryotic 4E-binding protein1 (4E-BP1) and S6 kinase-1 (S6K1).

Methods: Acidosis was induced in rats by gavaging with NH4Cl daily while pairfed controls were given saline. After 2 days rats from both groups were gavaged once with LEU or saline and sacrificed 45 mins later. PS was assayed in isolated extensor digitorum longus muscles of saline gavaged acidotic and control rats, incubated at PH 7.15 or 7.4 respectively, with or without LEU present. ^{14}C-phenylanine incorporation into protein was determined.

Results: PS in the absence of LEU was unaffected by PH. Addition of LEU increased PS significantly by 44±12 % (p<0.05) in pairfed control rat muscle, but was without significance in acidotic rat muscle. Signal transduction was assayed in plantaris muscle collected at sacrifice by Western immunoblotting. Phosphorylation of mTOR and 4E-BP1 increased significantly post-LEU gavage to a similar extent in acidotic and control rats. However LEU stimulated S6K1 phosphorylation was significantly attenuated in acidotic rats vs pairfed controls, increasing to 174±14 vs 309±25% above the basal control value, p<0.001.

Conclusions: In conclusion we have established that sustained acidosis attenuates LEU stimulated activation of signal transduction via the mTOR pathway at the level of S6K-1, a regulator of translation initiation and protein synthesis. This abnormality presumably contributes to the suppression of LEU induced protein synthesis in skeletal muscle and likely contributes to the muscle wasting of acidosis, common in kidney failure.

PUB079

Advanced Glycation End-Products Reduces Podocyte Adhesion via Activation of the Renin-Angiotensin System in Podocytes

Cailian Cheng,[1] Zhenda Zheng,[1] Xun Liu,[1] Ying Tang,[2] Tan-qi Lou.[1] *[1]Department of Nephrology, The 3rd Affiliated Hospital of Sun Yat-Sen University, Guangzhou, Guangdong, China; [2]Department of Nephrology, The 2nd Affiliated Hospital of Sun Yat-Sen University, Guangzhou, Guangdong, China.*

Background: Renin-angiotensin system and podocytopenia were involved in the pathogenesis of diabetic kidney disease and recent studies showed podocyte detach from the glomerular basement membrane played a key role in the process of podocytopenia. Advanced glycation end-products (AGEs) were involved in the progression of diabetic kidney disease. However, the effects of AGEs on podocyte adhesion and its possible mechanisms is poor known.

Methods: Immortalized mouse podocytes were exposed to various concentrations of AGEs (0, 20, 40, 80, 160 μg/ml) for different periods (6h, 12h, 24h, 48h), podocyte adhesive capacity was evaluated by cytometry and hexosaminidase assay. The expression levels of angiotensinogen (AGT), renin, and angiotensin II type 1 and 2 receptors (AT1R and AT2R) were examined by western blotting. Ang II levels were assayed by ELISA, and angiotensin converting enzyme (ACE) activity was evaluated by ultra violet spectrophotometry.

Results: Treatment with AGEs (80μg/ml) resulted in significant decrease in podocyte adhesion by 60%. AGT and AT1R expression, ACE activity, and Ang II levels increased significantly in podocyte lysates and conditioned culture media exposure to AGEs (80μg/ml) (P <0.05). Pretreatment with losartan and captopril partly improved the reduced adhesive capacity of podocytes compared with cells exposed to AGEs (85%±19% vs. 40%±20%, *P*<0.05), but it was still lower than that podocytes exposed to BSA.

Conclusions: Our findings indicate that AGEs activates the renin-angiotensin system in podocytes, which is partly involved in the down regulation of adhesive capacity induced by AGEs.

Effects of Leukemia Inhibitory Factor and Oncostatin M on IgA1-Producing Cells from Patients with IgA Nephropathy

Koshi Yamada,[1,2] Zhi Qiang Huang,[1] Milan Raska,[1,3] Zina Moldoveanu,[1] Hitoshi Suzuki,[2] Yusuke Suzuki,[2] Krzysztof Kiryluk,[4] Robert J. Wyatt,[5] Yasuhiko Tomino,[2] Bruce A. Julian,[1] Ali G. Gharavi,[4] Jan Novak.[1] *[1]University of Alabama at Birmingham, Birmingham, AL; [2]Juntendo University, Tokyo, Japan; [3]Palacky University, Olomouc, Czech Republic; [4]Columbia University, New York, NY; [5]University of Tennessee, Memphis, TN.*

Background: Galactose-deficient IgA1 (Gd-IgA1) is a key pathogenetic factor in IgA nephropathy (IgAN). Our recent GWAS associated a locus on chromosome 22q12.2 with elevated serum levels IgA in patients with IgAN. This locus contains genes encoding leukemia inhibitory factor (LIF) and oncostatin M (OSM) cytokines that play a role in mucosal immunity and inflammation. However, their effect on IgA1-producing cells is not known.

Methods: EBV-immortalized IgA1-secreting cells derived from the circulation or tonsils of IgAN patients and healthy controls (HC) were stimulated with LIF and OSM, and serum IgA1 and Gd-IgA1 levels were determined by ELISA. STAT3 and STAT1 phosphorylation was analyzed using SDS-PAGE and Western blotting and confirmed by using specific inhibitors of signaling.

Results: LIF and OSM decreased production of IgA1 in IgAN and HC cells. In contrast, production of Gd-IgA1 was increased by 15% after LIF and by 14% after OSM stimulation, but only in IgAN cells. LIF and OSM signaling was mediated through STAT1 but not STAT3 phosphorylation.

Conclusions: LIF and OSM enhanced production of Gd-IgA1 in the cells from IgAN patients but not in those from HC. This process was mediated by STAT1. This signaling pathway may represent a possible therapeutic target in IgAN.

Differential Expression of Uric Acid Transporters in the Vessels of the Normal Rat Leads to Distinct Responses to Uric Acid

Wei Chen,[1,2] Aaron Kennedy,[1] Seth B. Furgeson,[1] Carlos Alberto Roncal-jimenez,[1] Richard J. Johnson,[1,3] Diana I. Jalal.[1] *[1]Medicine/Renal, University of Colorado, Aurora, CO; [2]Nephrology, The First Affiliated Hospital, Sun Yat-Sen University, Guangzhou, China; [3]Medicine/ Nephrology, University of Florida, Gainseville, FL.*

Background: URAT1 (SLC22A12) & GLUT9 (SLC 2A9) are involved in uric acid transport. We have previously shown URAT1 is highly expressed in the abdominal aorta whereas GLUT9 is highly expressed in the thoracic aorta of the normal rat. We hypothesized that different spatial expression of these transporters leads to distinct responses to uric acid by vascular smooth muscle cells (VSMC).

Methods: VSMCs were isolated from the thoracic and abdominal aorta of male Sprague Dawley rats, then plated in DMEM with 10% FBS and Penicillin/ Streptomycin. The cells were treated with uric acid at 0, 2, 4, and 6 mg/dL. Intracellular uric acid was measured via QuantiChrom Uric Acid Assay Kit on cell lysates. MCP-1 in cell culture media was measured by ELISA. To determine if cell proliferation differed in response to uric acid between both cell lines, BrdU incorporation assay was performed at 0 and 6 mg/dL of uric acid.

Results: Intracellular uric acid increased in the abdominal VSMCs with higher uric acid dose; this was significant at 6 mg/dL (Figure 1). MCP-1 doubled in cell culture media of abdominal VSMC treated with 6 mg/dL of uric acid (p=0.002) but was unchanged in the media of the thoracic VSMCs. The percentage of BrdU positive cells increased with 6 mg/dL of uric acid in both cell lines but was significantly higher in the abdominal vs thoracic VSMCs (p=0.04).

Conclusions: Intracellular uric acid increases in response to uric acid in VSMCs expressing URAT1. This is associated with increased MCP-1 and greater cell proliferation. Further studies are needed to better understand the role of URAT1 in uric acid transport in VSMCs.

Aquaporin-2 Is Regulated by Integrin-Linked Kinase

Jose Luis Cano-peñalver,[1] Mercedes Griera,[1] Nuria Troyano,[1] Ines Mora,[1] Paloma Martín-sánchez,[1] Manuel Rodriguez-Puyol,[1] Diego Rodriguez-Puyol,[2] Sergio De Frutos Garcia.[1] *[1]Department of Physiology, Universidad de Alcalá, Alcalá de Henares, Madrid, Spain; [2]Research Unit, Hospital Universitario Principe de Asturias, Alcalá de Henares, Madrid, Spain.*

Background: Progressive interstitial fibrosis produces structural changes in the kidney, where abnormal extracellular matrix (ECM) may lead to functional changes in the tubular reabsortion. In the collecting tubules, the vasopressin-regulated Aquaporin isoform AQP2 is the main regulating water absorption channel. The AQP2 expression is mainly regulated by both transcriptionally and post-translationally pathways which includes its intracellular trafficking to the apical membrane of the tubule that facilitate the water absorption. However the molecular mechanisms implicated in both types of regulation are still under study. Since the traffic of the AQP2 depends in the phosphorilation of its structure, several kinases such those dependent of cAMP or cGMP have being studied. Very few studies have related the changes present in the ECM and their receptors, the integrins, in the AQP2 expression and trafficking regulation. We studied for the first time the implication of the kinase linked to integrins (ILK) in the transcriptional regulation of AQP2 and its intracellular location.

Methods: We used conditional ILK-deleted mice (ILK-cKO) compared with controls (WT). We analyzed urine volumes and its osmolality. Cortical and medullar expression of AQP2 and its intracellular location was determined by western blot, quantitative PCR and immunofluorescence.

Results: We observed a quite significant poliuria, with increased osmolality in the ILK-cKO mice urine compared with WT. In order to study the role of AQP2 regulation pathways we determined its mRNA and protein levels, both significantly decreased in ILK-cKO mice. We observed also a decreased presence of AQP2 in the apical membrane of the tubules in the animals where ILK was depleted.

Conclusions: We propose ILK as a major player in the tubular physiology and pathology since the lack of ILK decreases the AQP2-dependent water absorption, because its expression and presence in the tubular membrane is decreased.

Participation of Endoplasmic Reticulum Stress in the Pathogenesis of Spontaneous Glomerulosclerosis: Role of Intra-Renal Angiotensin System

Tadashi Sato,[1] Mohammad A. Aminzadeh,[2] Nosratola D. Vaziri.[2] *[1]Pediatrics, N.H.O. Ureshino Medical Center, Ureshino-City, Saga, Japan; [2]Nephrology and Hypertension, University of California, Irvine, CA.*

Background: Endoplasmic reticulum (ER) is the site of synthesis, folding, assembly, and degradation of proteins. Disruption of ER function leads to ER stress, which is marked by accumulation of unfolded proteins in the ER lumen. Detection of unfolded proteins by the ER membrane receptors triggers the ''unfolded protein response (UPR)'' designed to restore ER function via activation of the adaptive/cytoprotective responses. Failure of UPR or persistent stress triggers activation of ER stress-mediated apoptotic pathway. Several in vivo and in vitro studies have demonstrated the association of ER stress with glomerular diseases. Imai rats develop progressive glomerulosclerosis (GS), which is associated with oxidative stress, inflammation and activation of intra-renal angiotensin system, and can be prevented by AT-1 receptor blockade (ARB). Since persistent oxidative and inflammatory stresses trigger ER stress-induced apoptosis and tissue injury, we hypothesized that kidneys in the Imai rats may exhibit failure of the adaptive and activation of the apoptotic ER stress responses, which could be prevented by ARB.

Methods: To this end 10-week old Imai rats were randomized to untreated and ARBtreated groups and observed for 24 weeks.

Results: At age 34 weeks, untreated rats showed heavy proteinuria, azotemia, advanced GS, impaired ER stress adaptive/cytoprotective responses (depletion of UPR-mediating proteins), and activation of ER stress apoptotic responses. ARB treatment attenuated GS, suppressed intra-renal oxidative stress, restored ER-associated adaptive/cytoprotective system, and prevented the ER stress mediated apoptotic response in this model.

Conclusions: Thus, progressive GS in Imai rats is accompanied by activation of ER stress-associated apoptosis, which can be prevented by ARB.

Human Serum Reduces Shigatoxin 2-Induced Unfolded Protein and Ribotoxic Stress Response and Apoptosis in Human Podocytes

Anne Katrin Dettmar,[1] Elisabeth Binder,[2] Therese C. Jungraithmayr,[2] Moin Saleem,[3] Markus J. Kemper,[1] Reinhard Würzner,[2] Jun Oh.[1] *[1]University Hamburg-Eppendorf; [2]Medical University Innsbruck; [3]University of Bristol.*

Background: Shigatoxin 2, the active toxin in hemolytic uremic syndrome (HUS) activates the unfolded protein response (UPR), because of accumulation of unfolded proteins and the ribotoxic stress response through binding to ribosomes. In endothelial cells both pathways contribute to apoptosis, which leads to microangiopathy. Glomerular proteinuria is one early symptom in HUS-patients and persistent proteinuria is associated with a poorer renal outcome. Thus podocytes may be one target for Stx2.

Methods: Human podocytes were incubated with Stx2. Incubation medium was supplemented with fetal calf serum (FCS), serum from healthy human controls (normal human serum = NHS) and serum from pediatric HUS-patients. Lysates were tested for UPR and ribotoxic stress marker, caspase 3 (casp3), a key enzyme in apoptosis and Bcl-2, a prosurvival protein.

Results: Upon Stx2-incubation human podocytes showed an increase in IRE1 ("sensing" levels of unfolded proteins) and an increase in p-EIF2α (transcription factor, inhibiting further protein translation). When normal human serum (NHS) was given to the cells instead of fetal calf serum (FCS) the increases in both proteins were diminished. P38MAPK-α was activated upon Stx2 incubation, while p38MAPK-β (most likely anti-apoptotic) was not activated. NHS suppressed the activation of p38MAPK-α, but activated p38MAPK-β instead. Casp3 activity was increased after Stx2 after 48hrs. This peak was not found with NHS ($p<0.05$) but Bcl-2 was upregulated with NHS compared to FCS supplementation. Sera from HUS-patients did not diminish the activation of p38MAPK-α and casp3 to the same extent as NHS.

Conclusions: Stx2 induces unfolded protein and ribotoxic stress response, leading to apoptosis in human podocytes. Podocytes might be an additional target of Stx2-associated HUS. Activation and apoptosis can be blocked by NHS, but not completely by sera from HUS patients. These data suggest a potential circulating protecting factor in healthy humans, which might be consumed or blocked in patients with HUS.

PUB086

Expression of Genes Associated with Telomere Maintenance in Patients after Kidney Transplantation

Agnieszka Witkowska,[1] Grzegorz Hibner,[2] Joanna Zywiec,[1] Barbara Strzalka - Mrozik,[2] Joanna Gola,[2] Wladyslaw Grzeszczak,[1] Janusz Gumprecht.[1] *[1]Department of Internal Medicine, Diabetology and Nephrology, Medical University of Silesia, Zabrze, Poland; [2]Department of Molecular Biology, Medical University of Silesia, Sosnowiec, Poland.*

Background: Chronic administration of immunosuppressants has long-term consequences including higher risk of neoplasms development. The processes regulating telomere function have major influence on human cancer biology. The study aimed to assess the impact of immunosuppressive therapy on expression of genes associated with telomere maintenance and protection in patients after renal transplantation.

Methods: Expression profiles of 129 transcripts, which represented 70 genes, were assessed in peripheral mononuclear blood cells (PBMCs) with oligonucleotide microarray technique (HG–U133A Affymetrix) in 8 euglycemic transplant recipients (5M and 2F; aged 46.5±8.6 years) on a three drug immunosuppressive regimen including: cyclosporine, prednisone and mycophenolate mofetil or sodium and 4 healthy controls (2M and 2F; aged 59±4.5years). Statistical analysis was performed with use of Agilent GeneSpring GX 11.0 (unpaired t -test with asymptotic p-value corrected with Benjamini-Hochberg multiple test).

Results: Among the analyzed transcripts there were 4 with significantly different expression between the studied groups of subjects (Fold Change > 2.0, p-value < 0.05) shown in Table 1.

Gene symbol	p-value	Fold Change	Expression regulation in transplant recipients vs. controls	Association with telomere maintenance regulation
ACD	0.006	2.11	down	one of six core proteins (TPP1) in the telosome/ shelterin, mediates the access of telomerase to the telomere
TGFBR2	0.02	2.42	up	regulation of a telomerase transcription
MAP3K1	< 0.001	4.02	up	regulation of a telomerase transcription
YWHAB	0.002	2.97	up	nuclear transport of a telomerase

Conclusions: Our results show detrimental changes in telomere maintenance facilitating cell immortalization and carcinogenesis on a gene expression level in kidney transplant recipients. The outcomes may not only contribute to the knowledge of post-transplant cancer pathogenesis, but influence the strategy of immunosuppressive therapy in the future, as well.

PUB087

High Glucose Induces Autophagy in Podocytes Tean Ma,[1] Xinghua Chen,[1] Dongqing Zha,[1] Pravin C. Singhal,[2] Guohua Ding.[1] *[1]Division of Nephrology, Renmin Hospital of Wuhan University, Wuhan, Hubei, China; [2]Medicine, North Shore LIJ Hofstra Medical School, Great Neck, NY.*

Background: Autophagy is a cellular pathway involved in protein and organelle degradation. It is relevant to many types of cellular homeostasis and human disease. High glucose can induce podocyte injury, but it is still unknown about the relationship between high glucose and autophagy in podocytes. This study investigates the effects of high glucose on autophagy in podocytes.

Methods: (1) Conditionally immortalized mouse podocytes were cultured in vitro. The cultured podocytes were treated with either high glucose or normal concentration of glucose in the presence or absence of rapamycin and 3-methyladenine. Autophagy was evaluated by electron microscopy and detection of GFP-LC3 overexpression by fluorescence microscopy. Western blots examined LC3-2 and beclin-1. (2) Conditionally immortalized mouse podocytes were treated with either high glucose or normal glucose in the presence or absence of NAC. ROS generation was detected, and MnSOD and catalase was examined by Western blots.

Results: High glucose promoted autophagy in podocytes. Rapamycin further enhanced this effect which could be inhibited by 3-MA. The proautophagic effect of high glucose was associated with podocyte expression of LC3-2 and beclin-1, and antioxidants such as NAC inhibited high glucose-induced autophagy. High glucose induced the generation of ROS by podocytes in a time-dependent manner. High glucose also enhanced podocyte expression of MnSOD and catalase.

Conclusions: High glucose promotes autophagy in podocytes. High glucose-induced podocyte autophagy is mediated through the generation of ROS.

PUB088

The Activity of GSK-3β and Podocyte Injury in db/db Mutant Diabetic-Nephropathy Mice Liu Zhangsuo,[1] Guo Jia,[2] Wan Jia.[3] *[1]Department of Nephrology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan, China; [2]Department of Nephrology, The First Affiliated Hospital, Zhengzhou University; [3]Department of Nephrology, The First Affiliated Hospital, Zhengzhou University.*

Background: To investigate the activity of GSK-3β and podocyte injury in db/db mutant diabetic- nephropathy mice.

Methods: The db/+m mice (n=15) were served as control. And the db/db diabetic-nephropathy mice(n=30) were randomly divided into intervention group(n=15, subcutaneously injected with BIO, 320 μg/kg per day, since the mice were 90 days old.) and non-intervention group(n=15).When the mice were 90,110 (injection of BIO for 20 days),130 (injection of BIO for 40 days) day-old respectively, 5 mice of each group were sacrificed.Then the tissue of kidneys were used to observe the structure of glomerular by electron microscope or light microscope. The localization or expression of proteins was determined by immunofluorescence analysis, fluorescence quantitative PCR or Western blot.The glycogen synthase kinase-3β (GSK-3β) inhibitor 6-Bromoindirubin-3'-oxime (BIO) was used to inhibit the activity of GSK-3β which could be assayed by TRAPEZE enzyme detection kit.

Results: Compared with control, the glomerular basement membrane(GBM)of non-intervention group become more thick and the messegium was increased. And the expression of nephrin was less (P<0.05) combined with the increasing expression ofα-SMA, which mean the podocyte injury in db/db mutant diabetic- nephropathy mice. Although the protein expression of total GSK-3β had no obvious change, the activities of GSK-3β was enhanced in a time dependent manner in the non-intervention group. After BIO injection for 20 days, the activity of GSK-3β was inhibited but the expression of total GSK-3β had no obvious change. When BIO injection for 40 days but not 20 days, the thickness of GBM, the increasing of messegium and the expression of nephrin were alleviated compared with non-intervention group(P<0.05). But compared with db/+m mice, the pathological changes still existed.

Conclusions: The activity changes of GSK-3β may lead to the podocyte injury in db/db mutant diabetic- nephropathy mice. And BIO could partly ameliorate the expression of nephrin.

High Glucose Promotes Cellular Senescence in the Kidney by Inducing a Mild Hyperosmolar Stress Maria Del Nogal, Nuria Troyano, Jose Luis Cano-peñalver, Alicia Cortes, Gemma Olmos, Sergio De Frutos Garcia, Manuel Rodriguez-Puyol, Maria P. Ruiz-torres. *Department of Physiology, Universidad de Alcalá, Alcalá de Henares, Madrid, Spain.*

Background: Senescence is a stress response that withdraws the cell cycle and leads to morphological and functional cellular changes. Senescence appears in aged and diabetic kidney suggesting an important role on kidney dysfunction. Our aim was to analyze the role of the extracellular osmolarity induced by high glucose in human mesangial and rat kidney cellular senescence and the mechanism involved.

Methods: In order to increase extracellular osmolarity, Human mesangial cells (HMC) or Ex vivo rat kidney slices were treated with high glucose (HG) or the control osmolyte mannitol during different periods of time. Male Wistar rats were treated with mannitol, with streptozotocin to induce experimental diabetes or with vehicle. Cellular senescence was measured as β-galactosidase activity using a fluorescent substrate. p53, p21, p16 and Ras expression were measured by immunoblotting and immunohistochemistry. Ras activation was analyzed by pull down assay. Reactive oxygen species (ROS) production was evaluated by flow cytometry.

Results: Both HG and mannitol mildly increased extracellular osmolarity in HMC promoting cellular senescence by increasing p53, p21 and p16 protein expression. Both HG and Mannitol promoted an increase in reactive oxygen (ROS) production and the constitutive activation of Ras, however the inhibition of ROS and Ras prevented cellular senescence. Both streptozotocin and mannitol rats shown serum osmolarity and p53 and p16 protein expression increase compared with controls. Both HG- or mannitol-treated rat kidney slices shown increased p53 and p16 expression.

Conclusions: HG induced cellular senescence in HMC and rat kidney cortex by inducing extracellular osmolarity increase, since the control osmolyte mannitol reproduced the same results. This effect was ROS and Ras dependent.

Impact of Erythropoietin on Mononuclear Cells Signaling in Chronic Kidney Disease (CKD) Patients Stage 4 and 5 Mariusz Kowalczyk, Piotr Bartnicki, Jacek Rysz. *Department of Nephrology, Hypertension and Family Medicine, Lodz Medical University, Poland.*

Background: The main objective of the research was to study the influence of erythropoietin (Epo) on membrane cells phospholipids metabolism (myoinositol incorporation) which play a key role in a synthesis of secondary messengers such as inositol triphosphate and diacylglycerol.

Methods: 15 patients (7 women, 8 men) with CKD stage 4-5 and 20 healthy subjects (14 women, 6 men) were enrolled. Blood was sampled prior and after Epo treatment. Triplicate cultures of peripheral blood mononuclear cell (PBMC) were suspended in liquid nutrient with or without myo-[2-^{3}H]-inositol (INOZ) and phytohaemagglutinin (PHA) as shown in the table below. After incubation INOZ incorporation was estimated by a scintillation counter. Spontaneous activation (SpAct) and phytohemagglutinin-inducible activation (PHAAct) were calculated by the following equations: SpAct = [(PBMC + INOZ) - PBMC]; PHAAct = [(PBMC + PHA + INOZ) - (PBMC + PHA)].

Results:
Mean value results in study groups

	Healthy Subjects	CKD prior treatment	CKD after treatment
PBMC♦	42.7	43	42.4
PBMC+PHA♦	39.5	43.1	47
PBMC+INOZ♦	233.6	168	368.8
PBMC+INOZ+PHA♦	152.7	158.7	^227.1*
Sp Act♦	163 (82-260)	134 (45-198)	208 (120-451)
PHA Act♦	112 (73-142)	103 (42-179)	^182 (132-223)*
Age years	56.6±9	71.9±11	-
HGB g/dl	13.8	9.6*	^11.4*

♦dpm; *p<0.05 vs healthy subjects; ^p<0.05 vs CKD prior treatment

No statistical differences of INOZ incorporation in SpAct and PHAAct cultures were found in the group of healthy subjects and CKD patients prior treatment. INOZ incorporation in the group of patients after Epo treatment was significantly increased in PHAAct and insignificantly increased in SpAct cultures in comparison to the healthy subjects. INOZ incorporation in the group of patients after Epo treatment was significantly increased in PHAAct and SpAct cultures (p<0.05) in comparison to the patients group before treatment.

Conclusions: This study, despite its limitations, disclosed that INOZ incorporation after Epo treatment was significantly higher than before treatment. Therefore, Epo may be partially responsible for the synthesis of the secondary messengers and improvement of the cells signaling in CKD patients.

PUB091

Effect of the F11R Receptor Antagonist P4D on Human Umbilical Vein Endothelial Cell (HUVECs) Proliferation Moro O. Salifu, Arye Kremer, Anna Babinska. *Division of Nephrology, SUNY Downsate Medical Center.*

Background: The F11R/JAMA receptor is expressed on the surface of platelets, endothelial cells (EC) and smooth muscle cells and has been implicated in plaque formation and thrombosis and could be a potential therapeutic target in intimal hyperplasia. Here we examined the possibility that blockade of F11R /JAM using the specific F11R inhibitor peptide 4D (P4D) on human vein endothelial cells (HUVECs) could inhibit the proliferation of endothelial cells.

Methods: Cultured HUVEC were treated with increasing concentrations of P4D (0, 100, 250 or 500μM) alone (non-TREATED) or increasing concentration of P4D with TNFa and INFg (TREATED) and mitochondrial activity (Formazan production) was measured at different time points. Comparison of formazan production was made between the two groups at 24 hours and within each group.

Results: In non-TREATED HUVECs, there was no significant difference in formazan production at the three different concentrations of P4D compared to control. In TREATED HUVECs, we observed significantly higher inhibition of formazan production with increasing concentrations of P4D in a dose dependent manner (9% inhibition at 100μM, p=0.14, 18% inhibition at 250μM, p<0.002 and 28% inhibition at 500μM, p<0.005). There was statistically significant inhibition of formazan production between TREATED and non-TREATED groups at 250μM P4D (18% vs. 0.5%, p <0.005) and at 500μM (28% vs. 1.3%, p <0.005).

Conclusions: We observed a dose dependent inhibitory effect of P4D on mitochondrial activity of HUVECs only under inflammatory conditions but no effect on intact HUVEC. Further studies are needed to determine the role of P4D in intimal hyperplasia, characteristic of dialysis vascular access stenosis.

PUB092

Effect of the F11R Receptor Antagonist P4D on Human Smooth Muscle Cell (HSMCs) Proliferation Moro O. Salifu, Arye Kremer, Anna Babinska. *Division of Nephrology, SUNY Downstate Medical Center.*

Background: The F11R/JAMA receptor is expressed on the surface of platelets, endothelial cells and smooth muscle cells and has been implicated in plaque formation and thrombosis and could be a potential therapeutic target in intimal hyperplasia. Here we examined the possibility that blockade of F11R /JAM using the specific F11R inhibitor peptide 4D (P4D) could inhibit the proliferation of human smooth muscle cells (HSMC) in vitro.

Methods: Cultured HSMC were treated with increasing concentrations of P4D (0, 100, 250 or 500 μM) alone (non-TREATED) or increasing concentration of P4D with TNFa IL-1b and INFg (TREATED) and mitochondrial activity (Formazan production) was measured. Comparison of formazan production was made between the two groups at 24 hours and within each group.

Results: In non-TREATED HSMCs, there was significantly higher dose dependent P4D inhibition of formazan production (5.2%@100μM, 20.2%@250μM and 24.8%@500μM) compared to control ($p<0.05$). In TREATED HSMCs, there was also significantly higher dose dependent P4D inhibition of formazan production (8.5%@100μM, 16.6%@250μM and 25.6%@500μM) compared to control ($p<0.05$). There was no significant inhibition of formazan production between TREATED and non-TREATED groups at 250μM P4D (16.6% vs. 20.2%) and at 500μM (25.6% vs. 24.8%).

Conclusions: We observed a dose dependent inhibitory effect of P4D on mitochondrial activity of HSMCs under inflammatory and non-inflammatory conditions. Further studies are needed to determine the role of P4D in intimal hyperplasia, characteristic of dialysis vascular access stenosis.

PUB093

Nicotine Induces Apoptosis in Human Proximal Tubular Cells Joon Seok Choi, Chang Seong Kim, Eun Hui Bae, Seong Kwon Ma, Soo Wan Kim. *Department of Internal Medicine, Chonnam National University Medical School, Gwangju, Korea.*

Background: Cigarette smoking is considered as independent risk factor for progression of chronic kidney disease and nicotine is the major compound of cigarette. The present study was aimed to investigate the effect of nicotine on renal tubular epithelial cell apoptosis in vitro and explore the potential mechanisms involved.

Methods: Human proximal tubular epithelial (HK-2) cells were treated with 200 μM of nicotine. Cell viability was examined using MTT assay. The DCF-DA staining was used to measure intracellular levels of reactive oxygen species (ROS). The protein expression of extracellular signal-regulated kinase (ERK), P38 and c-Jun N-terminal kinase (JNK), NF-κB, Bax and Bcl-2 was determined by semiquantitative immunoblotting.

Results: Nicotine treatment resulted in dose-dependent decreases of cell viability and increases of ROS. Nicotine increased the expression of p-ERK, p-JNK and p-P38. Nicotine induced expression of p-ERK and p-JNK in HK-2 cells, which was attenuated by pretreatement of N-acetyl-cysteine. The expression of NF-κB started to increase 1 hour after nicotine exposure. Increased nuclear NF-κB activation was counteracted by inhibitors of ERK (PD98059) or JNK (SP600125). Nicotine decreased the expression of Bcl-2, while increased that of Bax.

Conclusions: These results suggest that nicotine induce apoptosis by increased ROS generation through activation of NF-κB and mitogen-activated protein kinase signaling pathways in HK-2 cells.

PUB094

High Glucose Induce Apoptosis through the PERK-eIF2α Endoplasmic Reticulum Stress Pathway in Peritoneal Mesothelial Cells Junichi Nakamata,[1] Hiroyuki Morimoto,[2] Ryoko Baba,[2] Nana Ishimatsu,[1] Tetsu Miyamoto,[1] Kaori Kanegae,[3] Ryota Serino,[1] Narutoshi Kabashima,[3] Yutaka Otsuji,[1] Yoshiaki Doi,[2] Masahito Tamura.[3] *[1]The 2nd Department of Internal Medicine, University of Occupational and Environmental Health, Kitakyushu, Japan; [2]The Department of Anatomy, University of Occupational and Environmental Health, Kitakyushu, Japan; [3]The Kidney Center, University of Occupational and Environmental Health, Kitakyushu, Japan.*

Background: It is important to maintain an adequate peritoneal function and structure for long-term PD therapy. Endoplasmic reticulum (ER) stress is induced by an accumulation of unfolded or misfolded protein in the ER, and it is associated with the progression of diabete mellitus. We investigated whether ER stress-induced apoptosis is involved in the glucose-induced peritoneal damage in cultured rat peritoneal mesothelial cells (PMCs).

Methods: The primary PMCs obtained from the parietal peritoneum of Wistar rats were treated with a high glucose culture medium. The cell viability of the PMCs was measured by a WST-1 assay. The induction of apoptosis was examined by a DNA ladder formation assay. The activation of the PERK-eIF2α pathway was determined by Western blotting. The subcellular localization of CHOP was analyzed by immunocytochemistry.

Results: The treatment of PMCs with glucose higher than 3% suppressed cell viability and induced DNA fragmentation. High glucose increased the phosphorylation of PERK and its downstream signal, eIF2α. High glucose also enhanced CHOP expression, which is a downstream element of eIF2α, and altered the subcellular localization of CHOP from cytosol to nucleus. Sal 003, an eIF2α inhibitor, partially attenuated the high glucose-induced suppression of cell viability, thus suggesting that other ER stress pathways such as ATF6 or IRE1, might also be involved in glucose-induced PMC apoptosis.

Conclusions: We demonstrated that high glucose induced ER stress-mediated apoptosis mainly via the PERK-eIF2α pathway in PMCs. These findings suggest that the ER stress-mediated apoptosis might be involved in glucose-induced peritoneal damage, thus indicating a potentially useful therapeutic approach by manipulating eIF2α in patients on PD therapy.

PUB095

The Role of GSK-3β in Epithelial-Mesenchymal Transition and Apoptosis of Podocytes with High Glucose Liu Zhangsuo,[1] Guo Jia,[1] Su Chenhao.[1] *[1]Department of Nephrology, The First Affiliated Hospital, Zhengzhou University; [2]Department of Nephrology, The First Affiliated Hospital, Zhengzhou University; [3]The First Affiliated Hospital, Zhengzhou University.*

Background: To investigate the role of GSK-3β (glycogen synthase kinase 3 beta) in epithelial-mesenchymal transition (EMT) and apoptosis of podocytes with high glucose.

Methods: The matured podocytes were cultured in RPMI 1640 medium with different concentration of glucose (5.6mmol/L, 12.5mmol/L, 30 mmol/L, 50 mmol/L for 48h) or different time (30mmol/L for 24h, 36h, 48h). Western blot or reverse transcription-PCR was used to detected the protein or mRNA expression. The viability or apoptosis of podocytes with different treatments were detected by MTT assay or flow cytometry. The activity of GSK-3β in different conditions was detected by using the GSK-3β activity assay kit. The leakage of bovine serum albumin in transwell cultured plates was analysed to study the functional loss of podocytes caused by high glucose.

Results: Both the protein and mRNA expression of nephrin were decreased while the expression of α-SMA was up-regulated by high glucose treatment in a dose- and time-dependent manner ($P<0.05$). And the leakage of bovine serum albumin was increased when the concentration of glucose increasing, which mean the injury and functional loss of podocytes. Companied with the increasing concentration of glucose, the cell viability was decreased and the Bcl-2 mRNA was decreased while the Bax mRNA expression increasing. This indicated the high glucose could lead the podocytes to apoptosis.

Although the total GSK-3β was not changed significantly ($P>0.05$), the activity of GSK-3β in podocytes was enhanced ($P<0.05$) and the expression of p-Ser9-GSK-3β was increased when the glucose increased.

Conclusions: High glucose could lead the EMT, loss of function and apoptosis of podocytes. The enhanced activity of GSK-3β caused by high glucose may be one of the mechanisms of podocyte injury.

PUB096

Polymorphonuclear (PMN) Cells Apoptosis in Chronic Kidney Disease (CKD) Patients Treated with Methoxy Polyethylene Glycol: Epoetin beta (Mircera) Piotr Bartnicki, Jacek Rysz. *Department of Nephrology, Hypertension and Family Medicine, Lodz Medical University, Poland.*

Background: In patients with CKD is observed increased PMN cells apoptosis quantified by flow cytometry using annexin V and propidium iodide staining. Erythropoietin (Epo) in these patients, beyond anemia correction seem to have renoprotective effect and slow progression of CKD. One of possible renoprotective mechanism of Epo is antiapoptotic effect. In this study we aimed to determine the effect of methoxy polyethylene glycol – epoetin beta (Mircera) on PMN cells apoptosis in predialysis patients with CKD.

Methods: 28 patients in predialysis and anemia, treated with Mircera, were enrolled. The healthy control group included 15 volunteers. Data about hemoglobin level (Hg) and estimated glomerular filtration rate (eGFR) are shown in the table below. Apoptosis of PMN cells was quantified by flow cytometry using annexin V and propidium iodide staining and changes of FAS, FAS Ligand, CD16 and CD11b activity were assessed by flow cytometry too using respective monoclonal antibody.

Results:
The study results.

	CKD before treatment	CKD after treatment	Control group
Hg [g/dl]	9.6 (9.1 – 10.1) *	11.6 (11.1 – 12.1) *, #	14.4 (13.3 – 14.9)
eGFR [ml/min]	16.4 (13.9 – 21.8) *	16.6 (14 .0 – 23.3) *	65 (63 – 74)
FAS [MFI]	29.4 (24.8 – 36.2) *	25.2 (20.1 – 29.4) #	23.7 (21.8 – 26.6)
FAS Ligand [MFI]	47.7 (41.4 – 54.0) *	42.9 (30.4 – 54.8)	36.5 (28.9 – 49)
CD16 [MFI]	242 (174 – 309) *	283 (232 – 359)	328 (260 – 458)
CD11b [MFI]	235 (122 -344)	273 (175 – 381)	166 (123 – 280)
ANXLL [%]	94.7 (89.1 – 96.2)	94.5 (92 – 96.4)	95.5 (92.6 – 96.8)
ANXLR [%]	2 (1.5 – 2.5) *	1.5 (0.7 – 1.9) #	1.1 (0.4 – 1.4)
ANXUR [%]	1.5 (1.0 – 2.6) *	1.0 (0.6 – 1.7)	1.0 (0.6 – 1.6)
ANXLR+ANXUR [%]	3.5 (2.4 – 5.1) *	2.6 (1.9 – 3.2) #	2.1 (1.3 – 3.2)
PI [%]	2.6 (1.3 – 5.0) *	2.4 (1.6 – 3.0) *	1.7 (1.5 – 2.1)

* $p < 0.05$ to control group, # $p < 0.05$ to CKD before treatment

We found significant ($p < 0.05$) correlation between Hg and ANXLR + ANXUR measured as Kendall's tau coefficient values.

Conclusions: These data suggest that methoxy polyethylene glycol – epoetin beta (Mircera) used in correction of anemia in patients with CKD might have antiapoptotic effect.

Suramin Alleviates Glomerular Injury and Inflammation in the Remnant Kidney Shougang Zhuang.[1,2] [1]*Department of Medicine, Rhode Island Hospital, Alpert Medical School, Brown University, Providence, Providence, RI;* [2]*Department of Nephrology, Shanghai East Hospital, Tongji University School of Medicine, Shanghai, China.*

Background: Although suramin, a compound that inhibits the interaction of multiple cytokines/growth factors with their receptors, can attenuate the development of renal interstitial fibrosis in the murine model of unilateral ureteral obstruction (UUO), it remains unclear whether suramin can alleviate glomerular and vascular lesions. Here we tested the efficacy of suramin in the remnant kidney after 5/6 nephrectomy, a model characterized by the slow development of glomerulosclerosis, vascular sclerosis, tubulointerstitial fibrosis and renal inflammation.

Methods: 5/6 of normal renal mass was surgically ablated in male rats. On the second week after surgery,rats were randomly divided into suramin treatment and non-treatment groups. Suramin was given at 10 mg/kg once per week for two weeks.

Results: In the remnant kidneyof mice receiving suramin, glomerulosclerosis and vascular sclerosis as well as inflammationwere ameliorated. Suramin also attenuated tubular expression of two chemokines, monocyte chemoattractant protein-1 and regulated upon expression normal T cell expressed and secreted (RANTES). After renal mass ablation, several intracellular molecules associated with renal fibrosis, including NF-kappaB p65, Smad-3,signal transducer and activator of transcription-3 and extracellular regulated kinase 1/2, are phosphorylated; suramin treatment inhibited their phosphorylation. Futhermore, suramin abolished renal ablation-induced phosphorylation of epidermal growth factor receptor and platelet derived growth factor receptor, two receptors that mediate renal fibrosis.

Conclusions: These findings suggest that suramin attenuates glomerular and vascular injury and reduces inflammatory responses bysuppression of multiple growth factor receptor-mediated profibrotic signaling pathways. Therefore, suramin may be a useful drug in preventing the fibrosis and sclerosis that characterizes progression of chronic kidney disease.

PUB098

Transforming Growth Factor-β Attenuates Prostaglandin E_2-Mediated Responses in Mouse Proximal Tubule Cells Rania Nasrallah, Fadey F. Farid, Andrew J. Karam, Richard L. Hebert. *Cellular and Molecular Medicine, Kidney Research Centre, University of Ottawa, Ottawa, ON, Canada.*

Background: The proximal tubule is the primary tubular segment affected in diabetic kidneys. Transforming growth factor (TGF)-β is increased by high glucose in the proximal tubule, serving as an important pathophysiological factor in the renal complications of diabetes. Prostaglandin (PG) E_2 regulates diabetic growth, cell fate, fibrosis and electrolyte balance under a number of conditions in different renal cells but the role of PGE_2 in this segment has not been established in the diabetic kidney.

Methods: In the mouse MCT proximal tubule cell line, we observed a 2.5 fold increase in TGF-β protein levels by Western blotting in response to high glucose. We hypothesized that PGE_2 can modify TGF-β dependent injurious responses in MCT cells. MCT cells were treated for 24 hours with 2ng/ml TGF-β in the presence or absence of 1 μM PGE_2.

Results: First TGF-β caused an 8-fold increase in fibronectin protein, which was augmented to 15-fold in the presence of PGE_2. PGE_2 alone however, resulted in a 2-fold increase in fibronectin. In contrast, TGF-β caused a 60% reduction in p27 levels but increased p21 by 5.4-fold, while PGE_2 increased p27 by 2.5 fold and reduced p21 by 70%. TGF-β co-treatment abolished p27 stimulation by PGE_2, but PGE_2 had no effect on TGF-β mediated induction of p21. PGE_2 also increased NaK-ATPase levels by 2-fold, and TGF-β attenuated this response by 50%. While neither TGF-β nor PGE_2 alone altered sgk1 levels (a known activator of NaK-ATPase), co-treatment resulted in a 33% reduction in sgk1 that may account for some of the observed TGF-β mediated attenuation of NaK-ATPase levels in co-treated cells.

Conclusions: Altogether our data indicate that though PGE_2 does not antagonize TGF-β mediated responses in MCT cells, TGF-β does attenuate the effects of PGE_2 with the exception of fibronectin. Future studies will examine the mechanisms associated with this interaction.

PUB099

The Correlation of the Anti-Plasminogen Antibodies with Disease Activity in ANCA-Associated Vasculitis Min Chen, Jian Hao, Ming Hui Zhao. *Renal Division, Department of Medicine, Peking University First Hospital, Beijing, China.*

Background: The patients with PR3-specific ANCA had antibodies against a protein coded by the antisense strand of the PR3cDNA ($cPR3^{105\text{-}201}$), which participated in the autoantigen complementarity as a potential mechanism of ANCA-associated vasculitis (AAV). Plasminogen was identified as a target of anti-$cPR3^{(105–201)}$. The purpose of the current study was to investigate whether anti-plasminogen antibodies can be used as a biomarker for assessing disease activity of AAV.

Methods: One hundred and four Chinese patients with AAV were recruited in the current study. Anti-plasminogen antibodies were detected in sequential serum samples at initial onset and remission of the disease. Association of anti-plasminogen antibodies with clinico-pathological paramenters was analyzed.

Results: The prevalence of anti-plasminogen antibodies was significantly higher in AAV patients 19/104 (18.3%), as compared with four 0/50 healthy control subjects (19/104 vs. 0/50, χ^2=8.8, *P*=0.003). The prevalence of anti-plasminogen antibodies was significantly higher in AAV patients in active phase of initial onset than in remission (19/104 vs. 1/48, χ^2=7.5, *P*=0.013). The level of anti-plasminogen antibodies (expressed as the percentage of positive control) correlated with the level of ESR (r=0.207, *P*=0.042), Scr (r=0.302, P=0.002), D-dimer (r=0.273, *P*=0.009) and the percentage of glomeruli with crescents (r=0.393, *P*=0.004). The level of BVAS, the prevalence of arthralgia, gastrointestinal involvement and the percentage of glomeruli with crescents with anti-plasminogen antibodies patients was significantly higher than that without anti-plasminogen antibodies patients (22.5±5.63 vs. 19.4±4.66, *P*=0.015, 63.2% vs.25.8%, >*P*=0.002, 57.9% vs. 21.1%, *P*=0.001 and 54.71% vs. 21.36%, *P*=0.002), respectively.

Conclusions: The level of anti-plasminogen antibodies in AAV patients was correlated with reduced renal function and the percentage of glomeruli with crescents. Anti-plasminogen antibodies might be a good biomarker for assessing disease activity of AAV.

Gene Polymorphisms of Interleukines-17 and Interleukin-17 Receptor Are Associated with End-Stage Kidney Disease Eun Young Kim, Wha-young Suk, Joo Hee Cho, Jungkook Wi, Hong Joo Lee, Young Wook Choi, Ju-Young Moon, Kyung-hwan Jeong, Tae-won Lee, Chun-Gyoo Ihm, Sang-Ho Lee. *Division of Nephrology Department of Internal Medicine, Kyung Hee University, Seoul, Korea.*

Background: Inflammation could be a causal factor in progression of chronic kidney disease. To date, there is convincing experimental and clinical evidences to support the notion that IL-17-producing T cells contribute to kidney injury in renal diseases. But it has never been studied about genetic relationship between ESRD and Th17 pathway.

In this study, we hypothesized that polymorphisms of interleukin 17 or their receptors may be associated with ESRD.

Methods: A total of 290 non-diabetic ESRD patients and 289 normal controls were included. We analyzed fourteen single-nucleotide polymorphisms (SNPs) located within the 4 genes of *IL17A, IL17E, IL17R* and *IL17RB.*

Results: The ESRD patients had a significantly higher allele frequency compared to control subjects for the *IL17E rs10137082*C* and *rs1124053*G* and *IL17R rs4819554*A* alleles. Genotyping analysis demonstrated that 3 SNPs (21.4%) among 14 were significantly associated with ESRD after adjusting for age and sex, which were showed by *IL17E rs10137082* (OR=1.50 dominant, OR=1.47 log-additive), *IL17E rs1124053* (OR=2.15 codominant2, OR=1.46 dominant, OR=1.94 recessive, OR=1.41 log-additive) and *IL17R rs4819554* (OR=1.52 codominant1, OR=1.86 codominant2, OR=1.62 dominant, OR=1.39 log-additive).

Conclusions: Three polymorphisms within the *IL17E* and *IL17R* genes are associated with ESRD independent of age and sex. This is first finding to suggest that polymorphisms of *IL17* genes affect the risk of development of ESRD.

Role of Glycoprotein Nonmetastatic Melanoma Protein B in Regulation of Inflammatory Responses of Macrophages in Hyperglycemia Satyesh K. Sinha,[1] Susanne B. Nicholas.[1,2] [1]*Research, Charles R Drew University of Medicine and Science, Los Angeles, CA;* [2]*David Geffen School of Medicine, University of California Los Angeles, Los Angeles, CA.*

Background: Several studies have demonstrated that diverse inflammatory molecules play a significant role in the setting of diabetic nephropathy (DN), one of the profound consequences of diabetic mellitus (DM). The process of inflammation requires the selective expression of genes in cells of the macrophage lineage. Glycoprotein nonmetastatic melanoma protein b (GPNMB), a growth factor, has been identified as a regulator of the inflammatory and phagocytic activities of macrophages. However, little is known about its role in the inflammatory responses of macrophages in hyperglycemia. Therefore, in the present study, we tested our hypothesis that high glucose suppresses the expression of GPNMB in activated macrophages, leading to aberrant cytokine release.

Methods: Murine macrophage cells (J774A.1) were cultured in RPMI 1640. Following serum starvation, the cells were treated with D-glucose (5, 25 and 40mM). The expression levels of GPNMB, CD36 and TGF-β were determined by immunoblotting. Concentrations of IL-6 and TNF-α in culture supernatants were assessed by enzyme-linked immunosorbent assay.

Results: High glucose treated macrophages exhibited significant reduction in the expression of GPNMB (30%) and an increase in the expression of CD36 (13%) and TGF-β compared to normal glucose. Relative to physiological level, under high glucose, secretion of IL-6 was 258% higher (12pg/ml vs. 43pg/ml) and TNF-α was 34% higher (70pg/ml vs. 94pg/ml).

Conclusions: These results suggest that GPNMB may play an important role in the regulation of inflammatory responses of macrophages in DN.

PUB102

Acoustic Radiation Force Impulse (ARFI)-Based Elastometry Possibly Represents Diminution of Blood Flow Rather than Tissue Fibrosis of the Kidneys in CKD Patients Ai Ogata,[1] Kenichiro Asano,[1] Yoko Ide,[1] Akiko Sankoda,[1] Keiko Tanaka,[1] Mana Nishikawa,[1] Masaru Kinomura,[1] Noriaki Shimada,[1] Masaki Fukushima.[2] *[1]Nephrology, Kurashiki Central Hospital, Kurashiki, Japan; [2]Internal Medicine, Shigei Research Institute Hospital, Okayama, Japan.*

Background: ARFI is a novel ultrasound method for quantitating tissue elasticity. Velocity of shear wave (Vs) which represents the stiffness of the organ is measured by a virtual touch tissue quantification technique. A higher Vs value implicates progression of fibrosis for chronic liver disease. In this study, the Vs value was measured in the kidneys of CKD patients at all stages and was compared with other clinical parameters.

Methods: Renal imaging and quantification were performed by using an Acuson S2000 ultrasound system (Siemens AG) in 319 CKD patients (M: 198 F: 121, age: 62.0±15.7). Mean Vs was determined after several measurements in each renal parenchyma. The main causes of chronic kidney injury were classified by histology and clinical course (glomerulonephritis: 129, diabetic nephropathy: 107, nephrosclerosis: 83). Estimated GFR was calculated by serum creatinine concentration and age. Brachial-ankle pulse wave velocity (baPWV) was measured within a year from Vs determination in 183 patients. Normal control values were measured in 14 healthy volunteers.

Results: In healthy controls, mean Vs was higher in the renal medulla than in the cortex. The Vs value measured in the right and left kidneys of a patient correlated well though the variation between individuals was considerably large. In CKD patients, Vs and eGFR showed a positive correlation. The correlation was weak in glomerulonephritis patients and Vs was the lowest in diabetic patients with low eGFRs. A negative correlation was obtained between Vs and baPWV. All these results suggest that progression of CKD and arteriosclerosis diminishes blood flow and reduces tension of the kidney which may be reflected by a low Vs value.

Conclusions: Vs possibly represents diminution of blood flow which succeeds arteriosclerosis rather than fibrosis of the kidneys in CKD patients. However, the variation of Vs between subjects is too large for the method to be applicable as is for clinical use.

PUB103

The Relationship among Depression and Treatment Compliance in Hemodialysis Patients Jin-mei Yin,[1] Kang-lai Li,[2] Nian-chang Chen,[1] Tan-qi Lou.[1] *[1]Department of Nephrology, The Third Affiliated Hospital, Sun Yat-sen University, Guangzhou, Guangdong, China; [2]Department of Special Care, The Third Affiliated Hospital, Sun Yat-sen University, Guangzhou, Guangdong, China.*

Background: To investigate the relationship among depression and treatment compliance in hemodialysis patients.

Methods: 79 hemodialysis patients were recruited and investigated with Beck Depression Rating Scale (BDI) for depression survey. According to the score of depression, patinets were divided into two groups (non-severe group and severe group). Assessmeng of treatment compliance including dialysis dose, water and salt control, rational drug use, reasonable exercise of compliance were analyzed.

Results: 62% patients were in the severe group. Compared to the non-severe group, the severe group were with poorer treatment compliance ($P < 0.05$). It shows that depression have a significant impact on treatment adherence.

Conclusions: Deprssion were common in hemodialysis patients. Depression had significant effect on treatment compliance, reducing the treatment effect, reducing the patient's quality of life.

Single Centre Review of Pregnant Patients Reviewed in a Joint Renal/ Obstetrics Clinic Maharajan Raman, Arvind Ponnusamy, Daniel J. Hall, Hayley L. Mcmanus, Philip A. Kalra, Teresa Kelly, David I. New. *Renal, Salford Royal NHS Trust Foundation, United Kingdom.*

Background: Patient with chronic kidney disease have less ability to cope with renal changes needed for a healthy pregnancy. Pregnancy in a CKD patient carries a risk to both mother and fetus.

Methods: We retrospectively reviewed data patients from Joint Renal/Obstetrics clinic. A total of 30 patients were reviewed between the period of 2005 till 2011. We excluded patients receiving dialysis and transplant patients.

Results: Mean age of pregnant patients were 28.1 years. At the time conception, there were 5 patients on ACE inhibitor and these were stopped immediately. There were no reported foetal abnormalities. Only eight patients had proteinuria at the time booking. Mean creatinine was 79 mircromol/l± 42. Three patients had creatinine over 130 umol/l. Average urine protein creatinine ratio in the first trimester was 149 g/mol, 2nd trimester was 151 and 3rd trimester was 238 g/mol Only nine patients were some form of anti-hypertensive. At 3 months, patient with pre-pregnancy creatinine more 130 umol/l had loss GFR and an increase in proteinuria of over 20%. 26 patients had successful delivery with 4 had miscarriage during the pregnancy. Average gestational birth weight was 2635 gms. Complication during pregnancy included pre-elampsia (2 patients), placenta previa, chorioamnionitis and increase of proteinuria. Mean serum creatinine and urinary PCR at 3 months post pregnancy was 89 umol/l and 140 gms.

Conclusions: In our group of patients there appears to be good maternal and fetul outcome. This is a result from a multidisciplinary team involving comprising nephrologists, obstetricians, midwives, dietician in the joint clinic.The baseline creatinine and proteinuria is associated with worsening in renal function post pregnancy in our cohort of patients as reported in the literature.

PUB105

Assessment of Cellular Mass Index (BCMI) for Bioimpedance Vector (BIVA) as a Marker of Muscle Mass in 212 Patients with CKD Guillermina Barril, Ángel Nogueira Pérez, Maria Bernardita Puchulu, Fernando F. Hadad, Secundino Cigarran, Sara Jericó, Jose-Antonio Sanchez-Tomero. *[1]Nephrology, Hospital U. de la Princesa, Madrid, Spain; [2]Nephrology, Hodpital U. de la Princesa, Madrid, Spain; [3]Nephrology, Hospital U. de la Princesa, Madrid, Spain; [4]Nephrology, Hospital Clinico, Madrid, Spain; [5]Nephrology, Hospital Da Costa, Burela, Spain; [6]Nephrology, Hospital U. de la Princesa, Madrid, Spain; [7]Nephrology, Hospital U de la Princesa, Madrid, Spain.*

Background: To evaluate in 212 patients from ACKD Unit the utility the BCMI by BIA Vctor(celular/talla2 mass) as a marker of muscle mass and its relationship to body composition, Kcorporal total (cell mass x 108.6), visceral proteins, inflammation, age, sex and ERCA fuerza of patients.

Methods: In the nutrition care BIVA with ERCA is performed in 212 patients HD01 monitor ERCA. Xedad men with a 59.4 overall.., Most frequent etiology Diabetes Mellitus 32.6% and compared the results between men and women according to whether BCMI <8 (Group 1) or => 8 (Group 2).

Results: We found 75 patients G2, 55% men and 33.4% are women and G1 with 135 patients, 66.7% men and 33.3% women, total body .xde significant higher in group 2. Results attached table. We found no significant differences. between groups:% total body water,% triceps fold,% arm muscle circumference and arm circumference. NP NA. HB. Total lymphocytes, Ccr and MDRD. If significant direct correlation between dynamometry BCMI and p 0.009, and inversely related to extracellular water. We found differences in both groups of men and women with BMI no significant differences in each group between men and women. We have divided the patients according BCMI<7,9 and =>8 showing significant differences with higher values in the goup with higher BCMI for Phase angle, Intracelular water, % len body mass, % mascle massm albumin nd prealbumin values. Patients with BCMI =>8 showing less PCR than lower than 7,9.

Conclusions: The correspondence BCMI and cell mass can be seen as a key parameter in the study of body composition with BIVA, interrelated with visceral proteins, inflammation AIC and parameters of muscle mass and muscle strength.

PUB106

Dilemmas in Diagnosing Active TB in CKD Population of India Dilip A. Kirpalani, Shrinivas Nalloor, Hardik Shah, Ashok L. Kirplani. *Nephrology, Bombay Hospital Institute of Medical Sciences, Mumbai, Maharashtra, India.*

Background: In India the incidence of TB in CKD is higher than that in the general population. The overlap of clinical and laboratory features of TB and azotemia makes that diagnosis of TB difficult. This study highlights the diagnostic dilemma due to TB in CKD & their solutions.

Methods: 330 consecutive new patients of CKD between stage I and V (excluding those already on anti TB therapy) were investigated for active TB.

Results: Incidence of TB overall – 34/330 (10.3%; CKD stage-wise I-3%, II-5%, III-4%, IV-6.5%, V-9.43%, VD -28%. Sites of TB: (N=43 sites/34 patients) :Pulmonary 12, Pleural 11, Lymph nodular 8, Skeletal 4, Peritoneal 2, Genito urinary 2 & Miliary, Thoracic empyema, Cerebral, Vocal cord 1 each. Method of confirming TB – Bacteriological 7/34(20.6%), Histopathological 13/34 (38.2%), Clinical 14/34 (41.2%) àexudative fluid with lymphocytic predominance 13/14, milary on imaging 1/14. Pitfalls in fluid analysis (N=32 samples/17patients) - Ascitic 6/32, pleural 26/32, using protein content criteria exudates 18/32, transudate 14/32. Cellular predominance in exudative fluid : neutrophillic 5/18, lymphocytic 13/18. ADA levels in exudative fluids higher than transudative fluids ($p<0.05$) but no exudative sample revealed abnormally high ADA.

Conclusions: 1. The incidence of TB is 15 times greater in CKD & it increases with severity of CKD

2. Cardinal symptoms of TB such as fever, cough, weight loss & anorexia may not be present.

3. Usual markers of TB such as high ESR, anemia, +ve MT have poor value in CKD.

4. A history of TB contact & the stage of CKD have high predictive value.

5. Extra pulmonary TB is more common in CKD.

6. The positive predictive value of chest x ray in thoracic TB is limited to 65% & a CT chest may be needed for confirmation.

7. Pleural & ascitic fluid protein estimation, ADA levels and cellular characteristics are frequently confounding.

8. Yield of AFB & histopathological confirmation from TB sites is limited to 60% & the remaining 40% cases are diagnosed by supportive laboratory, clinical judgment & circumstantial evidence. A high index of suspicion is the best way to avoid missing this dangerous comorbidity of CKD.

PUB107

Protecting against Obesity-Induced Chronic Kidney Disease Using Pro-Resolving Lipids Emma Borgeson,[1] Debra F. Higgins,[1] Paula Maderna,[1] Helen M. Roche,[2] Catherine Godson.[1] *[1]Diabetes Research Centre, The Conway Institute, University College Dublin, Dublin, Ireland; [2]Nutrigenomics Research Group, The Conway Institute, University College Dublin, Dublin, Ireland.*

Background: There is a growing appreciation that obesity and its associated complications reflect chronic low-grade inflammation. Recent evidence highlights that the resolution of inflammation is actively regulated by endogenously generated counter regulatory and pro-resolving lipid mediators, such as lipoxins (LXs) and resolvins. We have investigated the potential of LXs to attenuate adipose inflammation, which is linked to pathologies such as chronic kidney disease.

Methods: Adipose tissue explants from perigonadal depots of aging female C57BL/6J mice were used as model of age-associated adipose inflammation. The explants were incubated with vehicle or LXA_4, after which cytokine secretion and expression of insulin sensitizing signaling pathways were assessed. To investigate specific regulatory pathways we also explored the effect of LXA_4 on macrophage-adipocyte crosstalk *in vitro*.

Results: We report that LXA_4 (1 nM) attenuates adipose inflammation, decreasing IL-6 and increasing IL-10 expression ($p<0.05$). The altered cytokine milieu correlated with increased GLUT-4 and IRS-1 expression, suggesting improved insulin sensitivity. Further investigations revealed the ability of LXA_4 to rescue macrophage-induced desensitization of insulin-stimulated signaling and glucose uptake in cultured adipocytes. This was associated with preservation of Akt activation and reduced secretion of pro-inflammatory cytokines, including TNF-α.

Conclusions: We propose that LXA_4 may represent a potentially useful and novel therapeutic strategy to subvert adipose inflammation and insulin resistance and thereby protect against obesity related pathologies including chronic kidney disease.

PUB108

Comparison of Urine Biomarker Profiles between Kidney Donors with and without Nephrosclerosis on Biopsy and Diabetic Nephropathy Patients Michael P. Linnes, John C. Lieske, Samuel Edeh, Jennifer R. Geske, S. Jeson Sangaralingham, John C. Burnett, Andrew D. Rule. *Mayo Clinic, Rochester, MN.*

Background: Nephrosclerosis on renal biopsy is strongly correlated with age, but is inadequately detected by traditional kidney disease markers. This pilot study compared potential biomarkers relating to fibrosis, inflammation, and tubular injury in order to identify those that may be predictive of nephrosclerosis.

Methods: Sectioned and stained core-needle biopsies of living kidney donors at the Mayo Clinic from 2000 to 2008 were reviewed to identify those with nephrosclerosis (glomerulosclerosis, tubular atrophy, interstitial fibrosis, and arteriosclerosis) and banked urine. Donors without nephrosclerosis were matched to donors with nephrosclerosis on age and sex. Patients with diabetic nephropathy served as positive controls. Biomarkers were measured via ELISA and compared between the 3 groups.

Results: There were 46 kidney donors with nephrosclerosis (mean 12% of glomeruli sclerosed, 61% had interstitial fibrosis >5%, 92% had tubular atrophy, and 84% had arteriosclerosis), 46 matched donors without nephrosclerosis (mean 1.9% of glomeruli sclerosed, 0% had interstitial fibrosis, 2% had tubular atrophy, and 8% had arteriosclerosis) and 81 diabetic nephropathy patients. Biomarker levels differed in diabetics compared to donors (see table). Col-IV was increased in the donors with nephrosclerosis compared to donors without (median 3.2 vs 1.1 ug/L, p=0.008). A1M was higher in donors with >5% interstitial fibrosis compared to donor controls (5.5 vs. 2.5 ug/mL, p=0.028).

Urine biomarker levels

Biomarker (ng/mL)	Donors (n=92)	Diabetics (n=81)
Kim-1	0.50	1.13*
NGAL	14.2	32.6
LFABP	2.0	59.3*
THP (ug/mL)	18.0	7.6*
IL-18	.04	.07
Col IV	2.8	8.2*
MCP-1	187	437
aGST	0.7	2.6
π-GST	17	40
A1M (ug/mL)	5	25

*p<0.05 adjusted for Age, Sex, BMI, and UACR

Conclusions: There were notable differences in several urine biomarkers between diabetics and donors independent of traditional kidney disease markers. There were fewer differences in these biomarker between donors with and without nephrosclerosis. Imprecision of the renal biopsy pathology due to sampling variation may limit detection of biomarker associations.

PUB109

Construction of Gene Engineering *L.bulgaria* that Can Express Uricase and Creatininase and Its Function Research Yunsheng Jiang, Fang Liu, Yafen Jiang, Lin Sun, Fuyou Liu. *Department of Nephrology, Second Xiangya Hospital, Central South University, Changsha, Hunan, China.*

Background: Recent studies that artificial cell therapy such as therapeutic delivery of live bacteria may become the new strategies for the chronic renal failure. Lactic acid bacteria is generally regarded as safe bacteria. We recently do some research on this field.

Methods: We construct a combination of uricase gene and creatininase gene creatinine, and clone it to Lactobacillus bulgaricus(L.B), so that it could express uricase and creatininase, and then explore the ability of decomposing the urotoxin of creatinine and uric acid in the serum of patients with end-stage renal failure, genetic stability of the recombinant plasmid, as well as the activity of crude enzyme of gene engineering Lactobacillus bulgaricus(L.B-UC). On the other hand, we use the 5/6 nephrectomy rat as an animal model to explore the capacity of creatinine and uric acid removal of the L.B-UC *in vivo*, the improvement of serum lipid balance and its function in the development of chronic renal failure.

Results: From in vitro experiments we can confirm that L.B-UC has a strong decomposition to creatinine and uric acid, a good genetic stability, high activity of uricase andcreatininase; The in vivo studies indicated that the L.B-UC can decompose the Cr and UA, improve the dyslipidemia, and alleviate renal interstitial injury and fibrosis.

Conclusions: we sucessfully constructed the gene engineering Lactobacillus bulgaricus, which can decompose the Cr and UA, have good genetic stability, as well as improve the dyslipidemia, alleviate renal interstitial injury and fibrosis.

PUB110

Patient-Reported Complaints of Pruritus Are Common in Dialysis Patients but Infrequently Reflected in Physician-Reported ICD-9 Coding T. Christopher Bond, Gilbert Marlowe, Helen M. Wilfehrt, Amy Young, Mahesh Krishnan, Tracy Jack Mayne. *DaVita Clinical Research, Minneapolis, MN.*

Background: The Kidney Disease Quality of Life 36 (KDQOL) questionnaire—administered to all dialysis patients yearly at a large dialysis organization—quantifies itchiness. We hypothesized that patient-reported itchiness would not correlate with physician-coded pruritus given the relative priority placed on such diagnoses in medical coding.

Methods: We analyzed health records of 70,499 dialysis patients with available itchy skin data on KDQOLs (Jan 2009-May 2012) and compared these to associated physician-provided ICD-9 codes (698 or 698.x) for pruritus. The latter were collected predominantly by treating nephrologists as part of the medical justification for various dialysis-related labs and treatments.

Results: Sixty percent of patients report itchy skin on the KDQOL. The percentage of patients with ICD-9 codes of pruritus was low, and rose slightly with increasing patient-reported levels. The pruritus diagnostic code in these data has low sensitivity—with only 8.52% of patients who report being extremely bothered by itchy skin receiving a diagnostic code of pruritus.

Table. Physician diagnoses of pruritus by categories of patient-reported itchiness

During the past 4 weeks, to what extent were you bothered by itchy skin?	Patient-reported itchiness – n (%)	Physician diagnosis of pruritus – n (%)
Not bothered at all	28,070 (39.82%)	846 (3.01%)
Somewhat bothered	21,318 (30.24%)	859 (4.03%)
Moderately bothered	10,872 (15.42%)	509 (4.68%)
Very much bothered	6,520 (9.25%)	408 (6.26%)
Extremely bothered	3,719 (5.28%)	317 (8.52%)
Total	70,499 (100.00%)	2,939 (4.17%)

Conclusions: Data from a large dialysis organization suggest that physician-reported coding of pruritus does not typically reflect patient-reported itchiness. It is possible that patients do not report itchiness to physicians, physicians choose not to code pruritus, or perhaps physicians believe that itch is a symptom captured within the larger ESRD syndrome. The lack of options to adequately treat pruritus may complicate this situation.

Effectiveness and Safety of MIRCERA® in Patients with Anemia Associated with Chronic Kidney Disease: The MINERVA Study Aleix Cases,[1] Jose Portoles,[2] J. Calls,[3] Alberto M. Martinez-Castelao,[4] Domingo Sanchez-guisande,[5] Alfonso Segarra.[6] *[1]H.Clinic Barcelona, Spain; [2]H.U.Puerta de Hierro, Spain; [3]H.Manacor, Spain; [4]H.Bellvitge, Spain; [5]H.Barbanza, Spain; [6]H. Vall d'Hebron, Spain.*

Background: MIRCERA® is the first continuous erythropoietin receptor activator approved for treatment of anemia associated with chronic kidney disease (CKD). We assessed the effectiveness and safety of MIRCERA® in patients with CKD anemia in clinical practice.

Methods: Multicenter prospective observational study carried out in stage 3-5 CKD patients treated with MIRCERA® for a year.

Results: 227 patients were evaluated (mean age 71.2±14.7years; men 55.5%; main CKD etiology: diabetic nephropathy 27.8%): 85 (37.4%) on hemodialysis (HD; correction n=2, maintenance n=83) and 142 (62.6%) CKD not on dialysis (CKDND; correction n=31, maintenance n=111). Hb levels, MIRCERA® doses and dose adjustments are shown in the table.

	CKDND correction	CKDND maintenance	HD maintenance
Hb ranges, n(%)			
Baseline:			
<11g/dl	19(61.3)	24(21.8)	25(30.1)
11-13g/dl	12(38.7)	70(63.6)	49(59.0)
>13g/dl	0(0.0)	16(14.5)	9(10.8)
Month12:			
<11g/dl	7(33.3)	20(30.8)	15(28.8)
11-13g/dl	12(57.1)	42(64.6)	33(63.5)
>13g/dl	2(9.5)	3(4.6)	4(7.7)
Hb levels (g/dl), mean±SD			
Baseline	9.8±0.8	11.7±1.2	11.5±1.4
Month6	11.4±1.2	11.7±1.2	11.5±1.3
Month12	11.4±1.4	11.4±1.0	11.6±1.2
MIRCERA® doses (µg), mean±SD	89.8±45.3	98.1±66.5	171.0±105.7
No 1-year dose adjustments, mean±SD	0.3±0.5	0.7±1.1	2.1±1.9

No MIRCERA®-related adverse events were reported. Mean conversion doses of MIRCERA® were 90.8±48.8µg, 150.1±64.8µg and 230.6±115.8µg in patients previously receiving darbepoetin<40µg/epoetin<8000UI, darbepoetin40-80µg/epoetin8000-16000UI and darbepoetin>40µg/epoetin>16000UI,respectively. After 7.0±5.4months, they were 104.8±58.5µg p=0.006, 157.3±66.5µg p=0.269 and 188.9±148.0µg p=0.195,respectively. Mean 1-year dose adjustments were 0.3±0.5, 0.7±1.1 and 2.1±1.9 in CKDND correction, CKDND maintenance and HD maintenance patients,respectively.

Conclusions: Once-monthly MIRCERA® was effective and safe for CKD anemia management in clinical practice. Conversion doses of MIRCERA® were lower than those described in the SPC and there were a low number of dose adjustments.

PUB112

Functional Iron Deficiency, Is a Limiting Factor of IV Iron Use in Non Hemodialysis Renal Insufficiency Patrick Fievet. *Nephrologie Hemdoialyse, Groupe Hospitalier du Sud de l'Oise, Creil, France.*

Background: Iron deficiency is an important cause of anaemia in non dialysis chronic kidney disease (ND-CKD). The new forms of IV iron (IV Fe) allow use of high doses to treat it. This is interesting to protect venous capital and to reduce the number of administrations. Nevertheless The risk of iron overload has not been studied even though these patients are more exposed than haemodialysis patients since lack of regular blood loss.

Methods: We have studied the efficacy of high doses of low molecular weight iron dextran (LMWD) to correct iron deficiency ant to treat anaemia in ND-CKD. Total doses have been prescribed, according to Ghanzoni formula, taking account hemoglobin concentration (Hb) and patient's weight. 40 doses from 500 to 1600 mg (mean = 760 ± 291 mg) have been administered to 29 ND-CKD patients (DFG = 23.7 ±12.6 ml/min/1.73 m²) with iron deficiency defined by transferrin saturation (TSAT) lower than 20% and/or ferritin lower than 100 mg/L and treated by erythropoiesis stimulating agent (ESA) in 22 cases on 40. ESA doses have not been modified. Patients have been controlled 1 month later. Results of iron markers have been confronted to target values defined by KDOQI and ERBP.

Results: Hb has significantly increased (11,4 ± 1.4 vs 10.3 ± 1.3 g/dL, p < 0,001) as TSAT (22.6 ±8.5 vs 14.0 ±3.9%, p < 0,001) and ferritin (320 ±265 vs 97 ± 61 µg/L, p < 0,001). In 9 cases, ferritin reaches higher value than 500 mg/L after treatment exposing to risk of iron overload. Iron profile in these patients was compatible with functional iron deficency (ferritin values before treatment higher than others patients (169 ± 65 vs 76 ±42 µg/L, p = 0,03) whereas TSAT were identical (13,8 ± 3,7% vs 14.1 ±4%, NS)). In patients with ferritin upper 500 µg/L after treatment, Hb has not increased whereas it has in the others.

Conclusions: Administration of high doses of LMWD is efficient to correct iron deficiency and anemia in ND-CKD. High doses of IV Fe exposes to risk of iron overloadwithout efficacy on erythropoïesis, in patients with functional iron deficiency profile (TAST < 20% and ferritin > 150 µg/L). So it seems to be reserved for patients with ferritin lower or equal to 150 µg/L.

PUB113

Understanding the Molecular Basis of Ventricular Arrhythmias in Uremic Patients Elie El-Charabaty,[1] Georges Khoueiry,[1] Bertrand Mukete,[2] Estelle Torbey,[2] Suchita J. Mehta,[1] Roger Hajjar,[2] Suzanne E. El Sayegh.[1] *[1]Medicine, Staten Island University Hospital; [2]Mount Sinai School of Medicine.*

Background: Uremic cardiomyopathy characterized by LVH and interstitial fibrosis plays a vital role in fatal arrhythmias and sudden cardiac death (SCD) in CKD patients. The molecular basis of uremic cardiomyopathy is not completely understood. Few animal studies, showed a decrease in cardiac sarcoplasmic reticulum (SERCA2a) gene expression with CKD. Other studies showed that SERCA2a underexpression leads to action potential alternans, which is linked to SCD. We hypothesize that patients with stage 5 CKD have lower levels of SERCA2a protein compared to those with normal kidney function.

Methods: Brachial venous tissue was collected from 6 patients with stage 5 CKD at time of A-V fistula creation. Saphenous vein tissue from 6 patients with normal creatinine were collected at time of CABG to serve as the control group. RNA was isolated from these tissues using Trizol reagent. The RNA purity/concentration was assessed using A260/A280 ratio by spectrophotometry. DNA was prepared by using a high capacity cDNA reverse transcription kit. Serca2a gene was assessed using SYBR Green Fast Mix in reverse transcription-PCR.

Results: SERCA2a gene expression in the CKD versus the control group was calculated using PCR fold change method. Our analysis showed a 66% decrease in SERCA2a gene expression with uremic subjects versus control.

Conclusions: This is the first evidence that patients with CKD have an altered gene expression of SERCA 2a, a protein that plays a key role in cardiac cell calcium homeostasis during excitation-contraction coupling. Action potential alternans, a predictor of ventricular arrhythmias, was associated to SERCA2a deficiency in guineapig model. Our findings might suggest a molecular cause for the susceptibility of this population to arrhythmias and SCD. This will be the first vital step that will allow us in the future to link SERCA2a levels to action potential alternans, microvolt T-wave alternans, or ventricular arrhythmias on cardiac telemetry as electrophysiological evidence of increased susceptibility to lethal ventricular tachyarrythmias in this population.

PUB114

Subendocardial Viability Ratio, Albuminuria and Pulse Wave Velocity in Chronic Kidney Disease Patients Robert Ekart,[1] Nina Hojs,[2] Sebastjan Bevc,[2] Radovan Hojs.[2] *[1]Clinic for Internal Medicine, Department of Dialysis, University Clinical Centre Maribor, Maribor, Slovenia; [2]Clinic for Internal Medicine, Department of Nephrology, University Clinical Centre Maribor, Maribor, Slovenia.*

Background: Applanation tonometry can be used for pulse wave analysis (PWA) and pulse wave velocity (PWV) measurements. PWA provides information on subendocardial viability ratio (SEVR) or the Buckberg index, which is a non-invasive estimate of subendocardial perfusion. Albuminuria and chronic kidney disease (CKD) are associated with increased risk of cardiovascular disease. The purpose of our study was to evaluate the relationship between SEVR and albuminuria in CKD patients.

Methods: PWA and carotid-femoral PWV were performed (SphygmoCor, AtCor Medical, Australia) to determine SEVR and aortic stiffness in 74 patients with CKD (52 men, 22 women; age 60.7±12.6 years, range 22-88 years). Eighteen (24.3%) patients were diabetics. Albuminuria was determined with the urinary albumin/creatinine ratio (UACR), values were log-transformed. Standard laboratory analyses (cystatin C, cholesterol, triglycerides, hs-CRP) and 24-hour ambulatory blood pressure measurements (ABPM) (Schiller BR-102 plus, Switzerland) were performed.

Results: SEVR was 152.1±33.3 % (82-235 %), PWV was 11.7±3.5 m/s (5.95-23.03 m/s), UACR was 823.1±1264.4 mg/g and mean 24-hour systolic/diastolic ABPM was 137/77 mmHg. SEVR correlated with UACR (r=-0.331; p<0.004) and PWV (r=-0.349; p<0.002), but not with cystatin C, cholesterol, triglycerides, hs-CRP and 24-hour systolic/diastolic ABPM. Multiple regression analysis showed statistically significant association of SEVR with UACR (p<0.03) and PWV (p<0.002).

Conclusions: According to our data SEVR was associated with albuminuria and carotid-femoral PWV in CKD patients.

PUB115

Chronic Kidney Disease Is Associated with Poor Outcomes in Veterans with Peripheral Vascular Disease Jose Jesus Perez, Charles G. Minard, Ojas A. Naik, Venkataraman Ramanathan. *Division of Nephrology, Baylor College of Medicine, Houston, TX.*

Background: Peripheral vascular disease (PVD) and chronic kidney disease (CKD) coexist and share common risk factors including diabetes and hypertension. We studied the risk factors for PVD and the independent effect of CKD on patient outcomes and further vascular evaluation.

Methods: We retrospectively evaluated veterans who were referred for vascular study for symptomatic PVD. PVD was defined as: abnormal ankle-brachial index (0.7≥ABI≥1.3), abnormal digital pressure, or qualitative waveforms. CKD EPI calculation was used for GFR estimation. Veterans with a history of PVD were excluded. Primary end points included abnormal vascular study, further vascular evaluation after abnormal doppler, and a composite endpoint of ulcer, death, gangrene, rehospitalization, amputation, or osteomyelitis during one year of follow up. Logistic regression analysis was used to identify risk factors.

Results: 593 veterans had vascular evaluation during one year study period. Risk factors associated with abnormal vascular study include age >65 years (OR 2.1; 95%CI 1.4-3.2), smoking (OR 3.1; 95% CI 2.0-4.6), and African-American ethnicity (OR 1.7; 95% CI 1.1-2.6). In veterans with abnormal vascular studies, patients >65 years (OR 0.5, 95%CI 0.3-0.8, p 0.004) were less likely to have further studies, whereas smokers (OR 1.9, 95%CI 1.1-3.2, p 0.02) were more likely to get further work up. Other variables including history of diabetes, hypertension, hyperlipidemia, or ischemic heart disease did not influence the physician's decision for further tests. CKD did not have an independent effect on abnormal vascular study or further vascular evaluation after abnormal doppler exam. However, eGFR<60 was the only independent risk factor for reaching composite endpoint during follow up (OR 2.2, 95%CI 1.2-3.8, p 0.006).

Conclusions: In symptomatic veterans, CKD is neither an independent risk factor for abnormal vascular study nor does it influence referral pattern for further evaluation after abnormal doppler exam. There is no diagnostic or therapeutic nihilism towards CKD veterans. However, eGFR <60 ml/min is associated with poor patient outcomes during one year follow up.

PUB116

Ratings of Executive Functioning in Children and Young Adults with Moderate to Severe CKD Stephen R. Hooper,[1] Jerilynn Radcliffe,[2] Divya Moodalbail,[2] Kathryn Reiser,[2] Abbas F. Jawad,[2] Susan L. Furth.[2] *[1]UNC School of Medicine; [2]CHOP.*

Background: Cognitive deficits in individuals with moderate to severe CKD have been well documented. To date, however, few studies have examined ratings of executive functioning in children and young adults with CKD. Such measurement approaches may provide a cost effective strategy for nephrologists working with this population.

Methods: Cross sectional observational study comprising 18 children and young adults with CKD (eGFR below 60 ml/min/1.73m2), ages 8 to 25 years, followed by nephrology, transplant, and dialysis clinics. Instruments included the Behavior Rating Inventory for Executive Functioning (BRIEF) completed by either the parent (ages 8 to 18) or the older adolescent/young adult (ages 19 to 25). Scores across the two versions of the BRIEF were combined for comparison purposes. Initial data analyses included descriptive findings of the CKD sample, with elevated ratings of at least one standard deviation above the normative mean reflecting impairment.

Results: Median age was 15 yrs (Interquartile Range = 14-17.5 yrs.) and median eGFR was 32 ml/min/1.73m2. The sample was 76% male and 81% Caucasian. About 29% had transplant, and 5% were on dialysis after a failed transplant. Results showed that none of the Behavior Regulation scales were significantly elevated when compared to normative standards, with the Behavioral Regulation Index (BRI) falling within the average range (BRI T-Score = 54.22). In contrast, the Metacognitive Index (MI) was significantly elevated (MI T-Score = 62.5), with specific elevations on the Working Memory, Plan/Organize, and Organization scales. The Global Executive Composite (GEC) also was significantly elevated (GEC T-Score = 60.34), reflecting significant concerns for the presence of overall executive dysfunction in individuals with moderate to severe CKD.

Conclusions: These findings indicated the presence of mild executive dysfunction, with weaknesses noted in the areas of planning, organization, and working memory. It will be important for nephrologists to be aware of the executive capabilities of their patients, especially with respect to their impact on adherence to medical care and ongoing medical management.

PUB117

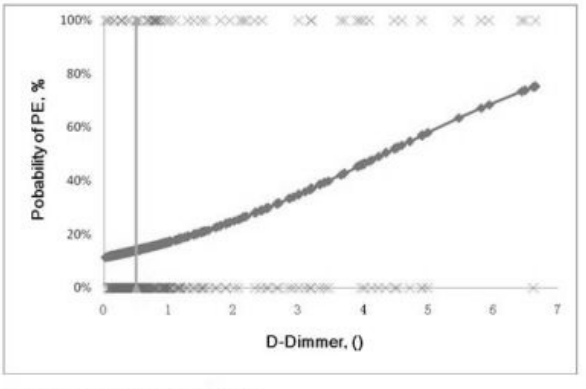
Risk Factors of Pulmonary Embolism in Patients with Nephrotic Syndrome, Results from a Large Retrospective Study Fude Zhou, Yihe Yang, Jicheng Lv, Min Chen, Ming Hui Zhao, Haiyan Wang. *Renal Division, Peking University First Hospital, Institute of Nephrology Peking University, Key Laboratory of Renal Disease, Ministry of Health of China, Beijing, China.*

Background: Nephrotic syndrome (NS) is associated with an increased risk for thromboembolic complications .Until now most studies focused on the renal vein thrombosis, few studies have ever evaluated risk of pulmonary thrombosis (PE) in nephrotic syndrome. In this study we assessed the risk of PE in a large, single-center, retrospective study and attempted to identify risk factors in these patients.

Methods: Patients with nephrotic syndrome who had received lung ventilation-perfusion scan between 2001 and 2011 from Peking University First Hospital were collected and analyzed. Multivariate Logistic regression was used to detect the independent risk factors of pulmonary embolism. Logistic regression was used to identify the threshold value of d-dimer.

Results: Among the 312 patients, 65 patients (20.8%) had pulmonary embolism. Elevated level of serum d-dimmer was an independent risk factor of pulmonary embolism on multivariate analysis. (OR= 1.543, 95%CI: 1.269-1.876). The cumulative probability of pulmonary embolism was in a linear association with the serum D-Dimmer level even within the normal range.

Figure 1:Logistic curve ofrisk of pulmonary embolism in nephrotic syndrome patients



Blue line: Logistic curve of probability of PE

Red cross: PE. 0% means the patient did suffered PE, 100% means the patient had suffered PE.

The Logistic curve was almost linear. The yielding points was not obvious.

Green Line: D-Dimmer =0.5.

While proteinuria at presentation and serum albumin which had been reported with deep vein thrombosis were not associated with pulmonary embosis (P>0.05).

Conclusions: In adult patients with nephrotic syndrome, high level of serum d-dimmer was closely associated with pulmonary embolism, while proteinuria or serum albumin was not.

PUB118

Prevalence of Anemia and Ferropenia in Patients with CKD Stages 3, 4 and 5 Not on Dialysis in Nephrology Units in Catalonia (The MICENAS I Study) Aleix Cases,[1] Alberto M. Martinez-Castelao,[2] Joan Fort,[3] Jordi Bonal,[4] Xavier Fulladosa,[2] J.M. Galceran,[5] J. V. Torregrossa,[1] Elisabeth Coll.[6] *[1]H. Clínic Barcelona, Spain; [2]H.Bellvitge, Spain; [3]H. Vall Hebron, Spain; [4]H. Germans Trias i Pujol, Spain; [5]Fundació Althaia, Spain; [6]Fundació Puigvert, Spain.*

Background: Anemia and ferropenia are common among CKD patients not on dialysis, but their prevalence and management in Catalonia are unknown.

Methods: Cross-sectional study conducted in nephrology units in Catalonia. Patients aged≥18 years, with CKD stages 3, 4 and 5 not on dialysis, with an Hb measurement in the previous 2 months who gave informed consent were recruited. Analysis criteria: Anemia Hb<13.5g/dL in men, Hb<12.0g/dL in women or patients receiving ESA therapy; Ferropenia:ferritin<100 ng/mL or TSAT<20%.

Results: 531 patients were recruited by 22 investigators, 504 were valid for analysis. 56.4% were men, mean age 7.8±15.5 years and mean time from CKD diagnosis 6.6±7.7 years. Regarding CKD Stage, 61.5% were in stage 3 (3a:23.0%, 3b:38.5%), 30.2% stage 4 and 8.3% stage 5. Mean Hb was 12.6±1.6g/dL, statistically significant differences were observed depending on CKD stage (Hb progressively decreased from 13.6±1.6g/dL in stage 3a to 11.4±1.2g/dL in stage 5,p<0.0001). Anemia prevalence was 58.5%, increasing in parallel with advancing CKD stages (3a:35.3%, 3b:52.1%, 4:73.7%, 5:97.6%). 53.5% of anemic patients were receiving treatment for it; 26.4% ESA and iron (in stage 5, 51.2% treated with both ESA and iron). 14.9% of the patients had Hb<11g/dL of whom 32.0% did not receive any treatment for anemia. 41.3% had Hb≥13g/dL, of whom 12.5% were receiving treatment for anemia (8.2% ESA). Ferropenia was found in 36.3% of anemic patients, but non statistically significant differences were observed among CKD stages. Among ferropenic patients, 36.4% did not receive any treatment for anemia, 35.5% received both iron and ESA and 17.8% only iron.

Conclusions: Anemia and ferropenia were frequent among CKD patients in stages 3, 4 and 5 not on dialysis attended in Catalonia nephrology units; the significant percentage of undertreated anemic patients found, suggests room for improvement in anemia management in this population.

PUB119

Angiotensin Type1 Receptor Blockers Reduce Accumulation of Methylglyoxal in Chronic Kidney Disease Patients Takehiro Suzuki,[1] Daisuke Saigusa,[2] Yasutoshi Akiyama,[1] Eikan Mishima,[1] Yoichi Takeuchi,[1] Sadayoshi Ito,[1] Takaaki Abe.[1] *[1]Division of Nephrology, Endocrinology, and Vascular Medicine, Tohoku University Graduate School of Medicine, Sendai, Japan; [2]Laboratory of Oncology, Pharmacy Practice and Sciences, Graduate School of Pharmaceutical Sciences, Tohoku University, Sendai, Japan.*

Background: Methylglyoxal (MG) is a spontaneously formed metabolite of carbohydrates and the pathological roles of MG have been postulated in diabetes and chronic kidney disease (CKD). The plasma MG level is also associated with increased risk of cardiovascular disease (CVD). Hence, a method(s) for reducing methylglyoxal is recommended. Ameliorative effects of Angiotensin type1 receptor blocker (ARB) for CKD and CVD were reported. Renoprotective mechanisms beyond renin-angiotensin system (RAS) blockade by ARB were not fully elucidated. We estimated the renoprotective effects of ARB by assessment of MG changes in the ARB treatment on patients with CKD.

Methods: 33 patients with CKD stage 2 to 5 received ARBs (olmesartan 5-40 mg/day, telmisartan 40-80 mg/day, losartan 25-50 mg/day, irbesartan 50-150 mg/day). Serum creatinine (S-Cr), serum lipid profiles, fasting blood glucose (FBG), HbA1c, blood count and office blood pressure were measured after 6 months from ARB started. The plasma MG was measured by ElectroSpray Ionization Liquid Chromatography/Mass Spectrometry (ESI/LC/MS).

Results: S-Cr decreased and estimated GFR (eGFR) increased significantly after ARB treatment. Both systolic and diastolic blood pressures were significantly lowered after ARB treatment. T-chol, LDL-chol, HDL-chol, tryglyceride, FBG, HbA1c, red blood cell counts and Hb were not significantly changed. ESI/LC/MS revealed that MG was significantly decreased. The correlation between MG and eGFR was evaluated by Spearman's correlation coefficients. However, the decrease of MG was not correlated significantly with eGFR or Cr (r =0.37532).

Conclusions: After the ARB treatment, eGFR improved and BP was decreased. The plasma MG level was also significantly decreased. These results suggest that treatment of ARBs could be a novel pharmacologic strategy in CKD patients.

Association of the Metabolic Syndrome with Death, Cardiovascular Events or Progression to Dialysis Initiation in Non-Diabetic Chronic Kidney Disease
Shailendra Sharma,[1] M. Chonchol,[1] Alfred K. Cheung,[2,3] James S. Kaufman,[4] Tom Greene,[3] Gerard John Smits,[1] Jessica B. Kendrick.[1] *[1]University of Colorado Denver, Aurora, CO; [2]VASLCHCS, Salt Lake City, UT; [3]University of Utah, Salt Lake City, UT; [4]VA Boston Healthcare System, Boston, MA.*

Background: Metabolic syndrome (MetS) is an important risk factor for death, cardiovascular events (CVE) and chronic kidney disease (CKD) in the general population. However, the relationship between MetS with death, CVE and kidney disease progression in CKD patients is unclear.

Methods: We performed an analysis on 495 non-diabetic patients with severe kidney disease, not yet on dialysis, who participated in the Homocysteine in Kidney and End Stage Renal Disease study. MetS was defined according to recent guidelines from the National Cholesterol Education Program. The primary outcomes were all-cause death, CVE (defined as composite event of myocardial infarction, stroke or lower extremity amputation) and progression to dialysis initiation. Cox proportional hazard models were used to evaluate the association between MetS with death, CVE, and dialysis initiation adjusted for important confounders.

Results: Mean (SD) age was 69 ± 11 years, 25% were black and mean (SD) eGFR was 18 ± 7 ml/min/1.73m^2. A total of 292 (59%) patients in the cohort met criteria for MetS. Patients with MetS were more likely than those without MetS to have a history of cardiovascular disease (CVD) (33% vs. 18%, p=0.006). Over a mean follow-up of 3 years, there were 169 (34%) deaths, 70 (14%) CVE and 246 patients (50%) initiated chronic dialysis. After adjustment for demographics, smoking status, alcohol use, body mass index, history of CVD and hypertension, systolic blood pressure, eGFR, albumin, and 25-hydroxyvitamin D level, presence of MetS was not associated with an increased risk of death (HR 0.80, 95% CI 0.58 to 1.11), CVE (HR 1.08, 95% CI 0.64 to 1.84) or progression to dialysis initiation (HR 0.91, 95% CI 0.69 to 1.18).

Conclusions: The presence of MetS was not independently associated with an increased risk of death, CVE or progression to dialysis initiation in non-diabetic patients with severe CKD not yet on dialysis.

Renal Lipodystrophy in Mild Chronic Kidney Disease Was Associated with Insulin Resistance and Ectopic Fat Accumulation
Hitoshi Minakuchi, Shu Wakino, Koichi Hayashi, Hiroshi Itoh. *Internal Medicine, Keio University, Tokyo, Shinanomachi35, Shinjuku, Japan.*

Background: Chronic kidney disease (CKD) is complicated with metabolic disorder including insulin resistance and dyslipidemia even at the early stages. These clinical conditions suggested abrogation of insulin effects on insulin-target tissues. This study was undertaken to delineate the mechanism for metabolic dysregulation and the role of ADMA in mild CKD.

Methods: 5-week-old SD rats were rendered CKD by hemi-nephrectomy or five-sixth nephrectomy. Twenty weeks after the operation, biochemical parameters in insulin target tissues were examined. Both serum and tissue levels of ADMA were measured by ELISA system. Tissue oxidative stress and fatty acid levels were examined by TBARS and Folch methods, respectively. In in vitro analysis, cultured 3T3L1-fibroblasts were differentiated into mature adipocyte with or without ADMA to examine its effects on adipocyte differentiation.

Results: Serum levels of creatinine, fasting glucose and free fatty acid and urinary protein excretion were increased in CKD rats. Oral glucose tolerance test and insulin tolerance test revealed that impaired glucose tolerance and insulin resistance were evident in CKD rats. Insulin stimulation failed to activate the Akt in adipose tissues. Both the average size of adipocytes and the expression levels of differentiation markers for adipose tissue including PPARγ were decreased in CKD rats. Tissue levels of ADMA and oxidative stress levels were increased in adipose tissue of CKD rats. Expression of DDAH2 and DDAH1 were decreased in adipose tisseu of CKD rats. Finally, ectopic tissue fatty acid accumulation in liver and muscle were increased in CKD rats. In vitro analysis revealed that ADMA inhibited adipocyte differentiation, triglyceride accumulation and insulin signaling as assessed by the phosphorylation levels of Akt .

Conclusions: In mild CKD, increased tissue levels of oxidative stress and ADMA in adipose tissue blocked insulin signaling and adipocyte differentiation. The disordered renal maturation indicated lipodystrophy, which were associated with systemic insulin resistance, dyslipidemia and ectopic fat accumulation in mild CKD.

PUB122

5-Aminolevulinic Acid Improves Erythropoietin Production in CKD
Sadamitsu Ichijo, Yasutoshi Akiyama, Takehiro Suzuki, Yoichi Takeuchi, Eikan Mishima, Sadayoshi Ito, Takaaki Abe. *Division of Nephrology, Endocrinology and Vascular Medicine, Tohoku University, Sendai, Miyagi, Japan.*

Background: In patients with chronic kidney disease (CKD), anemia is a clinical issue and the involvement of chronic inflammation has been postulated.

Recently this chronic inflammation, as well as uremic toxins, have been known to involve in reducing erythropoietin (Epo) production.

Moreover, it is reported that up-regulation of mitochondrial function may be one of the clues to restore Epo production.

5-aminolevulinic acid (5-ALA) is the first intermediate in the heme biosynthetic pathway and may have a potential to restore mitochondrial function. Here we examined the effect of 5-ALA on Epo production under inflammatory or uremic condition.

Methods: Human Epo-producing Hep3B cells were obtained from ATCC and cultured. Cells were cultured in inflammatory cytokineTNF-α (220U/ml) or a representative uremic toxin, indoxyl sulfate (IS, 0.3mM) with 5-ALA at the various concentrations under hypoxic condition (1% O2) for 24hr. Epo concentration in the medium was measured using ELISA kit. Epo and heme oxygenase-1 (HO-1) mRNA was measured by QT-PCR. Total heme (free heme and heme protein) was measured by fluorometric assay. The amount of HO-1 protein was also determined by Western blot.

Results: The Epo concentration in the culture medium was reduced by TNF-α and IS. Under the condition, 0.3μM and 1μM 5-ALA were significantly restored the reduction of Epo concentration. Although this effect of 5-ALA was also observed by 5-ALA alone, the simultaneous addition of ferrous fumarate (equal concentration) further potentiated the ALA effect. Under the condition, HO-1 protein was increased, suggesting the increase of free heme pool, although total amount of heme was not changed. Because 5-ALA have a potential to increase cytochrome C oxidase and may restore aerobic respiration, these data suggest that 5-ALA may involve the Epo production through the induction of certain heme proteins.

Conclusions: These data suggest that 5-ALA may have a potential to improve renal anemia by increasing Epo production under CKD condition. Further experiments should be necessary to elucidate the precise mechanism of 5-ALA.

PUB123

Hepcidin Is a Bioactive Marker for Iron Status in Non-Dialysis Chronic Kidney Disease Patients
Aya Eguchi, Ken Tsuchiya, Kosaku Nitta. *Tokyo Women's Medical University, Shinjyuku-ku, Tokyo, Japan.*

Background: Hepcidin (Hp), whose expression is stimulated by inflammation and by iron loading, is also the key mediator of renal anemia. However, since the Hp expression is affected by these different factors, its significance as iron status in CKD has been controversial issue.

Methods: Reliable measurement of serum Hp have been made possible by the ProteinChip system, we therefore investigated the iron status and Hp levels of non-dialysis CKD patients (stage IV, V) who had not received frequent erythropoiesis stimulating agent (ESA) or iron therapy.

In addition to the usual iron parameters, serum Hp levels were measured by SELDI-TOF MS-analysis, and IL-6was measured by enzyme immunoassay.

Results: The mean serum Hp level of the CKD patients (n=33) was 46.1±34.2ng/ml. Their Hp levels were significantly and positively correlated with their ferritin (P<0.001) and TSAT levels (P=0.01), and the low Hgb tended to be correlated with low Hp level (P=0.08). There were two distinct Hp levels in the CKD patients, low Hp levels group (mean Hp 19.7±13.4 ng/ml) and high Hp levels group (mean Hp 71.0±28.5 ng/ml), respectively. Serum ferritin was 68.7±45.3 ng/ml and TSAT was 25.8±10.1% in low Hp group, in contrast, 186.2±151.4 ng/ml and 36.4±11.6% in high Hp group. There was no difference of Hgb level between both groups, the dose of ESA administered was lower in low Hp group (P=0.03) and also low amount of ESA was necessarily to maintain the Hgb levels during the observational three months.

Conclusions: Since there has been no golden standard for iron status in advanced CKD patients, measurement of Hp level is one of the useful indicators of assessment of iron status to choose either ESA or iron regimen for maintaining the targeted Hgb levels. Especially, to manage an appropriate ferritin level with keeping Hp low, it is possible to reduce the prescribing dosage of the ESA.

PUB124

Effects of a Low Salt Diet on Glomeruli from Diabetic Apolipoprotein E Null Mice
Chris Tikellis,[1] Mark E. Cooper,[1] Merlin C. Thomas.[1] *[1]Diabetic Complications, Baker IDI Heart & Diabetes Institute, Melbourne, Victoria, Australia.*

Background: It is recommended that individuals with diabetes restrict their dietary sodium intake to <65mmol/day. But while salt intake is correlated with blood pressure, it also partly determines the activation state of renin-angiotensin-system (RAS), a key mediator of diabetes-associated glomerulosclerosis.

Methods: *ApolipoproteinE* KO (*apoE* KO) mice were allocated for the induction of diabetes with streptozotocin or citrate-buffer (controls) and further randomized to isocaloric diets containing, 0.05% (low salt), 0.3% (normal salt), or 2.5% (high salt) sodium with or without the ACE inhibitor, perindopril. After 6 weeks of study, glomeruli were isolated and markers/mediators of renal fibrosis assessed using RT-PCR and immunohistochemistry.

Results: A 0.05% sodium (low salt) diet was associated with significantly increased glomerular fibrogenesis in diabetic *apoE* KO mice, and increased glomerular expression of fibronectin, TGFb, CTGF, MMP-2, collagen I, III, and IV. This was associated with activation of the systemic RAS and increased expression of the angiotensin II type 1 receptor (AT1R) in diabetic glomeruli of mice on a low salt diet. A similar induction of fibrogenic markers was observed in diabetic *ACE2/apoE* KO mice that had a constitutively active RAS. In contrast, a diet containing 2.5% sodium (high salt) suppressed glomerular fibrogenesis associated with suppression of the RAS, with an efficacy comparable to ACE inhibition.

Conclusions: Whilst blood pressure lowering is an important goal for the management of diabetes, off-target actions of a low sodium diet, such as activation of the RAS, may contribute to less favourable outcomes in diabetic glomeruli.

PUB125

Daily Activity Levels Are Associated with Fractures in Stage 3-5 Chronic Kidney Disease Sarah L. West,[1,2] Scott G. Thomas,[2] Sophie Jamal,[1,2] Charmaine E. Lok.[2,3] *[1]Women's College Hospital, Toronto, ON, Canada; [2]University of Toronto, Toronto, ON, Canada; [3]Toronto General Hospital, Toronto, ON, Canada.*

Background: Fractures are common in patients with chronic kidney disease (CKD). We determined if daily activity levels could discriminate fracture status in men and women with stages 3-5 CKD.

Methods: We measured daily activity by triaxial accelerometry (StayHealthy RT3) worn for 7 consecutive days on the hip in men and women with stages 3-5 CKD. Each minute of activity was categorized as sedentary (vector magnitude <100), light (vector magnitude between 100-1771), or moderate/vigorous (vector magnitude ≥1772). Logistic regression and area under receiver operating characteristic curves (AUROC) determined whether daily activity could discriminate among those with and without self-reported low trauma fractures since the age of 40/prevalent vertebral fractures. Analyses were performed using STATA and were adjusted for stage of CKD.

Results: Subjects (n=45; n=25 men) were primarily Caucasian (69%) with a mean age of 61±18 years and weight of 76±18 kg. The most common cause of CKD was diabetes (n=15, 33%), most subjects had stage 3 CKD (n=21, 47%), and 14 subjects (31%) had prevalent fractures. Subjects participated in a mean of 1117±113 min/day of sedentary activity, 315±107 min/day of light activity, and 8±11 min/day of moderate/vigorous activity. Compared to those without fracture, those with fracture participated in more sedentary activity (1094±119 vs. 1167±82 min/day, p=0.04) and fewer minutes of light activity (337±113 vs. 267±79 min/day, p=0.04). Increased amounts of sedentary activity and participating in less light activity were associated with fracture (Odds Ratio (OR):1.01, 95% Confidence Interval (CI):1.00-1.02; OR:0.99, 95% CI:0.98-0.99, respectively). As well, both sedentary (AUROC:0.72, 95% CI:0.56-0.87) and light activity (AUROC:0.71, 95% CI:0.55-0.87) were able to discriminate among fracture status.

Conclusions: In conclusion, in our study, patients with stage 3-5 CKD and prevalent fractures participate in less activity compared to those without fractures. Larger, longitudinal studies are needed to confirm these findings.

Funding: Government Support - Non-U.S.

PUB126

Daily Activity Levels Are Associated with Tests of Neuromuscular Function in Stage 3-5 Chronic Kidney Disease Sarah L. West,[1] Maryum Chaudhry,[2] Tanya D. Dahonick,[2] Charmaine E. Lok.[1,2] *[1]University of Toronto, Toronto, ON, Canada; [2]Toronto General Hospital, Toronto, ON, Canada.*

Background: Patients with chronic kidney disease (CKD) report low energy with declines in kidney function which may affect their functional ability; however, the association between energy expenditure and functional tests in patients with stage 3-5 CKD has not been objectively measured.

Methods: In patients ≥18 years with stages 3-5 CKD (using NKF criteria by MDRD), we measured tests of neuromuscular function (NMT: timed up and go [TUG] & 6 minute walk [6MW]) and daily energy expenditure by triaxial accelerometry (StayHealthy RT3) worn for 7 consecutive days on the hip, and categorized activity as sedentary, light, or moderate/vigorous. Statistics were performed using SAS.

Results: Overall, 59 men and 44 women completed NMT/accelerometry assessments, with a mean age of 64 years. The primary cause of CKD was diabetes (25%) and the mean eGFR was 26±15 ml/min/1.73m^2. On average, subjects completed the TUG in 12±4 seconds, and walked 331±111 meters in 6 minutes. Subjects expended 397±263 kcal/day performing daily activities and were sedentary:1145±114 min/day were spent sedentary, while 288±114 and 7±10 min/day were spent completing light and moderate/vigorous activity, respectively. The TUG was negatively correlated with the number of kcal expended/day (r=-0.385, p<0.0001), the amount of light & moderate/vigorous activity/day (r=-0.471, p<0.0001;r=-0.331, p=0.0006), and was positively correlated with the amount of sedentary activity/day (r=0.504, p<0.0001). The 6MW was positively correlated with the number of kcal expended/day (r=0.293, p=0.004), the amount of light & moderate/vigorous activity/day (r=0.342, p=0.0007;r=0.372, p=0.0002) and was negatively correlated with sedentary activity (r=-0.392, p<0.0001).

Conclusions: Low daily energy expenditure (i.e. sedentary activity and reduced light and moderate/vigorous activity) is associated with impaired performance on the TUG/6MW. Since poor performance on NMT is associated with adverse clinical outcomes, future studies should evaluate whether improvements in daily activity energy expenditure translates into improved NMT and outcomes in patients with stage 3-5 CKD.

PUB127

Fetuin A: A Relationships with Inflammation and Secondary Hyperparathyroidism in Patients with End Stage Renal Disease Marek Kuzniewski,[1] Danuta Fedak,[2] Pawlica Dorota,[2] Maria Kapusta,[2] Wladyslaw Sulowicz.[1] *[1]Department of Nephrology, Jagiellonian University, Krakow, Poland; [2]Department of Clinical Biochemistry, Jagiellonian University, Krakow, Poland.*

Background: Fetuin A is a negative acute phase protein, which is produced constitutive by liver and negatively regulated by proinflammatory cytokines. Epidemiological studies have shown that fetuin A can act as systemic inhibitor of vascular calcifications in hemodialysed (HD) patients. Due to the fact that Chronic Kidney Disease (CKD) is characterized by Mineral and Bone Disorder syndrome, the aim of this study was to evaluate relationship between fetuin A concentrations in blood and calcification scores (CaSc) in the context of altered bone metabolism and diminished bone mineral content (BMD) caused by secondary hyperparathyroidism in patients with CKD.

Methods: We enrolled 71 hemodialysed patients, 31 women, 40 men, mean age 60 ± 12 year. C-reactive protein was determined nephelometrically, iPTH using Nichols method, Fetuin A measured by ELISA. CaSc was assessed by MSCT and BMD by DEXA.

Results: We observed statistically significant correlations between serum fetuin A concentrations and imaging techniques: log CaSc (r=-0.29; p=0.03), BMD femoral neck (r=0.26; p=0.04) and biochemical indices: log hsCRP (r=-0.31; p=0.02) and log iPTH (r=-0.31; p=0.02). After extracting the four groups: with iPTH ≤ 300 pg/mL, iPTH > 300 pg/ml, hsCRP ≤ 10 mg/L and hsCRP > 10 mg/L we have observed diminished fetuin A concentration in high PTH group in comparison do group with low PTH levels (p=0.03), and also in high hsCRP compared with low hsCRP group (p=0.01). The lowest fetuin A levels have the patients with high iPTH and high hsCRP levels.

Conclusions: Our results confirm that fetuin A may be influenced both by inflammatory state and by secondary hyperparathyroidism in hemodialysed patients. In those patients group low fetuin A levels may play a role in renal osteodystrophy, or renal osteodystrophy due to secondary hyperparathyroidism, may accelerate vascular calcifications via fetuin A bioavailability reduction.

PUB128

Calciphylaxis: A Multimodal Care Concept Including Sodium Thiosulfate Improving Outcome Gernot Schilcher,[1] Werner Ribitsch,[1] Alexander R. Rosenkranz,[1] Kathrin Popodi,[1] Barbara Binder,[2] Joerg H. Horina.[1] *[1]Division of Nephrology, Medical University of Graz, Austria; [2]Department of Dermatology, Medical University of Graz, Austria.*

Background: Calciphylaxis, predominantly observed in patients with chronic kidney disease (CKD), is a rare but life threatening disease characterized by painful ischemic skin ulceration. Despite increasing incidence and high mortality rates of up to 80% no definite therapeutic regimen is well established. Aim of our present retrospective analysis was to evaluate a therapeutic approach based on a multimodal care concept including (a) medical interventions (sodium thiosulfate, cessation of coumarins, high dose vitamin K, cinacalcet, cessation of vitamin D and calcium containing phosphate binders, prophylactic antibiotics, probiotics, opioids, laxatives), (b) extended nursing (pain control, patient bedding, no subcutaneous injections in any suspicious area), (c) dermatological wound management, (d) dietary modifications (low phophorus and low calcium diet), (e) surgical interventions (parathyreoidectomy in case of primary hyperparathyreoidism) and, optionally, (d) modification of dialysis modality in CKD 5D patients.

Methods: We report on a case series of 4 adult patiens (2 with CKD stage 3 and CKD stage 5D, respectively). Retrospectively collected clinical, laboratory and medication data from patients treated between June 2009 and January 2012 were analyzed. We compared our single center experience and mortality rates before and after implementation of the multimodal care concept and furthermore to previously published outcome data.

Results: All 4 patients (100%) treated according to the multimodal concept showed a complete remission compared to a survival rate of only 50% before implementation of the new approach.

Conclusions: A multimodal therapeutic approach aimed at disease reversal might improve outcome in patients with calciphylaxis. Additional individualized therapies such as parathyreoidectomy in patients with primary hyperparathyreoidism should be considered.

PUB130

Treatment of Hyperuricemia in Chronic Kidney Disease (CKD) Patients May Improve Renal Function Subir K. Paul, Narasimha R. Boorgu, Rajesh Boorgu, Shejuti Paul. *Shoals Kidney & Hypertension Center, Florence, AL.*

Background: Recent studies have demonstrated an association between hyperuricemia and CKD progression, hypertension and cardiovascular disease. In CKD patients with mild hyperuricemia reduction of serum uric acid level (UA) has been shown to be modestly beneficial to preserve estimated glomerular filtration rate (eGFR). We found an inverse correlation between UA and eGFR. (r=-0.37) and a positive correlation between UA and serum Creatinine (CR) (r=0.42). This study was undertaken to evaluate the effects of allopurinol on renal function in CKD patients with moderate to severe hyperuricemia.

Methods: 26 patients with mean age of 61.7 were studied. 19 were Caucasians. 7 were African-Americans. 18 were female. 8 were male. Serum UA, CR, and eGFR were obtained 6 to 12 weeks prior to initiation of therapy, at baseline, at three months and at six months subsequent to start of therapy. Allopurinol was given with dose of 100 to 200 mg daily. No lifestyle modification was initiated and no medications were changed. Data was evaluated by student's paired t-test and linear regression.

Results: During pre-treatment phase, serum UA increased from 9.18 mg/dL to 11 mg/dL (p<0.0001). With allopurinol therapy, Serium UA decreased to 6.9 mg/dL (p<0.0001) at 3 months and to 6.85 mg/dL (p<0.0001) at 6 months. In pretreatment phase serum CR increased from 1.82 mg/dL to 2.12 mg/dL (p<0.0001). With allopurinol therapy, serum CR decreased from 2.12mg/dL to 1.85 mg/dL (p<0.0001) at 3 months and to 1.78 mg/dL at 6 months (p<0.0001). In pretreatment phase estimated eGFR decreased from 40.50 mL/min/1.73 m^2 to 33.69 mL/min/1.73 m^2 (p<0.0001). With treatment eGFR improved from 33.69 mL/min/1.73m^2 to 39.12 mL/min/1.73 m^2 (p<0.0003) at 3 months and to 41.5 mL/min/1.73 m^2 (p<0.0001) at 6 months. All patients tolerated therapy well.

Conclusions: We conclude that in CKD patients correction with allopurinol therapy of moderate to severe hyperuricemia may improve serum CR and eGFR. Large, randomized, double blind, placebo-controlled studies are warranted.

PUB131

Uremic Disruption of Macrophage Cholesterol Transporter ATP-Binding Cassette A1 (ABCA1) Ryohei Kaseda,[1] T. Alp Ikizler,[2] Valentina Kon.[1] *[1]Pediatric Nephrology, Vanderbilt University, Nashville, TN; [2]Nephrology, Vanderbilt University, Nashville, TN.*

Background: Macrophage foam cell is central in atherogenesis. We previously showed that foam cell development in patients with end stage renal disease on hemodialysis (ESRD-HD) reflects reduced cellular cholesterol efflux due to impaired cholesterol acceptor functions of high density lipoprotein (HDL). In uninephrectomized mice, we linked the reduced cholesterol efflux to downregulation of macro-phage ABCA1. We now examine if uremia affects cellular cholesterol transporters.

Methods: Peripheral blood monocytes were isolated from patients with ESRD-HD (n=11) before and after dialysis and Control subjects with normal renal function (n=3). ABCA1, ABCG1 and scavenger receptor type I (SRBI) gene expression was measured by RT-PCR. Since the HDL particles normally stabilize ABCA1, we also examined the effect of HDL isolated from ESRD-HD and Control on gene and protein expression of this transporter in human macrophage-like THP-1 cells exposed to HDL of ESRD-HD or Control by RT-PCR and western blotting.

Results: Compared with Control, monocytes of ESRD-HD had reduced expression of ABCA1 (normalized mRNA, 1.27±0.23 vs 0.77±0.10, $p<0.05$) and SRBI (1.11±0.36 vs 0.45±0.03, $p<0.05$) but not ABCG1 (1.28±0.06 vs 1.00±0.18). This expression pattern was not affected by dialysis treatment. HDL isolated from ESRD-HD increased ABCA1 mRNA in THP-1 cells (HDL of Control: 1.01±0.02 vs HDL of ESRD-HD: 1.30±0.08, n=8 in each group, $p<0.05$), a response not paralleled by enhanced cellular protein levels which rather decreased by upon exposure to the uremic HDL (HDL of Control: 1.11±0.05 vs HDL of ESRD-HD: 0.97±0.08, n=13 and 11, respectively).

Conclusions: The results suggest that hemodialysis patients have monocytes with reduced cholesterol transporters reflecting divergent effects of uremic HDL on transcription and protein degradation of ABCA1 together an effect of the uremic milieu. The data suggest cholesterol transporters as a novel target to lessen CVD in this population.

PUB132

HEMOX: *In-Vitro* and *In-Vivo* Assessement of a Non-Invasive Optical Sensor for Monitoring Blood Volume Variations during Dialysis Elena Mancini,[3] Claudia Perazzini,[1] Andrea Visotti,[1] Irene Selle,[2] Stefano Severi,[1] Antonio Santoro.[3] *[1]HST-CIRI, University of Bologna, Italy; [2]Bellco Srl, Mirandola, Italy; [3]Nephrology, Dialysis and Hypertension, "S. Orsola-Malpighi" Hospital, Bologna, Italy.*

Background: Blood volume (BV) decrease is an accepted marker of cardiovascular refilling of patients undergoing dialysis. The aim of the present study was to evaluate HEMOX sensor's (Bellco s.r.l, Italy) performance in assessing hematocrit and RBV variations comparing it with the gold standard sensor Crit-Line (HemaMetrics,USA) both in *in-vitro* and *in-vivo*.

Methods: *In-vitro* tests were conducted in different operating conditions by changing blood pump flow, dialysis solution conductivity, initial hematocrit and ultrafiltration rate. 22 standard bicarbonate dialysis were carried out using 5 L of bovine blood, a Formula Therapy monitor (Bellco) and data was recorded simultaneously by HEMOX and Crit-Line. In addition, volume decrease observed in the scaled beaker containing the blood was considered. *In-vivo* study included 7 patients enrolled in Nephrology, Dialysis and Hypertension unit, S.Orsola-Malpighi Hospital Bologna. Every patient was monitored during 3 standard bicarbonate dialysis sessions. HEMOX and Crit-Line were used simultaneously and initial and final hematocrit were also measured by CBC in the hospital analysis Laboratory. All data were analyzed in MATLAB (MathWorks, Inc.).

Results: Comparison between HEMOX and Crit-Line was summarized by correlation coefficient (r_{RBV}, r_{Hct}), mean error and standard deviation for both RBV and hematocrit (e_{RBV}, e_{Hct}). *In-vitro*: $r_{RBV}=0.88$, $r_{Hct}=0.93$, $e_{RBV}=2.97\pm2.19$ ($p<0.05$), $e_{Hct}=1.77\pm1.02$ ($p<0.05$). *In-vivo*: $r_{RBV}=0.92$, $r_{Hct}=0.86$, $e_{RBV}=1.56\pm1.71$ ($p< 0.05$), $e_{Hct}=-1.18\pm1.64$ ($p< 0.05$). Comparison of HEMOX and Crit-Line with hematocrit Laboratory measures: $r_{LAB\text{-}HEMOX}=0.85$, $e_{LAB\text{-}HEMOX}=-1.99\pm1.79$ ($p<0.05$); $r_{LAB\text{-}CL}=0.85$, $e_{LAB\text{-}CL}=-1.76\pm1.89$ ($p<0.05$).

Conclusions: *In-vitro* and *in-vivo* studies and comparison with Laboratory results demonstrated that HEMOX and Crit-Line can be considered comparable. A good linearity between the sensors was found, together with amoderate variance of both sensors with respect to laboratory data and a systematic HEMOX underestimation.

PUB133

What Prompts Initiation of Renal Replacement Therapy in Older Patients? Helen Alston, Aine Burns. *Centre for Nephrology at University College London, Royal Free Hospital, London, United Kingdom.*

Background: Many patients start renal replacement therapy (RRT) to alleviate uremia. Symptoms often do not correlate with eGFR, and previous studies found the elderly and those with comorbidities have more uremic symptoms. Symptoms due to other chronic disease may be indistinguishable from uremia, leading to early RT starts but no resolution of symptoms. We conducted a baseline study to determine what proportion of patients start RRT solely to alleviate uremic symptoms, and to identify differences between older and younger populations.

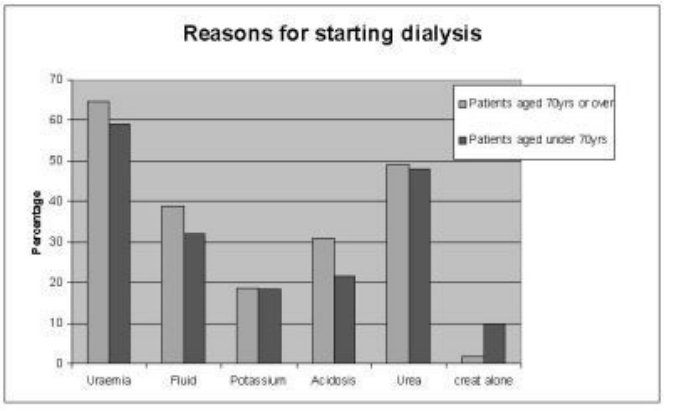
Methods: We reviewed the electronic patient record and blood results for all patients starting RRT in our unit Jan2009-Sept 2011 (n=254). We excluded failing transplants. We recorded age, gender, haemoglobin, eGFR, and Charlson comorbidity index. We coded the reasons for starting RRT. If multiple reasons were given, all were recorded. We noted unexpected RRT starts after acute deterioration in renal function (ie intercurrent illness).

Results: Our sample is characterised below:

Characteristics of our sample

	≥70yrs	<70yrs
Male	65.6%	65.1%
Mean Charlson comorbidity index	7.82	4.8
Diabetes	60.7%	52.6%
Ischaemic heart disease	49%	27.6%
Mean eGFR at initiation RRT	8.83	7.66
Mean Haemoglobin	10.26	9.91

Reasons for initiation of RRT are shown below:



There were also more unplanned starts in the older group (18.6% vs 13.8%). This was a higher incidence than expected.

Conclusions: Older dialysis patients form a distinct group, with higher comorbidities. They do not tolerate low eGFRs as well as younger patients, developing symptoms earlier. They are more likely to have diabetes and heart disease, and to have an unplanned start on RRT. It is vital to plan for deterioration in renal function even if renal function is currently stable. More work is needed to establish whether symptoms do in fact improve in this patients group following initiation of RRT.

PUB134

Immunogenicity of Investigational HEPLISAV Compared with Licensed Hepatitis B Vaccine (Engerix-B) in Patients with Chronic Kidney Disease (CKD) Robert Janssen, Sophia Rahman, Hamid Namini, William Heyward, Tyler Martin. *Dynavax Technologies Corporation.*

Background: Hemodialysis patients are at increased risk of hepatitis B virus infection. Current recommendations for CKD patients require 4 double-doses (2x20 mcg) of Engerix-B® (EB).

Methods: A multicenter, observer-blind, phase 3 study was conducted among 521 patients 18-75 years of age with CKD (GFR ≤ 45 mL/min/1.73 m^2) comparing 3 doses of HEPLISAV™ (H: 20 mcg rHBsAg+3000 mcg 1018 ISS Adjuvant, a toll-like receptor 9 agonist) given at 0, 1, and 6 months to 4 double-doses of EB (2x20 mcg rHBsAg+500 mcg alum) given at 0, 1, 2, and 6 months. Safety was evaluated for one year after the first study injection. Subjects were recruited at 69 sites in the US, Canada, and Germany and randomized 1:1 to receive H or EB. This represents the final immunogenicity and safety analyses.

Results: Among 507 subjects in the modified intent-to-treat population (H: 247; EB: 260), the mean age and gender distribution was similar in both groups. At Week 12, the seroprotection rate (SPR = anti-HBs ≥ 10 mIU/mL) in the H group (65.1%) was significantly higher than the SPR in the EB group (50.8%) with a difference in SPRs (H minus EB) of 14.3% (95% CI, 5.5%, 22.8%). At the primary endpoint at Week 28, the SPR in the H group (89.9%) was significantly higher than the SPR in the EB group (81.8%) with a difference in SPRs of 8.0% (95% CI, 1.7%, 14.3%). At Week 52, 28 weeks after the last study treatment, the SPR in the H group (84.3%) remained higher than the SPR in the EB group (77.3%) with a difference in SPRs of 7.1%. At Week 52, the percentage of subjects with anti-HBs ≥ 100 mIU/mL in the H group (66.8%) was significantly higher than in the EB group (49.1%) with a difference in the percentage of subjects with high antibody levels of 17.7%. At Week 52, the GMC in the H group (170.8 mIU/mL) was significantly higher than the GMC in the EB group (51.0 mIU/mL) with a ratio of GMCs of 3.40 (95% CI, 1.98, 5.84). The incidence of post-injection reactions and adverse events were similar in both groups.

Conclusions: In CKD patients, HEPLISAV induced significantly higher, earlier, and more durable seroprotection than Engerix-B and had a similar safety profile.

Restless Legs Syndrome in Children with Chronic Kidney Disease Sandeep K. Riar,[1] Roberta Leu,[2] Donald L. Bliwise,[3] Laurence A. Greenbaum.[1] *[1]Pediatrics, Division of Nephrology, Emory University and Children's Healthcare of Atlanta, Atlanta, GA; [2]Pediatrics, Division of Pulmonology, Allergy, Cystic Fibrosis and Sleep Medicine, Emory University and Children's Healthcare of Atlanta, Atlanta, GA; [3]Neurology, Psychiatry and Behavioral Sciences, Emory University School of Medicine, Atlanta, GA.*

Background: Restless leg syndrome (RLS) is increased in adults with chronic kidney (CKD) and it is associated with increased morbidity and mortality. There is limited information on RLS in children with CKD.

Methods: This was a prospective, questionnaire-based, cross-sectional study that included patients 8-18 years old with CKD from a tertiary pediatric nephrology center. Healthy children 8-18 years old from two community pediatric practices were included as controls. The primary outcome of interest was Restless Legs Syndrome (RLS), which was assessed via a questionnaire, with exclusion of mimics. Patients were also assessed for sleep quality, use of sleep medications, daytime sleepiness and health related quality of life.

Results: RLS prevalence was more prevalent in children with CKD (n= 124) than in 85 normal children (15.3% versus 5.9%, p-value 0.0355). Among children with CKD, there was no significant association between RLS and gender, race, body mass index, estimated GFR, duration of CKD, etiology of CKD, percentage of life with CKD, stage of CKD, or current treatment modality (dialysis vs. transplant vs. non-dialysis, non-transplant). Children with RLS were older (14.8 years vs. 13.1 years; p=0.03). Children with RLS were more likely to rate their sleep quality as fairly bad or very bad; 41.2% vs. 8.8%; p=0.003) and were reported to be more likely to use sleep medications (42.1% vs. 14.7%; p=0.01). RLS was also associated with lower health related quality of life by parent report (p=0.027). 5/19 patients with CKD and RLS had discussed RLS symptoms with a healthcare provider and only 1 patient had been diagnosed with RLS prior to this study.

Conclusions: RLS is increased in children with CKD compared to normal controls and appears to be underdiagnosed. Systematic screening for RLS and sleep problems appears warranted in children with CKD.

Analysis of the Basal Timepoint in the Cohort of the Multicenter Prospective and Observational Study of Atheromatosis in CKD in Spain (NEFRONA Study): Data on Intima-Media Thickness Angels Betriu, Montserrat Martinez-alonso, Jose M. Valdivielso, Elvira Fernandez. *IRBLleida.*

Background: There are no previous prospective studies assessing the impact of CKD on atheromatosis development, stratified by gender and age. The NEFRONA study is a multicenter prospective observational study monitoring, in patients in CKD 3 to 5D, the changes in atherosclerosis, and their relationship with biochemical and genetic biomarkers.

In the present abstract we report the data on median (mm) intima-media thickness (IMT) in the baseline time point of the NEFRONA cohort (2455 patients without previous CV event, at different stages of CKD), compared with a control population of 559 individuals without CKD.

Methods: Data on IMT was obtained with carotid ultrasound by the same team and assessed by one reader in a blinded fashion. Images from 6 different carotid territories were obtained (bulb, common and internal carotid in both sides). In case the territory presented a plaque, the IMT value was truncated to 1.5mm. We analyze the trend according to degree of CKD stratified by age and sex using logistic regression analysis for the values of IMT. Moreover we also analyze the effect of sex stratified by degree of CKD and age group.

Results: 2455 patients were enrolled of which 61% are male, 25% diabetics and a population of 559 controls of which 53% are male and 11% diabetics. 98% Caucasian in both groups.

Age (y)	No CKD (n=559)		CKD3 (n=944)		CKD4-5 (n=821)		CKD 5D (n=690)		Trend p value along CKD stage	
	M	W	M	W	M	W	M	W	M	W
25-35	.600	.563	.580	.548	.538	.520	.565	.543	.176	.270
35-45	.648	.580	.640	.638	.583	.598	.660	.615	.592	.191
45-55	.795	.680	.745	.620	.670	.660	.735	.670	.018	1.00
55-65	.818	.733	.840	.740	.848	.740	1.06	.788	.028	.361
65-75	.895	.805	1.00	.880	1.12	.830	1.13	.970	.002	.186

* p<0.01 men vs women

Conclusions: IMT increases along with age in all stages and in both sexes, strongly supporting the reliability of the measurements. IMT is lower in women than in men at all stages of CKD and age. The median IMT only shows a significant tendency for progression through the stages of CKD in men older than 55 years. Prospective analysis of the study will identify the risk and protective factors for progression of atherosclerotic disease, distinguished by gender, age and stage.

PUB137

Patients with Diabetic Kidney Disease Exhibit Endothelial Dysfunction Independent of CKD Stage Ulf Gunnar Bronas,[1] Marc L. Weber,[2] Mark E. Rosenberg,[3] Daniel Duprez.[2] *[1]Nursing, Univ of Minnesota, MN; [2]Medicine, Univ of Minnesota, MN; [3]Medicine, Univ of Minnesota, Mpls VAMC, MN.*

Background: Cardiovascular disease (CVD) is the leading cause of mortality in patients with chronic kidney disease due to type 2 diabetes (DKD). One of the initial mechanisms of the pathophysiology of atherosclerotic CVD involves endothelial dysfunction. The purpose of this study was to determine the relationship between CKD stage and indices of arterial function and structure in patients with stage 2-4 DKD.

Methods: Participants (n=91) with stage 2-4 DKD (62 male, age 64.1±9.2) underwent assessment of arterial function and structure. Endothelial function was studied by brachial artery flow mediated vasodilatation (FMD) using ultrasonography; endothelial- independent vasodilatation was assessed by sublingual nitroglycerine administration (NTG). Arterial stiffness was assessed by pulse wave velocity (PWV) and carotid incremental elastic modulus (cIEM). Arterial structure was examined by measuring the common carotid intima-media thickness (cIMT).

Results: There were no significant differences in demographics, medications, or medical variables between groups based on CKD stage. All groups exhibited impaired FMD (mean FMD=3.4%) compared to historical controls (FMD=8.9-10.5%). ANOVA did not indicate any significant differences between CKD stage in any of the indices of arterial function or structure. There were no significant associations observed between stage of CKD and indices of arterial function or structure.

Results

CKD Stage	FMD(%)	NTG(%)	cIEM(mm Hg)	PWV(m/s)	cIMT(mm)
	Mean(SD)	Mean(SD)	Mean(SD)	Mean(SD)	Mean(SD)
2 (n=24)	3.6(2.9)	9.7(5.0)	3287(1313)	8.1(1.6)	0.6(0.2)
3 (n=48)	3.4(3.3)	9.5(6.6)	3224(1186)	8.2(2.2)	0.7(0.3)
4 (n=19)	3.6(3.1)	10.2(3.9)	3572(1608)	8.5(1.6)	0.6(0.2)

Conclusions: Endothelial dysfunction occurs early in DKD, independent of CKD stage, and may contribute to the high incidence of CVD mortality in this population. Vascular smooth muscle function appears to be less affected in early DKD. This finding supports the need to initiate therapies to improve endothelial function in early stage DKD and to investigate interventions that target vascular dysfunction in this population.

PUB138

Role of Unphosphorylated STAT3 and HO-1 in Chronic Nicotine (NIC)-Induced Exacerbation of Renal Fibrosis Istvan Arany,[1] Dustin Reed,[1] Robert Kampen,[1,3] Christine Maric-Bilkan,[2] Luis A. Juncos.[2,3] *[1]Pediatrics, University of Mississippi Medical Center, Jackson, MS; [2]Physiology and Biophysics, University of Mississippi Medical Center, Jackson, MS; [3]Medicine/Nephrology, University of Mississippi Medical Center, Jackson, MS.*

Background: There is a strong epidemiological association between smoking (via NIC) and accelerated progression of chronic kidney disease (CKD). Smoking increases plasma levels of TGFβ1 (a known mediator of renal fibrosis), hence NIC-induced alterations in TGF β1 signaling may augment tubulointerstitial fibrosis and contribute to progression of CKD. Because un-phosphorylated STAT3 (U-STAT3) and heme-Oxygenase-1 (HO-1) are important factors regulating pro-fibrotic signaling. In this study, we tested if these two factors play a role in the adverse effects induced by chronic NIC on renal fibrosis.

Methods: *In vivo*: A mouse model of unilateral ureteral obstruction (UUO) was employed to assess effect of chronic NIC exposure on interstitial fibrosis as well as expression of HO-1 and U-STAT3 in the kidney exposed to chronic NIC.

In vitro: NRK-49F cells were used to study the impact of chronic NIC on TGFβ1-mediated activation of renal interstitial fibroblasts.

Results: Chronic NIC augmented tubulointerstitial fibrosis in the obstructed kidney as evidenced by expression of αSMA and Masson trichrome staining. This exacerbation of UUO-induced tubulointerstitial fibrosis was associated with increased expression of U-STAT3 and decreased expression of HO-1. In vitro, chronic NIC increased TGFβ1-mediated activity of the αSMA promoter in a U-STAT3-dependent manner while attenuating activation of the HO-1 promoter. In addition, activation of endogenous HO-1 by CoPP greatly diminished the promoter activity of αSMA.

Conclusions: Our results suggest that chronic NIC augments pro-fibrotic signaling by enhancing promoter activity of the αSMA gene via increased expression of U-STAT3 and down-regulation of HO-1. Manipulation of these pathways may present therapeutic means to ameliorate the adverse effects of chronic NIC/smoking.

PUB139

Effects of Tenofovir on CKD Progression Srujana Polsani,[1] Rakesh Malhotra,[1] Erian Shehu,[1] Anjali Acharya.[1] *[1]Jacobi Medical Center; [2]Albert Einstein College of Medicine, Bronx, NY.*

Background: Tenofovir is an effective first line agent in the treatment of human immunodeficiency virus infection. Tenofovir is known to cause proximal tubular injury and Faconi syndrome and is thought to have a low overall toxicity profile. Information on its effect on proteinuria decline in renal function and risk for chronic kidney disease (CKD) is limited. The aim of the study is to evaluate if tenofovir use is associated with increased risk of CKD, proteinuria, hypophosphatemia or faster decline in renal function in a inner city HIV population.

Methods: This is a retrospective chart review of patients with HIV followed in our institution. Information was collected from electronic medical records and/or personal interview with enrolled patients on demographic data, date of HIV diagnosis, HAART regimen, comorbidities, urinalysis, eGFR, serum phosphorus and rate renal function decline. CKD was defined as GFR <60 ml/min for > 3 months. Decline in renal function was defined as greater than 3ml/min in a year for 2 consecutive years. Hypophosphatemia was defined as serum phosphorus less than 3 mg/dl.

Results: Of the 200 patients enrolled 40 patients were excluded had insufficient laboratory data. 80.6% of patients were on tenofovir and 19.3% patients were on non tenofovir based regimen.

Table 1

	Tenofovir n=129 (80.6%)	Nontenofovir n=31(19.4%)
CKD3 and higher 3.2%(n=1)	6.9%(n=9)	3.2%(n=1)
Proteinuria	24%(n=31)	19.3%(n=6)
Hypophosphatemia	27.1%(n=35)	12.9%(n=4)
Renal function decline	7.5%(n=12)	0%(n=0)

Conclusions: Incidence of CKD in our patient population is similar to that shown in other studies.80% of patients were on Tenofovir. Tenofovir use was associated with a higher incidence of CKD, proteinuria and hypophosphatemia and faster rate of renal decline. These findings are being confirmed in a larger cohort. Limitation of the study is that only 20% of patients are on non tenofovir based regimen which may mask the difference between the groups. We recommend that patients on Tenofovir need to have estimations of GFR, UA, Urine albumin, protein, creatinine, urine and serum phosphorus on a regular basis.

PUB140

Hemoglobin Variation of Hospitalized Jehovah's Witness Patients with Chronic Kidney Disease Muhammad W. Khattak, Chioma O. Onyekwelu, Sandeep Aggarwal, Ziauddin Ahmed. *Department of Nephrology, Drexel School of Medicine, Philadelphia, PA.*

Background: Management of anemia and acute blood loss is challenging in Jehovah's Witness patients with different stages of CKD during hospitalization.. Primary prevention of anemia is important goal by using blood less protocol, and keeping adequate HG level by appropriate ESA and iron therapy. It is important to know the Hemoglobin (Hg) variation in clinical practice to formulate a standard policy to manage them during the hospitalization.

Methods: We reviewed the charts of 55 Jehovah's Witness patients with different stages of CKD admitted to our hospital for last two years. Mean age was 55 years, 35.7 % were Males, 64.3% females, 78.56 % African Americans and16.07 % were Caucasians and 5.36% hispanics. Thirty eight were CKD stages 5 on HD and 17 with different stages of CKD and not on HD.

The patients were covered under the blood less policy of the hospital where judicial blood drawn using small tubes was undertaken. The pre admission and discharge Hg were noted.

Paired t test was used to analyzed the variation of HG on admission and discharge.

Results: The mean Hg of patients with CKD stage 5 on HD on admission were 11.54 ±2.84 and on Discharge 11.36 ± 1.5 with p value of 0.026. Five out of 29 patients were within the goal or 10 gm and above on discharge. Ten patients or 26.3% were less than 10 gm of Hg on discharge.

The mean Hg of patient's with other stages of CKD who were not on HD was 10.2 ± 2.17. The discharge Hg was 9.35 ± 2.03 with p value of 0.21. Five out of 9 patients had Hg less than 10 or 55.5% on discharge.

Conclusions: The baseline Hg of CKD stage 5 were higher than the other stages of CKD may be due to routine use of ESA use in HD population. Despite use of blood less policy of the hospital the patients with CKD stage 5 on HD had significant decrease of Hg during hospitalization. This group needs a clear policy for primary prevention by maintenance of threshold HG level and evidence based aggressive treatment protocol with frequent ESA and Iron therapy for acute anemia during hospital course.

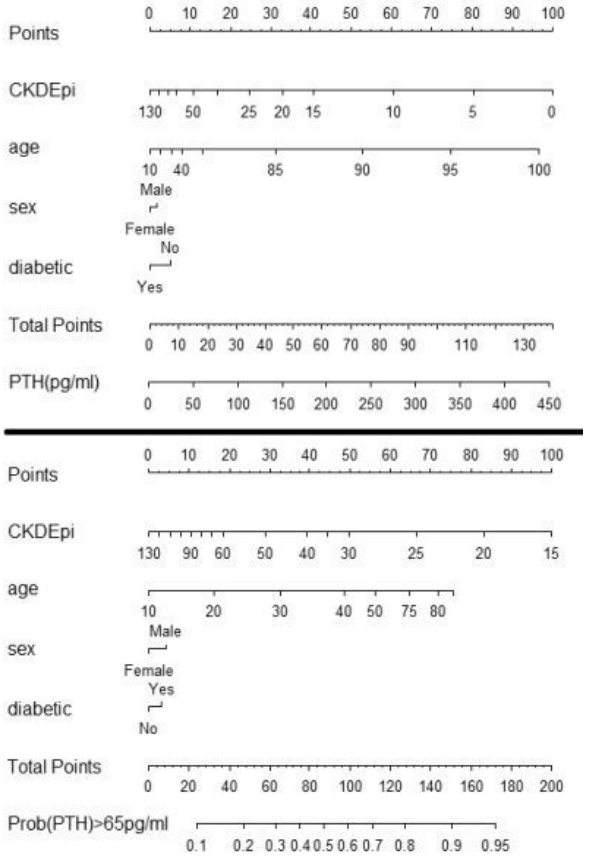
PUB141

An Equation to Estimate PTH Levels in CKD Patients Not Receiving VitD Receptor Activating Agents (ePTH) Kostas I. Sombolos,[1] John Boletis,[3] Dimitrios V. Vlahakos,[4] Kostas C. Siamopoulos,[5] Vassilios A. Vargemezis,[6] Pavlos Nikolaidis,[7] Christos E. Iatrou,[11] Eugene Daphnis,[10] Christos Argyropoulos,[9] Kostas Xynos.[8] *[1]Papanikolaou Hosp.; [2]Laiko Hosp.; [3]Attiko Hosp.; [4]Ioannina University Hosp.; [5]Alexandroupoli University Hosp.; [6]AHEPA Hosp., Thessaloniki, Greece; [7]Abbott Labs Hellas; [8]Abbott International; [9]Herakleion, University Hosp.; [10]Nikea Hospital, Athens.*

Background: Chronic Kidney Disease (CKD) complications are directly related to the level of renal function. Despite the availability of equations for eGFR, no tools exist for the prediction of CKD complications, e.g. Secondary Hyperparathyroidism(SHPT). We develop nomograms for estimating Parathyroid Hormone (ePTH) in CKD.

Methods: Age, sex, iPTH, diabetes(DM) and eGFR (CKD-Epi), from a cross-sectional epidemiology study in Greece, were used to develop spline models for PTH (as continuous and as> 65pg/ml i.e. the upper normal limit for the assay used). Model's discriminatory abilitity was assessed with R^2 (iPTH) & ROC (probability PTH>65 pg/ml) using the bootstrap(bst,2000 samples).

Results: A total of 516 pts who have never received therapy with vitamin D analogs were examined: 55%(women), 26%(diabetics); median(IQR) of: PTH 87.5(87.85), eGFR 34.5(25.6), distribution of patients in CKD stages: 1(6%),2(11%),3(43%),4(32%),5(9%) . Model performance for iPTH R^2: 0.22 & for PTH>65pg/ml ROC: 0.74. Corresponding nomograms are shown below:



Conclusions: It is possible to estimate PTH values (ePTH) based on demographics and eGFR. Nomograms and/or implementation of ePTH in smartphone applications, may reduce cost of CKD care by prioritize pts for SHPT screening (measured PTH) based on their likelihood of having an elevated ePTH. Addition of Ca and P values may improve model performance, but validation in other populations is required.

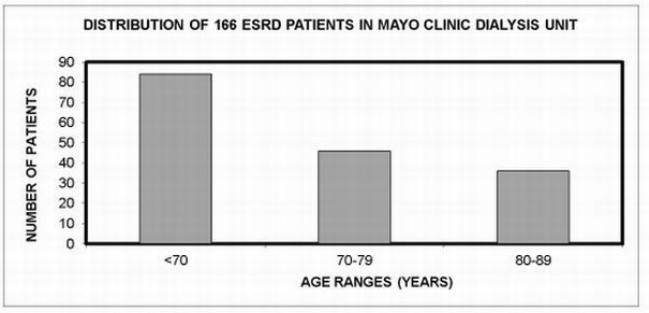
PUB142

Nondialytic Therapy (NDT) Is a Neglected Paradigm in US Nephrology Practice: It's Time for a Robust Reappraisal: This Is Not Rationing! Macaulay A. Onuigbo.[1,2] *[1]Medicine, Mayo Clinic, Rochester, MN; [2]Nephrology, Mayo Clinic Health System, Eau Claire, WI.*

Background: Non-dialytic therapy (NDT) is a growing modality of treatment for ESRD for a certain group of CKD patients, in the UK and in Europe, but not in the US. Over 500,000 US ESRD patients are on RRT. In 20 years, the rate of ESRD patients >75 years starting dialysis has almost tripled from 550 to 1550 per million. Elderly CKD patients >70 years with multiple co-morbidities and who slowly progress to ESRD, when managed by multidisciplinary teams (MDT), showed median overall survival (life expectancy) of 1.95 years; 65% one-year survival, not that different with dialytic therapy. NDT led to possibly better quality of life with less hospitalizations. In a recent UK study, over 3 years, 60% of NDT patients, aged >70 years, had no admissions at all. We studied NDT or lack thereof, in a Mayo Clinic HD Unit.

Methods: The census of a NW Wisconsin Mayo Clinic dialysis population was analyzed on May 15, 2012. The second objective was to document any recent NDT activity.

Results: Of a total current ESRD population of 166, 82 (49%) patients were aged 70 years and over, with 46 aged 70-79 years and 36 aged 80-89 years (Fig). NDT was virtually nonexistent. These older ESRD patients experienced frequent hospitalizations and it is unclear if their quality of life would be better than with NDT in a majority of them who concurrently have major multiple co-morbidities.



Conclusions: Virtually one half of the ESRD population in this NW Wisconsin Mayo Clinic HD unit were >70 years. NDT is a neglected paradigm in this practice, as in most US nephrology practices. The place of NDT modality of care for US ESRD patients demands urgent attention and reappraisal. It should be seen for what it is – another alternative to dialytic therapy in a specific group of older ESRD patients. Furthermore, it is not tantamount to rationing!

PUB143

Estimation of GFR: A Comparison of Methods in a Large Caucasian Population Ludwig F. Merker,[1] Baptist Gallwitz,[2] Katja Schoene,[3] Barbara Waldeck.[3] *[1]Diabetes- und Nierenzentrum Dormagen, Dormagen, Germany; [2]Medizinische Klinik IV, Universität Tübingen, Tübingen, Germany; [3]Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany.*

Background: There is only few data available from systematic comparisons between different methods of estimating GFR, so as Cockcroft-Gault (CG) vs MDRD vs CKD-EPI, in Caucasian people with type 2 diabetes (T2DM).

Methods: We recruited 2541 consecutive patients with T2DM from 245 primary care physicians in a prospective, randomized, cross-sectional epidemiological study according to GCP standard; pts. with CKD 5 were excluded. The following data was collected by questionnaire: antidiabetic and antihypertensive medication, renal status, hypertension and comorbidities. On site urinalysis was carried out by dipstick, the same for mircoalbuminuria (MAU). Central lab included HbA_{1c}, serum creatinine, albumin-creatinine-ratio (ACR) and lipid profile; eGFR (ml/min/1,73m^2) was estimated using MDRD formula, CKD-EPI formula and CG caculation. To ensure data quality 10 % of the study sites were monitored. The study was performed from 01-10/2011.

Results: Using the CG formula, 41.1 % had CKD 1, 35.9 % had CKD 2, 21.7 % had CKD 3 and 1.3 % had CKD 4. In contrast, estimating GFR by MDRD formula, 16.1 % had CKD 1, 54.7 % had CKD 2, 27.7 % had CKD 3 and 1.4 % had CKD 4. The correlation between MDRD estimation and CG formula overall was R=0.77, between CG and CKD-EPI slightly better with R=0.81 and MDRD and CKD-EPI showed quite similar results with an overall correlation of R=0.97. Regarding the BMI, the majority of patients with CKD 3 had a BMI of 20-35 kg/m^2. There was a positive correlation between the higher stadium of CKD and diabetes duration as well as the age of the study population and a negative correlation for BMI, independently of the gender and the methodology of eGFR calculation.

Conclusions: In Caucasian Germans and as previously shown by Levey et al., using the CG formula likely leads to overestimation of GFR, as MDRD formula seems to underestimate GFR: Using either CKD-EPI formula or MDRD gets to quite similar results. The correlation of renal impairment is positive for age and diabetes duration and negative for BMI for both genders.

PUB144

Thoracic Electrical Bioimpedance (TEB) in Cardiorenal Syndrome (CRS) Management: Relationship with Vectorial Bioimpedance (VBIA) in Chronic Kidney Disease (CKD) Patients Stage 2-5 Secundino Cigarran,[1] Juan Villa Rincon,[1] Emilio E. Gonzalez-parra,[2] Jesus Calvino.[3] *[1]Nephrology, Hospital Da Costa, Burela, Lugo, Spain; [2]Nephrology, Fundación Jimenez Díaz, Madrid, Spain; [3]Nephrology, Hospital Lucus Augusti, Lugo, Spain.*

Background: CRS may occur by renal and/or cardiac dysfunction. CKD take part of CRS type 2 and 4. When both coexist overhydration is the rule. TEB is a non-invasive, validate and valuable method of evaluating cardiac haemodynamic. VBIA is used to assess body composition in CKD. The aim of this cross-sectional study is to assess the agreement between TBE&VBIA.

Methods: 92 pts. 33.7% female, 47.8% diabetic, 26.2% LVEF < 55%. Mean age 70.89 ± 10.06 yr. Mean GFR-EPI 38.3 ±18.4 ml/min. Heart evaluation was assessed by Echo &TEB (Modular Hotman System. Hemo sapiens INC, Bucarest,Romania) determinating Cardiac Index CI, Lef Systolic Work index,LSWI, Inotropic State index ISI, Systemic Vascular Resistance Index SVRI, Thoracic Fluid conductivity TFC & Eyection Phase Contractility Index EPCI). VBIA used was EFG (Akern Firenza Ita). Hydration status (ECW,ICW TBW), nutritional status (BCM%, muscle, lean body mass & basal metabolism) were determinated. Data were processed with SPSS18 (SPSS INC, Chicago IL, USA). A test P < 0.05 was considered significant.

Results: TFC positively corelated with Na-K exchange, TBW, and negatively with BCM%, reactance and resistance. EPCI positively with TBW and resistance and negatively with BCM%.

Bivariate correlation TEB & VBIA parameters

Variable	Na-K exchange	BCM (%)	TBW (%)	Reactance (Ω	Resistance Ω
Systolic Volume (ml/m^2	106 (NS)	-147 (NS)	300 (p<0.001)	147(NS)	188 (p<0.05)
SVR (F.Ω/m^2)	-162NS)	262 (p<0.05)	-164 (NS)	-039(NS)	-245(p<0.05)
LSWI (g.m/m^2)	064 (NS)	-062(pp<0.05)	325 (p<0.001)	147 (NS)	188 (NS)
EPCI (l/min)	138 (NS)	-244 (p<0.05)	230 (p<0.05)	104 (NS)	294 (p<0.05)
TFC (1/Ω	433 (p<0.001)	-259 (p<0.05)	580 (p<0.001)	-264 (p<0.05)	-235 (p<0.05)
LVFE (%)	-367 (p<0.001)	300 (p<0.05)	-266 (NS)	140(NS)	-063 (NS)

NS= No significance. Person (significance)

Conclusions: TBE parameters correlated with VBIA parametres.TBE &VBIA are valuable tools in CKD patients to assess fluid overload and hemodynamic heart function Futher studies are required to develop and confirm this findings.

Equations Based on Enzymatically-Measured Serum Creatinine Significantly Overestimate GFR in Chinese Children with Kidney Injuries Mengchun Gong,[1] Xuemei Li,[1] Ke Zheng,[1] Yan Qin,[1] Hongmei Song.[2] *[1]Nephrology, Peking Union Medical College Hospital, Beijing, China; [2]Pediatrics, Peking Union Medical College Hospital, Beijing, China.*

Background: There is no data about glomerular filtration rate (GFR), measured through plasma or renal clearance of the exogenous markers, in the Chinese children.

Methods: We determined GFR with plasma clearance of ^{99m}Tc-DTPA in 92 hospitalized children with renal injury and compared the performance of ten different equations, biochemically based on sCr (4), sCysC (3) or their combination (3), in estimating GFR, with statistical parameters of linear correlation and regression, precision and accuracy.

Results: The Schwartz1976, Schwartz2009 and CKiD equations, the most widely accepted tools for GFR estimation in children, significantly overestimate GFR (bias 29.2, 29.1, 22.1, respectively, all p<0.0001 in the paired t-test between eGFR and nGFR). Compared with the other eight equations, the Counahan equation and the Filler equation produced eGFR with better correlation with nGFR, stronger explanation capacity of variance in nGFR, smaller bias, higher intraclass correlation coefficients, higher ratio of eGFR within nGFR±10% and eGFR within nGFR±30% and higher ratio of correct CKD staging.

Estimation Performance of the Eleven Equations

Equations	Mean mL/min/1.73m2	Bias mL/min/1.73m2	γ¶	R-square†	ICC‡	Ratio within 10%	Right Staging
Schwartz1976	126.2	29.2*	0.733	0.54	0.70	15	67
Schwartz2009	128.8	29.1*	0.766	0.59	0.73	17	69
Leger	90.8	-6.2	0.588	0.35	0.59	17	53
Counahan	96.1	-3.2	0.748	0.56	0.73	25	70
Filler	99.6	2.8	0.796	0.63	0.78	35	69
Zappitelli-CysC	88.8	-14.3*	0.796	0.63	0.78	25	60
Grubb	110.6	13.0*	0.795	0.63	0.68	17	67
CKiD	119.3	22.1*	0.808	0.64	0.80	19	72
Bouvet	75.6	-21.5*	0.588	0.35	0.62	25	48
Zappitelli-combi	150.1	53*	0.807	0.65	0.68	12	71

* significant bias between eGFR and nGFR in paird t-test;¶ linear correlation factor; † linear regression factor; ‡ ICC: intraclass correlation factor.

Conclusions: No equation based on enzymatically measured sCr is validated to evaluate renal function in the Chinese CKD children, indicating an urgent need for the development of a new GFR estimating equation based on data from this population.

PUB146

Pregnancy Outcomes in Chronic Kidney Disease Zichun Feng,[1] Charles G. Minard,[2] Rajeev Raghavan.[1,3] *[1]Medicine, Baylor College of Medicine, Houston, TX; [2]Biostatistics, Baylor College of Medicine, Houston, TX; [3]Nephrology, Baylor College of Medicine, Houston, TX.*

Background: Approximately 1 in 150 pregnant women have Chronic Kidney Disease (CKD). These women have a higher incidence of pre-eclampsia, preterm delivery, and adverse maternal / fetal outcomes. In pregnant women with severe CKD (eGFR<30ml/min), pregnancy outcomes and optimal time to initiate dialysis are unknown.

Methods: Ten pregnant women with severe CKD (not on dialysis) and 36 pregnant women with moderate CKD (eGFR 30-100 ml/min, proteinuria) were identified from chart review. Inclusion criteria were >20 weeks of gestation, baseline and interim serum creatinine values. All patients had follow-up and delivery at the same urban public hospital between 2000 and 2012. Comparison was also made to published data of pregnant women on hemodialysis. Statistical analysis was done with Fisher's exact test and nonparametric Kolmogorov-Smirnov test.

Results: Compared to women with moderate CKD, women with severe CKD have higher incidence of preterm delivery and reduction in eGFR during pregnancy (p<0.05).

Pregnancy Outcomes in CKD

Outcomes	Severe CKD	Moderate CKD	p-value
Preterm Delivery	90%	41%	0.01
Reduction in eGFR During Pregnancy	26.1%	0%	0.04
Preeclampsia	70%	63%	1.0
Intrauterine Growth Retardation	20%	6.3%	0.24

Both groups had similar rate of caesarean section and perinatal death (p=1.0). Adverse fetal outcomes in pregnant women with CKD are associated with: maternal hypertension, severe CKD, maternal proteinuria and pre-eclampsia (Odds Ratios= 1.33, 17.83, 1.73, 1.66, respectively). Diabetic nephropathy as the cause of CKD correlates with fewer adverse fetal outcomes, compared to other causes of CKD (Odds Ratio=0.22, 0.05-0.9). Finally, compared to published data in pregnant women on hemodialysis. This cohort of women with severe CKD (not on dialysis) have higher incidences of pre-eclampsia / eclampsia (12.5% vs 70%) and premature delivery.

Conclusions: In pregnancy, the severity of CKD correlates with a higher incidence of pre-term delivery, small for gestational age, and decline of maternal renal function. Pregnant women with severe CKD (eGFR < 30 ml/min) may benefit from pre-emptive initiation of dialysis.

PUB147

Serum Free Light Chains as Markers of Progression in Chronic Kidney Disease Hyun Chul Whang, Eun Sil Koh, Yu Ah Hong, Sungjin Chung, Cheol Whee Park, Yong-Soo Kim, Yoon-Sik Chang. *Department of Internal Medicine, The Catholic University of Korea College of Medicine, Seoul, Korea.*

Background: In patients with chronic kidney disease (CKD), as the glomerular filtration rate (GFR) reduces, the renal clearance of free light chains (FLC) decreases. The aim of this study was to investigate FLC as a marker for kidney damage and as predictors for progression of CKD.

Methods: Serum and urine FLC were assayed in 318 CKD patients and the control. Clinical and biochemical parameters including estimated GFR (CKD-EPI) were evaluated.

Results: There were no significant differences in age, gender, hs-CRP and LDH between the control and CKD group, however, serum kappa and lambda FLC levels were higher in the CKD group than in the control (p <0.01). In the univariate regression analysis, serum and urine kappa and lambda FLC, age and LDH level were associated with estimated GFR. In multivariate linear regression analysis, only serum kappa and lambda FLC were associated with eGFR (β=-1.435, p <0.01 for kappa and β=-1.227, p <0.01 for lambda, respectively). Furthermore, urine lambda was significantly associated with urine albumin after adjusting factors (β=1.63, p <0.01).

Conclusions: These data suggest that serum kappa and lambda FLC may be used as predictors for progressive renal dysfunction in patients with CKD, and urine lambda FLC might be a marker for the detection of kidney damage.

PUB148

Prevalence of Renal Dysfunction in HIV-Positive Patients in Rio de Janeiro Patricia Santiago,[1] Cynthia Cunha,[1] Sandra Wagner Cardoso,[1] Ruth Friedman,[1] Valdilea Veloso,[1] Beatriz Grinsztejn,[1] Jose H. Suassuna.[2] *[1]IPEC, FIOCRUZ, Rio de Janeiro, Brazil; [2]Nefrologia, UERJ, Rio de Janeiro, Brazil.*

Background: Widespread use of highly active antiretroviral therapy (HAART) has altered the course of HIV infection from a lethal disease to chronic medical condition. HIV-associated kidney disease changed likewise. We investigated the prevalence of kidney dysfunction and associated factors in people living with HIV in a country with free access to HAART.

Methods: This was a retrospective cross-sectional study of 2354 outpatients under follow-up in the calendar year 2008. Renal dysfunction was defined as a CKD-EPI eGFR of ≤ 60 ml/min. We collected demographic, clinical and laboratorial data.

Results: The cohort was mostly male (64%), white (67%) and young (80% under 50 yo). Median current CD4 count was 460 mm³ and median nadir CD4 was 189 mm³. Forty-two percent of the cohort had AIDS (CDC-1993) and 81% had a CD4 nadir < 350 cells/mm³. Nevertheless, 70% had undetectable viral load and 68% had ≥ 350 CD4+ cells/mm³ by the time of renal function assessment. Hypertension was the most common comorbidity (26%) followed by diabetes (9%). Six percent of the cohort was HCV+ and 3% had Hepatitis B. Only 17% of the cohort did not meet treatment criteria and were HAART-naïf. Fifty-two percent of patients started atazanavir or lopinavir and 33% still used one of them. Indinavir was previously used by 15% of the patients and 41% were exposed to tenofovir, of which 92% were current users. Median eGFR was 111.4 ml/min and 3.8% of the cohort had an eGFR ≤ 60 ml/min. Seven patients (0.4%) reached CKD stage V. Associated fators were age ≥ 50 years, ≤ 350 TCD4+ cells/mm3, diabetes, hypertension, past tenofovir use, past indinavir use, and current use of atazanavir or lopinavir.

Conclusions: Our cohort had advanced HIV infection but also free universal access to HAART. Age, comorbid degenerative diseases and advanced infection were detrimental to kidney health. Tenofovir, atazanavir and lopinavir showed potential nephrotoxicity. However the risk seems acceptable as, contrary to earlier series of untreated or under-treated patients, the point prevalence of kidney dysfunction was remarkably low.

Funding: Government Support - Non-U.S.

PUB149

Prevalence of Chronic Kidney Disease in High Risk Patients in a Primary Health-Care Petra Martínez, Laura Cortes-sanabria, Héctor R. Martínez Ramírez, Alfonso M. Cueto-Manzano. *Unidad de Investigación Médica en Enfermedades Renales, Instituto Mexicano del Seguro Social, Guadalajara, Jalisco, Mexico.*

Background: End-stage renal disease has remarkably increased. The magnitude of chronic kidney disease (CKD) in Mexico, particularly at early stage, is not completely known.

Methods: Aim. To determine the prevalence of CKD in patients with type 2 diabetes mellitus (DM2) of a primary health-care setting. A CKD screening in DM2 patients was performed in 3 Family Medicine Units; subjects ³18 years without previous diagnosis of renal disease or transitory cause of proteinuria were included. All patients were subjected to a questionnaire, blood pressure measurement and anthropometry. Serum creatinine was measured, and glomerular filtration rate (eGFR,Simplified MDRD/formula) estimated. A dipstick urinalysis and albuminuria-specific dipstick were performed in a random urine sample, and confirmed.

Results: One thousand eight patients were included: 760 had normal results and 248 had CKD (classified according with K/DOQI). 93 (37%) patients had stage 1, 87 (35%) stage 2, 54 (22%) stage 3, 12 (5%) stage 4 and 2 (1%) stage 5. For analysis, patients of stage 4 and 5 were considered together. The characteristics of patients with CKD are shown.

Prevalence of CKD for Stages

Variable	Stage 1,n93	Stage 2,n87	Stage 3,n54	Stage 4/5,n14
Age (yrs)	58±12	66±9	70±8	66±13
Duration of DM2 (yrs)	12(7-16)	14(9-20)	19(13-22)	20(15-15)
Hypertension,n(%)	47(50)	65(75)	43(80)	11(77)
Systolic blood pressure (mmHg)	126±19	136±17	132±20	137±22
Diastolic blood pressure (mmHg)	78±10	82±10	78±10	85±7
Triglycerides (mg/dl)	165(118-260)	181(221-235)	202(137-274)	147(132-177)
LDL-Cholesterol (mg/dl)	117±31	111±31	115±35	118±32
Hb1Ac (%)	9.3±2.4	8.9±2.3	8.4±2.0	7.5±1.5
eGFR (ml/ min/1.73m2)	110(103-126)	75(68-80)	47(41-57)	24(18-27)
Albuminuria/ Creatinuria (mg/g)	121(53- 291)	120(57-260)	180(52-436)	894(195-2847)

Conclusions: The 25% had CKD. From the latter subjects, 72% had early (stages 1 and 2), 22% intermediate (stage 3) and 6% had advanced CKD (stages 4 and 5). Patients displayed poor metabolic control. It is important to evaluate CKD in high risk populations (such as diabetics) in order to implement early nephroprotective measures.

PUB150

Genetic Impact on Renal Function Decay in Radical and Partial Nephrectomy Maria Teresa Sciarrone Alibrandi,[1] Francesco Trevisani,[1] Simona Delli Carpini,[1] Marco Simonini,[1] Tommaso Camerota,[2] Lino Merlino,[1] Laura Zagato Villa,[1] Elena Brioni,[1] Roberto Bertini,[2] Francesco Montorsi,[2] Patrizio Rigatti,[2] Paolo Manunta.[1] *[1]OU Nephrology, San Raffaele Scientific Institute, Milan, Italy; [2]OU Urology, San Raffaele Scientific Institute, Milan, Italy.*

Background: Historically, renal cancer has been treated with radical nephrectomy (RN). Consequently, many patients developed renal failure and several health problems associated with it, such arterial Hypertension and cardiovascular diseases. Partial nephrectomy (PN) is increasingly being used to treat patients with solid renal lesions. Preservation of renal function is also a relevant clinical consideration. PN is associated with more favorable postoperative renal function outcomes relative to RN in the setting of small renal masses. On the other hand onset of hypertension and chronic renal failure after nephron loss is quite variable among single patients who undergo renal surgery. Aim was to compare RN and PN in renal function outcome according to several genetic polymorphisms involved in blood pressure control.

Methods: 134 patients younger than 80 years with renal cell carcinoma in absence of metastates, treated by RN (n = 65) or PN (n = 69) at Urology Unit of our Hospital between 2005-2012. ΔGFR has been evaluated in the follow up (mean 23.5 months). Statistical analysis has been performed by GLM adjusted for sex, age, blood pressure, comorbid conditions, therapy and previous renal function.

Results: At follow up patients who underwent RN present a significant loss of DGFR vs the ones treated with PN (-23.9 ml/min vs -5.7 ml/min P<0.05). According to genetic polymorphisms a strong correlation has been observed between SIK1 gene (salt inducible kinase 1) and SLC12A1 gene (Na/K/Cl transporters) and the outcome of renal function decay.

Conclusions: Both genes seem to play a role in worsening renal after renal surgery independently from RN or PN used.

PUB151

Is the Chronic Kidney Disease Epidemiology Equation Useful for the Estimation of Glomerular Filtration Rate in Chinese Patients with Chronic Kidney Disease? Xun Liu,[1] Chenggang Shi,[1] Linsheng Lv,[2] Hua Tang,[1] Cailian Cheng,[1] Tan-qi Lou.[1] *[1]Division of Nephrology, Department of Internal Medicine, The Third Affiliated Hospital of Sun Yet-sun University, Guangzhou, Guangdong, China; [2]Operating Room, The Third Affiliated Hospital of Sun Yet-sun University, Guangzhou, Guangdong, China.*

Background: The Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equation is most accurate for estimating glomerular filtration rate (GFR) in U.S. population but requires more evaluations in other racial as well as ethnic minorities.

Methods: From January 2005 through December 2010, 1180 Chinese chronic kidney disease (CKD) patients were enrolled. SC was measured by the enzymatic method. Mean sGFR measured by ^{99m}Tc-DTPA GFR estimation was 46.5±27.1 (2.73-137.6) ml/min/1.73 m^2. The patients' GFRs were estimated by Cockcroft-Gault-equation (CG), 6-variable MDRD equation (MDRD1), 4-variable MDRD equation (MDRD4) and CKD-EPI equation. eGFR measured by the CKD-EPI equation was chosen as the reference GFR.

Results: The medians of difference of the Cockcroft-Gault-equation and the 4-variable MDRD equation were significantly less than the CKD-EPI equation. The median percents of the absolute difference of the Cockcroft-Gault-equation, the 6-variable MDRD equation and the 4-variable MDRD equation were significantly less than the CKD-EPI equation. The 15 to 50% accuracy of the Cockcroft-Gault-equation were all significantly higher than the CKD-EPI equation. Detailed performances are listed in Table 1.

Overall performance of difference and accuracy between eGFR

	Median of difference	Median % Absolute difference	15% Accuracy	30% Accuracy	50% Accuracy
CG	-1.34*	27.33*	29.4*	54.1*	78.3*
MDRD1	-2.11	30.90*	26.5	48.4	73.1
MDRD4	-1.40*	30.87*	26.4	48.3	71.9
CKD-EPI	-1.72	31.23	25.5	48.8	71.6

*:P<0.05 compared with CKD-EPI-GFR.

Conclusions: When SC was measured by the enzymatic method, the performances of the CKD-EPI equation was disappointing. The Cockcroft-Gault equation may be more suitable in Chinese patients with CKD.

Funding: Government Support - Non-U.S.

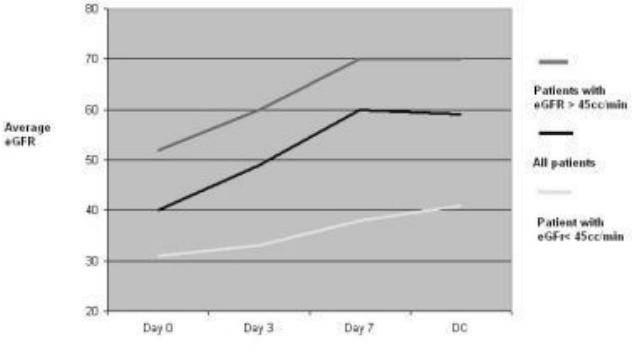
Can Critically Ill CKD Patients Augment Their GFR? Krunal M. Patel, George N. Coritsidis, Marie France R. DeLeon, Nechama Diamond, Kasun I. Navarathna. *Elmhurst Hospital Center, New York, NY.*

Background: Critically ill patients, primarily young and with trauma, have demonstrated the ability to augment their GFR. Augmentation is dependent on various mechanisms with renal function being paramount. Heightened GFR may play an important role in pharmacodynamics and especially in antibiotic dosage.

Methods: We reviewed the records of 212 neurocritically ill patients admitted to the surgical/trauma ICU at Elmhurst Medical Center in New York City between 2009 and 2011. Patients with CKD-EPI GFR (eGFR) >60cc/min/1.75m^2; those that developed AKI or had initial AKI with recovery later in the course were excluded. Charts were reviewed for APACHE II, eGFR and hospital length of stay (LOS) were calculated.

Results: In the remaining 36 patients with CKD, eGFR increased by 36% (42±2 to 57±5c/min, p=.0483, ANOVA). Age was 71±3, 50% were trauma and LOS was 28±6 days. In patients presenting with eGFR between 45 and 60cc/min, a 35% increase in GFR was seen (52±1 to70±5, p=.0098, ANOVA). No significant increase in eGFR was seen in patients who presented with eGFR ≤45 (n=17, p=.446). There were no differences in LOS between the eGFR subgroups.



Conclusions: Critically ill CKD patients were able to significantly increase their eGFR if admission eGFR was at least 45cc/min. No increase was seen in those patients with admission eGFR≤ 45 cc/min.

PUB153

Gait Speed as a Predictor of Dialysis and Mortality among Elderly with Stage 5 Chronic Kidney Disease Sameena Z. Iqbal, Leora Birnbaum, Sidi Salami, Ahsan Alam, Murray L. Vasilevsky, Elham Rahme, Gary Inglis, Paul E. Barre, Chi-lan Tran. *Medicine, McGill University Health Centre, Montreal, QC, Canada.*

Background: Gait speed is a validated tool to measure function in both the elderly and among those with chronic kidney disease. It has been proposed to consider a timed gait test of 10 feet or 3 meters back and forth to assess frailty among the elderly. The objective was to assess the association of gait speed in older subjects with Stage 5 CKD with the composite outcome of the progression to dialysis or all-cause mortality.

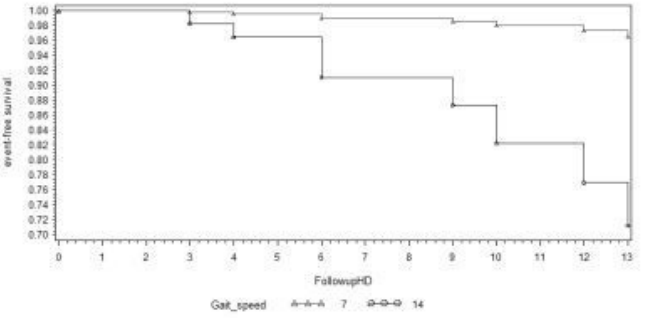
Methods: Between June 2010 and June 2012, we performed a prospective cohort study among individuals over the age of 65 with Stage 5 CKD at two tertiary care hospitals.

Results: In the study, 23 individuals were enrolled, 52% with diabetes type 2, 61% male and 13% African-American. The median age was 79 (65-87) years, median Charlson Comorbidity Score (CCS) was 5 (3-10), the baseline median eGFR was 13 (9-15) ml/min/1.73 m^2, and baseline median serum albumin was 37 (20-44) g/l. Upon enrollment, the median gait speed was 10.4 (6.0-21.6) seconds. During the two year observation period, there were 3 (13%) deaths and 9 (39%) dialysis starts. A Cox proportional hazard model was used to assess the association of gait speed with the composite outcome. The unadjusted and adjusted HRs are shown in table 1.

Cox Hazard model for composite outcome of dialysis start and mortality

Variable	Unadjusted HR (95% CI)	Adjusted HR (95% CI)
Gait speed (sec)	1.2 (1.01-1.4)	1.6 (1.04-2.4)
Serum Albumin (g/L)	0.9 (0.8-1.1)	0.8 (0.6-1.1)
baseline eGFR (ml/min/1.73m^2)	0.5 (0.4-0.8)	0.5 (0.3-0.8)
CCS	1.2 (0.9-1.8)	2.7 (1.1-6.6)

Event-free curves for gait speeds of 7 seconds compared to 14 seconds are shown in figure 1.



Conclusions: Gait speed may be a useful predictor of dialysis start and mortality in the elderly with stage 5 CKD, but a large prospective study is warranted.

PUB154

Laboratory Predictors of Kidney Disease in Pediatric Patients with SLE Sangeeta D. Sule,[1] Divya Moodalbail,[2] Julia R. Maisel,[2] Barbara A. Fivush,[1] Susan L. Furth.[2] *[1]Pediatrics, Johns Hopkins University, Baltimore, MD; [2]Pediatrics, Children's Hospital of Philadelphia, Philadelphia, PA.*

Background: Studies of adult patients with systemic lupus erythematosus (SLE) have shown an association between changes in complement and dsDNA levels with flares of overall disease. Renal specific outcomes have not consistently correlated with changes in these laboratory markers. Our goal was to determine if changes in C3, C4, and dsDNA levels were associated with renal disease in a longitudinal cohort of pediatric patients with SLE.

Methods: Longitudinal logistic regression models using generalized estimating equations to account for repeated measures were used to determine the association of C3, C4, and dsDNA titers with renal disease defined as proteinuria >3+ on urine dipstick or active urinary sediment defined as >5 rbc/hpf, >5 wbc/hpf or cellular casts. Patients were included in this analysis if they had at least 2 clinic visits within 6 months of each other. Patients were followed from time of entry into the cohort through Jan 31, 2012, the last date of follow-up.

Results: 47 children with SLE were followed in a retrospective cohort study. All patients had at least 2 longitudinal visits within 6 months. Patients were 90% female, 55% African American with a median age of diagnosis of 14 years. The median serum creatinine at initial presentation was 0.6 mg/dL, and 59% of these pts had dipstick proteinuria >1+. The median C3 level at presentation was 32 mg/dl; C4 was 12 mg/dl, both below normal values. A 1 mg/dl decrease in serum C3 between visits was associated with an increased risk of cellular casts (OR 1.5, p=0.003) and proteinuria (OR 1.1, p=0.02). There was no association with changes in C4 or dsDNA. Diffuse proliferative GN was associated with an increased dsDNA titer between visits, although not statistically significant (OR 2.2, p=0.07).

Conclusions: In this analysis, pediatric patients with SLE were more likely to have abnormal urinalysis if there were a decrease in serum C3 levels between visits. There was a trend towards increased dsDNA titers associated with diffuse proliferative GN. Abnormalities in SLE-specific labs over time can be predictive of renal disease.

PUB155

Distribution of Albuminuria and Low Glomerular Filtration Rate in a Surburb General Population in Beijng Yan Qin, Ke Zheng, Xiaohong Fan, Jianfang Cai, Xuemei Li. *Kidney Division, Peking Union Medical College Hospital, Beijing, China.*

Background: Chronic kidney disease (CKD) is becoming a major public health problem worldwide. The aim of this study was to screen for CKD among the general population of the surburb area of Beijing in China.

Methods: In an epidemiology study of the Pinggu District of Beijing, a total of 6287 participants aged over 18 years old were selected by systematic randomized cluster sampling. Participants were characterized by eGFR category as G1(>90), G2(60-89), G3a(45-59), G3b(30-44), G4 (29-15) and G5(<15 mL/)min/1.73 m^2. Albuminuria were characterized by ACR category as A1(ACR ≤30mg/g), A2(ACR 30-299mg/g), and A3(ACR≥300mg/g). The CKD-EPI eGFR equation was used for estimation of GFR.

Results: Albuminuria was present in 10.58% of the participants, but GFR less than 60 mL/min/1.73m^2 was found only in 0.76% of the study population. The prevalences are not higher than for other chronic diseases leading to an increased risk for cardiovascular disease mortality, such as hypertension (45.1%), diabetes (8.96%), metabolism syndrome (39.0%) and central obesity(52.7%) in the same population. When distributed to the CKD "heat map" generated by a composite ranking system of relative risks with the combinations of eGFR and ACR as the definition and classification of chronic kidney disease in KDIGO 2009 conference, the G1A1, G1A2 and G2A1stage was constituted by 81.53%, 8.45% and 7.37% of the population, respectively. While the participants in the higher risk stage for mortality or ESRD are summed up to only 0.27%. In multiple regression anlysis for this general population, ACR levels affected by total cholesterol level, serum uric acid level and intracellulerfluid which measured by Bioelectrical impedance analysis.

Conclusions: The combination of eGFR and ACR make clear the composite of CKD in general population and be helpful to make risk prediction. In this surburb general population, the higher prevalence of alubuminuria than low eGFR relatives with the high prevalence of metabolism disease.

PUB156

Outcome of Patients Diagnosed with Granulomatous Interstitial Nephritis Ben Anthony Oliveira, Sapna Shah. *King's College Hospital, United Kingdom.*

Methods: This retrospective study reports on all patients presenting with a histological diagnosis of granulomatous interstitial nephritis (GIN) between 2000 and 2012 at our unit.

Results: 21 patients were identified. 38% were of Black ethnicity, 57% were male and the mean age was 59 years. 8 cases were associated with sarcoidosis with evidence of extra-renal disease and 5 with renal-limited sarcoid. 5 patients had tuberculosis (TB) infection, 1 case was related to medication and 2 were idiopathic. The mean duration of follow-up was 46 months. Those with sarcoidosis presented with a mean eGFR of 23 mls/min, minimal proteinuria (0.4g/day) and serum angiotensin-converting-enzyme (ACE) of 106 mg/L. All were treated with prednisolone (mean dose 32 mg/day). Mean duration of treatment was 47 months. At 1 year, renal function and proteinuria had improved to 43 mls/min and 0.3g/24h respectively with a reduction in serum ACE to 32 mg/L. At the final clinic visit, renal function remained stable (mean eGFR 43 mls/min). Mean eGFR was 27 mls/min and proteinuria was 0.7g/day at presentation for those with TB infection. Treatment of TB infection in 3 patients was delayed by a mean of 29 months as TB cultures were negative. Development of extra-renal TB infection led to the initiation of treatment. However, response was disappointing as 2 patients developed end stage kidney disease and the remaining 3 patients had a mean eGFR of 24 mls/min at 1 year and 30 mls/min at last clinic visit. The idiopathic and medication related cases of GIN, presented with a mean eGFR of 46 mls/min and all commenced steroid therapy. During the first year, 1 patient died following an unexpected cardio-respiratory arrest. The mean eGFR at the last follow-up was 34 mls/min. In all groups, the degree of fibrosis on the renal biopsy did not correlate with outcome.

Conclusions: This study represents the largest cohort of patients with GIN in the UK and supports previous findings that patients with sarcoid have a favourable outcome with steroid treatment. Those with TB have an inferior prognosis perhaps due to delayed diagnosis. Efforts to expedite diagnosis along with a consideration of a trial of anti-TB therapy may be warranted in order to preserve renal function.

PUB157

Influence of High Blood Pressure on the Prevalence of Chronic Kidney Disease in Patients with Type 2 Diabetes Mellitus and Essential Hypertension Karla Gabriela Meza-torres, Laura Cortes-sanabria, Victor Omar Frías-navarro, Héctor R. Martínez Ramírez, Miguel Tapia Alanis, Erika Fabiola Gómez-garcía, Blanca Liliana Maldonado-ruiz, Alfonso M. Cueto-Manzano. *Unidad de Investigación Medica en Enfermedades Renales, IMSS, Guadalajara, Jalisco, Mexico.*

Background: Type 2 diabetes mellitus (DM2) and hypertension (HT) are leading causes of chronic kidney disease (CKD). Coincidence of metabolic and hemodynamic abnormalities results in higher frequency of cardiovascular and renal damage. However, there are scarce data about the prevalence of CKD in DM2 and essential HT.

Aim: To compare the prevalence of CKD of patients with DM2 (with and without HT) *vs* those with essential HT (without DM2).

Methods: Patients of 3 primary health-care units were randomly selected. Glomerular filtration rate was estimated (eGFR) from the simplified MDRD formula. Albumin/creatinine ratio was performed in a first morning urine sample. CKD was classified according to K/DOQI guidelines.

Results: 1480 patients were included. Main results are shown in the table.

Variable	DM2 (N 519)	DM2+HT (N 615)	HT (N 346)
Age (yrs)	57 ± 12	63 ± 10*	60 ± 11* †
Duration of DM2 (yrs)	8 (3-13)	10 (4-15)	-
Duration of HT (yrs)	-	7 (3-13)	8 (3-13)
Systolic BP (mmHg)	124 ± 18	137 ± 20*	135 ± 19*
Diastolic BP (mmHg)	74 ± 10	80 ± 11*	80 ± 10*
Glucose (mg/dL)	180 (122-229)	164 (113-202)*	100 (91-107)* †
Urine albumin/creatinine (mg/g)	61 (6-13)	86 (8-31)	9 (6-8)* †
Microalbuminuria, N (%)	66 (13)	110 (18)*	12 (3)* †
Macroalbuminuria, N (%)	17 (3)	44 (7)*	0* †
eGFR (mL/min/1.73m2)	95 (78-116)	84 (66-105)*	77 (67-91)* †
Presence of CKD, N (%)	113 (22)	208 (34)*	64 (18)†
Normal function	405 (78)	405 (66)*	281 (81) †
Stage 1	46 (9)	55 (9)	2 (1)* †
2	25 (5)	51 (8)*	7 (2)* †
3	33 (6)	72 (12)*	42 (12)*
4	8 (2)	29 (5)*	14 (4)*
5	-	1 (0.2)	-

*p<0.05 vs DM2; †p<0.05 vs DM2+HT

Conclusions: Prevalence of CKD was significantly higher in patients with DM2 with HT. Patients with HT (both diabetic or non-diabetic) had higher prevalence of intermediate-advanced CKD than non-hypertensive ones. It is important to perform CKD screening activities in DM, but it is also imperative to evaluate patients with HT, who are frequently relegated in this regard.

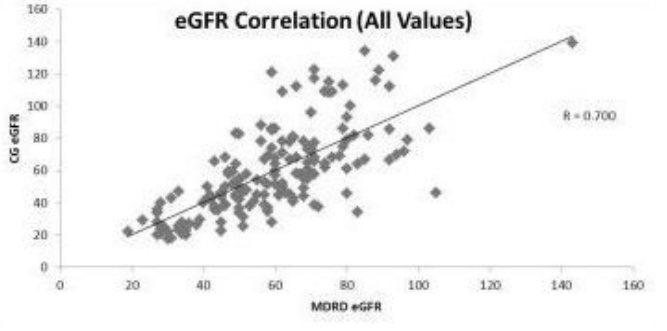
PUB158

Is There Sufficient Correlation or Difference in Using CG and MDRD Formulae to Calculate eGFR in ACS Patients Muhammad Ali Abdool, Hsu Pheen Chong, Mahvash Zaman, Matthew George Parry, Andrew Kuk, Bhavna Pandya. *Aintree University Hospital, Liverpool, United Kingdom.*

Background: In the UK and worldwide, there has been adoption of the 4 variable MDRD in reporting of eGFR and hence CKD staging. However, the cardiologists use CG in the calculation of CRUSADE bleeding risk scores. This can lead to potential confusion in using different formulae for GFR estimations, as well as clinical implications such as renal protection for peri-contrast procedures, ie. angiography and CT scans. Underestimation of eGFR is not as significant as overestimation as renal protection does little harm but can significantly minimise risk of Contrast Induced Nephropathy.

Methods: 166 patients admitted to Aintree University Hospital, Liverpool over a 5 month period (April - August 2012) with a diagnosis of NSTEMI had their notes analysed and eGFR calculated with the 2 formulae.

Results:



The number of patients with CKD 3 and above was 95 (57%) with the CG formula and 83 (50%) with the MDRD formula. There was adequate correlation between the calculated values for eGFR but when the data was subdivided into CKD stages, there was adequate correlation in only 86 (52%) patients.

When the 2 formulae are compared with each other with respect to moderate CKD, CG overestimates the eGFR in 3(4.2%) cases whereas MDRD overestimates in 17(23.3%) cases. This trend is similar in mild CKD with CG overestimating in 12(23.5%) cases compared to MDRD in 24(32.9%) cases. However, The trend is reversed for eGFR>90.

Conclusions: · About half of the population presenting with NSTEMI has moderate CKD or worse as calculated by both formulae

· There is good correlation between CG and MDRD absolute values (R=0.700, p<0.005) but this does not hold true when the data is categorised by CKD staging.

· With mild and moderate CKD, MDRD (43.2%) tends to overestimate compared to CG (18.1%)

· With eGFR>90 CG tends to overestimate compared to MDRD (85% vs 70%).

PUB159

Impacts of Serum Cystatin C and Creatinine on the Efficacy of Mild Renal Dysfunction in Patients with CKD Ke Zheng, Yan Qin, Xuemei Li. *Department of Nephrology, Peking Union Medical College Hospital, Beijing, China.*

Background: To investigate the impacts of serum creatinine(sCr) (including by Jaffe and enzymatic methods) and serum cystatin C(sCysC) within CKD patients in mild renal dysfunction, compared with dual-plasma-sample method (DPSM) to measure the glomerular filtration(GFR) with (99m)Tc Diethylene Triamine Pentaacetic Acid ((99m) Tc-DTPA) plasma clearance rate, to find the better predictor in the earlier stage of CKD.

Methods: nGFR of 300 patients with CKD were determined by dual-plasma-sample method (DPSM) to measure the glomerular filtration(GFR) with (99m)Tc Diethylene Triamine Pentaacetic Acid ((99m)Tc-DTPA) plasma clearance rate. Serum creatinine was detected with Jaffe and enzymatic methods. Serum cystatin C was detected by immunoturbidimetry simultaneously. To find out the optimal diagnostic value of sCr and sCysC at nGFR≤90ml/min/1.73m^2, Receiver Operating Curve(ROC) was used.

Results: The optimal cut off value of sCr(Jaffe)was 96 μmol/L, the optimal cut off value of sCr(enzymatic) was 88 μmol/L, the optimal cut off value of sCysC was 1.2mg/L. The value of area under curve(AUC) of sCr(Jaffe)was 0.892, the AUC value of sCr(enzymatic) was 0.878, the AUC value of sCysC was 0.924. There was significant difference of AUC value between sCysC and sCr(Jaffe and enzymatic)($p<0.05$).

Conclusions: Serum cystatin C is a better indicator than serum creatinine for predicting mild renal dysfunction in CKD patients.

PUB160

Early Nephropathy Detection According to a New Classification of Chronic Kidney Disease Miguel Tapia Alanis, Victor Omar Frías-navarro, Erika Fabiola Gómez-garcía, Blanca Liliana Maldonado-ruiz, Laura Cortes-sanabria, Héctor R. Martínez Ramírez, Karla Gabriela Meza-torres, Alfonso M. Cueto-Manzano. *Unidad de Investigacion Medica en Enfermedades Renales, Instituo Mexicano del Seguro Social, Guadalajara, Jalisco, Mexico.*

Background: A new classification of chronic kidney disease (CKD) was proposed by the Kidney Disease: Improving Global Outcomes (KDIGO) in 2011. The major point of revision of this classification was the introduction of a two-dimensional staging of the CKD according to the level of albuminuria in addition to the GFR level. Furthermore, the previous CKD stage 3 was subdivided into two stages (G3a and G3b). We estimated the prevalence of CKD in patients with type 2 diabetes mellitus and/or essential hypertension (HT) based on the new classification.

Methods: Three out of 24 primary health-care units were randomly selected; from these units, patients with DM2 or essential HT were randomly selected. Subjects with previous diagnosis of renal damage and secondary HT were excluded. Serum creatinine was measured and glomerular filtration rate (eGFR) estimated from the simplified MDRD formula. Albumin/creatinina ratio was performed in a first morning urine sample. CKD was classified according to KDIGO, 2011.

Results: One trousand four hundred eighty patiens were studied, (DM2 519; DM2+HT 615; HT 346) with mean age of 62 ±11 years, 936 (63%) women, median duration of DM 8 (3-15) and HT 7 (3-13) years respectively. The prevalence de CKD is shown in the table.

			Albuminuria stages, description and range (mg/g)				
			A1		A2	A3	
			Optimal and high-normal		High	Very high and nephrotic	
STAGE			<10%	10 - 29%	30 - 299%	300 - 1999%	>2000%
G1	HIGH	>105	18.2	5.1	3.1	0.8	0
	OPTIMAL	90 - 104	14	1.3	2.3	0.6	0.1
G2	MILD	75 - 89	16.6	3	2.3	0.5	0
		60 - 74	14.2	1.9	1.9	0.5	0
G3a	Mild moderate	45 - 59	5.1	1.1	2	0.8	0.1
G3b	Moderate severe	30 - 44	1.6	0.7	1	0.2	0.1
G4	Severe	15 - 29	0.2	0.1	0.2	0.3	0.1
G5	Kidney failure	<15	0	0	0.1	0	0

Conclusions: The prevalence global of CKD was 26%. Higher prevalence was observed on Stage G1 - A2, 6.5% of subjects had more risk of complications (G1-A3, G2-A3, G3a-A3, G3b-A2, G4-A1, G5-A1 stage).

PUB161

Ketoanalogue Supplementation Fails to Slow Decline of Renal Function in Chronic Kidney Disease Patients Li Ping Tan,[1] Anis Farhanah Abdul Rahim,[1] Chew Ming Wong,[1] Soo Kun Lim,[1] Yip-Boon Chong,[1] Kok Peng Ng,[1] Tee Chau Keng,[1] Wai Yew Kong,[1] Wan Ahmad Hafiz Wan Md Adnan,[1] Mun Hoe Wong,[1] Abdul Hafidz Muhammad Iqbal,[2] Li Han Lim,[1] Maisarah Jalalonmuhali.[1] *[1]Medicine, University of Malaya Medical Center, Kuala Lumpur, Wilayah Persekutuan, Malaysia; [2]Medicine, Universiti Teknologi MARA, Shah Alam, Selangor, Malaysia.*

Background: Ketoanalogues have been shown to reduce patient morbidity, relieve uremic symptoms and improve nutritional status in chronic kidney disease (CKD). We aim to study whether ketoanalogue supplementation in combination with a low protein diet managed to slow CKD progression.

Methods: This was a retrospective review. CKD patients using ketoanalogues within the time period of 2009 to 2010 under follow up in our center were identified. Control patients were randomly selected from the same clinic. All patients were counselled by renal dieticians regarding the adoption of a low protein diet. Blood pressure, serum creatinine, serum potassium, serum albumin, serum calcium and serum phosphate levels were obtained at baseline and at every 3 months for a year. statistical analysis was done using SPSS (version 19.0).

Results: 62 patients were recruited. 31 patients in the ketoanalogue group and 31 in the control group. Mean age was 68.5±9.3 years. Majority were male (n=37, 59.7%). The predominant cause of CKD was diabetic nephropathy (n=33, 53.2%). Mean blood pressures were lower at baseline for the ketoanalogue group (139/74±21/13mmHg) compared to control (151/77±23/15mmHg). Baseline renal function was worse in the ketoanalogue group with mean serum creatinine at 291.9±85.6 μmol/L (eGFR 18.4±7.7 ml/min/1.73m2) compared to 213.4±62.7 μmol/L (eGFR 26.8±10.2ml/min/1.73m2)($p<0.05$). At the end of 12 months, serum creatinine in the ketoanalogue group rose to 308.9±105.1 μmol/L, p=0.116 (eGFR 17.7±8.1 ml/min/1.73m2, p=0.42) compared to the control group (serum creatinine 257.2±115.7 μmol/L, p=0.06; eGFR 24.3±13.2 ml/min/1.73m2, p=0.09).

Conclusions: We were not able to demonstrate that the addition of ketoanalogues in combination with a low protein diet was able to significantly slow the decline of renal function in a mixed cohort of patients with CKD.

PUB162

Quality of Reporting of Randomization Methodology in Nephrology Trials Steven Fishbane,[1] Azzour Hazzan,[1] Shayan Shirazian,[2] Ezra Israel,[1] Giovanni F.M. Strippoli.[3] *[1]Division of Nephrology, Hofstra North Shore-LIJ School of Medicine; [2]Division of Nephrology, Winthrop-University Hospital; [3]Consorzio Mario Negri Sud, Italy.*

Background: Inadequate randomization procedures and reporting detract from a trial's value. The purpose of this analysis was to determine the quality of reporting on randomization in nephrology trials.

Methods: Randomized Controlled Trials (RCT) from 7/1/2010 - 6/30/2011 identified from general medical and nephrology journals by Medline search and Table of Contents reviews were abstracted for four aspects of randomization reporting, 1) sequence generation, 2) type of randomization, 3) allocation concealment, and 4) randomization implementation. For two critical criteria, randomization type and method of concealment allocation, predictors of acceptable reporting and related outcome effect size were studied.

Results: Only 5/74 (6.8%) articles reported sufficiently on all 4 criteria. There was no reporting on: 1) sequence generation in 59.5%, 2) randomization type (39.2%), 3) method of allocation concealment (58.1%) and randomization methodology (86.5%) of publications. For two key criteria (randomization type and allocation concealment), reporting was adequate in 32.4% of articles. Significant predictors of acceptable reporting were multicenter vs. single center studies and primary endpoints of time to event or binary vs. continuous. When reporting on these criteria was inadequate, studies had significantly increased effect size for the primary outcome (0.34±0.16 vs. 0.16±0.09, $P<0.001$).

Conclusions: Nephrology studies often have inadequate reporting of randomization methodology. Authors and journal editors should work to adhere to reporting standards.

Summary of Chinese Literature Review on Iron Use for IDA in CKD Patients

Bao Liu,[1] Rong Hao,[2] Zhong Li,[3] Xiaoyu Nie,[4] Tang Mi,[1] Yue Gao,[3] Hongyu Yang,[1] Shanlian Hu.[1] *[1]School of Public Health, Fudan University, Shanghai, China; [2]Vifor Pharma, Glattbrugg, Switzerland; [3]Shanghai Centennial Scientific, Shanghai, China; [4]Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD.*

Background: Iron deficiency anemia (IDA) is very common in patients with chronic kidney disease (CKD). Intravenous (IV) and oral iron are used to treat IDA in CKD patients.

Methods: A comprehensive literature search was conducted in China for 2006-2010. The sources of publications were China Academic Journals Full-text Database, Chinese media and web reports. 163 articles were identified using key words including IDA, anemia, IV iron, and oral iron.

Results: 65 articles reported iron use for IDA in CKD patients : 59 in HD-CKD, of which 51 compared IV to oral iron and concluded that IV iron had greater efficacy and fewer AEs. The other 5 in PD-CKD (2 on high vs. low dose) and 1 in ND-CKD came to the same conclusion.

Iron therapies for IDA in CKD patients

IDA Population	Therapy	No. of Publications	Treatment Effects	Adverse Events (AEs)
HD-CKD	IV vs. Oral Iron	51	IV iron: better efficacy (85-90% vs. 40-70%); higher response rate at week 4; faster and greater increase in Hb level at week 8; reduction of rHuEPO	Oral iron: more AEs-GI intolerance; reduced patient compliance; higher discontinuation
HD-CKD	Iron Sucrose vs. Iron Dextran	8	Similar efficacy	Iron sucrose: less and milder AEs, most can be tolerated by patients
PD-CKD	IV vs. Oral Iron	2	IV iron: greater increase in Hb, Hct, SF, TSAT levels	Oral iron: GI intolerance, treatment discontinuation; IV iron: mild allergic reactions without treatment
PD-CKD	Iron Sucrose (Venofer) vs. Iron Dextran (Cosmofer)	1	Iron sucrose: faster increase in Hb to target level; shorter treatment	Iron Sucrose: less allergic reactions
ND-CKD	Iron Sucrose vs. Polysaccharide iron complex	1	IV iron: greater increase in Hb, Hct, SF, TSAT levels	Iron Sucrose: no AEs observed

HD=Hemodialysis; PD=Peritoneal dialysis; ND=Non-Dialysis; SF=Serum Ferritin; TSAT=Transferrin Saturation

Conclusions: Literature generally recommended IV iron as a better therapy than oral iron due to the improved efficacy and less AEs. IV iron was also reported to be more cost saving.

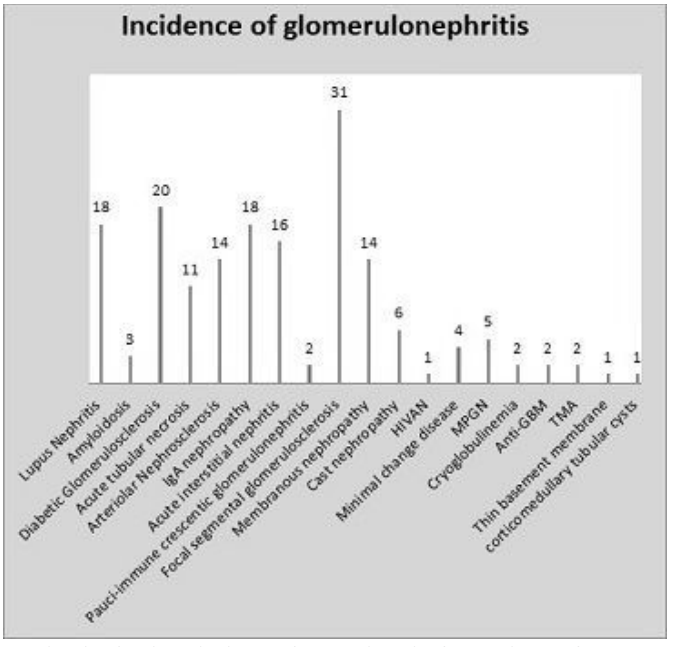
The Incidence of Biopsy-Proven Glomerulonephritis in New York City

Chadi Saifan, Rabih Nasr, Elie El-Charabaty, Suzanne E. El Sayegh, Morton J. Kleiner. *Nephrology, Staten Island University Hospital, Staten Island, NY.*

Background: In the U.S., there is limited epidemiological data that analyzed the trends of glomerular diseases, mostly because of the enormous differences in ethnicities among different locations. New York City is the most representative location of the nation because of the various people backgrounds. This is a descriptive analysis of biopsy-proven glomerulonephritis in NYC.

Methods: A retrospective review of the results of 168 pathology reports of all native renal biopsies performed in a university hospital of 714 beds from 2006 till 2011. Data was collected including age, sex, pathology report. Comparisons were made based on the incidence and the percentage of different age groups.

Results: The three most common glomerulonephritis (GN) are focal segmental glomerulosclerosis (19%), diabetic glomerulosclerosis (11.9%), and lupus nephritis (10.7%).



There is a female predominance of 59 % and a male of 41 %. The most frequent GN according to age groups are: [30-45]: 22%, [45-60]: 25%, and [60-75]: 22.6%.

Different categories of glomerulonephritis according to age-groups

	Age					
	0-15	15-30	30-45	45-60	60-75	75-90
LN	0	7	10	0	0	0
Amyloidosis	0	0	1	0	2	0
Diabetic GN	0	0	2	9	7	2

Conclusions: This descriptive review reflects the incidence of glomerulonephritis in a diverse population that can be extrapolated nationwide. The frequency of the different types of glomerulonephritis should be compared over time and across different countries to assess the trends of glomerular diseases, identify the risk factors and improve the treatment.

PUB165

Serum Phospholipase A_2 Receptor Autoantibodies (PLA_2R-AB) Predict Changes in Proteinuria in Patients with Membranous Nephropathy

Elion Hoxha,[1] Sigrid Harendza,[1] Ina E. Thiele,[1] Gunther Zahner,[1] Ulf Panzer,[1] Udo Helmchen,[2] Rolf A. Stahl.[1] *[1]III. Medizinische Klinik, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; [2]Nierenregister, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany.*

Background: PLA_2R-AB are detected in up to 80% of patients with primary membranous nephropathy (MN). Antibody levels could reflect disease activity and may help to manage patients. In order to test whether this hypothesis applies, we performed a multicenter, open, prospective observational study in patients with biopsy proven MN.

Methods: In this study, 201 patients from 145 centers in Germany and Austria with biopsy proven MN were included. No immunosuppressive therapy was allowed before the recruitment. A specific immunofluorescence-test was applied for PLA_2R-AB measurement.

Results: The mean age of the patients (137 males, 64 females) was 54.6±16.3 years. The first PLA_2R-AB measurement was performed 0.94±1.25 months after the time of renal biopsy. In 144 patients (72%) PLA_2R-AB were present. PLA_2R-AB levels neither correlated with the levels of proteinuria nor with serum creatinine at the first measurement. 12-months prospective follow up data are available from 83 patients. 59 of them received immunosuppressive treatment. In 31 of 63 PLA_2R-AB positive patients antibodies were no longer detectable or were significantly reduced after 10.4±3.9 months (mean titer at inclusion 5276 vs. 16). Proteinuria significantly decreased in these patients from 9.9±5.0 g/24h to 3.5±3.9 g/24h at 12 months ($p<0.001$). Reduction of proteinuria significantly correlated with the decrease in PLA_2R-AB levels (Fisher's exact test $p=0.002$).In the remaining 32 PLA_2R-AB positive patients antibody levels did not decrease (inclusion 2471

vs. 4887 at 12 months). Only 12 patients in this group had a reduction of proteinuria, while in the remaining 20 patients proteinuria did not decrease (6.8 g/24h vs 6.7 g/24h). Twenty of the 83 patients were negative for PLA_2R-AB. In these patients proteinuria significantly decreased from 7.7±7.5 g/24h to 1.5±1.3 g/24h at 12 months (p=0.002).

Conclusions: PLA_2R-AB levels predict response or failure of therapy in patients with MN when proteinuria is used as clinical parameter.

PUB166

Predialysis Care and Optimal Hemodialysis Initiation Habib Mawad, Stephanie Raymond-Carrier, Stephan Troyanov, Alexandra Renald, Francois Madore, Josee Bouchard, Jean-Philippe Rioux. *Nephrology Division, Hôpital du Sacré-Coeur de Montréal, Canada.*

Background: A significant proportion of chronic kidney disease (CKD) patients known to nephrologists still undergo suboptimal initiation of renal replacement therapy (RRT) thus increasing morbidity and mortality. We aim to identify risk factors associated with suboptimal hemodialysis (HD) initiation among patients followed at a predialysis clinic.

Methods: We conducted a chart review retrospective study of patients starting HD from 2008 to 2011 in our predialysis clinic. Optimal start implied outpatient setting and the use of an arteriovenous fistula (AVF). Baseline characteristics and predialysis management of patients starting HD were compared on the basis of optimal vs suboptimal start.

Results: A total of 88 patients were included of whom 22 had optimal starts. Suboptimal start was due to inpatient status in 38 cases (32 with central venous catheter (CVC) and 6 with AVF). The remaining 28 patients started HD with a CVC as outpatients. The main characteristics between the two groups are summarized in Table 1.

Comparison of patients with optimal and suboptimal start

	Optimal start (n=22)	Suboptimal start (n=66)	p-value
Age (yrs)	62+/- 14	67 +/- 12	NS
Gender (% male)	68	45	NS
Diabetic nephropathy (%)	32	50	NS
≥ 2 comorbidities (%)	60	74	NS
Predialysis F/U (months)	25 +/- 16	16 +/- 14	0.03
Initial HD refusal (%)	9	29	0.06
Acute event first dialysis (%)	0	42	< 0.001
Vascular surgeon referral (%)	100	65	0.03
AVF creation (%)	100	26	< 0.001
Mortality one year post dialysis initiation (%)	10	20	NS

One year after initiating dialysis, 29% of patients starting with AVF had switched to CVC and 3% of those starting with CVC had switched to AVF.

Conclusions: This study identified modifiable risk factors associated with suboptimal HD start. Early referral to a predialysis clinic among patients with progressive CKD should be promoted. Evaluation by a vascular surgeon need to be encouraged in predialysis patients and in patients starting dialysis with a CVC. A multidisciplinary team should continue to follow patients after initiation of dialysis to increase the proportion of patients with an AVF and potentially improve their outcome.

PUB167

The NEFIGAN Trial: A Phase 2b Multicenter, Randomized, Placebo-Controlled Study to Evaluate the Efficacy and Safety of Two Doses of NEFECON® in Primary IgA Nephropathy Patients at Risk of Developing ESRD: Rationale and Study Design Bengt C. Fellstrom,[1] Rosanna Coppo,[2] John Feehally,[3] Jürgen Floege,[4] Alan G. Jardine,[5] Petri K. Koskinen,[6] Francesco Locatelli,[7] Bart Dirk Maes,[8] Alex Mercer,[9] Manuel Praga,[10] Vladimir Tesar.[11] *[1]Uppsala University Hospital; [2]University Hospital Regina Margherita; [3]University of Leicester; [4]RWTH University of Aachen; [5]University of Glasgow; [6]HUCH; [7]Ospedale A.Manzoni; [8]Heilig Hartziekenhuis; [9]Pharmalink AB; [10]Hospital 12 de Octubre; [11]Charles University.*

Background: NEFECON is a new oral enteric-coated capsule formulation for the treatment of IgAN patients at risk of developing ESRD. NEFECON is designed to release the potent glucocorticosteroid (GCS), budesonide, in the distal ileum and ascending colon where the highly immune-active Peyer's patches reside, providing topical immunosuppression of the intestinal mucosa. Local immunosuppression by NEFECON aims to reduce B-cell activation and proliferation, and the subsequent production of polymeric IgA1, thereby decreasing mesangial deposition. The high first pass metabolism of budesonide (~90%) ensures systemic GCS-related side effects are minimal or absent. An exploratory study on 16 patients showed 6-month treatment with NEFECON (8 mg/day) was well-tolerated and conferred a significant reduction in albuminuria.

Methods: In a randomized, multicenter study, 90 patients at risk of progressive IgAN despite maximized ACEI/ARB therapy to reduce blood pressure and proteinuria, will be treated with placebo or NEFECON (8 mg/day OR 16 mg/day) for 9 months and followed up for a further 3 months. Main eligibility criteria: Biopsy verified IgAN

≥18 years

UPCR ≥0.5 g/g

eGFR ≥45 mL/min/1.73m^2.

Results: The primary efficacy objective is to investigate whether patients on NEFECON achieve a larger mean reduction in UPCR compared with patients on placebo at 9 months. Secondary objectives will evaluate whether other urine protein response criteria and eGFR are in favour of NEFECON.

Conclusions: Results from the study will clarify whether NEFECON is an effective, safe and well-tolerated steroid formulation in reducing risk of IgAN patients developing ESRD.

PUB168

Renal and Patient Survival in More Frequent Biopsied Glomerulonephritis in Castilla la Mancha (Spain) between 1994 and 2008 GLOMANCHA Study Results Jose Luis Conde Olasagasti,[1] Carmen Vozmediano,[3] Luisa Illescas,[2] Acevedo M. Ribó,[1] Serafin Tallon,[4] Francisco Rivera.[3] *[1]Nephrology, Complejo Hospitalario, Toledo, Spain; [2]Nephrology, Complejo Hospitalario Universitario, Albacete, Spain; [3]Nephrology, Hospital General Universitario, Ciudad Real, Spain; [4]Nephrology, Hospital Universitario, Guadalajara, Spain.*

Background: In 2009 a collaborative multihospitalary task-force was established in CLM to know and compare the clinical outcome of the more frequent biopsied GN between 1994 and 2008 followed up to mid 2011.

Methods: We included 765 adults with proven selected GN in four hospitals covering an 1.8 million population area:157 focal and segmental glomerulosclerosis (FSGS),166 membranous nephropathy (MN),170 IgA nephropathy (IgAN),147 lupus nephritis (LN) and 125 crescentic type III glomerulonephritis(CGNIII).The median follow-up was 6,89 years (range 0.01-17,5).

Renal and patient outcome were assesed by survival analysis methods (Kaplan-Meier) comparing crude survival between diagnostic categories (Log rank) and analyzing adjusted influence of age, sex,GN type,initial eGFR(MDRD) and proteinuria (Cox regression).End Stage Renal Disease (ESRD) means dialysis or renal transplant.

Results: Cumulative (%±SE) renal survival (alive and free of ESRD) after 5 and 10 years was:74±4 and 55±5 in FSGS; 83±3 and 75±4 in MN;75±4 and 64±5 in IgAN;94±2 and 91±3 in LN; 55±5 and 45±6 in CGNIII.Log rank test showed significant difference ($p<0.01$) between categories except IgAN vs FSGS. Cox regression shows independent predictive influence of age,sex, initial eGFR and proteinuria,and some histological diagnosis (LN better vs reference category)

Cumulative (%±SE) patient survival (alive in or out of ESRD) after 5 and 10 years was : 96±2-86±4 in FSGS; 91±3 - 83±4 in MN; 95±2 - 92±3 in IgAN; 96±2-93±3 in LN and 69±5-57±6 in CGNIII.Log rank test showed CGNIII as the worse (significant difference vs all categories) followed by MN, being LN the best prognostic diagnosis.After Cox regression adjustement, only age, sex and initial eGFR show independent predictive influence.

Conclusions: The observed figures are not different from those reported in recent medical literature.

Effects of Irbesartan on Inflammatory Cytokine Concentrations in Patients with Chronic Glomerulonephritis Shuichi Tsuruoka, Kunihiro Yamagata. *Nephrology, University of Tsukuba, Tsukuba, Ibaraki, Japan.*

Background: Some angiotensin receptor blockers including irbesartan increase PPAR-γ activity in vitro. Aim of this study was to evaluate the interaction between obesity and the effects of irbesartan on the inflammatory cytokines (such as adiponectin, hsCRP, IL-6, TNF-α and leptin) in patients with chronic glomerulonephritis.

Methods: Anti-inflammatory effects of irbesartan were evaluated for 26 weeks in 29 hypertensive non-diabetic chronic glomerulonephritis patients by prospective, single-arm study for 26 weeks. Body weight, blood pressure, and urinary protein excretion rate were also evaluated.

Results: After treatments with irbesartan (200 mg daily) for 26 weeks, blood pressure and proteinuria were significantly decreased (blood pressure from 142 ± 1/87 ± 1 to 131 ± 1/81 ± 1 mmHg and urine protein/creatinine ratio from 1030± 143 to 779 ± 121 mg/g Cr, $P<0.01$). BMI was not significantly changed after the study. Among inflammatory parameters, adiponectin concentration was significantly increased (11.1±0.9 to 11.8±0.7 mg/ml, $P<0.05$) and hsCRP concentrations were significantly decreased (1318±207 to 1095 ±147 ng/ml, $P<0.05$) after the treatment; however, changes of IL-6, TNF-α and leptin concentrations did not reach statistical significance. Moreover, the improvements of these five parameters by the treatment were positively correlated with patients' BMI at the initiation of the study, and the improvements were particularly prominent in those with BMI greater than 25. Improvement of proteinuria was significantly correlated with increase of adiponectin concentration but not with BMI. There was also a significant correlation between change of adiponectin and change of insulin concentration.

Conclusions: We concluded that irbesartan improved metabolic parameters in non-diabetic hypertensive chronic glomerulonephritis patients, especially those with high BMI. Improvement of adiponectin concentration may be important for reduction of proteinuria.

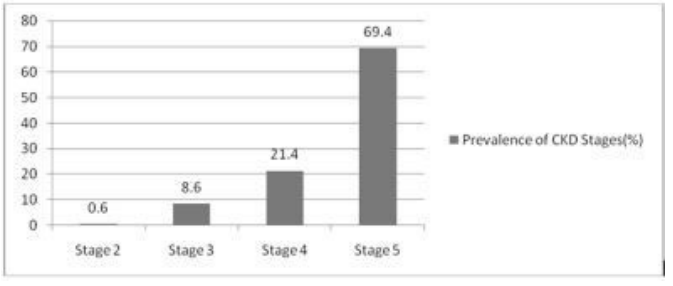
PUB170

Epidemiology of Chronic Kidney Disease in the Philippines: Baseline Data Extract from the Global Renal Information Database Kuyilan Karai Subramanian,[1] Romina Danguilan,[2] Youssef M.K. Farag,[1] Vanier Kethi-reddy,[1] Ajay K. Singh.[1] *[1]Renal Division, Department of Internal Medicine, Brigham and Women's Hospital, Boston, MA; [2]Department of Adult Nephrology, National Kidney and Transplant Institute, Quezon City, Philippines.*

Background: There is very limited information on chronic kidney disease (CKD) practice patterns in the Philippines due to lack of comprehensive prospective studies conducted on management of CKD and ESRD.The Philippine Renal Disease Registry(2009) reports diabetes (42%) as the leading cause of CKD followed by hypertension (25%) and glomerulonephritis (20%).

Methods: We conducted a prospective observational cohort study launched in 2009 in India, Malaysia, Vietnam, Philippines and Indonesia. A specifically designed computer database software application was developed to collect information on management of CKD and ESRD patients on dialysis in a longitudinal follow-up for 3 years.

Results: The sample comprised of 400 patients. Renal function data (serum creatinine levels) was available on 359 (90%) of subjects. The mean age of the cohort was 49.2±14.8 years. There was equal representation of gender, with 53.8% (n=193) males. Mean baseline serum creatinine at the baseline visit was 7.6±5.3 mg/dL, and the mean estimated glomerular filtration rate was 12.7±11.15 ml/min/m2. The most common cause of CKD in our cohort was primary chronic glomerulonephritis (33.1%), type 2 diabetes mellitus (31.2%) and hypertension (19.5%). Most of patients in this cohort were stage 5 CKD (69.4%) and stage 4 (21.4%).



Conclusions: This descriptive analysis report for the baseline data of the GRID project from Philippines revealed that the causes of CKD are similar to those observed in the Philippine Renal Disease Registry. We plan to do further analysis on the practice patterns of CKD in Philippines as well as other countries participating in GRID.

Outcomes of Patients with Anti-Neutrophil Cytoplasm Antibody (ANCA) Asscoiated Vasculitis (AAV) Following a Change from Oral to Intravenous Cyclophosphamide in a UK Regional Nephrology Unit Anisha Tanna, Suresh Mathavakkannan, Maria Prendecki, Barbara Thompson. *Lister Hospital, East &North Herts NHS Trust, Stevenage, United Kingdom.*

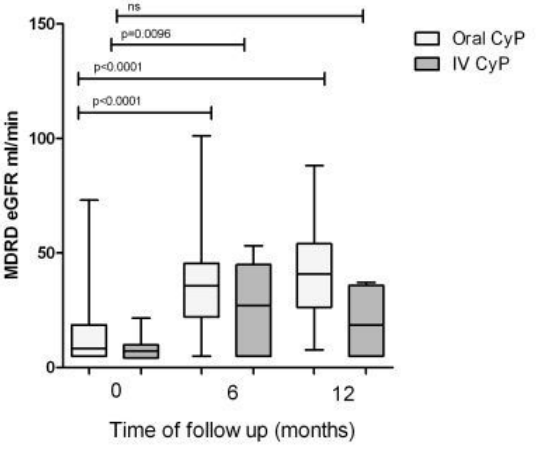
Background: Guidelines recommend using intravenous (IV) over oral Cyclophosphamide (CyP) for remission induction in ANCA associated vasculitis (AAV). Patients presenting dialysis dependent and treated with Plasma Exchange (PEX) have been excluded from large studies comparing these preparations. IV CyP has been used at our centre since 2008. We review outcomes following this change and include patients presenting dialysis dependent and treated with PEX.

Methods: Retrospective analysis was carried out on data from patients presenting to Lister with a new diagnosis of AAV between 01/01/2005 and 31/12/2011.

Results:

	Oral CyP	IV CyP	p=
N	46	9	
Age	64 (23-87)	57 (29-76)	
M:F	27:19	4:7	
Cumulative Dose (mg)	5581(600-20050)	2450 (1200-3750)	
Presenting EGFR(ml/min)	15 (5-73)	8.4 (5-22)	0.197
% Dialysis dependent at presentation	43.5	66.7	0.363
% Plasma exchanged	47.8	88.9	0.0579
% Failed to achieve remission	8.7	0	0.521
Mean total follow up (months)	44.3 (0.25-81.33)	18.8 (4.8-38.0)	0.024
Mean time to first relapse (months)	24.14	21.2	0.7492
% Death	15.2	11.1	0.608
% Significant infections	41.3	22.2	0.204
% leucopenia	34.8	22.2	0.403
Mean improvement in EGFR at 6 months (ml/min)	+ 19	+24	0.5
Mean improvement in EGFR at 12 months (ml/min)	+25	+13	0.2
Mean improvement in EGFR at end of follow up(ml/min)	+14	+13	0.784
% of patients presenting dialysis dependent who recover renal function at 12 months	70	50	0.679

Dialysis dependent analysed as eGFR 5ml/min.



Conclusions: Renal function improved significantly in both groups at the end of the study with a mean improvement in eGFR of 13-14 ml/min although with small numbers in the IV group there was no difference between groups. 46% of patients presenting dialysis dependent and plasma exchanged, recovered independent renal function.

PUB172

Practice Patterns of Treatment of Hyperuricemia and Predictors of Serum Uric Acid Level in Japanese Patients with Chronic Kidney Disease Miho Tagawa,[1] Takayuki Hamano,[2] Naohiko Fujii,[3] Enyu Imai,[4] Tadao Akizawa,[5] Kosaku Nitta,[6] Tsuyoshi Watanabe,[7] Seiichi Matsuo,[4] Hirofumi Makino,[8] Satoshi Iimuro,[9] Yasuo Ohashi,[9] Akira Hishida.[10] *[1]Kyoto Katsura Hospital; [2]Osaka University; [3]Hyogo Prefectural Hospital, Nishinomiya; [4]Nagoya University; [5]Showa University; [6]Tokyo Women's Medical University; [7]Fukushima Medical University; [8]Okayama University; [9]University of Tokyo; [10]Yaizu City Hospital.*

Background: The Japanese guidelines recommend pharmacologic treatment of asymptomatic hyperuricemia for patients with chronic kidney disease (CKD) if uric acid (UA) is > 8.0 mg/dL, which is exceptionally aggressive compared with other guidelines. The aim of the study is to examine practice patterns of treatment of hyperuricemia and predictors of UA level in Japanese CKD patients.

Methods: This is a cross sectional study on Chronic Kidney Disease Japan Cohort study (estimated glomerular filtration rate [eGFR] 10-59 ml/min/1.73m2 and age 20-75 years). Linear regression analysis was used to determine predictors of UA level.

Results: Median (interquartile range) age was 63 (54-70), 62.1 % were male. Mean (SD) eGFR was 28.8 (12.2) ml/min/1.73m2 and UA was 7.2 (1.6) mg/dL (n=2,977). As many as 45.5 %, 6.2 % and 3.2 % of subjects were on allopurinol, probenecid and citrate, respectively. Male sex, eGFR, body mass index, loop and thiazide diuretics, allopurinol, probenecid, alcohol use but not K sparing diuretics or citrate were significant predictors of UA level. UA was significantly higher at age <= 40 years compared with age 51-60 in male though UA did not differ across age categories in female (p for interaction=0.04).

Predictors of UA level by linear regression analysis

	Coefficients	95% CI		p
Male	0.96	0.58	1.34	<0.001
eGFR	-0.029	-0.034	-0.024	<0.001
Log BMI	0.99	0.13	1.85	0.03
K sparing diuretics	0.22	-0.03	0.48	0.09
Loop diuretics	0.48	0.33	0.63	<0.001
Thiazide diuretics	0.78	0.56	1.00	<0.001
Allopurinol	-0.60	-0.73	-0.48	<0.001
Probenecid	-0.62	-0.87	-0.38	<0.001
Citrate	0.18	-0.15	0.51	0.29
Alcohol use	0.13	0.002	0.26	0.046

Conclusions: Large proportion of Japanese CKD patients was on UA lowering agents and they were significant predictors of UA level.

PUB173

Glycemic Control with Intensive Insulin Treatment Is Fundamental to Renal Protection in Diabetes Anil K. Mandal, Linda M. Hiebert. *[1]University of North Florida, Jacksonville, FL; [2]University of Saskatchewan, Saskatoon, SK, Canada.*

Background: Diabetes is the main cause of end stage renal disease (ESRD). We questioned why diabetes patients develop ESRD. Current preventative measures such as use of angiotensin converting enzyme inhibitors (ACEI) and angiotensin receptor blocking drugs (ARB) may contribute. We investigated if renal preservation in diabetes is attainable without ACEI/ARB.

Methods: Forty-six office patients (28 female, 18 male), mean age 62.2 years (range 36-86 years), were followed for an average of 14.2 months (1.5-115 months). Diabetes as diagnosed by 2-h postprandial glucose (2hPPG) ≥ 11.1 mmol/L was treated with Glargine or detemir insulin, supplemented with regular insulin based on finger stick 2hPP and at bedtime. Anti-hypertensive therapy excluded ACEI/ARB. Laboratories were: glucose, serum creatinine (Scr), estimated glomerular filtration rate (eGFR), and glycosylated hemoglobin (HBA_{1c}). Values between first and last visits were compared (paired two-tailed t-test, $P<0.05$ significant). Patients were divided by 2hPPG < or > 11.1 mmol/L.

Results: Fasting glucose at last visit (8.4±0.6 mmol/L) was significantly lower than the first visit (10.3±0.7 mmol/L) in the all patients group, with significantly reduced Scr at last (100.3±5.2 µmol/L) compared to first visit (110.9±7.8 µmol/L). Little change was seen in eGFR between first and last visits in all groups (eGFR was consistent with chronic kidney disease (CKD) stage 2 in the majority of patients at the last visit). Less than half of patients achieved glucose control (2hPPG <11.1 mmol/L). HBA_{1c} was significantly reduced (9.14±0.52% vs. 7.60±0.45%, $p<0.0148$) in the <11.1 mmol/L group. Blood pressure was normal in all groups. Diastolic pressure at the last visit in the all patients group was lower than the first visit 81.6±1.9 vs. 77.0±1.5. $p<0.0297$).

Conclusions: Paradigm of therapy for glycemic and blood pressure control in this study, which excludes ACEI/ARB drugs, is proven effective for renal protection in diabetes.

Strategic Approach to Decrease Burden of Chronic Kidney Disease in the Texas Panhandle Tetyana L. Vasylyeva,[1] Sudha P. Chennasamudram,[1] Sharma S. Prabhakar,[2] Rodney Young,[1] Roger D. Smalligan.[1] *[1]Texas Tech University Health Sciences Center, Amarillo, TX; [2]Texas Tech University Health Sciences Center, Lubbock, TX.*

Background: The purpose of this study was to identify demographic specifics of chronic kidney disease (CKD) patients in the Texas Panhandle and to develop a strategic approach to improve quality of care.

Methods: To assess undiagnosed CKD among general population eGFR was measured among patients with unknown renal disease, who visited TTUHSC primary care (PCP) clinics. Also, a retrospective chart review of CKD patients attending nephrology clinics was performed with the collection of demographic data, creatinine, urinary protein excretion, lipid panel and HbA1c, etiology, duration of CKD, medication profile and family history. Data was compared to center for disease control (CDC) data.

Results: In PCP clinics 170 patients were recruited (average age 62±17 years; 64% women; 36% men). White were 76%, Hispanic - 7.6%, other races- 16.4%. CKD stage 1 was diagnosed in 23%, stage 2 in 48%, stage 3 in 27%, stage 4/5 in 2%. Risk factors for CKD included HTN (58%), DM (10%), and CVD (6%). Seventy percent patients with DM had been tested for microalbuminuria during the past year. For the retrospective chart review study, a total of 394 CKD patients' charts were reviewed (192 men and 192 women). Patient population was older than in the CDC database (66% over 65 years; 26% age 45-64; and 8% under 45). A majority of the patients had HTN as a cause of CKD, which is different from CDC database. Most patients were referred to the nephrology clinic at CKD stage 3. The average HbA1c in DM patients was 13±2.

Conclusions: This pilot study revealed a remarkably high number of patients who visited their PCP with no previously known renal disease, but decreased renal function. The major risk factor for CKD is age and HTN in the Panhandle in the Panhandle is HTN. The study helped to develop a strategic management approach and promote collaboration between PCPs and nephrologists in the area to improve identification and prevent the progression of CKD.

PUB175

Albuminuria Is an Independent Predictor of All-Cause and Cardiovascular Mortality in the Japanese Population: The Takahata Study Tsuneo Konta, Hiroko Sato, Kosuke Kudo, Kazuko Suzuki, Ami Ikeda, Kazunobu Ichikawa, Isao Kubota. *Department of Cardiology, Pulmonology, and Nephrology, Yamagata University School of Medicine, Yamagata, Japan.*

Background: Albuminuria is a known risk for premature deaths. However, the association between urinary albumin excretion and mortality is unknown in Japanese population. To clarify this point we conducted a longitudinal study in community-based subjects.

Methods: The participants of this study were 3446 subjects (male 45%, mean age 63 years) in Takahata town, Japan, that were registered and followed up for 7 years (median 6.2 years). Albuminuria was defined as urine albumin-creatinine ratio ≥30 mg/gCr in morning spot urine.

Results: The subjects with albuminuria (n=514, 14.9%) was older, and showed a higher prevalence of hypertension, obesity, diabetes and a lower values of eGFR than the subjects without albuminuria (n=2932, 85.1%). During the follow-up 138 subjects died. Kaplan-Meier analysis showed that an all-cause mortality was significantly increased along with the increase in urine albumin excretion (Log-rank $P<0.001$). The subjects with albuminuria showed a significantly lower survival rate than those without albuminuria (92.6% vs. 96.6%, Log-rank $P<0.001$). Cox proportional hazard model analysis with the adjustment for possible confounders showed that albuminuria was a significant and independent risk factor for all-cause and cardiovascular mortalities (hazard ratio [HR] 1.73, 95% confidence interval [CI] 1.11-2.70 for all-cause mortality, and HR 2.74, 95%CI 1.15-6.55 for cardiovascular mortality).

Conclusions: Albuminuria was a risk for all-cause and cardiovascular mortalities in Japanese population. For the early detection of high risk subjects and the prevention for premature death, albuminuria could be used.

PUB176

The Comparison of the Mortality Predictive Ability of Albuminuria and Dipstick Proteinuria in Local Inhabitants: The Takahata Study Hiroko Sato, Kosuke Kudo, Kazuko Suzuki, Ami Ikeda, Kazunobu Ichikawa, Tsuneo Konta, Isao Kubota. *Department of Cardiology, Pulmonology, and Nephrology, Yamagata University School of Medicine, Yamagata, Japan.*

Background: Albuminuria and proteinuria are known risk for premature mortality. This study compared the mortality predictive ability of albuminuria and proteinuria in Japanese local inhabitants.

Methods: We measured urinary albumin creatinine ratio (ACR) and proteinuria by dipstick at baseline survey and compared the predictive abilities for seven-year mortality of three cutoff points (albuminuria [ACR ≥30mg/g], trace proteinuria, 1+ proteinuria) in 3446 subjects at local health checkup in Takahata, Japan.

Results: The prevalence of albuminuria, ≥trace proteinuria and ≥1+ proteinuria were 514 (14.9%), 290 (8.4%) and 151 (4.4%) subjects, respectively. During the follow-up there were 138 deaths (4.0%) including 29 cardiovascular deaths. Kaplan-Meier analysis showed that an all-cause mortality was significantly increased along with the increase in ACR and proteinuria levels by dipstick (Log-rank $P<0.001$). The mortalities in subjects with albuminuria (7.4%), ≥trace proteinuria (7.2%) and ≥1+ proteinuria (9.3%) were higher than that in total subjects (4.0%). In Cox proportional hazard analysis all the three cutoff points were significant predictors for all-cause mortality in unadjusted model, however after the adjustment for possible confounders the significant association was observed only in albuminuria. For cardiovascular mortality, albuminuria, but not proteinuria was the significant predictor both in unadjusted and adjusted models.

Conclusions: The prevalence and predictive ability of albuminuria were higher than those of proteinuria by dipstick, suggesting albuminuria might be a superior predictor for seven-year mortality in local inhabitants.

KNOW-CKD (KoreaN Cohort Study for Outcome in Patients with Chronic Kidney Disease): A 10-Year Longitudinal Cohort Study of the Chronic Kidney Disease Kook-Hwan Oh,[1] Curie Ahn,[1] Dong Wan Chae,[1] Young-Hwan Hwang,[3] Soo Wan Kim,[4] Kyu Hun Choi,[2] Seung Hyeok Han,[2] Su-ah Sung,[3] Kyu-Beck Lee,[5] Wookyung Chung,[6] Ho Jun Chin,[1] Hayne C. Park,[1] Joongyub Lee,[1] Yong-Soo Kim.[7] *[1]Seoul National Univ.; [2]Yonsei Univ.; [3]Eulji Univ.; [4]Chonnam National Univ.; [5]Sungkyunkwan Univ; [6]Gachon Univ.; [7]Catholic Univ.*.

Background: The goals of the KNOW-CKD (KoreaN cohort study for Outcome in patients With Chronic Kidney Disease) study are 1) to establish a CKD cohort representing Korean CKD population for up to 10-year follow-up, and 2) to investigate the renal progression, mortality, complications, risk factors, and the genetic influence.

Methods: KNOW-CKD Research Group comprises nephrologists, pediatric nephrologists, epidemiologists and statisticians from eleven centers in Korea. KNOW-CKD will enroll 2,850 individuals with CKD stage from 1 to 5 between 2011 and 2015 and follow them up to 10 years. Dialyzed patients or those with allograft kidney are excluded. At enrollment and at pre-specified intervals, laboratory tests will be conducted on the kidney function, biochemical profiles, anemia, cardiovascular complication (echocardiography, coronary CT, arterial stiffness), and mineral bone disorder. A biobank is also established

for the DNA, serum and urine at regular interval. Information on the medical history, health questionnaires, QoL will also be collected. Web-based case-report forms (CRF) is developed for the systemic management of the patient data.

Results: As of the end of 2011, 753 adult CKD patients were enrolled in the cohort study. Patients were 52.2 years old on the average with 58.4% male. The etiologic diseases of CKD were GN (32.2%), diabetic nephropathy (17.2%), hypertensive nephropathy (16.2%), and others. The CKD stages were stages 1 to 2 (27.9%), stage 3 (40.1%), stage 4 (22.9%) and stage 5 (9%).

Conclusions: It is expected that KNOW-CKD cohort, when established, will represent Korean CKD population and provide information on the natural course, clinical manifestation including for various complications, predicting factors for adverse outcomes and treatment tools of CKD.

PUB178

Assessment of Lupus Nephritis in Youth at SLE Presentation Divya Moodalbail,[1] Susan L. Furth,[1,3] Julia R. Maisel,[1] Barbara A. Fivush,[2] Sangeeta D. Sule.[2] *[1]Pediatrics, The Children's Hospital of Philadelphia; [2]Pediatrics, Johns Hopkins Children's Center; [3]Epidemiology, University of Pennsylvania.*

Background: Nephritis is a devastating complication of SLE. Recent American College of Rheumatology (ACR) guidelines recommend that all patients with clinical evidence of active lupus nephritis (LN) undergo renal biopsy for classification of their glomerular disease.

Methods: Retrospective cohort study documenting demographics, serum, urinary investigations for children and adolescents aged 1 to 19 years with SLE, at disease presentation and follow up within 6 months in pediatric rheumatology/nephrology clinics at 2 tertiary care children centers (presentation between 2002 - 2011 at JHCC and 2007 - 2011 at CHOP). We did a systematic assessment for LN per ACR criteria (persistent proteinuria >3+ on dipstick and/or active urinary sediment >5 RBCs/hpf, >5 WBCs/hpf or cellular casts) and compared with biopsy performance and results.

Results: 90% of the 47 subjects in our cohort were female, 55% were African American. Median age of SLE diagnosis was 14 years (IQR 11 - 15 yrs), median serum creatinine at initial presentation was 0.6 mg/dL, and 19 (59%) had dipstick proteinuria (≥1+); 6 (32%) were ≥3+. In 20 (43%) subjects urine protein: creatinine ratio was assessed; 9(45%) had a ratio>2. Twenty three (64%) subjects met ACR criteria for LN. Retrospectively, 17 (36%) underwent kidney biopsy; 11 (64%) had diffuse proliferative LN (Class IV), 4 (24%) had focal proliferative LN (Class III), and 2 (12%) had membranous nephropathy (Class V). Of the 17 biopsied, dipstick protein results at initial visit was noted to be 4+ in 3, 3+ in 2, 2+ in 6, 1+ in 1, negative in 2 and unavailable in 3. Nine subjects with Class III - V LN had ≤2+ proteinuria.

Conclusions: Using ACR criteria, the majority (64%) of children in our SLE cohort had LN; only 36% had undergone kidney biopsy. Systematic assessment for LN including dipstick, microscopic urinalysis and urine protein: creatinine estimation should be standard practice in management of children with SLE. Our retrospective cohort suggests that even low levels of proteinuria (≤2+) rather than >3+ (as per ACR criteria), should be a consideration for kidney biopsy.

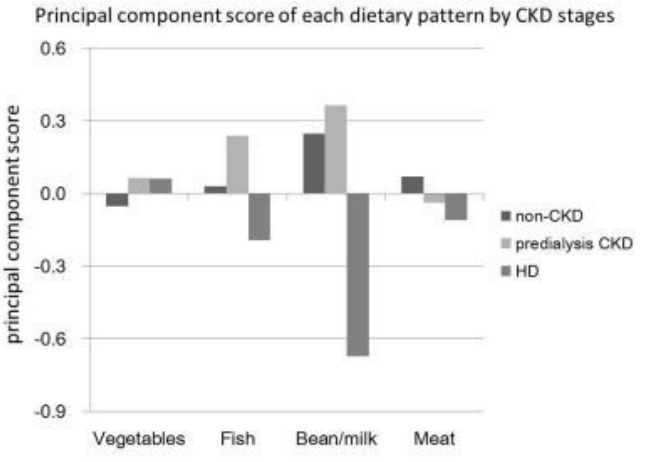
Dietary Patterns in Chronic Kidney Disease Patients: Joint Analysis of the Hisayama Study and the Dialysis Outcomes and Practice Study in Japan Kazuhiko Tsuruya,[1] Shingo Fukuma,[2] Takafumi Wakita,[2] Satoru Fujimi,[1] Yutaka Kiyohara,[1] Takanari Kitazono,[1] Tadao Akizawa,[3] Takashi Akiba,[3] Akira Saito,[3] Shunichi Fukuhara.[2] *[1]Kyushu University; [2]Kyoto University; [3]Steering Committee of JDOPPS.*

Background: Little is known on actual dietary intake in chronic kidney disease (CKD) patients. We attempted to identify dietary patterns in CKD patients and examined their differences by CKD stage and associations with laboratory markers.

Methods: In a cross-sectional study, we selected 2,356 non-CKD and 717 predialysis CKD patients from the Hisayama study, a population-based cohort, and 1,510 hemodialysis (HD) patients from the Japan Dialysis Outcomes and Practice Study between 2005 and 2007. Principal component analysis using data from a brief self-administered diet history questionnaire (BDHQ) helped us identify patterns and estimate principal component score by CKD stage. We examined the associations between score and levels of phosphorus and bicarbonate in HD patients by linear regression model, after adjusting for potential confounders. Each beta coefficient indicates mean difference of score, compared with the first tertile group.

Results: We identified 4 dietary patterns (vegetables, fish, bean/milk, and meat)based on 19 food items and found patterns of fish, bean/milk and meat less common in HD patients than in non-CKD and predialysis CKD patients.



Higher score for vegetable and fish were associated with reduced levels of phosphorus (beta -0.18, 95% CI -0.32 to -0.03 for third tertile of vegetable score) and bicarbonate (beta -0.98, 95% CI -1.85 to -0.11 for third tertile of fish score), respectively.

Conclusions: Of the 4 clinically interpretable dietary patterns identified, the vegetable pattern was associated with reduced phosphorus levels and the fish pattern with reduced bicarbonate in HD patients.

PUB180

Glycohemoglobin Not as Predictive as Fasting Glucose as a Measure of Prediabetes in Predicting Proteinuria Yuji Sato,[1] Yuichiro Yano,[3] Shouichi Fujimoto,[2] Tsuneo Konta,[2] Kunitoshi Iseki,[2] Toshiki Moriyama,[2] Kunihiro Yamagata,[2] Kazuhiko Tsuruya,[2] Hideaki Yoshida,[2] Koichi Asahi,[2] Kazuo Kitamura,[3] Tsuyoshi Watanabe.[2] *[1]Dialysis Division, University of Miyazaki Hospital, Miyazaki, Japan; [2]Steering Committee for the 'Research on the Positioning of Chronic Kidney Disease (CKD) in Specific Health Check and Guidance in Japan'; [3]Department of Internal Medicine, University of Miyazaki, Miyazaki, Japan.*

Background: There is little data on the assessment of prediabetes with proteinuria.

Methods: This is a cross-sectional cohort study assessing prediabetes with proteinuria. Using a nationwide health check-up database of 228,778 Japanese aged >20 years (median 66years; 39.3% were men; none had pre-existing cardiovascular disease), we examined the association between prediabetes and proteinuria (>1+ on dipstick) separately in prediabetes subjects diagnosed with the new HbA1c criterion only (PD-A1c), the impaired fasting plasma glucose only (PD-IFG) and fulfilling both criteria (PD-Both).

Results: According to ADA's criterion of 5.7-6.4% HbA1c and/or 100-125 mg/dl fasting plasma glucose, 43.8% of subjects were judged as having prediabetes. 53.7%, 21.7% and 24.5% of prediabetes subjects were divided into subclasses of PD-A1c, PD-IFG and PD-Both, respectively. Therefore, 21.7% of prediabetes subjects were missed using the new HbA1c criterion only. Compared with subjects with normal glucose tolerance, the odds ratio (OR) (95% confidence interval: CI) for the increased risk of proteinuria (>1+) in diabetes itself was 2.191 (2.081-2.307) and in whole prediabetes was 1.093 (1.046-1.142), when prediabetes was subdivided, OR for proteinuria in PD-IFG was 1.217 (1.140-1.300) and that in PD-Both was 1.249 (1.174-1.329), but that in PD-A1c was not significant, even after adjustment for significant covariates, such as age, sex, BMI, systolic blood pressure, antihypertensive medication, eGFR, lifestyle, lipid profile.

Conclusions: Prediabetes is a significant risk factor for proteinuria compared with completely normal glucose level, and subjects with prediabetes defined using IFG are at significantly higher risk for proteinuria than those defined by HbA1c only.

PUB181

Vascular Calcification on Plain Radiographs Is Associated with Carotid Intima Media Thickness, Malnutrition and Cardiovascular Events in Dialysis Patients Young Ki Son,[1] Hyun Kyung Nam,[2] You Jeong Oh,[3] Won Suk An,[1] Ki Hyun Kim,[1] Seong Eun Kim.[1] *[1]Nephrology, Dong-A University Hospital, Busan, Korea; [2]Nephrology, Busan Medical Center, Busan, Korea; [3]Nephrology, Dong-Eui Hospital, Busan, Korea.*

Background: Vascular calcification (VC) and carotid intima media thickness (CIMT) are highly correlated with cardiovascular (CV) disease. We hypothesized that significant VC on plain radiographs is associated with CIMT and CV events in dialysis patietns. In addition, we evaluated risk factors for VCprogression on plain radiographs in dialysis patietns.

Methods: In this two-year observational, prospective study, 67 dialysis patients were included. We checked plain radiographs at baselineand after 2 years.Laboratory tests and malnutritionscore were obtained at baseline, after 1 year, and after 2 years.

Results: The mean age of dialysis patients was 56.3 ± 10.3 years and the duration of dialysis was 41.3 ± 34.5 months. The prevalence of significant VC was 61.2% and the prevalence of carotid artery atheromatous plaque was 36.6% in enrolled dialysis patients. The prevalence of carotid artery atheromatous plaque(p = 0.025), CIMT(right: p = 0.045, left: p = 0.014), malnutrition scores and CRP were significantly higher in patients with significant VC compared to patients without significant VC. Serum albumin and total iron binding capacity were significantly lower in patients with significant VC compared to patients without significant VC. Patients without significant VC showed lower CV events by the Kaplan-Meier method (p = 0.015). VC progression was found in 35.7% among 56 patients followed up. Hemoglobin (Hb) was significantly increased according to elapsed time in patients who did not show VC progression on plain radiographs(10.3 g/dL at baseline, 10.8 g/dL after 1 year, 11.4 g/dL after 2 years). Hb (beta = - 0.458, p = 0.006)after 2 yearswas an independent factor for VC progression on plain radiographs.

Conclusions: Significant VC on plain radiographs was associated with CIMT, malnutrition, inflammation and CV events in dialysis patients. Conditions maintaining adaquate Hb maybe retard VC progression on plain radiographs in dialysis patients.

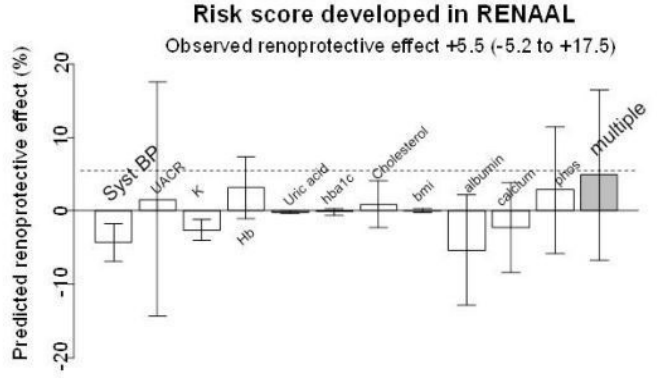
PUB182

Efficacy Estimation of Amlodipine on Hard Renal Outcomes Using Changes in Multiple Biomarkers Paul Smink,[1] Jarno Hoekman,[1] Hans-Henrik Parving,[2] Julia Lewis,[3] Dick de Zeeuw,[1] Hiddo Jan Lambers Heerspink.[1] *[1]Clinical Pharmacology, University Medical Center Groningen, Groningen, Netherlands; [2]Medical Endocrinology, University Hospital of Copenhagen, Copenhagen, Denmark; [3]Division Nephrology, Vanderbilt University, Nashville, TN.*

Background: We have developed and validated a multiple parameter risk response (PRO) score that combines short-term changes in multiple biomarkers to predict ARB drug effects on hard renal outcomes.[1] We questioned whether this PRO score can also be used to estimate the effect of CCB amlodipine on hard renal outcomes. 1 PA Smink et.al. The importance of short-term off-target effects in estimating the long-term renal and cardiovascular protection of ARBs.

Methods: Data from IDNT and RENAAL were used (2,661 type 2 diabetics with nephropathy). The PRO score was created using Cox analysis in the placebo group of RENAAL and subsequently applied to the baseline and month 6 measurements of the amlodipine arm of IDNT to predict long-term renal risk reduction. Predicted risk change was compared with the observed risk change (DSCR or ESRD) to test the accuracy of the PRO score.

Results: The change in blood pressure during amlodipine therapy predicted a -4.3% (95%CI -6.9 to -1.7) renal risk change as compared with placebo, whereas the actual amlodipine effect was a +5.5% (-5.2 to +17.5) renal risk change. As shown in the figure, amlodipine caused other changes in renal risk parameters that could add to the ultimate renal outcome.



The multiple PRO score (taking into account all changes) predicted a renal risk increase of 4.9% (-6.8 to +16.5) which is nearly the same as the observed drug effect.

Conclusions: A PRO score based on month-6 changes in multiple biomarkers performs better in estimating amlodipine's effect on hard renal outcomes than any change in single biomarkers. The PRO score thus works for two completely different antihypertensives.

PUB183

Primary Diffuse Mesangioproliferative Glomerulonephritis: Predictors of Renal Survival Mette K.M. Axelsen,[1] James G. Heaf,[2] Robert Smith Pedersen,[3] Torkell Ellingsen.[4] *[1]Nephrology B, Copenhagen University Hospital at Herlev, Herlev, Dominica; [2]Institute of Public Health, Aarhus University, Aaarhus, Denmark; [3]Flexdialysis A/S, Rungsted Kyst, Denmark.*

Background: Diffuse mesangioproliferative glomerulonephritis (MesP), with an incidence of 10.8/mio/year, is the most commonly diagnosed type of glomerulonephritis in Denmark. We describe the natural history of MesP and studied the relation between renal survival and baseline characteristics at the time of renal biopsy in a cohort with a follow-up of up to forty years.

Methods: The study is a historical cohort investigation. 140 patients with biopsy-proven MesP between 1967 and 2006 were included. Immunofluorescence was performed in 100; of these 46 had IgA deposits. Renal death was defined as patient death or need for dialysis or transplantation. Factors influencing renal survival were investigated using univariate and multivariate Cox proportional hazards regression analysis.

Results: Mean follow-up18 years ± 11.2, range 0.01-43.3. Mean age 34.2 years ± 17.9, range 5-80. Male: 62.9 %. Renal survival at 5, 10, 20 and 30 years was 87.1, 78.4, 58.6 and 49.9% Female survival was significantly better than male (70 vs. 40%). Multivariate analysis, adjusted for age, s-creatinine and nephrotic syndrome (NS) was performed for each sex individually, due to non-proportional survival curves for men and women. An increase in s-creatinine of 100 µmol/l was associated with a hazard risk (HR) of 1.88 (p<0.001) in women and 1.18 (p<0.001) in men. Older age was associated with a HR of 1.06 (p<0.001) in women and 1.05 (p<0.001) in men. NS had a poorer prognosis in men (HR 2.27, p<0.02), but not in women. There was no overall difference in prognosis between IgA positive and IgA negative patients, but in men, IgA positivity had a better prognosis.

Conclusions: Increasing age and s-creatinine are adversely associated with renal prognosis. Gender differences were seen: renal prognosis was better for women after 30 years of observation, and the detrimental effect of azotaemia was greater; nephrotic syndrome resulted in a significantly poorer prognosis in men, but not women. These findings suggest that the disease course and prognosis is different between men and women.

Nephrotic Patients with Membranous Nephropathy (MN) Treated with ACTH: Five Year Follow-Up Anna-lena Berg, Anneli Jonsson, Julia Dolinina, Omran Bakoush, Sten-erik Bäck. *Lund University, Lund, Sweden.*

Background: We previously reported that ACTH 1-24 (Synacthen Depot) has a lipid-lowering effect and also an ACTH-specific antiproteinuric effect in patients with Membranous Nephropathy (MN). ACTH might work directly via melanocortin receptors (MC 1-5) in white blood cells and/or the kidney. Clinical and experimental studies support our findings.

Methods: We now report 5 years follow up of 28 patients (10F/18M), median age of 63 years (34-85) with MN treated with ACTH. Six patients had previously been treated with the Ponticelli regimen, 3 patients with prednisolone/Cyclosporine (CsA) and 8 patients with prednisolone alone. Eleven patients had no earlier immunosuppressive treatment. Median time from MN diagnosis to initiation of ACTH treatment was 9.5 months (0.25-252). All patients received standard of care, including ACE-inhibitors/ARB, statins and other symptomatic therapies. Treatment with ACTH was started at 1 mg wk and was increased to a maximum of 1 mg twice weekly. The median duration of ACTH therapy was 10 months (2-24). Follow up data were obtained between 36-58 months after cessation of ACTH.

Results: With ACTH treatment, urinary albumin decreased from a pre ACTH median value of 4381 mg/L (3000-18398) to 270 mg/L (8-1802) with follow up median value 89 mg/L (0-1540; p< 0.0001 at both points), serum albumin increased from a pre ACTH median value of 20 g/L (8-30) to 35.5 g/L (22-49) with follow up median value 37 g/L (31-50; p<0.0001 at both points). e-GFR increased from a pre ACTH median of 56.5 mL/min/1.73m2 (14-104) to 62.5 mL/min/1.73m2 (16-96) post-ACTH (p<0.01). During follow up two patients required retreatment with ACTH for proteinuria relapse during the follow up period, and one patient progressed to ESRD. Five years after the initiation of ACTH therapy, 19 patients had complete remission (proteinuria <200 mg/L) and 8 patients had partial remission (proteinuria reduced by 50% to <2000 mg/L), and median eGFR for the group remains improved compared with baseline (65 mL/min/1.73m20).

Conclusions: Our 5 year observations suggest that ACTH may be useful to durably reduce proteinuria and preserve kidney function in patients with idiopathic MN.

PUB185

Analysis of 368 Non-Dialysis-Patients on Once Monthly C.E.R.A. Demonstrates High Stabilized Hemoglobin Values at Low C.E.R.A. Doses Christoph Wanner,[1] Thomas Rath,[2] Stefan N. Heidenreich,[3] Michael Koch,[4] Dirk Markus Henrich,[5] Frank Leistikow.[6] *[1]University Hospital, Würzburg, Germany; [2]Hospital, Kaiserslautern, Germany; [3]Renal Center, Aachen, Germany; [4]Renal Center, Mettmann, Germany; [5]Renal Center, Saarlouis, Germany; [6]Renal Center, Mannheim, Germany.*

Background: The TREAT-study results initiated a discussion about the interdependence between hemoglobin (Hb) -levels and erythropoiesis stimulating agents (ESA) -doses. The similar protocols of the German studies MERCUR (interventional) and SUPRA (non-interventional) in chronic kidney disease (CKD) stage IV patients (pts) allowed exploring the relation between ESA dose and Hb in pooled data.

Methods: Data were analyzed in ESA naïve pts showing at least one Hb value <10 g/dL followed by a treatment period of ≥3 months of stable Hb-values within defined ranges: <10, 10-11, 11-12, >12 g/dL. The primary and secondary Hb- targets of both studies were 11–12 and 11–13 g/dL. The 4 Hb- strata were further analyzed with respect to duration within the Hb-range, median dose, Nr of C.E.R.A. dose adaptations and incidence of AEs and SAEs (only for MERCUR within this stable period).

Results: 368 pts received at least one C.E.R.A. dose (safety population). The mean age was 68 years (18 – 94), 47.6% were females. The mean BMI was 27.9 kg/m² (16.3 - 48.4) and 44.8% suffered from diabetes. 62 pts displayed Hb-values within the defined ranges ≥3 months. The highest stabilized Hb – levels required the lowest C.E.R.A. doses.

Further results

Hb ranges, g/dl	< 10	10-11	11-12	> 12
Pts	25	12	15	10
Duration (Mo) Mean (SD)	4.54 (1.774)	4.14 (1.289)	3.68 (0.778)	4.88 (2.924)
Dose, µg, Median (Q1,Q3)	120 (75,150)	100 (75, 150)	100 (75, 100)	75 (50, 75)
Nr of dose-adap, Median (Q1, Q3)	2 (1,3)	1 (0.5, 2.5)	2 (0, 3)	0.5 (0,1)
Nr of SAE, MERCUR	5	1	0	0

Conclusions: In CKD non-dialysis pts, low doses of once monthly C.E.R.A. maintained stable high Hb-values (> 12 g/dl) potentially reflecting the background disease of the pts. The number of pts was too small to correlate the AE/SAE incidence with Hb-levels. These results need further evaluation in prospective controlled trials.

PUB186

Clinical and Biological Evolution of the More Frequent Biopsied Glomerulonephritis in Castilla la Mancha (Spain) between 1994 and 2008
Jose Luis Conde Olasagasti,[1] Elena Andres Mompean,[2] Elisa Pereira,[3] Ana Roca Muñoz,[1] Katia Matilde Perez,[2] Francisco Rivera.[3] *[1]Nephrology, Complejo Hospitalario, Toledo, Spain; [2]Nephrology, Hospital Universitario, Guadalajara, Spain; [3]Nephrology, Hospital General Universitario, Ciudad Real, Spain; [4]Nephrology, Complejo Hospitalario Universitario, Albacete, Spain.*

Background: In 2009 a collaborative task-force was established to investigate the progression and outcome of selected biopsied GN in CLM. (1994-2008).

Methods: Patients: 765 adults with histologically selected GN in four hospitals (1.8 million population area):157 focal and segmental glomerulosclerosis (FSGS).166 membranous nephropathy (MN),170 IgA nephropathy (IgAN),147 lupus nephritis (LN),125 crescentic type III glomerulonephritis(CGNIII).The median follow-up was 6,89 years (range 0.01-17,5). **Outcomes**:alive in or out of end stage renal disease (ESRD:dialysis or transplant),died, lost for follow up (LFU). Initial and final (for alive out of ESRD) renal situation was stratified and compared acording eGFR (MDRD) and level of proteinuria (Wilcoxon rank test).Association with outcomes and renal situation was assessed by binary logistic regression(covariates: age,sex,initial eGFRand proteinuria,and histological diagnosis).

Results: 118 died (46CGNIII,27MN,21FSGS 15IgA,9LN) 115 alive in ESRD (46 FSGS,38 IgA,17 RPGNIII,9 NM,5 LN) 483 alive out of ESRD (125 LN,120 NM,107 IgA,78 FSG,53 CGNIII),and 49 LFU accountig respectively for 15,4%,15,1% 63,1% and 6,4% of the cohort. After adjustement, ESRD or death,were significantly ($p<0.01$) associated wih initial eGFR and proteinuria,age,sex (male worse) and FSGS **Functional status**:Among 483 patients alive out of ESRD,50% have a eGFR (ml/min) >60, 34% 30 to 60 and 16% <30, being different ($p<0.00$) from initial.Individual renal situation was better (60,3%),same (17,1%), worse (22,5%) than in onset. In this self-selected group, progression to better renal situation was only significantly ($p<0.05$) associated wih initial eGFR and some diagnosis (FSGS worse).

Conclusions: Our results do not differ from those reported in literature.It's noteworthy the relative good prognosis of CGNIII once patients survive the first year.

Survey of Physical Activity and Dynamometry in Patients with Advanced Chronic Kidney Disease (ACKD) Guillermina Barril, Fernando F. Hadad, Maria Bernardita Puchulu, Ángel Nogueira Pérez, Jose-Antonio Sanchez-Tomero. *[1]Nephrology, Hospital Universitario de la Princesa, Madrid, Spain; [2]Nephrology, Hospital Clinico San Carlos, Madrid, Spain; [3]Nwphrology, Hospital U. de la Princesa, Madrid, Spain.*

Background: There is evidence of the importance of exercise in preserving muscle mass in patients with advanced chronic kidney disease ACKD.. There are useful tools that can help to assess status and muscle strength.

Methods: Assess muscle strength by dynamometry (Baseline 12-0240)in upper limbs in 98 patients inACKD Unit and correlate with physical activitythrough a basic survey of physical excercise performed. Parameters evaluated: age, gender, employment status, autonomy for functions of daily living, physical exercise ussually and type, difficulty climbing stairs, difficulty getting up from his chair, smoker and former smoker.

Results: 98 patients fronm a ACKD Unit were evaluated.61.5%men,xage 72.94 ± 12.88. no significantl diference between men and women, 72.9% inactive, 30.7% were current smokers, autonomous daily living 86.5%, sedentary49%, 57.3% walk normally, it costs up 28.1% of the chair, difficulty climbing stairs 62, 5%, realyzing regular exercise 44.8% and 55.2% having done exercise before. Dinamometries: xDizda 51.30±22.4, Ddcha 53.42±20.86 lbs. 27% have increased dynamometrtry left arm. There are higher dinamometry values in males than women and under 65 vsover 65years (0.000). We found inverse correlation between dynamometry values and age(0.000).

Patients who usually perform physical exercise have significantly higher dinamometrry than those who do not realize p0, 000 and 0.001 for Dizda Ddcha. In a high % of patients who had high exercise performed previously but they did not now retained higher dinamometrtry values than those who have not ever made.

Conclusions: 1.-The dynamometry is a useful tool for measuring muscle strength and monitor it over time.

2. - The men have larger values than women.

3.-Age was inversely correlated with dynamometry and musclestrength was greater in younger than 65 years

4.-Patients with regular physical exercise showed better muscle strength and have previously done to help preserve muscle strength over time.

PUB188

Underlying Cause of Chronic Kidney Disease (CKD) Could Be a Better Predictor of Stroke than Stage of CKD.(Miyagi Gonryo Study)
Tasuku Nagasawa,[1] Mariko Miyazaki,[1] Masaaki Nakayama,[2] Hiroshi Sato,[3] Sadayoshi Ito.[1] *[1]Nephrology, Hypertension and Endocrine, Tohoku University Graduate School of Medicine, Sendai, Miyagi, Japan; [2]Nephrology, Fukushima Medical University School of Medicine, Fukushima, Japan; [3]Clinical Pharamacology and Therapeutics, Graduate School of Pharmaceutical Sciences, Tohoku University, Sendai, Miyagi, Japan.*

Background: Chronic kidney diseases (CKD) are known to be risk factor of cardiovascular disease (CVD). Miyagi Gonryo Study is comprised 2,692 patients recruited from 11 outpatient nephrology clinics, classified into 4 groups by underlying renal disease (Primary renal disease:PRD, hypertensive nephrophathy:HN, diabetic nephropathy:DN, other nephropathies:ONs).We reported induction of renal replacement therapy (RRT) is higher than incidence of CVD.(Hypertens Res. 2011:1106-10). Prevalence of stroke in Japan is higher than that of United States. But relation between stroke and underlying cause of CKD is unclear.

Methods: In this study, we focused on background of stroke patients. During follow up 22.6 months from recruitment, total of 115 CVD events has occurred (stroke in 37 cases.), and 44 has dead.We analysed background of 37 patients.

Results: In 37 cases, 23 are cerebral infarction, 9 are cerebral hemorrhage and 3 are other intracranial event. Incidences of stroke of PRD, HN, DN, and ON were 0.3%, 3.0%, 1.9% and 2.4%, respectively. Level of blood pressure, age, and use of anti-platelet drugs are no difference between groups. 11 of 24 patients were recurrence of cerebral infarction. Incidence of cerebral infarction of general population of Japan is about 0.3%. Taken together, patients with HN and DN are extremely high risk of stroke. And history of cerebral infarction is also predictor of recurrence.

Conclusions: We conclude that underlying cause of CKD is much important than stage of CKD.

PUB189

Referral Pattern of Patients from an Indian Subpopulation in a Standalone Dialysis Setup Topoti Mukherjee, Nagesh Manjunath Rao. *Nephrology, DaVita NephroLife India Pvt. Ltd., Bangalore, Karnataka, India.*

Background: Contrary to the conventional approach of maintenance hemodialysis being a tertiary setup in a hospital in India, our dialysis unit (DaVita NephroLife) primarily focuses on providing quality dialysis services, while ensuring geographic convenience and financial comfort to the End Stage Renal Disease (ESRD) patients. This retrospective, explorative and observational study aims to survey and improve patient referral patterns in order to track morbidity and mortality as part of dialysis outcomes.

Methods: Patient demographics, referral modes and consulted specialities were recorded. Patients were segregated based on their mode of referral.

Results: Between December 2009 and May 2012, 2995 patients registered themselves with NephroLife for renal and allied complications. A total of 958 patients, comprising 32% of the sample size had presented for consultation on account of symptoms. 659 individuals (22%) were found to be comorbid during kidney disease screening camps. The rest 44% accounted for referrals by classifieds and other personal referrals. 30% of the nephrology consult registered for hemodialysis while the rest were for other renal concerns. Among the dialysis patients, 93%, 62% and 80% achieved a Kt/v of >1.2, haemoglobin of 10-12g/dl and albumin of >3.5g/dl respectively.

Conclusions: An encouraging statistic is the significant number of patients that have promptly presented for consultation upon feeling symptoms they felt were characteristic of renal disease. Also important is the substantial number of latent illnesses brought to light during screening camps. Other in–house facilities like patient education, laboratory, dietician, psychologist, vascular surgeon and family physician, in addition to clinical nephrology, have both drawn a steady patient pool and also helped better patient management, as evident from our outcomes. We conclude that standalone dialysis units are a feasible concept in India.

PUB190

The Clinical Presentation of Kidney Disease at Queen Elizabeth Central Hospital, Blantyre, Malawi Gavin Dreyer. *Queen Elizabeth Central Hospital.*

Background: Risk factors for kidney disease are prevalent in Malawi and include HIV infection, diabetes mellitus, hypertension and sepsis. No studies have examined how kidney disease presents to health services in Malawi. There is a pressing need to investigate the clinical presentation, aetiology and risk factors for kidney disease in Malawi to enhance clinical service provision, determine research opportunities and improve patient outcomes.

Methods: A new nephrology service at Queen Elizabeth Central Hospital has been established. Ward referrals and patients from the nephrology out-patient clinic in the first 12 months of the service were included in the study. Routine, fully anonymised, demographic

and clinical data were collected prospectively. Clinical and laboratory parameters were analysed by a nephrologist to determine the likely cause of kidney disease, need for kidney biopsy (although not currently available in Malawi) or dialysis therapy and confirmation of end stage kidney disease based on the best available clinical and laboratory evidence.

Results: 157 patients (83 inpatients) were referred in the first 12 months of the service, 89 male (56.7%), mean age 40.6 years, 53 (33.8%) HIV positive. The mean creatinine at presentation was 8.0 mg/dl (mean eGFR 30.1 ml/min/m^2). 113 (72.0%) patients presented with evidence of chronic kidney disease, 29 (18.5%) with acute kidney injury, and 9 (5.7%) with acute on chronic kidney disease. Glomerular disease was the primary renal disorder in 31.8% of patients with hypertension and diabetes mellitus accounting for the primary renal lesion in 10% of cases each. 47 (29.9%) patients presented with end stage kidney failure (eGFR < 15 ml/min and symptomatic), 40 (25.5%) required a kidney biopsy at presentation and 25 (15.9%) required emergency dialysis on the day of referral.

Conclusions: Patients present to QECH with advanced kidney disease and glomerular pathology is the main aetiological factor in line with findings from other studies in the region but the exact histological subtypes remain undefined. Problem based research combined with enhanced clinical services for identifying and treating early kidney disease could reduce the morbidity and mortality associated with kidney disease in Malawi.

PUB191

Urine Uric Acid Excretion in the Japanese Population: The Takahata Study Kazuko Suzuki, Tsuneo Konta, Hiroko Sato, Kosuke Kudo, Ami Ikeda, Kazunobu Ichikawa, Isao Kubota. *Department of Cardiology, Pulmonology, and Nephrology, Yamagata University School of Medicine, Yamagata, Japan.*

Background: Hyperuricemia is an established risk factor for end-stage renal disease and cardiovascular events and the serum levels of uric acid are largely regulated by urinary excretion of uric acid. To clarify the determinants of urinary uric acid excretion in general population, we conducted a community-based study, using the uric acid clearance-creatinine clearance ratio (UACr/CCr) as an index of urinary uric acid excretion.

Methods: The subjects were 2018 Japanese individuals (885 men, 1133 women, mean age 63 years) without history of kidney disease participated in local health checkups. The UACr/CCr was assessed in morning spot samples of urine and blood.The urinary uric acid excretion were classified into low (UACr/CCr <5.5%), normal (5.5-11.1%), and high (>11.1%).

Results: In this population, the proportions of low, normal, and high group of UACr/CCr were 40.4%, 39.0%, and 20.5%, respectively. The proportion of low UACr/CCr group was significantly higher in men (46.7%) than that in women (36.5%) (P <0.001). Multiple linear regression analysis showed that UACr/CCr values were related positively with estimated GFR and negatively with HbA1c and triglycerides in men, and were related positively with body mass index and negatively with age in women, respectively. Multivariate logistic analysis showed that the independent predictors for low UACr/CCr were aging, diabetes and renal insufficiency in men, and aging and high urinary sodium excretion in women, respectively.

Conclusions: This study showed that reduced urinary uric acid excretion was observed in the large part of Japanese population. The renal clearance of uric acid was associated with aging, comorbidities and dietary habit, and its association might be different by gender.

PUB192

Obesity as Risk Factor for Chronic Kidney Disease in the Moroccan General Population Monique M. Elseviers,[1] Mohammed Benghanem Gharbi,[2] Zamd Mohamed,[2] Abdelali Belghiti Alaoui,[3] Mohammed El Hassane Trabelssi,[3] Naima Benahadi,[3] Benyounès Ramdani,[2] Bayahia Rabia,[2] Marc E. De Broe.[1] *[1]Department of Health Sciences, University of Antwerp, Wilrijk, Belgium; [2]Moroccan Society of Nephrology; [3]Ministry of Health, Morocco.*

Background: The MaReMar study aims to investigate chronic kidney disease and associated risk factors in the general population of Morocco and to treat the population at risk during 5 years. We wondered if BMI and waist-hip ratio are valid parameters to evaluate the risk of obesity in the Moroccan population.

Methods: A random sample of the adult population of 2 middle-sized towns in Morocco was selected, stratified according to gender and age categories 26-40, 41-55 and 56-70. In the local health centre, consented subjects were screened by a structured questionnaire, clinical investigations (with body weight and height, waist and hip circumference) and blood and urine sampling. Obesity was defined has BMI >30 or a waist to hip ratio (WHR) >1 in male and > 0.85 in female.

Results: Baseline screening was performed in 10 524 participants, equally spread over the predefined gender and age strata. Mean bodyweight was 73.8 kg (SD13.9) in women and 74.6 kg (SD13.1) in men, with a mean BMI of 28.6 (SD5.2) and 24.9 (SD4.1) respectively. Obesity (BMI>30) was observed in 36.4% of women and 11.3% of men. Obesity was already present in 27.4% of women of 26-40yr, increasing to >40% in older age groups. Using WHR, more extreme differences were observed with obesity found in 53.5% of women and 4.6% of men. Health outcome parameters showed however, no significant differences in women compared to men for eGFR <60ml/min (2.5 versus 3.0%), blood pressure ≥140/90mmHg (22.5 versus 21.3%) and hyperglycemia >1.26g/L (17.8 versus 16.5%).

Conclusions: In Morocco, obesity is clearly more present in women than in men. Using WHR, more than half of the female population has to be considered as obese. Despite the difference in BMI, no significant gender differences could be observed in the prevalence of CKD, hypertension or diabetes.

PUB193

Intraclass Correlation Coefficients for Cluster Randomized Trials in CKD H. Lester Kirchner, Robert M. Perkins. *Geisinger Clinic, Danville, PA.*

Background: Cluster randomization trials (CRT) are a type of pragmatic clinical trial useful for testing new interventions in real-world settings. Large health care systems provide access to robust cohorts in which primary care clinics (PCC) may serve as the cluster unit. CRT requires sample size calculations which incorporate the intraclass correlation coefficient (ICC) and design effect (DEFF).The ICC measures variation between and within clusters and represents the lack of independence. The DEFF quantifies the inflation of sample size necessitated by clustering. The purpose of this study was to determine ICCs and DEFFs for common variables at the PCC level for CKD patients.

Methods: . Adult patients receiving primary care through Geisinger Clinic between January 1, 2001 and December 31, 2011, with stage 3-5 CKD and no history of renal replacement therapy were eligible for the study. Clinical data were obtained from the patients' most recent outpatient encounter prior to December 31, 2011 and before renal replacement therapy to mimic trial enrollment of prevalent CKD patients. ICCs were calculated from a random intercept linear model treating the PCC as the cluster.

Results: 12,215 adults met inclusion criteria from a total of 41 PCCs (median number of CKD patients/PCC was 214). The average age was 74.6 years with mean CKD duration of 5.9 years. 60.5% were male, 46.1% had diabetes, 23.1% had peripheral arterial disease, and 36.0% had proteinuria. The largest ICCs were observed for serum albumin (0.022) and diastolic BP (0.020) yielding DEFFs of 1.3 to >3.0. These results are similar to that seen in general primary care populations.

Variable	Mean (SD)	ICC (95% CI)
Cholesterol	166.3 (41.8)	.011 (.006, .021)
HDL	47.6 (14.7)	.001 (.000, .012)
LDL	89.3 (33.3)	.013 (.007, .023)
Albumin	4.0 (0.5)	.022 (.012, .036)
Serum Creatinine	1.5 (0.7)	.005 (.002, .011)
eGFR	53.2 (16.0)	.004 (.001, .010)
Systolic BP	127.3 (18.7)	.016 (.009, .027)
Diastolic BP	69.2 (10.4)	.020 (.011, .034)
Body Mass Index	30.5 (7.2)	.006 (.003, .014)

Conclusions: These findings imply that trial sample sizes for CRTs enrolling CKD patients will require substantially more subjects than traditional non-clustered designs.

PUB194

Obstacles and Constraints in the Implementation of a Population Based Screening Program of Chronic Kidney Disease in Morocco (MaReMar) Zamd Mohamed,[1] Mohammed Benghanem Gharbi,[1] Monique M. Elseviers,[2] Abdelali Belghiti Alaoui,[3] Mohammed El Hassane Trabelssi,[3] Naima Benahadi,[3] Ramdani Benyounes,[1] Bayahia Rabia,[1] Marc E. De Broe.[4] *[1]Moroccan Society of Nephrology; [2]University of Antwerp, Wilrijk, Belgium; [3]Ministry of Health, Morocco.*

Background: The MaReMar study estimated the prevalence of chronic kidney disease and the associated risk factors in a representative sample of the population of Morocco aged 26-70. We aim to highlight the difficulties faced in the implementation of the survey and in the recruitment of participants.

Methods: A stratified random sample of the population, using official voting lists, was taken. Recruitment was organized at the level of health care area. A trained nurse visited all selected subjects at home offering standardized information using a visual presentation of the planned investigations. An appointment was made for a visit at the local health center to perform the baseline renal screening.

Results: Main difficulties were the access to the electoral list (election period), the elaboration of the Electronic Case Report Form and the related software, training and motivation of the teams and financial issues. Among the selected participants, only 50.56% were found by investigators. The main causes were: incorrect addressesormissing persons (moving, students in other cities, slums which were eradicated in the meantime, travel or deaths). New lists were performed to resolve these difficulties. Among those found, 85.02% accepted to participate in the survey and 82.56% of them came to their first visit to the center. Of the last, 97.73% came the second visit which permit to confirm a possible abnormality detected during the screening.

Conclusions: MaReMar generated strategic informations on the prevalence of chronic kidney disease, hypertension, and diabetes in Morocco. It is also an important source of information on the difficulties encountered in the implementation of such survey in the field, allowing others to benefit from the experience of MaReMar team.

PUB195

Low Heart Rate Variability and Risk for Renal and Cardiovascular Outcomes and All-Cause Mortality in CKD: A CRIC Study Paul E. Drawz,[1,2] Denise C. Babineau,[1] Carolyn S. Brecklin,[2] Jiang He,[2] Radhakrishna Reddy Kallem,[2] Elsayed Z. Soliman,[2] Dawei Xie,[2] Amanda Hyre Anderson,[2] Mahboob Rahman.[1,2] *[1]Case Western Reserve University; [2]CRIC Study Group.*

Background: The goal of this study was to evaluate: 1) the characteristics associated with heart rate variability (HRV) and 2) the association between HRV and adverse outcomes in patients with CKD.

Methods: In the Chronic Renal Insufficiency Cohort study, a 10 second ECG was obtained at baseline. The relationships between clinical and demographic characteristics

and HRV, as measured by SDNN (standard deviation of all R-R intervals) and RMSD (root mean square of successive differences between all R-R intervals), were assessed using linear regression. Cox models were used to assess the association between baseline HRV and the relative hazard rate of renal outcomes, cardiovascular (CV) outcomes (composite of myocardial infarction, congestive heart failure, and stroke), and all-cause mortality.

Results: 3276 of the 3939 subjects in CRIC had available data and were included in the present analyses. Lower HRV was associated with older age, congestive heart failure, and diabetes, as well as elevated diastolic BP, phosphorus, FGF23, A1c, and C-reactive protein and marginally associated with low estimated glomerular filtration rate (eGFR) but not proteinuria. Median follow up was 4.2 years. In longitudinal analyses adjusted for age, gender, race, eGFR, and proteinuria, lower HRV was associated with an increased relative hazard ratio for renal outcomes (SDNN HR 1.11, *P*=0.02; RMSD 1.13, *P*=0.01), CV outcomes (SDNN 1.23, *P*<0.001; RMSD 1.14, *P*=0.02), and all-cause mortality (SDNN 1.20, *P*=0.007; RMSD 1.14, *P*=0.06). In fully adjusted models, lower HRV was not associated with renal outcomes but was marginally associated with an increased risk for CV outcomes (SDNN 1.10, *P*=0.08) and all-cause mortality (SDNN 1.13, *P*=0.09; RMSD 1.10, *P*=0.2).

Conclusions: HRV was associated with numerous risk factors for renal and cardiovascular disease. Independent of eGFR and proteinuria, lower HRV was associated with increased risk for renal and cardiovascular outcomes and all-cause mortality, although this effect was attenuated after adjustment for additional covariates.

PUB196

Late Referral of Children Who Develop Established Renal Failure: A 15 Year Renal Registry Study

Rishi Pruthi,[1] Manish D. Sinha,[2] Anna Casula,[1] Malcolm A. Lewis,[3] Fiona E.M. Braddon,[1] Yincent Tse,[4] Heather Maxwell,[5] Catherine O'Brien,[6] Carol D. Inward.[7] *[1]UK Renal Registry, Bristol, United Kingdom; [2]Evelina Childrens Hospital, London, United Kingdom; [3]Manchester Children's Hospital, Manchester, United Kingdom; [4]Royal Victoria Infirmary, Newcastle, United Kingdom; [5]Royal Hospital for Sick Children, Glasgow, United Kingdom; [6]Birmingham Children's Hospital, Birmingham, United Kingdom; [7]Bristol Royal Hospital for Children, Bristol, United Kingdom.*

Background: Early referral of children with chronic kidney disease (CKD) to a paediatric nephrology centre is recommended to minimise clinical complications related to CKD in childhood, as well as delaying progression to established renal failure (ERF), improving pre-emptive transplantation rates, and optimising renal replacement therapy (RRT) work up. There is currently no published data on late referral rates in the UK paediatric RRT population.

Methods: Using data provided by the UK Renal Registry we analysed all incident patients starting renal replacement therapy (RRT) aged >3months and <16years between 1996 and 2010. Late referral was defined as having seen a paediatric nephrologist less than 3 months from commencing RRT.

Results: Of 1554 eligible patients, analysis was performed on 1347 patients (86.7%) in whom late referral was calculable using registry data. Overall late referral was seen in 25.5% (n=343) of patients. Late referral was significantly lower in males 20.18% (n=156) than females 32.75% (n=188), P<0.0001, and highest in the 3-months-2 years age group 31.61% (n=49) p=0.0005. No significant differences in late referrals were noted amongst different ethnic groups, different UK paediatric centres, or when comparing late referrals over 5-year time intervals 2006-2010, 2001-2005, and1996-2000.

Conclusions: A significant proportion of children who develop ERF are referred late to nephrology units in the UK, with significantly higher rates seen in female patients and those under 2 years old. There is a need to understand these differences and the reasons behind late referral, to reduce its occurrence and the potential exposure to children of clinical complications that accompany late referral.

PUB197

First Report from the Chronic Kidney Disease (CKD) Registry, Queensland, Australia

Sree Krishna Venuthurupalli,[1,2] Wendy E. Hoy,[2] Zaimin Wang,[2] Helen G. Healy,[2,3] Anne Salisbury,[2] Robert G. Fassett.[2,3] *[1]Renal Medicine, Toowoomba Hospital, Toowoomba, Queensland, Australia; [2]Centre for Chronic Disease, University of Queensland, Brisbane, Queensland, Australia; [3]Renal Medicine, Royal Brisbane and Women's Hospital, Brisbane, Queensland, Australia.*

Background: CKD Queensland (CKD.QLD) is the first CKD surveillance system in Australia. Its CKD Registry, established in 2011, includes all CKD patients in QLD public renal services. We describe the profile of the first patients recruited.

Methods: After ethical and governance approval, and with informed consent, recruitment of CKD patients to the to the Registry has begun, with summary information from their practice sites transferred to a central repository.

Results: Over 2300 CKD patients have been recruited, from an estimated 15,000, and data of the first 1000 analysed. Mean age was 64.5 years and included 55% males and 31.6% of age ≥ 75 years, with less gender differential and more elderly patients, compared to QLD incident ESKD patients on Renal Replacement Therapy (RRT) (62% and 22% respectively). The aetiology of CKD was unknown (36%), renovascular disease (10.2%), diabetic nephropathy (5.8%) and hypertension (HT) (5.4%). Most patients had CKD stage 3 (43.5%) or 4 (31%) and 9% were stage 5, not on dialysis.

There were no major differences in age and gender between a large metropolitan/urban site (N=560) and two regional/rural sites (N=265). Renovascular disease and HT were more commonly attributed causes in urban compared with regional areas (18.2% vs. 4.8% and 9.6% vs. 2.5% respectively p<0.05), but an uncertain aetiology was more common in regional areas (44.2% vs. 31%).

Conclusions: The higher number of elderly in the CKD.QLD group than in QLD's RRT population probably reflects many CKD patients who do not ultimately receive RRT. The higher proportion of females suggests different outcomes and/or rates of progression of CKD, and/or selection biases for RRT. The greater proportion of CKD patients in regional areas with an uncertain CKD aetiology may be genuine or reflect lack of diagnostic resources. All will be better understood with an expanded group of CKD patients, and longitudinal surveillance of their course.

PUB198

Co-Prevalent Diabetes and Kidney Disease Does Not Increase Fracture Risk Compared to Diabetes or Kidney Disease Alone

Faraj Kargoli, Donald J. Mcmahon, Elizabeth Shane, Thomas L. Nickolas. *Columbia University Medical Ceneter, New York, NY.*

Background: Chronic Kidney Disease (CKD) and type 2 diabetes mellitus (DM) are both associated with increased fracture (Fx) risk. However, it is not fully clear whether co-prevalent CKD and DM (DM-CKD) is associated with higher Fx risk than CKD or DM alone. We conducted a cross-sectional analysis of the continuous National Health and Nutrition Examination Survey (NHANES) to test the hypothesis that patients with DM-CKD are at higher Fx risk than patients with either DM or CKD alone.

Methods: We included subjects, ≥40 yrs, enrolled in NHANES from 2000 to 2010 (n=26,070). DM status and a reported history of Fx at any site were ascertained from responses to NHANES questionnaires. CKD status was dichotomized based on an eGFR<60 ml/min. Continuous and categorical data are presented as means±SD and percents (%), respectively. Uni- and multivariate logistic regression were used to compare Fx prevalence rates.

Results: DM patients (n=2,240) had a mean age of 60±14 yrs, eGFR of 98±32 ml/min and body mass index (BMI) of 32±7; 25% were black, 49% were female and 12% reported a Fx. CKD patients (n=1,264) had a mean age of 73±12 yrs, eGFR of 47±12 ml/min and BMI of 28±5; 12% were black, 56% female and 16% reported a Fx. DM-CKD patients (n=530) had mean age of 71±10 yrs, eGFR of 44±14 ml/min and BMI of 32±8; 22% were black, 54% female and 13% reported a Fx. Compared to patients with DM or CKD, Fx prevalence was not higher in patients with DM-CKD (OR 1.10, 95%CI 0.83-1.46; OR 0.79, 95%CI 0.59-1.07, respectively for DM-CKD versus DM or CKD). However, prevalent Fxs were 41% more common in patients with CKD than with DM (OR 1.41, 95%CI 1.13-1.70). Adjustment for age, gender, race and BMI did not alter relationships between disease status and Fxs.

Conclusions: In summary, these analyses suggest that Fxs are more common in patients with CKD than with DM, but co-prevalent CKD and DM does not confer additional risk above that of patients with DM alone. Epidemiologic and mechanistic studies are needed to evaluate the effects of DM-CKD on site-specific Fx rates and the biochemical and microarchitectural basis of fragility in these common chronic diseases.

PUB199

Rate of GFR Decline Estimated Using Joint Models of GFR Slope Is Strongly Associated with Long-Term Outcomes in the MDRD Study

Seth Wright,[1] Hocine Tighiouart,[1] Tom Greene,[2] Liang Li,[3] Mark J. Sarnak.[1] *[1]Tufts Medical Center, MA; [2]University of Utah, UT; [3]Cleveland Clinic, OH.*

Background: The rate of decline of GFR over time intuitively relates to risk of ESRD and potentially death. However, assessment of this relationship has been limited by short follow-up.

Methods: 839 subjects from the MDRD randomized trial (conducted between 1989-1993 with iothalamate GFR (iGFR) measurements every 4 months; mean baseline iGFR of 32 ml/min/1.73 m^2) were included. Assessment of the relationship between slope of iGFR decline and the composite outcome of ESRD or death prior to ESRD was evaluated using a joint mixed linear model with both survival and rate-of-change components (described by Vonesh et al.) This approach allows use of all data regardless of timing of the endpoint. A hazard ratio was calculated for slope of decline and adjusted for baseline predicted iGFR as well as other risk factors associated with progression of kidney disease.

Results: Median follow-up was 5.9 years (range 0.25-18.6). Slope of iGFR during the trial showed a wide range (mean of -7.7 ml/min/1.73m^2/year in the quartile with most rapid decline and mean of +0.4 ml/min/1.73m^2/year in the quartile with least rapid decline). The endpoint was reached by 86% of subjects during long-term follow-up (ESRD 616, death prior to ESRD 106). There was a strong relationship between the slope of iGFR and risk of the endpoint (Table). This was not appreciably attenuated after multivariable adjustment.

	Hazard ratios (95%CI): unadjusted	Hazard ratios (95%CI): adjusted
iGFR slope, per 1 ml/min/1.73m^2/year more rapid decline	1.52 (1.44, 1.61)	1.48 (1.40, 1.56)
Predicted baseline iGFR, per 1 ml/min/1.73m^2 decrease	1.09 (1.08, 1.10)	1.09 (1.08, 1.10)

All HR were significant with p<0.001. Both models included slope and baseline iGFR; adjusted model included sex, age, race, proteinuria, MAP, transferrin level, cause of kidney disease, and HDL.

Conclusions: Slope of GFR during a short period is strongly associated with long-term outcomes using a joint modeling approach. Further investigation should explore how this relationship varies with time and methods of incorporation into prediction of outcomes in individual patients.

PUB200

Outcome of Late Steroid Resistant Nephrotic Syndrome in Children: A Study by the Midwest Pediatric Nephrology Consortium Caroline E. Straatmann, V. Matti Vehaskari. *Pediatrics, Louisiana State University Health Sciences Center, New Orleans, LA.*

Background: Idiopathic nephrotic syndrome (NS) is classified as steroid-sensitive or steroid-resistant. Some initially steroid-sensitive patients later develop steroid resistance, sometimes with histologic progression to focal segmental glomerulosclerosis (FSGS). Patients who develop late steroid resistance (LSR) often receive intensified immunosuppression (IS) with multiple, potentially toxic drugs. The impact of intensified IS on the long-term prognosis of these children is unknown.

Methods: Retrospective chart review was performed in 29 patients from 8 centers who developed LSRNS from 2002-2009 to evaluate outcome and impact of additional IS therapy. Outcome measures were: response of proteinuria to each drug, proteinuria and eGFR at latest follow-up, and number of adverse events. Role of demographic factors and histology in outcome was also analyzed.

Results: Nineteen males (66%) and 10 females (34%) were enrolled. There was equal distribution among whites and African-Americans. Median duration of follow-up was 75 months. Majority (72%) received treatment with ≤ 2 drugs. Calcineurin-inhibitors (CNIs) and mycophenolate mofetil (MMF) were most frequently used. Sixty-seven percent received steroids ≥50% of the total treatment time. CNIs had highest individual rate of remission (86%.) At final outcome, 70% percent of patients were in complete or partial remission. Three patients developed ESRD, but renal function was overall well-preserved with no significant change in estimated GFR over study period. Minimal adverse events were noted, with infection being most common. Age, ethnicity, or histology was not significantly associated with final outcome. More males remained nephrotic or developed ESRD (42% vs. 10%.) Patients with a shorter median time to development of LSR had significantly better final outcome.

Conclusions: Most LSR patients respond to additional non-steroid IS. Additional IS after documented non-response to 2 drugs may not be beneficial but does not seem to be deleterious either. LSRNS may have a relatively good long term outcome and the risk: benefit of escalating IS therapy in LSRNS does not appear to be highly unfavorable.

PUB201

Kidney Injury Markers in Nicaraguan Adolescents in a Region of an Epidemic of CKD of Unknown Etiology Daniel R. Brooks,[1] Oriana Ramirez-rubio,[1,2] Juan Jose Amador,[1] James S. Kaufman,[3] Chirag R. Parikh,[4] Usman Ahmed Khan,[4] Michael Mcclean,[1] Rebecca L. Laws,[1] Daniel E. Weiner.[5] *[1]Boston University School of Public Health; [2]Universidad Autonoma de Madrid; [3]VA Boston Healthcare System; [4]Yale University School of Medicine; [5]Tufts University School of Medicine.*

Background: An epidemic of CKD is occurring in Central America with over 20,000 deaths, mainly among younger men. Most studies have focused on occupational factors, but the early age at diagnosis suggests that initial injury may begin in childhood.

Methods: We studied markers of kidney injury in 200 students (age 12-18) with no work history from 4 schools in Nicaragua. Schools represented a range of risk based on adult CKD mortality data. Urine was tested by dipstick and analyzed for ACR, NGAL, NAG, and IL-18.

Results: Dipstick proteinuria (3%) or glucosuria (1%) were rare, and 8% had ACR >30 mg/g. The median IL-18 level (pg/ml) was higher than in healthy controls identified from other studies (45, IQR 21-115 vs. 15, IQR 7-28). The ratios of mean NGAL, NAG, and IL-18 levels are shown by sex and school in the table. Males had lower levels than females for all markers. The results by school were consistent with the a priori risk. Among males, the highest mean levels of NAG, NGAL, and IL-18 were at the highest risk school. Females at the two highest risk schools had elevated levels of NAG. Results were the same regardless of whether measurements were normalized for creatinine.

2	1.28 (0.86-1.90)	0.76 (0.45-1.27)	0.65 (0.40-1.05)
3	2.00 (1.36-2.94)	1.28 (0.77-2.13)	0.64 (0.40-1.04)
4 (highest risk)	2.27 (1.46-3.52)	1.40 (0.79-2.50)	0.57 (0.33-0.98)

Conclusions: The results suggest that tubular kidney injury may be present among youth in an area of epidemic CKD. If confirmed, factors in addition to occupational exposure should be studied as possible causes of CKD.

PUB202

Clinicopatholgical Manifestation in Elder Patients of Idiopathic Membranous Nephropathy Shinji Kitajima,[1] Tadashi Toyama,[1] Kiyoki Kitagawa,[1] Hitoshi Yokoyama,[2] Takashi Wada.[1] *[1]Department of Nephrology, Kanazawa University Hospital, Kanazawa, Japan; [2]Division of Nephrology, Kanazawa Medical University Hospital, Kanazawa, Japan.*

Background: The 20-year renal survival of Idiopathic membranous nephropathy (IMN) in Japanese adults with nephrotic syndrome was reported around 60%. On the other hand, the rate of remission, renal death, and patient death of elder IMN remains unclear so far. In this study, we evaluated the predisposing clinicopathological factors for elder IMN patients.

Methods: One hundred forty seven patients (85 males and 62 females; mean age 46.3 years) with biopsy proven IMN from 1965 to 2008 in Kanazawa Universitiy Hospital were evaluated in this study. The patients were followed for more than three years, or until renal or patient death. The patients were divided into elder group (aged 65 and over, 21 cases), or younger group (less than 65 years old, 126 cases). Clinicopathological factors, which might affect rate of remission, renal death, and patient death were evaluated.

Results: Rate of patients with nephrotic proteinuria were similar between two group (71.4%). Elder group showed higher remission rate (elder ; 73.3%, younger ; 60.0%). Based on the electron microscopic findings, the patients were assigned to two distinct groups, homogeneous type and heterogeneous type (synchronous electron dense deposits or various phases of dense deposits in basement membrane, respectively) as previously published in *Kidney International* in 2004. The rate of homogeneous type was higher in elder group (elder ; 75.0%, younger ; 58.2%). Although patient death rate (elder ; 9.5%, younger ; 5.5%) was higher in elder group, renal death rate was lower in elder group (elder ; 0%, younger ; 6.4%).

Conclusions: Patient death, rate of homogeneous type, and remission were higher in elder IMN patients. Therefore, elder IMN patients should be paid more attention in patient death as well as remission or renal death.

PUB203

Determinants of Serum Uric Acid and Associations with Cardiovascular Risk Factors in Chronic Kidney Disease Stage 3 Determinants of Serum Uric Acid and Associations with Cardiovascular Risk Factors in Chronic Kidney Disease Stage 3 Adam Kirk,[1] Natasha J. Mcintyre,[1] Richard J. Fluck,[1] Chris W. McIntyre,[1,2] Maarten W. Taal.[1] *[1]Renal Medicine, Royal Derby Hospital, Derby, Derbyshire, United Kingdom; [2]School of Graduate Entry Medicine and Health, Nottingham University, Derby, Derbyshire, United Kingdom.*

Background: Chronic kidney disease is an independent risk factor for cardiovascular (CV) events. Elevated serum uric acid (SUA) has been proposed as a mediator of this association. Our aim was to investigate factors influencing SUA and associations between SUA and CV risk factors.

Methods: We studied 1741 volunteers with eGFR 30-59 mls/min/1.73m^2. From each participant, medical history, demographics, blood and urine were analysed.

Results: Median age was 74 years. 60.4% of participants were female. Median eGFR was 53.2mls/min/l.73m^2. Median SUA was 379 µmol/L with 22.5% having hyperuricaemia. Univariate analysis identified positive correlations with age, serum phosphate, total protein, bicarbonate, cholesterol, HDL cholesterol, BMI, waist:hip ratio and pack years of smoking while an inverse correlation was observed with eGFR. Being male, diabetic, socially deprived (lowest quintile) or receiving diuretics was associated with a significant higher SUA. Allopurinol treatment was associated with lower SUA. Multivariable analysis identified eGFR, diuretics, male gender, BMI, allopurinol and serum total protein as independent determinants of SUA (Adjusted $R^2 = 0.39$). Additionally SUA concentration did not correlate with arterial pulsewave velocity but did with other markers of CV risk including diastolic blood pressure, skin autofluorescence, urine albumin:creatinine ratio and high sensitivity CRP and was higher in those with past history of cardiovascular disease.

Conclusions: SUA concentration is elevated in a significant proportion of persons with early CKD. Several potentially modifiable factors determine it. Correlations with several CV risk factors suggest that SUA may itself be a useful marker of CV risk. This will be tested during planned long term follow up of the cohort. Further randomized trials are required to assess the potential benefits of lowering SUA in persons with CKD.

PUB204

Heredity for Myocardial Infarction Demonstrates More than Two-Folded Increased Risk for Significant Renal Dysfunction in Middle-Aged Men Anders G. Christensson. *Nephrology and Transplantation, Clinical Sciences, Malmö, Malmö, Sweden.*

Background: We have evaluated a potential association between family history of MI and renal dysfunction during long-term follow up of a large, population-based cohort.

Methods: The cohort included 33,125 subjects (22 297 males and 10 828 females), aged 33-60 years at baseline, in a representative, population-based study which enrolled subjects from 1974 to 1992, in the city of Malmö. Median follow-up time was 26 years. Females were significantly older (6 years) than males, 49.7 years and 43.7, respectively, at inclusion. Heredity for MI was defined as mother or father having had MI and/or died from MI, and/or brother or sister having had MI. Estimated GFR (eGFR) was calculated from serum creatinine with the Cockroft-Gault (CG) and abbreviated Modified Diet and Renal Disease(MDRD) equations. We have used CG adjusted for body surface area as the method for GFR estimates in the following work. Every participant filled in a self-administered

questionnaire on medical and personal history including family history of cardiovascular disease. The impact of heredity was analysed using binary logistic regression.

Results: Mean GFR for males was 89±16 ml/min/1.73m2 and for females 83 ml/min/1.73 m2, respectively. Males with heredity for MI at the age of 43 years has a 2.5 times higher risk (p=0.02) of belonging to the group with GFR less than 45 ml/min/1.73m^2 compared to those without heredity.

GFR 45 ml/min. Males

	n	HR	p
Heredity for MI	22153	2.5	0.021
Previous MI	22153	9,8	0.004
Hypertension	22153	2.7	0.020
Diabetes	22153	2.9	0.061
BMI	22153	0.92	0.198
Cholesterol	22153	1.172	0.345
Age	22153	1.045	0.142

For the whole cohort the increased risk was 4.6 times (p=0.147). At a cut-off at 60 ml/min/1.73 m2 the HR was 2.4 (p=0.003) for the whole group and for males HR 1.5 (p=0.001). In the whole cohort previous MI sevenfolded (7.5, p=0.008) the risk of belonging to the group with GFR less than 45 ml/min/1.73m2. For males the HR was 9.8 (p=0,004).

Conclusions: These findings suggest that genetic variants may underly predisposition to CKD in patients with heredity for or history of MI. The genetic background remains largely unknown and needs further exploration.

PUB205

Treatment of Focal Segmental Glomerulosclerosis with ACTH Anna-lena Berg, Julia Dolinina, Omran Bakoush. *Lund University, Lund, Sweden.*

Background: We previously reported that synthetic ACTH1-24 (Synacthen Depot) improved proteinuria in patients with membranous nephropathy. Experimental data suggest that ACTH may reduce proteinuria via activation of melanocortin receptors expressed on white blood cells and/or in the kidney, independent of its effects on cortisol production.

Methods: 10 patients with severe Focal Segmental Glomerulosclerosis (FSGS) (median age 45 yr, range 19-66) were treated with ACTH. Prior to starting ACTH, all patients were treated with prednisolone in combination with other immunosuppressants, including cyclosporine, tacrolimus, mycophenolate mofetil and/or cyclophosphamide. Data was collected over a 3 yr period after replacing prednisolone with ACTH, while continuing therapy with a second immunosuppressive agent. Median time from FSGS diagnosis to initiation of ACTH therapy was 30 mo (range 2-108). Treatment with ACTH started at 1 mg/wk and was increased to a maximum of 1 mg 2x/wk. The median duration of ACTH therapy was 18 mo (range 7-48), and follow up data were obtained 0-29 mo after stopping ACTH. All patients were treated with standard of care, including ACEI/ARB, statins, and other symptomatic therapies.

Results: Urinary albumin decreased from a pre-ACTH median of 5517 mg/L (range 386-26061) to 1086 mg/L (range 69-3296) with ACTH, and remained low at last follow up (median 178 mg/L, range:17-4253) (p<0.01 at both time points vs baseline). Serum albumin increased from a pre-ACTH median of 23 g/L (range 15-35) to 35.5 g/L (range 23-44) after ACTH, and remained improved at last follow up (median 35 g/ L, range 21-43) (p<0.0001 at both points vs baseline). eGFR and serum creatinine did not change significantly with ACTH or at last follow up. Eight patients reached complete (proteinuria <200 mg/L; 3 patients) or partial (proteinuria reduced by 50% to <2000 mg/L; 5 patients) remission. At last follow up, 5 patients were in complete and 2 patients in partial remission, 2 patients were off immunosuppression and 7 patients remained on their second immunosuppressive agent, and one patient progressed to ESRD.

Conclusions: ACTH in combination with other immunosuppressive agents may be more effective than prednisolone for reducing proteinuria in patients with severe FSGS.

PUB206

Healthcare Use and Costs before and after Parathyroidectomy in Dialysis Patients Vasily Belozeroff,[1] Kerry Cooper,[1] Gregory P. Hess,[2] Chun-lan Chang.[2] *[1]Amgen Inc., Thousand Oaks, CA; [2]IMS Health.*

Background: Parathyroidectomy (PTX) is often done in dialysis patients when medical treatment fails to control secondary hyperparathyroidism (SHPT). Such patients typically have been treated with drugs that include vitamin D analogs and calcimimetics, and PTX is viewed by many as a cost-containing measure. Nevertheless, information about health resource utilization and costs before and after PTX is limited.

Methods: This retrospective cohort study used professional service and pharmacy claims to identify dialysis patients undergoing PTX from 1/1/2008-12/31/2010. Subjects with primary hyperparathyroidism or kidney transplant were excluded. Only patients with at least 6 months of information before and after PTX were considered. Prescription use, physician encounters, and surgical complications during the 6 months immediately before and after PTX are reported.

Results: The mean (SD) age of the 181 study subjects was 51 (15) years; 59% female; 80% on Medicare. Overall, the percentage of patients receiving medications to manage altered mineral metabolism increased from 67% before to 79% after PTX. Specifically, cinacalcet use decreased and oral vitamin D use increased resulting in mean (SD) monthly medication charges decrease from $486 (507) to $226 (288) (p<0.01). The mean (SD) number of physician encounters rose from 15 (14) before to 21 (22) after PTX (p<0.01) resulting in the corresponding increase in mean (SD) monthly charges from $1531 (2150) to $1965 (3317) (p=0.08). Hypocalcemia was the predominant diagnosis linked to post-surgical physician encounters occurring in 31% of all subjects; 84% of hypocalcemic episodes were managed in acute care facilities.

Conclusions: The cost of medications to manage SHPT decreased after PTX largely due to reduction in cinacalcet use, whereas vitamin D use increased likely to manage hypocalcemia. The frequency and cost of physician encounters, especially in acute care settings, were higher in the 6 months after PTX attributable largely to episodes of severe hypocalcemia. Overall, the reduction in prescription costs during the 6 months after PTX is outweighed by higher costs associated with physician care.

PUB207

The Clinical Usefulness of Serum Cystatin C Levels for Early Detection of Renal Impairment in General Population Yan Qin, Ke Zheng, Xiaohong Fan, Jianfang Cai, Xuewang Li, Xuemei Li. *Kidney Division, Peking Union Medical College Hospital, Beijing, China.*

Background: The aim of the study was to evaluate clinical usefulness of serum cystatin C levels for early detection of renal impairment in general population.

Methods: In the epidemiology study of Pinggu District of Beijing, a total of 6287 participants aged over 18 years old were selected by systematic randomized cluster sampling.The questionnaire, blood pressure, serum creatinine(E), cystatin C levels, and albumin-creatinine ratio (ACR) were determined. Anthropometric and body composition data were also collected at the same time.

Results: In this population 6239 participants (99.24%) present with mildly renal impairment (eGFR more than 60 mL/min/1.73m^2 with CKD –EPI eGFR equation) while the prevalence of albuminuria was 10.58%. ROC curve analysis showed that the cut-off value of serum cystatin C for eGFR<90, <75, <60 mL/min/1.73m^2 was 0.93 (sensitivty 80.68%, specificity 82.44%, AUC 0.89), 1.05 (sensitivty 91.78%, specificity 91.54%, AUC 0.957), 1.27mmol/l (sensitivty 91.78%, specificity 91.54%, AUC 0.984), respectively. On the other hand the cut-off value of serum creatinine(E) for eGFR<90, <75, <60 mL/min/1.73m^2 was 65.9 (sensitivty 84.34%, specificity 69.85%, AUC 0.868), 72.3 (sensitivty 97.96%, specificity 81.87%, AUC 0.967), 84.2μmol/l (sensitivty 100%, specificity 95.86%, AUC 0.996), respectively. In multiple regression analysis, serum cystatin C was affected by age, bodyweight, CrE, total cholesterol(TC), waist to hip ratio(WHR) and ACR. After the adjustment of other factors and controlled on confounding factors, the results of logistic regression analysis demonstrated that DM history, smoke history, drink history, and BMI,LDL-C,TC,UA, total fat and WHR may serve as risk factors of eGFR < 60 mL/min/1.73 m2, their odds ratios (OR) were 2.30, 1.79, 2.07, 1.04, 1.17, 1.11, 1.02, 1.03 and 92.47 (P<0.001) respectively. Higher literate level and inorganic weight might serve as protective factors with OR 0.52 and 0.69 (P<0.001), respectively.

Conclusions: In the general population, the detective ability of serum cystatin C is better than the serum creatinine for mildly-impaired renal function.

PUB208

Direct Renin Inhibition for IgA Nephropathy Andrew Lazar, Scot Eskestrand, Brandon Lazar. *Nephrology, Case Western Reserve University, Cleveland, OH.*

Background: IgA nephropathy is the most common primary glomerulonephritis throughout most developed countries of the world. Although this disorder was initially thought to follow a benign course, upwards of 30-40% of affected patients will progress to end stage renal disease over 25-30 years. It has been recognized that the intrarenal RAS system can manufacture angiotensin II locally, turning on NADPH oxidase and other proinflammatory pathways. It has been increasingly recognized that renin and prorenin directly, by acting on the Prorenin-renin receptor, can activate the RAS leading to angiotensin II production as well as AngII-independent mechanisms such as ERK-MAP kinase activation. Such receptors have been identified in both the mesangium and podocytes, raising the question of whether direct renin inhibition may be a treatment option for IgA nephropathy patients.

Methods: We identified two such patients with IgA nephropathy and proteinuria, started aliskiren in addition to an angiotensin receptor blocker at maxiumum dose. Both subjects had a normal creatinine. Blood pressure was less than 130/80 mmHg for both subjects prior to the addition on aliskiren. Both patients had microscopic hematuria.

Results: Within 10 weeks, subject one enjoyed a 67% drop in proteinuria, 86% by 4.5 months. Subject two enjoyed a drop of 56% at 6 months, 47% at two years. Blood pressure remained at goal, no symptoms of hypotension, no adverse effects. Both subjects had negative dipsticks for blood post-aliskiren.

Conclusions: As proteinuria reduction largely predicts renoprotection in many proteinuric renal disease outcome studies, results such as these are thought-provoking, and hypothesis-generating. Aliskiren was well-tolerated and was efficaceous in terms of proteinuria reduction, and may be a reasonable treatment option for IgA nephropathy patients, but warrants further evaluation.

PUB209

The Analysis of Prognosis and Risk Factor for CKD in HIV-Infected Japanese Patients Junya Yamamoto,[1] Daigo Nakazawa,[1] Yasunobu Ishikawa,[1] Naoko Matsuoka,[1] Akiko Sato,[1] Tasuku Nakagaki,[1] Sekiya Shibazaki,[1] Katsuya Fujimoto,[2] Tomoyuki Endo,[2] Saori Nishio,[1] Tatsuya Atsumi.[1] *[1]Department Medicine II, Hokkaido University, Sapporo, Hokkaido, Japan; [2]Department of Hematology, Hokkaido University, Sapporo, Hokkaido, Japan.*

Background: As HIV-infected patients live longer while receiving highly active antiretroviral therapy, chronic disease, in particular chronic kidney disease (CKD) has increased. In this study we aimed to evaluate the course and feature of CKD /HIV patients for long time.

Methods: We retrospectively followed 153 HIV patients who were treated at Hokkaido University hospital for more than a year (from 1990 to 2011). We recorded their CKD stage and various factor (age, gender, serum-creatinine, eGFR, serum albumin, proteinuria, hematuria, presence of hemophilia, HCV/HBV infection, diabetes mellitus, hypertension, hyperlipidemia). We evaluated the proportion of CKD stage at the end of visit and risk factor for progressive CKD by the univariate and multivariate regression analysis.

Results: First visit findings were the following; Age 44.5 years, serum-creatinine 0.80 mg/dl, eGFR 99.6 ml/min/1.73m^2, serum-albumin 4.38 g/dl (these data show average), men/women 149/4, proteinuria (≥1+) 11.3%, hematuria (≥1+) 6.1%, hemophilia 18.3%, HCV 22.3%, HBV 12.0%. The average of observation period was 7.1 years. The average of eGFR reduction rate in HIV patients was 2.9 %/year and was significantly higher than in general Japanese (0.36 %/year). The number of CKD stage at the end of visit was non-CKD; 75, CKD2; 66, CKD3; 11, CKD4; 0, CKD5; 1. During this course the following complications occurred; diabetes mellitus 7.8%, hypertension 15.6%, hyperlipidemia 23.8%. In CKD patients, age, the frequency of low eGFR (first visit), the presence of proteinuria and hypertension tended to be higher than in non-CKD patients. By multivariate regression analysis, age, low eGFR (first visit), proteinuria were significantly associated with the progression of CKD.

Conclusions: CKD was prevalent in HIV-infected Japanese patients, The eGFR levels were significantly decreased in HIV patients. Age, eGFR (first visit), presence of proteinuria could possibly be risk factor for the progression of CKD.

PUB210

Medication Adherence to Antihypertensive and Phosphate Lowering Medications in Hemodialysis Patients John Paul Harmon,[1] Martin Glen MacKinnon.[2] *[1]Medical Education, Dalhousie University, Saint John, NB, Canada; [2]Internal Medicine, Division of Nephrology, Horizon Health Network, Saint John, NB, Canada.*

Background: The Saint John Regional Hospital nephrology department dispenses prescription medication to almost all of its hemodialysis patients. This provides a relatively unique opportunity to study medication adherence in this population. Medication possession ration (MPR) is a commonly used formula that estimates medication adherence. It is used to calculate the percentage of time a patient has access to a medication using prescription refill history. Many trials consider an acceptable adherence rate to be greater than or equal to 80%.

Methods: We identified non-acute hemodialysis patients who had prescriptions filled between January 1, 2010 and October 31, 2011. In this retrospective study, we collected patient refill data for phosphate lowering and antihypertensive medications. A total of 37 patients met our inclusion criteria and gave consent. MPR values were calculated and compared to average serum phosphate levels, an average of pre- and post-dialysis blood pressures and average fluid removed on dialysis.

Results: Non-adherence (MPR <0.80) was seen in a significantly greater proportion of patients taking phosphate lowering medication (N=21 of 33, 64%) compared to antihypertensive medications (N=5 of 27, 19%) [$X^2(1, N = 37) = 10.54$, $p = .001$]. Patients who were adherent to phosphate lowering medication had significantly lower serum phosphate levels compared to their non-adherent counterparts.

Phosphate Lowering Medications

Mean combined MPR	Number of patients	Mean serum phosphate
<0.8	21 (64%)	2.07mmol/L
≥0.8	12 (36%)	1.73mmol/L

[$t(28)=2.31$, $p = .029$]

Medication adherence to antihypertensive medication was not a significant factor contributing to mean pre- and post-dialysis blood pressures or average fluid removed on hemodialysis.

Conclusions: Medication adherence is likely an important factor contributing to serum phosphate levels in hemodialysis patients. Clinicians should be aware of lower adherence rates to phosphate lowering medications and develop approaches to improve adherence as part of a comprehensive strategy for better serum phosphate control.

PUB211

Predictive Values of PTH[1-84] and of PTH[1-84] to PTH[non-1-84] Ratio for Mortality in Patients with Chronic Kidney Disease Cedric Gauci,[1,2] Benedicte Stengel,[2] Marc Froissart,[1,2] Jean-philippe Haymann,[3] Tilman B. Drueke,[4] Pascal Houillier.[1] *[1]Division of Physiology, HEGP Hospital, Paris-Descartes University, Paris, France; [2]Inserm U1018, CESP, Villejuif, France; [3]Division of Physiology, Tenon Hospital, Pierre and Marie Curie University, Paris, France; [4]Inserm U1088, Picardie University, Amiens, France.*

Background: Excessive serum 'intact' parathyroid hormone (iPTH) levels in dialysis patients are associated with an increase in the relative risk (RR) of mortality. The commonly used iPTH assays measure both PTH[1-84)] and PTH fragments that may exert actions opposite to those of PTH[1-84]. Thus, PTH[1-84] or the ratio of PTH[1-84] to PTH[non-1-84] could be better predictors for mortality than iPTH.

Methods: We tested these hypotheses in 343 CKD stage 2-5 patients from the French NephroTest cohort, age 59 years, men 73%, diabetes 26%. Serum PTH[1-84] and iPTH were measured by the Duo PTH assay (Scantibodies) (normal ranges, 5-36 and 15-66 pg/mL, respectively), and PTH[non-1-84] calculated as the difference between iPTH and PTH[1-84].

Results: Baseline PTH[1-84] was 34.7 pg/mL, and iPTH 49 pg/mL. Patients were subdivided according to baseline PTH[1-84] quartiles: Q1 [< 22 pg/mL], Q2 [22-35], Q3 [35-59], and Q4 [>59]. After a mean follow-up of 6 years, 10, 16, 20, and 29 deaths were observed in Q1, Q2, Q3, and Q4 patient subgroups respectively. Crude hazard ratios (HR) and 95% confidence intervals for all-cause mortality were 1.61 [0.73-3.55], 2.43 [1.14-5.19], and 5.31 [2.58-10.93] for Q2, Q3, and Q4 as compared with Q1 (reference). An adjusting model for age, gender, diabetes and 24hr proteinuria with stratification for baseline mGFR provided HR of 1.6 [0.70 - 3.66], 1.36 [0.60 -3.07], and 2.53 [1.14 – 5.59] for Q2, Q3, and Q4 respectively. Neither PTH[1-84] to PTH[non1-84] ratio nor iPTH alone were associated with mortality risk. Presence of diabetes and proteinuria conferred higher mortality RR.

Conclusions: In patients with CKD stages 2-5 a high PTH[1-84] level, but not iPTH or PTH ratio, is associated with an increased risk of mortality. Distinguishing total PTH from its fragments may be important in terms of patient outcomes.

Renal-Angiomyolipoma Related Conditions before and after Renal Artery Embolization or Nephrectomy: A US National Retrospective Cohort Study Hearns Charles,[1] Peter Sun,[2] Zhimei Liu,[3] Judith A. Prestifilippo,[3] John C. Hulbert,[4] John J. Bissler.[5] *[1]NYU Langone Medical Center; [2]Kailo Research Group; [3]Novartis; [4]Urologic Physicians PA; [5]University of Cincinnati.*

Background: This study aimed to compare renal angiomyolipoma (AML) related conditions before and after renal artery embolization (RAE) or nephrectomy in patients with AML in the United States.

Methods: We conducted a retrospective cohort study using three US national health claims databases (Years: 2000-2010; Covered population: >60 millions). AML patients with health plan enrollment in the year preceding and following newly observed embolization or nephrectomy were included. Each embolization or nephrectomy cohort was further divided into TSC-AML and sporadic AML subgroups based on patients' TSC claim history. The prevalence rates of AML related clinical conditions were estimated. Repeated measures analysis and bootstrapping methods were used to assess cross-period differences in these prevalence rates.

Results: The embolization cohort (N= 9,901) had a mean age of 50.6 years at the newly observed RAE. AML related conditions with significant post embolization increase (before vs. after) were unspecified disorder of kidney or ureter (17.1% vs. 19.2%, $p<0.05$), end stage renal diseases (1.6% vs. 2.3%, $p<0.05$), anemia in chronic kidney disease (1.8% vs. 2.4%, $p<0.05$), and gross hematuria (0.0% vs. 0.2%, $p<0.05$). Non-acute renal insufficiency increased in the TSC AML sub-cohort (5.8% vs. 6.0%, $p<0.05$), but decreased in the sporadic AML sub-cohort (4.8% vs. 4.0%, $p<0.05$) after RAE. The nephrectomy cohort (N=15,381) had a mean age of 52.2 years at the newly observed nephrectomy. Unspecified disorder of kidney or ureter (15.0% vs. 16.2%, $p<0.05$), anemia in chronic kidney disease (1.7% vs. 2.0%) and end stage renal diseases (1.5% vs. 1.8%, $p<0.05$) increased after surgery. These trends were consistent for TSC AML and sporadic AML. Other AML related conditions remained similar after the procedures.

Conclusions: This study suggested that after RAE or nephrectomy, the prevalence of some AML related clinical conditions in patients with AML seemed to increase. This association warrants further investigation.

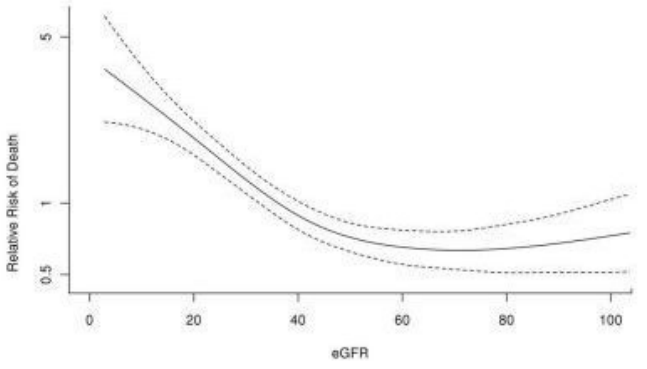
Chronic Kidney Disease Progression and Mortality in Liver Transplant Recipients Alina M. Allen, W. Ray Kim, Terry Therneau, Chun Fan, Andrew D. Rule, Julie Heimbach. *Gastroenterology and Hepatology, Biomedical Statistics, Nephrology, Transplant Surgery, Mayo Clinic, Rochester, MN.*

Background: Chronic kidney disease (CKD) is a common comorbidity in liver transplant (LTx) recipients. It is well known that CKD leads to increased mortality; the exact magnitude of mortality risk as a result of reduced renal function is not defined in LTx recipients.

Methods: A database that prospectively tracks all LTx recipients at this academic transplant program was queried to identify all adult primary LTx recipients. Our post-LTx

protocol incorporates glomerular filtration rate (GFR) at regular intervals. If measured GFR data were not available, it was estimated by using a formula that we previously developed based on age, sex, standardized serum creatinine, albumin and hemoglobin. Time-dependent Cox regression analysis was performed to evaluate the impact of GFR changes on survival.

Results: A total of 1860 liver transplant recipients met the eligibility criteria (median age was 52 years, 58% male and 78% Caucasians). After a mean follow-up of 7.6 years, 612 (32.9%) died and 58 (3.1%) underwent renal transplantation. The figure illustrates the influence of GFR on mortality. Mortality risk does not increase when GFR remained above 60 (CKD stage 2 or less); reduction in GFR below 60 was associated with significant increase in the risk of death. Thus, patients in CKD stage 3 had 1.17 fold increase ([HR]=1.17, 95%[CI]=0.89-1.55) in mortality, whereas CKD stage 4 had 2.5-fold increase (HR=2.5, 95%CI=1.8-3.45). As expected, patients with endstage CKD faced extremely high mortality risk (HR=4.24, 95%CI=2.69-6.67).



Conclusions: While early stage CKD (GFR>60) did not have demonstrable effect on mortality, reduction of GFR beyond CKD stage 3 increased mortality in an exponential fashion, thus prevention and early recognition of CKD in LTx recipients is important.

PUB214

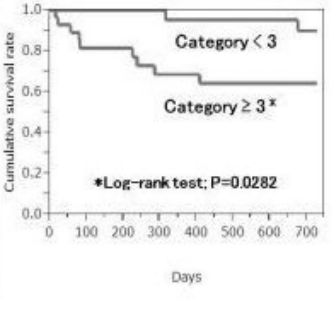
A New Risk Assessment of Myeloma Patients with Chronic Kidney Disease Using Proteinuria and Estimated Glomerular Filtration Rate Minoru Ando,[1] Ken Tsuchiya,[2] Kosaku Nitta.[2] *[1]Department of Nephrology, Tokyo Metropolitan Komagome Hospital, Tokyo, Japan; [2]Department IV of Internal Medicine, Tokyo Women's Medical University, Tokyo, Japan.*

Background: A 2009 Kidney Disease: Improving Global Outcomes (KDIGO) conference report proposed a category system adding emphasis on risk stratification for chronic kidney disease (CKD), combining proteinuria and estimated glomerular filtration rate (eGFR). This new category system could be useful to correctly identify myeloma patients at high risk for death.

Methods: A total of 106 patients were diagnosed as myeloma between August 2004 and September 2011 in our hospital. Among them, 48 patients (26 men, 22 women, mean age, 65 years) were prospectively followed-up over 2 years. eGFR at baseline was calculated based on serum creatinine and graded into 5 (≥90, 60-89, 45-59, 30-44, and 15-29 ml/min/1.73m^2). Proteinuria was separated as normal (dipstick test, negative), mild (dipstick test, ± or 1+), and heavy (dipstick test ≥2+). Myeloma patients were classified into 5 risk categories combining both variables. Cumulative survival rate was analyzed by the Kaplan-Meier method, which was stratified by presence and absence of CKD ≥risk category 3.

Results: Classification of all myeloma patients is shown in Table. Seventy-two (68%) had CKD with risk category ≥1, of which 26 (25%) were included in the highest risk category 4. During the 2-year follow-up, 7 out of 43 patients (16%) died, of which 4 (57%) were include in category 4. Cumulative survival rate was significantly lower in patients with CKD ≥risk category 3 (log-rank test; P=0.0282), shown in Figure.

n=106	Proteinuria		
eGFR	Negative	Mild	Heavy
≥90	Risk category 0 No CKD 34 (32.1%)	Risk category 1 18 (17.0%)	Risk category 3 14 (13.2%)
60-89			
45-59	Risk category 1 6 (5.7%)	Risk category 2 3 (2.8%)	Risk category 4 26 (24.5%)
30-44	Risk category 2 2 (1.9%)	Risk category 3 2 (1.9%)	
15-29	Risk category 3 1 (0.9%)		



Conclusions: The new category system may facilitate targeting CKD patients who are at high risk for death among a myeloma population.

PUB215

Outbreak Investigation in Nicaragua: Physician and Pharmacist Perceptions of Chronic Kidney Disease Madeleine Kangsen Scammell,[1] Oriana Ramirez-rubio,[1,2] Daniel R. Brooks,[1] James S. Kaufman,[3] Juan Jose Amador,[1] Daniel E. Weiner.[4] *[1]Boston University School of Public Health, Boston, MA; [2]Universidad Autonoma de Madrid, Madrid, Spain; [3]Boston University School of Medicine, Boston, MA; [4]Tufts Medical Center, Boston, MA.*

Background: Northwestern Nicaragua has a high prevalence of chronic kidney disease (CKD) of unknown etiology among young adult men. A high frequency of urinary tract infections (UTI) is also reported among men along with a syndrome described by manual laborers as "chistata." This study examines health professionals´ perceptions regarding etiology of CKD, UTI and chistata, and their treatment approaches, including use of potentially nephrotoxic medications.

Methods: Nineteen in-person semi-structured interviews were conducted in November 2010 among ten randomly selected physicians and nine pharmacists in the region. Using qualitative methods, responses were coded and analyzed for patterns of agreement or disagreement and the occurrence of themes.

Results: Health professionals perceived CKD as a serious and growing problem in the region, primarily affecting young men working as manual laborers without traditional risk factors for CKD. All interviewees regarded occupational and environmental exposure to sun, heat, and dehydration as critical factors associated with the occurrence of CKD, and noted that hydration practices may be influenced by perceived water contamination. These factors were also considered to play a role in the occurrence of chistata, often treated with non-steroidal anti-inflammatory drugs (NSAIDs), diuretics and antibiotics, including quinolones and aminoglycosides. Physicians acknowledged that the diagnosis of UTI was usually not based on microbial culture, and opined that the use of potentially nephrotoxic medications may be contributing to CKD.

Conclusions: Interviews provided evidence suggesting that diuretics, antibiotics and NSAIDs are widely used and sold over the counter for symptoms that may be related to volume depletion. Acute kidney damage coupled with volume depletion and exposures including medications and should be further evaluated as causal factors for CKD in this region.

PUB216

Prevalence of Chronic Kidney Disease in Egypt, Results from the Screening and Early Evaluation of Kidney Disease (SEEK-Egypt Study) Youssef M.K. Farag,[1] Ajay K. Singh,[2] Mohamed Kamel Farag.[3] *[1]Medicine - Renal, Brigham and Women's Hospital and Harvard Medical School, Boston, MA; [2]Medicine - Renal, Brigham and Women's Hospital and Harvard Medical School, Boston, MA; [3]Epidemiology, Mansoura University Faculty of Medicine, Mansoura, DK, Egypt.*

Background: Chronic kidney disease (CKD) is an inadequately recognized problem in developing countries, including Egypt. The lack of documented large scale population-based research evidence regarding the magnitude of CKD in Egypt is responsible in part for this knowledge gap. This is a health screening research project aimed at estimating the prevalence and risk factors of CKD in Egypt, identifying persons at increased risk for kidney disease, and encouraging at-risk persons to seek further evaluation with appropriate risk management from a healthcare provider.

Methods: We screened 600 apparently healthy subjects as a representative sample of the population of Nile Delta using multi-stage stratified random sampling technique. All subjects were interviewed by a previously trained physician, and data were collected through specifically designed questionnaire used in the SEEK study in other countries. Anthropometric measures and vital signs were recorded. Blood and urine samples were collected.

Results: 600 participants were included in the study. Males comprised 38.5%. Mean age was 42.85 years (±10.86). Mean eGFR was 100.15 ± 27.37 mL/min/1.73 m2. The main finding of this study is that the prevalence of CKD (based on the NKF criteria) is 8%. We found macroalbuminuria in 3% of our sample. When we included participants with abnormal urine albumin/creatinine ratio (UACR), the prevalence of CKD became 15%. CKD was highest among hypertensives ($p<0.001$) and those with high school educational level ($p=0.025$). There was no significant difference in the distribution of CKD as regard to gender or anemia status.

Conclusions: We report a prevalence of CKD of 8-15% from a representative sample from Northern Egypt. Screening programs of individuals at risk of CKD may play an important role in early detection and management of CKD.

PUB217

Stress and Burnout among Nephrology-Dialysis Staff: Results of a 2012 Survey in a Mayo Clinic HD Unit Macaulay A. Onuigbo.[1,2] *[1]College of Medicine, Mayo Clnic, Rochester, MN; [2]Nephrology, Mayo Clinic Health System, Eau Claire, WI.*

Background: The concept of burnout in the workplace was introduced in the late 1970s, mainly in a US context. Healthcare delivery is generally acknowledged to be a stressful industry but few studies in this area are available. Even far less reported is stress or burnout in nephrology practices.

Methods: A preliminary cross-sectional hand-delivered questionnaire-based survey of physicians, nurses, dialysis technicians, social workers and dieticians in a nephrology-

dialysis practice in Mayo Clinic, Eau Claire, WI using the Oldenburg Burnout Inventory (OLBI) (Fig 1) was carried out in January 2012.

The Oldenburg Burnout Inventory

Please provide the following code: The first two letters of your high school (e.g., City High School would be CI), the month and day of your mother's birthday (e.g., July 10 would be 0710), and the last two letters of the city you were born in (e.g., Wausau would be AU). Following the examples above, the code would be CI0710AU.

Please enter your code here: _____

	Strongly Agree	Agree	Neutral	Disagree	Strongly Disagree
1. I always find new and interesting aspects in my work.	5	4	3	2	1
2. There are days that I feel already tired before I go to work.	5	4	3	2	1
3. It happens more and more often that I talk about my work in a derogatory way.	5	4	3	2	1
4. After my work, I now need more time to relax than in the past to become fit again.	5	4	3	2	1
5. I can stand the pressure of my work very well.	5	4	3	2	1
6. Lately, I tend to think less during my work and just execute it mechanically.	5	4	3	2	1
7. I experience my work as a real challenge.	5	4	3	2	1
8. During my work, I often feel emotionally drained.	5	4	3	2	1
9. With the time, one loses the internal relationship with one's work.	5	4	3	2	1
10. After my work, I usually feel still totally fit for my leisure activities.	5	4	3	2	1
11. Sometimes I feel really sick about my work tasks.	5	4	3	2	1
12. After my work, I usually feel worn out and weary.	5	4	3	2	1
13. I cannot imagine another occupation for myself.	5	4	3	2	1
14. Normally, I can manage the amount of work well.	5	4	3	2	1
15. I get more and more engaged in my work.	5	4	3	2	1
16. When I work, I usually feel energized.	5	4	3	2	1

Results: Eighteen survey questionnaires were distributed across the clinic and sixteen were returned in a completed form, giving a response rate of 89%, mostly female nurses, age range 30-60, average age about 40 years. The average emotional exhaustion score on the OLBI was 2.66, consistent with a low level of emotional exhaustion. Similarly, the average disengagement score was 2.45, again consistent with a low level of disengagement.

Conclusions: The low level of emotional exhaustion and disengagement reported amongst was pleasantly surprising. Higher levels had been anticipated, especially with the inclusion of the dialysis nurses who have often expressed higher levels of anxiety about work-related stressors. The mixture of clerical and clinical staff may have affected the average results obtained from the staff survey. One recurring source of stressors for the staff revolved around the non user-friendliness of the EMR system(s). Further studies focused on specific healthcare professionals are planned in the near future.

PUB218

Radiocontrast Prophylaxis in Patients Receiving Chronic Dialysis Vandana A. Palan, Syed N. Babar, John A. Walker. *Medicine, UMDNJ - Robert Wood Johnson Medical School, New Brunswick, NJ.*

Background: Preserving residual renal function (RRF) in patients receiving chronic dialysis is desirable, since RRF may augment the efficacy of renal replacement therapy and is associated with a lower mortality risk. RRF may be threatened by the intravenous administration of iodinated radiocontrast (IRC) agents. Although radiocontrast prophylaxis (RP) has been studied extensively in the general chronic kidney disease (CKD) population, RP has received little attention in dialysis dependent CKD. The aim of this retrospective cohort study was to investigate the RP prescribing patterns employed in CKD patients receiving chronic dialysis.

Methods: The charts of all adult patients admitted during a six-month period to a single university hospital with ICD codes 585.5 or 585.6 and CPT codes for imaging procedures potentially requiring IRC were identified. Identified charts were reviewed for: 1) type of dialysis and 2) use and modality of RP.

Results: The records of 82 patients meeting the aforementioned criteria were identified; this set included 19 patients with Stage 5 CKD who were not receiving dialysis. Of the the 63 patients receiving chronic dialysis, 13 were not given IRC and were excluded from further analysis, thus yielding a final study cohort of 50 patients.The mean age (± SD) of this cohort was 64.8 ± 14.3 years; 37 were men, and 28 had diabetes mellitus. 42 patients were receiving hemodialysis (HD) and 8 were receiving peritoneal dialysis (PD). 10 of these 50 patients received at least one form of RP:

Types of Imaging Studies and RP Modality

			RP Modality			
Study Type	Total	RP Prescribed	IV Fluid	Acetylcysteine	Withhold ACEI/ARB	Other
Cardiac Catheterization	27	5	3	1	1	1
Fistulagram	13	3	3			
CT Scan	8	0				
Angiogram	2	2			2	

Conclusions: Only 20% of the study cohort received any type of RP; intravenous fluid was the most frequent RP modality. Patients receiving PD were more likely to receive RP than patients receiving HD (75% v. 9.5%, respectively, $p<0.01$). In contrast, 100% of non-dialysis Stage 5 CKD patients received RP. The basis for this relative under-prescription of RP ($p<0.01$) and its impact upon RRF or other parameters in the dialysis population are uncertain and merit further study.

PUB219

Assessment of Dose Relativity: Lanthanum Carbonate versus Sevelamer Rosamund J. Wilson,[1] J. Brian Copley.[2] *[1]Spica Consultants, Marlborough, United Kingdom; [2]Shire Pharmaceuticals, Wayne, PA.*

Background: Knowing the dose relativity of phosphate binders (PBs) may assist clinicians when reviewing a patient's PB regimen. However, the method used to assess dose relativity is critical, because patient type and disease severity may influence the choice and average doses of PBs used. Patient data from a large US dialysis provider that were compared retrospectively based on switches made between common PBs, suggested patients receiving lanthanum carbonate (LC) may have had different characteristics from patients placed on other PBs. Therefore, using such a database to estimate PB dose relativity may be sub-optimal.

Methods: Better estimates of dose relativity may be obtained from observational studies, in which individual patients switch PBs to determine the effectiveness of each, and from randomized clinical studies, in which patients fulfilling similar inclusion criteria are treated to a serum phosphate target and PB dose is reported. We conducted an extensive literature review, evaluated observational studies and reviewed large meta-analyses that assessed the dose relativity of sevelamer (Sev) to LC.

Results: One study in which individuals receiving Sev switched to LC, found that patients who were receiving a mean Sev dose of 7.6 g/day before switching, were receiving LC at 2.8 g/day after 12 weeks (Sev:LC = 2.7). Another study found that patients switching from Sev to LC received a mean Sev dose of 7.3 g/day before switching, and a mean LC dose of 2.3 g/day 1 year after switching (Sev:LC = 3.3). Among patients who switched from any binder, the mean dose of LC was 2.3 g/day, compared with a mean dose of 6.5 g/day for all patients on Sev prior to switching (Sev:LC = 2.8). Two meta-analyses gave dose relativity assessments of 2.7. The largest of these included over 3000 haemodialysis patients and 17 studies. These estimates are generally consistent with the World Health Organization defined daily doses of 6.4 g Sev and 2.25 g LC (Sev:LC = 2.8).

Conclusions: The choice and doses of PBs used in clinical practice that are summarized in large databases may be influenced by patient type and disease severity. Accurate dose relativity assessments may assist management of PB therapy.

PUB220

Nutritional Status in Haemodialysis Patients Receiving Lanthanum Carbonate Rosamund J. Wilson,[1] Pinggao Zhang,[2] J. Brian Copley.[2] *[1]Spica Consultants, Marlborough, United Kingdom; [2]Shire Pharmaceuticals, Wayne, PA.*

Background: Low serum albumin (alb) can be indicative of poor nutritional status and is a predictor of mortality in haemodialysis (HD) patients. The Dialysis Outcomes and Practice Patterns Study 4 (DOPPS-4) determined the proportion of HD patients achieving the KDOQI guideline alb level of ≥ 4.0 g/dL, and found wide variation between countries (8.5% to 42.5% of patients). This indicates a need to improve alb levels (and possibly outcomes) in HD patients and this may be achievable by increasing protein intake. However, increased protein intake is associated with increased intake of phosphate (P), which can lead to hyperphosphataemia.

Methods: To evaluate and compare the alb and P status of HD patients undergoing lanthanum carbonate (LC) therapy, we conducted post hoc analyses of two large studies: a randomized, controlled clinical study conducted in the EU (n = 510), and a real-world prospective observational study conducted in the USA (n = 2520). Neither study encouraged dietary measures to increase alb levels.

Results: In both studies, the proportion of patients with alb ≥ 4.0 g/dL was essentially unchanged while on treatment. After 24 weeks of treatment in the controlled study, alb ≥ 4.0 g/dL was achieved by 75% (167/223) of patients, and by 80% (97/121) of patients with simultaneously controlled P (3.5–5.5 mg/dL). In the real-world study after 16 weeks of treatment, alb ≥ 4.0 g/dL was achieved by 43% (847/1985) of patients and by 41% (286/694) of patients with simultaneously controlled P.

Conclusions: Most patients in the controlled study met the KDOQI target for alb, implying that patients in clinical trials may not be representative of the overall patient population. The real-world data are consistent with the best countries in DOPPS-4, and highlight that the majority of HD patients are not achieving this target. Measures to increase the proportion of patients achieving alb ≥ 4.0 g/dL, while controlling serum P, may therefore be beneficial. Among patients capable of augmenting their protein intake, increasing P-binder dose, or using high capacity P-binders such as LC, may allow improvements in nutritional status while maintaining simultaneous P control.

PUB221

Cost-Effectiveness of Lanthanum Carbonate for the Treatment of Hyperphosphatemia in Chronic Kidney Disease Michael S. Keith,[1] Therese M. Conner,[2] Rosamund J. Wilson.[3] *[1]Shire Pharmaceuticals, Wayne, PA; [2]Independent Consultant, Austin, TX; [3]Spica Consultants, Marlborough, United Kingdom.*

Background: Hyperphosphatemia associated with chronic kidney disease (CKD) significantly contributes to patient morbidity and mortality, as well as high treatment cost. Noncalcium phosphate (P)-binders control patients' serum P levels, and are recommended in the presence of hypercalcemia, adynamic bone disease, and vascular calcification. Despite growing interest in costs and outcomes, there have been few cost-effectiveness (CE) analyses of phosphate binder use in CKD. This review summarizes research on the economics of

the noncalcium P-binder lanthanum carbonate (LC) in predialysis and dialysis patients. An additional goal was to summarize cost data between LC and sevelamer hydrochloride (SH).

Methods: On-line databases were used to perform an extensive literature review of publically-available studies published between 2005 and 2011 inclusive. In addition, we evaluated other publically-available studies that reported costs and/or CE associated with LC.

Results: Seven studies of dialysis or predialysis patients were identified and reviewed. Two studies were US-based. Six employed decision analytic modeling methods. Three focused on the use of LC compared with existing treatments, concluding that LC is a cost-effective treatment for hyperphosphataemia. Further, one of these showed that CE ratios were particularly favorable for P > 6.6 mg/dL. Three studies showed cost savings with LC compared to SH, and two of these also demonstrated a lower pill burden with LC. One study provided a head-to-head CE comparison between LC and SH, and reported LC to be the more cost-effective treatment. Patients treated with LC had slightly higher total costs, but had improvements in quality-adjusted life years, survival and greater reductions in serum P levels, than patients treated with SH.

Conclusions: Current evidence indicates LC is a cost-effective treatment for hyperphosphatemia in both predialysis and dialysis patients when compared to calcium-based binders or SH. These findings have been reported in North America and Europe, using different methods.

PUB222

Willingness to Participate in Clinical Research and Perceived Risks of Autosomal Dominant Polycystic Kidney Disease (ADPKD) among African Americans Caitlin Blake, Terry J. Watnick, L. Ebony Boulware, Tariq Shafi, Michael J. Choi, Raquel Greer. *Johns Hopkins Medicine Institutions, Baltimore, MD.*

Background: Despite a similar prevalence of ADPKD in African Americans and Whites, African Americans have been markedly underrepresented in ADPKD research studies. Little is known about African Americans' perceived risks and knowledge of ADPKD or their perceived barriers to participating in ADPKD clinical research.

Methods: We conducted 3 focus groups of African American ADPKD patients (n=9) and 2 focus groups of their family members (n=7) to elicit their knowledge and perceived risks about ADPKD and to identify their self-identified barriers to participating in ADPKD clinical trials. We also solicited participants' input on ways to increase African American research participation. We audiotaped and transcribed focus groups, and 2 independent investigators identified themes raised within groups.

Results: Many participants had poor knowledge of the ADPKD inheritance pattern, the natural history of ADPKD, or how to modify their risk of progression. Participants also poorly understood the potential impact of ADPKD on their health and the health of their family members: "…I never had any symptoms. I never thought about my kids having it…." Participants identified several perceived barriers to participating in ADPKD studies including, potential risk of harm, medical mistrust, fear of being used as a guinea pig, lack of knowledge, lack of time, and lost wages. Additionally, participants cited a low perceived benefit of ADPKD studies: "They keep telling you there's no cure for it, so why are you experimenting on me." To increase the number of African Americans in ADPKD studies, participants suggested increasing ADPKD awareness, utilizing physicians and other ADPKD patients for recruitment, and engaging the community.

Conclusions: African American ADPKD patients and their family members had limited knowledge of ADPKD and identified several perceived barriers to participating in ADPKD clinical research trials. Findings from this study suggest community outreach and ADPKD patient ambassadors will be critical to increasing the recruitment of African Americans in clinical trials.

Healthcare Utilization by Medicaid Recipients Pre- and Post-Transfer of Care to an Adult Nephrologist Edward Iglesia,[1] Hannah P. Kim,[1] Kristi Bickford,[2] Maria E. Ferris.[2] *[1]Robert Wood Johnson Medical School, Piscataway, NJ; [2]University of North Carolina Kidney Center, Chapel Hill, NC.*

Background: Studies have shown poor patient outcomes post-transfer from pediatric to adult-focused health services. Healthcare utilization around transition has not been well-characterized. We examined healthcare utilization by young adults pre- and post-transfer to adult nephrology.

Methods: We performed a retrospective study of patients ≥18 years old followed at the UNC Kidney Center pediatric nephrology clinic who were active Medicaid recipients and had transferred care to an adult nephrologist. We defined transfer date as the first visit with adult nephrology after which the patient no longer had visits with pediatric nephrology. Data was extracted from the electronic health record and the Community Care of North Carolina Medicaid Provider Portal. Healthcare utilization outcomes included hospital admissions, length of stay (LOS), emergency department (ED) visits, outpatient (OP) visits, and imaging. Outcomes were determined pre- and post-transfer, and comparative analyses were performed using Wilcoxon signed rank sum tests.

Results: Twenty adult patients had transferred care from pediatric to adult nephrology and had Medicaid data available pre- and post-transfer. Patients transferred at 19.7±1.1 years of age, 55% were female, and 70% African American. Healthcare utilization was determined for a median of 15.5 months (IQR 8-22) pre- and post-transfer. There was an 81% increase in admissions (p=0.04) post-transfer. Changes in all other healthcare utilization outcomes were not statistically significant.

Healthcare utilization pre- and post-transfer to adult-focused health services

	Pre-transfer	Post-transfer	% change	p-value
Admissions	21	38	+81	.04
LOS (days)	76	123	+62	.11
ED visits	55	79	+44	.69
OP visits	224	211	-6	.75
Imaging	232	279	+20	.40

Conclusions: A significant increase in admissions was observed post-transfer. While not significant, there were substantial increases in the number of ED visits and imaging. These results might suggest the need for better systems of care and interventions surrounding the transfer of young adults with kidney disease to adult-focused services.

PUB224

Could We Do a Reallocation of Public Financial Resources in the Maintenance of Nephrology Departments in the National Health Service? Would It Be More Cost-Efficient? Juan Abascal Ruiz, Rafael Alvarez Lipe. *Nephrology and Medicine Preventive, Hospital Lozano Blesa, Zaragoza, Spain.*

Background: Throughout the years 2000-2011 we have studied the whole health activity of our department and the costs it generates. We have done the same with the Hospital general costs and their fraction assigned to our department.

Objectives: The care work developed in nephrology units by our department and its assistance complexity do not require the whole infrastructure which needs for its optimal operation a third level hospital. On the other hand, the labour legislation makes the costs of specialized staff be larger if the work is done within a hospital.

Methods: The established method has been: **For Human Resources the distribution of work loads measured in hours considering the hour as the unit of technical value. For the health assistance we have applied microeconomics techniques (analytical management) and established the doctrine of homogeneous functional group.**

Results: They are exposed for each homogeneous functional group (hospitalization, consultations and its areas, interventionist nephrology, hypertension maps, intravenous iron treatment, haemodialysis and peritoneal haemodialysis within nephrology unit and extra-departmental emergencies. The economic cost of human resources in our department is 47.61%. The functioning costs are 31.32%. The costs of using other services are 17.15% and the structure costs of other services are 3.65% of the Nephrology unit budget. **Discussion:** A more rational use of any resources allocated in budget to unit is sought by means of the application of technical criteria and social management (criteria in the expense of money coming from public origin).

Conclusions: 1. - The ability to negotiate is possible in the 83.85% of our Department's budget.

2. - The possibility of negotiating, the existing work legislation in the 47.61%.of the budget except in a very small margin.

3. - The saving percentage of 10 points is possible on the 10.90% of present budget.

4.- A change in present labour legislation would make possible a thorough negotiation with the 47.61% of the Human resources budget.

Greetings: To Luisa Moya.

PUB225

Economics Costs and Trends in a Hospital: It Is Bearable for a Nephrology Department? Juan Abascal Ruiz,[2] Rafael Alvarez Lipe,[1] Felipe A. Monrroy.[2] *[1]Nephrology, Hospital Lozano Blesa, Zaragoza, Spain; [2]Medicine Preventive and Social, Hospital Lozano Blesa, Zaragoza, Spain.*

Background: Summary: Our Department is located in a reference hospital of the Spanish National Health Service.

Aims: Studying economic alternatives to improve the rational use of the cost of sanitary services paid with money from taxes.

Methods: We studied the costs and the most significant trends of our service. The percentage of costs which means the use of other hospital services and the percentage allocated within the overall budget allocated to our department. We studied our cost structure and each of our services and functional units.

We worked with "microeconomics techniques" of "functional groups" using "homogeneous procedures".

Results: The cost of hospital stay in the year 2011 is 402.91€. The price of the first and second consultation in that year had a cost of €107.62 and € 64.56 respectively.

The costs of AVF, indwelling catheters and percutaneous biopsy were € 254.62, € 114.5 and € 62.46 for these techniques. The single-use equipment, imaging and depreciation and use of premises was € 171.0€, 111.21 and € 130.0.

The staff cost, measured in technical value units was 2 hours to doctor and nurse and nursing assistant in the case of AVF and biopsy and 1 hour for a permanent catheter; ½ hours in the case of catheters no permanent. The estimated office staff time is 1/6 time for all processes and non-health personnel (cleaning and caretaker is 1 hour, 1 / 2 hours in the association of AVF and 1 / 2 hours of cleaning in the case not permanent. The percentage of emergency doctor is not included in the calculation of internal cost.**erall unit of**

Discussion:

We have studied the legal framework of Spanish legislation(Agreement by production/ economic sectors) " Convenios laborales" of all compatible production framework compatible with hospital performance.

Conclusions: The maintenance of "Health care quality" in a global setting of economic crisis makes it necessary to deepen in the microeconomic studies and set alternatives for the rational use of public resources in the Health environment.

Greetings: To the Department of Computer science of the our Hospital and to Dña. Luisa Moya advice on writing in English.

PUB226

Fighting Bloody Diarrhea for HUS Prevention and Mitigation: Lombardy Regional HUS Network: An Update Gianluigi Ardissino,[1] Sara Testa,[1] Fabio Paglialonga,[1] Stefania Salardi,[1] C. Baldioli,[2] N. Borsa,[1] E. Cama,[2] A. Caprioli,[1] L. Cariani,[2] D. Casnaghi,[2] L. Daprai,[2] Rosaria Colombo,[1] F. Minelli,[2] A. Negri,[2] B. Osnaghi,[2] L. Parola,[2] A. Pellegatta,[2] D. Picicco,[2] S. Rampoldi,[2] A. Rosco,[2] R. Rubini,[2] F. Russo,[2] S. Sardini,[2] G. Scavia,[1] M. Seia,[1] Silvana Tedeschi,[1] Francesca Tel,[1] E. Torresani,[1] R. Tozzoli.[1] *[1]Center for HUS Control, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico; [2]Rete Regionale SEU.*

Background: Typical hemolytic uremic syndrome (tHUS) still represents a major public health problem caused by VTEC infection often presenting with bloody diarrhea.

Methods: To identify patients at risk for tHUS early in the course of the disease, a network connecting pediatric hospitals in Lombardy (10 millions gp) was developed with 53 units partecipating. Since May 28 2010 children with bloody diarrhea were tested for Shigatoxin (Stx) 1 and 2 with a Reverse Dot Blot commercial kit (EHEC Arnika). The objectives of the project were: 1. to increase the ability of the surveillance system in identifying the sources of VTEC infection; 2. to understand the mechanisms of Stx delivery to target organs; 3. to test the potential role of overhydration to prevent or mitigate renal and CNS involvement.

Results: So far 632 patients have been tested. Hereafter are the preliminary results. 34 (5,4%) were positive for VTEC (80% non-O157 – 65% with Stx 2). Among negative samples Salmonella (25,0%), Campylobacter (14,6%) and EPEC (8,4%) were the most common identified bacteria. Among patients with negative colture (41,0%) 2 patient had Henoch-Schonlein purpura, 2 Meckel diverticulum, 1 acute pancreatitis and 1 ulcerative colitis.

Conclusions: The surveillance system indicates that in Lombardy: bloody diahrrea in children is due to VTEC in a significant portion of cases, non-O157, particularly O26, play an important role and most strains produce Stx2.The role of stx-negative, eae-positive strains deserves further attention.

Acknowledgement: the project is feasible thanks to the members of the Regional HUS Network whose complete list is available at www.centroseu.org. The project has been supported by the " PROGETTO ALICE ONLUS – Associazione per la lotta alla SEU".

A Qualitative Assessment of Patient Educational Materials: The Role of Phenomenology in the Increasing Kidney Awareness Network (IKAN) Transplant Project Clarence Spigner,[1] Bessie A. Young.[1,2,3] *[1]Health Services, School of Public Health, Seattle, WA; [2]VA Puget Sound Health Care System, Nephrology, Health Services Research and Development, Seattle, WA; [3]Kidney Research Institue, University of Washington, Seattle, WA.*

Background: We investigated world views about patient education materials for chronic kidney disease (CKD) from people most affected by the disease. The phenomenological approach was felt to be most appropriate technique.

Methods: We developed and tested our interview guide based on prior key informant interviews and asked about familiarity with existing CKD educational materials. A purposeful sample of 12 African American subjects was recruited from dialysis, transplant recipients, living kidney donors, potential kidney donors and pre-dialysis patients. Interviews were administered by a trained moderator and digitally-recorded and transcribed verbatim for content analysis. A matrix was created listing every relevant quote reflective of the questions asked. To ensure reliability and validity, each member of the research team independently defined and sorted quotes in the matrix into "clusters of meanings" which, in turn, resulted in discerning the themes. Overlapping and repetition of themes was avoided as much possible through consensus between research team members until saturation was obtained.

Results: Subjects suggested an overreliance on information in DVDs, pamphlets, brochures, and the internet. Materials have instilled "awareness" and "confidence" by having increased patient knowledge. While self-education materials are generally "understandable," they are also sometimes "overwhelming," "clinical" and "broad." Educational information "had everything" if patients "knew where to look." Most patients readily identified with people-of-color seen in most materials. Information was generally "clear," "easy to understand," but not always as specific to their particular bio-medical or social issue.

Conclusions: Focus groups provided crucial insights into a seemingly over-reliance on print and electronic self-education media. Materials are highly informative, but can be more effective when developed with direct input of the patient population.

Gene Expression in Postnatal Mouse Kidney Development Bo Wu,[1] Debashis Sahoo,[2] James D. Brooks.[1] *[1]Urology, Stanford University, Stanford, CA; [2]Stanford Institute for Stem Cell Biology and Regenerative Medicine, Stanford University, Stanford, CA.*

Background: Obstruction and other processes that lead to renal damage can have different effects in adult versus developing kidneys. These differences could influence selection of biomarkers used for detection of renal damage. To date, gene expression changes that occur in mouse kidney development postnatally have been poorly characterized. We describehere a comprehensive gene expression of thedeveloping mouse kidney based on microarray profiling.

Methods: C57BL/6 mice were sacrificed and kidneys were harvested at embryonic day E19.5, and postnatal days P1, P3, P5, P7, P10, P14, P21, P28 and P35. RNA was extracted from kidneys and transcript profiling was performed using Agilent microarrays. Transcripts that undergo abrupt transitions in expression level over the time course were identified using StepMiner analysis. Ingenuity pathway analysis (IPA) was used to analyze the biological function and gene networks of gene expression data.

Results: Transcript levels were modulated significantly over the time course, with 6949 up-regulated and 6696 down-regulated. IPA was used to identify genetic pathways, networks and functions significantly altered over the time course. Interestingly, in days P10 to P14 gene functions significantly altered were up-regulated exclusively with the functions including lipid metabolism, small molecule biochemistry and molecular transport. Between days P5 to P7 down-regulated genes predominated with enriched functions including, gene expression, cell cycle, protein synthesis and embryonic development. For P14 to P21 enriched functions included DNA replication, cell cycle and tissue development. In the late stages (P21 to P28) functional enrichment was seen for cell-to-cell signaling, tissue development, cellular movement.

Conclusions: This study provides the most comprehensive temporal survey of postnatal kidney development to date which provides a framework for interpreting nephropathies, such as those induced by congenital obstruction.

PUB230

Changes of TRPC 6 and BK_{Ca} Channels in Undifferentiated and Differentiated Cultured Podocytes Pengjuan Xu,[1] Zhuo Yang.[1] *[1]Medical School, University of Nankai, Tianjin, China.*

Background: Podocytes, also called glomerular visceral epithelial cells, form an interdigitating network of foot process, synthesize components of the glomerular basement membrane and are the target of injury in many glomerular diseases. Transient receptor potential canonical (TRPC)6 channels and large-conductance Ca^{2+}-activated K^+ channels (BK_{Ca} channels) are two important ion channels locate on podocytes, which play an essential role in regulating calcium homeostasis cell signaling. In this report, expressions of TRPC 6 and BK_{Ca} channels in undifferentiated and differentiated podocytes were detected respectively by laser scanning confocal microscope.

Methods: In the present study, immunohistochemistry was used to determine the localization and expression of TRPC6 and BK_{Ca} channels in undifferentiated and differentiated podocytes.

Results: Results demonstrated that in undifferentiated podocytes, TRPC 6 was mainly located in nuclear regions. In differentiated podocytes, the expression of TRPC6 in the nuclear regions seemed almost all translocated to other regions, and the expression on the membrane increased. The same situation also occured to BK_{Ca} channels. It was observed that functional BK_{Ca} channels were expressed at a detectable but the low level on the surface of undifferentiated podocytes. And with the maturity of differentiation, the expression of BK_{Ca} channels on the surface of podocytes increased remarkably.

Conclusions: The development changes of the two ion channels may be part of a mechanism to maintain the stability of the glomerular filtration, and TRPC 6 and BK_{Ca} channels may play an important role in the podocyte differentiation. These results have implications for the physiology and development of kidney and will also serve as a baseline for future studies designed to investigate developmental changes of ion channel expression in podocytes.

Regulation of Prox1 Expression in the Renal Medulla by Osmolality *In Vivo* Yumi Kim, Wan-Young Kim, Sun-ah Nam, Hak Soo Kim, Jin Kim. *Anatomy and MRC for Cell Death Disease Research Center, The Catholic University of Korea, Seoul, Korea.*

Background: The transcription factor Prospero-related homeobox 1 (Prox1) is expressed in various internal organs and is related to their differentiations. In a previous study, we found that Prox1 was transiently expressed in the differentiating ascending thin limb (ATL) of Henle's loop in the developing renal papilla and remained only in the ATL in the initial part of renal papilla in adult mouse kidney. Furthermore, Prox1 was expressed in the osmotic conditions within the optimal range *in vitro*. In the present study, we extend our experiments to the *in vivo* situation. We examined whether osmolality affects the expression and distribution of Prox1 in the renal medulla in both postnatal developing mice and adult mice.

Methods: In the first experiment, adult male C57BL/6 mice were randomly divided into 3 groups: dehydrated mice given minimum water, hydrated mice given 3% sucrose in water, and control mice given free access to water for 7 days before death. In the second experiment, one-day-old pups were administered daily subcutaneous injections of furosemide (30 mg/kg) or vehicle for 4 or 7 days.

Results: In the first experiment, the immunoreactivity for Prox1 in the ATL was weak in the initial part of the renal papilla, but no immunoreactivity was observed in the terminal part of the renal papilla of the normal adult mouse. However, in the hydrated mice, Prox1 was expressed not only in the initial part of the renal papilla but also in the terminal part of the renal papilla. Moreover, the intensity of immunoreactivity for Prox1 was increased in the hydrated mice but markedly decreased in the dehydrated mice compared to the control group. In the second experiment, the immunoreactivity for Prox1 was considerably decreased in the papillae of furosemide-treated group, where the development of the ATL of Henle's loop was delayed, compare to vehicle-treated group.

Conclusions: These results suggested that the expression of Prox1 was regulated by osmolality and was required for the differentiation and maintenance of ATL in the developing and adult mouse kidney, respectively.

PUB232

Hypoxia Inducible Factor-1a Regulates Branching Morphogenesis in Kidney Development Kenji Tsuji, Shinji Kitamura, Hitoshi Sugiyama, Hirofumi Makino. *Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Scineces, Okayama, Japan.*

Background: The Kidneys are exposed under hypoxia condition (O_2 2-9%) in developing stage (Simon et al. Nat Rev Mol Cell Biol, 2008). Hypoxia-inducible factor (HIF), an important mediator for responding to hypoxia, is thought to play an important role in development. Although previous studies indicated that hypoxia enhances ureteric bud branching in vivo on kidney development (Akimoto et al, Landes Bioscience, 2005), they didn't reveal the relationship between HIF and branching morphogenesis. We examined whether the kidney development is regulated with HIF which was induced by hypoxia or not.

Methods: We harvested embryonic 13-days kidneys (E13K) from embryo rats and cultured under normoxia (20% O_2 / 5% CO_2) or hypoxia (5% O_2 / 5% CO_2) for 4 days. After the culture, we evaluated the kidneys on the point of morphology, gene expression and protein expression.

Results: E13Ks under hypoxia were observed significantly more branching than the E13Ks under normoxia (the numbers of end buds under hypoxia vs. normoxia were 57.7±12.5 vs. 40.6±6.6, respectively; $p<0.05$). In addition, HIF-1a and Ret expression increased under hypoxia condition in E13Ks. When we added HIF-1a inhibitors (digoxin or SiRNA of HIF-1a), Ret gene expression was inhibited under hypoxia condition, and we could not observe the increased branching under hypoxia condition (the number of end buds under hypoxia vs. under hypoxia with digoxin and under hypoxia with siRNA-HIF1a were 57.7±12.5 vs. 41.5±7.5 and 39.0±4.76, respectively; $p<0.05$).

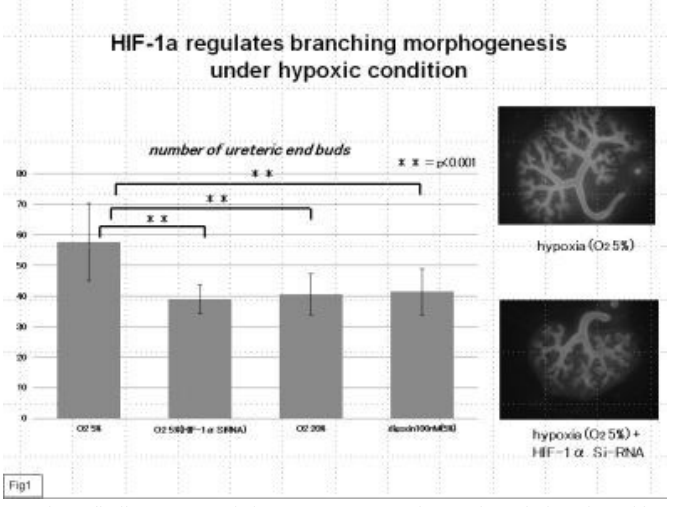

Fig1

These finding suggested that HIF-1a may make a role to induce branching morphogenesis in kidney development with GDNF / Ret signal pass way.

Conclusions: HIF-1a may regulate the branching morphogenesis via the signaling of RET/GDNF.

PUB233

HPSE2, a Gene Mutated in Human Urofacial Syndrome, Directs Neuro-Muscular Differentiation Neil A. Roberts,[1] Raphael Thuret,[2] Edward A. Mckenzie,[2] William G. Newman,[1] Emma N. Hilton,[1] Adrian S. Woolf.[1] *[1]Faculty of Medical and Human Sciences, University of Manchester, Manchester, United Kingdom; [2]Faculty of Life Sciences, University of Manchester, Manchester, United Kingdom.*

Background: Homozygous *HPSE2* mutations cause urofacial syndrome (UFS). UFS features congenitally dysmorphic and dysfunctional bladders associated with vesicoureteric reflux and renal failure. UFS individuals have a diagnostic grimace when smiling and some have severe constipation. *HPSE2* codes for heparanase-2 which binds heparan sulphate and inhibits endoglycosidase activity of heparanase-1. Normal human fetal bladders express *HPSE2*, with protein immunolocalised in nascent detrusor smooth muscle in a partially overlapping pattern with heparanase-1. Heparanase-2 is also immunodetected in ganglia and nerves in the bladder wall.

Methods: We studied heparanase-2 during *Xenopus tropicalis* development. Transcripts were measured by qPCR. Single cell embryos were injected with splice-variant or ATG morpholinos to knockdown *xhpse2*. Immunostaining was performed using an antibody raised to *Xenopus* heparanase-2.

Results: Wildtype embryos showed an increase in *xhpse2* after gastrulation, with expression maintained through organogenesis. Use of either morpholino caused a phenotype comprising a bent tail and protrusion in the proctodeal/cloacal zone. The latter was associated with absent gut looping; instead the gut remained as an ovoid endodermal mass. A similar defect has been reported after knockdown of *Foxf1*, a BMP4-activated transcription factor expressed in lateral plate mesoderm fated to form gut muscle. In wildtype embryos we detected heparanase-2 in skeletal and smooth muscle cells, and morphants had impaired gut muscularisation. Heparanase-2 was also expressed within the neural tube and hindbrain, and in nerves connected to these structures. Moreover, detailed examination of *xhpse2* morphants revealed poor progress of peripheral nerves in the face and trunk.

Conclusions: Our current and previous results support the conclusion that heparanase-2, which is mutated in patients with UFS, mediates neuro-muscular differentiation in both skeletal muscles and also in smooth muscle within viscera such as gut and urinary bladder.

Clinical and Genetic Analysis of a North East England Cystinuria Cohort Alice Hartley,[2] Noel Edwards,[1] Ann Marie Hynes,[1] Sarah Rice,[1] David T. Thwaites,[3] John Andrew Sayer.[1] *[1]Institute of Genetic Medicine, Newcastle University, Newcastle, Tyne and Wear, United Kingdom; [2]Department of Urology, Newcastle upon Tyne NHS Hospitals Foundation Trust, Newcastle upon Tyne, Tyne and Wear, United Kingdom; [3]Institute of Cell and Molecular Biosciences, Newcastle University, Newcastle upon Tyne, Tyne and Wear, United Kingdom.*

Background: Cystinuria is an inherited renal stone disorder secondary to tubular transport defects in the proximal tubule. We have examined clinical and biochemical characteristics from a cohort of patients from the North East of England.

Methods: Medical records and family history, together with serum and urine biochemistry data of 20 patients were reviewed. Genetic analysis was undertaken using exon PCR of all coding regions of the genes implicated in cystinuria (SLC3A1 and SLC7A9).

Results: The age of first episode of colic ranged from 2 to 48. Eleven patients (55%) had at least one first degree relative with cystinuria. All patients were diagnosed following stone analysis at presentation, or on urinalysis. Cystine staghorn calculi were seen in 12 patients (60%). Nineteen patients (95%) required surgical intervention and had an average of 6.3 procedures (ESWL, ureteroscopy and stone extraction, PCNL or open lithotomy). One patient reached end stage renal failure as a result of cystinuria. Abnormal baseline renal function was seen in fifteen patients (75%). Medical treatment options included Captopril, Penicillamine, Tiopronin, Potassium Citrate and Sodium Bicarbonate. Fourteen patients (70%) were on two or more of these therapies. Genetic analysis revealed that 3 patients were heterozygous or compound heterozygous for mutations in SLC3A1. Five patients had single or compound heterozygous mutations in the SLC7A9 gene and four patients showed a digenic pattern, with mutations in both SLC3A1 and SLC7A9.

Conclusions: Cystinuria is clinically and genetically a heterogeneous condition. Cystinuria predisposes patients to recurrent stone formation requiring multiple urological interventions. The morbidity associated with these procedures and with the condition itself is high and we advocate close liaison between Urology and Renal specialists to optimise patient management.

PUB235

Short-Term Effects on Efficacy Parameters with Tolvaptan in Subjects with ADPKD at Various Levels of Kidney Function Wendy E. Boertien,[1] Esther Meijer,[1] Paul E. de Jong,[1] Frank S. Czerwiec,[2] Dorothee Oberdhan,[2] Holly B. Krasa,[2] Ron T. Gansevoort.[1] *[1]Nephrology, UMC, Groningen, Netherlands; [2]Otsuka Pharmaceutical Development & Commercialization Inc., Rockville.*

Background: Tolvaptan, a vasopressin V2-receptor antagonist, delays disease progression in rodent models of ADPKD. To date, human ADPKD trials have focused in patients with preserved kidney function. In this trial, we investigated responses to tolvaptan in patients with various levels of kidney function.

Methods: ADPKD patients with a wide GFR range (18-148 mL/min) were studied at baseline and after 3 weeks tolvaptan (up to 120 mg/day). GFR was assessed as ^{125}I-iothalamate clearance and total kidney volume (TKV) by MR imaging.

Results: 27 patients (52% male; 46±10 y, GFR 69±39 mL/min) were included. At baseline lower GFR was associated with higher TKV ($p=0.002$), 24hr urinary volume ($p=0.05$), and lower urinary osmolality ($p<0.001$). Baseline GFR was not correlated with plasma tolvaptan concentration ($p=0.9$). The absolute as well as percentage change in 24hr urine volume and urine osmolality with tolvaptan was less in patients with lower GFR (absolute: $p=0.001$ and $p<0.001$; percentage: $p<0.001$ and $p=0.003$, resp.). Final treatment urine osmolality was low (median 139 mOsm/kg) and not associated with GFR ($p=0.7$), suggesting that patients reached maximal urine dilution capacity independent of GFR. TKV decreased after 3 weeks treatment (median -60 mL, $p<0.001$). Baseline GFR was not associated with the absolute change in TKV ($p=0.5$), whereas the association with percentage decrease in TKV reached borderline significance ($p=0.06$). Importantly, final as well as change in fractional free water clearance was higher in subjects with lower kidney function ($p<0.001$ and $p=0.001$, resp.), indicating that subjects with impaired GFR had more response per functioning nephron.

Conclusions: Response to tolvaptan on urinary volume, osmolality and TKV is lower in patients with impaired kidney function. Based on our results with respect to fractional free water clearance, we hypothesize that this is not due to decreased sensitivity for tolvaptan, but could be due to less functioning renal mass or structural renal abnormalities.

PUB236

Effect of Dietary Phosphate on the Progression of Polycystic Kidney Disease (PKD) Xiaofang Wang,[1] Hong Ye,[1] Maria V. Irazabal,[1] Rajiv Kumar,[1] Peter C. Harris,[1] Vincenzo Savica,[2] Vicente E. Torres.[1] *[1]Mayo Clinic, Rochester, MN; [2]U of Messina, Messina, Italy.*

Background: Phosphate content of the diet varies widely among individuals and may affect CKD progression.

Methods: To determine whether it affects PKD development we fed male (M) and female (F) PCK rats identical artificial diets except for the phosphorus content (low 0.2% LPD; intermediate 0.6% IPD; high 1.2% HPD) between 3 & 10 weeks of age.

Results: LPD caused growth retardation compared to the IPD, but did not change cyst area or fibrosis (not shown). HPD worsened PKD, more in female than in male rats. There was no effect on the liver cystic disease.

* P<0.05 † p<0.01 ‡ p<0.001 compared to IPD (unpaired t test) # Two-way ANOVA (p values) [a]pmol/mg protein [b]mg/g Creat

Moderate (IPD) and extensive (HPD) deposits of calcium phosphate were observed in the distal nephron and collecting ducts of female but not male rats. HPD rats had higher serum PTH and FGF23 and renal cAMP, without an increase in serum phosphorus, than IPD rats. Renal dopamine and sFRP4, measured because of reported upregulation by acute phosphate loading, were not increased. Increased susceptibility of female rats to renal calcium phosphate deposition which also occurs in women after phosphate loading may be due to more vigorous PTH and FGF23 responses.

Conclusions: Increased PKD severity in HPD rats is associated with enhanced renal deposition of calcium phosphate and likely due to mitogenic effects of inorganic phosphate or calcium phosphate deposition. These results suggest a possible effect of dietary phosphorus on PKD progression particularly in women.

PUB237

A Canine Autosomal Recessive Model of Collagen Type III Glomerulopathy Runa Rørtveit,[1] Frode Lingaas,[1] Tina Bønsdorff,[1] Anna Vigdis Eggertsdottir,[1] Ann Margaret Grondahl,[1] Ragnar Thomassen,[1] Agnes B. Fogo,[2] Johan Hogset Jansen.[1] *[1]Norwegian School of Veterinary Science, Oslo, Norway; [2]Vanderbilt University Medical Center, Nashville, TN.*

Background: Collagen type III glomerulopathy (Col3GP) is a rare renal disease characterized by massive glomerular accumulations of collagen type III. The disease occurs in both humans and animals, and has been presumed to be heritable with an autosomal recessive inheritance pattern. The pathogenesis is unknown. We have performed detailed investigation of a novel model of canine autosomal recessive Col3GP.

Methods: This spontaneously occurring canine disease was incidentally diagnosed in six mongrel dogs. We then established and studied a pedigree segregating the disease to investigate the genetic nature and inheritance of canine Col3GP, and eight additional affected offspring were produced. The age of the 14 affected dogs at euthanasia ranged from 41-326 days. Kidney autopsy specimens were studied by light microscopy, electron microscopy, immunohistochemistry and *in situ* hybridization. We assessed whether the Col3A1 gene was involved in the disease by performing a simple segregation analysis using polymorphic markers in the gene.

Results: 29 % of offspring (14/48, 5 males and 9 females) showed morphologic evidence of disease, strongly supporting a simple autosomal recessive inheritance pattern. Clinical signs of chronic renal failure including azotemia and/or proteinuria were observed in six of the affected dogs. Characteristic morphological findings of Col3GP were present in all affected dogs, including membranoproliferative pattern injury and massive glomerular collagen type III deposition. In situ hybridization for collagen III showed increased mesangial signal. Our initial genetic studies did not show evidence that the canine Col3A1 gene is mutated in the disease.

Conclusions: We propose that this canine Col3GP model may serve as an animal model of human Col3GP. This is the first animal model of Col3GP. Further studies of this phenotype in these dogs may have the potential to provide information on the pathogenesis and genetics of the disease in both animals and humans, and may thus contribute to the development of novel treatment.

PUB238

High-Resolution Melt as a Screening Method in ADPKD Grazia Maria Virzì,[1,2] Valentina Corradi,[1,2] Fiorella Gastaldon,[1] Maurizio Clementi,[3] Claudio Ronco.[1,2] *[1]Nephrology Dep., St Bortolo Hosp, Italy; [2]International Renal Research Institute Vicenza, IRRIV; [3]Clinical Genetics and Pediatrics, University of Padua, Italy.*

Background: ADPKD is an inherited condition caused by mutations at two genes (PKD1-PKD2). The genetic diagnosis of ADPKD is challenging because of the genetic heterogeneity and marked allelic heterogeneity at ADPKD genes. Hence, complete analysis of both genes is typically required in each patient. Several screening methodologies have been used to characterize the PKD genes.In this study, we explored the utility and robustness of High Resolution Melt (HRM) as a tool for mutation analysis of the PKD2 gene in ADPKD families.

Methods: HRM is a mismatch-detection method based on the difference of fluorescence absorbance behaviour during the melting of the DNA double-strand to denatured single-strands in a mutant sample as compared to a reference normal-control, after PCR amplification in the presence of intercalating fluorescent dye. Our families were previously screened by linkage analysis. Subsequently, HRM was used to characterize PKD2-linked-families. Amplicons that produced an overlapping profile sample vs control were not further evaluated; while those amplicons with profile deviated from the control were consequently sequenced.

Results: We analyzed 15 PKD2-linked families by HRM. We observed 10 different variations: 5 single nucleotide polymorphisms (83G>C, 108G>A, IVS1-16C>T, IVS3-22G>A, 1830G<A), 1 unknown variation (1459T>C) and 4 mutations. The mutations detected by HRM and confirmed by sequencing were: 1158T>A, 1459T>C, 2159delA, 2224C>T, 2533 C>T. In particular, the nonsense mutation 2533 C>T was found in 8/15 families (20 subjects). We had a ADPKD pre-symptomatic diagnosis in 8 subjects (mean age: 29 years) and we excluded ADPKD in 16 subjects (mean age: 28 years) by HRM and linkage analysis.

Conclusions: We have developed a strategy for rapid molecular mutation analysis of the PKD2 gene in ADPKD families, which utilizes a HRM-based pre-screening followed by Direct Sanger Sequencing of amplicons with abnormal melting profiles. This is a simple and good technique for PKD2 genotyping and may significantly reduce the time and the cost for diagnosis in ADPKD.

PUB239

Achievement and Maintenance of Blood Pressure Targets in HALT:PKD Vicente E. Torres,[1] Robert W. Schrier,[2] Arlene B. Chapman,[3] Ronald D. Perrone,[4] D. Miskulin,[4] Theodore I. Steinman,[5] Franz Winklhofer,[6] William E. Braun,[7] Marie C. Hogan,[1] Frederic F. Rahbari-Oskoui,[3] Kaleab Z. Abebe,[8] Michael F. Flessner.[9] *[1]Mayo Clinic, Rochester, MN; [2]U of Colorado, Denver, CO; [3]Emory U, Atlanta, GA; [4]Tufts U, Boston, MA; [5]Beth Israel, Boston, MA; [6]UKMC, Kansas City, KS; [7]Cleveland Clinic, Cleveland, OH; [8]U of Pittsburgh, Pittsburgh, PA; [9]NIH/NIDDK HALT Study Group.*

Background: HALT-PKD seeks to determine whether ACEI/ARB is superior to ACEI alone and low BP (<110/75) to standard BP (120-130/70-80) in delaying cyst progression in patients with eGFR >60 (Study A) and whether ACEI/ARB is superior to ACEI alone (BP target 110-130/70-80) in slowing eGFR decline in patients with eGFR 25-60 mL/min/1.73 m^2 (Study B).

Methods: Stepwise dosing of lisinopril (L) and telmisartan/placebo (T/P) (steps 1-4) followed by other agents (steps 5-10) is used to achieve BP targets. During 2006-2012, 519, 501, 500, 451, 293, 143 A and 458, 447, 437, 411, 232, 97 B patients completed 4, 12, 24, 36, 48, 60-mth follow-up. BP control is assessed by home BP measurements.

Results:

	Mths	Study A Std	Study A Low*a	Study B

PUB240

Assessment of DNA Variant Databases for Inherited Kidney Diseases for Clinical Relevance, Accessibility, Expertness of Curation and Currency
Judith A. Savige,[1] Hayat Dagher,[1] Margaret S. Povey.[2] *[1]Department of Medicine (Northern Health), University of Melbourne, Melbourne, Victoria, Australia; [2]Department of Genetics, Evolution and the Environment, University College, London, United Kingdom.*

Background: The Human Variome Project (HVP) recommends that gene-specific DNA variant databases contain clinical data, and are up-to-date, curated by experts and freely-available. A recent review identified 62 inherited renal diseases caused by mutations in 134 different genes (Hildebrandt, Lancet 2010). This study examined how many of these databases fulfilled the HVP recommendatations.

Methods: We used the disease name, MIM number, and gene name, alone or together with 'mutation' or 'database' to identify websites for gene-specific databases. For each, the total number of variants, and the number that could be accessed without charge, were noted, as of 1 March 2012. The numbers that contained clinical details, had a named or 'expert' curator, and had been updated within the previous 12 months, were also noted.

Results: There were databases for 61 (98%) of these 62 diseases (all excepting Multicystic kidney dysplasia, MIM 602868) and for 128 of the 134 (96%) corresponding genes (excepting CDC5L, USF2, SLIT2, MYOG, DLX5, and MSK3). Altogether there were 352 databases. One hundred and ninety-two (54.5%) databases were accessible without charge. All published variants were freely-available for 37 (27.6%) genes. Two hundred and fifty-one (71%) databases had fewer than 20 mutations, and 8 (6%) genes had no free database at all. One hundred and twenty-nine (37%) databases had no clinical information beyond the diagnosis. Sixty-one (17%) databases, including 4 of the largest, were curated by an individual expert or group of experts. The date of the most recent update was known for 285 databases and was within the previous 12 months for 168 (59%).

Conclusions: Most inherited renal diseases have a database for DNA variants. However, only half of these are free, and where they are, are often incomplete. In addition, about one third of databases have no clinical information, and few are curated by experts. Finally, there is much duplication with frequently more than one database per gene.

PUB241

Mutation Analysis in Japanese Patients with Congenital and Infantile Nephrotic Syndrome
Hironobu Mukaiyama,[1] Koichi Nakanishi,[1] Taketsugu Hama,[1] Hiroko Togawa,[1] Yuko Shima,[1] Kazumoto Iijima,[2] Norishige Yoshikawa.[1] *[1]Pediatrics, Wakayama Medical University, Wakayama City, Wakayama, Japan; [2]Pediatrics, Kobe University Graduate School of Medicine, Kobe, Hyogo, Japan.*

Background: Mutations in podocyte genes (*NPHS1*, *NPHS2*, *WT1*, and *LAMB2*) are associated with congenital (<3 months) and infantile (3-12 months) nephrotic syndrome (NS). However, the frequency of causative mutations in these genes in NS manifesting in the first year of life has not been fully investigated in Japan.

Methods: To clarify the role of mutations in these genes, all exons and exon-intron boundaries were investigated in consecutive, unrelated 33 patients from regional pediatric kidney disease centers, by PCR-direct sequencing.

Results: We detected disease-causing mutations in 60.6% (20 of 33) patients (85% in congenital and 3% in infantile). *NPHS2* mutation was not detected (Table).

	No. of patients	Total Mutations N (%)	*NPHS1* N (%)	*NPHS2* N (%)	*WT* N (%)	*LAMB2* N (%)	Not detected N (%)
All (CNS+INS)	33	20 (60.6)	12 (36.4)	0 (0.0)	7 (21.2)	1 (3.0)	13 (39.4)
CNS	20	17 (85.0)	12 (60.0)	0 (0.0)	4 (20.0)	1 (5.0)	3 (15.0)
INS	13	3 (23.1)	0 (0.0)	0 (0.0)	3 (23.1)	0 (0.0)	10 (76.9)

CNS = congenital nephrotic syndrome; INS = infantile nephrotic syndrome

Of a total 12 different *NPHS1* mutations 8 (3 missense, 3 nonsense, 1 small deletion, and 1 large deletion) were novel. The large deletion of *NPHS1* was detected by semi-quantitative PCR. C.2515delC in *NPHS1* was detected in 8 patients, suggesting a founder effect. All *NPHS1* mutations were associated with a large placenta. Patients with *WT1* mutations had early-onset (<4 months) end-stage renal disease. A patient with *LAMB2* mutations showed Pierson syndrome.

Conclusions: Although a large placenta is thought to be a non-specific feature of CNS, it may be a key to decide the order of mutation analysis. *NPHS2* mutations are reported to have an important role in NS manifesting in the first year of life in Europe and the United States. However, in Japan *NPHS2* mutation was not detected in the present study. *NPHS1*, *WT1* and *LAMB2* mutations are also responsible in a considerable part of CNS and INS in Japan.

PUB242

Differential Renal Gene Expression in ADPKD Compared to Other CKD Causes
Wei Wang, M. Chonchol, Robert W. Schrier, Berenice Y. Gitomer. *Department of Medicine, University of Colorado Denver, Aurora, CO.*

Background: ADPKD accounts for 4-10% of end-stage renal disease (ESRD) worldwide. The hallmark of ADPKD is the development of multiple renal cysts that replace the normal renal parenchyma. However the exact mechanism and identity of the factors influencing this process remain unclear. While animal models are useful for study of certain aspects of the disease process they also have limitations for study of human disease. Human ADPKD research is limited due to the availability of kidneys for research especially those from patients still in the early stages of disease. The majority of nephrectomies performed on ADPKD patients are those on subjects who have reached ESRD. It has been argued that kidneys from patients with advanced disease are not representative of ADPKD since it is difficult to differentiate changes due to ADPKD or ESRD itself. We hypothesized that ADPKD has a unique pathogenesis different from other causes of ESRD.

Methods: We selected several genes that were differentially expressed between ADPKD and normal kidneys and compared their expression in ADPKD kidneys and in kidneys from patients with ESRD due to other causes (CKD). Real time RT-PCR was used to measure renal mRNA levels. Gene expression was expressed as the ratio of the target gene/GAPDH.

Results: Renal *VEGF* mRNA levels were significantly lower in ADPKD kidneys compared to normal kidneys (0.9±0.2, n=5 vs 1.4±0.4, n=3, $p<0.05$) but significantly higher than those in CKD kidneys (0.9±0.2, n=5 vs 0.5±0.2, n=3, $p<0.05$). *HIF-1*β expression was significantly higher in ADPKD kidneys than in normal controls (4.78±2.34, n=4 vs 1.12±0.51, n=4, $p<0.01$) while there was no difference between the normal controls and CKD kidneys (1.12±0.51, n=4 vs 1.10±0.11, n=4, p=NS). Strikingly, *RUNX3* gene expression was much higher in ADPKD kidneys than in either normal controls or CKD kidneys (14.9±8.0, n=6, vs either 0.64±0.39, n=3 or 1.34±1.4, n=3, $p<0.05$).

Conclusions: Gene expression observed in kidneys from ADPKD patients with advanced disease differs markedly from that seen in kidneys from patients with other renal disease causes. This implies that ADPKD has its unique pathogenesis leading to ESRD.

PUB243

Mutation Analysis of UMOD and REN Genes in Pathological Diagnosed and Clinical Suspected MCKD2/FJHN Families
Mao-jing Liu, Yu-qing Chen, Yu Liang, Ying Liu, Su-xia Wang, Hong Zhang, Ming Hui Zhao. *Renal Division, Department of Medicine, Peking University First Hospital, Beijing, China.*

Background: Medullary cystic kidney disease 2 (MCKD2) and familial juvenile hyperuricemic nephropathy (FJHN) characterized by hypertension, hyperuricaemia, and progressive renal insufficiency, are reported to be caused by mutations in the UMOD, HNF-1β or REN genes. In this study we try to identify UMOD and REN gene mutations in pathological diagnosed and clinical suspected MCKD2/FJHN families.

Methods: 9 patients were included in this study, 3 of them were diagnosed as MCKD2 according to renal pathologic changes, and 6 of them were suspected to have MCKD2/FJHN due to clinical features and family histories of hyperuricemia or ESRD. The mean age was 24.2 years (18-40 years), with 5 males (5/9) and 4 females (4/9). 4 patients progressed to ESRD within 2-3 years of diagnosis. UMOD and REN gene mutation analysis were performed in all patients as well as some family members.

Results: Two types of UMOD mutations were identified in the 2 patients and their relatives. A novel heterozygous missense mutation(c.326T/A;p.Val 109 Glu), altering the epidermal growth factor-like domain(cbEGF3) in one family. This patient's mother and elder brother also have this mutaion without any clinical abnormalities. In another family, we found a previously reported UMOD gene mutation(c.744C/G;p.Cys248Trp), affecting D8C domain. This patient's mother and uncle have the same mutations, progressed to ESRD. Among 9 patients with MCKD2/FJHN phenotype, UMOD mutation was found in 2(22.2%). We failed to find any mutations in REN gene in all families.

Conclusions: A novel mutation (p.Val 109 Glu) and a previously reported mutation (p.Cys248Trp) of UMOD gene were detected in 2 cases (22.2%) with UMOD mutations. Genetic testing may be a useful tool in helping diagonosis of MCKD2/FJHN in patients suspecting MCKD2/FJHN without renal biopsy.

PUB244

Restoring Multidrug-Resistance Associated Protein 3 (MRP3) Reduces Proliferation through ERK/B-Raf Signaling Down-Regulation
Jong Hoon Park, Eun Sun Chang, Eun Young Park. *Biological Science, Sookmyoung Women's University, Seoul, Republic of Korea.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is one of common genetic disorder which is characterized by progressive cyst formation and resulting loss of renal function. In previous reports, numerous genes involved in cystogenesis were identified so far, we don't have effective drugs for polycystic kidney. Currently, in most of clinical cases, renal failure occurs.

Methods: We found that MRP3 is related to cyst formation using three-dimensional culture system. To determine the novel function of MRP3 in the kidney, we used RNAi system for knockdown and Abcc3 clone for over-expression. Immunohistochemistry-fluorescence was performed to evaluate MRP3 expression in PKD mouse model and human patients.

Results: MRP3 inhibition stimulates mitogen-activated protein kinases (MAPKs) and it reveals that MRP3 inhibition enhance cell proliferation. We also confirmed MRP expression in vivo level. MRP3 is significantly down-regulated in the kidneys of PKD2 knockout–Rescued mice and human ADPKD patients. Opposite of the results, we found that restored MRP3 reduces cell proliferation in vitro.

Conclusions: The results suggest that novel renal function of MRP3 which is related to cell proliferation. Reversely, MRP3 over-expression represses cell proliferation. Therefore, MRP3 restoring may be one of effective therapeutic approaches for polycystic kidney disease.

PUB245

Modeling of Epithelial Organization in PKD Cystogenesis Julio M. Belmonte,[1] Sherry G. Clendenon,[1] James A. Glazier,[1] Robert L. Bacallao.[2] *[1]Physics, Biocomplexity Institute, Indiana University, Bloomington, IN; [2]Medicine, Division of Nephrology, Indiana University, Indianapolis, IN.*

Background: Polycystic kidney diseases (PKD) are the most common genetic causes of end-stage renal disease. Despite discovery of PKD linked mutations, disease progression is unclear. Renal cysts, but not normal renal epithelia, express cadherin 8. In 3D culture, exogenous cadherin 8 expression, but not N-cadherin expression, causes renal epithelial cells to form cysts. Our hypothesis is that changes in cell-cell adhesion due to cadherin type switching drives cystogenesis.

Methods: Using CompuCell3D, open-source multiscale modeling software developed at the Biocomplexity Institute, we have begun development of a multiscale *in silico* model of cystogenesis based on differential adhesion data from *in vitro* cystogenesis experiments.

Results: Preliminary results show that cadherin type switching is sufficient to disrupt local tubule morphology and initiate the formation of cysts. Further development of the 3D *in silico* model will show how relative strengths and disruptions of cell-matrix and cell-cell interactions contribute to the formation of cysts from a renal tubule.

Conclusions: Despite the complexity of PKD, our mathematical model shows that cystogenesis can be described as an emergent phenomena arising from a single change in cell behavior. Our 3D model will generate testable hypotheses about the underlying processes involved in this disease progression that may lead to PKD treatments based on alteration of cell adhesion.

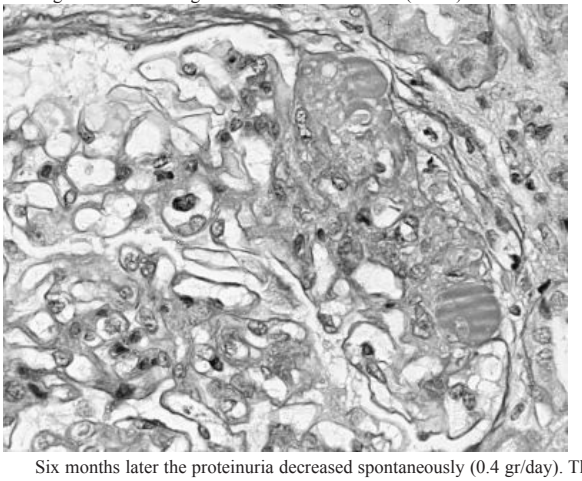
PUB246

Focal Segmental Glomerulosclerosis in Type 1 Gaucher Disease Alessandra Marega,[1] Stefano Pizzolitto,[2] Bruno Bembi,[3] Maria Gropuzzo,[1] Giulio Romano,[1] Clotilde Vallone,[1] Domenico Montanaro.[1] *[1]Department of Nephrology, Dialysis and Transplantation, SMM Hospital, Udine, Italy; [2]Department of Pathology, SMM Hospital, Udine, Italy; [3]Department of Rare Disease, SMM Hospital, Udine, Italy.*

Background: Gaucher disease (GD) is a genetic lysosomal disease characterized by deficiency in glucocerebrosidase. It induces the formation of Gaucher Cells (GC) that infiltrate bone marrow, spleen, liver, lungs and brain and are considered to be mainly responsible for the clinical manifestations. Renal complications do not seem to be part of the spectrum of GD.

Methods: 55 years old Caucasian man was diagnosed GD type 1 [c.1226A>G(N370S)/c.750A>G(Y212-K215del)] heterozygous. Due to progressive thrombocytopenia and splenomegaly he underwent splenectomy at age 56. At 72, the patient was diagnosed JAK2 positive myeloproliferative disorder (MPD). At 75, he was discovered to have heavy proteinuria (6 gr/die), with serum creatinine 1 mg/dl. Ramipril was started as antiproteinuric agent and oncocarbide for MPD. At 77 proteinuria was 8 gr/day and a renal biopsy supported the diagnosis of Focal Segmental Glomerulosclerosis (FSGS).



Six months later the proteinuria decreased spontaneously (0.4 gr/day). Then he died of sudden cardiopulmonary arrest. The autopsy revealed acute myocardial infarction and lung adenocarcinoma.

Results: GD with severe clinical and pathological renal involvement is exceptionally rare. In literature there are only few cases in which the renal involvement is characterized by heavy proteinuria and/or renal failure caused by the accumulation of GC in glomeruli and interstitium of the cortex; in another report a boy was diagnosed GD and mesangiocapillary glomerulonephritis. Here we have described a patient with GD and heavy proteinuria secondary to FSGS.

Conclusions: To our knowledge this is the first combination of FSGS and GD and the second case of JAK2 MDP and GD.

PUB247

Different Mitochondrial DNA Point Mutations in Four Mitochondrial Cytopathy Patients with Renal Involvement Honglang Xie, Shutian Xu, Qunpeng He, Yang Liu, Jinzhou Guo, Zhi-Hong Liu. *Research Institute of Nephrology, Jingling Hospital, Nanjing University Clinical School of Medicine, Nanjing, China.*

Background: Mitochondrial cytopathy is a heterogeneous disease with multiple organ system involvement. We report 4 mitochondrial cytopathy patients with 4 different mitochondrial DNA (mtDNA) point mutation and renal involvement.

Methods: DNA was isolated from peripheral blood leukocytes from four patients. Polymerase chain reaction was performed to amplify the mtDNA. Sequencing analysis was used to detect the presence of any point mutation of mtDNA.

Results: 1)General condition:cases includes a 74-yr male, a 13 yr male, a 18 yr female, and a 20-yr female. Nothing special in family history except for case 2, who has a diabetic family history, both his mother and brother died young. 2) Renal involvement:Case 1, 3 had nephrotic proteinuria (8.6 to 12.7g/d). All had hypoalbuminemia, interstitial-tubular function injury. Renal biopsy proved FSGS in case 2 and IgAN in case 3. 3)Systemic involvements:all of them were malnutrition and diabetes. Epileptic seizure were complicated in case 3 and 4, hearing loss were noticed in cases 1, 2 and 3, muscle weakness in case 1 and 3, arrhythmia in case 2, 3 and 4, heart failure in cases 1, 3, and 4, peripartum myocardiopathy in case 4, and anesthesia in case 1. Both case 2, 3 were preterm infants, complicated with microsomia, athrepsy, hypoevolutism and dysnoesia. Sequencing analysis proved presence of point mutation of mtDNA:8994G>A in case 1, 3243G>A in case 2, 8969 G>A in case 3 and her mother, 8277 T > C in case 4. 4)Prognosis:case 1 died of amyasthenia of respiratory muscle, pulmonary infection and respiratory failure; case 2 died of pulmonary infection; case 4 died of perinatal myocardiopathy and acute heart failure. But case 3 was sensitive to steroid and got complete remission of proteinuria and normal renal function, although 8969 G>A mutation was also demonstated in her mother, but no sign of mitochodrial cytopathy was noticed till now.

Conclusions: mtDNA 8969 G>A is a new point mutation to cause mitochondrial cytopathy. The prognosis of mitochondrial cytopathy with renal, heart and central nerval system involvement is poor.

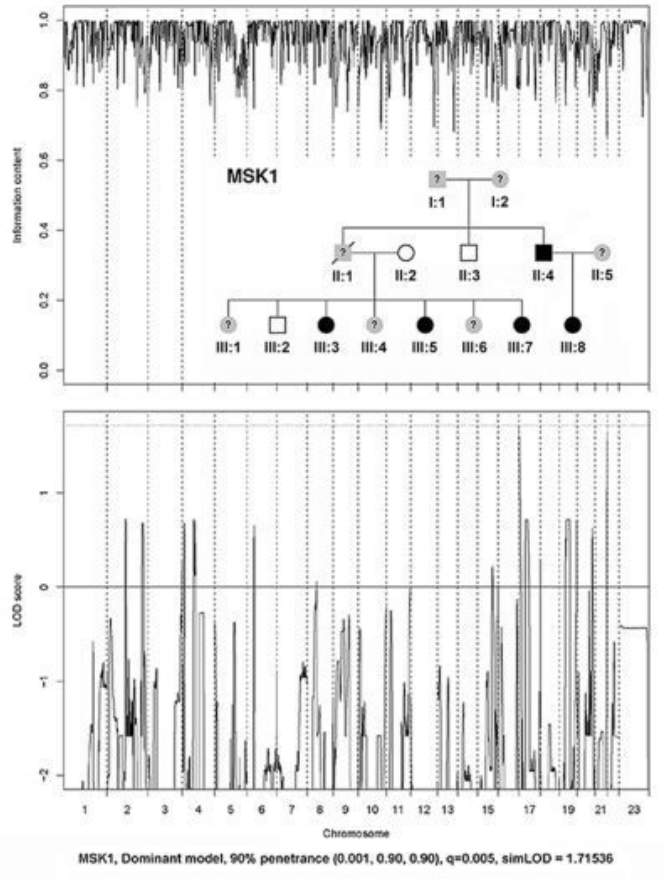
PUB248

Genome-Wide Linkage Scan and Whole Exome Sequencing in a Family with Medullary Sponge Kidney Young-Hwan Hwang,[1] Nicole M. Roslin,[2] Xuewen Song,[1] Moumita Barua,[3] Andrew D. Paterson,[2] York P. Pei.[1] *[1]Division of Nephrology, University Health Network and University of Toronto, Toronto, ON, Canada; [2]Program in Genetics and Genomic Biology, Hospital for Sick Children, Toronto, ON, Canada; [3]Division of Nephrology, Beth Israel Deaconess Medical Center, Boston, MA; [4]Division of Nephrology, Catholic University, Rome, Italy.*

Background: Medullary sponge kidney (MSK) is a relatively common but often undiagnosed disorder of renal malformation characterized by dilatation of precalyceal tubules. Patients with MSK have a high risk of nephrocalcinosis and nephrolithiasis. Most patients present sporadically but a few familial cases have been reported.

Methods: Here we report a multiplex family (MSK1) with a dominant segregation pattern for non-syndromic MSK. The proband (III:5) and two relatives (III:3, III:8) had definitive MSK (nephrocalcinosis, calyceal "blushing", and stones) based on ultrasound (US) and CT urogram while two other relatives (II:4, III:7) had probably MSK (nephrocalcinosis and stones) based on US. Two at-risk individuals (II:3, III:2) with a normal renal US >40 years of age were considered unaffected.



We performed a genome-wide linkage scan by genotyping 11 DNA samples from MSK1 using the Illumina Linkage-24 arrays and analyzed the data using Merlin.

Results: Simulations based on the pedigree structure (and 90% penetrance) yielded an max. expected LOD of 1.72. Under a dominant model with an allele frequency of 0.005, phenocopy rate of 0.001, and penetrance of 90%, we identified two suggestive linkage signals on chr. 17 and 21 with max. multipoint LOD score of 1.79 and 1.72, respectively. These results are consistent across a range of penetrances of 70-90%.

Conclusions: Whole exome sequencing (currently in-progress) focusing on the two regions of linkage signals provide a promising approach to identify the disease gene for MSK1.

PUB249

Phosphorylation of α Actinin 4 Regulates Its Binding Affinity with Actin

Wen Shen,[1] Astrid Weins,[2] Martin R. Pollak.[3] *[1]Division of Nephrology, Beth Israel Deaconess Medical Center, Boston, MA; [2]Department of Pathology, Brigham and Women's Hospital, Boston, MA; [3]Division of Nephrology, Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Point mutations in the actin binding domain of the actin crosslinker α actinin-4 (Actn4) cause FSGS and lead to increased affinity to actin filaments. We speculate that post-translational modification, phosphorylation, may regulate the actin binding affinity of Actn4.

Methods: The serine at residue 159 and tyrosine at residue 265, both identified as phosphorylation sites of Actn4, were substituted with a negatively charged amino acid aspartate and glutamate (S159D, Y265E) to mimic the phosphorylated state, or with a neutral amino acid alanine and phenylalanine (S159A, Y265F) to abolish phosphorylation. Actn4-actin binding affinity was studied by an actin co-sedimentation assay. GFP-tagged Actn4 mutants were transfected into murine podocytes and Cos7 cells. The localization of Actn4 was examined by confocal microscope.

Results: S159D showed markedly higher actin-binding affinity than WT, similar to that in disease-causing K255E mutant. S159A control did not significantly alter actin binding affinity. Y265E demonstrated a higher actin-binding affinity than WT, whereas its control Y265F had no effect. Y265E further increased actin binding affinity of K255E while S159D showed no additive effect. WT localized to stress fibers and focal adhesions. K255E was seen as a dense cytoplasmic aggregate. S159D showed a distribution similar to that in K255E. This effect was not seen in S159A control. Neither mutation affected the aggregation of the K255E. Y265E showed a localization similar to that seen in K255E while Y265F control showed a similar distribution as WT. Y265E caused further aggregation of K255E which appeared more punctate. Y265F did not have further effect on K255E. This result is consistent with our finding of co-sedimentation assay.

Conclusions: Our study showed that both S159D and Y265E mutants increase actin binding affinity of Actn4. Y265E further enhances actin binding affinity of K255E. S159D does not show additive effect. Phosphorylation of Actn4 seems to regulate its actin binding activity.

Genome Wide Transcriptome Analysis of Human Hypertensive Chronic Kidney Disease

Hyun Mi Kang,[1] Peter Choi,[2] Sang Youb Han,[3] Ae Seo Deok Park,[1] Yi-An Ko,[1] James M. Pullman,[4] Katalin Susztak.[1] *[1]Department of Medicine, University of Pennsylvania, Philadelphia, PA; [2]Department of Medicine, Albert Einstein College of Medicine, Bronx, NY; [3]Department of Medicine, Inje University, Ilsan Paik Hospital, Ilsan, Korea; [4]Department of Pathology, Albert Einstein College of Medicine, Bronx, NY.*

Background: Hypertension is one of the most common causes of end stage renal disease in the United States. Hypertensive nephropathy remains an elusive entity, with very few confirmatory biopsies and histological characteristics. In this study, we compared patients with hypertensive chronic kidney disease to those with normal renal function in the presence and absence of hypertension.

Methods: Human kidney tissue samples were obtained from elective nephrectomies. Samples with eGFR<60, and in absence of diabetes were classified as hypertensive nephropathy (HN). Tubular epithelial cells were isolated from glomeruli by manual microdissection. cDNA amplification fragmentation and labeling and finally Affymetrix GeneChip expression arrays (U133A 2.0) were used to analyze transcripts in samples.

Results: Genespring GX software was used for normalization and statistical analysis with Benjamini-Hochberg corrected two-tailed t-test with p value < 0.05 and > 1.5 fold change. We identified 1792 differentially expressed probesets in CKD tubules, with 1372 unique gene transcripts. Among them, the probesets with the highest fold change were albumin, epithermal growth factor, and uromodulin known to play a role in chronic kidney disease. Gene ontology of the differentially expressed genes highlighted metabolic processes, localization, establishment of localization, and immune system responses in statistically enriched terms. Of the metabolic processes, pathways related to fatty acid metabolism showed the strongest enrichment.

Conclusions: This is the first genome wide transcriptome analysis of tubular epithelial cells in human hypertensive nephropathy. These results demonstrate that multiple known and novel genes and pathways are regulated in the HN and they may play a role in the pathogenesis of HN or serve as biomarkers.

PUB251

The Expression Profiling of Intestinal Nutrient Transporter and Channel Genes in Rats with Renal Failure

Hironori Yamamoto, Mari Nakao, Otoki Nakahashi, Shoko Ikeda, Yutaka Taketani, Eiji Takeda. *Dept. Clinical Nutrition, University of Tokushima, Institute of Health Biosciences, Tokushima, Japan.*

Background: The understanding of intestinal function in chronic kidney disease (CKD) has been important elements in the clinical management of CKD with dietary and drug therapy. Numerous studies have indicated that CKD patients or model rats have enzymatic abnormalities and impairments of absorptive function in the small intestine. However, it is still unclear how the intestinal function, especially digestion and absorption of nutrients, is different from CKD. In order to estimate the functional changes in the intestine of CKD, in this study, we demonstrated the microarray analysis of global gene expression in intestine of adenine-induced CKD rat.

Methods: 8-week-old male Wister rats were fed on 0.75% adenine diet for about five weeks to induce the kidney failure. In addition, 5/6 nephrectomy rats were also prepared. The plasma levels of bood urea nitrogen, creatinine and phosphate were monitored by each specific test kit. Intestinal total RNA was extracted from the mucous from duodenum, DNA microarray analysis were performed using Affymextrix rat gene chip. For quantitative mRNA expression analysis was Real.

Results: DNA microarray analysis revealed that CKD caused great changes in gene expression in the rat duodenum: about 400 genes exhibited more than a two-fold change in expression level. Gene ontology analysis showed that a global regulation of genes by CKD involved in iron ion binding, alcoholic, organic acid and lipid metabolism. Furthermore, we found that the mRNA expression of transporter and channel genes which related to absorption of calcium, phosphate, iron and chloride were markedly reduced in intestine of CKD rats.

Conclusions: These results suggest that CKD may alter some nutrient metabolism in the small intestine by modifying the expression of specific genes. The intestinal transcriptome database of CKD might be useful to develop the novel drugs or functional foods for CKD patients.

Toll-Like Receptor 9 Gene Polymorphisms Contribute to Development of Proteinuria in Childhood IgA Nephropathy Shin-hee Kim,[1] Jin-soon Suh,[2] Byoung-Soo Cho.[3] *[1]Department of Pediastrics, School of Medicine, Kyng Hee Univerisity, Seoul, Republic of Korea; [2]Department of Pediastrics, School of Medicine, Kyng Hee Univerisity, Seoul, Republic of Korea; [3]Department of Pediastrics, School of Medicine, Kyng Hee Univerisity, Seoul, Republic of Korea.*

Background: Toll-like receptors (TLRs) play important roles in the immune responses of both innate and adaptive systems. There is increasing evidence that TLRs play a role in the development and progression of immune complex-mediated glomerulonephritis. In this study, we investigated the association of *TLR9* polymorphisms with the immunoglobulin A nephropathy (IgAN) in Korean children.

Methods: We analyzed two single nucleotide polymorphisms (SNPs) of *TLR9* gene (rs352140 and rs187084) using direct sequencing in 199 IgAN patients and 290 healthy controls. The IgAN patients were subgrouped by the presence of proteinuria (>4 mg/m^2/h), nephrotic-range proteinuria (>40 mg/m^2/h), gross hematuria, podocyte foot process effacement, and advanced pathological markers in renal biopsy such as interstitial fibrosis, tubular atrophy, or global sclerosis.

Results: In our case-control analysis, no association was found between *TLR9* SNPs and development of IgAN. In an analysis of associations between subgroups of IgAN and genotypes of each *TLR9* SNP, we found that rs352140 was associated with the presence of proteinuria [overdominant model, odds ratio (OR) = 0.55, 95% CI = 0.31–0.99, P = 0.046]. Moreover, both *TLR9* SNPs were associated with the presence of nephrotic-range proteinuria (rs352140: overdominant model, OR=0.21, 95% CI = 0.06–0.75, P = 0.013; rs187084: overdominant model, OR = 0.19, 95% CI = 0.05–0.75, P = 0.008).

Conclusions: Our data indicate that *TLR9* SNPs of rs352140 and rs187084 may contribute to the development of proteinuria in IgAN patients.

A Comprehensive Molecular Network for Congenital Anomalies of the Kidney and Urinary Tract: Integrating Genetic Findings Kirsten Y. Renkema,[1] Albertien M. Van Eerde,[1] Nayia Nicolaou,[1] Loes F.M. Van der Zanden,[2] Iris Van Rooij,[2] Nel Roeleveld,[2] Barbara Franke,[3,4] Ernie M.H.F. Bongers,[3] Geert Poelmans,[3,5,6] Nine V. Knoers.[1] *[1]Medical Genetics, University Medical Center Utrecht, Utrecht, Netherlands; [2]Epidemiology, Biostatistics, and HTA, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [3]Human Genetics, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [4]Psychiatry, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [5]Cognitive Neuroscience, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [6]Molecular Animal Physiology, Radboud University Nijmegen, Nijmegen, Netherlands.*

Background: Congenital anomalies of the kidney and urinary tract (CAKUT) form a spectrum of developmental malformations. CAKUT are the most common cause of end-stage renal disease in children. Animal and human studies have shown that defects in genes expressed during kidney and urinary tract organogenesis are important causal factors for CAKUT, though the biological mechanisms underlying CAKUT etiology are still poorly understood. Instead of focusing on individual genes, analyses that aim at the identification and integration of functional relationships between these genes are likely to lead to novel insights.

Methods: In this study, 185 candidate genes were selected based on experimental evidence implicating them in CAKUT pathogenesis. By applying a novel and innovative genetic network building approach, combining systematic bioinformatics and literature analyses, we integrated 129 of 185 CAKUT candidate genes into a comprehensive protein network.

Results: Glial cell line-derived neurotrophic factor (GDNF)-dependent signaling was shown to integrate the different signaling cascades. Moreover, three microRNA genes that were known to be differentially expressed in CAKUT patients, as well as their target genes, were integrated in the network.

Conclusions: This analysis provides important clues on the molecular etiology of CAKUT, being instrumental for the development of novel approaches aimed at early diagnosis and counseling of CAKUT patients and their relatives, and the identification of 'druggable targets' for treatment or even prevention of these disorders.

Early Endothelial Outgrowth Cells (eEOCs) and BMP-5 in Chronic Hypertensive and Diabetic Nephropathy Daniel Patschan, Susann Patschan, Gerhard A. Mueller. *Nephrology and Rheumatology, University Hospital Göttingen, Göttingen, Niedersachsen, Germany.*

Background: Early Endothelial Outgrowth Cells (eEOCs) protect mice from acute kidney injury. These effects can be augmented by eEOC pretreatment with Bone Morphogenetic Protein-5 (BMP-5). Aim of the study was to analyze modulatory effects of BMP-5 in an eEOC-based therapy of chronic hypertensive and diabetic nephropathy.

Methods: Male, 8-12 weeks old C57/Bl6N-mice underwent 5/6-nephrectomy in order to induce chronic hypertensive nephropathy, or they received STZ for inducing chronic diabetic nephropathy. Animals were systemically injected with syngeneic murine eEOCs at 1 and 2 weeks after surgery / the last STZ administration. Animals were analyzed 8 weeks later.

Results: Mice after 5/6-nephrectomy (5/6-N.) and STZ administration (STZ) displayed significantly impaired renal function at week 8 (5/6-N.: 0.24 ±0.01 mg/dl und STZ: 0.2 ±0.01 mg/dl vs. Controls (C.): 0.15 ±0.008 mg/dl, p<0.0001 und p=0.02). Only STZ treatment was associated with significant proteinuria (STZ: 1.4 ±0.16 mg/day vs. C.: 0.85 ±0.13 mg/day, p=0.01). Injection of either untreated or BMP-5 pretreated eEOCs in 5/6-N. was not associated with improved renal function but proteinuria was decreased. The latter effect was abrogated with BMP-5 pretreated cells. In diabetic animals renal function was improved after the administration of untreated and BMP-5 pretreated eEOCs (STZ + eEOCs: 0.125 ±0.008 mg/dl und STZ + eEOCs + BMP-5: 0.14 ±0.01 mg/dl vs. STZ: 0.2 ±0.01 mg/dl, p=0.001 und p=0.03). Proteinuria was reduced as well, this effects was more pronounced after Injections of BMP-5 treated cells (STZ + eEOCs + BMP-5 0.9 ±0.13 mg vs. STZ 1.4 ±0.16 mg, p=0.04).

Conclusions: Systemic eEOC therapy in chronic diabetic nephropathy improves renal function and proteinuria. Antiproteinuric effects are increased after eEOC treatment with BMP-5.

PUB255

Effects of Bone Marrow-Derived Mesenchymal Stem Cells Transfected with Hepotocyte Growth Factor Gene on Renal Fibrosis in Rats Jian-xin Wan. *Nephrology, The First Affiliated Hospital of Fujian Medical University.*

Background: To investigate the effects of bone marrow-derived mesenchymal stem cells (MSC) transfected with adenoviral vector carrying hepotocyte growth factor (HGF, Ad-HGF) on renal fibrosis in unilateral ureteral obstruction (UUO) rats.

Methods: MSC were transfected with Ad-HGF at the optimal gene transduction efficiency of 150 multiplicity of infection (MOI). The efficiency of transfection and the expression of HGF in the suspension were detected by RT-PCR and enzyme linked immunosorbent assay (ELISA) respectively. MSC-modified Ad-HGF marked by DAPI were detected in renal tissue by fluorescent microscope. Deposition of collagenous fibers in renal tissue were observed by Masson stain. The expressions of HGF and α-SMA in renal tissue were detected by immunohistochemistry. The expressions of HGF, α-SMA and fibronectin (FN) mRNA in renal tissue were detected by RT-PCR.

Results: MSC could be transfected efficiently as seed cells to accept target genes by Ad-HGF, and a higher level of expression of HGF in vitro, which persisted 16 days at least. Compared with the control group, the content of HGF in the supernatant after transfection increased time-dependently and peaked at 8 d. The expression of HGF mRNA were detected by RT-PCR, which persisted 11 days at least. DAPI-labeled transplantating cells were found in the obstructed kidney of rats at day 3, 7, 14 after transplantion. Results of Masson stain revealed that the range of collagenous fibers in renal tissue in UUO group was significantly larger than in transplanting groups. Compared with UUO group, the expression of α-SMA mRNA and protein were decreased in transplanting group. The expressions of HGF mRNA and protein in transplantion group were significantly higher than in UUO group. Simultaneously the expression of fibronectin mRNA in transplanting group was significantly lower than in UUO group.

Conclusions: This study suggests that transplantation of MSC modified with Ad-HGF are capable of homing to renal tissue of unilateral ureteral obstruction following renal artery infusion and could attenuate renal fibrosis.

PUB256

Astragaloside IV Promote the Proliferation of Adipose-Derived Stem Cells In Vitro Weiwei Wang, Wei Wang, Yan Jiang, Jinyuan Zhang. *Division of Nephrology, Jimin Hospital, Shanghai, China.*

Background: The proliferation ability of stem cells may be affected by microenvironment in the injury tissue. Astragaloside IV(Ast) could promote proliferation of stem cells. In this study, adipose-derived stem cells(ADSCs) were investigated under different concentration of Ast and different time point in vitro so as to select the most suitable intervention conditions and also to evaluate the feasibility for ADSCs cultrued with Ast.

Methods: The human adipose-derived stem cells(hADSCs) at passage 3 were used for the experiments. Cells were cultured in five groups and observed at 24hrs, 48hrs and 72hrs respectively. Control group cells were cultured in 10% FBS complete medium. Experimental group cells were cultured in 10% FBS complete medium with different concentration of Ast(10mg/l, 20mg/l, 30mg/l and 40mg/l). Cell proliferation was determined by Cell-Counting Kit-8 (CCK8) and proliferating cell nuclear antigen (PCNA) assay to select the most suitable intervention conditions (concentration and time point) and then hADSCs (under suitable intervention conditions) were identified by specific surface markers(CD moleculors) by FACS and differentiation abilities into osteoblasts, adipocytes and chondroblasts in vitro under appropriate conditions.

Results: CCK-8 examination showed that absorbanee values of cultured cells were significantly changed at different time points after treating with 10mg/l,20mg/l,30mg/l,40mg/l Ast. At 48hrs, 20mg/l and 30 mg/l Ast had the most significant effect on proliferation of cultured cells. Compared with 20mg/l group, proporition of hADSCs had no statistical difference in 30mg/l group. Expression of PCNA had also no statistical difference in the 20mg/l and 30mg/l groups for 48hrs. Control group and hADSCs cultured with 20mg/l Ast for 48 hours both expressed a high level of typical MSCs markers (CD29, CD44 and CD105).They could also differentiate into osteoblasts, adipocytes and chondroblasts in vitro under appropriate conditions.

Conclusions: The 20mg/l Ast for 48hrs could obviously promote the proliferation of hADSCs and have no influence on differentiation abilities, which may enhance the effect of hADSCs in tissue engineering.

Interaction between Cyclosporine A and Bone Marrow Mesenchymal Stem Cells, Their Conditioned Medium and Microvesicles in a Mouse Model

Maria Jose M.J. Ramirez-Bajo,[1] Stefania Bruno,[2] Chiara Pasquino,[2] Giovanni Camussi,[2] Josep Maria Campistol Plana.[1] *[1]Nephrology and Transplantation, Laboratori Experimental de Nefrologia i Trasplantament (LENIT), Hospital Clinic, Barcelona, Spain; [2]Internal Medicine, Molecular Biotechnology Center, University of Torino, Torino, Spain.*

Background: Adult stem cells have been extensively investigated for their regenerative and immunomodulatory properties. This process is orchestrated by cytokines and growth factors secreted by injured renal tissue which mobilize bone marrow mesenchymal stem cells (BM-MSCs) to the affected regions. Recent studies have suggested that this paracrine-endocrine mechanism between differentiated cells and stem cells mediated by microvesicles (MVs). Several studies with MSCs and their MVs treatment have showed acute kidney injury improvement but few studies have been done in chronic kidney disease. The objective is to determine the possible regenerative or preventive effect of BM-MSCs, their conditioned medium (CM) and MVs derived from them in a chronic nephrotoxic mouse model induced by Cyclosporine A (CsA).

Methods: Murine BM-MSCs were isolated from C57BL/6 mice and CM and MVs were obtained *in vitro* for being as part of the different therapies. Chronic nephrotoxic mouse model was induced by CsA 75 mg/Kg or vehicle for 4 weeks in male C57BL/6 being randomized in two groups: 1) Preventive group (PG), where three different therapies where weekly inoculated and 2) Regenerative group (RG), where mice were inoculated at week 2 and 3 after starting CsA treatment with MVs. BUN levels were determined in all animals. Histopathological kidney sections (hematoxylin/eosin and PAS stain) were scored for the percentatge of vacualization, tubular necrosis, casts, cyts and glomerular hialynosis.

Results: Survival rate in PG and RG groups was lower than CsA group. No differences were observed in BUN levels between treatments. RG showed better results than PG in histopathological analysis.

Conclusions: The application of three different therapies in a chronic nephrotoxicity mouse model induced by CsA showed an interaction between BM-MSCs, CM, MVs and CsA that decreases the mouse survival and increases the histopathological renal injury.

PUB258

Embryonic Kidney Provides a Niche for Bone Marrow-Derived Mesenchymal Stem Cells Differentiation into Epithelial Cells In Vitro

Qing-gang Li, Jiajia Wan, Jiayao Ji, Yuansheng Xie, Xiang-Mei Chen. *Renal Divison, Institute of Nephrology, State Key Laboratory of Kidney Disease, Beijing, China.*

Background: Renal tubule injury plays a major role in pathogenesis of acute kidney injury. Recent findings have demonstrated that bone marrow-derived mesenchymal stem cells (MSCs) can be differentiated into renal epithelial cells and promote tissue repair in an in vivo mouse model of acute renal failure, but the rate of cell differentiation is relatively low. The major reason for this lack of success is because developmental programs that differentiate MSCs into renal cells consist of numerous factors, some of which are as yet unknown. Some data showed that MSCs can differentiate into mature cells when supplied with a niche containing factors identical to those in the kidney developmental process.

Methods: In order to trace the MSCs, we used red fluorescent protein(RFP)-labeled murine MSCs. To assess if cultured MSCs were already differentiated into epithelial cells in vitro without embryonic kidney niche, the cells were subjected to RT-PCR analysis for specific epithelial marker genes. To test if a niche for epithelial cells can be provided by disaggregation/reaggregation of embryonic kidney cells, we used disaggregation/reaggregation method. In order to determine if whole embryonic kidney can provide a different niche, we injected MSCs into embryonic kidney and cultured with kidney organ culture system.

Results: No expression of Cadherin6 and E-Cadherin in MSCs were observed before culturing in the niche. When MSCs were mixed with embryonic kidney cells using disaggregation/reaggregation method, they migrated and surrounded ureteric bud, some of which integrated into intrinsic renal cells, not cell fusion. Only a few MSCs expressed E-cadherin which indicated epithelial cells. Compared to the first method, we found more MSCs can be differentiated into epithelial cells, taking part in development of renal tubule with intrinsic embryonic cells.

Conclusions: These results indicate that migration and recruitment of MSCs occurred in embryonic kidney niche. Furthermore, MSCs can be differentiated into renal cells.

PUB259

Poor Lysosomal Membrane Integrity in Proximal Tubule Cells of Haptoglobin 2-2 Genotype Mice with Diabetes Mellitus

Farid M. Nakhoul,[1] Nakhoul Nakhoul,[1] Rachel Lotan-miller,[2] Aviva Peleg,[1] Rabea Asleh.[2] *[1]Nephrology, Faculty of Medicine, Bar-Ilan Univer.; [2]Vascular Medicine Lab, Technion-Haifa, Israel.*

Background: The Haptoglobin (Hp) genotype is a major determinant of progression of Diabetic Nephropathy(DN) in DM patients. The major function of the Hp is to bind and modulate the fate of extracorpuscular Hb and its iron cargo. In humans we have 3 different Hp genotypes: Hp 1-1, 2-2, 2-1. Hp 1-1 is potent anti-oxidant and protective against DN than Hp 2-2. We have demonstrated an interaction between Hp genotype and DM on the accumulation of iron in renal proximal tubule cells (PCT) in mice.

Methods: All mice were C57B1/6 genetic background. Mice with Hp -2,2-1,1-1, were sacrified after DM duration of 3 months induced by SZT. We analyzed iron deposition by Transmission Electron Microscopy (TEM), Energy dispersive X-ray spectroscopy (EDX) and electron energy loss spectroscopy (EELS). We Assess lysosomal membrane integrity & lipid peroxides, redox-active chelatable iron, vit.E content in the PCT of different Hp genotypes treated with Vit.E or placebo.

Results: TEM, EDX,EELS: Accumulation of electron dense deposits (iron rich) in the lysosomes of PCT cells from Hp 2-2 (65±4% of all lysosom.) compared with Hp 1-1 DM mice (41±4% of all lysos.) $p<0.05$. A 2-fold increase in the amount of redox-active iron in the lysosomes of Hp 2-2 (0.56 ± 0.07 μM) vs those from Hp 1-1 DM mice (0.23 ± 0.14 μM, $p = 0.036$). Lysosomal membrane integrity was decreased in Hp 2-2 DM PCT l Vs Hp1-1, $P<0.003$. Vit. E supplement. Resulted in a significant 45% reduction in lysosomal redox-active iron in Hp 2-2 vs Hp 1-1 DM mice, decreased lysosomal lipid peroxidase (LP) in Hp 2-2 Vs Hp2-2 DM mice treated with placebo (75.7+/-9 vs 109.2+/-8.8 nmol LP/mg protein) $p=0.03$. A correlation between lysosome membrane α-tocophorol conc. And the degree of lysosomal membrane oxidation in Hp 2-2 DM mice but not in Hp 1-1, $p<0.003$.

Conclusions: Increased Iron deposits in PCT of DM mice with Hp 2-2, were associated with lysosomal membrane lipid peroxidation. Vit. E adm. To Hp 2-2 DM mice resulted in a significant decrease in intralysosomal iron induced oxidation. Iron induced renal PCT injury, may play a role in the development of DN.

Effects of HP Acthar Gel® in the STZ Rat Model of Diabetic Nephropathy

Christine M. Clemson,[1] Subba R. Chintalacharuvu,[2] David Young.[1] *[1]Research and Development, Questcor Pharmaceuticals, Ellicott City, MD; [2]IVP-Inflammation, Renal and Bone, Covance, Greenfield, IN.*

Background: H.P. Acthar® Gel (repository corticotropin injection; Questcor) is a long-acting formulation of the full sequence ACTH(1-39) that may include other pro-opiomelanocortin peptides. Prior evidence demonstrated that Acthar had a positive effect on renal function and pathology in animal models of FSGS, diabetic nephropathy and acute kidney injury (Gong, 2009; 2010, 2011; Wang 2010). Clinical evidence in human subjects with diabetic nephropathy also demonstrated Acthar's efficacy in improving renal function (Tumlin, 2011). Here we investigated whether Acthar can slow the progression of renal function loss in the STZ diabetic rat model.

Methods: Diabetes was induced in Wistar rats with a single dose of STZ (55 mg/kg) administered intravenously. At 6 weeks post STZ insulin management (2IU BID) and treatment commenced. The following groups were treated by s.c. injection QOD: placebo with insulin management; Acthar (10IU) with insulin management; Acthar (10IU) no insulin; α-MSH (10 ug) with insulin management and diabetic animals with no treatment or insulin. Treatment was for a total of 8 weeks post STZ and half the animals recovered with no treatment (except for insulin management) for an additional 4 weeks.

Results: Hyperglycemia occurred 4 days post STZ and renal function, measured by creatinine clearance, declined steadily over the 6 weeks prior to treatment. Acthar, with and without insulin management, slowed the progression of diabetic nephropathy compared to placebo and the comparator melancortin peptide, α-MSH, by several measures of renal function including creatinine clearance. Importantly, glycemia was not significantly worsened by Acthar treatment.

Conclusions: Acthar slowed progression of diabetic nephropathy in STZ rats with established disease by multiple measures of renal function. This preclinical evidence adds to the growing body of preclinical and clinical evidence that Acthar has beneficial effects on renal function and supports the clinical development of Acthar as a treatment for diabetic nephropathy, a non approved indication.

Abelmoschus manihot (L.) Medic, a Compound of Chinese Herbal Medicine, Improves Renal Inflammation and Glomerularsclerosis by Regulating p38MAPK and TGF-beta1/Smad Signaling Pathways in Diabetic Nephropathy

Yigang Wan,[1] Wei Sun.[2] *[1]Department of Traditional Chinese Medicine, Nanjing Drum Tower Hospital, the Affiliated Hospital of Nanjing University Medical School, Nanjing, Jiangsu, China; [2]Department of Nephrology, Jiangsu Provincial Hospital of Chinese Medicine, Affiliated Hospital of Nanjing University of Chinese Medicine, Nanjing, Jiangsu, China.*

Background: *Abelmoschus manihot (L.) Medic* (AM), a compound of Chinese herbal medicine has been applied extensively for treatment of patients with diabetic nephropathy (DN) in China. Accumulating evidences demonstrate that renal inflammation and glomerularsclerosis are determinants during glomerular injury progress under high-glucose condition. Among which, p38 mitogen-activated protein kinase (MAPK) and transforming growth factor (TGF)-beta1/Smad signaling pathways play critical roles respectively. We aim to investigate effects and mechanisms of AM on renal inflammation and glomerularsclerosis by regulating p38MAPK and TGF-beta1/Smad signaling pathway activities in streptozotocin (STZ)-induced nephropathy rats.

Methods: Rats were randomly divided into 3 groups, sham-operated group, AM-treated group, and vehicle given group, and sacrificed at weeks 8 after induction of DN induced by 2 consecutive intraperitoneal injections of STZ at 30 mg/kg dose with an interval of 1 week following unilateral nephrectomy. Daily oral administration of AM and vehicle (saline) was started after the second injection of STZ until the day of sacrifice. Proteinuria,

urinary albumin, blood glucose, biochemical indicators, pathological changes, and protein expressions of TGF-beta1, Smad3, Smad7, phosphorylated Smad 2/3 (p-Smad2/3), p38MAPK, and phosphorylated p38MAPK (p-p38MAPK) in glomeruli were examined, respectively.

Results: The p38MAPK and TGF-beta1/Smad signaling pathways were activated in DN rats. AM markedly down-regulated p-p38MAPK, p-Smad2/3, and TGF-beta1 protein expressions, and ameliorated proteinuria, renal function, mesangial lesions, and macrophage accumulation in glomerulus without lowering blood glucose level.

Conclusions: AM could improve renal inflammation and glomerularsclerosis by inhibiting p38MAPK and TGF-beta1/Smad signaling pathways activation in vivo.

Study on the Relationship between Plasma Activated Protein C and Atherosclerosis in Type 2 Diabetic Nephropathy

Li Wang. *Renal Department, Sichuan Academy of Medical Sciences & Sichuan Provincial People's Hospital, Chengdu, Sichuan, China.*

Background: Serum active protein C decreased(APC) obviously in diabetic patients and was reported to be negatively correlated with atherosclerosis, which may be associated with endothelial cell injury or inflammation. Inflammation was reported increased in patients with type 2 diabetic nephrology. So the objectives of this study were to investigate the relationship between plasma APC and atherosclerosis in type 2 diabetic nephropathy, and the mechanism of atherosclerosis in type 2 diabetic nephropathy.

Methods: 30 patients with type 2 diabetic nephrology(non-dialysis)were enrolled from April 2011 to July 2011. The carotid intima-media thickness(IMT) was measured by ultrasonography. APC, interleukin-1β (IL-1β), soluble vascular adhesion molecular-1 (sVCAM-1), soluble endothelial cell protein C receptor (sEPCR), soluble thrombomodulin (sTM) were assayed by ELISA. The relationship between these parameters and IMT were analyzed.

Results: 1) APC significantly decreased in type 2 diabetic nephropathy (2865.99±571.38pg/ml vs. 3227.70±300.44 pg/ml, p=0.005), while IMT(0.18±0.07cm vs. 0.06±0.02cm,p=1.67E-10),sTM(1.96±0.77ng/ml vs. 1.23±0.53ng/ml, p=3.22E-4),sEPCR(365.85±143.75ng/ml vs. 266.16±132.20ng/ml, p=0.010), sVCAM-1(493.55±411.26ng/ml vs. 85.10±76.99 ng/ml,p=2.4E-5), IL-1β(395.82±250.4pg/ml vs. 199.53±80.12 pg/ml,p=0.001)was higher in 2 type 2 diabetic nephropathy. 2) APC negatively correlated with albuminuria (r=0.402, p=0.027), IMT(r=-0.720,p=0.002), sTM(r=-0.505, p=0.005), sEPCR(r=-0.477,p=0.008), sVCAM-1(r=-0.437,p=0.018) and IL-1β(r=-0.564,p=0.002. IMT positively correlated with age(r=0.416, p=0.022), albuminuria (r=0.490, p=0.006), sTM(r=0.575, p=0.001), sEPCR(r=0.567, p=0.001), sVCAM-1(r=0.518, p=0.004), IL-1β(r=0.562, p=0.002), and hs-CRP(r=0.380, p=0.042). 3)APC concentrations were significantly different in different proteinuria groups and different IMT groups by ANOVA analysis(p=0.001,p=0.021).

Conclusions: Plasma APC significantly decreases in type 2 diabetic nephropathy patients, with possible association with inflammation or endothelial cell injury. Decreased plasma APC might be related to atherosclerosis in type 2 diabetic nephropathy.

Expression of Organic Anion and Cation Transporters in Experimental Diabetic Nephropathy

Maja Henjakovic,[1] Andrea Babelova,[2] Waja Wegner,[1] Birgitta C. Burckhardt,[1] Gerhard Burckhardt.[1] *[1]Department of Systemic Physiology and Pathophysiology, University Medical Center Göttingen, Göttingen, Germany; [2]Institute for Cardiovascular Physiology, Faculty of Medicine, Goethe-University, Frankfurt am Main, Germany.*

Background: Association between diabetic nephropathy and renal expression of organic anion transporters (Oats) and organic cation transporters (Octs) is unclear. The aim of this study was to identify sex-dependent changes of Oats and Octs in Zucker spontaneously hypertensive fatty rats (ZSF1), a rat model for diabetic nephropathy.

Methods: Kidneys of 18 week old ZSF1 female and male rats, and their lean controls were obtained from Charles River. Total RNA was isolated from kidney cortical slices and genes of interest were analyzed by real-time PCR. Renal sections were stained with periodic acid Schiff stain (PAS) and anti-fibronectin antibody to characterize structural changes induced by diabetes.

Results: Despite similar structure of renal tissue between lean males and females, lean males showed minor changes in tubular basement membrane and a higher accumulation of fibronectin than female rats. Glomerulosclerosis, tubulointerstitial fibrosis and protein casts in Bowman's space and in tubular lumen were stronger in obese male than in obese female rats. Oat1, Oat2, Oat3, the sodium-dependent dicarboxylate transporter 3 (NaDC3), Oct1 and Oct2 were significantly lower expressed in obese females than in lean females, whereas obese and lean ZFS1 male rats showed no difference. Expression of multidrug resistance-associated protein 2 (Mrp2) and Mrp4 remained unchanged in both sexes. Renal vimentin and E-cadherin were higher expressed in obese males compared to lean males. In females, no differences were observed. RNA level of transcription factor hepatocyte nuclear factor 4 (Hnf4a) was decreased in kidneys of obese female and male rats as compared to their lean controls, Hnf1b was decreased in ZSF1 females but not in males.

Conclusions: Diabetic nephropathy was associated with severe structural changes in male rats and milder renal injury with decreased expression of Oats and Octs in females, possibly leading to a decreased secretion of organic anions and cations (e.g. drugs).

Linagliptin Reduces High Glucose Induced Inflammatory and Fibrotic Markers in Human Kidney Proximal Tubular Cells

Muralikrishna Gangadharan Komala, Amanda J. Mather, Katherine Jane Pegg, Simon Gross, Carol A. Pollock, Usha Panchapakesan. *Renal, University of Sydney, Sydney, NSW, Australia.*

Background: Linagliptin is a Dipeptidyl Peptidase (DPP4) inhibitor used to lower blood glucose in type 2 DM. It inhibits cleavage of the endogenous incretin hormones GLP-1 and GIP, raising their levels and thus promoting insulin release and inhibiting glucagon secretion resulting in lowering of blood glucose. DPP4 inhibitors may have benefits other than glucose lowering as DPP4 also cleaves a host of additional peptides (not just GLP-1/GIP), thus regulating their biological function resulting in a range of possible outcomes. It would be desirable to have antidiabetic therapies with additional renoprotective effects beyond glucose lowering. We aimed to evaluate the effect of linagliptin on high glucose induced inflammatory and fibrotic markers in human kidney proximal tubular cells.

Methods: Immortalised Human Proximal Kidney cells (HK2 cells) were exposed to control (5mM) or high glucose (30mM) +/- linagliptin (30nM). Cells were harvested for nuclear binding assays, western blot, flow cytometry and supernatants were collected for ELISA. Inflammatory/fibrotic markers relevant to diabetic nephropathy like High Mobility Group Box Protein 1 (HMGB1), fibronectin, NFKB and TGFB were measured as endpoints.

Results: High glucose downregulated the expression of DPP4. Linagliptin reduced HMGB1 induced NFκB binding, independent of DPP4 cleaving of HMGB1. There was no effect on high glucose induced NFKb binding. High glucose-induced fibronectin expression was also reduced with linagliptin and this was associated with unchanged total TGFB levels.

Conclusions: The downregulation of DPP4 with high glucose may be due to shedding of the surface protein. In summary our data support a role for DPP4 inhibition in limiting the impact of extracellular mediators on renal tubular/tubulointerstitial pathology.

PUB265

The Targeting Design of Recombinant Protein C and Its Protection from Endothelial Cells Injury

Li Wang. *Renal Department, Sichuan Academy of Medical Sciences & Sichuan Provincial People's Hospital, Chengdu, Sichuan, China.*

Background: Important relationship between atherosclerosis and vascular endothelial damage in diabetic nephropathy (DN) was reported before, while active protein C (APC) may have a protective effect for endothelial cells. The objectives were to study the influence of these patients' serum on human vascular endothelial cells (HUVEC), to construct adenovirus with specific promoter and protein C targetedly express in endothelial cells and its protect effect for vascular endothelial injury.

Methods: 1) Cultured HUVEC in vitro;2 Construction, appraisal and packaging of restructuring adenovirus Ad-FIT-1/PC, transfected with HUVEC and human aortic smooth muscle cells (HA-vsmc); 3)Grouping HUVE into 4 groups: Control group, Black adenovirus group (AD group)(Ad-GFP transfected+thrombin), PC group (Ad-FLT-1/PC transfected), PC activation group (Ad-FLT-1/PC transfected+thrombin; APC). Apoptosis rate was analyzed;4) APC,sEPCR,sTM,VCAM-1,IL-1β in the supernatant of cell culture was measured by ELISA.

Results: 1)The intercellular space were wider, and the damaged cells were more in the intervention group than in the control. 2) Western blot showed increased PC expression in HUVEC after transfect with Ad-FLT-1/PC. 3)The apoptosis rate of APC group(1.53±0.39)% was lower than control group(5.16±3.53)%(P<0.05). 4)APC of APC group was higher than PC group and AD group. sEPCR of APC group was lower than the control. sTM in APC group was lower than the control, AD group and PC group. The VCAM-1 level of APC group was the lowest. IL-1 β in APC group was lower than the PC group.

Table1 Concentrations of biomarkers

Group	APC(ng/l)	sEPCR(ng/ml)	sTM(ng/ml)	VCAM-1(μg/l)	IL-1β(ng/l)
Control group	77.411±7.609	7.569±1.515	0.405±0.071	5.417±1.180	0.146±0.070
AD group	72.079±5.512	6.630±1.067	0.407±0.066	4.660±0.770	0.149±0.064
PC group	53.776±1.515	6.530±0.755	0.377±0.155	4.559±0.565	0.319±0.059
PC activated group	82.172±4.361	6.127±1.130	0.384±0.150	4.205±0.710	0.043±0.083

Conclusions: Serum of DN patients with atherosclerosis can affect HUVEC. Restructuring adenovirus Ad-FLT-1/PC can targeted transfect HUVEC, and express the PC. APC can protect HUVEC by restrain the apoptosis and reduce the secretion of inflammatory factors caused by DN serum.

Serum Retinol Binding Protein 4 Is Associated with Type 2 Diabetic Nephropathy

Jin Joo Cha,[1] Young Sun Kang,[1] Jung Eun Kim,[1] Mihwa Lee,[1] Hye Kyung Song,[1] Mi Jin Lee,[1] Young Youl Hyun,[2] Ji Eun Lee,[3] Hyunwook Kim,[3] Sang Youb Han,[4] Kum Hyun Han,[4] Nam Ho Kim,[5] Dae R. Cha.[1] *[1]Nephrology, Korea Univ., Korea; [2]Kangbuk Samsung Hosp.; [3]Wonkwang Univ.; [4]Inje Univ.; [5]Chonnam Univ..*

Background: Serum retinol binding protein 4(RBP4) is known to be associated with insulin resistance, obesity, and type 2 diabetes. Whether it can be used as a biomarker of diabetic complications remains undeterminable.

Methods: We investigated the association of RBP4 level in type 2 diabetic nephropathy (DN). In vivo study of the 236 patients, 71% were diagnosed as type 2 diabetes. These patients were divided into three groups (normoalbuminuria vs microalbuminuria vs macroalbuminuria). In vitro study we tried to examine the mechanism of RBP4 in renal cells.

Results: Total four groups including non-diabetic controls showed similar basal characteristics in age, sex, BMI, eGFR, Hb, serum albumin, CRP, lipid levels, etc. Diabetic patients had higher blood glucose levels and HOMA-IR index than controls. Interestingly, patients with macroalbuminuria showed higher serum RBP4 level compared to patients without diabetic nephropathy or with normoalbuminuria or with microalbuminuria. It is notable that RBP4 level was also increased in patients with lower creatinine clearance. In univariate and multiple regression analysis, 24-h albuminuria and systolic blood pressure were positively correlated with logRBP4 level. BMI was negatively correlated with that level. In case of other vascular complications of type 2 diabetes, RBP4 level was not increased in the patients with retinopathy and peripheral neuropathy. However, the patients with higher RBP4 had significantly increased risk of cardiovascular, peripheral arterial and cerebrovascular disease. Podocytes expressed their uptake of RBP4 strongly compared to other renal cells including mesangial and tubular cells. Treatment of RBP4 into podocytes induced the activation of insulin receptor substrate-1(IRS-1).

Conclusions: RBP4 may contribute to the pathogenesis of DN and be used as a novel biomarker of DN. It also might be used as an indicator of macrovascular complications in type 2 diabetes.

Anti-Inflammatory Effects of BMP7 on AGEs-Induced Tubular Injury Ruixi Li,[1] Wai Han Yiu,[1] Miao Lin,[1] Hao-Jia Wu,[1] Loretta Y.Y. Chan,[2] Joseph C.K. Leung,[1] Kar Neng Lai,[1] Sydney C.W. Tang.[1] *[1]University of Hong Kong; [2]Queen Mary Hospital.*

Background: Formation and accumulation of advanced glycation end products (AGEs) are remarkably accelerated in the diabetic kidney. We recently demonstrated that AGEs stimulated various pro-inflammatory and pro-fibrotic responses in cultured human proximal tubular epithelial cells (PTEC). Bone morphogenetic protein (BMP) 7 has been reported to confer renoprotective effects in a variety of cell types and disease models. However, data is lacking in AGEs-induced renal tubular inflammation. Our present study explored the therapeutic potential of BMP7 on AGEs-induced tubular injury and its possible mechanisms.

Methods: Primary human PTEC were growth-arrested and exposed to glycated human serum albumin (AGE-HSA) with or without recombinant human BMP7 (rhBMP7). Pro-inflammatory chemokines and cytokines were detected at both gene and protein levels by real-time PCR and ELISA, respectively. Inhibitors of different signaling pathways were used (SB203580, PD98059 and PDTC for p38 MAPK, p44/42 MAPK and NF-κB respectively) to study the involvement of these pathways.

Results: AGE-HSA induced PTEC expression of pro-inflammatory factors through multiple pathways - IL8 through both p38 and p44/42 MAPK pathways, sICAM-1 through p44/42, and MCP1 through p38 MAPK. Although PDTC suppressed the mRNA and protein expression of IL-6 and TNF-α induced by AGE-HSA, AGE failed to stimulate NF-κB under these experimental conditions, indicating involvement of other pathways. rhBMP7 (5-200 ng/mL) dose-dependently attenuated AGE-HSA (100 ug/mL)-induced expression of sICAM-1, MCP1, IL8, TNF-α and IL6 at both mRNA and protein levels. Moreover, rhBMP7 suppressed phosphorylation of p38, p44/42 which was induced by AGE-HSA.

Conclusions: Our *in vitro* results demonstrated that BMP7 can attenuate pro-inflammatory responses to AGE stimulation in PTEC via suppression of multiple signaling pathways including p38 and p44/42 MAPK. Its potential application as a therapeutic molecule warrants further investigation. This study is supported by a General Research Fund of the Research Grants Council (Grant number: HKU 7770/09M) of Hong Kong.

PUB268

Protective Effect of Rhein on Pancreatic β-Cells Jing Liu, Zhao-hong Chen, Cai-hong Zeng, Zhi-Hong Liu. *Research Institute of Nephrology, Jinling Hospital, Nanjing University School of Medicine, Nanjing, Jiangsu.*

Background: Rhein, an anthraquinone compound isolated from rhubarb, is effective in treating diabetic nephropathy (DN). We found Rhein can also lower blood glucose level of diabetic patients, raising the possibility of a protective effect of rhein on pancreatic β-cells. We set out to test this hypothesis.

Methods: Mouse β-cell line, NIT-1, was treated with high glucose in the presence or absence of rhein, followed by examinations of mitochondrial distribution of rhein with MitoTracker RED CMXRos, mitochondrial morphology with electron microscopy, mitochondrial function with JC-1 staining and ATP content, apoptosis by Annexin V staining, and β-cell function by insulin secretion.

Results: The autofluorescence of rhein was detected mainly in the cytoplasma and mostly overlapped with MitoTracker at mitochondria. Rhein restored mitochondrial morphology of β-cells in the treatment of high glucose and prevented the upregulation of Drp1, a protein involved in the establishment of mitochondrial morphology. Rhein also restored mitochondrial membrane potential and increased ATP content in the cells. Moreover, Rhein alleviated high glucose-induced apoptosis as shown by Annexin V staining, as well as its inhibitions of cytochrome C release, bax translocation, and caspase 3 and 9 activation in the cells. Lastly, Rhein was found to increase insulin secretion of the cells.

Conclusions: The rhein uptaken by β cells localizes mainly in mitochondria. Rhein protects β cell against high glucose-induced damage through preserving mitochondrial structure and function, as well as inhibiting apoptosis. Rhein is able to sustain insulin secretion of β-cells. These effects of Rhein on β-cells may explain blood glucose reducion observed in diabetic patients treated with Rhein.

PUB269

Valsartan Prevents High-Glucose-Induced Podocyte Apoptosis via inhibiting Nuclear Factor of Activated T Cells c1 Wei Shi, Ruizhao Li, Wenjian Wang, Juan Ma. *Division of Nephrology, Guangdong General Hospital, Guangdong Academy of Medical Sciences, Guangzhou, Guangdong, China.*

Background: Podocyte apoptosis, an early feature of diabetic nephropathy, has been proven to be prevented by angiotensin receptor blockers (ARBs), including valsartan. However, the underlying molecular mechanisms remain poorly understood. Multiple evidences showed the activated nuclear factor of activated T cells c1 (NFATc1) causing podocyte apoptosis. Interestingly, our present study showed that valsartan reduced high-glucose-induced activation of NFATc1 in podocytes and thus prevented podocyte apoptosis.

Methods: Conditionally immortalized mouse podocytes cultured in vitro were divided into 1) normal glucose group, 2) normal glucose plus Ionomycin group, 3) high glucose group, 4) valsartan plus high glucose group,5) 11R-VIVIT plus high glucose group and 6) high glucose plus DMSO group. The activated NFATc1 protein was measured by Western blot, and the cell apoptosis by flow cytometry with Annexin V-FITC/PI double staining.

Results: High glucose activated podocyte NFATc1 in a dose and time-dependent way, as well as ionomycin (NFAT activator). When treated with valsartan, the high-glucose-induced activation of NFATc1 was significantly attenuated. Meanwhile, the high-glucose induced podocyte apoptosis reached the peak at the point of 48 hours when valsartan significantly reduced podocyte apoptosis, as well as 11R-VIVIT (NFAT inhibitor).

Conclusions: Valsartan prevents high-glucose-induced podocyte apoptosis by attenuating the activation of NFATc1, suggesting that there may be a link between angiotensin receptors and activation of NFATc1 induced by high-glucose in podocytes.

PUB270

EP4 Selective Agonist Exacerbate Inflammation and Fibrosis of the Kidney in Streptozotocin Induced Diabetic Mice Riyaz Mohamed, Punithavathi Vilapakkam Ranganathan, Calpurnia Jayakumar, Ganesan Ramesh. *Medicine/Vascular Biology Center, Georgia Health Sciences University, Augusta, GA.*

Background: Diabetic nephropathy is currently the most common cause of end-stage renal disease (ESRD) in the western world. Exacerbated inflammation is known to contribute for the development and acceleration of nephropathy. COX-2 mediated production of inflammatory mediator is increased during diabetes, however their involvement in the progression diabetic kidney disease quite controversial. Here, we show the unexpected role of PGE2-EP4 pathways in inducing inflammation and nephropathy.

Methods: Diabetes was induced using streptozotocin in C57BL/6 mice. EP4 selective agonist ONO-AE1-329 was administered 1 week after confirmation of hyperglycemia at a concentration of 0.1mg/kg BW subcutaneously. Kidney function, fibrosis, albuminuria and inflammation were determined by measuring serum creatinine, Western blot analysis, immunostaining, ELISA and RT-PCR.

Results: Hyperglycemia causes enhanced COX-2 expression and PGE2 production which was associated with increased excretion of pro-inflammatory cytokine (TNFα) and chemokines (MCP-1 and IP-10). Moreover, albumin excretion, collagen and α-smooth muscle actin expression were increased by 12 weeks of diabetes. Increased fibrosis was associated with increased macrophage infiltration in the interstitium. To determine, the receptor that mediates PGE2 inflammatory activity in diabetic kidney, EP4 selective agonist was administered in control and diabetic mice. Administration of EP4 selective agonist exacerbated inflammatory cytokine and chemokine production, collagen I and IV, α-smooth muscle actin expression, glomerular sclerosis and albuminuria (167±25 vs. 71±16 μg/24hr, $p<0.001$) without altering blood glucose level.

Conclusions: Our data suggests that COX-2 mediated PGE2 production is detrimental to diabetic kidney and PGE2 mediates its pro-inflammatory and pro-fibrotic activity through EP4 receptor. Activation of EP4 receptor accelerates diabetic kidney disease.

PUB271

The Role of Toll-Like Receptor Proteins (TLR) 2 and 4 in Mediating Inflammation in Human Proximal Tubular Cells (PTC) Harshini Mudaliar,[1] Steven J. Chadban,[2] Huiling Wu,[2] Carol A. Pollock,[1] Usha Panchapakesan.[1] *[1]Renal, Kolling Institute of Medical Research, University of Sydney, Sydney, NSW, Australia; [2]Renal, Royal Prince Alfred Hospital, Sydney, NSW, Australia.*

Background: Inflammatory responses are central to the pathogenesis of diabetic nephropathy (DN). TLRs are ligand activated membrane-bound receptors which induce inflammatory responses through activation of nuclear factor-kappaB (NF-κB). TLR 2 and 4 are present in PTCs and are activated by high mobility group box-1 (HMGB1), an endogenous ligand pathological in DN.

Methods: HK2 cells (a human kidney PTC line) were exposed to 5mM(control), 11.2mM (approximating the diagnostic threshold for diabetes mellitus) and 30mM (high) glucose for 72h or 7 days. Cells were harvested for protein, mRNA and nuclear extract to assess for TLR 2, 4 and inflammatory markers. HMGB1-mediated NF-κB activation was investigated by silencing TLR 2 (siRNA) and inhibiting TLR 4 (TAK-242).

Results: 11.2mM glucose maximally increased TLR 2 and 4 expression, the release of HMGB1 and NF-κB binding with increased transcription of monocyte chemoattractant

protein-1 (MCP-1) and interleukin (IL)-8. Peroxisome proliferator-activated receptor gamma (PPARγ) transcription was reduced by exposure to 11.2mM glucose and increased with 30mM glucose. Recombinant HMGB1 induced NF-κB binding and this was prevented by TLR 2 silencing and TLR 4 inhibition. However, only TLR2 expression and subsequent NF-kB binding was sustained at 7 days.

Conclusions: 11.2mM glucose levels more significantly induced inflammation via the TLR 2 and 4 pathway compared to 30mM glucose. This may be related to the compensatory increase in PPARγ induced by exposure to 30mM glucose. Furthermore, HMGB1 mediates NF-κB binding in PTCs through both TLR 2 and 4. However, TLR2 is more likely to be the predominant mediator of NF-κB activation in PTCs.

PUB272

RAS Blockade Inhibits Bcl-2 Modifying Factor Expression and Prevents Hypertension, Tubulointerstitial Fibrosis and Tubular Apoptosis in Diabetic Akita Mouse Kidneys Hasna Maachi,[1] Chao-Sheng Lo,[1] Shaaban Abdo,[1] Shilin Li,[1] Isabelle Chenier,[1] Shao-Ling Zhang,[1] Janos G. Filep,[2] Julie R. Ingelfinger,[3] John S.D. Chan.[1] *[1]Res. Ctr., CHUM-Hotel Dieu Hospital, Montreal, QC, Canada; [2]Res. Ctr, Maisonneuve-Rosemont Hosp., Montreal, QC, Canada; [3]Pediatr Nephrol Unit, Mass Gen Hosp, Boston, MA.*

Background: We previously reported that pro-apoptotic protein Bcl-2 modifying factor (Bmf) is highly expressed in diabetic mouse renal proximal tubular cells (RPTCs) and induced RPTC apoptosis *in vitro.* We investigated the impact of renin-angiotensin system (RAS) blockade on Bmf expression and on hypertension and RPTC apoptosis in Akita mice (a model of type 1 diabetes).

Methods: Adult male Akita mice (11 weeks) were treated ± RAS blockers (losartan, 30 $mg.Kg^{-1}.day^{-1}$ and perindopril, 4 $mg.Kg^{-1}.day^{-1}$ in drinking water). Controls were untreated non-Akita littermates. We also examined the effect of angiotensin II (Ang II) on Bmf gene expression in cultured rat RPTCs. Plasma glucose, systolic blood pressure (SBP) and albuminuria were monitored weekly from 10 until 16 weeks. Kidneys were processed for histology and apoptosis studies. Renal proximal tubular angiotensinogen (Agt), Bmf, pro-fibrotic and pro-apoptotic gene and protein expression were evaluated by real time-qPCR and Western blotting, respectively.

Results: Akita mice developed hyperglycemia and significantly higher SBPs, kidney/body weight ratios and albuminuria as compared to non-Akita littermates. Kidneys from Akita mice displayed renal hypertrophy, tubulointerstitial fibrosis and tubular apoptosis as compared to non-Akita littermates. Increased expression of Agt, Bmf, transforming growth factor-beta1, collagen type IV and active caspase-3 were evident in RPTCs of Akita mice. Treatment with RAS blockers inhibited Agt and Bmf expression, prevented hypertension and albuminuria and attenuated kidney abnormalities in Akita mice. Finally, Ang II stimulated Bmf mRNA expression in RPTCs in a dose-dependent manner, and its effect was abolished in the presence of losartan and perindopril.

Conclusions: Ang II up-regulates Bmf expression and RAS blockade effectively inhibits Bmf expression and prevents hypertension and tubular apoptosis in diabetic kidneys.

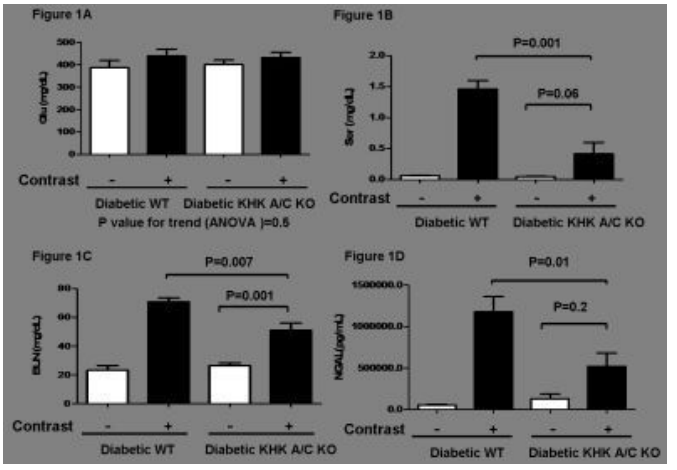
PUB273

Role of *Fructokinase* (KHK) in Contrast Induced Acute Kidney Injury in Diabetic Mice Wei Chen,[1,2] Miguel A. Lanaspa,[1] Katsuyuki Tanabe,[1] Diana I. Jalal,[1] Xueqing Yu,[2] Richard J. Johnson.[1] *[1]Division of Renal Diseases and Hypertension, University of Colorado Denver, Aurora, CO; [2]Department of Nephrology, The First Affiliated Hospital, Sun Yat-sen University, Guangdong, China.*

Background: Renal fructokinase (KHK) may have a novel role in diabetic renal disease. We aimed to elucidate the role of KHK A/C in the pathogenesis of contrast induced acute renal injuryin diabetic mice.

Methods: KHK A/C wild-type (WT) or knockout (KO) diabetic mice were injected with a contrast (isovue, 3 g iodine/kg), with pretreatment of indomethacin and N^G-nitro-L-arginine methyl ester. Serum and tissue samples were collected after 24 hours. CD68 was detected by immunofluorescence. For the *in vitro* studies HK2 and KHK silenced HK2 cells were treated with glucose and varying dosages of isovue. Cell viability was measured. Aldose reductase was detected bywestern blotting.

Results: KHK A/CWT diabetic mice developed significantly worse acute renal injury after isovue treatment compared with the KHK A/C KO diabetic mice, with higher serum creatinine, BUN and NGAL ($P = 0.001$, $P = 0.007$, $P = 0.01$ respectively), (Figure 1) more renal cortex vacuolization ($P < 0.0001$).



CD68 staining, MCP-1 and ICAM-1 mRNA were significantly higher in KHK A/C WT diabetic mice with isovue compared to the KHK A/C KO diabetic mice. *In vitro*, Isovue caused a direct dose-dependent reduction in proximal tubule cell viability. Moreover, lack of KHK A/C likely protects against the isovue toxicity on proximal tubule cells.

Conclusions: These studies provide the first evidence that contrast causes acute renal injury in diabetic mice may via mechanisms dependent on KHK A/C.

PUB274

In Vitro and In Vivo Competition between Glycation and Carbamylation Christine Pietrement,[1,2] Camille H. Nicolas,[1,2] Laetitia Gorisse,[2] Stephane Jaisson,[2,3] Philippe Gillery.[2,3] *[1]Pediatric Nephrology Unit, University Hospital; [2]FRE CNRS/URCA N° 3481, Faculty of Medicine; [3]Laboratory of Pediatric Biology and Research, University Hospital, Reims, France.*

Background: Glycation and carbamylation are two non-enzymatic post transcriptional protein modifications encountered during aging and diseases as diabetes and renal failure, and both involved in cardiovascular complications of these diseases. These reactions can theoretically compete for the same binding sites, which are often α or ε amino groups, but nothing is known about the real effect of one reaction on the other.

Methods: We studied the competition between carbamylation and glycation of albumin or total plasma proteins *in vivo* and *in vitro* by LC-MS/MS quantification of two specific biomarkers: carboxymethyllysine (CML) for glycation, homocitrulline (Hcit) for carbamylation.

Results: After 3 weeks *in vitro* incubation with 20 mM urea, human albumin carbamylation was enhanced: Hcit content reached 24.2 µmol/g of proteins, whereas it was only 18.8 µmol/g when 20 mM glucose was added to the incubation medium together with urea (22% inhibition, $p<0.05$). After 3 weeks incubation with 20 mM glucose, human albumin was specifically glycated with a CML content of 4.1 µmol/g. A 18% reduction of glycation was observed when 20 mM urea was simultaneously added ($p<0.05$). Seven weeks after subtotal nephrectomy on C57Bl6 mice (CRF) plasma Hcit was 253 nmol/g of proteins, but only 92 nmol/g in control mice and 120 nmol/g in streptozotocin-induced diabetic C57Bl6 mice ($p<0.05$). Nine weeks after streptozotocin injections, plasma CML was 189 nmol/g (+ 35% *vs* controls) and CML in CRF mice was 170 nmol/g.

Conclusions: *In vitro* experiments demonstrated the competition between glycation and carbamylation. Glycation competed more over carbamylation, perhaps because of different kinetics between the two reactions. Our mice model could not clearly evidence the influence of glycation on carbamylation. The development of a new diabetic CRF mice model will help to better characterize the *in vivo* competition between glycation and carbamylation which may have different deleterious effect in diabetes and renal failure.

PUB275

Therapeutic Effects of EGCG on Streptozotocin-Induced Diabetic Nephropathy in Mice Byung Chul Shin, Wan Soo Lee. *Internal Medicine, Chosun University Hospital, Gwangju, Republic of Korea.*

Background: Diabetic nephropathy is one of the most serious complications in diabetes mellitus and has been the most common cause of end-stage renal disease. Green tea extracts have antioxidant properties, and (-)-epigallocatechin 3-O-gallate (EGCG) is known to be the most abundant in green tea. Osteopontin (OPN) is a large phosphoglycoprotein adhesion molecule, and has emerged as a potentially key pathophysiologic contributor in diabetic nephropathy. We examined whether EGCG could amelliorate the development of diabetic nephropathy and its role of OPN.

Methods: Mice were injected intraperitoneally streptozotocin (STZ, 200mg/Kg) and induced diabetic nephropathy. After a 8weeks, EGCG were administrated at dose of 50, and 100 mg/Kg body weight. Serum glucose, BUN, creatinine and urine volume, protein, creatinine, Western blot assay of OPN and renal histologic and histochemistry were examinated.

Results: STZ-groups were decreased renal functions and increased urine protein amounts. EGCG-treated groups showed suppressed hyperglycemia, proteinuria and the levels of BUN and serum creatinine. Furthermore, EGCG reduced renal OPN accumulation and its protein expression in the kidney cortex as well as associated pathologic conditions.

Conclusions: These results suggest that EGCG ameliorates STZ-induced diabetic nephropathy by OPN suppression. The potential use of EGCG in the treatment of diabetic nephropathy should be further explored.

PUB276

Metabolic Syndrome Associated with Renal Failure & Cardiovasculopathy due to Deletion of the Gene Encoding the Canonical Transient Receptor Potential 1 (TRPC1) Channel: Role of Gene Dosage & Epigenetics in Phenotypes Bonnie Eby,[1] Meghan Pantalia,[1] Alexander Lau,[1] Richard Matthew Atkins,[1] Leonidas Tsiokas,[2] Kai Lau.[1,3] *[1]Medicine, University of Oklahoma Health Sciences Center, OKC, OK; [2]Cell Biology, University of Oklahoma Health Sciences Center, OKC, OK; [3]Medicine, VA Medical Center, OKC, OK.*

Background: TRPC channels have been implicated in cell proliferation & metabolism. TRPC1 expression is reduced in diabetes, but the relationship is unclear. In TRPC1 -/- mice, we noted obesity, dyslipidemia, insulin resistance, diabetes, hyperphagia, renal failure, cardiovasculopathy & a lower hematocrit (Hct). In the current studies, we excludeed the confounding influence of parental hyperphagia & obesity present in previous -/- breeders by now using only +/- mice as parents.

Methods: We studied the phenotypes of low-Hct, obesity & hyperglycemia in littermates (+/+, +/-, -/-) raised & nursed by identical +/- breeders, aged 12 to 21 weeks, to define the role of epigenetics accrued & transmitted by parents of various weights. Glucose tolerance test (GTT) was done at 29 weeks.

Results: Hct was reduced by 7% in only null mice regardless of litter orders, indicating 1 wild-type allele can keep Hct normal. Obesity was noted in only null mice, but Δ was greater (13 vs 4%) in later litters born to heavier (27 vs 18 g) & older breeders (19 vs 12 weeks). Data suggest obesity is prevented by 1 wild-type allele but expressed if missing both & inheriting enough epigenetic risk factors. In mice born to younger smaller dams with fewer epigenetic risks, abnormal GTT was noted in both +/- & -/- mice, indicating normal glucose tolerance needs 2 copies of the TRPC1 gene. In mice born to older larger dams, similar degrees of glucose intolerance were found in +/+, +/- & -/- mice, showing the epigenetic dominance in the hyperglycemia. GTT showed increases of 35, 20 & 19% for the 3 genotypes between mice born to younger thinner dams & mice born to older heavier dams.

Conclusions: Our data support the key role of the TRPC1 gene in keeping Hct normal, preventing obesity & glucose intolerance, but epigenetic risk factors from +/- breeders exert major impact on the hyperglycemic phenotype.

PUB277

Vitamin B6 Prevents the Cardiovasculopathy in Akita Mice and the Metabolic Syndrome Induced by Fructose:In-Vivo Correlation with Ex-Vivo Endothelial Functions Meghan Pantalia,[1] Bonnie Eby,[1] Uzma Hajiyani,[1] Alexander Lau,[1] Richard Matthew Atkins,[1] Kai Lau.[1,2] *[1]Medicine, University of Oklahoma Health Sciences Center, Oklahoma City, OK; [2]Medicine, OKC VA Medical Center, Oklahoma City, OK.*

Background: Hyperlgycemia stimulates advanced glycation end-products (AGE) contributing to diabetic complications. We recently reported the benefits of deleting the gene encoding the receptor for AGE in diabetic nephropathy. We now tested the hypothesis that inhibition of AGE by vit B6 confers end organ protection in states of insulin resistance & insulin deficiency.

Methods: Normal male mice were randomized to nothing, dextrose, fructose, or fructose + vit B6 in drinking water for 6 mon. Male Akita & control were randomized to vit B6 or nothing at 7 weeks of age. By established methods, we measured blood pressure (BP), blood glucose (BS), heart echo & aorta endothelial relaxation.

Results: Fructose raised fasting insulin, cholesterol, & weights of kidneys, hearts, & livers, all but liver mass normalized by concurrent vit B6. Vit B6 reduced BS in fructose- & dextrose-treated mice. Fructose raised systolic (S)BP (122 vs 113), diastolic (D)BP (96 vs 85), & mean arterial (MA)BP (104 vs 94), effects blocked by vit B6. SBP normalized by vit B6 (119 to 109) noted by tailcuff was confirmed by inta-arterial reading (118 to 105). Relaxation of aorta from fructose-treated mice was impaired but corrected by vit B6. At 5 & 10 mon, Akita mice had reduced left ventricular end-D volume (V), stroke V, & cardiac output, all prevented by vit B6. In Akita diabetics, vit B 6 blocked the increased SBP at 5 & 8 mon & the increased DBP & MABP at 8 mon. It corrected the endothelial dysfunctions seen in untreated diabetics.

Conclusions: Vit B6 confers anti-hypertensive & endothelial relaxing benefits in fructose-induced insulin-resistance & in insulin-deficient Akita diabetes. In fructose-induced metabolic syndrome, vit B6 prevents increases in weights of body, kidney, & heart, & normalized fasting blood glucose, insulin, & cholesterol. In Akita diabetics, vit B6 prevents cardiomyopathy. These data support the hypothesis that vit B6 protects end-organ from dysfunctions in states of increased AGE.

PUB278

Knockdown of Sodium-Glucose Cotransporter Type 2 in Human Renal Proximal Tubule Cells Prevents High Glucose-Induced Increase in TGFβ1 Maggie K. Diamond-stanic,[1,3] Michael A. Rose,[1,2] Young H. You,[3] Volker Vallon,[1,3] Kumar Sharma.[1,3] *[1]Veterans Administration San Diego Healthcare System, La Jolla, CA; [2]Veterans Medical Research Foundation, San Diego, CA; [3]University of California, San Diego, La Jolla, CA.*

Background: Sodium-glucose co-transporter type 2 (SGLT2) is located primarily on the apical membrane of renal proximal tubule cells and is responsible for the reabsorption of glucose from the glomerular filtrate. Inhibition of SGLT2 results in glucosuria and lowers blood glucose. Pharmacological inhibitors of SGLT2 are in clinical trials as treatment for diabetic mellitus. However, little is known about the effect of SGLT2 inhibition on proximal tubule cells themselves. We hypothesize that preventing luminal glucose uptake in proximal tubule cells may ameliorate diabetic kidney damage.

Methods: Primary cultures of human renal proximal tubule cells (hRPTC) (ScienCell) were cultured with siRNA directed against SGLT2 for 24 hours then treated with low (5.5 mM) or high glucose (25.5 mM) for 24 hours. SGLT2 and pAMPK were measured by western blot. TGFβ1 was measured by ELISA.

Results: Addition of SGLT2 siRNA resulted in a 34% decrease in expression of SGLT2 protein. High glucose induced a 236% increase in TGFβ1 release into the cell culture media under control (scrambled siRNA) conditions. Addition of SGLT2 siRNA abolished the high glucose-induced increase in TGFβ1. Increased expression of TGFβ by high glucose is associated with decreased activity of phospho-AMP kinase (pAMPK) in several glomerular cell types, and decreased pAMPK activity potentially contributes to diabetic kidney damage. We found no change in expression of pAMPK following 24 hour high glucose treatment in hRPTC, and this was not affected by addition of SGLT2 siRNA.

Conclusions: Our data demonstrate that the reabsorption of glucose in the proximal tubule cells via SGLT2 can stimulates TGFb1 release, potentially contributing to diabetic kidney damage. However, this does not occur in association with decreased expression of pAMPK. These data suggest that inhibition of SGLT2 may have direct beneficial effects on the diabetic kidney in addition to lowering blood glucose levels.

PUB279

High Glucose Induces Glomerular Endothelial-Mesenchymal Transition through TGF-β1 and TGF-β2 Hui Peng, Yuanqing Li, Canming Li, Zengchun Ye, Meirong Zhong, Tan-qi Lou. *Division of Nephrology, Department of Medicine, The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, Guangdong, China.*

Background: In recent years, increasing attention has been paid to the roles of endothelial-mesenchymal transition (EndMT) in tissue fibrosis. Our previous researches demonstrated that high glucose could induce endothelial-mesenchymal transition in renal glomerular endothelial cells, however, the mechanics of which are still unclear. The present study aims to investigate whether TGF-β contributes to EndMT process.

Methods: Primary rat renal glomerular endothelial cells were cultured for days in medium containing either normal glucose (NG: 5.5 mmol/l) or high glucose (HG: 30mmol/l), while cells cultured in medium containing 5.5 mmol/l glucose plus 25.5mmol/l mannitol were set as hyperosmotic control group (M). In some experiments, TGF-βtype 1 receptor inhibitor LY364947(10μmol/l)was added to the medium, while in solvent control group, DMSO was added. Real-time PCR was employed to detect TGF-β1 and TGF-β2 mRNA levels; western blotting, as well as confocal microscopy were employed to detect endothelial marker Claudin5 and mesenchymal marker α-SMA protein expression; and cell phenotype were also observed using confocal microscopy.

Results: It was showed that, compared to control group, high glucose stimulation for either 1 or 3 days led to increasing mRNA levels of both TGF-β1 ($p<0.05$, n=3) and TGF-β2 ($p<0.05$, n=3), while no significant difference was observed in hyperosmotic control group. Compared with control group, 5-day high glucose stimulation resulted in decreasing protein expressions of Claudin5 ($p<0.05$, n=3) and increasing protein expressions of α-SMA ($p<0.05$, n=3), while no significant changes were showed in hyperosmotic group. These changes could be inhibited by LY364947 ($p<0.05$, n=3) but not DMSO. When cells were exposed to high glucose, their phenotypes changed from a cobblestone shape to a spindle-liked one, which could also be attenuated by LY364947.

Conclusions: Our results indicate that high glucose may contribute to the EndMT of glomerular endothelial cells through TGF-β1 and TGF-β2 signaling pathway.

PUB280

Fenofibrate Ameliorates Diabetic Nephropathy though the Activation of PGC-1α-ERR-1α Signaling in *db/db* Mice Myung Hyun Lee, Yu Ah Hong, Cheol Whee Park, Ji Hee Lim, Sungjin Chung, Keunsuk Yang, Yong-Soo Kim. *Nephrology, St. Mary Hospital, Seoul, Korea.*

Background: Peroxisome proliferative-activated receptor gamma coactivator (PGC)-1α is a multifunctional transcriptional protein, acts as a 'molecular switch' in pathways controlling fatty acid oxidation and oxidative stress, and may be a critical link in the pathogenesis of type 2 diabetes and metabolic syndrome associated with estrogen-related receptor (ERR)-1α. We evaluated the renoprotective effect of fenofibrateassociated with improving lipotoxicity and oxidative stress through the change of PGC-1α-ERRα signalingon diabetic nephropathy in *db/db* mice.

Methods: Male C57 BLKS *db/db* mice and *db/m* controls at 8 weeks of age were divided to receive either a regular diet chow or a diet containing fenofibrate (0.2% wt/wt, n=6, respectively). The treated *db/m* mice and *db/db* mice were administrated fenofibrate for 2 months starting at age of 12 weeks, and were evaluated about renal functional and pathologic phenotypes and the PPARα-PGC-1α-ERR-1α pathway.

Results: Fenofibrate treatment dramatically reduced fasting blood glucose (P<0.05) and HbA1c levels (P<0.05) in db/db mice. Fenofibrate also ameliorated albuminuria (P<0.001) and decreased urine volume (P<0.001) in db/db mice. There was no difference serum creatinine level in all each groups. The mesangial area expansion, inflammatory cell infiltration, and the accumulation of intra-renal free fatty acid and triglycerides were significantly observed in db/db mice. A downregulation of PPARα suppressed PGC-1α and ERR-1α expressions and led to increases in oxidative stress and decreases fatty acid oxidation. Treatment of fenofibrate increased the PPARα expression and subsequently activated the PGC-1α-ERR-1α signaling, inactivation of the PI3K-Akt pathway, dephosphorylation of FoxO3a, and this all resulted in ameliorating oxidative stress and fatty acid oxidation.

Conclusions: Our results suggest that PPARα agonist improves lipotoxicity through activation of the PGC-1α-ERR-1α signaling in type 2 diabetic nephropathy and may be a potentially therapeutic modality to modulate PGC-1α-ERR-1α signaling to treat type 2 diabetic nephropathy.

PUB281

Prevalence of Non-Diabetic Nephropathies in Diabetic Patients

Antonello Pani, Andrea Angioi, Floris Matteo, Patrizia Melis, Riccardo Cao, Maura Conti. *Az G.Brotzu, Cagliari.*

Background: Diabetic Nephropathy(DN) is the second most common cause of ESRD in Europe. The natural history is an important clue for its clinical diagnosis. However,renal biopsy(RB) could reveal non diabetic renal lesions(NDRD) in 9-63% of patients(pts). Active urinary findings and rapidly progressive renal failure(RPRF)are suggestive of NDRD. We retrospectively selected 88 pts(S) with diabetes mellitus(DM) from among 1,374 pts who underwent RB between Jan 1994 and Feb 2012 to evaluate its prevalence. A control group(CG) of 26 DM1 pts included in the ESPRIT study to evaluate early DN in microalbuminuria(M) was chosen. Furthermore,we evaluated whether NDRD influences the degree of diabetic glomerulosclerosis(DGS).

Methods: ***Pts****(S/CG):mean age(yrs)*:61.7±13.9/38.6±11.4(p=0.00);*M/F:*1.59/1.84(p=NS);*DM1(%)*:8/100;*DM duration(yrs)*:11.9±9.5/20.2±8.5(p=0.05);*M onset(yrs)*:5.3±5.4/5.5±2.3(p=NS).Negative fundoscopy and urinecolture.***RB criteria(%)***:rapid onset nephrotic proteinuria(3.8) or syndrome(34.6);mild(≥0.5<1g/24h)(5.1) or moderate proteinuria(≥1<3g/24h)(20.5);acute nephritic syndrome(19.3);MH(16.7);granular UC(4.8);acute(2.6),chronic(12.9) or acute on chronic renal failure(6.4);RPRF(21.8).**Stats**:Chi-square,Fisher's exact,Wilcoxon's tests.

Results: NDRD(44.3%);**NDRD+DGS**(13.7%; **DGS**(42%). The most frequent renal diseases were: **membranous GN**(15.7%); **interstitial nephritis**(11.8%); **nephroangiosclerosis**(11.8%); **IgAN**(9.8%); **crescentic GN**(7.8%); **acute tubular necrosis**(7.8%); others(*Table 1*). Diabetic lesions in NDRD were compared to the CG and did not influence progression(*Table 2*).

Table 1: Histological diagnosis in selected patients: number of cases (n), selective relative percentages (%), absolute percentages (%tot).

Histological diagnosis	n	%	%tot
ACUTE TUBULAR NECROSIS	4	7,8	4,5
AMYLOIDOSIS	1	2,0	1,1
CAST NEPHROPATHY	2	3,9	2,3
CRESCENTIC GLOMERULONEPHRITIS	4	7,8	4,5
CRYOGLOBULINEMIA	3	5,9	3,4
FSGS, SECONDARY	3	5,9	3,4
IgAN	5	9,8	5,7
INTERSTITIAL NEPHRITIS	6	11,8	6,8
MEMBRANOUS GN	8	15,7	9,1
MESANGIOPROLIFERATIVE GN	1	2,0	1,1
MINIMAL CHANGE DISEASE	3	5,9	3,4
MPGN1	1	2,0	1,1
NEPHROANGIOSCLEROSIS	6	11,8	6,8
NON HODGKIN LYMPHOMA	1	2,0	1,1
NORMAL KIDNEY	1	2,0	1,1
POSTINFECTIOUS GN	1	2,0	1,1
THROMBOTIC MICROANGIOPATHY	1	2,0	1,1
total	51	100	58,0
NDRD	39		44,3
NDRD+DGS	12		13,7
DIABETIC GLOMERULOSCLEROSIS	37		42,0
Total	88		100

NDRD: non diabetic renal diseases; GN: glomerulonephritis; DGS: diabetic glomerulosclerosis; MPGN: membranoproliferative glomerulonephritis.

Table 2. Diabetic renal lesions compared in NDRD and control group.

Diabetic renal lesions	NDRD(%)	Control(%)	p
GLOMERULOSCLEROSIS SEGMENTAL AND DIFFUSE	10.0	30.0	NS
KIMMELSTIEL-WILSON NODULES	15.7	15.8	NS
MESANGIAL EXPANSION AND THICKENED GBM	84.2	84.2	0.06
ARTERIAL HYALINOSIS	33.3	62.6	NS
FIBRIN CAPS AND CAPSULAR DROPS	29.2	21.1	NS

GBM: Glomerular basement membrane

Conclusions: In our experience, the prevalence of NDRD in diabetic pts was 58%(NDRD=44.3%,NDRD+DGS=13.7%). NDRD should be suspected if clinical and urinary findings (normal fundoscopy, proteinuria,MH) differ from the natural history of DN. Close follow-up of diabetic pts from disease onset is crucial. NDRD does not influence diabetic renal lesions.

PUB282

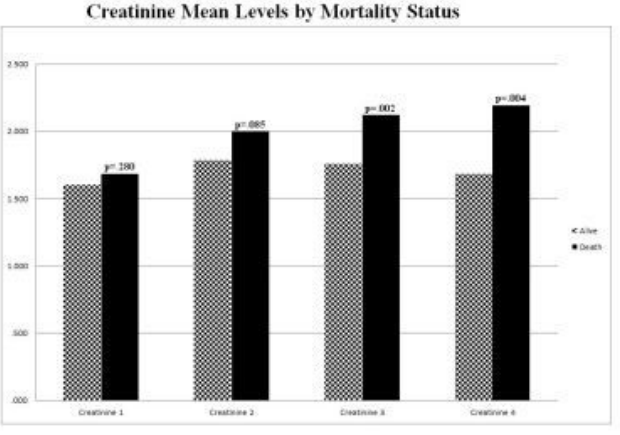
Morbidity and Mortality in Non Proteinuric Type 2 Diabetics with Chronic Kidney Disease: A Retrospective Study

Bijin Thajudeen,[1,2] Mordecai M. Popovtzer,[1] Pooja Budhiraja.[1,2] *[1]Medicine, Medicine, Southern Arizona Veterans Affairs Health Care System, Tucson, AZ; [2]Medicine, University of Arizona College of Medicine, Tucson, AZ.*

Background: Twenty percent of the diabetics progress to chronic kidney disease without albuminuria. Determinants of chronic kidney disease,natural course of renal dysfunction and mortality in this subgroup of diabetics has not been studied in great detail.

Methods: In a retrospective study design we followed medical records of 121 patients(all males) above the age of 40 years with Type 2 DM and chronic kidney disease in the absence of proteinuria for a mean follow up period of 5.1 years. Primary outcome measured were all cause mortality and requirement for hemodialysis. Secondary outcomes include 1)appearance of proteinuria 2) trend in the kidney function expressed as improvement or worsening of creatinine.

Results: All cause mortality was 33% with mean age of death of 75.9.Mortality was significantly related to higher creatinine at second year,third year, at end of follow up and duration of diabetes(p value 0.002, 0.004,0.027 respectively).



Most common cause of death was cardiovascular disease.5.8% of the patients ended up in hemodialysis.16% of the patients developed proteinuria at end of follow up and theses patients showed higher tendency for progression of renal failure.63% of the patients had improvement in renal function and theses patients showed tendency for better survival compared to patients whose renal function worsened at end of follow up period.

Conclusions: This observation suggests that in Type 2 diabetic patients with chronic kidney disease in absence of proteinuira, functional renal impairment may stem from reversible factors. Careful search for kidney damaging causes that are potentially reversible is recommended,which could subsequently improve mortality.

PUB283

Improved Prognosis in Diabetic Nephropathy

Gudbjörg Andrésdóttir,[1] Majken Linnemann Jensen,[1] Hans-Henrik Parving,[2,3] Peter Rossing.[1,2] *[1]Steno Diabetes Center, Gentofte, Denmark; [2]Aarhus University, Aarhus, Denmark; [3]Rigshospitalet, Copenhagen, Denmark.*

Background: Blocking the Renin-Angiotensin System (RAS) is thought to benefit kidney function independent of the regulation of blood pressure. However, long term effects of RAS blockade were questioned in register studies. Our aim was to evaluate long term decline in renal function in diabetic nephropathy (DN) during the last decade, compared to historic data in patients with type 1 and type 2 diabetes (DM).

Methods: This was an observational cohort study. Patients with DN at our center have annual measurements of ^{51}Cr-EDTA plasma clearance (GFR). We included all patients with at least 3 measurements during the years 2000-2010 and minimum 3 year follow-up. Since 2001, RAS blocking agents have been recommended to all our patients with DN (prescribed to >95% of our cohort). Results were compared with previously published data on decline in GFR from 1983 to 2000 (2003 for type 2 DM), before RAS blocking became standard treatment.

Results: The study included 315 patients with type 1 DM and 286 with type 2 DM.

Baseline characteristics	Type 1 DM	Type 2 DM
Age, (years)	47(11)	59(9)
Gender, (% M)	61%	76%
GFR, (ml/min/1.73m2)	78(29)	80(29)
HbA1c, (%)	9.2(1.4)	8.5(1.6)
Blood pressure, (mmHg)	140(17)/79(8)	149(17)/82(9
Albuminuria, (mg/24-h)	433[167-950]	414[247-818]
Total cholesterol, (mmol/L)	5.3(1.0)	4.8(1.3)
Follow up, (years)	8.6[5.6-9.9]	6.6[4.6-8.8]
GFR measurements, (n)	7[5-9]	6[4-8]

Values are means (SD) or median [IQ range]

For type 1 DM the rate of decline in GFR was reduced 19% (95%CI 5-34%, p=0.009) from historically 4.0(3.4), n=301, to 3.3(3.1) ml/min/year and for type 2 DM 14% (95% CI 4-28%, p=0.04) from historically 5.2(4.1), n=227, to 4.4(4.0) ml/min/year. Except

for increased diabetes duration for type 1 DM, lower blood pressure for type 2 DM, and lower albuminuria for both types in the present cohort, the historic and present cohorts were similar at baseline.

Conclusions: Modern treatment of diabetic nephropathy, including long term blockade of the RAS, preserves renal function better, not worse, than treatment used in the past where RAS inhibition was not standard treatment.

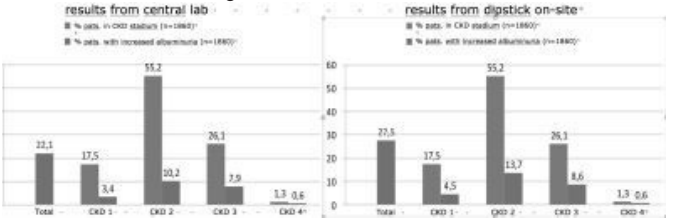
PUB284

CKD Stadium Is Not Associated with Albuminuria in Caucasian Type 2 Diabetics Ludwig F. Merker,[1] Baptist Gallwitz,[2] Katja Schoene,[3] Barbara Waldeck.[3] *[1]Diabetes- und Nierenzentrum, Dormagen, Germany; [2]Med. Klinik 4, Eberhard-Karls-Universität, Tübingen, Germany; [3]Boehringer Ingelheim Pharma GmbH & Co KG, Ingelheim, Germany.*

Background: There is few data available comparing microalbuminuria (MAU) to chronic kidney disease (CKD) stadium in patients with type 2 diabetes (T2DM). Also there are no systematic comparisons between on-site dipstick measurement of MAU resp. albumin-creatinine-ratio (ACR) vs. central lab analysis available.

Methods: We recruited 2541 consecutive patients with T2DM from 245 primary care physicians in a prospective, randomized, cross-sectional epidemiologival study according to GCP standard; pts. with CKD 5 were excluded. The following data was collected by questionnaire: antidiabetic and antihypertensive medication, renal status, hypertension and comorbidities. On site urinanalysis was carried out by dipstick, the same for MAU/ACR. Central lab included HbA_{1c}, serum creatinine, ACR and lipid profile; eGFR (ml/min /1,73m²) was estimated using MDRD formula. For MAU analysis, pts. with signs of urinary tract infection were excluded. We defined ACR < 30 mg/g creatinine as normal, 30-300 mg/g creatinine as MAU and >300 mg/g creatinine as makroalbuminuria (AU). Statistics are descriptive. The study was performed from 01-10/2011.

Results: The results of albuminuria findings central lab vss dipstick on-site in different CKD stadium is seen in this figure:



Independently, there was more albuminuria in men than in women, in higher BMI, in hypertension and in smokers.

Conclusions: Measurement of albuminuria with central lab vs. dip sticks results in a lower proportion of patients with MAU/AU. It is uncertain whether this resulted due to adsorption of albumin to the transport specimen or results from misreadings on-site. There is no correlation between MAU and CKD stage. MAU/AU is positively correlated with gender, BMI, hypertension and smoking.

PUB285

Thiazides and eGFR Decline in Patients with Diabetes Mellitus Type 2 and Hypertension Danny Vo,[1] P.T. T. Pham,[2] P.C. Pham.[1] *[1]UCLA-Olive View Medical Center, Sylmar, CA; [2]UCLA Medical Center, Los Angeles, CA.*

Background: Poor glycemic control and the use of diuretics in DM2 patients can both induce relative volume depletion. The combined effects on volume depletion could potentially induce intermittent acute tubular necrosis and accelerate kidney function decline. The current study examines the effect of hydrochlorothiazide (HCTZ), a mild diuretic, on the annual percentage of change in the estimated (MDRD) glomerular filtration rates (eGFR) in DM2 patients stratified by glycemic and blood pressure (BP) controls.

Methods: This is a retrospective study involving record retrieval of patients with DM2 and hypertension evaluated for any reason at UCLA-OVMC during 2009-2010. Data retrieved include age, gender, use of thiazides and other BP medications, eGFR, hemoglobin A1C (A1C), blood pressure, and albuminuria to creatinine ratio (ACR). Patients were stratified based on (tentative) JNC8 blood pressure goals and A1C<= or >7%. Differences in the annual percentage change in eGFR during follow-up between any 2 groups comparing those receiving thiazides vs. not were based on student's t-test.

Results: 755 patients' records were included. There were 69.3% female, with mean ± standard error age of 57±0.3 years, follow-up duration 628±5 days, systolic blood pressure 134±0.5, diastolic blood pressure 70±0.3 mmHg, A1C 8.3±0.05%, and ACR 119±17 mcg/mg. 49.3% were using thiazides. The percentages of change in the eGFR for the 4 groups are shown. There is a trend for slower eGFR decline with thiazides in patients with above goal SBP, particularly among those with A1C>7%.

SBP ≤ tentative JNC8 goal				SBP > tentative JNC8 goal			
A1C ≤ 7%		A1C > 7		A1C ≤ 7		A1C > 7	
No HCTZ (n=47)	HCTZ (n=48)	No HCTZ (n=255)	HCTZ (n=192)	No HCTZ (n=18)	HCTZ (n=22)	No HCTZ (n=61)	HCTZ (n=112)
1.7±1.9	-1.7±1.9	-0.7±0.8	-0.8±1.0	-1.2±2.4	1.7±2.1	-5.6±1.9	-0.7±2.7

p-values between No hydrochlorothiazides (No HCTZ) and HCTZ groups from left to right: 0.2; 0.9, 0.4, 0.1.

Conclusions: The use of thiazides in DM2 patients with BP above (tentative) JNC8 target does not accelerate but tends to decelerate eGFR decline. The protective effect trends more favorably in those with less well glucose control (A1C>7%).

PUB286

Therapeutic Efficacy of Combination of Angiotensin II Receptor Blockade and Thiazide in Hypertension and Microalbuminuria in Diabetic Subjects Tomoyuki Saito, Atsushi Aoki, San-e Ishikawa. *Department of Medicine, Jichi Medical University Saitama Medical Center, Saitama, Japan.*

Background: The present study was undertaken to determine whether combination therapy of losartan and hydrochlorothiazide (Los/Hyd) controls hypertension and microalbuminuria in type 2 diabetic subjects.

Methods: 47 type 2 diabetic subjects with hypertension were enrolled. They were 24 males and 23 females with the ages of 62.8 ± 8.1 years. They had been treated with normal dose of angiotensin II receptor blockade (ARB), but blood pressure could not be reduced below 130/80 mmHg. The ARB was replaced by Los/Hyd (50mg/12.5mg), and then blood pressure (BP) and microalbuminuria were determined 3 months later. If BP was not decreased to 130/80 mmHg at 3 months, losartan 50 mg was further administered.

Results: The administration of Los/Hyd for 3 months reduced systolic and diastolic BP from 146 ± 12 to 131 ± 13 mmHg and from 79 ± 12 to 75 ± 10 mmHg, respectively ($P < 0.01$). The achievement of lowering BP less than 130/80 mmHg was obtained in 28 subjects (60%). Microalbuminuria was markedly decreased from 100 ± 148 to 65 ± 113 mg/g creatinine during the 3 months period ($P < 0.001$). Because of no achievement of estimated BP, 19 subjects were added losartan 50 mg. 15 of 19 subjects thus obtained BP of less than 130/80 mmHg 3 months later. Finally, 43 of 47 subjects (91%) obtained BP of less than 130/80 mmHg during the 6 months period, namely systolic and diastolic BP to 126 ± 11 and 71 ± 9 mmHg, respectively. Also, microalbuminuria was further reduced to 35 ± 40 mg/g creatinine. Next, we analyzed 32 subjects with early stage of diabetic nephropathy. Systolic and diastolic BP decreased from 145 ± 12 to 125 ± 10 mmHg, and from 80 ± 12 to 71 ± 9 mmHg, respectively ($P < 0.001$). Microalbuminuria reduced from 71 ± 75 to 32 ± 39 mg/g creatinine ($P < 0.001$).

Conclusions: These results clarified that combination therapy of ARB and thiazide reduces BP and microalbuminuria in diabetic subjects who already had been treated with ARB. ARB and thiazide combination is a useful tool for preventing from hypertension and renal impairment in diabetic subjects.

PUB287

Renal Histological Lesions in Patients with Diabetes Mellitus: Clinical Correlations Loyana Teresa Teofilo Lima Silva, Camila Hitomi Nihei, Raquel Maria Maia, Elerson Costalonga, Michell Alves Oliveira, Denise M.A.C. Malheiros, Lectícia Jorge, Cristiane Bitencourt Dias, Rui Toledo Barros, Viktoria Woronik. *Nephrology, Medicine School University of Sao Paulo, Sao Paulo, Brazil.*

Background: The renal biopsy in diabetes mellitus patients with renal disease is controversial in literature. The aim of this study was to evaluate diabetic nephropathy (DN) and non diabetic nephropathy (NDN) in select patients with diabetes mellitus submitted kidney biopsy, and to correlate pathological with clinical and laboratory findings.

Methods: We performed a retrospective study by reviewing clinical and histological data of 77 diabetic patients submitted to renal biopsy at our center from 1999 to 2010. The glomerular filtration rate (GFR) was estimated using modified MDRD simplified equation.

Results: Of the 77 patients studied, 36 were diagnosed with DN (47%), 37 with NDN (48%), while 4 had concurrent DN and NDRD (5%). The most common NDN were membranous nephropathy (16%), igA nephropathy (14%), focal segmental glomerulosclerosis (11%), crescentic glomerulonephritis (11%), other (48%). Clinical features are summarized in table 1.

Baseline Features

	ND group	NDN group	p
n=73	n=36	n=37	
Age(y)	55,8±13	62,2±15,4	NS
Male	21(58%)	21(57%)	NS
Initial eGFR(ml/min)	34,3±23,2	45,9±33,6	0,09
Proteinuria(g/day)	4,9±3,0	4,6±3,9	NS
Hematuria	19(53%)	18(50%)	NS
Hypertension	34(94%)	26(70%)	0,001
Glycated Hemoglobin (%)	9,6±3,1	7,6±1,6	0,001
Nephrotic Syndrome	23(64%)	14(38%)	0.035
Follow up(mo)	27,6±27,7	47,5±42,9	0,03

Results are showed as mean ± SD or n(%)

ND group showed more patients with hypertension and nephrotic syndrome, higher levels of HbA1C as well as tendency lower eGFR. At the end of follow up, in DN group there was a tendency to a lower eGFR (16,1±12,9vs28,3±37,4 p=0,08) and more patients reached a eGFR < 60mlmin (100%vs78%, p=0,005).

Conclusions: Frequency of NDN is very high in our selected population. There was no strong predictor to differentiate DN from NDN by clinical or biochemical data. Our study demonstrated that renal biopsy is is necessary in selected cases. However, DN patients showed a tendency to a lower eGFR at the end of follow up.

PUB288

Left Ventricular Hypertrophy and Apelin: Is There a Link? Ana Paula Silva, André Fragoso, Cláudia Silva, Ana Pinho, Nelson Almeida Tavares, Nélio Santos, Fatima Rato, Marilia Faisca, Karina Soto, Pedro Neves. *Nefrologia, Hospital de Faro, Faro, Portugal.*

Background: As cardiovascular disease and renal failure are inextricably intertwined in the so called "cardio-renal syndrome", it is plausible to admit a connection between apelin and the development of cardiovascular disease in patients with renal failure. The aim of this study was to evaluate the link between the left ventricular hypertrophy (LVH) and the adipokines in type 2 diabetics with mild to moderate Kidney disease.

Methods: In this cross-sectional study, we included 78 type 2 diabetic patients (f=30 m=48), with a mean age of 61.9 years and a mean eGRF of 43.5 ml/min. At baseline, the patients underwent a complete clinical history and physical examination and several laboratory parameters were analyzed: inflammation (interleukin 6), mineral metabolism (phosphorus (P), calcium, PTH, vitamin D, FGF-23), oxidative stress (oxLDL), adipokines (apelin, resistin, visfatin), haemoglobin and albumin. Our population was divided in two groups. G I (n=54) without LVH and G II (n= 24) with LVH stratified according to gender. In the analysis we for comparison between groups we used the Student's t-test, and a logistic regression analysis was used to determine predictors of risk for LVH.

Results: We found that G=II showed higher levels of P (5.1 *vs* 3.9 mg/dL p=0.0001), PTH (223.1 *vs* 97.6 mg/dL p=0.0001), FGF -23 (346.2 *vs* 90.9 Ru/mL p=0.0001), IL6 (9.4 *vs* 4.5 pg/mL p=0.0001), oxLDL (67.4 *vs* 35.1 U/L p=0.0001), visfatin (118 *vs* 34.6 pg/mL p=0.0001), resistin (9.3 vs4.4 pg/mL p= 0.0001). and G II also showed lower levels of eGRF (31 vs 49 ml/min p=0.002), 25 (OH)D3 (11.7 *vs* 22.8 ng/mL p= 0.0001),albumin (3.8 vs 4.3 g/dL p=0.001), and apelin (78 *vs* 281.8 pg/mL p=0.0001). In multivariate analysis only lower apelin as a predictor independly of left ventricular hypertrophy, the OR= -7.8, 95% CI, -12.9 to -2.4, p=0.005.

Conclusions: In our study the adipokines, and particularly apelin, present themselves as new predictive elements, contributing for the completeness of diversified puzzle of cardiovascular risk biomarkers in type 2 diabetics with mild to moderate kidney disease.

PUB289

Adipokines and Oxidative Stress: Cardiovascular Mortality in Cardio-Renal Axis Dysfunction Ana Paula Silva, André Fragoso, Ana Pinho, Cláudia Silva, Nélio Santos, Nelson Almeida Tavares, Pedro Neves. *Nefrologia, Hospital de Faro, Portugal.*

Background: The interrelation between cardiovascular and chronic kidney disease, with each contributing to the pathogenesis of the other, leads to progression of both diseases. Several substances produced by adipocytes – adipokines (resistin and visfatin) and oxidative stress – have been implicated on the cardio-renal axis dysfunction and plays an important role in the pathogenesis of both cardiovascular and renal diseases. The purpose of this study was to evaluate the relationship of adipokines, and oxidative stress and cardiovascular mortality in type 2 diabetics with mild to moderate kidney disease.

Methods: In this cross-sectional study, we included 78 type 2 diabetic patients (f=30 m=48), mean age 61,9 years, mean eGFR 43,5ml/min. At baseline, the patients underwent a complete clinical history and physical examination and several laboratory parameters were analyzed: oxidative stress (oxLDL), adipokines (visfatin, resistin,adiponectin [APN]), inflammation (interleucin 6 (IL6). Our population was divided in two groups. G I (n=65) survivors and G II (n= 13) non survivors (CVD). In the analysis we used the Student's t-test for comparison between groups and the risk factors and their hazard ratio (HR) were calculated using Cox proportion.

Results: We found that G=II was older (73.3 *vs* 59.6 years p=0.0001) showed higher levels of resistin (9.0 *vs* 5.3 pg/mL p=0.0001), visfatin (143.5 *vs* 43.8 pg/mL p=0.0001), LVMI (135.2 *vs* 97.8 g/m^2 p=0.0001), oxLDL (78.9 *vs* 38.3 U/L p=0.0001),IL6 (8.4 *vs* 5.6 pg/mL p=0.013), and G II also showed lower levels of eGRF (23.6 *vs* 45.5 ml/min p=0.001), and APN (7.7 *vs* 33 ng/mL p= 0.0001). In multivariate Cox proportional hazard stepwise LR to identify independent risk factors of cardiovascular mortality.Resistin,visfatin, oxLDL, were found to predict patient survival (HR=12.3, 95% CI, 0.3 to 19.5, p=0.042), visfatin (HR= 5.5, 95% CI, 0.6 to 10.5, p=0.026) and oxLDL (HR= 11.6, 95% CI, 2.4 to 21.5, p=0.012) respectively.

Conclusions: In our study we found that adipokines and oxidative stress are biomarkers predictors of mortality cardiovascular in type 2 diabetic with mild to moderate kidney disease.

PUB290

Resolution of Hyperglycemia without Therapy in Diabetic End Stage Renal Disease Patients Paul G. Jenkins,[1] Piangwarin Phaosawasdi,[2] Fengyi Shen.[2] *[1]Milwaukee Kidney Associates, Milwaukee, WI; [2]Aurora Health Care, Milwaukee, WI.*

Background: The hyperglycemia (HG) of diabetes mellitus (DM) is thought to be responsible for diabetic nephropathy (DN) and thus end stage renal disease (ESRD) in diabetic patients (DP). Conversely, loss of renal function may ameliorate HG in DP. Our interest was to determine the prevalence of resolution of HG and diabetic therapy (DT) in ESRD DP in a single nephrology practice and look for possible contributing factors.

Methods: Records of our current and some recent dialysis patients (pts) were analyzed. Of 119 pts, 46%, or 55 pts, had been treated for DM and most had been clinically diagnosed with DN. Of these 55 DP, 38%, or 21 pts, were able to discontinue DT. The records of these 21 pts were analyzed. All of the 21 pts were treated with hemodialysis, none with peritoneal dialysis.

Results: Of the 21 pts, 52% were women and the mean age was 66.6 years. Insulin was used by 57% and oral agents by 62% of the pts. The duration of DM ranged from 8 years (yrs) to 40 yrs and duration of ESRD ranged from 1 to 13 yrs. A weight history could not be obtained in one pt. Table 1 summarizes patient features.

Patient Features

Yrs of DM	Yrs of ESRD	Yrs of DT	Yrs off DT	Weight loss*	Vision loss	Amputation
24.8	6.8	15.6	5.1	23.5 kg	62%	33%

*Applies to 20 pts

Conclusions: Our experience highlights the frequent development of euglycemia without drugs in diabetic patients with ESRD, most of whom were thought to have diabetic nephropathy and most of whom had other vascular sequelae of diabetes mellitus in the form of retinopathy or amputations. The relationship between renal function loss and hyperglycemia in diabetes mellitus may be multifactorial, but significant weight loss was a prominent feature of most of those pts who appeared "cured" of diabetes while left with the vascular complications. Thus exists the paradox of diabetic hyperglycemia causing kidney failure, but kidney failure, directly or indirectly, possibly curing diabetic hyperglycemia.

PUB291

Pharmacokinetics, Pharmacodynamics, Safety and Tolerability of the CCL2 Antagonist NOX-E36, a Novel Agent Being Investigated for Treatment of Diabetic Nephropathy Grit Landgraf,[1] Dirk Eulberg,[1] Stefan Zoellner,[1] Stephanie Vauleon,[1] Diana Beyer,[1] Frank Fliegert,[1] Matthias Baumann,[1] Carsten Schwenke,[2] Thomas Jax,[3] Thomas Forst,[4] Hermann G. Haller.[5] *[1]NOXXON Pharma AG, Germany; [2]SCO:SSiS Statistical Consulting, Germany; [3]Profil GmbH, Germany; [4]IKFE GmbH, Germany; [5]Clinic of Hypertension and Nephrology, Hannover Medical School, Germany.*

Background: NOX-E36 is a new Spiegelmer®-based therapeutic that specifically binds to and inhibits the pro-inflammatory chemokine CCL2 (MCP-1). Spiegelmers (L-stereoisomer RNA oligonucleotides) are chemically synthesized mirror-image oligonucleotides which are highly selective for their pharmacological target and potent inhibitors of target function.

Methods: The early clinical development program of NOX-E36 consists of a single dose first in human study and a multiple ascending dose Phase Ib study carried out in healthy subjects and type 2 diabetes mellitus patients. Both studies were randomized, double-blind and placebo-controlled. Pharmacodynamic effects were evaluated with mixed linear models.

Results: Single IV doses of up to 2 mg/kg NOX-E36, single SC doses up to 0.5 mg/kg, and 4-week multiple IV doses up to 0.25 mg/kg were safe and well tolerated. NOX-E36 had no clinically relevant effects on vital signs, ECG parameters and laboratory safety parameters. Plasma exposition was dose-linear and PK profiles were similar in healthy subjects and patients. NOX-E36 had a plasma half-life of ca. 50 h and SC bioavailability of ca. 50 %. Steady state was reached after 3-4 IV administrations. A clear and dose-dependent reduction of peripheral CD14+CCR2+ inflammatory monocytes of up to 60 % was observed in the single dose study. This effect was confirmed and certain anti-inflammatory, anti-glycemic and reno-protective effects of NOX-E36 were evaluated in the multiple dose study in patients.

Conclusions: NOX-E36 was safe and well tolerated, no MTD was reached. PK/PD parameters indicate that NOX-E36 effectively antagonizes the CCL2/CCR2 axis. First trends for dose-dependent anti-inflammatory and reno-protective effects were observed. Based on these data, a further study in albuminuric diabetics has been initiated (NCT01547897).

More Severe Secondary Hyperparathyroidism Is Associated with Diabetes Mellitus in Maintenance Hemodialysis Patients Kawin Tangdhanakanond, Sayed A. Kazi, Eric J. Bloom, Rasib Raja. *Nephrology, Albert Einstein Medical Center, Philadelphia, PA.*

Background: Bone mineral disorder is a common complication of chronic kidney disease (CKD). Although diabetes mellitus is the leading cause of CKD and is generally associated with poor outcomes, few and conflicting studies have evaluated bone mineral metabolism in CKD including end-stage kidney disease in the presence of diabetes mellitus.

Methods: We conducted a retrospective analysis on 94 hemodialysis patients at an outpatient hemodialysis unit. All patients received maintenance hemodialysis 3 times per week. Demographic and laboratory data including serum calcium, phosphorus, intact parathyroid hormone, and alkaline phosphatase levels were analyzed and compared between diabetic and nondiabetic patients.

Results: Compared with nondiabetic patients (n = 49), diabetic patients (n = 45) had a higher mean serum intact parathyroid hormone level (pg/mL) (433.66 ± 396.37, 282.79 ± 169.85, p=.018), and a lower mean serum calcium level (mg/dL) (8.79 ± 0.60, 9.08 ± 0.71, p=.036). Although there was no statistical significance, a higher mean serum alkaline phosphatase level (IU/L) (113.94 ± 90.09, 91.91 ± 69.85, p=.19) were shown in diabetic patients. Mean serum phosphorus levels were not statistically different. Urea reduction ratio, Kt/V, other biochemical parameters as well as, proportions of patients receiving cinacalcets, vitamin D analogues, and phosphate binders were comparable between the two groups.

Conclusions: Despite some previous small reports suggesting that diabetes mellitus might be associated with adynamic bone disease, our study showed that secondary hyperparathyroidism was more severe among maintenance hemodialysis patients with diabetes mellitus. Further studies exploring mechanisms of these differences and whether they contribute to more adverse clinical outcomes are warranted.

PUB293

What Factors Are Associated to the Progression of Diabetic Nephropathy? Sagrario Soriano, Victoria García, Maria Luisa Agüera, Raquel Ojeda, Alejandro Martin-Malo, Pedro Aljama-Garcia. *Nephrology, University Hospital Reina Sofia, Cordoba, Spain.*

Background: Diabetic nephropathy (DN) is the leading cause of chronic kidney disease (CKD) and needing for renal replacement therapy (RRT). In Spain, there are more than 35% of patients with diabetes mellitus type 2 and CKD.

The studies suggesting the identification of factors associated to the progression of DN are not conclusive. The aim of this study was to determine the factors that may influence in the progression.

Methods: We analyzed patients with CKD secondary to ND followed in the Nephrology (years 2005 to 2011) and collected data of demographic- clinical characteristic and laboratory parameter from the first visit until the end of follow-up (died or RRT).

Results: It were included 113 patients with a median follow up of 26 months. 8 patients died along the follow up. Baseline data (on arrival at Nephrology) were: Estimated glomerular filtration rate (MDRD-4) 21.6 ± 10.6 ml/min, creatinine levels 3.4 ± 2.9 mg/dl, HbA1c levels 7.7 ± 1.5%, and median proteinuria (ratio protein/creatinine) of 1.4 mg / mg.

Along follow up, 54.9% of patients have a decrease in MDRD-4 > 15% per year and 65.5% of patients requiring initiation of RRT after a 18.3±16 months since his arrival.

We compared the group of patients requiring RRT versus those who did not require.The patients who required RRT had higher proteinuria levels at baseline, CRP levels at baseline and more percent of retinopathy. There were not any significant differences between both groups in GFR and creatinine at baseline.

In renal survival study, the baseline levels of creatinine, CRP, proteinuria and BMI had some influence in the univariate analysis. Multivariate Cox proportional regression model showed that the factors really associated with renal survival were: the CRP leves at baseline and ratio protein/creatinine> 1 mg / mg at baseline.

Conclusions: In patients with advanced ND, the independent determinants of the progression were the presence of proteinuria and elevated inflammatory markers such as CRP at the moment of referring to the Nephrology Unit. Classical typical factors, as HbA1c and cardiovascular risk, were not really associated to the progression of ND.

PUB294

Estimation of Glomerular Filtration Rate in Chinese Patients with Type 2 Diabetes Xun Liu,[1] Chenggang Shi,[1] Linsheng Lv,[2] Hua Tang,[1] Cailian Cheng,[1] Tan-qi Lou.[1] *[1]Division of Nephrology, Department of Internal Medicine, The Third Affiliated Hospital of Sun Yet-sun University, Guangzhou, Guangdong, China; [2]Operating Room, The Third Affiliated Hospital of Sun Yet-sun University, Guangzhou, Guangdong, China.*

Background: Type 2 diabetes is a recognized public health problem in the world. In this study, we compared various modified modification of diet in renal disease study equations, which included the reexpressed MDRD equation, the Chinese equation, the previously Japanese equation and the new Japanese equation in Chinese patients with type 2 diabetes.

Methods: 210 type 2 diabetic patients were recruited. Serum creatinine (SC) level was measured by the enzymatic method. Standard glomerular filtration rate (sGFR) was measured by the ^{99m}Tc-DTPA method. The mean age was 62 (range 30-89) years. And the mean sGFR was 47.7 (range 5.9-116.7) ml/min per 1.73 m^2.

Results: The median of difference ranged from -11.3 ml/min/1.73 m^2 to 7.4 ml/min/1.73 m^2. The median percents of the absolute difference ranged from 32.8 ml/min/1.73 m^2 to 43.7 ml/min/1.73 m^2. Accuracy with a deviation less than 15% ranged from 20.0% to 23.8%. Accuracy with a deviation less than 30% ranged from 32.9% to 44.8%. Accuracy with a deviation less than 50% ranged from 57.6% to 71.0%. On the Bland–Altman plot, the precision ranged from 63.1 ml/min/1.73 m^2 to 135.8 ml/min/1.73 m^2. However, none of the equations had accuracies that reached the 70% while differing less than 30% from the sGFR. And the agreement limits of all the equations exceeded the prior acceptable tolerances defined as 60 ml/min/1.73 m^2.

Conclusions: When SC was measured by the enzymatic method, the performances of all the modified modification of diet in renal disease study equationsweredisappointing. Further improved formulas are needed to evaluate renal function in Chinese patients with type 2 diabetes.

PUB295

Effects of Renal Function on Canagliflozin (CANA) Pharmacokinetics (PK) and Pharmacodynamics (PD) in Non-Diabetic Subjects Damayanthi Devineni,[1] Thomas C. Marbury,[2] Christopher R. Curtin,[1] Nicole Vaccaro,[1] David Wexler,[1] An Vandebosch,[1] Ewa Wajs,[1] David Polidori.[1] *[1]Janssen Research & Development, LLC, Raritan, NJ; [2]Orlando Clinical Research Center, Orlando, FL.*

Background: CANA is a sodium glucose co-transporter 2 inhibitor in development for treating type 2 diabetes. This study evaluated the PK and PD of CANA in non-diabetic subjects with varying degrees of renal impairment compared with healthy subjects.

Methods: This open-label Phase 1 study enrolled subjects (N=40) with normal renal function as well as mild, moderate, and severe renal impairment (creatinine clearance ≥80, 50 to <80, 30 to <50, and <30 mL/min, respectively), and subjects with end stage renal disease (ESRD) requiring hemodialysis (HD). Subjects received a single dose of CANA 200 mg except those with ESRD, who received 1 dose post-HD and 1 dose pre-HD 10 days later.

Results: CANA area under the plasma concentration-time curve from time 0 to infinity (AUC_∞) and maximum plasma concentration (C_{max}) were slightly higher in subjects with mild renal impairment and modestly higher in subjects with moderate to severe impairment, but not ESRD, than in those with normal function. AUC_∞ and C_{max} for inactive CANA metabolites, M7 and M5, modestly increased in subjects with moderate to severe impairment. Urinary glucose excretion (UGE) after CANA administration decreased as renal function decreased. Following CANA treatment, the renal threshold for glucose (RT_G) was modestly higher in subjects with moderate to severe renal impairment than in subjects with normal function and mild impairment. CANA was well tolerated, with similar adverse event rates and no clinically relevant changes in laboratory parameters across groups.

Conclusions: Subjects with varying degrees of renal impairment had slightly or modestly increased CANA exposure, reduced UGE, and reduced RT_G lowering compared to subjects with normal function.

Table. Summary of PK and PD Parameters

	Renal Function					
	Normal (n = 8)	Mild impairment (n = 8)	Moderate impairment (n = 8)	Severe impairment (n = 8)	ESRD (post-HD) (n = 8)	ESRD (pre-HD) (n = 8)

PUB296

Management of Diabetes in Patients with Chronic Kidney Disease Marguerite Mccloskey, Roy Harper. *Ulster Hospital Dundonald, United Kingdom.*

Background: Management of diabetes in patients with chronic kidney disease (CKD) is challenging. Therapeutic options for patients with type 2 diabetes are limited because a reduced estimated glomerular filtration rate (eGFR) results in the accumulation of drugs and their metabolites, therefore insulin therapy remains the mainstay of treatment. The purpose of this audit was to determine the proportion of diabetic patients with CKD stages 4-5 reaching the glycated haemoglobin (HbA1c) targets in accordance with the National Institute of Clinical Excellence (NICE) guidance, and to make a comparison of glycaemic control with or without insulin therapy.

Methods: A search was performed on a computerised database of all current diabetic patients attending the Ulster Hospital Dundonald with an eGFR <30. We then searched for those on insulin therapy or not, and included the HbA1c level at their most recent hospital attendance, as well as some demographic details. We then analysed the data using an excel spread sheet.

Results: A total of 256 patients were attending with an eGFR <30. Of those 256 patients, there were 45% (116) male, 55% (140) female, 10% (27) type 1 diabetics, 88% (225) type 2 diabetics, and 2% (4) secondary diabetics. Age range was 30-98 with an average age of 72years. Seventy five per cent (193) were on insulin therapy, 25% (48) of which reached the NICE guideline HbA1c target of 6.5-7.5%, 25% (63) were not on insulin therapy, 44% (28) of which reached the target. Of the type 1 diabetic patients on insulin therapy, 15% (4/27) reached the target. Of the type 2 diabetics, 74% (166/225) were on insulin therapy, 27% (44/166) of which reached the target, 26% (59/225) were not on insulin therapy, 46% (27/59) of which reached the target. All of the secondary diabetics were not on insulin therapy, 25% (1/4) of which reached the target.

Conclusions: This data confirms that glycaemic control is difficult in patients with CKD. It also suggests that insulin therapy does not achieve good glycaemic control in this group of patients, and perhaps for type 2 diabetics, switching to insulin therapy may not be beneficial and perhaps they should remain on oral hypoglycaemic agents with appropriate dose adjustment.

PUB297

Is Ventricular Remodeling in ESRD Related to Pulmonary Edema in Diabetic Patients? Oonishi Takahiro. *Nephrology, Ise Red Cross Hospital, Ise, MIe, Japan.*

Background: Diabetic patients are often introduced into the hemodialysis due to pulmonary edema. Echocardiograhic LV hypertrophy(LVH) is probably a more frequent finding in hypertensive daiabetic patients than in hypertensive nondiabetic patients. We assume that there is a difference of the LVH between the diabetic and non-diabetic patients in CKD Stage5.

Methods: 89 patients who had introduced the hemodialysis from January, 2009 to December, 2011 in our hospital were examined, they were divided into 22 diabetic groups: (28 male, 10 female, mean age 68±11 years) and 65 non-diabetic group (male, 22 female, mean age 70±12 years). We measured LV mass index(LVMI) and RWT (relative wall thickness) by echocardiography when they had first time dialysis.

Results: Diabetic group is significant higher than nondiabetic group at RWT (0.45±0.08 vs 0.40±0.07, p<0.05) .No significant differences were found in both group at LVMI(g/m2) (176±32 vs 176±44,p=0.3).RWT was higher 0.45 in the patient of episodes of pulmonary edema than without pulmonary edema.

Conclusions: The diabetic group in CKD stage 5 has been changed from left ventricular remodeling to concentric left ventricular hypertrophy(LVH),however eccentric LVH by the volume overload was seen in non-diabetic group. Diabetic heart had accompany the concentric hypertrophy, because of that, the diabetes patient thought that Pulumonary edema is easy to happen.

PUB298

Cystatin C in Children on Chronic Hemodialysis Olivera Marsenic, Andrea Wierenga, Donna R. Wilson, Tripti Shrivastava, Garfield A. Simon, Anne M. Beck, Tiffany J. Swanson, Nisha S. Singh, Dorit Elberg, Gerard Elberg, Kevin Couloures, Dwayne D. Henry, Martin A. Turman. *Pediatric Nephrology, OUHSC, Oklahoma City, OK.*

Background: Cystatin C (CyC) has been suggested as a marker of middle-molecule (MM) accumulation, hemodialysis (HD) adequacy in adults, and as marker of residual renal function (RRF) in peritoneal dialysis. MMs are poorly removed with standard HD. High CyC is associated with increased cardiovascular disease (CVD) and mortality, and is atherogenic. CyC has not been studied in pediatric HD. This study investigated: 1) MM burden as represented by CyC, 2)CyC kinetics and 3)CyC as a marker of RRF, in pediatric HD.

Methods: 21 HD sessions and 21 interdialytic periods were analyzed in 7 patients (pts), 4 anuric (A), 3 nonanuric (NA), age 14.36±4.54 years (5-19), weight 53.66±28.95 kg (16-102). RRF was 1.63±0.11 ml/min/1.73m^2 (1.54-1.75), urine volume 475-906 ml/1.73m^2/day. CyC was measured before (pre-HD) and after (post-HD) 3 standard HD sessions in 1 week and prior to first session of the following week.

Results: Single-pool (sp) Kt/V was 2.09±0.86, ultrafiltration (UF) 4.61±1.98%, HD duration (t) 218±20 min, blood liters processed 1.04±0.23 l/kg. There was no difference (p>0.05) between pre-HD CyC 9.85±2.15 mg/l (A:9.48±2.33,NA:10.35±1.88,p>0.05) and post-HD CyC 10.04±2.83 mg/l (A:9.45±2.97,NA:10.82±2.58,p>0.05). There was no inter-HD rise in CyC. Weekly average pre-HD CyC per pt was 9.97±1.90 mg/l (A: 9.87±2.68,NA:10.10±0.23,p>0.05), and it correlated with age (r=0.808,p=0.027),Ht (r= 0.799,p=0.03),weight (r=0.471,p>0.05) and body surface area(r=0.583,p>0.05), but not with RRF (r=0.064).

Conclusions: We reached important novel conclusions that require further research:1) CyC does not rise between HD, is not removed by standard HD and remains at steady-state, thus elimination is extrarenal 2) low GFR does not affect CyC elimination, therefore CyC can not be used for estimation of low RRF 3) CyC increases with pt age and size 4) CyC (and likely other MMs) is not removed by standard HD and is very elevated, raising the risk of CVD and all-cause mortality; there is an urgent need to provide intensified HD regimens (routine in adults only) to children.

PUB299

Comparison of Cystatin C and Beta-2-Microglobulin Kinetics in Children on Chronic Hemodialysis Olivera Marsenic, Andrea Wierenga, Donna R. Wilson, Tripti Shrivastava, Garfield A. Simon, Anne M. Beck, Tiffany J. Swanson, Nisha S. Singh, Dorit Elberg, Gerard Elberg, Kevin Couloures, Dwayne D. Henry, Martin A. Turman. *Pediatric Nephrology, OUHSC, Oklahoma City, OK.*

Background: Middle-molecules(MM) are not monitored in children on hemodialysis(HD), but are accumulated and increase risk of cardiovascular disease and mortality. Intensified HD modalities remove MM but are not routinely available to children. Molecular properties of Cystatin C(CyC), 13kDa,potentially make it a preferred MM marker over Beta-2-Microglobulin(B2M), 12kDa. This study is the first to compare CyC and B2M kinetics in children to: 1)determine burden of MM 2) investigate if CyC can be used as marker of MM.

Methods: CyC and B2M were measured in 21 HD sessions during 1 week using cellulose diacetate low-flux high-efficiency dialyzer, in 7 patients(pts), age 14.36±4.54 years(5-19), weight 53.66±28.95kg(16-102). Blood sampling:at HD start(pre),1 and 2 hours(hr) into HD,at end of HD(post) for all sessions(n=21) and at 60min after first HD(eq) in each pt(n=7).

Results: Residual renal function(RRF) (3/7pts,1.54-1.75ml/min/1.73m^2) did not make a difference in pre-HD or post-HD CyC and B2M (p>0.05). Post-HD CyC(mg/l) 10.04±2.83 did not differ(p>0.05) from pre-HD CyC 9.85±2.15. Post-HD B2M(μg/ml) 38.87±7.12 was higher(p=0.006) than pre-HD B2M 33.27±7.41. EqCyC was not different from postCyC (11.07±3.14 vs 10.24±2.08,p>0.05). EqB2M was lower than postB2M (36.48±7.68 vs. 41.09±8.99,p=0.006). There was no change in CyC at 1 and 2 hr into HD. B2M increased by mean 8.72% at 1 hr and 20.72% at 2 hr into HD. CyC or B2M did not significantly correlate with spKt/V(2.09±0.86), ultrafiltration(4.61±1.98%), blood liters processed(1.04±0.23 l/kg) or HD duration(218±20 min).

Conclusions: 1) CyC and B2M are very elevated and not removed by standard HD 2) Low RRF does not have a role in CyC and B2M removal 3) CyC does not rise with dialytic process, and is unchanged 1 hour after 4) B2M is affected by dialytic process (rises during HD independant of UF, and decreases 1 hour after), thus it is not a good marker of MM removal. Intensified HD is needed for MM removal in children, with CyC used as MM marker of its adequacy.

PUB301

Pegloticase and Hemodialysis Marsha Wolfson, Sean Walsh, Peter Clarke. *Savient Pharmaceuticals, Inc., East Brunswick, NJ.*

Background: Pegloticase (KRYSTEXXA) is a recombinant mammalian uricase conjugated to monomethoxypoly (ethylene glycol) (mPEG), developed as an enzymatic treatment for patients with gout refractory to conventional therapy. Clinical trials have excluded dialysis patients, leading to questions regarding pegloticase dialyzability in these patients. The drug manufacturing process can serve as a simulated dialysis treatment since it includes molecular weight cut-off (MWCO) membranes prior to formulation.

Methods: Pegloticase was studied under commercial process conditions using six 100 kDa MWCO ultrafiltration membranes per run. As hemodialysis normally uses membranes with MWCO <70 kDa, the manufacturing process can be considered as an assessment of loss of pegloticase during hemodialysis. Six regenerated cellulose diafiltration cassettes provided 3m^2 of membrane surface area with MWCO of 100 kDa (Millipore-Ultracel PLCHK). Pegloticase was concentrated to approximately 10 mg/mL and diafiltered against 25 volumes of phosphate-buffered saline. Total quantities of protein before and after diafiltration were calculated and percent protein retention was determined.

Results: Retention of protein of 98% (n=19; SD 1.3%; RSD=1.3%) indicates that almost no pegloticase is lost through the filter.

Conclusions: Results suggest pegloticase is unlikely to be removed during hemodialysis. Hence, no dose adjustments are required to treat maintenance hemodialysis patients with pegloticase. A formal pharmacokinetic/pharmacodynamic study is planned to confirm these findings.

PUB302

Biocompatibility of Polysulfone Dialyzer Used Newly Developed Hydrophilic Polymer Hideki Kawanishi, Misaki Moriishi, Shinichiro Tsuchiya, Sadanori Shintaku. *Tsuchiya General Hospital, Hiroshima, Japan.*

Background: The polysulfone (PSf) membrane is now becoming the mainstream in the hemodialysis (HD) treatment because PSf membrane has a high membrane performance. Besides, most of PSf membranes hydrophilized by blending polyvinylpyrrolidone (PVP) are well known to have biocompatibility in clinical use. However, in recent years, the improvement in biocompatibility of the HD membrane is needed. Especially, when blood components adhere to the membrane, it is pointed out to generate the oxidative stress. Then, it aimed at creation of the HD membrane that did not adhere blood components based on the PSf membrane. We used a new hydrophilic polymer instead of PVP to the PSf membrane by taking note of the adsorbed water on it.

Methods: PSf dialyzer was developed used new hydrophilic polymer instead of PVP by taking note of the adsorbed water on the internal surface. We report the ex-vivo and clinical studies of biocompatibility of this PSf dialyzer (NV-dialyzers, Toray Medical Co., Japan).

Results: Solute removal capacity: Solutes removals were depended on the pore size distribution of PSf membrane. Reduction rate of beta2-microglobulin and albumin loss of NV-dialyzer on the condition of 4 hour, blood flow 300 mL/min are 74.5±5.2% and 2.5g/session, respectively.

The prevention of platelet adhesion (Ex-vivo,): Eight patients whole blood of DM and non-DM were applied on the internal surface of PSf hollow fibers cut in the longitudinal direction. The platelet adhesion counts on scanning electron microscope findings of NV of all patients' bloods were significant lower than CX-U (Toray), APS-SA (Asahikasei-kurare, Co), PES-S-alfa (Nipro, Co) hydrophilized by PVP.

Comparison of platelet activation marker on the dialysis patients (in vivo) : The platelet factor 4 (PF-4) and beta-thromboglobulin(TG) were compared on 4 weeks, 5 patients crossover studies of NV and APS-SA. The TG and PF-4 were increased on the patients of APS-SA, but it were significant decreased contrary on NV.

Conclusions: Applying the newly develop hydrophilic polymer, NV-dialyzer has superior biocompatibility which had a high performance, retained low elution and dramatically prevented the platelet from adsorbing to the surface.

Safe Use of Citric Acid Based Dialysate and Heparin Removal in Post-Dilution Online Hemodiafiltration Julien Aniort,[2] Thierry Petitclerc,[1] Caroline Creput.[1] *[1]Dialysis, Nephrology, AURA, Paris, Paris, France; [2]Nephrology, CHU Clermont Ferrand, Clermont Ferrand, France.*

Background: Anticoagulation of the blood circuit is essential to the success of a hemodialysis session. Heparin is the most used anticoagulant but exposes patients to several potentially serious risks such as bleeding and immuno-allergic thrombocytopenia. The use of a citric acid based dialysate (CitA-D) allows the reduction of heparin in conventional hemodialysis while maintaining dialysis adequacy. We evaluated the possibility of using CitA-D in post-dilution online hemodiafiltration (OL-HDF)and tested the possibility of heparin removal.

Methods: Ten chronic hemodialysed patients treated by post-dilution OL-HDF three times a week were included in a prospective study comparing usual chlorhydric acid based dialysate (ClA-D) versus CitA-D. During the use of the latter, heparin was first reduced by half the dose and, secondly, totally removed.

Results: For all (n=120) sessions using CitA-D, only one clotting episode of the blood circuit was observed during heparin-free period in one patient who was found to have an arterio-venous fistula stenosis. $(Kt/V)_{sp}$ remained the same in all cases. No adverse clinical effect or significant change in pre-dialysis serum bicarbonate, calcium, phosphate, parathormone and b2-m were observed during the study.

Conclusions: Our data indicates that the use of CitA-D in post-dilution OL-HDF is safe and allows heparin removal in most patients but this should be confirmed by larger long-term studies.

PUB304

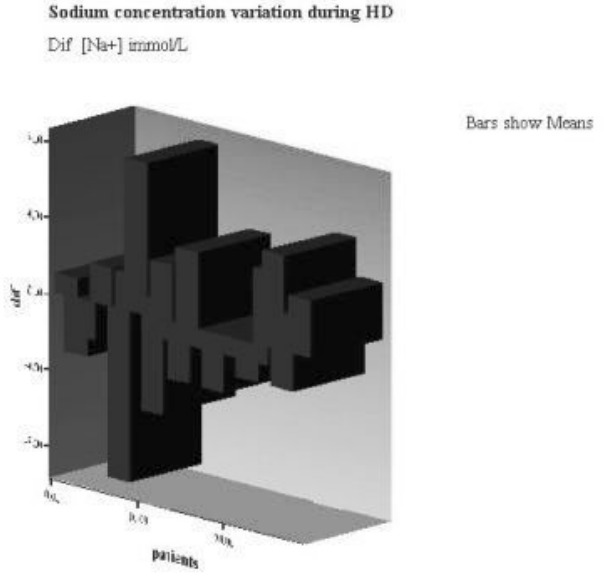
Blood Concentration Sodium Variation during Hemodialysis

Olga R. Carmona. *Nephrology, University of Uruguay, Montevideo, Uruguay.*

Background: During Hemodialysis (HD) most of serum sodium concentration [Na+] is removed by convection with water by ultrafiltration and a small concentration is removed by diffusion for the difference between plasma and dialysate sodium concentration. The purpose of this study is to determinate the serum sodium concentration variation (Δ [Na+]) during HD to adequate the dialysate sodium concentration [Na+]d in each patient.

Methods: Chronic Hemodialysis (HD) patients (n=28)were included measuring plasma sodium concentration,designed as Mean ± St, pre HD [Na+] and post HD[Na+] by potentiometry determination of sodium activity with an ion electrode, corrected by empirical factor. Dialysate sodium was fixed at 140 mmol/L. The error in the stimation due for the dialysis machine may be ± 3mmol/L.Interdialytic weight gain (IDWG)was measure in Kg. Student t test (p<0,05) was used to compare mean pre and post HD.Pearson correlation between Δ[Na+] and IDWG was considered.

Results: Average [Na+] pre HD was 137,75±3,99 mmol/L and the [Na+] post HD was 137,75 ± 2,72mmol/L.. The Δ[Na+] was 0,18±3,52mmol/L(student t test no significant,p<0,05), but with a range of variation from -9 to 8 mmol/L (7,14 ±3,34 mmol/L) at the end of HD. IDWG was 3,68±1,52Kg with a range from a 1 to 7,3 Kg. In the patient were the Δ[Na+] was +8mmol/L the IDWG was +5,70 Kg.There was not significant correlation between Δ[Na+] and IDWG.



Conclusions: Pre HD concentrataion of serum sodium may be used for individualizing the dialysate [Na+] in each patient, avoiding excesive +Δ[Na+] increase post HD with more increase of IDWG.

Funding: Government Support - Non-U.S.

Osteocalcin as a Useful Marker of Bone Metabolism, Cardiovascular Risk, and Nutritional Status in Hemodialyzed Patients

Krzysztof Hoppe, Krzysztof Schwermer, Dorota Radziszewska, Pawel Olejniczak, Bartlomiej Posnik, Peter Sawatiuk, Jolanta Kaczmarek, Dorota Sikorska, Krzysztof Pawlaczyk, Andrzej P. Oko. *Nephrology, Transplantology and Internal Diseases, Poznan University of Medical Sciences, Poznan, Poland.*

Background: Amongst chronically hemodialyzed (HD) patients, abnormalities of bone metabolism (BM) change due to age and end stage renal disease (ESRD) per se. Osteocalcin (Osc) is a marker of BM and an autocrine bone growth stimulating agent.

Methods: The study was performed on 136 HD pts. Overhydration (OH), calcium-phosphate product (CaP), serum Osc, NT-proBNP, cardiac troponin T (cTnT), blood pressure, and nutritional status were assessed during a 6 month period (at time 0 and 6 mo.). OH was determined using both clinical measures and bioimpedance (BIA), nutritional status was assessed using subjective global assessment (SGA), and the efficacy of HD - Kt/V. The studied group was divided into 2 subgroups according to age: grA (≤60 yo, n=58), grB (>60 yo, n=78). The aim of the study was to determine the effects of age and ESRD on abnormalities of BM and their relation to cardiovascular risk (CVD).

Results: At time 0 there was a tendency toward higher OH in grA, but surprisingly there was a significant decrease in OH (-20.8%; p<0.05) in grA and an opposite tendency in grB (+5.8%). The data shows a statistically significant under-estimation in OH measured clinically in comparison to BIA after 6 mo. in grB (2.76 vs. 3.48%; p<0.05) with higher clinical than BIA OH values in grA (3.42 vs. 2.80%; p<0.05). Improper management after clinical assessment in grB was confirmed with a significant decrease in Hb (11.6 vs. 10.7 g/dl) and slight non-significant decline in NT-proBNP (13200 vs. 13050 pg/ml) and cTnT (0.076 vs. 0.072 ng/ml) at 6 mo. Relations between Osc and other analyzed markers are presented in table 1.

Parameter	0 mo.	6 mo.
PTH	r=0.33; p<0.001	r=0.43; p<0.0001
Kt/V	r=0.33; p<0.02	r=0.16; p=0.06
SGA	r=-0.17; p=0.05	r=-0.15; p=0.08
NT-proBNP	r=0.27; p<0.002	r=0.20; p<0.02
cTnT	r=0.18; p<0.05	ns

Conclusions: Osc seems to be an important marker of BM, CVD and nutritional status in HD patients. However, it should be evaluated for interactions with other markers that measure adequacy of HD and CVD.

PUB306

Images in Hemodialysis

Raymonde Gagnon, Andrea Palumbo. *Medicine, McGill University Health Centre, Montreal, QC, Canada.*

Background: There is an increase in publication of striking photographs of various anatomical abnormalities in ESRD patients used for teaching purposes. These "Images" usually present clinical abnormalities requiring diagnosis and management.

Methods: On routine rounding, we looked for abnormalities visible to the naked eye in our chronic hemodialysis population. Most of the identified abnormalities involved vascular access.

Results: To our surprise, we readily found several significant abnormalities with anatomical features varying from common to the unseen. For instance, these Images include: 1) the scar of a dog's bite on the skin near an aneurysmal forearm A-V fistula (a powerful reminder of the recommended precautions to be taken by hemodialysis patients with companion animals); and 2) an A-V fistula with a buttonhole access located in the forearm of a patient with nephrogenic systemic fibrosis (due to gadolinium exposure) who is needling himself despite marked hand deformities.

Conclusions: Several patients on chronic hemodialysis presented obvious physical abnormalities which had not drawn previous emphasis, essentially because they did not require special attention with regards to further management. Nor did those abnormalities hinder delivery of hemodialysis treatment. Nonetheless, the Images proved to be excellent examples for clinical teaching because of their great visual impact.

PUB307

Prominent Accumulation of Protein-Bound Solutes in Hemodialysis Patients Reflects Limited Clearance by Hemodialysis Compared to Efficient Clearance by the Native Kidneys

Tammy L. Sirich,[1] Natalie Plummer,[1] Thomas H. Hostetter,[2] Timothy W. Meyer.[1] *[1]Medicine, VA Palo Alto HCS and Stanford University, Palo Alto, CA; [2]Medicine, Case Western Reserve University, Cleveland, OH.*

Background: Native kidneys efficiently clear protein-bound solutes by tubular secretion, a process not replicated by hemodialysis (HD). The current study assessed the extent to which this disparity in clearance mechanisms causes disproportionate elevation of the free concentrations of bound solutes in HD patients.

Methods: Clearances of the bound solutes hippurate (HIPP), indoxyl sulfate (IS), p-cresol sulfate (PCS), and the unbound solute creatinine (Cr) were measured in 5 HD and 5 normal (NL) subjects. Calculations were based on the *free levels* in plasma ultrafiltrate as these are the levels to which tissues are exposed. Clearances in NL subjects (k_{NL}) were calculated as the urine excretion rate divided by the plasma free level and for HD subjects (k_{HD}) as the dialytic removal rate divided by the mean of the pre- and post-dialysis plasma free levels.

Results: Results were (mean±sd, [a]p<0.05 vs Cr; [b]NL vs HD):

Solute	k_{HD} (ml/min)	k_{NL} (ml/min)	k_{HD}/k_{NL}	Plasma free level HD/Plasma free level NL
Cr	191 ± 6	154 ± 9[b]	1.2	12
PCS	589 ± 55[a]	1087 ± 196[a,b]	0.54	19
IS	582 ± 28[a]	2123 ± 396[a,b]	0.27	55
HIPP	253 ± 10[a]	1418 ± 134[a,b]	0.18	149

For Cr, k_{HD} was slightly above k_{NL}. With dialysis applied intermittently and the native kidneys functioning continuously, the plasma concentration ratio in HD compared to NL was approximately 12 to 1. Dissociation of solute from binding proteins as blood passes through the dialyzer allowed the k_{HD} of the bound solutes to rise above the k_{HD} of Cr. But k_{HD} of the bound solutes were much below the high native kidney clearances achieved by solute dissociation from binding proteins combined with tubular secretion. Reductions in k_{HD} below k_{NL} for the bound solutes were reflected by greater increases in the plasma free level of these solutes in HD compared to NL.

Conclusions: Increasing the dialytic clearances of bound solutes could prevent the disproportionate elevation in their levels observed with conventional treatment and, to the extent that they are toxic, improve patients' health.

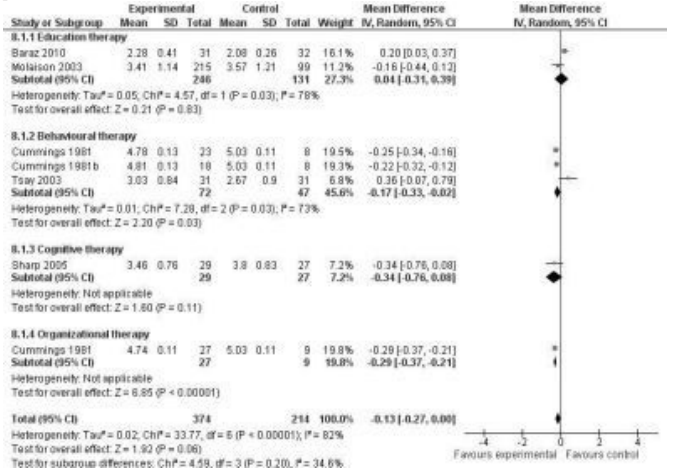
PUB308

Interventions for Promoting Adherence to Fluid Intake and Dietary Salt Restriction in Patients with End-Stage Kidney Disease: A Systematic Review Michelle M.Y. Wong,[1] Jonathan C. Craig,[2] Adeera Levin,[3] Giovanni F.M. Strippoli.[4] *[1]University of British Columbia; [2]Cochrane Renal Group and University of Sydney; [3]St. Paul's Hospital and University of British Columbia; [4]Mario Negri Sud Consortium, Cochrane Renal Group, University of Sydney, and Diaverum AB.*

Background: Volume overload is common in end-stage kidney disease (ESKD), and high interdialytic weight gain (IDWG) is associated with hypertension, cardiovascular events and mortality. Strategies to improve adherence to salt and fluid restriction have not been formally summarized. This was the aim of our systematic review.

Methods: We searched the Cochrane Renal Group specialized registry, Medline and EMBASE to April 2012 for randomized trials of non-pharmacological interventions to improve adherence to salt and fluid restriction, compared head-to-head or versus routine care, in ESKD patients, either not on dialysis, on hemodialysis, or on peritoneal dialysis. Data on mortality, cardiovascular events, quality of life and surrogate endpoints (including IDWG as a volume status measure) were extracted where available. A meta-analysis using random effects model with results expressed as relative risks or weighted mean differences with 95% confidence intervals was done and risk of bias assessed.

Results: Nine trials (n=914) were eligible, 8 in hemo and 1 in peritoneal dialysis. Participant age was 55.6 (SD 7.8) years, dialysis vintage 43.9 (SD 18.4). In hemodialysis patients, education and cognitive therapies did not significantly reduce end of treatment IDWG compared to routine care, while behavioral and organizational therapy (nurse phone calls) did.



There were no data on any hard end points.

Conclusions: Existing data on interventions to promote adherence to dietary salt and fluid restriction are limited and showed minimal or no benefit. Behavioral therapies may be promising but deserve further study.

PUB309

Weather Conditions Influence Interdialytic Weight Gain Only to a Minor Degree Mihaly Tapolyai,[1] Zsuzsa Taborine-Gonczi,[1] Maria Faludi,[1] Virag Reti,[1] Zsolt Lengvarszky,[2] Tibor Szarvas,[2] Klara Berta.[1] *[1]Fresenius Dialysis, Semmelweis University, Budapest, Hungary; [2]Mathematics, Louisiana State University Shreveport, Shreveport, LA.*

Background: Interdialytic weight gain (IDWG) is a measure of compliance as well as it is a predictor of outcome. Patients, however, feel that various weather conditions such as humid or hot weather is to blame for an increased IDWG.

Methods: We prospectively monitored 98 consenting chronic hemodialysis patients for their IDWG. We tabulated their week-end IDWG under 3 conditions in the summer of 2011. Weather data were obtained from the website of the Hungarian Meteorological Service. Weekend_1: humid (93%) warm (24 °C); Weekend_2: dry (38%) but hot (33 °C); and Weekend_3: dry (30%) and warm (24 °C) day. 56% of the patients were men, mean age 60.9 years with a mean residual urine of 362 ±493 mL/day; mean Kt/V: 1.4 ±0.25 mean albumin: 4.0 ± 0.4.

Results: The mean IDWG's did not differ significantly: Weekend_1: 2973 ±1386 mL Weekend_2: 2684 ±1368 mL Weekend_3: 2926 ±1311 mL. The Friedman 1-way ANOVA test could not find a significant difference (p: NS) among the three groups. However, a paired one-sample t test revealed a significant (p: 0.03) difference between Weekend_1 and Weekend_2 by a minor degree (289 mL) though not between the other pairings, indicating that only the ambient hot temperature seems to influence IDWG, not high air humidity.

Conclusions: We conclude that the ambient temperature and not humidity may to a small degree influence IDWG.

PUB310

Describing Nutritionally-At-Risk Hemodialysis (HD) Patients Who Receive Oral Nutrition Supplements (ONS) Rosa Hand,[1] Janeen B. Leon,[1] Lilian Cuppari,[2] Alison Leah Steiber.[1] *[1]Case Western Reserve University; [2]Federal University of Sao Paulo.*

Background: ONS have been shown to be effective at improving the nutrition status of HD patients.

Methods: This was a secondary analysis using data collected through on online nutrition algorithm for nutritionally-at-risk HD patients to determine which patients receive an ONS recommendation (ONS-Rec) from their dietitian and to describe the length of time patients receive the recommendation for. Analysis was performed using JMP 9.0 and significance was set at $p<0.05$.

Results: There were 64 patients at 140 algorithm visits with a dietitian-selected nutrition diagnosis of insufficient energy or insufficient protein, etiology of insufficient intake and barrier of lack of appetite. The median number of visits per patient was 2, range 1-7. At 47 of these visits patients received a new ONS-Rec (defined as not having received an ONS-Rec at the preceding visit). ONS-Recs tended not to carry over from visit to visit-only 19% received an ONS-Rec at 2 consecutive visits and only 1 patient had the ONS-Rec for 3 consecutive visits.

At 81% of the identified visits, patients had a diagnosis of insufficient energy (more likely to receive an ONS-Rec, p=0.05), at 74% of visits patients had a diagnosis of insufficient protein, and at 54% of visits patients had both problems (more likely to receive an ONS-Rec, p=0.0014).

Characteristics (mean ± SD or %) of patients and comparison of visits with and without ONS-Rec

Parameter	Patients (n=64)	Visits with ONS-Rec (n=47)	Visits without ONS-Rec (n=93)	P-value ONS vs no ONS
% Male	55	46	58	0.26
Age (years)	63 ± 16	67±15	64 ± 16	0.35
BMI (kg/m2)	28.4 ±7.4	27±6	28.5±7.4	0.38
Albumin (mg/dL)	3.8 ±0.4	3.67±0.4	3.78±0.4	0.23
% Bothered by a lack of appetite	97	92	63	0.0068
% Subjective Global Assessment score 1-5	57	76	53	0.22
nPNA (g/kg/day)	0.98±0.23	0.78±0.23	0.91±0.22	0.0451
Protein intake (g/kg/day)	0.82±0.36	0.88±0.43	0.82±0.37	0.52
Energy intake (% estimated needs)	77±24	69±31	74±28	0.57

Conclusions: This analysis shows nPNA and appetite are important in dietitian determination of patients who should receive an ONS-Rec in nutritionally-at-risk HD patients. More research should determine why ONS-Recs do not continue for more consecutive visits.

PUB311

Single Needle Cross Over with Citrasate: 2-Years Follow-Up Roberto Ervo. *Nephrology and Dialysis, Bordighera Hospital, Ventimiglia, IM, Italy.*

Background: At ASN 2011, we presented the preliminary data of a study on the improvement of the dialysis adequacy of a single needle Cross Over system thanks to the use of Citrasate, an acid concentrate containing citrate and a low amount of acetate. This study involved 6 patients for 10 months. The available literature on single needle dialysis refers to a period of max 6 months.

Methods: We continued our Follow-Up with our patients in single needle dialysis up to 20 months using Citrasate and collecting data of previous studies. In particular, we observed efficiency, performances and safety.

Results: As table shows, data did not change vs last year. Patients are clinically stable, no particular medication was necessary and no relevant change in dialysis adequacy was recorded as for Kt/V, treated blood volume and hemoglobin in compliance with the KDOQI standards. We deem it is due to various factors:

· A low recirculation in the arterovenous fistulae

· A control on Kt/V made by urea withdrawal 20 min before the end of dialysis

· The use of high surface filters with very biocompatibile membranes.

· Single needle therapy is carried out with the continuous operation of blood pumps without any interruption of the flow through the dialyzer (Cross-Over system)

· The dialysis bath with citrate (Citrasate) which increases the depurative performances probably thanks to the higher fiber patency (antifouling effect) with no significant variation in calcemia.

	SN-CO-CITR	SN-CO-CITR-24 MONTHS
Kt/V	1,37±0,39	1,58±0,33
Average Qb	260,25±6,04	254±5,48
Total Blood Volume	57,56±5,82	56,8±1,64
Ca	9,11±1,09	9,82±0,94

Conclusions: Literature reports no recent case of patients undergoing single needle dialysis for more than 6-12 months. We reached a 20 months period respecting the KDOQI standards by increasing, if necessary, the dialysis time within reasonable terms (max 4,30 hours).

Therefore, considering a flexible and tailored treatment which allows reducing the mortality risks in an elderly dialysis population which presents an increase in comorbidities and problems linked to the vascular tree depletion, single needle dialysis may be a valid alternative in the long period and avoids complications linked to an inadequate maturation of the arterovenous fistula and to extravasation.

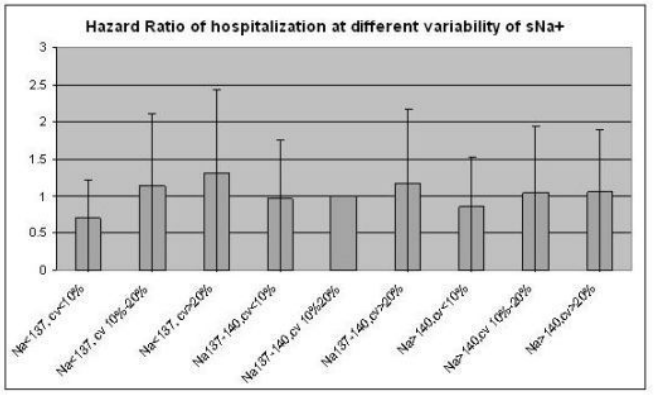
PUB312

Serum Sodium Variability Relates to Hospitalization in Hemodialysis Patients Joselyn Reyes,[1] Jochen G. Raimann,[1] Len A. Usvyat,[1] Stephan Thijssen,[1] Frank van der Sande,[2] Jeroen Kooman,[2] Nathan W. Levin,[1] Peter Kotanko.[1] *[1]Nephrology Research, Renal Research Institue/ Beth Israel Medical Center, New York, NY; [2]Nephrology, Maastricht University Medical Centre, Maastricht, Netherlands.*

Background: In hemodialysis (HD) patients recent reports indicated that pre-HD serum sodium (SNa+) concentrations show a certain level of temporal stability ("SNa+ setpoint"; Keen 2007). Increased variability of the pre-HD SNa+ over time has been shown to relate to increased mortality (Raimann 2012). We aimed to investigate the relation between SNa^+ variability and hospitalization in incident HD patients.

Methods: This cross-sectional cohort study included patients who started HD between 1/2001 and 7/2008 in clinics of the Renal Research Institute. Only patients that had at least 3 SNa^+ measurements during the first 3 months on HD were included. Follow-up time was 18 months. Patients were stratified by average SNa^+ of the first three months: (1) <137, (2) 137 to 141, (3) > 141 mEq/L; and by the SNa+ variability during the first year: coefficient of variation (CV) (1) <10%, (2) 10% to 20% and (3) >20%. Cox regression was used to compute hazard ratios (HR) of first hospitalization in months 13 to 18 adjusting for gender, race, age, vascular access, co-morbidities, systolic blood pressure, and eKt/V.

Results: 4451 HD patients (age 61±15.21, 56% male, 56 % diabetic, 43 % Blacks, 22 %) were studied. HR of hospitalization was lower in patients showing a lower degree of SNa+ variability at all levels of SNa+. This relation was particularly pronounced for the group with high variability and low SNa+.



Conclusions: Both SNa+ level and stability are associated with hospitalization in incident HD patients. In our study a lower variability of SNa+ is associated with fewer hospitalizations. Factors causing higher SNa+ variability remain to be elucidated.

PUB313

Isovolumetric Passive Flow Dialysate Delivery System: Proof of Concept Martin C. Gregory. *Division of Nephrology, University of Utah, Salt Lake City, UT.*

Background: Hemodialysis is life-sustaining treatment that is economically beyond the reach of half the people who may benefit from it worldwide. Passive flow dialysis is a concept of providing dialysis without the need for external sources of energy, thus potentially making hemodialysis available at low cost and without electricity (Ethn Dis. 2009;19[Suppl 1]:S1-65–S1-67). Several challenges must be overcome to make this practicable. This project addresses the first two: how to provide a flow of dialysate at constant rate and how to avoid uncontrolled movement of fluid to or from the patient.

Methods: A 1/3 scale model of a dialysate delivery system was constructed from 3 mm acrylic sheet. This consisted of a rectangular box of outer dimensions 12 x 12 x 24 cm, A second box 12 cm high was a loose sliding fit within the first box. A plastic bag was placed in the space within the outer box and below the inner box. This bag was connected by external tubing to a second bag in the space above the inner box. The upper bag was filled with water and the tubing initially clamped.

Results: The volume of water (representing dialysate) in the system is constant, being the difference in the volumes of the two rigid boxes. When the clamp on the tubing between the two bags was released, water flowed from the upper to the lower bag as the inner acrylic box rose (principle of downward displacement of liquid). The rate of delivery was constant during the middle 2/3 of the volume-time cycle but was irregular, and flow incomplete, near the beginning and end of delivery when hindrances from folding of the plastic bags became significant.

Conclusions: This small-scale model demonstrates the feasibility of isovolumetric delivery of dialysate for hemodialysis without external energy. When scaled up to provide 30 - 50 liters of dialysate, the problems with flow hindrance from bag crumpling would be expected to be less, but this remains to be shown.

Before passive flow dialysis is practicable, several further obstacles must be overcome, specifically: adding controlled removal of ultrafiltrate to this isovolumetric system, warming dialysate safely, and above all creating a reliable method for driving blood through the dialyzer without need for a pump.

Heparin-Induced Thrombocytopenia in Hemodialysis Patients Dulce M. Winterdaal,[1] Maria Isabel Gavidia,[2] Bernardo Fargier,[1] Silvia Villarroel,[3] Marquez Carlos,[4] Jesus R. Sierra,[1] Alfredo A. Plata,[1] Abdel J. Fuenmayor.[5] *[1]Nephrology Unit, University Hospital of the Andes, Mérida; [2]Venezuelan Institute of Social Insurances, Mérida; [3]Hemodialysis Unit, Ciudad Bolívar; [4]Metropolitan Hospital, Maturin; [5]Cardiovascular Research Institute, University of the Andes, Mérida, Venezuela.*

Background: Anticoagulation is necessary during hemodialysis (HD). Heparin-induced thrombocytopenia (HIT) should be suspected in patients who develop thrombocytopenia during heparin administration. The aim of this study was to determine the occurrence of HIT during HD sessions.

Methods: We designed a cross-sectional, randomized and multicenter trial. Patients submitted to HD were divided into three groups according to the dose of heparin administered. Group A comprised patients who received 100 UI/Kg of unfractionated heparin not exceeding a total dose of 5000UI. Group B, patients received 50UI/Kg of heparin. Group C patients did not receive heparin. All the patients were dialyzed 4 hours with hollow fiber dialyzers and Qb = 300ml/min, and Qd = 600ml/min. During the second dialysis of the week, the platelet count was measured at baseline, every hour, and at the end of the session. Differences were analyzed with ANOVA for an alpha value of $p< 0.05$.

Results: One hundred and four patients on HD were included. Group A was made up of 37 patients, Group B of 34 patients and Group C of 33 patients. Sixty and a half % of patients were male. Their mean age was 47.75 ± 16.12 years, and they had been on hemodialysis for 32.6 ± 29.71 months. The most common causes of admission to dialysis were diabetic nephropathy (30.7 %), nephroangioesclerosis (24%) and chronic glomerulonephritis (14.4 %). Brachiocephalic fistula (35.3%) and radiocephalic fistula (34,3%) accounted for vascular access. The platelet count measured before hemodialysis initiation was similar in the three groups ($p = 0.3$). Platelet count obtained at the different observation points did not differ either ($p > 0,05$) .

Conclusions: In these patients we did not observe any significant reduction in platelet count related to heparin use during the hemodialysis session.

PUB315

Comparision between Unipuncture and Bipuncture Tecqnique in Use of Vascular Heterografts: Pros and Cons Oana Rap,[1] Antonio Cabezas,[1] Maria Pilar Ruiz Valverde,[1] Francesc Barbosa,[2] Francesc J. Moreso,[2] Isabel Giménez Torrecilla,[1] Neus Rodriguez Farre,[1] Josep Carrió,[1] Josep Maria Mallafre Anduig.[1] *[1]Nephrology Department, Hospital de Sant Joan Despí "Moisès Broggi"- Fresenius Medical Care "Hospital Dos de Maig, Barcelona, Spain; [2]Nephrology Department, Centro de Diálisis Diagonal-Fresenius Medical Care, Barcelona, Spain.*

Background: Dialysis patients survival depends on duration of their vascular access. Many patients need vascular heterografts,because they exhausted great part of vascular accesses.The vascular grafts viability could be related on the number of punctures that received.

Methods: We analyzed 28 consecutive patients in chronic dialysis program with functional vascular grafts,in which was performed the unipuncture technique and 30 consecutive patients that received the classical bipuncture technique.The patients who left dialysis program(exitus,transplant)with functional graft and patients who continue dialysis currently using vascular graft were excluded for analyze the viability of vascular grafts.

Results: The age and sex distribution of patients was similar in the both groups.The equilibrated Kt/V was 1.37+0.24 in the unipuncture group and 1.56+0.38 in the bipuncture group,with p=0.06. The equilibrated Kt/V was higher in the bipuncture group, probably related by the fact that most of these patients received hemodiafiltration online.The viability of the vascular graft in the unipuncture group was 29.4+32 months and 18.4+12 months in the bipuncture group,with p=0.18.The total number of vascular accesses(catheters, native arteriovenous fistulas, grafts) previous of the actual graft, was 1.9+1.6 in the unipuncture group and 2.89+1.5 in the bipuncture group.Viability of vascular grafts was associated with age of patient at the time of graft collocation and with presence of vasculopathy,although without reaching statistical significance(p= 0.08,p=0.07).

Conclusions: We observed a tendency to higher viability with 11 months in the group receiving unipuncture technique compared with the bipuncture group,although not enough to reach statistical significance. The unipuncture technique was effective and safe for patients, according to current requirements of adequacy of dialysis.

PUB316

Do We Still Need Continuous Hemodiafiltration in Intensive Care? Hugo Mário Silva,[1] Pedro Francisco Azevedo,[1] Pedro V.A. Aguiar,[1] Raquel Gil,[1] Anibal Marinho.[2] *[1]Nephrology, HSA, Porto, Portugal; [2]Intensive Care, HSA, Porto, Portugal.*

Background: Severe acute kidney injury (AKI) is a multisystem clinical problem. Haemodynamically unstable patients are best managed using continuous hemodiafiltration (CVVHDF). Recently, sustained low-efficiency dialysis (SLED) was introduced as a method which theoretically combines the advantages of intermittent dialysis with those of CVVHDF.

Methods: Retrospective analysis, using a data base from the DO-RE-MI study, of 52 patients with AKI treated in our intensive care unit, who underwent either SLED (N=8) or CVVHDF (N=44) for more than three days and didn't have ESRD. We compared clinical

risk scores, volume status and mortality between SLED and CVVHDF subgroups. In a second analysis, intending to eliminate the positive selection bias of patients in SLED we compared only the patients who survived.

Results: Median age 64,3±33,3 years, 58,2% males, 84,4% with sepsis. No differences between subgroups in age, comorbidities and chronic renal disease prevalence. At time 0 SOFA score, PaO2/FiO2, noradrenaline dose(ug/Kg/min) and water balance(mL) in SLED and CVVHDF subgroup were respectively 11,4±3,7 vs. 10,3±4,0; 156,1±73,5 vs. 189,5±96,1; 0,58±0,77 vs. 1,17±1,66(*P*=0,04) and 1395,4±2278,9 vs. 949,3±3491,3. At 72h the same parameters were 12,5±3,9 vs. 15,1±3,5; 209,9±96,4 vs. 191,7±90,8; 0,36±0,82 vs. 1,36±1,99 and 2983±6083,8 vs. 975,7±6115,9. Mortality(%) was 25 vs. 75%(*P*=0,05). Restricting the analysis to patients who survived (SLED N=6, CVVHDF N=11) SOFA score, PaO2/FiO2 and noradrenaline dose at time 0 was 10,5±3,9 vs. 10,4±4,9; 174,9±69,9 vs. 202,0±122,2 and 0,33±0,3 vs. 0,66±0,78. At 72h the same parameters were 11,7±4,2 vs. 12,3±3,0; 227,7±106,7 vs. 209,6±86,7 and 0,08±0,1 vs. 0,38±0,51. On the end of third treatment, total water balance was +2426±4129,2 vs. -3099,0±7125,2mL(*P*=0,02).

Conclusions: CVVHDF is still the therapy of choice for more unstable patients in our hospital. Nevertheless, both techniques are clinically overlapping, which makes the choice of technique more dependent on financial/logistical issues rather than clinical aspects. CVVHDF was better in controlling volume status, rendering it a therapy of choice when hyperhydration is an important clinical issue.

PUB317

Filter Level Analysis of Factors Identifying Successful CRRT Discontinuation in Pediatric Patients Rebecca M. Lombel,[1] Mallika Kommareddi,[2] Theresa Mottes,[1] Neal B. Blatt,[1] Michael Heung,[2] David T. Selewski,[1] Heather A. Lesage-Horton.[1] *[1]Pediatrics, Univ of Michigan, Ann Arbor, MI; [2]Internal Medicine, Univ of Michigan, Ann Arbor, MI.*

Background: There is little consensus regarding timing of initiation or discontinuation (DC) of continuous renal replacement therapy (CRRT). Only two adult studies have specifically examined predictors of successful DC. We evaluated readily available clinical parameters to identify predictors of outcome at each CRRT filter DC over the course of therapy.

Methods: Retrospective single-center study of children requiring CRRT from November 2007 to April 2011. Baseline characteristics at the time of CRRT initiation were collected. Data at time of individual filter DC were collected including urine output (UOP) prior to DC, reason for filter DC (anticipated or not), use of diuretic challenge, and UOP following diuretic challenge/DC. The primary endpoint was re-initiation of CRRT or no return to CRRT at 24 hours post-DC. Univariate analysis and logistic regression models were used to predict outcome.

Results: 68 patients with 271 filters met inclusion criteria. At 24 hours from DC, 192 (71.9%) filters resulted in CRRT re-initiation; 55 (20.6%) did not return to CRRT and 20 (7.5%) ended with patient death. 8-hour UOP prior to DC, albumin and age were not significant predictors of outcome in our model. When a diuretic challenge was performed, the odds ratio of not returning to CRRT compared to re-initiation at 24 hours was 6.27 (CI 3.25, 12.11). For each 1 mL/kg/hr increase in UOP following diuretic challenge/DC, the odds ratio was 1.32 (1.03, 1.70). For each 1 point increase in PELOD score, the odds ratio was 0.95 (0.93, 0.98).

Conclusions: This study is a first step to identify clinical parameters that may predict need for CRRT at 24 hours from filter DC. Decision by the clinician to perform a diuretic challenge and UOP in the 6 hours after diuretic challenge/DC appear to be important factors in predicting outcome. We are analyzing additional variables at time of filter DC that, coupled with these results, may provide a model that can be studied prospectively to predict which pediatric patients display readiness for discontinuation of CRRT.

PUB318

Efficacy and Safety of Citrate-Based Anticoagulation in Patients with AKI in the Intensive Care Unit Fabien Stucker,[1] James Ashu,[1] Jérome Pugin,[2] Belen Ponte,[1] Laurent Brochard,[2] Pierre-Yves F. Martin,[1] Patrick Saudan.[1] *[1]Nephrology, Hôpitaux Universitaires de Genève, Geneva, Switzerland; [2]Intensive Care Unit, Hôpitaux Universitaires de Genève, Geneva, Switzerland.*

Background: A systemic anticoagulation is often required to prevent clotting of filter in ICU patients undergoing continuous renal replacement therapy (CRRT). A regional citrate anticoagulation (RCA) does not induce a systemic anticoagulation and prolongs the filter lifespan, but is associated with metabolic side-effects. We are conducting a randomized controlled trial with patients requiring CRRT to determine whether a RCA is more effective than heparin in terms of CRRT delivered dose and safety profile.

Methods: Patients: included if aged > 18 yrs with an AKI requiring CRRT. Exclusion criteria: active hemorrhagic disorder, pregnancy, history of heparin-induced thrombopenia, consent form not obtained. Methods: patients randomized to either CRRT with RCA (Prismocitrate, Gambro) or classical heparin anticoagulation. Treatment performed with Prismaflex (HDF mode, overall RRT dose 30ml/kg/h and filter change every 72 hours). Primary endpoints: effective daily RRT dose (% of prescribed dose) and filter lifespan. Secondary endpoints: survival at 28 days, number of hemorrhagical events requiring blood transfusions, severe metabolic complications (metabolic alcalosis with pH >7.55, metabolic acidosis with pH <7.25), ionized calcium < 1mmol/l.

Results: From October 2010 to April 2012, 52 patients were randomized among 120 treated with CRRT. Exclusion criteria were active hemorrhagic disorders or severe thrombocytopenia (21%), terminal liver failure (9%), chronic maintenance dialysis (25%) or others (45 %). Mean age was 60±9 years. Etiology of AKIs were medical (77%), surgical (12%) and posttraumatic (11%). Mean CRRT duration was 5±5 days. Effective daily RRT dose was 96±12% in the RCA group and 85±15% in the heparin group (p=0.057). 28-days mortality was 29% in the RCA group and 27% in the heparin group.

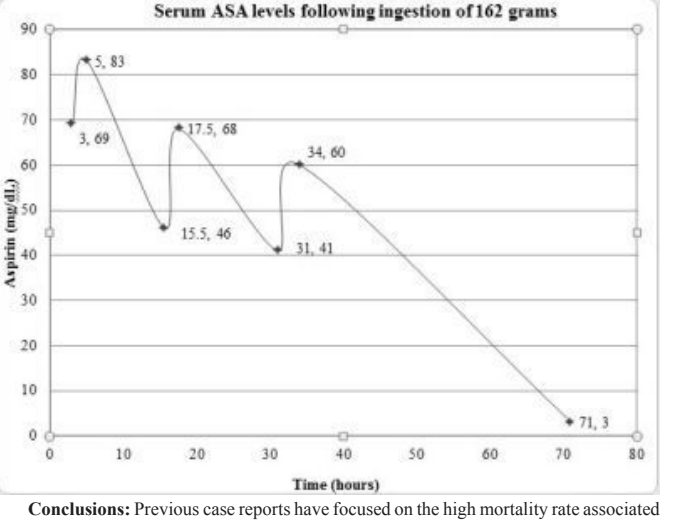
Conclusions: These preliminary results seem to show an advantage of RCA over heparin-based anticoagulation in terms of effective daily delivered RRT dose, which does not translate into a 28-day survival improvement.

PUB319

Survival of a Patient with Large Aspirin Ingestion Using Prolonged Hemodialysis and Continuous Renal Replacement Therapy Mansumeet Singh. *Nephrology, Creighton University, Omaha, NE.*

Background: Although aspirin poisonings are common, optimal management of this toxicological emergency is unclear given the variable pharmacokinetics of acetylsalicylic acid (ASA). We present a patient who survived a significant ASA ingestion (162 grams) after prolonged extracorporeal therapy.

Methods: A 56-year-old woman was transferred to our hospital 4.5 hours after ingesting 500 ASA pills (325 mg each). She was afebrile and hemodynamically stable (RR = 29, BP = 149/80 and HR = 107). Presenting symptoms included nausea, emesis, and tinnitus. 50mg of charcoal was administered. ASA levels were 69 mg/dL and 83 mg/dL at 3 hours and 5 hours post-ingestion, respectively. Given these toxic levels and the upward trend over time, hemodialysis (HD) was initiated. Although the ASA level trended down to 46 mg/dL during five and half hours of HD, a repeat measurement two hours after discontinuation was 68mg/dL. Accordingly, HD was resumed. During this 12-hour HD run, the ASA level trended down to 41 mg/dL. With cessation of HD, the level again rose to 60mg/dL within 3 hours. Given the refractory rebound in ASA levels, continuous renal replacement therapy (CRRT) was started and was continued for more than 36 hours until three consecutive ASA levels were below 3 mg/dL. This time, with the discontinuation of CRRT, the ASA levels remained below 3 mg/dL and the patient recovered without residual effects. In total it took ~18 hours of HD and ~36 hours of CRRT to remove ASA from her system.



Conclusions: Previous case reports have focused on the high mortality rate associated with large ASA ingestions despite the appropriate use of HD. Although unpredictable pharmacokinetics and the potential for rebound complicate the management of such patients, this case suggests that prolonged HD and/or CRRT might be a strategy for managing extremely large ASA poisonings.

PUB320

LVAD and Hemodialysis: Challenges of the New Millennium Imran F. Fatani, Dhiren Kumar. *Nephrology, VCUHS, Richmond, VA.*

Background: The number of patients with LVAD requiring Hemodialysis is rising. However, there is limited information regarding new set of challenges that arise with this patient population. This case series aims to outline our experience with 7 such patients.

Methods: This is a case series of 7 patients. A retrospective chart review was done of 7 patients requiring Hemodialysis after Heartmate II continuous flow LVAD placement. Challenges encountered with respect to Hemodynamic monitoring during dialysis, arrhythmias, infections and nutrition optimization were reviewed.

Results: Case series of 7 patients with Heartmate II LVAD requiring dialysis and their challenges including Hemodynamic monitoring protocol, infection management, nutrition, and arrhythmia management.

Conclusions: The patient population getting Ventricular Assist Devices is growing. LVAD's are more commonly being placed in older patients as destination devices and continue to be placed as bridge to heart transplant. These patients have many risk factors for chronic kidney disease or have pre-existing chronic kidney disease. They are at high risk for developing acute renal failure in the perisurgical period thereby requiring renal replacement therapy. We have done a chart review of 7 such patients at our institution. In this very high risk group of dialysis patients we have examined the challenges we have encountered specifically related to hemodynamic monitoring with dialysis, hypotension, arrhythmias, infections and nutritional optimization.

PUB321

Incidence of Central Venous Stenosis in Patients with Chronic Renal Failure after IJ Catheter Placement Mary S. Hammes, Amishi S. Desai, Brian Funaki, Annette Jean Herlitz. *Medicine, University of Chicago, Chicago, IL.*

Background: The arteriovenous fistula (AVF) is the preferred access for hemodialysis, with the successful creation dependent on presevation of veins. Previous damage to veins from B/P cuffs, phebolomy and peripherally inserted central venous catheters(PICC) limit sites for AVF creation. It is recommended that an alternative to a PICC line, a small bore internal jugular catheter (SBIJ) be used for short term access in patients with chronic renal failure (CRF) to preserve veins. The incidence of stenosis with SBIJ has not been studied. This investigation was performed to determine if complications including stenosis occur with SBIJ catheters.

Methods: Patients were enrolled by written consent if they had evidence of CRF stage 3 or greater (GFR<59 mL/min), end-stage renal disease or a history of renal transplantation and required short-term venous access with a central catheter. Subjects were screened for inclusion by daily review of the Procedure Service consult log by a Nephrologist. If patients agreed, they were scheduled for a SBIJ placement in Interventional Radiology. A venous Doppler was performed during insertion and removal of the SBIJ to evaluate for stenosis, thrombosis as well as the diameter of the IJ vein. Patient demographics and indication for SBIJ were recorded.

Results: 26 patients were enrolled and 28 SBIJ were placed, 2 patients had catheters placed on 2 separate occasions. Demographics included: 11 (42.3%) males and 14 (53.8%) African Americans, 8 (28.6%) had a solid organ transplant, 7 (25%) had stage 3 or greater CRF and 13 (46.4%) ESRD. Indications for catheter placement included: 13 (46.4%) immunosuppression, 11 (39.3%) antibiotics, 1 (3.6%) TPN and 3 (10.7%) a combination. A right SBIJ was placed in 23 (82.1%) subjects and a left in 5 (17.9%). The average number of catheter days was 16.7. The incidence of IJ thrombosis at time of line removal was evident in 1out of 26 subjects or 4%.

Conclusions: Placement of SBIJ catheters in patients with CRF for short term IV access is a safe procedure with a low risk of IJ thrombosis. Efforts to avoid PICC catheters should be made in this population as future permanent access may be required.

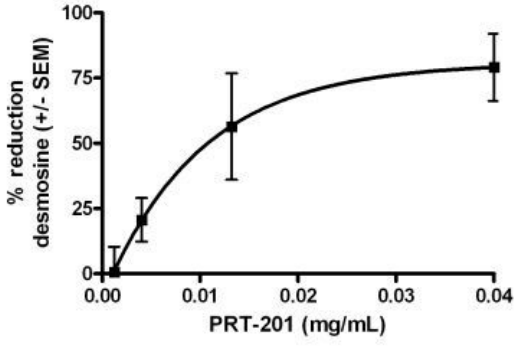
PUB322

Measurement of Elastin Content of Human Cephalic Vein Following Treatment with PRT-201, a Recombinant Human Type I Pancreatic Elastase Steven K. Burke,[1] Marco D. Wong,[1] Karen Macdonald,[2] Emma J. Moss,[2] Kimberly S. Bland,[1] Nicholas Franano.[1] *[1]Proteon Therapeutics, Inc., Waltham, MA; [2]Biopta Ltd., Glasgow, United Kingdom.*

Background: This study explored the effect of PRT-201 on elastin content of human cephalic veins obtained from recently deceased donors. The veins were studied in a perfusion myograph to simulate the pressure in the outflow vein of an arteriovenous fistula.

Methods: Veins were retrieved within 24 hours post-mortem, cut to 2.5 cm segments, and mounted on a myograph. Saline was perfused through the lumen of the segments at a transmural pressure of 25 and 50 mm Hg. PRT-201 0.0012, 0.004, 0.0132, and 0.04 mg/mL or saline was applied in a volume of 2.5 mL drop-wise over 10 minutes on the external surface of the vein followed by rinsing with saline. The vein segments were removed from the myograph and stored in saline for 3 hours at RT then at 4°C overnight before formalin fixation. Vein segments were cut into rings for desmosine (a protein cross-link unique to elastin) content by RIA, histology for the visualization of elastin fibers, and PRT-201 fluorescence. For fluorescence, PRT-201 was fluorescently labeled with Dylight 633 and dosed at a concentration of 0.012 mg/mL. Adventitial imaging was performed using laser scanning confocal microscopy at 633 nm.

Results: Figure 1 shows the percentage reduction in desmosine content by PRT-201 concentration.



Histology confirmed a concentration-related reduction in elastin fiber staining. Confocal miccroscopy demonstrated persistent localization of PRT-201 to elastin fibers following saline rinsing.

Conclusions: PRT-201 caused a concentration-related reduction in elastin content of human cephalic veins. PRT-201 remained bound to elastin in the vein after washing suggesting prolonged PRT-201 activity following a 10 minute-application.

PUB323

Uric Acid and Risk of Catheter Related Bacteremia in Hemodialysis Patients Pavan K. Annamaraju, Seyed-Ali Sadjadi, Navin Jaipaul. *Nephrology, VAMC, Loma Linda, CA.*

Background: In vitro studies demonstrate a paradoxical antioxidant effect of hyperuricemia in the extracellular milieu compared to its pro-oxidant effect in adipocytes. Similarly, previous clinical studies suggest hypouricemia impairs plasma antioxidant capacity in sepsis. It is biologically plausible, therefore, that uric acid (UA) level may modify the risk of catheter related bacteremia (CRB) in hemodialysis (HD) patients. We conducted a single center cohort study to determine if lower UA level may be independently associated with increased risk of HD CRB.

Methods: We identified by CPT code prevalent HD patients over a 2 year period who had tunneled catheter placed. Patients were followed for up to 1 year until they developed CRB or the end of the study period. CRB was determined by chart review and defined as ≥1 positive blood culture with the same organism, clinical signs of infection, and no alternative source for infection. Additional demographic and laboratory variables were collected and averaged over a 3 month period immediately preceding the CRB event. Patients with active malignancy, receiving chemotherapy, or missing UA levels were excluded. Ultimately, 51 patients were included in the final analysis performed using SPSS version 20.

Results: Refer to the table.

Comparison of Patients with and without CRB

Variable	No CRB (N=35)	CRB (N=16)	p-value
Age, years	61.4±12.6	59.0±10.7	0.49
Male sex, n	33	15	0.94
White race, n	23	10	0.26
Hypertension, n	35	16	-
Diabetes, n	28	11	0.38
Coronary artery disease (CAD), n	15	12	0.03*
Allopurinol use, n	2	2	0.40
Body mass index, kg/m²	27.3±5.7	27.5±6.8	0.95
Albumin, mg/dL	3.1±0.5	3.0±0.8	0.67
Calcium x Phosphorus, mg²/dL²	46.9±11.1	42.9±11.2	0.25
Ferritin, ng/mL	375.1±368.7	302.2±200.0	0.38
Uric acid (UA), mg/dL	6.7±1.3	5.8±0.8	0.004*

*p<0.05

The rate of CRB was 0.70/1000 catheter days. Each 1 mg/dL increase in UA level was associated with a 58% reduced risk of CRB (OR= 0.42; 95% CI 0.18-0.95), even after adjustment for CAD, catheter days, and dialysis vintage. Despite the small sample size, our study had 85.7% power to detect a 1 mg/dL difference in UA level between patients with and without CRB.

Conclusions: These findings suggest that lower UA level may be an independent risk factor for HD CRB.

PUB324

Tunnelled Hemodialysis Catheters: A Single Center Report on a Change in Access Delivery Jennifer Palfrey, Iain Moore, Debbie Sweeney, William Hinchliffe, Saeed Ahmed. *Department of Renal Medicine, City Hospitals Sunderland, Sunderland, United Kingdom.*

Background: Our renal unit has established experience of placing size 10 French independent hemodialysis catheters (Tesio®). Following promising data showing reduced infection & catheter dysfunction, we introduced use of a single split 14.5 French catheter with a spiral Z tip design (Palindrome™) for long term hemodialysis access.

Methods: We collected retrospective data from medical records and the renal database system for all patients who had undergone placement of Palindrome catheters from March 2010 until December 2011.

Results: Sixty-six lines were placed in 59 patients of whom 39% of patients had no long-term haemodialysis access prior to insertion of Palindrome. One line was placed into the femoral vein; all others were placed in the internal jugular vein (77% right-sided). No complications were experienced at the time of insertion. Seventy-two percent were placed using real time ultrasound guidance; the remainder also required fluoroscopic screening. We have of 7452 catheter days (excluding data from 5 patients who died with functioning lines insitu). Forty-four percent of lines remained in use at the end of the data collection period. Of the 32 lines removed, 50% were removed electively. Nineteen percent of lines were removed for infection. Catheter dysfunction accounted for 16% of line removals. In addition, 6% were removed for cuff slippage. Vascular compromise necessitated one line removal. Of the 5 patients with line dysfunction, 3 patients had another Palindrome line placed, 2 had a Tesio. Two patients lost central access requiring tunnelled femoral lines.

Conclusions: We have accrued significant experience in using Palindrome and Tesio catheters. We believe this to be the largest data set collected in a UK centre regarding Palindrome use. We have found them to be suitable for the majority of patients and note comparable data to previously reported. However, 28% of Palindrome lines required fluoroscopic assistance for placement, adding to access planning, resource availability and patient inconvenience. We continue using both types of tunnelled lines with individual vascular evaluation prior to selection of line type.

PUB325

Blood Access for an Armband Artificial Kidney through an In Situ DeBranched Vein Fistula Graft Arnold J. Lande'. *Lande' Device, LLC, Minneapolis, MN.*

Background: A wearable artificial kidney will benefit from durable blood access, likely on the forearm or arm, because that's where the blood is. Safety and small size of an Armband Artificial Kidney (AAK) could be furthered by tapping into A/V differential pressure, rather than utilizing a blood pump. Full anticoagulation of an ample 30 ml/min extracorporeal blood flow can be achieved while the patient remains safely merely prophylactically anticoagulated.

Methods: An elective In Situ DeBranched Vein Fistula Graft (VFG), with intermittent transdermal compressions, might serve the purpose. Review records of a common corrective procedure that results in the identical configuration, compulsory accessory vein obliteration by ligation or coil insertion. This procedure is familiar to nephrologists, vascular surgeons and radiologists because, in addition to balloon angioplasty, accessory vein obliteration is frequently employed to rescue a poorly maturing or failing hemodialysis fistula. All the arterial blood is directed through only one rapidly flowing draining vein. Longevity of the rescued vein may be considerably extended. An elective VFG for a wearable kidney is expected to benefit similarly. Intermittent moderated compressions over the VFG promise access to extracorporeal A --> V flowing blood for an AAK through small gauge cannulae inserted in a mature VFG.

Results: The literature is replete with records of excellent long term use of previously endangered fistulae, following accessory vein obliterations that rendered the fistula identical with a VFG. Also note satisfactory early use of pumpless arteriovenous CRRT. Number, length and diameter of hollow fibers, that reflect on resistance and efficiency, remain to be determined. Configuration of sorbent cartridge and means for powering dialysate flow through, remains to be determined.

Conclusions: The forearm or arm are likely locations for a wearable artificial kidney. Durable VFG access is promising for a FAK. The question of when to obliterate accessory veins remains open. Similar to current practice, one will likely observe a fistula for six weeks during maturation, before deciding on the best prospective VFG among the draining veins.

PUB326

A Single Centre Review of Procedures to Salvage Thrombosed Vascular Access between 2008 and 2012 Linda H. Bisset,[1] Richard O'Neill,[2] Greg Ramjas,[2] Jane Pikett,[1] Heather Ward,[1] Alastair J. Ferraro,[1] Charlotte Bebb.[1] *[1]Renal & Transplant Unit, Nottingham University Hospitals; [2]Department of Radiology, Nottingham University Hospitals, Nottingham, United Kingdom.*

Background: Our unit has a dialysis programme of approximately 400 pts, with <12% dialysing via tunnelled central venous catheters. Our vascular access surveillance programme using monthly measurements by Transonic© ultrasound dilution access flow monitoring, allows early detection of access problems and elective radiological intervention. Despite this, a small proportion of arterio-venous fistulae (AVF) and PTFE grafts (AVG) thrombose.

Methods: We retrospectively studied all vascular access thromboses between January 2008 and April 2012, interrogating our departmental databases and computerised hospital medical records to review outcomes of emergency intervention.

Results: 70 radiological interventions, on 51 AVF (39 brachial, 6 radial and 4 brachiobasilic) and 19 AVG were undertaken in 65 patients; mean age 59 years. The success rate was 84%. 90% underwent radiological thrombectomy with angioplasty; 10% required angioplasty alone. Four interventions occurred whilst patients awaited elective intervention. Five patients had stents inserted. Four patients subsequently underwent surgical intervention. During follow-up, 65% of access required re-intervention with 16% requiring a further emergency thrombectomy. Prior intervention had occurred in 54%. Only 29% had a recorded Transonic© flow rate <500ml/min pre-thrombosis. Pre-and post-access flow rates were available in 60% of cases; mean flow rate increased by 352mls/min. 91% were hospitalised due to their thrombosed access. Mean time from referral to procedure was <1 day (range 0-4). Their mean in-patient stay was 2.5 days. 83% of patients currently remain on the same vascular access.

Conclusions: Previous data from our unit reported that most radiological access intervention is performed electively. Nonetheless, a few of our patients' AVF and AVG clot requiring emergency intervention. Prompt radiological intervention results in an excellent success rate of >80%, minimising the need for central venous catheters and helping to maintain a high usage rate of native AVFs.

PUB327

Effects of Prolonged Ethanol Lock Exposure to Silicone- and Carbothane-Based Hemodialysis Catheters: A 26 Week Study Daniel L. Landry,[1,2] Harry Bermudez,[3] George Lipkowitz,[1,2] Stephen Sweet,[1,2] Gregory Lee Braden.[1,2] *[1]Renal Division, Baystate Medical Center, Springfield, MA; [2]Western New England Renal & Transplant Associates, Springfield, MA; [3]Polymer Science and Engineering, University of Massachusetts, Amherst, MA.*

Background: Antibiotic locks in catheter-dependent chronic hemodialysis patients reduce the rate of catheter-related blood stream infections (CRI), but may be associated with the development of resistant bacteria. Ethanol-based catheter locks may provide a safer alternative, however, there remains limited data on its effects on long-term catheter integrity.

Methods: We performed *in-vitro* testing of two common types of hemodialysis catheter – 9 silicone (SLC) and 9 carbothane (CBT)-based – with a 70% ethanol lock (EL) versus heparin lock (HL) for 26 weeks. Of the 9 catheters tested in each group, one catheter underwent baseline mechanical testing while 4 of the remaining 8 catheters were filled with either HL or EL. Lock solutions were changed thrice weekly to mimic a conventional hemodialysis schedule. We tested mechanical properties of the catheters at 13 and 26 weeks by examining stress at 400% strain and modulus of elasticity at both the upper and lower segments of each catheter. Scanning electron microscopy (SEM) was also performed to examine catheter ultrastructure at 26 weeks.

Results: There was no significant difference in stress/strain relationship or modulus of elasticity when comparing HL versus EL in SLC- or CBT-based catheters at 13 and 26 weeks. SEM examination revealed no gross evidence of damage to EL- versus HL-treated catheter surfaces at 26 weeks.

Conclusions: SLC- or CBT-based hemodialysis catheters exposed to a 70% EL for 26 weeks experienced no adverse effects on catheter integrity. Our data represents the first long-term *in-vitro* EL study to simultaneously examine different catheter polymers and catheter segments while also evaluating catheter ultrastructure using SEM. Given its low cost and potential to avoid antibiotic resistance, the EL appears to be a safe and promising option for the prevention of CRI in catheter-dependent hemodialysis patients.

PUB328

Vascular Access and Mortality: A Prospective Follow-Up Study in Two Danish Hemodialysis Centers Rie Io Glerup,[1] My Svensson,[2] Jens K. Madsen,[2] Henrik Carl Schønheyder,[3] Jeppe Hagstrup Christensen.[1] *[1]Department of Nephrology, Aarhus University Hospital, Aalborg, Denmark; [2]Department of Nephrology, Aarhus University Hospital, Aarhus, Denmark; [3]Department of Clinical Microbiologi, Aarhus University Hospital, Aalborg, Denmark.*

Background: Many hemodialysis (HD) patients are still dialyzed using tunneled catheters (TC) despite the use of TCs in these patients is controversial. The aim of the present study was to assess one year mortality in a well described HD population dialyzed on either TCs or arteriovenous fistulas (AVFs).

Methods: From December 2010 to March 2011 307 prevalent HD patients (HD vintage >3 months) from two major dialysis centers were enrolled. During a one year follow-up all-cause mortality was assessed. Patients were divided according to dialysis access, AVF or TC. Mortality rates were calculated using a Cox proportional hazards model, adjusting for age, HD vintage, and cardiovascular disease (CVD).

Results: 273 (89%) had an AVF and 34 (11%) had a TC. Baseline characteristics revealed that more TC patients had CVD, lower mean arterial pressure (MAP), and shorter HD vintage (Table). The crude one year mortality in the AVF group was 15% and 44% in the TC group. The adjusted hazard ratio (HR) comparing patients with TCs to those with AVF´s was 3.62 (95% CI 1.96; 6.71).

Baseline Information by vascular access

	Tunneled catheter (n=34)	AV fistula (n=273)	p
Age (years)	65.7 (±12)	65.1 (±15)	ns
Female sex (n)	16 (47.1)	91 (33.3)	ns
Hemodialysis vintage (months)	27.3 (±31)	52.6 (±53)	0.007
MAP (mmHg)	85.1 (±15)	94.3 (±16)	0.003
Diabetes (n)	12 (35.3)	71 (26.0)	ns
CVD (n)	23 (67.6)	130 (47.6)	0.03
Hemoglobin (g/dl)	11.3 (±1.1)	11.6 (±1.3)	ns
high sensitive C-reactive protein (mg/l)	12.4 (±14)	14.0 (±23)	ns
Procalcitonin (ng/ml)	0.46 (±0.3)	0.71 (±0.9)	ns
Albumin (g/dl)	3.8 (±0.5)	3.9 (±0.4)	ns
Fibrinogen (mg/dl)	490 (±123)	502 (±125)	ns

Values are given as means (±SD) or exact numbers (%)

Conclusions: We confirmed that the use of TCs in HD patients is associated with a high mortality risk. Bias may be a problem in the present design but mortality HR remained high after controlling for potential confounders. Thus, when possible AVF should be used in HD patients.

PUB329

Remote Resident Location Increases Likelihood of Catheter Usage in End Stage Renal Disease Lisa M. Miller,[1] Lavern M. Vercaigne,[2] Louise M. Moist,[3] Charmaine E. Lok,[4] Navdeep Tangri,[1] Paul Komenda,[1] Claudio Rigatto,[1] Julie Mojica,[5] Manish M. Sood.[1] *[1]Medicine, Section of Nephrology, University of Manitoba, Winnipeg, MB, Canada; [2]Pharmacy, University of Manitoba, Winnipeg, MB, Canada; [3]Medicine, Division of Nephrology, University of Western Ontario, London, ON, Canada; [4]Medicine, University of Toronto, Toronto, ON, Canada; [5]WRHA Critical Care/Medicine Information System & Research, University of Manitoba, Winnipeg, MB, Canada.*

Background: In Canada, a large proportion of ESRD patients reside in rural areas. We studied the association between resident location and incident vascular access for patients initiating dialysis between 2000-2009 using data from the Canadian Organ Replacement Registry.

Methods: Distance to nearest dialysis centre was calculated as the direct linear distance(km) between patient's primary residence postal code at dialysis initiation and closest dialysis centre, using Vincenty's formula and log transformed for analytic purposes. Multivariate logistic regression analysis was used to assess the association between distance (km) and initiating dialysis with a central venous catheter(CVC).

Results: In 25, 172 incident patients, 80% used a CVC and 20% used an arteriovenous fistula or graft. Patients residing remotely were more likely to initiate dialysis with a CVC (<5km 79.5%, 5-2km 78.6%, >20km 82.8%) and this effect persisted after adjustment for covariates (<5km OR referent, 5-20km OR 0.95 (CI 0.88-1.02, p NS), >20km OR 1.20 (CI 1.10-1.31, p<0.01)) A similar association was seen between distance and prevalent CVC use (>20km OR 1.25, (CI 1.16-1.35 p<0.01)). Duration of pre-dialysis care was a significant effect modifier (interaction p<0.01) as individuals with less pre-dialysis care (<1 yr) who resided remotely had significantly more CVCs than those who resided remotely but >1 yr pre-dialysis care (<1 yr care + reside >20km OR 1.24 (95% CI 1.03-1.48), 1-3 yr care + reside >20km OR 0.58(95%CI 0.49-0.68)). (OR referent <1 yr care + reside <5km).

Conclusions: Increasing distance from a dialysis provider is associated with initiation of dialysis with a CVC, independent of comorbidities and demographic factors. This effect is partially attenuated by longer pre-dialysis care.

PUB330

Prolonged Use of Tunnelled Femoral Arterial Catheter for Haemodialysis in a Patient with Central Venous Access Exhaution and Challenging Vascular Access Sourjya Kar, Paul Warwicker, Suresh Mathavakkannan. *Renal Medicine, Lister Hospital, Stevenage, United Kingdom.*

Background: Advances in practice have led to improved survival rates of our patients many of whom have undergone repeated central venous cannulation for prolonged periods of time. The consequence has been the emergence of central venous exhaution.

Objectives:

We are describing an elderly haemodialysis patient with central venous exhaution. When faced with a lack of viable access, a single tunnelled left femoral arterial teiso was inserted for emergency access. This was the arterial source for haemodialysis and the remaining right common illiac vein teiso was used for venous return to patient.This proved so successful that the arterial access was left in situ and no further access attempted.

Methods: The catheter insertion via the Seldinger technique was suprisingly well tolerated by the patient.The clinician had prior experience of arterial cannulation.

Results: The patient has been dialysing by this route for 2 years. The femoral arterial catheter was changed once (cuff loose) over a wire without complications.He had no infective complications. The average blood flows has been 170mls/min. He has been achieving dialysis adequacies (2 pool KT/V 1.42).

Conclusions: We described an unusual vascular access for a patient with central venous exhaution. The tunnelled arterial access, though being not the priority, can used for vascular access in selected patient population. The arterial line has been used for withdrawl of blood only and that has possibly kept the complication rate low.

Funding: Government Support - Non-U.S.

Galway Renal Access Study: Comparison of Thrombosis and Malfunction between Three Types of Permanent Hemodialysis Catheter Gerard M. Healy,[1] Wael F. Hussein,[1] Colm Pascal Keane,[1] Mark Curtin,[1] Sinead Clarke,[1] John Newell,[2] Alberto Alvarez-iglesias,[2] Louise Giblin,[1] David Lappin,[1] Donal N. Reddan.[1] *[1]Department of Nephrology, University College Hospital, Galway, Ireland; [2]HRB Clinical Research Facility, National University of Ireland, Galway, Ireland.*

Background: Tunnelled central venous catheters (TCVC) are used for dialysis patients awaiting formation of arteriovenous fistula (AVF) or those with failed AVF. They are often complicated by thrombosis and poor flow.

Methods: We reviewed flow malfunction in TCVCs inserted at a tertiary hospital from Jan 1st 2009 to July 30th 2011, with follow-up to Aug 31st 2011 or line removal. Kaplan Meier estimates of survivor function, log rank test and a Cox Proportional Hazards model were used to compare three TCVC types: Duraflow (DF) by Angiodynamics, Palindrome (PD) by Covidien and Jetflow (JF) by Jet Medical, while adjusting for patient characteristics. Outcomes were (1) total survival: days until line removal for flow malfunction and (2) tissue plasminogen activator (tPA) free survival: days until first tPA use or removal for flow malfunction.

Results: 92 patients had 145 TCVCs in situ for 34,318 days. TCVC type was unknown in 8 lines. 16%(N=23) of lines were PD, 31%(N=45) DF and 48%(N=69) JF. Except for hypertension (DF: 73%, PD: 43%, JF: 75%, p= 0.02), no difference was noted between groups regarding age, sex, anticoagulant use and comorbidities. Indications for TCVC insertion are listed in table1.

Indication for Insertion				
	DF (N=45)	PD (N=23)	JF (N=69)	P

21 lines (11.7%) were removed for malfunction. Mean total survival was 780 days (95% CI: 695-865). This was 470 (380-560), 521 (477-565) and 825 (728 – 922) for DF, PD and JF respectively (p = 0.09). tPA-free survival was 458 (365-551) days. Per line type, mean tPA-free survival was DF: 328 (237-420), PD: 292 (184-400), and JF: 509 (389-629) (p=0.23).

Conclusions: TCVC flow malfunction does not seem to be related to type of catheter. Further research is warranted. We will continue to monitor TCVC survival.

PUB332

Effect of Heparin and Aspirin on Vascular Access Patency Jerzy Glowinski,[1] Jolanta Malyszko,[2] Irena Glowinska,[2] Michal Mysliwiec.[2] *[1]Department of Vascular Surgery and Transplantation, Medical University, Bialystok, Poland; [2]Department of Nephrology and Transplantology, Medical University, Bialystok, Poland.*

Background: Native arteriovenous fistula remains the optimal vascular access for hemodialysis. Unfortunately, early failure occurs in nearly 50% of cases. The important role is played by thrombotic complications. The aim of the study was to assess the usefulness of low molecular weight heparin and aspirin in the prophylaxis of the early and late thrombosis of vascular access.

Methods: The number of 132 operations of vascular access for hemodialysis were performed on 120 consecutive patients. There were 110 native fistulas and 10 grafts, 9 basilic vein elevations and 3 ligations of accessory veins. The study group was composed of 60 patients with LMWH prescribed postoperatively as thrombosis prophylaxis, the control group was composed of 60 patients with no anticoagulative drugs. Additionally, we estimated an impact of aspirin on fistula patency. Twenty five of our patients took 75 mg of acetylosalicylic acid for cardiovascular indications.

Results: There were 3 postoperative bleedings in study group, and only one in control group. Reoperations were not required. One thrombosis of av fistula was noted in the study group, one av fistula and one graft were thrombosed in control group within 30 days. One year follow-up was completed by 102 patients. Four maturation failures required another anastomosis, 2 graft and 4 fistulas thrombosed within 12 months. Primary access 1year functional patency in study group was89.8% (44 from 49 pts), whereas 1year functional patency in non-heparin group was86.8% (46 from 53 pts). The study was completed by 21 patients on aspirin (of 25 enrolled), 1year patency rate was 85,7.

Conclusions: Heparin use in prophylaxis of thrombotic complications of vascular access in early postoperative period should not be recommended. Intake of aspirin does not show any advantage in one year observation period.

PUB333

Should Estimated Glomerular Filtration Rate Be the Sole Criterion to Refer Advanced Chronic Kidney Disease Patients for Pre-Emptive Arteriovenous Fistula? Neeraja Talakanti, Kavitha Potluri, David J. Leehey. *Dept of Renal and Hypertension, Edward Hines Jr. Veterans Hospital, Hines, IL.*

Background: Current KDOQI guidelines recommend referring patients for preparation for renal replacement therapy when estimated GFR is < 30 mL/min/1.73m^2, with arteriovenous fistula (AVF) placement at least 6 months before anticipated need for dialysis. However, the means of anticipating need for dialysis are not well delineated.

Methods: We did a retrospective chart review of CKD patients who underwent preemptive AVF placement during the period of 2004-2009 with a minimum follow-up of 2 years post AVF placement at Hines VA Hospital, IL. We evaluated eGFR at time of AVF placement and rate of eGFR decline over the 3-year period prior to AVF placement. Other data collected included age, cause of ESKD, proteinuria (by urine Pr/Cr), serum albumin, and average clinic blood pressure. We performed multivariate analysis to delineate the factors that best predict use of pre-emptive AVF within one year of placement.

Results: Of 138 CKD patients who underwent AVF placement, 11 died prior to dialysis, 7 had AKI and 3 had insufficient data. Of the 117 patients analyzed, mean eGFR at time of AVF placement was 17.4 ± 5.9 mL/min/1.73m^2, 96% had hypertension, 76% had urine Pr/Cr > 1 g/g, 74% had diabetes, 30% had CHF, and 28% had anemia requiring ESAs. 23 patients never required dialysis and 94 eventually required dialysis, 39 within 1 year of AVF placement and 55 after 1 year. Patients who required dialysis within 1 year of AVF placement had an eGFR of 14.5 ± 5 mL/min/1.73m^2 whereas those who did not require dialysis within 1 year had an eGFR of 20.5±5 mL/min/1.73m^2 (p=<0.001). Rate of decline of eGFR was somewhat higher in the group requiring dialysis than in the group who never required dialysis (mean/SD: 8.8 ± 7.4 vs. 7.4 ± 5.8 mL/min/1.73m^2/yr, p = 0.28). Multivariate analysis revealed that diabetic kidney disease, proteinuria >1 g/g, low serum albumin and eGFR of <15 mL/min/1.73m^2 at the time of AVF placement independently predicted need for dialysis within 1 year.

Conclusions: In most patients, eGFR of < 15 ml/min/1.73 m^2 can be used as sole criterion when considering pre-emptive AVF placement.

PUB335

Clinician Beliefs and Attitudes about Home Haemodialysis Allison Tong,[1,2] Suetonia Palmer,[3] Braden J. Manns,[4] Jonathan C. Craig,[1,2] Marinella Ruospo,[5] Letizia Gargano,[5] David W. Johnson,[6] Giovanni F.M. Strippoli.[1,5,7] *[1]Sydney School of Public Health, University of Sydney, Sydney, NSW, Australia; [2]Centre for Kidney Research, The Children's Hospital at Westmead, Sydney, NSW, Australia; [3]Department of Medicine, University of Otago, Christchurch, South Island, New Zealand; [4]Department of Medicine and Community Health Sciences, University of Calgary, Calgary, Canada; [5]Department of Clinical Pharmacology and Epidemiology, Mario Negri Sud Consortium, Bari, Italy; [6]Department of Nephrology, University of Queensland, Brisbane, QLD, Australia; [7]Diaverum Medical-Scientific Office Lund, Diaverum, Lund, Sweden.*

Background: Home hemodialysis (HD) is increasingly advocated as an alternative to in centre HD. This study aims to elicit clinician beliefs and attitudes about home HD.

Methods: Semi-structured interviews were conducted with nephrologists and nurses from dialysis centres within Diaverum AB.

Results: Forty-two clinicians from 15 centres in France, Italy, Portugal, Germany, Sweden and Argentina participated. Four themes were identified: external structural barriers (ready access to dialysis centres, inadequate housing conditions, unstable economic environment); centre capacity (availability of alternative treatments, competing priorities, commercial interests); clinician responsibility and motivation (preserving safety and security, lack of awareness, knowledge and experience, potential to offer lifestyle benefits, professional interest and advancement); and cultural apprehension (an unrelenting imposition, carer burden, attachment to professional healthcare provision, limited awareness).

Conclusions: Clinicians recognised the potential benefits of home HD, such as patient autonomy, but felt apprehensive and doubted its feasibility. Key barriers were commercial interests, financial disadvantage, concerns about patient safety and psychosocial burden, and lack of clinician awareness. Efforts are needed to promote home HD as an important option, improve knowledge about the patient benefits, establish home HD training programs, and to provide reassurance about patients' self-efficacy as demonstrated by international experience. Funding models that offer adequate reimbursement and may be warranted.

Funding: Pharmaceutical Company Support - Part-Funded by an Unrestricted Grant from Diaverum AB

PUB336

High Dose Quotidian Dialysis Is Associated with Improved Outcomes and Low Burnout

Jonathan Lorch,[1] Victor E. Pollak.[2] *[1]Medicine, The Rogosin Institute, New York, NY; [2]MIQS Inc., Boulder, CO.*

Background: KT/V is an imprecise, infrequently measured, surrogate for HD dose. We report on quotidian home HD in 77 patients prescribed a distinct high HD dose.

Methods: Any patient who initiated the first interview for eligibility was considered if they had the skill set adequate to learn the procedure and a home environment with suitable space, plumbing, and electrics. Patients were monitored remotely electronically and encouraged not to have a trained partner. To provide maximum HD for each patient treated with Fresenius machines, we prescribed 100L of blood to be processed 5-6 nights weekly over 6-8 hours, i.e. 500-600 L/week. NxStage patients were prescribed 30-60L of dialysate over 4-6 hours, 5-6 days or nights weekly, i.e., 300 L/week.

Results: Starting in 2001, 77 patients, average age 50.1 years, were followed to May 2012. Seven had 2 courses of home HD prior to and after failed transplants. In 65 treatment courses patients were monitored remotely and data including blood processed downloaded to the electronic medical record. These patients received 4.49 ± 0.86 treatments/week. Blood processed was 426.9 ± 109.5 L/week (6.35 ± 2.77 L/kg/week, and ~85% of prescribed). This was >2 fold greater than in 328 patients treated by in-center HD (2.84 L/kg/week). NxStage patients were dialyzed 3.83 ± 0.89 times weekly, ~76% of prescribed. Serum albumin was 41.6 ± 3.3 g/L. 11 patients died (mortality 5.46/100 years). 21 received a kidney transplant (10.4/100 years). 18 returned to in center HD. Medical necessity was the cause of return to in center HD in 12 (6/100 years), and patient preference, non-compliance, or non adherence in 6 (3/100 years).

Conclusions: High dose quotidian dialysis improves outcomes and is associated with low return to in-center HD by choice.

PUB337

The Benefits and Harms of Home versus In-Centre Haemodialysis: A Meta-Analysis

Suetonia Palmer,[1] Allison Tong,[2] Braden J. Manns,[3] Jonathan C. Craig,[2] Marinella Ruospo,[4] Letizia Gargano,[4] Giovanni F.M. Strippoli.[2,4] *[1]University of Otago; [2]University of Sydney; [3]University of Calgary; [4]Diaverum Bari.*

Background: Chronic kidney disease requiring dialysis is characterised by a heavy symptom burden, poor quality of life, and excessive risks of cardiovascular events and death. Uncontrolled data suggest dialysis conducted at home (home hemodialysis (HD)) offers improved survival, quality of life, and more flexible treatment schedules. However, data from observational studies are limited by confounding by selection; younger healthier patients are more likely to be offered home HD. Recent randomized trials of longer duration and increased frequency dialysis are suggesting improved survival and cardiovascular function. In this study, we aimed to summarize the available trial data for the effects of home versus in-center HD on mortality, quality of life, and symptom-burden in people with end-stage kidney disease.

Methods: We conducted a systematic review and meta-analysis of randomized controlled trials that included adults with chronic kidney disease and that compared in-center HD with home HD. We considered dialysis of any duration and frequency. Two reviewers systematically searched Cochrane and EMBASE databases to December 2011 without language restriction. We extracted details on participant characteristics, interventions, and risk of bias and summarized treatment effects on mortality, quality of life, and treatment durability (where possible) using random-effects model.

Results: A single randomized cross-over trial including 9 participants and comparing long home HD with short in-centre HD each for 8 weeks was identified by systematic searching. Quality of life was measured using the kidney disease quality of life instrument (KDQOL). Home HD resulted in fewer uremia-related symptoms and less physical suffering but interfered more with social activities and placed a greater treatment burden on families. No deaths or treatment withdrawals occurred.

Conclusions: Randomized trial data comparing home versus in-center HD are few and currently insufficient to guide clinical practice and policy. Given the potential benefits of home HD, a randomized trial is now needed.

PUB338

Extended Nocturnal Hemodialysis: Single Center Experience

Ana Rita Mateus Martins, Lucia Parreira, Ana Sofia Baptista Duque, Ilídio Rodrigues. *Barreiro, Nephrocare, Portugal.*

Background: Despite advances in dialysis, this therapy is still associated with high morbidity, mortality and costs.

Methods: The mortality, morbidity, hypertensive profile, bone mineral disease, anemia, efficacy of dialysis and nutrition were evaluated in 14 patients undergoing extended nocturnal hemodiafiltration (HDF) mean time 18,5 hours/week. Among this patients 5 were male, 1 had diabetes mellitus and 3 had cardiovascular disease. The mean age was 53,1 ± 10,3 years. At admission, average time on renal replacement therapy was 7,4 ± 4,7 years. The follow-up period was 13,6 ± 2,5 months. During the follow up one patient died and one received a kidney allograft. There were no intradialytic complications or failure of vascular access (13 with arteriovenous fistulas and 1 with graft).

Results: In all patients there was an improvement of dialysis efficiency (eKT/v 4,6 ± 6,1vs 0,7 ± 0,8 wk, p 0,000). Although hemoglobin levels (11,5 ± 0,8 vs 11,3 ± 0.7 g/dl, pns) remained unchanged, there was a significant reduction in erythropoiesis stimulating agent (ESA) consumption (121,1 vs 80,7 IU/kg/wk, p 0.000). Iron consumption (40.4 ± 25,3 vs 34,05 ± 37,9 mg/wk, pns) and ferritin values (434,2 ± 305,2 vs 392,9 ± 162,3 ng/ml, p 0,003) significantly decreased and nutritional parameters improved (nPCR 1,1 ± 0,1 vs 1,2 ± 0,7 g/kg/d, p 0,000). Serum calcium levels increased (8,2 ± 0,7 vs 8,9 ± 0,4 mg/dl, p 0.001) and there was a reduction in phosphatemia (4,8 to 4,5 mg/dl) allowing phosphate binder suspension in 4 patients and those reduction in 3; PTH values (688,2 ± 599,2 vs 560,9 ± 310,2 pg/ml, pns) were not affected. Both pulse pressure (67,6 ± 15,8 vs 63,5 ± 17,3 mmHg, p 0,035) and diastolic blood pressure (BP) (71,9 ± 7,3 vs 62,1 ± 13,6 mmHg, p 0,014) were significantly lower; antihypertensive medications consumption decreased (1,9 ± 1,4 vs 0,9 ± 0,8, p 0,008). Left ventricular (LV) mass, posterior wall and LV fractional shortening had a non significant reduction.

Conclusions: Therefore good patient adherence, improvement in dialysis efficacy, BP control, nutritional parameters, inflammatory markers, lower consumption of ESA, antihypertensive and phosphate binder medication were observed with this strategy.

PUB339

Real-World Diagnosis and Treatment Patterns of Iron Deficiency Anemia in Patients with Chronic Kidney Disease in China

Bao Liu,[1] Rong Hao,[2] Zhong Li,[3] Xiaoyu Nie,[4] Tang Mi,[1] Yue Gao,[3] Hongyu Yang,[1] Shanlian Hu.[1] *[1]School of Public Health, Fudan University, Shanghai, China; [2]Vifor Pharma Ltd., Glattbrugg, Switzerland; [3]Shanghai Centennial Scientific Co., Ltd, Shanghai, China; [4]Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MA.*

Background: In the past decade, our understanding of impact of iron deficiency anemia (IDA) on human health has advanced significantly. Iron supplementation may avoid, or at least delay, the need for erythropoiesis stimulating agents (ESA) in chronic kidney disease (CKD).

Methods: A comprehensive literature search and a survey with physicians were conducted to collect information on IDA diagnosis and treatment patterns in China. 163 publications were reviewed and 44 senior physicians specialized in nephrology, hematology and obstetrics/gynecology from national hospitals in Beijing, Shanghai, Guangzhou, Shenyang and Chengdu were interviewed. The questionnaire was also validated by information on lab tests and treatments collected from 91 patient cases.

Results: Hemoglobin (Hb), Red Blood Cell (RBC), and Iron Four (serum iron, ferritin, TSAT, and TIBC) are the top three (3) tests ordered by nephrologists. Review of patient cases confirmed this result.

Patient case lab tests review

Test	Observations (%); N=30	Mean	Median	P25	P75
Hemoglobin (g/dL)	29 (96.67)	8.78	9.30	7.60	10.30
Ferritin (ng/mL)	27 (90.00)	189.39	152.00	87.00	261.40
Serum Iron (umol/L)	16 (53.33)	9.91	10.14	7.95	12.50
Transferrin (g/L)	7 (23.33)	2.94	1.76	1.37	1.87
TSAT (%)	19 (63.33)	24.32	18.00	15.00	29.20
TIBC (umol/L)	6 (20.00)	50.03	50.46	40.70	59.30

TSAT = Transferrin Saturation; TIBC = Total Iron Binding Capacity

Nephrologists reported that they usually prescribe intravenous (IV) iron as the first line at a dose of 1000mg per course and targeted Hb levels of 12-13g/dL. Although price was not believed to be the most influential driver for using IV iron, 57% of those surveyed reported the restrictions of IV iron use due to cost.

Conclusions: Prevalence and disease burden of IDA in China is high, especially among CKD patients on dialysis. Appropriate diagnosis and treatment in clinical practice is important. National level guidelines need to be developed and strengthened in China.

PUB340

Superiority of Darbepoetin Alfa to Epoetin beta by Hepcidin Response
Shigeichi Shoji,[1] Masaaki Inaba,[2] Mitsuru Ichii,[2] Naoki Tsuboniwa,[1] Makoto Mitsuhashi,[1] Kenjirou Yamakawa,[1] Kyoko Norimine,[1] Senji Okuno,[1] Tomoyuki Yamakawa,[1] Eiji Ishimura,[3] Yoshiki Nishizawa.[2] *[1]Shirasagi Hospital, Osaka, Japan; [2]Department of Metabolism, Endocrinology, and Molecular Medicine, Osaka City University Graduate School of Medicine, Osaka, Japan; [3]Department of Nephrology, Osaka City University Graduate School of Medicine, Osaka, Japan.*

Background: Hepcidin is the key regulator of iron metabolism and is suppressed by erythropoietic activity (Pak M. et al. Blood 108:3735, 2006). The purpose was to evaluate the efficacy of erythropoiesis stimulating agents by hepcidin response.

Methods: Six hemodialysis patients with stable Hb levels by epoetin beta: EPO (3000 units x 3/week) were enrolled. After 4 weeks, EPO was switched to darbepoetin alfa: DPO (40 mcg weekly). No iron administration was done during the experiment. At each 0, 2nd, 4th, 7th and 28th days, serum Hb, Fe, TIBC, ferritin, Hepcidin-25 (by liquid chromatography tandem mass spectrometry), hs-CRP and IL-6 were measured.

Results: There was no significant change in Hb and ferritin in the EPO administration period. In the DPO period, Hb was increased (11.07±0.84 to 11.68±1.14 g/dL) and ferritin was decreased (105.7±61.8 to 52.5±36.9 ng/mL) significantly after 28 days. No significant change of hs-CRP and IL-6 was found in both period. Area under the percent change in serum hepcidin-time curve in DPO period was significantly greater than that in the EPO period (-348.0±92.4 *vs.* -178.4±131.5 %·day, $p = 0.030$).

Conclusions: Darbepoetin alfa seems to be superior to epoetin beta in erythropoietic activity by hepcidin response.

PUB341

NUTRIPEPA 2: A Prospective Randomized Interventional Study in Hemodialysed Patients with Protein-Energy Wasting
Bernard G.J. Hory. *Service de Nephrologie et de Medecine Interne, Centre Hospitalier, Ales, France.*

Background: Protein-energy wasting (PEW) results in an increase of cardiovascular mortality particularly in the case of Malnutrition Inflammation Syndrome (MIS). In a previous study (Nutripepa 1), we treated 13 cases of MIS for 12 months with PEPA membrane hemodialysis and nutrition intervention. Survival at 12 months was 92%; 66% of leptin was removed without removal of adiponectin. The aims of this study are to confirm our results, and to test the relationship between variation of adipocytokines concentration and mortality.

Methods: This multicenter, single-blind, prospective, randomized study, will compare the 12 month mortality of 2 groups of patients, the first treated with FDX membrane (poly Esther Arylate-PEPA) and the second treated with a non-adsorbing high permeability membrane ("control membrane"). All included patients must present signs of PEW, and will receive nutritional complements. They will be selected by french nephrologists (The Nutripepa Group). Patients and inclusion/exclusion criteria : 100 hemodialysed patients treated for at least 3 months on a non-adsorbing synthetic membrane with an equivalent area to PEPA (Polysulfone, Polyethersulfone, PolyArylethersulfone) will be included if serum albumin average will be less than 35 g /l and PINI score greater than or equal to 1. Exclusion criteria will be : insufficient vascular access, hepatopathy, amyloidosis, cancer, hemopathy, age less than 18y, pregnant women, allergy to PEPA. Methods: BMI, SGA score, albumin, Prognostic Inflamatory and Nutritional Index (PINI score) (Dessi et al), KT/V, nPCR will be determined at inclusion and at 3, 6, 9 and 12 months. Leptin, adiponectin and grhelin concentrations will measured at inclusion, and at 6 and 12 months. Agrements : The study received the agreements of Ethic's Committee of the CHU of Nimes and of the French Drug Agency (AFSSAPS).

Results: The mortality of the two groups will be compared. Correlations will be tested between mortality, BMI, albuminemia, PINI score and adipocytokines ratio.

Conclusions: At the present time, inclusion is in progress and 20 patients has been included. We observed 3 deaths on a 8 months follow-up confirming the high mortality of PEW.

PUB342

Understanding Diet Culture: The Impact of Dietitian Intervention upon Achieving Quality Patient Dialysis Outcomes in the Kingdom of Saudi Arabia
Ali Mohammed Allehbi,[1] Archie Dumdum Bunani.[2] *[1]Medicine - Nephrology, DaVita Lehbi Care - Saudi Arabia, Riyadh, Central Province, Saudi Arabia; [2]Clinical Services, DaVita Lehbi Care - Saudi Arabia, Riyadh, Central Province, Saudi Arabia.*

Background: Nutrition is an important aspect in hemodialysis care. Understanding how the culture of the Middle East influences an individual's diet, eating patterns and norms concerning food choices constantly presents a significant challenge in achieving improved dialysis outcomes. This study investigated the influence of dietitian intervention on mortality, adherence to dialysis prescriptions and Quality Patient Dialysis Outcomes (QPDO).

Methods: 284 hemodialysis patients were assessed using the Subjective Global Assessment tool (SGA) noting progress and regression.

Results: The results revealed SGA ratings of patients with A (86.26%), B (13.38%), and C (0.70%). These ratings were analyzed using cox regression with hazard ratio of 95% confidence interval. Patients who marked significantly as C in the Functional Capacity Items – *Dysfunction* (sp=1.45) showed highest risk to mortality, indicating that these individuals, despite dietitian Interventions had increased mortality related to other co-morbidities. Patients with changes on *eating habits* and had *ankle edema* during physical examination demonstrated a higher mortality risk (sp=1.40) at 3.44%. Results indicated that patients with a higher spKt/V (sp=1.58) than required (spKt/V >1.2) and with SGA rating of A were noted to have lowest risks to mortality and co-morbidities.

Conclusions: This study demonstrated the significant impact of dietitian intervention in reducing the mortality ratio of patients. The findings became the basis for self-made recipes designed for renal patients. Patients and families are invited to participate in cooking classes once every quarter enabling them to become self-reliant in selecting different foods and knowledgeable in identifying nutritional components on food labels.

Serum Soluble-Fas, Inflammation and Anemia in Acute Kidney Injury
Miguel A. Goes,[1,2] MArcelo Costa Batista,[2] Maria Dalboni,[2] Bento Santos,[1,2] Oscar Fernando Pavão dos Santos,[1,2] Ilson Iizuka,[1] Marcelino Durao,[1,2] Marcelo Batista,[1,2] Virgílio Pereira,[1,2] Julio Martin Monte,[1,2] Miguel Cendoroglo Neto.[1,2] *[1]Intensive Care Unit, Hospital Israelita Albert Einstein, Sao Paulo, SP, Brazil; [2]Nephrology Division, Federal University of Sao Paulo, Sao Paulo, SP, Brazil.*

Background: Anemia is common feature in critically ill patients. Serum soluble-Fas (sFas) levels are associated with anemia in chronic kidney disease. It is possible that sFas levels are also associated with anemia in acute kidney injury (AKI) patients. **Objective:** To investigate the relationship between serum levels of sFas, Epo, inflammatory cytokines and hemoglobin (Hgb) concentration in critically ill patients with AKI.

Methods: We studied 72 critically illpatients with AKI (AKI group; n= 53) or without AKI (non-AKI group; n=19), and 18 healthy volunteers. Serum sFas, Epo, TNF-a, IL-6, IL-10, iron status and Hgb concentration were analyzed in all groups. We also investigated the correlation between these variables in the AKI group.

Results: Critically ill patientshad higher serum levels of Epo. Hgb concentration was lower in the AKI group. Serum sFas, IL-6, TNF-a and ferritin levels were higher in the AKI group. Hgb concentration correlated negatively with serum IL-6 (r=-0.37, p=0.008), sFas (r=-0.35, p=0.01) and Epo (r=-0.27, p=0.04) while serum sFas correlated positively with iron levels (r=0.36, p=0.008) and IL-6 (r=0.28, p=0.04) in the AKI group. In multivariate analysis, after adjusting for markers of inflammation and iron store, only serum sFas levels (p=0.03) correlated negatively with Hgb concentration in the AKI group.

Conclusions: Serum Epo and inflammatory cytokines levels are elevated in critically ill patients with or without AKI. Serum levels of sFas are elevated and associated with anemia in critically ill patients with AKI.

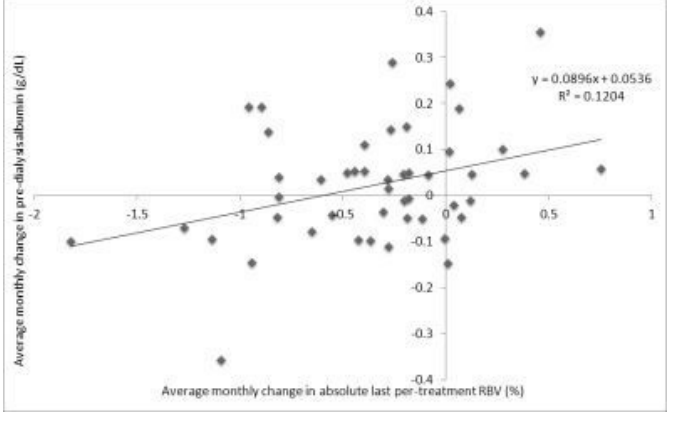
PUB344

Can Optimization of Intravascular Volume Improve Monitoring of Patient Parameters and Clinical Outcomes?
Nancy Ginsberg,[1] Patrice B. Taylor,[1,2] Lisa A. Pacelli,[1] Lynn Saunders,[1,2] Antoinette M. Ordish,[1,2] Len A. Usvyat,[1] Linda H. Ficociello,[3] Michael Black,[3] Claudy Mullon,[3] Jose A. Diaz-Buxo,[3] Mary T. Sullivan,[1] Peter Kotanko,[1] Paul Balter,[1] Paul M. Zabetakis.[1] *[1]Renal Research Institute, NY, NY; [2]University of North Carolina, Chapel Hill, NC; [3]FMC, Waltham, MA.*

Background: An on-going quality improvement (QI) project on fluid management using Crit-Line Blood Volume Monitors (CLM) has been running in 5 RRI clinics since May 2011. CLM measures changes in hematocrit, oxygen saturation and relative blood volume (RBV) during hemodialysis (HD). We aim to understand whether longitudinal changes in the amount of fluid removed during treatment are also associated with changes in serum albumin.

Methods: Data from 47 active hemodialysis (HD) patients at 5 RRI clinics that utilize Crit-line on a routine basis between May 1, 2011 and Apr 30, 2012 ("study period") were analyzed. Using simple linear regression, average monthly change per patient was computed for the following variables: absolute value of the last per-treatment RBV [RBV slope] and pre-dialysis serum albumin.

Results: The majority of patients were male (54%), black (61%), non-diabetic (62%), and had a mean age of 62.0 ±16.0 year. In a bivariate correlation, RBV slope was significantly and positively associated with changes in serum albumin (r=0.35, p<0.05).



Conclusions: This QI project implemented in the RRI clinics showed that higher reduction in blood volume as measured by Crit-Line during HD treatment was associated with increases in pre-dialysis serum albumin concentration. The analysis shows that for every 1% monthly change in RBV, 0.09 g/dL increase in pre-dialysis serum albumin may occur. These findings show the importance of considering intravascular volume parameters when establishing a prescription.

PUB345

Serum Albumin Dynamics in Incident HD Patients: Results of an International Study Rakesh Malhotra,[1] Adrian Marcos Guinsburg,[4] Aileen Grassmann,[3] Adam Tashman,[1] Cristina Marelli,[4] Eric Liu,[2] Frank van der Sande,[7] Inga Bayh,[3] Jeroen Kooman,[7] Laura Scatizzi,[3] Michael Etter,[2] Stephan Thijssen,[1] Edwin B. Toffelmire,[6] Yuedong Wang,[8] Len A. Usvyat,[1] Nathan W. Levin,[1] Franklin W. Maddux,[5] Peter Kotanko,[1] Daniele Marcelli.[3] *[1]Renal Research Institute, NY, NY; [2]Fresenius Asia Pacific Ltd, Hong Kong, Hong Kong; [3]Fresenius Medicare Care, Bad Homburg, Germany; [4]Fresenius Medical Care, Buenos Aires, Argentina; [5]Fresenius Medical Care, Waltham, MA; [6]Fresenius Medical Care Canada, Toronto, Canada; [7]Maastricht University Hospital, Maastricht, Netherlands; [8]University of California, Santa Barbara, CA.*

Background: Albumin is a powerful predictor of outcomes in HD patients (pts). We investigated longitudinal changes of albumin in incident HD pts in diverse worldwide population.

Methods: The MONitoring Dialysis Outcomes (MONDO) consortium consists of HD databases from RRI clinics (USA), FMC clinics in Europe, Asia, Latin America and Canada, Maastricht University (Netherlands) and KfH clinics (Germany). MONDO databases (other than KfH, Maastricht, and Canada) and FMC North America clinics were queried for albumin in incident HD pts who survived >24 months. Pts were stratified: Whites (Australia, Europe (17 countries), Argentina, US); Blacks (US); Chinese (Hong Kong, Taiwan, Singapore, US); and Korean (South Korea, US).

Results: 109281 HD pts from 23 countries were studied. Independent of race and region pts started HD with comparable albumin (mean bn 3.46 and 3.69 g/dL) followed by increase to 3.85 to 3.98 g/dL in the first 24 months after HD initiation.

Figure 1: Albumin levels in White and Black patients

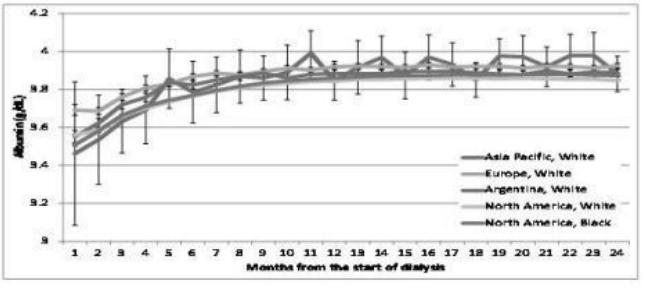


Figure 2: Albumin levels in Chinese and Korean patients

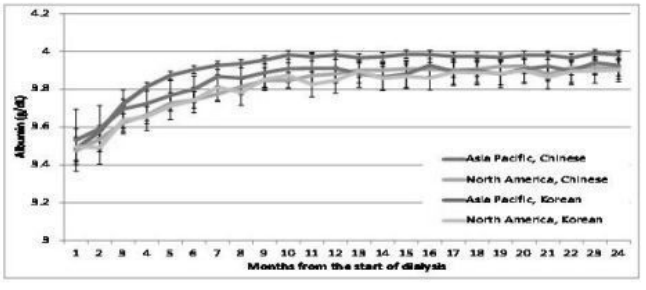

Conclusions: Our international study indicates comparable albumin at start of HD, independent of race and region. While practice patterns differ, pts experience remarkably similar increases in albumin by ~0.4 g/dL in the first 10 months after HD initiation.

PUB346

Cross-Sectional Study about Differences between Hemodialysis Schemes: Standard Intermittent Hemodialysis, Online Hemodiafiltration and Short Daily Dialysis in 57 Patients in HD Guillermina Barril, Fernando F. Hadad, Tania Monzon, Maria Bernardita Puchulu, Martin Giorgi, Jose A. Herrero, Jose-Antonio Sanchez-Tomero. *[1]Nephrology, Hospital U. de la Primcesa, Madrid, Spain; [2]Nephrology, Hospital U. de la Princesa, Madrid, Spain; [3]Nephrology, Hospital Clinico, Madrid, Spain.*

Background: There is evidence that high convective transport or most frequently hemodialysis (HD) can improve some parameters related to it. Objective: To compare demographic, vascular-access (VA), biochemical, blood pressure (BP), need erythropoietic agents(ESA), ESA resistance index and nutritional parameters in different HD schemes.

Methods: : We studied 57 patients from two HD units, with 45.4% men with a mean age of 72.07±11.96 years were 49.1% autologous-prothesis fistula (AVF) and the rest as permanent tunneled catheters (the percentage highest in HD standard). The HD schemes were: 21.1% in online hemodiafiltration (HDF), 28.1% in dailyHDHDD) and 50.9% standard hemodialysis(SHD). Parameters: Lymphocytes, albumin, prealbumin, creatinin, cholesterol, CRP, calcium, bicarbonate, ferritin, transferrin saturation inde (TSI), rate weekly urea reduction(PRU), systolic and diastolic pre HDBP.

Results: No significant differences in blood-flow between AVFvs catheter. Eight patients did not need ESA, two were from online HDF and six HDD. The online HDF showed higher significant difference vs SHD: creatinine (0.027), pre-HD systolic and diastolic BP (0.02), whereas bicarbonate was lower(0.09). By comparing HDE with HDD found significant differences for : systolic BP pre and post-HD (0.002), ESA units (0.006), calcium(0.041), ferritin (0.009) and CRP (0.007). While it was higher for HDD: lymphocytes(0.054), creatinine(0.010), albumin (0.019), prealbumin (0.012), cholesterol (0.018) and PRU(0.000) Significant difference was observed higher for online HDF in relation to HDD: ferritin(0.002), PRU(0.000), systolic BP(0.000) and diastoli(0.003) pre-HD.

Conclusions: The HDD demonstrated better biochemical, nutritional, urea kinetics, blood pressure control, and greater percentage of patients without AEE. The online HDF has advantages over the intermittent SHD. Is necessary to identify the pattern of HD tailored to the needs of patients.

PUB347

Relation between Depression and Anxiety and Daily Physical Activity in Maintenance Hemodialysis Patients Min Zhang,[1,2] Yinan Li,[2] Jun Chul Kim,[2,3] Bryan B. Shapiro,[2] Janos Porszasz,[2] Kamyar Kalantar-Zadeh,[2,4] Joel D. Kopple.[2,4] *[1]Div Nephrol, Tianjin Union Med Ctr, China; [2]Div Nephrol and Htn, LA BioMed Res Inst, Harbor-UCLA Med Ctr; [3]Div Nephrology, CHA Gumi Med Ctr, South Korea; [4]UCLA Schl Med & Pub Hlth, LA, CA.*

Background: Maintenance hemodialysis(MHD) patients have a high prevalence of depression and anxiety and also decreased degree of rehabilitation and daily physical activity(DPA). We examined whether there is a relationship between depression or anxiety and DPA in the MHD patients.

Methods: We measured DPA with the Actigraph GT3X+ Activity Monitor®, in 76 patients receiving MHD 3x/wk for ≥6 months and 40 healthy normals of similar age and gender. Subjects completed the Beck Depression Inventory(BDI), Beck Anxiety Inventory(BAI) and Hospital Anxiety and Depression Scale(HADS-D and HADS-A). Comparisons were adjusted for age and gender.

Results: Patients were 52±12SD years, 33% female, 40% diabetic; dialysis vintage was 55±45 months. Normals were 51±13 years and 40% female. Depression and anxiety by BDI and BAI were identified in 32% and 45% of patients, respectively. Compared to MHD patients, normals had a lower prevalence of depression(5%) and anxiety(2.5%) ($p<0.0001$for each comparison). The average daily vector magnitude for 7 consecutive days of DPA measurements was much lower in MHD patients vs Normals ($p<0.0001$). The average vector magnitude for DPA in MHD patients, measured over these last 7 days, was negatively correlated with the BDI depression score(r= -0.290,p=0.017). DPA on the day of hemodialysis(HD) was also correlated negatively with the degree of depression by BDI (p=0.033), and the DPA 2 days post-HD was correlated negatively with depression by BDI(r= -0.268,p=0.028) and the HADS-D(r= -0.254,p=0.038). DPA on the first day post-HD did not correlate significantly with BDI(p=0.054) or HADS-D(p=0.36) scores. There were no correlations between DPA and either BAI or HADS-A.

Conclusions: These findings indicate that in adult MHD patients the magnitude of depression, but not of anxiety, and DPA are strongly related. Our results confirm previous finding that the prevalence of depression and anxiety are greatly increased in MHD patients.

PUB348

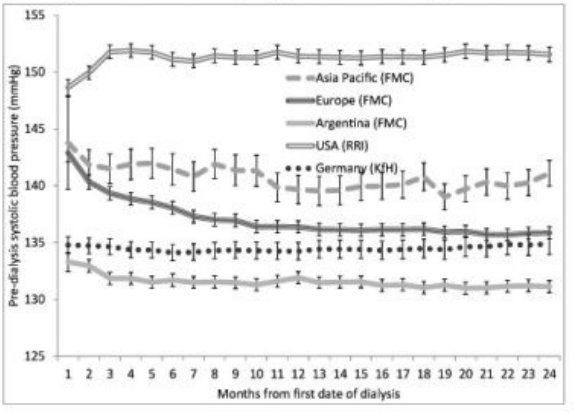
Pre-Dialysis Systolic Blood Pressure (SBP) and Erythropoietin Use: Results from an International Study Adrian Marcos Guinsburg,[4] Aileen Grassmann,[3] Adam Tashman,[1] Cristina Marelli,[4] Daniele Marcelli,[3] Eric Liu,[2] Frank van der Sande,[8] Gero D. von Gersdorff,[6] Inga Bayh,[3] Jeroen Kooman,[8] Laura Scatizzi,[3] Mathias Schaller,[6] Michael Etter,[2] Stephan Thijssen,[1] Edwin B. Toffelmire,[5] Yuedong Wang,[9] Len A. Usvyat,[1] Nathan W. Levin,[1] Peter Kotanko,[1] Claudia Barth.[7] *[1]Renal Research Institute, NY, NY; [2]Fresenius Asia Pacific Ltd, Hong Kong, Hong Kong; [3]Fresenius Medicare Care, Bad Homburg, Germany; [4]Fresenius Medical Care, Buenos Aires, Argentina; [5]Fresenius Medical Care Canada, Toronto, Canada; [6]Cologne University Medical Center, Cologne, Germany; [7]Kuratorium für Dialyse und Nierentransplantation e.V., Neu-Isenburg, Germany; [8]Maastricht University Hospital, Maastricht, Netherlands; [9]University of California, Santa Barbara, CA.*

Background: Given international differences in erythropoietin (EPO) use, we aimed to explore association bn EPO use and SBP patterns in diverse populations of HD pts.

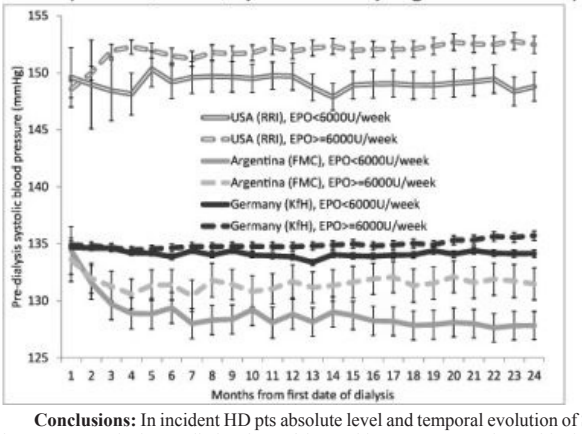
Methods: The MONitoring Dialysis Outcomes (MONDO) consortium consists of HD databases from RRI clinics (USA), FMC clinics in Europe, Asia, Latin America and Canada, Maastricht University (Netherlands) and KfH clinics (Germany). Other than Netherlands and Canada, these databases were queried for incident pts initiating HD bn 1/2000 and 12/2010 who survived >2yrs. In Germany, Argentina and US, pts were stratified based on weekly EPO dose (< or <=6,000U).

Results: We studied 1579 pts from Asia, 5503 from Europe, 25991 from Germany, 1813 from Argentina, 4296 from US. US pts start with highest SBP and experience SBP increase during first 4 mns. After stratification by EPO, SBP patterns were comparable in all databases studied.

Mean preSBP (95% CI) by region in incident patients



Mean preSBP (95% CI) by EPO dose by region in incident pts



Conclusions: In incident HD pts absolute level and temporal evolution of SBP differs between US and other studied regions of the world. SPB appears to be positively associated with EPO dose.

PUB349

Microcytosis Induced by a Larger Dose of Erythropoiesis-Stimulating Agents(ESA) without Iron Supplementation Is Improved Markedly by Oral Iron Administration in Hemodialysis Patients Shigeru Miyazaki,[1] Noriko Saito,[1] Masaaki Shimotori,[1] Kozo Ikarashi,[1] Tetsuo Morioka,[1] Hisaki Shimada,[1] Tadashi Yamamoto.[2] *[1]Shinraku-en Hosp., Niigata, Japan; [2]Inst. Nephrol., Niigata Univ., Japan.*

Background: Erythropoiesis-stimulating agents(ESA) have an ability not only to stimulate erythropoiesis, but also decrease serum level of hepcidin, which disturbs iron utilization for erythropoiesis, resulting in anemia improvement and also increase iron absorption through the proximal intestinal epithelium. Therefore, we examined the effects of administration of ESA with a large dose on the renal anemia and iron metabolism in hemodialysis patients.

Methods: ESA administration was increased from 5200±4300 U/week to 13000±7200U/week (Epoetin beta equivalent, p<0.001) in 30 hemodialysis patients with renal anemia. Complete blood count and iron metabolism marker was examined.

Results: Microcytosis(MVC(fl) 90.2±5.2 vs 81.4±5.0, p<0.0001) was observed 6 month after the high ESA dose administration in 20 out of 30 patients. This group of patients showed no improvement of anemia (Hb(g/dl) 9.6±0.9 vs 8.8±1.5, ns). Serum ferritin (ng/ml) decreased from 40.4±59.8 to 21.8±17.5(p<0.01). The other 10 patients without microcytosis showed the increase of Hb(9.1±1.2 vs 10.5±1.5, p<0.05) with decrease of MCV(95.5±4.6 vs 90.1±6.3, p<0.001), but these values were both in normal range. Serum ferritin decreased from 120.9±109.4 to 40.4±35.6(p<0.01). When 14 out of 20 patients of microcytosis were treated with oral iron supplementation (Fe 100mg/day), microcytic anemia was corrected promptly 3 months after the challenge (Hb 7.9±0.8 vs 11.3±1.9, p<0.0001). MCV was also improved from 78.9±3.8 to 88.1±4.8(p<0.0001). Serum ferritin was increased (16.0±8.4 vs 36.8±22.7, p<0.01), whereas TSAT (%) was unchanged.

Conclusions: Microcytosis induced by the increment of the ESA administration without adequate iron supplementation suggests that dietary iron is not sufficient for erythropoiesis in Japanese hemodialysis patients. In addition, oral iron supplementation dramatically ameliorated the microcytic anemia, suggesting that administration of ESA with a large dose improve the intestinal iron absorption even in hemodialysis patients.

PUB350

Effects of Omega-3 Fatty Acid Supplementation on Plasma Lipids in Hemodialysis Patients Denise Mafra,[1] Magali Monteath,[1] Najla Elias Farage.[2] *[1]Clinical Nutrition, Federal University Fluminense, Niteroi, Rio de Janeiro, Brazil; [2]RenalCor Clinic, Rio de Janeiro, Brazil.*

Background: Hemodialysis (HD) patients present changes in lipid profile and are at high risk for cardiovascular disease. Omega-3 fatty acids are known to have a cardio-protective effect and to reduce plasma triglycerides in subjects with normal renal function. The benefits of omega-3 for a wide range of general populations and a variety with health problems are apparent; however, the reports on the possible benefits for HD patients are still controversial. The aim of this study was to investigate the effect of omega-3 on plasma lipid levels in HD patients.

Methods: Thirty six HD patients from RenalCor Clinic in Rio de Janeiro, Brazil, were studied. Twenty one patients received 2400 mg of fish oil during four weeks (12M/9F; 53.7±12.4 yr, body mass index (BMI) 24.9±5.1Kg/m^2, average dialysis time 60 months) and fifteen patients did not receive supplementation (9M/6F, 46.5±16.6 yr, BMI 22.4±3.4Kg/m^2). The fasting plasma lipid levels were evaluated before and after the use of oil fish.The SPSS for Windows (version 11.0) was used as statistical program.

Results: Analysis of variance revealed no significant differences in age, dialysis time, waist circumference, body mass index and body fat between groups. Additionally, no pretest differences existed between groups for triglyceride, total cholesterol, LDL and HDL. No significant difference in plasma lipids was observed after fish oil supplementation (Table 1).

Plasma lipids levels before and after omega-3 fatty acids supplementation

Parameters	Omega-3 group		Control Group	
	Baseline	After 4 weeks	Baseline	After 4 weeks
Triglycerides (mg/dL)	107.1 (85.8)	107.7 (54.5)	98.8 (54.8)	110.1 (52.8)
Total cholesterol (mg/dL)	143.2 (31.6)	138.8 (38.6)	144.0 (38.2)	139.8 (31.3)
LDL (mg/dL)	101.1 (27.4)	101.4 (36.8)	104.1 (37.9)	101.3 (31.0)
HDL (mg/dL)	42.1 (9.9)	37.4 (8.9)	39.8 (11.8)	38.5 (8.5)

Conclusions: Our data seem to suggest that supplementation with of omega-3 capsules of fish oil content 2400mg during one month was not effective to improve the lipid profile in HD patients.

PUB351

Patterns and Predictors of Blood Transfusion among Hospitalized Hemodialysis Patients Ben C. Wong,[1] Pietro Ravani,[1] Braden J. Manns,[1] Xin Zhang,[1] Rick Chin,[1] Brenda Hemmelgarn,[1] Marcello Tonelli,[2] Matthew J. Oliver,[3] Robert R. Quinn.[1] *[1]University of Calgary, Calgary, AB, Canada; [2]University of Alberta, Edmonton, AB, Canada; [3]University of Toronto, Toronto, ON, Canada.*

Background: Hospitalized hemodialysis (HD) patients may be at increased risk of blood transfusion due to acute illness and relative erythropoietin resistance. The objective of this study was to quantify the risk of transfusion in the 90 days following hospital admission and identify predictors of transfusion risk.

Methods: Adult HD patients admitted to acute care hospitals between June 2004 and March 2008 in Calgary, Canada were identified. Administrative, lab, and blood transfusion records were used to identify baseline patient characteristics and outcomes of interest. Logistic regression was used to model the risk of transfusion in the 90 days following admission to hospital and to identify clinical predictors.

Results: A total of 559 patients experienced 884 hospital admissions. The risk of blood transfusion was 25% at 3 months, with the majority of transfusions occurring within 2 weeks of hospital admission. A lower baseline hemoglobin, a higher baseline transferrin saturation, and a history of peripheral vascular disease were independent predictors of transfusion risk. Age, sex, serum albumin, diabetes mellitus, a history of congestive heart failure, and a history of ischemic heart disease were not independently associated with the risk of transfusion. There was a statistically significant decrease in admission hemoglobin level and erythropoiesis stimulating agent (ESA) dosage over time, but the risk of transfusion remained constant.

Conclusions: Hospitalized HD patients were at a high risk of blood transfusion in the 90 days following admission, particularly those with lower baseline hemoglobin levels, higher baseline transferrin saturations, or a history of peripheral vascular disease. Future work will examine strategies aimed at reducing transfusion requirements in hospitalized HD patients.

PUB352

Relationship between Daily Physical Activity and Body Composition in Maintenance Hemodialysis Patients Yinan Li,[1,2] Min Zhang,[2] Janos Porszasz,[2] Kamyar Kalantar-Zadeh,[2] Joel D. Kopple.[2] *[1]Dept Nephrology, First Affiliated Hospital of Xiamen University, China; [2]Div Nephrology & Hypertension, Harbor-UCLA Medical Center, Los Angeles, CA.*

Background: MHD patients are considered to be physically less active than normal, but the factors affecting diminished physical activity are poorly understood. We assessed the relationship between DPA and body composition in MHD patients and healthy adults.

Methods: 76 clinically stable patients undergoing MHD 3x/week with vintage ≥6 months and 40 Normals were studied. Body composition measured the day after a HD, was assessed by Dual-Energy X-ray Absorptiometry(DEXA), DPA was measured with the Actigraph GT3X+ Activity Monitor®. The average daily vector magnitude for DPA was calculated as the square root of the sum of the squares of the three dimensional axes. All comparisons were adjusted for age and gender.

Results: Patients were 52±12years, 33% female, 40% diabetic; dialysis vintage was 55±45 mos. Normals were 51±13years, 40% female. DPA, averaged for 7 consecutive days, was much lower in MHD patients, 394,032 counts, vs 648,980 counts in Normals, p<0.0001. Body weight and body mass index were 78.8±21.0 kg and 27.8±5.7 kg/m^2 in MHD patients and 75.0±14.4 kg and 26.9±3.9 kg/m^2 in Normals. Average daily DPA and BMI were not different in diabetic vs non-diabetic patients. In MHD patients, DPA was negatively correlated with body weight (r = -0.31, p<0.05)[Fig.1] and body mass index (r= -0.34, p<0.01)[Fig.2]. No other measures of body composition were significantly associated with DPA in MHD patients. In Normals, there were no associations between DPA and body composition.

Conclusions: DPA is markedly reduced in MHD patients compared to normal controls. In MHD patients, DPA was negatively correlated with body weight and body mass index. This may reflect the likelihood that more obese MHD patients are physically less active.

C-Reactive Protein (CRP) and Serum Albumin Levels Are Significant Determinants of Death in Cases of Hemodialysis-Associated Sepsis Hitoshi Iwabuchi, Manabu Asano, Kenichi Oguchi. *Renal Unit, Ikegami General Hospital, Tokyo, Japan.*

Background: Infection remains the second major cause of death in patients undergoing dialysis in Japan. Therefore, strategies for combating sepsis are extremely important in these patients. We investigated cases of sepsis that developed in patients receiving maintenance hemodialysis in our facility and examined the bacteriological etiology and prognosis-related factors.

Methods: A case-control study of 288 patients receiving maintenance hemodialysis between 2001 and 2011 was carried out. All the patients experienced a fever of 38°C or higher and underwent blood culture because of suspicions about sepsis. The primary outcome measure was death, while prognosis-related factors included age, gender, dialysis record, diabetes, catheter placement, CRP, leukocyte count, blood platelet count, albumin value, and methicillin-resistant *Staphylococcus aureus* (MRSA).

Results: Of the 691 blood cultures performed, 19.8% were positive. Twenty-one bacterial species and 143 bacterial strains were identified respectively. Gram-positive cocci accounted for 75.5% of all. Especially Staphylococci accounted for 84.3% of the gram-positive cocci, while MRSA and methicillin-resistant coagulase-negative staphylococci (MRCNS) accounted for 70% of the entire staphylococcus population.

Ninety-one patients (50 men and 41 women) were clinically diagnosed with sepsis. Diabetic complications existed in 60 patients, while 56 patients had an indwelling catheter. Concomitant infections included 21 cases of catheter infection, 12 cases of urinary-tract infection and 9 cases of respiratory infection. Overall, 57 patients died, and approximately 50% of these patients had resistant staphylococci. Multivariate analysis showed that the levels of CRP [Odds ratio (OR) 0.0224, 95% confidence interval (CI) 1.008-1.113] and albumin [OR 0.0016, CI 0.054-0.507] concentrations are associated with an increased risk of mortality.

Conclusions: Managing potential risk factors such as the presence of an indwelling catheter and the evidence of malnutrition should take priority over all else. CRP and albumin values are the most important prognostic factors of hemodialysis-associated sepsis.

PUB354

Clinical Analysis of Malignant Tumors Surgery on Maintenance Hemodialysis Patients Xiaonong Chen, Xiaobo Ma, Tian Xu, Ping Zhu, Ying Qian, Nan Chen. *Ruijin Hospital, Shanghai Jiao Tong University.*

Background: To analyze the clinical characteristics and prognosis of ESRD patients on maintenance hemodialysis undergoing surgery of malignant tumors and to explore peri-operative risk and method of blood purification.

Methods: Patients on maintenance hemodialysis with a history of surgery of malignant tumors were enrolled from Jan. 2006 to Dec. 2011 in center of blood purification in our Hospital and clinical characteristics were collected.

Results: 22 patients on maintenance hemodialysis underwent an operation of malignant tumors during the study period including radical surgery for renal cell carcinoma, bladder cancer, intestinal cancer, breast cancer etc. There were 11 males and 11 females with an average age of 57.18±14.34(30~86) and an average dialysis age of 5.14±3.98(1~15). Types of the malignant tumors consisted of 9 urological tumors (6 cases of bladder cancer, 2 cases of renal carcinoma, 1 case of renal pelvic carcinoma), 6 digestive tumors (3 cases of colonic cancer, 1 rectal cancer, 1 gastric cancer, 1 gallbladder cancer), 6 breast cancer and 1 ovarian cancer. Before surgery, cardiopulmonary function, risk of anesthesia and other routines should be evaluated and serum hemoglobin level should be maintained above 100g/l and serum albumin level above 30g/l. Hemodialysis without heparin should be done one day before surgery, the day of surgery and 24 hours after surgery. The type and dose of anticoagulant can be regulated according to general status of patients. 5 cases (22.73%) were admitted to surgical ICU and underwent continuous renal replacement therapy (CRRT) comprising of CVVH, CVVHD, CVVHDF with an average case-time of 7.4±5.94 and a median dialysis duration of 6~12 hours. 2 patients died during hospitalization in department of surgery and hospitalized mortality rate was 9.09%.

Conclusions: The prevalence of malignant tumors was high in ESRD patients on maintenance hemodialysis and urological, digestive and breast cancer were predominant. Patients on hemodialysis with malignant tumors were eligible to undergo operation and survived in long-term follow-up. ESRD should not be regarded as a contraindication of surgery.

PUB355

Thrombotic Complications in ESRD Patients and Their Relevance to Biomarkers of Inflammation and Thrombogenesis Vinod K. Bansal,[2] Indermohan Thethi,[1] Debra Hoppensteadt,[1] Joesphine Cunanan,[1] Kristiyana Kaneva,[1] Rakesh Wahi,[1] Jawed Fareed.[1] [1]*Pathology, Loyola University Medical Center, Maywood, IL;* [2]*Nephrology, Loyola University Medical Center, Maywood, IL.*

Background: ESRD (End Stage Renal Disease) is kidney failure in the presence of low GFR and occurrence of signs and symptoms of kidney failure necessitating initiation of treatment by replacement therapy such as hemodialysis or transplant. ESRD has been associated with higher cardiovascular mortality including acute coronary syndrome and studies have shown that there may be an increase in inflammation and thrombosis markers in this patient population. In this study, we investigated the levels of biomarkers of inflammation and thrombosis and correlated these with clinical endpoints of acute thrombotic complications (arterial or venous) during a 14 month prospective follow up in ESRD patient population.

Methods: Blood samples were collected from 55 ESRD patients on maintenance hemodialysis and healthy volunteers were analyzed for markers of thrombosis and inflammation – d-Dimer, Thrombomodulin, C-reactive protein (CRP), Neutrophil Gelatinase-Associated Lipocalin (NGAL), Tumor Necrosis Factor Receptor 1 (TNFRI) and Neuron Specific Enolase (NSE). The levels were measured using biochip array technology with the Randox Evidence System (United Kingdom). Clinical endpoints were determined from chart review at the end of 14 months from the day of blood draw.

Results: 12 patients or 21.81 % of ESRD patient population suffered from acute thrombotic events during the 14 month follow up. Biomarkers levels were elevated for all biomarkers ranging from 48.8% - 667.5% in ESRD patients in comparison to healthy volunteers.

Conclusions: A high incidence of acute thrombosis was observed in the ESRD patient population which correlates with the high levels of markers of thrombosis and inflammation, particularly D-dimer and TNFRI, seen in these patients. This simultaneous activation of thrombotic and inflammatory pathways is evident in these patients.

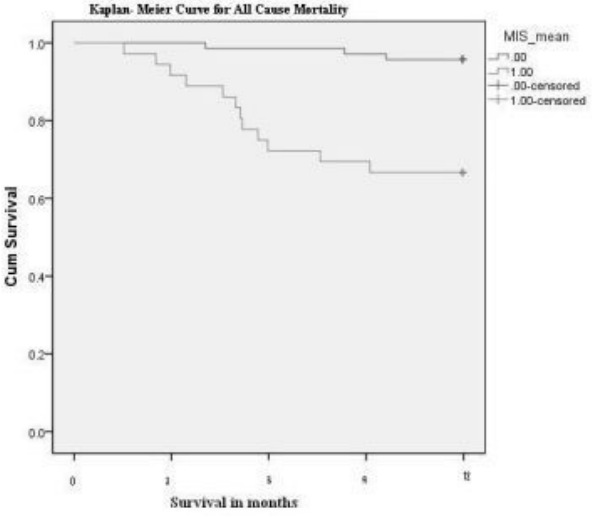
PUB356

Association of Malnutrition-Inflammation Score with Mortality in Haemodialysis Patients: 12months Prospective Study Christopher T. Agbo,[1] Sumith C. Abeygunasekara,[2] Abdelgalil Abdelrahman Ali.[3] *[1]Dept of Renal Medicine, Broomfield Hospital NHS, Chelmsford, Essex, United Kingdom; [2]Dept of Renal Medicine, Broomfield Hospital NHS, Chelmsford, Essex, United Kingdom; [3]Dept of Renal Medicine, Broomfield Hospital NHS, Chelmsford, Essex, United Kingdom.*

Background: There is increasing mortality risk associated with malnutrition and inflammation in haemodialysis patients. Malnutrition-Inflammation Score (MIS) is a comprehensive tool recently validated to assess malnutrition and inflammation in maintenance haemodialysis (MHD) patients. The aim of the study was to establish the association between MIS and mortality in MHD patients.

Methods: A total of 110 patients on MHD for at least 3 months from an East of England District Hospital were enrolled for this study,four patients dropped out. The MIS and variables such as C reactive protein(CRP) of each patient was recorded at the start of the study by two trained physicians,patients were follow up for 12 months and the primary outcome was mortality.

Results: Sixteen patients (15.1%) died during the study period, both logistic regression and Cox proportional hazard analyses showed MIS, CRP, Age and Haemoglobin as predictors of mortality. However, it was only the MIS and Age that had a strong association with mortality; p values 0.0001 and 0.002 respectively.



Cox Regression -Prediction of Short Term Survival

	B	SE	Wald	Sig	Exp(B)
Age(years)	0.120	0.039	9.642	0.002	1.128
MIS	0.374	0.101	13.750	0.000	1.454
Haemoglobin(g/l)	-0.655	0.366	3.205	0.073	0.519
Creatinine(umol/l)	-0.001	0.002	0.402	0.526	0.999
CRP(mg/l)	0.003	0.008	0.165	0.684	1.003
Weight(kg)	-0.026	0.021	1.563	0.211	0.975

Table 1

Conclusions: MIS has a strong association with mortality in maintenance haemodialysis patients and appears to be more superior to CRP. However, there was a significant correlation between MIS and CRP.MIS will be a useful tool in risk stratification of MHD patients in order to improve outcome.

Funding: Government Support - Non-U.S.

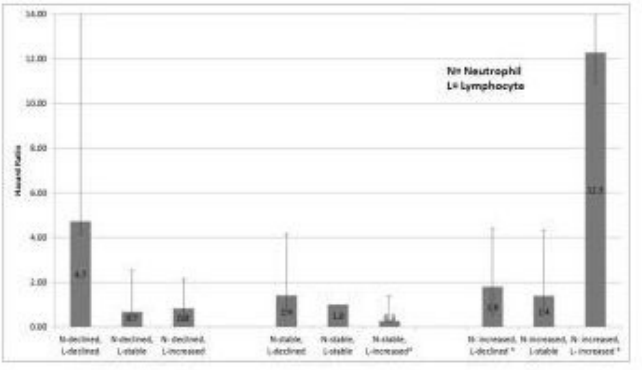
PUB357

Relationship between Trends in Neutrophil and Lymphocyte Counts and Mortality in Incident Hemodialysis Patients Rakesh Malhotra,[1] Len A. Usvyat,[2] Jochen G. Raimann,[2] Stephan Thijssen,[2] Nathan W. Levin,[2] Peter Kotanko.[2] *[1]UMDNJ-Newark; [2]Renal Research Institute.*

Background: The prognostic value of trends (increase or decrease) of neutrophil and lymphocyte counts is unclear. We analyzed the relationship of changes in neutrophils and lymphocytes and mortality in HD patients.

Methods: Incident HD patients treated in RRI clinics between 1/2000 & 12/2010 who survived atleast 12 months were included. Slopes of neutrophil & of lymphocyte counts were computed using linear regression of all available values between months 4 & 12 from the start of HD. Patients were stratified in 9 groups based on:(a)average rate of change in neutrophil % (declined:<-7%points/yr; stable:-7 to 7%points/yr; increased:>7points/yr) & (b)average rate of change in lymphocyte % (declined:<-5.5% points/yr; stable:-5.5 to 5.5%points/yr; increased:>5.5points/yr). Survival was analyzed in months 13 to 18 following HD initiation using a Cox model adjusted for age, gender, race, diabetes, access, BMI, SBP, body temp, nPCR, eKt/V, IDWG, UDV, & slope of neutrophil & lymphocyte counts.

Results: 2809 patients were studied (median(IQR) age at start of dialysis was 63(52-73) yrs, 55% male,& 46% Blacks). The Cox model showed that simultaneous increases in neutrophils & lymphocytes (HR=12.3;P=0.03) or decrease of neutrophils & lymphocytes (HR=4.7;P=0.14) were associated with increased mortality risk vs. reference group (stable neutrophils & lymphocytes). Decline in lymphocytes & increase in neutrophils increased death risk (HR=1.8;P=0.003) whereas increased lymphocytes with stable neutrophils exerted a protective effect on survival (HR=0.3;P=0.07).



Conclusions: Our result indicate survival advantage for patients with stable neutrophil and lymphocyte counts. Further studies are required to understand the roles of neutrophil and lymphocyte counts, their temporal trends and the prognostic significance of these trends.

PUB358

Effect of Shifting from Epoetin α to M-PEG Epoetin β on Hb Levels: A Single Dialysis Center Experience Massimo Torreggiani, Fabrizio Grosjean, Giovanni Montagna, Luca Semeraro, Loredana Picardi, Emanuela Efficace, Vittoria Esposito, Valter Piazza, Gabriella Adamo, Giuseppe Villa, Davide Catucci, Edoardo La Porta, Ciro Esposito. *Nephrology, Fondazione IRCCS S. Maugeri, Pavia, Italy.*

Background: Hemoglobin (Hb) target in hemodialysis patients is still not clear. Often, despite ESA therapy, oscillations of Hb levels are wide. In this study we aimed to evaluate the efficacy of a short-acting erythropoietin (EPO) and a continuous erythropoietin receptor activator (CERA) in a dialysis patient population treated consecutively with the two ESAs for one year.

Methods: We conducted a retrospective study on 10 prevalent patients in a single dialysis center. Inclusion criteria: age>18 years, on hemodialysis from at least two years, treatment with the same ESA for one year. Exclusion criteria: neoplasms, blood transfusions and major infectious episodes during the observation period.

Results: All 10 patients were treated with EPOα for the entire 2010 and then with CERA for 2011. The mean age of patients was 71.4±12.1 years (♂ 80%), 80% on bicarbonate dialysis and 20% on AFB. The average dose of ESA was 8035±4213 UI/week for EPOα and 136.2±72.8 μg/month for CERA. Mean Hb levels were higher during EPOα treatment (11.6±0.9 vs. 10.6±0.8 g/dl, p<0.01) than CERA. Percentage of Hb values≥12.5 or ≤10.5 g/dl was similar between the two treatments.

However, EPOα treatment was associated with a greater number of episodes of Hb≥12.5 g/dl (p<0.01), and a fewer number of episodes of Hb≤10.5 g/dl (p<0.01) than CERA. Iron asset, inflammatory state and dialysis dose were similar during the two treatments. EPOα use was associated with a saving of 84 €/month/patient compared to CERA (p<0.05).

Conclusions: CERA and EPOα have a similar efficacy in maintaining stable Hb values. Hb values were lower during CERA treatment but still in the range suggested by the FDA and the TREAT study. However, CERA treatment was more expensive.

PUB359

Both Darbepoetin α and Epoetin β Potentiate Equivalent Effect on Maintaining Hemoglobin Level after Rapid Correction with Blood Transfusion in Hemodialysis Patients Kenji Harada, Hidetoshi Kanai. *Division of Nephrology, Kokura Memorial Hospital, Kitakyusyu, Fukuoka, Japan.*

Background: Majority hemodialysis (HD) patients are administered erythropoiesis stimulating agent (ESA). They often need to be transfused of packed red blood cell (PRBC), on worsening of anemia control, such as bleeding (intestinal bleeding, surgical operation), inflammation, malnutrition. In general initial rise of hemoglobin (Hb) levels tends to higher for epoetin β than darbepoetin α. There are few reports to evaluate the rate of change of Hb levels after transfusion of PRBC and to compare the of ESAs on recovery from anemia.

Methods: We investigated the rate of change of Hb levels in HD patients after transfusion of PRBC(n=54, age 72 year old, male/female=40/16, HD duration 5.9±25years, average transfusion of PRBC 4.05U(1U=140ml), darbepoetin α1.027μg/kg/week; 160 USD, epoetin β149 IU/kg/week; 96 USD). We compared Hb levels before and 4 weeks after transfusion of PRBC, and economical performance of ESAs.

Results: Fifty-four HD patients were subjected. 35 patients were administered of darbepoetin α, 19 patients were administered of epoetin β. Before transfusion of PRBC, in darbepoetin α group average of Hb levels was 7.51(4.4-9.9), meanwhile in epoetin β group was 7.28(5.8-8.5). After four weeks later, darbepoetin α group average of Hb levels was 9.73(7.6-11.3), meanwhile in epoetin β group was 9.53(5.8-8.5). Average rate of change

of Hb levels in darbepoetin α and in epoetin β were 1.92 and 2.38 g/dl, respectively. There was no significant difference (p=0.401).

Conclusions: In short terms, darbepoetinαcan be equivalent to epoetin β for recovery from anemia. Administration of darbepoetin αafter transfusion of PRBC can be effective on correction of anemia, however, epoetin α is 39.9% inexpensive of darbepoetin α to achieve simillary effect. It is necessary to follow longer term the change of Hb levels.

PUB360

Birthweight and Cortisol Levels in Dialysed Patients

Katarzyna Szamotulska,[1] Stanislaw Niemczyk,[2] Joanna Matuszkiewicz-Rowinska,[3] Dorota Szostak-wegierek,[4] Kinga Giers,[2] Katarzyna Romejko-ciepielewska.[2] *[1]Dept. of Epidemiology, National Research Institute of Mother and Child, Warsaw, Poland; [2]Dept. of Nephrology, Military Institute of Medicine, Warsaw, Poland; [3]Dept. of Nephrology and Internal Diseases, Medical University of Warsaw, Warsaw, Poland; [4]Dept. of Preventive Medicine and Hygiene, Medical University of Warsaw, Warsaw, Poland.*

Background: Increase of cortisol levels in chronic kidney disease (CKD) patients is well established. There is also a growing body of evidence that fetal growth restriction is a risk factor for impaired renal function, and that adults born as growth restricted experience elevated cortisol levels.

The aim of the study was to explore cortisol levels in CKD patients in the context of their birthweight.

Methods: An interview regarding early life experience and family history was conducted with 26 hemodialysed (HD) patients and 43 controls with available fasting blood samples. Nineteen HD patients (56 +/- 12 years old, 12 men) and 27 controls (59+/-10 years old, 11 men), were able to give information on birthweight.

Birthweight was expressed in ranks, from <1 kg (rank 1) to >5 kg (rank 11). Three preterm births were excluded. Exact Mann-Whitney test, exact test for Spearman correlation coefficient and multivariate linear regression were applied.

Results: A validity of information on birthweight (BW) was confirmed by the expected associations of mean BW ranks with gender (F vs. M: 6.77 and 7.14), parity (0 vs. 1+: 6.75 and 7.07) and maternal smoking during pregnancy (yes vs.no: 6.50 and 7.00).

Average cortisol levels (mean+/-SD) amounted to 19.6+/-4.5 µg/dL in the HD group and 16.0+/-5.5 µg/dL in controls (p=0.025) and average rank of BW (mean+/-SD) was 7.11+/-1.13 and 6.84+/-0.99 (p=NS), respectively. There was a negative correlation between cortisol concentration and birth weight in the HD group (r=-0.388, p=NS) and in the control group (r=-0.381, p=NS). Multivariate model adjusted for gender revealed significant association of cortisol concentration with chronic kidney disease (beta=3.7, p=0.023) and lower birthweight (beta=-1.6, p=0.031).

Conclusions: Lower birthweight is an independent risk factor for increased cortisol level in dialysed patients.

PUB361

Fluid Overload and Inflammation in Chronic Hemodialysis

Joselyn Reyes,[1] Jochen G. Raimann,[1] Len A. Usvyat,[1] Stephan Thijssen,[1] Nathan W. Levin,[1] Peter Kotanko.[1] *[1]Nephrology Research, Renal Research Intitute, New York, NY; [2]Nephrology, Beth Israel Medical Center, New York, NY.*

Background: Chronic inflammation and fluid overload are key issues in hemodialysis (HD). Previously, an association between fluid overload and inflammation has been suggested, possibly related to bowel edema and endotoxin translocation. We aimed to investigate the relation between fluid overload and inflammation in a large cohort of chronic HD patients from the US.

Methods: In this retrospective cross-sectional cohort study we included all patients receiving HD between 1/2001 and 3/2012 in facilities of the Renal Research Institute who did not achieve prescribed target weight. The difference-to-target weight (DTTW; computed as actually achieved post-HD weight minus prescribed target weight) and the neutrophil-to-lymphocyte ratio (NLR) were employed as surrogate markers of fluid overload and inflammation, respectively.

Results: We studied 3565 HD patients (age 61±15 years, 56% male, 51 % diabetic, 50 % Blacks, 22 % with catheter as primary vascular access). In univariable regression analysis DTTW and NLR were positively correlated (R2 = 0.001; P=0.03). This association was corroborated in multivariable analysis with adjustment for age, race, sodium gradient, and vascular access (adjusted R^2=0.06; P=0.03).

Conclusions: It is clinically reasonable that fluid overload is more prevalent in patients who fail to achieve target weight. This reasoning provides the rational for employing DTTW as an indicator of fluid overload in an epidemiologic study. Applying this metric we show that fluid overload is associated with inflammation for reasons yet to be determined. Interventional studies are required to further explore if achieving normal fluid status results in reduced inflammation.

PUB362

Pleural Effusion in Haemodialysis Patients: Diagnostic Investigations and Outcome

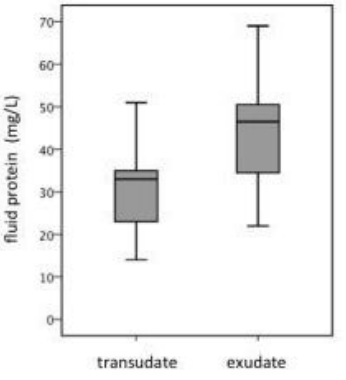
Richard W. Corbett, Damien Ashby. *Imperial College Kidney and Transplant Institute, Imperial College, London, United Kingdom.*

Background: Pleural effusion is common in dialysis patients – although usually transudative, exudative effusions are also frequent. Dialysis treatment often alters the clinical presentation, and the optimum diagnostic investigations are unknown.

Methods: In this retrospective study, all haemodialysis patients undergoing diagnostic aspiration during an 18 month period were identified from electronic records. Diagnostic data were collected and examined in the light of the final clinical diagnosis.

Results: Twenty-two pleural aspirations were identified in 19 patients (aged 30–83, mean 64.6) of which 9 were ultimately diagnosed as transudates. Amongst the remaining 13 cases there were 4 empyemas, and other effusions were parapneumonic (5) or due to malignancy (1), eosinophlia(1), tuberculosis (1) and blunt trauma (1).

Individual components of Light's criteria were poor indicators of effusion type, and in combination had sensitivity and specificity for non-transudative effusion of 92% and 44% respectively. Compared to transudates, exudates did have higher fluid protein levels (44.0 vs 30.2mg/L, p=0.018) and in ROC analysis, fluid protein was reasonably useful as a discriminator, with area under curve 0.782 (p=0.030).



CT imaging was available in all but 2 cases, and proved the most useful test, providing diagnostic accuracy beyond effusion type (for which it was 83% sensitive and 88% specific), but no single test was fully reliable and clinical judgement remained essential. Over a mean follow-up period of 271 days, median survival was 249 days, with no significant difference between effusion types (p=0.196).

Conclusions: Pleural fluid biochemistry is of limited diagnostic value in dialysis patients, in whom CT imaging provides the most useful information. In this group of patients mortality is high, and clinical judgement remains paramount.

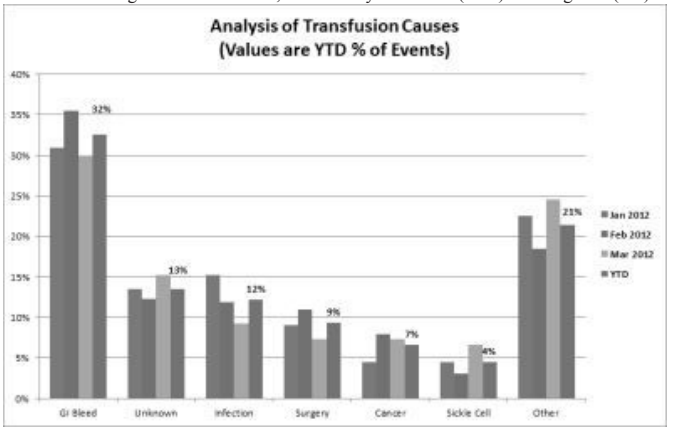
Why Patients Are Transfused: Causes and Hemoglobin Values

Kirk Finchem,[1] Patricia McCarley.[2] *[1]Clinical Operations, Renal Advantage, Inc, Franklin, TN; [2]Clinical Services, Renal Advantage, Inc, Franklin, TN.*

Background: In 2011 anemia protocols and practices were affected by an FDA ruling recommending new lower target hemoglobin (Hb) ranges, reimbursement changes that included ESAs as part of a bundled payment, and Quality Incentive Program (QIP) measures based on selected Hb parameters. The USRDS has reported increases in the monthly transfusion rates beginning in July 2011.

Methods: The study analyzed self-reported transfusion data from a system of 155 dialysis centers in the US over a 3-month period. Transfusion rates (events per 1,000 patient-months) were calculated for patients, grouped by monthly hemoglobin value. Diagnoses related to the reason for subject transfusions are also reported by monthly hemoglobin group, and on a consolidated basis.

Results: Gastrointestinal bleeding was the leading self-reported cause for transfusions, related to nearly one third of transfusions. "Unknown" causes were related to slightly more than one eighth of transfusions, followed by infections (12%) and surgeries (9%).



Transfusion events occurred at the rate of 14.8 per 1,000 patient-months during the three month study, which compared to a rate of 35 per 1,000 patient-month reported by USRDS for the period January thru September of 2011. Transfused patients experienced an average of 1.23 transfusion events during the present study.

Transfusions were more commonly associated with acute clinical factors (e., GI bleeding) than chronically low Hb values.

Transfused and non-transfused groups are compared. Hb levels are reported.

Conclusions: Transfusion events are frequently markers of important clinical changes in patient status. Center-level transfusion-awareness processes, relying on cues from patients and follow-up with hospitals are inadequate to provide actionable data. Clinicians must develop robust processes to identify and categorize transfusuion events.

PUB364

The Effect of Change in Anemia Control Range on System-Wide Hemoglobin Values Kirk Finchem,[1] Patricia McCarley.[2] *[1]Clinical Operations, Renal Advantage, Inc, Franklin, TN; [2]Clinical Services, Renal Advantage, Inc, Franklin, TN.*

Background: With the change in product warnings for erythropoetin stimulating agents (ESAs) (July 2011), some dialysis providers changed target ranges for anemia management.

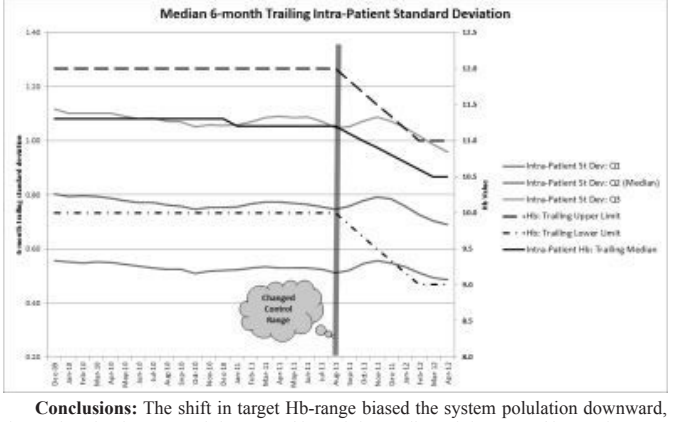
The retrospective study examined the impact on patient hemoglobin (Hb) of shifting target control range from (10 to 12 g/dL) to (9 to 11 g/dL). The study also considered the effect of the shift on the effectiveness of anemia management--i.e., the variability of intra-patient Hb values from month to month--as measure by intra-patient standard deviation of hemoglobin values on a 6 month trailing basis.

Methods: Target Hb range was shifted at all centers (as a change in clinical practice, rather than as a clinical trial) during August 2011.

Study patients (n=9,801 mean monthly patients) received dialysis treatment during the period May 2010 thru April 2012, within a system of 155 dialysis centers in the US, and had been on dialysis for more than 90 days. Further, only patients receiving ESAs during at least 2 of any 3 month period were included.

The fraction of patients with Hb<9 was calculated from the last monthly Hb for each patient. As a measure of control effectiveness, intra-patient Hb standard deviation was calculated for each patient on a trailing 6-month basis; the median value of the intra-patient standard deviation was determined.

Results: The target-range shift increased the faction of ESA patients with monthly hemoglobin values less than 9 g/dL from a mean value of 3.2% prior to the shift, to a mean value of 5.6% following the shift. The shift was associated with less intra-patient variability, as measured by the median intra-patient standard deviation.



Conclusions: The shift in target Hb-range biased the system polulation downward, decreasing the the mean Hb by 0.53 g/dL and the median Hb by 0.60 g/dL. At the same time, control effectiveness increased.

PUB365

Management and Outcome of Patients Receiving Chronic Outpatient Hemodialysis Following LVAD Implantation Judy L. Jang,[1] Anitha Vijayan,[1] Daniel W. Coyne,[1] Susan Joseph,[2] Scott C. Silvestry,[3] Sunil M. Prasad,[3] Tingting Li.[1] *[1]Renal Division, Washington University; [2]Cardiovascular Division, Washington University; [3]Division of Cardiothoracic Surgery, Washington University, St. Louis, MO.*

Background: Renal dysfunction occurs frequently in pts with heart failure (HF). In end-stage HF pts, mechanical circulatory support with LV assist devices (LVADs) is increasingly used as destination therapy or a bridge to heart transplant. No published information describes the management or outcomes of pts receiving chronic outpatient HD following LVAD implantation.

Methods: We conducted a retrospective single-center analysis of all pts who received chronic outpatient HD following LVAD placement. All pts were implanted with HeartMate II continuous-flow devices.

Results: A multidisciplinary team including nephrology, cardiology, and CT surgery was organized to coordinate pt care. Pt, family, and dialysis staff training of the LVAD was implemented prior to HD initiation. Six pts were identified between 2008-2012. 4/6 pts were male, 5 AA, 1 white, with ages between 25-59. 4/6 had CKD prior to initiation of HD, 1 had AKI, and 1 had ESRD which preceded HF. 5/6 received LVADs as a bridge to transplant, but only 1 survived to receive heart/kidney transplant. The pt with AKI recovered renal function. The remainder died on chronic HD at 2, 3, 4 mos, and at 2 yrs. The causes of death were infections(2), cardiac complications(1), and GI bleed(1). During HD, hemodynamic stability was achieved by maintaining LVAD flow rates at 4-6 L/min and MAP between 70-90 mmHg when obtainable, as systolic BPs were not always reliable. A change in symptoms was the most accurate indicator of clinical instability. Dry weight was established after careful assessment of hemodynamics, LVAD flow rates, and pulsatility index. Heparin was utilized without adverse events except in 1 pt with recurrent GI bleeding. All pts had tunneled HD catheters with blood flows of 350-450 ml/min. ESA was administered per standard protocol.

Conclusions: With increasing LVAD implantation and high rates of renal disease in HF, dialysis centers need to be prepared to provide optimal care of LVAD pts. Our description will help guide management of these pts.

PUB366

The Relationship of Cystatin C with Cardiovascular Risk Factors and Inflammatory Marker in Hemodialysis Patients Kyung Mi Park,[1] Hyung-Jong Kim,[1] Dong Ho Yang,[1] Il Park.[2] *[1]Internal Medicine, CHA Bundang Medical Center, CHA University, Seongnam, Republic of Korea; [2]Internal Medicine, South Korea Army Medical Center, Goyang, Republic of Korea.*

Background: Cystatin C is a predictive factor for cardiovascular disease(CVD). In a study for non-dialysis patients, pulse wave velocity(PWV) is related with cystatin C, but there have been limited data for hemodialysis(HD) patients. So, the purpose of this study was to evaluate the relationship among serum cystatin C, inflammatory marker and cardiovascular risk factors in the HD patients.

Methods: We performed a retrospective cross sectional study, enrolling 45 HD patients. We measured CRP, TNF-a, IL-6, insulin and glucose before HD, as well as pre- and post-HD cystatin C at baseline and after 1 month. The PWV was accessed within 1 month. Through the assessment of these laboratory data and the review of medical records, we calculated the Framingham risk score and HOMA-IR.

Results: The mean age was 55 years and 51% were male. The average of cystatin C before HD was 6.57mg/L, and we categorized three groups by Low(<6.49mg/L), intermediate and high(≥7.41mg/L). In these groups, there is no difference in age, BMI, lipid profile, IL-6 (2.87pg/ml, 4.40pg/ml, 4.85pg/ml), TNF-a (4.02pg/ml, 2.06pg/ml, 5.66pg/ml), CRP (0.36mg/dl, 0.09mg/dl, 0.24mg/dl), Framingham risk score(10.22%, 10.83%, 10.78%) and HOMA-IR(2.52, 2.49, 1.92). Also, in the relationship between serum cystatin C and cardiovascular risk factor, it was not associated with PWV, IL-6, TNF-a, CRP, Framingham risk score and HOMA-IR. However, there was a significant correlation between pre- and post-HD cystatin C(0.319, p=0.014) and this value had a strong correlation after the correction of difference in the dialysis membrane(0.596, p<0.001). It assumed that the dialysis membrane affected the concentration of cystatin C.

Conclusions: The serum cystatin C was not associated with cardiovascular risk factors in HD patients. We assumed that the serum cystatin C, with medium molecular weight, was dialyzed by HD, so there was a gap between in vivo production and the remaining amount. Prospective studies involving a longer period concerning the relationship between cystatin C and CVD are needed.

PUB367

Upregulation of Fibroblast Growth Factor and Vascular Endothelial Growth Factor in End Stage Renal Disease Patients May Be Related to Cardiovascular Events Kristiyana Kaneva,[1] Vinod K. Bansal,[2] Debra Hoppensteadt,[1] Joesphine Cunanan,[1] Jawed Fareed.[1] *[1]Pathology, Loyola University Medical Center, Maywood, IL; [2]Nephrology, Loyola University Medical Center, Maywood, IL.*

Background: Fibroblast Growth Factors (FGF) represent families of heparin binding growth factors and Vascular Endothelial Growth Factor (VEGF) are a potent mediator of angiogenesis and vasculogenesis in various diseases. We hypothesized that both of these growth factors may be upregulated in End Stage Renal Disease (ESRD) and may contribute to the cardiovascular events.

Methods: This study included 119 ESRD patients undergoing maintenance hemodialysis after appropriate IRB approval and patient consent. Citrated blood samples were collected prior to and immediately after the dialysis session. The blood samples were centrifuged for 15 minutes at 3000 g at 4°C and platelet poor plasma (PPP) was extracted. Citrated plasma was frozen at -70°C. Samples collected from ESRD patients were analyzed for the circulating levels of FGF-23 by using a sandwich ELISA kit (Millipore, St. Charles, Missouri). The VEGF analysis was carried out using Quantikine sandwich ELISA method (R&D Systems, Minneapolis, Minnesota). Plasma samples collected from normal male and female (n = 80) comprised the normal group.

Results: The FGF-23 levels ranged from 0 to 5934 pg/ml (Mean = 1861 pg/ml with S.E.M = 151) in contrast to the normal levels of 18.4 ± 6.1 pg/ml. Of the 119 patients, 67 (56.3%) had greater than 1000 pg/ml FGF-23 levels. The VEGF levels ranged broadly from 8.2 to 3673 pg/ml (Mean = 141 pg/ml with S.E.M = 50.1) in contrast to the normal levels of 8.7 ± 4.2 pg/ml. Of the 119 patients, 16 (13.4%) had VEGF levels greater than 100 pg/ml of which 4 (3.36%) had levels greater than 1000 pg/ml. No correlation was observed between the VEGF and FGF23 levels.

Conclusions: Measurement of FGF-23 and VEGF provides an additional mean to risk stratify the ESRD patients who may develop cardiovascular and cerebrovascular events. Furthermore, newer targets to modulate these growth factors may be useful in the overall management of these patients.

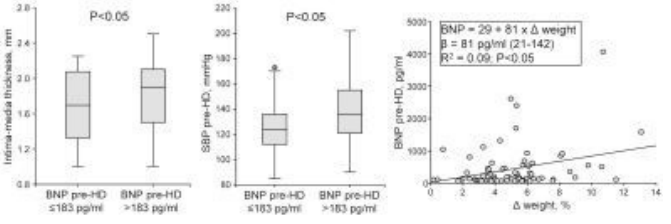
PUB368

Dry Weight, Systolic Blood Pressure and Intima-Media Thickness Predict Brain Natriuretic Peptide Levels in Hemodialysis Patients Paolo Lentini,[1] Luca Zanoli,[1] Valentina Pellanda,[1] Claudio Ronco,[2] Andrea Contestabile,[1] Graziella Berlingò,[1] Anna Basso,[1] Massimo de Cal,[2] Antonio Granata,[1] Roberto Dell'Aquila.[1] *[1]Nephrology, St Bassiano Hospital, Bassano del Grappa, Italy; [2]Nephrology, St Bortolo Hospital, Vicenza, Italy.*

Background: B-type natriuretic peptides (BNP) is an emerging marker of cardiac distress in patients with volume overload. High BNP levels in hemodialysis (HD) patients are correlated with development of pathological cardiovascular findings, including left ventricular hypertrophy, hypertension and increased end-diastolic volume, and with increased cardiovascular and overall mortality. Intima-media thickness (IMT) is a marker of vascular dysfunction well correlated with the cardiovascular risk. We supposed that BNP levels are dependent not only to the interdialytic weight variation (Δ) but also to the vascular dysfunction. Aim: To determine the factors associated with high BNP in chronic HD patients.

Methods: 74 subjects were enrolled. Hematological and biochemical variables were obtained by a pre-HD blood draw. We defined Pre-HD BNP>183 pg/mL as high BNP (were 183 is the median of BNP in our population). Δ weight was defined as [(pre-HD weight - dry weight)/ dry weight]. In all patients IMT of the common carotid artery was measured. Student t-test and chi-square test were used in this analysis.

Results: A total of 74 chronic HD patients were enrolled. The age was 63±13 years, males 54%, BNP 183 pg/mL (range IQ 91-499 pg/mL), IMT 1.76±0.39 mm. Δ weight (1%, OR 1.28, 95%CI 1.01-1.63;P<0.05), Systolic blood pressure (SBP) pre-HD (10mmHg, OR 1.28, 95%CI 1.01-1.61;P<0.05) and IMT (0.1mm, OR 1.22, 95%CI 1.05-1.43;P<0.01) were associated with high BNP pre-HD (Model AUC=0.73, P<0.001).



Conclusions: In chronic HD patients, BNP is influenced not only by the interdialytic weight variation, but also by the vascular function.

PUB369

Validity of the Charlson Comorbidity Index as a Predictor of Mortality in Australian Hemodialysis Patients Asanga Abeyaratne, Kelum Priyadarshana Gunaneththige Don, Kym M. Bannister. *Department of Nephrology, Royal Adelaide Hospital, Adelaide, South Australia, Australia.*

Background: Comorbidity is a significant predictor and confounder needing adjustment, for hemodialysis related mortality. The Charlson comorbidity index(CCI) is used to adjust for comorbidity in general medical patients and has been validated in small cohorts of ESRD patients outside of Australia. This study aimed to assess the CCI as a predictor in our hemodialysis population.

Methods: Demographic and comorbidity data was retrospectively collected on all hemodialysis patients (N=329, male 59%, indigenous 9.7%,dialysis through AV fistula 76.5%) from 12 satellite dialysis centers across South Australia from January 2008 to January 2009. A composite comorbidity index was calculated based on the weights proposed by Charlson. Outcome measure was three year survival.

Results: 140 died during the observation period. Diabetes(41.9%), congestive heart failure(27.6%), and myocardial infarction(14%) were the most prevalent comorbidities. Two cox regression models were evaluated and comprised of individual comorbidities and CCI respectively. Age and albumin were included in both models. Race, gender and vascular access were not significant predictors in multivariate analysis. In the first model age (Hazards ratio [HR] 1.02; 95% confidence interval [CI] 1.01-1.04 p<0.001), serum albumin (HR 0.94; 95% CI 0.92-0.98 p=0.002), diabetes (HR 1.42; 95% CI 1.01-2.03 p=0.04) and congestive heart failure (HR 1.46; 95% CI 1.1-2.11) were independent predictors. In the second model, CCI was the strongest predictor (HR 1.16; 95% CI 1.09-1.24 p<0.001) when adjusted for age and albumin, and had a c statistic of 0.65 and was slightly higher than the first model (c statistic 0.64). The CCI remained a strong predictor for two and one year mortality (HR 1.12 and HR 1.14 p<0.01).

Conclusions: The CCI is a simple linear integer scale easy to calculate and has strong predictive value for mortality in our study population. We recommend its inclusion in data collection models for prognostication.

PUB370

Body Size and Relationship to Outcomes in Asian Pacific Dialysis Patients Michael Etter,[1] Hugh Feidhlim Woods,[1] Len A. Usvyat,[3] Frank van der Sande,[2] Jeroen Kooman,[2] Nathan W. Levin,[1] Peter Kotanko.[1] *[1]Fresenius Asia Pacific, Hong Kong, Hong Kong; [2]Maastricht University Hospital, Maastricht, Netherlands; [3]Renal Research Institute, NY, NY.*

Background: In chronic hemodialysis (HD) patients, larger body size is associated with better outcomes. We aim to understand whether this observation extends to HD patients treated in South-east Asia region.

Methods: We studied incident HD patients treated in the Fresenius Medical Care Asia Pacific region who commenced tx bn 6/1/2002 and 9/30/2011. Only patients who survived >183 days on HD were included. Body mass index (BMI) based on the mean post-dialysis weight in the first 183 days was computed. Patient survival was observed in days 184 to 730 after HD initiation. Patients were stratified into tertiles of BMI and country.

Results: We studied 2854 patients (Australia, 144; South Korea, 185; Taiwan 2525). Patients in Australia start with the highest BMI values (25.3), followed by Taiwan (22.5), with South Korean patients having the lowest BMI of 22.2. Table 1 summarizes ranges of BMI in each tertile in each country.

Table 1. BMI (range; kg/m2) by country

	Tertile 1	Tertile 2	Tertile 3
Australia	14 to 23	23 to 26	26 to 38
Taiwan	16 to 21	21 to 23	23 to 36
South Korea	14 to 21	21 to 24	24 to 40

BMI did not associate with survival in South Korea. In Australia and Taiwan, significant differences were observed bn tertiles 1 and 3, with a longer median survival in tertile 3. Survival advantage was more pronounced in Australia than Taiwan (Australia 48 days; Taiwan 9 days).

	Australia	Korea	Taiwan
Tertile 1	651 (607-695)	716 (697-735)	712 (707-718)
Tertile 2	694 (665-722)	716 (697-735)	715 (710-720)
Tertile 3	699 (670-729)	713 (692-733)	721 (717-724)

Conclusions: Patient size is a predictor of patient outcomes in HD patients. Our analysis suggest that larger patients have better survival in Taiwan and Australia with the survival advantage of large size more pronounced in Australia. Larger patients do not experience a similar degree of survival advantage in South Korea (likely due to small N).

PUB371

Serum Sodium and Its Correlates in Asia Pacific Region Michael Etter,[1] Hugh Feidhlim Woods,[1] Len A. Usvyat,[3] Frank van der Sande,[2] Jeroen Kooman,[2] Peter Kotanko.[3] *[1]Fresenius Asia Pacific, Hong Kong, Hong Kong; [2]Maastricht University Hospital, Maastricht, Netherlands; [3]Renal Research Institute, NY, NY.*

Background: Serum sodium (sNa) is important predictor of outcomes in hemodialysis (HD) patients (pts). In US dialysis population, studies have shown that higher sNa is associated with higher albumin, systolic blood pressure, and better outcomes. We aim to explore these relationships in Australia, Taiwan, and South Korea.

Methods: We studied incident HD pts treated in the FMC Asia Pacific clinics who commenced tx bn Jun 1, 2002 and Nov 30, 2011. Only pts who survived the 183 days on dialysis, had >3 observations, and were >18 years old were included. Mean of patient parameters were computed in first 183 days.

Results: We studied 86 patients from Australia, 182 from South Korea, and 2592 from Taiwan. Pts in Australia start with the highest sNa values [mean±stdev] (138.5 mmol/L±2.5), followed by South Korea (137.7 mmol/L±2.5), with Taiwanese pts having the lowest sNa of 137.2 mmol/L±2.9 (p<0.05 between all 3 groups). Using unpaired t-test, male pts were more likely to have higher sNa in Taiwan but not the other 2 counties. Diabetics were more likely have lower sNa in all 3 countries (p<0.01 for Taiwan). Pearson correlation with sNa showed no significant correlation with age. Postweight and IDWG were positively associated with sNa in all 3 countries. Albumin was positively associated with sNa in Taiwan and Korea but not Australia. Contrary to most other studies, preSBP was negatively and significantly associated with sNa in South Korea and Taiwan. There was no significant association with preSBP in Australia (potentially due to small N).

	Age (yrs)	Albumin (g/dL)	PostWeight (kg)	preSBP (mmHg)	IDWG (kg)	Gender (1=Male)	DM Status (1=Diabetic)
Australia	-0.105	-0.006	.217*	0.033	0.01	0.181	-0.129
Korea	0.054	0.115	0.031	-.151*	0.137	-0.02	-0.15
Taiwan	-0.038	.236**	.108**	-.095**	.181**	.054**	-.219**

* p<0.05; ** p<0.01

Conclusions: Our findings suggest that pts from Australia have the highest sNa. Contrary to most studies in Caucasian and Black pts, our data shows that Chinese and Korean pts have a negative correlation between preSBP and sNa.

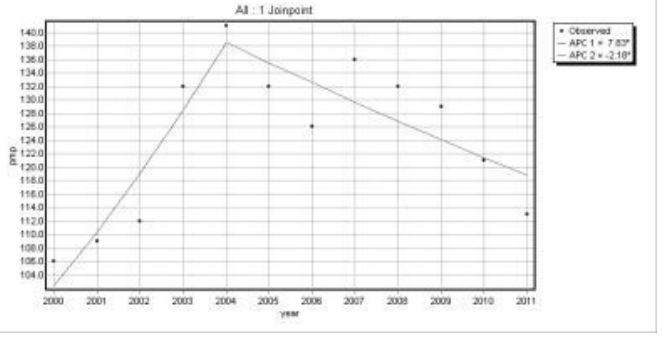
PUB372

Is Chronic Kidney Disease under Control at Last? The Incidence of Renal Replacement Therapy in Croatia Is Decreasing Svjetlana Cala. *Nephrology and Dialysis, Internal Clinic, Clinical Hospital Center Sestre Milosrdnice, Zagreb, Croatia.*

Background: Stabilization in the incidence of renal replacement therapy (RRT) for end-stage renal disease (ESRD) has been observed recently in some European countries, USA, and Japan. An update in Croatia 2000 to 2009 has shown arrest in incidence growth, and slowing the rise in prevalence of RRT. The aim of the present study was to follow on the epidemiological trends in RRT.

Methods: Data from the Croatian Registry of Renal Replacement Therapy (CRRRT) from 2000 to 2011 were analyzed. All patients treated by hemodialysis, peritoneal dialysis and transplantation were covered. Access to RRT was unrestricted. The incidence from day 91 on RRT was adjusted for age and gender of the mid-year population. Time trends were analyzed with Poisson regression and Joinpoint regression methods.

Results: The adjusted incidence of RRT was 106,1 per million population (pmp) in 2000, reached maximum of 140,4 pmp in 2004, and attained 113,3 pmp in 2011.



The year 2004 was identified as breaking point of 2 diverse incidence trends. From 2000 to 2004 incidence was increasing at an annual percentage change (APC) 7,8% (95%CI 2,4; 13,5). From 2004 to 2011 incidence was decreasing by APC -2,2% (95%CI -4,3; -0,0). During the last 5-year period, the decrease was the result of the reduction in the incidence in females: APC -3,2% (95%CI -5,8; -0,5), and stabilization in males: APC -1,5% (95%CI -0,4; 0,9).

Conclusions: After a rapid increase in the incidence of RRT in Croatia from 2000 to 2004, reduction of the incidence succeeded during the 2004-2011 period. The decrease of the incidence, despite unrestricted access to the RRT could be attributed to the prevention and treatment of cardiovascular diseases resulting in decreasing cardiovascular mortality, and simultaneously improving renal survival.

RAS Inhibitors Could Modulate the Changes in Left Ventricular Structure after Paricalcitol Therapy in Chronic Hemodialysis Patients Eduardo Baamonde,[1] Elvira Bosch,[1] Carlos Culebras,[2] Bilal El Hayek,[1] German Perez Suarez,[1] Cesar Garcia-canton,[3] Ignacio Ramirez,[1] Maria Dolores Checa.[3] *[1]Nephrology, AVERICUM, Spain; [2]Cardiology, Hospital Universitario Insular de Gran Canaria, Spain; [3]Nephrology, Hospital Universitario Insular de Gran Canaria, Spain.*

Background: Vitamin D may play an important role in reduction of Left Ventricular Hypertrophy (LVH) through modulation of the renin-angiotensin system (RAS). Several studies suggest that treatment with vitamin D may improve cardiac function in hemodialysis patients. Aim: analyze the changes in cardiac structure and function in two group of patients with secondary hyperparathyroidism: treated with and without RAS inhibitors, after 12 months of treatment with paricalcitol.

Methods: 44 chronic hemodialysis patients with secondary hyperparathyroidism (iPTH 300-800 pg/mL) treated with flexible doses of PCT. Baseline, and 12 months after Paricalcitol treatment, echocardiogram was performed and blood pressure, parameters of anemia and bone-mineral metabolism were measured We analyzed the evolution of patients treated with and without RAS inhibitors.

Results: At 12 months, left ventricular mass, left ventricular mass index and left ventricular posterior wall decrease significantly (LVM: 271.2 ± 112.2 vs 243.4 ± 93.1 g, p<0.05 - LVMI: 144.4 ± 50.3 vs 126.6 ± 43.2 g/m2, p=0.026 - LVPW 12.6 ± 2.5 vs 11.89 ± 2.1 mm, p= 0,045) In patients **not treated** with RAS inhibitors, left ventricular diastolic diameter (LVDD: 50.4 ± 4.6 vs 45.6 ± 6.3 mm, p = 0.017), left ventricular systolic diameter (LVSD: 29.3 ± 4.3 vs 24.8 ± 4,1 mm, p = 0.021), LVM (271.6 ± 86.4 vs 212.7 ± 60.9 g, p = 0.000) and LVMI (149.02 ± 36.6 vs 118.48 ± 28.1 g/m^2, p = 0.000) decrease significantly. In patients **treated** with RAS inhibitors only LVSD decrease significantly (p=0.004) We observed significantly decrease in the percentage of patients with LVH (65,9% vs 46,4% p=0.024).

Conclusions: Patients treated with PCT showed an improvement in left ventricular structure. Patients **not treated** with RAS inhibitors showed more evident changes of left ventricular structure, suggesting that the effects of PCT at the cardiovascular level could be less evident when using RAS inhibitors.

Serum Non-High-Density Lipoprotein Cholesterol (Non-HDL-C) Levels and Cardiovascular Mortality in Chronic Hemodialysis Patients Kosaku Nitta. *Department of Medicine, Kidney Center, Tokyo Women's Medical University, Shinjuku-ku, Tokyo, Japan.*

Background: Non-high-density lipoprotein cholesterol (non-HDL-C) has been proposed as a predictor of cardiovascular disease (CVD) in the general population. The aim of this study was to evaluate the utility of non-HDL-C in predicting CV mortality in chronic hemodialysis (HD) patients.

Methods: We calculated the serum non-HDL-C level of 259 HD patients by subtracting their high-density lipoprotein cholesterol (HDL-C) level from their total cholesterol (TC). Cox proportional hazards models were used to estimate the hazards ratio (HR) for CV mortality and the 95% confidence interval (CI). A receiver-operating characteristic (ROC) analysis was performed to estimate the relationship between the sensitivity and specificity of a diagnostic parameter.

Results: There were 44 deaths (17.0%) during the follow-up period, and 33 (12.7%) of the deaths were due to CVD. A multivariate Cox analysis with adjustements for age, diabetes, dialysis vintage, systolic blood pressure, serum albumin and lipid levels showed that non-HDL-C was an independent predictor of CV mortality (HR 1.015, 95% CI 1.004–1.025, P =0.0083). A ROC analysis showed that the plots of the non-HDL-C levels yielded significant specificity and sensitivity for predicting the risk of CVD mortality in HD patients (AUC, 0.62416; *p=0.0366*; cut-off value, 111.0 mg/dL). The Kaplan-Meier survival curves of the HD patients showed significant differences in CV mortality according to their tertiles with respect to serum non-HDL-C levels (*>p=0.0165*).

Conclusions: The results of this study suggest that the serum non-HDL-C level is a significant CV mortality predictor of chronic HD patients.

Abdominal Aortic Calcification Score as a Risk Factor for Cardiovascular Disease in Chronic Hemodialysis Patients Myung Jin Choi, Ja-Ryong Koo, Jong-woo Yoon, Jwa-kyung Kim, Sun Ryoung Choi, Min-Gang Kim. *Department of Internal Medicine, Hallym University Medical Center and Hallym Kidney Research Institute, Chuncheon, Kangwon-do, Republic of Korea.*

Background: Vascular calcification (VC) is strongly associated with cardiovascular morbidity and mortality in hemodialysis (HD) patients. Lateral abdominal radiography is a simple and inexpensive tool to detect the presence or severity of VC, compared to the other modalities such as electron bean or multi-slice computed tomography or series of radiographies in pelvis and hands. Using lateral abdominal radiography, we investigate the association between abdominal aortic calcification (AAC) and the development of cardiovascular disease (CVD) in maintenance HD patients.

Methods: Sixty-nine chronic HD patients (52.2 % male; 56.4 ± 1.6 years; median duration of HD 39.2 ± 5.4 months; 60.8 % diabetic) were enrolled. AAC score (range 0-24) were calculated as the sum of calcium deposit score along the anterior and posterior longitudinal walls of the abdominal aorta adjacent to L1-L4 lumbar vertebrae.

Results: The mean AAC score was 3.6 ± 4.1 (range 0-18) and 16 patients (23.3 %) had high AAC score (AAC score ≥ 7). During a mean follow-up period of 92.7 ± 3.2 weeks, there occurred 20 cases (4 fatal, 16 nonfatal) of CVD. Kaplan-Meier survival curve showed that probability of fatal and non-fatal CVD during follow-up period was significantly higher in high AAC score group (Log-Rank test, p=0.029) as compared with low AAC score group (AAC score < 7). In multivariate Cox proportional hazards model, significant independent risk factors for development of CVD were high AAC score (hazard ratio per 1 increase, 1.142; 95% confidence interval (CI), 1.035 to 1.260), high CRP levels (hazard ratio per 1mg/L increase, 1.031; 95% CI, 1.008 to 1.054) and low pre-dialytic diastolic blood pressure (hazard ratio per 1 mmHg increase, 0.927; 95% CI, 0.866-0.992).

Conclusions: AAC score assessed by simple lateral abdominal radiography could be an independent predictor of CVD events in HD patients. Considering easy availability and cost-effectiveness, evaluation of VC by AAC score may be an useful prognostic marker for CVD in chronic HD patients.
